ABSTRACT

A procedure for measuring the viscous damping of relatively large plate material (up to 40 inches × 14 inches × 2 inches) was developed utilizing the Hewlett-Packard 5451C Fourier Analyzer and impulse hammer technique under very low stress conditions. Testing environment can be lab air or nondistilled water in the temperature range from 30° F to 90° F.
The test procedure includes modal analysis that is expandable to other geometric shapes and varied material such as high damping alloys and composites both metallic and non-metallic.

I. INTRODUCTION

A. GENERAL

Ship silencing continues to be a major design requirement
in the construction and operation of submarines and surface
ships. It has been long established that both equipment and
personnel are adversely affected by unwatned noise and vibra-
tion. In today's environment both subsurface and surface,
with recent advances in acoustic devices the very surviva-
bility of the platform is directly related to own ship's
noise. Weapon platforms must be quiet enough to escape detec-
tion by sophisticated passive sonar devices as well as quiet
enough to prevent own ship's noise from interfering with
detection and prosecution of enemy targets.

The more traditional approach to ship silencing has been,
and continues to be, that of vibrations isolation. This ap-
proach requires that all sources of vibration to be placed
on resilient energy-absorbing mounts. This results in a
significant reduction in the transmission of vibrational
energy from the equipment and main engines to the surrounding
environment but is not totally satisfactory because these same
mounts must serve as shock mounts. In addition, any resilient
mount will have a peak efficiency in particular frequency
range with decreasing efficiency both above and below that
frequency range. The optimal solution would be to use

12

resilient mounts in conjunction with other methods of vibrational control to reduce the amount of vibration and noise generated as well as reducing the amount transmitted.

As with any design, today's ships are a compromise of requirements and cost considerations. However, the trend recently has been toward the design of equipment that is inherently quieter, which results in less noise and vibrational energy at the source. This current trend in design is currently being approached from many directions. Among these considerations are:

1. Extreme care in balancing of rotating machinery with consideration of vibrations during start up and coast down as well as steady state operation.

2. Selection of operating frequency as far removed from resonant frequencies as possible.

3. Close attention to component tolerances.

4. Possible use of high damping materials for machine elements as well as machine casings and load bearing structures.

The last category, use of high damping materials, is the furthest from being utilized to its maximum potential for noise and vibrational reductions.

Only recently has the designer even considered the internal capacity of a material alone with the traditional material properties of strength, fatigue resistance, toughness and corrosion resistance.

There are several commercially available high damping alloys that meet the strength requirements for most shipboard applications. It is recognized that each of the candidate materials may have unique properties that may cast doubt on their actual usefulness in the United States Navy. A more important problem exists, however. That is, the lack of a consistent method of measuring damping for a material under low stress, and high frequency range.

B. DAMPING

"Structural damping" refers to a structure's or structural component's capacity for dissipating energy, or, more precisely, to its capacity for removing from a structural vibration some of the energy associated with that vibration. The energy removed may be converted directly into heat, transferred to connected structures or ambient media [Ref. 1].

Damping has two primary effects: (1) It limits the steady-state motions of structures or systems in situations where these motions are controlled by an energy balance; and (2) It increases the rates at which the free (i.e., unforced) vibrations of structures decay.

Consider, for example, the classical lumped-parameter mass-spring dashpot system driven by a steady sinusoidal force that acts on the mass. For such a system it is possible to make the following observations: (1) For excitation frequencies that are considerably lower than the system resonance

frequency the applied force essentially is balanced by the spring force. The mass and dashpot here have virtually no effect. (2) For excitation frequencies that are considerably higher than the system resonance frequency, the applied force essentially is opposed by only the inertia force of the mass. In this case the spring and dashpot have virtually no effect.

(3) For excitation frequency near the system resonance frequency, the spring force and the inertia force essentially cancel each other, leaving only the dashpot (i.e., the damping element) to oppose the externally applied force. One may note that changes in the damping do not affect the system response for the first two of the above cases, but for an oscillatory force acting at the system's resonance, the vibration amplitude decreases with increasing damping.

In addition to the case of resonant or near-resonant excitation, there occur several other important steady-state or near-steady-state situations in which the responses of systems or structures are controlled by a balance between the energy input and the energy dissipations. These situations include cases of (1) broad-band excitation, and (2) spatially periodic excitation where the spatial period matches that of freely propagating waves. Because broad-band excitation generally encompasses several structural resonance frequencies, the structural responses of the excited modes, and each resonant modal response is controlled by damping.

If a structure (or a mechanical system) is deflected from its equilibrium position and then released, the structure vibrates with ever-decreasing amplitude on the result of damping, i.e., as the result of energy being removed from the oscillatory motions. Greater damping corresponds to the dissipation per cycle of a greater fraction of the vibratory energy, thus resulting in more tapid decay of the vibrations. In a somewhat similar manner, increased damping also results in the more rapid decay of freely traveling waves. For example, if a long beam is subjected to an oscillatory transverse force of a constant amplitude and frequency, such as near the center of the beam, then flexural waves travel away from the driving point in both directions. As the result of damping, the amplitude of these waves decreases with increasing distance from the point of application--with greater damping leading to lesser amplitudes at a given distance.

The practical consequences of effects mentioned above generally are the reasons one is interested in systems or devices that increase damping. Reductions in resonant or random responses result in decreased oscillatory stresses and increase in the fatigue life of structures, in the relia-bility of mechanical devices, and in mechanical impedance (which tends to improve the effectiveness of vibration isolation).

Reduction of the spatially resonant responses of a wall or panel leads to decreased sound transmission through that

structure for frequencies above the coincidence frequency.
Increased attenuation of propagating waves results in lesser
transmissions of vibrations to neighboring structures. More
rapid decay of free vibrations reduces the "ringing" sound of
structures, thus leading to less noise, particularly from
structures excited by repetitive impacts. This also tends
to reduce structural fatigue.

C.   MEASURES OF DAMPING

Damping may be quantified in terms of any of the previously
discussed primary effects. The corresponding commonly used
measures of damping, defined below, are interrelated as
follows: [Refs. 2,3]

$$\eta \;=\; \frac{\psi}{2\pi} \;=\; \frac{2.20}{f_n T_{60}} \;=\; \frac{\Delta_t}{27.3 f_n} \;=\; \frac{\delta}{\pi} \;=\; \frac{\Delta_\tau}{13.6} \qquad (1)$$

The loss factor η and damping capacity ψ are defined
directly in terms of the cyclic energy dissipation; the
damping capacity represents the fraction of the system's
vibrational energy that is dissipated per cycle of the vibra-
tion, and the loss factor similarly is defined as the frac-
tion of the system's energy that is dissipated per radian of
the vibratory motion.

On the other hand, T_{60}, Δ_t, are related to the rate of
decay of free vibrations. T_{60} denotes the reverberation
time (in seconds), defined (in analogy to the related

17

room-acoustic measure) as the time within which the vibration level of a system vibrating freely at a frequency f_n (Hz) decreases by 60 dB (i.e., the amplitude decreases to 1/1000 of its original value). A related measure, decay rate Δ_t (dB/sec), represents the rate of reduction of the vibration (acceleration or displacement velocity) level. The logarithmic decrement δ is defined as the natural logarithm of the ratio of a peak excursion of a freely vibrating system to the peak excursion one cycle (period) later. The spatial decay Δ_τ (dB/wavelength) represents the reduction in the steady-state vibration level with distance that occurs along a long beam vibrating in flexure.

It should be noted that none of the measurements of damping depend on how the energy is dissipated. Within a cycle these measures make no reference to any damping mechanism. On the other hand, some other commonly employed measures of damping are defined on the basis of viscous damping (i.e., damping that results from a retarding force that is proportional to the velocity. The ratio of the magnitude of that force to the velocity is called the viscous damping coefficient and is commonly designated by c.

If a simple mass-spring-dashpot system (where the dashpot provides a viscous retarding force characterized by c) is deflected from equilibrium and released, it typically oscillates with ever decreasing amplitude. However, if c is made large enough, no oscillations occur. Instead, the system

18

creeps toward its equilibrium position, never traversing it.
The smallest viscous damping coefficient for which this non-
oscillatory behavior is obtained--i.e., the viscous damping
that represents the dividing line between oscillatory and
nonoscillatory behavior is called the critical (viscous)
damping coefficient c_c. It obeys $c_c = 2\sqrt{km}$ where m denotes
the mass and k the spring stiffness. The "damping ratio"
c/c_c, also called the fraction of critical damping and often
given in terms of "percent of critical damping", is widely
used to indicate damping magnitudes.

Two other measures of damping are derived from the steady
state behavior of an ideal linear mass-spring-dashpot system
that is driven by a sinusoidal force of constant amplitude
[Ref. 4]. The amplification at resonance, often called "the
Q" of the system is defined as the ratio of the amplitude that
results at resonance to the amplitude that is obtained if
the force acts quasi-statically (i.e., a frequency consider-
ably below resonance). The proportional bandwidth b takes
account of the damping related broadening of the peak in a
plot of response amplitude versus frequency; this nondimensional
bandwidth is defined as f/f_n, where f denotes the difference
between the two frequences (one above, and one below the
resonance frequency f_n) at which the square of the response
amplitude is one-half of its maximum value. For values of
damping below critical, the aforementioned measure of damping
are related to each other and to the previously discussed
loss factor as:

19

$$\eta = \frac{c}{c_c} = \frac{1}{Q} = b \qquad (2)$$

D. DAMPING MECHANISMS

For linear, viscously damped systems, all of the measures of damping discussed previously are independent of the amplitude. Amplitude independence also occurs for other damping mechanisms, and approximate amplitude-independence occurs for almost all systems, provided the damping is relatively small. Thus, amplitude independence cannot be taken as an indication that a system is viscously damped; nevertheless, damping of systems with unknown energy dissipation mechanism is often characterized in terms of an equivalent viscous damping coefficient.

Indeed, much analysis is carried out with the (usually tacit) assumption that the damping is viscous--largely because viscous damping leads to linear differential equations that can be solved relatively easily. It is fortunate that for many practical problems, e.g., where only certain response maxima are of concern, the details of the damping mechanism are unimportant. Thus, one may obtain reasonable response predictions even with inaccurate damping force-versus-velocity representations. However, realistic damping models are required for the analysis of cases where one is interested in details of the response motions.

Unlike mass, a single physical phenomenon and stiffness, which results from a very few physical effects, damping may be caused by a great variety of phenomena. These phenomena include mechanical hysteresis (also called material damping or internal friction), electromagnetic effects (notably eddy currents), friction due to motion relative to fluids or solid surfaces, and energy transport to adjacent structural components or fluids (including by acoustic radiation). This great variety of phenomena that can produce damping generally make damping difficult to predict and to eliminate, but enables one to conceive a variety of means for increasing it.

II. NATURE OF THE PROBLEM

A. BACKGROUND

To date, the majority of damping research has been conducted on test specimens that are subjected to high stresses (i.e., torsional vibrations and vibrating cantilevered beams). For most United States Naval applications, structures and components are designed for operation at relatively low stresses.

Damping characteristics are shown to be highly stress dependent [Ref. 5]. Therefore, the damping values obtained at high stresses do not generally apply for most naval applications of ship silencing problems.

David W. Taylor Naval Ship Research and Development Center (NSRDC), Annapolis, Maryland is the focal point for testing and evaluating new high damping material for possible use for the United States Navy. Realizing the wide scope of the work necessary for the testing and evaluation of any new material, the author decided to approach NSRDC with a proposal to offer assistance in determining the damping of candidate material.

B. OBJECTIVE

To design a test procedure that allows the measurement of damping in a plate specimen at low stress with the following variables:

1. Plate specimen (40 inches × 14 inches × 1 inch) and 40 inches × 14 inches × 2 inches), or in proportionally reduced sizes.

2. Frequency: Damping testing will be conducted in the acoustic range (100-20,000 Hz).

3. Environment: Testing will be conducted in lab air and in nondistilled water. Temperature will range from 30°F to 90°F.

The test procedure includes a complete modal analysis that is expandable to other geometric shapes. Actual testing and verification of the procedure are conducted on the Hewlett-Packard 5451C Digital Fourier Analysis System. General information on the HP-5451C system is included in Appendix A.

