ABSTRACT

During recent years, there has been considerable effort made by various groups to advance the development of automatism in industry. An excellent example of this work is the "automation" program inaugurated at the Ford Motor Company.

Since the development of automatic machines will necessarily result in the transfer of functions and skills from the man to the machine, it would seem desirable to have available some method for determining the detailed functions performed by the man. This, then, is the objective of this thesis:

To develop a method for the analysis of human activity to determine the functions performed.

The steps followed in the development of the method were:

- (1) Development of a system of classification of human activity.
- (2) Development of a technique for observing and recording the basic data connected with human activity.
- (3) Development of a technique for analyzing the basic data.
- (4) Development of a method for portraying and summarizing the results.
- (5) Application of the method in a test case.

ABSTRACT

During recent years, there has been considerable effort made by various groups to advance the development of automatism in industry. An excellent example of this work is the "automation" program inaugurated at the Ford Motor Company.

Since the development of automatic machines will necessarily result in the transfer of functions and skills from the man to the machine, it would seem desirable to have available some method for determining the detailed functions performed by the man. This, then, is the objective of this thesis:

To develop a method for the analysis of human activity to determine the functions performed.

The steps followed in the development of the method were:

- (1) Development of a system of classification of human activity.
- (2) Development of a technique for observing and recording the basic data connected with human activity.
- (3) Development of a technique for analyzing the basic data.
- (4) Development of a method for portraying and summarizing the results.
- (5) Application of the method in a test case.

In developing the system of classification, human activity was first divided into sensory and manipulative activity. Sensory activity was further divided into visual, auditory and tactile activity. A study of the physiology of each sensory system was then made and a list of basic functions for that sensory system was prepared. Finally, these basic functions were used to develop the specific classifications of sensory activity.

The therbligs developed by the Gilbreths were used for the analysis of the manipulative activity.

The particular job chosen for the application of the method was the manufacture, by a skilled operator, of a gear blank on a Gisholt #4 Ram Type Turret Lathe.

The basic observable data of human activity consists of stimulus and corresponding response. In the application of the proposed method response activity was recorded directly, using motion-picture cameras. The stimuli data was then reconstructed from the film record with the aid of additional detailed information concerning the machine and the particular operation performed.

Standard micromotion analysis techniques were used for the analysis of the basic data with some modifications.

For the graphic portrayal of the results of the analysis, a "Total Activity Chart" was developed which is essentially a classified listing of the segments of activity in conjunction with a time scale.

Summaries of the results of the analysis were compiled including:

(1) A compilation of the frequency of occurrence and percent of total time spent in the performance of specific classifications of activity.

(2) A list of functions performed which are related to the control or action of the machine.

The results of the thesis are, first, the proposed method of analysis and, second, an example of its application.

Conclusions drawn from the development of the method and its application in a test case are:

(1) The detailed functions performed by a man in the operation of a machine can be determined by applying the method.

(2) The sensory functions related to the control or action of the machine can be determined.

(3) The frequency of occurrence and the percent of total time spent performing specific functions can be determined.

Recommendations for the further development and improvement of the method are given.

A PROPOSED METHOD FOR THE FUNCTIONAL ANALYSIS
OF MAN-MACHINE ACTIVITY TO AID IN THE
DEVELOPMENT OF AUTOMATIC DEVICES

INTRODUCTION

Development of Automatism

Since the beginning of the Industrial Revolution industrial progress in the purely technical sense has been associated with the transfer of function or skill from the man to the machine. In some instances this process has lead to the complete elimination of some work previously done by man; for example, the invention of spinning machines and looms has almost completely eliminated from modern society the work of spinning and weaving as a manual skill. In other instances this process has lead merely to the partial transfer of function or skill from the man to the machine; an example of this type is the development of the automatic screw machine from the turret lathe.

In more recent times this process of development has lead to the design of complete industrial processes from which the man has been completely eliminated, at least so far as direct participation is concerned. Many of these advances have come in the field of military or naval equipment. Here the driving motives have been time and complexity; either the problems were too complex to be solved by the people available, or they could not be solved in the time allowed. Also, in some cases the man's reaction time was too long to permit

the performance of some function with the desired degree of speed and accuracy. A prime example of this type is the development of the present system of naval gun control¹. Beginning with a crude system of centralized control and computing at the turn of the century, these systems have developed until now the tracking of targets, computing, aiming, loading and firing of the guns is done entirely without direct human participation.

In industry, since the same urgent driving motives have not been present, this development of fully automatic processes has been more gradual. Since the war, however, certain groups have embarked on programs specifically intended to eliminate as many human functions as possible from certain processes. An excellent example of this work in industry is ECME (electronic circuit manufacturing equipment) developed by John A. Sargrave, a British electrical engineer². This fully automatic equipment can produce three radio circuits a minute which are 80% complete. It should be noted that to make this process possible it was necessary to completely redesign the product. Another excellent example of this type of work is the "automation" program at the Ford Motor Company. Del S. Harder, Ford Vice-President of Production, has been credited with originating this term which has

¹"Key to the Automatic Factory, the Computers that Direct Guns Might Also Direct Machines", Fortune, 40 (Nov. 1949), 139-142.

²"The First Automatic Radio Factory", Fortune, 38 (Aug. 1948), 90-93.

been defined as "the automatic movement of parts between processing operations and synchronizing such movement with the production rhythm of the machine line"¹. The first application of these methods to a production line including machine tools was in the production of valve guide bushings at the Ford Highland Park Plant². In this line the castings are ground to length, centerless ground, drilled, reamed, formed, grooved, faced, bored, inspected and phosphate coated, all without being touched by human hands.

The development of these fully automatic processes is not entirely new to industry; some segments of industry employ automatic processes to a high degree. For instance, processes used in the chemical industry are, to a great extent, fully automatic. Also, the mass production bottling and packaging industries have long employed automatic methods of handling and control. The intentional development of automatic methods and processes throughout industry and particularly in the metal working and assembling industries, however, is a new departure.

Factors Which Encourage Automatism

Numerous factors have encouraged this new advance of automatism. In general, these factors may be classified as

¹A. H. Allen, Detroit editor of Steel, "Automation", Steel, 126 (April 3, 1950), 102.

²Nevin L. Bean, "Automation at the Highland Park Plant, Ford Motor Company", Machinery, 55 (June, 1949), 145.

either economic or technical. J. M. Delfs, Machinery Division, General Electric Corp., has clearly outlined the economic and technical factors which are encouraging this new development¹. Some of the economic factors are:

- (1) Labor rates and costs have increased rapidly in recent years.
- (2) Production volume for most products has greatly increased.
- (3) Manufactured products have become more complex.
- (4) Automatic controls have been found to give better quality and thus lower cost.
- (5) Automatic controls have been found to make more effective use of new cutting tool capabilities.

Some of the technical factors are:

- (1) New machine control systems have been introduced such as: (a) program control, (b) tracer control, (c) photoelectric line followers, (d) record playback systems, (e) Bullard "Man-au-trol", (f) Warner-Swazey "Electrocycle", (g) Arma Corp. "Arma-matic", etc.
- (2) New cutting tool materials have made possible the use of higher speeds and feeds and have thus reduced the machining part of the cycle of production.

¹J. M. Delfs, "Automatic Control of Machine Tools", Tool Engineer, 27 (Oct., 1951), 45.

- (3) The science of servo-mechanisms has been developed to a high degree of efficiency and this knowledge has become more widely available as an engineering technique.
- (4) Various types of computing and memory devices have been developed to a high degree of perfection and the knowledge of their capabilities has become widespread.
- (5) The technique of "automation" has been developed making use of hoppers, chutes, magazines, belt conveyors, iron hands, etc. These techniques have been widely publicized.

Proposals for Promoting Automatism

Various approaches to the problem of promoting or developing automation in industry have been proposed. Leaver and Brown, two Canadian physicists, claim that the greatest obstacle to the advancement of automation in industry is the current philosophy of machine design which designs the machine in terms of the product¹. They propose a new philosophy of machine design in which the machines would be designed in terms of the basic functions they would be required to perform.

A group of Harvard Business School students working under the leadership of John T. Diebold made a study of the

¹E. W. Leaver and J. J. Brown, "Machines Without Men", Fortune, 34 (Nov., 1946), 165.

problem of increasing automatism in industry and of the technology available for the solution of the problem¹. This group concluded that the development of automatic materials handling equipment was the most pressing problem in the development of automatic production processes. The solution proposed by this group is the use of standard production type machines connected by automatic materials handling and inspection equipment.

General Conclusions

In general, it may be concluded that the development of automatism in any segment of industry or the development of an automatic process for the manufacture of a particular product may require the solution of any or all of the following problems:

- (1) The redesign or modification of the product to make it more adaptable to automatic manufacture.
- (2) The redesign of the basic process of manufacture to make it more adaptable to automatic methods.
- (3) The redesign or modification of machine tools to adapt them to automatic loading and unloading and to adapt them for automatic control.
- (4) In some cases detector or receptor devices may require development or application.

