#### Abstract

The synthesis and structural characterization of zwitterionic $\left[\left(\eta^{6}-\mathrm{C}_{6} \mathrm{H}_{5}-\mathrm{BPh}_{3}\right) \mathrm{M}(\text { coe })_{2}\right.$ ] $(M=R h$, Ir $)$ cyclooctene complexes is described. Both complexes exhibit an unusual exo-endo conformation of both cyclooctene ligands in the solid state. However, an equilibrium between the endo-endo and exo-endo 10 rotational isomers arising from the hindered rotation about the metal-cyclooctene bond is observed in solution. Rotational barriers of around $65 \mathrm{~kJ} \cdot \mathrm{~mol}^{-1}(\mathrm{Rh})$ and $84 \mathrm{~kJ} \cdot \mathrm{~mol}^{-1}$ (Ir) have been determined by 2D EXSY NMR spectroscopy. The rotation process has also been studied by DFT calculations showing that the dynamic behaviour is a consequence of the oscillation of the cyclooctene ligands about the metalolefin bond instead of completing a full rotation.

## ${ }_{15}$ Introduction

Zwitterionic transition metal complexes composed of a cationic metal fragment and a negatively charged ancillary ligand within an overall neutral molecular framework have attracted considerable attention. ${ }^{1}$ Usually, these complexes exhibit the
${ }_{20}$ broad solubility and solvent tolerance of neutral species while maintaining the reactivity pattern of related cationic complexes, which have a limited solubility. ${ }^{2}$
Tetraphenylborate, $\mathrm{BPh}_{4}^{-}$, has been largely utilized as a weakly coordinating anion in transition metal-based chemistry resulting
${ }_{25}$ in the formation of discrete ionic metal complexes. ${ }^{3}$ However, the coordination ability of tetraphenylborate through the phenyl rings provide access to species featuring strong metal- $\eta^{6}$-arene interactions which remain as the most widely explored zwitterionic transition metal complexes. ${ }^{4}$ This is particularly true
${ }_{30}$ for rhodium chemistry where a range of zwitterionic rhodium(I) tetraphenylborate complexes containing both mono- and bidentate ligands such as $\left[\left(\eta^{6}-\mathrm{C}_{6} \mathrm{H}_{5}-\mathrm{BPh}_{3}\right) \mathrm{RhL}_{2}\right]\left(\mathrm{L}=\mathrm{PR}_{3}\right.$, ${ }^{5}$ $\mathrm{P}(\mathrm{OR})_{3},{ }^{6}$ ethylene ${ }^{7}$ ) and $\left[\left(\eta^{6}-\mathrm{C}_{6} \mathrm{H}_{5}-\mathrm{BPh}_{3}\right) \mathrm{Rh}(\mathrm{L}-\mathrm{L})\right]$ (L-L = diene, ${ }^{8}$ P-P, ${ }^{9} \mathrm{~N}-\mathrm{N}^{10}$ ), have been prepared.
${ }_{35}$ Of particular relevance are the diene complexes that have found application as catalyst precursors for useful synthetic transformations. Alper et al. demonstrated the ability of $\left[\left(\eta^{6}-\right.\right.$ $\left.\mathrm{C}_{6} \mathrm{H}_{5}-\mathrm{BPh}_{3}\right) \mathrm{Rh}($ cod $\left.)\right]$ (cod $=1,5$-cyclooctadiene) to catalyze a diversity of carbonylation reactions. ${ }^{11}$ More recently, this
${ }_{40}$ compound has also been shown to promote the arylation of several unsaturated compounds using tetraarylborate as phenyl source. ${ }^{12}$ On the other hand, complexes $\left[\left(\eta^{6}-\mathrm{C}_{6} \mathrm{H}_{5}-\right.\right.$ $\left.\mathrm{BPh}_{3}\right) \mathrm{Rh}($ diene $\left.)\right]($ diene $=$ cod, nbd, tfb$)$ have been proven to be efficient initiators for the polymerization of monosubstituted ${ }_{45}$ acetylenes. ${ }^{13}$ It has been found that the $\pi$-acidity of the diene ligand strongly influences the catalytic activity. ${ }^{14}$ In fact, the nbd and tfb zwitterionic complexes ( $\mathrm{nbd}=2,5$-norbornadiene, $\mathrm{tfb}=$ tetrafluorobenzobarrelene) have shown an outstanding catalytic activity allowing for the preparation of highly stereoregular ${ }_{50}$ poly(phenylacetylene)s. ${ }^{15}$
Our research interest has been recently focused on the synthesis
and catalytic applications of transition metal complexes containing heteroditopic ligands of hemilabile character that incorporate strong electron donors, such as phosphines and 55 carbenes. ${ }^{16}$ We have shown the potential of flexible hemilabile functionalized phosphine ligands of the type $\mathrm{Ph}_{2} \mathrm{P}\left(\mathrm{CH}_{2}\right)_{\mathrm{n}} \mathrm{Z}(\mathrm{Z}=$ $\mathrm{OR}, \mathrm{NR}_{2}$ ) for the design of efficient rhodium catalysts for the stereoregular polymerization of phenylacetylene, ${ }^{17}$ and the regioselective anti-Markovnikov oxidative amination of ${ }_{60}$ alkenes. ${ }^{18}$ In this context, we envisage the usefulness of the zwitterionic complex $\left[\left(\eta^{6}-\mathrm{C}_{6} \mathrm{H}_{5}-\mathrm{BPh}_{3}\right) \mathrm{Rh}(\text { coe })_{2}\right]$ for the synthesis of diene-free catalyst precursors by replacement of the labile cyclooctene ligands by functionalized phosphine ligands. ${ }^{19}$
We report herein on the synthesis and characterization of ${ }_{65}$ zwitterionic $\left[\left(\eta^{6}-\mathrm{C}_{6} \mathrm{H}_{5}-\mathrm{BPh}_{3}\right) \mathrm{M}(\text { coe })_{2}\right](\mathrm{M}=\mathrm{Rh}, \mathrm{Ir})$ complexes. Much to our surprise, we have found that both compounds exhibit a dynamic behaviour associated to restricted rotation of the coe ligands. Olefin complexes are typically dynamic in nature and, as matter of fact, the propeller-like rotation of bound ethylene about 70 the metal-olefin bond is a well-known process supported by abundant experimental work besides spectroscopic and theoretical studies. ${ }^{20,21}$ However, this phenomenon is much less common for cyclooctene complexes ${ }^{22}$ and, to our best knowledge, has never been reported for bis-cyclooctene complexes.