C. SCOPE OF WORK TO BE COMPLETED

NSRDC has provided four specimens for testing and to establish baseline data for future work. The test specimens currently on hand are: A) Cast manganese bronze, code DEQ; B) Cast nickel-aluminum bronze, code FTC; C) Steel plate, HY-130, code FTW; and D) Aluminum alloy, 5086-H116, code ESX. It is anticipated that after baseline data has been compiled for both air and water tests that additional specimens will be provided by NSRDC. These additional specimens are expected to include high damping alloys such as Sonoston and Incramute, as well as constrained layer specimens and composites, both metallic and non-metallic.

For the purpose of this thesis the following work was completed: (A) design and construction of the test chamber, (B) design of a test procedure for the evaluation of damping of specimen provided by NSRDC, (C) complete tank character- ization by impulse hammer techniques, (D) measurement of damping of the cast nickel-aluminum bronze, code FTC, speci- men by impulse hammer technique. All of the above testing was completed in lab air at normal ambient temperature.

III. DESIGN OF TEST CHAMBER AND THEORY OF CHARACTERIZATION

To accomplish the aforementioned objectives four major
steps must be accomplished: (A) design of a test chamber,
(B) characterization of the test chamber, (C) design of
experimental procedure of the measurement of damping, and
(D) utilization of the above test procedure for damping
measurement on a plate specimen supplied by NSRDC.

A. DESIGN OF TEST CHAMBER

Design of the test chamber was based on three major
considerations: (1) size of the largest specimen, (2) weight
of the largest specimen, and (3) environmental conditions
desired for testing. In addition, the fixture to support
the specimen had to hold the specimen rigid so that there
would be no swinging.

The overall outside dimension of the chamber (Figure 1)
was chosen to be a rectangular box 48 inches wide by 36 inches
deep by 72 inches high. This allowed for ample clearance for
the largest specimen (40 inches × 14 inches × 2 inches) on all
surfaces and to limit the amount of reflected acoustic energy
if acoustic absorption material was required on the inside
surfaces. The test chamber was constructed from one quarter
inch plate steel supported by a frame constructed from 2 inch
steel thick wall square tubing. The 2 inch square tubing

25
Figure 1. Experiment test chamber

was welded at all mating edges to give the desired rigidity and to prevent water entrapment (future corrosion problems).

The specimen fixture (Figure 2) was constructed from 3 inches × 2 inches thick wall steel tubing and is designed to give a deflection, from a 400 pound specimen, of less than 0.04 inch.

To accommodate various sized specimen the random frequency exciter base (Figure 3) can be adjusted within the 2 inch rectangular tubing frame work of the upper half of the rear panel (Figure 4). The random acoustic exciter can be adjusted from 8 inches below the specimen fixture to 24 inches below the specimen fixture. This feature allows for a wide variety of centered excitation from the end of a specimen plate to the center of a specimen plate.

To allow the removal and placement of various size specimen, the front panel of the test chamber is bolted to the test chamber frame and a water gasket is formed by using a RTV silicone adhesive sealant. Because of the bonding of the RTV all water test must be conducted with the steel front panel. For air testing the optional clear front panel may be used because no sealant is required.

The preservation of the test chamber was accomplished by sandblasting all steel parts, after protecting front panel and specimen fixture bolt threads, one spray paint coat of zinc chromate primer and one hand brushed top coat of enamel.

To allow testing in lab air and nondistilled water, the test chamber is water tight with a 1 inch, valved, drain
Figure 2.   Detail of specimen support fixture

28
Figure 3. Specimen exciter base with support mechanism

29
Figure 4. Inside rear panel of test chamber

30

line near the bottom of the tank. Heating and cooling of the tank is accomplished by copper tubing (3/8 inch O.D.) coiled over entire outside surface of the back panel (Figure 5). The coils are spaced 3 inches apart and are 40 inches wide. To heat or cool the test chamber a mixture of 50% ethol glycol (automative) antifreeze is supplied from a storage tank (Figure 6) at the desired temperature and is pumped through the heating and cooling coil.

The entire test chamber is insulated with one and one half inches of rigid foam insulation, with the exception of the rear panel, which is insulated with standard residential batt insulation.

B. THEORY OF THE CHARACTERIZATION OF TEST CHAMBER

The characterization of the test chamber was accomplished by use of the impulse technique for structural frequency response testing [Ref. 7] and the Fourier transfer function capability of the HP-5451C Fourier Analyzer.

1. Theory of Frequency Response Function

The measurement of the frequency response function is the heart of modal analysis. The frequency response function $H(f)$ is defined in terms of the single input/single output system, as the ratio of the Fourier transforms of the system output or response $v(t)$ to the system input or excitation $u(t)$, Equation (3).

$$H(f) = \frac{V(f)}{U(f)} \qquad (3)$$

31
Figure 5. Cooling/heating coil on outside of rear panel
Figure 6. Cooling/heating water tank with pump, heater and controller

33

where:

$V(f)$ = Fourier transform of system output $v(t)$

$U(f)$ = Fourier transform of system input $u(t)$.

The only requirements for a complete description of the frequency response function are that the input and output signals be Fourier transformable, a condition that is met by all physically realizable systems, and that the input signal be non-zero at all frequencies of interest. If the system is nonlinear or time-variant, the frequency response function will not be unique, but will be a function of the amplitude of the input signal in the case of a nonlinear system and a function of time in the case of a system with time-varying properties.

The frequency fesponse function may be computed directly from the definition as the ratio of the Fourier transforms of the output and input signals. However, better results are obtained in practice by computing the frequency response function as the ratio of the cross-spectrum between the input and output to the power spectrum of the input, Equation (4). This relationship is derived by multiplying the numerator and denominator of the right-hand side of Equation (1) by the complex conjugate of the input Fourier transform.

$$H(f) = \frac{G_{uv}(f)}{G_u(f)} \tag{4}$$

where:

$$G_{uv}(f) = U^*(f)V(f), \text{ cross-spectrum between } u(t) \text{ and } v(t)$$

$$G_{uv}(f) = U^*(f)U(f), \text{ power spectrum of } u(t)$$

$$U^* = \text{ complex conjugate of } U(f).$$

The usefulness of this form of the frequency response function can be seen by considering the practical single input/single output measurement situation, where $m(t)$ and $n(t)$ represent noise at the input and output measurement points, respectively.

The measured frequency response function $H'(f)$ is given by the equation:

$$H'(f) = \frac{Y(f)}{X(f)} = \frac{V(f) + N(f)}{U(f) + M(f)} \tag{5}$$

where the upper case letters denote the Fourier transform of the corresponding time domain signals.

In this form, the measured frequency response will be a good approximation of the true frequency response only if the measurement noise at both the input and output measurement points is small relative to the input and output signals. Multiplying the numerator and denominator of the right-hand side of Equation (5) by the complex conjugate of $X(f)$ yields

$$H'(f) = \frac{G_{uv}(f) + G_{un}(f) + G_{mv}(f) + G_{mn}(f)}{G_{u}(f) + G_{um}(f) + G_{mn}(f) + G_{m}(f)} \tag{6}$$

35

Now, if the measurement noise signals m(t) and n(t) are noncoherent with each other and with the input signal u(t), then the expected value of the cross-spectrum terms involving m and n in Equation (6) will equal zero, yielding

$$H'(f) = \frac{G_{uv}(f)}{G_u(f) + G_m(f)} = \frac{H(f)}{1 + \dfrac{G_m(f)}{G_u(f)}} \qquad (7)$$

where H(f) is the desired true frequency response function.

Thus, if the noise-to-signal ratio at the input measurement point $[G_m(f)/G_u(f)]$ is much less than 1, the measured frequency response will closely approximate the desired true frequency response function.

It should be pointed out here that there is an inherent bias error associated with the computation of the cross-spectrum and the magnitude of this bias error is inversely proportional to the number of averages in the computation. Thus, the greater the measurement noise, the greater the number of averages required to approach the expected value of the cross-spectrum between the input and the output measurement signals. With measurement techniques employing many averages, the bias error can usually be reduced to an insignificant level so that it is only necessary to minimize the noise in the measurement of the input signal. However, if there is significant measurement noise and only a few averages are used, then the computed values of the cross-spectrum terms

involving the noise signals in Equation (6) can be large relative to the true cross-spectrum, with resulting large errors in the measured frequency response function. In general, only a few averages are used in the impulse technique; otherwise, one of its major advantages--its speed--is lost. Therefore, it is important to minimize measurement noise in both the input and output signals when using the impulse technique. The cross-spectrum bias error and its effects are discussed in more detail in Reference 8.

Coherence Function. There is another important reason for computing the frequency response function in terms of the cross-spectrum: it allows the computation of the coherence function between the input and output signals. The coherence function is defined by the equation

$$\gamma_{xy}^2(f) \; = \; \frac{|G_{xy}(f)|^2}{G_x(f) G_y(f)} \tag{8}$$

According to the definitions of the power spectrum and the cross-spectrum, the coherence function will be identically equal to 1 if there is no measurement noise and the system is linear. The minimum value of the coherence function, which occurs when the two signals are totally uncorrelated, is 0. Thus, the coherence function is a measure of the contamination of the two signals in terms of noise and nonlinear effects, with very low contamination indicated for values close to 1.

Since the cross-spectrum is included in the definition of the coherence function, the cross-spectrum bias error must be reduced to an acceptable level if a good statistical estimate of the coherence function is to be achieved. As stated above, the number of averages used in the impulse technique is usually not great enough to significantly reduce the bias error. However, the coherence function is still useful for indicating the importance of noise in the impulse technique. This is because noise in the signals causes variance in the value of the coherence function with frequency. This effect is illustrated in the section on measurement procedures.

2. <u>Display of Frequency Response</u>

The frequency response function is complex--that is, it has associated with it both magnitude and phase. Therefore, it can be displayed in a number of forms, including magnitude and phase versus frequency, real and imaginary magnitudes versus frequency, and imaginary magnitude versus real magnitude. Each of these types of displays has its own particular usefulness. The most common type of display for structural frequency response data is magnitude and frequency plotted logarithmically. This type of display, with the magnitude in terms of compliance (ratio of displacement to force) is called a Bode plot. In this form of the frequency response function, resonances occur as peaks in compliance plots (points of maximum dynamic weakness) and all resonance peaks of equal damping have the same width regardless

of resonance frequency. Lines of constant dynamic stiffness have zero slope, and mass-dominated frequency response lines have a -12 dB-per-octave slope. Resonances occur as nearly circular arcs in the complex plane (real versus imaginary plot) with frequency increasing in a clockwise direction around the arc. In the case of real normal modes (which occur in systems with relatively low damping and with resonances well-separated in frequency), each resonance arc is approximately tangent with, and lies below, the real axis and is symmetric about the imaginary axis when the frequency response is expressed as compliance. The complex plane plot is useful when certain types of analytical curve fitting operations are being performed on the frequency response data. The plots of the real and imaginary magnitudes of frequency response versus frequency are most useful when dealing with real normal modes. In this case the resonances will occur as peaks in the imaginary magnitude plot and the real magnitude will pass through zero at the resonance frequency when the frequency response is expressed as compliance.

The frequency response characteristics of a structural element are determined by measuring a set of cross-frequency response functions as discussed in Reference 9. The cross-frequency response functions may be obtained by exciting at one location on the structure and measuring response at various locations, or by measuring the response at a single location to excitation at various locations. The resulting

frequency response functions comprise one column of the transfer matrix in the first case, and one row of the transfer matrix in the second case. Either set will, in general, completely define the modal characteristics of the structural element. In mathematical terms the set of frequency response functions yields the eigenvalues and eigenvectors, which are, in general, complex terms. The real part of an eigenvalue is the damping and the imaginary part is the frequency associated with a given resonance. Each eigenvector defines a resonance mode shape.

With real normal modes, each point on a structure is either exactly in-phase or exactly 180 degrees out-of-phase with any other point at the resonance frequency. Certain types of damping which are often encountered in practice will cause the eigenvectors to have non-zero imaginary components, resulting in complex mode shapes. When a mode is complex, the relative phase associated with a point on a structure is some value other than 0 or 180 degrees, with the result that node lines (lines of zero deflection) are not stationary. Precise description of complex modes requires that some type of analytical curve fitting technique be applied to the frequency response data.

