**RESULTS:** Groups were similar in age, height, weight, lean mass, protein and calcium intake. EA did not correlate significantly with BMD at any site. Dancers showed a moderate, nonsignificant, negative relationship between EA and BMD at the femoral neck ( $r = -0.65, p > 0.05$ ). When controlling for lean mass (LM), there were no significant differences in EA between groups: dancers= $29.9 \pm 17.0$  kcal/kg LM, runners= $24.2 \pm 8.0$  kcal/kg LM, and controls= $31.9 \pm 13.7$  kcal/kg LM. An ANCOVA (controlling for BMI) revealed that dancers have significantly greater mean BMD at the anterior-posterior spine ( $1.06 \pm 0.10$  g/cm<sup>2</sup>) than runners ( $0.94 \pm 0.07$  g/cm<sup>2</sup>) and controls ( $0.97 \pm 0.09$  g/cm<sup>2</sup>). Dancers also had significantly greater mean femoral neck BMD ( $0.97 \pm 0.13$  g/cm<sup>2</sup>) than controls ( $0.85 \pm 0.10$  g/cm<sup>2</sup>,  $p < 0.01$ ) but not runners ( $0.88 \pm 0.06$  g/cm<sup>2</sup>). Groups were similar in BMD at the whole body.

**CONCLUSION:** Our research shows that despite similarly low EA, dancers exhibit greater BMD at the spine than runners and controls. This implies that perhaps the loading nature of dancing has a greater positive impact on bone than running.

**2742** Board #14 June 1 9:30 AM - 11:00 AM

**Effects Of Resistance Training And Dried Plum Consumption On Bone Health In Breast Cancer Survivors**

Emily Simonavice<sup>1</sup>, Pei-Yang Liu<sup>2</sup>, Jasminka Z. Ilich-Ernst<sup>1</sup>, Jeong-Su Kim<sup>1</sup>, Bahram H. Arjmandi<sup>1</sup>, Lynn B. Panton, FACSM<sup>1</sup>. <sup>1</sup>Florida State University, Tallahassee, FL. <sup>2</sup>Akron University, Akron, OH.  
(No relationships reported)

In addition to normal age-related changes, breast cancer survivors (BCS) encounter many side effects from cancer treatments that negatively affect body composition. Specifically BCS have increased rates of bone turnover, and loss of bone mineral density (BMD). Studies have shown that both resistance training (RT) and/or dried plum (DP) consumption may elicit positive BMD changes.

**PURPOSE:** To evaluate the efficacy of a RT ( $n=14$ ) or RT+DP ( $n=13$ ) intervention to modulate BMD and biochemical markers of bone turnover in BCS during a six-month study.

**METHODS:** BCS ( $N=27$ , age:  $64 \pm 7$  yrs; BMI:  $27.7 \pm 5.5$  kg/m<sup>2</sup>) were evaluated for the following variables: muscular strength (chest press and leg extension) via one-repetition maximums (1-RM), total body and regional (lumbar spine, femur, and forearm) BMD via dual energy X-ray absorptiometry and biochemical markers of bone turnover [bone-specific alkaline phosphatase (BAP) and tartrate resistant acid phosphatase (TRAP-5b)]. RT consisted of two days/week of ten exercises including two sets of 8-12 repetitions at ~60-80% of 1-RM. RT+DP also consumed 90g of DP daily. All BCS were given a supplement containing 600mg Ca and 400 IU of Vitamin D to consume twice daily for the duration of the study. ANOVAs were utilized, and significance was set at  $p < 0.05$ .

**RESULTS:** No baseline differences were found between groups for any of the variables. No group x time interaction was detected for any variables. BCS significantly increased upper body (RT:  $68 \pm 20$  to  $82 \pm 21$  kg; RT+DP:  $72 \pm 24$  to  $96 \pm 22$  kg) and lower body (RT:  $72 \pm 19$  to  $88 \pm 28$  kg; RT+DP:  $77 \pm 17$  to  $99 \pm 19$  kg) strength. The RT+DP group lost BMD from baseline to 6M ( $0.476 \pm 0.059$  to  $0.464 \pm 0.054$  g/cm<sup>2</sup>). TRAP-5b was significantly decreased for the RT group ( $4.55 \pm 1.57$  to  $4.03 \pm 1.81$  U/L) while the RT+DP group significantly decreased TRAP-5b at a  $p=0.07$  ( $5.10 \pm 2.75$  to  $3.77 \pm 1.80$  U/L). All other BMD variables and BAP were maintained over the course of the study.

**CONCLUSIONS:** Our findings demonstrated that DP did not provide additional benefits to BMD or bone turnover markers compared to RT for the variables assessed. RT appears to be an effective way to improve markers of bone turnover in BCS. Further, RT maintained BMD at most sites; and may be an effective way to offset the negative changes that occur to bone as a result of cancer-related treatments and aging.

2743 Board #15 June 1 9:30 AM - 11:00 AM

**Association between Sarcopenia Status and Bone Density Classification in Older Men and Women**

Harshvardhan Singh<sup>1</sup>, Daeyol Kim<sup>1</sup>, Michael Bembem, FACS<sup>1</sup>, Mark Anderson<sup>2</sup>, Debra Bembem, FACS<sup>1</sup>. <sup>1</sup>University of Oklahoma, Norman, OK. <sup>2</sup>University of Oklahoma Health Sciences Center, Oklahoma City, OK.  
(No relationships reported)

A simultaneous presence of muscle and bone weaknesses associated with frailty contributes to high fracture risk in the older population, however, the associations between sarcopenia, appendicular skeletal muscle mass (ASM), relative skeletal muscle mass index (RSMI), bone free lean body mass (BFLBM), muscle strength, and osteoporosis are not as well known.

**PURPOSE:** To examine the association between sarcopenia status and bone mineral density (BMD) classification and to determine relationships between ASM, RSMI, BFLBM, and BMD at total body, trochanter, femoral neck, total hip, and lumbar spine sites in older men (n=27) and women (n=33) (55-75 years).

**METHODS:** BMD at total body, dual proximal femur (trochanter, femoral neck, total hip) and lumbar spine sites, ASM, BFLBM, and RSMI were measured using DXA. Subjects were classified as sarcopenic if they had a RSMI < 7.26 kg/ht<sup>2</sup> for men and < 5.45 kg/ht<sup>2</sup> for women. Calcium intake and physical activity levels were assessed by questionnaires. **RESULTS:** The prevalence of osteopenia/osteoporosis was 52%/7% for men, and 67%/3% for women. Sarcopenia was found in 24% of women and 14% of men. Chi-square analysis showed that sarcopenia status was not significantly associated with osteoporosis status (p>0.05). RSMI, ASM, and BFLBM had significant (p<0.01) positive correlations (r=0.39-0.68) with BMD at total body, trochanter, femoral neck, total hip, and lumbar spine sites. Multiple regression analyses showed RSMI (p<0.01), BFLBM (p<0.001), and ASM (p<0.001) were significant predictors of BMD at total hip, femoral neck, and spine while ASM alone was a significant (p<0.001) predictor for trochanter BMD.

**CONCLUSION:** Sarcopenia status was not found to be associated with BMD classification in older individuals. Surrogate measures of muscle mass such as BFLBM and ASM were found to be the best predictors for BMD status at sites measured.

2744 Board #16 June 1 9:30 AM - 11:00 AM

**Predictors of Bone Mass Density in Older Chinese Children**

Chao Wang<sup>1</sup>, Peijie Chen<sup>1</sup>, Lu Zheng<sup>2</sup>, Shoufu Yan<sup>2</sup>, Gang He<sup>3</sup>. <sup>1</sup>Shanghai University of Sport, Shanghai, China. <sup>2</sup>Capital University of Physical Education and Sports, Beijing, China. <sup>3</sup>The Chinese University of Hong Kong, Hong Kong, China.  
(No relationships reported)

**PURPOSE:** Predictors of bone mass density (BMD) were less examined among older Chinese children. Therefore, the purpose of this study was to investigate the association between physical activities, demographic factors and BMD in older Chinese children.

**METHODS:** Sixty three healthy Chinese children (boys = 25) aged 9 - 11 years participated in this study. Second, third and fourth middle phalanx BMD were measured by a MetriScan densitometer (Alara MetriScan, Hayward, CA) and mean values of these three phalanges were used in the analysis. Children's physical activity (PA) level was assessed by an ActiGraph GT3X+ accelerometer. Average time (minutes/day) spent on moderate to vigorous PA (MVPA) was calculated based on Freedson's age-specific cut-off counts. Body weight and height were also measured. Differences of BMD between genders were determined using independent-samples T test. Associations between physical activity, sex, age, weight, height, body mass index (BMI) and BMD were determined by Pearson correlations. Multiple regression analyses were used to further examine variables with significant associations.

**RESULTS:** BMD between boys and girls were similar (BMD: 0.220 ± 0.022 vs. 0.231 ± 0.023 g/cm<sup>2</sup>, p = 0.062). 90.5% of the children accrued at least 60 minutes of MVPA daily. No associations were found between sex, MVPA time, BMI and BMD. Age (r = 0.417, p = 0.001), weight (r = 0.486, p = 0.000), and height (r = 0.690, p = 0.000) were correlated with BMD. Further multiple regression analyses indicated that height (standardized coefficients β = 0.690, p = 0.000) was the only significant predictor of BMD and explained 47.6% of the BMD variance.

**CONCLUSIONS:** Height could be a predictor of BMD, accounting for 47.6% of the variance in BMD of older Chinese children.

**The Effects of Dance Training on Children's Foot Arch**

Jai-yuan Zhang, Kuo-Wei Tseng, Yu-Hua Tseng, Hung-Wen Cheng. *Taipei physical education college, Taipei, Taiwan.*  
(No relationships reported)

Since many dancing movements enhance the tone of foot flexors and strengthen the foot arch, dancing has been used as a rehabilitation exercise to treat flat feet. However if the soft tissues are overstretched, the stability of the arch could be reduced.

**PURPOSE:** This study aimed to investigate if dance training in childhood changes normal foot arch development.

**METHODS:** 60 children were involved in the study: children in grade three who had dance training (DT3, 8.8±0.3 yrs, n=15); children in grade six who had dance training (DT6, 11.9±0.3 yrs, n=15); children in grade three who had no dance training (NT3, 9.0±0.3 yrs, n=15); and children in grade six who had no dance training (NT6, 11.9±0.3 yrs, n=15). The bilateral non-weight bearing navicular drop index (NDI) in a sitting position, and the even-weight bearing NDI in a standing position were measured for all subjects.

**RESULTS:** On the non-weight bearing test, NDI of DT6 and UT6 were lower than DT3 and UT3 (0.563±0.056 & 0.527±0.034 vs. 0.675±0.084 & 0.616±0.079, p<0.05). This result of non-weight bearing test shows that there is a natural maturation in NDI. On the weight bearing tests, NDI of UT6 were lower than UT3 (1.369±0.064 vs. 1.500±0.192, p<0.05), but there was no significant difference between DT3 and DT6. Thus, the development of the foot arch is gradual and maturation occurred with age in groups who had no dance training, but this was not the case for the groups who had dance training.

**CONCLUSION:** Dancing during childhood might not influence the natural development of foot arch. But over-stretching movements may decrease the elasticity of the soft tissue in the feet, resulting in lowered foot arch and structural dysfunction.

**Bone Blood Flow at Rest and During Exercise in Humans Measured with Positron Emission Tomography**

Kari Kalliokoski<sup>1</sup>, Kimmo Kaskinoro<sup>2</sup>, Jukka Kempainen<sup>1</sup>, Juhani Knuti<sup>1</sup>, Ilkka Heinonen<sup>1</sup>. <sup>1</sup>University of Turku, Turku, Finland. <sup>2</sup>Turku University Hospital, Turku, Finland.  
(No relationships reported)

**PURPOSE:** Due to methodological difficulties bone blood flow in physiologically demanding conditions such as during physical exercise remains poorly characterised in humans. In the present study we measured bone blood flow in healthy young women and men at rest and during exercise using positron emission tomography and radiowater.

**METHODS:** In women, bone blood flow was measured in femoral bone at rest and during one leg intermittent isometric exercise with increasing exercise intensities. In men, femoral bone blood flow was determined at rest and during dynamic one leg exercise and under two physiological perturbations: during moderate systemic hypoxia (14 % O<sub>2</sub>) at rest and during exercise and during intra-femoral infusion of high-dose adenosine at rest.

**RESULTS:** In women, isometric exercise increased femoral bone blood flow from rest (1.8 ± 0.6 ml · 100 g<sup>-1</sup> · min<sup>-1</sup>) to low intensity exercise (4.1 ± 1.5 ml · 100 g<sup>-1</sup> · min<sup>-1</sup>, p = 0.01), but it did not increase it further with increasing intensity (3.5 ± 0.8 ml · 100 g<sup>-1</sup> · min<sup>-1</sup> during moderate intensity and 3.7 ± 1.1 ml · 100 g<sup>-1</sup> · min<sup>-1</sup> during highest intensity, p = 0.86 for differences

between exercise intensities). In men, resting femoral bone blood flow was similar as in women ( $1.5 \pm 0.5 \text{ ml} \cdot 100 \text{ g}^{-1} \cdot \text{min}^{-1}$ ,  $p = 0.26$ ) and dynamic one leg moderate-intensity exercise increased it to  $4.2 \pm 1.2 \text{ ml} \cdot 100 \text{ g}^{-1} \cdot \text{min}^{-1}$ ,  $p < 0.001$ . Breathing of hypoxic air did not change femoral bone blood flow at rest ( $1.5 \pm 0.4 \text{ ml} \cdot 100 \text{ g}^{-1} \cdot \text{min}^{-1}$ ,  $p = 0.79$ ) or during exercise ( $5.0 \pm 1.4 \text{ ml} \cdot 100 \text{ g}^{-1} \cdot \text{min}^{-1}$ ,  $p = 0.14$ ). Finally, intra-arterial infusion of adenosine increased bone blood flow to  $5.7 \pm 2.4 \text{ ml} \cdot 100 \text{ g}^{-1} \cdot \text{min}^{-1}$ , to the level comparable with moderate intensity dynamic exercise ( $p = 0.09$ ).

**CONCLUSIONS:** Resting femoral bone blood flow is similar in healthy young women and men and increases by physical exercise, but appears to level off with increasing exercise intensities, at least during intermittent isometric exercise. Moreover, while moderate systemic hypoxia does not change bone blood flow at rest or during exercise, intra-arterially administered pharmacological vasodilator adenosine is capable of enhancing bone blood flow in humans.

2747 Board #19 June 1 11:00 AM - 12:30 PM

**Indices of Local Muscle Function Are Weak Predictors of Femoral Neck Bone Structure in Pediatric Females**

Jodi N. Dowthwaite<sup>1</sup>, Melissa E. Zajdel<sup>2</sup>, Carol A. Sames<sup>1</sup>, Paula F. Rosenbaum<sup>1</sup>, Tamara A. Scerpella<sup>3</sup>, <sup>1</sup>SUNY Upstate Medical University, Syracuse, NY. <sup>2</sup>Princeton University, Princeton, NJ. <sup>3</sup>University of Wisconsin- Madison, Madison, WI. (Sponsor: Jill A. Kanaley, FACSM)  
(No relationships reported)

As hip fracture risk may be established during growth, pediatric screening and intervention may benefit public health.

**PURPOSE:** Muscle and physical activity indices were tested as predictors of femoral neck (FN) structure in young girls.

**METHODS:** Pre-menarcheal girls (46 gymnasts, 30 non-gymnasts) reported Tanner breast stage (TB) and prior year non-aquatic physical activity (PAL). Height and weight were measured. Hologic DXA scans (whole body, left FN) yielded total body non-bone lean mass (FFM) and bone metrics. Dynamometers assessed non-dominant hand grip (GR) and left hip flexion/extension (Takei; Biodex). Parsimonious regression models were developed to predict FN indices.

**RESULTS:** For all but buckling ratio (BR), TB + hip flexion peak torque (HFPT) and TB + GR predicted FN indices (model  $r^2 = 0.34 - 0.55$ ;  $0.40 - 0.64$ , respectively) ( $p < 0.001$ ). However, FFM entry obliterated HFPT and GR explanatory value, also obliterating TB predictive value for all but cortical thickness. For all but BR, FN indices were well-predicted by FFM models. For all but cross-sectional moment of inertia, models included PAL, gymnast status (GYM) or PAL + GYM. For all but BR, entry of GYM supplanted PAL; TB + PAL + GYM predicted BR.

**CONCLUSIONS:** Pre-menarche, FN indices are a function of maturity and size (FFM) and/or PAL; local muscle indices are inferior predictors to GR (remote muscle function index) and FFM. PAL predictive value provides evidence that non-aquatic exercise is osteogenic during growth. GYM predictive value supports high impact loading as an osteogenic model, but may simply reflect greater gymnast mean PAL. However, prediction of BR by both PAL and GYM suggests independent benefits of greater activity doses and high impact loading modalities.

**Effect of Treadmill Versus Elliptical Exercise on Calcaneal Stiffness Index Among College Age Females**

Kelly T. Maloney, Sandie R. Walker, Stephanie M. Otto. Gustavus Adolphus College, St. Peter, MN.  
(No relationships reported)

Osteoporosis is a disease that affects many older individuals, resulting in a decrease in bone density. Yung, et al. (2005) concluded that involvement in impact loading sports was associated with greater stiffness index (SI) of the calcaneus when compared to nonimpact sports and abstinence from sports. However, comparisons between the effectiveness of impact and nonimpact exercise equipment on calcaneal SI is less clear.

**PURPOSE:** To examine the effect of treadmill versus elliptical exercise on calcaneal SI.

**METHODS:** Nine college-age females were recruited for this cross-sectional design study. The independent variables were the treadmill training group and the elliptical training group, and the dependent variable was the change in stiffness index (SI) of the calcaneus. Calcaneal SI was tested at the beginning and end of a 10-week training session. The Calcium Rapid Assessment Method was also used to assess dietary calcium intake among participants.

**RESULTS:** Pearson product correlation analysis did not indicate a significant relationship between dietary calcium intake and calcaneal SI and therefore calcium was eliminated as a covariate in subsequent analyses. Paired sample t-test for the entire sample indicated significant improvements in calcaneal SI over the 10-week training period ( $t = -3.01$ ,  $p = .02$ ). However, when the sample was split by exercise group, paired sample t-tests were not significant ( $p > .025$ ). An independent sample t-test comparing the treadmill to the elliptical training group and using change in calcaneal SI as the dependant variable was also not significant ( $p > .05$ ).

**CONCLUSION:** In conclusion both treadmill and elliptical training resulted in increases in calcaneal SI over a 10-week period but we were unable to detect significantly more benefit from treadmill training, which was counter to our hypothesis. According to this study, both treadmill and elliptical exercise can improve calcaneal SI among college age women.

2749 Board #21 June 1 11:00 AM - 12:30 PM

**Predicting Skeletal Side Dominance From Functional Dominance: DXA, pQCT And QUS Findings**

Belinda R. Beck, FACSM, Benjamin K. Weeks. Griffith University, Gold Coast, Australia.  
(No relationships reported)

**PURPOSE:** Bone densitometry is typically performed on the “non-dominant” limb. While upper extremity functional dominance (writing hand) reliably predicts upper limb skeletal dominance, our experience suggested the same did not apply to the lower limb. In fact, the determination of lower extremity functional dominance is not straight forward. Consequently, the upper extremity dominance assumption is routinely extrapolated to the lower limb and densitometers are designed primarily for left hip scanning to accommodate the preponderance of right-handed individuals in the population. The aim of the current work was to determine the true nature of the association between functional and skeletal dominance of the lower limb. The ultimate goal is to establish a simple and reliable determinant of lower extremity skeletal dominance.

**METHODS:** 77 men (35.4±16.4 yrs) and 100 women (42.7±16.0 yrs) were recruited for bilateral femoral neck bone mineral density (FNBM; XR-800, Norland), calcaneal broadband ultrasound attenuation (BUA; QUS-2, Quidel), tibial peripheral quantitative computed tomography (XCT3000 Stratec) and limb anthropometry. Side dominance questionnaires and physical tasks were completed including the Waterloo Footedness Questionnaire, hop distance test, Pastor Day Marsden Test, handedness and footedness questions, and side preference for common postures (e.g. folding arms). Chi-square tests with crosstabs were run on all parameters using SPSS Version 19.

**RESULTS:** No significant association was observed between writing hand and any measure of lower limb skeletal dominance. Significant negative associations were found for strongest arm ( $p=0.01$ ) and kicking foot ( $p=0.04$ ) with FNBM dominance, and racquet hand with tibial cortical area at the 38% site ( $p=0.05$ ). Strongest arm was positively associated with dominant BUA ( $p=0.04$ ). A trend for lower limb skeletal dominance in the functionally non-dominant limb was observed for 85% of all bone parameters, excluding BUA.

**CONCLUSIONS:** Contrary to conventional thinking, skeletal dominance exists more commonly in the functionally non-dominant lower extremity. Findings bring into question the standard practice of densitometric scanning of the left lower extremity of right-dominant individuals when detection of minimum bone mass is desired.

**Estrogen is Required for Mechanical Loading Induced Restoration of Bone Following Disuse**

Joshua F. Yarrow<sup>1</sup>, Sean C. McCoy<sup>1</sup>, J Andries Ferreira<sup>2</sup>, Jennifer E. Pingel<sup>3</sup>, Bryan P. Conrad<sup>3</sup>, Thomas J. Wronski<sup>3</sup>, Alyssa A. Williams<sup>3</sup>, Stephen E. Borst<sup>1</sup>, Marybeth Brown<sup>2</sup>. <sup>1</sup>VA Medical Center, Gainesville, FL. <sup>2</sup>University of Missouri-Columbia, Columbia, MO. <sup>3</sup>University of Florida, Gainesville, FL  
(No relationships reported)

Both estrogen and mechanical loading regulate bone maintenance. For example, ovariectomy (OVX) reduces bone mineral density (BMD) and estradiol (E<sub>2</sub>) replacement fully prevents this loss. Similarly, hindlimb unloading (HLU), a model of disuse, induces BMD loss and re-ambulation (REAMB) reverses this loss. In addition, HLU worsens OVX-induced bone loss; however, it remains unknown whether REAMB and/or exercise (EX) alter BMD following combined OVX+HLU.

**PURPOSE:** To determine whether E<sub>2</sub> influences the REAMB-induced and/or EX-induced restoration of BMD following HLU of OVX rats.

**METHODS:** Eighty-one 5 month old female Sprague-Dawley rats were randomized into the following groups: 1) Baseline controls, 2) OVX controls, 3) OVX+E<sub>2</sub> controls, 4) OVX+ 4 weeks HLU, 5) OVX+E<sub>2</sub>+HLU, 6) OVX+HLU+ 2 weeks REAMB, 7) OVX+E<sub>2</sub>+HLU+REAMB, 8) OVX+HLU+REAMB+ 2 weeks climbing, jumping, and balancing EX, or 9) OVX+E<sub>2</sub>+HLU+REAMB+EX. Serial DXA scans were performed to track total body bone characteristics throughout the study and peripheral quantitative computerized tomography (pQCT) was utilized to determine differences in distal femoral metaphyseal bone mineral characteristics between groups.

**RESULTS:** Total body BMD increased 4-8% in all animals receiving supplemental E<sub>2</sub>, while BMD did not change in animals without E<sub>2</sub>. OVX reduced trabecular (t)BMD at the distal femoral metaphysis by 35% ( $p \leq 0.001$ ) and OVX+HLU exacerbated this loss by an additional 52% ( $p \leq 0.001$ ), while also reducing cortical (c)BMD by 11% compared with Baseline controls ( $p \leq 0.001$ ). E<sub>2</sub> protected against the OVX+HLU induced bone loss at the femoral metaphysis. However, in the absence of E<sub>2</sub>, REAMB did not reverse the OVX+HLU induced bone loss. Surprisingly, REAMB+EX was severely detrimental to bone following OVX+HLU, resulting in tBMD and cBMD measurements that were 91% and 7% below baseline controls ( $p \leq 0.001$ ). Conversely, the addition of E<sub>2</sub> to REAMB or REAMB+EX protected against the OVX+HLU induced bone loss.

**CONCLUSION:** E<sub>2</sub> influences the mechanical loading induced restoration of BMD and in the absence of estrogen, moderate-intensity exercise is severely detrimental to the restoration of BMD following disuse.

Supported by VA CDA-2 (JFY), VA Merit Award (SEB), NASA NA65-12300 (MB), and NIH AG15796 (MB).

**Acute Bone Marker Responses to Whole-Body Vibration and Resistance Exercise in Postmenopausal Women**

Debra Bembem, FACSM, Carmen Chrisman, Vanessa Sherk, Kaelin Young, Harshvardhan Singh, Jessica Smith, Michael Bembem, FACSM. *University of Oklahoma, Norman, OK.*  
(No relationships reported)

No studies to date have investigated the acute bone turnover marker (BTM) responses to resistance exercise and whole-body vibration (WBV) in postmenopausal women.

**PURPOSE:** To investigate the acute BTM responses to high-intensity resistance exercise with and without whole-body vibration exercise in postmenopausal women.

**METHODS:** Eight women (58 ± 2 years) participated in this randomized crossover control study. DXA was used to measure bone mineral density (BMD) of the total body, lumbar spine, and left and right hip. 1-RM testing was conducted for leg press, seated row, hip extension, shoulder press, hip abduction, and hip adduction isotonic resistance exercises. Subjects performed 3 blood draw sessions in randomized order separated by 2-week washout periods: 1) WBV + resistance exercise (WBV); resistance exercise only (RES); and no exercise (CON). For WBV, subjects stood barefoot, knees slightly flexed on vibration plate for 5, 1-minute bouts at 20 Hz and 1.25 mm (amplitude) separated by 1-minute rest intervals, followed by the resistance exercise. For RES, subjects completed 3 sets of 10 repetitions 80% 1-RM. WBV and RES had blood draws before (Pre), and immediately post (IP) exercise and CON had 2 blood draws at baseline and after 60 minutes of sitting. WBV also included a blood draw between the whole-body vibration and resistance exercise (VibP). Serum samples were measured for bone-specific alkaline phosphatase (Bone ALP) and tartrate-resistant acid phosphatase 5b (TRAP5b) with enzyme immunoassay (EIA) kits.

**RESULTS:** Bone ALP showed a significant time effect ( $p < 0.05$ ), increasing from Pre to IP. TRAP5b had a trend ( $p = 0.061$ ) for condition × time interaction as it increased Pre to IP only for WBV (Pre - 2.433 ± 0.327 U/L vs. IP - 2.659 ± 0.347 U/L). Neither marker showed a significant response at VibP. There were trends for WBV ( $p = 0.062$ ) and RES ( $p = 0.074$ ) TRAP5b % increases Pre-IP to be greater than the CON condition (10.2 ± 2.8%; 6.4 ± 3.1%; -0.60 ± 2.8%, respectively). TRAP5b % change Pre to VibP was significantly related to total body BMD ( $r = 0.82$ ,  $p < 0.05$ ).

**CONCLUSIONS:** The addition of whole-body vibration did not alter bone formation marker responses to acute resistance exercise, however, it elevated bone resorption levels immediately post resistance exercise.

**Focused Extracorporeal Shockwave Therapy For Non-Invasive Bone Stimulation In Scaphoid Non-Union**

Karsten Knobloch<sup>1</sup>, Robert Kraemer<sup>1</sup>, Frank Baetje<sup>2</sup>, Juergen Kopp<sup>3</sup>, Peter M. Vogt<sup>1</sup>. <sup>1</sup>Plastic, Hand and Reconstructive Surgery, Medical School Hannover, Hannover, Germany. <sup>2</sup>Shockwave Center, Hannover, Germany. <sup>3</sup>Plastic, Hand and Reconstructive Surgery, BG Frederikenstift, Hannover, Germany.  
(No relationships reported)

**PURPOSE:** Scaphoid non-union is a challenging problem. Bone stimulation using extracorporeal shockwave therapy (ESWT) has been traditionally applied on long bone pseudarthrosis only. We hypothesized that focused extracorporeal shockwave therapy is able to induce bony consolidation in scaphoid non-union both, after primary or secondary failed procedures.

**METHODS:** In a pilot case series a total number of 21 patients (76% males, mean age 36±15yrs, 30% active smokers) with persistent symptomatic scaphoid non-union were included in this pilot study. Distinct patterns of prior treatment were evident: a) no primary or secondary surgery (n=9), b) no primary surgery, secondary Matti Russe plasty with iliac bone grafting (n=9) or 1,2-ICSR vascularized graft (n=1), c) primary Matti Russe plasty, secondary STT arthrodesis (n=1) or others (n=2). A total number of 2.1±0.8 ESWT sessions (range 1-3) of high-energy focused ESWT were applied (Storz Duolith, 5000 impulses) 5±4 months following the last surgery. Level of evidence: IV (Case series).

**RESULTS:** In 95% a radiological consolidation of the scaphoid non-union was achieved (20 out of 21 patients) at 22±10 months of follow-up. No adverse effects of focused ESWT were noted. Patients' pain levels were considerably low with 2.0±2.2 (0=no pain, 10=severe pain) at 22±12months of follow-up. Only mild daily impairment with DASH scores at follow-up of 9±15 and a Michigan Hand Outcome Questionnaire (MHQ) with 85±18points at the affected side were noted in line with high patient satisfaction.

**CONCLUSION:** We conclude that focused ESWT is an effective non-invasive measure for scaphoid non-union both, in primary and in failed secondary cases in this pilot study.

2753 Board #25 June 1 11:00 AM - 12:30 PM

**Effect Of Pre-exercise Feeding On The Metabolic Response Of Bone To Treadmill Running**

Craig Sale<sup>1</sup>, Jonathan PR Scott<sup>2</sup>, Julie P. Greeves<sup>3</sup>, Anna Casey<sup>2</sup>, John Dutton<sup>4</sup>, William D. Fraser<sup>5</sup>. <sup>1</sup>Nottingham Trent University, Nottingham, United Kingdom. <sup>2</sup>QinetiQ Ltd, Farnborough, United Kingdom. <sup>3</sup>Army Recruiting and Training Division, Upavon, United Kingdom. <sup>4</sup>University of Liverpool, Liverpool, United Kingdom. <sup>5</sup>University of East Anglia, Norwich, United Kingdom.  
(No relationships reported)

**PURPOSE:** Feeding suppresses resting bone resorption but its effect on the response to acute weight-bearing exercise is unknown. We examined the effect of a mixed meal on the bone metabolic response to subsequent treadmill running.

**METHODS:** Ten active males aged 28 ± 4 y completed two, counterbalanced, 8 d trials. After a 3 d standardised diet, participants performed 60 min of treadmill running at 65% VO<sub>2max</sub> at 1000 h on Day 4 after an overnight fast (FAST) or a standardised breakfast (FED) taken at 0815 h. Blood was collected at baseline, before exercise, during exercise, for 3 h postexercise and on four follow-up days (FU1-FU4). Plasma was analysed for C terminal telopeptide region of collagen type 1 (β-CTX), N-terminal propeptides of procollagen type 1 (PINP), osteocalcin (OC), bone alkaline phosphatase (bone ALP), parathyroid hormone (PTH), albumin-adjusted calcium (ACa), phosphate (PO<sub>4</sub>), osteoprotegerin (OPG), cortisol, leptin and ghrelin. Data (mean±1SD) were analysed using linear mixed model ANOVA, with *post hoc* analysis by Dunnett's or Student Newman-Keuls tests.

**RESULTS:** β-CTX was the only bone marker affected by feeding. The decrease in pre-exercise β-CTX was greater (P<0.001) in FED (0.52±0.23 μg·L<sup>-1</sup> to 0.27±0.12 μg·L<sup>-1</sup>; -47%) compared with FAST (0.56±0.24 μg·L<sup>-1</sup> to 0.40±0.15 μg·L<sup>-1</sup>; -26%). During exercise, βCTX concentrations increased in both groups (to 0.35±0.18 μg·L<sup>-1</sup> in FED and 0.40±0.13 μg·L<sup>-1</sup> in FAST) and, at 1 h post-exercise, were not significantly different from baseline (FED: 0.49±0.21 μg·L<sup>-1</sup>; FAST: 0.48±0.18 μg·L<sup>-1</sup>). At 3 h post-exercise, concentrations were decreased (P<0.001) from baseline in FAST (0.36±0.14 μg·L<sup>-1</sup>; -33%), and were lower (P<0.001) than in FED (0.46±0.17 μg·L<sup>-1</sup>). PINP increased (P<0.001) during and immediately following exercise, whereas OC was decreased (P<0.001) after 30 min of exercise but was not different from baseline thereafter. ACa, PO<sub>4</sub>, PTH, OPG, cortisol, leptin and ghrelin all responded to exercise but were not significantly influenced by feeding.

**CONCLUSION:** Feeding suppressed β-CTX at rest but did not attenuate the increase in bone resorption during weight-bearing exercise. Indeed, β-CTX was higher in FED than in FAST after 3 h of recovery. These findings suggest no benefit of pre-exercise feeding in modulating the bone metabolic response to exercise.

**Vitamin D Status in Female Endurance Runners and Controls Based in the United Kingdom**

Katherine Brooke-Wavell<sup>1</sup>, Nicholas Peirce<sup>2</sup>, Sonia Jean-Philippe<sup>1</sup>, Emma Dowdall<sup>1</sup>, Fabio Terruzzi<sup>1</sup>, Greg Summers<sup>3</sup>, Noel Cameron<sup>1</sup>, Rachel Duckham<sup>1</sup>. <sup>1</sup>Loughborough University, Loughborough, United Kingdom. <sup>2</sup>Nottingham University Hospitals, Nottingham, United Kingdom. <sup>3</sup>Derby Hospitals, Derby, United Kingdom.

(No relationships reported)

Vitamin D is important for musculoskeletal health but insufficiency is common in the United Kingdom (UK). Vitamin D insufficiency in female runners could contribute to increased risk of stress fractures or future osteoporosis as well as other performance related dysfunction.

**PURPOSE:** This study examined whether 25-hydroxy vitamin D (25-OH D) differed between female endurance runners and less active women based in the United Kingdom; whether any seasonal variation in 25-OH D was observed in the runners and examined factors related to vitamin D status.

**METHODS:** Serum 25-OH D was assessed in late spring in 52 endurance runners and 27 controls who did not exceed exercise recommendations for health. All women were aged between 18 and 45 years. Measurements were repeated in the fall in 38 of the runners. Supplement use and vacations were assessed by questionnaires. Vitamin D concentrations were logarithmically transformed to achieve normal distribution prior to comparisons of means by analysis of variance.

**RESULTS:** The runners had lower body mass index than controls (19.8 ± 1.3 vs 22.8 ± 3.4 kgm<sup>-2</sup>) although height did not differ significantly between groups. Serum 25-OH D concentrations in spring were (median [inter-quartile range]) 90.8 [69.3-120.1] nmol/l in runners and 60.6 [49.3-94.6] nmol/l in controls. Log<sub>10</sub> 25-OH D concentrations were significantly higher in runners than controls (mean [SE] 1.98 [0.02] and 1.85 [0.04] respectively; p=0.004) but 25-OH D in runners did not differ between spring and autumn (2.01 [0.03] and 1.99 [0.02] respectively; p=0.694). Log<sub>10</sub>25-OH D was significantly higher in women who took supplements (p=0.003) and in those who had attended warm weather training camps or holidays in the previous 6 months (p=0.012).

**CONCLUSIONS:** Female endurance runners had better vitamin D status in spring than young female controls, with their values being within the range suggested as optimal. The runners did not demonstrate the seasonal changes that have been reported in previous studies in the United Kingdom. The better vitamin D status in runners than controls may be explained by higher sunshine exposure, consumption of supplements and low body fat content.

2755 Board #27 June 1 11:00 AM - 12:30 PM

**Effects Of Estrogen Deficiency And Resistance Exercise On Serum Undercarboxylated And Carboxylated Osteocalcin**

Danielle Day<sup>1</sup>, Wendolyn S. Gozansky<sup>2</sup>, Wendy M. Kohrt, FACSM<sup>3</sup>. <sup>1</sup>University of Massachusetts-Lowell, Lowell, MA. <sup>2</sup>Kaiser Permanente, Denver, CO. <sup>3</sup>University of Colorado Denver Anschutz Medical Campus, Aurora, CO.

(No relationships reported)

Osteocalcin (OCN), a bone formation marker, has two forms: undercarboxylated (uOCN) and carboxylated (cOCN). Each has been linked with differential effects on bone and other tissues. Independent changes in uOCN and cOCN have not been assessed in response to increased bone turnover as occurs with estrogen (E) deficiency.

**PURPOSE:** To determine the effect of E suppression, via gonadotropin-releasing hormone agonist (GnRHag), on serum uOCN and cOCN.

**METHODS:** Premenopausal women (n=15, 36±7 yrs) received 5 months of GnRHag, were randomized to E or placebo (PL) add-back, and half in each drug group were also randomized to resistance exercise 3d/wk (EX). Effects of drug and exercise on the change in serum uOCN and cOCN from baseline to 5 mo were analyzed by ANOVA.

**RESULTS:** uOCN increased only in PL (p=0.046), and there was no EX effect. Due to a trend for a drug\*EX interaction for cOCN (p=0.057), groups were analyzed separately. In PL, there was no EX effect on cOCN; however, a trend for increased cOCN in the E+EX group was seen (p=0.07).

**CONCLUSIONS:** Our findings suggest that E suppression results in increased uOCN and cOCN, which may be indicative of increased bone turnover; however, these data require support from measures of bone resorption. Interestingly, E add-back attenuated the increase in uOCN and stimulated cOCN but only when combined with EX. This result must be interpreted cautiously but may suggest a bone formation effect of exercise only in the E-replete condition.

**Lifelong Physical Activity and Knee Osteoarthritis Development in Mice**

Tricia Hubbard-Turner, Michael J. Turner. University of North Carolina @ Charlotte, Charlotte, NC.

(No relationships reported)

Knee osteoarthritis (OA) is a debilitating disease that affects an estimated 27 million Americans. Physical activity may be a way to treat and prevent its occurrence.

**PURPOSE:** To examine the effect of lifelong physical activity on the development of knee OA.

**METHODS:** Fifteen C57Bl/6J mice (8 male and 7 female) were individually caged with a running wheel, magnetic sensor and digital odometer, and fifteen mice (7 male and 8 female) individually housed without a running wheel. Each mouse was provided with standard chow and water ad libitum. Running wheel distance, duration and speed were recorded daily. A diagnostic ultrasound (SONOS 5500 Ultrasound and 15-6L ultrasound probe) was used to measure medial and lateral knee joint space in both hind limbs every month until the end of mice's lifespan.

**RESULTS:** Right medial ( $p=0.002$ ), right lateral ( $p<0.0001$ ), left medial ( $p=0.01$ ), and left lateral ( $p=0.007$ ) knee joint spaces were significantly smaller from months three to nine in the physically active C57Bl/6J mice. However, there was no significant difference between all knee joint spaces of the running and sedentary C57Bl/6J mice throughout the remainder of the lifespan. All hindlimb knee joint spaces significantly declined with aging ( $p<0.0001$ ).

Table 1. RM Joint Space (mm) in RUN and SED mice.

| Group | 3 Months | 16 Months | 30 Months |
|-------|----------|-----------|-----------|
| RUN   | .37±.003 | .13±.002  | .07±.002  |
| SED   | .39±.004 | .13±.007  | .07±.001  |

**CONCLUSIONS:** During the first 9 months of the lifespan, physical activity seemed to protect the joint from degeneration, however; after that there was no protective benefit. This may be due to the fact that C57Bl/6J mice are genetically known to develop OA at 9 months of age. Physical activity may have no impact on this genetic predisposition. But in those not genetically predisposed to develop OA, physical activity may be a method to reduce their risk of OA.

2757 Board #29 June 1 11:00 AM - 12:30 PM

### The Effect Of Life-long Endurance Training On The Mechanical Properties Of The Human Patellar Tendon, In Vivo

Christian Couppé<sup>1</sup>, René Svensson<sup>1</sup>, Jean- Francois Grosset<sup>1</sup>, Anders Karlsen<sup>1</sup>, Morten Olsen<sup>1</sup>, Mette Hansen<sup>1</sup>, Per Aagaard<sup>2</sup>, Michael Kjaer<sup>1</sup>, S. Peter Magnusson<sup>1</sup>.  
<sup>1</sup>University of Copenhagen, Faculty of Health Sciences, Copenhagen NV, Denmark. <sup>2</sup>University of Southern Denmark, Copenhagen NV, Denmark.  
(No relationships reported)

It remains unknown if life-long habitual endurance exercise can influence the aging human tendon. We hypothesise that life-long habitual endurance exercise can influence the mechanical properties of the human patellar tendon.

**PURPOSE:** To examine the effect of aging and life-long habitual endurance exercise on the mechanical properties of the human patellar tendon, *in vivo*.

**METHODS:** We recruited 15 healthy injury free master athletes (old trained men, O-Tr; running distance of 44±17 km/wk over 28±9 yrs (mean±SE)), 12 old untrained controls (O-Un) as well as 10 young men matched for current running distance (young trained, Y-Tr; 48±12 km/week) and 12 young untrained controls (Y-Un). MRI was used to assess whole tendon dimensions. Tendon mechanical properties were assessed with use of simultaneous force and ultrasonographic measurements during ramped isometric contractions. Data was analyzed using 2-way ANOVA.

**RESULTS:** For tendon CSA normalized to bodyweight an increase with age ( $P=0.0004$ ) and training ( $P=0.0003$ ) was observed. There was a significant interaction between age and training ( $P=0.02$ ), namely the master athletes had a greater CSA than any of the other groups (Tendon CSA: O-Tr, 6.4±0.3; O-Un, 4.8±0.2; Y-Tr, 4.8±0.2 and Y-Un, 4.4±0.2 mm<sup>2</sup>/kg<sup>2/3</sup>). The same relation was found using the non-normalized CSA. There was also an effect of age on max tendon stress ( $P<0.001$ ) (Max tendon stress: O-Tr, 45±3; O-Un, 55±4; Y-Tr, 74±5 and Y-Un, 61±7 MPa), which was mostly driven by the difference in CSA since no significant effect of age was observed on the max force. No other differences were found.

**CONCLUSIONS:** To our knowledge, these are the first data that demonstrate a higher tendon CSA in male master athletes. The results suggest that life-long habitual endurance exercise may reduce tendon stress by increasing tendon CSA thereby possibly reducing the risk of injury compared to old or young untrained/trained controls.

Supported by The Center for Healthy Aging, University of Copenhagen, The Danish Physiotherapy Association and The Danish Medical Research Council.

2758 Board #30 June 1 11:00 AM - 12:30 PM

### The Effect Of Post Pubertal Food Restriction On Bone Strength

Tiffany A. Butler, Amie L. Pole, Vanessa R. Yingling, FACSM. Temple University, Philadelphia, PA.  
(No relationships reported)

Low body weight is a risk factor for osteoporosis and weight loss has been associated with bone loss in animal and human models. However food restriction has also been linked with an increased life span. Food restriction during growth may affect calcium, protein and hormone levels and reduce peak bone mass altering cortical and trabecular bone structure. Timing of weight loss may be a factor because the pubertal years are a major period for bone accrual.

**PURPOSE:** To determine the effect of 30% food restriction in post pubertal (day 65) female rats on bone strength.

**METHODS:** 34 female Sprague Dawley rats (day 23) were randomly assigned into two groups, control (C) and food restriction (FR). On day 65, FR animals were fed 70% of control ad lib food intake for 6 weeks with a food preparation that was replete in micronutrients. After 6 weeks, right femurs were dissected and mechanically tested using a 3-point bend assay. Total fat from retroperitoneal and gonadal regions and triceps surae muscle were weighed.

**RESULTS:** 30% food restriction resulted in an 18% lower body weight compared to control. Statistical differences were found in total fat (13.14g ± 9.10g vs. 3.66g ± 1.50g,  $p<.05$ ) and percent muscle to fat (21.39% ± 15.44% vs. 61.95% ± 34.92%,  $p<.05$ ). However, no significant differences were found in mechanical strength between groups, but normalized to body weight peak moment (470.44 Nm/Kg ± 187.02 Nm/Kg vs. 606.97 Nm/Kg ± 52.37 Nm/Kg,  $p<.05$ ) and stiffness (32736.90 Nmm<sup>2</sup> ± 13979.51 Nmm<sup>2</sup> vs. 51429.80 Nmm<sup>2</sup> ± 5622.55 Nmm<sup>2</sup>,  $p<.05$ ) were significantly greater in the FR group. **Discussion:** Food restriction did not have a negative effect on cortical bone strength in fact strength relative to body weight showed FR bones were stronger. FR fat pads were 72% lower with muscle weights equal between groups indicating that body weight significantly decreased by fat mass. Increased percent muscle to fat weight indicates that lean body mass was maintained in the FR group.

**CONCLUSION:** Lower body weight resulting from short-term food restriction in post pubertal female rats resulted in a significant decrease in fat mass and an increase in bone strength relative to body weight. Food restriction post puberty has a positive effect on bone strength in the short term when micro nutrients are replete and muscle mass is maintained. Supported by NIAMS/NIH 1R03AR0575.

### Bone Density Changes Following Stress Fracture in Female Athletes

Rachel L. Duckham<sup>1</sup>, Nick Peirce<sup>2</sup>, Greg Summers<sup>3</sup>, Noel Cameron<sup>1</sup>, Katherine Brooke-Wavell<sup>1</sup>.  
<sup>1</sup>Loughborough University, Loughborough, United Kingdom.  
<sup>2</sup>Nottingham University Hospitals NHS Trust/ England and Wales Cricket Board, Loughborough, United Kingdom. <sup>3</sup>Derby Royal Hospital, Derby, United Kingdom.  
(No relationships reported)

Athletes who sustain stress fractures (FX) typically reduce weight-bearing exercise for 6-8 weeks before returning to loading activities. This reduction in loading may cause bone loss increasing the risk for low bone mineral density (BMD) and FX recurrence.

**PURPOSE:** To evaluate bone changes during the detraining and retraining phases following FX injury.

**METHODS:** A prospective, case-control design assessed bone changes in 8 cases diagnosed with FX and 7 matched controls (C). BMD and content (lumbar spine and femoral neck), hip geometric properties (section modulus and cross sectional area) and body composition were assessed at baseline (within 14 days of FX) and after 6-8 weeks, and 6-8 months using dual energy x-ray absorptiometry. Bone changes were evaluated between baseline and 6-8 weeks (detraining phase) and 6-8 weeks and 6-8 months (retraining phase). Repeated measures analysis of variance with a between-subject group factor was used to determine whether changes differed between FX and control groups. Level of significance was defined as  $P<0.05$ .

**RESULTS:** Three sacral, 2 femoral and metatarsal and 1 tibia FX were diagnosed. At baseline, cases were significantly shorter (FX: 1.639(0.009), C: 1.701(0.016) m,  $p=0.007$ ) and reported a higher prevalence of FX history than C (50% vs 0%), no other significant differences were found between groups. During the detraining phase, there were no statistically significant changes in menstrual function, body fat %, BMD or hip geometric properties in cases or controls. During the retraining phase, femoral neck BMD increased significantly in the injured leg of FX cases (mean (SE) 1.042(0.102) to 1.070(0.102) g/cm<sup>2</sup>,  $p=0.004$ ) with no significant change in the contra-lateral leg (1.036 (0.102) to 1.054(0.109) g/cm<sup>2</sup>). No significant bone gain was found in control subjects (healthy or "injured legs"). Changes in other bone parameters were small and not statistically significant in either group.

**CONCLUSION:** Six-to-eight weeks of reduced training following FX does not cause significant bone loss. Significant bone gain did occur in the injured leg of case athletes within 8-months

following FX once training had resumed. It is not clear why BMD increased above baseline values during retraining but it does seem that factors other than BMD may be associated with FX recurrence.

**2760 Board #32 June 1 11:00 AM - 12:30 PM**  
**Mechanical Loading With Or Without Weight-bearing Activity: Influence On Bone Strength In Female Adolescent Athletes**

David A. Greene, Geraldine A. Naughton, Elizabeth J. Bradshaw, Mark Moresi, Gaelle Ducher. *Australian Catholic University, Sydney, Australia.* (Sponsor: Giles Warrington, FACSM)

(No relationships reported)

Bone health is considered not to benefit from water-based sports due to their weight-supported nature, but available evidence primarily relies on DXA technology.

**PURPOSE:** The purpose was to investigate musculoskeletal health in the upper and lower body in well-trained adolescent female athletes using pQCT and compare these athletes with less active, age- and sex- matched peers.

**METHODS:** Bone mineral content, volumetric cortical and trabecular BMD, total and cortical area, and bone strength were assessed at the distal and proximal tibia and radius in four groups of adolescent females (mean age 14.9 years) comprising water polo players (n=30), gymnasts (n=25), track and field athletes (n=34), and non-active controls (n=28).

**RESULTS:** Water polo players did not show any benefit in bone strength or muscle size in the lower leg when compared with controls. In contrast, gymnasts showed 60.1% and 53.4% greater bone strength at the distal and proximal tibia, respectively, than non-active females ( $p < 0.05$ ). Similarly, track-and-field athletes displayed 33.9% and 14.7% greater bone strength at the distal and proximal tibia, respectively, compared with controls ( $p < 0.05$ ). In the upper body, water polo players had 31.9% greater bone strength at the distal radius, but not the radial shaft, and 15.2% larger forearm muscle cross-sectional area than controls ( $p < 0.05$ ). The greatest musculoskeletal benefits in the upper body were found in gymnasts.

**CONCLUSIONS:** Despite training at an elite level, female water polo players did not show any benefits in musculoskeletal health in the lower leg and only limited benefits in the upper body when compared with non-active girls.

**2761 Board #33 June 1 11:00 AM - 12:30 PM**  
**Ultrasound Evaluation Of The Patellar Tendon Cross-sectional Area And Its Relation To Maximum Force**

Konstantina Intziagianni, Michael Cassel, Steffen Mueller, Frank Mayer. *University Outpatient Clinic Potsdam, Potsdam, Germany.*

(No relationships reported)

It is widely accepted that the maximal force which can be produced by a muscle is directly proportional to the cross-sectional area (CSA) of its accompanying tendon. Mainly in rehabilitation this relation has to be considered regarding tendon strain with respect to knee joint positioning and related output force. Nevertheless it is unclear, if the theoretical basis could be reproduced in humans in rehabilitation relevant positions of the knee joint.

**PURPOSE:** To measure patella tendon CSA in different angle positions and contraction modes related to maximum output muscle force.

**METHODS:** In this pilot study eight healthy subjects ( $174 \pm 7.4$  cm,  $71.62 \pm 14.66$  kg,  $27.3 \pm 7.7$  yrs..) underwent a maximum isometric strength measurement of knee extension in a seated position at fixed angles ( $90^\circ$  and  $30^\circ$  knee flexion). During the measurements high resolution ultrasonography Patella tendon CSA was measured 2cm from the tendon insertion in the two position angles during rest and at 100% maximal voluntary contraction (MVC) in transverse scan. Data were analysed using T-test and Pearson correlation ( $\alpha = 0.05$ ).

**RESULTS:** Higher maximum force was measured in  $90^\circ$  ( $127.46 \pm 47.74$  F[N]) compared to  $30^\circ$  ( $94.59 \pm 36.10$  F[N]). A statistical significant difference was found between  $90^\circ / 30^\circ$  ( $73.51 \pm 7.22 / 79.22 \pm 17.89$  mm<sup>2</sup>  $p < 0.05$ ) measuring CSA during rest. No statistical significant difference could be shown during contraction ( $78.34 \pm 15.65 / 73.86 \pm 19.70$  mm<sup>2</sup>  $p > 0.05$ ). When normalizing CSA to output force (CSA/F[N]) and to CSA difference between rest and MVC ( $\Delta T / F[N]$ ) it could be shown that less force is related to a thicker tendon during rest and to a greater CSA reduction during contraction. No statistical significant correlation was found between CSA thickness during rest and maximum force in both angle positions ( $p > 0.05$ ) and between CSA reduction during contraction and maximum force ( $p > 0.05$ ).

**CONCLUSION:** Different angle positions can affect tendon thickness, while maximum muscle force production is depending on angle position. These findings might have impact in clinical practice due to the fact that patellar tendon has less strain in  $30^\circ$  in comparison to  $90^\circ$  and this might be related mainly to force and not to tendon CSA.

**The Painful Shoulder: Ultrasonographic Measurements of Supraspinatus Thickness, Pain Scores and Treatment**

Marni Hillinger, Christopher Visco. *New York Presbyterian - Columbia and Cornell, New York, NY.*

(No relationships reported)

Shoulder injury and pain complaints are common in the primary care, orthopedic and physiatric outpatient setting. The supraspinatus tendon is a commonly involved tendon in rotator cuff injuries. Musculoskeletal ultrasound is becoming a popular tool to aid in the diagnosis of pathologic conditions of the supraspinatus tendon.

**PURPOSE:** To determine whether a relationship may exist between supraspinatus thickness and pain scores among patients who present with a primary complaint of shoulder pain. We hypothesize that a positive correlation exists and that this could aid clinical development of targeted treatment strategies and earlier identification of those who require a more aggressive therapeutic approach.

**METHODS:** A retrospective analysis of supraspinatus thickness was performed by analyzing ultrasonographic shoulder examinations of patients who presented to the Columbia University musculoskeletal clinic with a primary complaint of shoulder pain. This included 58 separate shoulder studies among 52 different patients. An average thickness was obtained by utilizing the DICOM ultrasonographic software ruler tool. Outpatient records were reviewed including pertinent follow-up visits. Pain scores and treatment at the time of presentation and follow-up were recorded.

**RESULTS:** There was no correlation (Pearson correlation = -0.008) found between supraspinatus tendinous thickness and pain scores at the time of presentation. Average supraspinatus thickness was found to be  $0.506\text{cm} \pm 0.113$  among women and  $0.556\text{cm} \pm 0.157$  among men. Average pain score was found to be  $5.4 \pm 2.2$  among women and  $5.7 \pm 2.28$  among men on initial evaluation. Of those who followed-up, an average pain score at the time of re-assessment was  $3.5 \pm 2.63$ . 73% of patients were referred for physical therapy, 8% were referred for surgical evaluation and 27% underwent a steroid injection upon initial evaluation.

**CONCLUSIONS:** This study did not identify a correlation between ultrasonographically identified supraspinatus thickness and pain scores for patients who present with a primary complaint of shoulder pain. The majority of patients underwent conservative management. Future research should continue to distinguish ultrasonographically identifiable risk factors for the development of shoulder pathologies.

**Protein Consumption And The Occurrence Of Osteoporosis**

Jung A Kim, Byung-Sung Kim, Hyun-Rim Choi, Chang-Won Won. *KyungHee University Hospital, Seoul, Korea, Republic of.*

(No relationships reported)

**PURPOSE:** In many previous studies about amount of dietary protein effect on the risk of the osteoporosis, have showed conflicting results. In those studies, subjects and methods were inconstant and study result from the Asian population was insufficient. Therefore we tried to investigate the relationship between risk of the osteoporosis and the dietary protein of the Korean adults.

**METHOD:** We used the data from Korean National Health and Nutrition Examination Survey 4 (KNHANES 4; 2008-2009) for analysis. Participant who were 19 year-old or over and had never been treated for osteoporosis were included for analysis. Assessment of dietary intake obtained by 24-hour recall method and participants were grouped by the tertile of the amount of protein intake. The diagnostic criteria for the osteoporosis was lumbar or femur neck bone mineral density T-score  $\leq -2.5$  for this study. To analyze the influence of the amount of daily protein intake to the occurrence of osteoporosis, logistic regression analysis was used and the associated factors were adjusted through 4 steps.

**RESULTS:** Total 6,461 subjects were included in this study and 624 of among those were classified to the osteoporosis. For the lumbar osteoporosis, the highest tertile protein intake group has significantly lower odds compared to the lowest tertile group (OR 0.695, 95% CI 0.508–0.952) for women. But the significance was lost after associated factors were adjusted. For men, the highest tertile group has significantly lower odds compared to the lowest tertile group and it kept significance even after the associated factors were adjusted (OR 0.519, 95% CI 0.284– 0.949).

**CONCLUSION:** In this study, we found that sufficient daily protein intake is related with low occurrence of osteoporosis in Korean adults. To confirm the preventive effect of sufficient protein intake, further prospective study might be needed.

**2764 Board #36 June 1 11:00 AM - 12:30 PM**  
**Volumetric Bone Density, Bone Strength in Radius and Tibia in Healthy Chinese Population with Peripheral Quantitative Computed Tomography**  
Chi Kei Li<sup>1</sup>, Abdulaziz Farooq<sup>1</sup>, Bruce Hamilton<sup>1</sup>, Hakim Chalabi<sup>1</sup>, Jean Woo Wong<sup>2</sup>. <sup>1</sup>Aspetar, Doha, Qatar. <sup>2</sup>Chinese University of Hong Kong, Hong Kong, SAR, China.

(No relationships reported)

Peripheral Quantitative Computed Tomography (pQCT) measure volumetric bone density (BMD) of cortical (Cort) and trabecular (Trab) compartments separately in addition to calculating torsional bone strength defined by Polar strength strain index (polar SSI). It is independent of rotation and better reproducible compared with axial SSI which defined as the bending strength with respect to X and Y axis. Since remodeling always occurs early in Trab, unlike Dual Energy X-ray Densitometry which measure only areal bone mineral density, pQCT can monitor metabolic change quickly and precisely. However, baseline database is still limited especially in weight bearing sites (eg. lower limb).

**PURPOSE:** To provide a reference database of BMD and bone strength in radius (R) and tibia (T) for healthy Chinese population.

**METHODS:** A total of 183 males, 206 females aged between 20 - 70 y were scan with pQCT (Stratec XCT3000) on their non-dominant side distal (4%) and middle one third (33%) of R and T. BMD of Total, Cort and Trab region were assessed and polar SSI was calculated.

**RESULTS:** Males presented with significant higher values for all parameters (P<=0.036) compared with females except Cort BMD at T4%. Total BMD at R4% were higher compared to T4% (P<0.001) and Cort BMD at R33% were higher compared to T33% (P<0.001) in both gender. However, Trab BMD at R4% were lower compared to T4% (P<0.001) in both gender. When all parameters were stratified by gender and studied by age, data showed that Total and Trab BMD at R4% and T4% declined significantly in females after 50y (P<0.05) while males declined significantly after 60y (P<0.05). Cort BMD at R33% in females declined significantly after 50y while males declined significantly after 60y (P<0.05). Cort BMD at T33% and Polar SSI in females declined significantly after 50y while in males were stable across age groups (P<0.05).

**CONCLUSIONS:** This information is important in providing reference data for monitoring change in bone mineral density and bone strength using pQCT within a Chinese population.

**2765 Board #37 June 1 11:00 AM - 12:30 PM**  
**An Examination of Foot Parameters in Subjects with and without Chronic Ankle Instability**

Sara Naguib, Kathy Liu, Thomas W. Kaminski, FACSM. *University of Delaware, Newark, DE.*

(No relationships reported)

The foot is the base of the body's kinetic chain; therefore structure and function are essential in providing stability. Even minor differences in intrinsic foot structure can affect the proximal joints in the body and play a role in ankle sprains.

**PURPOSE:** To determine if differences in measurements of intrinsic foot structures exist in subjects with and without chronic ankle instability.

**METHODS:** A total of 47 physically active subjects participated in this study (30 females, 17 males, age=21.9±2.7 yrs., height=168.2±9.1 cm, mass=64.9±13.0 kg). All participants completed the Cumberland Ankle Instability Tool, resulting in 50 ankles in the stable group and 35 ankles in the unstable group. Measurements included: navicular height (NH), plantar fascia thickness (PFT), medial longitudinal arch angle (MLAA), and forefoot to rearfoot ratio (FR). NH was measured as the height of the navicular in a non-weight bearing stance. PFT was quantified using musculoskeletal ultrasound. MA was the angle of medial malleolus to the navicular to the base of the first metatarsal. FR was measured as the ratio of the width of the forefoot to rearfoot. All data were analyzed using an independent t-test (p<0.05).

**RESULTS:** Interestingly there were no significant differences in foot measurements between groups.

| Foot Parameter | Stable (mean±SD) | Unstable (mean±SD) | p-value |
|----------------|------------------|--------------------|---------|
| NH (mm)        | 4.10±0.63        | 3.95±0.59          | 0.086   |
| PFT (mm)       | 0.99±0.16        | 1.05±0.15          | 0.216   |
| MLAA (°)       | 149.48±8.70      | 147.08±6.51        | 0.151   |
| FR             | 1.92±0.17        | 1.85±0.16          | 0.114   |

**CONCLUSION:** Although no significant differences between the two groups were observed, all variables were trending towards statistical significance. Further research examining other characteristics and structures is necessary for a full understanding of the foot. A better understanding of the changes that occur in the foot after ankle sprains are essential to the prevention of ankle instability. Supported by NIH Delaware INBRE Grant P20RR016472-11.

**Site-Specific Increasing Bone Mass by Resistance Exercise**  
Chang-Sun Kim<sup>1</sup>, Jin-Hwan Yoon<sup>2</sup>, Dong-Ho Park<sup>3</sup>, Soon-Gil LIM<sup>4</sup>, Nam-Sub Back<sup>4</sup>. <sup>1</sup>Dongduk Women's University, Seoul, Korea, Republic of. <sup>2</sup>Hannam University, Daejeon, Korea, Republic of. <sup>3</sup>Inha University, Incheon, Korea, Republic of. <sup>4</sup>Yongin University, Gyeonggi, Korea, Republic of.

(No relationships reported)

**PURPOSE:** It is now established that mechanical load such as exercise is important for increase and consequently maintenance of bone mass. However, site differences in change of bone mineral density (BMD) by resistance exercise are unclear. The aim of this study was to evaluate the changes of BMD between the fore- and hind-limb induced by resistance exercise. This study was investigated effects of 12 weeks resistance exercise by climbing an incline on the changes of BMD and serum bone metabolic markers in growing rats.

**METHODS:** Twelve male F344 rats(203±12.4g), aged 8 weeks, were randomly divided into two groups: control rats(CON, n=6) and resistance exercise rats(EXE, n=6). EXE group performed training that climbed the ladder at 8 times a day, 5day a week for 12 weeks. After experimental period, rats were sacrificed and femur and humerus were removed for analysis of BMD and bone mineral content (BMC) by dual energy X-ray absorptiometry (DEXA, Lunar DPXL, USA). Serum calcium (Ca), phosphate (P) and osteocalcin (OC) were determined by biochemical markers of bone metabolism. The statistical difference on the results was analyzed by independent t-test.

**RESULTS:** There were significant differences for femoral BMC(CON 0.505±0.023 vs EXE 0.531±0.033 g, p<.05) and femoral BMD(CON 0.058±0.005 vs EXE 0.065±0.004 g/cm<sup>2</sup>, p<.001) between groups, respectively. There were no significant differences for humerus BMC(CON 0.228±0.016 vs EXE 0.239±0.015 g, p>.05) and humerus BMD(CON 0.033±0.006 vs EXE 0.038±0.006 g/cm<sup>2</sup>, p>.05) between groups, respectively. The serum Ca(CON 10.18±0.20 vs EXE 10.13±0.39 mg/dL, p>.05), P(CON 6.67±1.48 vs EXE 6.70±1.26 mg/dL, p>.05) and OC(CON 6.48±0.79 vs EXE 7.08±1.05 ng/mL, p>.05) showed no significantly difference between groups.

**CONCLUSIONS:** These results suggest that increase of BMD by resistance exercise with climbing the ladder was appeared in only weight-bearing hind-limb, namely this change of BMD might occur by site-specific.

---

**2767** Board #39 June 1 11:00 AM - 12:30 PM  
**The Effect of Calorie Restriction and Hypothalamic Suppression on Bone Strength during Puberty**  
Kathryn A. Mitchell, Amie L. McCoy, Megan E. Lunny, Vanessa Yingling, FACSM. Temple University, Philadelphia, PA.  
(No relationships reported)

Low energy availability and hypothalamic amenorrhea are both risk factors for developing insufficient bone mineral density (BMD) in young physically active women. The prevalence of osteopenia in women athletes is estimated to be between 22-50%.

**PURPOSE:** Determine the effect of calorie restriction and hypothalamic suppression on bone strength.

**METHODS:** 16 female Sprague-Dawley rats, age day 23, were randomly assigned to a control (C, n=8) group that received daily saline injections (.2cc) for 28 days and sacrificed at age day 50, or an experimental group (FR-G, n=8) that received daily injections of gonadotropin releasing hormone antagonist (GnRH-a, .2cc, dosage .2mg\*kg<sup>-1</sup>) and a 30% caloric restriction (no deficit in micronutrients) based on the control group's average daily consumption and were sacrificed on age day 50.

**RESULTS:** BW on day of sacrifice of the FR-G was significantly lower than control (15%, p<0.001) and the GnRH-a treatment was successful shown by significantly lower uterine and ovary weights in the FR-G group (80% and 75% respectively, p<0.001). The FR-G group had significantly lower total fat and gastrocnemius muscle weights as compared to control (70%, p<0.001 and 10%, p=0.03 respectively). However, the percent muscle per fat of the FR-G group was significantly higher than control (64%, p=0.001). There was no difference in absolute femoral peak moment, however when normalized for body weight the FR-G group was significantly higher than control (19%, p=0.004).

**CONCLUSION:** Hypothalamic suppression and caloric restriction pre-puberty reduced body weight, body fat, and muscle weight while increasing femoral peak moment relative to body weight. These results could suggest bone strength is more correlated with body composition than hypothalamic function.

**2768** Board #40 June 1 11:00 AM - 12:30 PM  
**Voluntary Wheel Running Does Not Protect Against Doxorubicin-Induced Osteopenia in the Growing Rat**  
Traci L. Parry<sup>1</sup>, Urszula T. Iwaniec<sup>2</sup>, Russell T. Turner<sup>2</sup>, Chia-Ying Lien<sup>3</sup>, Brock T. Jensen<sup>4</sup>, David S. Hydock<sup>1</sup>, Carole M. Schneider, FACSM<sup>1</sup>, Reid Hayward<sup>1</sup>.  
<sup>1</sup>University of Northern Colorado, Greeley, CO. <sup>2</sup>Oregon State University, Corvallis, OR. <sup>3</sup>National Taiwan University, Taipei, Taiwan. <sup>4</sup>Slippery Rock University, Slippery Rock, PA.  
(No relationships reported)

Despite numerous negative side effects, including osteopenia, doxorubicin (DOX) continues to be used clinically because of its high success rate in the treatment of an array of cancers. At this time it is unclear whether exercise can attenuate the deleterious effects of DOX on bone architecture.

**PURPOSE:** To determine whether voluntary wheel running attenuates the negative effects of DOX on bone in growing male rats.

**METHODS:** Male Sprague-Dawley rat pups (25 days old) were randomly assigned to one of four groups: sedentary control, SED+C; sedentary DOX, SED+DOX; voluntary wheel run control, WR+C; and voluntary wheel run DOX, WR+DOX. Animals received 2 mg/kg DOX i.p. or an equivalent volume of saline (1 mL) over 7 successive days. Beginning with the first day of injections, SED animals did not exercise while animals in WR groups were allowed free access to cage-mounted running wheels for a total of 10 weeks. Upon completion of the protocol, animals were sacrificed and tibia and femur excised for assessment of bone mineral content and density (tibia) via dual energy x-ray absorptiometry and cancellous and cortical bone architecture (femur) via micro computed tomography.

**RESULTS:** WR+C animals ran an average of 23 ± 3 km/wk while WR+DOX animals ran an average of 12 ± 3 km/wk. Treatment with DOX resulted in significantly lower tibial length and tibial bone mineral content and density (p < 0.05) compared to SED+C. The negative effects of DOX were observed in both the cortical and cancellous envelopes. Midshaft femur cortical cross-sectional area, cortical volume, and polar moment of inertia were significantly lower in DOX-treated rats compared to SED+C. Distal femur metaphysis cancellous bone volume/tissue volume was also lower in DOX-treated compared to SED+C rats. Voluntary wheel running did not protect against the detrimental effects of DOX treatment on the skeleton in developing rats.

**CONCLUSIONS:** DOX treatment in male rat pups suppressed bone growth and resulted in cancellous and cortical osteopenia. Voluntary wheel running during this time did not protect the growing skeleton against the negative effects of DOX treatment.

**2769** Board #41 June 1 11:00 AM - 12:30 PM  
**The Bone-specific Physical Activity Questionnaire (BPAQ) Predicts pQCT-derived Tibial Bone Strength**  
Benjamin K. Weeks, Belinda R. Beck, FACSM. Griffith University, Gold Coast, Australia.  
(No relationships reported)

The bone-specific physical activity questionnaire (BPAQ) was developed to account for the influence of habitual mechanical loading on the skeleton. A simple questionnaire is scored using algorithms incorporating load data for common activities. We have previously shown that the BPAQ predicts DXA-derived bone mass at clinically important sites in young adults better than other more generic measures of physical activity. The ability of the BPAQ to predict important indices of bone strength such as peripheral quantitative computed tomography (pQCT)-derived volumetric, geometric or composite strength parameters, however, was unknown.

**PURPOSE:** The aim of the current study was to determine the ability of the BPAQ to predict pQCT-derived bone strength parameters of the tibia.

**METHODS:** We recruited 427 healthy males and females between the ages of 5 and 77 years. Participants completed the BPAQ and a current (previous 12 months), past (birth to 12 months prior) and total physical activity score was calculated. Dominant tibiae were scanned using pQCT (XCT-3000, Stratec, Germany) at the 4% and 38% sites. Total density, cortical density, and trabecular density were calculated using host software. Additional composite and density-weighted strength parameters including strength-strain index (SSI) and fracture load were derived. Correlation and regression analyses were performed to determine relationships between BPAQ scores and parameters of tibial bone strength. Additionally, BPAQ predictors of bone strength were determined for young, middle, and older age groups.

**RESULTS:** Positive relationships were found between BPAQ scores and fracture load and SSI at the 38% sites for bending and torsional loads (r = 0.17-0.36, p<0.05). Current and past BPAQ scores predicted 4-19% of the variance in strength parameters (p<0.05). Alone, past BPAQ score predicted around 12% of the variance in bone strength parameters, and current BPAQ score added an additional 8% predictive ability to the model. Stratified by age group, the ability of the BPAQ to predict strength was greater for older subjects (R<sup>2</sup> = 0.20-0.53; p<0.05) than younger subjects (R<sup>2</sup> = 0.04-0.06; p<0.05).

**CONCLUSIONS:** Lifetime habitual mechanical loading determined by BPAQ predicts pQCT-derived bone strength indices of the tibia, and predictions strengthen with age.

**2770** Board #42 June 1 11:00 AM - 12:30 PM  
**Body Composition and Estrogen Exposure Display Differing Influences on Indices of Bone Health**  
Rebecca J. Toombs, Nancy I. Williams, FACSM, Mary Jane De Souza, FACSM. Penn State University, University Park, PA.  
(No relationships reported)

Dual-energy x-ray absorptiometry (DXA) measures areal bone mineral density (aBMD) rather than true volumetric BMD and geometrical properties. To provide better measurements of bone health when 3-dimensional imaging techniques are not available, DXA estimates of lumbar spine volumetric density and femoral neck strength have been created.

**PURPOSE:** This study explores the roles of body composition and estrogen exposure (E1G AUC) on lumbar spine bone mineral apparent density (BMAD), an estimate of volumetric density, and femoral neck cross sectional moment of inertia (CSMI) and cross sectional area (CSA), indices of bone strength, among exercising women.

**METHODS:** Body composition and aBMD were assessed by DXA in young, exercising women (n=58). BMAD was calculated from lumbar spine bone mineral content and area. In a subset of women, CSMI and CSA were estimated by the DXA software (n=25). Estrone-1-glucuronide was measured in daily urine samples collected for one cycle or monitoring period. Stepwise regression was used to determine the strongest predictors of BMAD, CSMI, and CSA.

**RESULTS:** Exercising ovulatory (Ov, n=31) and amenorrheic (Amen, n=27) women aged 23.1±0.8 years were similar in body mass (58.0±1.0 vs. 56.0±1.5 kg), body mass index (21.4±0.3 vs. 20.4±0.4 kg/m<sup>2</sup>), and lean mass (40.6±0.8 vs. 40.7±0.9 kg); however, Ov women had significantly higher percent body fat (26.2±0.7 vs. 23.4±1.2%, p=0.041) and BMAD (0.164±0.003 vs.

0.146±0.003 g/cm<sup>3</sup>, p<0.001) than the Amen women. CSMI and CSA did not differ between groups (Ov, n=11; Amen, n=14). When percent body fat, lean mass, and EIG AUC were entered into the model, only EIG AUC was a significant predictor of BMAD, explaining 14.0% of the variance, for all exercising women. However, lean mass and percent body fat but not EIG AUC were significant predictors of CSMI and CSA, together explaining 53.4% and 59.2% of the variance, respectively, among a subset of exercising women.

**CONCLUSION:** Among exercising women displaying a wide range of estrogen concentrations and percent body fat, EIG AUC was an important determinant of estimated volumetric density at the lumbar spine; whereas, body composition was a strong predictor of estimates of femoral neck strength.

Supported by the U.S. DoD, Army Medical Research and Materiel Command (PR054531).

2771 Board #43 June 1 11:00 AM - 12:30 PM

**Moderate Alcohol Intake Lowers Biochemical Markers Of Bone Turnover In Postmenopausal Women.**

Gianni F. Maddalozzo, FACSM<sup>1</sup>, Jill A. Marrone<sup>1</sup>, Adam Branscum<sup>1</sup>, Karin Hardin<sup>1</sup>, Lynn Cialdella-Kam<sup>1</sup>, Kenneth A. Philbrick<sup>1</sup>, Anne C. Breggia<sup>2</sup>, Clifford J. Rosen<sup>2</sup>, Russel T. Turner<sup>1</sup>, Urszula T. Iwaniec<sup>1</sup>. <sup>1</sup>Oregon State University, Corvallis, OR. <sup>2</sup>Maine Medical Center Research Institute, Scarborough, ME.  
(No relationships reported)

Epidemiological studies indicate that higher bone mass is associated with moderate alcohol consumption in postmenopausal women. However, the mechanisms for the putative beneficial effects of alcohol on bone are unknown. Excessive bone turnover, combined with an imbalance whereby bone resorption exceeds bone formation, is the principal cause for postmenopausal bone loss.

**PURPOSE:** This study investigated the hypothesis that moderate alcohol attenuates bone turnover following menopause.

**METHODS:** Serum levels of the formation marker osteocalcin and resorption marker CTx were measured following alcohol withdrawal for 14 days in 40 healthy postmenopausal women (56.3 ± 0.5 years of age, mean ± SE) who consumed 19 ± 1 g alcohol/day. Participants then consumed alcohol and were assayed the following morning.

**RESULTS:** Simple linear regression model was used to assess the relationship between alcohol intake and BMD, osteocalcin, and CTx at baseline. The correlation between serum osteocalcin and CTx was evaluated by linear regression using log-transformed data. To determine whether osteocalcin and CTx increased after abstinence from alcohol as predicted, a one-sided paired t-test was performed. One-sided paired t-tests were also used to determine if osteocalcin and CTx decreased on day 15 as predicted after participants consumed alcohol on the evening of day 14. At study initiation, bone mineral density at the trochanter and total hip were positively correlated to level of alcohol consumption. Serum osteocalcin and CTx increased following abstinence (4.1 ± 1.6%; p = 0.01 and 5.8 ± 2.6%; p = 0.02 compared to baseline, respectively). Osteocalcin and CTx decreased following alcohol re-administration compared to the previous day (-3.4 ± 1.4%; p = 0.01 and -3.5 ± 2.1%; p = 0.05, respectively), to values that did not differ from baseline (p>0.05).

**CONCLUSIONS:** Abstinence from alcohol resulted in increased markers of bone turnover whereas resumption of alcohol reduced bone turnover markers. These results suggest a cellular mechanism for the increased bone density observed in postmenopausal moderate alcohol consumers. Specifically, the inhibitory effect of alcohol on bone turnover attenuates the detrimental skeletal consequences of excessive bone turnover associated with menopause.

**Effects Of Caffeine Gum Use On Supramaximal Cycle Time To Exhaustion**

Kelly E. Johnson, Ken R. Drago, Eliseo A. Gonzalez, Wendy E.S. Repovich, FACSM. Eastern Washington University, Cheney, WA.  
(No relationships reported)

**PURPOSE:** This study examined the ergogenic effects of caffeine gum (CG) providing 120 mg of caffeine on total time to exhaustion (TTE) via a supramaximal cycle time to exhaustion test (STTE) at 120% of VO<sub>2peak</sub>.

**METHODS:** Seventeen, moderately active college students (23.2 ± 3.3 yrs old) volunteered for participation. To determine the 120% supramaximal test intensity subjects underwent three exercise bouts. First they completed a VO<sub>2peak</sub> test on an AB 839e cycle ergometer, which consisted of 2 min stages with increases of 50 Watts (W) per stage to volitional exhaustion. Both the respiratory exchange ratio (RER) and VO<sub>2</sub> were averaged over the last 30-s of each stage. The RER and VO<sub>2</sub> were then interpolated to calculate intensities corresponding to 15% and 30% of VO<sub>2peak</sub>. Subjects then cycled at these two intensities for 10-minutes each. The last 1min VO<sub>2</sub> average for each sub maximal test was plotted against their intensity of their VO<sub>2peak</sub> to extrapolate the workload at 120% VO<sub>2peak</sub>. Three STTE sessions were done using the Monark AB 839e cycle ergometer, a familiarization session, followed by two double-blind randomly assigned tests with CG or a placebo (PG). Subjects received and chewed either six pieces of CG or six pieces of PG for 5 minutes followed by 20 minutes of rest and a 10-minute warm up. To start the test subjects cycled at 70 repetitions per minute until there was a one minute plateau in VO<sub>2</sub>. The supramaximal intensity test began when the resistance was applied without warning to avoid anticipatory changes in VO<sub>2</sub> and VCO<sub>2</sub> kinetics. The length of time was recorded as the TTE.

**RESULTS:** Though TTE in seconds was longer with CG - 311.82 ± 119.28 vs. ± 119.28 using a paired t-test no significant differences were found for any variable (condition p=0.268, gender p=0.112, habituation p=0.873, condition by gender p=0.894, condition by habituation p=0.736, and condition by gender by habituation p=0.494).

**CONCLUSIONS:** The results of this study via CG revealed no significant differences for any variables measured. Therefore, this suggests that CG is no different than any other delivery method (patch or pills) for affecting supramaximal exercise.

2773 Board #45 June 1 9:30 AM - 11:00 AM

**The Effect of Caffeine on Anaerobic Performance: A Preliminary Study**

Steven R. Cherekos, Jonathan M. Engholm, Marie Boo, Anthony Bozzo, Mary C. Stenson. College of Saint Benedict and Saint John's University, Saint Joseph, MN.  
(Sponsor: Vincent J. Paolone, FACSM)  
(No relationships reported)

The ergogenic effects of caffeine on endurance exercise have been well documented; however, the effects of caffeine on maximal anaerobic exercise are not as well researched.

**PURPOSE:** To determine the effects of caffeine ingestion on anaerobic run test performance in college aged male and female club-sport athletes.

**METHODS:** A randomized, double-blind study was conducted on 4 healthy, active women and 4 healthy, active men (n=8). Subjects performed a maximal anaerobic run test (treadmill set at 7 mph at a 20% grade) 60 minutes after ingestion of 6 oz. sugar-free lemonade (placebo) or 6 oz. sugar-free lemonade with caffeine (5 mg/kg body mass). Heart rate, run time, and rating of perceived exertion (RPE) were recorded immediately at the end of the test. A series of 2x2 repeated measures ANOVAs were used to identify the influence of treatment and gender on time, work, power, and RPE.

**RESULTS:** No significant interaction was found between gender and treatment for run time with caffeine (Females (F): 40.25 ± 6.4s, Males (M): 57.3 ± 6.4s p>.05) and without caffeine (F: 34.0 ± 5.8s, M: 61.8 ± 5.8 s, p>.05). Three of the four females increased performance during the caffeine trial by an average of 8.7 ± 8.96s, while three of the four males decreased performance during the caffeine trial by an average of 7.3 ± 5.13s. No significant differences (p>.05) were found for RPE, power, or work between trial and gender.

**CONCLUSIONS:** Ingestion of 5 mg/kg body mass of caffeine 60 min prior to exercise may narrow the gender differences in time to exhaustion during maximal anaerobic exercise.

2774 Board #46 June 1 9:30 AM - 11:00 AM

**The Effect of Caffeine on Tennis Skill Performance in Collegiate Tennis Players**

Courtney S. Klein, Adam Clawson, Michael Martin, Michael J. Saunders, FACSM, Judith A. Flohr, Christopher J. Womack, FACSM, Marta K. Bechtel, Wade Dunham, Melyssa Hancock. *James Madison University, Harrisonburg, VA.*  
(No relationships reported)

Several prior studies confirm the efficacy of caffeine supplementation on endurance performance, yet there exists a paucity of data on the effect of caffeine on tennis performance. Pilot data from our lab suggest that a polymorphism of the CYP1A2 gene is associated with ergogenic caffeine response in cycling but this association is unknown for other athletic events.

**PURPOSE:** This study examined the efficacy of caffeine supplementation on tennis performance and whether a polymorphism of the CYP1A2 gene influenced the ergogenic response to caffeine.

**METHODS:** 18 (nine males, nine females) NCAA Division-1 collegiate tennis players (Ht = 176.0 ± 11.1 cm, Wt = 69.8 ± 12.0 kg, VO<sub>2</sub>max = 51.7 ± 5.9 ml/kg/min) completed two separate trials one hour after the ingestion of either 6 mg/kg of caffeine or a placebo, in double-blind fashion. The trials consisted of both 45 minutes of intermittent treadmill work (TW) and a tennis performance test (TPT). Average RPE and HR were recorded for both the TW and TPT. TPT involved nine repeated sessions in which a 6-ball drill (4 groundstrokes, 1 approach shot and 1 volley) was repeated 6 times. The total number of successful shots that they accrued (out of a possible 324) was recorded. DNA was obtained from whole blood samples and analyzed for presence of the C variant using polymerase chain reaction with allele-specific primers. Subjects were classified as AA homozygotes (N=7) or C allele carriers (N=9). Data were analyzed via a repeated measures ANOVA with treatment (caffeine, placebo) as the within-subjects factor and genotype as the between-subjects factor.

**RESULTS:** There was a main effect for treatment whereby caffeine significantly ( $P < 0.05$ ) improved the number of successful shots during the TPT (Caffeine = 295 ± 11 shots, Placebo = 289 ± 10 shots). There was also a strong trend ( $P = 0.052$ ) for a genotype x treatment interaction for HR during the TPT as caffeine raised HR in the AA homozygotes (Caffeine = 155 ± 17 beats/min, Placebo = 149 ± 13 beats/min) but not the C allele carriers (Caffeine = 150 ± 16 beats/min, Placebo = 153 ± 16 beats/min).

**CONCLUSION:** Caffeine supplementation positively impacts tennis performance in collegiate tennis players. There may be preliminary support for a greater physiological effect of caffeine in AA homozygotes.

2775 Board #47 June 1 9:30 AM - 11:00 AM

**Does Caffeine Intake Increases Energy Expenditure And Habitual Physical Activity? A Double-blind Randomized Crossover Trial**

Pedro B. Júdice, Analiza M. Silva, João P. Magalhães, Catarina N. Matias, Diana A. Santos, Paulo Armada-da-silva, Luís B. Sardinha. *Technical University of Lisbon, Lisbon, Portugal.*  
(No relationships reported)

Although the effect of caffeine on energy expenditure has been studied, its influence on physical activity (PA) during free-living conditions using objective measures of PA is limited.

**PURPOSE:** This study aimed to determine the impact of a moderate dose of caffeine on resting energy expenditure (REE), PA energy expenditure (PAEE), total energy expenditure (TEE), and daily time spent in sedentary (DTSS), light (DTSL), moderate (DTSM), and vigorous (DTSV) intensity activities in non-obese physically active males.

**METHODS:** A total of 30 non-smoker males, low caffeine users (<100 mg/day), aged 20-39 yrs [body mass (BM): 72.7 ± 8.8 kg; Height: 1.77 ± 0.07 m] were followed in a double-blind crossover experimental design with two conditions in a random sequence: caffeine (5 mg per kg of BM/day) and malt-dextrine as placebo, both through capsules. Conditions lasted for 4 days with a 3-day washout period. Evaluations were performed at baseline (visit-1), end of condition 1 (visit-2), and end of condition 2 (visit-3). Fat and fat-free masses (FFM) were assessed by dual energy x-ray absorptiometry. Accelerometry was used to estimate TEE, DTSS, DTSL, DTSM, and DTSV. REE was assessed by indirect calorimetry and PAEE calculated as [TEE - (REE + 0.1TEE)]. Daily food records were obtained. Repeated measures ANOVA and ANCOVA were used.

**RESULTS:** No differences were found ( $p > 0.05$ ) between caffeine and placebo intake for TEE (-0.1 ± 1310.0 kJ/day), REE (48 ± 687 kJ/day), PAEE (48 ± 1269 kJ/day), DTSS (-1 ± 61 min), DTSL (4 ± 36 min), DTSM (-3 ± 31 min), and DTSV (0.3 ± 4.6 min). After adjusting for FFM, caffeine increased DTSL compared to placebo (3.5 ± 5.8 min;  $p = 0.029$ ) but no differences ( $p > 0.05$ ) were observed for TEE (-0.1 ± 243.0 kJ/day), REE (48 ± 130 kJ/day), PAEE (48 ± 237 kJ/day), DTSS (-0.8 ± 10.4 min), DTSM (-3 ± 6 min), and DTSV (0.3 ± 0.8 min). No change in energy and macronutrients intake occurred over the trial ( $p > 0.05$ ).

**CONCLUSION:** Though a large individual variability was observed, a moderate dose of caffeine, independently of FFM, did not increase REE, TEE, and PAEE neither changed the DTSS, DTSM, and DTSV intensity activities in active young males, non-caffeine regular users. However, further research is required to understand the role of FFM as a mediator of the caffeine effect on the increased amount of time spent in light intensity activities.

2776 Board #48 June 1 9:30 AM - 11:00 AM

**Pre-Exercise Caffeine Ingestion Increases Post-Exercise Energy Expenditure**

Valentin E. Fernandez-Elias<sup>1</sup>, Juan Del Coso<sup>2</sup>, Juan F. Ortega<sup>1</sup>, Nassim Hamouti<sup>1</sup>, Ricardo Mora-Rodriguez<sup>1</sup>. <sup>1</sup>University of Castilla La Mancha, Toledo, Spain.  
<sup>2</sup>University of Castilla La Mancha, Madrid, Spain.  
(No relationships reported)

Caffeine is an ergogenic aid widely used prior and during prolonged exercise. However, its effects post-exercise are not well described.

**PURPOSE:** To investigate the metabolic, respiratory and cardiovascular post-exercise responses to graded caffeine ingestion.

**METHODS:** A randomized, double-blind, placebo controlled experimental design was used, with all subjects serving as their own controls. Twelve aerobically trained subjects (6 men and 6 women; mean VO<sub>2</sub>max = 54 ± 7 mL · min<sup>-1</sup> · kg<sup>-1</sup>) cycled for 60-min at 75% VO<sub>2</sub>max after ingesting placebo (0 mg · kg<sup>-1</sup> of caffeine) or 1, 3, 6 and 9 mg of caffeine per kg. Hourly during the 3 hours post-exercise, heart rate, blood pressure, ventilatory parameters were measured and blood samples analyzed for glucose, lactate and fatty acids. From VO<sub>2</sub> and VCO<sub>2</sub>, energy expenditure and substrate oxidation were calculated.

**RESULTS:** Pre-exercise ingestion of 9 mg · kg<sup>-1</sup> of caffeine raised 3-h post-exercise energy cost 15 % in comparison to placebo (233 ± 58 vs. 202 ± 49 kcal;  $P < 0.05$ ). Ventilation rate and tidal volume were elevated after the 9 mg · kg<sup>-1</sup> of caffeine compared to placebo (9.2 ± 2.5 L · min<sup>-1</sup> and 0.67 ± 0.29 L · breath<sup>-1</sup> vs. 7.8 ± 1.5 L · min<sup>-1</sup> and 0.56 ± 0.20 L · breath<sup>-1</sup>, respectively;  $P < 0.05$ ). In these two trials, tidal volume and ventilation were highly correlated ( $R^2 = 0.91$ ;  $P < 0.05$ ). Energy expenditure and ventilation were also highly correlated ( $R^2 = 0.88$ ;  $P < 0.05$ ). No significant differences were found among trials for substrate oxidation, heart rate, blood pressure, plasma glucose, lactate and free fatty acids.

**CONCLUSIONS:** Pre-exercise caffeine ingestion increased by 15% post-exercise energy expenditure only when ingesting a high dose (i.e., 9 mg · kg<sup>-1</sup>). Our data suggest that this increase in energy cost was mediated by increased tidal volume and ventilation. On the other hand, pre-exercise ingestion of a wide range of caffeine doses (1-9 mg · kg<sup>-1</sup>) does not alter the post-exercise cardiovascular response.

2777 Board #49 June 1 9:30 AM - 11:00 AM

**Assessing the Acute Influence of Perceived versus Actual Caffeine Intake on Aspects of Aerobic Performance**

Matthew J. Shaw, Justin D. Roberts. *University of Hertfordshire, Hatfield, United Kingdom.*  
(No relationships reported)

Various mechanisms have been proposed for the ergogenic effect of caffeine. In particular, increased neuromuscular activation, reduced perceptual effort and greater circulating catecholamines may favour endurance performance. However, for shorter high intensity events the potential for 'perceived' benefits may also be pertinent for performance gains.

**PURPOSE:** To determine whether caffeine supplementation is more effective at enhancing aerobic performance compared to both placebo and deception trials.

**METHODS:** Following familiarisation, 10 healthy males (age: 21.36 ± 0.76 years; weight: 73.81 ± 9.21 kg; VO<sub>2</sub>max: 46.91 ± 3.71 mL · kg<sup>-1</sup> · min<sup>-1</sup>) undertook 3x15km performance trials on a cycle ergometer. Subjects were randomly assigned either capsulated low dose caffeine (CA3 - 3mg · kg<sup>-1</sup> · bw<sup>-1</sup>), high dose caffeine (CA9 - 9mg · kg<sup>-1</sup> · bw<sup>-1</sup>) or cornflour placebo (PL). However, in one

of the caffeine trials subjects undertook a deception trial whereby PL was provided instead. During each trial, expired air analysis ( $\text{VO}_2$ :  $\text{L}\cdot\text{min}^{-1}$ ), power: weight ratio (P/W:  $\text{W}\cdot\text{kg}^{-1}$ ), cycling speed (kph), heart rate (HR: bpm), perceived exertion (RPE) and performance times were assessed.

**RESULTS:** Performance times significantly improved in CA9 compared to PL only ( $1708.40\pm 21.53$  and  $1820\pm 26.47$  seconds respectively,  $P=0.05$ ). No significant differences were observed across deception trials for performance times in comparison to PL, despite improvements during perceived CA3 or CA9 trials ( $1759.60\pm 19.06$  and  $1745.00\pm 15.51$  seconds respectively,  $P=0.09$ ). No significant differences were observed across trials for  $\text{VO}_2$ , HR or RPE indicating comparable intensity. No significant differences were observed for P/W, although higher ratios were observed in the perceived CA9 ( $2.55\pm 0.19 \text{ W}\cdot\text{kg}^{-1}$ ), actual CA3 ( $2.58\pm 0.16 \text{ W}\cdot\text{kg}^{-1}$ ) and CA9 ( $2.56\pm 0.37 \text{ W}\cdot\text{kg}^{-1}$ ) trials compared to PL ( $2.26\pm 0.10 \text{ W}\cdot\text{kg}^{-1}$ ). Average speed was significantly greater in CA9 compared to PL only ( $31.63\pm 0.40$  kph and  $29.72\pm 0.42$  kph respectively,  $P=0.04$ ).

**CONCLUSION:** Whilst 'perceived' benefits of caffeine ingestion may support exercise performance, significant effects may only be observed following consumption of higher dosages of actual caffeine. As perceived effort was not reduced, ergogenic benefits may be explained through increased myofibrillar recruitment.

---

**2778 Board #50 June 1 9:30 AM - 11:00 AM**  
**Dose-dependence Of Caffeine Supplementation On Cycling Performance**

Michael Martin, Nicholas D. Luden, Courtney S. Klein, Michael J. Saunders, FACSM, Marta K. Bechtel, Wade Dunham, Melyssa Hancock, Christopher J. Womack, FACSM. *James Madison University, Harrisonburg, VA.*  
(No relationships reported)

Prior data on the dose-dependence of caffeine supplementation for cycling performance is equivocal. The mechanisms influencing the variability of caffeine response are not fully known, although our lab has observed that a polymorphism of the CYP1A2 gene influences the ergogenic effect of caffeine.

**PURPOSE:** This study examined the effect of caffeine supplementation at two different dosages (3 and 6 mg/kg body weight) on a 40-km cycling time trial. We further sought to obtain initial data on whether the CYP1A2 polymorphism influenced the response at both a lower and high caffeine dose.

**METHODS:** 16 male cyclists (Ht =  $176.6 \pm 6.8$  cm, Wt =  $71.8 \pm 7.8$  kg,  $\text{VO}_{2\text{max}}$  =  $64.7 \pm 9.1$  ml/kg/min) completed three separate computer-simulated 40-km cycling time trials one hour after the ingestion of 3 mg/kg caffeine, 6 mg/kg caffeine and a placebo. Subjects were genotyped for the polymorphism of the CYP1A2 gene and classified as AA homozygotes (N=6) or C allele carriers (N=10). Data were analyzed via a repeated measures ANOVA with treatment as the within-subjects factor and genotype as the between-subjects factor.

**RESULTS:** There was a main effect for treatment whereby both doses of caffeine significantly ( $P < 0.05$ ) improved 40-km time (Placebo =  $74.1 \pm 5.4$  min, 3 mg/kg =  $72.7 \pm 4.6$  min, 6 mg/kg =  $71.6 \pm 4.7$  min). There were no significant differences between 40-km time at the two different caffeine doses. There was a trend ( $P = 0.10$ ) for a genotype x treatment interaction, whereby a greater magnitude of decrease in 40-km time was evident in the AA homozygotes (4.6% improvement at the 6 mg/kg dose) as compared to the C allele carriers (2.6% improvement at the 6 mg/kg dose).

**CONCLUSION:** Both a 3 mg/kg and a 6 mg/dose of caffeine improve 40-km cycling time. The magnitude of the effect was not significantly different between the two doses although the higher dose resulted in a performance one minute faster than the lower dose. Preliminary data support previous results, in that the effect of caffeine may be larger in AA homozygotes.

**2779 Board #51 June 1 9:30 AM - 11:00 AM**  
**Caffeine Does Not Affect Improvements In Cognition During Prolonged High-Intensity Exercise In Alert, Well-Trained Individuals**

Dennis P. Pollow, Jr, Brian T. Williams, Donald A. Joyce, Guogen Shan, Jennifer L. Temple, Luc E. Gosselin, FACSM, Peter J. Horvath. *State University of New York at Buffalo, Buffalo, NY.*  
(No relationships reported)

Evidence suggests that caffeine can act as an ergogenic aid during endurance exercise. While caffeine ingestion has been shown to improve cycling performance times in time trial races and exhaustive exercise, few studies have tested for cognitive function improvements during these tests.

**PURPOSE:** 1) To determine if caffeine ingestion can affect cognitive function and exercise performance outcomes during prolonged intense cycling and 2) To determine if the type of exercise trial can alter the effects of caffeine.

**METHODS:** Seven well-trained cyclists and triathletes ( $26.9 \pm 3.9$  y,  $\text{VO}_{2\text{peak}}$   $67.7 \pm 10.3 \text{ mL}\cdot\text{kg}^{-1}\cdot\text{h}^{-1}$ ) completed two trials to exhaustion at 90%  $\text{VO}_{2\text{peak}}$  and two 50k time trials, one hour after consuming a carbohydrate-electrolyte beverage (5ml/kg, 6.3% CHO, 18mmol/l sodium) and a capsule containing either 6 mg/kg caffeine or placebo (double-blind crossover design). Cognitive function was measured before and after exercise using a computerized ANAM® test and Stroop word-color test (also conducted during exercise).

**RESULTS:** Average wakefulness scores at baseline were  $1.9 \pm 0.5$ , indicating that subjects were at near peak alertness. After either exercise trial type, ANAM thruput scores increased by 9.4% compared to baseline ( $P < 0.0001$ ), while Stroop word-color test response time improved by 17.8% ( $P < 0.0001$ ). Neither cognitive test result was altered by the addition of caffeine. Caffeine did not significantly change exercise performance in either trial type. However, subjects were able to cycle an average of 65% longer during their second time to exhaustion trial compared to the first, regardless of supplementation (mean time = 78.4 and 51.5 min. respectively,  $P < 0.001$ ).

**CONCLUSION:** In alert, well trained athletes, high intensity endurance exercise can significantly improve simple and complex cognitive function, but is not enhanced with the addition of caffeine. The type of exercise trial does not alter the exercise-induced changes in cognitive function.

**2780 Board #52 June 1 9:30 AM - 11:00 AM**  
**Increased Time-trial Performance with Caffeine Ingestion is Independent of Fitness Level**

Jessica Duhon, Trisha Cottrell, Andrea Talhami Lozano, Kylan Aburto-Pratt, Todd A. Astorino. *CSU- San Marcos, San Marcos, CA.*  
(No relationships reported)

Previous data show that caffeine is an ergogenic aid for endurance exercise; however, the exact mechanism explaining its performance-enhancing effect is unidentified. Some speculate that it is only ergogenic in trained muscle.

**PURPOSE:** To examine the effects of caffeine intake on cycling performance in both endurance trained and recreationally active individuals.

**METHODS:** Eight endurance trained and 8 active men completed five trials of cycling on an electrically-braked cycle ergometer, with each bout separated by at least 48 h.  $\text{VO}_{2\text{max}}$  was higher ( $p < 0.05$ ) in trained ( $57.5 \pm 3.9 \text{ mL/kg/min}$ ) versus active men ( $46.5 \pm 6.3 \text{ mL/kg/min}$ ). Subjects completed two familiarization trials and three experimental trials over a 2 - 3 week period, with sessions consisting of a 10 km time trial simulating competitive cycling, characterized by changes in terrain. Drinks administered included two boluses of 5 mg/kg caffeine (C1 and C2) or placebo (PL = 5 mg/kg of glucose), which were mixed with 255 mL of cold water, diet 7-Up, and 1 package of Crystal Light and ingested 1 h pre-exercise. Subjects were blinded to the order of drink assignment, which was randomized, and were told that drinks contained carbohydrate to minimize placebo effects of caffeine. Heart rate (HR), Rating of Perceived Exertion (RPE), and time were recorded every 1.6 km. Repeated measures analysis of variance was used to evaluate differences in variables across distance and treatment.

**RESULTS:** Time trial performance was significantly increased ( $p < 0.05$ ) in both caffeine trials versus placebo for trained (C1 =  $17.07 \pm 0.99$  min; C2 =  $17.01 \pm 1.0$  min; PL =  $17.35 \pm 0.98$  min) and active men (C1 =  $18.50 \pm 0.61$  min; C2 =  $18.65 \pm 0.80$  min; PL =  $18.71 \pm 0.68$  min); however, there was no difference observed across fitness level (treatment X group interaction  $p > 0.05$ ). In both groups, 6 of 8 men revealed improved performance in C1 (-0.21 min) and C2 (-0.23 min) compared to placebo. HR and RPE increased during exercise ( $p < 0.05$ ) but were unaltered across treatment ( $p > 0.05$ ).

**CONCLUSIONS:** Caffeine was ergogenic for brief (< 20 min) "all-out" cycling performance in highly trained and moderately active individuals. Additional research is merited to confirm these findings in men and women varying in fitness level during other modalities of exercise.

2781 Board #53 June 1 9:30 AM - 11:00 AM

**The Metabolic And Performance Effects Of Caffeine Compared To Coffee During Exercise**

Rebecca Randell, Adrian B. Hodgson, Asker E. Jeukendrup. *University of Birmingham, Birmingham, United Kingdom.*  
(No relationships reported)

**BACKGROUND:** There is consistent evidence supporting the ergogenic effects following caffeine ingestion during exercise. Whether caffeine delivered through coffee has the same effects is still subject to debate.

**PURPOSE:** 1) To investigate the metabolic effects of caffeine and coffee during moderate intensity exercise. 2) To compare the performance enhancing effects of caffeine and coffee.

**METHODS:** In a single-blind, crossover study design, eight trained male cyclists/triathletes (Mean  $\pm$  SD: Age 36 $\pm$ 6y, Height 1.80 $\pm$ 0.04m, Weight 76.3 $\pm$ 7.2kg,  $\dot{V}O_2$  max 56.1 $\pm$ 6.9 ml/kg/min) completed 30 min of steady-state (SS) cycling at approximately 55%  $\dot{V}O_2$ max followed by a time trial (TT) lasting approximately 45 min. One hour prior to exercise each athlete consumed drinks consisting of either caffeine (5mg/kg), instant coffee (5mg/kg), instant decaf coffee or placebo.

**RESULTS:** The set workloads produced similar relative exercise intensities during the SS of 54.6% $\pm$ 0.7%, 55.4% $\pm$ 2.4%, 54.7% $\pm$ 2.7%, 55.0% $\pm$ 2.0%  $\dot{V}O_2$  max for caffeine, coffee, decaf and placebo respectively. There was no observed difference in carbohydrate or fat oxidation during SS for any of the ingested supplements. Performance times during the TT were significantly faster (~4.0%) for both caffeine and coffee when compared to placebo and decaf (39.51 $\pm$ 2.70, 39.40 $\pm$ 2.48, 41.38 $\pm$ 1.10, 40.31 $\pm$ 1.31 min respectively,  $p$ <0.05). The improvements in performance time were similar for both caffeine and coffee. Average power for caffeine and coffee during the TT was significantly greater when compared to placebo and decaf (267 $\pm$ 24W, 269 $\pm$ 24W, 260 $\pm$ 23W, 257 $\pm$ 16W respectively,  $p$ <0.05). No significant differences were observed between placebo and decaf during the TT.

**CONCLUSION:** The present study illustrates that both caffeine (5mg/kg) and coffee (5mg/kg) consumed 1 hour prior to exercise can improve endurance exercise performance. These improvements cannot be attributed to alterations in substrate metabolism as no change in fat oxidation was observed during the SS.

2782 Board #54 June 1 9:30 AM - 11:00 AM

**Does Effect of Caffeine Ingestion on Acute Hormonal Responses to Resistance Exercise**

Bo-Han Wu<sup>1</sup>, C.H. Yeh<sup>2</sup>, Jung-Chang Lin<sup>3</sup>. <sup>1</sup>Pingtung University of Science and Technology, Pingtung, Taiwan. <sup>2</sup>Chang Jung Christian University, Tainan, Taiwan. <sup>3</sup>Chinese Culture University, Taipei, Taiwan.

(No relationships reported)

Caffeine ingestion has been shown to affect hormonal responses to resistance exercise. However, few studies examined the dose effect of caffeine ingestion on acute hormonal responses to a single bout of resistance exercise.

**PURPOSE:** The purpose of this study was to investigate the dose effect of caffeine ingestion on acute hormonal responses to resistance exercise (RE).

**METHODS:** Twelve well-trained college male students (age, 21 $\pm$ 1.1 yr; mass, 72.8 $\pm$ 12.1 kg) who regularly perform RE participated in this study. All subjects perform 1RM test, then perform four treatments: high dose (HD, 6mg/kg), medium dose (MD, 4mg/kg), low dose (LD, 2mg/kg) and control (CON) in counter balance order. All subject intake caffeine 1 hour prior to RE, then, the subjects perform RE (2 exercises, 3 sets of 10 repetitions at 75% of 1RM). Blood samples collect prior to caffeine intake (pre-60), immediately prior to RE (pre-exe), and 0, 15, 30 min after RE (P0, P15, P30) for analysis of testosterone, cortisol, insulin, growth hormone, glucose, lactate and free fatty acid. Each experiment separated by 7 days. In this study, statistical analysis of a two-way analysis of variance (treatment by time) with repeated measures is applied. Statistical significance set at  $\alpha$  =.05.

**RESULTS:** After ingesting caffeine, the concentrations of free fatty acid (pre-exe) in HD, MD and LD (0.76 $\pm$ 0.12, 0.67 $\pm$ 0.17 and 0.46 $\pm$ 0.11 mmol/L) were significantly higher than CON (0.36 $\pm$ 0.05 mmol/L) ( $p$ <0.05). The responses of testosterone (P0, P15, P30) (10.87 $\pm$ 1.19, 10.23 $\pm$ 1.47 and 9.75 $\pm$ 1.32 vs. 8.15 $\pm$ 2.27, 8.15 $\pm$ 2.38 and 7.88 $\pm$ 2.47 ng/ml,  $p$ <0.05) and cortisol (pre-exe, P0, P30) (43.8 $\pm$ 10.46, 52.5 $\pm$ 10.68 and 48.57 $\pm$ 11.46 vs. 32.89 $\pm$ 11.87, 39.51 $\pm$ 13.88 and 37.72 $\pm$ 11.80 ng/ml,  $p$ <0.05) were significantly higher than CON in HD. In addition, the responses of GH (P15 & P30) (4.48 $\pm$ 2.93, 3.44 $\pm$ 2.15 vs. 6.77 $\pm$ 4.29, 5.32 $\pm$ 3.87 ng/ml,  $p$ <0.05) and insulin (P0, P15, P30) (33.22 $\pm$ 12.09, 32.98 $\pm$ 20.19 and 29.90 $\pm$ 12.78 vs. 45.83 $\pm$ 18.42, 45.82 $\pm$ 21.93 and 38.98 $\pm$ 22.20 pmol/L,  $p$ <0.05) were significantly lower than CON in HD and MD.

**CONCLUSION:** The results of this study indicated that moderate dose ( $\geq$ 4mg/kg) of caffeine ingestion prior to RE will significant affect the responses of anabolic and catabolic hormones around RE.

2783 Board #55 June 1 9:30 AM - 11:00 AM

**Acute Effects of Caffeine on Strength and Electromechanical Efficiency of the Biceps Brachii**

Michael A. Trevino<sup>1</sup>, Jared W. Coburn, FACSM<sup>1</sup>, Lee E. Brown, FACSM<sup>1</sup>, Daniel A. Judelson, FACSM<sup>1</sup>, Moh H. Malek, FACSM<sup>2</sup>. <sup>1</sup>California State University, Fullerton, Fullerton, CA. <sup>2</sup>Wayne State University, Detroit, CA.

(No relationships reported)

**PURPOSE:** Previous studies have suggested that caffeine may provide performance benefits during aerobic activities. The findings for strength and anaerobic performance, however, have been mixed. The purpose of this study was to examine the effects of caffeine on strength, mechanomyographic (MMG) amplitude, electromyographic (EMG) amplitude, and electromechanical efficiency (EME; the ratio of MMG amplitude to EMG amplitude), evaluated as the ratio of MMG amplitude to EMG amplitude of the biceps brachii.

**METHODS:** Thirteen male volunteers (21.4  $\pm$  1.3 y, 173.4  $\pm$  6.9 cm, 86.2  $\pm$  12.2 kg) came to the laboratory four times ( $\geq$  48 hours between visits). During the first experimental visit, subjects ingested a randomly assigned drink, either with or without caffeine (0, 5, or 10 mg $\cdot$ kg<sup>-1</sup> of body mass), and performed three maximal isometric muscle actions of the elbow flexors sixty minutes after ingestion to determine maximal isometric strength. MMG and EMG amplitude were measured from the biceps brachii during the isometric muscle actions. Visit two was identical to visit one, but one of the remaining two drinks not administered was assigned. Visit three was identical to visit two, but the one remaining drink not assigned was administered.

**RESULTS:** The results indicated that there were no significant differences ( $p$  > 0.05) for maximal strength (78.6  $\pm$  22.2, 79.1  $\pm$  19.0, 80.1  $\pm$  20.7 Nm), MMG amplitude (0.55  $\pm$  0.26, 0.68  $\pm$  0.29, 0.75, 0.56 m $\cdot$ s<sup>-2</sup>), EMG amplitude (0.0009  $\pm$  0.0006, 0.0012  $\pm$  0.0009, 0.0011  $\pm$  0.0007 V), or EME (709.6  $\pm$  302.7, 784.4  $\pm$  466.4, 844.9  $\pm$  727.8 rms MMG/rms EMG [m $\cdot$ s<sup>-2</sup>/V]) among the three caffeine conditions (0, 5, and 10 mg $\cdot$ kg<sup>-1</sup> of body mass, respectively).

**CONCLUSIONS:** The results suggested that ingestion of either 5 or 10 mg $\cdot$ kg<sup>-1</sup> of body mass of caffeine does not enhance strength, nor does it affect MMG, EMG, or EME.

**Caffeine Supplementation and Performance of a Reactive Agility Test in Elite Youth Soccer Players**

J. Bradley Jordan, Ajit D. Korgaokar, Richard S. Farley, Jwa K. Kim, John M. Coons, Jennifer L. Caputo. *Middle Tennessee State University, Murfreesboro, TN.*  
(Sponsor: Don W. Morgan, FACSM)

(No relationships reported)

Caffeine has been shown to provide ergogenic benefits to sports performance. However, limited research is available on the effects of caffeine on agility performance.

**PURPOSE:** The purpose of this study was to examine the effects of 6 mg $\cdot$ kg<sup>-1</sup> body mass of caffeine on performance of a reactive agility test (RAT) in youth soccer players.

**METHODS:** Using a double-blind, repeated-measures design, elite male youth soccer players ( $N$  = 12) completed 4 days of testing on the RAT after a standardized warm-up. Height and body mass were measured and players were accommodated to the RAT on Day 1. Day 2 was used to establish the participants' baseline performance on the RAT. Players were randomly assigned to caffeine or placebo on Day 3 and the condition was reversed on Day 4. Caffeine or placebo was ingested in a gelatin capsule 1 hour prior to performing the RAT. During days 2, 3, and 4, players completed 3 randomized run-throughs of the RAT with at least one run-through to the right and left sides to assess players performance to their dominant and non-dominant sides.

**RESULTS:** There were no significant differences in time to complete the RAT among baseline ( $M = 1.83$  s), caffeine ( $M = 1.78$  s), and placebo ( $M = 1.85$  s) run-throughs to the dominant side, *Wilks' Lambda*  $F(2, 10) = 1.214, p = .337, \eta^2 = .195$ . Also, there were no significant differences in time to complete the RAT between baseline ( $M = 1.85$  s), caffeine ( $M = 1.83$  s), and placebo ( $M = 1.92$  s) run-throughs to the non-dominant side, *Wilks' Lambda*  $F(2, 10) = 3.795, p = .059, \eta^2 = .431$ .

**CONCLUSIONS:** There was a trend toward caffeine improving the time to complete the RAT to the players non-dominant side indicated by the approaching significance value and the effect size. Caffeine may provide ergogenic benefit to elite male youth soccer players on a RAT, and continued research is recommended with a larger sample.

**Caffeine Enhances Time-Trial Performance and Preserves Muscle Activation During Leg, But Not Arm Cycling Exercise**

Christopher D. Black, University of Mississippi, University, MS. (Sponsor: Mark Loftin, FACSM)  
(No relationships reported)

A recent meta-analysis demonstrated that caffeine may lead to greater ergogenic effects on muscular strength and activation in the knee extensors compared to smaller muscle groups of the arms and leg. Few studies have examined whether caffeine exerts differential effects on endurance performance between the knee extensors and other, smaller muscle groups.

**PURPOSE:** To determine the effects of caffeine on muscular strength and activation, and endurance performance during arm and leg cycling.

**METHODS:** Fourteen caffeine naïve (9 women, 5 men) participants were tested on 6 occasions. Arm crank and leg cycling  $VO_{2\text{peak}}$  were determined during the initial two testing sessions. During sessions 3-6, participants performed 2 days of arm cycling and 2 days of leg cycling in a counter-balanced manner. A  $5\text{mg}\cdot\text{kg}^{-1}$  body-weight dose of caffeine or placebo was consumed in a double blind manner, 60 minutes prior to cycling. During the cycling exercise participants cycled for 30 minutes at 60% of  $VO_{2\text{peak}}$ , followed by a 10 minute, maximal effort time-trial. Maximal voluntary isometric strength (MVC), electrically evoked torque (EET), and percent activation (%Act) of the knee extensors (KE) and elbow flexors (EF) were determined using an interpolated-twitch protocol prior to (Pre), 60 minutes post treatment ingestion (Post60), and 20 minutes following the cycling exercise (PostEx).

**RESULTS:** Caffeine demonstrated no effect compared to placebo on  $\Delta\text{MVC}$ ,  $\Delta\text{EET}$ , or  $\Delta\%\text{Act}$  in the KE or EF at the Post60 time point ( $p \geq 0.09$ ) compared to Pre. Caffeine ingestion resulted in significantly greater work during the time-trial during leg ( $115.1 \pm 34$  vs.  $110.5 \pm 36$  kJ;  $p = 0.03$ ), but not arm ( $57.1 \pm 21$  vs.  $56.3 \pm 19$  kJ;  $p = 0.28$ ) cycling compared to placebo. Following the cycling exercise, caffeine preserved  $\Delta\%\text{Act}$  compared to the Post60 values in the KE ( $2.1 \pm 10.5\%$  vs.  $-1.1 \pm 12.5\%$ ;  $p = 0.02$ ) compared to placebo, but not in the EF ( $-7.4 \pm 8.8\%$  vs.  $-6.0 \pm 7.3\%$ ;  $p = 0.59$ ). Significant effects compared to placebo were not found for  $\Delta\text{MVC}$  and  $\Delta\text{EET}$  following cycling.

**CONCLUSIONS:** Caffeine was ergogenic during leg, but not arm cycling and this effect may be attributable to preserved muscle activation in the KE.

**2786** Board #58 June 1 9:30 AM - 11:00 AM  
**Even if Plasma Caffeine is Initially Elevated, Energy Drink Consumption Improves Cycling Performance**

David G. Lassiter, Lynne Kammer, Zhenping Ding, James Burns, Heontae Kim, Joowon Lee, John L. Ivy, FACSM, University of Texas at Austin, Austin, TX.  
(No relationships reported)

Energy drinks have been shown to improve aerobic exercise performance when participants have fasted from caffeine ingestion for 24 hours. The improvement in aerobic exercise performance due to energy drink consumption may be due to low baseline plasma caffeine becoming elevated to a high level.

**PURPOSE:** To compare the effects of an energy drink on cycling time-trial performance in athletes following a 24-hour caffeine abstinence.

**METHODS:** In a randomized crossover design 15 trained cyclists ages 20-45 (7 women,  $VO_{2\text{max}} \geq 45$  mL/kg/min; 8 men  $VO_{2\text{max}} \geq 55$  mL/kg/min) received either an energy drink (ED) (containing caffeine, glucose, taurine, panax ginseng root extract, l-carnitine, caffeine, glucuronolactone, inositol, guarana seed extract, and B vitamins) or a flavor-matched placebo (P) after a 24-hour caffeine abstinence. One hour later, participants completed a 35-kilometer time-trial ride on a cycle ergometer; time-to-finish (TTF) was recorded. Blood was drawn and analyzed for caffeine (CAFF) at three times; before drink ingestion, 40 minutes later, and during the final kilometer of the time-trial ride. Participants whose baseline CAFF was below 1000 ng/mL ( $n = 10$ ) were categorized as LO and those with baseline levels above 1000 ng/mL ( $n = 5$ ) were categorized as HI. Data were analyzed using repeated measures ANOVA.

**RESULTS:** TTF improved in all participants after receiving ED as compared to P ( $64.1 \pm 1.3$  minutes vs.  $66.1 \pm 1.3$ ,  $p < .001$ ). Improvement in cycling performance due to ED was seen in both LO ( $66.1$  to  $64.0$  minutes, a decrease of  $2.1 \pm 0.4$  minutes,  $p = .001$ ) and HI ( $66.2$  to  $64.3$  minutes, a decrease of  $1.9 \pm 0.5$  minutes,  $p = .014$ ) groups.

**CONCLUSIONS:** An ED prior to aerobic exercise can enhance cycling time-trial performance even if there are high circulating levels of caffeine prior to ingestion. Improved performance despite high baseline circulating caffeine levels suggests that other ingredients contribute to the supplement's ergogenic effect. Pre-supplementation with ED may benefit exercise performance when supplementation during exercise is not possible.

**Effects Of Carbohydrate-caffeine Supplementation On Repeated High-intensity Performance In Elite Female Athletes**

Chia-Lun Lee<sup>1</sup>, Ching-Feng Cheng<sup>2</sup>, Todd A. Astorino<sup>3</sup>, Chia-Jung Lee<sup>2</sup>, Hsin-Wei Huang<sup>2</sup>, Yu-Hsuan Kuo<sup>2</sup>. <sup>1</sup>Yu Da University, Miaoli County, Taiwan. <sup>2</sup>National Taiwan Normal University, Taipei, Taiwan. <sup>3</sup>California State University San Marcos, San Marcos, CA.  
(No relationships reported)

Caffeine (CAF) has been shown to improve performance during the early phase of repeated high-intensity sprint exercise (RSE); however some studies show that CAF also increases magnitude of physical stress represented by augmented blood lactate, glucose, and cortisol concentrations during the latter phase of RSE. No studies have investigated efficacy of combined carbohydrate (CHO) and CAF consumption during RSE in female athletes.

**PURPOSE:** To evaluate the effects of CHO and CAF supplementation on metabolism and RSE performance.

**METHODS:** Eleven female athletes (age =  $20 \pm 1$  yr, height =  $163.2 \pm 6.3$  cm, body mass (BM) =  $58.2 \pm 8.3$  kg) completed 4 trials separated by 7 d in a double-blind, randomized, counter-balanced crossover design: CAF, CAF+CHO, CHO, and PLA (placebo). Participants consumed  $6\text{mg}\cdot\text{kg}^{-1}$  BM of CAF or PLA 1 h prior to RSE and  $0.8\text{g}\cdot\text{kg}^{-1}$  BM of CHO drink (glucose) or PLA immediately before the start of the test, which was conducted on a cycle ergometer. RSE consisted of 10 sets of  $5 \times 4$ -s bouts of maximal sprint exercise with 20-s active recovery between bouts. Blood samples were obtained to assess changes in lactate, blood glucose, testosterone, and cortisol across time and treatment.

**RESULTS:** During the first set of RSE, peak power ( $597.0 \pm 107.2$  vs.  $573.6 \pm 110.5$  vs.  $573.2 \pm 121.9$  watts,  $p < 0.05$ ) and mean power ( $557.0 \pm 91.5$  vs.  $535.8 \pm 91.5$  vs.  $539.5 \pm 103.1$  watts,  $p < 0.05$ ) were significantly higher with CAF+CHO than in the CHO and PLA trials, but no significant differences were shown between CAF+CHO and CAF ( $p > 0.05$ ). During sets 6 to 7, peak power and mean power were significantly increased by 6.0 % with CAF+CHO versus CAF ( $p < 0.05$ ), but there were no significant differences in performance between CAF+CHO and CHO ( $p > 0.05$ ). In addition, no significant differences in performance were observed across treatments during sets 2-5 and 8-10 ( $p > 0.05$ ). Compared to placebo, blood lactate and glucose were significantly increased under CAF+CHO, CHO, and CAF ( $p < 0.05$ ), but no significant differences in testosterone or cortisol were found ( $p > 0.05$ ).

**CONCLUSIONS:** In female athletes, a combination of caffeine and carbohydrate improved RSE performance versus CHO alone during the early phases of sprint exercise, and performance during the latter phases may be further enhanced compared to caffeine alone.

**2788** Board #60 June 1 9:30 AM - 11:00 AM  
**The Effects Of Caffeinated "Energy Shots" On Distance Running Performance**

Matthew M. Schubert<sup>1</sup>, Todd A. Astorino<sup>2</sup>, John L. Azevedo<sup>1</sup>. <sup>1</sup>California State University, Chico, Chico, CA. <sup>2</sup>California State University, San Marcos, San Marcos, CA.  
(No relationships reported)

**BACKGROUND:** An emerging trend in sports nutrition is the consumption of energy drinks to improve performance. An even newer group of supplements now emerging are "energy shots", which are smaller in volume and calories than energy drinks but lack sugar. Due to their small volume, availability, price, and convenience, energy shots may prove to be a viable ergogenic aid for endurance performance. Caffeine, a widely-used ergogenic aid, is the main ingredient in these substances.

**PURPOSE:** To examine the effects of two commercial energy shots on 5-km treadmill running performance in well-trained runners.

**METHODS:** Six highly trained male runners ( $\text{VO}_{2\text{max}}$ :  $69.1 \pm 5.7 \text{ mL} \cdot \text{kg}^{-1} \cdot \text{min}^{-1}$ ; 5-km personal best:  $15.0 \pm 0.5 \text{ min}$ ) completed three trials separated by a minimum of 5 d, during which 59 mL of placebo (PLA; 0 mg caffeine), Guayakí Yerba Maté Organic Energy Shot™ (YM; 140 mg caffeine), or Red Bull Energy Shot™ (RB; 80 mg caffeine) were ingested 45 minutes before exercise. This was a randomized, single-blind, placebo-controlled crossover research design. During each trial, subjects performed a self-paced 5-kilometer time trial on a motorized treadmill. Subjects were able to control their pace via the treadmill interface, but were unaware of speed, elapsed time, and distance until the final 800 m.

**RESULTS:** Results demonstrated no significant effect of energy shot intake on performance compared to placebo (Mean  $\pm$  SD: PLA= $1046.7 \pm 74.8 \text{ s}$ ; YM= $1071.7 \pm 95.2 \text{ s}$ ; RB= $1053.2 \pm 60.8 \text{ s}$ ;  $p > 0.05$ ). However, magnitude-based inferences revealed that performance in the PLA condition was 2.3% faster than the YM condition, yielding a likely substantial benefit in performance, while the difference in 5-km performance between PLA and RB and RB and YM was unclear.

**CONCLUSIONS:** At the dosages used in this study, energy shot ingestion did not improve high-intensity (~96%  $\text{VO}_{2\text{max}}$ ), moderate duration (< 18 minutes) running performance in trained runners in a laboratory setting compared to a placebo. Though further research is warranted, these findings do not support use of energy shots as potential ergogenic aids in trained runners.

**Red Bull Energy Drink and Anhydrous Caffeine have Similar Benefits for Cycling Time Trial Performance**

Michael D. Leveritt<sup>1</sup>, Alannah Quinlivan<sup>2</sup>, Chris Irwin<sup>1</sup>, Gary D. Grant<sup>1</sup>, Sheilandra Dukie<sup>1</sup>, Ben Desbrow<sup>1</sup>. <sup>1</sup>Griffith University, Gold Coast, Australia. <sup>2</sup>University of Melbourne, Melbourne, Australia. (Sponsor: David Bishop, FACSM)  
(No relationships reported)

**PURPOSE:** To investigate the ergogenic effects of a commercial energy drink (Red Bull) compared with an equivalent dose of caffeine provided in capsules.

**METHODS:** Eleven well-trained male cyclists ( $31.7 \pm 5.9 \text{ yrs}$ ,  $82.3 \pm 6.1 \text{ kg}$ ,  $\text{VO}_{2\text{max}} = 60.3 \pm 7.8 \text{ mL} \cdot \text{kg}^{-1} \cdot \text{min}^{-1}$ ) participated in this study which employed a double-blind, placebo-controlled and cross-over design. On three occasions participants were provided with an "energy drink" and some capsules 90 minutes before commencing a time trial equivalent to one hour cycling at 75% peak power output. All treatments were randomly administered and included Red Bull (~9 mL·kg<sup>-1</sup> body mass, containing 3 mg·kg<sup>-1</sup> body mass caffeine + placebo capsules), encapsulated anhydrous caffeine (placebo energy drink + 3 mg·kg<sup>-1</sup> body mass caffeine capsules) or a placebo (placebo energy drink + placebo capsules). Throughout each trial, exercise time, heart rate (HR), blood lactate and rating of perceived exertion (RPE) were recorded.

**RESULTS:** Performance times were improved with Caffeine ( $120 \pm 259 \text{ s}$  or 3.1%) and Red Bull treatments ( $110 \pm 270 \text{ s}$  or 2.9%), compared to the placebo ( $p < 0.05$ ), with no significant difference detected between the two caffeinated treatments ( $p > 0.05$ ). Average HR and RPE was not significantly different across the three treatments, although there was a trend towards increased HR in both the Red Bull and Caffeine trials ( $P = 0.086$  and  $P = 0.068$  respectively). Blood lactate concentrations were greater in both the Caffeine and Red Bull trials after exercise, in comparison with the placebo condition.

**CONCLUSION:** Red Bull significantly improves endurance cycling performance to the same degree as the equivalent dose of anhydrous caffeine. Therefore the ergogenic benefits of red bull energy drink are most likely due to caffeine, with the other ingredients offering no observable additional benefit.

**Examining Football Players Energy Drink Use and Motivations for Combining Energy Drinks with Alcohol**

Conrad L. Woolsey<sup>1</sup>, Bert H. Jacobson<sup>2</sup>, Weston S. Kensing<sup>3</sup>, Niels C. Beck<sup>4</sup>, Alex Waigandt<sup>5</sup>. <sup>1</sup>Oklahoma State University, Tulsa, OK. <sup>2</sup>Oklahoma State University, Stillwater, OK. <sup>3</sup>Oswego State University, Oswego, NY. <sup>4</sup>University of Missouri Medical School, Columbia, MO. <sup>5</sup>University of Missouri, Columbia, MO.  
(No relationships reported)

Research suggests football players may be a subgroup of the population that is particularly attracted to the stimulating effects of energy drinks (EDs) both on and off the field. Evidence suggests ED consumption in combination with alcohol has become increasingly prevalent.

**PURPOSE:** To investigate the use of energy drinks among NCAA Division I football players and motivations for combining EDs with alcohol.

**METHODS:** Following IRB approval 41 football players from a large Midwestern NCAA D-I university voluntarily completed the Quick Drink Screen (QDS) quantity-frequency measure for alcohol, combined-use (EDs+alcohol), and ED use without alcohol. To measure motivations for combining EDs with alcohol, participants also completed the Brief Comprehensive Effects of Alcohol and Combined-Use Questionnaires.

**RESULTS:** Nearly half (42.5%) of participants consumed EDs without alcohol and 27.5% used EDs 2 or more days/wk during the previous year. Additionally, 20% reported ED-binge drinking (having 3 or more EDs on one occasion). Among alcohol drinkers ( $n = 33$ ), 39.4% mixed EDs with alcohol and 69% of those combined-users reported ED-binge drinking with alcohol. An ANOVA on age and combined-use indicated older players were significantly more likely to combine EDs with alcohol than younger players  $F(4,23) = 5.006$ ,  $p = .003$ . An ANOVA on race (white/black) and combined-use indicated significant differences on the number of alcoholic drinks when combining  $F(1,39) = 4.146$ ,  $p < .05$ , and greatest number of alcoholic drinks when combining  $F(1,39) = 4.135$ ,  $p < .05$ , with white players drinking more. Positive motivations for using EDs with alcohol yielded higher mean scores while combining on enjoying sex, being more sociable ( $M = 3.38$  alcohol; 3.88 EDs+alco), and feeling stronger ( $M = 2.88$  alcohol; 3.5 EDs+alco); however, no significant differences were found.

**CONCLUSIONS:** Mixing EDs with alcohol appears to be a common trend which may contribute to the increased risk for ED-binge drinking. ED use has previously been reported as a predominantly white male behavior. In this sample, ED use was proportionate with 42% of white and 45% of black players using EDs; however, results did indicate white players had a higher prevalence of combining EDs with alcohol. The use of EDs among athletes and their motivations for using EDs needs further study.

---

**2791** Board #63 June 1 9:30 AM - 11:00 AM

**High But Not Low Caffeine Ingestion Has An Acute Diuretic Effect At Rest**

Stavros A. Kavouras, FACSM, Costas N. Bardis, Petros Gregorakis, Anna Gavrieli, Mary Yannakoulia, Labros S. Sidossis. Harokopio University, Athens, Greece.  
(S.A. Kavouras: Consulting Fee; Gatorade Sports Science Institute.)

It is documented that low levels of caffeine ingestion does not induce chronic dehydration at rest, while it not clear if larger doses do have an acute diuretic effect.

**PURPOSE:** The aim of the present investigation was to examine the effect of low and high level of caffeine on fluid balance in habitual coffee drinkers at rest.

**METHODS:** Twenty-five healthy male and female adults (age:  $28 \pm 5 \text{ y}$ , body mass index:  $28 \pm 5$ , weight:  $84.6 \pm 7.7 \text{ kg}$ , height:  $1.79 \pm 0.01 \text{ m}$ ) ingested 200 ml of water (W) or coffee with low caffeine (3 mg/kg, LCAF), on two separate occasions. Nine subjects of them participated one a third trial ingesting coffee with high caffeine (6 mg/kg, HCAF). All subjects remained in the laboratory while urine samples were collected every 60 min for three hours. Mean caffeine consumption for LCAF was 254 mg and 552 mg for the LCAF and HCAF, respectively. The subjects were habitual coffee drinkers (2-3 cups per day) who abstained from foods and drinks containing caffeine or other methylxanthines 24 h before each study. All sessions were performed at 09:00 in the morning in a counterbalance, crossover manner, at least 5 days apart.

**RESULTS:** Cumulative urine volume during the 3 h period after caffeine ingestion induced greater diuresis in the HCAF trial ( $630 \pm 391 \text{ ml}$ ) when compared to W ( $292 \pm 165 \text{ ml}$ ) and LCAF ( $316 \pm 194 \text{ ml}$ ). No differences were found between the W and LCAF trials. Urine specific gravity was lower during the HCAF trial ( $1.011 \pm 0.006 \text{ g/ml}$ ) when compared to W ( $1.016 \pm 0.007 \text{ g/ml}$ ) and LCAF ( $1.016 \pm 0.006 \text{ g/ml}$ ).

**CONCLUSIONS:** The data suggest that high caffeine intake in the form of coffee can induce an acute diuretic effect, while low levels do not disturb fluid balance in healthy casual coffee drinking adults at rest.

**2792 Board #64 June 1 9:30 AM - 11:00 AM**  
**Effects of Increasing Dosages of Caffeine on Predicted VO2 Max**

Sarah Yenchik, Timothy A. VanHaitma, Andrea T. White, FACSM, Kerry M. Jacques. *University of Utah, Salt Lake, UT.*  
 (No relationships reported)

Caffeine is a mild stimulant that acts on the central nervous system and skeletal muscles, overriding fatigue signals, increasing heart rate at rest, and eliciting greater motor unit recruitment. Caffeine also positively affects performance by increasing endurance and increasing performance at high altitude. Other research has suggested that caffeine can decrease heart rate (HR) during submaximal exercise. Several submaximal exercise tests use heart rate to predict VO2max. Therefore, due to the varying response of heart rate to caffeine, the response of the predicted VO2max to caffeine is unknown.

**PURPOSE:** The purpose of this study was to determine the effect of caffeine ingestion on heart rate during submaximal exercise and on the subsequent predicted VO2max of active college age males.

**METHODS:** 12 moderately trained males (age 18-30 yrs) completed four testing procedures on four separate days: 1) VO2max test; 2-4) single-blind dosage of caffeine (0 (A), 3.5 (B) or 7 (C) mg/kg) administered orally 1 hour before testing. Participants completed the Forestry Step test and the Astrand Cycling test. Relative and absolute predicted VO2 max values were recorded and comparisons between caffeine dosages were made using repeated measures ANOVA.

**RESULTS:** There were no significant differences in mean predicted VO2 max following any of the caffeine trials for either the Forestry or Astrand test as compared to the placebo ( $p > .05$ ). However, according to Bland-Altman plots, Absolute Astrand (C-A) and the Relative Forestry (B-A) have trend lines with significant slope, which is indicative of some systematic variability and thus poor agreement and bias in the data.

**CONCLUSIONS:** These results suggest that consumption of caffeine does not have a measurable effect in moderately trained males on predicted VO2 Max from the Forestry or the Astrand tests. This also suggests that it may not be necessary to restrict participant's caffeine intake before clinical submaximal testing.

**2793 Board #65 June 1 9:30 AM - 11:00 AM**  
**Caffeine Ingestion Reverses the Circadian Rhythm Effects on Neuromuscular Performance in Highly Resistance-Trained Men**

Alvaro Lopez-Samanes, Jesus Garcia-Pallares, Juan F. Ortega, Valentin E. Fernandez-Elias, Ricardo Mora-Rodriguez. *University of Castilla La Mancha, Toledo, Spain.*  
 (No relationships reported)

Following a circadian rhythm pattern, neuromuscular performance declines in early mornings and late nights while peaks during midday. In turn, caffeine ingestion, an adenosine receptor inhibitor, has been accepted as an ergogenic aid with potential to improve neuromuscular performance (i.e., muscle strength and power).

**PURPOSE:** Investigate whether caffeine ingestion counteracts the morning reduction in neuromuscular performance associated with circadian rhythm.

**METHODS:** Twelve highly resistance-trained men underwent a battery of neuromuscular tests under three different conditions; *i*) morning (10:00 a.m.) with caffeine ingestion (i.e., 6 mg · kg<sup>-1</sup>; AM<sub>CAFF</sub> trial); *ii*) morning (10:00 a.m.) with placebo ingestion (AM<sub>PLAC</sub> trial); and *iii*) afternoon (18:00 p.m.) with placebo ingestion (PM<sub>PLAC</sub> trial). A randomized, double-blind, placebo controlled experimental design was used, with all subjects serving as their own controls. The test battery consisted in the measure of bar displacement velocity during free-weight full-squat (SQ) and bench press (BP) exercises against loads that elicit maximum strength (75% 1RM load) and muscle power adaptations (1 m·s<sup>-1</sup> load). In addition, maximum voluntary and electrically evoked (EVO<sub>C<sub>LEG</sub></sub>) isometric leg extension strength were measured to identify the caffeine's action mechanisms. Plasma norepinephrine concentration (NE) was measured after a standardized SQ intense bout (6 x 85% 1RM) as surrogate of maximal muscle sympathetic nerve activity since plasma NE is mostly derived from the spillover of the terminal nerve endings of the motoneurons.

**RESULTS:** In the PM<sub>PLAC</sub> trial, dynamic muscle strength and power output were significantly enhanced compared with AM<sub>PLAC</sub> (4.7%-7.5%;  $P < 0.05$ ). During the AM<sub>CAFF</sub> trial, strength and power increased above AM<sub>PLAC</sub> levels (4.6%-5.7%;  $P < 0.05$ ) except for BP velocity with 1 m·s<sup>-1</sup> load. Lastly, during AM<sub>CAFF</sub>, EVO<sub>C<sub>LEG</sub></sub> and NE were increased above AM<sub>PLAC</sub> trial (14.6% and 96.8%, respectively;  $P < 0.05$ ).

**CONCLUSIONS:** Overall, caffeine ingestion reversed the morning decreases in muscle strength and power output, raising performance to levels of the afternoon trial. The electrical stimulation data, along with NE, suggests that caffeine increases the neuromuscular performance via a direct effect in the muscle.

**2794 Board #66 June 1 9:30 AM - 11:00 AM**  
**The Effects of Caffeine on Long-Term Anaerobic Exercise**

Elizabeth M. Hendricks, Harold S. Kieffer, Jodie L. Haak. *Messiah College, Grantham, PA.* (Sponsor: Dan Drury, FACSM)  
 (No relationships reported)

**PURPOSE:** The purpose of this study was to examine effects of caffeine on a long-term anaerobic exercise protocol using the 90-second Wingate Test (WAnT90).

**METHODS:** Thirteen (5 males and 8 female, Age = 20.15±0.99 years) anaerobically trained athletes who were habitual caffeine consumers participated in a double-blind study that was randomized and counterbalanced using caffeine (5 mg/kg) and a placebo (equivalent mg of rice flour). One hour after ingesting the caffeine or placebo capsule, the subjects underwent a 2-minute prescribed warm-up on Monarch bicycle ergometer. The participant then performed a WAnT90 protocol using 0.05 kg per body weight as a constant resistance. Paired t-tests were conducted between the caffeine and placebo for peak power (PP), total power (TP), total power 30-s (TP30), total power 60-s (TP60), total power 90-s (TP90), and power decline for total work, 30-s, 60-s, and 90-s (PDT, PD 30, 60, and 90, respectively). The significance was set at  $p \leq 0.05$ .

**RESULTS:** The caffeine did not show a difference in PP; however, the caffeine trial did improve performance for TP, TP30 and TP60. In addition, TPD was improved with caffeine however; the rate of decline did not change across the 30-s intervals.

|          | TP (Watts) | TP60 (Watts) | TP90 (Watts) | TPD (% decline) |
|----------|------------|--------------|--------------|-----------------|
| Caffeine | 5850.47#   | 1733.53^     | 1366.36#     | 63.12%*         |
| Placebo  | 5593.26    | 1617.33      | 1242.66      | 67.29%          |

\* $p < 0.05$ , # $p < .01$ , ^ $p < 0.001$

**CONCLUSIONS:** As with other studies, peak power did not change following the ingestion of caffeine; however, caffeine did have a significant effect on long-term anaerobic performance. The increased power output with caffeine could be due adenosine antagonism and a decrease in pain perception and fatigue.

**A Moderate Exercise Protocol that Produces Significant Cardiac Hypertrophy in Rats**

Joseph W. Stames, FACSM, Bryan J. Feger, Lindsay A. Hixson. *University of North Carolina at Greensboro, Greensboro, NC.*  
(No relationships reported)

Chronic treadmill exercise by rats can result in cardiac hypertrophy and improved function; however, the intensity required is very high. At normal room temperature, core temperature during exercise rises to potentially lethal levels. In 2001, we carried out a study to investigate the interaction of temperature and exercise on myocardial phenotype using a moderate exercise protocol with environmental conditions adjusted to prevent exercise-induced increased core temperature (Am J Physiol 280:H2271,2001). As expected, the room temperature exercisers did not develop cardiac hypertrophy; however, to our surprise the group exercising at the same intensity but in a colder environment developed significant cardiac hypertrophy.

**PURPOSE:** To determine whether hypertrophy following moderate exercise training in the cold environment is associated with enhanced function consistent with exercise-induced hypertrophy following intense exercise training.

**METHODS:** Male, 10-wk-old Sprague-Dawley rats were divided into sedentary (S) and exercised (E) groups. E ran on a treadmill 5 days/week up a 6° incline for 4- or 9-wks. During wk 1, running time and speed was gradually increased to 30 minutes at 20 m/min (~70% VO<sub>2</sub>max). During wk 2 rats began running in a refrigerated room (6-8°C) with fur dampened and running time gradually increased to one hour per day, then held constant for the remaining wks. Animals were housed at 23°C when not running. Twenty-four hrs after the last exercise bout, hearts were weighed and connected to an isolated perfused working heart apparatus for evaluation of cardiac functional performance. Ventricular gene expression of  $\alpha$ - and  $\beta$ -MHC (myosin heavy chain) was determined in the 9-week group.

**RESULTS:** E displayed an increase in heart wt (P<0.05) compared to S of 9% and 23% after 4 and 9 wks, respectively. Cardiac function improved in E vs S as indicated by increases (P<0.05) of 24% in external work performed (Cardiac output x Systolic pressure, normalized for wt) and 20% in efficiency of external work (work/VO<sub>2</sub>). Gene expression was not different from sedentary values consistent with physiological hypertrophy.

**CONCLUSION:** Compared to exercise at ambient temperature, the cold-room exercise protocol is a more humane way to produce exercise-induced hypertrophy and improvement in function.

**Prevalence Of Cardiac Abnormalities In College Athletes When Exposed To Physiological And Thermal Stressors**

James D. Kingsley, Matt Tucker, Susan Yeargin. *Indiana State University, Terre Haute, IN.* (Sponsor: Lynn Panton, FACSM)  
(No relationships reported)

Cardiovascular pre-participation screening of collegiate student athletes is underutilized according to the American Heart Association. Physiological stress in the form of submaximal exercise and heat exposure can both alter cardiovascular function, possibly elucidating an abnormality via electrocardiogram (ECG).

**PURPOSE:** To investigate prevalence of cardiac abnormalities in college athletes when exposed to physiological and thermal stress.

**METHODS:** Eleven participants (males n=5; females n=6; 21 ± 1 yrs; 1.68 ± 0.05m; 60.0 ± 4.5kg; 56.1 ± 12.2 ml/kg/min) currently participating at the NCAA Division I level (track and field as well as cross country) volunteered for this study. Participants completed one maximal treadmill test and two submaximal treadmill tests (70% of VO<sub>2</sub> max) in two different environmental conditions: thermoneutral (TN: 24.8 ± 1.6°C) and hyperthermic (HT: 38.0 ± 2.2 °C) for 30 minutes. ECGs were recorded over 15 seconds at five minute intervals. PR interval duration, ST segment elevation/depression, and R and S wave amplitude were measured; ECGs were further analyzed for abnormalities. A repeated measures ANOVA was used to test the effects of condition by time.

**RESULTS:** No significant condition by time interactions were found for any variable (p>0.05). There were also no main effects (p>0.05) of condition. However, there were significant differences across time (p<0.05) manifested as a decreased PR interval (-19.1 ± 18.2%), R wave amplitude (-15.1 ± 12.3%), and increased S wave amplitude (+34.8 ± 29.1%). No main effects (p>0.05) were found for ECG abnormalities. However, high occurrences (56%) of incomplete left bundle branch block (ILBBB) were found.

**CONCLUSION:** Submaximal exercise in the hyperthermic condition did not significantly alter cardiovascular function in the parameters measured. In addition, the total number of ECG readings with abnormalities was higher in the hyperthermic condition compared to thermoneutral, most notable in incidences of ILBBB. Supported by funding from the College of Graduate and Professional Studies at Indiana State University

**Influence of the Menstrual Cycle on Resting and Exercise Left Ventricular Volumes and Twist Mechanics**

Amanda Q.X. Nio, Eric J. Stöhr, Michael Stembridge, Rob Shave. *University of Wales Institute, Cardiff, Cardiff, United Kingdom.* (Sponsor: Keith George, FACSM)  
(No relationships reported)

Currently, there is no consensus on the impact of cyclical changes in circulating female sex hormones across the menstrual cycle, on cardiac function at rest or during exercise.

**PURPOSE:** To compare left ventricular (LV) function at rest and during exercise across the early-follicular (EF) and mid-luteal (ML) phases of the menstrual cycle.

**METHODS:** Eight healthy females (mean±standard deviation; age 26±2 years; height 164.9±8.0 cm; body mass 58.5±7.6 kg; body fat 29±4%), with regular menstrual cycles (25-33 days), completed progressive supine cycling exercise during EF (Day 3-5) and ML (Day 19-27) phases. Participants completed four 4-min exercise stages at 10, 30, 50 and 70% peak power (151±52 W). LV volumes, septal wall velocity, isovolumic relaxation time and twist mechanics were assessed using cardiac ultrasound (Vividq, GE Healthcare), at rest and during each stage of exercise. Statistical analysis was performed using t-test for resting measures and two-way ANOVA for exercise measures. Alpha was set at 0.1.

**RESULTS:** At rest and during incremental exercise, diastolic blood pressure, cardiac output, heart rate, stroke volume, ejection fraction, end-systolic volume and peak systolic septal wall velocity at the level of the mitral annulus were similar between menstrual cycle phases. However, resting systolic blood pressure (ML 112±12 vs. EF 125±9 mmHg; p=0.05), peak apical rotation (ML 9.1±4.8 vs. EF 10.2±4.7 deg; p=0.01) and peak apical rotation velocity during diastole (ML -68±15 vs. EF -80±13 deg/s; p=0.03) were reduced during the ML phase. End-diastolic volume was influenced by the interaction between menstrual cycle phase and exercise intensity (p=0.06), with a larger volume at 70% exercise during the ML phase (ML 103±18 vs. EF 95±24 mL; p=0.09). Isovolumic relaxation time differed between menstrual cycle phase (p=0.001), and was shorter during the ML phase at 30% peak power (ML 53±7 vs. EF 64±10 ms; p=0.01) and 70% peak power (ML 44±8 vs. EF 49±9 ms; p=0.07).

**CONCLUSION:** Although global parameters of resting cardiac function were similar between the EF and ML phases, greater increases in apical rotation and diastolic rotation velocity with exercise in the ML phase likely result in greater LV suction during diastole. This might explain the enhanced EDV observed during moderate intensity exercise.

### Exercise Training Does Not Enhance Diastolic Function In Non-alcoholic Fatty Liver Disease Patients

Helen Jones<sup>1</sup>, Christopher K. Wong<sup>2</sup>, Malcolm I. Burgess<sup>2</sup>, Christopher J. Pugh<sup>1</sup>, Keith George, FACSM<sup>1</sup>, Margot Umpleby<sup>3</sup>, Fariba Shojaae-Moradie<sup>3</sup>, Graham J. Kemp<sup>4</sup>, Daniel J. Cuthbertson<sup>5</sup>. <sup>1</sup>Liverpool John Moores University, Liverpool, United Kingdom. <sup>2</sup>University Hospital Aintree, Liverpool, United Kingdom. <sup>3</sup>University of Surrey, Guildford, United Kingdom. <sup>4</sup>University of Liverpool, Liverpool, United Kingdom. <sup>5</sup>Univeristy Hospital Aintree, Liverpool, United Kingdom.  
(No relationships reported)

**PURPOSE:** Non-Alcoholic Fatty Liver Disease (NAFLD), the accumulation of triglycerides in the liver, is the hepatic manifestation of the metabolic syndrome. NAFLD is associated with an increased risk of chronic liver disease including cirrhosis, liver failure and hepatocellular carcinoma although cardiovascular disease (CVD) remains the leading cause of mortality. We have recently shown diastolic dysfunction in NAFLD patients when compared to age and BMI matched controls. The aim of this study was to examine the effect of exercise training on diastolic dysfunction in patients with NAFLD.

**METHODS:** Twelve sedentary patients with NAFLD, aged 50.9±11.7y, underwent a 16-week supervised exercise training program (30-45min, 3-5 times per week). Each patient underwent transthoracic echocardiography to determine left ventricular (LV) mass index, peak early (E) and atrial (A) diastolic flow velocities, the E/A ratio, peak early (E') diastolic tissue velocity at the septal mitral annulus and the E/E' ratio. Proton Magnetic Resonance (MR) Spectroscopy was used to determine liver fat and whole body MR imaging quantified abdominal visceral (VAT) and subcutaneous (SAT) adipose tissue. Fasting glucose, lipids, liver enzymes and V<sub>O<sub>2</sub></sub>max were assessed prior to and following training. Differences between baseline and post-training were analysed using paired t-tests.

**RESULTS:** Exercise training resulted in a significant improvement in V<sub>O<sub>2</sub></sub> max from 24.9±6.2 to 31.3±8.4 ml.kg.min<sup>-1</sup>, liver fat significantly reduced (25±2 vs 16±1%). There was a significant reduction in BMI (30.1±2.4 vs 29.4±2.8 kg/m<sup>2</sup>) and abdominal SAT (8.6±2.5 vs 8.0±2.5 L, P<0.05) but abdominal VAT was not different following exercise training. Despite these reductions in body composition and liver fat, there were no significant changes in any variable of myocardial performance: differences in LV mass (73.4±16.7 vs 82.7±18.2 g/m<sup>2</sup>), diastolic flow velocities (E/A ratio 1.10±0.30 vs 1.03±0.26) or diastolic tissue velocity (E' 6.6±1.4 vs 7.1±2.3 cm/s and E/E' 11.1±2.9 vs 11.0±3.0 cm/s).

**CONCLUSIONS:** These data indicate that exercise training did not improve diastolic function in NAFLD patients. Given that LV function is partially mediated by visceral adiposity the lack of improvement in diastolic function could be due to a lack of change in VAT volume.

2799 Board #71 June 1 11:00 AM - 12:30 PM

### Influence of Sex on Carotid Baroreflex Resetting and Function during Dynamic Exercise in Humans

Areum Kim<sup>1</sup>, Shekhar H. Deo<sup>1</sup>, James P. Fisher<sup>2</sup>, Paul J. Fadel, FACSM<sup>1</sup>. <sup>1</sup>University of Missouri, Columbia, MO. <sup>2</sup>University of Birmingham, Birmingham, United Kingdom.  
(No relationships reported)

Young men tend to exhibit greater pressor responses to exercise compared to age-matched women; however, the reason for these differences remains unclear. Appropriate arterial baroreflex resetting and function are requisite for normal blood pressure responses to dynamic exercise. However, to date, no studies have examined whether there are sex differences in arterial baroreflex resetting and function during dynamic exercise.

**PURPOSE:** To compare carotid baroreflex (CBR) resetting and function during dynamic exercise between young men and women.

**METHODS:** We studied 16 young men and 18 young women at rest and during leg cycling at 50% heart rate (HR) reserve. All women were studied during the early follicular phase of the menstrual cycle (days 2-5). Beat-to-beat HR (ECG) and mean arterial pressure (MAP; finger photoplethysmography) were measured. Five second pulses of neck pressure and neck suction (NS) from +40 to -80 Torr were applied to determine full CBR stimulus response curves for MAP and HR. In order to estimate the magnitude of exercise-induced baroreflex resetting, differences in the sum of the changes in centering point (CP), minimum response, threshold, and saturation from rest to exercise were calculated.

**RESULTS:** An upward and rightward resetting of the CBR function curve was observed during exercise in both men and women with a similar magnitude of CBR resetting for MAP (+68±10 women vs. +81±13 men a.u.; P>0.05) and HR (+160±12 women vs. +155±13 men a.u.; P>0.05) between sexes. However, for CBR control of MAP, young women exhibited significantly greater depressor responses to NS at rest that were not present during exercise. For CBR control of HR, there was a greater bradycardic response to NS in young women with the operating point (OP) located further away from CP on the CBR-HR curve during rest (OP-CP; -13±3 women vs. -3±3 men mmHg; P<0.05) and exercise (-31±2 women vs. -15±3 men mmHg; P<0.05).

**CONCLUSION:** Collectively, these findings suggest that sex does not influence exercise resetting of the arterial baroreflex. However, young women exhibit greater CBR control of HR during dynamic exercise, specifically against acute hypertension.

### The Effects Of A Multi-flavonoid Supplement On Vascular And Hemodynamic Parameters In Older Prehypertensives

Chelsea D. Curry<sup>1</sup>, Steven R. McAnulty<sup>1</sup>, Lisa S. McAnulty<sup>1</sup>, Hannah E. Wheeler<sup>1</sup>, Janice Welsh<sup>1</sup>, Rebecca M. Kappus<sup>2</sup>, Martin Hubner<sup>1</sup>, Scott R. Collier, FACSM<sup>1</sup>. <sup>1</sup>Appalachian State University, Boone, NC. <sup>2</sup>University of Illinois at Urbana-Champaign, Urbana, IL.  
(No relationships reported)

Antioxidants have been shown to increase vasodilation leading to increases in vascular distensibility, which would be of great benefit to individuals with elevated blood pressure. Our laboratory has shown beneficial changes in blood pressure (BP) and augmentation index (AIx) immediately post-exercise in young prehypertensives following two weeks of anti-oxidant supplementation. The purpose of this study was to investigate the potential additive effects of an acute aerobic exercise bout paired with two weeks of anti-oxidant supplementation (1 day=1000mg quercetin, 120 mg epigallocatechin 3-gallate [EGCG], 400 mg isoquercetin and 400 mg EPA-DHA (Q-EGCG)) on post-exercise hypotension in middle-aged (40-60 year old) pre-to stage-one hypertensives.

**METHODS:** 18 subjects (51.7±1.8, 50.8±1.8 years old, treatment and placebo group respectively) were randomly assigned either supplement or placebo group in double-blinded fashion. Systolic blood pressure (SBP), diastolic blood pressure (DBP) (Finometer), Augmentation Index (AIx), central and peripheral pulse wave velocity (cPWV, pPWV, respectively, SphygmoCor) were assessed pre- and post-exercise prior to and following 2 weeks of supplementation in a double-blind, counterbalanced design.

**RESULTS:** Following two weeks of supplementation, there was a significant decrease in resting SBP (132.2±5.4 pre-supplementation to 124.9±5.4 post, p<0.05) and mean arterial pressure (100.2±2.2 pre-supplementation to 94.6±4.4 post, p<0.05) following supplementation. No significant differences existed in DBP, AIx, cPWV or pPWV.

**CONCLUSION:** Two weeks of multi-flavonoid supplementation elicited a significant decrease in systolic blood pressure and mean arterial pressure in the treatment group.

This study was partially funded by an Appalachian State University research grant (Collier-PI).

### The Influences Of Protocatechuic Acid On Blood Pressure And Insulin-mediated Vascular Function In Hypertension

Sih-Han Wu<sup>1</sup>, Ai-Lun Yang<sup>1</sup>, Chia-Ting Su<sup>2</sup>. <sup>1</sup>Taipei Physical Education College, Taipei, Taiwan. <sup>2</sup>Fu Jen Catholic University, Taipei, Taiwan. (Sponsor: Chia-Hua Kuo, FACSM)  
(No relationships reported)

**PURPOSE:** Hypertension has been known to induce vascular impairments with the decrease of nitric oxide (NO) bioavailability. Moreover, oxidative stress has been recognized as an important factor for the pathogenesis of endothelial dysfunction and hypertension. Recently, protocatechuic acid (PCA; 3,4-dihydroxybenzoic acid), a simple phenolic acid, has been found to be a strong antioxidant. However, whether PCA induces beneficial effects on cardiovascular function in hypertensive status remains unknown. Therefore, we investigated the influences of PCA on blood pressure and vascular function in hypertension.

**METHODS:** Male spontaneously hypertensive rats were randomly divided into control (SHR) and PCA supplement (SHR+PCA) groups. Wistar-Kyoto (WKY) rats were used as the normotensive control group. The SHR+PCA group was supplemented with PCA adjusted from their daily water consumption for 8 weeks. At the end of experiments, resting blood pressure, glucose, and insulin level were measured and compared among three groups. In addition, the insulin-mediated vasorelaxation was evaluated in rat aortas using the organ bath system. The aortic protein expression, such as insulin receptor and endothelial nitric oxide synthase (eNOS), was also examined by Western blot analysis. This study was approved by the Institutional Animal Care and Use Committee of Taipei Physical Education College (Taipei, Taiwan).

**RESULTS:** We found that the PCA supplement significantly reduced the systolic blood pressure, glucose, and insulin level in the SHR+PCA group compared with the SHR group ( $p < 0.05$ ). Also, the PCA supplement induced higher insulin-mediated vasorelaxation in the SHR+PCA group than that in the SHR group ( $p < 0.05$ ). However, the endothelium-denuded insulin-mediated vasorelaxation was comparable among three groups. Moreover, the protein expression of insulin receptor and eNOS was significantly increased after the PCA supplement.

**CONCLUSIONS:** The 8-week PCA supplement could ameliorate the blood pressure and insulin-mediated vasorelaxation in hypertension. This vascular improvement was associated with the increase of insulin receptor and eNOS protein via the endothelium-dependent pathway.

### **Prenatal Programming of Hypertension by Dietary Protein Deprivation Alters Skeletal Muscle Reflex Function in Rats**

Masaki Mizuno, Khurum Siddique, Michel Baum, Scott A. Smith, FACSM. *University of Texas Southwestern Medical Center, Dallas, TX.* (Sponsor: Jere H. Mitchell, FACSM)

(No relationships reported)

The cardiovascular response to exercise is enhanced in hypertension. Recent studies using a rat model of essential hypertension have suggested that this exaggerated responsiveness is mediated, in part, by the skeletal muscle exercise pressor reflex (EPR). It remains unknown, however, whether EPR dysfunction manifests in other forms of this disease.

**PURPOSE:** To address this issue, EPR function was investigated in adult rats that were prenatally programmed to express hypertension as a result of maternal dietary protein deprivation. Prenatal programming of hypertension (PPH) in this manner is a commonly used model for the hypertension that develops in adults that were born small for gestational age.

**METHODS:** Pregnant Sprague-Dawley rats were fed either a 6% (PPH) or 20% (control) protein diet during the last half of the gestational period. In 10 PPH and 11 control adult offspring, EPR function was assessed by electrically-inducing hindlimb muscle contraction. The mechanically-sensitive component of the EPR was selectively activated by passively stretching hindlimb muscle while the chemically-sensitive component was stimulated by locally administering capsaicin (1.0  $\mu\text{g}/100 \mu\text{l}$ ) into the circulation of the hindlimb.

**RESULTS:** Resting systolic blood pressure was significantly higher ( $P < 0.05$ ) in PPH compared to control rats ( $140 \pm 3$  vs.  $128 \pm 3$  mmHg, respectively). Stimulation of the EPR evoked significantly larger increases in mean arterial pressure ( $\Delta\text{MAP}$  from baseline:  $40 \pm 7$  vs.  $20 \pm 4$  mmHg,  $P < 0.05$ ), heart rate ( $\Delta\text{HR}$  from baseline:  $19 \pm 3$  vs.  $5 \pm 1$  bpm,  $P < 0.05$ ) and renal sympathetic nerve activity ( $\Delta\text{RSNA}$ :  $198 \pm 29$  vs.  $68 \pm 14$  %,  $P < 0.05$ ) in PPH compared to control whereas developed tension was not different between groups ( $\Delta\text{Tension}$ :  $0.84 \pm 0.07$  vs.  $0.81 \pm 0.07$  kg). The MAP, HR and RSNA responses to selective activation of the mechanically and chemically-sensitive components of the EPR were likewise significantly greater in PPH compared to control.

**CONCLUSIONS:** These data demonstrate that the EPR is overactive in prenatally programmed hypertension. This is an important finding as it suggests that muscle reflex dysfunction is not unique to essential hypertension but may play a significant role in the generation of abnormal cardiovascular control during exercise in other forms of the disease. *Supported by NIH HL-088422*

### **Effect Of Resistance Exercise Training On Arterial Reservoir Pressure In Prehypertensive Men And Women**

Kevin S. Heffernan<sup>1</sup>, Eun Sun Yoon<sup>2</sup>, Justin Davies<sup>3</sup>, James E. Sharman<sup>4</sup>, Bo Fernhall, FACSM<sup>5</sup>, Sae Young Jae<sup>2</sup>. <sup>1</sup>Syracuse University, Syracuse, NY. <sup>2</sup>University of Seoul, Seoul, Korea, Republic of. <sup>3</sup>Imperial College, London, United Kingdom. <sup>4</sup>University of Tasmania, Hobart, Australia. <sup>5</sup>University of Illinois- Chicago, Chicago, IL

(No relationships reported)

**BACKGROUND:** The central blood pressure (BP) waveform is viewed as a composite of overlapping incident and reflected pressure waves. Recently, it has been suggested that the capacitance property of large central arteries also contribute to the morphology of the BP waveform (i.e. reservoir pressure). Resistance exercise training (RET) reduces central BP yet it appears to do this without changing pressure from wave reflections.

**PURPOSE:** The purpose of this study was to examine the contribution of the arterial reservoir to changes in central BP following RET in men and women with pre-hypertension.

**METHODS:** Twenty-one participants (age  $61 \pm 1$  yrs,  $n = 6$  male) with pre-hypertension (average SBP/DBP = 138/84 mmHg) were randomized to either 12-weeks of RET ( $n = 11$ ) or an inactive control group. Central aortic BP was derived from radial pressure waveforms using tonometry and a generalized transfer function. Also derived from BP waveforms were forward wave pressure, excess wave pressure, augmented pressure, augmentation index (AIx), left ventricular pressure effort, and reservoir pressure.

**RESULTS:** A significant group-by-time interaction for central systolic blood pressure (SBP) was noted ( $p < 0.05$ ). There was a reduction in central SBP following RET ( $134 \pm 5$  to  $129 \pm 4$  mmHg) and a slight increase in central SBP in the control group ( $130 \pm 5$  to  $133 \pm 4$  mmHg). There were also significant group-by-time interactions for forward wave pressure ( $p < 0.05$ ), excess pressure ( $p < 0.05$ ), and reservoir pressure ( $p < 0.05$ ). Following RET there were reductions in forward wave pressure ( $32 \pm 2$  to  $30 \pm 2$  mmHg) excess pressure ( $42 \pm 3$  to  $40 \pm 3$  mmHg) and reservoir pressure ( $38 \pm 3$  to  $35 \pm 3$  mmHg). There were slight increases in forward wave pressure ( $27 \pm 2$  to  $30 \pm 2$  mmHg), excess pressure ( $35 \pm 3$  to  $39 \pm 3$  mmHg), and reservoir pressure ( $31 \pm 3$  to  $35 \pm 3$  mmHg) in the control group. There were no changes in augmented pressure, AIx or left ventricular pressure effort in either group ( $p > 0.05$ ).

**CONCLUSIONS:** RET reduces central SBP in pre-hypertensive men and women. Changes in forward wave/excess wave pressure and reservoir pressure without changes in augmented pressure suggest that central SBP reduction with RET may be due to changes in the impedance and capacitance properties of arteries and not changes in pressure from wave reflections.

**2804** Board #76 June 1 11:00 AM - 12:30 PM

### **The Hemostatic Responses to Acute Exercise of an At Risk Obstructive Sleep Apnea Population**

Paul Nagelkirk, Steve Vesbach, Amanda Mallory, Trent Hargens. *Ball State University, Muncie, IN.* (Sponsor: Christopher Womack, FACSM)

(No relationships reported)

Obstructive sleep apnea (OSA) is a sleep disorder that places one at increased risk for cardiovascular disease (CVD) and CVD related events. Patients with OSA exhibit elevated coagulation and decreased fibrinolytic potential, both of which are associated with incidence of CVD and its sequelae. The hemostatic response to a stressor such as maximal exercise may differentiate clinical and demographic groups better than baseline profiles. Hemostatic exercise responses are also related to CVD morbidity and mortality. To date, no research has examined the impact of exercise on measures of coagulation and fibrinolysis in this population.

**PURPOSE:** To compare the fibrinolytic and coagulation responses to exercise between subjects at high risk for OSA and control subjects.

**METHODS:** Seventeen obese men and women (BMI =  $32.1 \pm 5.7$  kg/m<sup>2</sup>) completed the study: 8 at risk for OSA (apnea-hypopnea index =  $10.6 \pm 8.2$  events/hour) and 9 control subjects. Subjects performed maximal exercise tests on a cycle ergometer. Plasma concentrations of fibrinogen, active tissue plasminogen activator (tPA) and plasminogen activator inhibitor (PAI-1) were assessed at rest and immediately after exercise. Body composition was assessed by DXA. Risk for OSA was established through a screening result from an at-home sleep assessment device (Embletta).

**RESULTS:** OSA and CTRL groups were not different in regard to VO<sub>2</sub> max ( $21.7 \pm 5.5$  vs  $24.3 \pm 5.4$  ml/kg/min, respectively), BMI ( $34 \pm 6.5$  vs  $31.2 \pm 5.2$  kg/m<sup>2</sup>) or body composition ( $39.6 \pm 8.6$  vs  $38.1 \pm 11.1$  % fat). The OSA group was older than the CTRL group (47 and 30 yrs, respectively), but no hemostatic variable was correlated to age. Maximal exercise induced significant changes in each hemostatic variable, but no differences were observed between groups. tPA activity (OSA =  $0.99 \pm 0.13$  to  $7.21 \pm 1.64$  IU/ml; CTRL =  $1.02 \pm 0.12$  to  $6.76 \pm 1.86$  IU/ml) and fibrinogen concentration (OSA =  $367.6 \pm 94.9$  to  $377.7 \pm 91.1$  mg/dl; CTRL =  $365.9 \pm 76.2$  to  $413.3 \pm 114.4$  mg/dl) increased significantly ( $p < 0.05$ ). PAI-1 decreased in both groups (OSA =  $4.70 \pm 1.83$  to  $2.25 \pm 0.58$  IU/mL; CTRL =  $7.13 \pm 4.73$  to  $5.21 \pm 3.39$  IU/mL).

**CONCLUSIONS:** Results suggest that mild OSA (AHI 5-15 events/hr) may not impact coagulation or fibrinolytic potential. Future research needs to evaluate this response in subjects with more severe OSA.

2805 Board #77 June 1 11:00 AM - 12:30 PM

**Racial Differences in Blood Pressure Response and Vascular Function following 8-weeks of Aerobic Training**

Sushant M. Ranadive, Huimin Yan, Abbi D. Lane, Peng Sun, Rebecca Kappus, Marc D. Cook, Bo Fernhall, FACSM. *University of Illinois, Champaign, IL.*  
(No relationships reported)

African-Americans (AA) have higher prevalence of hypertension than Caucasians (CA) in the United States. In addition, AA have lower endothelial function and blunted peripheral vascular dilatation. These factors are known to directly contribute to end-organ damage.

**PURPOSE:** The purpose of this study was to examine the effects of aerobic exercise training on blood pressure response and vascular function in young white and African American individuals.

**METHODS:** 32 AA (9 men and 23 women) and 34 CA (19 men and 15 women) between the ages of 18-35 volunteered for the study, and completed a 4 week control period, followed by a 8 week aerobic exercise training period (30-60 min of exercise at 60-90% of maximal heart rate, 3 times/week). Women were tested during menses. Carotid, brachial and aortic blood pressures were measured using sphygmomanometry and applanation tonometry. Forearm blood flow (FBF) was measured by strain-gauge plethysmography before and during reactive hyperemia (RH). RH was induced by 5-min of brachial artery occlusion. All measurements were conducted in a supine position.

**RESULTS:** Brachial SBP decreased significantly in both groups ( $118 \pm 2$  to  $117 \pm 2$  to  $114 \pm 3$  vs.  $122 \pm 2$  to  $119 \pm 2$  to  $119 \pm 2$  mmHg;  $p < 0.05$ ), but the decrease in response to training was not significant, and there were no group differences. Aortic SBP was also not different between groups, and did not change with training ( $102 \pm 2$  to  $103 \pm 2$  to  $101 \pm 2$  vs.  $103 \pm 2$  to  $100 \pm 2$  to  $101 \pm 2$  mmHg;  $p > 0.05$ ). However, AA had a significantly lower peak FBF ( $18.04 \pm 1.49$  ml $\cdot$ min $^{-1}$  $\cdot$ 100 $^{-1}$ ) compared to CA ( $23.30 \pm 1.35$ ) only at the baseline but training had no significant effect on peak FBF in either group.

**CONCLUSIONS:** These data suggest that 8 weeks of aerobic training had no effect on BP in normotensive CA and AA, but our data suggest that a control period before initiation of training is important to assess the true effects of training on BP. Interestingly, AA have lower microvascular function despite similar BP compared to CA, but aerobic training had no effect on this. Future work is needed to determine if other interventions can affect the lower endothelial function in AA.

**Resveratrol Treatment Reverses Doxorubicin-Induced Vascular Dysfunction In Old Rat Mesenteric Arteries**

Melissa A. Whidden<sup>1</sup>, Nataliya Kirichenko<sup>2</sup>, Debapriya Dutta<sup>2</sup>, Jinze Xu<sup>2</sup>, Christiaan Leeuwenburgh, FACSM<sup>2</sup>, Nihal Tumer<sup>2</sup>. <sup>1</sup>West Chester University, West Chester, PA. <sup>2</sup>University of Florida, Gainesville, FL  
(No relationships reported)

Doxorubicin is an anti-tumor agent used in cancer chemotherapy. Unfortunately, doxorubicin is associated with endothelial damage and vascular dysfunction. Reactive oxygen species production may play a role in doxorubicin-induced vascular dysfunction. Resveratrol, a natural phytoalexin produced in grapes functions as an antioxidant and has been shown to exert cardioprotective effects.

**PURPOSE:** To determine the impact of resveratrol on doxorubicin-induced vascular dysfunction in old rat mesenteric arteries.

**METHODS:** Old (26 months) male F-344xBN rats were randomly divided into four groups; control (CON), doxorubicin (DOX), resveratrol (RES) and resveratrol + doxorubicin (RES + DOX). Resveratrol (5 mg/kg/day) was given to the rats in food pellets for 6 weeks while DOX (10 mg/kg body weight) was administered intraperitoneal 24 hours prior to sacrifice. Concentration-response curves to acetylcholine (ACh 10 $\cdot$ 9-10 $\cdot$ 5 M) with and without L-NAME (10  $\mu$ M) were evaluated in pressurized isolated second-order mesenteric arteries.

**RESULTS:** ACh-induced endothelium-mediated relaxation was significantly reduced in DOX treated rats when compared with controls. Relaxation to ACh (10 $\cdot$ 5 M) was  $76 \pm 2\%$  in control and  $38 \pm 4\%$  in DOX ( $P < 0.001$ ) arteries. While the low dose of RES failed to improve endothelium-dependent dilation in the old arteries ( $76 \pm 2\%$  vs.  $78 \pm 4\%$ ), RES significantly attenuated the DOX-induced reduction in dilation (ACh 10 $\cdot$ 5 M,  $70 \pm 4\%$  vs.  $38 \pm 4\%$ ,  $P < 0.01$ ). L-NAME decreased responses to ACh in CON and RES arteries and inhibited the already reduced responses in the DOX mesenteric arteries.

**CONCLUSION:** These findings demonstrate that a low dose of resveratrol contributes to the reversal of vascular endothelial dysfunction associated with doxorubicin treatment. This may have therapeutic potential when dealing with the cardiovascular complications associated with doxorubicin.

Supported by NIH AG17994, 1P30AG02874, and NIA T32 AG000196.

2807 Board #79 June 1 11:00 AM - 12:30 PM

**Exercise Training And Impaired Glucose Tolerance (IGT): Effects On Oxidative Stress And Arterial Stiffness.**

Conor M. McClean<sup>1</sup>, Andrea M. McNeilly<sup>1</sup>, Tom R. Trinick<sup>2</sup>, Ellie Duly<sup>2</sup>, Marie H. Murphy, FACSM<sup>1</sup>, Jim McLaughlin<sup>1</sup>, George Burke<sup>1</sup>, Gareth W. Davison, FACSM<sup>1</sup>. <sup>1</sup>University of Ulster, Newtownabbey, United Kingdom. <sup>2</sup>Ulster Hospital, Dundonald, United Kingdom.  
(No relationships reported)

Compared to normoglycaemic individuals, those with impaired glucose tolerance (IGT) have a greater risk of developing diabetes and subsequent cardiovascular complications. Research examining the efficacy of exercise in such individuals for measures of vascular function remains scarce.

**PURPOSE:** To examine the effects of aerobic exercise training on metabolic control, regional arterial stiffness and oxidative stress in individuals with IGT.

**METHODS:** Twelve obese participants (7 males and 5 females;  $48.0 \pm 9.4$  yrs;  $168.0 \pm 7.0$  cm;  $90.7 \pm 16.8$  kg; BMI  $32.4 \pm 7.0$  kg/m $^2$ ) with IGT participated in a 12 week training programme consisting of walking at 65% of maximum predicted heart rate (HR) for 5 d $\cdot$ wk $^{-1}$ . Pulse wave velocity (PWV) and blood pressure (BP) were examined pre and post training, while venous blood samples were also drawn for determination of glucose, blood lipids and indices of oxidative stress (lipid hydroperoxides - LOOH and superoxide dismutase - SOD).

**RESULTS:** Following training PWV ( $9.10 \pm 1.20$  m/sec vs.  $8.39 \pm 1.16$  m/sec), glucose ( $5.70 \pm 0.60$  mmol $\cdot$ L $^{-1}$  vs.  $5.45 \pm 0.60$ ), LOOH ( $1.20 \pm 0.47$   $\mu$ M $\cdot$ L $^{-1}$  vs.  $0.79 \pm 0.32$   $\mu$ M $\cdot$ L $^{-1}$ ), triacylglycerols (TAGs;  $1.53 \pm 0.51$  mmol $\cdot$ L $^{-1}$  vs.  $1.32 \pm 0.52$  mmol $\cdot$ L $^{-1}$ ), systolic BP ( $145 \pm 14$  vs.  $136 \pm 14$  mmHg) and body mass ( $90.7 \pm 16.8$  kg vs.  $87.6 \pm 15.7$  kg) decreased, respectively ( $P < 0.05$ ). There were no changes in SOD, high-sensitivity C-reactive protein (hs-CRP) or blood cholesterol (high-density lipoprotein cholesterol; HDL-C; low-density lipoprotein cholesterol; LDL-C), respectively ( $P > 0.05$ ).

**CONCLUSIONS:** This study illustrates that 12 weeks of moderate intensity aerobic training can improve upper limb vascular function in obese subjects with IGT. The observed changes are most likely due to improvements in TAGs and glucose metabolism, which may subsequently reduce oxidative stress generation.

2808 Board #80 June 1 11:00 AM - 12:30 PM

**Effects of Exercise on Endothelial Progenitor Cells in a High Glucose Environment**

Gayatri Guhanarayan, Anisha Patel, Stephanie Simoes, Sarah Witkowski. *University of Massachusetts, Amherst, MA.* (Sponsor: Barry Braun, FACSM)  
(No relationships reported)

**INTRODUCTION:** Endothelial Progenitor Cells (EPCs) are adult stem cells that play a key role in the repair and maintenance of the vascular endothelium. Diabetic individuals have impaired vascular function, which may be related to hyperglycemia and dysfunctional EPCs. Exercise may be a potent method to increase EPC function in patients with diabetes.

**PURPOSE:** To study the effects of a high glucose on EPC function and gene expression before and after an acute bout of exercise.

**METHODS:** 6 healthy males between the ages of 18-30 were recruited for the study. Blood draws were performed before and after an acute bout of exercise. Exercise consisted of treadmill running for 30mins at 70% HRRmax. Mononuclear cells were isolated and cultured using the CFU-Hill assay for a period of 5 days. Cells from before and after exercise were incubated either in control media (5mmol of glucose) or media with 15mmol of glucose. At the end of the 5 days, colony forming units (CFUs) were counted and RNA was isolated. Gene expression was determined via RT-PCR for NF $\kappa$ B, TGF $\beta$ 1, eNOS, MAPK, and TNF $\alpha$  and normalized to GAPDH. Efficiency was  $> 90\%$  for all targets and gene expression was calculated as fold-change from pre-exercise/low glucose condition using the  $\Delta\Delta C_t$  method

**RESULTS:** While there was no difference with acute exercise in the low-glucose condition, EPC eNOS gene expression tended to increase with exercise in the high glucose condition ( $p = 0.17$ ). MAPK gene expression tended to be higher after exercise (low glucose,  $p = 0.10$ ) with no changes in expression with high glucose. TGFB1 expression was highest after exercise in the high glucose condition ( $p = 0.16$ ). CFU-Hill counts and EPC gene expression for NFkB and TNFa did not differ between conditions.

**CONCLUSION:** These data suggest that gene expression of major factors associated with vascular dysfunction in diabetes are minimally changed in EPCs of healthy young men in response to glucose or exercise.

**2809** Board #81 June 1 11:00 AM - 12:30 PM  
**Comprehensive Vascular Function Testing Across The Menstrual Cycle**

Karen M. Birch, University of Leeds, Leeds, United Kingdom. (Sponsor: Keith George, FACSM)  
(No relationships reported)

Studies evaluating the impact of menstrual cycle variability in vascular function have shown decreased brachial artery flow mediated dilation (FMD) in the early luteal phase. However, a comprehensive quantification of FMD, low-flow mediated constriction (L-FMC) and the reactive hyperaemic response has not been evaluated.

**PURPOSE:** To determine the impact of menstrual cycle phase on FMD, L-FMC and reactive hyperaemia.

**METHODS:** 9 women ( $34 \pm 9$  yrs) attended the lab in the early follicular, late-follicular and mid-luteal phases of the menstrual cycle. After 30 min of supine rest, brachial artery vascular function was assessed using a 5-minute forearm ischemia protocol and ultrasound. Peak blood flow within 30 s of cuff deflation and FMD from 20s of end-diastolic diameters at baseline, compared to the mean of 3 maximal end-diastolic diameters during 2.5 min post ischemia were assessed. L-FMC was determined from the mean of 3 minimum end-diastolic diameters in the 30s before cuff deflation.

**RESULTS:** FMD did not differ with menstrual phase (**FMD Early Follicular:**  $8.2 \pm 1.4\%$ , **Late Follicular:**  $6.6 \pm 0.8\%$ , **Mid-luteal:**  $6.5 \pm 1.0\%$   $p = 0.20$ ). L-FMC exhibited a non-significant inverse pattern when compared to FMD with more constriction apparent at phases when FMD was greater (**L-FMC Early Follicular:**  $-0.65 \pm 1.0\%$ , **Late Follicular:**  $-1.1 \pm 0.6\%$ , **Mid-luteal:**  $-2.2 \pm 0.6\%$   $p = 0.35$ ). Total vascular reactivity (sum of the absolute values of FMD and L-FMC) was unaltered (**Total vascular reactivity Early Follicular:**  $9.6 \pm 1.3\%$ , **Late Follicular:**  $8.5 \pm 0.9\%$ , **Mid-luteal:**  $8.0 \pm 0.9\%$   $p = 0.28$ ). Normalization to the shear response had no effect. Finally, peak blood flow after cuff deflation (a measure of resistance vessel function) was also unaltered by menstrual phase.

**CONCLUSIONS:** These preliminary results suggest a lack of menstrual cycle fluctuation in vasodilatory and vasoconstrictive responses to the forearm ischemia protocol.

**2810** Board #82 June 1 11:00 AM - 12:30 PM  
**Endothelial Progenitor Cell Quantification in Young Adult Non-Smokers and Smokers by a Novel Gating Strategy**

Michael Kairaira, Deborah L. Fearheller, Ingrid Schmid, Christian K. Roberts, FACSM. UCLA, Los Angeles, CA.  
(No relationships reported)

**PURPOSE:** Endothelial progenitor cells (EPC) are an accepted predictor of cardiovascular disease risk. Accurate identification of EPC is debatable, and to date identifying markers and isolation techniques remain to be clearly established. Primitive EPC are conventionally defined as  $CD34^+CD133^+KDR^+$ . Few studies have investigated  $CD34^+$  EPC that are endothelial in nature, and their phenotype and relation to subsets of hematopoietic cells remain elusive. Thus, reliable flow cytometry acquisition and analysis strategies are needed as EPC comprise  $<1\%$  of peripheral blood mononuclear cells. Previously, it has been shown that long-term smoking decreases circulating  $CD34^+$  cells in older individuals. We designed and optimized a novel cytometry protocol for accurate enumeration of EPC in recreationally-active, non-smoking young adults ( $n=36$ ,  $23.3 \pm 0.6$ yr) compared to chronic smokers ( $n=28$ ,  $25.0 \pm 0.8$ yr) as part of a randomized-controlled trial (RCT) to investigate the effects of resistance training (RT) on vascular function in young, adult chronic smokers.

**METHODS:** Using a whole blood lysing method,  $2 \times 10^7$  cells were stained with a 5-color antibody panel and propidium iodide for dead cell exclusion.  $4 \times 10^6$  cells were acquired to achieve sufficient events to classify PC reliably as viable, side scatter<sup>low</sup>,  $CD45^{dim}$ ,  $CD3^+CD19^+CD33^+CD34^+$  and subdivide them into  $CD133^+$  and  $KDR^+$ . To improve the accuracy of rare EPC analysis in samples with varied red cell contamination of the gating region, we based our calculation of EPC frequency not on lymphocyte scatter gating, but on a novel strategy of a combination gate of  $CD45^{bright}$  and  $CD34^+$ .

**RESULTS:** Preliminary data show that compared to non-smokers, smokers have a higher percentage of  $CD133^+$  ( $50 \pm 2.1\%$  vs.  $42 \pm 2.9\%$ ,  $p=0.03$ ), but lower  $KDR^+$  within the  $CD34^+$  subset of cells ( $1.9 \pm 0.44\%$  vs.  $4.8 \pm 0.94\%$ ,  $p<0.01$ ). Interestingly though, smokers had a higher proportion of  $CD45^{bright}$  lymphocytes than non-smokers ( $88 \pm 2.4\%$  vs.  $72 \pm 4.6\%$ ,  $p<0.01$ ).

**CONCLUSION:** We demonstrated the ability to detect specific circulating EPC subsets using our novel gating strategy. In young smokers, compensatory mechanisms may prevent the decline in  $CD34^+$  cells before true endothelial dysfunction exists. Our ongoing RCT will determine if RT has an effect on the number of EPC and EPC subsets in chronic smokers.

**2811** Board #83 June 1 11:00 AM - 12:30 PM  
**Interactive Effects of Stress Reactivity and Usual Stress on Adolescents Cardiovascular Health**

James N. Roemmich, FACSM, Denise M. Fedra, April M. Seelbinder, Maya J. Lambiasi, Joan Dorn. University at Buffalo, Buffalo, NY.  
(No relationships reported)

Adolescents experience stressful situations at high rates during school. Psychological stress is associated with the progression of cardiovascular disease (CVD). The diathesis-stress model suggests that youth experiencing the greatest cumulative stress are at greatest risk for developing antecedents of CVD. Thus, youth with the greatest reactivity to a stressor may be at most risk for CVD pathogenesis, especially if they also incur frequent daily stressors, such as during a year of high school.

**PURPOSE:** To determine the relationships between the magnitude of CV stress reactivity and the amount of daily stress with the pathogenesis of CVD as characterized by carotid artery intima-media thickness (IMT) at the end of the school year.

**METHODS:** 23 boys and 19 girls age 13-16 y were studied for cardiovascular reactivity to an interpersonal speech stressor and usual stress (perceived stress scale-14) in August just before the start of the school year. Usual stress was measured again in October after the beginning of the school year. Carotid artery IMT was measured immediately after the school year the following June. Multiple regression was used to determine the interactive association of CV stress reactivity (e.g., systolic blood pressure (SBP) reactivity) and school year (October) stress on carotid artery IMT and BAR when covarying for resting SBP and baseline (August) level of usual stress.

**RESULTS:** As main effects, SBP reactivity to the speech stressor was associated with IMT ( $\beta = 0.005$ ,  $p < 0.005$ ), while school year usual stress was not ( $\beta = 0.002$ ,  $p \geq 0.17$ ). The interaction of SBP reactivity and school year usual stress was significant ( $p < 0.02$ ). The overall interaction model predicted that youth with low stress reactivity and low school stress; low reactivity and high stress; high reactivity and low stress; and high reactivity and high stress would have IMT of 0.44, 0.48, 0.55, and 0.50 mm, respectively.

**CONCLUSIONS:** With the methods used, higher stress reactivity and usual stress increased IMT by a predicted 25% and 12%, respectively. SBP stress reactivity predicts IMT better than usual stress, and children with the greatest reactivity to a stressor may be at the greatest risk for subclinical progression of CVD.

**Associations Between Sedentary Behaviour, Cardiometabolic Biomarkers And Vascular Health In Children**

Nicola D. Hopkins<sup>1</sup>, Gareth Stratton<sup>1</sup>, Nicola Ridgers<sup>2</sup>, Lee E F Graves<sup>1</sup>, Lynne M. Boddy<sup>1</sup>, Rebecca Gobbi<sup>1</sup>, Lawrence Fowweather<sup>1</sup>, Nigel T. Cable<sup>1</sup>, Daniel J. Green<sup>1</sup>.  
<sup>1</sup>Liverpool John Moores University, Liverpool, United Kingdom. <sup>2</sup>Deakin University, Melbourne, Australia. (Sponsor: Keith George, FACSM)  
(No relationships reported)

**PURPOSE:** Vascular function, measured via flow mediated dilation (FMD), is the earliest detectable manifestation of cardiovascular disease (CVD). Vascular dysfunction is a strong independent predictor of CV events and is present in children with CVD risk factors. Emerging evidence suggests that sedentary behaviour (SB) is independently associated with CVD and mortality. Currently the relationship between SB, vascular function and artery wall thickness is unknown. We therefore aimed to assess the association between FMD, carotid artery intima-medial thickness (cIMT) and SB in children.

**METHODS:** Using high resolution Doppler ultrasound we measured endothelial function and cIMT in 118 children (72[12.1±0.7; 46[12.1±0.7yrs). Sedentary behaviour was assessed using objective uni-axial accelerometry. Cardiometabolic biomarkers (insulin, glucose, HbA1c, C-peptide, triglycerides, total, HDL and LDL cholesterol, C - reactive protein and adiponectin) were measured in a subgroup of children (N=53, 28 female). Data was adjusted for age, maturation and physical activity level.

**RESULTS:** Daily, children engaged in 496.7±90.2 min of SB. There was no significant difference between girls and boys for percentage of accelerometer wear time spent in SB ((SB%) 68.6±12.9 vs 65.0±11.7 respectively p>0.05), FMD (9.3±4.3 vs 9.2±4.4 respectively, p>0.05) or cIMT (0.47±0.09 vs 0.49±0.08 respectively, p>0.05). Neither FMD (r=-0.00, p>0.05) nor cIMT (r=0.00, p>0.05) was associated with SB. FMD was significantly related only to C - peptide only (r=0.38 , p=0.01).

**CONCLUSION:** Our data suggest that SB is not associated with vascular health in children. This implies that interventions that aim to reduce SB *per se* in children may not be effective in terms of improving/maintaining vascular health. Further research is necessary to describe the mechanistic relationship, if any, between sedentary behaviour and cardiovascular risk. Additionally, our findings imply that C-peptide may contribute to regulation of vascular function.

**2813** Board #85 June 1 11:00 AM - 12:30 PM

**Cardiopulmonary Fitness and Cognitive Function: Association with Peripheral Vascular and Cerebrovascular Function**

Takashi Tarumi, Mitzi M. Gonzales, Bennett A. Fallow, Nantinee Nualnim, Hirofumi Tanaka, FACSM, Andrea P. Haley. *The University of Texas at Austin, Austin, TX.*

(No relationships reported)

Midlife cardiovascular and cerebrovascular disease risk is associated with an elevated incidence of late-life dementia. Habitual exercise has been suggested as an efficacious lifestyle intervention to prevent or delay the onset of cognitive decline. However, it is not clear how habitual exercise influences cognitive function and whether these relations may be mediated by enhanced peripheral vascular and/or cerebrovascular function.

**PURPOSE:** To examine the association between cognitive function and the key features of vascular and cerebrovascular function among middle-aged sedentary and endurance-trained adults.

**METHODS:** We studied 29 healthy sedentary and 32 endurance-trained adults aged between 41-65 years (24 males and 37 females) underwent a variety of vascular function measurements (carotid artery distensibility, brachial artery flow-mediated dilatation, and cerebrovascular reactivity to hypo- and hypercapnia) and a comprehensive battery of neuropsychological tests.

**RESULTS:** There were no significant differences in age, body mass, education level, and blood pressure between sedentary and endurance-trained subjects. Endurance-trained group demonstrated greater maximal oxygen consumption (VO<sub>2</sub>max) (44.6±1.6 vs. 26.1±1.1 ml/kg/min), common carotid artery distension (4.81±0.25 vs. 3.96±0.20 mm<sup>2</sup>) and distensibility coefficient (4.92±0.28 vs. 4.08±0.22 10<sup>-3</sup>/mmHg), brachial artery flow-mediated dilatation (6.63±0.61 vs. 4.87±0.63%), and total cognitive composite score (z-score: 0.13±0.08 vs. -0.15±0.10) than the control group (all P<0.05). Cerebrovascular reactivity to hypo- and hypercapnia was not different between the groups. Partial correlation analyses adjusted for age, sex, and education revealed that total cognitive composite score is significantly associated with VO<sub>2</sub>max (r=0.32) and cerebrovascular reactivity index (r=0.29). Moreover, VO<sub>2</sub>max was correlated with cerebrovascular reactivity index (r=0.29).

**CONCLUSION:** A greater cognitive function in endurance-trained adults is associated with aerobic fitness and cerebrovascular reactivity independent of potential covariates.

**2814** Board #86 June 1 11:00 AM - 12:30 PM

**The Effect Of Interrupting Prolonged Sitting With Intermittent Activity On Markers Of Thrombotic Risk**

Bethany J. Howard<sup>1</sup>, Steve F. Fraser<sup>2</sup>, Pameet Sethi<sup>1</sup>, Ester Cerin<sup>3</sup>, Neville Owen<sup>1</sup>, Bronwyn A. Kingwell<sup>1</sup>, David W. Dunstan<sup>1</sup>. <sup>1</sup>Baker IDI Heart & Diabetes Institute, Melbourne, Australia. <sup>2</sup>Deakin University, Melbourne, Australia. <sup>3</sup>The University of Hong Kong, Hong Kong, China. (Sponsor: Charles Matthews, FACSM)

(No relationships reported)

Prolonged sitting has been associated with an elevated risk of cardiovascular mortality and venous thrombosis. While the mechanisms underlying such relationships have not been fully elucidated, activation of blood coagulation pathways may be involved. The impact of interrupting acute prolonged sitting with intermittent activity on markers of thrombotic risk has not been studied. **PURPOSE:** To examine the acute effects of a single 7 hour period of prolonged sitting on blood coagulation markers with and without intermittent bouts of light- or moderate-intensity activity in sedentary older (45-65 yrs) overweight/obese adults.

**METHODS:** 19 overweight/obese adults (11 males/8 females; 53.8 ± 4.9yrs, BMI: 31.2 ± 4.1 kg.m<sup>-2</sup>) participated in a randomized three-period, three-treatment acute cross-over trial: 1) uninterrupted sitting; 2) sitting with 2-minute bouts of light-intensity treadmill walking every 20 minutes; and 3) sitting with 2-minute bouts of moderate-intensity treadmill walking every 20 minutes. Blood was collected at baseline (0hrs) whilst seated prior to consumption of a standardised mixed meal and at the completion of each condition (7hrs). Blood coagulation markers were measured and corrected for blood volume changes. All analyses were adjusted for age, sex, body mass, baseline outcome values and order effects.

**RESULTS:** Compared to uninterrupted sitting, plasma fibrinogen decreased (0.17g.l<sup>-1</sup> [0.01, 0.32], P <0.05) in the sitting with the light-intensity activity condition, but not the moderate-intensity activity condition. Both activity conditions resulted in small reductions in thrombin clotting time relative to uninterrupted sitting (light-intensity: 0.70s, [0.37, 1.02], P <0.001 and moderate-intensity: 0.57s, [0.25, 0.9], P <0.001). There were no significant between-condition differences in prothrombin time, activated partial thromboplastin time, von Willebrand factor and D-dimer.

**CONCLUSION:** Interrupting prolonged sitting with short, intermittent bouts of light-intensity walking reduced circulating fibrinogen in overweight/obese adults relative to uninterrupted sitting. Further investigation to optimise the timing and intensity of activity breaks is warranted to reduce possible thrombotic risk associated with prolonged sitting.

**Racial Differences In Cardiovascular Response Following An Acute Bout Of Aerobic Exercise**

Huimin Yan<sup>1</sup>, Abbi D. Lane<sup>1</sup>, Sushant M. Ranadive<sup>1</sup>, Rebecca M. Kappus<sup>1</sup>, Peng Sun<sup>2</sup>, Michael A. Behun<sup>1</sup>, Bo Fernhall, FACSM<sup>1</sup>. <sup>1</sup>University of Illinois at Urbana-Champaign, Champaign, IL. <sup>2</sup>East China Normal University, Shanghai, China.

(No relationships reported)

Post-exercise hypotension (PEH) is widely observed in Caucasians (CA). It is usually due to a reduction in peripheral vascular resistance that is not completely offset by a rise in cardiac output. It appears that African Americans (AA) may not exhibit PEH following aerobic exercise.

**PURPOSE:** To examine the cardiovascular responses following an acute bout of aerobic exercise in AA and CA.

**METHODS:** 24 young healthy Caucasians (CA, n = 12) and African Americans (AA, n = 12) performed 45 min of moderate intensity aerobic exercise on a treadmill at 70% of heart rate reserve. Before at rest, 20 min postexercise, and 40 min postexercise, cardiac output (CO), total peripheral resistance (TPR) and arterial compliance (compliance) were measured by finometer. Aortic blood pressures (BP), central (carotid-femoral), leg (carotid-femoral) and brachial (carotid-radial) pulse-wave velocity (PWV) were measured by applanation tonometry. An additional brachial BP was taken at 60 min after exercise. Time by race two-way ANOVA was used for statistical analyses.

**RESULTS:** See Table 1. Significant time effect was found in brachial SBP, aortic BPs, brachial PWV and CO (# p<.05). Significant race effect was found in brachial and central PWV (\$ p<.05). Significant interaction was found in brachial DBP (\* p<.05).

**CONCLUSIONS:** Although AA have higher central and peripheral arterial stiffness than CA, both groups exhibited comparable hemodynamic responses up to 40 min following acute aerobic exercise. AA did not exhibit PEH 60 min after exercise, in contrast to CA. Future work is needed to extend the time course of measurement and to examine the mechanisms underlying the BP response.

Table 1. Hemodynamic responses to an acute bout of aerobic exercise. Mean (SE)

|                   | CA          |             |             |             | AA          |

**Reduced Exercise Cerebral Blood Flow in Normotensive Young Adult Blacks with Exaggerated Exercise Pressor Response**

Vernon Bond, FACSM<sup>1</sup>, Raymond Blakely<sup>2</sup>, Rajagopalan Sridhar<sup>1</sup>, Janaki Kalyanam<sup>1</sup>, Richard G. Adams<sup>1</sup>, Richard M. Millis<sup>1</sup>, Thomas Obisesan<sup>1</sup>, Annapurni Jayam-Trouth<sup>1</sup>, Kamal Ameis<sup>3</sup>. <sup>1</sup>Howard University, Washington, DC. <sup>2</sup>University of Maryland Eastern Shore, Princess Anne, MD. <sup>3</sup>Georgetown University, Washington, DC.

(No relationships reported)

Cardiovascular disease is a major health disparity in the African American (AA) population. Extensive elevation in systolic blood pressure during exercise is an indicator for future hypertension and possible risk for cerebrovascular stroke.

**PURPOSE:** The purpose of this study was to monitor unilateral cerebral blood flow during exercise on an ergometer cycle in young normotensive AAs with and without an exaggerated blood pressure response to exercise (EEBPR).

**METHODS:** Five normotensive AA s (3 female, 2 male/18-28 yrs.) with an EEBPR, and five AA s (3 female, 2 male/18-28 yrs.) without an EEBPR were studied before and during exercise while monitoring unilateral cerebral blood flow. The EEBPR was defined in the study as an increase in systolic blood pressure  $\geq 50$  mm Hg above resting systolic blood pressure at a work intensity of 50% peak oxygen uptake (VO<sub>2</sub>peak). At rest and during six-minute steady state submaximal work at 30% and 50% VO<sub>2</sub>peak, blood flow in the right middle cerebral artery (MCAv) was measured using a 2 MHz pulse Doppler ultrasound system. Cardiac output (CO) was determined using cardiac impedance. Nonlinear spectral method of heart rate variability (HRV) was used to measure cardiac autonomic modulation. Blood pressure (BP) was determined by an automatic monitoring device. End tidal carbon dioxide (EtCO<sub>2</sub>) was assessed using a capnograph.

**RESULTS:** VO<sub>2</sub>peak and body composition did not differ significantly between groups. Baseline values of MCAv, HRV, BP, CO, and EtCO<sub>2</sub> were similar between groups with and without an EEBPR (P> 0.05). However, during submaximal exercise at 30% and 50% VO<sub>2</sub>peak, MCAv was lower by 40% and 37% respectively, in the EEBPR group compared to the group without an EEBPR (p value <0.05). Corresponding systolic BP during exercise was higher in the EEBPR group (P< 0.05). These differences in MCAv occurred in the absence of any differences in CO, HRV and EtCO<sub>2</sub> or cardiac Heather index between groups.

**CONCLUSIONS:** These findings suggest a diminished cerebral vascular function in the EEBPR group. This may be a result of changes in vascular structure and/or factors and metabolites involved in vasodilation.

**Whole Body Vibration Effects on Hemodynamics and Oxygen Consumption in Individuals with Spinal Cord Injury**

Ceren Yazar<sup>1</sup>, Bruce Gladden, FACSM<sup>2</sup>, David Pascoe, FACSM<sup>2</sup>, John Quindry, FACSM<sup>2</sup>, JoEllen M. Sefton<sup>2</sup>. <sup>1</sup>University of Alabama at Birmingham, Birmingham, AL. <sup>2</sup>Auburn University, Auburn, AL.

(No relationships reported)

**BACKGROUND:** Considering the potential of whole body vibration (WBV) exercise for activating paralyzed muscles via the Ia reflex loop and increasing the skeletal muscle metabolism, WBV exercise may provide a sufficient training stimulus for the cardiovascular system in individuals with spinal cord injury (SCI).

**Objective:** 1) Investigate the acute effects of WBV with varying frequencies on hemodynamic responses and steady-state oxygen consumption (VO<sub>2</sub> in ml/kg lean mass/min) in individuals with SCI and able-bodied individuals (AB); 2) Compare physiological responses between groups and among three different WBV frequencies.

**Design:** A 2 (group) x 3 (treatment) x 4 (time) repeated measures factorial design with repeated measures across treatment and time.

**Subjects:** 11 males with SCI (C4-T6; ASIA A and B; ages: 50.4±8.2) and 10 age and gender matched AB individuals (ages: 48.2±6.8).

**METHODS:** Using a randomized design subjects completed three WBV exercise sessions at 30, 40 and 50 Hz. Heart rate (HR), mean arterial blood pressure (MAP), stroke volume (SV), cardiac output (CO), VO<sub>2</sub>, and relative changes in oxygenated ( $\Delta$ HbMbO<sub>2</sub>), deoxygenated ( $\Delta$ HHbMb), and total ( $\Delta$ THbMb) heme groups were obtained during pre-WBV standing, WBV first minute, WBV steady-state, and post-WBV standing.

**RESULTS:** Both groups demonstrated a significant increase in VO<sub>2</sub>,  $\Delta$ HbMbO<sub>2</sub>, and  $\Delta$ THbMb; yet the increase was larger in the SCI group for VO<sub>2</sub> during WBV steady-state at 40 (p= 0.01; SCI: 6.1±0.6, AB: 5.4±0.7) and 50 Hz (p= 0.001; SCI: 6.9±1.2, AB: 5.3±0.7); and for  $\Delta$ HbMbO<sub>2</sub> (p≤ 0.0001) and  $\Delta$ THbMb (p≤ 0.0001) during post-WBV standing at 30 and 40 Hz.  $\Delta$ HHbMb did not significantly change in the AB group; where as a significant decrease was revealed in the SCI group following WBV. HR, MAP, SV, or CO did not significantly change in either group and no frequency effect was revealed.

**CONCLUSION:** The WBV parameters used in the present study do not appear to induce significant cardiovascular benefits for the individuals with SCI. Although the increase in VO<sub>2</sub> was higher in the SCI group as compared to the able-bodied group, these changes are comparatively small in relation to cardiovascular changes elicited by aerobic exercise. Future studies should investigate the potential mechanisms responsible for the observed increase in  $\Delta$ HbMbO<sub>2</sub> and  $\Delta$ THbMb in response to WBV.

**Exercise Training Does Not Protect Skeletal Muscle Contractile Function During Acute Femoral Artery Occlusion**

Tyler G. Robertson, R. Reed Lambert, Talon Anderson, William L. Sexton, FACSM. *A.T. Still University, Kirksville, MO.*  
(No relationships reported)

Exercise training is known to enhance vascular transport capacity in skeletal muscle through both arteriogenesis and angiogenesis which presumably enhances support for contractile activity. Not surprisingly, acute femoral artery ligation results in an abrupt fall in blood flow and microvascular PO<sub>2</sub> (PO<sub>2m</sub>) and an accelerated rate of muscle fatigue during subsequent contractions.

**PURPOSE:** The purpose of this study was to test the hypothesis that exercise training would enhance the development of collateral circulation to the lower leg thereby attenuating the fall in PO<sub>2m</sub> and the rate of fatigue during acute femoral artery occlusion.

**METHODS:** Female Sprague-Dawley rats (225-250 g) accustomed to treadmill running were randomly divided into exercise trained (ET, n=11) and sedentary (SED, n=8) groups. The training protocol consisted of 8 wks during which intensity and duration were progressively increased to 20 m/min at 20 degree incline for 60 min/d. After pentobarbital anesthesia (50 mg/kg ip) a snare was placed around the left femoral artery and the left extensor digitorum longus muscle (EDL) was isolated and the distal tendon was attached to a load cell interfaced with a Muscle Tension Analyzer. PO<sub>2m</sub> was measured with the phosphorescence quenching method using Oxyphor G2. PO<sub>2m</sub> and muscle tension were measured during a 30 s baseline, and continuously during 10 min of femoral artery occlusion 10 min and muscle contractions (1 Hz, 6V), and for 5 min after restoration of femoral artery flow.

**RESULTS:** Resting PO<sub>2m</sub> in the EDL was similar between groups (ET, 32 ± 3; SED 35 ± 3 mmHg). During femoral occlusion PO<sub>2m</sub> in ET and SED rats fell to 10 ± 1 and 11 ± 1 mmHg, respectively. Muscle twitch tension and fatigue (ET, 40 ± 9; SED, 33 ± 6%) during femoral occlusion were not different. After the reestablishment of femoral flow, the time constant for recovery of PO<sub>2m</sub> (ET 12 ± 6; SED 12 ± 3 s) and the recovery PO<sub>2m</sub> (ET 28 ± 2; SED 26 ± 2 mmHg) were similar. The time constants for the recovery of twitch tension were also not different between groups (ET, 38 ± 11; SED, 19 ± 6 s).

**CONCLUSION:** The results of this study do not support the notion that exercise training in healthy rats will enhance oxygen delivery and attenuate the decrement in contractile function during an acute low blood flow state. (Supported by the Graduate Program Committee, KCOM-ATSU.)

**Regulation of Cardiovascular Variables during Lower Body Negative Pressure and Cold.**

David J. Kean, Ellen L. Glickman, FACSM, Gabriel Sanders, Corey Peacock, John Gunstad, Matthew D. Muller. *Kent State University, Kent, OH.*  
(No relationships reported)

**PURPOSE:** To determine the effects cold has on cardiovascular variables during exposure to lower body negative pressure (LBNP).

**METHODS:** Eleven college aged men participated in two trials. Subjects were supine on a gurney with their lower extremities inserted into a LBNP box up to the level of the anterior superior iliac spine. Each trial consisted of a control period of 100 min followed by application of LBNP for 20 min and concluded with a 15 min recovery period. Both trials were carried out in the environmental chamber; the cold trial was performed at 10°C (cold) and the ambient trial was performed at 23°C (ambient). The order of trials was counterbalanced. Cardiovascular variables were measured using bioimpedance and brain oxygen saturation was measured using near infrared spectroscopy. A repeated measures analysis of variance was used to compare trials across time.

**RESULTS:** Brain oxygen saturation was significant for time, condition and there was an interaction. There was a greater decrease in brain oxygenation (SaO<sub>2</sub> ambient = 81 ± 7% vs. cold = 81 ± 7%) to recovery in the cold condition vs. the ambient condition (SaO<sub>2</sub> ambient = 81 ± 6% vs. cold = 73 ± 7%). Mean arterial pressure (MAP) was significant for time, condition and there was an interaction. There was a greater increase in mean arterial pressure (MAP= 74 ± 8 mmHg ambient vs. cold = 84 ± 13mmHg) to recovery in the cold condition vs. the ambient condition (MAP ambient = 79 ± 8 vs. cold = 95 ± 11mmHg). Refer to Table 1 for pre-LBNP, LBNP and recovery data, \* means p<0.05.

| Table 1                       | Pre-LBNP     | LBNP         | Recovery     |
|-------------------------------|--------------|--------------|--------------|
|                               | Ambient cold | Ambient cold | Ambient cold |
| Mean Arterial Pressure (mmHg) | 80±8 93±15*  | 81±7 93±9*   | 79±8 95±11*  |
| RSaO <sub>2</sub> (%)         | 80±5 62±8*   | 77±5 61±9*   | 81±6 62±9*   |

**CONCLUSION:** Increased MAP from cold exposure may maintain perfusion to the brain during an orthostatic challenge.

**2820** Board #92 June 1 11:00 AM - 12:30 PM  
**Cardiovascular And Perceptual Responses To Blood Flow Restricted Resistance Exercise Performed With Different Restrictive Cuffs**

Christopher A. Fahs, Lindy M. Rossow, Jeremy P. Loenneke, Robert Thiebaud, Takashi Abe, Vanessa D. Sherck, Michael G. Bembem, FACSM. *University of Oklahoma, Norman, OK.*  
(No relationships reported)

Low-intensity blood flow restricted (BFR) resistance exercise causes similar strength and hypertrophy adaptations compared to high-intensity resistance exercise. The type of restrictive cuff used during BFR resistance exercise may affect the response to this type of exercise.

**PURPOSE:** To determine if the type of restrictive cuff used during BFR resistance exercise influences the cardiovascular and perceptual responses during and following an acute bout of BFR exercise.

**METHODS:** In a randomized, cross-over study design, twenty-seven young men and women completed two bouts (4 sets each) of BFR knee extension exercising at 20% 1-RM while wearing either 5 cm (narrow cuffs) or 13.5 cm (wide cuffs) wide pneumatic cuffs inflated to 130% of their brachial systolic blood pressure. Measurements of brachial (bBP) and aortic (aBP) blood pressure (BP), heart rate (HR), and augmentation index (AIx) were taken before and after the restrictive cuffs were applied and inflated, after the 2<sup>nd</sup> (mid) and 4<sup>th</sup> (post) set of resistance exercise, and 5- and 15-min into recovery. Ratings of perceived exertion (Borg, 6-20 scale; RPE) and pain (1-10 scale) were assessed before exercise and after the 2<sup>nd</sup> and 4<sup>th</sup> set of exercise.

**RESULTS:** Applied cuff pressure was not different between the narrow and wide cuff bouts (152 vs 154 mmHg, p=0.616). During BFR exercise (mid), compared to the narrow cuffs, wide cuffs caused a greater elevation in HR (92 vs 78 bpm, p<0.05), central BP (systolic: 133 vs 119 mmHg, p<0.05; diastolic: 104 vs 86 mmHg, p<0.05), RPE (14 vs 13, p<0.05) and pain (5 vs 3, p<0.05) and a greater decrease in AIx (-4 vs 1 %, p<0.05).

**CONCLUSIONS:** These findings suggest that during low-intensity BFR resistance exercise wide cuffs cause greater demands on the cardiovascular system and increase ratings of pain and RPE to a greater extent compared to BFR resistance exercise with narrow cuffs inflated to the same pressure. Cuff application pressure may need to be adjusted depending on the width of the restrictive cuff to improve subject comfort and to standardize the degree of blood flow restriction.

**Impact Of Cardiovascular Fitness On Pentraxin 3 Levels In Response To Concurrent Stressors**

Chun-Jung Huang<sup>1</sup>, David A. McAlpine<sup>1</sup>, Heather E. Webb<sup>2</sup>, Robert L. Franco<sup>3</sup>, Supatchara E. Tangsilat<sup>4</sup>, Kathleen N. Beasley<sup>1</sup>, Gary H. Kamimori, FACSM<sup>2</sup>, Edmund O. Acevedo, FACSM<sup>3</sup>. <sup>1</sup>Florida Atlantic University, Boca Raton, FL. <sup>2</sup>Mississippi State University, Starkville, MS. <sup>3</sup>Virginia Commonwealth University, Richmond, VA. <sup>4</sup>University of New South Wales, Sydney, Sydney, Australia. <sup>5</sup>Walter Reed Army Institute of Research, Silver Spring, MD.  
(No relationships reported)

Pentaxin 3 (PTX3) is primarily generated by endothelial cells and monocytes/macrophages and has recently been identified as a biomarker of vascular inflammation in predicting cardiovascular events. Although recent studies have shown that exercise has a positive/negative effect on the release of plasma PTX3, no studies have examined whether cardiovascular fitness is associated with plasma PTX3 response to a combined (exercise and mental) stress.

**PURPOSE:** The purpose of this study was to examine the effect of cardiovascular fitness on plasma PTX3 and catecholamine (epinephrine [EPI] and norepinephrine [NE]) levels to a dual stress model. To elucidate possible mechanisms for the elevated PTX3 in response to dual stress, the relationships of EPI and NE with PTX3 were examined.

**METHODS:** Fourteen subjects were classified into high fit (N=7; VO<sub>2</sub>max = 50.99 ± 2.19 ml•kg<sup>-1</sup>•min<sup>-1</sup>) and low fit (N=7; VO<sub>2</sub>max = 36.27 ± 3.51 ml•kg<sup>-1</sup>•min<sup>-1</sup>) groups and completed two counterbalanced experimental conditions. The exercise-alone condition (EAC) consisted of cycling at 60% VO<sub>2</sub>max for 37 minutes, while the dual-stress condition (DSC) included 20 minutes of a mental stress while cycling for 37 minutes.

**RESULTS:** Plasma PTX3 revealed significant increases over time in both high fit and low fit group in response to EAC and DSC (p < 0.02). No difference in PTX3 levels was observed between EAC and DSC. Furthermore, significant time effect and time by fitness level interaction in plasma EPI and NE were found in both EAC and DSC with greater levels in high fit group (p < 0.05). Additionally, plasma PTX3 was not correlated with EPI and NE neither EAC nor DSC.

**CONCLUSION:** These results suggest that cardiovascular fitness may not affect the release of plasma PTX3 to stress reactivity although exacerbated EPI and NE are seen in DSC and high fit group. In addition, plasma PTX3 could be used as an inflammatory biomarker for exercise while mental stress does not modulate PTX3 levels.

### Femoral Blood Flow and Cardiac Output during Blood Flow Restricted Leg Press Exercise

Meghan Everett, Kyle Hackney, David Martin, Lori Ploutz-Snyder, FACSM. *NASA-JSC, Houston, TX.*

(No relationships reported)

Low load blood flow restricted resistance exercise (LBFR) causes muscle hypertrophy that may be stimulated by the local ischemic environment created by the cuff pressure. However, local blood flow (BF) during such exercise is not well understood.

**PURPOSE:** To characterize femoral artery BF and cardiac output (CO) during leg press exercise (LP) performed at a high load (HL) and low load (LL) with different levels of cuff pressure.

**METHODS:** Eleven subjects (men/women 4/7, age 31.4±12.8 y, weight 68.9±13.2 kg, mean±SD) performed 3 sets of supine left LP to fatigue with 90 s of rest in 4 conditions: HL (%1-RM/cuff pressure: 80%/0); LL (20%/0); LBFR<sub>DBP</sub> (20%/1.3 x diastolic blood pressure, BP); LBFR<sub>SBP</sub> (20%/1.3 x supine systolic BP). The cuff remained inflated throughout the LBFR exercise sessions. Artery diameter, velocity time integral (VTI), and stroke volume (SV) were measured using Doppler ultrasound at rest and immediately after each set of exercise. Heart rate (HR) was monitored using a 3-lead ECG. BF was calculated as VTI x vessel cross-sectional area. CO was calculated as HR x SV. The data obtained after each set of exercise were averaged and used for analyses. Multi-level modeling was used to determine the effect of exercise condition on dependent variables. Statistical significance was set *a priori* at p < 0.05.

**RESULTS:** Artery diameter did not change from baseline. BF increased (p < 0.05) after exercise in each condition except LBFR<sub>SBP</sub> in the order of HL (12.73±1.42 cm<sup>3</sup>•mean±SE) > LL (9.92±0.82 cm<sup>3</sup>) > LBFR<sub>DBP</sub> (6.47±0.79 cm<sup>3</sup>) > LBFR<sub>SBP</sub> (3.51±0.59 cm<sup>3</sup>). Blunted exercise induced increases occurred in HR, SV, and CO after LBFR compared to HL and LL. HR increased 45% after HL and LL and 28% after LBFR (p < 0.05), but SV increased (p < 0.05) only after HL. Consequently, the increase (p < 0.05) in CO was greater in HL and LL (~3 L/min) than in LBFR (~1 L/min).

**CONCLUSION:** BF during LBFR<sub>SBP</sub> was 1/3 of that observed in LL, which supports the hypothesis that local ischemia stimulates the LBFR hypertrophic response. As the cuff did not compress the artery, the ischemia may have occurred because of the blunted rise in CO or because arterial BP cannot overcome the cuff pressure. As LBFR<sub>DBP</sub> effectively reduced BF and CO with cuff pressures less than systolic BP, future studies should investigate the hypertrophic potential of LBFR at even lower cuff pressures.

### The Influence Of Spontaneous Sympathetic Bursts On Conduit Artery Shear Rate And Diameter In Humans

Seth T. Fairfax, Jaume Padilla, Paul J. Fadel, FACSM. *University of Missouri, Columbia, MO.* (Sponsor: Paul J. Fadel, FACSM)

(No relationships reported)

Recently, there has been interest in understanding the interaction between muscle sympathetic nerve activity (MSNA) and shear-induced dilation. This has primarily been examined using flow-mediated dilation (FMD) before and after perturbations that cause reflex-mediated increases in MSNA. However, whether spontaneous changes in resting MSNA alter conduit artery shear rate and diameter on a beat-by-beat basis has not been examined.

**PURPOSE:** To test the hypothesis that, under resting conditions, individual bursts of MSNA decrease shear rate and consequently decrease diameter of the common femoral artery (CFA).

**METHODS:** In 8 healthy young men, MSNA (peroneal nerve microneurography), heart rate (ECG), arterial blood pressure (finger photoplethysmography), and the diameter and mean velocity of the common femoral artery (duplex Doppler ultrasound) were measured continuously during 20 minutes of supine rest. Signal averaging was used to characterize the beat-by-beat changes in mean arterial blood pressure (MAP), CFA diameter and calculated CFA shear rate for 15 cardiac cycles following each MSNA burst.

**RESULTS:** A consistent and significant decrease in CFA shear rate occurred following spontaneous bursts of MSNA, reaching a peak change at about 8 seconds (-5.7% ± 1.6%, p < 0.05 vs. baseline). However, during this same time, an increase in CFA diameter (peak change of 0.3% ± 0.0%, p < 0.05 vs. baseline) was observed along with a rise in MAP (peak change of 3.0% ± 0.4%, p < 0.05 vs. baseline).

**CONCLUSIONS:** These preliminary findings indicate that on a beat-by-beat basis, CFA diameter does not decrease in response to a spontaneous burst of MSNA, but rather it increases. This suggests that CFA diameter is not influenced by spontaneous decreases in shear rate following MSNA bursts. In contrast, the increase in CFA diameter appears to be associated with an increase in blood pressure. Future studies examining the influence of MSNA burst pattern and size on shear-induced conduit artery dilation during resting conditions warrant consideration. Supported by NIH RO1HL093167

### Effect of Statins on Creatine Kinase Levels Before and After a Marathon Run

Amanda L. Zaleski<sup>1</sup>, Jeffrey A. Capizzi<sup>1</sup>, Kevin D. Ballard<sup>2</sup>, Christopher Troyanos<sup>3</sup>, Pierre A. D'Hemecourt, FACSM<sup>3</sup>, Paul D. Thompson, FACSM<sup>1</sup>, Beth A. Parker<sup>1</sup>.  
<sup>1</sup>Hartford Hospital, Hartford, CT. <sup>2</sup>University of Connecticut, Storrs, CT. <sup>3</sup>Children's Hospital, Boston, MA.

(No relationships reported)

**PURPOSE:** We sought to determine if statin users running a marathon exhibited greater evidence of muscle damage assessed by serum CK levels than marathon runners not using these medications.

**METHODS:** We measured serum levels of myoglobin, total creatine kinase (CK) and the CK myocardial (CK-MB), muscle (CK-MM) and brain (CK-BB) isoenzymes in 37 individuals treated with statins and in 43 non-statin treated controls running the 2011 Boston Marathon. Venous blood samples were obtained the day before (PRE) as well as within 1-hour (FINISH) and 24-hours after (POST) the race. Hematocrit and hemoglobin were used to adjust for changes in plasma volume. CK distribution was normalized using log transformation before analysis.

**RESULTS:** The increase in CK-MB 24 hours after exercise was also greater in statin users (PRE to POST: 1.1±3.9 to 8.9±7.0 U/L) than controls (PRE to POST: 0.0±0.0 to 4.2±5.0 U/L; p < 0.05 for comparison) whereas increases in muscle myoglobin did not differ at any time point between groups. Increases in CK at both FINISH and POST race measurements were directly related to age in the statin users (r<sup>2</sup>=0.13 and 0.14; p < 0.05) but not in controls (r<sup>2</sup>=0.02 and 0.00; p=0.42) suggesting that susceptibility to exercise-induced muscle injury with statins increases with age.

**CONCLUSIONS:** We conclude that statins increase exercise-related muscle injury.

**Training Status Does Not Influence Acute Exercise-induced Increases in Plasma Angiogenic Cytokines in Young Men**

Rian Q. Landers-Ramos<sup>1</sup>, Nathan T. Jenkins<sup>1</sup>, Espen E. Spangenburg<sup>1</sup>, James M. Hagberg, FACSM<sup>1</sup>, Steven J. Prior<sup>2</sup>. <sup>1</sup>University of Maryland, College Park, MD. <sup>2</sup>University of Maryland School of Medicine and Baltimore Veterans Affairs Geriatric Research, Education and Clinical Center, Baltimore, MD.  
(No relationships reported)

Angiogenic growth factors can provoke angiogenesis by acting directly on the endothelium or by initiating mobilization and/or enhancing function of circulating angiogenic cells (CACs) from the bone marrow. Endurance exercise may increase plasma levels of angiogenic cytokines, anti-inflammatory cytokines and colony-stimulating factors.

**PURPOSE:** To test the hypothesis that basal and acute exercise-induced levels of angiogenic cytokines differ between trained and untrained young men.

**METHODS:** Ten endurance-trained and ten sedentary healthy young men were studied. Maximal oxygen uptake (VO<sub>2</sub>max) was assessed using a graded treadmill running protocol. Subjects performed 30 minutes of treadmill running at 75% VO<sub>2</sub>max. Blood samples were obtained before and after exercise. Plasma levels of VEGF, basic fibroblast growth factor (bFGF), placental growth factor (PlGF), and soluble VEGF receptor (sFlt-1) were measured by multiplex ELISA. Data are presented as means ± SEM.

**RESULTS:** Contrary to our hypothesis, there were no statistically significant differences between groups in VEGF, bFGF, PlGF, or sFlt-1 before or after acute exercise ( $P > 0.05$ ). Examination of the main effect of acute exercise with groups combined indicated that VEGF did not change significantly ( $P > 0.05$ ), bFGF increased by ~25% ( $6.2 \pm 0.2$  vs.  $7.8 \pm 0.9$  pg/mL;  $P = 0.06$ ), PlGF increased by ~16% ( $16.2 \pm 0.7$  vs.  $18.7 \pm 1.3$  pg/mL;  $P < 0.05$ ), and sFlt-1 increased by 36% ( $166 \pm 7$  vs.  $225.6 \pm 11.5$  pg/mL;  $P < 0.001$ ). Previous data indicate a role for VEGF and angiogenic cytokines in acute exercise-induced mobilization of CACs from bone marrow and CAC function. However, our data do not support such a correlation between circulating angiogenic cytokines and previously published data on functional measures in CACs from these same subjects (Jenkins et al., J Appl Physiol., 2011).

**CONCLUSIONS:** Acute endurance exercise increases plasma bFGF, PlGF, and sFlt-1 levels in sedentary and endurance-trained young men, but cytokine levels did not differ by training status. We speculate that the relationship between training status and acute exercise-induced increases in angiogenic growth factors associated with CACs occur locally at the tissue level and may not be detectable at the systemic level.

**Arterial Compliance and Ultra-Endurance Aerobic Exercise: Analysis of Training and Racing Characteristics with Vascular Response**

Jamie F. Burr, Adam C. Ivey, C. Taylor Drury, Aaron A. Phillips, Darren ER Warburton. University of British Columbia, Vancouver, BC, Canada.  
(No relationships reported)

It is well established that regular moderate intensity aerobic exercise training is associated with increased arterial compliance; however, the vascular response to an acute bout of exercise is currently less clear. There exists evidence that some exercise (high intensity and long duration) may lead to decreases in arterial compliance (at least transiently).

**PURPOSE:** To assess training and racing-related characteristics of ultra-endurance running with regard to arterial compliance.

**METHODS:** Applanation tonometry (CR-2000, HDI) was used to measure both large (LA) and small artery (SA) compliance in competitive ultra-runners ( $n=10$ ) at rest, and following 45 km and 75 km of trail running. Maximal aerobic power (VO<sub>2</sub>max) was measured prior to competition and training practices including: running distance, duration and training intensity (RPE) were documented. Heart rate was recorded throughout the race. We used Pearson correlation for associations and a 3 (compliance) by 2 (high/low fitness) ANOVA for comparisons.

**RESULTS:** Baseline compliance was not associated with differences in training practices. However, a higher training RPE was associated with a higher VO<sub>2</sub>max ( $r=0.69$ ,  $p=0.03$ ) and race intensity (HR estimated VO<sub>2</sub> for 75 km;  $r=0.67$ ,  $p=0.05$ ). Higher VO<sub>2</sub>max and training RPE were associated with less SA stiffening at marathon distance ( $r=0.83$ ,  $p=0.006$ , and  $r=0.86$ ,  $p=0.003$ , respectively). The participants capable of maintaining the highest percentage of maximum throughout the race presented with the smallest changes in LA compliance ( $r=0.76$ ,  $p=0.02$ ) at 45 km. Comparison of arterial compliance at baseline with 45 km and 75 km revealed differential effects by fitness level ( $F=4.32$ ,  $p=0.04$ ) with decreased compliance at the 45 km mark in the least fit competitors. The SA compliance trended toward decreases at 75 km ( $p=0.056$ ).

**CONCLUSIONS:** The acute effects of exercise on arterial compliance appear to be largely intensity dependent and directly linked to aerobic fitness. Recent marathon-related findings demonstrating the lack of an effect on arterial compliance may be partially explained by the training and racing demands of marathon competition.

**Influence of Sleep Quality on Antioxidant Status, Vascular Function and Physical Performance in Heart Failure**

Daniel P. Credeur<sup>1</sup>, Nithya Mariappan<sup>2</sup>, Joseph Francis<sup>1</sup>, David Thomas<sup>3</sup>, Denzil Moraes<sup>3</sup>, Michael A. Welsch, FACSM<sup>1</sup>. <sup>1</sup>Louisiana State University, Baton Rouge, LA. <sup>2</sup>Pennington Biomedical Research Center, Baton Rouge, LA. <sup>3</sup>Our Lady of the Lake Regional Medical Center, Baton Rouge, LA.  
(No relationships reported)

Recent evidence indicates that a reduced quality of sleep is associated with increased risk for or exacerbation of cardiovascular disease. The mechanisms are unclear. We hypothesize poor sleep, contributes to increased oxidative stress, reduced vascular function and lower exercise tolerance.

**PURPOSE:** (1) to examine sleep quality in patients with chronic heart failure (CHF) and controls (CON), and (2) to determine the associations to antioxidant status, vascular function and physical performance.

**METHODS:** Fifteen CHF (age=62±8 yrs) and fifteen CON (age=55±5 yrs) cases were examined. The Pittsburgh Sleep Quality Index (PSQI) was used to assess sleep behavior. The PSQI assesses sleep quality and disturbances over several domains. A total PSQI score >5 characterizes individuals with poor sleep quality. Brachial artery flow-mediated dilation (BAFMD) was determined using ultrasonography. Total antioxidant status was determined using commercially available kits. Six-min walk distance and isometric handgrip strength were used to evaluate physical performance.

**RESULTS:** Total PSQI scores were higher (CHF:  $8.9 \pm 3.14$ ; CON:  $2.9 \pm 1.8U$ ;  $p=0.001$ ) and antioxidant status lower in CHF patients (CHF:  $22.52 \pm 5.43$ ; CON:  $35.82 \pm 10.12$  mM/mg;  $p=0.001$ ). BAFMD (CHF:  $2.98 \pm 1.49$ ; CON:  $6.21 \pm 1.21$ ;  $p=0.01$ ), 6-min walk distance (CHF:  $351.11 \pm 87.7$ ; CON:  $438.5 \pm 75.3$  m;  $p=0.001$ ) and handgrip strength (CHF:  $57.65 \pm 16.5$ ; CON:  $71.67 \pm 15.65$  kg;  $p=0.001$ ) were higher in CON subjects. PSQI total score was inversely related to BAFMD ( $r=-0.52$ ;  $p=0.03$ ). A MANOVA revealed that individuals scoring >5 on the PSQI had significantly lower BAFMD, antioxidant status, 6-min walk distance and handgrip strength ( $p=0.01$ ).

**CONCLUSION:** The "poorer" sleep quality consistently observed in CHF is associated with lower antioxidant capacity, lower vascular function and lower physical performance.

**Sprint Interval and Sprint Continuous Training Improves Aerobic Fitness but not Vascular Function or Repair**

Emma Harris, Mark Rakobowchuk, Karen M. Birch. University of Leeds, Leeds, United Kingdom. (Sponsor: Harry B. Rossiter, FACSM)  
(No relationships reported)

Shear stress is cited as a mechanism for exercise mediated improvements in vascular function. Sprint interval training (SIT) has been shown to be a time-efficient method for improving skeletal muscle oxidative capacity. However, little is known about the effects of repeated increments in shear stress during SIT on vascular function and repair, especially when compared to a continuous high intensity shear stress stimulus.

**PURPOSE:** To determine whether two types of sprint training programmes (interval vs. continuous) matched for total work can improve markers of vascular function and repair.

**METHODS:** 12 women (22 ± 2 yrs) completed 4 weeks of either SIT (n = 6) or continuous sprint training (CST; n = 6) on 3 days/week. SIT consisted of four 30 s Wingate tests separated by 4.5 min recovery. CST involved sprint cycling for ~3-4 min, until the participant reached the equivalent work achieved in four 30 s Wingate tests performed in their first training session. Prior to and following training,  $VO_{2peak}$  and lactate threshold (LT) were estimated from a cycling incremental exercise test. Vascular function was assessed from brachial artery flow-mediated dilation (FMD) and total vessel reactivity (TVR). Circulating progenitor cells (CPCs), an index of vascular repair, were defined as triple positive cells (CD45<sup>dim</sup>CD34<sup>+</sup>KDR<sup>+</sup>).

**RESULTS:** 4 weeks of SIT or CST improved  $VO_{2peak}$  (Pre SIT 2279 ± 360 ml/min, Post SIT 2523 ± 318 ml/min; Pre CST 2315 ± 222 ml/min, Post CST 2380 ± 160 ml/min;  $P \leq 0.05$ ) and increased LT (Pre SIT 773 ± 106 ml/min, Post SIT 877 ± 164 ml/min; Pre CST 819 ± 129 ml/min, Post CST 908 ± 136 ml/min;  $P \leq 0.05$ ), with no group x time interaction ( $P > 0.05$ ). CPCs did not significantly increase post training (Pre SIT 0.0020 ± 0.0012%/leukocytes, Post SIT 0.0026 ± 0.0022%/leukocytes; Pre CST 0.0024 ± 0.0023%/leukocytes, Post CST 0.0031 ± 0.0023%/leukocytes; time:  $P = 0.09$ ). FMD and TVR did not change following training in either group ( $P > 0.05$ ).

**CONCLUSION:** Despite the differences in the shear stress profile and training time, SIT and CST produced similar results. The improvement in aerobic fitness is consistent with previous studies and is suggestive of enhanced skeletal muscle metabolism. Conversely, training had minimal effect on vascular function and repair. This may be due to healthy vasculature at baseline, or a lack of systemic adaptation.

**2829** Board #101 June 1 11:00 AM - 12:30 PM

**Critical Microvascular Po<sub>2</sub> And Muscle Fatigue During Acute Femoral Artery Occlusion**

William L. Sexton, FACSM, R. Reed Lambert, Tyler G. Robertson. *A.T. Still University of Health Sciences, Kirksville, MO.*

(No relationships reported)

Muscle function is impaired in low flow states due, in part, to the reduction in oxygen delivery (QO<sub>2</sub>) relative to oxygen consumption (VO<sub>2</sub>). Surprisingly however, the degree of muscle fatigue during acute femoral artery occlusion is variable and may be associated with subtle differences in the QO<sub>2</sub> to VO<sub>2</sub> ratio, which can be estimated by measurement of microvascular PO<sub>2</sub> (PO<sub>2m</sub>) in the contracting muscle. Preliminary observations suggested that even small increases in PO<sub>2m</sub> during femoral artery ligation can attenuate muscle fatigue.

**PURPOSE:** The purpose of this study was to characterize the relationship between PO<sub>2m</sub> and muscle fatigue during acute femoral artery ligation in the rat extensor digitorum longus muscle (EDL).

**METHODS:** Female Sprague-Dawley rats (n=18, 243 ± 3 g) were anesthetized (pentobarbital, 45 mg/kg ip) and a 5-0 suture snare was placed around the left femoral artery. The left EDL was isolated and the distal tendon was cut and attached to a load cell interfaced with a Muscle Tension Analyzer. PO<sub>2m</sub> was measured using phosphorescence quenching (and Oxyphor G2). PO<sub>2m</sub> and twitch tension were recorded continuously throughout 30 s of baseline, femoral occlusion, 10 min of electrically-stimulated contractions (1 Hz, 6V), and for 4 min after release of the femoral artery snare.

**RESULTS:** After 30 s of baseline recording the femoral artery was occluded and PO<sub>2m</sub> fell from 23 ± 1 mmHg to 10 ± 1 mmHg within 40s. PO<sub>2m</sub> during contractions varied between 4 and 15 mmHg. When %fatigue was plotted against PO<sub>2m</sub>, a sharp inflection was noted a PO<sub>2m</sub> ~8 mmHg. When PO<sub>2m</sub> was greater than 8 mmHg (12 ± 1 mmHg) during femoral occlusion there was less muscle fatigue (12 ± 2%, n=8). However, when PO<sub>2m</sub> was less than 8 mmHg (6 ± 1 mmHg) there was marked fatigue (46 ± 7%, n=10).

**CONCLUSIONS:** These results suggest that, despite femoral artery occlusion, in some rats there was sufficient collateral blood flow to the EDL to maintain a critical PO<sub>2m</sub> (>8 mmHg) and sustain muscle twitch tension. However, in those rats in which PO<sub>2m</sub> in the EDL fell below 8 mmHg there was marked muscle fatigue. These results suggest there is a critical PO<sub>2m</sub> necessary to sustain contractile function in the rat EDL muscle. (Supported by the Graduate Program Committee, KCOM - ATSU.)

**Chronic Heart Failure Alters nNOS-mediated Control of Skeletal Muscle Microvascular O<sub>2</sub> Delivery and Utilization**

Steven Copp, Daniel Hirai, Scott Ferguson, Clark Holdsworth, Timothy Musch, FACSM, David Poole, FACSM. *Kansas State University, Manhattan, KS.*

(No relationships reported)

Chronic heart failure (CHF)-induced reductions in NO bioavailability impair peripheral vasomotor control and lower the resting and contracting microvascular O<sub>2</sub> delivery/O<sub>2</sub> utilization ratio (which sets the microvascular O<sub>2</sub> partial pressure,  $P_{O_{2mv}}$ , and represents the pressure head for capillary-myocyte O<sub>2</sub> flux). Given well-documented CHF derangements of endothelial function, the tacit presumption has been that reductions in NO bioavailability result exclusively from impaired eNOS function.

**PURPOSE:** To test the hypothesis that CHF alters nNOS-mediated control of skeletal muscle  $P_{O_{2mv}}$ .

**METHODS:** 10 healthy (left ventricular end diastolic function, LVEDP: 6±1 mmHg) and 12 CHF (coronary artery ligation, LVEDP: 13±1 mmHg,  $P < 0.05$ ) rats had their right spinotrapezius muscle exposed. Silver wire electrodes elicited 1 Hz (~6-8 V) twitch contractions for 3 minutes before and after acute nNOS inhibition via S-methyl-L-thiocitrulline (SMTC, 0.56 mg/kg i.a.).  $P_{O_{2mv}}$  was measured via infusion of the R2 probe and phosphorescence quenching. Blood flow was determined via infusion of radiolabelled microspheres and the reference sample technique. VO<sub>2</sub> was estimated from blood flow and  $P_{O_{2mv}}$  measurements via direct Fick calculation.

**RESULTS:** **Healthy:** SMTC increased resting baseline  $P_{O_{2mv}}$  (Con: 31±2, SMTC: 37±2 mmHg,  $P < 0.05$ ) via a 28% reduction in VO<sub>2</sub> and, upon contractions onset, speeded the time to reach 63% of the overall kinetics response (mean response time, MRT, Con: 23±2, SMTC: 17±1 s,  $P < 0.05$ ). During the contracting steady-state, SMTC reduced blood flow (↓17%,  $P < 0.05$ ) and VO<sub>2</sub> (↓17%,  $P < 0.05$ ) such that  $P_{O_{2mv}}$  was unaltered (Con: 23±2, SMTC: 23±2 mmHg,  $P > 0.05$ ). **CHF:** Conversely, SMTC did not alter resting baseline blood flow, VO<sub>2</sub>, or  $P_{O_{2mv}}$  (Con: 26±2, SMTC: 29±2 mmHg,  $P > 0.05$ ) or the MRT (Con: 23±3, SMTC: 21±3 s,  $P > 0.05$ ) upon contractions onset. Moreover, SMTC did not change steady-state blood flow or VO<sub>2</sub> thus resulting in an unchanged  $P_{O_{2mv}}$  (Con: 17±1, SMTC: 18±2 mmHg,  $P > 0.05$ ).

**CONCLUSION:** nNOS-mediated control of skeletal muscle microvascular function is compromised (and may be abolished) in CHF. The present data provide a clear mandate to pursue improvements in nNOS function when designing therapeutic interventions aimed at restoring NO bioavailability in CHF patients.

**2831** Board #103 June 1 11:00 AM - 12:30 PM

**Heart Rate Variability Following Two Different Exercise Modalities**

Michael R. Esco, Henry N. Williford, FACSM, Michele S. Olson, FACSM, Aindrea N. McHugh, Barbara E. Bloomquist. *Auburn University Montgomery, Montgomery, AL.*

(No relationships reported)

Various components of exercise prescription, e.g., intensity and duration, have been found to be associated with cardiac-autonomic recovery. However, it is not fully known if the recovery of the autonomic nervous system varies between different modes of exercise.

**PURPOSE:** The purpose of this study was to analyze cardiac-autonomic control, via heart rate variability (HRV), between acute bouts of treadmill (T) and cycle (C) exercise at the same intensity.

**METHODS:** Fourteen apparently healthy men participated in this study. Each subject performed maximal graded exercise tests on T and C ergometers on two separate days. The subjects returned to the lab on two additional days that were separated by 72 hours to 1 week. During these visits, they performed, in random order, 30-minute exercise bouts on T or C at 70% of their mode-specific VO<sub>2peak</sub>. Electrocardiography (ECG) was analyzed for 10-minutes before and 30-minutes after each exercise bout. The ECG was divided into three 5-minute segments during which paced breathing (12 breaths.min<sup>-1</sup>) took place as follows: the last 5-minutes of the pre-exercise period (Pre), and between 15-20 minutes (Post-1) and 25-30 minutes (Post-2) of the post-exercise period. HRV was analyzed for each 5-minute epoch via frequency domain as follows: normalized high frequency power (HFnu); normalized low frequency power to HFnu ratio (LF:HF).

**RESULTS:** HFnu (ms2) at Pre, Post-1, and Post-2 for T was  $50.9 \pm 11.7$ ,  $43.1 \pm 9.0$ , and  $47.4 \pm 7.9$ , respectively, and for C was  $50.7 \pm 10.0$ ,  $41.8 \pm 9.5$ , and  $44.8 \pm 8.4$ , respectively. LF:HF at Pre, Post-1, and Post-2 for T was  $0.8 \pm 0.5$ ,  $0.9 \pm 0.5$ , and  $0.8 \pm 0.3$ , respectively, and for C was  $0.8 \pm 0.5$ ,  $1.1 \pm 0.5$ , and  $1.0 \pm 0.4$ , respectively. There were no significant differences between HFnu or LF:HF ratio between T and C at Pre ( $p > 0.05$ ). HFnu and LF:HF at Post-2 were significantly different between the two modes ( $p < 0.05$ ). HFnu and LF:HF were significantly lower between Pre and Post-1 and 2 in C ( $p < 0.05$ ). However, HFnu was only significantly different between Pre and Post-1 ( $p < 0.05$ ), but not between Pre and Post-2 in T. LF:HF was not significantly different between Pre and either of the Post time points in T ( $p > 0.05$ ).

**CONCLUSIONS:** The results of this study suggest that C is associated with a greater disturbance of post-exercise cardiac-autonomic control compared to T.

**Heart Rate Response To An Orthostatic Challenge In The Early Postpartum Period**

Chantale R. Brun<sup>1</sup>, Michelle F. Mottola, FACSM<sup>2</sup>, Michel J. Johnson<sup>1</sup>. <sup>1</sup>University of Moncton, Moncton, NB, Canada. <sup>2</sup>The University of Western Ontario, London, ON, Canada. (Sponsor: Michelle F Mottola, FACSM)  
(No relationships reported)

Cardiovascular adaptations occur early in pregnancy and persist throughout gestation. Some of these cardiovascular changes may still be apparent in postpartum women for an unknown period of time. To date there is a paucity of research examining the postpartum period regarding the duration and magnitude of these cardiovascular changes, especially in regards to autonomic regulation. The actual role of the autonomic nervous system during pregnancy is poorly understood and therefore understudied in the postpartum period.

**PURPOSE:** To investigate the heart rate response to an orthostatic challenge in active women at two months postpartum.

**METHODS:** Women who were active throughout pregnancy were recruited at two months postpartum (PP; n=20). The control group was composed of similar active, non-pregnant women (in luteal phase of their menstrual cycle) with comparable physical activity backgrounds (NP; n=20). Heart rate (HR) was assessed after 20 minutes in a seated position and after 5 minutes in the standing position (standard 4-lead electrocardiogram, Sensor Medics, Vmax 29c).

**RESULTS:** HR measured in the seated position was significantly lower in the PP group (PP:  $68 \pm 2$  vs. NP:  $75 \pm 2$  bpm;  $p < 0.05$ ). After five minutes of standing, HR was also significantly lower in the PP group (PP:  $77 \pm 2$  vs. NP:  $85 \pm 2$  bpm,  $p[[\text{Unsupported Character - \&\#8249}]]0.001$ ). No difference occurred in the Delta HR response (standing HR - seated HR) between groups (PP:  $13 \pm 4$  vs. NP:  $9 \pm 3$ ,  $p = 0.454$ ).

**CONCLUSION:** Reactivity to an orthostatic challenge in postpartum women is similar to the non-pregnant response despite absolute HR values being significantly lower. The early postpartum period may reflect changes in the cardiovascular response at rest (in both positions related to a higher stroke volume (not yet returned to pre-pregnancy values) from late pregnancy. The fact that the relative values are not different between groups (i.e. their autonomic reactivity is the same) when HR is lower is an interesting observation that warrants further investigation.

**Autonomic and Cardiovascular Function of Hormone-Receptor Positive Breast Cancer Patients Following Treatment with Anthracycline-Containing Chemotherapy**

Whitney E. Hornsby<sup>1</sup>, Michel G. Khouri<sup>1</sup>, Susan G. Lakoski<sup>2</sup>, Phil Ainslie<sup>3</sup>, Jonathon Smirl<sup>3</sup>, Miranda West<sup>1</sup>, Amy Lane<sup>1</sup>, April Coan<sup>1</sup>, Fernando Ona<sup>4</sup>, James E. Klaunig<sup>5</sup>, David M. Kocaja<sup>5</sup>, Robert F. Chapman, FACSM<sup>6</sup>, Lee W. Jones<sup>1</sup>. <sup>1</sup>Duke University Medical Center, Durham, NC. <sup>2</sup>University of Texas Southwestern Medical Center, Dallas, TX. <sup>3</sup>University of British Columbia, Kelowna, BC, Canada. <sup>4</sup>Boston University, Boston, MA. <sup>5</sup>Indiana University, Bloomington, IN.  
(No relationships reported)

Anthracycline-containing chemotherapy [e.g., doxorubicin or epirubicin] is considered standard treatment for early-stage breast cancer, however it causes left ventricular (LV) dysfunction. This cardiac impairment manifests as increased cavity size (LV remodeling) and reduced left ventricular ejection fraction (LVEF), which may lead to heart failure. Current detection techniques (resting LVEF) are insensitive to detecting early cardiac impairment.

**PURPOSE:** To evaluate autonomic and cardiovascular function in breast cancer patients with preserved cardiac function (i.e., LVEF >50%).

**METHODS:** Thirty-nine women (26  $\pm$  23 months post chemotherapy) and 11 age-matched healthy women were studied. Autonomic function was assessed using heart rate (HR, ECG), heart rate variability (HRV, spectral analysis) and baroreflex sensitivity (BRS, transfer function analysis). A cardiopulmonary exercise test and echocardiography were performed to assess peak cardiovascular function ( $VO_{2peak}$ ) and cardiac function (LV volumes and LVEF), respectively. To explore time-based differences since completion of chemotherapy, patients were sub-classified into two distinct groups: Cohort I:  $8 \pm 5$  and Cohort II:  $45 \pm 18$  months.

**RESULTS:** Resting HR was higher among patients compared to controls ( $81 \pm 10$  versus  $63 \pm 8$ , beats.min<sup>-1</sup>;  $p < 0.01$ ); no differences were identified for HRV or BRS.  $VO_{2peak}$  was reduced in patients ( $24.3 \pm 4.6$  versus  $33.4 \pm 6.6$  mL.kg<sup>-1</sup>.min<sup>-1</sup>;  $p < 0.001$ ). Resting HR and  $VO_{2peak}$  were similar between breast cancer cohorts despite normalized LV volumes for Cohort II.

**CONCLUSION:** Breast cancer patients approximately 2 years after the completion of chemotherapy have significant impairments in cardiovascular (reduced  $VO_{2peak}$ ) and autonomic (elevated resting HR) function despite preserved LVEF. The magnitude of autonomic dysfunction and  $VO_{2peak}$  impairment was similar regardless of time since the completion of chemotherapy. Measurement of cardiac function alone may be insufficient to characterize cardiovascular health in early breast cancer patients. These results suggest an urgent need for therapeutic strategies (e.g. aerobic training) to prevent and/or treat global cardiovascular dysfunction in breast cancer patients.

**2834** Board #106 June 1 11:00 AM - 12:30 PM

**Volume of Physical Activity and Hemostatic Variables in Pregnant Women**

Christine Nicewonger<sup>1</sup>, Kelly Mattran<sup>2</sup>, Christopher J. Womack, FACSM<sup>2</sup>, Robert E. Lee<sup>2</sup>, Judith A. Flohr<sup>2</sup>. <sup>1</sup>Michigan State University, East Lansing, MI. <sup>2</sup>James Madison University, Harrisonburg, VA.  
(No relationships reported)

**PURPOSE:** To evaluate potential relationships between hemostatic variables and physical activity (PA) during pregnancy.

**METHODS:** Fasted blood draws (6-10AM) were obtained from 23 pregnant women (19-34yrs) and analyzed for tissue plasminogen activator (tPA) antigen, tPA activity, plasminogen activator inhibitor-1 (PAI-1) antigen, and vonWillebrand factor (vWF) antigen. PA was assessed by Modifiable Activity Questionnaire (MAQ) and converted to METmin/wk (MET). Average daily step count (STEP) was obtained from 2 week pedometer logs. Participants were grouped by MET as "meeting" (n=15) or "not meeting" (n=8) the American College of Obstetricians and Gynecologists' PA recommendations (450 MET) and by STEP as "sedentary" (<5,000 steps/day; n=12) or "at least low active" (5,000+ steps/day; n=4). Gestational age (GA), MET, STEP, and pre-pregnancy PA were possible predictors for hemostatic variables using forward stepwise multiple regression. Multiple linear regression provided y-intercept and slope, allowing extrapolation of pre-pregnancy dependent variables and mean expected changes over GA. ANCOVA determined if differences existed in hemostatic variables among PA groups, controlling for GA and pre-pregnancy PA.

**RESULTS:** Multiple regression results suggest that PAI-1 and tPA antigen were higher and tPA activity lower with increased GA ( $p < 0.05$ ) and GA and MET were significant predictors of tPA antigen ( $p < 0.01$ ). Linear regression using STEP classifications resulted in a significant difference in y-intercept for tPA antigen ( $p < 0.05$ ), suggesting that tPA antigen may be lower pre-pregnancy in women accumulating at least 5,000 steps/day vs. those who are sedentary. No significant slope differences were observed in hemostatic variables in relation to PA. ANCOVA analysis indicated a significant difference in tPA activity based on MET classifications ( $p = 0.04$ ).

**CONCLUSION:** The associations between PA and 1)tPA antigen and 2)tPA activity are novel and suggest that PA may help attenuate the extent of hypercoagulation in normal pregnancy. Future research is warranted as regular PA, independent of pregnancy, is known to enhance fibrinolytic profile and reduce blood coagulation potential in women of child-bearing age and pregnant women are predisposed to hypercoagulation-related health issues.

**2835** Board #107 June 1 11:00 AM - 12:30 PM  
**Sympathetic Nerve System May Contribute To Microvasculature Responses During Reactive Hyperemia In Women**  
Masahiro Horiuchi<sup>1</sup>, Tomoyasu Kadoguchi<sup>2</sup>, Koichi Okita<sup>1</sup>. <sup>1</sup>Hokusho University, Ebetsu, Japan. <sup>2</sup>Hokkaido University, Sapporo, Japan. (Sponsor: Kevin K McCully, FACSM)  
(No relationships reported)

Aging is associated with impaired endothelial function and menopause may accentuate endothelial dysfunction. Increased sympathetic nerve activity with advancing age is also associated with impaired endothelial dysfunction. These alterations might also affect not only vasodilatation of large arteries but also small artery function. Near infrared spectroscopy (NIRS) can allow to determine the relative changes of oxygenated hemoglobin (HbO<sub>2</sub>) in the small artery with high temporal resolution. However, little is known about small artery function of aged women.

**PURPOSE:** To determine the influence of aging and sympathetic nerve activity on small artery during reactive hyperemia in women.

**METHODS:** Ten young (22±0.4yrs, means± S.E.M.), 11 middle (42±0.5yrs) and 13 old healthy women (62±0.7yrs) were studied. Post occlusive reactive hyperemia was performed in supine position. NIRS signals were measured during 5 min of arterial cuff occlusion (cuff pressure > 50mmHg above systolic blood pressure), and during 3 min of post occlusive reactive hyperemia at their forearm muscle with and without sympathetic stimulation. Sympathetic nerve activity was stimulated induced by the cold pressor test (CPT) from the last 1-min during occlusion to the first 2-min during reactive hyperemia. The recovery time of HbO<sub>2</sub> is half the time required for the HbO<sub>2</sub> to reach maximal value in response to cuff release from the time of cuff occlusion.

**RESULTS:** Recovery time of HbO<sub>2</sub> without CPT in old (12.0±0.7sec) was significantly slower than that in young (8.4±0.4 sec) and middle women (10.2±0.5 sec, p<0.05, respectively), whereas no difference was observed between young and middle women. In contrast, CPT slowed the recovery time in HbO<sub>2</sub> in middle (12.0±0.6sec) and old (15.3±0.7sec) but not in young (9.5±0.5 sec). Moreover, there were significant differences in the recovery time of HbO<sub>2</sub> with CPT among subjects (p<0.05 respectively).

**CONCLUSIONS:** These results indicate that post menopausal women exhibit a delayed HbO<sub>2</sub> response during reactive hyperemia. Furthermore, sympathetic nerve system may be related to HbO<sub>2</sub> responses after middle age. We suggest that these alterations in HbO<sub>2</sub> kinetics are indicative of microvasculature dysfunction in these subjects.

**2836** Board #108 June 1 11:00 AM - 12:30 PM  
**Skeletal Muscle Metaboreflex is Enhanced in Postmenopausal Women**  
Jong-Kyung Kim<sup>1</sup>, Hosung Nho<sup>1</sup>, Charles L. Stebbins, FACSM<sup>2</sup>, Hyun-Tae Seo<sup>1</sup>, Kyung-Ae Kim<sup>1</sup>, Kwang-Il Kim<sup>1</sup>, Joon-Sung Park<sup>1</sup>, Hyun-Min Choi<sup>1</sup>. <sup>1</sup>Kyung Hee University, Yong In, Korea, Republic of. <sup>2</sup>University of California, Davis, Davis, CA. (Sponsor: Charles L. Stebbins, FACSM)  
(No relationships reported)

**PURPOSE:** To determine whether an elevated muscle metaboreflex contributes to the excessive blood pressure response to exercise in postmenopausal women.

**METHODS:** Thirty healthy female volunteers were studied (15 postmenopausal and 15 premenopausal). Stroke volume (SV), heart rate (HR), cardiac output (CO), systolic blood pressure (SBP), diastolic blood pressure (DBP), and total vascular conductance (TVC) were continuously assessed throughout the experiment. To activate the muscle metaboreflex, occlusion of the vasculature was induced via inflation of a blood pressure cuff (2 min) on the upper arm following static handgrip exercise.

**RESULTS:** Muscle metaboreflex activation increased mean arterial pressure (MAP) in both groups. However, this pressor response was greater in the postmenopausal women ( $\Delta$ MAP: 21.4±3 vs. 14.5±2 mmHg) (p<0.05) even though the corresponding increase in CO was less ( $\Delta$ CO: 0.0±0.2 vs. 0.3±0.2 L/min) (p<0.05). TVC decreased in both groups but was more pronounced in the postmenopausal group ( $\Delta$ TVC: -10.7±2.6 vs. -17.1±3.6 ml/min/mmHg) (p<0.05).

**CONCLUSION:** In conclusion, the exaggerated blood pressure response to exercise in postmenopausal women is mediated, in part, by an overactive metaboreflex that is associated with enhanced peripheral vasoconstriction.

---

**2837** Board #109 June 1 11:00 AM - 12:30 PM  
**Increases in Cerebrovascular Resistance in Patients with Mild Cognitive Impairment**  
Rosemary Parker<sup>1</sup>, Yongsheng Zhu<sup>1</sup>, Benjamin Tseng<sup>1</sup>, Estee Brunk<sup>1</sup>, Kyle Armstrong<sup>1</sup>, Kristen Martin-Cook<sup>2</sup>, Myron Weiner<sup>2</sup>, Rong Zhang<sup>1</sup>. <sup>1</sup>Institute for Exercise and Environmental Medicine, Dallas, TX. <sup>2</sup>University of Texas Southwestern Medical Center at Dallas, Dallas, TX.  
(No relationships reported)

**INTRODUCTION:** Brain perfusion is reduced in patients with Alzheimer's disease (AD). Whether this is a primary or contributing factor has not been established. Changes in cerebral hemodynamics in patients with mild cognitive impairment (MCI), often a prodromal stage of AD, has not been carefully studied.

**PURPOSE:** This study tested the hypothesis that global cerebral blood flow (CBF) is reduced in patients with MCI relative to age and education matched cognitively normal older adults.

**METHODS:** Twenty-one MCI patients (10 females, 67 ± 6 yr BMI: 24 ± 5 kg/m<sup>2</sup>) and 20 normal control subjects (14 females, 68 ± 7 yr, BMI: 22 ± 4 kg/m<sup>2</sup>) participated. Patients with MCI had a global Clinical Dementia Rating (CDR) score of 0.5 and scores ≤ 1SD below the appropriate norm on the Wechsler Logical Memory Test. Blood flow was measured using high resolution 2D and color Doppler ultrasonography in the internal carotid (ICA) and vertebral arteries (VA). Global CBF was calculated as a sum of both the ICA and VA measures. Transcranial Doppler (TCD) was used to measure CBF velocity (CBFV) in the middle cerebral artery (MCA). Cerebrovascular resistance (CVR) was calculated as mean blood pressure (MBP) divided by global CBF.

**RESULTS:** Baseline MBP did not differ significantly between MCI and control groups (91 ± 10 mmHg and 86 ± 12 mmHg respectively (p=0.11)). CBF was 10% lower in MCI than the normal controls (594.3 ± 105.4 vs. 657.4 ± 130.6 ml/min, p=0.10), but not statistically significant. No difference in CBFV was observed (MCI 51.8 ± 11.4 vs. Control 57.1 ± 16.2 cm/sec, p=0.24). However, cerebrovascular resistance was increased by 23% in MCI subjects (0.16 ± 0.03 vs. 0.13 ± 0.13 mmHg-min/ml, p=0.02).

**CONCLUSION:** The observed increase in CVR in MCI suggests that vascular mechanisms may be at play in prodromal AD. Development of pharmacological and/or non-pharmacological interventions such as exercise training to reduce CVR may improve brain perfusion to prevent or slow AD.

(No relationships reported)

Physical function and motor control deteriorate with aging. These deficits are likely to be exacerbated in patients with Alzheimer's disease (AD). However, whether this is the case for patients with Mild Cognitive Impairment (MCI), often a transitional stage between normal aging and AD, is not known.

**PURPOSE:** To evaluate physical function in patients with MCI.

**METHODS:** Twenty eight MCI patients (13 males, age 68±6 yrs, BMI 28±5), and 21 age and education matched cognitively normal adults (6 males, age 68±7 yrs, BMI = 26±4) underwent physical function assessment including level of aerobic fitness (VO2max), gait velocity, timed-up-and-go, functional reach, and reaction time. Diagnosis of MCI required a memory complaint, objective evidence of memory impairment as measured by the Logical Memory subscale of the Wechsler Adult Intelligence Test and no subjectively or objectively reported overall functional impairment indicated by a Clinical Dementia Rating (CDR) score ≤ 0.5.

**RESULTS:** No differences in physical function were observed in MCI patients when compared to the normal controls (see Table 1).

**CONCLUSION:** We did not find physical function deficits in patients with MCI. These findings suggest that exercise testing and training can be implemented safely in these patients to prevent further physical function decline at the early stage of neurodegenerative disease.

Table 1. Aerobic fitness, physical function, and cognitive performance in MCI and normal subjects.

|                  | VO2max<br>(ml/kg/min) | Gait<br>Velocity<br>(m/sec) | Timed Up-<br>and-Go (sec) | Functional<br>Reach (cm) | Reaction<br>Time (cm) | Logical<br>Memory<br>(immediate) | Logical<br>Memory<br>(delayed) |

**Aerobic Exercises Improve Cognition Function in Chronic Unpredictable Mild Stress-Induced Depressive Rats**

Yahong Jin<sup>1</sup>, Li Wen<sup>1</sup>, Lei Li<sup>1</sup>, Shixiang Chen<sup>2</sup>, Sai Zhang<sup>2</sup>. <sup>1</sup>Tianjin University of Sport, Tianjin, China. <sup>2</sup>Chinese People's Armed Police Forces Medical College, Tianjin, China.

(No relationships reported)

Studies had reported that aerobic exercises can improve cognition function in depression. Whether aerobic exercise is viable treatment for chronic unpredictable stress (CUMS)-induced depression is unclear, especially if it could prevent cognition decline when subjects were exposed to CUMS is still unknown.

**PURPOSE:** To investigate the effect of aerobic exercises on the cognition in CUMS-induced depression rats; to determine that the lack of 5-HT is the mechanism underlying the cognitive impairment in depressive rats.

**METHODS:** 32 four-month-old male SD rats were divided into 4 groups: common group (C), CUMS depression model group (D), CUMS and aerobic exercise group (DE), CUMS and fluoxetine group (DF). The D, DE and DF groups were exposed to CUMS for 4 weeks with or without access to 18-days 64%VO<sub>2</sub>max treadmill running or intragastric injection of antidepressant fluoxetine. On the end of CUMS, open-field test was performed, hippocampus and brain raphe nucleus were collected for 5-HT measurement. Group comparisons were made using one-way ANOVA.

**RESULTS:** Compared to the C group, the score of activity (43.00±16.56 vs. 80.17±19.17 frequency/5min, p<0.05) and space exploration tend (20.92±9.50 vs. 47.42±5.32, p<0.05) in open-field test were significantly declined, and 5-HT in hippocampus was decreased in the D group (29.07±0.56 vs. 31.54±0.88 ng/ml, p<0.05). Compared to the D group, the score of activity tend (79.50±15.85, 59.50±8.24 vs. 43.00±16.56, p<0.05) in open-field test in DE group was higher than the others. 5-HT level in hippocampus were increased (31.29±1.45, 32.43±1.22 vs. 29.07±0.56, p<0.05) in the DE and DF groups, and there were no differences between the DE and DF groups (31.29±1.45 vs. 32.43±1.22, p>0.05). 5-HT level in brain raphe nucleus was significantly increased in DE group (37.22±0.26, 36.25±0.36 vs. 36.24±0.10, p<0.05).

**CONCLUSIONS:** The cognitive impairment and the lower level of 5-HT were observed in CUMS-induced depressive rats. Aerobic exercises have antidepressant effects in CUMS-induced depression by promoting the produce of 5-HT in brain raphe nucleus. Results indicated the mechanisms underlying the antidepressant effects of aerobic exercises and of fluoxetine may be different.

**Type 1 Diabetes-associated Cognitive Decline: Nature And Magnitude - A Meta-analysis.**

Cajsa Tonoli<sup>1</sup>, Elsa Heyman<sup>2</sup>, Luk Buyse<sup>1</sup>, Nathalie Pattyn<sup>1</sup>, Serge Berthoin<sup>2</sup>, Romain Meeusen, FACSM<sup>1</sup>. <sup>1</sup>Vrije Universiteit Brussel, Brussels, Belgium. <sup>2</sup>Universitij Nord de France, Lille, France.

(No relationships reported)

**PURPOSE:** This meta-analysis was conducted to determine mechanisms and size of cognitive decline in patients with type 1 diabetes (T1D) and the potential associations with episodes of hypoglycemia (EoH), chronic hyperglycemia and early age of onset (EO).

**METHODS.** Pubmed and ISI Web of Knowledge were consulted to identify studies on cognitive function (CF) and on its possible determinants in T1D patients. Cohen's d statistics were used for calculating effect sizes (ES). Effect sizes (d) are defined as small = .3, medium = .5 and large = .8. Meta-analysis was performed where a minimum of 3 studies had assessed the same domain of CF.

**RESULTS.** According to the literature, mechanisms for cognitive decline are ascribed to EoH, chronic hyperglycemia and C-peptide/insulin deficiency. Results are shown in table 1. No significant differences were found between T1D children who did experience EoH vs. T1D children who did not experience EoH. There were insufficient studies on the association of CF with EoH or EO of diabetes in T1D adults, and with poor glycaemic control in T1D children to perform meta-analyses.

**CONCLUSION.** Cognitive decline seems to be related to an EO of diabetes and to high HbA<sub>1c</sub> levels. The magnitude of the cognitive decline is mild to moderate and is more severe in adults than in children; suggesting duration of diabetes and hyperglycaemia could have effects on CF. Considering its well-known positive effects on glycaemic control, physical activity could have beneficial effects for the CF.

Table 1: Estimates of the size of Cognitive decline in T1D.

| CF                 | T1D vs non-diabetic subjects |                   | EO (<4y) vs. late onset (>4y) of T1D |        | Poor controlled (HbA1c > 8%) vs. well-controlled T1D |                   |

**Dual-task Performance Facilitation In Older Adults**

Michel Audiffren<sup>1</sup>, Raphaëlle Chateau<sup>1</sup>, Phillip D. Tomporowski, FACSM<sup>2</sup>. <sup>1</sup>University of Poitiers, Poitiers, France. <sup>2</sup>University of Georgia, Athens, GA.  
 (No relationships reported)

The dual-task demands of motoric and cognitive processing have been of particular interest to gerontologists, who posit that age-related declines in sensorimotor processes increase the magnitude of task interference. Most studies show older adults' degradation in cognitive performance, which provides support for a "posture-first" hypothesis. The pattern of dual-task interference has not been consistent, however. Of particular interest are studies reporting improvements in cognitive performance during dual-task conditions compared to single-task conditions.

**PURPOSE:** To assess the influence of walking speed on young and older adults' cognitive test performance.

**METHODS:** 32 young adults (M age = 20.8 yr, range = 19-24 yr, 16 F) and 30 older adults (M age = 71.53 yr, range = 65-80 yr, 15 F) performed 3, 60-trial auditory switch tasks while standing, during a 5-min treadmill walk at a preferred speed, and during a 5-min treadmill walk at a speed 50% faster than preferred. The switch task measures the time required for an individual to inhibit an ongoing mental task and to initiate a different mental task, processes that are characteristic of executive function. Switch-task trials involved letter (vowel/consonant) or number (even/odd) discriminations to stimuli presented on headphones and recorded via two keys on a hand-held computer mouse.

**RESULTS:** A 2 X 3 mixed-model ANOVA was conducted with age (young, old), physical fitness level (high/low) as grouping factors and test condition (standing, walking preferred and walking fast) as a repeated measure factor. Separated analysis revealed Age x Condition interactions for local switch costs (F = 5.1, p < 0.01), mixed switch costs (F = 4.41, p < 0.05), and response time (F = 8.77, p < 0.001). Post-hoc analyses showed older adults' switch task performance was facilitated during both dual-task walking conditions compared to the single-task standing condition. Frequency of response errors for both young and old increased linearly across the three conditions (F = 11.32, p < 0.0001).

**CONCLUSIONS:** The dual-task facilitation of mental performance observed may be explained in terms of walking-induced arousal; alternatively, locomotion may provide a unique case for the study of dual-task interference.

**Physical Activity, Brain Function And Cognitive Performance In Young Adults - A Cross-sectional Study**

Janina Krell<sup>1</sup>, Sabrina Benzinger<sup>1</sup>, Klaus Boes<sup>1</sup>, Jeremias Engelmann<sup>1</sup>, Dominic Heger<sup>1</sup>, Felix Putze<sup>1</sup>, Tanja Schultz<sup>1</sup>, Alexander Stahn<sup>2</sup>. <sup>1</sup>Karlsruhe Institute of Technology, Karlsruhe, Germany. <sup>2</sup>Charité University Medicine, Berlin, Germany.  
 (No relationships reported)

There is growing interest in the study of exercise and cognition in both educational and health and care settings. In spite of mounting evidence that physical activity can induce a number of structural and functional changes in the brain and improves cognitive performance as well as neurocognitive health, so far most studies have focused either on children or the elderly population.

**PURPOSE:** To explore the association of physical (in-) activity, brain function and cognitive performance in young healthy university students in a prospective cross-sectional study.

**METHODS:** 154 young healthy participants (45 women, 109 men, 18 to 35 yrs) were tested for their endurance, strength and gross motor skills and grouped according to their performance. Event-related brain potentials and task performance were determined during a modified flanker task.

**RESULTS:** High fit subjects showed faster response times (423±35 vs. 441±44 ms, p<0.05), higher P3-amplitudes (6.4±2.2 vs. 5.2±1.9 µV, p<0.05), and shorter latencies (362±34 vs. 403±88 ms, p<0.05) than less fit subjects. Furthermore, endurance athletes showed larger P3-amplitudes than field athletes (3.7±1.5 vs. 2.7±1.1 µV, p<0.05). In addition, gross motor skills were positively associated with P3-amplitudes (2.7±1.2 vs. 3.7±1.8 µV, p<0.05), while strength was negatively related to P3-amplitude (6.3±1.5 vs. 5.1±2.0 µV, p<0.05).

**CONCLUSION:** Physical fitness may be beneficial to cognition and brain function in young healthy adults. Type of sport as well as type of physical performance may play a crucial role underlying this relationship. Endurance training as well as sports associated with high motor control might be particularly valuable in promoting cognition and brain health.

**The Relationship Of Sub-concussive Impacts And Cognition**

Douglas N. Martini, Steven P. Broglio. University of Michigan, Ann Arbor, MI.  
 (No relationships reported)

**PURPOSE:** Recently, the role of sub-concussive impacts on cognitive function has begun to garner attention. Emerging research has reported on the total number of impacts and cumulative linear (g's) and rotational acceleration (rads/s/s) sustained by athletes during a football season. How these impacts may influence cognitive functioning is not clear. The purpose of this investigation was to quantify the effect of sub-concussive impacts on neurocognitive function from a high school football season.

**METHODS:** During a three year investigation, 53 class 3A high school football players were fitted with the Head Impact Telemetry (HIT) System. Prior to each competitive season, each athlete completed a baseline assessment of cognitive function (ImPACT). The HIT System incorporates six single-axis accelerometers in a helmet and records linear and rotational acceleration. The ImPACT produces six subscores used to evaluate cognitive function following concussive events. Twelve athletes with diagnosed concussions were excluded from the analyses. Paired-sample t-Tests were used to analyze ImPACT scores between seasons. Pearson's Correlations were used to compare the HIT System data with the ImPACT data.

**RESULTS:** Participants reported significantly fewer concussion symptoms during the year two preseason assessment compared to year one ( $2.15 \pm 3.90$  vs  $3.39 \pm 3.38$   $p < .05$ ). No other ImPACT subscore produced significant paired-sample t-Test. No significant relationships were observed through Pearson's Correlations between cumulative HIT System data and ImPACT scores.

**CONCLUSIONS:** Other research has suggested there should be an age-related improvements on cognitive tests commonly used for concussion assessment. The athletes in this pilot study do not show the same improvements, but rather appear to have stunted cognitive function. While it is not entirely clear why, this may have been a result of cumulative sub-concussive impacts.

**2844** Board #116 June 1 9:30 AM - 11:00 AM

**Positive Relationship between Fitness and Academic Proficiency in Elementary and Middle School Youth**

Randal P. Claytor<sup>1</sup>, Keith Weiser<sup>1</sup>, Joshua S. Claytor<sup>2</sup>. <sup>1</sup>Miami University, Oxford, OH. <sup>2</sup>College of Wooster, Wooster, OH. (Sponsor: Helaine Alessio, FACSM)  
(No relationships reported)

**PURPOSE:** Determine the extent of the association between school-based measures of physical fitness and state-wide, standardized assessments of reading and math.

**METHODS:** PE teachers were provided and trained to administer the Fitnessgram. Pacer (P) assessed aerobic fitness (AF), paced 90degree push-up (PU) and paced curl-up (CU) assessed muscular fitness (MF); a fitness composite score (P, PU, & CU) was calculated. Individual Reading and Math (adjusted) scores from the Ohio Achievement Assessment (OAA) was collected from participating school districts.

**RESULTS:** PF data on 5295 youth (50% male; 29%-4th, 24%-5th, 19%-6th, 15%-7th, 12%-8th) from 18/88 counties, 22 school districts and 5/7 school district typologies (DT), based on geography and household income levels was collected. P, PU, CU, and FC were significantly correlated with OAA-R and OAA-M, respectively (all  $p < 0.0001$ ). Multivariate ANOVA detected significant Sex (P, PU, CU, FC, & OAA-R;  $p < 0.0001$ ), however (OAA-M, BMI-Z, & BMI% did not differ by Sex) and Grade (P, PU, CU, FC, OAA-R, OAA-M, BMI-Z, & BMI%;  $p < 0.0001$ ) main effects and a significant Sex X Grade interaction. Multiple regression determined that P, CU, & Sex were significantly ( $p < 0.0001$ ) associated with OAA-R; P, CU & PU were significantly associated with OAA-M. Grade, BMI%, & DT were not associated with either academic measure.

**CONCLUSIONS:** AF, MF and Sex (Reading only) are associated with standardized Reading & Math assessments in 4th - 8th graders. Additionally, Grade, BMI% and DT are not associated with Reading and Math proficiency scores in youth. These findings suggest PA that leads to PF is important for increased academic proficiency regardless of school-related geographic and socio-economic indicators. Policy makers and other stakeholders should use this information to implement creative ways to increase PA and PF before, during, and after the school day as an additional mechanism to enhance academic proficiency in youth.

