Aims

Valvular heart disease can be identified by calcification on coronary computed tomography angiography (CCTA) and has been associated with adverse clinical outcomes. We assessed aortic and mitral valve calcification in patients presenting with stable chest pain and their association with cardiovascular risk factors, coronary artery disease, and cardiovascular outcomes.

Methods and results

In 1769 patients (58 ± 9 years, 56% male) undergoing CCTA for stable chest pain, aortic and mitral valve calcification were quantified using Agatston score. Aortic valve calcification was present in 241 (14%) and mitral calcification in 64 (4%). Independent predictors of aortic valve calcification were age, male sex, hypertension, diabetes mellitus, and cerebrovascular disease, whereas the only predictor of mitral valve calcification was age. Patients with aortic and mitral valve calcification had higher coronary artery calcium scores and more obstructive coronary artery disease. The composite endpoint of cardiovascular mortality, non-fatal myocardial infarction, or non-fatal stroke was higher in those with aortic [hazard ratio (HR) 2.87; 95% confidence interval (CI) 1.60–5.17; $P < 0.001$] or mitral (HR 3.50; 95% CI 1.47–8.07; $P = 0.004$) valve calcification, but this was not independent of coronary artery calcification or obstructive coronary artery disease.

Conclusion

Aortic and mitral valve calcification occurs in one in six patients with stable chest pain undergoing CCTA and is associated with concomitant coronary atherosclerosis. Whilst valvular calcification is associated with a higher risk of cardiovascular events, this was not independent of the burden of coronary artery disease.

Keywords

aortic valve • mitral valve • computed tomography • computed tomography coronary angiography

Introduction

Valvular heart disease is an important cause of morbidity and mortality worldwide and shares similar risk factors with coronary artery disease.¹ Incidental calcification of the aortic or mitral valve on

computed tomography (CT) may identify patients with previously undiagnosed valvular heart disease. Coronary CT angiography (CCTA) is now a widely used non-invasive imaging modality, frequently the first-line investigation for patients with suspected coronary artery disease.^{2,3} Therefore, the identification of incidental

valvular calcification on CCTA represents a potentially important opportunity for screening and patient risk stratification.⁴⁻⁷

Aortic valve calcification is an established marker of aortic stenosis, with the aortic valve calcium score on CT associated with hemodynamic severity of aortic stenosis on echocardiography.⁸⁻¹⁰ Robust sex-specific aortic valve CT calcium score thresholds for severe aortic stenosis have been proposed, validated,^{11,12} and recommended in recent international guidelines for the assessment of aortic stenosis severity when echocardiographic assessments are discordant.¹³ Mitral valve annular calcification is also a frequent finding on CCTA and may be associated with mitral valve dysfunction.^{14,15} Previous studies have suggested that patients with aortic stenosis and mitral valve calcification have an increased frequency of cardiovascular mortality beyond that related to the valve, including an increased risk of myocardial infarction (MI) and stroke, although the mechanisms underlying these associations remain unclear.^{7,16,17}

In this study, we identified the prevalence and severity of incidental aortic and mitral valve calcification in patients undergoing CT as part of the Scottish Computed Tomography of the HEART (SCOT-HEART) trial, and assessed their association with cardiovascular risk factors, coronary artery disease, and cardiovascular outcomes.

Methods

Study design

In the SCOT-HEART multicentre randomized controlled trial, 4146 patients with suspected angina due to coronary artery disease were randomized to undergo either standard care or standard care and CT.¹⁸ The primary results of the SCOT-HEART trial have been published previously.¹⁹⁻²¹ Of the 1778 patients who subsequently underwent CT, 1769 images were available for analysis and included in this sub-study. Imaging included non-contrast CT for coronary artery calcium score and CCTA. The study was approved by the local ethics

committee and participants provided written informed consent. The data underlying this article will be shared on reasonable request to the corresponding author.

Demographic information and cardiovascular risk factors

Demographic information and information on cardiovascular risk factors were collected prospectively within the SCOT-HEART trial and obtained from the SCOT-HEART database.