75

## Results and discussion

Compound $\left[\left(\eta^{6}-\mathrm{C}_{6} \mathrm{H}_{5}-\mathrm{BPh}_{3}\right) \mathrm{Rh}(\text { coe })_{2}\right]$ (1) was prepared by reaction of $\left[\mathrm{Rh}(\mu-\mathrm{Cl})(\text { coe })_{2}\right]_{2}$ with a $10 \%$ excess of $\mathrm{NaBPh}_{4}$ over ${ }_{80}$ the stoichiometric amount ( 2 equiv) in methanol and isolated as a pale yellow solid in excellent yield. The compound was fully characterized by elemental analysis, mass spectrometry and multinuclear NMR spectroscopy. In addition, the zwitterionic character of $\mathbf{1}$ was further confirmed by an X-ray diffraction ${ }_{85}$ study, which showed the $\eta^{6}$-arene coordination of the tetraphenylborate anion (Figure 1a).

Figure 1. a) Molecular structure of $\left[\left(\eta^{6}-\mathrm{C}_{6} \mathrm{H}_{5}-\mathrm{BPh}_{3}\right) \mathrm{Rh}(\mathrm{coe})_{2}\right]$ (1). Only the two disordered cyclooctene molecules with higher occupancy have 5 been represented (C1A) to $\mathrm{C}(16 \mathrm{~A})$ ). b) Two schematic molecular structures of 1 showing the disorder of the cyclooctene molecules. The model with higher occupancy (A-labelled, left), with an endo conformation for $\mathrm{C}(1 \mathrm{~A})$ and $\mathrm{C}(2 \mathrm{~A})$, and exo for $\mathrm{C}(9 \mathrm{~A})$ and $\mathrm{C}(10 \mathrm{~A})$. On the right, the less abundant disordered complex (B-labelled) with an 10 alternate conformation of both olefins.

The metal complex results to show a half-sandwich structure with a $\eta^{6}$-coordination of one of the phenyl groups of the $\mathrm{BPh}_{4}{ }^{-}$anion and two $\eta^{2}$-cyclooctene ligands, linked through their olefinic bonds, completing the metal environment. Both coordinated 15 olefins exhibit clear static disorder and have been modeled on the base of two molecules with complementary occupancy factors ( 0.678 and $0.322(4)$ ). As it is shown in Figure 1b, the cyclooctene disorder determined in the crystal involves a formal $180^{\circ}$-rotation of the double bonds about the rhodium-olefin vector, together
20 with a modification of the G-Rh-M bond angle, from a mean value of $143.23(12)^{\circ}$ for the endo disposition to a value of $118.97(11)^{\circ}$ in the case of the exo conformation. Table 1 collects selected bond distances angles for $\mathbf{1}$, stating data only for the two disordered cyclooctene molecules with higher occupancy.

25 Table 1. Selected bond distances $(\AA)$ and angles $\left({ }^{\circ}\right)$ for the zwitterionic complexes $\left[\left(\eta^{6}-\mathrm{C}_{6} \mathrm{H}_{5}-\mathrm{BPh}_{3}\right) \mathrm{M}(\text { coe })_{2}\right](M=\operatorname{Rh}(\mathbf{1})$, Ir (2)).

${ }^{\text {a }}$ Only geometrical parameters for the most abundant disordered cyclooctene molecules are stated. *G represents the centroid of the $\mathrm{C}(17)$ -
${ }_{30} \mathrm{C}(22) \eta^{6}$-coordinated phenyl ring; $\mathrm{M}(1)$, and $\mathrm{M}(2)$ represent the midpoints of the $\mathrm{C}(1)-\mathrm{C}(2)$ and $\mathrm{C}(9)-\mathrm{C}(10)$ olefinic double bonds.