The frequency response function of an operating system can be computed if the system input and output signals meet previously stated requirements of Fourier transformability and non-zero value, assuming the system input and response

can be measured. However, in practice there are usually
multiple inputs to the system--either several inputs at
different locations or inputs in more than one direction at
a given location. In the case of multiple coherent inputs,
the complexity of the analysis is greatly increased. For
this reason, and the difficulty of accurately monitoring
operating inputs, frequency response measurements are usually
made by applying the system input "artificially" through
some type of exciter. It is in the form of the input signal
and the way it is applied to the structure that the wide
variety of frequency response testing techniques arises.

The usefulness of the impulse technique lies in the
fact that the energy in an impulse is distributed continu-
ously in the frequency domain rather than occurring at dis-
crete spectral lines as in the case of periodic signals.
Thus, an impulse force will excite all resonances within its
useful frequency range. The extent of the useful frequency
range of an impulse is a function of the shape of the im-
pulse and its time duration. For a square pulse the frequen-
cies of the zero crossings are at integral multiples of the
inverse of the time duration of the impulse, illustrating
the very important inverse relationship between the time
duration of an impulse and its frequency content.

The useful frequency range of an impulse is also a
function of the shape of the impulse. By varying the weight
and hardness of an impacting device and the manner in which

41

the impact is applied, the shape and time duration of the impulse produced can be varied to suit the measurement requirements.

a. Nonlinearities in the Structures

Excitation of a nonlinear system by a pure-random signal will yield the best estimate (in a mean-square sense) of the linear system response. Excitation by a pure sine wave is also useful for studying nonlinear systems because it allows precise control of the input spectrum level. However, the impulse technique, because of its very high ratio of peak level to total energy, is particularly ill-suited for testing nonlinear systems. Therefore, it is important to understand the various types of nonlinearities that can occur in structural systems and to be able to recognize nonlinearities in measured frequency response functions.

One of the most common types of nonlinearities encountered in structures is that due to clearance between parts. This type of nonlinearity is frequently encountered, for example, when testing gear systems and shafts mounted in bearings. The effects of this type of nonlinearity on measured frequency response functions when using impulse excitation are poor estimates of static stiffness values and poor repeatability of the frequency response estimates. Also, the apparent damping in the estimates will be greater than the actual examples.

The best method of dealing with this type of nonlinearity is to preload the system to take up clearances. Care must be taken when this is done, however, because any preload will change the boundary conditions of the structure and can itself lead to erroneous frequency response estimates. The usual approach is to apply the preload through a very soft spring so that the resonances associated with the preload lie below the frequency range of interest.

Another type of nonlinearity that is frequently encountered is nonlinear damping. Nonlinear damping effects are usually associated with joints in the structure, where the damping is a function of the relative displacement at the joint. In general, the frequency response estimates obtained by the impulse technique will agree most closely with those obtained with a low level of continuous excitation. However, if the point of excitation is close to a location where nonlinear damping occurs, there will be high relative motion at that location, and the apparent damping in the measured frequency response will be high. In systems with low damping, this will give the measured frequency response a discontinuous appearance, due to the varying level of damping as the response to the impulse attenuates with time.

The third type of nonlinearity that commonly occurs in structures is load-sensitive stiffness, where the spring rate of elastic elements either increases or decreases with load. The most direct way to identify this type of

nonlinearity is to measure frequency response as a function of static preload and observe the change in resonance frequencies.

    b.   Signal Processing

        The particular characteristics of an impulsive force signal and the resulting structural response signal make the impulse technique especially susceptible to two problems: noise and truncation errors. While these problems occur to some extent with other frequency response testing techniques, their unique importance in the impulse technique requires special signal processing methods.

        It was pointed out in the previous section that the usable frequency range for an impulse depends on the shape and time duration of the impulse. In order to insure that there is sufficient force over the frequency range of interest, it is necessary that the first zero crossing of the Fourier transform of the impulse be well above the maximum frequency of interest. For a given time duration the first zero crossing occurs at the lowest frequency for a square pulse. For that type of pulse the first zero crossing occurs at a frequency equal to the inverse of the time duration. A good rule of thumb, then, is to insure that the duration of the impulse is less than $2\Delta t$, where t is the sampling interval in the analog-to-digital conversion process. This would put the first zero crossing of the Fourier transform of a square pulse at the Nyquist folding frequency, and the

first zero crossing of other pulse shapes above the Nyquist folding frequency.

The sample length is equal to $N\Delta t$ where N is the number of digital values in each sample. A typical value of N is 1024. Thus, the duration of the impulse is very short relative to the sample length. This means that the total energy of noise represented in the time-sample can be on the order of the energy of the impulse, even for high signal-to-noise ratios. The noise problem is further aggravated when employing the zoom transform, which yields increased resolution in a given frequency band by effectively increasing the sample length.

With other techniques, the effects of noise are reduced by averaging the power spectrum and cross-spectrum functions prior to the computation of the frequency response function. However, only a few averages are usually used in the impulse technique. Otherwise, the time advantage of the technique is lost. Therefore, special time-sample windows have been developed for the impulse technique.

At first thought it might seem appropriate to just set all time-sample values beyond the impulse to zero, since it is known that the true signal value after the impulse is zero. However, this would be equivalent to multiplying the signal by a narrow rectangular window. In applying any type of window, it is important to keep in mind that multiplication by a window in one domain is equivalent to

convolution of the Fourier transforms of the window and the data in the other domain, resulting in distortion of the transformed signal. This distortion will be minimized by minimizing the width of the main lobe of the window transform and suppressing its side lobes. However, there is a fundamental conflict between these requirements and the reduction of noise in the time-sample because both the width of the main lobe and the amount of noise reduction are inversely proportional to the width of the window in the time domain. To further complicate the situation, suppression of the side lobes is generally achieved at the expense of broadening the main lobe.

A good compromise has been arrived at in practice in the form of a window with unity amplitude for the duration of the impulse and a cosine taper, with a duration of 1/16 of the sample time, from unity to zero.

Noise problems may also be encountered in the response signal, particularly when dealing with heavily damped systems and when using zoom transform analysis. In both cases the duration of the response signal may be short relative to the total sample time, so that noise may comprise a significant portion of the total energy in the time-sample even with relatively high signal-to-noise ratios. Another error in the response signal that is encountered when testing lightly damped structures occurs when the response signal does not significantly decay in the sample window. In this case

the resulting time-sample is equivalent to multiplying the true response signal by a rectangular window, with the result that the frequency resolution may not be sufficient to resolve individual resonances.

An exponential window has been developed to reduce the errors that occur in both situations described above. The window decays exponentially from 1 to a value of 0.05 in the sample time. It can be applied directly to the time-sample of the response signal or to the impulse response function. As with all windows, the exponential window does change the resulting measured frequency response function; but its only effect is to increase the apparent damping in the resonances. It does not change the resonance frequencies and, because the effect of the exponential window is the same on all frequency response measurements, it will not alter the measured mode shapes if applied to all measured frequency response functions. In addition to reducing noise and truncation errors, the exponential window will also reduce errors which often occur when testing lightly damped systems in which the damping varies with the measurement position on the structure.

Because the exponential window increases the apparent deamping in the resonance modes, there is a tendency of the window to couple closely spaced resonance modes. Zoom transform analysis may be required in some cases to allow sufficient resolution of closely spaced modes when using the exponential window.

47

Zoom transform analysis is discussed in some detail along with several examples in Reference 9. It is a very valuable tool in impulse testing, as it is in other frequency response measurement techniques. The effect of the zoom transform is to increase the resolution of the analysis by allowing independent selection of the upper and lower frequency limits of the analysis band. With the zoom transform, for example, it is possible to perform an analysis in the frequency range from 900 to 1000 Hz as opposed to the corresponding base-band range of 0 to 1000 Hz, resulting in a 10-to-1 increase in resolution, for a given sample size N, in the 900 to 1000 Hz band. Because of greatly increased resolution possible with the zoom transform, it can be effectively used in frequency response testing to separate closely spaced resonance modes.

There are two important effects of the zoom transform in the impulse technique, both associated with the resulting increase in sample time. The first effect is to make possible much better estimates of damping in lightly damped systems. This is due to the reduction of truncation errors in the sampled response signal. The second effect, mentioned previously, is aggravation of the noise problem in both the input and response signals. The second effect makes it essential that force and response windows be applied to the data in most cases when using the zoom transform with the impulse technique.

3. HP-5451C Fourier Transfer Function

A transfer function, as determined by the HP-5451C Fourier Analyzer, is a mathematical description of a system. It can be defined as:

$$\text{transfer function} = \frac{\text{Fourier transform of output}}{\text{Fourier transform of input}}$$

or equivalently,

$$\text{transfer function} = \frac{\substack{\text{average cross power spectrum} \\ \text{of input and output}}}{\substack{\text{average power spectrum} \\ \text{of input}}}$$

The coherence function measures the degree of causality between any two signals. It can, therefore, be used to check the validity of the transfer function. When a transfer function is computed it may not be obvious that there are extraneous inputs, or that the system is nonlinear. Both of these factors would introduce error in the computed transfer function. The "Transfer Function" program of the HP-5451C is used to compute the transfer and coherence functions. A program flow chart and a program listing are provided in Appendix B.

IV. THEORY OF THE TEST PROCEDURE TO MEASURE DAMPING

The design concept of the experimental procedure is based
on the Hewlett-Packard modal analysis software specifically
designed for the HP-5451C Fourier Analyzer. The theory
of the complex modes for damped oscillatory mechanical sys-
tems is described below, much of which is explained in
greater detail in the Modal Analysis Operating and Service
Manual (Option 402).

A. MODAL THEORY OF OPERATION [REF. 6]

Assume that the motion of a physical system can be des-
cribed by a set of n simultaneous second-order linear dif-
ferential equations in the time domain, given by,

$$M\ddot{x} + C\dot{x} + Kx = f \qquad (9)$$

where the dots denote differentiation with respect to time.

$$f = f(t)$$

is the applied force vector, and

$$x = x(t)$$

is the resulting displacement vector, while M, C, and K are
the $(n \times n)$ mass, damping, and stiffness matrices respectively.

50

Our attention will be limited to symmetric matrices, and to real element values in M, C, and K.

Taking the Laplace transform of the system equations gives

$$B(x)X(s) = F(s), \qquad (10)$$

where:

$$B(s) = Ms^2 + Cs + K \qquad (11)$$

Here s is the Laplace variable, and F(s) is the applied force vector and X(s) is the resulting displacement vector in the Laplace domain. B(s) is called the system matrix, and the transfer matrix H(s) is defined as

$$H(s) = B(s)^{-1} \qquad (12)$$

which implies that

$$H(s)F(s) = X(s) \qquad (13)$$

Each element of the transfer matrix is a transfer function. The elements of B are quadratic functions of s, and since $H = B^{-1}$, it follows that the elements of H are rational fractions in s, with det(B) as the denominator. Thus, H(s) can always be represented in partial fraction form.

If it is assumed that the poles of H, i.e., the roots of det(B) = 0, are of unit multiplicity, then H can be expressed as

$$H(s) = \sum_{k=1}^{2n} \frac{a_k}{s - P_k} , \qquad (n \times n) \qquad\qquad (14)$$

The poles occur at $s = P_k$ (zeros of det(B)), and each pole has n (n × n) residue matrix a_k associated with it. For an nth order oscillatory system, there will always be 2n poles, but they will appear in complex conjugate pairs. Each complex pair of poles causes a mode of vibration in the structure. The poles are complex numbers expressed as

$$P_k = -\sigma_k + i\omega_k \qquad\qquad (15)$$

where σ_k is the damping coefficient (a negative number for stable systems), and ω_k is the natural frequency of oscillation. The resonant frequency is given by

$$\Omega_k = \sigma_k^2 + \omega_k^2 \qquad (rad/sec) \qquad\qquad (16)$$

and the damping factor is

$$\zeta = +\frac{\sigma_k}{\Omega_k} \qquad\qquad (17)$$

These coordinates are shown in Figure 7. When $\zeta = 1$, mode (k) is said to be critically damped. It is also possible that $\zeta > 1$. For this case the poles of mode (k) lie along the real (or damping) axis in the S-plane and it is said to be super-critically damped.
Figure 7. Poles of a Mode (k)

Modal vectors (u_k) are now defined as solutions to the homogeneous equation

$$B_k u_k = 0 \qquad (10)$$

where:

$$B_k = B(p_k)$$

for all $k = 1, \ldots, 2n$.

