**CONCLUSION:** The accumulation of PA improved cardiorespiratory fitness although BMI was not changed in obese and overweight male adolescents. The  $PA_{accum}$  also improved cognitive functions such as vocabulary, space perception and inference. Accumulating short bouts of PA might be adopted to school in lunch break or recess to improve fitness and cognitive function in adolescents.

**Associations Between High-intensity Training, Body Composition And Fitness In Youth**

Katie M. Heinrich, Pratik M. Patel, Brian K. Sanborn, Nathaniel Fehl, Bryan S. Heinrich, Christian R. Larson. *Kansas State University, Manhattan, KS.* (Sponsor: Craig Harms, FACSM)

(No relationships reported)

Fitness is protective against childhood obesity. In particular, greater cardiorespiratory (CR) fitness is associated with less total and abdominal adiposity. High-intensity (HI) exercise is associated with greater CR fitness levels in youth, and is an overall key to improving fitness.

**PURPOSE:** This pilot study examined the relationship between changes in body composition and fitness for youth participating in a HI intervention as compared to active youth.

**METHODS:** The intervention group (IG;  $n=9$ , 8m, 1f) were ages 10-13 (mean=10.78y) and the comparison group (CG;  $n=6m$ ) were ages 10-12 (mean=11.17y). The IG participated in 4 weeks of HI exercise (2d/wk, 45m/session). Pre- and posttest assessments included measured body composition (height and weight for body mass index-BMI, waist circumference-WC, dual X-ray absorptiometry for bodyfat percentage-BF%) and fitness (power-Margaria-Kalamen step test, vertical and horizontal jumps; speed-40m dash; muscular endurance- curlsups and pushups; balance-Stork Balance Test; accuracy-wall toss test; agility-Illinois agility test; CR endurance-Fitnessgram Pacer).

**RESULTS:** Based on BMI %iles, 2 IG and 1 CG participants were overweight and 1 CG participant was obese. Based on WC %iles, 3 IG and 2CG participants were overweight. Based on BF%iles, 1 CG participant was overweight and 1 CG participant was obese. After 4 weeks, both groups averaged lower BMIs (IG =  $-.038\pm .44$ ; CG =  $-.234\pm 1.21$ ) and increased WC (IG =  $.498\pm 1.89$ ; CG =  $1.0\pm .77$ ). Significant differences existed between groups for change in BF% (CG =  $-.43$ , IG =  $.83$ ;  $p=.021$ ). For the IG, BMI was negatively associated with speed; BF% was negatively associated speed ( $p=.008$ ); and WC was positively associated with agility ( $p=.018$ ), but negatively with pushups ( $p=.014$ ). For the CG, BMI was positively associated with lower vertical jump ( $p=.031$ ).

**CONCLUSIONS:** Despite high activity levels, 33% of the IG and CG participants were overweight or obese. Children participating in the HI intervention did not see gains in CR fitness. Overall the IG improved BMI, but had increased WC and BF%. The increased BF%, despite lower BMI, resulted in decreased speed, while the increased WC resulted in greater agility, but lower muscular endurance for the IG. Lower BMI in the CG decreased power.

**1981** Board #27 MAY 31 9:00 AM - 10:30 AM

**Sex Differences in Childhood Athletic Performance**

Joel M. Stager<sup>1</sup>, Andrew Cornett<sup>2</sup>. <sup>1</sup>Indiana University, Bloomington, IN. <sup>2</sup>Indiana University/Eastern Michigan University, Bloomington, IN.

(No relationships reported)

**INTRODUCTION:** Growth and motor development literature suggests a two-way (age by sex) interaction for maturational traits and motor performance variables (Beunen & Malina, 1988). Much of the research in this area, however, focuses on sex differences around the adolescent growth spurt with little documentation of performance differences throughout childhood.

**PURPOSE:** The purpose of this study was to test for the presence of an age by sex interaction for a complex motor performance task and to determine whether or not sex differences exist for the performance of this task during childhood.

**METHODS:** The data for this project were provided by USA Swimming (USAS) and consisted of the best 50-yard Freestyle performance for all USAS registered male and female swimmers from 6-19 years of age that competed in the event from 2005-2010 ( $N = 1,193,362$ ). The distribution location was determined for each combination of age, sex and competition year using methods previously described (Hoaglin, 2006). ANOVA was then utilized to test the significance of the age by sex interaction.

**RESULTS:** ANOVA revealed a significant age by sex interaction effect ( $F(13, 65) = 136.2$ ,  $p < .001$ ). Simple effects analysis indicated that the location parameter was significantly lower (i.e., times were faster) for boys than girls for 8-10 and 13-19 year olds ( $p < .001$ ) while there was no difference in the location parameter between boys and girls 6-7 and 11-12 years old. The mean difference in the location parameter between boys and girls was significantly greater ( $p < .05$ ) for 13-19 year olds (2.64) than for 6-12 year olds (0.44).

**CONCLUSIONS:** The age by sex interaction for 50-yard Freestyle performance parallels the reported maturational changes. The marked acceleration in height, weight, and strength in boys beginning around 13 years magnifies the relatively small preadolescent sex differences. These traits play a crucial role in the increased performance difference between boys and girls from 12 to 13 years. While maturational traits play a role in adolescent performance differences, their role in childhood performance differences is unclear. Additional research is needed to determine whether or not the superior performance of boys relative to girls relates to physiological parameters and/or sex differences in participation and selection bias.

**1982** Board #28 MAY 31 9:00 AM - 10:30 AM

**Sex Specific Effects Of Integrative Neuromuscular Training On Fitness Performance In 7 Year Old Children**

Avery D. Faigenbaum, FACSM<sup>1</sup>, Gregory D. Myer, FACSM<sup>2</sup>, Anne Farrell<sup>1</sup>, Tracy Radler<sup>3</sup>, Marc Fabiano<sup>1</sup>, Jie Kang, FACSM<sup>1</sup>, Nicholas Ratamess<sup>1</sup>, Timothy E. Hewett, FACSM<sup>4</sup>. <sup>1</sup>The College of New Jersey, Ewing, NJ. <sup>2</sup>Cincinnati Childrens Hospital Medical Center, Cincinnati, OH. <sup>3</sup>Lore Elementary School, Ewing, NJ. <sup>4</sup>The Ohio State University, Columbus, OH.

(No relationships reported)

**PURPOSE:** To evaluate sex-specific effects of integrated neuromuscular training (INT) on selected health- and skill-related fitness components in children implemented during physical education (PE) classes.

**METHODS:** Forty children ( $7.6 \pm 0.3$  years) from two 2<sup>nd</sup> grade PE classes participated in this study. Classes were cluster randomized into PE plus INT (INT; 10 male, 11 female) or the control group (CON; 6 male, 13 female) who participated in traditional PE. INT was performed 2x/wk during the first approximately 15 min of each PE class and consisted of body weight exercises that focused on enhancing muscular strength, muscular power and fundamental movement skills. Main outcome measures were 8 health- and skill-related fitness tests.

**RESULTS:** At baseline, the male students demonstrated higher levels of performance in multiple fitness measurements as evidenced by significantly greater performance on the push-up, 0.8 km run, long jump, single-leg hop and shuttle run tests ( $p<0.05$ ). Significant time by group interactions were noted in INT females due to enhanced INT-induced gains in performance relative to CON on the curl-up, push-up, 0.8 km run, long jump, and single-leg hop ( $p<0.05$ ). Males did not demonstrate any interaction effects of training, but both INT and CON improved similarly in the 0.8 km run, long jump, single-leg hop and shuttle run post-training ( $p<0.05$ ).