**2845** Board #117 June 1 9:30 AM - 11:00 AM

**Associations Between Objectively Measured Physical Activity And Cognition In Adolescents: Evidence From The ALSPAC Cohort**

Josephine N. Booth<sup>1</sup>, Andy R. Ness<sup>2</sup>, Phillip D. Tomporowski<sup>3</sup>, Samantha D. Leary<sup>2</sup>, Carol Joinson<sup>2</sup>, James M. E Boyle<sup>1</sup>, John J. Reilly<sup>1</sup>. <sup>1</sup>University of Strathclyde, Glasgow, United Kingdom. <sup>2</sup>University of Bristol, Bristol, United Kingdom. <sup>3</sup>University of Georgia, Athens, GA. (Sponsor: David A. Rowe, FACSM)  
(No relationships reported)

Emerging findings suggest that Physical Activity (PA) influences executive functioning (EF) however there are inconsistencies in the literature. The strongest associations have been found for tasks assessing planning though effect sizes are not consistent across other aspects (e.g. working memory and switching). Effect sizes are also related to the amount of PA performed; however a paucity of evidence from studies using objectively measured PA precludes firm conclusions being drawn.

**PURPOSE:** To examine the relationship between objectively measured levels of PA and EF in English adolescents.

**Method:** 5593 participants (47.6% male) from the Avon Longitudinal Study of Parents and Children (ALSPAC) had valid accelerometer measurements of PA (at least 10 hours a day on a minimum of three days) at 11 years of age. PA was recorded as average counts per minute (cpm) and as daily number of minutes spent in moderate to vigorous physical activity (MVPA). Participants completed three tasks of EF from the Test of Everyday Attention for Children (TEA-Ch) assessing attention, inhibition and working memory.

**RESULTS:** Mean cpm was 604 (SD = 178) and the mean number of minutes per day spent in MVPA was 23 (SD=15). Moderate gender differences in PA were observed for cpm (effect size = 0.66, 95% CI 0.60-0.71) and daily minutes in MVPA (effect size = 0.70, 95% CI 0.65-0.75). Small to medium effect sizes (ranging from 0.18-0.40) were found for gender on all tasks of executive function. While further analysis is currently underway, preliminary findings indicate that both total volume of physical activity (cpm) and MVPA are predictive of EF at 11 but that the amount of variance explained is small (ranging from 0.1% - 0.6%).

**CONCLUSIONS:** Findings suggest that while PA is predictive of EF task performance the effects are small. Further work is underway to explore potential confounders as well as mediators and moderators of this relationship. One possibility is that PA is predictive of specific aspects of EF but not others. In addition, the findings may reflect the low amounts of MVPA observed in the present sample. These findings will lead to a greater understanding of the impact of PA on cognitive development and will have implications for research and policy concerning PA and education.

**2846** Board #118 June 1 9:30 AM - 11:00 AM

**Effects Of Physical Activity On The Aging Of Motor And Perceptual Inhibition**

Cedric T. Albinet<sup>1</sup>, Geoffroy Boucard<sup>1</sup>, Fabienne Collette<sup>2</sup>, Cedric A. Bouquet<sup>1</sup>, Michel Audiffren<sup>1</sup>. <sup>1</sup>University of Poitiers, Poitiers, France. <sup>2</sup>University of Liege, Liege, Belgium. (Sponsor: Phillip D. Tomporowski, FACSM)  
(No relationships reported)

Aging has a detrimental effect on behavioral inhibition (a core executive function), but physical activity (PA) appears to moderate this decline. However, different types of inhibition exist and for which the influence of aging and PA may differ.

**PURPOSE:** To evaluate the influence of age and regular PA on the performance of different cognitive tasks that separate perceptual and motor inhibition.

**METHODS:** Fifty adults participated in the study. Twenty-six young (Y, 20±2 yrs) and 24 older (O, 72±3 yrs) were classified as physically active (A) or sedentary (S), according to measures of past (Historical Leisure Activity Questionnaire, hours/week and METs-h/week) and present (Actigraph GT1M, steps/day and time spent/day in moderate to vigorous PA) PA. They performed the tasks developed by Nassauer and Halperin (2003), which assessed perceptual and motor inhibition. Performance in the inhibition tasks was assessed by Reaction Time (RT in ms) and response accuracy (% of correct responses) as a function of condition (no conflict vs. perceptual or motor conflict).

**RESULTS:** Overall, older were slower than young adults, and active people were faster than sedentary people. Preliminary results showed a differential effect of PA as a function of age and type of inhibition. Concerning motor inhibition, there was no effect of PA for the young groups ( $p > 0.05$ ). However, in the motor conflict condition, the OA group was significantly more accurate (95%) than the OS group (91%), although there was no significant RT difference ( $p = 0.09$ ) between the 2 groups (693±154 ms vs. 734±84 ms, for OA and OS respectively). Concerning perceptual inhibition, there was no effect of PA for the 2 groups of older ( $p > 0.05$ ). However, for the same accuracy level, YA were significantly ( $p < 0.05$ ) faster (485±64 ms) than YS (550±69 ms) in the perceptual conflict condition, although there was no RT difference in the no-conflict condition (350±24 ms vs. 357±26 ms, for the YA and YS respectively).

**CONCLUSION:** The effects of PA on inhibition appears to be moderated by both age and type of inhibition measured, deserving future research to understand the functionality of this dissociation.

Supported by a grant from Région Poitou-Charentes and FEDER.

**Air Pollution Exposure During Aerobic Training: Effects On Inflammatory Markers, BDNF And Cognitive Performances.**

Inge R. Bos<sup>1</sup>, Jef Vanparijs<sup>1</sup>, Patrick De Boever<sup>2</sup>, Nathalie Pattyn<sup>1</sup>, Luc Int Panis<sup>2</sup>, Romain Meeusen, FACSM<sup>1</sup>. <sup>1</sup>Vrije Universiteit Brussel (VUB), Brussels, Belgium. <sup>2</sup>Flemish Institute for Technological Research (VITO), Mol, Belgium.

(No relationships reported)

Exposure to Particulate Matter (PM) has been linked to inflammation and cognitive decline. It was shown that participation in an aerobic training program improves cognitive functions. Brain-Derived Neurotrophic Factor (BDNF) is a key mediator of the underlying mechanism. Recently, we found that the exercise-induced increase in BDNF serum level did not occur after cycling under high PM exposure.

**PURPOSE:** To investigate the effect of PM exposure during aerobic training on cognitive performances. The impact of PM exposure during the program is analyzed by white blood cell count (WBCC) and exhaled NO (eNO) as markers for respectively systemic and respiratory inflammation.

**METHODS:** 2 groups of inactive volunteers completed an aerobic training program of 12 weeks with 3 sessions/week, one group (n = 15) in the city of Brussels and the other group (n = 9) in the rural environment of Mol. Ultrafine Particle (UFP) concentration was measured during each training session. Before and after the program aerobic fitness (cooper test), white blood cell count (WBCC), exhaled NO (eNO), serum BDNF value and cognitive performances on the stroop test were analyzed.

**RESULTS:** UFP concentrations differed significantly with 7243.7 particles/cc in Brussels and 5625.2 particles/cc in Mol (p=0.003). Performances on the cooper test significantly improved (p<0.0001) with 15% in Brussels and 21% in Mol and did not differ between both groups (p=0.16). The group from Mol improved its performance on the stroop test, measured by stroop interference in the reaction time, with 69.3 ± 64.4 ms (p=0.023). In contrast, the group from Brussels did not improve its performance (7.4 ± 83.7 ms; p=0.74). Exhaled NO (+30%; p=0.006) and blood neutrophil concentration (+18%; p= 0.042) increased after the program in Brussels, whereas eNO (-3%; p = 0.80) and neutrophil concentration (-6%; p=0,65) did not differ after the program in Mol. No effects were found on serum BDNF value (p=0.96).

**CONCLUSIONS:** The results show that regular exercise in urban environment with high traffic - related air pollution increases markers of respiratory and systemic inflammation. In line with our previous findings where the exercise-induced increase in BDNF does not occur with exercise in polluted air, this study shows no improvements in cognitive performances with training in polluted air.

**Severe Drop in Body Core Temperature Following Four Cold Water Immersions**

Laura J. Palombo. Naval Health Research Center, San Diego, CA.

(No relationships reported)

**PURPOSE:** Previous studies have suggested that during severe cold water immersion, some subjects will reach a limit in thermal balance, as evidenced by the onset of a rapid drop in core temperature. Although the phenomenon is recognized, the percentage of the population that it occurs in has not been previously examined. The purpose of this study was to observe the minute by minute response of core temperature (T<sub>c</sub>) to multiple, consecutive cold water immersions.

**METHODS:** Nine male volunteers participated in this observational study. All subjects swallowed a core temperature monitoring pill (Mini Mitter) 7 hours prior to first immersion to ensure that the pill was properly located in the GI tract. Before entering the water, the volunteers underwent 60 min of intense physical training. At 1153 hours (air temp= 15°C, water temp = 15°C) subjects entered the ocean in cotton trousers, boots, and long-sleeved shirts, submersed up to the neck in the surf zone. Waves repeatedly washed over the head and neck during all immersions. The first immersion lasted 21 min. Subjects then stepped out of the ocean and stood on the beach for 4 minutes. Three subsequent re-immersions of 11, 10, and 4 min in duration followed, each separated by 4 min of standing on the beach. T<sub>c</sub> was recorded each minute of the 62-min protocol by monitors that were placed in waterproof packaging and worn on each subject's hip.

**RESULTS:** All 9 subjects completed the 62-min training evolution, and all were able to maintain their T<sub>c</sub> through the 3rd immersion. However, during the 4th immersion, 3 of the subjects had extremely rapid and large drops in T<sub>c</sub>. Specifically the rate of drop in T<sub>c</sub> during the 4th immersion was significantly (p < 0.05) greater (0.83 vs. 0.13°C·min<sup>-1</sup>), and the ending T<sub>c</sub> was significantly lower (34.13 vs. 37.17°C) in 3 of the subjects compared with the other 6. Furthermore, the mean % body fat, as determined by bioelectrical impedance, of the 3 subjects who demonstrated the rapid drop in core temperature was significantly less (15 vs. 18%) than in the other 6 subjects.

**CONCLUSIONS:** The results of the current study showed that one third of the subjects demonstrated a rapid and large drop in T<sub>c</sub> during the final stages of maximum tolerable cold water immersion. The physiological mechanisms responsible are unknown but may involve body fat insulation and/or shivering fatigue.

2849 Board #121 June 1 11:00 AM - 12:30 PM

**Thermoregulatory and Cardiovascular Responses During 60-minute Lower Body Cold Water Immersion**

Yongsuk Seo, Matthew D. Muller, Chul-Ho Kim, Edward J. Ryan, Ellen L. Glickman, FACSM. Kent State University, Kent, OH.

(No relationships reported)

**PURPOSE:** Lower body water immersion is used in athletics to improve endurance performance, but the effect of immersion duration on physiological responses is not known. The purpose of the current study was to compare the thermoregulatory and cardiovascular effects of 60 minute lower body water immersion (neutral versus cold).

**METHODS:** Nine healthy men (179.4±6.0 cm, 82.8±12.3 kg, 22.8±2.0 yrs, 8.4±4.8 % body fat) participated and were randomly assigned to both neutral (34.8±0.9°C) and cold (13.0±0.9°C) water immersion on separate mornings. In each session, participants rested in neutral air for 30 min followed by water immersion to the iliac crest for 60 min, then recovery for 15 min in neutral air. Rectal and mean skin temperatures were continuously monitored and recorded. Heart rate and stroke volume were measured every 10 min by impedance cardiography; brachial artery blood pressure was determined by automated sphygmomanometry.

**RESULTS:** A repeated measures ANOVA revealed a trial (Cold, Neutral) by time interaction for rectal temperature, mean skin temperature and mean arterial pressure (p<0.05). As shown in the table below, cold water immersion caused a significant stress to the body.

|                               |         | BASE     | 30 min Immersion | 60 min Immersion |
|-------------------------------|---------|----------|------------------|------------------|
| Rectal temperature (°C)       | NEUTRAL | 37.4±0.6 | 37.4±0.5         | 37.4±0.5         |
|                               | COLD    | 37.3±0.3 | 37.3±0.4         | 36.9±0.4*        |
| Mean skin temperature (°C)    | NEUTRAL | 32.1±1.0 | 34.1±0.8         | 33.8±0.6         |
|                               | COLD    | 32.4±0.4 | 27.4±0.5*        | 26.6±0.5*        |
| Mean arterial pressure (mmHg) | NEUTRAL | 83±10    | 73±8             | 76±4.6           |
|                               | COLD    | 82±8     | 81±11*           | 86±8*            |

Values are mean ± SD. \*Significant difference from neutral water immersion, P < 0.05.

**CONCLUSION:** These data suggest that longer than 30 minutes of lower body cold water immersion may be beneficial for endurance performance by reducing baseline core temperature. This study was funded by aZakelj Consulting & Design LLC.

**2850 Board #122 June 1 11:00 AM - 12:30 PM**  
**Thermoregulation during Lower Body Negative Pressure During the Cold.**

Ellen L. Glickman, FACSM, David J. Kean, Gabriel Sanders, Corey Peacock, Jacob Barkley, Matthew Muller. *Kent State University, Kent, OH.*  
(No relationships reported)

**PURPOSE:** To determine the effects cold has on thermoregulation during exposure to lower body negative pressure (LBNP).

**METHODS:** Eleven college aged men participated in two trials. Subjects were supine on a gurney with their lower extremities inserted into a LBNP pressure box up to the level of the anterior superior iliac spine. Each trial consisted of a control period of 100 min followed by application of LBNP for 20 min and concluded with a 15 min recovery period. Both trials were carried out in the environmental chamber; the cold trial was performed at 10°C (cold) and the ambient trial was performed at 23°C (ambient). The order of trials was counterbalanced. Mean skin temperature and rectal temperature was measured via skin thermistors. A repeated measures analysis of variance was used to compare trials across time. VO<sub>2</sub> was measured using a Parvo metabolic cart.

**RESULTS:** Mean skin temperature (T<sub>sk</sub>) was significant for time (p<0.001), condition (p<0.001) and there was an interaction (p<0.001). The interaction was due to a greater reduction in T<sub>sk</sub> from pre-LBNP (T<sub>sk</sub> ambient = 33.0±0.4°C vs. cold = 31.0±1°C) to recovery in the ambient condition vs the cold condition (T<sub>sk</sub> ambient = 33.7±0.9°C vs. cold = 28.9±2.0°C). Rectal temperature (T<sub>re</sub>) was significant for time (p<0.001) and there was an interaction (p=0.002). The interaction was due to a greater reduction in T<sub>re</sub> from pre-LBNP (T<sub>re</sub> ambient = 37.5±0.4°C vs. cold = 37.06±.2°C) to recovery in the ambient condition vs the cold condition (T<sub>re</sub> ambient = 37.2±0.2°C vs. cold = 36.9±0.3°C). VO<sub>2</sub> was significant for condition (p=0.028) only.

|                             | Pre-LBNP           | LBNP               | Recovery           |
|-----------------------------|--------------------|--------------------|--------------------|
|                             | Ambient Cold       | Ambient Cold       | Ambient Cold       |
| Mean skin temperature (°C)  | 33.9±0.7 9.3±1.3*  | 33.4±0.9 28.5±1.9* | 33.7±0.9 28.9±2*   |
| Rectal temperature (°C)     | 37.1±0.2 37.1±0.2* | 37.1±0.2 37.0±0.3* | 37.2±0.2 36.9±0.3* |
| VO <sub>2</sub> (ml/kg/min) | 4.9±1.1 6.3±1.6*   | 5.1±1.3 6.2±1.2*   | 5 ± 0.9 6.8±1*     |

**CONCLUSIONS:** Based on these data during cold exposure and orthostatic stress homeostasis is maintained due to adjustments in metabolism.

**2851 Board #123 June 1 11:00 AM - 12:30 PM**  
**Effect Of Microenvironment Temperature On Thermoregulatory And Perceptual Responses During Exercise In The Cold**

Colin R. Carriker<sup>1</sup>, Stephanie Campbell<sup>2</sup>, Adrienne Barr<sup>2</sup>, Lauren Stark<sup>2</sup>, Robert C. Pritchett<sup>2</sup>. <sup>1</sup>University of New Mexico, Albuquerque, NM. <sup>2</sup>Central Washington University, Ellensburg, WA.  
(No relationships reported)

In the cold, clothing may be necessary to ameliorate thermal insulation and reduce heat loss. Outer-garments in the present study were constructed of material marketed as windproof and intended to preserve the clothing microenvironment temperature (CME<sub>T</sub>) by preventing disruption of the inner air layer by cold ambient air.

**PURPOSE:** To investigate the effect of CME<sub>T</sub> on thermoregulatory and perceptual responses during moderate intensity exercise (~50% VO<sub>2max</sub>; 45 min) in a cold ambient temperature, T<sub>a</sub> (2±1°C; 66±6% humidity).

**METHODS:** A randomized crossover design was employed for 3 treatment garments of different thickness: Light (CL): 20 Denier, Medium (CM): 40 Denier, Heavy (CH): 70 Denier. Nine men (23.33±2.35 yr, 11.72±5.95 %Fat, VO<sub>2max</sub> 49.83±3.23 ml/kg/min) wore a treatment garment and baselayer pant/long sleeve shirt (100% polyester) composing a 2-layer ensemble. No hat/gloves were permitted. Trials were scheduled >2 days apart at the same time of day, 2 hr post-prandial. Testing occurred during winter/early spring months. Exercise consisted of 3 consecutive series of the following: 10 min treadmill walking at 10% grade and 5 min bench stepping (height at distal patella) with simulated wind (~1.5 m/s). Pace and cadence determined by ACSM walking/step equations at ~50% VO<sub>2max</sub>. A four site mean skin temperature (T<sub>sk</sub>) was employed (Hardy and Dubois 1938). Core temperature (T<sub>re</sub>) measured using a rectal thermistor probe. Thermal sensation, TS, ranged from -7 unbearably cold to +7 unbearably hot.

**RESULTS:** CME<sub>T</sub> and T<sub>sk</sub> were similar (p=0.108 and p=0.297 respectively) for CL, CM, CH over 45 min. CME<sub>T</sub> (17.34±2.61°C) was greater than T<sub>a</sub> (p<0.05). T<sub>re</sub> increased similarly (p=0.924) for CL, CM, CH over 45 min (1.23±0.31, 1.15±0.13 and 1.12°C±0.25; respectively) and was greater than rest after 15 min (p≤0.05) for all conditions. CH CME<sub>T</sub> declined the most over 45 min compared to CL and CM (-6.30±1.87, -6.21±1.53 and -3.67±1.82°C; respectively). A low correlation was seen between CME<sub>T</sub> and TS (r = -.03, p>0.05) and CME<sub>T</sub> and T<sub>re</sub> (r = -0.34, p<0.05). A moderate correlation was seen between T<sub>re</sub> and TS (r=0.53, p<0.05).

**CONCLUSION:** CME<sub>T</sub> declined over 45 min while both T<sub>re</sub> and TS increased. T<sub>re</sub> is more affected by work load in the cold than CME<sub>T</sub>. A windproof outer-garment preserved CME<sub>T</sub> above the ambient temperature but did not effect T<sub>re</sub> or TS.

**2852 Board #124 June 1 11:00 AM - 12:30 PM**  
**Effect Of Caffeine Gum And Exercise On Cold Induced Vasodilation In Human Finger**

Byeong Jo Kim, Dae Taek Lee. *Kookmin Univ., Seoul, Korea, Republic of.*  
(No relationships reported)

**PURPOSE:** This study examined whether chewing caffeine gum in conjunction with exercise would modify the cold induced vasodilation (CIVD) in human fingers.

**METHODS:** Two (no-caffeine; NC or caffeine intake; CI) by three (no-exercise; NE, 70% of VO<sub>2max</sub>; 70E, or all-out; AO) study design was employed. Ten non-cold acclimated healthy men (24.7±2.2 yrs, 175.0±5.1 cm, 71.3±7.4 kg, 16.0±6.3% body fat, 56.4±2.8 ml/kg/min VO<sub>2max</sub>) randomly participated in all six testings. In each session, subjects immersed their middle finger at 43°C water for 5 min followed by resting at ambient air for 10 min. During the resting, they either chewed caffeine gum (300 mg) or simply took a rest. Then they underwent one of three activity phases; NE for 20 min, 70E on a treadmill for 20 min, or AO with incremental exercise intensity. Upon completion of the activity phase, they immersed the middle finger at 5°C water for 20 min. And a blood sample was taken from antecubital veins. During testing, finger temperature from middle finger nail bed was measured. The lowest (T<sub>fmin</sub>) and the highest (T<sub>fmax</sub>) finger temperatures were recorded and the difference between T<sub>fmin</sub> and T<sub>fmax</sub> (T<sub>fdiff</sub>) were calculated. Time variable of CIVD such as the time period between min 0 and time at T<sub>fmin</sub> (Δtonset), time between at T<sub>fmin</sub> and at T<sub>fmax</sub> (Δtpeak), and Δtonset plus Δtpeak (Δtmax) were calculated.

**RESULTS:** Although main effects of caffeine and exercise were noticed, no interactions were found in T<sub>fmin</sub> and T<sub>fmax</sub>. T<sub>fdiff</sub> in NC-NE (6.9±1.6°C) was higher than CI-NE (4.8±1.2°C) (p<0.05). T<sub>fdiff</sub> in NC-AO (1.9±0.5°C) was lower than NC-NE and NC-70E (3.2±1.2°C) (p<0.05), and that in CI-AO (1.6±0.6°C) was lower than CI-NE (p<0.05). Caffeine did not impact on Δtonset, Δtpeak, and Δtmax but both 70E and AO shortened all time variables. No interactions were noticed in time variables of CIVD. Epinephrine level was higher in CI (291-400 pg/ml) than NC (106-362 pg/ml) (p<0.05) as well as in AO (362-400 pg/ml) than NE (106-291 pg/ml) and 70E (200-278 pg/ml).

**CONCLUSIONS:** The oral caffeine intake and exercise induced a small difference between the lowest and the highest finger temperatures. It appeared that exercise stimulus was stronger in modifying CIVD. Caffeine did not affect time variables of CIVD.

**2853** Board #125 June 1 11:00 AM - 12:30 PM  
**An Experimental Study of Practical Field Methods for Cold Casualty Protection**

Jennifer L. Brierley, Alberto Dolci, Neil P. Walsh, Samuel J. Oliver. *Bangor University, Bangor, United Kingdom.*  
(No relationships reported)

Hypothermia, particularly when combined with traumatic injury, is a significant contributor to fatalities in remote environments. It is therefore important to develop field methods to protect casualties from the cold whilst they await evacuation to more sophisticated medical facilities.

**PURPOSE:** To examine the thermoregulatory responses of men to four field methods following pre-cooling.

**METHODS:** Seven healthy males completed five trials in a randomised order. These included a thermo-neutral control trial (TC), where participants remained seated and fully clothed, and four cold trials. On each cold trial, dressed in shorts only, participants were cooled to 36°C core temperature in 13°C water after which they completed a 3-hour cold air test (CAT, 0°C) in one of four field methods, these included; 1. a polythene survival bag (PB), 2. PB with 70°C hot drink (PB+HD), 3. a triple-layered metallized sheeting Blizzard survival bag (BB), and 4. BB with chemical heat pads - Blizzard Heat (BB+HP). During each CAT drinks were consumed hourly equal to 6 ml·kg<sup>-1</sup> body mass. Non PB+HD trial drinks were served at 36°C. Core and mean weighted skin temperature, metabolic heat production and thermal comfort were assessed.

**RESULTS:** Prior to the CAT, time to reach 36°C was not different (31 ± 15 min,  $P = 0.50$ ). During the CAT, initial rewarming rate, afterdrop parameters (i.e. magnitude, time to nadir and return to 36°C) and core temperature were not different between the four field methods. However, compared with PB and PB+HD, skin temperature was greater (PB 25 ± 1, PB+HD 25 ± 1, BB 27 ± 2, BB+HP 28 ± 2, TC 32 ± 1 °C,  $P < 0.01$ ) and metabolic heat production was lower during BB and BB+HP (PB 133 ± 73, PB+HD 149 ± 74, BB 112 ± 73, BB+HP 96 ± 62, TC 57 ± 16 W·m<sup>-2</sup>,  $P < 0.01$ ). Indeed, metabolic heat production was similar to TC on BB and BB+HP by 30 min into CAT. Thermal comfort was also higher on BB+HP compared with PB+HD ( $P < 0.05$ ) but not different between other field methods.

**CONCLUSION:** Despite cold exposure, the four field methods supported re-warming to near resting core temperatures in shivering cold-casualties. However, less metabolic heat production was required to maintain core temperature in triple-layered metallized survival bags compared with polythene survival bags. Hot drinks had no measured thermoregulatory or perceptual benefit. Supported by ESF.

**2854** Board #126 June 1 11:00 AM - 12:30 PM  
**53 Hrs Of Sleep Deprivation On Oxygen Consumption (VO<sub>2</sub>) During Multiple Stages Of Acute Cold Exposure**

Katherine E. Pierce-Clark<sup>1</sup>, Tiffany A. Esmat<sup>2</sup>, Edward J. Ryan<sup>3</sup>, Ellen L. Glickman, FACSM<sup>3</sup>. <sup>1</sup>University of Mount Union, Alliance, OH. <sup>2</sup>Kennesaw State University, Kennesaw, GA. <sup>3</sup>Kent State University, Kent, OH.  
(No relationships reported)

**BACKGROUND:** It is well established that acute exposure to a cold environment elicits an increase in shivering thermogenesis and that oxygen consumption (VO<sub>2</sub>) must also increase to meet these demands. The impact of an additional stressor such as sleep deprivation, in conjunction with acute cold exposure, on VO<sub>2</sub> has yet to be extensively evaluated.

**PURPOSE:** To evaluate the effects of 53-hrs of sleep deprivation on VO<sub>2</sub> of young adult Caucasian males during multiple bouts of acute cold exposure.

**METHODS:** Eight males (22.8±1.7y) underwent two conditions [control (CON) or sleep deprivation (SDEP)] during which they were exposed to cold air (10°C) for 120-min, once per day, for 3 consecutive days (Stages 1, 2, and 3) beginning at 0600-hrs. Rectal temperature (T<sub>re</sub>), mean skin temperature (T<sub>sk</sub>), and oxygen consumption (VO<sub>2</sub>) were collected at baseline (BASE) and 5-, 15- and every 15-min thereafter for the duration of the 120-min trial (for 120-min).

**RESULTS:** VO<sub>2</sub> demonstrated a main effect across time for both conditions ( $p < 0.001$ ). During the CON trial, VO<sub>2</sub> (ml·kg<sup>-1</sup>·min<sup>-1</sup>) increased from 3.99±0.53 to 7.35±0.86, 3.76±0.57 to 6.83±1.15, and 3.54±0.45 to 7.87±2.00, for ACE stages 1, 2, and 3, respectively. During the SDEP trial, VO<sub>2</sub> (ml·kg<sup>-1</sup>·min<sup>-1</sup>) increased from 3.81±0.95 to 6.52±1.68, 3.58±0.97 to 6.59±2.38, and 3.93±0.55 to 7.46±0.7, for ACE stages 1, 2, and 3, respectively. A stage x time repeated measures ANOVA revealed a significant interaction ( $p = 0.05$ ). This interaction may be attributed to a differential increase in VO<sub>2</sub> during each ACE stage. Two additional separate two-way (stage x time) ANOVAs were conducted to determine whether the interaction was due to the SDEP or CON trial, but there were no significant interactions as BASE VO<sub>2</sub> did not significantly change during SDEP (3.81±0.95 vs. 3.58±0.97 vs. 3.93±0.55,  $p = 0.60$ ) or CON (3.99±0.53 vs. 3.76±0.57 vs. 3.54±0.45,  $p = 0.76$ ).

**CONCLUSION:** These data suggest that SDEP does not appear to affect an individual's metabolic response to acute cold exposure. Although VO<sub>2</sub> increased during each ACE there was no significant increase from ACE stage 1 to ACE stage 3.

**2855** Board #127 June 1 11:00 AM - 12:30 PM  
**Effect Of Clothing On Validity Of Devices Used To Estimate Core Temperature In Cold Environments**

Jason Ng<sup>1</sup>, Andrea M. DuBois<sup>1</sup>, Nicole E. Moyon<sup>1</sup>, Jeremy G. Tan<sup>1</sup>, Michelle R. Villa<sup>1</sup>, Lee E. Brown, FACSM<sup>1</sup>, Jared W. Coburn, FACSM<sup>1</sup>, Douglas J. Casa, FACSM<sup>2</sup>, Daniel A. Judelson, FACSM<sup>1</sup>. <sup>1</sup>California State University, Fullerton, Fullerton, CA. <sup>2</sup>University of Connecticut, Storrs, CT.  
(No relationships reported)

Many devices invalidly estimate core temperature in cold environments. Work showing this typically minimized subject clothing to maximize cold stress, substantially reducing external validity and questioning whether the devices might validly estimate core temperature when coupled with temperature-appropriate clothing.

**PURPOSE:** To investigate the effect of clothing on the validity of devices used to estimate core temperature in cold environments.

**METHODS:** Twelve healthy males (age=23±2 y, height=178.7±8.2 cm, mass=87.8±10.7 kg) completed two trials in cold conditions (6±1 °C, 64±10% RH), wearing either environmentally-appropriate (AC) or minimal clothing (MC). Subjects wore gloves, underwear, socks, and shoes in both trials. AC also included a headband, long-sleeved moisture-wicking shirt, and running pants, while MC was limited to athletic shorts. Each trial was comprised of 30 min resting equilibration, 90 min cycling at 60-70% of age-predicted maximum heart rate, and 30 min rest. Investigators measured rectal (T<sub>REC</sub>), aurial (T<sub>AUR</sub>), expensive axillary (T<sub>AXLE</sub>), inexpensive axillary (T<sub>AXLI</sub>), forehead sticker (T<sub>FOR</sub>), gastrointestinal (T<sub>GI</sub>), expensive oral (T<sub>ORLE</sub>), inexpensive oral (T<sub>ORLI</sub>), and temporal (T<sub>TEM</sub>) temperatures every 15 min. A mean bias of ±0.27 °C from T<sub>REC</sub> acted as the validity criterion.

**RESULTS:** Mean biases for T<sub>AUR</sub>, T<sub>FOR</sub>, and T<sub>TEM</sub> during AC significantly exceeded MC but never achieved the validity criterion. No significant differences existed in mean biases between AC and MC trials for T<sub>AXLE</sub>, T<sub>AXLI</sub>, T<sub>GI</sub>, T<sub>ORLE</sub>, and T<sub>ORLI</sub>. Only T<sub>GI</sub> achieved the validity criterion (AC mean bias=0.08±0.09 °C, MC mean bias=0.14±0.19 °C).

**CONCLUSIONS:** Clothing improved measurements covered by a snug headband (T<sub>AUR</sub>, T<sub>FOR</sub>, and T<sub>TEM</sub>) but not other sites (T<sub>AXLE</sub>, T<sub>AXLI</sub>, T<sub>ORLE</sub>, and T<sub>ORLI</sub>). Only T<sub>GI</sub> validly estimated core temperature. Even while wearing appropriate clothing, only a rectal thermometer or gastrointestinal pill should assess core body temperature in the cold.

**2856** Board #128 June 1 11:00 AM - 12:30 PM  
**Patterns Of Injury, Mood And Sleep Patterns Of Athletes Participating In An Arctic Ultra Marathon**

Scott M. Graham<sup>1</sup>, Chris Connaboy<sup>2</sup>, Colin Brow<sup>1</sup>, Mairi McKinley<sup>3</sup>. <sup>1</sup>UWS, Glasgow, United Kingdom. <sup>2</sup>Edinburgh Napier, Edinburgh, United Kingdom. <sup>3</sup>University of Abertay, Dundee, Dundee, United Kingdom.  
(No relationships reported)

**INTRODUCTION:** The 6633 was an ultra marathon held in the Canadian Arctic, 2009. Participants ran a 100 mile continuous stage over a period of 72 hours. Temperatures averaged -14oc day, -20oc night, low of -32oc (-42oc with wind chill). Type of injury, mood and sleep was assessed and documented throughout the race. Previous work has shown mood states to vary, and to be correlated to sleep patterns, in a cold environment. (Pedlar et al., Wild. and Environ. Med 18, 127-132. 2007).

**PURPOSE:** To document injuries, self reported sleep and profile mood states during an endurance race in an Arctic environment

**METHODS:** Eight male competitors (mean BMI 23 ± 12, Age: 31 ± 9.1 yrs) completed a 100 miles endurance running stage. Injuries were clinically assessed and recorded during each 24 hour period of exercise. Mood was assessed using the Brunel Mood Scale (BRUMS) (Terry et al., J. Sports Sci. 17, 861-872. 1999). A full self assessment sleep log was completed. Descriptive statistics and data analysis were performed using SPSS. Friedman's nonparametric test was used to compare differences specific psychological mood states, between and within groups.

Pearson's correlation coefficient analysis was used to investigate the degree of linear relationship between sleep patterns and recorded mood states (Anger, Confusion, Depression, Fatigue, Tension and Vigor). Differences were considered statistically significant at the  $p < 0.05$  level

**RESULTS:** All athletes presented with skin abrasion injuries, cold

condition injuries, dehydration and environmental related stress. Four subjects presented with soft tissue injuries. Vigour decreased continuously from the first 24 hours ( $p < 0.05$ ) whilst fatigue increased ( $p < 0.05$ ). This trend continued from start with values not recovering until recovery period post race. Continued activity resulted in increased levels of depression ( $p < 0.05$ ), tension ( $p < 0.05$ ) and confusion ( $p < 0.05$ ) which peaked at the 60 hour mark and decreased to the 72 hour mark. Mean sleep duration over the race period was 4:45 ± 00:12 hr: min.

**CONCLUSION:** Injury types and patterns documented were similar to those reported in other adventure and ultra distance events held in extreme environments. Consistent with previous work, data shows increased fatigue and reduced vigour in response to reduced sleep.

#### Salivary Cortisol Production during the Ride Across America (RAAM): A Case Study and Exploratory Analysis

Matthew A. Stults-Kolehmainen<sup>1</sup>, Chuck J. Abolt<sup>2</sup>, Craig E. Broeder, FACSM<sup>3</sup>, Amy M. Flewelling<sup>1</sup>, Amanda J. Salacinski<sup>1</sup>. <sup>1</sup>Northern Illinois University, DeKalb, IL. <sup>2</sup>Duke University, Durham, NC. <sup>3</sup>Exercising Nutritionally Clinical Research Partners, Naperville, IL.

(No relationships reported)

**PURPOSE:** The aim of this study was to investigate the variation in salivary cortisol during the Ride Across America.

**METHODS:** A 51 year old elite endurance cyclist competed in the RAAM ride. Descriptives are provided in Salacinski et al. (2011, MSSE, vol 43, p 536). Saliva was collected with oral swabs throughout two different time periods: 21 awakening and before sleep samples at baseline (4 weeks before race) and 23 samples during the event and before/after periods of rest. Salivary cortisol was analyzed with a Salimetrics immuno-assay and a Biotek plate reader.

**RESULTS:** The subject completed 6 days, 11 hours and 19 minutes of the race before discontinuing. His average speed, including rest stops, was 10.3 mph. His mean power was 199.5 W for days 1&2 and 124 W for days 4&5. The mean cortisol concentration for 7 baseline awakening samples was .71 µg/dL (SD = .09) and before bed was .15 µg/dL (SD = .07). Seven samples were discarded for possible blood and/or sports drink contamination, leaving 16 samples (awakening: M = .35 µg/dL, SD = .23; during-race: M = .64 µg/dL, SD = .16; before bed: M = .51 µg/dL, SD = .05). Saliva pH increased from baseline (M = 7.14, SD = .74) to race time (M = 8.38, SD = .60), while 2.54 kg of fat mass was lost from pre to post race.

**CONCLUSION:** The subject displayed a normal cortisol production rhythm at baseline; however, race values demonstrate a state of hyper-activation, catabolism, and dysregulation.

#### Effects of Varying Type of Physical Exercise on Children's Salivary Cortisol

Maria Chiara Gallotta, Emanuele Franciosi, Gian Pietro Emerenziani, Valerio Bonavolontà, Marco Meucci, Luigi di Luigi, Laura Guidetti, Carlo Baldari, FACSM. University of Rome, Rome, Italy.

(No relationships reported)

**PURPOSE:** Aim of this study was to investigate whether different physical exercise conditions could induce different exercise-related changes on children's salivary cortisol.

**METHODS:** Saliva collection of 48 children (8-11 years of age) took place before (Pre) and after (Post) 50 min of a traditional physical education (TPE) and of a coordinative physical education (CPE) lesson, respectively. Physical education (PE) sessions occurred at the same time (in the morning) of the same school day over 2 weeks. The school day was planned to have the same schedule every day during the experimental intervention with PE lessons preceded by academic classes. During the TPE lesson, children were instructed to exercise at a moderate to vigorous physical activity (MVPA corresponding to HR > 139 bpm) intensity without any specification on motor coordination. The CPE lesson, conducted at the same exercise intensity, was characterized by a high variability of motor coordination and skill learning demands.

**RESULTS:** Results showed that participants' salivary cortisol was significantly affected by Time (Pre vs Post) ( $5.51 \pm 4.50$  nmol/L vs  $4.01 \pm 2.70$  nmol/L,  $F = 5.74$ ;  $p = 0.02$ ), indicating a reduction of salivary cortisol after the two PE lessons independently of their content ( $F = 1.01$ ;  $p = 0.32$ ).

**CONCLUSION:** We found that varying types of physical exercise did not differentially affect children's salivary cortisol concentration. Moreover, a significant decrease of the cortisol concentrations occurred from pre- to post-exercise. Our findings suggest that physical education could act as a distractor, leading to a reduction of school stress. These activities were probably enjoyable and relaxing for children and in turn cortisol decreased.

### 2859 Board #131 June 1 9:30 AM - 11:00 AM

#### Stress Hormone Biomarker Response in Fit and Unfit Premenopausal Women to One-Hour Aerobic Run

Lee Berk, FACSM, Paula Cavalcanti, Janhavi Soni, Shreenath Varadarajan. Loma Linda University, Loma Linda, CA.

(No relationships reported)

Exercise modulates the release of stress hormones and other biomarkers relative to fitness level. Various cohort studies have shown differential modulation of cortisol (CORT), HGH, TSH, FT4, insulin (INS) and iron-oxygen-binding protein myoglobin (MYO) with different exercise modalities. However, few studies have examined the differential response to aerobic exercise in fit and unfit premenopausal women.

**PURPOSE:** To compare low vs. high fitness premenopausal women for stress hormones and MYO blood biomarkers levels at rest and in response to a 1-hr aerobic exercise.

**METHODS:** 21 fit and 14 unfit premenopausal women ages 20-50 years, mean  $\text{VO}_2 \text{ Max}$   $42.2 \pm 5.3$  and  $27.9 \pm 3.3$  mL/kg/min respectively, performed a 1-hr exercise 70-80% of max HR. Blood levels were determined at pre-exercise (Pr-E), immediate post-exercise (IPo-E) and 30 min post-exercise (30Po-E) for TSH, HGH, INS, FT4, CORT, 17β-Estradiol (17β-E) and MYO and adjusted for plasma volume shifts.

**RESULTS:** The proportion of menstrual states was similar in the two groups. 17β-E was not different between the fit and unfit group ( $94.6 \pm 54.6$  vs.  $90.7 \pm 66.8$  pg/mL respectively,  $p > .05$ ). A 2x3 Mix Factorial ANOVA showed significant differences between groups in mean TSH ( $F = 7.92$ ;  $p = .002$ ; mean ± SE was  $1.61 \pm .26$  for fit and  $2.42 \pm .31$  for unfit), HGH ( $F = 19.50$ ;  $p = .002$ ;  $5.71 \pm .69$  for fit and  $5.01 \pm .82$  for unfit), MYO ( $F = 96.26$ ;  $p < .001$ ;  $1.76 \pm .06$  for fit and  $1.76 \pm .67$  for unfit). Differences were found between Pr-E and 30min post exercise for TSH ( $p = .003$ ), HGH ( $p < .001$ ), MYO ( $p < .001$ ); Pr-E and IPo-E for MYO ( $p < .001$ ); and IPo-E and 30Po-E for TSH ( $p < .001$ ), HGH ( $p < .001$ ). One-way Repeated Measures showed difference in CORT levels over time in the fit group ( $F = 47.14$ ;  $p < .001$ ) and unfit group ( $F = 18.84$ ;  $p < .001$ ). The differences were between Pr-E and IPo-E (fit:  $p < .001$ ; unfit:  $p = .005$ ); also, between Pr-E and 30Po-E (fit:  $p = .007$ ; unfit:  $p < .001$ ), and between IPo-E and 30Po-E (fit:  $p < .001$ ; unfit:  $p = .001$ ). ANCOVA showed no difference between groups for INS ( $F = .26$ ;  $p = .873$ ) and FT4 at Pr-E ( $F = .49$ ;  $p = .489$ ).

**CONCLUSION:** Stress hormones CORT, HGH, TSH and MYO are differentially modulated in fit versus unfit premenopausal women. Further study is needed to elaborate the significance of these physiological differential responses, mechanisms and resultant stress implications in premenopausal women.

2860 Board #132 June 1 9:30 AM - 11:00 AM

**Capillary but Salivary Cortisol Samples Accurately Reflects Venous Cortisol Following Intense Exercise**

lee stoner<sup>1</sup>, Simon Fryer<sup>2</sup>, Tabitha Dickson<sup>2</sup>, Stephen Hillier<sup>3</sup>, Nick Draper<sup>2</sup>. <sup>1</sup>Massey University, Wellington, New Zealand. <sup>2</sup>University of Canterbury, Christchurch, New Zealand. <sup>3</sup>Tauranga Hospital, Tauranga, New Zealand. (Sponsor: Kevin K. McCully, FACSM)  
(No relationships reported)

**PURPOSE:** To determine whether capillary and salivary cortisol samples accurately reflect venous blood cortisol during intense exercise. Venepuncture is the establish "gold standard" for sampling cortisol, but is expensive, highly invasive and impractical for many experimental and clinical settings. Salivary free cortisol is a non-invasive and practical alternative; however, when cortisol concentrations exceed 500 nmol/l there is a lack of agreement between salivary and venous blood cortisol. No known research has assessed whether capillary cortisol accurately reflects venous blood cortisol across a range of concentrations.

**METHODS:** Eleven healthy male subjects (26.1 ± 5.0yrs) were recruited. Capillary, salivary and venous blood samples were collected pre and post (immediately post and post 5, 10, 15 and 20 minutes) a treadmill VO<sub>2</sub> max test.

**RESULTS:** A strong relationship was found between capillary and venous cortisol samples ( $r = 0.899$ ,  $P = <0.001$ ). Bland-Altman analysis revealed a small but random bias for lower cortisol concentrations with capillary versus venous cortisol sampling. Two-way repeated measures ANOVA revealed a non-significant ( $P = 0.340$ ) interaction between stage (time post-stress test) and sampling site. There was a moderate relationship between salivary and venous cortisol samples ( $r = 0.565$ ,  $p = 483.14.3$ ).

**CONCLUSIONS:** Capillary but not salivary is a valid technique for measuring whole bound cortisol following intense exercise.

2861 Board #133 June 1 9:30 AM - 11:00 AM

**Changes in Selected Blood, Endocrine, and Myocardial Markers Measured During 24-hour Continuous Cycling**

Serge P. von Duvillard, FACSM<sup>1</sup>, Rainer Hochgatterer<sup>2</sup>, Helmuth Ocenasek<sup>2</sup>, Martin Michl<sup>3</sup>, Karin Vonbank<sup>4</sup>, Sabine Würth<sup>1</sup>, Peter Hofmann, FACSM<sup>5</sup>, Gerhard Smekal<sup>1</sup>, Robert Berent<sup>6</sup>, Manfred Wonsch, FACSM<sup>7</sup>, Rochus Pokan, FACSM<sup>3</sup>. <sup>1</sup>University of Salzburg, Salzburg, Austria. <sup>2</sup>Hospital Linz, Linz, Austria. <sup>3</sup>University of Vienna, Vienna, Austria. <sup>4</sup>Medical University of Vienna, Vienna, Austria. <sup>5</sup>University and Medical University of Graz, Graz, Austria. <sup>6</sup>Centers for Cardiac Rehabilitation, Bad Schallerbach, Austria. <sup>7</sup>Centers for Cardiac Rehabilitation, St. Radegund, Austria.  
(No relationships reported)

**PURPOSE:** We measured changes in selected blood, endocrine, and myocardial markers during 24h continuous non-stop cycling in 8 highly endurance trained male cyclist (mean±SD: age: 39.4±7.9 yrs; Wt: 77.4±6.4 kg; Ht: 179.3±6.6 cm; BMI: 24.0±0.7). The mean power for 24h cycling expressed in Watts (W) was 162.8±24.9 and the mean relative oxygen consumption over 24h was 34.3±4.0 ml.kg<sup>-1</sup>.min<sup>-1</sup>.

**METHODS:** All tests were conducted on an electronically braked cycle ergometer (Excalibur-Sport, Lode, Groningen, The Netherlands). Blood samples were collected in the beginning and every 6h of the 24h in EDTA tubes and as serum. Each test started at 10:00 AM and concluded at 10:00 AM next day. Blood samples in the amount of 5x18 ml were collected from antecubital vein every 6h during each 24h test. In addition to numerous other variables we assessed changes in selected blood variables as follows: %hematocrit (%Hct), creatine kinase (CK), creatine kinase myocardial marker (CK-MB), insulin, N-terminal brain natriuretic peptide (NT-proBNP), somatotrophic hormone (STH), testosterone, and cortisol.

**RESULTS:** Statistical analysis revealed statistically significant differences from start to the end of 24h cycling for NT-proBNP (27.1±9.8 to 567.9±359.8), CK (181.4±60.2 to 860.1±528.4), decrease in %Hct (44.2±2.3 to 40.9±1.1) and a decrease in testosterone (3.8±0.6 to 1.2±0.7) all  $P < 0.001$ . CK-MB (24.0±0.0 to 30.3±8.3) increased significantly ( $P < 0.02$ ) at the end of 24h cycling; however, there were no significant difference for cortisol, STH or insulin responses ( $P > 0.05$ ).

**CONCLUSION:** The results of our study suggest that 24h non-stop cycling at an average workload of approximately 160 W alter the concentration of several blood markers. NT-proBNP concentration at the end of 24h cycle ergometry was pathologically high. The CK was expected to increase and so was a decrease in %Hct. Statistically significant increase in CK-MB may reflect the duration of exercise more than the workload. Almost all selected endocrine constituents (cortisol, STH, and insulin) remained largely unaltered suggesting that body can regulate hormonal and metabolic response very well. Blood testosterone decreased significantly after 24h of non-stop cycling; however, the exact mechanism as to why testosterone declined by 68% at the end of 24h cycling is not known.

2862 Board #134 June 1 9:30 AM - 11:00 AM

**Urinary Androgens Changes In Pre And Postmenopausal Women After 6 Months Of Aerobic Training**

M. Concepción Robles<sup>1</sup>, Javier Brazo<sup>1</sup>, Guillermo Olcina<sup>1</sup>, Antonio F. Toribio<sup>2</sup>, Carmen Crespo<sup>1</sup>, Rafael Timón<sup>1</sup>, Marcos Maynar<sup>1</sup>. <sup>1</sup>University of Extremadura, Cáceres, Spain. <sup>2</sup>University of Extremadura, Badajoz, Spain.  
(No relationships reported)

The postmenopausal period is associated with an estrogen and androgens deficiency. These hormonal alterations could be responsible for the increased morbidity. Physical activity could have an important regulating effect on female hormonal metabolism, although not necessarily the same in pre or postmenopausal women.

**PURPOSE:** To evaluate the effect of 6 months of aerobic exercise on urinary excretion of androgens in pre and postmenopausal women and to determine the basal urinary steroid profile.

**METHOD:** 20 premenopausal (PRE) (45.56 ± 4.06 years) and 20 postmenopausal (POST) (52.27 ± 3.80 years) women, all sedentary, were studied before and after a supervised 6 months exercise training program based on aerobic dance (60-70% maximal heart rate, 60 min/day, 3 days/week). Before and after the program, anthropometric data and VO<sub>2</sub> max were measured and overnight fasting urines samples were collected and analyzed by gas chromatography / mass spectrometry (GC/QMS). Steroids values were expressed as ng steroid / mg creatinine (cr). The data was analyzed by one-way ANOVA and by repeated measures, using a general linear model.

**RESULTS:** Both groups improved their VO<sub>2</sub> max after the aerobic exercise program (32.59±6.0 before vs 37.60±8.2 ml/min/kg after exercise in PRE  $p < 0.01$ ; 31.84±6.0 before vs 36.94±6.3 ml/min/kg after exercise in POST  $p < 0.01$ ). Important differences were observed between urinary androgens in both groups in basal values. Urinary testosterone (26.32±14.62 ng/mg cr PRE vs 20.50±13.18 ng/mg cr POST,  $p < 0.05$ ), DHEA (48.02±57.91 ng/mg cr PRE vs 11.38±11.21 ng/mg cr POST,  $p < 0.05$ ) and androstenedione levels (72.14±49.72 ng/mg cr PRE vs 45.44±31.71 ng/mg cr POST,  $p < 0.05$ ) were affected by menopause. After the exercise program, no changes in urinary androgens levels were observed in premenopausal women. However, the aerobic exercise caused an increase in urinary excretion of DHEA (11.38±11.21 ng/mg cr before vs 55.13±57.17 ng/mg cr after exercise  $p < 0.05$ ) in postmenopausal women.

**CONCLUSION:** Pre and postmenopausal women presented important differences in the basal levels of androgens. In postmenopausal women, moderate physical activity could raise levels of DHEA, probably due to an activation of the suprarenal gland. This elevation of androgens levels could bring health benefits for postmenopausal women.

2863 Board #135 June 1 9:30 AM - 11:00 AM

**Vitamin D Supplementation and Physical Performance in Adolescent Swimmers**

Naama W. Constantini, FACSM<sup>1</sup>, Netachen Livne<sup>2</sup>, Daniel Moran, FACSM<sup>3</sup>, Raanan Raz<sup>4</sup>, Gal Dubnov-Raz<sup>5</sup>. <sup>1</sup>Hadassah- Hebrew University Medical Center, Jerusalem, Israel. <sup>2</sup>Hebrew University, Rehovot, Israel. <sup>3</sup>Ariel University Center of Samaria, Tel Aviv, Israel. <sup>4</sup>Tel Aviv University, Tel Aviv, Israel. <sup>5</sup>The Edmond and Lily Safra Children's Hospital, Tel Hashomer, Israel.  
(No relationships reported)

Serum vitamin D levels have been shown to correlate with several physical functions, such as muscle power, velocity and balance, mostly in the elderly and in sedentary populations. Vitamin D insufficiency is extremely prevalent in the general population, including athletes, yet its effect on performance is unknown.

**PURPOSE:** To evaluate the effect of vitamin D supplementation on swimming performance, power and balance of young swimmers with vitamin D insufficiency.

**METHODS:** 54 competitive adolescent swimmers (age 13.8±1.5 yrs, 63% males) with serum vitamin D levels (25(OH)D) below 30 ng/mL were randomized to two groups. The supplementation group received 2,000 IU/d of vitamin D3 drops for 12 weeks during a winter training season, and the control group received placebo drops identical in appearance and flavor. Freestyle swimming performance was assessed by a modification of the Mader test: 400m at V2-3 (below anaerobic threshold), 400m at V3-4 (above anaerobic threshold), and 4X50m all-out

sprints. Swimming time and post-swim heart rate were measured for each stage of the test. Arm grip strength was measured using a dynamometer; balance was measured using the uni-pedaled stance test twice (eyes open/closed). All measures were taken pre- and post- intervention, and changes were calculated to serve as endpoints.

**RESULTS:** Mean serum 25(OH)D levels increased in the supplementation group (from 24.6±5.2 to 29.6±6.5 ng/ml,  $p<0.001$ ) and decreased in the control group (from 24.6±4.9 to 20.3±4.3 ng/ml,  $p<0.001$ ) during the study period. There were no significant between-group differences in swimming time, heart rate, strength, or balance changes post-supplementation. No significant correlations were found between age-adjusted vitamin D change in the whole study cohort, and changes in the measures of physical performance.

**CONCLUSION:** Vitamin D supplementation for 12 weeks to adolescent swimmers with vitamin D insufficiency did not affect swimming performance, power and balance, more than placebo. Despite the widespread concern that vitamin D insufficiency might influence sport performance, there is currently no evidence that improving vitamin D status would benefit these athletes. Additional studies in vitamin D deficient athletes and in other sport types are warranted.

---

**2864** Board #136 June 1 9:30 AM - 11:00 AM

**Adiponectin is Negatively Correlated with Testosterone in Male and Female Rats**

Luke A. Beggs<sup>1</sup>, Joshua F. Yarrow<sup>2</sup>, Sean C. McCoy<sup>2</sup>, Christine F. Conover<sup>2</sup>, Stephen E. Borst<sup>2</sup>. <sup>1</sup>University of Florida, Gainesville, FL. <sup>2</sup>VA Medical Center, Gainesville, FL.

(No relationships reported)

Adiponectin is an adipokine that is typically secreted in an inverse manner to adiposity, low concentrations of which are an independent risk factor for several metabolic disorders. The loss of endogenous sex-hormones increases adiposity in both males (M) and females (F) and has also been linked to a number of metabolic disorders including metabolic syndrome. Conversely, testosterone (T) administration generally reduces body fat. However, the influence of T on adiponectin requires further elucidation.

**PURPOSE:** To evaluate the effects of gonadectomy (GX) and supraphysiologic testosterone-enanthate (TE) administration on serum adiponectin in young M and F rats.

**METHODS:** Animals underwent GX or sham surgery and received either vehicle or TE (7.0 mg/wk, i.m.) for 28 days. Blood was collected at sacrifice for analysis.

**RESULTS:** Serum T was 3.3 ± 1.0 (SHAM-M), 0.1 ± 0.04 (GX-M), 41.5 ± 3.1 (GX+TE-M), 0.5 ± 0.1 (SHAM-F), 0.2 ± 0.04 (GX-F), and 46.7 ± 4.1 ng/mL (GX+TE-F). Serum estradiol (E<sub>2</sub>) was 4.6 ± 0.8 (SHAM-M), 3.0 ± 0.4 (GX-M), 6.4 ± 0.6 (GX+TE-M), 8.8 ± 0.7 (SHAM-F), 3.6 ± 0.4 (GX-F), and 5.3 ± 0.6 pg/ml (GX+TE-F). Serum adiponectin concentrations were 5760 ± 561 (SHAM-M), 7418 ± 429 (GX-M), 3132 ± 179 (GX+TE-M), 6348 ± 840 (SHAM-F), 10228 ± 589 (GX-F), and 3738 ± 255 ng/ml (GX+TE-F). Compared to SHAM, GX elevated adiponectin 29% (M;  $p<0.001$ ) and 34% (F;  $p<0.01$ ), while TE administration reduced adiponectin 58% (M) and 65% (F) compared to GX ( $p<0.001$ ) and by 46% (M) and 53% (F) compared to SHAM ( $p<0.001$ ). Strong negative correlations were present between T and adiponectin in both M ( $r=-0.747$ ,  $p<0.001$ ) and F ( $r=-.742$ ,  $p<0.001$ ). Conversely, E<sub>2</sub> was not significantly associated with adiponectin in either sex.

**CONCLUSIONS:** T, but not E<sub>2</sub>, was inversely associated with adiponectin in both M and F. This is despite the fact that we have previously reported that T administration in rats reduces retroperitoneal fat pad mass 45% below GX animals, and that adiponectin is typically inversely related to fat mass. This suggests that adiponectin is regulated not only by adiposity, but also by T. The metabolic consequences associated with an elevated adiponectin following GX and a reduced adiponectin following supraphysiologic T administration remain to be identified.

**Systemic PGF<sub>2α</sub> Metabolite Response to Resistance Exercise and Naproxen Sodium**

Christi Brewer, Mark Loftin, FACSM, John Garner, John Bentley, Elaine Day, Dwight Waddell. University of MS, University, MS.

(No relationships reported)

Prostaglandin F<sub>2α</sub> (PGF<sub>2α</sub>) is an endogenously produced growth factor that mediates satellite cell activity and protein incorporation into existing musculature after exercise-induced muscle injury. Accordingly, non-steroidal anti-inflammatory drugs, which inhibit prostaglandin production, have been shown to interfere with these cellular processes integral to adaptation and regeneration. Previous human research that has reported negative effects of drug-induced inhibition of PGF<sub>2α</sub>-mediated anabolic processes has limited its measurement to acute exercise, preventing decisive conclusions concerning concurrent use of analgesics with repeated resistance exercise.

**PURPOSE:** To determine if chronic consumption of naproxen sodium (440mg) inhibits adaptation to exercise using systemic sources of PGF<sub>2α</sub> metabolites.

**METHODS:** 23 recreationally-trained college-aged males were randomly assigned to receive either placebo (n=11) or naproxen sodium (n=12). Treatments were prophylactically administered in double-blind fashion with supervised upper body resistance exercise performed twice per week for 6 weeks. Venous blood (6ml) was sampled pre- and post-workouts 1, 7, and 11 and analyzed for PGF<sub>2α</sub> metabolites using enzymeimmunoassay. Factorial mixed design ANOVA was employed to determine acute and chronic differences in systemic plasma PGF<sub>2α</sub> metabolites (pg/ml).

**RESULTS:** Factorial analysis of metabolite concentrations (pg/ml) revealed significant effects of time ( $p<.005$ ) and acute exercise ( $p=.015$ ), with average systemic metabolite increases of 13.5±11.3 pg/ml in placebo-treated participants versus 2.7±24.2 pg/ml in naproxen-treated. Analysis of the acute metabolic response, expressed as a percent change pre- to post-exercise, revealed significant treatment effects, with naproxen sodium inhibiting the typical increase in PGF<sub>2α</sub> after resistance exercise nearly two-fold. Naproxen sodium was not found to inhibit the rate of strength or size development.

**CONCLUSIONS:** While functional outcomes of strength and size showed no significant treatment effects over 6 weeks, continued inhibition of the hormonal response to resistance exercise may delay attainment of muscular fitness goals.

**Effects Of Exercise Training On Insulin And Igf-1 Concentrations In Cerebellum Of Diabetic Rats**

Luciana Arantes, Natalia Bertolini, Rodrigo Moura, Maria Alice Rostom de Mello, Eliete Luciano. Sao Paulo State University, Rio Claro, Brazil.

(No relationships reported)

Physical activity has proven effective increase in metabolic control in diabetic rats, and is an important component in treatment of diabetes, but less is known concerning any effects of aerobic training on insulin and IGF-1 concentrations in cerebellum of diabetic rats.

**PURPOSE:** The present study investigated the role of swimming training on cerebral metabolism of insulin and IGF-1 concentrations in cerebellum of diabetic rats.

**METHODS:** Forty Wistar rats were divided in four groups: sedentary control (SC), trained control (TC), sedentary diabetic (SD), and trained diabetic (TD). Diabetes was induced by Alloxan (35 mg/kg b.w.), single dose injection. The mean blood glucose of diabetic groups was 367±40 mg/dl. Training program consisted in swimming 5 days/week, 1 h/day, 8 weeks, supporting a workload corresponding to 90% of maximal lactate steady state (MLSS). For MLSS determination, rats were submitted to three sessions of 25-min, in alternate days, supporting loads of 4, 5, or 6% of body wt. Blood samples were collected every 5 min for lactate determination. All dependent variables were analyzed by one-way analysis of variance (ANOVA) and a significance level of  $P < 0.05$  was used for all comparisons. At the end of the training period, rats were killed by decapitation and cerebellum was extracted. Insulin and IGF-1 contents determination was done by radioimmunoassay and ELISA commercial kit, respectively.

**RESULTS:** There was no difference between groups for cerebellum IGF-1 content (SC = 5.58±0.37 ng/mL/mg of wt; TC = 4.78±0.21 ng/mL/mg of wt; SD = 4.5±0.5 ng/mL/mg of wt; TD = 5.71±0.44 ng/mL/mg of wt). Insulin concentrations were not different between groups (SC = 8.8±1.3 uIU/mL/g; TC = 9.2±2.6 uIU/mL/g; SD = 9.3±2.4 uIU/mL/g; TD = 11±1.4 uIU/mL/g).

**CONCLUSION:** It was concluded that in diabetic rats, aerobic training does not induce alterations on cerebellum insulin and IGF-1 contents.

### Effect of Voluntary Wheel Running on the Sex-hormone of High-fat Feeding Impuberism Male Sd Rats

Yi Yan, XIE Minhao, SUN Jingquan, ZHAO Yan, LIU Junshi. *Beijing Sport University, Beijing, China.* (Sponsor: Tongjian You, FACSM)  
(No relationships reported)

The sex hormone imbalance and sexual development delay of obese boy are associated with the nutritional obesity of high-fat and high-energy diet. However, the effect of exercise on obesity-related sex hormone imbalance is still not well known.

**PURPOSE:** To compare the sex hormone level of high-fat feeding and normal diet SD rats in response to voluntary wheel running.

**METHODS:** 3-weeks newly weaned SD rats were randomly assigned to normal diet and high-fat diet group (normal diet sedentary: NS, n=8, normal diet exercise: NE, n=8, high-fat diet sedentary: FS, n=8, high-fat diet exercise: FE, n=8) groups. After one-week adaptive feeding and one-week adaptive training, rats of SE and FE group were individually placed into the wheel-cage to do voluntary wheel running 1 hour each half day, 5 days per week for 6 weeks. Food intake and running distance were monitored daily and body weight weekly. The testicle weight, testicle testosterone, estradiol; and serum testosterone, estradiol, luteinizing hormone and follicle-stimulating hormone were measured.

**RESULTS:** There were significant main negative effects of high-fat diet on bodyweight, testicle weight, serum estradiol (all  $p < 0.01$ ) and testicle testosterone ( $p < 0.05$ ). The 6-weeks voluntary wheel running had no significant effect on the bodyweight, testicle weight and sex hormone (all  $p > 0.05$ ) of NS and FS. Compared to NS, FS had not only lower level of bodyweight ( $129.69 \pm 17.16$  vs.  $336.67 \pm 29.32$  g,  $p < 0.01$ ), testicle weight ( $2.03 \pm 0.83$  vs.  $3.18 \pm 0.22$  g,  $p < 0.01$ ), but also lower serum testosterone detectable rate (37.5% vs 87.5%). The detected serum testosterone of FS was lower ( $49.17 \pm 32.20$  vs  $91.51 \pm 86.35$  ng/l) too. In addition, FS had higher level of serum estradiol ( $129.04 \pm 40.55$  vs.  $52.66 \pm 16.29$  g,  $p < 0.01$ ) than NS. There were no significant difference between NS and NE, FS and FE.

**CONCLUSIONS:** Long term high-fat diet will inhibit the growing development of newly weaned SD rats, and induce the imbalance of sex hormone. 6-weeks voluntary wheel running of two times per day can not potentially improve the growth of high-fat diet newly weaned SD rats. The effective exercise load needs to be further detected.

### Aerobic Exercise Training During Pregnancy Improves Mitochondrial Function In Human Placenta

Juanita Bustamante, Ph.D<sup>1</sup>, Robinson Ramirez-Velez, Ph.D<sup>2</sup>, Ana C. de Plata Aguilar, MS.c<sup>2</sup>, Analia Czerniczyniec, Ph.D<sup>1</sup>, Silvia Lores-Amaiz, Ph.D<sup>1</sup>. <sup>1</sup>University of Buenos Aires, Buenos Aires Argentina, Argentina. <sup>2</sup>University of Valle, Cali, Colombia.  
(No relationships reported)

**INTRODUCTION:** Aerobic exercise enhances mitochondrial biogenesis and performance, favoring tighter coupling between  $\beta$ -oxidation and trichloroacetic acid cycle, and may concomitantly improve mitochondrial function in skeletal muscle. In other tissues, aerobic exercise in non-pregnant women affects mitochondrial function however; it is not known whether exercise produces the same effect in human placental mitochondria.

**OBJECTIVES:** To determine the effects of aerobic exercise training in the second half of pregnancy on mitochondrial function from human placenta.

**METHODS:** This was a randomized, double-blinded, controlled clinical trial of 20 healthy primigravid women between 16 and 20 weeks' gestation. The training group (n=10) took part in aerobic exercise at an intensity of 50-65% of their maximum heart rate for 60 min, three times a week for 16 weeks. The control group (n=10) undertook their usual physical activity. Oxygen consumption, enzyme activity of respiratory complexes, and hydrogen peroxide production were measured as mitochondrial function parameters.

**RESULTS:** Oxygen consumption was not significantly affected by training. Activity of complex I-III of the mitochondrial respiratory chain was increased by 29% in human placental mitochondria from exercised women, as compared with control subjects ( $p < 0.05$ ). Also, significant increases of 45% and 27%, ( $p < 0.05$ ) were observed in complexes II-III and in complex IV respectively in placental mitochondria from exercised women, as compared with the controls. Mitochondrial H<sub>2</sub>O<sub>2</sub> production rate was decreased by 27% in placental mitochondria from exercised women, as compared with control subjects ( $p < 0.05$ ).

**CONCLUSION:** Aerobic training improves mitochondrial function in human placenta by increasing mitochondrial respiratory complexes activity and decreasing H<sub>2</sub>O<sub>2</sub> production. This intervention favors fetal oxygenation and substrate delivery and could help protection on gestational disorders associated to impaired mitochondrial function. Trial registration. NCT00741312.

### Effect Of Endurance Training On Nitric Oxide Synthase Activity And Expression In Human Placenta

Silvia Lores-Amaiz<sup>1</sup>, Robinson Ramirez-Velez<sup>2</sup>, Ana C. de Plata Aguilar<sup>2</sup>, Analia Czerniczyniec<sup>1</sup>, Juanita Bustamante<sup>1</sup>. <sup>1</sup>University of Buenos Aires, Buenos Aires Argentina, Argentina. <sup>2</sup>University of Valle, Cali, Colombia.  
(No relationships reported)

**INTRODUCTION:** Many studies have documented that placental development is altered by a variety of environmental factors such as aerobic exercise training which alter placental bed blood flow and/or oxygen delivery. The placenta lacks innervation, thus vascular tone regulation depends on endothelial release of vasoactive molecules such as nitric oxide (NO). Although exercise-induced increases in blood flow and in endothelial nitric oxide synthase (eNOS) expression have been reported; it is not known if exercise produces the same effect in human placenta. Objectives: To determine the effects of aerobic exercise training in the second half of pregnancy on eNOS expression and on NO production in human placenta.

**METHODS:** This was a randomized, double-blinded, controlled clinical trial of 20 healthy primigravid women between 16 and 20 weeks' gestation. The training group (n=10) took part in aerobic exercise at an intensity of 50-65% of their maximum heart rate for 60 min, three times a week for 16 weeks. The control group (n=10) undertook their usual physical activity. A spectrophotometric assay was used to measure NOS activity in cytosolic samples from placental tissue and Western Blot technique was used to determine endothelial NOS expression.

**RESULTS:** The ratio eNOS/ $\beta$  actin expression was 4-fold increased in cytosolic samples from exercised women. A 2-fold increase in NOS activity was observed in cytosolic samples from exercised women.

**CONCLUSION:** Training during pregnancy leads to an increase in eNOS expression and in total NO production in placental cytosol. Greater eNOS expression may also underlie the effects of exercise in the protection of gestational disorders associated to endothelial dysfunction. Trial registration. NCT00741312.

**Effects of Chronic Exercise on DNA Methyltransferase Expression in Mouse Testes**

Michael P. Marini, Lisa M. Guth, Andrew C. Venezia, Estefan P. Beltran, Espen E. Spangenburg, Stephen M. Roth, FACSM. *University of Maryland, College Park, MD.*

(No relationships reported)

**PURPOSE:** To examine the role of physical activity as represented by voluntary wheel running on the expression of DNA methyltransferases (DNMTs) in mouse testes.

**METHODS:** Male C57BL/6mice were randomly assigned to cages with exposure to an exercise running wheel (EX, n = 8), or cages without running wheels (SED, n = 10 from age 8 weeks to 28 weeks, at which point they were sacrificed and testes were extracted. Isoform-specific mRNA expression of isoforms of several genes that govern *de novo* attachment of DNA methylation marks (*Dnmt3a1*, *Dnmt3a2*, *Dnmt3b2/3*) were measured in testes and compared to a housekeeping gene (18s).

**RESULTS:** EX males ran an average of 3610 ± 581 m/24hrs over the 20-week intervention. There was no significant difference (p>0.05) in average testicular weight between EX (101.4 ± 3.9 mg) and SED(106.6 ± 2.6 mg) cohorts. Expression levels for *Dnmt3a1*, *Dnmt3a2* and *Dnmt3b2/3* showed no significant differences between EX and SED cohorts after 20 weeks of exercise intervention.

**CONCLUSIONS:** These preliminary findings indicate that physical activity as represented by voluntary wheel running does not affect expression of genes that govern *de novo* DNA methylation in mouse testes.

**Cardiovascular Time Courses During Prolonged Dry Apnea in Exercising Divers**

Renza Perini, Michela Capogrosso, Sabrina Donati, Andrea Sivieri, Guido Ferretti. *Università di Brescia, Brescia, Italy.*

(No relationships reported)

In static apnea, cardiovascular readjustments are such that, after an initial decrease in Heart Rate (HR) and increase in Blood Pressure (BP) (ph I, ~30 s duration), there are ~2 min of steady values (phII). Then HR and BP again decreases and increases, respectively, up to the end of apnea (ph III), possibly due to chemoreflex activation. We hypothesize that the end of ph II corresponds to physiological apnea breaking point. This being so, in case of increased metabolic rate (M'), duration of ph II would be shorter.

**PURPOSE:** to study the effect of increased M' on cardiovascular time courses during apnea.

**METHODS:** 8 divers (age 36±7 yrs) performed voluntary maximal apnea: A) sitting at rest; B) pedaling at 30 W on a cycle ergometer. BP (finger photo-plethysmography) and arterial O<sub>2</sub> saturation (SaO<sub>2</sub>, infrared spectroscopy) were continuously recorded before, during and after apnea. M' was measured before and after apnea by a metabolic cart. Beat to beat HR, systolic (Ps) and diastolic (Pd) pressures were obtained.

**RESULTS:** A) apnea lasted 227±62 s. In ph I (29±3 s), HR decreased from 98±11 b/min to 82±13 b/min, returning to control values (ctrl), Ps remained equal to ctrl (140±11 mmHg), Pd increased by 14 mmHg above ctrl (70±8 mmHg, p<0.05). In ph II (102±32 s), all parameters were stable, then HR fell to 57±5 b/min, while Ps and Pd increased, respectively, to 215±23 mmHg and 105±16 mmHg after 110±35 s (ph III). SaO<sub>2</sub> was 91±5 % at the end of ph II (p<0.05) and 75±13% at the end of apnea. B) apnea lasted 88±21 s, M' was twice as at rest. During the first 24±7 s (ph a), cardiovascular parameters remained unchanged. HR (112±9 b/min) was 15±10 b/min above exercise steady state values. Ps was 167±15 mmHg and Pd 81±15 mmHg. In the following 64±22 s (ph b), a continuous fall of HR and increase in Ps and Pd occurred. At the end of apnea, HR was 55±10 b/min, Ps 244±24 mmHg and Pd 112±13 mmHg. SaO<sub>2</sub> started to drop after ~30 s of apnea to 76±11% at the end.

**CONCLUSIONS:** apnea at exercise, with higher M', showed different cardiovascular trends from static apnea. The lack of stable cardiovascular values after the first phase a and the steep decrease in SaO<sub>2</sub> suggest early chemoreflex activation, inducing progressive bradycardia and hypertension. The absence of initial HR drop indicates that the level of autonomic activity affects the cardiac response to breath-holding.

2872 Board #144 June 1 9:30 AM - 11:00 AM

**Effects of Repeated 6-hour 100% Oxygen Dry Chamber Dives on Diver Performance and Orthostatic Tolerance**

John P. Florian, Erin E. Simmons, Barbara E. Shykoff. *Navy Experimental Diving Unit, Panama City, FL.*

(No relationships reported)

Shallow-water diving operations may require personnel to be immersed for extended periods of time, breathing either compressed air or 100% O<sub>2</sub>. Our lab recently documented the differential effects on physiological function of breathing air vs. oxygen during repeated 6-hr dives. While dynamic exercise performance (EP) and isometric strength are reduced more following O<sub>2</sub> dives than air dives, orthostatic tolerance is diminished more following air dives than O<sub>2</sub> dives. However, information regarding the effect of repeated exposures to hyperbaric O<sub>2</sub>, independent of water immersion, is limited.

**PURPOSE:** To characterize postdive performance and orthostatic tolerance following repeated 100% O<sub>2</sub> dry chamber dives.

**METHODS:** Twelve healthy men (27±1 yrs; VO<sub>2max</sub>: 51±2 ml/kg/min; mean±SEM) completed a single 6-hr dive (SD) and a dive week (DW: 5 consecutive 6-hr dives with 18-hr surface intervals) in a hyperbaric chamber while resting and breathing 100% O<sub>2</sub> at 1.35 ata. Dynamic EP (time-to-fatigue on treadmill at 85% of VO<sub>2max</sub>) was measured before and the day immediately after SD and DW. Isometric strength (maximal handgrip strength [MHS], time-to-fatigue at 40% of MHS) and orthostatic tolerance (70° head-up tilt [HUT] testing; endpoint: presyncope or censored at 15 min) were measured before and after each dive.

**RESULTS:** Dynamic EP decreased more after DW than SD (-38% vs +6%, p<0.01), a change comparable to previous O<sub>2</sub> dives in water. Handgrip time-to-fatigue was not affected by a single dive (p>0.8) or repeated dives (p>0.6). Average predive MHS tended to be lower than postdive MHS (p=0.06), but no changes in MHS across dive days were noted (p>0.09). Average HUT time was not affected by diving; however, the O<sub>2</sub> dives improved HUT time for one diver who was predisposed to orthostatic intolerance (DW predive vs. postdive: 9.5±1.6 vs. 14.0±0.7 min, p<0.04). These results also agree with our previous water immersion study showing that, although O<sub>2</sub> dives and air dives adversely affected hemodynamic stability during HUT, tilt time was reduced following air dives only.

**CONCLUSION:** Repeated exposure to hyperbaric O<sub>2</sub>, independent of water immersion, adversely affects dynamic EP, but not isometric strength. Breathing 100% O<sub>2</sub> during repeated dives may protect against diving-induced orthostatic intolerance.

**Acute Short Term Dim Light Exposure Can Lower Muscle Strength Endurance.**

Arnold G. Nelson, FACSM<sup>1</sup>, Joke Kokkonen<sup>2</sup>, Megan Mickenberg<sup>2</sup>. <sup>1</sup>LSU, Baton Rouge, LA. <sup>2</sup>BYU-H, Laie, HI.

(No relationships reported)

Since it has been shown that spending 18 hours under dim light conditions can result in reduced handgrip endurance, it was wonder if a shorter exposure to dim light (i.e. 1 hour) would have similar influence upon muscular strength endurance.

**PURPOSE:** This study compared the number of weighted knee extension lifts that could be done after spending 1 hour in either dim or bright light.

**METHOD:** Participants (6 women, 12 men, college students 19-26 years) performed knee extension lifts to exhaustion with a load approximating 40% of their body weight. Performances were done immediately following 1 hour of exposure to each of the following 3 conditions: dim light (<500 lx) (DL) and bright light (>40000 lx) (BL) and bright light plus 6 mg melatonin (BLM). A minimum of 48 hours separated each condition, and all participants started the exposures in a rested fed condition.

**RESULTS:** Average ( $\pm$  standard deviation) number of knee extension lifts for DL ( $51.4 \pm 14.7$ ) was significantly ( $p < 0.05$ ) lower than either BL ( $62.0 \pm 22.0$ ) or BLM ( $57.8 \pm 22.9$ ).

**CONCLUSION:** Exposure to one hour of dim light immediately prior to activity can result in a reduction in thigh muscle strength endurance. The decline in performance to short-term dim light exposure was similar to that found following longer-term exposure. Thus, it appears that light intensity can influence muscle endurance, however, at this time this effect cannot be related to endogenous melatonin production.

**Comparison Of Serum Toxic Metals Concentrations Between Athletes And Sedentary People**

Guillermo Olcina<sup>1</sup>, Carmen Crespo<sup>1</sup>, Francisco Llerena<sup>2</sup>, Javier Brazo<sup>1</sup>, Concepción Robles<sup>1</sup>, Marcos Maynar<sup>1</sup>, M<sup>a</sup> Jesús Caballero<sup>2</sup>. <sup>1</sup>Sport Sciences Faculty, University of Extremadura, Cáceres, Spain. <sup>2</sup>Faculty of Medicine, University of Extremadura, Badajoz, Spain.

(No relationships reported)

Toxic trace elements are present in human environment and they accumulate in the human body over lifetime. Research has shown how physical activity may influence in the metabolism of some minerals. However, there are not many studies about the effect of physical activity over toxic trace elements levels in biological tissues.

**PURPOSE:** The aim of this study was to compare the level of toxic elements: lead (Pb), cadmium (Cd), beryllium (Be), tellurium (Te), tungsten (W), rhenium (Re) and thallium (Tl) in serum samples between athletes and sedentary subjects living in the same geographical area.

**METHODS:** A Middle-distance male runners group ( $n=21$ ) (age,  $21.62 \pm 4.3$  yr; BMI,  $18.25 \pm 1.73$ ) and a sedentary men group ( $n=21$ ) (age,  $22.65 \pm 3.6$  yr; BMI,  $21.81 \pm 3.14$ ) belonging to the region of Extremadura (Spain) participated in this study. Morning midstream serum samples were collected in all participants in 10 ml polyethylene containers with EDTA as anticoagulant. Pb, Cd, Be, Te, W, Re and Tl were determined by ICP-MS (model NexION 300D). This model has a triple quadrupole mass detector, and a reaction cell / collision that allow operation in three modes STD (no reaction gas), KED or kinetic energy discrimination (with helium as collision gas) and DRC or reaction (with ammonia as reaction gas). Data between groups were compared. The Mann-Whitney test was performed for statistical analysis. A  $p$  value of  $<0.05$  was used to determine statistical significance.

**RESULTS:** Concentrations of toxic elements in serum from athletes versus sedentary subjects on  $\mu\text{g/L}$  were as follows: Pb ( $1.635 \pm 2.199$  vs  $0.162 \pm 0.271$   $p < 0.01$ ); Cd ( $0.083 \pm 0.0047$  vs  $0.046 \pm 0.027$ ,  $p < 0.01$ ); Be ( $0.062 \pm 0.036$  vs  $0.043 \pm 0.019$ ,  $p < 0.01$ ); Te ( $0.117 \pm 0.220$  vs  $0.118 \pm 0.188$ , ns); W ( $0.200 \pm 0.099$  vs  $0.116 \pm 0.117$ ,  $p < 0.01$ ); Re ( $0.087 \pm 0.085$  vs  $0.035 \pm 0.066$ ,  $p < 0.01$ ); Tl ( $0.139 \pm 0.062$  vs  $0.014 \pm 0.043$ ,  $p < 0.01$ ).

**CONCLUSIONS:** With the exception of Te, serum toxic metal concentrations from athletes were higher than from sedentary. This fact suggests that athletic training may increase the level of ingestion of these toxic metals from the environment (water, air) or their accumulation inside the body.

Supported by Government of Extremadura grant PRI08B130

**The Acute Effects of Flotation R.E.S.T. (Restricted Environmental Stimulation Technique) Following Maximal Eccentric Exercise**

Paul M. Morgan, Amanda J. Salacinski, Matthew Stults-Kolehmainen. Northern Illinois University, DeKalb, IL.

(No relationships reported)

Flotation REST involves compromising senses of sound, sight, and touch by creating a quiet, dark environment. The individual lies supine in a tank of Epsom salt and water heated to roughly skin temperature (34-35°C). Use of Flotation REST has been primarily for hospital patients resulting in decrements of stress, pain, blood pressure, and anxiety. Reductions appear to stem from the lack of proprioceptive stimuli resulting in decreased arousal of the sympathetic nervous system. Usefulness of flotation REST for recovery from exercise is unclear.

**PURPOSE:** To determine acute effects of flotation REST following maximal eccentric knee extensions and flexions.

**METHODS:** A randomized crossover study of twenty-four ( $N=24$ ) untrained male subjects ( $23.29 \pm 2.1$  yr,  $184.17 \pm 6.85$  cm,  $85.16 \pm 11.54$  kg) participated over a 14 day period. Subjects performed 50 maximal eccentric repetitions of knee extension and flexion on two occasions separated by one week. Either one hour flotation R.E.S.T. (FLOAT) or one hour seated control (SEAT) followed exercise. Blood lactate, glucose, and heart rate were measured pre and post exercise, and after FLOAT and SEAT. Torque was assessed prior to exercise, post FLOAT and SEAT, and over next two days. Omni-rating of perceived exertion (RPE) and pain of the knee extensors and flexors were recorded during torque measures. Visual analogue scale was used to measure delayed onset muscle soreness (DOMS) for six days following maximal eccentric exercise. Blood lactate and glucose, heart rate, RPE, pain, and torque analyzed with MANCOVA with baseline measures as covariates. DOMS comparisons made using MANOVA.

**RESULTS:** Mean blood lactate lower following FLOAT ( $1.11 \pm .27$  vs  $1.77 \pm .98$ ,  $p < 0.05$ ) as was mean pain of knee extensors ( $.67 \pm 1.03$  vs  $.99 \pm 1.26$ ,  $p < 0.05$ ). Mean torque (N-M) of knee extensors greater following SEAT ( $242.12 \pm 65.46$  vs  $223 \pm 58.03$ ,  $p < 0.05$ ). No significance observed in knee flexors, heart rate, glucose, RPE, pain of knee flexors, DOMS ( $p > .05$ ).

**CONCLUSION:** Flotation REST lowers blood lactate following a one hour flotation R.E.S.T. session, while alleviating pain in the knee extensors. Flotation REST appears to hinder ability to produce torque as proprioception is compromised. Therefore, flotation REST may help with recovery, but may also cause torque decrement in the following hour.

2876 Board #148 June 1 9:30 AM - 11:00 AM

**Comparison Of The Effects Of Cold Air (-110°C) And Water (8°C) Cryotherapy On Intramuscular Temperature**

Joseph T. Costello<sup>1</sup>, Kevin Culligan<sup>1</sup>, James Selfe<sup>2</sup>, Gráinne M. Hayes<sup>1</sup>, Ciarán D. McInerney<sup>3</sup>, Alan E. Donnelly<sup>1</sup>. <sup>1</sup>University of Limerick, Limerick, Ireland.

<sup>2</sup>University of Central Lancashire, Preston, United Kingdom. <sup>3</sup>Sheffield Hallam University, Sheffield, United Kingdom.

(No relationships reported)

Whole Body Cryotherapy (WBC) is a treatment growing in popularity with individual athletes and in team sports. Most WBC protocols involve repeatedly exposing minimally dressed individuals to extremely cold dry air (-110 to -140°C) for a short duration of time (2-4 min). A range of claims are made regarding WBC, though the evidence base for these is currently limited. The effects of WBC on intramuscular temperature (IM) may be central to some of the proposed benefits of WBC.

**PURPOSE:** To compare the effects of two modalities of cryotherapy, -110°C WBC and 8°C Cold Water Immersion (CWI) on IM.

**METHODS:** With ethical approval and written informed consent 10 healthy active male participants ( $23.6 \pm 2.7$  yr,  $180.9 \pm 5.8$  cm,  $87.2 \pm 17.8$  kg,  $26.5 \pm 4.3$  kg/m<sup>2</sup>,  $23.4 \pm 8.7\%$  body fat, measured via DXA,  $10.5 \pm 5.9$  mm thigh skin fold; mean  $\pm$  SD) participated in the study. Volunteers completed two treatment sessions, one CWI and one WBC a minimum of 7 days apart, with the treatment order randomised. IM was recorded 3cm below the subcutaneous fat layer in the right vastus lateralis using a flexible temperature probe, which was inserted through an indwelling

flexible cannula. Recordings were made every minute for 60 min before and after each of the treatments. During WBC participants stood in a chamber (-60±3°C) for 20 sec before entering the main chamber (-110°C±3°C) where they remained for 3 min and 40 sec. For CWI participants were seated in a tank filled with cold water (8±0.3°C) and immersed to the level of the sternum for 4 min. Absolute change in temperature from baseline every 10 min after treatment were analysed using a two-way ANOVA with repeated measures. The  $\alpha$ -level was set at 0.05.

**RESULTS:** Muscle temperature was significantly reduced at 20, 30, 40, 50 and 60 min after both cooling modalities ( $p<0.01$ ). A maximum reduction of 1.6 and 1.7°C, after WBC and CWI respectively, was recorded 60 min after treatment. However there was no significant difference between treatments ( $p=0.29$ ).

**CONCLUSIONS:** These results suggest that WBC is effective in producing a delayed reduction in IM that is similar to that experienced after CWI.

**Compare Manual-Wheelchair Driving Performance in Virtual and Real Environment**

Yu-Chun Liao<sup>1</sup>, Kai-Jie Sie<sup>2</sup>, Jiun-Ren Hwang<sup>3</sup>, Wen-Hsu Sung<sup>1</sup>, Tien-Yow Chuang<sup>4</sup>. <sup>1</sup>National Yang-Ming University, Taipei, Taiwan. <sup>2</sup>National Central University, Taipei, Taiwan. <sup>3</sup>National Central University, Taipei, Taiwan. <sup>4</sup>Taipei Veterans General Hospital, Taipei, Taiwan.

(No relationships reported)

People with physical disability usually need delivery aids to be independent in activities of daily life, and manual-wheelchair (MW) is one of the common delivery aids. Ability of MW driving is usually evaluated by therapists subjectively, partly underestimated and partly overestimated; whereas it is sometimes evaluated by clients' self-administered questionnaire, and is easily overestimated. We tried to develop a virtual reality MW driving system for evaluating the driving performance objectively.

**PURPOSE** Compare MW driving performance in virtual environment (VE) and real environment (RE).

**METHODS** Thirteen healthy adults were recruited to drive a modified MW in both VE and RE. The modified MW was equipped with sensors to measure the subject's driving actions. All subjects executed three tasks: 1.straight forward (SF), 2.straight backward (SB), and 3.S-type forward (STF) in both VE and RE. In VE-tests, visual image was displayed in head mounted display (HMD). Task Complete Time (TCT) and driving path Boundary Collision Times (BCT) were used to evaluate driving performance. Measured data was analyzed with paired sample t-test and the level of .05 was set for statistical significance.

**RESULTS** The average and standard deviations (SD) of BCT of SF, SB, and STF in VE were 0.07(±0.00), 0.38(±1.12) and 2.07(±1.32) respectively; and the values in RE were 0.00(±0.00), 0.15(±0.37) and 0.07(±0.27) respectively. Significant differences of BCT were found in the SF and STF test ( $p=0.00$ ). The average and SD of TCT (in seconds) of SF, SB, and STF in VE were 17.7(±7.5), 18.3(±11.0), and 33.4(±13.2) respectively, and the values in RE were 10.9(±4.1), 15.6(±7.8), and 20.5(±6.4) respectively. Significant difference of TCT was found in the STF test ( $p=0.00$ ). All of the average and SD in VE tests was greater than the relative values in RE, showing that driving performance was worse and varies greatly in VE. It may mainly result from the visual field limitation of HMD (field of view=40 degrees in diagonal). The limited visual field increased the difficulty of the tasks in VE.

**CONCLUSION** The MW driving performance in VE was worse than it in RE, and we found that it may result from the visual field limit of HMD. In the future, we expect that, after modifying the limited HMD visual field, we may use these tasks in VE to evaluate MW driving performance in RE.

**2878** Board #150 June 1 9:30 AM - 11:00 AM

**Does Cardiovascular Health/Fitness Protect Hearing Acuity in College Students Who Use Earbud Headphones?**

Helaine M. Alessio, FACSM, Ian Cramer, Lisa Treadway, Kendra Marchiondo, Sarah Stephenson, Sarah Wagner, Kathleen Hutchinson. *Miami University, Oxford, OH.*

(No relationships reported)

Although hearing loss has been associated with advanced age, two other factors have been shown to significantly impact hearing sensitivity: (1) use of earbud headphones when listening to personal listening devices (PLD) due to the way they funnel sounds into the ear canal and fail to block out ambient noises, and (2) cardiovascular (CV) health, due to the importance of circulation to and oxygen utilization in muscles and bones of the inner ear.

**PURPOSE:** Investigate factors that affect hearing acuity in college students who listen to PLDs.

**METHODS:** Hearing sensitivity, earbud use, CV health and other audiological, behavioral, and health-related variables were measured in a sample of college students (N=140). Hearing sensitivity was assessed in all subjects at multiple frequencies to determine normal and abnormal hearing levels across a normal spectra of listening frequencies. Volume and duration of actual listening when using PLDs were directly measured. Maximum oxygen consumption (VO<sub>2</sub>max), body mass index, daily physical activity (PA), and blood lipid levels (total cholesterol/high density lipoprotein {TC/HDL}) were assessed.

**RESULTS:** The majority of students listened within relatively safe decibel ranges, although standards for PLD's do not exist. The following trends were observed in this sample: hearing acuity was best in students who had rarely used PLDs (mean=4+/-2 vs. 8+/-2 dB), ( $p<.05$ ). There was no clear evidence for cardiovascular health/fitness as indicated by VO<sub>2</sub>max, BMI, TC/HDL, and PA providing protection against hearing loss in college students (Mean Right Ear High Frequency Pure Tone Threshold and Mean VO<sub>2</sub>max:  $r = 0.25$ , BMI:  $r = 0.06$ , daily PA:  $r = 0.00$ , and TC/HDL:  $r = 0.00$ ).

**CONCLUSION:** Using earbud headphones to listen to PLD's negatively impacts hearing acuity in college-aged students. There is no trend for high levels of cardiovascular health or fitness protecting hearing acuity compared with medium fit college aged students, regardless of listening habits.

**Mild Dehydration Decreases Repeated Hill Cycling Performance In The Heat**

Costas N. Bardis, Stavros A. Kavouras, FACSM, Giannis Arnaoutis, Marietta Markousi, Lena Kosti, Labros S. Sidossis. *Harokopio University, Athens, Greece.*

(No relationships reported)

Dehydration greater than 2% of body weight, decreases exercise performance. However, the effect of mild dehydration (<2%) is not clear.

**PURPOSE:** The purpose of this study was to determine the effect of mild dehydration on repeated hill cycling performance in a warm environment (32.5±0.2 °C).

**METHODS:** A randomized crossover design was used. Ten endurance cyclists (age: 29±6 years, weight: 75.5±6.9 kg, height: 1.78±0.07 m, VO<sub>2</sub>max: 52.4±3.3 ml·min<sup>-1</sup>·kg<sup>-1</sup> and Powermax: 358±18 W) completed on two separate trials a performance test consisted of three bouts of 5 km race pace hill cycling, followed by 5 km at 50% of max power output, in a laboratory ergometer. Before the performance test subjects cycled for an hour with or without water drinking, to ensure that subjects started the performance test euhydrated (EUH) or dehydrated (DEH) by 0±0% & -0.98±0.1%, respectively. After each 5 km cycling bout body weight was taken and subjects were rehydrated with water to avoid greater dehydration. Dehydration at the end of the test was for the EUH and DEH trials -0.55±0.1% and -1.7±0.1%, respectively.

**RESULTS:** Time to completion of the 1st, 2nd and 3rd 5km hilly cycling was faster in EUH trail (10.8±1.3 min, 11.0±1.3 min, 11.3±1.7 min) than the DEH trail (11.3±1.3 min, 11.7±1.8 min, 11.8±1.9 min); ( $P<0.05$ ). As a result, mean power output was significantly greater during EUH 268±56 W than DEH 254±58 W. Core temperature at the end of the performance test was greater in DEH 38.2±0.2 °C than EUH 37.9±0.3 °C; ( $P<0.05$ ). No significant differences were found between conditions for heart rate and lactic acid.

**CONCLUSION:** It was concluded that mild dehydration decreased cycling performance in a hot environment, possibly by inducing greater thermal load.

**Aerobic Fitness in Breast Cancer Survivors and High-Risk Control Group**

Dave Burnett, Jennifer Klomp, Patty Kluding, Charles Porter, Carol Fabian. *Kansas University Medical Center, Kansas City, KS.*  
(No relationships reported)

Breast cancer (BrCa) survivors are at increased risk of experiencing late and long-term effects of their treatment. Risk for recurrence of BrCa and cardiovascular disease (CVD) increases in long-term BrCa survivors largely because of the indirect effects of their diagnosis, including inactivity and weight gain. In addition, increased weight and inactivity are associated with primary BrCa. Inactivity can lead to low cardiorespiratory (CR) fitness level, which has been associated with CVD, BrCa, and all-cause mortality.

**PURPOSE:** Describe and compare CR fitness, measured as  $VO_{2\text{ peak}}$ , in BrCa survivors and women at high-risk for developing BrCa.

**METHODS:** Thirty BrCa survivors and 21 controls were matched by age and CVD risk. Breast cancer survivors were 50.5  $\pm$  5.6 years old and approximately 4.5 years from initial treatment. All BrCa survivors were treated with chemotherapy and/or left chest radiation and had at least 2 CVD risk factors. High-risk controls were 49.1  $\pm$  6.5 years old, had at least 2 CVD risk factors, and high-risk for BrCa. High-risk for BrCa included a family history of BrCa and multiple (> 1) breast biopsies, but had never been exposed to anti-hormonal therapy for BrCa prevention. All participants performed a graded maximal cardiopulmonary exercise test using indirect calorimetry while walking on a treadmill.

**RESULTS:**  $VO_{2\text{ peak}}$  mean values (+/- S.D.) for BrCa survivors resulted in 25.4 +/- 5.3 ml/kg/min compared to 26.3 +/- 4.5 ml/kg/min for high-risk controls. Comparison between BrCa survivors and high-risk controls was done using a Student's *t*-test, showing no significant difference in  $VO_{2\text{ peak}}$  ( $p = 0.52$ ). Twenty six of 30 BrCa survivors and all 21 high-risk controls tested below the 20th percentile based on their age group and gender for aerobic fitness as established by the American College of Sports Medicine.

**CONCLUSION:** Breast cancer survivors and high-risk controls in this study had a marked decrease in  $VO_{2\text{ peak}}$ , putting them at a higher risk for CVD, BrCa, and all cause mortality. Strategies to improve CR fitness should be targeted in future primary prevention and survivorship trials.

**Cardiorespiratory And Neuromuscular Deconditioning In Fatigued And Non-fatigued Breast Cancer Survivors**

Sarah E. Neil<sup>1</sup>, Riggs J. Klika, FACSM<sup>2</sup>, S Jayne Garland<sup>1</sup>, Donald C. McKenzie<sup>1</sup>, Kristin L. Campbell<sup>1</sup>. <sup>1</sup>*University of British Columbia, Vancouver, BC, Canada.*  
<sup>2</sup>*Cancer Survivor Center for Health and Wellbeing, Aspen, CO.*  
(No relationships reported)

**PURPOSE:** Fatigue is one of the most commonly reported side effects during treatment for breast cancer, and for some fatigue can continue for an extended period following treatment completion. Cancer-related fatigue is multi-factorial in nature, and one hypothesized mechanism of both development and persistence of cancer-related fatigue following treatment is cardiorespiratory and neuromuscular deconditioning. The purpose of this study is to compare measures of cardiorespiratory and neuromuscular deconditioning in breast cancer survivors who meet the ICD-10 criteria for cancer-related fatigue with breast cancer survivors who report no fatigue.

**METHODS:** Participants performed a graded incremental exercise test on a cycle ergometer for determination of power output at lactate threshold, lactate threshold as a percentage of peak power output, and absolute and relative  $VO_{2\text{ peak}}$ . Central and peripheral causes of muscle fatigue were assessed following a sustained contraction of the right quadriceps using the twitch interpolation technique and voluntary activation, peak force of the electrically-evoked twitch and the maximum voluntary contraction, and endurance time were measured.

**RESULTS:** The fatigue group reached lactate threshold at a lower power output than the control group (61.9 16.5 vs. 78.2 25.2 W,  $p=0.05$ ), but there were no differences between groups for lactate threshold as a percentage of peak power output (46.7 8.2 vs. 55.4 14.7%,  $p=0.10$ ), peak power output (134.4 36.2 vs. 146.8 49.4 W,  $p=0.46$ ), absolute  $VO_{2\text{ peak}}$  (1.53 0.37 vs. 1.79 0.36 L/min,  $p=0.08$ ), or relative  $VO_{2\text{ peak}}$  (22.9 4.7 vs. 25.2 7.5 ml/kg/min,  $p=0.33$ ). When adjusted for age, the fatigue group had a lower power output at lactate threshold (60.5  $\pm$  5.0 vs. CG 80.2  $\pm$  6.1 W,  $p=0.02$ ) and absolute  $VO_{2\text{ peak}}$  (1.50  $\pm$  0.09 vs. 1.83  $\pm$  0.11 L/min,  $p=0.03$ ). There were no significant differences in any of the neuromuscular parameters between groups.

**CONCLUSION:** These findings support the hypothesis that cardiorespiratory deconditioning may play a role in the development and persistence of cancer-related fatigue following treatment. Future research into the use of exercise training as a tool to improve cardiorespiratory deconditioning and thereby reduce this proposed aspect of cancer-related fatigue is warranted.

**2882** Board #154 June 1 11:00 AM - 12:30 PM  
**Effects Of Resistance Training On Muscular Strength, Body Composition And Functionality In Breast Cancer Survivors**

Takudzwa A. Madzima, Emily Simonavice, Pei-Yang Liu, Jasminka Z. Ilich, Jeong-Su Kim, Bahram H. Arjmandi, Lynn B. Panton, FACSM. *Florida State University, Tallahassee, FL.*  
(No relationships reported)

In addition to normal age-related changes, breast cancer survivors (BCS) encounter many side effects from cancer treatments that negatively affect muscular strength, body composition, and functionality. Studies have shown that resistance training (RT) in older adults can improve strength, body composition and functionality.

**PURPOSE:** To evaluate the efficacy of a RT intervention to modulate muscular strength, body composition, and functionality in BCS over a six-month period.

**METHODS:** Twenty-seven BCS (age: 64  $\pm$  7 yrs; BMI: 27.7  $\pm$  5.5 kg/m<sup>2</sup>) were measured pre and post training for the following variables: muscular strength (chest press and leg extension) via one-repetition maximums (1-RM), body composition (lean mass, fat mass, lean to fat mass ratio) via dual energy X-ray absorptiometry and functionality via the continuous scale physical functional performance (CS-PFP) test. RT consisted of two days/week of ten exercises including two sets of 8-12 repetitions at ~60-80% of 1-RM. Data were analyzed using one way analysis of variances. Significance was accepted at  $p < 0.05$ .

**RESULTS:** BCS significantly increased upper (70  $\pm$  22 to 88  $\pm$  22 kg) and lower body (71  $\pm$  23 to 89  $\pm$  30 kg) strength. There were no changes in lean mass (39.9  $\pm$  6.3 to 40.3  $\pm$  6.3 kg), fat mass (30.7  $\pm$  9.2 to 30.9  $\pm$  9.3 kg), percent body fat (43.0  $\pm$  5.2 to 42.8  $\pm$  5.1%), or the lean to fat mass ratio (1.36  $\pm$  0.31 to 1.37  $\pm$  0.30) over the 6 months of training. Total functionality significantly increased (66  $\pm$  12 to 74  $\pm$  12 units) along with the functionality subscales of upper body strength (64  $\pm$  16 to 71  $\pm$  17 units), lower body strength (59  $\pm$  15 to 69  $\pm$  16 units), balance and coordination (67  $\pm$  12 to 75  $\pm$  12 units), and endurance (67  $\pm$  12 to 75  $\pm$  12 units).

**CONCLUSIONS:** Six months of moderate RT significantly improved strength and functionality in BCS. Although, RT did not significantly alter body composition measures of lean and fat mass it did offset the negative decrements (loss of muscle, increase in adiposity) that usually occur as a result of cancer related treatments and aging. Funded in part by the California Dried Plum Board

**The Effect Prior Physical Activity has on Physiological and Psychological Outcomes in Cancer Survivors**

Andrew R. Smith<sup>1</sup>, Trent L. Lalonde<sup>1</sup>, Brent M. Peterson<sup>1</sup>, Jessica M. Brown<sup>1</sup>, Kurt Dallow, FACSM<sup>2</sup>, Reid Hayward<sup>1</sup>, Carole M. Schneider, FACSM<sup>1</sup>. <sup>1</sup>Rocky Mtn Cancer Rehab, Univ Northern Colorado, Greeley, CO. <sup>2</sup>North Colorado Family Medicine, Greeley, CO.  
(No relationships reported)

Cancer survivors are impacted by physical and emotional responses associated with diagnosis and treatment. Current research shows that exercise provides a positive effect in cancer survivors at various stages in their recovery.

**PURPOSE:** To investigate the effect physical activity level prior to beginning a cancer rehabilitation program has on physiological and psychological outcomes in cancer survivors following a supervised 3-month exercise intervention.

**METHODS:** Two hundred forty-seven cancer survivors participated in initial fitness assessments examining heart rate (HR), systolic (SBP) and diastolic blood pressure (DBP), cardiorespiratory fitness ( $VO_{2peak}$ ), and abdominal strength (crunches). In addition, subjects completed inventories assessing fatigue and depression. Subjects were divided into three groups based on self-reported physical activity prior to the initial assessment; none (no prior physical activity), low (< 150 minutes of prior physical activity per week), and moderate ( $\geq$  150 minutes of prior physical activity per week) according to ACSM guidelines. Subjects were given an individualized exercise prescription and participated in 3 months of supervised exercise. Subjects were reassessed following the 3-month intervention.

**RESULTS:** No significant differences ( $p>.05$ ) were found between prior physical activity and any of the physiological or psychological variables assessed following the 3-month intervention. However, significant improvements ( $p<.01$ ) were found when comparing percent change pre to post 3-month exercise in all physiological and psychological variables [HR (-2.56%), SBP (-1.45%), DBP (-1.20%),  $VO_{2peak}$  (+17.51%), crunches (+60.53%), fatigue (-2.13%), and depression (-2.24%).]

**CONCLUSION:** The results of this study suggest that cancer survivors demonstrate improved physiological and psychological outcomes following a supervised three-month exercise intervention regardless of their physical activity level prior to entering a cancer rehabilitation program.

2884 Board #156 June 1 11:00 AM - 12:30 PM

**Initial Physiological and Psychological Measures in Cancer Survivors During Treatment Versus Following Treatment**

Colin J. Quinn<sup>1</sup>, Jessica M. Brown<sup>1</sup>, Trent L. Lalonde<sup>1</sup>, Kurt Dallow, FACSM<sup>2</sup>, Reid Hayward<sup>1</sup>, Carole M. Schneider, FACSM<sup>1</sup>. <sup>1</sup>Rocky Mtn Cancer Rehab, Univ Northern Colorado, Greeley, CO. <sup>2</sup>North Colorado Family Medicine, Greeley, CO.  
(No relationships reported)

There have been suggestions that once cancer survivors complete treatment that exercise interventions can be similar to the apparently healthy population. This implies that the negative effects of cancer treatments occur during treatment with no lingering side-effects once treatment is completed.

**PURPOSE:** To compare cancer survivors' initial physiological and psychological assessment values during treatment to the initial values of cancer survivors' following treatment.

**METHODS:** Five hundred eighty-one cancer survivors participated in initial fitness assessments examining pulmonary function, cardiorespiratory fitness ( $VO_{2peak}$ ), muscular strength, resting heart rate and blood pressure. Additionally, participants completed inventories of depression, fatigue, and quality of life. Participants were separated into two groups, those who were in treatment ( $n=99$ ) and those who had completed treatment ( $n=482$ ).

**RESULTS:** Significant differences were found on the initial assessment values between groups for  $VO_{2peak}$  ( $p<.05$ ). Cancer survivors in treatment exhibited higher  $VO_{2peak}$  scores ( $24.06 \pm 7.6$  ml/kg/min) on the initial assessment compared to cancer survivors who had completed treatment ( $21.97 \pm 3.33$  ml/kg/min). No significant differences were found in measures of pulmonary function, muscular strength, resting heart rate and blood pressure. Initial psychological parameters (depression, fatigue, quality of life) were not significantly different between groups.

**CONCLUSION:** The higher initial  $VO_{2peak}$  values for cancer survivors during treatment suggest that the cumulative negative effects of cancer treatments occur throughout the treatment regimen. Cancer survivors following treatment have cumulative negative side-effects and therefore need to participate in an exercise intervention designed specifically for cancer survivors.

2885 Board #157 June 1 11:00 AM - 12:30 PM

**Validation of the Rocky Mountain Cancer Rehabilitation Institute Multistage Treadmill Protocol for Cancer Survivors**

Daniel Y.K. Shackelford, Jessica M. Brown, Trent L. Lalonde, David S. Hydock, Carole M. Schneider, FACSM. Rocky Mtn Cancer Rehab, Univ Northern Colorado, Greeley, CO.  
(No relationships reported)

Currently there is not a multistage treadmill protocol for cancer survivors. Most protocols have stages that are either too high in intensity or too long in duration and are highly stressful for cancer survivors. The Rocky Mountain Cancer Rehabilitation Institute (RMCRI) developed a treadmill protocol designed specifically for cancer survivors to address this issue.

**PURPOSE:** To validate the RMCRI multistage treadmill protocol for cancer survivors.

**METHODS:** Fifteen cancer survivors completed a randomized double validation study to compare oxygen consumption ( $VO_{2peak}$ ) between two protocols. The RMCRI treadmill protocol, using gas analysis to determine  $VO_{2peak}$ , was validated against the Bruce protocol. Participants completed the randomized trials one week apart in random order. The Bruce protocol  $VO_{2peak}$  was then compared with the  $VO_{2peak}$  recorded from the gas analysis for the RMCRI treadmill protocol. Additionally, ACSM's predicted  $VO_{2peak}$  equations were validated against the RMCRI protocol using gas analysis.

**RESULTS:** No significant differences ( $p=.98$ ) in  $VO_{2peak}$  were found between the RMCRI protocol and the Bruce protocol and these values were significantly correlated with the RMCRI gas analysis test ( $R^2=.712$ ,  $p=.003$ ). The  $VO_{2peak}$  achieved using RMCRI gas analysis compared to ACSM's predicted  $VO_{2peak}$  equations showed no significant difference ( $p=.72$ ). The  $VO_{2peak}$  values obtained with ACSM's predicted  $VO_{2peak}$  equations were significantly correlated with the  $VO_{2peak}$  values from the RMCRI protocol gas analysis ( $R^2=.830$ ,  $p<.001$ ). This suggests ACSM's predicted equations may be used in place of gas analysis for the RMCRI protocol.

**CONCLUSION:** The RMCRI multistage treadmill protocol which has shorter stages and lower intensities was better tolerated and less stressful for cancer survivors. Given the validity and strong correlations to other treadmill protocols, the RMCRI cancer specific protocol should be the standard for the determination of functional capacity ( $VO_{2peak}$ ) in cancer survivors.

2886 Board #158 June 1 11:00 AM - 12:30 PM

**Evaluation of Two Common Field Tests as Surrogate Measures of Strength in Breast Cancer Survivors**

Melissa J. Benton, FACSM, Maura C. Schlairet, David R. Gibson. Valdosta State University, Valdosta, GA.  
(No relationships reported)

Valid field measures of strength are potentially useful for clinical assessment of breast cancer survivors who are at risk for loss of strength, especially of the upper body, secondary to surgical mastectomy.

**PURPOSE:** To evaluate the relationship between two common field tests and two traditional laboratory measures of upper and lower body strength.

**METHODS:** Before and after 8 weeks of resistance training (RT), 20 female breast cancer survivors (42-80 years old) completed field testing using the Arm Curl test for upper body and Chair Stand test for lower body, followed by laboratory strength measurement using seated Chest Press for upper body and seated Leg Press for lower body. A minimum of 24 hours rest was insured between field and laboratory measurement sessions. The number of repetitions achieved in 30 seconds for the Arm Curl and Chair Stand tests was evaluated against the greatest weight pressed ten times (10RM) for the Chest Press and one time (1RM) for the Leg Press.

**RESULTS:** After 8 weeks of RT, upper and lower body strength increased significantly (Arm Curl =  $16.8 \pm 0.8$  to  $21.3 \pm 0.8$  repetitions; Chair Stand =  $14.4 \pm 1.3$  to  $17.1 \pm 1.2$  repetitions; Chest Press =  $14.2 \pm 1.1$  to  $26.5 \pm 1.4$  kg; Leg Press =  $61.6 \pm 2.9$  to  $82.6 \pm 6.1$  kg;  $p < 0.001$ ). Neither upper nor lower body strength, measured either by field or laboratory tests, was

significantly related to participant age, time since diagnosis, or mastectomy status. There was strong intraclass agreement between pre- and post-RT values for each laboratory and field test (ICC = 0.74-0.96). Pearson correlation analysis identified strong, positive relationships between all pre- and post-RT field tests ( $r = 0.60-0.81$ ,  $p < 0.01$ ), and between all pre- and post-RT laboratory tests ( $r = 0.56-0.88$ ,  $p < 0.05$ ). However, no relationship was found between upper or lower body field and laboratory tests ( $p > 0.05$ ), either before or after RT.

**CONCLUSIONS:** For clinical assessment of breast cancer survivors, use of either field or laboratory tests can provide reliable measures of change over time. However, based on our findings, field tests cannot be considered valid surrogates for actual laboratory measurement of either upper or lower body strength. Moreover, increased familiarity with laboratory tests based on training status does not affect these findings.

#### Assessment Of Field-attainable Variables For Use In The Quantification Of Physiological Load

Robert W. Wilson, II, Thomas S. Goepfinger, Bruce A. Wade, Ann C. Snyder, FACSM. *University of Wisconsin - Milwaukee, Milwaukee, WI.*

(No relationships reported)

The attainment of peak performance has led coaches to plan practice sessions, with the goal of either increasing or maintaining performance capabilities. Periodization advocates that this is accomplished by adjusting the training load through changing the volume and/or the intensity of the physical work performed. The periodized plan is a prescription of load; as such it does not provide a measure of each individual's internal physiological load (PL). Several methods have been proposed to calculate the individual PL in a field setting using heart rate (HR). Recent technological advances now allow for additional objective variables, such as respiration rate (RR), activity (ACT), percent of maximal HR (%HRmax), body posture (BP), skin temperature (ST), and peak acceleration (PA) data, which could enhance the assessment of PL, to be obtained.

**PURPOSE:** The purpose of the study was to determine if these additional variables enhance the assessment of PL. We hypothesize that a multiple variable equation will produce a better fit regression equation. We further hypothesize that using the Karvonen percent of maximal heart rate (%HRmaxK) with RR and/ or ACT will produce a better fit equation than using %HRmax alone.

**METHODS:** Twenty-two female NCAA DI soccer players completed sub-maximal and maximal effort tests while wearing a physiological monitor which collected HR, RR, ACT, %HRmax, BP, ST, and PA data at 1 second intervals, and a heart rate monitor which collected HR data averaged over five second epochs. %HRmaxK was also calculated using the Karvonen method. Blood was sampled at the end of each submaximal stage and the end of the maximal test for the determination of blood lactate concentration ([HLA]). Multivariate and uni-variate regression analyses were conducted.

**RESULTS:** Of the 538 regression analyses that were run, the best equation was cubic and included only the %HRmaxK variable ( $r=0.88$ ,  $R^2=77.9\%$ ,  $p<0.001$ ).

**CONCLUSION:** The best fit equation utilized only %HRmaxK not RR or ACT contrary to our hypotheses. This is due to the high variability of the RR data and the low variability of the ACT data. Therefore, this analysis indicates that HR expressed as %HRmaxK is the best variable for assessing PL. The cubic regression line is very similar to an expected lactate curve with a low slope at low intensities and a fast rise toward the end.

### 2888 Board #160 June 1 9:30 AM - 11:00 AM

#### Cross-validation Of The 20-meter Multiple Shuttle Test For Predicting Vo2max In Basketball And Soccer Players

Barbara E. Bloomquist, Michael R. Esco, Aindrea N. McHugh, Henry N. Williford, FACSM. *Auburn University Montgomery, Montgomery, AL*

(No relationships reported)

The 20-meter shuttle run test (MST) has been shown to be an accurate field parameter for predicting maximal oxygen consumption ( $VO_{2max}$ ) in field settings and is commonly used in aerobically trained individuals, such as soccer athletes. However, research examining the accuracy of the MST in athletes whose sport involves a mixed metabolic contribution from aerobic and anaerobic energy systems, such as basketball, has not been fully explored.

**PURPOSE:** The purpose of this study was to cross-validate the MST for predicting  $VO_{2max}$  between soccer and basketball collegiate male athletes.

**METHODS:** College-age male athletes (age range = 18 to 24 years) from the university's soccer ( $n = 49$ ) and basketball ( $n = 62$ ) teams were evaluated for  $VO_{2max}$  via open circuit spirometry and maximal graded treadmill testing (TMT). The athletes performed the MST and predicted  $VO_{2max}$  was calculated from the following regression equation:  $VO_{2max} = -27.4 + 6.0 * \text{maximal running speed}$  (Leger et al, 1989; Mercier et al., 1983).

**RESULTS:** The following cross-validation statistics were computed:  $r = 0.79$  ( $p < 0.01$ ),  $SEE = 4.01 \text{ ml} \cdot \text{kg}^{-1} \cdot \text{min}^{-1}$  and  $r = 0.82$  ( $p < 0.01$ ),  $SEE = 2.42 \text{ ml} \cdot \text{kg}^{-1} \cdot \text{min}^{-1}$  for the soccer and basketball athletes, respectively. The mean ( $\pm$  SD) values for  $VO_{2max}$  via TMT and MST were  $56.04 (\pm 6.54) \text{ ml} \cdot \text{kg}^{-1} \cdot \text{min}^{-1}$  and  $55.56 (\pm 5.36) \text{ ml} \cdot \text{kg}^{-1} \cdot \text{min}^{-1}$ , respectively, for the soccer athletes and  $51.60 (\pm 4.24) \text{ ml} \cdot \text{kg}^{-1} \cdot \text{min}^{-1}$  and  $53.60 (\pm 3.84) \text{ ml} \cdot \text{kg}^{-1} \cdot \text{min}^{-1}$ , respectively, for the basketball athletes. A paired  $t$ -test indicated that these values were not significantly different for the soccer ( $p > 0.05$ ) but were for the basketball ( $p < 0.05$ ) group. Bland-Altman Plots showed that the 1.96 SD of the bias ranged from  $-8.28 \text{ ml} \cdot \text{kg}^{-1} \cdot \text{min}^{-1}$  to  $7.32 \text{ ml} \cdot \text{kg}^{-1} \cdot \text{min}^{-1}$  in the soccer athletes and from  $-2.76 \text{ ml} \cdot \text{kg}^{-1} \cdot \text{min}^{-1}$  to  $6.76 \text{ ml} \cdot \text{kg}^{-1} \cdot \text{min}^{-1}$  for the basketball athletes.

**CONCLUSIONS:** The results of this investigation indicate that the MST is a moderate field predictor of  $VO_{2max}$  in collegiate soccer and basketball players. However, predicted  $VO_{2max}$  may be slightly higher than actual  $VO_{2max}$  in male basketball players.

### 2889 Board #161 June 1 9:30 AM - 11:00 AM

#### Cross-validation Of The 20-meter Shuttle Test For Predicting Vo2max In Male And Female Soccer Players

Aindrea N. McHugh<sup>1</sup>, Michael S. Green<sup>2</sup>, Michael R. Esco<sup>1</sup>, Henry N. Williford, FACSM<sup>1</sup>, Tyler D. Martin<sup>2</sup>, Barbara E. Bloomquist<sup>1</sup>, Robert Pritchett<sup>3</sup>. <sup>1</sup>*Auburn University Montgomery, Montgomery, AL* <sup>2</sup>*Troy University, Troy, AL* <sup>3</sup>*Central Washington University, Ellensburg, WA.*

(No relationships reported)

The 20-meter shuttle run (MST) has been shown to be an accurate test for predicting maximal oxygen consumption ( $VO_{2max}$ ) in field settings and is commonly used in soccer players. However, it is not fully known if the precision of the MST for predicting  $VO_{2max}$  in soccer athletes is sex-specific.

**PURPOSE:** The purpose of this study was to cross-validate the MST for predicting  $VO_{2max}$  between male and female collegiate soccer players.

**METHODS:** Eighty-nine male ( $n = 49$ ) and female ( $n = 40$ ) college soccer players (age range = 18 - 24 years) were evaluated for  $VO_{2max}$  using open circuit spirometry and maximal graded treadmill testing (GXT). Athletes performed the MST and predicted  $VO_{2max}$  was calculated from the following regression equation:  $VO_{2max} = -27.4 + 6.0 * \text{maximal running speed}$  (Leger et al., 1989).

**RESULTS:** The following cross-validation statistics were computed:  $r = 0.78$  ( $p < 0.01$ ),  $SEE = 4.14 \text{ ml} \cdot \text{kg}^{-1} \cdot \text{min}^{-1}$  and  $r = 0.49$  ( $p < 0.01$ ),  $SEE = 2.87 \text{ ml} \cdot \text{kg}^{-1} \cdot \text{min}^{-1}$  for the male and female subjects, respectively. Mean ( $\pm$  SD) values for  $VO_{2max}$  via GXT and MST were  $56.04 (\pm 6.54) \text{ ml} \cdot \text{kg}^{-1} \cdot \text{min}^{-1}$  and  $57.00 (\pm 5.51) \text{ ml} \cdot \text{kg}^{-1} \cdot \text{min}^{-1}$ , respectively, for the men and  $44.20 (\pm 3.25) \text{ ml} \cdot \text{kg}^{-1} \cdot \text{min}^{-1}$  and  $45.73 (\pm 3.75) \text{ ml} \cdot \text{kg}^{-1} \cdot \text{min}^{-1}$ , respectively, for the women. A paired  $t$ -test indicated these values were not significantly different for the men ( $p > 0.05$ ) but were for the women ( $p < 0.05$ ). Bland-Altman Plots showed that the 1.96 SD of the bias ranged from  $-7.13 \text{ ml} \cdot \text{kg}^{-1} \cdot \text{min}^{-1}$  to  $9.03 \text{ ml} \cdot \text{kg}^{-1} \cdot \text{min}^{-1}$  in the men and from  $-5.40 \text{ ml} \cdot \text{kg}^{-1} \cdot \text{min}^{-1}$  to  $8.56 \text{ ml} \cdot \text{kg}^{-1} \cdot \text{min}^{-1}$  for the women.

**CONCLUSIONS:** The results of this investigation indicate that the MST is a moderate field predictor of  $VO_{2max}$  in collegiate soccer players. However, MST may be slightly more accurate in a group of male compared to a group of female athletes. The mean value for predicted  $VO_{2max}$  was slightly higher ( $\sim 1.53 \text{ ml}$ ) than actual  $VO_{2max}$  in the female subjects.

**Prediction Of In-season Injuries Using A Preseason Functional Movement Screen In Collegiate Athletes**

Molly R. Winke<sup>1</sup>, Katie Dalton<sup>2</sup>, Jake Mendell<sup>2</sup>, Meghan Nicchi<sup>2</sup>. <sup>1</sup>East Stroudsburg University, East Stroudsburg, PA. <sup>2</sup>Skidmore College, Saratoga Springs, NY.  
(Sponsor: Patricia Fehling, FACSM)  
(No relationships reported)

**PURPOSE:** The Functional Movement Screen (FMS) is a tool to assess deficiencies in fundamental movement patterns such as balance, stability, and range of motion. Previous research has indicated that a low FMS score can be predictive of future athletic injury.

**PURPOSE:** To investigate the ability of the FMS to predict in-season injury rate among two groups of Division III collegiate athletes: those with a low composite score ( $\leq 14$ ) and those with a high composite score ( $>14$ ) on a pre-season FMS.

**METHODS:** At the start of their respective competitive seasons, FMS scores were obtained for 122 (97 men and 25 women) varsity collegiate athletes from seven sports. Injuries which required evaluation and treatment by certified athletic trainers were recorded using the SportsWare injury-tracking database. The primary hypothesis was assessed using a chi-square analysis. All other analyses were evaluated using an independent samples t-test.

**RESULTS:** A total of 84 injuries from 64 athletes were recorded during the course of the study. The injury rate for those with high ( $>14$ ) and low ( $\leq 14$ ) composite FMS score were not significantly different ( $p=0.15$ ). The mean FMS score from the injured group ( $15.4 \pm 2.3$ ) was only slightly lower than those in the uninjured group ( $16.4 \pm 2.8$ ) ( $p < 0.05$ ). The injury rate was not different between athletes with at least one asymmetry in any of the individual movements and athletes without asymmetry ( $p=0.62$ ). However, low scores on specific elements of the FMS (deep squat) were related to the occurrence of specific injuries (ankle sprain).

**CONCLUSIONS:** A low composite FMS score ( $<14$ ) did not predict injury in this group of Division III athletes. The small difference in mean FMS score between the injured and non-injured questions the utility of the composite score to identify those at risk of injury. Additional findings of this study suggest that individual scores from the seven movements that comprise the FMS, rather than the composite score, may be more predictive of who will sustain an injury and the type of injury sustained.

**A Prediction Equation for Determining Maximal Oxygen Uptake in Competitive Cyclists**

Frank Wyatt. *Midwestern State University, Wichita Falls, TX.*  
(No relationships reported)

Prediction equations for determination of oxygen uptake ( $VO_{2max}$ ) are well established for the general population. However, these equations often underestimate  $VO_{2max}$  in the endurance performance athlete.

**PURPOSE:** the purpose of this study was to establish a prediction equation for  $VO_{2max}$  in high level, performance cyclists.

**METHODS:** Subjects were 56 (n=49 males, n=7 females) competitive cyclists. Prior to testing, all subjects signed an informed consent approved by the Institutional Review Board for humans as subjects at Midwestern State University. Each subject tested on a cycle ergometer utilizing a cycling protocol with a beginning workload at 150 watts (w) for 5 minutes followed by 25 w increases every minute until volitional fatigue. Collected expired gases and heart rate (HR) were breath-by-breath and beat-by-beat, respectively and averaged every 20 sec. Maximal values were recorded at the end of the test. A backward stepwise multiple regression analysis was utilized to establish a prediction equation for  $VO_{2max}$  incorporating the following variables: height, weight, age, maximal power, maximal HR and time to exhaustion (TE). Associated variables significant at  $p < 0.05$  were selected as independent variables in the equation for predicting the dependent variable,  $VO_{2max}$ . After establishing a regression equation, a dependent samples t-test was run between true  $VO_{2max}$  values and predicted  $VO_{2max}$  values established from the equation. Statistical significance was set a priori at  $p \leq 0.05$ .

**RESULTS:** Mean (SD) demographic values were the following: age 21.9(7.1) y; height 176.9(6.5) cm; weight 73.9(9.8) kg. Group means (SD) at maximal were the following:  $VO_{2max}$  63.1(10.3)  $ml \cdot kg^{-1} \cdot bw^{-1}$ ; heart rate 194.6 (9.9)  $b \cdot min^{-1}$ ; power 349.6 (55.9) w; time to exhaustion (TE) 13.9 (9.4) min. The following prediction equation was established utilizing the independent variables body weight (BW, kg) and maximal power (MP, w):  $VO_{2max} = 59.08 - (0.67 \cdot BW) + (0.15 \cdot MP)$ . Group mean (SD) Estimated  $VO_{2max}$  from the equation was 62.01 (9.4)  $ml \cdot kg^{-1} \cdot min^{-1}$ . The dependent samples t-test between true  $VO_{2max}$  and estimated  $VO_{2max}$  indicated no significant differences.

**CONCLUSION:** These findings indicate the established equation may be used for prediction of maximal oxygen uptake in competitive level cyclists.

**Predictive Validity of Rating of Perceived Exertion: A Cross-culture Validation**

Li Peng<sup>1</sup>, Jiong Luo<sup>1</sup>, Jingcheng Wu<sup>1</sup>, Weimo Zhu<sup>2</sup>. <sup>1</sup>College of Physical Education, South-West University, Chongqing, China. <sup>2</sup>University of Illinois at Urbana and Champaign, Chongqing, IL. (Sponsor: Weimo Zhu, FACSM)  
(No relationships reported)

**PURPOSE:** To examine prediction accuracy of HR using the Borg Scale (RPE multiplied by 10) under different protocols and workout intensities with a Chinese sample.

**METHODS:** 7 healthy males (22.88±0.83 yr.) completed an incremental exercise (3 min at 50 Watts, followed by 50 Watt/3 min increases) to exhaustion on an electric braked bicycle, as well as each exercise at their 20, 40, 60, 80, and 100%  $VO_{2max}$  exercise intensities to steady state or exhaustion. HR and RPE by the Borg scale were measured at the end of each stage of incremental exercise and each steady exercise. The estimated HRs by Borg Scale (HR-e) were compared with the ones directly measured by Polar -RS400 using a correlated t-test.

**RESULTS:** Means and SDs of HR-e and HR-m are summarized below :

Comparison between HR-m and HR-e during incremental exercise

|    | 20% $VO_{2max}$    |       | 40% $VO_{2max}$    |        | 60% $VO_{2max}$    |        | 80% $VO_{2max}$   |        | 100% $VO_{2max}$   |        |

**CONCLUSION:** The Borg scale could accurately predict subjects' actual body status during steady exercise and low intensity (20% and 40%  $VO_{2max}$ ) of incremental exercise for the Chinese young adults, but its predictive accuracy reduced at the high-intensity from 60%  $VO_{2max}$  during incremental exercise.

2893 Board #165 June 1 9:30 AM - 11:00 AM

**Effects of Training Status on Bench Press Prediction Accuracy from Repetitions and Lifting Load**

Brandon Skoff<sup>1</sup>, Paul Reneau<sup>1</sup>, Michael J. Ryan<sup>1</sup>, Jerry Mayhew<sup>2</sup>, William F. Brechue, FACSM<sup>3</sup>, Thomas J. Pujol, FACSM<sup>4</sup>. <sup>1</sup>Fairmont State University, Fairmont, WV. <sup>2</sup>Truman State University, Kirksville, MO. <sup>3</sup>United States Military Academy, West Point, NY. <sup>4</sup>Southeast Missouri State University, Cape Girardeau, MO.  
(No relationships reported)

Many persons use 1-RM bench press prediction equations to estimate 1-RM to save time and reduce the possibility of injury. However, little is known of how training status impacts the predictive accuracy of these equations.

**PURPOSE:** To investigate the effect of trained vs untrained status on the accuracy of 1-RM prediction equations.

**METHODS:** 40 male subjects, 20 trained (TR) and 20 untrained (UTR) (age=21.7 ± 2.3 yrs; height=179.9 ± 6.2 cm; weight= 86.2 ± 9.7 kg) served as subjects. All subjects were instructed on proper bench press technique prior to performing the 1-RM. Three to five days later an additional bench press test consisting of weight load x maximal repetitions to volitional fatigue was performed. The second test results were utilized to estimate 1-RM from ten prediction equations. Seven of the equations were taken from published material and three from the world wide web (W). Data were analyzed via a repeated measures ANOVA within the UTR and TR data with Tukey *post hoc* follow-up.

**RESULTS:** UT and TR performed between three and seven repetitions using loads equivalent to 80 to 97% 1-RM. Five of the prediction equations produced estimates that were not significantly different (p>.05) from the actual 1-RM, and five equations overestimated 1-RM performance in both UTR and TR. The difference between predicted and actual 1-RM values for the same equations produced overestimations ranging from 2-6% in UT and from 3-5% in TR.

**CONCLUSIONS:** Some prediction equations for estimating 1-RM appear to be accurate while others tend to overpredict 1-RM performance. Training status does not appear to be a major factor impacting the predictive accuracy for selected equations.

**Accuracy of 1-RM Bench Press Prediction Equations in College-Age Men**

Paul Reneau<sup>1</sup>, Brandon Skoff<sup>1</sup>, Jerry Mayhew<sup>2</sup>, Michael J. Ryan<sup>1</sup>, Thomas J. Pujol, FACSM<sup>3</sup>, William F. Brechue, FACSM<sup>4</sup>. <sup>1</sup>Fairmont State University, Fairmont, WV. <sup>2</sup>Truman State University, Kirksville, MO. <sup>3</sup>Southeast Missouri State University, Cape Girardeau, MO. <sup>4</sup>United States Military Academy, West Point, NY.  
(No relationships reported)

Maximum Bench Press (1-RM) performance is often used as a measure of strength. However, prediction equations from maximal repetitions and load lifted are frequently used to predict 1-RM to reduce the possible risk of injury involved with 1-RM testing.

**PURPOSE:** To determine the accuracy of ten prediction equations for estimating 1-RM from sub-maximal repetitions and load lifted.

**METHODS:** 235 subjects (age = 20.3 ± 1.8 yrs; height = 179.5 ± 7.4 cm; weight = 78.9 ± 12.8 kg) with various levels of training experience served as subjects. All subjects were instructed in proper bench press technique prior to determination of 1-RM. An additional bench press test consisting of maximal repetitions (range = 3 to 10) performed with submaximal loads until volitional fatigue was utilized to estimate 1-RM from the prediction equations. Seven of the equations were taken from published material and three from the world wide web (W). Data were analyzed via a repeated measures ANOVA with a Tukey's *post hoc* test performed as needed. Alpha was set at p<.05 *apriori*.

**RESULTS:** Two of the prediction equations for 1-RM were not significantly different from actual 1-RM (p>.05), four equations over predicted (1.2-2.4%) while four under predicted (1.3-3.4%).

**CONCLUSION:** Although the results indicate that many rep-max prediction equations present significantly different estimates of 1-RM bench press, prediction errors are relatively small, hence allowing reasonable estimates of maximal strength in young men.

### Predictors Of 10 Km Performance

Ryan M. Broxterman, Carl J. Ade, Thomas J. Barstow, FACSM. *Kansas State University, Manhattan, KS.*

(No relationships reported)

**PURPOSE:** To determine the aerobic parameters that best predict 10 kilometer (km) running performance.

**METHODS:** On separate days 31 healthy subjects completed a maximal incremental test on a treadmill for determination of gas exchange threshold (GET) and maximal oxygen uptake ( $VO_{2max}$ ), and at least four constant speed tests to exhaustion on a treadmill for determination of the speed-duration relationship (critical speed (CS) and the finite distance that can be traversed above CS ( $D'$ )). On a different day each subject ran 10 km on an indoor 200 meter track.

**RESULTS:** While 10 km time was significantly inversely correlated with absolute GET ( $r^2 = 0.143$ ;  $p = 0.035$ ) and relative GET ( $r^2 = 0.224$ ;  $p = 0.007$ ), absolute  $VO_{2max}$  ( $r^2 = 0.231$ ;  $p = 0.006$ ) and relative  $VO_{2max}$  ( $r^2 = 0.558$ ;  $p < 0.0001$ ), it was best correlated with CS (hyperbolic CS,  $r^2 = 0.777$ ;  $p < 0.0001$ ; 1/time CS,  $r^2 = 0.847$ ;  $p < 0.0001$ ). 10km pace ( $10.4 \pm 1.9$  km·h<sup>-1</sup>) was significantly slower than the hyperbolic CS ( $11.7 \pm 2.0$  km·h<sup>-1</sup>) ( $p < 0.001$ ) and the 1/time CS ( $12.3 \pm 2.1$  km·h<sup>-1</sup>) ( $p < 0.001$ ), but was not significantly different from the speed at GET ( $9.6 \pm 2.1$  km·h<sup>-1</sup>) ( $p = 0.079$ ), despite the lack of significant correlation between these two measures ( $r^2 = 0.101$ ;  $p = 0.082$ ).

**CONCLUSION:** CS best predicts the average velocity and elapsed time for a 10 km running test.

2896 Board #168 June 1 9:30 AM - 11:00 AM

### Using High Resolution Accelerometers In Addition To Laboratory Measures Strongly Predicts 10k Running Performance

Lucas Wall<sup>1</sup>, Michael A. Busa<sup>1</sup>, Timothy Muth<sup>1</sup>, Joseph Hornyak<sup>2</sup>, Christopher Herman<sup>1</sup>, Erik Bolt<sup>3</sup>, Stephen J. McGregor<sup>1</sup>. <sup>1</sup>Eastern Michigan University, Ypsilanti, MI. <sup>2</sup>University of Michigan, Ann Arbor, MI. <sup>3</sup>Clarkson University, Potsdam, NY. (Sponsor: Andrew Coggan, FACSM)

(No relationships reported)

**PURPOSE:** The purpose of this study was to determine if high-resolution accelerometers (HRA) can be used with other laboratory measures ( $VO_2$  and lactate threshold) to predict performance in collegiate cross country runners.

**METHODS:** All subjects consented to procedures approved by EMU CHHS human subjects review committee. 7 NCAA Division 1 cross country runners ( $21.7 \pm 1.4$  yr,  $67.8 \pm 6.4$  kg,  $177.8 \pm 5.1$  cm,  $67.4 \pm 4.7$  ml/kg/min) completed 3,000m and 10,000m performance trials (3kTT and 10kTT), and 1 incremental trial on a treadmill, which included wearing an HRA (Microstrain, VT) superficial to the L3 vertebra at the approximate center of mass. Blood lactate levels (Lactate Pro, JP) and metabolic gases (Jaeger, CA) were measured to determine pace at LT (LTP),  $VO_{2max}$ , and speed at  $VO_{2max}$  (VmaxSpeed). Root-mean-square (RMS) of HRA signal was examined in three planes of motion (VT, ML, AP) and the Euclidian scalar (RES). The ratio of RMS of each axial acceleration to RES was determined ( $VT_{RA}$ ,  $ML_{RA}$ ,  $AP_{RA}$ ), as well as the axial and RES accelerations to speed ( $VT_{EC}$ ,  $ML_{EC}$ ,  $AP_{EC}$ ,  $RES_{EC}$ ). Laboratory measures and performance data were compared by correlation and stepwise regression using SPSS 19 (IBM, NY).

**RESULTS:** Relationships between measured variables and 3kTT are presented elsewhere. Mean 3kTT and 10kTT times were  $8.69 \pm 0.15$  and  $31.5 \pm 1.17$  min, respectively. LTP ( $19.77 \pm 0.90$ ) was correlated to 10kTT ( $r = -0.880$ ,  $p < 0.001$ ) and 3kTT was correlated with 10kTT ( $r = 0.698$ ,  $p < 0.001$ ). Linear stepwise regressions including LTP, 3kTT and other laboratory measures ( $VO_2$ ,  $VO_{2max}$ ) did not significantly improve relationships with 10kTT over LTP alone. When HRA parameters were added to LTP, 3kTT, and  $VO_{2max}$ , significant and substantially stronger relationships were obtained ( $r = 0.993$ ,  $p < 0.001$ ).

**CONCLUSION:** Adding HRA parameters to other laboratory or shorter performance measures improves performance predictions for the 10k in collegiate distance runners over standard laboratory measures or shorter performances alone. Further research is needed to determine if shorter performances can be used in the prediction (e.g. 1500m), or performance can be predicted in longer events (e.g. marathon) using this approach.

2897 Board #169 June 1 9:30 AM - 11:00 AM

### High Resolution Accelerometers In Conjunction With Laboratory And Performance Measures Accurately Predict Performance In 3000m

Aaron C. Stickel<sup>1</sup>, Michael A. Busa<sup>1</sup>, Lucas Wall<sup>1</sup>, Timothy Muth<sup>1</sup>, Joseph Hornyak<sup>2</sup>, Christopher Herman<sup>1</sup>, Erik Bolt<sup>3</sup>, Stephen J. McGregor<sup>1</sup>. <sup>1</sup>Eastern Michigan University, Ypsilanti, MI. <sup>2</sup>University of Michigan, Ann Arbor, MI. <sup>3</sup>Clarkson University, Potsdam, NY. (Sponsor: Andrew Coggan, PHD, FACSM)

(No relationships reported)

Previous attempts to predict running performance from laboratory measures, such as lactate threshold and  $VO_{2max}$ , have met with mixed success. Using high resolution accelerometers (HRA), we have previously demonstrated that differences in running economy can be explained, in part, by differences in acceleration profile.

**PURPOSE:** The purpose of this study was to determine if high-resolution accelerometers (HRA) could be used in conjunction with other laboratory measures ( $VO_2$  and lactate threshold) to accurately predict performance in the 3000m among collegiate distance runners.

**METHODS:** All subjects consented to procedures approved by EMU CHHS human subjects review committee. 7 NCAA Division 1 cross country runners ( $21.7 \pm 1.4$  yr,  $67.8 \pm 6.4$  kg,  $177.8 \pm 5.1$  cm,  $67.4 \pm 4.7$  ml/kg/min) completed 3,000m and 10,000m performance trials (3kTT and 10kTT), and 1 incremental trial on a treadmill, which included wearing an HRA (Microstrain, VT) superficial to the L3 vertebra at the approximate center of mass. Blood lactate levels (Lactate Pro, JP) and metabolic gases (Jaeger, CA) were measured to determine pace at LT (LTP),  $VO_{2max}$ , and speed at  $VO_{2max}$  (VmaxSpeed). Root-mean-square (RMS) of HRA signal was examined in three planes of motion (VT, ML, AP) and the Euclidian scalar (RES). The ratio of RMS of each axial acceleration to RES was determined ( $VT_{RA}$ ,  $ML_{RA}$ ,  $AP_{RA}$ ), as well as the axial and RES accelerations to speed ( $VT_{EC}$ ,  $ML_{EC}$ ,  $AP_{EC}$ ,  $RES_{EC}$ ). Laboratory measures and performance data were compared by correlation and stepwise regression using SPSS 19 (IBM, NY).

**RESULTS:** Relationships between measured variables and 10kTT are presented elsewhere. 3kTT was most strongly correlated with 10kTT ( $r = 0.69$ ;  $p < 0.001$ ), LTP ( $r = -0.67$ ;  $p < 0.001$ ) and  $VT_{RMS}$  ( $r = -0.65$ ;  $p < 0.001$ ), respectively. Linear stepwise regressions including 10kTT, LTP,  $VO_{2max}$  and HRA parameters resulted in a strong relationship with 3kTT ( $r = 0.97$ ,  $p < 0.001$ ). Variables such as VmaxSpeed and  $VO_2$  were excluded from the model.

**CONCLUSION:** Inclusion of HRA parameters with laboratory measures and 10kTT results in strong prediction of 3000m in collegiate distance runners. In particular, this approach is much stronger than speed at  $VO_{2max}$ , which has been suggested previously to accurately predict performance over various distances.

2898 Board #170 June 1 9:30 AM - 11:00 AM

### Prediction of Running Performances Utilizing the Running Energy Reserve Index

Govindasamy Balasekaran, FACSM<sup>1</sup>, Nidhi Gupta<sup>1</sup>, Visvasuresh Victor Govindaswamy<sup>2</sup>, Naveen Agrawal<sup>3</sup>. <sup>1</sup>Nanyang Technological University, Singapore, Singapore. <sup>2</sup>Texas A&M University at Texarkana, Texarkana, TX. <sup>3</sup>GE Water & Process Technologies, John F. Welch Technology Centre, Bangalore, India.

(No relationships reported)

Mathematical and physiological models to predict running performances are generally based on unverified assumptions which may reduce accuracy. Few models are able to predict for a wide range of distances.

**PURPOSE:** To predict all out 200m and 5000m track and treadmill running performances ranging from .19 s~ to 1339 s~ utilizing the running energy reserve index (RERI).

**METHODS:** 29 athletes [total: age:  $27.31 \pm 7.16$  yrs, BMI:  $22.04 \pm 1.95$  kg·m<sup>-2</sup>; endurance trained; ET = 9, sprinters; ST = 7 and middle distance; MD = 13] participated in this study. Additionally, 12 participated (age:  $24.45 \pm 6.44$  yrs, BMI:  $21.43 \pm 2.15$  kg·m<sup>-2</sup>) to calculate the value of c constant of the RERI model based on rational function. To determine maximal aerobic speed (MAS) athletes performed five-six laboratory sessions as follows: Astrand modified running maximal oxygen consumption test, submaximal discontinuous treadmill (SUBMAX) test,  $VO_2$  till exhaustion ( $T_{lim}$ ) tests at; velocity at  $VO_{2max}$  ( $vVO_{2max}$ ),  $v\Delta 50$  (median of  $vVO_{2max}$  and velocity at lactate threshold;  $vLT$ ) or  $v\Delta 50 + 5\% vVO_{2max}$ . Maximal anaerobic speed (MANs) was determined with a 50m sprint on the track. Also, athletes performed two all out 200m and 5000m track runs. The maximal aerobic energy ( $E_{MAS}$ ) and maximal anaerobic energy ( $E_{MANs}$ ) at corresponding speeds and estimated energy for 200m, 5000m and treadmill runs were established with submaximal efficiency equations. The RERI was computed with the ratio of  $E_{MANs}$  and  $E_{MAS}$ . Rational regression equation was fitted to the data of estimated energy at corresponding speeds of 200m, 5000m track runs and treadmill running trials as functions of run duration.

**RESULTS:** The measured value of c constant was .0185 with no significant differences between ET, ST and MD athletes. The predicted (P) and experimental (E) results for the total cohort had significant correlations from .96 to .99 ( $p \leq 0.01$ ): EMAnS ( $\text{ml} \cdot \text{kg}^{-1} \cdot \text{s}^{-1}$ ) [P(1.79  $\pm$  .24), E(1.78  $\pm$  .24)]; EMAS ( $\text{ml} \cdot \text{kg}^{-1} \cdot \text{s}^{-1}$ ) [P(0.80  $\pm$  .1), E(0.81  $\pm$  .11)] and RERIE [P(2.25  $\pm$  .36), E(2.25  $\pm$  .32)]. The RERI model predicted track and treadmill all out running performances to within an average of 2.26  $\pm$  1.89 % ( $R^2 = .99$ ) and 2.95  $\pm$  2.51 % ( $R^2 = .99$ ) respectively.

**CONCLUSION:** The RERI model may be accurate in predicting all out track and treadmill running performances for a wide range of distances from short, middle up to 5000m.

**2899** Board #171 June 1 9:30 AM - 11:00 AM

**Predicting Mets And Activity Type From Accelerometer Counts Using Different Machine Learning Tools**

Patty Freedson, FACSM<sup>1</sup>, Sarah Kozey-Keadle<sup>1</sup>, Kate Lyden<sup>2</sup>, John Staudenmayer<sup>1</sup>. <sup>1</sup>University of Massachusetts, Amherst, MA. <sup>2</sup>University of Massachusetts, Amherst, Amherst, MA.

(P. Freedson: Honoraria; Actigraph..)

There are numerous machine learning tools available for processing and interpreting accelerometer output to estimate METs and activity type. However, it is not known if certain machine learning tools are superior for translating accelerometer signals into MET estimates or for identifying activity type.

**PURPOSE:** To compare the accuracy and precision of 4 machine learning tools in estimating METs and detecting activity type from accelerometer counts.

**METHODS:** Four machine learning tools (neural network [NNET], classification/regression tree [CRT], support vector machine [SVM], and random forest [RF]) were used to estimate activity METs and activity type (household, locomotion and sport activity) in 277 adults using signal features from the GT1M Actigraph accelerometer counts (1 sec epoch). Hold-one-out cross-validation procedures were used to test the accuracy and precision of each of the models using measured METs and observed activity types as the criterion measures.

**RESULTS:** The table below presents the bias and rMSE for estimated METs, the correlations between measured and estimated METs and the accuracy of activity type classification.

|      | Bias   | rMSE  | r    | Classification accuracy |
|------|--------|-------|------|-------------------------|
| NNET | -0.003 | 1.44  | 0.81 | 96.5%                   |
| CRT  | -0.014 | 1.65* | 0.74 | 94.4%                   |
| RF   | 0.004  | 1.47  | 0.80 | 96.3%                   |
| SVM  | -0.001 | 1.50  | 0.79 | 96.4%                   |

\*significantly different than NNET, RF and SVM,  $p < 0.05$

**CONCLUSION:** The significantly higher rMSE for CRT is due to the less flexible nature of CRT. In general, all machine learning tools are accurate and precise in estimating METs and identifying activity type categories in a lab setting. Future investigations will apply these tools to free-living conditions.

**Estimated VO2max From The Rockport Walk Test On A Non-motorized Curved Treadmill**

Rhiannon M. Seneli, Ann C. Snyder, FACSM. University of Wisconsin - Milwaukee, Milwaukee, WI.

(No relationships reported)

The Rockport Walk Test (RWT) is a field test used to estimate maximal volume of oxygen uptake (VO2max). It consists of a one-mile walk on a measured track.

**PURPOSE:** To validate the Rockport Walk Test (RWT) on a non-motorized curved treadmill (CT).

**METHODS:** Twenty-three healthy adults (females = 10; 19-44 years old) who were sedentary to recreationally active volunteered for the study. One trial of the RWT was performed on a measured indoor track and another on the CT on different days at random. Subjects were instructed to walk one-mile at a brisk, steady pace. Heart rate (HR) and completion time were used to calculate VO2max using 6 different general and gender specific equations from previous research. Subjects also performed a treadmill graded exercise test (GXT) which was used as the criterion measure for VO2max measurements. Completion times and HR between the two RWT were compared using dependent t-tests. Estimated VO2max values were compared to results from the CT and overground as well as to observed values from the GXT through RM ANOVA, Pearson correlations (r), and Bland-Altman plots. The  $\alpha$  was set at .05.

**RESULTS:** There was no difference between completion times for the RWT in the overground and CT conditions but the CT produced significantly higher HR's. There was no difference between relative estimations of VO2max using the Kline et al. (1987) general and gender specific equations on the RWTC when compared to the Dolgener et al. (1994) equation on the RWTO ( $p = .561$  and  $.335$ ). There was no difference in the absolute estimations of VO2max for the RWTC with the Kline et al. (1987) general equation and the RWTO with the Dolgener et al. (1994) general equation ( $p = .204$ ). All VO2max estimations were significantly different from observed VO2max except for the estimation produced by the relative general Kline et al. (1987) equation on the RWTO. Despite high correlations ( $r = 0.75-0.91$ ) the RWTC underestimated VO2max.

**CONCLUSION:** The RWTC underestimates VO2max but may be beneficial if a new equation were created specifically for the CT.

**2901** Board #173 June 1 9:30 AM - 11:00 AM

**Predicting Twenty-Minute Power From Five Five-Minute Intervals in Competitive Cyclists**

Steven J. Albrechtsen, Jason R. Boynton. University of Wisconsin, Whitewater, WI.

(No relationships reported)

**PURPOSE:** The purpose of this research project was to compare the power achieved during five five-minute intervals and one twenty-minute effort. Five five-minute intervals is a commonly used workout for competitive cyclists who periodically replace a workout with one twenty-minute effort to obtain important information about power, but at the expense of a more productive workout.

**METHODS:** Nine cyclists competing at the category 3 level or above completed five five-minute intervals (5x5) separated by five minutes of recovery between intervals and one twenty-minute effort of continuous exercise (1x20) in separate exercise sessions in a random order on a Velotron computerized cyclist ergometer. Correlation coefficients and prediction equations were determined for the average 20 as a function of the average 5x5 in units of Watts and Watts/kg.

**RESULTS:** Correlating the average 5x5 (327.78 $\pm$ 31.70 W) with the average 1x20 (309.66 $\pm$ 30.28 W) in units of Watts resulted in a correlation coefficient of 0.9650 along with the following prediction equation: Average 1x20 (W) = 0.9218 [Average 5x5 (W)] + 7.5162. Correlating the average 5x5 (4.39 $\pm$ 0.47 W/kg) with the average 1x20 (4.16 $\pm$ 0.47 W/kg) in units of Watts/kg resulted in a correlation coefficient of 0.9747 along with the following prediction equation: Average 1x20 (W/kg) = 0.99868 [Average 5x5 (W/kg)] - 0.1721.

**CONCLUSION:** The results of this research project established the relationship between five five-minute intervals as a training technique to prepare for competition and one twenty-minute effort as a field test to evaluate training status with the intent of optimizing training to use five five-minute intervals as both a training technique and to evaluate training status without the need to interrupt the training schedule with one twenty-minute effort.

**A Retrospective Analysis Of Wellness And Fitness Assessments In College Freshman**

Amanda J. Peterson<sup>1</sup>, William F. Simpson, FACSM<sup>2</sup>, Glenn R. Carlson<sup>2</sup>. <sup>1</sup>Cooper Aerobics Center at Craig Ranch, McKinney, TX. <sup>2</sup>University of Wisconsin-Superior, Superior, WI.

(No relationships reported)

It is accepted that college students form their adult health behaviors during their college years. Educating first year students in respect to the importance of healthy behaviors can have a positive effect on their future.

**PURPOSE:** This investigation's purpose was to analyze 3 academic years worth [6 semesters] of fitness and wellness assessments completed by first year students during a health and wellness class at a small public liberal arts institution.

**METHODS:** As a portion of each student's course work, a wellness survey and fitness assessment was completed using a MicroFit computerized assessment package. A total of 332 males and 468 females were included in this cohort over the 6 semesters. Student who did not complete the entire assessment are not included in this analysis.

**RESULTS:** The wellness profile suggests that all students exercise 2-3 times per week, have fair eating habits, are not safety conscious and are exposed to moderate levels of stress. However, they are less likely to use tobacco products. The table illustrates fitness assessment data. Aside from the systolic reading for males, values are normal. Although BMI estimates are overweight for males, the corresponding % fat suggests a more active population. Est. max VO<sub>2</sub> values are skewed high. The YMCA protocol was used for prediction and may have overestimated.

**CONCLUSIONS:** This population reported low participation in exercise which one would anticipate a lower VO<sub>2</sub>. Based on these observations, first year students should be exposed to more educational and interventional programs involving exercise, proper nutrition and stress management programming. The Health and Wellness class addresses a variety of behaviors including the above.

|         | SBP/DBP             | BMI      | % Fat     | EST. VO <sub>2</sub> [mL/kg/min] |
|---------|---------------------|----------|-----------|----------------------------------|
| MALES   | 122.6±11.9/77.4±8.1 | 24.3±2.9 | 13.2±4.7  | 41.7±7.7                         |
| FEMALES | 112.1±10.9/74.8±6.1 | 25.8±6.2 | 24.06±6.2 | 37.6±8.9                         |

**Two Dimensional Differential Gel Electrophoresis Analysis of the Nucleus accumbens in High and Low Active Mice.**

David P. Ferguson, Lawrence J. Dangott, J. Timothy Lightfoot, FACSM. Texas A&M University, College Station, TX.

(No relationships reported)

Current literature suggests that physical inactivity is one of the leading causes of death in the United States. With this understanding there is a growing interest in the mechanism responsible for the drive to be physically active.

**PURPOSE** While there have been several genomic and gene expression studies, there has been no data presented regarding differential protein expression between high and low active subjects.

**METHODS** Thus, we extracted proteins from nucleus accumbens of previously phenotyped high active male C57L/J mice (n=3), low active male C3H/HeJ mice (n=3), high active C3C5 F2 male mice (n=3), and low active C3C5 F2 male mice (n=3). The F2 cohort served as a control to aid in the identification of changes in proteins only related to physical activity. The differential expression of the extracted proteins was determined using 2D-DIGE and DeCyder software (p<0.05). Candidate proteins were digested with trypsin and the peptides were analyzed by mass spectrometry for protein identification.

**RESULTS** We identified four proteins that were expressed differently between the high active and low active mice: L-lactate dehydrogenase B, calcineurin subunit B type 1, and heat shock proteins HSP90-alpha and beta.

**CONCLUSION** These data provide a clearer framework to investigate the mechanism responsible for voluntary physical activity.

**Effects of Physical Activity Ancestry on Aspects of Body Composition and Glucose Tolerance in Mice**

Lisa M. Guth, Andrew C. Venezia, Michael P. Marini, Estefan P. Beltran, Espen E. Spangenburg, Stephen M. Roth, FACSM. University of Maryland, College Park, MD.

(No relationships reported)

**PURPOSE:** To characterize the influence of a physical activity (PA) ancestry compared to a sedentary (SED) ancestry on aspects of body composition, glucose metabolism, and tissue characteristics in multiple generations of mouse offspring.

**METHODS:** 8-week old C57BL/6 mice (F<sub>0</sub>) were exposed to PA (computer-monitored voluntary wheel running, N=20) or a SED condition (no wheel access, N=20) for 12 weeks prior to breeding. PA males were bred with PA females and SED males were bred with SED females to obtain F<sub>1</sub> pups. F<sub>0</sub> PA animals had continued access to the running wheel during breeding, pregnancy, and weaning. F<sub>1</sub> pups were either sacrificed at 8 wk without exposure to PA (PA ancestry was the only distinguishing feature), or bred with like-ancestry F<sub>1</sub> animals to obtain the F<sub>2</sub> generation. Similarly, F<sub>2</sub> offspring were sacrificed at 8 wk without any PA exposure. Body, heart, liver, omental fat, and muscle (gastrocnemius, plantaris, soleus, TA, EDL) masses were recorded and intraperitoneal glucose tolerance (IPGTT) was measured in F<sub>1</sub> and F<sub>2</sub> offspring.

**RESULTS:** F<sub>0</sub> males and females ran an average of 4206 ± 634 and 5312 ± 637 meters/24 hours over the 12-wk pre-breeding period. In the F<sub>1</sub> generation, body mass tended to be higher in PA offspring (p = 0.05 and 0.06 for males and females). Liver mass was significantly higher in PA males (p < 0.05) and tended to be higher in PA females (p = 0.10). There were no differences in heart, omental fat, or muscle masses, though in the F<sub>2</sub> generation, average plantaris mass tended to be lower in SED males (p = 0.07). No other differences in body or tissue masses were observed. F<sub>2</sub> female mice with a PA ancestry had lower baseline blood glucose (p < 0.05) and tended to have lower IPGTT AUC (p = 0.06). No differences in blood glucose or glucose tolerance were observed in F<sub>2</sub> males or in the F<sub>1</sub> generation.

**CONCLUSION:** These findings suggest PA ancestry (independent of direct PA) has a limited influence on aspects of body composition and glucose metabolism in multiple generations of mouse offspring, but in a generation- and sex-specific manner.

This work was supported by NIH grants HD062868 and AG000268.

**A Quick One Tube Nested PCR-Protocol For Epo Transgene Detection**

Dirk A. Moser, Elmo E.W. Neuberger, Perikles Simon. *University of Mainz, Mainz, Germany.*  
(No relationships reported)

**PURPOSE:** Doping is particularly difficult to combat when it involves pharmaceuticals and therapeutic techniques that are still in development. With the very recent reports on successful gene therapies for several diseases, the likelihood for abuse of gene transfer techniques in elite sports is rapidly increasing. It is therefore very important to develop valid detection techniques for indicating the transfer of DNA (tDNA), with ultimate sensitivity and specificity.

**METHODS:** To date, three slightly different procedures have been developed, two using a real time PCR based approach and one using a primer-internal, intron-spanning PCR approach (spiPCR), each reported to reliably detect tDNA with high sensitivity. The specificity of these techniques, however, is still a matter of debate. Here we present a novel one-tube nested spiPCR approach that minimizes the chances for cross-contamination and shows increased sensitivity compared to non-nested PCR techniques. To further reduce the occurrence of false-positives based on cross-contamination, a multi-functional 19bp extended erythropoietin standard (EPO) was cloned which can be easily differentiated from EPO tDNA and can be used as an internal or external positive control.

**RESULTS:** The method described here combines the advantages of the three currently developed techniques for the detection of EPO gene doping in terms of sensitivity, specificity, the number of procedural steps and the chances for cross-contamination.

**CONCLUSIONS:** We hope that the sensitivity of the currently developed molecular biological detection techniques in combination with their ability to allow long-term detection will deter athletes from using gene transfer doping techniques.

**2906** Board #178 June 1 11:00 AM - 12:30 PM  
**Effects of Resistance Training on Skeletal Muscle Gene Expression Profiling in Overweight, Sedentary Young Men.**

Brian H. Chen, Daniel M. Croymans, Christian K. Roberts, FACSM. *UCLA, Los Angeles, CA.*  
(No relationships reported)

Previously, we demonstrated that resistance training (RT) improved glucose tolerance, independent of changes in body weight. However, the biologic pathways leading to improvements in insulin sensitivity/glucose tolerance with RT remain largely unknown.

**PURPOSE:** To comprehensively identify changes in skeletal muscle gene expression networks and their associations with changes in measures of glucose tolerance and other metabolic traits before and after this 12-week RT intervention.

**METHODS:** 18 sedentary, overweight young adult men (age =  $21 \pm 2$  years, BMI =  $31 \pm 3$  kg/m<sup>2</sup>) completed 12 weeks of RT, 3x/week, and were assessed for changes in markers of metabolic health and underwent an oral glucose tolerance (OGTT). Skeletal muscle biopsies were collected from the vastus lateralis before and after the intervention. Global mRNA levels were measured using the Illumina HumanHT Expression BeadChip. Weighted Gene Co-expression Network Analysis (WGCNA) was used to construct gene networks (comprised of multiple clusters/modules of genes) based on their degree of co-expression. Correlations were based on change (post- minus pre-intervention) values.

**RESULTS:** We identified 3 distinct modules of genes by hierarchical clustering of gene co-expression values. Summary expression values based on the average change in expression of the component genes of each module were correlated with changes in several traits. One module showed positive correlations with oxidized LDL cholesterol ( $r=0.51$ ,  $p=0.04$ ), glucose area-under-the-curve (AUC) from OGTT ( $r=0.45$ ,  $p=0.07$ ), insulin AUC ( $r=0.52$ ,  $p=0.03$ ), and QUICKI ( $r=-0.62$ ,  $p=0.01$ ). Enrichment analysis using DAVID (<http://david.abcc.ncifcrf.gov>) indicated that this module was highly enriched for genes involved in cell signaling, extracellular matrix, and cell adhesion. Module genes with the strongest correlations with oxidized LDL levels included *RAB32* ( $r=0.73$ ), *ITGB5* ( $r=0.68$ ), *CTGF* ( $r=0.67$ ), and *CMTM3* ( $r=0.66$ ); for insulin AUC, *AEBP1* ( $r=0.74$ ), *EIF4A1* ( $r=0.70$ ), and *ANXA2* ( $r=0.66$ ); and for QUICKI, *WBP5* ( $r=-0.81$ ), *LIMA1* ( $r=-0.77$ ), *EBF1* ( $r=-0.76$ ), and *KCTD12* ( $r=-0.74$ ).

**CONCLUSION:** We identified a set of genes enriched for cell signaling/adhesion, whose expression levels were related to the effects of RT on glucose tolerance and insulin resistance traits.

**Potential Wash-out of Vmat2 Gene Silencing by Exercise Exposure.**

Emily E. Schmitt, David P. Ferguson, J Timothy Lightfoot, FACSM. *Texas A&M University, College Station, TX.*  
(No relationships reported)

**PURPOSE:** To investigate potential exercise-induced washout of vivo-morpholinos targeted toward vesicular monomine transporter type 2 (*Vmat2*).

**METHODS:** We randomly assigned 24, eight week old male C57Bl/6J inbred mice to one of two groups: one group had access to running wheels while the other group had locked running wheels. All animals received tail-vein injections (11 mg/kg) of *Vmat2*-targeted vivo-morpholinos for three consecutive days. Starting 24 hours after the first injection and continuing every 24 hours thereafter, we sacrificed one mouse from each group and determined the expression of *Vmat2* using Western Blotting to track efficacy of gene knock-down.

**RESULTS:** There was no significant difference between the wheel running and the locked-wheel group in *Vmat2* expression ( $p=0.45$ ) across the 11 day post-injection period. As compared to baseline *Vmat2* expression (optical density - OD = 21.3%), there was complete knock-down of *Vmat2* expression on days 1-8 post-injection (OD = 0.0% on all days). On day 9-11 post-injection, *Vmat2* expression gradually increased until on day 11, it was similar to baseline values (OD = 20.0%).

**CONCLUSIONS:** The use of vivo-morpholinos transiently silenced *Vmat2* with no difference between wheel running and locked wheel groups. This data suggests that wheel-running does not increase the clearance of vivo-morpholinos.

**2908** Board #180 June 1 11:00 AM - 12:30 PM  
**High Fat Diet Enhances Tumorigenesis And Pro-tumoral Factors in the C3(1)SV40Tag Breast Cancer Mouse Model**

Jennifer Steiner<sup>1</sup>, J Mark Davis, FACSM<sup>1</sup>, Jamie McClellan<sup>1</sup>, Jeffrey Green<sup>2</sup>, E. Angela Murphy<sup>3</sup>. <sup>1</sup>University of South Carolina, Columbia, SC. <sup>2</sup>National Cancer Institute, Bethesda, MD. <sup>3</sup>University of South Carolina School of Medicine, Columbia, SC.  
(No relationships reported)

High fat diet (HFD) induced obesity increases the risk for breast cancer (BrCa); obese women have a greater risk of developing breast cancer and of dying from the disease than healthy women. However, few well supported mechanistic explanations in regards to the relationship between HFD induced obesity and BrCa exist.

**PURPOSE:** The purpose of this study was to determine the effects of HFD feedings on tumorigenesis in the C3(1)SV40Tag mouse model of BrCa and further to relate this to pro-tumoral factors expressed in the tumor microenvironment.

**METHODS:** Female C3(1)SV40Tag mice were assigned to a dietary treatment group (n=14-15), beginning at 4 wks of age: control (CON) diet (AIN76A), or high fat diet (HFD). The CON diet contained 11.5% kcal fat while the HFD diet had 41% kcal fat. All diets were identical in vitamin and mineral content. Body weight (BW) was measured weekly, and mice were examined bi-weekly for palpable tumors, from which tumor number and volume was recorded. At 18wks of age mice were sacrificed and all visible tumors were counted, measured, and excised. Tumor tissue was analyzed for pro-tumoral factors including mRNA gene expression of CD206 (a marker for pro-tumor M2 macrophage phenotype), VEGF (a mediator of angiogenesis) and TNF- $\alpha$  & IL-6 (pro-inflammatory cytokines) using RT-PCR. Tumor number and volume as well as BW were analyzed using a one-way repeated measures ANOVA and pro-tumoral factors were analyzed using Student's T-Tests. Significance was set at  $P<0.05$ .

**RESULTS:** HFD feedings significantly increased BW (wks 8-18), and body fat percentage (~70%) ( $P<0.05$ ). Tumorigenesis was greatly enhanced by HFD; tumor volume in HFD was ~50% greater than CON at 18wks ( $P<0.05$ ). HFD consumption increased tumor expression of CD206 (1.4 fold), VEGF (1.5 fold), IL-6 (~3 fold), and TNF- $\alpha$  (1.2 fold) compared to CON.

**CONCLUSIONS:** These data confirm the negative influence of HFD consumption on breast cancer in a transgenic mouse model and further provide evidence of a relationship between HFD and pro-tumoral factors related to tumor associated macrophages, angiogenesis and inflammation within the tumor microenvironment.

**Role of Ginseng extracts on Inflammatory Makers in the Adipose Tissue of Exhaustive Exercised Rats**

Yu-Yu Kao<sup>1</sup>, Hsien-Tang Lin<sup>1</sup>, Ming-Fen Hsu<sup>1</sup>, Feng-Chih Hsu<sup>2</sup>, Mallikarjuna Korivi<sup>1</sup>. <sup>1</sup>Taipei Physical Education College, Taipei, Taiwan. <sup>2</sup>National Taoyuan Agricultural & Industrial Vocational High School, Taoyuan, Taiwan. (Sponsor: Kuo Chia-Hua, FACSM)  
(No relationships reported)

**PURPOSE:** The present study was purposed to investigate the effect of ginseng extracts (Dammarane Oligo-Saponins, DS) against exhaustive exercise-induced changes in inflammatory markers in the adipose tissue of rat.

**METHODS:** Sprague Dawley rats (n=80) were divided into 4 groups: placebo (0.9% saline), DS (0.1 mg/kg bodyweight), DS20 (20 mg/kg b.w.), DS60 (60 mg/kg b.w.) and DS120 (120 mg/kg b.w.), and treated with respective doses of DS for 10 weeks. After the last dose half number of rats from each group (n=10) performed exhaustive exercise, and epididymal fat was collected immediately after exercise. mRNA levels of inflammatory makers including interleukin-1 $\beta$  (IL-1 $\beta$ ), IL-6, IL-10, tumor necrosis factor- $\alpha$  (TNF- $\alpha$ ), leptin and adiponectin were analyzed.

**RESULTS:** Exhaustive exercise significantly increased the mRNA levels of IL-10, leptin and adiponectin in placebo group compared to non-exercise rats. In contrast, IL-1 $\beta$  and IL-6 mRNA expressions were down-regulated, while, TNF- $\alpha$  mRNA was not significantly changed after exhaustive exercise. Interestingly, exercise-induced elevated IL-10 mRNA expression was significantly decreased in DS-treated groups with all doses.

**CONCLUSIONS:** Findings from this study concludes that oral administration of DS (20 mg/kg) may control the exhaustive exercise-induced inflammation. This study also suggests that high dosage (120 mg/kg) may have negative impact on inflammatory system.

**The Effect of Living High Training Low on Skeletal Muscular UPP and Protein Catabolism**

Ming Ye<sup>1</sup>, Junping Li<sup>2</sup>, Dongdong Li<sup>1</sup>, Zhen Ni<sup>2</sup>. <sup>1</sup>Capital University of Physical Education and Sports, Beijing, China. <sup>2</sup>Beijing Sports University, Beijing, China.  
(No relationships reported)

Previous researches showed that hypoxia can promote skeletal muscular protein degradation, the Ubiquitin-Proteasome Pathway (UPP) plays an important role in protein catabolism. Ubiquitin ligases Muscle ring finger 1 (Murf-1) and Muscle Atrophy F-box (MAFbx) can be regarded as markers of skeletal muscular protein degradation and UPP.

**PURPOSE:** To study the possible mechanism and influence of living high training low on skeletal muscular UPP and protein degradation.

**METHODS:** 160 Male SD rats were divided into 4 groups randomly: control group(C), normal exercise group(E), hypoxic group (H) and living high training low group(HiLo). Each group was divided into 1, 7, 14 and 28 days group. C group lived under normoxic circumstance; H group was exposed to normal pressure hypoxia for 10h/d, oxygen concentration was 13.6%; E group was performed treadmill exercise of 20m/min, 1h/d; the HiLo group's hypoxia exposure and exercise mode were as the same as H and E respectively. Murf-1 and MAFbx were tested by Q-T PCR, protein ubiquitination was tested by Western Blotting, 3-methylhistidine(3-MH) and corticosterone were tested by HPLC and ELISA respectively.

**RESULTS:** (1) Compared with C, Murf-1 mRNA of E, H and HiLo on the 1st day, Murf-1 mRNA of HiLo on the 7th day and Murf-1 mRNA of E, H and HiLo on the 14th and 28th day all increased (all P<0.05). (2) The change of skeletal muscular MAFbx mRNA was nearly the same as Murf-1 mRNA. (3) Protein ubiquitination of the E, H and HiLo at first increased and then decreased, and they increased on the 7th day, then decreased gradually, on the 14th day they declined as the same level of the 1st day. (4) Compared with C, 3-MH of H on the 14th day and 3-MH of E on the 28th day increased (all P<0.05), and 3-MH of HiLo on the 28th day increased (P<0.01). (5) Compared with C, the corticosterone of E, H and HiLo increased on the 1st day (all P<0.05), and they increased on the 7th, 14th, and 28th day too (all P<0.01).

**CONCLUSIONS:** Living high training low perhaps promotes the secretion of corticosterone significantly, which activates UPP and increases skeletal muscular protein ubiquitination, Murf-1 mRNA and MAFbx mRNA, which increase skeletal muscular protein degradation and 3-MH obviously. It shows that living high training low can activate UPP and enhance protein catabolism. Supported by KM200910029002.

**Heat and Hypoxia Cause Additive Increases in Heat Shock Protein 72 During Submaximal Exercise**

Douglas M. Jones<sup>1</sup>, Mia S. Green<sup>2</sup>, Jay H. Heaney<sup>1</sup>, Michael J. Buono, FACSM<sup>2</sup>. <sup>1</sup>Naval Health Research Center, San Diego, CA. <sup>2</sup>San Diego State University, San Diego, CA.  
(No relationships reported)

Individual stressors such as exercise, heat, and hypoxia have been shown to increase the plasma concentration of heat shock protein 72 (HSP 72). However, it is unclear how HSP 72 and other physiological markers of stress respond to the simultaneous combination of stressors.

**PURPOSE:** It has been proposed that both heat and hypoxia share the same induction pathway for HSP 72 expression. If this is true, then it could be hypothesized that combining both heat and hypoxia would have an additive effect on HSP 72 expression during submaximal exercise.

**METHODS:** Twelve healthy subjects completed 60-minute trials of moderate-intensity exercise (40% of maximal oxygen consumption) on a treadmill while exposed to four different environmental conditions: (1) 23°C, 20.9% O<sub>2</sub>, (2) 35°C, 20.9% O<sub>2</sub>, (3) 23°C, 16.5% O<sub>2</sub>, and (4) 35°C, 16.5% O<sub>2</sub>. Measurements of heart rate, core temperature, and perceived exertion were obtained throughout each trial. Postexercise blood samples were collected and analyzed for norepinephrine, epinephrine, and HSP 72.

**RESULTS:** Results showed that combining heat and hypoxia during submaximal exercise significantly increased systemic stress compared with similar intensity exercise in heat or hypoxia alone. This is evidenced by the fact that exercise in the combined heat and hypoxic environment caused significantly (P < 0.05) greater increases in heart rate, perceived exertion, and plasma norepinephrine concentration compared with exercise in heat or hypoxia alone. More importantly, combining the stressors of heat and hypoxia during submaximal exercise resulted in significantly (P < 0.05) greater plasma HSP 72 concentrations (17  $\pm$  6 ng/ml) compared with the other three trials, all of which had means of approximately 6  $\pm$  2 ng/ml.

**CONCLUSION:** Such data suggest that heat and hypoxia cause an additive increase in HSP 72 expression during submaximal exercise. By increasing HSP 72 using multiple stressors, the amount of cellular damage resulting from subsequent stressful environmental exposure may be reduced.

**Increases in Heart Rate and RPE Are Additive During Prolonged Exercise in Heat and Hypoxia**

Michael J. Buono, FACSM<sup>1</sup>, Mia Green<sup>1</sup>, Doug Jones<sup>1</sup>, Jay H. Heaney<sup>2</sup>. <sup>1</sup>San Diego State University, San Diego, CA. <sup>2</sup>Naval Health Research Center, San Diego, CA.  
(No relationships reported)

**PURPOSE:** To investigate the effects of a combined heat and hypoxic environment on HR and RPE during prolonged exercise.

**METHODS:** Twelve subjects completed 1 h trials of moderate-intensity exercise on a treadmill while exposed to four different environmental conditions: (1) 23°C, 20.9% O<sub>2</sub>, (2) 35°C, 20.9% O<sub>2</sub>, (3) 23°C, 16.5% O<sub>2</sub>, and (4) 35°C, 16.5% O<sub>2</sub>. HR, RPE, core temperature, and arterial oxygen saturation were measured every 5 minutes during the trials.

---

**RESULTS:** The mean±SD end-exercise HR was 108±10, 125±19, 116±13, and 133±17 bpm for the four conditions. Thus, compared with the control condition (23°C, 20.9% O<sub>2</sub>) heat alone increased HR 17 bpm, hypoxia alone increased HR 8 bpm, while heat+hypoxia increased HR 25 bpm. Likewise, end-exercise RPE was 9.8±1.5, 10.8±2.0, 10.4±1.6, and 11.6±2.1 for the four conditions, respectively. Thus, compared with the control condition, heat alone increased RPE 1.0 units, hypoxia alone increased RPE 0.6 units, while heat+hypoxia increased RPE 1.8 units. The mean arterial oxygen saturation was 96% during the two normoxic trials and 93% ( $P < 0.05$ ) during the two hypoxic trials. The mean end-exercise core temperature ranged between 37.7 and 37.9°C and was not significantly different for the four trials.

**CONCLUSIONS:** The results of the current study strongly suggest that the separate heat- and hypoxia-induced augmentations in HR and RPE during prolonged exercise are additive when the two stressors are combined. The additive effects were apparent even though there was no difference in core body temperature between the four conditions, suggesting that hyperthermia was not the mediating factor. The heat stress and degree of hypoxia used in the study were moderate and equal to what many athletes and military personnel experience on a regular basis. Thus, the practical applications of the current findings are widespread.

**2913** Board #185 June 1 9:30 AM - 11:00 AM  
**Impact Of Varying Levels Of Simulated Altitude On Balance**

James Schoffstall, Melissa Gogain, Taylor Clay. *Liberty University, Lynchburg, VA.* (Sponsor: Mel Williams, FACSM)  
(No relationships reported)

**PURPOSE:** The purpose of this study was to examine the effect of exposure to varying levels of simulated altitude on static and dynamic balance.

**METHODS:** Twenty subjects (9 males and 11 females; age: 21.2 ± .8 yrs) performed a static and dynamic balance test using a Biodex Balance System SD at various levels of simulated altitude [base 260 m (20.9% O<sub>2</sub>); 1500 m (17.2% O<sub>2</sub>); 3000 m (14.2% O<sub>2</sub>); 4500 m (11.8% O<sub>2</sub>); and 6000 m (9.8% O<sub>2</sub>)]. Altitude was simulated by creating a hypoxic environment using two Higher Peak hypoxic air generators feeding into a large 2-way valve attached to a V2 Mask. Statistical significance was determined through the use of repeated measures ANOVA, with post hoc pairwise comparisons.

**RESULTS:** The SpO<sub>2</sub> (%) levels were significantly different ( $p < 0.05$ ) among the assessed simulated altitudes: base (98%), 1500m (96%), 3000m (89%), 4500m (83%), and 6000m (75%). The subjects' HRs (bpm) were significantly different ( $p < 0.05$ ) among the assessed simulated altitudes: base (77 bpm), 1500m (84 bpm), 3000m (87bpm), 4500m (95 bpm), and 6000m (106 bpm). A significant difference ( $p < 0.05$ ) was noted in the static postural stability test between the 1500m level and the 6000m level for the overall score, and the anterior/posterior score. While significant differences were not observed between any of the other trials, the data demonstrated a trend for an increasingly poor balance score with higher altitudes. During the limits of stability dynamic balance test no significant differences were noted for either total time to completion or score. During the 6000m trial, 7 of the 20 subjects were unable to complete the testing due to abnormalities (headache, dizziness, nausea, or other signs of distress). A significant difference for SpO<sub>2</sub> existed between the subjects who were (77%) and were not (69%) able to complete the 6000m trial.

**CONCLUSIONS:** Based on the results of this study extreme simulated altitudes (6000m) can have a negative impact on static balance, which is not seen at lower simulated altitudes (1500 to 4500m).

This study was supported by funds from The Center for Research and Scholarship Fund of Liberty University.

**Impact of Hypoxia on Metabolic Gene Expression**

Dustin Slivka<sup>1</sup>, Matt Heesch<sup>1</sup>, Charles Dumke, FACSM<sup>2</sup>, John Cuddy<sup>2</sup>, Walter Hailes<sup>2</sup>, Brent Ruby, FACSM<sup>2</sup>. <sup>1</sup>University of Nebraska at Omaha, Omaha, NE. <sup>2</sup>University of Montana, Missoula, MT.  
(No relationships reported)

Hypoxia may be a potent stimulator for metabolic adaptation. However, the metabolic mechanism is not well characterized.

**PURPOSE:** To determine the impact of acute hypoxia on the expression of genes associated with anaerobic and aerobic metabolism after exercise.

**METHODS:** Twelve recreationally trained males (age 23.8 ± 3.8 y, mass 81.6 ± 11.6 kg, body fat 14.6 ± 7%, VO<sub>2</sub> peak 4.03 ± 0.60 L·min<sup>-1</sup>) exercised at an absolute workload associated with 60% VO<sub>2</sub> peak (158 ± 23 watts) in an altitude chamber that simulated the hypoxia associated with altitudes of 975 m (LOW) and 3000 m (HIGH) in a randomized order. Skeletal muscle biopsies were obtained from the vastus lateralis before exercise and after 4 hours of recovery. Gene expression was measured using real-time RT PCR and expressed using the  $\Delta\Delta$  CT method.

**RESULTS:** VO<sub>2</sub> was not different during exercise between LOW and HIGH (2.43 ± 0.56 L·min<sup>-1</sup> and 2.42 ± 0.35 L·min<sup>-1</sup>, respectively). Blood oxygen saturation was similar before each trial (LOW, 97.5 ± 0.9 %; HIGH, 97.7 ± 1.3 %) but was higher in LOW than HIGH during exercise ( $p < 0.05$ ; 97.0 ± 0.8 % and 91.1 ± 1.5 %, respectively) and recovery ( $p < 0.05$ ; 98.0 ± 0.5 % and 94.3 ± 1.4 %, respectively). Muscle glycogen reduced as a result of exercise ( $p < 0.05$ ) but was not different between trials. There were no differences between trials for COX, HIF, PGC1, FIS, MFN, OPA, HK or PFK ( $p > 0.05$ ) gene expression. However, COX, HIF, PGC1, FIS, MFN, HK and PFK increased as a result of exercise regardless of trial ( $p < 0.05$ ) while OPA did not.

**CONCLUSIONS:** These data indicate no differences in select metabolic gene expression between acute exercise at 975 m and 3000 m when absolute intensity is held constant despite differences in blood oxygen saturation.

**Effect Of 1-week Altitude Exposure On Circulating Stress Hormones In Male College Student**

Shu-Yun Lu<sup>1</sup>, Mei-Chih Chen<sup>2</sup>, Feng-Chih Hsu<sup>3</sup>, Ching-Hung Lin<sup>4</sup>. <sup>1</sup>National Tsing Hua University, Hsinchu, Taiwan. <sup>2</sup>Taipei Physical Education College, Taipei, Taiwan. <sup>3</sup>National Taoyuan Agricultural & Industrial Vocational High School, Taoyuan, Taiwan. <sup>4</sup>Yuan Ze university, Taoyuan, Taiwan. (Sponsor: Chia-Hua Kuo, FACSM)  
(No relationships reported)

**PURPOSE:** The purpose of this study was to investigate the effect of one week altitude physical activity on stress hormones in male subjects.

**METHODS:** Thirteen men (age: 17±1 years) were voluntarily participated in this study. All of the subjects lived at 1850 m high altitude level for one week. Circulating dehydroepiandrosterone sulfate (DHEA-S) testosterone, cortisol levels and white blood cell (WBC) were measured before, after and 1 week after altitude physical activity.

**RESULTS:** Our data shown the DHEA-S level was significantly increased 1-week after altitude exposure compared to before and after altitude physical activity. No significant difference in testosterone level was noticed before and after altitude physical activity. The cortisol level was significantly decreased after and 1-week later of altitude exposure compared to before altitude physical activity. We also found the number of WBC was significantly increased after and 1-week later altitude physical activity compared to baseline WBC count.

**CONCLUSIONS:** The results of the present study conclude that one week altitude physical activity can bring adaptation to stress and may improve health status by increasing the DHEA-S and decreasing the cortisol concentrations in men.

**Upland Indigenous in Taiwan may Have Better Anti-oxidative Capability in Response to Endurance Exercise at Altitude**

Jung-Chang Lin<sup>1</sup>, Sha Pu Lu Bi<sup>1</sup>, Chia-Chih Lin<sup>2</sup>, Yi-Ting Pan<sup>2</sup>, Yi-Tzu Lin<sup>2</sup>, Shih-Ling Chen<sup>3</sup>. <sup>1</sup>Chinese Culture University, Taipei, Taiwan. <sup>2</sup>National Dong Hwa University, Hualin, Taiwan. <sup>3</sup>Central Region Office, Ministry of Education, Taichung, Taiwan.  
(No relationships reported)

**PURPOSE:** To study anti-oxidative capability of upland indigenous (Atayal tribe) in Taiwan in response to endurance exercise at altitude.

**METHODS:** Fourteen (8 males and 6 females) Atayal tribe (ATA) and 18 (10 males and 8 females) Han race (HAN), who lived in sea level (age:  $19.8 \pm 1.2$  yrs vs.  $20.4 \pm 0.9$  yrs, height:  $168.9 \pm 8.8$  cm vs.  $163.4 \pm 6.4$  cm, weight:  $65.3 \pm 15.2$  kg vs.  $56.1 \pm 8.4$  kg,  $\text{VO}_2$  peak:  $36.7 \pm 8.4$  ml/min/kg vs.  $41.5 \pm 7.0$  ml/min/kg, peak power:  $180 \pm 56.7$  watts vs.  $172.1 \pm 26.2$  watts), were exposed to 2,400 m of altitude (ALT) or sea level (SEL), and stressed by ergometer exercise (70-75%  $\text{VO}_2$  peak 45 min + 90%  $\text{VO}_2$  peak to exhaustion). Plasma indicators showing oxidative damage in time courses (resting, immediately after, post 10 min, post 60 min, post 120 min and post 240 min of exercise) were analyzed. Repeated measures of ANOVA were used and the statistical significance was set at  $p < .05$ .

**RESULTS:** Main effects showed that significantly lower thiobarbituric acid reactive substance (TBARS) levels in ATA than in HAN in both environments (SEL: ATA vs. HAN  $7.68 \pm 0.67$   $\mu\text{M}$  vs.  $9.70 \pm 0.90$   $\mu\text{M}$ ; ALT: ATA vs. HAN  $8.31 \pm 0.89$   $\mu\text{M}$  vs.  $10.07 \pm 0.74$   $\mu\text{M}$ ,  $p < .05$ ), and so was glutathione peroxidase activity (SEL: ATA vs. HAN  $60.70 \pm 7.29$  U/mL vs.  $89.24 \pm 11.64$  U/mL; ALT: ATA vs. HAN  $57.98 \pm 6.59$  U/mL vs.  $79.35 \pm 10.67$  U/mL,  $p < .05$ ) and lactate values (SEL: ATA vs. HAN  $2.30 \pm 0.26$  mM vs.  $3.18 \pm 0.31$  mM; ALT: ATA vs. HAN  $2.74 \pm 0.27$  mM vs.  $3.48 \pm 0.29$  mM,  $p < .05$ ). However, TGS/GSSG values were higher in ATA than in HAN (SEL: ATA vs. HAN  $0.14 \pm 0.01$  vs.  $0.12 \pm 0.01$ ; ALT: ATA vs. HAN  $0.14 \pm 0.01$  vs.  $0.12 \pm 0.01$ ,  $p < .05$ ). There were no differences between ATA and HAN in other indicators including carbonyl proteins, superoxide dismutase and catalase activities, nitric oxide, creatine kinase activity.

**CONCLUSION:** Atayal tribe seems to have better capability of anti-lipid peroxidation in response to endurance exercise at altitude and may correlate with stronger non-enzymatic antioxidant capability.

Supported by Taiwan NSC grants 99-2410-H-034-055.

**2917 Board #189 June 1 9:30 AM - 11:00 AM**  
**Contribution Of Oxygen Cost Of Breathing To Changes In Running Economy After Altitude Training**

Jonathon L. Stickford, Abigail S. Laymon, Daniel P. Wilhite, Joseph W. Duke, Robert F. Chapman, FACSM, *Indiana University, Bloomington, IN.*  
(No relationships reported)

Several studies have documented improvements in running economy following altitude training in elite runners, but the underlying mechanism remains elusive. It has been theorized that the hypoxic stimulus and resulting added ventilation encountered during chronic hypoxic exposure may improve the oxygen cost of breathing upon return to sea level.

**PURPOSE:** To examine the extent to which possible changes in running economy after altitude training can be explained by changes in respiratory muscle oxygen consumption.

**METHODS:** Six elite male distance runners completed a 28-d altitude training intervention at 2150m following a "Live High - Train Low" training model. Prior to altitude ascension, running economy was examined by measuring submaximal oxygen uptake ( $\text{VO}_2$ ) and ventilation ( $\text{V}_E$ ) while running at 16, 18, and 20  $\text{km}\cdot\text{h}^{-1}$  on a treadmill at sea level. The following day, runners performed a eucapnic voluntary hyperpnea test mimicking the same levels of  $\text{V}_E$ , breathing frequencies, and tidal volumes observed during the previous day's running economy test for the determination of respiratory muscle  $\text{VO}_2$  ( $\text{VO}_{2\text{RM}}$ ). The same tests were performed on days 1 and 2 following return from altitude.

**RESULTS:** Running  $\text{VO}_2$  decreased ( $p < .05$ ) at every speed upon return from altitude compared to pre-altitude levels. The change in  $\text{VO}_2$  from pre-to post-altitude was  $0.38 \pm 0.12$   $\text{L}\cdot\text{min}^{-1}$ ,  $0.38 \pm 0.12$   $\text{L}\cdot\text{min}^{-1}$ , and  $0.50 \pm 0.09$   $\text{L}\cdot\text{min}^{-1}$  at 16, 18, and 20  $\text{km}\cdot\text{h}^{-1}$ , respectively. The changes corresponded to a decrease of  $11.0 \pm 3.3\%$ ,  $9.9 \pm 3.0\%$ , and  $11.7 \pm 1.9\%$  from pre-altitude  $\text{VO}_2$  measurements at 16, 18, and 20  $\text{km}\cdot\text{h}^{-1}$ , respectively. No changes from pre- to post-altitude were observed in  $\text{V}_E$  at any speed. Though  $\text{VO}_{2\text{RM}}$  remained unchanged following the altitude training period, mean values trended lower post-altitude. The change in  $\text{VO}_{2\text{RM}}$  accounted for 23.4%, 25.0%, and 27.5% of the improvement in running economy at 16, 18, and 20  $\text{km}\cdot\text{h}^{-1}$ , respectively.

**CONCLUSIONS:** Decreases in the oxygen cost of breathing accounts for approximately one-quarter of the improvement in running economy in elite distance runners after altitude training. The data suggests that the added ventilation with chronic training at altitude acts as an additional training effect for the respiratory musculature, which may contribute to altitude training-mediated performance improvements.

---

**2918 Board #190 June 1 9:30 AM - 11:00 AM**  
**Expiratory Flow Limitation Mitigates Increases In Exercise Ventilation In Elite Distance Runners After Altitude Training.**

Joseph W. Duke<sup>1</sup>, Jonathon L. Stickford<sup>1</sup>, Abigail S. Laymon<sup>1</sup>, Daniel P. Wilhite<sup>1</sup>, Timothy D. Mickleborough, FACSM<sup>1</sup>, Joel M. Stager<sup>1</sup>, James Stray-Gundersen, FACSM<sup>2</sup>, Benjamin D. Levine, FACSM<sup>2</sup>, Robert F. Chapman, FACSM<sup>1</sup>. <sup>1</sup>*Indiana University, Bloomington, IN.* <sup>2</sup>*Institute of Exercise and Environmental Medicine, Dallas, TX.*  
(No relationships reported)

Ventilatory acclimatization with chronic exposure to altitude typically results in a gain in the ventilatory response to exercise at any workload. However, a large proportion of elite endurance athletes demonstrate expiratory flow limitation (EFL) during heavy exercise and are thus mechanically constrained from increasing exercise ventilation ( $\text{VE}$ ) at high workloads. Whether EFL mitigates increases in  $\text{VE}$  at sea level, after chronic acclimatization to altitude, is unknown.

**PURPOSE:** To determine if the extent of EFL affects changes in  $\text{VE}$  from pre- to post-altitude in elite distance runners.

**METHODS:** Seventeen elite male distance runners were categorized into flow limited (FL;  $n = 9$ ) and non-flow limited (NFL;  $n = 8$ ) groups based on the percent of the tidal flow-volume loop that met the maximal flow-volume envelope during the final minute of a maximal graded exercise test at sea level (FL =  $51.5 \pm 4.8\%$ ; NFL =  $0\%$ ). Subjects completed 28d of training at moderate altitude (2,150m or 2,500m) using the "Live High-Train Low" model. Prior to and immediately upon return from altitude, subjects performed a maximal graded exercise test to quantify  $\text{VE}$  and maximal oxygen uptake ( $\text{VO}_{2\text{max}}$ ). Isocapnic hypoxic ventilatory response (HVR) was measured pre- and post-altitude. Statistical significance was accepted when  $p < 0.05$ .

**RESULTS:** HVR significantly increased in both FL and NFL after altitude training, demonstrating augmented ventilatory chemoresponsiveness. After altitude training, NFL significantly increased  $\text{VE}$  at 80% ( $107 \pm 5$  vs  $116 \pm 5$   $\text{L}\cdot\text{min}^{-1}$ ), 90% ( $135 \pm 8$  vs  $145 \pm 8$   $\text{L}\cdot\text{min}^{-1}$ ), and 100% ( $165 \pm 10$  vs  $184 \pm 9$   $\text{L}\cdot\text{min}^{-1}$ ) of  $\text{VO}_{2\text{max}}$ . However  $\text{VE}$  did not change in FL after altitude training at 80% ( $103 \pm 2$  vs  $103 \pm 4$   $\text{L}\cdot\text{min}^{-1}$ ), 90% ( $121 \pm 5$  vs  $127 \pm 4$   $\text{L}\cdot\text{min}^{-1}$ ), or 100% ( $161 \pm 6$  vs  $160 \pm 7$   $\text{L}\cdot\text{min}^{-1}$ ) of  $\text{VO}_{2\text{max}}$ . FL did not increase  $\text{VO}_{2\text{max}}$  ( $77.1 \pm 1.5$  vs  $77.7 \pm 1.1$   $\text{mL}\cdot\text{kg}^{-1}\cdot\text{min}^{-1}$ ) from pre- to post-altitude, whereas NFL demonstrated a significant increase ( $75.5 \pm 1.6$  vs  $79.8 \pm 1.3$   $\text{mL}\cdot\text{kg}^{-1}\cdot\text{min}^{-1}$ ).

**CONCLUSIONS:** Despite similar increases in ventilatory chemoresponsiveness in both groups, FL did not increase  $\text{VE}$  at any workload following altitude training. This is likely due to mechanical constraints imposed by expiratory flow limitation, which may hold implications for training and exercise performance during and after altitude training.

**2919 Board #191 June 1 9:30 AM - 11:00 AM**  
**Ventilatory Mechanics During Maximal Exercise after Altitude Training in Elite Distance Runners**

Daniel P. Wilhite, Abigail S. Laymon, Jonathan L. Stickford, Joseph W. Duke, Joel M. Stager, Timothy D. Mickleborough, FACSM, Robert F. Chapman, FACSM, *Indiana University, Bloomington, IN.*  
(No relationships reported)

Ventilatory acclimatization with chronic altitude training typically manifests as an increase in both peripheral chemoreceptor sensitivity and exercise ventilation ( $\text{VE}$ ). However, many elite distance runners experience mechanical limitations to  $\text{VE}$  at high work rates, affecting operational lung volumes. How ventilatory acclimatization affects ventilatory mechanics after altitude training has not yet been characterized.

**PURPOSE:** To determine the effect of 28 days of 'live high-train low' (LHTL) altitude training on measures of ventilatory mechanics during exercise in a group of elite distance runners.

**METHODS:** Six elite male distance runners ( $\text{VO}_{2\text{max}} = 79.5$  ml/kg/min) completed a 28 d LHTL altitude training intervention at 2150m. All testing procedures took place in the week prior to departure, and again 1-2 d after returning to sea-level. For each session, subjects completed an isocapnic hypoxic ventilatory response (HVR) test, followed by a graded treadmill exercise test to exhaustion.  $\text{VE}$ , tidal volume, breathing frequency, degree of expiratory flow-limitation (EFL), end-expiratory lung volume, end-inspiratory lung volume, and duty cycle were measured during the last minute of the maximal exercise test. Subjects with 50% or more EFL were considered flow-limited.

**RESULTS:** During maximal exercise, 5 of the 6 subjects were flow-limited ( $59 \pm 7\%$ ). From pre- to post-altitude training, the HVR slope significantly increased ( $p < .05$ ) from 0.34 to 0.75  $\text{L}/\text{min}/\%\text{SaO}_2$ , indicating an increase in ventilatory chemoresponsiveness. However, there was no significant change ( $p > .05$ ) in  $\text{VE}$  from pre- to post-altitude ( $157.3 \pm 11.1$  to  $158.7 \pm 16.8$   $\text{L}/\text{min}$ ). Additionally, there were no significant changes ( $p > .05$ ) in lung volumes or values for variables describing ventilatory mechanics after altitude training.

**CONCLUSIONS:** The inability of altitude-mediated ventilatory acclimatization to manifest as an increase in  $\text{VE}$  during maximal exercise in the elite runners is likely due to the high number of flow-limited subjects in our sample. The absence of a change in operational lung volumes, despite a strong increase in ventilatory chemoresponsiveness, may reflect a balance between a mechanical limitation to expiratory flow production at lower lung volumes and the minimization of inspiratory muscle work at higher lung volumes.

2920 Board #192 June 1 9:30 AM - 11:00 AM

**Effect Of Altitude Training At 1800m For Four Days On Ventilatory Chemosensitivity**

Takahide Kato<sup>1</sup>, Masataka Nakano<sup>2</sup>, Takamasa Mizuno<sup>3</sup>, Toshiyuki Ohya<sup>3</sup>, Takaaki Matsumoto<sup>3</sup>. <sup>1</sup>Toyota National College of Technology, Toyota, Japan. <sup>2</sup>Aichi Toho University, Nagoya, Japan. <sup>3</sup>Chukyo University, Toyota, Japan. (Sponsor: Kaoru Kitagawa, FACSM)  
(No relationships reported)

Chronic high altitude exposure leads to an increase in hypoxic ventilatory response (HVR), as an index of the ventilatory chemosensitivity to hypoxia. Moreover, recent study has shown that HVR increased after three nights in hypoxic exposure at 2650m. In Japan, most of altitude training is performed in 2000m or less. However, no study has been made to clarify the changes in ventilatory chemosensitivity for short-term exposure at an altitude of less than 2000m. Two nights in hypoxic exposure at 1800m elevated ventilation during exercise, although this experiment did not show the changes in HVR2). Therefore, we hypothesized that short-term exposure at an altitude of less than 2000m may increase HVR. It is expected that to clarify the hypothesis will provide a novel impact on Japanese altitude training.

**PURPOSE:** In field work, the purpose of this study was to investigate the effect of altitude training with short-term exposure at 1800m on ventilatory chemosensitivity.

**METHODS:** Five males and one female student endurance runners (mean age = 16.5 ± 1.0 years) participated in this study. Subjects carried out altitude training at 1800m for four days including three nights in a row. In order to estimate a changes in ventilatory chemosensitivity, HVR and hypercapnic ventilatory response (HCVR) were measured three times in each subject; 1) before altitude training (Pre) ; 2) after altitude training (Post); 3) one week after the cessation of altitude training (De).

**RESULTS:** HVR increased after altitude training (0.259 ± 0.093 l/min/% Pre, 0.544 ± 0.306 l/min/% Post, 0.370 ± 0.242 l/min/% De) (P< 0.05). HCVR didn't change after altitude training (1.408 ± 0.575 l/min/torr Pre, 1.672 ± 0.408 l/min/torr Post, 1.637 ± 0.391 l/min/torr De).

**CONCLUSION:** These results show that altitude training at 1800m for four days raise hypoxic chemosensitivity, but not affect hypercapnic chemosensitivity.

**When Posture is Controlled, Acute Hypoxia does not Decrease Core Temperature**

Kayli Dalton, Viktoria Brautigam, Michael J. Buono, FACSM. San Diego State University, San Diego, CA.

(No relationships reported)

It has been reported that acute hypoxia causes a reduction in core temperature in humans. It was hypothesized that this occurs due to both a decrease in metabolic rate and an increase in skin blood flow. However, other studies have found that core temperature decreases with changes in posture. The methods in previous studies finding hypoxia to decrease core temperature did not control for postural changes.

**PURPOSE:** Thus, further examination is warranted to examine the effect of hypoxia on core temperature while controlling for posture change.

**METHODS:** Ten healthy adults, between the ages of 18 and 45 were recruited to participate. Subjects completed one trial consisting of breathing normoxic air (20.9%) for a 2 hour period and hypoxic air for a 1 hour period, while systematically changing posture. During this time core temperature and skin blood flow were recorded every 5 minutes.

**RESULTS:** Mean core body temperature significantly (p < 0.05) decreased by 0.4 °C when the subjects transitioned from a standing to lying position. However, acute hypoxia, which reduced the mean oxygen saturation to 85%, did not significantly affect core temperature.

**CONCLUSION:** Such results suggest that when posture is controlled, acute hypoxia does not significantly decrease core body temperature. Thus, the results of previous studies that have reported decreases in core temperature with acute hypoxia, but failed to control for posture, need to be questioned.

**Effect of Acute Hypoxia on Exercise-Induced Blood Oxidative Stress**

Graham R. McGinnis<sup>1</sup>, Brian Kliszczewicz<sup>1</sup>, Matthew Barberio<sup>1</sup>, Christopher Ballmann<sup>1</sup>, Bridget Peters<sup>1</sup>, John Cuddy<sup>2</sup>, Dustin Slivka<sup>3</sup>, Charles Dumke, FACSM<sup>2</sup>, Brent Ruby, FACSM<sup>2</sup>, John Quindry, FACSM<sup>1</sup>. <sup>1</sup>Auburn University, Auburn, AL. <sup>2</sup>University of Montana, Missoula, MT. <sup>3</sup>University of Nebraska, Omaha, NE.

(No relationships reported)

Hypoxia has been characterized by decrement in exercise performance or decreased maximal workload. Exercise and exposure to altitude have been shown to elicit cellular hypoxia independently and combined. Similarly, these stimuli also elicit perturbations in redox balance.

**PURPOSE:** The purpose of this study was to examine the effect of hypobaric chamber-simulated-hypoxia on exercise induced blood oxidative stress at variable relative intensities.

**METHODS:** Physically active males (n=12) completed 2 graded exercise tests on an electronically braked cycle ergometer starting at 95 W, increasing 35 W every 3 min until volitional fatigue or cadence < 50 rpm. VO<sub>2</sub>peak and Wmax were measured at low altitude (975m, "lowALT") and high altitude (3000m, "highALT") simulated in a hypobaric chamber. Wmax at both altitudes was used to program workloads for subsequent trials. In a randomized counterbalanced cross-over design, subjects completed 3, 60 min exercise bouts at combinations of lowALT or highALT at workloads corresponding to 60 percent VO<sub>2</sub>peak measured at 975m or 3000m (lowINT and highINT, respectively). The conditions were paired: lowALT:highINT, lowALT:lowINT, and highALT:lowINT. Subjects remained in the ambient altitude for 4 hr recovery. Blood was drawn from the antecubital vein pre-, 0, 2 and 4 hours post exercise and analyzed for biochemical markers of oxidative stress. Samples were assayed for Ferric Reducing Ability of Plasma (FRAP), Trolox Equivalent Antioxidant Capacity (TEAC), Lipid Hydroperoxides (LOOH) and Protein Carbonyls (PCs). Results were adjusted for plasma volume shift and were analyzed with repeated measures ANOVA, significance set at p < 0.05.

**RESULTS:** LOOH were elevated in highALT:lowINT group immediately post and 2HR post. highALT:lowINT was significantly elevated from lowALT:highINT at 2HR post. Main effects were seen in FRAP (for TRIAL, lowALT:highINT vs. lowALT:lowINT), PCs (for TIME), LOOH (for TRIAL and TIME) and TEAC (for TIME).

**CONCLUSIONS:** These results suggest that acute hypoxia induced by hypobaric elevation increases the oxidative stress response during exercise. Funded by USAMR&MC #W81XWH-10-2-0120 to B Ruby

**Health-Related Fitness Program, Health Content Knowledge and Physical Activity Levels in Elementary School Students, Taiwan**

Mei-Yao Huang<sup>1</sup>, Chun-Chieh Kao<sup>2</sup>, Chien-Chih Chou<sup>3</sup>. <sup>1</sup>National Taiwan Sport University, TauYao, Taiwan. <sup>2</sup>Ming Chuan University, TauYao, Taiwan. <sup>3</sup>Taipei Physical Education College, Taipei, Taiwan.

(No relationships reported)

One area of major concern related to physical inactivity is the rapid increase in obesity among child and adolescent. According to the United Nations (2011), 26.8 percent of children in Taiwan between the ages of 6-12 are obese - the highest number in Asia. This trend is of particular concern because obesity has been identified as a key determinant of cardiovascular risk in the adult population.

**PURPOSE:** The purpose of this study was to determine whether or not the Hart Power educational curriculum affected the health content knowledge and physical activity levels of elementary children.

**METHODS:** Two certified elementary physical education teachers and their students (n= 180) at two different schools in Taiwan participated in the study. One teacher and school were involved as a treatment group and received the health-related fitness program for ten weeks which was adapted from American Heart Association's Heart Power educational curriculum that is a descendant of the Heart RX Program developed in 1985. The other used as a comparable group and receive a traditional physical education. The Heart Health Cognitive Test (HHCT) was used to assess knowledge change in pre-test, post-test, and follow-up test. The System of Observing Fitness Instruction Time (SOFIT) was used to determine student's activity levels.

**RESULTS:** The results indicate a) students who received the health-related fitness program were more knowledgeable than the students who did not received; b) For the physical activity levels, no statistically significant difference was found between two groups.

**CONCLUSION:** Physical education is a class in which children should be able to reach recommended amounts of physical activity for a healthier lifestyle. Teachers may need to modify existing strategies and curriculum models to assist students to be physically active as recommended for that healthy lifestyle. It is unknown how the Healthy People 2012 objectives will impact physical education, but many policy makers now are aware of the benefits of regular physical activity. Meanwhile, if schools are to carry the major responsibility for activity promotion for youth, changes will need to be made. These changes could increase the frequency and length of physical education classes, or provide the after school program to enhance their level of physical activity.

**2924** Board #196 June 1 11:00 AM - 12:30 PM  
**Characteristics Associated With Risk Factor Reduction Following Heart Health Intervention In Urban Teenagers**

Paul S. Fardy, FACSM, Henry Wang, Ann Azzolini. *Queens College, Flushing, NY.*  
(No relationships reported)

Early onset of coronary disease (CD) and risk factors (RF) make a compelling case for school-based intervention. High prevalence of CD and RF in African American and Latino adults illustrates a special need for early intervention in these populations.

**PURPOSE:** To determine characteristics associated with RF reduction in urban teenagers following a school-based heart health program, Physical Activity and Teenage Health (PATH).

**METHODS:** Five hundred thirty-one female and three hundred forty-seven male subjects were tested in three New York City high schools before and following twelve weeks intervention consisting of exercise and health education taught within the schools' physical education curriculum. RF measures included body mass index (BMI), % body fat (BF), systolic (Sp) and diastolic (Dp) blood pressures at rest, total cholesterol, cardiovascular fitness (CVF), habitual physical activity (PA), and cigarette smoking. Pre to post changes were determined by gender for each RF and were divided into four groups according to the magnitude of change: (1) mean to +1sd, (2) +1 to +2sd, (3) mean to -1sd, (4) -1 to -2sd. The following characteristics were then evaluated in relation to magnitude of RF change: SES and pre-intervention BMI, BF, PA, CVF, heart health knowledge, and self perception of health. Means of each characteristic were calculated for each of the four groups on each RF. Mean differences were assessed by ANOVA and Tukey multiple range test.

**RESULTS:** Significant RF reduction ( $P<0.05$ ) was observed for boys and girls in Sp, Dp, BF, BMI and CVF. Magnitude of RF reduction was associated with pre-intervention PA, CVF, BMI and BF.

**CONCLUSION:** Greatest RF reduction was consistently observed in subjects who were least active, least fit, and most overweight. Findings are important in developing intervention program strategies for urban teenagers and illustrate the need for varying teaching methods according to fitness and fatness.

**Impact Of After School Fitness And Mentoring Program On Gpa In Latino Middle School Students.**

Paula E. Papanek, FACSM. *Marquette University, Milwaukee, WI.*  
(No relationships reported)

The Youth Empowered to Succeed program (YES) was designed to provide afterschool fitness and college mentors to assist with homework and as peer educators to Latino middle school students. The original 6<sup>th</sup> grade cohort consisted of a total of 33 students (18 girls and 15 boys) selected from a single charter school at risk for obesity and/or low academic achievement. After 6 quarters (1.5yrs) 28 of the original 33 remain enrolled and actively participating (85%).

**PURPOSE:** To determine the impact of moderate and vigorous daily fitness programing and mentoring on overall academic achievement as indicated by cumulative GPA in Latino middle school students.

**METHODS:** Exercise physiology students developed and implemented daily training protocols with 6 wk macrocycles focusing on aerobic, lower extremity strength, power or cross-training/game-like activities under the guidance of faculty. Training consisted of 1 hour daily/5 days per week with most students participating at least 3 days per week then 1 hour of academic mentoring. Boys and Girls were trained and mentored separately. Training consisted of body weight support, med ball, game simulations, plyometric based programing that emphasized a sense of play including relays. Annual measurements included PACER, sit-ups, curl-ups, broad jump, and hand grip dynamometry to progress programs and provide feedback to individual students. De-identified and coded GPA data was provided by the school and analyzed by ANOVA  $p<0.05$ .

**RESULTS:** Age matched control students (not enrolled in YES) (N=33) demonstrated a progressive and statistically significant drop in cumulative GPA over the 1.5 yr of the study ( $2.66 \pm 1.13$  to  $2.46 \pm 1.17$  mean  $\pm$  stdev) while the YES cohort (N=28) maintained cumulative GPA over the duration ( $2.62 \pm 0.95$  to  $2.77 \pm 0.87$ ).

**CONCLUSION:** A combined fitness and mentoring program by college students completely offset the drop in academic performance in Latino middle school students as measured by GPA. Supported by DHHS/OMH. 1 YEPMP090044-02

**2926** Board #198 June 1 11:00 AM - 12:30 PM  
**Girls Learning Interrelated Techniques Targeting Environmental Risks (GLITTER): Feasibility of a Pilot Obesity Intervention**

Michelle B. Stockton<sup>1</sup>, Barbara S. McClanahan<sup>1</sup>, Tammy Overacker<sup>2</sup>. <sup>1</sup>University of Memphis, Memphis, TN. <sup>2</sup>University of Arkansas, Fayetteville, AR. (Sponsor: Heather Chambliss, FACSM)  
(No relationships reported)

**PURPOSE:** Preadolescent girls are a priority population for obesity prevention efforts. The purpose of this study was to determine the feasibility of a multi-systemic home-based behavioral intervention targeting the prevention of excessive weight gain in girls aged 8-10 years.

**METHODS:** A one-group pre-test/post-test design was used to determine the feasibility and efficacy of a multi-component home-based 12-week intervention targeting obesity in girls. The objective of the intervention was to determine how obesity made sense for each girl by systematically evaluating the socioecologic factors that influence body mass index (BMI), diet, and physical activity and to tailor the strategies for change to specific identified needs. The primary outcomes were BMI %ile and body fat percent at 6-months of follow-up. Secondary outcomes were diet and physical activity behaviors.

**RESULTS:** Of the 18 girls and families recruited, 14 completed the study (78% retention rate). At baseline, the girls were an average age of 9.6 years (SD = 0.6) and had an average BMI of 25.7 kg/m<sup>2</sup> (SD = 4.8). At 6 months' follow-up, average BMI percentiles decreased from the 94<sup>th</sup> to the 92<sup>nd</sup> percentile and body fat percent decreased from 39.3% to 38.02%. Although changes were in the desired direction, the differences in pre/post BMI percentile and body fat percent were not significant ( $p = 0.31$ ;  $0.45$  respectively). Diet and physical activity behaviors changed in the expected direction. Physical activity levels increased from 3.1(SD = 1.9) days of physical activity per week to 3.4 (SD = 1.7). There was also an increased consumption of fruits and vegetables and a decreased consumption of junk food. All of the parents reported that they enjoyed the program, their health promotion specialist, and the convenience of the home-based program. Parents also reported a high satisfaction with the amount of sessions and phone calls. Overall the parents indicated that the program helped them become aware of diet and physical activity behaviors necessary and specific to their daughter and family.

**CONCLUSIONS:** This home-based intervention targeting girls and their families is a promising and feasible obesity prevention program. Specifically, identifying multi-levelled strategies of 'best fit' for the families appears to have impact on the health of the girls.

**Group Randomized Trial Of A Novel Physical Activity Program To Increase Physical Fitness And Motor Skills In Children**

Louise A. Kelly, Antonio S. McNeil, Brittany Kennedy, Blake Carney, Andrew Atkins, Malcolm Mostoles, Welsh Welsh, Spencer Wendt, Kathryn Wallace, Emily Hnath, Marcus McKinnon. *California Lutheran University, Thousand Oaks, CA.*

(No relationships reported)

**PURPOSE:** To compared changes in physical fitness, motor skill performance and body composition after a modified 8-week novel structured physical education program “Gameday” when disseminated in teacher lead format (TL), a physical education specialist format (PESL) versus a control (C).

**METHODS:** 8-week single blinded group randomized trial, 217 children (age 4.2 ±0.2) were randomly assigned to 1) Control (C;n= 47); 2) Teacher Led physical activity (TL;n=76), or 3) Physical Education specialist led physical activity (PESL;n=94). Participants in the TL and the PESL groups received 100 minutes of physical activity per week. The C received standard curriculum over the same period. The following were measured pre and post intervention: Level of motor skill was assessed using the 11-point Movement Assessment Battery for Children. Physical Fitness was assessed using the Fitnessgram®. Body composition was assessed using BMI, BMI percentiles and waist/hip circumference. ANCOVA with post-hoc pairwise comparisons assessed Across intervention group effects.

**RESULTS:** A significant overall intervention effect was found for trunk lift (P<0.01), sit and reach (P<0.01), kick (P=0.008), ball bounce (P=0.007), leap (P=0.004), punt (P<0.001), and Two - hand strike (P=0.039).

**CONCLUSIONS:** The Gameday program appears promising as a population-based approach to increasing physical fitness and enhancing motor skills performance in children.

2928 Board #200 June 1 11:00 AM - 12:30 PM

**High-intensity Training And Cardio-metabolic Risk Marker Changes In Adolescents: Project FFAB (Fun Fast Activity Blasts)**

Kathryn L. Taylor<sup>1</sup>, Alison L. Inner<sup>1</sup>, Liane B. Azevedo<sup>1</sup>, Susan Bock<sup>2</sup>, Alan M. Batterham, FACSM<sup>1</sup>. <sup>1</sup>*Teesside University, Middlesbrough, United Kingdom.* <sup>2</sup>*Durham University, Durham, United Kingdom.*

(No relationships reported)

Low-volume, high-intensity exercise holds promise for cardio-metabolic health promotion, but sustainable interventions must be practical and engaging.

**PURPOSE:** To determine the impact of a school-based, high-intensity exercise intervention on cardio-metabolic risk markers in 13-15 year olds.

**METHODS:** We recruited 102 adolescents (64 male) from four schools. In an exploratory controlled before-and-after design, two schools were assigned to the Intervention condition (n=41) and two to the Control (n=61), matching for socioeconomic status. The intervention comprised four sets of 45 s maximal effort exercise (boxing, dance, soccer and basketball drills) with 90 s rest between sets, up to three times a week for 10 weeks. The number of sets was increased by one every two weeks. Control group participants maintained their usual routine. Outcomes (before and after) were blood lipids and glucose, waist circumference, C-reactive protein, blood pressure, physical activity levels (7-day accelerometry; Evenson cutpoints), aerobic fitness (multistage fitness test), and carotid artery intima-media thickness. The difference in the change from baseline (intervention minus control) was estimated for each outcome, with sex, the baseline value, and maturity offset as covariates. Triglyceride values were first log-transformed prior to analysis. We adopted a magnitude-based inferences framework, calculating the probability (Q) that the true population effect was greater than the minimum important difference (Cohen’s d of 0.2 standard deviations).

**RESULTS:** Compliance was indicated by 75% of the intervention group completing at least 70% of the scheduled sessions. There was a mean reduction (intervention vs. control) in triglycerides of 24% (90% confidence interval, 11 to 35%). The probability (Q) that the true population effect was greater than the minimum important difference was 0.96 - “very likely to be” important. Mean waist circumference reduced by 2.7 cm (1.4 to 4.1 cm) - “likely to be” important (Q = 0.78). Mean daily moderate to vigorous physical activity increased by 14.3 minutes (-0.4 to 28.9 minutes; “likely to be” important, Q = 0.84). There was no substantial effect on any other outcome.

**CONCLUSION:** Interventions of this type might be feasible for targeting aspects of cardio-metabolic health in adolescents.

2929 Board #201 June 1 11:00 AM - 12:30 PM

**High Intensity Aerobic Training Improves Quality Of Life In Obese Adolescents**

Mara C. Lofrano-Prado<sup>1</sup>, James O. Hill<sup>2</sup>, Humberto Jose G. Silva<sup>3</sup>, Larissa S. Albuquerque<sup>3</sup>, Lisianny C. Nascimento<sup>3</sup>, Wagner L. Prado<sup>3</sup>. <sup>1</sup>*Federal University of Pernambuco, Recife, Brazil.* <sup>2</sup>*University of Colorado, Denver, CO.* <sup>3</sup>*University of Pernambuco, Recife, Brazil.*

(No relationships reported)

Obesity has adverse physical, social and psychological consequences that can negatively affect quality of life (QOL). However, nowadays data regarding to the effects of exercise intensity on QOL in obese adolescents are limited.

**PURPOSE:** To verify the effects of aerobic training intensity on QOL in obese adolescents submitted a 12 weeks of multidisciplinary intervention.

**METHODS:** Sample size was composed by 36 obese adolescents (15.46±1.56y). BMI 34.48±3.88kg/m<sup>2</sup>, from both genders, enrolled in multidisciplinary therapy (physical, psychological, nutritional and clinical). Adolescents were randomly allocated in two experimental groups - Low exercise intensity - subjects exercised on a treadmill at intensity corresponding to 20% bellow ventilatory threshold I (VTI); High exercise intensity - subjects exercised on a treadmill at VTI intensity. All exercise sessions were isocaloric (350Kcal) and 3 times each week. QOF was assessed by Generic Questionnaire for Evaluation of Quality of Life ‘Medical Outcomes Study SF-36’. Data were analyzed by means of scores and compared by two-way ANOVA, and Duncan’s test as post-hoc.

**RESULTS:** Both exercise intensities decreased body mass, body mass index and fat mass and increased fat free mass (p≥0.00). Table 1 shows the domains of QOF.

Table 1: Effects of aerobic training intensity on QOL in obese adolescents

|       |                           | Low Intensity |             | High Intensity |              |
|-------|---------------------------|---------------|-------------|----------------|--------------|
|       |                           | Pre           | Post        | Pre            | Post         |
| SF-36 | Physical Functioning      | 86.57±12.25   | 92.36±8.87* | 77.94±17.14    | 91.17±13.63* |

#### Microvascular Perfusion Increases Following Eccentric Exercise Of The Gastrocnemius

Noelle M. Selkow<sup>1</sup>, Daniel C. Herman<sup>2</sup>, Zhenqi Liu<sup>2</sup>, Joseph M. Hart<sup>3</sup>, Jay Hertel, FACSM<sup>3</sup>, Susan A. Saliba<sup>2</sup>. <sup>1</sup>Illinois State University, Normal, IL. <sup>2</sup>University of Virginia, Charlottesville, VA.  
(No relationships reported)

Blood flow during isometric and concentric contractions has been shown to increase substantially in a healthy population immediately following exercise, however microvascular blood flow after eccentric contractions have not been studied. Eccentric contractions cause reversible muscle damage, therefore changes in blood flow could be observed over the inflammatory phase in the first 48 hours following exercise.

**PURPOSE:** To examine the effects of unilateral, eccentric exercise to the gastrocnemius on microvascular perfusion over 48 hours.

**METHODS:** An IV was placed in the antecubital vein for the delivery of the contrast agent (microbubbles) to 18 healthy subjects (3 Males, 15 Females; Age: 22.2 ± 2.2 years; Height: 166.0 ± 11.9 cm; Weight: 69.4 ± 25.0 kg). Subjects performed unilateral eccentric exercises on a randomly selected leg. Heel-lowering exercises were performed off of a step to the beat of a metronome in the sequence of 50 repetitions, 5 minutes rest, 50 repetitions. Microvascular perfusion (blood volume (dB), blood flow (dB/sec), and blood flow velocity (sec-1)) was measured before, immediately (within 5 minutes) and 48 hours after the eccentric exercise using contrast-enhanced ultrasound.

**RESULTS:** Blood volume and flow both significantly increased immediately and 48 hours after exercise (p<.05). Baseline measurements were 5.88 ± 1.33 dB and 2.34 ± 0.41 dB/sec and increased to 12.20 ± 3.31 dB (42%) and 4.53 ± 1.05 dB/sec (80%), respectively after exercise. At 48 hours, compared to baseline, blood volume and flow were still elevated to 9.64 ± 2.53 dB (28%) and 3.74 ± 0.80 dB/sec (54%), respectively. These results yielded high effect sizes immediately (blood volume ES = 2.51 (1.64-3.39) and blood flow ES = 2.89 (1.95-3.82)) and 48 hours after exercise (blood volume ES = 1.86 (1.08-2.64) and blood flow ES = 2.20 (1.37-3.03)). There was no change in blood flow velocity from baseline (.41 ± .06 sec-1) to post-exercise (.36 ± .04 sec-1) and at 48 hours (.38 ± .03) (p>.05).

**CONCLUSIONS:** Following eccentric exercise, we observed an increase in blood flow and blood volume within the microvasculature of the gastrocnemius over 48 hours. Supported by NIH Grant RR00847 and the Curry School of Education at the University of Virginia.

### 2931 Board #203 June 1 9:30 AM - 11:00 AM

#### Repeated High Force Eccentric Exercise: Effects on Delayed Onset Muscle Soreness, Myoglobin and Creatine Kinase

Emad S. Hassan<sup>1</sup>, H. D. Tabbat<sup>2</sup>, R. B. Al-Tounisi<sup>3</sup>. <sup>1</sup>College of Sport Science and Physical Activity King Saud University, Riyadh, Saudi Arabia. <sup>2</sup>College of Applied Medical Sciences King Saud University, Riyadh, Saudi Arabia. <sup>3</sup>Prince Faisal bin Fahd Sports Medicine Hospitals, Riyadh, Saudi Arabia.  
(No relationships reported)

**PURPOSE:** This study examined the hamstring muscles' ability to adapt to high force eccentric exercise by monitoring the changes in serum Myoglobin (Mb), Creatine Kinase (CK) activity and muscle soreness (using the Visual Analog Scale VAS).

**METHODS:** The study involved fifty four healthy and moderately fit young men from the 23 ± 4 years age group. These were distributed as subjects for three types of experiments with 18 men in each. In experiments I and II (N=18 each) subjects performed two bouts of high force eccentric exercise at the hamstring muscles (by knee extension), while in experiment III they performed four bouts of the exercise. In experiment I, after performing the first bout of exercise, they were split into three subgroups (A, B, and C of six men in each) to perform the second bout after a period of 3, 6, and 9 weeks, respectively. Similarly, in experiment II (the three subgroups D, E, and F), performed the second exercise bout after 1, 2, and 3 weeks, respectively. In experiment III (group G), they performed an additional three exercise bouts spaced 1 week apart. Muscle soreness, serum Mb and CK were measured 6 and 24 hours (prior to, and after) each exercise. The fluid intake of all participants in this study was controlled during the experiments.

**RESULTS:** In experiment I, no significant differences in muscle soreness, serum Mb and CK were found between the first and second bouts. However, in experiment II, a significant decrease in muscle soreness, serum Mb and CK was found on exercise bout 2, in comparison to bout 1 (P < 0.05). In experiment III, muscle soreness, serum Mb and CK were the highest after performing the first bout, while measurements after bouts 2, 3, and 4 were not significantly different from one another.

**CONCLUSIONS:** These results conclude that performance of eccentric exercise results in an adaptation that lasts for a minimum of 3 weeks, with the greatest adaptation occurring after the first bout of exercise.

---

### 2932 Board #204 June 1 9:30 AM - 11:00 AM

#### Effects of Repeated Maximum Endurance Strength Exercise on Muscle Damage and Repair

Eisuke Hiruma<sup>1</sup>, Shizuo Katamoto<sup>2</sup>, Masakazu Umimura<sup>3</sup>. <sup>1</sup>Teikyo University, Tokyo, Japan. <sup>2</sup>Juntendo University, Chiba, Japan. <sup>3</sup>Umimura Hospital, Chiba, Japan.  
(No relationships reported)

**PURPOSE:** To determine relationship among muscle damage, recovery and adaptation following repeated bouts of daily muscle endurance exercise in 3 or 7 consecutive days.

**METHODS:** The 40 female subjects (age: 21.1 ± 1.8 yr), had performed in some moderate exercise regularly, were assigned to one (one-group: n=9), three repeated exercise (3-group: n=9) or seven repeated exercise groups (7-group: n=12). This study examined creatine kinase activity (CK), dorsiflexed ankle joint angle (ROM), scale of perceived pain during resting (SPrest), maximum circumference of calf muscle (CCM), isometric muscle strength on lower leg (IMS) and long jumping of one leg (OLJ) in before and after daily exercise for 3 or 7 days of exercise periods. In the exercise period, the subjects performed the maximum calf raise exercise at 1 movement per 2 seconds until the subjects could not maintain the speed of movement. Subjects counted daily walking steps by walking step counter during this study.

**RESULTS:** All subjects walked 7000 to 8000 steps per day. CK after the initial exercise significantly increased (p<0.05) and the peak CK was on Day 4 in three groups, but the recovery times in 3- and 7-group were longer as compared with that in one-group. SPrest (p<0.01) in three groups were significantly elevated from Day 1, and the peak SPrest in one-, 3- and 7-group were on Day 2, Day 3 and Day 4, respectively. OLJ in three groups decreased significantly (p<0.01). OLJ and SPrest in three groups returned to the baseline in 3 days after the peak SPrest. There were no significant changes of IMS and CCM. ROM in each group significantly decreased during each exercise period (p<0.01) and these values did not fully returned. Both indicators of muscle damage after Day 3 were decreased, but these were not recovered during this study.

**CONCLUSIONS:** The results of this investigation suggest that muscle adaptation can be brought by continuous muscle endurance exercise for three or seven days, but the flexibility of muscle was not returned to the initial level during this study. The muscle adaptation alleviates the indicators of muscle damage and muscle function after repeated bouts of daily exercise. The daily walking may effects on swelling.

---

### 2933 Board #205 June 1 9:30 AM - 11:00 AM

#### The Effects of Different Passive Warm-Up to Eccentric Exercise on Exercise Performance and Muscle Damage

Chen-Feng Tsai, Hui-mei Lin, Yu-Lin Ning, Kuo-Wei Tseng. Taipei Physical Education College, Taipei, Taiwan.  
(No relationships reported)

**PURPOSE:** To determine the effects of two different modalities of passive warm-up and exercise without warm-up on exercise performance and recovery on muscle damage.

**METHODS:** 16 volunteers were participated in this study (age = 23.88 ± 2.42 y/o), and all of subjects were involved into control group (CON), passive warm-up with heat pack (HP) and

ultrasound diathermy (USD). Each subject processed 30 repeated bouts of eccentric exercise with 80% MVC level after passive warm-up. Serum CK, MVC, ROM and CIR were measured before, immediately after exercise and at 2nd, 4th, 7th, and 10th days post-exercise.

**RESULTS:** CK on 4th day post exercise had significant difference from pre-test in CON ( $2.61 \pm 0.77$  vs.  $2.01 \pm 0.18$ ,  $p < 0.05$ ) and HP ( $2.27 \pm 0.30$  vs.  $1.96 \pm 0.16$ ,  $p < 0.05$ ) groups, but not in USD ( $2.19 \pm 0.26$  vs.  $1.97 \pm 0.19$ ,  $p > 0.05$ ). MVC in CON was lower than HP and USD in each day (fig.1). ROM of elbow joint in all groups showed significant decrease after eccentric exercise ( $p < 0.05$ ), especially the CON. ROM in USD and HP groups showed significant decrease after eccentric exercise only on 2nd day post exercise. There were significant difference between USD and the other two groups on 2nd, 4th, 7th, 10th day.

**CONCLUSION:** USD and HP have better muscle strength and performance than CON. According to the recovery procedure, USD took lesser damage on muscles than HP and CON. USD had lesser swelling **then HP and CON in recovery stage after exercise.**

---

**2934 Board #206 June 1 9:30 AM - 11:00 AM**

**Alterations in Neuromuscular Junction Morphology Following Contraction-induced Injury: Exploring Neurological Contributions to Force Loss**

Stephen J.P. Pratt<sup>1</sup>, Chris W. Ward<sup>2</sup>, Sameer B. Shah<sup>3</sup>, Richard M. Lovering<sup>1</sup>. <sup>1</sup>University of Maryland School of Medicine, Baltimore, MD. <sup>2</sup>University of Maryland School of Nursing, Baltimore, MD. <sup>3</sup>University of California San Diego School of Medicine, San Diego, CA. (Sponsor: Ed McFarland, FACSM)

(No relationships reported)

High force lengthening contractions are associated with muscle damage, which is often defined within the context of the assay used to examine it. No one finding can account for the changes in contractility after injury, but considerable attention has been dedicated to myofiber damage in an attempt to understand mechanisms underlying force loss. The neuromuscular junction (NMJ) may display alterations in neuron-dependent changes in synaptic organization.

**PURPOSE:** To compare the NMJ morphology in healthy and injured muscles induced by lengthening contractions.

**METHODS:** We used a recently described injury model. Unilateral injury to the quadriceps was induced by 30 maximal lengthening contractions through an 80° arc of knee motion in Sprague-Dawley rats ( $n=6$ ). Injured and contra-lateral non-injured muscles were prepared for immunolabeling and staining by snap freezing and longitudinal sectioning (50  $\mu$ m), or by perfusion fixation and whole mount. Light microscopy was used to identify cell membranes to ensure that the totality of the sampled NMJs were within the borders of the myofiber. Motor neurons were labeled with anti-neurofilament antibodies. The pre-synaptic NMJ was identified by labeling with SV2 (synaptic vesicles) and the post-synaptic acetylcholine receptors (AChRs) were identified by alpha-bungarotoxin staining. Sections were imaged and analyzed using Image J software to measure total perimeter, total area, stained perimeter and stained area of NMJs.

**RESULTS:** Quadriceps injury was confirmed by a significant loss of isometric torque ( $37 \pm 6\%$ ). This muscle injury resulted in altered NMJ dimensions; both pre- and post-synaptic images demonstrated a less continuous perimeter and a more fragmented appearance. Quantitatively, injury resulted in changes of NMJ total perimeter (decreased 23%), total area (decreased 19%), stained perimeter (decreased 19%), and stained area (increased 7%).

**CONCLUSIONS:** The data show that muscle strain injury causes morphological changes to the NMJs. Due to the short time course used here, changes in NMJ morphology among injured myofibers is likely not due to regeneration or a change in myofiber size. This focus toward the NMJ represents a paradigm shift from more prevalent myocentric perspectives on injury.

**2935 Board #207 June 1 9:30 AM - 11:00 AM**

**Effect Of NSAID Use On Muscle Injury: A Systematic Review And Meta-Analysis**

Brooke Adler, Laura B. Brown, Kimberly M. Morelli, Gordon L. Warren, FACSM. Georgia State University, Atlanta, GA.

(No relationships reported)

There is debate as to whether non-steroidal anti-inflammatory drug (NSAID) use is beneficial following muscle injury. Some studies have even suggested that NSAID use may be detrimental to the injured muscle.

**PURPOSE:** Conduct a systematic review and meta-analysis of the research literature to determine if NSAID use decreases muscle injury as assessed by soreness, strength loss, and/or blood creatine kinase level.

**METHODS:** Searches for studies testing the effect of NSAID use on muscle injury were performed using 10 electronic databases (e.g., PubMed, Cochrane Library, EMBASE). This yielded 693 studies that were then screened and excluded if they did not meet the following inclusion criteria:  $>5$  on PEDro scale, use of placebo, oral NSAID administration in human studies, injury to skeletal muscle, and outcome measures of soreness, strength, or blood creatine kinase level. Thirty-two peer-reviewed articles were deemed suitable for analysis. Meta-analyses were run using a random-effects model and standardized mean differences (ES) calculated from data extracted from the articles.

**RESULTS:** For all studies and markers combined, NSAID use was found to elicit a significant, small-to-moderate decrease in the markers of muscle injury (overall ES=0.29;  $p=0.003$ ). Because heterogeneity of between-study ES was moderate to large ( $I^2 = 59\%$ ;  $p < 0.001$ ), moderator variables that could potentially explain this heterogeneity were probed using subgroup analysis or meta-regression. The only moderator variable exhibiting a significant effect was the injured muscle's location ( $p=0.004$ ); NSAID use was more beneficial in studies conducted on lower-extremity muscles compared to studies using upper-extremity muscles (subgroup ES of 0.54 vs. 0.01, respectively). No significant effect was found for the following moderator variables: type of outcome measure ( $p=0.49$ ), crossover vs. independent-group studies ( $p=0.54$ ), subject gender ( $p=0.28$ ), human vs. animal studies ( $p=0.81$ ), type of NSAID ( $p=0.39$ ), NSAID dosage ( $p=0.09$ ), duration of NSAID use ( $p=0.86$ ), and when NSAID use began ( $p=0.65$ ).

**CONCLUSION:** Overall, our analysis supports NSAID use for reducing the markers of injury after muscle injury. Additional research is required to determine why NSAID use appears to be more effective when lower-extremity muscles are injured.

**2936 Board #208 June 1 9:30 AM - 11:00 AM**

**Smokers Exhibit Blunted Changes in Muscle NF $\kappa$ B Activity after Eccentric Exercise**

Nina A. Moore, Stuart R. Chipkin, Priscilla M. Clarkson, FACSM. University of Massachusetts, Amherst, MA.

(No relationships reported)

**PURPOSE:** For unknown reasons, smoking increases the risk for musculoskeletal injury and prolonged healing. We used an eccentric exercise (muscle damaging) model to determine potential mechanisms to explain this risk. Eccentric exercise results in alterations to gene expression leading to muscle regeneration through myogenic signaling. The transcription factor NF $\kappa$ B can stimulate myogenesis through proliferation and differentiation via canonical and non-canonical pathways, respectively. We hypothesized that smokers (SM) would have altered NF $\kappa$ B signaling after eccentric exercise, potentially explaining impaired muscle regeneration and increased risk for injury.

**METHODS:** Healthy, sedentary men, 10 SM and 9 non-smokers (NS) ( $23 \pm 1$  y), performed 100 maximal eccentric contractions with the non-dominant knee extensors (EX). 48h later, muscle biopsies were taken from both legs (vastus lateralis; non-exercised leg served as the control (CON)). A custom-designed PCR array was used to compare mRNA expression between legs. NF $\kappa$ B activity was quantified with antibodies against p65 (canonical) and Rel-B (non-canonical). Data are mean  $\pm$  SEM.

**RESULTS:** Gene expression change after exercise was significantly different between NS and SM in 7 of 44 genes examined. The largest difference between NS and SM was IKK $\alpha$  expression with 2.3-fold upregulation vs -2.0-fold downregulation, respectively ( $p=0.026$ ). Since IKK $\alpha$  can activate NF $\kappa$ B signaling, we quantified NF $\kappa$ B activity. In the CON leg, SM activity was lower than NS for p65 ( $0.023 \pm 0.01$  vs  $0.06 \pm 0.008$  OD) but not Rel-B. In response to exercise NS had reduced p65 signaling ( $0.06 \pm 0.008$  CON vs  $0.01 \pm 0.005$  EX) while SM had no alteration ( $0.023 \pm 0.01$  vs  $0.022 \pm 0.01$ ). Rel-B signaling was increased in NS with exercise ( $0.046 \pm 0.02$  CON vs  $0.067 \pm 0.04$  EX); however, this did not reach significance. SM Rel-B activity was not different with exercise ( $0.044 \pm 0.01$  CON vs  $0.045 \pm 0.01$  EX).

**CONCLUSIONS:** In response to exercise: 1) IKK $\alpha$  mRNA was increased in NS but decreased in SM; 2) p65 activity decreased in NS while there was no change in SM. These data suggest impaired IKK $\alpha$  activation of NF $\kappa$ B p65 pathway and blunted myogenic signaling in SM and may indicate a mechanism through which smoking may impair muscle regeneration. Supported by a grant from the US Army Medical Research and Materiel Command

**Does A Secondary Loss Of Strength Occur Following Induction Of Muscle Injury?**

Gordon L. Warren, FACSM, Amy K. Farthing, Bemene B. Piaro, Sam R. Coley, Clint W. Satterfield, Chris D. Vlahos, James E. Lewis. *Georgia State University, Atlanta, GA.*

(No relationships reported)

It is known that there is an immediate loss of strength following virtually all types of muscle injury. There is debate as to whether a secondary loss of strength occurs in the ensuing 1 to 3 days. This issue is important to resolve because it can influence if and how these injuries are treated.

**PURPOSE:** Conduct a systematic review and meta-analysis of the research literature to determine if a secondary loss of strength occurs after muscle injury.

**METHODS:** Searches were performed using 4 electronic databases (i.e., PubMed, CINAHL, Cochrane Library, and OpenSigle). Search terms included: skeletal muscle AND (injur\* OR damag\*) AND (strength OR force OR torque). 106 peer-reviewed articles were deemed suitable for analysis. Meta-analyses were run using a random-effects model and standardized mean differences calculated from data extracted from the articles.

**RESULTS:** For all studies combined, a moderate increase in strength was found to occur between immediately post-injury and days 1, 2 and/or 3 post-injury (overall effect size [ES] = 0.40,  $p < 0.0001$ ). Strength was also found to increase progressively from day 1 to day 3 post-injury ( $p < 0.0001$ ; ES of 0.27, 0.50, and 0.65 for days 1, 2, and 3, respectively). Because heterogeneity of between-study ES was large ( $I^2 = 84\%$ ;  $p < 0.0001$ ), moderator variables that could potentially explain this heterogeneity were probed using subgroup analysis or meta-regression. There was no significant difference in overall ES between studies using humans and those using animals ( $p = 0.81$ ). Additionally, there were no significant differences among studies using differing muscle groups ( $p > 0.22$ ). The only moderator variable showing a significant effect was gender ( $p = 0.01$ ); studies utilizing females exhibited a slower rate of strength recovery after injury (overall ES = 0.29) compared to studies using males only (overall ES = 0.55).

**CONCLUSION:** Overall, our analysis does not support the occurrence of a secondary loss of strength following muscle injury. In fact, the data indicate that a significant increase in strength occurs over the first 3 days after injury.

2938 Board #210 June 1 9:30 AM - 11:00 AM

**Ibuprofen Prolongs Functional Deficits after a Repeated Bout of Downhill Treadmill Running**

Michael S. Green<sup>1</sup>, Tyler D. Martin<sup>1</sup>, Amanda K. Benson<sup>1</sup>, Benjamin T. Corona<sup>2</sup>, Christopher P. Ingalls, FACSM<sup>3</sup>. <sup>1</sup>Troy University, Troy, AL. <sup>2</sup>United States Army Institute of Surgical Research, Fort Sam Houston, TX. <sup>3</sup>Georgia State University, Atlanta, GA.

(No relationships reported)

Non-steroidal anti-inflammatory drugs (NSAIDs) are commonly used to treat symptoms associated with exercise-induced muscle injury. Recent research raises the possibility that NSAIDs could have detrimental effects on the adaptation of muscle in response to repeated damaging exercise bouts.

**PURPOSE:** To determine the effect of NSAID (ibuprofen) supplementation on the adaptive response typically exhibited by skeletal muscle following novel eccentric contractions.

**METHODS:** Twenty-six male ( $n = 8$ ) and female ( $n = 18$ ) subjects (mean values  $\pm$  SD; age =  $22.2 \pm 3.4$  y, height =  $1.68 \pm 0.10$  m, weight =  $71.0 \pm 16.8$  kg, body fat =  $24.5 \pm 8.0$  %) performed two downhill treadmill runs (DTR1, DTR2) separated by 14d. After DTR1 only, subjects received either ibuprofen ( $1,200 \text{ mg}\cdot\text{d}^{-1}$ ;  $n = 13$ ) or placebo (flour;  $n = 13$ ) in a randomized, double-blind, gender-balanced manner for 3d. Maximum voluntary isometric quad strength (MVC) and serum creatine kinase activity (CK) were assessed at baseline, and immediately, 1, 2, and 3d post-DTR1 and DTR2.

**RESULTS:** DTR1 induced a significant and similar degree of lower extremity muscle injury in both treatment groups. Groups combined exhibited  $13.6 \pm 1.3$ ,  $10.6 \pm 1.6$ , and  $6.4 \pm 1.6$  % MVC deficits immediately, 1, and 2d post-injury, respectively, with full recovery 3d post-injury. Also, CK ( $826 \pm 183 \text{ U}\cdot\text{L}^{-1}$ ) peaked for both groups 2d post-injury. Following DTR2, the placebo group exhibited an immediate MVC deficit ( $9.0 \pm 2.0$  %) but was fully recovered 1d post-injury; evidence of the well-established repeated bout effect. Meanwhile, although the ibuprofen group exhibited a similar deficit ( $10.1 \pm 2.0$  %) in MVC immediately post-DTR2 compared to placebo, MVC remained significantly reduced by  $7.3 \pm 2.4$  and  $5.1 \pm 2.3$  % 1 and 2d post-injury, respectively, and did not fully recover until 3d post-injury. Although not affected by treatment condition, CK was lower at all times post-DTR2 compared to post-DTR1.

**CONCLUSION:** Consumption of  $1,200 \text{ mg}\cdot\text{d}^{-1}$  of ibuprofen for 3d following an initial novel bout of eccentric contractions significantly diminished the well-established neuromuscular adaptation (repeated bout effect) that commonly occurs following injurious exercise. Athletes should use caution when utilizing NSAIDs to treat lower extremity muscle pain.

**Effect Of Kinesiotaping On Muscle Damage Parameters Following Eccentric Muscle Contractions**

Kyu-Wan Lee, Seung-Hwan Kim, Jooyoung Kim, Joohyung Lee. *Kookmin University, Seoul, Korea, Republic of.*

(No relationships reported)

It is well known that repetitive eccentric muscle contractions induce muscle damage. Kinesiotaping has been designed for better blood flow and removal of fatigue materials in athletic performance. Also, it has been claimed to be useful to reduce pain but the mechanism is still unclear.

**PURPOSE:** To investigate the effect of kinesiotaping application on muscle damage markers following eccentric muscle contractions.

**METHODS:** Total 32 healthy males who had not participated within the past 6 months were recruited. Each subject was randomly assigned to either control (CON,  $n=8$ ), treatment only during exercise (KTEXE,  $n=8$ ), treatment during exercise and immediately after exercise (KTEXPO,  $n=8$ ), or treatment during exercise and 24 hour after exercise (KT24,  $n=8$ ). Each subject performed 2 sets of 25 eccentric muscle contractions of the elbow flexors. Measurements included maximal isometric force (MVC), muscle soreness (SOR), range of motion (ROM), and serum creatine kinase activity at pre, post, 24, 48, 72 and 96 hours after exercise.

**RESULTS:** There was a significant group by time interaction in MVC where KT24 had a less decrease in muscle strength and a faster recovery after exercise compared to CON and KTEXE ( $p=0.006$ ). A significant group by time interaction was shown in SOR where KTEXPO and KT24 had lower soreness compared to CON and KTEXE ( $p=0.001$ ). In ROM, there was a significant interaction in flexed arm angle ( $p=0.027$ ) but no significant group by time effect in relaxed arm angle ( $p=0.155$ ). Additionally, a significant group by time interaction was shown in CK activity where KT24 had a lower increase in CK activity compared to KTEXE ( $p=0.043$ ).

**CONCLUSIONS:** Application of kinesiotaping has demonstrated a positive effect on muscle damage markers following eccentric muscle contractions when the treatment was persistent for at least 24 hours compared to short period treatment.

2940 Board #212 June 1 9:30 AM - 11:00 AM

**Eccentric Contractions of Gastrocnemius Induce Sciatic Nerve Injury in Wistar Rats**

Kihyuk Lee<sup>1</sup>, Koji Kobayashi<sup>1</sup>, Riki Ogasawara<sup>2</sup>, Arata Tsutaki<sup>1</sup>, Eisuke Ochi<sup>3</sup>, Koichi Nakazato<sup>1</sup>. <sup>1</sup>Nippon Sport Science University, Tokyo, Japan. <sup>2</sup>University of Tokyo, Tokyo, Japan. <sup>3</sup>Meiji Gakuin University, Kanagawa, Japan.

(No relationships reported)

Muscle strain injury is considered to be caused by severe eccentric contractions (ECs). In our study on rat gastrocnemius (GST) muscle, we showed that ECs with a larger range of motion and/or faster angular velocity cause functional and histological damage to the muscle. Although GST crush injury not only induces damage in the muscle but also in the nerve, whether ECs of the GST muscle induce nerve tissue injury has not yet been determined. We hypothesized that ECs with faster angular velocity induced connecting nerve damage, as observed during crush injury.

**PURPOSE:** To examine the effects of GST ECs on sciatic nerve by using an animal model.

**METHODS:** Wistar rats were randomly divided into the following 3 groups; control ( $n = 6$ ), fast EC group (FAST; angular velocity:  $180^\circ/\text{sec}$ ;  $n = 12$ ), and slow EC group (SLOW; angular velocity:  $30^\circ/\text{sec}$ ;  $n = 12$ ). Animals in the 2 EC groups were further divided into 2 groups as day 3 and day 7 groups ( $n = 6$  in each group). Twenty ECs were performed using electrical stimulation of the GST and simultaneous forced dorsiflexion of the ankle joint (from  $0^\circ$  to  $45^\circ$ ). For confirming functional deficit, isometric tetanic forces were measured at predetermined

times (i.e., days 1, 2, 3, 5, and 7) after the ECs. On days 3 and 7 after the ECs, the sciatic nerve branches were harvested and analyzed using western blotting. A 2-way ANOVA followed by a post hoc test was performed to compare the isometric tetanic torques and the results of western blotting.

**RESULTS:** A significant torque deficit was observed from days 1 to 7 after the ECs in the FAST as compared to the SLOW (day 1: 13% and day 7: 20% [ $p < 0.05$ ]; day 2: 31%, day 3: 22%, and day 5: 27% [ $p < 0.01$ ]). The level of myelin sheath protein zero (p0) on day 7 FAST was significantly lower than those in the other groups (day 7 FAST vs. day 7 SLOW: 0.2-fold,  $p < 0.05$ ; day 7 FAST vs. day 3 FAST: 0.5-fold,  $p < 0.05$ ). A significantly higher level of macrophage-related protein (ED1) was also observed on day 7 FAST as compared to the day 3 FAST (day 7 FAST vs. day 3 FAST: 2.0-fold,  $p < 0.05$ ). TrkC level in the day 7 FAST was also significantly higher than those in the other groups (day 7 FAST vs. day 7 SLOW: 3.3-fold,  $p < 0.05$ ; day 7 FAST vs. day 3 FAST: 9.6-fold,  $p < 0.05$ ).

**CONCLUSIONS:** The fast ECs of the GST muscle induced myelin sheath damage, macrophage invasion, and TrkC expression in the sciatic nerve, suggesting a nerve injury.

**Mild Eccentric Exercise Increases HSP 72 Content In Adult And Late Middle-Aged Rats**

Catherine E. Amara, Evan J. Lewis, Andrew H. Ramsook, Marius Locke. *University of Toronto, Toronto, ON, Canada.* (Sponsor: Ira Jacobs, FACSM)  
(No relationships reported)

Heat Shock Proteins (HSPs) are thought to protect cells from protein damaging stressors by stabilizing denatured or unfolded proteins. In response to the stress of exercise, the ability to increase HSP 72 content has been shown to be intensity-dependent and appears to be diminished with advanced age. Furthermore, HSP 72 content is higher in slow-twitch vs. fast-twitch muscle and might offer increased cellular protection in slow twitch muscle in response to stressors, including aging.

**PURPOSE:** To determine whether a relatively mild exercise stress is sufficient to elicit an increase in HSP 72 content in the vastus intermedius (VI) and white gastrocnemius (WG) and whether this response is similar in adult (A) and late middle-aged (LMA) rats.

**METHODS:** 30 adult (6 months) and LMA (24 months) F344BN rats were divided into groups of 6: control (C), level exercise ( $16\text{m}\cdot\text{min}^{-1}$ ) sacrificed immediately post-exercise (L0) or after 48 hours (L48) and eccentric exercise ( $16\text{m}\cdot\text{min}^{-1}$ , 16 degree decline) sacrificed immediately post-exercise (E0) or after 48 hours (E48). SDS-PAGE followed by Western Blotting was performed to assess muscle HSP 72 content. A nested ANOVA with a Tukey post hoc analysis was used to determine significant difference ( $p < 0.05$ ) between groups.

**RESULTS:** For both age groups and in both muscles, no change in HSP 72 content was observed at L0 or E0. At E48, but not L48, HSP 72 content was increased in the VI for both A and LMA rats compared to level and control groups, respectively, with no differences between age groups observed. Pooled data from both age groups revealed a 20% increase in HSP 72 content at E48 compared with control. We did not detect constitutively expressed or exercise-induced HSP 72 for any group in the WG.

**CONCLUSIONS:** Even mild eccentric exercise is capable of increasing HSP 72 content in the VI and this adaptive response is preserved into late middle-age.

**2942** Board #214 June 1 9:30 AM - 11:00 AM

**The Effects Of High Powered Laser Therapy On Muscle Repair**

Matthew Christopher Kostek, Diana Delgado. *University of South Carolina, Columbia, SC.*  
(No relationships reported)

**High powered laser therapy is an emerging modality used in rehabilitation; however its effectiveness in enhancing healing skeletal muscle has not been previously investigated.**

**PURPOSE:** The purpose of this study was to determine the effect of high powered laser treatment on markers of muscle damage and repair.

**METHODS:** Male and female subjects ( $n=16$ ) were recruited for this study and underwent a muscle damage protocol standardized in our laboratory. Participants underwent exercise induced muscle damage (20 sets of 10 repetitions of eccentric contractions of the vastus lateralis) using an isokinetic dynamometer. Damage was confirmed by creatine kinase assays (300% increase,  $P < 0.05$ ) and loss of force production ( $\sim 30\%$ ,  $P < 0.05$ ). Forty-eight hours after damage, laser was administered to one leg while the contra-lateral leg served as the control. Six hours after laser treatment, bilateral muscle biopsies were collected from each participant. Biopsies were examined for markers of muscle repair (IGF1 splice variants).

**RESULTS:** Our damage protocol increased IGF1 gene expression ( $2.1 \pm$  fold,  $P < 0.05$ ) while the effects of laser treatment are currently inconclusive. Additional subjects are currently being examined.

**CONCLUSIONS:** Preliminary results suggest that while our damage protocol is effective there is no effect of high powered laser on IGF1 gene expression.

---

**2943** Board #215 June 1 9:30 AM - 11:00 AM

**Mesenchymal Stem Cells Contribute to Vascular Growth in Skeletal Muscle in Response to Eccentric Exercise**

Heather D. Huntsman, Carmen Valero, Kai Zou, Nicole Zachwieja, Marni D. Boppart. *University of Illinois at Urbana-Champaign, Champaign, IL.* (Sponsor: Jeff Woods, FACSM)  
(No relationships reported)

Tissue health is critically dependent on vascularization to support growth and function following injury. In addition to multiple implications in the regenerative potential of other tissues, mesenchymal stem cells have been shown to promote vessel formation both *in vivo* and *in vitro*. Our recent work has established that transgenic overexpression of the  $\alpha 7$  integrin in skeletal muscle ( $\alpha 7\text{Tg}$ ) can enhance the presence of Sca-1<sup>+</sup>CD45<sup>+</sup> mesenchymal stem cells (mMSCs) which facilitate myogenesis.

**PURPOSE:** The purpose of this study was to determine the extent to which angiogenesis is increased in  $\alpha 7\text{Tg}$  muscle following acute or repeated bouts of eccentric exercise and elucidate a role for mMSCs in this event.

**METHODS:** mMSCs were isolated from  $\alpha 7\text{Tg}$  muscle by fluorescent activated cell sorting (FACS) and pericyte markers were examined by flow cytometry. Wild type (WT) and  $\alpha 7\text{Tg}$  mice (5 wk) were subjected to single or multiple bouts (3x/wk, 4 wks) of downhill running exercise. Additionally, DiI-labeled mMSCs were injected into WT mice. Measures of angiogenesis and vessel growth were evaluated by immunohistochemistry.

**RESULTS:** A large percentage of isolated mMSCs were positive for pericyte markers. DiI-labeled mMSCs injected into WT muscle migrated to the vascular niche and incorporated directly into vessels. Although capillary: fiber ratio, capillary density and tortuosity index did not increase, the number of large vessels was significantly increased in  $\alpha 7\text{Tg}$  muscle following single and repeated bouts of exercise ( $p < 0.05$ ; 3-fold for repeated bouts) and in WT muscle receiving mMSC transplantation ( $P < 0.05$ ; 48%).

**CONCLUSION:** This study demonstrates that mMSCs contribute to vascular growth in skeletal muscle in response to eccentric exercise, and that this adaptation is coordinated with increased myogenesis previously reported. Well-orchestrated responses similar to this may be a key mechanism in the successful regeneration of several tissue types.

Supported by grants from the National Science Foundation, and the Ellison Medical Foundation.

**Differential Expressions Of Tendon-related Markers After Fast/slow Velocity Lengthening Contractions In Rat Gastrocnemius Muscle**

Eisuke Ochi, PhD<sup>1</sup>, Koichi Nakazato, PhD<sup>2</sup>. <sup>1</sup>Meiji Gakuin University, Yokohama, Japan. <sup>2</sup>Nippon Sport Science University, Tokyo, Japan.  
(No relationships reported)

Although muscle strain injury is one of most important issues in sports medicine, there is little known about the molecular events on regeneration process and embryonic formation in vivo injured muscle.

**PURPOSE:** The purpose of this study was to examine the effects of lengthening contractions (LCs) on tendon-related markers signaling pathways. We hypothesized that tendon-related markers are important role for the recovery from muscle injury.

**METHODS:** We employed our originally developed device with two LC modes to modulate the intensity in rat gastrocnemius muscle. Male Wistar rats ( $n = 18$ ) were randomly divided into fast velocity LCs group (FAST, 180deg/s,  $n = 6$ ), slow LCs group (SLOW, 30deg/s,  $n = 6$ ), and control group (control,  $n = 6$ ). The FAST and SLOW rats were anesthetized with isoflurane

(aspiration rate, 450ml/min, concentration, 2.0%). The triceps surae muscle of the right hindlimb was then electrically stimulated with forced isokinetic dorsi-flexion (30°/s and from 0 to 45°). Tissue contents and localizations of tenomodulin, scleraxis, and myostatin were measured by western blotting and immunohistochemistry. The mRNA expression of type I collagen alpha 2 (colla2) and mohawk was evaluated using real time reverse transcriptase polymerase chain reaction. One-way ANOVA was used to compare the body mass, muscle mass, protein and mRNA analysis.

**RESULTS:** No significant changes were observed in both body mass and hindlimb muscles between three groups. The torque was significantly lower in FAST than in SLOW (day2; 59.9±17.2 vs. 101.5±22.9 mNm,  $P < 0.01$ ). Tenomodulin and myostatin and colla2 mRNA showed significantly enhanced expression in FAST than in the other two groups (tenomodulin; ~2.5 fold,  $P < 0.01$ , myostatin; ~3.8 fold,  $P < 0.01$ , colla2; ~8.5 fold,  $P < 0.05$ ). Immunohistochemical staining in FAST, but not in SLOW, was mainly localized in connective tissues between muscle fibers. On the other hands, scleraxis and mohawk mRNA in SLOW was significantly higher than that in control (scleraxis; ~2.7 fold,  $P < 0.01$ , mohawk; ~6.7 fold,  $P < 0.05$ ).

**CONCLUSIONS:** We conclude that fast LCs cause an increase in connective tissue fibrosis through the activated myostatin signaling pathway. In addition, the present results suggest that the severity of LCs-induced damage cause different expressions of tendon-related markers.

#### Effects Of Cardiorespiratory Fitness On Brain Responses To Visual Food Images

Nero Evero, Laura Hackett, Robert D. Clark, Suzanne Phelan, Todd A. Hagobian. *California Polytechnic State University, San Luis Obispo, CA.* (Sponsor: Andrew Subudhi, FACSM)

(No relationships reported)

High cardiorespiratory fitness is associated with suppressed appetite, but little is known about brain responses to food cues in people of different levels of cardiorespiratory fitness.

**PURPOSE:** To determine the effects of exercise on brain responses to visual food cues in high cardiorespiratory fitness (HF) and low cardiorespiratory fitness (LF) adults.

**METHODS:** After an overnight fast, 14 HF (21.7 ± 4.1 yr, 23.7 ± 3.1 kg/m<sup>2</sup>, 51.4 ± 5.6 ml/kg-min) and 16 LF (22.6 ± 3.6 yr, 23.5 ± 1.8 kg/m<sup>2</sup>, 38.0 ± 4.4 ml/kg-min) healthy individuals completed 60 minutes of high-intensity exercise (83% HR<sub>max</sub>) on a cycle ergometer or 60 minutes of rest (no-exercise) in a counterbalanced, cross-over fashion. Immediately after each condition, blood oxygen level-dependent responses to high-energy food compared to neutral cues (non-food) were measured during an fMRI scan using an ANOVA.

**RESULTS:** In HF relative to LF, high-energy cues compared to neutral cues significantly increased brain activity ( $P < 0.005$ , uncorrected) in regions of the cerebellum (Crus I and lobule 9), superior temporal gyrus and putamen. In the HF group alone, high-energy cues compared to neutral cues significantly increased activation ( $P < 0.005$ , uncorrected) in the precuneus and gyrus rectus and decreased activation in the superior frontal gyrus (medial surface), inferior frontal gyrus (opercular part), middle occipital gyrus and superior parietal gyrus after exercise. In the LF group alone, high-energy cues compared to neutral cues significantly decreased activation ( $P < 0.005$ , uncorrected) in the inferior frontal gyrus (triangular part), orbitofrontal cortex, insular cortex, middle and inferior occipital gyrus, fusiform gyrus and putamen after exercise.

**CONCLUSION:** We observed that cardiorespiratory fitness levels play a role in the effects of exercise on activity in frontal and visual brain regions involved in food processing. These data appear to suggest that LF individuals have a greater suppressive affect in brain regions that regulate appetite.

#### Effects of Parental Physical Activity on Hippocampal Gene Expression in C57BL/6 Mice

Andrew C. Venezia, Lisa M. Guth, Michael P. Marini, Estefan P. Beltran, Espen E. Spangenburg, Stephen M. Roth, FACSM. *University of Maryland, College Park, MD.*

(No relationships reported)

Physical activity has been demonstrated to maintain and enhance cognitive function. The beneficial effects of physical activity appear to be mediated through changes in expression of brain derived neurotrophic factor (*Bdnf*) and insulin-like growth factor 1 (*Igf1*), though the effects of parental voluntary wheel running on the expression of these genes in offspring has not been investigated.

**PURPOSE:** To examine the effect of parental physical activity on offspring's mRNA expression of genes critical for exercise-induced improvement of cognitive function.

**METHODS:** At 8 weeks of age, C57BL/6 mice were individually housed with (PA; n=20) or without (SED; n=20) access to a computer monitored voluntary running wheel for 12 weeks. At 12 weeks, PA males were bred with PA females and SED males bred with SED females (F0 generation); the resultant offspring make up the F1 generation. Mice in the PA condition maintained access to a voluntary running wheel for the duration of breeding, pregnancy (males and females separated), and weaning. After the weaning period, the F1 offspring were housed in sedentary cages regardless of parental condition. At 8 weeks of age, the offspring were sacrificed and hippocampi removed. Total RNA was isolated from the hippocampus and expression of total *Bdnf*, *Bdnf* transcript IV, and *Igf1* mRNA were assessed via quantitative (*Bdnf* & *Bdnf* IV) and gel based (*Igf1*) RT-PCR.

**RESULTS:** During the 12 week pre-breeding period, males and females ran an average of 4206 ± 634 and 5312 ± 637 meters/24 hours, respectively. We found no significant difference in expression of *Bdnf*, *Bdnf* IV, or *Igf1* between the F1 offspring of PA and SED mice.

**CONCLUSION:** These findings indicate that parental voluntary wheel running does not affect offspring neurotrophin and/or growth factor gene expression in the mouse hippocampus.

This work was supported by NIH grant HD062868.

### 2947 Board #219 June 1 11:00 AM - 12:30 PM

#### The Effect of Endurance Exercise and SIRT Activation on Brain Function on Rats Artificially Selected to High or Low Running Capacity

Zsolt Radak<sup>1</sup>, Linda Sarga<sup>1</sup>, Lauren Koch<sup>2</sup>, Steve Britton<sup>2</sup>, Istvan Boldogh<sup>3</sup>. <sup>1</sup>Semmelweis University, Budapest, Hungary. <sup>2</sup>University of Michigan, Ann Arbor, MI. <sup>3</sup>UTMB, Galveston, TX. (Sponsor: Li Li Ji, FACSM)

(No relationships reported)

**PURPOSE:** Sirtuins are NAD<sup>+</sup>-dependent protein deacetylases and suggested regulators of aging, fat and sugar metabolisms and brain function. Resveratrol, an activator of SIRT1 has been shown to reduce plaque pathology in a transgenic model of Alzheimer diseases, and knock out of this enzyme significantly impair brain function. Here tested the role exercise and resveratrol treatment on brain function on low and high running capacity rats.

**METHODS:** In the present study we tested the effects of resveratrol on rats selectively bred over 24 generations for intrinsic aerobic high running capacity (HRC) or low running capacity (LRC). LRC and HRC animals were supplemented with either vehicle control or resveratrol (1000 mg/kg, oral dosing in every second day) for 4 months. Biochemical measurements were done from the hippocampus.

**RESULTS:** Exercise training over improved balance in both the HCR and LCR animals as measured by rotarod test (10-15% amelioration/groups), while in open field tests, LCR rats supplemented with resveratrol has increased exploratory behavior compared with control group. In the new object recognition LCR rats had better performance compared to HCR animals and opposite was true for long term memory. Histochemistry data showed that resveratrol alone and with exercise increased neurogenesis in both groups. While the acetylation of by 8-oxoguanine DNA glycosylase (OGG1) 8-oxoG repairing enzyme was higher in LCR groups than in HCR animals and this correlated well with the activity of SIRT1. Western blots assays show that acetylated lysine and OGG1 levels were decreased in the resveratrol-fed animal

**CONCLUSIONS:** One of the objective of the study was, to test whether regular training could overcome the health problems caused by genetic setup of LCR rats. Our data show, that regular exercise is a powerful tool to prevent genetics associated metabolic problems. Moreover, our data revealed that resveratrol selectively effects brain performance. It appears that life-style modification, physical activity and/or nutrition beneficially effects physiological performance. The biochemical analysis of hippocampus suggest that some of the beneficial changes in the brain could be mediated through SIRT1, which could included DNA repai

**Factorial Validity of Responses to the Post Concussion Symptom Scale (PCSS)**

Scott G. Piland<sup>1</sup>, Kevin K. Byon<sup>2</sup>, Trenton E. Gould<sup>1</sup>, Hyung Lee<sup>2</sup>, Jessica R.D. Mills<sup>2</sup>, Michael S. Ferrara<sup>2</sup>. <sup>1</sup>The University of Southern Mississippi, Hattiesburg, MS. <sup>2</sup>The University of Georgia, Athens, GA. (Sponsor: Michael J. Webster, FACSM)  
(No relationships reported)

The significant role played by self-reported symptoms in the diagnosis and determination of recovery from the brain injury of concussion, accentuates the need for the continual psychometric evaluation of summative self-report symptom instruments. Strength of inferences drawn from composite scores depends upon the quality and quantity of such available validity evidence. A 4-factor measurement model has been suggested, via exploratory factor analysis methods, to describe responses to the Post Concussion Symptom Scale (PCSS).

**PURPOSE:** To confirm the factorial validity of the 4 factor response structure of both non-concussed and concussed athlete responses to the PCSS instrument found within the ImPACT computerized neurocognitive exam.

**METHODS:** Responses from non-concussed (N=908) and concussed athletes (N=146) enrolled at a southeastern Division I institution were used for this retrospective analysis. A total of three separate CFAs (i.e., two CFAs with baseline data sets and one CFA with injured sample) using Maximum Likelihood methods were performed to fit the PCSS model, which was hypothesized as four factors with 22 items (i.e., Migraine, Neuropsychiatric, Sleep, and Cognitive). Several model fit indexes were employed, including  $\chi^2$ ,  $\chi^2/df$ , CFI, and RMSEA.

**RESULTS:** Goodness of fit indexes revealed that the four-factor measurement model did not fit the data well. Values of model fit indices were as follows:  $\chi^2 = 2381.18$  ( $p < .001$ );  $\chi^2/df = 11.73$ ; CFI = .541; RMSEA = .154 (90% CI = .148 - .159). Following model re-specification as guided by modification indices, an analysis using the second subsample demonstrated that again, the measurement model did not fit the data ( $\chi^2 = 2413.02$  ( $p < .001$ );  $\chi^2/df = 11.89$ ; CFI = .516; RMSEA = .154 (90% CI = .148 - .159). Lastly, goodness of fit indices revealed that the injured responses to the PCSS measurement model also did not fit the data ( $\chi^2 = 824.51$  ( $p < .001$ );  $\chi^2/df = 4.06$ ; CFI = .656; RMSEA = .145 (90% CI = .135 - .156).

**CONCLUSION:** Responses of both non-concussed and concussed athletes failed to support the posited four-factor measurement model of the PCSS. Such evidence reduces the strength of inferences that can be drawn from the clinical use of the four symptom clusters and suggest that the summative self-report instrument may require a novel theoretical measurement framework.

**Acute Effect Of A Stretching Session On Electroencephalogram And Behavioral Responses In Healthy Young Adults**

Bruno M. Costa<sup>1</sup>, Thiago T. Guimarães<sup>1</sup>, Lucenildo S. Cerqueira<sup>2</sup>, Alessandro O. Carvalho<sup>1</sup>, Fernando A.M.S. Pompeu<sup>2</sup>, Andréa C. Deslandes<sup>1</sup>. <sup>1</sup>Laboratório de Neurociência do Exercício-UGF, Rio de Janeiro, Brazil. <sup>2</sup>Laboratório de Biometria-EEFD-UFRJ, Rio de Janeiro, Brazil.  
(No relationships reported)

The scientific literature shows no studies that have investigated the acute effect of passive static stretching on behavioral and physiological responses. Empirical reports suggest an increased sense of well being after an acute bout of stretching.

**PURPOSE:** The aim of this study was to investigate the acute effect of a stretching session on the cortical activity (EEG), mood and anxiety of young healthy adults.

**METHODS:** Seventeen healthy young men with  $23.52 \pm 2.57$  years old,  $68.9 \pm 11.3$  kg and  $1.72 \pm 0.08$  m (mean  $\pm$  standard deviation) were recruited. The experimental procedure consisted of the evaluation of mood and anxiety through the scales of the Profile of Mood State (POMS) and State and Trait Anxiety Inventory (STAI), and the asymmetry of the EEG alpha frequency band (8 to 13 Hz). It was analyzed the electrode pairs Fp1Fp2, F3F4, F7F8, and P3P4. Evaluations were performed before and immediately after a session of tree sets of 30 seconds of passive static stretching exercises for four different positions involving the major muscle groups, with 30 seconds recovery between the sets.

**RESULTS:** The Wilcoxon test showed significant differences for the POMS factors depression ( $p=0.017$ /  $z=-2.388$ ), fatigue ( $p=0.024$ /  $z=2.257$ ), confusion ( $p=0.036$ /  $z=-2.097$ ) and total mood disturbance ( $p=0.011$ /  $z=-2.536$ ) and showed no significant difference for the abnormal variable Fp1Fp2 ( $p=0.463$ /  $z=0.734$ ). The natural log of the absolute power of alpha frequency band were analyzed by tree way ANOVA and also showed no difference between moments.

**CONCLUSIONS:** The stretching session led to an improvement in mood, but the other variables did not follow the same trend.

**Effects Of Exercise During Human Pregnancy On The Newborn's Brain**

Elise Labonte-LeMoyné, Daniel Curnier, Dave Elleberg. University of Montreal, Montreal, QC, Canada. (Sponsor: Francois Peronnet, FACSM)  
(No relationships reported)

**PURPOSE:** Accumulating evidence suggests that an active lifestyle is beneficial for cognition in children, adults and the elderly. Recently, studies using the rat animal model found that maternal exercise during pregnancy has a beneficial influence on the development of the foetal brain (i.e., increased hippocampal neurogenesis) that ultimately leads to functional changes for the newborn rat pups (i.e., better memory and learning abilities). The aim of the present study was to verify if in humans an active lifestyle during pregnancy has an impact on the newborn's brain.

**METHODS:** Twenty-two women are enrolled in the study and were randomly assigned to an active or a sedentary group. The active group was asked to exercise a minimum of 20 minutes, 3 times per week, at a minimal intensity of 55% of their maximal aerobic capacity. The sedentary group did not exercise. Monitoring was done using a daily exercise log with pedometer readings and the periodic wearing of an accelerometer. Other measures taken include a nutrition journal, and pre-pregnancy exercise habits. The effect of exercise during pregnancy on the newborn's brain was investigated 8 - 12 days post partum by means of the mismatch negativity (MMN), a neurophysiological brain potential that is associated to auditory sensory memory and measured with electroencephalography. Mann-Whitney test was used to investigate statistical significance of results.

**RESULTS:** No significant difference was found between the two groups for mean amplitude ( $P > 0.5$ ). On the other hand, mean median latency at the left and right fontal locations (F3 & F4) was significantly slower for the babies of the active mothers (258ms.) than the babies of the sedentary mothers (180 ms.). ( $z=-2.324$ ,  $p=0.20$ ).

**CONCLUSION:** These findings suggest that exercise during pregnancy has an impact on the development of the newborn's brain.

**Brain Imaging During Exercise- Comparison of Electroencephalography and Near-Infrared Spectroscopy**

Vera Abeln<sup>1</sup>, Christopher D. Askew<sup>2</sup>, Tobias Vogt<sup>1</sup>, Stefan Schneider<sup>1</sup>. <sup>1</sup>German Sport University, Cologne, Germany. <sup>2</sup>School of Exercise and Nutrition Sciences, Queensland University of Technology, Brisbane, Australia. (Sponsor: Romain Meeusen, FACSM)  
(No relationships reported)

During the past decade, near-infrared spectroscopy (NIRS) has been used as a surrogate method to monitor changes in brain activity during exercise. Other more direct brain-imaging methods, such as fMRI, are not feasible because of the motion restrictions required for optimal imaging. Recently, new developments have enabled brain imaging of exercising subjects via electroencephalography (EEG) (Brümmer et al., 2011). While both methods, NIRS and EEG, are reported to be sensitive to cortical activation during exercise, the relationship between these two brain-imaging methods is still questionable.

**PURPOSE:** To compare changes in cortical activity measured by NIRS and EEG in parallel during an incremental bicycle test.

**METHODS:** 32-channel EEG and 4-Channel NIRS were applied to record electrocortical and hemodynamic changes within the brain during an incremental bicycle exercise test of 10 healthy subjects ( $26 \pm 6.0$  yrs). The incremental exercise protocol commenced at 50 W and increased by 50 W every five minutes until subjective exhaustion. EEG and NIRS were recorded prior,

during and post-exercise. For EEG, low-resolution brain electro magnetic tomography (LORETA) was used to localize changes of electrocortical activity within the left and right prefrontal and parietal cortex. Oxygenated hemoglobin concentration (O2Hb) and the oxygenation index (HbDiff) within the same brain areas were analyzed using NIRS.