Although the heavy disorder of the cyclooctene molecules (and 35 also those of a phenyl group and the solvent molecule) precludes obtaining precise structural parameters, from the data determined for 1 a clear asymmetry in the $\eta^{6}$-arene coordination is evident (Rh-C(arene) distances in the range $2.250-2.410(3) \AA$ ), most probable as a consequence of the different dispositions of the
40 cyclooctene ligands on the other side of the metal coordination sphere.
The most striking feature of the molecular structure of $\mathbf{1}$ is the different relative disposition of both cyclooctene ligands. The $=\mathrm{CH}$ protons of a coe ligand are directed towards the Rh-arene ${ }_{45}$ fragment (exo conformation) whereas those of the second coe ligand point away this fragment (endo conformation). Interestingly, nearly all the " $\mathrm{M}(\text { coe })_{2}$ " rhodium(I) and iridium(I) complexes structurally characterized, including both square planar ${ }^{23}$ and 18 electron complexes having arene or polycyclic
50 aromatic hydrocarbons, ${ }^{24}$ exhibit an endo-endo conformation, with the notable exception of a heterobimetallic Pd-Ir complex featuring a functionalized 2-indenylidene pincer ligand that displays an $\operatorname{Ir}(\text { coe })_{2}$ metal fragment with an exo-endo disposition. ${ }^{25}$
${ }_{55}$ The ${ }^{1} \mathrm{H}$ NMR spectrum of $\mathbf{1}$ in $\mathrm{CD}_{2} \mathrm{Cl}_{2}$ at room temperature showed featureless resonances for the protons of the coordinated phenyl ring, which suggests some kind of fluxional behaviour. Unexpectedly, the spectrum obtained at 253 K showed two sets of high-field shifted sharp resonances corresponding to ${ }_{60}$ coordinated phenyl rings, which are indicative of the presence of two different $\eta^{6}$-arene species in a $1: 1$ ratio. Both species were also observed in the ${ }^{13} \mathrm{C}\left\{{ }^{1} \mathrm{H}\right\}$ NMR spectrum that displays two sets of three upfield-shifted doublet resonances for the CH carbons of the coordinated phenyl ring due to coupling with
${ }_{65}$ rhodium. The ${ }^{1} \mathrm{H}-{ }^{1} \mathrm{H}$ NOESY spectrum shows strong exchange cross-peaks between the ortho, meta and para protons, respectively, besides of weak NOE cross-peaks, which indicate that both species interconvert in solution (Figure 2a). The exchange process is also observed for the $=\mathrm{CH}$ resonances of the
70 cyclooctene ligands (Figure 2b) which strongly suggests the presence of two rotamers arising from the hindered rotation about the Rh-coe bond imparted by the bulky $\eta^{6}-\mathrm{C}_{6} \mathrm{H}_{5}-\mathrm{BPh}_{3}$ ligand.

Reliable assignment for the ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}\left\{{ }^{1} \mathrm{H}\right\}$ resonances of both rotamers was achieved by combination of the ${ }^{1} \mathrm{H}-{ }^{1} \mathrm{H}$ COSY, ${ }^{13} \mathrm{C}$ APT and ${ }^{1} \mathrm{H}_{-}{ }^{13} \mathrm{C}$ HSQC spectra (see SI). The analysis of the spectroscopic data is in agreement with an equilibrium between 5 the endo-endo and exo-endo rotamers (Figure 3).

Figure 2. Selected regions of the ${ }^{1} \mathrm{H}-{ }^{1} \mathrm{H}$ NOESY NMR spectrum of $\mathbf{1}$ in $\mathrm{CD}_{2} \mathrm{Cl}_{2}$ at 253 K : a) $\left(\eta^{6}-\mathrm{C}_{6} \mathrm{H}_{5}-\mathrm{B}\right) \mathrm{Rh}$ region, b) olefinic $=\mathrm{CH}$ region $(\boldsymbol{\Delta}$ 10 endo-endo rotamer, unlabeled resonances exo-endo rotamer).

The exo-endo rotamer displays two distinct resonances for the $=\mathrm{CH}$ protons at 3.62 (exo) and 2.68 ppm (endo) in the ${ }^{1} \mathrm{H}$ NMR spectrum, which points to an ideal $C_{\mathrm{s}}$ symmetry, if free rotation of the phenyl rings and a low rotational barrier about the arene5 rhodium axis is assumed. Accordingly, two resonances were observed for the $=\mathrm{CH}$ carbons at $74.84\left(J_{\mathrm{C}-\mathrm{Rh}}=13.2 \mathrm{~Hz}\right.$, endo $)$ and $63.02 \mathrm{ppm}\left(J_{\mathrm{C}-\mathrm{Rh}}=12.0 \mathrm{~Hz}\right.$, exo $)$ in the ${ }^{13} \mathrm{C}\left\{{ }^{1} \mathrm{H}\right\}$ spectrum. In agreement with the ideal $C_{2 \mathrm{v}}$ symmetry, the endo-endo rotamer shows a single resonance at 2.54 ppm for the $=\mathrm{CH}$ protons, 20 however, a broad coalesced resonance at 78.32 ppm was observed for the equivalent olefinic carbons.

Figure 3. Equilibrium between the endo-endo and exo-endo rotamers in zwitterionic complexes $\left[\left(\eta^{6}-\mathrm{C}_{6} \mathrm{H}_{5}-\mathrm{BPh}_{3}\right) \mathrm{M}(\text { coe })_{2}\right]$ (M $\left.{ }_{25}=\mathrm{Rh}, \mathrm{Ir}\right)$.