**CONCLUSIONS:** These findings indicate that INT is an effective and time-efficient addition to PE to enhance motor skills and promote physical activity in children. The 2<sup>nd</sup> grade females in the current study showed greater sensitivity to the effects of INT.

1983 Board #29 MAY 31 9:00 AM - 10:30 AM

**Establishing Criterion-Health Related Standards for Muscular Fitness Tests in High School Adolescents**

Pedro F. Saint-Maurice<sup>1</sup>, Gregory Welk, FACSM<sup>1</sup>, Ryan D. Burns<sup>2</sup>, James C. Hannon<sup>2</sup>. <sup>1</sup>Iowa State University, Ames, IA. <sup>2</sup>University of Utah, Salt Lake City, UT.  
(No relationships reported)

**BACKGROUND:** Physical fitness has been associated with risk of low back pain (LBP) in youth. Therefore, it is important to identify feasible and accurate field tests to identify individuals at risk for this condition.

**PURPOSE:** The purpose of this study was to test utility of different fitness field tests to predict self-reported LBP in high school adolescents.

**METHODS:** A sample of 100 high school (9<sup>th</sup> and 10<sup>th</sup> grade students) participated in the project as part of a supplemental school physical fitness evaluation. Participants first completed a survey instrument designed to assess the presence (and degree of) low back pain. On subsequent days, participants completed a battery of different physical fitness tests including: trunk extension test (in inches), dynamic curl-up (in number of repetitions), static curl-up (in seconds), plank (in seconds), lateral plank (in seconds), and the sit-and-reach test (in cm). The performance on the fitness tests were converted into z-scores and sums were then computed for all possible combinations of Z-scores from 2 and 3 tests. Receiver operator characteristic curves (ROC) were used to test the utility of the various combinations to predict self-reported LBP.

**RESULTS:** Girls classified "with LBP" (n=11) had Z-scores below average on all the tests (-0.60 to -0.12). Z-scores for girls that reported "No LBP" (n=19) ranged from -0.07 to 0.05. The static curl-up and the lateral plank tests combined were the best indicator of LBP in girls (AUC=0.69; Sensitivity=90.9, Specificity=52.6). The same analyses for males were inconsistent and revealed that males "with LBP" and males with "No LBP" did not differ on their fitness performance tests.

**CONCLUSIONS:** The ROC properties indicate that these tests can identify adolescents' girls with LBP (Sensitivity) however, the low value for Specificity indicate that girls with "No LBP" can be misclassified as being at risk for LBP. The same approach for males had mixed findings and therefore requires further testing.

---

1984 Board #30 MAY 31 9:00 AM - 10:30 AM

**Bilateral Deficit In Vertical Jumping In Children And Adolescent Male And Female Athletes**

Gregory C. Bogdanis, Panagiotis Veligeas. University of Athens, Athens, Greece.  
(No relationships reported)

It has been reported that power output per leg is less in two-leg jumps than in single leg jumps. This phenomenon has been termed bilateral deficit and has been attributed to a reduced neural drive that may be lower in pre-pubertal children compared with post-pubertal teenagers and adults. However, it is not certain that a bilateral deficit exists in children and especially in young females.

**PURPOSE:** To examine bilateral deficit in vertical jumping in male and female child and adolescent athletes.

**METHODS:** One hundred and seventy children with at least 2 years of training experience in track and field were divided into four groups according to age and gender: (pre-pubertal boys: n=45, age: 10.1±0.1 yrs, 141±1 cm, 36.0±0.9 kg; pre-pubertal girls: n=42, 10.1±0.1 yrs, 140±1 cm, 37.3±1.2 kg; adolescent boys: n=41, 15.0±0.1 yrs, 171±1 cm, 61.5±1.4 kg; adolescent girls: n=42, 14.8±0.1 yrs, 161±1 cm, 52.8±1.1 kg). Participants performed one-leg and two-leg counter movement jumps without arm swing on a contact mat. The bilateral jump deficit index was calculated as: 1-(right+left leg jump height)/two-leg jump height x 100. Peak leg power output during jumping was also calculated and was scaled with body mass. Differences between boys and girls and the two age groups were analyzed using two way ANOVA.

**RESULTS:** Jump height and leg peak power were similar in pre-pubertal boys and girls (24.8±0.7 vs. 24.2±0.7 cm and 30.0±1.1 vs. 29.2±1.2 W, respectively). However, jump height and leg peak power were higher in adolescent boys compared to girls (37.8±0.8 vs. 29.3±0.9 cm and 49.0±0.8 vs. 40.2±1.0 W, respectively, p<0.01). The bilateral index was positive for males in both age groups (2.0±1.3% and 1.9±1.2%) indicating lack of bilateral deficit. This was also the case for the pre-pubertal girls (bilateral index: 0.1±1.2%). However, adolescent females showed a negative bilateral index (-3.3±1.5%), with the sum of the single leg jumps being significantly greater than the two-leg jump (30.3±1.0 vs. 29.3±0.9 cm, P<0.05).

**CONCLUSION:** There was a lack of bilateral deficit in vertical jumping in pre-pubertal boys and girls and also in adolescent boys. The manifestation of bilateral deficit only in adolescent girls may be explained by superior motor skill ability (i.e. balance on one leg and jump) of girls over boys in that age.

1985 Board #31 MAY 31 9:00 AM - 10:30 AM

**Improved Movement Skill Competency in a Preschooler Physical Activity Intervention**

Anthony Dyrek, Anne R. Lindsay, Teresa Byington, Madeleine Sigman-Grant, Minggen Lu, Brett Campbell. University of Nevada Reno, Las Vegas, NV. (Sponsor: Lawrence A Golding, FACSM)  
(No relationships reported)

Mastery of fundamental movement skills in preschoolers is critical to the acquisition of gross motor task development. Since these fundamental movements form the basis for games, dance and sports that emerge in the later years, it is recommended that children are taught in the early years. All 4 Kids, developed by the University of Nevada Cooperative Extension is a preschool nutrition and physical activity intervention program that uses noncompetitive physical activities, such as dance, to teach essential movement patterns.

**PURPOSE:** To examine the effect of the All 4 Kids preschool physical activity and dance intervention on movement patterns.

**METHODS:** 321 preschool children in Head Start centers across southern Nevada participated in this study. They were divided into intervention and comparison groups. All children completed a movement assessment that evaluated fundamental, spatial, and temporal movement patterns. After the initial assessments the children in the intervention group participated in the 9-week All 4 Kids program while the comparison group continued with standard Head Start curriculum. The program utilized dances with a wide range of movement skills as recommended in Pre-Kindergarten physical development standards. Post assessments were conducted on both groups at the end of 9 weeks.

**RESULTS:** Using an ANCOVA, children's combined movement skills in the intervention group demonstrated a significantly higher composite score than the control group (n=179, p<.001) and a significantly greater ability to cross the midline of the body (n=321, p<.014). The intervention group also demonstrated a significant increase (p=.022) towards meeting the state's balance standard of 5 seconds, as compared to the comparison group (p=.511). Preschoolers in the intervention group showed a significant increase (n=170, p<.001) in the number of hops for 15 seconds.

**CONCLUSIONS:** Provision of music and movement skills that focus on skill development with intended outcomes for learning are critical to maintaining an active lifestyle beyond the preschool years. Preschool interventions should involve a wide range of antecedent movements such as those mentioned in national and state Pre-K standards. This study demonstrates that the All 4 Kids program is a viable teaching tool that can improve a child's movement skills.