**RESULTS:** Electrocortical activity within prefrontal and parietal brain regions showed increases with exercise intensity and decreases post-exercise. Prefrontal O2Hb and HbDiff increased with increasing exercise intensity, but showed no change (O2Hb left + right, HbDiff right) or even a further increase (HbDiff left) following exercise. O2Hb increased within parietal regions during and post-exercise, whereas HbDiff first increased but then decreased from the 2nd last to the last measurement during exercise and increased again following exercise.

**CONCLUSION:** Localized EEG activity and NIRS derived O2Hb and HbDiff levels responded differently during incremental bicycle exercise. This indicates that NIRS activity may not accurately reflect electrocortical activity and that brain NIRS data during exercise should be interpreted with caution.

**Cortical Current Density Oscillations In The Motor Cortex Are Correlated With Muscular Activity During Pedaling Exercise**

Stefan Schneider<sup>1</sup>, David Rouffet<sup>2</sup>, Francois Billaut<sup>2</sup>. <sup>1</sup>German Sport University, 50933 Koeln, Germany. <sup>2</sup>Victoria University, Melbourne, Australia.

(No relationships reported)

**PURPOSE:** Despite modern imaging techniques, assessing and localizing changes in brain activity during whole-body exercise is still challenging and has not been attempted successfully so far.

Using an active electroencephalography (EEG) system in combination with source localization algorithms and EMG recordings, this study aimed to assess, display and localize changes in brain cortical activity and to correlate these oscillations with oscillating electromyography (EMG) activity during pedaling exercises at moderate and high intensities.

**METHODS:** Experienced cyclists volunteered for this study. The task consisted of a standardized warm up followed by cycling bouts of ~2 min at 1, 2, 3, 4 and 5 W.kg<sup>-1</sup> at 90 rpm and interspersed by sufficient recovery to limit fatigue. EEG activity was recorded on 32 sites across the motor cortex (M1). Surface electromyography (EMG) activity was recorded from 14 lower-limb muscles. EEG and EMG patterns were time normalized to describe simultaneous changes in brain and muscle activity within the pedaling cycle. Averaging 100 cycles at different power outputs revealed a high correlation between the changes in muscular activity in the lower limbs and oscillations in cortical current density (CCD) within M1 (MNI 0/-40/60).

**RESULTS:** With increasing exercise intensity a linear increase in cortical current density in M1 as well as in EMG activity was noticeable, whereas activity patterns remained comparatively stable across different exercise intensities. Furthermore oscillations showed a clear and highly significant correlation between cortical activity within M1 and EMG activity when applying a latency of 30-50ms.

**CONCLUSIONS:** Results demonstrate that it is possible to assess and localize brain cortical activity during moderate to high-intensity cycling exercise using EEG in combination with source localization algorithms. Results of this study might help to further evaluate the effects of central vs. peripheral fatigue during exercise.

**Catechol-O-Methyltransferase Genotype Influences Cognitive Performance and Concussion History in College Football Players**

Mark H. Sundman<sup>1</sup>, Eric E. Hall, FACSM<sup>1</sup>, Robert A. Gardner<sup>1</sup>, Walter R. Bixby, FACSM<sup>1</sup>, Paul C. Miller<sup>1</sup>, Stephen E. Folger<sup>1</sup>, Matthew C. Kostek<sup>2</sup>, Bradley S. Gordon<sup>2</sup>, Kenneth P. Barnes<sup>1</sup>. <sup>1</sup>Elon University, Elon, NC. <sup>2</sup>University of South Carolina, Columbia, SC.

(No relationships reported)

Catechol-O-Methyltransferase (COMT) is a gene that is active in the breakdown of dopamine and norepinephrine in the prefrontal cortex. It has two alleles, Val and Met, yielding three possible genotypes (Val/Val, Val/Met, Met/Met). The Val allele promotes higher enzyme activity resulting in greater levels of dopamine degradation and lower dopamine levels in the prefrontal cortex. Research suggests that those with Met/Met and Val/Met genotypes have better cognitive performance due to the lower enzyme activity associated with the Met allele. Additionally, previous findings show that Val/Val and Val/Met populations have higher concussion rates, which may be due to higher levels of dopamine degradation due to the Val allele.

**PURPOSE:** To investigate association between COMT and executive cognitive function in student-athletes and how certain genotypes affect concussion history.

**METHODS:** 18 college football players (age 18.077 years) were genotyped for COMT. Participants then performed cognitive tests using Immediate Post-Concussion Assessment Cognitive Testing (ImPACT). ImPACT obtains concussion history and measures cognitive function by using several neuropsychological tests involving word discrimination, attention span, response variability, working memory and recall, and reaction time.

**RESULTS:** 7 subjects were Met/Met genotype and 11 were Val/Met. Met/Met subjects scored higher on verbal memory test ( $p = .329$ ), visual memory test ( $p = .080$ ), and visual motor test ( $p = .163$ ). Results also show that only 14% of Met/Met subjects reported history of concussions while 27% of Met/Val subjects reported suffering at least one concussion.

**CONCLUSIONS:** While data collection is ongoing, our preliminary data supports previous findings that the Val allele decreases cognitive performance and increases risk of concussions.

Partially supported by a grant from American Medical Society for Sports Medicine.

**Running Modulates Hippocampal Acetylcholine In Operant Conditioning**

Kun Liu, Lu Zheng, Reziwan Yimiti. Capital Institute of Physical Education, Beijing, China.

(No relationships reported)

**PURPOSE:** Physical activity is benefit to learning and memory. Although numerous studies have demonstrated that physical activity play important roles in neurogenesis and brain function, the effect of physical activity on the variation of neurotransmitters in cognitive processes has not been elucidated clearly. Previous studies have demonstrated that acetylcholine (ACh) plays a critical role in hippocampus in learning, memory construction and retrieval. However, whether running improves learning and memory by changing hippocampal ACh has not been sure. It is hypothesized in this study that running could improve the cognitive performance by modifying release of hippocampal ACh. Thus the present study was designed to determine the effect of regular running on behavior performance of operant conditioning (OC) and monitor the level of hippocampal ACh during performance of OC.

**METHODS:** In vivo microdialysis coupled with high performance liquid chromatography (HPLC) and electrochemical detection (ECD) were used for sampling and ACh detecting. Male Sprague Dawley rats were randomly assigned to running and operant conditioning (running-OC group) and operant conditioning (OC group). Furthermore, an electric foot shock (E-shock) group and a free moving (FM) group were settled as control. The correct response rate in running-OC group increased significantly faster than OC group ( $P < 0.05$ ). The hippocampal ACh levels were recorded during the retrieval performance of OC after 12 weeks of running and/or OC training.

**RESULTS:** The hippocampal ACh transiently increased in the retrieval performance of OC and decreased to the basal levels after OC training. Running caused a lower transiently increase of hippocampal ACh level ( $185.21 \pm 16.51\%$ ,  $n = 5$ ,  $P < 0.05$ ) in running-OC group than the ACh level ( $213.75 \pm 23.38\%$ ,  $n = 5$ ,  $P < 0.05$ ) in OC group. The increased hippocampal ACh level ( $291.83 \pm 28.65\%$ ,  $n = 5$ ,  $P < 0.05$ ) is highest in E-shock group of rats and had no significant change in FM group of rats.

**CONCLUSIONS:** These findings indicate that the enhanced OC performance by running is correlated with modulation of hippocampal ACh level. The contents of this study could be significant for understanding the neurochemical mechanism underlying cognitive functions enhanced by physical activity.

### Do Voluntary Activation Deficits Contribute To Eccentric Weakness Following Intermittent Running?

Ryan G. Timmins<sup>1</sup>, Nuala M. Dear<sup>1</sup>, David A. Opar<sup>1</sup>, Morgan D. Williams<sup>2</sup>, Anthony J. Shield<sup>1</sup>. <sup>1</sup>Queensland University of Technology, Kelvin Grove, Australia. <sup>2</sup>University Glamorgan, Pontypridd, United Kingdom.  
(No relationships reported)

Hamstring strain injuries (HSI) are the predominant non-contact injury in many sports. Eccentric hamstring muscle weakness following intermittent running has been implicated within the aetiology of HSI. This weakness following intermittent running is often greater eccentrically than concentrically, however the cause of this unique, contraction mode specific phenomenon is unknown.

**PURPOSE:** To determine if this preferential eccentric decline in strength is caused by declines in voluntary hamstring muscle activation.

**METHODS:** Fifteen recreationally active males completed 18 × 20m overground sprints. Maximal strength (concentric and eccentric knee flexor and concentric knee extensor) was determined isokinetically at the velocities of  $\pm 180^{\circ}.s^{-1}$  and  $\pm 60^{\circ}.s^{-1}$  while hamstring muscle activation was assessed using surface electromyography, before and 15 minutes after the running protocol.

**RESULTS:** Overground intermittent running caused greater eccentric (27.2 Nm; 95% CI = 11.2 to 43.3;  $p=0.0001$ ) than concentric knee flexor weakness (9.3 Nm; 95% CI = -6.7 to 25.3;  $P=0.6361$ ). Following the overground running, voluntary activation levels of the lateral hamstrings showed a significant decline (0.08%; 95% CI = 0.045 to 0.120;  $P<0.0001$ ). In comparison, medial hamstring activation showed an increased level of activation following intermittent running (0.12%; 95% CI = 0.049 to 0.030;  $P = 0.0102$ ).

**CONCLUSIONS:** Eccentric hamstring strength is decreased significantly following intermittent overground running. Voluntary activation deficits in the biceps femoris muscle are responsible for some portion of this weakness. The implications of this finding are significant because the biceps femoris muscle is the most frequently strained of all the hamstring muscles and because fatigue appears to play an important part in injury occurrence.

### Multiscale Entropy Is Sensitive To Speed Constraint But Not Fatigue In High-intensity Running Intervals

Timothy R. Lindsay<sup>1</sup>, Stephen J. McGregor<sup>2</sup>, Timothy D. Noakes<sup>1</sup>. <sup>1</sup>University of Cape Town, Cape Town, South Africa. <sup>2</sup>Eastern Michigan University, Ypsilanti, MI.  
(No relationships reported)

**PURPOSE:** Long range inter-stride correlations are well established for running gait. Previous research suggests that long range correlations decrease over time in a bout of intense running. We aimed to confirm this finding in a series of high-intensity runs with several complimentary non-linear analyses. We hypothesized decreasing correlations with increasing interval number in high-intensity conditions.

**METHODS:** Ten trained runners completed two track sessions: a high-intensity session (HI) of 5\*2000m following pacing lights (~75% of peak incremental test speed, mean final RPE = 16.4) and a low-intensity session (LO) of 5\*2000m at < 75% MHR and < RPE 13 (mean speed = 56% of peak, mean final RPE = 11.1). Stride time series were generated from peak accelerations of each gait cycle, measured by foot-mounted accelerometers (G-Link, Williston, VT). We used detrended fluctuation analysis (DFA), power spectral density (PSD), rate of moment convergence (RMC), and multiscale entropy analysis (MSE). We applied a 2\*5 (intensity\*interval) ANOVA for DFA and PSD and a 2\*5\*10 (intensity\* interval\*scaling window) ANOVA for MSE data. All analysis was done with Matlab (Natick, MA).

**RESULTS:** DFA indicated 100/100 trials and PSD indicated 98/100 trials showing significant statistical persistence (> 2 SD from random). Where DFA differed from (PSD+1)/2 by more than 0.1 (41/100 trials), a relatively slow RMC increased confidence of long range correlations in all but a few trials. There were no intensity or interval effects for DFA and PSD ( $p > 0.05$ ). There was an intensity effect for MSE. HI had higher overall entropy than LO (mean = 1.77 vs. 1.70,  $p = 0.03$ ). There were no other main effects or interactions.

**CONCLUSIONS:** We confirmed ubiquitous long range correlations in both HI and LO. Only MSE was sensitive to intensity, but did not change with accumulated intervals. Higher entropy in HI suggests increased disorder and lower constraint. Evidently, organismic/physiological constraint changing with time and exertion exerted a relatively minor influence compared to task/speed constraint. The latter constraint was apparently the highest when subjects were required to run at a very low intensity. These results do not agree with previous research, but we have demonstrated the sensitivity of MSE to differences in relative running intensity.

### Relationship between Hip Strength and Trunk Motion in Collegiate Cross Country Runners

Kevin R. Ford, FACSM, Jeffery Taylor-Haas, Katlin Genthe, Jason Hugentobler. *Cincinnati Children's Hospital, Cincinnati, OH.*  
(No relationships reported)

**PURPOSE:** Hip strength may directly relate to abnormal running mechanics and contribute to the high incidence of overuse injuries in distance runners. The purpose of this study was to determine the relationship between hip isokinetic strength and trunk motion during treadmill running.

**METHODS:** Isokinetic hip strength and treadmill running kinematics were collected on 24 collegiate cross country runners (14 m, 10 f). Each subject completed a running protocol on a treadmill at a self-selected speed (3.6m/s). Kinematic data was collected with retroreflective markers attached to the thorax, pelvis, and each lower extremity segment (thigh, shank, foot). Thorax and pelvis range of motion (ROM) were calculated from initial ground contact to toe off. Pearson correlation coefficients were used to determine the relationship between strength and ROM ( $p<0.05$ ). Differences between male and female athletes were tested with mixed design ANOVAs ( $p<0.05$ ).

**RESULTS:** Isokinetic hip extension and abduction torque had significant inverse correlations to thorax ROM during stance phase of running ( $r=-0.60$ ,  $r=-0.53$ ). Frontal plane pelvic drop ROM was also significantly correlated to hip strength (extension  $r=-0.49$ ; abduction  $r=-0.44$ ). Female runners had significantly decreased normalized strength (hip extension  $1.8\pm 0.4Nm/kg$   $p<0.05$ ; hip abduction  $1.0\pm 0.2Nm/kg$   $p<0.05$ ), increased pelvic drop ( $13.1\pm 2.6^{\circ}$   $p<0.05$ ), and thorax ( $34.5\pm 7.0^{\circ}$   $p<0.05$ ) ROM compared to males (hip extension  $2.5\pm 0.5Nm/kg$ ; hip abduction  $1.3\pm 0.2Nm/kg$ ; pelvic drop  $8.9\pm 1.9^{\circ}$ ; thorax  $22.6\pm 3.5^{\circ}$ ).

**CONCLUSIONS:** Increased hip strength resulted in decreased ROM for both pelvic drop and trunk rotation during the stance phase of running in collegiate athletes.

### Impact Shock Attenuation is Increased with Rearfoot Running Compared to Forefoot Running

Allison H. Gruber<sup>1</sup>, Timothy R. Derrick<sup>2</sup>, Joseph Hamill, FACSM<sup>1</sup>. <sup>1</sup>University of Massachusetts, Amherst, MA. <sup>2</sup>Iowa State University, Ames, IA.  
(No relationships reported)

Rearfoot (RF) and forefoot (FF) running differ in the vertical ground reaction force (vGRF) profile by the presents of an impact peak in RF running. The absence of this impact peak has led some to suggest FF running may be beneficial at preventing running overuse injuries. However, the differences in vGRF profile in the time domain suggests that the frequency content of the

vGRF, and thereby the frequency content of the impact shock, may also differ. Changes in the amplitude of each frequency contained in the impact shock wave may affect how the body attenuates these frequencies.

**PURPOSE:** To determine the difference in shock attenuation between the RF and FF running footfall patterns.

**METHODS:** Ten natural RF runners and 10 natural FF runners ran on a treadmill at 3.5 m/s for 3 minutes with each footfall pattern. Piezoelectric accelerometers were affixed to the frontal bone of the head and the distal antero-medial tibia. Acceleration data were collected at 1200 Hz. A DFT was performed on 15 consecutive stance phases then normalized to 1 Hz bins. The degree of shock attenuation was calculated with a transfer function by:  $10\log_{10}(\text{PSD}_{\text{head}}/\text{PSD}_{\text{tibia}})$ . A mixed factor ANOVA was used to assess differences in attenuation at frequencies 1 - 50 Hz ( $\alpha = 0.05$ ).

**RESULTS:** RF running resulted in a gain of the head signal components relative to the tibia at frequencies between 1 - 2 Hz ( $p < 0.05$ ) whereas FF running resulted in a gain at frequencies between 4 - 6 Hz. Attenuation was greater during RF running for frequencies between 5 - 11 Hz, 14 - 20 Hz and 42 - 47 Hz ( $p < 0.05$ ). FF running resulted in an insignificant increase in attenuation of frequencies between 25 - 29 Hz.

**CONCLUSIONS:** Increased attenuation of the head signal components relative to the tibia at frequencies between 10 - 20 Hz may reflect the increased amplitude of the impact peak in the RF pattern. The differences in kinematics and muscular demands between RF and FF running may explain the increased attenuation of the impact shock wave in RF running. Passive mechanisms, such as absorption of frequencies by the heel fat pad, bone and other tissues, may be responsible for the increased degree of attenuation in high frequency components with RF running. Alternatively, active mechanisms responsible for attenuating low frequency components may not provide sufficient attenuation to maintain head stability.

**Age and Performance Related Differences in Adolescent Running Biomechanics**

Richard W. Kruse, John Henley, Chris Church, Ryan Bober, Daveda Taylor, Nancy Lennon, Kathleen O'Brien, Freeman Miller. *Alfred I. duPont Hospital for Children, Wilmington, DE.*

(No relationships reported)

Several studies have focused on associations between biomechanical gait abnormalities and prevalent running injuries. Few have looked at the changes that occur due to natural development and training. Young or untrained runners may have natural characteristics that pre-dispose them to injury and these tendencies may disappear as the runner gains experience.

**PURPOSE:** The purpose of this study is to determine the biomechanical differences associated with age and performance in children.

**METHODS:** Sixty-six subjects (29 boys, 37 girls), uninjured for prior 6 months, ages 8-20 years old participated in the study. Subjects were stratified by age into three groups: 8-11, 12-14, and 15-20 years old. The older subjects (14-20) were separately stratified by self-reported mile performance as good (< 5 min/mile), average (< 6 min/mile), and poor (> 6 min/mile or unreported). Kinetic and kinematic data was obtained for each subject during over-ground running at 9 mph ( $\pm 5\%$ ). Steady state was determined by ensuring that the braking and propulsion ground reaction forces within 25 %.

**RESULTS:** With age, cadence decreases ( $192 \pm 13$  steps/min to  $166 \pm 9$  steps/min;  $p < 0.05$ ) and step length increases ( $254 \pm 18$  cm to  $294 \pm 19$  cm;  $p < 0.05$ ). Normalized joint variability decreased with age, although this was not significant ( $1.6 \pm .2$ , young, to  $1.0 \pm .4$ , old). Age correlated with a shift from hip flexion power in youth as a primary means of propulsion ( $5 \pm 2$  N to  $3 \pm 1$  N;  $p < 0.05$ ) to ankle power in older runners ( $8 \pm 2$  N to  $12 \pm 2$  N;  $p < 0.05$ ). Older age also correlated with greater knee flexion range of motion ( $24 \pm 4^\circ$  to  $28 \pm 5^\circ$ ;  $p < 0.05$ ). This effect was consistent with increased knee flexion absorption power ( $-6.8 \pm 3$  N to  $-12 \pm 4$  N;  $p < 0.05$ ). Loading rate was significantly higher in younger runners ( $120 \pm 41$  N/BW/S) than older runners ( $88 \pm 27$  N/BW/S). Good self-reported milers had lower cadence ( $162 \pm 8$  steps/min vs.  $168 \pm 10$  steps/min) and a longer stride ( $305 \pm 14$  cm vs.  $286 \pm 18$  cm) than poor milers. Good milers trended toward less joint variability than poor milers, although this was not significant. Finally, the loading rate was significantly greater in faster milers ( $98 \pm 23$  N/BW/S) than slower milers ( $77 \pm 28$  N/BW/S).

**CONCLUSION:** Running biomechanics differ with age and performance level particularly in height-related, variability, and power generation variables.

**2960** Board #232 June 1 9:30 AM - 11:00 AM

**Whole Body Kinematic Compensatory Mechanisms Are Magnified As Runners Fatigue Over 10 Km At Race Pace**

Desi Fuhr, Pierre Gervais, Douglas Gross, Michael Kennedy. *University of Alberta, Edmonton, AB, Canada.* (Sponsor: Darren DeLorey, FACSM)

(No relationships reported)

During a 10 km run at race pace, changes in lower extremity mechanics have been reported in male runners however mechanical changes over 10 km in female runners is unknown. Upper body mechanics at race pace has not been reported in either gender.

**PURPOSE:** To examine whole body running mechanics in female distance runners during a simulated 10 km race on a treadmill.

**METHODS:** Nine female distance runners (age:  $32.1 \pm 4.2$  yrs; ht:  $166.7 \pm 7.4$  cm; wt:  $57.8 \pm 7.0$  kg;  $\text{VO}_2\text{max} = 3.24 \pm 0.50$  L/min) completed a graded exercise test (Day 1); 10 km time trial (Day 2); and simulated 10 km treadmill run (DAY 3). Treadmill speed was 95 % of average running velocity of the Day 2 time trial. Reflective markers were placed bi-laterally and kinematic data were sampled at 120Hz at 50 m (BASE), 4450 m (MID) and 9950 m (END) using a 6-camera optoelectronic motion capture system. Bi-lateral mechanical measures calculated: stride frequency, maximum elbow flexion and maximum knee flexion (swing phase).

**RESULTS:** Stride frequency decreased for both the left and right legs (BASE to MID by 1.27strides/min for both and by 1.66 strides/min from MID to END ( $p > 0.05$ ). Overall maximum knee flexion during swing phase increased for both the left and right legs (BASE to END by  $4.3^\circ$  ( $p > 0.05$ ). Although not significant, maximum elbow flexion increased for both left and right limbs (BASE left:  $137.6 \pm 6.7^\circ$ ; END left:  $145.1 \pm 6.7^\circ$ ; BASE right:  $134.6 \pm 11.6^\circ$ ; END right:  $146.0 \pm 10.7^\circ$ ;  $P < 0.05$ ) **CONCLUSION:** These results indicate that changes in mechanics occur throughout the simulated 10 km run and these changes are magnified as runner's fatigue. Mechanical changes such as these may be compensatory in nature. Increased elbow flexion may have assisted propulsion by increasing the amount of lift acting on the body and ultimately increasing the individual's total flight time. This, combined with increased knee flexion, seem to be key coping strategies to maintain pace with fatigue induced step frequency decreases.

**Muscle Activity During Running With Different Body Weight Support Mechanisms**

John A. Mercer, FACSM<sup>1</sup>, John A. Mercer, FACSM<sup>1</sup>, Bryon Applequist<sup>1</sup>, Kenji Masumoto<sup>2, 1</sup> UNLV, Las Vegas, NV. <sup>2</sup>Fukuoka Prefectural, Fukuoka, Japan.

(No relationships reported)

There are different mechanisms to provide body weight (BW) support during running. For example, deep water running (DWR) provides 100% BW support whereas a lower body positive pressure (LBPP) treadmill (e.g., Alter-G) can provide varying levels of body weight (BW) support. However, muscle activity during running with different BW support mechanisms is not fully understood.

**PURPOSE:** To compare lower extremity muscle activity during DWR and running using a LBPP treadmill with different amounts of BW support.

**METHODS:** Subjects (6 females, 2 males;  $40 \pm 6.5$  years;  $173 \pm 7.2$  cm;  $66.9 \pm 11.7$  kg) completed DWR and LBPP treadmill running conditions. LBPP was set to provide BW support such that the subjects weighed 60% and 80% of BW. Two styles of DWR were used: High knee (DWR-HK) and cross-country (DWR-CC). Prior to testing, preferred stride frequency (PSF) at a self-selected speed was determined running on a treadmill (no BW support). Both of the LBPP treadmill conditions (i.e., 60% and 80% of BW) were done at the self-selected speed and PSF and each DWR condition (i.e., DWR-HK and DWR-CC) at PSF. Muscle activity was recorded from the rectus femoris (RF), biceps femoris (BF), gastrocnemius (GA), and tibialis anterior (TA) of the right lower extremity using telemetry surface electromyography (EMG). Average EMG (AVG) and root mean square (RMS) were calculated for each muscle across 15-s. Repeated measures analysis of variance were used to compare SF and EMG among conditions.

**RESULTS:** SF was not different between conditions ( $80.6 \pm 9.2$ ,  $83.5 \pm 11.5$ ,  $78.8 \pm 8.2$ ,  $81.0 \pm 6.1$  strides/min for DWR-HK, DWR-CC, 60% and 80% of BW conditions, respectively;  $p > .05$ ). RF (both AVG and RMS) were different between conditions ( $p < .05$ ). In addition, BF (both AVG and RMS) were each different between conditions ( $p < .05$ ).

**CONCLUSIONS:** The mechanism of BW support nor style of DWR influenced GA or TA muscle activity during running at the same SF. However, RF and BF muscle activity were influenced not only by the mechanism of BW support but also the style of DWR.

**2962 Board #234 June 1 9:30 AM - 11:00 AM**  
**Effect of Body Weight Support on Spatiotemporal Running Mechanics**

Matthew F. Moran, Andrew B. Sullivan, Brendan J. Rickert. *Sacred Heart University, Fairfield, CT.*  
*(No relationships reported)*

Running on a treadmill (TM) that artificially reduces body weight (BW) via differential air pressure (DAP) has been shown to reduce (i) vertical ground reaction forces, (ii) muscular activity, and (iii) metabolic cost; but gait mechanics may be altered depending on the level of BW support. These findings explain the potential use of DAP TMs for both injury rehabilitation and performance enhancement. Despite the obvious applications, the relationship between BW support and spatiotemporal (stride rate, stride length) mechanics is not clearly understood. In order to improve training prescription and running mechanics specificity from DAP TMs to overground running, the current investigation systematically investigated the effects of BW support level on spatiotemporal running mechanics.

**PURPOSE:** To determine the effects of body weight support in a DAP treadmill on the spatiotemporal gait mechanics in male distance runners.

**METHODS:** Ten well-trained male runners (age 20.4 ± 2.0 yrs; height 1.78 ± 0.08 m; mass 63.9 ± 6.0 kg; years of competitive running 8.3 ± 2.4) voluntarily ran at a self-selected sub-maximal pace for 34 continuous minutes on a DAP TM at six different levels of BW (100%, 90%, 80%, 70%, 60%, and 50%). BW was either systematically reduced (n=5) from 100% to 50% or increased (n=5) from 50% to 100%. Following each 5-minute segment, a 1-minute run segment at ±5% BW was allocated to ease the transition before the next BW level. Heart rate (HR), ratings of perceived effort (RPE), and high-speed sagittal plane video (210 Hz) were collected for each trial. Stride rate (SR), stride length (SL), and stance-to-swing cycle times (SS) were computed for each segment from video analysis. All dependent variables were compared using repeated-measures ANOVAs with post hoc tests in PASW Statistics 18.

**RESULTS:** SR and SL, normalized to leg length, was significantly different for all loading conditions (p < .04) with the exception of 60% compared to 70% BW (p = .12, .13).

**CONCLUSIONS:** In a group of well-trained male distance runners, SR was significantly decreased and SL was significantly increased as the simulated BW was reduced in 10% increments. Clinicians and coaches utilizing DAP TMs should be aware of the resulting gait timing alterations and consider devices, such as a metronome, to increase cadence as BW support is increased.

**2963 Board #235 June 1 9:30 AM - 11:00 AM**  
**Are Three-Dimensional (3D) Single Leg Step Down Kinematics Correlated to 3D Running Kinematics?**

Anne-Marie V. Fox, Nicolas S. Hatamiya, Richard B. Souza, Anthony C. Luke, FACSM. *University of California, San Francisco, San Francisco, CA.*  
*(No relationships reported)*

As the worldwide popularity of running has steadily increased, so has the incidence of running-related injuries. Distinct frontal and transverse plane running kinematics have been linked with prevalent running-related injuries, such as patellofemoral pain. For clinicians without access to a treadmill, it would be useful to examine if similar kinematic patterns are demonstrated in other tasks, such as a single leg step down (SLSD).

**PURPOSE:** To determine if three-dimensional (3D) SLSD kinematics are correlated to 3D running kinematics.

**METHODS:** 19 healthy subjects (9 male, 10 female; age = 28.4 ± 4.96 years; weight = 63.6 ± 10.9 kg; height = 1.69 ± 0.09) ran on a treadmill at a self-selected pace for 6 minutes. Immediately following, 5 SLSD repetitions were completed from a height of 17 cm at a self-selected rate. For both activities, a 10 camera motion capture system (250 Hz) and cluster based marker set were used to measure kinematics. Pearson correlation coefficients were used to assess the association between SLSD and running kinematics.

**RESULTS:** Significant correlations (p < 0.05) were found for 3 of the 5 kinematic variables measured (Table 1). A strong correlation of 0.81 was found for mean knee external rotation. Moderate correlations ranging from 0.45 to 0.58 were found for all the frontal plane kinematic measurements.

**CONCLUSIONS:** These results suggest that many running kinematic measurements, which have been linked to running-related injuries, are at least moderately associated with SLSD kinematics. This association may prove to be useful for clinicians treating runners; however, further research is necessary to investigate the link between clinical observations and 3D kinematics.

**Effect Of Lower Extremity Mass And Inertia Manipulation On Swing Phase Sprint Mechanics**

Chee-Hoi Leong<sup>1</sup>, William J. McDermott<sup>2</sup>, Alena M. Grabowski<sup>3</sup>, Craig P. McGowan<sup>4</sup>, James C. Martin, FACSM<sup>1</sup>. <sup>1</sup>University of Utah, Salt Lake City, UT. <sup>2</sup>TOSH - The Orthopedic Specialty Hospital, Salt Lake City, UT. <sup>3</sup>Massachusetts Institute of Technology, Cambridge, MA. <sup>4</sup>University of Idaho, Moscow, ID.  
*(No relationships reported)*

Maximal sprinting speeds are influenced by stance and swing phase mechanics. Because swing phase mechanics may account for substantial variations in inertial characteristics, assessing the kinematics and kinetics is essential to identifying factors that may limit maximal sprinting speed.

**PURPOSE:** To examine the effects of lower extremity mass and inertia manipulation on swing phase sprint mechanics across un-weighted (UW), weighted 100 g (W100), and weighted 300 g (W300) conditions, using mass bilaterally added to the dorsal surface of the feet.

**METHODS:** Fifteen healthy subjects (mean age = 22.6 ± 7.4 years) performed successive bouts of sprinting up to their maximum voluntary speed under three weighted conditions. An eight-camera 3D Eva Real Time motion capture system and a motorized high-speed 3D force sensing treadmill were used to collect synchronized kinematic and kinetic data. One-way repeated measures ANOVAs were used to compare maximal sprinting speeds, and kinematic and kinetic variables.

**RESULTS:** Maximal sprinting speed for both the W100 (8.0 ± 1.0 m/s) and W300 (7.7 ± 1.0 m/s) conditions were reduced by 3.0 ± 3.4 % and 6.2 ± 3.9 % respectively compared to the UW condition (p < 0.05). Maximum hip flexion power for the W300 (14.0 ± 13.2 W/kg) condition was reduced by 11.1 ± 3.9 % compared to the UW condition (p < 0.05). Hip angular velocity at maximum hip flexion power for the W300 (10.1 ± 1.7 rad/s) condition was reduced by 5.0 ± 11.8% compared to the UW condition (p < 0.05). There were no significant changes in knee flexion angles and hip joint moment at maximum hip flexion power.

**CONCLUSIONS:** Inertial manipulation reduced maximal sprinting speed and maximum hip flexion power. These data suggest that increased inertial characteristics of the swing limb play an important role in determining maximum sprinting speed. While increased foot inertia did cause a reduction in maximal sprint speed, this reduction was not due to limitations in hip power. The significant effect on hip angular velocity but not on the hip joint moment suggests further analyses are required regarding the generation of hip flexion power.

2965 Board #237 June 1 9:30 AM - 11:00 AM

### Vertical Acceleration To The Ground Can Be A Greater Component Contributing To Higher Sprinting Performance

Takeshi Oyama<sup>1</sup>, Yoshiharu Fujieda<sup>2</sup>, Hisataka Ambe<sup>3</sup>, Jumpei Hayashi<sup>3</sup>, Kenichi Suijo<sup>4</sup>, Hiroshi Yamauchi<sup>5</sup>, Kazuo Ura<sup>6</sup>. <sup>1</sup>Gunma Prefectural Maebashi Nishi High School, Gunma, Japan. <sup>2</sup>Tokyo Gakugei University, Tokyo, Japan. <sup>3</sup>Division of Health and Sport Education, The United Graduate School of Education, Tokyo Gakugei University, Tokyo, Japan. <sup>4</sup>Department of Preventive Medicine and Public Health, Tokyo Medical University, Tokyo, Japan. <sup>5</sup>Part-time Lecturer, Faculty of Sciences, Toho University, Chiba, Japan. <sup>6</sup>Casio Computer Co., LTD., Tokyo, Japan.  
(No relationships reported)

**Background** The top running speed of 100 m sprints are yielded by the accumulated accelerations of the first half to the goal. It is unfortunately impossible for us human beings to transmit all muscle powers directly into horizontal drive due to our body joint structure.

**PURPOSE:** In this study we investigated the changes of 3 - dimensional accelerations (Za vertical to the ground, Ya vertical to X and horizontal to the ground, Xa horizontal to the ground and toward the goal) of the sprinting athletes.

**METHODS:** Subjects of 13 Japanese male high school athletes underwent a single time-trial of 100 m sprint, wearing a triaxial accelerometer on their center of the gravity in the lower abdominal area. All through 100 m distance, 5 sets of split times and speeds were recorded at each 20 m section (the 1st section of 0-20 m as S1, the 2nd 20-40 m S2, the 3rd 40-60 m S3, the 4th 60-80 m S4 and 5th 80-100 m S5). Based on their total 100 m sprinting time, the upper 7 participants who showed better results were defined as the Faster and the other 6 as the Slower.

**RESULTS:** Compared the measured accelerations between the Faster and the Slower, Za of the Faster was statistically greater than that of the Slower at S4 ( $-1,691.42 \pm 373.76$  m/s<sup>2</sup> vs.  $-2,498.77 \pm 341.19$  m/s<sup>2</sup> p<0.05). The Faster also demonstrated tendencies of higher Za than those of the Slower at S1 ( $-1,868.72 \pm 407.57$  m/s<sup>2</sup> vs.  $-2,633.97 \pm 372.05$  m/s<sup>2</sup> p<0.1) and S2 ( $-1,667.65 \pm 374.15$  m/s<sup>2</sup> vs.  $-2,423.58 \pm 341.55$  m/s<sup>2</sup> p<0.1) respectively. On the other hand, Xa produced no significant differences at all sections. Discussions These findings indicate that it is difficult to predict the sprinters performance by only using horizontal acceleration data. We should consider that vertical acceleration, which is supposed to be a product of reaction force from the ground by transferring energy of the runners' body weight and their leg muscle strength to the ground, can be a greater component contributing to higher sprinting performance.

**CONCLUSION:** Vertical acceleration to the ground can be a greater component contributing to higher sprinting performance.

### History of Low Back Pain affects Pelvis and Trunk Rotation During a Lift-Lower Task

Joseph F. Seay, Shane G. Sauer, Peter N. Frykman, Tanja Roy. *US Army Research Institute of Environmental Medicine, Natick, MA.*  
(No relationships reported)

Low Back Pain (LBP) is common, with most cases resolving within 2 weeks. Research has shown increased risk of LBP in healthy (pain-free) athletes with a history of LBP (HBP). Bending at the waist and twisting is an occupational risk factor for LBP, however few studies have explored differences in lifting mechanics between healthy people with and without HBP; insight into these differences could elucidate adaptations that occur due to LBP.

**PURPOSE:** To compare transverse plane range of motion of the trunk (ROM<sub>t</sub>) and pelvis (ROM<sub>p</sub>) during a sustained asymmetric repetitive task between a HBP group and a group with no history of LBP (NBP).

**METHODS:** N=18 Soldiers (n=9 men/group) participated in a box lift-lower task. A 11-kg box with handles was lifted for 10 min at 12 cycles/min. The box started at ankle height in front of the volunteer, was lifted to a shelf 45° off-center at waist height, and lowered to the start position. Lifting side was alternated during the trial. Kinematic data were collected during min 1 and 9 (min1, min9). 2-way ANOVA (Group X Time) were performed for ROM<sub>t</sub> and ROM<sub>p</sub>. Effect sizes (ES) were calculated as the mean difference relative to a pooled SD.

**RESULTS:** ROM<sub>t</sub> and ROM<sub>p</sub> were similar at min1. At min9, HBP group did not change, however these ROM both *decreased* in NBP group (Fig 1). ES > 1.0 further indicated large practical differences.

**CONCLUSIONS:** Differences between groups over time demonstrate residual consequences of LBP in an occupational scenario, even though the HBP group was pain-free for > 6 months prior to data collection. The decreased axial ROM over time may represent a lack of adaptability in the HBP group compared to those who never had LBP, and may lend insight as to why individuals with HBP are at increased risk for re-injury.

2967 Board #239 June 1 11:00 AM - 12:30 PM

### Lumbar Spine Kinematics in Marine Corps Soldiers Carrying Heavy Loads

Ana E. Rodriguez-Soto<sup>1</sup>, Andrew Jensen<sup>2</sup>, Rebecca Jaworski<sup>2,3</sup>, Karen Kelly<sup>3</sup>, Lawrence Frank<sup>1</sup>, Samuel R. Ward<sup>1</sup>. <sup>1</sup>University of California, San Diego, La Jolla, CA. <sup>2</sup>San Diego State University, San Diego, CA. <sup>3</sup>Naval Health Research Center, San Diego, CA.  
(No relationships reported)

Higher incidence of lumbar spine pain, perhaps due to heavy load carriage, has been observed in US military troops.

**PURPOSE:** To measure kinematic changes in the lumbar spines of Marines carrying heavy loads. We hypothesized that heavy loads would induce increased lumbar lordosis and disc compression.

**METHODS:** Sagittal T2 MR images of the lumbar spine were acquired on a 0.6T vertical MRI scanner in 8 active-duty Marines. Each Marine was scanned without load (BL), immediately after donning body armor and a backpack (total 50.8 kg), after 45 min of standing with the load (SL), after walking for 45 min with load (WL), and after 45 min of side-lying recovery. Custom software was used to measure lumbar spine kinematics, enabling measurement of whole spine angles, intervertebral angles, and regional disc heights. Repeated measurements ANOVAs and post hoc Sidak tests were used to identify significant differences between tasks ( $\alpha = 0.05$ ).

**RESULTS:** The overall position of the spine was significantly more horizontal during the SL ( $53.5 \pm 8.7^\circ$ ) and WL ( $54.5 \pm 5.2^\circ$ ) tasks compared with the unloaded task ( $85.2 \pm 3.3^\circ$ ). Lumbar lordosis was reduced during the SL ( $46.0 \pm 10.6^\circ$ ) and WL ( $38.6 \pm 17.5^\circ$ ) tasks compared with the unloaded task ( $52.3 \pm 11.6^\circ$ ). Sagittal intervertebral angles were significantly reduced in each loading task at L4-L5 (BL= $12.2 \pm 3.3^\circ$ , SL= $3.9 \pm 4.0^\circ$ , WL= $4.9 \pm 4.2^\circ$ ) and L5-S1 (BL= $10.6 \pm 3.9^\circ$ , SL= $2.9 \pm 1.2^\circ$ , WL= $3.6 \pm 2.1^\circ$ ), suggesting that reduced lordosis was driven by L4-L5 and L5-S1 flexion. Significant disc compression was evident anteriorly at L4-L5 (BL= $17.3 \pm 0.9$ mm, SL= $14.4 \pm 1.4$ mm, WL= $15.3 \pm 1.5$ mm) and L5-S1 (BL= $15.6 \pm 2.3$ mm, SL= $12.8 \pm 0.9$ mm, WL= $13.3 \pm 1.9$ mm), but was actually reduced in the posterior region at L4-L5 (BL= $10.8 \pm 1.3$ mm, SL= $13.0 \pm 1.9$ mm, WL= $12.8 \pm 2.0$ mm) and L5-S1 (BL= $9.9 \pm 1.1$ mm, SL= $12.1 \pm 1.1$ mm, WL= $11.8 \pm 1.3$ mm). All kinematic variables returned to baseline levels after 45 min of side-lying recovery.

**CONCLUSIONS:** Heavy load carrying induced lumbar spine flexion and only anterior disc compression, contrary to our initial hypothesis. These findings suggest a postural strategy aimed at centralizing a heavy posterior load over the base of support. This strategy may minimize intervertebral compression, but it may also make the lumbar spine susceptible to shear-load-induced injuries. (US ARMY RDECOM N6311610MP00182)

**2968** Board #240 June 1 11:00 AM - 12:30 PM  
**The Effect of Pregnancy on Torso Kinematics during Gait**

Jean L. McCrory, FACSM<sup>1</sup>, April J. Chambers<sup>2</sup>, Ashi Daftary<sup>3</sup>, Mark S. Redfern<sup>2</sup>. <sup>1</sup>West Virginia University, Morgantown, WV. <sup>2</sup>University of Pittsburgh, Pittsburgh, PA. <sup>3</sup>West Penn Allegheny Health Systems, Pittsburgh, PA.  
(No relationships reported)

Numerous anatomical changes occur during pregnancy that may be related to gait alterations, which in turn may be related to increased reports of lumbar and pelvis pain during pregnancy. While other researchers have reported changes in hip and ankle biomechanics, none have quantified torso kinematics related to the “waddling gait” that pregnant women are anecdotally said to exhibit.

**PURPOSE:** The purpose of this study was to examine the effects of pregnancy on torso mechanics during gait.

**METHODS:** Data were collected on 29 pregnant subjects in the mid-second and third trimesters and on 40 control women. An 8 camera motion capture system (120 Hz) was used to collect data of subjects walking at their freely chosen speed along an 8 meter laboratory runway. Subjects wore a modified Helen Hays marker set. Right foot heel strike (RHS) and left foot toe off (LTO) were determined from force plate data (1080 Hz). The 3D angles of the thorax (i.e. upper torso) and pelvis were determined at RHS. The frontal plane movement of the C7 marker and the ranges of motion of the thorax and pelvis during gait were determined between RHS and LTO. An ANOVA was performed to determine if differences existed between pregnant women in their second trimester, third trimester, and controls ( $\alpha=0.05$ ).

**RESULTS:** There was significantly ( $p<0.01$ ) more frontal plane motion of C7 between the third trimester ( $6.5 \pm 2.7$ cm), second trimester ( $5.6 \pm 1.9$  cm), and controls ( $4.7 \pm 1.8$ cm) during the stride. At RHS, the sagittal plane position of the thorax was more extended ( $p<0.01$ ) as pregnancy advanced (third trimester:  $-6.6 \pm 4.5^\circ$ , second trimester:  $-3.5 \pm 5.1^\circ$ , Con:  $1.7 \pm 5.1^\circ$ ). No other differences in thorax and pelvis mechanics were noted.

**CONCLUSIONS:** Pregnant women demonstrated more frontal plane motion of C7 during gait, particularly in the third trimester. Because no differences in frontal plane angles of the thorax and pelvis were seen between groups, this movement of C7 is likely due to a side-to-side shifting of the body rather than a leaning. Pregnant women demonstrated a backward leaning of the thorax, which is likely to counterbalance a forward position of the center of mass due to increasing abdominal size. \*Funding: NIOSH K01 008458.

**2969** Board #241 June 1 11:00 AM - 12:30 PM  
**The Efficacy of “The 11” Injury Prevention Program With Regard to Knee and Trunk Motion**

Yasuaki Saho<sup>1</sup>, Issei Ogasawara<sup>2</sup>, Yasuharu Nagano<sup>3</sup>, Tomohiro Ogai<sup>4</sup>, Masakatsu Setojima<sup>4</sup>, Toru Fukubayashi<sup>1</sup>. <sup>1</sup>Waseda University, Saitama, Japan. <sup>2</sup>Mukogawa Women’s University, Hyogo, Japan. <sup>3</sup>Niigata University of Health and Welfare, Niigata, Japan. <sup>4</sup>Ryutsukeizai University, Ibaraki, Japan.  
(No relationships reported)

The injury prevention program created by the FIFA is called “The 11.” It is especially useful in the prevention of non-contact injuries. However, it is unclear how this program helps reduce injuries.

**PURPOSE:** To identify the effect of “The 11” on knee and trunk motion.

**METHODS:** Eight male collegiate soccer players were recruited for this study. The players performed “The 11” twice a week for 6 months. Before and after the intervention, knee and trunk movements were recorded using a three-dimensional motion analysis system while the subjects performed cutting tasks. Cutting tasks were performed on a force plate after running. Tasks like side step, crossover step, or forward running were randomly selected and were conducted in two situations: anticipated and unanticipated. In the anticipated situation, subjects were informed about the task in advance. In the unanticipated situation, random visual cues were presented at the moment when subjects reached about 2.5m from the force plate. Only the side step task was analyzed. In each trial, we calculated knee joint angle (flexion/extension, abduction/adduction and tibial rotation) and trunk inclination (forward and lateral) using the point cluster technique, from 100 msec before foot-contact (FC) to toe-off. Each variable at 100 msec before FC, at the time of FC, and the peak value during FC was calculated in each task. Student t-test was used to compare the difference between the conditions before and after intervention ( $\alpha=0.05$  was considered significant).

**RESULTS:** The peak knee abduction angle was significantly lower after intervention than before intervention in the unanticipated sidestep task ( $6.2 \pm 3.7$  vs.  $12.1 \pm 4.3$ ,  $p<0.05$ ). The tibial external rotation angle at the time of FC after intervention was significantly lower than before intervention in the unanticipated sidestep task ( $5.7 \pm 6.8$  vs.  $10.1 \pm 8.3$ ,  $p<0.05$ ). Other knee variables and all trunk variables did not change.

**CONCLUSIONS:** “The 11” can reduce ACL injury risk as, in the anticipated situation, the knee abduction angle decreased after intervention. In this way, “The 11” can reduce sports injuries. However, trunk motion remained unchanged despite “The 11’s” core stability exercise and the instructions for trunk alignment during jumping and stepping. Some training components of this program can be improved.

---

**2970** Board #242 June 1 11:00 AM - 12:30 PM  
**Electromyographic Analysis of Trunk and Hip Muscles During Swiss Ball Bridging Exercises Performed With Two Different Ankle Positions**

Rafael F. Escamilla, FACSM, Joseph M. Carinci, Edward Barakatt, Paul Broyer, Christian Butler, Jenny Ferguson, Amanda Morgan, Ricardo Morales, Ryan Rhoads. California State University, Sacramento, Sacramento, CA.  
(No relationships reported)

**PURPOSE:** Bridging exercises are commonly used in training and rehab to enhance core stability. Some trainers recommend dorsiflexing the ankles during bridging exercises to facilitate the gluteus maximus and inhibit the hamstrings. Our purpose was to compare trunk and hip muscle activity during 3 two-leg and 2 one-leg bridging exercises on a swiss ball using two different ankle positions: 1) ankle plantar flexion (PF); 2) ankle dorsiflexion (DF).

**METHODS:** Twenty healthy males and females between 22-27 y.o. served as subjects. Surface electrodes were positioned on the subject’s right side over the upper rectus abdominis (RA), external oblique (EO), internal oblique (IO), erector spinae (ES), latissimus dorsi (LD), gluteus maximus (GMA), gluteus medius (GME), medial hamstrings (MH), lateral hamstrings (LH), rectus femoris (RF), tensor fascia latae (TF), and adductor longus (AL). EMG data were collected from an EMG system during a 5 s isometric hold after obtaining the bridge position. EMG data were normalized by maximum voluntary muscle contractions. Differences in muscle activity were assessed by a one-way repeated measures Analysis of Variance ( $p < 0.01$ ).

**RESULTS:** During the two-leg bridge with knees flexed and the ball under the upper back, activity from the RF, AL, and IO was significantly greater with DF compared to PF. During the two-leg bridge with knees flexed and feet on ball, muscle activity from the RF, TF, AL, ES, and GME was significantly greater with DF compared to PF. During the two-leg bridge with knees flexed and feet on ball, muscle activity from the LH was significantly greater with PF compared to DF. During the one-leg bridge with knees extended and right foot on ball, muscle activity from the GMA was significantly greater with DF compared to PF. During the one-leg bridge with knees flexed and right foot on ball, there was no significant difference in muscle activity between PF and DF positions.

**CONCLUSIONS:** Of the 5 bridging exercises assessed, GMA was greater in DF than PF in only 1 exercise, and LH was greater in PF than DF in only 1 exercise, which implies that DF does not consistently result in greater GMA activity and less hamstring activity during bridging exercises on a ball. Moreover, DF did result in overall greater hip and trunk activity compared to PF during these bridging exercises.

**2971** Board #243 June 1 11:00 AM - 12:30 PM  
**Threshold for EMG Onset Detection of Trunk Muscles In Golf Swing**

Pedro Pezarat-Correia<sup>1</sup>, Luísa M. Silva<sup>1</sup>, João Rocha Vaz<sup>1</sup>, Sérgio Marta<sup>1</sup>, Maria António Castro<sup>2</sup>, Andreia Di Paula<sup>1</sup>, Orlando Fernandes<sup>3</sup>. <sup>1</sup>Faculdade de Motricidade Humana, Lisboa, Portugal. <sup>2</sup>Escola Superior de Tecnologia e Saúde de Coimbra, Coimbra, Portugal. <sup>3</sup>Universidade de Évora, Évora, Portugal.  
(No relationships reported)

**PURPOSE:** The aim of this study was to compare temporal parameters of the trunk muscles EMG activation with two different threshold methods.

**METHODS:** Eight subjects performed ten golf swings (five with pitch, five with 4-iron). Surface EMG was recorded on both sides of trunk muscles: Rectus Abdominis (RA), External

Oblique (EO) and Erector Spinae (ES). Two methods were used for onset determination differing on threshold calculation. Method A threshold was determined by the baseline activity recorded between two maximum voluntary contraction (MVC) whereas method B calculates the mean of EMG activity before the beginning of BackSwing [-1000:-500 ms]. After threshold calculation some restrictions were established to onset calculation: a) search for onset begins 150ms before DownSwing and 150ms before BackSwing for left EO; b) 50 samples window will move forward until its' mean is higher than threshold throughout the ascendant parts of the signal. Visual inspection was performed.

**RESULTS:** Repeated Measures three factors ANOVA showed significant differences ( $p=.001$ ) between muscles for the two methods, but there were no differences in the clubs used ( $p=.521$ ). Paired-Samples T test showed similar results between methods for RA (left -  $p=.190$ ; right -  $p=.320$ ). Furthermore, both methods were appropriate for this muscle, representing the percentage of maximum EMG peak (PM) of 19% and 9% for left and right sides, respectively (left A -  $19\pm 13\%PM$  B -  $19\pm 13\%PM$ ; Right A -  $9\pm 7\%PM$  B -  $9\pm 7\%PM$ ). EO showed the greatest inter and intra subject variability with significant differences ( $p\leq .01$ ) between methods. In this muscle the onset was calculated at lower levels which could represent an anticipation of the true onset (left A -  $11\pm 4\%PM$  B -  $6\pm 2\%PM$ ; right A -  $5\pm 5\%PM$  B -  $4\pm 5\%PM$ ). ES showed significant differences between methods ( $p=.001$ ) with method A revealing better accuracy than method B that determined the onset at a higher percentage of the maximum of activation (left A -  $5\pm 3\%PM$  B -  $21\pm 13\%PM$ ; Right A -  $6\pm 5\%PM$  B -  $26\pm 12\%PM$ ).

**CONCLUSIONS:** Both methods are applicable to RA and the baseline MVC threshold is more accurate for ES. The OE shows high variability and both methods anticipate its onset calculation. In the EMG analysis of golf swing, onset calculation should be adjusted to each trunk muscle.

**Base A Concept For Health Promotion In Logistic Workers With Manual Box Lifting Activities**

Bettina Wollesen<sup>1</sup>, Heiko Lex<sup>2</sup>, Klaus Mattes<sup>1</sup>. <sup>1</sup>University of Hamburg, Hamburg, Germany. <sup>2</sup>University of Bielefeld, Bielefeld, Germany.

(No relationships reported)

Common occupational health problems are musculoskeletal disorders, especially low back pain. Increased reports of back symptoms are associated with physical demands of work, like lifting many heavy weights during a short time period especially when lifting is executed not ergonomically.

**PURPOSE:** The study examined a workplace intervention (BASE concept) to reduce physical stresses of manual lifting processes in a logistic company. It was conducted in three stages: description of the implementation (1), evaluation of outcome-effects of the ergonomic box lifting technique after a 10 week intervention (2) and examining learning and lasting effects (after 3 months) of workers' knowledge and behaviour with regard to health orientated box lifting.

**METHODS:** Video analysis and questionnaires were used in stage (1) for a breakdown analysis. Stage (2) and (3) collected intervention effects with a controlled pre-post design (t1-t3; N=51 male logistic workers;  $37.8\pm 10.8$  y.) The lifting process was evaluated with the PILE-Test. A 3-way ANOVA (group x weight lifting (kg) x repeated measurement) checked the interactions within common limits of significance (95% confidence interval). The cognitive representation of ergonomic object lifting was assessed by the structural dimension analysis of mental representation (with a critical value at  $\lambda_{crit} = .68$ ).

**RESULTS:** The breakdown analysis revealed common problems of repeated manual lifting processes like low back pain (65%). The workers who participated in the intervention showed a more ergonomic movement (F (5,51);  $p = .02$ ) initiated by a more functional cognitive representation in long term memory ( $\lambda_{crit} = 1.0$ ).

**CONCLUSIONS:** The BASE concept can be described as an intervention which improves ergonomic lifting successfully with lasting effects. We suggest that especially this group of employees, with little motivation to participate in health prevention interventions, benefit from the whole methodological approach of this intervention.

**The Effects of Kinesio Taping on Muscular Endurance of Deep Neck Flexors: A Pilot Study**

Yen-Cheng Lee<sup>1</sup>, Chich-Huang Yang<sup>2</sup>, Lan-Yuen Guo<sup>1</sup>. <sup>1</sup>Kaohsiung Medical University, Kaohsiung, Taiwan. <sup>2</sup>Tzu Chi University, Hualien, Taiwan.

(No relationships reported)

Kinesio taping (KT) has been applied in clinics for many years. However, previous studies did not have a clear conclusion in relation to the effects of KT for muscular performance. Previous researches mentioned that poor posture of neck may alter the muscular moment arm and the endurance was deteriorated as consequence. This present study examined whether the KT had the effect on changes in muscle length of the deep neck flexors in attempt to alter muscular endurance.

**PURPOSE:** To investigate the effects of KT on muscular endurance of deep neck flexors.

**METHODS:** Six healthy participants, three males (mean age  $20.0 \pm 1.0$  years) and three females (mean age  $22.0 \pm 4.3$  years) were recruited in this study. Custom-designed neck strength measure instrument, with examined between days and with-in days reliability as  $ICC=0.968-0.988$ , was used to measure the muscular endurance of deep neck flexors in two conditions (KT and without KT). KT was applied on levator scapulae and upper trapezius, subjects were asked to maintain maximal voluntary contraction (MVC) of craniocervical flexion till fatigue. We quantified muscular endurance by investigating muscle fatigue time which defined the time of the muscle moment drop to 50% of its peak value. Wilcoxon Signed-Rank Test was used to compare the differences of muscle fatigue time and muscle strength between the two taping conditions.

**RESULTS:** The mean muscle fatigue time without KT was  $26.3 \pm 22.0$  seconds and with KT was  $26.6 \pm 20.7$  seconds. There was no significant difference between two taping conditions ( $p>0.05$ ). There was also no significant difference on mean peak muscle moment between two conditions ( $p>0.05$ ),  $46.3 \pm 17.1$  kg-cm vs.  $48.0 \pm 14.0$  kg-cm as without KT vs. with KT respectively.

**CONCLUSION:** The application of Kinesio taping over the upper trapezius and levator scapulae may not be a useful taping method to enhance the muscular endurance of deep neck flexors.

2974 Board #246 June 1 11:00 AM - 12:30 PM

**Changes in Lumbopelvic Mechanics Following Ultrasound Guided Nerve Block in the Superior Gluteal Nerve**

Carmen G. Cooper<sup>1</sup>, Karen Kendall<sup>1</sup>, Chirag Patel<sup>2</sup>, Michael B. Pohl<sup>3</sup>, Preston Wiley<sup>4</sup>, Carolyn Emery<sup>4</sup>, Reed Ferber<sup>1</sup>. <sup>1</sup>Running Injury Clinic, University of Calgary, Calgary, AB, Canada. <sup>2</sup>Foothills Hospital, University of Calgary, Calgary, AB, Canada. <sup>3</sup>University of Kentucky, Lexington, KY. <sup>4</sup>Sports Medicine Centre, University of Calgary, Calgary, AB, Canada. (Sponsor: Louis Osternig, FACSM)

(No relationships reported)

The Trendelenburg test (TT) has been described as a functional screening measure of ipsilateral hip abductor (HABD) strength and as an indicator of contralateral frontal plane pelvic stability. Few studies have specifically tested this hypothesis and no study has used a nerve block procedure to evaluate the function of the HABD.

**PURPOSE:** To assess the effect of superior gluteal nerve inhibition, and subsequent reduced function of the HABD, on the frontal plane kinematics of the pelvis during the TT and while walking.

**METHODS:** Baseline HABD maximal voluntary isometric contraction (MVIC) data were collected on 7 male subjects (median (interquartile range): 31yrs (22 to 32yrs); 176cm (168 to 181cm); 73kg (67 to 81kg)) with a force dynamometer. Baseline biomechanical data were measured using retro-reflective markers placed on the pelvis during a standardized 30s TT and while level treadmill walking at 1.34m/s. An ultrasound-guided nerve block (UNB) of the right superior gluteal nerve was performed and MVIC and biomechanical measures were repeated. Variables of interest included contralateral magnitude of pelvic drop (cMPD) during the TT and contralateral pelvic excursion (cPE), calculated from 10 consecutive footfalls during walking. Post UNB MVIC output was calculated as a percent change from baseline. Digitization was completed using Vicon Motus v9 software. Non-parametric statistical analyses using Wilcoxon signed-rank tests determined differences, if any, following the UNB.

**RESULTS:** A 52% reduction in HABD MVIC was measured following the UNB (Baseline:  $3.3$  (3.0 to 4.0); UNB:  $1.8$  (1.7 to 2.4);  $p=0.02$ ). No differences were found in cMPD (Baseline:  $0.4$  (-4.1 to 1.7); UNB:  $-1.4$  (-3.1 to 0.8);  $p=0.99$ ) during the TT, or cPE (Baseline:  $5.5$  (4.6 to 6.3); UNB:  $6.4$  (4.8 to 6.7);  $p=0.13$ ) while walking.

**CONCLUSIONS:** No significant changes in frontal plane pelvic kinematics were measured despite a significant drop in HABD MVIC, during the TT or while walking. These results suggest that the HABD may not be the primary frontal plane stabilizers of the pelvis. Further study is needed to determine if TT is adequate as a functional screening measure for HABD strength and frontal plane stability of the pelvis.

2975 Board #247 June 1 11:00 AM - 12:30 PM

**Multifidus Cross-sectional Area In Hungarian Gymnasts With And Without Back Pain - A Preliminary Study**

Caisa Brooks<sup>1</sup>, Aaron Johnson<sup>1</sup>, J. William Myrer<sup>1</sup>, Martina Uvacsek<sup>2</sup>, Miklos Toth<sup>2</sup>, Pat Vehrs, FACSM<sup>1</sup>, Ronald Hager<sup>1</sup>, Alyssa Symres<sup>1</sup>. <sup>1</sup>Brigham Young University, Provo, UT. <sup>2</sup>Semmelweis University, Budapest, Hungary.  
(No relationships reported)

Gymnasts often experience back pain due to added loads and sport specific demands. It is important to develop protocols to decrease back pain in order to allow athletes to perform at optimal levels.

**PURPOSE:** To correlate multifidus muscle cross-sectional area (CSA) to low back pain in Hungarian gymnasts.

**METHODS:** Thirteen gymnasts (males n=2, females n=11, age: 21.5 ± 1.8 years, body mass: 62.3 ± 9.5 kg, height: 1.7 ± .08 m.) were analyzed using ultrasound imaging. Participants completed a back functional index and self-reported history of back pain. Gymnasts were divided into two groups, those with and those without back pain. From a prone position, cross-section images of the right (R) and left (L) multifidus at all lumbar spinal levels were captured from video clips of each participant at rest and during contraction. Researchers capturing the images and measuring CSA were blinded to the participant group assignment. Muscle CSA was measured when the athlete was fully relaxed; clips of the muscle during contraction were used to help determine the muscle borders. The muscle borders were indicated by tracing the fascia surrounding each muscle and cross sectional area was computed by the ultrasound software. Differences in groups were determined by ANOVA, alpha at .05.

**RESULTS:** There is a significant difference in CSA between those gymnasts with and without back pain (p = .025), but not between R and L sides (p = .81) within groups.

**CONCLUSIONS:** Gymnasts with low back pain demonstrated smaller multifidus CSA than their pain-free counterparts. A study involving elite cricket players reported similar results. Specific strengthening of multifidus may be warranted.

Multifidus cross-sectional area (cm<sup>2</sup>) in Hungarian Gymnasts

| Lumbar Level | No Lumbar Pain Right | No Lumbar Pain Left | Lumbar Pain Right | Lumbar Pain Left |
|--------------|----------------------|---------------------|-------------------|------------------|
| L1           | 2.4 ± .4             | 2.5 ± .5            | 2.3 ± .4          | 2.4 ± .4         |

**Relationship Of Back Muscular Endurance With Anthropometric Measures In Firefighters**

John M. Mayer, Ren Chen, Simon Dagenais, James L. Nuzzo, Joe L. Verna, William S. Quillen, FACSM. University of South Florida, Tampa, FL.  
(No relationships reported)

Firefighters are at risk of experiencing low back pain that may lead to reduced physical function, disability, and work loss. Decreased muscular endurance of the back is associated with abnormal anthropometric measures and may increase the risk of low back pain in the general population. However, this relationship has not been explored in firefighters.

**PURPOSE:** To assess the relationship between various anthropometric measures and back muscular endurance in firefighters.

**METHODS:** Assessments were conducted in full duty, healthy, career firefighters without low back pain from Tampa Fire Rescue (Florida, US) who participated in a randomized controlled trial. Anthropometric measures included height, body weight, body fat percentage assessed with BodPod, and thickness of the abdominal and lumbar multifidus muscles assessed with ultrasound. Isometric muscular endurance was assessed for the back with the Modified Biering Sorensen Test and core with the Plank Test. Relationships between variables were explored using Pearson's correlation.

**RESULTS:** 96 firefighters (87 male, 9 female) enrolled in the study. For back muscular endurance, significant (p < 0.05) correlations were noted with age (r = -0.29), body weight (r = -0.45), body fat percentage (r = -0.46), and thickness of the transverse abdominis, internal and external oblique abdominis, and L4-L5 multifidus muscles (r = -0.24 to r = -0.41). For core muscular endurance, significant (p < 0.05) correlations were noted with body weight (r = -0.43), body fat percentage (r = -0.54), and thickness of the L4-L5 multifidus muscles (r = -0.32 to r = -0.46).

**CONCLUSIONS:** Both increased body weight and body fat percentage were correlated with decreased muscular endurance of the back. Future research is needed to assess the impact of improving body composition on back muscular endurance to reduce the risk of low back pain.

2977 Board #249 June 1 11:00 AM - 12:30 PM

**Atrophy and Asymmetry of Trunk Muscles In Combative Sports Athletes with Lumbar Intervertebral Disc Degeneration**

Kazunori Iwai<sup>1</sup>, Takashi Okada<sup>2</sup>, Koichi Nakazato<sup>3</sup>, Kazunori Irie<sup>3</sup>, Kenji Hiranuma<sup>3</sup>. <sup>1</sup>Hiroshima National College of Maritime Technology, Hiroshima, Japan. <sup>2</sup>Ryotokuji University, Chiba, Japan. <sup>3</sup>Nippon Sport Science University, Tokyo, Japan.  
(No relationships reported)

A high incidence and prevalence of lumbar intervertebral disc degeneration (LDD) was found in combative sports with high demands on the spine. Similarly, low back pain (LBP) also occurs in combative sports. Although there are many relevant factors for LBP, it should be noted that LBP has been associated with cross-sectional areas (CSAs) of trunk muscles. However, little is known about an association between LDD and CSAs in combative athletes.

**PURPOSE:** This study examined whether the presence of LDD affects the size and symmetry of CSAs of trunk muscles in combative sports athletes.

**METHODS:** Participants in this study were 151 collegiate combative sports athletes. A total of 755 lumbar intervertebral discs from L1/2 to L5/S1 in 151 athletes were assessed using MRI and a comprehensive grading system of LDD (grades I-V). All 151 athletes were divided into 2 groups: LDD and non-LDD. CSAs of trunk muscles at the L3/4 disc level were measured on MRI. CSAs were calculated using an image analysis software, and grouped into 5 large areas because they had poorly defined borders. Each of the 5 areas was represented by the same CSA on the left and right sides of the transverse image (rectus abdominis, obliques, psoas, quadratus lumborum, and erector spinae). CSAs of the athletes were compared between the LDD and non-LDD groups using an unpaired Student's t-test. A paired t-test was employed for comparisons of CSAs between the left and right sides. The level of statistical significance was adjusted based on p < 0.05.

**RESULTS:** Sixty-nine athletes had LDD at 1 or more disc levels (45.7%). The LDD grade for the lower 2 disc levels was significantly higher than that for the other disc levels (p < 0.001). CSAs of trunk muscles in the LDD group were significantly smaller than those in the non-LDD group (rectus abdominis: p < 0.05; obliques: p < 0.05; quadratus lumborum: p < 0.01; erector spinae: p < 0.001). Furthermore, CSAs were significantly asymmetrical between the left and right sides in the LDD group (obliques: p < 0.05; quadratus lumborum: p < 0.001).

**CONCLUSION:** This study suggested the association between the presence of LDD and atrophy and asymmetry of trunk muscles in combative sports athletes.

**Bicycle Design Influence on Lumbar Spinal Anatomy**

Stephen T. Jones, MD, Philip J. Blount, MD, FACSM, Daniel T. Hankins, MD, Brittney N. Tubbs, Allen R. Moore, William T. Rosenblatt. *University of MS Medical Center, Jackson, MS.*

(No relationships reported)

**PURPOSE:** The purpose of this study is to compare intervertebral foramen diameter in the lumbar spine in the neutral standing position to that of an appropriately fit recumbent bike, hybrid bike, and diamond racing frame.

**METHODS:** Single participant was used to obtain lateral radiographs of intervertebral foramina diameters both standing and on three bicycle formats. Subject was placed on an appropriate fit recumbent bike, hybrid bike, and diamond racing bike. MSK radiologist was incorporated to standardize angling of x-ray beam and analysis of data collection.

Images were analyzed on the Philips iSite PACS system including measurement of the lumbosacral angle and the cross sectional area (CSA) of the intervertebral foramina at L3-4, L4-5, and L5-S1. The lumbosacral angle was taken as the angle between lines drawn along the vertical axis of L5 and S1. The freehand region of interest (ROI) tool was used to measure the CSA by tracing the osseous borders of the foramen on the lateral radiograph. The lateral radiograph provides a summation of the right and left foramen when the osseous borders are traced along the posterior vertebral line, pedicles, and articular facets of each intervertebral foramen level.

**RESULTS:** Cross sectional area measurements were recorded. Cross sectional area was lowest in standing at all measured disk levels. L5-S1 was smallest level in standing and on all bikes tested. Recumbent bike foramina cross sectional area was lower than the other two tested bicycles at L4-5 and L5-S1.

Lumbosacral angle measurements were also recorded. Lumbosacral angle measurements were similar between the tested bikes but higher in all bikes relative to the standing position.

There was a statistically different measurement in intervertebral foramen diameter of the bicycles when compared to standing.

**CONCLUSIONS:** Bicycle design and fit does influence intervertebral foramen anatomy.

**Chronological Trends and Limits to Running Performances and Physiological Attributes of World Record Holders**

R. Hugh Morton. *Massey University, Palmerston North, New Zealand.* (Sponsor: Glenn A Gaesser, FACSM)

(No relationships reported)

The International Amateur Athletic Federation provides readily accessible data on the progression of ratified world records over the years in running events at distances from 100m to the marathon for both men and women.

**PURPOSE:** To investigate trends and limits to performances and physiological attributes of world class runners.

**METHODS:** In one dimension, for any given distance the chronological trend can be well modeled by a simple single exponential decline towards an ultimate finite limit. In the other dimension, for any given point in time existing records provide information on the physiological performance attributes of the "composite" records holder. These attributes are estimated using the 3-parameter critical power model of human bioenergetics, in which a linear feedback system links maximal voluntary effort to the declining energy availability as the race progresses. In both dimensions an indicator variable can be incorporated to account for gender differences. In so doing, for both men and women, predictions are made for records at common distances and at ten year intervals for the next fifty years; ultimate records are estimated and compared with estimates made in the past by others; and the physiological attributes of the composite ultimate super male and female runners are compared to both current composite and individual values.

**RESULTS:** Women's records have been improving at a faster rate than men's, and have stabilised at around 90% relative to men's. Ultimate forecasts are consistent with those made by other investigators. Aerobic power as represented by critical speed has been increasing significantly over the years, women always below men, and relativity is now stable at around 90%. Anaerobic power as represented by maximal instantaneous velocity trends similarly, but current relativity is around 95%. On the other hand, anaerobic (distance) capacities have been declining over the years; much more so for women than men, and are now about equal.

**CONCLUSION:** Although both male and female running performances have improved significantly over the years, parallel improvements in only two of three estimated physiological parameters occurred, while the third declined. This counter-intuitive inverse relationship is perhaps not unexpected as it has been observed in other exercise settings.

2980 Board #252 June 1 9:30 AM - 11:00 AM

**Skill Differences for Elite Sprint Freestyle Competitive Swimmers**

Tetsuya Tanaka<sup>1</sup>, Yutaka Yoshimura<sup>1</sup>, Michio Yasukawa<sup>1</sup>, Kazuo Oishi<sup>2</sup>. <sup>1</sup>*Chuo University, Tokyo, Japan.* <sup>2</sup>*Rikkyo University, Tokyo, Japan.*

(No relationships reported)

Recently the techniques of competitive swimmers have been analyzed during the start phase and the turn phase to improve performance. However, in most cases these techniques have been assessed subjectively with no quantitative evidence.

**PURPOSE:** The purpose of this study was to analyze skills of streamlining and dolphin kicking during the turn phase and provide quantitative evidence of their value or lack of same.

**METHODS:** The subjects were 6 elite Japanese sprint freestyle competitive swimmers. All were members of the winning team at the 2011 Japan intercollegiate swimming championship. A speed meter that measures a subject's forward velocity by pulling a fine wire over a generator (Maglischo, 2003) was used. This speed meter recorded their intracyclic velocity changes during a 15m maximum effort freestyle swim following a turn. The swim included an underwater dolphin kicking phase of approximately 5m (5.18±2.07m). An underwater video analysis system was also used to check their streamlining, kicking, and stroking techniques. Based on the video data, the authors derived the length of the kicking cycle and the rate of rise during it. The rate of rise was determined as the velocity divided by the maximum water depth which was then multiplied by the dolphin kicking time. Both the rate of rise and the distance per kick (DPK) were measured for each of the 6 swimmers from the collected data.

**RESULTS:** There was a significant relationship between the time required to traverse 15m after the turn (8.21±0.44sec) and DPK (0.79±0.07m/kick) for all of the 6 swimmers (r=-0.89, P=0.017). There was also a significant (r=-0.86, P=0.028) relationship between the time to 15m and the rate of rise (0.22±0.09m/sec). Namely when the DPK and rate of rise were greater, the time to 15m was faster. The multiple regression analysis obtained was as follows: Y = -3.55X1 - 2.17X2 + 11.39 (where Y = the time required, X1 = DPK, and X2 = the rate of rise). The multiple regression analysis showed significant relationships between the time to 15m and both the DPK and the rate of rise (R<sup>2</sup>=0.908, F=14.84, P=0.028).

**CONCLUSIONS:** Improvements in DPK and the rate of rise during dolphin kicking may be important factors for improving swimming times to 15m following turns. Reference: Maglischo, E. W. (2003) Swimming Fastest. Human Kinetics.

2981 Board #253 June 1 9:30 AM - 11:00 AM

**A Descriptive Profile of Musculoskeletal Testing of Elite Junior Tennis Players**

Todd S. Ellenbecker<sup>1</sup>, Mark S. Kovacs<sup>2</sup>, Tetsuro Sueyoshi<sup>1</sup>. <sup>1</sup>Physiotherapy Associates Scottsdale Sports Clinic, Scottsdale, AZ. <sup>2</sup>Kennesaw State University & United States Tennis Association Player Development Incorporated, Kennesaw, GA. (Sponsor: T. Jeff Chandler, FACSM)  
(No relationships reported)

The use of musculoskeletal testing to prevent injury and enhance performance is an integral part of the comprehensive care of elite athletes by sports medicine professionals. Sport specific descriptive data aids in the interpretation of these tests and helps to define characteristic adaptations inherent in certain homogenous populations.

**PURPOSE:** The purpose of this study is to present the descriptive findings of a sport specific musculoskeletal profile in elite junior tennis players.

**METHODS:** Since 2003, 140 male (M) (mean age 17.5) and 141 female (F) (mean age 16.6) players without injury underwent musculoskeletal testing to measure strength and flexibility using a standardized testing protocol by one tester. These tests included stabilized measurement of hip and shoulder ROM, isokinetic strength testing, one leg stability test, hypermobility index, and scapular evaluation. Bilateral extremity testing was performed to formulate both dominant (D) and nondominant (ND) extremity profiles. Descriptive statistics were used to produce separate male and female profiles.

**RESULTS:** The average number of years of competitive tennis play was 8.72 M & 7.04 F. 73% M & 98 F players used a 2 handed backhand. Consistent with prior reports, both (M) and (F) players had less (D) arm internal rotation range of motion (ROM) and greater external rotation ROM. Nearly symmetrical hip ROM was measured bilaterally. 20% of the M and 59% of the F were positive for hypermobility using the Beighton Index. M players failed the one-leg stability test at a rate of 65% on the D limb and 67 on the ND limb with 55% of F failing the test on their D limb and 64% on their ND limb. Visually identified scapular pathology was identified on the D arm 73% in M and 64% in F as opposed to 53% M and 46% on the ND extremity. Grip strength was greater on the dominant arm in both M and F players. Characteristic patterns of external and internal rotation strength were measured. Data presented in Table 1 below.

**CONCLUSIONS:** These data show specific musculoskeletal adaptations in elite tennis players as well as present the rate of positive tests findings (test failure) indicating increased injury risk. These data are meant to further the understanding and aid in the interpretation of musculoskeletal testing in elite junior tennis players.

2982 Board #254 June 1 9:30 AM - 11:00 AM

**Strength: Volume Ratio For The Forearm In Climbers And Non-climbers**

Vanesa España Romero<sup>1</sup>, Phillip B. Watts, FACSM<sup>2</sup>. <sup>1</sup>Northern Michigan University, Marquette, MI. <sup>2</sup>University of South Carolina, Columbia, SC. <sup>2</sup>Northern Michigan University, Marquette, MI.  
(No relationships reported)

Many climbers and coaches perceive strength in the muscles that control finger position critical to high-level performance. It has also been recognized that handgrip strength is higher in rock climbers than non-climbers. It is well accepted that muscle cross-sectional area or mass is directly related to maximum force capability, however, whether applied experience in rock climbing affects the relationship between muscle size and maximal strength is not known. The purpose of this study was to examine if a strength: size ratio for the forearm differed between climbers and non-climbers.

**METHODS:** Twenty-eight experienced climbers (age = 25.2±9.6 yr) and 26 active adults non-climbers (age = 21±1.7) volunteered as subjects. Height and weight body were evaluated. Maximal handgrip strength (HG) was measured by dynamometry and finger force (FF) via a piezoelectric force sensor fitted with a plate to accept the distal digits of four fingers. Resting forearm volume (FAV) was determined via water displacement.

**RESULTS:** Significantly higher HG and FF were found in both hands for climbers compared with non-climbers expressed both in kg and kg per body weight (P<0.01). Significant differences were not found for FAV between climbers (1311.6 ± 397.3 ml and 1283.9 ± 380.1 ml for right and left hands respectively) and non-climbers (1382.1 ± 556.7 ml and 1326.2 ± 548.3 ml for right and left hands respectively) for either right hand or left hand (P>0.05). However, the ratio of HG to FAV (HG:FAV) and the ratio of FF to FVA (FF:FVA) were significantly higher for climbers versus non-climbers for both hands (P<0.01).

Right FAV was significantly correlated with height (r=0.42, P<0.05), weight (r=0.59, P<0.01), and right and left handgrip strength (r= 0.55, P<0.01 and r= 0.46, P <0.05, respectively) in climbers. However, right FAV was only correlated with weight in the non-climbers. Similar results were found for left FAV.

**CONCLUSIONS:** The higher HG and FF in climbers relative to non-climber controls supports a specificity of training effect on the associated muscle groups. That the ratios of handgrip strength to forearm volume and finger force to forearm volume are higher for climbers vs. controls suggest that neural factors instead of hypertrophy may account for much of the strength differences between climbers and non-climbers.

2983 Board #255 June 1 9:30 AM - 11:00 AM

**Perceived Stress and Salivary Cortisol in Collegiate Track and Field Athletes. A Pilot Study.**

Cynthia Ferrara, FACSM, Laura Donigian, Julie Lorden, Matthew Read, Joshua Turner. *University of Massachusetts Lowell, Lowell, MA.*  
(No relationships reported)

**PURPOSE:** The purpose of this pilot study was to examine changes in perceived stress and salivary cortisol levels in four student track and field athletes over an eight month period. We hypothesized that perceived stress and salivary cortisol levels would be higher during the in season compared to the off season and salivary cortisol levels would be related to perceived stress.

**METHODS:** Measurements of psychological stress (Recovery-Stress Questionnaire for Athletes, RESTQ-52) and saliva samples for measurement of salivary cortisol were collected weekly. In season and off season values for each athlete individually and for the group were compared by t-tests and relationships between stress values and salivary cortisol were examined using Pearson correlations. Results are presented as means±SEM. Statistical significance was set at p<0.05.

**RESULTS:** From September to April, a total of 101 saliva samples and 90 RESTQ-52 surveys were collected and analyzed. Athletes who completed at least 60% of the surveys and saliva collections (1 male and 3 females) were included in the final analysis, which included 69 saliva samples and 77 RESTQ-52 surveys. Salivary cortisol levels were elevated but not statistically higher during the in season compared to the off season, when considering individual athletes or overall averages (6.1±0.7 vs. 5.0±0.9 nmol/L, p=0.3, respectively). General, emotional, and social stress values were not statistically higher during the in season compared to the off season (1.1±0.2 vs. 1.4±0.2, 1.6±0.2 vs. 1.5±0.2, 1.9±0.3 vs. 1.7±0.2, respectively, for the overall averages). Salivary cortisol levels were not significantly associated with general, emotional, or social stress values.

**CONCLUSIONS:** The results of this pilot study suggest that salivary cortisol levels may increase in athletes during the in-season compared to off-season. Levels of perceived stress may not be associated with salivary cortisol, a physiological marker of stress. Additional studies are needed with a larger sample size and to determine effective ways to monitor perceived and physiological stress in athletes, and the effects of stress on performance and risk of injury or illness.

Supported by UMass Lowell School of Health and Environment Creativity grant and Graduate Student Association grant.

**Changes In Locomotor, Respiratory And Autonomic Nervous Systems During Simplified Tai Chi Exercise**

Kaiyu Xiong, Ruiyu Yang, Hui He. *Beijing Sport University, Beijing, China.*  
(No relationships reported)

**PURPOSE:** The purpose of this study was to investigate the influence of age and training level on locomotor, respiratory and autonomic nervous system during tai chi exercise.

**METHODS:** Forty adults including young group(Y, 20-24 years old) and older group(O, over 55 years old) was divided into high level(H) group and control(C) group with 10 subjects in each one. Subjects in high level group had tai chi for over 15 years, and those in control group for 1-3 years. Test synchronously biomechanics and dynamic parameters, electromyography, cardiopulmonary function and heart rate variability indexes by QUALISYS, portable electromyography instrument, Cortex and Polar during three times simplified Tai chi exercise.

**RESULTS:** (1) Average discharge rate of lateral deltoid in H group was apparently higher than C group(P<0.05, P<0.01) during Grasp the peacock's tail (the third session of simplified Tai chi) exercise; (2) Average RR interval, RLX baseline, SD1 and RMSSD in young adults' high level group(YH) were significantly higher than young adults' control group(YC)(P<0.05), but

there was no significant difference between older adults' high level group(OH) and older adults' control group(OC); (3)Low Frequency(LF)/High Frequency(HF) in recovery period was lower than exercise period in YH group(180.1±42.4 vs. 346.6±75.9) and OH group(186.3±67.7 vs. 345.0±107.4), but higher in YC group(346.6±109.0 vs. 216.0±62.5) and OC group(316.3±59.6 vs. 202.6±62.2); (4) Tidal volume and expiratory time in YH group were significantly higher than YC group(P<0.05, P<0.01), and respiratory rate was significantly lower than YC group(P<0.05). There was no significant change between OH group and OC group; (5)Average RR interval was in high correlation with indexes of gaseous metabolism in H group (P<0.01).

**CONCLUSION:** There are important influences on respiratory and autonomic nervous systems in training level, and age can have effect heart rate variability indexes.

**2985** Board #257 June 1 9:30 AM - 11:00 AM

**The Use of Session-RPE Method for Quantifying Training Load in Elite Taekwondo Athletes.**

Erika Casolino<sup>1</sup>, Cristina Cortis<sup>2</sup>, Carlo Minganti<sup>3</sup>, Corrado Lupo<sup>1</sup>, Laura Capranica<sup>1</sup>. <sup>1</sup>University of Rome Foro Italico, Rome, Italy. <sup>2</sup>University of Cassino, Cassino, Italy. <sup>3</sup>University of Catanzaro, Catanzaro, Italy. (Sponsor: Carl Foster, FACSM)  
(No relationships reported)

In general, heart rate (HR) responses are used to control the internal training load (ITL) in different sports. A more practical method to monitor ITL is based on subjective ratings of perceived exertion (RPE) in relation to the duration of the training session (Session-RPE).

**PURPOSE:** The aim of the present study was to evaluate the convergent validity between two methods for quantifying ITL in elite taekwondo athletes: the Edward's ITL method based on HR and the Foster's Session-RPE method based on subjective evaluation of efforts, respectively.

**METHODS:** Twenty-eight elite black belt taekwondo athletes (F = 11; M = 17; age: 23.0 ± 3.3 yr; body mass: F = 59.4 ± 7.3 kg, M = 71.9 ± 10.7 kg) with at least 5 yr of training experience consisting of 2 hr session<sup>-1</sup> for 6 days<sup>-1</sup> week<sup>-1</sup> participated in the study. Over 6 weeks, 36 training sessions (6 training sessions week<sup>-1</sup>; duration range: 22-113 min) were monitored obtaining 279 HR and RPE recordings.

**RESULTS:** Significant (P<0.05) correlations emerged between Session-RPE and Edward's ITL for individuals (range: 0.50-0.97), group (r = 0.58), and training objectives (i.e., technical/tactical: r = 0.49; physical conditioning: r = 0.48).

**CONCLUSION:** The present findings support the use of Session-RPE as a valid tool for quantifying the internal training load of elite taekwondo athletes during regular training sessions. In considering that Session-RPE can be easily administered without requiring expensive apparatus, coaches could profit of this method to monitor the individual responses of athletes to their training plans.

**2986** Board #258 June 1 9:30 AM - 11:00 AM

**The Effect of Ability and Technique on VO<sub>2</sub> and Heart Rate Drift in Rock Climbers**

Simon M. Fryer<sup>1</sup>, Tabitha Dickson<sup>1</sup>, Nick Draper<sup>1</sup>, Gavin Blackwell<sup>1</sup>, Lee Stoner<sup>2</sup>. <sup>1</sup>University of Canterbury, Christchurch, New Zealand. <sup>2</sup>University of Massey, Wellington, New Zealand. (Sponsor: Kevin K. McCully, FACSM)  
(No relationships reported)

Previous research has speculated that the disproportionate rise in heart rate for a given VO<sub>2</sub> seen in rock climbing may be due to anxiety or nervousness, an increased amount of time spent in isometric contraction or the presence of the metaboreflex.

**PURPOSE:** To examine technique, psychological and physiological factors which affect the VO<sub>2</sub> : heart rate relationship in intermediate, advanced and elite rock climbers.

**METHOD:** The current study measured rest frequency, total static time and the percentage of static time which was spent resting as well as anxiety, heart rate and VO<sub>2</sub> responses in intermediate (n=12), advanced (n=19) and elite (n=15) rock climbers. All climbers performed at or near their maximum self reported on-sight grade (19/22/25+ Ewbank respectively).

**RESULTS:** Findings revealed a non-significant differences (p>0.05) between intermediate, advanced and elite climbers for pre climb heart rate, state anxiety and self confidence. The intermediate climbers displayed a disproportionate rise in heart rate for VO<sub>2</sub> throughout the climb whereas advanced and elite climbers showed an initial elevation before mimicking the linear relationship seen in their VO<sub>2max</sub> trials. Significant differences (P<0.05) were observed between intermediate, advanced and elite groups for rest frequency, total static time and the percentage of static time which was spent resting.

**CONCLUSION:** Our findings suggest anxiety plays no part in the observed disproportionate rise in heart rate during rock climbing. The sufficient amount of rest time during climbing appears to help maintain the heart rate: VO<sub>2</sub> relationship similar to that seen during a VO<sub>2max</sub> trial.

**2987** Board #259 June 1 9:30 AM - 11:00 AM

**Effects Of Autonomic Tone On Short Versus Long Distance Performances In Swimmers**

Martina A. Maggioni<sup>1</sup>, Arsenio Veicsteinas<sup>2</sup>, Pietro L. Invernizzi<sup>1</sup>, Claudio Ciapparelli<sup>3</sup>, Paolo Castiglioni<sup>2</sup>, Giampiero Merati<sup>1</sup>. <sup>1</sup>University of Milan, Milano, Italy. <sup>2</sup>Don C. Gnocchi Foundation, Milan, Italy. <sup>3</sup>DDS Sport Center, Settimo Milanese, Italy.  
(No relationships reported)

Whatever the swimming specialty, swim training programs generally consist of high volume, which may shifts the heart rate (HR) autonomic control towards vagal predominance. Although it is accepted that an enhanced parasympathetic tone may improve performance on long distances, it is poorly known whether it may affect performance on short distances.

**PURPOSE:** To evaluate resting autonomic tone and swimming performance on short and long distances in highly trained swimmers.

**METHODS.** Two groups of national-level swimmers (all males, crawl specialists) were evaluated: short (S: 50-100 m; n=13; 24±3 yrs) and long (L: 1500 m; n=9; age 19±1 yrs) distance specialists. All swimmers belonged to the same team and were similar for training level. Beat-by-beat HR was recorded at rest in the morning, in supine position, by a HR monitor for 15 minutes. HR variability indexes were calculated from time (RMSSD, pNN50, indexes of vagal tone) and frequency (LF, Low Frequency and HF, High Frequency as absolute values and in normalized units (nu); LF/HF ratio, index of sympathovagal balance) domains. The anaerobic threshold was evaluated by an incremental swimming test with lactate measurements.

**RESULTS.** The percentage of swimmers who showed resting bradycardia tended to be higher in L (78%) than in S (54%) group. HRV indexes did not significantly differ between groups: RMSSD 67±23 vs 66±11 ms, pNN50 40±17 vs 48±10%, LFnu 62.3±12.3 vs 54.4±14.8, HFnu 37.6±12.3 vs 45.6±14.8, LF/HF 2.1±1.9 vs 1.5±1.0 (S vs L group, respectively). In S group, 50 m best time correlated positively (p<0.05) with RMSSD (r=0.64), pNN50 (r=0.73) and absolute HF power (r=0.64), and negatively with LFnu (r=-0.56), but not with anaerobic threshold. On the contrary, in L group 1500 m did not correlate with RMSSD, pNN50 and absolute HF power (although negative trends were perceived), negatively correlated with absolute LF power (r=-0.65 p=0.05), positively correlated with LFnu (r=0.72, p=0.02), and tended to increase with anaerobic threshold.

**CONCLUSION.** L swimmers were not more hypervagotonic than S swimmers, and such adaptation tended to be positively associated with anaerobic threshold. Conversely, high vagal tone appeared somehow detrimental on short swimming performance, as it negatively predicts performance on 50 m events, whereas anaerobic threshold did not.

**2988** Board #260 June 1 9:30 AM - 11:00 AM

**Sex Differences In Marathon Performance With Advanced Age: Nature Or Nurture?**

Alyssa Stevens, Sandra K. Hunter, FACSM. Marquette University, Milwaukee, WI.  
(No relationships reported)

The sex difference in marathon performance increases with age however the influence of participation rates of men and women are not established.

**PURPOSE:** To determine: (1) if the sex difference in finishing place of marathon performance (1<sup>st</sup>-10<sup>th</sup> place) altered with advanced age, and (2) the association of participation ratios with the sex difference in running velocity.

**METHODS:** Running times of the first 10 placed men and women finishers and the numbers of men and women finishers who competed in the New York City (NYC) Marathon were analyzed. Online data was retrieved for 31 yrs (1980 to 2010). The running times of 3850 men and 3363 women were included in the analysis.

**RESULTS:** The men were faster than women across all age groups (13.9%,  $P<0.001$ ). Velocity decreased across the age groups (5.1 m/s for 20-29 yrs and 2.9 m/s for 70-79 yrs for the top finisher,  $P<0.001$ ). The sex difference in running velocity increased across age groups ( $P<0.05$ ) and decreased across the 31 yrs but more so for the older age groups (age x year,  $P<0.05$ ). The sex difference in velocity increased with the place of the runner (11.0% for 1<sup>st</sup> place to 15.5% for 10<sup>th</sup> place) consistently for all age groups ( $P<0.05$ ). The widening sex difference between 1<sup>st</sup> and 10<sup>th</sup> place was due to greater decrements in velocity of women compared with men (10<sup>th</sup> place was  $81.5 \pm 7.2\%$  vs  $86.5 \pm 6.7\%$  of top finisher). The sex difference in velocity with place also decreased across years between 1980 and 2010 (12.8% to 9.9%,  $P<0.05$ ). The ratio of men to women finishers decreased from 6.8 in 1980 to 1.8 in 2010. The ratio however, decreased more for the older age groups than the younger across years (age x year,  $P<0.05$ ). The men to women ratio in 1980-1985 to 2006-2010 changed from 4.0 to 1.0 for the 20-29 yrs and 23.6 to 5.9 for the 70 to 79 yrs. Importantly, there was a positive association between the ratio of men to women finishers within a 10 year age group over the 31 years and the sex difference in velocity ( $r=0.57$ ,  $r^2=0.33$ ,  $P<0.05$ ).

**CONCLUSION:** The widening sex difference in performance with increased place of the finishers is due to the greater relative decline in velocity of the women across place compared with the men. Furthermore, sex differences in marathon running times over the last 31 years were predicted by participation rates of men and women, especially with advanced age.

**Comparison of Running Economy Between Sexes in Ultra-Marathon Runners and Marathon Runners**

Laura Christine Streeper. *San Francisco State University, San Francisco, CA.* (Sponsor: Marialice Kern, FACSM)  
(No relationships reported)

Many researchers have examined sex differences in running economy (RE) in short, middle, and marathon distance runners. However, few investigations have focused primarily on sex differences in RE in ultra-marathon (UMar) runners (>42.2km) and marathon (Mar) runners.

**PURPOSE:** To investigate sex differences in RE in UMar and Mar runners.

**METHODS:** Maximal oxygen consumption ( $VO_{2max}$ ) was measured via a graded exercise test in all participants. Oxygen consumption was then measured in male (M) and female (F) UMar and Mar runners (Age range: 24-60; Mar-M: n=6; Mar-F: n=7; UMar-M: n=9; UMar-F: n=6) during 6 minutes of treadmill running at: 1) 6 mph and 1° grade and 2) 80% of  $VO_{2max}$  and 1° grade. RE was calculated as  $mlO_2 \cdot kg^{-1} \cdot km^{-1}$ . Heart rate (HR) and rating of perceived exertion (RPE) were recorded during each condition. An independent t-test was used to examine differences in variables between the male runners (UMar-M and Mar-M) and female runners (UMar-F and Mar-F). All tests were considered significant at the 0.05 level.

**RESULTS:** The males ran faster than the females at 80% of  $VO_{2max}$  ( $13.72 \pm 0.24$  vs.  $11.59 \pm 0.45$  km/hr,  $p<0.01$ ). Although there were no significant sex differences in RE at 80% of  $VO_{2max}$  (M:  $198.61 \pm 3.40$ , F:  $209.89 \pm 5.19$   $mlO_2 \cdot kg^{-1} \cdot km^{-1}$ ,  $p=0.074$ ). RE at 6mph was significantly different between the sexes with the male runners exhibiting superior RE compared to the females (M:  $192.80 \pm 3.41$ , F:  $204.72 \pm 4.35$   $mlO_2 \cdot kg^{-1} \cdot km^{-1}$ ,  $p=0.038$ ). The males had a significantly higher HR during 80% of  $VO_{2max}$  compared to the females ( $163.40 \pm 2.65$  vs.  $150.77 \pm 3.26$  bpm,  $p<0.01$ ), but there was no sex-difference in HR at 6mph (M:  $129.2 \pm 2.9$ , F:  $133.7 \pm 4.2$  bpm). Furthermore, the males had a significantly higher maximal HR compared to the females ( $183.9 \pm 2.1$  vs.  $175.0 \pm 2.9$  bpm,  $p=0.016$ ). RPE did not significantly differ between sexes at either intensity (80%: M:  $13.7 \pm 0.3$ , F:  $13.2 \pm 0.5$ ,  $p=0.40$ ; 6mph: M:  $8.93 \pm 0.3$ , F:  $10.2 \pm 0.6$ ,  $p=0.052$ ).

**CONCLUSION:** The finding that RE is greater at 6mph in male UMar and Mar runners suggests that male runners are more economical at a sub-maximal speed compared to the females.

**Heart Rate Variability in Orthostatic Test During Different Training Periods in Elite Swimmers**

Esa Hynynen<sup>1</sup>, Xavier Iglesias<sup>2</sup>, Belén Feriche<sup>3</sup>, Carmen Calderón<sup>4</sup>, Xavier Ábalos<sup>2</sup>, Jairo Vázquez<sup>2</sup>, Anna Barrero<sup>2</sup>, Lara Rodríguez<sup>2</sup>, Benjamin D. Levine, FACSM<sup>5</sup>, Ferran A. Rodríguez, FACSM<sup>2</sup>. <sup>1</sup>KIHU - Research Institute for Olympic Sports, Jyväskylä, Finland. <sup>2</sup>INEFC, University of Barcelona, Barcelona, Spain. <sup>3</sup>FCAyD, University of Granada, Granada, Spain. <sup>4</sup>Sierra Nevada High Altitude Training Center, Granada, Spain. <sup>5</sup>IEEM/UT Southwestern, Dallas, TX.  
(No relationships reported)

Intense training has been shown to change the autonomic modulation of the heart in endurance athletes assessed by heart rate variability (HRV) analysis. In overtraining state HRV diminished in athletes of different sports.

**PURPOSE:** This study investigated the effects of intensified training and tapering on HRV in elite swimmers.

**METHODS:** Eleven elite swimmers (7 F and 4 M, age  $17.9 \pm 1.9$  y) lived and trained for 8 weeks before national championships qualifying for European championships. This follow-up period was divided to following microcycles: preparatory general, intensified training, preparatory specific, pre-competition (tapering), and competition periods. RR-intervals were recorded every morning in supine (8-min) and orthostatic (6-min) positions with beat-by-beat heart monitors. Breathing was paced to 12 breaths/min. HRV was analyzed from the last 5-min period of both positions with FFT and autoregressive (AR) spectral power analysis. TRIMPs of every training session were calculated to estimate training. Results are presented as averages of each period and expressed in relative changes.

**RESULTS:** Training load increased during the intensified training period (+86%,  $p=0.01$ ) and progressively decreased during the pre-competition and competition periods from the pre-week. HF spectral power during supine rest increased during intensified training (+38%,  $P=0.03$ ) but recovered to baseline thereafter and stayed near baseline levels during tapering and competition periods. LF/HF ratio during supine rest progressively increased from preparatory general to tapering (+58%,  $P=0.02$ ) and competition periods (+66%,  $P=0.01$ ).

**CONCLUSION:** The present findings are different from previous literature of HRV in endurance athletes. Intensive training has been reported to decrease HRV acutely and a rebound was observed after a relative resting period. In this study, increase of HRV seemed to be related to positive coping with increased training stress of elite swimmers. Interpretation of LF/HF ratio has been questionable, but it has been used as an indicator of the balance of autonomic nervous system. Therefore, these findings suggest that the sympathetic activity of elite swimmers may increase during rest as an anticipatory effect of competition period.

**Oxygen Uptake And Cardiopulmonary Demands Of World-class Judoist Performing The Uchikomi Fitness Test**

Ramdane Almansba, Andrée-Anne A. Parent, Jean P. Boucher, FACSM, Alain S. Comtois. *University of Quebec in Montreal, Montreal, QC, Canada.*  
(No relationships reported)

**PURPOSE:** To describe the pulmonary gas exchange and metabolic demand during an intermittent test simulating judo combat, the Uchikomi Fitness Test (UFT).

**METHODS:** Four male world-class judoists (age =  $22 \pm 3$  years, weight =  $75.93 \pm 7.06$  kg and height =  $175.25 \pm 7.06$  cm) completed the UFT three weeks before the Pan American judo Championships 2011. The  $VO_2$  and cardiopulmonary responses were assessed at rest and during UFT using a telemetry system (Cosmed K4b<sup>2</sup>). Aerobic energy (W-aerobic) was equal to the difference between the  $VO_2$  area integrated during UFT and the  $VO_2$  at rest. The anaerobic energy was calculated with the accumulation oxygen deficit (AOD) as described by Medbo et al (1996). The workload during UFT was quantified subjectively using Borg's scale (RPE).

**RESULTS:** Mean $\pm$ SD of the following variables at rest were: BMI =  $24.83 \pm 1.54$   $kg \cdot m^{-2}$ , body fat =  $14.60 \pm 4.17\%$ , lean mass =  $43.53 \pm 2.40\%$ ,  $[La]_{rest}$  =  $2.15 \pm 0.47$   $mmole \cdot l^{-1}$ , HR =  $57 \pm 6$   $beat \cdot min^{-1}$ ,  $VO_{2rest}$  =  $4.31 \pm 0.33$   $ml \cdot min^{-1} \cdot kg^{-1}$ , right and left handgrip strength (HGS) =  $52 \pm 9$  and  $53 \pm 8$  Kg, respectively. During UFT HR $_{mean}$  =  $174 \pm 5$   $beats \cdot min^{-1}$ ,  $VO_{2peak}$  =  $45.72 \pm 2.20$   $ml \cdot min^{-1} \cdot kg^{-1}$ , VE =  $118.50 \pm 7.40$   $l \cdot min^{-1}$ , W-aerobic =  $38.89 \pm 2.80$   $ml \cdot kg^{-1}$ , AOD =  $10.48 \pm 3.58$   $ml \cdot kg^{-1}$ , breathing frequency =  $49 \pm 6$   $br \cdot min^{-1}$ , oxygen pulse =  $21.10 \pm 3.97$   $ml \cdot beat^{-1}$  and tidal volume =  $2.5 \pm 0.22$  l/br. The total number of Uchikomi was  $53 \pm 3$  and post effort right and left HGS =  $53 \pm 11$  and  $55 \pm 6$  Kg, respectively. Peak values for HR,  $[La]_{3min}$ , RQ and RPE were  $187 \pm 6$   $beats \cdot min^{-1}$ ,  $15.13 \pm 1.08$   $mmol \cdot l^{-1}$ ,  $1.26 \pm 0.08$ ,  $18 \pm 2.16$ , respectively. In addition, significant correlations were found between  $VO_{2peak}$  and total number of uchikomi (0.94,  $p<0.05$ ) and between total number of Uchikomi and world ranking list of judoists (-0.98,  $p<0.01$ ).

**CONCLUSIONS:** Comparable cardiopulmonary demands were recorded during judo combat by Ahmaidi et al. (1999). This would suggest that the UFT is representative of the effort provided during judo combat and can be used to predict the judoists's performances.

**Acute Effects of an Elastic Device on Bench Press Performance in Young Resistance Trained Males**

Xin Ye, Daeyoel Kim, Christopher A. Fahs, Jeremy P. Loenneke, Robert S. Thiebaut, Eonho Kim, Lindy M. Rossow, Kyle A. Sherk, Takashi Abe, Travis W. Beck, Debra A. Bembien, FACSM, Michael G. Bembien, FACSM. *University of Oklahoma, Norman, OK.*  
(No relationships reported)

The one-repetition maximum (1RM) bench press is a standard method to assess upper body strength. Recently, a novel elastic supportive device was developed to increase maximal bench press training loads.

**PURPOSE:** To investigate the acute effects of wearing a supportive elastic device during a high load bench press on strength, average power output, average bar velocity, and the reliability of those measures in resistance trained males.

**METHODS:** Eleven men aged 18-35 years completed 4 testing sessions, each separated by 1 week and at the same time of day. On visit 1, subjects were familiarized with the use the elastic device and on the 2<sup>nd</sup> visit were assessed for 1RM bench press strength, bar velocity, and power. During the 3<sup>rd</sup> and 4<sup>th</sup> visits, subjects reproduced their original 1RM efforts wearing the elastic supportive device. Then the bench press loads were increased until a new 1RM value was obtained (SS 1RM). Average bar velocity and average power output was also determined for each trial. Reliability was assessed by paired t-tests and Pearson correlation coefficients between visits 3 and 4, and differences across the 3 testing visits were assessed by repeated measures ANOVA with statistical significance set at  $p \leq 0.05$ .

**RESULTS:** Reliability for SS 1RM was excellent between visits 3 and 4 ( $r=0.981$ ,  $p<0.001$ ) and the means were within 2.1 kg ( $p=0.124$ ). For measures of power, the correlations for bar velocity and average power were low and non-significant; there were also no differences between means between the two days. Significant improvement for 1 RM ( $p<0.001$ ) was found with a 15.1% increase, but no differences for velocity and power between visit 2 and visits 3 and 4. The correlation between each individual's 1RM percentage increase and their original 1RM was low and non-significant. When comparing the original 1RM in different lifting situations (visits 2, 3, and 4), both average bar velocity ( $p<0.001$ ) and average power output ( $p<0.001$ ) significantly increased.

**CONCLUSIONS:** These results suggest that using the elastic device can significantly increase the bench press training loads and power in a reliable and consistent manner.

(No relationships reported)

**One-repetition maximum test (1RM) has been long used as an appropriate method of measuring isotonic muscle strength. Regarding oxidative stress, augmented xanthine oxidase activity in cytosol of muscle cells is apparently more related to overproduction of reactive oxygen species (ROS) during strength exercises than mitochondrial processes. Thus, key metabolites of iron homeostasis and purine metabolism have been currently suggested as accurate biomarkers of redox metabolism during resistance exercise. Abrupt drops in performance, exacerbated inflammation processes, and injury risks are notoriously associated to excessive production of ROS in athletes.**

**PURPOSE:** This work aims to evaluate the role of iron and uric acid in the plasma redox status of young athletes after strength exercise.

**METHODS:** Young college athletes ( $n = 11$ ; age  $23.1 \pm 2.6$  years; height,  $174.1 \pm 6.9$  cm; weight  $78.2 \pm 8.2$  kg) performed a 1RM test for chest press (pectoralis major extension) after a standard warming protocol (5 min-general warm up, 5 min-upper body stretching, and 1 set of 10 repetitions at estimated 60% 1RM). Blood samples (10 mL) were collected immediately before and 5 min after the 1RM test (pre-/post effect), and glycemia, xanthine oxidase (XO) and creatine kinase (CK) activities, and Trolox-equivalent antioxidant capacity of plasma (TEAC) were compared to total iron, heme-iron, uric acid, and thiobarbituric acid reactive substance (TBARS, biomarker of lipid oxidation) concentrations in plasma.

**RESULTS:** Significant higher glycemia (ca. 10%;  $p = 0.0432$ ) and iron content in plasma (84%;  $p = 0.011$ ) were related to 63% lower TEAC levels ( $p = 0.0067$ ) after the 1RM test. However, only tendencies for higher XO activity ( $p = 0.245$ ) and uric acid concentrations ( $p = 0.181$ ) were evidenced in plasma. Pre-/post 1RM analyses revealed no significant changes in both CK and TBARS indexes.

**CONCLUSIONS:** Iron-related oxidative stress conditions were imposed by maximal strength effort in young subjects, culminating in severe depletion of antioxidant capacity in plasma. Although immediate (oxidative) lesions were not observed, further analyses are necessary to evaluate long-term effects. Purine metabolism is still suggested as a potential source of ROS during strength/resistance exercise. Financial support: FAPESP, CAPES & CNPq (Brazil).

**An Analysis Of The Physiological Demands Of Race Riding Using A Horse Racing Simulator**

SarahJane Cullen<sup>1</sup>, Adrian McGoldrick<sup>2</sup>, Gillian O Loughlin<sup>1</sup>, Gregory May<sup>1</sup>, Paul L. O Connor<sup>1</sup>, Giles D. Warrington, FACSM<sup>1</sup>. <sup>1</sup>Dublin City University, Dublin 9, Ireland. <sup>2</sup>Turf Club, The Curragh, Ireland.  
(No relationships reported)

Despite the international popularity of horse racing, the physiological demands of this challenging sport remain largely unknown. Paramount to all jockeys is the need to chronically maintain a low body mass, necessary to attain the stipulated competition riding weights, whilst maintaining a sufficient level of physical conditioning in order to compete in several races each day.

**PURPOSE:** To determine the physiological demands of simulated race riding.

**METHODS:** Eighteen male trainee jockeys (age  $16 \pm 1$ yr; height  $1.67 \pm 0.05$ m; body mass  $55.68 \pm 5.5$ kg; BMI  $19.88 \pm 1.65$ kgm<sup>-2</sup>; % body fat  $8.13 \pm 1.65$ %) performed a maximal incremental cycle ergometer test starting at 60W and using 25W increments to volitional exhaustion for determination of maximal oxygen consumption (VO<sub>2</sub> max) and maximum heart rate (HR<sub>max</sub>). Two race simulation trials were then completed on a horse racing simulator at a velocity of 30km/hr. Trial 1: a simulated race for the typical time duration to cover a race distance of 1400m. Trial 2: a simulator riding test to exhaustion. A recovery period of 5 minutes was provided between each trial. Physiological function was assessed through measurement of respiratory metabolic measures and heart rate.

**RESULTS:** Mean VO<sub>2</sub> max during the incremental cycle ergometer test was  $57.11 \pm 4.72$  ml/kg/min, with the mean ventilatory threshold (VT) occurring at  $81.2 \pm 5.4$ % VO<sub>2</sub> max and HR<sub>max</sub> was  $188 \pm 12$  beats/min. During the simulated race over 1400m (Trial 1), peak oxygen consumption (VO<sub>2</sub> peak) was  $75 \pm 11$ % of VO<sub>2</sub> max while peak heart rate (HR<sub>peak</sub>) was recorded as  $86 \pm 7$  % HR<sub>max</sub>. In contrast, during the simulator riding to exhaustion (Trial 2) VO<sub>2</sub> peak and HR<sub>peak</sub> were  $82 \pm 10$ % and  $87 \pm 8$ % of the maximal values attained in the incremental cycle test, respectively.

**CONCLUSION:** Determination of the physiological demands of simulated riding provides a clearer insight and understanding of the specific requirements of these athletes during training and competition. The novel results from this study suggest horse racing is a very demanding sport, requiring jockeys to perform close to their physiological limit to be successful. Further research is required to determine the specific physiological demands of horse racing during actual competition.

**Differences in Running Acceleration and Economy between Collegiate Runners and Cyclists Identified Using High-Resolution Accelerometers**

Zachary J. Maino, Lucas J. Wall, Andrea D. Workman, Joshua P. Gordon, Stephen J. McGregor. *Eastern Michigan University, Ypsilanti, MI.* (Sponsor: Andrew Coggan, FACSM)  
(No relationships reported)

We previously reported differences in running economy between highly trained runners and triathletes using high-resolution accelerometry (HRA) and indirect calorimetry, which were partly attributed to greater training volume in the runners.

**PURPOSE:** To determine the differences in axial accelerations and running economy between collegiate runners (RUN) with high or low  $\dot{V}O_{2max}$  and cyclists (CYC) of comparable cardiovascular fitness during treadmill locomotion.

**METHODS:** Subjects gave informed consent to procedures approved by the EMU-CHHS Human Subjects Review Committee. 16 NCAA DI distance runners, divided by  $\dot{V}O_{2max}$  into HI ( $66.3 \pm 0.4$  kg,  $68.7 \pm 1.9$  ml/kg/min) or LO ( $66.1 \pm 0.5$  kg,  $59.9 \pm 5.1$  ml/kg/min), and 8 cyclists (CYC;  $73.5 \pm 4.9$  kg,  $60.7 \pm 3.8$  ml/kg/min) performed incremental  $\dot{V}O_{2max}$  trials starting at 8 kph and increasing 2 kph every 3 min until exhaustion while wearing HRA (Microstrain, VT; 617 Hz). Accelerations in g were recorded for vertical (VT), anterior/posterior (AP), medial/lateral (ML), axes and Euclidian resultants were computed (RES). Group comparisons were made for 10-14kph. Axial root mean square (RMS), RMS relative to speed (EC), and ratio of RMS/RES (Ra) were compared between groups. Expired gases were collected using an Oxycon Mobile (Viasys, CA).  $\dot{V}O_2$  was used to determine  $O_2$  cost ( $O_2C$ ) and energy expenditure (EE). HRA parameters and metabolic parameters were compared by MANCOVA using PASW 17.0 (SPSS; IL)  $\alpha=0.05$ .

**RESULTS:** CYC  $\dot{V}O_{2max}$  was significantly lower than HI ( $p<0.05$ ), but not different than LO. CYC acceleration parameters were significantly greater ( $p<0.05$ ) for  $ML_{RMS}$ ,  $AP_{RMS}$ ,  $VT_{RMS}$ , and  $RES_{RMS}$  compared to both HI and LO.  $ML_{RA}$  was also significantly greater for CYC vs. HI and LO ( $p<0.05$ ), but  $VT_{RA}$  and  $AP_{RA}$  were both lower for CYC than HI and not significantly different from LO.  $O_2C$  was lower in CYC vs. HI ( $177.5 \pm 19.5$  vs.  $184.13 \pm 21.0$  ml/kg/km), but not different from LO. RER was higher in CYC vs. HI and LO ( $1.0 \pm 0.06$  vs.  $0.89 \pm 0.1$  and  $0.86 \pm 0.1$ , respectively), therefore, EE was not different between groups.

**CONCLUSION:** These data show that CYC accelerate more in all axes in absolute terms than HI and LO, however in CYC,  $AP_{RA}$  and  $VT_{RA}$  were similar to LO. Therefore, despite training, running economy ( $O_2C$ ) may be less dependent on absolute accelerations than the relationship between VT and AP, relative to RES.

### Physiological Testing In Road Cycling, Metabolic And Cardiorespiratory Differences Between Long- And Short-stage Protocols

Carlos González-Haro<sup>1</sup>, Iñigo San Millán<sup>2</sup>, Javier Butragueño<sup>3</sup>, Jesús Escanero<sup>1</sup>. <sup>1</sup>School of Medicine, University of Zaragoza, Zaragoza, Spain. <sup>2</sup>University of Colorado School of Medicine, Denver, CO. <sup>3</sup>Laboratory of Exercise Physiology, Technical University of Madrid, Madrid, Spain.

(No relationships reported)

Most scientific studies use short duration stages test protocols (1-4 min) to measure the physiological responses of road cyclists. Recently, a new protocol with longer stages (10-min) has been proposed to measure in a more accurately way the physiological responses to exercise in road cyclists. However, it has not been compared to a shorter stage protocol.

**PURPOSE:** To compare the effects of a long- and a short-stage test on metabolic and cardiorespiratory responses in road cyclists.

**METHODS:** 21 well-trained road cyclists performed two incremental tests until exhaustion on cycle ergometer with a week of difference. The first test involved short stages ( $T_1$ ) (warm-up: 100 W·10 min<sup>-1</sup>, started at 200 W, increments: 30 W·3 min<sup>-1</sup>), the second test involved long stages ( $T_2$ ) (warm-up: 2 W·kg<sup>-1</sup>·10 min<sup>-1</sup>, increments: 0.5 W·kg<sup>-1</sup>·10 min<sup>-1</sup>).  $\dot{V}O_2$ ,  $\dot{V}CO_2$ , HR and  $[La]_b$  were measured throughout the test. Fat and carbohydrate oxidation rates ( $FAT_{OXR}$  and  $CHO_{OXR}$ ) were estimated by means of Frayn's equations. Results in  $T_1$  were interpolated at the same relative workload than  $T_2$ . All data of both tests was compared by Students' t-test for paired data. Statistical significance was set at 0.05.

**RESULTS:**  $T_1$  was shorter than  $T_2$  ( $35:30 \pm 3:57$  vs.  $53:44 \pm 10:29$  min,  $p<0.001$ ). Maximal parameters were higher in  $T_1$  vs.  $T_2$  ( $PO_{Peak}$ :  $4.41 \pm 0.68$  vs.  $4.10 \pm 0.53$  W·kg<sup>-1</sup>,  $p<0.01$  and  $323 \pm 39$  vs.  $302 \pm 36$  W,  $p<0.01$ ;  $HR_{max}$ :  $185 \pm 12$  vs.  $177 \pm 10$  ppm,  $p<0.001$ ;  $[La]_b$  max:  $9.51 \pm 3.00$  vs.  $6.76 \pm 2.62$  mM,  $p<0.001$ ;  $\dot{V}O_{2Peak}$ :  $4.38 \pm 0.50$  vs.  $4.10 \pm 0.54$  L·min<sup>-1</sup>,  $p<0.05$ ;  $CHO_{OXR}$ :  $6.22 \pm 1.06$  vs.  $3.57 \pm 1.17$  g·min<sup>-1</sup>,  $p<0.001$ ) although  $FAT_{OXR}$  was lower in  $T_1$  vs.  $T_2$  ( $0.37 \pm 0.13$  vs.  $0.65 \pm 0.47$  g·min<sup>-1</sup>,  $p<0.001$ ). In general, all physiological parameters were significantly higher in  $T_1$  vs.  $T_2$ , except at  $4.5$  W·kg<sup>-1</sup> where HR,  $[La]_b$  and  $\dot{V}O_2$  did not shown differences.  $FAT_{OXR}$  was significantly lower for  $T_1$  vs.  $T_2$  at all intensities.

**CONCLUSION:** There were physiological differences between a long and short stage protocol throughout the test. The bioenergetics of both protocols are different. Short stage protocols are more glycolytic due to a faster initiation of the physiological stress response. Due to the longer duration of stages, a long stage protocol is more lypolytic and it could be more suitable for physiological testing of road cyclists due to the more aerobic nature of road cycling events.

2997 Board #269 June 1 9:30 AM - 11:00 AM

### Gravity-Assisted Downhill Mountain Biking: Physiological Demands and Health Benefits

Taylor Drury, Jamie F. Burr, Adam C. Ivey, Darren E.R. Warburton. University of British Columbia, Vancouver, BC, Canada.

(No relationships reported)

Participation in mountain biking, a form of off-road cycling, is becoming increasingly prevalent. While the physiological demands and health benefits of cross-country mountain biking have been well investigated, little research exists regarding the physiological effects of downhill mountain biking (a gravity propelled form of off-road cycling).

**PURPOSE:** To characterize the physiological demands of gravity-assisted downhill mountain biking during standard riding conditions.

**METHODS:** Oxygen consumption ( $\dot{V}O_2$ ) and heart rate (HR) were measured in 20 (12m, 8f) cyclists during a typical downhill ride. Measures of HR, blood pressure (BP), and hand grip strength were taken prior to and immediately following a downhill ride. Participants also reported a rating of perceived exertion (RPE) for the duration of the ride. Following the downhill ride, each participant completed a standardized incremental exercise test on a cycle ergometer, during which HR, BP, RPE, and  $\dot{V}O_2$  were recorded. Individual linear regressions were constructed from the exercise test matching  $\dot{V}O_2$  with HR, RPE and BP, and allowing comparison of exercise responses while riding and in the laboratory. Paired samples t-tests were used to compare the changes in blood pressure and grip strength pre and post ride, as well as the difference between the forecast and measured riding HR, BP, RPE.

**RESULTS:** The average  $\dot{V}O_2$  and HR while riding were  $23.6 \pm 6.6$  mL·kg<sup>-1</sup>·min<sup>-1</sup> (52 ± 14% of maximal capacity), and 146 ± 11 bpm (80 ± 6% of max), respectively. More than 65% of the ride duration occurred at an intensity level associated with improvements in health and fitness, according to current ACSM guidelines. Riding HR and RPE were elevated above the levels predicted for the measured metabolic demands (HR + 21 bpm,  $p = 0.001$ , RPE +3,  $p < 0.001$ ). In addition, post-ride grip strength was reduced by  $5.2 \pm 9.8$  kg ( $p = 0.04$ ) compared to pre-ride measurements, indicating significant muscular fatigue.

**CONCLUSION:** Participation in gravity-assisted downhill mountain biking presents substantial physiological demands at intensities that are associated with health and fitness benefits.

### Running Efficiency: Sprinters Vs. Distance Runners

Lindsey M. Kunkel, Maura L. Baumstark, Katie L. Wargo, Colin B. Hanna. University of Central Missouri, Warrensburg, MO.

(No relationships reported)

**INTRODUCTION:** In the world of running, one of the most important concepts is running economy, which is a measure of how efficiently a person uses oxygen while running at a given pace.

**PURPOSE:** The purpose of this research project was to compare two different types of collegiate level runners. Sprinters and distance runners were compared to determine which type of runner is more efficient in their running techniques. It was hypothesized that distance runners are more efficient.

**METHODS:** Eight distance runners and eight sprinters were assessed for lean mass using air displacement plethysmography. Subjects were assessed for  $\dot{V}O_2$  consumption at a submaximal level, using a treadmill. All subjects ran at a 0.0 incline for 7 minutes at a 6.0 mph pace. The heart rate was measured and recorded with a heart rate monitor as well as weight (kg) and height (cm).

**RESULTS:** Distance runners had a mean oxygen consumption of  $42.56 \pm 1.8$  ml/kg/LBM as compared to sprinters, with  $43.22 \pm 2.6$  ml/kg/LBM. Distance runners had a mean LBM percentage of 81.16%, while sprinters had an average of 87.4%. A T-test was applied to tell if the means of the results were different enough to be beyond chance. The T-test result was 0.28, which indicated that the difference in the mean oxygen consumption was not significant enough to say that one group was more efficient than the other.

**CONCLUSION:** Based on the data collected, the conclusion supports the hypothesis that distance runners are more efficient than sprinters when running 6 mph. Although the means of oxygen consumption data indicated that distance runners were more efficient, the difference was not significant. Therefore, each runner runs efficient enough for their type of race. Additionally the data indicates that sprinters have significantly higher lean body mass average percentage. However, their level of oxygen consumption was still higher at a submaximal level. Thus, according to the results, lean body mass percentage does not affect running economy. **Key Words:** running efficiency, lean body mass, oxygen consumption.

**Acute Metabolic And Mechanical Effects Of Different Sprint Workouts In High Level Sprinters**

Pedro Jiménez-Reyes<sup>1</sup>, Victor Cuadrado-Penafiel<sup>2</sup>, Fernando Pareja-Blanco<sup>3</sup>, Manuel Alejandro Ortega-Becerra<sup>3</sup>, Juan Jose González-Badillo<sup>3</sup>. <sup>1</sup>Catholic University of San Antonio, Murcia, Spain. <sup>2</sup>University of Castilla La Mancha, La Mancha, Spain. <sup>3</sup>Pablo de Olavide University, Seville, Spain.  
(No relationships reported)

Knowledge of acute effects of training load in sprint training sessions is essential for improving performance. The ultimate goal of training is to prepare athletes to perform at their best at important competitions. Therefore, it's a need the training load's individualization for sprint training.

**PURPOSE:** To analyze the acute metabolic and mechanical response to different sprint workouts (SW). SW with different number of repetitions (R) for each subject in short distance traveled (DT) and SW with same number of R in long DT.

**METHODS:** Eighteen high level sprinters (age  $23.1 \pm 4.4$  yr, body mass  $73.7 \pm 4.6$  kg, height  $177.6 \pm 5.9$  cm; body fat  $9.6 \pm 2.9\%$ ) took part in this study. Six sessions separated by a week were performed. Three sessions for 40, 60 and 80m performed at highest possible speed up to lose 3% of speed with 4, 6 and 8 minutes rest between sets (same ratio work/recovery for different DT); thus, different R for the same DT [(x)RxDT]. Other three sessions performed over 150, 250 and 500m with the same R and DT for all subjects: 3xDT with 15 minutes rest between sets. Mechanical responses (i.e. height performance in countermovementjump (CMJ) and speed loss) and metabolic responses (i.e. blood lactate, uric acid and ammonia concentrations) were measured pre-exercise, during exercise each repetition performed and post-exercise.

**RESULTS:** CMJ height loss pre-post session were significant for all sprint workouts analyzed and highly correlated to metabolic responses ( $r = 0.86-0.98$ ). The speed losses produced in the successive sprints presented a high relation between the distances and reduction in CMJ height. These losses were between 9.1% for 40m and 26.3% for 500m. The fatigue, measured as CMJ height loss, increases with DT, and, is strongly correlated to lactate ( $r = 0.93$ ), uric acid ( $r = 0.86$ ) and ammonia ( $r = 0.98$ ).

**CONCLUSIONS:** The metabolic stress developed during the effort can be estimated by controlling CMJ because of the high correlation between CMJ and blood lactate, uric acid and ammonia concentrations. The high correlations found between mechanical (speed and CMJ height losses) and metabolic (lactate, uric acid and ammonia) measures of fatigue highlight the utility and validity of using CMJ to monitor training load in different sprint workouts and quantify objectively neuromuscular fatigue during sprint workouts.

**Physiological Correlates Of Cycling Efficiency, Economy And Performance In Elite Junior Cyclists**

Elias Zacharogiannis, Vasilis Anastopoulos, Giorgos Paradisis, Nikos Dimitriadis, Evangelos Rousopoulos, Athanasia Smirniotou. *Athens University, Athens, Greece.*  
(No relationships reported)

Among of the proposed determinants of cycling performance is cycling economy (CE) and work efficiency (WE). Enhanced CE is accompanied by a decrease in the percentage of VO<sub>2</sub>max required to sustain a given mechanical work. Improvements in WE can also theoretically maximize cycling performance as it is a measure of effective work and is expressed as a percentage of total energy expended that produces external work. Data in the literature are limited to elucidate the contribution of WE and CE in cycling endurance performance.

**PURPOSE:** The aim of this study was to investigate the correlation of WE and CE with physiological parameters. The contribution in 3 km indoor individual time trial of WE and CE was also studied.

**METHODS:** Subjects were eleven elite junior road cyclists (age  $17.7 \pm 0.5$  years, body mass  $66.8 \pm 4.9$  kg, body height  $176.3 \pm 7.4$  cm, VO<sub>2</sub>max  $69.7 \pm 2.56$  ml.kg<sup>-1</sup>.min<sup>-1</sup>). Physiological parameters were determined by continuous incremental testing. This protocol had steps of 2 min and increments of 30 W. Cyclists also performed two exhaustive trials in random order at 90%VO<sub>2</sub>max (tlimit90) and 100%VO<sub>2</sub>max (tlimit100) seven days apart. Five days after the last exhaustive trial cyclists performed an individual 3 km time trial on an indoor wooden track. CE was calculated as  $\text{watt.L}^{-1}\text{.min}^{-1}$ , while WE expressed as the ratio of work accomplished per minute (watt) was converted to kcal.min<sup>-1</sup> to energy expended per minute (in kcal.min<sup>-1</sup>).

**RESULTS:** Mean  $\pm$  sd WE and CE were  $20.11 \pm 1.03\%$  and  $84.23 \pm 4.28$  watt.L<sup>-1</sup>.min<sup>-1</sup>. WE and CE did not correlate with VO<sub>2</sub>max, power at VO<sub>2</sub>max, tlimit90, tlimit100, maximal blood lactate concentration and the 3 km cycling performance ( $p > 0.05$ ). WE was only related with ventilatory threshold ( $r = 0.62$ ,  $p = 0.04$ ). WE also presented a weak ( $r = -0.45$ ,  $p = 0.12$ ) relationship with 3km performance time. CE was only related with maximal pedalling revolutions ( $r = 0.65$ ,  $p = 0.03$ ).

**CONCLUSIONS:** Although WE and CE has been proposed to be the physiological criterion for efficient performance the data of the present study does not support their use for evaluation of cycling performance. Future research may elucidate better this by studying longer distances with a larger subject number.

3001 Board #273 June 1 9:30 AM - 11:00 AM

**Interaction Among Vo<sub>2</sub> Kinetics, Acid-base Status And Running Speed During On-track 800-m Running**

Tomoharu Kitada, Hisashi Naito, Yoshito Konno, Shizuo Katamoto. *Juntendo University, Chiba, Japan.*  
(No relationships reported)

During 400-m running, a fall in VO<sub>2</sub> has been observed towards the end of the race. The decline in running speed as well as this fall in VO<sub>2</sub> has been found to be correlated with acid-base status. The lactic acidosis therefore may contribute to the decline in running speed directly by perturbing contractile mechanisms, and also indirectly by impairing O<sub>2</sub> supply. The interactions among VO<sub>2</sub> kinetics, acid-base status and running speed during 800-m running however has not been studied to date. It is of interest whether decline in running speed during 800-m running would result from similar fatigue mechanisms to those of 400-m running.

**PURPOSE:** To investigate VO<sub>2</sub> kinetics, acid-base status and running speed during on-track 800-m running.

**METHODS:** Seven male 800-m runners (age:  $19.4 \pm 1.7$  y-o, season best:  $120.4 \pm 3.1$  s) performed a maximal 800-m running for the best performance on track, following a warm-up. They also ran 400-m and 600-m on different days at the pace resembling that of 800-m running to collect blood samples at these distances. VO<sub>2</sub> was measured by the K4b2 portable gas exchanges system. The average running speed was calculated for each 100-m using digital moving images (60 Hz). Breath-by-breath gas data were averaged within each 25-m. Blood samples (pH, HCO<sub>3</sub><sup>-</sup> and Lactate) were taken from the ear-lobe after the warm-up and then 1-min after completing each trial to be analyzed.

**RESULTS:** The average 800-m performance time was  $130.3 \pm 4.5$  s. The running speed peaked ( $24.5 \pm 0.8$  km•h<sup>-1</sup>) in the first 100-m then decreased gradually towards the end ( $20.9 \pm 1.8$  km•h<sup>-1</sup>). VO<sub>2</sub> peaked ( $55.5 \pm 3.3$  ml•kg<sup>-1</sup>•min<sup>-1</sup>) about 425-m and remained similar until the end of the trial. For the acid-base status parameters, only the pH values at 400-m were negatively correlated with the decline in running speed in the last 200-m intervals. ( $r = -0.77$ ,  $p < 0.05$ ).

**CONCLUSIONS:** For Japanese collegiate 800-m athletes, VO<sub>2</sub> remained elevated throughout the latter half of 800-m running, implying that the decline in running speed towards the end of the event could not be attributed to a fall in VO<sub>2</sub>. The ability to prevent a profound decrease of pH until 400-m may be the key to maintaining faster running speed near the end of the race.

3002 Board #274 June 1 9:30 AM - 11:00 AM

**Comparison of Sport Vision Between two Elite Athletes of Volleyball and Shooting**

Yi-Jia Lin<sup>1</sup>, Cheng-Hsiu Lai<sup>1</sup>, Chia-Hua Kuo<sup>1</sup>, Shih-Wei Chou<sup>2</sup>, Alice May-kuen Wong<sup>2</sup>. <sup>1</sup>Taipei Physical Education College, Taipei, Taiwan. <sup>2</sup>Chang Gung Memorial Hospital, Tao-yuan, Taiwan.  
(No relationships reported)

Sports vision is fundamental for both volleyball (V) and shooting (S) disciplines but may be different between. Quantification of sport vision may help differentiate the components of sport vision required and also assess any training effects, if possible.

**PURPOSE:** For preliminary comparisons of sport vision between two disciplines of sports, i.e., volleyball and shooting.

---

**METHODS:** Two female elite athletes, one of volleyball and the other of shooting (Aged: V/S=22/29 years, BHT: V/S=178/161 cm, BWt: V/S=67/73 kg, career duration: V/S=9/12 years) were recruited to receive training which includes whole body stretching and strengthening exercise for one month. Visual performance was measured by a sport vision measurement software, including dynamic visual acuity (DVA), eye movement (EM), peripheral vision (PV), and momentary vision (MV). DVA was measured in four directions including left-to-right, right-to-left, up-to-down, and down-to-up. Measured variables were compared between two disciplines as well as before and after training.

**RESULTS:** For the comparison between two disciplines before training, better PV (V:24.9 vs. S:3.1 degrees) and MV (V:400 vs. S:600 pixels/frame) were found in volleyball. For the comparison of the post-test data, better EM (V:100 vs. S:200), PV (V:31.2 vs. S: 3.1 degrees) and MV (V:200 vs. S:600 pixels/frame) as well as DVA in right to left direction were found in volleyball. For training effect, all the items were improved in volleyball disciplines. However, effect of training was found only in DVA scores in shooting discipline.

**CONCLUSION:** Better PV and MV in volleyball suggested that peripheral vision and momentary vision were important to track ball between two groups of players. Better DVA in shooting suggested that dynamic visual acuity was essential to track targets in free dimension from fixed head position. Difference in sports-specific characteristics response to training was found mainly in PV. It can be explained that, for the shooting, focus ability was more important than PV within the range of shooting gun, therefore PV test conducted in shooting players was suggested to modify. Although peripheral vision was essential for the shooting performance; however, it may only be true when the evaluation was conducted in the distance larger than the length of the shooting gun.

**Comparisons in Running Economy and Mechanics between Collegiate Pole Vaulters and Runners using High-Resolution Accelerometers**

Andrea D. Workman, Shean Conlon, Tim Muth, Anna Daoud, Aaron Stickel, Stephen J. McGregor. *Eastern Michigan University, Ypsilanti, MI.*

(No relationships reported)

Sprint and plyometric training have both been shown to improve running economy in distance runners. Pole vaulters are both sprint and plyometric trained athletes who do not perform endurance training. We have previously used high resolution accelerometers (HRA) to demonstrate differences in kinematics that contribute to running economy. The purpose of this study was to compare running economy and mechanics between NCAA Division I Pole Vaulters (PV) and Cross Country Runners (XC) using HRA's during an incremental treadmill test. We hypothesized that despite lower aerobic fitness, PV would be more economical runners than XC.

**METHODS:** 8 collegiate PV athletes, 5 males (19.6 ± 0.67 yr, 74.3 ± 3.7 kg, 54.2 ± 2.6 ml/kg/min) 3 females (19.25 ± 0.94 yr, 66.8 ± 0.7 kg, 42.6 ± 1.9 ml/kg/min) and 15 male collegiate XC athletes (22.1 ± 1.5 yr., 66.5 ± 5.7 kg, 71.1 ± 5.2 ml/kg/min) consented to procedures approved by EMU-CHHS-Human Subjects Committee and performed an incremental running test (VO<sub>2max</sub>) consisting of 3 minutes stages, beginning at 8 kph and increasing 2 kph until exhaustion while wearing tri-axial HRA's (Microstrain, VT). Group comparisons were made from 10 kph to 14 kph. Accelerations for vertical (VT), anterior/posterior (AP), medial/lateral (ML), axes were recorded and Euclidean resultants were computed (RES). Axial root mean square (RMS), RMS relative to speed (EC), and ratio of RMS/RES (RA) were compared between PV and XC athletes to determine if differences in acceleration profiles could be identified between the two groups. Expired gasses were collected using an Oxycon Mobile (Viasys, CA). VO<sub>2</sub> and RER were used to determine O<sub>2</sub> cost (O<sub>2</sub>C) and energy expenditure (EE). MANOVAs were performed using SPSS 19.0 (IBM, NY)  $\alpha = .05$ .

**RESULTS:** XC exhibited greater VT<sub>RA</sub> and AP<sub>RA</sub> than PV (p<.001) but ML<sub>RMS</sub>, ML<sub>RA</sub> and AP<sub>RMS</sub> were lower (p<.001). O<sub>2</sub>C was lower (p<.001) in PV (173.1 ± 13.7 vs 181.5±22.6, respectively) at every speed but RER was greater, therefore EE (p=.151) was not different among groups.

**CONCLUSION:** PV indeed exhibited better O<sub>2</sub>C than XC, but energy expenditure was not different between groups. Differences do exist in acceleration profiles between PV and XC, but these do not seem to contribute to reduced energy expenditure of running, as differences in O<sub>2</sub>C appear to relate to metabolic differences between PV and XC.

**3004 Board #276 June 1 9:30 AM - 11:00 AM**

**Field Testing vs. Physiological Testing in Novice Marathoners**

Christopher J. Lundstrom, Stacy J. Ingraham, Ph.D., Gregory S. Rhodes. *University of Minnesota, Minneapolis, MN.*

(No relationships reported)

**INTRODUCTION:** Field testing, such as the use of time-trials (TT) and training races are utilized to assess and predict performance in endurance races. TTs have been studied as a method of predicting performance at races of different distances. VO<sub>2</sub>MAX has been considered one of the best physiological predictors of performance in endurance sports. Lactate threshold, running economy, and peak treadmill running velocity during a VO<sub>2</sub>max test (PTV) are also factors used in predicting running performance.

**PURPOSE:** To compare VO<sub>2</sub>MAX, PTV, and TT as predictors of marathon (26.2 mile) performance in novice marathoners.

**METHODS:** Forty-seven novice and minimally-experienced college-aged subjects (13 male, 34 female) age 21.1 +/- 2.8 years, trained for and completed a marathon as part of a university course. Three TTs were performed: a 3200 meter, 3 months prior to the marathon; a 1/2-marathon, (13.1 miles), 2 months prior; and a second 3200M, 10 days before the marathon. Forty-seven subjects completed the first 3200M, and 41 subjects completed the additional TTs. The VO<sub>2</sub>MAX test was conducted on a treadmill one to three weeks prior to the marathon, using a graduated protocol with starting speed adjusted according to time-trial results. PTV was defined as the treadmill speed during the final stage of the test, with velocity adjusted for treadmill elevation.

**RESULTS:** Using Pearson's correlations, VO<sub>2</sub>MAX, PTV, and three TTs were correlated with marathon finishing time (p<.01). While the correlation values were not significantly different, the half marathon and second 3200M TT had a higher correlational value specific to the marathon finish time (r = 0.91 and 0.89) than either the first 3200M TT (r = .85), VO<sub>2</sub>MAX (r = -0.78), or PTV (r = 0.81).

**CONCLUSIONS:** TTs of distances shorter than the marathon, VO<sub>2</sub>MAX and PTV correlate with marathon finish time. TTs closer to the date of the marathon had higher correlation values with marathon time than PTV or VO<sub>2</sub>MAX, though the differences were not statistically significant. Conducting testing at distances closer to the race distance or closer to the date of the race may strengthen the association. While this method does not provide the additional physiological data available through laboratory testing, it is less expensive and easier to conduct and shows a relationship to finish time.

**Proposal Of A Specific Exercise Test For Taekwondo Athletes: Comparison To Traditional Cardiopulmonary Exercise Test**

Gabriel Espinosa<sup>1</sup>, Jonas Lirio Gurgel<sup>1</sup>, Flávia Porto<sup>2</sup>, Allan Sales<sup>1</sup>, Renata Castro<sup>1</sup>, Renata Castro<sup>1</sup>, Antonio Claudio Nobrega<sup>1</sup>. <sup>1</sup>Fluminense Federal University, NITERÓI, Brazil. <sup>2</sup>Gama Filho University, Rio de Janeiro, Brazil.

(No relationships reported)

**PURPOSE:** Compare the cardiorespiratory responses of a treadmill incremental exercise test (TREADtest) and a Tae Kwon Do incremental exercise test (TKDtest).

**METHODS:** Seven (5 men and 2 women) Brazilian Taekwondo elite athletes (age: 21.29 ± 3.35yrs; weight: 77.20 ± 11.32kg; height: 1.75 ± 0.10m) were submitted to a two-day protocol separated by 2 to 7 days. 1st day: anthropometric assessment TKDtest and familiarization to the treadmill. 2nd day: TREADtest. The TKDtest was based on the most common kick technique (dolio chiagi), work increment was given by kick frequency (increment of 3 kicks per minute) and each stage took one minute. The test was interrupted when the subject could not respect the sonorous stimulus for three consecutive kicks. The TREADtest was an individualized ramp and was based on predict VO<sub>2</sub>max obtained by a questionnaire (Wisén et al., 2002). Maximum velocity was determined based on ACSM equation. Initial velocity for all subjects was 60% of maximum predict velocity and increment was calculated for test duration of 10 minutes. Shapiro Wilks test were applied for confirmation of normality, a bi-caudal paired-samples Student t test was applied to verify significance differences between the two tests (TREADtest and TKDtest). The significance level was set at  $\alpha = 0.05$ .

**RESULTS:** For all analyzed variables there was no significant difference between the TREADtest and TKDtest (see table -1).

**Table 1 - Results from the comparison of the two exercise tests TREADtest x TKDtest.**

|            | VO2peak       | VT1           |              | VT2           |              | HRpeak  | Time at Peak    |
|------------|---------------|---------------|--------------|---------------|--------------|---------|-----------------|
|            | (ml.kg.min-1) | (ml.kg.min-1) | (%VO2peak)   | (ml.kg.min-1) | (%VO2peak)   | (bpm)   | (s)             |
| TREADtest  | 46.93 ± 8.39  | 37.99 ± 9.24  | 80.22 ± 8.76 | 41.83 ± 7.93  | 89.10 ± 6.01 | 193 ± 9 | 560.71 ± 175.31 |
| TKDtest    | 47.95 ± 9.56  | 41.99 ± 9.89  | 87.21 ± 6.21 | 44.46 ± 9.74  | 92.31 ± 4.25 | 195 ± 9 | 383.14 ± 137.80 |
| t-Test (α) | 0.68          | 0.11          | 0.14         | 0.34          | 0.27         | 0.61    | 0.06            |

**CONCLUSION:** The presented data did not show differences between the TREADtest and TKDtest for the tested sample. These results suggest that the new specific protocol developed is valid to assessment cardiorespiratory capacity of Tae Kwon Do athletes.

**3006 Board #278 June 1 9:30 AM - 11:00 AM**

**Examination of Warm-up Effects by Highly Concentrated Artificial Carbonic Acid Water Forearm-Bathing**

Akihiro Taimura<sup>1</sup>, Masaru Matsunami<sup>2</sup>, Masashi Sugawara<sup>1</sup>, Masaki Nakagaichi<sup>1</sup>. <sup>1</sup>Nagasaki University, Nagasaki, Japan. <sup>2</sup>Beppu Mizobe Gakuen College, Beppu, Japan.

(No relationships reported)

Warm-up induces increased muscle metabolism and muscle temperature. Immersion in highly concentrated artificial carbonic acid water might induce not only skin vasodilation but also increased oxygen consumption and blood flow in skeletal muscle (Yamamoto N, Hashimoto M, 2008).

**PURPOSE:** This study examined the effects of warm-up by observing the influence of highly concentrated artificial carbonic acid water bathing before exercise.

**METHODS:** Subjects were 10 male students who consented to participate in the present study. After immersing both upper arms in highly concentrated artificial carbonic acid water (38°C) or tap water (38°C) for 20 minutes, they exercised using a portable hand ergometer at 20w for 10 minutes in an artificial climate chamber (26°C, 40%rh). The skin blood flow, the skin temperatures, heart rate, sub-lingual temperature, thermal sensation and thermal comfort were measured.

**RESULTS:** The skin blood flow of non-immersed parts (upper arm) with carbonic acid water during immersion decreased to 97±5%, but that with tap water increased to 118 ± 7%. And during exercise, that with carbonic acid water increased to 190 ±13% and with tap water increased to 269 ± 28%. There was no significant difference between each, but that with carbonic acid water during exercise was more effective in suppressing an increase skin blood flow than with tap water. The skin temperatures of non-immersed parts with carbonic acid water during exercise decreased to 0.44 ± 0.18°C and with tap water decreased to 0.31 ± 0.09°C. The decrease of that with carbonic acid water was significantly larger than with tap water (P < 0.05). Heart rate with carbonic acid water during exercise increased to 29.78 ± 8.49 bpm and with tap water increased to 34.10 ± 10.24 bpm. That of with carbonic acid water during exercise more significantly attenuated an increase than that of with tap water.

**CONCLUSIONS:** Carbonic acid water had a larger decline of skin blood flow and skin temperature of active parts, and larger attenuation of increase of heart rate during exercise compared to tap water. These data indicate that immersion in highly carbonic acid water might have a warm-up effect. Future study will require whole body bathing, and exercise, because this study concentrated only on both arm bathing and exercise.

**3007 Board #279 June 1 9:30 AM - 11:00 AM**

**Speed Training: Impact of Land vs Aquatic Environment**

Jon Adams, Paul Reneau, Michael J. Ryan. Fairmont State University, Fairmont, WV.

(No relationships reported)

**PURPOSE:** To investigate which type of training method; land or water, would be more beneficial to increase speed.

**METHODS:** Twenty healthy students, 10 male and 10 female, served as subjects (age= 21.1 + 1.89yr). Subjects initially participated in a 30yd, 60yd, 100yd, and 200yd maximal sprint to establish pre-training times. Subjects were then divided into two training groups; land or water, for a three week training period. Both groups consisted of five males and five females each. Each group was given the same workout consisting of speed drills and plyometrics performed 3 times per week. Subjects were then re-tested for post-training times at the same distances. Data between groups pre and post test times were analyzed using an independent t-test. Data within group's pre to post training times were analyzed using a dependent t-test.

**RESULTS:** A significant difference (p<.05) was found between the pre-training and post-training times for both groups across all distances. No significant difference (p>.05) was found between the two groups pre-training results or post-training results for all distances.

**CONCLUSIONS:** These results indicate that three weeks of training increases a persons speed irrelevant of whether they utilize dry land or water as the training environment. Additionally, the data suggested there is no difference between land and water on increasing a persons speed.

| Sprint Distance | Pre Train Land | Pre Train Water | Post Train Land | Post Train Water |
|-----------------|----------------|-----------------|-----------------|------------------|
| 30 yards        | 4.29(.54)      | 4.45(.58)       | 4.16(.42)*      | 4.39(.60)*       |
| 60 yards        | 7.94(1.22)     | 8.15(1.13)      | 7.72(.96)*      | 8.01(1.14)*      |
| 100 yards       | 13.44(2.15)    | 13.83(2.41)     | 13.11(1.80)*    | 13.71(2.44)*     |

**Effect of High-Intensity Interval Training On Stride Distance During Treadmill Double-Pole Roller-Skiing**

Phillip B. Watts, FACSM, Molly E. Burger, Jordan D. Dalgord. Northern Michigan University, Marquette, MI.

(No relationships reported)

**PURPOSE:** Short-term high intensity interval training (HIT) improves maximal aerobic power and time-trial performance in competitive events. Whether HIT improves power output and stride characteristics during repetitive techniques such as double-poling in XC skiing is unknown. The purpose of this study was to test effects of a short-term double-poling (DP) HIT regimen on average stride distance (SD) during treadmill roller-skiing.

**METHODS:** 12 collegiate XC skiers signed informed consent to participate in the study (age = 21.5±1.2 yr). Subjects completed 4x30 sec DP intervals on a motorized treadmill at 4.92, 5.14, 5.36 and 5.59 m·sec<sup>-1</sup> at a constant 2.6% grade and with 2 min resting recovery between intervals (PRE). Digital video was recorded in the frontal plane during each interval. The time between pole tip contacts with the treadmill belt for the last three strides at each speed was determined using MaxTRAQ 2D analysis software. Average SD at each speed was calculated from the total time interval for the 3 strides. Following PRE testing each subject completed a series of 6 HIT training bouts evenly spaced over a 16-day period. The HIT sessions involved repetitions of 30-sec maximal DP intervals on a modified VASA Ergometer with 2.5-min rest between repetitions. The 6 HIT sessions involved 4, 4, 6, 6, 8, and 4 repetitions respectively. During the first (HIT1) and final HIT (HIT6) sessions VO<sub>2</sub> was measured via expired air analysis and average power in Watts (Pavg) was recorded from the VASA ergometer for each interval. Within 2 days of the final HIT session each subject repeated the treadmill rollerski protocol (POST).

**RESULTS:** Peak HIT VO<sub>2</sub> was unchanged over the training period (56.0±12.5 vs 51.6±7.7 ml·kg<sup>-1</sup>·min<sup>-1</sup> for HIT1 vs HIT6 respectively) however peak Pavg was higher (p<.05) for HIT6 (318.9±115.2 W) vs HIT1 (293.6±110.4 W). No significant differences were found between PRE and POST for SD at any speed during the treadmill rollerski intervals. SD values at 5.59 m·sec<sup>-1</sup> were 5.24±1.89 and 5.43±1.78 m·stride<sup>-1</sup> for PRE and POST respectively.

**CONCLUSIONS:** Short term HIT training for double-poling improves peak average power in the specific training mode without a change in peak VO<sub>2</sub>. The mode-specific training effect does not carry over to treadmill rollerski performance.

#### Effect of Hypohydration and Environment on Dynamic Postural Stability

Robert W. Kenefick, FACSM, Kurt J. Sollanek, Brett R. Ely, Samuel N. Cheuvront, FACSM, Michael N. Sawka, FACSM. *U.S. Army Research Institute of Environmental Medicine, Natick, MA.*

(No relationships reported)

Postural balance is critical to physical performance, completion of work tasks and a potential contributor to accidents. However, the influence of environmental temperature and hydration state has not been well studied.

**PURPOSE:** To determine the impact of hypohydration and a range of environmental temperatures on measures of dynamic balance.

**METHODS:** Following 5 days of training to reduce learning and within subject variation, 32 men (22 ± 4 yr) were divided into four matched cohorts (n=8), and tested (Biodes Balance System) in one of four T<sub>a</sub> (10, 20, 30, 40°C) while eu- (EUH) and hypohydrated (HYPO; -4% body mass via exercise-heat exposure). Training and testing consisted of three, 20 second trials where volunteers, wearing t-shirt and shorts, stood on an unstable platform and attempted to hold it in a level position. Balance measures consisted of % time in region A (%A), mean deflection (MD), and overall stability index (OSI).

**RESULTS:** Overall, core temperatures were stable across each environment. Skin temperature increased by -4°C with each 10°C increase in T<sub>a</sub> and thermal sensation was markedly different (p<.05) in each environment, with no effect of HYPO. Intra-individual %CV calculated from training days 3-5 was 14.1% (%A), 24.6% (MD), and 22.5% (OSI). In general, HYPO vs. EUH balance measures were not different (p>.05) thus, EUH and HYPO trials were collapsed. A mixed model ANOVA revealed differences (p<.05) between 10°C vs. other environments for %A, MD and OSI.

**CONCLUSION:** Hypohydration of -4% body mass does not alter dynamic postural stability. However exposure to cold does appear to negatively impact dynamic postural stability which may be related to low skin temperatures and thermal sensation. Individuals who work, train or compete in the cold should be aware that dynamic postural stability may be compromised, possibly increasing risk for accidents or injury.

The opinions or assertions contained herein should not be construed as official or reflecting the views of the Army or the DoD.

### 3010 Board #282 June 1 11:00 AM - 12:30 PM

#### A Comparison Of Hyperhydration Vs. Ad Libitum Fluid Intake Strategies On Markers Of Oxidative Stress

Angela R. Hillman<sup>1</sup>, Mark C. Turner<sup>2</sup>, Daniel J. Peart<sup>1</sup>, Lee Taylor<sup>2</sup>, Jason C. Siegler, FACSM<sup>3</sup>. <sup>1</sup>University of Hull, Hull, United Kingdom. <sup>2</sup>University of Bedfordshire, Bedford, United Kingdom. <sup>3</sup>University of Western Sydney, Penrith, Australia.

(No relationships reported)

Both in vitro and in vivo work has demonstrated that dehydration augments oxidative stress while euhydration can attenuate this trend. Similarly, in vitro work has demonstrated hyperhydration can attenuate oxidative damage. Glycerol is often employed as a hyperhydrating agent that is evenly distributed among the intra- and extracellular compartments, which would likely maintain cellular integrity providing protection against oxidative stress.

**PURPOSE:** The purpose of this experiment was to compare pre-exercise hyperhydration with glycerol (G) or water (W) to no hyperhydration (C) on markers of oxidative stress.

**METHODS:** Seven trained males (28 ± 8 yrs, 178.4 ± 7.8 cm, and 73.2 ± 9.6 kg) were hyperhydrated by consuming either 1.2 g of glycerol·kg<sup>-1</sup> body mass (BM) in 26 ml·kg<sup>-1</sup> BM or an equal volume of aspartame flavoured water. Drinks were evenly administered every 30 min for a 120 min period followed by a 90 min time trial (TT) in a hyperthermic environment (35°C and 40% RH). Blood was drawn pre-ingestion (PRE), post-ingestion/pre-exercise (PI), post exercise (PE), and one hour post exercise (1HR) and analysed for whole blood total (TGSH) and oxidised (GSSG) glutathione, as well as plasma glycerol, protein carbonyl (PC), and lipid hydroperoxide (LOOH) concentrations.

**RESULTS:** Hyperhydration increased BM (0.6 ± 0.2 kg, p < 0.01) and plasma volume (6.1 ± 0.7%, p < 0.01) PI and increased total fluid retained PE (1.8 ± 0.1 L, p < 0.01). Plasma glycerol concentration increased PI and remained elevated at 1HR in G (peak: 4.5 mmol/L, p < 0.01). TGSH increased PI to PE in G and W (p < 0.01), while GSSG was lower PI and PE in G vs. C (p = 0.03). PC concentration increased PE during the C trial only (p = 0.04). Furthermore, PC concentration had a moderate negative relationship with hydration status PRE to PI (r<sub>2</sub> = -0.4, p = 0.01) as well as PI to PE (r<sub>2</sub> = -0.3, p = 0.04). There were no significant changes in LOOH (p < 0.05). Core, mean body, and skin temperatures as well as heart rate increased with exercise (p < 0.01 for all) but were not different between trials. Finally, there was no difference between trials for total distance covered (p > 0.05) or mean power output (p > 0.05).

**CONCLUSION:** Hyperhydration enhanced fluid balance and attenuated oxidative stress; however this did not translate to any thermoregulatory or performance enhancements during exercise.

---

### 3011 Board #283 June 1 11:00 AM - 12:30 PM

#### Hypohydration Impairs Strength And Alters Peripheral And Corticospinal Excitatory Output

Jo Bowtell<sup>1</sup>, Gareth Avenell<sup>2</sup>, Katya N. Mileva<sup>2</sup>. <sup>1</sup>Exeter University, Exeter, United Kingdom. <sup>2</sup>London South Bank University, London, United Kingdom.

(No relationships reported)

Muscle isometric (MVC) and isokinetic (IK) strength is impaired by hypohydration, due at least in part to reduced central drive. However, it is not clear whether this is due to hypohydration *per se* or accompanying hyperthermia, and no neural excitability data are available.

**PURPOSE:** To investigate whether the hypohydration-induced decline in muscle strength is related to altered peripheral and corticospinal excitatory output.

**METHODS:** 7 male trained taekwondo players completed two trials (hypohydrated, Hy; euhydrated, Eu) comprising 6x15 min cycling bouts at 85% HR<sub>max</sub> at 40°C and 50% relative humidity, with core temperature (T<sub>c</sub>) measured throughout. MVC and IK (90°·s<sup>-1</sup>) strength and skin temperature (T<sub>sk</sub>) were measured pre and post, and peripheral (femoral nerve) and transcranial magnetic stimulation were applied during MVC to quantify voluntary activation (VA) and evoked potential amplitude in vastus medialis (Mwave and motor evoked potential, MEP respectively). Data were analysed with 2way repeated measures ANOVA.

**RESULTS:** Body weight decreased by 2.7±0.1% in Hy, but there was no difference between conditions in pre and post T<sub>c</sub> (pre: 37.3±0.1 vs post: 37.4±0.1, Eu; pre: 37.3±0.2 vs post: 37.6±0.1, Hy; °C) or T<sub>sk</sub> (pre: 18.5±0.3 vs post: 18.6±0.1, Eu; pre: 18.7±0.2 vs post: 18.1±0.2, Hy; °C) in either condition. Both MVC (pre: 677.1±50.8 vs post: 645.9±55.2, Eu; pre: 679.2±68.7 vs post: 576.6±57.5, Hy; Nm) and IK eccentric (pre: 646.3±84.0 vs post: 559.5±67.9, Eu; pre: 745.3±91.0 vs post: 505.4±47.4, Hy; Nm) strength decreased to a greater extent in Hy (condition x time interaction, P<.05), but the decrease in VA was not significantly different between conditions (Hy: -8.9±3.7, Eu: -5.2±3.1 %). Mwave amplitude decreased significantly from pre (3.96±0.77, Hy; 4.14±1.15, Eu; mV) to post (-10.1±13.3, Hy; -28.7±18.5, Eu; %, P<.05). MEP amplitude was higher in Eu (1.53±0.28, pre; 2.01±0.37, post) than Hy (1.39±0.18, pre; 1.39±0.32, post; mV; P=0.09).

**CONCLUSIONS:** The hypohydration-induced reduction in strength does not appear to be due to greater reductions in voluntary activation. Excitatory output was enhanced in the hypohydrated condition, presumably in an inadequate attempt to preserve function in the face of reduced contractility.

Supported by European Hydration Institute.

**Does Dehydration affect Peak Loading Rate during Landing in Adolescent Boys following Intermittent Exercise?**

Jason C. Dorman<sup>1</sup>, Szu-Ping Lee<sup>2</sup>, Thayne A. Munce<sup>1</sup>, Paul A. Thompson<sup>1</sup>, Ashley L. Miller<sup>1</sup>, Christopher M. Powers, FACSM<sup>2</sup>, Michael F. Bergeron, FACSM<sup>1</sup>.  
<sup>1</sup>Sanford USD Medical Center, Sioux Falls, SD. <sup>2</sup>University of Southern California, Los Angeles, CA.

(No relationships reported)

Injury risk reduction in youth sports is an ongoing priority. A potential contributing factor for a greater risk of certain musculoskeletal injuries during prolonged exercise is an increase in peak loading rate (PLR). Elevated loading rates have been linked to several lower extremity injuries, and fatigue is one factor common in sport that may increase these rates. We hypothesized that the combined effect of fatigue and dehydration would compound the problem.

**PURPOSE:** To investigate the influence of dehydration ( $\approx 2\%$  body weight deficit) on measures of PLR during a one-hop jump test in young athletes before and after an intermittent, moderate-intensity bout of exercise.

**METHODS:** Twenty-five physically active adolescent boys ( $16.6 \pm 0.9$  yr) were grouped into one of three exercise conditions: Dehydration-hot (DE-HOT: 35°C, 50% relative humidity (rh), with no fluid replacement), hydration-hot (HY-HOT: 35°C, 50% rh with fluid replacement) or hydration-mild (HY-MILD: 22.2°C, 50% rh with fluid replacement). Exercise trials consisted of one 60-min bout of intermittent exercise (alternating treadmill running @ 60%  $\dot{V}O_{2max}$  & cycle ergometry @ 40%  $\dot{V}O_{2max}$ ). Immediately before (PRE) and after (POST) each exercise bout, PLR was assessed by the performance of a unilateral one-hop jump test on a force platform.

**RESULTS:** Peak measures of core body temperature, heart rate, rating of perceived exertion, and thermal stress rating were significantly higher in the DE-HOT ( $39.1 \pm 0.4^\circ\text{C}$ ,  $187.4 \pm 12.1$  bpm,  $16.0 \pm 2.0$ ,  $11.0 \pm 0.6$ ) and HY-HOT ( $38.9 \pm 0.5^\circ\text{C}$ ,  $182.3 \pm 11.8$  bpm,  $16.1 \pm 3.0$ ,  $11.6 \pm 0.8$ ) groups vs. the HY-MILD ( $38.1 \pm 0.3^\circ\text{C}$ ,  $161.0 \pm 14.6$  bpm,  $11.6 \pm 1.3$ ,  $8.4 \pm 0.9$ ) group ( $p < 0.01$ ). Mean PLR progressively increased Pre vs. Post in each exercise condition bout, as seen by the Pre vs. Post differences (DE-HOT  $1243 \pm 1758$ , HY-HOT  $792 \pm 2304$ , HY-MILD  $403 \pm 1321$  body weight/sec), though not statistically significant.

**CONCLUSIONS:** One hour of moderate-intensity, intermittent exercise, similar to that commonly experienced in youth sports, did not result in significant changes in PLR. Contrary to our hypothesis, inducing dehydration did not result in a consistent decrease in PLR. Therefore, greater levels of dehydration may be required to see an increase in injury risk during landing.

**Deep Ocean-Based Desalted Mineral Water Attenuate Dehydration Exercise-Induced Oxidative Stress and Inflammation in Healthy Young Men**

KUNG-KUN YANG<sup>1</sup>, Chien-Wen Hou<sup>1</sup>, Feng-Chih Hsu<sup>2</sup>, Sheng-Chih Huang<sup>1</sup>, Mallikarjuna Korivi<sup>1</sup>. <sup>1</sup>Taipei Physical Education College, Taipei, Taiwan. <sup>2</sup>National Taoyuan Agricultural & Industrial Vocational High School, Taoyuan, Taiwan. (Sponsor: Kuo Chia-Hua, FACSM)

(No relationships reported)

**PURPOSE:** Dehydration for long time in the body cause oxidative stress and influence other biochemical parameters. Exercise under high temperature conditions cause dehydration, which is probably due to the loss of minerals from the body. In the present study, we investigated the effect of deep ocean-based mineral water (DOMW) supplementation on dehydration exercise-induced oxidative stress and inflammation levels in young men.

**METHODS:** Twelve-young healthy male college students were recruited for this double-blind crossover study. Dehydration was achieved by performing the treadmill running at 40%  $\dot{V}O_{2max}$  under 30°C in a closed room, leading to 3% body weight loss. Then subjects were orally supplemented with deep ocean-based desalted mineral water (DOMW, N=6) or pure water (placebo, N=6) in a volume equivalent to 1.5 fold of their body weight loss, and consumed in 150-min. Malondialdehyde (MDA), interleukin (IL-6), erythropoietin (EPO), testosterone, myoglobin and lactate dehydrogenase (LDH) levels were measured in the blood before exercise, 4-h and 24-h after exercise.

**RESULTS:** Dehydration exercise-induced lipid peroxidation was evidenced by increased ( $P < 0.01$ ) MDA levels along with increased IL-6 concentration in both trial. However, MDA and IL-6 levels were significantly suppressed in DOMW received trial during recovery compared to placebo trial. Estimated EPO was not significantly altered in placebo trial, but increased ( $\sim 130\%$ ,  $P = 0.06$ ) in the DOMW trial. Rise in myoglobin (muscle damage marker) and drop in testosterone, which normally observed after exercise, were significantly attenuated in the DOMW trial.

**CONCLUSIONS:** From our findings, it is concluded that deep ocean-based desalted mineral water is able to attenuate the oxidative damage and suppress the inflammation caused by dehydration exercise.

**Beverage Sodium Concentration and Total Ionic Load Increase Post-Exercise Fluid Retention**

Lindsay B. Baker, Adam J. Reimel, Kelly A. Barnes, Ryan P. Nuccio, John R. Stofan. *Gatorade Sports Science Institute, Barrington, IL.*

(L.B. Baker: Salary; PepsiCo.)

Replacement of Na is important for post-exercise rehydration. However, the potential additive effect of other electrolytes, such as K, Cl, Mg, and Ca in promoting rehydration is not well understood.

**PURPOSE:** To compare the impact of beverage [Na] and total ionic load (combined mEq/L from Na, K, Cl, Mg, and Ca) on rehydration in athletes.

**METHODS:** After a 10-h (overnight) fast, 18 men ( $25 \pm 2$  y,  $72 \pm 2$  kg) exercised (70-75%  $HR_{max}$ ) for 90 min in a warm room (27°C, 57% rh) without drinking. After exercise, subjects sat at rest for a 4-h rehydration period. From min 30 to 80 of rehydration, subjects drank 1 of 5 beverages in a volume equivalent to 100% of fluid losses (sweat and urine) incurred during exercise. The 5 beverages were consumed in random order in 5 separate trials and consisted of flavored water with no electrolytes (PLA) or 6% carbohydrate-electrolyte solution with 18 mEq/L Na and 32 mEq/L ionic load (LL), 18 mEq/L Na and 110 mEq/L ionic load (LH), 36 mEq/L Na and 59 mEq/L ionic load (HL), or 36 mEq/L Na and 110 mEq/L ionic load (HH). Subjects voided their bladder and were weighed at min 90, 120, 180, and 240 to determine percent fluid retention throughout the 4-h rehydration period. Data are reported as means  $\pm$  stdev.

**RESULTS:** Subjects lost  $2.3 \pm 0.5\%$  of body mass during exercise and consumed  $1656 \pm 382$  mL of beverage during rehydration (consistent across all trials,  $P > 0.05$ ). In general, fluid retention increased as beverage [Na] and total ionic load increased ( $51.3 \pm 15.8\%$ ,  $57.4 \pm 16.8\%$ ,  $63.2 \pm 15.3\%$ ,  $65.3 \pm 15.8\%$ , and  $69.2 \pm 14.6\%$  for PLA, LL, LH, HL, and HH, respectively). At 3 and 4-h of rehydration, fluid retention was higher with LH, HL, and HH vs. PLA and with HL and HH vs. LL ( $P < 0.05$ ). There were trends for higher fluid retention with LL vs. PLA ( $P = 0.057$ ), LH vs. LL ( $P = 0.074$ ), and HH vs. LH ( $P = 0.077$ ). Fluid retention did not differ between LH and HL ( $P = 0.533$ ) or HL and HH ( $P = 0.203$ ). Total urine volume decreased as beverage [Na] and total ionic load increased ( $813 \pm 359$  mL,  $687 \pm 302$  mL,  $616 \pm 332$  mL,  $571 \pm 275$  mL, and  $515 \pm 297$  mL for PLA, LL, LH, HL, and HH, respectively). Total urine volume was lower with LL, LH, HL, and HH vs. PLA and with HH vs. LL ( $P < 0.05$ ).

**CONCLUSION:** In agreement with previous studies, increasing beverage [Na] increased fluid retention; however, total ionic load also improved fluid retention, especially when beverage [Na] was relatively low.

---

**3015** Board #287 June 1 11:00 AM - 12:30 PM

**Influence Of Deep Ocean-based Desalted Mineral Water On Performance After Dehydration Exercise Regimen**

Chien-Wen Hou<sup>1</sup>, Yi-Ming Yeh<sup>2</sup>, Feng-Chih Hsu<sup>3</sup>, Mallikarjuna Korivi<sup>1</sup>. <sup>1</sup>Taipei Physical Education College, Taipei, Taiwan. <sup>2</sup>Hsin Sheng College of Medical Care and Management, Taoyuan, Taiwan. <sup>3</sup>National Taoyuan Agricultural & Industrial Vocational High School, Taoyuan, Taiwan. (Sponsor: Kuo Chia-Hua, FACSM)

(No relationships reported)

**PURPOSE:** Exercise under high temperature conditions cause dehydration that causes loss lot of minerals, which simultaneously influence the individual performance. The present study was purposed to investigate the impact of deep ocean-based desalted mineral water (DOMW) on athlete's performance after performing the dehydration exercise regimen.

**METHODS:** In this double-blind cross over study, we recruited twelve healthy young men. All the subjects were performed prolonged treadmill running at 40%  $\text{VO}_2\text{max}$  under 30°C leading to 3% body weight loss. Then subjects were orally supplemented with deep ocean-based desalted mineral water (DOMW, N=6) or pure water (placebo, N=6) in the volume equivalent to 1.5 fold of their body weight loss, and consumed in 150-min. One-week after washout crossover trial was performed. Leg explosive power (instantaneous force change measured by force plate), maximal aerobic capacity ( $\text{VO}_2\text{max}$ ) and changes in heart rate variability (HRV) were measured at 4-h and 24-h during post-exercise recovery.

**RESULTS:** We found that exercise challenge caused a significant drop in explosive power at 4-h of recovery. However, DOMW supplementation showed higher recovery rate in explosive power above the placebo trail. Furthermore, only in DOMW trail,  $\text{VO}_2\text{max}$  was significantly improved with concurrent increased heart rate variability (HRV) during recovery.

**CONCLUSIONS:** The result of the present study provides some supportive evidences that deep ocean-based desalted mineral water can accelerate recovery in physical performance after prolonged exercise challenge under high temperature condition.

**3016** Board #288 June 1 11:00 AM - 12:30 PM

**Rehydration and Cognitive Performance after Moderate Endurance Exercise in a Hot and Humid Environment in Women**

Yajun Chen, Stephen H.S. Wong, FACSM, Fenghua Sun. *The Chinese University of Hong Kong, Hong Kong, Hong Kong.*

(No relationships reported)

**PURPOSE:** this study was to observe the effectiveness in rehydrating women and the cognitive performance after a 60 min moderate endurance exercise in a hot and humid environment of three different beverages.

**METHODS:** Ten active eumenorrheic women ( $n = 10$ , mean  $\pm$  S.E.M; 22.6  $\pm$  0.8 years, 56.5  $\pm$  6.1 kg; 37.9  $\pm$  4.6 ml $\cdot$ kg<sup>-1</sup> $\cdot$ min<sup>-1</sup> and 185  $\pm$  3 beats $\cdot$ min<sup>-1</sup>) ran for 60 min on three occasions on a level treadmill at 60%  $\text{VO}_2\text{max}$ . Each trial was performed in a hot and humid environment (29.2  $\pm$  0.9 °C, 71%  $\pm$  5% relative humidity) and was separated by at least seven days. During 4 hr REC, the subjects consumed either a volume of a carbohydrate electrolyte beverage (CE), lemon tea (LT), or distilled water (DW) equal to 150% of the body weight lost during the previous run. The fluid was consumed in 6 equal volumes at 30, 60, 90, 120, 150, and 180 min of REC. A battery of CogState tests in Chinese Version was selected in sequence: four-choice reaction time, visual vigilance, match-to-sample, repeated acquisition, and grammatical reasoning, to provide information on a variety of cognitive parameters on arrival, immediately after exercise, and at the end of 4 hr recovery period.

**RESULTS:** By the end of REC, of the ~1.4% BW fluid losses, 55.6  $\pm$  14.0%, were replaced when the CE was ingested during the 4 hr REC. This is higher compared with 45.6  $\pm$  15.7 % when the LT was drunk ( $p < 0.05$ ), and 40.9  $\pm$  9.3 % when DW was consumed ( $p < 0.05$ ). When compared with DW, the CE drink improved ( $p < 0.05$ ) the speed performance of Detection in the end of 4 hr REC (2.55  $\pm$  0.10 vs. 2.50  $\pm$  0.13 vs. 2.47  $\pm$  0.09). The carbohydrate drink, CE and lemon tea, are both benefiting to the accuracy performance of working memory compared to DW ( $p < 0.05$ ) (CE vs. LT vs. DW: 1.26  $\pm$  0.08 vs. 1.16  $\pm$  0.13 vs. 1.08  $\pm$  0.07).

**CONCLUSION:** During a 4 hr REC following exercise in a hot environment, a CE solution is a more effective rehydration beverage than other drinks typically consumed in Hong Kong, such as LT and DW. In addition, when compared to DW, the carbohydrate drink, especially the CE, also have the potential benefits for the Working memory, Detection, and Learning in a short-term REC following a moderate exercise in hot environment.

**3017** Board #289 June 1 11:00 AM - 12:30 PM

**Mild Dehydration Impairs Exercise and Cognitive Performance During a Cycle-Based Simulated Ice Hockey Game**

Matthew S. Palmer, Rachel L. Driscoll. *University of Guelph, Guelph, ON, Canada.* (Sponsor: Lawrence L Spriet, FACSM)

(No relationships reported)

Dehydrating by ~2% body mass (BM) during moderate intensity exercise and stop and go sports has been shown to decrease physical performance, brain blood flow and cognitive function. On average, ice hockey players lose 1.3% BM during a game with 1 in 3 players losing between 1.8 - 4.3% BM, but few studies have examined the effects of mild dehydration on hockey performance.

**PURPOSE:** To determine if mild dehydration in hockey players ( $n = 9$ , 1.80  $\pm$  0.01 m, 77.0  $\pm$  2.9 kg, 21  $\pm$  0 years, 56.8  $\pm$  1.9 mL $\cdot$ kg<sup>-1</sup> $\cdot$ min<sup>-1</sup>) affects exercise performance, perceived exertion (RPE), cognitive performance (modified Stroop test), and reaction time in period 3 (P3) of a cycle-based protocol to simulate an ice hockey game, as compared to staying hydrated with a carbohydrate-electrolyte solution (CES).

**METHODS:** Subjects performed a cycle-based intermittent sprint protocol that was designed to simulate an ice hockey game on two occasions and either restricted their fluid intake prior to exercise and did not ingest fluid (DEH), or drank 500 mL of water 1-2 hours prior to exercise and fully replaced sweat losses with a CES (HYD).

**RESULTS:** Subjects lost a total of 1.7  $\pm$  0.2% BM following P2 and 2.5  $\pm$  0.2% BM after P3. RPE was higher in P3 for the DEH group (18.1  $\pm$  0.4 vs. 17.2  $\pm$  0.7,  $p < 0.05$ ). Performance of a modified Stroop test following the protocol was lower in DEH (Score; 147  $\pm$  54 vs. 216  $\pm$  74,  $p < 0.05$ ). Reaction time assessed after the protocol however, was improved in DEH (212  $\pm$  9 vs. 262  $\pm$  32 ms,  $p < 0.05$ ). Sprint performance decreased over time in both groups but was lower in P3 in DEH (179.7  $\pm$  7.7 vs. 186.0  $\pm$  8.0 kJ,  $p < 0.05$ ). Mean  $T_c$  was not different between groups, but  $\Delta T_c$  increased sharply in P1 in DEH (1.0  $\pm$  0.1 vs. 0.6  $\pm$  0.0  $\Delta^\circ\text{C}$ ,  $p < 0.05$ ). Mean sprint HR was higher in P1 (174  $\pm$  3 vs. 171  $\pm$  3 bpm,  $p < 0.05$ ) and P2 (178  $\pm$  2 vs. 176  $\pm$  2 bpm,  $p < 0.05$ ) in DEH, but similar in P3 (176  $\pm$  2 vs 174  $\pm$  3 bpm).

**CONCLUSIONS:** Mild dehydration had a negative impact on perceived exertion and exercise performance in period 3 of a cycle-based simulated hockey game. Performance of a modified Stroop test was also impaired after the game. Hockey players benefited from improved cognitive and physical performance later in a simulated hockey game, by ingesting a CES to minimize body mass losses. Supported by GSSI and NSERC Canada.

**3018** Board #290 June 1 11:00 AM - 12:30 PM

**Effects of Hyperthermia and Dehydration on Physiological and Perceptual Measurements During Exercise in Two Environments**

Julie K. DeMartini, Douglas J. Casa, FACSM, Robert A. Huggins, Megan VanSumeren, Rachel Karslo, Rebecca L. Stearns, Lindsay J. DiStefano, Lawrence E. Armstrong, FACSM, Carl M. Maresh, FACSM. *University of Connecticut, Storrs, CT.*

(No relationships reported)

Limited research has evaluated combined effects of hyperthermia and dehydration on body temperature, heart rate, and perception during exercise while carrying a military rucksack.

**PURPOSE:** Evaluate separate and combined effects of hyperthermia and dehydration (%BML) on rectal temperature ( $T_{re}$ ), heart rate (HR), and rating of perceived exertion (RPE) during exercise while carrying a 20.5 kg load.

**METHODS:** Twelve males (age = 20  $\pm$  2 y, height = 182  $\pm$  8 cm, body mass = 74.0  $\pm$  8.2 kg, body fat = 9  $\pm$  3%,  $\text{VO}_2\text{max}$  = 57.0  $\pm$  6.0 mL $\cdot$ kg<sup>-1</sup> $\cdot$ min<sup>-1</sup>) completed four randomized, 90-min treadmill bouts (1.34-1.78m $\cdot$ s<sup>-1</sup>; 5% grade) in a climate controlled chamber under two hydration states and two environmental conditions: euhydrated temperate (EUT), dehydrated temperate (DYT), euhydrated hot (EUH), and dehydrated hot (DYH). Temperate and hot conditions were performed in 18  $\pm$  0.2°C, 50  $\pm$  3.5% RH, and 34  $\pm$  0.3°C, 45  $\pm$  4.5% RH, respectively. Dependent variables were recorded prior to (PRE), at 45-minutes (MID), and post (POST) exercise. Data were analyzed via two-way (condition X time) repeated measures ANOVA and Tukey post-hoc tests.

**RESULTS:** %BML was greater in DYT and DYH than EUT and EUH (-3.80  $\pm$  1.22% and -5.66  $\pm$  1.57% vs. 0.10  $\pm$  0.90% and -1.30  $\pm$  0.85%, respectively;  $p < .001$ ). A significant interaction occurred for  $T_{re}$  ( $p < .001$ ), HR ( $p = .007$ ), and RPE ( $p = .001$ ). At MID, DYH  $T_{re}$  exceeded EUT and EUH (38.7  $\pm$  0.29°C vs. 37.86  $\pm$  0.25°C, 37.96  $\pm$  0.51°C, respectively), while at POST, DYH  $T_{re}$  exceeded EUT, HYT, and EUH (39.32  $\pm$  0.43°C vs. 37.86  $\pm$  0.33°C, 38.22  $\pm$  0.29°C, 38.25  $\pm$  0.63°C, respectively). At MID, DYH HR exceeded EUT and DYT (156  $\pm$  17 bpm vs. 135  $\pm$  15 bpm and 138  $\pm$  13 bpm) and remained higher POST (175  $\pm$  12 bpm vs. 132  $\pm$  12 bpm, 145  $\pm$  10 bpm, respectively). In addition, HR POST in EUH exceeded EUT (156  $\pm$  17 bpm vs. 132  $\pm$  12 bpm, respectively). At MID, DYH RPE exceeded EUT (16  $\pm$  2 vs. 13  $\pm$  1, respectively). At POST, DYH RPE exceeded EUT and DYT (18  $\pm$  1 vs. 14  $\pm$  2, 14  $\pm$  2, respectively).

**CONCLUSIONS:** Combined effects of hyperthermia and dehydration had additive, detrimental effects on  $T_{re}$ , HR, and RPE compared to individual effects. Most notably, DYH resulted in a 1.1°C (2°F) increase in  $T_{re}$  compared to EUH and DYT. This suggests a greater risk for exertional heat stroke when individuals are both dehydrated and hyperthermic while carrying a load, as is the case with military personnel.

---

3019 Board #291 June 1 11:00 AM - 12:30 PM

**Influence of Dehydration on Internal Body Temperature Changes During Exercise In The Heat: A Meta-Analysis**

Robert A. Huggins, Jessica L. Martschinske, Kristin Applegate, Lawrence E. Armstrong, FACSM, Douglas J. Casa, FACSM. *University of Connecticut, Storrs, CT.*  
(No relationships reported)

Dehydration (DHY) increases the rise of internal body temperature (T) compared to a euhydrated state during exercise in the heat. Numerous original research studies have quantified the effect of DHY on T; however a wide range has been reported (0.01-0.43°C·1%BML<sup>-1</sup>) difference.

**PURPOSE:** To systematically review the current literature to determine  $\Delta T$  per 1% body mass loss (%BML) difference.

**METHODS:** PubMed, SPORTDiscus, Web of Science, Rehabilitation & Physical Medicine, CINAHL and Cochrane Reviews were searched from inception to March 2011 with limitations on human subjects and English. Key words included: *dehydration, dehydrated, hypohydration, hypohydrated, hyperthermia, hyperthermic, core temperature, and core body temperature.* Original research articles which met these criteria were included: 1) reported mean and SD of valid T and %BML difference 2) hyperthermia  $\geq 38.9^\circ\text{C}$  in one trial condition, 3) exercise mode was similar between conditions other than hydration status. Of the 1192 articles retrieved, 281 examined the effects of DHY on T during exercise. Twenty original research studies met the inclusion criteria and were scored using the Physiotherapy Evidence Database (PEDro) Scale (7.0  $\pm$  0.6). Means and SD for trial conditions were compiled for final  $^\circ\text{C}$  and %BML difference. Meta-analysis was performed to determine pooled and weighted mean differences (MD) between the greater and lesser DHY trials for  $^\circ\text{C}$  and %BML difference.

**RESULTS:** Final weighted MD for  $^\circ\text{C}$  were (0.54 $^\circ\text{C}$ , 95% CI 0.51 to 0.54) and %BML difference (2.45%, 95% CI 2.42 to 2.48). For every 1% BML difference, T increased 0.22 $^\circ\text{C}$  during exercise in the heat.

**CONCLUSION:** This meta-analysis precisely defines the rise in T for exercising individuals per 1% BML difference. Clinically, this information confirms that the rise in T is increased with greater body mass loss. Furthermore, sports medicine personnel and researchers can better determine the rise of T in an individual exercising in the heat based on their %BML difference and prevent heat illness.

3020 Board #292 June 1 11:00 AM - 12:30 PM

**Validation of the OMNI Perceived Sweating Scale during Treadmill Walking while Wearing Thermal Protective Clothing**

Fredric L. Goss, FACSM, Robert J. Robertson, FACSM, Michael Gallagher, Jr., Luke Haile, Julia Morley, Joe Suyama, David Hostler. *Univ. of Pittsburgh, Pittsburgh, PA.*  
(No relationships reported)

**PURPOSE:** Concurrent and construct validation of the OMNI Sweating Scale was examined using adult male (n=16) and female (n=5) subjects. This category scale contains verbal and pictorial descriptors positioned along a narrow (1-10) numerical range.

**METHODS:** Subjects were 27.9  $\pm$  4.6 years old, weighed 73.5  $\pm$  15.5 kg, were 174.5  $\pm$  9.4 cm tall and had a maximal oxygen uptake of 50.3  $\pm$  8.3 ml·kg<sup>-1</sup>·min<sup>-1</sup>. Subjects ingested a thermistor capsule for the measurement of core temperature approximately 8 hrs before the experimental trial. Weighted mean skin temperature was calculated using the following formula: Tsk = chest (0.25) + back (0.25) + thigh (0.30) + arm (0.20). Concurrent validity was established by correlating OMNI sweating scale ratings (OMNI-SW) with core (Tc) and weighted mean skin (Tsk) temperatures obtained during treadmill walking while wearing firefighter thermal protective clothing. Construct validity was established by correlating OMNI-SW with a construct specific 10 cm visual analogue scale (VAS).

**RESULTS:** Tc ranged from 37.1  $\pm$  0.1 $^\circ\text{C}$  to 38.9  $\pm$  0.1 $^\circ\text{C}$  and Tsk ranged from 33.8  $\pm$  0.1 $^\circ\text{C}$  to 38.7  $\pm$  0.1 $^\circ\text{C}$ . OMNI-SW ranged from 1-10 and distributed as a positive linear function of Tc (r = 0.75, p < 0.01) and Tsk (r = 0.81, p < 0.01). OMNI-SW distributed as a positive linear function of the VAS responses which ranged from 0-10 cm (r = 0.97, p < 0.01).

**CONCLUSIONS:** Concurrent and construct validity were established for the OMNI Sweating Scale in healthy adults performing treadmill walking while wearing firefighter thermal protective clothing.

---

3021 Board #293 June 1 11:00 AM - 12:30 PM

**Effect Of The Vasopressin2 Receptor On Sweat Composition, Fluid Balance And Performance**

Tamara D. Hew-Butler, FACSM<sup>1</sup>, Jed Hummel<sup>1</sup>, Brian Rider<sup>1</sup>, Elizabeth Jones<sup>1</sup>, Jeff Cross<sup>1</sup>, Qin Xu<sup>2</sup>, Nikhil Sharma<sup>2</sup>, Joseph G. Verbalis<sup>2</sup>. <sup>1</sup>*Oakland University, Rochester, MI.* <sup>2</sup>*Georgetown University Medical Center, Washington DC, DC.*  
(No relationships reported)

Previous data revealed statistically significant linear relationships between sweat, urine and blood sodium concentration ([Na<sup>+</sup>]) as well as arginine vasopressin ([AVP]) during steady-state running.

**PURPOSE:** To determine if sweat sodium concentration is regulated by [AVP] through activation of the Vasopressin2 (V2) receptor.

**METHODS:** 10 subjects participated in 3 double-blind randomized trials ingesting a: placebo, V2 agonist or V2 antagonist. Each treadmill trial consisted of 60 minutes running at 60% peak speed (Steady-State) followed by an incremental test to exhaustion (Performance). Blood, urine and saliva samples were collected at baseline and following both Steady-State and Performance segments. Sweat samples were obtained after the Steady-State and Performance segments from side-by-side shoulder patches, followed by a whole body washdown. Water was allowed ad libitum.

**RESULTS:** Significant decreases (p<0.05) in urine [Na<sup>+</sup>] noted with the V2 antagonist (18; 16; 31mmol/L) versus the placebo (106; 82; 57mmol/L) and V2 agonist (132; 89; 65mmol/L) (Baseline mean; after Steady-State mean; after Performance trial mean, respectively). Significant increases (p<0.05) in plasma [Na<sup>+</sup>] noted from baseline vs. after Performance in the: placebo (143 vs. 145mmol/L), V2 agonist (143 vs. 146mmol/L) and V2 antagonist (143 vs. 148mmol/L) trials and between the placebo vs. V2 antagonist after Performance. Similar increases in endogenous [AVP] from baseline to performance noted with the V2 agonist (0.4 vs. 2pg/mL) and V2 antagonist (0.2 vs. 4pg/mL) trials and between placebo vs. V2 antagonist after Performance. Significant increases (p<0.05) in saliva [Na<sup>+</sup>] noted from baseline vs. after Performance in the: V2 agonist (18 vs. 33mmol/L) and V2 antagonist (18 vs. 42mmol/L) trials. No significant difference in sweat [Na<sup>+</sup>] seen between the placebo (80; 14mmol/L), V2 agonist (77; 13mmol/L) or V2 antagonist (82; 12mmol/L)(after Performance sweat patch; whole body washdown) trials. No significant difference in performance between the placebo (586sec), V2agonist (612sec) and V2 antagonist (617sec) trials.

**CONCLUSION:** Sweat [Na<sup>+</sup>] is not regulated by the V2 receptor. Increased plasma [Na<sup>+</sup>] and [AVP] with the V2 antagonist had no detrimental effect on performance, with a trend towards augmented performance.

3022 Board #294 June 1 11:00 AM - 12:30 PM

**Determinants of Sweat Na<sup>+</sup> Concentration in Elite Athletes Training in a Hot and Humid Environment**

Raúl A. Rosario, Jessica A. Frontanés, Farah A. Ramírez-Marrero, FACSM, Osvaldo Hernández, Walter R. Frontera, FACSM, Anita M. Rivera-Brown, FACSM. *Center for Sports Health and Exercise Sciences, University of Puerto Rico School of Medicine, San Juan, Puerto Rico.*  
(No relationships reported)

Reductions in serum sodium concentration and exercise-associated skeletal muscle cramps have been related to high sodium losses during exercise in the heat.

**PURPOSE:** To determine factors associated with sweat sodium concentration in elite heat acclimatized athletes training in a hot and humid environment.

**METHODS:** Elite athletes (N=109; males=73 females=36; mean age= 25.2  $\pm$  4.9 yr) were tested during training sessions (mean duration=82.9  $\pm$  22.5 min) in running, cycling, beach volleyball, soccer, tennis, and fencing in a hot and humid climate (WBGT=30.1  $\pm$  1.8 $^\circ\text{C}$ ). Exercise intensity was estimated using an accelerometer worn by the athletes during the entire session. Acute changes in body mass were used to estimate sweat rate. A sweat sample was collected with an absorbent patch to measure sweat [Na<sup>+</sup>]. Saliva samples were obtained for genetic analysis in athletes with high sweat [Na<sup>+</sup>].

**RESULTS:** The average training time in a hot and humid climate in the past month (3,056.7  $\pm$  2,477.5 min) indicated that the athletes were heat acclimatized. The mean sweat [Na<sup>+</sup>] was 67.5  $\pm$  22.2 mmol/L. Gender, environmental heat stress, and training time in the heat in the past month were not significantly correlated with sweat [Na<sup>+</sup>]. Stepwise multiple regression revealed that

sweat rate ( $1.3 \pm 0.5$  L/h) and exercise intensity ( $3,976.7 \pm 2,466.5$  activity counts/min) accounted for approximately 16% of the sweat  $[Na^+]$  ( $R^2=0.16$ ,  $P<0.001$ ). Sweat  $[Na^+]$  and total sweat  $Na^+$  loss was similar in athletes with a history of muscle cramps ( $68.5 \pm 23.1$  mmol/L and  $2,191.5 \pm 1,131.8$  mg) compared to those reporting no cramping ( $66.9 \pm 22.2$  mmol/L and  $2,176.4 \pm 1,255.3$  mg),  $P > 0.05$ . Twenty nine athletes with a sweat  $[Na^+] > 70$  mmol/L and sweat  $[Cl^-] > 60$  mmol/L provided saliva samples for genetic analysis. One athlete was identified as having heterozygous presence of the  $\Delta F508$  mutation in the CFTR gene and had a history of whole body muscle cramps.

**CONCLUSIONS:** In heat acclimatized elite athletes training in a hot and humid environment, sweat sodium concentration is related to exercise intensity and sweat rate but not to gender, environmental heat stress, or heat exposure time in the previous month.

**3023** Board #295 June 1 11:00 AM - 12:30 PM

### Preventing Mild Dehydration with a Carbohydrate Electrolyte Solution Improves Performance during an Ice Hockey Scrimmage

Mark E. Linseman, Matthew S. Palmer, Heather M. Logan-Sprenger, Lawrence L. Spriet, FACSM. *University of Guelph, Guelph, ON, Canada.*

(M.E. Linseman: Salary; GSSI paid my graduate student stipend, but did not have a say in how the study was conducted.)

Mild dehydration (1.5-2%) is associated with increased core temperature (Tc), heart rate (HR) and mental fatigue (MF), and decreased performance during "stop-and-go" sports such as basketball and soccer. Similar studies in ice hockey players are scarce, and many ice hockey players lose more than 1.5% body mass (BM) through sweating during games.

**PURPOSE:** To investigate the effects of remaining hydrated with a carbohydrate electrolyte solution (CES) vs. dehydrating by 1.5-2% BM on Tc, HR, on-ice performance, and MF during ice hockey.

**METHODS:** High-level male hockey players ( $n = 14$ ,  $21.3 \pm 0.2$  yrs,  $80.1 \pm 2.5$  kg,  $182 \pm 1.2$  cm) participated in a randomized crossover study. Players performed a set of three on-ice performance drills before and after a 70-min on-ice hockey scrimmage. Players ingested no fluid to progressively dehydrate by 1.5-2% BM (NF), or ingested CES to maintain BM (CES).

**RESULTS:** Peak Tc was lower in CES than in NF ( $38.69 \pm 0.10$  vs.  $38.92 \pm 0.11$  °C,  $p < 0.05$ ). Tc peaked at ~49 min in CES and ~44 min in NF, and was lower throughout the scrimmage in CES. In-game HR was not different between trials. In the last 20 min of play, CES players committed fewer turnovers/min with the puck ( $1.6 \pm 0.3$  vs.  $3.1 \pm 0.7$ ,  $p < 0.05$ ) and completed a higher percentage of attempted passes ( $78 \pm 5$  vs.  $51 \pm 8\%$ ,  $p < 0.05$ ). From 30-50 min, CES players had higher mean skating speed ( $3.57 \pm 0.10$  vs.  $3.45 \pm 0.12$  m/s,  $p < 0.05$ ) and time at high effort ( $179 \pm 11$  vs.  $159 \pm 11$  s,  $p < 0.05$ ). Mean post-scrimmage sprint skating drill time was faster in CES ( $26.33 \pm 0.26$  vs.  $26.81 \pm 0.32$  s,  $p < 0.05$ ). There were no between-trial differences in shooting or slalom drill performance. MF, assessed by two post-trial questionnaires, was lower in CES. Hockey Fatigue Questionnaire total score ( $29.5 \pm 2.8$  vs.  $37.1 \pm 1.6$ ,  $p < 0.05$ ) and Profile of Mood States fatigue subsection score ( $15.1 \pm 1.3$  vs.  $19.4 \pm 1.0$ ,  $p < 0.05$ ) were lower in CES. Since responses to mild dehydration were highly variable, individual data were also analyzed. Players demonstrating improved skating performance in CES tended to have lower Tc and MF in CES, and a BM that was higher than the mean.

**CONCLUSION:** Maintaining BM with a CES resulted in decreased Tc, improved skating and puck handling performance, and decreased mental fatigue, compared to dehydrating by 1.5-2% BM during an on-ice hockey scrimmage. Supported by GSSI and NSERC Canada.

**3024** Board #296 June 1 11:00 AM - 12:30 PM

### Effective Microorganism-x Attenuates The Hit-induced Increases In Plasma Superoxide Dismutase Within A Hot Humid Environment

Lee Taylor<sup>1</sup>, Ben J. Lee<sup>2</sup>, Adrian W. Midgley<sup>3</sup>, Peter Watt<sup>4</sup>, Lars R. McNaughton, FACSM<sup>5</sup>, Paul C. Castle<sup>1</sup>. <sup>1</sup>The University of Bedfordshire, Bedford - Bedfordshire, United Kingdom. <sup>2</sup>Coventry University, Coventry, United Kingdom. <sup>3</sup>University of Hull, Hull, United Kingdom. <sup>4</sup>University of Brighton, Eastbourne, United Kingdom. <sup>5</sup>Edgehill University, Ormskirk, United Kingdom. (Sponsor: Lars McNaughton, FACSM)

(No relationships reported)

Extracellular HSP72 (eHSP72) increases in response to aerobic and resistance exercise stress, no such data is available with regard to the impact of high-intensity interval training (HIT) within hot or temperate environments. *In vitro*, effective microorganism-x (EMX) can attenuate certain pro-inflammatory and redox balance responses. Supplementation of EMX may play a role in mediating any HIT induced alterations in redox balance and eHSP72 expression.

**PURPOSE:** Elucidation of the eHSP72 response and redox balance disturbances of HIT within temperate and hot conditions and the impact of EMX supplementation on such responses.

**METHODS:** Six recreationally active male subjects reported to the laboratory on 6 occasions. **Visit 1:**  $VO_{2max}$ . **2:** Maximal Anaerobic Running Test (MART). **3-6:** Four high intensity interval running protocols ( $HIT_{RPT}$ : ~40 minutes duration,  $20 \times 10$  secs fast high intensity runs at peak MART velocity, interspersed with 80 sec of active recovery at 35%  $VO_{2max}$ ). Two visits were completed in temperate conditions ( $HIT_{RPT}$ ) ( $20.4 \pm 1.7$  °C;  $41 \pm 4.2\%$  RH), and 2 in hot and humid conditions ( $HIT_{RPH}$ ) ( $34.7 \pm 2.0$  °C;  $51.7 \pm 4.5\%$  RH), with EMX supplementation ( $HIT_{RPT/EMX}$  or  $HIT_{RPH/EMX}$ ) or without (placebo) ( $HIT_{RPT/PLA}$  or  $HIT_{RPH/PLA}$ ). Typical physiological measures were recorded throughout with blood lactate and glucose assessed quarterly. Venous whole blood samples were obtained at rest pre and immediately post completion of  $HIT_{RPT}$  for assessment of plasma eHSP72 and superoxide dismutase (SOD) using commercially available ELISAs.

**RESULTS:** Plasma eHSP72 increased significantly pre- to post  $HIT_{RPT}$  ( $F = 62.1$ ,  $p < 0.001$ ), with eHSP72 in  $HIT_{RPT}$  increased by  $0.8$  ng·mL<sup>-1</sup> (95% CI =  $0.3$  to  $1.2$  ng·mL<sup>-1</sup>,  $p = 0.005$ ), compared to  $1.5$  ng·mL<sup>-1</sup> in  $HIT_{RPH}$  (95% CI =  $1.1$  to  $1.9$  ng·mL<sup>-1</sup>,  $p < 0.001$ ). Plasma SOD activity significantly increased pre- to post  $HIT_{RPT}$  ( $F = 70.1$ ,  $p < 0.001$ ), with SOD in  $HIT_{RPT}$  significantly increasing  $0.10$  U·mL<sup>-1</sup> (95% CI =  $0.047$  to  $0.16$  units,  $p = 0.001$ ), compared to a  $0.22$  U·mL<sup>-1</sup> increase in the  $HIT_{RPH}$  (95% CI =  $0.16$  to  $0.28$  U·mL<sup>-1</sup>,  $p < 0.001$ ). SOD activity was  $0.10$  U·mL<sup>-1</sup> significantly higher in  $HIT_{RPH/PLA}$  compared to the  $HIT_{RPH/EMX}$  (95% CI =  $0.045$  to  $0.16$  U·mL<sup>-1</sup>,  $p = 0.001$ ).

**CONCLUSION:** EMX supplementation may convey some protection to the HIT induced disturbances to redox balance within a hot and humid environment.

**3025** Board #297 June 1 11:00 AM - 12:30 PM

### The Effect Of Selected Foods On Urinary pH

Jo M. Welch, Jason C. Davis. *Dalhousie University, Halifax, NS, Canada.*

(No relationships reported)

Sodium bicarbonate consumed before a competition can delay metabolic acidosis by raising the pH level in the body but this intake can be unpleasant and cause indigestion.

**PURPOSE:** To test the hypothesis that certain foods consumed in one snack can alter urinary pH similarly to sodium bicarbonate.

**METHODS:** Nine healthy subjects (5 men), aged 19-26, were assigned to one of three treatment groups and proceeded to subsequent treatments based a Latin square design. Each treatment consisted of a small meal which was anticipated to elicit an acidic, basic, or neutral response. Subjects consumed the same standardized diets during each day prior to the mid-afternoon experimental snacks. Urine samples were analyzed for pH and hydration before and also 2 hours after consumption of each snack. Subjects completed all three diets with a minimum of one washout day between treatments. The difference between pre-meal and post-meal urine pH was analyzed using repeated measures ANOVA.

**RESULTS:** Urine pH decreased by an average of 0.281 after an acidic snack while changes in urine pH for neutral and basic snacks dropped by 0.006 and 0.034 respectively. Pairwise comparisons showed a trend towards significance between the acidic and neutral snacks ( $p=0.07$ ) and between the acidic and basic snacks ( $p=0.06$ ) but no difference between the neutral and basic snacks. Urinary pH was not correlated with hydration status.

**CONCLUSION:** Both the basic and neutral snacks resulted in a higher urinary pH than did the acidic snack. Attention to pre-competition diet could play a role in delaying metabolic acidosis in athletes in some sports.

### Time To Plasma Sodium Accumulation Of Three Different Beverages Of Varying Sodium Concentration At Rest

Rachel Sharpe<sup>1</sup>, Dawn M. Minton<sup>1</sup>, Toni M. Torres-McGehee<sup>1</sup>, Thomas P. Dompier<sup>2</sup>, J Mark Davis, FACSM<sup>1</sup>. <sup>1</sup>University of South Carolina, Columbia, SC.

<sup>2</sup>DatalysCenter, Indianapolis, IN.

(No relationships reported)

The National Athletic Trainers' Association recommends adding 0.3 - 0.7 g/L sodium ( $Na^+$ ) to fluids ingested 2 - 3 hrs prior to exercise to prevent negative effects of  $Na^+$  depletion. Optimum time of ingestion before exercise and amount of  $Na^+$  needed to raise plasma sodium concentration ( $[P_{Na^+}]$ ) in  $Na^+$  depleted individuals has yet to be determined.

**PURPOSE:** To examine changes in  $[P_{Na+}]$  and urine  $[Na^+]$  ( $[U_{Na+}]$ ) in euhydrated and  $Na^+$  depleted individuals ( $[P_{Na+}] < 137.5$  mmol/L) over a period of 3 hrs of rest following ingestion of 3 different beverages of varying  $[Na^+]$ .

**METHODS:** A randomized crossover design examined the effects of water (W), carbohydrate electrolyte beverage (CEB), and enhanced CEB (E-CEB) on  $[P_{Na+}]$  and  $[U_{Na+}]$ . Participants were given 500 mL of assigned beverage and electrolyte measures were taken over 3 hrs of rest. CEB was commercially available and the E-CEB was a packet, added to the CEB, containing additional electrolytes.  $[P_{Na+}]$  and  $[U_{Na+}]$  were analyzed using ion selective electrodes ( $Na^+/K^+$  Easylyte, Medica Corporation, Bedford, MA).

**RESULTS:** Participants were 9 (3 male and 6 female; mean age = 22.1 yr, weight = 66.5 kg, height = 67.2 cm) moderately active individuals from the surrounding area. Mean  $[Na^+]$  for W = 0 g/L, CEB = 5.1 g/L, and E-CEB = 12.5 g/L. Repeated measures ANOVA was used to calculate  $[P_{Na+}]$  and  $[U_{Na+}]$  changes over 3 hours (180 min). We found a significant increase in overall  $[P_{Na+}]$  from 0 to 150 min (134.9 mmol/L to 136.4 mmol/L,  $p = 0.045$ ) and 0 to 180 min (134.9 mmol/L to 137.1 mmol/L,  $p = 0.003$ ). There was a significant increase in overall  $[U_{Na+}]$  from 0 to 180 min (6.5 mmol/L to 14.2 mmol/L,  $p = 0.002$ ). No significant difference were found between the 3 beverage groups for  $[P_{Na+}]$  and  $[U_{Na+}]$  across time. Although not statistically significant, only the E-CEB increased  $[P_{Na+}]$  above our cutoff for  $Na^+$  depletion (mean  $[P_{Na+}]$  at 180 min = 137.7 mmol/L).

**CONCLUSION:** While participants' overall  $[P_{Na+}]$  increased over time, the CEB and E-CEB were not significantly different from W. The CEB or E-CEB did not significantly increase  $[P_{Na+}]$  in our  $Na^+$  depleted participants during rest. While hydration protocols should be individualized, the time and amount of  $Na^+$  suggested by the recommendations should be further examined and adjusted accordingly to ensure individuals are sodium balanced prior to physical activity.

**Urinary Parameters Are Relevant Hydration Markers In Real Life Conditions**

Alexis Klein<sup>1</sup>, Romain Barnouin<sup>2</sup>, Sebastien Vergne<sup>1</sup>, Deborah Metzger<sup>2</sup>, Nicolas Girard<sup>2</sup>, Agnes Demazieres<sup>2</sup>, Isabelle Guelinckx<sup>1</sup>, Nathalie Pross<sup>2</sup>, Erica Perrier<sup>1</sup>.  
<sup>1</sup>Danone Research, Palaiseau, France. <sup>2</sup>Forenap, Rouffach, France.

(No relationships reported)

**PURPOSE:** Despite its importance for health, knowledge on what optimal hydration status is and how it could be evaluated is conflicting. Previous works indicate that 24h urine parameters can differentiate fluid intake habits, and that they may be valid hydration markers under real life conditions. However to confirm this, assessment of their adjustment to mild changes in fluid intakes is needed.

The purpose of this study was: first to determine if urinary parameters of hydration change rapidly in response to modifications of fluid intake; and second to assess whether shorter urine collection periods are adequate to accurately reflect hydration status.

**METHODS:** Forty-eight participants (age:  $24.7 \pm 3.1$  yrs; BMI:  $22.4 \pm 1.6$  kg/m<sup>2</sup>) were classified as Low (n=29) or High drinkers (n=19), and completed a 6-day inpatient parallel group trial. During the first 2 days (baseline), participants followed a fluid regimen quantitatively comparable to their self-reported intake habits (1.0L/d for Low drinkers and 2.5 L/d for High drinkers). In the second 3 day phase, fluid intakes between groups were reversed. Urine was collected in three to five-hour intervals during waking hours.

**RESULTS:** Statistical comparisons showed that the 24h urinary osmolality (Uosm), Specific Gravity (USG), and color were significantly higher in the Low as compared to High drinker group at baseline ( $841 \pm 180$  vs.  $332 \pm 52$  mOsm/kg;  $1.022 \pm 0.004$  vs.  $1.010 \pm 0.002$ ;  $5.4 \pm 1.0$  vs.  $2.6 \pm 0.6$ ; respectively;  $p < .001$ ). This was also the case for shorter collections. Moreover, these parameters were significantly altered by fluid intake modification in both groups ( $p < .001$ ), with the alterations being statistically significant on the first day of the intervention. No differences were observed for blood osmolality (Bosm) whatever the group or the period.

**CONCLUSIONS:** The study confirms that parameters such as 24h urinary volume, color, Uosm, USG, but not Bosm accurately detect mild changes in hydration status. Moreover, findings support use of shorter urine collection periods to this aim. Urinary parameters appear as most sensitive markers to differentiate low and high drinkers, and to detect changes in hydration status caused by modifications of fluid intake mimicking the ones that can be encountered in real life conditions.

This study has been granted by Danone Research

**Effect of Skin Surface Contamination on Sweat Mineral Concentration During Heat Acclimation.**

Matthew R. Ely<sup>1</sup>, Robert W. Kenefick, FACSM<sup>1</sup>, Samuel N. Cheuvront, FACSM<sup>1</sup>, Troy D. Chilver<sup>1</sup>, Craig P. Lacher<sup>2</sup>, Henry C. Lukaski, FACSM<sup>2</sup>, Scott J. Montain, FACSM<sup>1</sup>. <sup>1</sup>USARIEM, Natick, MA. <sup>2</sup>USDA, Grand Forks, ND.

(No relationships reported)

Heat acclimation reportedly conveys conservation in sweat mineral concentrations. It was recently reported that removing surface contamination through comprehensive cleaning of the skin surface negated sweat micro-mineral reductions during prolonged sweating. It is unknown if the sweat mineral conservation reported with heat acclimation may also be an artifact of surface contamination.

**PURPOSE:** To measure sweat mineral concentrations during heat acclimation and determine if surface contamination plays a role in the reported decrements of sweat minerals.

**METHODS:** Sweat mineral concentrations were measured in ten male volunteers from arm bag and scapular pouches on day 1, 5, and 10 of a heat acclimation protocol. To assess the potential contribution of skin contamination the initial mineral residue of the skin on the arm/hand was assessed with a 10-ml distilled water rinse. The arm was then meticulously cleaned to minimize surface contamination and sweat samples were obtained 20-25 minutes after the initiation of exercise using an arm bag. Additionally, sweat was simultaneously and serially sampled (two times each day) from a cleaned (WASH) and un-clean (No-WASH) site on the scapular surface via pouch technique. All rinse and exercise sweat samples were analyzed by spectrometry for Ca, Cu, Fe, Mg, and Zn.

**RESULTS:** No heat acclimation effect on sweat micro-minerals was observed. Sweat mineral concentrations from the WASH site were relatively low and did not change between Day 1, 5, or 10 or within each day of heat acclimation (Ca:  $0.29 \pm 0.14$  mmol/L, Cu:  $0.58 \pm 0.81$   $\mu$ mol/L, Fe:  $0.12 \pm 0.22$   $\mu$ mol/L, Mg:  $0.04 \pm 0.04$  mmol/L, Zn:  $1.45 \pm 1.33$   $\mu$ mol/L). The initial mineral concentration from the No-WASH site did not change from Day 1, 5 or 10 but were significantly greater than concentrations from WASH and declined 45-57% from initial to subsequent samples within each day becoming similar to the WASH site. The arm/hand surface rinse micro-mineral concentrations were higher than the sweat samples from the cleaned skin.

**CONCLUSION:** When the skin surface is not cleaned mineral residue inflates initial sweat mineral concentrations. Heat acclimation does not confer a reduction in sweat Ca, Cu, Fe, Mg, or Zn concentrations.

**3029** Board #301 June 1 9:30 AM - 11:00 AM

**Absenteeism In A Metropolitan Law Enforcement Agency Weight Loss Competition**

Allen R. Mullins<sup>1</sup>, Robert W. Boyce, FACSM<sup>1</sup>, Tyler K. Willett<sup>1</sup>, Glenn R. Jones<sup>2</sup>, Edward L. Boone<sup>3</sup>. <sup>1</sup>University of North Carolina Wilmington, Wilmington, NC 28403, NC. <sup>2</sup>Work Physiology Associates Inc, Charlotte, NC. <sup>3</sup>Virginia Commonwealth University, Richmond, VA 23284, NC. (Sponsor: Robert W Boyce, FACSM)

(No relationships reported)

Evaluation of absentee patterns provides valuable insight into effective health promotion programs. Little has been published regarding absenteeism in weight loss competitions in law enforcement agencies.

**PURPOSE:** To report absenteeism outcomes of a police weight loss competition and compare participants who completed the program with irregular attendees.

**METHODS:** A police department held a twelve week weight loss competition involving five person teams composed of civilians and sworn officers. Weigh-ins were held at beginning and bi-weekly. Teams recording most weight loss won. ANOVA procedures were used to compare starting body mass of those who completed all weigh-ins (Reg) with three irregularly attending groups: Those missing the final weigh-in (Irreg1), those missing two or more weigh-ins (Irreg2), and those weighing-in at week 2 & missing all other weigh-ins (Irreg3). The proportion of those absent, expressed as a percent, was used to evaluate trends: Police vs. civilians, gender comparisons, and obese vs. non-obese.

**RESULTS:** 381 participants began the competition: 260 sworn officers and 121 civilians; 137 females and 244 males. All participants attended the first weigh-in & 14% failed to complete the final weigh-in. Reg were significantly ( $p \leq 0.01$ ) lighter,  $99.9 \pm 22.6$  kg at the start of the program than groups Irreg2,  $110.6 \pm 26.1$  kg and Irreg3,  $124.8 \pm 30.9$  kg. Comparing the Reg group with the Irreg1 group, the Reg group had significantly ( $p \leq 0.05$ ) greater losses in body mass at week 2 and between weeks 2 and 4;  $1.8 \pm 1.8$  kg vs.  $1.2 \pm 1.4$  kg and  $1.0 \pm 1.5$  kg vs.  $0 \pm 1.4$  kg, respectively. The Reg group also had significantly ( $p \leq 0.001$ ) greater weight loss than the Irreg2 group between weeks 2 and 4;  $1.0 \pm 1.5$  kg vs.  $-0.3 \pm 1.4$  kg, respectively. Civilians had a higher percentage of absences than police, 19% vs. 12%. Also, obese police had more absenteeism than non-obese police, 14% vs. 8% at program completion.

**CONCLUSION:** The police weight loss competition was effective with 86% of participants completing the program. Higher absenteeism by civilians and the more obese indicate that creative promotions directed at these groups may further enhance future program participation. Also, higher body mass and lower weight loss reported in irregular attendees supports the premise that full participation is associated with success.

**3030 Board #302 June 1 9:30 AM - 11:00 AM**

**Health Promotion Initiative to Reduce Body Fat and Increase Fat Free Mass among Active U.S. Military and DOD Civilians**

Robert T. Gobble<sup>1</sup>, Ronald D. Williams, Jr.<sup>1</sup>, Barry P. Hunt<sup>1</sup>, Jeremy T. Barnes<sup>2</sup>, Jeremy P. Loenneke<sup>3</sup>. <sup>1</sup>Mississippi State University, MSU, MS. <sup>2</sup>Southeast Missouri State University, Cape Girardeau, MO. <sup>3</sup>University of Oklahoma, Norman, OK.

(No relationships reported)

**PURPOSE:** Recent studies have indicated that many military personnel exceed U.S. Army standards for body composition and weight. Body fat (BF) percentage is considered a critical measure for soldiers as it may impact the U.S. Army's overall mission. The purpose of this study was to test the effectiveness of a brief individualized intervention to improve the body composition of active duty U.S. Army members (AD) and Department of Defense (DOD) civilians (CV).

**METHODS:** Using the constructs of the Health Belief Model (HBM), a 12-week comprehensive health and nutrition program was designed for active military (n=20) and DOD civilians (n=15) at Area 1, United States Army Garrison, South Korea. This program utilized a combination of health education and fitness initiatives designed to increase physical activity and healthy dietary behaviors of participants. Mean (SD) age of the participants was 32.34(8.51). Mean (SD) subject characteristics for AD participants (17 male, 3 female) were age 30.15(7.45) yrs, weight 85.3(12.2) kg, and BF 23.34(7.53). Mean (SD) subject characteristics for CV participants (8 male, 7 female) were age 35.27(9.19) yrs, weight 88.1(20.0) kg, and BF 30.13(7.01).

**RESULTS:** Paired t-tests determined pair-wise differences between pre- and post-test BF and FFM measurements using a Bonferroni corrected alpha level of 0.05. Among all participants, mean BF was reduced from 24.41(8.98) to 20.99(7.78) ( $t(34)=5.678$ ,  $p \leq .001$ ), while weight decreased from 86.5(15.8) to 83.6(15.6) ( $t(34)=4.403$ ,  $p \leq .001$ ). Among AD participants, reductions occurred in both mean BF 20.91(8.67) to 18.12(6.71) ( $t(19)=3.556$ ,  $p=.002$ ) and weight 85.3(12.2) to 83.1(12.7) ( $t(19)=3.556$ ,  $p=.002$ ). Among CV participants, reductions occurred in both mean BF 27.96(7.93) to 24.18(7.71) ( $t(14)=4.339$ ,  $p=.001$ ) and weight 88.1(20.0) to 84.3(19.3) ( $t(14)=2.949$ ,  $p=.011$ ).

**CONCLUSIONS:** A brief health promotion initiative designed for military base personnel can have significant impact on overall body composition. U.S. Army health and fitness specialists could utilize the HBM to design and implement programs to improve body composition among military base personnel.

**3031 Board #303 June 1 9:30 AM - 11:00 AM**

**The Use of Nutritional Supplements for Weight Modification by U.S. Army Soldiers**

Krista G. Austin<sup>1</sup>, Emily K. Farina<sup>1</sup>, Christina Carvey<sup>2</sup>, Harris R. Lieberman<sup>2</sup>. <sup>1</sup>Oak Ridge Institute for Science and Education; United States Army Research Inst. for Environ. Med., Natick, MA. <sup>2</sup>United States Army Research Institute for Environmental Medicine, Natick, MA.

(No relationships reported)

U.S. Army Soldiers must meet body weight and composition standards to remain in the military, and may use nutritional supplements (NS) purported to assist in weight modification (WM).

**PURPOSE:** This study investigated factors associated with Soldiers' WM goal, and examined the relationships between NS use and weight goals.

**METHODS:** Data were collected (N=990 Soldiers) at 11 Army bases. Participants completed a survey which included questions regarding WM goal (lose, gain or maintain) and NS use. Supplements were categorized as energy drinks (E), sport nutrition products (SNP) or dietary supplements (DS). DS were sub-categorized according to purported functionality as health, weight-loss, weight-gain or other DS. Logistic regression and  $\chi^2$  were used to investigate associations.

**RESULTS:** Forty-three percent of respondents desired weight loss, 38.1%±1.8 weight maintenance and 18.2%±1.4 weight gain. Former smokers (OR, 95% CI = 2.02, 1.33-3.06) and individuals with higher BMI (OR, 95% CI: overweight = 6.33, 4.16-9.62; obese = 18.13, 10.38-31.66;  $p < 0.01$ ) or age (OR, 95% CI: 30-39y = 2.72, 1.58-4.70; > 2.74, 1.44-5.24;  $p < .01$ ) were more likely to want to lose weight. Respondents desiring weight gain were more likely to be male (OR, 95% CI = 2.06, 1.0-4.27;  $p = .05$ ) and more than twice as likely to have high Army physical fitness scores (APFT; OR, 95% CI: APFT 240-289 = 2.0, 1.24-3.25; APFT 290-299 = 2.68, 1.47-4.91; APFT >300 = 2.92, 1.47-5.82;  $p < 0.01$ ). Most respondents (70.3%±1.7) consumed some form of NS; however overall NS use was not related to WM goal. Respondents who wanted to lose or maintain weight were less likely to consume E (OR, 95% CI: lose = 0.63, 0.46-0.87; maintain = 1.21, 0.88-1.65;  $p < 0.01$ ) and weight-gain DS (OR, 95% CI: lose = 0.17, 0.08-0.39; maintain = 0.99, 0.51-1.92;  $p < 0.01$ ) than respondents desiring to gain weight. No other NS categories were significantly related to weight goal.

**CONCLUSION:** WM goal is related to multiple health behaviors including tobacco use, physical fitness score and self-perception of health and eating behavior. NS are consumed in this population regardless of WM goal. Soldiers desiring to lose or maintain weight are less likely to use E and DS.

**3032 Board #304 June 1 9:30 AM - 11:00 AM**

**Body Mass Change Patterns In A Metropolitan Police Department Weight Loss Competition**

Tyler K. Willett<sup>1</sup>, Robert W. Boyce, FACSM<sup>1</sup>, Allen R. Mullins<sup>1</sup>, Glenn R. Jones<sup>2</sup>, Edward L. Boone<sup>3</sup>. <sup>1</sup>UNC Wilmington, Wilmington, NC. <sup>2</sup>Work Physiology Associates Inc., Charlotte, NC. <sup>3</sup>Virginia Commonwealth University, Richmond, VA.

(No relationships reported)

Weight management is essential for police physical fitness programs. Documentation of weight loss patterns aid in the design of programs to encourage weight maintenance.

**PURPOSE:** To report the outcomes of a weight loss intervention and evaluate weight loss patterns in police officers over a 12 week weight loss competition with an emphasis on differences between genders and BMI categories.

**METHODS:** A police department held a 12 week weight loss competition. Teams were comprised of 5 members including civilians and sworn officers. The teams recording the most weight loss during the competition would win. For this analysis, only sworn officers were used. Comparisons between genders and among BMI categories were made related to the total amount of change and weight lost over each 2 weeks of the study. T-tests and an ANOVA with repeated measures were used.

**RESULTS:** 381 participants began the competition. 225 officers participated in all 7 weigh-ins. Mean body mass lost over 12 weeks was 5.26 kg with a starting body mass of  $101.01 \pm 20.8$  kg. Mean BMI decreased from  $32.3 \pm 5.6$  to  $30.6 \pm 5.2$ . There was a significant ( $p \leq 0.001$ ) total weight loss at each weigh-in. Females had a significantly ( $p \leq 0.001$ ) lower starting,  $81.9 \pm 15.8$  kg vs.  $105.9 \pm 19.0$  kg, and final,  $77.6 \pm 15.0$  kg vs.  $100.4 \pm 17.3$  kg, body mass than males. Females had a significantly ( $p \leq 0.001$ ) lower BMI at starting,  $29.6 \pm 6.0$  vs.  $32.9 \pm 5.3$ , and final,  $28.1 \pm 5.6$  vs.  $31.2 \pm 4.9$ , weigh-ins. Normal and overweight BMI categories had significantly ( $p \leq 0.05$ ) less body mass changes,  $1.4 \pm 2.0$  kg &  $3.8 \pm 2.9$  kg, from the 3 obese classes,  $6.1 \pm 4.1$  kg &  $6.2 \pm 4.8$  kg &  $9.4 \pm 7.9$  kg. The extreme obese category had significantly ( $p \leq 0.05$ ) greater changes than the 3 lowest BMI categories from start to final and from the first 2 weeks of the program. In weeks 2-4, only the extreme obese category lost significantly ( $p \leq 0.05$ ) greater body mass than the other categories. However, this relationship declined from weeks 4 to 12. No differences were found in the amount of change among any of the groups from weeks 6 to 12.

**CONCLUSION:** Weight loss competitions can be an effective tool to promote health and fitness programs for police. Males and females had similar weight loss patterns. Special programming may be necessary for the more obese after the initial start of the program. Physiological factors may influence this pattern.

---

3033 Board #305 June 1 9:30 AM - 11:00 AM

**Using Self-efficacy to Predict Weight Loss in Overweight and Obese Individuals**

pouran D. Faghri, FACSM, Santana Galbo, Jessica Ehrentraut., Kamyar Momeni. *University of Connecticut, Storrs, CT.*

(No relationships reported)

Over the last two decades there have been significant increases in the rate of overweight and obesity in the US. Weight loss as low as 5% has been shown to reduce or eliminate disorders associated with obesity. Improving individual self-efficacy via increasing knowledge, skill and improving attitude has been shown to be a strong predictor of weight-control behavior.

**PURPOSE:** To implement a workplace weight loss program for overweight and obese employees that focused on improvement of weight loss self-efficacy (WLSE), exercise self-efficacy (ESE), and movement through the stages of change (SOC) while promoting healthy eating behaviors, and to compare its effectiveness between those who lost at least 5% of their weight and those who did not.

**Design:** Ninety-nine overweight and obese employees (BMI>25) from a healthcare organization participated in this 28-week workplace weight loss program. Mean body weight and BMI was 205+/- 4 (lb) and 34.82+/- 7, respectively. Average age was 46+/- 11 and 90 % were female. All participants received consultation with a dietitian/health educator emphasizing self-efficacy, knowledge, attitude and skill development on weight management, exercise and healthy eating practices. Weight, WLSE, ESE, HES, and movement through SOC were measured pre-post intervention and compared between those who lost at least 5% of their body weight and those who did not.

**RESULTS:** Overall, significant weight loss was observed pre-post intervention (p<0.05). Significant improvements in WLSE, ESE, SOC, and HES were observed in those who lost at least 5% of their body weight (p<0.05). Waist circumference, self-reported general health, and energy level were also improved among those who lost 5% of body weight (p<0.05).

**CONCLUSIONS:** This study incorporates constructs of behavioral theory of self-efficacy into a weight loss program. The two self-efficacy measures correlate significantly with weight loss. Results found direct relationship between losing weight and improvements in WLSE, ESE, eating habits and SOC. Using behavioral techniques to improve self-efficacy can be effective to promote weight loss in overweight and obese people and can produce better outcomes.

Supported by CDC Grant TS-1444

3034 Board #306 June 1 9:30 AM - 11:00 AM

**Weight Management Goals and Practices at a Southeastern University**

Lauren E. Bigham, Bridget Melton, Jody Langdon, Rebecca Riggs. *Georgia Southern University, Statesboro, GA.*

(No relationships reported)

**PURPOSE:** With the high rates of obesity within the college setting, it is imperative to develop culturally appropriate lifestyle and weight management programs within the college environment. The purpose of this study was to explore gender and race in self-reported weight change/maintenance (WC/M) goals and practices of weight management at a medium sized southeastern university.

**METHODS:** Through a qualitative, cross-sectional descriptive research design, data was collected via an on-line survey from 2172 students.

**RESULTS:** Chi-square analysis revealed significant relationships between gender and WC/M goals as well as race and WC/M goals. Females were found to be more likely to want to lose weight (OR = 2.85; 95% CI = 2.40-3.41) while men were more likely to want to gain weight (OR = 5.04; 95% CI = 3.83-6.63). African Americans were more likely to want to gain weight (OR = 1.73; 95% CI = 1.33-2.25) while Latinos were more likely to want to lose weight (OR = 2.41; 95% CI = 1.40-4.17).

**RESULTS:** indicated that participants utilized the practices of dieting, exercise, diet pills, and vomiting/laxatives to lose weight or maintain body weight (39.4%, 67.7%, 7.0%, and 3.5%). Chi-square analysis demonstrated significant relationships (p < .05) between gender and dieting, exercise, and diet pills, with females being more likely to use each of these methods (OR = 2.06, 95% CI = 1.72-2.47; OR = 2.32, 95% CI = 1.93-2.79; OR = 1.48, 95% CI = 1.04-2.11).

Chi-square analysis revealed significant relationships (p < .05) between race (African American and White) and dieting, exercise, and vomiting/laxative use, with Whites being more likely to use dieting (OR = 1.68, 95% CI = 1.36-2.08), and exercise (OR = 1.46, 95% CI = 1.18-1.79). African Americans were more likely to use vomiting/laxatives (OR = 1.96, 95% CI = 1.18-3.24).

**CONCLUSION:** Significant relationships were found between both gender and race while assessing WC/M goals and weight management practices. Further research is warranted since culturally competent attitudes and behaviors cannot be effectively promoted until the possible relationship between current WC/M intentions and behavioral practices are further explored. Gaining a better understanding of gender/racial differences may aid educators in developing culturally competent curriculum and instruction.

---

3035 Board #307 June 1 9:30 AM - 11:00 AM

**The Added Effect of Technology on a Behavioral Weight Loss Program in Severely Obese Individuals**

Jessica L. Unick<sup>1</sup>, Kevin O'Leary<sup>1</sup>, John M. Jakicic, FACSM<sup>2</sup>, Rena R. Wing<sup>1</sup>. <sup>1</sup>*The Miriam Hospital and Warren Alpert Medical School at Brown University, Providence, RI.* <sup>2</sup>*The University of Pittsburgh, Pittsburgh, PA.*

(No relationships reported)

Because of their BMI and low levels of physical activity (PA), severely obese individuals would benefit from weight loss (WL) programs that maximize changes in these domains.

**PURPOSE:** To collect pilot data to examine whether adding a novel technology component to a standard behavioral weight loss (SBWL+TECH) program improves WL and increases PA at 6 months compared to SBWL alone.

**METHODS:** 27 severely obese participants (42.1 ± 10.0 years; 45.1 ± 4.0 kg/m<sup>2</sup>) were randomized to SBWL (n= 13) or SBWL+TECH (n=14). Both groups were asked to attend weekly group meetings for 6 months, reduce caloric intake to 1500-1800 kcal/day, and gradually increase PA to 250 min/week. In addition, SBWL+TECH participants were provided with an armband which objectively measures energy expenditure, a digital display watch which provides real-time PA feedback, and access to a website to record food intake. Weight and PA were objectively assessed at baseline and 6 months.

**RESULTS:** Retention rates (SBWL: 92% vs. SBWL+TECH: 79%; p>0.05) and the number of group sessions attended (SBWL: 18.7 ± 4.6 vs. SBWL+TECH: 21.2 ± 3.0; p>0.05) were high in both groups. The percent change in body weight at 6 months did not differ by treatment arm in either completers analyses (SBWL: -7.8 ± 6.7% vs. SBWL+TECH: -10.0 ± 7.1%) or with baseline weight carried forward (SBWL: -7.2 ± 6.8% vs. SBWL+TECH: -7.9 ± 7.5%; p's=0.46-0.70). Changes in all PA variables at 6 months were not statistically different between groups (p>0.05). However, the increase in the number of steps per day over the 6 month period was more than double in SBWL+TECH compared to SBWL (SBWL+TECH: +2706 ± 2823 steps/day vs SBWL: +1383 ± 2030 steps/day). Similarly, SBWL+TECH increased time spent in moderate-to-vigorous intensity PA (MVPA) by 21.4 ± 31.6 min/day which was more than 3 times as great as that seen in SBWL (6.4 ± 18.8 min/day).

**CONCLUSIONS:** Methods for increasing PA in the severely obese are needed, given their lower than average PA. This study provides preliminary evidence to suggest that adding a technology component to a SBWL program, which aids in the self-regulation of PA behaviors, may assist with increasing PA in this population. Future research should examine whether the magnitude of PA change seen in this study would be similar with a larger sample size and whether PA improvements can be sustained long-term.

### Effects Of Acute Exercise On The Accuracy Of Air-displacement Plethysmography In Young Adults

Ronald Otterstetter<sup>1</sup>, Jessica Viar<sup>1</sup>, Jonathan Naylor<sup>1</sup>, Sandra Krone<sup>1</sup>, Kathryn Tessmer<sup>2</sup>. <sup>1</sup>The University of Akron, Akron, OH. <sup>2</sup>Youngstown State University, Youngstown, OH. (Sponsor: Gary H. Kamimori, FACSM)  
(No relationships reported)

**INTRODUCTION:** Air displacement plethysmography (ADP) body composition systems utilize an exact pre-test protocol that must be followed for each trial. This protocol includes no eating, drinking, or exercising at least 2 hours prior to testing. Previous research has shown that body temperature changes influence the results when using ADP as a measurement; however exercise was not the method used to increase body temperature.

**PURPOSE:** To determine the effect of post-exercise body temperature changes on body composition results using ADP.

**METHODS:** Forty two young adults (18-30 yrs) participated in the study (24 females, 18 males). Resting heart rate was measured to calculate exercise intensity. After exercise intensity was calculated, an ADP test done according to instructions outlined by the manufacturer. Upon completion of the ADP test, the subject exercised on a treadmill at moderate intensity (~65% Heart Rate Reserve) for 30 minutes to increase body temperature. Another ADP trial followed the physical activity. A chamber temperature (CT) was also measured during each of the trials using a thermistor to assess temperature changes. Fat mass (FM), Fat Free mass (FFM), percent body fat (%BF), and (CT) were compared pre and post-exercise.

**RESULTS:** Paired sample T-tests revealed significant differences ( $p < 0.05$ ) between pre-exercise %BF and post-exercise %BF ( $21.3 \pm 9.8\%$  vs  $19.6 \pm 10.2\%$ ), pre-exercise chamber temperature and post-exercise chamber temperature ( $72.9 \pm 2.1$  °F vs  $73.5 \pm 2.0$ °F), and pre-exercise FM vs post-exercise FM ( $32.9 \pm 17.3$  lbs vs  $30.5 \pm 17.7$  lbs). FFM showed no significant difference.

**DISCUSSION:** This investigation demonstrates the importance of following the manufacturer's recommended pre-test protocol as the accuracy of the ADP testing may be compromised, resulting in lower FM and %BF estimations.

### Comparison of Air-Displacement Plethysmography Results Using Predicted and Measured Lung Volumes Over Time

Rachele M. Kappler<sup>1</sup>, Megan Reinking<sup>1</sup>, Kathryn Tessmer<sup>2</sup>, Ronald Otterstetter<sup>1</sup>. <sup>1</sup>The University of Akron, Akron, OH. <sup>2</sup>Youngstown State University, Youngstown, OH. (Sponsor: Gary H. Kamimori, FACSM)  
(No relationships reported)

Rachele Kappler, Megan Reinking, Kathryn Tessmer, Ronald Otterstetter. Department of Sport Science & Wellness Education, The University of Akron, Akron Oh 44325-5103; Department of Human Performance and Exercise Science, Youngstown State University, Youngstown, OH 44555

**INTRODUCTION:** Air displacement plethysmography (ADP) body composition systems can use either measured or predicted lung volumes (LV) in their measurement. The difference in the accuracy of the predicted value and the repeatability of the measured value in each trial is an important factor in the accuracy of the test result. Tests that are done over a period of time can be significantly influenced by these measurements.

**PURPOSE:** To compare the variability and accuracy of ADP tests using predicted and measured LV over time.

**METHODS:** Twenty-four adults (18-30 yrs) participated in the study. Each subject underwent 3 ADP tests over a period of three weeks, with one week between tests. At each testing session, subjects were tested using a predicted LV protocol and a measured LV protocol. Testing order was randomized. LV and percent body fat (%BF) were compared between testing modes and between assessment times.

**RESULTS:** A two-way within-subjects ANOVA was conducted to examine the effect of the mode of lung volume assessment (measured or predicted) and time (day 1, 2, 3) on lung volume and the effect of the mode of body fat assessment (measured or predicted) and time on body fat. LV did not differ significantly ( $p > 0.05$ ) on the two modes of assessment (measured or predicted). Time also was not significant ( $p > 0.05$ ), therefore LV did not differ on the days it was assessed. Subjects responded in the same manner in both modes of assessment regardless of the time assessed. Mode is not significant ( $p > 0.05$ ), therefore % BF did not differ on the two modes of assessment. Time is also not significant ( $p > 0.05$ ), therefore %BF did not differ on the days it was assessed. Subjects responded in the same manner in both modes of assessment (measured and predicted) regardless of the time assessed.

**DISCUSSION:** This investigation demonstrates that the method used to determine LV during ADP testing does not significantly affect the final body composition result. Also, the results from tests performed over an extended period of time are not affected by LV measurement method.

### Accuracy of Air Displacement Plethysmography Body Composition Measure in Estimating Resting Metabolic Rate in Adults

Chris Faciana<sup>1</sup>, Kelsey F. O'Driscoll<sup>2</sup>, Laura McElrath<sup>1</sup>, Stephanie Pence<sup>1</sup>, Ronald W. Mendel<sup>2</sup>, Ronald Otterstetter<sup>1</sup>. <sup>1</sup>The University of Akron, Akron, OH. <sup>2</sup>University of Mount Union, Alliance, OH. (Sponsor: Gary H. Kamimori, FACSM)  
(No relationships reported)

**PURPOSE:** The purpose of this study was to determine the accuracy of an air displacement plethysmography (ADP) body composition measure in estimating resting metabolic rate (RMR). The specific aim was to quantifiably compare the estimated metabolic rate from air displacement plethysmography to the actual metabolic rate measured using indirect calorimetry via a standard metabolic cart.

**METHODS:** Fifty-eight apparently healthy (18-45 yrs) male ( $n=20$ ) and female ( $n=38$ ) subjects participated in the trial. All subjects were instructed to adhere to the following pretest instructions: 1) Fast 12 hours prior to the test 2) Avoid strenuous exercise 24 hours prior to the test 3) Wear tight fitting clothing (i.e. lycra or spandex material) and 4) refrain from nicotine and alcohol for 24 hours prior to testing. Each subject was required to lie down in a quiet room for a total of 30 minutes during the indirect calorimetry obtainment of resting metabolic rate (RMR) via the metabolic cart (MC) method. The first 15 minutes of the RMR data was discarded and the average  $\text{VO}_2$  of the following 15 minutes was used as the subjects RMR. Upon completion of the MC RMR, subjects moved directly to ADP testing following the manufacturers standardized protocol whereby an estimated RMR was obtained.

**RESULTS:** RMR measurements from the MC ( $1868.6 \pm 487.1$  kcals) and estimates from the ADP ( $1428.2 \pm 306.7$  kcals) were statistically significant ( $p \leq 0.05$ ).

**CONCLUSIONS:** Significant differences in RMR measurements were found between indirect calorimetry and the estimated value obtained from the ADP measure. This could cause confusion and be prohibitive in proper nutritional recommendations for people wanting to alter body composition.

3039 Board #4 June 1 2:00 PM - 3:30 PM

**Ability of New Upright Bioimpedance Analyzer to Estimate Fat-Free Mass in Adults**

James J. McCormick, Jason R. Beam, Hung-Sheng Hsu, Michelle G. Kulovitz, Guillermo G. Martinez, Christine M. Mermier, Ann L. Gibson. *University of New Mexico, Albuquerque, NM.*

(No relationships reported)

A major goal of applied body composition assessment is the development of valid methods to accurately estimate fat-free mass (FFM).

**PURPOSE:** To evaluate the accuracy of a new upright analyzer (InBody 520) to estimate FFM in comparison to underwater weighing (UWW).

**METHODS:** Fifty men (29.3±13.4 yrs, 181.4±8.5 cm, 95.8±28.4 kg, 27.7±4.7 kg/m<sup>2</sup>) and fifty women (22.2±4.2 yrs, 165.8±4.7 cm, 68.0±11.9 kg, 24.6±3.7 kg/m<sup>2</sup>) volunteered to have FFM assessed using the InBody 520 and UWW. Standard pre-test guidelines for body composition assessment were followed and residual volume was measured using oxygen dilution. The constant error (CE), standard error of the estimate (SEE), and total error (TE) were determined to evaluate the accuracy of the InBody 520 when compared to UWW for men and women. Bland-Altman plots were compiled to further investigate methodologic bias between the reference and InBody 520 between men and women.

**RESULTS:** There was a significant difference (p<0.05) in FFM between UWW and the InBody 520 for men (UWW:75.52±18.17kg, InBody: 72.37±16.67kg) and women (UWW:46.16±5.76, InBody: 45.35±5.08kg). There was large individual variance in FFM between UWW and the InBody 520 for both men and women. The CE, SEE, and TE were lower in the women (0.81, 2.35, 2.30, respectively) than in the men (3.15, 4.88, 4.78, respectively). Bland-Altman plots indicated FFM was not estimated within 2SD for 6 men and 3 women.

**CONCLUSIONS:** The results of this study showed that when compared to UWW the InBody 520 underestimated FFM in both men and women. The InBody 520 was more accurate in estimating FFM in the women than in the men.

3040 Board #5 June 1 2:00 PM - 3:30 PM

**Validity of Bioelectrical Impedance Analysis Instruments for the Measurement of Body Composition in Collegiate Gymnasts**

Jeremy T. Barnes<sup>1</sup>, Jason D. Wagganer<sup>1</sup>, Jeremy P. Loenneke<sup>2</sup>, Ronald D. Williams, Jr.<sup>3</sup>, Yugandhar Arja<sup>1</sup>, Graeme W. Kirby<sup>1</sup>, Thomas J. Pujol, FACSM<sup>1</sup>. <sup>1</sup>*Southeast Missouri State University, Cape Girardeau, MO.* <sup>2</sup>*Oklahoma University, Norman, OK.* <sup>3</sup>*Mississippi State University, Starkville, MS.*

(No relationships reported)

**PURPOSE:** The body composition of gymnasts is frequently assessed. Many different methods are used including underwater weighing, bioelectrical impedance analysis (BIA) and skinfolds (SKF). The purpose of this study was to determine the validity and of various BIA machines and SKF for estimating percent body fat (%fat) in female collegiate gymnasts.

**METHODS:** Body composition was assessed via Tanita BF-350, Tanita BF-522, Omron HBF-510W, Omron HBF-306C, SKF and estimates of %fat were compared to dual-energy X-ray absorptiometry (DXA), which served as the criterion estimate. Ten female Division I collegiate gymnasts were studied (age 19.1 (1.3) yrs, height 1.66 (0.06) m, weight 60.73 (6.44) kg, and BMI 21.98 (1.22) kg/m<sup>2</sup>).

**RESULTS:** The validity of the %fat estimates (BF-350, BF-522, HBF-510W, HBF-306C, and SKF) was based on the evaluation of each method versus the criterion value from the DXA by calculating the mean, SD, coefficient of determination (r<sup>2</sup>), and standard error of estimate (SEE) from linear regression analysis. To assess the average deviation of individual scores from the line of identity, total error (TE) was calculated for each field method. Paired t-tests determined pair-wise differences between measurements using a Bonferroni corrected alpha level of 0.01. The mean %fat results were as follows: the Tanita BF-350 = 21.67 ± 3.35, the Tanita BF-522 = 21.74 ± 3.51, the Omron HBF-510W = 26.14 (2.96), the Omron HBF-306C = 18.36 (2.07), SKF = 19.50 (3.16), and the DXA = 21.06 (3.39). Mean differences were observed with HBF-510W (p=0.002) and HBF-306C (p=0.001) when compared to DXA. The r<sup>2</sup> values ranged from 0.079 (BF-350) to 0.713 (HBF-306C); SEE values ranged from 1.92%fat (HBF-306C) to 3.44%fat (BF-350); and total error (TE) values ranged from 3.19%fat (SKF) to 5.62%fat (HBF-510W).

**CONCLUSIONS:** For female collegiate gymnasts, the Tanita BF-350, Tanita BF-522, and SKF provide the best estimates of %BF based on their acceptable TE values (<4%fat). These methods provide a valid assessment of body composition in non-laboratory settings. However, neither the Omron HBF-510W nor the Omron HBF-306C can be recommended for estimating %fat based on this preliminary analysis.

---

3041 Board #6 June 1 2:00 PM - 3:30 PM

**A New BIA Equation Estimating the Body Composition of Young Non-Hispanic Black Women**

Jody L. Clasey, FACSM<sup>1</sup>, Kelly D. Bradley<sup>1</sup>, James W. Bradley<sup>1</sup>, Brian A. Irving<sup>2</sup>, Leslie J. Crofford<sup>1</sup>. <sup>1</sup>*University of Kentucky, Lexington, KY.* <sup>2</sup>*Mayo Clinic, Rochester, MN.*

(No relationships reported)

Obesity has dramatically increased in the past decade and is a major health concern. Several minority populations have reported greater incidence of overweight and obesity, including non-Hispanic black (NHB) women where a reported 78.0% aged 20-39 yrs are classified as overweight (OW; BMI > 25.0 < 29.9 kg/m<sup>2</sup>) or obese (OB; BMI > 30 kg/m<sup>2</sup>). To accurately assess the effectiveness of new strategies to prevent or combat obesity, valid, reliable, and sensitive methods of evaluating baseline and post-treatment measures of body composition are essential. One of the difficulties of conducting obesity research is identifying a safe, non-invasive, economical (cost and time), valid method of assessing body composition that can be used in the laboratory, clinic or field setting and is well-tolerated by subjects. Bioelectric impedance analysis (BIA) fulfills many of the requirements to be considered an optimal body composition method; however the lack of population specific equations with representative numbers of healthy weight (HW), OW and OB obese subjects can be problematic.

**PURPOSE:** To develop and cross-validate a new BIA body composition equation for young NHB women.

**METHODS:** Subjects included 89 (42 HW, 25 OW, 22 OB) young NHB women ages 18-30 yr. Using a single frequency (50 kHz) tetra-polar BIA unit and total body DXA scans as the criterion method, a BIA regression equation was developed and then cross-validated using the "leave-one-out" method.

**RESULTS:** The new equation was DXA FFM = -21.0 + 0.136(Wt) + 0.448(Ht) - 0.0296(Imp) where DXA FFM = DXA fat-free mass (kg); Wt = body weight (kg); Ht = standing height (cm); Imp = impedance (ohms). There was no significant mean difference between the DXA FFM (45.8±6.7 kg) and the new BIA equation FFM (45.9±6.2 kg). Using this equation 85.9% of the variance in DXA FFM was explained by the model. Cross-validation results demonstrated a small amount of statistical shrinkage by explaining 84.5% of the variance in DXA FFM. The 95% confidence interval for the predicted value of DXA FFM is  $y' \pm 5.054$  kg.

**CONCLUSION:** The new BIA equation will help to provide an accurate method to estimate the body composition of young NHB women in a variety of field, clinical and research settings. The use of this equation may help to identify effective intervention strategies to prevent or combat obesity in this population.

3042 Board #7 June 1 2:00 PM - 3:30 PM

**Time Course Of Postural Fluid Shifts In A Sample Of Healthy Adults: Preliminary Data Findings**

Ann L. Gibson, Jason R. Beam, Michelle G. Kulovitz, Micah N. Zuhl, Christine M. Mermier. *UNM, Albuquerque, NM.*

(No relationships reported)

Standard body composition guidelines indicate participants should be supine for at least 10 minutes before assessment via bioelectrical impedance analysis (BIA). Little research has been found substantiating this guideline or addressing standing posture prior to assessment with new vertical BIA devices. Extracellular water (ECW) and intracellular water (ICW) from multifrequency BIA (MFBIA) are used to measure total body water (TBW) and estimate fat-free mass (FFM) and body cell mass.

**PURPOSE:** This study investigated the time required for ECW and ICW to stabilize in standing and supine positions.

**METHODS:** Forty-five healthy volunteers (36 ± 16 yrs, 169.6 ± 9.1 cm, 68.2 ± 10.2 kg) followed standard pretest guidelines for body composition assessment. ECW and ICW were measured via MFBIA (Xitron Hydra 4200) every 5 minutes for 30 minutes per position. The starting position was counterbalanced. A 2-min seated period preceded assumption of each posture. FFM was

calculated in accordance with the MFBIA analyzer manual ( $FFM = 1.106 * ECW = 1.521 * ICW$ ). A 2 (posture) x 6 (time) repeated measures ANOVA was conducted to investigate possible differences in postural fluid shifts over time. Significant main effects were further evaluated using paired samples t-tests.

**RESULTS:** There were significant within-group main effects over time for supine ECW, ICW, TBW, FFM, and standing ECW ( $p < .05$ ). There was no significant main effect for posture. Pairwise comparisons revealed significant differences between each 5-min increment (5 - 10, 10 - 15, 15 - 20, 20 - 25, 25 - 30 min) for supine ECW and ICW; supine FFM differed between 10 and 15 min ( $p < .01$ ). Standing ECW pairwise differences were found for the first three 5-min increments ( $p < .01$ ).

**CONCLUSIONS:** The results of this study indicate that waiting 5 min is sufficient for the stabilization of calculated TBW and FFM for both supine and standing positions. However, if MFBIA is used for measuring ECW and ICW, more time is needed for stabilization in the standing and supine positions.

**Techniques for Undertaking DXA Whole Body Scans in Tall and/or Broad People**

Alisa Nana<sup>1</sup>, Gary R. Slater<sup>2</sup>, Will G. Hopkins, FACSM<sup>3</sup>, Louise M. Burke, FACSM<sup>1</sup>. <sup>1</sup>Australian Institute of Sport, Bruce, Australia. <sup>2</sup>University of Sunshine Coast, Maroochydore, Australia. <sup>3</sup>Auckland University of Technology, Auckland, New Zealand.

(No relationships reported)

**PURPOSE:** Dual energy x-ray absorptiometry (DXA) is becoming a popular tool to measure body composition in athletes, owing to its ease of operation and comprehensive analysis. However, many athletes are taller and/or broader than the active scanning area of the DXA bed. The aim of this study was to investigate the reliability of DXA measures of whole body composition summed from two or three partial scans.

**METHODS:** Physically active young adults (15 females, 15 males) underwent one whole body and 4 partial DXA scans in a single testing session under standardized conditions. The partial scanning areas were head, whole body from neck region down, right side and left side of the body. Body composition estimates from whole body were compared with the addition of partial scans simulating different techniques to accommodate tall, broad, or tall and broad subjects. Magnitude of changes in the mean of DXA estimates were assessed by standardization.

**RESULTS:** For tall, and tall and broad subjects, body composition estimates from summed partial scans that included the head scan were substantially different to body composition estimates from the whole body scan. Summing with the head scan over-estimated ~2 kg of lean and ~1 kg of fat mass. For broad subjects, the addition of right and left body scans produced no substantial difference in body composition estimates compared to whole body scan.

**CONCLUSIONS:** Strategies can be undertaken with DXA technology to accommodate subjects who are broader than the scanning bed, however, whole body composition estimates in tall, or tall and broad subjects include error. Further work is needed to develop other standardized protocols to estimate body composition in tall and very tall athletes.

This investigation was supported by funding from the Physique and Fuel Centre program of the Australian Institute of Sport (AIS) and RMIT University, and the AIS Sports Nutrition Discipline.

**3044** Board #9 June 1 2:00 PM - 3:30 PM

**Differences in DXA Anthropometric Measurements between Female Collegiate Soccer Players and Gymnasts**

Jason D. Waggoner<sup>1</sup>, Graeme W. Kerby<sup>1</sup>, Zane G. Alcantara<sup>1</sup>, Jeremy P. Loenneke<sup>2</sup>, Jeremy T. Barnes<sup>1</sup>, Thomas J. Pujol, FACSM<sup>1</sup>. <sup>1</sup>Southeast Missouri State University, Cape Girardeau, MO. <sup>2</sup>University of Oklahoma, Norman, OK.

(No relationships reported)

Engaging in weight-bearing activity has been shown to improve body composition and increase BMD. For sport specific athletes, changes in body composition and BMD are important indicators of adaptations to exercise training. Comparison of body composition across sports can be utilized as an indicator of potential health issues, such as the female athlete triad (i.e., low BMD, poor nutrition, and lack of regular menstrual cycle).

**PURPOSE:** To compare the differences in anthropometric measurements between female Division I collegiate soccer players and gymnasts utilizing Dual-Energy X-ray Absorptiometry (DXA).

**METHODS:** Eleven (20+1y) normal weight (BMI: 22.7±1.2 kg-m<sup>-2</sup>) female collegiate soccer players and eleven (20+1y) normal weight (BMI: 22.6±1.1 kg-m<sup>-2</sup>)

gymnasts were tested using DXA (GE Prodigy Series X Model 8743). Data points analyzed were weight (kg), height (m), bone mineral density (g/cm<sup>2</sup>), body fat percentage and fat free mass (kg). An independent samples t-test was used to test for statistical significance between groups. All analyses were performed using SPSS v19.0 statistical software package. Values are presented as (mean±SEM). Statistical significance was set at  $p < 0.05$

**RESULTS:** The soccer players were significantly taller than the gymnasts ( $p=0.04$ ). No statistical significance was noted for any other variable across the two groups. The mean values were as follows: BMD [1.27 vs. 1.27g-cm<sup>2</sup> ( $p=0.94$ )], Weight [62.4 vs. 59.5kg ( $p=0.33$ )], Height [1.68 vs. 1.63m ( $p=0.04$ )], body fat [26.7 vs. 23% ( $p=0.11$ )], and fat free mass [46.4 vs. 46.5kg ( $p=0.95$ )] (all data listed as soccer vs. gymnast).

**CONCLUSIONS:** Other than height differences, no other anthropometric measurements showed any significant difference when comparing female collegiate soccer players to female collegiate gymnasts. Past research has indicated the likelihood of gymnasts exhibiting low BMD and low body fat percentages; however the group of gymnasts utilized in this study exhibited healthy BMD and body compositions.

**3045** Board #10 June 1 2:00 PM - 3:30 PM

**Comparison of Body Composition Measurement Techniques in College Wrestlers**

Jerry Mayhew<sup>1</sup>, Jana L. Arabas<sup>1</sup>, Timothy M. Schwegler<sup>1</sup>, Thomas Redman<sup>1</sup>, David Schutter<sup>1</sup>, Jody L. Clasey<sup>2</sup>. <sup>1</sup>Truman State University, Kirksville, MO. <sup>2</sup>University of Kentucky, Lexington, KY.

(No relationships reported)

Wrestling has a long history of weight-loss abuse which prompted the NCAA to enact regulations controlling the degree of weight loss based on skinfold measurements. The equation selected to predict %fat was the Lohman equation (1981) which was developed using hydrostatic weighing as the criterion. Few studies have evaluated various body composition measurement techniques against the new criterion measure of total body DXA scans for determining %fat.

**PURPOSE:** To compare selected methods of determining body fat in college wrestlers.

**METHODS:** NCAA Division II wrestlers ( $n = 23$ ;  $M \pm SD$ : age = 19.6 ± 0.8 y, weight = 78.2 ± 13.7 kg, BMI = 25.6 ± 3.8 kg/m<sup>2</sup>) were evaluated using 4 body composition techniques: DXA, hand-to-hand BIA, leg-to-leg BIA, and skinfolds. Both BIA techniques used an athletic setting and measured at a single frequency (50 kHz). Skinfolds (SKF) were measured at 9 sites and used to predict %fat using 4 athletic-specific prediction equations [Lohman (1981), Tipton-Oplinger (1984), and two Jackson-Pollock equations (1978)].

**RESULTS:** Repeated-measures ANOVA with Bonferroni *post hoc* testing revealed significant differences among the techniques. DXA %fat was significantly greater (17.1 ± 5.3%) than all other techniques. The Jackson-Pollock 7SKF equation %fat (9.4 ± 3.4%) was not significant different from the hand-to-hand BIA %fat (11.3 ± 4.9%). Hand-to-hand BIA %fat was not significantly different from the Lohman equation %fat (12.5 ± 3.8%). The Lohman equation %fat was not significantly different from the leg-to-leg BIA %fat (13.3 ± 5.8%). The Jackson-Pollock 3SKF equation %fat (8.4 ± 2.7%) and the Tipton-Oplinger equation %fat (7.7 ± 2.5%) were significantly lower than all other methods but not significantly different from each other. All techniques were highly correlated with DXA %fat ( $r = 0.93$  to  $0.95$ ), except for leg-to-leg BIA %fat ( $r = 0.57$ ) and hand-to-hand BIA %fat ( $r = 0.61$ ). Minimum wrestling weight calculated using the Lohman equation (71.6 ± 10.1 kg) would have been 5.8% greater than when calculated from DXA (67.7 ± 9.2 kg).

**CONCLUSIONS:** Measurement of %fat in college wrestlers from DXA would yield %fat values that were 3.8% to 9.4% higher than with other prediction techniques. This would result in an average of 4.8% greater body weight loss allowance than when using the Lohman equation.

---

3046 Board #11 June 1 2:00 PM - 3:30 PM

**Relation of Common Field Measures of Body Composition and DXA in Older Adults**

Sarah H. Sellhorst, Keli L. Thomas, William F. Riner, Jr., FACSM. *University of South Carolina Lancaster, Lancaster, SC.*  
(No relationships reported)

Body Mass Index (BMI) is a measure of the relationship between height and weight and correlates with body fat percentage in the young and middle age adults. However, older adults experience changes in body composition that alter the relationship between BMI and body fat percentage. Excess body fat and obesity are often associated with a myriad of health problems that lead to considerable morbidity, impaired quality of life, and premature death.

**PURPOSE:** To determine a suitable, non-invasive, inexpensive method of determining body composition in older adults.

**METHODS:** Thirty-seven older adults were recruited from senior centers and senior focused programs (15M/22F, 65.98 ± 7.24 yr, 167.30±7.55cm, 76.04 ± 15.57 kg). Total body fat % (BF%) was measured by dual-energy x-ray absorptiometry (Lunar IDX). The standard Body Mass Index (BMI) calculation was used, as well as the Deurenberg et. al.(1991) equation for BF%. One paired T-test was performed (DXA BF% vs. Deurenberg BF%). Correlational analysis was performed on all variables.

**RESULTS:** No significant differences ( $\alpha = .05$ ) were found between DXA BF% and Deurenberg BF%. Correlational results are listed below:

|         | Deurenberg BF% | BMI    | W/H Ratio |
|---------|----------------|--------|-----------|
| DXA BF% | r=.801*        | r=.395 | r=.129    |

\*significant at  $p<.01$

**CONCLUSIONS:** BF% calculated by the Deurenberg et. al.(1991) equation seems to be a better field measure of body composition than BMI or W/H ratio in community dwelling older adults.

3047 Board #12 June 1 2:00 PM - 3:30 PM

**Correlations of Body Composition Estimates Derived from Four Devices in Female Collegiate Athletes**

Morgan Tapper, M. Dot Fullwood, Lucinda Salvaggio, Annie Peck, Alicia Olsen, Buddy Macuha. *San Francisco State University, San Francisco, CA.* (Sponsor: Marialice Kern, FACSM)  
(No relationships reported)

The accurate determination of body fat in female athletes is a valuable tool used by coaches and trainers to help athletes maximize performance. Historically, hydrostatic or underwater weighing (UWW) has been used as the "gold standard" for estimating body composition, but is costly and time consuming. Using UWW as our criterion score, percent Body Fat (%BF) was derived using 3 easy and affordable assessment tools: an ImpSFB7 bioimpedance spectroscopy (BIS) device, the Bod Pod (BP), and 7-site skinfold (SKF).

**PURPOSE:** To determine which of these 3 techniques were comparable to UWW values.

**METHODS:** Fourteen female collegiate basketball players were recruited (19.2 ± 0.2 yrs; 169.7 ± 2.2 cm; 67.1 ± 3.1 kg). All subjects were asked to follow pretest guidelines and all measurements were completed in one visit. Body composition was assessed by four methods. BIS, SKF, BP and UWW. All BIS measurements were conducted with the subject lying in a supine position, with arms at their sides. SKF estimated body density by Jackson et al. (1980) equations for white and black females. Residual lung volume was estimated for UWW. Body density was converted to body fat using Siri's equation (1956)(Caucasian) and Schutte's equation (Afro-American, 1984). For the Bod Pod, thoracic lung volume was directly measured or, in 3 cases estimated when the subjects had excessive difficulty with the protocol. The data were analyzed by simple correlations using SPSS version 20.

**RESULTS:** The BIS and BP correlated with UWW with r-values of 0.872 ( $p<0.01$ ) and 0.699 ( $p<0.05$ ), respectively. No relationship was found between SKF and UWW. Stepwise regression found BIS to predict the criterion score ( $R=0.826$ ,  $p<0.002$ ), while BIA and BP together significantly predicted the criterion score ( $R=0.904$ ,  $p<0.001$ ).

**CONCLUSION:** BIS and BP were accurate in estimating %BF in female collegiate basketball players and can be used with confidence since they are less prone to operator error and take less time.

3048 Board #13 June 1 2:00 PM - 3:30 PM

**Reliability And Validity Of The Hpi Caliper And Body Composition Formula**

Kimberly Trocio, Christopher Chavez, Jon Garcia, Lawrence A. Golding, FACSM, Judy Goldman, Paul Hafen, Audra Hannston, Stephen Harris, Michael Jarrett, Hanaa Shaheen, Greg Stalker, Antonio S. Santo. *University of Nevada, Las Vegas, Las Vegas, NV.*  
(K. Trocio: Contracted Research - Including Principle Investigator; Health Profile Institute.)

**BACKGROUND:** The Health Profile Institute (HPI) Osteo Caliper has been extensively used throughout Sweden for the past 30 years to assess body composition. Skeletal breadth measurements of the right and left wrists, knees, and ankles using the caliper, waist and hip circumference measurements, age, gender, height, weight, and exercise routine are used in a regression equation that estimates percent body fat. The advantages of the HPI caliper include its ease of use, quick obtainment of measurements, portability, and low-cost.

**PURPOSE:** The purpose of this study was to evaluate the reliability and validity of the HPI Osteo Caliper and formula as a method for estimating body composition.

**METHODS:** 64 subjects (28 females & 36 males) with a mean age, height, and weight of 33.7 ± 14.5 y, 169.3 ± 11.5 cm, and 70.6 ± 16.9 kg, respectively, completed well recognized measures of body composition during a single laboratory visit. PASW Statistics 18 software was used to analyze the data using Pearson's methodology.

**RESULTS:** Mean percent fat was 21.4 ± 9.4, 21.6 ± 8.9, 17.2 ± 7.8, and 21.4 ± 8.8 for hydrostatic weighing, Bod Pod, BIA, and the HPI Caliper formula, respectively. Statistical analysis revealed significant correlations between the percent fat determined from the Bod Pod, BIA, and the HPI formula when compared with hydrostatic weighing (.96, .83, & .93, respectively). Moreover, the percent fat determined from the HPI formula showed significant correlations with the Bod Pod, BIA, and hydrostatic weighing (.91, .83, & .93, respectively).

**CONCLUSION:** The HPI Osteo Caliper generates results comparable with other well established body composition techniques and therefore, may be a useful, alternative tool for healthcare and fitness professionals to estimate body composition in apparently healthy adults.

---

3049 Board #14 June 1 2:00 PM - 3:30 PM

**Validation Of The Bodymetrix Ultrasound System For Percent Body Fat**

Jean P. Boucher, FACSM<sup>1</sup>, Gabriel Chamberland<sup>1</sup>, Mylene Aubertin-Leheudre<sup>1</sup>, David H. Jones<sup>2</sup>, Ron Rehel<sup>2</sup>, Alain S. Comtois<sup>1</sup>. <sup>1</sup>UQAM, Montreal, QC, Canada. <sup>2</sup>Concordia University, Montreal, QC, Canada.  
(No relationships reported)

The Body Metrix (BM) system (IntelaMetrix, CA) is an affordable computer based ultrasound system that provides rapid body composition assessment. We present preliminary data comparing percent body fat (%BF) as measured using the BM system and a DEXA as a reference measurement.

**PURPOSE:** To establish the validity of the BM computer based ultrasound system for the quantification of %BF.

**METHODS:** %BF was calculated on 10 university aged participants (5 females, 5 males) using the BM system with the Jackson and Pollock 7 sites equation (1978). A DEXA was also used as a reference to measure %BF on the same subjects. The Bland and Altman (1986) statistical procedure was used to determine the validity of the BM %BF.

---

**RESULTS:** The level of agreement between both devices was equal to -0.6% BF. As well, no significant correlation was found between the score difference from both devices and the score average of both devices ( $r = -0.17, p=0.641$ ). The regression analysis between the BM system and the DEXA showed a significant correlation ( $r=0.71, p=0.023$ ) with a SEE of  $\pm 3.93$  %BF.

**CONCLUSIONS:** Both devices can be used interchangeably within the range of 10 to 30% BF. The data obtained on a limited number of subjects ( $n=10$ ) show good agreement and the BM system underestimates by 0.6% on average when compared to the DEXA.

**3050** Board #15 June 1 2:00 PM - 3:30 PM

**Validity Of Futrex-6100 X/L For Estimating Body Composition In Elite Male Rowers.**

Kristina L. Kendall<sup>1</sup>, David H. Fukuda<sup>1</sup>, Abbie E. Smith<sup>2</sup>, Robert P. Hetrick<sup>1</sup>, Joel T. Cramer, FACSM<sup>3</sup>, Jeffrey R. Stout<sup>1</sup>. <sup>1</sup>University of Oklahoma, Norman, OK. <sup>2</sup>University of North Carolina-Chapel Hill, Chapel Hill, NC. <sup>3</sup>Oklahoma State University, Stillwater, OK.  
(No relationships reported)

For athletes competing in weight categories, accurate measurements of body composition are important to optimize performance, and to evaluate the effectiveness of training and nutritional regimes on fat and fat-free mass during periods of weight reduction.

**PURPOSE:** The purpose of this study was to examine the validity of near-infrared interactance (NIR) estimates of percent body fat (% fat) and fat-free mass (FFM) using the Futrex 6100 X/L in elite male rowers.

**METHODS:** Twenty Olympic-caliber male oarsmen (mean age  $\pm$  SD= 24.6 $\pm$ 2 years) volunteered to serve as subjects. Body composition measurements were obtained from NIR and hydrostatic weighing (HW). The statistical analyses included constant error (CE), standard error of estimate (SEE), correlation coefficients ( $r$ ), and total error (TE).

**RESULTS:** NIR estimates of % fat were not significantly correlated to those values from HW ( $r=.023, p=0.924$ ) with a SEE of 3.2%. The Futrex 6100 X/L produced a non-significant CE (-0.54,  $p=0.604$ ); however, the TE value exceeded Lohman's recommendation of <4.0% (TE=4.5%). NIR estimates of FFM were significantly correlated to those values from HW ( $r=0.962, p<0.001$ ), with a SEE of 2.2 kilograms (kg). CE was non-significant (CE=-0.83,  $p=0.354$ ) and total error was "fairly good" according to Lohman (TE=3.9kgs).

**CONCLUSION:** The findings from the present study indicated that the Futrex-6100 X/L resulted in TE values that were too large to be of practical value for % fat, but acceptable for FFM estimates. Research suggests that FFM is a significant predictor of rowing success, therefore, the Futrex 6100 X/L may provide a quick and portable alternative to HW for estimating FFM in elite male rowers.

**3051** Board #16 June 1 2:00 PM - 3:30 PM

**Yearly Changes in the Body Composition and Body Build of Young Female Swimmers**

Robert W. Lewis Jr, Daniel A. Traylor, Haley C. Bergstrom, Terry J. Housh, FACSM, Glen O. Johnson, FACSM, Richard J. Schmidt, Dona J. Housh, FACSM. University of Nebraska, Lincoln, Lincoln, NE.  
(No relationships reported)

| Variable                    | Mean $\pm$ SD    | r vs. age | Yearly change rate |
|-----------------------------|------------------|-----------|--------------------|
| % fat (%)                   | 14.1 $\pm$ 6.1   | 0.44      | 1.0                |
| FFW (kg)                    | 36.9 $\pm$ 10.0  | 0.82      | 3.2                |
| BW (kg)                     | 43.5 $\pm$ 13.6  | 0.82      | 4.4                |
| HT (cm)                     | 149.3 $\pm$ 14.0 | 0.85      | 4.7                |
| FFW/HT (kg/cm)              | 0.2 $\pm$ .05    | 0.78      | 0.01               |
| biacromial/bi-iliac (cm/cm) | 1.2 $\pm$ 0.1    | -0.21     | -0.01              |
| Sum 4 SF (mm)               | 59.0 $\pm$ 20.0  | 0.55      | 4.3                |
| Sum 4 Dia (cm)              | 24.7 $\pm$ 17.0  | 0.65      | 0.5                |
| Sum 4 Circ (cm)             | 121.1 $\pm$ 17.0 | 0.77      | 5.1                |

Few studies have examined age-related changes in the body composition and body build of young swimmers.

**PURPOSE:** The purpose of this study was to determine the yearly rate of changes in the body composition and body build characteristics of young female swimmers.

**METHODS:** Seventy-one female swimmers (age  $\pm$  SD: 11.7  $\pm$  2.6 yr; range: 7.1-16.9 yr) served as subjects. Body composition characteristics (% fat and fat-free weight (FFW)) were determined from underwater weighing using the age-specific conversion constants of Lohman. Skinfolds (SF: triceps, scapular, suprailiac, and thigh), diameters (Diam: biacromial, bi-iliac, elbow, wrist, knee, and ankle), and circumferences (Circ: biceps extended, forearm, thigh, and calf) were measured using Lange calipers, a broad blade anthropometer, and Lufkin tape with Gullick handle, respectively. Height (HT) and body weight (BW) were determined using a wall scale with Broca plane and a physician's scale, respectively. Simple linear regression was used to examine the relationships for age versus each body composition and body build variable. The table below includes the mean ( $\pm$  SD) values for each dependent variable, the correlations ( $r$ ) with age, and the yearly change rates (slope coefficients of the linear regression models).

**RESULTS:** There were significant positive relationships for age versus all dependent variables except biacromial/bi-iliac diameters.

**CONCLUSION:** These data indicated that the yearly changes in body composition and body build characteristics in young female swimmers were consistent with those of female athletes in other sports. The age-related changes in these parameters may contribute to the improvements in performance that occur across age in swimmers.

$r=0.23, p < 0.05$

**3052** Board #17 June 1 2:00 PM - 3:30 PM

**The Relationship between Body Composition and Performance on the Army Physical Fitness Test**

Ali Lierman, David Q. Thomas, Jeff Schusler. Illinois State University, Normal, IL.  
(No relationships reported)

It is not known which parameters of body composition are the strongest predictors of physical fitness, nor is it clear whether body fat and physical fitness are related to each other, or whether they are independent risk factors. Attempts have been made to determine if body composition can be a predictor of physical performance in different populations, however the results vary.

**PURPOSE:** To determine if there is a relationship between clinical body composition assessments and performance on the Army Physical Fitness Test (APFT).

**METHODS:** Forty-one cadets (males:  $n=32$ , age: 20.5  $\pm$  1.8 years, ht: 178.9  $\pm$  6.41cm, mass: 79.1  $\pm$  7.8 kg; females:  $n=9$ , age: 20.6  $\pm$  1.5 years, ht: 163.7  $\pm$  5.2 cm, mass: 63.4  $\pm$  8.4 kg) participated in the study. Body composition assessments included height, weight, waist and hip circumferences, skinfolds and air displacement plethysmography via the Bod Pod. Skinfold sites were separated into axial (abdominal, suprailiac crest, subscapular, and mid-axillary) and appendicular (appendicular skinfolds: triceps, biceps, anterior thigh and medial calf) skinfolds. Scores from the APFT included maximum number of sit-ups performed correctly in 2 minutes, maximum number of push-ups performed correctly in 2 minutes and time to complete a 2 mile run were obtained with the cadet's consent from the Department of Military Science database.

**RESULTS:** There were no significant correlations ( $p > 0.05$ ) for males between the APFT scores and any of the body composition measurements. For the female subjects, only one significant correlation was found between sit-up score and lean mass,  $r= 0.72$  ( $p < 0.05$ ). Correlation coefficients between body composition assessments and total APFT scores ranged from  $r= -0.03$  to 0.03 for males and -0.38 to -0.08 for females.

**CONCLUSION:** The present study indicated that in a sample of ROTC cadets, who fall within the acceptable ranges for Army body composition standards, no significant correlations were found for body composition and APFT scores in the male subjects and only one significant correlation was found for females (lean mass and sit-up score). It may be assumed from this study that if cadets fall within Army body composition standards, body composition does not factor into their performance on the APFT.

**3053** Board #18 June 1 2:00 PM - 3:30 PM

**Fat Mass: Accumulation And Distribution In Athletes And Military Personnel**

Martin E. Wennblom, William F. Brechue, FACSM. *United States Military Academy, West Point, NY.*

(No relationships reported)

Fat mass (FM) accumulation is associated with physical activity level.

**PURPOSE:** Compare FM accumulation in two populations of highly trained individuals with different performance goals.

**METHODS:** Male athletes (n=411; age: 21.2±3.3 yrs; NCAA, international, or Olympic level competitors) and United States Military Academy cadets (n=100; 20.5±1.4 yrs) were measured for body composition. BMI, W/H ratio and shape (modeled to a cylinder) were calculated.

**RESULTS:** Height, %fat, W/H, and shape were similar, while athletes had significantly greater body mass (M), FM, FFM, and BMI. FM and FFM were significantly related in athletes ( $y=0.68^{0.0384x}$ ;  $R^2=0.58$ ), but not cadets ( $y=0.12x+3.1$ ;  $R^2=0.04$ ). M is predictive of %fat in athletes ( $y=0.2785x-9.9802$ ;  $R^2=0.70$ ) not cadets ( $y=0.1833x+0.0655$ ;  $R^2=0.13$ ). Cadets (n=97) and athletes (n=333) were similar in height, %fat, FM, W/H, and shape; however, athletes had a greater M (~13 kg) and FFM (~10 kg) when controlling %fat range (6-26%). %fat, FM, FFM, BMI, W/H, and shape were similar in cadets, wrestlers and boxers; each have M restrictions and when compared to the remaining athlete population (height and weight matched), the restricted M group had greater FM (~1.5 kg) and lesser FFM (~1.8 kg) while BMI, W/H, and shape were similar.

**CONCLUSIONS:** In the same M range, cadets have a greater range of %fat. Athletes carry a greater percentage of FFM at a given FM and shape. Weight class restrictions appear to favor a slightly greater fat and lesser FFM accumulation without altering shape.

**3054** Board #19 June 1 2:00 PM - 3:30 PM

**Anthropometry Profiles of Elite Rugby Union Players During a Competitive Season**

Michael Naylor<sup>1</sup>, Joseph B. Taylor<sup>2</sup>. <sup>1</sup>English Institute of Sport, London, United Kingdom. <sup>2</sup>English Institute of Sport, Manchester, United Kingdom.

(No relationships reported)

**PURPOSE:** To examine anthropometric measures in professional Rugby Union players during a competitive season and the changes between two preseasons.

**METHODS:** Body weight and the sum of eight skinfolds were evaluated on five occasions between two successive preseasons for positional groups of backs (fullback, wing, centre, fly half and scrum half playing positions, n = 13), front row forwards (prop and hooker playing positions, n = 9), second row forwards (n = 5) and back row forwards (n = 5). Analyses comprised two-way repeated-measures ANOVA, one-way ANOVA and paired-sample t-tests with repeated contrasts and bonferroni *post-hocs*. Statistical significance was set at  $p<0.05$  and data are reported as means with 95% confidence intervals (m, CIs).