In addition, pre-multiplying B times the equation (14) for H(s), multiplying by the scalar $(s-p_k)$ and letting $s = p_k$ gives

$$B_k a_k \ = \ 0 \qquad\qquad (19)$$

It follows by comparison of (10) with (19) that every column of a_k must contain the modal vector u_k, for each $k = 1,\ldots,2n$.

Similarly, post multiplying B times the equation (14) for H(s), multiplying by the scalar $(s-p_k)$, and letting $s = p_k$ gives

$$a_k B_k \ = \ 0 \qquad\qquad (20)$$

for each $k = i,\ldots,2n$. This can be rewritten as

$$B_k^t a_k^t \ = \ 0 \qquad\qquad (21)$$

where t denotes the transpose.

But B_k, and hence a_k, is assumed to be symmetric so equation (21) is the same as (19) and it follows that each row of a_k must also contain the vector u_k for each $k = 1,\ldots,2n$.

In order to satisfy the above conditions a_k must have the form

$$a_k \ = \ A_k u_k u_k^t \qquad (n \times n) \qquad (22)$$

where A_k is a scalar.

This pervasiveness of the modal vectors throughout the transfer function matrix is evidence of the so-called global property of a mode of vibration.

In these terms, H can be rewritten as

$$H = \sum_{k=1}^{2n} \frac{A_k}{s-p_k} u_k u_k^t \qquad (23)$$

and this is easily written in matrix form as

$$H = U L U^t \qquad (n \times n) \qquad (24)$$

where the columns of U comprise the u_k modal vectors:

$$U = [u_1 \ u_2 \ \cdots \ u_{2n}] , \qquad (n \times 2n) \qquad (25)$$

and L is a diagonal matrix containing all s dependence

$$L = \begin{bmatrix} \dfrac{A_1}{s-p_k} & & & \\ & \ddots & & \\ & & \ddots & \\ & & & \dfrac{A_{2n}}{s-p_{2n}} \end{bmatrix} \qquad (2n \times 2n) . \qquad (26)$$

Pre-multiplying H by U^t, equation (13), can be written as

$$(U^t U L)(U^t F) = (U^t X) \qquad (27)$$

so that U^t transforms the spatial vectors F and X to vectors $U^t F$ and $U^t X$ in modal coordinates. Similarly $U^t U L$ is the modal representation of H. Since $B(P_k)u_k = 0$, it follows that $B(P_k^*)u_k^* = 0$, so the modal vector associated with the conjugate pole (P_k^*) is u_k^* (the conjugate of u_k).

Thus, the above U matrix always contains conjugate pairs of modal vectors, and the L matrix always contains elements corresponding to conjugate pole pairs along its diagonal.

If U_1 is defined as that $(n \times n)$ part of U associated with positive poles, then U_1^* will correspond to the negative poles. Similarly, L can be broken into two parts, L_1 comprising the positive poles, and L_2 comprising the negative poles. It can then be represented

$$H = U_1 L_1 U_1^* + U_1^* L_2 U_1^{*t} \tag{28}$$

or in partitioned form as

$$H = [U_1 \vdots U_1] \begin{bmatrix} L_1 & \vdots & 0 \\ \cdots & \vdots & \cdots \\ 0 & \vdots & L_2 \end{bmatrix} [U_1^t \vdots U_1^{*t}] \tag{29}$$

Each of these sub-matrices is $(n \times n)$ and only L_1 and L_2 are functions of s.

$$L_1 = \begin{bmatrix} \dfrac{A_1}{s-p_1} & & \\ & \ddots & \\ & & \dfrac{A_n}{s-p_n} \end{bmatrix} , \quad L_2 = \begin{bmatrix} \dfrac{A_1}{s-p_1} & & \\ & \ddots & \\ & & \dfrac{A_n}{s-p_n^*} \end{bmatrix} \tag{30}$$

Then H can be written as:

$$H = \sum_{k=1}^{n} u_k u_k^t \frac{a_k}{s-p_k} + u_k^* u_k^{*t} \frac{A_k}{s-p_k^*} \tag{31}$$

Each element of the H matrix has a different zero in the S-plane, depending upon the values of A_k and u_k at each point, but the poles of each element of H are common, and occur at $s = p_k$ and $s = p_k^*$.

1. Identification of Modal Parameters

Because of the form of the a_k matrix, only one row or column of the transfer matrix need be measured and analyzed, since all processes of measuring the transfer matrix, the unknown parameters in equation (14) (i.e., the complex values of p_k and the complex values of the elements of one row or column or the residue matrix a_k) are identified.

Once one row or column of a_k has been identified, it is then possible to construct the rest of the rows and columns in a_k. For example, if the qth column of a_k is given by a_{kq}, then

$$a_{kq} = A_k u_{qk} u_k \tag{32}$$

where uq_k is the qth component of the modal vector. Since $A_k u_{qk}$ is a scalar, it is clear that the vector of modal residues a_{kq} is proportional to the modal vector u_k, for each $k = 1, \ldots, 2n$.

Since A_k is a scaling constant it can be assumed that either $A_k = 1$ or the square root of $u^t u = 1$ without loss of generality in the following derivation.

Suppose $A_k = 1$, then

$$a_k = u_k u_k^t \qquad (33)$$

and for the qth column or row of a_k

$$a_{kq} = u_{qk} u_k \qquad (34)$$

Hence the qth element of a_{kq} is

$$a_{kqq} = (u_{qk})^2 \qquad (35)$$

Since u_{qk} is a scalar, equation (34) can be rewritten

$$u_k = \frac{a_{kq}}{u_{qk}} \qquad (36)$$

and substituting this back into (33) gives

$$a_k = \frac{a_{kq} a_{kq}^t}{(u_{qk})^2} \qquad (37)$$

or using equation (35)

$$a_k = \frac{a_{kq} a_{kq}^t}{a_{kqq}} \qquad (38)$$

Hence the entire matrix a_k and therefore, the entire transfer function matrix H(s) can be constructed once one row or column of residues a_{kq} has been identified as well as the pole locations pk, for each $k = 1, \ldots, 2n$. The residue a_{kqq}

is at the driving point of the structure, i.e., the point where the structure is excited.

2. Impulse Response of Complex Modes

It has been shown that a mode of vibration is represented by a complex conjugate pair of poles and a complex conjugate pair of modal vectors in the transfer matrix. Hence for a single mode of vibration (k) the transfer matrix is written

$$H_k(s) \;=\; \frac{a_k}{s-p_k} \;+\; \frac{a_k}{s-p_k} \qquad (n \times n) \qquad\qquad (39)$$

It is convenient to remove a factor of 2i from the residue matrix, that is to define another residue matrix r_k such that

$$r_k \;=\; 2_i \, a_k \qquad\qquad\qquad (40)$$

Then the transfer matrix is written as

$$H_k(s) \;=\; \frac{r_k}{2i(s-p_k)} \;-\; \frac{r_k}{2i(s-p_k)} \qquad\qquad (41)$$

Each component of this matrix exhibits the rectangular (or coincident--quadrature) from shown in Figure 8 for each valued r_k.
Figure 8. Transfer Function for a Single Mode of
          Vibration

Taking the inverse Laplace transform of (41) gives

$$x(t) \quad = \quad \frac{r_k}{2i} e^{p_k t} - \frac{r_k^*}{2i} e^{p_k^* t} \tag{42}$$

$$x(t) \quad = \quad |r_k| e^{-\sigma_k t} \, \text{sine}(\omega_k t + \alpha_k) \tag{43}$$

where α_k = the angle of the complex residue r_k.

Equation (43) is the impulse response of a complex
mode of vibration. The mode shape is defined by the magnitude
$|r_k|$ and the phase angle (α_k) at each point on the structure.

60

The mode shape matrix is printed in the Modal System in terms of these magnitude and phase angles.

3. Modal Mass, Damping and Stiffness and Scaled Mode Shapes

Recall that the assumed symmetry of H(s) along with the global nature of mode shapes implies that the residue matrix for each mode is proportional to $u_k u_k^t$. If $Qk = 2iA_k$, then equation (22) becomes

$$r_k = Q_k u_k u_k^t \qquad (n \times n) \qquad (44)$$

Once a row or column of each residue matrix r_k has been identified, the mode shape vectors U_k can be calculated to within a constant of proportionality. This vector can be scaled large or small, if desired, by suitable choice of Q_k. Criteria for choosing Q_k will emerge from a discussion of modal mass, damping, and stiffness.

Consider a single degree of freedom system represented by

$$m x + c \dot{x} + k \dot{x} = f \qquad (45)$$

where m, c, and k are scalars. The Laplace Transform gives

$$(ms^1 + cs + k)X(s) = F(s) \qquad (46)$$

so that

$$H(s) = \frac{X(s)}{F(x)} = \frac{\frac{1}{m}}{s^2 + \frac{c}{m}s + \frac{k}{m}} \qquad (47)$$

61

If the damping factor is less than one, the polynomial in the denominator can be factored.

$$H(s) = \frac{\frac{1}{m}}{(s-p)(s-p^*)} \tag{48}$$

where

$$p = \frac{-c}{2m} - \sqrt{(\frac{c}{2m})^2 - \frac{k}{m}} \tag{49}$$

$$p = \frac{-c}{2m} + i\sqrt{\frac{k}{m} - (\frac{c}{2m})^2} \tag{50}$$

$$p = -\sigma + i\omega, \quad \sigma > 0, \; \omega > 0 \tag{51}$$

and

$$p^* = -\sigma - i\omega \tag{52}$$

To express Equation (48) in the partial fraction form of Equation (39), solve for a and a^*.

$$H(s) = \frac{\frac{1}{m}}{(s-p)(s-p^*)} = \frac{a}{(s-p)} + \frac{a^*}{(s-p^*)} \tag{53}$$

$$\frac{\frac{1}{m}}{(s-p^*)}\bigg|_{s=p} = [a + \frac{a^*(s-p)}{(s-p^*)}]_{s=p} \tag{54}$$

$$\frac{\frac{1}{m}}{2i\omega} = a \tag{55}$$

$$\frac{\frac{1}{m}}{-2i\omega} = a^* \tag{56}$$

$$H(s) = \frac{\frac{1}{m\omega}}{2i(s-p)} + \frac{\frac{1}{m\omega}}{2i(s-p^*)} \tag{57}$$

The residue r can be found from Equations (40), (41), and (57).

$$r = \frac{1}{m\omega} \tag{58}$$

Now note that Equations (50), (51), and (58) give m, c, and k in terms of r, ω, and σ.

$$m = \frac{1}{r\omega} \tag{59}$$

$$c = 2\sigma m \tag{60}$$

$$k = (\omega^2 + \sigma^2)m \tag{61}$$

For multiple degree of freedom systems, the analogous definitions are made for each mode k.

$$m_k = \frac{1}{Q_k \omega_k} \tag{62}$$

$$c_k = 2\sigma_k m_k \tag{63}$$

63

$$k_k = (\omega_k^2 + \sigma_k^2)m_k \qquad (64)$$

Equations (44), (62), (63), and (64) are used to calculate modal mass, damping, and stiffness and scaled mode shapes in the Print Step. Q_k is arbitrary so it can be chosen to give unit mass, unit $u^t u$, etc.

The modal mass, stiffness, and damping coefficients can be interpreted as being the masses, dampers, and springs of decoupled, single degree of freedom systems. These systems are equivalent to the original system under a change of coordinates.

4. Measurement Implications of Modal Theory

A fundamental assumption of modal testing is that a mode of vibration can be excited from anywhere on an elastic structure, except of course along its node lines (zero points) where it can't be excited at all. This is another way of stating the result derived earlier (i.e., that the same modal vector--scaled by a different component of itself--is contained in every row and column of the transfer matrix). In addition, modal frequency and damping are constants which can be identified in any element of the transfer matrix, i.e., any transfer function taken from the structure.

It is important to recognize that this global mode shape concept exists within certain spatial boundaries, beyond which vibrations will not readily propagate. If two linear systems are completely isolated, then a single composite mode including both systems is not meaningful.

Conversely, it is important to include enough spatial points in the measured data set to describe all of the vibration modes of interest. If some region of a bounded system is not monitoried or excited, or if points are not chosen sufficiently close together, then some modes cannot be adequately represented.

When a system is represented by the partial fraction form of its transfer matrix, a closed form solution for the displacement at any point, for any combination of modes, is readily obtainable using simple matrix-vector multiplication. This is particularly helpful when the response is only to a few modes of interest.