1986 Board #32 MAY 31 9:00 AM - 10:30 AM

**Self Reported Physical Activity, Body Composition and Aerobic Fitness of Hispanic Elementary School Children**

Julio Morales<sup>1</sup>, Jose A. Santiago<sup>2</sup>. <sup>1</sup>Lamar University, Beaumont, TX. <sup>2</sup>Sam Houston State University, Huntsville, TX.  
(No relationships reported)

**PURPOSE:** Compare levels of PA, AF and Body Mass Index (BMI) and ascertain the effect PA on the attainment of the FITNESSGRAM<sup>®</sup> Healthy Fitness Zone in elementary school Hispanic children.

**METHODS:** Participants were fifty, fifth grade Hispanic boys (n = 24; M Age = 11.7 yrs., M Ht = 1.49m, M Wt = 48.9 kg.) and girls (n = 26; M Age = 11.5 yrs., M Ht = 1.47 m, M Wt = 44.3 kg.) from an urban school in the Southwest US. Variables measured were: Height (HT), weight (WT), body mass index (BMI), percent fat (FAT), aerobic fitness (AF) as measured by the PACER<sup>®</sup> test, and PA as measured by the Physical Activity Questionnaire for Older Children (PAQ) (Crocker et al, 1997). All measures were taken in the same month by a trained teacher as part of the Physical Education class. Descriptive statistics and independent samples t-tests were used to examine the differences between boys and girls. Logistic regression was used to assess

the effect of PA and other variables on achieving the FITNESSGRAM® Healthy Fitness Zone (HFZ) for FAT and AF. All significance tests were done at  $p < 0.05$  level.

**RESULTS:** Boys and girls were found to be significantly different on the PACER test ( $M = 29.21$ ,  $SD = 11.59$  vs.  $M = 21.5$  laps respectively),  $t(48) = 2.62$ ,  $p = .012$ , and PAQ ( $M = 3.15$ ,  $SD = .72$ ; vs.  $M = 2.75$ ,  $SD = .60$  respectively),  $t(48) = 2.10$ ,  $p = .041$ . The logistic regression model with gender (GEN), AGE, BMI and PAQ for achieving the HFZ was significant for FAT but not for AF. The model was significant,  $X^2(4, N = 50) = 38.30$ ,  $p < .05$ ; explained between 53% and 71% of the variance and correctly classified 86% of the cases. However, only BMI and GEN made significant contributions to the model.

**CONCLUSIONS:** Results show a difference between the important variables of AF and PA for boys and girls. Although PA has been found to be related to both BMI and AF; in this case it does not appear to have an important contribution to predicting the likelihood of achieving the corresponding HFZ. The lack of a significant relationship in the present group may suggest that PA's effect is confounded by other factors. It could be speculated that the young age of the subjects may not allow for the level of variability on the trait to ascertain differences. Additionally, self report PA has been found to have low levels of reliability in children that may have affected these results.

---

**1987** Board #33 MAY 31 9:00 AM - 10:30 AM

**Adolescents Engaged In At Least Five Hours Of Physical Activity Weekly Show Numerous Health Benefits**

Claudia J. Brahler, Nicholas J. Hess, Bret M. Lorenzo, Mary I. Fisher, Betsy Donahoe-Fillmore, Terri Glenn. *University of Dayton, Dayton, OH.* (Sponsor: Paul Vanderburgh, FACSM)

(No relationships reported)

**PURPOSE:** To determine if scores on the Oswestry-Disability Index (ODI), body composition, back health or fitness indicators were significantly different in healthy adolescents based on the number of minutes per week they spend engaged in physical activity.

**METHODS:** A convenience sample of 152 healthy adolescents (age 14-18 years; 68 males and 84 females) provided written informed consent to participate in this study. Measured variables included hip flexion active range of motion (AROM), v-sit, lumbar lateral flexion AROM, a trunk extension hold, number of sit-ups in a minute and 90/90 hamstring length. Additionally, subjects completed the International Physical Activity Questionnaire (IPAQ) focused on organized physical activity participation and the Oswestry-Disability Index (ODI). Subjects were divided into 3 groups based on the number of minutes per week they spent in physical activities PA Group 1: 120 minutes or less, PA Group 2: 121 - 300 minutes, and PA Group 3: more than 300 minutes. One-way ANOVA and univariate general linear model (GLM) tests were completed.

**RESULTS:** ANOVA tests revealed that for PA Groups 1, 2 and 3 the means and associated p values were respectively, BMI, 25.61, 23.31, 23.03  $p = 0.026$ ; sit-ups in one minute 33.87, 39.00, 41.48  $p = 0.001$ ; and ODI scores 12.40, 17.29, 10.10  $p = 0.003$ . Because, on average, females scored higher than males on the ODI (15 vs 9.8, respectively  $p = 0.011$ ), a Univariate GLM test was completed with both gender and PA Group entered as factors and ODI as the dependent variable. With gender statistically controlled, PA Groups 1 and 3 still had significantly lower ODI scores compared to PA Group 2. Based on the ODI scores, twenty four percent of the adolescents were classified as having clinically significant back disability (ODI score > 20%). Lastly the ODI scores for adolescents were better correlated with weekly PA than any of the other common clinical measurements for back motion.

**CONCLUSIONS:** The level of physical activity that approximates the Surgeon General's Vision for a Healthy and Fit Nation 2010 recommendation of 60 minutes per day, appears to promote healthy back function, body composition and fitness indicators all of which are associated with overall improved health status.

---

**1988** Board #34 MAY 31 9:00 AM - 10:30 AM

**Are Aerobic and Anaerobic Capacities in CUSSA Junior Alpine Ski Racers Improving? A Seven Year Follow-up.**

Kelley Holmes<sup>1</sup>, Emily Willaert<sup>1</sup>, Mark Blegen, FACSM<sup>2</sup>, David Bacharach, FACSM<sup>1</sup>. <sup>1</sup>St. Cloud State University, St. Cloud, MN. <sup>2</sup>University of St. Catherine, St. Paul, MN.

(No relationships reported)

**INTRODUCTION:** Central Region 1 of the US Ski and Snowboard Association (USSA) encourages athletes to participate in fitness evaluations as part of the selection process for Team Central. Over the past seven years, the 20m pacer test (aerobic) and 40cm box jump test (anaerobic) have been used to estimate individual capacities. Normative data have been used to provide feedback to athletes for the last three years as a motivational tool to encourage improvement.

**PURPOSE:** To determine if providing normative data to athletes would help them achieve higher levels of fitness on the aerobic 20m pacer test and anaerobic 40cm box test.

**METHODS:** Subjects ( $N=121$ ) were junior alpine skiers age 10-19 and members of the Central USSA. Data were collected from 2005 to 2011 on skiers who were able to complete both the aerobic and anaerobic portions of the test. Subjects performed a 20m pacer test to determine  $VO_{2max}$  and a 60s 40cm box jump. Minimum values from norms generated by Stielow and Bacharach (2010) were used to compare average values for each age and gender group over the seven years.

**RESULTS:** Recommended minimum values for each age and gender were compared to actual values from predicted aerobic capacity ( $VO_2$  ml/kg/min) and 60s box jump scores recorded each year. Paired t-tests were performed with a Bonferroni adjustment to account for potential Type I errors and  $P < .008$  was used to determine significance. No differences were noted for any group. A trend toward a decrease in aerobic capacity for female subjects age 15-19 yrs over this seven year period was observed ( $P < .009$ ).

**CONCLUSIONS:** Although annual fitness assessments have been able to provide recommended levels and quartile rankings for athletes to achieve on aerobic and anaerobic capacity tests, no improvements have been seen in these athletes. Perhaps maintaining fitness levels could be considered better than the downward trend seen in non-athletes of this age range over a similar time period (Science Daily, 2006); however, it appears clear that fitness parameters are not an area of great focus for these aspiring athletes. If athletes from Central Region 1 of USSA want to be competitive at a national level, they will have to address the deficit seen in these data.