Computed tomography

CT imaging was performed using a 64 (Brilliance 64, Philips Medical Systems, Netherlands and Biograph mCT, Siemens, Germany) or 320 multidetector (Aquilion ONE, Toshiba Medical Systems, Japan) scanner. Non-contrast electrocardiogram-gated CT for coronary calcium scoring and contrast-enhanced CCTA were performed as described previously.¹⁸

Assessment of valvular calcification

All CCTA images were visually assessed for the presence of aortic or mitral valve/annulus calcification (Figure 1). Quantitative assessment of the aortic valve and mitral calcification was performed on non-contrast CT imaging using the Agatston scoring method as previously described.^{12,15,22} Non-contrast images with 3-mm slices and 3-mm increment were assessed using semi-automatic software (VScore, Vital Images, USA). A threshold of 130 Hounsfield units was used for the identification of calcification. For cases where the location of the valve was uncertain on non-contrast images, contrast-enhanced CCTA was used to visually confirm the anatomy.

Clinical outcomes

Outcome information was obtained from national electronic health linkage data provided by the electronic Data Research and Innovation Service (eDRIS) of the National Health Service (NHS) Scotland. Outcomes were confirmed by review of the patient health records

Figure 1 Calcification of the aortic (A) and mitral (B) annulus (yellow arrow in patients with co-existing coronary artery disease (white arrow).

where required. Surgical coding information was used to identify patients who underwent aortic or mitral valve surgery using the OPCS (Office of Population Censuses and Surveys) 4 Classification of Surgical Operations and Procedures.

Statistical analysis

The primary composite endpoint of this sub-study was cardiovascular mortality, non-fatal MI, or non-fatal stroke. Quantitative data are presented as mean and standard deviation or, if the data were not normally distributed, median and interquartile intervals. Statistical significance was assessed using Pearson's χ^2 test, Fisher's exact test, Students *t*-test, or Mann-Whitney *U* test, as appropriate. Correlations were assessed using Spearman's rank order correlation (0–0.19 very weak, 0.2–0.39 weak, 0.40–0.59 moderate, 0.6–0.79 strong, and 0.8–1 very strong). Hazard ratios (HRs) and 95% confidence intervals (CIs) are presented. Ordinal regression analysis was performed to assess the effect of cardiovascular risk factors on aortic and mitral valve calcification. Multivariable analysis was performed including valvular calcification, coronary artery calcification, and the presence of obstructive coronary artery disease. Outcome data were analysed using Cox proportional hazards regression and presented graphically using cumulative incidence plots of the time to the first event. Statistical analysis was performed using R version 3.5.0 (R Foundation for Statistical Computing, Vienna, Austria). A statistically significant difference was defined as a two-sided *P*-value <0.05.

Results

Study population

Of the 4146 patients recruited into the study, 2073 were randomized to CT and 1769 CT scans were available and of suitable quality for analysis. Valvular calcification (Table 1) was identified in 273 (15%) patients, with aortic valve calcification occurring in 241 (14%) patients, mitral calcification in 64 (4%) patients, and combined aortic and mitral calcification in 32 (2%) patients. After 4.82 ± 1.13 years of follow-up, 53 patients had met the composite endpoint: cardiovascular mortality ($n = 4$), non-fatal MI ($n = 38$), or non-fatal stroke ($n = 11$).

Aortic valve calcification

Independent predictors of the presence of aortic valve calcification (Figure 2) were age [odds ratio (OR) 1.11; 95% CI 1.08–1.15; $P < 0.001$], male sex (OR 2.62; 95% CI 1.87–3.70; $P < 0.001$), hypertension (OR 1.39, 95% CI 1.02–1.88; $P = 0.037$), diabetes mellitus (OR 1.81; 95% CI 1.09–2.97; $P = 0.020$), and a prior history of cerebrovascular disease (OR 2.30; 95% CI 1.32–3.96; $P = 0.003$).

Patients with aortic valve calcification had a higher coronary artery calcium score [390 (interquartile range, IQR 61–1105) Agatston units (AU)] compared to those without aortic valve calcification [8 (IQR 0–145) AU, $P < 0.001$, Figure 3]. Patients with aortic valve calcification

Figure 2 Multivariable analysis of cardiovascular risk factors and the presence of aortic valve or mitral calcification. Age (years); male gender compared to female gender; smoking status compared to non-smokers; total cholesterol concentration per unit increment; symptoms compared to those with non-anginal chest pain; Risk_score, ASSIGN cardiovascular risk score; AF, atrial fibrillation; BMI, body mass index; CHD, previous history of coronary heart disease; CVD, previous history of cerebrovascular disease; FH, family history of coronary heart disease; HBP, hypertension; PVD, previous history of peripheral vascular disease; * $P < 0.05$; ** $P < 0.01$; *** $P < 0.001$.

were also more likely to have non-obstructive (41%) or obstructive (51%) coronary artery disease than patients without aortic valve calcification ($P < 0.001$). However, 9% ($n = 21/241$) of patients with aortic valve calcification had no coronary artery calcification, and 80% ($n = 907/1127$) of patients with coronary artery calcification had no aortic valve calcification. A correlation was observed between the aortic valve calcium score and coronary artery calcium score, but this was only weak ($r = 0.23$, $P < 0.001$, Figure 3).