The primary purpose for using modal coordinates to describe the dynamics of a linear vibration structure is that it drastically reduces the amount of time and effort necessary to measure the dynamics in a laboratory. The essence of the modal concept is that once one row or column of the transfer function matrix has been determined, the entire matrix and hence the entire dynamics of the structure can be specified.

In order to obtain valid modal results with the Modal Analysis system, several important assumptions of the modal theory described here must be satisfied.

1. The structure must exhibit the behavior of a linear system. If you are not able to successfully curve fit equation (14) to measured transfer function data, then the behavior may not be linear.

2. The structure must exhibit the reciprocity of symmetry property. This can be verified by comparing the transfer function obtained from an excitation measurement at point A and response measurement at point B with the transfer function obtained from an excitation at point B and response at point A. This should be the same.

3. The structure must have distinct pole pairs. Since the Modal Analysis system uses analytical expression (6) to perform the curve fitting, it cannot fit repeated poles (repeated roots of det(B) = 0 because this expression was derived under the assumption that the poles are unique. This condition can be difficult to detect in one set of transfer function measurements. To insure that the poles are unique you should measure a different row or column of the transfer function matrix, and compare the mode shapes from the two sets of measurements. If they are not identical there is a strong possibility of repeated roots.

4. There may be more than one modal vector corresponding to a given pole, due to certain kinds of boundary conditions on the structure, i.e., symmetric conditions along several axes. To insure that this is not happening, you should compare modal vectors obtained from two or more rows or columns of the transfer matrix.

5. The transfer function $H(s)$ is defined in terms of an input force and a response displacement. Response velocity or acceleration can be converted to displacement. But non-force Modal Analysis system will calculate, print, and display modal data (i.e., poles and residues) for such measurements, however. The exceptions are the four mode shape scaling procedures that produce modal mass damping and stiffness. The system logica will reject an attempt to calculate these values, unless motion in response to force was measured.

V.   PROCEDURE OF TEST CHAMBER CHARACTERIZATION

A.   PROCEDURE OF DATA COLLECTION

After construction of the test chamber, preservation and painting, installation of cooling/heating coils, and installation of all insulation, the following is the procedure used for final characterization of the test chamber (with front panel removed).

1.   Draw a 2.54 inch × 2.54 inch grid on entire inside surface of the test chamber. This grid is used to record location of impact or excitation, as well as location of response transducer (Figure 9).

2.   Re-install exciter and support framework; re-install specimen fixture with specimen in place; and re-install test chamber top. Drill 1/4 inch hole through specimen for attachment of exciter driver rod. Install exciter driver rod with Force Transducer in place (Figure 10). NOTE: Acoustic exciter and force transducer will not be used in this work. For impulse hammer testing disconnect exciter from specimen.

3.   Using accelerometer mounting wax, attach pick-up transducer to desired location. Connect signal conditioners and wiring as instructed in the operating manuals. System flow chart is presented in Figure 11. Impulse hammer, signal conditioners and typical attachment of pickup transducer are
Figure 9. Detail of 10 cm × 10 cm grid on inside of experiment test chamber

69
Figure 10.   Exciter drive mechanism with force transducer

70
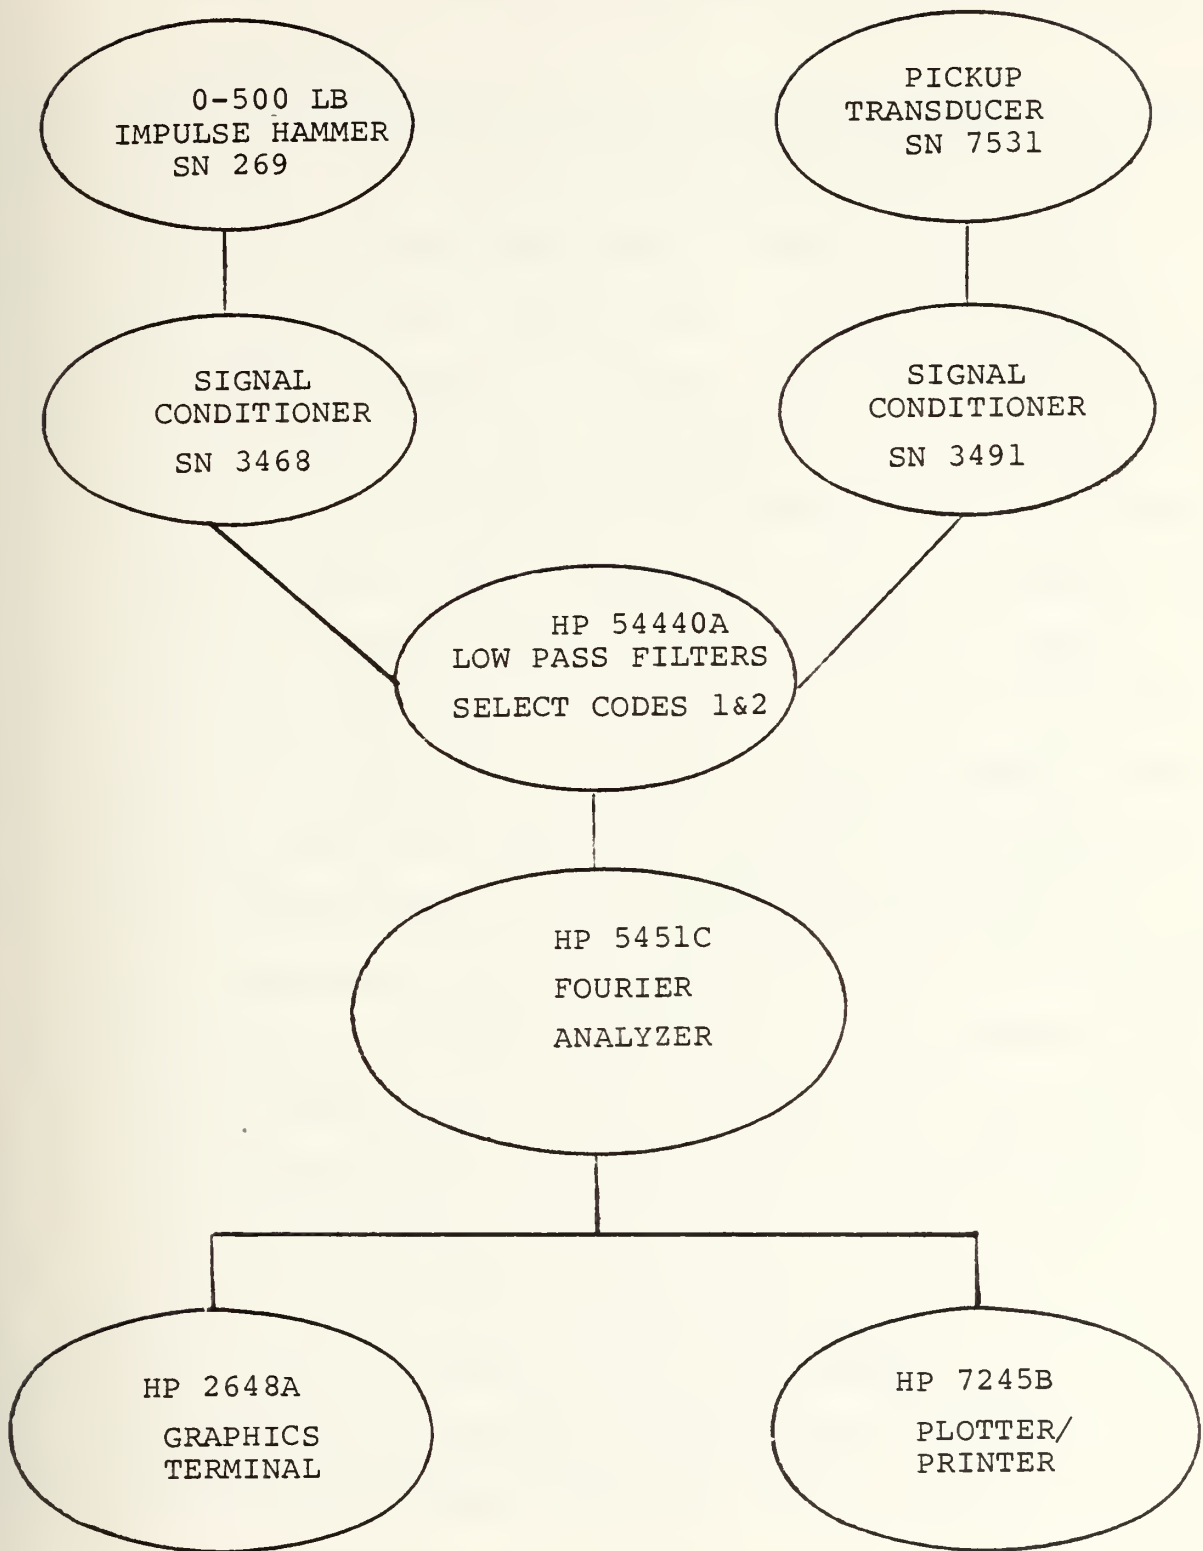

Figure 11. Impulse hammer technique flow chart

presented in Figures 12 and 13. All calibration data
of sensors and mounting and instructions are included
in Appendix C.

4.   Turn on the HP-5451C Fourier Analyzer (HP-2648A Graphics
Terminal will automatically be energized). Insert
"Modal" disk into disk drive. Energize disk drive.
When "Disk Ready" light comes on "Boot" the system as
outlined in volume 1 of System Operating Manual (Figures
14 and 15). Activate user assignable keys f1 and f2
on the graphics terminal to "Graphics Mode" and "Alpha
Mode" respectively. Procedures for key assignments are
found in volume 5 of the Computer Operating Manual.

5.   From this point on, the procedure for taking impulse
data is interactive. Locally generated computer pro-
grams, which are designed to allow the data generated
by impulse hammer technique to be stored and later
processed by the off-line Modal software, are presented
in Appendix D. What follows is a typical step-by-step
impulse data taking session assuming pick-up transducer
at location L051 and hammer impulse location at L066
The following abbreviations will be used:

C = computer keyboard entry

D = graphics terminal display

G = graphics terminal entry

R = user response

Step Number

1. Normal "Boot" of modal with f1 & f2 programmed.

2. D: SET UP DATA NUMBER? (1 to 5).

3. R;C: 2 [ENTER] (want to preserve Demonstration data
   in set up #1, set ups #2 through #5 are available).

4. D: LIST(1), EDIT(2), FINISH(3)?

5. R;C: 2 [ENTER] (must enter particular transducer
   specifications and general information for
   a particular test).

6. D: LABEL?

7. R;G: TANK CHARACTERIZATION [RETURN] (title of
   particular test).

8. D: LINE NOS.? (FIRST,LAST).

9. R;G: 1,6 [RETURN] (you may modify one or any
   sequential series of lines of the set up data).

10. D: 1. NO. OF MEASUREMENTS?

11. R;G: 16 [RETURN] (A measurement is one record of
    storage on the disk. One record is 1024 words
    in length, and a test is n measurements stored
    in n contiguous records on the disk).

12. D: STARTING LOCATION OF MEAS. STORAGE (1 to 485).

13. R;G: 5 [RETURN] (storage location 1 through 255 are
    on the removable disk, and storage locations
    266 to 485 are on the fixed disk).

14. D: DATA BLOCK SIZE? (64 to 2048).

15. R;G: 1024 [RETURN] (block size of 1024 will give
    maximum zoom capability).

16. D: 4. POLAR TRANS. FUNCT. DISPLAY? LINEAR(1) or

      LOG(2) MAGNITUDE.

17. R;G: 2 [RETURN].

18. D: 5. TRANSDUCER UNITS? ENGLISH(1), METRIC(2).

19. R;G: 1 [RETURN].

20. D: TRANSDUCER SCALE FACTORS (VALUE,UNITS)

      1 = MV/G, 2 = VM/IPS, 3 = MV/IN, 4 = MV/LB

      A. INPUT?

21. R;G: 10.6,4 [RETURN] (values are obtained from

      calibration data of sensors).

22. D: B. RESPONSE?

23. R;G: 10.12,4 [RETURN].

24. D: G. AMPLIFIER GAINS?

      A. INPUT?

25. R;G: 1 [RETURN] (enter transducer amplifier switch

      setting).