The authors want to acknowledge and thank Region 1 coaches and parent-volunteers who assisted with data collection.

**1989** Board #35 MAY 31 9:00 AM - 10:30 AM

**Acute Effects of Static and Dynamic Stretching on Agility Performance with a Skill Component in Elite, Youth Soccer Players**

Ajit Korgaokar, J. Bradley Jordan, Richard S. Farley, Jennifer L. Caputo. *Middle Tennessee State University, Murfreesboro, TN.* (Sponsor: Don Morgan, FACSM)

(No relationships reported)

Static stretching has been shown to decrease maximal force production and negatively affect explosive actions such as agility movements. Minimal research has been conducted using a skill component, such as dribbling a ball in soccer, to compare static vs. dynamic stretching on agility performance.

**PURPOSE:** To examine and compare the effects of static and dynamic stretching on agility performance while dribbling a ball through the Balsom agility course in elite youth soccer players.

**METHODS:** Elite, male soccer players ( $N = 14$ ), completed 4 trials of the Balsom agility test while dribbling a soccer ball. Height, age, and body mass were recorded and participants were familiarized with the Balsom agility test during the first trial. Randomized and counterbalanced trials of the Balsom agility test preceded by static or dynamic stretching were administered after a standardized warm-up (control condition). Standardized warm-up consisted of 3 minutes of self-paced light jogging and 2 minutes of passing and running with a ball. The muscles targeted for both the static and dynamic treatments were the hamstrings, quadriceps, and the Gastrocnemius and Solei. Differences between the times from the control condition and each treatment were calculated.

**RESULTS:** The mean difference between the control condition and the stretching trials was 0.34 sec for the static stretching protocol and 0.15 sec for the dynamic stretching protocol. No statistically significant difference was found between the effects of static and dynamic stretching on agility performance,  $F(1,13) = 0.61$ ,  $MSE = .426$ ,  $p = .45$ . A high mean square error (.426) indicated large within-group differences on agility performance.

**CONCLUSION:** The results do not support the preferential use of a static or a dynamic stretching protocol over a general warm-up prior to sport-specific agility tasks in youth soccer players. The addition of a sport-specific skill component, dribbling a ball, to an agility test may increase within-subject variance in trials involving youth soccer players.

**1990** Board #36 MAY 31 9:00 AM - 10:30 AM  
**High Intensity Interval Training Versus Traditional Preseason Training in High School Football Athletes**

Fred Hale, Christine Lo Bue-Estes, Timothy N. Harvey, Anthony Spencer. *Mercyhurst College, Erie, PA.*  
(No relationships reported)

Sport specific training is central to implementing proper exercise protocols to achieve maximal performance outcomes. In many sports coaches will not employ training based on appropriate metabolic specificity.

**PURPOSE:** To assess improvement in anaerobic capacity via measuring: 40 yd dash, vertical jump, and agility based on, intervention specificity in varsity football athletes, with a minimum of 2 years previous playing experience.

**METHODS:** A convenience sample of 50 athletes (aged 17-18 years) was identified to participate in the project. Athletes were randomly assigned to two groups: an Aerobic group (n=25) or a High Intensity Interval Training (HIIT) group (n=25) and stratified by position type. Over the course of 10 weeks in preseason the additional training consisted of approximately 20 minutes of work, for both groups, with aerobic group running at 65-85% of RPE based capacity at a 1:2 work rest ratio (WRR), and the HIIT group working at >85% of RPE based capacity at 1:2 WRR for weeks 0-6, and 1:1 WRR for weeks 7-10. 40 yd dash, vertical jump, and shuttle run were assessed before and after completion of 10-week aerobic or HIIT intervention. Change scores were calculated for each group before and after the 10 week training period. One tailed, paired t-tests were used to compare change scores across both exercise interventions.

**RESULTS:** Both groups improved over the course of 10 weeks, with no difference between groups for the shuttle run (HIIT = 2.69, Aerobic = 2.84). The HIIT group, however, showed a greater improvement than the aerobic group for: 40 yard dash (3.90, 2.03; p=0.001), and vertical jump (9.05, 4.09, p=0.001).

**CONCLUSIONS:** Implementing a high intensity training protocol in adolescent varsity football athletes translates into greater improvements for speed and vertical jump, compared to aerobic intervention of a similar duration. Improvements in these variables will hopefully translate into greater on-field successes based on improved metabolic capacity, due to sport specific HIIT.

---

**1991** Board #37 MAY 31 9:00 AM - 10:30 AM  
**Gender-Based Differences in Sprint and Acceleration Capacities in Very Young Athletes**

Daniel H. Serravite<sup>1</sup>, Brian Biagioli<sup>2</sup>, Charmaine DeFrancesco<sup>1</sup>, Joseph White<sup>2</sup>, Joseph F. Signorile<sup>2</sup>. <sup>1</sup>Florida International University, Miami, FL. <sup>2</sup>University of Miami, Coral Gables, FL. (Sponsor: Arlette Perry, FACSM)  
(No relationships reported)

Sport performance is determined to a large extent by the acceleration capacity of the athlete. This is especially true for team sports like soccer where field dynamics rapidly change. Even though sprinting and acceleration seem to be crucial to soccer, little is known about the gender-specific sprinting and acceleration characteristics of very young soccer players.

**PURPOSE:** The purpose of this study was to investigate the gender-related differences in sprint speed, acceleration and lower body power in 8 to 10 year old soccer players.

**METHODS:** 57 boys and 66 girls from 8 to 9 (U9) and from 9 to 10 (U10) years of age were evaluated (28 U9 boys [8.6 yr ± 0.4], 29 U10 boys [9.6 yr ± 0.3], 31 U9 girls [8.6 yr ± 0.3] and 37 U10 girls [9.6 yr ± 0.3]) in sprint and jump performance. Split times at 5m, 10m, 20m and 30m to allow the analysis of partial velocities (V5m, V10m, V20m and V30m) and accelerations (A0-5m; A5-10m; A0-10m; A10-20m) were evaluated during a 30m sprint using electronic timing gates. To assess leg power each subject performed 3 countermovement jumps (CMJ) on a pressure-sensitive mat. Leg power was computed using the best and mean CMJ heights and body weight.

**RESULTS:** Multivariate ANOVA analysis revealed a gender by age group interaction for V5m, A0-5m and A5-10m. Separate analyses of V5m by age showed that at U9 boys were faster than girls, but at U10 girls were faster than boys. This interaction was also reflected in the A0-5m, where boys had a greater acceleration than girls at U9 (p= 0.007), but girls showed a greater acceleration than boys at U10 (p= 0.001). Interestingly, although the analysis of V10m only showed main effects of age, with U10 faster than U9, the analysis of the A5-10m interaction revealed that U10 boys had a greater acceleration than girls (p < 0.001). There was a significant main effect of age for height, weight, and leg power showing increments with age, U10 were taller, heavier and more powerful than the U9.

**CONCLUSION:** Both gender and age uniquely contribute to velocity and acceleration in linear fashion in very young athletes. This is especially true in short sprints up to 10 meters. However, these differences were not explained by weight or power.