¹ John T. Diebold, et al, "Making the Automatic Factory a Reality", a Harvard Business School Report.

- (5) Finally the integration and regulation of all the elements of the process by some control unit will be required.

OBJECTIVE

By definition, an automatic machine or process is "self-acting" or "self-regulating"; it is a process which acts or performs without human control. Since the development of automatic machines or processes will result in the transfer of functions and skills from the man to the machine, it would seem natural and logical to ask the question: What functions are performed by the man which are essential to the process and must, therefore, be incorporated into the machine or automatic device? To answer this question it would seem desirable to have available some technique or method of analyzing human activity to determine the functions being performed. This, then, is the objective of this investigation:

To develop a method for the analysis of human activity to determine the functions performed.

One of the questions asked by the Harvard Group in their study of automatism in industry was: "What is the function of man in our present manufacturing processes?"¹ In answering the question this group listed the following broad functions performed by men in industry today:

- (1) The operation of production type machines.
 - (a) Loads and unloads the machine.
 - (b) Visually inspects each piece as it is removed from the machine.

¹Ibid.

- (c) Watches the machine to detect any irregularities in its performance.
- (2) Operation of non-production type machines.
 - (a) All the functions listed above.
 - (b) Moves the tool or workpiece to perform the required machining operation.
 - (c) Typically has much greater control over the movement of the various parts of the machine.
- (3) Paper work.
- (4) Materials handling.
- (5) Production, cost and quality control.
- (6) Inspection.
- (7) Supervising semi-automatic processes.
- (8) Machine set-up work.
- (9) Maintenance work.
- (10) Assembly.

The consideration of these functions in terms of other questions asked by the group lead to several very useful conclusions, one of which was previously cited; however, this list would be of very little use to the machine or process designer actually faced with the problem of designing an automatic device. For this purpose a much more detailed knowledge of the functions of the existing man-machine combination would be required. It should be understood, then, that the objective to be achieved by this proposed analysis method is a much more detailed determination of the functions performed.

SCOPE OF THE THESIS

The scope of the present study has been limited to the development of the method of analysis. The logical steps in the development of the method are:

- (1) Development of a system of classification of human activity.
- (2) Development of a technique for observing and recording the basic data connected with human activity.
- (3) Development of a technique for analyzing the basic data.
- (4) Development of a method for portraying and summarizing the results.
- (5) Application of the method in a test case.

In practice, the application of the method did not occur as a separate step, rather, it was necessarily an integral part in the development of the method. This relationship will be maintained in the following discussion.

Choice of Application

Since most of the time spent on this investigation was in the development of the method of analysis, it was necessary to severely limit the number and variety of applications of the method. For this reason, the type of work to be analyzed was first limited to repetitive jobs in the metal cutting industry. Then a typical job on a ram type turret lathe was selected for the application of the method. The particular job chosen was the manufacture, by a skilled

operator, of a gear blank on a Gisholt #4 Ram Type Turret Lathe. It was felt that the performance of this particular job on this type of machine would be fairly representative of repetitive jobs in the metal cutting industry.

PROPOSED SYSTEM OF CLASSIFICATION OF HUMAN ACTIVITY

Necessity for a System of Classification

To repeat, the objective of this investigation is the development of a method for the analysis of human activity to determine the functions performed. Analysis is defined as the separation of anything into constituent parts or elements or as an examination of anything to distinguish its component parts separately or in their relation to the whole. An analysis of human activity, therefore, can be thought of as the separation of human activity into its constituent parts or elements. From this definition it is seen that the first requirement for a method of analysis is a system of classification of human activity into detectable segments or parts. Furthermore, since the ultimate objective of the analysis is to determine the function or purpose performed by the activity, the classification should be made according to the purpose or duty performed.

Grouping into Sensory and Manipulative Activity

The directly observable data concerning human activity is of two forms: stimulus and response. In this respect a stimulus may be thought of as anything which can be detected by an individual which elicits a response. It is the function of the sensory processes to act as the receptors of stimuli. Associated with the stimulus is an act of the body or its members (usually some movement) which is termed the response.

In performing work, the most typical activity is the manipulation of objects or controls by the hands; consequently, in this study, response acts will be referred to as manipulative activity. From these considerations two broad classifications of human activity may be established, namely:

- (1) Receptor or sensory activity.
- (2) Effector or manipulative activity.

Use of Therbligs

In this method the standard therblig classifications have been used for the analysis of the hand motions and manipulations¹. Since most of the manipulative activity occurs in conjunction with the therblig Use, this is not entirely satisfactory; however, the descriptions given with the therbligs overcome this difficulty. In this connection, only the motion of the hand with regard to the object with which it is in contact is described; the end function performed by the machine as a result of this activity is described separately.

Further Division of Sensory Activity

Sensory activity can be further divided according to the sensory system which acts as the receptor of the stimulus. For the purposes of this study only those sensory systems which act as the receptors of exterior stimulus are of interest.

¹Marvin E. Mundel, Motion and Time Study, (New York: Prentice-Hall, 1950), 226.

The one exception to this is the kinesthetic sense, certain functions of which have been grouped with tactile functions for the purpose of simplifying the analysis. Thus, sensory activity may be further sub-divided according to:

- (1) Visual activity.
- (2) Auditory activity.
- (3) Tactile activity.

General Approach to the Development of Specific Classifications

In developing the specific classifications of activity for each sensory system, the first step has been to describe briefly the physiology of the particular sensory system. From this description a list of the elemental functions or capabilities of the particular sensory system has been prepared.

When examined it is seen that these elemental functions of a particular sensory system are usually concerned with the elemental qualities or characteristics of objects. Typically, however, the individual observes objects not in terms of their elemental qualities but, rather, as "total" objects which result from the subconscious combination of all the elemental qualities of the object. This is an example of the psychological process of perception¹.

¹Floyd L. Ruch, Psychology and Life, (third edition; Chicago: Scott, Foresman and Company, 1948), 277.

Also, by the subconscious perception of various "cues" connected with the particular sensory processes, the individual is able to determine the spatial relationships of objects. Finally, the response of an individual to a particular stimulus depends upon the meaning associated with that stimulus. This association of meaning with stimulus is another example of the process of perception¹. In the development of the sensory functions, these concepts of the perceptive processes have been used to develop typical functions which are combinations of the elemental functions connected with the sensory system; these will be called compound functions. Also, these concepts have been used in the development of specific classifications of sensory activity in which the purpose performed is more closely related to the meaning attached to a particular stimulus than to the fundamental nature of the stimulus itself.

Since the goal of this method of analysis is practical application, the more common or typical of these "fundamental" and "compound" functions have been selected as the "basic" functions or capabilities of the particular sensory system. These "basic" functions of the particular sensory system are used to develop the specific classifications of sensory activity. It is essential, here, that the

¹J. R. Kantor, Principles of Psychology, I., (Bloomington, Indiana: The Principia Press, 1949), 249.

distinction between the functions or capabilities of a particular sensory system and the specific classifications of sensory activity be clearly understood. These specific classifications of sensory activity should be thought of as descriptions, in terms of purpose performed, of detectable segments of sensory activity; as such, they consist of two essential parts, namely, a description of the sensory class (i.e., looking, listening or touching) and a description of the purpose or intent of the activity. Each classification is defined along with its beginning and end points and a mnemonic abbreviation is assigned. Where useful, examples are given. A concise summary of the classifications is included in the appendix for quick reference.

CLASSIFICATION OF VISUAL ACTIVITY

As a background for the development of the classifications of visual activity, a brief description of the physiology of the eye and the psychological processes of the sense of sight will be given. Excellent expositions of this material can be found in any standard encyclopedia¹ or textbook of general psychology^{2,3}.

In outline, the physiology of the visual sensory system might be described as follows: light impinges upon the cornea of the eye, is transmitted through the pupil to the lens by which it is focused upon the retina of the eye. The retina is a light-sensitive surface and transforms the light energy into nervous impulses which are transmitted by the optic tract to the occipital lobe or visual area of the brain cortex.

The Eye

The important functional components of the human eye are the pupil, iris, lens and retina. The pupil is the opening through which the light passes; its size is varied by the reflex action of the iris in response to varying intensities

¹"Vision and Sight", The Encyclopedia Britannica, (1950), XXXIII, 199.

²Floyd L. Ruch, op. cit., 239.

³Wayland F. Vaughan, General Psychology, (revised edition; New York: The Odyssey Press, 1939), 83.

of light. The lens focuses the light from the momentary "object of attention" onto the retina; its curvature is varied by reflex action for objects at different distances.