26. D: B. RESPONSE?

27. R;G: 1 [RETURN]

28. D: LIST(1), EDIT(2), FINISH(3)?

NOTE: At this point (1) may be entered and all data may

be checked. If any corrections are required, enter (2)

and use procedures outlined in steps 5 through 27.

29. R;G: 3 [RETURN].

NOTE: The "set up" portion of the test is now complete.

The next step is the "measure" portion.

30. D: STEP NUMBER? (1 to 5).

31. R;C: 2 [ENTER] (the computer is now in the "measure"
            mode).

32. D: TRANS(1), RANDOM(2), DISK(3), USER(4),
            FOURIER/ZOOM/GRAPHICS(5)?

33. R;C: 5 [ENTER] (the HP 5451-C is now ready to set
            up for an impulse test).

34. R;C: SELECT BLOCK SIZE (1024 MAX FOR ZOOM)

         SET ADC FREQUENCY RANGE AS DESIRED

         SET TREGGER TO INTERNAL

35. R;C: [JUMP] 0 [SPACE] 1 [ENTER] (this command calls

         the user programs 1,50,51,52, and 59 for use).

         TRANSFER FUNCTION MEASUREMENTS

         ARE HP FILTERS INSTALLED?

36. D: (0 = NO 1 = YES)

37. R;C: 1 [ENTER]

38. D: CUT-OFF FREQUENCY (CHANNEL NO)?

 NOTE: To eliminate unwanted or meaningless data beyond

 range of impulse hammer, enter channel number above which

 the computer will not sampel data.

         EXAMPLE: 0-500 lb. hammer useful range is from

                   0-6000 Hz, with block size 1024 selected

                   channels above 307 are meaningless.

39. R;C: 307 [ENTER]

40. D: IMPACT (1) OR RANDOM (2) EXCITATION?

41. R;C: 1 [ENTER]

42. D: NO. OF AVERAGES?

43. R;C: 4 [ENTER]

44. D: BASEBAND OR ZOOM MEASUREMENT?

     (0 = BASEBAND 1 = ZOOM)

45. R;C: 0 [ENTER] (first measurement must be baseband).

46. D: BASEBAND IMPACT MEASUREMENT

     PRESS CONTINUE FOR MEASUREMENT

NOTE: At this point trigger and analog-Digital Converter
levels need to be set to do this. The following keg
strodes should be done.

47. R;C: SET REPEAT/SINGLE SWITCH TO REPEAT

     PRESS ANALOG IN

     SET ADC RANGE SWITCHES AND TRIGGER SLOPE AND LEVEL

     SET ADC TO SINGLE WHEN READY AND PRESS CONTINUE

48. R;C: [CONTINUE].

 NOTE: Impact 4 times. The computer will beep after each
 data entry. After the computer processes the data the
 ready light will come on and the data in Block 0 will
 be displayed on the small screen of the computer.
 Processed data are stored in the following locations and
 can be displayed by the key strokes:

     [DISPLAY]0 [ENTER] Log transfer function

     [DISPLAY]1 [ENTER] Coherence

     [DISPLAY]2 [ENTER] Input power spectrum

     [DISPLAY]3 [ENTER] Output power spectrum

     [DISPLAY]4 [ENTER] Cross power spectrum

     [DISPLAY]5 [ENTER] Raw data

To obtain hard copy of any of the above outputs execute the
following key commands [USER[5821 [SPACE] 35 [ENTER]. Then
enter [USER] [PLOT] [ENTER]. To return plotting to graphics
execute [USER] 5821 [SPACE] 6 [ENTER], and when the Graphics
Terminal is in the Graphics mode (depress f1) and [USER]
[PLOT] [ENTER] is executed all plotting to be sent to the
graphics terminal. To continue, f2 must be depressed. After
all preliminary graphing is completed on baseband data press
[continue]. Typical plots of baseband data are presented in
Figures 16 through 20.

    49.   D: PRESS CONTINUE WHEN READY

    50.   R;C: [CONTINUE]

    51.   D: SAVE DATA?

PRESS CONTINUE FOR MEASUREMENT

62. R;C: 2 [ENTER]

NOTE: Whenever zoom is being done new data is required.

63. R;C: [CONTINUE]

NOTE: For zoom measurement the impact should be a series

of rapid impacts with a varying interval between impacts.

The trigger light will remain lit thorughout the data

taking session.

64. D: ANALYZING THROUGHPUT DATA "TYPICAL"

CNTR FREQ 1479 HZ/DIV 125.0

DF: 000.2441406 BLOCKS LEFT 25

ZOOM POWER 4

NOTE: After data has been analyzed and desired plots
made as described in step 43, ZOOM data should be stored
for later use by the off-line modal software. A rec-
commended data sheet is shown in Figure 21. It is
important to log number of measurements and start loca-
tion of measurement storage.

65. D: PRESS CONTINUE WHEN READY

NOTE: Generally it is desired to make multiple tests at
different locations at the same frequency range so that a
modal analysis can be done at a later time.

66. R;C: [CONTINUE]

67. D: SAVE DATA?

    (0 = No 1 = YES)

NOTE: The data taking session can be repeated by entering
"0".

68. R;C: 1[ENTER]

69. D: DATA STORAGE NO.?

70. R;C: XXX[ENTER]

NOTE: Data storage registers 0 through 500 are available
for permanent storage of the data.

71. D: MAKE ANOTHER MEASUREMENT?

        (0 = NO 1 = YES)

NOTE: From this point the steps 57 through 71 will be
repeated for as many zoom measurements as desired. Each
zoom measurement will be stored in a next higher record
number with the begin record number known.

From this point on, the procedure for the mode identification and damping measurement is covered in Reference 6. For the tank characterization the modes identified and damping measured at the particular modes are presented in Table II.

B. TEST CHAMBER MAJOR MODES AND DAMPING

To identify the major modes and measure the damping of the test chamber the polar plot of the baseband band was divided into 10 sections (Figure 22), and each section was zoomed using the same pickup location and using the same impact location on left, right, deck and back panel.
Figure 22. Polar presentation of transfer function for baseband of the test chamber

TABLE I

TEST CHAMBER FREQUENCY SECTIONS

SECTION NO.	START FREQ. (Hz)	STOP FREQ. (Hz)	CNTR. FREQ. (Hz)	DELTA FREQ. (Hz)
1	423	1,138	781	1.395
2	976	1,471	1,221	0.977
3	1,583	2,247	1,780	1.786
4	2,247	2,715	2,481	1.221
5	2,735	3,321	3,028	1.627
6	3,340	3,711	3,525	0.977
7	3,711	4,493	4,102	1.953
8	4,473	4,805	4,639	0.814
9	4,805	5,411	5,108	1.630
10	5,411	5,723	5,567	0.814

A modal analysis of each section was completed. Major modes and damping for each major mode was analyzed. The results are presented in Table II. Test data are included in Appendix E.

TABLE II

TEST CHAMBER MODES AND DAMPING FACTORS

SECTION NO.	NO. OF MODES	AVERAGE DAMPING FACTORS (%)	STANDARD DEVIATION OF DAMPING
1	3	0.5895	0.3059
2	2	0.3642	0.0035
3	10	0.8918	0.2458
4	12	0.7375	0.5084
5	10	0.3601	0.1934
6	6	0.2763	0.1065
7	8	0.3115	0.2176
8	3	0.2219	0.0627
9	10	0.1787	0.0873
10	2	0.1660	0.0525

The overall average damping factor of the test chamber is 0.4667% with an overall standard deviation of 0.3689%.

VI. PROCEDURE FOR DAMPING MEASUREMENT OF SPECIMEN

A. SPECIMEN SECURED IN FIXTURE INSIDE TEST CHAMBER

The test specimen (cast nickel-aluminum bronze, code FTC) was secured in the test chamber, impact locations A, B, C, are shown in Figure 23. To identify the major modes and measure the damping factor of the specimen the 0 to 500 lb. impulse hammer was used for the frequency range up to approximately 6000 Hz, and the 0 to 50 lb. impulse hammer was used for the frequency range from approximately 5000 Hz to approximately 12,000 Hz. Baseband polar plots for each impulse hammer at each location are shown in Figures 24 through 29. It should be noted that there is very good correlation between the 0-500 lb. impulse hammer and the 0-50 lb. impulse hammer. Additionally, there is very good correlation between various impact locations.

Utilizing the baseband data (0-500 lb. impulse hammer), obtained for impact location B, five frequency ranges were investigated. Additionally, using the baseband data obtained from the 0-50 lb. impulse hammer at location B, the frequency ranges of three additional ranges were investigated. Specimen Frequency sections are listed in Table III. Specimen modes and damping factors are presented in Table IV. Measurement data and rough log sheets are included in Appendix F.
Figure 23. Cast nickel-aluminum bronze, code FTC specimen secured in the test chamber with impact locations identified

TABLE III

SPECIMEN FREQUENCY SECTIONS (SPECIMEN FIXED)

SECTION NO.	START FREQ. (Hz)	STOP FREQ. (Hz)	CNTR. FREQ. (Hz)	DELTA FREQ. (Hz)
1	410	937	673	1.395
2	840	2,598	1,758	4.882
3	2,598	3,340	2,969	1.953
4	4,043	4,512	4,277	1.221
5	4,747	5,508	5,127	1.953
6	5,713	7,276	6,494	4.069
7	7,276	9,620	8,448	6.104
8	9,620	11,380	10,500	4.883

Modal analysis of the specimen sections was completed and the results are shown in the following table

TABLE IV

SPECIMEN MODES AND DAMPING FACTORS (SPECIMEN FIXED)

SECTION NO.	NO. OF MODES	AVERAGE DAMPING FACTORS (%)	STANDARD DEVIATION OF DAMPING FACTOR
1	1	0.1755	----
2	2	0.2173	0.1088
3	3	0.0559	0.0063
4	2	0.0883	0.0025
5	2	0.0958	0.0576
6	6	0.1310	0.0542
7	5	0.0917	0.0541
8	5	0.1000	0.0396

The overall average damping factor for the specimen is about 0.1112% with an overall standard deviation of about 0.0601%.

B. SPECIMEN REMOVED FROM FIXTURE AND TEST CHAMBER

In order to ascertain the effects of the specimen fixture and test chamber, one additional test was conducted on the same specimen. During this test the specimen was removed from the fixture and test chamber. The specimen was laid flat on 3/4 inch foam rubber. No other support was provided.

Response and impulse hammer locations are identical to the previous test. Frequency ranges for use of the large (0-500 lb.) impulse hammer and small (0-50 lb.) impulse hammer remained unchanged.

The baseband plots for large and small impulse hammer for locations A, B, and C are presented in Figures 30 through 35. For the large impulse hammer four ranges of zoom were completed, and for the small impulse hammer five additional sections were zoomed. Specimen frequency sections are tested in Table V.

TABLE V

SPECIMEN FREQUENCY SECTIONS (SPECIMEN FREE)

SECTION NO.	START FREQ. (Hz)	STOP FREQ. (Hz)	CNTR FREQ. (Hz)	DELTA FREQ. (Hz)
1	1094	1954	1524	2.441
2	1915	3555	2735	4.883
3	3575	4610	4092	3.255
4	4610	5293	4951	1.953
5	4688	6299	5493	4.069
6	6250	7227	6738	2.441
7	7276	8594	7935	3.441
8	8545	9473	9009	2.441
9	9424	11,190	10,307	4.883

Modal analysis was compled on the free specimen, and the results are tabulated below in Table VI.

TABLE VI

SPECIMEN MODES AND DAMPING FACTORS (SPECIMEN FREE)

SECTION NO.	NO. OF MODES	AVERAGE DAMPING FACTORS (%)	STANDARD DEVIATION OF DAMPING FACTOR
1	2	0.0885	0.0064
2	5	0.1264	0.0774
3	1	0.0339	N/A
4	3	0.0265	0.0017
5	2	0.0295	0.0020
6	4	0.0250	0.0080
7	5	0.0331	0.0195
8	3	0.0209	0.0123
9	3	0.0301	0.0069

Again, all raw data sheets are included in Appendix F. The overall average damping factor for the free specimen is about 0.0500% with an overall standard deviation of about 0.0504%.