**Association Between Suspected Fatty Liver, Obesity, Inflammation And Cardiorespiratory Fitness In Portuguese Youth**

Clarice Martins, Andréia Pizarro, Luísa Aires, Gustavo Silva, Jorge Mota, Maria Paula Santos. *Faculty of Sports, Porto, Portugal.*  
(No relationships reported)

Nonalcoholic fatty liver disease (NAFLD) is one of the most frequent complications associated with excess adiposity and a number of variables, similar to current risk factors, have been associated to NAFLD in the pediatric population. However, few studies have addressed the association between suspected fatty liver, obesity, inflammation and fitness in children, as a possible diagnostic for predicting future NAFLD.

**PURPOSE:** To analyze the association between serum aminotransferase (ALT), waist circumference (WC), C-reactive protein (CRP), and cardiorespiratory fitness (CRF) in school children.

**METHODS:** A total of 79 obese students (40 girls and 39 boys), 10-11 year-olds (±60), with abnormal serum ALT from Porto public schools comprised the sample. Measurements included CRF (20-m Shuttle Run Test), WC (NHANES protocol), CRP and ALT (Cholestech LDX® analyser). Pearson correlation and general linear model with Bonferroni's adjustments for multiple comparisons were used to examine the differences in the measured variables, adjusting for CRF and gender.

**RESULTS:** The analysis showed negative correlations between fitness and the measured variables. Significant correlations were observed for WC (p=.002), CRP (p=.012) and ALT (p=.004). Data showed a significant main effect for CRF in ALT (p=.008) but not in WC (p=.057) nor PCR (p=.223). The gender main effect and the gender\*CRF group interaction were not significant (p>.05) for WC, PCR and ALT.

**CONCLUSIONS:** CRF is negatively associated to WC, PCR and ALT, and present a significant effect in ALT values in obese children.

**1993** Board #39 MAY 31 9:00 AM - 10:30 AM  
**The Influence Of Wrist-worn Accelerometer Wear Location On Free-living Physical Activity In Adolescents**

Edward M. Davila, Daniel P. Heil, FACSM. *Montana State University, Bozeman, MT.*  
(No relationships reported)

The use of accelerometry-based wrist-worn activity monitors (AM) to measure free-living physical activity (PA) is popular in research settings. Although previously evaluated in adults, no research has investigated the impact of wrist-worn AM location (dominant [D] vs non-dominant [ND] or left [L] vs right [R]) on measurements of free-living PA in adolescents.

**PURPOSE:** The aim of this study was to evaluate the influence of wrist-worn AM wear location (D vs ND and L vs R) on measures of free-living PA in adolescents 12-17 years old.

**METHODS:** Eight boys (Mean±SD: 14±2 yrs, 53.9±13.6 kg, 160.5±14.5 cm, 20.6±2.3 body mass index [BMI]) and 12 girls (14±2 yrs, 56.1±9.9 kg, 160.3±7.4 cm, 21.4±2.6 BMI) participated in the study. Subjects wore two AMs for 7 consecutive days (24 hr/day), with one AM attached to the dorsal side of each wrist using locking plastic wrist bands. Subjects were instructed to engage in their usual daily activities. After downloading the raw AM data to a computer, previously validated regression algorithms were used to transform and summarize the data into counts (counts/day), activity energy expenditure (AEE; kcals/day), and duration of time (T; minutes/day) for 1, 5, and 10 minute bout durations (BDs) within light (L) and moderate-to-vigorous (MV) intensity categories for each AM. Dependent variables (CNT, AEE, T) for each BD within L and MV intensity between each AM (D vs ND and between L vs R) were compared using two-factor (AM Location x BD) multivariate repeated measures ANOVA (α=0.05). Scheffe's post-hoc analyses (α=0.01) were performed for all pairwise comparisons when indicated by the ANOVA. Pearson's correlation was used to analyze the relationship between dependent variables for all BDs within L and MV intensities between AMs (D vs ND and L vs R) (α = 0.05)

**RESULTS:** No significant differences were found amongst all dependent variables for any BD within L or MV intensity between AMs. There were high correlations ( $r = > 0.85$ ,  $p$ -value  $< 0.0001$ ) between dependent variables for all BDs within L and MV intensities between AMs.

**CONCLUSION:** These data indicate that wrist-worn AM location has no significant influence on PA outcome variables in adolescents under free-living conditions. Researchers can now give participants the option to choose which wrist they would prefer the monitor to be placed when being assessed.

**The Effect of High School Sports Participation on Collegiate Level Physical Fitness and Physical Activity**

Patrick Schneider<sup>1</sup>, Jeanne Sowers<sup>1</sup>, Sarah Adams<sup>1</sup>, Christine Manville<sup>1</sup>, Lynne Shores<sup>1</sup>, Mary Dietrich<sup>2</sup>. <sup>1</sup>Belmont University, Nashville, TN. <sup>2</sup>Vanderbilt University, Nashville, TN.

(No relationships reported)

**PURPOSE:** The purpose of this study was to assess the effect of high school (HS) sports participation on physical fitness (PF) and physical activity (PA) levels in college among males and females.

**METHODS:** 113 students (50 males, 63 females) enrolled in a university level wellness class participated in the study. Participants completed a PF battery consisting of cardiorespiratory fitness (CRF), muscular endurance (ME), body composition (BC) and flexibility (FX) assessments. In addition, they completed a survey to determine HS sports participation (collegiate athletes were excluded). Self-reported PA levels were assessed to determine current PA status. Normally distributed values (CRF, BC, FX) are summarized as mean $\pm$ SD; skewed values (ME) are summarized using median values (25<sup>th</sup>, 75<sup>th</sup> IQR). ANOVAs were used to compare main and interaction effects of gender and HS sports participation on CRF, BC, and FX; a Kruskal-Wallis test was used for ME. Activity levels by gender and HS sports participation were compared using Chi-Square Tests of Independence.

**RESULTS:** There were no statistically significant differences in PF measures between HS athletes and non-athletes among genders.

|                 | Female HS athletes | Female HS non-athletes | Male HS athletes | Male HS non-athletes |
|-----------------|--------------------|------------------------|------------------|----------------------|
| CRF (ml/kg/min) | 46.7 $\pm$ 4.8     | 46.6 $\pm$ 4.0         | 53.9 $\pm$ 4.8   | 51.3 $\pm$ 6.7       |
| ME (reps)       | 30 (23,34)         | 25 (21,31)             | 30 (25,40)       | 30 (21,34)           |
| BC (% fat)      | 32.4 $\pm$ 7.4     | 30.7 $\pm$ 7.0         | 18.7 $\pm$ 6.9   | 14.8 $\pm$ 4.4       |
| FX (cm)         | 36.8 $\pm$ 7.6     | 35.0 $\pm$ 7.3         | 30.6 $\pm$ 8.3   | 28.3 $\pm$ 9.0       |

Statistically significant gender differences were observed for each PF measure except ME (males  $>$  CRF; females  $>$  BC, FX, each  $p < .001$ ) and males tended to be less active than females in this study ( $p = .006$ ). Furthermore, it appeared that male HS non-athletes tended to be less active than either female HS athletes or non-athletes, as well as male HS athletes ( $p = .024$ ).

**CONCLUSION:** The lack of statistically significant differences between PF measures of HS athletes and non-athletes in college may be due to the relatively homogenous fitness levels of students in this study.

**Physical Activity Change And Its Relationship With Change In Insulin Resistance (HOMA-IR)**

Kristi L. Storti<sup>1</sup>, Marquis S. Hawkins<sup>1</sup>, Jennifer N. Cooper<sup>1</sup>, Kelley Pettee Gabriel<sup>2</sup>, Kim Sutton-Tyrrell<sup>1</sup>, Andrea M. Kriska, FACSM<sup>1</sup>. <sup>1</sup>University of Pittsburgh, Pittsburgh, PA. <sup>2</sup>University of Texas Health Science Center at Houston, Austin, TX.