**RESULTS:** Weight differed between playing positions ( $F(3, 28) = 37.883, p<0.01$ ) but did not vary across the season. Backs (m = 90.53 kg, CIs = 87.03 to 93.98) were lighter than all other positions (all  $p<0.01$ ) while Back Row (m = 106.49 kg, CIs = 101.17 to 112.31), Second Row (m = 115.75 kg, CIs = 110.18 to 121.31) and Front Row (m = 115.10 kg, CIs = 110.95 to 119.25) were similar ( $p>0.05$ ). The sum of eight of skinfolds differed as a function of season stage and playing position ( $F(12, 112) = 6.575, p<0.01$ ). Sum of eight skinfolds for front row players were greater than those of all other positions at each stage of the season (all  $p<0.05$ ) while all other positions were similar (all  $p>0.05$ ). The general trend within each playing position was a decrease in skinfolds from pre-season one through to the end of season one and a subsequent increase at pre-season two. However, the sum of eight skinfolds at pre-season two did not exceed those at pre-season one. Specifically, the sum of eight skinfolds decreased between pre-season one and two in backs ( $t(12)=5.704, p<0.01, m = 9.67$  mm, CIs = 5.98 to 13.36) and the front row ( $t(8)=7.837, p<0.01, m = 32.55$  mm, CIs = 22.98 to 42.14). There were non-significant decreases in the skinfolds between pre-seasons for second row ( $t(4)=1.821, p=1.43, m = 9.66$  mm, CIs = -5.07 to 24.39) and back row players ( $t(4)=2.763, p>0.05, m = 18.18$  mm, CIs = -0.89 to 36.45).

**CONCLUSIONS:** The results show the case rugby team reduced skinfolds during the season whilst maintaining body mass. The sum of eight skinfolds were also lower at pre-season two compared to pre-season one in all playing positions.

---

**3055** Board #20 June 1 2:00 PM - 3:30 PM

**Handgrip Strength Enhances the Utility of Traditional Body Composition Parameters with Predicting Percent Body Fat**

James K. Taylor<sup>1</sup>, Michael R. Esco<sup>1</sup>, Henry N. Williford, FACSM<sup>1</sup>, Aindrea N. McHugh<sup>1</sup>, Barbara E. Bloomquist<sup>1</sup>, A. Jack Mahurin<sup>2</sup>. <sup>1</sup>Auburn University Montgomery, Montgomery, AL. <sup>2</sup>Montgomery Family Medicine Residency Program, Montgomery, AL.

(No relationships reported)

Body mass index (BMI) and waist circumference (WC) are two body composition parameters with important health and fitness implications. However, these markers do not distinguish between body fat mass (FM) and fat-free mass and are not accurate predictors of total body fat percentage (BF%) when used alone. Dual-hand-grip strength (HGS) is a crude indicator of total body strength and has been shown to vary through a wide range of body masses. It is not fully known if HGS can be used with BMI and WC in a model to predict BF%.

**PURPOSE:** This research study was designed to determine if BF% could be predicted with BMI, WC, and HGS in a general population of men and women.

**METHODS:** Sixty-four apparently healthy adults (37 men and 27 women) served as the subjects for test validation. Criterion BF% was determined via dual energy x-ray absorptiometry. The relationship between the independent variables (BMI, WC, HGS, and sex) and criterion BF% was determined via stepwise regression. An additional cohort of 23 subjects (16 men and 7 women) was used to cross-validate the regression model. Validity was confirmed by correlation, standard error of the estimate (SEE), and the method of Bland-Altman.

**RESULTS:** The regression analysis showed that BMI, WC, HGS, and sex were independently associated with FM. The regression equation was as follows: predicted FM (kg) = (2.095 x BMI) - (HGS x 0.077) + (WC x 0.552) + (sex x 4.730) - 50.139 ( $r = 0.96, R^2 = 0.92, p < 0.001$ ). Predicted BF% = (predicted FM / total body mass [kg]) x 100. When cross-validated, there was no significant difference between Criterion BF% (34.6% +/- 10.2%) and Predicted BF% (35.4% +/- 9.6%) ( $p = 0.34$ ). Cross-validation revealed the following statistics:  $r = 0.94, p < 0.001, SEE = 3.7\%$ . The Bland-Altman statistics indicated that the CE/Bias (predicted - criterion BF%) = 0.8% and the limits of agreement (95% confidence intervals) were -6.2% to 7.9%.

**CONCLUSIONS:** This study showed that BMI, WC, HGS, and sex could potentially be used to in a regression model to predict BF%. However, it should be noted that this was a pilot study that included fairly low sample sizes for the validation and cross-validation cohorts. Therefore, further research is needed to confirm the present results.

---

**3056** Board #21 June 1 2:00 PM - 3:30 PM

**Differences in Ratings of Perceived Exertion Between Weight Classifications.**

Janelle C. r. Sester, Amanda J. Salacinski, Marilyn Looney, Matthew Stults-Kolehmainen. *Northern Illinois University, Dekalb, IL.* (Sponsor: John B. Bartholomew, FACSM)

(No relationships reported)

**PURPOSE:** The purpose of this study was to investigate OMNI ratings of perceived exertion (OMNI-RPE) among normal weight and obese individuals at each stage of the modified Balke treadmill test. A secondary purpose was to determine differences between groups for OMNI-muscle hurt, RER, heart rate (HR) and oxygen consumption ( $VO_2$ ).

**METHODS:** Participants of normal weight (BMI<25 kg/m<sup>2</sup>; n=17) and obese status (BMI<30 kg/m<sup>2</sup>; n=12) completed two days of testing. A 6-minute walk test was completed two days before the modified Balke to evaluate subject safety. A 2 x 3 mixed model ANOVA (group x stage) was used to compare all variable means for the normal weight vs. the obese group. When it was appropriate post hoc dependent t-tests were calculated when needed.

**RESULTS:** No interactions were found between group and stage for any variables with the exception of muscle hurt ( $p < .004$ ). The obese group reported higher OMNI-RPE ( $p = 0.002$ , power=0.90), higher HR ( $p = 0.003$ , power=0.88) and significantly lower  $\dot{V}O_2$  ( $p = 0.027$ , power=0.62) than the normal weight group for all stages of the Modified Balke. These data suggest that obese women perceive exercise as harder than normal weight women during an incremental treadmill test.

**CONCLUSIONS:** OMNI-RPE, HR, and  $\dot{V}O_2$  data suggest that obese women have differing physiological and perceptual responses than normal weight women at the same exercise intensity, which suggests the need for modified exercise recommendations for obese women. Further research is needed to determine if these differences may explain reduced exercise participation for obese women.

---

**3057** Board #22 June 1 2:00 PM - 3:30 PM

**Lower Limb Body Composition Is Associated To Passive Knee Flexibility And Acute Mechanical Adaptations**

Tiago Neto, Sandro R. Freitas, João R. Vaz, Ana Isabel Carita, Maria João Valamatos, Pedro Mil-Homens. *Faculdade de Motricidade Humana, Oeiras, Portugal.*  
(No relationships reported)

**PURPOSE:** People vary in flexibility in terms of range of motion, resistance to stretch and acute mechanical adaptations during stretching. Several researchers have mentioned body composition (BC) as a main factor for flexibility differences. However, there is still controversies and unknown for the relation between flexibility and BC. The present study's goal was to determine how BC and anthropometric measures of lower limb associates to passive knee extension (PKE) flexibility.

**METHODS:** Twenty-five male persons ( $21.8 \pm 2.9$  years,  $73.9 \pm 8.9$  kg,  $1.75 \pm 0.1$  m) with PKE flexibility deficit were subject to an anthropometric and BC assessment (Dual-Energy X-ray Absorptiometer, DXA) and a maximal PKE protocol of 5 repetitions (velocity of 2°/s; 90 seconds in static phase; and 15 seconds rest interval) without feeling discomfort or pain. Knee passive torque - range of motion (PT-ROM), *vastus medialis* and *semitendinosus* electromyographic activity (EMG) were recorded during the protocols. All the measurements were done on the same day. Viscoelastic stress relaxation (VSR), amplitude (N-m), knee passive stiffness (KPS, in N-m<sup>0</sup>), and lower limb regional components of BC were determined. Specific MatLab<sup>®</sup> routines were used for data analysis. A critical level  $p = 0.05$  was considered for statistical analysis.

**RESULTS:** Thigh muscle and bone mass, as well as thigh perimeter, showed a moderated correlation with PT ( $r = 0.45$ ;  $r = 0.6$ ;  $r = 0.59$ , respectively), ROM ( $r = 0.46$ ;  $r = 0.5$ ;  $r = 0.5$ ), and VSR ( $r = 0.46$ ;  $r = 0.49$ ;  $r = 0.5$ ). Thigh muscle mass was also correlated with KPS ( $r = 0.42$ ). Subjects ( $n = 10$ ) with larger thigh perimeter, superior thigh muscle mass, and higher thigh bone mass showed, respectively, more 41% PT, 39% VSR, and 11% ROM, when compared to the thinnest subjects. All these differences and correlations were significant ( $p < 0.05$ ). Muscular EMG was lower than 3% of maximal voluntary contraction in all tests.

**CONCLUSIONS:** Passive knee flexibility seems to be moderately related with lower limb body composition. In particular, thigh perimeter and muscle mass are associated with passive stiffness and viscoelastic stress relaxation. More research is needed to understand what influences range of motion, resistance to stretch and acute mechanical adaptations to stretching.

---

**3058** Board #23 June 1 2:00 PM - 3:30 PM

**Weight-Related Concerns & Characteristics of a Female Substance Abuse Population**

Anne R. Lindsay<sup>1</sup>, Sara Velasquez<sup>1</sup>, Cortney Warren<sup>2</sup>, Minggen Lu<sup>3</sup>. <sup>1</sup>University of Nevada Reno, Las Vegas, NV. <sup>2</sup>University of Nevada Las Vegas, Las Vegas, NV. <sup>3</sup>University of Nevada Reno, Reno, NV. (Sponsor: Melinda Manore, FACSM)  
(No relationships reported)

Research demonstrates that more women use illicit stimulant-type drugs than men due to its appealing side effects including loss of appetite, substantial weight loss and elevation of self-esteem. During substance abuse recovery, however, women often report rapid weight gain and body dissatisfaction expressing weight concerns as a trigger for relapse. Dietary restriction, energy & dietary supplements, tobacco and anorexic & bulimic practices often become the "self treatment-of-choice".

**PURPOSE:** To determine WT-related concerns of women in substance abuse treatment.

**METHODS:** 340 female participants were recruited from nine substance abuse treatment facilities in southern Nevada (outpatient and residential court-ordered, self-referral). Participants' average age was 33.75 years ( $SD = 10.75$ ). Average length of time in recovery was 12.5 months ( $SD = 39.4$ ).

Participants completed questionnaires to assess drug history and WT concerns prior to completing a health and body image program. Body Measurements (WT, height, and 4-site skinfold measurements - abdomen, ilium, tricep and thigh) were also conducted pre-intervention.

**RESULTS:** Stimulants were the most common drug of choice (61.3% of sample) followed by alcohol (17.6%), opiates (11.6%) and all others (9.5%). Average body fat was 30.48%, ( $SD = 7.37$ ); average BMI was 28.26, ( $SD = 6.31$ ). Drugs were used as a method for WT loss often, usually or always for 34.3% of the sample. Other methods used for WT loss included exercise (49.7%), caloric restriction (41.4%), diet pills (37.9%), starvation (25.5%) and energy supplements (22.4%).

The majority (70.5%) was concerned about WT gain in recovery; 43.0% had concern that gaining WT could trigger drug relapse and 28.0% had concern about using drugs to lose WT after leaving treatment. Participants' actual measured WT was significantly higher than the WT at which they felt most comfortable  $p < 0.001$ .

**CONCLUSIONS:** Females in substance abuse treatment were overly concerned about their weight and weight gain. Validating these weight concerns is critical to successful recovery. Interventions that educate and address concerns associated with weight are warranted in this population. Programs that address body image and healthy lifestyles may decrease relapse and treatment dropout, especially for women.

---

**3059** Board #24 June 1 2:00 PM - 3:30 PM

**Associations Between Calf Fat And Muscle Density, Calf Soft Tissue Areas, And Total And Leg Soft Tissue Mass.**

Vanessa D. Sherk<sup>1</sup>, Debra A. Bembem, FACSM<sup>2</sup>. <sup>1</sup>University of Colorado Denver, Aurora, CO. <sup>2</sup>University of Oklahoma, Norman, OK.  
(No relationships reported)

Peripheral Quantitative Computed Tomography (pQCT) is becoming increasingly used for muscle and fat area assessments. Dual Energy X-ray Absorptiometry (DXA) is often added to these studies to give body composition information since data reporting the associations between pQCT- and DXA-derived soft tissue measures are scarce.

**PURPOSE:** To determine associations between pQCT-derived soft tissue density and area measures and DXA-derived soft tissue mass.

**METHODS:** Healthy men ( $n = 55$ ) and women ( $n = 59$ ) ages 20-59 had their leg and total body composition (bone-free lean body mass (BFLBM), fat mass (FM), body fat %) assessed by DXA and their calf fat and muscle cross-sectional area (FCSA and MCSA) and density (FDen and MDen) measured at 66% of tibia length. Marrow fat (MarFat) was also examined. Data are reported as mean  $\pm$  SE.

**RESULTS:** Men had significantly ( $p < 0.01$ ) greater total ( $61.3 \pm 1.0$  vs.  $40.7 \pm 1.1$  kg) and leg ( $21.0 \pm 0.4$  vs.  $14.1 \pm 0.3$  kg) BFLBM and MCSA ( $89.5 \pm 1.7$  vs.  $69.6 \pm 1.6$  cm<sup>2</sup>) than women. Women had significantly ( $p < 0.01$ ) greater leg ( $10.6 \pm 0.6$  vs.  $7.0 \pm 0.5$  kg) FM, and FCSA ( $32.9 \pm 2.1$  vs.  $16.9 \pm 2.1$  cm<sup>2</sup>) than men. FDen was significantly ( $p < 0.01$ ) higher in men ( $9.9 \pm 0.8$  vs.  $1.6 \pm 0.4$  mg/cm<sup>3</sup>), but MDen was not different between sexes. FDen was negatively correlated with FCSA, total and leg FM, and body fat % ( $r = -0.5$  -  $-0.7$ ,  $p < 0.001$ ) and positively related to MCSA, total and leg BFLBM ( $r = 0.4$ - $0.5$ ,  $p < 0.001$ ). Total FM was predicted by FCSA, wt, FDen, ht, and age ( $R^2 = 0.89$ ,  $p < 0.01$ ). FCSA, wt, sex, and FDen predicted leg FM ( $R^2 = 0.90$ ,  $p < 0.01$ ). Sex, MCSA, ht, MDen, and wt predicted total BFLBM ( $R^2 = 0.82$ ,  $p < 0.01$ ). MCSA, ht, MDen, wt, and sex predicted leg BFLBM ( $R^2 = 0.87$ ,  $p < 0.01$ ). Relative to total bone area, the proportion of 'fatty' marrow was not different between men and women ( $13.4 \pm 0.6\%$  vs.  $12.5 \pm 0.7\%$ ,  $p > 0.05$ ), but there was a trend ( $p = 0.07$ ) for the density of 'fatty' marrow to be greater in women ( $16.0 \pm 5.1$  vs.  $14.3 \pm 4.7$  mg/cm<sup>3</sup>).

**CONCLUSIONS:** Calf soft tissue area and density, along with ht, wt, and sex, strongly predict total and leg soft tissue mass. Fat density measures appear to be especially influenced by fluid content, possibly due to differences in lipid content or levels of inflammation. Further research will be needed to determine if changes in adipose cell size can be detected by changes in fat density.

**3060** Board #25 June 1 2:00 PM - 3:30 PM  
**The Precision of Thigh Fat and Lean Mass Measures from Dual-energy X-ray Absorptiometry**

Cemal Ozemek, Matthew P. Harber, Leonard A. Kaminsky, FACSM. *Ball State University, Muncie, IN.*  
(No relationships reported)

Dual x-ray absorptiometry (DXA) is becoming an effective tool to measure total body fat and lean mass characteristics in diverse populations. Software enhancements have provided options to obtain body region assessments of clinical value such as android fat. As sarcopenia has been recognized as a serious health issue, there is a need for useful methods to quantify body mass, especially lean mass, changes in specific regions of the body.

**PURPOSE:** The purpose of this study was to assess the precision of DXA measurement of lean and fat mass of the thigh in a heterogeneous population.

**METHODS:** A total of 30 subjects (14 males and 16 females), ranging from ages 24 to 88 y (n=6 < 25 y, n=9 between 25 - 50 y, n=9 between 50 - 75 y, and 6 > 75 y) had a total body DXA scan (GE Lunar Prodigy). Subjects were measured in a supine position with legs strapped together to minimize movement during image acquisition. Scans were analyzed in triplicate with Encore Version 13.40 software to quantify fat and lean mass of the right thigh, as defined by the segment between the inferior borders of the ischial tuberosity and superior surface of the intercondyloid eminence. Coefficient of variations (CV) were calculated for the three separate analyses from the image for each subject, while a repeated measures ANOVA was used to test differences between the 3 measures.

**RESULTS:** There was a wide range of thigh fat mass (641.7 to 7498.7 g) and lean mass (2379.7 to 7629.0 g) between subjects. No significant differences existed between the 3 analyses for both fat and lean mass (p = 1.00). CV values ranged from 0.1 - 2.5% for fat and 0.1 - 2.0% for lean mass while mean CVs were 0.9% and 0.7%, respectively.

**CONCLUSION:** DXA imaging is capable of quantifying fat and lean mass of the thigh with a high level of precision. Regional DXA measures may provide a reasonable alternative for quantifying fat and lean mass of body segments compared to the gold standard of magnetic resonance imaging (MRI). Additional study of the potential for DXA to provide accurate regional fat and muscle mass measurements is warranted.

**An Investigation of the Relationship Between Body Satisfaction and Body Composition among College Students**

Cherilyn N. Hultquist, Lauren Miller, John R. McLester, FACSM, Christine Wood. *Kennesaw State University, Kennesaw, GA.*  
(No relationships reported)

Body satisfaction is influenced by self-perception and external factors, such as media images and social norms. Examining levels of body satisfaction among college students (CS) could identify the need for services on college campuses to help students achieve and maintain a healthy body fat % (BF%) and body image.

**PURPOSE:** To examine the differences between body satisfaction and BF% among CS by sex and body mass index (BMI) and to determine levels of body satisfaction before and after body fat testing and investigate the differences of self-estimated BF% and measured BF%.

**METHODS:** Participants were 208 CS (95 males, 113 females), aged  $24.4 \pm 6.2$  yrs, who volunteered to answer questionnaires, the Social Physique Anxiety Scale (SPAS), and undergo body fat testing with Dual Energy X-ray Absorptiometry (DXA).

**RESULTS:** A comparison by sex revealed a difference ( $P < 0.001$ ) on the SPAS with males and females scoring  $26.2 \pm 1.1$  and  $33.3 \pm 0.8$  respectively, indicating that males have lower levels of anxiety about their physiques. There was a difference ( $P < 0.001$ ) in SPAS scores when compared by BMI category of  $\leq 24.9 \text{ kg/m}^2$  and  $\geq 25.0 \text{ kg/m}^2$  where individuals with a BMI  $\geq 25.0 \text{ kg/m}^2$  had higher SPAS scores. There was also a decrease in levels of appearance satisfaction after BF% was assessed and test results were explained to subjects ( $P = 0.018$ ). There was no interaction by sex; both males (pre =  $5.0 \pm 0.2$ , post =  $4.9 \pm 0.2$ ) and females (pre =  $4.3 \pm 0.2$ , post =  $4.0 \pm 0.2$ ) satisfaction levels decreased but one not more than the other ( $P = 0.457$ ). Finally, self-estimated BF% compared to measured BF% revealed that all subjects underestimated their BF% ( $P < 0.001$ ).

**CONCLUSION:** Males have higher levels of body satisfaction than females and satisfaction for both sexes was negatively affected by knowledge of BF%. Physique anxiety was higher among students with a BMI above  $25.0 \text{ kg/m}^2$ , and subjects underestimated their BF% and became less satisfied with their bodies once they knew their BF%. It appears that CS do not have an accurate self-concept regarding their body image. Health and fitness classes and programs on campuses need to provide students with information about BF% and how to develop a positive self-image. An accurate measure of BF% could help inform CS about the current state of their bodies and help guide them in developing a proper diet and exercise plan.

---

**3062** Board #27 June 1 3:30 PM - 5:00 PM  
**Prevalence of Eating Disorder Risk and Body Image among Collegiate Male Swimmers & Divers**

Toni M. Torres-McGehee<sup>1</sup>, Dawn M. Minton<sup>1</sup>, Eva V. Monsma<sup>1</sup>, Daniele Albert<sup>2</sup>, Jeremy R. Searson<sup>1</sup>. <sup>1</sup>University of South Carolina, Columbia, SC. <sup>2</sup>Gardner-Webb University, Boiling Springs, NC.  
(No relationships reported)

Male athletes may represent similar eating disorder (ED) risks as females and may predispose themselves to different body image (BI) issues. Discrepancy between perceived BI (PBI) and desired BI (DBI) has been associated with a variety of maladaptive thoughts and behaviors, but little is known about clothing type and BI perceptions from others (e.g., perception of what others perceive about that athlete's body).

**PURPOSE:** To estimate prevalence of ED risk characteristics and behaviors; and to investigate BI dissatisfaction associated with clothing type (daily clothing-DC, uniform-UN) and perceptions from others (peers-P, parents-PA, coaches-CO).

**METHODS:** Male collegiate swimmers (n=124) and divers (n=12) from NCAA Division I institutions (n=9) participated in an online survey. Participants self-reported height, weight, ideal weight, PBI and DBI in clothing type, and perceptions from others in DC. Eating Attitudes Test was used to estimate ED risk. Gender-base BMI silhouette was used to assess BI dissatisfaction.

**RESULTS:** Prevalence for ED risk was estimated for all males at 19.9% (swimmers = 19.4% and divers = 25.0%). All males reported bingeing (10.3%), vomiting (2.2%), using diet pills or laxatives (1.5%), and engaging in excessive exercise (8.8%) to control or lose weight. A 2 (DC, UN) x 2 (PBI, DBI) ANOVA with repeated measures on the last 2 factors indicated a significant within subjects effect  $F(1,135) = 5255.4$ ;  $p < 0.01$ ,  $\eta^2 = .98$ . An interaction for clothing  $F(1,135) = 6.82$ ;  $p = 0.01$ ,  $\eta^2 = .05$  revealed that swimmers' had overall greater BI dissatisfaction in UN compared to DC. A second 3 (P, PA, CO) x 2 (PBI, DBI) ANOVA with repeated measures on the last 2 factors indicated a significant within subjects effect  $F(1,135) = 4224.4$ ;  $p < 0.01$ ,  $\eta^2 = .97$ . An interaction for perceptions  $F(1,135) = 5.52$ ;  $p = .02$ ,  $\eta^2 = .04$  revealed that P, PA, or CO's DBI of the swimmer was larger than their PBI.

**CONCLUSION:** Male swimmers presented ED risk characteristics and behaviors along with BI dissatisfaction. Although in a normal male BMI range, swimmers wanted to be larger in their UN compared to DC. Additionally, P, PA, and CO's perceptions of what these athletes look like compared to what they should look like are implicated in BI dissatisfaction, warranting further examination as correlates of maladaptive thoughts and behaviors.

3063 Board #28 June 1 3:30 PM - 5:00 PM

**Thin Women Display Hedonic Treadmill Tendencies Regarding Their Weight Vs. Overweight Counterpart!**

Lorena Martin<sup>1</sup>, Barbara Kahn<sup>2</sup>, Andrew Perkins<sup>3</sup>. <sup>1</sup>University of Miami, Coral Gables, FL. <sup>2</sup>University of Pennsylvania, Philadelphia, PA. <sup>3</sup>The University of Western Ontario, Ontario, ON, Canada. (Sponsor: Arlette C. Perry, FACSM)  
(No relationships reported)

**PURPOSE:** The purpose was to examine any potential differences in self-esteem, body image, and body attitude between thin and overweight women. We expected that women who self-described themselves as thin should reveal balanced identities, whilst overweight women would exhibit unbalanced identities.

**METHODS:** A series of Implicit Association Tests (IAT; Greenwald, McGhee and Schwartz 1998) were used to assess the three constructs of interest: Self-Esteem, Self-Body Association, and Body Attitude. The IAT is a well-established measure in social and cognitive psychology designed to indirectly measure the strength of association between concepts in memory using a simple computer-based categorization task.

**RESULTS:** The ANOVA analysis revealed a significant difference on the body image and body attitude IATs, such that thin participants exhibited a stronger self-association with imagery consistent with thin body size (Mthin = .63, Moverwt = 52,  $p = .037$ ) and more positive attitudes toward thin body imagery (Mthin = .51, Moverwt = .39,  $p = .044$ ), but did not reveal significant increase in self-esteem compared to overweight participants (Mthin = .49, Moverwt = .51,  $p = .65$ ). Further, thin individuals revealed a smaller current body image (Mthin = 3.4, Moverwt = 6.0,  $p < .001$ ; smaller number is thinner), a smaller ideal body image (Mthin = 2.6, Moverwt = 3.8,  $p < .001$ ), a smaller self-ideal discrepancy (Mthin = .72, Moverwt = 2.39,  $p < .001$ ), and a smaller self-society ideal discrepancy (Mthin = .80, Moverwt = 3.5,  $p < .001$ ) than the overweight individuals. Finally, correlational analysis of the thin participants revealed a negative correlation between current body size and implicit self-esteem (such that the thinner your current body size, the lower your implicit self-esteem) and a positive correlation between worry about becoming overweight and increased implicit self-esteem. None of these correlations obtained for the overweight group.

**CONCLUSION:** In light of these counterintuitive findings, overweight females revealed a balanced identity in memory, while thin participants did not.

3064 Board #29 June 1 3:30 PM - 5:00 PM

**Coping With Weight-related Discrepancy & Impact On Self-regulation: Development Of The WEIGHT-COPE**

Mark D. Faries<sup>1</sup>, John B. Bartholomew, FACSM<sup>2</sup>. <sup>1</sup>Stephen F. Austin State University, Nacogdoches, TX. <sup>2</sup>University of Texas-Austin, Austin, TX.  
(No relationships reported)

**PURPOSE:** To develop a reliable and valid measure (WEIGHT-COPE) to assess coping responses to weight-related discrepancy in women. The decision to create such a measure stemmed from difficulties in consistent regulation of weight-related behavior.

**METHODS:** The WEIGHT-COPE and other relevant measures were completed online by 470 females ages 18-35 years from all BMI categories. Data were analyzed in an exploratory factor analysis.

**RESULTS:** The EFA revealed a 40-item measure consisting of eight coping factors: Exercise/Physical Activity, Healthy Eating, Cutting Calories/Appetite Suppression, Supplement Use, Monitor/Planning, Disengage/Denial, Camouflage, and Acceptance/Positive Reframing. All factors were internally consistent ( $\alpha = 0.71$  to  $0.89$ ), and converged with other pertinent measures of weight satisfaction, weight controllability/changeability, social physique anxiety, self-esteem, weight loss efficacy, physical activity level, dietary intake and objectified body consciousness. To test theoretical implications on future self-regulation of weight loss behavior, a structural regression model was run utilizing the resulting factors. The factors interacted in a theoretically-driven pattern, illustrating that coping responses to weight-related discrepancy may have varied impacts on weight loss behavior choice.

**CONCLUSIONS:** The present findings provide preliminary support for the WEIGHT-COPE and suggest that individuals cope with weight-related discrepancy in different ways, which may then have various impacts on future self-regulation of weight loss behavior.

**The Effects Of Two Weeks Of Sprint Interval Training In Spinal Cord Injured (SCI) Persons**

Christopher R. Harnish<sup>1</sup>, Jonathan A. Daniels<sup>2</sup>, Jewel R. Moore<sup>2</sup>, Roy T. Sabo<sup>3</sup>, David R. Gater<sup>2</sup>. <sup>1</sup>Hunter Holmes McGuire VAMC/Virginia Commonwealth University, Richmond, VA. <sup>2</sup>Hunter Holmes McGuire VAMC, Richmond, VA. <sup>3</sup>Virginia Commonwealth University, Richmond, VA. (Sponsor: Gary Sforzo, FACSM)  
(No relationships reported)

Persons with chronic SCI exhibit a high prevalence of metabolic syndrome. The potential medicinal benefits for sprint interval training (SIT) among able-bodied individuals may have important implications for SCI, however data for arm crank ergometry (ACE) SIT are not unavailable.

**PURPOSE:** To elucidate the effects of two weeks of SIT in persons with SCI.

**METHODS:** 9 males with chronic SCI, T1-T10, completed the study that included a continuous  $VO_{2Peak}$  test and DXA to estimated body composition. Three OGTT's were completed - baseline, 2 weeks later (Pre), and 48 hrs Post training, with 24 hr dietary recall completed for each of these tests. Six SIT sessions were completed on a Monark 891E ACE over 2 weeks. Subjects cranked against 3.5% body mass for 30 sec completing 4 sprints session 1, then 5, 5, 6, 6, and finally 7 sprints in the final session. All data are presented as medians (Q1, Q3), and a Wilcoxon test ( $\alpha=0.05$ ) was used to determine pre and post changes. Area under the curve (AUC) was calculated using the trapezoidal rule and peripheral insulin sensitivity ( $S_p$ ) was estimated using ISI-Cederholm.

**RESULTS:** Men were age 47 (44, 56.8), 181.6 (168.8, 184.5) cm tall, weighed 86.8 (72.8, 94.4) kg, 34.6 (30, 37.5) %Fat, &  $VO_{2Peak}$  1.51 (1.33, 2.05)  $L \cdot min^{-1}$ . Dietary analysis indicated subjects consumed 1907 (1288, 2751) kcal, consisting of 50.5 (38.7, 57.8)% CHO and 31.0 (26.3, 37.9)% Fat. Participant's average work during sprints increased from 5.66 to 6.22 kJ (about 10%) between the first session and last. AUC changes for either glucose or insulin failed to show significant changes. ISI-Cederholm 151.6 (145.2, 176.0) baseline, 179.2 (162.7, 190.8) Pre, and 165.2 (141.0, 202.3) Post, also did not show significant changes either. Close inspection of the data show large variation between the three OGTT periods.

**CONCLUSIONS:** Persons with SCI have a high training capacity, but ACE SIT may not provide a sufficient training stimulus to overcome the metabolic changes and variability seen here. The high variability for the OGTT's within and between subjects cannot be explained by dietary analysis and support the unique metabolic environment seen among SCI. These data also suggest that the OGTT may not be a suitable test for training evaluation in SCI. More research is needed to determine the efficacy of ACE SIT for other non-SCI populations.

---

3066 Board #31 June 1 2:00 PM - 3:30 PM

**Accelerometer-derived Physical Activity And Lower Extremity Functional Changes In Patients Undergoing Spinal Decompression Surgery**

Matthew P. Buman<sup>1</sup>, Ma Agnes Martinez Ith<sup>2</sup>, William L. Haskell, FACSM<sup>3</sup>, Matthew Smuck<sup>2</sup>. <sup>1</sup>Arizona State University, Phoenix, AZ. <sup>2</sup>Stanford University School of Medicine, Redwood City, CA. <sup>3</sup>Stanford University School of Medicine, Stanford, CA.

(No relationships reported)

Objective methods are needed to better quantify behavioral and functional outcomes following spine surgery. To date accelerometers have not been widely used to evaluate surgical outcomes despite their promise to detect small but meaningful changes in activity following surgery. Maintained lower extremity function in late life is known to reduce morbidity and mortality.

**PURPOSE:** To assess changes in physical activity (objective and self-report) and lower extremity function in patients with lumbar spinal stenosis undergoing spinal decompression surgery.

**METHODS:** Patients wore an accelerometer for 7 consecutive days (Actigraph GT3x+), completed a validated self-report physical activity questionnaire (CHAMPS questionnaire) and a short battery of lower extremity physical performance tests (Short Physical Performance Battery [SPPB]: gait, leg strength, and standing balance) at baseline (T0), 1-month post-operation (T1), and 3-month post-operation (T2). Moderate-vigorous physical activity (MVPA) was defined using published thresholds ( $\geq 1952$ cts/min) accelerometer data and standard metabolic equivalents ( $\geq 3.0$  METS) for reported activities. Mixed-effects models were fitted to examine within-group changes in these variables.

**RESULTS:** Patients (N=14) were 57% female, 43% Caucasian, overweight ( $27.6 \pm 5.1$  kg/m<sup>2</sup>), and of older age ( $73.4 \pm 8.1$  years). Patients wore the accelerometer for 4.8, 5.5, and 3.5 valid days (defined as  $>10$ hrs of wear time) at T0, T1, and T2, respectively. Improvements in accelerometer and self-reported MVPA were not significant ( $p > .05$ ); however, effect sizes were moderate to large for accelerometer-derived MVPA at T1 (diff=9.6mins,  $d=0.98$ ) and T2 (diff=8.0mins,  $d=0.4$ ), and small for self-reported PA at T1 (diff=5.3mins,  $d=.01$ ) and T2 (diff=99.2mins,  $d=0.3$ ). Improvements in SPPB scores were significant (F[2,19.1],  $p=.01$ ), with large effects sizes at T1 (diff=1.9,  $d=1.6$ ) and T2 (diff=1.5,  $d=0.8$ ). Sub-analyses revealed SPPB total score changes were due to gait and leg strength, but not standing balance.

**CONCLUSIONS:** Initial evidence suggests that changes in MVPA and lower extremity function following decompression surgery are detectable. Future research is needed to confirm these results in a larger sample and with longer-term follow-up.

3067 Board #32 June 1 2:00 PM - 3:30 PM

**Eight Weeks Functional Training Improves Muscle Endurance, Balance, Power, Speed In Athletes With Disabilities**

Heather Pennington, Cynthia Schroeder, Elizabeth Feutz, Meghan Reid. Lindenwood University, St. Charles, MO.

(No relationships reported)

**PURPOSE:** The purpose of this study was to determine whether a high intensity functional training program was effective in improving athletic muscle endurance (ME), dynamic balance (DBAL), power (P), and speed (S) in athletes with various disabilities.

**METHODS:** Nine individuals (Mean age = 18, Males n = 6, Females n = 3) with disabilities varying from cerebral palsy, visual impairment, spinal cord injury, and spina bifida participated. Each athlete performed pre and post-tests which consisted of: 1 min push-up, 1 min sit-up, stabilometer, vertical jump (VJ), medicine ball throw (MBT), and 40 yard dash. Athletes participated in one 45 minute training session per week for 8 weeks. Training sessions included a dynamic warm-up, a high intensity training incorporating ladder agility drills, hurdles for balance and flexibility, sand pit for balance, bodyweight core training, muscle strength and endurance exercises, cable columns for core strength, medicine balls for power and core stability, over-speed workouts on treadmills, stability balls for balance, tennis balls for hand-eye coordination, and an appropriate cool down.

**RESULTS:** Eight weeks of functional training considerably improved ME (40.6% sit-ups, 40.0% push-ups), DBAL (178%), P (13.0% MBT), and S (10.6%).

**CONCLUSIONS:** These results indicate that an 8 week functional training program was effective in improving muscle endurance, dynamic balance, power, and speed in athletes with various disabilities.

---

3068 Board #33 June 1 2:00 PM - 3:30 PM

**Amplified C-reactive Protein To Protein Glycation Ratio In The Frozen Shoulder Patients**

Wei-Hong Jean<sup>1</sup>, Li-Yuan Tsao<sup>2</sup>, Chia-Hua Kuo, FACSM<sup>3</sup>. <sup>1</sup>Far Eastern Memorial Hospital, New Taipei, Taiwan. <sup>2</sup>National Taipei College of Business, Taipei, Taiwan. <sup>3</sup>Taipei Physical Education College, Taipei, Taiwan.

(No relationships reported)

Exercise training is encouraged for all in the prevention and treatment of metabolic disorders. However, degenerative musculoskeletal disorder can be a barrier for exercise participation. Adhesive capsulitis of the shoulders result in limitation of active and passive range of motion of all directions and so called "frozen shoulder". This problem causes severe pain and affects daily activity and exercise ability. Diabetic patients have five times prevalence rate of frozen shoulder compared to general populations. Hyperglycemic protein glycation plays a critical role in low-grade chronic inflammation and may implicate degenerative joint disease in elderly.

**PURPOSE:** This cross-sectional study aimed to compare C-reactive protein (CRP) and glycosylated hemoglobin (HbA1C) ratio between normal and frozen shoulder patients.

**METHODS:** Fifty middle-aged subjects were divided into 4 groups according to the cut-off criteria of pre-diabetes: fasting glucose (FG > 100) and glycosylated hemoglobin A1C (HbA1C > 5.7%) for CRP comparison. CRP to HbA1C ratio in 3 frozen shoulder patients (aged  $54.3 \pm 1.2$  years) was measured against 12 age-matched normal subjects (aged  $54.3 \pm 1.2$  years).

**RESULTS:** Among fifty subjects, CRP levels increased with HbA1C levels, but this relationship was not linear in nature. In particular, the distribution of escape-from-the-norm values increased with HbA1C level. Relationship between both variables becomes linear when CRP variance is logarithmically compressed, suggesting that CRP increase is amplified with the magnitude of protein glycation.

**CONCLUSION:** Our data suggest that chronic inflammation amplified with protein glycation among middle-aged subjects. Frozen shoulder patients displayed an amplified CRP to HbA1C ratio (3 folds) against the normal subjects. This preliminary finding provides ground for investigating the possible metabolic origin of frozen shoulder, and the possibility of using hypoglycemic intervention as an adjuvant therapy of conventional rehabilitation modality treating degenerative joint disease.

3069 Board #34 June 1 2:00 PM - 3:30 PM

**Hip Muscle Strength, Bilateral Ratios, Antagonistic Ratios and Single Leg Squat Performance in Persons with Low Back Pain and Controls**

Jennifer Satterfield, Ken Queliza, George J. Davies, Bryan L. Riemann. Armstrong Atlantic State University, Savannah, GA.

(No relationships reported)

Many persons suffer from lower back pain (LBP), but causes are not fully understood. Few studies have examined the hip musculature strength differences in persons with LBP history and whether it contributes to movement deviations during the single leg squat.

**PURPOSE:** To compare isometric strength, antagonistic ratios, bilateral ratios of the hip muscles and qualitative single leg squat performance between healthy and persons with a history of LBP.

**METHODS:** Fifteen men with ( $1.78 \pm 0.08$ m,  $80.7 \pm 15.6$ kg,  $21.9 \pm 3.9$  yrs, Oswestry Disability Questionnaire score =  $29.1 \pm 22.8$ ) and without ( $1.78 \pm 0.05$ m,  $72.7 \pm 11.8$ kg,  $20.2 \pm 2.5$  yrs) LBP history completed isometric strength evaluation of the hip flexor, extensor, adductor (HAD), abductor (HAB), internal rotator and external rotator using hand held dynamometry. Strength assessment order was randomly determined for each subject. Average strength values across three trials were computed and normalized to body mass. Antagonistic and bilateral strength ratios were computed. Furthermore, participants completed the National Academy of Sports Medicine (NASM) single leg squat assessment (SLSA), however only errors associated with hip musculature imbalance were considered for analysis. A pilot reliability study for the strength assessments yielded intraclass correlational coefficients (3, k) between .91 to .98. Three factor analyses of variance (ANOVA) were conducted for the strength values (group by limb by muscle action) and antagonistic ratios (group by limb by ratio). Two factor ANOVA were conducted for the bilateral ratios (group by muscle action). Chi square analyses were used to compare errors during the SLSA.

**RESULTS:** No significant ( $P > .05$ ) isolated strength or bilateral ratios differences between the groups existed. Post hoc analysis of a significant group by antagonist ratio interaction ( $P = .009$ ) for HAB:HAD revealed the LBP group to have a 19% lower ratio than the control group ( $P = .007$ ). There were no significant SLSA error differences between the groups.

**CONCLUSIONS:** Although the isometric strength and bilateral ratios did not differ between the LBP and control groups, the LBP demonstrated significantly smaller HAB:HAD ratios than the controls. This study also shows that the NASM SLSA did not detect HAB:HAD differences between LBP sufferers and non-LBP sufferer.

**3070 Board #35 June 1 2:00 PM - 3:30 PM**  
**Reducing Injuries is NOT Enough - It Also Helps to Win**

Jeremy A. Gentles, *East Tennessee State University, Johnson City, TN.*  
(No relationships reported)

Much of the current literature related to injuries in sport has addressed the influence of a particular exercise intervention on a specific type of injury without considering changes in sport performance.

**PURPOSE:** To investigate an interdisciplinary approach to athlete development and its initial effects on injury rates and measures of performance in collegiate baseball.

**METHODS:** In October 2008, an NCAA Division I baseball team began working with a sport performance enhancement group (SPEG) which consists of a collaborative effort between sport coaches, sport medicine and sport science departments. Injury rates were calculated for each academic year from 2006/2007 through 2010/2011. As part of the athlete monitoring program provided through SPEG, peak force was measured using an isometric mid-thigh pull from 2008/2009 through 2010/2011. Team win percentage and home runs were also reported from 2003/2004 through 2010/2011.

**RESULTS:** Compared to 2006/2007 and 2007/2008, injury rates during 2008/2009 decreased 40% and 16%, 2009/2010 decreased 64% and 48%, while 2010/2011 decreased 33% and 6%. Team mean allometrically scaled isometric peak force (IPFa) increased each year from 2008/2009 through 2010/2011 (200.6 N, 229.6 N, 244.2 N). IPFa during 2009/2010 and 2010/2011 were significantly greater than 2008/2009 ( $p = .001$  and  $.002$ ). Win percentage increased from 2008/2009 through 2010/2011 (47%, 53%, 63%) and the 2010/2011 win percentage was higher than any other year since 2003/2004. Total team home runs during 2009/2010 and 2010/2011 were higher than any other season since 2003/2004.

**CONCLUSIONS:** These results seem to indicate that the collaborative efforts of SPEG were able to substantially reduce injury rates while increasing lab based and on-field performance.

---

**3071 Board #36 June 1 2:00 PM - 3:30 PM**  
**Influence Of Verbal Instruction For Center Of Gravity Position And Sex On Landing Muscle Activity**

Yuji Kanoh<sup>1</sup>, Masanori Takemura<sup>2</sup>, Koji Kurita<sup>3</sup>, Mitsuharu Kaya<sup>4</sup>, Motoaki Tsuchiya<sup>5</sup>, Junzo Tsujita<sup>2</sup>. <sup>1</sup>*Reseisha College of Medicine and Sport, Osaka, Japan.* <sup>2</sup>*Hyogo College of Medicine, Nishinomiya, Japan.* <sup>3</sup>*Physical Conditioning Production, Osaka, Japan.* <sup>4</sup>*Hyogo University of Health Science, Kobe, Japan.* <sup>5</sup>*MJ Consultant, Osaka, Japan.*  
(No relationships reported)

We have reported that the verbal instruction to move a center of gravity (COG) forward was increased ankle dorsiflexion and trunk anterior tilt during landing, which resulted in decreasing of quadriceps activity and increasing of the quadriceps/hamstring co-contraction EMG ratio (H/Q ratio) in male subjects.

**PURPOSE:** To evaluate the efficacy of verbal instructions on COG position to alter landing muscle activity in female subjects, and compared with the results using male subjects.

**METHODS:** A cross-over interventional study. Seven healthy female students [mean age (SD): 19.8 (0.7) yrs] performed 3 jumping and landing tasks: normal landing (N); landing after the instruction to move a COG forward (ANT); landing after the instruction to move a COG backward (POS). Sagittal plane motion, ground reaction force and electromyography of quadriceps (the vastus medialis (VM) and vastus lateralis (VL) muscles) and hamstring (the semitendinosus (ST) and biceps femoris (BF) muscles) were recorded during the landing phase (i.e. the interval from initial round contact to peak knee flexion). The H/Q ratio was calculated as the mean activation of ST and BF to mean activation VM and VL. For statistical analysis, 3-way ANOVA was used, and multiple comparisons by LSD with all variables and tasks as within-subject variable and sex as between-subject variable.

**RESULTS:** In female subjects, the results of ankle dorsiflexions (degree) at N, ANT, and POS were 24.4 (4.26), 26.2 (2.79), and 18.7 (6.47), knee flexions were 94.1 (6.08), 94.2 (4.15), and 92.0 (7.61), hip flexions were 97.3 (5.98), 94.3 (11.50), and 101.2 (7.66), and trunk anterior tilts were 27.6 (5.68), 26.3 (12.02), and 27.9 (9.39), respectively. In female and male, ankle dorsiflexion at POS was significantly smaller at N and ANT. Between sexes, knee and hip angle, and trunk anterior tilts in female were smaller than in male. The H/Q ratios in female were 43.4 (10.08), 38.7 (22.10), and 31.3 (21.56), respectively at N, ANT, and POS. The H/Q ratio had no sex difference (in male; 33.4 (15.72), 48.4 (18.92), and 27.1 (7.68), respectively). However, the H/Q ratio at POS was lower than at ANT.

**CONCLUSION:** Sex differences were not recognized in muscles activity during landing tasks. Therefore, changing of movement during landings should be emphasized as part of ACL injury-prevention programs.

**Reliability of Translation of Center of Force Using Portable Pressure Mapping Device in Older Adults**

Marjorie A. King<sup>1</sup>, Marie E. Trombulak<sup>1</sup>, William I. Eissler<sup>1</sup>, Ryan S. Kempson<sup>1</sup>, Thomas R. Boucher<sup>1</sup>, Jean P. Boucher, FACSM<sup>2</sup>, Jon D. Lurie<sup>3</sup>. <sup>1</sup>*Plymouth State University, Plymouth, NH.* <sup>2</sup>*University of Quebec, Montreal, Montreal, QC, Canada.* <sup>3</sup>*Dartmouth College, Hanover, NH.*  
(M.A. King: Contracted Research - Including Principle Investigator; Tekscan.)

Falls in the elderly are the most common cause of non-fatal injuries and hospital admissions from trauma (CDC 2011). Falls prevention screening is a critical element in the efforts to reduce these injuries. A portable testing device allows for the screen to be brought to the elderly rather than have them travel to a testing site.

**PURPOSE:** To determine the reliability of a portable measurement device, utilizing pressure mapping, for measuring translation of center of force in older adults.

**METHODS:** Forty-five (10 males; 35 females) physically active older adults ( $m = 71.8 + 4.6$  yrs.,  $m = 162.7 + 12.3$  cm,  $m = 75.6 + 17.96$  kg) participated in balance testing across three days after signing an informed consent document. Five measures across six conditions were tested within 24 to 72 hrs. of the previous test day. The variables of area, distance, variability (SD of distance), A-P and R-L excursion were computer generated under the six conditions of two-feet eyes open (2FEO), two feet eyes closed (2FEC), right foot eyes open (RFEO) and eyes closed (RFEC), left foot eyes open (LFEO) and eyes closed (LFEC). Subjects were asked to stand quietly for 30 seconds, for five trials, with arms relaxed at side, viewing an eye level target on the wall. A tracing of foot position was taken to ensure similar stance positioning within each day across trials.

**RESULTS:** ICCs (2,3) ranged from moderate (0.67 for variability 2FEO) to high (0.93 for distance 2FEC). Thirteen out of the 15 eyes open ICCs are at 0.73 or better, while all 15 eyes closed ICCs are at or over 0.71. One of the lowest ICC values (0.68) was for the LFEO condition with 41 of 45 being R foot dominant. The ICCs in all the other measurements and conditions range from good (0.71) to very good (0.93), for both eyes opened and closed.

**CONCLUSIONS:** This portable pressure mapping device provides several stable measurements for postural balance in an older adult population across days without constraining arm position. This device appears to be an appropriate tool to measure postural balance in the older adult. Future research should address validation of the variables to current clinical measures for falls risk. (NH-INBRE) NIH Grant Number 1P20RR030360-01 from the INBRE Program of the National Center for Research Resources (CFDA# 93.389)

---

**3073 Board #38 June 1 2:00 PM - 3:30 PM**  
**Effect Of Topical Menthol Gel On Power Output During 30-second High Intensity Anaerobic Exercise**

Will C. Hawkins, Michael E. Rogers, FACSM, Jeremy A. Patterson, FACSM, Cali K. Simmons. *Wichita State University, Wichita, KS.*  
(No relationships reported)

Menthol-based gels have been reported to reduce acute pain and reduce inflammation. However, the effect of topically applied menthol on power output during high intensity anaerobic bouts has not been studied.

**PURPOSE:** To determine if the topical application of menthol enhances power output during a 30-second sprint.

**METHODS:** 30 participants (14 male; 16 female) aged 20-38 ( $24.4 \pm 4.8$ ) years each completed two trials, one with menthol gel and one without, with 48 hours between trials. For the trial with gel, a dose of 1ml of gel for every 200 cm<sup>2</sup> sq cm of surface area was applied bilaterally to the thigh of each participant. For both trials, following a brief (2-3 sec) unloaded acceleration period, participants pedaled as fast as possible against a load of 0.75 kg • kg<sup>-1</sup> body mass for 30 sec. Peak and average power for the 30 sec trials, average power for each 5 sec interval, and overall fatigue index were recorded.

**RESULTS:** Mean  $\pm$  SD of the two trials are provided below. There were no significant differences ( $p < 0.05$ ) in any variable between trials. Additional analyses also revealed that, although males achieved greater power outputs compared to females, there were no differences between trials when grouped by gender.

**CONCLUSION:** Many products including topical gels have been theorized to improve human performance during high intensity anaerobic exercise. Menthol-based gels have long been accepted as a chemical cryotherapy agent but this study indicates that menthol gels do not increase power output. Future studies should explore the benefits of menthol based topical gels on recovery from DOMS.

**Comparison Of Isotonic And Isokinetic Measurements Of Extension/flexion Strength And Quadriceps-hamstring Ratio.**

Bryanne Bellovary<sup>1</sup>, Caitlin Glendenning<sup>1</sup>, Alexander R. Wolfe<sup>1</sup>, Erich J. Petushek<sup>2</sup>, Sarah K. Leissring<sup>1</sup>, Mitchell L. Stephenson<sup>1</sup>, Erika Purdy<sup>1</sup>, Bailey M. Hagner<sup>1</sup>, Randall L. Jensen, FACSM<sup>1</sup>. <sup>1</sup>Northern Michigan University, Marquette, MI. <sup>2</sup>Michigan Technological University, Houghton, MI.  
(No relationships reported)

Isokinetic dynamometry assessment is the preferred choice for quantifying quadriceps-hamstring ratio (Q/H), but at significant financial cost. Isotonic strength equipment such as flexion and extension weight machines are less expensive and may be a valid alternative for assessing Q/H ratio.

**PURPOSE:** To assess the relationship between 5 RM knee extension/flexion load and maximum Q/H torque ratios assessed using isotonic and isokinetic resistance machines, respectively.

**METHODS:** 21 Division II women soccer players (Mean  $\pm$  SD Age = 19.9  $\pm$  1.1 years; Height = 165.4  $\pm$  7.2 cm; Mass = 63.1  $\pm$  7.1 kg) were assessed for strength measures of the right leg. Knee extension and flexion strength was assessed using isotonic weight machines at angles of 75 and 50 degrees, respectively. Following appropriate warm up sets and two minutes rest, a 5 RM was obtained for knee extension and flexion. A Biodex System 4.0 isokinetic dynamometer was used to assess peak torque of knee extension/flexion at 300 degrees/s. A self-selected 5 rep warm up was performed, followed by one minute rest; 10 reps were then performed at maximum. Intraclass and Pearson Correlation analyses were used to assess the relationship between isotonic and isokinetic: knee extension, flexion and Q/H ratio measures. Additionally, a Paired t-Test was used to compare the differences between Q/H ratio assessed via isotonic and isokinetic machines.

**RESULTS:** Intraclass and Pearson Correlation Coefficients were respectively 0.562 and 0.396 for flexion (mean isotonic: 49.6  $\pm$  8.21 kg & isokinetic: 58.9  $\pm$  9.5 Nm); 0.861 and 0.756 for extension (mean isotonic: 58.2  $\pm$  10.0 kg & isokinetic: 76.1  $\pm$  9.7 Nm); and 0.745 and 0.595 for the Q/H ratio. The Biodex Q/H ratio was 1.31  $\pm$  0.20 while the weight machine ratio was 1.18  $\pm$  0.19. Significant mean differences were found between isotonic and isokinetic Q/H ratios ( $p < 0.01$ ).

**CONCLUSION:** Due to a significant difference and moderate correlation between measurement protocols, isotonic weight machines cannot be used to determine Q/H ratio. Variations in speed, range of motion and number of repetitions completed may all have influenced the differences between isotonic and isokinetic measurements.

**3075 Board #40 June 1 2:00 PM - 3:30 PM**

**Adaptations In Scapular Kinematics Among Pitchers And Position Players Over The Course Of A Baseball Season**

Robert Lynall<sup>1</sup>, Kevin Laudner, FACSM<sup>1</sup>, Keith Meister<sup>2</sup>. <sup>1</sup>Illinois State University, Normal, IL. <sup>2</sup>Texas Metroplex Institute for Sports Medicine and Orthopedics, Arlington, TX.  
(No relationships reported)

Baseball pitchers have been reported to have an increased prevalence of shoulder injury compared to position players. Such injuries have been empirically linked to scapular dyskinesis.

**PURPOSE:** To determine if throwing arm scapular kinematic differences exist between baseball pitchers and position players over the course of a baseball season.

**METHODS:** Sixteen asymptomatic professional baseball pitchers and 16 position players participated. We measured scapular upward rotation at 0°, 60°, 90°, and 120° of humeral elevation, as well as forward scapular posture prior to (covariate) and at the conclusion (dependent variable) of a 140 game baseball season. We conducted separate 1-way analyses for all measurements ( $p < .01$ ).

**RESULTS:** The covariate adjusted means for position players' scapular upward rotation at 0°, 60°, 90°, and 120° of humeral elevation were 3.9°  $\pm$  4.8°, 11.6°  $\pm$  4.7°, 24.4°  $\pm$  2.36°, and 38.5°  $\pm$  2.7°. The covariate adjusted means for the pitchers' scapular upward rotation at each humeral elevation angle were 4.9°  $\pm$  2.7°, 8.7°  $\pm$  6.4°, 20.7°  $\pm$  5.0°, and 37.6°  $\pm$  3.8°. The position players had significantly greater scapular upward rotation at 60° ( $p = .007$ , between group mean difference = 2.9°, effect size = .45) and 90° ( $p = .006$ , between group mean difference = 3.6°, effect size = .73) of humeral elevation compared to the pitchers. There were no significant differences for scapular upward rotation at 0° ( $p = .93$ ) or 120° ( $p = .29$ ) of humeral elevation. The covariate adjusted means for the position players' and pitchers' forward scapular posture were 0.54mm  $\pm$  0.44mm and 0.30mm  $\pm$  0.69mm. Forward scapular posture was not significantly different between groups ( $p = .23$ ).

**CONCLUSIONS:** Our results show that position players have significant increases in scapular upward rotation at 60° and 90° of humeral elevation at the conclusion of the baseball season compared to pitchers. Due to the repetitive arm elevation required for the throwing motion over the course of a season, the increased scapular upward rotation demonstrated by position players may be beneficial in reducing their risk of injury. However, this lack of increase in pitchers may make them more susceptible to such injuries and may partially explain their higher incidence of shoulder injury compared to position players.

**Electromyography Comparison Of Three Isometric Lumbar Spine Extensor Strengthening Exercises**

Alyssa Smyres<sup>1</sup>, Aaron W. Johnson<sup>1</sup>, Ulrike H. Mitchell<sup>1</sup>, Joseph W. Myrer<sup>1</sup>, Jeffery B. Feland<sup>1</sup>, Matt K. Seeley<sup>1</sup>, Caisa Brooks<sup>1</sup>, Brett Mortensen<sup>1</sup>, Jim Anderson<sup>2</sup>.  
<sup>1</sup>Brigham Young University, Provo, UT. <sup>2</sup>Central Utah Clinic, Provo, UT.  
(No relationships reported)

Low back pain is a common issue among adults. Muscle weakness is related to pain. During rehabilitation patients perform back strengthening exercises to help alleviate their back pain. Some patients are not able to assume a prone unsupported lumbar extension position used to strengthen back muscles. To address this issue, two new sitting lumbar extension exercises have been introduced; assessment of their efficacy is important.

**PURPOSE:** To compare 3 lumbar extensor strengthening exercises' activation of lumbar erector spinae (LES), lumbar multifidus (LM), and external oblique (EO).

**METHODS:** Eighteen healthy people (age 31 ± 13 years, weight 68.6 ± 11.7 kg, height 1.77 ± .08 m) with no back pain were recruited to participate in the study. Three EMG surface electrodes were placed on participants' right back and abdomen over the LM, EO, and LES muscles. Each participant performed three maximal voluntary isometric contraction tests in order to normalize the data for comparison. Three isometric exercises were then performed in random order; muscle activation was recorded for each of the three exercises: 1) Prone unsupported lumbar extension; 2) sitting isometric lumbar extension against a resistance band with varying direction of resistance; 3) sitting isometric lumbar extension against a weighted pulley. EMG data were analyzed using customized software in Matlab. Repeated measures ANOVA was performed (SPSS 19).

**RESULTS:** No significant differences in muscle activation were seen across exercises (p > .05 in all comparisons).

**CONCLUSIONS:** Muscle activation was comparable across the three exercises. Each of these exercises may be used to strengthen lumbar extensors.

Normalized EMG (% MVIC) comparison of three isometric lumbar strengthening exercises

|                             | Prone Unsupported Extension | Sitting Band | Sitting Pulley |
|-----------------------------|-----------------------------|--------------|----------------|
| Right Lumbar Erector Spinae | 17.2 ± 8.9                  | 18.3 ± 7.8   | 17.5 ± 7.6     |
| Right Lumbar Multifidus     | 8.4 ± 6.4                   | 11.5 ± 7.4   | 15.3 ± 9.4     |
| Right External Oblique      | 6.8 ± 4.7                   | 6.2 ± 3.6    | 10.4 ± 5.3     |

3077 Board #42 June 1 2:00 PM - 3:30 PM

**The Effects Of Sternoclavicular Joint Icing On Balance Performance Of Weight Lifting Sportsmen**

Cheng-Hsiu Lai<sup>1</sup>, Yi-Liang Cheng<sup>1</sup>, Yu-Tsai Tu<sup>2</sup>, Shih-Wei Chou<sup>2</sup>. <sup>1</sup>Taipei Physical Education College, Taipei City, Taiwan. <sup>2</sup>Chang Gung Memorial Hospital, Taipei City, Taiwan. (Sponsor: Chia-Hua Kuo, FACSM)  
(No relationships reported)

Weight lifting involves weight loading to the neck, potential acute or chronic neck injuries are likely.

**PURPOSE:** To evaluate the balance outcomes of the weight lifting sportsmen after the icing effects on the sternoclavicular joints.

**METHOD:** A 2x2 factorial design between group and pre-post factors was conducted. We recruited 25 weight lifting sportsmen, randomly assigned into icing group (number: 13; age, 20.3 ± 1.2 years; body height, 168.4 ± 6.9 cm; body weight, 62.1 ± 11.2 kg) and non-icing group (number: 12; age, 21.6 ± 1.2 years; body height, 167.0 ± 8.8 cm; body weight, 82.0 ± 10.1 kg). A computerized posturography, the Smart Balance Master (Neuro Com Inc., Clackamas, Oregon, USA) was selected to acquire postural stability measurement under defined conditions. After icing intervention, the boxers were measured again for their balance performance.

**RESULT:** In the sensory organization test (SOT), statistic significance was showed in conditions 1, 2, 6 and composite score of the main group effect, conditions 3, 4, 6 and composite score of the main pre-post effect, and all condition except condition 5 and composite score of the interaction effect. No statistic significance was noted in sensory analysis. In post-hoc analysis for significant interaction, significant pre-post effect occurred mainly in the icing group. No significant group difference occurred before icing, but significant group difference did after icing.

**CONCLUSION:** Icing over the sternoclavicular joints of the weight lifting sportmen may help their balance performance in terms of SOT.

3078 Board #43 June 1 2:00 PM - 3:30 PM

**Clinical Examination Of The Shoulder In A Group Of Disabled Athletes In Wheelchair**

Bruno Sesboue<sup>1</sup>, Bertrand Bouju<sup>1</sup>, Jean-Yves Guinestre<sup>1</sup>, Christophe Hulet<sup>2</sup>. <sup>1</sup>IRMS, CAEN, France. <sup>2</sup>Orthopedic Surgery, CAEN, France.  
(No relationships reported)

The prevalence of the use of a wheelchair, manual or electric, in 1999 was 62 per 10,000 inhabitants in France, about 361,000 users. The shoulder joint is the one most often complain manual wheelchair users.

**PURPOSE:** The aim of this work is to justify an assessment of the shoulder in the follow-up of the disabled to prevent the occurrence of lesions that cause a major degradation of their autonomy or, alternatively, to take charge as soon as these injuries.

**METHODS:** Twelve disabled athletes, 10 males and 2 females (yrs: 46.5 ± 11.5, weight: 71.4 ± 16.5 kg, in wheelchair since 16.4 ± 8.1 yrs) volunteered for this study and signed an informed consent. They were handbikers (9) or basketball players (3), in leisure or in competition. They were all right-handed. We have done a clinical examination and an evaluation of Constant's score and DASH (disabilities of the arm, shoulder and hand) score. We have also made an echography of the joints, always by the same operator.

**RESULTS:** Seven sportsmen reported a painful episode earlier and 6 had a current pain. 10 had signs of injury of the rotator cuff and 6 signs of impingement. The Constant's score was not different for the right arm and for the left one (99 vs 92; p > 0.05) and the DASH score was at 8.83. There was an aspect of ultrasonic lesion for 8 patients. In the literature, pain is present in 31 to 73% (50% in this study) of the subjects and rotator cuff lesions in 66% vs 92% in our sample. Functional scores seem less pertinent for disabled sportsmen likely because of their strength and of a high pain threshold.

**CONCLUSIONS:** Because of this high prevalence of shoulder pain, we think that the clinical examination of the shoulder has to be incorporated to the annual assessment of disabled sportsmen. We have also to educate sportsmen to accomplish the good movement on the wheelchair.

3079 Board #44 June 1 2:00 PM - 3:30 PM

**Benefits of Partnered Strength Training in Couples Coping with Prostate Cancer: The Exercising Together Project**

Kerri M. Winters-Stone, FACSM, Karen S. Lyons, Jessica Dobek, Lillian M. Nail, Jill A. Bennett, Tomasz M. Beer. Oregon Health & Science University, Portland, OR.  
(No relationships reported)

Prostate cancer impacts not only the patient but also the family and particularly, spouses that provide care. Physical health is compromised in prostate cancer survivors (PCS) and in spouse caregivers, but no intervention has addressed this problem in both partners simultaneously.

**PURPOSE:** To evaluate the benefits of a 6-month partnered strength-training program, Exercising Together (ET), on physical function and body composition in PCS and spouses.

**METHODS:** 64 couples, consisting of an older PCS (>60 years old) and his spouse, were randomized to the ET program or usual care (UC). Data from couples completing the study were used for preliminary analysis (ET: n=32, UC: n=27). Outcomes were upper and lower body strength measured by 1-RM bench press (BPmax; lbs) and leg press (LPmax; lbs) and timed 5-time chair rise and sit (CHAIR; sec); gait by 4m walk speed (UW; m/s); physical function by the physical performance battery (PPB); and body composition by DXA (% body fat (%BF); lean mass (LM; kg), fat mass (FM; kg). Repeated measures ANCOVA, controlling for age, tested for significant group differences over time on each outcome within patients and spouses. The impact of androgen deprivation therapy (ADT) on patient outcomes was explored by repeating analyses excluding men on ADT (n=11).

**RESULTS:** Among the full sample of PCS significant group differences were found for BPmax only (p<0.03); however, when excluding PCS on ADT, significant group differences were found for BPmax (ET: +13.0 lbs vs. UC: +6.1 lbs, p<0.03); LPmax (ET: +12.8 lbs vs. UC: +3.9 lbs, p<0.01) and %BF (ET: -0.7% vs. UC: +0.2% p=0.04). Among spouses, significant group differences were found for BPmax (ET: +8.0 lbs vs. UC: -0.2 lbs; p<0.001), LPmax (ET: +11.7 lbs vs. UC: +2.3 lbs; p<0.001), CHAIR (ET: -1.1 sec vs. UC: +0.3 sec; p<0.03), and PPB (ET: +0.5 vs. UC: -0.1; p<0.03), with near significance for LM (ET: +0.6 kg vs. UC: -0.1 kg; p=0.05).

**CONCLUSIONS:** Our preliminary analysis suggests that Exercising Together may be an effective and efficient strategy to maintain physical health in couples coping with prostate cancer.

**Lack of Endogenous Pain Inhibition During Exercise In People With Chronic Whiplash: An Experimental Study**

Jessica Van Oosterwijk<sup>1</sup>, Jo Nijs<sup>1</sup>, Mira Meeus<sup>1</sup>, Michel Van Loo<sup>2</sup>, Lorna Paul<sup>3</sup>. <sup>1</sup>Vrije Universiteit Brussel, Brussel, Belgium. <sup>2</sup>Red Cross, Antwerp, Belgium.

<sup>3</sup>University of Glasgow, Glasgow, United Kingdom. (Sponsor: Romain Meeusen, FACSM)

(No relationships reported)

Evidence for altered central pain processing and central sensitization in chronic whiplash associated disorders (CWAD) is accumulating. Dysfunctional descending inhibitory action is one of the major characteristics of central sensitization and has been studied during exercise in some chronic pain conditions but no data regarding the response of people with CWAD to exercise are available.

**PURPOSE:** To examine the efficacy of endogenous pain inhibitory systems during exercise and exercise response in CWAD patients during two different types of exercise.

**METHODS:** Twenty-two women with CWAD and 22 healthy sedentary

controls performed a submaximal and a self-paced, physiologically limited exercise test on a cycle ergometer on two separate occasions. The exercise tests were undertaken with cardiorespiratory monitoring. Before and after the exercise bouts, subjects filled out questionnaires to assess health status, and underwent pain pressure threshold (PPT) measurements. Throughout the study, subjects' activity levels were assessed using accelerometry in order to monitor potential influences of daily activity levels. Possible changes in any of the outcome measures in response to exercise were compared between the two groups, and between the two types of exercise, using repeated measures ANOVA.

**RESULTS:** In CWAD PPTs decreased following submaximal exercise, whereas they increased in healthy subjects. The same effect was established in response to the self-paced, physiologically limited exercise, with exception of the PPTs measured at the calf which increased. A worsening of the CWAD symptom complex was reported post-exercise. Fewer symptoms were reported in response to the self-paced, physiologically limited exercise. In addition, no differences in submaximal exercise capacity or daily physical activity were observed between people with CWAD and controls.

**CONCLUSIONS:** The present study is the first to examine and suggest an impaired descending endogenous pain inhibition during exercise in CWAD patients, and hence provides additional evidence for the presence of central sensitization in CWAD. Submaximal exercise triggers post-exertional malaise, while a self-paced and physiologically limited exercise will trigger less 'severe' symptoms, and therefore seems more appropriate for CWAD patients.

**3081** Board #46 June 1 2:00 PM - 3:30 PM

**Objective Quantification of Forces Used with Joint Play and Manual Therapy Techniques for the Shoulder**

J. E. King<sup>1</sup>, George J. Davies<sup>1</sup>, Michael Tankovich<sup>1</sup>, Cale Jacobs<sup>2</sup>, Bryan L. Riemann<sup>1</sup>. <sup>1</sup>Armstrong Atlantic State University, Savannah, GA. <sup>2</sup>ERMI Medical Devices, Atlanta, GA. (Sponsor: T. Jeff Chandler, FACSM)

(No relationships reported)

Physical therapists regularly perform joint mobilizations on patients with glenohumeral (GH) hypomobility. Currently, no studies have measured the forces applied by clinicians during GH joint mobilizations leaving a need to objectively document the actual applied forces.

**PURPOSE:** To examine the forces applied by a clinician during passive range of motion assessments (PRMA).

**METHODS:** A hand held dynamometer (LafayetteFAB12-0380) recorded force applied during each PRMA on 30 (15 males, 15 females, age 23.4±2.3yrs) subjects. Exclusion criteria: previous shoulder surgery or injury within the last year. Dominant (D) and nondominant (ND) shoulder of each subject were tested with three repetitions of four PRMA: anterior glide (AG), posterior glide (PG), external rotation (ER), and internal rotation (IR). Testing positions were randomized and data collection was blinded from the senior author who performed all PRMA. For ER and IR PRMA, forces were multiplied by the olecranon to ulnar styloid process distance to determine resulting torques. Average forces across the three repetitions for each PRMA were computed along with correlational analyses between each PRMA with height, mass, and body mass index. Separate gender by limb ANOVA were conducted for each PRMA; statistical significance considered  $\alpha < .05$ .

**RESULTS:** No significant relationships for any of the correlational analyses ( $r = -.27$  to  $.23$ ). No significant differences between genders. No statistically significant differences between limbs for ER (D=15.3±5.0Nm, ND=14.1±3.7Nm,  $P=.072$ ) and IR (D=13.4±3.4Nm, ND=13.2±3.6 Nm,  $P=.482$ ) PRMA. For both the AG (D=124.5±15.7kg, ND=131.3±16.7,  $P=.051$ ) and PG (D=184.2±28.2 kg, ND=148.0±14.7kg  $P<.001$ ) PRMA, the ND was greater than the D, however, statistical significance was only attained for PG.

**CONCLUSION:** This study provides some objective data quantifying the forces and torques used during PRMA; however, further research is needed quantifying the forces clinicians apply, along with the forces needed to create a plastic deformation in non-contractile tissue with mobilization techniques for individuals with GH hypomobility. In addition, testing was performed on healthy active individuals; the extent to which these results reflect persons with pathological conditions is unknown.

**Binge Drinking Following Resistance Exercise: Effect on Muscle Power Recovery**

Nosa O. Idemudia, Jakob L. Vingren, Harsh H. Buddhadev, Anthony A. Duplanty, Kiannah R. Williams, Joe Chua, David W. Hill, FACSM. University of North Texas, Denton, TX.

(No relationships reported)

Alcohol impairs recovery of isokinetic performance following muscle damaging resistance exercise but no knowledge exists regarding alcohol's effect on recovery of performance in explosive isotonic movements following resistance exercise that induces only limited muscle damage.

**PURPOSE:** To investigate the effect of alcohol on recovery from resistance exercise for explosive performance measures.

**METHODS:** Nine healthy men (Mean ± SD: 24.8 ± 3.2 years, 176 ± 7 cm, 86.4 ± 14.6 kg) completed 2 identical acute heavy resistance exercise tests (AHRET) separated by 1 week. The AHRET consisted of 6 sets of 10 repetitions of smith machine squats at 80% of 1-repetition maximum (1-RM) with 2 min of rest between sets. From 10-20 minutes post-AHRET participants

consumed either 190 proof grain alcohol (EtOH) equal to 1.086 g of alcohol per kg lean mass (82-122 ml total) or no alcohol (Placebo) diluted in an artificially sweetened and calorie free beverage. The participants were blinded to conditions and the order of conditions was counter-balanced. Blood alcohol concentration (BAC) was measured using a breathalyzer. Sixty-five minutes pre-exercise, participants ingested a meal replacement beverage (33.5 kJ per kg body mass). Before the AHRET (PRE) and the following morning (AM), participants performed three high pulls and three bench press throws with 30% of 1-RM, and 10 consecutive vertical jumps, all at maximal effort. Peak power was measured for all exercises. Muscle soreness was measured using analog scales at PRE and AM.

**RESULTS:** BAC peaked 60-90 min post-exercise in all participants ( $0.084 \pm 0.017$  g·dl<sup>-1</sup>) on alcohol ingestion days. No effect of alcohol was found for peak power in the high pull (EtOH, PRE:  $1658 \pm 432$  W, AM:  $1659 \pm 260$  W; Placebo, PRE:  $1599 \pm 397$  W, AM:  $1579 \pm 301$  W), bench press throw (EtOH, PRE:  $1120 \pm 276$  W, AM:  $1105 \pm 295$  W; Placebo, PRE:  $1119 \pm 202$  W, AM:  $1089 \pm 257$  W), or vertical jump (EtOH, PRE:  $52.6 \pm 13.5$  W·kg<sup>-1</sup>, AM:  $48.5 \pm 6.3$  W·kg<sup>-1</sup>; Placebo, PRE:  $52.2 \pm 9.4$  W·kg<sup>-1</sup>, AM:  $47.9 \pm 9.0$  W·kg<sup>-1</sup>). Leg soreness increased moderately from PRE to AM with no difference between conditions.

**CONCLUSION:** A moderate BAC does not appear to affect explosive upper or lower body power capability on the morning following a heavy squat session that induces only limited muscle damage.

**3083** Board #48 June 1 3:30 PM - 5:00 PM

**Oral Nicotine Administration Affects Muscular Force and Anaerobic Performance but Not Vertical Power.**

Toby Mündel, Marine Machal. *Massey University, Palmerston North, New Zealand.* (Sponsor: Timothy Derek Mickleborough, FACSM)

(No relationships reported)

We have previously demonstrated that nicotine administration improves cycling time to exhaustion but does not influence 1h cycling time-trial performance. Nicotine remains neither a banned substance nor restricted (i.e. available over-the-counter), but since previous studies only assessed endurance exercise performance we sought to determine whether shorter duration exercise might be influenced by prior nicotine administration.

**PURPOSE:** To determine whether acute oral nicotine administration affects measures of muscle force, vertical power or anaerobic performance.

**METHODS:** Nine physically active males ( $24 \pm 3$  y;  $78 \pm 15$  kg;  $179 \pm 13$  cm) completed three trials in which 30 min prior to testing subjects chewed 2 mg (LO) or 4 mg (HI) of nicotine gum or a flavor-matched placebo (PLA) gum, the order of which was randomized. During each trial, measures of peak and average peak isometric, concentric and eccentric leg extensor force were made followed by 3 vertical counter-movement jumps and a 30 sec Wingate test. Heart rate was measured before and after administration and venous blood samples were obtained for determination of pH, HCO<sub>3</sub><sup>-</sup> and to confirm the presence of nicotine.

**RESULTS:** No order effects were observed for any performance or physiological data, whilst nicotine was confirmed ( $n = 3$ ). Peak and average peak isometric and eccentric force were significantly affected (LO > PLA; all  $p < 0.05$ ) whilst peak and average peak concentric force were similar across trials (both  $p > 0.05$ ). Counter-movement jump height was similar across trials ( $p > 0.05$ ). Peak power (LO < PLA;  $p < 0.05$ ) and anaerobic fatigue (LO & HI < PLA;  $p < 0.05$ ) during the Wingate test were significantly affected but anaerobic capacity remained similar across trials ( $p > 0.05$ ). pH and HCO<sub>3</sub><sup>-</sup> showed similar responses across trials (both  $p > 0.05$ ) although both were reduced following the Wingate (both  $p < 0.05$ ), whilst heart rate was significantly affected (LO & HI > PLA; both  $p < 0.05$ ).

**CONCLUSION:** 2 mg nicotine administration via gum 30 min prior to exercise significantly improved isometric and eccentric leg extensor force and reduced anaerobic fatigue and peak power during a 30 sec Wingate test.

**3084** Board #49 June 1 3:30 PM - 5:00 PM

**Sports Activity And Use of Tobacco Products Among Young Males in Finland in 1999-2010**

Matti J. Mäntysaari<sup>1</sup>, Ville Mattila<sup>2</sup>, Susanna Raisamo<sup>3</sup>, Harri Pihlajamäki<sup>4</sup>, Arja Rimpelä<sup>3</sup>. <sup>1</sup>*Aeromedical Centre, Helsinki, Finland.* <sup>2</sup>*Tampere University Hospital, Tampere, Finland.* <sup>3</sup>*University of Tampere, Tampere, Finland.* <sup>4</sup>*University of Helsinki, Helsinki, Finland.*

(No relationships reported)

Certain types of sport have been suggested to explain differences in youth tobacco use, e.g. in USA smokeless tobacco has been linked to baseball.

**PURPOSE:** The association between sports activity (intensity and type of sport) and the current use of snus (Swedish snuff), cigarette smoking, and the combined use of these tobacco products (dual use) was studied among young Finnish males.

**METHODS:** 16,746 male conscripts completed a survey during the first days of their conscription during the years 1999-2010 (median age 19, response rate 95%). Main outcome measures were self-reported daily/occasional use of snus, cigarette smoking, and dual use. Logistic regression analysis was used to assess the association between sport activity, type of sport, and several socio-economic background variables.

**RESULTS:** Over the study period (1999-2010), cigarette smoking decreased from 42% to 34%, snus use increased from 5% to 12%, and dual use increased from 7% to 13% ( $p < 0.001$ ). Regular competitive sports training (defined as high-intensity sports activity) was positively associated with use of snus (odds ratio [OR] 10.2; 95% confidence interval [CI]: 7.8-13.5) and negatively with cigarette smoking (OR 0.2; 95% CI: 0.1-0.3). In multivariate models team sports were clearly associated use of snus. Ice hockey showed the strongest association with snus use (OR 1.6; 95% CI: 1.4-1.9) and dual use (OR 2.0; 95% CI 1.8-2.3), followed by other team sports for snus use (OR 1.5; 95% CI: 1.3-1.8) and dual use (OR 1.8; 95% CI: 1.6-2.0).

**CONCLUSIONS:** The intensity and type of training were clearly associated with snus use. Competitive sports training was positively associated with use of snus. Team sports were associated with increased use of snus and combined use of snus and cigarettes. These findings should be taken into account when planning and implementing preventive strategies.

**3085** Board #50 June 1 3:30 PM - 5:00 PM

**The Effects of Momordica Charantia Supplement Diets and Endurance Training on Bone Material in Rats**

Ting-yu Lin<sup>1</sup>, Young-Yu Liang<sup>1</sup>, Tsang-Hai Huang<sup>1</sup>, Sandy S. Hsieh<sup>2</sup>, Hung-Hao Wang<sup>2</sup>. <sup>1</sup>*National Cheng Kung University, Tainan, Taiwan.* <sup>2</sup>*National Taiwan Normal University, Taipei, Taiwan.*

(No relationships reported)

Momordica charantia (MC) supplement has been verified regarding its capability in activating peroxisome proliferate-activated receptors (PPARs) downstream pathways. PPAR downstream pathways are related to skeletal homeostasis. Thus, it would be valuable to investigate MC supplement on bone metabolism. Besides, whether regular exercise interacts with MC on bone metabolism is also unknown.

**PURPOSE:** To investigate the effects of endurance exercise (EXE) and MC supplement diets on bone qualities in growing rats.

**METHODS:** Seventy-two male SD rats (7 weeks old) were randomly divided into six groups, which were the 0%MC, 5%MC, 8%MC, 0%MC+EXE, 5%MC+EXE, and 8%MC+EXE groups ( $n=12$  for each). After six-week experimental period, all animals were sacrificed. Bone samples were collected and stored for biomechanical properties analysis. Two-way (MC×EXE) ANOVA was used for statistical analysis ( $\alpha=.05$ ).

**RESULTS:** In exercise main effect, exercise groups showed significantly lower body weight (g) (EXE:  $393.0 \pm 6.6$  < non-EXE:  $422.0 \pm 6.6$ ,  $p < 0.05$ ) and lower epididymis fat tissue weight (g) (EXE:  $0.96 \pm 0.06$  < non-EXE:  $1.64 \pm 0.06$ ,  $p < 0.05$ ). In MC main effects, the MC supplement groups showed significant lower values in cortical bone thickness (mm) (8%MC:  $0.69 \pm 0.10$  & 5%MC:  $0.70 \pm 0.10$  < 0%MC:  $0.74 \pm 0.10$ ,  $p < 0.05$ ), the area of cortical bone (mm<sup>2</sup>) (8%MC:  $7.92 \pm 0.15$  & 5%MC:  $8.29 \pm 0.15$  < 0%MC:  $8.76 \pm 0.16$ ,  $p < 0.05$ ), the area of total cross section (mm<sup>2</sup>) (8%MC:  $13.65 \pm 0.32$  & 5%MC:  $14.06 \pm 0.32$  < 0%MC:  $14.99 \pm 0.33$ ,  $p < 0.05$ ), and yield load (N) (8%MC:  $117.1 \pm 2.9$  & 5%MC:  $117.7 \pm 2.9$  < 0%MC:  $128.4 \pm 3.0$ ,  $p < 0.05$ ). Regarding MC×EXE interaction, significant level was shown in fracture load (N) (*post hoc* comparison of simple main effects: 5%MC:  $130.3 \pm 30.8$  < 5%MC+EXE:  $143.5 \pm 13.1$ ; 0%MC:  $171.0 \pm 22.6$  > 5%MC:  $130.3 \pm 30.8$  & 8%MC:  $137.0 \pm 16.0$ ,  $p < 0.05$ ), stiffness (0%MC:  $300.8 \pm 75.1$  > 0%MC+EXE:  $249.3 \pm 30.0$ ; 5%MC:  $220.1 \pm 37.9$  < 5%MC+EXE:  $254.3 \pm 55.3$ ; 0%MC:  $300.8 \pm 75.1$  > 5%MC:  $220.1 \pm 37.9$  & 8%MC:  $232.5 \pm 37.0$ ,  $p < 0.05$ .) and cross-sectional moment of inertia (0%MC:  $12.35 \pm 3.10$  > 5%MC:  $9.34 \pm 1.58$  & 8%MC:  $9.17 \pm 1.93$ ,  $p < 0.05$ ).

**CONCLUSIONS:** There seemed to be negative effects of the MC supplement diets on bone materials. Endurance exercise showed modification on MC's effects in bone material.

**Stage Specific Effects Of Curcumin On Intestinal Polyp Development In ApcMin/+ Mice**

Jamie L. McClellan, Jennifer L. Steiner, Reilly Enos, J. Mark Davis, FACS, E. Angela Murphy. *University of South Carolina, Columbia, SC.*  
(No relationships reported)

Numerous pre-clinical studies argue for curcumin's chemopreventive potential in colon cancer. In fact, we recently reported that curcumin can reduce polyp size and number in the Apc<sup>Min/+</sup> mouse model of intestinal tumorigenesis. However, there is no evidence on its stage-specific effects in colon cancer.

**PURPOSE:** Our overall purpose was to conduct a prevention study (to reduce disease incidence), intervention study (to reduce disease progression in animals with incident disease), and prevention plus intervention study (to examine the prevention to progression continuum) with a 0.2% curcumin diet.

**METHODS:** Male Apc<sup>Min/+</sup> mice were randomly assigned to either placebo or 0.2% curcumin diet. Mice were further assigned to their specific treatment stage as follows: Prevention (4-11 wks), Intervention (11-18wks), or Prevention + Intervention (4-18 wks). Tissues were collected at 18 weeks of age and intestines were analyzed for polyp number and size (>2 mm, 1-2 mm, and <1 mm).

**RESULTS:** The Prevention treatment reduced overall intestinal polyps by 26% (P<0.05) that was largely attributed to a decrease in the number of medium sized polyps (52%) (P<0.05). Similarly, the Prevention + Intervention treatment reduced total polyps by 26% (P<0.05) and medium polyps by 44% (P<0.05). However, the Intervention treatment increased overall polyp number by 56% (P<0.05), medium sized polyps by 47% (P<0.06) and large sized polyps by 62% (P<0.05).

**CONCLUSION:** While curcumin's chemopreventive effects in colon cancer have been well documented there have been no studies that have examined the stage-specific responses. We show a beneficial effect of curcumin on polyp progression when administered as a Prevention or Prevention + Intervention treatment. However, administration of curcumin as an Intervention results in an increase in polyp number and size. These findings highlight the importance of examining stage-specific effects of various bioactive dietary components in order to determine appropriate timing of effective treatment.

This work was supported by a grant from the National Cancer Institute (R21 CA135377) to E.A.M.

**Prevalence of Combining ADHD Medications with Exercise Among College Students**

Jennifer M. Rivero, Kirsten Granados, Richard Viskochil, Cameron C. Carter, Barry Braun, FACS. *University of Massachusetts, Amherst, MA.*  
(No relationships reported)

Attention-deficit/hyperactivity disorder (ADHD) is commonly treated using stimulant medications. Use of these medications in combination with intense and/or prolonged exercise can elevate body temperature and blood pressure more than exercise alone. It is well documented that ADHD medications are used without a prescription on college campuses for the purposes of enhancing academic performance, frequently in conjunction with energy drinks that are typically high in caffeine. Combining exercise with ADHD medications and energy drinks may be dangerous but the scope of the potential problem is unknown.

**PURPOSE:** To determine the prevalence of college students who exercise while using ADHD medications, with or without energy drinks, on the University of Massachusetts Amherst campus.

**METHODS:** 10,000 full-time undergraduate students at the University of Massachusetts, Amherst were randomly selected from a list generated by the University's Registrar office. These students were invited (via e-mail) to participate in an online survey. The survey was composed of 5 questions regarding the use of ADHD medications and frequency with which students combined them with exercise and/or energy drinks.

**RESULTS:** 517 students (5.2%) responded to the surveys sent. 25.3% of respondents reported taking ADHD medications, of which 71.0% (18.0% of total respondents) reported taking them without a prescription. Of the 93 students who took ADHD medications without a prescription, 37 reported combining the medications with exercise and 19 of those students reported also consuming an energy drink within 3 hours of exercising.

**CONCLUSION:** Although preliminary, data from over 500 undergraduate students at UMass Amherst suggests that 7.1% (1,526 students if the sample is representative) are exercising while using ADHD medications without a prescription. With so many students using ADHD medications with no medical oversight, understanding the potential health risks of combining these medications with exercise and energy drinks is imperative.

**Erythropoietin Administration Acutely Stimulates Resting Energy Expenditure In Healthy Young Men**

Britt Christensen, Mikkel H. Vendelbo, Thomas Krusenstjerna-Hafstrom, Michael Madsen, Steen B. Pedersen, Niels Jessen, Niels Moller, Jens Otto L. Jorgensen. *Aarhus University Hospital, Aarhus C, Denmark.*  
(No relationships reported)

**PURPOSE:** Treatment with recombinant human erythropoietin (rHuEpo) improves insulin sensitivity in patients with end-stage renal disease. Furthermore, animal studies indicate that Epo increases fat oxidation. However, the metabolic effects of rHuEpo have never been experimentally studied in healthy humans. The aim was to investigate the effects of an acute rHuEpo bolus on substrate metabolism and insulin sensitivity in healthy young men.

**METHODS:** Ten healthy young men (Age: 23 ± 0.7, BMI: 23.5 ± 0.4 kg/m<sup>2</sup>, Hemoglobin: 9.5 ± 0.2 mmol/l, Hematocrit: 44.8 ± 0.6 %) were recruited after written informed consent in accordance with the declaration of Helsinki. They were studied in a single-blinded, randomized, cross-over design with a 2-week wash-out period and received 400 IU/kg rHuEpo or placebo on two separate occasions. Substrate metabolism was evaluated by indirect calorimetry and amino acid and glucose tracer infusions, insulin sensitivity with a hyperinsulinemic euglycemic clamp, and PCR and western blotting was performed on skeletal muscle biopsies measured protein expression and content, respectively.

**RESULTS:** Resting energy expenditure (REE) increased significantly after rHuEpo [Basal; 1863.3 ± 67.2 (kcal/day) (placebo) vs. 2041.6 ± 81.2 (rHuEpo) p<0.001, Clamp; 1903.9 ± 68.3 (placebo) vs. 2015.7 ± 114.4 (rHuEpo), p=0.03]. This increase in REE could not be explained by changes in mRNA levels of uncoupling protein 2 or 3. Fat oxidation in the basal state tended to be higher after rHuEpo, and the relative degree of suppression of fat oxidation during the clamp was higher during rHuEpo treatment as compared to placebo [Basal; 0.71 ± 0.06 (mg/kg/min) (placebo) vs. 0.97 ± 0.10 (rHuEpo) p=0.053, Clamp; 0.44 ± 0.07 (placebo) vs. 0.55 ± 0.10 (rHuEpo), p=0.401, Interaction: p=0.033]. These changes could not be explained by changes in mRNA levels of CPT1 and PPARα, or AMPK and ACC protein phosphorylation, all proteins involved in fat metabolism. Insulin stimulated glucose disposal, glucose metabolism, and whole-body and forearm protein metabolism did not change significantly in response to rHuEpo.

**CONCLUSIONS:** A single injection of rHuEpo acutely increases REE in healthy human subjects. This calorogenic effect is not accompanied by distinct alterations in the pattern of substrate metabolism or insulin sensitivity.

---

**3089**     *Board #54*     **June 1**     **3:30 PM - 5:00 PM**

**Australian Coaches' Knowledge Of Prohibited Substances And The Wada Anti-doping Policy**

Rhonda Orr, Matthew Grassmayr, Rona Macniven, Anne Grunseit, Adrian Bauman, Cloe Cummins. *The University of Sydney, Sydney, Australia.* (Sponsor: Mike Climstein, FACS)  
(No relationships reported)

Athletes consult coaches as a trusted source of knowledge about performance enhancing and prohibited substances and anti-doping. Yet, little is documented of coaches' knowledge in these areas.

**PURPOSE:** To determine Australian coaches' knowledge of the WADA Prohibited Substances List and Anti-Doping Policy.

---

**METHODS:** A psychometrically tested questionnaire with mostly close-ended questions (yes/no/not sure) (91%) was used. A list of 30 substances comprising prohibited, recreational, nutritional and therapeutic substances and methods were required to be identified as banned at all times, banned in competition only or Don't Know in accordance with the WADA Prohibited Substances List. Questions probed knowledge of the Monitoring Program, aspects of the Code and penalties for doping violations.

**RESULTS:** Participants comprised 338 coaches of athletes competing at International (32%), National (29%) or State or First Division (39%) levels across a range of 22 team and individual sports, most commonly athletics, swimming and basketball. Coaches demonstrated generally limited knowledge of the prohibited status of 30 listed substances. Overall 34% correctly identify the banned status of substances and 26% did not know. Coaches were most knowledgeable about the banned status of Anabolic Steroids, Growth Hormone, Erythropoietin, Caffeine, Alcohol and Blood Doping. More than 68% of coaches incorrectly believed that the recreational substances Amphetamines, Cocaine, Ecstasy, Heroin and Marijuana were banned at all times according to the WADA List. Poor awareness was displayed for prohibited therapeutic medications such as Diuretics, Opioids, Beta Blockers, Beta 2 Agonists and Insulin, where responses ranged from 0 to 48% correct. Seventy percent of respondents knew the penalty for doping violations in their sport, 50% believed that banned substances could be taken by an athlete if prescribed by a doctor and 31% did not know whether all substances on the Prohibited List were performance enhancing. Only 22% knew what the Monitoring Program was.

**CONCLUSION:** Coaches demonstrated limited, but variable, knowledge of the prohibited status of substances and inconsistent knowledge of aspects of the Anti-Doping Policy. It is essential that coaches also be provided with targeted educational resources in these key areas.

### Accelerometer-determined Physical Activity And Lower Body Muscle Distribution In Japanese Women

Naotoshi Mitsukawa<sup>1</sup>, Madoka Ogawa<sup>2</sup>, Mark Loftin, FACSM<sup>3</sup>, Takashi Abe<sup>4</sup>. <sup>1</sup>Toyo Gakuen University, Nagareyama, Japan. <sup>2</sup>University of Tokyo, Kashiwa, Japan. <sup>3</sup>University of Mississippi, Oxford, MS. <sup>4</sup>University of Oklahoma, Norman, OK.  
(No relationships reported)

It has been reported that dual X-ray absorptiometry (DXA)-measured appendicular muscle mass is associated with daily physical activity (average step count and duration time of moderate exercise [ $>3$  METs]) in the elderly. Although age-related site-specific muscle loss was observed in the lower body, the relationship between age-related change in lower body muscle distribution and daily physical activity is unknown. **PURPOSE:** To investigate the relationship between muscle distribution of lower body and accelerometer-determined daily physical activity. **METHODS:** Fifty-one elderly women (mean age 66.0 [SD 7.1] yrs) volunteered. Muscle thickness (MTH) was measured by B-mode ultrasound at seven sites on the anterior (quadriceps [QF] 30%, 50%, and 70% of thigh length) and posterior (hamstring [HM] 50% and 70% of thigh length) aspects of the thigh and the anterior (tibialis anterior [TA] 30% of lower leg length) and posterior (triceps surae [TS] 30% of lower leg length) aspects of the lower leg. Habitual daily activities during consecutive 30 days were recorded using an accelerometer, and the exercise intensity was classified 10 graded levels from sedentary (level 0) to light (levels 1-3), moderate (levels 4-6) and vigorous (levels 7-9) exercise. Total duration time for each level of exercise intensity as well as average daily step count was calculated.

**RESULTS:** The daily step count and total duration times of light, moderate and vigorous exercise averaged 7826 (SD 3183) steps per day and 59 (SD 20), 22 (SD 17) and 2 (SD 2) min per day, respectively. Absolute MTH did not correlate ( $P>0.05$ ) to limb length. Average daily step count was positively correlated with the TA-30% MTH ( $r=0.31$ ,  $p=0.03$ ) and TS-30% MTH ( $r=0.35$ ,  $p=0.01$ ), but not the MTH of the thigh. There was no significant ( $P>0.05$ ) correlation between duration time of light exercise and MTH of the thigh and lower leg. However, duration time of moderate exercise was positively correlated ( $p<0.05$ ) with the TA-30% MTH ( $r=0.35$ ) and TS-30% MTH ( $r=0.35$ ), and vigorous exercise duration time was not only correlated ( $p<0.05$ ) with the lower leg MTH (TA-30%,  $r=0.30$ ; TS-30%,  $r=0.28$ ), but also with QF-50% MTH ( $r=0.29$ ).

**CONCLUSIONS:** Amount of daily step count and moderate/vigorous exercise duration are associated with lower leg MTH. Quadriceps MTH is only associated with vigorous exercise.

---

**3091** Board #56 June 1 2:00 PM - 3:30 PM

### Effects Of Salsa Dance Training On Measures Of Balance And Muscle Power In Older Adults

Thomas Muehlbauer<sup>1</sup>, Urs Granacher<sup>1</sup>, Stephanie A. Bridenbaugh<sup>2</sup>, Madeleine Wolf<sup>3</sup>, Ralf Roth<sup>3</sup>, Yves Gschwind<sup>2</sup>, Irene Wolf<sup>2</sup>, Rui Mata<sup>3</sup>, Reto W. Kressig<sup>2</sup>. <sup>1</sup>Friedrich-Schiller-University Jena, Jena, Germany. <sup>2</sup>Basel University Hospital, Basel, Switzerland. <sup>3</sup>University of Basel, Basel, Switzerland.  
(No relationships reported)

Deficits in static and particularly dynamic postural control as well as in muscle power have frequently been associated with an increased risk of falling in older adults. Salsa dancing involves moves that are challenging for both postural control and leg muscle strength/power and may thus have great potential for the promotion of balance and muscle power in older adults.

**PURPOSE:** The objective of this study was to investigate the effects of salsa dancing on measures of static/dynamic postural control and leg extensor power in healthy seniors.

**METHODS:** Twenty-eight physically active (~12 h/week) older adults were randomly assigned to an intervention group (INT;  $n = 14$ ; age  $71.6 \pm 5.3$  years; 9 females, 5 males) that conducted an 8 week progressive salsa dancing program (2 times/week) or a control group (CON;  $n = 14$ ; age  $68.9 \pm 4.7$  years; 8 females, 6 males). Static postural control was measured during one-legged stance on a balance platform and dynamic postural control was obtained while walking on an instrumented walkway. Leg extensor power was assessed during a countermovement jump on a force plate.

**RESULTS:** Program compliance was excellent with participants of the INT group completing 92.5% of the dancing sessions. A tendency towards an improvement in selected measures of static postural control (11-13%,  $p = 0.09$ ) was observed in the INT group as compared to the CON group. Significant Group x Test interactions were found for stride velocity (11%,  $p < 0.01$ ), for stride length (6%,  $p < 0.01$ ), and for stride time (4%,  $p < 0.01$ ) in favor of the INT group. However, salsa dancing did not have significant effects on various measures of gait variability (4-11%, all  $p > 0.05$ ) and leg extensor power (12%,  $p > 0.05$ ).

**CONCLUSIONS:** Salsa dance training proved to be a safe and feasible exercise program for older adults accompanied with a high adherence rate. Age-related deficits in measures of static and particularly dynamic postural control can be mitigated by salsa dancing in older adults. Program parameters (e.g., duration/frequency of dance training) as well as the high initial physical activity level of our participants could be responsible for the non-significant findings in gait variability and leg extensor power.

**3092** Board #57 June 1 2:00 PM - 3:30 PM

### Relationship Between The Habit Of Exercise And Sense Of Coherence Among Retired Males In Japan

Shintaro Endo, Hidetoshi Kanou, Kazuo Oishi. Rikkyo University, Niiza-shi, Japan.  
(No relationships reported)

Former studies have pointed out that retirement is a serious life event for Japanese men. The habit of exercising is one approach with potential to solve the problem. As well as its physical benefits, it is suggested that the habit may influence the improvement of elder people's quality of life (QOL), influencing elements such as purpose in life with a beneficial effect on their health. Recently, Sense of Coherence (SOC) has been examined attention as a life factor related to health. SOC is thought to exist in individuals with experience of extreme stressors that nonetheless can maintain psychophysical health. Former studies reported that strong SOC and the habit of exercising were related in older people. However, it has not been clarified what factors are associated with SOC and the habit of exercising in retired men.

**PURPOSE:** The purpose of this study was to clarify whether to the habit of exercising among retired males in Japan affects their SOC.

**METHODS:** The subjects were 260 retired Japanese males (mean age  $66.9 \pm 4.0$  years) living in metropolitan areas. The Japanese version of SOC-3 (Togari et al., 2007) was used to estimate the level of SOC. Additional questions were asked concerning the habit of exercising (e.g., "How frequently and how long have you taken part in exercising?" "What did you get from continuing to take part in exercising?").

**RESULTS:** Subjects were divided into two groups: one with the habit (HS) and the other without the habit (NS) of exercising. A Mann-Whitney test showed that the SOC score in the HS group ( $n = 182$ , mean  $\pm$  SD:  $9.0 \pm 2.1$ ) was significantly higher than that in the NS group ( $n = 78$ , mean  $\pm$  SD:  $8.3 \pm 2.1$ ) ( $U = 5696$ ,  $p < 0.05$ ). Multiple-regression analysis showed the enhancement of respondents' sense of fulfillment ( $\beta = 0.24$ ,  $p < 0.01$ ) and the improvement of their life skills ( $\beta = 0.24$ ,  $p < 0.01$ ), were positively associated with SOC ( $R^2 = 0.12$ ,  $p < 0.001$ ) individually. Therefore, these two experiments might show that SOC is enhanced by exercising.

**CONCLUSIONS:** These results suggested that successful experiences such as getting a sense of fulfillment and improved life skills through the habit of exercising enhanced SOC.

### Effect Of Practicing Tai Chi On Postural Control Depends On Levels Of Skill Mastery

Katsuhiko Amano<sup>1</sup>, Shigenobu Yamaguchi<sup>1</sup>, Kenji Nishihata<sup>2</sup>, Kazuo Funato<sup>3</sup>, Hiroshi Fujinaga<sup>4</sup>. <sup>1</sup>Kanto Gakuen University, Ohta, Japan. <sup>2</sup>Kobe International University, Kobe, Japan. <sup>3</sup>Nippon Sport Science University, Tokyo, Japan. <sup>4</sup>Wakayama University, Wakayama, Japan.

(No relationships reported)

**PURPOSE:** It is well known that Tai Chi (TC) practice helps the elderly maintain or enhance postural control ability. In the present study we have demonstrated that such an effect does not necessarily depend on the number of years of practice, but on the level of mastery of fundamental TC movements.

**METHODS:** Thirty-six female TC practitioners (aged 55 to 74 yrs) participated in this study. They were classified into the three groups consisting of 12 experts (Ex), 12 semi-experts (sEx) and 12 non-experts (N). The experts and semi-experts have passed qualifying tests for instructorship in their TC organization. Passing the expert-level of qualifying tests requires practitioners to master the 24 fundamental TC movements and postures and to have the ability to teach them. The semi-experts are required to be able to perform the movements and postures accurately. The subjects were instructed to close their eyes and stand still for 30 seconds on a pressure-sensitive foot analysis platform (WINPOD, Medicauteurs CO., LTD., France) with one leg or two legs. The fluctuations of center of foot pressure (COP) were recorded at a frequency of 10 Hz. Detrended fluctuation analysis was used to compute a scaling exponent  $\alpha$ . The rectangular area (AREA) and the total length (LNG) of COP trajectories were calculated with the WINPOD software.

**RESULTS:** In two-leg standing, no significant correlations were found between the COP variables ( $\alpha$ , AREA, LNG) and the number of years of TC practice and no significant differences were found in the COP variables among the three groups (LNG: Ex 271mm, sEx 224mm, N 228mm, ns). On the other hand, there were significant differences in the COP variables among the three groups in one-leg standing (LNG: Ex 399mm, sEx 472mm, N 573mm,  $p < 0.05$ ). And there were significant differences in the scaling exponent  $\alpha$  between Ex and N ( $0.98 \pm 0.05$  vs  $0.83 \pm 0.07$ ,  $p < 0.05$ ).

**CONCLUSIONS:** These results suggest that (1) the beneficial effect of practicing TC on postural stability in elderly women might depend on the quality of TC training, not necessarily on years of practice and (2) a one-leg standing test provides more useful information to assess dynamic control processes of the postural system.

### First Step To Active Health - Online Plus: Pilot Study

Nicole L. Rogers, Sahar Amini, Mindy Slimmer. *Wichita State University, Wichita, KS.* (Sponsor: Michael E. Rogers, FACSM)

(No relationships reported)

The Internet has a vast capacity for disseminating patient-oriented interventions to improve the quality of the nation's care. Web-based interventions provide inexpensive delivery of components of effective, but expensive interventions, such as personal feedback and individual goal-setting.

**PURPOSE:** The aim of this project is to implement, and demonstrate the efficacy of, a blended delivery multi-component physical activity program.

**METHODS:** The experimental group (FSAH-O) consisted of 30 male and females (age =  $68.7 \pm 5.5$  yrs). The control group ( $N = 15$ ;  $74.7 \pm 6.2$  yrs) was drawn from a similar project. The program consisted of flexibility, strength, and balance training, and cardio-respiratory activity. Participants met 1 day/week for 8 weeks for 50 minutes of exercise at a senior center while supplementing class with home exercise 2 days/week. Participants were given access to a program web site (a user-friendly, interactive, secure, online method to motivate, educate, and track activity). Program effectiveness was assessed using the Senior Fitness Test (SFT) (chair stand, arm curl, chair sit and reach, 8-foot up & go, scratch test, and 12-min walk); balance (movement velocity (MVL), endpoint excursion (EPE), maximum EPE (MXE), and directional control (DCL) for forward (F), right (R), left (L) and back (B) movements).

**RESULTS:** No baseline difference existed between groups. Repeated measures ANOVAs revealed group x time interactions ( $p < 0.05$ ) on most measures. SFT improvements were noted in the FSAH-O group: Chair Stand 10%, Arm Curl 22%; Up-&-Go 8%; 12-min Walk 18%. With respect to LOS, EPE and MXE improved in two directions (R 21%, R 8%; L 7%, L 7%). The control group did not change on any variable.

**CONCLUSIONS:** The internet-based program successfully motivated older adults to initiate and maintain a physical activity program. Participating in an 8-week blended FSAH-O program improved FF, and 2 of 4 balance measures. Improvements were noted for most functional fitness tests. EPE and MXE balance improved in the left and right direction and there was a trend for improvement in front and back directions. A longer intervention may result in greater balance improvements.

**3095** Board #60 June 1 2:00 PM - 3:30 PM

### Effect Of Age-related Site-specific Sarcopenia On Gait Velocity And Functional Ability

Madoka Ogawa<sup>1</sup>, Naotoshi Mitsukawa<sup>2</sup>, Mark Loftin, FACSM<sup>3</sup>, Takashi Abe<sup>4</sup>. <sup>1</sup>University of Tokyo, Kashiwa, Japan. <sup>2</sup>Toyo Gakuen University, Nagareyama, Japan. <sup>3</sup>University of Mississippi, Oxford, MS. <sup>4</sup>University of Oklahoma, Norman, OK.

(No relationships reported)

Sarcopenia induced functional impairment and physical disability has been observed in both cross-sectional and longitudinal studies. Recently we reported that sarcopenia is observed as a site-specific loss of skeletal muscle mass, especially for the quadriceps and abdominal muscles. However, it is unknown whether the site-specific sarcopenia is associated with disability of gait and physical function.

**PURPOSE:** To investigate the relationship between age-related site-specific loss of thigh muscle and functional ability and gait performance.

**METHODS:** Fifty-three relatively active women aged 52-83 years (22 middle-aged [aged 52-65 years] and 31 old [aged 66-83 years]) volunteered. Muscle thickness (MTH) was measured by ultrasound at five sites on the anterior quadriceps [QF] 30%, 50%, and 70% of thigh length and posterior (hamstring [HM] 50% and 70% of thigh length) aspects of the thigh. MTH was expressed in terms relative to thigh length (MTH/L). Maximum and usual walking speeds (began walking two meters before the start line and walked to the end of a 20 meter corridor), zig-zag walking time (walked 10 meters apart with alternating right/left direction), sit-to-stand time (performed a 10 repeated sit-to-stand), climbing stair (10 steps) test time, and maximum voluntary isometric knee extension and flexion strength (Biodex System-3) were measured.

**RESULTS:** Age was inversely correlated with the QF-50% MTH/L ( $r = -0.28$ ,  $P = 0.045$ ), but not the HM-50% MTH/L ( $r = 0.10$ ,  $P = 0.47$ ). Age was also inversely correlated with the ratio of QF/HM 50% MTH ( $r = -0.33$ ,  $P = 0.02$ ), thus the site-specific muscle loss of the thigh was observed in the present sample. There were no significant correlations ( $P > 0.05$ ) between the QF/HM 50% MTH ratio and maximum ( $r = 0.03$ ) and usual ( $r = -0.07$ ) walking speeds, sit-to-stand test ( $r = -0.12$ ), and climbing stair test ( $r = 0.08$ ). However, the QF/HM 50% MTH ratio was tended to be correlated to zig-zag walking test ( $r = -0.26$ ,  $P = 0.06$ ). In addition, the QF/HM 50% MTH ratio was also correlated with isometric knee flexion strength ( $r = 0.40$ ,  $P = 0.01$ ), but not to knee extension strength ( $r = 0.25$ ).

**CONCLUSION:** Age-related site-specific loss of thigh muscle may associate with decrease in task performance requiring agility and dynamic balance such as zig-zag walking.

3096 Board #61 June 1 2:00 PM - 3:30 PM

### Strength and Power as Predictors of Functional Fitness for Senior Adults

Kelsey Hubble<sup>1</sup>, Kayla Garver<sup>1</sup>, Dalton Delaney<sup>1</sup>, TaNiqa Ward<sup>1</sup>, Michelle Gray<sup>2</sup>, Melissa Powers<sup>1</sup>. <sup>1</sup>University of Central Oklahoma, Edmond, OK. <sup>2</sup>University of Arkansas, Fayetteville, AR.  
(No relationships reported)

**INTRODUCTION:** There are many physiological declines that occur with aging, two of which involve muscular strength and power. Previous research indicates that muscular power may be the better predictor of functionality for this population. Additional research should be conducted to investigate this further using a variety of functional measures. This research would assist in providing evidence for the case and help health professionals understand which health component(s) to focus on when attempting to help senior adults maintain functionality.

**PURPOSE:** The purpose of this study was to determine if strength and power are predictors of functional fitness for senior adults and if so, which the better predictor is.

**METHODS:** Forty-six senior adults over the age of 75 years completed the Short Physical Performance Battery (SPPB), hand-grip (HG) assessment, the Senior Fitness Test (SFT), chair stand power test, and one-repetition maximum (1RM) testing. SPPB, HG, and SFT were utilized as functional measures. The SPPB is a survey functional assessment evaluating balance, gait, and chair stands. Handgrip was measured with a handgrip dynamometer. The maximum of each hand was averaged as the measurement. The SFT includes chair stands (CS), arm curl (AC), 8-foot Up-and-Go (UpGo), sit-and-reach (SR), back scratch (BS), and 6-Minute walk (WALK). The chair stand power test was utilized to determine average power and involved 10 explosive chair stand trials. Lastly, six 1RM tests were combined to quantify total strength. Multiple regression analyses were conducted to determine whether strength or average power was the best predictor for functional fitness.

**RESULTS:** Strength and power were indicated as significant predictors collectively for SPPB, CS, AC, UpGo, and HG ( $p = .004, p = .001, p = .011, p = .036,$  and  $p < .001$ , respectively). When comparing power and strength, power emerged as the only significant individual predictor for SPPB, CS, AC, and UpGo ( $p = .002, p = .001, p = .042, p = .002,$  and  $p = .014$ , respectively). Conversely, total strength was indicated as the significant predictor for HG ( $p < .001$ ). Neither strength nor average power was indicated as a significant predictor for WALK, BS, and SR.

**CONCLUSION:** These results suggest that average power may be a better predictor for the functional fitness of older adults than strength.

### Sixteen Weeks of Soccer or Strength Training Improve Physical Performance in 65-75 Year-old Untrained Males

Thomas Rostgaard Andersen<sup>1</sup>, Jakob Friis Schmidt<sup>1</sup>, Emil Sundstrup<sup>2</sup>, Markus D. Jakobsen<sup>2</sup>, Mogens T. Petersen<sup>1</sup>, Therese Hornstrup<sup>1</sup>, Morten B. Randers<sup>1</sup>, Charlotte Suetta<sup>3</sup>, Per Aagaard<sup>4</sup>, Peter Krstrup<sup>5</sup>, Jens Bangsbo<sup>1</sup>. <sup>1</sup>University of Copenhagen, Copenhagen, Denmark. <sup>2</sup>National Research Centre for the Work Environment, Copenhagen, Denmark. <sup>3</sup>Bispebjerg Hospital, Copenhagen, Denmark. <sup>4</sup>University of Southern Denmark, Odense, Denmark. <sup>5</sup>University of Exeter, Exeter, United Kingdom.

(No relationships reported)

Participation in recreational soccer (association football) is an effective way of improving performance levels. In addition, life-long exposure to football training has been shown to preserve explosive muscle power in elderly male football players. However, the effect of soccer training on physical performance in untrained elderly has not been investigated.

**PURPOSE:** To examine the effects of 16 weeks of recreational soccer training or explosive strength training on aerobic, intermittent and strength performance in sedentary elderly men.

**METHODS:** Twenty-four healthy, sedentary elderly men (age:  $69 \pm 0.7$  yrs) were assigned to either a soccer training group (SOG; N=9), strength training group (STG; N=9) or control group (CG; N=6). Subjects in SOG and STG trained 2x60 min per week. SOG performed small-sided soccer games (4 v 4; 4x12-min game periods). STG performed heavy load leg exercises (4x8 repetition maximum). Oxygen uptake ( $VO_2$ ), heart rate (HR) and respiratory exchange ratio (RER) were determined during an exhaustive incremental cycle exercise test. Intermittent endurance capacity was examined using the Yo-Yo intermittent endurance test level 1 (Yo-Yo IE1). Isometric maximal voluntary contraction (MVC) and rate of force development (RFD) was evaluated at 70 degree knee flexion. Values are mean  $\pm$  SEM.

**RESULTS:** After 16 weeks of training, maximum oxygen uptake was increased ( $p < 0.05$ ) in SOG ( $27.5 \pm 1.8$  vs.  $32.1 \pm 1.7$  mL\*min<sup>-1</sup>\*kg<sup>-1</sup>), but not altered in STG and lowered ( $p < 0.05$ ) in CG. RER and HR at exhaustion were not different between trials in any group. Yo-Yo IE1 performance was improved ( $p < 0.05$ ) only in SOG ( $455 \pm 92$  vs.  $588 \pm 148$  m). HR at the end of Yo-Yo IE1-test did not differ between trials. Peak RFD was improved ( $p < 0.05$ ) in STG ( $1334 \pm 175$  vs.  $1674 \pm 132$  Nm/s), but not in SOG and CG. MVC was unchanged in all groups.

**CONCLUSION:** Participation in recreational football training is an effective way of improving aerobic fitness and intermittent endurance capacity in elderly males, whereas, explosive strength training is superior to soccer training in the development of neuromuscular function in elderly.

Informed consent was obtained from all subjects. The study was supported by FIFA-Medical Assessment and Research Centre (F-MARC) and The Danish Ministry of Culture. Conflicts of interest: none declared.

### Effects of Recreational Soccer on the Cardiovascular Risk Profile in Elderly Untrained Healthy 65-75-year-old Men

Jakob Friis Schmidt<sup>1</sup>, Thomas Rostgaard Andersen<sup>1</sup>, Therese Hornstrup<sup>1</sup>, Morten B. Randers<sup>1</sup>, Jens J. Nielsen<sup>1</sup>, Charlotte Suetta<sup>2</sup>, Per Aagaard<sup>3</sup>, Lars J. Andersen<sup>4</sup>, Peter Krstrup<sup>5</sup>, Jens Bangsbo<sup>1</sup>, Peter Riis Hansen<sup>4</sup>. <sup>1</sup>University of Copenhagen, Copenhagen, Denmark. <sup>2</sup>Bispebjerg Hospital, Copenhagen, Denmark. <sup>3</sup>University of Southern Denmark, Copenhagen, Denmark. <sup>4</sup>Gentofte Hospital, Copenhagen, Denmark. <sup>5</sup>University of Exeter, Exeter, United Kingdom.  
(No relationships reported)

A sedentary lifestyle increases the risk of cardiovascular diseases and physical exercise can counteract these effects. However, the effects of soccer on the cardiovascular risk profile in elderly men have not been determined.

**PURPOSE:** To determine the effects of 16 weeks of recreational soccer on the cardiovascular risk profile in elderly healthy men.

**METHODS:** Fifteen sedentary men (age  $68.6 \pm 3.5$  years) were randomized to a soccer-training group (SG; n=9) or a control group (CG; n=6). In addition, 12 master elite soccer players (age  $69.2 \pm 3.7$  years) served as an active control group (EG). SG trained twice weekly for 45-60 min (mean 1.5 times/week, average heart rate 81 %), CG had no change in sedentary lifestyle, and EG continued with the usual soccer training (2 times/week). Testing was performed at baseline and after 16 weeks with measurements of maximum oxygen uptake ( $VO_{2max}$ ), resting heart rate, blood pressure, body composition (DEXA scan), oral glucose tolerance test (OGTT), lipid profile and vascular function with peripheral arterial tonometry.

**RESULTS:** During the study period SG reduced body mass index (BMI) ( $26.1 \pm 1.3$  to  $25.5 \pm 1.2$  kg/m<sup>2</sup>;  $p < 0.01$ ), with no change in CG and a decrease in EG ( $24.2 \pm 0.6$  to  $23.9 \pm 0.5$ ;  $p < 0.05$ ). Reductions in total body fat percentage ( $28.2 \pm 2.3$  to  $26.6 \pm 2.5$ %;  $p < 0.05$ ), android fat mass ( $37.1 \pm 3.0$  to  $34.7 \pm 3.0$  kg;  $p < 0.05$ ), and gynoid fat mass ( $31.0 \pm 2.0$  to  $28.7 \pm 2.4$  kg;  $p < 0.05$ ) were observed in SG, with no change in CG and EG. Cardiovascular fitness improved in SG with a 11% reduction of resting heart rate ( $65 \pm 3.3$  to  $58 \pm 2.2$  bpm;  $p < 0.001$ ) and 17% increase in  $VO_{2max}$  ( $27.5 \pm 1.8$  to  $32.1 \pm 1.7$  ml kg<sup>-1</sup> min<sup>-1</sup>;  $p < 0.001$ ), while  $VO_{2max}$  decreased in CG ( $29.8 \pm 1.7$  to  $27.2 \pm 1.8$  ml kg<sup>-1</sup> min<sup>-1</sup>;  $p < 0.05$ ) and EG ( $35.7 \pm 0.8$  to  $33.9 \pm 0.8$  ml kg<sup>-1</sup> min<sup>-1</sup>;  $p < 0.05$ ). Two subjects in SG had impaired glucose tolerance (IGT) at baseline, which was normalized after 16 weeks of soccer. Two subjects in CG and 2 in EG developed IGT during the study period. Lean body mass, lipid profile, vascular function, and blood pressure remained unchanged in all groups.

**CONCLUSION:** Sixteen weeks of recreational soccer improves the cardiovascular risk profile in elderly sedentary men, especially with marked increase in cardio-respiratory fitness. Recreational soccer is an attractive physical intervention aimed at reduction of cardiovascular risk.

Informed consent was obtained from all subjects. The study was supported by FIFA-Medical Assessment and Research Centre (F-MARC) and the Danish Ministry of Culture.

3099 Board #64 June 1 2:00 PM - 3:30 PM

### Maximal Exercise Can Be Accurately And Reliably Achieved In Healthy, Sedentary Seniors

Dean Palmer, Graeme Carrick-Ranson, Kara Boyd, Naoki Fujimoto, Sheryl Livingston, Dan Creson, Jeff Hastings, Benjamin Levine, FACSM. *IEEM, Dallas, TX.*  
(No relationships reported)

Maximal aerobic power ( $VO_{2max}$ ) is generally accepted as the best measure of cardiorespiratory fitness. However, there is skepticism whether a true  $VO_{2max}$  is achievable in healthy, sedentary seniors.

**PURPOSE:** 1) Determine whether an elderly population is able to achieve previously published  $VO_{2max}$  criteria, and 2) Establish test-retest reliability of maximal metabolic and hemodynamic variables in seniors.

**METHODS:** We studied 59 healthy, sedentary senior men and women (ages  $67.5 \pm 5.4$ ).  $VO_{2max}$  was measured using the Douglas Bag (DB) method during an incremental treadmill protocol where a constant speed was established and the grade was increased 2% every two minutes. DB gas fractions were measured with a mass spectrometer. DB ventilation volume and heart rate (HR) were measured via Tissot spirometry and a 12-lead ECG, respectively. Predicted maximum HR was calculated using the formula  $210 - (0.65 \times \text{age})$ . All participants completed the identical protocol on two occasions separated by a mean of  $5.4 \pm 4.8$  weeks.

**RESULTS:** Maximal values are in the table below. In 115 of the 118 total tests performed (98%), at least two of three criteria [ $RER \geq 1.10$ ,  $VO_2$  change in last two workloads  $\leq 150$ ml/min and  $HR > 85\%$  of age predicted maximum] for  $VO_{2max}$  were achieved. Typical error expressed as a coefficient of variation (%) between visits 1 and 2 maximal values for  $VO_2$ , HR and respiratory exchange ratio (RER) were 3.9, 2.2 and 4.4, respectively.

**CONCLUSION:** The present study suggests that reliable  $VO_{2max}$  measurements are achievable in healthy, non-frail seniors. This knowledge will enhance the quality of exercise prescription in older adults.

| $VO_{2max}$ acceptance criteria | Visit1 $VO_2^*$ | Visit2 $VO_2$ | Visit1 $\Delta VO_2^{**}$ | Visit2 $\Delta VO_2$ | Pred HR | Visit1 HR | Visit2 HR | Visit1 RER | Visit2 RER |
|---------------------------------|-----------------|---------------|---------------------------|----------------------|---------|-----------|-----------|------------|------------|
| Mean                            | 23.1            | 23.4          | 97.1                      | 65.1                 | 166.1   | 164.9     | 163.6     | 1.21       | 1.19       |
| SD                              | 4.8             | 4.8           | 88.7                      | 58.6                 | 3.5     | 11.3      | 11.1      | 0.08       | 0.08       |

\* $VO_2 = VO_{2max}$  (ml·kg<sup>-1</sup>·min<sup>-1</sup>)

\*\* $\Delta VO_2 =$  change in absolute  $VO_2$  between the  $VO_{2max}$  stage and the previous workload (ml/min)

3100 Board #65 June 1 2:00 PM - 3:30 PM

### Validity of USB Electronic Pedometer Using 3D Accelerometer Technology for Assessing Physical Activity Intensity

Ken Rung Tu<sup>1</sup>, Shun Ping Lin<sup>2</sup>, Jin jong Chen<sup>3</sup>. <sup>1</sup>National Yang-Ming University, Taipei, Taiwan. <sup>2</sup>China University of Science and Technology, Taipei, Taiwan. <sup>3</sup>Exercise and Health Science Research Center, Taipei, Taiwan.

(No relationships reported)

Pedometer was the most popular intervention tool used to promote daily walking. It has been demonstrated that walking performance (speed and distance) is highly correlated with longevity and cognitive function in elderly population. Unfortunately, traditional pedometers can only indicate total activity but not speed or physical activity (PA) intensity. An USB electronic pedometer using 3D accelerometer technology to detect and record the up-down steps was designed not only to record total PA but also walking speed (steps per minute, SPM). However, the relationship between physiological PA intensity (MET) and SPM during daily locomotion activities has not been studied.

**PURPOSE:** The purposes of this study were (1) to investigate the correlation between SPM and MET of level locomotion activity, and (2) to determine the SPM cut-points for moderate and vigorous locomotion PAs.

**METHODS:** Fourteen male college students (mean age:  $20.4 \pm 1.65$  yrs, height:  $170.3 \pm 4.78$  cm, weight:  $74.9 \pm 16.8$  kg) were recruited to perform 4 different speed level locomotion activity: normal walking (3km/hr), brisk walking (5km/hr), jogging (7km/hr), and running (8km/hr). During each activity, step frequency (SPM) was measured using an USB electronic pedometer, and physiological PA intensity ( $O_2$  consumption) was also measured using a metabolic measurement system. The SPM cut-points of the pedometer for moderate PA and vigorous PA were determined using 3MET and 6MET for each individual respectively.

**RESULTS:** The  $O_2$  consumption of 3km/hr, 5km/hr, 7km/hr, and 8km/hr were  $10.26 \pm 1.45$ ,  $15.66 \pm 1.44$ ,  $26.98 \pm 2.02$ , and  $33.61 \pm 2.53$  ml/min/kg respectively. A significant and strong correlation between SPM and MET was found ( $r=0.90$ ,  $p<0.0001$ ). The 3MET moderate PA and 6MET vigorous PA were normal walking and jogging. The SPM cut-points of the pedometer for moderate and vigorous PAs were  $95 \pm 5$  SPM and  $125 \pm 10$  SPM, respectively.

**CONCLUSION:** The correlation between SPM and MET of level locomotion activities was high. Two step frequencies,  $95 \pm 5$  SPM and  $125 \pm 10$  SPM from the USB electronic pedometer, were recommended to be moderate and vigorous PAs cut-points. The accumulated evidence herein provides ample support that the USB electronic pedometer is a valid option for assessing total PA and intensity in research and practice.

3101 Board #66 June 1 2:00 PM - 3:30 PM

### The Health-related Quality of Life Associated with Health Predictors, in Diabetic and Hypertensive Older Adults

Pedro Bezerra<sup>1</sup>, Dalia Alves<sup>2</sup>, Olga Pontedeira<sup>2</sup>. <sup>1</sup>Viana do Castelo Polytechnic Institute & Research Centre in Sports Sciences, Health Sciences and Human Development, Viana do Castelo, Portugal. <sup>2</sup>Viana do Castelo Polytechnic Institute, Viana do Castelo, Portugal.

(No relationships reported)

The health-related quality of life has been assessed by a number of measures including the individual perception of health. The SF-36v2 questionnaire is one of the instruments widely used at population level and comprises eight measures including physical functioning (PF) and role physical (RP). Grip strength and walking ability are known to be associated with muscular functioning and activities of daily living. Any decreasing or impairment may predict disability and mobility deficits. Whether functional capacity status is related to individual perception of health in older diabetic and hypertensive adults it is not well established.

**PURPOSE:** the aim of the study was to investigate the relationship between the perception of health and health predictors, assessed as handgrip test (HandT) and 6 minutes walking test (6MW), in older diabetic (DG)/non-diabetic (nDG) and hypertensive (HTG)/non-hypertensive (nHTG).

**METHODS:** one hundred and nine (24 DG and 85 nDG; 59 HTG and 50 nHTG) older adults ( $77.0 \pm 5.3$  yrs,  $68.2 \pm 9.7$  Kg,  $1.55 \pm 0.10$  m), were recruited from local population. The subjects were tested on HandT and 6MW, and completed the SF-36v2. ANOVA was performed to detect group differences. Pearson coefficient of correlation was used to assess the relationship between PF and RP subscales, and physical fitness tests. Significance was set at  $p < 0.05$ .

**RESULTS:** Non-significant differences were found between DG and nDG in all variables. The nHTG showed high scores on fitness tests (HandT left; [F (1, 107) = 7.119,  $p < 0.01$ ], HandT right; [F (1, 107) = 5.721,  $p < 0.05$ ], and 6MW; [F (1, 107) = 3.957,  $p < 0.05$ ] than HTG, but no-significant differences were found on PF and RF. In the nDG, both the RP and PF were related with fitness tests ( $r = 0.35$  to  $0.46$ ,  $p < 0.01$ ). In the HTG the RP and PF were related with fitness tests ( $r = 0.33$  to  $0.57$ ,  $p < 0.01$ ) while in the nHTG only the PF was related with fitness test ( $r = 0.36$  to  $0.45$ ,  $p < 0.01$ ).

**CONCLUSION:** The diabetes does not appear to affect the perception of health and functional capacity. Hypertensive patients appear to influence functional capacity but do not affect their perceptions of health. The findings also indicate that low scores on perception of health status may indicate difficulties in performing activities of daily living especially within older individuals experiencing hypertension.

**3102 Board #67 June 1 2:00 PM - 3:30 PM**

**Effects Of Navy SHAPE On Fitness Parameters, Functional Movement Screening (FMS) And Self-reported Sitting Time.**

Carol Kennedy-Armbruster<sup>1</sup>, Lisa Sexauer<sup>2</sup>, William Wyatt<sup>1</sup>, John B. Shea<sup>1</sup>. <sup>1</sup>Indiana University, Bloomington, IN. <sup>2</sup>Navy CNIC, Washington, DC. (Sponsor: Ellen Evans, PhD, FACSM)

(No relationships reported)

Evaluation of the efficacy of site-based fitness interventions to enhance health status, especially for military active duty, is costly and time consuming. Few interventions have targeted the 40+ age group in the military.

**PURPOSE:** To evaluate the effects of a supervised exercise program (SHAPE) on fitness, functional movement screening (FMS) and self-reported sitting time. **Method:** Two health fitness specialists (HFS) were placed on three Navy bases to deliver SHAPE(6 mos; personal training, group exercise, education and lifestyle physical activity encouragement) to military volunteer personnel (44.5 ± 5 y) from 2007 to 2011; n=75 assessments after 2-4 months; n=28 assessments after 4-6 months. Health status measures included sub-maximal oxygen consumption, blood pressure, weight, strength, flexibility and adiposity assessed via Polar Trifit 4.9.1 system and functional movement screening (FMS). Self-reported sitting time, reflected in % of day was also collected.

**RESULTS:** Collapsing across training site average improvements in fitness were achieved for VO2 (+7%), flexibility (+13%), strength (+5%), adiposity (-4%), and body weight (-1%) after 2-4 months. All biometric tests except for weight (-1%) at the 4-6 month reassessment continued to improve; VO2 (+9%), flexibility (+19%), strength (+9%), and adiposity (-5%) and remained significant. SBP and DBP were also significant at the 4-6 month reassessment (SBP = (-3%), DBP = (-6%), p<0.05). FMS improved at 2-4 months (p=0.012) and continued to improve at 4-6 months (p<0.01). FMS average scores were 13.7 for assessment 1; 15.1 assessment 2 and 15.5 assessment 3. A strong trend existed for reductions in sitting time at 2-4 mos (p=0.058) which continued at 4-6 mos (p=0.056) with the latter representing a reduction of 22.3% in the # of individuals who sit 75% or more of the day.

**CONCLUSION:** Site based fitness programs with active duty military participants (>40 yrs) can improve biometric fitness indices up to 4-6 months. Functional movement capacity improved and Self-reported sitting time may also be reduced in response to the intervention.

Support: Navy headquarters (CNIC) & Indiana University service contract (HDQMWR-08-C-0036)

**3103 Board #68 June 1 2:00 PM - 3:30 PM**

**Fitness Secular Trends of Shanghai Older Women and Local District Impact: 2000-2010**

Chunhua Zhang<sup>1</sup>, Benhao Fan<sup>2</sup>, Xin Liu<sup>3</sup>, Weimo Zhu, FACSM<sup>4</sup>. <sup>1</sup>Shanghai University of Sport, Shanghai, China. <sup>2</sup>Shanghai Sports Bureau, Shanghai, China.

<sup>3</sup>Shanghai Research Institute of Sports Science, Shanghai, China. <sup>4</sup>University of Illinois at Urbana-Champaign, Urbana, IL.

(No relationships reported)

The population of aging women in Shanghai, China, as in many other cities around the world, is rapidly increasing. While in general many older Shanghai women are concerned about their health and participate in exercise regularly, some participation difference across local districts was observed. No study has confirmed these differences using fitness outcomes.

**PURPOSE:** To examine the 2000-2010 trends of older women's physical fitness across Shanghai districts, China.

**METHODS:** The Shanghai data from the Chinese National Fitness Surveys in 2000 and 2010, including samples from six districts, were used for the analysis and only 60-69 year old females were included. The means and confidence intervals of six fitness measures were computed by year and were compared by district using ANOVA.

**RESULTS:** Means of fitness measures by district and year are summarized in the table below. Some district differences were confirmed in the fitness changes between 2000 and 2010 (\*= p<.05). For example, BMI increase was found only in one district.

| Variable/District   | Xuhui  |         | Yangpu |         | Jiading |         | Pudong |         | Songjiang |         | Fengxian |         |
|---------------------|--------|---------|--------|---------|---------|---------|--------|---------|-----------|---------|----------|---------|
| Test Year           | 2000   | 2010    | 2000   | 2010    | 2000    | 2010    | 2000   | 2010    | 2000      | 2010    | 2000     | 2010    |
| n                   | 79     | 70      | 75     | 70      | 75      | 70      | 72     | 70      | 80        | 70      | 78       | 70      |
| Age                 | 64.32  | 64.21   | 64.29  | 64.29   | 64.32   | 64.01   | 64.07  | 64.33   | 64.81     | 64.21   | 64.33    | 63.86   |
| BMI                 | 24.80  | 24.36   | 24.76  | 25.19   | 24.23   | 24.25   | 25.02  | 25.03   | 23.26     | 24.32   | 22.22    | 24.4*   |
| Grip Strength (kg)  | 22.39  | 24.56*  | 22.70  | 25.24*  | 21.97   | 24.45*  | 23.22  | 25.80*  | 20.32     | 21.56   | 21.39    | 24.51*  |
| Balance (s)         | 5.01   | 8.17*   | 6.77   | 11.43*  | 9.48    | 18.21*  | 6.10   | 9.50*   | 6.75      | 9.16    | 4.54     | 8.00*   |
| Reaction Time (s)   | 0.7897 | 0.5039* | 0.6709 | 0.5170* | 0.9747  | 0.5571* | 0.8308 | 0.5776* | 0.8683    | 0.7260* | 0.8401   | 0.7344* |
| Sit and Reach (cm)  | 5.06   | 6.48    | 7.62   | 6.94    | 8.91    | 11.23*  | 5.86   | 8.25*   | 10.33     | 9.63    | 11.57    | 9.86    |
| Vital Capacity (ml) | 1770   | 1803    | 1482   | 1667*   | 1434    | 2023*   | 1802   | 1797    | 1554      | 1959*   | 1617     | 2076*   |

**CONCLUSION:** While the older Shanghai women population maintained a good level of physical fitness during the past decade, some district differences were confirmed. Future study should explore and examine key factors that contribute to the differences and develop intervention plans accordingly.

**3104 Board #69 June 1 2:00 PM - 3:30 PM**

**Impact of Moderate Intensity Physical Activity on the Functional Fitness of Older Women**

Amy L. Morgan, FACSM<sup>1</sup>, Nicole L. Rogers<sup>2</sup>, Nobuo Takeshima<sup>3</sup>, Sahar Amini<sup>2</sup>, Samuel Ofei-Dodoo<sup>2</sup>. <sup>1</sup>Bowling Green State University, Bowling Green, OH.

<sup>2</sup>Wichita State University, Wichita, KS. <sup>3</sup>National Institute of Fitness and Sports, Kanoya, Japan.

(No relationships reported)

As adults reach advanced ages, the purpose of physical activity shifts from disease prevention to functional fitness (FF) and mobility. Higher levels of FF contribute to the ability to live independently.

**PURPOSE:** To determine the amount of activity necessary to positively impact functional fitness, by determining cutoff points in which additional minutes in moderate/vigorous physical activity (MVPA) do not further improve functional fitness.

**METHODS:** FF was assessed by the Senior Fitness Test (Chair Stand, Arm Curl, 6 min Walk, Up-and-Go, Sit and Reach, and Back Scratch) in 125 women (73.42 ± 8.84 yrs) from 2 Midwestern communities. Participants wore an accelerometer for 7 days without altering their normal activity. Accelerometer data were downloaded, MVPA determined via proprietary filtering, and time spent in each intensity (sedentary, low, moderate, vigorous) was calculated. A 5 day average of time spent in MVPA was organized into 4 groups (see Table).

**RESULTS:** ANOVAs revealed significant differences between groups on all measures except sit and reach. Results indicate a threshold of 20 min, suggesting that engaging in more MVPA yields no additional statistical gain on the lower body strength and mobility measures of chair stand, up-and-go, and 6 min walk. With regard to upper body strength and flexibility, less than 10 min of MVPA is detrimental to performance.

Table 1. Functional Fitness

| MVPA (min)  | n  | 6 min Walk (yd) | Chair (#) | Up & Go (s) | Curl (#)  | Scratch (in) |
|-------------|----|-----------------|-----------|-------------|-----------|--------------|
| 0:00-9:59   | 58 | 462±137*        | 11±3.5*   | 7.05±2.24*  | 16.0±5.0  | 9.7±13.54    |
| 10:00-19:59 | 27 | 538±174*        | 14±3.0*   | 5.56±1.16*  | 20.0±6.0† | 6.48±8.35†   |
| 20:00-29:59 | 14 | 607±95          | 15±4.0    | 5.41±1.19   | 20.0±6.5† | 3.89±8.78†   |
| 30:00+      | 22 | 687±90          | 16±4.5    | 4.52±0.95   | 20.5±4.0† | 2.91±6.32†   |

\* different from 20:00min (p < .05) † different from 0:00 (p < .05)

**CONCLUSIONS:** A threshold of 20 min of MVPA per day is recommended to assist in the maintenance of lower body function in older women. While ACSM recommends that to maintain health all adults accumulate at least 30 minutes of MVPA 5 days/wk, our data suggest that at least 20 min may be sufficient to maintain lower body function in older women.

### 3105 Board #70 June 1 2:00 PM - 3:30 PM

#### Evaluation of Countermovement Jump in Old Women: Are Center of Mass Position Requirements Met?

Cristina Cortis, PhD<sup>1</sup>, Pietro Picerno, PhD<sup>2</sup>, Michela Cavallucci<sup>3</sup>, Caterina Pesce, PhD<sup>4</sup>, Laura Capranica<sup>3</sup>. <sup>1</sup>University of Cassino, Cassino, Italy. <sup>2</sup>Sensorize Motion Sensing Technology, Rome, Italy. <sup>3</sup>University of Rome "Foro Italico", Rome, Italy. <sup>4</sup>University of Rome, Rome, Italy. (Sponsor: Carl Foster, FACSM)  
(No relationships reported)

Considered representative of functional ability in old individuals, muscle power of lower limbs is routinely evaluated from estimates of countermovement jump (CMJ) height. In field studies optical cells and contact mats are widely used, assuming that the height of the center of mass at take-off and landing coincide. For this reason, individuals are required to maintain a vertical alignment during the jump and to land with their lower limbs fully extended. However, no study investigated if older individuals actually meet these criteria.

**PURPOSE:** To investigate the relationship between CMJ parameters of older individuals in field settings.

**METHODS:** After a familiarization trial, 22 old women (age: 70±7 years; body mass: 60.6±10.1 kg; height: 160.1±6.1 cm; BMI: 23.8±3.6) were instructed to perform a fast downward movement immediately followed by a fast upward moment and to jump as high as possible keeping their hand on the hips and landing with their legs fully extended. During the execution of the CMJ, instantaneous vertical acceleration, velocity, and displacement of the centre of mass were recorded by means of a wireless 3D inertial measurement unit (FreePower, Sensorize, Italy) positioned on the trunk at the L5 level. Peak velocity (Vpeak), force (Fpeak), and power (Wpeak) were recorded, and differences between the height of the center of mass at take-off and landing (DeltaHCM) were calculated. Finally, jump height was estimated from flight time. A correlation analysis (p<0.05) was used to verify the relationship between CMJ parameters.

**RESULTS:** Jump height (10.9±3.5 cm) significantly (p<0.0001) related with Vpeak (r=0.9; 1.3±0.2 m/s), Wpeak (r=0.8; 19.2±4.2 W/kg), and DeltaHCM (r=0.8; 6.4±2.6 cm), whereas no correlation emerged with respect to Fpeak (9.6±2.9 N/kg).

**CONCLUSIONS:** Findings indicate that peak force may not be the best measure to assess vertical jump performance of older individuals, who strongly rely on their capability to coordinate fast and powerful muscle contractions. Furthermore, DeltaHCM highlighted the presence of knee flexions at landing, which increase flight time and lead to overestimates of jump heights. Therefore, evaluations of CMJ performances in older individuals should not rely solely on flight time estimates.

### 3106 Board #71 June 1 2:00 PM - 3:30 PM

#### Changes in Health-related Physical Physique Measures of Shanghai Older Males between 2000 and 2010

Benhao Fan<sup>1</sup>, Xin Liu<sup>2</sup>, Chunhua Zhang<sup>3</sup>, Weimo Zhu, FACSM<sup>4</sup>. <sup>1</sup>Shanghai Sports Bureau, Shanghai, China. <sup>2</sup>Shanghai Research Institute of Sports Science, Shanghai, China. <sup>3</sup>Shanghai University of Sport, Shanghai, China. <sup>4</sup>University of Illinois at Urbana-Champaign, Urbana, IL.  
(No relationships reported)

Little is known of the Chinese older male' health-related physical physiques.

**PURPOSE:** To examine the status and changes of Shanghai older males' physical physique between 2000 and 2010.

**METHODS:** The data of Shanghai older adults (60 yr. or above) from the Chinese National Fitness Surveys in Year 2000 (n=467, mean age = 64.69 yr.), 2005 (n=420, 64.40 yr.), and 2010 (n=421, 64.29 yr.) were used for the study. The means and confidence intervals of Height, Weight, BMI, Chest circumference, Waist, Hip, Waist-to-hip ratio (WHR) were computed by year and were compared across years using ANOVA. In addition, status of BMI (<18.5 = Under Weight [UW], 18.5≤BMI<24 = Normal Weight [NW], 24≤BMI<28 = Over Weight [OW], & BMI≥28 = Obese [OB]) were computed.

**RESULTS:** Mean differences across years (later years minus earlier years) of the physique measures are summarized below. (\*= p<.05)

|             | Height (cm) | Weight (kg) | BMI (kg/cm2) | Chest circumference (cm) | Waist (cm) | Hip (cm) | WHR    |
|-------------|-------------|-------------|--------------|--------------------------|------------|----------|--------|
| 2005 - 2000 | 0.86*       | 2.27*       | 0.63*        | 0.94*                    | 1.69*      | 0.39     | 0.016* |
| 2010 - 2005 | 0.78        | 2.41*       | 0.66*        | 3.26*                    | 3.19*      | 1.22*    | 0.023* |
| 2010 - 2000 | 1.64*       | 4.68*       | 1.29*        | 4.2*                     | 4.88*      | 1.61*    | 0.039* |

It was also found more older males in Shanghai became overweight or obese during the past decade.

| Test Year/BMI | UW    | NW     | OW     | OB     |
|---------------|-------|--------|--------|--------|
| 2000          | 8.78% | 56.10% | 28.48% | 6.64%  |
| 2005          | 4.05% | 52.86% | 35.48% | 7.62%  |
| 2010          | 2.38% | 40.62% | 46.56% | 10.45% |

**CONCLUSION:** Several keys health related physical physiques of Shanghai older males showed a negative change during the past decade. Actions to stop and revise the negative change trend are urgently needed.

---

3107 Board #72 June 1 2:00 PM - 3:30 PM

**Over-ground Vs. Treadmill Walking In Older Adults: Comparison Of Accelerometry Counts And Metabolic Demands**

Nancy W. Glynn<sup>1</sup>, Adam J. Santanasto<sup>1</sup>, Mark A. Newman<sup>1</sup>, Christopher A. Taylor<sup>2</sup>, Anne B. Newman<sup>1</sup>, Bret H. Goodpaster<sup>1</sup>. <sup>1</sup>University of Pittsburgh, Pittsburgh, PA. <sup>2</sup>Centers for Disease Control, Atlanta, GA.  
(No relationships reported)

Mechanics between treadmill and over-ground walking may be different potentially due to gait. Differences in metabolic costs and energy expenditure associated with these bouts of activity are largely unknown for older adults.

**PURPOSE:** To compare metabolic demands, accelerometry counts, energy expenditure and physiologic parameters associated with treadmill and over-ground walking in older adults.

**METHODS:** Ten people (mean±SD age 70.6 ± 6.4 years) participated in a physical activity (150 min/wk of treadmill walking) and weight loss intervention. The short physical performance battery (SPPB) measured physical function. Mean oxygen consumption (COSMED K4b<sup>2</sup>), accelerometry counts (GT1M, ActiGraph, Pensacola, FL) and age-predicted heart rate (APHR) were measured concurrently during two walking bouts: usual pace 40m over-ground walk (mean gait speed 1.1 m/s, range 0.9 - 1.3 m/s) and usual pace 2 minute treadmill walk at the same gait speed. Energy expenditure in metabolic equivalents (METs) was obtained from averaging breath-by-breath COSMED samples for each bout.

**RESULTS:** Participants were high-functioning with mean SPPB scores of 10.4 ± 1.6 out of 12. A separate treadmill protocol measured mean VO<sub>2peak</sub> (27.3, range 21.5 - 38.3 ml/kg/min). At the same gait speed, mean VO<sub>2</sub> was 15% higher during the treadmill bout (10.0 ± 2.6 ml/kg/min) compared to over-ground walking (8.7 ± 1.1 ml/kg/min). Further, energy demand was 16% higher (mean 2.9, range 1.5 - 3.7 vs 2.5, range 1.8 - 3.1 METs) and activity counts were 20% higher (mean 1375, range 540 - 2496 vs 1147, range 504 - 1588 counts/min), for treadmill and over-ground walking, respectively. Participants reached an average of 68% (range 57 - 84%) of APHR during the treadmill compared to 57% (range 37% - 72%) for over-ground walking. All results are p<.10.

**CONCLUSION:** Preliminary findings suggest that metabolic cost, accelerometry counts, energy expenditure and physiologic parameters related to treadmill walking are higher at the same gait speed, potentially due to biomechanical differences. Using a treadmill for exercise testing or training in older adults may lead to premature fatigue or undesirable physiologic challenge. This may be of particular concern for those with low fitness or impaired mobility.

3108 Board #73 June 1 2:00 PM - 3:30 PM

**Jump Test Performance and Sarcopenia Status in Older Men and Women**

Michael Bemben, FACSM, Harshvardhan Singh, Daeyool Kim, Eonho Kim, Debra Bemben, FACSM. University of Oklahoma, Norman, OK.  
(No relationships reported)

Jumping mechanography uses maximal countermovement jumps to test measures such as jump power (JPow). Recently, it has been shown to be a safe method for assessing muscle function in older adults, however, little is known about the relationships between JPow, muscle strength, and sarcopenia status.

**PURPOSE:** To investigate the relationships between jump performance variables, muscle strength, and sarcopenia status in older men (n=27) and women (n=33) (55-75 years).

**METHODS:** Body composition was measured by a total body DXA scan to obtain appendicular skeletal muscle mass (ASM), bone free lean body mass (BFLBM) and relative skeletal muscle mass index (RSMI). Subjects were classified as sarcopenic if they had a RSMI < 7.26 kg/ht<sup>2</sup> for men and < 5.45 kg/ht<sup>2</sup> for women. Three vertical jumps on a jump mat were performed to assess JPow, jump velocity (Jvel), and jump height (JHt). Leg strength was measured by 1-RM testing for leg press (LP), right (RHAb) and left hip abduction (LHAb) isotonic resistance exercises.

**RESULTS:** Sarcopenia was found in 20% of the subjects; 24% of women and 14% of men. Sarcopenia (n=12) and normal (n=48) groups did not differ in age, or in physical activity levels. There was a significant group difference (p<0.01) in JPow, which was about 24% lower in sarcopenia group compared to the normal group (651.1 ± 41.7 watts vs. 851.0 ± 27.4 watts). JPow, Jvel, and JHt were significantly (p<0.01) positively correlated with ASM and BFLBM. There also were significant (p<0.01) positive correlations (r = .43 to .71) between jump test variables (JPow, Jvel, JHt) and leg strength measures (LP, RHAb, LHAb).

**CONCLUSION:** Jump test variables, especially jump power and jump height, were correlated with lean tissue and leg strength in older adults. The large difference in jump power between sarcopenic and normal subjects suggests this test may be useful for muscle function screening in aging populations.

3109 Board #74 June 1 2:00 PM - 3:30 PM

**Does Exercise Experience Affect Physical Function and Body Composition in PMW After Intervention?**

Huei-Jhen Wen<sup>1</sup>, Tzai-Li Li<sup>2</sup>, Pao-sheng Yen<sup>3</sup>, Paun-Yen Chong<sup>4</sup>. <sup>1</sup>Tzu Chi University, Hualien City, Taiwan. <sup>2</sup>National Taiwan Sport University, Taoyuan, Taiwan. <sup>3</sup>Tzu Chi Hospital, Taichung, Taiwan. <sup>4</sup>Tzu Chi Hospital, Hualien City, Taiwan. (Sponsor: Wojtek J. Chodzko-Zajko, FACSM)  
(No relationships reported)

**PURPOSE:** To explore the effects of group-based step aerobic (GBSA) intervention on physical function and body composition in postmenopausal women (PMW) with or without exercise experience (EE).

**METHODS:** 45 healthy PMW (age 58.7±3.7 years) were recruited in the study and randomly assigned to either an exercise group (EG, n=30) or control group (CG, n=15). EG were further divided into 2 groups with or without EE. Subjects in EG with EE (EGE, n=14) accept progressive high-intermediate intensity (75-85% maximal HR reserved, HRR) GBSA exercise for 10 weeks before this study, 3 days/week, 60-90 minutes/day, and following a 6-week detraining. Subjects in EG without EE (EGN, n=16) did not have EE before this study. EG (EGE and EGN) participated in high-intermediate intensity GBSA intervention for another 15 weeks, 75-85%HRR, 3 days/week, and 60-90 minutes/day. CG did not attend regular exercise. All subjects were asked to measure physical function (chair stand and 2 km walk test), and body composition (lean body mass percentage, fat percentage, whole body bone mineral density) by dual-energy X-ray absorptiometry at baseline and after 15 weeks. All data were analyzed by a two-way ANOVA (group×time). Significant level was set at α=.05.

**RESULT:** Performances in EGE after 15 weeks intervention were significantly better than those in CG in chair stand (33.6±6.5 vs. 27.3±6.1 times/30sec, p=.01) and 2 km walk (108.1±56.6 vs. 76.7±22.4 indexes, p=.02); whereas no significant differences among groups after intervention were found in body composition.

**CONCLUSION:** A 15-week GBSA significantly improves physical function in PMW. However, exercise experience does not appear to significantly affect physical function and body composition in PMW.

This study was granted by National Council of Science (NSC 100-2410-H-320-014).

3110 Board #75 June 1 2:00 PM - 3:30 PM

**A Portable 4-Step Stair Climb Task is a Valid Method to Determine Muscle Power and Function in the Elderly**

Amy Rolston, Petra Martins, Lucinda Salvaggio, Taylor Marcell. California State University Stanislaus, Turlock, CA.  
(No relationships reported)

**PURPOSE:** Stair climbing is an increasingly difficult task of daily living for older adults that is dependent upon many factors of fitness and performance such as muscular strength, power, agility, and balance of the lower body. The purpose of this study was to validate a portable 4-step stair climb task as a functional measure of muscular power in a group of community dwelling older adults.

**METHODS:** 36 participants (23 women & 13 men) with an average (± SD) age of 75.1 ± 7.3 yrs and a BMI of 26.6 ± 3.8 kg/m<sup>2</sup> have completed a health screening and senior fitness test including 1-RM seated isotonic leg-press, isotonic leg-press power at 70% 1-RM, balance (Romberg, unipedal, foam stance), gait, and 4-step stair climb task.

**RESULTS:** For the men, their 1-RM lower-body strength was  $258.1 \pm 94.6$  lbs and measured power was  $338.1 \pm 160.3$  W or  $3.7 \pm 1.5$  W/kg. For the women, their 1-RM lower-body strength was  $172.4 \pm 44.8$  lbs and measured power was  $145.7 \pm 74.7$  W or  $2.2 \pm 1.1$  W/kg. The calculated power during stair climbing was  $335.2 \pm 94.8$  W or  $3.7 \pm 1.0$  W/kg for the men and  $198.9 \pm 59.3$  W or  $3.1 \pm 0.9$  W/kg in the women. Normal gait speed was  $1.14 \pm 0.22$  m/s in men and  $1.22 \pm 0.29$  m/s in the women. Stair climb power was correlated with measured power ( $r = 0.74$ ,  $p = 0.001$ ), gait ( $r = 0.57$ ,  $p = 0.001$ ), balance ( $r = 0.68$ ,  $p = 0.001$ ), and age ( $r = -0.55$ ,  $p = .001$ ) in the whole group.

**CONCLUSIONS(S):** These data suggest that a portable 4-step stair climb task is a valid measure of lower body power and muscle function in the elderly and that this task appears to require greater than 70% of maximal effort.

---

**Relationship of Body Composition and Muscular Strength in Young And Middle-Aged Women**

Pamela D. Swan, FACSM, Robin De Weese. *Arizona State University, Phoenix, AZ*  
(No relationships reported)

Absolute strength generally increases with body size but decreases with age. It is unknown whether body size or body composition influences the relationship of age on peak muscular strength or fatigue.

**PURPOSE:** To determine the relationship of fat mass (FM), fat free mass (FFM), and body size (BMI) to knee extensor peak torque (PT) and muscular fatigue in young (Y) and middle-aged (MA) women.

**METHODS:** 132 women from two age cohorts (Y: 18-33 yrs,  $n = 70$  and MA: 45-65 yrs,  $n = 62$ ) participated. Subjects with musculoskeletal problems and those who had participated in strength training in the previous three months were excluded. Body composition was estimated by bioelectrical impedance analysis. Isokinetic PT of the knee extensors was assessed at  $60^\circ/\text{sec}$  and the fatigue index (FI) was calculated as the percent decline of PT during 50 maximal repetitions at  $240^\circ/\text{sec}$ . Data were assessed for normality and appropriate correlation techniques were used to compute relationships between PT and FI with body composition variables. Differences in PT between age and BMI groups (normal, N: 18-24 kg/M<sup>2</sup>; overweight, OW: 25-29 kg/M<sup>2</sup>; obese, O: 30+ kg/M<sup>2</sup>) were assessed by ANOVA.

**RESULTS:** Both cohorts were similar ( $p > 0.05$ ) in body weight (Y:  $68.1 \pm 18.6$  kg; MA:  $70.6 \pm 13.0$  kg) and FFM (Y:  $45.9 \pm 5.2$  kg; MA:  $45.1 \pm 3.9$  kg) but MA had significantly ( $p < 0.05$ ) higher FM (Y:  $22.2 \pm 13.8$ ; MA:  $25.5 \pm 10.0$ ). In Y, FFM was strongly correlated with PT ( $r = 0.63$ ;  $p < .000$ ). There were no significant correlations between FFM or FM and PT in MA. PT was correlated with FI in the combined groups ( $r = 0.18$ ;  $p = .04$ ) but FI was significantly lower (greater endurance) in MA than Y. PT normalized for body mass or FFM was similar between age groups. Relative PT significantly decreased with increasing BMI categories: (N: 1.2 ft-lb/kg; OW: 1.05 ft-lb/kg; O: 0.8 ft-lb/kg;  $p < .000$ ).

**CONCLUSION:** MA women have less PT but greater muscular endurance than Y. Higher FM was not detrimental to absolute PT in Y or MA, but was detrimental to relative PT in both groups. As women get larger, their strength relative to their body weight decreases. FM may attenuate the relationship between PT and body mass in both Y and MA women, but may enhance muscular endurance in MA women.

**Self-paced Walking Is Predicted By Leg Strength And VO<sub>2</sub>max And Not The Ventilatory Threshold.**

Konstantina Katsoulis<sup>1</sup>, Catherine E. Amara<sup>1</sup>, Bradley C. Hansen<sup>2</sup>, Liza Stathokostas<sup>2</sup>, John J. Koval<sup>2</sup>, Donald H. Paterson, FACSM<sup>2</sup>, David A. Cunningham, FACSM<sup>2</sup>. <sup>1</sup>University of Toronto, Toronto, ON, Canada. <sup>2</sup>University of Western Ontario, London, ON, Canada.  
(No relationships reported)

Walking speeds decrease with advancing age. However, given the variation in duration, distance covered and determination of pace in currently used walking assessments, it is not clear what physiological measure(s) of the aging process they reflect.

**PURPOSE:** To determine the key factors predicting self-paced walking (SPW) speeds in a large random survey of healthy and independently living men and women aged 55 to 86 years.

**METHODS:** Older men ( $70.5y \pm 8.8$ ;  $n = 208$ ) and women ( $71.5y \pm 8.4$ ;  $n = 231$ ) performed 4 X 20 metre indoor walk at the following self-selected paces: slow, normal, fast and very fast with time being recorded to the nearest second and averaged among trials. In addition, maximum aerobic power (VO<sub>2</sub>max) was determined on a treadmill with subsequent determination of the ventilatory threshold (T<sub>VE</sub>). Measures of other potential walking pace predictors included, plantar flexion (PF) strength, hip flexion, height, body mass and symptom of anxiety and depression scale score. Multiple linear regression analyses were used to determine key predictors ( $p < 0.05$ ) of walking speeds.

**RESULTS:** SPW at slow speed was significantly related to anxiety/depression ( $r^2 = .150$  and  $.107$  for male and females, respectively); this factor did not enter the regression at any other speed. The major contributors to SPW were VO<sub>2</sub>max ( $r^2 = 0.171$  and  $0.396$  in normal and very fast walking, respectively), PF strength ( $r^2 = 0.416$  in very fast walking) and BMI ( $r^2 = 0.228$  and  $0.437$  in normal and very fast walking, respectively) in men, while in women the strongest predictor of normal pace was VO<sub>2</sub>max ( $r^2 = 0.237$ ) and VO<sub>2</sub>max and PF strength ( $r^2 = 0.518$  and  $0.534$ , respectively) for very fast walking. VO<sub>2</sub>max was correlated with T<sub>VE</sub> ( $r = .84$  and  $.83$  for men and women, respectively), but in the presence of VO<sub>2</sub>max, T<sub>VE</sub> was not a significant determinant of SPW.

**CONCLUSIONS:** VO<sub>2</sub>max is a stronger predictor of SPW speeds than T<sub>VE</sub>, accounting for a greater portion of the variance with increasing speeds. PF strength further improves the prediction of walking performance at very fast speeds. Together, these results suggest that the amount and quality of muscle are important determinants of self-selected speeds of walking.

**Resting Metabolic Rate Changes in Women Following Different Exercise Training Programs**

Trista Manikowske, Donna J. Terbizan, FACSM, John Schuna, Jared Tucker, Bryan Christensen, Ardrith Brunt, Yeong Rhee. *North Dakota State University, Fargo, ND*  
(No relationships reported)

Research examining changes in resting metabolic rate (RMR) following an exercise training program has shown inconsistent results. While evidence suggests resistance training (RT) increases fat-free mass (FFM) and subsequently RMR, results of some studies have suggested that FFM increases in women may not elicit increases in RMR. Additional research in women is needed to explore the effects of RT, and combined resistance and aerobic training (COM) on FFM and RMR.

**PURPOSE:** The purpose of this study was to evaluate FFM and RMR changes in women after a 12 week RT or COM program.

**METHODS:** Eighteen women aged 38-61 years were randomized to a RT or COM group, with training occurring three times per week. Both groups participated in resistance workouts which included 30 min of upper and lower body exercises where fatigue occurred between 8-12 repetitions. The COM group then participated in 30 min of moderate intensity cardiovascular exercise during each training session. Pre- and post-test RMR data was collected in a fasted state, following 30 min of rest, for a minimum of 20 min. FFM was calculated by subtracting fat mass from total body mass, where fat mass was derived by multiplying total body mass by percent body fat measured via the Jackson-Pollock skinfold technique. Two-factor (group x time) repeated measures analysis of variance (ANOVA) was used to evaluate group differences and time-related changes in FFM and RMR. The relationship between FFM and RMR change scores was evaluated using a Pearson correlation. Alpha was set  $< .05$  for all analyses.

**RESULTS:** Significant increases (mean  $\pm$  SE) in FFM ( $+1.5 \pm .7$  kg,  $p = .045$ ) and RMR ( $+77.4 \pm 26.1$  kcal,  $p = .01$ ) were found for the entire sample from pre- to post-test. No significant differences in FFM (RT =  $54.1 \pm 2.2$  kg, COM =  $50.9 \pm 2.0$  kg,  $p = .30$ ) or RMR (RT =  $1477.5 \pm 73.1$  kcal $\cdot$ day<sup>-1</sup>, COM =  $1427.9 \pm 65.4$  kcal $\cdot$ day<sup>-1</sup>,  $p = .62$ ) were found between the RT and COM groups. In addition, no significant group x time interactions were found for the FFM ( $p = .85$ ) and RMR ( $p = .41$ ) analyses. FFM and RMR change scores were highly correlated ( $r = .68$ ,  $p < .01$ ).

**CONCLUSIONS:** Results indicate that FFM and RMR significantly increased among women in this sample after 12 weeks in a RT or COM exercise program. Neither training modality (RT or COM) proved superior in eliciting RMR or FFM changes in this study.

**3114 Board #79 June 1 2:00 PM - 3:30 PM**  
**The Portable 4-step Stair Climb Task Is a Valid Measure of Muscle Power and Function in Community Living Older Adults**

Petra Martins, Amy Rolston, Lucinda Salvaggio, Taylor Marcell. *California State University Stanislaus, Turlock, CA.*  
(No relationships reported)

**PURPOSE:** Falls in the elderly are often caused by frailty and have been shown to be a leading cause of mortality and morbidity. Stair climbing is an essential task of daily living and may be a useful measure in the evaluation of frailty in older adults. The purpose of this study was to evaluate the reliability of using the portable 4-step stair climb task as a quick assessment of muscle power and its relationship to measures of health and balance in a large group of community living older adults.

**METHODS:** Subjects consisted of 219 women with an average ( $\pm$  SD) age of  $70.6 \pm 8.5$  yrs, height  $160.4 \pm 7.9$  cm, weight  $73.0 \pm 16.7$  kg, and BMI of  $28.4 \pm 6.1$  kg/m<sup>2</sup>; there were also 91 men with an average age of  $75.5 \pm 7.7$  yrs, height  $174.8 \pm 9.5$  cm, weight  $84.9 \pm 14.8$  kg, and BMI of  $27.7 \pm 4.5$  kg/m<sup>2</sup>. Subjects participated in community based health fairs held in the Central Valley of California; they performed the Fullerton Senior Fitness Battery, a standardized balance assessment, gait analysis, and timed 4-step stair ascent. Stair climbing power was calculated using body weight (kg), vertical distance climbed (m), and time (sec). For data analysis, subjects were divided by age-groups and sex and the data compared using 2 x 3 ANOVA (IBM SPSS v 19).

**RESULTS:** Stair climb power was correlated with age ( $r = -0.27$ ,  $p = 0.001$ ), unipedal balance ( $r = 0.34$ ,  $p = 0.001$ ), balance summary score ( $r = 0.27$ ,  $p = 0.001$ ), functional reach ( $r = 0.16$ ,  $p = 0.03$ ), grip strength ( $r = 0.39$ ,  $p = 0.001$ ), chair stands ( $r = 0.30$ ,  $p = 0.001$ ), gait speed ( $r = 0.46$ ,  $p = 0.001$ ), and the 8' timed up and go test ( $r = -0.57$ ,  $p = 0.001$ ). Significant sex differences were observed for body weight ( $84.6 \pm 13.2$  men &  $71.4 \pm 15.4$  women), body fat ( $31.3 \pm 4.6\%$  men &  $39.3 \pm 6.6\%$  women), and grip strength ( $80.2 \pm 20.1$  lb men &  $49.6 \pm 13.9$  lb women), however there were no sex differences in balance, flexibility, chair stands (#), or the TUG. Stair ascent power was greater in men in both absolute ( $244.9 \pm 106.6$  W men &  $172.0 \pm 68.8$  W women) and relative ( $2.89 \pm 1.12$  W/kg men &  $2.42 \pm 0.87$  W/kg women) terms. These power values also decreased between the seventh and ninth decades in both men and women.

**CONCLUSION(S):** The portable 4-step stair climb task appears to be both a reliable and valid measure of muscle power as it is highly correlated with common measures of function in community-dwelling older adults.

**3115 Board #80 June 1 2:00 PM - 3:30 PM**  
**Influence Of Age-Related Skeletal Muscle Mass Loss On Serum Lipid/Lipoprotein Profiles And Blood Pressure In Healthy Japanese Men**

Takashi Abe<sup>1</sup>, Michael Bembem, FACSM<sup>1</sup>, Mark Loftin, FACSM<sup>2</sup>. <sup>1</sup>University of Oklahoma, Norman, OK. <sup>2</sup>University of Mississippi, Oxford, MS.  
(No relationships reported)

It has been postulated that age-related skeletal muscle loss (Sarcopenia) contributes to metabolic and cardiovascular diseases, although these relationships have not been confirmed by published research.

**PURPOSE:** We investigated the relationships between skeletal muscle mass (SMM) and serum lipid and lipoprotein concentrations and resting blood pressure in healthy Japanese men.

**METHODS:** Six hundred eighty-seven men were screened with those exhibiting clinically relevant diseases (mostly hypertension and diabetes) excluded. As a result, 414 healthy men aged 40-76 years (239 middle-aged [aged 40-59 years] and 175 older [aged 60-76 years]) were used for data analyses. Muscle thickness (MTH) and subcutaneous fat thickness (FTH) were measured by ultrasound at nine sites on the anterior and posterior aspects of the body. FTH was used to estimate the body density, from which fat mass and fat-free mass (FFM) was calculated, and MTH was used to estimate the whole body and thigh SMM. Serum total (TC) and high-density lipoprotein cholesterol (HDL) concentrations were measured using overnight fasting samples. Resting systolic (SBP) and diastolic (DBP) blood pressures were also measured.

**RESULTS:** Percent body fat (%Fat) was similar ( $P > 0.05$ ) between middle-aged ( $16.9$  [SD  $3.0$ ] %) and older ( $16.3$  [SD  $3.2$ ] %) groups, while percent SMM (whole body SMM divided by body weight) was lower in the older group ( $32.6$  [SD  $3.3$ ] %) than in the middle-aged group ( $34.1$  [SD  $2.8$ ] %). Whole body and thigh SMM were lower ( $P < 0.01$ ) in the older group ( $17.8$  [SD  $3.0$ ] kg and  $6.4$  [SD  $1.2$ ] kg, respectively) than in the middle-aged group ( $20.7$  [SD  $2.8$ ] kg and  $7.5$  [SD  $1.2$ ] kg). %Fat was directly correlated with TC ( $r = 0.327$ ,  $P < 0.01$ ), SBP ( $r = 0.098$ ,  $P = 0.046$ ) and DBP ( $r = 0.183$ ,  $P < 0.01$ ), and inversely correlated with HDL ( $r = -0.333$ ,  $P < 0.01$ ) and HDL/TC ( $r = -0.487$ ,  $P < 0.01$ ). Percent SMM was directly correlated ( $P < 0.01$ ) with HDL ( $r = 0.170$ ) and HDL/TC ( $r = 0.147$ ), and inversely correlated with SBP ( $r = -0.106$ ,  $P = 0.03$ ). However, there were inverse correlations between absolute SMM as well as SMM index (divided by height square) and HDL or HDL/TC.

**CONCLUSIONS:** Age-related SMM loss appears to be associated with lower risk profiles. Percent SMM as well as %Fat is a good predictor of measured risk factors.

**Muscle Quality Measurement Techniques: Changes Among Age-Stratified Elderly Adults**

Abbie E. Smith<sup>1</sup>, Jeffrey R. Stout<sup>2</sup>, Kristina L. Kendall<sup>2</sup>, David H. Fukuda<sup>2</sup>, Joel T. Cramer, FACSM<sup>3</sup>, Jordan R. Moon<sup>4</sup>. <sup>1</sup>University of North Carolina Chapel Hill, Chapel Hill, NC. <sup>2</sup>University of Oklahoma, Norman, OK. <sup>3</sup>Oklahoma State University, Stillwater, OK. <sup>4</sup>United States Sports Academy, Daphne, AL.  
(No relationships reported)

Muscle quality (MQ) is muscle strength expressed relative to segmental muscle mass and may be important for identifying early onset sarcopenia. **PURPOSES:** To evaluate upper- and lower-body MQ measurements and body composition [fat mass (FM); muscle mass (MM); percent fat (%Fat)] using dual-energy x-ray absorptiometry (DEXA) and segmental bioelectrical impedance spectroscopy (BIS) across age cohorts.

**METHODS:** 93 elderly men and women (Mean SD; age:  $72.5 \pm 6.0$  yrs; Ht:  $168.4 \pm 8.9$  cm; Wt:  $72.6 \pm 13.8$  kg) were stratified by age (65-67 yrs = Grp 1; 68-71 = Grp 2; 72-75 = Grp 3; 76-79 = Grp 4; 80-89 = Grp 5). Body composition, arm, and leg MM was measured with DEXA and BIS, while upper- and lower-body muscle strength was assessed with handgrip dynamometry (GRIP) and maximal concentric isokinetic leg extensions (EXT  $60^\circ\text{s}^{-1}$ ), respectively. MQ was calculated for DEXA and BIS-derived MM for upper- [GRIP (kg)/MM (kg)] and lower-body [EXT  $60^\circ\text{s}^{-1}$  (Nm)/MM (kg)].

**RESULTS:** For upper- and lower-body BIS MQ, Grp 1>5, Grp 2>5, and Grp 3>5 ( $p < 0.05$ ). For lower-body DEXA MQ, Grp 1>5, Grp 2>5, and Grp 4>5 ( $p < 0.05$ ). There were no differences among age groups for upper-body DEXA MQ ( $p > 0.05$ ). When collapsed across age, BIS over-predicted MM compared to DEXA for upper- ( $19.2 \pm 9.5$  kg vs.  $11.7 \pm 2.1$  kg;  $p < 0.05$ ) and under-predicted lower-body ( $6.9 \pm 2.7$  kg vs.  $8.1 \pm 2.4$  kg;  $p < 0.05$ ). There were no differences among measurement techniques or age groups for FM ( $p = 0.055$ - $0.866$ ).

**CONCLUSION:** MQ may be a good indicator of early-onset sarcopenia when changes in MM are too small to quantify with BIS or DEXA alone. Based on stronger correlation coefficients, DEXA may be better for upper-body MQ, while both BIS and DEXA methods are suitable for lower-body MQ measurements. Future studies are needed to establish normative MQ and changes in MQ with strength training. Study sponsored by Abbott Nutrition, Columbus, Ohio

**3117 Board #82 June 1 2:00 PM - 3:30 PM**  
**Vitamin D Status is Not Associated with Muscle Mass or Physical Function in Older Adults**

Chad Straight<sup>1</sup>, Christie Ward<sup>1</sup>, Mina Mojtahedi<sup>2</sup>, Rudy Valentine<sup>2</sup>, Mary Ann Johnson<sup>1</sup>, Ellen Evans, FACSM<sup>1</sup>. <sup>1</sup>University of Georgia, Athens, GA. <sup>2</sup>University of Illinois, Urbana-Champaign, IL.  
(No relationships reported)

Low vitamin D concentrations have been implicated in the age-related decline in muscle mass and physical function evident in older adults. However, the relationship between vitamin D status and physical function remains incompletely characterized.

**PURPOSE:** Therefore, the aim of this study was to investigate the association between vitamin D status, lean mass, and indices of lower-extremity physical function (LEPF) in older adults.

**METHODS:** Community-dwelling older adults ( $n = 139$ , 73 male;  $69.3 \pm 6.6$  years) underwent assessments for vitamin D status, body composition and LEPF. Serum concentrations of 25-hydroxyvitamin D [25(OH)D] were ascertained via ELISA and low vitamin D was defined as serum 25(OH)D  $< 20$  ng/ml. Whole-body and regional soft tissue composition was assessed via dual-energy X-ray absorptiometry. Muscle quality (MQ) was calculated as maximal voluntary contraction of the quadriceps muscle normalized for mineral-free lean mass (MFLM) of the upper leg. LEPF was measured via the timed up-and-go test (UPGO), 400-m walk, and 30-second chair stand test. Partial correlations controlled for sex and month of blood draw were performed to

examine the association of vitamin D concentration with body composition and LEPP. Analysis of covariance adjusted for sex and month of blood draw was conducted to analyze differences in MQ, MFLM and LEPP between those with low vitamin D and those with serum 25(OH)D  $\geq$  20 ng/ml.

**RESULTS:** Approximately 64.0% of the cohort had low serum 25(OH)D concentrations (serum 25(OH)D < 20 ng/ml). Vitamin D levels were not significantly associated with upper leg MQ or MFLM of the total or upper leg. Likewise, there was no association between 25(OH)D and UPGO time, 400-m walk time, or performance on the 30-second chair stand test. There were no differences in upper leg MQ or total leg MFLM between those with low serum 25(OH)D and those with serum 25(OH)D  $\geq$  20 ng/ml (both  $p > 0.05$ ). Moreover, there were no differences between groups in UPGO time, 400-m walk time, or 30-second chair stand performance (all  $p > 0.05$ ).

**CONCLUSION:** These data suggest that vitamin D status is not associated with measures of body composition or LEPP in older men and women. Further research should attempt to elucidate the role of potential mediators of the relationship between vitamin D and physical function in older adults.

**3118** Board #83 June 1 2:00 PM - 3:30 PM

**Predicting 8-foot Up Go From Exercise Self-efficacy, Balance Confidence, Depressive Symptoms, And Life Satisfaction**

Zac Geary. University of Central Oklahoma, Edmond, OK.

(No relationships reported)

Zac Geary<sup>1</sup>, Kelsey Hubble<sup>1</sup>, Pam Farris<sup>1</sup>, Justin Steffy<sup>1</sup>, Dalton Delaney<sup>1</sup>, Simon Smith, Tyler Karnes<sup>1</sup>, Blake Hamill<sup>1</sup>, Taniqua Ward<sup>1</sup>, Kayla Garver<sup>1</sup>, Paul House<sup>1</sup>, Melissa Powers<sup>1</sup>, and Michelle Gray<sup>2</sup>. University of Central Oklahoma, Edmond, OK<sup>1</sup>, University of Arkansas, Fayetteville, AR<sup>2</sup>

In order to initiate programs to prevent or reverse the deterioration in functional fitness which can be found in an aging population, it is important to have effective screening tools that can help determine the functional fitness levels in this population. Screening surveys are easy to administer and can be conducted from remote locations which allows more individuals to be screened quickly.

**PURPOSE:** The purpose of this study was to determine if exercise self-efficacy, balance confidence, depressive symptoms, and life satisfaction can predict performance on the 8-foot Up-and-Go (UpGo) test. **METHOD:** Thirty-six senior adults over the age of 75 years who volunteered to participate in an exercise program completed the following surveys: Exercise Self-Efficacy (ESE), Activities-Specific Balance Confidence (ABC), Center for Epidemiological Studies Depression Scale (CESD), and Satisfaction with Life Scale (SLS). Participants also completed the UpGo test which is a measure of functional dynamic balance and agility and is part of the Senior Fitness Test developed by Rikli and Jones (1999). A multiple regression analysis was conducted to examine the aforementioned predictive variables on the UpGo.

**RESULTS:** Overall, 67% of the variability in UpGo performance can be attributed to ESE, ABC, CESD, and SLS. In this model, ABC, CESD, and SLS were indicated as significant predictors of UpGo ( $p = .000$ ,  $p = .038$ ,  $p = .033$ , respectively). The ESE was not a significant predictor for the UpGo ( $p = .319$ ), while the ABC was the strongest predictor for the UpGo with a partial correlation of  $-.761$  ( $p < .001$ ).

**CONCLUSION:** These results indicate that the ABC, CESD, and SLS surveys are effective in predicting functional fitness levels in a senior population. Utilizing these surveys allow health-care professionals to identify elders at-risk for functional limitations and to recommend programs designed to improved functionality. This early intervention can possibly help reduce the need for assistance and loss of independence.

**3119** Board #84 June 1 2:00 PM - 3:30 PM

**The Association Between Incidental Physical Activity and Cardiorespiratory Fitness**

Trevor O'Neill, Morgan Craig-Broadwith, Robert Ross, FACSM. Queen's University, Kingston, ON, Canada.

(No relationships reported)

Cardiorespiratory fitness (CRF) is a strong predictor of cardiovascular disease and mortality. The association between structured physical activity (activity that meets consensus guidelines) and CRF is well established. Yet, the association between incidental physical activity (IPA; sporadic, unstructured physical activity that does not meet consensus guidelines) and CRF remains less clear.

**PURPOSE:** The primary objective of this study was to determine whether the duration and the expenditure of objectively measured IPA were associated with CRF in abdominally obese, adult men and women. A secondary objective was to determine whether sporadic moderate physical activity (MPA; accrued in bouts less than 10 min) was associated with CRF.

**METHODS:** Participants were abdominally obese (waist circumference >102 cm in men and >88 cm in women), self-reported inactive and weight-stable men ( $n=26$ ) and women ( $n=62$ ). IPA encompassed light physical activity (LPA; 1-2.99 METs), sporadic MPA (3-5.99 METs) and sporadic vigorous physical activity (VPA;  $\geq 6$  METs). IPA was measured using the SenseWear Pro Armband (SWA) collected over a period of 7 days, and was categorized into duration (min/day) and expenditure (MET-min/day). CRF, measured as peak oxygen consumption per unit of time (peak  $\text{VO}_2$ ), was assessed using a graded treadmill test.

**RESULTS:** Participants accumulated an average of  $318.6 \pm 125.2$  min of IPA per day, which was composed of  $277.3 \pm 117.3$  min of LPA and  $40.8 \pm 16.8$  min of MPA. Both duration ( $r^2=0.45$ ,  $p<0.05$ ) and expenditure ( $r^2=0.44$ ,  $p<0.05$ ) of IPA were significantly associated with CRF independent of sex, however upon further control for body mass index (BMI) and age neither association remained significant ( $p>0.10$ ). Both duration ( $r^2=0.65$ ,  $p<0.05$ ) and expenditure ( $r^2=0.66$ ,  $p<0.05$ ) of sporadic MPA were significantly associated with CRF after control for covariates.

**CONCLUSIONS:** The principle finding is that IPA is not associated with CRF after control for BMI; however, sporadic MPA remains an independent predictor of CRF in abdominally obese adults. This finding suggests that while intensity of physical activity is important for improvement in CRF, benefits are not restricted to MPA that conforms to consensus guidelines. These initial findings have important public health implications.

**Functional Outcomes of Exercise Progression Models in the Elderly**

Jason D. Allen<sup>1</sup>, Jennifer L. Robbins<sup>1</sup>, Neil Johanssen<sup>2</sup>, Mitch VanBruggen<sup>1</sup>, Daniel Credeur, FACSM<sup>3</sup>, Brandon Hollis<sup>3</sup>, Johanna L. Johnson<sup>1</sup>, Timothy Church<sup>2</sup>, William E. Kraus, FACSM<sup>1</sup>, Eric Ravussin<sup>2</sup>, Conrad Earnest<sup>2</sup>, Katherine L. Ham<sup>1</sup>, Carl Pieper<sup>1</sup>, Michael A. Welsch, FACSM<sup>3</sup>. <sup>1</sup>Duke University Medical Center, Durham, NC.

<sup>2</sup>Pennington Biomedical Research Center, Baton Rouge, LA. <sup>3</sup>Louisiana State University, Baton Rouge, LA.

(No relationships reported)

A challenge for our aging nation is to define interventions that can abate the decline in functional capacity and prevent a loss of independence.

**PURPOSE:** To determine differences between; (A) 4 weeks of a regionally specific training stimulus (RSTS) versus standard aerobic exercise training (AET); and (B) the effects of subsequent 8 weeks of progressive whole-body training protocol; on  $\text{VO}_{2\text{peak}}$  and combined 1RM strength (CIRM); and (2).

**METHODS:** Subjects over 70yr, who scored between 218-490yards on a 6MWT were randomized to AET or RSTS for the first 4 weeks (Phase 1). AET consisted of walking/biking at 40-60% of HRR. RSTS consisted of specific muscle group exercises focused on the calf, thigh, buttocks, arms, shoulders, and torso. Each exercise was performed for 3 to 5mins, at ~40-70% of the MVC of the primary muscle group of interest. Subjects in both groups exercised for 60mins 3days per week and were progressed as tolerated. Subsequently, all subjects were advanced to a well-rounded, whole-body exercise program using established ACSM guidelines (Phase 2).

**RESULTS:** Both groups included 54 subjects, age =  $76 \pm 5$  yrs. After adjustment for baseline, there was a group by time effect in favor of RSTS for  $\text{VO}_{2\text{peak}}$  following phase 2 (see fig). Additionally, RSTS showed greater gains than AET in CIRM following both phase 1 ( $+40$ lbs vs.  $+17$ lbs,  $p<0.01$ ) and phase 2 ( $+35$ lbs vs.  $+19$ lbs,  $p<0.01$ ).

**CONCLUSION:** The gains in aerobic capacity and maximal strength at the end of phase 2 were superior in those who used RSTS during phase 1. These results suggest RSTS may serve as a physiological primer able to remove peripheral barriers that limit functional capacity, in the elderly.

Supported by IRC1AG035822-01 and the Duke University Claude D. Pepper OAIC (AG0287) to JDA

#### Effects of Acute Exercise on Expressions of Natural Killer Cell Receptors

Masatoshi Suzui<sup>1</sup>, Kazuyoshi Takeda<sup>2</sup>, Hideo Yagita<sup>2</sup>, Ko Okumura<sup>2</sup>, Pang N. Shek<sup>3</sup>, Roy J. Shephard, FACSM<sup>4</sup>, <sup>1</sup>Meiji University, Tokyo, Japan. <sup>2</sup>Juntendo University, Tokyo, Japan. <sup>3</sup>Defence R & D Canada-Toronto, Toronto, ON, Canada. <sup>4</sup>University of Toronto, Toronto, ON, Canada.  
(No relationships reported)

**PURPOSE:** Mobilization and cytotoxicity of natural killer (NK) cells are regulated by cell surface receptors such as adhesion molecules, chemokine receptors and activating/inhibitory receptors. In this study, we examined the effects of acute exercise on the expression of these various cell surface molecules and receptors.

**METHODS:** Six healthy male college students (20.7 ± 1.2 yrs olds) exercised on the cycle ergometer for 30 min at intensities depending on individual onset of blood lactate accumulation level (70-85%VO<sub>2</sub>max). Venous blood samples were collected at rest (PRE), just before the end of exercise (END) and 30 (POST 30), 60 (POST 60), 120 (POST 120) and 180 (POST 180) min after exercise. The phenotype and density of CD16, CD56, CD44, CD62L, CD159a, CD197, CD212, CD226, CD314, CD335 and CX<sub>3</sub>CR<sub>1</sub> on CD56<sup>dim</sup> NK cells were determined by flow cytometry. Cytotoxicity was measured using a <sup>51</sup>Cr release assay.

**RESULTS:** With regard to adhesion molecules, the percentage of CD62L (L-selectin)<sup>negative</sup> cells in total CD56<sup>dim</sup> NK cells significantly increased at END (p=0.0217) and returned to PRE values at POST 30. These changes induced a decreased expression of CD62L at END. We also observed decreased expression of CD44 (HCAM, p=0.0002) and CX<sub>3</sub>CR<sub>1</sub> (Fractalkine Receptor, p=0.0167) at END. On the other hand, regarding to the NK cell activating receptors, the expressions of CD335 (NKp46) increased at END (p=0.0073), and then decreased to below PRE values at POST 120 (p=0.0362) and POST 180 (p=0.0019). The expressions of CD226 (DNAM-1, p=0.0495) and CD212 (IL-12R, p=0.0063) were also decreased at POST. Expression of CD16 (Fc gamma-R1II) decreased at END (p=0.0146) but returned to PRE levels at POST 30. Total cytotoxicity (E/T=20/1) increased at END (p=0.046) and decreased during the recovery period (p=0.0006-0.0153), but lytic units per NK cell remained unchanged throughout the experiment.

**CONCLUSION:** These results suggest that changes in adhesion molecules expression contribute to NK cell mobilization. Acute exercise also influenced the expression of other NK cell activating receptors but these changes do not directly related to per cell cytotoxicity.

This study was supported by the Grant-in-Aid for Scientific Research (B), Japan Society for the Promotion of Science, No. 21300257.

#### The Effect Of The Training-competition Phases In Immune Response In Triathlon

Blanca R. Rangel-Colmenero<sup>1</sup>, Germán Hernández-Cruz<sup>1</sup>, Fernando Ochoa-Ahmed<sup>1</sup>, Adrián J. Rosas-Taraco<sup>2</sup>, Jeanette M. Lopez-Walle<sup>1</sup>, Oscar Salas-Fraire<sup>2</sup>.  
<sup>1</sup>Facultad de Organización Deportiva UANL, Monterrey, Mexico. <sup>2</sup>Facultad de Medicina, UANL, Monterrey, Mexico.  
(No relationships reported)

**PURPOSE:** The immune response was analyzed during the pre-competition and competition training periods for Master triathlon athletes of Monterrey, Mexico to establish the physiological bases for Mexican athletes as the main objective and as result, to apply personalized training programs.

**METHODS:** The sample was composed of 12 male triathlon athletes, with ages between 28 to 45 years, all signed an informed consent, blood samples were taken, for the quantification of the immune response cells, trough spectrophotometric techniques in reference laboratory. The blood samples were taken weekly early in the morning before the athlete begun their physical activity during a five week training phase, during the competition phase, the blood samples were taken: immediately after competition, two hours after competition, forty eight hours and seven days after competition. During the week after competition the athletes performed light physical activity for recovery.

**RESULTS:** All the analyzed variables presented a high significance difference (P<0.01) between takes, the leucocytes and neutrophils showed a normal level behavior during the pre competition phase, immediately after they finished their competition and two hours after competition, a high significance increment was observed (takes 6 and 7) to return to normal levels during the one week post competition recovery phase. The eosinophils, basophils, lymphocytes and monocytes, showed a contrary behavior to the phenomena described before, during the pre competition phase they did not show significant changes, but right after the competition was over, the cell concentration diminished in high significance way and they acquire their normal level after the one week post competition recovery phase.

**CONCLUSIONS:** The immune response reflected a change in the number of blood cells of the athletes after performing exhausting physical activity, these cells acquire their normal levels after a week recovery period. It is important to emphasize that in an individual way each athlete showed a different response to training. The results presented in this study were an average, in some cases the athletes showed higher or lower values concluding that integral physical personalized training is strictly necessary for triathlon as a sport and also to avoid over training.

### 3123 Board #88 June 1 3:30 PM - 5:00 PM

#### Effect Of Ultra-Endurance Exercise On Markers Of Inflammation, Hemolysis, And Hepcidin

Renate M. Leithauser<sup>1</sup>, Heinz J. Roth<sup>2</sup>, Michael Doppelmayr<sup>3</sup>, Holger Finkemagel<sup>4</sup>, Serge P. von Duvillard, FACSM<sup>3</sup>, Lawrence A. Golding, FACSM<sup>5</sup>, Ralph Beneke, FACSM<sup>6</sup>. <sup>1</sup>University of Essex, Colchester, United Kingdom. <sup>2</sup>Laboratory Limbach, Heidelberg, Germany. <sup>3</sup>University of Salzburg, Salzburg, Austria. <sup>4</sup>Performance Testing Unit, Bad Berleburg, Germany. <sup>5</sup>University of Nevada, Las Vegas, NV. <sup>6</sup>Phillips University, Marburg, Germany.  
(No relationships reported)

Endurance exercise such as marathon running has been shown to induce immunological responses similar to those seen in inflammation. It has also been identified as potentially leading to hemolysis. Hepcidin, recently recognized as a key regulator of systemic iron metabolism, has been found to be increased following a marathon race possibly induced by an exercise related increase in interleukin-6 (IL-6), a marker known to induce an acute phase response. It remains unknown whether ultra-endurance exercise leads to a more pronounced hepcidin response due to a cumulative effect of hemolysis and acute phase response.

**PURPOSE:** To investigate the effect of a 216-km run on leukocyte count and hemoglobin (hb), plasma concentrations of IL-6, C-reactive protein (CRP), haptoglobin and hepcidin in experienced endurance runners.

**METHODS:** Venous blood samples were obtained from seven highly-trained male athletes (mean (SD): 52.0 (10.6) yrs, 176.6 (9.4) cm, 75.9 (7.8) kg) before the start of the race, after 42 km and after termination of the race for the analysis of the above listed markers.

**RESULTS:** Hb did not change significantly during the race (g/dl: 14.3 (0.6); 14.8 (1.0); 14.0 (1.2), p>0.05). Leukocytes and CRP at test termination (11.7 (2.1) x10<sup>9</sup>/l and 33.2 (22.4) mg/l) were higher (p<0.05) compared to pre-run (6.0 (1.3) x10<sup>9</sup>/l and 1.0 (0.6) mg/l) and 42 km (8.4 (2.4) x10<sup>9</sup>/l and 1.0 (0.5) mg/l). Haptoglobin was decreased at 42 km (g/l: 0.60 (0.16) vs. 0.83 (0.22) pre-run, p<0.001) with no significant change thereafter (0.68 (0.29) g/l). IL-6, below detection level (< 2 ng/l) at km0, showed a significant increase at 42 km (8.8 (3.9) ng/l, p<0.001). The further increase at test termination (17.2 (16.7) ng/l) did not reach statistical significance. Hepcidin levels did not change significantly during the race (µg/l: 183.4 (59.7); 182.6 (70.2); 167.4 (49.0), p>0.05).

**CONCLUSIONS:** The clear increases in leukocytes and CRP throughout the race indicate inflammation probably induced by the increase of IL-6 in the early phase of the race. The haptoglobin decrease after 42 km demonstrates some hemolysis during the same period. Although inflammation has been described previously to stimulate hepcidin production, hepcidin remained unchanged during this ultramarathon in non-anemic males.

**Chronic Changes In Serum IL-6 And TNF- $\alpha$  Following 12 Weeks Of Concurrent Resistance And Aerobic Exercise Are Dependent On Exercise Mode And May Affect Adaptation.**

Brad S. Lambert, Justin P. Dobson, Dr. Stephen F. Crouse, FACSM. *Texas A&M University, College Station, TX.*  
*(No relationships reported)*

**PURPOSE:** To examine physiological responses to concurrent resistance and land treadmill training (RT-LTM) compared to concurrent resistance and aquatic treadmill training (RT-ATM) and the chronic effect of each on serum TNF- $\alpha$  and IL-6 (cytokines associated with chronic inflammation, CVD, and skeletal muscle metabolism).

**METHODS:** Twenty-six untrained subjects (M: n=13, 98.6 $\pm$ 17.1kg, 182.2 $\pm$ 6.2cm, 34 $\pm$ 11yrs, F: n=13, 78.9 $\pm$ 14.0kg, 165.1 $\pm$ 5.1cm, 38 $\pm$ 11yrs) were screened to assess VO<sub>2max</sub>, Bcomp (DEXA), and strength (Lifts: leg press, chest press, leg curl, lat pull, leg ext, triceps push-down, biceps curl). Subjects were then randomized into 2 groups (RT-LTM<sup>m=6, f=7</sup> | RT-ATM<sup>m=7, f=6</sup>). Each performed progressive RT (2/wk, 3 x 8-12 @ 60%-->80% 1RM) for 12 wks. Both groups also performed 12 wks of aerobic LTM or ATM (60-->85%VO<sub>2max</sub>) respectively. ATM or LTM occurred immediately following RT sessions and in isolation on a 3<sup>rd</sup> day during the wk. Kcal/session: Wk 1-6 = 250-->500 kcal/session, Wk 6-12 = 500 kcal/session. Baseline tests were re-performed at wk 6 and after training. Blood samples were obtained in the rested state before and after training. Serum TNF- $\alpha$  and IL-6 was analyzed using a multiplex assay kit (Luminex®, Millipore®). A 2x2 Mixed Model ANOVA w/ repeated measures was used to examine absolute and relative changes in the independent variables listed in the table.

**RESULTS:**

| INDEP. VAR.  | Lean Mass (kg)                  | Fat Mass (kg)                    | %Body Fat (%)                    | VO <sub>2max</sub> (ml/kg/min)   | Total Strength (lbs)              | IL-6 (pg/dl)                       | TNF- $\alpha$ (pg/dl)             |

| % $\Delta$ = Calculated From Each Individual Subjects Change From Baseline |                                 |                                  |                                  |                                  |                                   |                                    |                                   |
| RT-LTM   | 2.56% $\pm$ 1.39 <sup>†,a</sup> | -6.49% $\pm$ 2.38 <sup>†,a</sup> | -5.78% $\pm$ 1.80 <sup>†,a</sup> | 14.06% $\pm$ 2.34 <sup>†,a</sup> | 21.29% $\pm$ 1.13 <sup>†,a</sup>  | 125.92% $\pm$ 36.56 <sup>†,a</sup> | -1.82% $\pm$ 5.99 <sup>a</sup>    |
| RT-ATM   | 4.20% $\pm$ 0.93 <sup>†,b</sup> | -2.14% $\pm$ 1.55 <sup>b</sup>   | -4.10% $\pm$ 1.49 <sup>†,a</sup> | 4.51% $\pm$ 3.04 <sup>†,b</sup>  | 27.07% $\pm$ 1.74 <sup>†,b</sup>  | 28.05% $\pm$ 34.69 <sup>b</sup>    | -13.04% $\pm$ 5.40 <sup>†,b</sup> |

Values are means  $\pm$  SE. % $\Delta$  = Individual change from baseline. Like letters = not significantly different between groups, <sup>†</sup>=Significant change from baseline ( $\alpha \leq 0.05$ ).

**CONCLUSION:** Chronic RT-LTM and RT-ATM training elicit different effects on markers of chronic inflammation which may be related to differing health and fitness outcomes observed between our groups.

**3125 Board #90 June 1 3:30 PM - 5:00 PM**  
**Effects of Exercise Training on Inflammatory and Hypoxic Gene Expression in White Adipose Tissue**

Melissa A. Linden<sup>1</sup>, Yair Pincus<sup>1</sup>, Stephen A. Martin<sup>1</sup>, Jeffrey A. Woods, FACSM<sup>1</sup>, Tracy Baynard<sup>2</sup>. <sup>1</sup>University of Illinois at Urbana-Champaign, Champaign, IL.  
<sup>2</sup>University of Illinois at Chicago, Chicago, IL.  
*(No relationships reported)*

Obesity contributes to the development of inflammation and lifestyle related diseases, such as type II diabetes mellitus. Exercise training can have anti-inflammatory effects but it is unclear if it is a potent enough stimulus to positively affect white adipose tissue (WAT) and glucose regulation in the presence of an obesigenic diet.

**PURPOSE:** To determine the effect of 12 weeks of a very high fat (VHF) diet and/or exercise training (EX) on glucose regulation and inflammatory and hypoxic gene expression within white adipose tissue.

**METHODS:** Male C57BL/6J mice (n=39) were randomized into four groups: low-fat (LF)/sedentary (SED), LF/EX, VHF/SED, and VHF/EX. The VHF and LF diets were 60% and 10% fat, respectively. The mice were placed on the diet and exercise intervention concomitantly. Exercise training consisted of treadmill running 5 d/wk at 12 m/min, 5% incline, 40 min/d for 12 weeks. A subset of mice had intraperitoneal glucose tolerance tests (IPGTT). Quantitative real-time PCR was used to determine gene expression of inflammatory and hypoxia markers within white adipose tissue.

**RESULTS:** Animals given the VHF diet gained more weight than mice on the LF diet (p<0.05) but weight gain was partially attenuated by exercise training (p<0.05). The VHF diet also increased epididymal fat pad weight relative to total body mass (p<0.05). Animals on the VHF diet had impaired glucose tolerance as indicated by increased area under the glucose curve (p<0.05), with exercise training having no effect (p>0.05). The VHF diet increased gene expression markers of inflammation, tumor necrosis factor alpha, interleukin-1 receptor antagonist (IL-1ra), interleukin-6 (IL-6), and interleukin 10 (IL-10) (p<0.05), within the WAT. Exercise was able to reduce the expression IL-1ra in animals on a VHF diet (p<0.05). The VHF diet increased hypoxia inducible factor 1(HIF-1) but exercise training did not attenuated HIF-1 gene expression in the VHF diet fed animals (p>0.05).

**CONCLUSION:** Concomitant exposure to moderate exercise training for 12 weeks may help reduce body weight but does not show robust effects in stemming inflammation within the WAT. Supported by University of Illinois Research Board seed grant.

**3126 Board #91 June 1 3:30 PM - 5:00 PM**  
**Effects of Exercise Training in Mice Models of Graft Versus Host Disease**

Carmen Fiuza-Luces<sup>1</sup>, Africa González-Murillo<sup>2</sup>, Isabel Colmenero<sup>2</sup>, Jesús Martínez Palacios<sup>3</sup>, Alejandro Lucia<sup>1</sup>, Manuel Ramírez<sup>2</sup>. <sup>1</sup>Universidad Europea de Madrid, Madrid, Spain. <sup>2</sup>Hospital Infantil Universitario Niño Jesús, Madrid, Spain. <sup>3</sup>CIEMAT, Madrid, Spain. (Sponsor: Carl Foster, FACSM)  
*(No relationships reported)*

**PURPOSE:** Graft vs. host disease (GVHD) is a major complication of hematopoietic stem cell transplantation (HSCT), with a morbimortality of 30-40%. We evaluated the effects of post-HSCT aerobic training on several aspects of GVHD in a murine acute (cytotoxic, C57BL/6J) and chronic model (inflammatory, BALB/C): clinical course, post-HSCT immune cell reconstitution and cytokine profile.

**METHODS:** Twenty C57BL/6J (H-2<sup>b</sup>) and twenty-eight BALB/C (H-2<sup>d</sup>) female adult recipient mice (age: 8-12wk) were assigned to an exercise (EX; n=11 C57BL/6J mice, and n=15 BALB/C) or sedentary control group (CONT; n=9 C57BL/6J, n=13 BALB/C). All mice were adapted to treadmill running 3d before completing a maximal test; thereafter they were total-body irradiated before HSCT. All mice were transplanted through the tail vein (with donor bone marrow cells (10x10<sup>6</sup>/mouse) and donor splenocytes (20x10<sup>6</sup>/mouse<sub>C57BL/6J</sub> and 10x10<sup>6</sup>/mouse<sub>BALB/C</sub>)). The exercise program started 2d after HSCT, lasted 11wk (5 sessions/wk), and ended with a second maximal test; running speed and inclination, and exercise duration were gradually increased over time. GVHD was monitored daily with a severity score that incorporates (individually and in combination) 5 clinical parameters: weight loss, posture (hunching), activity, fur texture, and

skin integrity. Before HSCT, 21d and 54d post-HSCT, and in the day of death, we collected blood samples for immune cell reconstitution (B220, CD3, CD4, CD8, Mac1 subpopulations) and cytokine analysis (IL2, IL4, IL6, IL17A, TNF- $\alpha$  and INF $\gamma$ ).

**RESULTS:** In C57BL/6J, physical capacity significantly increased in EX and decreased in CONT whereas in BALB/C, the decline in physical capacity was attenuated in EX ( $P=0.001$  and  $P=0.021$  for the between-group comparison, respectively). We found a significant group\*time interaction effect for total clinical score ( $P=0.002$ ) and mice hair ( $P<0.001$ ) in C57BL/6J, and for activity ( $P<0.001$ ) and hunching ( $P=0.045$ ) in BALB/C, all reflecting a beneficial effect of exercise. The exercise benefits were not accompanied by significant improvements in immune cell reconstitution or inflammatory profile ( $P>0.05$  for interaction effects).

**CONCLUSIONS:** Aerobic exercise seems to have a beneficial effect on the clinical course of GVHD, especially in its less severe model

#### Changes Of Tlr4 Signaling-mediated Protein Expression With Endurance Exercise In Rats

Hyo Jeong Kim, Hyo Seong Yeo, Hyeong Tae Kwon, Chang Keun Kim. *korea national sport univ., seoul, Korea, Democratic People's Republic of*

(No relationships reported)

The innate immune response is the first line of defence against infectious disease. A group of proteins that comprise Toll or Toll-like family of receptors (TLRs) has been suggested as one of the markers associated with immune and inflammatory responses. TLR4 among the TLRs produces a response by lipopolysaccharide (LPS) and controls inflammatory responses.

**PURPOSE:** This study was performed to demonstrate the change of TLR4 signaling-mediated protein expressions in skeletal muscle during the recovery of intensive endurance exercise.

**METHODS:** Sprague-Dawley rats (12weeks,  $n=35$ ) were randomly divided into five groups ( $n=7$  each) to time period of the exercise (pre, post 0 h, 30min, 1 h and 6 h). The rats ran on the rodent treadmill for 1 hour at the level of 75–80%  $VO_{2max}$  (28m/min). The change of TLR4, MyD88 protein expression and NF $\kappa$ Bp65 DNA binding activity were analyzed by western blotting in Extensor Digitorum Longus (EDL) muscle.

**RESULTS:** TLR4 protein expression was significantly decreased by 41% ( $p=0.036$ ) with the intensive endurance exercise, whereas MyD88 was not changed. NF $\kappa$ B significantly increased by 51% ( $p=0.014$ ) at 1h of recovery, but returned to the resting level 6 h post exercise.

**CONCLUSIONS:** These results suggest an interaction between TLR4 and NF $\kappa$ B suggesting that exercise-induced change of TLR4 expression may serve as a messenger molecules to defence inflammatory response in rat skeletal muscle.

#### Lymphocyte Apoptosis And TNF- $\alpha$ In Smokers And Non-smokers Following Different Intensity Of Exercises

Kyung-Shin Park<sup>1</sup>, Yang Lee<sup>2</sup>, Brian K. McFarlin, FACSM<sup>3</sup>. <sup>1</sup>Texas A&M International University, Laredo, TX. <sup>2</sup>Texas A&M University, College Station, TX. <sup>3</sup>University of Houston, Houston, TX.

(No relationships reported)

Chronic smokers have an antioxidant imbalance and suppressed immunity, which may make them more susceptible to post exercise immune suppression. It is possible that the concentration of inflammatory cytokines may be differentially altered after exercise in smokers vs. non-smokers.

**PURPOSE:** The purpose of the study was to examine changes in inflammatory cytokines and lymphocyte apoptosis after exercise in smokers compared to non-smokers.

**METHODS:** Fourteen physically inactive smokers (SM,  $\geq 1$  pack year,  $n=7$ ) and non-smokers (NS,  $n=7$ ) aged 18 to 26 (SM:  $20.67 \pm 0.96$  vs. NS:  $20.17 \pm 0.26$ , *Mean* $\pm$ *SE*) were recruited. Each subject completed three treadmill runs at different intensities in a random order (60%, 70%, and 80% of  $VO_{2max}$ ). Running distance for all three runs was equivalent to 30-min run at 70%  $VO_{2max}$ . Lymphocyte apoptosis and levels of inflammatory cytokines (TNF- $\alpha$ , IL-4,6,10) were analyzed at rest (PRE), immediately after (POST), and 1 h following (1H) each run. Data was analyzed using two-way repeated measures ANOVA with  $P<0.05$ .

**RESULTS:** Lymphocyte apoptosis increased following all three running trials in dose dependent manner to exercise intensity ( $P=0.01$ ). SM had greater lymphocyte apoptosis than NS at POST following 60% ( $12.5 \pm 0.62\%$  vs.  $9.97 \pm 0.51$ ,  $P=0.008$ ) and 70% trials ( $17.53 \pm 0.57\%$  vs.  $15.6 \pm 0.41$ ,  $P=0.018$ ). There was no significant difference for lymphocyte apoptosis for either SM or NS at Post following 80%  $VO_{2max}$  run. SM showed higher level of TNF- $\alpha$  as compared to NS ( $47.0 \pm 4.3$  pg/ml vs.  $30.4 \pm 4.7$ ,  $P=0.025$ ) and TNF- $\alpha$  at Post was significantly higher in both SM ( $55.5 \pm 5.1$ ,  $P=0.023$ ) and NS ( $34.0 \pm 5.5$ ,  $P<0.023$ ) than Pre (SM:  $41.3 \pm 4.3$ , NS:  $29.5 \pm 4.7$ ) and 1h post (SM:  $44.2 \pm 4.1$ , NS:  $27.7 \pm 4.4$ ).

**CONCLUSIONS:** Smokers had greater lymphocyte apoptosis compared to non-smokers following runs at 60% and 70%  $VO_{2max}$ , but not following a run at 80%  $VO_{2max}$ ; however, changes in TNF- $\alpha$  did not appear to explain this effect. More research is needed to understand the mechanisms that contribute to the apoptosis following exercise in smokers.

#### Circulating TWEAK Is Affected By High-intensity Intermittent Exercise In Healthy Children

Thanh Nguyen<sup>1</sup>, Joyce Obeid<sup>1</sup>, Hilde E. Ploeger<sup>1</sup>, Tim Takken<sup>2</sup>, Brian W. Timmons<sup>1</sup>. <sup>1</sup>McMaster University, Hamilton, ON, Canada. <sup>2</sup>University Medical Center Utrecht, Utrecht, Netherlands. (Sponsor: Boguslaw Wilk, FACSM)

(No relationships reported)

Tumor necrosis factor related weak inducer of apoptosis (TWEAK) is a potent muscle degrading cytokine. In children, the rate of muscle growth is greatest around the age of peak height velocity (PHV). While physical activity is considered a biological requisite for healthy growth and development, the mechanisms translating exercise into healthy growth during childhood are not well understood.

**PURPOSE:** To examine the effects of moderate-intensity continuous exercise (MICE) and high-intensity intermittent exercise (HIIE) on TWEAK in healthy children at different stages of growth.

**METHODS:** Twenty-five healthy children (mean age:  $13.6 \pm 2.4$  years, 5 females) had their peak aerobic mechanical power (PMP) determined using an incremental cycling test. MICE, consisting of 2 x 30-min bouts of cycling at 50% PMP, and HIIE, consisting of 6 sets of 4 x 15-sec bouts of cycling at 100% PMP, were performed one week apart. Venous blood was drawn at rest (REST), at end of exercise (EX-END) and after 60 min of recovery (REC). Serum was analyzed for TWEAK using ELISA. Comparisons were done between children at the age of PHV ( $n=7$ , 2 females) and children who were either before or after the age of PHV using repeated measures two-way ANOVA.

**RESULTS:** In response to HIIE, TWEAK decreased at EX-END ( $718.8 \pm 136.7$  pg/ml,  $p<0.05$ ) compared to REST ( $1144.3 \pm 534.5$  pg/ml,  $p<0.05$ ) in children at the age of PHV. TWEAK at EX-END was lower in children at the age of PHV ( $718.8 \pm 136.7$  pg/ml) compared to children who were not ( $1112.8 \pm 389.4$  pg/ml,  $p<0.05$ ). In addition, the change from rest was greater for children at the age of PHV ( $-407.5 \pm 486.6$  pg/ml) than children who were not ( $-13.5 \pm 342.8$  pg/ml,  $p<0.05$ ) for HIIE (Main effect for group,  $p<0.05$ ). MICE had no effect on TWEAK.

**CONCLUSIONS:** The muscle degrading cytokine, TWEAK, was decreased by HIIE in children who are in a phase of rapid growth. The reduced TWEAK levels may be a mechanism by which exercise reflecting children's natural physical activity patterns helps promote growth.

#### Circus Physical Exercise Decrease Partially Excessive Activation Of T Lymphocytes In Overweight Children

Cesar Miguel Momesso<sup>1</sup>, Silvia Guirado<sup>1</sup>, Kim Caçula<sup>1</sup>, Fabio Takeo<sup>2</sup>, Cristina Cassoni<sup>1</sup>, Cristiane Borges<sup>1</sup>, Vinicius Coneglian<sup>2</sup>, Tania Pithon-Curi<sup>1</sup>, Rui Curi<sup>2</sup>, Renata Gorjão<sup>1</sup>. <sup>1</sup>UNICSUL, São Paulo, Brazil. <sup>2</sup>USP, São Paulo, Brazil.

(No relationships reported)

Obesity associated with sedentary lifestyle can lead to changes in the immune system function, resulting in the development of inflammatory diseases. The occurrence of these diseases may be related to a change in the primary control exerted by T lymphocytes

**PURPOSE:** The aim of this study was to evaluate the mechanisms of lymphocyte activation in overweight children, when performing or not circus physical exercises.

**METHODS:** The studied group was composed by 60 children, pubescent, divided in four subgroups: Overweight Children (OWC) (10.67 ±0.90 years old and BMI 23.02 ±2.74); Overweight Exercise (OWE) (10.00 ±1.41 years old and BMI 24.64 ± 3.03); Eutrophic Children (EC) (11.00 ±1.24 years old and BMI 17.51 ±1.98); and Eutrophic Exercise (EE) (10.60 ±1.06 years old and BMI 16.80 ±2.53). OWE group practiced circus activities twice a week, during six months. CD95 and CD25 expression in CD4+ lymphocytes and T regulatory cells (Treg) percentage were evaluated by flow cytometry; proliferative capacity by incorporation of thymidine and lymphocyte mRNA expression of IL-35, TGF-beta, IL-2 and IL-10 was determined by real time PCR.

**RESULTS:** A higher lymphocyte proliferative capacity was observed in OWC and OWE groups when compared to EC (3509 ±887.2; 2694 ±560.4 and 1768 ±208.2 cpm, respectively). The same was observed in comparison to EE (2313 ±111 cpm) groups. In the CD95 expression, EC (953.9 ±101.2) and EE groups (736.7 ±194.6) showed higher values than the OWC group (522.1 ±125) and OWE group (551.6 ± 144.5). The percentage of Treg was lower in OWC than in EC and EE groups. mRNA expression of IL-35 and IL-10 was lower in OWC and OWE groups in relation to EC and EE. Plasma cytokine concentration was not altered in any group. These results indicate that an imbalance in lymphocyte regulation occurs in overweight children. These cells are involved in the suppression of excessive activation of peripheral lymphocytes evidenced by proliferation assay. In addition, a lower expression of CD95 is related to a fail in the inhibition of excessive lymphocyte proliferation.

**CONCLUSIONS:** These alterations indicate that overweight children are more prone to develop diseases related to immune system function and circus exercises partially revert these factors.

**The Time Course For Changes In Leukocyte Count In Response To Exercising In A Hot Environment**

Wade L. Knez<sup>1</sup>, Kelly B. Knez<sup>1</sup>, Jonathan Peake<sup>2</sup>. <sup>1</sup>Aspetar, Qatar Orthopaedic and Sport Medicine Hospital, Doha, Qatar. <sup>2</sup>The University of Queensland, Brisbane, Australia.

(No relationships reported)

Exercising in a hot environment is associated with a multitude of cardiovascular alterations such as an increase in core temperature, dehydration and cardiac drift. However, there is minimal research investigating the time course of changes in leukocytes in response to exercise and thermal stress. Additionally, it is not known whether there is a critical point in core temperature for alterations in leukocytes.

**PURPOSE:** To investigate the time course of changes in blood leukocyte relative to core temperature during and following endurance exercise in a hot environment.

**METHODS:** Eight recreational cyclists (age=30.9±2.2 yrs; height=177.9±4.1 cm; mass=74.5±4.5 kg) completed a VO<sub>2</sub>max in hot conditions (35°C, 70% RH) to determine 60% of peak power output. One week later the participants returned to the laboratory and cycled at this intensity until they reached a core temperature of 38.5°C. Blood was sampled before, during, and after (0, 10, 25, 35, 45, post 10 and post 20 mins) exercise. Statistical analysis was completed using marginal models with a level of significance set at P<0.05.

**RESULTS:** Cycling at 60% of peak power output until core temperature reached 38.5°C showed an effect of time on circulating numbers of neutrophils (F=22.1, P<0.001), lymphocytes (F=8.3, P<0.001), monocytes (F=8.1, P<0.001) and eosinophils (F=4.5, P=0.002). However, these alterations in leukocytes were not related to changes in core temperature during exercise and recovery.

**CONCLUSION:** Changes in leukocytes appear to be more sensitive to the exercise duration rather than changes in core temperature. Furthermore, these data showed that there was no critical core temperature for change in leukocyte count.

3132 Board #97 June 1 3:30 PM - 5:00 PM

**Heat Potentiates Epinephrine-induced Interleukin-6 In C2c12 Cells**

Steven S. Welc, Thomas L. Clanton. University of Florida, Gainesville, FL

(No relationships reported)

Circulating IL-6 is elevated in conditions such as hyperthermia and exercise. Skeletal muscle (SM) is a known producer of IL-6 in a variety of conditions and it may play a role in the whole body immune response. Furthermore, SMs are known for their heat generating capability. Previously, we have identified heat as a unique stimulus of IL-6 in SM in both cell culture, *in vitro*, and *in vivo* mouse muscle.

**PURPOSE:** Objectives of this study: 1) to determine if C2C12 cells produce more IL-6 in response to epinephrine (EPI) when combined with an acute heat stimulus, 2) to compare the response of myoblasts and myotubes to these combined stimuli, and 3) to investigate the pattern of secreted cytokines and chemokines that are up-regulated in response to EPI alone and in combination with heat.

**METHODS:** C2C12 cells were grown to 80% confluence, then supplemented with EPI (100 ng/ml) and simultaneously exposed to 37 °C or 42°C for 1 hr. Cells were then harvested or allowed to recover at 37°C for 1 and 2 hr. In a separate experiment, cells were treated with varying doses of EPI (0.1, 1, 10, and 100 ng/mL) and kept at 37°C for 6 hr or treated at 42°C for 1 hr and allowed to recover for 5 hr, post-heat. The cellular supernatant was sampled and analyzed for protein(s) using both ELISA and Luminex.

**RESULTS:** Significant up regulation of IL-6 mRNA was seen in myoblasts and myotubes in response to EPI (P<.05). In myoblasts the addition of heat to the EPI stimulus potentiated the increase of IL-6 when compared to EPI alone (P<0.05); the amplification of the IL-6 mRNA response spanned 3 hr. In contrast, with myotubes, heat-potentiated IL-6 mRNA was not seen until 2 hr. In addition to the IL-6 signal, multiple cytokines and chemokines were up regulated in response to EPI and potentiated when co-stimulated with heat.

**CONCLUSION:** These results further demonstrate that hyperthermia is a functional stimulus for IL-6 mRNA and protein in SM. Furthermore, the results suggest that the myoblast phenotype is more responsive to heat as a co-stimulus than myotubes. The influence of muscle derived cytokines on the systemic immune response is still poorly understood. Our results suggest that SM produces more IL-6 when temperature is up-regulated. We speculate that SM may play a role in the elevations of circulating IL-6 seen in exercise, hyperthermia, and other stressors.

**Six-minute Walk Test And Physical Activity Are Associated With Hs-crp In Community Dwelling Older Adults**

Flavia C. Wanderley<sup>1</sup>, André Moreira<sup>2</sup>, Carmo Palmares<sup>3</sup>, José Oliveira<sup>1</sup>, Joana Carvalho<sup>1</sup>. <sup>1</sup>Research Center in Physical Activity, Health and Leisure, Faculty of Sport Sciences, University of P, Porto, Portugal. <sup>2</sup>Faculty of Medicine, University of Porto, Porto, Portugal. <sup>3</sup>Faculty of Medicine, University of Porto,, Porto, Portugal.

(No relationships reported)

Increase physical activity (PA) and fitness is recommended for health promotion and disease prevention in adults but there is conflicting evidence regarding the extent to which high levels of PA and aerobic fitness prevented low-grade chronic inflammation in older adults.

**PURPOSE:** This study aimed to observe the correlates and associations between aerobic fitness and daily physical activity with biomarkers of inflammation.

**METHODS:** Eighty-five old individuals (21 men, 68.0±5.5years, BMI = 28.3±4.5 kg/m<sup>2</sup>) were analyzed: aerobic fitness (six-minute walk test; 6MWT), objectively assessed PA (accelerometers, counts/min), body composition (DXA), interleukin (IL) 6 (IL-6) and 10 (IL-10), Tumor necrosis alpha (TNF-alpha), interferon-gamma (IFN-gamma) and high-sensitive C-reactive protein (hs-CRP) were assessed. Pearson correlation analysis was used to assess the relationship between 6MWT, PA and inflammatory biomarkers. To examine the shared variance between 6MWT, PA and biomarkers, linear regression analyses were employed.

**RESULTS:** Inverse associations were observed between 6MWT and hs-CRP ( $r = -0.359$ ;  $p < 0.01$ ) as well as between PA and hs-CRP ( $r = -0.311$ ;  $p < 0.05$ ). Data from linear regression reinforced that 6MWT ( $p < 0.01$ ) as well as PA ( $p < 0.01$ ) were significantly associated with hs-CRP even when models were adjusted to trunk fat, inserting this covariable in models increased from 11.7 to 22.6% ( $p < 0.01$ ) and from 8.3 to 22.2% the hs-CRP variance explained by the models (6MWT and PA, respectively).

**CONCLUSION:** Our study reinforces the idea that lower fitness and PA levels are related with low-grade chronic inflammation as assessed by hs-CRP. Supported by the Portuguese Foundation for Science and Technology (grants number, PTDC/DES/108780/2008 and SFRH/BD/33124/2007)

3134 Board #99 June 1 3:30 PM - 5:00 PM

**Effects of 12-weeks Walking Program on Oxidative Stress Markers in Older Adults**

Masaki TAKAHASHI, Masashi Miyashita, Jong-Hwan Park, Noriaki Kawanishi, Harumi Hayashida, Hyun-Shik Kim, Yoshio Nakamura, Shizuo Sakamoto, Katsuhiko Suzuki. *Waseda University, Tokorozawa, Japan., Saitama, Japan.*  
(No relationships reported)

Oxidative stress is associated with the increased risk of atherosclerosis and cardiovascular disease. Oxidative stress or chronic inflammation increase with advancing age and regular exercise exerts anti-oxidant/inflammatory effects. However, it remains unclear whether exercise at an amount lower than currently recommended confers such anti-oxidant/inflammatory effects in older adults.

**PURPOSE:** The purpose of this study was to investigate the effects of 12 weeks of supervised walking program below the current recommended amount of exercise on oxidative stress and antioxidant capacity in older adults.

**METHODS:** Twenty-eight older adults (65-78 yr) were assigned into either control (N = 14) or exercise (N = 14) group. Exercise program consisted of walking 30-60 min/session on 2 days of the week for 12 weeks. Blood samples were taken at baseline and after 12 weeks in both groups. Fasting plasma concentration of reactive oxygen metabolites (d-ROMs), advanced oxidation protein products (AOPP), thiobarbituric acid reactive substances (TBARS), myeloperoxidase (MPO), biological antioxidant potential (BAP), thioredoxin (TRX) and activity of superoxide dismutase (SOD), catalase (CAT), glutathione peroxidase (GPX) were measured.

**RESULTS:** Plasma d-ROMs concentrations tended to be decreased only in the exercise group after 12 weeks compared with the baseline values (P=0.05). Compared with the control group, there was a significant decrease in plasma AOPP concentrations after 12-weeks walking program (P<0.05). Plasma BAP, TRX concentrations and GPX activity were significantly increased only in the exercise group after 12 weeks compared with the baseline values (P<0.05). Plasma CAT activity was significantly decreased only in the exercise group after 12 weeks compared with the baseline values (P<0.05). Plasma TBARS, MPO concentrations and SOD activity did not change significantly in both groups after 12 weeks. **CONCLUSIONS:** These findings demonstrate that a 12 week of walking program equivalent to an amount of exercise below the current minimum recommendation in older adults may attenuate basal oxidative stress and increase protection against oxidative stress by increasing antioxidant capacity.

3135 Board #100 June 1 3:30 PM - 5:00 PM

**Physical Exercise And Immunosenescence: Can We Play For Healthy Ageing?**

Elisa Calabria<sup>1</sup>, Silvia Pogliaghi<sup>1</sup>, Kenneth Dyar<sup>2</sup>, Gianluca Salvagno<sup>1</sup>, Carlo Morandi<sup>1</sup>, Gian Cesare Guidi<sup>1</sup>, Stefano Schiaffino<sup>2</sup>, Federico Schena<sup>1</sup>, Carlo Capelli<sup>1</sup>.  
<sup>1</sup>University of Verona, Verona, Italy. <sup>2</sup>Venetian Institute of Molecular Medicine, Padova, Italy.  
(No relationships reported)

Ageing is accompanied by the modification and the progressive dysfunction of systemic immunity. High and moderate intensity dynamic exercise can affect gene expression profiles of human white blood cells even after a single bout of exercise. However, it is not clear how the genes implied in immune system modulation may be regulated in response to physical exercise and whether the immune cells of elderly people can be responsive to the "exercise stimulus".

**PURPOSE:** To characterize the interplay of ageing and physical activity in the process of immunosenescence by using a large-scale approach based on microarray analysis.

**METHODS:** We evaluated the transcriptional profile of whole blood cells (WBCs) produced by single bouts of exercise of different intensities. Experiments have been carried out on two groups of 10 healthy men of different age (50±5 and 70±5 yy) recruited locally. Both groups performed in two different occasions 30 min of constant workload cycling exercise corresponding to 80% and 60% of V'O<sub>2max</sub>. RNA-stabilized blood samples were obtained 30 min before and 1hr after each constant load tests. Gene expression of WBCs was evaluated using whole genome microarray expression analysis with Affymetrix Human Gene 1.0 ST arrays.

**RESULTS:** Results from Gene Set Enrichment Analysis highlighted age-related differences at the baseline connected to immune response, stress response, cellular metabolic pathways and cell death. In both groups the exercise performed at different intensities brought about slightly different signature, and the observed patterns differed as a function of age. Several known gene pathways related to cell proliferation, cellular metabolism, cytokine regulation, inflammation and cellular differentiation were modified.

**CONCLUSIONS:** Ageing alters gene expression profile of immunocompetent cells. A single bout of physical exercise can modulate the activity and the interactions of immunocompetent cells and blood cells composition.

---

3136 Board #101 June 1 3:30 PM - 5:00 PM

**Lymphocyte Subset Response To An Acute Bout Of Exercise Following A Night Of Sleep Disruption**

Lesley Ingram<sup>1</sup>, Richard Simpson<sup>2</sup>, Eva Malone<sup>1</sup>, Geraint Florida-James<sup>1</sup>. <sup>1</sup>Edinburgh Napier University, Edinburgh, United Kingdom. <sup>2</sup>University Of Houston, Houston, TX.  
(No relationships reported)

Lymphocyte subsets that demonstrate high cytotoxic capabilities (Natural Killers (NK) cells, KLRG1+/CD8+ T-cells) are highly responsive to acute exercise, which may suggest a role for cytotoxic T-cells during post-exercise immune surveillance. Sleep disruption (DS) is known to alter biological rhythms and catecholamine responses to acute stress. As the mobilisation of cytotoxic lymphocytes with exercise is governed by β<sup>2</sup> adrenergic receptors and catecholamines, DS could alter lymphocyte trafficking in response to exercise.

**PURPOSE:** To determine if a night of DS alters cytotoxic lymphocyte mobilisation and extravasation in response to acute exercise.

**METHODS:** Ten male cyclists (age (27 ± 8 years), height (176 ± 7 cm), mass (74 ± 8 kg) performed a 40k TT on a cycle ergometer. Using a randomised cross-over experimental design, participants completed two further trials cycling for 1hour at 90% of the mean wattage obtained from the 40km TT, following either a night of DS (woken every hour of the night over an 8 hour period) or a night of undisturbed sleep (US) (left undisturbed for an 8hour period). Heart rate (HR) was recorded and the Epworth Sleepiness Scale (ESS) was completed during trials. Blood lymphocytes were isolated before, immediately after, and 1 h post exercise and assessed for cell surface expression of CD45RA, CD45RO, γδ TCR and KLRG1, and lymphocyte subset markers (CD3, CD4, CD8, CD56) by 4-colour flow cytometry.

**RESULTS:** Following the DS trial, sleepiness and rating of perceived exertion (RPE) was significantly elevated, whereas average HR was lowered during exercise. Numbers of all lymphocyte subsets (CD3+, CD3+/CD4+, CD3+/CD8+, CD3-/CD56+) increased with exercise. Baseline lymphocyte counts and lymphocyte subset counts were unaffected by DS, however total lymphocytes and CD3-/CD56+ NK-cells were mobilized in greater numbers in response to exercise following DS compared to US. Cortisol, epinephrine and norepinephrine were also unaffected by DS.

**CONCLUSION:** One night of sleep disruption lowers the heart rate response and amplifies the mobilisation of NK-cells in response to acute exercise. These data indicate that altered sleep patterns could interfere with the trafficking of cytotoxic lymphocytes in response to acute exercise and might play a role in athlete infection susceptibility.

---

3137 Board #102 June 1 3:30 PM - 5:00 PM

**The Effect of Tai Chi Chuan on Th1 / Th2 Balance in Middle-aged and Older Women**

Beibei Luo, Ru Wang, Yajun Zhang, Peijie Chen. *Shanghai University of Sport, Shanghai, China.*  
(No relationships reported)

**PURPOSE:** Tai Chi Chuan (TCC) exercise improves cellular immune function by increasing the ratio of interferon-γ (IFN-γ) and interleukin-4 (IL-4). And regulatory T cell (Treg) may play a role in regulating T helper (Th) cell differentiation. However, the gene level changes of Treg and Th cells under TCC exercise remains to be determined. Therefore, this study investigated the effect of TCC exercise on cytokines and co-stimulatory molecules mRNA expression of Th and Treg cells in middle-aged and older women, to explore the possible mechanism that TCC exercise promotes Th1/Th2 balance under Treg's regulation.

**METHODS:** 34 middle-aged and older women were assigned to TCC group (TCC: 16, age: 59.23±2.49) and control group (CON: 18, age: 59.68±3.01). All subjects had no experience of TCC. Before (PRE) and after (POST) the TCC exercise, we used real-time polymerase chain reaction to test the mRNA expression of Th and Treg cytokines and co-stimulatory molecule:

transforming growth factor- $\beta$  (TGF- $\beta$ ), interleukin-10(IL-10), cytotoxic T lymphocyte antigen 4 (CTLA-4), IL-4 and IFN- $\gamma$ , normalized by GAPDH. And CD4+CD25+CD127low Treg cells in peripheral blood were detected by flow cytometry.

**RESULTS:** Before TCC exercise program, there were no significant differences between TCC group and CON group in mRNA expression of cytokines and co-stimulatory molecules, or the percentage of Treg cells in CD4+ T cells. After TCC exercise, the mRNA expression of IFN- $\gamma$  (TCC: 2.60 $\pm$ 0.46, CON: 1.08 $\pm$ 0.22,  $p$ <0.01) and IFN- $\gamma$ /IL-4 ratio were significantly increased in TCC group (TCC: 5.12 $\pm$ 1.15, CON: 3.38 $\pm$ 0.22,  $p$ <0.05). The percentage of Treg cells in CD4+ T cells in TCC group was higher than control group (TCC: 10.77 $\pm$ 0.80, CON: 7.22 $\pm$ 0.28,  $p$ <0.01). In addition, we found an increasing on mRNA expression of TGF- $\beta$  (PRE: 4.48 $\pm$ 0.46, POST: 1.46 $\pm$ 0.53,  $p$ <0.01), CTLA-4 (PRE: 55.46 $\pm$ 6.03, POST: 208.27 $\pm$ 26.31,  $p$ <0.01) and IL-10 (PRE: 68.23 $\pm$ 7.30, POST: 102.60 $\pm$ 17.18,  $p$ <0.01) in TCC group after 32-week exercise. It indicates that Treg cells mediators negatively affect the Th2 cytokines mRNA expression, therefore increase Th1 cytokines mRNA expression.

**CONCLUSIONS:** Long-term TCC exercise enhances the number of Treg cells and the mRNA expression of Treg cells mediators that helps to improve Th1/Th2 balance in middle-aged and older women.

**3138** Board #103 June 1 3:30 PM - 5:00 PM

**Inflammatory Response Induced By Treadmill Exercise To Fatigue In Mice**

Albená Nunes-Silva, Priscila Teles Toledo, Bárbara Maximino Rezende, Fernando Lopes, Elisa Couto Gomes, Mauro Martins Teixeira, Vanessa Pinho. *Universidade Federal de Minas Gerais (UFMG), Belo Horizonte, Brazil.*

(No relationships reported)

Researches show that during an acute bout of exercise there is an activation and mobilization of immune cells into circulation, a change in pro-inflammatory cytokine production an increase in neutrophil count and in ROS production through oxidative burst process. These indicate changes in biologic redox state and onset of an extremely potent inflammatory process in response to exercise. Nevertheless, the kinetics of inflammatory markers on blood and muscular tissue immediately and hours after an exercise bout is not fully elucidated.

**PURPOSE:** The aim of this study is, thus, to investigate the kinetics in exercise-induced inflammatory markers in mice running to fatigue.

**METHODS:** C57/BL6 animals performed exercise to fatigue in a treadmill. Blood and muscle tissue samples were collected. Creatine kinase (CK) was assessed by CK-NAC kit. Leukocyte recruitment was assessed by intravital microscopy and cytokines by ELISA.

**RESULTS:** Preliminary results show an enhancement (4 $\pm$ 1 to 5.9 $\pm$ 1.4 mMol/dL) in plasma lactate concentration immediately after exercise. CK increased from basal levels (300 $\pm$ 55.3 U/L) at 6h (720 $\pm$ 182.6 U/L) and 12h (691 $\pm$ 114.6 U/L) after exercise to fatigue. There was an increase leukocyte rolling from basal level (10.2 $\pm$ 2.6 cells) at 3h (75.4 $\pm$ 27.7 cells), 6h (98.7 $\pm$ 16.6 cells), 12h (129.5 $\pm$ 20.20 cells) and 24h (51.7 $\pm$ 19.5 cells) after exercise. The adhesion cell was increased 6h (5.4 $\pm$ 5.8 cells) when compared with control group (0.5 $\pm$ 0.5 cells). Treatment with apocynin (NADPH oxidase inhibitor) 30min before exercise completely reduced this cell recruitment. An increase in IL-10 concentration was observed 6h post-exercise (57.3 $\pm$ 22.2 to 104.4 $\pm$ 42.8 pg/100mg muscle tissue) when compared with control group (without apocynin), but there were no changes, at any time-point, in the other analysed cytokines (IL-6, TNF- $\alpha$ , KC, MIP-2 e IL-1 $\beta$ ). In addition, the total number of cells in the blood increased 12h (71.0 $\pm$ 28.5  $\times$ 10<sup>5</sup>/ml) and 24h (80.2  $\pm$  12.5  $\times$ 10<sup>5</sup>/ml) after exercise when compared with control group (28.6 $\pm$ 10.8  $\times$ 10<sup>5</sup>/ml). The number of neutrophils and lymphocytes also increased 12h and 24h after exercise when compared with control group.

**CONCLUSIONS:** These findings suggest that exercise to fatigue leads to a cross-talk between immune system and muscular tissue.

---

**3139** Board #104 June 1 3:30 PM - 5:00 PM

**Estradiol  $\beta$  Receptor Expression on Human B-lymphocytes in Response to Acute Heavy Resistance Exercise**

Maren S. Fragala<sup>1</sup>, William J. Kraemer, FACSM<sup>2</sup>, Megan R. Wolf<sup>2</sup>, Andrea M. Mastro<sup>3</sup>, Craig R. Denegar<sup>2</sup>, Jeff S. Volek<sup>2</sup>, Jay R. Hoffman, FACSM<sup>1</sup>, Carl M. Maresh, FACSM<sup>2</sup>. <sup>1</sup>University of Central Florida, Orlando, FL. <sup>2</sup>University of Connecticut, Storrs, CT. <sup>3</sup>The Pennsylvania State University, University Park, PA.

(No relationships reported)

Estradiol has previously been attributed for mediating gender differences in physiological responses to tissue damage. Since the neuro-endocrine and immune systems coordinate the body's response to such stress, we hypothesized that estradiol  $\beta$ -receptors (ER) on b-lymphocytes may coordinate such communications and explain the protective responses previously reported in women.

**PURPOSE:** The purpose of this investigation was to examine ER expression on circulating b-lymphocytes in response to an acute bout of heavy resistance exercise in men and women.

**METHODS:** Using a within subject design, fifteen resistance trained women (n=7; age= 22 $\pm$ 3 y) and men (n=8; age= 25 $\pm$ 5 y) performed a heavy resistance exercise squat protocol (6 sets of 5 reps at 90% 1RM) (EX) and a control test (CON) in a balanced, randomized order. Blood samples were collected before, during and after the exercise and control trials. ER expression on circulating lymphocytes was evaluated with flow cytometry and serum estradiol was assayed by ELISA.

**RESULTS:** Serum estradiol did not significantly differ between men (CON=48.0 $\pm$ 22.3 pg $\cdot$ ml<sup>-1</sup>) and women (CON=86.5  $\pm$  60.5 pg $\cdot$ ml<sup>-1</sup>) nor change during recovery to the exercise stress in men (6 HR POST-EX = 49.7 $\pm$ 13.6 pg $\cdot$ ml<sup>-1</sup>; 24 HR POST-EX=60.1  $\pm$  15.1 pg $\cdot$ ml<sup>-1</sup>) or women (6 HR POST-EX = 73.9 $\pm$ 35.8 pg $\cdot$ ml<sup>-1</sup>; 24 HR POST-EX=105.4  $\pm$  66.9 pg $\cdot$ ml<sup>-1</sup>). ER on b-lymphocytes showed large inter-individual variations before exercise (relative fluorescence = 22.3 - 28.8) and trends for differences at 6-hours post-exercise (relative fluorescence = 32.1 - 54.4). However, no significant gender differences or changes in response to the exercise protocol were observed.

**CONCLUSIONS:** Present findings reveal that estradiol- $\beta$  receptors on b-lymphocytes unlikely explain gender differences in physiological responses to tissue damage elicited by acute heavy resistance exercise. It is possible that interactions may occur beyond the recovery period measured in the present study or it may be that ER on muscle tissue, rather than b-lymphocytes, dictate the protective effects of estradiol previously reported in women.

**Men and Women Differ in Antimicrobial Protein Expression**

Trevor Gillum, Tara Holguin, Layla Riley. *California Baptist University, Riverside, CA.*

(No relationships reported)

Antimicrobial proteins (AMP) potentially serve as a defense against upper respiratory tract infections (URTI) and may be altered by exercise. Limited data is available regarding the role of moderate exercise intensity and AMP expression. In addition, no studies have addressed potential sex and menstrual phase differences in AMP expression after moderate exercise.

**PURPOSE:** To quantify sex and menstrual phase differences in AMP expression before and after treadmill running.

**METHODS:** 19 healthy, college age men and women (9 men: 11.5 $\pm$ 4.2 %BF, 63.0 $\pm$ 5.4 ml-1kg FFM-1min-1; 10 women: 18.7 $\pm$ 3.8 %BF, 62.6 $\pm$ 9.4 ml-1kg FFM-1min-1) completed 2 bouts of treadmill running at 70% VO<sub>2</sub>pk for 45 min. Exercise sessions were separated by 14.9 $\pm$ 2.7 days. Women were counterbalanced to be tested in the follicular (day 4.1 $\pm$ 1.1) and luteal (day 20.2 $\pm$ 1.0) phase. Saliva was collected pre, post, and 1 hr post exercise in the morning after an overnight fast. Saliva was analyzed for lactoferrin (Lac), lysozyme (Lys), and immunoglobulin A (IgA) using ELISA.

**RESULTS:** Lac Osm: $\mu$ g was higher in follicular (165 $\pm$ 97) compared to luteal (148 $\pm$  117)( $p$ <0.05), but was not affected by exercise. Lac concentration (pre: 11012 $\pm$ 903 ng/ml, post: 20729 $\pm$ 16833 ng/ml) secretion rate (pre: 6122 $\pm$ 5943 ug/min, post: 12374 $\pm$ 11492 ug/min) and Osm: $\mu$ g (pre: 142 $\pm$ 115, post: 226 $\pm$ 166) increased from pre to post exercise ( $p$ <0.05), but was not different between sexes. IgA concentration (243 $\pm$ 219 ug/ml; 194 $\pm$ 93 ug/ml) and Osm: $\mu$ g (3.1 $\pm$ 1.5; 2.4 $\pm$ 0.9) was higher in women compared to men ( $p$ <0.05), but did not change after exercise. Lys concentration (56539 $\pm$ 21903 ug/min, 22954 $\pm$ 14766 ug/min) secretion rate (36300 $\pm$ 25698 ug/min, 17090 $\pm$ 15391 ug/min), and Osm: $\mu$ g (817 $\pm$ 391, 309 $\pm$ 201) was higher in men compared to women ( $p$ <0.05), but did not change with exercise.

**CONCLUSIONS:** Previous reports suggest that individuals who habitually exercise experience fewer URTI, and this has been related to AMPs. Since Lys and IgA were unaffected by moderate exercise, Lac may be a more sensitive marker of immune function after aerobic exercise and thus warrants future research. Additionally, women may experience more URTI than men, and this could be explained by the menstrual and sex differences shown in AMP expression.

#### Acute Responses of Lipoprotein Fractions Following a Single Bout of Exercise in Postmenopausal Women with Hypercholesterolemia

Yunsuk Koh, Allen Sexton, Kavya Chelikani, Daniel Chilek, Douglas Boatwright, Rick Carter, FACSM. *Lamar University, Beaumont, TX.*

(No relationships reported)

Abnormal lipoprotein fractions are associated with accelerated atherosclerosis and premature cardiovascular disease (CVD). Sedentary postmenopausal women, in particular, have elevated risk factors for CVD than premenopausal or male counterparts. Aerobic exercise at moderate intensity may positively modify the lipoprotein profiles, yet there is only limited research examining how a single bout of aerobic exercise can affect the serum lipoprotein fractions in hypercholesterolemic postmenopausal women.

**PURPOSE:** To examine the acute responses of serum lipoprotein fractions ( $\alpha$ , pre- $\beta$ , and  $\beta$ ) over the 48-hour period following a single bout of moderate intensity aerobic exercise in hypercholesterolemic postmenopausal women.

**METHODS:** Thirteen sedentary, hypercholesterolemic (defined as TC > 200 mg/dl; average TC = 241.7 mg/dl) postmenopausal women (age = 57.4 years), who were not on hormone replacement therapy or lipid lowering medications, volunteered for the study. Participants performed both exercise and rest trials in random order. For the exercise trial, participants performed a single bout of aerobic exercise at 60% of heart rate reserve on the treadmill until 400 kcal were expended. Participants came to the laboratory for blood draws only during the rest trial. Serum samples were collected at pre (0), 24, and 48 hours after each trial (exercise or rest) to analyze the lipoprotein fractions using electrophoresis.

**RESULTS:** A 2 X 3 [trial (exercise and rest) X time (0, 24, and 48 hours)] repeated measures ANOVA revealed that the  $\alpha$ -lipoprotein fraction in the exercise trial (35.67%) was significantly higher ( $p = 0.006$ ) than the rest trial (34.85%), while the  $\beta$ -lipoprotein fraction in the exercise trial (56.79%) was significantly lower ( $p = 0.001$ ) than the rest trial (57.63%). As for the main effect for time, the  $\beta$ -lipoprotein fraction at 24 hours (56.27%) was significantly ( $p = 0.008$ ) lower than 0 (57.83%) or 48 hours (57.53%). However, there was no trial X time interaction in changes in the  $\beta$ -lipoprotein fraction. The pre- $\beta$  fraction remained unchanged.

**CONCLUSION:** A single bout of aerobic exercise requiring 400 kcal can positively modify the serum  $\alpha$ - and  $\beta$ -lipoprotein fractions in postmenopausal women with hypercholesterolemia.

#### Exercise Energy Expenditure and Postprandial Lipaemia in Girls

Keith Tolfrey, Alex Engstrom, Caoileann Murphy, Alice Thackray, Robert Weaver, Laura Barrett. *Loughborough University, Loughborough, United Kingdom.*

(Sponsor: Keith George, FACSM)

(No relationships reported)

Acute bouts of exercise attenuate postprandial lipaemia in adolescent boys compared with rest although not in a dose-dependent manner. However, it is not clear if these findings apply to girls as their postprandial triacylglycerol (TAG) response to exercise has not been examined previously.

**PURPOSE:** To examine the effect of 30 and 60 min of moderate intensity treadmill walking on postprandial [TAG] in healthy girls.

**METHODS:** Fourteen 10 to 14 year old girls completed three, 2 day trials in a counter-balanced crossover design separated by 14 days. On day one, they rested (CON), or completed 30 min (EX30) or 60 min (EX60) of intermittent treadmill exercise at 56% peak VO<sub>2</sub> inducing energy expenditures of 752 and 1487 kJ respectively. On day two, after a 12-h fast, a capillary blood sample was taken for fasting [TAG] before a high-fat milkshake (80 kJ·kg<sup>-1</sup> body mass) was consumed. Further blood samples were taken hourly over a 6-h postprandial rest period for [TAG].

**RESULTS:** Differences in fasting [TAG] were small across the conditions (Effect Size (ES) = 0.08,  $P = 0.07$ ), with a trend for lower [TAG] in EX60 compared with CON ( $P = 0.05$ ). Postprandial [TAG] was lower during EX30 and EX60 compared with CON (ES = 0.41,  $P = 0.01$ ). The total area under the [TAG] versus time curve was lower by 17% in EX30 (95% confidence interval (CI) -33 to 2%,  $P = 0.05$ ) and by 29% in EX60 (95% CI -48 to -4%,  $P = 0.04$ ) compared with CON; EX30 and EX60 were not different from each other (14%; 95% CI: -34 to 11%,  $P = 0.21$ ).

**CONCLUSION:** This study demonstrates for the first time that both 30 and 60 min of walking, with energy expenditures of 752 and 1487 kJ, attenuated postprandial [TAG] in girls. However, the difference between EX30 and EX60 did not support a dose-response change in postprandial lipaemia.

#### Low Rip140 Expression Uncovers The Central Role Of The Akt-pkc $\zeta$ Axis In The Regulation Of Insulin-mediated Fatty Acid Oxidation In Skeletal Muscle Cells

Silvana Constantinescu, Lorraine P. Turcotte, FACSM. *University of Southern California, Los Angeles, CA.*

(No relationships reported)

Receptor interacting protein 140 (RIP140) is a well-known negative regulator of oxidative capacity and prior data from our lab has shown that low expression of this transcription factor increases insulin-mediated FA oxidation in skeletal muscle cells.

**PURPOSE:** To provide mechanistic insights for this metabolic shift, we measured the effects of low RIP140 expression on the mRNA and protein expression of proteins and signaling intermediates implicated in the regulation of FA oxidation (COX4, PGC-1 $\alpha$ , (FAT)/CD36, FATP1, CPT1, MCAD, AKT, PKC- $\zeta$ ).

**METHODS:** L6 myotubes were treated with siRNA sequences for either RIP140 (RIP140) or a negative control (control) and incubated with insulin.

**RESULTS:** Treatment with RIP140 siRNA sequences significantly ( $P < 0.05$ ) reduced RIP140 mRNA (47%) and protein (54%) content and significantly ( $P < 0.05$ ) increased COX4 (98%) and PGC-1 $\alpha$  (77%) mRNA expression indicating that, as expected, oxidative capacity was increased in RIP140 siRNA-treated cells. Down-regulation of RIP140 increased ( $P < 0.05$ ) FATP1 (317%), (FAT)/CD36 (51%) and CPT1 (84%) mRNA expression but unexpectedly decreased ( $P < 0.05$ ) MCAD mRNA expression (34%). Interestingly, at the protein level, RIP140 down-regulation did not affect ( $P > 0.05$ ) protein content of CPT1 and FATP1 but it decreased ( $P < 0.05$ ) total (38%) and plasma membrane (50%) (FAT)/CD36 protein content. Down-regulation of RIP140 decreased AKT<sup>ser473</sup> (23%) and PKC- $\zeta$ <sup>Thr403/410</sup> (56%) phosphorylation but did not affect AKT<sup>thr308</sup> phosphorylation.

**CONCLUSION:** Our data suggest that the high rates of insulin-mediated FA oxidation that accompany low RIP140 expression are mediated by a reduction in AKT and PKC- $\zeta$  signaling.

### 3144 Board #109 June 1 2:00 PM - 3:30 PM

#### Comparison Of Fat Oxidation And Total Energy Expenditure During Interval And Continuous Training Sessions

Ken J. Hetlelid, Karianne V. Brovold, Stephen Seiler, FACSM. *University of Agder, Kristiansand, Norway.*

(No relationships reported)

This study was conducted to quantify fat metabolism among endurance-trained men during high-intensity interval running.

**PURPOSE:** We: 1) quantified the total energy expenditure and substrate oxidation among well-trained men during a high-intensity interval session and a continuous session matched for average workload, 2) compared relative fat oxidation during a high-intensity interval session and a continuous session to the maximal fat oxidation rate identified by fatmax protocol and 3) compared the energy expenditure after a high-intensity interval session and a continuous session, based on EPOC.

**METHODS:** Nine well-trained male runners (VO<sub>2</sub>max: 68.1  $\pm$  3.6 ml.kg<sup>-1</sup>.min<sup>-1</sup>) completed preliminary testing followed by an interval session and a continuous session in randomised order. Blood lactate (La-) and blood gasses were quantified throughout. The sessions lasted 48 minutes and were performed at a 1.7% incline. Individual running velocities were calculated

corresponding to 40% (rest periods), 65% (continuous session) and 90% (work periods) of VO<sub>2</sub>max. Interval bouts consisted of 6 x 4 minutes work periods separated by 4 minutes rest periods. Substrate oxidation was calculated from gas exchange with corrections for RER >1.0.

**RESULTS:** Despite identical work, a significant difference was found in energy expenditure between the interval session and the continuous session, 3207 ± 325 kJ vs 2962 ± 309 kJ, (p < 0.001). Fat oxidation tended to be higher during the continuous session (755 ± 440 kJ) compared with interval exercise (533 ± 219 kJ), but the difference was not significant (p = 0.170). Fatmax occurred at 65 ± 8% of VO<sub>2</sub>max (0.55 ± 0.17 g·min<sup>-1</sup>), while fat oxidation accounted for 25 ± 14% (0.39 ± 0.22 g·min<sup>-1</sup>) and 17 ± 8% (0.27 ± 0.11 g·min<sup>-1</sup>) during continuous and interval sessions respectively. Blood pH and [HCO<sub>3</sub><sup>-</sup>] stabilized from work bout one to six, (from 7.35 ± 0.03 to 7.35 ± 0.05) and (from 20.8 ± 1.9 to 19.4 ± 3.5 mmol·L<sup>-1</sup>) respectively. We found no difference in energy expenditure based on 15 min EPOC between the continuous session (25 ± 28 kJ) and interval session (27 ± 28 kJ).

**CONCLUSION:** Well-trained runners oxidized significant amounts of fat during high-intensity exercise, equal to ~50% of fat oxidation achieved at fatmax.

**Physical Training Reduces Serum Leptin In Rats, But Not Adiponectin**

Emidio -. Matos-Neto, Michele Trindade, Francisco Torres-Leal, Lucas Pantaleão, Miriam Fonseca-Alaniz, Marcelo Rogero, Julio Tirapegui. *University of São Paulo, São Paulo, Brazil.*

(No relationships reported)

**Physical training reduces serum leptin in rats, but not adiponectin**

1Emidio M. Matos-Neto, 1Michele C.C. Trindade, 2 Francisco L. Torres-Leal, 1Lucas C. Pantaleão, 3Miriam H. Fonseca-Alaniz, 4Marcelo M. Rogero, 1Julio Tirapegui. 1Faculty of Pharmaceutical Sciences, 2Institute of Biomedical Sciences, 3 Heart Institute, University of Sao Paulo 4School of Public Health, University of Sao Paulo, Sao Paulo/SP.

Physical training (PT) is an effective intervention in reducing the risk and in the treatment of chronic diseases associated with low-grade systemic inflammation. In this regard, studies show that this effect may be mediated via body fat reduction, with decreased release of proinflammatory adipokines and increased synthesis and release of anti-inflammatory adipokines.

**PURPOSE:** To investigate the effects of PT on body composition and serum concentrations of leptin and adiponectin in rats.

**METHODS:** Fifteen male adult Wistar rats (259.42 ± 1.27 g), under standard experimental conditions, received AIN-93M diet and water *ad libitum*. Animals with similar weights were distributed into two groups: trained group (TG) (n = 8) and sedentary group (SG) (n = 7). TG underwent PT on a treadmill for 8 weeks in the dark cycle. For morphometric analysis, aliquots of cell suspension were assessed under an optical microscope with graduated scale in order to evaluate adipocyte volume. Serum leptin and adiponectin levels were assessed by multiplex immunoassay using commercial kits.

**RESULTS:** Food intake was 107.4 ± 2.99 g/week for TG and 93.69 ± 4.83 g/week for SG. There was no significant difference in body mass changes between SG and TG (364.5 ± 19 g and 340.1 ± 3.96 g, respectively, p = 0.15). TG animals showed significant fat reduction (32.57 ± 2.22%) compared to SG (74.79% ± 16.14). We found that the adipocyte volume in the TG was significantly reduced (258.7 ± 27.74 pL), compared to SG (604.2 ± 138.3 pL) (p = 0.01). Serum leptin levels of TG animals were significantly reduced (8.68 ± 0.78 ng / mL (TG) vs. 19.2 ± 2.3 ng / mL (SG), p = 0.001), but there was no significant difference in the adiponectin levels ( 33.07 ± 3.89 pg / mL (TG) vs. 34.16 ± 1.14 pg / mL (SG), p = 0.830).

**CONCLUSION:** Physical training was able to reduce body fat, adipocyte volume and leptin levels, but did not promote change in adiponectin levels. **FINANCIAL SUPPORT:** FAPESP, CNPq

**Metabolic Inflexibility in the Acute Exercise Response of Type 2 Diabetics.**

Ciara O'Hagan<sup>1</sup>, Paul Medlow<sup>2</sup>, Josianne Rodrigues Krause<sup>3</sup>, Colin Murphy<sup>3</sup>, Gerard Colleran<sup>3</sup>, Gareth W. Davison, FACSM<sup>2</sup>, Colin AG Boreham, FACSM<sup>1</sup>, Giuseppe De Vito<sup>1</sup>. <sup>1</sup>University College Dublin, Dublin, Ireland. <sup>2</sup>University of Ulster, Belfast, United Kingdom. <sup>3</sup>Institute of Technology Tallaght, Dublin, Ireland. (Sponsor: Carl Foster, FACSM)

(No relationships reported)

**PURPOSE:** Metabolic flexibility (MF) has been defined as the ability to match fuel use to fuel availability. It is suggested that MF is diminished in type 2 diabetes and in obese, insulin-resistant adults, and that this is related to the accumulation of intramuscular lipids. Chronic exercise training has been shown to improve MF in response to hyperinsulinemic clamping and acute or chronic feeding of high-fat or high carbohydrate diets in type 2 diabetics, but MF responses to acute exercise bouts have not been investigated.

**METHODS:** 16 overweight males [8 control (CON), 8 type 2 diabetic (T2D)] participated in this study. Subjects completed an incremental treadmill test from which an estimated VO<sub>2max</sub> was obtained, and workloads corresponding to 25%, 35% and 45% of estimated VO<sub>2max</sub> were calculated. On a separate visit after an overnight fast, fasted respiratory exchange ratio (RER) was obtained by indirect calorimetry, as an average over 10 minutes of measurement after 15 minutes of supine rest. Subjects then completed a 6 minute steady-state exercise bout on the treadmill at each of the pre-determined individualised intensities. ΔRER was calculated as the difference between fasted and steady-state exercise RER.

Data are presented as means ±SD. Between group differences were analysed by unpaired Student's T-test, with significance set at p < 0.05.

**RESULTS:** CON were younger (51 ± 5.7 vs 59 ± 6.4 years) and fitter (37.2 ± 3.6 vs 30.2 ± 8.1 ml/kg/min estimated VO<sub>2max</sub>) than T2D, with no difference in BMI (32.2 ± 5.1 vs 30.7 ± 1.4 kg/m<sup>2</sup>). T2D had significantly higher glycosylated haemoglobin (7.7 ± 0.8 vs 5.7 ± 0.3 %) and fasting plasma glucose (8.6 ± 1.5 vs 5.2 ± 0.6 mmol/L) than CON. There was no difference in resting RER between the groups (T2D 0.79 vs CON 0.78). Exercise RER was consistently higher in CON than T2D, and this was reflected by significant differences in ΔRER at the 25% and 35% intensities (25%: -0.03 vs 0.09, 35%: -0.02 vs 0.05) and a non-significant difference at 45% (-0.06 vs -0.03).

**CONCLUSION:** These data suggest that individuals with type 2 diabetes have impaired MF in response to acute submaximal exercise challenges, relative to healthy controls.

Supported by grants from the Irish Research Council for Science, Engineering and Technology, and the Higher Education Authority Technological Sector Research: Strand 3.

**Strength Training Ameliorates Non-alcoholic Fatty Liver Disease And Adiposity In Rats Fed On Fructose-rich Diet**

José D. Botzezzelli, Lucieli T. Cambri, Pedro P. Scarioti, Ana C. Ghezzi, Leandro P. Moura, Rodrigo A. Dalia, Carla Ribeiro, Amanda C. Silva, Maria A. Mello. *Sao Paulo State University, Rio Claro-SP, Brazil.*

(No relationships reported)

**PURPOSE:** Over the last three decades, the fructose consumption in developed countries increased almost 500%. The timing of the increase in the prevalence of obesity coincides with the increased use of fructose in the diet in developed countries. Physical exercise is a powerful weapon used to reduce weight gain and triglyceride content in human beings and experimental mode. The aim of this study is to analyze the effect of strength exercise on triglycerides (TG) concentration in the liver (non-alcoholic fatty liver disease marker), heart and visceral adipose tissue (adiposity marker).

**METHODS:** Thirty two male Wistar (120 days old) rats were randomly separated into four groups with eight rats per group: C (AIN-93 diet), F (High-fructose diet), CS (AIN-93 diet+ Strength training) and FS (High-fructose diet+ Strength training). C was composed by animals fed on balanced diet (AIN-93) whereas the F group by animals fed on a fructose rich diet (60% fructose). The S groups were subjected to a strength training protocol consisting in four series of ten jumps in water separated by one minute of rest, five days/week. After eight weeks the animals were killed via sodium thiopental administration to evaluate the triglyceride concentration (µmol/mg) using commercial kit. The results were statistically analyzed by two-way ANOVA and the significance level was set at p ≤ 0.05, different letters indicate significant difference.

**RESULTS:** Liver [TG] was higher in the F groups compared to C groups: C= 6.4 ± 1.9<sup>a</sup>, CS= 9.2 ± 2.7<sup>a</sup>, F= 72.8 ± 25.2<sup>b</sup>, FS= 22.8 ± 6.2<sup>c</sup>. No difference was observed on heart [TG]: C= 0.6 ± 0.2<sup>a</sup>, CS= 0.6 ± 0.1<sup>a</sup>, F= 0.6 ± 0.1<sup>a</sup>, FS= 0.6 ± 0.2<sup>a</sup>. Mesenteric [TG] was lower in C group compared to other groups: C= 46.1 ± 5.2<sup>a</sup>, CS= 59.5 ± 6.0<sup>a</sup>, F= 57.5 ± 10.2<sup>b</sup>, FS= 51.2 ± 12.9<sup>b</sup>. Retroperitoneal [TG] was higher in F group compared to the others, also CS group showed the lowest [TG]: C= 70.1 ± 5.4<sup>a</sup>, CS= 56.1 ± 6.0<sup>b</sup>, F= 115.7 ± 28.5<sup>c</sup>, FS= 65.7 ± 9.2<sup>ab</sup>.

**CONCLUSIONS:** Fructose consumption led the animals to adiposity and non-alcoholic fatty liver disease. The heart [TG] of animals was not affected by diet or exercise training. Strength physical training was effective to protect the animals against the triglycerides infiltration in the liver and in the visceral adipose tissue. Supported by FAPESP Grant: 2009/ 15336-9

3148 Board #113 June 1 2:00 PM - 3:30 PM

**Exercise Training Combined With  $\alpha$ -Lipoic Acid Ingestion Attenuates LDL Oxidation In Obesity With Impaired Glucose Tolerance**

Andrea McNeilly<sup>1</sup>, Jane McEneny<sup>2</sup>, Marie H. Murphy, FACS<sup>1</sup>, Nida Nadeem<sup>2</sup>, Tom Trinick<sup>3</sup>, Ellie Duly<sup>3</sup>, Anna Novials<sup>4</sup>, Gareth W. Davison, FACS<sup>1</sup>. <sup>1</sup>University of Ulster, Belfast, United Kingdom. <sup>2</sup>Queens University, Belfast, United Kingdom. <sup>3</sup>Ulster Hospital, Dundonald, United Kingdom. <sup>4</sup>Hospital Clinic, Barcelona, Spain.  
(No relationships reported)

Obese subjects with impaired glucose tolerance (IGT) are more susceptible to oxidative stress and cardiovascular disease than healthy individuals.

**PURPOSE:** This randomised controlled investigation was designed to test the hypothesis that  $\alpha$ -lipoic acid supplementation and exercise training may elicit favourable clinical changes in obese subjects with IGT.

**METHODS:** All data were collected from 24 obese (BMI  $\geq$  30 kg/m<sup>2</sup>) IGT patients. Following participant randomisation into two groups, fasting venous blood samples were obtained at baseline, and before and following intervention. The first group consisted of 12 participants who completed a 12 week control phase followed by 12 weeks of chronic exercise at 65% HR<sub>max</sub> for 30 minutes a day, 5 days per week, while ingesting 1 gram per day of  $\alpha$ -lipoic acid for 12 weeks. The second group consisted of 12 participants who completed the same 12 week control phase, but this was followed by 12 weeks of 1 gram per day of  $\alpha$ -lipoic acid supplementation only (no exercise).

**RESULTS:** The main findings show a comparatively greater rate of low density lipoprotein (LDL) oxidation in the group consisting of  $\alpha$ -lipoic acid only ( $p < 0.05$  vs. pre intervention), although total oxidant status was lower post intervention ( $p < 0.05$  vs. baseline) in this group. However, exercise and  $\alpha$ -lipoic acid in combination attenuates LDL oxidation. Furthermore, in the  $\alpha$ -lipoic acid plus exercise training group, total antioxidant capacity was significantly increased ( $p < 0.05$  vs. baseline and pre intervention). Body fat percentage and waist and hip circumference decreased following exercise training ( $p < 0.05$  vs. post intervention). There were no selective treatment differences for a range of other clinical outcomes including glycaemic regulation ( $p > 0.05$ ).

**CONCLUSION:** These findings report that  $\alpha$ -lipoic acid ingestion may increase the atherogenicity of LDL when ingested in isolation of exercise, suggesting that in IGT the use of this antioxidant treatment does not ameliorate metabolic disturbances, but instead may detrimentally contribute to the pathogenesis of atherosclerosis and development of CVD. However, when  $\alpha$ -lipoic acid is combined with exercise, this atherogenic effect is abolished.

3149 Board #114 June 1 2:00 PM - 3:30 PM

**AMPK $\alpha$ 2 Down-Regulation Prevents Voluntary Wheel Running-Induced Changes in Glucose Uptake but not in Fatty Acid Uptake in Mouse Skeletal Muscle**

Marcia J. Abbott, Lorraine P. Turcotte, FACS<sup>1</sup>. University of Southern California, Los Angeles, CA. (Sponsor: Lorraine P. Turcotte, FACS<sup>1</sup>)  
(No relationships reported)

Exercise training has been deemed a beneficial treatment for obesity and insulin resistance induced by a high fat diet and may modulate its metabolic effects via AMPK activation, a key signaling molecule in metabolic regulation.

**PURPOSE:** To determine whether AMPK $\alpha$ 2 activity in skeletal muscle is required to obtain exercise training benefits while under high fat-fed conditions.

**METHODS:** Wild type (WT) and AMPK $\alpha$ 2 dominant negative (DN) male C57BL/6 mice were divided into control diet  $\pm$  voluntary wheel running (CD, n=10; VWR, n=10) or high fat diet (60% fat Bio-Serv)  $\pm$  VWR (HFD, n=12; VWR+HFD, n=12). After 6 wks, hindlimbs were perfused (550 $\mu$ M palmitate, 6mM glucose, [1-<sup>14</sup>C]palmitate, and 450 $\mu$ U/ml insulin).

**RESULTS:** In CD mice, VWR increased ( $P < 0.05$ ) FAU (46%) and FAO (267%) in WT mice but it had no effect on GU ( $P > 0.05$ ). The DN transgene decreased ( $P < 0.05$ ) FAU (43%) and raised ( $P < 0.05$ ) FAO (224%) but was not associated with further changes with VWR ( $P > 0.05$ ). In HFD mice, VWR increased ( $P < 0.05$ ) GU by 41% (10.1 $\pm$ 1.8 vs. 14.0 $\pm$ 1.0  $\mu$ mol/g/hr) in the WT mice, FAU by 93-108% in both WT (3.9 $\pm$ 0.7 vs. 7.4 $\pm$ 0.3 nmol/min/g) and DN (4.0 $\pm$ 0.3 vs. 8.2 $\pm$ 0.9 nmol/min/g) mice but did not alter ( $P > 0.05$ ) FAO in either group. In CD mice, VWR increased ( $P < 0.05$ ) pERK1/2 (120%) and pJNK1/2 (26-39%) in WT mice and similar VWR-induced increases in pERK1/2 (110%;  $P < 0.05$ ) and pJNK1/2 (39%;  $P < 0.05$ ) were observed in DN mice. In contrast to results obtained in CD mice, pERK1/2 in HFD mice was increased ( $P < 0.05$ ) by the DN transgene (36%) but was not affected ( $P > 0.05$ ) by VWR in either WT or DN mice. Conversely, pJNK1/2 in HFD mice was not affected ( $P > 0.05$ ) by the DN transgene but was reduced (41-45%;  $P < 0.05$ ) by VWR in both WT and DN mice.

**CONCLUSION:** Under HFD conditions, AMPK $\alpha$ 2 signaling appears to be required for VWR-induced changes in GU but not for changes in FA metabolism that may be maintained by a rise in ERK1/2 signaling.

3150 Board #115 June 1 2:00 PM - 3:30 PM

**Lipolytic And Glucoregulatory Responses To Feeding And Exercise In Obese And Lean Children**

Joseph R. Pierce, Gabriel H. Geyer, Cody Squibb, Jeannette M. Mazzawi, Kimberly B. Heidal, Robert C. Hickner, FACS<sup>1</sup>. East Carolina University, Greenville, NC.  
(No relationships reported)

**INTRODUCTION:** The effect of exercise on subsequent metabolic responses to eating has not been determined in lean or obese youth, despite the demonstrated positive effects of prior exercise on meal responses in adults.

**PURPOSE:** To determine whether or not an exercise bout can improve subsequent meal metabolic (lipolytic and glucoregulatory) responses in prepubescent children.

**METHODS:** Overnight fasted obese (n=56) and lean (n=34) children (>95th and <85th percentile of age-adjusted BMI, respectively) had microdialysis (MD) probes (CMA/20, CMA Microdialysis, Chelmsford, MA) placed in subcutaneous abdominal adipose tissue (SCAT). Following 60 min of equilibration, interstitial metabolites (glycerol and glucose) were collected in the MD dialysate prior to and following breakfast, exercise, and lunch. Interstitial glycerol and glucose were analyzed on an automated microdialysis analyzer (CMA 600; CMA Microdialysis, Chelmsford, MA). Dialysate comparisons were made between subjects categorized by BMI or exercise/control groups with repeated measures ANOVA. Data are mean  $\pm$  SD, and the  $\alpha$ -level was set at  $p \leq 0.05$ .

**RESULTS:** As expected, obese children had poor lipolytic suppression following a meal vs. lean counterparts (delta MD glycerol: -12.3  $\pm$  18.3 vs. -35.1  $\pm$  32.3  $\mu$ M, respectively;  $p < 0.01$ ). The lipolytic response in obese children to a second identical meal was no longer different from lean children (delta MD glycerol: -4.4  $\pm$  19.2 vs. -8.1  $\pm$  17.2  $\mu$ M, obese vs. lean, respectively;  $p = 0.36$ ), and was dependent on an acute exercise bout between the meals ( $p < 0.01$ ). MD glucose was increased following both meals ( $p < 0.01$ ) prior to and following exercise, and this response was higher in lean children in both cases ( $p < 0.01$ ). However, glucose responses were not dependent on exercise between the two meals ( $p = 0.37$ ).

**CONCLUSION:** These results suggest that poor suppression of lipolysis following feeding in obese children can be improved by implementation of a pre-meal exercise bout; however, glucose responses to a subsequent meal do not seem to be sensitive an exercise bout.

3151 Board #116 June 1 2:00 PM - 3:30 PM

**Hypotriglyceridemic Effect Of High-intensity Interval Aerobic Exercise**

Labros S. Sidossis<sup>1</sup>, Elena Bellou<sup>2</sup>, Maria Maraki<sup>2</sup>, Eirini Bouchalaki<sup>2</sup>, Tonia Kouka<sup>2</sup>, Dimitra Sklaveniti<sup>2</sup>, Stavros Kavouras, FACS<sup>1</sup>. <sup>1</sup>University of Texas Medical Branch at Galveston, Galveston, TX. <sup>2</sup>Harokopio University, Athens, Greece.  
(No relationships reported)

Continuous aerobic exercise, resulting in energy expenditure (EE) of >500-600kcal, lowers very-low-density-lipoprotein-triglyceride (VLDL-TG) concentrations 12-15 hours after exercise. This effect is manifested via an increase in VLDL-TG clearance whereas VLDL-TG production remains unchanged. In contrast, high-intensity interval aerobic training, (~450 kcal/exercise bout) reduces VLDL-TG concentration 48h after the last exercise bout via a decrease in VLDL-TG secretion from the liver.

**PURPOSE:** To examine the duration and the mechanism of the hypotriglyceridemic effect of a single bout of high-intensity interval aerobic exercise on VLDL-TG kinetics, 14 and 48 hours (h) after exercise cessation.

**METHODS:** Eight healthy sedentary men (VO<sub>2</sub>peak: 2.7±0.4 L/min, BMI: 23.1±2.2 kg/m<sup>2</sup>, age: 24±6 years) participated in three stable isotope-labeled tracer infusion studies, a) 14h after exercise (60 and 90% of peak oxygen consumption in 4 min intervals for a total of 32min (HIIE)), b) 48h after HIIE and c) control (REST), in a random order and after an overnight fast. Subjects replicated their diet for two days prior to the infusion studies and avoided any form of physical activity, other than walking. Kinetic data were analyzed using the monoexponential approach.

**RESULTS:** The mean gross energy expenditure of the exercise bouts was 331±47 kcal. VLDL-TG concentration was 22% lower at 14h (0.28±0.13mmol/L p<0.05) after HIIE compared to control (0.36±0.16mmol/L). VLDL-TG clearance rate increased by 21% after 14h (35.38±7.23 ml/min p<0.001) but not after 48h (32.46±8.23 ml/min p>0.05) of HIIE compared to control (29.19±5.42 ml/min). Hepatic VLDL-TG secretion rate was not different at 14h (2.86±1.12µmol/l/min p>0.05) or 48h (3.0±0.84 µmol/l/min p>0.05) after HIIE compared to control (3.00±1.26 µmol/l/min).

**CONCLUSION:** Acute, high-intensity interval exercise reduces fasting triacylglycerolemia in men 14h after the exercise bout via an increase in VLDL-TG clearance. This type of exercise seems to be sufficient to induce a hypotriacylglycerolemic effect despite the low energy cost of the exercise session. However, the effect is short-term and lasts less than 48 hours.

**Aerobic Exercise Training Improves Adiponectin To Leptin Ratio And Insulin Resistance In Obese Adolescent Girls**

Song Y. Park<sup>1</sup>, Yeong H. Baek<sup>2</sup>, Kook-Eun Seo<sup>2</sup>, Marcos A. Sanchez-Gonzalez<sup>3</sup>, Robert D. Sawyer<sup>4</sup>, Da-Joon Seo<sup>2</sup>, Jin Han<sup>5</sup>, Arturo Figueroa<sup>3</sup>. <sup>1</sup>University of Utah, Salt Lake City, UT. <sup>2</sup>Pusan National University, Busan, Korea, Republic of. <sup>3</sup>Florida State University, Tallahassee, FL. <sup>4</sup>Utah Valley University, Orem, UT. <sup>5</sup>Inje University, Busan, Korea, Republic of.  
(No relationships reported)

**INTRODUCTION:** Increased body fat, particularly in the abdomen, is associated with metabolic abnormalities including insulin resistance (IR) and resultant hyperinsulinemia in adolescents. In addition, abdominal obesity is associated with negative balance of adiponectin and leptin.

**PURPOSE:** The purpose of this study was to examine the effect of aerobic exercise training on IR and metabolic risk factors in obese girls.

**METHOD:** Twenty five obese girls (mean ± SEM, body mass index: 30 ± 3 kg/m and age: 16 ± 1 years) were randomly assigned to a control group (CON, n= 10) or exercise training group (EX, n= 15; 30 min of supervised treadmill exercise at 65-70% of heart rate maximum, 3 days/week) for 12 weeks. Fasting levels of glucose, homeostasis model assessment of IR, insulin, adiponectin, and leptin as well as body composition (bioelectrical impedance) were assessed pre and post. **Result:** An increase in adiponectin to leptin (A/L) ratio (P < .05) and decreases in homeostasis model assessment of IR (HOMA-IR) (P < .01), insulin (P < .01), body weight (P < .05), waist circumference (P < 0.01), and BMI (P < 0.01) were evident after EX compared with CON. The changes in adiponectin (+1.7 ± 0.7 µg/ml, P < 0.05) and leptin (-4.4 ± 1.9 ng/ml, P < 0.05) in EX were significantly changed as compared to CON. However, post EX values of leptin and adiponectin were not significantly improved compare to pre EX values (18.2 ± 2.4 vs 13.8 ± 1.9 ng/ml, and 6.2±0.8 vs 7.9±0.1 µg/ml, P<0.07, respectively). No significant changes in lean mass and body fat percentage were observed in both groups.

**CONCLUSION:** 12-weeks of aerobic exercise training improves IR and A/L ratio occurred independently of significant changes in adiponectin and leptin levels. Therefore, A/L ratio may be a better indicator of changes in obesity as a consequence of aerobic training than individual adipocytokines in obese girls.