Restricted rotation of the cycloctene ligands was also observed in the analogous iridium compound $\left[\left(\eta^{6}-\mathrm{C}_{6} \mathrm{H}_{5}-\mathrm{BPh}_{3}\right) \operatorname{Ir}(\mathrm{coe})_{2}\right]$ (2). Compound 2 was prepared by reaction of the solvato species $\left[\mathrm{Ir}(\mathrm{coe})_{2}\left(\mathrm{Me}_{2} \mathrm{CO}\right)_{\mathrm{x}}\right]^{+}$with $\mathrm{NaBPh}_{4}$ in acetone and isolated as a ${ }_{30}$ white solid in good yield. The ${ }^{1} \mathrm{H}$ NMR spectrum of $\mathbf{2}$ in $\mathrm{CD}_{2} \mathrm{Cl}_{2}$ showed the presence of the endo-endo and exo-endo rotamers in a 3:1 ratio. As it was observed for 1, the $=\mathrm{CH}$ protons of the coe ligands for the exo-endo rotamer were found to be shifted significantly downfield ( 3.52 and 2.46 ppm ) compared to the ${ }_{35}$ endo-endo rotamer ( 2.10 ppm ). In the same way, the $=\mathrm{CH}$ carbons were found upfield-shifted for the exo-endo rotamer ( 57.62 and 45.06 ppm ). However, in contrast with 1, this resonance for the endo-endo rotamer was observed as a sharp singlet at 62.64 ppm . The molecular structure of the iridium
40 zwitterionic compound 2 has been determined by an X-ray diffraction study. As suggested from the similar cell parameters, complexes $\mathbf{1}$ and $\mathbf{2}$ resulted to be isotypic in the solid state. An analogous molecular structure has been found, with minor changes in the structural parameters (see Table 1), most probably
${ }_{45}$ associated to small differences in the crystalline disorder.
The Ir-G(centroid) distance (1.806(2) $\AA$ ) in $\mathbf{2}$ is similar to that reported in 1, and again a broad range of Ir-C bond distances (2.233(6)-2.401(5) A) has been observed. However, it is interesting to remark that these M-C(arene) distances, in both ${ }_{50}$ complexes, exhibit an analogous pattern having two significantly shorter distances ( 2.250 and 2.261(3) $\AA$ in $\mathbf{1}$, and 2.233(6) and 2.241(5) A in 2), and a clearly longer distance for the ipso carbon (2.410(3) $\AA$ in 1, and 2.401(5) $\AA$ in 2). The two shortest Rh-C distances are nearly trans-disposed to the olefinic bonds, showing
${ }_{55}$ the electronic inter-ligand influence through the metal.
Although the olefinic $\mathrm{C}=\mathrm{C}$ bond distances seems not to be sensitive to the electronic or steric effects, as they exhibit statistically identical values for the two coe molecules in both complexes, and similar to the values reported in related ${ }_{60}$ systems, ${ }^{24}$ the M-C(olefin) distances clearly showed a dependence of the endo/exo disposition, having shorter M-C bond distances for the endo conformations (2.172(3) in 1, and $2.163(5) \AA$ in 2) and longer for the exo dispositions (2.244(3) in 1, and 2.198(8) $\AA$ in 2).
${ }_{65}$ The three rotational isomers of complexes $\left[\left(\eta^{6}-\mathrm{C}_{6} \mathrm{H}_{5}-\right.\right.$ $\left.\left.\mathrm{BPh}_{3}\right) \mathrm{M}(\mathrm{coe})_{2}\right](\mathrm{M}=\mathrm{Rh}$, Ir $)$ have been optimized by DFT calculations using the B3PW91 functional and its relative free energy calculated through frequency analysis. The most stable isomer of the rhodium compound is the exo-endo, being the endo${ }_{70}$ endo isomer just at $\Delta \mathrm{G}=2.8 \mathrm{~kJ} \cdot \mathrm{~mol}^{-1}$ above it. The exo-exo is the less stable isomer by $\Delta \mathrm{G}=32.8 \mathrm{~kJ} \cdot \mathrm{~mol}^{-1}$ above the first one. This suggests that only the exo-endo and endo-endo isomers are close enough in energy to be involved in the observed equilibrium while the exo-exo remains unobserved. ${ }^{26}$ For the iridium
75 compound a similar relationship has been calculated. The highest energy isomer is the exo-exo which is at $\Delta \mathrm{G}=41.7 \mathrm{~kJ} \cdot \mathrm{~mol}^{-1}$ above the exo-endo while the endo-endo is just at $\Delta \mathrm{G}=2.0$ $\mathrm{kJ} \cdot \mathrm{mol}^{-1}$ above it.
The rotation process between the exo-endo and endo-endo ${ }_{80}$ conformers of the rhodium compound has been studied by a
series of partial optimizations using a z-matrix coordinates setup and driving the dihedral angle which governs the olefin rotation towards +180 and $-180^{\circ}$ values in $15^{\circ}$ steps spanning a full rotation of one of the coe ligands. In this z-matrix coordinate system the endo-endo isomer is located at $+16^{\circ}$ and the more stable endo-exo at $185^{\circ}$ (Figure 4). The electronic total energy profile shows some irregularities, which reflect the variable environment of the olefin ligand during the rotation process that can lead to diverse steric interactions. The most relevant feature 10 is the location of two different energy maxima which suggest that the easiest isomerization pathway could be an oscillation of the coe ligand (windshield wiper motion) between its two minimum energy positions through the lowest energy barrier (around 46 $\mathrm{kJ} \cdot \mathrm{mol}^{-1}$ of electronic energy, interpolated from the rotation scan) 15 instead of completing a full rotation which would imply ca. 23 $\mathrm{kJ} \cdot \mathrm{mol}^{-1}$ of additional electronic energy to surmount the highest barrier which should be a less probable event.

Figure 4. Energy profile for the rotation process interconverting the endo20 endo and exo-endo rotational isomers in complex $\left[\left(\eta^{6}-\mathrm{C}_{6} \mathrm{H}_{5}\right.\right.$ $\left.\left.\mathrm{BPh}_{3}\right) \mathrm{Rh}(\mathrm{coe})_{2}\right](\mathbf{1})$.