(No relationships reported)

Insulin resistance (IR) is associated with type 2 diabetes and the development of coronary heart disease. Physical activity (PA) is associated with decreased risk of IR. Less is known about whether time spent in different intensities of PA may be associated with decreased risk of IR.

**PURPOSE:** To determine the impact of PA change, as measured by accelerometer, on insulin sensitivity in overweight, sedentary adults aged 20-45 years, involved in a lifestyle intervention, which included a PA component.

**METHODS:** The Slow Adverse Vascular Effects of excess weight (SAVE) trial evaluated relationships between weight loss, dietary sodium, and vascular health. Subjects were randomly assigned to a regular or reduced sodium diet, and all received a one-year nutrition and PA intervention. PA data were collected at baseline and 12 months using an AM7164 ActiGraph accelerometer. Freedom threshold values were applied to describe time in different intensity levels. Total body movement was assessed via total counts per day (CTS). Homeostatic model of assessment of insulin resistance (HOMA-IR) was computed using fasting insulin and glucose measures. Linear mixed models were used to examine the impact of change (baseline to 12 months) in total time spent (min/d) being sedentary (SED), in light intensity PA (LPA), moderate to vigorous intensity PA (MVPA) and change in HOMA-IR. Model 1 adjusted for time (yrs) since baseline, age, sex, race, current smoking status, wear-time, and randomization group. Models 2, 3, and 4 additionally controlled for BMI; baseline MVPA; and change in MVPA, respectively.

**RESULTS:** From baseline to 12 months, MVPA and SED significantly increased, LPA significantly decreased. Improvements in HOMA-IR score were noted from baseline to 12 months [mean (SD) 2.9 (2.1) vs. 2.7 (1.6), respectively ( $p=0.11$ )]. Changes in MVPA and SED from baseline to 12 months were not associated with change in HOMA-IR. Change in LPA and CTS was significantly inversely related to change in HOMA-IR ( $p=0.02$  and  $p < 0.0001$ , respectively) after adjusting for BMI and MVPA change ( $p < 0.05$ ).

**CONCLUSIONS:** LPA and CTS were related to HOMA-IR rather than MVPA alone, likely reflecting the small amount of time spent in the latter. Interventions should focus on total movement rather than just increasing high intensity movement for insulin sensitivity.

**1996** Board #42 MAY 31 8:00 AM - 9:30 AM

**How Much Exercise Is Needed To Improve Insulin Sensitivity In Sedentary Adults?**

Francesca Amati<sup>1</sup>, John J. Dubé<sup>2</sup>, Katelyn Fleishman Allison<sup>2</sup>, Valentin Rousson<sup>1</sup>, Bret H. Goodpaster<sup>2</sup>. <sup>1</sup>University of Lausanne, Lausanne, Switzerland. <sup>2</sup>University of Pittsburgh, Pittsburgh, PA.

(No relationships reported)

**PURPOSE:** Exercise improves insulin sensitivity (IS) and is a first line for the prevention and treatment of type 2 diabetes. The extent to which IS response is dose-dependent is not known. The purpose of this study was to examine whether or not exercise dose was associated with improvements in IS following four months of exercise training in previously sedentary adults.

**METHODS:** Fifty-five healthy volunteers (F=34, M=21, mean age 54 $\pm$ 15) participated in a 16-week supervised endurance exercise intervention with a pre/post intervention design. IS was assessed by euglycemic hyperinsulinemic clamp,  $VO_{2peak}$  by a GXT and body composition by DXA. Exercise dose, expressed as average kcal expended/week, was computed as the product of exercise intensity, duration and frequency. Paired T-tests, correlations and multivariate regression models were used.

**RESULTS:** At baseline 20% of the volunteers had class II obesity, 35% class I obesity, 33% were overweight and 13% were in the normal range. Improvements with intervention were observed for BMI (30.5 $\pm$ 4.4 vs. 29.5 $\pm$ 3.9,  $P < 0.001$ ),  $VO_{2peak}$  (1.9 $\pm$ 0.6 vs. 2.2 $\pm$ 0.7 L/min,  $P < 0.001$ ) and IS (367 $\pm$ 112 vs. 450 $\pm$ 130 mg/min,  $P < 0.001$ ). Average exercise frequency was

3.91±0.85 sessions/week and mean energy expended was 1094±519kcal/week. Improved IS was significantly related to exercise dose in a graded dose response relationship. No evidence of threshold or maximal dose-response effect was observed. Notably, even an exercise dose of ~400 kcal/week was associated with a significant improvement in IS. Furthermore, the IS gain was higher for the subjects starting with a lower IS. Age and gender did not influence this dose-response relationship.

**CONCLUSION:** This study identifies a graded dose-response relationship between exercise dose and improvements in IS. The implication of this observation is of importance for the adaptation of exercise prescription in clinical situations. These data reinforce the concept that more insulin resistant individuals at risk for developing type 2 diabetes attain greater benefit by performing more exercise, but that there is no obvious exercise volume threshold for these benefits. Taken together these data corroborate the notion that one exercise prescription does not fit all clinical circumstances and that a little exercise is better than nothing.

**Effects Of A 12-week Exercise Training And Sedentary Time Reduction Program On Fasting Insulin Secretion**

Richard Viskochil, Sarah Kozey-Keadle, Corianne Oliver, Barry S. Braun, FACSM, Patty S. Freedson, FACSM. *University of Massachusetts-Amherst, Amherst, MA.*  
(No relationships reported)

Exercise training typically increases peripheral insulin sensitivity, which may reduce insulin secretion. Whether interventions designed to reduce sedentary time result in similar changes in insulin secretion has not been established.

**PURPOSE:** To determine changes in fasting insulin secretion, hepatic extraction (HE) and HOMA2-%B following exercise training (EX), an intervention designed to reduce sedentary time (rST), or combined exercise training and reduced sedentary time (EX+rST).

**METHODS:** 48 sedentary, overweight subjects were randomized to 12 weeks of: 1) EX (n=13), 5 days/wk at 50-60% heart rate reserve, 2) rST (n=13), targeted instruction designed to increase steps/day and reduce sedentary time, 3) Ex+rST (n=14) exercise training plus reductions in sedentary time or 4) control (CON, n=8). Sedentary time and steps/day were assessed using an activPAL wearable monitor. Glucose, C-peptide and insulin concentrations were determined using the glucose oxidase method and radioimmunoassay. HOMA2-%B was calculated using the HOMA2 calculator. Differences across conditions in C-peptide, fasting hepatic extraction (Insulin/C-peptide) and HOMA-%B were determined using paired t-tests and one-way ANOVA.

**RESULTS:** Both exercise groups increased VO<sub>2</sub>max (EX=9%, EX+rST=12%) indicating improved cardiovascular fitness. Sedentary time was significantly lower in the rST (4%) and EX+rST (7%), did not change in EX group, and increased in CON (4%). Steps/day significantly increased in EX, rST and EX+rST but not in CON. There were no pre- to post differences in fasting C-peptide concentrations (E=0.86 ± 0.39 vs 0.76 ± 0.32, rST= 1.33 ± 0.72 vs. 1.34 ± 0.66, EX+rST= 0.87 ± 0.39 vs 0.87 ± 0.33, CON= 1.19 ± 0.45 vs. 1.24 ± 0.43) However there was a decrease in HE in the rST group (13%±8%[pre] vs 11%±8% [post], p=.04). There were no differences in HOMA-%B in any group.

**CONCLUSIONS:** Exercise training and/or sedentary behavior reduction interventions did not alter fasting insulin secretion, however the rST intervention decreased hepatic insulin extraction, indicating that adaptations to reduced sedentary time may occur at the liver.