VII.   RESULTS AND CONCLUSIONS

Mode identification was accomplished utilizing the zoom feature of the HP-5451C Fourier Analyzer.   After a baseband test was conducted and results stored (Figure 22), any section could be chosen to zoom.   For example, zooming section 1 of the test chamber results in a plot as shown in Figure 36. The initial display will be in polar form and must be converted to rectangular (one button function on the HP-5451C) as shown in Figure 37.   As shown in Figure 38, the coherence for this test was very good, and the data may be assumed to be accurate.   For mode identification it is necessary to get a Nyquist plot of the data (in rectangular form).   The Nyquist plot is vector representation of the real vs. imaginary values of the data.   On a Nyquist a pure mode would sweep out a perfect circle.   Modes with differing damping factors exhibit circles with varying radius.   Figure 39 shows the Nyquist plot of the zoom data.   Note there are many modes present with greatly varying damping factors.   Individual modes can be isolated by inspection of a small portion of the rectangular data.   For example, Figure 40 shows the rectangular plot from about 675 Hz to about 850 Hz.   If the isolated portion is converted to Nyquist, as shown in Figure 41, the major mode at 772 Hz is readily identified.   The Nyquist plots can be smoothed (made more circular) by higher resolution.   That is, complete a zoom measurement on a smaller frequency band.

117
Figure 40. Zoom of test chamber, section 1. Isolated portion of rectangular data
Figure 41. Zoom of test chamber, section 1. Isolated portion of Nyquist plot

119

All modes identified for the test chamber and the specimen (both fixed and free) are listed in the tables included in Appendices E and F.

It was noted that there are many more modes for the test chamber than for the specimen, but that is expected because the test chamber is a much more complex system, and the boundary conditions are considerably more complex.

The number of modes for the specimen in the test chamber is found to be 26, whereas the number of modes of the specimen separated from the test chamber is 28. This is good agreement, and it should be noted that the modes of the test chamber did not increase the number of observed modes of the specimen.

The average damping factor observed for the test chamber is about 0.47%, which is a typical value for plain carbon steel. The average damping factor for the specimen (fixed) is about 0.11%, and for the specimen (free) is about 0.05%. As expected, the fixing of one end of the specimen in the test chamber did increase the measured damping factor, but with more testing it is possible to quantify the increase and make suitable corrections.

A plot of damping factors vs. frequency for the test chamber is presented in Figure 42. The damping factor is higher at lower frequencies with the maximum damping factors being in the range of 1500-3000 Hz. After 3000 Hz the damping factor averages out to about 0.2% at higher frequencies.

TEST CHAMBER
Figure 42. Test chamber--damping factor vs. frequency

121

For the specimen, damping factors vs. frequency (for both fixed and free) are presented in Figures 43 and 44. Like the test chamber, the damping factor appears to be higher at lower frequency for the fixed specimen, and without question this same trend is observed for the free specimen. The fixed specimen damping factor levels out to about 0.10% at higher frequencies, and for the free specimen it levels out to about 0.025%.
Figure 43. Specimen damping factor vs. frequency (specimen fixed)

123
Figure 44. Specimen damping factor vs. frequency (specimen free)

VIII. <u>RECOMMENDATIONS FOR FUTURE WORK</u>

1. Expand the test procedure to include random excitation of test specimen for the energy input and measurement of responses up to 15,000 Hz.

2. Conduct similar tests on various materials including high damping materials such as Incramute and Sonoston.

3. Investigate the temperature dependence of viscous damping, especially for constrained layer and non-metallic composites.

4. Investigate the changes in damping for materials immersed in a water medium at varying temperatures.

APPENDIX A

THE HP-5451C FOURIER ANALYZER

The HP-5451C Fourier Analyzer System performs analysis
of time and frequency data containing frequencies from DC
to 50 KHz. The system analyzes time-series data such as
mechanical vibrations, sonar echoes, tidal action, biomedi-
cal phenomena such as brain waves and nerve impulses,
voltages and currents in electronic systems, and acoustic
phenomena. These analyses may detect signals hidden in noise,
or may locate critical functions in complex systems. Both
continuous and transient data may be processed.

Keyboard programming allows the following operations
automatically without special software:

A. Forward and inverse Fourier transform

B. Magnitude and phase spectrum

C. Power and cross power spectrum

D. Transfer function

E. Coherence function

F. Convolution

G. Auto and cross correlation

H. Hanning and other weighting functions

I. Histogram

J. Scaling

K. Ensemble averaging (time and frequency)

Six editing keys operate an on-line resident editor so that a sequence of steps configured into an automatic measurement procedure may be changed on-line without the need to do off-line editing, compiling and testing. In fact, the series of steps or programs used to perform a particular operation can be stored on the Disc for easy re-entry into the Fourier Analyzer.

Data input and output is likewise controlled from the keyboard. Data can be entered in analog form through the four channel Analog-to-Digital Converter, or in digital form.

Results of all operations are displayed on the oscilloscope. In addition, results can be printed out in decimal numbers or plotted on the Graphics Terminal or an X-Y plotter.

The Fourier Analyzer is a completely calibrated system; all displays and data output are accompanied by a scale factor relating them to physical units. This calibration results from digital techniques being used in all computations.

SPECIFICATIONS
(Specifications describe the standard system's warranted performance.)

ANALOG-TO-DIGITAL CONVERTER
Input Voltage Range: ±0.125V to ±8V peak in steps of 2.
Input Coupling: dc or ac.
Input Channels: 2 channels wired for 4 standard. 4 channels optional with plug-in cards.
Resolution: 12 bits including sign.
Input Frequency Range: dc to 50 kHz, 5 Hz to 50 kHz, ac coupled (100 kHz optional).
Sample Rate:
  Internal: 100 kHz max. (1, 2, 3, or 4 channels simultaneously). (200 kHz optional on 1, 2, 3, or 4 channels.) [50 kHz max. (3 or 4 channels simultaneously).†]
  External: An external time base may be used to allow external control of the sampling rate up to 100 kHz (200 kHz optional). One sample can be taken for each clock pulse (TTL level).
Internal Clock Accuracy: ±0.01%.

DISPLAY UNIT
Vertical Scale Calibration: Data in memory is automatically scaled to give a maximum on-screen calibrated display. The scale factor is given in volts/division, volts²/division, or in dB offset.
Log Display Range: 80 dB with a scale factor ranging from 0 to +998 dB. Offset selectable in 4 dB steps.
Linear Display Range: ±4 divisions with scale factor ranging from 1×10^{-512} to 5×10^{512} in steps of 1, 2, and 5.
Digital UP/DOWN Scale: Allows 8 up-scale and 2 down-scale steps (calibrated continuous scale factor).
Horizontal Scale Calibration:
  Linear Sweep Length: 10, 10.24 or 12.8 divisions.
  Log Horizontal: 0.5 decades/division.
  Markers: Intensity markers every 8th or every 32nd point.

BASE SOFTWARE
Transform Accuracy: The expected rms value of computational error introduced in either the forward or inverse FFT will not exceed 0.1% of the rms value of the transform result.
Dynamic Range: >75 dB for a minimum detectable spectral component in the presence of one full scale spectral component after twenty ensemble averages for a block size of 1024.

EXECUTION TIMES*
Fourier Transform: <55 ms
Stable Power Spectrum Average: <80 ms
Stable Tri-Spectrum Average: <220 ms

REAL TIME BANDWIDTHS*
Fourier Transform: >7.5 kHz
Stable Power Spectrum Average: 5.4 kHz
Stable Tri-Spectrum Average: 1.9 kHz

MASS STORAGE SOFTWARE
MAXIMUM REAL TIME DATA ACQUISITION RATE (Single Channel):
BS 256: 10 kHz
BS 1024: 39 kHz (25 kHz†)
BS 4096: 80 kHz (30 kHz†)

OFF-LINE BSFA SOFTWARE
Center Frequency Range: dc to one-half the Real Time Data Acquisition Rate.
Center Frequency Resolution: Continuous resolution to the limit of the frequency accuracy for center frequencies >0.02% of the sampling frequency.
Frequency Accuracy: ±0.01%
Bandwidth Selection: In steps of f/5n where n = 2, 3, 4, etc.
Max. Resolution Enhancement: >400
Dynamic Range:* 90 dB from peak out-of-band spectral component to the peak level of the passband noise. 80 dB from peak in-band spectral component to the peak level of the passband noise.
Out-of-Band Rejection: >90 dB
Passband Flatness of the Digital Filter: ±0.01 dB

ENVIRONMENTAL CONDITIONS
Temperature Range: 0°C to 40°C (104°F).

*For band limited random noise type signals at block size 1024, no display, no Hanning.
**After eight ensemble averages of a power spectrum at block size 1024. Reduced by 10 dB at the exact center of the band.
†These rates apply to systems with modules 5466B and 54451A/B having a serial prefix lower than 1842.

SUPPLEMENTAL CHARACTERISTICS

(Supplemental Characteristics are intended to provide useful information for system applications by giving typical, but not warranted, performance parameters.)

ANALOG-TO-DIGITAL CONVERTER

Input Impedance: 1 MΩ in parallel with <75 pf.

Sample Rate Control:

Maximum Frequency Mode: Maximum frequency selectable from 0.1 Hz to 50 kHz (100 kHz optional) in steps of 1, 2.5, 5. This mode automatically sets maximum frequency independent of block size.

Frequency Resolution Mode: Frequency resolution selectable from 0.2 mHz to 1000 Hz in steps of 1, 2, 5. This mode automatically sets frequency resolution and sample record length independent of block size.

Input Mode: There is a buffered and non-buffered analog mode. In the buffered mode, other operations can be performed on previously collected data while the ADC collects current input data into a buffer.

DISPLAY UNIT

Data may be displayed in single sweeps or refreshed continuously in the following forms:

Y Axis	X Axis
Amplitude	Time (Linear or Log)
Real Part	Frequency (Linear or Log)
Imaginary Part	Frequency (Linear or Log)
Magnitude (Linear or Log)	Frequency (Linear or Log)
Phase	Frequency (Linear or Log)
Imaginary Part (NYQUIST PLOT)	Real Part

CRT Positioning: Three markers to aid in adjusting trace position as well as vertical and horizontal controls are provided for display positioning.

Origin: Left edge of display, zero amplitude.

+FS: Positive full scale, center of display.

−FS: Negative full scale, center of display.

Analog Plotter Output: Any displayed data can be output to a plotter or remote oscilloscope. HP 10640B interface is required for operation.

Amplitude: 0.5V per oscilloscope display division.

Linearity: 0.1% full scale.

Interpolation: Linear interpolation in 0.05% steps.

Type of Display: Points, bars, or continuous (interpolation).

BASE SOFTWARE

System Accuracy and Range: The Fourier Transform is implemented using conditional scaling for maximum accuracy with no data overflows allowed. All calculations use floating point arithmetic on a block basis with full 16- and 32-bit arithmetic where applicable.

Data Word Size: 16-bit imaginary with 32 bits preserved for double precision functions. Division, addition, or subtraction operations performed in 16 or 32 bits depending on data.

Maximum Block Size: 4096 time domain points.

Minimum Block Size: 64 time domain points.

Permanent Data Space: 28K words (16K words standard in systems with serial prefix below 1842, optionally expandable to 28K with option 011).

Permanent Program Space: 32K words.

BSFA SOFTWARE

Maximum BSFA Blocksize: 1024 time domain points. (2048 with option 670.) See also Table 5-1 in BSFA section of manual.

MASS STORAGE

Disc Unit:

Capacity: 2.45 megawords

Data Transfer: 2.5 million bits/second

Discs: 2 (1 fixed, 1 removable)

% of Real Time at 100 kHz ADC Sampling Rate (Single Channel):
BS 256: 10%   **BS 1024:** 39% (25%†)   **BS 4096:** 80% (30%†)

Number of Records Per File:

Data Block: 214 records (4096 blocksize maximum/record).

ADC Throughput: 199 records (4096 blocksize max./record).

Program Stack: 138 records (470 steps/record).

ASCII Text: 690 records (128 words/record).

Index: 69 records (10 pointers/record).

System Coreload: 4 records (32K words/record).

Common: 286 records (256 words/record).

Overlay: 20 overlays (8K words maximum, 7K words maximum with option 261 or 265).

OPTIONS 261 & 265

The magnetic tape options are used for ADC Throughput only.

Maximum Real Time Data Acquisition Rate (Single Channel):

Opt. 261		Opt. 265	
BS 256:	6 kHz	BS 256:	9 kHz
BS 1024:	12 kHz	BS 1024:	21 kHz
BS 4096:	15 kHz	BS 4096:	30 kHz

Number of Tracks: 9

Read/Write Speed: 45 ips

Density: Option 261, 800 bpi; Option 265, 1600 bpi.