A higher proportion of patients with aortic valve calcification met the composite endpoint compared to patients without aortic valve calcification [6.6% ($n = 16/241$) vs. 2.4% ($n = 37/1528$), $P = 0.002$; HR 2.87; 95% CI 1.60–5.17; $P < 0.001$ (Figure 4)]. However, on multivariable analysis, only coronary artery calcium score was an independent predictor of the composite endpoint (Table 2).

Mitral valve calcification

The only independent predictor of the presence of mitral valve calcification (Figure 2) was age (OR 1.09; 95% CI 1.03–1.15; $P = 0.002$). Patients with mitral calcification had a higher coronary artery calcium score [413 (IQR 36–1056) AU] compared to those without mitral

calcification [18 (IQR 0–202) AU, $P < 0.001$, Figure 4]. Patients with mitral calcification were also more likely to have both non-obstructive (45%) and obstructive (44%) coronary artery disease compared to patients without ($P < 0.001$). However, 14% ($n = 9/64$) of patients with mitral calcification had no coronary artery calcification, and 95% ($n = 1072/1127$) of patients with coronary artery calcification had no mitral calcification. There was no correlation between mitral valve calcium score and coronary artery calcium score ($r = 0.03$, $P = 0.68$, Figure 4).

Patients with mitral valve calcification were more likely to meet the composite endpoint compared to patients without mitral valve calcification [9.4% ($n = 6/64$) vs. 2.8% ($n = 47/1705$), $P = 0.01$]; HR 3.50; 95% CI 1.47–8.07; $P = 0.004$ (Figure 4). However, on multivariable analysis only coronary artery calcium score was an independent predictor of the composite endpoint (Table 3).

Discussion

In this large multicentre randomized controlled trial of patients undergoing CT for stable chest pain, we have shown that valvular