**3153** Board #118 June 1 2:00 PM - 3:30 PM

**Brisk Walking Alters Postprandial Lipemia After Fructose Ingestion Differently In Normal-weight And Obese Individuals**

Tim Heden, Ying Liu, Monica L. Kearney, Lauren J. Sims, Kevin C. Dellsperger, Adam T. Whaley-Connell, Anand Chockalingam, Lauryn M. Nyhoff, Michael H. Thomas, Jill A. Kanaley, FACSM. University of Missouri, Columbia, MO.  
(No relationships reported)

Elevated postprandial triacylglycerol (TAG) concentrations are an independent risk factor for cardiovascular disease. Ingestion of fructose rich mixed meals amplifies the postprandial TAG response compared to fructose free mixed meals. Aerobic exercise performed prior to ingestion of a mixed meal lowers postprandial TAG concentrations. However, it has not been established if prior aerobic exercise lowers postprandial TAG to a fructose rich mixed meal.

**PURPOSE:** To determine the effect of 1 h of brisk walking performed 12 h prior to ingestion of a fructose rich mixed meal on postprandial lipemia in normal-weight and obese individuals.

**METHODS:** On two separate occasions 10 normal-weight (BMI < 25 kg/m<sup>2</sup>) and 10 obese (BMI > 30 kg/m<sup>2</sup>) individuals ingested a 600 calorie meal (45% carbohydrate [7.3% fructose], 40% fat, and 15% protein) in the morning after a 12 h overnight fast. Brisk walking (1 h, 55-60% maximal oxygen consumption) was performed 12 h prior to one of these two occasions (EX) while no exercise was performed prior to the other (NoEX). Blood samples were taken at baseline and 1, 2, 3, 4, and 6 h after the meal and analyzed for TAG, total cholesterol (TC), high density lipoprotein cholesterol (HDL-C), and low density lipoprotein cholesterol (LDL-C). The incremental area under the curve (iAUC) was used to quantify postprandial responses. A mixed model ANOVA with Bonferroni post hoc tests were used to compare iAUC values.

**RESULTS:** In normal-weight individuals, EX significantly reduced the postprandial TC response 150% (EX: -10 ± 26 mg/dL 6h, NoEX: 20 ± 31 mg/dL 6h, P = 0.02) and LDL-C response 143% (EX: -17 ± 12 mg/dL 6h, NoEX: 8 ± 20 mg/dL 6h, P = 0.02). In obese individuals, brisk walking significantly reduced the postprandial TAG response 18% (EX: 381 ± 168 mg/dL 6h, NoEX: 454 ± 217 mg/dL 6h, P = 0.02) and attenuated the reduction in HDL-C (EX: -2 ± 6 mg/dL 6h, NoEX: -6 ± 6 mg/dL 6h, P = 0.02).

**CONCLUSION:** Performing 1 h of brisk walking lowers the postprandial TAG response and attenuates the drop in HDL-C after a fructose rich mixed meal in obese individuals. Furthermore, brisk walking lowers the postprandial TC and LDL-C response in normal-weight individuals. Collectively, brisk walking prior to ingestion of a fructose rich mixed meal differentially, but beneficially, alters postprandial lipemia in normal-weight and obese individuals.

**Long Chain Fatty Acid Transport Limitation After Endurance Training Is Improved By Ppar-δ Agonist**

Alexandra Malgoyre, Julia Tonini, Alexandre Prola, Nadine Simler, Thomas Chaillou, Bernard Serrurier, Xavier A. Bigard, Hervé Sanchez. IRBA CRSSA, LA TRONCHE cedex, France. (Sponsor: Major Robert Carter III, FACSM)  
(No relationships reported)

Fatty acid oxidation is increased by aerobic exercise, but long chain fatty acids (LCFA) utilization is a well-known limiting factor of sub-maximal exercise duration. Although endurance performance is improved by PPAR-δ agonist, the effects of endurance training associated with a PPAR-δ agonist on fatty acids utilization remain unclear.

**PURPOSE:** To clarify the limiting steps of fatty acid utilization after endurance training, we studied PPAR-δ agonist effect on LCFA transport in skeletal muscle mitochondria.

**METHODS:** Four groups of female rats were constituted: sedentary (S) and trained (T), treated by vehicle (V) or GW0742 (GW). The training program consisted in 5 running sessions/week for 5 weeks on a treadmill. Treatment was administered during the last 3 weeks. Endurance performances were determined through both a maximal aerobic velocity test (MAV) and time to exhaustion at 65% of individual MAV (T65). Maximal mitochondrial oxidative capacity (V<sub>max</sub>) for palmitoyl-carnitine (PC) and palmitoylCoA (PCoA) were measured in plantaris skinned fibers. Mitochondrial sensitivity (1/Km) was calculated with a Michaelis-Menten model.

**RESULTS:** Endurance training increased aerobic performance in both V (MAV: +53%, p<0.001 / T65:+53%, ns) and GW groups (MAV: +47%, p<0.001 / T65: +65%, p<0.05). Despite an increase of 3-HAD activity (+59% ; p<0.001) after training, both V<sub>max</sub> for PC and PCoA were not altered. Normalized to maximal oxidative capacities, V<sub>max</sub> PC decreased to 13% in TV (p<0.05) compared to 19% in SV. Nevertheless, compared to TV rats, V<sub>max</sub> PC increased in TGW (+37%, p<0.05) and PC relative utilization level is corrected at 18%. A lesser modification was observed for V<sub>max</sub> PCoA in TGW (+17%, ns). In addition, sensitivity to PCoA was decreased after training (-100%, p<0.05), but treatment by GW compensated this effect.

**CONCLUSIONS:** Endurance performance is slightly improved by a PPAR-δ agonist treatment associated with aerobic training. Both CPT-1 and CPT-2 steps could explain the limitation of LCFA oxidation after endurance training. A PPAR-δ agonist could correct CPT-2 limitation and partially CPT-1 one. Moreover alteration of PCoA sensitivity with endurance training could be one of the molecular basis underlying the cross over concept since fatty acid oxidation would be shifted to higher LCFA concentration.

3155 Board #120 June 1 2:00 PM - 3:30 PM

**Lipotoxicity In Cardiomyocytes: Reversal By Aerobic Training**

Marcia N. Alves<sup>1</sup>, Ulrik Wisløff<sup>1</sup>, Danilo Roman-Campos<sup>2</sup>, Pedro Almeida<sup>2</sup>, Terje Larsen<sup>3</sup>, Jaqueline Alvarez-Leite<sup>2</sup>, Silvia Guatimosim<sup>2</sup>. <sup>1</sup>NTNU, Trondheim, Norway. <sup>2</sup>UFMG, Belo Horizonte, Brazil. <sup>3</sup>University of Tromsø, Tromsø, Norway.  
(No relationships reported)

Sedentary lifestyle and unhealthy diets leads to obesity and associated cardiovascular diseases. Lipotoxicity effects in cardiac cells are poorly known.

**PURPOSE:** As training optimizes fatty acid oxidation in skeletal muscle cells even with excess of fats, we studied the effect of excess of saturated fatty acid palmitate on ventricular myocytes isolated from distinct models of metabolic disease (db/db and apolipoprotein E knockout, ApoE KO mice) and mice submitted (TR) or not (CT) to physical training.

**METHODS:** Cardiomyocytes were incubated with palmitate, we studied its effects on Ca<sup>2+</sup> signaling, action potential and reactive oxygen (ROS) levels. Exposure of cardiac cells from CT mice to palmitate led to Ca<sup>2+</sup> signaling dysfunction characterized by a reduced ( $\Delta F_0/F_0 = 4.8 \pm 0.2$  vs.  $3.6 \pm 0.2$   $\Delta F_0/F_0$ ,  $p < 0.01$ ) and slowed (decay time =  $230.3 \pm 5$  vs.  $255.5 \pm 5.3$  ms,  $p < 0.01$ ) Ca<sup>2+</sup> transient. Interestingly, palmitate had not worsened the behavior of cardiomyocytes from db/db and ApoE KO mice. To understand Ca<sup>2+</sup> signaling dysfunction induced by palmitate in cardiac cells from CT mice, we measured action potential and reactive oxygen species (ROS) levels.

**RESULTS:** There were no changes in action potential duration, but cells from CT mice exposed to palmitate increased ROS levels (DHE Fluorescence levels  $98.48 \pm 16.16$  vs.  $197.8 \pm 22.79$  a.u.,  $p < 0.01$ ). We investigated whether cells from TR mice were protected from palmitate induced Ca<sup>2+</sup> signaling dysfunction. Ca<sup>2+</sup> transient amplitude and kinetics in cardiomyocytes from TR mice were enhanced (vs. CT) and not altered by palmitate exposure ( $\Delta F_0/F_0 = 5.7 \pm 0.3$  vs.  $5.2 \pm 0.2$ , ns and decay time =  $224.5 \pm 3.1$  vs.  $223.7 \pm 3.5$  ms). Cardiomyocytes from TR mice presented significantly reduced basal ROS levels, still palmitate was able to induce ROS increase (DHE =  $16.13 \pm 3.30$  vs.  $72.17 \pm 12.85$  a.u.,  $p < 0.01$ ).

**CONCLUSION:** Excessively increased fatty acid levels do not aggravate Ca<sup>2+</sup> signaling dysfunction in cardiac cells from db/db and ApoE KO mice, but are related to Ca<sup>2+</sup> signaling dysfunction in ventricular myocytes from CT mice. Moreover, physical training confers the ability to cardiomyocytes to deal with fatty acid excess, as seen by the lack of effect of palmitate in the Ca<sup>2+</sup> transient, probably due to reduced basal production of superoxides by mitochondria in these cells. Supported by: NTNU and Capes

3156 Board #121 June 1 2:00 PM - 3:30 PM

**Regular Endurance Exercise Improves The Diminished Hepatic Carnitine Status In Mice Fed A High Fat Diet**

Karsten Krüger<sup>1</sup>, Robert Ringseis<sup>2</sup>, Janine Keller<sup>2</sup>, Aline Couturier<sup>1</sup>, Gaiping Wen<sup>2</sup>, Frank Hirche<sup>3</sup>, Gabriele I. Stangl<sup>3</sup>, Klaus Eder<sup>2</sup>, Frank C. Mooren<sup>1</sup>. <sup>1</sup>Dept. of Sports Medicine, Giessen, Germany. <sup>2</sup>Institute of Animal Nutrition and Nutrition Physiology, Giessen, Germany, Giessen, Germany. <sup>3</sup>Institute of Agricultural and Nutritional Sciences, Martin-Luther-University Halle-Wittenberg, Halle (Saale), Germany, Halle, Germany.  
(No relationships reported)

**PURPOSE:** Carnitine is an essential metabolite that has a number of important functions in intermediary metabolism. Metabolic stress induced by chronic high-fat (HF) diet feeding or genetically induce diabetes impairs carnitine status.

Therefore, we tested the hypothesis that regular endurance exercise (EE) improves the HF diet-induced impairment of carnitine status through stimulating the expression of hepatic genes involved in carnitine synthesis and uptake.

**METHODS:** Eighteen male C57BL/6 mice were assigned to three groups: group S received a standard diet, group HF received a HF diet (20% of total energy as protein, 35% as carbohydrate, and 45% as fat), and group HFEE received an HF diet and was regularly exercised on a treadmill at an intensity corresponding to 80% VO<sub>2</sub>max. Before and after exercise exercise capacity was determined by mice spirometry and glucose tolerance was measured. Carnitin and its precursors and co-activators were determined by qPCR, western blotting and tandem mass spectrometry.

**RESULTS:** After 10 wk, mice of the HF and the HFEE groups were highly obese and insulin resistant compared with mice of the S group, but mice of the HFEE group were less insulin resistant than those of the HF group. The HF group had significant lower carnitine concentrations and mRNA and protein levels of genes involved in carnitine synthesis and uptake in the liver than the S group (-20%), whereas these parameters did not differ between the S group and the HFEE group. In addition, mice of the HF group had a reduced expression of PPAR- $\alpha$  and its co-activators, which was attenuated in mice of the HFEE group.

**CONCLUSIONS:** These findings indicate that regular EE reverses an HF diet-induced impairment of hepatic carnitine content by stimulating hepatic carnitine synthesis and uptake. Furthermore, we demonstrated an increase of PPAR- $\alpha$  and its co-activators suggesting a PPAR- $\alpha$  dependent mechanism.

---

**Physical Training and Detraining and Cardiac Lipid Metabolism**

Amanda Christine Silva Sponton, Leandro Pereira Moura, Michel Barbosa Araújo, Rodrigo Augusto Dalia, Marcelo Costa Junior, Maria Alice Rostom Mello. *Sao Paulo State University, Rio Claro, Brazil.*  
(No relationships reported)

**PURPOSE:** This study was designed to analyze body weight gain and triglyceride (TG) concentration, total lipids, protein/DNA ratio and lipogenic rates in the heart of rats submitted to physical training and subsequent detraining.

**METHODS:** Thirty weanling Wistar rats were utilized and divided into three groups: Control sedentary rats (C), Trained rats (T) submitted to physical exercise throughout the experiment, and Detrained rats (D) submitted to physical exercise for half of the experimental period and kept sedentary until the end of the study. The training protocol began when the rats were 28 days old and consisted of swimming 1hr per day, 5 days per week, at 80% of their individual anaerobic threshold (LAN), as previously determined by a lactate minimum test. The physical training lasted 16 weeks for the T group and 8 weeks for the D group.

**RESULTS:** Physical exercise throughout experiment (T group) decreased the body weight (g): (C:  $429.07 \pm 66.23$ ; T:  $353.43 \pm 51.01$ ; D:  $426.64 \pm 74.13$ ) and increased the heart lipogenic rates ( $\mu\text{mol 3H incorporated/hxg}$ ) when compared with the D group: (C:  $23.63 \pm 2.05$ ; T:  $24.52 \pm 2.78$ ; D:  $21.02 \pm 2.66$ ). The other heart metabolic markers did not show differences between groups, TG (mg/g): (C:  $3.58 \pm 0.38$ ; T:  $3.74 \pm 1.44$ ; D:  $3.48 \pm 0.51$ ), Total lipids (mg/100mg): (C:  $4.28 \pm 0.65$ ; T:  $4.95 \pm 0.92$ ; D:  $5.08 \pm 0.61$ ) and protein/DNA ratio (UI): (C:  $14.38 \pm 4.77$ ; T:  $16.28 \pm 4.70$ ; D:  $13.78 \pm 3.05$ ).

**CONCLUSIONS:** In summary, physical exercise at 80% of LAN, attenuates body weight gain but, increased fat synthesis in the heart. Moderate physical exercise and its cessation did not alter other cardiac aspect beyond fat accumulation.

---

3158 Board #123 June 1 2:00 PM - 3:30 PM

**Effects of Normobaric Hypoxic Training on Changes in Whole Body Adiposity and Regional Lipid Accumulation**

Toshiyuki Kurihara, Takuma Morishima, Kazushige Goto, Takafumi Hamaoka, FACSM. *Faculty of Sports and Health Sciences, Ritsumeikan University, Shiga, Japan.*  
(No relationships reported)

Previous studies demonstrated that muscular lipid content was correlated with total body fat and abdominal adipose tissue in obese men. Some studies indicated that 6 weeks of moderate intensity physical activity for obese men reduced visceral adipose tissue (VAT) but did not elicit any change in intramyocellular lipid (IMCL) content (Gan et al. 2003). However, the other study showed that moderate intensity training of 16 weeks for obese old people increased IMCL despite decreased fat mass of the body (Dubé et al. 2008).

**PURPOSE:** To examine the effects of a short-term endurance training in normobaric hypoxic circumstances for sedentary young men on IMCL and extramyocellular lipid (EMCL) accompanied with whole body and regional adiposity including the VAT, subcutaneous abdominal adipose tissue (SAT), and intrahepatic lipid (IHL).

**METHODS:** Twenty-one sedentary healthy men participated in this study (Age 24.3 ± 5.5 yrs, BMI 25.5 ± 3.0 kg/m<sup>2</sup>). Subjects conducted 12 time training sessions during a 2 or 4 week period. Each training session was lasting 60 min with a cycle ergometer at 65% of maximal oxygen uptake (VO<sub>2max</sub>) under normobaric hypoxic condition (FiO<sub>2</sub> = 0.15). Before and after the training period, cross-sectional areas of VAT and SAT were determined by magnetic resonance imaging (MRI), and IMCL and EMCL of the right vastus lateralis muscle and IHL were evaluated by 1H-magnetic resonance spectroscopy. Body composition was measured by dual energy X-ray absorptiometry (DXA).

**RESULTS:** After the training period, body mass and body fat mass did not change significantly. IMCL was significantly increased from 11.1 ± 2.0 mmol/kg to 14.5 ± 5.6 mmol/kg (P < 0.05). EMCL was not significantly changed from 25.8 ± 19.5 mmol/kg to 18.9 ± 10.3 mmol/kg (P = 0.11). IHL was significantly decreased from 59.8 ± 14.9 % to 50.0 ± 21.1 % (P < 0.01). VAT and SAT were not significantly changed (VAT: 53.4 ± 39.6 cm<sup>2</sup> → 50.6 ± 39.7 cm<sup>2</sup>, P = 0.06, SAT: 185.4 ± 43.9 cm<sup>2</sup> → 183.1 ± 43.4 cm<sup>2</sup>, P = 0.49).

**CONCLUSIONS:** These results indicated that the short-term endurance training in hypoxic condition increased the IMCL contents with no changes in EMCL, abdominal adipose tissue and whole body fat, but with decreasing IHL. This study was partly supported by the Nakatomi Foundation.

**The Effect of Conjugated Linoleic Acid on Fat Oxidation Following Short Term Aerobic Exercise.**

Sarah J. C. Brice, Justin D. Roberts. *University of Hertfordshire, Hatfield, United Kingdom.*

(No relationships reported)

There is evidential research supporting the use of conjugated linoleic acid (CLA) as an ergogenic nutraceutical to enhance fatty acid oxidation and improve total fat: lean muscle ratios. However, the potential benefit of CLA in normal weight females undertaking light aerobic exercise requires investigation.

**PURPOSE:** To determine the effect of CLA supplementation during a controlled 4 week aerobic exercise intervention on fat oxidation and body composition compared to a matched placebo (PL).

**METHODS:** Following familiarisation, 21 untrained female subjects (Age: 20.95 ± 1.77 years; Height: 163.25 ± 5.80 cm; Weight: 64.06 ± 4.53 kg) undertook baseline laboratory assessments for maximal oxygen uptake (VO<sub>2max</sub>: 1.231 ± 0.265 L·min<sup>-1</sup>), peak fat oxidation (FAT<sub>MAX</sub>: 0.128 ± 0.037 g·min<sup>-1</sup>) and body composition. Subjects were then randomly assigned to one of three conditions: 1) 3g·d<sup>-1</sup> gelatin capsule CLA; 2) 3g·d<sup>-1</sup> gelatin capsule PL (olive oil) or 3) control only, no supplementation/exercise (CON). Supplements were administered weekly in a double-blind manner. For the CLA/PL groups, participants undertook 3x30 minutes exercise weekly at individual FAT<sub>MAX</sub> over a 4 week intervention period. Fat oxidation was assessed via stoichiometric calculations utilising expired air sampling at week 2 and 4. Fat mass (FM) and fat free mass (FFM) were also measured at these time points.

**RESULTS:** Baseline FAT<sub>MAX</sub> was not significantly different between conditions at week 0 (P=0.207). However, by week 4, FAT<sub>MAX</sub> was significantly greater with CLA compared to CON only (0.204 ± 0.022 g·min<sup>-1</sup> and 0.115 ± 0.0433 g·min<sup>-1</sup>; P=0.02). Baseline FM and FFM was not significantly different between conditions at week 0 (P=0.87 and P=0.78 respectively). Additionally, no significant differences were found for either FM (CLA: 20.03 ± 1.39 kg; PL: 20.31 ± 0.88 kg; CON: 20.20 ± 2.83 kg; P=0.99) or FFM (CLA: 43.47 ± 1.19 kg; PL: 44.57 ± 1.06 kg; CON: 44.65 ± 1.71 kg; P=0.79) between conditions at week 4.

**CONCLUSION:** Acute CLA supplementation may enhance maximal fat oxidation rates. It is possible that the *trans*-10, *cis*-12 isomer found in CLA may augment the activity of carnitine palmitoyl transferase responsible for mitochondrial beta-oxidation. CLA supplementation did not improve body composition over a four week exercise intervention in untrained female subjects.

**Niacin Supplementation Limits Fat Utilization During Short-Term Cycling Exercise**

Greggory R. Davis, Cardyl Trionfante, Arnold G. Nelson, FACSM. *Louisiana State University, BATON ROUGE, LA.*

(No relationships reported)

The hydrolysis of fatty acids (FA) from triglyceride (TG) molecules in adipose tissue may be a limiting factor in aerobic exercise performance and impaired hydrolysis may be linked to the development of insulin resistance. Niacin, also known as nicotinic acid or vitamin B3, decreases TG breakdown and FA mobilization in adipose tissue while caffeine enhances FA mobilization from adipose tissue.

**PURPOSE:** To determine how time to exhaustion and substrate utilization are affected by caffeine versus niacin supplementation during a progressive-intensity aerobic exercise bout lasting less than 30 min.

**METHODS:** 17 young, healthy, active, untrained males completed three identical progressive-intensity aerobic exercise trials. Utilizing a balanced, randomized double blind crossover design, participants were administered one of three supplements, caffeine (C) (5mg/kg of body weight), niacin (N) (1000 mg), or placebo (P) 30 minutes prior to each trial. Substrate utilization was determined through gas analysis and time to exhaustion was recorded for each trial. Each trial was separated by a one week wash-out period.

**RESULTS:** N treatment had significantly higher (p<0.05) respiratory quotient (RQ) compared to P and C (N=0.98 ± 0.05 vs. P=0.88 ± 0.05 vs. C=0.88 ± 0.06) (mean ± std. dev.) and consequently, percentage of carbohydrate (CHO) utilization was higher for N compared to P and C (N=80% ± 13 vs. P=61% ± 17 vs. C=62% ± 20). Time to exhaustion was significantly different for all three trials (N=24.4 ± 3.8 vs. P=25.5 ± 3.1 vs. C=27 ± 3.4).

**CONCLUSIONS:** In untrained individuals, progressive-intensity aerobic exercise lasting less than 30 min is highly dependent on the body's ability to utilize CHO for fuel, however the ability to mobilize FA's from adipose is also critically important for this type of performance.

**3161** Board #126 June 1 2:00 PM - 3:30 PM

**Effects Of Ovariectomy And Resistance Training On Lipid Metabolism And Oxidative Stress In Rats Liver**

Mateus M. Domingos, Maria Fernanda Cury Rodrigues, Uliana Sbeguen Stotzer, Danilo Rodrigues Bertucci, Markus Vinicius Campos Souza, Camila do Valle Gatto, Yone Sato, Heloisa Sobreiro Selistre de Araújo, Sérgio Eduardo de Andrade Perez. *Federal University of Sao Carlos, Sao Carlos, Brazil.*

(No relationships reported)

Estrogen deficiency is associated with hepatic steatosis (HS), through changes in gene expression of molecules related to fat oxidation and lipogenesis and increased oxidative stress (OS). Resistance training (RT) may reduce the HS in ovariectomized (Ovx) rats.

**PURPOSE:** To assess the effects of RT on the gene expression of molecules related to lipid metabolism and OS markers in the liver of ovariectomized rats (Ovx).

**METHODS:** Adult Sprague-Dawley rats were divided into four groups (n = 8 per group): sham sedentary (Sham-Sed), Ovx sedentary (Sed-Ovx), Sham-Rt and Ovx-Rt. A 10-week RT period during which the animals climb a 1.1 m vertical ladder with weights attached to their tails. The sessions were performed three times a week, with 4-9 climbs. Gene expression was analyzed by RT-PCR by the  $\Delta\Delta C_t$  method. The EO was measured by levels of reduced glutathione (GSH) and oxidized glutathione (GSSG), lipid peroxidation (LP), concentration of vitamin E. A two-way analysis of variance (ANOVA) test was used to compare the variables RT with Ovx.

**RESULTS:** The Ovx decreased the gene expression of molecules related to fat oxidation, carnitine palmitoyltransferase I (53%, p<0.05) and  $\beta$ -hydroxyacyl-CoA dehydrogenase (27%, p<0.05), increased of molecules related to lipogenesis, sterol regulatory element-binding protein-1c (106%, p<0.05), and stearoyl CoA desaturase-1 (109%, p<0.05), decreased in the (GSH / GSSG) ratio (28%, p<0.05), vitamin E concentration (45%, p<0.05), no significant change was detected of the LP. The ovariectomy-induced changes in expression of molecules related to lipid metabolism were restored by RT. However, the OS markers were not reversed by the RT.

**CONCLUSION:** The present results indicate that the RT has important effects on the prevention of HS in Ovx animals, through changes of molecules related to hepatic lipid metabolism. Nevertheless, the RT program adopted did not reverse the effects of Ovx in hepatic OS markers.

3162 Board #127 June 1 2:00 PM - 3:30 PM

**Effect Of Lifelong trans-Fatty Acid Intake On Exercise Capacity In Senescence-accelerated Mice**

Gregory C. Henderson, Marc A. Tuazon. *Rutgers University, New Brunswick, NJ.* (Sponsor: Shawn M. Arent, FACSM)

(No relationships reported)

During the aging process, there is a reduced capacity for physical exertion that impairs functionality. Both aerobic exercise capacity ( $VO_{2peak}$ ) and strength are reduced with age, and lifestyle choices may impact the severity of the decline. Specifically the types of dietary fats consumed may moderate the relative decline in physical function.

**PURPOSE:** Using the senescence-accelerated SAMP8 mouse model, a model for sarcopenia and other age-related disabilities, we studied the effect of dietary *trans*-fatty acids upon body composition, aerobic exercise capacity, and strength.

**METHODS:** From weaning, male SAMP8 mice were assigned either to control diet (Con) containing no partially hydrogenated oils or a diet from which 2 percent of energy was from *trans*-fatty acids (TFA diet). At 25 weeks of age (young, Y) and at 60 weeks of age (old, O), body composition was measured by magnetic resonance,  $VO_{2peak}$  with an enclosed treadmill and metabolic measurement system, and strength with a grip strength meter. Strength and  $VO_{2peak}$  were normalized for fat-free mass (FFM). Results were analyzed by analysis of variance and planned comparisons.

**RESULTS:** There was an age related increase in body fat mass ( $P < 0.05$ ), but this increase was blunted on the TFA diet such that O-TFA was significantly different ( $P < 0.05$ ) from O-Con (Y-Con,  $3.2 \pm 0.6$ ; Y-TFA,  $3.3 \pm 0.7$ ; O-Con,  $7.5 \pm 1.8$ ; O-TFA,  $3.9 \pm 0.4$  g body fat). There was an age-related decrease in  $VO_{2peak}$  and grip strength on the Con diet ( $P < 0.05$ ). The TFA diet caused an additional reduction in  $VO_{2peak}$  at young age ( $P < 0.05$ ) (Y-Con,  $11,148 \pm 345$ ; Y-TFA,  $10,185 \pm 181$ ; O-Con,  $10,139 \pm 199$ ; O-TFA,  $10,284 \pm 211$  mL/gFFM/hr). As well, in comparison to Con, the TFA diet led to a trend for further reduction of grip strength at old age (Y-Con,  $6.0 \pm 0.6$ ; Y-TFA,  $5.9 \pm 0.5$ ; O-Con,  $5.5 \pm 0.2$ ; O-TFA,  $4.7 \pm 0.4$  grams force / g FFM) (O-Con vs O-TFA,  $P = 0.056$ ).

**CONCLUSIONS:** The SAMP8 mouse model exhibits age-related declines in physical function. Furthermore, consumption of a diet containing even a modest amount of *trans*-fatty acids leads to further impairment in exercise capacity. This may be related to dysregulation of lipid metabolism and deposition. The results have implications for effects of dietary fatty acid composition upon incidence of sarcopenia and loss of functionality across the lifespan.

3163 Board #128 June 1 2:00 PM - 3:30 PM

**Effect Of Post-exercise Dietary Intervention On The Markers Of Energy Metabolism And Lipid Synthesis**

Wen-Hsin Chang<sup>1</sup>, Yi-Ting Pan<sup>2</sup>, Mei-chih Hsu<sup>2</sup>, Shene-Pin Hu<sup>3</sup>, Jen-Fang Liu<sup>3</sup>. <sup>1</sup>*Kaohsiung Medical University, Kaohsiung, Taiwan.* <sup>2</sup>*National Taiwan Sport University, Taoyuan, Taiwan.* <sup>3</sup>*Taipei Medical University, Taipei, Taiwan.*

(No relationships reported)

Intense or prolonged physical exercise causes the loss of body water, the depletion and exhaustion of fuel stores, imbalances in the status of nutrients and various homeostatic disturbances of hormones. In the process of recovery after exercise, nutrition intervention is a central consideration for rehydrating and refueling the body.

**PURPOSE:** The study was to investigate the effects of different dietary composition after exercise on energy metabolic markers and the protein expression of lipid synthesis-related genes in healthy men.

**METHODS:** Twelve healthy male subjects ( $21.3 \pm 0.4$  yr,  $52.8 \pm 1.2$   $VO_{2max}$ ) participated in a randomized, crossover-design diet intervention, where they consumed either water (300 mL, Control diet; CON), 75g glucose drink (300 mL, 300 Kcal, Glucose diet; GD), or an isocaloric balanced diet (300 Kcal, 60% carbohydrate, 26% fat, and 14% protein, Normal diet; ND) after a medium-intensity exercise test (65  $VO_{2max}$ , 30 min), with 2 weeks rest period in between. Blood samples were taken before exercise and at 0 (Eat-0), 1 (Eat-1), 2 (Eat-2), and 3 (Eat-3) hours after eating.

**RESULTS:** Compared with the CON, the GD and ND consumption significantly elevated glucose ( $116 \pm 5.8$  vs.  $104 \pm 4.3$  vs.  $84.4 \pm 1.7$  mg/dL for GD, ND, and CON, respectively,  $p < 0.05$ ) and insulin ( $28.0 \pm 2.9$  vs.  $21.6 \pm 2.5$  vs.  $4.24 \pm 0.4$  mU/L,  $p < 0.05$ ) concentrations and decreased free fatty acid ( $0.17 \pm 0.06$  vs.  $0.24 \pm 0.05$  vs.  $0.54 \pm 0.06$  mmol/L,  $p < 0.05$ ) level at 1 hour after eating. Serum TG concentration was greater for ND than GD and CON ( $69.7 \pm 3.9$  vs.  $57.7 \pm 3.2$  &  $54.8 \pm 3.3$  mg/dL,  $p < 0.05$ ). However, the protein expression of ChREBP (carbohydrate responsive element binding protein), ACC (acetyl-coenzyme A carboxylase), and FAS (fatty acid synthase), the markers of lipid synthesis, did not differ between diets.

**CONCLUSION:** Findings from this study show that a balanced diet consumption after exercise have a greater influence on energy utilization, but not on the protein expression of lipid synthesis-related genes.

3164 Board #129 June 1 2:00 PM - 3:30 PM

**Effects of Training Intensity on Non-Alcoholic Fatty Liver and Its Related Genes Expression in Mice**

Jinkyung Cho, Youngmin Kim, Sungwoo Park, Hyunsik Kang. *Sungkyunkwan University, Suwon, Korea, Republic of.*

(No relationships reported)

**PURPOSE:** To investigate the effects of moderate- (MT) and interval training (IT) on fatty liver and its complications induced by a high-fat diet (HF).

**METHOD:** Mice (C57BL/6, 5 wks old) were divided into standard chow and sedentary (SC+SD, n=10) for 16 weeks and HF (n=30) groups. Mice submitted to HF remained sedentary for the first 8 wks, and were divided into sedentary (HF+SD, n=10) or MT (HF+MT, n=10) or IT (HF+IT, n=10) for the remaining 8 wks. The primary outcomes of the study included HOMA-IR, hepatic and serum lipids, serum adiponectin, liver enzymes including ALT and AST, and hepatic mRNAs for sterol-regulatory element binding protein (SREBP) 2 and its target genes.

**RESULTS:** A 16-wk high-fat (60%) diet resulted in significant increases in hepatic TG (SC+SD  $20.3 \pm 5.9$  vs. HF+SD  $50.4 \pm 4.8$  mg/mg,  $p=0.001$ ), HOMA-IR (SC+SD  $3.4 \pm 2.3$  vs. HF+SD  $19.7 \pm 7.2$ ,  $p=0.001$ ), and serum ALT (SC+SD  $31.5 \pm 7.2$  vs. HF+SD  $236 \pm 49.2$  U/L,  $p=0.001$ ) along with decreased adiponectin (SC+SD  $4.29 \pm 0.64$  vs. HF+SD  $3.45 \pm 0.48$   $\mu$ g/ml,  $p=0.007$ ). Exercise training induced significant reductions in hepatic TG (HF+SD  $50.4 \pm 4.8$  vs. HF+MT  $40.9 \pm 8.1$  mg/mg,  $p=0.032$  or HF+IT  $38.4 \pm 6.2$  mg/mg,  $p=0.015$ ), serum TC (HF+SD  $208.2 \pm 34.1$  vs. HF+MT  $180.2 \pm 12.5$  mg/dl,  $p=0.547$  or HF+IT  $169.0 \pm 22.2$  mg/dl,  $p=0.028$ ), HOMA-IR (HF+SD  $19.7 \pm 7.2$  vs. HF+MT  $10.1 \pm 7.4$ ,  $p=0.01$  or HF+IT  $9.5 \pm 5.4$ ,  $p=0.006$ ), serum ALT (HF+SD  $236.0 \pm 49.3$  vs. HF+MT  $187.8 \pm 36.8$  U/L,  $p=0.023$  or HF+IT  $149.1 \pm 48.3$  U/L,  $p=0.001$ ), and adiponectin (HF+SD  $3.4 \pm 0.5$  vs. HF+MT  $3.6 \pm 0.3$   $\mu$ g/ml,  $p=0.595$  or HF+IT  $4.3 \pm 0.7$   $\mu$ g/ml,  $p=0.004$ ). Exercise training reversed HF-induced decrease in LDLr mRNA (HF+SD  $3.03 \pm 0.33$  vs. HF+IT  $4.30 \pm 0.19$ ,  $p < 0.001$ ) and HF-induced increase in collagen mRNA (HF+SD  $24.80 \pm 4.14$  vs. HF+IT  $10.75 \pm 0.49$ ,  $p < 0.001$ ). SREBP2 mRNA of the HF+IT ( $6.60 \pm 1.8$ ) was higher than those of the HF+SD ( $2.2 \pm 0.54$ ,  $p=0.019$ ) or the HF+MT ( $3.4 \pm 0.20$ ,  $p=0.059$ ). Similarly, p-AMPK/AMPK ratio ( $0.99 \pm 0.07$ ) of the HF+IT was higher than those of the HF+SD ( $0.70 \pm 0.06$ ,  $p < 0.001$ ) or the HF+MT ( $0.88 \pm 0.04$ ,  $p=0.010$ ).

**CONCLUSION:** The findings of the study suggest that exercise training, especially an interval mode, might be an effective means against fatty liver and its metabolic complications associated with HFD.

**The Effects Of Short And Long Term Watercress Ingestion On Exercise-induced DNA Damage And Lipid Peroxidation**

Gareth W. Davison, FACSM<sup>1</sup>, Fogarty Mark<sup>2</sup>, George Burke<sup>1</sup>, John Brown<sup>1</sup>, Ciara Hughes<sup>1</sup>. <sup>1</sup>*University of Ulster, Belfast, United Kingdom.* <sup>2</sup>*Napier University, Edinburgh, United Kingdom.*

(No relationships reported)

Pharmacological antioxidant vitamins are routinely used for a prophylactic effect against exercise-induced oxidative stress. However, large doses are often required and may lead to a state of pro-oxidation and oxidative damage. Watercress contains compounds beyond their nutritional value which may increase protection against exercise-induced oxidative stress

**PURPOSE:** This randomised controlled investigation was designed to test the hypothesis that acute (consumption 2 hours prior to exercise) and chronic (eight weeks consumption) watercress supplementation can attenuate exercise-induced oxidative stress.

**METHODS:** Ten ( $n=10$ ) apparently healthy male subjects (age  $23 \pm 4$  yrs, stature  $179 \pm 10$  cm and body mass  $74 \pm 15$  kg), randomly assigned to either a control (no supplementation) or watercress supplementation group, volunteered to give blood at baseline (pre-supplementation), at rest (pre-exercise) and following exercise. Each subject completed an incremental exercise test to volitional exhaustion following acute and chronic watercress supplementation or control.

**RESULTS:** The main findings show an exercise-induced increase in DNA damage and lipid peroxidation over both acute and chronic control supplementation phases ( $P<0.05$  vs. supplementation), while acute and chronic watercress attenuated DNA damage and lipid peroxidation and decreased hydrogen peroxide accumulation following exhaustive exercise ( $P<0.05$  vs. control). A marked increase in the main lipid soluble antioxidants ( $\alpha$ -tocopherol,  $\gamma$ -tocopherol and xanthophyll) was observed following watercress supplementation ( $P<0.05$  vs. control) in both experimental phases.

**CONCLUSION:** These findings suggest that short and long term watercress ingestion has potential antioxidant effects against exercise-induced DNA damage and lipid peroxidation.

**3166** Board #131 June 1 2:00 PM - 3:30 PM

**The Effects of Fish Oil Supplementation on Markers of Inflammation in Chronic Kidney Disease Patients**

Erika Deike<sup>1</sup>, Rodney Bowden<sup>2</sup>, Jen Moreillon<sup>2</sup>, Jackson Griggs<sup>3</sup>, Ronald Wilson<sup>2</sup>, Matt Cooke<sup>2</sup>, Brian Shelmadine<sup>2</sup>, Alexander Beaujean<sup>2</sup>. <sup>1</sup>Wayland Baptist University, Plainview, TX. <sup>2</sup>Baylor University, Waco, TX. <sup>3</sup>Family Health Center, Waco, TX. <sup>4</sup>Victoria University, Victoria, Australia.  
(No relationships reported)

**PURPOSE:** A characteristic of chronic kidney disease (CKD) is excessive production of pro-inflammatory cytokines. The benefits of fish oil (FO) for an extensive range of populations and health concerns are apparent, yet the anti-inflammatory benefits for non-dialysis CKD patients are equivocal. Therefore, the purpose of this study was to investigate the effects of daily consumption of FO on IL-1 $\beta$ , IL-6, and TNF- $\alpha$  for 8 weeks in non-dialysis CKD patients.

**METHODS:** The study was conducted using a double blind, randomized, placebo-controlled experimental design. Thirty-one non-dialysis CKD patients were followed prospectively for 8 weeks while supplementing FO (2.4g/day (1400 mg EPA + 1000 mg DHA) or placebo (safflower oil) in their diet. **MAIN OUTCOME MEASURES:** IL-1 $\beta$ , IL-6, and TNF- $\alpha$  were all measured as markers of inflammation at pretest and at 8-weeks.

**RESULTS:** One-way ANOVA revealed no significant differences in IL-6 ( $p=.06$ ), IL-1 $\beta$  ( $p=.18$ ), and TNF- $\alpha$  ( $p=.20$ ) between groups at baseline. Additionally, no pretest differences existed between groups for age ( $p=.549$ ), weight ( $p=.324$ ), waist circumference ( $p=.086$ ), gender ( $p=.591$ ) and ethnicity ( $p=.875$ ). ANCOVA was calculated using compliance, age, gender, ethnicity, body weight, and waist circumference as covariates. No significant differences were discovered between groups after FO supplementation for IL-6 ( $p=.453$ ), and TNF- $\alpha$  ( $p=.242$ ). A significant difference was discovered for IL-1 $\beta$  ( $p=.050$ ) with lower levels in the FO group.

**CONCLUSIONS:** The results of this study is in agreement with some previous studies that suggest that FO supplementation has no effect on plasma pro-inflammatory cytokines TNF- $\alpha$  or IL-6, but does have an effect on IL-1 $\beta$  in non-dialysis CKD patients. The protective effects in this study and others are due primarily to eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA) found in FO. Inflammation plays a significant role in cardiovascular disease in CKD patients with novel approaches needed to reduce the risk of cardiovascular disease.

**3167** Board #132 June 1 2:00 PM - 3:30 PM

**Maximizing Fat Utilization Postexercise with a Novel Low Glycemic Carbohydrate Meal**

Ryan J. Lubbe<sup>1</sup>, Nicholas T. Kruse<sup>1</sup>, Marcus W. Barr<sup>1</sup>, Bruce R. Hamaker<sup>2</sup>, Michael R. Kushnick<sup>1</sup>. <sup>1</sup>Ohio University, Athens, OH. <sup>2</sup>Purdue University, West Lafayette, IN.  
(No relationships reported)

Exercise can increase lipolysis and fat oxidation. Conversely, ingesting carbohydrate (CHO) increases insulin concentration and blunts lipolysis. As compared to higher glycemic index (GI) food, low GI food may be valuable in reducing blood glucose and insulin responses and, therefore, are valuable as postexercise meals to maintain elevated fat oxidation during recovery.

**PURPOSE:** To evaluate metabolic cost ( $\dot{V}O_2$ ) and substrate utilization (RER) after consumption of a low GI CHO, high GI CHO, and control (500mL H<sub>2</sub>O) during the recovery from a previous bout of exercise.

**METHODS:** A repeated-measures ANOVA model was used with LSD post hoc analyses where applicable. Means  $\pm$  standard deviations are presented. Ten healthy, non-smoking, college-aged men ( $21 \pm 2$  yrs) with average body composition ( $14.00 \pm 1.82$  % fat) and above average aerobic fitness ( $53.20 \pm 2.87$  mL/kg/min) were recruited. Participants completed three trials each in random order. Each trial began with a treadmill walk at 60% of their predetermined  $\dot{V}O_{2max}$  until 300kcal were expended, followed by consumption of 300kcal of a low GI CHO, high GI CHO, or a control. Then measurements of ventilatory gases were made during a two hour recovery period.

**RESULTS:** There were no significant differences in  $\dot{V}O_2$  among trials. However, RER was significantly different among trials and across time - presented in the table below.

**CONCLUSION:** In this sample, consuming a low GI CHO after a bout of exercise helped to maintain fat oxidation during the first hour of a two hour recovery.

### Treatment Of Acute Lateral Ankle Sprain With Tape Or Brace: A Randomized Controlled Trial

Ellen Kemler, Ingrid P. van de Port, Arno Hoes, Frank J.G. Backx. *University Medical Centre Utrecht, Utrecht, Netherlands.*  
(No relationships reported)

**PURPOSE:** Ankle sprains are the most common sports injuries often leading to pain and other impairments including physical limitations and recurrences of an ankle sprain. The risk of re-spraining within a period of 3 years after the initial ankle sprain ranged from 3 to 34%. Since the nineties functional treatment of ankle sprains is recommended. Nowadays, the regular treatment of an acute lateral ankle sprain includes ankle taping, the use of an ankle brace is conventional to prevent re-injuries. The purpose of this randomized controlled clinical trial is to investigate the effect of a 4-week treatment with an ankle brace (soft brace) compared to the treatment with ankle tape on recurrent sprain and residual symptoms within one year in patients with an acute lateral ankle sprain.

**METHODS:** Patients (aged > 18 yrs) with an acute lateral ankle sprain caused by an inversion trauma were included after visiting the emergency departments of two participating hospitals, their GP practitioner or physiotherapist. All participants were sequentially randomized to the treatment group (ankle brace) or control group (ankle tape). A sports physician conducted an anamnesis and a physical exam during which the ankle was examined for swelling, discoloration by hematoma, limited dorsoflexion and tenderness at baseline. Tests were performed to measure passive and active ankle stability. After baseline measurements, a 4-week treatment with brace or tape started. At week 5, 9, 13, 26 and 39 post-trauma, patients had to fill in online questionnaires asking about re-injuries and residual symptoms. After 52 weeks a final assessment with a physical exam by a sports physician took place.

**RESULTS:** In total 157 patients with an acute lateral ankle sprain participated in the study. Within 52 weeks after the initial injury 11 patients in the tape group and 13 in the brace group re-injured their ankle (HR 1.1, 95% CI 0.5 to 2.5). Of the residual symptoms, only the anterior drawer sign test showed a significant difference detrimental to the brace group (OR 3.3, 95% CI 1.3-8.1).

**CONCLUSIONS:** The ankle brace, is not more effective in the treatment of acute lateral ankle sprains. However, results suggest equal effectiveness which might lead to the conclusion that both ankle tape and ankle brace can be used to treat lateral ankle sprains.

### Risk Factors Associated with Running Injuries in the United States Army

Tyson Grier, Michelle Canham-Chervak, Vancil McNulty, Bruce H. Jones, FACSM. *Army Institute of Public Health, Aberdeen Proving Ground, MD.*  
(No relationships reported)

Running injuries result from the interaction of a number of extrinsic and intrinsic risk factors.

**PURPOSE:** To identify risk factors associated with injuries attributed to running in U.S. Army Soldiers.

**METHODS:** Participants were male soldiers in a deploying U.S. Army unit (n=1320). Injury data, limited duty days, physical fitness, tobacco use, and previous Army physical fitness test (APFT) scores were obtained by survey. APFT variables (push-ups, sit-ups and 2 mile run) were converted into quartiles (Q), where Q1 = lowest performance and Q4 = highest performance. Odds ratios (OR) and 95% confidence intervals (95% CI) were obtained from multivariable logistic regression.

**RESULTS:** Overall injury incidence for the prior 12 months was 49% (n=652), with 28% of injured Soldiers (n = 180) attributing their injuries specifically to running. Limited duty profiles were given to 76% of the Soldiers (n=137) injured while running, with 62% (n=80) of the profiles limiting duty from 1-30 days. Higher risk of injury was independently associated with higher BMI (OR= BMI 26-29/BMI<24) = 1.98, 95%CI 1.07-3.65), (OR (BMI 30+/BMI<24) = 2.27, 95%CI 1.10-4.71), miles road marched per month (OR (5.1-10 miles/≤5 miles) = 1.86, 95%CI 1.03-3.34), (OR(20.1 miles/≤5miles) = 1.98, 95%CI 1.06-3.68), and poor aerobic endurance as measured by 2 mile run performance (OR (Q2/Q4) = 1.99, 95%CI 1.07-3.72), (OR (Q1/Q4) = 2.25, 95%CI 1.18-4.29). A lower risk of injury was independently associated with resistance training 1-2 times a week compared to no resistance training (OR (1-2 times per week/none) = 0.50, 95%CI 0.29-0.85).

**CONCLUSION:** Running-related injuries accounted for over a quarter of all reported injuries. Countermeasures to prevent such injuries might entail enhancing aerobic endurance, decreasing excess body fat, reducing the number of miles road marched per month, and resistance training 1-2 times per week.

---

**3170** Board #135 June 1 3:30 PM - 5:00 PM

### Air Evacuated Non-Battle Injuries Diagnosed As Sport-Related Musculoskeletal Conditions, Us Army 2001-2010

Morgan Clennin, Bonnie J. Taylor, Keith G. Hauret, FACSM, Bruce H. Jones, FACSM. *Army Institute of Public Health, Aberdeen Proving Ground, MD.*  
(No relationships reported)

Sports and exercise are leading causes (23%) of non-battle injuries (NBIs) requiring medical air evacuation from ongoing military operations in Iraq and Afghanistan. Epidemiologic reports of sport-related injuries often capture traumatic injuries (ICD-9 codes 800-959) but not injury-related musculoskeletal (MSK) conditions (ICD-9 codes 716-739) which include overuse and recurrent injuries. Since injury-related MSK conditions are not routinely monitored it is difficult to ascertain their impact on lost duty days, operational readiness, and Soldier quality of life.

**PURPOSE:** To examine the incidence, rates, and causes of sports-related MSK injuries requiring air evacuation of deployed Army soldiers from Iraq or Afghanistan (2001-2010).

**METHODS:** Air evacuation records were used to identify Soldiers air evacuated from Iraq or Afghanistan between Oct 2001 and Dec 2010 for MSK NBIs (ICD-9 codes 716-739). Cause of injury was determined by experienced coders based on incident narratives. Analyses used descriptive statistics to report incidence, rates and cause.

**RESULTS:** Of the 7,304 MSK NBIs air evacuations, 998 were sports-related. Physical training was the leading cause (25%), followed by weightlifting (24%) and basketball (23%). The rate of sports-related MSK conditions was nearly double for Soldiers in the 30+ year age group (9.0 per 10,000 deployed Soldiers) compared to the <30 year age group (4.8 per 10,000 deployed Soldiers). Soldiers in the 30+ year age group had a significantly greater rate of basketball (p<0.01), physical training (p<0.01), football (p<0.05), and weightlifting (p<0.01) MSK injuries. Overall, knee (25%), back (14%), shoulder (14%), and ankle (13%) were the body parts associated with the majority of these injuries. On average, 81% of Soldiers air evacuated with sports-related MSK injuries are not returned to theater.

**CONCLUSIONS:** As a leading contributor to potentially preventable injuries, strategies to mitigate sports-related MSK NBIs should be implemented into existing injury safety programs. Injury prevention programs for sports-related MSK injuries must receive adequate resources to provide Soldiers with protective gear and additional tools.

---

**3171** Board #136 June 1 3:30 PM - 5:00 PM

### Life-threatening Injuries Attributable To Sports Activity

William P. Meehan, III, Rebekah Mannix. *Children's Hospital Boston, Boston, MA.*  
(No relationships reported)

**PURPOSE:** Determine the proportion of life-threatening injuries (LTIs) attributable to sports activity.

**METHODS:** We examined the National Hospital Ambulatory Care Survey database for emergency department visits between the years 1999 and 2008. LTIs were defined as International

Classification of Diseases, 9th Revision codes for skull fracture [800.x-802.xx, 803.x-804.xx], cervical spine fractures [805.xx-806.10], intracranial hemorrhage [852.xx-853.xx], traumatic pneumothorax/hemothorax [860.00-860.05], liver lacerations [864.xx], and/or spleen lacerations [865.xx], traumatic aortic aneurysm or rupture [901.0; 902.0] and gastric/duodenal rupture [537.89]. We defined sport-related as having an external cause of injury code that was exclusively sport-related or when a text search of the visit confirmed the injury was sport-related.

**RESULTS:** Of the 300,394 observed ED visits, 0.5% (95% CI 0.5, 0.5) were for LTIs. Overall, 14% (95% CI 12, 17) of LTIs were sport-related, representing 890,000 ED visits in the 10 year sample. Of all visits for LTIs in children, 31% were sport-related (95% CI 25, 37); including 39% of all LTIs in children ages 6-18 years. In adults, 9% of LTIs (95% CI 7, 11) were sport-related. For adults aged 19-44 years, 12% (95% CI 9, 15) of LTIs of the head and neck were sport-related.

Of all pediatric cervical spine fractures, 23% (95% CI 6.5, 55) were sport-related. Seven percent (95% CI 4, 11) of cervical spine injuries in adults were due to sports injuries, representing 110,000 cervical spine injuries in the 10 year sample. Sports injuries accounted for 10% (95% CI 5, 20) of intracranial hemorrhages in adults, 4% (95% CI 1, 15) in children.

**CONCLUSION:** An estimated 89,000 LTIs secondary to sports activity occur annually. Nearly 40% of all life threatening injuries sustained by children between the ages of 6 and 18 years are sport-related. This represents a unique opportunity for prevention. Rule changes, protective equipment, and focused training have proven effective in decreasing sports injuries in the past. Given the proportion of all life-threatening injuries attributable to sports, and the ability to control the circumstances surrounding athletic injuries, further study of life threatening injuries in athletics is warranted.

---

**3172** Board #137 June 1 3:30 PM - 5:00 PM

**Seasonal Differences in Injury Risks in Basic Combat Training**

Phillip Garrett, Elizabeth Clearfield, Ashly Westrick, Keith G. Hauret, Joseph J. Knapik, FACSM, Bruce H. Jones, FACSM. *United States Army Institute of Public Health, Aberdeen Proving Ground, MD.*

(No relationships reported)

Injuries during Army Basic Combat Training (BCT) have been previously found to be higher in the summer than in the fall season and correlated with daily high temperatures (Knapik, Ann Occup Hyg 46:15, 2002).

**PURPOSE:** To compare the injury risks (cumulative incidence %) across all four seasons during BCT.

**METHODS:** Army Training and Doctrine Command provided electronic rosters for all BCT recruits arriving at Fort Jackson, South Carolina, for one year (1 October 2009 through 30 September 2010). Rosters were linked to injury data from the Defense Medical Surveillance System. Injuries were identified based on specific International Classification of Diseases (ICD-9) codes. Seasons were defined as BCT classes (10 weeks long) beginning in particular months as follows: Summer (SU): July; Fall (F): October; Winter (W): January; Spring (SP): April. The injury incidence for each season was calculated as: recruits with  $\geq 1$  injury/total recruits X 100%. Risk ratios (RR) with 95% confidence intervals (95%CI) were determined using W as the reference time period.

**RESULTS:** Participants were 9,262 men and 4,363 women. Injury risks in W, SP, SU, and F were respectively 20.1%, 24.6%, 25.1%, and 21.6% for men, and 45.8%, 53.8%, 51.7%, and 47.3% for women. For men, injury risks in the SU and SP were higher than in the W (RR[SU/W]=1.25, 95% CI=1.13-1.38; RR[SP/W]=1.22, 95% CI=1.10-1.35, respectively) and tended to be the same in F (RR[F/W]=1.08, 95% CI=0.96-1.21). For women, injury risks in the SU and SP were higher than the W (RR[SU/W]=1.13, 95% CI=1.04-1.23; RR[SP/W]=1.18, 95% CI=1.08-1.28, respectively), but not in the F (RR[F/W]=1.03, 95% CI=0.95-1.13). The correlation between average high daily temperature and injury incidence was 0.94 for men and 0.79 for women. Average daily high temperatures ranged from 97.2°F (SU) to 55.9°F (W).

**CONCLUSIONS:** Compared to the winter, injury rates in BCT were higher in the SU and SP and about the same in the F. Daily high temperatures are predictive of injury risks.

---

**3173** Board #138 June 1 3:30 PM - 5:00 PM

**Physical Fitness Tests' Ability To Predict Injuries In Officer Candidates And Their Association To FMS**

Peter J. Lisman<sup>1</sup>, Francis G. O'Connor, FACSM<sup>1</sup>, Patricia A. Deuster, FACSM<sup>1</sup>, Chris G. Pappas<sup>2</sup>, Joseph J. Knapik<sup>3</sup>. <sup>1</sup>Uniformed Services University of the Health Sciences, Bethesda, MD. <sup>2</sup>Womack Army Community Hospital, Fort Bragg, NC. <sup>3</sup>Public Health Command (Prov), Aberdeen Proving Grounds, MD.

(No relationships reported)

Low overall scores in physical fitness and Functional Movement Screening (FMS) appear to be related to an increased incidence of musculoskeletal injury in active military populations; however, the injury predictive ability of individual physical fitness tests (PFT) and their relationship to FMS is unclear.

**PURPOSE:** Determine whether the pull-up to exhaustion (PUE) test, 2-min abdominal crunch (AC), and 3-mi run for time (RT) were predictive of subsequent injury occurrence in Marine Corps Officer Candidate School (OCS) training. Also we assessed the association between specific PFT and FMS tests.

**METHODS:** Subjects included 874 male (22.4±2.7) candidates enrolled in either six (n = 447) or ten (n = 427) weeks of OCS. Prior to OCS, candidates completed a PUE, 2-min AC, 3-mi RT, and FMS. FMS consisted of deep squat, hurdle step, inline lunge (IL), shoulder mobility, active straight leg raise (SLR), push-up, and rotary stability tests. Injury incidence data were gathered throughout training and grouped as "any", "overuse", or "traumatic". Data were dichotomized for RT ( $\geq 20:53$  vs.  $< 20:53$ ), PUE ( $\geq 17$  vs.  $< 17$ ) and AC ( $\geq 100$  vs.  $< 100$ ). FMS test scores were grouped as "high" (score of 3) vs. "low" (score of 1 or 2).  $\chi^2$  statistics were used to evaluate group differences in injury risk and determine associations between PFT and FMS tests.

**RESULTS:** Candidates were 1.71 times more likely to suffer an injury if they had a RT  $\geq 20:53$  ( $p < 0.001$ ); 36.9% of persons with a RT  $\geq 20:53$  suffered an injury compared with 25.5% of those with a RT  $< 20:53$ . Likewise, candidates with a RT  $\geq 20:53$  were 1.7 and 1.65 times more likely to suffer a traumatic (28.7 vs. 19.2%,  $p = 0.001$ ) or overuse injury (12.1 vs. 7.7%,  $p = 0.03$ ), respectively, compared to a RT  $< 20:53$ . In contrast, both PUE and AC tests were independent of injury. RT was not associated with any specific FMS test, whereas PUE  $\geq 17$  were associated with high FMS scores in squat ( $\chi^2 = 5.91$ ,  $p = 0.015$ ), IL ( $\chi^2 = 8.32$ ,  $p = 0.004$ ), SLR ( $\chi^2 = 4.20$ ,  $p = 0.04$ ), and push-up ( $\chi^2 = 6.96$ ,  $p = 0.008$ ) tests. AC  $\geq 100$  were associated with high FMS scores in squat ( $\chi^2 = 6.29$ ,  $p = 0.012$ ) and IL ( $\chi^2 = 18.09$ ,  $p < 0.001$ ).

**CONCLUSION:** RT  $\geq 20:53$  was associated with increased injury risk while PUE had the greatest association with high FMS test scores. Further work is needed to determine what combination of PFT and FMS tests are more suitable for predicting injuries.

**3174** Board #139 June 1 3:30 PM - 5:00 PM

**Impact of Injuries from Sports, Exercise, and Recreational Activity among Active Duty Military Personnel**

Keith G. Hauret<sup>1</sup>, Sheryl A. Bedno<sup>2</sup>, Tze-Cheg Kao<sup>3</sup>, Bruce H. Jones, FACSM<sup>1</sup>, Kelly Loring, FACSM<sup>4</sup>. <sup>1</sup>Army Institute of Public Health, Aberdeen Proving Ground, MD. <sup>2</sup>Eisenhower Army Medical Center, Fort Gordon, GA. <sup>3</sup>Uniformed Services University of the Health Sciences, Bethesda, MD. <sup>4</sup>20th Medical Group, Ellsworth Air Force Base, SD.

(No relationships reported)

Injuries are the biggest health problem for U.S. military forces in peacetime and combat, impacting the health and readiness of Service members (SMs). Sports and exercise are leading causes of injury hospitalizations among non-deployed SMs and non-battle injury air evacuations among deployed SMs. Because medical providers do not record causes of injury in medical records, the true magnitude of this injury problem is unknown.

**PURPOSE:** To determine the incidence of injuries from sports, exercise and recreational activity (SERA) among active duty SMs and describe the leading injury-causing activities and their associated injury types.

**METHODS:** Eleven questions about injuries within the past 12 months were added to the April 2008 Status of Forces Survey of Active Duty Service Members (SOFA0801). Survey design and weighting of self-reported responses produced population estimates (weighted percents with standard errors [SE]) for overall injury incidence, SERA injury incidence, injury types, injury causing activities, and days of limited duty. SUDAAN was used for all analyses.

**RESULTS:** Overall, 48.9% (SE=0.7) of SMs sustained an injury in the past 12 months and 25.4% (SE=0.6) reported at least one SERA injury. SERA injury incidence was nearly the same for men (25.3%; SE=0.6) and women (26.1%; SE=1.6). Running accounted for 45.1% (SE=1.4) of SERA injuries overall, 42.6% (SE=1.5) among men, and 58.1% (SE=3.5) among women. Among those injured while running, the leading injury types were sprained joint (21.7%; SE=1.7), strained muscle (19.3%; SE=1.6), tendonitis/bursitis (16.8%; SE=1.5) and fracture (7.5%; SE=1.3). Ankle and knee sprains accounted for 54.9% (SE=4.5) and 28.7% (SE=4.0) of joint sprains from running, respectively. Among all SMs with a joint sprain, 19.5% (SE=2.4) required 2 - 7 days of limited duty, 18.4% (SE=2.4) required 8 - 14 days, and 28.8% (SE=3.0) required more than 15 days.

**CONCLUSION:** This evaluation provides leaders with strong evidence for a significant contribution of sports, exercise, and recreational activity to the overall injury problem in the military services. It highlights the need to identify risk factors for SERA injury and to develop training programs that lower the associated injury risks, especially from running since it accounts for nearly half of the SERA injuries.

**3175**     *Board #140*     **June 1**     **3:30 PM - 5:00 PM**

**Association Between Anatomic Alignment And Musculoskeletal Injuries In Recreational Runners: Cohort Prospective Study.**

Aline C.A. Carvalho, Ms, Luiz Carlos Mr Hespagnol Junior, Leonardo O.P. Costa, Mr, Alexandre D. Lopes, Mr.. *University São Paulo City, São Paulo - SP, Brazil.*  
(No relationships reported)

**BACKGROUND:** Much has been said about the influence of factors such as the alignment of the lower limbs and the development of musculoskeletal injuries in runners, but little evidence supports this hypothesis.

**OBJECTIVE:** To describe the anatomical alignment of the lower limbs, to measure the prevalence and incidence of musculoskeletal injuries related to running, to examine the associations between the characteristics of these injuries and anatomical alignment, and describe the major injuries among runners and the anatomical regions most affected.

**METHOD:** A prospective cohort study composed of 89 recreational runners who underwent measures of bilateral Q angle, subtalar angle, medial longitudinal arch and length discrepancy of lower limb and were followed for a period of 12 weeks. We performed descriptive analysis and verification of the association between the characteristics of anatomical alignment of the runners and injuries. The incidence of injuries was calculated using survival analysis and the association between potential risk factors and time of injury was determined by Cox regression models.

**RESULTS:** Participants of the study were on average 44 years-old (SD = 10), without major changes in the alignment of lower limbs and presented an association between changes in Q angle and the discrepancy of Q angle with musculoskeletal injuries. The prevalence of musculoskeletal injuries related to running was 61.8%, the incidence over 12 weeks was 27%, being tendinopathies and muscle injuries the most common injuries and the knee and the leg as the most affected regions.

**CONCLUSIONS:** It was possible to identify the association of the discrepancy between the Q angles and the angles Q changes with injuries in runners. We also identified tendinopathies and muscle injuries as major injuries and the knee as the most affected region.

---

**3176**     *Board #141*     **June 1**     **3:30 PM - 5:00 PM**

**Epidemiology and Outcomes of Concussions in Major League Baseball**

Vincent Moretti, Leslie Schwindel, Jonathon Watson, Mark Hutchinson, FACSM. *University of Illinois at Chicago, Chicago, IL.*  
(No relationships reported)

**PURPOSE:** All contact sports carry the risk for concussions, but limited data exists on such injuries in baseball, particularly at the professional level. The purpose of this study is to document the epidemiology of concussions in Major League Baseball (MLB) and to quantify the impact of these injuries upon player performance.

**METHODS:** Data on MLB concussions occurring between 2001 and 2010 was gathered from MLB disabled list records. For each player identified, additional data was gathered from online game summaries and player profiles. Recorded variables included player position, date of injury, age at injury, injury situation, source of trauma, and date of return to play. Performance statistics were compiled for each player for the 15- and 30-day periods immediately after they returned to play. Identical statistics from the 30-days immediately pre-injury served as a control. Statistical analysis was performed using two-sided z-test for proportions with a significance level of 0.05.

**RESULTS:** 33 concussions were identified, 8 from 2001-2005 (per game incidence=0.03%) and 25 from 2006-2010 (per game incidence=0.10%). Average age at injury was 29 years. 9 players were concussed by batted balls (27.3%), 8 by pitched balls (24.2%), 7 by fielder-runner collisions (21.2%), 6 by fielder collisions (18.1%), and 3 by swung bats (9.1%). Nearly a third (30.3%) of injuries were to catchers. On average, players were unable to play for 67 days (range 1-349) or 38 games (range 1-152) after a concussion. 4 players (12.1%) never returned to MLB. Batting average through the first 15 days (0.237, p=0.423) and the first 30 days (0.252, p=0.970) after returning from injury were insignificantly decreased from the pre-concussion average (0.253). On-base percentage through 15 days (0.302, p=0.237) and 30 days (0.326, p=0.996) was insignificantly decreased from pre-injury (0.326). Slugging percentage through the first 15 days back (0.358, p=0.013) was significantly decreased from pre-injury (0.412), but not through the first 30 days back (0.393, p=0.290).

**CONCLUSIONS:** The recognition and reporting of concussions in MLB is increasing, with a near 3-fold increase in just the past 5 years. The impact of this injury can be significant, resulting in lengthy time on the injured list, temporary performance decreases, and even the end of careers.

---

**3177**     *Board #142*     **June 1**     **3:30 PM - 5:00 PM**

**Risk Factors for Stress Fractures in United States Army Basic Combat Training: A Retrospective Analysis of 632,440 Recruits**

Joseph J. Knapik, FACSM<sup>1</sup>, Scott J. Mountain, FACSM<sup>2</sup>, Susan M. McGraw<sup>2</sup>, Tyson Grier<sup>1</sup>, Matthew R. Ely<sup>2</sup>, Bruce H. Jones, FACSM<sup>1</sup>. <sup>1</sup>*US Army Institute of Public Health, Aberdeen Proving Ground, MD.* <sup>2</sup>*US Army Research Institute of Environmental Medicine, Natick, MA.*  
(No relationships reported)

Stress fractures (SF) are a common and debilitating problem in United States (US) Army Basic Combat Training (BCT). Previous studies indicate that the medically diagnosed incidences of SF range from 0.8 to 5.1% of all male recruits.

**PURPOSE:** To examine demographic and physical risk factors for SF in a large cohort of male basic trainees.

**METHODS:** This retrospective cohort study utilized databases at the Armed Forces Health Surveillance Center. All male US recruits participating in US Army BCT from January 1997 to January 2007 were identified based on date of entry into the US Army. Birth year and race/ethnicity were obtained from the Defense Manpower Data Center Master Personnel File and physical characteristics (height and weight) were obtained from the Military Entrance Processing Station database. Body mass index (BMI) was calculated as weight/height<sup>2</sup>. Cases were recruits medically diagnosed with inpatient or outpatient SF in the Defense Medical Surveillance System. Data were analyzed using logistic regression; odds ratios (OR) and 95% confidence intervals (95%CI) were calculated. Age, height, weight and BMI were categorized into strata and baseline strata (RR=1.00) selected as the youngest age group (<19 years), average height (175-180 cm) and weight (71-78 kg), and normal BMI (18.5-24.9 kg/m<sup>2</sup>).

**RESULTS:** There were 475,745 male recruits in the survey period and they had an overall SF incidence of 19.3 cases/1,000 recruits. Factors that increased SF risk included older age (OR(>30 yrs/17-19 yrs)=3.4, 95%CI=3.1-3.7), greater stature (OR(≥185 cm/175-180 cm)=1.2, 95%CI=1.1-1.3), higher body weight (OR(≥87 kg/71-78 kg)=1.2, 95%CI=1.1-1.3), lower BMI (OR(<18.5 kg/m<sup>2</sup>/18.5-24.9 kg/m<sup>2</sup>)=1.7, 95%CI=1.5-1.9), higher BMI (OR (≥30 kg/m<sup>2</sup>/18.5-24.9 kg/m<sup>2</sup>)=1.1, 95%CI=1.1-1.2), and white race/ethnicity (OR (white/black)=1.7, 95%CI=1.6-1.9; OR (white/Asian)=1.2, 95%CI=1.1-1.5).

**CONCLUSIONS:** This was the largest sample of military recruits ever examined for SF since it included virtually the entire US Army male recruit population over a 10-year period. SF risk was elevated among male BCT recruits who were older, taller, weighed more, had lower or higher BMI, and/or were of white race/ethnicity.

---

**3178**     *Board #143*     **June 1**     **3:30 PM - 5:00 PM**

**Sports Injuries Among US Army Soldiers Deployed To Operations Iraqi And Enduring Freedom, 2001-2010.**

Shuva Dawadi, Keith G. Haurert, Bonnie J. Taylor, Morgan N. Clennin, Bruce H. Jones, FACSM. *Army Institute of Public Health, Aberdeen Proving Ground, MD.*  
(No relationships reported)

Participation in sports and athletics is a major part of a Soldier's life and a major cause of serious, nonfatal injuries in the military. These injuries result in outpatient visits, inpatient hospitalizations, and medical air evacuations as well as substantial lost duty days and decreased military readiness.

**PURPOSE:** Determine the incidence and rate of sports and exercise-related (SER) injuries requiring medical air evacuation of US Soldiers deployed for Operations Iraqi Freedom (Iraq) and Enduring Freedom (Afghanistan) from 2001 to 2010 and describe the injury type and anatomical location of injury.

---

**METHODS:** Air evacuation records were reviewed for Soldiers medically air evacuated from Iraq or Afghanistan for SER injuries (October 2001-December 2010). Narrative case history and diagnosis codes were used to determine incidence and rates of SER injuries and incidence of injury type, and anatomical location of injury.

**RESULTS:** Overall, 19,595 Soldiers were air evacuated for non-battle injuries (NBIs) from 2001 to 2010. For injuries with an identifiable cause (n=13,372), sports and exercise were the leading cause comprising 23% of NBIs (n=3,075; rate: 3/1,000 person-years). Sixty-one percent of SER injuries were caused by three activities: basketball (25%), physical training (19%), and American football (17%). The rest of the activities involved weightlifting (15%), wrestling/combat (7%), volleyball (4%), soccer (3%), softball (3%), and other specified sport activities (6%). This latter category included activities such as boxing, baseball, frisbee, swimming and diving, track and field, mountaineering, boating, hockey, and rugby. The leading injury types were sprain/strains/ruptures (27%), fractures (25%), and dislocations (18%). Knee (26%), ankle/foot (15%), wrist/hand (14%), and shoulder (14%) were the leading anatomical locations of injury.

**CONCLUSIONS:** Even in a dangerous combat environment, sports and exercise are an important cause of non-fatal injuries. These injuries, many of which are preventable, negatively impact soldier work performance and unit readiness during deployments. Identifying or developing and evaluating prevention strategies targeted to prevent these SER injuries is recommended to lessen this impact.

---

**3179** Board #144 June 1 3:30 PM - 5:00 PM

**The Feasibility Of Examining Psychological States As Risk Factors For Injury: A Pilot Study**

Ian Shrier, FACSM<sup>1</sup>, John S. Raglin, FACSM<sup>2</sup>, Janette Powell<sup>3</sup>, Emily B. Levitan<sup>4</sup>, Murray A. Mittleman<sup>5</sup>, Russell J. Steele<sup>6</sup>. <sup>1</sup>McGill University, Montreal, QC, Canada. <sup>2</sup>Indiana University, Indianapolis, IN. <sup>3</sup>Cirque du Soleil "O", Las Vegas, NV. <sup>4</sup>University of Alabama at Birmingham, Birmingham, AL. <sup>5</sup>Harvard University, Boston, MA. <sup>6</sup>McGill University, McGill University, QC, Canada.

(No relationships reported)

**PURPOSE:** To test the feasibility of a prospective study designed to examine the role of psychological states on the risk of injury.

**METHODS:** We measured psychological traits at baseline (mood, ways of coping and anxiety), and psychological states every day (1-item questions on anxiety, sleep, fatigue, soreness, self-confidence) before performances in Cirque du Soleil artists of the show "O". Additional questions were added once per week to better assess anxiety (20-item) and mood. Questionnaires were provided in English, French, Russian and Japanese, representing the first or second language for all participating artists. Injury and exposure data were extracted from electronic records that are kept as part of routine business practices.

**RESULTS:** The 43.9% (36/82) recruitment rate was more than expected. Most artists completed the baseline questionnaires in 15min, a weekly questionnaire in <2min and a daily questionnaire in <1min. We improved the formatting of some questions during the study, and adapted the wording of other questions to improve clarity. There were no dropouts during the entire study, suggesting the questionnaires were appropriate in content and length.

**CONCLUSIONS:** A prospective study collecting psychological state data every day from subjects who train and work regularly together is feasible.

---

**3180** Board #145 June 1 3:30 PM - 5:00 PM

**Overuse Injuries Associated With Mountain Biking: Is Single Speed Riding A Predisposing Factor?**

Michael T. Lebec, Kortny Cook, Drew Baumgartel. Northern Arizona University, Flagstaff, AZ.

(No relationships reported)

Pedaling a mountain bike with a single gear option is thought to require greater physical effort than riding a bike with multiple gears through which the rider may shift. For this reason, it has been proposed that riding a single geared mountain bike is associated with greater risk for overuse injury. This hypothesis, however, has not been investigated.

**PURPOSE:** The study's purpose was to compare the incidence of self-reported overuse injuries in individuals who ride mountain bikes with single and multiple gear systems.

**METHODS:** Data were collected from 402 Arizona mountain bikers responding to an online survey. Respondents were asked to report personal demographics, characteristics of their mountain bikes, riding volume and style, as well as mountain bike related overuse injuries sustained in the past year. Based on previous literature on cycling overuse syndromes, a logistic regression model was constructed to determine associations between explanatory variables and reported overuse injuries. Independent variables incorporated into the final model included gender, type of bike ridden (single gear, multiple-g geared, or both), and average number of hours ridden per week.

**RESULTS:** Statistical analyses suggest no differences in self-reported overuse injuries among riders of single or multiple geared mountain bikes. However, individuals who reported spending considerable time riding both single AND multiple geared bikes were significantly more likely to report an overuse injury than those only riding a single or multiple geared bike (p=0.036). A follow-up analysis of injury by anatomical region revealed a significant difference in the odds of a knee injury for those who did not ride both types of bikes as compared to those who did (p=0.042). Significance for other anatomical regions was not found.

**CONCLUSIONS:** Findings suggest individuals riding both single and multiple geared mountain bikes are significantly more likely to report an overuse injury than those only participating in one type of riding. It is hypothesized that single and multiple geared mountain biking are associated with different biomechanical demands. Bikers participating in both styles of riding may develop inefficient motor patterns and subject their tissues to greater stress levels.

**3181** Board #146 June 1 3:30 PM - 5:00 PM

**Epidemiology Of Meniscal Injuries In US High School Boys' Football, Ice Hockey, and Lacrosse**

David M. Swenson<sup>1</sup>, R. Dawn Comstock<sup>2</sup>, David C. Flanigan<sup>1</sup>, Thomas M. Best, FACSM<sup>1</sup>. <sup>1</sup>The Ohio State University, Columbus, OH. <sup>2</sup>Nationwide Children's Hospital, Columbus, OH.

(No relationships reported)

High school athletes sustain millions of injuries each year, many of which are knee injuries. Knee injuries, specifically meniscal injuries, are relatively common in high-impact sports such as boys' football, ice hockey, and lacrosse which involve frequent and rapid pivots and player-to-player contact. Meniscal injuries often require surgery or prolonged rehabilitation, and can result in long-term sequelae such as knee pain and osteoarthritis.

**PURPOSE:** Describe the epidemiology of meniscal injuries in US high school boys' football, ice hockey, and lacrosse.

**METHODS:** High school sports-related injury data was collected from 2008/09-2010/11 for boys' football, ice hockey, and lacrosse. We calculated overall injury rates, meniscal injury rates, and rate ratios.

**RESULTS:** From 2008/09-2010/11, certified athletic trainers reported a total of 7902 football, 528 ice hockey, and 758 lacrosse injuries during 2,065,536 football athlete exposures [AEs], 220,974 ice hockey AEs, and 339,971 lacrosse AEs. Overall injury rates were 3.83 per 1000 AEs in football, 2.39 in ice hockey, and 2.23 in lacrosse. Competition injury rates were significantly higher than practice for football (12.3 vs. 2.12 per 1000 AEs; RR 5.79, 95% CI 5.54-6.05), ice hockey (5.84 vs. 0.75 per 1000 AEs; RR 7.81, 95% CI 6.34-9.62), and lacrosse (4.40 vs. 1.27 per 1000 AEs; RR 3.47, 95% CI 3.00-4.01). Knee injuries accounted for 15.4% of all injuries in these sports, and 8.3% of all knee injuries involved the meniscus. Meniscal injury rates were 0.051 per 1000 AEs in football, 0.032 in ice hockey, and 0.015 in lacrosse. Overall meniscal injury rates were higher during competition than practice (RR 5.58, 95% CI 3.87-8.06). Over half (58.1%) were treated with surgery. Most were new (87.9%) as opposed to recurrences of previous meniscal injuries, and person-to-person contact (47.3%) was the most common mechanism.

**CONCLUSIONS:** Full-contact sports have high rates of injury, including knee injuries. Meniscal injuries are serious and frequently require surgery and expensive diagnostic evaluations. Targeted interventions should aim to reduce the incidence of meniscal injuries in US high school boys' football, ice hockey, and lacrosse to prevent long-term sequelae such as knee pain and osteoarthritis.

**3182** Board #147 June 1 3:30 PM - 5:00 PM  
**Risk Factors for Closed Head Injuries in Military Parachuting**

Bria S. Graham<sup>1</sup>, Joseph J. Knapik, FACSM<sup>1</sup>, Kyle Hoedebecke<sup>2</sup>, Shawn Rankin<sup>3</sup>, Kevin Klug<sup>3</sup>, Stanley Proctor<sup>3</sup>, Ryan Steelman<sup>1</sup>, Tyson Grier<sup>1</sup>, Bruce Jones, FACSM<sup>1</sup>. <sup>1</sup>US Army Public Health Command, Aberdeen Proving Ground, MD. <sup>2</sup>Womack Army Hospital, Ft Bragg, NC. <sup>3</sup>Concurrent Technologies Corporation, Fayetteville, NC.  
(No relationships reported)

Closed head injuries appear to have become an increasing problem in military parachuting. A recent study of an operational airborne unit found that injuries of this type accounted for 31% of all injuries (Knapik, Aviat Space Environ Med 82:797, 2011). However, few studies have specifically examined factors that might be related to head injuries in military parachuting.

**PURPOSE:** The purpose of this investigation was to examine risk factors associated with closed head injuries during military parachuting.

**METHODS:** Participants were soldiers in the 82<sup>nd</sup> Airborne Division at Fort Bragg, NC who performed parachute training jumps between June 2010 and September 2011. Injury data was collected directly on the parachute drop zone and verified by a physician using clinical records. Soldiers jumped with either the T-10 parachute or the newer T-11 parachute. Wind speed data was collected using an anemometer on the drop zone. Data on jump types (combat load or no combat load) and time of day (night or day) and were obtained from routine 82<sup>nd</sup> Airborne Division reports. Chi-square statistics, risk ratios (RR) and 95% confidence intervals (95%CI) were calculated.

**RESULTS:** There were 57,606 total parachute descents and 611 total injuries (10.6/1,000 jumps), with 210 of the 611 injuries (34%) classified as closed head injuries (3.6/1,000 jumps). A higher risk of closed head injury was associated with use of the T-10 parachute (RR [T10/T11]=3.2, 95%CI=1.3-7.6), high wind speeds (RR[high/low]=2.2, 95%CI=1.0-4.9), combat loads (RR[load/ no load]=3.0, 95%CI=2.2-4.0), and night jumps (RR [night/day]=1.8 95%CI=1.4-2.4).

**CONCLUSIONS:** The data indicate that the T-10 parachute, higher wind speeds, combat loads, and night jumps increase the risk of closed head injuries during military parachuting in an operational military unit.

**3183** Board #148 June 1 3:30 PM - 5:00 PM  
**Prevalence, Severity And Mechanism Of Acute Injuries In Male Elite African Youth Soccer Players**

Suzanne Jacobs. Tshwane University of Technology, Pretoria, South Africa.  
(No relationships reported)

A survey of injury rate for children in community sport reported the highest rate of injuries among soccer, when compared to other sport.

**PURPOSE:** The purpose of this study was to investigate the prevalence, severity and mechanisms of injury in male elite African youth soccer players.

**METHODS:** The study was conducted on hundred and sixty nine (N=169) male elite African youth soccer players aged 14 to 18 years from eleven countries in the African Continent. Data was collected retrospectively and included prevalence of injuries over a two-season period. A self-administered questionnaire was used to collect the data for this study. Descriptive statistics, Chi-Square Analysis and Independent t-tests were used for statistical analysis.

**RESULTS:** A total of 132 players sustained 544 injuries with a prevalence rate of 78%. More injuries were recorded during training (55%) than during competition (45%). Injuries during training showed statistical significant differences regarding playing position (p<0.05), with midfielders showing significantly higher injury rates. The injuries during training were most prevalent in the ankle (21%), groin (11%), finger (10%), shoulder (10%) and knee (9%). Body sites most commonly injured during competition showed similarities with the body parts injured during training. The distribution of injuries according to body part was unrelated to playing position. Most injuries were of minor severity accounting for 50% and 52% of injuries in training and competition respectively. The major mechanisms of injury in both training and competition were running, tackled, tackling and shooting.

**CONCLUSION:** The male elite youth soccer players in the present study had a higher injury rate compared to those studies in the literature. The injuries were most often of minor severity and the most frequent body part injured was the ankle joint. Since the ankle joint comprised a large proportion of the injuries, future studies aimed at preventive strategies for injuries in the ankle joint are recommended, especially at school level. Prevention programmes, fair play, and the continuing improvement of skills may reduce the incidence of injuries in the long term.

**3184** Board #149 June 1 3:30 PM - 5:00 PM  
**Risk Factors Associated With Lower Leg Injuries in the United States Army**

Morgan K. Anderson, Tyson Grier, Michelle Canham-Chervak, Timothy T. Bushman, Malikhah Waaqid, Bruce H. Jones, FACSM. Army Institute of Public Health, Aberdeen Proving Grounds, MD.  
(No relationships reported)

Lower leg injuries (region of the knee to foot) are a leading injury type among U.S. Army basic trainees, however this has yet to be investigated in Army operational units.

**PURPOSE:** To examine risk factors for lower leg injuries in a deploying Army unit.

**METHODS:** Male soldiers (n=1708) ages 18-30 were administered a survey querying unit physical training, personal fitness training, Army physical fitness test (APFT) scores, tobacco use, and injury. The APFT consists of a 2 mile run, push-ups and sit-ups. APFT scores were converted into quartiles (Q) where Q4 = lowest performance and Q1 = highest performance. Odds ratios (OR) and 95% confidence intervals (95% CI) from a multivariable analysis were calculated.

**RESULTS:** Of the 972 Soldiers that reported an injury within the last 12 months, 418 (43%) reported a lower leg injury. Of these lower leg injuries, 245 (59%) Soldiers were placed on limited duty profiles with 53% being placed on limited duty for  $\geq 30$  days. Individuals with the slowest run times had an increased risk of lower leg injury compared to individuals with faster run times (Q2/Q1) (OR = 1.61, 95% CI 1.11 to 2.33), (Q3/Q1) (OR = 1.71, 95% CI 1.18 to 2.48), (Q4/Q1) (OR = 2.57, 95% CI 1.76 to 3.75). Cross-training  $\geq 4$  times a week increased the risk of lower leg injury compared to those that did not participate in cross-training (OR  $\geq 4$  times per week/No cross-training) = 1.64, 95% CI 1.02 to 2.65. A marginal association found for tobacco use (OR (Smoker/Nonsmoker) = 1.27, 95% CI 0.98 to 1.65).

**CONCLUSION:** Lower leg injuries are a leading injury type in deploying Army units. There is a need for further evaluation and a plan to increase aerobic endurance, decrease tobacco use, and determine the appropriate amount of cross-training needed per week in an effort to reduce limited duty days attributed to injuries.

**3185** Board #150 June 1 3:30 PM - 5:00 PM  
**Running Related Injury, Mileage And Q-angle: A Prospective Follow-up Study.**

Daniel Ramsgov<sup>1</sup>, Rasmus Nielsen<sup>2</sup>, Sten Rasmussen<sup>3</sup>. <sup>1</sup>Aarhus University Hospital – Aalborg Hospital. Ortopaedic Surgery Research Unit. Aalborg University, Faculty of Health Science and Technology, Aalborg, Denmark. <sup>2</sup>Aarhus University Hospital – Aalborg Hospital. Ortopaedic Surgery Research Unit. Faculty of Health Science, Aarhus University, Denmark., Aarhus, Denmark. <sup>3</sup>Aarhus University Hospital – Aalborg Hospital. Ortopaedic Surgery Research Unit., Aalborg, Denmark.  
(No relationships reported)

The Quadriceps angle (Q-angle) may be associated with the development of Running Related Injuries (RRI). Only a few studies have investigated the association between Q-angle, and the likelihood of RRI. These studies have not led to any firm conclusions, on the link between Q-angle and development of RRI. To our knowledge, none of these studies have taken mileage into account, which may be an important part of the causal pathways leading to injury development.

**PURPOSE:** To investigate if mileage to RRI differs between novice runners with different Q-angles.

**METHODS:** Participants were recruited via an online questionnaire. Inclusion criteria's were, age 18-65, running must not have exceeded 10km in total the past year, healthy individuals, consent to run at least two times per week over a 10 week period. Q-angle was measured at baseline, using a standard goniometer, the participant lying supine and the quadriceps relaxed. Participants were divided into three groups (Q-low  $\leq 10^\circ$ , Q-normal  $10^\circ$ - $14^\circ$ , Q-high  $\geq 15^\circ$ ). All training data was collected by a GPS watch, handed out at baseline. The data was uploaded to an online training journal, accessible to the researchers. No guidelines were given to running intensity, time or distance. The Kaplan-Meier method was used to estimate survival mileage until RRI in each group. If a participant reported an injury, their survival mileage was eliminated, they underwent examination and the RRI was diagnosed. To evaluate the outcome, cox-regression model was used to calculate the Hazard Ratio (HR) between groups, with Q-normal as the reference group.

**RESULTS:** N = 60 included, 3 participants excluded, due to missing training data. N = 114 legs was analyzed, divided between 57 participants (n = 30 male, n = 27 female). 14 injured legs was reported, divided between 9 participants (Q-low  $\leq 10^\circ$  RRI = 7, Q-normal  $10^\circ$ -  $14^\circ$  RRI = 5, Q-high  $\geq 15^\circ$  RRI = 2). HR for the Q-low  $\leq 10^\circ$  was (1.3, CI 95% 0.4 - 4.4,  $P_{\text{value}}$  0.609), HR for the Q-high  $\geq 15^\circ$  was (0.6, CI 95% 0.1 - 3.2,  $P_{\text{value}}$  0.558).

**CONCLUSION:** Novice runners with Q-angles lower or higher than  $10^\circ$ - $14^\circ$ , don't have a statistical significant higher hazard rate of sustaining RRI, while running at least, two times per week, over a 10 week period.

---

**3186** Board #151 June 1 3:30 PM - 5:00 PM

**Gender Comparisons of Sports/Recreation- and Training-Related Injuries Among U.S. Service Members in Operation Iraqi Freedom**

Mitchell J. Rauh, FACSM, Hilary J. Aralis, Caroline A. Macera, FACSM, Jamie Bartlett, Andrew J. MacGregor, Peggy P. Han, Michael R. Galameau. *Naval Health Research Center, San Diego, CA.*

(No relationships reported)

**PURPOSE:** The aim of this cross-sectional study was to determine the distribution of sports/recreation- and training-related (SRT) injuries among service members deployed in OIF.

**METHODS:** We studied 1,372 U.S. military personnel (110 females, 1,262 males) who sustained at least one SRT-related injury while deployed in Iraq. Data included all nonbattle injuries that resulted from participation in an SRT-related activity. An injury was defined as any complaint that required the attention of a military health care provider, regardless of time lost from duty. Injury distributions were calculated for body location, injury type, and injury severity. Chi-square analyses were used to compare these injury distributions by sex.

**RESULTS:** Overall, 1,518 injuries were reported with similar injury rate ratios (IRRs) for females (120 injuries, IRR=1.09) and males (1,398 injuries, IRR=1.11) during SRT-related activities. Most injuries (80.0%) were mild in nature (Injury Severity Score=1). No significant differences were found between sexes for injury severity ( $p=0.46$ ). Overall, a slightly higher percentage of lower extremity injuries were sustained by females (45.8% vs. 39.4% [males]) and upper extremity injuries incurred by males (34.3% vs. 30.8% [females]). The most common lower extremity body region affected was the lower leg/ankle (40.1%), and the most common upper extremity body region affected was the shoulder/upper arm (47.6%). Sprains/strains (74.5%), contusions (8.8%), and fractures (8.6%) were the most common injury types, with similar distributions between females and males ( $p=0.26$ ). Sprain/strain injuries were most frequent at the lower leg/ankle and shoulder/upper arm regions, with significant differences between injuries incurred by males and females (foot/toes more frequent among females, shoulder/upper arm more common among males) ( $p=0.002$ ). Foot/toe fractures were more common among females ( $p<0.0001$ ). While fractures were most frequent at the hand/wrist/fingers, dislocations were most common at the shoulder/upper arm.

**CONCLUSIONS:** Results suggest that deployed service members sustaining injuries during SRT-related activities were likely to incur an extremity injury, especially sprains/strains. Most injuries were not likely to cause significant time lost from duty.

---

**3187** Board #152 June 1 3:30 PM - 5:00 PM

**A Hospital-Based Study of Pediatric Sport and Recreational Injuries**

Thomas Schuch<sup>1</sup>, Carma Hanson<sup>2</sup>, Brett J. Goodwin<sup>1</sup>, Mark Romanick<sup>1</sup>, Dennis J. Caine<sup>1</sup>. <sup>1</sup>University of North Dakota, Grand Forks, ND, <sup>2</sup>Altru Health System and Safe Kids Grand Forks, Grand Forks, ND. (Sponsor: James Whitehead, FACSM)

(No relationships reported)

Nearly 30 million children and adolescents participate in organized sports annually in the United States. It is estimated that 3.7 million of these participants report to hospital emergency rooms (ER) each year with injury.

**PURPOSE:** To describe the frequency and distribution of pediatric sports and recreational injuries treated at a regional hospital over a 10-year period.

**METHODS:** The study used a retrospective case series design. Institutional Review Board approval was obtained from the University of North Dakota and Altru Health System. The hospital's ER database was searched for sports and recreational injuries affecting children ages 1-19 years using ICD-9 "E" codes.

**RESULTS:** During 2000-2009, 2,855 pediatric sports and recreational injuries were treated at the hospital ER. Although injuries were distributed throughout all months, September was marked by a relative high percentage of injuries (18%). The majority of injuries were sustained by males (74.2%). The peak frequency of injuries occurred at ages 11-13 for girls and 13-15 years for boys. The forearm was injured most often (18.3%), followed by head/neck (17.3%), and hand (16.8%) injuries. Bicycle-related injuries were most common (20.5%), especially among children  $\geq 14$  years of age, followed by football (19.7%) and hockey (16.2%), which were more common among older children and youth. Soft tissue injuries were the most common injury type (28.8%), followed by fractures (25.5%). Acute epiphyseal injuries accounted for 8.6% of all fractures. Two hundred and three concussions were treated, with most (79.8%) affecting youth 10-19 years. Concussions were commonly associated with football (24.6%), hockey (21.7%), and bicycling (21.7%). The vast majority of injuries were treated and released on the same day (99.7%). There were no fatalities.

**CONCLUSIONS:** Although denominator, and therefore injury rate data are lacking, this case series provides an estimate of the relative frequency of sport and recreational injury in a region, and gives an estimate of the morbidity load on a hospital ER. It is evident that some age groups, and some sports and recreational activities, should be targeted for further prevention and research efforts.

**3188** Board #153 June 1 3:30 PM - 5:00 PM

**Epidemiology of Volleyball Injuries in Young Females**

Gerardo E. Miranda, Deric Lopez, Manuel Mas, William Micheo, FACSM. *University of Puerto Rico School of Medicine, San Juan, PR.*

(No relationships reported)

Volleyball is currently among the most common club sports in the United States and Puerto Rico. Although, adolescent girls make up the largest number of athletes associated with this organization, epidemiologic studies in this population are limited.

**PURPOSE:** To describe volleyball related injuries in young females in Puerto Rico; identify injury patterns, and risk factors.

**METHODS:** A retrospective descriptive study was done. One hundred and five (105) young females (avg age 13.6 years) from local volleyball club leagues participated in the study. Each participant filled a written questionnaire. It included demographic, and current or previous injury information. For those with volleyball related injury, localization, mechanism, type, game versus practice situation, time elapsed since symptoms started, intervention/s, and severity of injury were included. The primary outcome measure is the frequency of volleyball related injury, evaluated by anatomic area, type, mechanism, and etiology. Secondary outcome measures include association of injury to position played, other sport participation, time of exposure, and game versus practice situation.

**RESULTS:** Ninety two percent (92%) of girls had more than 2 years of club volleyball experience, and sixty one percent (61%) reported history of at least one volleyball related injury and one hundred and two (102) injuries were reported. The lower extremities accounted for most acute injuries (51%); the ankle was the most commonly injured body part (35%). In the upper extremities acute injuries involved mostly the wrist and hand. Meanwhile, overuse injuries were evenly distributed in the shoulder, back/trunk, and knee. The most common mechanism of acute injuries was contact with floor and contact with another player, whereas overuse injuries occurred without contact, and occurred more frequently during practice (54%). Additionally, the front row positions were injured more often than the back row players.

**CONCLUSION:** Young female front row players are at high risk for acute volleyball injuries involving the ankle. Further research needs to be done in this population and other age groups, gender, and competition levels, in order to better understand if these elements alter injury mechanism, risk factors, and to plan preventive measures.

---

---

3189 Board #154 June 1 3:30 PM - 5:00 PM

**Injury Risk Associated with Functional Movement Screening in the United States Army.**

Timothy T. Bushman, Tyson Grier, Michelle Canham-Chervak, Morgan K. Anderson, Malukah Waajid, Bruce H. Jones, FACSM. *Army Institute of Public Health, Aberdeen Proving Ground, MD.*

(No relationships reported)

Functional Movement Screening (FMS) is a measurement tool that aims to predict risk of injury in physically-active populations.

**PURPOSE:** To investigate injury risk associated with FMS in a deploying U.S. Army unit.

**METHODS:** Male Soldiers (n=807) ages 18-49 completed FMS which involved seven exercises: deep squat, hurdle step, in-line lunge, shoulder mobility, active straight leg raise, trunk stability pushup, and rotary stability. Each test had a range of 0-3 points with a maximum possible score of 21 if the individual demonstrated sound biomechanics throughout each movement and experienced no pain. If pain was present, the individual automatically scored a zero for that particular test. FMS scores were categorized into four categories, ≤14, 15-16, 17-18, 19-21. Injury occurrence within the last 12 months was collected by survey. Injury risk ratios (RR) and 95% confidence intervals (95% CI) comparing FMS categories are presented.

**RESULTS:** Overall injury incidence for the prior 12 months was 41% (n=340). We found that a higher risk of injury was associated with lower FMS scores (RR ≤14/19-21) = 1.95, 95% CI 1.57-2.41. However, intermediate FMS scores were not significantly different (RR 15-16/19-21) = 1.15, 95% CI 0.88-1.51 and (RR 17-18/19-21) = 1.16, 95% CI 0.91-1.47. During FMS, 57% (n=462) of the Soldiers experienced pain on at least one of the seven tests. Individuals who experienced pain and scored a zero or a one out of a possible three points (pts) had a higher risk of injury than their counterparts for the deep squat (RR 0pts/3pts)= 1.59, 95% CI 1.28-1.97, hurdle step (RR 0pts/3pts) = 1.81, 95% CI 1.47-2.23, in-line lunge (RR 0pts/3pts) = 1.82, 95% CI 1.51-2.20, shoulder mobility (RR 0pts/3pts) = 1.84, 95% CI 1.49-2.27, shoulder mobility (R/R 1pts/3pts) = 1.52, 95% CI 1.08-2.13, trunk stability push-up (RR 0pts/3pts) = 1.42, 95% CI 1.14-1.77, and rotary stability (RR 0pts/3pts) = 1.42, 95% CI 1.06-1.92.

**CONCLUSION:** Consistent with previous literature, a FMS score of ≤14 suggested higher risk of injury. Based on this study, experiencing pain on one of six specific tests indicated an elevated risk for injury. These findings suggest further attention may need to be paid to these particular tests in order to accurately quantify a Soldier's risk for injury with FMS.

---

3190 Board #155 June 1 3:30 PM - 5:00 PM

**Incidence, Mechanisms, and Severity Of Game-related College Football Injuries On Artificial Versus Natural Grass**

Michael C. Meyers, FACSM. *Montana State University, Bozeman, MT.*

(M.C. Meyers: Contracted Research - Including Principle Investigator; FieldTurf, USA.)

In the past, serious injuries were attributed to playing on artificial turf. New generations of artificial turf were developed to duplicate the playing characteristics of natural grass. Only one study has been reported comparing game-related, college football trauma between the two surfaces.

**PURPOSE:** To quantify incidence, mechanisms, and severity of game-related collegiate football injuries on artificial turf versus natural grass.

**METHODS:** A total of 27 universities were evaluated over five competitive seasons for injury incidence, injury category, time of injury, injury time loss, player position, injury mechanism, primary type of injury, grade and anatomical location of injury, type of tissue injured, head, knee and shoulder trauma, and environmental factors.

**RESULTS:** A total of 786 college games were evaluated for football injuries sustained while playing on artificial or natural grass, with 387 (49.2%) games played on artificial versus 399 (50.8%) games played on natural grass. A total of 4,041 injuries were documented, with 1,664 (41.2%) occurring during play on artificial as compared to 2,377 (58.8%) on natural grass. Statistical analysis per 10 team games indicated significantly lower (p<0.05) total injury incidence rates of 43.0 on artificial (95% confidence interval, 42.2-43.5) versus 59.6 on natural grass (95% CI, 58.8-59.7). Significantly lower minor injury incidence rates of 35.0 (95% CI, 34.2-35.5) versus 48.6 (95% CI, 47.8-48.9; p<0.05), significantly lower substantial injury incidence rates of 5.1 (95% CI, 4.6-5.6) versus 6.7 (95% CI, 6.3-7.2; p<0.05), and significantly lower severe injury incidence rates of 2.9 (95% CI, 2.5-3.4) versus 4.2 (95% CI, 3.8-4.7; p<0.05) were documented on artificial versus natural grass, respectively. Findings also indicated significantly less trauma (p=0.040 to 0.0001) on artificial turf when comparing injury time loss, injury category and situation, grade of injury, injuries under various field conditions, and temperature. No significant differences in head, knee or shoulder trauma were observed between playing surfaces.

**CONCLUSION:** Artificial turf is, in many cases, safer than natural grass. The findings of this study, however, may only be generalizable to this level of competition and this specific surface.

---

3191 Board #156 June 1 3:30 PM - 5:00 PM

**Widespread Education & Mandatory Product Warning Labels Are Keys To Preventing US Weight Training Injuries & Deaths**

V. Pateson Lombardi, Richard K. Troxel. *University of Oregon, Eugene, OR.*

(No relationships reported)

**PURPOSE & METHODS:** To document weight training-associated injuries and deaths and to compare more recent trends with data we have monitored over the past 20 yr, we examined US Consumer Product Safety Commission (CPSC) National Electronic Injury Surveillance System, Death Certificate and Reported Incidence files from 2008 to present.

**RESULTS:** For 2008, 2009, and 2010, respectively, there were an estimated 79027, 86307, and 94692 hospital-reported weight training injuries - a 9-10% increase per yr. Most injuries involved males (~80%) and the 15-24 yr (31%) and 25-44 yr (29%) age groups. Strains/sprains were common (42%) with lower trunk (20%), shoulder (13%), upper trunk (11%), and finger (9%) primary injury sites. From May 2008 until July 2011, we documented 18 deaths associated with weight training equipment. Fifteen (83%) involved males, 14 (78%) implicated the bench press, 12 (67%) occurred in the home, and 11 (61%) involved neck or chest compression with asphyxia. For the first time, there was an adult female fatality involving a blunt trauma mechanism and the bench press.

**CONCLUSIONS:** These fatalities continue to demonstrate that the bench press is the highest risk exercise especially when performed without a spotter in the home. Though the CPSC denied our Mar 2003 request for mandatory warning labels on bench presses, our recent data supports our contentions that widespread adult and adolescent education and mandatory product warnings are the keys to preventing weight training injuries and deaths.

3192 Board #157 June 1 3:30 PM - 5:00 PM

**Injuries in Amateur and Professional Wheel Gymnastics**

Max D. Kauther, Silvia Rummel, Björn Hussmann, Sven Lendemann, Christian Wedemeyer. *University of Duisburg/Essen, Essen, Germany.*

(No relationships reported)

**PURPOSE:** Wheel gymnastics is an acrobatic sport with a tradition of nearly 100 years. It is known from gymnastic competitions as well as from shows. So far, there have been no studies or case reports about injuries in wheel gymnastics.

**METHODS:** This retrospective study of wheel gymnasts surveyed 51 professionals, 100 semi-professionals and 352 amateurs by questionnaire.

**RESULTS:** 7925 injuries and 422 overuse syndromes were found in 988718.9 hours of training leading to a loss of 17310.3 training days. Professionals reported significantly (p < 0.001) more injuries and overuse syndromes with significantly more injuries of the wrist (p < 0.001), knee (p < 0.001), hip/thigh (p = 0.003), ankle/foot (p = 0.013) and elbow (p = 0.033). Significant differences were found in the time per injury rate. Amateurs practised 155.8 hours, semi-professionals 221.8 hours and 331.7 hours until one injury occurred. The most frequent pain was found in the region of the wrist, spine, shoulder and ankle. A positive correlation significant at the 0.0001 level was found between the average pain frequency and the average frequency of wearing protective gear of the elbow, wrist, knee and ankle.

**CONCLUSIONS:** This study firstly describes specific injuries of wheel gymnastics. This sport bears the danger of falling from up to 3 meter height on bare floor. Physicians should be aware of the common risks in this highly acrobatic kind of gymnastics. The severity of injuries in wheel gymnastic should not be underestimated

**3193**    *Board #158*    **June 1**    **3:30 PM - 5:00 PM**  
**Intrinsic And Extrinsic Risk Factors For Tennis Injuries**

Janine Stubbe<sup>1</sup>, Rebecca Kuiper<sup>1</sup>, Jasper Stege<sup>1</sup>, Ariëtte van Hespem<sup>1</sup>, Babette Pluim<sup>2</sup>. <sup>1</sup>TNO, Leiden, Netherlands. <sup>2</sup>Royal Netherlands Lawn Tennis Association, Amersfoort, Netherlands.  
(No relationships reported)

In addition to the well-documented beneficial effects, sport can have a negative side effect in the form of sports injuries. The total number of sports injuries in the Netherlands is about 3.6 million per year. Two-thirds of all medically treated sports injuries are associated with nine sports, including tennis.

**PURPOSE:** The objective of this study was to investigate the incidence, nature, and severity of tennis injuries, and to examine risk factors for tennis injuries. Method: In April 2010, baseline information on recreational tennis players aged 16 years and older was collected. Self-reported surveys containing items about personal characteristics, tennis-specific information and injury history were handed out by tennis trainers during practice sessions at three tennis academies in Amsterdam. After three (July 2010) and six months (October 2010) tennis players received a survey sent by e-mail containing items about sustaining an injury and match and training exposure. Injury incidences were calculated (e.g. the number of injuries per 1,000 hours tennis). Furthermore, logistic regression analyses were conducted to assess the risk factors for sustaining a tennis injury. The main outcome measure of the logistic regression analyses was whether the person sustained an injury during the data collection period or not. Injury was defined as physical complaints caused by playing tennis and resulting in a time loss from tennis of at least one day.

**RESULTS:** A total of 151 injuries were reported: 58% of the injuries were classified as acute and 36% as recurrent. The most common locations were: elbow, shoulder, lower back, calf, and ankle. Most injuries affected the players' tennis participation: 42% was classified as severe, 25% as moderate, and 13% as minor. The overall incidence rate was 3.55 injuries per 1,000 hours of tennis. Injury risk in tennis gradually increased with exposure (OR = 1.004).

**CONCLUSION:** Tennis has a high injury rate and injury risk gradually increases with exposure (OR = 1.004). More research is needed to examine the risk factors associated with tennis injuries.

---

**3194**    *Board #159*    **June 1**    **3:30 PM - 5:00 PM**  
**Video Incident Analysis of Concussion Mechanisms in Boys' High School Lacrosse**

Shane V. Caswell<sup>1</sup>, Andrew E. Lincoln<sup>2</sup>, Reginald E. Dunn<sup>2</sup>, Jon L. Almquist<sup>3</sup>. <sup>1</sup>George Mason University, Manassas, VA. <sup>2</sup>Union Memorial Hospital, Baltimore, MD. <sup>3</sup>Fairfax County Public Schools, Falls Church, VA.  
(No relationships reported)

**PURPOSE:** To describe common game play scenarios and mechanisms of injury associated with concussion in boys' high school lacrosse using game video.

**METHODS:** Video of 518 boy's high school lacrosse games were captured by trained videographers during the 2008 and 2009 seasons. When an injury occurred, a log entry was recorded to include the time of injury, the body part injured, and the player number. Videotapes were analyzed using StudioCode (Sportstec USA, Camarillo, CA) software to identify event characteristics. Video data were linked to the injury report filed by the athletic trainer (AT) for further detail and verification.

**RESULTS:** 44 incidents (20 in 2008 and 24 in 2009) were determined to be a concussion, 34 (77%) of which had sufficient image quality for analysis. Most 22 (65%) head injuries involved varsity level athletes compared with 12 (35%) at junior varsity. 23 (67%) concussions occurred in the attacking zone compared with 10 (34%) in the midfield zone. All (100%) concussions resulted from intentional player-to-player bodily contact. Players were most often injured while playing the midfield (18, 53%) and defense (n=9, 27%) positions and attempting to pick up a loose ball (n=16, 47%) or when ball handling (n=14, 41%). Most frequently the striking player's head (27, 79%) was used in the collision and in 59% (n=20) the struck player's head was the initial point of impact. In 24 (71%) of cases a subsequent impact with the playing surface was suffered immediately following the initial impact. In 9 (26%) collisions a penalty was called.

**CONCLUSION:** This study identified intentional bodily collisions in which the striking player used his head to initiate contact as the most frequent cause of concussion. Concussions most often occurred during the acts of competing for a loose ball and ball handling. Since the time this study was conducted, rule changes have been enacted that prohibits deliberately initiating contact to an opponent's head or neck with a stick, or any part of the body. Further investigation of preventive measures such as the education of coaches and officials, enforcement of new rules designed to prevent head-to-head contact is warranted to reduce the incidence of concussion injuries in boys' lacrosse. Supported by the National Operating Committee on Standards for Athletic Equipment and US Lacrosse.

---

**3195**    *Board #160*    **June 1**    **3:30 PM - 5:00 PM**  
**Injury Rates For Collegiate And High School Rugby Players**

Maggie McGinty<sup>1</sup>, Donald C. LeMay<sup>2</sup>. <sup>1</sup>The Ohio State University Medical Center, Columbus, OH. <sup>2</sup>Ohio Heath, Columbus, OH. (Sponsor: James R. Borchers, FACSM)  
(No relationships reported)

**PURPOSE:** There have been many studies done in reference to professional rugby world wide. However, there are few studies that evaluate the injury rates of tournaments that involve amateur High School and College athletes. Furthermore, there are minimal studies looking at female injury rates in rugby. We examined the distribution of injuries in this age group of rugby athletes with an epidemiological retrospective study of injuries that were reported to the medical tent during a two day rugby tournament from 2008 to 2010.

**METHODS:** There were 76 female and 111 male teams in attendance with a total of 131 female and 159 male matches played over the three year period. Data was collected during the injury screening and during the treatment course by ATC's, PT's, and physicians via an injury report and consent forms completed in the medical tent during the two days of competition each year.

**RESULTS:** A total of 1140 female and 1665 male athletes played in the tournament with a total of 168 female (TFI) and 162 male (TMI) injuries were reported to the medical tent for evaluation. Those injuries were classified as Concussions, Upper Extremity, Lower Extremity and Lacerations. Concussions represented 14.8%, UE represented 44.8%, LE represented 32.7% and Lac represented 5.7% of all injuries reported. The injury rate decreased from Saturday to Sunday in 2008 from 55% to 44%; in 2009 from 56% to 43% and in 2010 from 73% to 26%. Females sustained more concussions (17% of TFI) and lower extremity injuries (36% of TFI). Males reported a higher rate of lacerations needing sutures (11% of TMI). Both males and females had near equal injury rate to the upper extremity (44% females and 45% males).

**CONCLUSION:** Our study shows that even though there were less female teams/athletes participating in the tournament, they had a higher injury rate compared to males. The data also shows a decrease in reported injuries on the second day of the tournament that could be attributed to athletes waiting to see their Primary Care Providers at home and the desire not to be pulled from competition. Further studies could be done to evaluate the reason for the difference between the male and female rate of injury reported. Also, a more rugby-specific injury tracking system could help with reporting positional injury rates along with high school vs. collegiate injury rates.

---

**3196**    *Board #161*    **June 1**    **3:30 PM - 5:00 PM**  
**12-Month Incidence of Exercise Injuries in Community-dwelling Older Adults Following an Exercise Intervention**

Rob Little, Liza Stathokostas, Dave Humphreys, Don H. Paterson, FACSM. University of Western Ontario, London, ON, Canada.  
(No relationships reported)

Fear of injury is reported as a barrier to exercise by older adults. However the literature is limited in describing exercise injuries in older adults.

**PURPOSE:** To evaluate the 12 month incidence of, and describe injuries to, previously sedentary community dwelling older adults (>60y) following an 8-week supervised exercise program.

**METHODS:** Data were collected from the "Get Fit for Active Living" 8-week exercise. A self-reported questionnaire was used to document the injuries incurred in the 12 months post-exercise intervention. Linear regression analysis was conducted to identify co-variants related to injury outcome.

**RESULTS:** 167 people completed the questionnaire. 63 respondents were male and 104 were female. 23 people (13%) reported injuries. 41% of injuries were to the lower extremities, 27% were upper extremity, 23% involved the trunk, and 9% affected multiple areas. The most common type of injury was repetitive/overuse muscle strains (32%, n=7), 5 were acute muscle strains, and 8 were ligament sprains. Over-exertion/strenuous movements were the most common cause of injury (n=9), followed by 6 overuse/repeated strains and 5 falls. Walking accounted for half

of the activities during which injury occurred. Following that were stretching and swimming (both 9%, i.e. 2 injuries in each of these activities). 70% of injuries reported required medical treatment, with 75% being visits to a physician, 12% to a physical therapist, one walk-in clinic and one emergency room visit. 44% were not able to continue exercising immediately. Return-to-activity time varied from 1 to 182 days. Univariable regression analysis was performed using sex, age, and exercise volume as correlates, but none were significantly associated with injury occurrence.

**CONCLUSIONS:** These results showed similar or lower exercise-related injury rates as compared with previous reports on younger and middle-aged adults, however the definition of, and criteria for "injury" reporting varies in the literature. This study indicates that older adults taking up exercise are not at an increased risk of injury, and participation in an intervention - where the instruction of safe participation is taught - might confer some "protective" effect. Supported by CIHR.

3197 Board #162 June 1 3:30 PM - 5:00 PM

**Mechanism Of Injury Trends For Shoulder Injuries In Interscholastic Sports: 2007-2009**

Jennifer M. Medina McKeon, Erin M. Hagedorn, Timothy L. Uhl, Heather M. Bush. *University of Kentucky, Lexington, KY.*

(No relationships reported)

**PURPOSE:** For the shoulder, injuries and injury prevention are focused predominantly on baseball and softball. Systematic investigation of shoulder mechanism of injury (MOI) is an important step to risk factor analysis and injury prevention program development. The purpose was to describe trends shoulder MOIs in interscholastic athletes.

**METHODS:** Epidemiological data were collected by certified athletic trainers for injured high schools athletes at 7 high schools during the 2007-08 and 2008-09 academic years. Shoulder injury relative incidence rates (RIR) and 95% confidence intervals (CI) were calculated per 10,000 athlete-exposures (AE). The variable MOI, was separated into the following categories: contact with person (Person), contact with surface (Surface), contact with apparatus (Apparatus), Noncontact, Overuse, and Other. For MOI, shoulder injury frequency was converted into a percentage of the total number of shoulder injuries reported per sport.

**RESULTS:** A total of 135 shoulder injuries occurred during 188,925 AEs. Results are reported for the 4 sports with the highest incidence rates of shoulder injury (Wrestling, Football, Softball, Baseball). For wrestling RIR = 53.5 [30.0,76.9]; football, RIR = 14.6 [10.9, 18.2]; softball, RIR = 10.0 [4.8,15.2]; and baseball, RIR = 8.6 [4.6, 12.6]. For MOI, contact injuries accounted for a considerable percentage of shoulder injuries in football (Person = 36.8%; Surface = 63.8%) and wrestling (Person = 57.9%; Surface = 19.0%), with few reported in baseball (Person = 0%; Surface = 11.0%) and softball (Person = 0%; Surface = 7.1%). In contrast, noncontact injuries accounted for a distinct percentage of shoulder injuries in baseball (Noncontact = 16.7%; Overuse = 66.7%) and softball (Noncontact = 28.6%; Overuse = 64.3%), with relatively few injuries reported in wrestling (Noncontact = 0%; Overuse = 0%) and football (Noncontact = 5.2%; Overuse = 5.2%).

**CONCLUSIONS:** While shoulder injury prevention programs tend to focus on preventing overuse injuries, a considerable number of shoulder injuries occur during football and wrestling, and tended to be contact in nature. Further exploration of these contact injuries, including research associated with the development shoulder injury prevention programs for contact-related injuries may be warranted.

---

3198 Board #163 June 1 3:30 PM - 5:00 PM

**Incidence And Risk Factors Of Running-Related Injuries: A Prospective Cohort Study**

Luiz C. Hespagnol Junior, Leonardo Oliveira Pena Costa, Alexandre Dias Lopes. *São Paulo Running Injury Group (SPRunIG) of Universidade Cidade de São Paulo (UNICID), São Paulo, Brazil.*

(No relationships reported)

Beside the positive effects of running, this activity may cause musculoskeletal injuries. An understanding of the incidence of injury and the risk factors associated with injuries in runners can assist in the implementation of prevention strategies in this population.

**PURPOSE:** To determine the incidence of running-related injuries in a cohort of amateur runners and to identify the aspects of training that are associated with running-related injury.

**METHODS:** In this prospective cohort study, 200 amateur runners answered a fortnightly online survey containing questions about their running training routine. These runners were followed-up for a period of 12 weeks. The incidence of injuries was calculated using survival analysis and the association between potential risk factors and time of injury was determined by Cox regression models.

**RESULTS:** A total of 191 runners completed all follow-up surveys (i.e. completeness of follow up=95.5%). A new RRI was observed in 34.6% (n = 66) of our sample, which is equivalent to 8 injuries per 1000 hours of exposure to running. The mean pain intensity was 1.4 (SD = 1.3) evaluated by a 10-point (1-10) pain numerical rating scale (NRS). The main types of RRI reported were muscle injuries (18.2%, n=12) and low back pain (13.6%, n=9), followed by plantar fasciitis (10.6%, n=7), and tendinopathies (9.1%, n=6). The anatomical areas most commonly affected were the thigh and the leg (18.2%, n=12 each one), followed by knee (16.7%, n=11), and foot (16.7%, n=11). The variables related to training characteristics that had a value of p<0.05 at least in the log rank test (univariate analysis) were included in the multivariate Cox regression model. The variables associated with RRI in the Cox regression analysis were duration of training greater than 60 minutes (hazard ratio (HR)=1.9; 95% confidence interval (CI)=1.0 to 3.4); training on mixed terrains (HR=3.4; 95% CI=1.8 to 6.2); and performing interval training (HR=1.9; 95% CI=1.1 to 3.3).

**CONCLUSION:** The incidence of RRI was 34.6% or 8 injuries per 1000 hours of exposure to running. The RRI risk factors observed in this population were performing endurance exercise (running) for over 60 minutes, training on mixed terrain (uphill and downhill), and perform interval training.

---

3199 Board #164 June 1 3:30 PM - 5:00 PM

**Ability Of Previous Exercise Frequency To Predict Injuries In Officer Candidates And Its Association To FMS**

Selasi Attipoe<sup>1</sup>, Peter Lisman<sup>1</sup>, Francis G. O'Connor, FACSM<sup>1</sup>, Patricia A. Deuster, FACSM<sup>1</sup>, Chris G. Pappas, FACSM<sup>2</sup>, Joseph J. Knapik, FACSM<sup>3</sup>. <sup>1</sup>Uniformed Services University, Bethesda, MD. <sup>2</sup>Womack Army Community Hospital, Fort Bragg, NC. <sup>3</sup>Public Health Command, Aberdeen Proving Grounds, MD.

(No relationships reported)

Low levels of previous physical activity are predictive of future injury risk. Recently, an association between Functional Movement Screen (FMS) scores  $\leq 14$  and incidence of musculoskeletal injury was reported. However, the injury predictive value of specific exercise mode training frequencies (SETF) and their relationship to FMS is unclear.

**PURPOSE:** To determine whether self-reported frequency of running, weight-training (WT), and "general" exercise or sports (GES) would predict subsequent injury in Marine Corps Officer Candidate School (OCS) training. We also assessed the association between SETF and FMS tests.

**METHODS:** Participants included 874 male (22.4 $\pm$ 2.7 yrs) candidates enrolled in either six (n = 447) or ten (n = 427) weeks of OCS. Prior to beginning OCS, candidates completed a questionnaire and underwent FMS. Questions included self-reported frequencies for running, WT, and GES. FMS consisted of deep squat, hurdle step, inline lunge, shoulder mobility, active straight leg raise (SLR), push-up, and rotary stability tests. Injury incidence data were gathered throughout training and grouped as "any", "overuse", or "traumatic". WT frequency was grouped as  $\leq 1$ , 2-4, or  $\geq 5$ x/wk, whereas running and GES were grouped as  $< 5$  or  $\geq 5$ x/wk. FMS test scores were grouped as "high" (score of 3) vs. "low" (score of 1 or 2).  $\chi^2$  statistics were used to evaluate group differences in injury risk and determine associations between SETF and FMS tests.

**RESULTS:** Candidates were 1.6 times more likely to suffer an overuse injury if they reported a GES frequency  $< 5$ x/wk (p = 0.028); 14.1% of persons who reported a GES frequency  $< 5$ x/wk suffered an injury compared with 9.3% with frequencies  $\geq 5$ x/wk. In contrast, both running and WT frequencies were independent of injury. Increased WT frequency was associated with high FMS scores for SLR ( $\chi^2 = 9.87$ , p = 0.007), whereas running frequency  $\geq 5$ x/wk was associated with low FMS scores in shoulder mobility ( $\chi^2 = 4.71$ , p = 0.03). GES frequency  $\geq 5$ x/wk was associated with low FMS scores for squat ( $\chi^2 = 6.21$ , p = 0.013) and rotary stability ( $\chi^2 = 5.72$ , p = 0.017) tests.

**CONCLUSION:** GES frequency  $< 5$ x/wk was associated with increased overuse injury risk. Although weak associations were found between SETF and high FMS test scores, the implications of these findings remain to be determined.

---

3200 Board #165 June 1 3:30 PM - 5:00 PM

**Incidence And Prevalence Of Main Running-Related Injuries: A Systematic Review**

Alexandre Dias Lopes<sup>1</sup>, Luiz Carlos Hespanhol Junior<sup>1</sup>, Leonardo Oliveira Pena Costa<sup>1</sup>, Simon Yeung<sup>2</sup>. <sup>1</sup>São Paulo Running Injury Group (SPRunIG) of Universidade Cidade de São Paulo (UNICID), São Paulo, Brazil. <sup>2</sup>Hong Kong Polytechnic University, Hong Kong, China.  
(No relationships reported)

There is no consensus in the literature about what are the incidence and prevalence of main musculoskeletal injuries in runners.

**PURPOSE:** The objective of this study was to systematically review the data available on incidence and prevalence of main running-related musculoskeletal injuries (RRMI).

**METHODS:** Searches were conducted on EMBASE, MEDLINE, SPORTDISCUS, LILACS and SCIELO databases, with no limits of date and language of publication, being the searches conducted in March 2011. We considered eligible articles related with RRMI that describe the incidence or prevalence rates of RRMI. We excluded studies that reported only the type of injury or anatomical region, studies conducted with injured runners only, and studies with incomplete data or some other reason that precluded interpretation of which would be the incidence and prevalence rates of the main RRMI in runners. The extracted data were: first author, publication year, study design, description of the population of runners, RRMI definition and the name of each RRMI with their rates of incidence or prevalence.

**RESULTS:** Among the 2781 titles, eight of them were considered eligible for the review. Most articles had moderate risk of bias and just one fulfilled less than a half of the risk of bias criteria. The main RRMI were: patellar tendinopathy (incidence ranged from 5.5% to 22.7%; prevalence ranged from 6.3% to 18.5%), medial tibial stress syndrome (incidence ranged from 13.6% to 20.0%; prevalence ranged from 7.8% to 11.1%), Achilles tendinopathy (incidence ranged from 9.1% to 10.9%; prevalence ranged from 6.2% to 18.5%), plantar fasciitis (incidence ranged from 4.5% to 10.0%; prevalence ranged from 5.2% to 17.5%), patellofemoral syndrome (incidence ranged from 5.5% to 6.9%; prevalence ranged from 5.5% to 15.6%) and iliotibial band syndrome (incidence ranged from 1.8% to 9.1%; prevalence ranged from 4.7% to 10.5%).

**CONCLUSION:** The main RRMI found in this systematic review were: (1) patellar tendinopathy, (2) medial tibia stress syndrome, (3) Achilles tendinopathy, (4) plantar fasciitis, (5) patellofemoral syndrome, and (6) iliotibial band syndrome.

3201 Board #166 June 1 3:30 PM - 5:00 PM

**Comparison of Neutral Spine and Hamstring Stretch for Relief of Hyperlordotic Lumbar Pain**

Jolie Bookspan. *Neck and Back Pain Sports Medicine, Philadelphia, PA.* (Sponsor: Catherine Ratzin Jackson, FACSM)  
(No relationships reported)

**PURPOSE:** Widespread prescription for lower back pain (LBP) is hamstring stretching. Some patients report relief, others, worsening. A pilot study of 167 subjects found no relation between hamstring flexibility and LBP. Subsequent independent studies confirm no relation between hamstring flexibility and LBP. Sufferers of disc injury and spinal stenosis often worsen with flexion, contraindicating hamstring stretch during active pain. Previous work determined that hyperlordosis (swayback) results in one form of LBP by compression of facets and soft tissue, and shortening lumbar height. Neutral spine (NS) lengthens and unloads, directly stopping LBP. Momentary incidental lumbar lengthening during hamstring stretch briefly stops symptoms. It is proposed that temporarily reversing swayback with hamstring stretching became confused with the separate entity of flexibility. The purpose of this study is to compare a neutral spine method, Ab Revolution (AR) with conventional hamstring stretching (HS) for LBP from hyperlordosis.

**METHODS:** Plot study of 167 subjects measured degrees hamstring flexibility using straight leg raise test, compared to nominal measures of active LBP, previous LBP, or never LBP. Of initial 167 N, 113 had active LBP. Of these 113, 92 reported wanting to bend forward, lift one leg, sit, or bring knees to chest to relieve symptoms. 4 were lost to follow up. Remaining 88 were divided into two groups: AR N=43, Daily conventional hamstring stretching HS=43. Outcome measures of neutral spine NS, flexibility, and LBP were assessed at day 1, 6 weeks, and 6 mos, analyzed using Chi-Square.

**RESULTS:** AR showed sig reduction of LBP during daily activities (40 of 43) using NS. HS group showed no significant reduction in LBP: 41 of 44 increased hamstring flexibility, 43 had brief symptom relief during stretch but return to pain with upright stance and activities of daily living, 43 were measured no NS. 18 of 44 had increase in LBP.

**CONCLUSIONS:** Incidental lumbar flexion from hamstring stretch, not hamstring flexibility, briefly reduces LBP by reversing swayback. Hamstring stretch is stopgap, indirect, not curative, may aggravate symptoms, and over time create new ones. Lumbar lengthening to neutral through AR is functional, and gives sustainable pain relief by directly stopping causes of LBP from hyperlordosis.

3202 Board #167 June 1 3:30 PM - 5:00 PM

**Costs of Physical Activity-Related Musculoskeletal Injury In Community-Dwelling Women**

Alison K. Herrmann<sup>1</sup>, James R. Morrow, Jr.<sup>2</sup>, James T. Morrison<sup>3</sup>, Madelena Ng<sup>1</sup>, Laura F. DeFina<sup>4</sup>, Robert M. Kaplan<sup>1</sup>. <sup>1</sup>UCLA School of Public Health, Los Angeles, CA. <sup>2</sup>University of North Texas, Denton, TX. <sup>3</sup>UCLA Health System Patient Safety Institute (PSI), Los Angeles, CA. <sup>4</sup>The Cooper Institute, Dallas, TX.  
(No relationships reported)

**PURPOSE:** Despite a substantial literature documenting benefits of physical activity (PA), regular exercise is also associated with some risks. For example, the risk of musculoskeletal injury (MSI) increases with greater exercise frequency. MSI is associated with financial costs including the costs of medical care and time lost from work. The purpose of this study was to evaluate the economic costs associated with PA-related MSI in community-dwelling women.

**METHODS:** Participants included 918 women in the WIN Study. Participants reported weekly on their PA behaviors and MSI incidence via the Internet for up to 3 years. Costs were estimated by review of medical records and through self-reports of medical care use. Participants reported MSI and provided consent to obtain health records. Components of costs included time missed from work, physician visits, medical facility contacts, and prescription medications. Frequencies of each item were tabulated and then weighted by estimated costs using prevailing charges in Dallas, TX. In addition to medical costs, we considered the costs of non-physician providers, durable medical equipment, radiology services, and over-the-counter medications.

**RESULTS:** Among the 918 participants, MSI data were available for 245 women reporting MSI associated with PA. Within this group of women, there were 2323 episodes of expenditure or contact with the health care system. Total costs of the episodes ranged from \$0.00-\$18,934. The modal cost was \$0.00 with a mean of \$433 (SD=\$1670). The distribution of injury costs was positively skewed with nearly all participants reporting no or very low costs.

**CONCLUSION:** About one in four community-dwelling women who are physically active experience a MSI. The great majority of these injuries are minor. Large expenses associated with these MSI are quite rare. Our analysis does not consider the potential costs associated with improved physical fitness. However, it is likely that the long-term costs savings resulting from PA outweigh the minor costs associated with a physically active lifestyle.

3203 Board #168 June 1 3:30 PM - 5:00 PM

**Systematic Review of Methodology in Ski Injury Research**

Kristen A. Scopaz<sup>1</sup>, John Hatzenbuehler<sup>1</sup>, Tyler Bernaiche<sup>2</sup>, Christina Holt<sup>1</sup>, Kahsi Threlkeld<sup>1</sup>, William Dexter, FACSM<sup>1</sup>. <sup>1</sup>Maine Medical Center, Portland, ME. <sup>2</sup>Tufts University School of Medicine, Boston, MA.  
(No relationships reported)

Skiing and snowboarding cause numerous injuries. Research efforts using information from a ski clinic at a major northeastern resort proved difficult given missing and inconsistent data. Most ski injury research data collection methods are retrospective or survey-based. A standardized data collection tool will improve the quality of ski and snowboard injury research, which is needed to develop injury prevention strategies and manage ski injuries.

**PURPOSE:** To perform a systematic review of ski injury literature focusing on methodology for data collection.

**METHODS:** Medline and SPORTDiscus databases were searched using key words "ski\* injur\*" and "snowboard\* injur\*", limited to human studies in English in the past 20 years. Inclusion criteria were original studies that looked specifically at injuries to skiers or snowboarders and described data collection methods. Two reviewers screened the articles for inclusion. For any discrepancies, discussion with a third reviewer was conducted to reach consensus. For each included article, the methods section was reviewed and categorized according to method type.

**RESULTS:** 185 studies met inclusion and exclusion criteria. Almost all (179, 97%) were observational. Only 5 were experimental including 3 randomized controlled trials. There was one methodological study. Of the 179 observational studies, 8 (5%) were cohort, 29 (16%) case-control, 117 (65%) cross-sectional, 22 (12%) case series, and 3 (2%) were prospective case studies. Overall, 10 (5%) studies were fully prospective, 74 (40%) reported prospective collection of data with a retrospective analysis, and 101 (55%) were retrospective or not clearly defined. 72 studies included data collected at a ski mountain including from ski clinics, ski patrol and surveys. 91 studies used data collected at hospitals or medical clinics. Other sources of data included mailed or distributed surveys, injury surveillance databases, and death certificates. 61 studies utilized more than one data collection method.

**CONCLUSIONS:** Multiple methods of variable quality exist for collecting ski injury research data. A standardized data collection tool would improve the quality and implications of such research. Subsequently our aim is to create a ski injury data collection tool that provides consistent data.

### Project VIA BRAZIL: Active Living, Finding Healthy Ways

Tania Bertoldo Benedetti<sup>1</sup>, Andiara C. Schwingel<sup>2</sup>, Wojtek Chodzko-Zajko, FACSM<sup>2</sup>, Giovana Zarpellon Mazo<sup>3</sup>, Eleonora d'Orsi<sup>1</sup>, Marcia Ory<sup>4</sup>. <sup>1</sup>Universidade Federal de Santa Catarina, Florianópolis, Brazil. <sup>2</sup>University of Illinois at Urbana-Champaign, Urbana-Champaign, IL. <sup>3</sup>Universidade do Estado de Santa Catarina, Florianópolis, Brazil. <sup>4</sup>School of Rural Public Health, TAMU, TX.

(No relationships reported)

In recent years several Federal initiatives in Brazil have focused on physical activity promotion. Most programs offer only traditional group-based exercise classes. Although exercise classes have shown to be very effective in improving health of participants, they tend to be relatively high cost and are able to reach only a small percentage of the eligible population.

**PURPOSE:** Project VIA Brazil is an ongoing research project that compares advantages and disadvantages of traditional group-based exercise programs with an evidence-based behavioral change program designed to promote physically active lifestyles among older Brazilians.

**METHODS:** Project VIA Brazil enrolled 100 community dwelling older adults aged 60 years and older living in Florianópolis, Southern Brazil. They were divided among two intervention groups: traditional exercise class (GE) and a behavioral change program (GB); and a control group (GC). GE group consisted of a 3-month aerobics class, 3 times per week, 60 min each; whereas GB group a 12-session 'Active Living Every Day' program. The programs were offered in public health centers through the city.

**RESULTS:** In this presentation we describe the outcome of the qualitative component of the analyses that using the RE-AIM public health evaluation model, explored the reach, adoption, implementation, and sustainability of the two interventions. Key staff members at participating health centers were interviewed as well as selected older adult participants. Our data suggest that both traditional exercise programs and behavioral change programs have merit and that public health centers should consider offering a combination of classes to maximize the reach of physical activity promotion efforts.

**CONCLUSIONS:** Traditional exercise programs and more modern behavioral change programs each have merit and both should be considered as important elements of physical activity promotion.

3205 Board #170 June 1 2:00 PM - 3:30 PM

### Effects of Seated Pedaling on Calorie Expenditure and Perceived Productivity

Peggy A. Plato, Heather A. McDowell. San Jose State University, San Jose, CA. (Sponsor: Craig Cisar, FACSM)

(No relationships reported)

Obesity is a major problem in the US population, and a sedentary lifestyle contributes to this problem. Despite public health efforts promoting the importance of physical activity, the majority of U.S. adults do not meet the minimal activity recommendations. Because adults are increasingly spending time seated, often in front of a computer monitor, interventions that fit into this lifestyle and increase energy expenditure have potential to positively impact health and well-being.

**PURPOSE:** To evaluate the efficacy of a seated leg pedaling device for increasing calorie expenditure and perceived productivity.

**METHODS:** Participants (3 men, 7 women, 22.8 ± 0.5 yrs, 167.9 ± 3.2 cm, 69.1 ± 4.5 kg) were recruited from a university lecture class that met 2 days per week. One day each week participants used the device, pedaling at their own pace, and recorded the number of revolutions completed during the 50 min class. On both pedaling (P) and non-pedaling (NP) days, participants completed a survey at the end of class rating their perceived productivity (1= low, 5 = high). Following the 4 week intervention, calorie expenditure was measured during seated rest and while pedaling.

**RESULTS:** Pedaling significantly increased calorie expenditure compared to seated rest (1.7 ± 0.1 vs. 1.1 ± 0.1 Kcal/min respectively, p<0.001). Although Kcal expenditure increased by only 0.6 Kcal/min, using the pedaling device 4 hr/day, 5 days/week would increase energy expenditure by 37,440 Kcal/year, equivalent to a 4.8 kg weight loss if calorie intake remained constant. Participants reported that the pedaling device was comfortable and easy to use. Perceived energy level (3.5 ± 0.3 P vs. 3.0 ± 0.3 NP, p<.01), motivation (3.4 ± 0.2 P vs. 3.0 ± 0.3 NP, p<0.05), and alertness (3.5 ± 0.2 P vs. 3.1 ± 0.3, p<0.05) were higher when pedaling during class. There were no significant differences in perceived ability to focus and participation in class between pedaling and non-pedaling days.

**CONCLUSION:** A leg pedaling device can be used at work or school to increase energy expenditure during seated activities. Although the additional energy expenditure is small, over time it can impact energy balance and help individuals reach or maintain healthier body weights. Additionally, this low level physical activity may increase energy, motivation, and alertness while working.

3206 Board #171 June 1 2:00 PM - 3:30 PM

### Do User Intentions and Health Feedback Influence Exergame Duration of Use and Measured Exertion?

Eric B. Hekler<sup>1</sup>, Frank X. Chen<sup>2</sup>, Abby C. King, FACSM<sup>2</sup>. <sup>1</sup>Arizona State University, Phoenix, AZ. <sup>2</sup>Stanford University, Stanford, CA.

(No relationships reported)

Although previous research suggests some exergames (e.g., Wii Fit, Kinect) promote moderate intensity or more vigorous physical activity (e.g., >3 METs), little is known about the impact of intentions (e.g., game vs. exercise) or health feedback (e.g., calorie trackers) on exertion and duration of use.

**PURPOSE:** Determine if a person's intentions when using an exergame (i.e., as a game or as "exercise") and presence of health feedback (i.e., calorie counter displayed or not) result in greater perceived and actual exertion and time spent using Kinect Dance Central.

**METHODS:** : A randomized 2x2 (exercise vs. game intention; calorie counter vs. not) experiment was conducted among university students and staff. Participants (N=42, Mage=26.5±7.2, 59.5% men; 61.9% reported regular exercise) were recruited via local advertisements and listservs and invited to participate in a 90-minute "stress relief" study. Participants were excluded if they owned and/or regularly used the Xbox Kinect. All participants received a 5-minute Kinect and supervised dance tutorial and then were left alone to use the program for as long as they desired. The "intention" manipulation was accomplished via [a] an oral instruction with references to the action as either "exercise" or "game" and [b] setting-based contextual cues (e.g., "Exercise time. Have a great workout!" was written below the monitor for the Exercise condition). Participants either had the program's "workout mode" (i.e., a calorie counter and duration of use of the system) turned on or off. Manipulations were tested and refined prior to the experiment. Perceived exertion was measured via the Borg Scale. Actual exertion (i.e., average METs across the time using the program) was measured via the Zephyr Bioharness. Time spent using the program was measured via stop watch.

**RESULTS:** ANOVA analysis revealed a significant main effect of intention on duration of use (F=5.2, p<0.05, Me=49.2±9.6, Mg=39.7±14.4) but not feedback or feedbackXintention (ps>0.25). There were no significant predictors of perceived or actual exertion (ps>0.54, sample M<sub>per</sub>=12.8±1.7, M<sub>met</sub>=4.5±1.1).

**CONCLUSIONS:** Results suggest that this sample of young adults, when using an exergame framed as “exercise”, used it for a longer time than those for whom the program was framed as a “game.”

**3207**    *Board #172*    **June 1**    **2:00 PM - 3:30 PM**  
**Changes in Preservice Classroom Teachers’ Activity Levels through Participation in a Physical Education Infusion Program**  
Tan Leng Goh, James C. Hannon. *University of Utah, Salt Lake City, UT.* (Sponsor: Janet M. Shaw, FACSM)  
(No relationships reported)

Preservice classroom teachers (PCTs) have an influence on the health and wellbeing of school children.

**PURPOSE:** To examine changes in the physical activity (PA) levels of PCTs at the end of a 12-week intervention program, Physical Education Programming Infusion (PEPI).

**METHODS:** Participants were 19 female PCTs (Age = 28.4±7.2yrs). The 30-minute weekly PEPI was infused into a required semester-long science methods course. The objective of PEPI was to provide PCTs the skills to integrate movement and healthy lifestyle knowledge into classroom subjects. Activities were also structured to help PCTs to become aware of their personal PA behaviors. To assess the participants’ PA levels, they wore pedometers (New Lifestyle NL-1000) over 6 consecutive days at the start and end of the PEPI. Difference in baseline and post PA levels was assessed by paired-sample t-test. Participants also completed open-ended questionnaires to examine their experiences using the pedometers. Thematic analysis was used to analyze the questionnaires.

**RESULTS:** There was a significant difference in average daily step counts ( $p < 0.05$ ) between baseline (7553±3365) and post-intervention (8421±4476). There was also a significant difference in weekend step counts ( $p < 0.05$ ) between baseline (5841±4201) and post-intervention (7942±4786). Results from the open-ended questionnaires revealed that: 1) participants became more aware of their PA levels through the pedometer activity, 2) wearing the pedometer motivated them to exercise more, 3) they set goals to increase their PA levels, and 4) they find that a similar pedometer activity is feasible to be implemented with their school children.

**CONCLUSIONS:** Pedometers were used as an assessment of the PCTs’ PA levels and a tool to motivate them to be active. Post-intervention step counts of PCTs increased as they became more aware of their PA levels. In designing and implementing courses to train PCTs to become future physical educators, it is important to help them become aware of their personal PA behaviors, identify benefits of an active lifestyle and encourage them to pursue activities that they enjoy. Consequently, this will strengthen their beliefs in their positions as PA role models. Future research should address barriers and facilitators among PCTs to meet the recommended 10,000 steps per day.

**Cost-effectiveness Of A Pedometer-based Versus Time-based Physical Activity Prescription Program: The Healthy Steps Study**  
Gregory S. Kolt<sup>1</sup>, William Leung<sup>2</sup>, Toni Ashton<sup>2</sup>, Grant M. Schofield, III<sup>3</sup>, Nicholas Garrett<sup>3</sup>, Ngaire Kerse<sup>2</sup>, Asmita Patel<sup>3</sup>. <sup>1</sup>*University of Western Sydney, Sydney, Australia.* <sup>2</sup>*University of Auckland, Auckland, New Zealand.* <sup>3</sup>*Auckland University of Technology, Auckland, New Zealand.* (Sponsor: Karen Croteau, FACSM)  
(No relationships reported)

Physical activity (PA) promotion interventions based in primary care settings have demonstrated effectiveness. As older adults are at particular risk of several non-communicable diseases, and particularly those related to physical inactivity, examining methods of engaging them in cost-effective programs is important.

**PURPOSE:** To investigate the cost-effectiveness of a pedometer-based versus time-based PA prescription program (the New Zealand Green Prescription) in improving PA and health-related quality of life in low-active older adults.

**METHODS:** Participants in the Healthy Steps study were 330 low-active adults aged 65 years and older (mean age 74.1± 6.1 years) recruited through primary care physicians. Participants were randomized into either a pedometer-based or a standard time-based Green Prescription where they received 3 telephone counselling sessions over 12 weeks based on increasing PA. Outcomes were measured at baseline, 3 months (end of intervention) and at 12 months (follow-up). PA was assessed with the Auckland Heart Study Physical Activity Questionnaire, health-related quality of life was measured with the EQ-5D, with utility scores based on the New Zealand tariff 2 for cost-effectiveness analysis. Quality-adjusted life years (QALY) were calculated using these utility scores. Costs included public and private healthcare costs and exercise/PA-related personal expenditure. The 259 participants who completed the 12-month follow-up and who submitted full cost and healthcare utilization data were included in the analysis.

**RESULTS:** There were no significant between-group differences in costs. Cost-effectiveness acceptability curves showed that, compared to the standard time-based Green Prescription, the pedometer-based Green Prescription was statistically cost-effective for the 3 cost categories (community care costs, exercise and community care costs, and all costs), as well as for all QALY thresholds. At a New Zealand cited threshold of \$20,000 per QALY the pedometer Green Prescription had a probability of being between 93% and 96% cost-effective for the 3 cost categories.

**CONCLUSIONS:** Outcomes indicate that pedometer-based Green Prescriptions may be cost-effective in increasing PA and health-related quality of life over 12 months in previously low-active older adults.

**Use and Tailoring of an Evidence-Based Physical Activity Behavior Change Program in a Worksite Population**  
Bhibha M. Das<sup>1</sup>, Steven J. Petruzzello, FACSM<sup>2</sup>. <sup>1</sup>*University of Georgia, Athens, GA.* <sup>2</sup>*University of Illinois at Urbana-Champaign, Urbana, IL.*  
(No relationships reported)

As the overweight and obesity rates rise, so do health care costs in the US. Employers often bear the brunt of these rising costs along with the side effects of overweight and obesity, such as increased presenteeism and absenteeism. An excellent intervention for the growing overweight and obesity epidemic is worksite wellness programs, a recent trend in the field of health education.

**PURPOSE:** To assess the effects of an evidence-based physical activity (PA) behavior change program on mass transit employees.

**METHODS:** Active Living Every Day (ALED), originally designed as a 20-wk program, was condensed into a 6-wk format for this study and delivered in 2 phases. Phase 1 (P1) presented the 6-wk version in its original format, without any tailoring. Phase 2 (P2) received a 6-wk version, tailored for the mass transit population. Tailoring was done with focus groups at the end of P1, using the Nominal Group Technique.

**RESULTS:** In P1 (age = 47.6 ± 9 yrs, BMI = 32.5 ± 8.9 kg/m<sup>2</sup>), significant changes were seen in “caring about consequences to others” (P = 0.05), “increasing healthy opportunities” (P = 0.007), “committing oneself” (P = 0.005), and “reminding oneself” (P = 0.04). These factors were all part of the processes of change. For P2 (age = 46.6 ± 11.7 yrs, BMI = 32.1±1.9 kg/m<sup>2</sup>), significant changes were seen in decisional balance (P = 0.029), “increasing healthy opportunities” (P = 0.006), “substituting alternatives” (P = 0.017), “rewarding oneself” (P = 0.041), “reminding oneself” (P = 0.034), sleep quality (P = 0.004), PA affect (P = 0.001), PA enjoyment (P = 0.001), perceived stress (P = 0.004), reduced motivation (P = 0.024), and overall physical and mental health (P = 0.02). Comparing the non-tailored to the tailored version of ALED, statistically significant changes were exhibited in two measures: “increasing healthy opportunities” (P = 0.013) and physical fatigue (P = 0.002).

**CONCLUSIONS:** It is inconclusive to determine whether tailoring the ALED intervention had any significant impacts on the outcome measures. The ALED intervention is a relatively inexpensive and easy to implement worksite wellness program and did demonstrate significant changes in participants’ processes of change, sleep quality, perceived stress, fatigue, physical activity enjoyment, and overall physical and mental health status.

**3210**    *Board #175*    **June 1**    **2:00 PM - 3:30 PM**  
**Effectiveness of an Exercise Program in Improving Balance in Adults Diagnosed With HIV**  
Francheska Mojica<sup>1</sup>, Glorimar Garcia<sup>2</sup>, Martin Rosario<sup>1</sup>, Alexis Ortiz<sup>1</sup>. <sup>1</sup>*University of Puerto Rico-Medical Sciences Campus, San Juan, Puerto Rico.* <sup>2</sup>*La Perla de Gran Precio, San Juan, Puerto Rico.*  
(No relationships reported)

Balance impairments are common in adults diagnosed with HIV as a consequence of infection and from secondary effects of medications. Such impairments could predispose this population to falls and decreased mobility.

**PURPOSE:** To assess balance with eyes open and eyes closed after a three-month physical fitness exercise program.

**METHODS:** Participants (n = 23) were assessed previous to participating in a community-based physical fitness exercise program and three months after program initiation. Balance was measured with a MatScan™ (Tekscan, Boston, MA) as the displacement of the center of pressure in cube centimeters in two conditions; eyes open and eyes closed. Eyes open represented visual, vestibular, and proprioceptive systems integration whilst eyes closed represented only vestibular and proprioceptive systems. Paired t-tests were used to compare pre and post balance values for both conditions.

**RESULTS:** Balance values with the eyes open improved significantly (p = 0.04) from baseline (3.78 ± 1.4 cm2) to three months (0.84 ± 0.14 cm2) post exercise participation. Although, balance with eyes closed improved over time (2.26 ± 0.56 cm2 - 1.42 ± 0.37 cm2), such improvement was not statistically significant (p = 0.15).

**CONCLUSIONS:** Participation in a fitness program appears to improve balance with opened eyes suggesting improvement throughout the visual, vestibular, and proprioceptive systems. Balance with closed eyes appears to improve with a smaller magnitude suggesting most improvements occur first through the visual system. **ACKNOWLEDGEMENTS:** Thanks to the support of La Perla de Gran Precio.

**3211** Board #176 June 1 2:00 PM - 3:30 PM

### Effect Of A 45-minute Exercise Session On Total Activity In Normal-weight And Obese Women

Tyler Clark, Bliss Hanlon, Bruce W. Bailey, Michael Larson, James D. LeCheminant, FACSM. Brigham Young University, Provo, UT.

(No relationships reported)

**PURPOSE:** The purpose of this study was to compare total physical activity level in normal-weight and obese women under two separate conditions (an acute bout of exercise; non-exercise). This study used a matched subject design (except for BMI) with treatment conditions randomized and counter-balanced.

**METHODS:** Seventeen normal-weight (31.4±9.2 y, 22.8±1.3 kg/m2) and 17 obese (32.9±9.0 y, 34.0±4.9 kg/m2) women completed testing for both conditions. During the exercise condition, participants completed an early morning (8-9am) exercise session on a motor-driven treadmill at 3.8 mph and 0% grade for 45 continuous minutes. Each participant was fitted with an accelerometer immediately prior to the exercise session and wore it continuously for the following 24-hours. There were no instructions or limitations on subsequent activities. During the non-exercise session participants wore an accelerometer on the same day of the week (1 week later), for the same 24-hour period, but did not complete a supervised exercise session and received no instructions or limitations on physical activities.

**RESULTS:** For both the normal-weight and obese women, the exercise condition resulted in significantly more total physical activity (accelerometer counts), moderate-intensity activity (min), vigorous-intensity activity (min), moderate-to-vigorous intensity activity (MVPA) min, and less sedentary time (min) than the non-exercise condition (P<0.05). Physical activity counts were 73% and 57% higher during the exercise condition than the non-exercise condition for the non-obese and obese group, respectively. There was a significant group\*condition interaction for MVPA (F=4.48; P=0.043) with the obese women showing less MVPA on the exercise day (20 min less) than the normal-weight group.

**CONCLUSIONS:** A supervised and planned exercise bout dramatically increases total physical activity in normal-weight and obese women compared to a day without planned exercise. The normal-weight women spontaneously obtained more MVPA on the exercise day than the obese women.

**3212** Board #177 June 1 2:00 PM - 3:30 PM

### Are Changes In Sedentary Behavior And Steps Maintainable After A 3-month Intervention?

Amanda Libertine, Sarah Kozye-Keadle, Patty S. Freedson, FACSM. University of Massachusetts, Amherst, MA.

(No relationships reported)

Exercise training studies have been conducted to increase physical activity (PA) in overweight, sedentary individuals. More recently, sedentary time reduction (STR) interventions have targeted decreases in sedentary behavior (SB). Short-term changes in these behaviors may occur; however, follow-up evaluations are not commonly done.

**PURPOSE:** To determine if maintenance in PA and SB 3-months following a training study is better in a STR, exercise only (EX), or exercise and STR (EX-STR) group.

**METHODS:** Overweight/obese (n=47) individuals completed a 3-month training study. Participants were randomized into 1 of 3 groups: 1) STR: met weekly with a researcher who gave recommendations to reduce SB and increase PA, 2) EX: exercised 5 days/week, and 3) EX-STR: combination of EX and STR. The interventions were effective in eliciting behavioral change from baseline to 3-months. Thirty-one participants (BMI= 33.6± 4.58 kg·m<sup>-2</sup>; age= 45.2±10.19 years) agreed to the follow-up. Participants wore an activPAL(AP) monitor at end of study (M3) and 3-months post-study (M6). The AP recorded time spent sitting/lying, standing, and stepping. Percent sedentary (%SED) was calculated as sitting time/monitor wear time. Steps/day (surrogate for PA) were also determined. Linear mixed effects models were used to test for differences in %SED and steps within and between groups.

**RESULTS:** EX and STR maintained %SED and EX-STR did not. %SED was significantly higher in EX than STR at M6. The % change from M3 to M6 in steps/day for STR, EX, and EX-STR was 22.8, 26, and 43.3%, respectively.

|    | %Sed (mean) |      |        | Steps (mean) |        |          |
|----|-------------|------|--------|--------------|--------|----------|
|    | STR         | EX   | EX-STR | STR          | EX     | EX-STR   |
| M3 | 64.2        | 67.5 | 60.9a  | 9067.9b      | 9722.5 | 12191.9b |
| M6 | 62.0c       | 68.6 | 65.7*  | 7000.2*      | 7194*  | 6917.9*  |

adifferent than EX at M3, bdifferent than EX-STR at M3, cdifferent than EX at M6, \*different from M3 to M6 (p<0.05 for all)

**CONCLUSION:** These data suggest it may be more feasible to sustain reductions in %SED following an STR than maintaining an increase in PA following exercise training.

### Community Walking Program Promotes Physical Activity in Adults and Youth for 10 years

Nobuko Hongu, Shuang Huang, Linda M. Block, Cathy L. Martinez, Barron J. Orr, Sharon Hoelscher Day, Nicholas B. Knutson, Yuta T. Torrey, Robin B. Harris. The University of Arizona, Tucson, AZ. (Sponsor: Linda Houtkooper, FACSM)

(No relationships reported)

**PURPOSE:** Cooperative Extension professionals strive to educate community members about healthy lifestyles, including physical activity and nutrition. The University of Arizona Cooperative Extension developed the Walk Across Arizona (WAAZ), state-wide, community team-based walking promotion program and has implemented it for 10 years (2001-2011). The program goals are to encourage individuals and families to increase their physical activity by joining a walking team and to increase satisfaction with being in a community and to decrease social isolation of people within communities.

**METHODS:** WAAZ participants were recruited by word of mouth, program fliers, and community newspapers. Participants enrolled in the program by completing an on-line registration form and brief survey including demographic characteristics of the participants, their usual physical activity behaviors, fruits and vegetable intakes, and community involvement. During the program the participants reported the steps or miles they walked weekly. The total miles walked by the teams were posted on the WAAZ Web site (<http://cals.arizona.edu/walkacrossaz/>). Following completion of each 8-week program, participants were provided incentives and asked to complete program assessments.

**RESULTS:** The WAAZ program started with 329 participants (34 teams). Over the past 10 years 1,328 teams with 11,589 participants walked over 2.4 million miles during the program. The community planning Task Force and collaborations with community organization partners helped extend outreach of WAAZ statewide with inclusion of youth and people with limited resources.

The changes in fruits and vegetable intakes during the program were associated with reported average walking miles per week. The program also promoted a sense of belonging among participants in a community. In 2011, 791 participants, 6 to 99 years old recorded walking an average of 21 miles per week, and 170 miles per person during 8-week program. Currently, 2 schools (n=58) are participating in the WAAZ program as a part of their PE classes.

**CONCLUSION:** A community team-based walking program effectively promotes physical activity. The WAAZ program is a model that can provide research based physical activity, and nutrition education resources to promote healthy lifestyles within a community.

**Effect Of Physical Activity On Primary Care Total Number Of Visits In Inactive Patients**

Carne Martin-Borràs<sup>1</sup>, Maria Giné-Garriga<sup>1</sup>, Anna Puig-Ribera<sup>2</sup>, Carlos Martin-Cantera<sup>3</sup>, Antonio Cuesta<sup>4</sup>, Mercè Solà<sup>5</sup>, PPAF Group<sup>6</sup>. <sup>1</sup>FPCEE Blanquerna, Universitat Ramon Llull, Barcelona, Spain. <sup>2</sup>Universitat de Vic, Vic, Spain. <sup>3</sup>IDIAP Jordi Gol, Barcelona, Spain. <sup>4</sup>Universidad de Málaga, Málaga, Spain. <sup>5</sup>Institut Català de la Salut, Sant Joan Despí, Spain. <sup>6</sup>Institut Català de la Salut, Catalonia, Spain. (Sponsor: Viswanath Unnithan, FACSM)

(No relationships reported)

Inactive people with multiple morbidities are associated with increased health costs. Previous reviews of physical activity programs have assessed their effects on health and functional outcomes. None, to our knowledge, have examined their effects on primary care utilization in terms of number of visits.

**PURPOSE:** To assess the effectiveness of a primary care based physical activity program on altering the total number of visits to the healthcare centre among inactive population seen in primary care, over 27-month period.

**METHODS:** 362 primary healthcare patients (283 women, 79 men) (66.52 ± 12.33 years old) not undertaking 30 minutes of moderate intensity physical activity on at least five days of the week were randomly allocated into two groups (Control Group, CG=172; Intervention Group, IG=190). IG went through a 3-month standardized physical activity program linked to community resources. CG met once a month for educational and social meetings. Total numbers of consultations to the healthcare centre, registering the total number of visits during the twelve months prior and after the program, were assessed. Consultations included face-to-face and home visits by GPs or nurses, and also out-of-hours visits to the healthcare centre. Secondary outcomes for IG and CG were self-reported health status documented via the SF-12 survey, and assessed at baseline (month 12), at the end of the intervention (month 15), and at 6 and 12 months follow-up after the end of the intervention (month 21 and 27, respectively). An analysis of covariance (ANCOVA) was performed for all outcome measures.

**RESULTS:** Consultations of the IG participants showed a significant decline relative to those in the CG (p < 0.05) (mean score ± SD in number of visits of participants in the IG and CG groups were 9.32 (3.25) and 15.79 (4.82), respectively in month 27).

**CONCLUSIONS:** In summary, our findings indicate that our intervention reduces the number of consultations, which is a direct measure of health economic costs.

**Intensive Lifestyle Modifications Reduce Lp-PLA2 Mass In Patients With HIV Lipodystrophy**

Kevin S. Chapman<sup>1</sup>, Joshua S. Wooten<sup>1</sup>, Preethi Nambi<sup>2</sup>, Baiba K. Gillard<sup>2</sup>, Vijay Nambi<sup>2</sup>, Henry J. Pownall<sup>2</sup>, Lynne W. Scott<sup>2</sup>, Christie M. Ballantyne<sup>2</sup>, Ivonne Coraza<sup>2</sup>, Ashok Balasubramanyam<sup>2</sup>. <sup>1</sup>Southern Illinois University Edwardsville, Edwardsville, IL. <sup>2</sup>Baylor College of Medicine, Houston, TX.

(No relationships reported)

Patients with HIV-associated dyslipidemia have exhibited Lp-PLA<sub>2</sub> levels above what is observed in patients with coronary heart disease (CHD), which may indicate accelerated development of CHD.

**PURPOSE:** To assess if an intensive diet and exercise (D/E) program independently and combined with fenofibrate and niacin provided added benefits to usual medical care at reducing circulating Lp-PLA<sub>2</sub> mass and CCL5/RANTES in patients with HIV dyslipidemia.

**METHODS:** Participants (n=107) were randomized to five study groups: 1) Usual care; 2) D/E; 3) D/E with fenofibrate (160 mg/d); 4) D/E with niacin (2 g/d); and 5) D/E with fenofibrate and niacin for 24 weeks. General linear models (SPSS 18.0) was used to compare the five randomized groups with respect to Lp-PLA<sub>2</sub> mass and CCL5/RANTES while controlling for age, baseline BMI, baseline CD4<sup>+</sup> T-cell count, baseline viral load, duration of HIV, and duration of antiretroviral drug therapy, as well as the baseline outcome value. Statistical significance was set at P<0.05.

**RESULTS:** Following the 24-week intervention, Lp-PLA<sub>2</sub> concentration (Table 1) was significantly lower in patients who participated in D/E only, D/E plus fenofibrate, and D/E plus niacin than patients receiving usual medical care. Interestingly, there was no significant difference in Lp-PLA<sub>2</sub> mass between patients who received D/E only, D/E plus fenofibrate and D/E plus niacin. No significant differences were observed between groups for CCL5/RANTES concentrations following the 24-week intervention.

**CONCLUSIONS:** This study is first to demonstrate that when compared to standard medical care, plasma Lp-PLA<sub>2</sub> mass can be reduced by an intensive D/E program in patients with HIV dyslipidemia.

Supported by NIH Grant R01 HL73696 (A.B.).

Table 1. Lp-PLA<sub>2</sub> and RANTES levels following the 24-week intervention.

| Group | Lp-PLA <sub>2</sub><br>(ng/mL)<br>Baseline | Lp-PLA <sub>2</sub><br>(ng/mL)<br>Post-treatment | RANTES<br>(pg/mL)<br>Baseline | RANTES<br>(pg/mL)<br>Post-treatment |
|-------|--|--|-------------------------------|-------------------------------------|
| 1     | 415.1 ± 138.2                              | 436.0 ± 88.8                                     | 42.4 ± 25.8                   | 47.4 ± 30.5                         |

3216 Board #181 June 1 3:30 PM - 5:00 PM

**Intense Training Improves Prognosis On An Ex-elite Athlete With Smoldering Multiple Myeloma**

Daniel A. Boulosa<sup>1</sup>, Laurinda Abreu<sup>2</sup>, Anthony S. Leicht<sup>3</sup>. <sup>1</sup>Universidade Católica de Brasília, Brasília, Brazil. <sup>2</sup>Lavadores, Vigo, Spain. <sup>3</sup>James Cook University, Townsville, Australia.

(No relationships reported)

**PURPOSE:** To evaluate the influence of a supervised training program on: changes in serum monoclonal protein level (i.e. IgG), percentage of bone marrow plasma cells (BMPCs), performance, and cardiac autonomic control (i.e. heart rate [HR] variability [HRV]) on a female diagnosed with smoldering multiple myeloma.

**METHODS:** A 38-year-old female patient with smoldering multiple myeloma and former elite youth athlete, was followed for four years while participating in a high intensity training regime designed for the development of various physical capacities. HRV was evaluated via time (root mean square of successive differences [RMSSD]) and frequency (low [LF] and high [HF]) domain parameters with analysis of two 24 hrs R-R recordings per week during a six week period at the middle and the end of the follow-up. Changes in muscular strength, muscular endurance, and aerobic capacity; IgG levels, and BMPCs were evaluated throughout the entire follow-up.

**RESULTS:** HRV parameters exhibited significant ( $p < 0.01$ ) increments (18-29%) in RMSSD, LF, HF with the LF/HF ratio being ( $2.28 \pm 0.41$  vs.  $2.22 \pm 0.43$ ,  $p = 0.595$ ) unchanged. Exercise performance was significantly improved (e.g. 233 % increase in maximum number of pull-ups, and 22% increase in 1 repetition maximum bench press). Similarly, IgG levels exhibited a significant ( $p < 0.001$ ) reduction (44%, from 3,290 mg-dL<sup>-1</sup> vs. 1,840 mg-dL<sup>-1</sup>) while BMPCs also decreased from 20% to 10%.

**CONCLUSIONS:** The current case report results indicated that an intense training program designed for the development of various physical capacities, and adapted to the patient's former elite training background, significantly improved exercise performance, cardiac autonomic control, and hematologic function that may improve long-term prognosis for smoldering multiple myeloma. Examination of similar exercise training for other cancer populations may assist in the development of treatment regimes for improved prognosis.

3217 Board #182 June 1 3:30 PM - 5:00 PM

**Three-Dimensional Global Area Tracking is a Valuable Quantitative Parameter for Left Ventricular Function in Athletes**

Victor C. Wang<sup>1</sup>, Frank Mayer<sup>1</sup>, Marc Dorenkamp<sup>2</sup>, Klaus Bonaventura<sup>3</sup>. <sup>1</sup>University Outpatient Clinic Potsdam, Potsdam, Germany. <sup>2</sup>Charité - Universitätsmedizin Berlin, Berlin, Germany. <sup>3</sup>Klinikum Ernst von Bergmann, Potsdam, Germany.

(No relationships reported)

The one- and two- dimensional echocardiography offers established methods for quantitative evaluation of left ventricle systolic function such as the measurements of the ejection fraction by Teichholz or Simpson. In recently developed three-dimensional (3D) speckle tracking, the result of area tracking is used as a new method with global strain measurement to quantify global and regional left ventricular function. Global area tracking can be calculated by the time-to-peak area tracking related to the heart cycle and may offer an alternative to current echocardiographic standards for quantitative assessment of global left ventricular function in athletes.

**PURPOSE:** The aim of this study is to determine the correlation between ejection fraction and global area tracking in cardiovascular patients and athletes.

**METHODS:** Standard 3D speckle tracking echocardiography was performed in 21 healthy athletes (age  $23 \pm 4.8$  yr, height  $186 \pm 9.4$  cm, weight  $84 \pm 10.2$  kg) and 9 cardiovascular patients. Ejection fraction and area tracking values were calculated by 3D wall motion tracking software. Echocardiography measurements of 3 consecutive beats were taken from each subject during the tests. Mean values of 3 measurements from both ejection fraction and area tracking were calculated for Spearman's rho correlation tests for nonparametric statistical comparisons.

**RESULTS:** Mean values for ejection fraction were  $55 \pm 5\%$  in athletes and  $55 \pm 8\%$  in patients. Mean values for global area tracking were  $-39 \pm 4\%$  in athletes and  $-38 \pm 6\%$  in patients. All three groups of the subjects (21 athletes, 9 patients and combined group of 30 subjects) showed significant negative correlation between ejection fraction and area tracking. Correlations were found for athletes  $\rho = -.776$ , for cardiovascular patients  $\rho = -.929$  and for combined group  $\rho = -.855$ . All correlations were significant ( $p < 0.01$ ) (2-tailed).

**CONCLUSION:** Significant negative correlations between ejection fraction and area tracking were found regardless of different physical fitness and cardiovascular conditions in athletes and cardiovascular patients.

3218 Board #183 June 1 3:30 PM - 5:00 PM

**Regular Exercise As A Protective Factor Against Obesity Risk Among Extreme Sleep Phenotypes In Athletes**

Christopher P. Herrera, Abdulaziz Farooq. ASPETAR-Qatar Orthopaedic & Sports Medicine Hospital, Doha, Qatar.

(No relationships reported)

Recent studies suggest a strong relationship between extreme sleep phenotypes (e.g. short and long sleepers) and higher obesity rates in the general population. Increased adiposity and a lack of physical activity are reported to mediate this relationship. Notably, sleep phenotype has not been explored in an athlete population but is of interest given the apparent differences in lifestyle patterns of physical activity compared to the general population which may attenuate the risk of obesity.

**PURPOSE:** To determine the influence of regular physical activity in athletes on factors underlying the relationship between sleep and obesity risk.

**METHODS:** Football players ( $n = 111$ ,  $23.6 \pm 5$  years, range 17-35) from the Qatar Stars League who were attending pre-competition screening assessments during August 2011 were queried using a standardized sleep questionnaire. The Arabic version of the Pittsburgh Sleep Quality Index (PSQI) was used to determine the quantity and quality of sleep. The reported total sleep time was used to establish sleep phenotype: short 9h. Height and weight were assessed from chart review and used to calculate body mass index (BMI, kg/m<sup>2</sup>). The percent body fat (BF) was determined by DEXA scan. All athletes underwent hematological investigations for lipid profile (cholesterol - HDL, LDL - and triglyceride). Between-group comparisons were made using ANOVA and the association between sleep quantity (TST) and BMI or BF was determined by pearson correlation.

**RESULTS:** Sleep phenotype was normally distributed: short (18%), regular (66.7%), and long (15.3%). Sleep quality was worse in short sleepers (PSQI  $7.2 \pm 2$ ) compared to regular (PSQI  $5.2 \pm 2$ ) and long (PSQI  $5.5 \pm 2$ ) sleepers ( $p < 0.05$ ). Total cholesterol, HDL, LDL and triglycerides were similar between groups ( $p$  values range 0.39-0.91). TST was poorly associated with BMI ( $r = -0.11$ ,  $p = 0.27$ ) and BF ( $r = -0.02$ ,  $p = 0.85$ ).

**CONCLUSIONS:** The relationship between sleep phenotype and higher obesity risk was not present in this group of football players. Although the mechanisms remain unclear, regular sports participation likely plays a protective role against increased obesity risk in athletes with extreme sleep phenotype.

3219 Board #184 June 1 3:30 PM - 5:00 PM

**Sleep Quality and Daytime Sleepiness in High-Performance Athletes**

Andreas Mierau, Kim Reuland, Julia Mierau, Heiko K. Strueder. German Sport University, Cologne, Germany.

(No relationships reported)

There is strong scientific evidence that metabolic, neuroendocrine, immunologic, restorative physiologic, memory and psycho-motor functions are negatively affected by sleep restriction. Elite athletes are particularly exposed to factors that may impair sleep quality such as mental and physical stress and forced shifts of the individual circadian sleep/wake phase due to training and competition schedules. The quality of sleep among elite athletes, however, is not well documented.

**PURPOSE:** To determine sleep quality, daytime sleepiness and chronotype distribution in Luxembourgian elite athletes as well as to analyze the role of gender and time of season in this context.

**METHODS:** 23 (11 females: 21.4 ± 2.3 years; 171.2 ± 8.7 cm; 61.3 ± 6.1 kg and 12 males: 19.9 ± 1.9 years; 179.2 ± 8.3 cm; 72.8 ± 8.6 kg) Luxembourgian elite athletes from different sports completed three online questionnaires with regard to their sleep quality (Pittsburgh Sleep Quality Index: PSQI), the daytime sleepiness (Epworth Sleepiness Scale: ESS) and the individual chronotype (Athlete Morningness/Eveningness Scale: AMES). Respondents were also asked to specify their individual time of the season (preparation, competition, transition or rest period).

**RESULTS:** 39% of the athletes who participated in this survey were chronotyped as "normal" or "moderate morning type" and 22% as "moderate evening type" with no effect of gender. 40% of the athletes scored greater than or equal to 5 on the PSQI, indicating poor sleep quality. There was no effect of gender but a trend towards better sleep quality in the competition if compared to the transition period and in the transition if compared to the rest period. Furthermore, 17% of the athletes had ESS scores higher than 10 and 13% higher than 14 indicating abnormal and clinically relevant daytime sleepiness, respectively.

**CONCLUSION:** The current study suggests that there is a relatively high prevalence of poor sleep quality in elite athletes. Moreover, our results suggest that time of the season could be a crucial factor for sleep disturbances. In combination with our results on daytime sleepiness we conclude that individual sleep schedules including daytime naps could be helpful to improve sleep quality and to reduce daytime sleepiness in elite athletes.

**3220** Board #185 June 1 3:30 PM - 5:00 PM

**Exhaled Nitric Oxide Predicts Airway Inflammation Of The Rugby Players During Training Camp**

Tomoko Imai<sup>1</sup>, Shoji Takayanagi<sup>1</sup>, Masahiro Takemura<sup>1</sup>, Takuo Furukawa<sup>1</sup>, Kazuhiro Shimizu<sup>1</sup>, Takeo Akama<sup>2</sup>, Shunpei Miyakawa<sup>1</sup>, Koichi Watanabe<sup>1</sup>. <sup>1</sup>University of Tsukuba, Tsukuba, Japan. <sup>2</sup>Waseda University, Tokorozawa, Japan.

(No relationships reported)

A high prevalence of exercise induced respiratory symptoms, bronchial hyper responsiveness (BHR) and airway inflammation have been reported in athletes. The exhaled nitric oxide fraction (FeNO) has been proposed as a useful marker of airway inflammation. Previous studies reported changes in FeNO during and after exercise. Practice load and bout during training camp seemed to be higher than those of daily training. So airway inflammation may be higher during training camp than during daily training. However, there had been not investigated with FeNO during training camp.

**PURPOSE:** The purpose of the study is to investigate the airway inflammation of rugby players during training camp

**METHODS:** 69 rugby players participated in this study. We measured their FeNO before training camp (Pre), during middle of training camp (mid-camp) and at the end of training camp (end-camp). They were also asked about the history of respiratory symptoms. FeNO were measured by using a portable MINO (NINOX MINO).

**RESULT:** The rugby players average age, height and weight were 19.5±5.1yr, 176.4±6.2cm, 83.6±13.4kg. Twenty of 69 who reported respiratory symptoms had asthma or past history of asthma. And thirty-two of them had allergy such as allergic dermatitis, nasal inflammation, allergic rhinitis, and food allergy. FeNO of the Pre was 28.2±28.6ppb. 27 rugby players exceeded the normal limit of airway inflammation level (FeNO<25). FeNO of the mid-camp and end-camp were 25.3±15.8ppb, 25.6±16.2ppb. 15 players whose Pre NO levels were under the limit exceed airway inflammation level during camp. Players of less than FeNO<13ppb didn't exceed the FeNO≥25.

**DISCUSSION:** We found 42% of all players had airway inflammation without past history of asthma. 15 rugby players with Pre FeNO ≥13ppb exceeded normal airway inflammation level during camp. Strenuous training of camp may influence response to developing of their airway inflammation. Those whose Pre exceeded 50ppb showed the decline FeNO during the camp. It was suggested that training of the previous day might be influence on the FeNO level of next day.

**CONCLUSION:** Many rugby players who trained hard had airway inflammation. If the athletes FeNO levels are over 13 ppb before the training camp, airway condition of the athletes might change according to training load or training condition.

**Stress Habituation and Alterations in Perceived Stress Predict BMI Percentile Changes Across a School Year.**

April M. Seelbinder, Denise M. Fedra, Joan Dorn, James N. Roemmich, FACSM. University at Buffalo, Buffalo, NY.

(No relationships reported)

Adolescents experience stressful situations at a high rate during school. Indeed, school is the most common source of stress for teens. This high rate of stress may promote increases in adiposity during a developmental period important for establishing the adult physique. Adiposity gains may be the result of teens engaging in common stress coping behaviors; snacking on energy dense foods, television, and reduced physical activity; all of which may increase adiposity. Adolescents who experience repeated bouts of the same stressors during the school year and continue to react to them would be most at risk for gains in adiposity. However, teens who habituate faster, or reduce their responding to repeated presentations of the same stressor may seek out fewer obesogenic coping mechanisms, which may be protective against gains in adiposity.

**PURPOSE:** To determine the relationship between alterations in perceived stress levels and BMI percentile across a school year, and to determine whether the rate of habituation to stress is associated with alterations in BMI percentile.

**METHODS:** 41 adolescents ages 13-16 y completed the Perceived Stress Survey-14 prior to the beginning and at the end of the academic year. Adolescents' height and weight was also measured at both time points. The stress habituation protocol was completed once and consisted of 6 mental serial subtraction trials and measured the rate of reduction in perceived stress across trials. 34 of the 41 adolescents completed the habituation protocol.

**RESULTS:** When controlling for gender, race, family position on the social ladder and change in physical activity, increases in perceived stress across the school year predicted ( $\beta = 0.44$ ,  $p < 0.02$ ) increases in BMI percentile. When using the same covariates, a rapid reduction in (quicker habituation) perceived stress to repeated presentations of the same stressor was associated ( $\beta = 28.1$ ,  $p < 0.05$ ) with smaller changes in BMI percentile.

**CONCLUSIONS:** Increases in adolescents' perceived stress during a school year may promote increases in BMI percentile. A greater habituation to repeated presentations of the same stressor may be protective against increases in BMI percentile. Supported by a UB 2020 Interdisciplinary Research Development Fund.

**3222** Board #187 June 1 2:00 PM - 3:30 PM

**Body Fat Percentage Predicts HRQoL over Measures of Fitness and Activity in Postmenopausal Sedentary Women**

Elizabeth S. Edwards, Layne E. Eidemiller, Christopher J. Womack, FACSM, Judith A. Flohr. James Madison University, Harrisonburg, VA.

(No relationships reported)

**PURPOSE:** The purpose of this study was to determine the association of Health-Related Quality of Life (HRQoL) with certain anthropological measures, cardiovascular fitness, muscular strength, and physical activity (PA) in sedentary postmenopausal women.

**METHODS:** Data was collected at baseline on thirty-four postmenopausal sedentary women (age 57.9 ± 4.7 yrs.) as part of a larger pilot study. Measurements included: waist circumference (WC), body fat % via DXA (BF%), maximum relative oxygen consumption (VO2max), chest press, leg press, and physical activity via the IPAQ. Chest press and leg press 1RM were estimated from 5RM measurements, and then were converted to ratios by dividing the weight lifted by body weight. HRQoL was evaluated using the CDC 4-question Healthy Days module. Bivariate Pearson's correlations were used to identify variables that were associated with HRQoL. Stepwise regression was then used to identify variables that significantly predicted HRQoL.

**RESULTS:** The average number of healthy days in the previous month was  $23.5 \pm 8.8$ . Both BF% ( $r = -0.47, p = .006$ ) and VO<sub>2</sub>max ( $r = 0.40, p = .021$ ) were significantly associated with HRQoL, but neither measure of muscular strength nor IPAQ were significantly correlated with HRQoL. In the regression model, only BF% significantly predicted HRQoL,  $b = -0.69, t(32) = -2.97, p = .006$ . BF% explained a significant proportion of the variance in HRQoL,  $R^2 = 0.22, F(1,32) = 8.83, p = .006$ .

**CONCLUSIONS:** BF% explained a significant proportion of HRQoL, whereas measures of cardiovascular and muscular fitness, as well as physical activity, did not. This is contrary to what has been reported previously in the literature, which have consistently indicated a correlation between HRQoL and self-reported PA. However, previous studies have primarily used other forms of measuring HRQoL, such as portions of the Short Form-36, as well as various self-report methods for PA. Additionally, it should also be noted that HRQoL correlated highly with VO<sub>2</sub>max and IPAQ, which may indicate that BF% mediates the effect of cardiovascular fitness and PA on HRQoL.

---

**3223** Board #188 June 1 2:00 PM - 3:30 PM

**Assessment of VO<sub>2</sub>max and Body Composition Following a 3-Month Wellness Intervention for Severe Mental Illness**

Jeremy A. Patterson, FACSM<sup>1</sup>, Rachel M. Drake<sup>1</sup>, Alisha Shoenecker<sup>2</sup>, Judy A. Johnston<sup>3</sup>. <sup>1</sup>Wichita State University, Wichita, KS. <sup>2</sup>Breakthrough, Wichita, KS. <sup>3</sup>University of Kansas School of Medicine, Wichita, KS.

(No relationships reported)

Maximal aerobic capacity (VO<sub>2</sub>max) is a good indicator of overall health and is commonly measured in the general population, but often goes overlooked in individuals with severe and persistent mental illness (SMI).

**PURPOSE:** To assess the VO<sub>2</sub>max, weight, and BF% in individuals with SMI, before and after a wellness intervention.

**METHODS:** Weight, BF%, and VO<sub>2</sub>max were measured pre and post a 3-month wellness intervention that included exercise promotion, dietary education, and group activities. VO<sub>2</sub>max was assessed by the YMCA bike test and BF% by skinfolds. Baseline measures compared to endpoint were analyzed with all participants, separated by gender and disorder.

**RESULTS:** 49 individuals ( $43 \pm 13.20$  yrs/ $27/22$  m/f) were assessed. SMI classifications were: schizophrenia ( $n=11$ ), bipolar disorder ( $n=17$ ), schizoaffective disorder ( $n=14$ ), major depressive disorder (MDD) ( $n=7$ ). No significant difference was observed between pre / post measurements of BF% in all diagnoses except MDD. Males with MDD benefited from a wellness intervention reporting a significantly lower BF% ( $p(.036); p<0.05$ ). No significant change in VO<sub>2</sub>max was observed following the intervention ( $p(.0358); p<0.05$ ). Individuals with SMI continually rated in the very poor to poor classifications for VO<sub>2</sub>max.

**CONCLUSION:** Individuals with SMI tend to have low VO<sub>2</sub>max and high BF%. Individuals in the current study did not statistically benefit from a wellness intervention in terms of BF% and VO<sub>2</sub>max except males with MDD. Males with MDD significantly lowered their BF% following a wellness intervention. Although this study statistically found no significant increase in VO<sub>2</sub>max in this cohort following a wellness intervention, it is worth noting the variations in test results in this study. 14 of the participants showed significant improvements from pre to post ( $26.63 \pm 6.93$  to  $35.00 \pm 9.05$  ml/kg/min respectively) and 9 of the participants that started with a higher VO<sub>2</sub>max showed equally, significant decreases ( $35.56 \pm 11.62$  to  $26.20 \pm 10.16$  ml/kg/min), suggesting how complicated this type of study is with this population. Many participants will experience set backs that rapidly affect their health and others that can remain stable and adapt to a routine will benefit greatly, as was observed in our study.

Supported by RWJ Foundation Grant.

**3224** Board #189 June 1 2:00 PM - 3:30 PM

**Objectively Measured Physical Activity Characteristics and Depressive Symptoms in Older Latino Adults**

Eduardo E. Bustamante<sup>1</sup>, Alexis F. Manning<sup>2</sup>, Beth A. Staffileo<sup>2</sup>, Louis Fogg<sup>2</sup>, JoEllen Wilbur<sup>2</sup>, David X. Marquez, FACSM<sup>1</sup>. <sup>1</sup>University of Illinois at Chicago, Chicago, IL. <sup>2</sup>Rush University Medical Center, Chicago, IL.

(No relationships reported)

**PURPOSE:** Older Latinos have the highest rates of major depression among racial/ethnic groups in the US, a problem that is compounded by barriers to care, resulting in high unmet need. Latinos report the least leisure-time physical activity (LTPA) but participate in the most objectively-measured PA of any racial/ethnic group due to high levels of non-LTPA (i.e. household, occupational, and transportation PA). The influence of non-LTPA, best captured by accelerometry, on depressive symptoms in minority populations has been understudied. Thus, the purpose of this study is to examine the relationship between characteristics of objectively-measured PA (i.e., dose, intensity, and bout duration) and depressive symptoms in older Latinos.

**METHODS:** A total of 174 older Latinos ( $\geq 50$ ) completed interview style questionnaires and wore a triaxial accelerometer for 7 days. Output was used to estimate time spent in light, moderate, and vigorous intensity PA categorized by Miller (2010) cutpoints. Multiple linear regression analyses were used to predict Center for Epidemiologic Studies Depression Scale (CES-D) score. Established correlates of depression in older Latinos (i.e., age, gender, income, disability, education, acculturation, marital status, chronic disease, perceived health, and perceived hardship) were entered first. Then PA variables (i.e., minutes of total PA/day [dose], light, moderate, and vigorous PA/day [intensity], and minutes of light and moderate PA in 10-min bouts/day [bout duration]) were entered separately as additional terms to test for increments in variance explained by the model.

**RESULTS:** Most participants were female (74%), Mexican (55%), and Latino-oriented (85%). Twenty-two percent met CES-D criteria for possible depression ( $\geq 16$ ). Daily minutes of moderate PA ( $M = 30.3, SD = 28.4, \beta = -.18, \Delta R^2 = .02, p < .05$ ) and minutes of moderate PA in 10-min bouts ( $M = 12.1, SD = 17, \beta = -.22, \Delta R^2 = .04, p < .01$ ), but not daily minutes of total, light, or vigorous PA, emerged as significant independent predictors of depressive symptoms.

**CONCLUSIONS:** Results provide preliminary evidence that the relationship between depressive symptoms and PA in older Latinos is driven by moderate PA and PA in 10-min bouts, while light PA and PA in shorter bouts may have a smaller impact on depressive symptoms in this population.

---

**3225** Board #190 June 1 2:00 PM - 3:30 PM

**Association of Park Access with Usual Stress of Adolescents**

Denise Feda, April Seelbinder, Samina Raja, Li Yin, James Roemmich, FACSM. University at Buffalo, Buffalo, NY.

(No relationships reported)

Chronic usual stress is associated with obesity, weight gain, disorders of growth, development, and metabolism, and is also a risk factor for chronic diseases, such as cardiovascular disease. Previous studies have found that the presence of subjective measures of green space in adolescents' built environment may protect against daily psychological stress, but did not control for the potential stress reducing benefits of physical activity.

**PURPOSE:** To determine the association between objective measures of neighborhood park area and usual stress of adolescents, while controlling for physical activity.

**METHODS:** 32 boys and 36 girls, ages 12-15, completed one-week of accelerometer and activity recording. Adolescents completed the PSS-14 measure of perceived stress, and parents completed a demographic questionnaire. Neighborhood built environment and park access variables were calculated using a geographic information system (GIS) and ArcGIS 9 and Network Analyst software. A network 0.5 mile was used for distance calculations. Accelerometer data were screened for completeness by trained researchers and converted to METs. Multiple regression was used to test the association of park area and the interaction of park and gender with usual stress while controlling for socioeconomic status and physical activity.

**RESULTS:** Separate models of neighborhood total park area (ft<sup>2</sup>) ( $\beta = -0.000007, p \leq 0.05$ ) and percentage of park area ( $\beta = -67.53, p \leq 0.03$ ) both predicted usual stress.

**CONCLUSIONS:** Access to neighborhood parks and green space may buffer usual stress of adolescents, even when controlling for socioeconomic status and the protective effects of exercise on stress. Supported by NIH Grant HD055270.

### The Relationship of Socio-Demographic Characteristics and Nutrition Knowledge in Triathletes

Daniel Christopher Washmuth, Celines Martinez, Valerie George. *Florida International University, Miami, FL.*  
(No relationships reported)

Previous studies have shown that as a person's nutrition knowledge increases, nutritional content of consumed food improves. A number of socio-demographic factors can influence nutrition knowledge. The relationship of socio-demographic characteristics and nutrition knowledge in Triathlete is unknown even though nutrition plays a key role in performance and in overall health.

**PURPOSE:** To determine the relationship of socio-demographic characteristics (i.e., gender, age, education, income, and marital status) on the nutrition knowledge of triathletes.

**METHODS:** An online survey was conducted in the fall of 2011. Emails were sent to potential participants through triathlon clubs and organizations in the U.S. asking them to complete the four sections of the *Nutrition Knowledge Questionnaire; Dietary Recommendations, Sources of Food/Nutrients, Choosing Everyday foods, and Diet-Disease Relationship* (Wardle and Paramater, 2001).

**RESULTS:** A total of 104 triathletes (54 female, 50 male) completed the questionnaire. The mean percent correct score was; *Dietary Recommendations* ( $68 \pm 19$ , mean  $\pm$  S.D.), *Sources of Food/Nutrients* ( $70 \pm 21$ ), *Choosing Everyday Foods* ( $60 \pm 2$ ). Marital status influenced nutrition knowledge, with triathletes who reported being married having a significantly ( $p < 0.05$ ) higher Total Nutrition Knowledge (TNK) score (69%) compared to single (50%). The majority (45%) were college graduates, 40% had post graduate degrees. Eighty eight percent reported income  $>$  \$50,000. There was a significant correlation ( $p < 0.05$ ) between TNK score and education and household income. The scores in the *Choosing Everyday Foods* were the lowest out of all the categories. The triathletes reported that they believed the recommendations for fruits and vegetables was 4 servings/day.

**CONCLUSIONS:** The high level of education and income of these Triathlete perhaps provided them with the opportunity to learn more about nutrition either through formal education or guidance of a nutritional professional. However, athletes with less education and lower income may be in need of assistance to increase nutrition knowledge. Since the score for the category, *Choosing Everyday Foods* was the lowest, Triathletes need more education to help them understand how they can apply nutrition knowledge in making healthy food choices.

---

**3227** Board #192 June 1 3:30 PM - 5:00 PM

### Education to Empower Collegiate Athletes to Fuel for Better Health and Performance

Kelly M. Ping, Nanna L. Meyer. *University of Colorado, Colorado Springs, CO.*  
(No relationships reported)

**PURPOSE:** The demands of combining academics and athletics put college athletes under pressure to succeed, and in order to be successful, athletes must have an understanding of how to effectively fuel their bodies. Research shows that athletes with a higher level of sport nutrition knowledge make better choices related to the intake of food and fluids, which positively affects performance, health, and social interactions. The purpose of this study was to enhance athletes' sport nutrition knowledge and dietary behavior through interactive educational approaches.

**METHODS:** Twenty-nine athletes were assigned to the experimental group (EXP; females=20; males=9; freshmen=10, sophomores=10, juniors=7, seniors=2) and 13 athletes to the control group (CON; females=6; males=7; freshmen=3, sophomores=6, juniors=3, seniors=1). EXP included cross-country (7), track (6), soccer (8), and softball (3) players with an average of  $19 \pm 1.2$  y, height of  $172 \pm 9.8$  cm, and weight of  $66.4 \pm 10.2$  kg. CON consisted of cross-country (9), softball (2), and volleyball (2) players, who opted out of the intervention. Each participant completed a previously validated and reliable sport nutrition knowledge questionnaire at the beginning and the end of the 6-month intervention, which was comprised of 4 interactive workshops using experiential learning (i.e. fueling for performance, grocery shopping, cooking/eating together, and body image and acceptance). It was hypothesized that EXP would have improved sport nutrition knowledge and dietary behaviors compared to CON.

**RESULTS:** Paired t-tests showed that EXP increased nutrition knowledge, while CON did not (EXP:pre SNK:  $43.7 \pm 9.1$ ; post SNK:  $50.6 \pm 4.8$  [ $p < 0.001$ ]; CON pre SNK:  $48.2 \pm 6.6$  and post SNK:  $49.0 \pm 10.1$  [ $p = 0.914$ ]). Behaviorally, EXP showed a significant increase in daily vegetable consumption (pre:  $2.0 \pm 1.6$ ; post:  $2.2 \pm 1.5$ ;  $p = 0.006$ ) and a trend in weekly food preparation (pre:  $2.1 \pm 2.2$ ; post:  $3.0 \pm 2.3$ ;  $p = 0.053$ ) with no difference in CON from pre to post.

**CONCLUSION:** This study shows that providing interactive learning opportunities to college athletes improves sport nutrition knowledge and dietary behaviors, such as eating more vegetables and preparing meals more frequently at home or in the dorms.

**3228** Board #193 June 1 3:30 PM - 5:00 PM

### Anaerobic Performance In Women Is Unaffected By An Eight-week Lacto-ovo Vegetarian Diet

Emily J. Sauer, Jessica Knurick, Gavin Moir, Shala E. Davis, FACSM. *East Stroudsburg University, East Stroudsburg, PA.*  
(No relationships reported)

Vegetarian diets are associated with health benefits such as lower incidence of diabetes, obesity, and ischemic heart disease. Despite these benefits, the consequences of a vegetarian diet on athletic performance have been questioned. Specifically, the effects of vegetarianism on anaerobic performance are largely unexplored.

**PURPOSE:** The purpose of this study was to evaluate the effects of a vegetarian diet on anaerobic performance.

**METHODS:** Twenty-two recreationally active women ( $21.7 \pm 1.6$  years) were matched and assigned to either a lacto-ovo vegetarian (LO;  $n = 11$ ) or omnivorous (OM;  $n = 11$ ) diet for 8 weeks. Subjects were tested prior to (PRE), midway (MID), and following the 8 week diet (POST). Wingate anaerobic cycle tests were performed to determine peak power (PP) and fatigue index (FI). Lean body mass (LBM) was assessed using air displacement plethysmography. Repeated measures ANOVA were used to analyze LBM, FI, and PP.

**RESULTS:** There was no difference in PP between LO (PRE:  $628.8 \pm 42.0$ W; MID:  $719.4 \pm 52.3$ W; POST:  $679.7 \pm 47.9$ W) and OM (PRE:  $645.9 \pm 67.4$ W; MID:  $663.5 \pm 58.5$ W; POST:  $640.2 \pm 53.8$ W) at any time point ( $p = 0.6$ ) or as a result of diet ( $p = 0.6$ ). There was no difference in FI between LO (PRE:  $68.7 \pm 5.1$ %; MID:  $62.3 \pm 3.5$ %; POST:  $66.5 \pm 4.7$ %) and OM (PRE:  $62.3 \pm 3.3$ %; MID:  $71.5 \pm 3.4$ %; POST:  $69.7 \pm 3.5$ %) at any time point ( $p = 0.5$ ) or as a result of diet ( $p = 0.8$ ). There were no differences in LBM in either group (LO:  $48.4 \pm 1.7$ kg (PRE);  $47.7 \pm 1.7$ kg (MID);  $43.0 \pm 4.6$ kg (POST). OM:  $44.8 \pm 3.4$ kg (PRE),  $46.6 \pm 2.3$ kg (MID),  $46.9 \pm 2.4$ kg (POST)) at any time point ( $p = 0.8$ ) or as a result of diet ( $p = 0.2$ ).

**CONCLUSION:** The present study found that anaerobic performance and lean body mass is unaffected by an 8 week lacto-ovo vegetarian diet. Future studies should evaluate the effects of a vegetarian diet on athletes to assess anaerobic athletic performance.

---

**3229** Board #194 June 1 3:30 PM - 5:00 PM

### The Effects of a Vegetarian Diet on Anaerobic Capacity and Body Composition

Jessica R. Knurick, Shala E. Davis, FACSM, Emily J. Sauer, Gavin L. Moir. *East Stroudsburg University, East Stroudsburg, PA.*  
(No relationships reported)

The adoption of a vegetarian diet is a growing trend amongst both the general and athletic populations today. However, despite the evidence of health advantages, there is considerable speculation regarding the efficacy of a vegetarian diet on anaerobic, strength-based performance.

**PURPOSE:** To evaluate the effects of an 8-week forced lacto-ovo vegetarian (LO) diet on anaerobic capacity and body composition in active females aged 19-24.

**METHODS:** In an 8-week interventional design, 22 women (21.73 ± 1.61 years) were matched and assigned to either an LO (n=11) or omnivorous (OM; n=11) group. The LO group abstained from eating meat, fish, and poultry, while maintaining activity level during the 8 weeks. Mean power, 1RM squat strength, and body fat percentage were all assessed in both groups at pre, mid, and post testing periods.

**RESULTS:** There were no significant changes in mean power output from pre to post testing within or between dietary groups (Pre-OM: 375.20 ± 83.67, Post-OM: 375.32 ± 78.94, Pre-LO: 412.76 ± 86.00, Post-LO: 403.94; p > 0.05). 1RM squat performance significantly increased in both groups at each testing session (Pre-OM: 139.44 ± 27.66, Mid-OM: 160 ± 28.5, Post-OM: 171.11 ± 20.73, Pre-LO: 172.5 ± 41.98, Mid-LO: 181 ± 42.48, Post-LO: 198 ± 35.1; p 0.05). No changes in body fat percentage were experienced from pre to post testing within or between dietary groups (Pre-OM: 26.02 ± 7.53, Post-OM: 26.75 ± 7.75, Pre-LO: 24.99 ± 4.67, Post-LO: 26.24 ± 3.24; p > 0.05).

**CONCLUSION:** Adherence to either an LO or OM diet over an eight-week period was shown to have no effects on anaerobic capacity or body composition measures.

**3230 Board #195 June 1 3:30 PM - 5:00 PM**

**Nutritional Evaluation of Physical Active Individuals Assisted in Nutrition Clinic from a Brazilian Federal University**

Aline G. Amorim, Fabiana B. Ferreira, Jessica Mm Moraes, Maria En Santos, Patricia P. Correa. *Federal University of Maranhao, Sao Luis, Brazil.*  
(No relationships reported)

**BACKGROUND:** Nutritional requirements of physically active individuals differ from sedentary individuals, and the dietitians's approach is important in this context.

**PURPOSE:** To evaluate, from a nutritional point of view, physical active subjects attending a sports nutrition clinic in a federal university from Brazil.

**METHODS:** Data regarding physical activity, anthropometry (Body Mass Index-BMI, waist circumference) and food (use of dietary supplements, food frequency according to Food Pyramid groups, 24-hour recall) were obtained from patients, assisted by a nutritionist, who practice regular physical activity (active for at least 3 months, 3 times / week). Data were analyzed using unpaired t-test between gender, where p<0,05 was considered significant.

**RESULTS:** The group consisted of 22 patients, with mean age 36.8 ± 18.6 years. From these, 14 were male (63.6%), and 8 were female (36.4%). 50% of the male individuals and 35.7% of the female preferred weightlifting, while others 35.7% of the female tended to walking. According to BMI, both male (25.0 ± 4.8 kg/m<sup>2</sup>) and female (26.8 ± 4.6 kg/m<sup>2</sup>) were overweight. However, four women (28.6%) were obese, while only one man (12.5%) exhibited such diagnosis. Only 3 patients reported the use of nutritional supplements. A higher frequency was observed for bread, grains and other starches (81.8%), sugar (77.3%), dairy products (72.7%), fats (72.7%) and fruits (68.2%) intake. The energy intake was 3126.0 ± 571.1 Kcal / d for male and 1613.0 ± 191.5 Kcal/ d for female (p <0.05). The protein intake reached 2.1 ± 1.3 and 1.1 ± 0.5 g protein/ Kg body weight for male and female (p<0.05), respectively. Carbohydrate intake did not differ between genders (5.9 ± 3.4 and 3.4 ± 2.9 g carbohydrate/ Kg body weight for men and women, respectively).

**CONCLUSION:** The subjects were mostly female and overweight, in spite of the regular exercise practice. Male subjects had twice the energy intake and protein intake relative to body weight compared to women, who still presented more obese individuals. The patient's nutritional intake should meet their nutritional requirements in order to reverse or even prevent health outcomes that are incompatible to good life style, such as adequate energy consumption, low sugar and fat intake. **ACKNOWLEDGEMENTS:** FAPEMA for financial support

**3231 Board #196 June 1 3:30 PM - 5:00 PM**

**Dietary Supplement Habits of Soldiers of 101st Airborne Division Air Assault**

Kim Crawford<sup>1</sup>, Matthew E. Darnell<sup>1</sup>, Heidi Stapel<sup>1</sup>, Mita T. Lovalekar<sup>1</sup>, John P. Abt<sup>1</sup>, Timothy C. Sell<sup>1</sup>, Larry J. McCord<sup>2</sup>, Michael D. Wirt<sup>2</sup>, Takashi Nagai<sup>1</sup>, Jennifer B. Deluzio<sup>1</sup>, Scott M. Lephart<sup>1</sup>. <sup>1</sup>University of Pittsburgh, Pittsburgh, PA. <sup>2</sup>101st Airborne Division (Air Assault), Fort Campbell, KY.  
(No relationships reported)

To achieve optimal military readiness, Soldiers are turning to dietary supplements (DS) to increase strength, endurance, alertness and overall health.

**PURPOSE:** Evaluate DS habits of 101<sup>st</sup> Airborne Division (Air Assault) Soldiers.

**METHODS:** A total of 390 Soldiers (Age 28.2 ± 6.6 years; BMI 26.5 ± 3.5 kg/m<sup>2</sup>) completed a diet history including a detailed DS questionnaire.

**RESULTS:** Sixty-one percent of Soldiers consumed at least one DS, of these 58% consume multivitamin supplements (MV), 32% whey protein, 16% energy drinks, 10% creatine and 10% nitric oxide (Table 1). Fifty-one percent consume more than one DS.

Table 1: Dietary Supplement Use, Perceived Benefits and Adverse Reactions

| Supplement   | Purpose of Use  | Usage   | Perceived Benefit   | Adverse Reaction  |
|--------------|---|---|---|---|
| MV           | Supplement diet & improve health<br>Improve performance<br>Improve joint health                                 | Military Training (MT) 52%<br>Deployed (DP) 24%<br>Both 24% | More energy/less fatigue<br>Fewer colds<br>Increase well being                    | Nausea  |
| Whey         | Increase muscle mass, strength, recovery<br>Improve performance<br>Supplement diet and improve health           | MT 53%<br>DP 25%<br>Both 16%                                | Increase muscle mass<br>Recovery<br>Weight/body fat loss                          | Decrease appetite<br>Weight gain  |
| Energy Drink | Improve physical performance<br>Improve cognitive function<br>Improve joint health                              | MT 37%<br>DP 34%<br>Both 29%                                | Feel more energized<br>Alertness<br>Stay awake                                    | Jittery feeling<br>Dehydration<br>Indigestion<br>Crashing feeling<br>Dependency |
| Creatine     | Increase muscle mass, strength, recovery.<br>Improve performance<br>Supplement diet and improve health          | MT 50%<br>DP 29%<br>Both 17%<br>N/A 4%                      | Increase work out duration/intensity<br>Increase muscle strength, size, endurance | Upset stomach<br>Dehydration  |
| Nitric Oxide | Increase muscle mass, strength, recovery.<br>Improve physical performance<br>Supplement diet and improve health | MT 53%<br>DP 18%<br>Both 18%<br>N/A 11%                     | Increase energy to workout<br>Less muscle soreness<br>Improve quality of workout  | None reported   |

**CONCLUSION:** Soldiers are using DS to correct nutrient inadequacies and improve the quality of the daily diet, to optimize adaptations from training and expedite recovery and to improve health and physical readiness. Future efforts should focus on educating Soldiers to use foods, fluids and nutrient timing as a safer and more effective alternative to DS.

3232 Board #197 June 1 3:30 PM - 5:00 PM

**Use of Dietary Supplements by Puerto Rican Athletes at the 2010 Central American-Caribbean Games**

Lucía R. Martínez<sup>1</sup>, Alexis Ortiz<sup>2</sup>, Carolyn Cardona<sup>1</sup>, Iván Cancel<sup>1</sup>, Iván Soto<sup>1</sup>, Carmen Nevárez<sup>2</sup>. <sup>1</sup>University of Puerto Rico-Río Piedras Campus, San Juan, Puerto Rico. <sup>2</sup>University of Puerto Rico-Medical Sciences Campus, San Juan, Puerto Rico. (Sponsor: Farah Ramírez-Marrero, FACSM)  
(No relationships reported)

It has been reported that athletes at different competition levels and of diverse countries look to enhance athletic performance through the use of dietary supplements (DS). However, research on the use of DS by Puerto Rican national athletes is very limited.

**PURPOSE:** To determine dietary supplementation practices of athletes representing Puerto Rico at the 2010 Central American and Caribbean Games.

**METHODS:** Three hundred and fifty athletes (194 men, 156 women) of 23 sports participated in the study. Mean age ( $\pm$  SD) was 23.8  $\pm$  7.8 years, mean competitive years was 8.9  $\pm$  5.4, and training time ranged between 11 to over 25 hours per week. Dietary supplement use was determined through a questionnaire that included: demographic profile, use of DS, reasons for use, sources of information, and places where DS are purchased. Analyses consisted of frequencies and percentages of the variables of interest.

**RESULTS:** Seventy percent (70%) of the athletes reported having used DS in the past 12 months (64.7% men, 78.4% women). Of these, sports drinks (89.3%), multivitamins (65.8%), B12 (32.9%), and protein powder (28.8%) were the DS most used. The main reasons for using DS were to enhance athletic performance (49.4%), health maintenance (47.3) and to increase energy levels (46.1%). The most frequently reported sources of information were the nutritionist/dietitians (35.8%), strength and conditioning coaches (34.6%), and physicians (32.5%). Supplements were mostly obtained in health food stores (44.9%).

**CONCLUSION:** Athletes representing Puerto Rico at the 2010 Central American and Caribbean Games demonstrated dietary supplementation practices similar to those reported by national athletes in other countries.

3233 Board #198 June 1 3:30 PM - 5:00 PM

**Dietary Supplementation of High Performance Korean and Japanese Judoists**

Jongkyu Kim<sup>1</sup>, Namju Lee<sup>1</sup>, In-ho Cho<sup>1</sup>, Misook Lee<sup>1</sup>, Junghoon Nam<sup>1</sup>, Sung-sook Jung<sup>2</sup>, Hyun-chul Cho<sup>2</sup>. <sup>1</sup>Sports Science Institute, Korea National Sport University, Seoul, Korea, Republic of. <sup>2</sup>Yong-in University, GyeonGi-Do, Korea, Republic of.  
(No relationships reported)

**PURPOSE:** This research investigated the use of dietary supplements patterns and doping awareness among high-ranked Judoists in two countries.

**METHODS:** Korean (70 males and 31 females) and Japanese (37 males and 34 females) national Judo team members divided into two groups (high and low competitive performance levels) according to their international and national rankings.

**RESULTS:** Among Koreans, 59% consumed dietary supplements, whereas 61% of the Japanese consumed dietary supplements. Among Koreans, 88% at the high and 51% at the low competitive performance level consumed dietary supplements, while 68% of high and 57% of low competitive performance level Japanese consumed dietary supplements. The most commonly consumed dietary supplements among Koreans were oriental supplements (34%), vitamins (23%), and protein powder (12%). However, vitamins (45%), protein powder (33%), and minerals (15%) were most commonly consumed among Japanese. Surprisingly, 38% Judoists of both countries had not received any proper education about anti-doping, while 44% had not received about anti-doping list knowledge. In addition, there was a significant difference in education about anti-doping ( $p < 0.001$ ) between high and low competitive performance levels of Korean Judoists. However, Korean Judoists received significantly less anti-doping education than Japanese Judoists ( $p < 0.001$ ). The associations for anti-doping education and anti-doping list knowledge with the use of dietary supplements were 3.46 (95% CI = 1.31-9.12) and 1.63 (95% CI = 0.71-3.76), respectively.

**CONCLUSIONS:** Our findings showed similar trends as previous studies. However, interestingly, we found that Judoists' use of dietary supplement was increased as they experienced anti-doping education.

3234 Board #199 June 1 3:30 PM - 5:00 PM

**Nutritional Supplement of Triathletes and Source of Supplement Information**

Celines Martinez, Daniel Washmuth, Valerie George. Florida International University, Miami, FL  
(No relationships reported)

Triathlon competitions are made up of three disciplines (swim, bike, run). They can take anywhere from a couple of hours (i.e., sprint triathlon) to over 14 hours (i.e., ironman). Such rigorous activities require adequate nutrition and perhaps in some instances supplements. Little is known about what supplements are being used by Triathlete and where these athletes get their information.

**PURPOSE:** To evaluate the use of nutritional supplements by triathletes, their source of information and purpose for using supplements.

**METHODS:** An online survey was conducted in the fall of 2011. Emails were sent to potential participants through triathlon training clubs and organizations in the U.S. The email invited triathletes to complete the *Supplement Use Survey* created by Froiland et al (2000).

**RESULTS:** One hundred and twenty six triathletes (63 male, 63 female) were surveyed, ranging in age from 18-75 years. The majority (87%) were between 25-54 years of age. Approximately, 60% of the participants reported using supplements  $\geq$  5 times/wk and 28%, 2-4 times/wk. The most frequently used supplements were multivitamins (80%), whey protein (65%), meal/calorie replacement drinks (67%), and fish oils (66%). The most common sources of information for supplements were; fellow athletes (68%), magazines (57%), books (54), and the internet (48%). Only 32% of participants reported receiving nutritional supplement information from a Sports Nutritionist/Registered Dietitian. A large portion of the participants (56%) reported that the reason they used supplements was to prevent injury and illness.

**CONCLUSIONS:** The majority of triathletes in this study reported using a wide variety of supplements but only about a third of those athletes reported seeking information from nutrition professionals before engaging in a supplement regimen. Triathletes have special nutritional needs and would benefit from working with nutrition professionals to ensure they are using the appropriate supplements to achieve optimum nutrition.

**Impact Of National Policy For The Reduction Of Obesity In School In Mexico**

Ma. Teresa Melchor Moreno<sup>1</sup>, Fredy Hernan Polo<sup>2</sup>, Jose G. Montaña Corona<sup>1</sup>, Fernando Cervantes Aguayo<sup>1</sup>. <sup>1</sup>Universidad de Guanajuato, Leon, Mexico. <sup>2</sup>Universidad Nacional de Trujillo, Trujillo, Peru, Peru. (Sponsor: Universidad de Guanajuato, FACSM)  
(No relationships reported)

**PURPOSE:** Demonstrate the impact of national physical activation to reduce obesity in schoolchildren 10 to 12 years in the municipality of León, Mexico.

**METHODS:** Evaluated a total of 180 children (100 girls and 80 boys (10 - 12 years). Physical activity level (PAL) was obtained through physical activity questionnaires (PAQ) behavior in relation to physical activity was assessed following the transtheoretical model of Prochaska, environmental factors with socio-environmental survey intra-and extra-curricular.

**RESULTS:** 30 percent of the children showed risk of overweight and obesity, two thirds of these children are female, 47 percent reported adverse environment and 14 percent were found in the contemplation stage. In general, children with an attitude of action were of normal weight, with an average BMI of 20.6 &#177; 2.8, with respect to adverse environment there was no difference between children in the contemplation stage and the action stage (p &#8804 0.05)

**CONCLUSIONS:**The greatest influence on the transition from the contemplation stage to action was given by family and social environment of the school.

**Physicians' Views and Experiences of Counseling for Physical Activity: The New Zealand Green Prescription Program**

Asmita Patel<sup>1</sup>, Grant M. Schofield<sup>1</sup>, Gregory S. Kolt<sup>2</sup>, Justin W.L. Keogh<sup>3</sup>. <sup>1</sup>AUT University, Auckland, New Zealand. <sup>2</sup>University of Western Sydney, Sydney, Australia. <sup>3</sup>Bond University, Gold Coast, Australia. (Sponsor: Karen Croteau, FACSM)

(No relationships reported)

Asmita Patel, Grant M. Schofield, Gregory S. Kolt, Justin W.L. Keogh AUT University, Auckland, New Zealand, University of Western Sydney, Sydney, Australia, Bond University, Gold Coast, Australia (Sponsor: Karen Croteau, FACSM)

Regular physical activity is beneficial in both the prevention and management of chronic health conditions. A large proportion of adult New Zealanders, however, are insufficiently active. To assist in increasing population levels of physical activity (PA) in New Zealand, the Green Prescription (GRx), a primary care, PA scripting program with ongoing telephone-based support was developed.

**PURPOSE:** To identify why physicians counsel for PA and administer GRxs. A secondary aim was to examine physicians' views and experiences of GRx counseling for the management of depression.

**METHODS:** Individual face-to-face interviews were conducted with 15 primary care physicians. Interviews were audio-taped and transcribed. Data were analyzed using an inductive thematic approach.

**RESULTS:** Physicians counseled for PA and administered GRxs for both primary preventive (e.g., weight control) and secondary management (e.g., diabetes management) purposes. Physicians reported that the benefits of the GRx program centred around two main themes: (i) a non-medication approach to a healthier lifestyle and (ii) the ongoing specialized support provided by the exercise counselor through the telephone counseling. The only main theme that emerged regarding physicians perceived barriers to GRx use related to time constraints around the consultation. PA in general and PA prescribed through the GRx program were viewed by physicians as beneficial for the management of depression.

**CONCLUSION:** GRxs are being administered to individuals who can benefit from physical activity (i.e., those with pre-existing conditions and/or weight problems). GRxs may also be used to promote PA in currently healthy, but low-active and sedentary individuals. Such individuals are at risk for future health-related problems because of their inactive lifestyle. More research is required into the role that the GRx can have in helping manage depression. Supported by Health Research Council of New Zealand Grant 05/279.

**3237** Board #202 June 1 2:00 PM - 3:30 PM

**Variation Of Knowledge Of ACSM Physical Activity Recommendations With The Use Of Different Information Sources**

Luis Leite<sup>1</sup>, Paulo Gonçalves Pinheiro<sup>2</sup>, Dulce Leal Esteves<sup>3</sup>, Kelly O'Hara<sup>3</sup>, Ricardo Gouveia Rodrigues<sup>2</sup>, Rui Brás<sup>3</sup>. <sup>1</sup>Beira Interior University, Covilha, Portugal. <sup>2</sup>Beira Interior University - Research Unit in Business Sciences, Covilha, Portugal. <sup>3</sup>Beira Interior University & CIDESD, Covilha, Portugal.

(No relationships reported)

Increasing efforts to disseminate ACSM Physical Activity (PA) Recommendations have been made, and the use of both traditional forms and new technologies tools has increased. Nevertheless, little investigation focus on the effect of the use of different information sources and the extent to which knowledge has diffused through a population (knowledge retention).

**PURPOSE:** This study aims to examine whether knowledge the American College of Sports Medicine (ACSM) PA recommendations for Health Promotion varies by the use of different information sources.

**METHODS:** The study included a randomly recruited sample of 848 subjects (54.5% M; 45.5% F), 42.0±19.6 y. The awareness of ACSM PA Recommendations was assessed as indicated by Bennett et al., 2009. A survey was designed to (1) identify main information sources and (2) relate knowledge retention on adequate PA for health benefits and PA information sources.

**RESULTS:** All information sources investigated revealed low adherence. The main information sources identified were friends/family (2.90±1.175); sport professionals (2.81±1.408); Medical doctors (2.65±1.381) and school teachers (2.63±1.406). Recommendations knowledge was significantly higher (p<.05) when information source are sport professionals. Recommendation knowledge was significantly lower (p<0.05) for Internet users (information source Internet or social networks).

**CONCLUSIONS:** Despite efforts to promote PA and widespread knowledge on ACSM recommendations, few (about a quarter) Portuguese adults can accurately identify adequate PA characteristics for health improvement. Sport professionals are the information source that better widespread knowledge on ACSM PA recommendations. The use of new information technologies as PA information source seems to lead to lower level of knowledge, what could be related with quality of PA information on web.

These findings highlight the limited ability to enhance knowledge from existing PA information sources and the need for more effective strategies to widespread accurate information. **Awareness Of ACSM Physical Activity Recommendations for Health Promotion Among Portuguese Population**

Sergio Vieira<sup>1</sup>, Dulce Leal Esteves<sup>2</sup>, Paulo Gonçalves Pinheiro<sup>3</sup>, Kelly O'Hara<sup>2</sup>, Rui Brás<sup>2</sup>. <sup>1</sup>Beira Interior University, Covilha, Portugal. <sup>2</sup>Beira Interior University & CIDESD, Covilha, Portugal. <sup>3</sup>Beira Interior University - Research Unit in Business Sciences, Covilha, Portugal.

(No relationships reported)

Regular moderate physical activity (PA) has an important influence on health and well-being, but is not clear if people know the adequate PA characteristics for health improvement.

**PURPOSE:** This study aims to examine the extent to which knowledge of the ACSM PA recommendations has diffused through the Portuguese population and whether the knowledge of those recommendations varies by age, gender and education level.

**METHODS:** The study included a stratified randomly recruited sample of 848 subjects (54.5% M; 45.5% F), 42.0±19.6 y. divided in 4 age groups: young (Y): 210 subjects, 15-24 years; young adults (YA): 224, 25-39 years; adults (A) 206, 40-60 years; older (O), 208, > 60 years. The awareness of ACSM Physical Activity Recommendations for Health Promotion was assessed as indicated by Bennett et al., 2009.

**RESULTS:** Almost a quarter of respondents (26.3%) were accurately knowledgeable of the ACSM physical activity recommendations. Recommendations knowledge was slightly higher among women (27.5%) than men (25.5%) and increase with age: Y: 20.1%; YA: 23.2%; A: 27.7% and O: 29.0%. No significant differences were found on recommendations knowledge among the different educational levels investigated.

**CONCLUSIONS:** Despite efforts to promote PA and widespread knowledge on ACSM recommendations, the majority of Portuguese population (73.7%) can not accurately identify adequate PA characteristics for health improvement. These findings highlight the need for more effective campaigns to widespread ACSM recommendations for health promotion.

**Measuring Progress In The Implementation Of The U.S. National Physical Activity Plan**

Daniel B. Bornstein<sup>1</sup>, Kelly E. Evenson<sup>2</sup>, Sara B. Satinsky<sup>2</sup>, Amy A. Eyster<sup>3</sup>, Ross C. Brownson<sup>3</sup>, Russell R. Pate, FACSM<sup>1</sup>. <sup>1</sup>University of South Carolina, Columbia, SC. <sup>2</sup>University of North Carolina - Chapel Hill, Chapel Hill, NC. <sup>3</sup>Washington University - St. Louis, St. Louis, MO.  
(No relationships reported)

Evaluation of a national physical activity (PA) plan is critical to its overall success; yet, most national PA plans from around the world lack a formal evaluation process. Authors of the U.S. National Physical Activity Plan (NPAP), released in 2010, are committed to evaluation, seeking evidence of achievements and opportunities for improvement. To provide this evidence, change in population levels of PA is a logical outcome to measure; however, it likely will not be evident for years or decades and is influenced by a multitude of factors. Therefore, it is necessary to have more proximal indicators, such as implementation of the NPAP's strategies, which target policy and environmental change.

**PURPOSE:** To identify progress and barriers encountered by six, sector-specific teams leading implementation of the NPAP.

**METHODS:** Quarterly reports were developed and disseminated to six sector-specific teams (Business and Industry; Education; Health Care; Parks, Recreation, Fitness, and Sports; Public Health; Transportation, Land Use, and Community Design) that lead implementation of the NPAP, and documented the following: work being done; progress toward goals; barriers to reaching goals; products or programs developed; practice/policy changes; lessons learned; contributions from external sources; and media coverage generated.

**RESULTS:** Across sector teams, overall efforts to advance the NPAP's strategies occurred in four key areas: 1) generating federal policies, best practice guidelines, national standards, and surveys; 2) educating state-level staff on guidelines; 3) encouraging message promotion by high-level public officials; and 4) generating relevant media coverage. Within each sector team, activities specific to their prioritized strategies were documented, including: products developed; contributions received; lessons learned; and barriers encountered.

**CONCLUSION:** Teams responsible for implementing the NPAP have made demonstrable progress and have reported barriers to advancing the NPAP's sector-specific strategies at national, state, and local levels. Results of these initial efforts may inform similar future attempts to advance physical activity policy at national, state, and local levels.

3240 Board #205 June 1 2:00 PM - 3:30 PM

**Partnership for Active Community Environments: Translating Research to Action**

Barbara S. McClanahan<sup>1</sup>, Michelle B. Stockton<sup>1</sup>, Sue E. Clark<sup>1</sup>, Rick McClanahan<sup>2</sup>. <sup>1</sup>University of Memphis, Memphis, TN. <sup>2</sup>City of Bartlett, Bartlett, TN. (Sponsor: Healthier Chambliss, FACSM)  
(B.S. McClanahan: Contracted Research - Including Principle Investigator; PI on NIH grant.)

**PURPOSE:** PACE (Partnership for Active Community Environments) is an interdisciplinary collaborative working to increase understandings of supports and barriers to building active, vibrant neighborhoods. Using a community-based participatory research (CBPR) design a townhall meeting of diverse groups of built environment professionals (n=175) was held and action items were identified and prioritized. Encouraging the adoption and maintenance of healthy behaviors through support and increased use of the local 'greenline' (rails-to-trails) emerged as a priority action.

**METHODS:** Through observation and key informant interviews perceptions of safety risks were identified as a significant barrier to physical activity in a low-income, urban neighborhood of high crime and poverty. Using a CBPR design an elementary school adjacent to the high risk area was identified as a target of intervention. PACE members worked with stakeholders (principal, board chair, teachers) and community leaders (neighborhood development corporation, neighborhood association leaders) to identify strategies to address safety concerns, enhance physical activity and encourage the adoption of healthy lifestyles.

**RESULTS:** School leaders and community stakeholders prioritized clearing land adjacent the greenline to address safety concerns and suggested developing a school garden on the land providing 'garden to cafeteria' opportunities for learning and healthful eating. PACE identified and facilitated partnerships to support the initiative. Students worked with PACE staff, community leaders and volunteers to clear ground, prepare soil (spread 2000+ pounds lime), plant and harvest the wide variety of produce. Harvested foods were incorporated into school meals and students were invited to take additional produce home. Observations and key informant interviews revealed that perceptions of safety and student use of the greenline (physical activity) were enhanced.

**CONCLUSIONS:** PACE's collaborative efforts to encourage the adoption and maintenance of healthy behaviors through CBPR practices were successful and can serve as a model for other communities.

3241 Board #206 June 1 2:00 PM - 3:30 PM

**Should We Treat Workplace Inactivity like Occupational Hazards such as Chemical Exposure?**

Donald E. Watenpugh. University of North Texas Health Science Center, Fort Worth, TX. (Sponsor: Peter B. Raven, FACSM)  
(No relationships reported)

**PURPOSE:** We need to redefine how workers, employers, and policymakers address workplace inactivity. People are increasingly inactive at their jobs as technological evolution reduces physical work. This chronic inactivity reduces fitness and creates risk of myriad diseases, such as obesity, sleep apnea, cardiovascular disease, diabetes, and osteoporosis. Risks of occupational inactivity rival risks of other more obvious hazards such as chemical exposure and noise, yet workers are not currently "protected" from sedentary jobs like they are from more established hazards.

**METHODS:** Our current approach to workplace inactivity dictates that workers exercise during off-hours to remain healthy. If one applies this logic to hazards like harmful chemicals or noise, those would be acceptable as long as the exposures ceased outside the workplace. Clearly, we view inactivity differently than other hazards, yet the health risks are at least as severe. Also, more people confront occupational inactivity than hazards such as chemicals. Furthermore, the culture of most workplaces fails to acknowledge risks of chronic inactivity, nor the value of sporadic workday activity for improving alertness, cognition, and thus productivity. For example, employers often provide break time and specific areas for smoking, yet to do this for exercise may be considered distracting, counterproductive, and/or too expensive.

**RESULTS:** Sufficient data exist to designate inactivity as a serious yet preventable workplace hazard that deserves workday intervention. Data also demonstrate that physically active workers are more productive, use less sick time, and experience fewer injuries, which in turn reduces medical expenses. While the ultimate responsibility to exercise remains with the individual, both employers and sedentary workers benefit if employers facilitate workday activity. Unfortunately, employers often fail to protect workers from hazards, even with clear evidence of reduced healthcare expenses and increased productivity from such protection.

**CONCLUSIONS:** Policymakers must act to require that workplaces promote and enable brief periodic workday physical activity. Designation of inactivity as a bona fide health hazard will force the issue to the level needed for meaningful action from regulators and thus workplaces.

3242 Board #207 June 1 2:00 PM - 3:30 PM

**Policy and Environmental Assessment to Improve Community Health in Physical Activity, Nutrition, and Chronic Disease**

Janet R. Wojcik<sup>1</sup>, Hope Matthews<sup>2</sup>, Thomas Bell<sup>2</sup>, Susan Collier<sup>3</sup>, Deborah Hayworth<sup>4</sup>. <sup>1</sup>Winthrop University, Rock Hill, SC. <sup>2</sup>City of Rock Hill Parks, Recreation & Tourism, Rock Hill, SC. <sup>3</sup>South Carolina Department of Health and Environmental Control, Rock Hill, SC. <sup>4</sup>United Way of York County, Rock Hill, SC. (Sponsor: Melanie Poudevigne, FACSM)  
(No relationships reported)

South Carolina is considered one of the unhealthiest states. It ranks 1<sup>st</sup> in the nation for deaths due to stroke, 5<sup>th</sup> highest for adult obesity, 6<sup>th</sup> highest for diabetes, and 7<sup>th</sup> highest in childhood obesity (CDC, 2011; SC Budget & Control Board, 2007). In York County, 29.7% of adults are obese, 8.8% have Type 2 diabetes, and 24.4% are physically inactive (CDC, 2008). Recent BMI data collected at 13 schools on 3<sup>rd</sup> and 4<sup>th</sup> grade students revealed over 40% are either overweight or obese.

**PURPOSE:** To perform community-wide assessments across different sectors to guide the development of a three-year Community Action Plan (CAP).

---

**METHODS:** The CHANGE tool (CDC, 2010) was used to rate from 1-5 the existing written policies and supportive environments for physical activity (PA), nutrition, tobacco, chronic disease management, and leadership in the Community-At-Large (CAL) (n=1), K-12 schools (n=3), worksites (n=5), community institution/organizations (n=3), and health care organizations (n=5). CHANGE data were combined with current initiatives from a community coalition and recent data on health behaviors, obesity, bikeability, and food deserts.

**RESULTS:** Scores of 0-20% are considered low, 41-60% moderate, and 81-100% high. Some of the lower scores were in PA, especially K-12 policy (36% and 40% for 2 schools) with the CAL at 55% for environment but 75% for policy. Nutrition scores, in both policy and environment, were < 40% in at least 5 sites, plus the CAL. Tobacco scores were good (10 sites >60%), mostly due to local and state smoking policies. In chronic disease management, only 1 worksite scored below 40% in both policy and environment, but overall worksites and health care agencies were higher-scoring >60%. In leadership across all sectors, environment scores (6 sectors >80%) exceed policy (6 sectors <40%), suggesting managers may be supportive of implementing new policy.

**CONCLUSION:** The initial goal for the CAP is to develop better wayfinding for bike routes and trails to increase PA. Additional goals will include increasing access to healthy food, chronic disease leadership, and tobacco-free spaces. Overall, to improve community health, there is a large need to develop sustainable written policies across all sectors.

Supported by ACHIEVE from CDC Healthy Communities and National Recreation and Park Association

**3243** Board #208 June 1 2:00 PM - 3:30 PM

**The Benefits Of Promotion Of Physical Activity For Companies**

Vincent H. Hildebrandt<sup>1</sup>, J.H. Stubbe<sup>1</sup>, J.W. Velthuisen<sup>2</sup>, W. Van Mechelen, FACSM<sup>3</sup>. <sup>1</sup>TNO, Leiden, Netherlands. <sup>2</sup>PwC, Amsterdam, Netherlands. <sup>3</sup>VU University Medical Center, Amsterdam, Amsterdam, Netherlands.

(No relationships reported)

**PURPOSE:** To assess the benefits of promotion of physical activity for companies on macro-economic level.

**METHODS:** Data of the Dutch Monitor on Physical Activity (PA) and Health during 2006-2009 were analyzed (N=5020, total for 4 years). The monitor is a representative sample of the Dutch population, interviewed by telephone (average annual response rate: 54%). Questions were asked about demographic characteristics, PA, chronic illnesses, lifestyle factors and sickness absence. A logit model was used to estimate the probability of having a disease given the PA, socio-economic variables (gender, age, education, employment) and lifestyle variables (BMI, smoking and alcohol consumption). Furthermore, it was investigated whether these differences evolved into changes in the annual number of days of absenteeism

from work. Next, the monetary value of different physical activity stimulation scenarios was quantified. One scenario used the PA public health guideline (at least 5 days per week at least 30 minutes at least moderate intensity PA), the other used the high intensity PA guideline (at least three times per week high intensity PA during at least 20 minutes). All scenarios were compared to the 'as is' situation in order to calculate the productivity benefits or losses of changes in the level of physical activity.

**RESULTS:** Promotion of PA resulted in lower costs of absenteeism from work related to sickness. If all Dutch workers would comply with the high intensity guideline who currently do not, annual savings would be maximal: \$1280 million (moderate intensity guideline: \$550 million savings). A more realistic scenario in which promotion of PA would result in an increase of the number of Dutch workers complying with the guidelines of approximately 20-25% would still give substantial savings (\$520 million for high intensity PA and \$330 million for moderate intensity PA).

**CONCLUSIONS:** Promotion of PA results in substantial savings for companies due to less absenteeism related to sickness, in particular when high intensity PA is promoted.

**Effect Of Differing Intensities Of Exercise On Affect And Enjoyment**

Steven J. Petruzzello, FACSM, Annie Nekoliczak, Megan Nickrent, Tina A. Mattila. *University of Illinois at Urbana-Champaign, Urbana, IL.*

(No relationships reported)

The benefits of exercise are well-known and well-documented, yet adherence to exercise regimens is low. There is an intuitive connection between exercise enjoyment and increasing adherence to exercise programs. Exercise intensity may influence affect and enjoyment during exercise, which may help in prescribing exercise programs and increasing adherence rates.

**PURPOSE:** To examine the intensity-affect relationship and its influence on exercise enjoyment.

**METHODS:** Participants (N=14; 7 females, 7 males; M age = 21.7 ± 2.7 yrs) exercised at two different intensities [below ventilatory threshold (bVT), above ventilatory threshold (aVT)]. Heart rate (HR; Polar monitor) was assessed throughout each condition; affect was assessed pre-, immediately post-, 10-min post-, and 20-min post-exercise; enjoyment (PACES) was assessed immediately post-exercise; and Rating of Perceived Exertion (RPE) was assessed during exercise with Feeling Scale (FS) and Felt Arousal Scale (FAS) responses assessed before, during, and after exercise.

**RESULTS:** Self-reported enjoyment was significantly different between the two conditions (P = 0.049), with greater enjoyment following the bVT condition (M=110.3 vs M=105.6). Some differences in pre- to post-exercise affect were seen, with reductions in Tiredness, and Calmness following exercise regardless of intensity condition. Energy increased following bVT and aVT; Tension increased following the aVT condition relative to the bVT condition. During exercise, aVT resulted in a greater reduction in affective valence than the bVT condition, which resulted in a steady increase in valence (P<0.001). Finally, affective valence during bVT was significantly related to enjoyment (rs= 0.35 - 0.50); there were no significant correlations between the affect measured during aVT exercise and self-reported enjoyment.

**CONCLUSIONS:** The findings are consistent with previous research and extend that research by examining the link between affect and enjoyment. Exercise at intensities above the VT results in decreasing affective valence and less enjoyment. This would presumably lead to reduced adherence, although this awaits further study.

---

**3245** Board #210 June 1 3:30 PM - 5:00 PM

**The Effects of an Acute Bout of Moderate Intensity Aerobic Exercise on Creative Potential**

Zachary Zenko<sup>1</sup>, Logan Keinholtz<sup>2</sup>, Michael Frank<sup>3</sup>, Christine Alozie<sup>2</sup>, Jennifer Hershelman<sup>2</sup>, Sharon Hamilton, PhD<sup>2</sup>. <sup>1</sup>University of Pittsburgh, Pittsburgh, PA.

<sup>2</sup>Edinboro University, Edinboro, PA. <sup>3</sup>University of South Florida, Tampa, FL.

(No relationships reported)

**PURPOSE:** The purpose of this study was to determine if an acute bout of exercise, at the minimum recommended exercise intensity and duration needed to elicit cardiovascular benefits, would induce significantly improved creative potential.

**METHODS:** 35 low-health risk university students (mean-Age: 19.92, SD ± 1.51; mean-QPA 3.3, SD ± .5) were randomly assigned to either a sedentary control group or an experimental group. The experimental group, immediately prior to measurement of creative potential, individually participated in the Standard Balke treadmill protocol to obtain 20 minutes of aerobic exercise at 60-80% heart rate reserve. All participants took the Abbreviated Torrance Test for Adults (ATTA) as a measurement of creative potential which yielded two reliable scores: Fluency and Flexibility. The ATTAs were coded and scored by two researchers who were not present during administration, and who were blind to the conditions. A t-test was used to compare the mean composite score of the two measures between groups, and analyzed for statistical significance (p < .05).

**RESULTS:** The control group's mean was 27.85 (SD ± 7.46) compared to the experimental group's mean of 31.17 (SD ± 3.74). This yielded non-statistically significant results (p = .103)

---

**CONCLUSIONS:** Previous literature suggests a significant improvement in creative potential induced by exercise. Results of this study suggest there are no statistically significant benefits to creative potential induced by an acute bout of aerobic exercise. It is possible that the exercise intensity and duration of the current study is not enough to yield benefits to creative potential. Future research may benefit from a within groups experimental design which utilizes different measures of creative potential in order to ensure a minimal learning effect.

**3246** Board #211 June 1 3:30 PM - 5:00 PM

**Relationships between Mood and Salivary Immunoglobulin A Level in Tailored Exercises**

Hisashi Mitsuishi, Takayuki Ishiwata, Haruyasu Kato, Shinntaro Endo, Kiminobu Yasumatsu, Hidetoshi Kano, Takashi Nigorikawa, Tetsuya Matsuo, Makoto Matsuyama, Kazuo Oishi. *Rikkyo University, Niiza-shi, Saitama, Japan.*

*(No relationships reported)*

**BACKGROUND:** It is well known that exercise is effective to improve mental health and immune functions. In particular, studies have shown evidences of tailored exercises (intensity, frequency, type, etc.) being beneficial for people with mood disorders who are not in the habit of exercising, such that their mood and mucosal immunity improves. However, psychological indicators of mood, i.e., questionnaires, and physiological indicators of immune function, i.e., salivary activity of immunoglobulin A (sIgA level), are typically evaluated individually. Therefore, it is not clear if there is a relationship between the mood and sIgA levels associated with tailored exercise programs for people who do not have the habit of exercising.

**PURPOSE:** We investigated the relationships between the mood and sIgA levels in response to tailored short-term less intense or moderately intense exercises.

**METHODS:** We examined the effects of acute exercise on the mood and sIgA levels in 10 healthy male university students who did not have the habit of exercising. A mood scale was used to evaluate the psychological responses (positive engagement, tranquility, negative affect). The sIgA levels were measured by ELISA. Data were collected at 3 different stages (before, during, and after the exercise) for 2 different types of exercises, i.e., tailored (strength training and walking) and un-tailored (step exercise and indoor hockey).

**RESULTS:** According to the Spearman rank-correlation test, there were significant relationships between the mood and sIgA levels during and after tailored exercises. In particular, significant positive correlations were observed between "positive engagement" and sIgA levels ( $r=0.82, p<0.05$ ) and between "tranquility" and sIgA levels ( $r=0.68, p<0.05$ ). There were significant negative correlations between "negative affect" and sIgA levels ( $r=-0.64, p<0.05$ ). However, there was no significant relationship between the mood and sIgA levels in the cases of un-tailored exercises.

**CONCLUSIONS:** These findings may help clarify the relationship between the mood and sIgA levels and show why tailored exercise is more effective than un-tailored exercise for evaluating stress in people who do not have the habit of exercising.

---

**3247** Board #212 June 1 3:30 PM - 5:00 PM

**Exercise-Induced Dehydration Has No Effect on Alcohol Pharmacokinetics but Influences Willingness to Drive**

Chris Irwin, Alison Goodwin, Michael Leveritt, Andrew K. Davey, Ben Desbrow. *Griffith University, Gold Coast, Australia.* (Sponsor: Louise Burke, FACSM)

*(No relationships reported)*

**PURPOSE:** This study investigated the influence of exercise-induced dehydration on alcohol pharmacokinetics and subjective ratings of impairment following an acute moderate dose of alcohol.

**METHODS:** Twelve male volunteers ( $22.6\pm 4.2$  yrs,  $77.22\pm 6.85$  kg body weight,  $180.5\pm 5.0$  cm; values are mean $\pm$ SD) participated in 3 experimental trials completed in a randomised cross over design and separated by at least 7 days. In one trial, participants exercised to cause dehydration of  $\sim 2.5\%$  body weight loss (DA trial). For the other trials, participants were required to be in a rested and euhydrated state (A1 and A2 trials). A set volume of alcohol was then consumed in each trial and participants were monitored over a 4 hr period. Blood (BrAC) and breath (BrAC) alcohol samples were collected throughout and analysed to calculate pharmacokinetic variables associated with the blood alcohol curve. Total urine production, estimates of BrAC, and subjective ratings of mood, intoxication and impairment were also recorded throughout each trial.

**RESULTS:** There was no difference in the pharmacokinetics of alcohol between any of the trial conditions. BrACs were higher than BACs for 2 hrs following alcohol consumption, but lower at measures taken 3 and 4 hrs post ingestion in all of the trials. Total urine production was greater in the euhydrated trials ( $1182\pm 393$  ml vs.  $300\pm 125$  ml,  $p<0.05$ ), with significantly more urine produced in the first 2 hrs after alcohol ingestion ( $1039\pm 378$  ml vs.  $190\pm 121$  ml,  $p<0.05$ ). Participants' ratings of confusion and intoxication were significantly lower in the DA trial compared to the A2 trial, and they were also more willing to drive a car a short distance under these conditions.

**CONCLUSIONS:** These findings suggest that subtle changes in total body water as a result of exercise induced sweat loss, has no impact on alcohol pharmacokinetics. However, dehydration may influence the subjective effects of alcohol and increase the likelihood of risk-taking behaviours such as drink-driving. This may have direct implications for individuals who consume alcohol following physical activity and then consider driving a motor vehicle.

---

**3248** Board #213 June 1 3:30 PM - 5:00 PM

**Optimal Categorization Of A Facial Scale For Assessing Real-time Enjoyment Of Children's Physical Activity**

Cheryl A. Howe, Danielle S. McElhiney, Brian A. Ragan. *Ohio University, ATHENS, OH.* (Sponsor: Minsoo Kang, FACSM)

*(No relationships reported)*

Enjoyment is purported to be positively correlated with physical activity participation in children. However, to truly understand the relationship between enjoyment and physical activity participation, a real-time tool to assess children's perception of enjoyment of different types of games and activities is essential. The Facial Affective Scale is thought to be a way of measuring pain and other constructs in children and has been used for measuring enjoyment.

**PURPOSE:** To optimize response categorization of the Facial Affective Scale for assessing children's real-time perception of enjoyment of various types of games and physical activities.

**METHODS:** Elementary school children ( $N = 23$ ; 8 - 12 y) volunteered to play 5 common children's games at least 4 times each during 5 - 10 sessions of an existing afterschool program. Immediately after playing each game for 9-10 min, each child independently answered questions related to the context of the game using a series of 9 facial expressions ranging from happy to sad. The Rasch Rating Scale Model was used to optimize the response categories (e.g., faces). The criteria used for optimization were: 1) the response options must be ordered; 2) each option must be most probable somewhere on the scale; and 3) each option must have outfit statistics  $< 2.0$ .

**RESULTS:** The original 9-face scale indicated poor performance. Five of the 9 faces were out of order (Thurston thresholds: 0.85, 0.18, -1.33, -0.68, 0.62, 0.06, 0.16, 0.14), only 3 faces were most probable on the scale and all had acceptable outfit statistics (MNSQ: 0.59 - 1.32). Based on these results the 9-face scale was then collapsed from 123456789 to 111112223. This collapsed scale optimized the response options with order (Thurston thresholds: -0.76, 0.76), each option was most probable somewhere on the scale, and all had acceptable outfit statistics (MNSQ: 0.84 - 1.09).

**CONCLUSIONS:** The results of the 9-face scale clearly indicated that children do not discriminate 9 different levels of enjoyment. The 3-face scale proposes a clearer measure of children's real-time perception of enjoyment of physical activity.

---

**3249** Board #214 June 1 3:30 PM - 5:00 PM

**The Effect of Moderate Intensity Aerobic Exercise On Risk Preferences**

Kaylee L. Davis, David L. Dickinson, Chelsea D. Curry, Ashley N. Lightner, Scott R. Collier, FACSM. *Appalachian State University, Boone, NC.*

*(No relationships reported)*

Many physiological and psychological changes post-exercise may alter an adult's decision-making. It has been shown that physiological changes can affect decision making, therefore exercise may play a role in modulating decisions. The purpose of this study was to profile the risky choices over monetary gains and losses made by adults following a 30-minute bout of aerobic exercise versus a no-exercise control day and a return-to-baseline day.

**METHODS:** 18 subjects (40-60 years-old) made 3 visits to the Vascular Biology and Autonomic Studies Laboratory during three weekdays. Visit 1 consisted of anthropometric measures followed by a decision task battery that included a risky choice task, which was followed by a graded exercise test (VO<sub>2</sub>peak). During visit 2 the subject exercised on a treadmill for 30 minutes at 65% of their VO<sub>2</sub>peak and then took the decision task battery. Visit 3 was comprised of the decision task battery and represented a return-to-baseline. Individual trial-level data (n=120 total risky choices per subject) was analyzed using Stata statistical software (v9). A random effects probit model was used to estimate baseline and post-exercise likelihood of making riskier choices.

**RESULTS:** On baseline and return-to-baseline days, our data show subjects are risk-averse over monetary gains but risk-seeking over monetary losses. Probit estimates show a significantly increased probability of choosing a riskier gamble on a given trial in the Gains condition (p<.05) post-exercise. We find no significant post-exercise effect on risky choice in the Loss condition (p=NSD).

**CONCLUSION:** Following exercise, individuals are less risk-averse over monetary gains and the physiological changes that occur with exercise contribute to this condition. Since success on certain economic outcomes depends on one's willingness to take monetary risk, these data suggest that regular exercisers may hold an advantage in certain decision-making contexts.

---

**3250** Board #215 June 1 3:30 PM - 5:00 PM

**Impact of Interval Duration on Affect in Healthy Young Adults**

Samuel J. Greeley<sup>1</sup>, Larry H. Collins<sup>1</sup>, Elizabeth A. Hubbard<sup>1</sup>, Jamie L. Ohara<sup>2</sup>, Marcus W. Kilpatrick<sup>1</sup>. <sup>1</sup>University of South Florida, Tampa, FL. <sup>2</sup>Villanova University, Villanova, PA. (Sponsor: John Bartholomew, FACSM)  
(No relationships reported)

Research investigating the dose-response relationship between exercise intensity and affect suggests that exercising at intensities above the ventilatory threshold elicits a decline in affect. The literature to date has focused almost exclusively on continuous exercise. No research to date has examined affective responses to interval training.

**PURPOSE:** Determine the impact of interval protocols differing in interval length on affective valence and enjoyment.

**METHODS:** Sixteen healthy participants (9 male, 7 female; mean age = 23 years) completed a maximal cycle ergometer test and two counterbalanced trials of interval cycling matched for work, intensity, duration, and work-to-recovery ratio. Each trial lasted 20 minutes inclusive of the warm-up and cool-down. The intensities for both trials alternated between 90% (work) and 10% (recovery) of peak power. The work-to-recovery ratio for each trial was 1:1, with one trial utilizing 30-sec intervals and the other 60-sec intervals. Affect was assessed before, during, and after exercise. Enjoyment was assessed post-exercise.

**RESULTS:** Data were analyzed using pairwise comparisons. Affect was similar between groups at baseline (p > 0.05) and steadily declined over time during the work portions of exercise (p < 0.05). The decline in affect during exercise was significantly greater during the 60-sec trial compared to the 30-sec trial (p < 0.05). Affect increased during recovery periods from work phases during both trials (p < 0.05). Affect increased back to baseline in both trials immediately following the cool-down (p < 0.05). Enjoyment was not different between trials (p < 0.05).

**DISCUSSION:** Findings suggest that although affect declined during both trials, it is somewhat preserved during the 30-sec trial compared to the 60-sec trial. Affect was also shown to rebound during recovery periods. Despite the greater decline in affect during the 60-sec trial, enjoyment was not different between trials. The results of this study suggest that the length of exercise intervals impacts affective response, but not enjoyment. Future studies should examine altering other variables (e.g. intensity, work-to-recovery ratio) to determine their role in influencing affect and enjoyment.

---

**3251** Board #216 June 1 3:30 PM - 5:00 PM

**Comparison Of Psychophysiological Responses Between Self-paced Walking On Treadmill And Overground In Obese Women**

Cosme F. Buzzachera<sup>1</sup>, Kleverton Krinski<sup>2</sup>, Hassan M. Elsangedy<sup>2</sup>, Maressa P. Krause<sup>3</sup>, Luis AG Freitas<sup>4</sup>, Julia Z. Durigan<sup>4</sup>, Antonio C. Dourado<sup>4</sup>, Wagner de Campos<sup>2</sup>, Fredric L. Goss, FACSM<sup>5</sup>, Sergio G. da Silva<sup>2</sup>. <sup>1</sup>University of North Paraná, Londrina, Brazil. <sup>2</sup>Federal University of Parana, Curitiba, Brazil. <sup>3</sup>Technological University of Parana, Curitiba, Brazil. <sup>4</sup>State University of Londrina, Londrina, Brazil. <sup>5</sup>University of Pittsburgh, Pittsburgh, PA. (Sponsor: Fredric L. Goss, FACSM)  
(No relationships reported)

**PURPOSE:** To determine whether environmental settings (treadmill vs overground) influence physiological, perceptual, and affective responses of obese women to exercise at a self-selected pace.

**METHODS:** Thirty females (age 44.39±9.58 yr; BMI 34.72±8.51 kg.m<sup>-2</sup>), participated in this study. During the orientation session, individuals underwent an initial screening, anthropometric measurements, and familiarization with the experimental procedures. Next, subjects were submitted to a maximal treadmill test. In the two experimental trials, participants performed 30-min bouts of treadmill and overground walking at a self-selected pace, which were completed in a counterbalanced order. At least 48h separated experimental trials. During each 30-min walking bout at a self selected pace, physiological (oxygen uptake, VO<sub>2</sub>) responses were recorded continuously. Perceptual (6-20 Borg-RPE for the overall body) and affective (Feeling Scale) responses were determined every 5-min throughout the test. A paired t-test was used to compare physiological, perceptual and affective responses between the conditions.

**RESULTS:** The overground walking speed was significantly faster than treadmill walking (1.41±0.15 m.sec<sup>-1</sup> and 1.36±0.18 m.sec<sup>-1</sup>, respectively, p<.022) during the 30-min bout of self-paced exercise. However, subjects walked in a higher %VO<sub>2</sub>max during treadmill walking (68.18±1.87%VO<sub>2</sub>max) than overground walking (66.91±2.16 %VO<sub>2</sub>max) (p<.024). Similarly, ratings of perceived exertion were higher during treadmill walking (12.50±0.72) than overground condition (11.84±0.71) (p<.032). In addition, affective response was more positive during the session of overground walking (2.01±0.62) than during treadmill (1.53±0.74) (p<.014).

**CONCLUSIONS:** These data extend previous findings by showing that environmental setting influences physiological, perceptual, and affective responses during exercise at a self-selected pace. Self-paced exercise performed overground resulted in lower perceptual and more positive affective responses. Considering that walking at self-selected pace performed overground can lead to a sensation of "feeling good," the utilization of this strategy should be recommended for using with obese women who are seeking for engaging in an exercise training.

**3252** Board #217 June 1 3:30 PM - 5:00 PM

**Concurrent Validity of an Exercise Enjoyment Scale Using Physiological and Psychological Criteria**

Amanda M. Haile<sup>1</sup>, Luke Haile<sup>2</sup>, Monica Taylor<sup>1</sup>, Alex Shafer<sup>1</sup>, Kris Wisniewski<sup>1</sup>, Deldin Anthony<sup>1</sup>, George Panzak<sup>1</sup>, Frederick L. Goss, FACSM<sup>1</sup>, Elizabeth Nagle, FACSM<sup>1</sup>, Robert J. Robertson, FACSM<sup>1</sup>. <sup>1</sup>University of Pittsburgh, Pittsburgh, PA. <sup>2</sup>Ferrum College, Ferrum, VA.  
(No relationships reported)

Exercise Enjoyment (EE) has been investigated using pre- and post- exercise measures. However, how EE changes throughout a progressively incremented exercise bout is unknown.

**PURPOSE:** To assess concurrent validity of a newly developed Exercise Enjoyment Scale using the following criterion variables; (1) oxygen consumption (VO<sub>2</sub>; l·min<sup>-1</sup>), (2) heart rate (HR; b·min<sup>-1</sup>), (3) power output (PO; W), (4) ratings of perceived exertion (RPE), and (5) affect (A).

**METHODS:** A multiple-observation, within subject, cross-sectional design was employed. Eleven males (22.9 ± 3.4 years), and ten females (22.1 ± 2.7 years) performed a load-incremented cycle ergometer test to obtain VO<sub>2</sub>peak (l·min<sup>-1</sup>). VO<sub>2</sub>, HR, PO, RPE, and A were recorded each minute. EE, A, and RPE were measured using the Exercise Enjoyment Scale, Feeling Scale, and OMNI-RPE Cycle Scale respectively. The EE scale is a bipolar metric with categories ranging from +5 (very enjoyable) to -5 (very unenjoyable). The center category is 0. Data for each subject at each test stage were entered into the correlation/regression model. Concurrent validity was established by correlating values of EE with VO<sub>2</sub>, HR, PO, RPE and A.

**RESULTS:** EE ranged from +5 to -5. As VO<sub>2</sub>, HR, PO, and RPE increased, on-stimulus exercise enjoyment rating decreased. A strong positive relation was noted between EE and A. (See Table).

**CONCLUSIONS:** In young female and male adults, findings demonstrated concurrent validity for a newly developed EE scale where both psychological and physiological criterion variables were employed during cycle ergometry. It is proposed that on-stimulus EE responses can be used in conjunction with affect responses and RPE to develop programs that promote exercise adoption and maintenance.

|                    | VO2 (l·min <sup>-1</sup> ) | HR (b·min <sup>-1</sup> ) | PO (W) | RPE    | A     |
|--------------------|----------------------------|---------------------------|--------|--------|-------|
| Exercise Enjoyment | -0.24*                     | -0.41*                    | -0.39* | -0.51* | 0.89* |

**3253 Board #218 June 1 3:30 PM - 5:00 PM**

**Salivary Cortisol Analysis On Infants In Different Environments, Land And Water Activities And At Rest.**

Marta Martins<sup>1</sup>, Ana Palmeira-de-Oliveira<sup>2</sup>, Nuno Garrido<sup>3</sup>, Tiago Barbosa<sup>4</sup>, Aldo Costa<sup>5</sup>. <sup>1</sup>ESDRM - CIDESE, Rio Maior, Portugal. <sup>2</sup>CICS-UBI Health Sciences Investigation Center, Covilhã, Portugal. <sup>3</sup>UTAD - CIDESE, Vila Real, Portugal. <sup>4</sup>IPB - CIDESE, Bragança, Portugal. <sup>5</sup>UBI - CIDESE, Covilhã, Portugal. (Sponsor: Carlo Baldari, FACSM)  
(No relationships reported)

A whole set of new motor skills significantly changes the ways in which the infants' body moves and interacts with the environment. Aquatic activity programs are related with the acquisition of positive effects on infants' motor development in. Infants' acute physiological response during activity, particularly the salivary cortisol, is a suitable parameter to be assessed. It can provide important information about hypothalamic-pituitary-adrenal (HPA) axis activity under normal conditions and in response to stress. The determination of cortisol in saliva has become popular for human research on stress reactions.

**PURPOSE** The aim of this study was to compare the cortisol level on infants in different environments: land activity, water activity and at rest.

**METHODS** 17 infants were included (22.5 ± 8.7 months) all had with background in a baby swimming program at least 6 months. Salivary cortisol levels were assessed with a Salimetrics® kit. Both land and swimming sessions were oriented by a professional instructor, according to a child centered method and children were constantly accompanied by their parents. The land skills performed were about motor coordination (gross and fine) and manipulation of didactic material. The aquatic skills performed were composed by immersions, jumps and displacements (in prone position, autonomous, vertical position, with didactic material and in back position). Cortisol samples were always taken at the same time of day for all (9 and 10 am) and at the same day of the week. A K-S one-sample test, Wilcoxon rank test and Spearman's rank correlation coefficient test were used to analyze data.

**RESULTS** The cortisol mean levels obtained were: water activity (WA)=0,117±0,64µg/dL; land activity (LA)=0,100±0,34µg/dL and at rest (R)=0,150±0,84µg/dL. No statistical differences were found between LA, WA and R cortisol values. Positive correlation was found between the LA and the R cortisol values (r=0,826; p=0,011).

**CONCLUSION** Salivary cortisol levels are similar for the three conditions above, demonstrating the absence of stress-related activity. After 6 months of aquatic experience, the stress level in the water looks identical to rest or other physical activity. We may also speculate that, in infants whose activity is new, or do the activity without parents, cortisol levels might be higher.

**3254 Board #219 June 1 3:30 PM - 5:00 PM**

**Comparison Of Affective Responses To Exercise When Intensity is Self-selected versus Imposed**

Kristen M. Lagally, FACSM<sup>1</sup>, Shannon O'Hara<sup>1</sup>, Anthony J. Amorose<sup>1</sup>, Liana Suhadolnik<sup>1</sup>, Jonathan Kurka<sup>2</sup>. <sup>1</sup>Illinois State University, Normal, IL. <sup>2</sup>Arizona State University, Phoenix, AZ  
(No relationships reported)

Allowing individuals to have autonomy over the intensity of their physical activity may lead to more positive affective responses about exercise when compared to situations where intensity is imposed.

**PURPOSE:** The purpose of this study was to compare affective responses between two exercise conditions: 1) where intensity is imposed (i.e. low autonomy) and 2) where intensity is self-selected (i.e. high autonomy).

**METHODS:** Eleven subjects (6 women, 5 men; age = 22.2±3.8 years, VO<sub>2</sub>max = 53.1±12.1 ml·kg<sup>-1</sup>·min<sup>-1</sup>) performed a maximal exercise test to allow determination of relative workloads in the subsequent experimental sessions, which involved 30 minutes of treadmill exercise. During the first experimental session, participants were asked to self-select a speed and grade that they would prefer for a workout and were permitted to adjust intensity at 5-minute intervals. For the second session, the speed and grade were imposed by the investigator, but were the same as in the self-selected session. Speed, grade and heart rate responses were hidden from participants in both sessions.

**RESULTS:** Participants self-selected intensities that ranged from 68-91% (M±SD=80.7±7.3%) of measured maximal heart rate. Manipulation checks found no significant differences in intensity (i.e. heart rate and RPE) between sessions but found that perceived autonomy was significantly higher in the self-selected session. Repeated-measures ANOVA (Session: self-selected vs. imposed X Time: pre- vs. post-exercise) indicated a significant interaction for positive affect (partial Eta squared = .31). Positive affect increased over time in both sessions, but there was a greater increase in the self-selected session (self-selected=2.15 vs. 3.12; imposed=2.06 vs. 2.70).

**CONCLUSIONS:** These results suggest that perceived autonomy is related to affective responses to exercise.

**3255 Board #220 June 1 3:30 PM - 5:00 PM**

**Tracking Cardiovascular Responses To Anticipation Of An Exercise Test In Cardiac Rehabilitation: A Preliminary Test**

Shawn N. Fraser<sup>1</sup>, Megan Lefebvre<sup>2</sup>. <sup>1</sup>Athabasca University, Athabasca, AB, Canada. <sup>2</sup>University of Alberta, Edmonton, AB, Canada.  
(No relationships reported)

Cardiovascular reactivity (CVR) refers to relatively high heart rate (HR) and blood pressure (BP) increases in the face of a mental stressor. CVR may be a concern for heart patients since it may precede ischemic events and CVR may be an indicator of relatively poor prognosis. Anticipation of an exercise tolerance test (ETT) results in rapid increases in HR and BP and has been used as a stressor in heart patient to study CVR. However, it is not clear how CVR changes associated with an ETT change after a course of cardiac rehabilitation (CR).

**PURPOSE:** To examine CVR, specifically HR and systolic (SBP) and diastolic blood pressure (DBP) responses, to anticipation of an exercise tolerance test before and after a course of CR.

**METHODS:** CVR was recorded for 76 patients at baseline and for a subsample of 23 patients who completed 6 weeks of CR. Identical procedures were used for baseline and post-CR data collection. Resting HR and BP were measured 3 times, 1 minute apart, by an automated oscillometric BP monitor after the patient had been seated quietly and alone for 5 minutes. The patient was then prepped for an ETT and met in the exercise stress testing lab by the researcher. Standing HR and BP measures were taken by the same automated BP device after 1 and 3 minutes of standing on the treadmill immediately prior to beginning exercise. The mean of the 3 seated measures was considered the resting BP and HR. Peak BP and HR standing were used to calculate the cardiovascular response to anticipation of exercise. CVR was defined as peak BP and HR minus resting BP and HR, respectively.

**RESULTS:** Anticipation of exercise resulted in significant increases (all p's < .002) in CV parameters with an average CVR at baseline for HR, SBP and DBP of 4.0 bpm, 16.6 mmHg, and 13.5 mmHg, respectively. CVR after a course of CR for HR, SBP and DBP were 4.3 bpm, 15.9 mmHg, and 9.2 mmHg (ps < .001). Differences between baseline and post-CR CVR was significant only for the change in DBP (p = .05).

**CONCLUSION:** Patients responded with a predictable increase in HR and BP in anticipation of an ETT before and after a course of CR. After CR, DBP increases in anticipation of an ETT were lower in magnitude than before CR. Future research should investigate specific components of CR that may help reduce CVR.

**3256 Board #221 June 1 3:30 PM - 5:00 PM**  
**The Effect Of A 45-minute Exercise Session On Neural Responses To Pictures Of Food In Normal-weight And Obese Women**

James D. LeCheminant, FACSM, Bliss Hanlon, Jenny Roberts, Michael Larson, Bruce W. Bailey. *Brigham Young University, Provo, UT.*  
(No relationships reported)

**PURPOSE:** This study examined the effect of acute exercise on neural responses to pictures of food in normal-weight and obese women. Strong neural responses to pictures of food may be an index of food motivation. Participants of both groups were matched (except for BMI) and conditions (exercise vs. non-exercise) were randomized and counter-balanced.

**METHODS:** Fifteen normal-weight ( $31.6 \pm 9.6$  y;  $22.6 \pm 1.3$  kg/m<sup>2</sup>) and 15 obese ( $32.5 \pm 9.5$  y;  $34.3 \pm 5.1$  kg/m<sup>2</sup>) women completed an exercise and non-exercise day, each performed on the same day of the week. During the exercise condition, each participant completed an early morning (8-9am) exercise session on a motor-driven treadmill at 3.8 mph and 0% grade for 45 continuous minutes. During the non-exercise condition, participants were tested for body composition between 8-9am. Each participant was immediately tested for food motivation subsequently for both conditions. To test for food motivation, participants were shown a continuous stream of pictures of food and flowers (control) matched for picture intensity and while neural activity was monitored, via electroencephalogram. Data were analyzed using a 2-group x 2-exercise condition x 2-picture type repeated measures analysis of covariance on event-related potential (ERP) amplitudes.

**RESULTS:** There was not a significant group\*exercise condition\*picture type interaction ( $P > 0.05$ ). However, when the normal-weight and obese women were combined, there was a significant exercise condition\*picture type interaction for late positive potential ( $F = 4.62$ ,  $P = 0.04$ ) with participants showing less neurological response to food pictures (-15%) following a 45-minute exercise bout.

**CONCLUSIONS:** The sample of women studied did not show neurological differences in response to pictures of food based upon BMI. However, exercise decreased neurological responses to food, which may indicate lower food motivation.

**3257 Board #222 June 1 3:30 PM - 5:00 PM**  
**Effect Of Capillary Blood Sampling On Psychological And Perceptual Responses During Load Incremented Cycle Ergometry**

Anthony R. Deldin, Alex B. Schafer, Wisniewski Kris, Haile Amanda, Robertson J. Robert, FACSM, Nagle F. Elizabeth, FACSM, Goss L. Fredric, FACSM.  
*University of Pittsburgh, Pittsburgh, PA.*  
(No relationships reported)

Blood sampling that occurs in medical and research settings can produce adverse psychological reactions. Whether a similar response occurs during exercise testing has not been investigated.

**PURPOSE:** The purpose of this investigation was to determine the effect of capillary blood sampling on psychological and perceptual responses at the ventilatory breakpoint (V<sub>pt</sub>).

**METHODS:** A multiple observation, within subject, cross-sectional design was employed. Eleven males (age  $21.5 \pm 3.3$  years), and ten females (age  $22.7 \pm 2.7$  years) performed two load incremented cycle ergometer tests (Trial A and Trial B) to determine VO<sub>2peak</sub> (l\*min<sup>-1</sup>). Trial A included capillary blood lactate (BLA) measurements taken during the last minute of each stage. Trial B used an identical protocol without the BLA measurements. The order of administration of Trial A and Trial B was counter-balanced. The psychological/perceptual dependent variables measured during the last 30 seconds of each stage were: 1) Affect Valence (AV); 2) Felt-Arousal (FAS); 3) Rating of Perceived Exertion for the overall body (RPE-O); 4) Exercise Enjoyment (EE); and 5) Perceived intensity level (INT). A paired samples t test was used to examine between trial differences in psychological and perceptual variables measured at the V<sub>pt</sub>.

**RESULTS:** There were no statistically significant between trial differences found for AV, FAS, RPE-O and EE measured at the V<sub>pt</sub>. The perceived INT at the V<sub>pt</sub> was significantly ( $*p < 0.05$ ) higher in Trial A than Trial B (Table 1).

**CONCLUSIONS:** The inclusion of capillary blood sampling during a load incremented cycle ergometer exercise test does not adversely affect psychological or perceptual responses to exercise.

Table 1

|         | AV          | FAS         | RPE-O       | EE          | INT*       |
|---------|-------------|-------------|-------------|-------------|------------|
| Trial A | 1.29 ± 1.87 | 3.30 ± 1.22 | 5.14 ± 1.42 | 1.14 ± 1.96 | 2.81 ± .75 |
| Trial B | 1.43 ± 1.57 | 3.25 ± 1.21 | 4.67 ± 1.53 | 1.24 ± 1.48 | 2.38 ± .74 |

**3258 Board #223 June 1 3:30 PM - 5:00 PM**  
**Response Normalized Affect, Enjoyment, And RPE At The Ventilatory Breakpoint In Recreationally Active Young Adults**

Alex Shafer, Kristofer Wisniewski, George Panzak, Erik Willis, Elizabeth Nagle, FACSM, Robert Robertson, FACSM, Fredric Goss, FACSM. *University of Pittsburgh, Pittsburgh, PA.*  
(No relationships reported)

Response normalized ratings of perceived exertion (RPE) corresponding to the ventilatory breakpoint (V<sub>pt</sub>) have been identified in children and adults using the OMNI Scale of Perceived Exertion, and can be used for exercise prescription. However, empirical support for response normalized affect and enjoyment associated with the V<sub>pt</sub> is lacking. A better understanding of affect and enjoyment of exercise may lead to more positive exercise experiences, and enhance long term exercise adherence.

**PURPOSE:** To determine the response normalized affect (A), exercise enjoyment (EE), and RPE-Overall corresponding to the V<sub>pt</sub> during cycle ergometer exercise.

**METHODS:** Ten males ( $21.7 \pm 3.4$  yrs) and ten females ( $22.7 \pm 2.6$  yrs) completed a load incremented cycle ergometer protocol to measure peak oxygen uptake (VO<sub>2peak</sub>). The V<sub>pt</sub> was determined for each subject as the %VO<sub>2peak</sub> at which Ve:VO<sub>2</sub> increased without an accompanying increase in Ve:VCO<sub>2</sub>. The exercise time associated with the V<sub>pt</sub> was then used to determine the corresponding A, EE, and RPE. A, EE, and RPE were measured each minute of exercise using the Feeling Scale, Exercise Enjoyment Scale, and OMNI RPE-Cycle Scale, respectively.

**RESULTS:** Values are means ± SD. The V<sub>pt</sub> corresponded to  $69.3 \pm 8.4$  %VO<sub>2peak</sub> and a heart rate of  $155.3 \pm 12.8$  beats·min<sup>-1</sup> for the combined sample. Ratings at the V<sub>pt</sub> were: A ( $+1.4 \pm 1.8$ ), EE ( $+1.5 \pm 1.6$ ) and RPE ( $4.8 \pm 1.1$ ) for males, and A ( $+1.4 \pm 1.8$ ), EE ( $+1.4 \pm 1.7$ ) and RPE ( $5.4 \pm 1.5$ ) for females. There was no difference ( $p > 0.05$ ) in A, EE, or RPE at V<sub>pt</sub> between males and females.

**CONCLUSION:** Response normalized OMNI RPE-V<sub>pt</sub> noted presently is consistent with previous reports involving progressively incremented cycle ergometer exercise. Exercise intensities corresponding to the V<sub>pt</sub> produce positive affect and enjoyment responses in recreationally active young adult males and females. These easily measured, non-invasive perceptual analogs of the V<sub>pt</sub> may be used to self-select exercise intensity. This may lead to improved compliance to exercise programs designed to enhance health-fitness.

**3259 Board #224 June 1 3:30 PM - 5:00 PM**  
**Impact Of Aerobic Exercise Of Varying Intensities On Craving In Cannabis-dependent Adults**

Stephen P. Bailey, FACSM, Evan Adler, Laura Hamilton. *Elon University, Elon, NC.*  
(No relationships reported)

Acute aerobic exercise has been shown to reduce craving for cigarettes in smokers; however, exercise intensity does not appear to have a unique impact on craving for cigarettes. While there is very limited evidence suggesting that regular exercise reduces cannabis craving in cannabis-dependent adults, it is unclear if acute exercise impacts cannabis craving in a manner similar to craving for cigarettes..

**PURPOSE:** The purpose of this investigation is to determine if aerobic exercise of varying intensities changes cannabis craving in cannabis-dependent adults.

**METHODS:** Ten cannabis-dependent adults (Age = 33±2 years; BMI=29.3±2.7) completed 3 randomly applied experimental trials at the same time of day. All subjects were currently enrolled in an outpatient treatment program for addiction and had been abstinent from cannabis use for at least 30 days prior to participation as determined by urinalysis. Experimental trials consisted of 30 minutes of rest, light aerobic exercise (45-50% predicted maximal heart rate), or moderate aerobic exercise (65-70% predicted maximal heart rate). Craving for cannabis, was recorded before, immediately after, 15 minutes after exercise, and 30 minute after exercise using a 20 cm visual analog scale. Subjects also completed the Marijuana Craving Questionnaire (MCQ-SF) before, immediately after, 15 minutes after, and 30 minute after exercise.

**RESULTS:** Craving for cannabis was unchanged as a result of light exercise. In comparison, craving for cannabis was reduced ( $p<0.05$ ) as a result of moderate exercise at IPE (-59.6 +7.5%), 15 minutes post exercise (-53.8+7.8%), and 30 minutes post exercise (-34.6+4.5%). Craving for cannabis actually increased during the resting condition ( $p<0.05$ ) (IPE=90.4+24.5%; 15 Post=120.6.1 +28.5%; 30 Post=160.9+58.6%). Exercise had no impact on responses to the MCQ-SF.

**CONCLUSIONS:** The results of this investigation suggest that craving for cannabis in cannabis-dependent adults is reduced by aerobic exercise at a moderate intensity and this positive effect is present for at least 30 minutes after the cessation of exercise.

#### Effects Of Drop Landing Height On Bilateral Asymmetry On Ground Reaction Forces During Depth Jumps

Nathan Tamargo, William Thomsen, George Davies, Bryan L. Riemann. *Armstrong Atlantic State University, Savannah, GA.* (Sponsor: T. Jeff Chandler, FACSM)  
(No relationships reported)

Previous research considering depth jumps at heights of .2m, .4m and .6m demonstrated greater bilateral vertical ground reaction force (vGRF) and time asymmetry at lower heights compared to higher. Because depth jumps are often conducted from heights greater than .6m, there is a need for further research.

**PURPOSE:** To determine the effect of height on vGRF differences and temporal differences between dominant and nondominant limbs during depth jumps.

**METHODS:** Twenty-nine physically-active male college-age subjects (22.7±2.6yrs, 1.78±0.07m, 80.5±14.3kg) with prior plyometric training experience performed DJ from heights of .30m, .45m, .60m, .75m, and .90m in random order. Four trials from each height were completed. Subjects dropped onto two forceplates, immediately performed a maximal jump and then landed back onto the forceplates a second time. Peak vGRF difference between the limbs for both the drop and second landing phases were determined and expressed in body weight units. Ground contact (GC) and ground off (GO) time differences (TD) between the dominant and nondominant limbs for the depth phase were also computed. Two factor (phase by height) analysis of variance (ANOVA) was conducted for peak vGRF difference, while separate one factor (height) ANOVA were conducted on GC and GO TD.

**RESULTS:** A significant phase by height interaction was revealed for peak vGRF difference ( $P<.001$ ). Post hoc comparison between phases, within each level of height, revealed drop peak vGRF to be significantly less ( $P=.001$ ) than the second landing peak vGRF at .30m, whereas the drop peak vGRF was significantly greater than the second landing peak vGRF at .75m ( $P<.001$ ) and .90m ( $P<.001$ ). Post hoc comparisons within the drop phase demonstrated peak vGRF to be significantly greater at each level of height. There were no height differences within the second landing phase. GC TD became significantly more symmetrical as drop height increased ( $P<.001$ ). There were no significant height differences for GO TD.

**CONCLUSIONS:** As DJ height increases, the peak forces became more asymmetrical between limbs (dominant>nondominant). This may have implications on training adaptations and increase risk of impact related injuries. Future research should consider changes to exercise execution and instructions given to clients.

#### A Comparative Electromyographic Analysis Of The Shoulder Muscles During Elevation In The Scapular Plane

Hayato Yamamoto<sup>1</sup>, Masanori Takemura<sup>2</sup>, Koji Kurita<sup>3</sup>, Yuji Kanoh<sup>4</sup>, Mitsuharu Kaya<sup>5</sup>, Motoaki Tsuchiya<sup>6</sup>, Junzo Tsujita<sup>2</sup>. <sup>1</sup>*Yamamoto Trainers Project, Kyoto, Japan.* <sup>2</sup>*Hyogo College of Medicine, Nishinomiya, Japan.* <sup>3</sup>*Physical Conditioning Production, Osaka, Japan.* <sup>4</sup>*Riseisha College of Medicine and Sports, Osaka, Japan.* <sup>5</sup>*Hyogo University of Health Science, Kobe, Japan.* <sup>6</sup>*MJ Consultant, Osaka, Japan.*  
(No relationships reported)

**BACKGROUND:** Although previous studies have reported EMG activities of the supraspinatus muscle (SS) during shoulder elevation in the scapular plane with humeral internal rotation (Empty can; EC) and with humeral rotation in neutral (Full can; FC), the better exercise for functional strengthening SS has not yet been clearly established. In addition, there were only few reports that prescribed to define a glenohumeral joint rotation angle.

**PURPOSE:** To clarify whether supraspinatus muscle activity was reinforced more in the EC position than FC position using EMG analysis, and to verify the effectiveness of functional exercise of SS for baseball player.

**METHODS:** Thirty-one baseball players (means (SD) age: 19.5 (0.8) yrs) participated in this study. Each subjects performed scapular plane abduction (60 degree, 5 sec isometric contraction) with two positions (EC and FC) and 7 loads (0, 0.5, 1.0, 1.5, 2.0, 2.5, 3.0 kg) at random. Surface EMG was recorded from the muscle belly of SS, infraspinatus (the upper portion; IS), middle deltoid (MD), and posterior deltoid (PD) muscles, and mean integrated EMG [iEMG; normalized as the relative exercise loads (kg)] was analyzed. Each position was determined by the lateral, medial epicondyle and head of humerus position. A 3-way repeated-measures ANOVA was used for statistical analysis. **RESULTS:** In all muscles for both position, gradual increases in iEMG were observed with load increases [ex. SS; in EC: 0.06 (0.55), 0.43 (0.30), 1.03 (0.43), 1.65 (0.48), 1.89 (0.31), 2.93 (0.84), 3.29 (0.74), and in FC: 0.81 (0.51), 1.59 (0.76), 2.53 (1.15), 3.51 (1.16), 4.23 (1.4), 5.61 (1.78), 6.90 (2.02), respectively 0, 0.5, 1.0, 1.5, 2.0, 2.5, 3.0 kg load]. At SS, MD, and PD, the interactions between position and loads were significant effects ( $F=52.83$ ,  $p<.01$ ), the EMG activity in EC were higher than in FC at all loads. Then, the ratio of increase of SS activity with increased of the loads was lower than a ratio of deltoid activity increase. The difference between positions in IS was not recognized.

**CONCLUSION:** The result of this study showed that SS activity was reinforced in EC. But this position did not selectively activate SS. However, we think that it is useful to exercise in EC as SS exercise of the baseball player because of effective use of shoulder muscles, included deltoid muscle.

### 3262 Board #227 June 1 3:30 PM - 5:00 PM

#### Impact of Load on Resistance Training Circuit Volume and Energy Expenditure

Peter M. Magyari, Caleb Williams. *University of North Florida, Jacksonville, FL.* (Sponsor: Peter Ronai, FACSM)  
(No relationships reported)

**The use of resistance training (RT) in comprehensive exercise programs designed to address weight loss has gained widespread popularity. The impact of load on circuit RT volume and energy expenditure (EE) is less broadly understood.**

**PURPOSE:** To determine the impact of load on volume and EE during circuit RT.

**METHODS:** Nineteen college aged male subjects with a minimum of two months RT experience completed 1RM testing on eight pieces of RT equipment. Subjects were subsequently randomized to perform a RT circuit at either 60 or 80% of 1 repetition maximum (1RM), returning to perform the remaining protocol after a minimum of 72 hours rest. Each exercise in the circuit was performed to maximal volitional fatigue. Rest between exercises was standardized at two minutes. Total volume was calculated by multiplying load by repetitions and EE in joules (J) was calculated by multiplying the force (newtons) by the vertical displacement of the weight stack (meters) by the number of repetitions. A t-test was utilized to determine if a difference exists between group means at 60 and 80% of 1RM. Significance was set at  $p < 0.05$ .

