Abstract: High pressure die-casting alloys were not basically suitable for T6 treatment. The partial solution treatment was developed to enhance the mechanical properties for a new designed die-cast Al-Mg-Zn-Si alloy. The strengthening mechanism was that the $Mg_{32}(Al,Zn)_{49}$ intermetallics and equilibrium $MgZn_2$ phase formed in the as-cast microstructure were partially dissolved into the α -Al matrix during solutionising and the fine semi-coherent η' - $MgZn_2$ phases were precipitated during subsequent aging. Consequently, a unique microstructure was obtained by the co-existence of equilibrium $MgZn_2$ and metastable η' - $MgZn_2$ phase in the α -Al matrix, together with the un-changed Mg_2Si eutectic and remnant $Mg_{32}(Al,Zn)_{49}$ intermetallics in the Al-Mg-Zn-Si alloy.

Key Word: Aluminium alloys; Mechanical property; Microstructure; Heat treatment; High pressure die-casting.

1 The application of thin-wall components made by high pressure die-casting of aluminium
2
3 alloys is one of the preferred options to make light weight structures in automotive industry
4
5 [1,2]. However, the existing die-cast Al alloys based on Al-Si, Al-Si-Cu and Al-Mg-Si
6
7 systems are generally not desirable to provide required mechanical properties, in particular,
8
9 the yield strength and elongation under as-cast condition [3,4]. This has been partially
10
11 attributed to the presence of substantial amount of porosity in die-castings, which result in the
12
13 inapplicability of standard full solution and ageing treatment to enhance the mechanical
14
15 properties [5,6]. Although a quick solution treatment process was developed for die-cast
16
17 Al-Si-Cu alloys to eliminate blistering and porosity [7, 8], the elongation of the existing
18
19 Al-Si-Cu alloys is still hardly satisfied by industrial requirements.
20
21
22
23
24
25
26
27
28

29 Recently, a die-cast Al-Mg-Zn-Si alloy was developed by forming specific intermetallics
30
31 ($Mg_{32}(Al,Zn)_{49}$, Mg_2Si and $MgZn_2$) under as-cast condition [9]. One of the significant
32
33 advantages was that the alloy was designed for precipitation strengthening through
34
35 solutionising and ageing. However, when a solutionising process at 490-510°C for 30-60 min
36
37 was applied, the Al-Mg-Zn-Si alloy was prone to forming blisters or overfiring because the
38
39 equilibrium reaction of Al-MgZn₂ eutectic was about 470 °C [5]. Therefore, it is essential to
40
41 develop a new heat treatment for the Al-Mg-Zn-Si alloy to improve simultaneously the yield
42
43 strength and elongation without overfiring or forming blisters. In this paper, we study the
44
45 strengthening mechanism of the Al-Mg-Zn-Si alloy after being partially solutionised and
46
47 subsequently aged. The microstructure and mechanical properties of the alloy were reported
48
49 and discussed.

1 The die-cast Al-10.2Mg-2.7Si-3.2Zn (wt.%) alloy was prepared and cast in a 4500 KN high
2
3 pressure die casting machine. The partial solution was performed at 430 °C for different times,
4
5 and subsequent ageing was performed at 160 °C for 90 min. Scanning electron microscopy
6
7 (SEM) and transmission electron microscopy (TEM) were used to analyse the mechanism of
8
9 improving the mechanical properties.
10
11
12
13
14
15

16 Figure 1a shows the mechanical properties of the Al-Mg-Zn-Si alloy after partial solution at
17
18 430 °C for different times. It was clear that the ultimate tensile strength (UTS) was only
19
20 slightly increased from 350 MPa to 362 MPa over the different solutionising times. However,
21
22 the elongation was significantly increased from 2.7% under as-cast condition to 5.5% after
23
24 being solutionised for 60 min and further to 9.6% when the solution time was 150 min.
25
26 Meanwhile, the yield strength was decreased from 220 MPa to 150 MPa. Obviously, the
27
28 partial solution could significantly alter the elongation but reduce the yield strength.
29
30
31
32 Furthermore, as shown in Figure 1b, the yield strength, UTS and elongation was 285 MP, 386
33
34 MPa and 5.0%, respectively, for the Al-Mg-Zn-Si alloy after partial solution at 430 °C for 60
35
36 min and aged at 160 °C for 90 min. Compared with those under as-cast condition, the yield
37
38 strength, UTS and elongation was increased by 29.5%, 10.3% and 85.2%, respectively.