**Longitudinal Analysis of Police Stress and the Metabolic Syndrome**

Hyeelim Yoo, Warren D. Franke, FACSM. *Iowa State University, Ames, IA.*  
(No relationships reported)

**PURPOSE:** To assess and compare the change in the prevalence of the metabolic syndrome and its components over time (2001- 2007) and to determine whether changes in stress affect the metabolic health risk among police officers.

**METHODS:** Perceived Stress and metabolic risk factors were assessed in 171 police officers in 2001 and again in 2007.

**RESULTS:** The perceived stress score (PSS) and the metabolic syndrome score (zMS) were not meaningfully different from 2001 to 2007. The prevalence of high body mass index, hypertension, and elevated triglycerides increased from 2001 to 2007. Overall, the prevalence of the metabolic syndrome increased from 17.5% in 2001 to 28.7% in 2007. The PSS in 2007 was highly correlated with the PSS in 2001 ( $r = 0.44$ ) and zMS in 2007 was strongly correlated with zMS in 2001 ( $r = .68$ ). Neither the change in perceived stress over time nor baseline perceived stress predicted the development of the metabolic syndrome in 2007 among police officers.

**CONCLUSIONS:** The prevalence of the metabolic syndrome and its several individual components increased over 6 years among LEOs. Stress as assessed by the PSS does not contribute to the development of metabolic health risk after a 6 year follow-up.

**Prevalence of Cardiovascular Risk Factors in Indians with Coronary Artery Disease**

Shraddha M. Khialani, Hetal D. Poptani, Priyanka M. Mehat, Anjali S. Zende, Aashish S. Contractor. *Asian Heart Institute, Mumbai, India.*  
(No relationships reported)

**PURPOSE:** The prevalence of Coronary Artery Disease (CAD) has progressively increased in India during the latter half of the last century. Although there are studies available from West regarding prevalence of conventional cardiovascular risk factors (CVRF) in patients been diagnosed to have heart disease there is limited information on the same in Indian patients. This is vital as these risk factors do have an implication on the progression of the disease. Therefore the aim of the paper is to assess the risk factors in Indian patients diagnosed to have CAD.

**METHODS & RESULTS:** In this cross-sectional study, five hundred consecutive patients with CAD were included and data on major CVRFs was obtained in them. Mean age of male patients was 52.4 +/- 9.2 years while that of females was 61.8 +/- 6.9 years. However 30.1% of males (142/472) were below the age of 45 years. 68.4% of patients had a positive family history. The mean BMI was 26.7 +/- 3.9 kg/m<sup>2</sup>. 32.6% were normal weight while 67.4% had BMI > 25 kg/m<sup>2</sup>. 83.6% of patients had dyslipidemia. The mean lipid profile of patients (144/500) not on lipid lowering drugs were Total cholesterol- 195.6 +/- 44.3 mg/dl, LDL- 125.7 +/- 36.2 mg/dl, HDL- 37.8 +/- 7.5 mg/dl, Triglycerides- 160 +/-71.6 mg/dl. 59.8% patients were hypertensives, while the mean blood pressure of normotensives was 113.6/70.6 mm Hg. 35.6% reported history of smoking. 54.8% of patients had pre-diabetes or diabetes. The average fasting blood sugar of patients not on any drugs for diabetes was 106.7 +/- 22.7 mg/dl. 44.8% patients reported that they were sedentary while 55.2% patients reported moderate physical activity.

**CONCLUSIONS:** The present study shows high prevalence of most of the conventional risk factors especially family history, obesity, dyslipidemia, hypertension, diabetes and lack of physical activity.

**Regional Differences In Physical Activity And Chronic Diseases In The United States**

David R. Bassett, FACSM, Scott Conger, Eugene Fitzhugh. *University of Tennessee, Knoxville, TN.*  
(No relationships reported)

**PURPOSE:** To examine whether there are regional disparities in physical activity, that might contribute to the high rates of chronic disease in the Southern US.

**METHODS:** Behavioral Risk Factor Surveillance System (BRFSS) data were used to determine adult physical activity, obesity, diabetes, and hypertension prevalence in 50 states. American Community Survey (ACS) data were used to determine the percentage of workers who commute on foot or by bicycle. Each state was placed into 1 of 4 regions, as defined by the U.S. Census Bureau. Data were analyzed using one-way ANOVAs to test for significant differences among regions.

**RESULTS:**

|                    | South          | Midwest       | Northeast     | West          | P value |
|--------------------|----------------|---------------|---------------|---------------|---------|
|                    | X (SD)         | X (SD)        | X (SD)        | X (SD)        |         |
| % Walk to Work     | 1.9            | 3.1           | 4.2           | 3.6           | <0.0001 |
| % Bike to Work     | 0.2            | 0.5           | 0.4           | 1.0           | <0.0001 |
| Physically Active  | 44.9(3.5)a,b,c | 49.9(3.5)d,c  | 52.1 (3.2)d   | 54.5 (3.3)a,d | <0.0001 |
| Inactive (no LTPA) | 27.1(3.4)a,b,c | 22.2 (2.4)d   | 21.8 (2.7)d   | 20.2 (2.3)d   | <0.0001 |
| Obesity %          | 28.8 (2.2) b,c | 27.1 (1.0)c,d | 23.9 (2.2)a,d | 24.2 (2.3)a,d | <0.0001 |
| Diabetes %         | 9.8 (1.0)a,b,c | 7.5 (1.2)d    | 7.8 (0.8)d    | 7.1 (0.9)d    | <0.0001 |
| Hypert %           | 30.6(2.2)a,b,c | 26.8 (2.1)d   | 27.1 (1.3)d   | 25.0 (2.3)d   | <0.0001 |

<sup>a</sup> = sig. different from Midwest; <sup>b</sup> = sig. different from Northeast; <sup>c</sup> = sig. different from West; <sup>d</sup> = sig. different from South

At the state level, physical inactivity is positively related to rates of obesity (r=0.7440) and diabetes (r = 0.8613). Southern states have the highest rates of physical inactivity, and the highest rates of obesity and diabetes. Active commuting (bike + walk) is inversely related to rates of obesity (r=0.4520) and diabetes (r=0.5752).

**CONCLUSION:** The South has higher rates of physical inactivity, and lower rates of active commuting, than other regions. In addition, the South has higher rates of obesity, diabetes, hypertension, and coronary heart disease.

**2001 Board #47 MAY 31 8:00 AM - 9:30 AM**

**The Awareness, Treatment, And Control Of Hypertension In A Supervised Wellness Program**

Miriam E. Pearman, Diana Gilleland, Daniel Bonner, David Donley, James Thomas, Randy Bryner. *West Virginia University, Morgantown, WV.* (Sponsor: Stephen Alway, FACSM)

(No relationships reported)

Though awareness, treatment, and control for hypertension (HT) have improved, the current control rates (34%) are still far below the Healthy People 2010 goal of 50%.

**PURPOSE:** To determine, in a supervised wellness program, a) the percent of individuals with uncontrolled HT (SBP > 140mmHg or DBP >90mmHg) at baseline and b) the affects of 12 months of supervised exercise in the following subpopulations: 1) not diagnosed with HT 2) medicated HT 3) ≥50 years old with medicated HT.