Experimental rotational rates and barriers for $\mathbf{1}$ and 2 were obtained from magnetization transfer experiments using 2D EXSY NMR spectroscopy. This method has been increasingly 25 applied to the study of complex kinetic processes, fluxional behaviour, rotational barriers and conformational analysis. ${ }^{27}$ The essential feature of a quantitative 2D EXSY experiment is the relationship between the intensity of the cross-peaks and the rate constants for chemical exchange. The forward and backward ${ }_{30}$ exchange rate constants, $k_{1}$ and $k_{-1}$, for the rotamer equilibrium endo-endo $\leftrightarrows$ exo-endo in complexes $\mathbf{1}$ and 2 (Figure 3) were determined by integration of the cross-peaks between the para resonances of the $\eta^{6}$-arene in both interconverting species in the ${ }^{1} \mathrm{H}$ 2D-EXSY NMR spectrum. The integrals of the exchanged 35 cross-peaks were processed using the EXSYCalc program to give the rate constants $\left(k\right.$ and $\left.k_{-1}\right),{ }^{28}$ and the activation energies by using the Eyring equation (see SI). The kinetic parameters for the endo-endo $\leftrightarrows$ exo-endo equilibrium are summarized in Table 2.
The forward and backward exchange rate constants, $k_{1}$ and $k_{-1}$, for 40 the rhodium complex 1 were calculated to be $2.59 \mathrm{~s}^{-1}$ with an associated activation barrier of $64.5 \mathrm{~kJ} \cdot \mathrm{~mol}^{-1}(273 \mathrm{~K})$. However, the iridium complex 2 showed smaller rate constants, 0.016 and $0.051 \mathrm{~s}^{-1}$, and consequently higher activation barriers of 83.81 and $80.91 \mathrm{~kJ} \cdot \mathrm{~mol}^{-1}(300 \mathrm{~K})$. Noteworthy, the calculated
${ }_{5}$ equilibrium constants obtained from the determined rate constants $\left(k_{1} / k_{-1}\right)$ are in good agreement with those experimental values obtained from the same sample by integration of both resonances in an experiment recorded with the same relaxation time.

Table 2. ${ }^{1} \mathrm{H}$ 2D EXSY-derived rate constants ( $k_{1}$ and $k_{-1} / \mathrm{s}^{-1}$ ) and activation energies $\left(\Delta \mathrm{G}_{1}{ }^{\#}\right.$ and $\left.\Delta \mathrm{G}_{-1}{ }^{\#} / \mathrm{kJ} \cdot \mathrm{mol}^{-1}\right)$ for the endo-endo $\leftrightarrows$ exoendo equilibrium in zwitterionic $\left[\mathrm{M}\left(\eta^{6}-\mathrm{C}_{6} \mathrm{H}_{5}-\mathrm{BPh}_{3}\right)(\text { coe })_{2}\right](\mathrm{M}=\mathrm{Rh}$, Ir) complexes. ${ }^{\text {a }}$

65
Rotation about the $\mathrm{M}\left(\eta^{6}\right.$-arene) bond axis in zwitterionic [ $\eta^{6}$ $\left.\mathrm{C}_{6} \mathrm{H}_{5}-\mathrm{BPh}_{3}\right) \mathrm{ML}_{n}$ ] complexes is expected to have a low rotational barrier under no steric constrains. In fact, restricted rotation has only been observed in complex $\left[\left(\eta^{6}-\mathrm{C}_{6} \mathrm{H}_{5}-\mathrm{BPh}_{3}\right) \mathrm{Rh}(\mathrm{dppb})\right]$ (dppb $70=1,4$-bis(diphenylphino)butane) down to $194 \mathrm{~K} .{ }^{29}$ Most probably this effect is a consequence of the size of the seven-membered chelate ring that produces steric interference with the phenyl groups of the tetraphenylborate fragment.
To the best of our knowledge, the only examples for which the 75 free energy of activation for the cyclooctene rotation about the metal-cyclooctene bond axis has been determined are complexes $\left[\left(\eta^{5}-\mathrm{C}_{9} \mathrm{H}_{7}\right) \operatorname{Ir}(\right.$ coe $\left.)(\mathrm{CO})\right]$ and $\left[\left(\eta^{5}-\mathrm{C}_{5} \mathrm{H}_{5}\right) \operatorname{Ir}(\right.$ coe $\left.)(\mathrm{CO})\right]$, the indenyl complex exhibiting a significantly lower rotational barrier than the corresponding cyclopentadienyl complex, 60.7 and 84.5 ${ }_{80} \mathrm{~kJ} \cdot \mathrm{~mol}^{-1}$, respectively. ${ }^{22 \mathrm{~b}}$ Interestingly, the propeller-like ethylene rotation in related complexes $\left[\left(\eta^{5}-\mathrm{C}_{9} \mathrm{H}_{7}\right) \operatorname{Ir}\left(\mathrm{C}_{2} \mathrm{H}_{4}\right)(\mathrm{CO})\right]$ and $\left[\left(\eta^{5}-\right.\right.$ $\left.\left.\mathrm{C}_{5} \mathrm{H}_{5}\right) \operatorname{Ir}\left(\mathrm{C}_{2} \mathrm{H}_{4}\right)(\mathrm{CO})\right]$ showed comparable rotational barriers of 58.1 and $83.6 \mathrm{~kJ} \cdot \mathrm{~mol}^{-1}$, respectively. ${ }^{30}$ As it has been found in our zwitterionic $\left[\left(\eta^{6}-\mathrm{C}_{6} \mathrm{H}_{5}-\mathrm{BPh}_{3}\right) \mathrm{M}(\text { coe })_{2}\right]$ complexes, the ethylene 85 rotation barrier in the $\operatorname{Ir}(\mathrm{I})$ complex $\left[\left(\eta^{5}-\mathrm{C}_{5} \mathrm{H}_{5}\right) \operatorname{Ir}\left(\eta^{2}-\mathrm{C}_{2} \mathrm{H}_{4}\right)_{2}\right]$ is higher than in the $\mathrm{Rh}(\mathrm{I})$ complex $\left[\left(\eta^{5}-\mathrm{C}_{5} \mathrm{H}_{5}\right) \mathrm{Rh}\left(\eta^{2}-\mathrm{C}_{2} \mathrm{H}_{4}\right)_{2}\right]$, 80.6 and $65.6 \mathrm{~kJ} \cdot \mathrm{~mol}^{-1}$, respectively. ${ }^{31}$
In contrast to $\left[\left(\eta^{6}-\mathrm{C}_{6} \mathrm{H}_{5}-\mathrm{BPh}_{3}\right) \mathrm{Rh}\right.$ (diene)], the bis-cyclooctene complex $\left[\left(\eta^{6}-\mathrm{C}_{6} \mathrm{H}_{5}-\mathrm{BPh}_{3}\right) \mathrm{Rh}(\text { coe })_{2}\right]$ (1) showed no catalytic ${ }_{90}$ activity for the polymerization of monosubstituted acetylenes illustrating the key role of the diene ligand in the former efficient initiators. On the other hand, preliminary reactivity studies have shown that replacement reactions on $\mathbf{1}$ take place quite slowly under thermal conditions suggesting that the cyclooctene ligands 95 are far less labile than previously thought, thereby limiting their application as synthetic precursor when using highly sensitive hemilabile phosphines. As an example, reaction of 1 with two equiv of $\mathrm{PPh}_{3}$ to give $\left[\left(\eta^{6}-\mathrm{C}_{6} \mathrm{H}_{5}-\mathrm{BPh}_{3}\right) \mathrm{Rh}\left(\mathrm{PPh}_{3}\right)_{2}\right]^{5 \mathrm{a}}$ required 1 hour at 333 K in tetrahydrofurane/methanol (3:1) (70\% isolated 100 yield).