64
65

66 Figure 2 is the backscattered SEM microstructure of the Al-Mg-Zn-Si alloy under as-cast
67
68 condition and after being solutionised at 430 °C for 60 min. It was clear that a large number
69
70 of white $Mg_{32}(Al,Zn)_{49}$ intermetallics were located among the primary α -Al phase or between

1 the eutectic cell and the primary α -Al phase in the as-cast samples (Figure 2a and c). The
2
3 $Mg_{32}(Al,Zn)_{49}$ intermetallics showed a sharp edge and irregular morphology. After the partial
4
5 solution treatment, most of the white $Mg_{32}(Al,Zn)_{49}$ intermetallics were dissolved into the
6
7 α -Al matrix (Figure 2b). the volume fraction and sizes were dramatically decreased and the
8
9 edges became blunt (Figure 2d). On the other hand, the morphology and the volume fraction
10
11 of Mg_2Si eutectic was maintained no change after partial solution due to the low solution
12
13 temperature and the short solution time, which indicated that the Mg_2Si eutectic would not
14
15 provide positive effect on the improvement of mechanical property after partial solution. In
16
17 addition, it should be noted that blisters formed on the casting surface and overfired
18
19 microstructure are two critical detrimental factors to affect the mechanical properties of
20
21 die-cast alloys. If the solution temperature was high and/or the solution time was long, the
22
23 mechanical properties of die-castings was deteriorated [5]. Therefore, the solution at 430 °C
24
25 for 60 min was selected for further study because the $Mg_{32}(Al,Zn)_{49}$ intermetallics was
26
27 partially retained in the microstructure and the mechanical properties were improved in the
28
29 subsequently aged Al-Mg-Zn-Si alloy.

37
38
39
40
41
42

43 In order to understand the strengthening mechanism, TEM and high resolution TEM
44
45 (HRTEM) observations were performed for the Al-Mg-Zn-Si alloy after being solutionised at
46
47 430 °C for 60 min and subsequently aged at 160 °C for 90 min. The corresponding
48
49 microstructural characteristics are presented in Figure 3. It was obvious that a large number
50
51 of fine precipitates with 5-10 nm size were homogeneously distributed in the α -Al matrix
52
53 (Figure 3a). Further, the corresponding select area diffraction patterns (SADP) in the area
54
55 under the $[112]_{Al}$ zone axis in Figure 3b showed that several weak diffraction spots were
56
57
58
59
60
61
62
63
64
65

1 located at the $1/3$ and $2/3$ 220_{Al} positions in addition to the diffraction spots from the α -Al
2
3 matrix. These typical diffraction information indicated that the fine precipitates were most
4
5 likely the η' phase with a HPC structure, which was a metastable phase of MgZn_2 phase and
6
7 was always found in Al-Zn-Mg-(Cu) alloys as the most important strengthening phase when
8
9 the alloys reached a peak hardness [10][11]. Based on the SADP, the orientation relationships
10
11 between the η' phase and the Al matrix could be described as $[\bar{1}2\bar{1}3]_{\eta'}/[112]_{\text{Al}}$ and $(\bar{1}010)_{\eta'}$
12
13 $//(\bar{2}20)_{\text{Al}}$ (Figure 3b). The corresponding fast Fourier transform (FFT) of HRTEM image was
14
15 displayed at the lower right corner in Figure 3c, where several clear diffraction streaks were
16
17 also found at the $1/3$ and $2/3$ 220_{Al} positions. Based on the previous research in the
18
19 Al-Zn-Mg-Cu alloy [10][11], it was known that η' phases actually had four equivalent
20
21 variants, and the η' phase in Figure 3c only belonged to the one of four η' variants [11].
22
23 Therefore, its interface characteristics could be further analysed.
24
25
26
27
28
29
30
31
32
33
34