**RESULTS:** Both mean RT volume (12,655 kg ± 2085) and EE (68.0 kJ ± 10.8) at 60% 1RM were significantly greater than RT volume (8,741 kg ± 1675) and EE (46.8 kJ ± 8.4) at 80% 1RM.  
**CONCLUSIONS:** In this study, a 20% reduction in circuit RT load from 80 to 60% 1RM increased total RT volume and calculated EE by about 45%.

**3263** Board #228 June 1 3:30 PM - 5:00 PM

**Shoulder Muscle Activation of Novice and Experienced Weightlifters during Dumbbell Bench Press Exercises**

Adrianne L. Phillips, Joshua Luczak, George Davies, Bryan L. Riemann, *Armstrong Atlantic State University, Savannah, GA.* (Sponsor: T. Jeff Chandler, FACSM)  
(No relationships reported)

Bench press exercises are commonly used for development of chest and shoulders muscles. Altering the trunk inclination angle changes the angle of the resistive force relative to the body and therefore changes the resistive force line of action. Whether the effects occur similarly for both experienced and novice weightlifters remains unknown.

**PURPOSE:** To compare muscle activity of the anterior deltoid (AD), clavicular (CPM) and sternal (SPM) portions pectoralis major, and upper trapezius (UT) by surface electromyography (sEMG) between horizontal (HBP), incline (IBP), and military (MBP) bench press in experienced and novice women weightlifters.

**METHODS:** sEMG data were recorded at the dominate arm UT, AD, CPM and SPM for 12 experienced female weightlifters (64.33±10.08kg, 1.69±0.07m, 23.0±2.8yrs) and 12 novice (64.58±8.02kg, 1.69±0.04m, 22.6±1.7yrs) female weightlifters. Five repetitions each were performed at horizontal (0°), incline (45°), and military (85°) bench presses. Exercise order was randomized between participants. Average sEMG amplitude for each repetition phase (concentric, eccentric) was computed and averaged across the five repetitions. Separate group by exercise by phase analyses of variance were conducted.

**RESULTS:** No significant differences were found between experienced and novice weightlifters. For both UT and AD, within both phases, the MBP was significantly greater than IBP which in turn was significantly greater than the HBP. For SPM during both phases HBP and IBP were significantly greater than MBP. For CPM, during the concentric phase HBP was significantly greater than IBP which in turn was significantly greater than MBP, however, during the eccentric phase IBP was significantly greater than both the HBP and MBP.

**CONCLUSIONS:** While there were no differences related to lifting experience, as expected there were differences revealed between the three bench presses. Of the three bench presses, the MBP targeted the UT and AD during both the concentric and eccentric phases. For the pectoralis major, the HBP and IBP equally worked the sternal part during both phases, whereas the CPM was targeted during the concentric phase by the HBP and the IBP during the eccentric phase. These results provide evidence for selecting exercises in resistance and rehabilitation programs.

**3264** Board #229 June 1 3:30 PM - 5:00 PM

**Effects Of Blood Flow-restricted Low-intensity Muscle Contractions Using An Elastic Band On Muscle Activation**

Tomohiro Yasuda<sup>1</sup>, Kazuya Fukumura<sup>1</sup>, Takayuki Ohtsuka<sup>1</sup>, Taira Fukuda<sup>1</sup>, Yusuke Uchida<sup>1</sup>, Haruko Iida<sup>1</sup>, Yugo Chujo<sup>1</sup>, Yoshiaki Sato<sup>2</sup>, Tatsuya Yamasoba<sup>1</sup>, Toshiaki Nakajima<sup>1</sup>. <sup>1</sup>The University of Tokyo, Tokyo, Japan. <sup>2</sup>KAATSU International University, Rajagiriya, Sri Lanka.  
(No relationships reported)

Low-load resistance exercise with blood flow restriction (BFR), named as Kaatsu training, leads to increased muscle activation and its response is an important factor of muscle hypertrophy. Compared with machines or free weights, an elastic band is an effective tool for resistance training in older subjects or patients with a lower level of activities. However, Kaatsu exercise using an elastic band has not been explored.

**PURPOSE:** To examine the effect of BFR contractions using an elastic band on muscle activation.

**METHODS:** Nine healthy men (ages 23-41 yrs) performed elbow extension and flexion contractions (four sets respectively) by using an elastic band (Thera-Band) with BFR or CON (unrestricted blood flow). During the BFR session, subjects wore pressure cuffs on the proximal region of both arms which were inflated to 170-260 mmHg. Surface electromyography (EMG) was recorded from the triceps brachii and biceps brachii muscles, and mean integrated EMG (iEMG) was analyzed. Blood lactate concentration was obtained before and immediately after both exercises. Ratings perceived exertion (RPE) was measured immediately after the last set of each contraction.

**RESULTS:** For elbow extension contractions, iEMG increased (p<0.05) progressively during the contractions in the BFR (~46%), which was greater (p<0.05) than those in the CON at the last set. For elbow flexion contractions, there was a progressive increase (p<0.05) in iEMG during the contractions in the BFR (~69%), which was greater (p<0.05) than those in the CON from 2nd to last set. No significant changes in muscle activation were observed in the CON for elbow extension (~12%) and flexion contractions (~23%). Blood lactate concentration increased (p<0.05) in both sessions and was greater (p<0.05) than the CON with the BFR (2.1 and 3.6 mmol/L, respectively). Following the contraction bout, increased iEMG was correlated with blood lactate concentration and RPE in elbow extension (r=0.65 and 0.60, both p<0.01) and flexion contractions (r=0.52, p<0.05 and r=0.68, p<0.01).

**CONCLUSIONS:** Our results suggest that Kaatsu training using an elastic band enhances muscle activation during muscle contractions, which may be an effective method to promote muscle hypertrophy in older subjects or patients with a lower level of activities.

**3265** Board #230 June 1 3:30 PM - 5:00 PM

**The Effects Of Intensity On Blood Glucose Concentration In Lower Body Free Weight Resistance Training**

Cardyl Trionfante, Gregory R. Davis, Arnold G. Nelson, FACSM. *Louisiana State University, Baton Rouge, LA.*  
(No relationships reported)

Previous studies have found that resistance training can significantly affect blood glucose and lactate concentrations (pre/post-ex). Observations also suggest that high intensity low volume (HILV) sets with low rest time can result in lower post-ex blood lactate levels compared to low intensity high volume (LIHV) sets. It has been theorized that low volume sets increase the amount of time under tension (TUT) utilizing the immediate phosphagen (PCr) pathways while high volume sets increase the amount of TUT utilizing glycolytic pathways. If TUT is matched for both protocols, then one can theorize that increased time in glycolysis would increase blood lactate levels to the point of stimulating hepatic glucose output, resulting in increased blood glucose (BG) concentration.

**PURPOSE:** The purpose of this study is to find the effects of treatment (HILV, LIHV) on BG concentration during lower body resistance training.

**METHODS:** Ten healthy college age subjects selected for the study. A one repetition max (1RM) test determined workloads for each protocol (HILV=80%, LIHV=55%). The box squat was chosen for the exercise protocols. Subjects participated in both protocols (HILV, LIHV) with a week separating trials. In order to match TUT and total workout time (rest time + TUT), each protocol had a different rest time (HILV- 30 sec, LIHV- 180 sec) to accommodate the difference in repetitions completed per set. Immediately before and after the box squat protocols, a finger prick test was administered to measure BG (Pre, Post-ex).

**RESULTS:** An effect for time (Pre-86, Post-92) was found statistically significant (p=.006). The effects of treatment (HILV/LIHV) did not have any statistical significance (p=.52).

**CONCLUSION:** This study along with others have shown that resistance training sessions can increase BG (Pre-86, Post-92) concentration regardless of treatment (HILV, LIHV). A possible cause for increased BG is that build-up of metabolic byproducts (ex: lactate, H+ via glycolysis) can increase sympathetic nervous activity (increasing anaerobic metabolism further) which can stimulate hepatic glucose output.

**Natural Bodybuilding Contest Preparation - A Six-Month Case Study**

Lindy M. Rossow<sup>1</sup>, David H. Fukuda<sup>1</sup>, Jeremy P. Loenneke<sup>1</sup>, Christopher A. Fahs<sup>1</sup>, Kristina L. Kendall<sup>1</sup>, Abbie E. Smith<sup>2</sup>, Jeffrey R. Stout<sup>1</sup>, Michael G. Bemben, FACSM<sup>1</sup>. <sup>1</sup>University of Oklahoma, Norman, OK. <sup>2</sup>University of North Carolina Chapel Hill, Chapel Hill, NC.  
(No relationships reported)

A detailed examination of the physiological changes that accompany preparation for a drug-free, "natural," bodybuilding competition has never been performed.

**PURPOSE:** The purpose of this study was to provide a comprehensive physiological profile of a natural professional male bodybuilder as he prepared for competition.

**METHODS:** Before (baseline) and during each month of six months of contest preparation, the following measurements were performed: brachial blood pressure (bBP), pulse wave velocity (PWV), pulse wave analysis, calf and forearm blood flow, cardiac ultrasound, dual-x-ray absorptiometry (DXA), 3-site skinfolds, and Profile of Mood States (POMS). At baseline, 3-months, and 6-months into preparation, blood and resting energy expenditure (REE) were assessed. Every other month, 1-RMs and VO2max were assessed. Diet was recorded daily.

**RESULTS:** Results from the first month (March) to the last measurement date are presented in Table 1. Due to the subject's low heart rate (HR) in the later months, several cardiovascular measurements could not be obtained. If a measurement was unable to be obtained in the sixth month of contest preparation, September, the last month of measurement is stated.

**CONCLUSION:** As the bodybuilder prepared for competition, in general, he experienced desirable cardiovascular and body composition changes along with a decrease in strength and resting energy expenditure.

**Table 1.**

| Measurement                              | March (Baseline) | Last Measurement |
|--|------------------|------------------|
| bBP (mmHg)                               | 132/69           | 104/56           |
| Aortic BP (mmHg)                         | 105/69           | 88/67 July       |
| HR (bpm)                                 | 53               | 27               |
| Stroke Volume Index (ml)                 | 44               | 69               |
| Cardiac Output Index (L/min)             | 2.4              | 1.9              |
| Calf Blood Flow (ml/min/100ml tissue)    | 1.7              | 1.6              |
| Forearm Blood Flow (ml/min/100ml tissue) | 2.4              | 1.6              |
| Central PWV                              | 5.8              | 3.8              |
| Femoral-Tibialis Posterior PWV           | 9.2              | 8.4              |

**Effects on Leg Muscle Activity using the Compression Belt on Squat Exercise**

Koji Kurita<sup>1</sup>, Masanori Takemura<sup>2</sup>, Yuji Kanoh<sup>3</sup>, Mitsuharu Kaya<sup>4</sup>, Motoaki Tsuchiya<sup>5</sup>, Junzo Tsujita<sup>2</sup>. <sup>1</sup>Physical Conditioning Production, Osaka, Japan. <sup>2</sup>Hyogo College of Medicine, Nishinomiya, Japan. <sup>3</sup>Reseisha College of Medicine and Sport, Osaka, Japan. <sup>4</sup>Hyogo University of Health Science, Kobe, Japan. <sup>5</sup>MJ Consultant, Osaka, Japan.

(No relationships reported)

Resistance training at low loads with blood flow restricted by the use of specific compression belt has been shown to induce muscle hypertrophy and strengthening. However, it is unclear that acute effects on muscle activity with the use of specific compression belt.

**PURPOSE:** To compare the EMG activity of directly compressed muscle (multi joints muscles) and indirectly compressed muscle (single joint muscles) with and without specific compression belt on femoral proximal region.

**METHODS:** A cross-over interventional study. Nine healthy adults (5 women and 4 men), mean age (SD) age: 29.4 (8.8) yrs, performed 3 sets (5sec. set interval: 15sec) of static squat position (bilateral squat (BS) and single leg squat (SS)) during three different conditions; pre non-compressed (Pre), compressed on femoral proximal region (Comp) and post non-compressed (Post). In the condition of Comp, a specially designed elastic compression cuff belt (30 mm wide) was placed at the most proximal position of the upper leg, and inflated to a pressure calculated by the individual's maximum pulse wave at resting condition. Surface EMG was recorded from the muscle belly of the rectus femoris (RF; a directly compressed muscle), and vastus lateralis (VL; an indirectly compressed muscle) muscles, and mean integrated EMG: iEMG; normalized as the relative exercise intensity (%) was analyzed (used a 3-way repeated measures analysis of variance, and a Least Significant Difference (LSD) multiple post hoc test).

**RESULTS:** The activity of muscles in BS (54.6 (10.3) %) were higher than in SS (84.9 (14.1) %) (F=96.6, p<0.01). The interaction between muscles and squat positions was not significant (F=5.24, p>.05). The interactions between compressive condition and muscles had significant effects (F=6.23, p<0.01), and Pre (71.4 (%)) and Post (67.1%) non-compressed were higher compared to Comp (60.7%) in the RF (F=16.72, p<0.01). However, activity in the VL was not different (Pre=76.4%, Comp=72.2%, Post=70.7%, F=3.00, p>.05).

**CONCLUSION:** Decreases in activity of the directly compressed upper leg muscle during static squat exercise with a compression belt on femoral proximal region might be influenced by mechanical effect.

**3268 Board #233 June 1 3:30 PM - 5:00 PM**

**Reliability Of An Instrument To Determine Power In The Bench Press**

Tiffany J. Patrick<sup>1</sup>, David Bellar<sup>2</sup>, Jim M. Clemons<sup>2</sup>, Lawrence W. Judge<sup>3</sup>, Matt Lydum<sup>1</sup>, Ellen L. Glickman, FACSM<sup>4</sup>. <sup>1</sup>Defiance College, Defiance, OH. <sup>2</sup>University of Louisiana at Lafayette, Lafayette, LA. <sup>3</sup>Ball State University, Muncie, IN. <sup>4</sup>Kent State University, Kent, OH.

(No relationships reported)

Power is an attribute often measured in athletics by sport scientists, coaches and teachers; therefore, it is important to have reliable options to quantify it.

**PURPOSE:** The purpose of this investigation was to examine the reliability of a commercially available optical wire encoder based device with digital readout for assessing power during the bench press.

**METHODS:** Six male (height: 186.4±3.6 cm, weight: 128.0±12.4 kg) and six female (height: 163.5±6.7 cm, weight: 65.3±14.6 kg) NCAA division 1 track and field athletes volunteered for the investigation. Participants underwent two testing sessions, each consisting of a dynamic warm-up followed by three maximum power bench presses at 50% of a one repetition maximum (1RM) previously determined a week prior to data collection. Data were analyzed for reliability within each session, and also between two testing dates, separated by one week using intraclass correlations coefficients (ICC) and Anova.

**RESULTS:** Results indicated very strong reliability between the three measurements for the first session ( $F = 0.752$ ,  $p = 0.482$ ,  $ICC=0.985$ ) and second session ( $F = 1.642$ ,  $p=0.217$ ,  $ICC=0.984$ ). In examining the test-retest reliability between the separate test dates, the average power was significantly different ( $F=5.666$ ,  $p=0.036$ ) but participants' peak power did not differ ( $F=1.140$ ,  $p=0.309$ ).

**CONCLUSIONS:** Results suggest that the device demonstrated reliability within testing sessions and also when assessing peak power over a period of one week.

**3269 Board #234 June 1 3:30 PM - 5:00 PM**  
**Effect of Footwear on Impact Absorption from a Vertical Jump**

James J. Tufano, Joe LaPorta, Vanessa L. Cazas, Jeremy G. Tan, Leah Truong, Lee E. Brown, FACSM. *CSU Fullerton, Fullerton, CA.*  
(No relationships reported)

**PURPOSE:** The purpose of this study was to examine the effect of footwear on impact absorption while landing from a vertical jump.

**METHODS:** Twenty-seven recreationally trained females (23±2.2 yrs, 162.94±7.37 cm, and 62.02±8.79 kg) participated in this study. Following a 5-minute cycling warm-up, each subject completed three vertical jumps while wearing one of two different types of footwear: bare feet (BF) or minimalist shoes (MS; Fila Skeletons). The order in which the footwear was worn was randomized until each subject had jumped with both conditions in the same visit. All counter-movement vertical jumps were performed on a force plate with hands placed on the hips. Thirty seconds of rest was given between trials and 2 minutes were allotted between conditions. Impact absorption rate (IAR) was calculated by dividing the peak impact force by the time from foot contact to peak impact force. Relative impact absorption rate (RIAR) and relative peak impact force (RPIF) were also calculated.

**RESULTS:** Paired-samples t-tests revealed no differences in IAR between the BF (38640.01±22296.11 N/s) and MS (39158.95±22044.76 N/s) conditions. There were also no differences in RIAR between the BF (63.75±34.23 N/s/N) and MS (64.82±34.65 N/s/N) conditions or in RPIF between the BF (4.28±1.23 times body weight) and MS (4.24±1.28 times body weight) conditions.

**CONCLUSIONS:** The results of this study indicate that while landing from a vertical jump, the absolute and relative impact forces experienced while barefoot or wearing minimalist shoes were similar. Additionally, the rate of absorption was not different between minimalist shoes and being barefoot. Therefore, wearing minimalist shoes may not be warranted in an attempt to affect impact absorption during plyometric activities.

**3270 Board #235 June 1 3:30 PM - 5:00 PM**  
**The Efficacy Of Combining Weight-bearing Exercises With A Newly-developed Perceived Exertion Scale In Middle-aged Men**

Kazufumi Terada<sup>1</sup>, Toshiaki Nakatani<sup>1</sup>, Hidetoshi Ue<sup>2</sup>, Masakazu Nadamoto<sup>1</sup>, Reiko Shiomi<sup>1</sup>. <sup>1</sup>Tenri University, Nara, Japan. <sup>2</sup>Kyoto City University of Arts, Kyoto, Japan.  
(No relationships reported)

**PURPOSE:** The rate of perceived exertion is an easy and practical way to monitor the intensity of resistance exercise in a field setting. The weight-bearing exercise is safer than a resistance training using the weight for in middle-aged person. The purpose of this study was to investigate the effect of exercises with one's own bodyweight by measuring exercise intensity with the newly-developed perceived exertion Japanese scale (S-scale, on a 4-point scale) in middle-aged Japanese men.

**METHODS:** Twenty-five healthy men (age range, 40-69 years) were randomly and equally assigned to an exercise training intervention group (EG, n = 13) or a control group (CG, n = 12). EG members performed a structured exercise regimen consisting of group-based and home-based training with their own bodyweight, performing repetitions until they reached a perceived exertion intensity of 3 out of 4 (S-scale). Participants performed one set of each exercise, which included resistance training of the upper (push-up) and lower (squat) limbs and abdominal (sit-up) muscles, 3 times a week for 12 weeks. The outcome measures were body composition, abdominal girth, and blood pressure, as well as the 30-second chair-stand test (CS-30), vertical force in sit-to-stand movement from a chair, vertical jump (VJ), shoulder horizontal adduction (SHA, a test of muscle strength), 30-second sit-up test, leg muscle power using the bicycle ergometer, center of foot pressure (a static equilibrium function test), 2-min step test, and chair sit-and-reach test.

**RESULTS:** There were no incidents of injury or musculoskeletal damage because of the exercise program. At baseline, each group was well matched in physical characteristics. After 12 weeks of intervention, the EG showed significantly greater improvements ( $p < 0.05$ ) in measures of CS-30 (+11%), VJ (+20%), and SHA (+15%). The CG experienced no significant changes. We identified a statistically significant two-factor interaction between the exercise and control groups in the CS-30 ( $F = 19.8$ ,  $p < 0.01$ ) and VJ ( $F = 34.4$ ,  $p < 0.01$ ).

**CONCLUSION:** These results suggest that weight-bearing exercises performed in conjunction with the newly-developed perceived exertion scale provide safe and effective resistance training in middle-aged men.

**Kinetic Comparison Of Free Weight Bench Press And Slow Velocity Isokinetic Chest Press**

Mike T. Lane, Andrew C. Fry, Mike W. Aldrighetti, Matt Andre, Zachary Graham. *University of Kansas, Lawrence, KS.*  
(No relationships reported)

There is limited knowledge comparing maximal force production on free weight bench press to isokinetic horizontal chest press machines, especially machines that operate at slow speeds (<2 m/s) that purport to result in greater forces.

**PURPOSE:** To compare force development on a free weight 1 repetition maximum (1 RM) bench press and an isokinetic chest press machine (Exerbotics, Tulsa, OK) in recreationally trained men.

**METHODS:** Recreationally trained males participated in the study ( $X \pm SD$ ; n=10, age =22.8±2.6 yrs, ht =1.83±0.06 m, body wt =81.3±7.9 kg). Subjects performed the exercise sessions in random order. One session was a free barbell bench press performed on a ProSpot bar (FW; Prospot Fitness Inc. Pompano Beach, FL) while on a 1-D force plate (Rough Deck, Rice Lake, WI) to measure force at 1000 Hz using a Biopac (Goleta, CA) acquisition system. 1RM FW bench presses were determined, after a brief warm up, followed by regular load increments until a maximal effort was achieved. Kinetic variables (maximum and mean force, time to maximum force) during the 1 RM lift were then determined. During the other session, subjects performed a max effort bench press on an isokinetic chest press (CP) using an interfaced acquisition system sampling at 252 Hz/ROM. Sessions were performed one week apart.

**RESULTS:** Max FW force = 2998.5±686.0 N, mean FW force = 2203.8±662.3 N compared to max CP force = 2887.9±527.3 N and mean CP force = 2203.7±371.4 N for the concentric action. For the eccentric action, Max FW force = 2806.2±642.7 N and mean FW force = 2135.4±766.7 N, compared to max CP force = 2948.4±657.9 N, and mean CP force = 1980.6±521.5 N. There was no significant difference between any of the concentric or eccentric force measures using independent t-tests ( $p>0.05$ ). Mean time to peak force was 0.026±0.0180 s for FW and 3.390±.7110 s for CP, which was significantly different.

**CONCLUSIONS:** These data indicate there is no difference in maximal or average force produced during either modality, but there is a difference in where maximum force occurs in the range of motion based on the time to maximum force. Both FW and CP produce similar forces, but the time to maximum force is significantly faster using FW.

This project is supported in part by Exerbotics.

3272 Board #237 June 1 3:30 PM - 5:00 PM

**Does Vibration Counteract the Static Stretching-induced Deficit on Muscle Force Development?**

Paulo Sergio Chagas Gomes<sup>1</sup>, Igor A. Fernandes<sup>1</sup>, Greg Kawchuk<sup>2</sup>, Yagesh N. Bhamhani<sup>2</sup>. <sup>1</sup>Universidade Gama Filho, Rio de Janeiro, Brazil. <sup>2</sup>University of Alberta, Edmonton, AB, Canada.  
(No relationships reported)

**INTRODUCTION:** The maintenance of both neural activation and intrafusal mechanical sensitivity state are hypothetically implicated in the counteraction of the static stretching-induced impairment on power performance when muscle vibration is simultaneously imposed.

**PURPOSE:** To determine the residual acute vibration-stretching effect on ground reaction forces, muscle pre-activation levels, short latency stretch reflex responses, and performance during execution of depth jumps (DJ).

**METHODS:** Eleven amateur athletes performed a set of three 45cm-DJs before and immediately after three 30s-sets of static stretching exercise with (VSTR) and without (STR) simultaneously imposed muscle vibration (45 Hz, 5mm). DJ height (DJH), contact time (CT), ground reaction force peak (GRFP), time to peak (TP), and electromyographic data including Vastus Lateralis onset/levels of pre-activation and short latency stretch reflex onset (SLRO) and amplitude (SLRA) were recorded.

**RESULTS:** No changes were induced on DJH after both VSTR ( $32.1 \pm 2.2$  vs.  $32.3 \pm 3.5$  cm) and STR ( $32.7 \pm 2.1$  vs.  $32.1 \pm 2.6$  cm). However, STR-induced decrements on GRFP ( $2161.9 \pm 52.0$  vs.  $2144.9 \pm 46.3$  N,  $P = .031$ ) and TP ( $22.8 \pm 7$  vs.  $25.4 \pm 9$  ms,  $P = .050$ ) as well as an increment in CT when compared to VSTR post measurements (STR  $271.9 \pm 84.9$  vs. VSTR  $250.5 \pm 74.2$  ms,  $P = .046$ ) followed a delay in SLRO ( $25.2 \pm 5.7$  vs.  $29.8 \pm 5.4$  ms,  $P = .032$ ) and reduced pre-activation levels ( $29.3 \pm 20.3$  vs.  $23.11 \pm 20.3$  % maximal isometric voluntary contraction [MIVC]) of Vastus Lateralis. When vibration was simultaneously imposed to stretching, there was no evidence of significant changes in high-speed force production variables such as GRFP ( $2154.2 \pm 51.5$  vs.  $2156.5 \pm 41.3$  N), TP ( $24.4 \pm 6.7$  vs.  $23.1 \pm 7.0$  ms) and CT ( $256.9 \pm 72.7$  vs.  $250.5 \pm 74.2$  ms). Vastus Lateralis SLRO ( $26.7 \pm 4.8$  vs.  $27.7 \pm 5.4$  ms), SLRA ( $60.2 \pm 17.5$  vs.  $59.1 \pm 14.4$  % Maximal SLRA) and pre-activation onset ( $86.9 \pm 39.9$  vs.  $86.5 \pm 31.9$  ms) and levels ( $27.4 \pm 17.6$  vs.  $24.4 \pm 19.61$  % MIVC) remained unchanged after VSTR.

**CONCLUSION:** Mechanical vibration, when applied simultaneously to static-stretching exercise, appeared to be effective in counteracting decreased MTU stiffness-induced high-speed force production deficit during stretch shortening cycle performance.

**Postactivation Potentiation Improves Sprint Performance in Collegiate Football Players**

Donovan S. Conley, FACSM, Austin M. Bright, Tiffany R. Kellerman, Paige K. Pollard, Katie A. Reikofski, Tammy K. Evetovich, FACSM. Wayne State College, Wayne, NE.  
(No relationships reported)

Recently, researchers reported that 100-m sprint performance improved significantly following a preload stimulus of 4 repetition maximum parallel back half-squats in collegiate women (Linder, E.E. et al., *J. Strength Cond. Res.* 24:1184-1190, 2010). However, it is unknown whether a similar preload stimulus will elicit improvement in sprint performance in collegiate football players.

**PURPOSE:** The purpose of this study was to determine the effects of postactivation potentiation (PAP) on 36.6 m sprint performance after a preload set of 3 repetition maximum (3RM) parallel back half-squat exercises in collegiate football players.

**METHODS:** Seven healthy resistance trained National Collegiate Athletic Association Division II male football players that included defensive backs, wide receivers, and running backs (mean  $\pm$  SD; age:  $20.4 \pm 1.6$  y; weight:  $87.81 \pm 8.25$  kg; height:  $184.3 \pm 7.2$  cm; body composition:  $10.6 \pm 3.1$  %) volunteered to participate in the study. Subjects were randomly assigned to two 36.6 m sprint warm-up protocols to include: 1) Control (C) protocol which consisted of a 5 min warm-up on a cycle ergometer at 25 W, 5 min rest, 36.6 m sprint test, a second 5 min rest interval followed by a second 36.6 m sprint and 2) PAP protocol which consisted of a 5 min warm-up on a cycle ergometer at 25 W, 5 min rest, 36.6 m sprint test, a second 5 min rest interval, a warm-up of 8 repetitions at 50% 1RM squat, 2 min rest, 3RM squat, 8 min rest, and a final 36.6 m sprint test. All 36.6 m sprint times were assessed on an indoor track using a touch pad activated Brower TC timing system.

**RESULTS:** Paired t-tests showed that 36.6 m sprint performance was significantly ( $p < 0.05$ ) lower following the PAP (4.6014 .17995 sec) versus the best sprint trial for the C (4.6714 .18050 sec) protocol and the first sprint trial (4.6557 .19603 sec) completed prior to the PAP treatment.

**CONCLUSIONS:** We conclude that a preload 3RM parallel back half-squat warm-up significantly improves sprint performance compared to a general cycle warm-up. Our data suggests that postactivation potentiation produced by a 3RM parallel back half-squat improves sprint performance in collegiate football players.

**Response Of Individual Muscles To Neuromuscular Electrical Stimulation Training Of Knee Extensors**

Kei Masani<sup>1</sup>, Ali S. Hassan<sup>1</sup>, Dmitry G. Sayenko<sup>1</sup>, Daichi Nozaki<sup>2</sup>, Milos R. Popovic<sup>3</sup>. <sup>1</sup>Toronto Rehabilitation Institute, Toronto, ON, Canada. <sup>2</sup>University of Tokyo, Tokyo, Japan. <sup>3</sup>University of Toronto, Toronto, ON, Canada. (Sponsor: Minoru Shinohara, FACSM)  
(No relationships reported)

Neuromuscular electrical stimulation (NMS) is one of the most popular advanced methodologies for athletes to gain muscle strength. Usually, NMS uses a pair of large electrodes to stimulate one muscle group (Group Stimulation, GS) instead of stimulating individual muscles. To design effective training protocols, the response of individual muscle to GS must be examined.

**PURPOSE:** 1) To identify the unique force vector produced by individual knee extensors, and 2) to investigate the contribution of individual knee extensors to the force vectors produced by GS in NMS training.

**METHODS:** Six subjects ( $30.0 \pm 8.9$  yrs) sat on a chair and three knee extensors (vastus medialis, vastus lateralis, and rectus femoris) were individually stimulated. Additionally, knee extensors were stimulated simultaneously as a group using regular NMS electrodes at three different locations (GS1-3). The unit force vectors in the isometric condition were calculated for individual muscles and for GS1-3. The relative contribution of individual muscles to GS1-3 was estimated based on an assumption that the force vector measured during each GS was a linear vector summation of force vectors of the three individual muscles.

**RESULTS:** Fig. 1 and Fig. 2 shows the unit force vectors and the contribution for individual muscles, respectively. The unit force vector was statistically different among the three knee extensors (MANOVA,  $p < 0.001$ ). The contributions of the three knee extensors were statistically different among muscles (ANOVA,  $p < 0.001$ ), while not different among GS1-3 ( $p = 0.09$ ).

**CONCLUSIONS:** Each knee extensor has a unique force vector. Distinct contributions from individual muscles were found, suggesting that NMS training may unevenly affect knee extensors.

**A Comparison of EMG Activity Between Dumbbell Bench, Barbell Bench and Vertical Chest Press**

Aaron Morton, Jeremy Townsend, Heather Moore, Ludmila Cosio-Lima. The University of West Florida, Pensacola, FL.  
(No relationships reported)

**PURPOSE:** In a resistance-training program, increasing upper body strength is important if the participant is currently involved in a sport in which body-to-body contact is necessary. Therefore, it is necessary to discover which exercises are the most effective at developing upper body strength. Although there have been several studies examining the effects of the dumbbell bench press and barbell bench press as well as the barbell bench press and machine bench press on electromyographic (EMG) activity, few studies have compared the EMG activity of all 3 types of exercise. Therefore, the purpose of this study is to compare the effects of the dumbbell bench press, barbell bench press and vertical chest press on EMG of the anterior deltoid and the pectoralis major.

**METHODS:** Thirteen recreationally trained (exercise individually 2-3 times per week and bench press a minimum of 61.4 kg), college age males height (178±6.2cm), weight (84.2±15.3kg), barbell bench press max (109.95±20.41kg) students from the HLES department at UWF volunteered for this study. All volunteers were randomized to perform a barbell bench press, dumbbell bench press or a vertical chest press exercise at 70% of their 1RM on barbell bench press while wearing EMG electrodes. A repeated measures ANOVA was used to analyze the data.

**RESULTS:** Dumbbell bench produced the greatest anterior deltoid activity (1254.6 ± 377.7 Hz) while the vertical bench recorded the greatest pectoralis major activity (615.0 ± 162.3 Hz). There were no significant differences in muscle EMG activity between the 3 exercises for either muscle groups ( $p < 0.05$ ).

**CONCLUSIONS:** The results of this study were consistent with the findings in earlier studies indicating no significant differences between barbell bench-press and dumbbell bench. Vertical chest press seems to have a slightly greater mean activation of the pectoralis major when compared to the other two exercises.

**3276** Board #241 June 1 3:30 PM - 5:00 PM

**Electromyographic Analysis of the Infraspinatus Muscle during Several Shoulder Elevation Tasks**

Shunsuke Fujitake<sup>1</sup>, Masanori Takemura<sup>2</sup>, Tetsuji Ishida<sup>3</sup>, Chihiro Dehara<sup>4</sup>, Junzo Tsujita<sup>2</sup>. <sup>1</sup>Tachiiri Orthopedics, Kyoto, Japan. <sup>2</sup>Hyogo College of Medicine, Nishinomiya, Japan. <sup>3</sup>Shiga Medical Center for Children, Moriyama, Japan. <sup>4</sup>Gakkenotshi Hospita, Seika, Japan.  
(No relationships reported)

The shoulder muscles recruitment pattern during shoulder elevations at several initial arm positions has not yet been clearly understood.

**PURPOSE:** To compare the activity in shoulder muscles, particularly the infraspinatus muscle during shoulder elevation at several initial arm positions.

**METHODS:** Ten healthy without shoulder diseases adults (3 female and 7 male), means (SD) age: 25.5 (5.4) years, height: 166.5 (9.1) cm, weight: 58.6 (12.1) kg, participated in this study. Each subjects performed maximal voluntary isometric contractions (MVIC) of shoulder flexion, abduction, external rotation (1st position). Then they performed 3 times isometric contractions (5 sec) of shoulder elevation at 30 degrees with 3 kg weight loads, within frontal plane (abduction; [ABD]), scapula plane [Scaption], sagittal plane (flexion; [Flex]), diagonal plane (flexion and abduction) with shoulder external rotation [DiaER], diagonal plane with shoulder internal rotation [DiaIR], and external rotation with therapeutic band load of equivalent of 3 kg weight loads at 1st position (0 degrees of shoulder flexion and abduction, with elbow flexion; [1stER]). Surface EMG was recorded from the muscle belly of infraspinatus (the upper portion; [ISup], and the lower portion; [ISlo]), supraspinatus [SS], upper trapezius [T], anterior deltoid [DA], and middle deltoid [DM] muscles, and mean integrated EMG [iEMG; normalized as MVIC; (%)] was analyzed. A 3-way repeated-measures ANOVA was used for statistical analysis.

**RESULTS:** The activity (%iEMG) of ISlo were 37.6 (24.9) at ABD, 41.9 (19.6) at Scaption, 47.3 (14.9) at Flex, 57.5 (15.8) at DiaER, 80.5 (29.6) at DiaIR, and 48.7 (12.7) at 1stER, then DiaIR was significantly higher than other positions ( $p < .05$ ). In the activity of ISup, DiaIR [47.2 (17.8)] and 1st ER [48.7 (12.0)] were significantly higher ( $p < .05$ ) than ABD [35.9 (16.2)], Scaption [39.3 (13.5)], Flex [41.3 (12.3)], and DiaER [39.5 (13.2)], however DiaIR and 1stER was not difference.

**CONCLUSION:** The result of this study showed that ISlo activity at DiaIR was higher than at 1stER. Although 1stER exercise is popular training method, we think that diagonal (flexion and abduction) and spiral (internal to external rotation) pattern is more useful as functional exercise pattern in infraspinatus muscle.

**3277** Board #242 June 1 3:30 PM - 5:00 PM

**Neuromuscular Responses to Power Exercise Using Weight Stack Device With and Without Rubber Band Resistance**

Heikki Peltonen, Keijo Häkkinen, Janne Avela. University of Jyväskylä, Jyväskylä, Finland.  
(No relationships reported)

Power training improves the ability to produce explosive muscle strength or/and contractile rate of force development. During a single explosive repetition, when using weight-based resistance, reduced force, velocity, power, and muscle activity during the latter range of movement occurs. This suggests that the stress of loading occurs over a brief part of the range of motion.

**PURPOSE:** To determine whether additional rubber band resistance will induce greater neuromuscular fatigue compared to typical WS power loading.

**METHODS:** 15 physically active men (20-35 yrs) without systematic weight training background acted as subjects. A knee extension loading protocol, which consisted of 5 x 5 x 40% 1RM load with 3 min rest between sets, was performed with each extension as fast as possible. Subjects used the same weight stack (WS) device during both loadings; the only difference being a rubber band (WS+RB) attached between the weight stack and the ground during the other loading. Acute neuromuscular responses were assessed by measuring force (F100ms and Fmax), rate of force development (RFD) and muscle activity (EMG100ms, EMGmax and frequency) during maximal isometric voluntary contraction before and after the loading. Electrical stimulation was used to measure resting (RT) and superimposed twitch forces (to determine activation level, AL) and M-wave parameters. In addition, blood samples were drawn and lactate levels (La) were analyzed.

**RESULTS:** Fmax decreased after both loadings (WS+RB -13±4%,  $p < 0.01$ , WS -9±8%,  $p < 0.05$ ). Large decreases occurred in F100ms (WS -27±26%,  $p < 0.01$ , WS+RB -16±10%,  $p < 0.001$ ). The decline in maximal RFD was also similar ( $p < 0.001$ ) after both loadings. However, AL declined significantly only after WS+RB loading (-5±7%,  $p < 0.05$ ), while EMG100ms declined only in WS (-24±22%,  $p < 0.01$ ; WS vs. WS+RB  $p < 0.01$ ). La was higher ( $p < 0.01$ ) after WS+RB than WS loading. No changes were observed in RT, EMGmax, frequency, or M-wave parameters after either loading.

**CONCLUSION:** Both power loading models induced clear signs of neuromuscular fatigue, in which the greatest decreases occurred in rapid force production. However, since in WS+RB AL reduced significantly, and RT was unaffected, additional rubber band resistance with WS may alter the neural properties more efficiently as compared to loading with WS only.

**Growth Of Rpe During Resistance Exercise**

John P. Porcari, FACSM, Carl Foster, FACSM, Jos J. de Koning, FACSM, Jeena Lucas-Kormarek, Glenn Wright, Scott Doberstein. University of Wisconsin-La Crosse, La Crosse, WI.  
(No relationships reported)

**PURPOSE:** RPE grows in a scalar manner during sustained, whole body ambulatory exercise such as running and cycling. This study was conducted to determine whether RPE increases in a similar way during resistance exercise.

**METHODS:** Resistance trained men (N=21) performed 4 sets of bench press & leg press with resistance calculated to cause fatigue in 5, 10, 20 or 30 repetitions pm 4 days separated by at least 48 hr. RPE was measured after each repetition using the category-ratio scale.

**RESULTS:** Regardless of the number of repetitions completed, RPE increased throughout each set in a linear fashion. Normalized to the % maximal repetitions across all levels of resistance, RPE had scalar properties, and there was a strong relationship between RPE and % repetitions ( $R^2=0.93$ ).

**CONCLUSION:** This study supports the concept that RPE increases in a scalar manner with relative fatigue during resistance exercise just as it does during whole-body ambulatory activity.

**3279** Board #244 June 1 3:30 PM - 5:00 PM

**Shoulder Muscle Activation Of Novice And Weight-trained Females During Push-ups On An Unstable Surface**

Brittany E. Russell, Jennifer Lindsay Newsome, Bryan L. Riemann. Armstrong Atlantic State University, Savannah, GA. (Sponsor: T. Jeff Chandler, FACSM)  
(No relationships reported)

Performing closed kinetic chain exercise on an unstable surface increases the muscle stability demands. In contrast to the research conducted considering lower extremity and muscle activation during training on unstable surfaces, there is a lack of research on the upper extremity. Furthermore whether acute responses differ between weight-trained versus untrained subjects is unknown.

**PURPOSE:** To compare shoulder muscle activation of novice (untrained) and experienced weight lifters during three different push-up variations.

**METHODS:** Muscle activity of the dominant arm biceps brachii (BI), triceps (TR), upper trapezius (UT), anterior deltoid (AD), sternal (SPM) and clavicular (CPM) portions of the pectoralis major and the serratus anterior (SE) were measured by way of surface electromyography (EMG) in 12 novice 64.33±10.08kg, 1.69±0.07m, 23.0±2.8yrs and 12 experienced (64.58±8.02kg, 1.69±0.04m, 22.6±1.7yrs) weight lifters. Subjects performed five repetitions of three push-up variations, stability discs under hands, stability discs under feet, no stability disc, in a random order. Average EMG amplitude during the concentric phase of each push up variation repetition was computed and averaged across the five trials. Separate group by push up variation analysis of variance was used for each muscle with statistical significance considered at P<.05.

**RESULTS:** With the exception of the BI, exercise had significant effects on muscle activity. Four muscles, SPM, CPM, AD and TR, demonstrated significantly higher activity during PUH and SPU compared to PUF. UT demonstrated significantly greater activity during PUH compared to SPU and PUF. SA demonstrated significantly greater activity during SPU compared to PUH. SPM, CPM, and TR, demonstrated group effects with the novice group eliciting significantly greater activity than the experienced lifters.

**CONCLUSIONS:** Performing push-ups with the hands on the discs did not increase muscle activity compared to standard push-ups. This suggests that PUH can be used to promote stabilizer activity without compromising prime mover activation. Perhaps explaining the reduction in activation for PUF compared to SPU was a change in center of mass position. Higher activation in novices is likely explained in differences in push-up execution.

### Validity of Bioelectrical Impedance Measurement in Predicting Fat-Free Mass of Chinese Children and Adolescents

Lin Wang, Stanley Sai-Chuen Hui, FACSM. *The Chinese University of Hong Kong, Hong Kong, Hong Kong.*

(No relationships reported)

The validity of bioelectrical impedance analysis (BIA) equations for estimating fat-free mass from in Chinese children and adolescents has not been verified.

**PURPOSE:** The study aims to develop BIA equations for the estimation of fat-free mass (FFM) that are appropriate for Chinese children and adolescents.

**METHODS:** A total of 255 healthy Chinese children and adolescents aged 9-19 years old (127 males and 128 females) participated in the bioelectrical impedance measurement at 50 kHz between the hand and the foot, as well as the criterion measure of FFM using dual-energy X-ray absorptiometry (DEXA). Multiple regression analysis was employed to develop prediction equations for FFM from BIA measurement. A double cross-validation approach was used to determine the predictive accuracy of developed BIA equations. Differences between measured and predicted FFM were examined by Bland-Altman analysis. Bland-Altman plots were also generated to illustrate the residual errors.

**RESULTS:** Using multiple linear regression and cross-validation against DEXA measurement, a FFM prediction equation was produced as follow: FFM (kg) = 1.613 + 0.742 × height (cm)<sup>2</sup>/impedance (Ω) + 0.151 × body weight (kg); R<sup>2</sup> = 0.95; SEE = 2.45kg; CV = 6.5%. The mean difference between DEXA-measured and predicted FFM was 0.02 ± 2.45 kg; 95% limits of agreement was -4.78 to 4.82 kg FFM.

**CONCLUSIONS:** From the data collected in the present study, a BIA equation for predicting FFM of Chinese children and adolescents has been developed. The equation is applicable over a larger range of body sizes and age. With the use of appropriate BIA equation, BIA can provide a practical and valid measurement of body composition among Chinese children and adolescents.

### Regression Models to Predict Abdominal Obesity With Waist Circumference in Children

João P. Magalhães<sup>1</sup>, Diana A. Santos<sup>1</sup>, António Palmeira<sup>2</sup>, Sandra Martins<sup>2</sup>, Fátima Baptista<sup>1</sup>, Ezequiel M. Gonçalves<sup>1</sup>, Cláudia S. Minderico<sup>2</sup>, Luís B. Sardinha<sup>1</sup>.

<sup>1</sup>Faculty of Human Kinetics technical University of Lisbon, Lisbon, Portugal. <sup>2</sup>Lusofona University, Lisbon, Portugal.

(No relationships reported)

**BACKGROUND:** Waist circumference (WC) is positively correlated with abdominal fat content, and it is considered a good anthropometric indicator for diagnosing abdominal obesity across different age groups, including children. Investigation has confirmed that early obesity in childhood is associated with an increased risk of chronic diseases in adult ages.

**PURPOSE:** To develop and cross-validate prediction equations to estimate abdominal obesity based on waist circumference, independently for boys and girls in children.

**METHODS:** Abdominal body fat (ABF) was assessed using Dual Energy X-ray Absorptiometry (DXA) in 271 boys and 241 girls aged 10.3 ± 0.6 years. ABF was measured in a region of interest between L2-L4. WC was measured according to the NIH protocol (on the superior border of the iliac crest), to the WHO protocol (between the lower rib and iliac crest), and to Lohman's protocol (on the narrowest part of the torso). Prediction equations were established, independently for boys and girls, using a cross validation method. One hundred and eighty boys and 161 girls were used to develop the two prediction equations (2/3 of the sample). Cross validation was performed on a representative hold-out sample of 91 boys and 80 girls (1/3 of the sample). Cross-validation included paired samples t-tests and analysis of Pearson Correlation Coefficient (r), and standard error of estimate (SEE).

**RESULTS:** Because the NIH protocol yielded the highest correlation coefficient with ABF, we selected this variable to develop and validate the prediction models. Mean values for ABF in the hold-out sample were 0.7 (± 0.54) kg and 0.86 (± 0.56) kg, for boys and girls, respectively. Both equations cross-validated very well, for girls (r=0.92 and SEE=0.225 kg) and for boys (r=0.92 and SEE=0.211 kg). There were no differences in the mean values between both equations and ABF assessed with DXA (p >0.05). The new prediction equation for boys was ABF = 0.058 \* WC - 3.053 and for girls ABF = 0.061 \* WC - 3.192.

**CONCLUSIONS:** These results indicate that the prediction equations perform very well to predict ABF assessed with DXA for both boys and girls. With these models including a very simple measurement such as WC, one can readily estimate a fatness atherogenic phenotype.

---

3282 Board #3 June 2 8:00 AM - 9:30 AM

### Comparison of Waist Circumference Measurements Using Different Protocols in Children

Diana A. Santos<sup>1</sup>, João P. Magalhães<sup>1</sup>, Analiza M. Silva<sup>1</sup>, António Palmeira<sup>2</sup>, Sandra Martins<sup>2</sup>, Fátima Baptista<sup>1</sup>, Ezequiel M. Gonçalves<sup>1</sup>, Cláudia S. Minderico<sup>2</sup>, Luís B. Sardinha<sup>1</sup>. <sup>1</sup>Faculty of Human Kinetics, Technical University of Lisbon, Cruz-Quebrada, Portugal. <sup>2</sup>Lusofona University, Lisboa, Portugal.

(No relationships reported)

**BACKGROUND:** An atherogenic phenotype can be identified using a practical anthropometric measure such as the waist circumference (WC), as it is strongly associated with abdominal fatness. However, there is no agreement between studies on the location of this measurement, mainly when considering national reference percentiles.

**PURPOSE:** We aimed to compare three different protocols in the assessment of WC in children, independently for boys and girls.

**METHODS:** A total of 512 children (271 boys and 241 girls), aged 10-11 years (10.3 ± 0.6) were evaluated. WC was measured according to the NIH protocol (on the superior border of the iliac crest), to the WHO protocol (between the lower rib and iliac crest) and to Lohman's protocol (measured on the narrowest part of the torso). Statistical analysis included repeated measures and regression analysis.

**RESULTS:** Mean values for WC in girls were: NIH, 66.6 ± 8.6 cm; WHO, 63.5 ± 7.9 cm; and Lohman's, 62.5 ± 7.5 cm. In boys the mean values for WC were: NIH, 65.2 ± 8.8 cm, WHO, 63.5 ± 8.1 cm, and Lohman's, 62.8 ± 7.6 cm. Significant differences between protocols were observed in both genders, and these differences remained significant even adjusting for body mass index (BMI). Further we tested if the differences between protocols were related with the mean of WC measured by the different protocols. In all cases a significant association (p<0.001) was observed (Girls: NIH/WHO, r = 0.32; NIH/Lohman, r = 0.39; WHO/Lohman, r = 0.38. Boys: NIH/WHO, r = 0.53; NIH/Lohman, r = 0.57; WHO/Lohman, r = 0.42). A positive association was also observed between the difference of the protocols and BMI for all measurements and genders.

**CONCLUSIONS:** In this sample of children aged 10 and 11 years old, there are differences in the WC mean values when using different protocols. Moreover, the differences between measures were dependent on the BMI and WC values, meaning that in children with higher BMI and WC the differences of choosing different locations may be amplified. Our results reinforce the importance of accurately choosing the location of the WC measurement, mainly if considering reference values as a criterion for health outcomes.

**3283** Board #4 June 2 8:00 AM - 9:30 AM

**Modification Of School Adiposity According To Nutritional Status: An Analysis Of 20 Years**

Tatiane K. Ferrari, Gerson Luis M. Ferrari, João Pedro Silva Júnior, Leonardo Silva, Luis Carlos Oliveira, Victor K. Matsudo. *Physical Fitness Research Center from São Caetano do Sul, São Caetano do Sul, Brazil.*

(No relationships reported)

**PURPOSE:** To analyze the adiposity changes over 20 year-period, according to the nutritional status in schoolchildren.

**METHODS:** Sample is part of the Ilhabela Mixed-Longitudinal Project on Growth, Development and Physical Fitness\*, which is held since 1978. From a data base of 16.000 schoolchildren of both sexes, 1096 students, 488 males and 606 females, from 7 to 10 years-old of both sexes, in the prepubertal stage of sexual maturation. The project was approved by the Ethics Committee. The selected data were part of a database from 1990/1991 (Initial), 2000/2001 (10 years) and 2010/2011 (20 years). The variables analyzed were: body mass (kg), body height (cm) and fatness (mm): average of seven skinfolds (biceps, triceps, subscapular, suprailiac, midaxillary, abdominal and calf). Children were classified in normal, overweight and obesity. The statistical analysis used was Kruskal-Wallis test for nonparametric data and ANOVA one-way for parametric data, followed by post-hoc Scheffé. The level of significance adopted was  $p < .01$ .

**RESULTS:** In a period of 20 years, adipose tissue increased significantly in both sexes, markedly in boys. In males, there was a significant increase in subcutaneous adipose tissue in overweight and obesity groups after a period of 20 years. Among females, there was a significant increase in the normal weight and overweight groups after a period of 20 and 10 years, respectively.

**CONCLUSIONS:** During the 20 years analyzed, there were changes in adiposity, even when analyzed for nutritional status. It showed that individuals may have similar body mass indexes, although may vary in proportion and distribution of subcutaneous adipose tissue.

**Comparison Of Percent Body Fat And BMI In Tracking Of Body Composition Among Adolescents**

Wenhao Liu, Randall A. Nichols, Traci D. Zillifro. *Slippery Rock University, Slippery Rock, PA.*

(No relationships reported)

**PURPOSE:** To examine the extent to which differences may exist between percent body fat (%BF, converted from triceps and calf skinfolds) and BMI in tracking of adolescents' body composition.

**METHODS:** BMI and %BF (from the two-site skinfold) were assessed for 102 boys (mean age = 11.6 ± .58) and 112 girls (mean age = 11.47 ± .51) at the beginning of their 6<sup>th</sup> grade (baseline), the end of the 6<sup>th</sup> grade (follow-up 1), the end of the 7<sup>th</sup> grade (follow-up 2), and the end of the 8<sup>th</sup> grade (follow-up 3). Spearman rank correlations and percentage agreements in extreme quartiles were calculated to estimate the stability in body composition measured with the two different methods across the three academic years. Chi-square tests were used to examine differences in the percentage agreements between sexes. In addition, body composition scores at the baseline and the follow-up 3 were compared using paired-samples t tests.

**RESULTS:** Spearman rank correlations for BMI between baseline and each of the three follow-ups were .96, .88, and .88 for boys and .97, .94, and .89 for girls, with little difference between sexes. The corresponding coefficients for %BF were .82, .73, and .66 for boys and .82, .83, and .75 for girls, and they were relatively low in relation to those for BMI and girls had higher tracking of %BF than did boys in the last two follow-ups. As for the percentage agreements in extreme quartiles, the results of chi-square indicated that boys had significantly lower stability in staying in lower quartiles of %BF than girls ( $p < .001$ ). That is, at the last two follow-ups, only 36.8% and 38.9% boys initially in the lower quartiles of %BF remained in the same quartiles, whereas 60.0% and 63.6% of girls remained in the lower quartiles during the same period. Further, t tests revealed that boys' %BF decreased significantly ( $p < .001$ ) during the three years, from 25.70 ± 19.95 to 20.84 ± 10.78, whereas boy's BMI and girls' %BF and BMI all increased significantly.

**CONCLUSIONS:** The study indicates that tracking levels in %BF (from the two-side skinfold) are lower than those in BMI for adolescents, especially for boys. This may due to the fact that boys tend to become less fat as they gain more muscle compared with girls during the puberty period. We suggest that %BF and BMI not be used interchangeably when measuring body composition for male adolescents.

**3285** Board #6 June 2 8:00 AM - 9:30 AM

**Evaluation Of Body Fat Patterning In Children With Non-Syndromal and Syndromal Pediatric Obesity**

Pamela M. Wright, Daniela A. Rubin, Diobel Castner, Daniel A. Judelson, FACSM. *California State University Fullerton, Fullerton, CA.*

(No relationships reported)

Prader-Willi Syndrome (PWS) is the most characterized form of congenital obesity presenting with hypogonadism and growth hormone deficiency. Adults with PWS typically show increased fat mass in the limbs compared to non-syndromal obese adults who tend to have increased fat mass in the trunk. To our knowledge, these differences in fat patterning have not been studied in children.

**PURPOSE:** To describe fat patterning in children with PWS as it compares to children with non-syndromal obesity.

**METHODS:** Thirteen children with PWS and 43 obese (OB=body fat >95th percentile) children ages 8-11 y participated. Children completed measurement for body mass, stature, and waist circumference (WC), in addition to a total body dual x-ray absorptiometry. Body fat percentage was derived for total, trunk, gynoid, and android fat. Body mass index (BMI) was calculated.

**RESULTS:** Independent t-tests showed that children with PWS and non-syndromal OB children had similar BMI (PWS: 26.0 ± 8.0 kg/m<sup>2</sup>; OB: 27.0 ± 5.0 kg/m<sup>2</sup>) and WC (PWS: 89.0 ± 18.0 cm; OB: 90.0 ± 13.0 cm) ( $p > 0.05$ ). In addition, no significant differences ( $p > 0.05$  for all) were observed for total body fat (PWS: 47.1 ± 9.2%; OB: 43.2 ± 6.0%), trunk fat (PWS: 46.1 ± 11.1%; OB: 45.1 ± 6.2%), gynoid fat (PWS: 54.1 ± 6.0%; OB: 50.3 ± 5.0%), and android fat percentage (PWS: 52.3 ± 11.2%; OB: 52.4 ± 6.0%).

**CONCLUSION:** Our results showed that children with non-syndromal obesity had similar body fat percentage and distribution as those with syndromal obesity. The differences between our findings and previous results in adults may be explained by 1) the frequent use of growth hormone replacement therapy (which changes body composition) in children with PWS or 2) a presumed lack of circulating sex hormones in this young sample.

**3286** Board #7 June 2 8:00 AM - 9:30 AM

**Bmi Growth Curve of Children In Jiangsu, China: 6-18 Yr. Old**

Peiyu Chen<sup>1</sup>, Yuling zou<sup>1</sup>, Shusheng Shi<sup>1</sup>, Weimo Zhu<sup>2</sup>. <sup>1</sup>Nanjing Normal University, Nanjing, China. <sup>2</sup>University of Illinois at Champaign-Urbana, Champaign, IL.

(No relationships reported)

**PURPOSE:** Growth curves are used widely to evaluate the growth status of individuals or a population. Using the 2010 data of by the National Physical Fitness Surveillance of Jiangsu province, China (JPC), the purposes of this study was to construct body mass index (BMI) growth curves.

**METHODS:** Height and weight of 38,047 boys and 38,255 girls of JPC, 6-18 yr. old were measured in 2010. Their BMI were computed and growth curves were fitted with the Cole's LMS method for boys and girls, respectively. The 3<sup>rd</sup>, 5<sup>th</sup>, 10<sup>th</sup>, 15<sup>th</sup>, 25<sup>th</sup>, 50<sup>th</sup>, 75<sup>th</sup>, 85<sup>th</sup>, 90<sup>th</sup>, 95<sup>th</sup> and 97<sup>th</sup> centiles were constructed and the results were compared with reference values of CDC in 2000 and WHO in 2006.

**RESULTS:** At the age of 6 years old, the medians were 16.08 kg/m<sup>2</sup> and 15.42 kg/m<sup>2</sup> for boys and girls, respectively. The 50<sup>th</sup> centile curves increased with age by gender and reached to 19.68 kg/m<sup>2</sup> for boy and 19.66 kg/m<sup>2</sup> for girl at age of 14. After that age, the curve of the boy still increased, but the trend became stable for the girls. They reached to 21.08 kg/m<sup>2</sup> and 20.18 kg/m<sup>2</sup> at age 18, respectively. The 50<sup>th</sup> centile curve and 85<sup>th</sup> centile of JPC boys differed in shape from those by CDC and WHO. JPC boys were fatter in early to mid-childhood but less so in adolescence. For JPC girl, 50<sup>th</sup> and 85<sup>th</sup> centile curves had almost the same trend with those by CDC and WHO before mid-childhood, but after age of 15, JPC girls became leaner (Figure).

**CONCLUSION:** The reference centile curves of BMI clearly described the children growth status. The prevalence of overweight and obesity among children of JPC have been becoming more and more serious, especially for the boys before 15 years old.

---

**3287** Board #8 June 2 8:00 AM - 9:30 AM

**Correlates of Relative Skeletal Muscle Index in Young Males: Lower-Limb Strength and Body Composition Measures.**

T. Brock Symons, Jody L. Clasey, FACSM. University of Kentucky, Lexington, KY.

(No relationships reported)

Relative skeletal muscle index (RSMI), the sum of appendicular mineral free lean mass divided by height squared (kg/m<sup>2</sup>), has been found to correlate with strength and body bone density measures in young females. The associations between RSMI and lower-limb muscle function and measures of body composition is less well understood in young males and may be body site specific.

**PURPOSE:** To explore the potential relationship between RSMI and measures of lower-limb muscle function and total body and regional measures of body composition in 21 young males (age 25 ± 4 yrs).

**METHODS:** Total body and right and left proximal femur dual energy x-ray absorptimetry (DXA) scans were used to determine RSMI and total body and regional measures of mineral free lean mass (MFL), bone mineral content (BMC), and bone mineral density (BMD). Right lower-limb muscle function was evaluated with knee extensor isometric (MVC; knee angle 90°) and isokinetic concentric (CON; at 90°/s and 180°/s) peak torque (PT), peak work (PW), and peak average power (PP). Pearson's zero-order correlation coefficients were computed to determine significance (p<0.05).

**RESULTS:** RSMI (9.7 ± 0.9 kg/m<sup>2</sup>) was significantly correlated to both total body MFL mass and BMD (66.1 ± 8.9 kg; r=0.80 and 1.3 ± 0.5 g/cm<sup>2</sup>; r=0.43), but not total body BMC. Right and left total proximal femur BMC was found to be related to RSMI (45.1 ± 6.0 g; r=0.54 and 45.7 ± 5.5 g; r=0.55); whereas, right and left total proximal femur BMD was not. Right and left femoral neck BMC correlated with RSMI (6.6 ± 1.0 g; r=0.55 and 6.6 ± 0.9 g; r=0.52); however, no relationship was found between RSMI and BMD. Only right greater trochanter BMC was related to RSMI (16.6 ± 2.9 g; r=0.55). RSMI correlated with MVC (343.0 ± 78.1 Nm; r=0.65) and CON PT at 90°/s and 180°/s (234.8 ± 45.3 Nm; r=0.64 and 182.8 ± 38.9 Nm; r=0.60). CON PW was associated with RSMI at both angular velocities (90°/s: 254.4 ± 53.7 J; r=0.54 and 180°/s: 209.2 ± 46.2 J; r=0.57). RSMI was not associated with CON PP.

**CONCLUSION:** Previously, RSMI was found to correlate with lower-limb muscle function and BMD in young females. Our results in young males are in agreement regarding lower-limb muscle function but differ with respect to BMD. **3288** Board #9 June 2 8:00 AM - 9:30 AM

**Accuracy Of Obesity Cut-off Values Of BMI and Waist-to-hip Ratio For Koreans With Intellectual Disabilities**

Miyoung Lee<sup>1</sup>, Haeja Chun<sup>2</sup>, Bo Fernhall, FACSM<sup>3</sup>. <sup>1</sup>Koomin University, SEOUL, Korea, Republic of. <sup>2</sup>Soon Chun Hyang University, SEOUL, Korea, Republic of. <sup>3</sup>University of Illinois at Chicago, Chicago, IL. (Sponsor: Bo Fernhall, FACSM)

(No relationships reported)

**PURPOSE:** The obesity cut-off value of Koreans is typically a body mass index (BMI) of ≥25kg/m<sup>2</sup>. In addition, a waist-to-hip ratio (WHR) of >0.8 for females and >0.9 for males increases the risk of health. These cut-off values have not been validated for Koreans with intellectual disabilities (ID). The purpose of study was to examine the accuracy of cut-off values of BMI and WHR for persons with intellectual disabilities in Korea.

**METHODS:** A total of 93 healthy individuals with intellectual disabilities in Korea (ages 18-50yrs; 65 males, 168.07±9.78cm, 70.13±14.79kg vs. 28 females, 154.24±8.27cm, 56.65±10.73kg) participated. Body fat % (BF%) was estimated by DXA (Hologic, USA) as the criterion measure, and the cut-off values of the obesity was set at 25% for male and 32% for females. To examine the accuracy of cut-off values for BMI and WHR, *R* adjusted for gender was calculated from the linear regression analysis, and ROC analyses were conducted to determine the true-positive (Sensitivity; ST) and false positive (1-specificity; SF) rates utilizing SPSS 19 (IBM SPSS Inc., USA).

**RESULTS:** BMI and WHR were highly correlated with BF% (*R* =.86 and .73, respectively). In terms of the area of ROC curves, BMI was .93 (95%CI: .91-1.00) for males and .89 (.76-1.00) for females, which is an excellent agreement. WHR showed .93(.87-.99) and .67(.44-.93) for males and females, respectively. Based on cut-off values, the ST and SF of BMI at ≥25kg/m<sup>2</sup> were .96 vs. .19 for males and 1.00 vs. .53 for females, respectively. On the other hand, ST and SF of WHR were 1.00 vs. .56 for males and .67 vs. .41 for females.

**CONCLUSIONS:** The standard cut-off values of BMI for both males and females are relatively accurate to determine the obesity for Koreans with ID, but false positive rates are less acceptable. With the obesity cut-off of BMI ≥30kg/m<sup>2</sup>, ST and SF are increased up to 1.00 vs. .78 and 1.00 vs. .82 for both genders, respectively. On the other hand, WHR is less accurate than BMI, especially for females with ID. Larger sample size is required to generalize the findings from this study to the target population.

This work was partially supported by the new faculty research program 2010 of Kookmin University and Soon Chun Hyang University in Korea.

**3289** Board #10 June 2 8:00 AM - 9:30 AM

**Body Composition For Health And Performance: A Survey By The Working Group Of The IOC**

Nanna L. Meyer<sup>1</sup>, Jorunn Sundgot-Borgen<sup>2</sup>, Timothy G. Lohman<sup>3</sup>, Timothy R. Ackland<sup>4</sup>, Ronald J. Maughan, FACSM<sup>5</sup>, Arthur D. Stewart<sup>6</sup>, Suzanne Smith<sup>7</sup>, Wolfram Mueller<sup>8</sup>. <sup>1</sup>University of Colorado and United States Olympic Committee, Colorado Springs, CO. <sup>2</sup>The Norwegian School of Sport Sciences, Oslo, Norway. <sup>3</sup>University of Arizona, Tucson, AZ. <sup>4</sup>University of Western Australia, Perth, Australia. <sup>5</sup>Loughborough University, Loughborough, United Kingdom. <sup>6</sup>Robert Gordon University, Aberdeen, United Kingdom. <sup>7</sup>University of Colorado, Colorado Springs, CO. <sup>8</sup>Karl-Franzens University and Medical University of Graz, Graz, Austria.

(No relationships reported)

Low body mass (BM) and lean physique to enhance performance are the norm in weight-sensitive sports.

**PURPOSE:** To assess current use of body composition (BC) methods and identify problems and solutions with current BM and BC approaches.

**METHODS:** A 24-item survey was developed, including demographic and content questions related to BC methods. Content validity was obtained by review of the Ad Hoc Research Working Group on BC for Health and Performance of the IOC Medical Commission (n=7). The survey was distributed among international sporting organizations in electronic format. Frequencies and Chi-square analyses were computed.

**RESULTS:** 216 individuals responded, from 33 countries, representing various institutions, sports, and competitive levels. Of the sample, 86% currently assess BC, most frequently using skinfolds (ISAK: 50%; conventional: 40%; both: 28%), DXA (38%), BIA (29%), ADP (17%), and hydrostatic weighing (10%). Of those using skinfolds, more use ISAK at the international level, whereas conventional approaches are more common at regional/national level (p=0.006). The physiologist/sport scientist (54%) and sports dietitian/nutritionist (57%) were most frequently the professionals assessing BC, followed by MDs and ATCs, with some reporting the coach (5%). 36% of 116 respondents assess hydration status: more do so at international than regional/national level (p=0.028). Of 125 subjects answering the question of whether they thought that BC assessment raised problems, 69% said "yes", with most providing ideas for solutions. The most compelling solutions appeared to center around alternatives to BM and BC, such as frame size and height but most responses were sport-specific.

**CONCLUSIONS:** Results show a high use of BC, variable standardization, and high perception of problems related to BM and BC in sport. Future work should emphasize BC standardization and sport-specific use of parameters other than BM and BC.

3290 Board #11 June 2 8:00 AM - 9:30 AM

**Evaluation of Contributions Fitness and Health Behaviors to Predict Body Composition of US College Students**

Daniel C. S. Yeung, Rickie Lee Marker-Hoffman, Matthew G. Hinman, Jeanne D. Johnston. *Indiana University, Bloomington, IN.* (Sponsor: Georgia C. Frey, FACSM)

(No relationships reported)

**PURPOSE:** Evaluate the relative contributions physical fitness and health behaviors to predict body composition of US college students.

**METHODS:** College students from a mid-Western university were recruited via face-to-face contact, email, and fliers. Physical fitness was assessed with three measures: PACER multi stage 20-meter shuttle run, modified pull-up (MPU), and one-minute sit-up. Anthropometric assessment included height, weight, and average of 3 waist circumference measurements. Body composition (BC) was measured by bioelectrical impedance analysis (BIA). Self-reported questionnaire of health behaviors included physical activity, eating, sleeping and drinking habits. Outliers were identified and variables were transformed to ensure normality, where necessary. A stepwise regression analysis was performed to determine which variables are effective when predicting BC.

**RESULTS:** A total of 352 students were recruited. With 4 of them excluded as outliers, 149 males and 199 females were included in analysis. The best model included the following predictors: sex, square root of body mass index, MPU, logarithmic transformation of total physical activity, waist circumference and number of days having breakfast ( $R^2=0.84$ ,  $SEE=3.27$ ). An alternative model which did not include fitness testing variables was tested. Significant predictors of this model were sex, perceived general health, logarithmic transformation of alcohol consumption, square root of sleeping problems ( $R^2=0.55$ ,  $SEE=5.53$ )

**CONCLUSIONS:** Sex, physical fitness measures and health behaviors were significant predictors of BC in US college students. The alternate model which included just sex and health behaviors, without anthropometric measurements and fitness testing, was also effective when predicting BC.

---

3291 Board #12 June 2 8:00 AM - 9:30 AM

**Effects Of Telephone Intervention On Maintaining Fat Loss And Fitness Level Following Summer Intervention Program**

David A. Martinez<sup>1</sup>, Christopher R. Lopez<sup>1</sup>, Alejandra Cantu<sup>1</sup>, Areli Garcia<sup>2</sup>, Kyung-Shin Park<sup>2</sup>. <sup>1</sup>J. B. Alexander High School, Laredo, TX. <sup>2</sup>Texas A&M International University, Laredo, TX.

(No relationships reported)

**It is known that children gain most of extra weight and lose physical fitness during summer months due to physical inactivity and an increase in food intake. Summer intervention may reduce the prevalence of obesity in children; however reduction in body fat may be regained after finishing summer intervention.**

**PURPOSE:** The purpose of this study was to determine the effects of 8 week summer lifestyle intervention and 10 month follow-up telephone intervention on changes in body composition and level of physical fitness in Hispanic Children.

**METHODS:** 21 overweight or obese students (over 85 percentile in BMI score) aged 9-16 yrs completed 8 week summer intervention including 15 hour physical activity and 2 hour nutritional education per week and bi-weekly diet program. Students were later randomly assigned to follow-up telephone intervention for 10 months (TI) and control (CON). Physical characteristics, sit and reach (flexibility), grip strength (muscular strength), and 1 mile walking (estimated  $VO_{2max}$ ) were obtained before, a week after (POST) and 10 months following 8 week summer intervention (YEAR).

**RESULTS:** We previously reported (*Med Sci Sports Exerc* 43(5): S624, 2011) that eight week summer lifestyle intervention significantly reduced % body fat and improved flexibility, muscular strength, and estimated  $VO_{2max}$  in 21 students. TI statistically maintained % body fat (POST:23.7±2.1%→ YEAR:25.9±2.3, Mean±SE,  $P=.134$ ), flexibility (31.9±1.4cm→30.4±1.8,  $P=0.43$ ), and estimated  $VO_{2max}$  (44.1±1.66ml·kg<sup>-1</sup>·min<sup>-1</sup>→42.7±1.4,  $P=.215$ ). during 10 month telephone intervention period. CON lost all improvement during 10 month follow-up period: %body fat (22.2±2.0%→26.9±1.8,  $P=.001$ ), flexibility (32.7±1.7→27.3±1.2,  $P=.03$ ), and estimated  $VO_{2max}$  (45.9±1.8→39.8±2.0,  $P=.005$ ). Muscular strength was slightly increased in both TI and CON, but it was not significant.

**CONCLUSIONS:** 8 week summer lifestyle intervention improved body composition and level of physical fitness in Hispanic children. Results indicate that telephone intervention is an effective tool to maintain the improvement in body composition and levels of fitness obtained from an intensive summer lifestyle intervention program.

---

3292 Board #13 June 2 8:00 AM - 9:30 AM

**Variations in Regional and Total Adiposity in Active Individuals**

Kelli A. Carlson, David Q. Thomas, Adam Morris, Jillian Barnas, Laura Cooley, Laura Matter, Elizabeth Boyer. *Illinois State University, Normal, IL.*

(No relationships reported)

Physical activity has been demonstrated to be one of the best countermeasures to increasing overweight and obesity. However, the relationship between the type of physical activity one participates in and regional and total adiposity has not been adequately studied. Additionally, the distribution of adipose tissue has been linked to diabetes and cardiovascular and metabolic diseases.

**PURPOSE:** To determine the variations in regional and total adiposity in active individuals.

**METHODS:** Fifty college aged students participated in the study. The men comprised groups of recreationally competitive athletes (RCA; n = 13) and recreationally active men (RCM; n = 13). The women comprised groups of collegiate athletes (CA; n = 12) and recreationally active women (RAW; n = 12). Body composition measures included height, weight, waist circumference, truncal (subscapular, abdominal, mid-axillary, suprailiac crest) and appendicular skinfolds (anterior thigh, medial calf, tricep and bicep), and whole body adiposity via air-displacement plethysmography.

**RESULTS:** Descriptive data (means and standard deviations) were calculated for each group (RCA - Age: 20.2 ± 1.36; Waist: 79.9 ± 3.84; Trunk: 43.5 ± 11.91; App 32.9 ± 8.99; BF 10.1 ± 3.85; RCM - Age: 21.3 ± 1.84; Waist 80.4 ± 4.03; Trunk, 39.8 ± 7.89; App 31.7 ± 9.25; BF 10.4 ± 3.62; CA - Age: 20.1 ± 0.67; Waist: 69.7 ± 6.89; Trunk: 55.3 ± 21.40; App: 59.6 ± 12.75; BF: 21.6 ± 5.0; RAW - Age 20.1 ± 0.51; Waist 71.0 ± 3.32; Trunk: 66.7 ± 25.07; App 77.3 ± 24.93; BF: 25.3 ± 5.25). Paired-sample t-tests showed no significant differences (alpha = 0.05) for any score when comparing the two men's groups together or the two women's groups together except for the women's sum of appendicular skinfolds ( $t = 2.07$ ;  $p \leq 0.05$ ).

**CONCLUSION:** Variations in physical activity classification does not appear to effect total or regional adiposity in active college age individuals with the exception of the sum of appendicular skinfolds between female collegiate athletes and recreationally active females. Potential explanations for this include that at this age, active individuals are similar in body composition regardless of the reason for why they are active. Further investigation into why recreationally active females store more adipose appendicularly than collegiate female athletes is necessary..

---

3293 Board #14 June 2 8:00 AM - 9:30 AM

**Comparisons of Body Composition and Self-Perception of Body Type Among College Students**

Mark W. Baldis<sup>1</sup>, Tim Anderson<sup>2</sup>, Michael Coles<sup>2</sup>, Felicia Greer<sup>2</sup>. <sup>1</sup>Rocky Mountain University of Health Professions, Provo, UT. <sup>2</sup>California State University Fresno, Fresno, CA.

(No relationships reported)

Previous research suggests that individual perception of body size varies by gender and race, and that some cultural groups are more accepting of overweight body types. If particular groups of individuals positively value a specific body type, or erroneously classify their own body weights as acceptably healthy, when in fact they are deemed to be clinically overweight or obese, then they may be unreceptive to typical approaches toward weight management. This may result in an increased risk for the development of obesity-related chronic diseases.

**PURPOSE:** To examine the relationship between perceived body image and actual body composition, across race and gender, in a group of 240 college-aged students.

**METHODS:** Participants underwent skinfold body composition assessment and completed a questionnaire designed to elicit perceptions of body image and body weight status. Data summary of this cross-sectional study design included comparative descriptive statistics, frequencies, and relative frequencies.

---

**RESULTS:** Results suggested that one in four females, regardless of race, categorized as in the acceptable range for body fat percentage, identified themselves as overweight. Nearly 22% of males and 38% of female participants were categorized as overweight or obese, with 14 females and one male categorized as obese. Overweight and obese female participants were more than twice as likely as men to misperceive their overweight status. Only 44% of overweight and obese women correctly identified their weight category, whereas nearly 8 of 10 overweight and obese male participants accurately identified themselves as overweight or obese. Over half of all Asian (56%), Black (50%), and Hispanic (67%) males, categorized as in the acceptable range for body fat percentage, identified themselves as overweight. Over half of White males (57%) and females (80%), and Black females (50%), categorized as overweight, perceived themselves to be of "about the right weight". A far greater percentage of males (48%) compared to females (28%) fell into the lean category.

**CONCLUSION:** The results of this study suggest that there is a great deal of heterogeneity in the perception of body type. Clearly, men and women, and different ethnic groups, perceive their own body types quite differently, and incongruity exists even within groups.

---

3294 Board #15 June 2 8:00 AM - 9:30 AM

**Can Self-reported BMI Be Used As A Valid Measure Among Novice Runners?**

Martin S. Juul, Rasmus O. Nielsen, Sten Rasmussen. Aarhus University Hospital - Aalborg Hospital, Aarhus, Denmark.  
(No relationships reported)

There is an increased risk of running related injuries (RRI) among novice runners with a Body Mass Index (BMI) above 25. Information about BMI can be collected through questionnaires, when studies investigate if there is an association between BMI and RRI among novice runners. But can self-reported BMI be used as a valid measure compared to BMI measured with a calibrated weight.

**PURPOSE:** To determine the validity of self-reported BMI among novice runners.

**METHODS:** Data on BMI was obtained from a prospective follow-up study investigating the link between training exposure and the development of RRI. Healthy novice runners between the age of 18 to 65 and without lower extremity injuries were able to participate in the study. During July and August 2011 the participants were included in the study based on an online questionnaire. 1532 persons completed the questionnaire, of these, 970 were invited to a test at baseline after meeting the requirements for participation. Information about BMI was obtained in two ways; firstly, from the online based questionnaire where the participants had to report height and weight themselves. Secondly, the weight was measured with calibrated weight (Tanita SC-330) while their height was measured with a tape measure. Based on these data BMI were calculated based on the equation:  $BMI = \text{mass (kg)} / (\text{height (m)})^2$ . Paired t-test was used to compare mean difference between self-reported BMI and measured BMI. Bland Altman limits of agreement were used to calculate the 95 % prediction limits.

**RESULTS:** A total of 931 participants were measured and eligible to participate, of these, 2 were excluded due to data loss. The gender distribution was; 464 women with a mean age of  $36.8 \pm 10.0$  and a measured BMI of  $25.4 \pm 4.2$  and 465 men with a mean age of  $37.6 \pm 10.6$  and a measured BMI of  $26.6 \pm 3.8$ . Compared with measured BMI both men and women had a significant lower mean self-reported BMI of  $-0.23 [-0.34; -0.12]$ ,  $p < 0.001$  and  $-0.41 [-0.51; -0.31]$ ,  $p < 0.001$ , respectively. Among men and women the 95% limits of agreement were from  $-2.63$  to  $2.72$  and from  $-2.56$  to  $1.74$ , respectively.

**CONCLUSION:** Based on the findings from current study, BMI based on self-reported height and weight should be used with caution if the association between BMI and RRI is investigated.

3295 Board #16 June 2 8:00 AM - 9:30 AM

**The Relationships between Stress, Physical Activity and Body Composition in Women**

Jenelle R. Walker, Darith James, Pamela Swan, FACSM. Arizona State University, Phoenix, AZ.  
(No relationships reported)

**Stress can affect the intention-behavior relationship for physical activity (PA)** and elicit physiological responses that can affect health (Logan & Barksdale, 2008; McEwen & Lasley, 2003). Central or visceral obesity is now accepted as an independent risk factor for many chronic diseases. The physiological stress response has been shown to increase central body fat. PA may have an influence on this relationship.

**PURPOSE:** To describe the relationships between stress, body fat distribution and PA in women.

**METHODS:** This cross sectional study recruited women (25-65 years; N = 78) from the local Phoenix metropolitan area. A subgroup was randomly selected for objective measures of stress (morning saliva cortisol samples: 4 samples-15 min time periods), PA (Actigraph GT1M-7 day period), estimated VO<sub>2</sub> (submaximal Treadmill Test), %body fat (%BF-Bioelectrical Impedance) and waist circumference (WC).

**Analysis:** Subjects were grouped by cortisol levels into tertiles using area under the curve values. Data were analyzed using Pearson correlations, one-way ANOVA and Post Hoc analyses with PASW 18.

**RESULTS:** Descriptive statistics of the subgroup (N = 26) were mean age ( $41 \pm 10$  y), %BF ( $32 \pm 10.8$ ), WC ( $79.6 \pm 12.9$  cm), minutes of PA ( $141.85 \pm 114.8$ ) and estimated VO<sub>2</sub> ( $34.2 \pm 6.4$  ml/kg/min). A positive association was shown for stress level and %BF ( $r = .359$ ,  $p = .029$ ) and WC ( $r = .379$ ,  $p = .056$ ). An inverse association was shown for %BF and estimated VO<sub>2</sub> ( $r = -.785$ ,  $p = .000$ ) and minutes of PA ( $r = -.363$ ,  $p = .068$ ). Significant between group differences were found when comparing stress to %BF between the lowest and highest stress groups ( $p = .031$ ). Significant between group differences were found when comparing stress to estimated VO<sub>2</sub> ( $p = .024$ ) and to PA level ( $p = .034$ ) in the two highest stress groups.

**CONCLUSION:** Stress had a positive association with %BF and WC. %BF had an inverse association with PA and level of fitness. Participants with the lowest level of stress had higher %BF. Stress values were lower for those who had higher fitness levels and greater minutes of PA per week. These results indicate that PA can affect stress and %BF in women. Considering the increasing rates of metabolic diseases associated with inactivity properly coping with stress may be a key factor in improving health.

---

3296 Board #17 June 2 8:00 AM - 9:30 AM

**Does the Body Adiposity Index (BAI) Predict Change in CVD Risk Factors in Obese Women?**

Anne E. Mishler, John M. Kacicic, FACSM. University of Pittsburgh, Pittsburgh, PA.  
(No relationships reported)

Excess adipose tissue increases risk for cardiovascular (CVD) and other chronic diseases. The Body Adiposity Index (BAI), computed with measures of height and hip circumference, has recently been recommended for estimating adiposity. However, whether BAI is more predictive of change in CVD risk factors following weight loss compared to traditional measures of adiposity (weight and waist circumference) is unclear.

**PURPOSE:** To examine the association between change in BAI, weight, and waist circumference and change in CVD risk factors in overweight and obesity adults across a 6 month weight loss intervention.

**METHODS:** 184 female subjects (BMI:  $32.6 \pm 4.2$  kg/m<sup>2</sup>; Age:  $37.7 \pm 5.6$  kg/m<sup>2</sup>) participated in a 6-month behavioral weight loss intervention. Subjects were prescribed a reduced calorie diet (1200-1500 kcal/d). Subjects were also prescribed structured home-based exercise of 150-300 min/wk at a moderate-to-vigorous intensity. Weight, waist circumference (WC), BAI, along with fasting total cholesterol (CHOL), HDL cholesterol (HDL), LDL cholesterol (LDL), triglycerides (TRIG) were assessed at 0 and 6 months.

**RESULTS:** Weight ( $-8.3 \pm 4.8$  kg), WC ( $-6.5 \pm 8.3$  cm), and BAI ( $-3.5 \pm 2.3$ ) significantly decreased from 0 to 6 months ( $p < 0.05$ ). Weight change was significantly ( $p < 0.001$ ) associated with change in WC ( $r = .51$ ) and BAI ( $r = .79$ ). CHOL ( $-5.7 \pm 21.7$  mg/dl), TRIG ( $-16.4 \pm 41.1$  mg/dl), and LDL ( $-10.3 \pm 25.9$  mg/dl) decreased, whereas HDL increased ( $+1.3 \pm 7.0$  mg/dl). Change in weight ( $\beta = 1.708$ ,  $t = 6.230$ ,  $p < .001$ ), but not WC or BAI, predicted change in CHOL. Change in BAI ( $\beta = 0.513$ ,  $t = 2.333$ ,  $p = 0.021$ ), but not change in weight or WC, predicted change in HDL ( $R^2 = 0.024$ ,  $p < 0.05$ ). Neither change in weight, WC, or BAI predicted change in LDL or TRIG.

**CONCLUSIONS:** The weight loss intervention was effective at reducing weight, WC, and BAI, and this was accompanied by reductions in CHOL, TRIG, and LDL, and improvement in HDL. While BAI was more predictive of change in HDL than either weight or WC, BAI was not predictive of change in LDL or TRIG. BAI was not superior to change in weight to predict change in CHOL. Thus, further investigation is necessary to determine the utility of the BAI for predicting changes in risk factors with the context of a behavioral weight loss intervention. Supported by the National Institutes of Health (HL64991)

3297 Board #18 June 2 8:00 AM - 9:30 AM

**Dehydration and Acute Weight Gain in Mixed Martial Arts Fighters Prior Competition.**

Adam Jetton<sup>1</sup>, Alan Utter, FACSM<sup>1</sup>, Marcus Lawrence<sup>1</sup>, Tracie Haines<sup>1</sup>, Marco Meucci<sup>2</sup>. <sup>1</sup>*Appalachian State University, Boone, NC.* <sup>2</sup>*The "Università degli Studi di Roma Foro Italico", Rome, Italy.*  
(No relationships reported)

**PURPOSE:** The purpose of this investigation was to characterize the magnitude of dehydration and acute weight gain (AWG) in mixed martial arts (MMA) fighters prior competition.

**METHODS:** Urinary measures of hydration status and body mass were determined at ~24 h prior and then again ~2 h prior to competition in 40 MMA fighters (mean ± SD, age: 25.2 ± 4.1 yr, height: 1.77 ± 0.07 m, body mass: 75.80 ± 9.17 kg). AWG was defined as the amount of body weight the fighters gained in the ~22 h period between the official weigh-in and the actual competition.

**RESULTS:** On average, the MMA fighters gained 3.40 ± 2.18 kg or 4.4% of their body weight in the ~22 h period prior to competition. Urine specific gravity (Usg) significantly decreased ( $p < 0.001$ ) from 1.028 ± 0.007 to 1.020 ± 0.009 during the rehydration period. 40 % of the MMA fighters presented with a Usg of greater than 1.021 immediately prior to competition indicating significant or serious dehydration.

**CONCLUSIONS:** MMA fighters undergo significant dehydration and fluctuations in body mass (4.4 % avg) in the 24 h period prior to competition. Urinary measures of hydration status indicate that a significant proportion (40%) of MMA fighters are not successfully rehydrating prior competition and subsequently competing in a dehydrated state.

**Determinant Factors To Discriminate The Efficiency Index For Achieving A Body Mass Index Of 25**

Miguel A. Rojo-Tirado, Ana B. Peinado, Pedro J. Benito, on behalf of the PRONAF Study Group. *Technical University of Madrid, Madrid, Spain.*  
(No relationships reported)

Most studies have described how the body weight loss is when different treatments are compared, while others have also compared it by sex, or have taken into account psychosocial and lifestyle variables. However, it would be interesting to know how much body weight a person could lose before initiating an intervention, only knowing the body composition variables.

**PURPOSE:** To create a model to estimate the efficiency index for achieving a body mass index (BMI) of 25 (EIBMI25), determining the importance of each variable.

**METHODS:** One hundred eighty-five overweight and obese people (BMI: 25-34.9 kg•m<sup>-2</sup>), aged from 18 to 50 years, participated in the study. Four types of treatments were randomly assigned: strength training (S), endurance training (E), strength and endurance training (SE), and control group (C). All participants followed a 25% caloric restriction diet. The EIBMI25 expresses the way in which the participants achieved the BMI of 25, representing this goal the 100% of efficacy. A multivariate discriminant model including the variables age, sex, height, type of treatment (T), initial body weight (BW), initial fat mass (FM), initial muscle mass (MM) and initial bone mineral density (BMD) were performed having into account the groups above and below the mean of the EIBMI25. The discriminant model was built using the inclusion method in SPSS PASW 18 allowing us to find a function that could predict the efficiency index that an overweight or obese person could achieve in a 6 months weight loss intervention.

**RESULTS:** The discriminant model obtained would discriminate between the two groups of EIBMI25 with 84.3% of correct classification. The discriminant function obtained was (Wilks' Lambda=0.499,  $p < 0.001$ ):

Discriminant score = 9.015 - (0.018 x age) + (0.631 x sex [0=female; 1=male]) - (12.684 x height) - (0.202 x T [1=S; 2=E; 3=SE; 4=C]) + (0.077 x BW) + (0.118 x FM) + (0.021 x MM) + (1.189 x BMD).

**CONCLUSION:** The developed model could predict the EIBMI25 in the following way: if the discriminant score is close to 0.95 the range of EIBMI25 will be from 68.55 to 90.76 %, and if it is close to -1.05 the range will be from 90.76 to 117.35 %.

**Reduction In Muscle Capillary Is Inversely Associated With Vegf Expression In Non-obese Type 2 Diabetic Rats**

Hiroyo Kondo<sup>1</sup>, Hidemi Fujino<sup>2</sup>, Shinichiro Murakami<sup>2</sup>, Fumiko Nagatomo<sup>3</sup>, Naoto Fujita<sup>2</sup>, Akihiko Ishihara<sup>3</sup>. <sup>1</sup>*Nagoya Women's University, Nagoya, Japan.* <sup>2</sup>*Kobe University, Kobe, Japan.* <sup>3</sup>*Kyoto University, Kyoto, Japan.*  
(No relationships reported)

**PURPOSE:** Capillary regression is a major risk factor for complications in type 2 diabetes. In diabetic skeletal muscle, the angiogenesis would impair and involve multifactorial processes with both pro- and/or anti-angiogenic factors. Therefore, the purpose of the present study was to observe the muscle capillary architecture and to investigate changes in pro- and anti-angiogenic gene expressions within the soleus muscle of non-obese type 2 diabetic rats.

**METHODS:** Goto-Kakizaki (GK) type 2 diabetic (9 weeks old) and age-matched wild-type Wistar (Con) rats were used in this study. Plasma glucose, glycosylated haemoglobin (HbA1c), insulin level, and succinate dehydrogenase activity (SDH) were measured. The three-dimensional capillarization in soleus muscle was visualized and VEGF protein was measured by immunoblotting. Furthermore, the expression levels of HIF1 $\alpha$ , angiogenic factors (VEGF and angiopoietin-Tie2 pathways) and anti-angiogenic factor were quantified by TaqMan probe using real-time PCR.

**RESULTS:** Plasma glucose and HbA1c levels were significantly higher in GK than in Con rats. Insulin level in GK was lower than that of Con rats. Fiber cross-sectional area and capillary density in the soleus muscles were not significantly different between GK and Con rats. Visually, the capillaries had a smaller diameter in GK than Con rats and the mean capillary volume of GK was significantly low by 47% relative to the Con in soleus muscle. The SDH activities in muscle fiber of GK were lower than those in Con rats. The expression level of VEGF protein was not different between the GK and Con rats. Additionally, the mRNA expression levels of angiogenic factors (HIF-1 $\alpha$ , Flt-1, angiopoietin-1, and Tie2) were down-regulated in the GK, whereas VEGF and angiopoietin-2 were unaffected. These results suggest that the vasculature was destabilized in diabetic muscle. Furthermore, thrombospondin-1 level was higher in the GK than the Con.

**CONCLUSIONS:** These results indicate that a decrease in angiogenic and an increase in anti-angiogenic factor expressions may play an important role in capillary regression in skeletal muscle associated with diabetes.

**Subcellular Localization And Differential Expression Of Two Novel Anti-hif-1 $\alpha$  Variants**

Suzan Tug, Hendrik Forster, David Callau, Dirk Moser, Perikles Simon. *Social Science, Media and Sports, Mainz, Germany.*  
(No relationships reported)

Hypoxia Inducible Factor 1 (HIF-1 $\alpha$ ) is the most eminent Transcription Factor in the context of cellular response to hypoxia. To date, there have been identified more than 100 HIF-regulated genes. HIF-1-mediated pathways influence angiogenesis, metabolic adaptation, innate immune response and survival and apoptosis of cells. Although the structure of HIF-1 $\alpha$  and its

mechanisms are well known, the knowledge about the regulation of HIF-1 $\alpha$ , especially transcriptional and post-transcriptional, is still incomplete. Especially the expression of natural antisense transcripts (aHIF-1 $\alpha$ -variants) has not been studied in detail so far.

**PURPOSE:** We aimed to explore expression and localization of two so far unknown aHIF-1 $\alpha$ -variants under defined conditions *in vitro* and *in vivo* to enlarge the state of knowledge of the posttranscriptional regulation of HIF-1 $\alpha$ .

**METHODS:** We broadly analyzed the HIF-1 $\alpha$  gene locus on chromosome 14 by dint of UCSC genome browser. We considered several aspects, in particular mRNAs and *Expressed Sequence Tags*, CpG-islands, Poly-A-signals and transcription factor binding sites. *In silico* analysis, was followed by selection of primers to explore the expression of aHIF-1 $\alpha$  variants. Two unknown aHIF-1 $\alpha$ -variants emerged which were analyzed in *in vivo* and *in vitro* trials.

**RESULTS:** Expression of the two novel aHIF-1 $\alpha$  variants, terminating in exon 2 (aHIF-1 $\alpha$ Ex2) and exon 14 (aHIF-1 $\alpha$ Ex14) was confirmed in different cell lines. We verified them as spliced antisense variants of the HIF1 $\alpha$ -gene locus by sequencing and *in silico* analysis. Expression analysis of cellular fragments with GAPDH and 7sk as housekeeping genes allowed us to identify aHIF-1 $\alpha$ Ex2 as nuclear and aHIF-1 $\alpha$ Ex14 as cytoplasmatic variant. *In vitro* trials revealed that both variants are differentially expressed after induced hypoxia (CoCl<sub>2</sub>) and that aHIF-1 $\alpha$ Ex14 expression correlates significantly with the HIF-1 $\alpha$  splice variants with and without exon 14 ( $r=0.953$  and  $0.949$ , respectively). However, exercise induced hypoxia *in vivo* (half marathon) showed no effect on expression of the two antisense RNAs.

**CONCLUSION:** Due to their specific localization, ubiquitary and differential expression in response to hypoxia, both aHIF-1 $\alpha$ -variants are presumably associated with the regulation of HIF1 $\alpha$  and thereby with the regulation of HIF-1.

### The Effect Of Short-term Exercise On VEGF And Vessel Growth Of Middle-aged Brain

Jo-Ping Lee<sup>1</sup>, Chin-Lung Fang<sup>1</sup>, Chia-Hua Kuo<sup>2</sup>. <sup>1</sup>National Taiwan Normal University, Taipei, Taiwan. <sup>2</sup>Graduate Institute of Sports Science, Taipei, Taiwan.  
(No relationships reported)

**PURPOSE:** A determinant onset of aging in hippocampus has been evident at middle age. Angiogenesis, critical for maintaining brain health, was known to be enhanced by exercise. However, the expression of angiogenic and age-related inflammatory factors in response to exercise was not well-clarified in hippocampus. This study investigated the effects of acute and short-term exercises on the capillary density and expression of angiogenic and inflammatory factors of young and middle-aged brain regions.

**METHODS:** 3- and 12-month old male Sprague-Dawley rats were assigned to young control (YC), young exercise (YE), old control (OC) and old exercise (OE). Hippocampus and motor cortex were collected after single and 3-week swimming exercise. The protein expression of VEGF, VEGF receptors, Angiopoietin and its receptor, RAGE and CD68 with capillary density were analyzed.

**RESULTS:** Comparing to YC, ~2-fold expressions of partial angiogenic factors (Flt-1 and Ang-1) and CD68 were determined in OC motor cortex but not hippocampus. Only for young, angiogenic factors in both brain regions significantly responded to acute exercise but with no further changes observed after 3-week swimming. Meanwhile, capillary density was significantly higher in YE than YC for both brain regions after 3-week swimming but not in the middle-aged (Motor cortex:  $316.6 \pm 19.5$  vs.  $492.6 \pm 41.0/\text{mm}^2$ ; Hippocampus:  $303.3 \pm 24.5391.2 \pm 20.2/\text{mm}^2$ ). Otherwise, the inflammatory response expressed by CD31 was noted in OE, particularly in hippocampus.

**CONCLUSIONS:** These findings suggested angiogenic factors can be modulated to perform the appropriate vascular network following the exercise challenge in the brain. Importantly, exercise might accomplish an environment for middle-aged brain toward angiogenesis.

Key words: angiogenesis, age, swimming exercise, hippocampus

### The Influence of Resistance Training on Primary Hemostatic Responses

Brent C. Creighton, Brian Kupchak, Juan Aristizabal, Hui Ying Luk, David Hooper, David Looney, Jeff S. Volek, FACSM, Carl M. Maresh, FACSM, William J. Kraemer, FACSM. University of Connecticut, Storrs, CT.  
(No relationships reported)

**OBJECTIVE:** The growing incidence of acute cardiovascular diseases (CVD) has propelled the investigation of potential ways to help combat this epidemic. The likely connection between platelet activity and the development of CVD has raised the question of whether or not platelet function varies in exercising individuals. Prolonged resistance training has been linked to a possible reduction in hyperaggregability of platelets, especially following acute strenuous exercise. The present investigation was designed to explore the effects of an acute resistance exercise test (AERET) and recovery on the primary hemostatic system in both resistance trained and untrained individuals.

**METHODS:** Ten resistance trained (RT) (mean  $\pm$  SE, age,  $26.0 \pm 1.4$  yr; height,  $175.1 \pm 2.7$  cm; weight,  $79.6 \pm 4.3$  kg) and ten untrained (UT) individuals (age,  $26.4 \pm 2$  yr; height,  $170.3 \pm 2.4$  cm; weight,  $67.9 \pm 5.4$  kg) performed an AERET (6 sets of 10 repetitions of heavy squats @ 80% 1-RM). Blood samples were obtained before, immediately after and at 15, 60 and 120 minutes following the AERET. Blood samples were analyzed for platelet count, von Willebrand Factor (vWF), Beta Thromboglobulin ( $\beta$ -TG) and Platelet Factor 4 (PF4).

**RESULTS:**  $\beta$ -TG showed differences ( $P < 0.05$ ) between RT and UT at +15 min ( $32.8 \pm 2.6$  IU/ml vs.  $46.2 \pm 3.1$  IU/ml) and +60 min ( $28.2 \pm 2.6$  IU/ml vs.  $39.0 \pm 3.6$  IU/ml), respectively. Both groups showed a main effect for time in platelet count, vWF and  $\beta$ -TG following the AERET, whereas PF4 remained unchanged. All blood variables returned to baseline values by 120 minutes following exercise.

**CONCLUSION:** RT individuals demonstrated reduced platelet activation *in vivo* in response to an acute bout of heavy resistance exercise compared to UT individuals. Reduced platelet activation could be attributed to training status as shown by reduction in plasma levels of  $\beta$ -TG measured in the RT group.

### A 12 Week Of Aerobic Exercise Training On VEGF Related Proteins After 3 Month Detraining In Human Skeletal Muscle

Yu Nah Jeon, Zhou Xiang Shan, Ah Young Lee, Hyo Jeong Kim, Chang Keun Kim. Korea national sport university, seoul, Korea, Democratic People's Republic of Korea.  
(No relationships reported)

The VEGF gene may be directly linked to angiogenesis with a higher specificity for stimulating vascular endothelial cells. Increased expression of VEGF may play an important role in the primary mechanism responsible for increasing the capacity of aerobic metabolism within cardiac and skeletal muscles. Hypoxia-inducible factor-1 $\alpha$  (HIF-1 $\alpha$ ) can also be a factor when skeletal muscle cells are exposed to hypoxic environment.

**PURPOSE:** The present study was performed to investigate the effect of long-term endurance training on VEGF and HIF-1 $\alpha$  protein expressions in skeletal muscles after 3 month detraining.

**METHODS:** Five female aerobic athletes and age matched five untrained subjects were participated in the present study. All subjects refrained regular physical activities for three months before this study. The exercise program, for the experimental group, consisted of 10-minute stretching and 60-minute treadmill walking with 60-80% of  $\text{VO}_2\text{max}$  for 12 weeks. Muscle samples obtained from vastus lateralis before and after training, and analyzed a relevant protein expressions using SDS-PAGE and Western blotting.

**RESULTS:** There were no differences between the two groups in total VEGF protein expression. The protein expression of VEGF 165 isoform increase by 37.5% ( $p = .014$ ) in untrained group, whereas unchanged in trained group. The same trend was demonstrated that HIF-1 $\alpha$  protein expression in untrained group increased by 69.4% ( $p = .015$ ), whereas unchanged in trained group.

**CONCLUSIONS:** A 12 week of aerobic training may not induce an increase in vascular endothelial cell growth related protein expression in well-trained athletes even after 3 month detraining.

3304 Board #25 June 2 9:30 AM - 11:00 AM

**High-Intensity Endurance Training but not Vitamin C Changes Vascular Responsiveness in Diabetic Rats**

Juan M. Murias, Oscar A. Campos, Katharine E. Hall, Matthew W. McDonald, Kenneth N. Grise, Christopher W.J. Melling, Earl G. Noble. *The University of Western Ontario, London, ON, Canada.* (Sponsor: Donald H. Paterson, FACSM)  
(No relationships reported)

Type I diabetes is associated with endothelial dysfunction and reduced bioavailability of nitric oxide (NO), resulting in impaired vasodilation. High-intensity endurance training improves endothelium-dependent vasodilation. Additionally, antioxidants are likely to reduce oxidative stress and increase NO bioavailability.

**PURPOSE:** To examine the effects of short-term high-intensity endurance training and Vitamin C on endothelium-dependent vasodilation in different arteries within the vasculature.

**METHODS:** Twenty male Sprague-Dawley rats were assigned to a control diabetic (CD; n=10) or a high-intensity endurance training (HI; n=10) group. Diabetes was induced with Streptozotocin and insulin pellets were implanted to maintain glucose concentration within 9-15 mM. HI exercised on a treadmill with a 6% grade at 27 m/min, 5 times a week, 1 h a day for 6 weeks. Rats were sacrificed 15 h after their last bout of exercise. Femoral and aorta arteries were excised, cleaned of connective tissue and rings of ~2 mm length were mounted onto a myography system. Vasorelaxation responses to acetylcholine (ACh  $10^{-4}$ , (ACh)) and ACh  $10^{-4}$  plus Vitamin C  $10^{-4}$  (VIT C) were measured and modeled as a mono-exponential function using non-linear regression.

**RESULTS:** The adjustment for the vasorelaxation response ( $\tau$ ) was faster in HI (6.1s) compared to CD (9.2s) ( $p<0.05$ ). The  $\tau$  of the femoral artery was shorter (6.0s) than that of the aorta artery (9.3s). Adding vitamin C resulted in no significant changes in the responsiveness of the vessels (overall response 7.6s and 7.8s for ACh and VIT C, respectively with no interaction effects). The time delay (TD) before the onset of vasorelaxation did not differ between groups or vessels but was shorter in ACh (4.1s) compared to the VIT C (4.5s) condition ( $p<0.05$ ). Thus, the mean response time ( $\tau$ +TD) remained the same in both conditions (ACh, 11.7s and VIT C, 12.3s) but it was still shorter in HI (10.3s) compared to CD (13.7s) and in the femoral (10.4s) compared to the aorta (13.5s).

**CONCLUSION:** Although vascular responsiveness was faster in response to HI in both the aorta and femoral arteries, the rate of adjustment in the femoral was always faster than in the aorta. Finally, adding vitamin C as an antioxidant resulted in no further changes in the dynamic adjustment of the vessels.

**Effects Of Exercise Training On Endothelium-Dependent Vasodilation In Cerebral Arteries**

Scott A. Spier, Elisa Boyd, Amanda de Jong, Landon Evans. *University of Texas at Tyler, Tyler, TX.*  
(No relationships reported)

Endothelium-dependent vasodilation and endothelial nitric oxide synthase (eNOS) protein expression are enhanced with exercise training in the peripheral vasculature. However, the effect of exercise training on endothelium-dependent vasodilation of the cerebral vasculature has not been well established.

**PURPOSE:** The purpose of this study was to test the hypothesis that exercise training enhances endothelium-dependent vasodilation of large cerebral arteries.

**METHODS:** Dose-response relationships for endothelium-dependent and endothelium-independent vasodilation were determined in posterior communicating arteries (PCoA) of sedentary (SED) and exercise-trained (ET) male rats. ET rats ran on a motorized rodent treadmill at 15 m/min (15° incline), 60 min/day, 5 d/wk for 10 wk. PCoA were isolated from the brain of both SED and ET rats, cannulated, and pressurized to 90 cm H<sub>2</sub>O via hydrostatic reservoirs. Luminal diameter changes were determined in response to the endothelium-dependent vasodilator, Bradykinin (BK) ( $10^{-13}$  -  $10^{-7}$  M) and the endothelium-independent, direct vascular smooth muscle dilator, sodium nitroprusside (SNP,  $10^{-10}$  -  $10^{-4}$  M).

**RESULTS:** Responsiveness to BK was greater in PCoA of ET rats ( $83 \pm 3\%$  of maximal possible vasodilation) compared to SED rats ( $50 \pm 8\%$  of maximal possible vasodilation), whereas responsiveness to the endothelium-independent vasodilator SNP was not different between PCoA of SED and ET rats ( $91 \pm 3\%$  vs.  $89 \pm 4\%$  of maximal possible vasodilation, respectively).

**CONCLUSION:** These data demonstrate that exercise training results in enhanced endothelium-mediated vasodilation in PCoA, whereas vascular smooth muscle sensitivity of PCoA to nitric oxide is unaffected by exercise training.

3306 Board #27 June 2 9:30 AM - 11:00 AM

**Impact of Training Status on Vascular Health in Young Adult Males**

Anita T. Cote, Aaron A. Phillips, Shannon S.D. Bredin, Darren E.R. Warburton. *University of British Columbia, Vancouver, BC, Canada.*  
(No relationships reported)

The benefits of physical activity for cardiovascular health are irrefutable. Aortic stiffness and cardiovagal baroreceptor sensitivity (BRS) are strong predictors of cardiovascular disease risk and mortality. Lower pulse wave velocity (PWV; an index of arterial stiffness) and higher BRS have been shown in habitually active individuals in comparison to their physically inactive counterparts. In addition, endurance training has been shown to improve PWV and BRS in both apparently healthy and clinical populations. However, the effects of chronic high volume and intensity exercise (as typically performed by highly trained endurance athletes) on vascular health is not clear.

**PURPOSE:** To assess various indicators of vascular health in highly trained cyclists and normally active young adults.

**METHODS:** Eleven male category 1/2 road racers (ET; Age =  $28 \pm 6$  (SD) yr) and eleven normally active males (NA; Age =  $32 \pm 6$  (SD) yr) participated in this study. Measures included self-reported training volume/intensities and directly assessed vascular function (PWV, BRS and arterial compliance), maximal aerobic power ( $VO_{2max}$ ), and body composition (DEXA).

**RESULTS:** The groups did not differ in age, body composition, or blood pressure. The ET group had significantly higher  $VO_{2max}$  and power output ( $59.7 \pm 6.2$  vs.  $46.8 \pm 5.1$  mL·kg<sup>-1</sup>·min<sup>-1</sup> and  $405 \pm 61$  vs.  $327 \pm 48$  W, respectively;  $p<0.01$ ). Of the vascular measures, large artery compliance (LAE) and BRS were significantly higher in ET ( $23.2 \pm 6.1$  vs.  $18.8 \pm 3.0$  mL·mmHg<sup>-1</sup> and  $35.7 \pm 17.0$  vs.  $22.7 \pm 9.5$ , respectively). However, no significant differences were evident for PWV, heart rate variability, or small artery compliance. There were significant relationships between resting LAE and the ratio of spectral analysis of RR interval ( $r=0.57$ ;  $p<0.01$ ) and LAE with BRS ( $r=0.56$ ,  $p<0.01$ ). All measures were within published norms for healthy young adults.

**CONCLUSIONS:** The results of this study suggest that training status in healthy young adults may affect arterial compliance and BRS; however, PWV does not appear to be as affected. The impact of a dose response on vascular health requires further research.

3307 Board #28 June 2 9:30 AM - 11:00 AM

**The Effect Of Cerebral Blood Flow On Central Chemoreflex During Orthostatic Stress**

Shigehiko Ogoh<sup>1</sup>, Hidehiro Nakahara<sup>2</sup>, Kazunobu Okazaki<sup>3</sup>, Tadayoshi Miyamoto<sup>2</sup>. <sup>1</sup>Toyo University, Kawagoe-shi, Saitama, Japan. <sup>2</sup>Morinomiya University of Medical Sciences, Osaka-shi, Osaka, Japan. <sup>3</sup>Osaka City University, Osaka-shi, Osaka, Japan.  
(No relationships reported)

**PURPOSE:** Central respiratory chemoreflex is reset during orthostatic stress, such that minute ventilation ( $V_E$ ) is greater for a given end tidal carbon dioxide ( $P_{ET}CO_2$ ). However, the underlying physiological mechanism(s) for this remains unclear. We hypothesized that postural reductions in cerebral blood flow (CBF) modify the central ventilatory chemoreflex.

**METHODS:** To test this hypothesis, we examined the relationship between changes in middle cerebral artery mean blood velocity (MCA  $V_{mean}$ ) and  $V_E$  in subjects breathing different levels of inspired  $CO_2$  (0, 3.5, 5%  $CO_2$ ) while in the supine position and undergoing simulated orthostatic stress (lower body negative pressure; LBNP, -40mmHg). Ten healthy men with a mean age of  $23.6 \pm 1.9$  yr (mean  $\pm$  S.D.) voluntarily participated in this study.

**RESULTS:** LBNP decreased MCA  $V_{mean}$  and tended to increase  $V_E$ , regardless of the level of inspired  $CO_2$ . As expected, the regression line relating  $V_E$  to  $P_{ET}CO_2$  was shifted leftwards from supine to LBNP. The average sensitivity (i.e. slope) of the  $V_E$ - $P_{ET}CO_2$  relationship was enhanced during LBNP ( $0.40 \pm 0.02$  at supine to  $0.44 \pm 0.03$  l/min/mmHg during LBNP; mean  $\pm$  S.E.;

P=0.003). In contrast, cerebral CO<sub>2</sub> reactivity (the sensitivity of the MCA  $V_{\text{mean}}\text{-P}_{\text{ET}}\text{CO}_2$  relationship) was significantly decreased during LBNP from  $1.43 \pm 0.18$  to  $1.36 \pm 0.17$  cm/s/mmHg (P=0.001). Orthostatic stress induced-changes in  $V_E$  were significantly associated with decreases in MCA  $V_{\text{mean}}$  from supine to LBNP (P=0.018), but were not associated with changes in  $P_{\text{ET}}\text{CO}_2$  (P=0.2).

**CONCLUSIONS:** These findings support our hypothesis that postural reductions in CBF modify the central ventilatory chemoreflex by moving its point of operation. We speculate that orthostatic stress induced decreases in CBF attenuate the “washout” of CO<sub>2</sub> from the brain and result in augmented increases in  $V_E$  via the central chemoreflex.

**Low-dose Aspirin Attenuates Heart Rate but not Blood Pressure Increase during Isometric Exercise in Humans**

Rachel C. Drew, Matthew D. Muller, Michael D. Herr, Cheryl Blaha, Jessica Mast, Todd Nicklas, Lawrence I. Sinoway. *Pennsylvania State University, Hershey, PA.*  
(No relationships reported)

Muscle afferent feedback is known to contribute towards the increased heart rate (HR) and mean arterial blood pressure (MAP) observed during exercise. Group III and IV afferent nerve fiber endings (muscle mechanoreceptors and metaboreceptors, respectively) can both be stimulated by metabolites produced during muscular work. However, the role of one such metabolite, thromboxane A<sub>2</sub>, in causing the increased HR and MAP during exercise in humans is unknown.

**PURPOSE:** Therefore, we sought to determine the effects of blocking thromboxane A<sub>2</sub> production via low-dose aspirin on HR and MAP during isometric calf exercise in humans.

**METHODS:** Nine young, healthy subjects (4 male) attended on 2 separate days and performed 2 trials on each day; a 2-min baseline followed by either 1.5mins of further rest (0% maximal voluntary contraction (MVC)), or 1.5mins of one-legged isometric calf exercise at 70% MVC (70% MVC). One visit was after having taken a placebo (Pla) for 7 days, and one visit after taking low-dose (81mg) aspirin (Asp) for 7 days. The order of visits was counterbalanced, as was the order of trials within each visit. HR (ECG) and MAP (Finapres) were continuously recorded during all trials.

**RESULTS:** Baseline HR was similar in all trials over both visits ( $59 \pm 2$ ,  $61 \pm 2$ ,  $61 \pm 3$  and  $63 \pm 3$  b.min<sup>-1</sup> for 0% Pla, 70% Pla, 0% Asp and 70% Asp, respectively). HR did not change significantly from baseline during either of the 0% MVC trials. However, the HR increase from baseline observed during 70% MVC with aspirin ( $11 \pm 3$  b.min<sup>-1</sup>) was significantly lower than during 70% MVC with placebo ( $15 \pm 3$  b.min<sup>-1</sup>) (P=0.046). Baseline MAP was similar in all trials over both visits ( $87 \pm 2$ ,  $86 \pm 3$ ,  $85 \pm 2$  and  $85 \pm 3$  mmHg for 0% Pla, 70% Pla, 0% Asp and 70% Asp, respectively). MAP did not change significantly from baseline during either of the 0% MVC trials. The MAP increase from baseline observed during the 70% MVC with aspirin ( $93 \pm 3$  mmHg) was similar during 70% MVC with placebo ( $93 \pm 3$  mmHg).

**CONCLUSION:** These results suggest that low-dose aspirin attenuates the increase in HR but not MAP during isometric calf exercise in humans. This is likely due to reduced metabolite stimulation of muscle afferents during exercise when thromboxane A<sub>2</sub> production is inhibited, which affects the control of HR more than MAP.

**3309** Board #30 June 2 9:30 AM - 11:00 AM

**Muscle Metaboreflex Modulates Dynamic Cardiovascular and Cerebrovascular Responses to Acute Hypotension in Humans**

Masashi Ichinose<sup>1</sup>, Kazuhito Watanabe<sup>2</sup>, Bun Tsuji<sup>2</sup>, Takeshi Nishiyasu<sup>2</sup>. <sup>1</sup>Meiji University, Tokyo, Japan. <sup>2</sup>University of Tsukuba, Tsukuba, Japan.  
(No relationships reported)

During heavy exercise, the arterial baroreflexes and the muscle metaboreflex are hypothesized to be activated, and to interact in ways that lead to modulation of the primary cardiovascular reflex responses. However, the interaction of these two reflexes in cerebral circulation has never been investigated.

**PURPOSE:** We aimed to investigate whether the muscle metaboreflex modulates arterial baroreflex-mediated cardiovascular responses as well as cerebrovascular responses to acute hypotension in humans.

**METHODS:** Acute hypotension was induced nonpharmacologically in six healthy subjects by releasing bilateral thigh cuffs after nine minutes of suprasystolic resting ischemia with and without muscle metaboreflex activation (via post exercise muscle ischemia after one minute static handgrip exercise at 50% MVC). We simultaneously measured beat-to-beat mean arterial blood pressure (MAP), heart rate (HR), cardiac output (CO), forearm blood flow (FBF) and middle cerebral artery mean blood velocity (MCAVM). Changes in measured variables induced via thigh cuff release were determined relative to their concomitant baseline values.

**RESULTS:** The thigh cuff release evoked rapid reductions in MAP, FBF, forearm vascular conductance and MCAVM and rises in HR, CO, TVC and cerebrovascular conductance index to similar extent in control and during muscle metaboreflex activation. The muscle metaboreflex activation enhanced the arterial baroreflex mediated peripheral vasoconstriction as evidenced by an earlier start of MAP recovery (control vs. muscle metaboreflex activation; length of time before the start of MAP recovery,  $11.5 \pm 1.1$  vs.  $5.8 \pm 0.7$  s,  $p < 0.05$ ) and faster returns of MAP and TVC to the baseline ( $0.9 \pm 0.2$  vs.  $2.3 \pm 0.5$  and  $-5.4 \pm 1.1$  vs.  $-9.8 \pm 1.1$  %,  $p < 0.05$ ). In addition, the rate of regulation, an index of cerebral autoregulation, was enhanced during muscle metaboreflex activation ( $0.189 \pm 0.018$  vs.  $0.310 \pm 0.020$ /s,  $p < 0.05$ ). Furthermore, MCAVM recovered faster with muscle metaboreflex activation ( $1.3 \pm 0.1$  vs.  $4.3 \pm 0.6$  %,  $p < 0.05$ ).

**CONCLUSION:** These results suggest that during muscle metaboreflex activation, the arterial baroreflex mediated peripheral vasoconstriction as well as the cerebral autoregulation to acute hypotension are augmented and result in a faster recovery for the cerebral blood flow.

**3310** Board #31 June 2 9:30 AM - 11:00 AM

**Contribution of Endothelin-1 to Skeletal Muscle Blood Flow and Oxygen Consumption during Exercise**

Zachary Barrett-O'Keefe, Stephen J. Ives, Joel D. Trinity, Garrett Morgan, Matthew J. Rossman, Jayson R. Gifford, Anthony J. Donato, Russell S. Richardson, D. Walter Wray. *University of Utah, Salt Lake City, UT.*  
(No relationships reported)

**PURPOSE:** Although it has been documented that endothelin-1 (ET-1) - mediated vasoconstriction is attenuated during exercise in an intensity-dependent manner, the role of endogenous ET-1 in regulating skeletal muscle blood flow and its ultimate effect on oxygen consumption (VO<sub>2</sub>) over a large spectrum of exercise intensities is unknown.

**METHODS:** Six healthy men and women ( $25 \pm 2$  yrs) performed knee-extensor exercise at 20, 40, 60, 80, and 90% of maximal work rate (WR<sub>max</sub>) before and after local ET-1 receptor subtype A (ET<sub>A</sub>) blockade (intra-arterial infusion of BQ-123 at 10 nmol/min/l thigh volume). Arterial blood pressure (femoral arterial catheter), heart rate (3-lead ECG), single-leg blood flow (Doppler ultrasound), single-leg arterial-venous oxygen difference (a-VO<sub>2diff</sub>) (blood gases), and single-leg VO<sub>2</sub> were determined at rest and during all levels of exercise.

**RESULTS:** At rest, ET<sub>A</sub> receptor inhibition did not alter leg blood flow, a-VO<sub>2diff</sub>, or single-leg VO<sub>2</sub> (P>0.05). In contrast, ET<sub>A</sub> receptor inhibition during exercise induced an ~18% increase in leg blood flow of the exercising limb across all levels of exercise (P<0.05). This increase in leg blood flow was accompanied by a ~10% increase in single-leg VO<sub>2</sub> (P<0.05) across all work rates, in light of an unaltered a-VO<sub>2diff</sub> (P>0.05) between control and BQ-123 trials. Heart rate and arterial blood pressure increased in an intensity-dependent manner during exercise, but did not differ between the control and BQ-123 trials (P>0.05).

**CONCLUSION:** These data reveal, for the first time, an ET<sub>A</sub> receptor-mediated restraint of skeletal muscle blood flow during knee-extensor exercise in young, healthy humans, and further suggests that altering blood flow will directly augment VO<sub>2</sub>.

**ATP<sub>γ</sub>S Does Not Potentiate the Muscle Chemoreflex Response to Lactic Acid**

Audrey J. Stone, Katsuya Yamauchi, Anna K. Leal, Marc P. Kaufman. *Penn State College of Medicine, Hershey, PA.*  
(No relationships reported)

**PURPOSE:** Birdsong et al. (Neuron 68: 739-749, 2010) have shown that acute exposure to ATP potentiated acid sensing ion channel (ASIC) evoked currents from single dorsal root ganglion cells innervating hindlimb muscles of rats. This finding prompted us to determine whether the results seen in a freshly dissociated single cell preparation in vitro would translate to an in vivo preparation.

**METHODS:** We measured the pressor and cardioaccelerator responses to injecting lactic acid (24mM; 0.4mL), an ASIC agonist, into the femoral artery of decerebrated, unanesthetized rats (N=6) whose hindlimbs were freely perfused both before and after administration of ATP $\gamma$ S (200mg/kg), a stable agonist of purinergic 2 receptors.

**RESULTS:** We found that the increase in mean arterial pressure evoked by lactic acid after ATP $\gamma$ S was not different from the increase evoked by lactic acid before ATP $\gamma$ S (15 $\pm$ 2mmHg vs. 14 $\pm$ 2mmHg, respectively;  $p>0.05$ ). The increase in heart rate evoked by lactic acid after ATP $\gamma$ S was significantly but modestly greater than the increase evoked by lactic acid before ATP $\gamma$ S (3 $\pm$ 1 beats per min vs. -2 $\pm$ 1 beats per min, respectively;  $p<0.05$ ).

**CONCLUSION:** ATP $\gamma$ S does not appear to potentiate the muscle chemoreflex evoked by lactic acid in rats with freely perfused hindlimbs. Supported by NIH RO1-HL030710 and P01 HL096570.

**Sex Differences In Cardiac Autonomic Modulation And Baroreflex Sensitivity Following Differential Exercise Training**

Ashley N. Lightner, Chelsea D. Curry, Scott R. Collier, FACSM. *Appalachian State University, Boone, NC.*

(No relationships reported)

Maintained balance between sympathetic and parasympathetic tone within the cardiac autonomic systems is a vital component of cardiovascular regulation. Heart rate variability (HRV) and baroreflex sensitivity (BRS) are non-invasive clinical measures used to assess cardiac autonomic modulation and pressor sensitivity. Aerobic exercise (AE) training has been shown to increase HRV and BRS; however, little is known concerning a sex specific response following AE or resistance exercise (RE) training. The purpose of this study was to assess short-term AE training versus RE training on HRV and BRS in a mixed-sex hypertensive cohort.

**METHODS:** Forty pre- to stage-1 essential hypertensives between the ages of 33 and 60 years old (20 men, 20 women) underwent either AE training [30 minutes of treadmill exercise, 3 days per week at 65% of peak oxygen consumption] or RE training (3 sets of 10 repetitions for 9 major muscle groups, 3 days per week at 65% of 10 repetition maximum). Demographics, electrocardiogram (ECG) recordings, beat-to-beat blood pressure (BP), and a heads-up tilt test were performed at baseline, pre and post-4 week training period. A rmANOVA was employed to determine differences (mode (resistance vs. aerobic) x time (pre- vs. post) x sex (male vs. female)).

**RESULTS:** A significant increase in BRS was shown in males and females (7.98  $\pm$  1.49 to 8.95  $\pm$  1.72 ms mm<sup>-1</sup> Hg<sup>-1</sup>, 4.54  $\pm$  1.59 to 5.97  $\pm$  1.83 ms mm<sup>-1</sup> Hg<sup>-1</sup>, respectively) following AE training; however, RE training, showed decreases in BRS in males and no change in females. Following RE training a significant increase in LF:HF ratio was shown in males, yet decreases in females (286.56  $\pm$  149.24 to 417.25  $\pm$  175.8 ms<sup>2</sup>, 86.5  $\pm$  247.48 to 40.6  $\pm$  291.54 ms<sup>2</sup>, respectively).

**CONCLUSIONS:** The increase in LF:HF may explain the decreases seen in BRS in men following RE training, deriving a better benefit for RE training for women.

**Calf Muscle Oxygen Saturation In Peripheral Artery Disease Patients With Different Types Of Leg Pain**

Polly S. Montgomery<sup>1</sup>, Donald E. Parker<sup>1</sup>, Aman Khurana<sup>1</sup>, Steve M. Blevins<sup>1</sup>, Raphael M. Ritti-Dias<sup>2</sup>, Andrew W. Gardner<sup>1</sup>. <sup>1</sup>University of Oklahoma Health Science Center, Oklahoma City, OK. <sup>2</sup>Pernambuco University, Pernambuco, Brazil.

(No relationships reported)

**PURPOSE:** To compare calf muscle hemoglobin oxygen saturation (StO<sub>2</sub>) and exercise performance during standardized treadmill exercise in patients with peripheral artery disease (PAD) who describe different types of exertional leg pain, and to compare secondary outcomes consisting of daily ambulatory activity and exercise performance during a 6-minute walk test.

**METHODS:** One hundred fourteen PAD patients were evaluated on leg pain symptoms using the San Diego claudication questionnaire, which defined patients as having atypical exertional leg pain (n = 31), claudication (n = 37), or leg pain on exertion and rest (n = 46). Patients were evaluated on a standardized, graded treadmill test during which calf muscle StO<sub>2</sub> was continuously monitored, 6-minute walk test, walking impairment questionnaire (WIQ), and ambulatory activity monitored during one week.

**RESULTS:** All patients experienced symptoms during the treadmill test consistent with claudication. The groups were not significantly different on the primary outcomes of time to reach the minimum calf muscle StO<sub>2</sub> (p = 0.350) and peak walking time (p = 0.238) during treadmill exercise. Patients with atypical leg pain had the highest daily ambulatory activity for total strides per day (p = 0.032), average daily cadence (p = 0.010), maximum cadences for durations between 5 min (p = 0.035) and 60 min (p = 0.029), speed score on the WIQ (p = 0.006), and lowest rating of perceived exertion at the end of the 6-minute walk test (p = 0.017).

**CONCLUSIONS:** PAD patients with atypical leg pain have vascular-mediated limitations in exercise performance during standardized treadmill testing similar to patients with claudication, but they have higher levels of daily ambulatory activity in the community setting and higher perceived ambulatory function. The clinical significance is that all symptomatic PAD patients, irrespective of their leg pain type, should be treated to improve symptomatology.

**3314** Board #35 June 2 9:30 AM - 11:00 AM

**Evidence That Meal Fat Content Does Not Impact Hemodynamic Reactivity to Repeated Mental Stress Tasks**

Veronica J. Poitras, David J. Slattery, Briar B. Findlay, Kyra E. Pyke. *Queen's University, Kingston, ON, Canada.*

(No relationships reported)

Psychological stress is known to evoke physiological responses, including increases in mean arterial blood pressure (MAP). There is some evidence that both a single high fat (HF) meal and short-term elevations in dietary fat intake enhance hemodynamic reactivity to laboratory stressors. Stress reactivity has been shown to relate to cardiovascular risk, and interactions with diet may be important.

**PURPOSE:** To determine the impact of a HF meal on the magnitude and stability of reactivity to varied mental stressors, as assessed by the peak changes in MAP and its constituents (i.e. cardiac output and total peripheral resistance) from baseline to during stress ( $\Delta$ MAP<sub>peak</sub>,  $\Delta$ CO<sub>peak</sub>,  $\Delta$ TPR<sub>peak</sub>).

**METHODS:** On two different days, separated by 14  $\pm$  5.4 days, 10 healthy males (23.2  $\pm$  3.3 yrs) consumed either a HF (48g fat) or low fat (LF; 0g fat) meal (~940 calories each). On each day, subjects performed 4 hourly STs (10 mins each in duration). STs consisted of mental arithmetic (3 tasks) or a speech (5 tasks), and were interspersed with the intention of providing a varied stimulus to minimize habituation.

**RESULTS:** Data are mean  $\pm$  SD. Postprandial lipemia was greater following consumption of the HF vs LF meal (HF vs LF: 1.37  $\pm$  0.87 vs 0.87  $\pm$  0.38 mmol/L, P=0.03). Pre-ST MAP did not differ within (P=0.27) or between (P=0.69) HF and LF meals.  $\Delta$ MAP<sub>peak</sub> did not differ between meals (HF vs LF: 19.6  $\pm$  10.6 vs 21.3  $\pm$  7.4 mmHg, P=0.41), however within meals, reactivity was attenuated by the 4<sup>th</sup> ST ( $\Delta$ MAP<sub>peak</sub> ST-1 vs ST-4: 22.1  $\pm$  8.8 vs 16.8  $\pm$  8.1 mmHg, P=0.02). There was also no significant difference in  $\Delta$ CO<sub>peak</sub> or  $\Delta$ TPR<sub>peak</sub> either within or between meals (HF vs LF:  $\Delta$ CO<sub>peak</sub> 1.9  $\pm$  0.92 vs 2.0  $\pm$  0.96 L/min, P=0.60;  $\Delta$ TPR<sub>peak</sub> 3.1  $\pm$  3.4 vs 3.2  $\pm$  2.3 mmHg/L/min, P=0.94). There was considerable within-subject variability in reactivity to the range of tasks presented (within-subject  $\Delta$ MAP<sub>peak</sub> range of 14.6 mmHg  $\pm$  7.3 across STs), however the range of reactivity did not differ between HF and LF meals (P=0.36).

**CONCLUSIONS:** Contrary to previous reports, meal fat content did not impact hemodynamic reactivity to laboratory stressors. These data also provide evidence of minimal habituation in hemodynamic responses to varied mental STs performed 8 times over 2 laboratory visits, with wide variation in reactivity within individuals.

---

3315 Board #36 June 2 9:30 AM - 11:00 AM

**Left Ventricular Mechanics Following Ultra-endurance Exercise - Impact Of Dehydration**

Eric J. Stöhr<sup>1</sup>, David A. Low<sup>2</sup>, Amanda Q. X. Nio<sup>1</sup>, Lee Eldridge<sup>3</sup>, Rob Shave<sup>1</sup>. <sup>1</sup>Cardiff Metropolitan University, Cardiff, United Kingdom. <sup>2</sup>Imperial College London, London, United Kingdom. <sup>3</sup>Brunel University, West London, Uxbridge, United Kingdom. (Sponsor: Prof. Keith George, Liverpool John Moores University, UK, FACSMM)

(No relationships reported)

Previous studies have shown a significant reduction in left ventricular (LV) twist and strain ('LV mechanics') following ultra-endurance exercise, however, this may be caused by accompanying dehydration and not exclusively reflect cardiac impairment.

**PURPOSE:** To examine the influence of dehydration upon LV mechanics following ultra-endurance exercise.

**METHODS:** Six male cyclists (age: 30±6 years) performed two 6h cycling trials, one with maintained hydration (EUHY) and one with ~2% dehydration (DEHY). Exercise intensity was fixed at 15% below a lactate concentration of 4 mmol. In both the EUHY and DEHY trial, LV volumes and mechanics were measured at three time points: i) pre, ii) post and iii) 24h post cycling exercise. Significant effects of exercise or dehydration as well as their interaction were identified using 2-way repeated measures ANOVA.

**RESULTS:** End-diastolic volume (EDV) and stroke volume (SV) decreased significantly post 6h cycling in both EUHY and DEHY ( $\Delta$ EDV: ~-18±10 ml,  $\Delta$ SV: ~-16±7 ml) while heart rate was significantly higher post exercise in both trials ( $\Delta$ : ~-21±10 bpm). The ratio of early to late diastolic filling velocity (E/A) declined post exercise in both trials ( $\Delta$ -0.70±15). Radial strain was unaltered while circumferential strain was mildly reduced post EUHY and DEHY ( $\Delta$ -4±2%). In contrast, diastolic basal rotation velocity was significantly enhanced post DEHY compared with EUHY (74±21 vs. 63±22 deg·sec<sup>-1</sup>,  $P=0.03$ ). All values returned to pre exercise levels 24h post exercise. **Discussion:** The decline in EDV and SV observed in the present study was similar to that seen in previous investigations ( $\Delta$ 20ml and  $\Delta$ 17ml, respectively). However, post ultra-endurance exercise LV strain and twist indices were not reduced further in the DEHY compared with the EUHY trial. In fact, diastolic basal rotation velocity was significantly enhanced post DEHY.

**CONCLUSION:** Moderate dehydration (2%) does not exacerbate the change in LV volumes, heart rate or LV mechanics post ultra-endurance exercise. Therefore, the present data provide evidence that previously shown reductions in LV mechanics following competitive ultra-endurance events are likely caused by reductions in LV function and not by hydration status.

**Non-invasive Assessment From Micro- To Macro Circulation: A Feasibility Study**

Kate Austin, Daniel Credeur, Michael Welsch. Louisiana State University, Baton Rouge, LA.

(No relationships reported)

The Erythrocyte-Endothelial (EE) gap, pulse wave analyses and velocity (PWV), and large conduit artery flow mediated dilation (FMD) are considered independent barometers of vascular health. Few studies exist that have examined each of these measures in the same individual.

**PURPOSE:** To determine the feasibility of assessing micro- to macrovascular function in young individuals with varying degrees of fitness.

**METHODS:** Ten subjects (male=2, female= 8, age= 23.0±5.08 years) participated in this study. Subjects rested for 10 minutes in the supine position prior to determining microvascular structure, arterial stiffness, and changes in brachial artery diameter before and after forearm occlusion (FMD). Red blood cell velocity (RBCV) and EE-Gap were examined in sublingual capillaries using OPS-imaging (Capiscope, KK technology, Exeter, UK). To assess arterial stiffness, a carotid-to-radial pulse wave velocity (PWV) was performed using tonometry. FMD was defined as the peak change in brachial artery diameter, which was determined by ultrasonography. In addition, subjects participated in a 12-minute run to measure fitness.

**RESULTS:** RBCV and EE-gap values were similar to healthy populations (84.58±25.23µm/sec and 0.86±0.15µm, respectively). Average aortic SBP, DBP, and PWV were 101.3±9.25mmHg, 71.5±8.44mmHg and 6.91±0.93m/sec, which are considered average for this population. The mean BAFMD was 5.84±3.27%, [Range: 1.19-10.34]. The average rank for the 12-min run was 35.65±32.06%.

**CONCLUSION:** The vascular measurements of this study are indicative of an apparently healthy population and in line with current literature. Non-invasive measurement of micro- and macro vessel function may lead to a more comprehensive understanding of vascular health, and appreciation for possible interrelationships between biomarkers.

**Acute Dietary Nitrate Supplementation on Resting and Exercising Muscle Hemodynamic Control in the Rat**

Scott K. Ferguson<sup>1</sup>, Daniel M. Hirai<sup>1</sup>, Steven W. Copp<sup>1</sup>, Clark T. Holdsworth<sup>1</sup>, K Sue Hageman<sup>1</sup>, Andrew M. Jones, FACSMM<sup>2</sup>, Timothy I. Musch, FACSMM<sup>1</sup>, David C. Poole, FACSMM<sup>1</sup>. <sup>1</sup>Kansas State University, Manhattan, KS. <sup>2</sup>University of Exeter, Exeter, United Kingdom.

(No relationships reported)

Nitric oxide (NO) bioavailability modulates both O<sub>2</sub> supply and demand within the O<sub>2</sub> transport pathway. A nitrate-rich diet has been shown to elevate NO bioavailability following its reduction to nitrite and NO via NO synthase-independent pathways. Recently, dietary nitrate supplementation has been shown to reduce blood pressure and reduce the O<sub>2</sub> cost of submaximal exercise in humans (Bailey et al, 2009, J Appl Physiol). Despite these observations, the effects of dietary nitrate supplementation on skeletal muscle blood flow (BF) at rest and during exercise remain unknown.

**PURPOSE:** To test the hypothesis that acute dietary nitrate supplementation decreases resting and exercising mean arterial pressure (MAP) while preserving hindlimb skeletal muscle BF during exercise.

**METHODS:** Young male Sprague-Dawley rats (3-6 months) were randomized into control or nitrate-supplemented groups. Nitrate supplementation was administered in drinking water via 2.5 ml/day of nitrate-rich beetroot juice (0.065 mmol/ml). Either untreated (control, n=8) or nitrate supplemented (BR, n=8) tap water was available ad libitum for 3 days while daily consumption was verified. Following supplementation, BF was assessed using radiolabeled microspheres at rest and during treadmill running (20 m/min, 5% grade).

**RESULTS:** BR supplementation decreased MAP significantly by 15% at rest (control: 138 ±4; BR: 117 ±7 mmHg;  $P\leq 0.05$ ) and 10% during exercise (control: 136 ±3; BR: 123 ±6 mmHg;  $P\leq 0.05$ ). Similar BF values for 28 individual hindlimb muscles resulted in no change in total hindlimb BF at rest (control: 17 ± 2; BR: 23 ± 3 ml/min/100g;  $P>0.05$ ) or exercise (control: 114 ± 8; BR: 116 ± 10 ml/min/100g;  $P>0.05$ ).

**CONCLUSIONS:** Dietary nitrate supplementation did not change exercising hindlimb BF and, therefore, O<sub>2</sub> delivery despite a reduced arterial driving pressure; providing evidence for an improved hemodynamic response to exercise. Combined with recent results that nitrate supplementation reduces the O<sub>2</sub> cost of exercise, these data support the hypothesis that nitrate supplementation elevates O<sub>2</sub> delivery relative to O<sub>2</sub> demand, which suggest one potential mechanism by which nitrate supplementation improves metabolic control.

**Sex Affects Autonomic Recovery Following A 45-min Bout Of Aerobic Exercise**

Kanokwan Bunsawat<sup>1</sup>, Peng Sun<sup>2</sup>, Huimin Yan<sup>2</sup>, Sushant M. Ranadive<sup>2</sup>, Rebecca M. Kappus<sup>1</sup>, Abbi Lane<sup>1</sup>, Tracy Baynard<sup>1</sup>, Bo Femhall, FACSMM<sup>1</sup>. <sup>1</sup>The University of Illinois at Chicago, Chicago, IL. <sup>2</sup>The University of Illinois at Urbana-Champaign, Urbana-Champaign, IL.

(No relationships reported)

**INTRODUCTION:** Heart rate variability (HRV) reflects autonomic function and is an indicator of cardiovascular health. Previous research has shown that autonomic balance is shifted towards greater sympathetic and less parasympathetic modulation following exercise. However, sex differences in autonomic recovery following aerobic exercise are not well delineated.

**PURPOSE:** To examine sex differences in autonomic recovery following a 45-min bout of aerobic exercise in healthy individuals.

---

**METHODS:** Heart rate (HR), HRV frequency-domain parameters and brachial blood pressures were obtained at rest and following exercise in 60 healthy individuals (31 males and 29 females). Low-frequency (LF) and high-frequency (HF) power, low-frequency to high-frequency ratio (LF/HF), low-frequency normalized units (nLF), and high-frequency normalized units (nHF) of HRV were evaluated in the supine position, before and at 30 and 60 minutes following 45 min of walking at 70% of heart rate reserve.

**RESULTS:** Men exhibited higher LF/HF at rest and increased LF/HF more than women after exercise ( $205.97 \pm 29.68$  to  $595.38 \pm 73.08$  to  $209.21 \pm 80.34$   $\text{ms}^2$  vs.  $159.56 \pm 32.63$  to  $355.17 \pm 38.28$  to  $167.42 \pm 42.08$   $\text{ms}^2$ ,  $p < 0.05$  for interaction). Men also exhibited higher nLF ( $0.61 \pm 0.03$  to  $0.76 \pm 0.03$  to  $0.72 \pm 0.03$   $\text{ms}^2$  vs.  $0.51 \pm 0.04$  to  $0.61 \pm 0.03$  to  $0.54 \pm 0.03$   $\text{ms}^2$  and lower nHF at baseline and following exercise ( $0.38 \pm 0.03$  to  $0.22 \pm 0.03$  to  $0.27 \pm 0.03$   $\text{ms}^2$  vs.  $0.47 \pm 0.04$  to  $0.47 \pm 0.04$  to  $0.44 \pm 0.03$   $\text{ms}^2$ ;  $p < 0.05$  for time and sex effects).

**CONCLUSION:** Women and men exhibit different HRV responses following aerobic exercise. The higher nLF and lower nHF coupled with a greater increase in the LF/HF ratio following exercise suggests men exhibit reduced vagal but increased sympathetic dominance following submaximal exercise compared to women. Future work is needed to determine if this is related to increased risk of untoward events during and following exercise in men compared to women.

**Cerebral Hemodynamic Responses During Carbon Dioxide Rebreathing, Aerobic Exercise And Cognition**

Hercules Grant, Mayank Rehani, Yagesh Bhambhani. *University of Alberta, Edmonton, AB, Canada.* (Sponsor: Bob Haennel, FACSM)  
(No relationships reported)

Increases in cerebral blood volume (total Hb) and oxyhemoglobin (O<sub>2</sub>Hb) with concomitant declines in deoxyhemoglobin (HHb) measured by near infrared spectroscopy (NIRS), collectively referred to as hemodynamics, are indicative of neuronal activation.

**PURPOSE:** To determine the inter-relationship between these acute hemodynamic responses during CO<sub>2</sub> rebreathing which increases cerebral blood flow, aerobic fitness and cognition in healthy males.

**METHODS:** Informed consent was obtained from eight healthy males (20 - 58 yrs, predicted VO<sub>2max</sub> =  $35.06 \pm 8.5$  ml/kg/min) with high school to university education. NIRS was used to measure the acute changes (peak minus baseline) in hemodynamic responses over the prefrontal lobe during 5% CO<sub>2</sub> rebreathing for 90 sec, Astrand/Rhyming test to predict VO<sub>2max</sub>, and digit span testing, (a subset of Wechsler Adult Intelligence Scale IV).

**RESULTS:** Significant increases were observed in total Hb and O<sub>2</sub>Hb with concomitant declines in HHb during CO<sub>2</sub> rebreathing and cycle ergometry. Cognition elicited a trend of increasing O<sub>2</sub>Hb and decreasing HHb with digit span scores which was not significant. Changes in O<sub>2</sub>Hb and total Hb were significantly correlated with relative VO<sub>2max</sub> ( $r = 0.792$  and  $0.841$  respectively), but not with cognition. Change in PetCO<sub>2</sub> (surrogate for cerebral blood flow) was significantly correlated with relative VO<sub>2max</sub>, ( $r = 0.721$ ,  $P < 0.05$ ). Correlation between delta PetCO<sub>2</sub> and [O<sub>2</sub>Hb] during cycling was approaching significance ( $r = 0.586$ ,  $P < 0.10$ ).

**CONCLUSIONS:** Higher levels of prefrontal neuronal activation are associated with enhanced aerobic fitness. However the relationship between these increases in neuronal activation and cognition were not evident, possibly due to the heterogeneity of the small sample evaluated.

**Hemodynamic Mechanism of Rate Pressure Product Increase at Voluntary Exhaustion during Maximum Incremental Test**

Marcelo G. Boia Nascimento<sup>1</sup>, Ricardo Jaco<sup>2</sup>, Hugo R. Paulista<sup>3</sup>, Tacio S. Santos<sup>4</sup>, Renata E. Dantas<sup>1</sup>, Marcio R. Mota<sup>1</sup>. <sup>1</sup>*Centro Universitario de Brasilia-UNICEUB, Brasilia, Brazil.* <sup>2</sup>*Universidade de Brasilia-UnB, Brasilia, Brazil.* <sup>3</sup>*Universidade de Brasilia-UnB, Brasilia, Brazil.* <sup>4</sup>*Centro Universitario de Brasilia, Brasilia, Brazil.*  
(No relationships reported)

Rate pressure product (RPP) is a physiological indicator that includes the heart rate (HR) for systolic blood pressure (SBP) product. It is used to evaluate the cardiovascular stress and its increase may occur through HR's rise, SBP's rise, or both. The knowledge of responsible variable for RPP increase at voluntary exhaustion (VE) during maximum incremental test (MIT) is important for a better understanding of MIT hemodynamic.

**PURPOSE:** To determinate the responsible variable for RPP increases at VE during MIT.

**METHODS:** Took part in the study 10 active female subjects ( $25 \pm 5$  years;  $165 \pm 7$  cm;  $62 \pm 11$  kg;  $27 \pm 6\%$  body fat). MIT was done with a Bruce's non inclination adapted treadmill protocol (Centurion 300 - Micromed) with 5.5 km/h initial velocity and 1 km/h per minute increment until VE. HR and SBP were recorded at rest and at VE (FS150 Frequency Meter - Polar and BP 3AC1-1 Digital Sphygmomanometer - Microlife, respectively). A non-parametric statistics data analysis was made through Mann-Whitney test.

**RESULTS:** There were significant differences between rest RPP and VE RPP ( $8.211 \pm 994$  mmHg/bpm vs.  $16.367 \pm 2.520$  mmHg/bpm,  $p < 0.01$ ), between rest HR and VE HR ( $67 \pm 8$  bpm vs.  $150 \pm 8$  bpm,  $p < 0.01$ ), but not between rest SBP and VE SBP ( $124 \pm 6$  mmHg vs.  $128 \pm 16$  mmHg).

**CONCLUSION:** RPP increase at VE during MIT is mediated by HR's rise.

**3321 Board #42 June 2 9:30 AM - 11:00 AM**  
**Hemodynamic Response to Active Standing in Swimmers with Orthostatic Intolerance: Prevalence of Initial Orthostatic Hypotension**

William N. Lampe, Michael D. Kennedy. *University of Alberta, Edmonton, AB, Canada.*  
(No relationships reported)

Orthostatic intolerance or hypotension (OH) defined as a transient decrease  $> 20$  mmHg in systolic blood pressure (SBP) and/or a transient decrease  $> 10$  mmHg in diastolic blood pressure (DBP) within 3 min of standing has been reported in endurance athletes. However the prevalence of initial orthostatic hypotension (IOH) (defined as a transient decrease in SBP;  $> 40$  mmHg and/or DBP;  $> 20$  mmHg within 15 seconds of active standing) has not been examined in endurance athletes.

**PURPOSE:** The purpose of this study was to determine the prevalence of IOH in trained male swimmers with OH and to determine the hemodynamic response to active standing.

**METHODS:** 10 male swimmers with no reported history of syncope (age:  $20.8 \pm 1.5$  yrs; ht:  $178.0 \pm 7.6$  cm; wt:  $79.9 \pm 8.5$  kg) completed an active stand orthostatic challenge test (5 min supine, 3 min standing). Subjects reported no physical activity, or caffeine or alcohol consumption within the previous 12 hours. Arterial blood pressure was measured continuously by finger photoplethysmography (Finometer Medical Systems). Mean Arterial Pressure (MAP), SBP, DBP, Heart Rate (HR), Stroke Volume (SV) and Total Peripheral Resistance (TPR) were derived from beat by beat blood pressure and averaged over 3 cardiac cycles.

**RESULTS:** 8 of 10 swimmers met both SBP and DBP, 1 met SBP and 1 met DBP OH criteria (mean decrease of  $30.6 \pm 13.3$  and  $14.7 \pm 6.5$  mmHg for SBP and DBP respectively). IOH was observed in 8 of 10 swimmers (Decrease of SBP:  $48.8 \pm 19.3$  mmHg; Decrease of DBP:  $29.6 \pm 10.0$  mmHg; Decrease of MAP:  $36.2 \pm 12.2$  mmHg) with MAP nadir occurring at  $8.7 \pm 2.8$  sec returning to baseline value at approximately  $18.2 \pm 3.4$  sec after standing. The primary hemodynamic response with decreasing MAP to nadir was increase in HR of  $37.5 \pm 13.6$  beats/min reaching a maximum at  $16.8 \pm 10.9$  sec after standing. MAP return to baseline from nadir was associated with a mean increase in TPR of 43.2%, a mean increase in SV of 15.8% and a mean increase in HR of 4.2%.

**CONCLUSION:** These results suggest that IOH is prevalent in male swimmers with OH. In response to active standing an immediate uptake in HR with a latent increase in TPR act to equilibrate MAP from nadir.

---

**3322 Board #43 June 2 9:30 AM - 11:00 AM**  
**Cardiorespiratory Response to Continuous Passive Motion Exercise in People with Spinal Cord Injury**

Sangouk Wee, Konstantinos Vrongistinos, Shane D. Stecyk, Taeyoung Jung, Byron Lai. *California State University Northridge, Northridge, CA.*  
(No relationships reported)

Continuous passive motion exercise (CPME) is commonly implemented for people with spinal cord injury (SCI). Many individuals with paralysis use CPME for their rehabilitation programs, but the research on its cardiorespiratory effects is limited.

**PURPOSE:** To investigate the cardiorespiratory responses to CPME in individuals with SCI.

**METHODS:** Eleven individuals with SCI (6 men and 5 women, 40.7±9 yr) and 11 healthy controls (6 men and 5 women, 35.8± 5 yrs) completed performing 3 exercise modes on separate days in a randomized order. Participants were also subject to an orientation visit to determine exercise intensity. The modes of exercise included 6-minute active arm ergometer exercise at their submaximal level which was set at 60-80% of maximum heart rate in order to estimate the maximum oxygen consumption, 20-minute seated CPME (passive cycling movement) and 20-minute supine-lying CPME (passive walking movement) at a matched movement speed. A telemetric metabolic system was used to compare the cardiorespiratory variables among three exercise modes. Test sessions were separated by minimum of 24 hours to avoid any carry-over effect from the previous session.

**RESULTS:** Multivariate analysis of variance (MANOVA) revealed significant differences in the oxygen consumption in the SCI group between the pre-exercise baseline and steady state exercise during the supine-lying CPME (Multivariate Pillai's Trace = .615,  $F_{(1,20)}=11.161$ ,  $p=.012$ ) and during the seated CPME (Multivariate Pillai's Trace = .562,  $F_{(1,20)}=8.972$ ,  $p=.020$ ). The levels of oxygen consumption were 8% (seated) and 14% (supine) of the estimated maximal oxygen consumption respectively.

**CONCLUSIONS:** Our findings suggest that CPMEs elicit an increase of cardiorespiratory responses, which may lead to favorable training effects on cardiorespiratory fitness in people with SCI.

**3323** Board #44 June 2 9:30 AM - 11:00 AM

**Time-course And Reliability Of Hemodynamic Responses To An Isometric Handgrip Protocol**

Claudia M. Meirelles<sup>1</sup>, Paulo Sergio C. Gomes<sup>2</sup>, Yagesh N. Bhamhani<sup>3</sup>. <sup>1</sup>Escola de Educação Física do Exército, Rio de Janeiro, Brazil. <sup>2</sup>Universidade Gama Filho, Rio de Janeiro, Brazil. <sup>3</sup>University of Alberta, Edmonton, AB, Canada.  
(No relationships reported)

Isometric handgrip (IHG) training leads to significant reductions in blood pressure (BP) and improves endothelial function assessed by flow mediated brachial artery dilation (FMD). Nevertheless, the acute hemodynamic responses elicited by IHG have not been fully explored.

**PURPOSE:** To describe the time-course of the acute effects of a IHG protocol on FMD, BP and muscle blood volume (Mbv)/oxygenation (Mox), and evaluate the reliability of the last three measures.

**METHODS:** 15 healthy volunteers (7 females, 26.7±6y, 75±17kg, 170.4±7.3cm) completed two visits to the laboratory. After a 10-min rest period, subjects performed four sets of 2-min bilateral IHG at 30% of their maximum voluntary contraction, intercalated by 1-min rest interval. Brachial artery diameter (BAD) was measured using high-resolution ultrasonography. BP was measured by oscillometry. Mbv and Mox range values (difference between maximum and minimum absolute values) from the flexor digitorum profundus of right forearm were monitored by dual wave near infrared spectroscopy.

**RESULTS:** Time-course analyses indicate non-significant changes in BAD (t-test  $P=0.10$ ), only discrete ranges in Mbv and Mox, and no significant changes in BP (ANOVA with repeated measures). Absolute values obtained for all variables and ICC are presented, revealing poor to excellent reliability.

| BAD (mm)  | Baseline                     | End of 1st set               | 70-s rec                     |                              |

| MAP       | 91±8<br>R=.81 (P=.01)        | 88±8mmHg<br>R=.69 (P=.00)    | 89±8<br>R=.63 (P=.01)        | 91±10<br>R=.47 (P=.09)       |

Rec: recovery

**CONCLUSION:** IHG exercise has a negligible acute effect on FMD, BP and Mbv/Mox; monitoring BP by oscillometry is a reliable way of assessing BP changes, whereas Mbv and Mox ranges were moderately reliable, supporting their utilization in this type of exercise.

**Resistance Exercise Protocols With Similar Total Work:Rest Ratio Induce Different Cardiovascular Responses**

Anderson C. Paulo<sup>1</sup>, Valmor Tricoli<sup>2</sup>, Andréia C.C. Queiroz<sup>2</sup>, Gilberto Laurentino<sup>3</sup>, Cláudia L.M. Forjaz<sup>2</sup>. <sup>1</sup>University Nove de Julho; University Paulista, São Paulo, Brazil. <sup>2</sup>School of Physical Education and Sport, University of São Paulo, São Paulo, Brazil. <sup>3</sup>University Paulista, São Paulo, Brazil.  
(No relationships reported)

A resistance exercise (RE) protocol composed of 3x15:90s (sets x reps : rest) interval is usually recommended for people with cardiovascular diseases. During RE, there is a huge increase in blood pressure (BP) which enhances the risk of an acute event, such as a stroke. We hypothesized that a RE protocol with shorter sets may attenuate BP increase during RE.

**PURPOSE:** To investigate the cardiovascular, metabolic and perception of effort responses to different RE protocols with similar total work:rest ratio (WR).

**METHODS:** Three RE protocols were tested: 3x15:88s, 9x5:22s, and 45x1:4s. All of them had a WR of 45 repetitions to 176s of rest. To test the hypothesis, 10 healthy men (26±3yrs) and 10 women (25±5yrs) performed, in random order, the three protocols using the knee extension exercise with an intensity of 50% 1RM. BP was measured before and during exercise by finger photoplethysmography. The largest increase in BP observed every 15 repetitions was analyzed. In addition, the mean BP stress throughout the RE protocols was calculated by the area under the BP curve. Blood lactate concentration and perception of effort (PE) were measured after each protocol. Data were compared by a three-way ANOVA for repeated measures and significance was set to  $P < 0.05$ .

**RESULTS:** Systolic BP (98±40 vs. 87±33 and 79±33mmHg), HR (68±21 vs. 47±16 and 45±21bpm), rate pressure-product (22451±9549 vs. 15537±8114 and 15654±8110mmHg.bpm), lactate (3±1 vs. 2.0±1 and 2.0±1mmol.L<sup>-1</sup>), and PE (9.3±0.6 vs. 8.2±1.1 and 7.7±1.4) were significantly higher in the 3x15:88s compared to the 45x1:4s and 9x5:22s protocols. Diastolic BP was higher in the 3x15:88s and 45x1:4s compared to the 9x5:22s (59±28 and 55±26 vs. 45±19mmHg). In contrast, the area under BP and HR curves were not different between the protocols. In all protocols and analyses, males showed higher changes in BP than females.

**CONCLUSIONS:** Compared to the 3x15:88s, the 9x5:22s and the 45x1:4s protocols reduced the BP and HR peaks during exercise execution without changing the total cardiovascular stress. Thus, our results suggested that RE protocols with shorter sets and rest periods with intermediate duration may attenuate BP increase during RE.

3325 Board #46 June 2 9:30 AM - 11:00 AM

**Acute Cardiovascular Response To Mud-pack Treatment In Hypertensive Subjects Under Therapy**

Arsenio Veicsteinas<sup>1</sup>, Luca Agnello<sup>2</sup>, Martina A. Maggioni<sup>1</sup>, Susanna Rampichini<sup>1</sup>, Giampiero Merati<sup>2</sup>. <sup>1</sup>University of Milan, Milan, Italy. <sup>2</sup>Don C. Gnocchi Foundation, Milan, Italy.  
(No relationships reported)

Hypertensive subjects often develop a blunted cardio-vagal baroreflex sensitivity and an imbalance between sympathetic and parasympathetic tone; this may reduce the adaptation of cardiac output and peripheral resistances to warm environments. Such reactions may be enhanced by anti-hypertensive drugs, especially those inhibiting the angiotensin II-mediated vasoconstriction. Therefore, the immersion in hot mud typical of SPA treatment may cause hypotension in these patients.

**PURPOSE:** To evaluate the acute cardiovascular effects of mud-pack treatment in pharmacologically treated hypertensive patients.

**METHODS:** 28 subjects (M/F 10/18; 67±11 yrs, m±SD) were divided in 2 groups, matched for age and anthropometric characteristics: normotensive (N) and hypertensive (H) subjects, treated with beta-blockers, ACE-inhibitors or angiotensin II receptor antagonists (no diuretics). Beat-by-beat systolic (SBP) and diastolic blood pressure (DBP)(finger pletismography), and heart rate (HR) were recorded before, in supine position (10 min), and during mud-pack treatment (mud temperature 42°C, 15 min). Cardiac output and total peripheral resistance were calculated from the computed aortic-flow waveform. HR variability spectral indexes of sympathovagal balance (HF, High Frequency; LF, Low Frequency and LF/HF ratio) were finally calculated.

**RESULTS:** Compared to basal (pre-treatment) conditions, mud treatment tended to decrease SBP (difference between mud immersion and basal condition; H: -6±16 mmHg; N: -3±5 mmHg), whereas DBP did not differ (H: -2±7 mmHg; N: 7±5 mmHg) in both groups. HR significantly increased (p<0.05) in both groups (H: 7±6 bpm; N: 8±4 bpm). Cardiac output decreased significantly (p<0.01) in H subjects only (H: -1.5±2.0 l/min; N: -0.5±1.6 l/min), whereas total peripheral resistances decreased in H and increased in N subjects (H: -160±237 l/min; N: 97±124 dyn·s/cm<sup>5</sup>)(p<0.05). LF/HF ratio slightly but not significantly increased in both groups (H: 0.1±1.5; N: 0.7±1.6), as a results of an increase in LF and a reduction of HF, the latter being significant (p<0.05) in H subjects only.

**CONCLUSIONS:** Mud-pack treatment seems to be safe in pharmacologically treated hypertensive subjects. Partially supported by FoRST (Fondazione per la Ricerca Scientifica Termale, Italy).

3326 Board #47 June 2 9:30 AM - 11:00 AM

**Progressive Handgrip Exercise: Evidence of Attenuated Nitric-oxide Dependent Vasodilation and Blood Flow Regulation with Age**

Joel D. Trinity<sup>1</sup>, D Walter Wray<sup>1</sup>, Melissa A.H. Witman<sup>1</sup>, Gwenael Layec<sup>2</sup>, Zachary Barrett-O'Keefe<sup>2</sup>, Stephen J. Ives<sup>1</sup>, Jaime D. Conklin<sup>1</sup>, Russell S. Richardson<sup>1</sup>. <sup>1</sup>George E. Whalen VA Medical Center, Salt Lake City, UT. <sup>2</sup>University of Utah, Salt Lake City, UT.  
(No relationships reported)

**PURPOSE:** The purpose of this investigation was to better understand the altered role of nitric oxide (NO) with age and the potential for exercise-induced vasodilation of the brachial artery (BA) to assess NO bioavailability.

**METHODS:** BA blood flow (Doppler ultrasound), diameter, and shear rate were measured in response to progressive handgrip exercise with and without eNOS inhibition (intra-arterial infusion of L-NMMA) in 7 older subjects (69 ± 2 yr). Handgrip exercise was performed at 15, 25, 40, and 50% of maximal voluntary contraction and comparisons were made to our published observations in young adults (Wray et al. 2011).

**RESULTS:** The relationship between the change in BA diameter and shear rate was attenuated by 4 fold in the old (r = 0.66, p < 0.01; slope = 0.00013 ± 0.00004) compared to the young (r = 0.73, p < 0.01; slope = 0.00049 ± 0.00012, p = 0.002). Unlike the young, where eNOS inhibition ablated this relationship (r = 0.1, p = 0.5; slope = 0.00005 ± 0.00006), the diameter/shear rate response remained statistically unchanged in the old (r = 0.61, p < 0.01; slope = 0.00011 ± 0.00007). However, eNOS inhibition attenuated the BA diameter increase by 50% in the old compared to the 70% reduction in the young, indicating a substantial yet reduced role of NO with age. Blood flow was unaffected by eNOS inhibition in the old which contrasts with the ~25% reduction documented in the young.

**CONCLUSION:** These findings reveal that with age both shear stress mediated BA vasodilation and BA blood flow are less NO dependent during handgrip exercise and support the use of the progressive handgrip paradigm as a valid and novel approach to the non-invasive assessment of NO bioavailability in humans across the lifespan.

3327 Board #48 June 2 9:30 AM - 11:00 AM

**LBNP Effect On Rapid Changes In Stroke Volume And Cardiac Output At Exercise Onset**

Aurelien Bringard<sup>1</sup>, Alessandra Adami<sup>1</sup>, Christian Moia<sup>1</sup>, Nazzareno Fagoni<sup>2</sup>, Enrico Tam<sup>3</sup>, Guido Ferretti<sup>1</sup>. <sup>1</sup>University Medical Center, University of Geneva, Geneva, Switzerland. <sup>2</sup>University of Brescia, Brescia, Italy. <sup>3</sup>University of Verona, Verona, Italy.  
(No relationships reported)

**PURPOSE:** The kinetics of cardiac output (CO) at the onset of exercise is characterized by two phases. The first rapid phase (phase I), which has a time constant of less than 5 s, is generally attributed to the sudden withdrawal of vagal tone. Yet the hypothesis was put forward that a mechanical effect related to sudden increase in venous return at exercise start might also play a role, especially by increasing stroke volume (SV) via the Frank-Starling mechanism. If the latter was the case, then application of increasing levels of lower body negative pressure (LBNP) would generate a progressively greater increase in phase I amplitude (A1) of SV at exercise start, which may also affect A1 for CO.

**METHODS:** To test this hypothesis, 8 healthy subjects (24.8 ± 5.0 years) repeated 3 transitions of 5 min moderate (50 W) pedaling exercise in supine position, with 0 (control), -15, -30 and -45 mmHg of LBNP. The pulse pressure waveform of a left hand's finger was continuously recorded using Portapress device, allowing calculation of CO, SV and heart rate (HR) on a beat-by-beat basis using Modellflow method (Wesseling et al., 1993). After superimposition of the 3 transitions, kinetics of CO, SV and HR were fitted using bi-exponential model, and the amplitude of phase one (A1) amongst the 4 conditions was compared using repeated ANOVA (with Tukey post-hoc test).

**RESULTS:** A1 of SV was significantly increased from 7.5 ± 3.7 and 9.5 ± 3.8 to 16.7 ± 12.4 and 21.4 ± 7.9 ml, for 0 (control), -15, -30 and -45 mmHg of LBNP respectively. By contrast, A1 of HR was reduced (p = 0.05) with increasing LBNP level. As a consequence, A1 of CO exhibited only a trend (p = 0.06) to increase from 1.93 ± 0.79 to 2.42 ± 0.72, 3.01 ± 1.47 and 3.19 ± 0.82 l.min<sup>-1</sup>, for 0 (control), -15, -30 and -45 mmHg of LBNP respectively. The time constant of phase 1 was ranged between 1.5 and 3.5 s and remained unaffected by LBNP exposure for either SV, HR or CO.

**CONCLUSIONS:** The tested hypothesis was supported by the results in so far as A1 of SV was increased. However, this change did not translate into an equivalent change in CO, because of the concomitant reduction of A1 of HR, possibly due to a weaker vagal activity during LBNP exposure before exercise started. We conclude that the amplitude of the first phase of CO kinetics is indeed under dual control: neural and mechanical.

3328 Board #49 June 2 9:30 AM - 11:00 AM

**Gender Disparity In Cardiac AMPK Activation In Response to Exhaustive Exercise**

Kevin D. Brown<sup>1</sup>, Edward D. Waggy<sup>1</sup>, Matthew Peterson<sup>1</sup>, Min Du<sup>1</sup>, Nair Sreejayan<sup>1</sup>, Ji Li<sup>2</sup>, D Paul Thomas, FACSM<sup>1</sup>. <sup>1</sup>University of Wyoming, Laramie, WY. <sup>2</sup>State University of New York at Buffalo, Buffalo, NY.  
(No relationships reported)

A single bout of exercise activates 5'-AMP-activated protein kinase (AMPK) in a graded fashion in both heart and skeletal muscle. In humans a gender difference in exercise-induced AMPK activation (P-AMPK) in vastus lateralis m. has been reported, with males showing a ~200% increase compared to a non-significant rise in females. Whether this gender difference in P-AMPK response to exercise also applies to the heart is unknown.

**PURPOSE:** To investigate whether this sex difference in AMPK activation to exercise also occurs in the heart, we measured left ventricular (LV) AMPK response to exhaustive exercise in both sedentary (SED) and trained (TR) male and female C57BL/6 mice.

**METHODS:** TR mice ran on a motorized treadmill at progressively increasing speeds up to 22m/min, 1hr/day, 6 days/wk for 12 wks. TR and SED mice of both genders were sacrificed immediately following exercise to the point of exhaustion and compared to SED resting controls. LV was rapidly excised, freeze-clamped, homogenized and AMPK activity measured by <sup>32</sup>P-ATP radioimmunoassay with S-Adenosyl methionine (SAMS) as substrate.

**RESULTS:** Irrespective of gender, trained mice demonstrated a relative cardiac hypertrophy (HW/BW) compared to sedentary mice (males 5.28 ± 0.20 vs. 4.30 ± 0.18 mg/g; females 4.97 ± 0.15 vs. 4.45 ± 0.14 mg/g; P < 0.001 and P < 0.05 respectively). Regardless of training status, male mice (n=19) demonstrated a ~3.5-fold higher AMPK response to the same level of exhaustive exercise compared to female mice (n=18) (0.117 ± 0.009 vs. 0.034 ± 0.003 nmols/mg/min; P < 0.001). Irrespective of gender, trained mice also exhibited higher AMPK activity (P < 0.05) compared to sedentary counterparts.

**CONCLUSION:** As AMPK is recognized as a fuel regulator in the heart under stressful conditions including ischemia, the sex- and training-induced differences in cardiac AMPK response to exhaustive exercise warrant further investigation.

**Acute Sedentary Behavior and Markers of Cardiometabolic Risk: A Systematic Review of Intervention Studies**

Travis J. Saunders, Richard Larouche, Rachel C. Colley, Mark S. Tremblay, FACSM. *Children's Hospital of Eastern Ontario Research Institute, OTTAWA, ON, Canada.*

(No relationships reported)

**PURPOSE:** North Americans spend half their waking hours engaging in sedentary behavior. Although several recent interventions suggest that short bouts of uninterrupted sedentary behavior may result in acute increases in cardiometabolic risk, this literature has not been reviewed systematically. The purpose of the present study was to systematically review the impact of uninterrupted sedentary behavior lasting ≤7 days on markers of cardiometabolic risk (insulin sensitivity, glucose tolerance, and lipid levels) in humans.

**METHODS:** Interventions were identified through systematic searches of Medline and Embase, and screened by 2 independent reviewers

**RESULTS:** A total of 22 interventions were identified that examined the impact of imposed sedentary behaviour on biomarkers of interest. The majority of these studies focused on healthy young men, with very little identified research on females or other age groups. We found consistent, moderate quality evidence that uninterrupted sedentary behaviour ≤7 days results in moderate and deleterious changes in insulin sensitivity and plasma triglyceride levels, respectively. In contrast, there is inconsistent, very low quality evidence linking uninterrupted sedentary behaviour with changes in glucose tolerance, HDL or LDL Cholesterol.

**CONCLUSIONS:** These findings suggest that uninterrupted bouts of sedentary behaviour should be avoided in order to prevent or attenuate transient increases in metabolic risk.

**Measurement of Leg Blood Flow During Exercise Using Strain Gauge Plethysmography: Effect of Venous Occlusion Pressure**

Christopher D. Askew, James A. Matthews. *Queensland University of Technology, Kelvin Grove, Queensland, Australia.* (Sponsor: Jeff Coombes, FACSM)

(No relationships reported)

Venous occlusion strain gauge plethysmography (VOP) is well established as a non-invasive technique for the measurement of limb blood flow. While the susceptibility of the technique to movement artefact has limited its use primarily to the assessment of resting blood flow, VOP has recently been shown to compare favourably with Doppler ultrasound for the measurement of contraction-by-contraction blood flow during lower limb exercise. Before VOP can be recommended for use during exercise, the effect of venous occlusion on muscle performance needs to be determined. Furthermore, it is plausible that exercise in the upright position, which increases venous pressure in the lower limbs, would negate or minimise the need for venous occlusion, although this has not been tested.

**PURPOSE:** To compare the effect of standard (60 mmHg), low (30 mmHg) and no (0 mmHg) venous occlusion pressure on leg blood flow and muscle fatigue during intermittent isometric plantar flexion exercise.

**METHODS:** Eighteen male participants (age: 21 ± 2 y) attended three testing sessions, 7 days apart, and performed a 5-min intermittent isometric plantar flexion exercise test at a target force of 50% MVC, with one of three venous occlusion pressures (thigh cuff at 0, 30 or 60 mmHg) in a random order. Contraction-by-contraction blood flow data were fitted to a biexponential curve to determine the mean response time and magnitude of blood flow. MVCs were performed before and after each bout of exercise to determine the magnitude of fatigue.

**RESULTS:** Muscle fatigue, relative to pre-test MVC force, increased with increases in occlusion pressure (mean ± SD: 0mmHg = 9.86 ± 6.45; 30mmHg = 13.66 ± 6.04; 60mmHg = 13.41 ± 5.30%, p<.05). Blood flow mean response time was longer (0mmHg = 20.80 ± 7.49; 60mmHg = 23.46 ± 7.53 s; p<.05) and magnitude was higher (0mmHg = 53.04 ± 14.98; 60mmHg = 56.92 ± 12.90 ml/100ml/min; p<.05) at 60 mmHg compared with 0 mmHg, but was not different to the 30 mmHg condition.

**CONCLUSION:** The use of a standard venous occlusion pressure of 60 mmHg to measure lower limb blood flow during exercise has a negative effect on muscle fatigue. This effect may be minimised, without significantly influencing blood flow, by using an occlusion pressure of 30 mmHg.

**Chronotropic and Perceptual Responses To Deep Water Running**

Fiddy Davis, Bhamini Rao. *Manipal University, Udupi, India.*

(No relationships reported)

Deep Water Running (DWR) is gaining popularity as a means to maintaining and improving cardiorespiratory endurance in people for whom weight bearing aerobic exercise is contraindicated. However there is limited knowledge about the chronotropic and perceptual responses of the body to DWR.

**PURPOSE:** To compare the Heart Rate (HR) and Rating of Perceived Exertion (RPE) responses during Treadmill Running (TMR) and DWR and to investigate the relationship between HR and RPE in these environments

**METHODS:** 10 male recreational athletes aged between 18 and 30 years performed TMR and DWR on two different days at six incremental levels of speed (6,7,8,9,10 & 11 kmph).

Participants exercised for four minutes in each level and were given eight minutes recovery between levels. DWR was performed by immersing the individual till the neck level in an upright position using a floatation device. At the end of each level, HR and RPE were measured. HR was measured using a radio telemetric tester and RPE was measured using modified Borg's scale.

**RESULTS:** Paired t-test and Wilcoxon signed rank test was used to measure the difference in HR and RPE across environments in each level. HR was significantly lower in DWR than in TMR in all levels of speed except the first two levels of speed (p=0.29 & 0.24) and RPE was significantly higher in DWR at all levels of speed. The mean HR difference in the last four stages was 20 beats/min. Pearson product moment correlation was used to measure the relationship of the dependent variables. HR and RPE had a moderate correlation in TMR and DWR (0.670 and 0.580). Regression analysis was performed and an equation was derived to predict HR during DWR from RPE.

**CONCLUSIONS:** HR was found to be consistently lower and RPE was consistently higher in DWR than in TMR for a given workload. HR in DWR can be predicted through RPE with this equation (6.29 x RPE + 110.48)

**The Effect Of Nicotine On Cardiorespiratory Responses And Energy Expenditure During Exercise**

Takashi Nakagata<sup>1</sup>, Hisashi Naito<sup>1</sup>, Hiroyuki Kobayashi<sup>2</sup>, Shizuo Katamoto<sup>1</sup>. <sup>1</sup>*Juntendo University, Tokyo, Japan.* <sup>2</sup>*University of Tsukuba, Tsukuba, Japan.*

(No relationships reported)

**PURPOSE:** Recently, nicotine patches or chewing gums have been often prescribed for smokers to quit smoking. To date, studies have investigated the effect of nicotine on cardiorespiratory responses and energy expenditure during exercise to reveal any possible cautions to be taken when prescribing exercise. These studies however used a fixed low exercise intensity, so that the

effect of nicotine on cardiorespiratory responses and energy expenditure during varying exercise intensities, especially exhaustion remains to be investigated.

To examine the effects of transdermal nicotine patch on cardiorespiratory responses and energy expenditure during incremental pedaling exercise.

**METHODS:** Twelve healthy males aged 21-29 year-old performed an incremental step exercise on a cycle ergometer at a cadence of 60 rpm (initially 0.5 kp, increased by 0.5 kp until 4.0 kp every 4 min) on two occasions. Subjects were administered either a placebo (control) or 7 mg transdermal nicotine patch 10 hr before the exercise using a randomized-order cross-over method. The patch was attached on the left arm until the completion of the exercise. Heart rate (HR), the volume of oxygen consumption (VO<sub>2</sub>), energy expenditure (EE), respiratory exchange ratio (RER), rate of perceived exertion (RPE), and blood lactate (La) were measured at each exercise intensity. Data were analyzed using two-way repeated measures ANOVAs.

**RESULTS:** Four out of twelve subjects exhausted and terminated exercise at 3.5 kp for both placebo and nicotine conditions. RPE for the eight subjects who could pedal at 4.0 kp ranged between 15 and 18. VO<sub>2</sub>, EE, RER and La responses during the incremental exercise were similar between placebo and nicotine. Only HR was affected by nicotine (P = 0.005), and was higher for nicotine condition for all intensities investigated compared to control (mean difference=6.3%).

**CONCLUSIONS:** A 7 mg transdermal nicotine administration resulted in slightly higher HR compared to control. Therefore, the nicotine effect should be taken into consideration when estimating physical fitness level or determining exercise intensities using HR during exercise.

**Noninvasive Optical Quantification of Absolute Blood Flow and Oxygen Consumption Rate in Exercising Skeletal Muscle**

Katelyn Gurley, Yu Shang, Guoqiang Yu. *University of Kentucky, Lexington, KY.*

(No relationships reported)

Many common diseases (peripheral vascular disease, fibromyalgia) affecting skeletal muscle involve moderate to severe impairments in circulatory and metabolic functions. A hybrid optical instrument combining near-infrared spectroscopy (NIRS) and diffuse correlation spectroscopy (DCS) has been developed to noninvasively monitor multiple tissue hemodynamic parameters. Using this hybrid instrument with a few simple physiological manipulations, we demonstrate, for the first time, a noninvasive optical method for obtaining the absolute measurements of blood flow, oxygenation, and oxygen consumption rate in exercising muscle.

**PURPOSE:** To noninvasively monitor absolute blood flow, oxygenation and oxygen consumption rate in skeletal muscle.

**METHODS:** DCS monitors relative blood flow (rBF) by measuring the speckle fluctuations caused by moving red blood cells, while NIRS measures tissue absorption and scattering to determine tissue blood oxygen saturation (StO<sub>2</sub>). Relative oxygen consumption rate (rVO<sub>2</sub>) is calculated by the Fick principle using the measured StO<sub>2</sub> and rBF. Absolute baseline blood flow (BF) and VO<sub>2</sub> were characterized in the forearm of 7 healthy subjects using venous and arterial occlusions, respectively. Both parameters were manipulated by 5 minutes of rhythmic isotonic handgrip exercise, while absolute values of BF and VO<sub>2</sub> during exercise were determined by multiplying rBF and r VO<sub>2</sub> with absolute baselines. Previous problems with muscle fiber motion artifact in optical measurements during exercise were mitigated in this study by using a gating algorithm to determine the contraction status of the muscle based on the position of the handgrip device.

**RESULTS:** Baseline BF and VO<sub>2</sub> values were 1.7 ± 0.5 ml/100ml/min and 3.6 ± 0.8 μmol O<sub>2</sub>/100ml/min, respectively. During exercise, values of BF and VO<sub>2</sub> increased to 9.8 ± 4.0 ml/100ml/min and 17.5 ± 5.2 μmol O<sub>2</sub>/100ml/min. These values are comparable to those found in the literature using other techniques (strain gauge, catheter).

**CONCLUSIONS:** Our results show that DCS/NIRS can noninvasively monitor absolute BF, StO<sub>2</sub>, and VO<sub>2</sub> in exercising muscle. The information provided by such measurements can be highly valuable in assessing the functionalities of the microcirculation and metabolism in regards to skeletal muscle disease.

3334 Board #55 June 2 9:30 AM - 11:00 AM

**Accumulating Short Bouts Of Exercise Negates The Postprandial Impairment Of Endothelial Function In Adolescent Boys**

Matthew J. Sedgwick, John G. Morris, Mary E. Nevill, Laura A. Barrett. *Loughborough University, Leicestershire, United Kingdom.*

(No relationships reported)

An impairment in endothelial function is considered a key factor in the development and progression of atherosclerosis. The ingestion of high-fat meals impairs endothelial function in adults, and continuous exercise has been shown to attenuate this impairment. No study has investigated if high-fat meals impair endothelial function in adolescents, but the young tend to exercise in short bouts, and the benefits of such patterns of exercise have yet to be established.

**PURPOSE:** To investigate the effects of accumulating short bouts of exercise on postprandial endothelial function in adolescent boys.

**METHODS:** Seven adolescent boys (mean ± SD, age 12.7 ± 0.5 years, weight 44.9 ± 9.4 kg, BMI 20.2 ± 2.8 kg·m<sup>-2</sup>) completed two, 2-day main trials (control and exercise) in a counterbalanced cross-over design. On day 1 participants were either inactive (control trial) or completed six 10-min bouts of running, with each bout interspersed with 50 min rest, at 70% peak oxygen uptake (exercise trial). On day 2 participants consumed a high-fat breakfast (0 h) and lunch (3.5 h). Endothelial function was assessed (as flow-mediated dilation (FMD)) in the fasting state and 3 h following each meal.

**RESULTS:** There was no difference in fasting FMD between the control and exercise trial (P = 0.250). In the control trial flow-mediated dilation was lower, compared to the fasting (F) measure, following breakfast (B) and lunch (L) (F vs. B: 8.2 ± 1.7 vs. 5.4 ± 1.7 %, P = 0.006; F vs. L: 8.2 ± 1.7 vs. 5.5 ± 1.4 %, P = 0.027). This represented a reduction in FMD, compared with fasting values, of 34% and 33% respectively. In the exercise trial flow-mediated dilation was not different, compared to the fasting measure, following breakfast and lunch (F vs. B: 8.8 ± 1.5 vs. 8.7 ± 2.0%, P = 1.000; 8.8 ± 1.5 vs. 8.0 ± 1.9%, P = 0.588).

**CONCLUSION:** The ingestion of high-fat meals impaired endothelial function in the seven boys studied, suggesting that the postprandial period is a time when even healthy adolescent boys may be susceptible to atherosclerotic development and progression. However, the impairment in endothelial function was attenuated when a series of short bouts of exercise were performed in the day preceding consumption of the meals.

3335 Board #56 June 2 9:30 AM - 11:00 AM

**Comparison of Intra-arterial vs Manual Auscultation of Blood Pressure During Exercise in Healthy Humans**

Sarah E. Baker<sup>1</sup>, Courtney M. Wheatley<sup>1</sup>, Eric M. Snyder<sup>1</sup>, Michael J. Joyner, FACSM<sup>2</sup>, Bruce D. Johnson<sup>2</sup>, Thomas P. Olson<sup>2</sup>. <sup>1</sup>University of Arizona, Tucson, AZ.

<sup>2</sup>Mayo Clinic and Foundation, Rochester, MN.

(No relationships reported)

**PURPOSE:** Blood pressure (BP) is a key measure of cardiovascular function. As such accurate measurement is important to ensure proper clinical evaluation, diagnosis, and treatment. We compared intra-arterial (Direct) vs. cuff auscultation (Manual) measurement techniques at rest and during multiple steady-state submaximal exercise intensities.

**METHODS:** Sixty-four adults (age=29±1, 52% female, ht=174±1 cm, wt=73±2 kg, BMI=24.1±0.4 kg/m<sup>2</sup>, BSA=1.87±0.03 m<sup>2</sup>) participated in the study. Blood pressure was measured directly via radial artery catheter and manually by brachial auscultation with sphygmomanometry at rest and during two levels of submaximal steady-state exercise (9 min at 40% and 75% max watts). Cardiac output was measured via open circuit acetylene uptake. Measures were taken in triplicate (1x every 3 min).

**RESULTS:** At rest, low and moderate intensity Direct measurement demonstrated a significant elevation in systolic (SBP) and diastolic (DBP) blood pressure (Bias for SBP: 22±13, 29±19 and 27±23 mmHg and DBP: 5±10, 5±12 and 17±15 mmHg; rest, low and moderate intensity respectively, p<0.001 for all). At rest, the correlation and agreement between the two methods was modest (SBP: r=0.56, bias=+22 mmHg; DBP: r=0.53, bias=+5 mmHg, p<0.001 for both). Although there was good correlation and agreement with SBP at low and moderate intensity, we noted the Manual method demonstrated a weaker relationship for DBP (SBP: r=0.74 and 0.74; bias=+30.2 and +26.8 mmHg; DBP: r=0.39 and 0.28; bias= +7.1 and +13.4 mmHg, for low and moderate intensity respectively, p<0.001). Further, Manual measurement demonstrated a greater slope for the relationship between pulse pressure and cardiac output (13.6±0.4 vs 12.3±0.4, p=0.03). These changes resulted in a narrowing of the difference in PP between techniques during moderate intensity.

**CONCLUSIONS:** Our results suggest that as exercise intensity increases Manual DBP tends to bias low compared to Direct DBP, which when combined with parallel increases in SBP, leads to no differences in pulse pressure between methods at moderate intensity exercise. Due to the use of PP in calculation of other cardiovascular parameters (MAP, SVR), the intensity of exercise is an important consideration when determining the most appropriate technique for measurement of BP.

3336 Board #57 June 2 9:30 AM - 11:00 AM

**Effects Of Aerobic Cycle Exercise In The Evening On The Following Nocturnal Sleep And Its Hemodynamic Response**

Yoshiyuki Fukuba, FACSM, Shizuka Myouken, Masako Yamada, Hideaki Kashima, Chizuko Fujihara, Akira Miura, Masako Y. Endo. *Prefectural University of Hiroshima, Hiroshima, Japan.*  
(No relationships reported)

**PURPOSE:** It is not well established as to whether the nocturnal sleep would be affected by the preceding exercise in daytime. While the exercise is known to elicit acutely a reduction in blood pressure (BP) for approximately 2-3 hours (i.e. post-exercise hypotension: PEH) even in healthy subjects, it is still unclear as to whether the PEH would be lasting until the bedtime of the following night. We, therefore, determined the effect of aerobic exercise in early evening on the quality/quantity of sleep and its hemodynamic response in the following night, not in laboratory, but in subject's own bedroom.

**METHODS:** 12 healthy young male subjects (age: 18-25 yr) participated first in preliminary protocol, in order to check whether he could accustom to equip the ambulatory BP recording device for one day from the early evening to the noon of next day and the special watch for continuous HR recording for bedtime, without exercise intervention. As a result, 10 of 12 subjects had no serious disturbance to usual daily life including the bedtime. Then 10 subjects performed two main protocols either with or without the cycle ergometer exercise (60 min at 50% HR reserve) in early evening (i.e. 1st day), in random order. The ambulatory monitoring of BP/HR (Holter type) and physical activity by accelerometer (AW-16 Actiwatch) were started from the late afternoon (i.e. 30 min before exercise) to the noon of next day (i.e. 2nd day). In addition, the special watch (NEM-T1 Toshiba) for identifying the sleep stage by HRV analysis was equipped, instead of the constraint EEG monitoring, during the bedtime. To avoid any effect induced by the food intake, the standardized contents of lunch and dinner of 1st day and breakfast of the 2nd day were offered.

**RESULTS:** There were no substantial differences in the objective indices of sleep between with and without preceding exercise. Compared to control (i.e. without exercise), the mean value of BP during nocturnal sleep showed a tendency to be lowered by the preceding exercise.

**CONCLUSIONS:** The aerobic exercise in early evening has no acute effect to the sleep itself, but some residual effect to the hemodynamic response during sleep, i.e. the prolonged PEH.

**Effect Of Altitude Of Residence On The Cardiovascular Responses To Dynamic And Isometric Hand-grip Exercise At 4900 Meters**

Andrew Grant, Marta Perez, John E. Davis. *Alma College, Alma, MI.*  
(No relationships reported)

Previous studies have documented the beneficial physiological adaptations to living at high altitude. However, few studies have examined exercise responses for residents from a variety of altitudes at very high altitude.

**PURPOSE:** To examine the influence of altitude of residence on cardiovascular responses during dynamic and isometric exercise when exposed to very high altitude.

**METHODS:** Thirty subjects voluntarily participated in the study after giving informed consent and completing the Lake Louise survey for acute mountain sickness. Subjects were recruited and tested at the Mount Chimborazo refugio in Ecuador located at 4900 meters. This is an optimal location because many Ecuadorians and tourists who reside at a variety of altitudes can easily drive to the refugio. All measurements were taken immediately upon arrival at the refugio. Subjects were divided into three groups based on their altitude of residence: low altitude - LOW (0-1500 m), moderate altitude - MOD (1500-3000 m), and high altitude - HIGH (>3000 m). A maximum voluntary contraction (MVC) using a hand-grip dynamometer was performed for each subject. Each subject then performed 30 contractions on the dynamometer at 50% MVC. Following the dynamic contractions, they performed an isometric contraction at 50% of MVC until they reached 25% of MVC. Heart rate, oxygen saturation, and systolic and diastolic blood pressure were measured before the exercise and during the dynamic and isometric exercise.

**RESULTS:** Average heart rates at rest and during both dynamic and isometric exercise were significantly higher in LOW (105±8.2, 112.7±9.5, 112±12.8 bpm) when compared to MOD (84.5±16.2, 91.7±12.6, 91.3±11.8) and HIGH (78.9±17.6, 80.0±10.3, 84.3±11.9). Also, average oxygen saturation was significantly lower at rest and during dynamic exercise in LOW (72.3±15.1, 71.4±10.3%) compared to MOD (78.7±5.5, 81.1±4.1) and HIGH (82.4±3.7, 85.0±3.9). Although changes were observed in systolic and diastolic blood pressure and oxygen saturation at rest and during dynamic and isometric exercise, these values were not statistically significant between groups (p>0.05).

**CONCLUSION:** Altitude of residence had an important influence on resting cardiovascular responses at very high altitude. However, the additive effect of exercise was similar in all three groups.

3338 Board #59 June 2 9:30 AM - 11:00 AM

**Role of Free Radicals in the Regulation of Systemic Vascular Resistance in Chronic Heart Failure**

Melissa A.H. Witman<sup>1</sup>, John McDaniel<sup>2</sup>, Stephen J. Ives<sup>1</sup>, Anette S. Fjeldstad<sup>1</sup>, Jia Zhao<sup>1</sup>, Josef Stehlik<sup>1</sup>, D. Walter Wray<sup>1</sup>, Russell S. Richardson<sup>1</sup>. <sup>1</sup>University of Utah, Salt Lake City, UT. <sup>2</sup>Kent State University, Kent, OH.  
(No relationships reported)

**PURPOSE:** To better elucidate the link between free radicals and hemodynamic control in patients with chronic heart failure (CHF), we studied 10 patients and 10 age-matched healthy controls at rest and during handgrip exercise with either an acute oral antioxidant cocktail (AOC (Vitamin C, E, and  $\alpha$  lipoic acid)) or placebo (PL) in a balanced, cross-over design.

**METHODS:** To assess central and peripheral hemodynamics, mean arterial pressure (MAP), cardiac output (CO), systemic vascular resistance, brachial artery blood flow, and peripheral (arm) vascular resistance were determined.

**RESULTS:** Compared to controls, patients with CHF exhibited greater oxidative stress, measured by thiobarbituric acid reactive substances (TBARS) (~40%), and evidence of endogenous antioxidant compensation, measured by superoxide dismutase (SOD) activity (~45%). The AOC increased plasma ascorbate (~32%) in both the CHF patients and controls. The ingestion of the AOC had significant systemic hemodynamic effects which were only evident in the patients with CHF, both at rest and throughout exercise. Specifically, the AOC reduced MAP (~5%) and SVR (~12%) but increased CO (~10%). In contrast, peripherally, brachial artery blood flow tended to be reduced, and peripheral (arm) vascular resistance was unchanged in response to AOC consumption.

**CONCLUSIONS:** Based upon the recognized link between free radicals and sympathetic nerve activity in patients with CHF, these data imply that systemic vascular resistance in this population appears, at least in part, to be free radically-mediated, however, this finding does not appear to be the direct result of muscle-specific changes in peripheral vascular resistance.

---

3339 Board #60 June 2 9:30 AM - 11:00 AM

**Exercise-induced Cardioprotection Is Triggered By Cytosolic, And Not Mitochondrial Reactive Oxygen Species**

Chad R. Frasier, Hetal D. Patel, Luke M. Stewart, David A. Brown. *East Carolina University, Greenville, NC.* (Sponsor: Peter A. Farrell, FACSM)  
(C.R. Frasier: Contracted Research - Including Principle Investigator; D.A. Brown.)

Exercise provides potent and sustainable cardioprotection that is unparalleled by any other preconditioning stimuli. Although the benefits of exercise are clear, the cellular factors responsible for triggering the protection are not understood. Previous reports in the literature have indicated that production of reactive oxygen species (ROS) during exercise may initiate a protective signaling cascade, but the intracellular site(s) of ROS production remain unclear.

**PURPOSE:** To determine if bursts of ROS during exercise promote a cardioprotective phenotype, and to ascertain the intracellular locus of ROS production.

**METHODS:** Female Sprague-Dawley rats were assigned into a sedentary handling control (Sed) or an exercise trained (Ex) group. Animals in the Ex group were placed on a treadmill for ten consecutive days for 15/30/15 meters per minute for 15/30/15 minutes. Approximately 10 minutes before exercise animals received an i.p. injection of the mitochondria-targeted antioxidant MTP-131 (1.5 mg/kg), the NADPH oxidase inhibitor apocynin (5 mg/kg), or saline. Twenty-four hours after the last session hearts were placed on the cannula of a Langendorff apparatus and exposed to 25 minutes of global ischemia followed by two hours of reperfusion.

**RESULTS:** As expected, Ex decreased infarct size ( $53 \pm 3$  and  $42 \pm 2\%$  for Sed and Ex respectively;  $P < 0.05$ ). Treatment of Sed animals with MTP-131 led to a significant decrease in the size of infarction ( $41 \pm 3\%$ ;  $P < 0.05$  vs. Ex saline). Apocynin abolished the cardioprotective effects of exercise ( $53 \pm 2\%$ ;  $P < 0.05$  vs. Sed saline).

**CONCLUSIONS:** By using both a mitochondria-targeted antioxidant and an inhibitor of NADPH oxidase we were able to determine that the locus of ROS production during exercise plays a vital role in cell signaling. Our results suggest that ROS generated through NADPH oxidase, and not within the mitochondria, are potent signaling molecules involved in exercise-induced cardioprotection. Future experiments that seek to investigate the signaling mechanisms downstream of ROS production by NADPH oxidase. This study was supported by American Heart Association Predoctoral Fellowship 11PRE7590086 and Stealth Peptides, Inc.

**3340** Board #61 June 2 9:30 AM - 11:00 AM

**Hemoglobin A1c, Glycemia, Fitness And Associated Risk Factors In Older Adults**

Raul A. Martins, Ana M. Teixeira, Manuel T. Verissimo. *University of Coimbra, Coimbra, Portugal.*

(No relationships reported)

Epidemiological evidence suggests that glycosylated hemoglobin (HbA1c) is associated with cardiovascular risk. Age is associated with several risk factors as increased body fat, deterioration of the lipid profile, decrease of the cardiorespiratory fitness, or diabetes. Sex differences have been found on some variables associated with cardiovascular risk.

**PURPOSE:** To analyze the relationships between HbA1c and other cardiovascular risk factors in older women and men.

**METHODS:** Participated 72 women ( $77.5 \pm 8.4$  yrs) and 46 men ( $75.5 \pm 6.8$  yrs). Fasting venous blood was taken to determine HbA1c, glycemia, HDL-cholesterol, LDL-cholesterol, triglycerides, and high-sensitivity C-reactive protein (hs-CRP). Body weight, waist circumference, BMI, blood pressure, resting heart rate, peak heart rate, and functional fitness variables (peak  $VO_2$ , lower and upper strength, and velocity, agility and dynamic balance) were measured. Associations between variables were assessed with bivariate correlations and partial correlations. MANOVA was used to assess differences between women and men and between age stages.

**RESULTS:** According to the IDF (2005) cut-off points for waist circumference on European people, 85% of women ( $\geq 80$  cm) and 66% of men ( $\geq 94$  cm) exhibit central obesity. Obese ( $5.6 \pm 0.9\%$ ) had higher HbA1c ( $p < 0.05$ ) than non-obese ( $5.3 \pm 0.4\%$ ) participants. Women ( $5.6 \pm 0.8\%$ ) had similar HbA1c than men ( $5.4 \pm 0.7\%$ ). Older (80+ years-old) participants ( $5.6 \pm 0.7\%$ ) had similar HbA1c than younger (65-79 years-old) participants ( $5.5 \pm 0.8\%$ ). HbA1c correlated with glycemia ( $r = 0.607$ ;  $p < 0.01$ ), triglycerides ( $r = 0.493$ ;  $p < 0.01$ ), and BMI ( $r = 0.298$ ;  $p < 0.01$ ), independently of the age, and not correlated with HDL-C, LDL-C, body weight, waist circumference, and functional fitness.

**CONCLUSIONS:** HbA1c in older adults is not influenced by sex or by age. Regional distribution of obesity as measured by the waist circumference is not related with HbA1c. However BMI is positively associated. HbA1c does not associate with functional fitness, blood pressure or heart rate.

**Exercise-induced Ischemic Preconditioning: A Systematic Review And Meta-analysis**

Francois lalonde<sup>1</sup>, Paul Poirier<sup>2</sup>, Danis Arvais<sup>1</sup>, Daniel Curmier<sup>1</sup>. <sup>1</sup>Universite De Montreal, Montreal, QC, Canada. <sup>2</sup>Universite Laval, Quebec, QC, Canada.

(No relationships reported)

**PURPOSE:** Brief intervals of ischemic insult followed by reperfusion of an organ results in the ability to withstand subsequent prolonged periods of ischemia. This phenomenon is known as ischemic preconditioning (IPC) and contributes in delaying myocardial infarction, suppressing arrhythmias and improving post-ischemic functional recovery. A non-surgical way to induced ischemic preconditioning came from the warm-up phenomenon in patients with coronary artery disease (CAD). Warm-up phenomenon occurs when angina is induced by a first exercise which is attenuated by a short rest before resuming the same first exercise at the same or greater intensity. IPC induced by exercise can be demonstrated by a significant decrease of ECG signs of myocardial ischemia on the second of two exercise tests performed within a short interval.

**METHODS:** A literature search was performed in January 2011 using PubMed, Embase, CINAHL Plus with Full Text and Web of Science. The main key words limited to human studies were: ischemic preconditioning, warm-up phenomenon and exercise. Articles were reviewed by two readers and were selected for statistical analysis. The analysed parameters on ECG were: total stress test time, time to 1 mm (ST segment depression) STD, rate-product at 1 mm STD, maximal STD, maximal rate-product and recovery time.

**RESULTS:** The systematic review on electronic database resulted in 218 articles of which 32 of them (1 033 patients) fulfilled to selection criteria. Results of statistical analysis compared the first test (as the source of IPC) versus a second or third exercise test. Time to 1 mm STD was greater in subsequent test: Standard mean deviation (SMD) 0.77 (0.56-0.98),  $p < 0.0001$ ; rate-product at 1mm STD: SMD: 0.61 (0.36-0.86)  $p < 0.0001$ ; maximal STD: SMD -0.82 (-1.08- -0.56)  $p < 0.001$ ; recovery time: SMD -1.00 (-1.53- -0.48)  $p = 0.0002$ .

**CONCLUSIONS:** This is the first meta-analysis and systematic review showing that exercise-induced IPC have positives outcomes on ECG parameters. Result summary show that CAD patient can improve their exercise performance on a second stress test after a short period of rest. Further study are needed to assess the role of exercise-induced IPC in rehabilitation programs.

**Physical Therapy Interventions In Patients With Heart Disease And Intercostal Pains. A Randomised Controlled Trial**

Astrid T. Berg<sup>1</sup>, Inger Lise Aamot<sup>1</sup>, Aud Hiller<sup>1</sup>, Stig Slordahl<sup>2</sup>. <sup>1</sup>St. Olavs Hospital, Trondheim, Norway. <sup>2</sup>Norwegian University of science and Technology, Trondheim, Norway.

(No relationships reported)

Studies shows that patients presenting chest pain is a common problem to general practitioners and accident- and emergency departements. The symptom creates anxiety that it represents a life-threatening event and numerous investigations often follow. Musculoskeletal causes are common, but frequently overlooked with estimations showing that 20 to 25% of non-cardiac chest pain has a musculoskeletal basis. No studies concerning treatment of chest pain from the intercostal muscles were found by search in various databasis.

**PURPOSE:** To evaluate the effect of two different physical therapy interventions in patients with known heart disease and intercostal pains.

**METHODS:** The study included 29 patients (mean age  $61 \pm 9.3$  years), 6 women and 23 men. The inclusion criteria were increasing chest pain during cardiac rehabilitation classes. Patients were randomised to either deep friction massage and heat-pack (A) or heat-pack only (B) and given a maximum of 8 individual treatments. Pain was evaluated by using Visual Analogue Scale (VAS) 0 to 100, where 0 is no pain and 100 intolerable pains. VAS score was registered at inclusion, post treatment and 3 months after the last treatment session and included 3 different scores: pain here and now (1), mean pain last 14 days (2) and worst pain attack last 14 days (3). In addition all patients received oral information regarding their pain condition.

**RESULTS:** Group A scored at baseline: (1) 45.5 (20-76), (2) 50 (26-81), (3) 60 (24-96). Group A scored at post treatment: (1) 6.5 (0-47), (2) 9.5 (0-46), (3) 14 (0-47). Group A scored at 3 months: (1) 10.5 (0-28), (2) 10 (0-28), (3) 10.5 (0-35).

Group B scored at baseline: (1) 40 (3-81), (2) 50 (5-80), (3) 65 (5-96).

Group B scored at post treatment: (1) 15 (1-71), (2) 15 (2-65), (3) 22 (0-90).

Group B scored at 3 months: (1) 5 (1-77), (2) 16 (0-82), (3) 26 (0-82). Both interventions gave statistically significant pain reduction from pre to post treatment, evaluated by VAS-scale. No statistic significance between the groups was obtained at any time. No adverse effect were recorded during treatment.

**CONCLUSIONS:** Both deep friction massage and heat-pack and heat-pack only, gave significant reduced pain. These physical therapy interventions gave promising results in treating intercostal pains and the findings may have important clinical implications.

### Investigation Of C-reactive Protein And Leptin As Biomarkers Of Obesity With Potential Clinical Utility

Rachel A. Friedman<sup>1</sup>, Scott Lyons<sup>2</sup>, James Navalta<sup>2</sup>, Mark Schafer<sup>2</sup>, Scott Arnett<sup>2</sup>. <sup>1</sup>Washington University, St. Louis, MO. <sup>2</sup>Western Kentucky University, Bowling Green, KY.

(No relationships reported)

Obesity is a major health problem in the United States with life-threatening associated disease states. Obesity itself is considered a problematic condition due to the chronic effects it has on the body. Intense exercise also stresses the body, putting humans in recovery from exercise in a condition that may be analogous to a disease state.

**PURPOSE:** The purpose of this study was to examine biomarkers associated with obesity (CRP and Leptin) before and after continuous and intermittent bouts of exercise in an obese sample vs. a non-obese sample.

**METHODS:** The obese group's biomarkers at rest were compared to those of the non-obese group after exercise. Eighteen male subjects performed a VO<sub>2</sub> max test and a series of three Wingate tests in a cross-over study design. Blood was taken PRE, POST, and 1-HR POST.

**RESULTS:** During the VO<sub>2</sub> max test, the non-obese group's CRP levels decreased POST and returned to baseline 1-HR POST, while the obese group's CRP levels increased immediately after and returned to baseline after 1 hour (changes not significant). Significant differences were noted between groups PRE on the VO<sub>2</sub> max testing day with the obese group's resting levels at .94±.54 mg-dl<sup>-1</sup> and the healthy group's at .49 ±.27mg-dl<sup>-1</sup> and in Leptin levels on the Wingate test day with the obese group's at 18.68±13.29ng-ml<sup>-1</sup> and the non-obese group's at 5.39±4.24 ng-ml<sup>-1</sup>. On the Wingate test day, the CRP responses were the opposite of those on the VO<sub>2</sub> max day, with a significant change in CRP from POST to 1-HR POST in the obese group (1.18±.72 to .97±.60 mg-dl<sup>-1</sup>). Serum Leptin levels for both groups increased POST after both exercise modes and returned to baseline 1-HR POST (changes not significant). Non-obese participants were examined individually. Two of them demonstrated the possibility of being at-risk for obesity based on post exercise elevations in CRP and Leptin on at least 3 of the 4 conditions (CRP-VO<sub>2</sub>, CRP- Wingate, Leptin-VO<sub>2</sub>, and Leptin-Wingate) that caused the levels of the biomarkers to approach the obese group's at rest. Three additional subjects demonstrated two elevations and reported parental obesity. Therefore, five participants could potentially be "at-risk" based on the assumptions of the present study.

**CONCLUSION:** These results suggest CRP and Leptin could possess the ability to classify individuals in a "pre-obesity state."

### Offloading and Vascular Responses to CLEAR Cleat Cycling by Individuals at Risk of Diabetic Foot Ulceration

Ryan T. Crews, Steven R. Smith, Shannon B. Liu. *Rosalind Franklin University, North Chicago, IL.*

(No relationships reported)

Exercise has been associated with improved wound healing. While diabetic foot ulcers (DFU) are exceptionally difficult to heal, the location of the wounds prohibit most types of exercise. The wounds typically develop in part due to the forces applied to the feet during weight bearing activities, and healing requires offloading of the wounds. The CLEAR Cleat was designed to allow individuals with forefoot DFU to be able to safely participate in aerobic exercise that utilizes the lower limbs.

**PURPOSE:** This study sought to determine whether cycling with the CLEAR Cleat offloaded the forefoot of individuals at high risk for DFU in comparison to cycling with standard pedals and athletic shoes. It also investigated whether the exercise improved blood flow to the forefoot.

**METHODS:** Ten subjects with diabetic peripheral neuropathy, with or without addition DFU risk factors, were recruited to participate (aged 52±9 y; BMI 33±5). Individuals were excluded if they had an active DFU. Each subject completed two 5-minute stationary cycling sessions at the same self-selected cadence and resistance level. Standard athletic shoes and pedals were used during one session, and the CLEAR Cleat was used with their highest risk foot during the other session. Plantar pressure data was collected during the cycling sessions by in shoe pedobarography. Perfusion levels (tpu - total perfusion units) were examined at the hallux by a surface laser Doppler probe, pre and post each cycling bout.

**RESULTS:** The CLEAR Cleat significantly (p<.05) offloaded the forefoot. The peak pressure (10.9±10.6 vs. 69.0±43.5 kPa) and pressure time integral (15.4±16.0 vs. 76.4±28.8 kPa\*S) were both reduced. The cycling significantly increased microcirculation at the hallux during both cycling conditions (pre 3.15±2.9 vs. post 6.8±6.3 tpu).

**CONCLUSIONS:** These results suggest that the CLEAR Cleat will allow individuals with DFU to exercise in a manner that will not be detrimental to their wounds. The increased vascularity in these high risk subjects indicates that the cycling may improve blood flow to forefoot DFU and therefore aid healing. Based upon these promising results, additional research to determine whether the CLEAR Cleat improves healing and/or general health of individuals with DFU is planned. Partially supported by NIH grant T35DK074390.

### No Effect Of Kinesio Taping On Jump Performance In Female Track And Field Athletes

Thorsten Schiffer<sup>1</sup>, Anne Möllinger<sup>2</sup>, Billy Sperlich<sup>1</sup>, Daniel Memmert<sup>1</sup>. <sup>1</sup>German Sport University Cologne, Cologne, Germany. <sup>2</sup>University Heidelberg, Heidelberg, Germany.

(No relationships reported)

**PURPOSE:** Previous studies have indicated that kinesio taping (KT) alters muscle activation and proprioception in patients. Since muscle activation and proprioception are known to influence the jumping performance it was the aim of the study to test the hypothesis whether the application of KT enhances the jumping performance of healthy non-injured elite female track and field athletes.

**METHODS:** A double one-legged jump test was performed before and after application of KT and immediately after removal. Eighteen German female elite track and field athletes (age: 21 ± 2 years, active time in their sport: 13 ± 4 years, posture: 172 ± 4 cm, body mass 62 ± 5 kg) participated in the study.

**RESULTS:** The results revealed no significant differences in jumping performance between the tests (p>0.05, d=0.26).

**CONCLUSIONS:** These findings demonstrate that KT applied onto the muscles had no influence on the jumping performance in healthy non-injured female elite athletes.

### A Comparison of Proprioceptive Neuromuscular Facilitation Techniques: Partner Assisted vs. Theraband® Stretch Strap Unassisted Modalities

Meaghan Maddigan, Ashley Peach, David Behm. *Memorial University of Newfoundland, St. John's, NL, Canada.*

(No relationships reported)

**PURPOSE:** Proprioceptive neuromuscular facilitation (PNF) stretching typically requires a stretching partner therefore it is not viable for a single individual. The use of a strap may allow individuals to integrate the contract and relax segments of the PNF technique alone. However, the effectiveness and benefits of a stretch strap for PNF stretching are unknown. **The purpose of this study was to compare and investigate the effects of the Thera-Band® Stretch Strap - unassisted PNF on hip joint range of motion (ROM), reaction time (RT) and movement time (MT).**

**METHODS:** Thirteen healthy and recreationally active adults, six male and seven female ranging from 19 to 33 years in age participated in this study. Participants were subjected to 5 different stretch interventions in a random order on separate days. The five different stretch conditions which were implemented were: 1) isometric, 2) concentric and 3) eccentric contractions - all using the Thera-Band® Stretch Strap for resistance and maximum ROM - and 4) partner isometric PNF which were all compared to 5) static stretching. RT, MT, dynamic, active, and passive hip flexion ROM were measured twice before and after the intervention and dynamic angular velocity was calculated during the dynamic stretch.

**RESULTS:** There was a positive main effect for time ( $p < 0.05$ ) with all the stretching conditions, increasing by 2.6%, 2.75% and 5.37% from pre- to post-intervention with dynamic, active and passive stretches respectively. There was a negative main effect for time ( $p < 0.05$ ) with dynamic angular velocity decreasing 9.2% from pre- ( $70.54 \pm 4.03$  degrees/sec) to post-intervention ( $64.01 \pm 3.55$  degrees/sec). As well there was a negative main effect ( $p < 0.05$ ) with regards to MT, pre- ( $0.47 \pm 0.027$  sec) and post-intervention ( $0.49 \pm 0.023$  sec). However, there were no significant differences found in the participants RT pre-post stretching and there was no interaction between the stretch conditions for any of the measures.

**CONCLUSION:** Theraband® Stretch Strap may be used as an alternative to assisted PNF protocols as it can provide similar increases in ROM.

### The Relationship Between The Toe Exercises And The Medial Longitudinal Arch

Takashi Shiroshita<sup>1</sup>, Toru Fukubayashi<sup>2</sup>. <sup>1</sup>Gumma PAZ College, Gumma, Japan. <sup>2</sup>Waseda University, Saitama, Japan.

(No relationships reported)

**PURPOSE:** The toes play an important role, yet the toe flexor strength is poorly understood. We have been researching clinical and electromyogram (EMG) studies about the toe exercises we developed. However, the relationship between the toe exercises and the medial longitudinal arch (MLA) was unclear. The purpose of this study is to examine the relationship between the toe exercises and MLA.

**METHODS:** The subjects were 35 feet of 21 participants (11 males 17 feet, 10 females 18 feet), whose mean age was  $23.1 \pm 4.5$  years old. The participants performed three toe exercises and the towel gathering exercise. The three toe exercises were isotonic contractions (10 times) of the great toe flexor, 2nd-to-5th toe flexors and 3rd-to-5th toe flexors.

All subjects randomly performed the three toe exercises and the towel gathering exercise. Before and after each exercise, we assessed MLA using the navicular drop test (NDT) Brody developed.

This study was performed with the consent of the Ethics Committee for Human Research of Waseda University and Gumma Paz College.

For statistical analysis we performed Repeated ANOVA using IBM SPSS Statistics 19. Results were considered significant at values of  $p < 0.05$ .

**RESULTS:** NDT of before the training was 4.50 mm (within the range of the normal value). NDT of the towel gathering was 5.20mm, showing significant drop in comparison with before exercise. Also, in the great toe exercise, it was 5.39mm, showing a significant drop in comparison with before ( $p < 0.05$ ). In the 2nd-to-5th toe flexors and 3rd-to-5th toe flexors exercises, these were 3.16mm, 3.28mm respectively, those exercises showed significantly no drop in comparison with before ( $p < 0.05$ ).

**CONCLUSIONS:** The towel gathering and the great toe flexor exercise significantly decreased MLA. In regard to the great toe flexor exercise, the tendency was stronger. On the other hand, the exercises of 2nd-to-5th toe flexors and 3rd-to-5th toe flexors increased MLA.

This study has limits, as it was not possible to get rid of influence of fatigue. We consider that it is necessary to study the toe exercises we developed by longitudinal method research.

**3348** Board #69 June 2 8:00 AM - 9:30 AM

### Electromyographic Analysis of the Lower Extremity Position during Trunk Exercise in Prone Position

Tetsuji Ishida<sup>1</sup>, Masanori Takemura<sup>2</sup>, Shunsuke Fujitake<sup>3</sup>, Chihiro Dehara<sup>4</sup>, Moonhwa Park<sup>5</sup>, Yu Hashiguchi<sup>5</sup>, Junzo Tsujita<sup>2</sup>. <sup>1</sup>Shiga Medical Center for Children, Moriyama, Japan. <sup>2</sup>Hyogo College of Medicine, Nishinomiya, Japan. <sup>3</sup>Tachiiri Orthopedics, Kyoto, Japan. <sup>4</sup>Gakkentoshi Hospital, Seika, Japan. <sup>5</sup>Graduate School of Medicine, Kyoto University, Kyoto, Japan.

(No relationships reported)

**PURPOSE:** To compare the electromyographic (EMG) activity of local and global muscles in lumborum at various hip positions of lower extremity during lower trunk muscles exercises in prone position.

**METHODS:** Fifteen healthy adults (10 males and 5 females, means (SD) age; 26.7 (4.3) years) participated in this study. Each subjects performed maximal voluntary isometric contractions (MVIC) of trunk extension, then they performed three exercises for back muscles in the prone position. Those three exercises were hip extension at hip abduction of 0 degree (EXT), hip extension at hip abduction of 20 degree and hip internal rotation (similar to PNF pattern, EXT-ABD-IR), and hip extension at hip abduction of 20 degree and hip external rotation (EXT-ABD-ER). Surface EMG was recorded from the muscle belly of longissimus thoracis (LT), iliocostalis lumborum (IC), lumbar multifidus (LM) and gluteus maximus (GM) muscles, and EMG root mean square (RMS) were calculated and normalized to MVIC (%MVIC). Furthermore, the LM : contralateral IC, LM : contralateral LT, LM : ipsilateral IC, and LM : ipsilateral LT ratio were calculated as the local : global muscles activity ratio. Statistical analysis were performed a 3-way analysis of variance (ANOVA) with exercises and muscles activity ration as within-subject variable and sex as between-subject variable and a Least Significant Difference (LSD) multiple comparison test.

**RESULTS:** The activity (%MVIC) of ipsilateral LM were 48.9 (26.8) at EXT, 52.2 (29.1) at EXT-ABD-IR, and 53.8 (26.2) at EXT-ABD-ER. The muscles activity ratio at EXT, EXT-ABD-IR, and EXT-ABD-ER were 1.32 (0.67), 1.51 (0.72), 1.40 (0.74) as LM : contralateral IC, 1.53 (0.98), 1.72 (1.06), 1.49 (1.16) as LM : contralateral LT, 1.56 (0.73), 1.55 (0.65), 1.68 (0.79) as LM : ipsilateral IC, and 1.64 (1.05), 1.61 (0.81), 1.85 (1.26) as LM : ipsilateral LT, respectively. The LM : contralateral IC and TL were significantly higher EXT-ABD-IR compare to EXT and EXT-ABD-ER. Although the LM : ipsilateral IC and TL were not difference.

**CONCLUSION:** The result of this study showed that the prone back muscles exercise with hip extension at hip abduction of 20 degree and hip internal rotation (similar to PNF diagonal and spiral functional pattern) was activated selectively the lumbar multifidus muscle as local muscles.

**3349** Board #70 June 2 8:00 AM - 9:30 AM

### Precision Of The GE Lunar iDXA Densitometer for the measurement of Total Body Composition and Fat Distribution in Severely Obese Adults

Tamara E. Carver<sup>1</sup>, Nicolas V. Christou<sup>2</sup>, Ross E. Andersen, FACSM<sup>1</sup>. <sup>1</sup>McGill University, Montreal, QC, Canada. <sup>2</sup>McGill University Health Centre, Montreal, QC, Canada.

(No relationships reported)

Bariatric surgery is the most effective treatment for severe obesity. Rapid weight loss leads to changes in lean tissue mass, fat mass, and bone mass. No study has evaluated the precision of the GE Lunar iDXA™ (GE Healthcare, USA) in measuring body composition among severely obese patients.

**PURPOSE:** To evaluate the precision of the iDXA for total body composition and fat distribution measurements.

**METHODS:** 36 severely obese participants with a mean age of  $45 \pm 10$  yrs, BMI of  $48.3 \pm 10.5$  kg/m<sup>2</sup>, and mean body mass of  $136.4 \pm 20.4$  kg took part in the study. Two consecutive iDXA scans of the total body with repositioning were conducted for each participant. The coefficient of variation (CV), the root-mean-square (RMS) averages of standard deviations of repeated measurements, and the corresponding 95% least significant change (LSC) were calculated.

**RESULTS:** Precision was excellent for all measurements particularly for total body percentage fat (%TBF), fat free mass (FFM), total fat mass (TBF), total body lean mass (TBL), and bone mineral content (BMC) (RMS 0.407%, 0.690 kg, 0.706kg, 0.693kg, 0.035kg; CV 0.79%, 0.97%, 1.00%, 1.02%, and 1.12% respectively). Precision was better for gynoid fat distribution (%FG) (RMS 0.627kg; CV 1.30%) than for android fat distribution (%AF) (RMS 1.096 kg; CV 1.86%).

**CONCLUSIONS:** The Lunar iDXA provided excellent precision for total body composition measurements and is the first study to assess reproducibility of the GE Lunar iDXA in severely obese adults.

| Precision of the GE Lunar iDXA Densitometer for the Measurement of Total Body Composition |       |        |              |        |

**3350 Board #71 June 2 8:00 AM - 9:30 AM**

**Electromyographic Analysis of the Upper Limb Position during Trunk Exercise in Prone Position**

Chihiro Dehara<sup>1</sup>, Masanori Takemura<sup>2</sup>, Tetuji Ishida<sup>3</sup>, Shunsuke Fujitake<sup>4</sup>, Junzo Tsujita<sup>2</sup>. <sup>1</sup>Gakkentoshi Hospital, Seika, Japan. <sup>2</sup>Hyogo College of Medicine, Nishinomiya, Japan. <sup>3</sup>Shiga Medical Center for Children, Moriyama, Japan. <sup>4</sup>Tachiiri Orthopedics, Kyoto, Japan.  
(No relationships reported)

**PURPOSE:** To compare the EMG activity of local and global muscles in lumborum and thoracic at various positions of upper-limb during back muscles exercises in prone position.

**METHODS:** Fifteen healthy adult (10 males and 5 females, means (SD) age; 26.7 (4.3) years) performed back muscles exercises in prone position with the depression and retraction in the right scapulothoracic joint and raising upper-limb at three different upper-limb starting positions (0 degree, 160 degree (similar to PNF) and 180 degree of abduction). Surface EMG analysis of the muscle activity of the thoracic part of the longissimus thoracis (LT), iliocostalis lumborum (IC), lumbar multifidus (LM) and latissimus dorsi (LD) were measured. For each of the muscles root mean square (RMS) was calculated and was normalized to the amplitude in maximal voluntary contraction (%MVC). Statistical analysis was performed using ANOVA and multiple comparisons.

**RESULT:** Left LM, LT and IC were activated significantly at 180 degree compared to 0 degree of abduction and left LT and IC were activated significantly at 180 degree compared to 160 degree of abduction [%MVC (SD) of 0.160 and 180 degree of abduction: left LM; 43.4 (29.2), 44.9 (18.9), 33.1 (13.6), left LT; 28.1 (9.3), 31.0 (8.6), 36.1 (11.6), left IC; 27.3 (12.6), 29.3 (12.5) 33.1 (13.6)]. Right LD were activated significantly at 0 degree compared to 180 degree and 160 degree of abduction [%MVC (SD) of 0.160 and 180 degree of abduction: right LD; 191.0 (83.8), 136.7 (74.6), 112.5 (57.5)].

**CONCLUSION:** The present study suggested that both LM, local muscles, and LT and IC, the global muscles were activated significantly at 180 degree compared to 0 degree of abduction. It was suggested that the LM could not activate selectively by different positions of upper-limb during back muscles exercises in prone position in this study. To increase the LM activity, therapists should increase trunk extension loads of the exercise in clinical practice. Also, the increase of the LM activity was not affected by facilitative effect of the increased LD activity. It is suggested that the EMG activity in local and global muscles of lumborum and thoracic at various positions of upper-limb during back muscles exercises in prone position for LBP should be analyzed, because of previous studies showed the lower activity of LM.

**3351 Board #72 June 2 8:00 AM - 9:30 AM**

**Association Of Adiposity And Muscle Quality With Physical Function Differs In Young And Old Women**

Rebecca D. Larson<sup>1</sup>, Ellen M. Evans, FACSM<sup>1</sup>, Mark M. Mistic<sup>2</sup>. <sup>1</sup>UGA, athens, GA. <sup>2</sup>Northern Illinois University, DeKalb, IL.  
(No relationships reported)

Whole body adiposity (%Fat) and leg muscle quality (MQ), defined as strength per mineral free lean mass (MFLM), both have been shown to impact lower extremity physical function (LEPF) in older women. However, the muscle strength measurement (isometric, isokinetic, fatigue) may impact MQ and its subsequent relation to LEPF. Moreover, the %Fat and MQ associations with LEPF may differ in young and old women.

**PURPOSE:** The aims of this study were to investigate if age impacts: 1) the relation between %Fat, MQ and LEPF, and 2) if different muscle strength indices used to calculate MQ impact the association between MQ and LEPF.

**METHODS:** Younger (YOUNG: 20-30 yrs, n = 37) and Older (OLD: 64-80 yrs, n = 39) women were assessed for %Fat and upper leg MFLM via DXA. Strength assessments, leg extensions performed on an isokinetic dynamometer, included: a) maximal isometric (IM), b) isokinetic [at 60 deg/sec (IK60) and 180 deg/sec (IK180)] and c) a 25 repetition fatigue protocol (FTG) at 180 deg/sec. MQ-IM, MQ-IK60, MQ-IK180, and MQ-FTG were calculated as Nm/MFLM(kg). LEPF was determined by an up and go (UPGO) challenge.

**RESULTS:** As expected, YOUNG had lower %Fat, more leg MFLM, greater MQ, and faster UPGO time, compared to OLD (all p < 0.05). In YOUNG, although MFLM was associated with UPGO (r = -0.44, p = 0.007), no measures of MQ were related to UPGO (all p > 0.05). Conversely in OLD, MFLM was not related to UPGO (p > 0.05) while MQ-IK60, MQ-IK180, and MQ-FTG were negatively associated with UPGO (MQ-IK60; r = -0.36, MQ-IK180; r = -0.37, and MQ-FTG; r = -0.40 (all p < 0.05). %Fat was not related to UPGO in YOUNG; however, higher %Fat was associated with slower UPGO times in OLD (r = 0.32, p = 0.048).

**CONCLUSION:** Younger women's physical function is most dependent on the lean mass of the leg and not MQ or adiposity, whereas the physical function of older women is impacted on the quality of the muscle and adiposity, which may be in part related to muscle activation and/or fat infiltration into the muscle.

**3352 Board #73 June 2 8:00 AM - 9:30 AM**

**Exercise, Support, And Education Enable Hispanic Parents And Children To Combat The Effects Of Obesity**

Susan Shore, Kathryn Ecklund, Zachary McGill, Eles Altamirano, Jennifer Blair, Falcicy Bowman, Brigitte Dubon, Patricia Huesca, Natasha Kane, Katherine Skorupa, Giselle Kurywachak, Kerry Lane, Johanna Szin. *Azusa Pacific University, Azusa, CA.*  
(No relationships reported)

**PURPOSE:** The incidence of childhood obesity has reached unprecedented proportions, with rates in the Hispanic population being especially high. There is a link between obesity and cardiovascular disease risk factors including hyperlipidemia, diabetes, and hypertension. Exercise is known to have a moderating effect on these risk factors. The purpose of this study was to evaluate the effect of multidimensional intervention on the incidence of obesity and associated risk factors in a population of Hispanic mothers and children.

**METHODS:** Thirteen Hispanic mothers (average age 36.8 + 5.2 years) and their 14 children (average age 9.8 + 1.1 years) volunteered to participate in a twice weekly after school program of exercise, group support, and education in a Los Angeles area elementary school. At baseline and following 10 weeks of intervention, the following data was taken: resting heart rate and blood pressure, height, weight, body fat measurements (using ultrasound), blood cholesterol, sugar, and CReactive Protein (from finger stick blood draws), Behavioral Assessment Scale for Children, Personality Inventory for Youth, and the Parent Child Relationship Inventory. Parents completed a 2 day diet log, and distance was measured for both parents and children during a 12 minute walk/run. Individualized results were reported to parents and children during educational sessions.

**RESULTS:** At baseline, 84.6% of mothers and 78.6% of children were overweight or obese. After intervention, changes were as follows: Despite no significant changes in BMI, percent body fat, or psychosocial variables, mothers' total cholesterol dropped an average of 9.92 points (p<0.039), and blood glucose dropped 11.92 points (p<0.007). Systolic blood pressure decreased

from 131.08 to 117.67, ( $p < 0.001$ ). Average distance walked in 12 minutes increased by 21.97% ( $p < 0.009$ ). In children, there were no significant changes in blood work; however, systolic blood pressure dropped an average of 6.63 mm Hg ( $p < 0.039$ ). Average distance run in 12 minutes increased by 13.27% ( $p < 0.0001$ ).

**CONCLUSION:** A twice weekly program of exercise, group support, and education for Hispanic mothers and their children was associated with positive changes in some cardiovascular risk factors associated with obesity.

**Comparison Of Handheld Device And Electromechanical Dynamometer For Measuring Plantarflexion Force**

Federico Pozzi, Ali Alnahadi, Adam Marmon, Lynn Snyder-Mackler. *University of Delaware, Newark, DE.*  
(No relationships reported)

Measurements of muscle force are a standard component of clinical examinations. Handheld devices (HH) provide quick and reliable measure of muscle force; however the amount of resistance provided by the clinician may influence the reading. Electromechanical dynamometers (ED) allow better experimental control and provide more accurate measurements of force, but are expensive and are difficult to set up.

**PURPOSE:** to assess the concurrent validity of measuring plantarflexion force (PFF) with a HH using the ED measurements as a gold standard.

**METHODS:** Five healthy subjects (2M/3F,  $25 \pm 4$  yr age,  $1.72 \pm 0.12$  m,  $68.5 \pm 12.9$  kg) were recruited for the study. PFF of the right limb was assessed with an ED and a HH by the same experienced clinician. During testing, subjects lay supine, with the ankles flexed to  $90^\circ$ . Subjects were asked to push as hard as possible; for the ED testing, the ED arm was fixed and for the HH testing, the device was held on the ball of the foot by the clinician. Lever arm was constant between conditions. For each device, three trials were collected and one minute rest was given between trials. The order of testing was randomized. The peak value from each trial was averaged and compared between devices using an interclass correlation coefficient (ICC). Pearson Product Moment correlations were calculated between conditions and between PFF from each device and body mass.

**RESULTS:** Peak PFF ICC was  $-0.191$  ( $p = .641$ ). PFF from HH and ED were not significantly correlated ( $r = -0.271$ ,  $p = .659$ ). Body mass was significantly correlated with ED force measures, but not with HH measures (Figure 1).

**CONCLUSION:** The lack of a relation between HH measurements of PFF to the gold standard or body mass suggests that HH does not provide valid and accurate measures of PFF.

---

**3354 Board #75 June 2 8:00 AM - 9:30 AM**  
**Neuromuscular Responses to Acute Whole Body Vibration**

Caroline J. Ketcham, Paul C. Miller, George Wentz, Andrea Gross, Kelly Brand, Paul Riuli. *Elon University, Elon, NC.* (Sponsor: Eric E. Hall, FACSM)  
(No relationships reported)

Whole body vibration (WBV) has shown to positively impact neuromuscular activity. Studies have shown significant improvements in muscular strength and power following acute bouts of WBV in trained participants (Cochrane et al., 2009; Cochrane et al., 2008; Stewart et al., 2009). Less is understood about the exact mechanisms for these changes in strength and power.

**PURPOSE:** The purpose of this research is to explore the neuromuscular mechanisms underlying changes in contractile function following an acute bout of WBV. It was hypothesized that WBV may alter neuromuscular activation resulting in changes to anaerobic power production.

**METHODS:** Twelve non-resistance trained male and female completed this study ( $20.6 \pm 0.9$  yrs). The experimental protocol required three days of testing for each participant. Day one was a familiarization trial. On days two and three, participants were randomly assigned to either no vibration or WBV condition. Participants then completed a 6-stage cycle ergometer anaerobic power test. EMG was recorded during each stage.

**RESULTS:** There was a significant condition effect for EMG activity with lower EMG activity during the cycling task following the WBV condition ( $p < .05$ ). These were not related to differences in power production between the conditions ( $p > .05$ ).

**CONCLUSIONS:** These results support the hypothesis that WBV does impact muscle function. Specifically, lower muscle activity followed WBV while maintaining the same level of power output suggesting improved muscular efficiency.

**3355 Board #76 June 2 8:00 AM - 9:30 AM**  
**Cardiovascular And Metabolic Responses To Exercising With The Glidetrak Compared To Running**

Aaron W. Johnson, Pat Vehrs, FACSM, James George, Gil Felingham, Jordan Perry. *Brigham Young University, Provo, UT.*  
(No relationships reported)

**PURPOSE:** To evaluate the cardiovascular and metabolic responses of treadmill exercise using the GlideTrak (GT) device as compared with unassisted treadmill (UT) exercise. Previous research indicates that the GT reduces ground reaction forces by 85%; thus, one would expect the exercise intensity to be less when using this device. Because the GT may provide a viable form of exercise for those who cannot otherwise exercise independently (due to amputation, obesity, injury, or arthritic joints) we sought to understand the exercise response of this device.

**METHODS:** Participants were 20 healthy untrained individuals (male: 11, female: 9) with an average age of  $22 \pm 2.1$  years, height of  $1.71 \pm .13$  m, and body mass of  $72.4 \pm 14$  kg. For both GT exercise and UT exercise, a submaximal exercise test protocol was completed, which included a series of 3-minute stages: walking at a natural pace, walking at a self-selected brisk walking pace, walking at a brisk pace with a 2% grade, and jogging at a self-selected speed. Following 3 minutes of jogging, the incline of the treadmill was increased by 2% each stage until the participant reached an RER of 1.0 or 90% of the age-predicted maximal HR. Steady-state VO<sub>2</sub> and HR were recorded during each stage. After a 10-15 minute rest, the participant completed a graded maximal exercise test to determine VO<sub>2</sub>max. After a 3 minute warm-up period, participants jogged at a self-selected speed. Every minute thereafter we increased the incline by 1.5% until VO<sub>2</sub>max was achieved. In the GT condition we increased the incline 2% and the speed by 1 mph until VO<sub>2</sub>max was achieved.

**RESULTS:** We examined the HR/VO<sub>2</sub> relationship in both modes of exercise. There was an overall gender effect between genders across both modes of exercise. There was a statistical difference between exercise modes ( $p < .05$ ) in VO<sub>2</sub>max (GT:  $38.1 \pm 7.0$ , UT:  $49.0 \pm 9.0$ ), HRmax (GT:  $183.5 \pm 9.0$ , UT:  $194.3 \pm 9.0$ ), RPE (GT:  $17.9 \pm 1.9$ , UT:  $19.4 \pm 0.6$ ), and in MPHmax (GT:  $6.9 \pm 2.2$ , UT:  $5.8 \pm 0.7$ ), but not in RER (GT:  $1.1 \pm 0.05$ , UT:  $1.1 \pm 0.04$ ).

**CONCLUSIONS:** The GT allows for appropriate cardiovascular training, but compared with UT exercise the VO<sub>2</sub> response is about 15-20% lower at any given exercise HR. To experience a similar cardiovascular training effect, those who use the GT device should work at a higher relative percentage of HRmax while maintaining a comparable RPE response.

---

**3356 Board #77 June 2 8:00 AM - 9:30 AM**  
**Association Between Physical Activity Levels And Chronic Disease Risk In Early Postpartum.**

Melanie Bonin<sup>1</sup>, Yaiza Cordero-Rodriguez<sup>2</sup>, Stephanie-May Ruchat<sup>1</sup>, Ashley Smith<sup>1</sup>, Michelle F. Mottola, FACSM<sup>1</sup>. <sup>1</sup>Univ. of Western Ontario, London, ON, Canada. <sup>2</sup>Universidad Politecnica de Madrid, Madrid, Spain.  
(No relationships reported)

The early postpartum period is a critical time period for women to return to being physically active in order to reduce weight retention from pregnancy. Weight retention, body mass index (BMI), waist circumference and waist:hip ratios may be important predictors of future chronic disease risk.

**PURPOSE:** To examine daily physical activity levels and cardiovascular disease risk factors in women at two months postpartum (6 normal weight (NW); BMI=18.5-24.9kg/m<sup>2</sup>, 18 overweight (OW); 25-29.9kg/m<sup>2</sup> and 16 obese (OB);  $\geq 30$ kg/m<sup>2</sup>).

**METHODS:** Physical activity was assessed at 2 months postpartum using an accelerometer and a pedometer worn simultaneously fixed on a belt for an average of 5 days. The 3 BMI groups were compared for chronic disease risks and physical activity levels using ANOVA.

**RESULTS:** At 2 months postpartum, NW, OW and OB women presented similar ( $p > 0.05$ ) waist:hip ratios, all greater than 0.85, and similar weight retention, all greater than 3.0 kg. NW women had a waist circumference  $< 88$  cm, however, NW and OW women had a lower waist circumference than OB women ( $84.3 \pm 11.2$  cm,  $91.7 \pm 5.2$  cm and  $109.0 \pm 13.3$  cm, respectively,

p<0.05). NW and OW reported higher pedometer daily step counts than OB women (NW: 8784±2927 steps/day, OW: 8219±1981 steps/day, OB: 6134±1843 steps/day; p<0.05). Uploaded accelerometer daily step counts were higher in OW (9364±2299 steps/day) but not in NW (8234±3701 steps/day), compared to OB women (6572±2777 steps/day, p<0.05). Comparing pedometer (self-reported) and accelerometer step counts, the pedometer significantly underestimated daily step counts in OW women (-1145 ±2194, p=0.02).

**CONCLUSIONS:** Women at 2 months post-delivery, irrespective of their BMI, are at risk for long-term chronic disease and are not meeting the step recommendations of 10,000 steps per day. OB women presented the highest risk for chronic disease and were classified in the low active category, indicating that the promotion of an early healthy postpartum lifestyle is particularly important in OB women. The difference found in step counts obtained from a pedometer compared to an accelerometer in OW women needs to be further examined.

Funded by CIHR & Rx&D Health Research Foundation of Canada. SMR is funded by a postdoctoral fellowship from the Canadian Diabetes Association.

**3357** Board #78 June 2 8:00 AM - 9:30 AM

**Physiological and Psychological Responses to a Longitudinal Rehabilitation Program**

Jessica M. Brown<sup>1</sup>, Trent L. Lalonde<sup>1</sup>, Kurt Dallow, FACSM<sup>2</sup>, Reid Hayward<sup>1</sup>, Carole M. Schneider, FACSM<sup>1</sup>. <sup>1</sup>Rocky Mtn Cancer Rehab, Univ Northern Colorado, Greeley, CO. <sup>2</sup>North Colorado Family Medicine, Greeley, CO.

(No relationships reported)

Physiological and psychological improvements have been well noted in cancer survivors after an exercise intervention. To date, little research has been done on the effects of a long-term exercise training program.

**PURPOSE:** To assess the physiological and psychological responses to exercise training in cancer survivors over a 21 month exercise intervention.

**METHODS:** Thirty-four cancer survivors, including 9 males and 24 females, participated in a cancer rehabilitation program consisting of 60 minute exercise training sessions, three days per week for 21 months. Each session included cardiovascular, muscular strength, muscular endurance, flexibility, and balance training. Physiological and psychological assessments which examined cardiorespiratory fitness, muscular endurance, depression, fatigue, and quality of life were conducted at the onset of the program (INTL), at three months (1ST), and every six months until four reassessments were completed (2ND, 3RD, and 4TH, respectively.)

**RESULTS:** Significant improvements were observed in all measures (p<0.05), except muscular endurance. Cardiovascular endurance improved 12.1% (p=.002) at onset (INTL to 1ST) and although additional improvement occurred, it was not significant. Likewise, total fatigue decreased -33.9% (p<.0001) from INTL to 1ST while subsequent improvements were not significant. Depression was shown to decrease -17.9% (p=.043) and -17.6% (p=.025) from INTL to 1ST and 3RD to 4TH, respectively. Although the main effects for muscular endurance yielded no significance, pairwise comparisons revealed a 32.9% improvement from INT to 1ST (p=0.011). Total quality of life did not improve at onset, but a significant 10.1% increase (p=.006) occurred from 2ND to 3RD reassessments.

**CONCLUSION:** A 21 month full-body exercise program has been shown to elicit improvements in physiological and psychological measures in cancer survivors. The greatest improvements occur during the first three months of training then plateau. This suggests that a 3-month exercise intervention is sufficient to return cancer survivors to normal functional capacity.

**3358** Board #79 June 2 8:00 AM - 9:30 AM

**Forearm Deoxygenation Measured By Nirs During A New Handgrip Exercise Protocol In Patients With Mitochondrial Myopathy**

Bert M. Celie, Jan Boone, Joel Smet, Jan De Bleecker, Rudy Van Coster, Jan Bourgeois. Ghent University, Ghent, Belgium.

(No relationships reported)

Mitochondrial myopathy (MM) is a multisystemic disorder and contains a very large spectrum of different diseases providing a large scale of symptoms. The golden standard for diagnosis remains muscle biopsy with histochemical analysis. The validity and reliability of near infrared spectroscopy (NIRS) as an appropriate technique to measure non invasively tissue oxygenation was well established on muscle tissue at rest and during exercise.

**PURPOSE:** We propose a new handgrip exercise protocol using NIRS for relative evaluation of microvascular oxygen extraction in a MM population. The reliability of this protocol has been established in a previous study.

**METHODS:** Two groups of subjects were studied: 12 patients with severe MM and 12 age- and gender matched untrained controls. The patient's and control subject's age, height and body weight were respectively (mean values ± SE) 30.42 ± 13.28 and 30.83 ± 13.06 years, 166.6 ± 11.25 cm and 177.38 ± 9.56 cm, 62.34 ± 15.74 kg and 78.24 ± 16.45 kg. The protocol started with an arterial occlusion of the forearm until a steady state in deoxy[Hb+Mb] was reached. The handgrip exercise protocol until exhaustion consisted of 2-min periods (½ Hz) at different intensities (% MVC) separated by a 60-s rest period. The changes in deoxy[Hb+Mb] during each work step (i.e., the mean of the maximum 10-s) were expressed relative to this amplitude.

**RESULTS:** Significant differences were found between patients and control subjects for every submaximal and maximal intensity. The percentual deoxy[Hb+Mb] (mean values ± SE) at 20% (p=0.019), 30% (p<0.001), 40% (p<0.001), 50% (p=0.002) and 60%MVC (p<0.001) for patients were respectively 9.45 ± 6.70%, 13.52 ± 6.70%, 12.73 ± 8.75%, 20.47 ± 12.24%, 17.94 ± 8.06% and for control subjects respectively 21.17 ± 16.29%, 34.04 ± 15.93%, 39.81 ± 19.03%, 49.65 ± 25.2% and 62.4 ± 21.14%. The percentual maximal deoxy[Hb+Mb] (p<0.001) (mean values ± SE) was respectively for patients 24.96 ± 8.47% and for controls 72.82 ± 23.56%.

**CONCLUSION:** Microvascular O<sub>2</sub>-extraction is significantly lower in a MM population during this protocol, which can be used as an evaluation tool of the muscle oxidative capacity for the MM patients.

**3359** Board #80 June 2 8:00 AM - 9:30 AM

**Individual Training Response In Allogeneic Stem Cell Transplant Patients Depending On Baseline Fitness Level**

Joachim Wiskemann<sup>1</sup>, Dirk Jaeger<sup>1</sup>, Cornelia M. Ulrich<sup>1</sup>, Gerhard Huber<sup>2</sup>, Peter Dreger<sup>3</sup>, Rainer Schwerdtfeger<sup>4</sup>, Martin Bohus<sup>5</sup>. <sup>1</sup>National Center for Tumor Diseases, Heidelberg, Germany. <sup>2</sup>University Heidelberg, Heidelberg, Germany. <sup>3</sup>University Clinic Heidelberg, Heidelberg, Germany. <sup>4</sup>German Clinic for Diagnostic, Wiesbaden, Germany. <sup>5</sup>Central Institute of Mental Health, Mannheim, Germany.

(No relationships reported)

Before, during and after allogeneic stem cell transplantation (allo-HSCT) patients experience considerable physical, psychological and psychosocial distress. Besides GvHD and infections, particularly reduced physical performance and functioning as well as high levels of fatigue affect patient's quality of life negatively. Physical exercise therapy constitutes a potentially promising intervention to reduce treatment-related side effects of allo-HSCT and consequently enhance the rehabilitation process.

**PURPOSE:** To determine the individual training response of allo-HSCT patients depending on their baseline fitness level.

**METHODS:** In a multicenter RCT105 patients were equally randomized to an exercise (EX) and a social contact group (Control). Exercisers trained in a home-based setting prior to hospital admission, during inpatient treatment and 6-8 weeks period after discharge (partly self-administered with an intervention manual and DVD). Physical performance was assessed via 6-minute walk test (6MWT) and handheld dynamometry (HHD). In order to analyze individual training response patients in the EX were categorized as "fit" (>80% of their predicted fitness scores) or "unfit" (<80% of their predicted fitness scores).

**RESULTS:** Regarding maximal voluntary isometric strength in knee extensor muscles patients in the "unfit" group declined about 6,4% over the whole study period whereas the "fit" group loses 30,8% in average (p<0.05). Comparable results could be reported for all other measured muscle groups. Also the 6MWT distance showed a significant better development for the "unfit" vs. the "fit" group (+13,4% vs. -3,7%, p<0.05). Furthermore, a better development in physical performance was significantly associated with less treatment-related side effects (e.g. cancer-related fatigue, p<0.05).

**CONCLUSION:** The effect of exercise training on physical fitness in allo-HSCT patients is related to their performance level at baseline. Oncologists and exercise therapists should be aware of the importance of exercise in initial unfit patients during allo-HSCT and communicate/interpret a potential fitness loss in initial fit patients in the right way.

Supported by German José Carreras Leukaemia Foundation (R05/33p)

3360 Board #81 June 2 8:00 AM - 9:30 AM

**Whole Body Vibration Compared To Biking On The Warm-up Effect Of The Lower Extremity**

Kevin Myers, Cameron Shumway, J. Brent Feland, A. Wayne Johnson, Kent Crossley, Dennis L. Eggett. *Brigham Young University, Provo, UT.* (Sponsor: J. Ty Hopkins, FACSM)  
(No relationships reported)

Use of whole body vibration training (WBV) platforms is becoming increasingly popular. With facilitation of lower extremity muscle contraction, it has been suggested that WBV can function as a good form of warm-up.

**PURPOSE:** To determine the effectiveness of WBV training on increasing intramuscular temperature (IMT) of the medial gastrocnemius (MG) and vastus lateralis (VL) compared to traditional bike warm-up.

**METHODS:** 20 male subjects (avg age  $21.4 \pm 2.3$  yrs) with less than  $\frac{1}{2}$  cm subcutaneous fat levels over the VL and MG qualified for this study. 10 subjects in each of two groups (bike, vibration). Resting baseline muscle temperatures of the VL (1.5 cm depth) and MG (.5 cm) were made using intramuscular thermistors. IMT's were measured two more times: immediately following either 5 minutes of pedaling at 70watts or oscillating WBV at 26Hz/4mm amplitude. Then immediately following another 5 minutes of biking or WBV.

**RESULTS:** Data were analyzed using a 3 factor mixed models analysis of covariance blocking on individual subjects, with baseline temperature being the covariate. A post hoc Tukey pairwise comparisons of means was used where needed. No significant differences in treatment existed ( $p=0.2247$ ) or in the muscle\*treatment interaction ( $p=0.9672$ ). Temperatures did significantly increase over time ( $p=0.0097$ ), with only vibration showing a significant increase in temperature from 2nd to 3rd temperature measurement ( $p < 0.0001$ ).

**CONCLUSIONS:** Both treatments are effective at increasing IMT. While no statistical difference was found between bike and vibration treatments, the mean changes were: MG = .50C (bike) and .97C (vibration) and VL = 1.58C (bike) and 1.95C (vibration). Thus, oscillating platform vibration appears to show a trend towards greater IMT increases, particularly after the first 5 minutes as compared to bike pedaling. This increase in temperature may also be correlated to the performance enhancements reported in the vibration training literature, although this has yet to be shown. Further investigation of temperature responses in other muscle groups and at different frequencies is needed.

---

3361 Board #82 June 2 8:00 AM - 9:30 AM

**The Intra-Hemodialytic Protein And Exercise(IHOPE) Study: Rationale And Study Design**

Ken Wilund<sup>1</sup>, Bo Fernhall, FACSM<sup>1</sup>, Shane Phillips<sup>2</sup>, Edward McAuley, FACSM<sup>1</sup>, Emily Tomayko<sup>1</sup>, Barbara Yudell<sup>1</sup>, Peter Fitschen<sup>1</sup>, Hae Ryong Chung<sup>1</sup>, Jinhee Jeong<sup>1</sup>, Brandon Kistler<sup>1</sup>, Elizabeth Jeans<sup>2</sup>. <sup>1</sup>University of Illinois @ Urbana-Champaign, Urbana, IL. <sup>2</sup>University of Illinois @ Chicago, Chicago, IL.  
(No relationships reported)

**PURPOSE:** Chronic kidney disease (CKD) patients receiving hemodialysis therapy suffer from a variety of co-morbid diseases. Protein malnutrition and muscle wasting are especially common, and these lead to reduced muscle strength and function. Physical inactivity exacerbates these functional declines, and also promotes cardiovascular disease (CVD) and bone disorders. In an attempt to deter functional declines and wasting, the National Kidney Foundation has increased the protein recommendation for dialysis patients to 1.2 g/kg/day. Previous acute studies indicate that intradialytic oral protein supplementation, with or without concomitant intradialytic exercise, may help reverse the negative protein balance that occurs during dialysis. However, little is known regarding the efficacy of chronic protein supplementation and exercise training in dialysis patients. To study this question, we recently initiated a randomized, controlled clinical trial called the Intra-Hemodialytic Oral Protein and Exercise (IHOPE) study.

**METHODS:** We will recruit ~150 dialysis patients over 5 years to complete this study. At baseline, 6 and 12 months, we will measure a variety of factors related to physical function, cardiovascular disease risk, body composition, and quality of life (QOL). Following baseline testing, subjects will be randomized to 1 year of either intradialytic 1) non-protein (control) supplement, 2) whey protein supplement, or 3) whey protein supplement and endurance exercise training.

**RESULTS:** During our first year of the study, we enrolled 39 patients ( $n = 13/\text{group}$ ). Selected baseline characteristics of the current participants include the following: 1) average age =  $52.7 \pm 10.5$ ; 2) gender = 44% male; 3) BMI =  $32. \pm 8.5$ ; 4) serum albumin =  $4.0 \pm 0.4$  g/L; 5) diabetes prevalence = 58%. There are no statistically significance differences in these variables between groups.

**CONCLUSIONS:** When completed, this study will provide novel information regarding the long-term effects of oral protein supplementation and exercise training on clinical outcomes and the QOL in hemodialysis patients. Results from this study will enable clinicians to make more informed decisions regarding the extent to which these low-cost treatment strategies should be included as a component of the standard care in their clinics.

3362 Board #83 June 2 8:00 AM - 9:30 AM

**The Influences of 4-Week Walking Training with Blood Flow Restriction on Lower Limb Strength in Elderly**

Wei-Hsiu Lin, Che-Yu Kuo. *National Chiayi University, Chiayi, Taiwan.*  
(No relationships reported)

Few researches indicated that walking with blood flow restriction (BFR) increase the lower limb strength in elderly. In previous studies, the training intensity of BFR-group was relatively higher than no BFR group (NBFR-group) since both groups were trained at the same walking speed instead of the same percentage of maximal heart rate reserve (MHR).

**PURPOSE:** To investigate the influences of 4-week BFR-walking training with the intensity at 35%~45% MHR on lower limb strength in elderly.

**METHODS:** Eleven physical active men and women ( $62 \sim 73$  yrs;  $160.2 \pm 7.2$  cm;  $66.5 \pm 8.4$  kg) participated in this study and were divided into BFR ( $n = 6$ ) and NBFR ( $n = 5$ ) groups. The individual cuff pressure of BFR-group was set at 50% of complete blood occlusion pressure. All of the subjects performed 20-minute treadmill walking at 35%~45% MHR, 5 days/wk for 4 weeks. The muscle strength of isokinetic knee extension/flexion and ankle dorsi/plantar flexion were evaluated using Biodex System 4 and the testing angular velocities were set at 60°/s and 180°/s for knee; 60°/s and 120°/s for ankle. Two-way mixed design ANOVA was performed to compare all the variables.

**RESULTS:** After 4-week walking training, the dorsiflexion peak torque and total work in BFR-group improved 6.9%~9.1% and 1.8%~14.3% respectively; plantar flexion peak torque and total work in BFR-group improved 26.6%~28.3% and 35.9%~41.1% respectively (plantar flexion total work at 120°/s increased significantly after training,  $p < .01$ ).

**CONCLUSIONS:** BFR-walking training at 35%~45% MHR enhance the calf strength but the thigh strength. Low training intensity and wide cuffs might limit the training effect on thigh muscles.

3363 Board #84 June 2 8:00 AM - 9:30 AM

**Increasing Strength And Muscle Mass In Hiv+ Men Recovering From Substance Abuse**

Carianne M. Cregar<sup>1</sup>, Jakob L. Vingren<sup>1</sup>, John H. Curtis<sup>1</sup>, Kiannah Williams<sup>1</sup>, Julius F. Cantu<sup>2</sup>, David W. Hill, FACSM<sup>1</sup>. <sup>1</sup>University of North Texas, Denton, TX. <sup>2</sup>Homeward Bound, Inc., Dallas, TX.  
(No relationships reported)

The combination of substance (drug and/or alcohol) abuse and infection with human immunodeficiency virus (HIV) can result in the development of several co-morbidities, including muscle wasting. Resistance training could, therefore, be an important tool in the treatment of substance addiction/abuse and HIV.

**PURPOSE:** The purpose of this study was to examine the effect of resistance training on measures of muscle mass and strength in the context of co-occurring substance abuse and HIV.

**METHODS:** Seventeen untrained men (Mean  $\pm$  SD:  $42 \pm 11$  years,  $89.7 \pm 16.0$  kg,  $179.7 \pm 9.1$  cm,  $18.9 \pm 5.5$  %fat) who are infected with HIV and enrolled in an in-patient substance addiction/abuse treatment program completed six weeks of either resistance training (RT) (three sessions per week) or no-exercise prescription (Control). Before (Pre) and after (Post) the 6-week period, anthropometric (e.g., body mass, skinfolds, and circumferences), strength (bench press and isometric squat), and power (vertical jumps) measurements were obtained.

**RESULTS:** Predicted bench press 1-repetition maximum (1-RM) increased significantly ( $p < 0.05$ ) for RT (Pre:  $73.4 \pm 23.4$  kg; Post:  $85.0 \pm 30.4$  kg) but not for Control (Pre:  $54.9 \pm 24.6$  kg; Post:  $57.3 \pm 27.0$  kg). Peak isometric squat force increased significantly for RT (Pre:  $2627 \pm 1071$  N; Post:  $2892 \pm 1171$  N) but not for Control (Pre:  $2411 \pm 675$  N; Post:  $2394 \pm 592$  N). Peak vertical jump power also increased significantly for RT (Pre:  $35.9 \pm 3.5$  W·kg<sup>-1</sup>; Post:  $36.2 \pm 5.0$  W·kg<sup>-1</sup>) but not for Control (Pre:  $33.9 \pm 3.9$  W·kg<sup>-1</sup>; Post:  $35.7 \pm 4$  W·kg<sup>-1</sup>). Muscle mass

increased significantly for RT (Pre: 46.4 ± 8.2 kg; Post: to 50.5 ± 8.1 kg) but not for Control (Pre: 46.9 ± 13.0 kg; Post: 47.8 ± 12.4 kg). Upper arm and forearm circumference increased only for RT. No adverse effects of the resistance training program were observed.

**CONCLUSION:** Resistance training for six weeks increases muscle strength and power, and induces muscle hypertrophy, in men who are infected with HIV and recovering from substance abuse. These findings support the efficacy for including resistance training in the standard of care for men with HIV undergoing in-patient treatment for substance **addiction/abuse**.

**3364** Board #85 June 2 8:00 AM - 9:30 AM

**Do Parameters Of Exercise Capacity Predict Mortality In Adolescent With Cystic Fibrosis?**

Erik Hulzebos, Hanna Bomhof-Roordink, Pauline van de Weert - van Leeuwen, Bert Arets, Tim Takken. *University Medical Center Utrecht, Utrecht, Netherlands.*  
(No relationships reported)

**PURPOSE:** Several determinants, such as lung function, nutritional status and exercise capacity ( $VO_{2max/kg}$ ), are known to be associated with mortality in patients with Cystic Fibrosis (CF). The aim of the current study was to develop a model to predict survival from parameters derived from a cardiopulmonary exercise test (CPET), in addition to resting lung function.

**METHODS:** Data of 127 adolescents with CF (57 girls and 70 boys, mean age 12.7 ± 0.9 years, mean forced expired volume in 1 sec ( $FEV_1$ ) = 77.7%<sub>predicted</sub> ± 15.6%) were available for analysis. Cox regression analysis was performed to determine which (combination) of parameters was best in predicting mortality and/or lung transplantation.  $FEV_1$ ,  $VO_{2max/kg}$ , peak minute ventilation ( $VE_{max}$ ),  $VE_{max}/VO_{2max}$ ,  $VE_{max}/VCO_{2max}$  and breathing reserve ( $1 - (VE_{max}/MVV)$ ) were included in one model. A backward selection procedure was used. All predictors were also dichotomized; ROC curves were used to determine the criterion value, and combined into one model.

**RESULTS:** Mean duration of follow-up was 7.5 ± 2.7 years, 9 patients died and 6 underwent lung transplantation. The best model to predict survival in this population included  $FEV_1$  expressed as percentage of predicted and  $VE_{max}/VO_{2max}$ . This was both the case when variables were used continuously ( $FEV_1$ %pred. ( $HR=918$ ,  $p<.001$ ) and  $VE_{max}/VO_{2max}$  ( $HR=1.088$ ,  $p=.02$ ) or dichotomized ( $FEV_1$ %pred. ( $HR=19.368$ ,  $p<.001$ ) and  $VE_{max}/VO_{2max}$  ( $HR=5.179$ ,  $p=.03$ ).

**CONCLUSIONS:** This findings show the relevance of performing a CPET in adolescents with CF because  $VE_{max}/VO_{2max}$  combined with  $FEV_1$ %<sub>predicted</sub> is a significant predictor of survival. In clinical practice this can be used to distinguish patients with a lower risk and patients at risk and to offer the patients at risk additional therapy and/or a more intensive follow-up.

**3365** Board #86 June 2 8:00 AM - 9:30 AM

**Therapeutic Effects Of Whole Body Vibration On Chronic Knee Osteoarthritis**

Ho Jun Lee<sup>1</sup>, Dong Yeon Cha<sup>2</sup>, Min-Kyun Oh<sup>3</sup>, Kyung Jae Yoon<sup>4</sup>. <sup>1</sup>Dongguk University, College of Medicine, Goyang-si, Gyeonggi-do, Korea, Republic of. <sup>2</sup>Dongguk University, College of Medicine, Gyeongju-si, Gyeongsangbuk-do, Korea, Republic of. <sup>3</sup>Gyeongsang National University Hospital, Jinju-si, Gyeongsangnam-do, Korea, Republic of. <sup>4</sup>Kangbuk Samsung Hospital, Sungkyunkwan University, School of Medicine, Seoul, Korea, Republic of.  
(No relationships reported)

**PURPOSE:** To investigate the effect on pain reduction and strengthening of whole body vibration in chronic knee osteoarthritis

**METHODS:** Thirty six female patients were randomly divided to study group and control group. Study group patients performed whole body vibration (20 minutes, 3 times) with home based exercise and control group only home based exercise for 8 weeks. 11 patients in each group completed study. We measured pain intensity with Numeric Rating Scale, functional scales with Korean Western Ontario McMaster score. We also measured strength with isokinetic and isometric torque and dynamic balance with a kind of balance board before training and at 1 and 2 month after training.

**RESULTS:** Pain intensity was significantly decreased in each group and change of pain intensity was significantly larger in study group (1.5±1.7 vs 0.6±2.9,  $p=0.04$ ) at 2 months after training. Functional scales improved in both groups but no significant differences of changes between groups (8.5±11.7 vs 2.1±9.2). Isokinetic strength of right quadriceps and isometric strengths of both quadriceps improved in both groups but no significant differences of changes between groups (isokinetic, right: 15.65±10.91 vs 10.30±8.2, isometric (right/left): 13.98±16.91/13.06±14.54 vs 16.33±19.19/19.13±15.75). Isokinetic strength of left quadriceps did not improve in both groups (change: 8.70±11.88 vs 2.84±19.03). Dynamic balance improved in both groups but no significant differences of changes between groups (anterior-posterior: 0.96±1.16 vs 1.28±2.12, medial-lateral: 1.75±2.05 vs 0.73±1.00).

**CONCLUSIONS:** In chronic knee osteoarthritis patients, whole body vibration and home based exercise reduced pain intensity and increased strength of right quadriceps and dynamic balance. When compared with home based exercise, whole body vibration had additional effect only in pain reduction.

---

**3366** Board #87 June 2 8:00 AM - 9:30 AM

**The Effect of Preconditioning on Initial Physiological and Psychological Assessments Following Treatment**

Brent M. Peterson<sup>1</sup>, Trent L. Lalonde<sup>1</sup>, Kurt Dallow, FACSM<sup>2</sup>, Reid Hayward<sup>1</sup>, Carole M. Schneider, FACSM<sup>1</sup>. <sup>1</sup>Rocky Mtn Cancer Rehab, Univ Northern Colorado, Greeley, CO. <sup>2</sup>North Colorado Family Medicine, Greeley, CO.  
(No relationships reported)

Exercise has been associated with the improvement of various physiological and psychological variables in cancer survivors post cancer treatment. However, little information exists on the role prior physical activity may have on functional capacity.

**PURPOSE:** To assess the differences between prior physical activity and the initial physiological and psychological assessments in cancer survivors following treatment.

**METHODS:** A total of 412 cancer survivors that had undergone radiation and/or chemotherapy were eligible for this study. Participants completed comprehensive physical assessments and Piper fatigue and Beck depression inventories. Functional capacity was determined during an initial assessment including  $VO_{2peak}$  (multistage treadmill protocol). Prior physical activity (PA) was defined as being none (1), low (2), and moderate (3) based on frequency, intensity, and duration according to the ACSM guidelines. A multivariate analysis of variance (MANOVA) determined the group variance differences.

**RESULTS:** There was a significant ( $p<.05$ ) main effect for prior PA. Post hoc pairwise comparisons determined that there were significant ( $p<.05$ ) differences between groups 1 and 3 for  $VO_{2peak}$  (21.23 ± 6.70 vs. 23.46 ± 7.02 mL·kg<sup>-1</sup>·min<sup>-1</sup>, respectively), groups 1 and 3, and groups 2 and 3 for fatigue (5.09 ± 2.23 vs. 4.28 ± 2.19 and 5.07 ± 2.03 vs. 4.28 ± 2.19, respectively) and groups 1 and 3 for depression (12.03 ± 7.74 vs. 9.90 ± 6.19, respectively). Moderately active individuals showed greater initial assessment values for functional capacity ( $VO_{2peak}$ ). Additionally, greater decreases were observed in fatigue and depression in the moderate activity group.

**CONCLUSION:** Cancer treatment-related side-effects lengthen the recovery process post treatment for cancer survivors. The results of this study demonstrate the importance of moderate prior physical activity for the attenuation of treatment-related reductions in functional capacity, fatigue and depression.

**3367** Board #88 June 2 8:00 AM - 9:30 AM

**Evidence Of Functional Aerobic Impairment Among Adults Living With HIV**

Jason R. Jagers<sup>1</sup>, Vivek K. Prasad<sup>1</sup>, Wesley D. Dudgeon<sup>2</sup>, Erica McDivitt<sup>2</sup>, Stephanie Burgess<sup>1</sup>, Steven N. Blair, FACSM<sup>1</sup>, Gregory A. Hand, FACSM<sup>1</sup>. <sup>1</sup>University of South Carolina, Columbia, SC. <sup>2</sup>The Citadel, Charleston, SC. (Sponsor: Gregory A. Hand, FACSM)  
(No relationships reported)

**PURPOSE:** Published results from our lab show that males living with HIV exhibit functional aerobic impairment (FAI) as indicated by a 25% lower age predicted  $VO_2$  max. It is well established that a lower aerobic capacity increases the risk of chronic disease and all-cause mortality among healthy populations. Currently no investigation has assessed aerobic capacity in a sample of HIV+ females. The purpose of this study was to examine aerobic capacity, as measured by peak  $VO_2$ , in a sample of HIV+ adults.

**METHODS:** Preliminary data was used from an ongoing exercise intervention that included a total of 10 males and 15 females. All participants underwent a maximal exercise treadmill test at baseline prior to randomization in which  $VO_2$ , heart rate, and blood pressure were assessed. FAI was determined if the participant exhibited a peak  $VO_2 \leq 25\%$  of their age-predicted  $VO_2$ .

**RESULTS:** Both males and females exhibited FAI (males: FAI = 37%; females: FAI = 47%) according to their age-predicted VO<sub>2</sub> max. When separated by gender males had a peak VO<sub>2</sub> of 24.16 ± 2.52, whereas females had a significantly lower peak VO<sub>2</sub> of 15.37 ± 0.97 (p = 0.001). Both genders had a peak heart rate significantly less than their age predicted max (males: 138 ± 8 bpm; females: 136 ± 5 bpm).

**CONCLUSIONS:** These results agree with previously published data that show males living with HIV often present FAI, possibly due to a sedentary lifestyle and/or disease related fatigue. The current data indicate that females living with HIV have greater FAI compared with males. Caution should be taken when prescribing aerobic exercise with this population and should be initiated at a light intensity less than the current recommendations for the general population.

This project is supported by the NIH/NINR and Thera-Band®

**3368 Board #89 June 2 8:00 AM - 9:30 AM**

**Knee Osteoarthritis And The Efficacy Of Home-based Kinesthesia, Balance & Agility Exercise Training**

Matthew W. Rogers<sup>1</sup>, Nauris Tamulevicius<sup>2</sup>, Stuart J. Semple<sup>1</sup>, Zarko Krkeljas<sup>3</sup>. <sup>1</sup>University of Zululand, KwaDlangezwa, South Africa. <sup>2</sup>Barry University, Miami Shores, FL. <sup>3</sup>North-West University, Potchefstroom, South Africa.

(No relationships reported)

Knee osteoarthritis (OA) is one of the most frequent causes of physical disability and pain among older persons. Evidence suggests incorporating kinesthesia, balance and agility (KBA) exercise with resistance training (RT) results in greater improvements than RT alone. However, the efficacy of KBA alone is unknown.

**PURPOSE:** To determine the efficacy of a home-based KBA knee OA exercise program to improve symptoms and quality of life.

**METHODS:** Fifty-four persons age ≥ 50y with knee OA were randomly assigned to 8-weeks KBA, RT, KBA + RT, or Sham. Participants trained 3 times per week for 40 minutes. KBA utilized exercises such as cross-over walking, side-stepping, and backward stepping, plus single-leg static and dynamic balancing. RT used elastic resistance bands for open chain lower extremity exercises. KBA + RT performed selected exercises from each technique to ensure the total exercise exposure remained equal. Sham applied inert lotion daily in a manner that avoided self-massage. Outcomes included the OA specific WOMAC Index of Pain, Stiffness, & Physical Function (PF), community activity level, exercise self-efficacy, and self-report knee stability.

**RESULTS:** Thirty-three participants completed the trial. Analysis of Variance comparing baseline, mid-point, and follow-up measures revealed significant (p < 0.05) improvements in WOMAC Pain, Stiffness, PF, and Total scores among KBA (n = 8), RT (n = 8), KBA + RT (n = 9), and Sham (n = 8), with no differences between groups. There were no significant changes in community activity level. Only Sham improved exercise self-efficacy. Knee stability was significantly improved in the RT and Sham conditions.

**CONCLUSION:** The three exercise conditions appeared relatively equal for reducing the symptoms of knee OA. Sham results indicate a strong placebo effect. However, Sham WOMAC improvements peaked at 4-week mid-point, whereas improvement in the exercise conditions continued at 8-weeks. In conclusion, our results indicate that KBA, RT, or a combination of the two administered as home exercise programs are effective in improving symptoms and quality of life among persons with knee OA. Patient preferences, costs, and convenience should be considered when choosing an exercise rehabilitation approach for knee OA.

**3369 Board #90 June 2 8:00 AM - 9:30 AM**

**Effects of Atorvastatin on Resting and Peak Exercise Blood Pressure**

Marianne L. Mentch<sup>1</sup>, Beth A. Parker<sup>2</sup>, Jeffrey A. Capizzi<sup>2</sup>, Adam S. Grimaldi<sup>2</sup>, Priscilla M. Clarkson, FACSM<sup>3</sup>, Stephanie M. Cole<sup>3</sup>, Stuart Chipkin<sup>3</sup>, Justin Keadle<sup>3</sup>, C. Michael White<sup>2</sup>, Paul D. Thompson, FACSM<sup>2</sup>, Linda S. Pescatello, FACSM<sup>1</sup>. <sup>1</sup>University of Connecticut, Storrs, CT. <sup>2</sup>Hartford Hospital, Hartford, CT. <sup>3</sup>University of Massachusetts, Amherst, MA.

(No relationships reported)

Statins reduce low density lipoprotein cholesterol and decrease cardiovascular events. They are also reported to lower resting blood pressure (BP), but this is controversial.

**PURPOSE:** To determine if 80mg of atorvastatin reduces resting BP and peak systolic BP (SBP) on a graded exercise test.

**METHODS:** Subjects were double-blinded and randomized to 80mg·d<sup>-1</sup> of atorvastatin (n=202) or placebo (n=217) for 6 months. Resting BP and peak SBP were measured by auscultation at baseline and 6 months. Repeated measures ANCOVA tested differences in resting BP and peak SBP over 6 months by drug treatment group and gender with age and body mass index (BMI) as covariates.

**RESULTS:** Subjects were 44.1 ± 0.8 yr (mean ± SEM) with resting BP of 118.9 ± 0.6/75.3 ± 0.5 mmHg and BMI of 26.4 ± 0.2 kg·m<sup>-2</sup>. Men (n=203) had higher resting BP (121.6 ± 0.9/76.5 ± 0.7 vs. 116.2 ± 0.9/74.1 ± 0.7 mmHg) and peak SBP (177.5 ± 1.9 vs. 161.3 ± 1.7 mmHg) than women (n=216) (p=0.000). Subjects reduced resting SBP (atorvastatin, -4.0 ± 0.8; placebo -3.0 ± 0.7 mmHg) (p=0.000), but not diastolic BP (p=0.86) or mean arterial pressure (p=0.76) over 6 months, regardless of atorvastatin or placebo. However, women on atorvastatin (n=103) tended to reduce resting SBP 3.0 ± 1.5 mmHg more than women on placebo (n=113) (p=0.06). There was no difference in resting SBP between atorvastatin and placebo among men (p=0.66). In the total sample, peak SBP was not different between atorvastatin and placebo over 6 months (p=0.99). However, women on atorvastatin reduced peak SBP 6.4 ± 3.3 mmHg more than women on placebo over 6 months (p=0.02). There was no difference in peak SBP between atorvastatin and placebo among men (p=0.13).

**CONCLUSION:** Participation in a clinical trial reduced resting SBP, independent of assignment to atorvastatin or placebo. Moreover, in women but not men, atorvastatin reduced resting SBP and peak SBP more than placebo, and atorvastatin did not influence resting and peak SBP among men. The mixed findings regarding the antihypertensive effects of statins may be attributable to not accounting for trial and drug placebo effects and gender differences. Supported by NHLBI/NIH grant RO1 HL081893A2.

**3370 Board #91 June 2 8:00 AM - 9:30 AM**

**Heart Rate Recovery in Juvenile Idiopathic Arthritis: Relationship with Aerobic Fitness, Disease Subtype and Severity**

Joyce Obeid<sup>1</sup>, Marco van Brussel<sup>2</sup>, Brian W. Timmons<sup>1</sup>, Tim Takken<sup>2</sup>. <sup>1</sup>McMaster University, Hamilton, ON, Canada. <sup>2</sup>University Medical Center Utrecht, Utrecht, Netherlands. (Sponsor: Boguslaw Wilk, FACSM)

(No relationships reported)

Youth with JIA may be at an increased risk of developing cardiovascular (CV) disease, with early signs of atherosclerosis manifesting as young as 4 years of age. Heart rate recovery (HRR) following maximal exercise is a strong predictor of CV health and all-cause mortality in adults. The relationship between HRR and health outcomes in JIA is of considerable interest as HRR may represent a simple clinical tool to facilitate early detection of CV impairment in this population.

**PURPOSE:** To compare HRR in JIA and healthy controls and to examine potential associations between HRR, fitness- and disease-related variables in JIA.

**METHODS:** Sixty-two children with polyarticular, oligoarticular and systemic JIA as well as 50 healthy controls performed a graded, maximum-effort cycling test to assess aerobic fitness (VO<sub>2peak</sub>). The highest achieved power output and oxygen uptake were taken as the peak work rate (W<sub>peak</sub>) and VO<sub>2peak</sub>, respectively. Heart rate (HR) was measured at rest, continuously throughout and after exercise by ECG. HRR was calculated as the difference between peak HR (HR<sub>peak</sub>), and HR at 1-min post-exercise. Disease duration and number of swollen joints were also assessed in JIA. Independent sample t-tests were used to examine differences between JIA and healthy controls. Multiple regression analysis was used to determine significant predictors of HRR in JIA.

**RESULTS:** HRR at 1-min post-exercise was similar between youth with JIA and healthy controls (50 ± 14 vs. 53 ± 14 bpm, p>0.25), as was HRR expressed as a percentage of heart rate reserve (61.5 ± 18.5 vs. 59.4 ± 15.8%, p=0.51). The strongest significant predictors of HRR in JIA included JIA subtype (systemic vs. others), age at testing, W<sub>peak</sub>, and HR<sub>peak</sub> in the following model:  $HRR (bpm) = 114.804 - 11.041 \times JIA (0=oligo-, poly-JIA; 1=systemic) - 2.338 \times \text{age at testing} + 9.395 \times W_{peak} - 0.373 \times HR_{peak}$  (R<sup>2</sup> = 0.33; SEE = 12.2). Inclusion of BMI, VO<sub>2peak</sub>, disease duration and/or joint count did not improve HRR prediction.

**CONCLUSIONS:** While HRR is similar between JIA and healthy controls, it appears that the type of JIA (systemic) may play an important role in modulating HRR. Future work should focus on linking HRR in youth with systemic JIA to more direct markers of CV damage.

Joyce Obeid was supported by a CIHR Michael Smith Foreign Study Supplement.

**3371 Board #92 June 2 8:00 AM - 9:30 AM**  
**Steps/min and Mets During Incremental Exercise In Hispanic Adults Living With and Without Hiv Infection**

Celina Corteguera, Farah A. Ramirez-Marrero, FACSM. *Univ. of Puerto Rico, San Juan, Puerto Rico.*  
(No relationships reported)

A walking cadence of 100 steps/min or more is used to demark moderate intensity level activity (at least 3 METs). However, because resting  $\text{VO}_2$  is higher among people living with HIV, such cadence might represent a different MET value.