## Conclusions

The zwitterionic $\left[\left(\eta^{6}-\mathrm{C}_{6} \mathrm{H}_{5}-\mathrm{BPh}_{3}\right) \mathrm{M}(\text { coe })_{2}\right] \quad(\mathrm{M}=\mathrm{Rh}$, Ir $)$ 5 complexes have been prepared from standard cyclooctene starting materials in good yield. The solid-state crystal structures of both complexes show an unusual exo-endo disposition of the cyclooctene ligands. In solution, both complexes exhibit an interesting dynamic behaviour associated to the hindered rotation 10 about the metal-cyclooctene bond imparted by the bulky $\eta^{6}$ $\mathrm{C}_{6} \mathrm{H}_{5}-\mathrm{BPh}_{3}$ ligand. The equilibrium between the endo-endo and exo-endo rotational isomers has been fully characterized by means of 2D NMR correlation spectroscopy. Both rotamers were found in 1:1 ratio in the rhodium complexes whereas the endo${ }_{5}$ endo rotamer predominated in the iridium complex (3:1 ratio). DFT calculations in both complexes have shown that the energy of exo-exo rotational isomer is well over that of the more stable endo-endo isomer. In contrast, the exo-endo and endo-endo rotational isomers are close enough in energy, which is in full
20 agreement with the observed equilibrium. Average rotational barriers of around $65 \mathrm{~kJ} \cdot \mathrm{~mol}^{-1}(\mathrm{Rh})$ and $84 \mathrm{~kJ} \cdot \mathrm{~mol}^{-1}$ (Ir) have been determined experimentally by 2D EXSY NMR spectroscopy. The energy profile for the rotation process interconverting the endoendo and exo-endo rotational isomers strongly suggests that the
25 most probably isomerization pathway is a windshield wiper motion of the cyclooctene ligands instead of completing a full rotation. Finally, preliminary reactivity studies on these zwitterionic complexes have shown that the cyclooctene ligands are less labile than could be expected.

## ${ }_{30}$ Experimental

## Synthesis

All experiments were carried out under an atmosphere of argon using Schlenk techniques. Solvents were obtained from a Solvent Purification System (Innovative Technologies). Oxygen-free 35 solvents were employed throughout. $\mathrm{CD}_{2} \mathrm{Cl}_{2}$ was dried using activated molecular sieves. Standard literature procedures were used to prepare the starting materials $\left[\mathrm{Rh}(\mu-\mathrm{Cl})(\mathrm{coe})_{2}\right]_{2}^{32}$ and $\left[\operatorname{Ir}(\mu-\mathrm{Cl})(\mathrm{coe})_{2}\right]_{2} .{ }^{33}$

## Scientific Equipment

${ }_{40}$ Elemental analyses were carried out in a Perkin-Elmer 2400 CHNS/O analyzer. NMR spectra were recorded on a Bruker Avance 400 spectrometer. ${ }^{1} \mathrm{H}(400.13 \mathrm{MHz})$ and ${ }^{13} \mathrm{C}(100.61$ $\mathrm{MHz}) \mathrm{NMR}$ chemical shifts are reported in ppm relative to tetramethylsilane and referenced to partially deuterated solvent
${ }_{45}$ resonances. Coupling constants $(J)$ are given in Hertz. ${ }^{1} \mathrm{H}$ 2D EXSY NMR spectra were recorded on a Bruker Avance 500 spectrometer operating at 500.13 MHz . Spectral assignments were achieved by combination of ${ }^{1} \mathrm{H}-{ }^{1} \mathrm{H}$ COSY, NOESY, ${ }^{13} \mathrm{C}$ DEPT and APT, ${ }^{1} \mathrm{H}-{ }^{13} \mathrm{C}$ HSQC and ${ }^{1} \mathrm{H}-{ }^{13} \mathrm{C}$ HMBC experiments.
${ }_{50}$ Electrospray mass spectra (ESI-MS) were recorded on a Bruker MicroTof-Q using sodium formiate as reference.