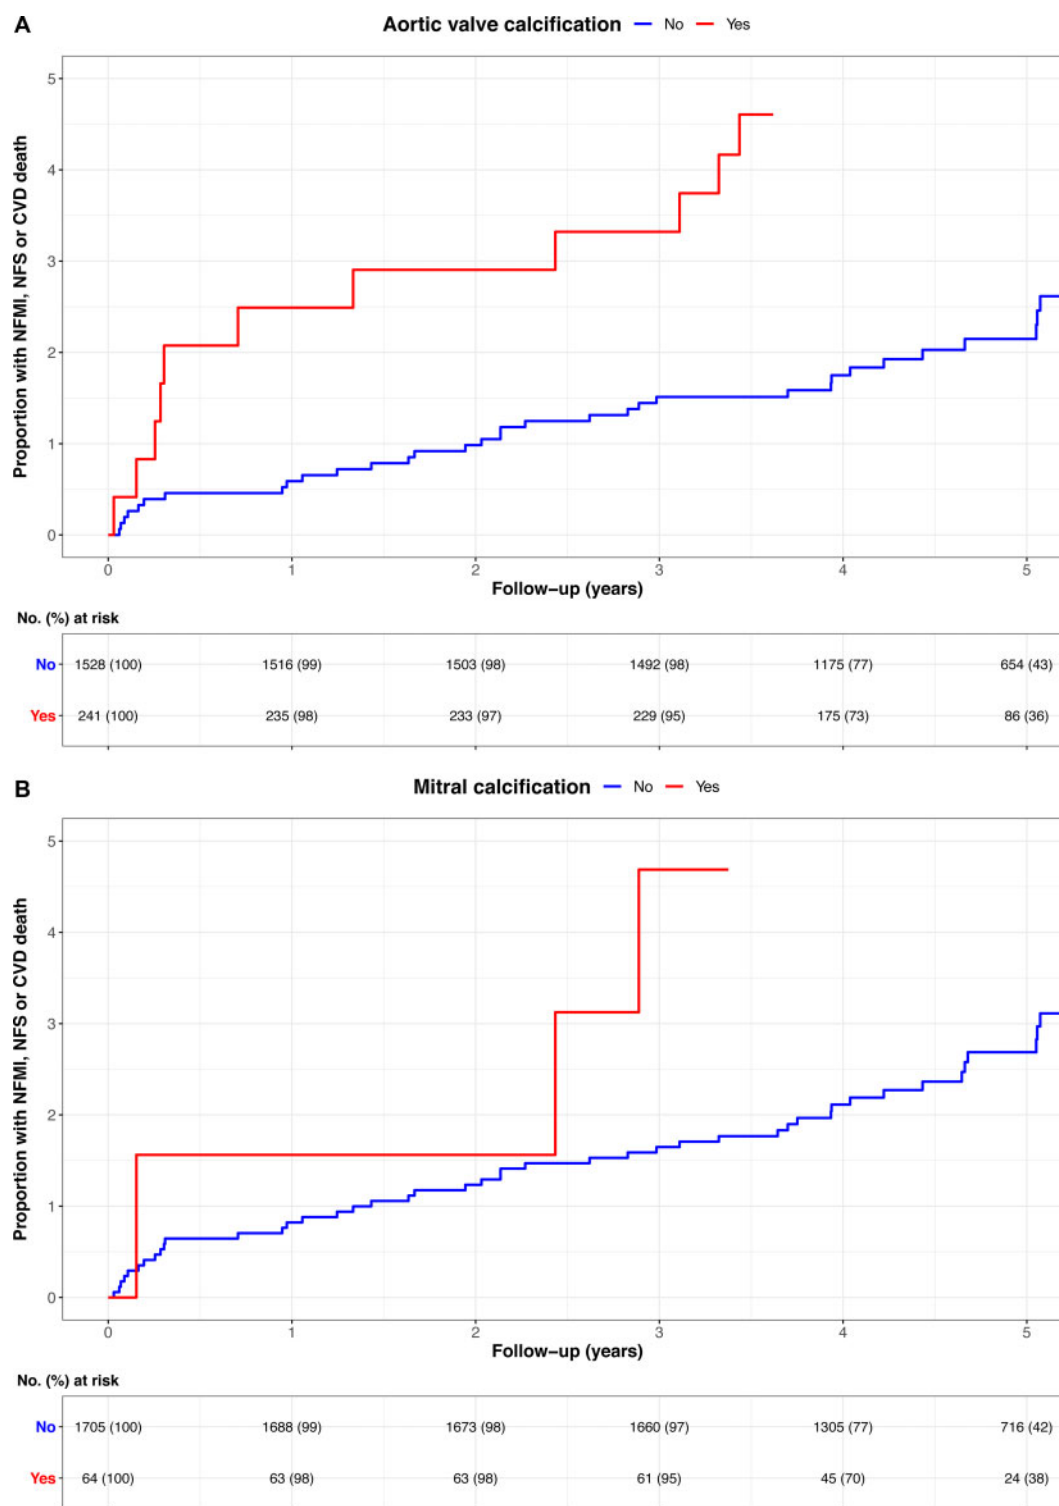

Figure 4 Cumulative incidence plot showing the association of the presence of (A) aortic valve calcification and (B) mitral calcification on the composite endpoint of cardiovascular death (CVD), non-fatal myocardial infarction (NFMI), or non-fatal stroke (NFS). The adverse outcomes associated with valve calcification were no longer evident once the burden of coronary atherosclerosis was considered in the multivariable model.

patients with coronary artery disease had valvular heart disease. Thus, the presence of valvular heart disease could be a trigger to assess the coronary arteries, but the presence of coronary artery disease is not an indication for valvular assessment with echocardiography.

Our study has several limitations. This includes the small number of clinical events and that patients were managed according to routine clinical practice rather than having management prescribed on the basis of the imaging findings. The prevalence of valvular calcification and cardiovascular risk factors varies depending on the cohort studied. The age range of the SCOT-HEART population meant that mild calcification was the most common pathology and that the 5-year duration of follow-up might not have been sufficient for this early stage of disease to result in clinical events. In addition, the SCOT-HEART participants were recruited from cardiology outpatient clinics with suspected angina due to coronary artery disease. Although two-thirds of the patients were ultimately diagnosed as not having angina due to coronary artery disease, these results may not be representative of asymptomatic patients or the general population. Finally, we do not have data on the progression of valve calcification in this cohort which in other studies appears unrelated to cardiovascular risk factors but is most closely associated with the severity of baseline valve disease and calcification.

Conclusion

Valvular calcification is a frequent incidental finding on CCTA and is associated with cardiovascular risk factors and the presence of coronary artery disease. Whilst patients with aortic or mitral valve calcification demonstrate a three-fold increased risk of future adverse cardiovascular events, this appears to be mediated by co-existent coronary artery disease.