The Retina

The retina is by far the most complex and important element of the eye and will be described in more detail. The surface of the retina consists of a multitude (about 7,000,000) of cones and rods, each connected by nerve tissue to the main optic tract. The arrangement of the cones and rods is non-homogenous. Only cones are found at the center of the retina (called the fovea centralis) and here they are packed very close together. Toward the periphery of the retina the cones become fewer and the rods more numerous, until - on the outermost periphery - there are very few cones. The connections of the cones and rods to the optical fibres of the optical nerve are also non-homogenous. Near the center of the retina, each cone or rod is connected to an individual nerve fibre of the optic tract. Further away from the fovea several rods (or cones) will be joined to a single optic nerve fibre until at the periphery of the retina, as many as 200 may be joined together on a single "party line". Each cone or rod by a chemical process (the exact nature of which is not known) serves as an elementary "detector" of light energy. Light of sufficient intensity impinging on the sensory element causes nerve "pulses" to be transmitted to the brain cortex. Variations in intensity of

the light cause the frequency of the pulses to vary - increased intensity causing increased frequency. The rods and cones respond differently to light energy. Evidence indicates that the cones function in some way (not known exactly) as the detectors of color, whereas, the rods can detect only brightness. Also, the rods are more sensitive than the cones and thus are used under conditions of dim illumination.

Depth Perception

Since the retina is a surface, the single eye is capable of producing only a two dimensional picture; typically, however, we perceive our surroundings in three dimensions. This visual perception of depth or distance is made possible by various phenomenon connected with the sense of light. The principal factors which make possible the visual perception of depth are:

- (1) Binocular retinal disparity. Because of the separation of the eyes, the images produced on the retinas by relatively near objects are different. This disparity is one factor in the visual perception of depth.
- (2) Convergence. Again, because of binocular separation, the eyes must be directed to converge on the stimulus object and this provides another cue for the perception of depth.
- (3) Accomodation. The accomodation of the eyes for objects at different distances affords another cue for

the perception of depth.

Secondary factors in depth perception are:

- (1) Distinctness of objects seen at a distance.
- (2) Lights and shadows.
- (3) Relative position of the objects.
- (4) Relative rates of apparent motion.
- (5) Relative size of known objects.

Directional Characteristics of the Eye

The preceding discussion has been concerned primarily with the receptor properties of the eye; i.e., those properties by which the eye functions as a receiver of visual stimuli. In order to receive visual stimuli, however, the eye must be directed toward the particular stimuli object and must be accommodated for the reception of stimuli from that object.

As previously discussed, the center of the retina, the fovea, consists entirely of cones which are closely packed together and each of which is connected by an individual nerve fibre to the occipital lobe of the brain. Also, the cones function under bright (daytime) illumination and are believed to be the detectors of color. Thus it is seen that under daytime conditions of illumination the fovea is the most sensitive area of the retina and, consequently, for most efficient vision the image of the stimulus object must be centered and focused on the fovea. This centering action is accomplished by movements of the eyeball and head

(the eyeball being essentially spherical in shape and capable of being rotated around vertical and lateral axis).

A convenient term for describing movements of the eye is the Line of Sight (LOS) which will be defined in this study as the line from the center of the pupil to the point of fixation of the eye when the eye is fixed on a particular point.

Finally, the eyelid may be activated to cover the eye. This occurs either during sleep or as a reflex action to protect the eye from damage or to lubricate the cornea of the eye.

In conclusion, it is seen that the functions of the eye are of a dual nature - primarily, as a receptor of visual stimuli and, secondarily, as a responder to internal stimuli or nerve action. For a description of the functional activity of the sense of sight to be continuous and complete it should include descriptions of both phases of this activity.

Elemental Functions of Vision

Based upon the preceding discussion of the physiology of the eye and the subconscious perception of various "cues", the following elemental functions or capabilities of the sense of sight may be listed:

- (1) The determination of the direction of an object relative to the body.

- (2) The detection of the movement of an object within the field of vision.
- (3) The determination of the color of light from an object.
- (4) The determination of the form or outline of an object.
- (5) The determination of the depth or distance of an object.
- (6) The determination of the surface finish of an object.
- (7) The determination of the intensity of light from an object.

Compound Functions of Vision

These elemental functions or capabilities of vision are concerned with the elemental qualities or characteristics of objects. Typically, however, we perceive combinations of these elemental qualities as other qualities or characteristics or as total objects; i.e., we ordinarily perceive "wholes" and not parts. Thus, by combining certain of these elemental functions of the sense of sight other functions or capabilities are obtained which are quite typical and common to the sense of sight. The more common of these "compound" functions of the sense of sight are:

- (1) The determination of the shape of an object - a combination of the perception of outline and depth.
- (2) The determination of the size of an object - a combination of shape (outline and depth) and distance.

- (3) The determination of the location of an object - a combination of direction and distance.
- (4) The determination of the relative position of two objects - a combination of direction and depth.

Selected Basic Functions of Vision

Since the goal of this method is practical application, the more common or typical of these "elemental" and "compound" functions will be selected as the "basic" functions of vision. Those selected are:

- (1) The determination of Direction.
- (2) The detection of Movement.
- (3) The determination of Color.
- (4) The determination of Distance.
- (5) The determination of Surface Finish.
- (6) The determination of Shape.
- (7) The determination of Size.
- (8) The determination of Location.
- (9) The determination of Position.
- (10) The determination of Intensity.

The relation between the basic functions of the sense of sight and the basic stimuli which the system is capable of detecting should be understood. A stimulus was described previously as anything in the immediate environment of an individual which can be detected or determined and which elicits a response. Within this meaning, then, the sense of sight may be considered capable of detecting those basic

1870

...

...

...

...

...

...

stimuli underlined in the list above.

These "basic" functions of vision have been used as a foundation for the development of the specific classifications of visual activity which follow. The classes of visual activity have been divided into two groups, response activities and sensory activities, corresponding to the dual nature of the functions of the sense of sight.

The Classifications of Visual Activity

Response Activity

(1) Movement of the Line of Sight (M).

Consists of changing the direction of the LOS of the eye from one object to another object whose location is known.

Begins when the LOS begins to shift from the first object.

Ends when the LOS of the eye is fixed on the second object.

(2) Closed or Covered (CL).

Consists of the time during which the eyelids are closed or the eyes are covered by some opaque object and thus the reception of visual stimuli is not possible except in the gross sense - blinding light, radical changes in light intensity, etc. The purpose of this activity is either to protect the eye from injury by foreign objects or intense light or to lubricate the cornea.

Begins when the eyelids begin to close or when some opaque object begins to cover the eyes.

Ends when the eyelids begin to open or when the opaque object begins to uncover the eye.

Examples: (a) Winking of the eye. (b) Covering of the face with a welding shield.

(3) Wander (W).

Consists of the characteristic movement of the LOS when no purpose is being performed by the visual sense (i.e., no visual stimuli are the object of attention); may include the temporary fixation of the LOS on an irrelevant object or may consist of a random motion of the LOS.

Begins with any random motion of the LOS or the fixation of the LOS on any irrelevant object.

Ends when the LOS begins to move to some particular stimulus object.

Sensory Activity

(1) Movement (MV).

Consists of viewing a moving or rotating object to determine its rate or direction of movement or rotation.

Begins when the LOS becomes fixed on a moving or rotating object.

Ends when the LOS moves from the object or when the movement ceases.

Note: This classification does not include the viewing of the short, slow movements connected with the final positioning of one object relative to another.

(2) Color (CR).

Consists of viewing an object to determine its color or viewing several objects to discriminate between their colors.

Begins when the LOS becomes fixed on a particular object or when the LOS begins to oscillate between several selected objects.

Ends when the LOS begins to move to some different object.

(3) Surface Finish (SF).

Consists of viewing an object to judge the quality of its surface finish.

Begins when the LOS becomes fixed on a particular object or when the LOS begins to move across the surface of the object in some patterned or random way.

Ends when the LOS moves from the object.

(4) Shape (SH).

Consists of viewing an object to determine its shape.

Begins when the LOS becomes fixed on the particular object or when the LOS begins to move across the object in some patterned fashion.

Ends when the LOS moves from the object.

(5) Size (SZ).

Consists of viewing an object to determine its size.

Begins when the LOS becomes fixed on the particular object or when the LOS begins to move across the object in some patterned manner.

Ends when the LOS moves from the object.

(6) Location (L).

Consists of viewing an object to determine its direction and/or distance from the body.

Begins when the LOS becomes fixed on the particular object.

Ends when the LOS begins to move from the object.

Examples: (a) Looking at an object toward which the hand is moving or which the hand is grasping. (b) Looking at "reference" points while walking.

(7) Position (P).

Consists of viewing an object to determine its position relative to another object.

Begins when the LOS becomes fixed on the "central" object in the situation or when the LOS begins to alternate rapidly from one object to the other in the situation.

Ends when the LOS begins to move finally away from one or the other objects.

Examples: (a) Looking at a pointer on a scale to determine its position relative to the scale either for information or to control the final positioning of the pointer.

(8) Intensity (IT).

Consists of viewing an object to determine the intensity of the light from the object.

Begins when the LOS becomes fixed on the particular object.

Ends when the LOS moves from the object or when the intensity has been determined.

(9) Search (S).

Consists of the movement of the LOS of the eye to determine the presence and/or location of a particular object whose precise location is not known.

Begins when the LOS begins to move from the first stimulus object.

Ends when the LOS is fixed on the second stimulus object.

(10) Identity (ID).

Consists of viewing an object to determine its identity.