## $\left[\left(\eta^{6}-\mathrm{C}_{6} \mathrm{H}_{5}-\mathrm{BPh}_{3}\right) \mathbf{R h}(\mathbf{c o e})_{2}\right](\mathbf{1})$

$\mathrm{NaBPh}_{4}(210 \mathrm{mg}, 0.614 \mathrm{mmol})$ was added to a yellow suspension
of $\left[\mathrm{Rh}(\mu-\mathrm{Cl})(\text { coe })_{2}\right]_{2}(200.0 \mathrm{mg}, 0.279 \mathrm{mmol})$ in methanol (12 ${ }_{55} \mathrm{~mL}$ ). The suspension was stirred for 5 h to give a pale yellow solid which was separated by filtration, washed with methanol (4 x 4 mL ) and dried in vacuum. Yield: $92 \%$ ( 330 mg ). Anal. Calcd for $\mathrm{C}_{40} \mathrm{H}_{48} \mathrm{BRh}: \mathrm{C}, 74.77$; $\mathrm{H}, 7.53$. Found: C, 74.21 ; H 7.19. Spectroscopic analysis at 253 K showed the existence of two ${ }_{60}$ rotamers, endo-endo ( $R 1$ ) and exo-endo ( $R 2$ ), in $1: 1$ ratio. ${ }^{1} \mathrm{H}$ NMR (400.13 MHz, $298 \mathrm{~K}, \mathrm{CD}_{2} \mathrm{Cl}_{2}$ ): $\delta 7.45-7.00(\mathrm{~m}, 30 \mathrm{H}$, $\mathrm{BPh}_{3}$ ), 6.86, 6.71 (br m, 2H each, $\mathrm{H}_{\mathrm{p}}$ ), 6.36 (br m, $2 \mathrm{H}, \mathrm{H}_{\mathrm{o}} / \mathrm{H}_{\mathrm{m}}$ ), 6.16 (br m, $4 \mathrm{H}, \mathrm{H}_{\mathrm{o}} / \mathrm{H}_{\mathrm{m}}$ ), 5.92 (br m, $\left.2 \mathrm{H}, \mathrm{H}_{0} / \mathrm{H}_{\mathrm{m}}\right)\left(\eta^{6}-\mathrm{C}_{6} \mathrm{H}_{5}\right), 3.76$ (br m, 2H, $=\mathrm{CH}$, coe), 2.83-1.03 (m, 54H, $=\mathrm{CH}$ and $>\mathrm{CH}_{2}$, coe).

## Theoretical Calculations

All computations were performed using the Gaussian 09 package. ${ }^{34}$ The structures of the minima were fully optimized 5 without geometrical constraints and confirmed by frequency calculations. The rotation of the cyclooctene ligand was studied by setting up a z-matrix definition for the molecule and driving the relevant dihedral through a full rotation (see SI). Calculations were carried out using the B3PW91 functional and the basis sets 10 used were: LANL2DZ supplemented with an f function ${ }^{35}$ and its associated ECP for rhodium and 6-31G** for the rest of atoms.

## Crystal Structure Determination

Single crystals for the X-ray diffraction study of $\mathbf{1}$ and 2 (irregular blocks) were grown by slow diffusion of methanol into 15 concentrate solutions of the compounds in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ at 253 K . Xray diffraction data were collected at $100(2) \mathrm{K}$ on a Bruker APEX DUO CCD diffractometer with graphite-monochromated Mo-K radiation $(\lambda=0.71073 \AA)$ using narrow $\omega$ rotations $\left(0.3^{\circ}\right)$. Intensities were integrated with SAINT-PLUS program ${ }^{36}$ and 20 corrected for absorption effects with SADABS. ${ }^{37}$ The structures were solved by direct methods with SHELXS $-97^{38}$ and refined, by full matrix least-squares on $F^{2}$, with SHELXL-97. ${ }^{39}$ Both structures were refined first with isotropic and later with anisotropic displacement parameters for non-H atoms. At this ${ }_{25}$ point, ADP's revealed that both crystal structures showed a similar static disorder involving both cyclooctene ligands. Eventually two disordered cyclooctene moieties were included in the refinement with some feeble geometrical restrictions to model each of the two olefins present in the complexes $\left[\left[\left(\eta^{6}-\mathrm{C}_{6} \mathrm{H}_{5}\right.\right.\right.$ $\left.\left.{ }_{30} \mathrm{BPh}_{3}\right) \mathrm{M}(\mathrm{coe})_{2}\right]$; in the case of $\mathbf{1}$ a unique complementary occupancy factor was used for both coe molecules (0.678/0.322(4)), while in the case of 2 each disordered coe was refined with an independent complementary occupancy ( $0.776 / 0.224(8)$ and $0.578 / 0.422(10))$. Eventually only the two 35 most abundant coe molecules allow the refinement with anisotropic displacement parameters, while isotropic thermal parameters were used for the less abundant disordered molecules. An additional partial molecule ( 0.25 occupancy factor) of a disordered dichloromethane molecule was also present in both 40 crystal structures. This solvent molecule was observed highly disordered and modelled in the best possible way (see supplementary material). Hydrogen atoms (except those of the disordered $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ solvent) were included for both complexes from calculated positions and refined with positional and ${ }_{45}$ displacement riding parameters.