Data Transfer Rate: Option 261, 36K cps max.; Option 265, 72K cps max.

Rack Height: 610 mm (24 in.)

POWER REQUIREMENTS, SIZE, WEIGHT

Power Source: 115/230 volts ±10%, 50/60 Hz. 1800 watts typical for base system.

Size: Dimensions are for a typical system (excluding cabinet and terminal).

Height: 771 mm (28 in.);   **Width:** 425 mm (16¾ in.);

Depth: 616 mm (24¼ in.).

Cabinet:

Panel Height: 1422 mm (56 in.)

Overall: 1631 mm (64¼ in.), height; 533 mm (21 in.), width; 762 mm (30 in.), depth.

Weight: Net weight for a base system (excluding terminal) — 163.3 kg (358 lbs.).

Price and Ordering Information: Consult the 5451C Fourier Analyzer System's Ordering Information Guide.

SYSTEM INSTALLATION

Included in the 5451C System is on-site installation. On installation, a trained Hewlett-Packard representative will perform an operational demonstration to ensure that the system is functioning normally.

TRAINING

A course on Fourier analysis and system operation is optionally available at HP's Santa Clara, California facility. On-site training can also be provided, if desired.

†These percentages apply to systems with modules 5466B and 5445IA/B having a serial prefix lower than 1842.

HP-5451C TRANSFER FUNCTION AND POWER SPECTRUM
FLOW CHART AND PROGRAM LISTING

This appendix contains flow charts and listings of the pre-written soft key programs shipped on the 5451C operating disc pack. These programs are for the Gold Key F2 (Transfer Function) and F5 (Power Spectrum) soft keys. The purposes for including these flow charts and listings are as follows:

1. For those who wish to modify the programs to better fit specific applications.

2. As an example for those who wish to write their own soft key programs.

3. As a model for re-entering portions that may have been accidentally written over on the disc (programs reside in unprotected areas).

As an aid toward rapid understanding of these programs, a certain programming "style" has been used. As a result of this style, the programs are longer than they would otherwise need to be, but are easier to comprehend. Some elements of the style are described below.

BLOCK STRUCTURE THROUGH USE OF LABELS

The code in the programs is organized in "blocks" — functional segments which are delimited by LABEL instructions. A convention is followed in the choice of label numbers. The beginning of each block is designated by a label number ending in a multiple of 50, e.g. L1050. The block ends with the label 9 higher, e.g. L1059. Within the block, label numbers are between these limits, e.g. L1051, L1052 etc. One block may contain others — each will use the above delimiting convention.

Although the use of these labels lengthen the programs, it makes them much easier to understand, and to correlate with the flow diagrams. For example, when several branches of a program go to the same point, each branch will jump to its own appropriate label. Since these labels all appear together at one point in the program, one can tell that multiple branches converge at that point. An example is in the Transfer Function program, stack 54, where labels 1209, 1259 and 1609 all appear together. This is just one example of the way in which complex internal linkages in the program are made more visible.

BRANCHING THROUGH USE OF "COMPUTED GOTO's"

In most complex programs, branching is common. One means of branching is to use an IF statement, provided in Keyboard language by the "GOLD KEY" "SKIP" instruction. When there are more than two possible branches, however, use of IF branching tends to get complicated, involving multiple decision points. The "Computed GoTo" or "switch" type of branching statement is more suitable in such cases for simplicity of understanding. It has been used extensively in these keyboard programs, even for simple two way branching. By standardizing on it, the code becomes recognizable and easier to read.

In Keyboard language, the "Computed GoTo" is implemented by computing the number of a label and jumping to it. The following is an example.

```
L 1050                          Start of branch block

Y A+  0   1050   11D            Set variable 0 to 1050
                                + (the value of variable
    .                           11)

J 0D                            Jump to the label number
                                in variable 0

L 1051                          Code to be executed if
   .                            variable 11 = 1
   :
   :

J 1059                          Go to end of block

L 1052                          Code to be executed if
   .                            variable 11 = 2
   :
   :
   :

L 1059                          End of branch block
```

USE OF SUBROUTINES

In these programs there are several functions which have been set up as subroutines. These include the parameter entry routine (see below) and the measurement routines. The measurement routines are handled this way to simplify the flow of the main program and allow easy replacement of the measurement code in case you modify it in some way.

PARAMETER ENTRY ROUTINE

Since these programs ask the operator for many input parameters, a single subroutine, LABEL 100 in STACK 0, handles all the parameter entries. The routine is called with variable parameters 1 and 2 equal to the lower and upper limits on the range of allowable operator inputs. The routine reads your input, checks it against the range limits, and, if it is valid, passes it back to the calling program in (floating point) variable parameter 2000. If the input is out of range, this routine notifies you and waits for the new input. The routine will not return to the calling program until a valid input has been received.

PRECAUTIONARY NOTES

The following precautions apply to the operation of the preprogrammed measurements:

1. When using the standard software zoom (BSFA), the measurement blocksize can be no larger than 1024. When using the Option 670 Fourier Preprocessor for BSFA measurements, the maximum blocksize is 2048.

2. The maximum center frequency you may specify for a BSFA measurement is 32767 Hz.

3. The messages CF WHAT? or BW WHAT? may result if the center frequency and/or bandwidth you have chosen for your measurement are such that the BSFA analysis band is either less than 0 or greater than the ADC Fmax setting. Specifying different parameters should remove this problem.

131

4. The message DL WHAT? may occur when performing the on-line BSFA measurment. This is because the display is active during the on-line measurement. To remove this problem, either reduce the measurement bandwidth (thereby increasing the zoom power and lowering the data rate into the computer), or edit the appropriate keyboard stacks (stack 56 for transfer function, stack 61 for power spectrum) to remove parameter n3 from the calls to User Prog 45 for the on-line measurement (refer to commented program listings which follow).

5. When performing an off-line BSFA measurement with an optional Mag Tape unit, perform the following steps before making the measurement.

    Set:

        ADC SAMPLE MODE to INTERNAL KHz/μs
        MULTIPLIER to 100/10/5
        INPUT SELECTOR to A
        TRIGGERING to FREE RUN
        OVERLOAD VOLTAGE A to CHECK

    Enter:

        BLOCKSIZE 4096 ENTER
        MASS STORE 32 ENTER
        MASS STORE 22 SPACE 1 SPACE 150 ENTER
        MASS STORE 32 ENTER

    This writes 150 records of data on the magtape so that the magtape will be able to position to record 135 on the tape when the ADC throughput is performed. It will position by looking for the interrecord gaps written by the WRITE ADC throughput command.

6. After completing a BSFA measurement, be sure that all data space declared by the zoom programs is released by pressing RESTART.

As you go through the flow charts and commented listings, remember that these are only examples of programming the soft keys F1 through F6 on the Keyboard. It is up to you to determine which, if any, portions of these programs should be maintained. Because these programs are stored in unprotected areas of the Disc, there is the possibility they can be written over. If this should happen, you should enter the program stacks from the listing, substitute your own program, or copy from your back-up disc.

The soft key programs and the associated ASCII text and variable parameters were originally stored on the system disc pack in Files 3,4, and 7. The records used are as follows:

File 3 (Keyboard Programs)

    Record 0
    Records 51 through 62

File 4 (Text Buffers)

    Text buffers 51 through 55
    ASCII records 3245 through 3449 *

File 7 (Common)

    Common) Record 0

*This assumes that there are 3700 records in File 4. If not, the first and last ASCII text records may be computed as follows:

First record number = NR − (5 × last text buffer number)

Last record number = NR − (5 × first text buffer number) + 4

    where NR = number of records in File 4.

The allocations above should be kept in mind so the above records are not inadvertently altered or destroyed when using the Fourier system. Should you wish to alter the allocations, you will also have to modify the keyboard programs to reflect such changes.

ACCELEROMETER MOUNTING WAX
Model 080A24

PCB PIEZOTRONICS

Petro-Wax functions to transfer motion from the test object to the sensor. It is used to couple the sensor directly to the test object. It is a convenient, temporary mounting replacement for studs and permanent adhesives.

An elastic interface structure with heavy damping, it forms quickly to irregular surfaces to facilitate easy mounting of sensors. This pliable wax enables the sensor to be mounted in nearly any convenient spacial coordinate system.

In conjunction with the sensor, the wax forms a heavily damped spring-mass system. The frequency response is a function of transducer mass, mounting area, depth of wax, and test temperature. As the amount of wax at the interface of the sensor and test object increases, the first resonance of the system decreases, which limits the frequency response of the fixturing (see graphs). This mounting technique is primarily for use at room temperature. The wax cannot be used effectively at high or low temperatures.

How to use: (1) To insure a secure and valid fixture, be certain all surfaces are free of oil and dirt.
(2) Apply the wax directly to the base of the transducer or to the adhesive mounting base. The amount of wax used depends on your individual application. Use of the adhesive mounting base helps keep the transducer clean.
(3) Press the sensor firmly against the test structure to insure secure mounting and as little wax at interface as possible. This provides the best frequency response.
(4) Procede with measurement.

PETRO-WAX is available in quantity from: Katt & Associates

PCB CALIBRATION CERTIFICATE

IMPACT FORCE HAMMER

Model No. 086B_03_

Transducer Model No. _——_

Transducer Serial No. _269_

Hammer Calibrator: PCB Model _904A_

Pendulous Mass _0.72_ lb (_326_ gm)

including accelerometer

Date: _3-23-83_

Initials: _P.J._

PCB PIEZOTRONICS, INC.

Customer:
General Resources Sever..

Invoice No:
_22414_

Basic Force Transducer Sensitivity _10.60_ mV/lb (reference)
(for stationary installations)

Reference Accelerometer Sensitivity _10.12_ mV/g (302A'S/N _753!_)

Ratio: Force Transducer Sensitivity/Accelerometer Sensitivity _1.05_ (_6.02_)
        (from test of mass impacting stationary hammer)

HAMMER SENSITIVITY (3) (with 2.7 gm Al/Plastic, Al/Steel, Al/Rubber Tips)

Configuration	with Steel Extender	with Al. Extender	with No Extender
Ratio: Force/Acceleration Sensitivity (2)	1.026		0.972
Hammer Sensitivity mV/lb	10.38		9.84
Difference: (1) (%)	−2.1%		−7.7%

NOTES: (1) Difference from reference sensitivity of force transducer

(2) In transfer fuction testing, the important factor is the ratio of
    sensitivities.

(3) Because of normal behavior of the hammer structure, the apparent
    sensitivity of the hammer in motion differs from the stationary
    calibration of the force transducer. It is less by a factor
    proportional to the ratio of the mass of the impact cap and seismic
    distributing mass in the transducer to the total mass of the
    hammer structure. Using a heavier hammer head or installing the
    force transducer on the structure only changes the problem. A
    heavier hammer head tends to penetrate the test object or cause
    multiple bouncing. When mounted on the test object, the inertial
    mass in the transducer causes it to act as an accelerometer sensing
    motion of the test object.

Hammer Sensitivity:

CONFIGURATION	Tip	STEEL	VINYL	
	Extender	NONE	STEEL	
SCALING FACTOR (SENSITIVITY RATIO)		.198	.124	
HAMMER	mV/lb	113.3	70.9	
SENSITIVITY	(mV/N)	25.5	15.9	

NOTES:

1. The sensitivity ratio (Sa/Sf) is the scaling factor for converting structural transfer measurements into engineering units. Divide results by this ratio.

2. Each specific hammer configuration has a different sensitivity. The difference is a constant percentage, which depends on the mass of the cap and tip assembly relative to the total mass of the head. Calibrating the specific hammer structure being used automatically compensates for mass effects.

Effective mass [_____] with 302A07 attached and vinyl capped plastic tip.

APPENDIX D

LOCALLY GENERATED USER KEYBOARD PROGRAMS

The locally generated keyboard programs presented in the
next six pages allow the use of impulse technique or random
excitation while utilizing the Modal package of the HP-5451C
Fourier Analyzer. Each program and subprogram is identified
by the first line of the program listing. Program number 1
(identified by the -1 on line 1) is the control program,
and from this program subprograms 50, 51, 52, 53, 54, 58
and 59 are called as needed.

All eight programs are automatically loaded into the
computer memory when the following command is executed, as
discussed in Chapter V, step number 35,

[JUMP] 0 1 [ENTER]