Begins when the LOS becomes fixed on the particular object, or, if the object is large, when the LOS begins to move over the object in some patterned way.

Ends when positive or negative identification is completed and may or may not consist of a movement of the LOS from the object.

(11) Termination (T).

Consists of viewing an object or exterior activity¹ to detect terminal signals or conditions, i.e., signals or conditions which indicate the initiation or termination of that activity or some related activity.

Begins when the LOS becomes fixed on the object or activity which is the source of the signal.

Ends when the signal is received or when the LOS moves from the object or activity.

Examples: (a) Looking at a traffic signal to detect a change in the signal.

¹Note: As used here an "exterior activity" means some activity with which the hands are not in direct contact.

(12) Monitor (MR).

Consists of viewing an automatic or uncontrolled activity to detect any abnormal, unusual or undesirable conditions of the activity.

Begins when the LOS becomes fixed on the particular activity.

Ends when the LOS moves from the activity or when some abnormal or unusual condition requiring response is detected.

Examples: (a) Watching the cutting action of a turret lathe when the lathe is operating in power feed. (b) Watching the cutting action of an automatic screw machine.

(13) Control (C).

Consists of viewing a controlled, exterior activity¹ to determine its momentary condition or progress.

Begins when the LOS becomes fixed on the particular activity.

Ends when the LOS moves from the particular activity or the activity ceases.

Examples: (a) Watching the cutting action on a turret lathe when the hand is controlling the feed of the tool.

(14) Ready (R).

Consists of viewing letters, words and/or numerals to determine their meaning.

Begins when the LOS becomes fixed on or moves in a patterned manner across the letters, words and/or numerals.

¹Note: As used here an "exterior activity" means some activity with which the hands are not in direct contact.

Ends when the LOS moves from the letters, words and/or numerals.

(15) Mathemation (MM).

Consists of viewing some mathematical array to determine its end or resultant meaning.

Begins when the LOS becomes fixed on the mathematical display or begins to move in a patterned way across the mathematical display.

Ends when the LOS moves from the display or when the corresponding response is completed.

Examples: (a) The activity of the eye while adding columns of figures. (b) The visual activity connected with the multiplication of numbers.

(16) Count (CT).

Consists of viewing several objects to determine their total number.

Begins when the LOS begins to move from object to object in some patterned way.

Ends when the LOS moves from the objects or when the total has been determined.

CLASSIFICATION OF AUDITORY ACTIVITY

As a basis for the classification of auditory activity a brief description will be given of the physiology of the components of the ear^{1,2}. The ear, the sensory organ of hearing, consists of five main parts: the outer ear, the middle ear, the inner ear, the organ of Corti and the auditory tract to the brain. The operation of the auditory sensory system may be described briefly as follows: sound waves are received by the outer ear, transmitted by the middle ear to the inner ear where the sound energy is transformed by the organ of Corti (the auditory detector organ) into nerve impulses which are then transmitted to the auditory centers of the brain.

The Ear

The visible portion of the ear consists of the expanded flap called the auricle and the meatus, the tube which terminates in the eardrum. The auricle serves no auditory purpose since its dimensions are too small in relation to the wave-lengths of sound to effect the direction of the waves.

The middle ear is an irregularly shaped, air filled cavity in the temporal bone in which is suspended, by the

¹"Hearing", The Encyclopedia Britannica, (1950), XI, 297.

²Floyd L. Ruch, op. cit., 262.

tympanic muscles, the auditory ossicles which is essentially a mechanical connection between the eardrum and the oval window of the inner ear.

The inner ear is a complex space in the temporal bone and is divided into two primary functional parts; first, the vestibule and semicircular canals which perform functions in connection with bodily equilibrium of the organism and, second, the cochlea which contains the auditory sensory apparatus.

The Cochlea

The cochlea is a spiral shaped space divided into two main parts, the vestibular and tympanic canals which are joined at the end of the spiral. The basilar end of the vestibular canal is separated from the middle ear by the oval window to which is attached the stapes, a link in the auditory ossicles. The basilar end of the tympanic canal is separated from the middle ear by another membrane, the round window. The partition between the vestibular canal and the tympanic canal is made up, in part, by a membrane called the basilar membrane upon which lies a complex structure, the organ of Corti, in which the auditory receptor cells, the hair cells, are imbedded. Another membrane, called Reissner's membrane, separates the organ of Corti from the vestibular canal. This space is filled with another fluid called endolymph. Each hair cell is connected to an individual nerve fibre forming part of the auditory tract to the brain. Vibrations of the foot plate at the end of the stapes cause

pressure variations (and consequent motion) in the fluids in the cochlea which are detected by the hair cells and transformed into nerve pulses which are then transmitted to the brain.

Theories of Hearing

The action of the organ of Corti is not precisely known particularly as concerns the detection of the pitch variations of sound. Several theories have been advanced to explain this phenomenon. One of the earliest and most popular theories, known as the resonance theory, is based upon the idea that the cochlea contains a series of resonators which by their physical characteristics respond only to discrete frequencies of sound. Another theory, the frequency theory, is based on the idea that the pressure waves are converted directly into nerve pulses of corresponding frequency which are then transmitted to the brain. Both of these theories have serious limitations and a later theory - the resonance-volley theory - incorporates principles of both the earlier theories in an effort to overcome these difficulties. The exact nature of the hearing process, however, is not known.

Sound

Physically, sound is a wave propagation of energy in the form of pressure and density variations in the media of transmission. As such, its essential character is determined

in terms of the frequency, intensity and form of the wave motion. These physical properties of sound correspond to the psychological phenomenon of pitch, loudness and timbre. Pitch and loudness are characteristics of the simplest sounds (pure tones). Timbre, on the other hand, is a function of the complex combination of these two fundamental qualities, since it depends upon the number and intensity of the various overtones in the sound. The exact nature of auditory detection is not known; however, it may be assumed from the above discussion that the simplest and most elemental function performed by the ear or the sense of hearing is the determination of pitch and loudness.

Binaural Phenomenon

The determination of the direction of sounds by hearing alone is generally inaccurate. In addition to the inherent limitations of the sense of hearing for this purpose, the very nature of the propagation of sound limits the accuracy of determination; i.e., sound waves will bend around corners and reflect off of surfaces so that the true direction of the source cannot be determined from the terminal direction of the sound at the ear. The determination of the direction of a sound is made possible by the subconscious perception of four types of binaural differences, namely, the relative intensity, time of incidence, phase and complexity. The action of these various cues is dependent upon the

frequency and timbre of the sounds. These factors will not be discussed here except to note that high tones are localized with difficulty, low tones more readily and noise with comparative ease. Positions up and down or ahead and behind are not distinguished by binaural cues.

From this discussion of the physiology of the ear and the subconscious perception of various "cues" connected with the auditory system, the following basic functions or capabilities of audition may be listed:

- (1) The determination of the Pitch of a periodic sound (tone).
- (2) The determination of the Loudness (or intensity) of a sound.
- (3) The determination of the Timbre of a sound (including the detection of noise).
- (4) The determination of the Direction of a sound.
- (5) The detection of the Movement of the source of a sound.
- (6) The gross determination of the Distance to a source of sound.

The Classifications of Auditory Activity

(1) Loudness (LD)

Consists of listening to a sound to determine its loudness.

Begins with the reception and/or attention to the sound.

Ends when the reception or attention to the sound ceases or its loudness has been determined.

(2) Pitch (PC)

Consists of listening to a single tone or several tones simultaneously to determine their pitch.

Begins with the reception and/or attention to one or more tones.

Ends when the reception or attention ceases or when the pitch has been determined.

(3) Timbre (TB)

Consists of listening to one or more tones to determine their timbre either separately or together.

Begins with the reception and/or attention to one or more tones.

Ends when the reception or attention ceases or the timbre has been determined.

(4) Location (L)

Consists of listening to a sound to determine its direction of incidence and/or estimate the distance to its source.

Begins with the reception and/or attention to the sound.

Ends when the reception or attention ceases or when the direction of incidence of the sound and/or the distance to

the source have been determined.

(5) Movement (MV)

Consists of listening to a sound to detect and/or determine the direction of any movement of the source of the sound.

Begins with the reception and/or attention to a sound.

Ends when the reception or attention ceases or the movement has been determined.

(6) Identity (ID)

Consists of listening to a sound to determine the identity of the sound and/or its source.

Begins with the reception and/or attention to the sound.

Ends when the reception or attention ceases or when the sound has been identified.

(7) Search (S)

Consists of listening to or for a particular sound to detect its presence and determine the location of its source.

Begins with the attention to or for the particular sound.

Ends when the attention ceases or the presence of the sound is detected and the location of the source is determined.

(8) Termination (T)

Consists of listening to or for a particular sound to detect the initiation or termination of some activity connected with the particular sound.

Begins with the attention for or to the particular sound.

Ends with the reception or cessation of the sound.

(9) Monitor (MR)

Consists of listening to the sounds from an automatic activity to detect any abnormal, unusual or undesirable conditions of the activity.

Begins with the reception and/or attention to sounds from the activity.