**PURPOSE:** We tested the hypothesis that MET values would be lower in adults living with HIV infection compared to non-HIV adults exercising at the same intensity level.

**METHODS:** A group of 88 Hispanic adults (58 HIV and 30 non-HIV) completed a resting  $\text{VO}_2$  test, and a graded exercise test ( $\text{VO}_2\text{max}$ ) using the modified Bruce protocol while wearing an accelerometer. METs, heart rate (HR), and steps/min were measured in each stage of the protocol and compared between groups using ANOVAs and linear regressions.

**RESULTS:** The HIV group had lower MET values compared with the non-HIV group in all stages of the protocol except the first (1.7 mph, zero inclination) where MET values were not different between groups. HR response during all stages was not different between groups, and step cadence in the HIV group was higher compared to the non-HIV group only in the first stage of the protocol. A 100 steps/min cadence was equivalent to 5.8 METs in the HIV group and 7.8 METs in the non-HIV group.

**CONCLUSION:** The use of MET values to identify exercise intensity, functional capacity and/or energy expenditure must be population specific to prevent errors, particularly among Hispanic adults living with HIV infection. Funded by NIH/CTSA KL2-RR024151

**3372 Board #93 June 2 8:00 AM - 9:30 AM**  
**Factors Influencing The Effect Of Exercise On Bone Mass Density In Women With Postmenopausal Osteoporosis**

Antonio Sgadari, Marianna Broccatelli, Simona De Bellonia, Alessia Rabini, Roberto Bernabei. *Catholic University of Sacred Heart, Rome, Italy.*  
(No relationships reported)

Osteoporosis is a condition resulting in an increased risk of skeletal fractures due to a reduction in the density of bone tissue. Interventional studies based on physical exercise programs have demonstrated modest increases in bone mineral density (BMD) in older postmenopausal women. It has been argued that in this population the capacity of the skeleton to adapt to mechanical stress of exercise is impaired due to a series of factors such as inadequate intake of specific nutrients, altered hormonal status, low level of physical activity (PA), and medications or comorbidities which may facilitate osteoporosis.

**PURPOSE:** To investigate if subject's characteristics, lifestyle habits, medications, comorbidities, dietary intake of nutrients, calcium and Vit.D, level of PA in everyday life, influenced the effect of an exercise program on BMD in 155 women with postmenopausal osteoporosis.

**METHODS:** Forty-seven women with lumbar or femoral osteoporosis, regularly exercising at the University Hospital Fitness Facility for >1 year, were recruited (EXE group); 108 sedentary women attending the Outpatient Clinic and matched by gender, age, duration of the observation period, and BMD values, were allocated to the control group (SED group). Main outcome was percent change in BMD. Concurrent diseases, medications, risk factors for osteoporosis, level of PA (Paffenbarger scale), dietary intake of macronutrients as well as of Ca, K, and P were recorded.

**RESULTS:** The mean ( $\pm$ s.d.) follow-up time was 37.7 $\pm$ 15.4 months in the EXE and 36.0 $\pm$ 17.3 in the SED group. The age was 66.2 $\pm$ 6.3 years, with no differences between the two groups. During the follow up time the BMD increased from 0.688 $\pm$ 0.087 to 0.710 $\pm$ 0.100  $\text{g}\cdot\text{cm}^{-2}$  ( $p=0.008$ ) in the EXE group and decreased from 0.697 $\pm$ 0.099 to 0.688 $\pm$ 0.107  $\text{g}\cdot\text{cm}^{-2}$  in the SED group ( $p=0.038$ ); the difference between the two groups was significant ( $p<0.001$ ). Neither the pharmacological treatment nor the dietary intake of calories, macro- and micro-nutrients significantly affected the change in BMD. Also, the change in BMD among subjects in the higher tertile of PA was not different from that of those in the lower tertile (3.4 $\pm$ 1.2 vs. 2.1 $\pm$ 0.9%,  $p=0.09$ ).

**CONCLUSIONS:** A physical exercise program was effective in improving BMD in postmenopausal women; this effect was not influenced by several modifiable factors.

**Influence of Protective Clothing on Endurance Capacity, Thermoregulation and Fluid Balance in Fencers**

Mario Weichenberger, Yuefei Liu, Martina Velders, Jürgen M. Steinacker, FACSM. *University of Ulm, Ulm, Germany.*  
(No relationships reported)

Fencers wear special protective clothing to prevent injuries during fencing bouts consisting of jacket, breeches, glove and mask. This equipment may affect thermoregulatory processes and could therefore impact on the athlete's performance.

**PURPOSE:** To analyze the influence of protective clothing on endurance capacity, thermoregulation and fluid balance in fencers.

**METHODS:** 9 German junior top-level fencers (16.9  $\pm$  1.2 yrs) underwent two Fencing-specific Endurance Tests (FET) in a cross-over study in random order with protective clothing (PC) or normal sportswear, respectively. FET was conducted with a weapon and fencing-specific footwork forwards and backwards on a fencing ground (planche). Subjects started at 3 km/h and speed was increased by 1 km/h every 3 minutes up to exhaustion ( $v_{\text{max}}$ ). Heart rates [HR] and blood lactate [LAC] were determined during FET; hematocrit [HC], body weight [BW] and body temperature [TEMP] were measured before and after the tests.

**RESULTS:** Due to PC athletes lost more BW ( $\Delta$  0.62  $\pm$  0.12kg vs. 0.42  $\pm$  0.08kg,  $p<.01$ ) as a result of higher loss of water, had a greater increase of HC ( $\Delta$  4.9  $\pm$  1.5% vs. 2.9  $\pm$  1.1%,  $p<.01$ ) and a greater rise of TEMP ( $\Delta$  0.7  $\pm$  0.1°C vs. 0.4  $\pm$  0.1°C,  $p<.01$ ). Wearing PC resulted in lower  $v_{\text{max}}$  (7.4  $\pm$  0.7 km/h vs. 8.1  $\pm$  0.4 km/h,  $p<.05$ ) and lower performances at blood lactate concentrations of 2 mmol/l (5.2  $\pm$  0.5 km/h vs. 5.7  $\pm$  0.5 km/h,  $p<.05$ ) and 4 mmol/l (6.2  $\pm$  0.5 km/h vs. 6.8  $\pm$  0.6 km/h,  $p<.01$ ). HR were higher in athletes with PC during and 5 minutes after FET ( $p<.05$ ). Athletes with PC had a higher LAC concentration for movement speed higher than 6 km/h (3.7  $\pm$  1.2 mmol/l vs. 2.8  $\pm$  1.0 mmol/l,  $p<.05$ ).

**CONCLUSIONS:** Wearing protective clothing increases perspiration and body temperature and lowers endurance performance in fencers. These negative effects due to the protective clothing should be taken into consideration during a fencing tournament, where athletes have to perform 10 to 15 bouts. Whether the ingestion of cold beverages to regulate fluid balance and body temperature has a significant effect on counteracting performance decrements has to be verified in further studies.

---

**3374 Board #95 June 2 9:30 AM - 11:00 AM**  
**Examination Of The Impact Of A Cooling Product On Cycling Performance In The Heat**

Walter R. Bixby, FACSM, Amanda B. Mischo, Paul C. Miller, Stephen P. Bailey, Eric E. Hall, FACSM. *Elon University, Elon, NC.*  
(W.R. Bixby: Contracted Research - Including Principle Investigator; Daniale LLC.)

Exercising in the heat has adverse consequences for physical performance. Little evidence exists examining the impact of a cooling strategy during the event.

**PURPOSE:** To examine if a cooling strategy during an event in the heat can reduce the negative effects commonly seen and thus positively impact performance and perception.

**METHODS:** 7 experienced male cyclists performed a graded exercise test and two time trials (TT) on 3 separate days on a Velotron. Days two and three were identical with the exception of the treatment condition and were performed in an environmentally controlled chamber set to 30 degrees Celsius with 60% humidity. Participants were given 10 minutes to warm-up. Following

the warm-up, heart rate and affect were recorded. Participants then completed a 30K TT as fast as they could. Heart rate and affect were recorded at ¼, ½, ¾ of the way through, at the end and 15 minutes after the TT. On one day participants wore a cooling product and the order of presentation was counterbalanced.

**RESULTS:** One way Repeated Measures ANOVAs were calculated for Average Watts, MPH, and Time across the two TT conditions. No significant results were found: Watts cooling 247.99 (51.99) and non-cooling 244.49 (53.47); MPH cooling 24.43 (2.01) and non-cooling 24.21 (2.06); and Time cooling 46:20 (3:48) and non-cooling 46:32 (4:03). A two way (2 Condition x 2 Time) RM ANOVA was calculated for lactate and a significant Time main effect was found,  $F(1, 6) = 13.83, p < .05$ , pre 3.56 (.94) post 11.50 (1.61). Two way (2 condition x 6 Time) RM ANOVAs were calculated for HR and Affect. A significant time main effect was found for HR,  $F(5, 30) = 113.74, p < .01$ . Heart rate increased from baseline throughout the time trial and began to return to baseline levels 15 min into recovery. A significant time main effect was found for Affect,  $F(5, 30) = 10.08, p < .05$ . Participants felt progressively worse throughout the time trial and then rebounded to near baseline levels 15 minutes after the time trial.

**CONCLUSIONS:** The cooling product did not have a statistically significant impact on performance or affect during and following a time trial in the heat. Participants performed 13 seconds faster while wearing the cooling product which could have significant real world impact.

**Effects of Wearing Arm Progressive Compression Sleeves on Upper-body Muscular Performance in Trained Men**

Maria Claudia C. Pereira<sup>1</sup>, Diego Jesus<sup>1</sup>, Saulo R. Soares<sup>1</sup>, Rogerio A. Guedes<sup>1</sup>, Carlos A. Vieira<sup>2</sup>, João B. Ferreira-Junior<sup>1</sup>, Lee E. Brown, FACSM<sup>3</sup>, Martim Bottaro<sup>1</sup>.  
<sup>1</sup>University of Brasília, Brasília, Brazil. <sup>2</sup>Federal University of Goiania, Goiania, Brazil. <sup>3</sup>California State University Fullerton, Fullerton, CA.  
 (No relationships reported)

Investigations have demonstrated that progressive lower-body compression garments (shorts and stockings) can enhance repetitive jump power and running economy. Recently, the use of upper-body compression garments, such as arm progressive compression sleeves, has become popular in sports that require muscular strength, endurance, and power (e.g., basketball, volleyball, tennis, standup paddle, etc.). However, the benefits of these garments on muscular performance still need to be investigated.

**PURPOSE:** To investigate the effects of wearing compression sleeves (CS) on force production and muscle fatigue of the elbow flexor in trained men.

**METHODS:** Eight healthy resistance trained young men (20.4 ± 3.1 yrs; 71.7 ± 6.0 kg) volunteered to take part in this study. Testing was conducted using a balanced and randomized treatment design with two experimental conditions consisting of: 1) compression sleeves (CS), and 2) placebo sleeve (PS) with no compression. Peak torque (PT) and total work (TW) testing consisted of four sets of 10 maximal isokinetic elbow flexion repetitions at 60°.s<sup>-1</sup> on a Biodex System 3 dynamometer.

**RESULTS:** PT and TW are presented in Table 1. No significant differences were found between the CS and PS conditions. However, PT and TW decreased significantly ( $p < 0.05$ ) between sets (1<sup>st</sup> > 2<sup>nd</sup> > 3<sup>rd</sup> > 4<sup>th</sup>) from both conditions.

Table 1.

|    | Peak Torque (N.m) |            |           |          | Total Work (Joules) |              |             |            |
|----|-------------------|------------|-----------|----------|---------------------|--------------|-------------|------------|
|    | 1st set           | 2nd set    | 3rd set   | 4th set  | 1st set             | 2nd set      | 3rd set     | 4th set    |
| CS | 62.4±7.4*         | 52.3±6.9†  | 49.2±5.5‡ | 47.5±7.4 | 921.6±95.1*         | 734.8±64.9†  | 611.8±38.0‡ | 539.6±31.8 |
| PS | 65.1±13.1*        | 56.9±11.4† | 53.4±9.4‡ | 50.6±8.3 | 969.4±153.4*        | 763.4±108.8† | 626.8±55.2‡ | 571.3±52.2 |

\* Higher than 2nd, 3rd, and 4th ( $p < 0.05$ ); † higher than 3rd, and 4th ( $p < 0.05$ ); ‡ higher than 4th ( $p < 0.05$ )

**CONCLUSION:** These results indicate that compression sleeves commonly worn by athletes and fitness enthusiasts during training and competition do not contribute to improved elbow flexion muscle strength or work capacity during repetitive high-intensity resistance exercise tasks.

**3376 Board #97 June 2 9:30 AM - 11:00 AM**

**Effects of Nanobionic Textile T-shirt on Maximal Anaerobic Power**

Evangelos Roussopoulos, Giorgos Paradisis, Elias Zacharogiannis, Nikolaos Dimitriadis. *Track and Field Sector, University of Athens, Athens, Greece.*  
 (No relationships reported)

Nanobionic is a textile, made of bio-ceramic materials, that reflects back to human body the far-infrared rays that body emits. Although there are research data regarding the use of far infrared rays to improve performance and to speed up recovery from exercise, reports on their effect on maximal anaerobic power are scarce.

**PURPOSE:** The aim of this study was to investigate the effects of a Nanobionic t-shirt on maximal anaerobic power during exercise.

**METHODS:** Twelve (7 men, 5 women) healthy active subjects (age 28.2 ± 5.7 years, body mass 71.2 ± 16.1 kg, height 173.9 ± 9.5 cm) agreed to participate in the study. A double blind cross over design was used with subjects visited the lab twice for the placebo (PT) and experiment test (ET). Maximal anaerobic power parameters were determined through the wingate anaerobic test (WAnT) which was performed on a cycle ergometer (Monark 894E, Sweden) against a resistance of 0.075 kg kg body mass<sup>-1</sup>. Peak power (PP) determined as the highest value over the first 5-s period of testing, mean Power (MP) as the average Power for the whole period of 30 s, % of Power Drop (%PD) as the difference of the PP minus the minimum power divided by the PP (PP-MP/PP).

**RESULTS:** All anaerobic power parameters showed significant improvements ( $P < 0.05$ ) in the ET condition compared to PT condition (Table).

**CONCLUSIONS:** Nanobionic t-shirt improves anaerobic power parameters; however the triggering mechanisms that produce these changes should be subject of future research which could explain the physiological basis behind the outcome of the present study.

Mean ± SD and % difference of all anaerobic power parameters for the ET and PT conditions

|       | Peak power (watt/kg) | % drop power | RPM max (rev/min) | Mean power (watt/kg) | Post WAnT lactate (mmol/l) |
|-------|----------------------|--------------|-------------------|----------------------|----------------------------|
| ET    | 10.23±2.10           | 55.08±9.76   | 193.17±23.10      | 7.05±1.24            | 16.05±3.14                 |
| PT    | 10.64±2.00           | 57.96±8.36   | 199.08±23.25      | 7.28±1.17            | 14.97±2.87                 |

**3377 Board #98 June 2 9:30 AM - 11:00 AM**

**Nanobionic Textile T-shirt: Its Effect On The Parameters Of Cardiorespiratory Function**

Nikos Dimitriadis, Evangelos Roussopoulos, Georgios Paradisis, Elias Zacharogiannis. *Athens University, Athens, Greece.*  
 (No relationships reported)

Nanobionic is a high quality technological textile, made of bio-ceramic materials, that reflects back to our body the far infrared rays our body emits. The exposure of living organisms to far infrared radiation has been documented to induce an increase in temperature of the body tissues, dilate cutaneous blood vessels as well as arterioles and venules promoting blood circulation and thus promoting metabolic rate. Although there are published research data regarding the use of far infrared rays to speed up recovery from exercise, reports on their effect on the cardiorespiratory parameters are scarce.

**PURPOSE:** The aim of this study was to investigate the effects of a Nanobionic t-shirt on the parameters of cardiorespiratory function during exercise.

**METHODS:** Twenty two (11 men, 11 women) healthy active subjects (age  $27.7 \pm 4.4$  years, body mass  $68.3 \pm 13.6$  kg, body height  $173.2 \pm 8.7$  cm) agreed to participate in the study. A double blind cross over design was used. Cardiorespiratory parameters were determined by continuous exhaustive incremental testing with an open circuit spirometry. This protocol had steps of 2 min and increments of 1km.h<sup>-1</sup>. After the first evaluation with active t-shirt (ET) or with identical inactive t-shirt (PT) the subjects 7-14 days performed the second exhaustive trial.

**RESULTS:** Mean values for the ET or PT of VO<sub>2</sub>max ( $51.76 \pm 6.5$  v  $49.62 \pm 6.87$  ml.kg<sup>-1</sup>.min<sup>-1</sup>) velocity at VO<sub>2</sub>max ( $14.61 \pm 1.73$  v  $13.77 \pm 1.72$  km.h<sup>-1</sup>), the velocity at the ventilatory threshold ( $11 \pm 1.48$  v  $10.2 \pm 1.79$  km.h<sup>-1</sup>), total treadmill time (789.5 k, maximal heart rate and maximal blood lactate concentration ( $12.19 \pm 1.9$  v  $10.75 \pm 1.75$  mmol.l<sup>-1</sup>) and maximal heart rate ( $191.5 \pm 7.9$  v  $188.9 \pm 8.4$  b.p.m) were significantly different ( $p < 0.01$ )

**CONCLUSIONS:** Nanobionic t-shirt improves cardiorespiratory parameters and endurance performance. The triggering of metabolism through its reflective properties on far infrared rays should be subject of future research and may explain the physiological basis behind the outcome of the present study.

**3378 Board #99 June 2 9:30 AM - 11:00 AM**  
**The Effect of EnergyCare™ Bands on Selected Physical Performance Tests**

Andy O'Neill, Anthony Caterisano, FACSM. *Furman University, Greenville, SC.*  
(No relationships reported)

**BACKGROUND:** In today's world athletes attempt to find a product that will improve their health and athletic performance. EnergyCare™ bands, claim to improve athletic performance in a variety of areas such as strength, power, flexibility, speed and balance. Although no previous studies on EnergyCare™ bands have been done, other studies on similar products have produced mixed results.

**PURPOSE:** To determine the effectiveness of EnergyCare™ bands on flexibility, strength, power, speed, and balance.

**METHODS:** College-age males (N=13) were tested in a double-blind format in the areas mentioned above. Students performed five tests: strength (isometric bench press), flexibility (sit and reach), balance (one foot balance test), power (vertical jump), and speed (10 yard dash). Each test was performed five times with five different conditions: those being two active bands (2AB), two placebos (PB), one active leg and one placebo arm (AL), one active arm and one placebo leg (AA), and no bands (NB). Students were randomly assigned condition order and performed all 5 tests in the same order each time. A MANOVA with a Tukey post hoc test was used to analyze the data.

**RESULTS:** There was no significant difference among power, speed, flexibility, and strength across the five experimental conditions. A significant difference exists in the balance tests measured in seconds was as follows: 2AB =  $8.52 \pm 2.26$  ( $p=.003$ ), PB =  $3.47 \pm 0.39$ , AL =  $3.59 \pm 0.31$ , AR =  $3.70 \pm 0.56$ , NB =  $2.86 \pm 0.54$ .

**CONCLUSIONS:** It appears that EnergyCare™ bands do not have an ergogenic effect on strength, power, speed or flexibility. However, the data suggests that balance may be positively affected when using both the active ankle and wrist bands, which may benefit athletes who compete in sports that emphasize balance.

**The Efficacy of a Lower Limb Compression Garment in Accelerating Recovery from a Marathon Run**

Jessica Hill<sup>1</sup>, Glyn Howatson, FACSM<sup>2</sup>, Ken van Someren<sup>3</sup>, Ian Walshe<sup>2</sup>, Charles Pedlar<sup>1</sup>. <sup>1</sup>*St Mary's University College, Twickenham, United Kingdom.*  
<sup>2</sup>*Northumbria University, Newcastle, United Kingdom.* <sup>3</sup>*English Institute of Sport, Marlow, United Kingdom.*  
(No relationships reported)

Strenuous physical activity can result in exercise induced muscle damage (EIMD) particularly if the exercise is unaccustomed or of a long duration. The EIMD is characterised by a number of symptoms including muscle soreness, inflammation and reduced muscle function. Numerous interventions have been used to reduce the symptoms associated with EIMD, however few have examined the efficacy of compression garments following sports specific paradigms.

**PURPOSE:** To investigate the efficacy of a lower limb compression garment in accelerating recovery from indices of muscle damage following a Marathon run.

**METHODS:** Twenty four subjects (n= 7 female, n= 17 male, mean  $\pm$  SD age  $42 \pm 10$  yrs, height  $176 \pm 8.6$ cm and body mass  $77.4 \pm 11.0$  kg) completed a Marathon run before being assigned to a treatment or placebo group. The treatment group wore lower limb compression tights for 72 hours following the Marathon run, the placebo group received a single treatment of 15 min sham ultrasound following the Marathon run. Perceived muscle soreness, maximal isometric voluntary contraction (MIVC) and serum markers of creatine kinase (CK) and c-reactive protein (C-RP) were assessed before the Marathon, immediately after, and at 24, 48 and 72 hours post Marathon.

**RESULTS:** All subjects completed the Marathon run (mean  $\pm$  SD finish time 03:46:45  $\pm$  00:22:00 in the compression group and 03:39:27  $\pm$  00:33:10 in the placebo group). Muscle soreness, assessed using a visual analogue scale, was significantly lower ( $p < 0.05$ ) in the compression group at 24 h post Marathon when compared to the placebo group ( $13.9 \pm 13.0$ mm and  $36.4 \pm 11.6$ mm respectively). There were no significant group effects for MVIC, CK and C-RP ( $p > 0.05$ ).

**CONCLUSIONS:** There is some evidence to suggest that compression garments result in improved perceptions of recovery. However, the use of a lower limb compression garment does not attenuate markers of muscle damage or inflammation, nor does it accelerate the recovery of muscle function following a Marathon run.

**Whole Body Compression Garment Promotes Muscular Strength Recovery After Strenuous Resistance Exercise**

Kazushige Goto, Takuma Morishima. *Ritsumeikan University, Kusatsu, Japan.* (Sponsor: Robert Kraemer, FACSM)  
(No relationships reported)

A recent study demonstrated that the use of whole body compression garment (CG) during 24 h after exercise enhances muscular strength the following day. However, detailed time-course changes in muscular strength from wearing CG remains unclear.

**PURPOSE:** We determined time-course changes in muscular strength, anabolic hormones and inflammatory responses after resistance exercise throughout 24 h recovery period with CG.

**METHODS:** Nine trained athletes conducted strenuous resistance exercise (3-5 sets, 9 exercises) in two different conditions, either wearing (CG trial) or not wearing (NCG control trial) the CG during a 24 h recovery period. Muscular strength, hormonal concentrations and inflammatory responses were evaluated continuously.

**RESULTS:** In both trials, one-repetition maximum (1RM) for chest press (upper limb) was significantly decreased after resistance exercise ( $P < 0.05$ ). However, the CG trial showed significantly faster recovery during 3-8 h after the exercise than the NCG trial ( $P < 0.05$ ). Similarly, recovery of maximal isometric strength for knee extension (lower limb) was significantly faster in the CG trial at 24 h after the exercise ( $P < 0.05$ ). The CG trial showed significantly lower muscle soreness and fatigue at rest on next morning compared with NCG trial ( $P < 0.05$ ). No significant difference was observed in the responses of blood lactate, creatine kinase (CK), myoglobin, free testosterone, insulin like growth factor(IGF)-1, interleukin (IL)-6, and IL-1 receptor antagonist throughout the 24h recovery period between trials.

**CONCLUSION:** These results indicate that the use of compression garment during post-exercise facilitates muscular strength recovery after strenuous exercise. For an upper body, promotion of strength recovery appears to be found within 24 h (3-8h) after the exercise.

### Improving Measures of Stride Length Using a High Velocity Resistance Training Program

Timothy J. Leszczak, Lisa E. Henning, Samantha M. Hart, Tristan G. Trotter. *Austin Peay State University, Clarksville, TN.*  
(No relationships reported)

Research has indicated that improving strength and functional performance in older adults can be accomplished through various training programs. However, few have looked at the use of a high velocity training program on improving measures of stride length.

**PURPOSE:** The purpose of this study was to see if a high velocity training program can improve stride length in community dwelling older adults.

**METHODS:** Eight older adults (5 F, 3 M) over the age of 65 completed the 12 week exercise intervention, and had an average ( $\pm$  SD) age at  $82.25 \pm 9.45$  years. All participants completed an informed consent and received medical clearance from their physician. They were tested three times during the 12-week exercise intervention (pre-intervention, mid-intervention, and post-intervention) on stride length, gait velocity, 8-foot up-and-go, chair stand, and arm curl. The training program consisted of three days per week for 12 weeks, and all exercises were progressed using weighted vest, medicine balls, and ankle weights. The exercises performed were standing hip flexion, standing hip extension, standing heel raises, chair stand, medicine ball slams, medicine ball bounces, and lifting a medicine ball from ground to standing position.

**RESULTS:** A paired samples t-test ( $\alpha = .05$ ) was used to analyze the data to see if within group differences existed between pre-and post-intervention on the aforementioned variables. Results indicated that significant differences existed for gait velocity,  $t(8) = -2.77, p = .03$ ; chair stand,  $t(8) = 3.35, p = .01$ ; and arm curl,  $t(8) = 2.58, p = .04$ .

**CONCLUSION:** Although significant differences were not observed in the stride length variable, gait velocity did improve suggesting that strength may have affected walking ability. This group may have increased their walking frequency enabling them to improve their walking time.

---

**3382** Board #103 June 2 8:00 AM - 9:30 AM

### Comparison Of High- And Low-velocity Training In Older Adults: Regional Body Composition Measures

Melissa Powers<sup>1</sup>, Michelle Gray<sup>2</sup>, Kayla Garver<sup>1</sup>, Simon Smith<sup>1</sup>. <sup>1</sup>*University of Central Oklahoma, Edmond, OK.* <sup>2</sup>*University of Arkansas, Fayetteville, AR.*  
(No relationships reported)

Recently, studies have been conducted examining the impact of high-velocity resistance training on functionality among elders. However, it remains unclear if high-velocity training improves body composition especially when compared to training at a lower velocity.

**PURPOSE:** The purpose of this study was to compare regional body composition changes following high-velocity resistance training to those experienced following low-velocity training. The researchers hypothesized that no regional body composition differences would be seen between the two training methods, but that both protocols would improve body composition.

**METHODS:** Seventeen adults over the age of 75 years completed one year of training. Participants were randomly assigned to either high-velocity, low-intensity (HV) or low-velocity, high-intensity (LV) training. HV participants completed 24 weeks of LV before transitioning to HV. Regional body composition was assessed using an iDXA total body scan which measured fat mass (FM) and lean tissue mass (LTM) of the gynoid and android regions. Appendicular FM and LTM as well as the ratio of appendicular LTM to appendicular FM were calculated. Assessments were taken at baseline, 24 weeks, and after one year of training. ANOVA with repeated measures was used to analyze interaction and main effects for each outcome ( $\alpha = .007$ ).

**RESULTS:** No significant interaction effects were observed. A time effect was seen for gynoid LTM,  $F = 7.72, p = .002$ . Post hoc tests reveal a significant loss of LTM from baseline to 24 weeks. Interesting, univariate effect sizes indicate differing effect of training on gynoid LTM from 24 weeks through one year. In the gynoid region, the HV group lost LTM ( $d = 0.138$ ), while the LV group experienced maintenance of LTM ( $d = 0.034$ ).

**CONCLUSION:** Although not statistically significant, we observed a slight decrease in LTM following HV training, while the LV group experienced no change in LTM. This difference may be due to the intensity of training which was not consistent in this study. The HV group trained at a low intensity (50% of 1-repetition maximum), while the LV group trained at a high-intensity (80% of 1-repetition maximum). These results indicate the need for further study. It is recommended that this study be repeated with intensity held constant between the two training protocols.

**3383** Board #104 June 2 8:00 AM - 9:30 AM

### Leg Strength Declines with Advancing Age Despite Chronic Endurance Exercise in Active Older Adults

Taylor J. Marcell<sup>1</sup>, Petra Martins<sup>1</sup>, Steven A. Hawkins, FACSM<sup>2</sup>, Robert A. Wiswell, FACSM<sup>3</sup>. <sup>1</sup>*California State University Stanislaus, Turlock, CA.* <sup>2</sup>*California Lutheran University, Thousand Oaks, CA.* <sup>3</sup>*University of Southern California, Los Angeles, CA.*  
(No relationships reported)

**PURPOSE:** Recent physical activity guidelines for older adults have included recommendations for resistance training and intensity, whereas earlier versions focused solely on low intensity walking activities. We have previously collected longitudinal data on highly active seniors who have exclusively participated in running as a form of exercise to evaluate whether running alone was sufficient to prevent age-associated sarcopenia.

**METHODS:** Ninety-five very active older men ( $n = 59$ ) and women ( $n = 36$ ) were selected from a population of 237 master athletes participating in a longitudinal study at the University of Southern California. Subjects attend biannual comprehensive physiologic testing between May 1987 and December 2001. Isokinetic knee extension and isometric knee extension and flexion strengths were assessed using a Kin Com dynamometer (500H). Subjects self-reported training and performance data including 5 kilometer, 10 kilometer, and marathon distances.

**RESULTS:** Data were evaluated combined and by age tertiles (50-54 yr, 55-64 yr, & 65-80 yr). Average time between tests was  $4.8 \pm 2.0$  yrs. VO<sub>2</sub> max declined significantly in men ( $48.4 \pm 9.9$  to  $44.8 \pm 9.8$  ml/kg/min;  $p = 0.001$ ) and women ( $43.5 \pm 8.0$  to  $40.6 \pm 9.3$  ml/kg/min;  $p = 0.009$ ). Isometric flexion and extension strengths declined in both men and women at all angles measured (e.g., knee-extension at 60°:  $251.2 \pm 55.3$  N to  $199.8 \pm 56.7$  N;  $p = 0.001$  men &  $158.8 \pm 34.0$  N to  $126.2 \pm 32.5$  N;  $p = 0.001$  women), whereas isokinetic concentric and eccentric strength changes did not reach statistical significance due to large variability in our measures.

**CONCLUSION(S):** Older adults who use aerobic activity as their sole means of exercise demonstrate small losses in aerobic fitness but larger losses in muscle strength. Thus, running alone will not prevent sarcopenia. The largest declines in fitness and strength were associated with those adults who decreased their running volume.

---

**3384** Board #105 June 2 8:00 AM - 9:30 AM

### Changes in Self-Reported Fatigue in Postmenopausal Women Induced by Diet or Exercise Behavior Change

Christie L. Ward<sup>1</sup>, Bhibha M. Das<sup>1</sup>, Dolores D. Guest<sup>2</sup>, Ellen M. Evans, FACSM<sup>1</sup>. <sup>1</sup>*University of Georgia, Athens, GA.* <sup>2</sup>*University of Southern Illinois, Springfield, IL.*  
(No relationships reported)

Fatigue is a common clinical complaint among older women. In older adults, poorer body composition, specifically increased adiposity (%Fat) and decreased mineral free lean mass (MFLM), have been linked to increases in self-reported fatigue. The relation between changes in body composition, mediated by behavior modification involving weight loss or exercise, and fatigue in postmenopausal women is not well established.

**PURPOSE:** The aim of this study was to assess the impact of a weight loss diet (WL-D) or resistance training exercise (EX) on self-reported fatigue.

**METHODS:** Sedentary obese (BMI  $\geq$  30-35 kg/m<sup>2</sup>) age matched-women (n=31, 65.0 $\pm$ 5.4 yr, range=59-80 yr) were randomized to a WL-D (n=17) or EX (n=14) intervention for 16 weeks. Weight status and body composition were determined from measures of height, weight and DXA. Fatigue was assessed using the Multidimensional Fatigue Inventory, in which higher scores indicate greater fatigue in the dimension of interest [general (GEN), physical (PHY), mental (MEN), reduced activity (R-ACT), reduced motivation (R-MOT)].

**RESULTS:** Complete data were collected on 22 participants (WL-D n=10, EX n= 12). No differences in %Fat, MFLM, physical activity level or any dimensions of fatigue were found between groups at baseline (all p>0.05). As expected, WL-D decreased body mass (3.6 $\pm$ 4.3 kg, p=0.03), %Fat (1.04 $\pm$ 1.6%, p=0.07) and MFLM (1.3 $\pm$ 1.8 kg, p=0.04), while EX reduced %Fat (1.1 $\pm$ 1.2%, p=0.01) with a concomitant increase in MFLM (0.75 $\pm$ 0.82 kg, p=0.01). WL-D decreased PHY (p=0.045) and R-ACT (p=0.01), while EX reduced R-ACT only (p=0.02). Median splits of each group based on GEN were analyzed to determine if changes in fatigue responses were differentially affected by initial levels of fatigue. In WL-D with lower initial GEN, R-MOT decreased (p=0.02), while WL-D with higher levels of initial GEN reduced both PHY (p=0.03) and R-ACT (p=0.01) over the course of the intervention. When evaluated by initial fatigue level, EX groups demonstrated no significant changes in any dimension of fatigue.

**CONCLUSION:** Weight loss and exercise in obese sedentary older women may differentially attenuate perceptions of fatigue with the effects being impacted by initial level of fatigue. Behavioral interventions to reduce fatigue are warranted.

**Effects Of Resistive Training On Strength, Self Efficacy, And Physical Activity In An Elderly Population**

Elizabeth K. Bailey, Elizabeth Cooper. *Elon University, Elon, NC.* (Sponsor: Stephen P. Bailey, FACSM)  
(No relationships reported)

Sarcopenia can affect a range of quality of life issues and exacerbate a loss in self efficacy with aging. Resistive training is shown to result in increased strength across the lifespan, and to have positive effects on measures of quality of life and self-efficacy in older adults. These positive outcomes could result in increased physical activity in the elderly, mediating further sarcopenia.

**PURPOSE:** The purpose of this study is to investigate the effect of resistive training on measures of strength, balance, self efficacy and physical activity in an elderly independent living population.

**METHODS:** Participants were recruited via the newsletter of a local retirement community. All interested participants were enrolled in the study once they were cleared for resistive exercise training (N=15, Age=81.3 + 2.3yrs). Prior to the start of the program and upon its conclusion, participants completed the Self Efficacy Scale (SES), and the Physical Activity Scale for the Elderly (PASE). Upper and lower body strength was evaluated via a timed bicep curl test and hand grip dynamometer, and up and go and sit to stand timed trials respectively. Balance was evaluated using the tandem walk test. Biweekly resistive training sessions over 8 weeks consisted of the 8 exercises described in the Strong Women Stay Young program (SWSY). Level of resistance was determined individually using a questionnaire developed for the SWSY program that estimates current level of strength.

**RESULTS:** An improvement in lower body strength (Sit to Stand: Pre=12.2 + 0.62 repetitions in 30 sec, Post=14.15 + 0.74 repetitions in 30 sec, p<0.01; Up and Go: Pre = 6.99 + 0.28 sec, Post = 6.2 sec + 0.26 sec, p<0.01) was observed and increased physical activity reported on the PASE (Pre=94.46 +15.04, Post=120.53 + 14.26; p=0.02). No other significant changes were noted. The relative improvement in PASE was correlated with a reduction in the time to complete the Up and Go test (r=-0.54; p=0.05).

**CONCLUSION:** The results support the efficacy of offering resistive training in this population, and suggest a need for further evaluation in a larger group to determine other potential positive outcomes.

**Effects of Resistive Training upon Functional Tests in Community Dwelling Older Females**

Anntionette N. Roquemore, Thomas S. Marzilli, Joyce E. Ballard, FACSM. *University of Texas at Tyler, Tyler, TX.*  
(No relationships reported)

**PURPOSE:** was to test the effects of 8-weeks of resistive training upon functional tests related to independent living.

**METHODS:** Study was approved by the University's Institutional Review Board (IRB). Thirty females (60-81 years of age), recruited from the community, were screened by their physicians, and signed informed consents. Volunteers were randomly assigned to exercise class or a control group. Age, body weight, standing height, and pre-exercise blood pressures were obtained on all clients. Exercise group was tested pre and post training with 1-Repetition Max, (1-RM) on 10 machines: 5-Upper Body stations/5-Lower Body Stations. Functional tests, assessed pre and post in both groups, were: 2-minute stepping in place, 30-sec chair-stand, 30-sec 5-lb arm curl, 8 ft up and go, back-scratch, chair sit & reach and 6-min walk (done only by exercise group). The exercise class was conducted 2 days/wk for 65 min/session. Exercise logs were compiled for activity (primarily walking) performed outside of class. Kinesiology students acted as personal-one-on-one trainers for the exercise participants. Statistical procedures were: means  $\pm$  SDs, t-tests, and 2X2 ANOVAs (2 groups by pre/post tests). Significance was determined at p  $\leq$  0.05.

**RESULTS:** "t" tests on pretests values between exercise and control groups were not significant for age (yrs), body weight (lbs), standing height (ins), systolic BP (mmHg), or diastolic BP (mmHg). For the exercise group, pre-post paired sample "t"-tests on 1-RM were significant (p<.001) reported as % change at all 10 machines: [Upper Body: (Chest Press (39.3%), Biceps Curl (56.3%), Low Mountain Row (51.3%), Lat Pull (40%), Back Extension (52.9%)] and [Lower Body (Seated Leg Extension (60%), Seated Leg Curl (39.9%), Double Leg Press (99.5%), Leg Abductors (43.1%), & Leg Adductors (55.8%)]. ANOVAs on functional tests revealed significant training effects for groups by tests interactions: 2-minute stepping in place, 30-sec chair stand, 8 ft up and go, 30-sec arm curl and non-significant results for, back scratch and chair sit. Paired "t" test for 6-minute walk in exercise group was also significant.

**CONCLUSION:** An 8-week exercise program showed improvement in strength at 10 sites. Older adult women should be encouraged to increase their strength in order to improve their quality of life.

**3387 Board #108 June 2 8:00 AM - 9:30 AM**  
**Effects of Resistive Exercise on Brain-Derived Neurotrophic Factor**

James S. Williams, FACSM, Kevin W. McCurdy. *Texas State University, San Marcos, TX.*  
(No relationships reported)

**INTRODUCTION:** Brain-derived neurotrophic factor (BDNF) is a member of the growth factor family that has been shown to regulate neuronal plasticity and health. An acute bout of endurance exercise elevates serum levels of BDNF in both animal and human models. The effects of resistive exercise on serum BDNF levels in humans are lacking and conflicted.

**PURPOSE:** To determine the effects of an acute resistive exercise bout on serum BDNF concentrations in humans.

**METHODS:** Subjects included 13 males (25.1  $\pm$  3.9 yr; 69.7  $\pm$  1.8 in; 89.4  $\pm$  11.4 kg; mean  $\pm$  SD) that were recreationally active but not engaged in competitive sports. The 1 repetition maximum (1RM) was assessed on each subject for six exercises (bench press, squat, lat pulls, tricep extension, shoulder press, hamstring curl). After 48-72 hrs of rest, the subjects completed a bout of resistive exercise at 75% 1RM for each exercise that included 3 sets of 10 repetitions with 2-3 min of rest between each set. Blood samples for serum BDNF and lactate were obtained pre and ~ 5 min after the resistive exercise bout.

**RESULTS:** A small but significant increase (p < 0.05; 14%) in serum BDNF was detected following the resistive exercise bout (.57  $\pm$  .04 ng/ml) when compared to pre-exercise values (.50  $\pm$  .06 ng/ml). As expected, a significant increase (p < 0.05) in lactate occurred following the resistive exercise bout (11.93  $\pm$  2.71mmol/L) when compared to pre-exercise values (1.61  $\pm$  0.66 mmol/L) however, the increase in lactate was not correlated (p > 0.05; r = .21) with the increase in serum BDNF.

**CONCLUSIONS:** An acute bout of resistive exercise upregulates serum BDNF concentrations but the increase does not appear to be associated with high levels of lactate. Resistive training may be an effective mode of exercise to improve neuronal health.

3388 Board #109 June 2 8:00 AM - 9:30 AM

**Resistance Training Prevents Age-related Decline in Exercise Tolerance but not in VO<sub>2</sub>MAX of Older Runners: Preliminary Results of the Sao Silvestre Older Runners Cohort Study**

Emmanuel Gomes Ciolac, Leonardo Kenji Hirao, Júlia Maria D'Andréa Greve, Luiz Eugênio Garcez-Leme. *Institute of Orthopedics and Traumatology, School of Medicine, University of São Paulo, Sao Paulo, Brazil.*

(No relationships reported)

**PURPOSE:** The purpose of present study was to investigate the effects of resistance training on maximal and submaximal parameters of cardiorespiratory fitness (CRF) of older runners.

**METHODS:** Twenty-four elderly male runners (age 69±0.9 years; time of training 21±7.2 years; training frequency 4.5±0.6 days·wk<sup>-1</sup>; training volume 57.5±10.9 km·wk<sup>-1</sup>) performed a graded exercise test before (T1) and after (T2) 8.9±0.2 years of follow-up. The subjects were divided into two different groups: resistance trained older runners (REG, subjects that continued endurance training and initiated a resistance training program 3.1±0.6 years before T2; n=11) and control older runners (CG, subjects that continued endurance training but did not performed resistance training; n=13). Submaximal and maximal parameters of CRF were compared between the two groups.

**RESULTS:** Data are displayed in Table 1. Both groups reduced similarly maximal oxygen consumption (VO<sub>2</sub>MAX) after follow-up (REG = 17.7±2.6%; CG = 23.1±4.9%), but the reduction of VO<sub>2</sub> at respiratory compensation point (VO<sub>2</sub>RCP) was lower in REG than CG (13.8±3.4% vs. 22.1±5.1%; p<0.05). Tolerance time to reach respiratory compensation point (TT<sub>RCP</sub>) and TT<sub>MAX</sub> were reduced in CG after follow-up, but did not change significantly in REG. Maximal heart rate (HR) reduced similar in both groups, but lower reduction of HR<sub>RCP</sub> was observed in REG than CG (4.4±2.6% vs 10.9±1.4%, p=0.03).

**CONCLUSION:** Lower reductions of VO<sub>2</sub>RCP, TT<sub>RCP</sub>, TT<sub>MAX</sub> and HR<sub>RCP</sub> (but not VO<sub>2</sub>MAX and HR<sub>MAX</sub>) were found in REG than CR. These results suggest that regular resistance training may have important implications for reducing age-related decline in CRF of older runners.

Table 1. Graded exercise test parameters

| Variable  | Resistance Trained Runners |            | Control Runners |            |
|---|----------------------------|------------|-----------------|------------|
|   | Before                     | After      | Before          | After      |
| HRRCP (bpm)   | 151.9±5.9                  | 144.0±3.5* | 156.0±4.2       | 139.0±4.1* |
| HRMAX (bpm)   | 170.7±3.9                  | 163.7±3.2* | 172.5±5.4       | 161.8±3.4* |
| TTRCP (min)   | 10.9±0.9                   | 10.1±0.5   | 9.5±0.5         | 7.5±0.5*†  |
| TT2MAX (min)  | 15.5±0.8                   | 14.9±0.6   | 13.8±0.7†       | 12.2±0.5*† |
| VO <sub>2</sub> RCP (ml·kg <sup>-1</sup> ·min <sup>-1</sup> ) | 38.1±1.4                   | 32.8±1.7*  | 35.3±1.3        | 26.5±1.5*† |
| VO <sub>2</sub> MAX (ml·kg <sup>-1</sup> ·min <sup>-1</sup> ) | 45.6±1.5                   | 37.4±1.4*  | 42.8±1.4        | 32.4±1.5*† |
| RER   | 1.15±0.02                  | 1.17±0.02  | 1.13±0.01       | 1.17±0.02  |

\* Different from before follow-up at same group (p<0.05). † Different from resistance trained runners at same period (p<0.05). HR, heart rate; TT, tolerance time; VO<sub>2</sub>, oxygen uptake; RCP, respiratory compensation point; MAX, maximal.

**Resistance Training Induces Positive Effects On Risk Of Falls, Muscle Strength, And Dual Task Performance In Oldest Old Institutionalized Frail Patients**

Mikel Izquierdo<sup>1</sup>, Alvaro Casas<sup>2</sup>, Fabrício Zambóm<sup>1</sup>, Nora Millor<sup>3</sup>, Alicia Martínez-Ramirez<sup>4</sup>, Teresa Marcellán<sup>5</sup>, Ana Ruiz de Gordo<sup>5</sup>, Fermín Cía<sup>5</sup>, Pablo Lecumberri<sup>4</sup>, Marisol Gómez<sup>4</sup>. <sup>1</sup>Public University of Navarre, Tudela, Spain. <sup>2</sup>Hospital of Navarre, Pamplona, Spain. <sup>3</sup>Government of Navarre, Pamplona, Spain. <sup>4</sup>Public University of Navarre, Pamplona, Spain. <sup>5</sup>Residencia Casa Misericordia, Pamplona, Spain.

(No relationships reported)

The syndrome of frailty describes older people at a higher risk for adverse health outcomes. It is a condition with a complex etiology and pathophysiology. Exercise multicomponent programs and specially resistance training are currently the most relevant interventions to slow down disability and other adverse outcomes. Limited information is available about its effects on balance, gait and falls in the oldest old frail population.

**PURPOSE:** To examine the effects of 12 weeks resistance program on muscle strength, balance, gait and decrease in number and risk of falls in oldest old frail institutionalized patients.

**METHODS:** Participants were included in the study using Fried Criteria. Measurements of upper and lower limb muscle strength (hand grip, flexor hip and knee extensor strength), gait speed (5 m walking test), dual task paradigm (verbal and arithmetic) balance performance (FICSIT-4 Tests of Static Balance: parallel, semi-tandem, tandem, and one-legged stance tests) as well as Time up and Go and rise from a chair tests were conducted before and after intervention. Before starting the program all participants received Individual medical evaluation and were assigned to a twice-weekly 12 weeks progressive resistance program (8-10 reps of 40-60% of 1RM) combined with balance retraining exercises progressing in difficulty.

**RESULTS:** Strength training significantly increased hip flexor (25% P<0.01), knee extensor strength (22%; P<0.01) and rise from a chair test (70%; P<0.01). Strength training-induced gains were also observed in gait velocity and dual task performance (8% and 17%; P<0.10 and P=0.09, respectively). Significant increases in semi-tandem static balance test (P<0.01) were also observed. Significant decrease of incidence (p<0.001) and risk of falls (P<0.01) were observed.

**CONCLUSION:** 12-weeks progressive resistance program combined with balance exercises have positive effects on incidence and risk of falls, muscle strength, dual task performance, gait velocity and balance performance in very elderly institutionalized frail patients. Supported in part by grants of Spanish Ministry of Health, Institute Carlos III, Department of Health of the Government of Navarra and Government of Spain (CSD) RD06/013/1003 and 87/2010 and 008/EPB10/11.

**Periodized Resistance Training and Supplementation: Effects on Body Composition and Muscular Performance in Older Men**

Matthew G. Villanueva, Jiaxiu He, E. Todd Schroeder, FACSM. *University of Southern California, Los Angeles, CA.*

(No relationships reported)

Investigations examining the effects of non-linearly periodized resistance training (RT) programs designed to promote concurrent increases in lean mass, muscular strength, and functional performance in older men are limited.

**PURPOSE:** To examine the effects of a 12-week RT program with and without creatine and protein supplementation on changes in lean mass, muscular strength, and physical function in older men.

**METHODS:** 22 men, 68.1±6.1 years, 176.8±7.7 cm, 82.7±11.1 kg (mean±SD), were randomized to one of three groups: control (C; n=8); RT only (RT; n=7); and RT combined with supplementation (RTS; n=7). A progressive, total-body RT program was performed 3 days/week for 12 weeks, with supervision. Creatine supplementation (pill form): RTS participants consumed 0.3 g/kg body weight/day for 5 days and then 0.07 g/kg body weight/day until completion of the 12-week program. RTS participants also consumed a ready-to-drink whey protein supplement (35g) immediately post-training and on non-training days. Exercise testing occurred pre- and post-RT intervention to determine changes in body composition (dual-energy x-ray absorptiometry), 1-RM machine chest press (CP) and leg press (LP) strength, and dynamic power (Margaria power stair climb; DP).

**RESULTS:** ANOVA revealed no differences in baseline characteristics among the three treatment groups ( $p>0.05$ ). Independent sample t-tests (C vs. mean of RT and RTS) revealed: RT and RTS groups experienced significantly greater increases in 1-RM CP ( $25\pm 7$  kg and  $20\pm 8$  kg) and 1-RM LP ( $172\pm 46$  kg and  $198\pm 110$  kg) ( $p<0.0001$ ), notable increases in lean mass ( $0.78\pm 1.83$  kg and  $1.33\pm 1.67$  kg;  $p=0.07$ ), and notable decreases in fat mass ( $-1.36\pm 1.93$  kg and  $-0.95\pm 1.78$  kg;  $p=0.17$ ) and percentage body fat ( $-1.36\pm 2.11\%$  and  $-1.63\pm 1.49\%$ ;  $p=0.06$ ); changes in DP were not significant ( $p>0.05$ ). However, additional analyses revealed near significant differences in DP between the RT and RTS groups ( $+58\pm 309$  watts vs.  $+371\pm 361$  watts;  $p=0.06$ ).

**CONCLUSIONS:** 12 weeks of periodized RT increased muscular strength in older men but did not significantly improve body composition or dynamic power performance. Furthermore, the addition of creatine and protein supplementation with RT provided no additional enhancements in body composition, muscular strength, or dynamic power performance.

---

**3391** Board #112 June 2 8:00 AM - 9:30 AM

**Resistance Training with or without Protein and Creatine Induces Comparable Aerobic Benefits in Older Men**

Lindsey Jayne Anderson, Matthew Villanueva, E. Todd Schroeder, FACSM. *University of Southern California, Los Angeles, CA.*

(No relationships reported)

**PURPOSE:** To examine the effects of a 12-week resistance training (RT) intervention alone or with creatine and whey protein supplementation (S) on bone mass and aerobic function in older men.

**METHODS:** 22 men  $68\pm 6$  yrs,  $176.8\pm 7.7$  cm,  $82.7\pm 11.1$  kg (mean $\pm$ SD) were randomized into control (CON; N=9), RT (N=6), or RT with S (RTS; N=7). After 12 weeks, some CON participants were further randomized into RT (N=3) or RTS (N=4) for 12 weeks of exercise. Bone mineral density (BMD) and content (BMC) were measured by dual energy x-ray absorptiometry and cardiorespiratory fitness assessed with a 4-minute walk test (estimated VO<sub>2</sub>max) and 400-meter walk time. Creatine dose: 0.3g/kg BW/day (days 1-5) then 0.07g/kg BW/day (day 6+). 35g whey protein drink was consumed daily; immediately after exercise or at home on non-training days. Periodized RT was performed 3 days/week. Some RT/RTS participants served as their own control (CON crossovers) resulting in two distinct statistical analyses. CON vs. RT or RTS (3-group) compared the 1st randomization (N=9 vs. 6 or 7). RT vs. RTS (2-group) compared the 2nd randomization (N=9 vs. 11). Between-group baseline (BL) and 12-week change differences were determined by ANOVA with Bonferroni post-hoc (3-group) or independent t-tests (2-group). Within-group 12-week changes were determined by paired-sample t-tests (2 and 3-group).

**RESULTS:** BL characteristics were not different between groups (2 or 3-group;  $P>0.05$ ). In the 3-group analysis, RT (N=6) significantly increased VO<sub>2</sub>max by  $2.5\pm 1.8$  ml/kgXmin<sup>-1</sup> ( $7.1\pm 5.2\%$ ;  $P=0.02$ ); however, 12-week changes were not different between groups at the adjusted  $\alpha$ -level (0.017). In the 2-group analysis, VO<sub>2</sub>max significantly increased by  $2.2\pm 1.6$  ml/kgXmin<sup>-1</sup> ( $6.3\pm 4.7\%$ ;  $P=0.004$ ) for RT (N=9) and  $1.3\pm 1.8$  ml/kgXmin<sup>-1</sup> ( $3.6\pm 5.0\%$ ;  $P=0.04$ ) for RTS (N=11). Both training groups significantly decreased mean 400-meter walk time by  $24.4\pm 21.1$  seconds ( $11.6\pm 9.4\%$ ) for RT (N=9;  $P=0.008$ ) and  $16.1\pm 16.8$  seconds ( $9.3\pm 10.5\%$ ) for RTS (N=11;  $P=0.01$ ); between-group changes were not different (2-group;  $P>0.05$ ). BMD and BMC did not significantly change (2 or 3-group;  $P>0.05$ ).

**CONCLUSIONS:** 12 weeks of progressive total body RT did not affect bone mass but did improve cardiorespiratory fitness; however, RT with creatine and whey protein supplementation did not provide additive effects.

---

**3392** Board #113 June 2 8:00 AM - 9:30 AM

**Effects of a Comprehensive Exercise Program on Functional Capacity of Older Adults**

Trinh D. Nguyen, Peggy A. Plato. *San Jose State University, San Jose, CA.* (Sponsor: Craig Cisar, FACSM)

(No relationships reported)

Although lifespan is increasing, many older adults experience functional impairments and a loss of independence in their later years. An effective intervention for older adults should incorporate activities to enhance functional capacity, as well as being enjoyable to enhance compliance. There is limited research examining functional capacity in older adults following an exercise program that uses body weight as resistance.

**PURPOSE:** To compare the effects of a whole body exercise program (EXER) and a walking program (WALK) on functional capacity of older adults.

**METHODS:** Participants were randomly assigned to a 2 day per week EXER program, incorporating warm-up and stretching activities; upper and lower body, abdominal, and balance exercises; and perceptual-motor games (16 F, 6 M,  $75.5\pm 1.6$  years) or WALK program, walking for 30-45 min at a self-selected pace (3 F, 1 M,  $65.8\pm 1.1$  years). Upper body power (30 s arm curl test), lower body power (30 s sit-to-stand test), static balance (balancing on one foot with eyes open), and dynamic balance and agility (8-foot up-and-go test) were measured before and after the 8 week programs. Statistical significance was adjusted to  $p<0.005$ .

**RESULTS:** The EXER program enhanced functional capacity by increasing upper ( $15.2\pm 1.4$  arm curls pre vs.  $19.3\pm 1.6$  post,  $p<0.001$ ) and lower body power ( $12.8\pm 0.9$  sit-to-stand reps pre vs.  $15.4\pm 1.2$  post,  $p=0.001$ ), and improving agility and dynamic balance ( $7.55\pm 0.34$  s for 8-foot up-and-go pre vs.  $6.43\pm 0.27$  s post,  $p<0.001$ ). There were no significant differences in static balance as a result of the EXER program. In contrast, the WALK group significantly improved static balance in the right leg ( $15.87\pm 4.52$  s pre vs.  $27.90\pm 5.12$  s post,  $p=0.004$ ) and approached significance in the left leg ( $16.30\pm 5.30$  s pre vs.  $28.23\pm 6.61$  s post,  $p=0.018$ ). Although participants in the walking group improved other measured components of functional capacity, there were no significant differences due to low statistical power.

**CONCLUSION:** Older adults can improve components of functional capacity by exercising 2 days a week for 8 weeks using either a whole body exercise program or a self-paced walk. Participants reported that the EXER program, performed in a group setting without external weight, was enjoyable, as well as being physically and mentally stimulating.

**3393** Board #114 June 2 8:00 AM - 9:30 AM

**Strength Prior To Endurance Intra-session Exercise Sequence Optimizes Neuromuscular And Cardiovascular Gains In Elderly Men**

Eduardo L. Cadore<sup>1</sup>, Mikel Izquierdo<sup>2</sup>, Cristine Lima Alberton<sup>1</sup>, Ronei Silveira Pinto<sup>1</sup>, Matheus Conceição<sup>1</sup>, Giovanni Cunha<sup>1</sup>, Régis Radaelli<sup>1</sup>, Martim Bottaro<sup>3</sup>, Guilherme Treis Trindade<sup>1</sup>, Stephanie Santana Pinto<sup>1</sup>, Luiz Fernando Martins Krueh<sup>1</sup>. <sup>1</sup>Federal University of Rio Grande do Sul, Porto Alegre - RS, Brazil. <sup>2</sup>Public University of Navarre, Tudela - Navarre, Spain. <sup>3</sup>University of Brasília, Brasília - DF, Brazil.

(No relationships reported)

**PURPOSE:** To investigate the cardiorespiratory and neuromuscular adaptations to different intra-session exercise sequences during concurrent training in elderly.

**METHODS:** Twenty-six healthy elderly men ( $64.7\pm 4.1$  years), were randomly placed into two concurrent training groups: strength prior to (SE, n=13) or after (ES, n=13) endurance training. Subjects trained strength and endurance training 3 times per week performing both exercise types in the same training session. The peak oxygen uptake (VO<sub>2</sub>peak), maximum aerobic workload (W<sub>max</sub>), absolute (VT1 and VT2) and relative (VT1% and VT2%) ventilatory thresholds, as well workloads at VT1 and VT2 (WVT1 and WVT2) was evaluated during a maximal incremental test on a cycle ergometer before and after the training. In addition, force per unit of active muscle mass (i.e. muscle quality - MQ) was evaluated by the quotient between maximal dynamic strength (one repetition maximum test) of the knee extensors and the quadriceps femoris muscle thickness (sum of the muscle thickness of the four muscles) determined by ultrasonography. The training-related effects were assessed using a two-way Analysis of Variance with repeated measures (group x time).

**RESULTS:** There were no modifications after training in the VT1, VT2, VT1%, VT2%. There was significant increases on WVT1 only in SE ( $61.5\pm 13.0$  watts vs.  $75.0\pm 10.2$ ,  $P<0.05$ ), as well significant increases on WVT2 in both groups (SE:  $94.2\pm 15.0$  vs.  $111.5\pm 16.5$  watts; ES:  $104.2\pm 27.9$  vs.  $122.9\pm 24.9$  watts,  $P<0.001$ ). There was significant increase on the VO<sub>2</sub>peak, with both groups showing increases (SE:  $27.4\pm 6.1$  vs.  $29.5\pm 6.6$  ml\*kg\*min<sup>-1</sup>; ES:  $26.6\pm 6.9$  vs.  $28.8\pm 6.6$  ml\*kg\*min<sup>-1</sup>,  $P<0.001$ ), without difference between groups; as well significant increase on the W<sub>max</sub> (SE:  $121.0\pm 13.4$  vs.  $143.9\pm 19.8$  watts; ES:  $125.2\pm 40.8$  vs.  $155.3\pm 44.0$  watts,  $P<0.001$ ) without difference between SE and ES. The quadriceps femoris force per unit of muscle mass increased in both groups (SE:  $1.95\pm 0.32$  vs.  $2.47\pm 0.32$  kg\*mm<sup>-0.67</sup>; ES:  $2.03\pm 0.26$  vs.  $2.33\pm 0.32$  kg\*mm<sup>-0.67</sup>,  $P<0.001$ ), but the increase was significant higher in SE compared to ES ( $27.5\pm 12.7$  vs.  $15.2\pm 10.3\%$ ,  $P<0.02$ ).

**CONCLUSION:** The intra-session exercise sequence had no influence in the maximal endurance power to concurrent training, but had influence in the magnitude of the muscle quality enhancements.

---

3394 Board #115 June 2 8:00 AM - 9:30 AM

**Effects Of A Core Instability Training On Trunk Strength/Mobility And Balance Performance In Seniors**

Urs Granacher<sup>1</sup>, Thomas Muehlbauer<sup>1</sup>, Andre Lacroix<sup>2</sup>, Katrin Roetger<sup>2</sup>, Albert Gollhofer<sup>2</sup>. <sup>1</sup>Friedrich-Schiller-University Jena, Jena, Germany. <sup>2</sup>Albert-Ludwigs-University Freiburg, Freiburg, Germany.  
(No relationships reported)

Deficits in balance and muscle strength/power have frequently been associated with an increased risk of falling in older adults. Traditionally, balance and/or resistance training were applied to counteract these intrinsic fall risk factors. Core instability training involves exercises that are challenging for both, trunk muscles and postural control and may thus have the potential to induce benefits on trunk strength/mobility and balance performance.

**PURPOSE:** The objective of this study was to investigate the effects of a core instability training on measures of core strength, trunk mobility, and dynamic postural control in healthy seniors.

**METHODS:** Thirty-two older adults were randomly assigned to an intervention group (INT; n = 16; age 70.8 ± 5.3 years; 8 females, 8 males) that conducted a 9 week progressive core instability training program (3 times/week) or a control group (CON; n = 16; age 70.2 ± 4.7 years; 9 females, 7 males). Maximal isometric strength (MIS) of the trunk flexors/extensors as well as trunk mobility in the sagittal (SAP) and the frontal (FRP) plane were measured before and after the intervention program. Dynamic postural control was tested while walking 10 m on an opto-electric walkway.

**RESULTS:** Program compliance was excellent with participants of the INT group completing 92.4% of the training sessions. Significant Group x Test interactions were found for MIS of the trunk flexors (34%, p < 0.001) and trunk extensors (21%, p < 0.001), for trunk mobility in SAP (11%, p < 0.001) and FRP (11%, p = 0.06) directions, and for stride velocity (9%, p = 0.018), stride time (5%, p = 0.01), and stride length (3%, p = 0.05) in favor of the INT group.

**CONCLUSION:** Core instability training proved to be a safe and feasible exercise program for older adults accompanied with a high adherence rate. Age-related deficits in measures of core strength, trunk mobility, and walking performance can be mitigated by core instability training in older adults. Thus, this training regimen could be used as an alternative to traditional balance and/or resistance training.

**Response of Blood Lipids and Adipocytokines to 32-week Exercise Training Without Dietary Intervention**

Joana Carvalho<sup>1</sup>, Elisa A. Marques<sup>1</sup>, Diana Tuna<sup>2</sup>, Tiago Guimarães<sup>3</sup>, Jorge Mota<sup>1</sup>. <sup>1</sup>University of Porto- Faculty of Sport, CIAFEL, Porto, Portugal. <sup>2</sup>Hospital of S. João, Porto, Portugal. <sup>3</sup>University of Porto- Faculty of Medicine, Porto, Portugal.  
(No relationships reported)

Regular exercise training is strongly recommended because of its therapeutic and protective effects against several risk factors for the development of cardiovascular diseases, including obesity and dyslipidemia. Recent studies have implicated adipocytokines in the regulation of atherosclerosis and insulin resistance, however the existing evidence has focused on weight-loss interventions and concomitant fat mass reduction, thus the independent effects of exercise training without weight loss need to be further investigated.

**PURPOSE:** To determine the effects of 32-week exercise training on blood lipid profile and adipocytokines in older adults.

**METHODS:** Forty-seven healthy older adults (61-84 years) participated in an exercise training intervention that included resistance exercise training (2 days/week) plus a multicomponent weight-bearing impact exercise training (1 day/week) for 32 weeks. Outcome measures included body fat and lean mass, total cholesterol (TC), triglycerides (TG), high-density lipoprotein cholesterol (HDL-C), low-density lipoprotein cholesterol (LDL-C), glucose, adiponectin (ADT) and resistin (RST) before and after intervention. A two-way (group and time) factorial ANOVA, with repeated measures on one factor (time), was performed for differences in main effects and time by group interactions for each dependent variable.

**RESULTS:** After 32 weeks, both men and women significantly decreased TC (3.6±15.9%), TG (2.9±33.4%), and ADT (4.8±21.7%), while LDL-C, glucose, and TC/HDL-C ratio remained unchanged. In addition, RST significantly increased by 38.9% (p<0.001). No significant body weight, fat mass and lean mass alterations were observed after exercise training, and changes in body composition variables were not correlated with change in ADT and RST concentrations after 32 weeks.

**CONCLUSIONS:** Exercise training without weight loss is associated with a significant decrease in ADT and an increase in RST levels in older adults. Results further support the beneficial role of long-term exercise training on improving lipid risk factors.

Supported by Foundation for Science and Technology (FCT) Grant PTDC/DES/108780/2008 - FCOMP-01-0124-FEDER-009606, and individual grant SFRH/BD/36319/2007.

3396 Board #117 June 2 8:00 AM - 9:30 AM

**Low-Intensity Resistance Training Using an Elastic Band Improves Muscle Mass and Function in Older People**

Kenji Matsutani, Koji Sato, Motoyuki Iemitsu, Toshiyuki Kurihara, Tetsuya Kimura, Tadao Isaka, Takafumi Hamaoka, FACSM, Satoshi Fujita. *Ritsumeikan University, Kusatsu, Japan.* (Sponsor: Takafumi Hamaoka, FACSM)  
(No relationships reported)

Age associated decrease in skeletal muscle and function (sarcopenia) leads to an increased risk of fall, fracture, and bedridden. Resistance exercise is a useful intervention to increase skeletal muscle mass and strength in older adults. Previous study has shown exercise intensity is a critical factor in muscle hypertrophy and strength gain associated with resistance exercise; however, another recent study has also suggested that even 30% 1-RM with high exercise volume stimulates muscle anabolism.

**PURPOSE:** To investigate whether the low-intensity resistance training using an elastic band improves muscle mass and function in older men and women.

**METHODS:** We performed a 3-month randomized controlled trial: 28 healthy older men and women (age: 67.9±6.7 yr) were assigned to either training (men: n=5, women: n=9) or control group (men: n=5, women: n=9). Exercise intensity of elastic band (Thera-Band) was measured by loadcell. Subject performed the elastic band resistance training two times per week for 12 weeks (13 lower and upper body exercises including 3 leg exercises, one set of 10 reps, RPE: 13-15). Quadriceps muscle cross sectional area (CSA) was measured by MRI and free fat mass was assessed by DXA. Knee extension and flexion strength were measured by BIODEX, and measurements of functional strength were also assessed.

**RESULTS:** Exercise intensities of band exercises were 43.2±14.2% and 40.2±9.7% MVC in knee extension and elbow flexion, respectively. Changes in quadriceps muscle CSA and free fat mass were significantly higher in training group (CSA: 4.1%, FFM: 3.3%) compared to control group (CSA: -1.3 %, FFM: -0.6%) (P<0.05). Change in knee extension strength was significantly higher in training group (11.5%) compared to control group (-2.1%) (P<0.05). However, no significant difference was observed in knee flexion strength in either group. Scores of 8-ft Up & Go and 30-second Chair stand improved significantly after resistance training (P<0.05). However, no significant change in grip strength or flexibility was observed.

**CONCLUSION:** Although exercise intensity of elastic band was approximately 40% MVC, muscle mass and function were improved significantly after 12 weeks of resistance training in older men and women.

3397 Board #118 June 2 8:00 AM - 9:30 AM

**Effects Of A University-based Exercise Program Intervention As Compared To Community-dwelling Seniors**

B. Sue Graves, Anita D'Angelo, HFS. *Florida Atlantic University, Boca Raton, FL.*  
(No relationships reported)

**PURPOSE:** This study compared balance (postural control) and fitness levels of seniors, who attended a structured twelve-week university-based exercise program, to other community-dwelling individuals.

**METHODS:** Twenty seniors (P) participated in three supervised exercises sessions per week, performing both walking and resistance exercise (70.6±7.3 yrs, 171.4±7.6 cm, 82.4±3.8 kgs). Another group (C) of fourteen seniors (64.3±8.0 yrs, 166.6±8.4 cm, 75.7±1.5 kgs), who exercised on their own, were compared to the first group. Each group was tested at the beginning and end of twelve weeks. Both groups were evaluated using the Senior Fitness Test for measures of functional strength, aerobic endurance, dynamic balance and agility, and flexibility, plus the Sensory Organization Test.

**RESULTS:** Following the twelve-week training period, there were no significant improvements in either group for the Senior Fitness Test (Chair Stand (sec), P, 13.4+3.87, C 14.57+2.44, p=0.32; Arm Curls (n), P, 16.3+3.55, C 15.64+3.17, p=0.58; Sit and Reach (in), P, 2.84+3.55, C 1.07+2.48, p=0.21; Back Scratch (in), P, -2.51+4.21, C -2.25+4.81, p=0.87; Eight-foot Up and Go (sec), P, 5.41+0.91, C 5.41+1.20, p=0.98; Six Minute Walk (sec), P, 609.8+67.27, C 647.5+104.9, p=0.25). The Sensory Organization Test was not significant for between the groups (P, 83.2+2.87, C 82.21+4.02, p=0.46). C was also significantly younger (p<0.02) and were more recreationally active.

**CONCLUSIONS:** The results of this university-based exercise program indicate the need to include additional training for flexibility, dynamic balance, and agility in the structured exercise program, since no differences were seen between groups in the performance measures.

**3398** Board #119 June 2 8:00 AM - 9:30 AM

**Effect of Body Mass-Based Squat Training on Knee Extensor Strength in Frail Elderly**

Eiji Fujita, Yasuhide Yoshitake, Yohei Takai, Hiroaki Kanehisa. *National Institute of Fitness and Sports in Kanoya, Kagoshima, Japan.*

(No relationships reported)

For the elderly individuals with lower force-generation capacity, training program which mainly consisted of body mass-based exercises can be a measure to improve knee extensor torque (KET). However, the magnitude of the exercise-induced gain in KET has a large inter-individual variation. Considering that the muscular activity of the quadriceps femoris muscles (QF) during the squat exercise is associated to KET relative to body mass (KET/BM), the strength improvement by the training will depend on the association between KET/BM and the activity level of QF during the squat exercise before intervention.

**PURPOSE:** This study aimed to examine 1) the effect of body mass-based squat training on KET in frail elderly, and 2) how the extent of the gain in KET can be associated with the muscular activity level of QF during the exercise before intervention affects.

**METHODS:** Eleven frail elderly individuals aged 74 to 88 yrs who used the long-term care insurance system voluntarily participated in a training program consisted of body mass-based squat using a standard chair (34 reps/day, 3days/week, 12weeks). Before and after the intervention, KET during maximal isometric voluntary contraction (MVC) and electromyogram (EMG) activities of the rectus femoris (RF) and vastus lateralis (VL) muscle during MVC and the squat tasks were determined. The rectified EMG signals during the squat task were averaged and normalized as the relative value (%EMGmax) to that during MVC. The %EMGmax values for RF and VL were averaged and used an index of QF activity levels during the squat task (QF %EMGmax).

**RESULTS:** The squat training increased KET/BM by 22.8%, and decreased QF %EMGmax by -35.4% compared to before intervention. The relative change in KET/BM were correlated to the QF %EMGmax before the intervention ( $r = -0.68, P < 0.05$ ).

**CONCLUSIONS:** While body mass-based squat training is effective to improve KET/BM in frail elderly, the magnitude of the strength improvement depends on the association between KET/BM and the activity level of QF during the squat exercise before intervention.

**3399** Board #120 June 2 8:00 AM - 9:30 AM

**Short-term Changes in Resistance Training Exercise Confidence in Young and Older Adults**

Sandor Dorgo<sup>1</sup>, Rebecca J. Reed-Jones<sup>1</sup>, Chandrasekhar Bulusu<sup>1</sup>, Chantal A. Vella<sup>2</sup>. <sup>1</sup>University of Texas at El Paso, El Paso, TX. <sup>2</sup>University of Idaho, Moscow, ID.

(No relationships reported)

Improving exercise confidence is essential for untrained individuals to promote long-term exercise adherence. However, it is unclear what training intensity is needed to improve one's exercise confidence.

**PURPOSE:** To compare changes in resistance training exercise confidence using traditional resistance (TR) and minimal resistance (MR) intensities between untrained groups of older adults (OA) and younger adults (YA) over a three-week period.

**METHODS:** 39 untrained OA (mean±SD age: 67.5±5.9 y) and 28 YA (mean±SD age: 23.3±3.9 y) with no experience in resistance training were randomly assigned to either TR or MR group. Two exercises were used: the bench press representing a multi-joint exercise, and the triceps pressdown as a single-joint exercise. Subjects performed three sets of 10 repetitions on two days/week for three weeks. Subjects in the TR group trained at 75% of 1RM intensity, while subjects in the MR group used minimal (< 10% of 1RM) intensity. Subjects rated their level of confidence on executing the two exercises using a 100-point visual analog scale with anchors, at the end of each week. Data were compared between OA and YA, as well as between the TR and MR groups using a general linear mixed model with alpha level set at p<0.05.

**RESULTS:** There were no baseline differences in the bench press confidence between OA (32.6±31.7) and YA (27.7±28.5) and between TR (33.6±30.8) and MR (26.7±29.4) (p≥0.203), or in the triceps pressdown confidence between OA (33.3±29.1) and YA (32.5±29.4) and between TR (33.7±28.9) and MR (32.1±29.6) (p≥0.426) groups. There was a significant time effect for all groups for both exercises (p<0.001) as confidence scores increased by 52% to 111%. Non-significant group (TR vs. MR) by time (p≥0.479) and group (TR vs. MR) by age (OA vs. YA) by time (p≥0.478) interactions were observed. However, the age (OA vs. YA) by time interaction was significant for both the bench press (p=0.039) and the triceps pressdown (p=0.023).

**CONCLUSION:** Our data showed that untrained OA and YA initially indicated similarly low levels of exercise confidence for the two resistance training exercises. Exercise confidence improved significantly in both OA and YA regardless of the exercise intensity. Our findings also suggest that exercise confidence of YA increased at a greater rate compared to OA within the three-week period.

**How Mode of Exercise Affects Accuracy of BodyBugg and PolarHR Monitor Estimates of Caloric Expenditure**

Austin W. Bills, Julie E. Taylor. *Southern Utah University, Cedar City, UT.*

(No relationships reported)

**INTRODUCTION:** Various methods for estimating energy expenditure have become available to aid individuals in monitoring their caloric expenditure and managing caloric intake accordingly. Two popular devices for estimating caloric expenditure were tested in this research; the BodyBugg (Bodymedia, Pittsburg, PA) and the RS400 Heart Rate Monitor (Polar Electro Inc. Lake Success, NY).

**PURPOSE:** Determine the validity of these devices compared to direct measures of VO<sub>2</sub>. A secondary purpose was to determine if two different modes of exercise would affect the accuracy of these two devices: treadmill and rowing exercise.

**METHODS:** Twelve men and twelve women ages 18-60 years were recruited. This study was approved by the IRB of Southern Utah University. Participants completed informed consents and health histories to ensure they were apparently healthy. Prior to exercise, participants were fitted with a BodyBugg, a HR monitor and a face mask to collect expired gases. All participants performed 24 minutes of submaximal (60%-70% max HR) treadmill exercise. Twelve participants on a separate day also performed 24 minutes of submaximal rowing exercise (n=6 men, 6 women). Following the exercise bout, caloric expenditure from both devices was recorded and compared to caloric expenditure measured via indirect calorimetry using oxygen consumption and RER (VCO<sub>2</sub>/VO<sub>2</sub>) levels. Paired t-tests were used to compare caloric estimates from each device relative to VO<sub>2</sub> measures. Statistical significance was set at p< 0.05.

**RESULTS:** BodyBugg overestimated caloric expenditure during treadmill exercise by 1.4 kCals/min ( $\pm 1.6$ ) for men and 0.6 kCals/min ( $\pm 0.8$ ) for women ( $p < 0.05$ ). Polar HR monitor overestimated during rowing exercise on average by 2.0 kCals/min ( $\pm 1.2$ ) for men only ( $p < 0.05$ ).

**CONCLUSION:** The BodyBugg may be more accurate for exercises requiring upper body emphasis while the Polar HR monitor may be more accurate for lower body exercises (especially for men). Consumers should consider their most common mode of exercise prior to purchasing either device.

**3401** Board #122 June 2 9:30 AM - 11:00 AM

**The Benefits of Electrical Muscle Stimulation on Resting Metabolism**

Craig Broeder, FACSM<sup>1</sup>, Dimitria Vandarakis<sup>1</sup>, Amanda J. Salacinski<sup>2</sup>, Steven M. Mauk<sup>3</sup>, Laurie A. Schubert<sup>1</sup>, Richard Hickey, III<sup>2</sup>. <sup>1</sup>Exercising Nutritionally, LLC, Naperville, IL. <sup>2</sup>Northern Illinois University, DeKalb, IL. <sup>3</sup>Adrian College, Adrian, MI.  
(No relationships reported)

**PURPOSE:** Electrical muscle stimulation (EMS) use has shown improvements in muscle strength and endurance. Thus, EMS may have a positive effect on energy expenditure during EMS muscles activation. This study determined the effects of a FDA approved medical grade electrical muscle stimulator system on enhancing energy expenditure at rest in healthy, active adults.

**METHODS:** Thirty-eight subjects (males =19; females =19) participated. Each subject performed the following items: a Block short-form food frequency questionnaire, body composition assessment (Inbody 520), a free-living physical activity assessment (BodyMedia Armband), a maximal aerobic capacity treadmill test (VO2 max), practice resting metabolic rate (RMR) and EMS accommodation training, and two standardized RMR trials with and without Contour MX9 EMS activation. The resting trials with and without EMS were performed in duplicate. The EMS level was set to the strength setting at level 3 (Contraction Phase = 6-sec at 85Hz; Rest Phase = 4-sec at 10hz).

**RESULTS:** Subject characteristics were age ( $27.9 \pm 6.9$  yrs), Wt ( $168.1 \pm 37.4$  lbs), BodyFat ( $21.2 \pm 8.7\%$ ), VO2 max ( $44.0 \pm 8.3$  ml/kg/min), 24-hr energy expenditure ( $2,881 \pm 637$  kcal), Daily Steps ( $10,630 \pm 4,687$ ). Test-retest data showed that both the non-EMS (Delta: 1.2%; r-value: 0.93; SEE: 15 kcal; p-value 0.0001) and EMS trials (Delta: 0.8%; r-value: 0.94; SEE: 27 kcal; p-value 0.0001) were highly reliable. In men, EMS activation increased RMR 22% ( $p=0.001$ ) and HR 13% ( $p=0.01$ ). In women RMR and HR increased 16% ( $p = 0.0005$ ) and 14% ( $p=0.03$ ), respectively. Interestingly, when subjects were divided into low vs high EMS tolerance levels (% of max EMS unit activation output), both groups showed similar increases in RMR (Low = 19% and High = 20%, NS). Abdominal lean muscle mass showed the highest independent correlation to the EMS activation effect for all subjects (r-value: 0.89,  $p = 0.0001$ ). Compared to predicted RMR values, 47% of the subjects had non-EMS RMR values > predicted. In contrast, RMR with EMS, 76% of the subjects exceeded the predicted norm (Chi Square = 9.40,  $p=0.002$ ).

**CONCLUSIONS:** These results indicate the Contour MX9 EMS system acutely increases a person's RMR. Future studies need to determine the chronic effects of EMS on muscle metabolism including insulin sensitivity and glucose tolerance.

**3402** Board #123 June 2 9:30 AM - 11:00 AM

**Effects Of Using Active Video Game On Body Weight And Fat Mass In Adults: A Randomized Intervention Trial**

Motohiko Miyachi<sup>1</sup>, Haruka Murakami<sup>1</sup>, Ryoko Kawakami<sup>1</sup>, Yuko Gando<sup>2</sup>, Azusa Sasaki<sup>1</sup>, Satoshi Hanawa<sup>1</sup>, Aiko Hirotsako<sup>1</sup>, Tatsuya Nishikata<sup>3</sup>. <sup>1</sup>National Institute of Health and Nutrition, Tokyo, Japan. <sup>2</sup>Waseda University, Tokorozawa, Japan. <sup>3</sup>NKS data, Tokyo, Japan.  
(No relationships reported)

**BACKGROUND:** Active video game systems controlled through arm gestures and motions and force plate-controlled video games (Wii Fit Plus) are becoming increasingly popular. We previously revealed that time spent playing one-third of activities supplied by Wii Fit Plus can count toward the daily amount of exercise required according to the guidelines provided by the ACSM and AHA which focus on 30 minutes of moderate-intensity daily physical activity five days a week.

**PURPOSE:** To examine the effects of home-based intervention using Wii Fit Plus on body weight and composition.

**METHODS:** Randomized controlled trial conducted in 2010. A total of 40 adult men ( $n=6$ ) and women ( $n=34$ ) aged 21 to 50 yrs participated. Participants were randomly assigned to an intervention group ( $n=20$ ) or a control group ( $n=20$ ) after baseline measurements. The intervention group have played favorite games for 200 min per every week for one month. At baseline and after one month, height, weight, waist circumference, %fat, and lean body mass were measured.

**RESULTS:** One-month data were available for 39 men and women. The intervention group showed significant differences from controls in baseline to one-month changes in body weight (-2.0 kg,  $P < 0.001$ ), waist circumference (-1.8 cm,  $P < 0.001$ ), and body fat mass (-0.9 kg,  $P < 0.01$ ). There was no such between-group difference in %fat (-0.4%, NS) and lean body mass (-0.6 kg, NS).

**CONCLUSIONS:** The daily use of active video game systems controlled through arm gestures and motions and force plate-controlled video games (Wii Fit Plus) is efficacious for body weight and fat mass reductions in adults.

**3403** Board #124 June 2 9:30 AM - 11:00 AM

**Comparing The Energy Cost Of Two Body Shaper Undergarments During Walking**

Claire Brady, Corey A. Rynders, Frank I. Katch, FACSM, Arthur Weltman, FACSM. University of Virginia, Charlottesville, VA.  
(No relationships reported)

**PURPOSE:** We previously reported that wearing a body shaper undergarment with built in resistance bands increased the energy cost of walking by 3-5% compared to wearing usual undergarments. The present study compared the energy cost of wearing the resistance band body shaper undergarment (ShaToBu, Mayfair Tech Montreal Canada) to a commercially available shaper undergarment without resistance bands.

**METHODS:** Fifteen women completed testing (mean $\pm$ SD; age= $41.3 \pm 14.0$  yr; BMI= $28.4 \pm 3.4$  kg/m<sup>2</sup>). Subjects completed two continuous 10-min treadmill walking tests separated by 15-min of seated rest. Treadmill percent grade was 5% over the first 5-min and increased to 10% over the last 5-min. The ShaToBu body shaper undergarment was worn during one of the walking tests and a commercially available shaper was worn during the other with order randomized. Indirect calorimetry assessed energy expenditure (EE) throughout the walk (Oxycon Mobile, Cardinal Health, Yorba Linda, CA).

**RESULTS:** Wearing the undergarment with resistance bands resulted in a 4.6% higher EE at 5% grade,  $5.9 \pm 1.3$  kcal vs.  $5.6 \pm 1.2$  kcal ( $p=0.01$ ).

**CONCLUSIONS:** The body shaper with resistance bands increased the energy cost of walking uphill at 5% grade (typical of an activity of daily living) by 4.6%. This difference in EE is virtually identical to the differences reported previously with usual undergarments and suggests that the resistance bands, rather than the compressive nature of the garment, accounts for the increased EE. Wearing a body shaper during activities of daily living that increases EE may help to offset the small energy gap (~30 to 50 kcal daily) commonly associated with yearly weight gain.

Supported by an unrestricted gift to the University of Virginia from Mayfair Tech, Inc. F.I. Katch, and A. Weltman serve as scientific advisors to Mayfair Tech, Inc.

**3404** Board #125 June 2 9:30 AM - 11:00 AM

**Energy Cost of Active and Sedentary Music Video Games: Drum and Handheld Gaming versus Walking**

Scott Mazzetti, Michael T. Kolankowski, Vincent Gutierrez, Brittany S. Wilkerson, Matthew Overstreet, Edwin R. Miranda, Ryan Sapp, Christina Orcino. Salisbury University, Salisbury, MD.  
(No relationships reported)

**PURPOSE:** The purpose of this study was to compare energy expenditure during and after active and handheld video game drumming compared to walking on a treadmill.

**METHODS:** Eleven experienced college-aged men performed four protocols, one per week, after an overnight fast. Expired air was collected during (30min) and after (30min) active drumming on a drum pad (DRUM), virtual drumming on a handheld gaming device (HANDHELD), walking on a treadmill at 35% of VO<sub>2</sub>max (WALK), and no-exercise seated control (CTRL). DRUM and HANDHELD song lists were identical.

**RESULTS:** Significant differences ( $p \leq 0.05$ ) among the average rates of energy expenditure (kcal.min<sup>-1</sup>) included WALK > DRUM > HANDHELD (see Table). There were no significant differences in the rates of energy expenditure among groups during recovery. Total energy expenditure was significantly greater ( $p \leq 0.05$ ) during WALK ( $231 \pm 80.0$  kcal) compared to DRUM ( $177 \pm 31.0$  kcal) and HANDHELD ( $112 \pm 24.9$  kcal), and greater during DRUM compared to HANDHELD.

**CONCLUSIONS:** Active video game drumming significantly increased energy expenditure compared to handheld, but energy expenditure was greatest during walking. Thus, traditional aerobic exercise remains important for achieving the minimum amount and intensity of physical activity for health. Energy expenditure with handheld video game drumming was nearly identical to no-exercise control, demonstrating that handheld video game devices provide essentially no stimulus for increased metabolism.

**3405** Board #126 June 2 9:30 AM - 11:00 AM

**Multi-sensor Armband Quantification Of Energy Expenditure During Loaded Vs Unloaded Uphill Walking**

Amine N. Issa, Nicole M. Herman, Micah W. Johnson, John W. Kelsey, Andrew D. Miller, Thomas P. Olson, Bruce D. Johnson. *Mayo Clinic, Rochester, MN.*  
(No relationships reported)

**PURPOSE:** The BodyMedia© Sensewear armband measures movement (biaxial accelerometry), heat flux and galvanic skin response (GSR) to derive energy expenditure (EE) using customized algorithms. This EE estimation has compared favorably to doubly labeled water techniques, and thus, has been used in a growing number of clinical and non-clinical studies. However, quantifying EE during loaded vs. unloaded treadmill exercise is difficult due to the high reliance of algorithms on motion data. The purpose of the present study was to determine the ability of standard device algorithms for tracking EE during uphill walking with and without a backpack, and if inadequate, to determine how closely the measured physiological metrics tracked EE.

**METHODS:** Eight healthy males, (age=34±3 yrs, ht=180±8 cm, wt=78±4 kg) were recruited and performed 2 separate walking tests on a motor driven treadmill. The first included walking for 15 min at 2 mph followed by 15 min at 2 mph with 10, 17.5, and 25% grades. Subjects rested, re-hydrated and subsequently repeated the study with a 15% body weight backpack. Measures of metabolic rate were determined with the Sensewear device and compared with indirect calorimetry using a cardiopulmonary gas exchange system (Medical Graphics©)

**RESULTS:** The average metabolic rates (VO<sub>2</sub>) for walking with no backpack were 7.3, 18.7, 24.9 and 30.4 ml/kg/min at 0, 10, 17.5 and 25% grade, respectively. These values increased progressively using a backpack (8.4, 21.9, 30.8, 40.0 ml/kg/min,  $p < 0.05$ ). The EE estimation by the armband showed a poor but significant correlation with indirect calorimetry with or without the pack ( $r = 0.49$ , and  $0.45$ ,  $p < 0.0001$ , respectively), but significantly underestimated EE under all conditions ( $p < 0.0001$ ). No single metric was found to accurately track energy expenditure. Heat flux ( $r = 0.52$ ,  $p = 0.0005$ ) and GSR ( $r = 0.49$ ,  $p = 0.0041$ ) were the best predictors of energy expenditure in the no pack trial, and GSR was the only variable with a significant correlation ( $r = 0.62$ ,  $p = 0.0008$ ) in the with-pack trial. Using a multiple linear regression model, GSR, heat flux, and biaxial acceleration could only account for 78% of the change in EE.

**CONCLUSION:** For uphill walking on a treadmill, improved algorithms and additional sensors, such as heart rate, may be necessary to adequately quantify metabolic rate.

**3406** Board #127 June 2 9:30 AM - 11:00 AM

**A Single-Bout of 30-Min Aerobic Exercise Increases Resting Metabolism and Fat Oxidation in Young Women**

Lidia G. De Leon<sup>1</sup>, Belen Feriche<sup>2</sup>, Claudia E. Carrasco-Legleu<sup>1</sup>, Ofelia Urita<sup>1</sup>, Diana Espino<sup>1</sup>. <sup>1</sup>University of Chihuahua, Chihuahua, Chih., Mexico. <sup>2</sup>University of Granada, Granada, Spain.  
(No relationships reported)

Physical activity has demonstrated a consistent contribution to weight loss in men and women, but intensity and duration of exercise have different impact on the magnitude of changes in resting metabolism, so results can be very heterogeneous. Describing changes on resting energy expenditure and respiratory quotient is essential to understand their relationship with body weight and clarify the influence of physical activity on weight control.

**PURPOSE:** To determine the effect of a single-bout of 30-min aerobic exercise at 50% of maximal oxygen uptake on resting energy expenditure and respiratory quotient in sedentary young women with normal weight or overweight.

**METHODS:** Twenty six sedentary healthy women, 18 to 35 years of age, 19 with normal weight (NW) and 7 overweight or obese (OW) were measured by height, weight and body mass index (BMI). Maximal oxygen uptake (VO<sub>2</sub>max) was obtained by an exercise stress testing before to perform a single-bout of 30-min-treadmill walking at 50% of VO<sub>2</sub>max. Resting energy expenditure (REE) and respiratory quotient (RQ) were measured by indirect calorimetry before and after the workload. Descriptive statistics and paired t test at a  $p < 0.05$  significance level were used.

**RESULTS:** Age, height and VO<sub>2</sub>max were similar in both groups. Body weight was 37% higher in OW than in NW ( $77.8 \pm 10.3$  and  $56.7 \pm 5.6$  kg respectively,  $p < 0.001$ ). OW had greater BMI than NW ( $29.4 \pm 2.6$  vs  $22.1 \pm 1.9$  kg/m<sup>2</sup>,  $p < 0.001$ ). Absolute REE was higher in OW than in NW, before the exercise ( $1502 \pm 236$  vs  $1260 \pm 178$  Kcal/day,  $p = 0.009$ ) but this relationship was inverted when adjusted by body weight ( $19.4 \pm 2.9$  vs  $22.2 \pm 2.5$  Kcal/day/kg respectively,  $p = 0.049$ ). NW increased REE/kg after 30-min workload from  $22.2 \pm 2.5$  to  $23.6 \pm 2.7$  Kcal/day/kg,  $p = 0.050$ , while OW group had a wide-ranging response (from  $19.4 \pm 2.9$  to  $21.4 \pm 4.8$  Kcal/day/kg respectively,  $p = 0.118$ ). RQ showed a significant decrease after 30-min workload in NW from  $0.74 \pm 0.09$  to  $0.70 \pm 0.07$ ,  $p = 0.006$ .

**CONCLUSIONS:** REE and RQ showed a reciprocal response to a short session of moderate-intensity exercise in NW, but, this level of physical activity was not able to produce effects in OW. It is possible that evident lower fat oxidation rate in OW group, may suppose important repercussions in body weight control.

---

**3407** Board #128 June 2 9:30 AM - 11:00 AM

**The Reliability and Validity of the COSMED Fitmate Canopy System for Assessing Resting Metabolic Rate**

Dimitria Vandarakis<sup>1</sup>, Amanda J. Salacinski<sup>2</sup>, Craig E. Broeder, FACSM<sup>1</sup>. <sup>1</sup>Exercising Nutritionally, Naperville, IL. <sup>2</sup>Northern Illinois University, DeKalb, IL, IL.  
(No relationships reported)

**PURPOSE:** This study's purpose was to determine the reliability and validity of measuring resting metabolic rate (RMR) with COSMED's FitMate™ metabolic system using a canopy dilution set-up compared to a previously validated research grade RMR system (COSMED Quark CPET) in 30 healthy adults (Age:  $28.4 \pm 7.0$  yrs, Weight:  $79.9 \pm 20.2$  lbs, Percent Body Fat:  $22.5 \pm 8.6$  %).

**METHODS:** Subjects were randomly assigned to start RMR testing on either the FitMate™ or Quark CPET for four 10-minute measurements (Equalled 20-mins per system tested). Prior to testing, subjects were required to fast 4-hours from food, caffeine, and nicotine. Subjects were not allowed to exercise intensely 12-hrs prior RMR testing. Immediately before the RMR measurements, subjects rested in the supine position for 20-mins in a semi-dark room. Then the ventilatory hood was placed over the subject's head and they rested an additional 15 mins accommodating to the hood set-up while both systems were calibrated. Ambient room temperature was kept at  $22 \pm 1^\circ\text{C}$ .

**RESULTS:** Test-retest intra-class correlations were excellent for all parameters tested (r-value Range: 0.95-0.99,  $p \leq 0.0001$ ). There were no significant differences in Ve (Fitmate:  $33.0 \pm 8.7$  liters/min; CPET:  $32.8 \pm 8.5$  liters/min,  $P = 0.48$ ) RMR (Fitmate:  $1771 \pm 473$  kcal/day; CPET:  $1787 \pm 402$  kcal/day,  $P = 0.55$ ), VO<sub>2</sub> (Fitmate:  $255 \pm 68$  mls; CPET:  $260 \pm 60$  mls,  $P = 0.17$ ), and heart rate (Fitmate:  $62 \pm 15$  bpm; CPET:  $61 \pm 14$  bpm,  $P = 0.32$ ) between the two systems.

**CONCLUSIONS:** These results suggest the FitMate™ can be used with canopy dilution for RMR measurements with the same outcome as more expensive laboratory grade equipment. This will aid wellness and health club facilities in offering this type of measurement, which normally could not occur because the cost was prohibitive.

3408 Board #129 June 2 9:30 AM - 11:00 AM

**The Relationship Between Resting Metabolic Rate, Cardiorespiratory Fitness, And Body Composition**

Robin P. Shook, E. Patrick Crowley, John C. Sieverdes, Kelly Kavanaugh, Madison Demello, Vivek Prasad, Jason Jagers, Gregory A. Hand, FACSM, Steven N. Blair, FACSM. *University of South Carolina, COLUMBIA, SC.* (Sponsor: Steven N. Blair, FACSM)  
(No relationships reported)

**PURPOSE:** Recent research has shown considerable variability of resting metabolic rate (RMR) across various populations, both in absolute values and those adjusted for body weight. The purpose of this study was to examine the relationships between RMR, cardiorespiratory fitness (CRF), body mass index (BMI), and body fat (BF).

**METHODS:** RMR was measured in healthy adults using a ventilated hood system. Participants arrived fasted for at least 12 hrs and having refrained from alcohol or exercise for at least 24 hrs. Participants rested in a supine position under a ventilated hood for 30 minutes, followed by a 30 minute RMR gas collection period. Height and weight were measured and BMI was calculated as body weight (kgs)/height (meters)<sup>2</sup>. CRF was measured via a metabolic cart during a modified Bruce treadmill protocol. BF was calculated as the percentage of total weight identified as fat tissue by dual x-ray absorptiometry.

**RESULTS:** Of the original sample of 55 healthy adults, 48 (22 males and 26 females; mean age 27±3 years) met the criteria for a successful exercise treadmill test (one of the following: plateau of VO<sub>2</sub>, plateau of heart rate, respiratory exchange ratio ≥1.15, or rating of perceived exertion ≥17). The mean±standard deviation BMI for the sample was 26.7±4.5 (men: 27.0±4.2; women: 26.4±4.7) with a mean percent BF of 30.2 (men: 24.7±7.3; women: 34.8±7.6). RMR ranged from 0.17 to 0.32 L/min (men: 0.25±0.037; women: 0.21±0.03) resulting in a mean relative RMR 2.97±0.34 ml/kg/min (men: 2.99±0.33; women: 2.94±0.35). Mean CRF was 37.6 ± 9.2 ml/kg/min (men: 42.1±7.9; women: 33.8±8.5). A statistically significant relationship was detected between CRF and RMR (r=0.61, p<0.0001) in an unadjusted analysis. After adjusting for BMI, a statistically significant relationship remained between RMR and CRF (p=0.0054). However, after replacing BMI with BF the association between RMR and CRF was no longer significant (p=0.0817).

**CONCLUSIONS:** The results of this study indicate that after controlling for BF percent, RMR was not associated with CRF in a sample of normal to obese young adults. These findings demonstrate the role of metabolically active fat free mass in RMR, which may be overlooked if BMI is the only indicator of body fatness examined.

This study was supported by the Coca Cola Corporation.

**The Effect Of Combined Training On Immune Functioning, Metabolic Variables, And Qol In Hiv-infected Individuals**

Eduard Tiozzo<sup>1</sup>, John E. Lewis<sup>1</sup>, Arlette Perry, FACSM<sup>2</sup>, Allan Rodriguez<sup>1</sup>, Dushyantha Jayaweera<sup>1</sup>, Janet Konefal<sup>1</sup>, Angelica Melillo<sup>1</sup>, Larry Chen<sup>1</sup>, Evan Long<sup>1</sup>. <sup>1</sup>University of Miami Miller School of Medicine, Miami, FL. <sup>2</sup>University of Miami, Coral Gables, FL  
(No relationships reported)

Highly-active antiretroviral therapy (HAART) has improved the prognosis of HIV-infected individuals. Unfortunately it has also been associated with impaired functional capacity and development of metabolic perturbations which increases health risk.

**PURPOSE:** This study tested the hypothesis that a combined cardiorespiratory and resistance exercise training (CARET) intervention may result in significant health benefits in HIV-infected individuals receiving HAART.

**METHODS:** Thirty-seven HIV-infected men and women, predominantly of lower socioeconomic status (SES), were recruited and randomly assigned to: 1) a group of moderate-intensity CARET for three months or 2) a control group receiving no exercise intervention for three months. At baseline and following the intervention, physical characteristics (body weight, body mass index, waist circumference, and blood pressure), physical fitness variables (estimated VO<sub>2max</sub> and one repetition maximum for upper and lower body), metabolic variables (fasting glucose and serum lipids), immune functioning (CD4+ T Cell count, CD4/CD8 ratio, and HIV RNA viral load), and quality of life (SF-36 Health Survey) were measured.

**RESULTS:** Exercise participants evidenced increases in estimated VO<sub>2max</sub> (21%, p < 0.01), upper body strength (15%, p < 0.05), and lower body strength (22%, p < 0.05), while showing reductions in waist circumference (-2%, p < 0.05), and fasting glucose (-16%, p < 0.05). While the control group showed a significant decrease in CD4+ T cell count (-16%, p < 0.05) from baseline, the exercise group maintained a more stable count following training (-3%, p = 0.39). Finally, the exercise participants showed self-reported improvements in physical (11%, p < 0.03) and mental (10%, p < 0.02) quality of life.

**CONCLUSIONS:** Our study demonstrated that a three-month, supervised, and moderate intensity CARET program performed three times a week, can result in significant improvements in physical characteristics, physical fitness, metabolic variables, and physical and mental quality of life. Furthermore, the same intervention resulted in more favorable immunological responses following training in HIV-infected individuals of lower SES.

3410 Board #131 June 2 8:00 AM - 9:30 AM

**The Effect of Exercise Intensity on Chemotherapy Completion Rate in Early-Stage Breast Cancer Patients**

Lianne B. Dolan<sup>1</sup>, Karen Gelmon<sup>2</sup>, Donald C. McKenzie<sup>1</sup>. <sup>1</sup>University of British Columbia, Vancouver, BC, Canada. <sup>2</sup>British Columbia Cancer Agency, Vancouver, BC, Canada.  
(No relationships reported)

The association between survival and the maintenance of chemotherapy dose intensity has been established in early-stage breast cancer (EBC) patients. However, the influence of exercise on the planned chemotherapy dose, (RDI), has been poorly documented.

**PURPOSE:** The purpose of this study is to investigate the effect of exercise intensity during a supervised exercise program on chemotherapy completion rate in women undergoing treatment for early-stage breast cancer.

**METHODS:** Women with EBC receiving adjuvant chemotherapy who participated in a personalized, thrice weekly, supervised exercise program (E), were matched with similar patients undergoing usual care (UC). Subjects were matched based on treatment (6 cycles of FEC-D between 2008-2010), age and body surface area (BSA). Relative dose intensity (RDI), and variables that may influence a reduction in chemotherapy dose (hospitalization days, neutrophil counts, and hemoglobin concentration) were compared between groups.

**RESULTS:** Baseline characteristics between each group of 30 women were similar (age; E= 49.1± 8.4 years, UC= 49.0± 8.6 years, P= 0.916, BSA; E= 1.75 ± 0.27 m<sup>2</sup>, UC= 1.75 ± 0.25 m<sup>2</sup>, P= 0.925). RDI for patients who chose to incorporate short bouts of high intensity exercise (80-90% VO<sub>2peak</sub>) into their program received 91.9± 8.7% of their planned dose. RDI for UC was similar at 90.1± 9%, (P =0.42). Exercise did not have a negative impact on the myelosuppressive effects of chemotherapy (# of episodes where neutrophil counts dropped below 1.0g/L, P= 0.53, decline in hemoglobin concentration, P=0.285), nor did it cause increased risk of hospitalization (P=0.67).

**CONCLUSION:** Women undergoing FEC-D treatment for EBC can incorporate bouts of higher intensity exercise without negatively impacting their treatment.

3411 Board #132 June 2 8:00 AM - 9:30 AM

**Voluntary Exercise Decreases Tumorigenesis in the C3(1)SV40Tag Mouse Model of Breast Cancer**

E. Angela Murphy<sup>1</sup>, Jennifer L. Steiner<sup>2</sup>, J. Mark Davis, FACSM<sup>2</sup>, Jamie L. McClellan<sup>2</sup>, Martin D. Carmichael<sup>2</sup>. <sup>1</sup>*School of Medicine, University of South Carolina, Columbia, SC.* <sup>2</sup>*University of South Carolina, Columbia, SC.*  
(No relationships reported)

Many observational epidemiologic studies suggest an association between exercise and breast cancer risk. However, the lack of controlled experimental studies that examine this relationship and the mechanisms involved weaken the basis for inferring a causal relationship. Further, the optimal mode, intensity and duration of exercise have yet to be determined.

**PURPOSE:** To examine the relationship between voluntary wheel running activity and breast cancer progression in C3(1)SV40Tag mice.

**METHODS:** Female C3(1)SV40Tag mice were assigned to either exercise (Ex) or sedentary (Sed) treatment (n=9/group). Beginning at 4wks of age C3(1)SV40Tag mice were either placed in a cage with a running wheel (Ex) or in a cage with a locked running wheel (Sed). Mice were examined weekly and at sacrifice (24 wks) for palpable tumors, and tumor number and volume was recorded. At 24wks of age mice were sacrificed and all visible tumors were counted, and measured. Heart weight was also recorded as an indicator of training status.

**RESULTS:** Voluntary wheel running significantly reduced average tumor volume by ~40% at sacrifice (24 wks) (P<0.05) but not tumor number. When Ex mice were grouped by average wheel running distance, a dose dependent effect of exercise on tumorigenesis was observed; mice running  $\geq 3,000\text{m/d}$  had a ~70% reduction in tumor volume at sacrifice. Heart weight expressed as a percentage of total body weight was increased following Ex (P<0.05), indicating that this mode of physical activity provides a sufficient training stimulus.

**CONCLUSIONS:** These data provide strong support for a beneficial effect of voluntary wheel running on tumor progression in the C3(1)SV40Tag mouse model of breast cancer as well as preliminary evidence of a dose-dependent effect of this type of exercise on mammary tumorigenesis. However, further research is necessary to fully understand this relationship and the mechanisms involved.

**Voluntary Exercise Decreases Tumor Grade in a Mouse Model of Metastatic Breast Cancer**

Jorming Goh<sup>1</sup>, Shu Xian Lee<sup>1</sup>, Emma Endicott<sup>1</sup>, David McDonald<sup>2</sup>, Julio Vasquez<sup>2</sup>, Warren Ladiges<sup>1</sup>. <sup>1</sup>*University of Washington, Seattle, WA.* <sup>2</sup>*Fred Hutchinson Cancer Research Center, Seattle, WA.*  
(No relationships reported)

Although studies report a protective effect of exercise against breast cancer, the biological mechanisms are unclear.

**PURPOSE:** To investigate mechanisms of protective effects of exercise in a mouse model of breast cancer.

**METHODS:** 6-week old Polyoma Middle T Oncoprotein (PyMT) mice were housed singly with access to freely rotating wheels (voluntary exercise) or locked wheels (sedentary) for one month. Mice were monitored weekly for tumor growth. Quantitative Magnetic Resonance was used to assess body composition. Mammary tumors were quantified for tumor burden, formalin-fixed, paraffin-embedded, and stained with Hematoxylin and Eosin (H&E). H&E stained tumors were histologically scored (grade1-4); higher scores reflecting increased tumor invasion and poorer prognosis. Tumors were immunostained and digitally quantitated for CD34 and Ki-67. Outcomes were compared using Student's t-test. Correlational analyses were assessed using Pearson's correlation.

**RESULTS:** Mice ran a median distance of 17.49km daily. Running distance was not correlated with lean body mass (Pearson  $r=0.59$ ,  $p=0.075$ ), fat mass (Pearson  $r=0.28$ ,  $p=0.46$ ), heart weights (Pearson  $r=-0.24$ ,  $p=0.54$ ) or tumor burden (Pearson  $r=-0.28$ ,  $p=0.47$ ). Normalized lean body mass and fat mass were similar between exercised and sedentary mice (80.08 $\pm$ 0.463 vs. 80.87 $\pm$ 0.4794%,  $p=0.25$ ; 9.22 $\pm$ 0.3213 vs. 9.63 $\pm$ 0.4317%,  $p=0.44$ ). Tumor grades were lower in the exercise group compared with the sedentary group (grade 2.0 $\pm$ 0.2236 vs. 3.056 $\pm$ 0.294;  $p=0.01$ ). Tumor burden was not different between groups (1.016 $\pm$ 0.2082g/cm vs. 1.198 $\pm$ 0.2102g/cm;  $p=0.55$ ). Tumors both groups showed comparable CD34 and Ki-67 labeling (CD34: 0.729 $\pm$ 0.4639% vs. 1.39 $\pm$ 0.3439%,  $p=0.37$ ; Ki-67: 24.46 $\pm$ 4.726 vs 20.88 $\pm$ 5.745,  $p=0.68$ ).

**CONCLUSION:** Voluntary exercise is associated with reduced tumor grade, suggesting that exercise attenuates tumor invasion and improves prognosis. The absence of exercise effects on tumor burden, proliferation and vascularization may be due to the short duration of exercise training.

---

3413 Board #134 June 2 8:00 AM - 9:30 AM

**Immuno-modulatory Effects Of Aerobic Exercise Training In Dss - Induced Ulcerative Colitis**

Marc D. Cook, Steve Martin, Jeffrey Woods. *University of Illinois Urbana-Champaign, Urbana, IL.*  
(No relationships reported)

Inflammatory bowel diseases, such as ulcerative colitis, significantly reduce physical functioning and decrease the quality of life in afflicted patients. Preliminary studies have shown that there is a positive correlation between physical activity, reduced inflammatory biomarkers and inflammatory-related disease activity indices.

**PURPOSE:** The purpose of this study was to determine whether 6 weeks of moderate exercise training reduces inflammation and sickness behavior associated with colitis in a mouse model.

**METHODS:** Colitis was induced by dextran sodium sulfate (DSS)

treatment in treadmill exercised (Ex/DSS, 8-12 m/min for 6 weeks- 5x/week) or sedentary (Sed/DSS) C57Bl/6 male mice while control mice received water (Ex/H2O, Sed/H2O) (n=13/group). DSS (2%) was given in drinking water over 5 days. Sickness outcomes were assessed by changes in food and fluid intake, body weight (BW), and locomotor activity (LMA). Mice were euthanized and brains and colons were harvested at 3 days post cessation of DSS administration (Day 8) for analysis of inflammatory gene expression.

**RESULTS:** Proinflammatory gene expression (2 $\Delta\Delta\text{CT}$ ) in the colon were as follows: IL-6 (Sed+H2O: 1.63 $\pm$ 1.1; Sed+DSS: 16.44 $\pm$ 34.3; Ex+DSS: 390.7 $\pm$ 515.6; Ex+H2O:1.34 $\pm$ 1.2); IL- $\beta$  (Sed+H2O: 1.55 $\pm$ 1.3; Sed+DSS: 7.54 $\pm$ 13.6; Ex+DSS: 115.22 $\pm$ 154.3; Ex+H2O: 1.13 $\pm$ 1.2); TNF- $\alpha$  (Sed+H2O: 2.85 $\pm$ 3.7; Sed+DSS: 3.6 $\pm$ 4.0; Ex+DSS: 15.56 $\pm$ 19.8; Ex+H2O: 1.59 $\pm$ 2.1). Statistical analysis showed a significant intervention\*treatment (Ex+DSS) effect for IL-6 ( $F_{1,52} = 6.83$ ;  $p=0.012$ ), IL- $\beta$  ( $F_{1,52}=6.33$ ;  $p=0.015$ ) & TNF $\alpha$  ( $F_{1,52} = 5.323$ ;  $p=0.025$ ). Sickness outcomes and brain cytokines were not different between groups.

**CONCLUSIONS:** Six weeks of exercise training caused intensified local colon inflammation in mice treated with DSS. While DSS-treated mice exhibited reductions in food and fluid intake, BW, LMA when compared to the water-only groups, prior exercise training did not exacerbate these symptoms associated with colitis. These data demonstrate that exercise can modulate local inflammation in response to DSS-induced acute ulcerative colitis. Further investigation is essential to characterize these effects and elucidate the mechanism that drives this exacerbated immune response in the colon.

---

3414 Board #135 June 2 8:00 AM - 9:30 AM

**Exercise Training Enhances Recipient Survival With No Benefit to Long-term Engraftment Following Bone Marrow Transplantation**

Michael De Lisio, Gianni Parise. *McMaster University, Hamilton, ON, Canada.*  
(No relationships reported)

Exercise training has profound systemic effects which ultimately induce positive adaptations in numerous body tissues. Recently, we have demonstrated increased bone marrow cell survival and proliferation in response to exercise training which may be attributable to increased quality of the niche.

**PURPOSE:** The present study determined the extent to which exercise-induced alterations in the bone marrow microenvironment can increase success of bone marrow transplantation (BMT).

**METHODS.** In our BMT assay, recipient C57Bl/6 mice remained sedentary (SED) or were exercise trained on a treadmill (EX; 3d/wk, 8 wks). Both groups of mice had their native marrow ablated prior to receiving GFP-labeled donor marrow. Successful BMT was established by recipient survival, and both donor-derived blood reconstitution, and total (donor- and recipient-derived) blood reconstitution measured by flow cytometry. One and 4 days post-BMT, donor cell homing, as well as apoptosis, determined by activated caspase-3/-7 activity, were determined in the bone marrow cavity by flow cytometry.

**RESULTS.** Whereas only 25% of SED survived, 82% of EX recipients survived the BMT. Homing of donor-derived marrow cells to the recipients' marrow cavity acutely post-BMT was not altered in EX, but EX mice displayed decreased levels (10%,  $p < 0.05$ ) of activated caspase-3/7 1 day following BMT. The acute inhibition of marrow cell apoptosis in EX resulted in increased total blood cell reconstitution at 3.5 months post-BMT in EX (37%,  $p < 0.05$ ), but did not improve donor-derived reconstitution.

**CONCLUSION.** Exercise training increases recipient survival post-BMT with increased total blood cell reconstitution. Donor-derived reconstitution was not improved, possibly due to enhanced competition for niche availability created by the inhibition of apoptosis with exercise.

**3415** Board #136 June 2 8:00 AM - 9:30 AM

**Effects of Tai Chi Exercise on T-lymphocytes Subgroups of Non-small Cell Lung Cancer Post-surgery Survivors**

Zhang Yajun<sup>1</sup>, Ru Wang<sup>1</sup>, Bei bei Luo<sup>1</sup>, Peijie Chen<sup>1</sup>, Dinghai Yu<sup>2</sup>. <sup>1</sup>*School of Kinesiology, Shanghai University of Sport, Shanghai, China.* <sup>2</sup>*School of Wu Shu, Shanghai University of Sport, Shanghai, China.*

(No relationships reported)

**PURPOSE:** T-lymphocyte mediating immunoreactions plays a vital role on antitumor immunity, CD4<sup>+</sup>/CD8<sup>+</sup> lymphocytes make main effects on killing cancer cells, and the T helper to suppressor cell ratio (CD4<sup>+</sup>:CD8<sup>+</sup>) implies T cellular immunity balance. Many researches proved that long term tai chi exercise could improve cellular immunity, so we hypothesize that a 16-week tai chi exercise may have positive effect on variations of total T cell (CD3+T lymphocyte) and T-lymphocyte subgroups.

**METHODS:** Thirty-two post-surgical NSCLC survivors were randomized two groups, the tai chi exercise group (TCC) and the control group (CON). Among them, 27 participants completed the study (TCC: n=14, CON: n=13). Subjects in TCC performed 24 type standardized movement every other day for 16 weeks and lasted 45 to 60 minutes every time, and the control group maintained daily life. Before and after tai chi exercise, peripheral blood sample was collected to isolate lymphocytes, then use flow cytometer to analyze percentage of CD3+T lymphocyte and CD4+/CD8+T lymphocyte subpopulation.

**RESULTS:** There were significant changes in CD3+T lymphocyte, CD4+T lymphocyte, and the ratio of T helper to suppressor cells (CD4:CD8 ratio) in post-surgical NSCLC survivors over a 16-week tai chi exercise. Percentage of CD3+T lymphocyte ( $60.26 \pm 12.38$  vs  $55.26 \pm 12.44$ ,  $P < 0.05$ ) and CD4+T lymphocyte ( $35.62 \pm 9.83$  vs  $32.97 \pm 8.27$ ,  $P < 0.05$ ) significantly declined compared to pre-training in TCC. CD4:CD8 ratio significantly ( $1.62 \pm 0.78$  vs  $1.88 \pm 0.80$ ,  $P < 0.05$ ) increased compared to pre-training in TCC, but there was no significant change in the control group.

**CONCLUSIONS:** A 16-week tai chi exercise program enhances T cellular immunity via elevating the ratio of T helper to suppressor cells.

---

**3416** Board #137 June 2 8:00 AM - 9:30 AM

**Regular Tai Chi Chuan Exercise Decreases the Number Of Type 2 Cytokine-producing Cells In Postsurgical Nonsmall Cell Lung Cancer Survivors**

Ru Wang<sup>1</sup>, Jing Liu<sup>2</sup>, Yajun Zhang<sup>1</sup>, Beibei Luo<sup>1</sup>, Peijie Chen<sup>1</sup>, Dinghai Yu<sup>2</sup>. <sup>1</sup>*School of Kinesiology, Shanghai University of Sport, Shanghai, China.* <sup>2</sup>*School of Wu Shu, Shanghai University of Sport, Shanghai, China.*

(No relationships reported)

**PURPOSE:** Tai Chi Chuan (TCC) exercise is beneficial for treatment of diseases such as cardiovascular malignancies and rheumatoid arthritis. Its possible benefits to lung cancer survivors, however, remain to be determined. The effect of a 16-week TCC exercise intervention on CD4<sup>+</sup> helper T cells (Th1 and Th2) and CD8<sup>+</sup> cytotoxic T cells (Tc1 and Tc2) in postsurgical nonsmall cell lung cancer survivors was investigated.

**METHODS:** A controlled study was performed in 13 lung cancer survivors who practiced TCC and 14 control lung cancer survivors who did not practice TCC. The whole blood count, main hormone levels (cortisol, catecholamine,  $\beta$ -endorphin), and cytokines (IFN- $\gamma$ , IL-4) of Th1/Th2 and Tc1/Tc2 reaction were measured before (t = 0) and after (t = 16 weeks) a 16-week TCC exercise intervention.

**RESULTS:** Th2 and Tc2 levels at t = 16 weeks in the TCC group remained unchanged ( $1.55 \pm 0.47$  vs  $1.79 \pm 0.89$ ,  $P > 0.05$ ) and significantly decreased ( $22.41 \pm 8.94$  vs  $18.82 \pm 6.87$ ,  $P < 0.05$ ), respectively, while a significant increase in both the Th2 ( $1.61 \pm 0.75$  vs  $2.92 \pm 1.26$ ,  $P < 0.05$ ) and Tc2 ( $17.65 \pm 6.10$  vs  $19.13 \pm 5.78$ ,  $P < 0.05$ ) levels was observed in the control group at t = 16 weeks. No significant changes in the Th1 and Tc1 levels were observed, except for a significant decrease in the Tc1 level ( $24.20 \pm 10.43$  vs  $20.74 \pm 7.74$ ,  $P < 0.05$ ) at t = 16 weeks in the control group. The IFN- $\gamma$  (Type 1 cytokines including Th1 and Tc1) significantly decreased ( $37.90 \pm 11.99$  vs  $34.43 \pm 0.95$ ,  $P < 0.05$ ) in the control group and decreased, but not significantly ( $42.53 \pm 11.07$  vs  $40.58 \pm 13.16$ ,  $P < 0.05$ ), in the TCC group at t = 16 weeks. The IL-4 level (Type 2 cytokines including Th2 and Tc2) significantly increased ( $19.08 \pm 6.45$  vs  $21.69 \pm 6.41$ ,  $P < 0.05$ ) in the control group, but significantly decreased ( $23.95 \pm 8.80$  vs  $20.61 \pm 7.13$ ,  $P < 0.05$ ) in the TCC group at t = 16 weeks. A significant increase in the cortisol level was observed at t = 16 weeks in the control group and a significant decrease in the level of catecholamine was observed at t = 16 weeks in the TCC group.

**CONCLUSIONS:** A 16-week TCC exercise intervention prevented the increase of circulating Th2 and Tc2 cell levels, but not of Th1 and Tc1 cells, in nonsmall cell lung cancer survivors, suggesting that TCC may have a role in ameliorating the balance of humoral and cellular immunity and possibly potentiating human immunity against tumors.

**A Muscle-Secreted Protein SPARC Suppresses Colon Tumorigenesis via Apoptotic Effect**

Wataru Aoi<sup>1</sup>, Yuji Naito<sup>2</sup>, Tomohisa Takagi<sup>2</sup>, Yuko Tanimura<sup>2</sup>, Yoshikazu Takanami<sup>3</sup>, Yukari Kawai<sup>4</sup>, Hiroshi Ichikawa<sup>5</sup>, Toshikazu Yoshikawa<sup>2</sup>. <sup>1</sup>*Kyoto Prefectural University, Kyoto, Japan.* <sup>2</sup>*Kyoto Prefectural University of Medicine, Kyoto, Japan.* <sup>3</sup>*Otsuna Women's University, Kyoto, Japan.* <sup>4</sup>*Louis Pasteur Center for Medical Research, Kyoto, Japan.* <sup>5</sup>*Doshisha University, Kyoto, Japan.*

(No relationships reported)

Several epidemiological studies have shown that regular exercise can prevent the onset of colon cancer, although the mechanism involved is unclear. Recently, we identified a muscle-secreted protein SPARC (secreted protein acidic and rich in cysteine) which is elevated in circulation in response to exercise. In a mouse model of colon cancer, regular exercise suppressed the generation of tumorigenesis in colon obtained from wild-type mice, but not found in SPARC-null mice.

**PURPOSE:** To investigate the mechanism of anti-tumorigenesis effect via SPARC induced by exercise.

**METHODS:** Firstly, we investigated the effect of SPARC on colon tumorigenesis in azoxymethan (AOM)-injected SPARC-null and wild-type mice. The mice carried out six weeks of regular low-intensity exercise after AOM injection. The numbers of aberrant crypt foci (ACF) and terminal deoxynucleotidyl transferase dUTP nick end labeling (TUNEL)-positive cells were counted in the colon. Expression of apoptotic-related proteins was measured by immunoblotting. Secondly, colon26 cells were cultured in the presence or absence of mouse recombinant SPARC (mrSPARC) or medium obtained from cyclic-stretched C2C12 myotubes. Cell proliferation and apoptotic effect were examined.

**RESULTS:** Regular exercise significantly reduced the formation of ACF in wild-type mice (number:  $4.8 \pm 0.7$  to  $2.0 \pm 0.6$  count,  $P < 0.01$ ) but not SPARC-null mice. TUNEL assay showed that regular exercise increased the number of apoptotic colon cells in wild-type mice (apoptotic index: from  $0.66 \pm 0.11$  to  $0.92 \pm 0.09\%$ ,  $P < 0.05$ ); however, there was no difference between the sedentary and exercised SPARC-null mice. Furthermore, regular exercise increased the levels of cleaved caspase-3 and -8 in wild-type mice but not SPARC-null mice. In vitro studies, addition of both mrSPARC and the conditioned medium significantly prevented proliferation of colon cancer cells, along with an elevation of apoptotic cells.

**CONCLUSIONS:** A muscle-secreted protein SPARC suppresses colon tumorigenesis via caspase-3 and -8 dependent apoptosis.

**Effect Of Resistance Training On Vcam-1 And Cortisol In Hiv+ Men Recovering From Substance Abuse**

John H. Curtis<sup>1</sup>, Jakob L. Vingren<sup>1</sup>, Anthony A. Duplanty<sup>1</sup>, Carianne M. Cregar<sup>1</sup>, Julius F. Cantu<sup>2</sup>, David W. Hill, FACSM<sup>1</sup>. <sup>1</sup>*University of North Texas, Denton, TX.* <sup>2</sup>*Homeward Bound, Inc, Dallas, TX.*

(No relationships reported)

Human immunodeficiency virus (HIV) and substance abuse (drug and/or alcohol) independently impair the cardiovascular and immune systems; importantly, the combination of HIV infection and substance abuse might produce more than an additive effect on these systems. An elevated concentration of vascular cell adhesion molecule 1 (VCAM-1) is a novel risk factor for cardiovascular disease and an elevated concentration of cortisol can impair immune function. HIV infection and substance abuse can cause elevations in VCAM-1 and cortisol.

**PURPOSE:** The purpose of this study was to examine the effect of resistance training on resting concentrations of VCAM-1 and cortisol.

**METHODS:** Sixteen men (42 ± 11 years, 180.4 ± 9.1 cm, 89.2 ± 20.7 kg) infected with HIV who were enrolled in an intensive 60-day in-patient substance addiction/abuse treatment program were recruited and assigned to one of two groups using randomization: supervised resistance exercise 3 times per week (RT) or no exercise training (Control) for six weeks. Before (Pre) and after (Post) the 6-week period, resting and fasted blood samples were obtained and analyzed for VCAM-1 and cortisol concentrations.

**RESULTS:** VCAM-1 did not change following the 6-week period for RT (Pre: 352 ± 170 ng·ml<sup>-1</sup>; Post: 380 ± 182 ng·ml<sup>-1</sup>) or Control (Pre: 303 ± 224 ng·ml<sup>-1</sup>; Post: 306 ± 223 ng·ml<sup>-1</sup>). Similarly, no changes in cortisol were observed for RT (Pre: 603 ± 97 nmol·l<sup>-1</sup>; Post: 617 ± 132 nmol·l<sup>-1</sup>) or Control (Pre: 726 ± 257 nmol·l<sup>-1</sup>; Post: 720 ± 218 nmol·l<sup>-1</sup>). No adverse effects of the intervention were reported.

**CONCLUSION:** A six-week resistance training program does not elicit changes in VCAM-1 or cortisol concentrations in men infected with HIV who are undergoing an intensive in-patient substance addiction/abuse treatment program.

### Effect of Branched-chain Amino Acids Supplementation on Moderate Exercise Induced Changes In Circulating Lymphocyte Subsets

Kaori Matsuo<sup>1</sup>, Xiumin Zhang<sup>2</sup>, Farmawati Arta<sup>3</sup>, Jiro Kikuchi<sup>3</sup>, Shizuka Ogawa<sup>3</sup>, Akira Motokawa<sup>3</sup>, Izumi Tabata, FACSM<sup>1</sup>, Ryoichi Nagatomi, FACSM<sup>3</sup>.  
<sup>1</sup>Ritsumeikan University, Kusatsu, Japan. <sup>2</sup>Jilin University, Changchun, China. <sup>3</sup>Tohoku University School of Medicine, Sendai, Japan.

(No relationships reported)

**PURPOSE:** Intense long-duration exercise could lead to altered basal immune parameters probably due to a significant decrease in the circulating level of plasma glutamine. The decrease in plasma glutamine concentration as a consequence of intense long-duration exercise was shown to be reversed by BCAA supplementation. Moderate exercise induces remarkable changes in circulating number of lymphocyte subsets such as NK, NKT and T cells. However, less is known whether administration of high-dose BCAA would modulate the immune parameters to a single bout of moderate exercise. The aim of the present study is to investigate the effect of BCAA supplementation on the number of circulating immune cells during and after moderate exercise.

**METHODS:** Ten healthy, young male triathletes of age 21.8 ± 1.5 yr participated in the present double-blind, placebo-controlled study. Each subject performed four trial conditions in a random order with at least a seven-day interval: exercise + BCAA (14 g), exercise + placebo, sedentary + BCAA, and sedentary + placebo. Exercise was performed on a bicycle ergometer for 1 h at 60% VO<sub>2</sub>max. BCAA or placebo supplements were given orally 20 min before exercise. Blood samples were collected 30 min before exercise, immediately after and 2 h post-exercise. Plasma catecholamines (epinephrine, norepinephrine and dopamine) were measured by high-performance liquid chromatography. Plasma cortisol concentrations were determined by radioimmunoassay. Complete blood count analysis was performed using an automated hematology analyzer. Lymphocytes subsets were determined by flow cytometry.

**RESULTS:** Exercise induced significant elevations in the concentrations of plasma catecholamines. Plasma catecholamines were remarkably increased immediately after exercise. However, no significant change was observed in plasma cortisol. BCAA did not modify the stress hormone responses to exercise. Exercise led to significant increases in numbers of leukocytes and lymphocyte subsets including NK cells, NKT cells, CD8+ and CD3+CD8+CD45RO+ T cells. However, no significant modification effect of BCAA was observed on these basal immune parameters to exercise.

**CONCLUSIONS:** BCAA had no modification effect on the hormonal and immune parameter changes in response to moderate exercise.

### Endurance-training Effects On Intracellular Calcium And Iron In Cd4+ Lymphocytes In Young And Old Men

Suzanne Broadbent, Dr. Southern Cross University, Lismore NSW, Australia.

(No relationships reported)

**PURPOSE:** Intracellular calcium (Ca<sup>2+</sup>) and iron (Fe<sup>3+</sup>) are critically involved in intracellular signalling within CD4<sup>+</sup> cells yet little is known of long-term exercise effects on these variables in relation to CD4<sup>+</sup> activation and function. We investigated the effects of 12 months of aerobic/endurance exercise on Ca<sup>2+</sup> and Fe<sup>3+</sup> concentrations within CD4<sup>+</sup> lymphocytes in old and young men compared to sedentary controls.

**METHODS:** We compared young (30±5 yr) trained (TRY, n=14) and sedentary (UTY, n=12) men to older (69±5) trained (TRO, n=14) and sedentary (UTO, n=10) men for 12 months. The TRY group completed daily endurance training (60-120 min day, 60-80% VO<sub>2peak</sub>) while the TRO group cycled for three 60 min sessions per week (60-75% VO<sub>2peak</sub>). Venous blood was analysed every month for resting lymphocyte counts. CD4<sup>+</sup> cells were separated and stimulated with thapsigargin to quantify Ca<sup>2+</sup>, using Fluo-3 AM and flow cytometry. Further CD4<sup>+</sup> lymphocytes were incubated with Calcein AM to assess Fe<sup>3+</sup> (flow cytometry).

**RESULTS:** The TRY group had a significantly higher CD4<sup>+</sup> concentration than UTY for 4 months (37±7%, p<0.05); no CD4<sup>+</sup> count difference between TRO and UTO. Ca<sup>2+</sup> was significantly higher in January for all groups (TRY=298±5 nM; UTY=260±15 nM; TRO=160 nM; UTO=210 nM) with significant increases also in September A and July. TRY and UTY had significantly higher peak Ca<sup>2+</sup> (70±4%, 20±3%) compared to TRO and UTO. UTO Ca<sup>2+</sup> was significantly higher in September A but lower in January compared to TRO; TRY was higher in November compared to UTY. There was an inverse relationship between Ca<sup>2+</sup> and Fe<sup>3+</sup>, with significantly lower Fe<sup>3+</sup> in January-February (all groups), July (TRO, UTO) and September A (TRY, UTY). TRY and UTY (January) had less Fe<sup>3+</sup> (-66±6%, -65±6%, p<0.05) than TRO and UTO (February). TRY had significantly higher Fe<sup>3+</sup> than UTY in November; UTO had higher Fe<sup>3+</sup> than TRO in May.

**CONCLUSIONS:** Training had little effect on Ca<sup>2+</sup> and Fe<sup>3+</sup> although CD4<sup>+</sup> increased in the TRY group. Significant spikes in Ca<sup>2+</sup> and Fe<sup>3+</sup> may relate to increased intracellular signalling and/or transcription, and seasonal changes in CD4<sup>+</sup> function, during January, July and September. Age-related differences in Ca<sup>2+</sup> and Fe<sup>3+</sup> may be due to changes in intracellular Ca<sup>2+</sup>/Fe<sup>3+</sup> storage and signalling with ageing.

**3421** Board #142 June 2 9:30 AM - 11:00 AM

### Dietary Nucleotide Supplementation Improves The Immune Response After Strenuous Exercise In A Cold Environment

Daniel Martínez-Puig<sup>1</sup>, Joan Riera<sup>2</sup>, Victoria Pons<sup>2</sup>, Carles Chetrit<sup>1</sup>. <sup>1</sup>BIOIBERICA S.A., Palafoxs, Spain. <sup>2</sup>Centre d'Alt Rendiment (GIRSANE), Sant Cugat del Vallés, Spain.

(D. Martínez-Puig: Contracted Research - Including Principle Investigator; BIOIBERICA S.A.)

Strenuous exercise has been classically associated to immune-suppression and consequently to an increased risk of infections, especially at the upper respiratory tract.

**PURPOSE:** The aim of the present study was to test the impact of a specific nucleotide formulation (Inmunactive, Bioiberica, Spain) on the immune function of athletes after a heavy exercise bout in cold conditions.

**METHODS:** Twenty male taekwondo athletes with a mean (±SD) age, height, weight, percent body fat, of 21.4±6.3 years, 178.1 ±8.5 cm, 73.86±12.6 kg, 12.53±3.2 % were included in a double-blind placebo-controlled trial. Two weeks before the test, all the subjects performed a cycling maximal incremental test to determine his maximal oxygen uptake (VO<sub>2</sub>max), and the corresponding Watts at 60% (W1) 70% (W2) and 90% (W3) of VO<sub>2</sub>max were calculated by linear interpolation.

The subjects were randomly divided into two groups of 10 subjects and were supplemented with placebo or Inmunactive at 600mg/day during a period of 30 days. On day 0 and on day 30 each subject undertook an exhaustion exercise test using a cycloergometer at work corresponding to W1 for 10 min, W2 for 20 min and W3 until fatigue. Skin temperature (T<sub>sk</sub>), core temperature (T<sub>c</sub>), heart rate (HR), lactate [La] and rating of perceived exertion (RPE) was recorded during the test. Immediately before, 30 minutes, 150 minutes and 24 hours after the test, blood and saliva samples were obtained for determination of blood cell concentrations, index of total lymphocyte proliferation (LTP) and salivary immunoglobulin A (SIgA).

**RESULTS:** On day 30, LTP decreased at 24h after the exercise test in the placebo group but not in the Inmunactive group (-15,34±5,25 vs 13,15±4,97, P<0,01). SIgA differences between Day 1 and Day 28 were significant at 150 min post exercise with a greater decline in subjects taking placebo compared to those taking nucleotides (1,85±1,9 vs -0,50±2 mg/dL, P<0,05). No differences were detected in physiological parameters such as Tsk, Tc or HR. On day 30, the RPE was lower (P<0,05) in subjects of Inmunactive group compared to placebo after 10, 20 and 30 min of exercise.

**CONCLUSIONS:** These findings suggest that supplementation with a nucleotide-based product for 4 weeks could counteract the impairment of immune function after heavy exercise.

**The Effect Of Docosahexaenoic-rich Fish Oil Supplementation On Cytokines Production By Neutrophils And Lymphocytes Before And After A Marathon Race**

Vinicius Coneglian Santos<sup>1</sup>, Adriana Cristina Levada-Pires<sup>1</sup>, Samia Rocha Alves<sup>2</sup>, Tânia Crisitna Pithon-Curi<sup>2</sup>, Rui Curi<sup>1</sup>, Maria Fernanda Cury-Boaventura<sup>2</sup>.

<sup>1</sup>Universidade de São Paulo, São Paulo, Brazil. <sup>2</sup>Universidade Cruzeiro do Sul, São Paulo, Brazil.

(No relationships reported)

**PURPOSE:** Prolonged intense exercise such as marathon race is associated with transient suppression of immune function and alterations on neutrophils and lymphocytes function.

**OBJECTIVE:** The aim of this study was to investigate the effect of docosahexaenoic (DHA)-rich fish oil (FO) supplementation on cytokines production by neutrophils and lymphocytes before and after a marathon race.

**METHODS:** Twenty one athletes participated in this study, eight marathon runners were supplemented with 3 g of FO daily for 60 days (FO group) and thirteen athletes were not supplemented (C group). The cytokines (IL-1ra, IL-2, IL-10 and TNF- $\alpha$ ) production by lymphocytes and neutrophils ( $2 \times 10^6$ ) were determined in the culture supernatant before and after race.

**RESULTS:** In the C group, marathon race decreased IL-2, TNF- $\alpha$  and IL-10 production by lymphocytes (by 55%, 95% and 50 %, respectively) and IL-1ra (by 80%) production by neutrophils. The FO supplementation decreased IL-1ra (by 48%) and increased IL-10 (by 82%) production by neutrophils but not altered cytokines production by lymphocytes before and after the marathon race.

**CONCLUSION:** DHA-rich FO supplementation prevented the decrease in cytokine production by lymphocytes and had a partial anti-inflammatory effect on cytokines production by neutrophils.

**Training Of A Female World-elite Rower In Pre-olympic Year**

Yongming Li<sup>1</sup>, Wei Zi<sup>2</sup>, Chunmei Cao<sup>3</sup>, Xiaoping Chen<sup>4</sup>, Ulrich Hartmann<sup>1</sup>. <sup>1</sup>Faculty of Sport Science, University of Leipzig, Leipzig, Germany. <sup>2</sup>Faculty of Sport Science, Henan University, Kaifeng, China. <sup>3</sup>Department of Physical Education, Tsinghua University, Beijing, China. <sup>4</sup>Faculty of Sport Science, Ningbo University, Ningbo, China. (Sponsor: Ralph Beneke, FACSM)

(No relationships reported)

Rowing is an aerobic-dominated sport with approximate 80% of aerobic energy supply. Therefore, a huge amount of training is required to be emphasized on aerobic endurance. For training practice it is also important to know the load structure of different intensity categories.

**PURPOSE:** This study aims to analyze the training intensity distribution of a Chinese women single scull (W1x) in pre-Olympic year, who was successful several times in world championships and Olympic Games (OG).

**METHODS:** The training load of a W1x sculler (32yrs, 177cm, 71kg, 18yrs of training experience as rower) in pre-Olympic year was analyzed according to the recording of actual training. All the rowing on water and ergometer, as well as cross-training (running and cycling) from October, 2007 to OG in 2008 was documented in minutes. As established by Seiler et al., three zones of intensity were divided by lactate threshold 1 (LT1, approximate 2 mM) and lactate threshold 2 (LT2, approximate 4 mM).

**RESULTS:** In the observed period, 5827km (127km/week) were covered by the W1x, including 4202km on water, 910km on ergometer, and 715km in running and cycling. When divided by intensity zones, 75.2% of the distance was distributed in zone 1. The percentage of zone 2 and zone 3 was 22.4% and 2.4%, respectively. After dividing the training year into preparatory period (October to middle of March) and competition period (middle of March to OG), it was found that the training at or around lactate threshold (zone 2) decreased significantly from 34.4% in the preparatory period to 8.7% in the competition period, which was sacrificed by increasing the training volume in zone 1 and 3 from 63.5% to 88.6%, and from 2.1% to 2.7%, respectively.

**CONCLUSIONS:** Compared with the so-called polarized-training model on the basis of diary record of training session, the training of the studied subject on the basis of recording every actual training minute is, otherwise, pyramid-like. This is not in line to the findings of Seiler et al. Quantification of training load based on training sessions can overestimate the high intensity volume (zone 3), which deviates from the physiological background of training in endurance sports.

---

**3424** Board #145 June 2 8:00 AM - 9:30 AM

**The Effect of 8 Weeks of Race Walk Training on Maximum Oxygen Capacity**

Erika R. Shaver, Anthony Caterisano, FACSM, Ian Whatley, Raymond F. Moss. *Furman University, Greenville, SC.*

(No relationships reported)

Race walking is a competitive sport that has somewhat limited popularity in the US despite its inclusion as an Olympic event. Little research has been done on the fitness benefits of this low-impact form of aerobic training compared to other higher impact aerobic activities.

**PURPOSE:** To test the efficacy of an 8-week race walking program on maximum oxygen uptake (VO<sub>2</sub>max) among untrained women.

**METHODS:** Ten untrained women (mean age = 26.3 ± 1.8 yr.) volunteered to participate in the study. All subjects were tested for VO<sub>2</sub>max via open circuit spirometry on a motorized treadmill using a modified Astrand graded exercise protocol pre- and post-training. Over the 8-week training period subjects were instructed on proper race walking technique and individually trained by a coach 2-3 days per week for 20-30 minutes per day, starting with 20 minutes per day but progressing each week until each was training 30 minutes per day 3 days per week. Data were analyzed using a T-test.

**RESULTS:** Subjects showed a significant increase in VO<sub>2</sub>max from 36.73±1.22 ml/kg/min to 39.03±1.28 ml/kg/min (P<0.01), which represents a 6.26% improvement.

**CONCLUSIONS:** The improvement in VO<sub>2</sub>max of 6.26% is in line with similar training results found in studies using the same time frame but different higher impact training modes. These results suggest that race walking is a viable alternative to other high impact modes of aerobic training with the potential for less injury risk associated with these traditional modes.

3425 Board #146 June 2 8:00 AM - 9:30 AM

**Change in Aerobic Efficiency Among Novice Female Race Walkers Following 8 Weeks of Training**

Anthony Caterisano, FACSM, Erika R. Shaver, Ian Whatley, Raymond F. Moss. *Furman University, Greenville, SC.*  
(No relationships reported)

Race walking is an Olympic track and field event that requires strict adherence to rules on proper walking form. Novice race walkers must master specific techniques for legal race walking or face disqualification for breaking form during a race.

**PURPOSE:** To measure the aerobic efficiency of novice race walkers and see how it changes during a 4 week and 8 week time period of training.

**METHODS:** Ten untrained, females (mean age = 26.3 ± 1.8 yr.) volunteered and were tested for baseline  $\text{VO}_2\text{max}$  via open circuit spirometry on a motorized treadmill, using a modified Astrand graded exercise test. Following an orientation day in which subjects learned proper race walking technique, they returned to the lab and were tested for  $\text{VO}_2$  while race walking at 14 MPH on a motorized treadmill. Subjects were individually trained 2-3 days per week for 20 - 30 minutes per workout, with a gradual progression from 20 min./workout, 2 days/wk. to 30 min./workout 3 days/wk. The 14 MPH race walking testing protocol was performed after week 4 of training. After week 8 of training the  $\text{VO}_2\text{max}$  and the 14 MPH race walking test were repeated. The  $\text{VO}_2$  data were expressed as a % of  $\text{VO}_2\text{max}$  for each testing interval. In addition, stride length and frequency were monitored during the 14 MPH trials using a Dartfish™ analysis. An ANOVA with a Tukey post hoc test was used to analyze differences between means.

**RESULTS:** As training progressed from week 1 through week 8 the subjects showed a significant decrease in the % of  $\text{VO}_2\text{max}$  needed to maintain the 14 MPH race walk. Statistical analysis showed a significant difference between % of  $\text{VO}_2\text{max}$  as follows: Week 1 (67.26 ± 2.49%) week 4 (66.54 ± 2.69%) and week 8 (63.01 ± 2.12%,  $p \leq 0.05$ ). This was accompanied by a significant increase in stride rate as follows: week 1 (141.85 ± 7.16 strides/min.) week 4 (142.85 ± 8.62 strides/min.) and week 8 (145.38 ± 9.161 strides/min.,  $p \leq 0.05$ ).

**CONCLUSIONS:** The results of this study suggest that aerobic efficiency among novice race walkers can be improved in 8 weeks of training and that the improvements appear to be related to increased stride frequency.

3426 Board #147 June 2 8:00 AM - 9:30 AM

**Effect Of Different Dose Of Exercise Volume And Intensity On Peak O2 Consumption In Adult Men**

Jiashi Lin, Yi Yan, Hao Su, Yueqin Yang, Xian Guo, Yan Zhao, Minhao Xie. *Beijing Sports University, Beijing, China.* (Sponsor: Lili Ji, FACSM)  
(No relationships reported)

**PURPOSE:** Although higher levels of cardiorespiratory fitness (CRF) associate with lower cardiovascular disease (CVD), the exercise prescription required for the optimal enhancement is not known, moreover, the mechanisms for the different effects of volume or intensity on peak  $\text{O}_2$  consumption ( $\text{VO}_{2\text{peak}}$ ) remain sparse. This study was to determine whether exercise prescriptions differing in volume or intensity also differ in their CRF after 12 weeks training, and investigate the mechanisms for increases in  $\text{VO}_{2\text{peak}}$  with different dose.

**METHODS:** A total of 67 sedentary subjects aged 40-49yr were assigned to participate for 12 weeks in a control group or in one of three exercise groups: 1) low volume/moderate intensity (LVMI, equivalent of ~19km/wk, 1200kcal/wk at 40-55% $\text{VO}_{2\text{peak}}$ ), 2) low volume/vigorous intensity (LVVI, ~19km/wk, 1200kcal/wk at 65-80% $\text{VO}_{2\text{peak}}$ ) and 3) high volume/vigorous intensity (HVVI, ~32km/wk, 2000kcal/wk at 65-80% $\text{VO}_{2\text{peak}}$ ). Participants were instructed to not change their usual diet throughout the study. The 47 subjects who complied with these guidelines served as the basis for the main analysis.  $\text{VO}_{2\text{peak}}$  and time to exhaustion (TTE) were tested before and after 12 weeks training. Maximal cardiac output (Q) and stroke volume (SV) were measured using echocardiography, maximal arterial-venous  $\text{O}_2$  difference ( $a\text{-vO}_{2\text{diff}}$ ) was calculated from the equation:  $a\text{-vO}_{2\text{diff}}(\text{ml O}_2/100\text{ml blood}) = \text{VO}_2(\text{L}/\text{min})/(\text{Q}/\text{L}/\text{min}) \times 100$ .

**RESULTS:** All exercise groups increased  $\text{VO}_{2\text{peak}}$  and TTE compared to the baseline.  $\text{VO}_{2\text{peak}}$  increased significantly ( $p < 0.05$ ) in both LVVI (29.36 ± 5.31 ml/kg/min vs 34.33 ± 4.18 ml/kg/min) and HVVI (32.11 ± 7.67 ml/kg/min vs 37.35 ± 5.80 ml/kg/min) groups, 16.9% and 16.4% respectively; the LVVI resulted in greater improvement than the LVMI (29.28 ± 3.91 ml/kg/min vs 31.71 ± 4.11 ml/kg/min). It seems that  $\text{VO}_{2\text{peak}}$  is respond to intensity not volume. Maximal  $a\text{-vO}_{2\text{diff}}$  increased in all exercise groups, but Q and SV only enhance in the two vigorous groups.

**CONCLUSIONS:** Although exercising at level of 19km/wk at 40-55% $\text{VO}_{2\text{peak}}$  is sufficient to increase  $\text{VO}_{2\text{peak}}$ , the vigorous intensity is more variable for increase  $\text{VO}_{2\text{peak}}$ . The improvement of Q and SV are better than  $a\text{-vO}_{2\text{diff}}$  for enhance  $\text{VO}_{2\text{peak}}$ .

3427 Board #148 June 2 8:00 AM - 9:30 AM

**ACSM Recommended Exercise Reduces Intrahepatic Triglyceride And VLDL-TG Secretion Rate In Obese Individuals With Nafld**

Erik Kirk<sup>1</sup>, Shelby Sullivan<sup>2</sup>, Bettina Mittendorfer<sup>2</sup>, Bruce Patterson<sup>2</sup>, Samuel Klein<sup>2</sup>. <sup>1</sup>*Southern Illinois University Edwardsville, Edwardsville, IL.* <sup>2</sup>*Washington University in St. Louis School of Medicine, Saint Louis, MO.*  
(No relationships reported)

**Nonalcoholic fatty liver disease (NAFLD) and alterations in hepatic lipoprotein kinetics are common metabolic complications associated with obesity. Caloric restriction is often advocated for treating NAFLD, however, the effects of exercise alone on intrahepatic triglyceride (IHTG) content and VLDL-triglyceride (TG) secretion rate is unknown.**

**PURPOSE:** The aim of this study was to evaluate the effect of the American College of Sports Medicine physical activity guidelines for adults on IHTG content and VLDL kinetics in obese persons with NAFLD.

**METHODS:** Eighteen obese people (BMI=38.1 ± 4.6 kg/m<sup>2</sup>) with NAFLD were randomized to 16 weeks of verified exercise training (45-55%  $\text{VO}_{2\text{peak}}$ , 30-60 min x 5 days/week; n=12) or observation (control; n=6). Liquid formula dietary supplements were provided to prevent exercise-induced weight loss. Magnetic resonance spectroscopy and stable isotope tracer infusions in conjunction with compartmental modeling were used to evaluate IHTG content and hepatic VLDL-TG secretion rates.

**RESULTS:** Exercise training resulted in a 10.3 ± 4.6% decrease in IHTG content ( $p < 0.05$ ), but did not change total body weight (103.1 ± 4.2 kg and 102.9 ± 4.2 kg before and after training) or percent body fat (38.9 ± 2.1% and 39.2 ± 2.1% before and after training). Although not significant ( $p = 0.07$ ), exercise training did show a 5% reduction in VLDL-TG secretion rate (17.7 ± 3.9  $\mu\text{mol}/\text{min}$  and 16.8 ± 5.4  $\mu\text{mol}/\text{min}$  before and after training).

**CONCLUSIONS:** Performing physical activity as recommended by the ACSM reduces IHTG content and hepatic lipoprotein kinetics in obese persons with NAFLD.

3428 Board #149 June 2 8:00 AM - 9:30 AM

**Recumbent Cross-Training is a Viable Exercise Option for Overweight Adults**

Heidi B. IglayReger, Timothy A. Muth, Christine A. Robert, Mark D. Peterson, Paul M. Gordon, FACSM. *University of Michigan, Ann Arbor, MI.*  
(No relationships reported)

Though recumbent fitness equipment is a valuable exercise and rehabilitation tool, particularly for older or physically disabled populations, it is an underutilized modality in other populations. Overweight individuals often gravitate towards recumbent equipment, as these low-impact modalities are better tolerated. However, the metabolic cost of recumbent exercise is not clearly defined in this population, precluding its endorsement by health care professionals.

**PURPOSE:** To assess the metabolic cost of recumbent cross-training (rX) and recumbent bicycling (rB) in overweight adults at prescribed and self-selected intensities.

**METHODS:** Subjects performed exercise on a recumbent cross-trainer (utilized arms and legs) and a recumbent bicycle at 60% of treadmill  $\text{VO}_2$  max (int60) and at a self-selected intensity (intSS). The orders of these testing days and intensities were counterbalanced. Resistance was varied to achieve these intensities while cadence remained constant (80 spm/rpm); subjects were blinded from workloads.  $\text{VO}_2$  and VE dynamics (K4b2, Cosmed, Rome, Italy), heart rate (Polar Team2, Polar Electro, New Hyde Park, NY), blood pressure and ratings of perceived exertion (RPE) were measured throughout condition. Subjects completed a questionnaire after both intensities of exercise on each piece of equipment (4 total) to assess overall ratings of the exercise equipment. Differences between conditions were assessed via paired t-tests. Data presented as mean ± SE.

**RESULTS:** Sixteen (n=8 female) overweight (BMI 31 ± 1 kg/m<sup>2</sup>) adults (40 ± 3y, range 20-54y) completed this study. Both objective (HR and  $\text{VO}_2$ ) and subjective (RPE) exertion were higher

in int60 vs. intSS for rX (HR, VO<sub>2</sub> RPE: 129±3bpm, 18.4±1.0 ml·kg<sup>-1</sup>, 15±1 vs. 113±6bpm, 13.8±1.1 ml·kg<sup>-1</sup>, 12±1, p<0.05 all), but not for rB (p>0.05 all). There were no differences in int60 for rX vs. rB, though intSS HR and VO<sub>2</sub> were lower in rX vs. rB (rB 131±6bpm, 16.9±0.7 ml·kg<sup>-1</sup>, p<0.05). Exercise equipment preference did not differ between modalities or intensities.

**CONCLUSIONS:** Though overweight individuals chose to exercise at a lesser intensity while rX, both rX and rB elicited metabolic responses consistent with recommended exercise intensities for weight management and provide a viable low-impact activity for this population.

**The Effect Of Rubber Tube Harness Training Device On Selected Physiological Variables In Young Male Subjects**

Anita Haudum, Jürgen Birklbauer, Roland Sieghartsleitner, Christoph Gonaus, Serge P. von Duvillard, FACSM, Erich Müller. *University of Salzburg, Hallein-Rif, Austria.*

(No relationships reported)

**PURPOSE:** We investigated the effect of rubber tube harness training device where the rubber tubes were attached between the ankle and the lower back on selected physiological and metabolic variables during constant running speed of 30 min in healthy male subject (mean±SD: age 26.3±8.4 yrs; Wt: 74.4±2.5 kg; Ht: 178.0±8.7 cm; BMI: 23.3±1.6 kg.m-2).

**METHODS:** 18 subjects were divided into 2 groups. One group (N=10) served as experimental (EG) and the other (N=8) as comparison group (CG). Both groups underwent the same tests of 30min at constant speed of 10.5 km.h-1. Test 1 (T-1) was conducted in the beginning with and without rubber tube harness in both groups, followed by Test 2 (T-2) after 7 wk, and again 7 wk after the last test (T-3). Both groups trained for a total of 18 training sessions for 7 wk for 45min during first wk, increasing time to 50min (at wk 2) and 55min at wk 4-7; however, the CG group trained without rubber tube harness throughout 7 wk and conducted the same constant running training sessions.

**RESULTS:** Statistical analysis, repeated measure analysis of variance revealed no statistically significant difference for oxygen uptake, minute ventilation, breathing frequency, tidal volume, caloric unit cost (P>0.05). The only metabolic variable that was significant was blood lactate (LA) (P<0.05). There were statistically significant differences in blood LA in T-1 between both groups running with and without rubber tubes only (P<0.05). At T-2, there was a significant reduction in blood LA for EG with rubber tube harness running from T-1 to T-2 (P<0.006) and for CG between T-1 and T-2 for running without the tubes (P<0.05). There were no statistical differences at T-3.

**CONCLUSION:** Our results suggest that the use of this training device does not appear to yield additional training benefits but the use of rubber tube harness device may be useful as a training modality. However, changes in testing protocol, intensity of training, duration and frequency may also alter the test results as well as better control of the comparison group.

**3430 Board #151 June 2 8:00 AM - 9:30 AM**

**Comparison of Alter-G Treadmill Run Training to Land Treadmill Training**

Dustin P. Joubert<sup>1</sup>, Brad S. Lambert<sup>1</sup>, Nicholas P. Greene<sup>2</sup>, Stephen F. Crouse, FACSM<sup>1</sup>. <sup>1</sup>Texas A&M University, College Station, TX. <sup>2</sup>University of Virginia, Charlottesville, VA.

(No relationships reported)

**PURPOSE:** The Alter-G (AG) treadmill utilizes a lower-body inflation chamber to decrease an individual's body weight and impact while running. There is little research investigating the long-term training effects of this device, particularly in comparison to land treadmill (LT) training.

**METHODS:** Ten subjects (5 male, 5 female; 37 ± 12 yrs; 83 ± 29 kg) performed a Bruce treadmill protocol to determine VO<sub>2</sub>max at the beginning and end of 12-weeks of AG training at 70% body weight. Subjects trained 3 days/week progressing from 60-85% VO<sub>2</sub>max and from 250-500 kcal/session. DEXA body composition was also assessed. AG subjects were then matched with 10 subjects (5 male, 5 female; 41 ± 11 yrs; 86 ± 18 kg) who had previously completed the same training prescription for LT at full body weight and underwent the same physiological testing. For all independent variables, the change (End - Beginning) was calculated for each group. The change data were analyzed using a 2 (group) x 1 (change) SAS mixed model ANOVA with a Tukey's post hoc test for group. The main effect for group was used to determine between group significance. Within group significance was determined using p-values for least square means estimates for each group's change scores.

**RESULTS:** See table.

|                 | Body Mass (kg) | % Fat      | Fat Mass (g) | Lean Mass (g) | FM Arms (g)  | FM Trunk (g)  | Bruce Time (min) | VO <sub>2</sub> max (ml/min) | VO <sub>2</sub> max (ml/kg/min) |
|-----------------|----------------|------------|--------------|---------------|--------------|---------------|------------------|------------------------------|---------------------------------|
| AG (n=10)       | 0.8 ± 2.5      | -0.9 ± 2.0 | -330 ± 1842  | 1086 ± 1185** | 27 ± 192     | -409 ± 1247   | 0.55 ± 0.95**    | 160.5 ± 160.4**              | 2.2 ± 2.0**                     |
| LT (n=10)       | -1.2 ± 2.3     | -0.5 ± 1.3 | -1069 ± 1626 | -324 ± 1712   | -139 ± 222** | -816 ± 1205** | 1.58 ± 0.37**    | 272.2 ± 298.0**              | 3.7 ± 3.6**                     |
| Between p-value | 0.087          | 0.593      | 0.354        | 0.046*        | 0.091        | 0.467         | 0.005*           | 0.310                        | 0.281                           |

Values mean change ± SD.  
p-values in table for between group differences. \*p < 0.05 between groups.  
Within group significance indicated in group rows. \*\*p < 0.05 within group.

**CONCLUSIONS:** AG training did equally well in improving VO<sub>2</sub>max but achieved lower gains in Bruce time compared to LT. AG increased lean mass, while LT decreased fat mass in more regions. This was in line with the overall tendency towards slight body mass increases in AG and slight weight loss in LT. Overall, AG had a positive effect on fitness markers, but was less specific at improving run performance.

**Metabolic Cost Comparison Of Running On An Aquatic Treadmill With Water Jets And Land Treadmill With Incline**

Ryan Porter, Sarah Blackwell, Gerald Smith, FACSM, Dale Wagner, Dennis Dolny. *Utah State University, Logan, UT.*

(No relationships reported)

**PURPOSE:** This study investigated whether running on a land treadmill (TM) at specific inclines provides a comparable energy expenditure (EE, oxygen consumption,

**METHODS:** Sixteen participants completed two trials on separate days on a TM and ATM. For each trial subjects performed eighteen, 3-4 min submaximal runs at three self selected speeds (slow, medium, and fast) with either water jet resistances of 0-100% of maximum jet flow capacity in 20% increments during ATM or inclines of 0-10% in 2% increments during TM. Trials were separated by at least 48 hours. Oxygen consumption (VO<sub>2</sub>), heart rate (HR), and rate of perceived exertion (RPE) were recorded during each trial. Repeated Measures ANOVA (GLM) with post hoc analysis identified location of significant differences

**RESULTS:** VO<sub>2</sub> increased (p<0.001) in linear fashion during TM with each increase in incline. When running at similar speeds with no resistance (jets or incline) or with 20% jets ATM yielded lower (p<0.001) VO<sub>2</sub> than TM. ATM with 40% jets matched EE during TM at 0% incline. ATM with 60% jets EE was similar to TM with 4% incline while EE was greater (p<0.01) during ATM 80% and 100% jets compared to TM with 8% and 10% incline. Comparable relationships were observed for HR while RPE was similar for ATM and TM except at 80 and 100% jets in ATM that were greater (p<0.01) compared to TM 8 and 10%.

**CONCLUSIONS:** While TM yields a linear increase in EE with increasing incline, ATM with jet flows yield a non-linear increase with little change in EE with jet resistance changes from 0-20%, linear increase in EE from 20-60% with an exponential increase in EE from 60-100%. This relationship may be a result of non-linear application of drag forces on the torso created by the velocities of the water jets. With appropriate selection jet resistances in ATM can be used to mimic EE during inclined TM running on land.

3432 Board #153 June 2 8:00 AM - 9:30 AM

**Effects of Intermittent Hypoxia or Hyperoxia during High-Intensity Interval Training on Endurance Determinants**

Ting Yao Wang, male, Mein Mein Lee, female, Chun Yi Shih, male, Kuei Hui Chan, female. *National Taiwan Sport University, Taoyuan County, Taiwan.*  
(No relationships reported)

Comparing with breathing normoxia, hyperoxia improves exercise performance and decreases blood lactate concentrations in steady-state and hypoxia enhances responses of cardiac output, heart rate, ventilation, and sympathoadrenergic activity during exercise. High-intensity interval training (HIT) provides an up-regulated contribution on both of aerobic and anaerobic metabolism which enhances the availability of ATP and improves the energy status in working muscle. Breathing intermittent hypoxia or hyperoxia during HIT may provide different effects in endurance determinants.

**PURPOSE:** To compare the effects of inspiring hypoxia, normoxia or hyperoxia in recovery intervals during HIT on  $\dot{V}O_{2\max}$ , ventilatory threshold (VT) and time to fatigue (Tlim).

**METHODS:** Twenty four healthy male participants were randomly assigned to hypoxia (N=8, 22.3±2.5 yrs, 16%  $O_2$ ), normoxia (N=8, 22.3±1.9 yrs, 20.9%  $O_2$ ) or hyperoxia (N=8, 21.9±3.3 yrs, 60%  $O_2$ ) groups and assessed by continuous incremental running test on treadmill before and after training. Participants performed HIT (7 bouts, 4-min interval at 90%  $\dot{V}O_{2\max}$ , 2-min rest between intervals) with different oxygen concentration provided in recovery intervals in 2 weeks (3 d-wk<sup>-1</sup>).

**RESULTS:** There was no significant difference among groups in all variables before training ( $p>0.05$ ). After training, the hypoxia and normoxia groups significantly improved VT (hypoxia: 2.73±0.22 vs. 2.94±0.13 m/s; normoxia: 2.56±0.37 vs. 2.82±0.41 m/s,  $p<0.05$ ) and Tlim (hypoxia: 1094.4±50.5 vs. 1140.0±78.5 seconds; 1090.0±52.1 vs. 1121.9±41.6 seconds,  $p<0.05$ ). The hypoxia group also increased the  $\dot{V}O_{2\max}$  (3.63±0.71 vs. 3.96±0.66 L/min,  $p<0.05$ ). However, there was no significant difference in  $\dot{V}O_{2\max}$ , VT and Tlim in hyperoxia group after training.

**CONCLUSIONS:** Intermittent hypoxia during HIT may improve more aerobic capacity than breathing normoxia in the recovery intervals. However, breathing higher oxygen concentration in recovery intervals during HIT may inhibit the improvement of aerobic capacity.

**Hyperventilation-induced Alkalosis as a Strategy for Improved Intermittent Sprint Performance**

Akihiro Sakamoto, Hisashi Naito. *Juntendo University, Chiba, Japan.*  
(No relationships reported)

During high-intensity exercise, a fall in intra- and extracellular pH is a major cause of muscle fatigue. Induced alkalosis by ingesting sodium bicarbonate has been shown to improve performance when the exercise task is repeated and incurs a substantial metabolic challenge. Hyperventilation can provide similar effects on blood pH, however its effect on exercise performance has been studied using low intensities or a single bout of exercise (unsuitable exercise for maximally eliciting buffering effects), thus producing no ergogenic effect.

**PURPOSE:** To investigate the effect of hyperventilation performed during recovery separating repeated maximal pedaling.

**METHODS:** This was a randomized, crossover, counter-balanced study, where subjects performed both control and hyperventilation conditions on two occasions. Ten power-trained males (age: 21 ± 2 y-o, training experience: 6 ± 2 yrs, training frequency: 5 ± 1 times/wk) performed 10 × 10 s maximal pedaling on a cycle ergometer (7.5 % body mass, kp) with 60 s recovery between sets. Spontaneous breathing was performed during recovery for the control. For the hyperventilation condition, subjects breathed at 60 breaths/min during the last 30 s of recovery, with expired breaths being monitored breath-by-breath and the tidal volume adjusted so that the end-tidal  $PCO_2$  was below 25 mmHg before each sprint. Peak and mean power outputs, blood pH,  $PCO_2$  and  $[La^-]$  were measured during the exercise.

**RESULTS:** Blood pH was elevated and  $PCO_2$  was lowered by hyperventilation at any time points measured ( $p < 0.001$ ). Condition effect was not significant for both peak and mean power outputs. A significant condition × time interaction (peak power:  $p = 0.035$ , mean power:  $p = 0.021$ ) however meant that the progressive reduction of power output was attenuated by hyperventilation.  $[La^-]$  had been expected to become higher for hyperventilation, associated with greater  $H^+$  efflux and sustained glycolytic energy supply, but were similar between conditions. Increased activity of respiratory muscles may have accelerated  $[La^-]$  clearance and countered the anticipated increase of  $[La^-]$ ; although the exact mechanism remains unknown.

**CONCLUSION:** Hyperventilation-induced alkalosis enhanced performance recovery during repeated maximal pedaling in the later exercise bouts.

No grant for this study.

**Endurance Performance, Total Haemoglobin Mass and Blood Volume Post Recombinant Human Erythropoietin Use in Trained Individuals**

Jérôme Durussel<sup>1</sup>, Tushar Chatterji<sup>1</sup>, Evangelia Daskalaki<sup>1</sup>, Diresibachew Haile<sup>2</sup>, Zeru Bekele<sup>2</sup>, Neal Padmanabhan<sup>1</sup>, Sandosh Padmanabhan<sup>1</sup>, Rajan K. Patel<sup>1</sup>, Timothy D. Noakes<sup>3</sup>, Günter Gmeiner<sup>4</sup>, John D. McClure<sup>1</sup>, Yannis P. Pitsiladis, FACSM<sup>1</sup>. <sup>1</sup>University of Glasgow, Glasgow, United Kingdom. <sup>2</sup>Addis Ababa University, Addis Ababa, Ethiopia. <sup>3</sup>University of Cape Town, Cape, South Africa. <sup>4</sup>Seibersdorf Labor GmbH, Seibersdorf, Austria.  
(No relationships reported)

Recombinant human erythropoietin (r-HuEpo) increases total haemoglobin mass (tHb), induces haemoconcentration and enhances exercise performance. Less is known about the time course of these mechanisms post r-HuEpo administration.

**PURPOSE:** To determine the effects of r-HuEpo during and post administration on tHb and related haematological profiles, plasma (PV) and blood (BV) volume and running performance.

**METHODS:** 10 endurance trained subjects (age: 26.1 ± 4.4 yrs, body mass: 68.8 ± 3.0 kg, height: 179.0 ± 5.9 cm) received r-HuEpo injections of 50 IU · kg<sup>-1</sup> body mass every two days for 4 weeks. tHb, PV and BV were weekly determined using the optimized CO-rebreathing method until 4 weeks after administration. 3,000 m time trials were performed pre, post administration and at the end of the study. Changes over time in tHb, PV and BV were assessed. Data were analyzed using t-test or repeated measures ANOVA as appropriate.

**RESULTS:** During r-HuEpo administration, tHb increased significantly by 0.59 g · kg<sup>-1</sup> · wk<sup>-1</sup> (95% confidence interval (CI) 0.45 to 0.73,  $p < 0.001$ ) from 13.2 ± 0.8 to 15.6 ± 1.2 g · kg<sup>-1</sup>, PV significantly decreased by 1.91 ml · kg<sup>-1</sup> · wk<sup>-1</sup> (CI -2.64 to -1.17,  $p < 0.001$ ) from 57.5 ± 4.1 to 51.2 ± 2.9 ml · kg<sup>-1</sup> and BV remained unchanged (-0.13 ml · kg<sup>-1</sup> · wk<sup>-1</sup> 95% CI -1.21 to 0.95,  $p = 0.78$ ). From week 1 to week 4 post r-HuEpo administration, the rate of decrease in tHb was similar to that of the increase during administration (-0.70 g · kg<sup>-1</sup> · wk<sup>-1</sup>, CI -0.91 to -0.49,  $p < 0.001$ ) but tHb was still significantly elevated at 4 weeks post administration compared to baseline (14.0 ± 0.9 vs. 13.2 ± 0.8;  $p = 0.030$ ). PV remained decreased post administration (0.06 ml · kg<sup>-1</sup> · wk<sup>-1</sup>, CI -1.30 to 1.43,  $p = 0.92$ ), while a significant decrease in BV was observed from 96.6 ± 7.1 to 90.4 ± 5.0 ml · kg<sup>-1</sup> (-1.88 ml · kg<sup>-1</sup> · wk<sup>-1</sup>, CI -3.68 to -0.07,  $p = 0.043$ ). Running performance improved by 5.5 ± 2.2% post administration (9.99 ± 0.87 min vs. 10.59 ± 1.04 min;  $p < 0.001$ ) and remained enhanced by 3.5 ± 2.5% 4 weeks after r-HuEpo compared to baseline (10.24 ± 1.01 min vs. 10.59 ± 1.04 min;  $p = 0.014$ ).

**CONCLUSION:** Running performance was improved following 4 weeks of r-HuEpo administration and remained elevated 4 weeks post administration compared to baseline. These performance effects coincided with r-HuEpo-induced elevated tHb and reduced PV compared to baseline.

3435 Board #156 June 2 8:00 AM - 9:30 AM

**High Volume Rowing Training Increases Serum Hepcidin And Ferritin**

Burkhardt Schleipen, Martina Velders, Katja Machus, Gunnar Treff, Constantin Mayer, Carola Wagner, Jürgen M. Steinacker, FACSM. *University of Ulm, Ulm, Germany.*  
(No relationships reported)

Hepcidin is a central regulator of iron metabolism through its ability to bind to the iron transporter ferroportin. Hepcidin is produced in the liver and suppresses intestinal iron absorption and stimulates iron retention in the reticuloendothelial system. Hepcidin expression increases in response to chronic infections. We hypothesized that a high intensity and high volume training increases hepcidin production.

**PURPOSE:** To analyze the effects of an intense rowing training with high volume on iron metabolism and hepcidin levels.

**METHODS:** 8 male rowers (17.8± 0.4 years, 84.3± 8.3 kg, 191.1± 4.4 cm) of the German Junior National Team were examined 5 times during a 4 week training camp in preparation for the world championships. Training intensity and volume were increased in the first two weeks followed by a tapering phase. Hepcidin, ferritin, transferrin (Tf) and soluble transferrin receptor (sTfR) were analyzed in serum samples by ELISA.

**RESULTS:** Hepcidin increased significantly during the intense phase of the training camp (11.5 ± 3.9 - 25.5 ± 13.5 µg/l, p<.05). Ferritin, with its double role as an acute phase protein and iron store, increased non-significantly in the early phase of the training camp (68.5 ± 16.9 - 90.4 ± 28.5 µg/l, ns). Both ferritin and hepcidin levels decreased during the later phase of the training camp and returned to baseline levels at the end. Tf and sTfR remained at baseline levels at all time points. Iron increased significantly during the initial phase of intense training and remained at elevated levels throughout the training camp (11.7 ± 3.2 - 19.2 ± 8.7 µmol/l).

**DISCUSSION:** The significant rise of hepcidin and the increase of ferritin in the beginning of the high volume/intensity training is most likely an acute phase reaction to the unaccustomed training load. With training adaptation and during tapering ferritin and hepcidin levels decreased to baseline levels after 3 weeks. Iron stores were not changed according to unchanged Tf and sTfR-levels. However the increased iron levels indicate a disturbance in iron metabolism. Our results show that high volume/intensity training leads to increased hepcidin levels. Further research is required to investigate the regulation of hepcidin through different training regimes and its impact on iron metabolism.

**3436 Board #157 June 2 8:00 AM - 9:30 AM**  
**Analysis of Yoga, Pilates and Standing Abdominal Exercises: An Electromyographic Study**

Michele Olson, FACSM. Auburn University Montgomery, Montgomery, AL.

(No relationships reported)

**PURPOSE:** Yoga, Pilates and standing exercises such as the “cross chop” have become widespread in fitness and conditioning for abdominal training. However, the utility of these exercises is largely undetermined. Thus, the purpose of this study was to determine and analyze the activation of the Rectus abdominis (RA) and External obliques (EO) during these exercises using electromyography (EMG).

**METHODS:** 15 adults (26.2 yr.) participated in the study. Nine exercises were tested: Yoga Boat, Yoga Dolphin Plank on Ball, Pilates Criss Cross, Pilates Sidebend, Standard Crunch, Standing Bicycle, Standing Cross Chop, Standing Front Crunch, Standing Sidebend. For EMG analysis, electrode pairs were applied over the area of each muscle according to Juker et al. 1998. During testing, EMG signals were monitored, amplified and processed through a Biopac converter (sampling rate 2,000 Hz). Maximal Voluntary Isometric Contractions (MVIC) were determined for normalization. Repeated measures ANOVA (p < 0.05) with Bonferroni adjustments was used to determine significant differences and assess pairwise contrasts.

**RESULTS:** The normalized results for RA and EO (% MVIC) were, respectively: Yoga Boat 75.96; Dolphin Plank-Ball 65.87; Pilates Criss Cross 65.83; Sidebend 63.40; Standard Crunch 64.79; Standing Bicycle 27.34; Cross Chop 22.29; Front Crunch 18.23; (standing) Sidebend 18.22. More specifically, the following were shown for RA activity (p. < 0.05): Yoga Boat > Dolphin Plank-Ball, Pilates Criss Cross, Sidebend, Standard Crunch > Standing Bicycle > Cross Chop, Front Crunch, (standing) Sidebend. For EO activity (p. < 0.05): Yoga Boat > Dolphin Plank-Ball > Pilates Criss Cross > Standard Crunch > Pilates Sidebend > Standing Bicycle > Cross Chop > Front Crunch, (standing) Sidebend.

**CONCLUSIONS:** Results show that “mat” exercises such as Yoga, Pilates and the Standard Crunch activated the RA and EO to a substantially higher degree compared to the standing abdominal exercises producing intensities generally above 60% MVIC. Researchers have suggested a threshold activation of 60% of MVIC for strength development and more modest intensities (20-40%) for endurance. Thus, the standing abdominal exercises tested here are likely not suited for developing strength but may be more appropriate for developing muscular endurance.

**3437 Board #158 June 2 8:00 AM - 9:30 AM**  
**Static Stretching with Short Duration Does Not Inhibit Subsequent 100-m Sprint Performance in Sprinters**

Yu-Ju Tsai<sup>1</sup>, Hsin-Wei Huang<sup>1</sup>, Pin-Hui Chen<sup>1</sup>, Yu-Hsuan Kuo<sup>1</sup>, Ching-Feng Cheng<sup>1</sup>, Wen-Tzu Tang<sup>2</sup>. <sup>1</sup>National Taiwan Normal University, Taipei, Taiwan.

<sup>2</sup>National Taiwan Sport University, Taoyuan County, Taiwan.

(No relationships reported)

Static stretching (SS), especially the total duration per muscle is longer than 90-s, before strength and power exercises has been showed to impair the performance in the untrained individuals. However, some studies reported that the performance impairments could be due to the duration of stimuli, e.g., > 30-sec for each SS, were excessively long compared with common practice.

**PURPOSE:** To determine the acute effects of SS exercise with short duration on the sprint performance in elite sprinters.

**METHODS:** Thirteen collegiate sprinters (age, 21.3 ± 2.1 yrs, height, 170.6 ± 6.3 cm, weight, 58.1 ± 8.9 kg; 6 males and 7 females) voluntarily participated in this randomized crossover designed study, and completed 2 trials separated by at least 2 days: SS and CON. After ~20-min specific warm-up, consisted of a series of dynamic movements, skip and hopping drills, and sprints, participants in the SS trial performed 4 repetitions of 15-sec SS exercise with 60-s rest interval for each muscle group (hamstrings, quadriceps, gastrocnemius and gluteus), while participants in the CON trial were asked to quietly sit on a chair for 12-min. After treatments, the sit-and-reach test was used to assess the flexibility. And then, participants were instructed to perform the 100-m sprint test, which was timed with an electronic timing system with gates set at 0, 20, 40, 60, and 100 m. Blood lactate (La) and ammonia (NH<sub>3</sub>) concentrations were also measured during the 100-m sprint test.

**RESULTS:** The flexibility in SS (25.0±10.0 cm) was significantly higher than that in CON trial (22.1±9.4 cm) (p<0.05, η<sup>2</sup>=0.36). There were no significant differences on the La and NH<sub>3</sub> levels before and after the 100-m sprint test between trials. No significant differences were found on the time of 100-m between trials (SS vs. CON, 12.14±0.87 vs. 12.15±0.86 sec, p>0.05), as well as the other segmental or cumulative time of 100-m. Changes in flexibility between SS and CON trials were significantly correlated with the changes in the last 20-m sprint time between trials (r=0.73, p<0.05).

**CONCLUSIONS:** Flexibility could be improved by the stretching stimuli with short duration, and the 100-m sprint performance in sprinters might not be inhibited by SS in this manner. However, the last 20-m sprint time might be compromised by the better flexibility of hamstrings and lower back muscles.

---

**3438 Board #159 June 2 8:00 AM - 9:30 AM**  
**Walking While Carrying a Golf Bag for 18 Holes Decreases Golf Performance**

Alan P. Jung, FACSM, Jacob T. Dellinger, Jeremy G. Cox, John K. Petrella, FACSM. Samford University, Birmingham, AL.

(No relationships reported)

**PURPOSE:** To evaluate golfers' driving accuracy, driving distance, and swing pattern while walking or riding in a golf cart.

**METHODS:** Twelve collegiate golfers (7 male and 5 female, ages 19-22 years) were recruited from a university golf team to participate in this study. To be included each participant had to be capable of shooting an 18-hole round of golf of 75 or less on average (handicap 3). Each participant completed two 18-hole rounds of golf separated by at least 48 hours. In one round the participants walked the 18-hole course while carrying a golf bag with 14 clubs. In the other trial participants rode in golf carts for 18 holes and did not carry their clubs. A Vector Pro launch monitor (Winston-Salem, NC) was placed at the tee box on holes 1 and 17 to measure ball speed, club head speed, and club angle. A handheld range finder was used to determine the driving distance from tee box to fairway. A cone was placed in the middle of the fairway, and driving accuracy was determined by measuring the perpendicular (left to right) distance from the cone to the ball.

**RESULTS:** A repeated measures ANOVA was performed to determine changes from hole 1 to hole 17. In the riding trial there was a significant increase in driving distance from hole 1 (243.8±44.2 yards) to hole 17 (250.6±43.8 yards; p=0.006), while in the walking trial there was a significant decrease in driving distance from hole 1 (252.6±34.6) to hole 17 (240.3±38.1 yards; p=0.02). In the riding trials there was no difference from hole 1 to hole 17 for ball speed, club head speed, accuracy or club angle (p=0.13-0.63). However, in the walking trial there was a significant decrease in performance from hole 1 to hole 17 for accuracy (p=0.001) and club angle (p=0.02). There was no difference in ball speed or club head speed between holes 1 and 17 in the walking trial (p=0.09-0.13). Additionally, participants recorded significantly lower values for distance (p=0.001), accuracy (p=0.003), and club angle (p=0.02) in the walking trial when compared to the riding trial.

**CONCLUSIONS:** Findings indicate a decrease in golf performance when walking and carrying clubs as measured by driving distance, driving accuracy, and club angle.

3439 Board #160 June 2 8:00 AM - 9:30 AM

**Effect Of Ultra-endurance Swimming In Open Water On Autonomic And Hormonal Responses: A Case Study**

Giuseppe Cibelli<sup>1</sup>, Mario De Rosas<sup>1</sup>, Maria I. Roselli<sup>1</sup>, Antonio I. Triggiani<sup>1</sup>, Anna A. Valenzano<sup>1</sup>, Giulia De Ioannon<sup>2</sup>, Maria F. Piacentini<sup>2</sup>, Laura Capranica<sup>2</sup>.

<sup>1</sup>University of Foggia, Foggia, Italy. <sup>2</sup>University of Roma Foro Italico, Roma, Italy. (Sponsor: Carl Foster, FACSM)

(No relationships reported)

**PURPOSE:** To investigate the effect of ultra-endurance swimming on the autonomic nervous system (ANS), the hypothalamic pituitary adrenocortical (HPA) axis, and sympatho-adrenomedullary (SAM) responses.

**METHODS:** A male athlete (48 years, 68 kg, 172 cm, BMI 23.2 kg/m<sup>2</sup>) performed an ultra-endurance swimming in open water (42.2 nm; 78.154 Km). Salivary cortisol (sC), alpha-amylase (sAA) and heart rate variability (HRV) were monitored at rest, 15 minutes before the start, at 90 min and 18 hrs of the recovery phase. Salivary biomarkers were analyzed using commercial kits. The HRV was measured in 5-min segments of paced breathing and quantified by time and frequency domain analysis and the Poincaré plot analysis. Intervals between heartbeats (R-R intervals), square root of the mean squared successive differences between normal-to-normal RR intervals (RMSSD), the ratio (%) of successive R-R interval differences >50ms (pNN50), low-frequency power (LF) (from 0.04 to 0.15 Hz), high frequency power (HF) (from 0.16 to 0.40 Hz), instantaneous beat-to-beat variability (SD1) and continuous beat-to-beat variability (SD2) of the data were considered.

**RESULTS:** the athlete finished the ultra-endurance swimming in 23:44 hr:min. During the swimming, heart rate ranged between 120-125 beats.min<sup>-1</sup>. At 90 min after arrival, marked sAA (58.1 to 117.7 U/ml) and sC (3.5 to 81.0 nmol/l) increases were observed, which returned to pre-swimming levels at 18 hrs of recovery. Compared to rest, lower R-R intervals (925.7 to 695.8 ms), RMSSD (23.1 to 14.6 ms), pNN50 (2.0 to 0.0 %), LF (824 to 197 ms<sup>2</sup>), HF (174 to 47 ms<sup>2</sup>) and SD1 (19.0 to 10.3 ms), SD2 (74.2 to 30.4 ms) values were observed at 90 min after arrival, which persisted at 18 hrs of the recovery.

**CONCLUSION:** Low-intensity long-duration swimming elicits a relevant ANS, HPA and SAM responses. In particular, HRV analysis evidenced a strong decrease of HRV parameters, thus reflecting short- and long-term variability, while the sympathovagal balance remained unchanged. Interestingly, hormonal markers returned to pre-swimming levels after 18 hrs of recovery, while HRV variables did not turn back, suggesting that the cardiac response to low-intensity long-duration workload could be differently influenced by both adaptive central and peripheral autonomic and hormonal patterns.

---

3440 Board #161 June 2 8:00 AM - 9:30 AM

**Intramuscular Temperature Responses of 4 Lower Extremity Muscles to Whole Body Vibration Training**

Cameron Shumway, Kevin Myers, J. Brent Feland, Kent Crossley, A. Wayne Johnson, Dennis Eggett. *Brigham Young University, Provo, UT.* (Sponsor: J. Ty Hopkins, FACSM)

(No relationships reported)

Prior research, although very limited, has reported that whole body vibration training (WBV) can increase arterial blood flow and increase quadriceps temperature. The current popularity and widespread use of WBV platforms has suggested they are good for a warm-up effect, but only two studies exist which have only observed quadriceps temperature changes.

**PURPOSE:** The purpose of this study was to investigate the effect of WBV training on intramuscular temperature (IMT) changes in the vastus lateralis (VL), medial gastrocnemius (MG), tibialis anterior (TA), and the semitendinosus (ST), and to compare these results to a non-vibrating control condition.

**METHODS:** 40 male subjects (avg age 22.6 ± 2.4 yrs) with ½ cm or less subcutaneous fat over each muscle of interest completed this study. Subjects were randomized into one of the 4 different muscles of interest (10 per group). Subjects then completed two treatment periods (control and vibration). Treatment orders were balanced. Resting baseline IMT of the muscles were made using intramuscular thermistors (VL and ST (1.5 cm depth), TA and MG (.5 cm depth)). IMT's were measured two more times: immediately following 5 60-second bouts of standing in a semisquat position (40 degrees of knee flexion and 30-seconds between bouts), and then immediately following a second set of similar bouts. The vibration condition differed from the control by imposing oscillating WBV at 26Hz/4mm amplitude during the semisquat bouts.

**RESULTS:** Data were analyzed using a mixed models analysis of covariance blocking on individual subjects, with baseline temperature being the covariate. Tukey post hoc comparisons used where needed. A significant increase in all 4 muscles occurred with vibration (p<0.0001). In the control condition, the ST did not increase (p=0.3890) and the MG significantly decreased in temperature (p=0.0001). Main effect of control did not significantly change from 1st to 2nd bout of semisquats.

**CONCLUSIONS:** WBV produced greater temperature gains than the control condition for all muscles, with the greatest change seen in the VL (2.06 C). WBV training in standard static semisquat position is effective for increasing IMT of these 4 muscles, but how this compares to other forms of traditional warm-up remains unknown.

---

3441 Board #162 June 2 8:00 AM - 9:30 AM

**Pennation Angle Changes, Muscle Architecture, and Whole Body Vibration Training**

Kent Crossley, J. Brent Feland, A. Wayne Johnson, Dennis Eggett. *Brigham Young University, Provo, UT.* (Sponsor: J. Ty Hopkins, FACSM)

(No relationships reported)

Muscle architecture changes with age, size and location, which effects force production. Whole Body Vibration (WBV) has been shown to increase strength, power and vertical jump in recent studies. One possible explanation for these acute increases in performance without cross sectional area changes could be due to pennation angle alterations.

**PURPOSE:** The purpose of this study was to determine if whole body vibration training could influence pennation angle changes of the medial gastrocnemius (MG).

**METHODS:** 21 subjects (23.95 ± 1.77yrs, 175.65 ± 8.1cm, 74.03 ± 9.59Kg) were randomly placed into two treatment groups (control, vibration). Subjects layed in a prone position for ultrasound imaging of the right MG at a point 5cm superior to the distal end of the muscle belly (10 Mhz). Images were taken with the foot placed in subtalar neutral. Vibration subjects stood in a semi-squat position on an oscillating vibration platform (26Hz, 4mm amplitude) for 10-one minute vibration bouts with 30-second rest periods between bouts. Control subjects were asked to remain seated for the same treatment time as the vibration group. Ultrasound images were taken post treatment/control from the same location. Pennation angles were measured and averaged for each image.

**RESULTS:** Data were analyzed using a one-way analysis of covariance with the pre-treatment pennation value as the covariate. Post treatment pennation angles were found to have significantly decreased in the control group (p=0.0143, 1.57° ± 2.69°) but not in the vibration group (p=0.2134, 1.38° ± 2.21°).

**CONCLUSIONS:** As a muscle shortens, the angle of pennation increases. Therefore, we might theorize that WBV limits change in the angle of pennation. This may allow the muscle to produce more force. Since we did not look at force production, further research is needed to investigate if these pennation differences translate into isolated plantar flexion force changes following WBV.

3442 Board #163 June 2 8:00 AM - 9:30 AM

**The Effects Walking With And Without Poles On Body Composition In Women With Metabolic Syndrome**

Dortris A. Downs, Michael Holmstrup, Carla Murgia. *Delaware State University, Dover, DE.* (Sponsor: Erica M. Jackson, FACSM)

(No relationships reported)

Metabolic syndrome (MetSyn) has become common, with an estimated 50-75 million people affected in the US alone. MetSyn is characterized by obesity, dyslipidemia, high blood pressure, and a large waist circumference. Research has provided evidence that walking with Nordic poles can increase ones heart rate, and energy expenditure. The question is, if heart rate and energy expenditure are increased in normal individuals, are there similar effects for individuals diagnosed with MetSyn?

**PURPOSE:** The purpose of this study was to compare the effects of walking with and without Nordic walking poles on several indices related to MetSyn following 12-weeks of training.

**METHODS:** Nine obese women (40-64 yr) were assigned to walking groups, either with or without poles. Baseline and follow-up measurements for waist and hip circumference, blood pressure (BP), and body composition were collected. Subjects were monitored for exercise intensity during training (70% of age predicted maximum heart rate). A repeated measure ANOVA was used to analyze the effect of training on body composition variables. The confidence level was set at 95%.

**RESULTS:** Significant reductions were found between pre and post weight ( $P=0.035$ ), hip circumference ( $P=0.019$ ) and BP measurements ( $P=0.025$ ), with significantly greater improvements in the group who walked with Nordic poles. There was no significant effect of training on waist circumference ( $P=0.776$ ), lean body mass ( $P=0.431$ ), or fat mass ( $P=0.389$ ).

**CONCLUSION:** The evidence provided by this study supports the notion that walking with poles has an increased effect on lowering BP, and reducing weight and girth measurements, which may contribute towards a reduction in MetSyn risk.

#### Get Fit Together Intervention: Group Fitness Participation Produces Positive Health Benefits

Jinger S. Gottschall<sup>1</sup>, Justin L. Jones<sup>1</sup>, Jackie Mills<sup>2</sup>, Bryce Hastings<sup>2</sup>. <sup>1</sup>The Pennsylvania State University, University Park, PA. <sup>2</sup>Les Mills International, Auckland City, New Zealand. (Sponsor: W. Larry Kenney, FACSM)  
(No relationships reported)

It is no longer surprising to hear the alarming statistics regarding the rise of obesity without a parallel surge in physical activity within the United States. In response to this troubling trend, multiple federal agencies, including the American College of Sports Medicine, recommend 60 minutes of cardiovascular activity 3-5 days per week and 8-10 muscular strength as well as flexibility exercises 2 days per week. Numerous studies have quantified how these established guidelines improve cardiovascular function, augment bone density, reduce total body fat, and enhance daily living performance. These previous findings are based upon the utilization of a singular exercise modality or the quantification of lifestyle physical activity. Group fitness is one method presently promoted to meet exercise recommendations but the effectiveness of a comprehensive program has never been experimentally tested.

**PURPOSE:** To evaluate if a multimodal group fitness intervention can singularly produce physiological and musculoskeletal health benefits by utilizing the established physical activity prescription.

**METHODS:** 29 sedentary, but otherwise healthy, adults (11 men and 18 women) between the ages of 25-40 years completed the midpoint testing of a 30-week group exercise program based upon the recommended guidelines. The protocol started with a 6-week familiarization period, continued with a 12-week block of 6 group fitness classes per week (3 cardiovascular, 2 strength, 1 flexibility), and concluded with a final 12-week block of 7 classes per week (4 cardiovascular, 2 strength, 1 flexibility). We completed a submaximal oxygen consumption treadmill test, fasting blood draw and iDXA scan for each participant at 3 time points (baseline, midpoint, conclusion) and analyzed the data using a paired t-test ( $p < 0.05$ ).

**RESULTS:** Compared to the baseline measurements, the midpoint measurements demonstrated that the participants mean oxygen consumption increased by 34%, triglycerides decreased by 11%, LDL decreased by 6%, pelvic bone mineral density increased by 8%, and total body fat mass decreased by 4% (all values  $p < 0.01$ ).

**CONCLUSIONS:** Group fitness can be utilized as a modality to meet the physical activity prescription while producing optimal physiological and musculoskeletal health benefits.

#### Online Fitness Course Effectiveness in Increasing Physical Activity, Improving Fitness Scores, and Encouraging Healthy Choices

Karen K. Dennis, Cheri A. Toledo. Illinois State University, Normal, IL. (Sponsor: Dale D. Brown, FACSM)  
(No relationships reported)

Given the current trends of physical inactivity, overweight and obesity rates, and chronic disease prevalence, understanding appropriate levels of physical activity, healthful nutrition, and risk reduction for chronic-disease is crucial. While many colleges and universities offer, and some even require, courses that instruct students on these topics, they are offered in a traditional face-to-face environment which may limit the number of students able to receive the instruction. Online instruction as to healthy activity, nutrition, and chronic-disease-prevention techniques is a way to reach more individuals.

**PURPOSE:** The purpose of this study was to identify the effectiveness of an online personal health and fitness course in terms of enhancing or modifying choices related to physical activity, nutrition, and chronic-disease prevention, and to also identify changes in pre- and post-class fitness assessments.

**METHODS:** Study participants were 30 students, predominantly female (60%) seniors (76.7%), enrolled in a post-secondary completely online personal health and fitness course. Data sources used were a survey of activity, nutrition, and chronic disease prevention choices, and pre- and post-class fitness-testing results.

**RESULTS:** Survey results show that as a result of learning in the class, most participants (85.2%) increased physical activity during the course from what they were prior to the beginning of the course, even though the class did not meet face-to-face, most (70.3%) consciously made nutrition choices that met the dietary guidelines "Almost Always" and "Often", and most (77.7%) considered the choices they were making and how those choices might affect risk for developing chronic disease "Almost Always" and "Often." A paired samples t-test indicated that pre- and post-fitness testing changes in the mile-run time, the cardiac-fitness level, the curl-up test, the push-up test and rating, and thigh flexibility were statistically significant. Physical fitness test results show improvements ranging from 12.1 to 16.2%.

**CONCLUSION:** This online course was effective in increasing physical activity participation, fitness scores, and healthy nutrition and chronic disease prevention choices, which may be beneficial reducing the rates of physical inactivity, obesity, and chronic disease.

### 3445 Board #166 June 2 9:30 AM - 11:00 AM

#### Cardiorespiratory Fitness And Cognition - The Dr'S Extra Study

Rainer Rauramaa, FACSM<sup>1</sup>, Pirjo Komulainen<sup>1</sup>, Maija Hassinen<sup>1</sup>, Kai Savonen<sup>1</sup>, Tuomo Hänninen<sup>2</sup>, Miia Kivipelto<sup>3</sup>. <sup>1</sup>Kuopio Research Institute of Exercise Medicine, Kuopio, Finland. <sup>2</sup>Kuopio University Hospital, Kuopio, Finland. <sup>3</sup>Karolinska Institutet, Stockholm, Sweden.  
(No relationships reported)

The clinical relevance of cardiorespiratory fitness is nowadays well understood. The connection between cardiovascular risk factors and impaired cognitive function has become more and more apparent. While randomized controlled trials have shown the potential of regular aerobic exercise in preserving cognitive function, the role of cardiorespiratory fitness in this regard is less well understood.

**PURPOSE:** To study the impact of cardiorespiratory fitness on specific cognitive domains in older individuals.

**METHODS:** A population sample of 1346 men and women aged 57-78 years who participated in the Dose-Responses to Exercise Training Study (DR's EXTRA). Cardiorespiratory fitness was assessed as maximal oxygen uptake ( $VO_{2max}$ ;  $ml \cdot kg^{-1} \cdot min^{-1}$ ) by a respiratory gas analysis in an electrically braked bicycle ergometer. Cognitive function was evaluated using the Consortium to Establish a Registry for Alzheimer's disease (CERAD) neuropsychological test battery. Sum scores for immediate memory, delayed memory, verbal performance, visual performance and Mini-Mental State Examination were calculated. Logistic regression analysis was used to analyze the relative risk of cognitive impairment during four years across baseline  $VO_{2max}$  tertiles. Linear mixed model analysis was applied to find out the association of cardiorespiratory fitness on cognitive change. :

**RESULTS:** Individuals in the highest gender specific  $VO_{2max}$  tertile at baseline had 53% lower risk for incident poor immediate memory ( $P=0.022$ ) and 45% lower risk for incident poor delayed memory ( $P=0.038$ ) compared to those in the lowest  $VO_{2max}$  tertile during four years. One unit increase in  $VO_{2max}$  was associated with improved immediate memory ( $\beta=0.06$ ,  $P<0.001$ ), delayed memory ( $\beta=0.06$ ,  $P<0.001$ ), verbal performance ( $\beta=0.09$ ,  $P=0.001$ ) and Mini-Mental State Examination ( $\beta=0.02$ ,  $P=0.059$ ), after adjustment for potential confounders. :

**CONCLUSIONS:** Higher levels of cardiorespiratory fitness associate favourably with cognition, especially with preserving memory function. The present results are an additional proof of the clinical importance of achieving and keeping fitness.

---

3446 Board #167 June 2 9:30 AM - 11:00 AM

**Cardiorespiratory Fitness Among Adults with Severe Mental Illness**

Gerald J. Jerome<sup>1</sup>, Deborah Rohm Young, FACSM<sup>2</sup>, Kerry J. Stewart, FACSM<sup>3</sup>, Bernadette A. Cullen<sup>3</sup>, Arlene T. Dalcin<sup>3</sup>, Carl Latkin<sup>4</sup>, Lawrence J. Appel<sup>3</sup>, Gail L. Daumit<sup>5</sup>. <sup>1</sup>Towson University, Towson, MD. <sup>2</sup>University of Maryland, College Park, MD. <sup>3</sup>Johns Hopkins School of Medicine, Baltimore, MD. <sup>4</sup>Bloomberg School of Public Health, Baltimore, MD.

(No relationships reported)

**PURPOSE:** The feasibility of maximal and submaximal assessment of cardiorespiratory fitness (CRF) among adults with severe mental illness (SMI) was examined and their fitness levels were compared with national data. The association of CRF with psychological factors (diagnosis, severity of psychiatric symptoms, depression) and traditional cardiovascular disease risk predictors (BMI, adiposity, blood pressure, cholesterol, lipids) were also examined.

**METHODS:** The Activating Consumers to Exercise through Peer Support (ACE) trial was designed to examine the effectiveness of peer support on adherence to a 4 month pilot exercise program for adults with SMI (N = 107). Study measures included maximal (graded treadmill test) and submaximal (six-minute-walk) assessment of CRF; standardized measurements of height, weight and blood pressure; percent body fat assessed by dual-energy X-ray absorptiometry; fasting blood test; and self-report measures of depression and severity of psychiatric symptoms.

**RESULTS:** The average age was 47 years (SD = 10) with 78% females and 76% African-American. Compared to a national sample from the Cooper Center Longitudinal Study, 95% of the current sample had below average fitness levels as measured on the graded treadmill test with average MET levels of 5.9(SD = 2.2) for participants and 6.2(SD = 2.3) for peer leaders. There was a significant association between MET levels from the treadmill test and distance walked in the six-minute-walk ( $r = 0.36, p < 0.001$ ). Lower MET levels were associated with higher BMI ( $r = -0.34, p < 0.001$ ) and percent body fat ( $r = -0.37, p < 0.001$ ), but were not associated with blood pressure, cholesterol, or lipids. There was no association between MET levels and primary psychiatric diagnosis, depression, or severity of symptoms.

**CONCLUSION:** Both maximal and submaximal assessment of CRF was feasible among adults with severe mental illness. The uniformly low baseline CRF and the association of fitness with BMI and adiposity indicated programs to increase physical activity were warranted among adults with SMI.

Supported by a National Institute of Mental Health Grant 5R34MH0078613.

3447 Board #168 June 2 9:30 AM - 11:00 AM

**Effects of 10 wk Commuter Cycling on Cardiovascular Fitness, Lipids, Insulin Sensitivity and Body Composition**

B James Novis, Elaine A. Hargreaves, Nancy J. Rehrer, FACSM. University of Otago, Dunedin, New Zealand.

(No relationships reported)

Commuter cycling interventions have resulted in mixed effects on body composition and blood lipid profiles, whereas insulin sensitivity has not been investigated.

**PURPOSE:** The purpose of this study was to examine effects of commuter cycling on body composition and health parameters.

**METHODS:** Males and females were recruited and completed a questionnaire regarding present physical activity and commuting practices and a graded cycle ergometry test (VO<sub>2</sub>peak). Group assignment was randomised and matched for sex and fitness. The intervention group (IG) (n=14, age 39 ± 7 yr, body mass 77 ± 11 kg, VO<sub>2</sub>peak 2.8 ± 0.8 l•min<sup>-1</sup>) was given bicycles and asked to cycle commute for 100+ min / wk for 10 wk. The control group (CG) (n=14, age 34 ± 8 yr, body mass 70 ± 7 kg, VO<sub>2</sub>peak 2.6 ± 0.7 l•min<sup>-1</sup>) was to continue using motorised transport. Baseline (T0) testing included cholesterol fractions, triglycerides, C-reactive protein, fasting insulin and glucose (HOMA-IR) and body composition (mass, waist-to-hip ratio (WHR), skin folds) and was repeated wk10 (T10). Data were analysed using a two-factor (group x time) repeated measures ANOVA.

**RESULTS:** Analyses included 13 participants per group. IG cycled 152 ± 60 min / wk. No change in body fat over time (P=0.910) or between groups (Interaction P=0.997) was observed (IG T0: 30 ± 8, T10: 30 ± 8; CG T0: 27 ± 7, T10: 27 ± 8 %). WHR decreased over time (P=0.005) and was different (Interaction P=0.007) between groups (IG T0: 0.85 ± 0.08, T10: 0.81 ± 0.08; CG T0: 0.81 ± 0.06, T10: 0.81 ± 0.07). No change in body mass over time (P=0.157) or between groups (Interaction P=0.686) was observed (IG T0: 76.8 ± 10.7, T10: 77.0 ± 9.5; CG T0: 69.8 ± 6.7, T10: 70.3 ± 6.7 kg). VO<sub>2</sub>peak did not change over time (P=0.181) but was different (Interaction P=0.043) between groups (IG T0: 2.8 ± 0.8, T10: 3.1 ± 0.7; CG T0: 2.7 ± 0.7, T10: 2.6 ± 0.7 l•min<sup>-1</sup>). There were no significant changes within or between groups for blood parameters.

**CONCLUSION:** Commuter cycling for ~150 min / wk for 10 wk improves cardiovascular fitness, does not alter body mass or percentage fat, but may influence fat distribution. The lack of significant changes in blood parameters may be due to inadequate volume of exercise or duration of the intervention. Supported by the New Zealand Heart Foundation.

3448 Board #169 June 2 9:30 AM - 11:00 AM

**Effects of Physical Educational Class On Improving Physical Fitness In Stroke Out-patients**

long pio chio<sup>1</sup>, Pei Jhen Lee<sup>1</sup>, Hsuei Chen Lee<sup>1</sup>, Ku Chou Chang<sup>2</sup>, Jin Jong Chen<sup>1</sup>. <sup>1</sup>National Yang-Ming University, Taipei, Taiwan. <sup>2</sup>Chang-Gung Memorial Hospital, Kaohsiung, Kaohsiung, Taiwan.

(No relationships reported)

Stroke survivors tend to have a sedentary lifestyle due to the sequela, hence, it may increase the chance of recurrent stroke and cardiovascular diseases. Previous studies have showed that moderate intensity physical activity could improve physical fitness. Even the physicians recommend them to have more exercises to promote the fitness, the stroke out-patients still claim that the details about the exercise prescription are not clear.

**PURPOSE:** This study aimed to investigate the possibility to implement the physical education class for the mild stroke outpatients while waiting for the regular OPD consultation and to see its effects on improving the physical fitness.

**METHODS:** This was a quasi-experimental study. Exercise group received 3 sessions of supervised exercise class during the visit of the OPD (1 session/month) and 12-week home-based exercise program. Each physical educational class contained the warm-up, cardiopulmonary fitness training, strengthening and balance training for 40 minutes. Between two sessions, the patients were instructed to do the home program through telephone visit. Control group received only one exercise consultation session during the first visit. Outcome measures include body composition, muscle strength, 6-minute walk test (6MWT), gait speed, flexibility and Berg balance scale (BBS). Measurements were conducted at baseline and 12<sup>th</sup> week.

**RESULTS:** Eighty five mild stroke patients were recruited: 42 in exercise group and 43 in control group. There were 71 males and 14 females; with mean age 62.8 ± 9.5 yrs. After 12 weeks, the exercise group demonstrated greater improvements than the control group on most physical fitness measures, including the 6MWT (↑73.6 vs. ↑27.2 meters, p=0.001), 10 meter walk time (↓1.81 vs. ↓0.34 sec, p=0.004), upper limb muscle strength index (lb/kg, ↑0.31 vs. ↑0.15, p<0.001), lower limb muscle strength index (lb/kg, ↑0.55 vs. ↑0.25, p=0.003) and balance function (BBS ↑1.64 vs. ↑0.05, p=0.003).

**CONCLUSIONS:** Physical educational class combined with home exercise program potentially improved physical fitness for those mild stroke outpatients. From the result of this study, physical educational class is a practical and low cost strategy that gives a positive effect for mild stroke outpatients.

3449 Board #170 June 2 9:30 AM - 11:00 AM

**Effects Of Hospital-based Intervention On Physical Fitness, quality Of Life For Sedentary Care-giving Housewives**

Wen-Hui Huang, Jin-Jong Chen, Hsuei Chen Lee. Yang-ming Exercise Health Science Institute, Taipei, Taiwan.

(No relationships reported)

**BACKGROUND:** Due to heavy housework and many other barriers, care-giving housewives lead a sedentary lifestyle. They tend to get overweight, low back pain, poor physical fitness, and have lower quality of life and mental health. So, we developed the eight-week hospital-based exercise intervention (HEI) using day-care treatment duration of their children twice per week to provide an accessible exercise time for them to promote their physical fitness, self-efficacy and quality of life.

**PURPOSE:** To investigate the effects of HEI on physical fitness and quality of life for sedentary care-giving housewives

**METHODS:** Sixty-six sedentary care-giving housewives were recruited as volunteers and assigned into two groups: HEI group (n=31) and control group (CG, n=35). HEI program consisted of 16 sessions including 8 walking sessions and 8 yogalates sessions. Yogalates class focused on training their core muscle groups including abdominal, back and pelvic muscles. Control group

received one exercise consultation session during the first visit. Outcome measures comprised: 1) Questionnaires: personal characteristics, self-efficacy and quality of life (SF-36); 2) Health-related physical fitness: BMI, muscle endurance, flexibility, sit-up and cardiopulmonary endurance. Measurement was conducted at baseline and 9th week.

**RESULTS:** After 8 weeks exercise intervention, the HEI had significant improvements on all physical fitness items, such as upper and lower extremity muscle endurance (from  $19.8 \pm 5.5$  to  $24.7 \pm 5.2$ ,  $p < 0.01$ ), sit up (from  $13.7 \pm 8.1$  to  $19.0 \pm 8.5$ ,  $p < 0.01$ ), flexibility (from  $22.3 \pm 10.4$  to  $27.3 \pm 9.8$ ,  $p < 0.01$ ) and cardiopulmonary endurance (from  $53.0 \pm 13.6$  to  $59.3 \pm 11.5$ ,  $p < 0.05$ ). The quality of life had significant improvement, especially on mental health (from  $55.0 \pm 16.8$  to  $66.8 \pm 17.2$ ,  $p < 0.01$ ) and self-efficacy score had elevated significantly too. (from  $19.7 \pm 3.7$  to  $22.3 \pm 3.6$ ,  $p < 0.01$ ) However, the CG had no significant improvement on physical fitness, self-efficacy and quality of life ( $p > 0.05$ ).

**CONCLUSION:** The small-group hospital-based and caregiver-focused intervention model made housewives more active and satisfied from exercise. Truly, the intervention program improved their physical fitness, self-efficacy and quality of life significantly.

**Exercise Behaviors, Quality Of Life, And Burnout Among Physician Trainees: The Effect Of An Incentivized Fitness Program**

Jacob L. Sellon, Christopher J. Weight, Collette R. Lessard, Edward R. Laskowski, FACSM, Susan C. Karpinski, Fred M. Green, Steven H. Rose, Kerry D. Olsen, Tait D. Shanafelt. *Mayo Clinic, Rochester, MN.*

(No relationships reported)

**PURPOSE:** Resident well-being is important for providing an optimal learning environment and high quality patient care. According to the American Medical Association Code of Medical Ethics, "Residents and fellows are obligated, as are all physicians, to monitor their own health and level of alertness so that these factors do not compromise their ability to care for patients safely." Previous studies have indicated that graduate medical trainees have low overall wellness and high rates of burnout. We studied the effects of a prospective, incentivized fitness program on exercise habits, quality of life, and burnout among physician trainees in a large single institution cohort.

**METHODS:** All graduate medical trainees at Mayo Clinic Rochester ( $n=1159$ ) were invited to complete a baseline survey. Questions included demographics, fitness behavior (Department of Health and Human Services [HHS] 2008 Physical Activity Guidelines for Americans), quality of life (100-point visual analog scale), and burnout (abbreviated Maslach Burnout Inventory). All residents were then invited to participate in an incentivized fitness challenge. This consisted of 12 weeks of self-directed exercise for which points were awarded for various exercise activities. After the contest, both participants and non-participants were asked to complete a follow-up survey.

**RESULTS:** 628 trainees participated in the baseline survey (54%), and 242 (21%) enrolled in the fitness program. At baseline, there were no significant differences between program participants and non-participants with regard to demographics, medical training level, exercise habits, quality of life and burnout. 532 (46%) residents completed the follow-up survey. Following the program, participants were much more likely to meet current HHS Physical Activity Guidelines (OR 3.2 95% CI 2.2-4.8) and had a higher overall quality of life (72.4 vs 62.2,  $p < 0.0001$ ) compared to non-participants. There was a trend toward lower burnout measures in program participants compared to non-participants, but this was not statistically significant.

**CONCLUSIONS:** An incentivized fitness program significantly improved exercise behavior and quality of life ratings among physician trainees. Promoting healthy exercise behaviors among physician trainees may also decrease physician burnout.

**3451** Board #172 June 2 9:30 AM - 11:00 AM

**Alcohol Intake is an Independent Predictor of Metabolic Syndrome Risk as well as Cardiorespiratory Fitness**

Meiko Asaka, Hiroshi Kawano, Tomoko Aoyama, Shizuo Sakamoto, Mitsuru Higuchi, FACSM. *Waseda University, Tokorozawa, Saitama, Japan.*

(No relationships reported)

Cardiorespiratory fitness (CRF) is known as an independent predictor of metabolic syndrome (MS). On the other hand, some studies show that alcohol intake is associated with risk of MS. However, little is known whether alcohol intake is also independent predictors of MS as well as CRF.

**PURPOSE:** To examine the association of CRF and alcohol intake with MS risk in Japanese adults.

**METHODS:** Participants included 227 Japanese men ( $n = 110$ ) and women ( $n = 117$ ) aged 20-70 years. Alcohol intake was assessed by a self-administered diet history questionnaire. CRF was assessed by measuring  $VO_{2max}$ . The visceral fat cross-sectional area was evaluated by MRI, and blood pressure, fasting HDL-cholesterol, triglyceride, glucose were measured as indices of MS risk factors. MS risk score was calculated by a number of the risk factors from criteria value of MS. Participants were classified into three alcohol intake status categories (Non-: 0g/day, Moderate: < 22g/day, and Heavy: > 22g/day) and two CRF categories (Low and High based on reference values established in "Exercise and Physical Activity Reference for Health Promotion 2006").

**RESULTS:**  $VO_{2max}$  and alcohol intake were significantly correlated with MS risk score ( $r = -0.256$  and  $0.284$ ,  $p < 0.001$ , respectively) after adjusting for sex, age and smoking status. Multiple linear regression analysis revealed that both  $VO_{2max}$  and alcohol intake were independently correlated with MS risk score ( $\beta = -0.26$  and  $0.24$ ,  $p < 0.001$ , respectively) after adjusting for sex, age, smoking status, energy intake and step-counts. The MS risk score of Heavy alcohol intake group (MS risk score:  $1.6 \pm 0.2$ ) was significantly higher than that of Moderate group ( $0.9 \pm 0.1$ ,  $p = 0.001$ ). MS risk score of High CRF group ( $0.9 \pm 0.1$ ) was lower than that of Low CRF group ( $1.3 \pm 0.9$ ,  $p = 0.021$ ). High CRF group had significantly and slightly lower MS risk score than Low CRF group in Non- ( $p = 0.028$ ) and Moderate ( $p = 0.059$ ) alcohol intake groups. However, there was no significant difference of MS risk score between High and Low CRF group in Heavy alcohol intake group.

**CONCLUSIONS:** These results suggested that alcohol intake is an independent predictor of MS as well as CRF in Japanese people, and heavy alcohol intake has higher risk of MS even with high CRF.

**3452** Board #173 June 2 9:30 AM - 11:00 AM

**Body Composition, Physical Activity, Aerobic Fitness, And Metabolic Profile In High-fit High-fat 18 Year-olds**

Sigurbjörn Á. Arngrímsson, Erlingur B. Richardsson, Anna S. Ólafsdóttir. *University of Iceland, Laugarvatn, Iceland.* (Sponsor: Ellen M. Evans, FACSM)

(No relationships reported)

Although the prevalence of metabolic risk factors is well known in adults, it is not well described among individuals in their late teens.

**PURPOSE:** The purpose of the study was to examine metabolic risk factors among 18 year-old high-school students and to compare students attending vocational vs. traditional high-schools.

**METHODS:** The participants (147 boys and 130 girls) were randomly selected from three high-schools in Reykjavik, Iceland. Physical activity (PA) was assessed with pedometers and aerobic fitness (fitness) with a maximal oxygen uptake test on a treadmill. Height, weight, waist circumference (WC), and body mass index (BMI) were determined and percentage body fat (%Fat) assessed with dual energy X-ray absorptiometry. Resting blood pressure (BP) and fasting serum lipids and glucose were measured.

**RESULTS:** According to BMI, 23.3% of the students were overweight/obese, 20.4% had elevated WC, and 50.8% had higher %Fat than recommended. In addition, 11.2% of the participants had lower high-density lipoprotein, 8.4% higher low-density lipoprotein, and 8.8% higher triglycerides than advised and 10.2% had borderline or high systolic BP. In contrast, 84.4% of the students had average or higher levels of fitness. Regardless, only 34.4% of the participants reached the recommended levels of daily PA. Only a handful of the students had increased fasting glucose levels. Higher proportion of boys than girls were classified as obese (%Fat  $p = 0.042$ , BMI  $p = 0.049$ ) and with borderline or high systolic BP ( $p < 0.001$ ), but relatively more boys had also very good fitness level ( $p < 0.001$ ). No gender differences were found in the proportions across PA ( $p = 0.706$ ), diastolic BP ( $p = 0.139$ ), glucose ( $p = 0.357$ ), or serum lipids ( $p = 0.293-0.901$ ) classifications except that higher fraction of girls had elevated total cholesterol ( $p = 0.014$ ). Students in vocational schools had lower levels of fitness and PA, and higher %Fat, WC, and BP ( $p < 0.05$ ).

**CONCLUSION:** Although fitness among Icelandic 18 year-olds seems generally good, their PA is low and %Fat greatly elevated. Serum lipids and systolic BP are also raised in about 10% of the teenagers. Students in vocational schools measure worse on fitness, PA, BP and most body composition variables. Interventions aiming at increasing PA and decreasing adiposity are needed in this age group.

**Association between Age and Fitness among Men and Women Entering Basic Combat Training**

Shamola Greene, Joseph J. Knapik, FACSM, Andrea Harris, Bria Graham, Ryan Steelman, Keith Hauret, Bruce H. Jones, FACSM. *U. S. Army Institute of Public Health, Aberdeen, MD.*  
(No relationships reported)

The association between age and fitness in the military has been examined in operational units (Knapik, *J Aging Phy Fit* 4:234, 1996) but not among new recruits just entering United States (U.S.) Army Basic Combat Training (BCT). Recruits in BCT represent a broad cross section of the U.S. since they come from all parts of the country.

**PURPOSE:** This was a cross-sectional examination of age-related differences in physical fitness among men and women entering BCT.

**METHODS:** The Army Physical Fitness Test (APFT) consists of a 2-minute maximal effort push-up (PU) event, a 2-minute maximal effort sit-up (SU) event, and a 2 mile run for time (RUN). The Resident Individual Training Management System (RITMS) was queried for age and entry level APFT scores of Soldiers entering BCT from 1 October 2009 to 30 September 2010. There were a total of 53,574 men and 9,885 women who had these values. PU, SU, and RUN data was plotted by age and each event was analyzed using two-way analysis of variance (age by gender). Average yearly performance changes were estimated from the slope of the linear regression of age on PUs, SUs, or RUN.

**RESULTS:** The mean  $\pm$  standard deviation (SD) PU, SU, and RUN for men was 41  $\pm$  15 repetitions (reps), 48  $\pm$  14 reps, and 16.1  $\pm$  2.3 minutes; for women these values were 19  $\pm$  13 reps, 42  $\pm$  16 reps, and 19.9  $\pm$  2.9 minutes. The age range was 17 to 42 years with a mean SD of 22  $\pm$  4.53. PUs declined very slightly by age ( $p < 0.01$ ) but the difference was small between age groups amounting to no more than 2 reps; there was no gender by age interaction ( $p = 0.96$ ). SUs and RUN declined with age ( $p < 0.01$  for both), and there was a gender by age interaction ( $p < 0.01$  for both).

**CONCLUSION:** Among BCT recruits, and within the age groups examined here, there was little change in PU performance across the age groups. SU and RUN performance declined with age and the pattern differed slightly for men and women.

3454 Board #175 June 2 9:30 AM - 11:00 AM

**A Twenty Year Epidemiological Analysis of Fitness and Medical Trends in College Students**

Meagan Beyers, Megan Jones, Silas Pearman. *Furman University, Greenville, SC.*  
(No relationships reported)

**PURPOSE:** This cross sectional study was designed to assess medication and orthopedic trends in college age students.

**METHODS:** A Physical Activity Readiness Questionnaires (PAR-Q) analyzed trends with regards to medical conditions, over the counter and prescription drug use, and other health issues in college students from a private liberal arts college from 1990 to 2010 (N=1413).

**RESULTS:** Over the twenty year period, there was an increase in over the counter and prescription drug use ( $p < .01$ ). Specific drugs with increased usage included digestive, ADD/ADHD, oral contraceptives, acne, anti-depressants, allergy, and medications. Women took more allergy, acne, anti-depressants, and all other medications ( $p < .01$ ) while men took more medications for ADD/ADHD ( $p < .01$ ). Overall, a total of 46% of students were on at least one medication with an additional 5% of students on two or more medications. In addition, the data showed the 5% of students had heart murmurs, 10 % of students had asthma, and 12% of students reported orthopedic issues, with women students reporting more orthopedic conditions ( $p < .01$ ).

**CONCLUSION:** Over the twenty year period, there was a significant increase in over the counter and prescription drug usage as well as increase in asthma and orthopedic conditions. These trends reflect the increased use of prescription drugs as well as possible sports specialization connected to orthopedic injuries.

**Association between Physical Fitness and Discharge and Recycling Risk among Male Army Recruits**

Andrea Harris, Joseph Knapik, Shamola Greene, Keith Hauret, Bria Graham, Ryan Steelman, Bruce Jones. *US Army Institute of Public Health, Aberdeen Proving Ground, MD.*  
(No relationships reported)

**INTRODUCTION:** Discharges are individuals who are removed from military service and in Basic Combat Training (BCT) recruits are generally discharged due to medical conditions, inability to adapt to the military for psychological reasons, or inability to perform critical military tasks. Recycling involves extending the normal training period so the recruit can have additional time to meet required BCT performance criteria. A previous study examined the association between fitness and discharge incidence (Knapik, *Milit Med* 166:641, 2001) however no prior investigation has examined fitness as a risk factor for recycling.

**PURPOSE:** To examine the relationship between entry-level physical fitness and discharge and recycle incidence among men in BCT.

**METHODS:** Resident Individual Training Management System (RITMS) was queried for all male basic trainees beginning training between October 1, 2009 and September 30, 2010. There were 99,700 male recruits in the database and 54,630 had entry-level Army Physical Fitness Test (APFT) scores. The APFT consisted of a 2-minute maximal effort push-up (PU) event, a 2-minute maximal effort sit-up (SU) event and a 2-mile run for time (RUN). The final status of the recruit (graduation, discharge or recycle) was also obtained from RITMS. Recruits were placed into performance quartiles (Q1=high performance through Q4=low performance) on each of the 3 APFT events. The association between final status and fitness were assessed by examining discharge or recycle risk at each quartile. Risk ratios (RR) and 95% confidence intervals were examined by comparing each quartile to Q4.

**RESULTS:** Men were at higher discharge risk if they had lower performance on PUs (RR[Q4/Q1]=4.5, 95% CI=3.7-5.4), SUs (RR[Q4/Q1] = 3.15, 95% CI= 2.66-3.74), or a RUN (RR[Q4/Q1] = 2.39, 95% CI= 2.04-2.80) Men were also at higher recycle risk if they had low performance on PUs (RR[Q4/Q1]=4.06, 95% CI=3.29-3.33), SUs (RR[Q4/Q1]= 3.52, 95% CI=2.84-4.37) or the RUN (RR[Q4/Q1] = 2.73, 95% CI = 2.23-3.33). For all 3 APFT events there was a dose-response such that any lower fitness level was associated with higher discharge or recycle risk, compared to the next highest fitness level.

**CONCLUSIONS:** Among men in BCT, lower fitness levels were associated with higher discharge or recycling risk in a dose-response manner.

3456 Board #177 June 2 9:30 AM - 11:00 AM

**Different Measures of Adiposity, Cardiorespiratory Fitness, And All-cause Mortality In Men**

James R. Morrow, Jr., FACSM<sup>1</sup>, Stephen W. Farrell<sup>2</sup>, Carrie E. Finley<sup>2</sup>, Allen W. Jackson, FACSM<sup>1</sup>, Scott M. Grundy<sup>3</sup>, Gloria L. Vega<sup>3</sup>. <sup>1</sup>North Texas, Denton, TX. <sup>2</sup>The Cooper Institute, Dallas, TX. <sup>3</sup>University of Texas-Southwestern Medical Center, Dallas, TX.  
(No relationships reported)

**PURPOSE:** Examine the relationship among three differently defined adiposity categories on all-cause mortality in men stratified by cardiorespiratory fitness (CRF).

**METHODS:** A cohort of 36,836 apparently healthy men underwent a comprehensive physical examination at The Cooper Clinic between 1970 and 2006. Clinical measures included Body Mass Index (BMI), Waist Circumference (WC), Percentage of Body Fat (%Fat), and CRF determined by maximal treadmill exercise duration. Participants were grouped into 4 adiposity categories: Group 1 = normal weight for all 3 adiposity exposures, Group 2 = overweight for 1 exposure, Group 3 = overweight for 2 exposures, Group 4 = overweight for all 3 adiposity exposures. Hazard ratios (HRs) were computed with Cox regression analysis with adjustment for age, exam year, and smoking status. Because BMI and WC are more common adiposity measures, we performed additional mortality analyses using different combinations of BMI, WC, and CRF.

**RESULTS:** During a mean follow-up of 15.5  $\pm$  8.1 years, 2294 deaths occurred. Adjusted HRs across adiposity groups were 1.0 (referent), 1.10, 1.18, and 1.71 for Groups 1-4 respectively ( $p$  trend  $< 0.0001$ ). While further adjustment for CRF attenuated this pattern, the trend was still significant ( $p = 0.01$ ). When grouped into categories of fit and unfit (upper 80% and lower 20% of CRF distribution), mortality rates (per 10,000 man-years) were significantly lower in fit compared with unfit men within each of the 4 adiposity groups. Examination of the effects of various combinations of BMI, WC, and CRF on mortality, resulted in similar mortality rates in men who had normal BMI and normal WC as compared to men with high BMI and normal WC (13.4 vs. 14.4 deaths per 10,000 man-years respectively). Men with high BMI and high WC had the highest mortality (23.9 deaths per 10,000 man-years). Within all BMI and WC combinations, fit men had substantially lower mortality than unfit men.

**CONCLUSION:** Compared to men normal on all 3 adiposity exposures, men with an increasing number of adiposity exposures had greater risk of all-cause mortality. Mortality risk was attenuated in all 4 adiposity groups by achieving at least a moderate level of CRF. Utilizing various adiposity exposures to determine risk of all-cause mortality in men may be misleading unless CRF is also considered.

**3457** Board #178 June 2 9:30 AM - 11:00 AM

**The Combined Influence Of Sedentary Behavior And Physical Activity On Cardiorespiratory Fitness**

Rute Santos<sup>1</sup>, Micheal Pratt<sup>2</sup>, Anthony D. Okely<sup>3</sup>, Jorge Mota<sup>1</sup>, Carla Moreira<sup>1</sup>, Manuel J. Coelho-e-Silva<sup>3</sup>, Susana Vale<sup>1</sup>, Luis B. Sardinha<sup>5</sup>. <sup>1</sup>Research Centre in Physical Activity, Health and Leisure. Faculty of Sport - University of Porto, Porto, Portugal. <sup>2</sup>National Center for Chronic Disease Prevention and Health Promotion, CDC, Atlanta, United States of America., Atlanta, GA. <sup>3</sup>Interdisciplinary Educational Research Institute, University of Wollongong, NSW, Australia., Wollongong, Australia. <sup>4</sup>Research Centre of Anthropology and Health. Faculty of Sport Sciences and Physical Education, University of Coimbra, Portugal, Coimbra, Portugal. <sup>5</sup>Exercise and Health Laboratory, Faculty of Human Movement-Technical University of Lisbon, Portugal., Lisbon, Portugal.

(No relationships reported)

**PURPOSE:** The aim of this study was to analyze the combined influence of objectively measured sedentary behavior and physical activity (PA) on cardiorespiratory fitness (CRF) in 2 506 Portuguese children and adolescents aged 10 to 18 years.

**METHODS:** CRF was assessed with the Fitnessgram 20m shuttle-run test. PA and sedentary behaviour were assessed with accelerometry. Participants were classified as meeting current PA guidelines for youth vs not meeting; and as low vs High sedentary (according to the median value of sedentary time/day by age and gender); and then grouped as follows: Low Active - High Sedentary; Low Active - Low Sedentary; High Active - High Sedentary; High Active - Low Sedentary. Binary logistic regression models were constructed to verify the relationship between high CRF and the combined influence of PA/sedentary behavior, adjusting for age, gender and body mass index.

**RESULTS:** Participants classified as high active/low sedentary (OR=1.849; 95%CI:1.246-2.744), as well as those classified as low active/low sedentary (OR=1.297; 95%CI:1.034-1.626) were more likely to be fit, compared with those from the low active/high sedentary group.

**CONCLUSIONS:** These findings suggest that PA levels may not overcome the deleterious influence of high sedentary time. Our data stress the importance of promoting PA and discouraging sedentary behavior.

---

**3458** Board #179 June 2 9:30 AM - 11:00 AM

**Sarcopenic-obesity Is Associated With Physical Fitness Independently Physical Activity**

Junghoon Kim<sup>1</sup>, Kai Tanabe<sup>1</sup>, Noriko Yokoyama<sup>1</sup>, Suga Yoko<sup>2</sup>, Shinya Kuno<sup>1</sup>. <sup>1</sup>University of Tsukuba, Ibaraki, Japan. <sup>2</sup>Tsukuba Wellness Research. Co., Ltd., Ibaraki, Japan.

(No relationships reported)

Decreased muscle mass (sarcopenia) and increased fat mass (obesity) with aging may contribute to difficulties with physical fitness, respectively. However, a limited number of studies have examined the association between sarcopenic-obesity and physical fitness.

**PURPOSE:** The primary aim of this study was to investigate the prevalence of sarcopenic-obesity from a large cohort of Japanese. We was also examined whether sarcopenic-obesity contribute to decrease physical fitness independently level of physical activity.

**METHODS:** This cross-sectional observational study including total 7915 healthy Japanese men and women 20-80 years of age who recruited between 2006 and 2010. We measured muscle mass and body fat mass using bioelectrical impedance. Physical activity was measured using a pedometer with an accelerometer for 7 days. The physical fitness test was based on the method of the Japan Fitness Test that comprised five items, and total scores of the test were calculated (scores of each item: 1-10). Lowest gender-specific quartile in total score was defined as poor physical fitness. Sarcopenia was defined as skeletal muscle mass index of two SD below the sex-specific mean value for a younger reference group (<40 years, n=1494) from the entire study population. We also defined obesity based on criteria of the Japan Society for the Study of Obesity.

**RESULTS:** The prevalence of sarcopenia-obesity was significantly increased with aging ( $P<0.05$ ). The odds ratio for poor physical fitness was 3.7 (95%CI: 2.65-5.32) and 3.6 (95%CI: 2.70-4.83) for individuals with sarcopenic-obesity, compared with healthy body composition group in men and women, respectively ( $P<0.001$ ), after adjusted for age, BMI, and physical activity. These trends were similar across level of physical activity.

**CONCLUSIONS:** The results of this cross-sectional observational study suggest that sarcopenic-obesity is associated with poor physical fitness independently physical activity using measured a pedometer with an accelerometer.

**3459** Board #180 June 2 9:30 AM - 11:00 AM

**Associations between Cardiorespiratory Fitness Level and Health-Related Quality of Life: A Cross-Sectional Study of Apparently Healthy Adult Females.**

Robert A. Sloan<sup>1</sup>, Susumu S. Sawada, FACSM<sup>2</sup>, Corby K. Martin, FACSM<sup>3</sup>, Robert R. Kraemer, FACSM<sup>4</sup>, Steven N. Blair, FACSM<sup>5</sup>. <sup>1</sup>Health Promotion Board, Singapore, Singapore. <sup>2</sup>Tokyo Gas, Tokyo, Japan. <sup>3</sup>Pennington Biomedical Research Center, Baton Rouge, LA. <sup>4</sup>Southeastern Louisiana University, Hammond, LA. <sup>5</sup>University of South Carolina, Columbia, SC. (Sponsor: Susumu Sawada, FACSM)

(No relationships reported)

Currently there is a dearth of evidence available on the relationship between cardiorespiratory fitness (CRF) and health-related quality of life (HRQoL) in apparently healthy adult females.

**PURPOSE:** To investigate the relationship between CRF level and HRQoL in apparently healthy adult females.

**METHODS:** We evaluated the association of CRF and HRQoL of 634 U.S. Navy and civilian (Age: 18-49 yr) females who were given a submaximal exercise test and health risk appraisal which included the Short Form-12v2 (SF-12v2) from 2005-2007. CRF was measured by using the Balke-Ware submaximal treadmill test; women were assigned to low (referent), moderate, and high CRF categories based on tertiles. Physical component summary (PCS) and mental components summary (MCS) scores were considered to be above the norm if summary scores were  $\geq 50$  respectively.

**RESULTS:** Odds Ratios (ORs) and 95% confidence intervals (95% CIs) for CRF versus MCS-12 and PCS-12 scores were obtained by using a logistic regression model. Taking into consideration age, systolic blood pressure, BMI, cigarette smoking, and alcohol intake, the table shows the associations between CRF with PCS and MCS scores.

---

|                 | Low (referent) | Moderate           | High               | p for trend |
|-----------------|----------------|--------------------|--------------------|-------------|
| n               | 158            | 263                | 213                |             |
| PCS             |                |                    |                    |             |
| % PCS $\geq$ 50 | 62.7           | 68.8               | 77.9               |             |
| Age-adjusted OR | -              | 1.38 (0.91 - 2.10) | 2.32 (1.44 - 3.76) | 0.001       |
| Multivariate OR | -              | 1.26 (0.81 - 1.98) | 1.95 (1.14 - 3.34) | 0.014       |
| MCS             |                |                    |                    |             |
| % MCS $\geq$ 50 | 60.1           | 58.2               | 65.3               |             |
| Age-adjusted OR | -              | 0.94 (0.63 - 1.42) | 1.30 (0.83 - 2.03) | 0.205       |
| Multivariate OR | -              | 0.94 (0.62 - 1.45) | 1.31 (0.79 - 2.15) | 0.247       |

**CONCLUSION:** The results of this cross-sectional study suggest that higher levels of CRF are associated with an increased likelihood of PCS and MCS scores above the norm. A significant p for trend was apparent for PCS but not MCS.

**3460 Board #181 June 2 9:30 AM - 11:00 AM**

**Long-term Trends In Cardiorespiratory Fitness And The Incidence Of Dyslipidemia.**

Susumu S. Sawada, FACSM<sup>1</sup>, I-Min Lee, FACSM<sup>2</sup>, Hisashi Naito<sup>3</sup>, Takashi Okamoto<sup>1</sup>, Koji Tsukamoto<sup>1</sup>, Takashi Muto<sup>4</sup>, Yasuki Higaki<sup>5</sup>, Hiroaki Tanaka<sup>5</sup>, Steven N. Blair, FACSM<sup>6</sup>. <sup>1</sup>Tokyo Gas Health Promotion Ctr., Tokyo, Japan. <sup>2</sup>Harvard Medical School, Boston, MA. <sup>3</sup>Juntendo University, Chiba, Japan. <sup>4</sup>Dokkyo Medical University School of Medicine, Tochigi, Japan. <sup>5</sup>Fukuoka University, Fukuoka, Japan. <sup>6</sup>University of South Carolina, Columbia, SC.  
(No relationships reported)

**PURPOSE:** Cardiorespiratory fitness is associated with a lower risk of dyslipidemia. However, there are no cohort studies that have assessed the relationship between long-term trends in cardiorespiratory fitness and the incidence of dyslipidemia. Thus, we investigated this issue in Japanese males.

**METHODS:** We evaluated the long-term trends in cardiorespiratory fitness and incidence of dyslipidemia among 3,650 Japanese men (age: 22-40) who were free of dyslipidemia at baseline. Participants were given a submaximal exercise test at least four times over seven years (1979-1985). We modeled the trend in fitness over seven years for each man using simple linear regression. Participants were then divided into quartiles based on the regression coefficient (slope) from the model. During the follow-up period 1985-2004, 227 men developed dyslipidemia. The development of dyslipidemia was based on self-report of current drug therapy for dyslipidemia at a subsequent medical examination in 2004. Odds ratios and 95% confidence intervals (95% CI) for the incidence of dyslipidemia were obtained using the logistic regression model.

**RESULTS:** Men in the lowest quartile of the distribution decreased in cardiorespiratory fitness over the seven years (median slope, -1.26 ml/kg/min), while men in the highest quartile increased in fitness (median slope, 1.31 ml/kg/min). Adjusting for age, initial fitness level, body mass index, cigarette smoking, alcohol intake, and a family history of dyslipidemia, and using the lowest quartile as reference, the odds ratios and 95% CI for the 2nd through 4th quartiles were 0.74 (0.50-1.11), 0.69 (0.45-1.05), and 0.48 (0.29-0.78), respectively (P = 0.004 for trend).

**CONCLUSIONS:** These results suggest that the long-term trend in cardiorespiratory fitness is a predictor of the incidence of dyslipidemia in Japanese males.

**3461 Board #182 June 2 9:30 AM - 11:00 AM**

**Cardiorespiratory Fitness And Subclinical Atherosclerosis In Men With Type 2 Diabetes**

Sae Young Jae<sup>1</sup>, Kevin S. Heffernan<sup>2</sup>, Yoon-Ho Choi<sup>3</sup>, Bo Fernhall, FACSM<sup>4</sup>. <sup>1</sup>University of Seoul, Seoul, Korea, Republic of. <sup>2</sup>Syracuse University, Syracuse, NY. <sup>3</sup>Samsung Medical Center, Seoul, Korea, Republic of. <sup>4</sup>University of Illinois, Chicago, IL.  
(No relationships reported)

Type 2 diabetes is a major risk factor for the development of atherosclerosis and cardiovascular disease mortality. Conversely, high levels of cardiorespiratory fitness have a strong protective effect against cardiovascular disease mortality in patients with type 2 diabetes.

**PURPOSE:** We tested the hypothesis that higher levels of cardiorespiratory fitness are inversely associated with subclinical atherosclerosis in 746 (age 53 $\pm$ 7 yrs) men with type 2 diabetes.

**METHODS:** We measured brachial ankle pulse wave velocity (PWV) and common carotid intima media thickness (CIMT) as indexes of subclinical atherosclerosis. Carotid atherosclerosis was defined by carotid intima media thickness >1.0mm. Cardiorespiratory fitness (CRF) was directly measured by peak oxygen uptake using expired gases analysis during a standard treadmill test.

**RESULTS:** Peak oxygen uptake was inversely correlated with PWV (r=-0.27, p<0.05) and CIMT (r=-0.24, p<0.05). Peak oxygen uptake was independently associated with CIMT ( $\beta$ =-0.15, p<0.05), but not PWV (p=0.12), in multivariable regression models that adjusted for age, BMI, waist girth, TC/HDL-C and CRP. After adjusting for established risk factors, high and moderate cardiorespiratory fitness were associated with lower odds ratios for having carotid atherosclerosis 0.49 (95% CI, 0.30 - 0.81), and 0.59 (95% CI, 0.38 - 0.92), respectively, as compared with low cardiorespiratory fitness. Each one metabolic equivalent increment higher cardiorespiratory fitness was associated with 27% (OR = 0.73; 95% CI, 0.61 - 0.87) lower prevalence of carotid atherosclerosis.

**CONCLUSIONS:** These results suggest that high cardiorespiratory fitness is inversely associated with common carotid intima media thickness independent of established risk factors in men with type 2 diabetes.

**Fitness, Physical Activity And Aortic Intima-media Thickness In Adolescents**

Katja Pahkala<sup>1</sup>, Olli J. Heinonen<sup>1</sup>, Olli Simell<sup>2</sup>, Jorma S.A. Viikari<sup>2</sup>, Tapani Rönnemaa<sup>2</sup>, Harri Helajärvi<sup>1</sup>, Harri Niinikoski<sup>2</sup>, Olli T. Raitakari<sup>2</sup>. <sup>1</sup>Paavo Nurmi Centre, Turku, Finland. <sup>2</sup>University of Turku, Turku, Finland. (Sponsor: Raija Laukkanen, FACSM)  
(No relationships reported)

**PURPOSE:** We recently reported a favorable association between leisure-time physical activity and a surrogate marker of atherosclerosis, aortic intima-media thickness (aIMT), in adolescents (1). The aim of this study was to investigate whether cardiorespiratory fitness is associated with aIMT independently of physical activity.

**METHODS:** Cardiorespiratory fitness was measured with maximal cycle ergometer test in 17-year-old adolescents (n=378) participating in an atherosclerosis prevention study (STRIP). To describe the data, the adolescents were divided into three groups according to tertile cut-off points for fitness. Physical activity was assessed using a self-administered standardized questionnaire. A physical activity index (MET h/wk) was calculated by multiplying weekly mean leisure-time exercise intensity, duration and frequency. Ultrasonography was used to examine aIMT. Four measurements of aIMT covering the far wall segment were taken and the mean of these measurements was used. Complete data on fitness, physical activity, aIMT and covariates used for adjustment were available among 312 adolescents. A linear regression model was used for the analyses.

**RESULTS:** Fitness was inversely associated with aIMT [beta (SE) = -0.0036 (0.0011), p=0.0012; adjusted for gender, body mass index, HOMA-IR, and HDL/total cholesterol, triglyceride and C-reactive protein concentration. Mean (SD) aIMT was 0.49 (0.10) mm in high fit girls and 0.54 (0.11) mm in low fit girls. In boys, the corresponding values were 0.53 (0.10) mm and 0.58 (0.13) mm. The inverse association between fitness and aIMT remained after further adjustment for physical activity [beta (SE) = -0.0030 (0.0013), p=0.026].

**CONCLUSIONS:** In adolescents, cardiovascular fitness is favorably associated with aIMT independently of physical activity. Since fitness can be improved only by exercise, a physically active lifestyle should be encouraged to support cardiovascular health.

Supported by the Finnish Ministry of Education and Culture, the Finnish Cultural Foundation and the Juho Vainio Foundation.

**Cardiorespiratory Fitness, Body Mass Index, and Chronic Heart Failure Mortality in Men.** Stephen W. Farrell<sup>1</sup>, Carrie E. Finley<sup>1</sup>, Nina B. Radford<sup>2</sup>, and William L. Haskell<sup>3</sup>, FACSM

<sup>1</sup>The Cooper Institute, Dallas TX <sup>2</sup>The Cooper Clinic, Dallas TX <sup>3</sup>Stanford University, Palo Alto CA

**PURPOSE:** To examine the associations between baseline cardiorespiratory fitness (CRF) and body mass index (BMI) with chronic heart failure (CHF) mortality in men.

**METHODS:** 40,723 men without a personal history of cardiovascular disease underwent a comprehensive baseline health examination between 1971 and 2006. Clinical measures included BMI and CRF quantified as duration of a maximal treadmill exercise test. Participants were divided into low (bottom 20% of distribution), moderate (next 40% of distribution), and high (highest 40% of distribution) CRF categories. Standard cut points were used to identify BMI categories. Hazard ratios (HRs) were computed with Cox regression analysis.

**RESULTS:** During a mean follow-up period of 19.8 ± 9.4 years, 92 CHF deaths occurred. Following adjustment for age, exam year, systolic blood pressure, smoking status, and personal history of diabetes, HRs across incremental CRF categories were 1.0, 0.40, and 0.24, while adjusted HRs across incremental BMI categories were 1.0, 1.92, and 3.61 (P for trend < 0.0002 for each). When grouped into categories of fit and unfit (upper 80% and lower 20% of CRF distribution respectively), the HR was significantly lower in fit (HR=0.24) compared with unfit men (referent) within the normal weight BMI category. Within the overweight and obese BMI categories, fit men had substantially lower HRs than unfit men; however these differences did not reach statistical significance.

**CONCLUSION:** Higher baseline levels of CRF are associated with substantially lower CHF mortality rates in men. Among normal weight men, only those who attain at least a moderate level of CRF experience reduced CHF mortality.

**Cardiorespiratory Fitness As A Predictor Of Non-cvd Non-cancer Mortality In Men**

Xuemei Sui<sup>1</sup>, Timothy S. Church, FACSM<sup>2</sup>, Duck-chul Lee<sup>1</sup>, Enrique G. Artero<sup>1</sup>, Ali Ahmed<sup>3</sup>, Steven N. Blair, FACSM<sup>1</sup>. <sup>1</sup>University of South Carolina, Columbia, SC. <sup>2</sup>Pennington Biomedical Research Center, Baton Rouge, LA. <sup>3</sup>University of Alabama at Birmingham, Birmingham, AL.  
(No relationships reported)

**PURPOSE:** The inverse association between cardiorespiratory fitness (CRF) and mortality from cardiovascular disease (CVD) and cancer is well established. However, studies on CRF and death from other causes are scant. We sought to evaluate the five major cause-specific non-CVD and non-cancer deaths with CRF in the Aerobics Center Longitudinal Study.

**METHODS:** Participants were 35,408 men (mean±SD age 43.2±9.3 yr) who were free of known CVD and cancer at baseline, and completed a maximal treadmill exercise test during a preventive examination at the Cooper Clinic, Dallas, TX between 1974 and 2002. CRF was quantified as maximal treadmill exercise test duration and was grouped for analysis as low, moderate, and high. Cause-specific non-CVD non-cancer deaths were grouped into 5 major categories: diabetes and kidney disease; chronic respiratory disease; acute respiratory and infectious disease; injuries; and all other non-CVD non-cancer deaths.

**RESULTS:** A total of 702 non-CVD non-cancer deaths occurred during an average 17 years of follow-up. After adjusting for age, examination year, smoking, drinking, BMI, hypertension, diabetes, and hypercholesterolemia, hazard ratios (95% confidence intervals) across ascending categories of CRF were 1.00 (referent), 0.60 (0.49-0.73), 0.53 (0.41-0.67) for overall non-CVD non-cancer deaths (trend P < 0.0001); 1.00 (referent), 0.57 (0.40-0.82), 0.32 (0.19-0.54) for diabetes and kidney diseases (trend P < 0.001); 1.00 (referent), 0.30 (0.17-0.50), 0.09 (0.04-0.21) for chronic respiratory diseases (trend P < 0.001); 1.00 (referent), 0.73 (0.46-1.16), 0.43 (0.24-0.77) for acute respiratory and infectious diseases (trend P = 0.004); 1.00 (referent), 0.79 (0.58-1.09), 0.79 (0.54-1.16) for injuries (trend P = 0.28); and 1.00 (referent), 0.53 (0.38-0.74), 0.50 (0.34-0.74) for any other non-CVD non-cancer causes deaths not falling into the 4 categories above (trend P = 0.001), respectively.

**CONCLUSIONS:** Higher levels of CRF were significantly associated with lower risk of mortality from non-CVD non-cancer causes including diabetes and kidney disease, acute and chronic respiratory disease. These results suggest a physically active lifestyle may reduce non-CVD non-cancer deaths which make up a substantial portion of adult mortality. Supported by NIH grant DK088195.

Blair, FACSM<sup>7</sup>, Luis A. Moreno<sup>2</sup>, Manuel J. Castillo<sup>1</sup>. <sup>1</sup>School of Medicine, Department of Physiology, University of Granada, Granada, Spain. <sup>2</sup>GENUD (Growth, Exercise, Nutrition and Development) Research Group, University of Zaragoza, Zaragoza, Spain. <sup>3</sup>Immunonutrition Research Group, Department of Metabolism and Nutrition, Institute of Food Science, Technology and Nutrition (ICTAN), Spanish National Research Council, Madrid, Spain. <sup>4</sup>Inserm U995, School of Medicine, IFR114, University of Lille2, Lille, France. <sup>5</sup>Department of Social Medicine, Preventive Medicine and Nutrition Clinic, University of Crete, Heraklion, Crete, Greece. <sup>6</sup>School of Physical Activity and Sport Sciences (INEF), Universidad Politécnica de Madrid, Madrid, Spain. <sup>7</sup>Department of Exercise Science, University of South Carolina, Columbia, SC.  
(No relationships reported)

**PURPOSE:** Muscular fitness is being increasingly recognized in the prevention of cardiovascular diseases. This study examines the association of muscular fitness with nontraditional cardiometabolic biomarkers in adolescents.

**METHODS:** Healthy Lifestyle in Europe by Nutrition in Adolescents (HELENA) cross-sectional study. A total of 639 adolescents (296 boys) from 9 European countries, aged from 12.5 to 17.5 y, were included in this report. A muscular fitness score was computed as sum of age- and gender-specific z-scores of handgrip strength / body weight and standing long jump. Cardiorespiratory fitness was estimated using the 20m shuttle run test. Age- and gender-specific z-scores of C-reactive protein (CRP), complement factors C3 and C4, leptin, and white blood cells were summed to create a cluster of nontraditional cardiometabolic biomarkers. Sex, age, pubertal stage and country were used as confounders. Additional models also adjusted for homeostasis model assessment of insulin resistance (HOMA-IR) and sum of 4 skinfolds.

**RESULTS:** Muscular fitness was negatively associated with single and clustered cardiometabolic biomarkers (standardized  $\beta$  from -0.393 to -0.116, all P values < 0.01). Additional adjustments for cardiorespiratory fitness and HOMA-IR weakened the associations, but they still remained significant. The association was no longer significant when adjusting for sum of skinfolds. The odds ratios (OR) for having a high clustered risk (above or equal 1 SD) was 5.0 [95% confidence interval (CI) = 2.3-11.1] in the lowest quartile of muscular fitness compared with the highest quartile, after adjusting for basic confounders plus cardiorespiratory fitness and HOMA-IR. When adjusting also for sum of skinfolds, the OR decreased to 1.8 (95%CI = 0.7-4.4). Decreasing values of clustered cardiometabolic risk were observed across incremental levels of muscular fitness in both non-overweight (P = 0.002) and overweight adolescents (P < 0.001).

**CONCLUSIONS:** Muscular fitness is inversely associated with nontraditional cardiometabolic biomarkers in adolescence, and the association seems to be at least partly mediated by adiposity. Preventive strategies for youth should focus not only on decreasing adiposity and increasing cardiorespiratory fitness, but also on enhancing muscular fitness.

**3466** Board #187 June 2 9:30 AM - 11:00 AM

**Associations Of Physical Activity And Fitness With Cognitive Status In Community-dwelling Older Adults**

Kenji Narazaki<sup>1</sup>, Eri Matsuo<sup>1</sup>, Takatori Honda<sup>1</sup>, Yu Nofuji<sup>1</sup>, Koji Yonemoto<sup>2</sup>, Shuzo Kumagai<sup>1</sup>. <sup>1</sup>Kyushu University, Fukuoka, Japan. <sup>2</sup>Kurume University, Fukuoka, Japan. (Sponsor: Kiyoji Tanaka, FACSM)

(No relationships reported)

Physical activity is a promising intervention candidate for preventing or delaying cognitive decline often emerged in the aging process. However, association between physical activity and cognitive status has been still unclear in community-dwelling older people. Furthermore, there have been limited findings regarding the association between physical fitness and cognitive status in the population.

**PURPOSE:** To examine whether physical activity and fitness are associated with cognitive status in community-dwelling older adults.

**METHODS:** As part of a community-based cohort study for a Japanese local town, 2,629 participants older than 65 years were involved in this study (74±6 yrs, male: 41.9%). A tri-axial accelerometer device was employed to quantify daily physical activity level (PAL). Hand-grip strength (HGS) and gait speed (GAS) were measured with conventional methods as indices of physical fitness. Cognitive status (COS) was determined as a score using the Japanese version of the Montreal Cognitive Assessment (MoCA). The associations of the PAL, HGS, and GAS with the COS were tested by 3 linear regression models for respective pairs, each involving the adjustment for age, sex, and years of education. Additional one-way ANCOVA (covarying for age and education) was performed to compare the COS among sex-adjusted quintile groups formed in each physical index.

**RESULTS:** The HGS (27.0±8.1 kg) and GAS (1.7±0.4 m/s) were associated with the COS ( $\beta=0.301$  and  $\beta=0.193$ , respectively,  $p<.0001$ ). Only weak association was found between the PAL (2.6±2.2 METs-hour/day) and COS ( $\beta=0.070$ ,  $p<.0001$ ). Being consistent with the results of the regression analyses, the ANCOVAs showed significant main effects for the HGS (F=18.11,  $p<.0001$ ) and GAS (F=18.24,  $p<.0001$ ) but not for the PAL (F=2.32,  $p=0.0548$ ).

**CONCLUSION:** Hand-grip strength and gait speed were associated with the cognitive status quantified by the MoCA score in community-dwelling older adults after adjusting for age, sex, and education. In contrast, the device-based physical activity level demonstrated only weak association with the cognitive status. Further investigations are needed to examine associations of other indices regarding physical activity and fitness with cognitive status in the population. Supported by a grant from Sasaguri town, Japan to SK.

**3467** Board #188 June 2 9:30 AM - 11:00 AM

**The Joint Association Of Fitness And Fatness To All-cause Mortality: A Meta-analysis**

Vaughn Barry<sup>1</sup>, Meghan Baruth<sup>2</sup>, Michael Beets<sup>2</sup>, Steven Blair, FACSM<sup>2</sup>. <sup>1</sup>Middle Tennessee State University, Murfreesboro, TN. <sup>2</sup>University of South Carolina, Columbia, SC.

(No relationships reported)

**PURPOSE:** Two recent systematic review articles concluded cardiorespiratory fitness (CRF) has a stronger effect than weight status on all-cause mortality. The purpose of this study was to quantify the joint association of these variables (i.e. CRF and weight status) on mortality from all causes using quantitative meta-analytical methodology.

**METHODS:** A systematic literature search was performed using PubMed (1980 to June 2010) and an assessment of recent review articles. Studies were included if they were 1) prospective studies, 2) jointly assessed CRF and body mass index (BMI) with all-cause mortality, and 3) objectively measured CRF and BMI. Articles were excluded from the analysis if the referent group was not normal weight, fit individuals. Seven articles and were included in the final analysis. CRF and BMI levels were reported as fit vs. unfit and fat vs. normal weight. Individuals were considered unfit if they were in the lowest 20% of the study cohort or had a maximal aerobic capacity of < 5 METs. BMI categories were > 18.5 kg/m<sup>2</sup> to < 25.0 kg/m<sup>2</sup> (normal weight) and  $\geq$  25.0 kg/m<sup>2</sup> (fat). Pooled hazard ratios were assessed for each subgroup using a random-effects model and fit-normal weight individuals as the referent group.

**RESULTS:** Compared to fit-normal weight individuals, unfit individuals had twice the mortality risk regardless of fatness level (unfit-normal weight, 2.07, 95% CI, 1.66-2.59; unfit-fat, 2.08, 95% CI, 1.70-2.55). Fit-fat individuals had similar mortality risks (1.10, 95% CI, 0.95-1.27) to fit-normal weight individuals.

**CONCLUSIONS:** Individuals with low CRF have twice the risk of death from all causes regardless of BMI categorization. Moderate to high CRF levels significantly reduces the all-cause mortality risk associated with excess weight. Therefore, maintaining moderate to high CRF levels is important for normal weight, overweight and obese individuals.

**Environment Perception For PA And Nutrition: Relationship With Health-related Fitness**

Marlene M. Rodrigues, Ana P. Pascoal, Joana C. Martins, Ana J. Rodrigues, Mario A. Botelho, Helder Rodrigues, Ana P. Marques, M. Joao C A Almeida. *University of Madeira, Funchal, Portugal.*

(No relationships reported)

A shift in eating habits, patterns and levels of physical activity during the last decades, may explain the dramatic increase in the prevalence of overweight and obesity. Understanding how those changes continue to occur, and which factors may play different roles in different populations, is necessary for developing better strategies.

**PURPOSE:** The objectives of this study were to compare health-related indicators, sports participation, eating habits and perception of physical environment between adolescents from two different islands in Portugal, as well as to identify the best predictors of a high and very high percent body fat (%BF).

**METHODS:** Participants in this study were 326 boys and girls. Prevalences of overweight and obesity were determined according to Cole et al. (2000), %BF was estimated according to Slaughter et al. (1998), and participants classified in health risk categories according to Lohman (1987). Aerobic fitness was assessed with the Fitnessgram 20 m pacer test (The Cooper Institute for Aerobics Research, 2007). Sport participation, eating habits (Wilson et al., 2008) and perception of the physical environment (Evenson et al., 2006) were assessed by self-report questionnaire.

**RESULTS:** 29% of the participants were overweight or obese, 30.4% were in the high or very high categories for %BF, 61.4% were below the healthy zone for aerobic fitness, and 64.7% indicated Physical Education as the only structured physical activity they regularly participated in. There were significant differences between the two islands in prevalence of sport participation and perception of the physical environment. It was found that the perception of fruits' and vegetables' availability (OR: 0.854; 95%CI 0.746 - 0.977) and identifying geographic barriers in the physical environment (OR: 1.127; 95%CI 1.023-1.240) were both predictors of a high or very high %BF.

**CONCLUSION:** The development of intervention strategies aimed at reducing adiposity should have in mind the physical, social and cultural environment in which the participant is inserted. Sponsored by the Research Center of Sport, Health and Human Development (CIDESD) and the Department of Education in Madeira Autonomous Region

**In Search of Relationship Between Physical Fitness and Body Image**

Qin Lai<sup>1</sup>, Huihong Zhang<sup>2</sup>. <sup>1</sup>Wayne State University, Detroit, MI. <sup>2</sup>Southeast University, Nanjing, China. (Sponsor: Hermann-J Engels, FACSM)  
(No relationships reported)

A recent meta-analysis revealed exercise was strongly related to body image (Hausenblas & Fallon, 2006). An individual with higher level of self-assessments toward her/his body, particularly appearance, tended to increase physical activity and maintain a healthy body composition. However, the previous research rarely utilized a quantitative measure of fitness to analyze how body image contributed to physical fitness development in large sample sizes, especially in different cultural settings.

**PURPOSE:** To determine the relationship between physical fitness and body image to locate which dimensional body-self relations was related to fitness tests in a large sample size of college students in China.

**METHODS:** Participants (n=563, aged at 17-21) were randomly selected from three urban universities in China. A standardized fitness test battery was adopted to assess cardiovascular endurance, speed, flexibility, and strength. A Chinese version of the Multidimensional Body-Self Relations Questionnaire (MBSRQ) was distributed to the students for body image assessments after the completion of fitness tests. Fitness and body images relation was analyzed by forward stepwise regression and Pearson's correlation.

**RESULTS:** Forward stepwise regression revealed only fitness subsets of MBSRQ including self-reported fitness evaluation and orientation reliably predicted total physical fitness scores ( $R^2 = .23$ ). Pearson's correlation analysis demonstrated that self fitness evaluation or orientation had a strong relationship with cardiovascular endurance performance ( $r = .13$ ,  $p < .01$ ) and speed performance ( $r = .21$ ,  $p < .01$ ). The other subsets including appearance and health were not related to the fitness scores.

**CONCLUSION:** The findings indicated that fitness test performance could be predicted by self-evaluation of fitness and attitude toward fitness. Unlike previous studies with participants in the North America, the present research failed to detect a relationship between fitness performance and appearance and health evaluations in Chinese students. It suggested different cultural settings might regulate the effects of behavioral factors on fitness development.

3470 Board #191 June 2 9:30 AM - 11:00 AM

**Peak Oxygen Uptake And Leisure Time Physical Activity In 4427 Healthy Adults: The Hunt Study**

Bjarne M. Nes, Inre Janszky, Lars J. Vatten, Ulrik Wisløff. Norwegian University of Science and Technology, Trondheim, Norway.  
(No relationships reported)

Leisure time physical activity (LTPA) of a sufficient dose to increase cardiorespiratory fitness ( $VO_{2peak}$ ) may yield numerous health benefits. Current guidelines suggest that adults should perform moderate intensity activity at least 150 minutes per week, or high intensity activity at least 75 minutes per week.

**PURPOSE:** The aim of the study was to examine how self-reported LTPA at different levels of weekly duration and relative intensity associates with  $VO_{2peak}$  and estimated weekly energy expenditure in a large population.

**METHODS:** A total of 4427 adults, 19-89 yrs, and free from cardiovascular disease (2158 men; mean age 48.4, BMI 26.6, and 2269 women; mean age 48.0, BMI 25.4), were tested for directly measured  $VO_{2peak}$  (mean 44.3 and 35.9  $mL \cdot kg^{-1} \cdot min^{-1}$  for men and women, respectively). Information on LTPA was collected through a detailed questionnaire containing questions on frequency, duration and relative intensity (Borg 6-20 scale). Subjects were grouped according to gender, total LTPA (min/week) and low (Borg scale 6-11), moderate (Borg scale 12-13) or high (Borg scale 14-20) relative intensity. Weekly LTPA energy expenditure was estimated by multiplying the subject's oxygen uptake in litres per minute ( $L \cdot min^{-1}$ ) at their reported Borg scale rating by 5  $kcal \cdot min^{-1}$  and further multiplying by minutes per week. A general linear model was applied adjusting for age, BMI, education, occupational physical activity and smoking.

**RESULTS:** Both men and women reporting  $<90$  min/week (group mean, 47 min/week) and high intensity had considerably higher  $VO_{2peak}$  than the inactive groups (45.1 vs. 41.0 and 35.1 vs. 32.9  $mL \cdot kg^{-1} \cdot min^{-1}$  for men and women, respectively, both p-values  $<0.001$ ). A comparable  $VO_{2peak}$  were observed among men and women reporting  $>150$  min/week (group mean, 217 min/week) and moderate intensity (44.5 and 36.3  $mL \cdot kg^{-1} \cdot min^{-1}$  for men and women, respectively). Estimated weekly energy expenditure, however, were more than 4 times higher in the moderate intensity - high duration groups compared to the high intensity-low duration groups (2988 vs. 713  $kcal/week$  in men and 1964 vs. 429  $kcal/week$  in women, both  $p < 0.001$ ).

**CONCLUSION:** LTPA patterns of high duration - moderate intensity and low duration - high intensity were associated with similar  $VO_{2peak}$ , despite large differences in weekly energy expenditure.

3471 Board #192 June 2 9:30 AM - 11:00 AM

**Running and All-cause Mortality Risk - Is More Better**

Duck-chul Lee<sup>1</sup>, Russell R. Pate, FACSM<sup>1</sup>, Carl J. Lavie<sup>2</sup>, Steven N. Blair, FACSM<sup>1</sup>. <sup>1</sup>University of South Carolina, Columbia, SC. <sup>2</sup>Ochsner Health System, New Orleans, LA.  
(No relationships reported)

**PURPOSE:** We examined the association between running and all-cause mortality risk in 52,656 adults (26% women) aged 20-100 years (mean age 43) who had a medical examination during 1971-2002 in the Aerobics Center Longitudinal Study.

**METHODS:** Participants were free of cardiovascular disease (CVD), cancer, abnormal resting or exercise electrocardiogram, and diabetes at baseline, and had  $\geq 1$  year of follow-up. Running and other physical activities were assessed on the medical history questionnaire by self-reported leisure-time activities during the past 3 months. Mortality follow-up was through 2003 using the National Death Index. Cox regression was used to quantify the association between running and mortality after adjusting for baseline age, sex, examination year, body mass index, current smoking, heavy alcohol drinking, hypertension, hypercholesterolemia, parental CVD, and levels of other physical activities.

**RESULTS:** During an average follow-up of 15 years, 2,984 deaths occurred. Approximately 27% of adults participated in leisure-time running. Runners had 19% lower risk of all-cause mortality compared with non-runners, with U-shaped mortality curves for distance, speed, and frequency. The hazard ratios (95% confidence intervals) of all-cause mortality were 0.78 (0.64-0.96), 0.85 (0.73-0.99), 0.73 (0.60-0.89), 0.75 (0.57-0.97), 0.90 (0.67-1.22), and 0.95 (0.73-1.24) in 0.1-4.9, 5.0-9.9, 10.0-14.9, 15.0-19.9, 20.0-24.9, and  $\geq 25.0$  miles/week of running distance; 0.90 (0.75-1.08), 0.79 (0.68-0.91), 0.73 (0.61-0.86), and 0.93 (0.73-1.19) in 1-5, 6, 7, and  $\geq 8$  miles/hour of running speed; and 0.81 (0.49-1.32), 0.65 (0.46-0.92), 0.81 (0.65-0.997), 0.82 (0.71-0.94), 0.81 (0.66-0.99), 0.86 (0.65-1.14), and 0.95 (0.69-1.33) in 1, 2, 3, 4, 5, 6, and 7 days/week of running frequency, respectively, compared with no running after adjusting for confounders including levels of other physical activities.

**CONCLUSIONS:** Running distances of 0.1-19.9 miles/week, speeds of 6-7 miles/hour, or frequencies of 2-5 days/week were associated with a lower risk of all-cause mortality, whereas higher mileage, faster paces, and more frequent running were not associated with better survival.

**Relationships Between Specific Back-Fitness Tests and the Occurrence of Back Injuries in Firefighters**

Karlie J. Moore, Salvador Jaime, Katherine B. Gunter. *Oregon State University, Corvallis, OR.*  
(No relationships reported)

Firefighters (FFs) experience a high incidence of back injuries; near 50% of FFs have experienced at least one back injury throughout their career and the primary reason for early retirement from disability is back injury. An assumption exists that fit FFs experience fewer back injuries, yet the true relationship between FF's fitness level and incidence of back injury is understudied. It is not clear what specific aspects of fitness are related to the occurrence of back injuries or what tests may be conducted to better understand a FF's risk of experiencing a back injury.

**PURPOSE:** To investigate the relationships between specific back-fitness tests and the occurrence of back injuries in firefighters.

**METHODS:** 118 FFs from three fire departments completed a back injury survey and eight back-fitness tests: A modified Schober test for lumbar flexion (LF) and lumbar extension (LE), a trunk rotation flexibility test to the right (RR) and left (RL), a back endurance "row" test with 20 lb weights (BE), a back strength test using dynamometry (BS), a hamstring endurance "kickback" test (HE) and a prone chin-up test (PC). The survey asked if FFs had experienced 0, 1, 2 or 3+ back injuries throughout their careers along with other relevant parameters. A zero-inflated poisson regression was utilized to 1) identify the variables that predict injury rate, and 2) identify the variables that predict the FFs who never experience back injuries. To account for exposure time, # of years as a FF was included in the model.

**RESULTS:** 59 FFs reported 0 back injuries, 24 FFs reported 1, 14 FFs reported 2, and 21 FFs reported 3+ back injuries. The # of injuries was significantly related to LE ( $p < .01$ ) and BS ( $p = .05$ ). For FFs who reported  $\geq 1$  back injury, improving LE capability by one cm lowers the expected # of back injuries during a career by 34.4%. For every standard deviation increase in BS (27 kg), a FF's odds of never having a back injury improve tenfold. There was no association between # of back injuries and LF, RR, RL, BE, HE and PC.

**CONCLUSION:** Possessing an adequate level of back strength and lumbar flexibility appears to reduce the risk for back injuries among FFs. An intervention needs to be conducted to confirm that improving/preserving these aspects of fitness lowers the occurrence of back injuries for FF's.

**3473 Board #194 June 2 8:00 AM - 9:30 AM**  
**Physiological Measurement Comparison From A Portable Sensor System And Standard Laboratory Equipment During Graded Exercise**

Jeffrey B. Powell, Aitor Coca, Kim Jung-Hyun, W. Jon Williams, Raymon J. Roberge. *NIOSH/CDC/NPPTL, Pittsburgh, PA.*  
(No relationships reported)

Physiological monitoring in real time can offer valuable information on the biomedical status of workers engaged in strenuous activities.

**PURPOSE:** This study compares the accuracy of a commercially available portable sensor system to standard laboratory physiological monitoring equipment for real-time monitoring of heart rate (HR) and respiratory rate (RR) responses during treadmill exercise.

**METHODS:** Six healthy subjects completed a maximal graded exercise test (GXT) wearing the portable sensor system and a standard laboratory physiological monitoring system. The treadmill protocol consisted of stages in which workload increased every 30 seconds starting at 1.7mph/0% incline and ending at 3.5mph/25% incline. The study variables, HR and RR, were recorded simultaneously breathe by breathe using the two systems. The variables were then summarized at time points of rest and workloads ( $O_2$ ) equal to 30, 50, 70, 90 and maximum. Paired sample t-tests and Spearman correlation coefficients ( $r_s$ ) were calculated to compare the variables.

**RESULTS:**

| VO2  | Heart rate (beats-min-1) |             |       |     | Respiratory rate (breaths-min-1) |            |       |     |
|------|--------------------------|-------------|-------|-----|----------------------------------|------------|-------|-----|
|      | Standard                 | Portable    | p     | rs  | Standard                         | Portable   | p     | rs  |
| Rest | 72.0(7.3)                | 76.5(7.2)   | 0.04  | .89 | 16.0(6.7)                        | 16.2(4.0)  |       | .71 |
| 30%  | 96.3(5.8)                | 109.3(14.5) | 0.03  | .32 | 23.8(4.9)                        | 22.4(5.0)  |       | .94 |
| 50%  | 128.7(13.5)              | 130.3(8.7)  | > .05 | .90 | 28.2(5.9)                        | 25.7(4.8)  | > .05 | .83 |
| 70%  | 146.3(6.9)               | 146.9(6.5)  |       | .94 | 32.0(5.4)                        | 31.7(5.2)  |       | 1.0 |
| 90%  | 171.3(9.3)               | 171.7(8.4)  |       | 1.0 | 37.5(9.5)                        | 37.2(9.1)  |       | 1.0 |
| MAX  | 182.2(9.9)               | 181.2(8.3)  |       | 1.0 | 42.8(12.4)                       | 41.8(10.9) |       | .94 |

Values are mean (SD) (n=6),  $VO_{2max}$ : 50.8 (4.3) ml/kg/min, p-value: Paired samples t-test

**CONCLUSION:** The results of this study show HR and RR measurements by portable sensor system in subjects performing GXT are comparable to those from a standard physiological monitoring system. However, there was a greater HR measurement variability during rest and exercise less than 50%  $VO_{2max}$ , while HR and RR measurement accuracy increased at higher exercise intensities. This study demonstrates the accuracy of the portable sensor system for real-time monitoring of physiological parameters and suggests usefulness for physiological research in the field.

**3474 Board #195 June 2 8:00 AM - 9:30 AM**  
**Self Reported Exercise during Deployment Correlates with Measured Fitness Outcomes**

Bradley J. Warr<sup>1</sup>, Brent A. Alvar<sup>2</sup>, Marilyn A. Sharp<sup>1</sup>. <sup>1</sup>U.S. Army Research Institute of Environmental Medicine, Natick, MA. <sup>2</sup>Rocky Mountain University of Health Profession, Provo, UT.  
(No relationships reported)

There is currently little data evaluating soldiers' physical activity levels and exercise programs or the accuracy of surveys to characterize fitness training during deployment. The typical deployed unit conducts 24 hr operations, making unit level physical fitness training difficult to conduct; most soldiers maintain their fitness by completing training in an autonomous manner.

**PURPOSE:** To determine the validity of survey questions regarding frequency and duration of purposeful exercise in deployed soldiers.

**METHODS:** Seventeen male infantry soldiers (age=26±5.7 y/o, ht=178.5±6.2 cm, wt=83.9±11.8 kg) from the Arizona National Guard completed a  $VO_2$  peak test ( $VO_{2p}$ ), 1RM bench-press (BP), 1RM back-squat (BS), and survey questions pertaining to frequency and duration of aerobic exercise, strength training, and sports participation. Fitness testing and surveys were completed both prior to deployment and within 10 days of returning from deployment. Spearman Rho correlations were used to determine significant relationships between survey questions and measured physical fitness variables, with  $p \leq .05$ .

**RESULTS:** Soldiers' reported activity for the 12 months prior to deployment did not correlate with the measured pre-deployment VO<sub>2</sub>, BP, and BS. However, reported activity levels during deployment did correlate with measured VO<sub>2</sub>, BP, and BS at post-deployment. More than 47% of the soldiers performed aerobic activity at least 3 days per week, while 53% trained for 30 min or more per session. Frequency of aerobic activity was significantly correlated to VO<sub>2</sub> (r=.68), but duration was not. More than 64% performed strength training 3 or more days per week, while 76% conducted 30 min or more per session. Frequency and duration of strength training were both significantly correlated to BP (r=.69, r=.63) and BS (r=.55, r=.69). Only 18% of the soldiers participated in sports activities at least one day per week for more than 30 min per session. Frequency and duration of sports activities were both significantly correlated to VO<sub>2</sub> (r=.54 r=.55).

**CONCLUSION:** Based on the measured physical fitness variables, the survey questions utilized pertaining to purposeful exercise provide reasonable indices of the frequency and duration soldiers are exercising during deployment.

**The Effects Of Football Equipment On 20-yard Agility In High School Seniors**

Katie C. Morgan, Brian J. Campbell, Torie M. Guidry, Cole M. Thompson, Lauren E. Miller, Stefan L. Bergeron, Brittany S. Richard. *University of Louisiana at Lafayette, Lafayette, LA.*

(No relationships reported)

Senior high school football players are more physically developed than most underclassman. The majority have experienced a minimum of four years of a regulated strength and conditioning program. Previous studies have suggested football equipment decreases high school football players' pro-agility (20-yd shuttle run), however four-year seniors may have a different profile than underclassmen.

**PURPOSE:** To assess the effects of football equipment on 20 yard Pro-agility times in senior football players.

**METHODS:** 15 high school football players (weight= 79.42 ± 7.17 kg) served as participants. Players were timed in the 20 yard Pro-agility test with (AE) and without (AN) standard football equipment. Testing was administered by experienced hand held timers on a natural grass field. Participants were randomly assigned to perform two trials under each condition and the faster of the two trials for each condition was recorded and used for analysis. A paired samples t-Test was utilized to compare AE and AN conditions.

**RESULTS:** No significant difference was noted between AE and AN [t=1.967, p > .05].

**DISCUSSION:** The results support investigating football equipment effects on different levels of high school football. Senior high school football players are more likely physically developed than most underclassman, have more experience with the presence of football equipment, and a majority have undergone four years of a regulated strength and conditioning program. Since the 20-yd agility times of seniors were not significantly affected by football equipment, the 3 levels of underclassmen must be studied further to assess where equipment starts to significantly hinder agility.

**Comparison Between Two Gps System Device To Asses Speed And Acceleration**

Fernando Pareja-Blanco<sup>1</sup>, Pedro Jiménez-Reyes<sup>2</sup>, Luis Suárez-Arrones<sup>1</sup>. <sup>1</sup>Faculty of Sport, Pablo de Olavide University, Sevilla, Spain. <sup>2</sup>Catholic University of San Antonio, Murcia, Spain.