Crystal Data for 1: $\mathrm{C}_{40} \mathrm{H}_{48} \mathrm{BRh} \cdot 0.25 \mathrm{CH}_{2} \mathrm{Cl}_{2} ; M=663.74$; yellow block $0.221 \times 0.134 \times 0.117 \mathrm{~mm}^{3}$; triclinic; $P-1 ; a=$ 8.9933(5), $b=10.5938(6), c=17.9914(10), \alpha=79.8632(8), \beta=$ ${ }_{50} 79.6103(7), \gamma=84.0189(8)^{\text {o }} ; Z=2 ; V=1655.02(16) \AA^{3} ; D_{c}=$ $1.332 \mathrm{~g} / \mathrm{cm}^{3} ; \mu=0.584 \mathrm{~mm}^{-1}$; min. and max. absorption correction factors 0.8819 and $0.9359 ; 2 \theta_{\max }=60.74^{\circ} ; 19376$ reflections collected, 9114 unique $\left(R_{\text {int }}=0.0231\right)$; number of data/restraints/parameters $9114 / 36 / 550$; final GOF $1.035 ; R_{1}=$ 550.0556 (7824 reflections, $I>2 \sigma(I)$ ); $w R\left(F^{2}\right)=0.1256$ for all data; largest difference peak $1.247 \mathrm{e} / \AA^{3}$, observed in the spatial region of one of the disordered coe molecules. In this complex, also one
of the non-coordinated phenyl groups of the $\mathrm{BPh}_{4}{ }^{-}$anion showed static disorder; a simple model with two isotropic $\mathrm{C}_{6} \mathrm{H}_{5}$ groups 60 with identical occupancy were included in the refinement.

Crystal Data for 2: $\mathrm{C}_{40} \mathrm{H}_{48} \mathrm{BIr} \cdot 0.25 \mathrm{CH}_{2} \mathrm{Cl}_{2} ; M=753.03$; colorless block $0.273 \times 0.221 \times 0.176 \mathrm{~mm}^{3}$; triclinic; $P-1$; $a=$ 9.0451(9), $b=10.6166(10), c=18.0547(17), \alpha=78.6882(12), \beta$ $=79.8650(13), \gamma=83.4888(11)^{\circ} ; Z=2 ; V=1668.0(3) \AA^{3} ; D_{c}=$ ${ }_{65} 1.499 \mathrm{~g} / \mathrm{cm}^{3} ; \mu=4.070 \mathrm{~mm}^{-1}$; min. and max. absorption correction factors 0.4029 and $0.5345 ; 2 \theta_{\max }=58.14^{\circ} ; 17480$ reflections collected, 8303 unique ( $R_{\text {int }}=0.0204$ ); number of data/restraints/parameters 8303/38/473; final GOF $1.158 ; R_{1}=$ 0.0458 (7570 reflections, $I>2 \sigma(I)$ ); $w R\left(F^{2}\right)=0.1116$ for all data; ${ }_{0}$ largest difference peak $3.327 \mathrm{e} / \AA^{3}$. Five residuals over $1 \mathrm{e} / \AA^{3}$ were observed in the final Fourier map; the three more intense were in close proximity to the metal (with no chemical sense) and the two additional in the region of the disordered coe molecules.

## Acknowledgments

${ }_{75}$ Financial support from the Spanish Ministerio de Economía y Competitividad (MINECO/FEDER) of Spain (CTQ2010-15221 and CONSOLIDER INGENIO CSD2009-00050), the Diputación General de Aragón (DGA/FSE-E07) and the ARAID Foundation, is gratefully acknowledged.

26 Although the tiny resonance at $\delta 3.41 \mathrm{ppm}$ in the ${ }^{1} \mathrm{H}$ NMR spectrum of $\mathbf{1}$ could be tentatively assigned to the exo-exo rotational isomer, we do not have conclusive evidence as neither exchange cross peaks ( ${ }^{1} \mathrm{H}-$ ${ }^{1} \mathrm{H}$ NOESY) nor correlation $\left({ }^{1} \mathrm{H}^{-13} \mathrm{C}\right.$ HSQC) could be observed in the NMR spectra (see SI).

## Graphical abstract

Synthesis and Dynamic Behaviour of Zwitterionic [ $M\left(\eta^{6}\right.$ $\left.\left.\mathbf{C}_{6} \mathbf{H}_{5}-\mathrm{BPh}_{3}\right)(\mathbf{c o e})_{2}\right](\mathrm{M}=\mathrm{Rh}, \mathrm{Ir})$ Cyclooctene Complexes

Jesús J. Pérez-Torrente,* Marta Angoy, Daniel Gómez-Bautista, Adrián Palacios, M. Victoria Jiménez, F. Javier Modrego, Ricardo Castarlenas, Fernando J. Lahoz and Luis A. Oro

The zwitterionic $\left[\left(\eta^{6}-\mathrm{C}_{6} \mathrm{H}_{5}-\mathrm{BPh}_{3}\right) \mathrm{M}(\text { coe })_{2}\right] \quad(\mathrm{M}=\mathrm{Rh}$, Ir $)$ cyclooctene complexes show an unual equilibrium between the endo-endo and exo-endo rotational isomers arising from the hindered rotation about the metal-cyclooctene bond.