Ends when the reception or attention ceases or when some abnormal or unusual condition is detected.

(10) Control (C)

Consists of listening to the sound from a controlled activity to determine its momentary condition and/or progress.

Begins with the reception and/or attention to the sound from the activity.

Ends when the reception or attention ceases.

(11) Speech (SP)

Consists of listening to speech to determine the meaning implied.

Begins with the reception and/or attention to speech.

Ends when the reception or attention ceases.

CLASSIFICATION OF TACTILE ACTIVITY

Sensory Systems of the Skin

In developing the classifications of tactile activity, the sensory system of the skin will first be discussed^{1,2,3}. The surface of the skin contains several kinds of sensory nerve endings which act as the receptors for a variety of stimuli. The structure of these end-organs varies considerably and the exact nature of the process by which they transform stimuli into nerve pulses is not known. The three fundamental types of touch sensation are pressure, temperature (hot and cold) and pain. The pain sensations are not of interest in this study and will not be discussed.

Distribution of Sensitivity

The distribution of the sensory end-organs over the surface of the skin is not uniform. When the surface of the skin is explored with very fine stimuli, it is found that sensitivity to stimulation is limited to certain very small areas. These "spots" are distinct for each kind of stimulus so that there are separate spots for pressure, heat, cold and pain. The sensitivity of a given region of the

¹"Skin, Sensory Functions of", The Encyclopedia Britannica, (1950), XX, 750.

²Tufts College Institute for Applied Experimental Psychology, Handbook of Human Engineering Data, (second edition), Part V.

³Floyd L. Ruch, op. cit., 268.

skin depends upon the density of distribution of these spots. Generally the distribution of these stimulus spots varies together for all four senses; however, there are exceptions - for one, the finger tips, which are highly sensitive to pressure but relatively insensitive to pain. This distribution of the sensory system makes possible the detection of the location of a particular touch stimulus on the skin surface and the rough determination of the area of contact of the object with the skin. Since this function or capability of localization and determination of area is so closely associated with the stimulus itself, this function will not be distinguished separately in the following discussion.

Pressure Sense

The sensation of pressure is experienced when an object contacts the skin and produces a displacement or movement of the sensory end-organs. When the object is vibrating the sensation of vibration is experienced. Thus, the pressure sensory system is capable of detecting static or moving contact and vibrations of an object in contact with the skin. In this study, for convenience, static contact will be termed simply "contact" and moving contact will be termed "slip". The pressure sense is subject to fatigue and adaption effects and, consequently, the pressure sensation of a static contact will cease after a certain time.

Thermal Sense

The sensation of temperature is of two kinds; first, the sensation of warmth and, second, the sensation of cold. Corresponding to these two kinds of sensation the skin has two separate receptor systems - cold spots and warm spots. The stimulus for these receptor organs is the transfer of heat to or from the surface of the skin. The stimulus for the warm spots is the transfer of heat to the skin while that for the cold spots is the transfer of heat from the skin. Objects which are at the same temperature as the skin do not stimulate the sensation of temperature. Adaption of the thermal sensory system occurs after continuous exposure to some temperature stimulus; i.e., the "thermal zero point" or "point of indifference" varies with continued exposure. Thus, the thermal sensory system is capable of detecting the transfer of heat to or from the skin or the difference in temperature between the skin and objects in contact with the skin. This capability or function will be referred to here as the detection of temperature.

Basic Tactile Functions

From the preceding discussion of the tactile sensory systems, the following basic functions may be listed:

- (1) The detection of the contact of an object with the skin.
- (2) The detection of slip of an object in contact with the skin.

(3) The detection of vibration of an object in contact with the skin.

(4) The detection of the temperature of an object relative to the temperature of the skin.

Kinesthesia^{1,2}

The discussion of the sensory systems to this point has been concerned with the exteroceptors, i.e., the sensory organs which act as the receptors of external stimuli. There is another group of sensory systems called proprioceptors which consist of receptors which react to internal stimuli. Proprioception, in turn, is subdivided into two parts - kinesthesia, which is concerned with the movements and position of the body members and equilibrium which is concerned with the orientation of the body in space. Of the two, only kinesthesia is of interest here.

The receptors of the kinesthetic sense are nerve cells located in the muscles, tendons and joints of the body. When the body members move these receptors are stimulated by stretch and pressure and produce the kinesthetic sensations of movement and position of the body members and, also, the force applied by the body members. When associated with some

¹Handbook of Human Engineering Data, op. cit.

²Floyd L. Rush, op. cit., 272.

particular external object or activity, these kinesthetic sensations provide information concerning external objects or conditions. Thus, through the perception of kinesthetic sensations the following functions may be performed:

- (1) The determination of the location of objects in contact with the body extremities.
- (2) The detection of the movement of objects in static contact with the body extremities.
- (3) The determination of the force of reaction of an object in contact with some body extremity to the force applied.
- (4) The determination of the weight of an object held by the hand.

In order to simplify the analysis technique and the portrayal of the final results, these kinesthetic functions have been grouped with the touch functions in the development of specific classifications of "tactile" activity.

The Classifications of Tactile Activity

(1) Vibration (V)

Consists of touching an object to detect the presence and/or determine the character of the vibrations of the object.

Begins with contact and/or attention to the character of the vibrations.

Ends when contact or attention ceases or when the character of the vibration has been determined.

(2) Temperature (TR)

Consists of touching an object with the hand or fingers to determine its temperature relative to the hand.

Begins with contact and/or attention to the temperature of the object.

Ends when contact ceases or when the temperature has been determined.

Note: This may include placing the hand in close proximity to an object for this purpose.

(3) Location (L)

Consists of touching an object to determine its direction and/or distance from the body.

Begins with contact with the object.

Ends when contact ceases or the location has been determined.

(4) Weight (WT)

Consists of holding an object in suspension with the hand to determine its weight.

Begins when the body becomes suspended.

Ends when the suspension ceases or the weight has been determined.

(5) Grasp Control (GC)

Consists of determining the touch stimuli (such as slip, contact, force) from an object which the hand is grasping, holding or using to gain and/or maintain effective control over the object.

Begins when the hand begins to grasp a particular object.

Ends when the hand ceases to touch the object.

Note: This activity may occur simultaneously with other tactile activity.

(6) Surface Finish (SF)

Consists of touching a surface by random or patterned motions of the hand or fingers to determine the quality (roughness or smoothness) of the surface finish.

Begins when the hand touches the surface.

Ends when contact or motion of the hand or fingers ceases or the quality has been determined.

(7) Position (P)

Consists of touching an object to determine its position relative to another object. May consist of touching the two objects simultaneously with one or both hands or detecting the force of reaction against the hand when the two objects are in contact.

Begins when the hand or hands touch the objects.

Ends when contact ceases or when the final position of the objects has been established.

(8) Shape (SH)

Consists of touching an object to determine its shape.

Begins when the hand touches the object.

Ends when contact ceases or when the shape of the object has been determined.

(9) Size (SZ)

Consists of touching an object to determine its size.

Begins when the hand or hands touch the object.

Ends when contact ceases or the size of the object has been determined.

(10) Search (S)

Consists of a random (groping) or patterned movement of the hand or hands through an area or over a surface to detect the presence and/or locate a particular object (may be a vibrating source) whose precise location is not known.

Begins when the hand or hands begin to move as described above.

Ends when the hand or hands cease their characteristic motion or when the particular object is located.

(11) Identity (ID)

Consists of touching an object to determine its identity.

Begins when the hand touches the object.

Ends when contact ceases or when identity is established.

(12) Count (CT)

Consists of touching several objects simultaneously or in succession to determine their total number.

Begins when the hand begins to touch the objects.

Ends when contact ceases or when the total number has been determined.

(13) Termination (T)

Consists of touching an object to detect a touch stimulus indicating the initiation or termination of some activity related to the particular stimulus.

Begins with contact and/or attention to or for the particular touch stimulus.

Ends when contact or attention ceases or when the particular stimulus is received.

(14) Monitor (MR)

Consists of touching an object mechanically connected with an automatic activity to detect any abnormal, unusual or undesirable conditions of the activity.

Begins with the reception and/or attention to the touch stimuli from the activity.

Ends when the reception or attention ceases or when some abnormal condition occurs.

(15) Control (C)

Consists of touching some object mechanically connected with a controlled activity to determine its momentary condition and/or progress.

Begins with the reception and/or attention to the touch stimuli from the activity.

Ends when the reception or attention ceases.

(16) Idle (I)

Consists of the period during which the sense of touch is performing no purpose.

Begins when the hand ceases to be in contact with any object.

Ends with contact with any object.

PROCEDURE FOR
COLLECTING AND RECORDING THE BASIC DATA

As previously noted in the development of the system of classification, the observable data of human activity consists of stimulus and corresponding response. This concept led to the division of human activity into sensory activity and response activity. The response activity of the man includes movements of the head and eyes, movements of the body, and movements of the hands (both between controls and in the manipulation of controls). Also, various actions of the machine occur in conjunction with the manipulative activity of the man. Sensory activity was further divided into visual, auditory, and tactile activity.