(No relationships reported)

Recently, GPS tracking systems have been used to assess the physical demands in some sports. The validity of GPS devices for measuring distance traveled in team sport and endurance athletes have been investigated and there have been studies for assessing speed in active subjects, but none so far has used GPS of 15 Hz.

**PURPOSE:** To analyze and compare two GPS system device to asses speed and acceleration in sprint races.

**METHODS:** Ten physically active male subjects (age: 19.3 ± 2.3 years, stature: 1.77 ± 0.07 m, body mass: 72.7 ± 9.6 kg) randomly chosen from a population of physically active students and sport team athletes were selected. The correlations between peak acceleration and peak speed obtained from a GPS 1 Hz and 15 Hz with sprint time (at 5, 10 and 30-m) measured with timing lights were determined. Forty-three individual sprints were recorded concurrently with timing lights (Microgate, Bolzano, Italy), a GPSports SPI Elite (1 Hz) and GPSports SPI PRO X (15 Hz) (GPSports System, Canberra, Australia). The light sensors were set at 0, 5, 10 and 15-m for the sprints of 15-m and at 0, 30, 40 and 50-m for the sprints of 50-m. From a standing start 40-cm behind the starting gates, the subjects performed a maximal effort sprint over 15m and 50-m. The subjects were instructed before the sprint to produce maximal efforts for the sprint. To determine the test-retest reliability of the GPS device, each subject completed at least two sprints of each distance on two separate. Pearson's correlation coefficients and 90% confidence intervals (90%CI) were calculated according to the methods of Hopkins.

**RESULTS:** The correlation coefficients between measures of GPS 1 Hz and GPS 15 Hz in sprints of 15m and 50m were 0.02 in acceleration, and for peak speed were significant for 15m (0.68) and 0.50m (0.96). Correlations coefficients between times 5, 10 and 15m measured with timing lights and maximum acceleration and speed measured with GPS were highly significant (r=0.95-0.98).

**CONCLUSIONS:** The results of this study demonstrated a close correlation between peak speeds measured with GPS (1 and 15 Hz) and sprint time in 30, 40 and 50m. The use of GPS may be an alternative to timing lights for assessing sprint performance in 30m and longer distances, however the low sampling rate (1 and 15 Hz) reduce the sensitivity of these measures, especially over shorter distances.

**A Comparison Of The Physiological Demands Of Rowing On The Rowperfect And Concept II Rowing Ergometer**

Niamh Ni Cheilleachair<sup>1</sup>, Andrew Harrison<sup>1</sup>, Giles Warrington, FACSM<sup>2</sup>. <sup>1</sup>University of Limerick, Limerick, Ireland. <sup>2</sup>Dublin City University, Dublin, Ireland.

(No relationships reported)

Ergometer rowing is a popular method of optimizing dry-land training. Rowing ergometers are widely used in the assessment of rowing performance and in national selections.

**PURPOSE:** The purpose of this study was to compare the physiological demands of rowing on the Rowperfect and Concept II rowing ergometers.

**METHODS:** Thirteen trained male rowers participated in the study. Selected physiological responses to an incremental test and a 4-minute maximal test were investigated on the Rowperfect and Concept II. The submaximal incremental test consisted of 3-minute stages at a fixed exercise intensity and predetermined stroke rate followed by 30 seconds recovery. The test commenced at 170 W with 30 W increments until a clear inflection point on the workload-lactate curve was observed, after which one additional increment was completed. During each 30 seconds recovery an earlobe blood sample was taken to determine blood lactate concentration (Bla) and RPE was recorded. Heart rate (HR) (bpm) was measured continuously during the test. On completion of the final incremental stage there was a 2 minute recovery before the 4 minute maximal performance test. This test was to establish the maximal distance which could be covered and to examine the mean power output (MPO) obtained on the 2 rowing ergometers. During the test, time and stroke rate were the only variables visible to the subjects, to ensure any pacing effect was minimised. Each subjects power output and stroke rate were recorded throughout the test. A post-exercise blood lactate sample was obtained after 5 minutes to establish peak lactate concentrations.

**RESULTS:** Blood lactate was significantly higher on the Concept II for all exercise intensities from 170 to 290 W (P<0.05). In contrast no significant difference was found with HR and RPE. During the 4 minute maximal performance test MPO was significantly higher on the Rowperfect (P<0.05) while distance was significantly higher on the Concept II (P<0.05) but no significant difference in peak blood lactate was observed.

**CONCLUSION:** These results indicate that the Concept II places greater physiological demands on rowers than the Rowperfect at fixed exercise intensities. These differences may be due to the different dynamics and mechanics of the two rowing ergometers or inter-ergometer variation in displayed power output.

3478 Board #199 June 2 8:00 AM - 9:30 AM

### An Evaluation of Army Physical Fitness Scores across Classes among Reserve Officer Training Corps Cadets

Keith Leiting, Jake Reed, David Land, Michael H. Stone, Mike W. Ramsey. *East Tennessee State University, Johnson City, TN.*  
(No relationships reported)

**PURPOSE:** The goal of the study was to compare standard military physical fitness scores among Reserve Officer Training Core (ROTC) cadets of varying years of involvement.

**METHODS:** Forty four male and female cadets (38 male, 6 female) performed a scheduled APFT test at the beginning of the fall collegiate semester. Instruction and demonstration of proper technique for push-up and sit-up events was provided prior to the test. Each cadet was given two minutes to perform as many push-ups and two minutes to perform as many sit-ups as possible, followed by the two mile run for shortest time conducted on a 400 meter rubber track. All raw scores and times were recorded on the Army Physical Fitness Scorecard as per FM 21-20, following which differences were obtained used the 4x4 multivariate analysis of variance (MANOVA) (Training, 1992). Tukey's HSD post hoc test were completed to determine differences between classes once significance was found.

**RESULTS:** Significant differences were noted for push up score, sit up scores and total scores ( $p < 0.05$ ; Table 1), however 2 mile run score was not significant ( $p > 0.05$ ; Table 1). MSI cadets scored significantly lower than MSII, MSIII, MSIV in all categories ( $p < 0.05$ ; Table 1). There were no significant differences found between MSII, MSIII, and MSIV for any of the scores ( $p > 0.05$ ; Table 1).

**CONCLUSION:** MSI cadets are less physically fit as determined by the APFT scores. Interestingly the MSII, MSIII, and MSIII do not seem to increase their physical fitness levels despite their continued involvement with the FM 21-20 training protocol.

|       | Push Up Score | Sit Up Score | Two Mile Score | Total Score   |
|-------|---------------|--------------|----------------|---------------|
| MSI   | 56.6±13.00    | 60.75±29.11  | 51.75±41.13    | 169.13±69.67  |
| MSII  | 87.5±9.18*    | 87.13±11.84* | 84.88±17.11    | 259.50±34.81* |
| MSIII | 87.86±12.12*  | 88.57±13.02* | 74.00±27.39    | 250.43±45.77* |
| MSIV  | 81.86±13.13*  | 90.71±10.17* | 82.93±10.00    | 255.50±25.95* |

Table 1: Data is means ± SD. \* denotes sig. dif. ( $p < 0.05$ ) from MSI

### Relationship of Body Mass to Army Physical Fitness Test Performance in College ROTC Cadets

Andrea M. Kobermann<sup>1</sup>, Jerry L. Mayhew<sup>1</sup>, Guy D. Leahy<sup>2</sup>, Todd Crowder<sup>3</sup>. <sup>1</sup>Truman State University, Kirksville, MO. <sup>2</sup>Davis-Monthan Air Force Base, Tucson, AZ. <sup>3</sup>United States Military Academy, West Point, NY.  
(No relationships reported)

A fundamental requirement of the college Army ROTC program is a successful level of achievement standing on the Army Physical Performance Test (PFT). The test includes 2-min push-ups (PU), 2-min sit-ups (SU), and 2-mile distance run (RUN). The tests are converted to point values and summed to produce a total fitness score. Traditionally, the tests are scored in absolute terms for each gender, disregarding the influence of body mass on performance. Questions have been raised whether such a scoring system is equitable across the body mass continuum.

**PURPOSE:** To evaluate the relationship of body mass and BMI to PFT components and total fitness score among college ROTC cadets.

**METHODS:** ROTC cadets (41 M and 21 F; age = 20.2 ± 1.3 y, body mass = 77.3 ± 13.1 kg, BMI = 24.4 ± 2.8 kg/m<sup>2</sup>) were evaluated for PU, SU, and RUN during routine class testing. Point values were assigned according to standard Army tables for each gender with a maximum score of 100 for each item.

**RESULTS:** Men had significantly better absolute performance scores on PU (82% higher), SU (19% higher), and RUN (20% higher) than women. Body mass (BM) was not significantly correlated in both genders with PU (M,  $r = -0.06$ ; F,  $r = -0.08$ ), SU (M,  $r = 0.00$ ; F,  $r = 0.07$ ), RUN (M,  $r = -0.02$ ; F,  $r = -0.19$ ), and total score (M,  $r = -0.03$ ; F,  $r = -0.07$ ). BMI was not significantly different between the genders and also nonsignificantly correlated with PU ( $r = -0.01$ ), SU ( $r = -0.07$ ), RUN ( $r = -0.24$ ), and total score ( $r = -0.13$ ). Although men had slightly higher scoring points on all tests, only the PU score was significantly different between genders (M = 95.2 ± 20.4 vs F = 81.8 ± 24.2). Analysis of standardized beta weights from linear regression for each gender produced equitable contributions for each tests to total performance score: PU (M = 25%; F = 27%), SU (M = 35%; F = 42%), and RUN (M = 31%, F = 39%). If a gender factor was added to the linear regression, it made no addition contribution to the explained variance in performance scores in explaining the total performance score.

**CONCLUSIONS:** Body mass and BMI differences do not appear to impact PFT in college men and women ROTC cadets. This may be related to the routine emphasis on and participation in regular physical fitness training for college ROTC cadets and may not apply to regular Army personnel.

3480 Board #201 June 2 8:00 AM - 9:30 AM

### Relationship Between Systemic And Local Physiological Response To Graded Exercise Assessed With Near-infrared Spectroscopy

Luca Pollonini<sup>1</sup>, Rebecca Re<sup>2</sup>, Patrick Howell<sup>1</sup>, Karishma Prasad<sup>1</sup>, Clifford Dacso<sup>1</sup>, Richard Simpson<sup>1</sup>. <sup>1</sup>University of Houston, Houston, TX. <sup>2</sup>Politecnico di Milano, Milan, Italy.  
(No relationships reported)

Heart rate monitors (HRM) represent an effective method for recreational and professional training. However, HRM assess only the systemic response to exercise and need to be paired with periodic assessment of exercise capacity to guide personalized training. In this project, we developed a wearable device that integrates measurements of systemic and local physiological parameters to quantitatively assess exercise capacity.

**PURPOSE:** 1) To validate an integrated device that simultaneously measures electrocardiography (ECG), photoplethysmography (PPG) and near-infrared spectroscopy (NIRS) parameters in real-time. 2) To study the interplay between systemic and local physiological response to graded exercise.

**METHODS:** We used ECG and PPG to derive systemic measures such as heart rate (HR) and systolic time intervals (STI), whereas NIRS was used to measure concentrations of oxy-hemoglobin ([HbO<sub>2</sub>]), deoxy-hemoglobin ([HHb]), total hemoglobin ([tHb]) and tissue oxygenation index (TOI%) in the right vastus lateralis. Fifteen subjects (10 males, age 25.4±4.6yrs) were asked to perform a graded exercise on a stationary bike (50W +15W/min) maintaining a pedaling cadence of 60rpm, until volitional exhaustion or inability to sustain the cycling rate. ECG, PPG and NIRS data were collected simultaneously to respiratory gas measurements with a metabolic cart.

**RESULTS:** HR and [HHb] increased linearly during the exercise, whereas STI decreased linearly. [HHb] was linearly correlated to VO<sub>2</sub> ( $r > .92$ ,  $p < .0001$ ) at individual level and the slope of such linear correlation was indicative of the VO<sub>2</sub>max of each subject ( $r = .84$ ) and the exercise time to VO<sub>2</sub>max ( $r = .69$ ). After the exercise onset, [HbO<sub>2</sub>], [tHb] and TOI% maintained their basal value for a time interval after which they decrease linearly. The ventilatory threshold (VT) determined by V-slope was linearly related to the peak value of [HHb] at the end of exercise ( $r = .67$ ). The correspondent time of VT was also related to the deflection point of TOI% ( $r = .63$ ).

**CONCLUSIONS:** The quantitative assessment of the systemic and muscular physiological response to exercise is consistent with energy expenditures measured by metabolic cart. The proposed wearable sensor represents a valid tool that complements HRM by providing a more complete description of the exercise activity.

**3481** Board #202 June 2 8:00 AM - 9:30 AM  
**Walking Performance Assessed by Incremental Shuttle and Six-minute Walking Tests among Older Tennis Practitioners**

Ricardo L. F. Guerra, Arino Anjos, Victor Zuniga Dourado. *UNIFESP, Santos, Brazil.*  
(No relationships reported)

The regular practice of physical exercise reduces the decline of functional fitness and tennis practice is a possibility for this

**PURPOSE:** Walking is an important activity of daily living, is associated to health status and balance, and also is a popular form of physical exercise for the conditioning of middle-aged and older adults. However, there are few studies assessing the effects of the practice of tennis in walking ability in this age group.

**PURPOSE:** to evaluate walking performance and body composition in middle aged and older tennis practitioners by two widely used field tests, the incremental shuttle (ISWT) and six-minute (6MWT) walking tests.

**METHODS:** Twenty-one male volunteers ( $60 \pm 5$  years) were divided into two groups: 10 subjects practicing tennis (PT) and 11 non-practicing tennis (NPT). Tennis regimen consisted of at least 3 months of practical, 3x/wk, and 1 h/day. The participants in the NPT group were non-trained (i.e., < 150 min/wk of regular exercise). Peak values of oxygen uptake ( $VO_2$ ), carbon dioxide output, minute ventilation and heart rate (HR), among others variables, were monitored by a portable telemetric system (K4 Cosmed) during each third ISWT and 6MWT. During the ISWT, the ventilatory equivalents were used to assess  $VO_2$  at ventilatory threshold ( $VO_2VT$ ). The total distances traveled on ISWT and 6MWT were registered in meters (ISWD and 6MWD) and in percentage of predicted values (%). Body composition was assessed by bioelectrical impedance. The statistic was made using student t test.

**RESULTS:** We were not able to find differences between groups related to body composition variables. During the ISWT, the PT group presented higher ( $p < 0.05$ ) peak  $VO_2$  ( $29 \pm 5$  versus  $22 \pm 2$  ml/kg/min),  $VO_2VT$  ( $19 \pm 3$  versus  $15 \pm 1$  ml/kg/min), ISWD [ $626 \pm 90$  ( $116 \pm 13$ ) versus  $540 \pm 76$  m ( $96 \pm 10\%$ )], and peak HR ( $89 \pm 10$  versus  $75 \pm 13\%$  of maximum). We did not find significant differences in physiological responses to the 6MWT as well as in 6MWD between groups.

**CONCLUSION:** These data allow us to suggest that tennis may be a field of practice for maintenance walking performance, especially aerobic capacity, in middle aged and older adults and the ISWT appears to assess this condition better than the 6MWT.

Supported by FAPESP grant n. 2007/08673-3.

**3482** Board #203 June 2 8:00 AM - 9:30 AM  
**Relationship Between Physical Fitness, Body Composition And Cardiovascular Risk Factors In Healthy Individuals**

Steven Mann, Judith Allgrove, James Brown, Alfonso Jimenez. *University of Greenwich, Medway, United Kingdom.*  
(No relationships reported)

Worldwide obesity levels have more than doubled since 1980 and in 2008 1.5 Billion adults were overweight (WHO Fact Sheet N°311). Obesity is a leading risk factor of cardiovascular (CV) disease, while high body fat percentages are associated with Type 2 diabetes and further CV complications. Behavioural change such as an increase in physical activity has been suggested as a method of reducing these risks (Pedersen & Saltin 2006).

**PURPOSE** To assess the relationship between behaviour, as reflected by physical fitness markers: maximal aerobic capacity ( $\dot{V}O_{2max}$ ) and muscular strength, health status and CV risk.

**METHODS** This is the first phase of a study into the effects of fitness centre based exercise on CV health and wellbeing. 105 participants (73 female, 32 male), mean  $\pm$ SD age:  $42.2 \pm 5.7$  yrs, height:  $168.8 \pm 8.4$  cm, weight:  $82.7 \pm 17.8$  kg, predicted  $\dot{V}O_{2max}$ :  $35.4 \pm 9.1$  ml/kg/min free from chronic health conditions, performed a battery of health assessments to measure; predicted (Modified Blake protocol - Fitmate Pro), muscular strength (sub-maximal 1rep max), estimated body fat percentage (BF%) using a BODPOD, blood pressure (BP), cholesterol (LDX Cholestech), resting heart rate (RHR) as a marker of CV efficiency, and C-Reactive Protein (CRP), a marker of chronic inflammation ( $n=29$ ) (LDX Cholestech). Participants were then randomly assigned to either structured gym based exercise or unstructured gym based exercise. A control group receiving physical activity counselling was also included.

**RESULTS** Initial baseline findings show moderate correlations between and strength in Chest Press (CP) ( $R=0.317$ ,  $P=0.002$ ) and Lateral Pull Down (LPD) ( $R=0.308$ ,  $P=0.002$ ), and strength also moderately correlated with BF% ( $R=-0.583$ ,  $P=0.000$ . CP.  $R=-0.513$ ,  $P=0.000$ . LPD.  $R=-0.476$ ,  $P=0.000$ . Leg Press.  $R=-0.340$ ,  $P=0.001$ ). BF% was positively associated with RHR ( $R=0.315$ ,  $P=0.001$ ) and CRP ( $R=0.417$ ,  $P=0.02$ ). No clear relationship was identified between markers of physical fitness and cholesterol levels or BP.

**CONCLUSION** The initial findings show that increased predicted and muscular strength as indicators of physical fitness are associated with decreased BF%. Further, increased BF% is associated with a higher RHR and CRP. However no relationship between cholesterol and BP with levels of physical fitness was found within this cohort.

**3483** Board #204 June 2 8:00 AM - 9:30 AM  
**A Comparison of Two Different Body Positions Used During Rowing**

Daniel G. Syrotuik, Bill Reynolds, Jack Bennett, Pierre Gervais, Gordon J. Bell. *University of Alberta, Edmonton, AB, Canada.*  
(No relationships reported)

The amount of power output (PO) generated during a rowing stroke is partly dependent on the length of the stroke and this can be enhanced by using a greater extension at the finish position of the stroke. However, there is little research that has compared the differences of performing the rowing stroke at varying lean-back (LB) positions.

**PURPOSE:** The purpose of this study was to compare two different LB positions during 3 different graded exercise trials on a Concept II rowing machine.

**METHODS:** Nine men and 5 women with a mean age ( $\pm$  SD), height, body mass and peak of 29 (11) yrs, 185.6 (11.4) cm, 84.8 (15.9) kg, 51.2 (6.9) ml $\times$ kg $^{-1}$  $\times$ min $^{-1}$  and 25 (4) yrs, 171.4 (8.1) cm, 74.6 (7.7) kg and 44.9 (5.3) ml $\times$ kg $^{-1}$  $\times$ min $^{-1}$  respectively, volunteered. Light reflective markers were taped to anatomical landmarked positions on the body and specific sites on the rowing machine. Motion data for the rowing exercise trials were collected at 60Hz using 5 Qualisys ProReflex motion capture cameras. Three randomized, rowing exercise bouts at 3 different intensities lasting 3-5 minutes each were performed on a Concept IID rowing machine: rowing at a PO of 125, 150 and 175 w and a stroke rate (SR) = 18, 22 and 24 strokes $\times$ min $^{-1}$  in an upright position; rowing at a PO of 125, 150 and 175 w without controlling SR; and, rowing at a SR of 18, 22 and 24 strokes $\times$ min $^{-1}$  without controlling PO. Both of these latter trials were performed at the same extended LB position.

**RESULTS:** There was a significant different hip angle of  $\sim 29^\circ$  at the finish between the upright body position and both extended LB positions regardless of the SR used or the PO generated. The distance the handle moved throughout the rowing stroke was longer ( $P < 0.05$ ) in the two LB positions ( $1.57 \pm 0.16$  and  $1.58 \pm 0.14$  m) versus the upright position ( $1.37 \pm 0.15$  m). The velocity that the handle moved was significantly faster in the greater LB position at the same SR ( $1.41 \pm 0.1$  m/s $^2$ ) versus the LB at the same PO ( $1.31 \pm 0.06$  m/s $^2$ ) or compared to the upright body position ( $1.26 \pm 0.12$  m/s $^2$ ).

**CONCLUSION:** A more extended LB body position (hip angle of  $\sim 140^\circ$ ) results in a greater rowing handle movement compared to a more upright body position regardless of the SR used or PO generated and produces a greater handle velocity at the same SR. As a result, the greater LB position produced 12% greater PO at the same SR.

**3484** Board #205 June 2 8:00 AM - 9:30 AM  
**The Comparison Of EMG And O2 Consumption Between Non-motorized And Motorized Treadmill Running**

Takahiro Nakama, Akihiro Sakamoto, Katamoto Shizuo. *Juntendo University, Inzai, Chiba, Japan.*  
(No relationships reported)

Non-motorized treadmill (NT), on which the users need to accelerate the belt themselves and require the safety and body stabilization by wearing a harness or holding onto the surrounding railing. Recently, the newly designed curve-shaped NT has been developed, and this type of NT has eliminated all the concerns above. Running can be performed upright, with the speed able to be altered freely, so that it may better simulate running situations similar to conventional motorized treadmill (MT) to a certain extent. However, because of the curved shape, belt friction and the need for belt acceleration, greater physiological stresses may be imposed on users compared to MT or track running. The knowledge of exact physiological responses on NT is necessary to precisely prescribe exercise programs when NTs become available at many fitness facilities.

**PURPOSE:** The purpose was to compare HR,  $VO_2$  and iEMG of lower limbs between NT and MT runnings.

**METHODS:** Six trained male endurance runners (aged between 20-23 years old) ran on a NT and MT at the speed of 8, 11 and 14 km/h in a randomized order (3 min for each trial), with 5 min rest between trials. For each trial, VO2 was measured between the 2nd and 3rd minutes, while HR and EMG from the gluteus maximus(GM), biceps femoris(BF), medial gastrocnemius(MG), rectus femoris(RF), vastus medialis(VM), and tibialis anterior(TA) were recorded between 2'30" and 2'40".

**RESULTS:** Faster speeds produced greater HR ( $p < 0.001$ ), VO2 ( $p < 0.001$ ) and iEMG ( $p < 0.01$ ). VO2 and HR were significantly higher for the NT compared to MT ( $p < 0.001$ ). iEMG was also significantly higher for the NT ( $p < 0.05$ ) except VM and TA. Significant condition  $\times$  speed interactions for VO2 ( $p < 0.001$ ) and iEMG ( $p < 0.05$ ) meant that the condition effects were more pronounced for faster speeds.

**CONCLUSIONS:** NT running results in higher HR, VO2 and iEMG of lower limbs (except VM and TA) than that in MT running. These discrepancies of physiological responses need to be considered when prescribing exercise programs for NT users.

Nogrant for this study.

**3485 Board #206 June 2 8:00 AM - 9:30 AM**

**Relationships Between Free Testosterone, Cortisol, and Anaerobic Performances In Recreationally-trained Subjects**

Matthew J. Andre<sup>1</sup>, Andrew C. Fry<sup>1</sup>, Jason B. Winchester<sup>2</sup>, Arnold G. Nelson, FACSM<sup>3</sup>, Jatin P. Ambegaonkar<sup>4</sup>, Shane V. Caswell<sup>4</sup>. <sup>1</sup>University of Kansas, Lawrence, KS. <sup>2</sup>Midwestern State University, Wichita Falls, TX. <sup>3</sup>Louisiana State University, Baton Rouge, LA. <sup>4</sup>George Mason University, Manassas, VA.  
(No relationships reported)

Free testosterone (FT) and its ratio to cortisol (FT/C) has been correlated with jumping and sprinting ability in football, soccer, throwing, handball, and volleyball athletes (Cardinale & Stone, 2006; Nelson et al., 2009; Winchester et al., 2008a). One study has also reported significant relationships in a recreationally-trained population (Winchester et al., 2008b).

**PURPOSE:** To examine relationships among salivary FT or FT/C and anaerobic performances in recreationally-trained individuals.

**METHODS:** Saliva was collected from 17 recreationally-trained college males, followed by testing for vertical jump (VJ), standing broad jump (SBJ), and 36.6m (40yd) sprint (SPR). Saliva samples were analyzed in duplicate for FT and cortisol (C) via ELISA. Pearson product correlation coefficients (r) examined relationships between salivary FT or FT/C and performance ( $p < 0.05$ ).

**RESULTS:** Mean VJ (cm), SBJ (m), and SPR (seconds) were  $58.1 \pm 2.3$ ,  $2.22 \pm 0.06$ , and  $5.51 \pm 0.10$ , respectively. Mean FT (nmol/L), C (nmol/L), and FT/C were  $1.09 \pm 0.2$ ,  $5.89 \pm 1.4$ , and  $0.29 \pm 0.04$ , respectively.

|                   | Vertical Jump | Standing Broad Jump | Sprint |
|-------------------|---------------|---------------------|--------|
| Free Testosterone | 0.37          | 0.08                | -0.21  |
| Cortisol          | 0.02          | 0.25                | -0.01  |
| Free Tes/Cort     | 0.21          | 0.11                | -0.22  |

No correlations were statistically significant.

**CONCLUSION:** The results of this study suggest that FT, C, and FT/C are not related to vertical jump, standing broad jump, or sprint performance in non-athletic, but physically-active, populations. Further research is needed to determine relationships between endocrine profiles and anaerobic performances for this population.

**3486 Board #207 June 2 8:00 AM - 9:30 AM**

**Stability Ball Sitting During Semi-Recumbent Exercise**

Charles R.C. Marks, Jenna Leach, Deborah Wagner, Leslie Schachinger, Blake Brennan, Steven Grapsas. *Oakland University, Rochester, MI.* (Sponsor: Tamara Hew-Butler, FACSM)  
(No relationships reported)

**PURPOSE:** This study predicted that stability ball sitting during semi-recumbent exercise will affect cardiorespiratory, electromyography, and kinematic parameters when compared to chair sitting.

**METHODS:** Sixteen healthy young adults underwent two semi-recumbent graded exercise tests to volitional fatigue over two consecutive days: one stability ball sitting, the other chair sitting (order randomized). Pedaling while sitting behind a cycle ergometer and holding onto cycle seat was used for the semi-recumbent position. VO2 and heart rate (HR) were continuously measured. During two stages of exercise right side flexor digitorum (FD), erector spinae (ES), external oblique (EO), quadriceps (QC), hamstrings (HM), and gastrocnemius (GN) % MVC EMGs were measured; also, video of the right hip back view was taken for vertical (Hip V) and lateral (Hip L) displacement. Repeated measures ANOVA with paired-t test for *post hoc* analysis ( $P < 0.05$ ) were done.

**RESULTS:** All participants achieved the same peak power output for both tests. VO2, HR, ES, and HM had non-significant sitting mode main effects and interactions ( $P \geq 0.353$ ) while EO tended towards significant sitting mode main effect ( $P = 0.113$ ). FD, GN, and QC had significant sitting mode main effects ( $P \leq 0.042$ ). Hip V and Hip L also had significant sitting mode main effects ( $P \leq 0.004$ ). The table below reports the mean  $\pm$  sd for all but ES and HM.

| Table       | Ball        | Chair         | Ball        | Chair        |
|-------------|-------------|---------------|-------------|--------------|
|             | VO2         | l/min         | HR          | b/min        |
| 50% of Peak | 1.59 + 0.31 | 1.56 + 0.39   | 140 + 14    | 142 + 11     |
| Penult      | 2.47 + 0.60 | 2.49 + 0.70   | 174 + 11    | 175 + 10     |
| Peak        | 2.89 + 0.71 | 2.80 + 0.68   | 185 + 9     | 185 + 9      |
|             | GN          | EMG %         | QC          | EMG %        |
| Stage 1     | 35.1 + 11.6 | 45.9 + 17.7 * | 15.0 + 7.6  | 14.6 + 4.8   |
| Stage 2     | 40.3 + 13.2 | 45.6 + 15.5   | 18.1 + 7.8  | 24.2 + 8.7 * |
|             | FD          | EMG %         | EO          | EMG %        |
| Stage 1     | 14.4 + 6.1  | 11.6 + 8.1 *  | 27.1 + 20.7 | 25.2 + 17.5  |
| Stage 2     | 19.4 + 7.9  | 16.8 + 8.7    | 38.6 + 42.2 | 26.3 + 16.7  |
|             | Hip V       | cm            | Hip L       | cm           |
| Stage 1     | 3.2 + 0.9   | 2.5 + 1.8     | 4.6 + 1.7   | 1.1 + 0.48 * |
| Stage 2     | 4.7 + 1.8   | 2.1 + 0.5 *   | 5.5 + 1.9   | 2.3 + 0.7 *  |

\* Ball versus Chair Paired-t  $P < 0.019$

**CONCLUSION:** It is concluded that the stability ball may alter arm and leg muscle recruitment patterns with an increase in coronal plane hip motion during semi-recumbent exercise but without affecting cardiorespiratory parameters.

Supported in part by an Oakland University Faculty grant.

**Gross Mechanical Efficiency And Physical Strain During Submaximal Cyclic Arm-leg Cruiser@ Exercise**

Lucas H. van der Woude<sup>1</sup>, Liesbeth Simmelink<sup>2</sup>, Ilse Borgesius<sup>1</sup>, Florentina Hettinga<sup>1</sup>, Rien Dekker<sup>2</sup>. <sup>1</sup>Center for Human Movement Sciences, University Medical Center Groningen, Groningen, Netherlands. <sup>2</sup>Center for Rehabilitation, University Medical Center Groningen, Groningen, Netherlands. (Sponsor: TWJ Janssen, FACSM)

(No relationships reported)

**PURPOSE:** The Cruiser@ ergometer (Enraf Nonius, The Netherlands) is a testing and training device, which allows combined asynchronous arm-leg exercise in a stable recumbent sitting position. As such it is frequently used in Dutch rehabilitation as a cardiorespiratory fitness intervention for lower limb impaired persons.

**PURPOSE:** To compare gross mechanical efficiency (GE) and physical strain during steady state submaximal Cruiser, cycling and upper body handbike exercise.

**METHODS:** 22 Healthy men (n=10; 24±1.8yrs; 79±10.5kg) and women (n=12; 22.1±2.4; 65.8±10.2kg) enrolled in a series of 4 submaximal steady state exercise tests on the Cruiser, a bicycle ergometer, a handbike on a motor driven treadmill and again the Cruiser. In each mode subjects performed a series of six 3min bouts (PO=20-45W) at a constant cadence. Oxygen uptake, energy cost, ventilation, breathing frequency, heart rate and RPE were monitored. GE was derived from PO and energy cost.

**RESULTS:** Cruiser GEs (45W; men: 13.0±1.3%, woman: 15.0±3.1%) were not significantly different from cycling (45W; men: 13.2±1.9%, women: 14.6±1.9%), yet both were significantly higher than in handcycling (45W; men: 11.2±0.8%, women: 12.2±2.1%; P<0.05). A similar pattern was found for each of the physical strain parameters: a comparable strain between Cruiser and bicycle test, yet a significantly higher strain for handcycling (P<0.05). Apart from RPE, the repeated Cruiser tests did not show significant differences.

**CONCLUSIONS:** Submaximal Cruiser exercise is a cyclic form of large muscle exercise, comparable in efficiency and physical strain to cycling. As such it seems a safe, repeatable and effective exercise mode, involving both asynchronous upper and synchronous lower body work.

**3488** Board #209 June 2 9:30 AM - 11:00 AM

**Validation Of The Actiheart For Estimating Physical Activity Related Energy Expenditure In Pregnancy**

Katarina Melzer<sup>1</sup>, Matteo Lazzeri<sup>2</sup>, Stephane Armand<sup>3</sup>, Michel Boulvain<sup>3</sup>, Bengt Kayser<sup>2</sup>. <sup>1</sup>Swiss Federal Institute of Sports, Macolin, Switzerland. <sup>2</sup>Institute of Movement Sciences and Sports Medicine, Geneva, Switzerland. <sup>3</sup>University Hospitals of Geneva, Geneva, Switzerland.

(No relationships reported)

**PURPOSE:** The Actiheart (CamNtech Ltd., Cambridge, UK), a combined heart rate and movement sensor device, was shown to give precise estimates of activity energy expenditure (AEE) among men and non-pregnant women. The objective of this study was to assess the validity of the individually calibrated Actiheart in pregnant women against indirect calorimetry in a laboratory setting.

**METHODS:** Ten healthy pregnant women (aged 32.9±3.2 yrs, pre-pregnancy BMI=21.0±2.4 kg/m<sup>2</sup>, 36.9±2.4 weeks of gestation) walked at 3, 4, 5, and 6 km/h on a treadmill, cycled at 25W and 50W on an ergometer and stepped on and off a 15 cm high step. During each routine, AEE was measured simultaneously with the Actiheart (AEEa) and indirect calorimetry (AEEcalo). AEE measurements were compared with paired Student's t-test, and their agreement with Bland and Altman plots.

**RESULTS:** The mean AEEcalo were not significantly different from AEEa for any activity except for cycling at 50W (-45 J/kg/min, p=0.01). Cumulated AEEa and AEEcalo, combining all activities, were not different (p=0.9). All data points (100%) fell within ±2SD for all activities except for walking at 6km/h (89% of data points). All data points fell within ±2SD for the sum of all speeds of walking (3, 4, 5, and 6 km/h).

**CONCLUSIONS:** The Actiheart can be used as a valid method for AEE estimation in pregnant women. The data serve as valuable information for improving the assessment of AEE in pregnancy and clarifying the association between activity and particular health outcomes in this population group.

**3489** Board #210 June 2 9:30 AM - 11:00 AM

**The Energy Cost Of Carrying A Portable Metabolic Analyser**

Lars McNaughton, FACSM, Andy Sparks. Edge Hill University, Ormskirk, United Kingdom.

(No relationships reported)

**PURPOSE:** Portable gas analysers, such as the Cosmed and Metamax, are commonly used in exercise and sporting activities, and such systems have been shown to be both valid and reliable. Little is known however, of the impact on energy expenditure (EE) on individuals that are required to carry them during exercise bouts.

**METHODS:** Eight male participants of (Mean ± SD) age 25.0±9.47y, body mass 78.5±8.39kg, and height 183±0.8 cm, completed two random incremental exercise bouts on a motorised treadmill. Following 4 min of standing, the participants walked at 4km.h<sup>-1</sup> and then completed a progressive exercise test with 4 min stages and 2km.h<sup>-1</sup> increments until volitional exhaustion. The experimental (PT) trial required participants to complete the exercise bout whilst wearing a portable respiratory gas analysis system (Metamax 3B, Cortex, Germany). During the control trial (C) the weight of the gas analyser was supported by a harness adjacent to the treadmill. Throughout each exercise trial, heart rate (HR) and rating of perceived exertion (RPE) were measured and respiratory gases were used to calculate EE via indirect calorimetry. All data were analysed using ANOVA with Repeated Measures; significance was p< 0.05.

**RESULTS:** During the exercise bouts, the rate of EE increased as the intensity of exercise increased (p<0.001). There was a significantly greater rate of EE during PT between the running speeds of 7 - 14 km/hr (p<0.05), but no significant differences were observed during standing, walking or at maximal exercise (p>0.05). There were no significant effects of wearing the gas analyser on VO<sub>2</sub> max. (4.10±0.53, and 4.28 ±0.75 for the C and PT trials respectively), HR or RPE.

**CONCLUSION:** Portable gas analysis systems have no effect on the energy expended during standing, walking for short periods, or during maximal exercise, but significantly increase the energy demands of submaximal running when carried on the person.

3490 Board #211 June 2 9:30 AM - 11:00 AM

**The Energy Expenditure of Long Distance Double - Handed Offshore Sailing**

Carlo Capelli<sup>1</sup>, Christel Galvani<sup>2</sup>, Marta Alberti<sup>1</sup>, Luca Ardigo<sup>1</sup>, Federico Daniele<sup>3</sup>. <sup>1</sup>School of Exercise Science, Verona, Italy. <sup>2</sup>School of Exercise Science, Milano, Italy. <sup>3</sup>School of Exercise Science, Udine, Italy.

(No relationships reported)

The studies describing the energy expenditure during offshore sailing regattas are very rare. This is rather disappointing, if we consider that in offshore sailing several environmental and tactical factors may place a considerable physical load and mental stress on our body.

**PURPOSE:** The aim of the study consists in assessing the energy expenditure during long distance offshore sailing and in describing the physical activity intensity involved in this type of competition. **METHODS:** Six subjects (age:  $46.3 \pm 3.4$  yy; BMI:  $26.7 \pm 1.7$  kg/m<sup>2</sup>,  $\dot{V}O_{2max}$ :  $2.97 \pm 0.56$  l/min) participated in the study. During the regatta (double handed, 500 miles in the North Adriatic, lasting 3- 5 days) the subjects wore an activity monitor (Actiheart, CamNtech, E) that allows estimate energy expenditure, physical activity level (PAL) and minutes spent at each level of intensity (sedentary, S, < 1.5 MET; light, L, 1.5 - 2.9 MET; moderate, M: 3.0 - 6.0 MET; vigorous, V: > 6.0). The time spent at each level of intensity was evaluated using one-way ANOVA; pairwise comparisons were performed using Student-Newman-Keuls test.

**RESULTS:** Daily energy expenditure (TEE) amounted, on the average to  $3408 \pm 453$  kcal per day; daily activity energy expenditure (AEE) amounted to  $1208 \pm 339$  kcal per day. PAL, calculated as TEE divided by resting energy expenditure (RMR, estimated with Schofield formula), was  $1.8 \pm 0.2$ . Subjects spent a significant ( $p < 0.001$ ) longer period of time in S ( $643 \pm 193$  min per day) and L ( $516 \pm 177$  min per day) than in M ( $95 \pm 34$  min per day) and V ( $6 \pm 4$  min per day) activity. On the average, the subjects slept 5 times per day ( $\pm 1.4$ ) for about 36 minutes ( $\pm 9$ ) in each sleeping period.

**CONCLUSION:** TEE per day and PAL during double-handed offshore sailing race turned out to be similar to that measured using double-labeled water technique in single-handed offshore sailing ( $3451$  kcal/day and  $2.1$ , respectively). Moreover, this study reports for the first time, not only TEE, but also AEE and the time spent sleeping and that performing activities of different intensity. The high TEE seems to be likely the consequence of the short and rare periods of sleep spent during the competition than of the bouts of moderate to vigorous physical activity.

3491 Board #212 June 2 9:30 AM - 11:00 AM

**Exercise Intensity and Performance Analysis of Taekwondo Combats in Master Athletes**

Francesco Tornello<sup>1</sup>, Laura Capranica<sup>1</sup>, Carlo Minganti<sup>2</sup>, Salvatore Chiodo<sup>3</sup>, Antonio Tessitore<sup>1</sup>. <sup>1</sup>University of Rome, Rome, Italy. <sup>2</sup>University of Catanzaro, Catanzaro, Italy. <sup>3</sup>University of Catanzaro, Rome, Italy. (Sponsor: Carl Foster, FACSM)

(No relationships reported)

Since martial arts are widely practiced at all ages, the main argument is about to evaluate their impact on health. In a review, Bu et al. (2010) reported a general positive influence, however most of the studies were not conducted during official combats and no information is available for master athletes.

**PURPOSE:** Thus, this study aimed to investigate heart rate (HR) responses and performance analysis of Taekwondo (TKD) master athletes combats.

**METHODS:** Twelve official combats of master athletes (age:  $39 \pm 4$  yrs) were observed during the 1st European Masters Games (Venice, Italy, 2011). The HR exercise intensities were determined by the time spent by athletes at three classes of efforts (90% of individual HRpeak). A time motion analysis was applied to measure the duration of actions in relation to three classes of combat phases: Fighting (F), No Fighting (NF) and Stoppage (ST). The technical and tactical analysis was carried out to analyze: a) the points scored with a kick (1, 2, 3 and 4 points) and punch performed with a clear technique and points scored with a not clear one; b) the strategy adopted for actions (i.e. attack, defence and evasive maneuvers, blocks, etc.); An ANOVA for repeated measure with significance set at  $p \leq 0.05$  was applied for statistical analysis.

**RESULTS:** The HR analysis showed a significant difference for classes of efforts ( $p90\%$  and  $81-90\%$  of individual HRpeak, respectively). The time motion analysis revealed a significant difference between classes of combat phases ( $p=0.002$ ) with a mean duration of  $1.94 \pm 0.48$ ,  $6.26 \pm 1.83$  and  $12.97 \pm 6.74$  seconds and a mean frequency of occurrence of  $40.8 \pm 5.1\%$ ,  $48.7 \pm 3.7\%$  and  $10.5 \pm 5.7\%$  for F, NF and ST, respectively. The technical and tactical aspects showed differences for technique and for strategy analyses. Post-hoc revealed that the "1 point scored with a kick" class ( $59.8 \pm 15.8\%$ ) and the attack class ( $50.6 \pm 18.9\%$ ) were different from all other classes of their respective specific analyses ( $p < 0.001$ ).

**CONCLUSIONS:** This study indicate that the TKD master competition posed a high load on athletes, who, probably due to being former senior athletes, were able to be engaged in a high intensity activity, which requires to be monitored to have a positive impact on health. REFERENCES: Bu et al. (2010). JEBM, 3, 205-219.

3492 Board #213 June 2 9:30 AM - 11:00 AM

**Estimating Energy Expenditure From Accelerometry And Physiological Sensors In One Device**

Mary Rosenberger<sup>1</sup>, William Haskell, FACSM<sup>1</sup>, Fahd Albinali<sup>2</sup>, Selene Mota<sup>2</sup>, Jason Nawyn<sup>2</sup>, Stephen Intille<sup>3</sup>. <sup>1</sup>Stanford University, Palo Alto, CA. <sup>2</sup>Massachusetts Institute of Technology, Cambridge, MA. <sup>3</sup>Northeastern University, Boston, MA.

(No relationships reported)

**PURPOSE:** Estimate energy expenditure from physiological sensors contained in the Zephyr Bioharness in addition to an accelerometer using advanced analytical methods.

**METHODS:** A variety of sedentary behavior, daily activities and exercises were measured with the Zephyr Bioharness, an Actigraph, and an Oxycon Mobile portable metabolic unit in 15 men and 27 women ages 18 to 72. The Bioharness is worn similar to a heart rate monitor, but measures motion (accelerometer - ACC), heart rate (HR), respiration rate (RR), and skin temperature. The Actigraph is worn on the hip and measures motion in a summary similar to the accelerometer on the Bioharness. METs were estimated from the Bioharness data using a two regression mixed model based on the coefficient of variation (CV) of the accelerometer signal to detect activity type. This is similar to the Crouter two-regression model that was used to estimate METs from the Actigraph. A comparison of the identification of moderate to vigorous intensity physical activity (MVPA) from the individual physiologic signals using ROC analysis is also provided.

**RESULTS:** Sedentary behavior was identified on the bioharness using ROC analysis with an area under the curve of 0.77, and ambulation was separated from other non-sedentary activities with an area under the curve of 0.91 based on the CV of the accelerometer signal. Mixed model analysis provided the two-regression predictions resulting in an overall mean error of 0.17 (+/- 0.68) METs for the Bioharness. As a comparison, Crouter methods resulted in a mean error of 0.42 (+/- 1.5) METs for the Actigraph. For identifying MVPA from each of the signals, the area under the ROC was 0.73 for RR, 0.83 for HR, 0.83 for ACC, and 0.88 for the combined signal.

**CONCLUSIONS:** Estimates from this advanced analysis confirm the addition of physiological variables to accelerometer-based data improve energy expenditure calibration over a single accelerometer. For the typical measurement of interest, minutes in MVPA, HR and ACC are the best indicators of intensity, but a combination improves the separation of exercise and non-exercise activities.

---

3493 Board #214 June 2 9:30 AM - 11:00 AM

**Does Exercise Mode or Protocol Alter the Chronotropic Index?**

Denise, L. Smith, FACSM<sup>1</sup>, David A. Barr<sup>1</sup>, Eric M. Hultquist<sup>1</sup>, Wesley K. Lefferts<sup>1</sup>, Jeannie M. Haller<sup>1</sup>, Patricia C. Fehling, FACSM<sup>1</sup>, Thomas W. Storer<sup>2</sup>, Christopher B. Cooper, FACSM<sup>2</sup>. <sup>1</sup>Skidmore College, Saratoga Springs, NY. <sup>2</sup>UCLA, Los Angeles, CA.

(No relationships reported)

It is well known that  $\dot{V}O_{2max}$  is protocol-dependent with higher values typically reported during treadmill protocols compared to cycle ergometry. During incremental exercise there is generally a robust coupling between heart rate (HR) and oxygen uptake ( $\dot{V}O_2$ ). However, the effect of exercise mode and protocol on the relationship between HR and  $\dot{V}O_2$ , expressed as the chronotropic index (CI) (slope of the regression line; HR vs.  $\dot{V}O_2$ ) has not been established.

**PURPOSE:** To determine if exercise mode or test protocol affects the CI.

**METHODS:** Ten male participants (age,  $21 \pm 2$  yr; height,  $177 \pm 9$  cm; weight,  $76.3 \pm 3.0$  kg) each completed 5 graded exercise tests: 3 treadmill tests (Bruce, UCLA, Wellness Fitness Initiative (WFI)), a field-based running test (Shuttle) and a cycle test.  $\text{VO}_2$  and HR were measured during each test.

**RESULTS:** Data are presented in table. All tests were considered maximal as all participants achieved  $\text{VO}_{2\text{max}}$  according to ACSM criteria.  $\text{VO}_{2\text{max}}$  during the cycle protocol was significantly lower than during Bruce and WFI ( $P < 0.05$ ). None of the other protocols differed from each other. There was no significant difference in the CI or y-intercept across protocols.

| Protocol | Peak HR (b·min <sup>-1</sup> ) | $\text{VO}_{2\text{max}}$ (ml·kg <sup>-1</sup> ·min <sup>-1</sup> ) | CI             | y-intercept     |
|----------|--------------------------------|---|----------------|-----------------|
| Bruce    | $187 \pm 9$                    | $54.9 \pm 7.5^*$  | $31.8 \pm 5.9$ | $56.1 \pm 14.2$ |
| UCLA     | $192 \pm 12$                   | $52.2 \pm 8.0$  | $33.5 \pm 8.2$ | $56.5 \pm 12.9$ |
| WFI      | $192 \pm 8$                    | $54.1 \pm 6.8^*$  | $31.7 \pm 6.6$ | $60.7 \pm 12.1$ |
| Shuttle  | $189 \pm 12$                   | $52.9 \pm 5.0$  | $35.3 \pm 9.4$ | $45.7 \pm 23.7$ |
| Cycle    | $186 \pm 11$                   | $47.8 \pm 8.3$  | $35.8 \pm 9.2$ | $59.7 \pm 12.5$ |

\* $P < 0.05$

**CONCLUSION:** The findings from this study support previous research showing that  $\text{VO}_{2\text{max}}$  is protocol-dependent. However, the robust linear relationship between HR and  $\text{VO}_2$  is unaffected by exercise mode or protocol.

**Energy Expenditure During Sessions of static Stretching**

Ricardo A. Simões, Marcio A.G. Sindorf, Pamela R.G. Gonelli, Marcelo C. Cesar. *UNIMEP - Methodist University of Piracicaba, Piracicaba, Brazil.*

(No relationships reported)

American College of Sports Medicine (ACSM) recommends stretching exercises as part of a program for health to maintain and improve flexibility. Stretching exercise has also an energy expenditure that could contribute to weight maintenance programs, besides providing an efficient method of heating for more intense exercises. However, there is the need for a study to evaluate the energy cost of static stretch exercise in young women.

**PURPOSE:** To evaluate energy expenditure during a static stretch session in young women, as recommended by ACSM.

**METHODS:** Subjects were 12 women ( $23.3 \pm 3.5$  years;  $58.8 \pm 6.1$  Kg;  $1.7 \pm 0.1$  m;  $21.2 \pm 1.3$  kg/m<sup>2</sup>) engaged in physical training for a minimum of 6 months. Energy expenditure was measured in 3 non-consecutive days by metabolic gas analyzer and telemetry system. Resting energy expenditure (REE) was done with subjects on 3 hours fasting and 30 minutes rest in supine position, the measures were taken at rest for 12 minutes. The first 2 minutes were discarded and an average of the 10 remaining minutes was used to determine the REE. The stretch energy expenditure (SEE) was measured during static stretches session for about 5 minutes. Stretch exercises were done in stand position, one repetition per muscle group and each position were held for 20 seconds for major muscle groups following exactly the order - biceps, triceps, shoulders, back posterior chain, latissimus dorsi, chest, posterior lower extremity chain, quadriceps and adductor muscles. Mean and standard deviation ( $\pm$ SD) for all variables were calculated and expressed in kilocalories per minute (kcal/min). Normal distribution of the data was checked by Shapiro-Wilk's test and Friedman test was used for the comparison among the variables.

**RESULTS:** On days 1, 2 and 3 REE were respectively  $1.1 \pm 0.4$ ,  $1.0 \pm 0.3$ ,  $0.9 \pm 0.2$  and SEE were  $2.0 \pm 0.6$ ,  $1.9 \pm 0.2$  and  $1.9 \pm 0.3$  kcal/min. The results show no significant differences in the measured variables at REE and SEE among days 1, 2 and 3 ( $p > 0.05$ ) but there was a significant increase ( $p < 0.05$ ) in energy expenditure between REE and the SEE on all 3 days of evaluation.

**CONCLUSIONS:** The results show that the energy expenditure of young women is significantly increased while performing static stretches, about twice, in relation to REE.

Supported by FAPESP, CAPES and CNPq.

**The Relationship Between Muscle Activation And Ratings Of Perceived Exertion Across Four Exercise Modes**

Ryan P. McGrath, Kathy D. Browder. *University of Idaho, Moscow, ID.*

(No relationships reported)

Previous research reported that dual action (arms & legs) elliptical trainer (ET) exercise elicits lower RPE than other forms of exercise (Hughes et al, 2005). However, why RPE is lower has not been explained.

**PURPOSE:** To determine the relationship between rating of perceived exertion (RPE) and muscle activation in ET, dual action (arms+legs) recumbent bike (DB), a treadmill (TM), and single-action (legs only) recumbent bike (SB).

**METHODS:** Ten males and four females (Age:  $21 \pm 2$  yr; Height:  $177.9 \pm 10.0$  cm; Weight:  $77.4 \pm 13.7$  kg) volunteered as subjects. Each subject warmed up 5 min on a stationary bike, and then completed 6 minutes of exercise on each machine in randomized order with 3 min rest period between bouts. The metabolic workload was standardized across machines at  $\sim 31.3$  ml·kg<sup>-1</sup>·min<sup>-1</sup>. Overall RPE (O-RPE), central RPE (C-RPE), and peripheral RPE (P-RPE) were measured at the end of each exercise bout. EMG activity of the biceps brachii (BB), pectoralis major (PM), triceps brachii (TB), middle deltoid (MD), gastrocnemius (GA), gluteus maximus (GM), vastus lateralis (VL), and biceps femoris (BF) was sampled continuously at 1000 Hz for 6 consecutive strides at the end of each minute of exercise. A one-way repeated measures ANOVA was calculated to determine differences across machines.

**RESULTS:** No significant differences were found in C-RPE ( $p = 0.256$ ; C-RPE<sub>ET</sub>:  $11 \pm 2$ ; C-RPE<sub>DB</sub>:  $12 \pm 2$ ; C-RPE<sub>SB</sub>:  $12 \pm 3$ ; C-RPE<sub>TM</sub>:  $11 \pm 3$ ) across machines. P-RPE was significantly less ( $p < 0.002$ ) in ET ( $10 \pm 2$ ) versus DB ( $12 \pm 2$ ); SB ( $13 \pm 3$ ); and TM ( $11 \pm 3$ ). O-RPE was significantly less ( $p < 0.007$ ) in ET ( $11 \pm 2$ ) and TM ( $12 \pm 3$ ) versus DB ( $13 \pm 2$ ) and SB ( $13 \pm 3$ ). GA activation was less in ET than in SB, DB, or TM ( $p < .001$ ; GA<sub>ET</sub>:  $66 \pm 27$   $\mu$ V; GA<sub>DB</sub>:  $116 \pm 51$   $\mu$ V; GA<sub>SB</sub>:  $104 \pm 42$   $\mu$ V; GA<sub>TM</sub>:  $136 \pm 51$   $\mu$ V). BB activation was greater in DB and ET ( $p < .001$ ; BB<sub>ET</sub>:  $96 \pm 93$   $\mu$ V; BB<sub>DB</sub>:  $95 \pm 68$   $\mu$ V; BB<sub>SB</sub>:  $19 \pm 10$   $\mu$ V; BB<sub>TM</sub>:  $26 \pm 18$   $\mu$ V). TB activation was greater in DB ( $p < .002$ ; TB<sub>ET</sub>:  $55 \pm 36$   $\mu$ V; TB<sub>DB</sub>:  $97 \pm 79$   $\mu$ V; TB<sub>SB</sub>:  $39 \pm 25$   $\mu$ V; TB<sub>TM</sub>:  $45 \pm 44$   $\mu$ V). MD activation was greatest in DB and TM, and least in SB ( $p < .001$ ; MD<sub>ET</sub>:  $39 \pm 23$   $\mu$ V; MD<sub>DB</sub>:  $69 \pm 40$   $\mu$ V; MD<sub>SB</sub>:  $24 \pm 15$   $\mu$ V; MD<sub>TM</sub>:  $59 \pm 33$   $\mu$ V).

**CONCLUSION:** Lower P-RPE and O-RPE in ET may be related to decreased muscle activation in the lower leg, specifically the GA, and less dependent on upper extremity muscle activation. Supported, in part, by SportsArt, Inc.

**Relationship Of Metabolic Costs Of Aquatic Treadmill Versus Land Treadmill Running**

Sarah Blackwell, Ryan Porter, Gerald Smith, FACSM, Dale Wagner, Dennis Dolny. *Utah State University, Logan, UT.*

(No relationships reported)

**PURPOSE:** This study investigated whether running using water jets in an aquatic treadmill (ATM) reflects energy expenditure (EE, oxygen consumption,  $\text{VO}_2$ ) while running at faster speeds on a land treadmill (LTM).

**METHODS:** Sixteen participants completed two trials on separate days on a LTM and ATM. For the ATM trial subjects performed eighteen, 3-4 min submaximal runs at three self selected speeds (slow, medium, and fast) with either water jet resistances of 0-100% of maximum jet flow capacity in 20% increments. For LTM subjects ran at the same speeds at 0% incline. Trials were separated by at least 48 hours. Oxygen consumption ( $\text{VO}_2$ ), heart rate (HR), and ratings of perceived exertion (RPE) were recorded during each trial. Regression analysis estimated TM  $\text{VO}_2$  from running speed ( $\text{VO}_2$ , ml·kg·min<sup>-1</sup>) =  $6.1034 + 4.37 \cdot \text{TM speed}$  ( $R^2 = 0.95$ ,  $\text{SEE} = 0.93 + 0.87$  ml·kg·min<sup>-1</sup>). Regression analysis produced prediction equations to estimate LTM running speeds based on ATM EE with adding jet resistances.

**RESULTS:** At the same speed ATM VO<sub>2</sub> EE with 0 and 20% jet settings were lower than TM. However by ATM 40% jet resistances VO<sub>2</sub> was greater ( $p < 0.02$ ) than LTM. Differences in ATM VO<sub>2</sub> associated with each jet setting (0, 20, 40, 60, 80, and 100%) corresponded to a change (M±SD) in comparable LTM speed of -1.00 (.90), -0.96 (.82), +0.91 (.72), +1.53 (1.14), +3.05 (1.16), and 4.47 (1.32) miles per hour respectively.

**CONCLUSIONS:** These results demonstrate that the ATM jets have the potential to provide an added metabolic challenge to mimic TM running that is ~4.5 mph faster. One potential benefit is to use ATM with jets to allow subjects to experience a training load that may be much greater than their current/chronic orthopedic condition might allow.

**Effects Of Delayed Onset Muscle Soreness On Maximal Incremental Exercise Test Results**

Bryna C r Christmas<sup>1</sup>, Lee Taylor<sup>2</sup>, Jason C. Siegler, FACSM<sup>3</sup>, Adrian W. Midgley<sup>1</sup>. <sup>1</sup>The University of Hull, Hull, United Kingdom. <sup>2</sup>The University of Bedfordshire, Bedford, United Kingdom. <sup>3</sup>The University of Western Sydney, Sydney, Australia. (Sponsor: Jason Siegler, FACSM)

(No relationships reported)

**PURPOSE:** Delayed onset muscle soreness (DOMS), is considered one of the most common forms of sports injury. Training or competing with DOMS may result in a less than optimal training intensity or significant decrements in exercise performance. Despite numerous studies investigating the effects of DOMS on exercise performance, no definitive studies have investigated the effects of DOMS on maximal incremental treadmill test results, which was the objective of the present study.

**METHODS:** Twenty healthy males, randomly allocated into a control group (n = 10) and experimental group (n = 10), completed three tests on three separate occasions (familiarisation, pre and post intervention tests). The experimental group also completed an intervention test consisting of eccentric knee extension and flexion exactly 48 h prior to the post intervention test.

**RESULTS:** No significant changes were observed in any of the dependent variables pre-post intervention in the control group. In the experimental group, the median change in perceived muscle soreness was 58, 59 and 40 mm at 24 h, 36 h and 48 h post-intervention compared to pre-test intervention ( $p = 0.001$ ). Maximum voluntary isokinetic peak torque of the knee extensors decreased by 8% ( $p = 0.006$ ) and 18% ( $p = 0.005$ ) in the dominant and non dominant leg respectively and by 37% ( $p = 0.012$ ) for knee flexion in the dominant leg. During the post-intervention test, time to exhaustion decreased by 9% ( $p = 0.001$ ) and maximal blood lactate concentration decreased by 11% ( $p = 0.005$ ) compared to the pre test intervention. Furthermore, energy expenditure for the same treadmill velocity increased by 17% ( $p = 0.04$ ).

**CONCLUSIONS:** The results from the present study suggest that performing a maximum incremental exercise test with DOMS, results in individuals failing to achieve their maximum treadmill velocity, which could invalidate the results obtained from this test. Additionally, running efficiency is reduced whilst suffering from DOMS.

**Simultaneous Observation for Oxidative Stress and Muscle Damage with High-Intensity Kendo Training**

Kazuha Kizaki<sup>1</sup>, Tomoyoshi Terada<sup>1</sup>, Hajime Arikawa<sup>1</sup>, Tomio Tajima<sup>2</sup>, Kazunori Hosoe<sup>3</sup>, Hajime Imai<sup>4</sup>, Seiichi Era<sup>1</sup>. <sup>1</sup>Gifu University Graduate School of Medicine, Gifu, Japan. <sup>2</sup>National Defense Academy, Yokosuka, Japan. <sup>3</sup>Kaneka Corporation, Osaka, Japan. <sup>4</sup>Gifu University Faculty of Education, Gifu, Japan.

(No relationships reported)

Kendo is a Japanese martial art based on traditional samurai swordsmanship. Despite kendo having a long history in Japan, few studies have examined the effects of kendo training on the human body. Human serum albumin (HSA) is the most abundant serum protein found in the bloodstream and is composed of both reduced and oxidized forms. We have developed a convenient chromatographic method for the separation of both forms of HSA and have reported dynamic changes in the redox state of HSA in health, disease and aging.

**PURPOSE:** To examine both oxidative stress and skeletal muscle damage caused by kendo training over a four-day period, we measured the ratio of reduced to oxidized HSA for oxidative stress, and serum concentrations of creatine kinase (CK) and myoglobin (Mb) for skeletal muscle damage.

**METHODS:** Seventeen male students from the National Defense Academy and Gifu University, all elite kendo athletes (20.0 ± 1.0 yrs) participated in this training camp. Blood samples for the analysis of serum levels of HSA, CK and Mb were drawn just before and after the training period. Differences between the mean values were tested for significance using paired t-test.

**RESULTS:** The four-day kendo training significantly lowered the percentage of reduced HSA from 78.9 ± 2.3% (before) to 73.9 ± 2.6% (after the training,  $p < 0.0001$ ). Simultaneously, the training also noticeably elevated serum levels of both CK (132 ± 64 IU/L before and 530 ± 255 IU/L after the training,  $p < 0.0001$ ) and Mb (23 ± 4 ng/mL before and 77 ± 34 ng/mL after the training,  $p < 0.0001$ ).

**CONCLUSION:** These findings suggest that the four-day intensive kendo training period gave rise to oxidative stress and skeletal muscle damage for male collegiate kendo athletes.

**3499** Board #220 June 2 9:30 AM - 11:00 AM

**Menstrual Cycle Effect on Metabolic Acidosis During High Intensity Intermittent Exercise**

Deborah Van Langen, Jessica Brown, Ryanne Carmichael, Nicole Pollard, Sarah Schultz, Daniel Sheehan, Tracey Matthews, Vincent Paolone, FACSM. *Springfield College, Acton, MA.*

(No relationships reported)

Ovarian hormonal fluctuations throughout the menstrual cycle have been associated with a decline in exercise performance. When comparing genders performing the same mode of exercise, women have different fatigue characteristics such as lower lactate and CO<sub>2</sub> levels. It has been reported that females use lactate as a substrate more effectively than males during high intensity exercise. Menstrual cycle phase can have an impact on pH balance therefore influencing metabolic acidosis.

**PURPOSE:** The study was designed to determine if differences exist in metabolic acidosis in women between the luteal and follicular phase of the menstrual cycle during high intensity intermittent exercise.

**METHODS:** The subjects (N = 10) participated in two separate 75 minute cycling sessions determined by menstrual cycle phase. Each 75 minute session was divided into 5 separate 15 minute exercise bouts consisting of 5 minutes of high intensity exercise followed by 10 minutes of active and passive recovery. The intensity of the high intensity bout corresponded to 90% of maximal wattage determined by a V(dot)O<sub>2</sub>peak test. The variables evaluated were lactate (mmol/L) and CO<sub>2</sub> (ml·kg<sup>-1</sup>·min<sup>-1</sup>). Two factorial ANOVAs were computed to determine if significant interactions existed.

**RESULTS:** A significant interaction was observed between accumulation and clearance over the 75 minute time period for lactate (mmol/L) and CO<sub>2</sub> (ml·kg<sup>-1</sup>·min<sup>-1</sup>). No significant difference existed between menstrual cycle phases. These data reflect differences in acid base balance between accumulation and clearance of lactate (mmol/L) and CO<sub>2</sub> (ml·kg<sup>-1</sup>·min<sup>-1</sup>).

**CONCLUSIONS:** Impaired physical performance during menstrual cycle phases has been associated with symptoms such as fatigue, fluid retention, weight gain, mood changes, and dysmenorrhea. In this study, menstrual cycle phase had no effect on metabolic acidosis during high intensity incremental exercise therefore suggesting no effect on exercise performance. Subjects cleared less lactate (mmol/L) and CO<sub>2</sub> (ml·kg<sup>-1</sup>·min<sup>-1</sup>) during the active and passive rest periods than expected. As a result, lactate (mmol/L) and CO<sub>2</sub> (ml·kg<sup>-1</sup>·min<sup>-1</sup>) accumulation created less of a delta showing the inability to clear lactate and CO<sub>2</sub> between the exercise sessions.

**3500** Board #221 June 2 9:30 AM - 11:00 AM

**Physiological Changes Over Four Maximal Incremental Cycling Tests Within One Day**

Friederike Scharhag-Rosenberger<sup>1</sup>, Anja Carlsohn<sup>1</sup>, Stefan Schuler<sup>1</sup>, Carsten Lundby<sup>2</sup>, Frank Mayer<sup>1</sup>, Jürgen Scharhag, FACSM<sup>1</sup>. <sup>1</sup>University of Potsdam, Potsdam, Germany. <sup>2</sup>University of Zurich, Zurich, Switzerland.

(No relationships reported)

It remains unknown to what degree one or more maximal exercise tests may influence the physiological response to yet another maximal exercise test performed within a single day. This is unfortunate since multiple tests within one day are used in scientific studies and also in the evaluation of athletes.

**PURPOSE:** To investigate the impact of repeated maximal incremental cycling tests on physiological variables in trained and untrained individuals.

**METHODS:** Eight trained (T) and eight untrained (UT) subjects (T: 4 m/4 f, 25 ± 3 yrs, BMI 23 ± 3 kg/m<sup>2</sup>, VO<sub>2</sub>max: 64 ± 6 ml/min/kg; UT: 4 m/4 f, 27 ± 3 yrs, BMI 22 ± 1 kg/m<sup>2</sup>, VO<sub>2</sub>max 44 ± 4 ml/min/kg) performed four maximal stepwise incremental cycling tests separated by 1.5 h of passive rest. Carbohydrate and energy requirements for rest and exercise were individually calculated and covered by means of standardized meals before the first and between the following tests.

**RESULTS:** Maximal power output did not change significantly over the four tests in the T group (306 ± 41 vs. 309 ± 40 vs. 307 ± 41 vs. 306 ± 41 W; P = 0.23), but decreased from the third test in the UT group (201 ± 35 vs. 198 ± 36 vs. 192 ± 33 vs. 186 ± 30 W; P < 0.01). VO<sub>2</sub>max remained unchanged in both groups (P = 0.32 and P = 0.33, respectively). The heart rate curve was elevated from the third test in the T group and from the second test in the UT group (total increase: 6 ± 6 and 9 ± 8 /min; P < 0.05). The individual anaerobic threshold (IAT; T: 183 ± 30 W; UT: 125 ± 25 W) increased in the T group from the second, and in the UT group from the fourth test (total increase: 12 ± 8 and 10 ± 10 %; P < 0.05). Pre-exercise epinephrine and norepinephrine levels increased from the first to the fourth test in the T group (P < 0.05), but not in the UT group (P = 0.24 and P = 0.11, respectively). Post-exercise catecholamine concentrations did not change in either group (P ≥ 0.14).

**CONCLUSIONS:** If maximal performance parameters are assessed, it is recommended that trained and untrained individuals perform up to four and two incremental cycling tests on one day, respectively. As submaximal cardiocirculatory and metabolic parameters changed from the second test on, only one test should be performed if these parameters are the prime focus.

**3501 Board #222 June 2 9:30 AM - 11:00 AM**

**Study Of The Linearity Relationships Between Cardiorespiratory Variables And Velocity In Maximal Incremental Exercise Test**

Jonas L. Gurgel<sup>1</sup>, Flavia Porto<sup>2</sup>, Gabriel Espinosa<sup>1</sup>, Felipe Amorim Cunha<sup>3</sup>, Paulo de Tarso Veras Farinatti<sup>3</sup>. <sup>1</sup>Fluminense Federal University, Niteroi, Brazil. <sup>2</sup>Gama Filho University, Rio de Janeiro, Brazil. <sup>3</sup>Rio de Janeiro State University, Rio de Janeiro, Brazil.  
(No relationships reported)

**PURPOSE:** The propose of this study was to evaluate the linearity relationships between cardiorespiratory variables (VO<sub>2</sub>; VO<sub>2</sub>R; HR; HRR) and velocity, and was verified witch relationship presented a better fit to the identity line.

**METHODS:** Participated on this study 33 aerobic trained men (22 ± 4 yrs, 70.8 ± 7.7kg, 1.76 ± 0.68m and 11.5 ± 3.4%BF). On the first day resting VO<sub>2</sub> and resting HR was determined, the anthropometric measurements were taken, and the participants were habituated to the equipment and test protocols. On the second day the incremental exercise testing was performed, using individualized ramp protocol and was based on predict VO<sub>2</sub>max obtained by a questionnaire. Maximum velocity was determined based on ACMS equation. Initial velocity for all subjects was 60% of maximum predict velocity. Tests were considered maximal when three of the four criteria proposed by Midgley et al. (2009) were attained. For statistical analyze, firstly Passing and Bablok regressions of each cardiorespiratory variable and velocity were obtained for every subject. Then Shapiro Wilks test were applied for confirmation of normality, after that a repeated measures analysis of variance with Post-hoc LSD Fisher's was tested. The significance level was set at α=0.05.

**RESULTS:** Data from Passing and Bablok regressions can be seen in table 1.

**Table - Results from linear regression of each tested variable**

|                               | Intercept |                     | Slope  |                  | Cusum test for linearity |
|-------------------------------|-----------|---------------------|--------|------------------|--------------------------|
|                               | a         | 95%CI               | b      | 95%CI            |                          |
| Velocity vs VO <sub>2</sub>   | -0,1731   | -0,2039 to -0,1468  | 1,1731 | 1,1415 to 1,2071 | (P>0.10)                 |
| Velocity vs VO <sub>2</sub> R | -0,247    | -0,2804 to -0,2179  | 1,247  | 1,2135 to 1,2838 | (P>0.05)                 |
| Velocity vs HRC               | 0,3447    | 0,3261 to 0,3627    | 0,6605 | 0,6392 to 0,6822 | (P<0.01)                 |
| Velocity vs HRR               | -0,01809  | -0,04970 to 0,01307 | 1,0276 | 0,9917 to 1,0649 | (P<0.01)                 |

**CONCLUSION:** The presented data showed significant differences for almost all Passing and Bablok regressions, except for HRR and velocity in which both, intercept and slope, were inside confidence interval range. These results suggest that HRR, between all tested variables, appears to be the best potential parameter for submaximal exercise prescription.

**3502 Board #223 June 2 9:30 AM - 11:00 AM**

**Analysis of Time Spent Into Four Different Intensity Levels During Regular Spinning Classes**

Luiz Guilherme G. Porto<sup>1</sup>, Daniel Saint Martin<sup>2</sup>, Giliard Lago<sup>3</sup>, Guilherme E. Molina<sup>4</sup>, Luiz Fernando Junqueira Jr.<sup>5</sup>. <sup>1</sup>Brasilia University Center - UniCEUB and Cardiovascular Laboratory - University of Brasilia Faculty of Medicine - UnB, Brasilia, Brazil. <sup>2</sup>Brasilia University Center - UniCEUB, Brasilia, Brazil. <sup>3</sup>UniEURO University Center, Brasilia, Brazil. <sup>4</sup>UniEURO - University Center and University of Brasilia Faculty of Medicine, Cardiovascular Laboratory - UnB, Brasilia, Brazil. <sup>5</sup>Cardiovascular Laboratory - University of Brasilia Faculty of Medicine - UnB, Brasilia, Brazil.  
(No relationships reported)

Created in the 80s, Spinning has hugely grown during the last 2 decades. As an indoor physical activity performed on stationary bikes, Spinning is usually commercialized as an efficient exercise to foster cardiovascular fitness and weigh loss. However, its absolute and relative intensity has been poorly described.

**PURPOSE:** To evaluate the absolute and relative time spent into four different effort intensities during regular Spinning classes performed by young and middle aged adults.

**METHODS:** A cross-sectional study was done with 12 young adults (group 1 - G1), from 18 to 35 yrs and 12 middle aged adults (group 2 - G2), from 36 to 64 yrs, recruited from 5 fitness centers randomly selected in Brasilia-Brazil. HR was registered with a RS800 Polar monitor during the whole classes each 5 seconds. Each volunteer had 3 classes monitored to obtain the mean HR of each moment. Effort intensity was defined as percentage ranges of individual maximal heart rate (MHR: 220 - age), in 4 HR zones: very heavy (VH: ≥ 94% of MHR); heavy (HY: 77 - 93% of MHR); moderate (MD: 64 - 76% of MHR) and light (LT: <64% of MHR). Absolute and relative time spent in each HR zones by G1 and G2 were compared by (Mann-Whitney test). Differences were considered significant when p-value <0.05.

**RESULTS:** Mean Spinning classes duration was 46:58min. For all volunteers (n=24), mean time in each HR zones were: VH - 3:23min (7.0%); HY - 24:27min (52.3%); MD - 11:43min (24.9%) and LT - 7:25min (15.7%). Time spent in VH zone was higher for G2 (5:37min - 11.5%) than for G1 (1:09min - 2.6%) (p=0.02). There were no significant differences for HY zone (26:58min - 55.3% for G1 vs 23:03min - 49.3% for G2); for MD zone (10:25min - 21.5% for G2 vs 13:03min - 28.3% for G1) and for LT zone (5:41min - 11.6% for G2 vs 9:11min - 19.8% for G1) (p>0.14).

**CONCLUSIONS:** We observed that most of the time (51.9% for G1 and 66.8% for G2) of Spinning classes was performed on heavy or very heavy intensity. Older participants completed their Spinning sections accumulating more time on the very heavy intensity compared to the younger group. Regarding to exercise safety, this situation should be avoided, considering that age above 45 years for men and 55 years for women is considered a risk factor for cardiovascular disease.

**3503 Board #224 June 2 9:30 AM - 11:00 AM**

**Paintball Is A Blast, But Is It Exercise? Heart Rate And Accelerometry In Boys Playing Paintball.**

Michelle B. Jarvi<sup>1</sup>, Brandon S. Shaw<sup>2</sup>, Ina Shaw<sup>3</sup>, Gregory A. Brown, FACSM<sup>1</sup>. <sup>1</sup>University of Nebraska Kearney, Kearney, NE. <sup>2</sup>Tshwane University of Technology, Johannesburg, South Africa. <sup>3</sup>Monash South Africa, Johannesburg, South Africa.  
(No relationships reported)

Paintball has been played as an organized sport since the 1980's and is essentially a game of tag, except instead of touching an opponent by hand opponents are tagged by shooting them with a paintball that leaves a tell-tale mark indicating who (or what) has been eliminated. Although many people have played paintball in the past 30 years, there has only been one previous evaluation of paintball as physical activity. Procarri et al. (2004) observed an average heart rate of 68-73% of maximal while playing paintball, but noted that it could not be determined how much of the increase in heart rate was due to physical activity and how much was due to the excitement of game play.

**PURPOSE:** This project used accelerometry and heart rate monitors to evaluate the quantity and intensity of physical activity in boys playing paintball. This project also evaluated the changes in heart rate due to physical activity and excitement while playing paintball.

**METHODS.** Eleven boys ( $12.7 \pm 1.0$  y,  $51.5 \pm 11.3$  kg,  $161.8 \pm 10.1$  cm) engaged in a graded exercise test in order to develop a heart rate/oxygen consumption correlation. Then, on a separate day, the boys played 7 games of outdoor paintball while wearing a heart rate monitor and accelerometer. The games had a stated 20 minute time limit, but players who were marked were eliminated from game play. The starting and stopping time of each game was recorded, along with the time each boy was eliminated during the game. **RESULTS.** During the 6 hours of paintball playing, the boys played paintball for a total of  $80.6 \pm 10.0$  minutes with an average length of game play  $11.5 \pm 6.2$  minutes. Average heart rate during the 6 hours of paintball play was  $127.4 \pm 6.5$  beats/min, representing ~40% of heart rate reserve. During the 6 hours of paintball play the boys accumulated  $141.8 \pm 24.3$  minutes of moderate and  $6.1 \pm 4.6$  minutes of intense physical activity. During game play the boys accumulated  $63.2 \pm 15.1$  minutes of moderate intensity activity and  $2.6 \pm 2.8$  minutes of vigorous activity.

**CONCLUSIONS.** A day of paintball play provides some intense physical activity and enough moderate physical activity to promote health. However, a considerable amount of the physical activity occurred during the time before and after game play, when the boys were walking from the staging area to the playing field and vice versa.

**3504** Board #225 June 2 9:30 AM - 11:00 AM

**The Difference in Caloric Expenditure between Walking and Jogging in Adults**

Joseph L. Andreacci, FACSM<sup>1</sup>, Curt B. Dixon, FACSM<sup>2</sup>, Kevin Moyer<sup>1</sup>, Tara Campbell<sup>1</sup>, Dustin Pine<sup>2</sup>, Rachel Hikes<sup>2</sup>. <sup>1</sup>Bloomsburg University, Bloomsburg, PA. <sup>2</sup>Lock Haven University, Lock Haven, PA.

(No relationships reported)

**PURPOSE:** To examine the energy expenditure (EE) differences between walking and jogging one-mile on a treadmill.

**METHODS:** Fifty-seven females and fifty-four males (age  $20.7 \pm 1.4$  years) participated in this study. All subjects performed a 1-mile walk and a 1-mile jog on a motorized treadmill, during the same exercise session. Oxygen consumption ( $\text{VO}_2$ ) and EE were measured continuously via a ParvoMedics metabolic measurement system. Heart rate and OMNI-RPE were measured throughout both of the exercise bouts.

**RESULTS:** When compared to walking, jogging 1-mile resulted in a significantly ( $P < 0.001$ ) higher total EE (women =  $105.3 \pm 17.7$  vs.  $82.4 \pm 13.9$  kcals; men =  $147.2 \pm 22.5$  vs.  $114.5 \pm 16.9$  kcals),  $\text{VO}_2$  (women =  $33.8 \pm 3.8$  vs.  $15.0 \pm 2.7$  mL/kg/min; men =  $37.1 \pm 6.1$  vs.  $16.3 \pm 3.8$  mL/kg/min), HR (women =  $174 \pm 15$  vs.  $120 \pm 16$  beats/min; men =  $169 \pm 16$  vs.  $115 \pm 17$  beats/min), and OMNI-RPE (women =  $4.3 \pm 2.1$  vs.  $1.3 \pm 1.0$ ; men =  $4.5 \pm 1.5$  vs.  $2.0 \pm 1.2$ ) in both genders.

**CONCLUSIONS:** Although total EE was higher when jogging, the mean difference between exercise modes was relatively small (women = 22.9 kcals; men = 32.7 kcals). From a practical standpoint, health and fitness professionals may want to determine whether the extra energy expenditure is worth the additional physiological and anatomical stress that often accompanies jogging. In unconditioned individuals, compliance with exercise programs may be improved with the less stressful walking mode with only a few less calories expended during the workout.

**3505** Board #226 June 2 9:30 AM - 11:00 AM

**Effect of Neuromuscular Electrostimulation via the Peroneal Nerve on Muscle Soreness Following Intense Intermittent Exercise**

Richard A. Ferguson, Victoria R. Paley, Joshua C. W. Ewens, Liam M. Heaney, James Redden. Loughborough University, Loughborough, United Kingdom.

(R.A. Ferguson: Contracted Research - Including Principle Investigator; Sky Medical Technology.)

Numerous techniques are reported to enhance recovery following intense exercise, including active recovery, cryotherapy and compression garments under the premise that enhanced blood flow facilitates the removal of metabolites associated with muscle damage; however, there is equivocal support for such claims. It was recently observed that a novel technique of neuromuscular electrostimulation (NMES) of the lower limb via the peroneal nerve augments venous, arterial and microvascular blood flow (Tucker et al. Int J Angiol, 19:31, 2010). It is possible that this could enhance the recovery process following intense intermittent exercise.

**PURPOSE:** To examine the effects of NMES of the lower limb on muscle soreness following prolonged intermittent exercise.

**METHODS:** Ten ( $22 \pm 1$  yr,  $180 \pm 7$  cm,  $78 \pm 7$  kg) male games players performed a 90 min ( $2 \times 45$  min) intermittent shuttle running test on three separate occasions. Following exercise one of the following recovery interventions were applied: control passive recovery (CON); graduated compression sock (GCS); neuromuscular electrical stimulation (NMES). Interventions were applied 1 hr after the exercise and maintained for at least 12 hrs. Measurements of perceived muscle soreness (PMS) were made before, immediately, 1, 24, 48 and 72 hrs following exercise.

**RESULTS:** PMS increased ( $P < 0.05$ ) in all conditions immediately and 1 hr post-exercise, and remained elevated compared to baseline in CON at 24 and 48 hrs. At 24 and 48 hrs PMS was lower ( $P < 0.05$ ) in NMES compared to CON whereas there was no difference between GCS and CON.

**CONCLUSION:** The use of a novel NMES device reduces perceived muscle soreness and is superior to GCS in reducing perceived muscle soreness following intense intermittent exercise.

**3506** Board #227 June 2 9:30 AM - 11:00 AM

**Physical Fitness Before and After Weight Restoration in Anorexia Nervosa**

Marta Alberti<sup>1</sup>, Carlo Capelli<sup>1</sup>, Marwan ElGhoch<sup>2</sup>, Simona Calugi<sup>2</sup>, Riccardo Dalle Grave<sup>2</sup>. <sup>1</sup>University of Verona, Verona, Italy. <sup>2</sup>Villa Garda Hospital, Garda (VR), Italy.

(No relationships reported)

No systematic data have been systematically collected to classify the functional level of cardiovascular, muscular and resistance performances in patients with Anorexia Nervosa (AN) before and after weight restoration, even though AN are considered to be more physically active and to engage longer periods of moderate-intense physical exercise than the general population.

**PURPOSE:** To investigate the effects of cognitive behavioral therapy (CBT) on physical fitness of patients with AN and to evaluate the feasibility of the Eurofit Physical Fitness Battery test (EPFTB) in this population.

**METHODS.** Physical fitness was assessed with an adapted version of the EPFTB (Endurance: 6' walking test; Arm strength: hand grip; Abdominal: sit up; Leg strength: standing broad jump; Balance: flamingo balance; Flexibility: sit and reach) administered to 24 female AN inpatients (BMI:  $14.3 \pm 1.5$  kg/m<sup>2</sup>), pre and post CBT treatment, and to 58 healthy females (BMI:  $21.17 \pm 2.57$  kg/m<sup>2</sup>) of the same age ( $24.4 \pm 9.2$  vs.  $25.9 \pm 9.1$  yy, respectively,  $z=1.39$ ,  $p = 0.165$ ). AN group underwent test on the second day of the admission and the last week before the hospital discharge.

**RESULTS.** EPFTB tests showed good feasibility, but some AN patients refused to sustain some of them at the admission. CBT was associated with a significant improvement in BMI (from  $14.3 \pm 1.5$  to  $18.8 \pm 1.2$ ,  $Z = 4.20$ ,  $p < 0.001$ ) and in 4 out of 6 EB tests ( $p < 0.05$ ) in the AN group. However, both in pre and post conditions, AN patients generally showed lower EPFTB scores than the control group (all  $p < 0.001$ ), with the exception of sit up score.

**CONCLUSIONS.** Adapted EPFTB can be recommended for evaluating physical fitness parameters in AN patients. Physical fitness is lower in AN patients than in controls both at baseline and after weight restoration. These data suggest the need to associate to the classical inpatient treatment of AN specific therapeutic strategies to improve physical fitness.

**Improved Flexibility and Core Strength in Four Different Levels of Acute Pilates**

Bryan K. Christensen, Lori A. Burns, Sherri N. Stastny. North Dakota State University, Fargo, ND.

(No relationships reported)

Bryan K. Christensen, Lori A. Burns, Sherri N. Stastny

North Dakota State University, Fargo, ND

The popularity of Pilates has increased over the last 10 years substantially. Pilates has been shown in previous studies to improve core strength and endurance, low back pain, flexibility, posture, and body alignment.

**PURPOSE:** This study evaluated the effects of a five-week Pilates class on core strength and flexibility in four different levels of Pilates classes.

**METHODS:** Forty-one female participants ( $45.7 \pm 8.2$  yrs old) underwent a pre-test and a post-test consisting of a back saver sit-and-reach test, trunk rotation test, plank test, and an abdominal six-rep max test. Each participant was involved in either a Beginners, Essential, Essential Plus, or Intermediate Pilates class. The treatment lasted five weeks and was performed on

the STOTT Reformer. A MANOVA was used to assess the differences in effects among the four groups within the dependent variables. A univariate ANOVA was conducted for each dependent variable.

**RESULTS:** The MANOVA was found to be significant ( $p < .0001$ ). The ANOVA results showed that all four dependent variables in all four of the classes were statistically significant (F values ranged from 8.54 to 88.21,  $p$  values ranged from .029 to  $<.0001$ ). The Beginner's class improved the most in the trunk rotation test (20.95%) as well as the back-saver sit-and-reach (27.13%), while the Essential Plus class improved the most in the plank test (37.13%) and six-rep max test (28.77%).

**CONCLUSIONS:** Five weeks of Pilates was long enough to significantly increase core strength and flexibility in four different levels of classes. This was true even for the subjects in the intermediate class who had completed the three previous levels of Pilates classes prior to the study.

**3508 Board #229 June 2 9:30 AM - 11:00 AM**

**Effectiveness Of PNF On Passive And Active Range Of Motion In Ballet Dancers**

Camille Candelario<sup>1</sup>, Farah Ramirez-Marrero, FACSM<sup>1</sup>, Lucia Martínez<sup>1</sup>, Alexis Ortiz<sup>2</sup>. <sup>1</sup>University of Puerto Rico, San Juan, Puerto Rico. <sup>2</sup>University of Puerto Rico-Medical Sciences Campus, San Juan, Puerto Rico.

(No relationships reported)

Flexibility is an essential physical characteristic for ballet dancers as performance artists.

**PURPOSE:** To determine the effect of proprioceptive neuromuscular facilitation (PNF-contract relax agonist contract) in passive and active range of motion on ballet students during a développé à la second maneuver.

**METHODS:** Ballet dancers were randomized into experimental (n = 34) and control (n = 23) groups. The experimental group underwent a PNF intervention twice a week for eight weeks. Training sessions included three repetitions in four different ballet positions. Baseline measures included leg angles during a passive and active développé à la second maneuver by using Dartfish™. Follow-ups were performed at four and eight weeks.

**RESULTS:** Repeated measures analysis of covariance (repANCOVA) with baseline measures and years of experience as covariates were used for analyses. Post-hoc comparisons were performed when appropriate. RepANCOVA for passive flexibility showed significant between (p = 0.30) and within (p = 0.02) group differences with the experimental group showing greater flexibility across time. Post-hoc analyses revealed significant differences between groups at four (p = 0.01) and eight (p = 0.01) weeks with greater flexibility values in the intervention group. Post-hoc analyses also show significant changes from baseline to four weeks (p < 0.01) and baseline to eight weeks (p < 0.01) in the intervention group. Active flexibility showed marginally significant differences between groups (p = 0.087) and significant changes across time (p = 0.038). Post-hoc analyses showed an increase in active flexibility in the intervention group from baseline to the fourth week (p = 0.01) and from baseline to eight week (p < 0.01).

**CONCLUSION:** Proprioceptive neuromuscular facilitation enhances dynamic flexibility during a développé à la second maneuver in ballet dancers. The addition of PNF to ballet training could enhance dancing performance by improving dynamic flexibility.

**3509 Board #230 June 2 9:30 AM - 11:00 AM**

**Lumbar And Pelvic Flexions Differ Between Men And Women Matched For Sit-and-reach Score**

Constance M. Mier, FACSM, Belinda S. Shapiro. Barry University, Miami Shores, FL.

(No relationships reported)

The sit-and-reach (SR) test assesses hamstring and lumbar spine flexibilities. Compared to women who generally have greater hamstring flexibility and a higher SR score, men demonstrate a different spine posture in a full reach position. It is possible that men and women who obtain similar SR scores do so with different spine and pelvic angles.

**PURPOSE:** To compare spine and pelvic angles during the SR test in men and women matched for SR scores. We hypothesized that men would demonstrate greater thoracic (T), greater lumbar (L) and lower pelvic (P) angles.

**METHODS:** Twenty one men (Mean ± SD; age 24 ± 5 yr, body mass 79.1 ± 11.4 kg, body height 175.1 ± 7.8 cm) were matched with 21 women (age 22 ± 3 yr, body mass 65.9 ± 10.3 kg, body height 164.91 ± 7.3 cm) having the same SR score. Each participant completed a standard SR test. Markers were placed at T1, T12 and L5 vertebrae to identify T, L and P angles during video analyses (Dartfish v4.0 software). Hamstring flexibility was measured with the passive straight leg test (PSLR) using Dartfish to analyze hip joint angle. Gender differences were tested with student independent t-test.

**RESULTS:** Mean SR scores were 47.9 ± 7.0 (27.5 - 58) cm for men and 47.9 ± 6.8 (27 - 58) cm for women. Results shown in the table below indicate that men achieved the same SR score as women with greater L, lower P and similar T angles. The added effect of L and P flexions were similar between men and women.

**CONCLUSION:** Women demonstrated better hamstring flexibility evident from the PSLR test and pelvic angle during the SR. Despite this, men were capable of achieving the same SR score with greater lumbar flexion. These results show that the SR score does not adequately evaluate lumbar spine and hamstring flexibility differences between men and women.

|      | Men         | Women      | p value | Effect Size | Power |
|------|-------------|------------|---------|-------------|-------|
| T    | 54.5±10.8°  | 53.3±7.3°  | .68     |             |       |
| L    | 26.4±9.9°   | 21.2±7.3°  | .05     | .63         | .51   |
| P    | 97.1±8.7°   | 104.0±9.2° | .02     | .77         | .68   |
| L+P  | 123.5±13.2° | 125.3±8.5° | .62     |             |       |
| PSLR | 89.2±8.2°   | 97.1±10.6° | .01     | .83         | .74   |

**Comparison between Blood Lactate Concentrations in Different Swimming Incremental Protocols**

Kelly de Jesus<sup>1</sup>, Ana Sousa<sup>1</sup>, Karla de Jesus<sup>1</sup>, Marisa Sousa<sup>1</sup>, Pedro Figueiredo<sup>1</sup>, Susana Soares<sup>1</sup>, Carlo Baldari, FACSM<sup>2</sup>, Laura Gudetti<sup>2</sup>, João Paulo Vilas-Boas<sup>1</sup>, Ricardo Fernandes<sup>1</sup>. <sup>1</sup>Faculdade de Desporto da Universidade do Porto, Porto, Portugal. <sup>2</sup>University of Rome, Rome, Italy. (Sponsor: Carlo Baldari, FACSM)

(No relationships reported)

In intermittent incremental protocols blood lactate concentrations ([La]) are used to assess relevant variables associated with swimmer's performance, particularly the anaerobic threshold and the energy cost of exercise. However, some literature refers that to accurately determine the [La] corresponding to each step of the incremental protocol, each one should be of 4min duration (or more).

**PURPOSE:** To compare the [La] kinetics in three variants of a swimming intermittent incremental protocol (with different step lengths).

**METHODS:** Six national level swimmers (21±2.16 yrs, 1.79±0.32 m, 71.75±1.89 kg, and 11.25±3.59 yrs of competitive experience) performed, in a randomized order, 7x200, 7x300 and 7x400 m front crawl intermittent incremental protocols until exhaustion, with increments of 0.05 m/s between steps, 30 s rest intervals, and 24 h resting period in-between (the velocity of each step was common to the three protocols). Capillary blood samples were collected from the ear lobe during the intervals, at the end of exercise, and at the 3<sup>rd</sup> and 5<sup>th</sup> min of the recovery period (Lactate Pro, Japan). These data allowed assessing the blood lactate profile through the [La] vs. velocity curve modeling method using Matlab software (The Mathworks Inc., USA). Friedman's test statistic was used to compare each step of the intermittent incremental protocols with different step lengths (p<0.05).

**RESULTS:** [La] values had a similar behavior along the three variants of incremental protocols: (i) 1.2 IQR 0.9-1.6mmol/l to 7.17 IQR 6.2-8.9mmol/l in the 7x200; (ii) 1.1 IQR 0.8-1.4mmol/l to 7.03 IQR 6.3-8.6mmol/l in the 7x300; and 1.1 IQR 0.9-1.4mmol/l to 6.7 IQR 6.4-8.1mmol/l in the 7x400m. No differences were detected between each step of the three protocols (p>0.05).

**CONCLUSION:** Distances of 200, 300 or 400 m seem not to induce different [La] kinetics along the studied incremental intermittent protocol. This evidences that, due to pragmatic reasoning, coaches should use the incremental test of 200 m steps, once it's simpler and faster and swimmers will be easier motivated to perform a maximal effort. **ACKNOWLEDGEMENTS:** Supported by grants PTDC/DES/101224/2008 (FCOMP-01-0124-FEDER-009577) and CAPES 5431-10-7/2011

**3511 Board #232 June 2 8:00 AM - 9:30 AM**

**Three Phase Response of Blood Lactate Concentration in Incremental and Constant Load Exercise**

Peter Hofmann, FACSM<sup>1</sup>, Gerhard Tschakert<sup>1</sup>, Hannes Schwarz<sup>2</sup>, Alexander Mueller<sup>2</sup>, Werner Groeschl<sup>1</sup>, Rochus Pokan, FACSM<sup>3</sup>, Serge P. vonDuvillard, FACSM<sup>4</sup>. <sup>1</sup>University and Medical University of Graz, Graz, Austria. <sup>2</sup>University of Graz, Graz, Austria. <sup>3</sup>University of Vienna, Vienna, Austria. <sup>4</sup>University of Salzburg, Salzburg, Austria.

(No relationships reported)

According to the lactate shuttle theory, two turn points and three distinct phases of lactate metabolism may be detected during incremental and from several constant load exercise bouts.

**PURPOSE:** The aim of our study was to determine the three phase response in incremental and from constant load cycle ergometer exercise tests according to the lactate shuttle theory.

**METHODS:** Six healthy male subjects (age: 32.0±6.0 yrs; height: 179.9±3.6 cm; body mass: 73.1±10.5 kg; VO<sub>2max</sub>: 4.9±0.5 l.min<sup>-1</sup>) performed a maximal incremental cycle ergometer exercise (IE) test (40W start; 20W.min<sup>-1</sup> increments). The first (LTP<sub>1</sub>) and the second (LTP<sub>2</sub>) lactate turn point and the first (VT<sub>1</sub>) and the second (VT<sub>2</sub>) ventilatory turn points were determined by means of linear regression break point analysis. Constant load exercise (CE) tests (30 min) were performed at 40 W and at LTP<sub>1-1</sub>, LTP<sub>1</sub>, LTP<sub>1+1</sub>, LTP<sub>1+2</sub>, LTP<sub>2-2</sub>, LTP<sub>2-1</sub>, LTP<sub>2</sub>, LTP<sub>2+1</sub>, and LTP<sub>2+2</sub> workloads (110±37 W, 130±37; 150±37 W, 164±38 W, 188±36 W, 217±39 W, 237±38 W, 257±39 W, and 268±36 W). Heart rate (HR) and gas exchange variables were determined continuously and blood lactate concentration (La) was determined at rest, at the end of every workload step (IE), every 5 min (CE) and during 3 min of active and 3 min passive recovery.

**RESULTS:** Power output in IE was 336.7±38.8 W (max), 242.5±39.5 W (LTP<sub>2</sub>) and 135.3±40.5 W (LTP<sub>1</sub>). VT<sub>1</sub> (149.2±41.3 W) and VT<sub>2</sub> (242.8±36.7 W) were not significantly different from LTP's. La was 12.2±2.1 mmol.l<sup>-1</sup> (max), 3.8±0.8 mmol.l<sup>-1</sup> (LTP<sub>2</sub>) and 1.3±0.3 mmol.l<sup>-1</sup> (LTP<sub>1</sub>). Subjects completed 30 min of CE up to LTP<sub>2-1</sub> and stopped earlier with increasing work load (LTP<sub>2</sub>: 25 min; LTP<sub>2+1</sub>: 11.3 min; LTP<sub>2+2</sub>: 7.8 min). La values were 0.9±0.2 (40 W), 1.0±0.3 (LTP<sub>1-1</sub>), 1.2±0.4 (LTP<sub>1</sub>), 1.6±0.5 (LTP<sub>1+1</sub>), 2.0±0.6 (LTP<sub>1+2</sub>), 3.3±0.7 (LTP<sub>2-2</sub>), 6.2±1.6 (LTP<sub>2-1</sub>), 9.6±2.7 (LTP<sub>2</sub>), 11.5±2.1 (LTP<sub>2+1</sub>), and 13.7±1.4 (LTP<sub>2+2</sub>). 5 of 6 subjects obtained a lactate steady state at LTP<sub>2-1</sub>.

**CONCLUSION:** In support of the lactate shuttle theory, two distinct turn points and three phases of lactate metabolism were detected during both IE and CE. LTP's distinguished the lactate curve into different metabolic domains, were significantly related to the CE lactate response and may therefore serve as markers of exercise performance and describe the main metabolic indicators for constant load exercise training.

**3512 Board #233 June 2 8:00 AM - 9:30 AM**

**Comparison of Physiological and Perceptual Markers Identified at Ventilatory Breakpoint (Vpt) and Lactate Inflection Point (Lpt)**

Elizabeth F. Nagle, FACSM<sup>1</sup>, Nik Sachidanand<sup>2</sup>, Deborah J. Aaron, FACSM<sup>1</sup>, Vincent C. Arena<sup>1</sup>, Fredric L. Goss, FACSM<sup>1</sup>, Andrea M. Kriska, FACSM<sup>1</sup>, Kristi L. Storti<sup>1</sup>, Robert J. Robertson, FACSM<sup>1</sup>. <sup>1</sup>University of Pittsburgh, Pittsburgh, PA. <sup>2</sup>University of Buffalo, Buffalo, NY.

(No relationships reported)

Vpt and Lpt are used to prescribe exercise intensity for fitness programming and endurance training. Response normalized RPE corresponding to Vpt has been previously identified using the OMNI Scale of Perceived Exertion. Whether perceptual and physiological markers associated with the Vpt are similar to responses occurring at the Lpt has not been determined.

**PURPOSE:** To compare %VO<sub>2max</sub>, HR (b.min<sup>-1</sup>) and OMNI RPE-Overall (O), RPE-Legs (L), and RPE-Chest/Breathing (C) responses identified at the Vpt and Lpt.

**METHODS:** A combined sample of 6 males (29.0 ± 1.0 yrs) and 8 females (29.0 ± 1.0 yrs) completed graded submaximal and maximal treadmill protocols to determine Lpt, Vpt, and maximal oxygen uptake (VO<sub>2max</sub>; ml.kg<sup>-1</sup>.min<sup>-1</sup>). Vpt was determined as %VO<sub>2max</sub> at which Ve:VO<sub>2</sub> increased without accompanying increases in Ve:VCO<sub>2</sub>. Lpt was determined as the %VO<sub>2max</sub> at which there was an intersection of slopes derived from linear models expressing blood lactate as a function of power output. RPE-O, L, and C were measured during the last 30 seconds of each stage using the OMNI Scale. Exercise time associated with Vpt and Lpt was used to determine corresponding HR, %VO<sub>2max</sub>, and RPE.

**RESULTS:** Using a combined sample of males and females, similar physiological and perceptual markers were identified at the Vpt and Lpt with the exception of heart rate (p<0.05).

Table 1.

|     | HR (b.min-1)  | %VO2max     | RPE-O     | RPE-L     | RPE-C     |
|-----|---------------|-------------|-----------|-----------|-----------|
| Vpt | 152.51±23.49* | 61.39±9.45  | 4.71±2.23 | 4.71±2.12 | 4.36±2.20 |
| Lpt | 138.21±14.52  | 57.76±10.51 | 4.57±1.86 | 4.43±1.78 | 4.36±2.02 |

**CONCLUSIONS:** Results support previous studies identifying physiological links between Vpt and Lpt. Perceptual markers identified at Lpt were similar to Vpt and previous response normalized studies using the OMNI Scale. Using group normalized RPE equivalent to Lpt may provide an alternative method to prescribe self-regulated training intensities for sport performance and fitness applications.

**3513 Board #234 June 2 8:00 AM - 9:30 AM**

**Invasive And Non-invasive Specific Tests For Aerobic And Anaerobic Parameters Determination In Females Basketball Players**

Bruno H. F. Camargo<sup>1</sup>, Gustavo G. Araujo<sup>2</sup>, Claudio A. Gobatto<sup>3</sup>, Nathalia A. Vieira<sup>1</sup>, Leonardo H. D. Messias<sup>1</sup>, Fúlvio B. Manchado-Gobatto<sup>1</sup>. <sup>1</sup>Methodist University of Piracicaba - UNIMEP, Piracicaba, Brazil. <sup>2</sup>Federal University of Alagoas - UFAL, Maceió, Brazil. <sup>3</sup>University of Campinas - UNICAMP, Limeira, Brazil.

(No relationships reported)

The basketball games are composed by intermittent exercises with aerobic and anaerobic activities.

**PURPOSE:** to evaluate the aerobic and anaerobic parameters of female basketball players using non-invasive (adapted RAST and critical velocity model) and invasive (lactate minimum) methods.

**MATERIAL AND METHODS:** Twelve well trained female basketball players (19±1 yrs) were submitted to five days of tests. First, the athletes accomplished four intensities (10 to 14km/h) running in "shuttle" (20-m) exercise until exhaustion (set to occur between 1 and 10 min). The 'velocity versus 1/time to exhaustion' linear fit was used to determine the aerobic (critical velocity - CV) and anaerobic running capacity (ARC). The invasive protocol adopted was the lactate minimum test (LM), composed by two phases: hyperlactatemia induction and incremental test, separated by 8min of passive recovery. The first phase used the "running anaerobic sprint test" (RAST) adapted to basketball. The method consisted of 6 maximum "shuttle" sprints of 35-m (2 x 17.5-m), separated by 10s recovery, determining the minimal (Pmin), medium (Pmed) and maximal (Pmax) power and fatigue index (FI). The incremental phase consisted of 5 stages (3 min) of shuttle running efforts (20-m) of 7, 8, 9, 10, 12 km/h. Blood samples were collected at the end of each stage. The LM parameters (intensity and blood lactate concentration) were analyzed using a polynomial fit. Paired t-Student test and Pearson product-moment correlation were used to statistical analysis (p<0.05).

**RESULTS:** The CV was obtained at  $10.3 \pm 0.2$  km/h and estimated ARC was  $73.0 \pm 3.4$  m. The RAST promoted the lactate peak at  $5.9 \pm 0.2$  mM and determined the Pmax ( $3.6 \pm 0.2$  W/Kg), Pmed ( $2.8 \pm 0.1$  W/Kg), Pmin ( $2.3 \pm 0.1$  W/Kg) and FI ( $30 \pm 3\%$ ). The LM intensity was 8.7% lower than CV ( $9.47 \pm 0.13$  Km/h) and these parameters were not significantly correlated ( $r=0.23$ ). The LM (blood lactate) was  $3.1 \pm 0.3$  mM, showing interesting and significant correlation with lactate peak ( $r=0.78$ ).

**CONCLUSION:** The specific non-invasive method can be used to determine the aerobic and anaerobic parameters in female basketball players. However, as occurs in others sport modalities, CV upper estimate the LM intensity.

**Blood Acid-Base Status Response And Running Performance At Different Constant Loads**

Thiago F. Lourenço. UNICAMP, Campinas, Brazil.  
(No relationships reported)

The maintenance of blood acid-base status (ABSb) is primarily accomplished by adjusting the partial pressure of CO<sub>2</sub> in the lungs. For exercise intensities above the respiratory compensation point (RCP), the buffering limited capacity of blood and the hyperventilation controlled by the central nervous system are insufficient to control ABSb. Despite the importance of RCP in this control, no study has investigated the ABSb response during constant load at or higher than RCP running speed (sRCP). **PURPOSE:** Analyze the runners ABSb response after 10-km running performed at three different constant loads.

**METHODS:** With at least 72 hours rest between the tests, twenty-five amateur runners ( $34.6 \pm 5.7$  yrs;  $68.7 \pm 10.2$  kg; 10-km performance  $48.9 \pm 7.3$  min e  $VO_{2max}$  de  $40.9 \pm 6.5$  ml\*kg/min) performed a maximum effort protocol to determine the running speed related to VT (sVT), RCP (sRCP) and  $VO_{2max}$  (s $VO_{2max}$ ) and three 10-km races at constant load on the sVT, sRCP and V1 (sRCP +  $[0.25 * (sVO_{2max} - sRCP)]$ ).

**RESULTS:** All runners that ran at sVT and sRCP completed 10-km with no changes in blood pH ( $7.48 \pm 0.05$  vs  $7.51 \pm 0.02$ ,  $p > 0.05$ ), even with increased in blood lactate ( $2.8 \pm 0.8$  vs  $5.5 \pm 4.2$  mmol\*L<sup>-1</sup>) and decreased in bicarbonate ( $25.4 \pm 2.8$  vs  $22.2 \pm 4.2$  mmol\*L<sup>-1</sup>,  $p < 0.05$ ). At V1 intensity, only three of sixteen runners completed 10-km. The others completed only  $5.2 \pm 2.2$  km with a significant decrease in pH ( $7.48 \pm 0.02$  vs  $7.33 \pm 0.04$ ,  $p < 0.05$ ) and bicarbonate ( $24.1 \pm 0.5$  vs  $14.6 \pm 1.0$  mmol\*L<sup>-1</sup>,  $p < 0.05$ ).

**CONCLUSIONS:** All runners that ran at sVT and sRCP completed 10-km with no changes in blood pH ( $7.48 \pm 0.05$  vs  $7.51 \pm 0.02$ ,  $p > 0.05$ ), even with increased in blood lactate ( $2.8 \pm 0.8$  vs  $5.5 \pm 4.2$  mmol\*L<sup>-1</sup>) and decreased in bicarbonate ( $25.4 \pm 2.8$  vs  $22.2 \pm 4.2$  mmol\*L<sup>-1</sup>,  $p < 0.05$ ). At V1 intensity, only three of sixteen runners completed 10-km. The others completed only  $5.2 \pm 2.2$  km with a significant decrease in pH ( $7.48 \pm 0.02$  vs  $7.33 \pm 0.04$ ,  $p < 0.05$ ) and bicarbonate ( $24.1 \pm 0.5$  vs  $14.6 \pm 1.0$  mmol\*L<sup>-1</sup>,  $p < 0.05$ ).

**3515 Board #236 June 2 8:00 AM - 9:30 AM**  
**Applying Lactate Analysis to Establish and Monitor Intensity during Interval Training in Coronary Heart Disease Patients**

Jeffrey W. Christle<sup>1</sup>, Ulrik Wisloff<sup>2</sup>, Axel Pressler<sup>1</sup>, Martin Halle<sup>1</sup>. <sup>1</sup>Technical University of Munich, Munich, Germany. <sup>2</sup>Nowegian university of Science and Technology, Trondheim, Norway.  
(No relationships reported)

**PURPOSE:** Relatively high-intensity aerobic interval training (AIT) has been shown to be effective in coronary artery disease (CAD) therapy. To prescribe and monitor training intensity during interval training, percent heart rate (%HR) and ratings of perceived exertion (RPE) from exercise testing (CPET) are the most commonly used methods, but have limitations. This study examines the potential of arterial lactate kinetics to aid in the prescription and monitoring of exercise intensity during AIT.

**METHODS:** Thirty-five clinically stable CAD patients (age  $64 \pm 7$ , 66% male) performed stepwise peak exercise testing (CPET) to volitional exhaustion. Heart rates at 50% to 60% and 80% to 90% of peak aerobic capacity ( $VO_{2peak}$ ) were calculated and used to establish interval training intensities. Patients performed one bout of AIT (see figure). Heart rate was recorded continuously and RPE and [lactate]<sub>a</sub> data were collected at rest and during the last 10 seconds of each interval. [lactate]<sub>a</sub> data was then graphically analyzed and evaluated using a 4 mmol/L lactate steady state threshold (LSST) to indicate a relevant anaerobic contribution.

**RESULTS:** Heart rate targets were reached in  $> 85\%$  of all intervals. Mean [lactate]<sub>a</sub> was substantially over the 4 mmol/L LSST (4.14 mmol/L in moderate-intensity phases and 4.65 mmol/L in high-intensity phases). Data for HR and RPE correlated well to changes in load during exercise training ( $r^2 = 0.81$ ), whereas [lactate]<sub>a</sub> did not correlate to any of the other parameters (see table).

**CONCLUSIONS:** During aerobic interval training, a constant accumulation of lactate in both the high and low intervals results in the majority of training being performed at above the lactate steady state threshold.

**3516 Board #237 June 2 8:00 AM - 9:30 AM**  
**Kinetics Of Lactate Removal After Brazilian Jiu Jitsu Match**

Tacito P. Souza-Junior<sup>1</sup>, Daniel Pinheiro<sup>2</sup>, André Luis Amaral Rodrigues Almeida<sup>3</sup>, César Cavinato Cal Abad<sup>4</sup>. <sup>1</sup>Federal University of Parana, Curitiba, Brazil. <sup>2</sup>Unisantana, São Paulo, Brazil. <sup>3</sup>Inforfisc, São Paulo, Brazil. <sup>4</sup>Heart Institute (InCor) of University of São Paulo Medical School, São Paulo, Brazil. (Sponsor: Carlo Baldari, FACSM)  
(No relationships reported)

The Brazilian Jiu Jitsu is one of the most practiced martial arts in the World but the number of studies about this sport is still poor. Traditionally, analysis of lactate concentrations have been used in different types of martial arts to determine the physiological profile, competitive performance, metabolic demand and the effect of physical training.

**PURPOSE:** Verify the analysis of blood lactate during two simulated Jiu-Jitsu matches.

**METHODS:** Twenty-one male athletes (age  $28.33 \pm 6.45$  years, height,  $1.75 \pm 1.0$  cm, body weight,  $78.07 \pm 9.40$  kg, percent fat,  $14.29 \pm 4.79\%$ , years of practicing,  $11.03 \pm 2.4$ ) performed two simulated 10-min match with a 48-hour interval. In both matches blood lactate were collected before and after each bout.

**RESULTS:** Lactate at rest, heating, 1, 5 and 10 min were, respectively ( $0.94 \pm 0.20$ ,  $2.19 \pm 0.78$ ,  $10.05 \pm 1.73$ ,  $7.77 \pm 1.69$ ,  $6.28 \pm 1.30$  in bout 01 and  $0.96 \pm 0.14$ ,  $1.98 \pm 0.78$ ,  $9.46 \pm 0.96$ ,  $7.24 \pm 1.24$  e  $5.74 \pm 1.10$  in bout 02). There were significant differences among all the moments of the same match (One-way ANOVA;  $p < 0.05$ ) but no difference for the same times between the bouts was found. The Pearson's correlation about the lactate of two matches was 0.95 while the correlation between the matches at rest, heating, 1, 5 and 10 minutes were, respectively 0.59, 0.60, 0.47, 0.44, 0.47 ( $p < 0.05$ ).

**CONCLUSION:** Our data suggest that the Brazilian Jiu Jitsu fight is very intense and use glycolysis to produce energy. The blood lactate concentration in two fights at 48 hours of intervals are repeatable and can be used for assessment, prescription and monitoring the specific training when performed with the same opponents.

**3517 Board #238 June 2 8:00 AM - 9:30 AM**  
**Identification Of The Maximal Lactate Steady State In Obese Zucker Rats**

Jeeser A. Almeida. Catholic University of Brasilia, Brasilia, Brazil.  
(No relationships reported)

Exercise has been widely applied in the weight loss control, especially for obesity treatment. However, determination of an appropriate intensity of exercise for obese rats (Zucker fa/fa) it was undefined until now. It is well known that maximal lactate steady state (MLSS) has been considered the gold standard for identification of aerobic capacity. Nevertheless this value was not identified in obese Zucker rats at the moment.

**PURPOSE:** This study aims to identify the maximum lactate steady state (MLSS) in obese Zucker rats in order to provide a more effective tool for the exercise training prescription of this animal model.

**METHODS:** In order to make such determination, obese Zucker and lean Wistar rats were here utilized. After adaptation of animals to treadmill running, the MLSS was determined by using three different velocities (10 m.min<sup>-1</sup>, 12.5 m.min<sup>-1</sup> and 15 m.min<sup>-1</sup> for Zucker and 15 m.min<sup>-1</sup>, 20 m.min<sup>-1</sup> and 25 m.min<sup>-1</sup> for lean Wistar rats).

**RESULTS:** In order to ensure the differences between body weight animals, T test was applied. Significant differences were observed in Zucker (390.0 ± 18.8 g) and Wistar rats (227.3 ± 26.2 g) (P < 0.05). The MLSS was defined as the highest blood lactate concentration that increased up to 1 mmol.L<sup>-1</sup> during constant exercise. In obese Zucker rats, the MLSS was found in a considerable lower velocity (12.5 m.min<sup>-1</sup>) in comparison to lean Wistar rats (20 m.min<sup>-1</sup>).

**CONCLUSIONS:** In summary, the identification of MLSS in obese Zucker rats provides a better intensity determination for exercise on a treadmill running for this animal model.

**3518 Board #239 June 2 8:00 AM - 9:30 AM**

**The Effects of Swimming Recovery on the Clearance of Lactate after a Maximal Swim Effort**

Joshua D. Guggenheimer, Daniel de Moraes. *University of North Dakota, Grand Forks, ND.*

(No relationships reported)

Active recovery following high-intensity exercise may limit the accumulation of unwanted metabolites and prevent acidosis in active tissues, thus augmenting future performances.

**PURPOSE:** To examine the effects of different recovery protocols on the removal of lactate following a maximal-effort swim bout.

**METHODS:** 8 experienced collegiate swimmers (4 male, 4 female) were recruited for this study. Each participant took part in 4 days of testing, including a familiarization session. On 3 different occasions, participants completed a standardized warm up, a single 200yd maximal effort swim, and 15 min of either backstroke (BR), freestyle (FR), or passive (PR) recovery. Recovery paces for BR and FR were set at 175% of 100yd trial time. PR consisted of quiet sitting for 15 min. Blood lactate samples were collected before warming up (PRE), 3-min post 200yd maximal-effort swim trial (T0), after 5-min of recovery (T5), 10-min of recovery (T10), and 15-min of recovery (T15). A 3 x 5 ANOVA with repeated measures was conducted. Alpha was set at 0.05. Tukey's post hoc analysis was used to further examine main effects.

**RESULTS:** The RM ANOVA indicated a significant interaction between protocol and time (F(8, 58) = 12.29, p < 0.001) in regards to lactate. Main effects were found for both protocol (F(2, 14) = 12.18, p = 0.001), and time (F(2.22, 15.56) = 413.32, p < 0.001) as they pertained to blood lactate levels. Follow-up pairwise comparisons indicated significant differences between passive recovery and freestyle recovery (p = 0.013), and between passive recovery and backstroke recovery (p = 0.017) and their respective effects on blood lactate concentrations.

**CONCLUSION:** Both active recoveries were more efficient in metabolizing lactate when compared to passive recovery. These findings provide coaches with data suggesting that both swimming strokes are efficient methods of active recovery. In fact, 75% of the participants in this study deemed backstroke as their preferred method of recovery. Therefore, the results of this study encourage coaches to promote either recovery stroke for their swimmers, knowing that they are both equally effective methods of recuperating from high-intensity performances.

**3519 Board #240 June 2 8:00 AM - 9:30 AM**

**Muscle Fatigue And Blood Lactate Following Three Different Antagonist Pre-load Conditions**

Rodrigo L. Carregaro<sup>1</sup>, Rafael Cunha<sup>2</sup>, André Martorelli<sup>2</sup>, Saulo Martorelli<sup>2</sup>, Diego Jesus<sup>2</sup>, Saulo R. Soares<sup>2</sup>, Carlos Gomes de Oliveira<sup>3</sup>, Lee E. Brown, FACSM<sup>4</sup>, Martim Bottaro<sup>2</sup>. <sup>1</sup>Universidade Federal de Mato Grosso do Sul (UFMS), Campo Grande-MS, Brazil. <sup>2</sup>Universidade de Brasília (UnB), Brasília-DF, Brazil. <sup>3</sup>Universidade Federal do Rio de Janeiro (UFRJ), Rio de Janeiro-RJ, Brazil. <sup>4</sup>California State University Fullerton, Fullerton-CA, CA.

(No relationships reported)

Preload of antagonist muscles can be achieved by reciprocal actions (RA) or by opposing muscle actions with reduced rest between sets. However, studies comparing different strategies of antagonist preload are scarce and present insufficient evidence concerning neuromuscular responses.

**PURPOSE:** To evaluate the acute effects of three different antagonist pre-load conditions on knee extensor neuromuscular fatigue and blood lactate responses.

**METHODS:** 24 healthy men (23.5 ± 3.6 years) were tested across 4 days on 3 different preload isokinetic (60°.s<sup>-1</sup>) exercise protocols with 1 minutes rest between sets, separated by 72 hours: 1) Traditional (TR; 4 sets of 10 unilateral isokinetic knee flexions [KF] followed by 4 sets of 10 unilateral isokinetic knee extensions [KE]); 2) RA (4 sets of 10 reciprocal isokinetic concentric KF and KE); and 3) Super-set (SS; 4 sets of 10 KF immediately followed by 10 KE). Vastus medialis (VM) EMG muscle fatigue was measured using Dimitrov's (2001) Fatigue Index (FI). Blood lactate concentration was measured at rest, 3, and 5 min after the 4 sets for each protocol.

**RESULTS:** VM FI and blood lactate concentrations are presented in Table 1. During SS, the FI was greater than RA and TR (p < 0.05). The SS protocol also presented greater (p < 0.05) concentrations of blood lactate when compared to RA and TR.

**Table 1.**

|    | VM Fatigue Index (%) |           |           |           | Blood Lactate [mmol/L] |               |               |               |
|----|----------------------|-----------|-----------|-----------|------------------------|---------------|---------------|---------------|
|    | 1st set              | 2nd set   | 3rd set   | 4th set   | Rest                   | Immediate     | 3 min         | 5 min         |
| TR | 109 ± 7              | 93 ± 7    | 98 ± 7    | 98 ± 7    | 0.89 ± 0.34            | 4.99 ± 0.93†  | 5.92 ± 1.06†  | 5.98 ± 1.11†  |
| RA | 121 ± 7              | 100 ± 7   | 93 ± 7    | 111 ± 7   | 0.92 ± 0.30            | 4.86 ± 0.92†  | 5.82 ± 1.45†  | 6.08 ± 1.41†  |
| SS | 130 ± 10*            | 120 ± 10* | 117 ± 10* | 122 ± 10* | 0.86 ± 0.31            | 6.05 ± 1.05*† | 7.10 ± 1.16*† | 7.15 ± 1.15*† |

\*Greater than RA and TR (p < 0.02)

†Greater than rest (p < 0.05).

**CONCLUSION:** These results indicate that when compared to TR and RA antagonist preload protocols, the SS protocol provides greater levels of neuromuscular fatigue and is more metabolic demanding. Thus, trainers and physical therapists should avoid prescription of the SS protocol in special populations such as elderly, children and individuals undergoing cardiac or pulmonary rehabilitation.

**3520 Board #241 June 2 8:00 AM - 9:30 AM**

**Timing of Blood Lactate Collection Following Maximal Anaerobic and Aerobic Exercise in Female Adolescent Athletes**

Catherine Gaul, Lynne A. Stuart-Hill, Leanne J. Dickau. *University of Victoria, Victoria, BC, Canada.*

(No relationships reported)

Peak blood lactate concentration (BL) is regularly used to reflect the contribution of anaerobic metabolism to exercise performance. Serial blood samples are often collected at 1, 3, and 5 min post-exercise to account for any delay in lactate transport from muscle to blood and to enhance accuracy of peak measures being obtained. Such procedures were developed with adult populations and are used for both aerobic and anaerobic exercise.

**PURPOSE:** To determine optimal timing protocols for BL measurement in adolescent female athletes following maximal anaerobic and aerobic exercise tests.

**METHODS:** Seventeen elite adolescent female soccer players (16.3 ± 0.8 yrs) completed two maximal tests to exhaustion on a motorized treadmill, with continuous monitoring of heart rate, on separate days: 1) Cunningham Anaerobic Speed test (AST), involving sprint running at 20mph and an 8% incline, and 2) Maximal Graded Exercise test (MGXT) to measure maximal aerobic power. For each test, finger prick BL was measured 5 min pre-test and at 1, 3 and 5 min post-test following standardized procedures using a Lactate Pro analyzer.

**RESULTS:** BL did not differ between the three post-AST collection times, however 9 of the 15 participants (60%) reached peak BL at 3 min post-AST (11.4 ± 2.3 mmol.L<sup>-1</sup>) with 5 participants reaching peak BL at 1 min and 3 others reaching it at 5 min post-AST. All participants (100%) attained peak BL at 1 min post-MGXT (9.6 ± 2.3 mmol.L<sup>-1</sup>, p < 0.05). BL was significantly higher (p < 0.05) at 1 min than at 3 min (8.3 ± 2.2 mmol.L<sup>-1</sup>) or 5 min (7.1 ± 2.1 mmol.L<sup>-1</sup>) post-MGXT. Mean peak BL values were significantly higher post-AST (11.9 ± 2.2 mmol.L<sup>-1</sup>) than post-MGXT (p < 0.05).

**CONCLUSION:** Appropriate timing of BL samples in adolescent female athletes depends upon the type of exercise performed. Collecting BL at 1 minute post-maximal aerobic performance and at 3 min post-maximal anaerobic running in adolescent female athletes provides the most consistent and accurate peak values. The advantage of a single BL measurement following maximal exercise includes fewer risks related to serial collection, reduced potential participant stress and substantially lower testing costs. These findings will help direct timing of blood sample collection to improve the accuracy of this metabolic measurement in paediatric populations.

---

**3521 Board #242 June 2 8:00 AM - 9:30 AM**  
**The Relationship Between Onset Of Blood Lactate Accumulation, Body Weight, And Balance Ability In 20-70 Years-old Subjects**

Burkhard Weisser, Julia Last. *University of Kiel, Kiel, Germany.* (Sponsor: Reinhard Ketelhut, FACSM)  
(No relationships reported)

Good balance ability is an important predictor not only for the prevention of falls but also for general health. The decrease in balance ability during aging is well documented. Balance training is able to increase balance ability in all age groups, but only few elderly subjects participate in specific programs. It is unclear, which other factors might influence the decrease in balance with aging.

**PURPOSE:** To investigate the correlation of balance ability with aerobic exercise performance (onset of blood lactate accumulation at lactate 4nM, OBLA) and with body weight.

**METHODS:** OBLA was measured using standard bicycle testing (Watt/kg body weight). Balance ability was determined by a validated one-way frontal moving slap with integrated sensor and associated software. Correlations were calculated for balance ability with OBLA and body weight in 296 subjects (age 20-70 years, 147 female, 149 male). In addition, results were analysed in subgroups; younger versus older (20-44 and 45-77 years of age) and active versus sedentary (less than 2 hours vs. > 2 hours of moderate activity per week)

**RESULTS:** Body weight (mean value +/- standard deviation) was 74 +/- 15 kg, OBLA was 2.0 +/- 0.6 Watt/ per kg body weight and balance ability was 4.8 +/- 1.3 (arbitrary units). There was a positive correlation between OBLA and balance ( $r=0.38$ ;  $p<0.05$ ) and a negative correlation between body weight and balance ( $r=-0.41$ ;  $p<0.05$ ). Balance ability decreased with age, whereas the correlations remained significant in the group 45-70 years of age both in active and sedentary persons.

**CONCLUSION:** Balance ability decreases with age. Aerobic capacity is positively associated with balance ability, whereas there was a negative correlation between body weight and balance. Thus, elderly subjects might benefit not only from specific balance training but also from general aerobic activity. Higher body weight is a risk factor for worsening balance ability, although a causal relationship remains to be shown.

---

**3522 Board #243 June 2 8:00 AM - 9:30 AM**  
**Determination of Anaerobic Threshold by the Breakpoint of Locomotor Respiratory Coupling**

Masanori Takemura<sup>1</sup>, Mitsuharu Kaya<sup>2</sup>, Junzo Tsujita<sup>1</sup>, Yoshitaka Oku<sup>1</sup>. <sup>1</sup>*Hyogo College of Medicine, Nishinomiya, Japan.* <sup>2</sup>*Hyogo University of Health Science, Kobe, Japan.*  
(No relationships reported)

Locomotion and respiration are coupled during various exercises such as running and cycling, a phenomenon called locomotor respiratory coupling (LRC). We have reported that ventilatory efficiency is optimized during LRC, and that LRC is most often observed at the ventilatory threshold (VT). Then, in the present study, we developed a novel method to determine anaerobic threshold (AT), the breakpoint of LRC (BPLRC).

**PURPOSE:** To evaluate whether BPLRC corresponds to AT such as the respiratory compensation point (RC), VT, and onset of blood lactate accumulation (OBLA).

**METHODS:** Seventeen healthy subjects (8 females and 9 males; age, 25 ± 7 years) volunteered for this study. Ten subjects (Group 1) underwent the incremental exercise test using a cycle ergometer twice, which included a spontaneous breathing trial and a controlled breathing trial to measure BPLRC. The other 7 subjects (Group 2) underwent the incremental exercise test with controlled breathing to measure BPLRC, and blood lactate concentrations were measured. During a controlled breathing trial, we forced subjects to achieve LRC by adjusting their breathing frequency at 30 breaths per min and their pedaling rate at 60 rpm. Subjects declared the breakpoint when they could not maintain LRC (BPLRCself). Additionally, we calculated the breakpoint from the time course of workload and breathing frequency using the two-line regression method (BPLRCcalc). We evaluated the correlations between BPLRCs and several ATs, including RC, VT, and OBLA. ATs and BPLRCs being expressed as workload (W).

**RESULTS:** In Group 1 (n=10), the single regression analysis indicated that BPLRCself (162 ± 35W) was most suitable for predicting RC (161 ± 33W) during spontaneous breathing (R = 0.877; regression coefficient, 0.823;  $p < 0.001$ ). Then in all subjects, it indicated that BPLRCself (156 ± 31W) was suitable for predicting RC (154 ± 37W) during controlled breathing (R = 0.742; regression coefficient, 0.898;  $p < 0.01$ )

**CONCLUSION:** BPLRC, the self-reported breakpoint during incremental exercise at which a subject cannot maintain LRC with controlled breathing at 30 bpm and a pedaling speed of 60 rpm, is a good predictor of RC. Because determining BPLRC does not require special equipment and the threshold is easily determined by self-reporting, we conclude that BPLRC is a practical AT variable.

**Blood Lactate Levels are Lower Following Intense Exercise with the Use of a Mouthpiece**

Wesley D. Dudgeon<sup>1</sup>, Timothy P. Scheett<sup>2</sup>, Larry A. Buchanan<sup>1</sup>, Ashley E. Strickland<sup>1</sup>, Dena P. Garner<sup>1</sup>. <sup>1</sup>*The Citadel, Charleston, SC.* <sup>2</sup>*The College of Charleston, Charleston, SC.* (Sponsor: Gregory A. Hand, FACSM)  
(No relationships reported)

Custom fit lower mandible performance mouthpieces (MP) have recently been shown to decrease cortisol during both anaerobic and aerobic exercise as well as improved gas exchange (O<sub>2</sub> utilization & CO<sub>2</sub> production) during aerobic exercise, thus showing the potential to improve performance and/or recovery.

**PURPOSE:** This study examined the effect of a performance mouthpiece (ArmourBite Mouthwear) on blood lactate levels in 12 collegiate males who regularly performed lower body resistance exercises.

**METHODS:** At least 7 days following determination of a one repetition maximum (1RM), subjects completed 2 trials of 6 sets of 10 repetitions of back squats with 2 minutes rest between sets, and were given 7 days between trials. Resistance was set at 80% of each subject's 1RM and resistance was adjusted during testing so 10 repetitions were completed during each set. The order of treatment (i.e. use of MP) was randomized and blood was sampled as follows for determination of blood lactate (Lactate Plus, Nova Biomedical, Waltham, MA): pre exercise, after 3 sets (mid), post exercise, 30, 60 and 120 minutes post exercise.

**RESULTS:** There was no difference in lactate (mmol/L) immediately pre exercise ( $0.88 \pm 0.23$  (MP) vs.  $0.97 \pm 0.29$ ;  $P=.25$ ) or 120 min post exercise ( $1.30 \pm 0.70$  (MP) vs.  $1.28 \pm 0.33$ ;  $P=.45$ ) and there was a trend for a difference at mid-point ( $9.95 \pm 2.03$  (MP) vs.  $11.95 \pm 2.91$ ;  $P=.09$ ). The MP group had lower lactate immediately post exercise ( $11.65 \pm 2.31$  (MP) vs.  $13.85 \pm 2.80$ ;  $P=.006$ ), 30 minutes post exercise ( $4.53 \pm 2.14$  (MP) vs.  $6.06 \pm 1.57$ ;  $P=.03$ ) and 60 minutes post exercise ( $2.13 \pm 1.03$  (MP) vs.  $2.82 \pm 0.88$ ;  $P=.03$ ).

**CONCLUSIONS:** This data shows that the use of a custom fit lower mandible MP can reduce blood lactate levels following intense resistance exercise. When viewed in light of the published effect of MPs on lowering cortisol levels, this suggests that MP use decreases stress during exercise recovery, potentially improving human performance.

### Effects of Metatarsal Pad and Foot orthotics on Leg Muscle Activities and Foot Pressure

Hongjae Lee<sup>1</sup>, Jung-Ja Kim<sup>2</sup>, Jung-kyu Choi<sup>2</sup>, In-Sik Park<sup>2</sup>. <sup>1</sup>Ilsanpaik Hosp., Inje Univ, Goyang, Korea, Republic of. <sup>2</sup>Chonbuk National University, Jeonju, Korea, Republic of.

(No relationships reported)

**PURPOSE:** to evaluate the effects of metatarsal pad (MP) and foot orthotics on leg muscle activities and foot pressure.

**METHODS:** 15 healthy young females who had no cavus foot or flat foot were participated in this study. The subjects walked on a treadmill under four different experimental conditions: 1) barefoot, 2) MP only (Pad Only), 3) a soft insole with MP (Soft+MP), and 4) a rigid insole with MP (Rigid+MP). During walking, foot pressure data such as force, peak pressure, mean pressure, force-time integral and pressure-time integral were collected. Also, EMG activities of lower limb muscles such as tibialis anterior(TA), lateral gastrocnemius(GCM), rectus femoris(RF), and biceps femoris(BF) were gathered.

**RESULTS:** In the foot pressure analysis, the peak pressures(kPa) of 2.3 metatarsal head area were 303.1 with Barefoot, 293.8 with MP Only, 288.4 with Soft+MP(p<.05), and 301.6 with Rigid+MP. The pressure-time integrals (kPa\*sec) were 7439.7, 7071.2, 6330.4(p<.05), and 7084.4 respectively in the same order. The dynamic EMG findings (uV) of TA muscle showed that 17.69 with Barefoot, 15.75 with MP Only, 13.43 with Soft+MP, 12.52 with Rigid+MP (p<.05). The findings of lateral GCM showed 19.15, 19.42, 17.85 and 17.67. That of RF showed 10.29, 8.81, 7.14, and 6.31(p<.05). That of BF showed 8.61, 7.93, 7.51, and 7.73 respectively in the same order above.

**CONCLUSIONS:** In the foot pressure analysis, there was significant reduction in case of soft insole with MP than rigid insole. On the other hand, the EMG study showed significant reduction of leg muscles activity in case of rigid insole with MP than soft insole, especially in TA muscle.

### Use of Tekscan Matscan® to Detect Static Rearfoot Position Through the Evaluation of Rearfoot Pressure.

David A. Titcomb, Mark Blais, Richard Lane. Liberty University, Lynchburg, VA. (Sponsor: Melvin Williams, FACSM)

(No relationships reported)

With the advancement of technology, many clinicians have been able to complement their foot examinations with the use of computerized foot pressure analysis systems.

**PURPOSE:** The purpose of this study was to test the hypothesis that a biomechanical pressure mat system would reliably detect static rearfoot position based on static heel pressure analysis compared to clinical examination by a licensed podiatrist.

**METHODS:** Static plantar pressure profiles of 35 subjects across a wide age range (20-89 years; mean age ± SD, 41.0 ± 22.1 years) were obtained using a biomechanical pressure mat system. Subjects with acute injury or clinical evidence of calcaneal fat pad atrophy were excluded from the study. Each subject underwent static plantar pressure assessment by standing barefoot on the calibrated pressure mat with feet in rectus position. A one frame "snapshot" (digital foot pressure image) of both right and left feet was recorded once the subject was standing in a static state. After plantar pressure data were collected, the distribution of both right and left rearfoot pressures of each foot was analyzed. Clinical software was utilized to create two separate masks over each rearfoot digital image, equally dividing it into medial and lateral regions. In each mask, average medial and lateral rearfoot pressure was determined and compared. Each rearfoot was then placed into one of three categories: inverted (greater lateral pressure), everted (greater medial pressure) or neutral (medial and lateral pressures within .03kg). After the plantar pressure assessment was performed, both of the subject's feet were examined by a licensed podiatrist to categorize their standing rearfoot position as being either inverted, everted, or neutral (rectus). A chi-square analysis with Kappa concordance test was performed comparing the pressure mat results to clinical examination findings.

**RESULTS:** A non-significant chi-square ( $p = .365$  ( $p > .05$ )). Kappa = .17 indicated no significant relationship between the two measures.

**CONCLUSIONS:** The biomechanical pressure mat did not reliably detect static rearfoot position based on rearfoot pressure distribution when compared rearfoot position observed during clinical examination. Grant funding provided by The Center for Research and Scholarship Fund of Liberty University #014\_022610.

3526 Board #247 June 2 9:30 AM - 11:00 AM

### Intrasession Reliability Of Insole In-shoe Plantar Pressure Measurements In Different Foot Areas

Niklas Koenig, Andreas Stoll, Frank Mayer, Heiner Baur. University of Potsdam, Potsdam, Germany.

(No relationships reported)

In-shoe plantar pressure distribution measurements have shown good reliability. However, controversy still exists about the minimum number of steps required to collect reliable data.

Intrasession protocols reduce systematic and random error to a minimum and can therefore evaluate the maximal precision of a measurement tool. Consequently, it allows the determination of requirements that are prerequisite for the application as well as the analysis of day-to-day variability.

**PURPOSE:** To determine the intrasession reliability of plantar pressure measurements of an average of 3, 10 and 20 steps in five foot areas and thus, to assess the minimal number of steps which should be collected.

**METHODS:** Seventeen healthy participants ( $27 \pm 4y$ ,  $180 \pm 8cm$ ,  $74 \pm 9kg$ ) walked at 5km/h on a treadmill. Custom-made synthetic shoes were used to attach the pressure measurement insoles (99 sensors, 100Hz) to the foot. For each subject 50 steps of the right foot were collected. Clinically relevant parameters (e.g.: peak-pressure [PP], peak-mean-pressure [PMP in kPa]) as well as time related measures (e.g.: force-time-integral [FTI in N\*s], pressure-time-integral [PTI in kPa\*s]) were calculated. The first and last 3 (Ave3), 10 (Ave10) or 20 (Ave20) steps were averaged for statistical analysis. Intrasession reliability was analysed by the intraclass correlation coefficient (ICC), the test-retest-variability (TRV in %) and the Bland-Altman bias and limits of agreement.

**RESULTS:** Overall ICC was  $>0.90$ . TRV ranges 1.30-31.82% with highest values in the midfoot (PTI=20.44%) and toe (PTI=23.24%) area for Ave3. Inclusion of more steps reduces TRVs (Ave20: Midfoot PTI=6.23%) and increases ICC (Midfoot PTI=0.97). FTI showed the highest systematic error in all measurements (Ave10=1.63%).

**CONCLUSIONS:** Plantar pressure distribution measurements reveal good intrasession reliability. Limitations are present in low loading sites like the toe and the midfoot area. Here, inclusion of more steps increases reliability. Consequently, ten steps are recommended for the collection of reliable plantar pressure measurements.

### Changes In Achilles Forces During Locomotion After 6 Months Of Growth In Youth 10-14 Years

Jennifer Neugebauer, David Hawkins. University of California, Davis, Davis, CA.

(No relationships reported)

For youth, Achilles tendon (AT) forces during locomotion may differ as a result of sex, growth over time, and/or physical activity level (PAL).

**PURPOSE:** The purposes of this study were (1) determine if peak force in the AT (FAT) and peak normalized FAT (nFAT) during walking and running in growing youth differed at the start and end of 6 months, and (2) test if sex, PAL, and/or growth rate (GR) affected FAT and nFAT.

**METHODS:** 22 girls (11.2 ± 0.2 years) and 20 boys (13.6 ± 0.1 years) were tested at the start of the study (0 months (mos)) and after 6 mos. These age ranges represent the primary growth years. Subject height and mass were measured. GR was calculated as the change in height between testing sessions. PAL was assessed by Physical Activity Questionnaire (PAQ). Subjects completed 3 target-speed walk (TSW), 3 target-speed run (TSR), 3 self-selected speed walk (SSW) and 3 self-selected run (SSR) trials (1.2 ± 0.1 m/s and 2.6 ± 0.1 m/s TSW and TSR). Kinematics and ground reaction forces were collected using a video system (Motion Analysis, Santa Rosa, CA) and a force plate (Kistler, Amherst, NY) respectively. FAT (N) and nFAT (BW) were determined using inverse dynamics. Repeated measures multiple regressions were used to determine if testing session, PAL, GR, and sex had significant relationships with FAT and nFAT (Bonferroni adjusted  $p < 0.004$ ).

**RESULTS:** GR was similar for boys (2.1%) and girls (2.4%). FAT and nFAT during SSW and SSR did not differ at 0 and 6 mos (mean FAT at 0 and 6 mos: SSW 1243 ± 31 N; SSR 2168 ± 112 N;  $p > 0.06$ ). Sex was not a significant predictor of FAT or nFAT in SSW, SSR, TSW, or TSR ( $p > 0.008$ ). GR and PAL were not significant predictors of FAT or nFAT during SSW or SSR ( $p > 0.005$ ). FAT during TSW increased at 6 mos (1163 ± 62 N at 0mos, 1230 ± 57 N at 6mos). FAT during TSR (mean FAT 0 and 6 mos: 2089 ± 46 N) and nFAT during TSW and TSR did not differ at 0 and 6 mos ( $p > 0.006$ ). Growth and PAQ had a significant negative relationship with nFAT during TSR.

**CONCLUSIONS:** nFAT during walking and running did not differ at 6 mos compared with 0 mos. AT forces (both FAT and nFAT) during walking and running did not differ between sexes. FAT increased at 6 mos only in TSW. GR and PAQ affected nFAT in TWR only and otherwise did not affect AT forces. Of the factors investigated, no consistent relationship between GR, PAL, and sex with AT forces during locomotion were found.

**An Analytic Transformation of Hallux Dorsiflexion Measured using Skin Marker Set and Bone-mounted Marker Array**

Rebecca Frimenko, Patrick Riley, W. B. Lievers, Jeff Crandall, Richard Kent. *University of Virginia, Charlottesville, VA.*

(No relationships reported)

**PURPOSE:** Assessment of risk in injury biomechanics requires both living subjects for normal range of motion tasks and cadaver subjects for injury and tolerance definition. Motion capture consisting of arrays of optical markers uses skin-mounted marker sets on living subjects and bone-mounted arrays on cadavers. The presence of soft tissue and simplified anatomical representations in skin-based measurement methods introduce error between the motion of the joint and the skin-based estimate. This study develops a function for relating sagittal plane dorsiflexion of the 1<sup>st</sup> metatarsophalangeal (1MTP) joint from skin-based markers to measurements from bone-mounted arrays.

**METHODS:** 5 cadaver limbs were instrumented with 8 skin markers and 3 arrays of 4 markers rigidly attached to the bone (Skin: tibia, medial and lateral malleolus, heel, proximal and distal 1<sup>st</sup> and 5<sup>th</sup> metatarsals, distal hallux. Bone: calcaneus, 1<sup>st</sup> metatarsal, proximal hallux). An 8-camera Vicon system was used as each foot was moved from flat-foot through toe-off. 1MTP joint angle estimates were obtained from the skin marker set using OpenSim. 6-degree-of-freedom motion of the 1st metatarsal and the 1st proximal phalanx was determined from the motion of the bone-mounted marker array (Shaw et al. 2009).

**RESULTS:** A linear regression to the cross-plot of the two definitions was found to adequately capture the relationship between the two definitions of 1MTP dorsiflexion angle ( $r^2 = 0.8414$ ) (Fig. 1).

**CONCLUSION:** A relationship was found between the 1MTP dorsiflexion angle estimated using an 8-marker skin set and that based on marker arrays mounted directly to bone.

**Reference:** Shaw G et al. *Stapp Car Crash J.* 53,1-48. 2009.

Fig. 1 - data reported by the skin and bone marker sets.

**3529** Board #250 June 2 9:30 AM - 11:00 AM

**Effects of Semi-Rigid Ankle Orthoses on Athletic Tasks Following a Fatiguing Bout of Exercise**

James A. Yaggie, Christina Smith, Andrew Miller, Rebekah Trimbach. *University of Findlay, Findlay, OH.*

(No relationships reported)

Articulated semi-rigid ankle orthoses (SRAO) are used prophylactically in sport to aid in the functional stability of the ankle and to reduce the incidence of recurring injury. The literature suggests that many of these injuries occur late in activity when the lower extremity may be fatigued and refined technique begins to diminish. Despite the perceived protection of the SRAO, athletes, coaches and clinicians are often concerned with the restriction the SRAO may pose on athletic performance.

**PURPOSE:** Determine the effect of SRAO on performance selected tasks, following fatiguing activity.

**METHODS:** 20 subjects (age = 22.7 yrs ± 1.2; wt = 71.7 kg ± 13.0; ht = 171.7 cm ± 9.4; leg length = 90.9 cm ± 4.7) without lower extremity trauma within 2 years, consented participation. Randomized trials for balance [Star Excursion Balance Test (SEBT)], agility [shuttle run (SR)], and power [vertical jump (VJ)] were compared between 4 conditions [fatigued, braced (FB); fatigued, un-braced (FUB); non-fatigued, braced (NFB); non-fatigued, un-braced (NFUB)]. Participants were bilaterally fitted with a well-known, commercially available SRAO for all braced trials. Two, Wingate supramaximal exercise bouts were used as the fatiguing protocol. RMANOVA was performed to determine main effects using (task x condition; SPSS, IL;  $\alpha = .05$  for all tests).

**RESULTS:** No main effects for VJ & SR were observed under any of the bracing conditions. Main effect for bracing was observed for the raw SEBT scores. Tukey pairwise comparisons revealed that there were significant increases in distance reached for the posterior-medial direction (NFB = 82.7 cm ± 2.6; FB = 86.4 ± 1.9;  $\Delta = 3.7\%$ ;  $p = .046$ ) and medial direction (NFB = 67.3 cm ± 3.1; FB = 71.8 ± 2.2;  $\Delta = 4.1\%$ ;  $p = .039$ ) during the braced conditions. Although subjects reported that the SRAO anecdotally restricted ROM during most SEBT directions involving inversion and eversion, overall performance was not hindered by the application of the brace. Further, the only main effects observed with functional performance involved increases in SEBT that could likely be attributed to comfort and confidence of motion while wearing an ankle device.

**CONCLUSION:** An articulated, semi-rigid orthosis effectively limits motions at the ankle, but does not appear to hinder athletic performance following a fatiguing bout.

**3530** Board #251 June 2 9:30 AM - 11:00 AM

**Mechanics of a Biomechanical Energy Harvesting Ankle Device During Walking**

Robert W. Gregory, Rebecca A. Zifchock, William F. Brechue, FACSM. *United States Military Academy, West Point, NY.*

(No relationships reported)

With the increasing use of portable electronics in the military, the need for mobile electrical power sources has increased. The power demand for these devices is typically met by batteries. However, conventional batteries take up a significant percentage of a soldier's combat load. Therefore, biomechanical energy harvesting devices have been considered as an alternative to batteries. One such device has been designed to harvest energy from the motion of the ankle joint during walking.

**PURPOSE:** To investigate the differences in gait kinematics and kinetics when walking with and without a biomechanical energy harvesting ankle device (SPARK; Spring Active, Inc.; Tempe, AZ).

**METHODS:** Kinematic (step length and step rate) and kinetic (peak vertical ground reaction force and impulse) variables were measured during treadmill walking in 6 (4 male, 2 female) healthy adult subjects. The subjects walked 7-10 min at 4.83 km/h for each of four conditions: 1) No rucksack/No SPARK, 2) No rucksack w/SPARK, 3) Rucksack (30% BW)/No SPARK, and 4) Rucksack (30% BW) w/SPARK.

**RESULTS:** There were no significant differences in step length, step rate, and impulse when walking with and without the SPARK device for both the rucksack and no rucksack conditions. However, there was a strong trend ( $p = 0.07$ ) towards larger peak vertical ground reaction forces when using the SPARK device. The kinematic and kinetic results are presented in the table below (mean ± SD).

|                    | Walk w/o Rucksack |             | Walk w/Rucksack |             |
|--------------------|-------------------|-------------|-----------------|-------------|
|                    | No SPARK          | SPARK       | No SPARK        | SPARK       |
| Step Length (m)    | 0.74 ± 0.02       | 0.73 ± 0.07 | 0.75 ± 0.03     | 0.74 ± 0.04 |
| Step Rate (step/s) | 1.82 ± 0.07       | 1.87 ± 0.19 | 1.81 ± 0.07     | 1.83 ± 0.11 |
| Peak vGRF (BW)     | 1.25 ± 0.05       | 1.36 ± 0.10 | 1.23 ± 0.08     | 1.32 ± 0.05 |
| Impulse (BW·s)     | 0.57 ± 0.02       | 0.58 ± 0.06 | 0.57 ± 0.02     | 0.56 ± 0.03 |

**CONCLUSION:** The SPARK device allowed the subjects to maintain normal gait kinematics and kinetics while achieving 2.5-3.5 W continuous power output (single foot) while walking at 4.83 km/h. This prototype demonstrates the feasibility of a soldier-ready biomechanical energy harvesting device for field use.

**3531** Board #252 June 2 9:30 AM - 11:00 AM

**Lateral Foot Loading Pattern Concurs With Increased Disintegration Of The Postero-medial Achilles Tendon Region**

Bruno Vieira<sup>1</sup>, Suzan de Jonge<sup>1</sup>, Noël Keijsers<sup>2</sup>, Robert Rozenberg<sup>1</sup>, Herwin L.D. Horemans<sup>1</sup>, Henk-jan Aanstoot<sup>3</sup>, Harrie Weinans<sup>1</sup>, Henk J. Stam<sup>1</sup>, Stephan F.E. Praet<sup>1</sup>, Hans T.M. van Schie<sup>1</sup>. <sup>1</sup>Erasmus MC University Medical Center Rotterdam, Rotterdam, Netherlands. <sup>2</sup>Sint Maartenskliniek, Nijmegen, Nijmegen, Netherlands. <sup>3</sup>Diabetes Center for Pediatric and Adolescent Diabetes Care and -Research, Rotterdam, Netherlands.

(No relationships reported)

Research suggest that excessive pronation (EP) of the foot contributes to Achilles tendinopathy, however it is still not possible to predict who is at risk. From a biomechanical perspective, EP generates a more rapid and repeated transition of the foot from supination to pronation and backwards. This creates a "bow string" loading of the Achilles tendon (AT). In accordance, ultrasonographic (US) and MR imaging of symptomatic ATs often show irregularities in the medial midportion.

**PURPOSE:** To study foot biomechanics as etiological factor in subclinical AT tendinosis.

**METHODS:** AT structure of 20 healthy, asymptomatic subjects (18-60 yr) was examined through ultrasonographic tissue characterization (UTC).[1] In contiguous US images, 3D-stability of echo-patterns was quantified with dedicated algorithms and 4 echo-types were discriminated: I) intact and aligned tendon bundles; II) discontinuous or waving tendon bundles; III) fibrillar components; IV) mainly cellular components and fluid in amorphous tissue. Tendon disintegration was quantified as the sum of echo-types III + IV. Dynamic plantar pressure measurements from a 2m pressure plate during 5 walking trials were documented and normalized for foot size, foot progression angle and total pressure.[2]

**RESULTS:** The percentage level of tissue type III+IV (%III+IV) postero-medial (PM) in the AT (7.03±9.53%) was significantly higher than lateral (2.19±2.64%, p < 0.05) or central (1.16±3.31% p < 0.05) regions. Foot pressure dynamics from AT with PM %III+IV > 3.50 (n=20 feet) showed a more lateral center of pressure and roll-over pattern (0.56±0.89%) when compared to AT with PM %III+IV < 3.50 (-1.585±0.88%, p<0.05), with a lower roll-over speed (> 3.50: 0.49±0.16 nU/s vs < 3.50: 0.64±0.19 nU/s, p<0.05). Hallux-to-Meta-I pressure ratio, as indicator for functional hallux stiffening,[3] was higher in AT with PM %III+IV < 3.50.

**CONCLUSION:** AT disintegration in PM region may be related to a more lateral foot loading pattern. Functional hallux stiffening may protect against AT tendinosis.

**The Effect Of Foot Orthoses On Peroneal H-reflex In Treadmill Walking, A Pilot Study**

Antje Reschke, Martin Wolter, Marlene Schoepflin, Niklas Koenig, Frank Mayer, Heiner Baur. University Outpatient Clinic Potsdam, Potsdam, Germany.

(No relationships reported)

Although the biomechanical effect of foot orthoses is not completely understood, positive effects are attributed to sensorimotor adaptations next to mechanical processes. The analysis of H-reflex response of the ankle stabilizer M. peroneus longus (PL) may give further insight into foot orthoses triggered adaptations.

**PURPOSE:** To investigate the influence of a foot orthosis with medial arch support (O) compared to no orthosis (NO) on PL motor neuron excitability in treadmill walking.

**METHODS:** 35 healthy physically active participants were recruited. From 11 subjects (26.5 ± 2.5 yrs., 1.78 ± 0.08 m, 72 ± 10 kg, 4 ± 1.6 training sessions/wk) H-reflex of PL could be deduced. This cohort performed 2 randomized walking trials on a treadmill at 5 km/h. The stimulating electrode was placed on the nervus fibularis communis in the fossa poplitea and PL-EMG was recorded. Stimulus was applied with a 300 ms delay after initial heel strike in midstance. Accordingly, recruitment curves were created (50 measuring points, square impulse: 300 V; 500 µs duration; stimulation-interval: 10 s; increase interval of stimulation intensity: 0.2 mA). Maximum H-reflex amplitude and M-wave were obtained and Hmax/Mmax-ratio was calculated. Descriptive analysis was followed by t-test for dependent samples (p<0.05) (mean and SD of Hmax/Mmax-ratio and 95% CI of the difference).

**RESULTS:** 7 of 11 participants showed an enhanced H-reflex activity of PL among the insole condition compared with no insole. The foot orthoses modification resulted in higher but not statistically significant mean PL Hmax/Mmax-ratio compared to no arch support (NO: 0.16 (± 0.07)/ O: 0.22 (± 0.17); CI of the difference: -0.18 - 0.06 (p= 0.32).

**CONCLUSIONS:** Wearing a medial arch support insole had no significant effect on sensorimotor response of PL muscle during treadmill walking in healthy persons. However, individual responses to a standardized arch support were highly variable. This pilot work suggests the systematic analysis of different arch heights, velocities and stimulation instants during gait. Moreover a higher number of subjects and patients with chronic ankle instability may help to further validate the approach of sensorimotor effects of foot orthoses.

**Experimentally Induced Anterior Knee Pain Immediately Reduces Involuntary And Voluntary Quadriceps Activation**

Jihong Park, David H. Chinn, Adam C. Squires, J. Ty Hopkins, FACSM. Brigham Young University, Provo, UT.

(No relationships reported)

**PURPOSE:** To examine the immediate effects of experimentally induced anterior knee pain on involuntary and voluntary quadriceps activation.

**METHODS:** A 3X3 randomised controlled laboratory study with repeated measures was used. Thirteen, neurologically sound volunteers (age: 21.9 ± 3.2 year, height: 1.7 ± 3.1 m, mass: 76.6 ± 10.1 kg) underwent three different conditions (pain, sham, and control). The vastus medialis peak Hoffmann reflex normalized by the peak Motor response (H:M ratio) was used to measure involuntary quadriceps activation. Quadriceps central activation ratio (CAR) using maximal isometric knee extension torque (Nm) was calculated to assess voluntary quadriceps activation. Measurements were recorded at precondition (baseline), condition (immediate post injection), and 20min-postcondition. To induce anterior knee pain and sham condition, 5% sodium chloride and 0.9% sodium chloride (total volume of 1.0 ml for each condition), respectively, were injected into the infrapatellar fat pad on the dominant leg. No injection was performed for the control condition. The visual analogue scale was measured every two minutes throughout the data collection.

**RESULTS:** Our pain model increased perceived pain immediately after the 5% hypertonic saline injection and pain lasted for 12 minutes on average (F<sub>40,743</sub>=16.85, P<0.0001). During the pain condition subjects showed a 12% decrease in H:M ratio (F<sub>2,59</sub>=8.64, P<0.001), a 34% decrease in maximal isometric knee extension torque (F<sub>2,59</sub>=5.89, P=0.005), and a 5% decrease in CAR (F<sub>2,59</sub>=3.83, P=0.03).

**CONCLUSIONS:** Our data showed that joint pain may be an independent factor to alter function of the muscles surrounding the painful joint. Both involuntary and voluntary inhibitory pathways may play a role in an immediate reduction of muscle activation. Pain control in the acute stage of a joint injury and during chronic joint injury is important not only to decrease perceived pain but also to initiate disinhibition of the surrounding musculature and prevent chronic joint loading.

**Hip Muscle Recruitment During Weightbearing and Non-Weightbearing Exercises**

David Wallace, Thomas Durant. *Quinnipiac University, Hamden, CT.*  
(No relationships reported)

**INTRODUCTION:** Studies have suggested that hip strength is a modifiable risk factor for knee osteoarthritis. The purpose of this study was to examine the recruitment of hip musculature during various therapeutic exercises. **PARTICIPANTS:** Twenty healthy active volunteers between the ages of 18-25 years old participated in the study.

**METHODS:** Surface EMG recorded the muscle activity of the gluteus maximus (GMax) and gluteus medius (GMed) as subjects performed three sets of five repetitions of the following exercises: (1) Forward Step-up, (2) Side Step-up, (3) 10 repetition maximum (RM) sidelying hip abduction and (4) 10 RM prone hip extension. The normalized peak EMG was determined during each repetition and then averaged across all trials. Using repeated measure ANOVAs, comparisons of the peak EMG activity were made between each exercise. Alpha was set at 0.05.

**RESULTS:** Performing a 10 RM sidelying exercise recruited GMed significantly greater than remaining exercises ( $P<0.05$ ). GMed demonstrated greater activity than GMax during each exercise with the exception of the prone hip extension ( $P<0.05$ ).

**DISCUSSION:** These results suggest that performing a 10 RM non-weightbearing exercise results in greater muscle activity than a functional weightbearing exercise without load. In addition, forward and side-step ups fail to effectively recruit GMax. GMed was recruited to a higher extent during the stepping tasks; however, further research is needed to examine the impact of external loading on GMed recruitment during stair stepping exercise.

**Coupled Valgus Collapse Due To Internal Rotation: An Important Factor In the ACL Injury Mechanism**

Ata M. Kiapour<sup>1</sup>, Carmen E. Quatman<sup>2</sup>, Jason W. Levine<sup>1</sup>, Samuel C. Wordeman<sup>2</sup>, Timothy E. Hewett, FACSM<sup>2</sup>, Vijay K. Goel<sup>1</sup>, Constantine K. Demetropoulos<sup>1</sup>.  
<sup>1</sup>University of Toledo, Toledo, OH. <sup>2</sup>The Ohio State University, Columbus, OH.  
(No relationships reported)

Valgus collapse has been associated with cases of ACL injury. Keen debate has focused on the roles of valgus and tibial internal rotation on loading of the anterior cruciate ligament (ACL). The relative importance and nature of this interaction in the ACL injury mechanism are controversial.

**PURPOSE:** To understand the coupling between internal rotation and valgus orientation, and their effects on ACL strain.

**METHODS:** 17 cadaveric legs (45±7 yrs) potted at the mid-femur and fixed at 25° of flexion to a 6-DOF force couple testing apparatus. An unconstrained pure moment was applied to the tibia over a continuous range of ±50 Nm abduction-adduction under 1200 N quadriceps and 800 N hamstrings loads. Joint kinematics were collected using an Optotrak 3020 system. A DVRT transducer was used to calculate ACL strain. Specimens were first tested under isolated abduction-adduction loading. Subsequently, tests were repeated with the addition of 20 Nm internal rotation. Subsequently, specimens were evaluated in a series of impact tests simulating landing under combinations of valgus, internal rotation and anterior shear. Specimens were tested until failure.

**RESULTS:** 20 Nm pure internal rotation moment produced significant 6.4±3° coupled valgus rotation of the tibia ( $P<0.0005$ ) with 4.2±3% ACL strain. 50 Nm pure abduction moment produced 6.2±3° valgus rotation with 3.6±3% ACL strain. ACL strain and valgus under either 20 Nm pure internal rotation or 50 Nm pure abduction were not statistically different. No significant coupled internal rotation was observed under 50 Nm pure abduction moment. Axial impact generated a mean 9.1±8 mm anterior tibial translation (ATT) and 15 ACL injuries in 17 limbs. A general regression model showed that internal rotation significantly decreased ATT under axial impact ( $P=0.03$ ), while valgus did not play a significant role on ATT ( $p=0.12$ ).

**CONCLUSION:** Data demonstrated unidirectional coupling between internal rotation and valgus. Our data indicate that while internal rotation may play an important role in ACL injury, it is the coupled valgus motion associated with internal rotation that acts to load the ACL. Supported by NIH Grants RO1 AR056259 and RO1 AR049375.

**Previous Hamstring Strain Injury Reduces Knee Strength And Biceps Femoris Activation**

David Opar<sup>1</sup>, Nuala M. Dear<sup>1</sup>, Ryan G. Timmins<sup>1</sup>, Morgan D. Williams<sup>2</sup>, Anthony J. Shield<sup>1</sup>. *Queensland University of Technology, Brisbane, Australia.* <sup>2</sup>University of Glamorgan, Pontypridd, United Kingdom.  
(No relationships reported)

Hamstring strain injuries (HSI) are the primary injury sustained across a number of sports. A concern is that re-injury rates are also high and previous hamstring injury is the most significant risk factor for future injury. These observations suggest that the maladaptations that occur following HSI require attention, particularly neural maladaptations. Of interest is whether alterations in neural function are responsible for the prolonged eccentric weakness seen following HSI.

**PURPOSE:** To determine if previous HSI lead to reductions in voluntary activation during concentric and eccentric contraction at fast and slow movement velocities.

**METHODS:** Thirteen participants had a history of unilateral HSI within the last 18 months but were currently active in their chosen sport. A further 15 participants formed the control group and had no history of HSI. All participants completed a familiarisation session and one testing session which consisted of maximal isokinetic concentric and eccentric contractions of the knee flexors at ±60°.s<sup>-1</sup> and 180°.s<sup>-1</sup> and maximal isokinetic concentric contractions of the knee extensors at +60°.s<sup>-1</sup> and 180°.s<sup>-1</sup>. Medial hamstring and biceps femoris activation was assessed using surface electromyography.

**RESULTS:** Previous HSI resulted in lower knee flexor torque at -180°.s<sup>-1</sup> (Mean diff = 21Nm; 95%CI = 10-31Nm;  $p<0.05$ ), -60°.s<sup>-1</sup> (Mean diff = 18Nm; 95%CI = 9-28Nm;  $p<0.05$ ), +60°.s<sup>-1</sup> (Mean diff = 14Nm; 95%CI = 6-22Nm;  $p<0.05$ ) and +180°.s<sup>-1</sup> (Mean diff = 9Nm; 95%CI = 3-16Nm;  $p<0.05$ ) in the injured leg compared to the contralateral limb. Lower voluntary biceps femoris activation at long muscles lengths at -180°.s<sup>-1</sup> (Mean diff = 0.13; 95%CI = 0.06 - 0.19;  $p<0.05$ ) and -60°.s<sup>-1</sup> (Mean diff = 0.13; 95%CI = 0.05 - 0.22;  $p<0.05$ ) was also found in the previously injured leg compared to the contralateral limb. No difference was found for voluntary activation of the medial hamstrings at any speed. In the control group there were no differences in torque or voluntary activation between dominant and non-dominant limbs.

**CONCLUSION:** Strength deficits during both concentric and eccentric contractions are found following HSI. It appears that lower voluntary activation is partially responsible for this strength deficit during eccentric contractions.

**The Influence of Analysis Epoch on Knee Kinetics Related to Anterior Cruciate Ligament Injury**

Marc Norcross<sup>1</sup>, J. Troy Blackburn<sup>2</sup>. <sup>1</sup>Oregon State University, Corvallis, OR. <sup>2</sup>University of North Carolina at Chapel Hill, Chapel Hill, NC.  
(No relationships reported)

Peak internal knee extension moment (KEM) and anterior tibial shear force (ATSF) are commonly identified during landing tasks between the time from initial ground contact (IGC) until peak knee flexion (PKF) to infer anterior cruciate ligament (ACL) loading. However, ACL injury likely occurs within the initial 100 ms following ground contact (INI), and the magnitude of ACL loading attributable to KEM and ATSF is mitigated as knee flexion angle increases during landing. As such, it is unknown whether identification of these variables during an epoch more closely aligned with the time of injury might be more appropriate for inferring ACL loading.

**PURPOSE:** To compare the magnitude, time of peak, and knee flexion angle at KEM and ATSF identified during INI and PKF. We hypothesized that when identified during INI, KEM and ATSF would demonstrate similar magnitudes, but occur sooner after IGC and at lesser knee flexion angles compared to KEM and ATSF identified during PKF.

**METHODS:** Dominant leg lower extremity kinematics and kinetics were measured in 50 healthy subjects (25 F, 25M) during a double leg jump landing from a 30cm box onto a force plate. Paired samples t-tests compared the magnitude, time of peak, and knee flexion angle at peak between KEM and ATSF identified during INI and PKF, respectively.

**RESULTS:** Peak KEM ( $0.177 \text{ BW} \cdot \text{Ht}$  vs.  $0.175 \text{ BW} \cdot \text{Ht}$ ,  $p = 0.047$ ) and ATSF ( $0.95 \text{ BW}$  vs.  $0.88 \text{ BW}$ ,  $p < 0.001$ ) were greater when identified during PKF than during INI. However, when identified during INI, KEM ( $62.2 \text{ ms}$  vs.  $51.9 \text{ ms}$ ,  $p = 0.024$ ) and ATSF ( $122.9 \text{ ms}$  vs.  $64.4 \text{ ms}$ ,  $p < 0.001$ ) occurred sooner after IGC and with the knee positioned in lesser flexion (KEM:  $55.1$  vs.  $53.0$ ,  $p = 0.010$ ; ATSF:  $71.2$  vs.  $59.1$ ,  $p < 0.001$ ) than when identified during PKF.

**CONCLUSION:** The results indicate that identifying KEM and ATSF during INI may be more appropriate for inferring ACL loading. Although small reductions in the magnitudes of KEM and ATSF were noted when identified during INI, these peak kinetics occurred earlier and with the knee positioned in lesser flexion, likely indicating greater ACL loading. Moreover, as the results obtained using each analysis epoch differed, peak KEM and ATSF were identified in some participants more than 100 ms after IGC when using PKF; and after the time when ACL injury likely occurs. Future studies should identify KEM and ATSF during INI.

### Changes in Hip Muscle Performance and Lower Extremity Biomechanics Following a Hip-Focused Training Program

Kristen M. Stearns, Christopher M. Powers, FACSM, USC, Los Angeles, CA.

(No relationships reported)

Females have a higher incidence of ACL injury compared to males. Decreases in hip and knee flexion during landing, along with increased knee valgus angles and moments, have been identified as potential risk factors for ACL injury in females. Deficits in hip muscle performance have been proposed as an underlying cause of "at risk" lower extremity biomechanics.

**PURPOSE:** To determine if an intervention program aimed at improving hip muscle rate of force development (RFD) can influence lower extremity biomechanics during a drop-jump task in females.

**METHODS:** Twenty recreationally active females (18-25 years of age) participated in biomechanical and RFD testing before and after a 4 week training program (3 times/week, 30 min/session) consisting of hip-focused plyometric and balance perturbation exercises. Hip abductor (HA), hip extensor (HE), and knee extensor (KE) maximal RFD was assessed during a rapid isometric contraction using a custom testing set-up (ie. load cell aligned perpendicular to the segment being tested). Lower extremity kinematics and kinetics were obtained as subjects performed a double-leg drop-jump from a 36 cm platform. Variables of interest were calculated over the early deceleration phase of landing and included peak hip and knee flexion angle, peak knee abduction angle, and peak knee adductor moment. Differences pre- vs. post-training were evaluated using paired-samples t-tests ( $p \leq 0.05$ ).

**RESULTS:** Post-training, there was a significant increase in HA RFD ( $757.9 \pm 164.4$  vs.  $863.5 \pm 220.2 \text{ Nm/ms}$ ;  $p=0.002$ ) and HE RFD ( $1253.3 \pm 440.4$  vs.  $1368.6 \pm 436.7 \text{ Nm/ms}$ ;  $p=0.0002$ ). There was no significant difference in KE RFD ( $792.3 \pm 204$  vs.  $823.3 \pm 214.0 \text{ Nm/ms}$ ;  $p=0.15$ ). Biomechanical testing revealed a significant increase in the peak knee ( $89.6 \pm 7.7$  vs.  $92.3 \pm 8.7^\circ$ ;  $p \leq 0.001$ ) and hip flexion angle ( $79.3 \pm 8.4$  vs.  $83.9 \pm 9.6^\circ$ ;  $p=0.04$ ); and decreases in the peak knee abduction angle ( $5.3 \pm 3.9$  vs.  $3.9 \pm 3.6^\circ$ ;  $p \leq 0.02$ ) and the peak knee adductor moment ( $0.24 \pm 0.1$  vs.  $0.18 \pm 0.1 \text{ Nm/kg}$ ;  $p \leq 0.003$ ).

**CONCLUSIONS:** Changes in lower extremity biomechanics following training were primarily driven by increases in hip muscle RFD as opposed to knee extensor RFD. We propose that injury prevention training programs targeting hip muscle RFD may be important in mitigating biomechanical risk factors associated with ACL injury in females.

### Knee Rotational Kinematics After Anterior Cruciate Ligament Reconstruction Using Computer Navigation

Jothi Murali<sup>1</sup>, Robert Shalvoy<sup>1</sup>, Nicholas Beretta<sup>2</sup>, Elizabeth I. Drewniak-Watts<sup>2</sup>, Susan E. D'Andrea<sup>2</sup>. <sup>1</sup>Brown University Warren Alpert School of Medicine, Providence, RI. <sup>2</sup>Gait and Motion Analysis Laboratory, Providence VA Medical Center, Providence, RI.

(No relationships reported)

**BACKGROUND:** It is unknown whether in vivo dynamic biomechanical testing demonstrates restored rotational stability in patients with single-bundle ACL reconstruction performed using computer navigation.

**PURPOSE:** To investigate the intraoperative and in vivo range of tibial rotation (ROM) in patients with ACL reconstruction (ACL-R) performed using computer navigation. The authors hypothesized that the tibial ROM during walking and two pivoting tasks is comparable to the contralateral leg (CL).

**METHODS:** Intraoperative rotational data was collected for ten subjects using a computer navigational system (OrthoPilot). Subjects performed walking trials and two pivoting tasks consisting of a stair descent and a two-footed platform jump, at a mean follow-up time of 18.1 months post-reconstruction. The peak internal (IR), peak external (ER), and ROM of the ACL-R and CL knees were measured with a motion capture system (Qualisys). Independent t-tests were performed to investigate significant differences between the two limbs. Statistical significance was set at  $p < 0.05$  a priori.

**RESULTS:** Intraoperative ROM values significantly decreased ( $p = .0023$ ) from  $44.1^\circ$  pre-reconstruction to  $30.8^\circ$  post-reconstruction. ROM for ACL-R and CL during stair descent ( $32.4^\circ$  vs.  $32.3^\circ$ ), platform ( $28.5^\circ$  vs.  $28.3^\circ$ ), walking stance phase ( $12.9^\circ$  vs.  $12.6^\circ$ ) and walking swing phase ( $14.3^\circ$  vs.  $12.9^\circ$ ) did not significantly differ. However, ACL-R peak IR values were significantly lower than CL peak IR values for stairs, platform, and stance ( $16.0^\circ$  vs.  $18.2^\circ$ ;  $15.4^\circ$  vs.  $17.5^\circ$ ;  $1.8^\circ$  vs.  $4.4^\circ$ , respectively). Peak ER values increased significantly in the ACL-R limb vs. CL for all tasks ( $16.4^\circ$  vs.  $14.1^\circ$ ;  $13.1^\circ$  vs.  $10.9^\circ$ ;  $11.1^\circ$  vs.  $8.1^\circ$ ;  $16.3^\circ$  vs.  $13.5^\circ$ ).

**CONCLUSION:** Anatomic single-bundle ACL reconstruction using computer navigation restores rotational stability during walking and two high-demand tasks at intermediate-term follow-up. Although overall tibial ROM is comparable to an uninjured knee, alterations in the peak IR and ER may have implications for future development of osteoarthritis in these patients.

### Hip Function in Femoroacetabular Impingement

Alexander B. Dillon, Deepak Kumar, Anthony Luke, FACSM, Thomas M. Link, Sharmila Majumdar, Richard B. Souza. University of CA San Francisco, San Francisco, CA.

(No relationships reported)

**PURPOSE:** Cam-type femoroacetabular impingement (FAI), with an anatomic deformity at the femoral head-neck junction, is a known risk factor for hip osteoarthritis. Repetitive contact of the deformity with the labrum and cartilage during daily activities can lead to traumatic degeneration. The purpose of this study is to evaluate the hip kinematics and kinetics during a variety of common daily tasks in subjects with FAI and healthy matched controls.

**METHODS:** 7 patients with cam-type FAI (5 M, 2 F; mean age =  $36.6 \pm 9.7$  years, mean BMI =  $26.2 \pm 6.9$ ) and 14 normal volunteers (10 M, 4 F; mean age =  $30.4 \pm 10.6$  years, mean BMI =  $23.3 \pm 2.8$ ) had 3T hip MRI scans to evaluate anatomical deformity. 3-D motion analysis was performed for four tasks: 1) gait, 2) deep-squat, 3) drop jump, 4) single leg hop. Timed Up and Go (TUG) was used for functional performance. Student's t tests were used for between group comparisons and paired t-test for involved and contralateral side ( $\alpha = 0.05$ )

**RESULTS:** During walking, FAI group had less flexion-extension motion compared to contralateral side and a similar trend was seen when compared to controls ( $p = 0.068$ ). During the drop jump, FAI group had more external rotation at the hip compared to controls with similar trend seen when compared to contralateral side ( $p = 0.073$ ). FAI group absorbed less power while flexing during drop jump. During drop jump ( $p = 0.067$ ) and deep-squat ( $p = 0.058$ ), FAI group showed a trend for lower external rotation moment when compared to controls. Finally, patients were significantly slower ( $9.7 \pm 1.3$  sec) than controls ( $8.4 \pm 0.9$  sec) at completing the TUG task.

**CONCLUSIONS:** Reduced sagittal motion was consistent with the literature. During drop-jump, lower hip power while flexing could be due to poor eccentric control resulting from hip and leg muscle weakness. Greater external rotation motion and lower external rotation moment during drop-jump and deep-squat indicate forced motion due to the cam deformity and avoidance of internal rotation during deep hip flexion. Finally, while the difference in TUG was small, it does indicate that the patients' condition adversely affects their mobility. Abnormal pathomechanics can lead to altered load patterns which can affect cartilage health. Future analysis will correlate functional biomechanics and the cartilage T1rho and T2 relaxation times.

---

3541 Board #262 June 2 9:30 AM - 11:00 AM

**Influence of Hip Flexibility on Dynamic Alignment During the Overhead Squat Test in Adolescent Athletes**

Anh-Dung Nguyen<sup>1</sup>, Michelle C. Boling<sup>2</sup>, Ashley N. Varone<sup>1</sup>, Kristin L. Keene<sup>1</sup>, Lindsay J. DiStefano<sup>3</sup>. <sup>1</sup>College of Charleston, Charleston, SC. <sup>2</sup>University of North Florida, Jacksonville, FL. <sup>3</sup>University of Connecticut, Storrs, CT. (Sponsor: William R. Barfield, FACSM)  
(No relationships reported)

The overhead squat test is a clinical screening tool that may be used to assess dynamic malalignments of the lower extremities that potentially increase the risk of knee injuries. While rotational flexibility of the hip has been suggested to contribute differences in lower extremity motion during the overhead squat, this relationship remains unclear.

**PURPOSE:** To determine the influence of hip range of motion on hip and knee kinematics during the overhead squat test.

**METHODS:** Clinical measures of hip internal (HIR) and external (HER) rotation range of motions were measured on the dominant limb of 76 adolescent athletes (48 M, 28 F: 15.7±1.2 yrs, 173.9±11.0 cm, 67.9±12.9 kg) as part of a larger, multi-center risk factor screening project. Three-dimensional kinematics of the hip and knee during the descent phase (start to maximum knee flexion) were also assessed during five consecutive overhead squats. The average of three trials for HER and HIR, and five trials for peak hip and knee kinematics were used for analyses. Separate step-wise linear regressions determined the extent to which HIR and HER predicted hip and knee kinematics during the overhead squat in males and females.

**RESULTS:** In males, HER was a positive predictor of hip flexion ( $R^2 = .210$ ,  $P = .002$ ) and hip adduction ( $R^2 = .110$ ,  $P = .032$ ) motion during the overhead squat. HIR was a significant positive predictor of knee external rotation motion, explaining 20.4% of the variance ( $P = .003$ ). In females, HER was a significant negative predictor of knee valgus motion, explaining 15.5% of the variance ( $P = .046$ ) while HIR was a significant negative predictor of knee flexion motion, explaining 19.0% of the variance ( $P = .026$ ).

**CONCLUSIONS:** Based on these results, flexibility of the hip internal and external rotators influence joint motions during the overhead squat test. This may in part be due to the changes in the length-tension relationship of the surrounding muscles, which can lead to dynamic malalignments known to be predictive of knee injuries. Ongoing research is examining whether these range of motion differences increase the risk of knee injuries in adolescent athletes.

Supported by University of North Florida Faculty Development Research Grant.

**A Comparison of Eversion Ankle Function Between Stable and Chronically Unstable Ankles**

Brad P. Dieter, Kathy D. Browder. University of Idaho, Moscow, ID.  
(No relationships reported)

**PURPOSE:** To compare the peak evertor torque (PT), average evertor torque (AT), and angular displacement at peak torque (PT) of chronically unstable ankles and their contralateral stable ankle.

**METHODS:** Ten males (Age=21±2 yr; Height=182±8 cm; Weight=80±7 kg) with one chronically unstable ankle (CU) and one stable ankle (ST) volunteered to participate in this study. Prior to testing, each participant completed a five-minute lower extremity stretching program. Using an isokinetic dynamometer, each participant performed maximal efforts of concentric and eccentric eversion were completed at 60/s and 180/s for each ankle. A 2 x 2 x 2 (Contraction Type x Testing Speed x Ankle Stability) multivariate analysis of variance (MANOVA) was completed to determine differences for AT, PT, and PT. An analysis of variance (ANOVA) was performed as a post hoc test where differences occurred.

**RESULTS:** Significant main effects for Testing Speed ( $p < .015$ ) and for AT, PT, PT across Contraction Type ( $p < .004$ ). No significant main effects were found for Ankle Stability. No significant interactions were found for any dependent variable. At 60/s, the ankle was more inverted when peak torque occurred than at 180/s (PT<sub>60</sub>=11±10; PT<sub>180</sub>=7±8;  $p < .01$ ) Peak torque also occurred in a more inverted position during the eccentric phase than during the concentric phase (PT<sub>CON</sub>=7±10; PT<sub>ECC</sub>=13±8;  $p < .004$ ). In all subjects, AT and PT during eccentric contractions were consistently higher than during concentric contractions (AT<sub>CON</sub>=14.6±3.5 Nm; AT<sub>ECC</sub>=22.8±6.0 Nm;  $p < .003$ ) (PT<sub>CON</sub>=18.4±4.4 Nm; PT<sub>ECC</sub>=32.8±9.7 Nm;  $p < .002$ ).

**CONCLUSIONS:** The lack significant differences for PT, AT, or PT between chronically unstable ankles and stable ankles, suggests that muscle weakness and proprioceptive loss may not be the primary reason for chronic ankle instability.

---

3543 Board #264 June 2 9:30 AM - 11:00 AM

**Knee Biomechanics Of A Crossover Task Following A Neuromuscular Training Program**

Ashley Rickman<sup>1</sup>, Nelson Cortes<sup>1</sup>, Eric Greska<sup>2</sup>, Jatin P. Ambegaonkar<sup>1</sup>, James Onate<sup>3</sup>. <sup>1</sup>George Mason University, Fairfax, VA. <sup>2</sup>Old Dominion University, Norfolk, VA. <sup>3</sup>The Ohio State University, Columbus, OH.  
(No relationships reported)

High-risk knee biomechanics in the frontal and sagittal planes have been shown to predispose female soccer players to anterior cruciate ligament (ACL) injuries. Neuromuscular training programs have been shown to improve knee biomechanics during athletic tasks. Despite such efforts, the injury rate remains steady over the past decade.

**PURPOSE:** The aim of this study was to examine the effect of a 10-month neuromuscular training program on knee biomechanics during the execution of a crossover cutting task (CO).

**METHODS:** Eighteen injury-free female collegiate soccer players with no history of ACL injury (age=19.6±1.0 years, mass=63.1±5.7 kg, height =1.67±0.05 m) volunteered for the study. Subjects performed 5 trials of an unanticipated CO cutting task before and after completing a 10-month neuromuscular training program during soccer off-season. The training program was performed two times per week and consisted of plyometric, agility, and speed development exercises. The unanticipated CO task was triggered by an automated system that projected a scenario onto a screen simulating an actual soccer event. Lower extremity biomechanics were evaluated during the CO task using a 3D motion capture system and 2 force plates. Paired *t*-tests evaluated differences between pre- and post-training for each dependent variable. Alpha level was set *a priori* at 0.05.

**RESULTS:** Significant differences included decreases in the knee adduction angle at initial contact ( $8.61^\circ \pm 4.78^\circ$  to  $3.61^\circ \pm 7.17^\circ$ ;  $P = 0.029$ ), and knee flexion moment at initial contact ( $-0.15 \pm 0.12$  Nm/kgm to  $-0.02 \pm 0.14$  Nm/kgm;  $P = 0.029$ ). No other statistically significant differences were observed ( $p > 0.05$ ).

**CONCLUSION:** The neuromuscular training produced some knee biomechanical changes. While the participants at pre-training had an increased knee adduction angle, post-training they were closer to neutral alignment, possibly suggesting an increase in frontal plane control. The decreased knee flexion moment at initial contact post training may represent an increased knee extensor activity in the sagittal plane, which may be disadvantageous to the ACL. Overall, neuromuscular training programs should focus on increasing knee frontal plane control, as well as target other neuromechanical characteristics that may influence joint mechanics.

3544 Board #265 June 2 9:30 AM - 11:00 AM

**Stability Of Knee-Ankle Joint Coupling Variability Measures During Walking In Chronic Ankle Instability**

Patrick O. McKeon<sup>1</sup>, Matthew C. Hoch<sup>2</sup>, David R. Mullineaux<sup>3</sup>. <sup>1</sup>University of Kentucky, Lexington, KY. <sup>2</sup>Old Dominion University, Norfolk, VA. <sup>3</sup>University of Lincoln, Lincoln, United Kingdom.  
(No relationships reported)

Alterations in knee and ankle sagittal plane kinematics have been identified in those with chronic ankle instability (CAI). The joint coupling variability between these joints and the stability of their relationship over time during gait in those with CAI is unknown. This information is critical for understanding the interaction between these 2 joints in this population.

**PURPOSE:** To determine the inter-session reliability of ankle-knee joint coupling variability during walking in those with CAI.

**METHODS:** Twelve adults with CAI (6 males, 6 females) participated. The CAI group reported 5 ± 5 previous ankle sprains, 8 ± 7 episodes of instability in the past 3 months. On 2 testing sessions separated by 1 week, all subjects walked on a treadmill instrumented with force plates at a speed of 1.32 m/s. Three-dimensional ankle and knee kinematics of the self-reported worse limb were captured for 30 seconds using a 15 camera motion analysis system. Gait cycles (GC) were normalized to 101 points from initial contact (0%) to subsequent initial contact of the same limb (100%) identified from force plate data. Vector-coding coefficients (VCC) ranging from 0 (no variability) to 1 (maximum variability) were calculated for 5 nonconsecutive GC for all subjects on each day. Peak VCC were found for the stance and swing phases. Intraclass correlation coefficients (ICC 2,1) were calculated for the reliability of peak VCC across days.

**RESULTS:** Peak VCC in stance (Day 1 mean = 0.55 ± 0.26, Day 2 = 0.57 ± 0.26, ICC = 0.79, SEM = 0.10, p = 0.001) and swing phases (Day 1 mean = 0.73±0.15, Day 2 mean = 0.64 ± 0.20, ICC = 0.76, SEM = 0.08, p = 0.001) were found to be highly reliable. The peak for stance consistently occurred in mid-stance (40-48% of GC) and in the terminal swing phase (98-0% of GC).

**CONCLUSION:** Individuals with CAI exhibited very stable ankle-joint coupling variability patterns during walking across 2 different days. The timing and magnitude of peak joint coupling variability were consistent across the 2 days of testing. The peaks in coupling variability were associated with the transitions between absorption and propulsion (mid-stance) and swing to stance phases (terminal swing). Ankle-knee joint coupling variability appears to be reliable over time in those with CAI and offers insight into the stability of the relationship around gait transitions.

**3545 Board #266 June 2 9:30 AM - 11:00 AM**  
**Perceptions of Function Differ from Quantitative and Qualitative Tests of Physical Performance After ACL Reconstruction**

Caitlin Gollehon, Maggie Dewitz, Jenna Kokes, Ryan L. Mizner. *University of Montana, Missoula, MT.*  
*(No relationships reported)*

There are a wide variety of assessments available to quantify outcomes post anterior cruciate ligament reconstruction (ACLR). Most studies use questionnaires to measure patients' perception of their functional ability. Others employ assessments like the Y balance test and hop test to quantify physical performance. Relatively few studies go so far as to include 3D motion analysis of patients completing sports related tasks. The relative interplay between these levels of outcome assessments as they relate to evaluation of outcomes after ACLR remains understudied.

**PURPOSE:** To assess the relationships present between a wide variety of means to quantify clinical outcomes in patients with unilateral ACL reconstruction.

**METHODS:** Participants included 17 (7 males) physically active (≥ 4 Tegner Scale) subjects, ages 16-31 with unilateral ACLR. A onetime session was completed where participants were assessed with an 8 camera Vicon system with force plates for peak knee flexion moment during a single leg land (SLL) and vertical ground reaction forces (VGRF) during a drop vertical jump (DVJ). Patients completed the International Knee Documentation Committee (IKDC) questionnaire. Performance was quantified by the difference between limbs for both the anterior reach of the Y Balance Test and the single leg hop for distance.

**RESULTS:** Our results show that the IKDC was only significantly correlated to the Hop test for distance (r=0.62, p=.008). The Hop test was significantly correlated to peak knee moment during the SLL (r=0.59, p=0.013), but was not correlated to asymmetries in VGRF during the DVJ land (r=0.16, p= 0.53). The Y balance is not correlated with asymmetry in VGRF during the DVJ (r=-0.16, p= 0.54) or the peak knee moment during the SLL (r= -0.35, p= 0.17).

**CONCLUSION:** No one measure seems to give a complete picture of an athlete's outcome following ACLR. None of the correlations between measures were strongly correlated to each other. While the commonly used questionnaires are inexpensive they fail to relate to qualitative assessment of the motion analysis. The performance assessments were a closer approximation of the motion analysis, but the motion analysis seems to provide additional information to quantify performance. A broad assessment is needed to fully appreciate patient outcomes after ACLR.

**Functional Weight Bearing Exercises Normalized to Leg Length Among Males and Females**

Lucinda E. Bouillon, Jacqueline Wihelm, Patricia Eisel, Jessica Wiesner, Megan Rachow, Lindsay Hatteberg. *University of Findlay, Findlay, OH.*  
*(No relationships reported)*

Researchers have used various step heights and lunge distances when assessing functional exercises. These height and distance variations make comparisons difficult between gender and tasks. Leg length differences may also affect the ability to perform the task.

**PURPOSE:** Determine if muscle activity of the rectus femoris (RF), rectus abdominus (RA), external oblique (EO), erector spinae (ES), gluteus medius (GMed), gluteus maximus (GMax), tensor fascia latae (TFL), and biceps femoris (BF) differs between gender among three single-limb weight bearing exercises using normalized leg length distances.

**METHODS:** Twenty men (23.2± 2 yrs, 1.8±.09m; 85± 20 kg) and 20 women (23.2± 2 yrs, 1.6±.07m; 86± 7 kg) who were healthy and recreationally active participated in the study. Surface electromyography (SEMG) and 2-D video were used to collect SEMG data for the RF, RA, EO, ES, GMed, GMax, TFL, and BF muscles of the dominant lower extremity. Maximal voluntary isometric contractions (MVIC) were used to normalize SEMG root mean square values for each muscle, which were expressed as %MVIC. Participants completed unilateral functional exercises (step down, forward lunge, and side-step lunge) in a randomized exercise order. The subjects performed 2 x 10 repetitions at a pace of 80 bpm. Distances for each exercises were normalized to the participant's lower limb length, (25% step down, 65% forward lunge, 80% side-step). Descriptive statistics, ANOVAs, and ICCs with 95% confidence intervals were calculated. Normalized SEMG values were analyzed using 8 X 3 X 2 ANOVA with follow up using Bonferroni post-hoc testing.

**RESULTS:** Descriptive statistics found males were taller and heavier compared to the women. No differences were found between gender by task for the eight muscles. Regardless of gender, the step down task resulted in higher GMax %MVIC compared to lunge, (p=0.002). Step down exercise was also higher for GMed %MVIC than lunge (p=0.002) and side step (p=0.013). ICC<sub>3,1</sub> ranged from moderate to high (0.74 to 0.97) for the three tasks.

**CONCLUSIONS:** Muscle activity was similar for males and females during the step down, side-step and lunge with distance normalized to the participant's leg length. The step down task recruited higher GMax %MVIC activity when compared to the lunge, and greater GMed %MVIC activity than lunge and side step tasks.

**3547 Board #268 June 2 9:30 AM - 11:00 AM**  
**Efficacy Of Goniometry-based Q-angle For Measuring Change**

Lawrence W. Weiss, FACSM, Kelley G. Hammond, Brian K. Schilling, Lucas C. Ferreira. *The Univ. of Memphis, Memphis, TN.*  
*(No relationships reported)*

*Quadriceps angle (Q-angle)* has been used to reflect the extent of genu valgum and may have implications for activity selection, training considerations, and/or potential medical interventions. Q-angle evaluation must be stable and sufficiently precise in adults if it is to have clinical and/or research utility.

**PURPOSE:** To establish the stability reliability, precision, and minimum difference needed to represent a change in Q-angles obtained using surface goniometry.

**METHODS:** Q-angle was assessed for 25 men and 27 women with surface goniometry on two separate occasions separated by 48 hours. Well-rested subjects assumed a supine position with: 1) extended hips and knees, 2) a neutral hip rotational position, 3) a neutral foot position, and 4) a contracted quadriceps femoris muscle. The axis of a manual goniometer was placed over the center of the right patella with the fixed arm situated over the anterior-superior iliac spine and the mobile arm over the center of the tibial tuberosity. Stability reliability was calculated using intraclass correlation (ICC, 2-way random) and precision by standard error of measurement (SEM). 95% limits of agreement (LOA) was also calculated to estimate the magnitude of difference needed to represent actual change. Acceptable ICC's were set at ≥0.70 for reliability.

**RESULTS:** The following ICC (SEM) were found: all subjects = 0.88 (1.0 deg), men = 0.77 (1.0 deg), women = 0.85 (1.0 deg) (See Table 1).

**CONCLUSION:** The surface goniometry protocol described herein was reliable for all subjects, men only, and women only. Although precision also appeared to be reasonable, a minimum difference of three degrees would be needed to represent a change or difference in Q-angles.

Table 1. Q-angle based on surface goniometry.

| Subjects | n  | Mean1 (SD1) (deg) | Mean2 (SD2) (deg) | ICC  | ICC Conf Limits | SEM (deg) | SEM Conf Limits | 95% LOA (deg) |
|----------|----|-------------------|-------------------|------|-----------------|-----------|-----------------|---------------|
| All      | 52 | 11 (3.2)          | 11 (3.1)          | 0.88 | 0.81 - 0.92     | 1.0       | 0.9 - 1.3       | 3.0           |
| Men      | 25 | 9 (1.9)           | 9 (2.1)           | 0.77 | 0.58 - 0.88     | 1.0       | 0.8 - 1.3       | 3.0           |
| Women    | 27 | 13 (2.6)          | 13 (2.9)          | 0.85 | 0.73 - 0.92     | 1.0       | 0.8 - 1.3       | 3.0           |

**The Acute Effect of Pre-exercise Static and Dynamic Stretching of the Leg Extensors**

Jocelyn Riordan, Barbara L. Warren. *University of Puget Sound, Tacoma, WA.*  
(No relationships reported)

**The Acute Effect of Pre-exercise Static and Dynamic Stretching of the Leg Extensors in Trained and Untrained Females**

Jocelyn Riordan & Barbara L. Warren, ACSM  
University of Puget Sound, Tacoma, WA

**INTRODUCTION:** Although warm-up and stretching exercises are routinely used as physical preparation before athletic events, stretching immediately prior to an event may negatively affect performance.

**PURPOSE:** The purpose of this study was to investigate the acute effects of pre-exercise static and dynamic stretching on peak torque of the knee flexors in trained and untrained females.

**METHODS:** Fifteen healthy, college aged, female NCAA Division III athletes (mean age= 20.2 years, height= 171±7.7 cm weight= 71±9.2 kg) and fifteen healthy, female non-athletes (mean age= 20.93, height= 167±5.2 cm, weight= 68.7±9.9 kg) were tested on a Cybex NORM isokinetic dynamometer. Subjects completed two familiarization sessions and three experimental testing sessions. In all sessions, subjects warmed up on a stationary bike for five minutes and performed one of three randomly assigned stretching protocols (no stretching, static or dynamic stretching). Subjects then performed eight maximal knee extensions through a 90 degree range of motion at each of three descending velocities (180, 120 and 60 deg/s). Flexion was held constant at 300 deg/sec for all velocities and there was a 60 second rest period following each velocity set. A repeated measures ANOVA was used to analyze data with  $\alpha < 0.05$ .

**RESULTS:** There were no significant ( $p < 0.05$ ) differences observed in the peak torque production between the three stretching protocols when comparing athletes and non-athletes.

**CONCLUSION:** In this population of athletes and non-athletes female athletes, the type of stretching performed prior to exercise did not appear to affect the peak knee torque produced, indicating that either static or dynamic stretching is acceptable prior to exercise, regardless of activity level.

Research was funded by a Math and Science Summer Research Fund.

**Relationships Among Core Stability, Dynamic Balance, and Functional Movement Screen For Collegiate Baseball and Softball Players**

Trina L. Hosang, Ryan M. Hoffman, Richard A. Maag, Greg S. Barga, Cindy Bouillon. *The University of Findlay, Findlay, OH.*  
(No relationships reported)

**PURPOSE:** Injuries in baseball and softball players may be the result of inadequate core strength, poor dynamic balance, or asymmetrical movement patterns. The Functional Movement Screen® (FMS) assesses core, balance, and movement patterns. The aim of this study was to examine if a relationship exists among the FMS, core stability, and dynamic balance tests.

**METHODS:** Seventeen Division II collegiate athletes (7 baseball, 10 softball; 19.0 ± 1.2 years) Randomized measurements consisted of four tests: [double leg lowering: degrees (DLL); trunk extensor endurance: repetitions (EE); Star Excursion Balance Test (SEBT); and FMS]. The athletes performed 3 excursions of the SEBT (anterior, postmedial, and postlateral) bilaterally. A composite reach distance (sum of 3 directions and divided by 3 times LL and multiplied by 100). This score was recorded as % of LL. The FMS included seven tests that were summed together for each limb (R total score, L total score) and was scored by two raters for all tasks. All tests were performed three trials and best score was recorded. Repeated-measures ANOVAs were performed to compare change in time (pre and post season) for core stability and SEBT scores. Wilcoxon Signed Rank test was performed to assess time for FMS scores. Spearman Rho correlation assessed the relationship among core stability, SEBT, and FMS scores. Inter- and intraclass-coefficients (ICC) were used to examine rater and ratings across trials.

**RESULTS:** No relationships were found among outcome measurement scores. A time effect was found for the SEBT scores pre-to post season with improvement for the right composite score from 83% to 89% of LL ( $p > .001$ ) and the left increased from 81% to 88% of LL ( $p = .001$ ). The ICCs were very reliable for the two raters (.99 to 1.0) and between trials (.81 to .98).

**CONCLUSIONS:** Core stability, SEBT, and FMS tools were reliable between two raters and across trials among the collegiate athletes, however no relationships were found among these outcome measures. The only change that was found was an increase in excursion distance on right (6% of LL) and left (7% of LL). Right and left limb distance were <4cm suggesting bilateral dynamic balance symmetry among the athletes. Clinicians and coaches should be aware that scores on the core stability and dynamic balance tests do not relate to FMS scores.

**Asymmetry in Stop Jump Mechanics Correlates to Asymmetry in Deep Squat Mechanics in Patients 6 Months Following ACL Reconstruction**

Robert J. Butler, Boyi Dai, William E. Garrett, FACSM, Robin M. Queen. *Duke University, Durham, NC.*  
(No relationships reported)

Asymmetries in lower extremity loading are well documented between the surgical and non-surgical side following Anterior Cruciate Ligament (ACL) reconstruction during jump landings. In order to alter these asymmetries a number of programs have focused on altering landing mechanics with various forms of feedback. However, no studies have examined how the asymmetries in the jump landing correlate with more fundamental movement patterns, like a deep squat, that may provide a more controlled environment for intervention development.

**PURPOSE:** To examine how asymmetries in lower extremity mechanics during a stop jump task correlated with asymmetries in lower extremity mechanics during a deep squat.

**METHODS:** Twelve patients who were six months following ACL reconstruction were recruited for the study. All patients were cleared for jumping activities by their medical physician. The patients underwent a standard motion analysis for a stop jump and bilateral deep squat. The asymmetry (Surgical - Non Surgical) for peak sagittal plane lower extremity motion as well as the vertical ground reaction force impulse was examined. Asymmetry values during the stop jump were correlated to the values obtained during the deep squat using Pearson product moment correlations. Statistical significance was established at  $p < 0.05$ .

**RESULTS:** Asymmetry in the vertical impulse during the stop jump was significantly correlated with asymmetry during the deep squat ( $p < 0.04$ ,  $r = 0.61$ ). Similarly the asymmetry in the peak vertical ground reaction force during the eccentric phase of the deep squat was correlated with the asymmetry in the peak vertical ground reaction force ( $p = 0.03$ ,  $r = 0.62$ ) and the peak knee angle ( $p = 0.02$ ,  $r = 0.67$ ) during the stop jump. Statistically significant correlations were also observed between the peak knee flexion asymmetry during the deep squat and the asymmetry in the vertical impulse ( $p < 0.01$ ,  $r = 0.78$ ), peak ankle motion ( $p < 0.01$ ,  $r = 0.77$ ) and peak knee flexion ( $p < 0.03$ ,  $p = 0.64$ ) during the stop jump.

**CONCLUSIONS:** Asymmetries in landing mechanics strongly correlate to asymmetries during the deep squat pattern. As a result, it may be appropriate to focus interventions and injury prevention programs on more fundamental movement patterns when attempting to address asymmetries in higher level tasks like jump landings.

### The Effect of Betaine on Delayed Onset Muscle Soreness

J. Luke Pryor<sup>1</sup>, Casey Cathrall<sup>2</sup>, Marq Bittarelli<sup>2</sup>, Timothy Reynolds<sup>2</sup>, William Rogers<sup>2</sup>, Thomas Swensen<sup>2</sup>. <sup>1</sup>University of Connecticut, Storrs, CT. <sup>2</sup>Ithaca College, Ithaca, NY.

(No relationships reported)

**PURPOSE:** We examined the effects of betaine supplementation on delayed onset muscle soreness (DOMS) in 14 male and 18 female college students (mean  $\pm$  SD; height = 170.0  $\pm$  10.2 cm, weight 73.8  $\pm$  11.6 kg, and age = 19.2  $\pm$  1.0 years).

**METHODS:** Subjects were familiarized with all laboratory tests: peak torque for triceps extension using the Cybex isokinetic dynamometer, relaxed arm angle (RANG), brachium circumference, active elbow range of motion (AROM), visual analog soreness scale (VAS), and the profile of mood states (POMS). Subjects were matched paired based on dominant arm peak torque into initial treatment groups in a double-blind, cross-over design. Subjects consumed either 2.5 grams of betaine in 355 ml of Gatorade or 355 ml of Gatorade every day for seven days prior to the intervention and throughout the 96 hr post-intervention; a two week washout separated trials. Exercise intervention consisted of two sets of 20 repetitions of eccentric triceps extensions on the cybex; subjects used their dominant arm for the first treatment and non-dominant arm for the second. Data were collected before intervention, and at 24, 48, 72, and 96 hr post-intervention and analyzed with a two-way, repeated measures ANOVA; alpha was set at 0.05.

**RESULTS:** There were no treatment differences or interactions between groups. Tukey's post hoc revealed across time peak torque ( $p < 0.05$ ) and AROM ( $p < 0.05$ ) decreased by 12 and 3.3%, respectively, whereas arm circumference ( $p < 0.01$ ), RANG ( $p < 0.05$ ), and VAS ( $p < 0.01$ ) increased by 3, 19, and 39%, respectively.

**CONCLUSION:** The exercise intervention induced DOMS, but betaine supplementation did not ameliorate its effects compared to placebo.

### Effects of Betaine Supplementation on Strength and Power Adaptations Following an 8-week Resistance Training Program

Will Martin<sup>1</sup>, Rhonda Boros<sup>1</sup>, Robert Sawyer<sup>2</sup>, Joaquin Gonzales<sup>1</sup>. <sup>1</sup>Texas Tech University, Lubbock, TX. <sup>2</sup>Utah Valley University, Orem, UT. (Sponsor: Jacalyn McComb, FACSM)

(No relationships reported)

Betaine is present in a variety of foods and occurs naturally in the body as a choline metabolite and potent methyl donor. Betaine may play a role in exercise performance by working as an osmolyte or by enhancing creatine synthesis. Short-term supplementation of betaine has been shown to increase muscular strength, power, and endurance during a single bout of resistance exercise. However, no long term studies (greater than 4 wks) have examined the effects of betaine supplementation on performance measures such as strength and power.

**PURPOSE:** The purpose of this study was to examine the effects of betaine supplementation on training adaptations in college-aged males following an 8-week resistance training program.

**METHODS:** Eleven college aged, resistance trained males (22.6 $\pm$ 1.1yr; 180.2 $\pm$ 6.7 cm; 86.4 $\pm$ 11.0 kg) were randomized to a betaine supplementation (B, n=6) or placebo (Pl, n=5) group. Betaine supplementation consisted of 1.25 g of powder (BetaPower, Danisco Limited) dissolved in 10 oz of Gatorade, ingested twice daily throughout the 8 week study. The placebo was 10 oz of Gatorade only, ingested twice daily. Both treatments were provided in a double blind fashion. All subjects completed an 8 week, 3 x/week, whole body resistance training program with undulating periodization. Light days = 3 sets of 12-14RM, moderate days = 3 sets of 8-10RM, heavy days = 3 sets of 3-5RM. Subjects were tested pre and post training for body composition, bench press and squat 1-RM, bench press and squat repetitions to exhaustion (at 75% 1-RM), vertical jump power, and Profile of Moods States.

**RESULTS:** Both groups increased bench press 1RM (B = 264  $\pm$  83.9 to 280  $\pm$  75.5 lbs, Pl = 258  $\pm$  72.2 to 279  $\pm$  65.4 lbs;  $P < 0.05$ ), squat 1RM (B = 315  $\pm$  76.4 to 342  $\pm$  56.8 lbs, Pl = 309  $\pm$  63.0 to 342  $\pm$  44.4 lbs;  $P < 0.05$ ), and peak power from maximum squat vertical jump (B = 7106  $\pm$  628.5 to 7264  $\pm$  402.1 watts, Pl = 6702  $\pm$  848.1 to 6961.5  $\pm$  791.0 watts;  $P < 0.05$ ). However, there were no significant differences between groups on any measure.

**CONCLUSION:** It appears that betaine supplementation coupled with an 8-week periodized resistance training program does not have an effect on strength and power adaptations over and above that of the training program itself. Supported by Danisco - Health and Nutrition.

### Betaine Supplementation Enhances Circulating Anabolic Hormones And Akt Muscle Signaling In Humans

Jenna M. Apicella<sup>1</sup>, Elaine C. Lee<sup>2</sup>, Brooke L. Bailey<sup>3</sup>, Catherine Saenz<sup>1</sup>, Jeffrey M. Anderson, FACSM<sup>1</sup>, Stuart A.S. Craig<sup>4</sup>, William J. Kraemer, FACSM<sup>1</sup>, Jeff S. Volek<sup>1</sup>, Carl M. Maresh, FACSM<sup>1</sup>. <sup>1</sup>University of Connecticut, Storrs, CT. <sup>2</sup>Mount Desert Island Biological Laboratory, Salisbury Cove, ME. <sup>3</sup>Florida Atlantic University, Boca Raton, FL. <sup>4</sup>Danisco A/S, Tarrytown, NY.

(No relationships reported)

**PURPOSE:** The aim of this study was to further investigate betaine ergogenicity. Specifically, we characterized betaine effects on circulating hormone concentrations and Akt muscle signaling proteins.

**METHODS:** Twelve men (age, 19.7  $\pm$  1.23 years; body fat, 18.7  $\pm$  7.0%) performed an Acute Exercise Test (AET) before and after two weeks of supplementation with either betaine (B) (1.25g BID) or placebo (P) with a two-week washout period between treatments. Circulating (serum/plasma) GH, IGF-1, cortisol, and insulin were measured. Vastus lateralis muscle samples were analyzed for select signaling proteins (Akt, p70 S6k, AMPK).

**RESULTS:** B (vs. P) supplementation increased GH (mean  $\pm$  SD (Area Under the Curve, AUC), B: 40.72  $\pm$  6.14, P: 38.28  $\pm$  5.54,  $p = 0.060$ ) and IGF-1 (mean  $\pm$  SD (AUC), B: 106.19  $\pm$  13.44, P: 92.45  $\pm$  10.14,  $p = 0.010$ ), but decreased cortisol (mean  $\pm$  SD (AUC), B: 1149.63  $\pm$  80.83, P: 1228.53  $\pm$  130.32,  $p = 0.007$ ). There were no differences in insulin (AUC). B increased resting total muscle Akt ( $p = 0.003$ ). B potentiated phosphorylation (relative to P) of Akt (Ser473) and p70 S6k (Thr389) ( $p = 0.016$  and  $p = 0.005$ , respectively). Phosphorylation of AMPK (Thr172) decreased during both treatments (both  $p = 0.001$ ).

**CONCLUSION:** Betaine supplementation fostered an anabolic endocrine profile: increased GH and IGF-1 and decreased cortisol. This hormonal profile suggests signaling that promotes increased protein synthesis. We conclude that betaine supplementation may provide ergogenic benefit via a heightened anabolic endocrine profile that supports increases in protein synthesis.

3554 Board #275 June 2 8:00 AM - 9:30 AM

### Magnesium Status In The Metabolic Syndrome

Stella L. Volpe, FACSM<sup>1</sup>, Lauren Forte<sup>2</sup>. <sup>1</sup>Drexel University, Philadelphia, PA. <sup>2</sup>University of Pennsylvania, Philadelphia, PA.

(No relationships reported)

Magnesium (Mg) status has been shown to be compromised in individuals with the metabolic syndrome (MetSyn) and type 2 diabetes mellitus (T2DM). Most researchers and clinicians have used serum Mg to evaluate Mg status; however, serum Mg levels are not the best indicator of Mg status. Ionized Mg, red blood cell (RBC) Mg, and urinary Mg using the Mg Loading Test (MLT) are all better markers of Mg status.

**PURPOSE:** The purpose of this study was to evaluate the Mg status, using four different methods, in individuals with the MetSyn or T2DM. This study is part of a larger clinical trial that is on-going.

**METHODS:** Participants arrived at the Clinical and Translational Research Center at the University of Pennsylvania, after an overnight fast, to be evaluated for Mg status. Serum Mg, ionized Mg, RBC Mg, and urinary Mg via the MLT were all assessed.

**RESULTS:** Our 23 participants (10 men, 13 women) were 55.6±9.9 years of age and had a body mass index (BMI) of 35.1±3.6 kg/m<sup>2</sup>. Serum Mg levels were 1.98±0.2 mg/dL (normal values 1.8 mg/dL). Ionized Mg concentrations were 0.48±0.05 mmol/L (normal values 0.5 mmol/L). RBC Mg concentrations were 1.94±0.3 nmol/L (normal values 1.5 nmol/L). Finally, MLT results were 19.12±9.8% (normal values 15.5%).

**CONCLUSIONS:** Evaluation of four methods of assessing Mg status in this small sample size of participants with MetSyn and T2DM showed that serum and RBC Mg levels were overestimated, and ionized Mg and MLT may have underestimated Mg status. However, because MLT is considered a gold standard of assessing Mg status, we conclude that ionized Mg may be the best method for analyzing Mg status, if MLT cannot be used.

**High Isoflavones and Magnesium as Anti-Inflammatory Agents to Enhance Performance of Aerobic and Resistance Exercise**

Brooke E. Starkoff, Robert A. DiSilvestro, Brian C. Focht, FACSM, Steven T. Devor, FACSM. *The Ohio State University, Columbus, OH.*

(No relationships reported)

Free radical accumulation initiates inflammation during exhaustive exercise and may subsequently induce fatigue through mechanisms that damage myofibrillar proteins. Protecting against free radical damage is essential in maintaining cell function. Many nutritional agents, including high isoflavone soy protein and magnesium, have claimed to aid in reducing free radical accumulation and thus delaying muscle fatigue.

**PURPOSE:** To evaluate the change in aerobic and resistance exercise performance following a 4-week nutritional intervention aimed to delay fatigue via anti-inflammatory agents. We tested the hypothesis that, compared with subjects who consumed low isoflavone soy protein (CON), those who consumed high isoflavone soy protein (HIGH) or low isoflavone combined with magnesium (MG) will see a delay in fatigue during aerobic and resistance exercise.

**METHODS:** Subjects were a subsample of young adults (18-30 years) participating in a similar study. Following an initial fitness evaluation to determine 1-repetition maximum (1RM), subjects returned to perform an exercise assessment including a 70% 1RM for chest press, biceps curl, and leg extension to exhaustion followed by 2 sets of upright rows; one set of 50 and another to fatigue. Subjects then ran 3 miles, cycled for 25 minutes, and lastly completed a 90 second step-test. Time, distance, and steps were recorded, respectively. Each subject was assigned to 1 of 3 supplement combinations containing low or high isoflavone soy protein, pumpkin seed oil, and/or magnesium glycinate to consume for 4-weeks. Subjects then returned to repeat the same pre-intervention exercise assessment.

**RESULTS:** Univariate ANOVA analysis revealed that all treatments resulted in significant, comparable pre- to post-intervention improvements in chest press, biceps curl, leg extension, cycling, and step test performance ( $p \leq 0.05$ ). Additionally, the treatment main effect for cycling performance approached significance ( $p = 0.06$ ). Post hoc analysis of change in performance revealed that the HIGH treatment resulted in superior improvement in cycling performance when compared to the CON treatment ( $d = .937$ ).

**CONCLUSIONS:** Nutritional supplementation with high isoflavone soy protein may provide an attenuation of muscle fatigue during aerobic exercise.

**25(OH)D Status is Not Related to Bone Mineral Density or Inflammatory Cytokines in Collegiate Athletes**

Regina M. Lewis, Maja Redzic, Peter B. Shores, David T. Thomas. *University of Kentucky, Lexington, KY.* (Sponsor: Jody L Clasey, FACSM)

(No relationships reported)

Vitamin D insufficiency is becoming increasingly prevalent in the athletic population, especially among athletes who primarily train and compete indoors. Studies have suggested that in some populations, including the elderly, there is an inverse relationship between 25(OH)D status and bone mineral density (BMD). Recently, suboptimal 25(OH)D levels have also been associated with increased inflammatory cytokine expression and frequency of illness and injury; variables which may be detrimental to achieving optimal athletic performance.

**PURPOSE:** As part of a novel, randomized, placebo-controlled, double-blinded, Vitamin D trial, we examined the baseline relationship between 25(OH)D, BMD, and inflammatory cytokines in 37 collegiate swimmers and 8 divers.

**METHODS:** Prior to the start of the athletic season in late August, blood was drawn to measure 25(OH)D and cytokine levels. Measures of lumbar spine (LS), proximal dual-femur, and total body BMD were obtained by DXA. Questionnaires collected dietary and lifestyle data.

**RESULTS:** Mean 25(OH)D levels were 55.6 ± 2.3 ng/mL with a range of 33 ng/mL to 93 ng/mL. Seventeen percent of the sample had 25(OH)D levels less than 40 ng/mL. Mean BMD for the proximal femur, LS, and total body were 1.27 ± 0.02 g/cm<sup>2</sup>, 1.11 ± 0.01 g/cm<sup>2</sup>, and 1.20 ± 0.1 g/cm<sup>2</sup> respectively. Correlations were examined between 25(OH)D status proximal femur BMD ( $r = -0.08$ ;  $p = 0.96$ ), LS BMD ( $r = 0.09$ ;  $p = 0.53$ ), and total body BMD ( $r = -0.11$ ;  $p = 0.47$ ). Mean concentration of TNF-alpha was 10.98 ± 1.38 pg/ml and IL-6 was 4.0 ± 1.38 pg/ml. Correlations were examined between 25(OH)D status and TNF-alpha ( $r = -0.05$ ;  $p = 0.76$ ), and IL-6 ( $r = -0.11$ ;  $p = 0.48$ ).

**CONCLUSION:** While these findings are preliminary in nature, they demonstrate no significant relationship between 25(OH)D and bone or cytokine measures in athletes who primarily train and compete indoors. Perhaps preseason resistance and dry-land training have a stronger association with these measures in this population. Additional studies are needed to determine if season-long Vitamin D supplementation can improve body composition, decrease inflammation, and improve overall health in Vitamin D insufficient indoor athletes.

**The Effects of 4 Weeks Vitamin D3 Supplementation on Athletic Performance**

Adrian B. Hodgson<sup>1</sup>, Andrew J. Ingham<sup>2</sup>, Jonathon Martin<sup>1</sup>, Timothy Roberts<sup>1</sup>, Asker E. Jeukendrup<sup>1</sup>. <sup>1</sup>University of Birmingham, Birmingham, United Kingdom.

<sup>2</sup>Aston University, Birmingham, United Kingdom.

(No relationships reported)

**BACKGROUND:** Vitamin D deficiency is a growing pandemic worldwide. Growing evidence in the elderly has shown that individuals with a higher vitamin D status (>75nmol/L) exhibit improved musculoskeletal performance. However it is unknown whether improving vitamin D status in athletes' leads to improved athletic performance.

**PURPOSE:** To investigate the effects of 4 weeks vitamin D3 supplementation on a number of indicators of aerobic and anaerobic performance as well as muscle strength.

**METHODS:** 36 endurance trained male cyclists/triathletes (Age 39±8y, Height 1.80±0.66m, Weight 76.3±6.2kg, VO<sub>2</sub> max 60.0±3.8 ml/kg/min) were recruited and randomly assigned into one of four supplementation groups: Placebo (PLA), 1500IU D3/d, 3000IU D3/d and 6000IU D3/d, lasting for 4 weeks, as part of a double blind study design. Athletes reported to the lab for 2 days of performance testing pre and post supplementation, including VO<sub>2</sub> max test, 1 repetition max single leg strength test (1RM), maximal voluntary contraction hand grip test, 1 hour time trial and repeated Wingate tests. All data collection was performed at latitude of 52°29'N, between December and March.

**RESULTS:** Pre supplementation, 53% and 33% of athletes were vitamin D deficient (>50 nmol/L) and insufficient (50-75 nmol/L) respectively. Vitamin D supplementation caused 25(OH)D to increase to a sufficient status (>75 nmol/L), while those receiving PLA saw small non significant changes to 25(OH)D. Small significant improvements in 1 RM leg extension for those athletes receiving 6000IU were observed on both the dominant (5.3±1.4kg (6000IU) and 2.0±1.9kg (PLA)  $p < 0.05$ ) and non dominant leg (5.8±1.0kg (6000IU) and 1.5±1.8kg (PLA)  $p < 0.05$ ). Furthermore there was a tendency for peak power output to improve during the wingate test for 3000IU/d and 6000IU/d, however this difference did not reach significance. For the remaining performance tests no difference was observed.

**CONCLUSIONS:** The study shows that 4 weeks vitamin D supplementation, above the currently debated IOM RDI 600IU/d, can improve vitamin D status in athletes. Small significant improvements in 1RM leg extension performance were observed at the highest dose. Based on these results it could be argued that the potential benefits of vitamin D to athletic performance may be specific to resistance based exercise.

3558 Board #279 June 2 8:00 AM - 9:30 AM

**Vitamin D Status, Adiposity and Performance Measures in College-Aged Students**

Laura Forney<sup>1</sup>, Tara Henagan<sup>2</sup>, Conrad Earnest, FACSM<sup>2</sup>, Loren Johnson<sup>1</sup>, Todd Castleberry<sup>1</sup>, Laura Stewart<sup>1</sup>. <sup>1</sup>Louisiana State University, Baton Rouge, LA. <sup>2</sup>Pennington Biomedical Research Center, Baton Rouge, LA.  
(No relationships reported)

Studies suggest that increased serum concentrations of 25-hydroxyvitamin D (25-OHD) are associated with slowing the development of many age-related chronic diseases. Recent data supports a positive relationship between 25-OHD and muscle synthesis, strength, power and decreased body fat in elderly individuals. However, these findings have not been consistently replicated in younger, healthy populations.

**PURPOSE:** To investigate the relationship between 25-OHD levels, body composition, measures of aerobic fitness and muscular strength and power in a young, physically active population.

**METHODS:** Twenty-six subjects (9 male, 17 female, 23.4 ± 3.9 years old) reported to the lab six times for testing. Blood was drawn to determine 25-OHD concentrations using an ELISA. Primary outcomes included: Body composition (DXA); resting metabolic rate, VO<sub>2</sub>max, power output (Wingate); and strength (8RM of bench press, upright row, leg extension and leg flexion). While our primary analysis included all participants, we also performed a sub-group analysis on those individuals considered to be sub-optimal or lower (<30 ng/mL); LOW (n=11, 22.15 ± 0.85 ng/mL) and HIGH (n=15, 40.59 ± 2.51 ng/mL).

**RESULTS:** Overall, we observed no significant correlations between 25-OHD and any major outcome variables. While the HIGH 2-OHD group showed a positive correlation between RMR and 25-OHD status (r = .622; p<.05), neither group showed a significant correlation between 25-OHD levels and our other designated outcomes.

**CONCLUSIONS:** RMR was significantly correlated with 25-OHD status in individuals with normal 25-OHD levels, indicating there may be an underlying mechanism relating 25-OHD to body composition and increased energy expenditure.

3559 Board #280 June 2 8:00 AM - 9:30 AM

**Vitamin D Status among Norwegian National Team Athletes Living at Latitude 60°N**

Christine Helle<sup>1</sup>, Kirsti Bjerkan<sup>2</sup>. <sup>1</sup>Olympiatoppen, The Norwegian Olympic and Paralympic Committee and Confederation of Sports, Oslo, Norway. <sup>2</sup>Oslo University Hospital, Oslo, Norway.  
(No relationships reported)

There is increasing evidence that many athletes are vitamin D deficient. Athletes at risk are those participating in indoor sports, those living at higher latitudes and those with dark-pigmented skin. The high latitude of Norway indicates that vitamin D status is a concern among Norwegian athletes. Vitamin D deficiency may have severe health consequences including risk of bone injuries. Additionally it is discussed whether vitamin D deficiency affects performance and the athlete's ability to train effectively through its impact on muscle function and the immune system.

**PURPOSE:** 1) To determine the vitamin D status of Norwegian national team athletes living at latitude 60°N; and 2) to evaluate training (outdoor vs indoor) and dietary factors affecting their vitamin D status.

**METHODS:** Athletes representing national teams were invited to participate in the study. Blood tests were analysed for serum 25-hydroxyvitamin D (25(OH)D). Serum 25(OH)D levels were defined as deficient (<50 nmol/L); insufficient (<80 nmol/L); and sufficient (>80 nmol/L). Vitamin D intake were calculated from 7-day weighed food records using a computerized nutrient database.

**RESULTS:** Fifty-five women (mean±SD: 24±4 yrs) and 78 men (24±3 yrs) participated. Mean 25(OH)D-level was 82±30 nmol/L. Seventeen (13%) athletes had levels consistent with vitamin D deficiency (range: 15-49 nmol/L), 47 (25%) had levels defined as insufficient and 69 (52%) had levels defined as sufficient (80-162 nmol/L). Athletes training outdoors (n=108) had higher 25(OH)D-levels than athletes training indoors (n=25), 85±25 vs 69±34 nmol/L (p=0.02). Mean vitamin D intake was 5.3±3.4 µg (0.6-8.0 µg), and 85% (n=113) did not meet the RDA of 7.5 µg vitamin D in Norway.

**CONCLUSIONS:** The mean 25(OH)D-level of athletes living at altitude 60°N were within sufficient levels, still half of the athletes had levels regarded as deficient or insufficient. Due to these results, we recommend screening of vitamin D deficiency in Norwegian athletes. Athletes training outdoors had significant higher 25(OH)D-level than those training indoors, suggesting further research on the sun exposure effect on vitamin D status in athletes living at high altitudes. In general Norwegian athletes should be recommended to increase their vitamin D intake to meet the RDA.

3560 Board #281 June 2 8:00 AM - 9:30 AM

**Micronutrient Intake In Young Athletes**

Juliane Heydenreich, Anja Carlsohn, Karsten Linné, Frank Mayer. University of Potsdam, Potsdam, Germany.  
(No relationships reported)

A balanced diet is important to maintain growth, health and athletic performance. Adequate micronutrient intake in athletes is required to prevent nutrient deficiencies and concomitant diseases. However, little is known about habitual micronutrient intake of young German athletes.

**PURPOSE:** To analyze micronutrient intake of young German athletes and to identify micronutrients where supply is crucial.

**METHODS:** 252 young German athletes were included in the study (55 % male; 12 ± 1 yrs; 158 ± 9 cm; 46 ± 9 kg; 20 ± 4 % body fat). Dietary intake was recorded for three days using a validated dietary protocol. Intake of 25 micro nutrients was analyzed based on the German Food Database. Micronutrient intake was compared with German recommended daily intake (RDI) for children. Data are given in mean ± SD. Student's t-test was used to test for differences between genders (α=0.05).

**RESULTS:** Intake of folic acid, vitamin E and iron was significantly higher in males than in females (p<0.05; table 1). No male and only 2 females reached RDI for folic acid. RDI for vitamin D was not achieved by 96 % of males and 95 % of females. Fluoride intake was below RDI in 98 % of all athletes. Two thirds of females did not reach RDI for iron. Overall, males did not reach RDI of 7 ± 3 micronutrients, and females failed to meet RDI of 8 ± 4 of the 25 micronutrients analyzed (p=0.016).

**CONCLUSION:** Crucial amounts of intake were identified for folic acid, vitamin D, vitamin E, iodine and fluoride. Therefore, intake of those micronutrients must be increased. In addition should be discussed if implementation of nutritional education programs can lead to a higher micronutrient supply.

Table 1: Extract of critical micro nutrient intake of male and female young German athletes

| Micro nutrient    | Males       |          | Females     |          | p-values |
|-------------------|-------------|----------|-------------|----------|----------|
|                   | Mean Intake | % of RDI | Mean Intake | % of RDI |          |
| Folic acid [µg/d] | 232 ± 62    | 58 ± 16  | 211 ± 61    | 53 ± 15  | 0.010    |
| Vitamin D [µg/d]  | 2.2 ± 1.4   | 44 ± 28  | 2.2 ± 1.5   | 44 ± 30  | 0.928    |
| Vitamin E [mg/d]  | 12.2 ± 4.3  | 94 ± 33  | 10.7 ± 3.7  | 97 ± 34  | 0.004    |
| Fluoride [µg/d]   | 934 ± 342   | 47 ± 17  | 873 ± 347   | 44 ± 17  | 0.164    |
| Iodine [µg/d]     | 109 ± 39    | 61 ± 22  | 105 ± 43    | 58 ± 24  | 0.356    |
| Iron [mg/d]       | 15.1 ± 4.0  | 126 ± 33 | 14.0 ± 3.6  | 93 ± 24  | 0.014    |

3561 Board #282 June 2 8:00 AM - 9:30 AM

**Low UV Index Does Not Increase The Risk Of Stress Or Lower Limb Fractures**

Scott J. Montain, FACSM<sup>1</sup>, Susan M. McGraw<sup>1</sup>, Matthew R. Ely<sup>1</sup>, Tyson Grier<sup>2</sup>, Joseph J. Knapik, FACSM<sup>2</sup>. <sup>1</sup>US Army Research Institute of Environmental Medicine, Natick, MA. <sup>2</sup>US Army Public Health Command, Aberdeen Proving Ground, MD.  
(No relationships reported)

Low vitamin D status increases the risk of stress fractures. As Ultraviolet (UV) light is required for vitamin D synthesis, low UV light availability is thought to increase the risk of vitamin D insufficiency and poor bone health.

**PURPOSE:** To determine if individuals with low UV intensity at their home of residence are at increased risk of developing stress and lower limb fractures during Army Basic Combat Training (BCT).

**METHODS:** A retrospective cohort study utilized the Armed Forces Health Surveillance Center data repository. Basic trainees were identified from January 1997 to January 2007. Cases were recruits diagnosed with stress and lower limb fractures during BCT. The recruit's home of record (HOR) was identified from the Defense Manpower Data Center database. The average annual UV intensity at the recruits' HOR was determined using a U.S National Weather Service database and stratified into low (0-3.9); moderate (4.0-5.4), and high (5.5+) UV index regions.

**RESULTS:** The dataset had 553,078 males and 117,948 females. There were 211,603, 243,637 and 215,786 recruits in the low, moderate and high UV index regions, respectively. Compared to men, females had greater risk of developing stress fractures (odds ratio (OR)= 4.3, 95%CI= 4.2-4.4, p<0.01). Contrary to the hypothesized effect, male and female recruits from low UV index areas had a slightly lower risk of stress fractures (male OR (low UV/high UV)= 0.92, 0.87-0.97; females OR= 0.89, 0.84-0.95, p<0.01) and were at similar risk for lower limb fractures (male OR= 0.97, 0.88-1.06; female OR= 0.95, 0.81-1.10) than recruits from high UV index areas. Blacks had lower risk of stress and lower limb fractures than non-blacks, and there was no indication that Blacks from low UV areas were at increased risk for bone injuries.

**CONCLUSIONS:** The UV index at home of record is not predictive of stress or lower limb fractures in BCT. These data indicate that solar intensity is not a risk factor for poor bone health in young USA adults.

**Behavioral and Electrophysiological Performance during Task Switching in College Students with Different Cardiorespiratory Fitness Levels**

Fu-Jie Kang<sup>1</sup>, Chia-Liang Tsai<sup>2</sup>, Feng-Ying Chou<sup>3</sup>, Tzu-Chi Chen<sup>2</sup>. <sup>1</sup>Kaohsiung Chang Gung Memorial Hospital of the Chang Gung Medical Foundation, kaohsiung, Taiwan. <sup>2</sup>National Cheng Kung University, Tainan, Taiwan. <sup>3</sup>Chi Mei Medical Center, Tainan, Taiwan.  
(No relationships reported)

In contrast to the many studies examining the behavioral and neural indexes of cognitive functioning in individuals with different physical activity levels, there is a lack of research focused on the relationship between cardiorespiratory fitness and behavioral and event-related potential (ERP) performance of cognitive processing.

**PURPOSE:** The current study was to investigate whether individuals with higher cardiorespiratory fitness had better executive control function during task switching using a behavioral measure (i.e., reaction time, RT) and the P3 component.

**METHODS:** Thirty-eight male college students were separated into high fitness (n=19, VO<sub>2max</sub>=58.17±6.06 mL\*kg<sup>-1</sup>\*min<sup>-1</sup>) and low fitness (n=19, VO<sub>2max</sub>=36.17±4.09 mL\*kg<sup>-1</sup>\*min<sup>-1</sup>) groups on the basis of their cardiorespiratory fitness by measuring maximal oxygen consumption. Participants simultaneously performed a task switching paradigm which consisted of two conditions: a pure task condition (e.g., 111111...222222...) and a mixed-task condition (e.g., 112211...) with concomitant electrophysiological recording. Behavioral performance and ERP measures were separately submitted to a mixed-model analysis of variance (ANOVA).

**RESULTS:** A conditional difference (i.e., switching cost) on RT was observed for the high fitness (34.46±49.07ms) and low fitness (80.52±73.68ms) groups (both p<.05), but the main effect of group did not reach significance. In terms of the electrophysiological characteristics, although there was no significant difference between both groups with regard to P3 latency, the P3 amplitude was significantly larger in the high fitness (7.26±5.01µV) group than in the low fitness (3.97±2.71µV) one (p<.05). In addition, the P3 amplitude during the pure task condition (6.43±4.31µV) was larger compared to the mixed-task condition (3.97±2.71µV) only for the low fitness group (p<.05).

**CONCLUSION:** Male college students with higher cardiorespiratory fitness exhibited better neurophysiological performance with regard to executive control function as represented by the task switching paradigm.

**Keywords:** cardiorespiratory fitness, college student, event-related potential, task switching

**Ambulatory Status in Multiple Sclerosis is Linked to Disease Progression and Brain Atrophy**

Anette S. Fjeldstad<sup>1</sup>, Hanieh Seraj<sup>1</sup>, Monica Rojas<sup>1</sup>, Dee Husebye<sup>1</sup>, Noel G. Carlson<sup>2</sup>, John W. Rose<sup>1</sup>. <sup>1</sup>University of Utah, Salt Lake City, UT. <sup>2</sup>VA Medical Center, Salt Lake City, UT.  
(No relationships reported)

Progressive disability is prevalent in patients with multiple sclerosis (MS) and frequently impacts ambulatory status. Improving knowledge of the disease progression in MS may advance treatment strategies and facilitate clinical assessment of the degree of central nervous system (CNS) degeneration.

**PURPOSE:** The objective of these studies is to examine the relationship between brain atrophy, disease progression, and ambulatory status in MS patients.

**METHODS:** A total of 398 MS patients participating in the Intermountain MS Project were classified by disease course (310 Relapsing Remitting (RR-MS); 88 Primary Progressive (PP-MS) & Secondary Progressive (SP-MS)) and ambulatory status (unassisted, assisted or wheelchair). Brain MRI scans were reviewed for all patients to determine which individuals demonstrated a high degree of atrophy of either or both of the cerebral hemispheres and corpus callosum. Correlations between brain atrophy with disease course and ambulatory status were evaluated.

**RESULTS:** Two significant associations were observed among these patients. First, patients with progressive forms of the disease (PP-MS, SP-MS) had a higher incidence of brain atrophy (43%) than RR-MS patients (17%) (p < 0.0001 (Fisher's Exact Test)). Second, patients that required ambulatory assistance (or wheelchair) had a significantly higher incidence of brain atrophy (42%) than unassisted patients (15%) (p < 0.0001).

**CONCLUSIONS:** There was a significant relationship between brain atrophy, disease progression and ambulatory status. These results suggest that incidence of brain atrophy is associated with disease progression (PP-MS, SP-MS) and an enhanced need for ambulatory assistive devices. Neurodegenerative processes are implicated as a contributor to disability in this patient population and may be associated with other biomarkers of disease progression.

3564 Board #285 June 2 9:30 AM - 11:00 AM

**The Intensity And Amount Of Daily Physical Activity Necessary For Maintaining The Neurocognitive Function**

Ken Kimura<sup>1</sup>, Akitomo Yasunaga<sup>2</sup>, Kohei Sato<sup>3</sup>, Ai Hirasawa<sup>3</sup>, Yukihiko Ito<sup>4</sup>. <sup>1</sup>Tokyo Denki University, Tokyo, Japan. <sup>2</sup>Bunka Gakuen University, Tokyo, Japan. <sup>3</sup>Japan Women's College of Physical Education, Tokyo, Japan. <sup>4</sup>FANCL Research Institute, Yokohama, Japan.  
(No relationships reported)

**PURPOSE:** Recently, there has been emerging evidence that a regular physical exercise program can reduce neurocognitive attenuation caused by aging in elderly people. Likewise, it has been reported that daily physical activity also has an important role in regards to maintaining cognitive health in the elderly. However, it is still not clear exactly what intensity and amount of daily physical activity are most effective in guarding against neurocognitive decline. The present study conducted a cross-sectional assessment to define the intensity and amount of daily physical activity which would have a favorable influence on neurocognitive function.

**METHODS:** More than 100 people aged over 60 years old participated in this study. They wore an electronic accelerometer throughout their waking hours for a month or more to assess the amount and intensity of their individual daily physical activity. This recorded the number of steps per day and the duration per day as one of ten intensity levels (0.5, 1 to 9). Executive cognitive function was evaluated with a task-switching reaction time (RT) test measuring percent RT increase in the switching task, correct response rate, and intra-individual coefficient of variation (ICV).

**RESULTS:** Within this study, stepwise multiple regression analysis revealed that the amount of 4 Mets intensity of daily physical activity could have a positive influence on the executive performance (i.e., explained 29.3% of the variance in ICV (p=.012)).

**CONCLUSIONS:** The present study's data suggests that moderate physical activity in daily life maintains proper neurocognitive function. In this study, we will confirm the validity of the results by using further analysis taking into account latent confounders such as physical fitness level, QOL, social and cognitive activity, and nutrition.

3565 Board #286 June 2 9:30 AM - 11:00 AM

**Effects of Acute Exercise on Visuospatial Attention in Undergraduates with Different Levels of Cardiopulmonary Fitness**

Chia-Liang Tsai<sup>1</sup>, Tzu-Chi Chen<sup>1</sup>, Feng-Ying Chou<sup>2</sup>, Yu-Ting Tseng<sup>1</sup>, Meng-Chih Hsieh<sup>1</sup>. <sup>1</sup>National Cheng Kung University, Tainan, Taiwan. <sup>2</sup>Chi Mei Medical Center, Tainan, Taiwan.  
(No relationships reported)

To date, no study has examined the effects of acute exercise on covert orienting of a visuospatial attention task in undergraduate students with different levels of cardiopulmonary fitness.

**PURPOSE:** The aim of the present study was to assess the effects of acute exercise on executive function using the endogenous Posner paradigm by comparing behavioral (e.g., reaction time, RT) and event-related potential (ERP) performance.

**METHODS:** Twenty-eight undergraduate students aged 18-24 years were assessed by a continuous graded maximal exercise test to identify their cardiorespiratory fitness and divided into high-cardiopulmonary (n=14) and low-cardiopulmonary (n=14) groups. All undergraduate students performed the endogenous Posner paradigm task with ERP recording before and after a 30-min bout of acute exercise. The behavioral and ERP performances in the pre-exercise session were taken as the baseline and compared with those in the post-exercise session in both groups. The behavioral and ERP results were subjected separately to repeated measures ANOVA. A level of p < .05 was accepted as statistically significant.

**RESULTS:** In the pre-exercise session, the low-cardiopulmonary group had significantly longer RT (278.89±48.03 vs. 236.40±27.93ms, p<.05) and smaller P3 amplitude (8.09±4.88 vs. 11.59±3.47µV, p<.05) than the high-cardiopulmonary group. After acute exercise, the high-cardiopulmonary group showed faster RT (236.40±27.93 vs. 216.13±23.10ms, p<.05) and greater P3 amplitude (11.59±3.47 vs. 14.26±4.26µV, p<.05) as compared to in the pre-exercise session. However, the low-cardiopulmonary group only exhibited the effect of acute exercise on the RT (278.89±48.03 vs. 257.11±33.50ms, p<.05).

**CONCLUSION:** These findings showed that behavioral performance could be improved in the Posner paradigm task in undergraduate students with low- and high-cardiopulmonary fitness. However, the electrophysiological signal was only significantly affected in the undergraduate students with high-cardiopulmonary fitness.

3566 Board #287 June 2 9:30 AM - 11:00 AM

**Measurement of Attention from a Cognitive Neuroscience Perspective: An Essential Element of Human Performance**

Bartlett A.h. Russell, Fallon Goodman, Brad D. Hatfield, FACSM. University of Maryland, College Park, College Park, MD. (Sponsor: Bradley D. Hatfield, FACSM)  
(No relationships reported)

**PURPOSE:** Cognitive reserve, or the amount of residual neural processing capacity available to attend to unexpected stimuli and contexts, is a critical component of adaptive human performance and may be inversely related to primary task load. The purpose of this study was to find an objective measure of cognitive reserve, which would provide a way to study how factors such as expertise, stress, and personality types affect performance in sporting contexts.

**METHODS:** To objectively index cognitive reserve, Electroencephalography (EEG) was used to record brain responses to task-irrelevant sounds in 21 healthy adults while they completed "Easy" and "Difficult" serial subtraction tasks. Auditory probes were standard (180ms complex tone + 520ms of silence) and deviant (100ms complex tone + 600ms of silence) sounds played in a pseudorandom, 80/20 "Oddball" ratio. EEG was time-locked to tone onset and averaged to examine differences in the Event Related Potential (ERP) waveforms in each condition. It was predicted that as task difficulty increased, the amplitude of the attention-sensitive P2 component would decrease, reflecting a decrease in cognitive reserve.

**RESULTS:** As expected, as primary task difficulty increased, percent accuracy (F(2,17) = 32.55, p < 0.001) and number of subtractions attempted (F(2,17) = 172.63, p < 0.001) decreased. Though plots show decreased P2 amplitude in the Difficult compared to the Easy task condition, contrary to prediction, the difference was not significant (F(1,16) = 1.108, p = 0.308). Additionally, plots show a depression in later potentials in the Difficult compared to the Easy condition, that was closer to, but also failed to reach significance (F(1,16) = 2.781, p = 0.115).

**CONCLUSIONS:** This study failed to distinguish between conditions and was thus unable to index cognitive reserve. This may be partly because the self-paced tasks allowed participants to adjust speed as difficulty changed, thus limiting differences between conditions. Future studies should control pacing to determine whether this method may still provide a useful metric for gauging cognitive reserve in various human performance contexts.

---

3567 Board #288 June 2 9:30 AM - 11:00 AM

**An fMRI Investigation of the Relationship Between Physical Activity and Executive Function in Older Adults**

Katie Becofsky<sup>1</sup>, Gerhild Ullmann<sup>2</sup>, Roger Newman-Norlund<sup>1</sup>, Harriet G. Williams<sup>1</sup>. <sup>1</sup>University of South Carolina, Columbia, SC. <sup>2</sup>Clemson University, Clemson, SC. (Sponsor: Sara Wilcox, FACSM)  
(No relationships reported)

**PURPOSE:** The purpose of this study was to test whether cognitive executive function and level of physical activity are related in healthy older adults. We predicted that the self-reported level of physical activity would be positively correlated with the intensity of brain activation recorded during the execution of a task requiring executive function.

**METHODS:** A sample of older adults (n=12, 75% female, mean age=70 +/- 5.7) underwent an initial session in which they completed the Physical Activity Scale for the Elderly based on their physical activity behavior during the previous week. Each subject completed computer-based versions of two executive function tasks, Trail Making Test A & B, while undergoing functional magnetic resonance imaging (fMRI).

**RESULTS:** First, we examined the contrast (Trails B - Trails A) in order to identify cortical sites specifically involved in cognitive flexibility and inhibition, two important components of executive function. A large cluster of voxels (306) in the left inferior frontal gyrus (brodmann's area 47; coordinates -50, 38, 10) was significantly more active during execution of the Trails B as compared to the Trails A task ( $t=6.6$ ,  $p < .001$ ). A smaller cluster (19 voxels) in the left premotor cortex (brodmann's area 6; coordinates -60, 6, 12; 19 voxels) was also more active during execution of the Trails B task ( $t=5.25$ ,  $p < .001$ ). Subsequent correlational analyses examining the relationship between the strength of these activations and self-reported physical activity were not significant ( $r = .36$  and  $r = .28$  for brodmann's area 6 and 47, respectively).

**CONCLUSIONS:** In healthy older adults, cognitive flexibility and inhibition were associated with increased activity in the left inferior frontal gyrus and left premotor cortex. Brain activity recorded during execution of an executive functioning task was not significantly correlated with self-reported physical activity. Future studies might use a larger sample size and/or adopt objective measures of physical activity to examine the association between physical activity and executive function in healthy older adults.

---

**3568** Board #289 June 2 9:30 AM - 11:00 AM

**Cardiorespiratory Fitness and the Effects of Acute Exercise on Executive Function in Young Adults**

Feng-Ying Chou<sup>1</sup>, Chia-Liang Tsai<sup>2</sup>, Tzu-Chi Chen<sup>2</sup>, Yu-Ting Tseng<sup>2</sup>. <sup>1</sup>Chi Mei Medical Center, Tainan city, Taiwan. <sup>2</sup>National Cheng Kung University, Tainan city, Taiwan.

(No relationships reported)

Few studies have assessed the relationship between cardiorespiratory fitness and event-related potential with regard to executive functioning, and thus the current findings are somewhat inconclusive.

**PURPOSE:** The aim of this study was to examine cardiorespiratory fitness and the effects of acute moderate aerobic exercise on executive function by comparing behavioral and electrophysiological performance in young adults.

**METHODS:** After using a graded maximal exercise test to measure cardiorespiratory fitness by assessing maximal oxygen uptake, twenty-eight young male adults were classified into high fitness ( $n=14$ ,  $VO_{2max}=57.69\pm 6.84$  mL\*kg<sup>-1</sup>\*min<sup>-1</sup>) and low fitness ( $n=14$ ,  $VO_{2max}=37.24\pm 3.53$  mL\*kg<sup>-1</sup>\*min<sup>-1</sup>) groups. Each participant performed a task switching paradigm, which included a pure task condition with a repeated single task (e.g., AAAAAA...) and a mixed-task condition with different tasks using an alternating-runs paradigm (e.g., AABBA...), before and after a 30-min session of acute exercise on a treadmill with a carefully controlled workload intensity (60%  $VO_{2max}$ ) while the behavioral and electrophysiological indices were collected. A mixed-model analysis of variance (ANOVA) was used to analyze reaction time (RT), P3 latency, and P3 amplitude.

**RESULTS:** A smaller switching cost on RT was only shown for the high fitness group relative to the low fitness group in the post-exercise session (18.85±45.68 vs. 64.45±67.68 ms,  $p<.05$ ). The P3 amplitude in the high fitness group was significantly larger in the post-exercise session compared to the pre-exercise one (8.30±5.73 vs. 6.51±5.33  $\mu$ V,  $p<.05$ ) in the mixed-task condition. In addition, in the post-exercise session, the P3 amplitude was significantly larger for high fitness group relative to the low fitness one (8.30±5.73 vs. 4.90±4.43  $\mu$ V,  $p<.05$ ).

**CONCLUSION:** Based on the behavioral performance results, high fitness adults demonstrated a more efficient executive function than the low fitness ones in the post-exercise session. In addition, the acute exercise used in this work improved the electrophysiological performance of the higher fitness adults when performing the task switching paradigm.

**Keywords:** cardiorespiratory fitness, acute exercise, executive function, task switching, event-related potential

**Practice With A Prophylactic Brace Alters Knee Flexion During a Run Stop Jump Task**

Jeff Nessler, Natalie Terwilliger, Andres Lopez, Trevor Long-Anastasia, Jacob Studer. California State University, San Marcos, San Marcos, CA.

(No relationships reported)

Anterior cruciate ligament (ACL) injuries are among the most prevalent in sports. Previous study has related decreased knee flexion at specific points during athletic maneuvers with increased likelihood of ACL injury, and a knee brace that promotes increased knee flexion might therefore contribute to reduced risk. Unfortunately, athletes may be hesitant to wear a prophylactic knee brace during competition. These individuals may therefore benefit from a brace that can promote motor learning such that athletes demonstrate increased knee flexion even when the brace is not worn.

**PURPOSE:** To determine whether one week of practice with a knee extension constraint brace can promote increased knee flexion while un-braced at the instant of greatest ground reaction force (GRF) during a run-stop-jump (RSJ) task.

**METHODS:** Seventeen recreationally active athletes performed 3 RSJ tasks both with and without the knee brace (6 trials total). Ten subjects then took their brace home and were instructed to use it for at least 3 hours over 3 exercise sessions throughout the following week. The remaining 7 subjects did not use the brace during the week. All subjects returned one week later and repeated the 6 RSJ tests. Data were acquired via eight camera Vicon motion capture system and two Bertec force platforms, and were analyzed using custom routines written in MATLAB.

**RESULTS:** When the second visit was compared to the first for subjects who wore the brace throughout the week, knee flexion angle was increased at the instant of greatest GRF during the RSJ trials in which the brace was not worn, though this increase was not significant (34.49±13.48° vs 51.99±15.86°,  $p=0.109$ ). No change in knee angle at the instant of greatest GRF was noted for the control group. Both groups demonstrated significant increases in knee flexion at the instant of touch down during the push off phase of the jump (14.5±11.62 vs. 23.46±17.01,  $p=0.046$  for both groups combined).

**CONCLUSIONS:** These data suggest that a knee extension constraint brace has potential for use as a training tool in teaching athletes to avoid movements that might place them at higher risk for ACL injury. While initial results are promising, future study with additional subjects and more specific training regimens will be useful for understanding these effects in greater detail.

**The Effects of Ankle Support on Kinematics and Kinetics of Maximal Vertical Jumping Performance**

Justus D. Ortega, James H.N. Kealialio. Humboldt State University, Arcata, CA.

(No relationships reported)

Evidence suggests that ankle support such as adhesive tape and ankle braces restrict range of motion at the ankle joint. However, it is unclear how ankle support may affect functional performance.

**PURPOSE:** To investigate the effects of prophylactic ankle support on the kinematics and kinetics of the lower limbs during vertical jumping performance.

**METHODS:** Kinematic and kinetic data were collected for 12 healthy young NCAA Division II Collegiate female athletes (age 22.3 ± 3.6 yrs, mass 65.8 ± 9.4 kg) jumping without ankle support and with two different types prophylactic ankle supports (ankle stabilizing orthosis brace and closed Gibney basket weave ankle tape). For each of the three conditions, subjects performed three maximal height jumps with five minutes rest between each jump. For each jump, maximum center of mass (CoM) jump height was measured using a force platform. In addition, we used digital motion capture and force platform data to quantify ankle, knee, and hip joint angle, torque, and power output. We used a MANOVA to determine statistical differences due to ankle support.

**RESULTS:** Center of mass jump height were similar between the two ankle support conditions (tape = 53.5 ± 7.1 cm and brace = 52.0 ± 7.3 cm) and the “no support” condition (51.2 ± 7.0 cm, p=0.506). However, maximal plantar flexion motion during the force phase of the jump was reduced by approximately 23% in both ankle support conditions (24° ± 6) compared to the “no support” condition (31° ± 7; p=0.016) without affecting maximum joint torque and power generation at the ankle, knee or hip joints (Table 1).

**CONCLUSION:** The results of this study suggest that the use of prophylactic ankle support effectively reduces excessive ankle motion without compromising jump performance.

Lower limb kinematics and kinetic during maximum height jumping

**A Commercialized Mouthguard Material Compared to a Family of Novel Thermosetting Materials**

Trenton E. Gould, Olivia D. McNair, Scott G. Piland, Daniel A. Savin. *The University of Southern Mississippi, Hattiesburg, MS.* (Sponsor: Michael J. Webster, FACSM)

(No relationships reported)

Mouthguards have been shown to provide a protective effect against orofacial injury. However, the most common material (i.e., ethylene vinyl acetate or EVA) has been demonstrated to have mechanical and thermal performance limitations.

**PURPOSE:** To synthesize two novel thiol-ene networks (TENs) and compare their physical, mechanical and thermal characterizations to a commercial, EVA-based (EVA), mouthguard material

**METHODS:** The durometer hardness, water absorption, tear strength, impact attenuation, glass transition, loss modulus, and storage modulus of the EVA and synthesized mouthguard materials were tested according to ASTM guidelines. Thermal measurements were acquired with standard differential scanning calorimetry (DSC) and dynamic mechanical analysis (DMA) techniques. Tests were conducted on 5 separate specimens at both room 23 ± 2°C and intra-oral 37 ± 2°C temperatures. Several 2 (temperature) X 3 (material) factorial ANOVAs were conducted with Tukey HSD post-hoc tests as necessary.

**RESULTS:** DSC results noted different mean glass transition temperatures (F2,12 = 10119.64, p < .05) between the materials. A Tukey HSD post hoc test revealed two homogeneous subsets with EVA as sole membership in one group and AMTEN and UMTEN as members of the second group. DMA results confirmed the finding (F2,12 = 3911.13, p < .05) and follow-up results. Mean hardness decreased at a greater rate (F2,24 = 20.29, p < .05) for UMTEN than it did for either AMTEN or EVA at approximate intra-oral temperature. Water absorption rate between temperatures was equivocal for UMTEN and EVA and higher (F2,24 = 43.77, p < .05) for AMTEN. The rate of decrease in tear strength was greater (F2,24 = 67.75, p < .05) for UMTEN than for AMTEN or EVA at the elevated temperature. The mean impact resistance increased for EVA and decreased for AMTEN and UMTEN materials (F2,24 = 113.65, p < .05) at intra-oral temperature.

**CONCLUSIONS:** Urethane-based TENs are promising as a thermosetting class mouthguard material with values matching or exceeding those obtained by EVA-based mouthguard materials across multiple types of physical, mechanical, and thermal tests. In order to abate orofacial injury, it is important to continue making strides in novel material development and testing to offer the best protection possible.

**3572 Board #293 June 2 8:00 AM - 9:30 AM**

**Performance Effects of a Self-Adapted Jaw Repositioning Mouthguard in Male Athletes**

Devon L. Golem, Shawn M. Arent, FACSM. *Rutgers University, New Brunswick, NJ.*

(No relationships reported)

Previous evidence suggests that jaw repositioning mouthguards may improve anaerobic performance. However, the technical and expensive process of development often limits accessibility of these ergogenic aids. Manufacturers have attempted to produce a more affordable, self-adapted (SA) jaw repositioning mouthguard.

**PURPOSE:** To determine the effects of a SA jaw repositioning mouthguard on aspects of physical performance in athletes.

**METHODS:** College-aged, male athletes (N = 13, M<sub>wt</sub> = 77.5 ± 3.4 kg, M<sub>ht</sub> = 174.5 ± 1.9 cm, M<sub>age</sub> = 21.0 ± 0.5 yr.) participated in this crossover study. Subjects were randomly assigned to order of use of the SA jaw repositioning mouthguard (SA), a placebo mouthguard (PLA), and a no-mouthguard control (CON). Following a familiarization and fitting session, subjects completed 3 separate testing sessions in which they completed a dynamic balance test, vertical jump (VJ), hexagon agility test, 3-repetition maximum test for bench press (3RM BP), and maximal aerobic capacity treadmill test (VO<sub>2max</sub>).

**RESULTS:** RM ANOVA revealed a trend for significant difference on time in center balance (P=.078). Follow-up tests suggested that this was due to a trend for improved balance with SA compared to PLA (SA: 19.1 ± 1.8 s; PLA: 16.9 ± 1.3 s, P=.064). The difference between SA and CON was not significant (CON: 17.9 ± 1.5 s, P=.16). There were no significant condition effects for VJ (CON: 23.0 ± 0.6 in; PLA: 22.9 ± 0.6 in; SA: 22.5 ± 0.6 in; P = 0.43), agility (CON: 11.1 ± 0.5 s; PLA: 10.8 ± 0.3 s; SA: 10.5 ± 0.3 s; P = 0.19), 3RM BP (CON: 95.8 ± 5.3 kg; PLA: 94.2 ± 5.3 kg; SA: 95.5 ± 5.2 kg; P = 0.11), or VO<sub>2max</sub> (CON: 46.8 ± 4.1 ml/kg/min; PLA: 47.0 ± 4.3 ml/kg/min; SA: 47.7 ± 4.1 ml/kg/min; P = 0.73).

**CONCLUSION:** The SA jaw repositioning mouthguard did not generally affect performance when compared to the CON and PLA conditions. Neuro-dentistry techniques may be required to promote jaw positioning necessary to elicit improvements in performance. The absence of significant differences still supports the use of mouthguards for safety. The recommendation for mouthguard use is often ignored by athletes concerned about possible negative influences on performance. This study provides evidence that mouthguard use does not interfere with physical performance. Funding was provided by Shock Doctor™

**Change In Hind Foot Kinematics: Effect Of Footwear**

Mako Fukano, Toru Fukubayashi. *Waseda University, Tokyo, Japan.*

(No relationships reported)

The relationship of athletes and footwear is important to sports performance. The bones and soft-tissues of the hind foot act as a shock attenuator at foot strike and the relative bony motions within the hind foot are the subject of intense research interest for their roles in lower extremity pathology. However, there is little quantity data of the effect of footwear on the hind foot kinematics.

**PURPOSE:** The purpose of this study was to demonstrate the footwear effects on the hind foot kinematics during landing.

**METHODS:** 6 healthy male subjects participated in this study (age: 23.4±3.4 y. o., height: 172.5±6.1 cm, weight: 63.3±10.8 kg). IRB approved informed consent was obtained from all subjects. All subjects performed single leg landing from a height of 10 cm with the knee extended under two conditions; barefoot and shod. All trials were recorded using cineangiography at a rate of 60 Hz. CT scans from 15 cm proximal to the lateral malleolus to the plantar surface were obtained for each foot/ankle using CT imaging with a slice thickness of 0.4 mm. 3D bone surface models of the tibia, talus and calcaneus were created from the CT images. In vivo three dimensional bone positions during landing were determined using 3D-2D model-image registration techniques with bone models and single-plane cineangiographic images between the times of toe contact and 250 msec after landing. All angles were referenced to zero at the toe contacts.

**RESULTS:** The range of motion of the talocrual joint in shod condition was comparable between shod and barefoot conditions. The range of motion of the subtalar joint in shod condition was significant smaller than that of barefoot. The range of motion of dorsiflexion/plantarflexion at the subtalar joint between barefoot and shod conditions were 5°±3 and 4°±3, respectively. Range of motion of eversion/inversion were 6°±3 and 5°±2°, respectively and external/ internal rotation were 6°±2° and 4°±2°, respectively.

**CONCLUSION:** This study suggested that footwear effect a change in the kinematics of the hind foot during landing.

### Mechanical Evaluation Of Elastic Devices Used In Resistance Training.

Wagner Martins, Rafael Souza, Juscelino Blasczyk, Michel Santos Silva, Ariel Vieira, Hugo Paulista, Ricardo Oliveira. *Universidade de Brasília, Brasília, Brazil.*  
(No relationships reported)

**PURPOSE:** Determine Load vs. Strain (LS) values of Elastic Devices (ED) (Elastos®) in a laboratory traction test.

**METHODS:** Our sample was composed by 105 ED (elastic tubes with average 7cm) of 7 different diameters (identified by different colors) with hooks at their extremities. For the test we utilized a traction machine (MTS® System Corporation, model MTS 810). To measure the elastic force, a load cell with capacity of 100kgf and sensitive of 2mV/V was connected to one extremity of the ED and the upper arm of a traction machine, and the other extremity was connected to the inferior arm of machine. To measure force and dislocation data, we used the Station Manager Software MTS 810. The dislocation speed for each ED was 5 mm/min. The room temperature was constant at 23° Celsius and 50% air relative humidity. The tests were realized at the Mechanical Engineer's Lab (University of Brasilia). Statistical analysis was realized using average and standard deviation for each color at each stretching position.

**RESULTS:** We obtain results for each sample of each color (15 samples for each color) for loads at 50%, 100%, 150% and 200% stretching.

**CONCLUSIONS:** The traction test allowed the determination of values for LS of ED used in this study, offering a possibility of quantitative control of intensity, an important variable to manipulate the resistance training

Loads vs. Strain values

### Linear Impact Energy Attenuation Of A Novel American Football Helmet Liner

David E. Krzeminski, James T. Goetz, Nadine M. Lipka, Andrew P. Janisse, Scott G. Piland, Trenton E. Gould, James W. Rawlins. *University of Southern Mississippi, Hattiesburg, MS.* (Sponsor: Michael J. Webster, FACSM)  
(No relationships reported)

Abating sport-related concussion necessitates evaluation of protective head gear product claims. Research associated with the initial development of a novel inner liner technology was published in peer reviewed scientific literature. Furthermore, multiple patents have been awarded to the American football helmet manufacturer for the novel liner technology.

**PURPOSE:** To verify, further define, and substantiate published findings and product claims related to linear impact energy management of a thin-walled collapsible air chamber (absorbers).

**METHODS:** Absorbers (N=15) from three adult football helmets were impacted at predefined velocities of V1=1.3 m/s, V2=2.3 m/s, V3=3.0 m/s, V4=4.0 m/s, and V5=4.7 m/s using an instrumented drop tower. Force data were acquired via an 88 kN load cell and compression behavior was captured via high speed video at 2100 fps.

**RESULTS:** Mean peak compression forces, mean maximum compression height, and percent compression were: V1 (734.67 N ±30.98; 21.78 mm ±.33; 42.6%), V2 (955 N ±13.11; 13.04 mm ±.60; 65.6%), V3 (1637.67 N ±12.42; 7.70 mm ±.35; 76.8%), V4 (9254.67 N ±297.61; 5.01 mm ±.36; 86.8%), and V5 (15849 N ±401.43; 4.04 mm ±.05; 89.4%). A bell-shaped curve was observed at V1, while V2 and V3 exhibited trapezoidal behavior. V4 and V5 curves exhibited an initial trapezoidal region followed by a leptokurtic region.

**CONCLUSIONS:** Impulsive forces appear to be ideally managed up to a V3 threshold, whereas reported velocities associated with on-field outer shell impacts exceed 7.0 m/sec. Thus, focal outer shell impacts should be investigated to examine the degree to which velocity is diminished prior to liner load transfer and the extent adjacent absorbers participate. Additionally, the leptokurtic region of the V4 and V5 curves indicates a third phase that may be defined as densification as demonstrated by the compression approaching 90%. Further investigation into physical, mechanical, and thermal characteristics of shock absorber constituent materials is warranted to potentially provide higher levels of prevention of sport-related concussion.

**3576 Board #297 June 2 8:00 AM - 9:30 AM**

### Evaluation Of Novel Football Helmet Liner Claims

Andrew P. Janisse, Nadine M. Lipka, James T. Goetz, David E. Krzeminski, Trenton E. Gould, James W. Rawlins, Scott G. Piland. *University of Southern Mississippi, Hattiesburg, MS.* (Sponsor: Michael J. Webster, FACSM)  
(No relationships reported)

Athletes have been reported to incur multiple impact exposures during practice and games. To abate injury, protective head gear liner systems must match up to product claims. A novel liner associated with a new design of football helmet is comprised of multiple thin-walled air-filled chambers (absorbers), each outfitted with a foam-filled pad purported to improve impact attenuation and maintain chamber durability.

**PURPOSE:** To investigate specific claims, detailed in the patent literature, that the foam-filled pad improves impact force attenuation and durability of the absorber system.

**METHODS:** Absorbers (N=18) were randomly assigned into two groups: foam pad intact (n=9) and removed (n=9). Absorber attenuation and durability were assessed across three impact velocities (V1=1.3 m/s, V2=3.0 m/s, V3=4.0 m/s) via 15 impacts at one minute intervals. Force data were obtained using an instrumented drop tower. For each impact velocity, a 2 (Condition: pad, no pad) X 15 (Trials: impacts 1-15) mixed model repeated measures ANOVA was conducted.

**RESULTS:** No interaction or main effects were observed for peak compression force at V1. However, between, within and interaction effects were found at V2 (F(1,4)=70.51, p=.001, f=4.36; F(14,56)= 32.13, p=.001, f=2.84; and F(14,56)=17.25, p=.001, f=2.06, respectively). V3 elicited both a between (F(1,4)=213.43, p=.001, f=7.00) and within (F(14,56)=18.01, p=.001, f=2.13) effect, but no interaction effect.

**CONCLUSIONS:** No improvement in damping or durability was provided with foam pad at V1. Absorber force attenuation degraded over multiple impacts at V2 and V3. The foam pad improved force attenuation and absorber durability at V2, but this protective effect diminished at V3. Findings provide velocity-specific support for the novel helmet liner claims.

**Watts Up - Measuring Power. A Mobile Device For Measuring Muscular Power: A Validation Study**

Andy Matthews, Rachel Klimetz, Michelle Gray. *University of Arkansas, Fayetteville, AR.*  
(No relationships reported)

The testing of speed and power is vital to accurately assessing many sport movements and activities of daily living. The current devices used to measure power accurately in a lab setting are prohibitively expensive and limited in the movements that can be performed. Many of the field measures for power are contraindicated for older adults. The Tendo Weightlifting Analyzer (Tendo; Tendo Sports Machines, Trencin, Slovak Republic) device is both affordable and flexible in the measures that can be taken. The Tendo can be used to safely measure power in an older adult population, and can assess sport specific movement.

**PURPOSE:** The purpose of this study was to compare the power measurements of the Tendo to two well-established measures of power in an attempt to validate the Tendo.

**METHODS:** Fifty-two individuals ( $n = 52$ ) participated in a field measure and a lab measure in an attempt to validate the Tendo. The field measure included connecting the participant to the Tendo and performing a vertical jump as measured on a Vertec Jump Training System (Vertec, Sports Imports, Hilliard, OH). Participants repeated attempts until failing to move an additional vane on two consecutive attempts. The lab measure included connecting the participant to the Tendo and analyzing power in knee extensions using the Biodex isokinetic dynamometer (Biodex; Biodex Medical Systems, Inc. Shirley, NY). The Biodex was set to move at 240 degrees/second. The average maximum power in watts from the Tendo and average watts from the Biodex were paired. A Pearson's product moment correlation coefficient was performed comparing the Tendo and the vertical jump results as well as comparing the Tendo and the Biodex results.

**RESULTS:** A significant positive correlation was found in both the established field and power measures when compared to the Tendo. The Tendo and Biodex outputs resulted in a large positive correlation ( $r = .55, p = .01$ ). The Tendo and Vertec outputs resulted in a similarly large positive correlation ( $r = .55, p = .01$ ).

**CONCLUSION:** These results indicate a strong correlation between the Tendo and both the Vertec and the Biodex validating the use of the Tendo as an appropriate measure of power in both lab and field settings. The flexibility and ease of use of the Tendo open the possibility of studies of power that were formerly unrealistic.

**3578** Board #299 June 2 8:00 AM - 9:30 AM  
**A Comparison of Three Brands of Knee Wrap on Peak Knee Torque**

Glen E. Fincher, II, Steven K. Rohr, Taylor D. Sams. *Ashland University, Ashland, OH.*  
(No relationships reported)

**PURPOSE:** The purpose of this study was to determine if there were statistically significant differences in the effects of three commonly used brands of knee wrap (EFS, Inzer Gripper, and Titan RPM) on peak knee torque among highly strength trained collegiate athletes.

**METHODS:** Eight healthy male, highly strength trained competitive collegiate athletes, ranging in age from 19-22, were utilized in this study. A CSMI Humac Norm isokinetic extremity testing system was used to evaluate peak torque during continuous passive movement isokinetic leg extension with knees (a) unwrapped and (b) wrapped (utilizing each of the three brands of knee wrap). The "crossed" taping method was utilized in this study. Paired samples t-tests were used to determine if there were statistically significant differences between the "wrapped" and "unwrapped" conditions. One-way analysis of variance was then used to determine if there were statistically significant differences in peak torque among the three knee wrap brands during the testing conditions. Alpha levels were set a priori at 0.05 to determine statistical significance.

**RESULTS** (reported by mean change  $\pm$  SD): The changes in peak torque utilizing EFS ( $23.38 \pm 11.11$  ft-lb), Inzer Gripper ( $25.50 \pm 8.62$  ft-lb), and Titan RPM ( $23.50 \pm 8.90$  ft-lb) were all significant compared to the unwrapped condition ( $p = 0.000$ ). There were no significant differences in peak knee torque among the three brands of knee wrap utilized in this study ( $p = 0.684$ ).

**CONCLUSIONS:** The data from this study indicate that the use of knee wraps, regardless of brand, significantly improve peak knee torque among highly strength trained male collegiate athletes. The data also indicate that there are no significant differences among EFS, Inzer Gripper, and Titan RPM knee wrap brands with respect to peak isokinetic knee torque.

**3579** Board #300 June 2 8:00 AM - 9:30 AM  
**Effects of Chaining Design on 1km Time Trial Performance Over Six Weeks in Competitive Cyclists and Triathletes**

Robert D. Clark, Christiane R. O'Hara, Todd Hagobian, Karen McGaughey. *Cal Poly State Univ, San Luis Obispo, CA.*  
(No relationships reported)

**PURPOSE:** The purpose of this study was to examine the effects of chaining type (circular vs. the non-circular Rotor Q-Ring) on performance during a 1km time trial and physiological responses over a six week period.

**METHODS:** Eight competitive male cyclists and triathletes were pre-tested using the original circular chaining. Graded submaximal exercise tests were followed by the 1km time trial with subjects using their own racing bicycle. The circular chainings were then removed and replaced with Rotor Q-Rings during the intervention period. Subjects trained and raced with this alteration to their bicycles and repeated the submaximal and 1km performance tests for the next four weeks. Post-testing occurred with the original circular chainings for the final week of testing. Oxygen consumption, carbon dioxide output, heart rate, ventilation, respiratory exchange ratio, and perceived exertion were continuously measured during the submaximal tests. Blood lactate concentration was measured during the last 30 s of each three minute stage.

**RESULTS:** The main findings were: Significant increases in performance in the 1km time trial with Rotor Q-Rings compared to circular chainings. Subjects completed the time trial on average 1.6 seconds faster ( $p < 0.05$ ), increased average speed approximately 0.7 kph ( $p < 0.05$ ), and increased average power approximately 26 watts ( $p < 0.05$ ). Furthermore, these performance measures were consistent during the four weeks employing the Rotor Q-Rings. Post-test performance levels returned to initial values during week 1 pre-testing with the circular chainings.

**CONCLUSION:** It appears from this study that cycling with the Rotor Q-Ring offers an ergogenic effect that is apparent after only one week of exposure and that long term physiological adaptations are not required. It appears that the coordinative structure employed during cycling is well adapted to this alteration in the bicycle drivetrain.

**Validation Of A Novel Mouthguard For Measurement Of Linear And Rotational Accelerations During Head Impacts.**

James Mattson, Rebecca Shultz, Jeremy Goodman, Scott Anderson, Daniel Garza. *Stanford University, Stanford, CA.*  
(No relationships reported)

**PURPOSE:** As many as 3.8 million sports-related brain injuries occur annually in the United States, yet our understanding of the mechanism remains unclear. Cadaveric and animal studies have sought to characterize this mechanism, including relative contributions of linear and rotational accelerations of the head. Methods for measuring head impacts have included laboratory reconstruction of concussive events and utilization of instrumented helmets. This study seeks to validate the use of an instrumented mouthguard (MG) to measure head impacts in vivo.

**METHODS:** Three instrumented MGs (X2Impact, Seattle) were individually placed and secured with an adjustable mandible in a helmeted headform of similar dimensions as a Hybrid III anthropometric headform. Linear accelerometers and gyroscopes were mounted at the head's center of gravity (CG). The headform was impacted using a twin-wire drop test to the standards of the National Operating Committee on Standards for Athletic Equipment from a minimum of 7 heights ranging from .05m to 1.72m, with at least 5 drops per height. Impact locations were from  $-180^\circ$  to  $180^\circ$  azimuth in  $45^\circ$  increments at elevations of  $0^\circ$ ,  $45^\circ$ , and  $90^\circ$ . A custom analysis software (X2Impact, Seattle) transformed MG accelerations to calculate peak linear acceleration (PLA), peak rotational velocity (PRV), and peak rotational acceleration (PRA) of the head's CG. Mixed effected linear models compared transformed data from MGs to data from the CG sensors, creating 95% confidence intervals for  $r^2$ , slope, and average offset.

**RESULTS:** Analysis showed strong correlations for PLA ( $r^2 = .9374 \pm .0047$ ), PRV ( $r^2 = .9663 \pm .0026$ ), and PRA ( $r^2 = .8822 \pm .0086$ ). Slopes of linear regressions were  $.976 \pm .009$  for PLA,  $.988 \pm .007$  for PRV, and  $1.039 \pm .014$  for PRA. Average percent offsets were  $-2.88 \pm 2.16\%$  for PLA,  $3.61 \pm 2.32\%$  for PRV, and  $2.83 \pm 4.85\%$  for PRA. Average offset for location of impact was  $1.63 \pm 3.74^\circ$  azimuth and  $-1.57 \pm 0.48^\circ$  in elevation.

**CONCLUSIONS:** Results from this study showed that instrumented MGs can accurately measure head impacts. Utilization of this device will provide further characterization of linear and rotational biomechanics of head impacts in helmeted and non-helmeted sports, with future studies allowing for stronger understanding of possible thresholds and mechanisms of traumatic brain injury.

**Effects Of A Soccer Specific Warm-up And A Competitive Match On Knee Proprioception**

José Oliveira<sup>1</sup>, Eduardo Salgado<sup>1</sup>, Fernando Ribeiro<sup>2</sup>. <sup>1</sup>*University of Porto, Faculty of Sport, Porto, Portugal.* <sup>2</sup>*CESPU, Polytechnic Health Institute of the North, Gandra PRD, Portugal.*

*(No relationships reported)*

Changes in skeletal muscle function induced by pre-participation warm-up and prolonged fatiguing exercise might lead to alterations of proprioception, namely knee joint position sense.

**PURPOSE:** To assess the effect of pre-participation warm-up and fatigue induced by an official soccer match on knee joint position sense of soccer players.

**METHODS:** Fourteen healthy adult male soccer players (age:  $25.9 \pm 4.6$  years old) were assessed for rate of perceived exertion and knee joint position sense at rest, immediately after a standard warm-up (duration 25 min), and immediately after a competitive soccer match (90 minutes duration). The evaluation of rate of perceived exertion was performed using Borg's rating of perceived exertion scale (scale of 6 to 20 points). Subjects were considered to be fatigued if they reported an RPE of 15 or above. Knee joint position sense of the dominant limb was evaluated by ipsilateral active limb matching responses of a passively determined position, without visual input, in open kinetic chain.

**RESULTS:** Perceived exertion increased significantly from rest to the other assessments (rest:  $8.6 \pm 2.0$ ; after warm-up:  $12.1 \pm 2.1$ ; after soccer match:  $18.5 \pm 1.3$ ;  $p < 0.001$ ). Compared to rest, after the warm-up, absolute angular error decreased significantly ( $4.1 \pm 2.0^\circ$  vs  $2.0 \pm 1.0^\circ$ ;  $p < 0.05$ ). After the match, absolute angular error ( $8.7 \pm 3.8^\circ$ ) increased significantly comparatively to both rest and the end of warm-up ( $p < 0.05$ ). The relative error showed directional bias with underestimation of the test position.

**CONCLUSIONS:** Joint position sense acuity was increased by pre-participation warm-up exercise and decreased by soccer match induced fatigue.