35 According to the obtained orientation relationships and HRTEM in Figure 3, the spacing of $(\bar{3}$
36
37 $030)_{\eta'}$ plane and $(\bar{1}2\bar{1}2)_{\eta'}$ plane were calculated as 0.148 nm and 0.241 nm, respectively.
38
39 Therefore, the lattice parameters of η' precipitate could be deduced as: $a=0.513$ nm and
40
41 $c=1.409$ nm, which were a little bigger than the lattice parameters proposed by Kverneland (a
42
43 $= 0.496$ nm and $c = 1.402$ nm) [12]. Furthermore, the lattice misfit δ between the η'
44
45 precipitate and the Al matrix could be calculated as only 3.4% using the spacing of two
46
47 parallel crystal planes $(\bar{3}030)_{\eta'}$ and $(\bar{2}20)_{\text{Al}}$. The 4.3% misfit indicated that the η' precipitates
48
49 had a semi-coherent interface with the Al matrix, which inevitably introduced a strain field in
50
51 the surroundings in the Al matrix. Figure 3d showed the strain map of η' precipitates in the
52
53 α -Al matrix calculated by Geometric Phase Analysis in $[\bar{2}20]_{\text{Al}}$ direction. A maximum 5%
54
55
56

58
59
60
61
62
63
64
65

1 tensile strain was found at the interface, as marked by an ellipse in Figure 3d. Therefore, the
2
3 η' precipitates could become the effective obstacles of dislocation movement to strengthen
4
5
6 the Al-Mg-Zn-Si alloy.
7

8
9
10 Furthermore, in order to understand the behaviour of precipitates phase in the α -Al phase,
11
12 TEM images were taken for the alloy under as-cast and under partial solution and aged
13
14 conditions, as shown in Figure 4. It was seen that numerous plate-shaped equilibrium
15
16 η -MgZn₂ phase with 200~300 nm long were found in the as-cast microstructure (Figure 4a).
17
18 After the partial solution and ageing, in addition to a large number of fine η' precipitates, a
19
20 portion of equilibrium η -MgZn₂ phase still existed in the α -Al matrix (Figure 4b). The
21
22 co-existence of fine η' precipitates and equilibrium η -MgZn₂ phase is unique microstructural
23
24 features for the partially solutionised and aged Al-Mg-Zn-Si alloy, which not only can
25
26 improve the elongation, but also can enhance the yield strength because of the precipitation
27
28 of fine semi-coherent η' phases. In the meantime, the relatively low solutionising temperature
29
30 is preferred because it can retard the formation of blisters on the casting surface and benefit
31
32 the dimensional stability of die-casting Al alloys.
33
34
35
36
37
38
39
40
41
42

43
44 In conclusion, the partial solution treatment of die-cast Al-Mg-Zn-Si alloy is effective to
45
46 control the improvement of yield strength and elongation simultaneously, which also benefits
47
48 the reduction of porosities and blisters by applying relatively lower solutionising temperature
49
50 and shorter time in comparison with the conventional solutionising process. The
51
52 strengthening mechanism is that the equilibrium MgZn₂ phase in the α -Al phase and the
53
54 $\text{Mg}_{32}(\text{Al,Zn})_{49}$ intermetallics formed in the as-cast microstructure are partially dissolved into
55
56
57
58
59
60
61
62
63
64
65

1 the α -Al matrix during solutionising, and fine metastable η' phases are precipitated from the
2
3 α -Al matrix in the subsequent aging. This unique microstructure is characterised by the
4
5 co-existing of equilibrium MgZn_2 and metastable η' phase in the primary α -Al phase, together
6
7
8 with the un-changed Mg_2Si eutectic and remnant $\text{Mg}_{32}(\text{Al,Zn})_{49}$ intermetallics in the die-cast
9
10
11 Al-Mg-Zn-Si alloy.