The response activity of the man and the action of the machine can be recorded for analysis using motion-picture cameras and micro-motion analysis techniques. The description of the sensory activity must necessarily be in terms of the stimuli received. The direct observation and recording of all the stimuli received by a man in the operation of a machine, even for a short period of time, would be an extremely complex problem, particularly for the visual and tactile stimuli. Consequently, the method used for recording the data in this study was to record the response and machine activity on motion-picture film, and to reconstruct the sensory activity and stimuli data from detailed information concerning the machine and the part being manufactured.

Machine Data

For the purpose of reconstructing the sensory activity, the following types of information concerning the machine and the part being manufactured are required:

- (1) A background knowledge of the characteristics and operation of the machine.
- (2) Detailed information concerning the individual machine controls.
- (3) Detailed information concerning the dials and indicators associated with the machine.
- (4) Detailed information concerning the machine sounds which occur during the manufacture of the particular part.
- (5) Detailed information concerning the particular part being manufactured.

Specific details of the information required and the methods used for collecting this information follow.

First, a careful study of the operation and maintenance pamphlets for the particular machine should be made in order to gain a background of knowledge concerning its characteristics and operation. If the analyst is not familiar with the machine, some skilled operator should be requested to explain the details of the machine and its operation. If possible, the analyst should operate the controls of the machine and perhaps produce some parts.

When the analyst has become familiar with the machine and its operation, arrangements should be made to collect the

detailed information concerning the machine controls, dials, and machine sounds.

The detailed information required concerning the machine controls includes (for each control):

- (1) A complete description of the movements of the control and the corresponding purpose performed.
- (2) A complete description of the tactile stimuli produced by the manipulation of the controls, including:
 - a. A notation of the tactile stimuli produced in terms of the basic tactile stimuli previously listed on page 41.
 - b. A notation of the source or "object" of the stimuli; i.e., a description of the action of the mechanism producing the tactile stimuli.
 - c. A complete description of any visual stimuli (other than the actual motion of the control) which may be produced by the movements of the control. This description should be made in terms of the basic stimuli previously listed on page 23.

The detailed information required concerning the dials and indicators associated with the machine includes (for each):

- (1) A detailed description of the nature of the movement of the dial or pointer and the controls (if any) with which the dial is associated. Also, notation should be made of the graduations of the dial or scale and the location of any fixed reference indices.

(2) A detailed description of the visual stimuli produced by the dial in terms of the basic visual stimuli previously listed on page 23.

In this particular application, the information concerning the machine controls and dials was collected and recorded together. The assistance of the machine operator was obtained and the analyst actually operated the various controls to determine the required information. No data sheet for the recording of this information was used. The information was prepared and presented in typewritten form, as can be seen by referring to Appendix B.

Job or machine sounds usually occur in conjunction with the use of some machine control. They may also occur in conjunction with some typical machine action (such as cutting action) or in conjunction with some automatic operation. For the collection and recording of this information, a form was developed with columns for the following information:

(1) Associated Control Activity. A specific description of the movement of the control associated with the particular sound.

(2) Source. A description of the action of the machine mechanism which produces the sound.

(3) Time Key. Some key (such as control position) for determining the time of occurrence of the sound from the film record.

(4) Characteristics. A description of the sound in terms of its fundamental qualities such as: Loudness, duration, pitch (if any) and timbre.

(5) Significance. The significance (in terms of machine action or condition) of the occurrence of the particular sound.

This information was obtained in much the same way as the information concerning the controls and dials, viz., with the assistance of a skilled operator and by the actual manipulation of the controls of the machine.

Finally, information concerning the part being manufactured in the particular job chosen for study should be obtained. The following information is required:

- (1) A sketch of the part.
- (2) Notation of the feeds and speeds used.
- (3) A detailed description, in sequence, of the operations required to make the part.

This information should usually be available in the form of a process sheet for the manufacture of the particular part; this was the source of the information used in this study. A copy of the process sheet for the job is included as Appendix A.

Film and Sound Recording Technique

The second major step in the application of the method and recording the basic data is making the film and sound record of the performance of the particular job. As stated

previously, motion-pictures were taken of the performance of the particular job. This provided a detailed record of the performance of the job. Standard micro-motion study filming techniques were used¹. Some modifications of technique were made to provide for the simultaneous filming of separate activity and the recording of sound. Sound recordings may or may not be required for this type of analysis depending upon the detail and accuracy desired. When accurate data concerning the time of occurrence of sounds is needed and no "keying" action of the machine is available, the sound recordings may be required. Sound recordings were taken of this particular job and the recording method for this procedure will be described. This record was not used in the analysis, however, since adequate "machine action keys" were available to determine the time of occurrence of the significant sounds from the film record.

¹M. E. Mundel, op. cit., 208.

Film Record

A film speed of 16 frames per second (or 1000 frames per minute) was used. Two cameras were used as follows:

(1) "Face" Camera. The purpose of this camera was to record accurately the movements of the operator's head and eyes. The analysis of this film record provides an accurate determination of the time of movements of the Line of Sight.

Factors which were considered in setting up this camera:

(a) The camera was located to parallel the normal line of sight of the operator as nearly as possible. This required getting as low as possible, since the operator typically looks down to operate the machine.

(b) The camera was located as close to the operator as possible to simplify determinations of changes in the LOS.

(c) The camera was panned to insure that the operator's head was in the field of the camera at all times.

(d) A light was located to illuminate the operator's eyes.

(2) "Side" Camera. The purpose of this camera was to record the movements of the operator's hands and head. Also, any controls or tools that the operator actually manipulates were included in the field of this camera.

Factors considered in locating this camera:

(a) The camera was located to one side of the operator and at a distance of about fifteen feet. Camera height was approximately six feet.

(b) Lights were located to illuminate the side of the head, the hands and the machine controls.

Sound Record

The "job sounds" which are of most interest are:

(1) tool noises and (2) machine control noises. The microphone was placed close to the operator and directed to facilitate the "pick-up" of the desired sounds. When possible, the recording should be made when other machines in the vicinity are not in operation in order to reduce the "background noise level". A directional microphone might also be used and should be directed to minimize pick-up of "motor noise". A standard Revere magnetic tape recorder was used.

Time Record

Since the record of activity is made in three parts, an accurate measurement of time in each record is essential in order to synchronize the analysis elements. The use of some synchronizing signal is required.

(1) Film. Time record on the film may be made by using a microchronometer in the field of the camera or by using synchronous motor driven cameras. Note: the inclusion of a microchronometer in the field of view of the "face camera" would be undesirable. In this application, synchronous motor cameras were used.

(2) Synchronizing signal. Some signal to provide a common time reference in all three records is required. This was

provided by using "clap boards".

Personnel Required

In addition to the machine operator, the following assistance was found desirable:

- (1) "Face" camera operator.
- (2) "Side" camera operator.
- (3) Sound recorder operator and "director".

LOCATION OF CAMERAS

PROPOSED TECHNIQUE FOR ANALYSIS OF THE BASIC DATA

A frame by frame analysis of the film record was made using standard micromotion analysis equipment, including a single frame projector¹. Because of the additional machine data which had to be considered and because of the difficulty of correlating the various sensory and manipulative activities, it was found convenient to divide the analysis into the following parts:

- (1) Analysis of manipulative, machine and tactile activity.
- (2) Analysis of visual activity.
- (3) Analysis of auditory activity.

Analysis of Manipulative, Machine and Tactile Activity

Because of the close relationship of the manipulative, machine and tactile activity, they were analyzed together. Being predominately an analysis of response activity this part of the analysis was the simplest to make and was, therefore, done first. Also, making this analysis provided a detailed knowledge of the performance of the job and thus simplified the succeeding analysis of sensory activity. The basic data used for this part of the analysis consisted of:

- (1) Side camera film.
- (2) Description of machine controls and dials.
- (3) Process sheet.

¹M. E. Mundel, op. cit., 222.

- (4) List of classifications of tactile activity and a table of therbligs.

A form¹ was designed to aid in the analysis of the basic data. Sections of the form were provided for time data, manipulative activity data, machine activity data and tactile activity data. Columns were provided for the following information:

Time Data:

- (1) Frame - the frame counter reading at the beginning of the element.
- (2) Subtracted time - the inclusive time for that element.
- (3) Cumulative time - the total elapsed time to the end of that element.
- (4) Corrected time - the corrected time for that element².

Manipulative Activity Data:

- (1) Symbol - the therblig classification for that element.
- (2) Object - the object with which the hand was in contact during that element (if any).
- (3) Description - a "pictorial" description of the motion of the hand relative to the object with which it was in contact (if any).

¹Appendix "D".

²There was a slight variation in the camera drive speeds. To compensate for this all times were related or "corrected" to "face camera time". See Appendix "F" for details.

Machine Activity Data:

(1) Description - a description of the machine action resulting from the concurrent manipulative activity. This might also be thought of as the end result or purpose of the hand motion.

Tactile Activity Data:

(1) Symbol - the mnemonic abbreviation for the selected classification of tactile activity.

(2) Object - the source of the touch stimulus (either the object with which the hand was in contact itself or some machine action).

(3) Stimulus - the stimulus being received or expected during the segment of activity described in terms of the basic tactile stimuli previously listed¹.

(4) Purpose - the immediate, elemental purpose of the sensory activity.

Since the analysis of the manipulative and machine activity is almost identical to standard micromotion analysis, this part was analyzed first for each segment.

In the analysis of the tactile activity, it is extremely important that the objective be kept constantly in mind; i.e., to determine the immediate, elemental purpose being performed by the sensory activity. The sequence followed in this determination was:

¹Page 41.

- (1) Determine the source of the stimulus.
- (2) Determine the nature of the stimulus.
- (3) Determine the purpose performed by the sensory activity.
- (4) Finally, assign the proper classification of tactile activity.

Analysis of Visual Activity

After the analysis of manipulative, machine and tactile activity was completed, the next step was the analysis of visual activity. The basic data used for this part of the analysis was:

- (1) Side camera film.
- (2) Face camera film.
- (3) Description of the machine controls and dials.
- (4) Process sheet.
- (5) The classifications of visual activity.

As stated previously, the primary purpose of the face camera film is to provide accurate time data for the movements of the LOS of the eyes. In performing the analysis it was found convenient to project the face camera film and the side camera film concurrently - the face camera film for accurate determination of time and the side camera film for determination of the object of attention of the eye and for determination of the related activity.

A special form¹ was prepared for the analysis of the

¹Appendix "C".

basic data. This form is practically identical to the tactile activity section of the Manipulative and Tactile Activity Data Sheet. Columns were provided for the following information:

Time Data (face and side camera):

- (1) Frame - the projector frame counter reading at the beginning of the element.
- (2) Time - the subtracted time for that element.
- (3) Cumulative time - the cumulative time through that element.

Since the face camera times were used as the basic reference, the cumulative times were obtained from that data.

Visual Activity Data:

- (1) Symbol - the mnemonic abbreviation of the selected classification of visual activity.
- (2) Object - the source of the stimulus.
- (3) Stimulus - the basic nature of the stimulus described in terms of the basic visual stimuli¹.
- (4) Purpose - the immediate, elemental purpose of the visual activity.

The sequence of steps followed in determining the proper classification of visual activity was the same as for tactile activity:

- (1) Determine the source of the stimulus.

¹Page 41.

(2) Determine the nature of the stimulus.

(3) Determine the purpose being performed by the visual activity.

(4) Assign the proper classification to the particular segment of activity.

Analysis of Auditory Activity

In this particular application, since adequate "time keys" were available for determining the time of occurrence of the significant sounds, no analysis of the sound recording was required. Instead, the data from the Job Sound Data Sheet was copied directly on the "Total Activity Chart" to be described in the next section.

In the event that an analysis of the sound recording is required to determine the time of occurrence of the various sounds, the use of a simple audio rectifier-filter in conjunction with a pen recording oscillograph would probably be satisfactory. This method was tested.

PROPOSED METHOD FOR PORTRAYING AND SUMMARIZING
THE RESULTS OF THE ANALYSIS

With such a mass of detailed information resulting from the analysis of the basic data, some method of portraying and summarizing this information was essential. For portraying the results of the analysis a special form called a "Total Activity Chart" was developed¹. The general features of this form are similar to the conventional "simo-chart" developed by the Gilbreths for use in micro-motion analysis².

Total Activity Chart

In the development of this form, the following factors were considered:

- (1) The form should provide for a listing of the functions performed according to the major classifications of activity.
- (2) The form should provide for notation of the specific classification of each segment of activity.
- (3) The form should provide for notation of the important facts concerning each segment of activity.
- (4) The form should provide for the correlation of concurrent segments of activity.

¹Appendix "G".

²M. E. Mundel, op. cit., 226.

(5) The form should provide for the notation of the meaning associated with significant stimuli.

For these purposes, a classified listing of the segments of activity in conjunction with a time chart was found to be satisfactory.

In the manipulative, machine and sensory sections of the chart, the column labels and information are identical to those of the several analysis and data sheets. The "purpose" for the sensory activity has been omitted since this is indicated by the specific classification of the sensory activity.

An additional column labeled "meaning" has been included. The purpose of this column is to provide some means of indicating the major segments of "total" activity, i.e., some means of indicating the major segments of integrated sensory-manipulative-machine activity. Another purpose is to provide a means for indicating the meaning associated with the "significant" stimuli - "significant" stimuli being those which indicate the initiation or termination of some major segment of "total" activity.

Summary of the Results of the Analysis

In addition to the "Total Activity Chart", the following summaries of information have been compiled from the basic data for each major classification of sensory activity:

(1) A compilation of the frequency of occurrence of the specific classifications of activity.

(2) A determination of the percentage of time spent performing each specific type of activity.

(3) A list of the "significant" functions or duties performed by each sensory system - by "significant" functions is meant functions related to the control or action of the machine (as opposed to motor coordination).

Compilation of Frequency of Occurrence
And Percent of Total Time

Visual Activity:

	<u>Classification</u>	<u>Frequency</u>	<u>Percent Time</u>
(CL)	Closed	2	0.26
(W)	Wander	1	0.26
(M)	Movement of the LOS	41	6.95
(L)	Location	22	10.4
(MV)	Movement	14	25.0
(P)	Position	35	29.8
(C)	Control	4	8.9
(R)	Read	6	*
(MR)	Monitor	7	18.4

Tactile Activity:

	Classification	L. H.		R. H.		Combined	
		Freq.	%	Freq.	%	Freq.	%
(I)	Idle	31	43.7	35	39.2	66	41.4
(GC)	Grasp Control	39	30.2	63	36.7	102	33.4
(T)	Termination	7	7.3	10	6.4	17	6.8
(C)	Control	6	10.9	7	11.4	13	11.2
(L)	Location	4	4.8	6	2.2	10	3.5
(P)	Position	4	1.5	11	4.2	15	2.8
(MR)	Monitor	1	1.7	0	0	1	0.8

*Occurs in conjunction with other activity. Time not measured but assumed small.

Auditory Activity:

<u>Classification</u>	<u>Frequency</u>	<u>Percent Time</u>
(T) Terminal	14	- *

List of "Significant" Functions

Visual:

- (1) Aid in controlling the cutting action by determining its momentary condition and progress.
- (2) Regulate advance of tool to work.
- (3) Regulate positioning of indexing stop.
- (4) Regulate setting of micrometer dial.
- (5) Regulate positioning of square turret tools so turret can be indexed.
- (6) Determine setting of coarse-fine feed selector.
- (7) Control adjustment of coolant flow.
- (8) Monitor cutting action to detect unusual conditions.
- (9) Observe progress of hexagonal turret retract.
- (10) Observe progress of turret indexing.
- (11) Observe progress of hexagonal turret advance.
- (12) Observe use of carriage binder.
- (13) Observe setting of coarse-fine feed selector.
- (14) Observe movement of micrometer dial.
- (15) Observe positioning of feed engaging lever.

*Time not measured but very small.

Tactile:

- (1) Detect initiation of cutting action.
- (2) Aid in control of cutting action by determining condition and progress.
- (3) Control of grasp - gaining and maintaining control of machine controls.
- (4) Detect termination of turret indexing.
- (5) Control positioning of hand for subsequent grasp.
- (6) Control positioning of power feed lever.
- (7) Detect contact of carriage with indexing stop.
- (8) Aid in controlling the positioning of indexing stop.
- (9) Monitor cutting action to detect abnormal conditions.
- (10) Control positioning of carriage binder.
- (11) Control positioning of coarse-fine feed selector.

Auditory:

- (1) Detect initiation of hexagonal turret indexing.
- (2) Detect completion of hexagonal turret indexing.
- (3) Determine when hexagonal turret can again be indexed (for skip indexing).
- (4) Verify proper positioning of power feed lever.
- (5) Detect disengagement of power feed lever.
- (6) Detect completion of square turret indexing.
- (7) Determine when square turret can again be indexed (for skip indexing).

SUMMARY OF RESULTS AND CONCLUSIONS

Results

The results of this thesis are, first, a proposed method for the functional analysis of human activity including:

(1) A system for the functional classification of human activity.

(2) A technique for observing and recording the basic data of human activity.

(3) A technique for the analysis of the basic data.

(4) A method for portraying and summarizing the results. And, second, an example of the application of the method in a test case.

Conclusions

Based upon the development of the method of analysis and its application in a specific case, the following conclusions are made:

(1) This method of analysis can be applied to determine the detailed functions performed by a man in the routine operation of a machine tool¹.

(2) From this information a list of sensory functions related to the control or action of the machine can be compiled.

¹This statement is not meant to imply that the reliability of the method of analysis has been established - reliability meaning the ability of different analysts to produce similar results using the same basic data.

(3) Also, from this information the frequency of occurrence and percent of total time spent in the performance of specific functions can be determined.

Recommendations

For the further development and improvement of this method, the following recommendations are made:

(1) That the reliability of the method of analysis be determined and, where necessary, modifications of the method be made to improve the reliability.

(2) That the validity of the method as an aid in the development of automatic devices be determined. This might be done by comparing the results of an analysis of a man-machine combination performing some work with the actual functions performed by an automatic machine performing the same work.

(3) The actual application of the method to develop an automatic device in some simple work situation.

(4) The development of a color code for use with the "Total Activity Chart".

(5) A study of the use of the method for the analysis and measurement of skill.

(6) A study of the application of the method for the determination of training requirements.

APPENDIX A

PROCESS SHEET
FOR THE MANUFACTURE OF A GEAR BLANK

Speeds and feeds pre-set.

RPM - low, 557 rpm.

Feed - .002 in.

Set up for #4 Gisholt.

Hexagonal Turret:

1. Stock Stop - Position stock to length by moving ram slide forward against stop. Use hydraulic feed lever according to specifications to bring stock to length.
2. Center Drill - Move ram slide forward against stop.
3. Rough Drill - Move drill up to stock. Engage power feed. Depth regulated by stop.
4. Ream. Move reamer up to stock. Engage power feed. Depth regulated by stop.

Cross Slide:

1. Rough turn O.D. Set index stop to #1. Set micrometer dial to #1 and then engage longitudinal power feed lever.
2. Finish turn O.D. - Retain index stop #1, set micrometer dial to #2, then engage longitudinal power feed lever.
3. Form 0.625 O.D. - Set index stop #2, lock apron against stop. Turn tool into the work by handwheel one full turn past dial 3 to dial 3.
4. Chamfer - Set index stop #3, operate cut off tool 1/8 inch into work, then back slide so that chamfer tool engages work up to dial 4.
5. Cut-off - Retain stop #3, use lateral handwheel, run tool up to work, then engage lateral power feed, continue

power feed until piece is severed from bar and bar face is completely machined.

Note: In this particular job, the first operations under both the hexagonal turret and the cross slide were omitted to cut down the time.

APPENDIX B

MACHINE CONTROLS

DESCRIPTION OF MACHINE CONTROLS AND DIALS

FOR A

GISHOLT NO. 4 RAM TYPE UNIVERSAL TURRET LATHE

Controls used in this particular job:

A. Spoked Handwheel

Rotates freely in either direction. Used to advance, retract and index turret.

Clockwise - Retracts, unlocks and indexes turret.

Counter-clockwise - Advances and locks turret.

Touch Stimuli:

Advancing.

- (1) Vibration and force of initial contact of tool with work.
- (2) Vibration of cutting action and reaction force.
- (3) Vibration of contact of turret ram with stop screws and reaction force.

Retracting.

- (1) Vibration of contact and action of unclamping mechanism and reaction force.
- (2) Vibration of contact and action of turret indexing mechanism reaction force.
- (3) Vibration of contact of turret ram with back stop and reaction force.

B. Square Turret Lateral Feed Handwheel and Crank

Rotates freely in either direction. Used to advance and retract the square turret (i.e., cross feed).

Clockwise - advance.

Counter-Clockwise - retract.

Touch Stimuli:

Advancing.

- (1) Vibration of initial contact of tool with work.
- (2) Vibration of cutting action.

C. Lateral Feed Micrometer Dial

Dial turns with lateral feed handwheel. Used to indicate accurately the depth of lateral feed of the tool. Dial is graduated in 0.001 in. and marked every 0.010 in. Numbered clips are provided on the dial to indicate depth settings. The dial is positioned relative to a fixed index at the top of the dial.

Visual Stimuli:

- (1) Position of dial and clips relative to fixed index.
- (2) Movement of dial and clips relative to fixed index.

D. Square Turret Longitudinal Feed Handwheel and Crank

Rotates freely in either direction. Used to traverse the side carriage right and left (i.e., feed longitudinally in and out).

Clockwise - traverse right.

Counter-clockwise - traverse left.

Touch Stimuli:

Left Traverse.

- (1) Vibration of initial contact of tool with work.
- (2) Vibration of cutting action.
- (3) Contact of apron with stop.

E. Side Carriage Feed Selector Lever

Moves up and down through a limited arc with positive stops at both ends. Has four positions with a detent for each position. These detents are not readily felt. Used to set the power feed rate for the side carriage either for lateral feed, longitudinal feed or both.

Touch Stimuli:

- (a) Positive stops at ends of arc.
- (b) Detent action.
- (c) Meshing action of gears.

F. Side Carriage Feed Selector Dial

Dial made in form of an arc and is integral with the Feed Selector Lever with which it moves. Used to select side carriage power feed. Eight (8) feeds can be selected, four (4) coarse (red) and four (4) fine (black). Numbers are arranged in pairs. Dial is positioned relative to a fixed index above lever axis of rotation.

Visual Stimuli:

- (1) Numbers indicating feed selections.
- (2) Red and Black colors corresponding to coarse and fine feed.
- (3) Position of dial relative to the fixed pointer.
- (4) Movement of dial relative to fixed pointer.

G. Side Carriage Coarse-Fine Feed Selector

A small finger operated lever which moves quite easily when gears are meshed. Moves through a 180 deg. arc with positive stops at both ends. Has two positions.

"Coarse" - right.

"Fine" - left

"Coarse" and "fine" markers are attached to the lever and indicate setting when lever is in final position.

Touch Stimuli:

- (1) Meshing of gears.
- (2) Lever against positive stop.

Visual Stimuli:

- (1) "Coarse"
- (2) "Fine"

H. Square Turret Lateral Feed Engaging Lever

Moves up and down through a small arc between two positions. Spring loaded down against a positive stop. Held in up position by a spring loaded plunger. Lever handle rotates down to retract plunger. Used to engage and disengage lateral power feed clutch.

Up - engage.

Down - disengage.

Touch Stimuli:

- (1) Upper positive stop and vibration of plunger action.
- (2) Spring loaded movement of lever when rotation of handle retracts plunger.
- (3) Bottom positive stop.

I. Side Carriage Longitudinal Feed Engaging Lever

Action identical to Lateral Feed Engaging Lever, except that action of Apron Stop Roll (Indexing Stop) trips out power feed. Used to engage and disengage longitudinal power feed clutch.

J. Side Carriage Indexing Stop

Rotates through 360 deg. Has six (6) positions, each marked with a small number stamped in the metal. A knurled ring around the stop roll facilitates rotation of the stop. All six positions have a detent for final positioning. The stop in the top position is the one that functions; there is no fixed index relative to which the stops are positioned. Used to trip the longitudinal power feed accurately and also as a location for cross slide movement.

Touch Stimuli:

- (1) Detent Action.

Visual Stimuli:

- (1) "1", "2", -----, or "6".
- (2) Position and movement of a particular number relative to top of stop roll.

K. Square Turret Indexing Lever

A ratchet type lever. Rotates in and out through approximately 180 deg. each way. Used to lock and unlock and index the turret.

Touch Stimuli:

Moving in.

- (1) Release of pressure and force when turret unlocks.
- (2) Vibration and force of contact of ratchet with indexing mechanism.
- (3) Force of positive stop when turret locates in next position.

Moving out.

- (1) Vibration of action of ratchet mechanism.
- (2) Increased pressure and force when turret is locked in position (a binding type of action).

L. Carriage Binder

Rotates through about a 60 deg. horizontal arc. Has two positions, in and out. Used to lock (bind) the side carriage in a specific position.

- In - binds carriage.
- Out - releases carriage.

Touch Stimuli:

- (1) Moving in - Increase of pressure and force due to binding action.
- (2) Moving out - Decrease of pressure and force when carriage is released.

Controls Not Used in Particular Job

- 1. RPM Selector Dial and Pointer.
- 2. RPM Selector Handwheel.
- 3. Cutting Speed Selector Dial.
- 4. Workpiece Diameter Dial.
- 5. Cutting Speed Selector Ring.
- 6. Speed Trip Lever.
- 7. Direct or Pre-Set Selector Lever.
- 8. Power Motor Control Push Button.
- 9. Motor Speed Selector.
- 10. Coolant Switch.
- 11. Spindle Clutch Lever.
- 12. Side Carriage Stop Bar Lever.
- 13. Chuck and Bar Feed Control Lever.
- 14. Hand Oil Pump Lever.
- 15. Side Carriage Forward-Reverse Power Feed Selector Lever.
- 16. Hexagonal Turret Power Feed Trip Lever.
- 17. Hexagonal Turret Feed Engaging Lever.
- 18. Hexagonal Turret Feed Selector Dial.
- 19. Hexagonal Turret Feed Selector Lever.
- 20. Hand Oil Pump Lever.
- 21. Hexagonal Turret Stop Screws.

TIME DATA CORRECTIONS

The face camera times were assumed to be correct and the side camera time values were corrected to correspond to them.

Referring to the graph, it will be seen to be divided into two linear segments A and B.

Letting:

x = time (face camera)

y = time (side camera)

k = conversion factor for segment A or B.

$x = ky$

Average values of $k_A = 1.145$

$k_B = 1.138$