**METHODS:** Data were collected on 455 individuals, (mean age 52.72 ± 0.7 SE) including self reported HT diagnoses, HT medications, and measured BP. Monthly resting BPs were collected for the first year of participation. Paired sample t-tests determined significance for changes over time.

| RESULTS:                 | 1)Not Diagnosed w/HT  | 2) Medicated HT  | 3) ≥50 w/Medicated HT   |
|--------------------------|---|--|---|
| a)Uncontrolled           | 21.3%   | 41.5%  | 58.2%   |
| b) Time effect at 12 mo. | SBP:133.85 v. 126.85,p =0.001 DBP: 79.78 v. 74.47,p < 0.001 | SBP: 149.56 v. 134.44, p < 0.001 DBP 87.77 v. 79.61, p < 0.001 | SBP: 149.44 v. 136.31, p < 0.001 DBP: 87.33 v. 79.56, p < 0.001 |

**CONCLUSION:** In a wellness program, the percent of individuals unaware of HT (21.3%) is below the national average (30%); the percent of uncontrolled treated HT in the total (41.5%) and ≥50 population (58.2%) are also below the national average (64%). With a year's participation in a supervised wellness program, there is a statistically significant decline in BP to healthy norms.

**DISCUSSION:** Individuals joining a wellness program have better awareness and control of BP than the general population; those that are uncontrolled benefit from a year's participation.

**2002 Board #48 MAY 31 8:00 AM - 9:30 AM**

**Physical Activity: An Extra Minute a Day May Keep the Doctor Away**

Elena Boiarskaia. *University of Illinois Urbana-Champaign, Urbana, IL.* (Sponsor: Weimo Zhu, FACSM)

(No relationships reported)

It has been shown that regular physical activity (PA) decreases the risk of metabolic syndrome; yet, it is unclear how the effects of PA differ at various points of the distribution of a particular measure. Quantile regression (QR) (Koenker & Bassett, 1978) provides this insight by describing the effect of an input variable at any quantile of the distribution of the outcome variable.

**PURPOSE:** To examine differences in effect of accelerometer-determined moderate intensity PA in minutes per day on measures associated with metabolic syndrome using QR.

**METHOD:** PA data and outcome measures were obtained from the National Health and Nutrition Examination Survey (NHANES) 2003-2004 data for 3,199 adults aged 18-85, 49% male, with an average age of 50 (SD = 19.93) and average BMI of 27.88 (SD = 5.69). Determined using an ActiGraph monitor, moderate intensity PA was defined as ≥ 2020 intensity counts per minute for adults. Controlling for age, gender and BMI, the effects of moderate intensity PA on waist circumference (WC), blood pressure (BP) and plasma glucose levels (GLU) were analyzed using QR.

**RESULTS:** QR revealed that the effect of each additional minute of moderate intensity PA on WC was significant (p < .05) for all quantiles, but increasingly stronger for men above 60th percentiles (WC ≥102 cm). On average the reduction of WC was .11 cm (SD = .01), but men at the 95th percentile (WC = 123 cm) benefited by reductions of .19 cm (SD = .05). Similar results were found for women. Moderate intensity PA had a significant negative effect on GLU, but only above 40th percentiles (GLU ≥ 91 mg/dL). The strongest reductions of .07 mg/dL (SD = .02) were experienced above 85th percentiles (GLU ≥ 108 mg/dL). On average, PA did not appear to have an effect on systolic BP; however, QR showed that there were significant reductions of about .02 mmHg between 15th and 70th quantiles (101 ≤ BP ≤ 128 mmHg) for each additional minute of PA.

**CONCLUSION::**Differences in impact of moderate intensity PA on the various outcome variables across quantiles were found. Individuals considered at risk according to their WC and GLU benefited more from each additional minute of moderate intensity PA than those who were relatively healthy. On the other hand, those who were within the healthy range of systolic BP experienced significant benefits from PA, while those at the extreme ranges did not.

**Interrelationships Between Depression, Physical Activity, Homocysteine And Metabolic Syndrome**

Paul D. Loprinzi<sup>1</sup>, Bradley J. Cardinal, FACSM<sup>2</sup>. <sup>1</sup>*Bellarmine University, Louisville, KY.* <sup>2</sup>*Oregon State University, Corvallis, OR.*

(No relationships reported)

Since studies have demonstrated a link between metabolic syndrome and cardiovascular disease, understanding factors that may influence metabolic syndrome is of great interest. Although inconclusive, studies have reported an association between depression and metabolic syndrome, with additional findings indicating that endothelial function, as measured by homocysteine levels, may be an important marker of metabolic syndrome.

**PURPOSE:** Given that previous studies have demonstrated links between physical activity and depression, endothelial function and metabolic syndrome, the purpose of the present study was to simultaneously examine the interrelationships among these variables in a nationally representative sample of the U.S. adult population.

**METHODS:** Data from the 2005-2006 National Health and Nutrition Examination Survey were used. After exclusions, 1,146 participants were included in the analyses. Physical activity was

objectively measured using accelerometry; demographic variables and depression were assessed using a questionnaire; and the biological variables were evaluated from blood samples. Multivariate linear and logistic regression was used to assess the interrelationships while controlling for potential confounders. Having metabolic syndrome was coded as 0.

**RESULTS:** The odds ratios between depression and metabolic syndrome, moderate-to-vigorous physical activity (MVPA) and metabolic syndrome, and homocysteine and metabolic syndrome were 0.91 ( $P = 0.36$ ), 1.28 ( $P < 0.001$ ), and 0.007 ( $P < 0.06$ ), respectively. The beta coefficients between depression and MVPA and MVPA and homocysteine were -0.33 ( $P < 0.001$ ) and 0.001 ( $P = 0.11$ ), respectively.

**CONCLUSIONS:** Depression was not associated with metabolic syndrome nor was homocysteine associated with MVPA or metabolic syndrome; however, depression was significantly inversely associated with MVPA, which in turn, was inversely associated with metabolic syndrome. Although future prospective studies are needed to better characterize the direction of these relationships, the present findings suggest that physical activity may directly influence metabolic syndrome as well as indirectly through reductions in depression symptoms.

**2004 Board #50 MAY 31 8:00 AM - 9:30 AM**

**Physical Activity, Body Fat And Glycemic Control In A Type 2 Diabetic Portuguese Sample**

César C. Oliveira<sup>1</sup>, Joana Carvalho<sup>2</sup>, José Ribeiro<sup>2</sup>. <sup>1</sup>*Polytechnic Institute of Viana do Castelo, Melgaço, Portugal.* <sup>2</sup>*Research Centre in Physical Activity, Health and Leisure, Faculty of Sport, University of Porto, Porto, Portugal.*  
(No relationships reported)

Diabetes mellitus has emerged as one of the main concerns to human health in current century. Previous research has emphasized the importance of an active lifestyle in the prevention and management of this disease. Furthermore, the amount of body fat is also known to influence glycemic control, as evaluated by the percentage of glycated hemoglobin A1c (A1c).

**PURPOSE:** to characterize physical activity levels, amount of body fat and glycemic control of a type 2 diabetic sample.

**METHODS:** Data was obtained from 104 previously sedentary Portuguese type 2 diabetic mellitus patients (mean age 65.8±6.7 years; 68 women and 36 men). Circulating levels of A1c were evaluated using blood sample analysis. Daily steps were assessed by accelerometry during one week (GT1M, Actigraph, LLC). Body composition was measured with DEXA (Hologic QDR) and subjects were classified as underfat, healthy (H), overfat (O) and obese (OB) in accordance with Gallagher et al. guidelines.

**RESULTS:** The prevalence of O+OB was high, with more than 92% of the subjects being considered O+OB. The number of daily steps for H, O and OB was 9480±3169, 7995±3087 and 7401±2723, respectively ( $p > 0.05$ ); subjects spent an average of 48±25 min/day (H), 37±23 min/day (O) and 32±21 min/day (OB) in moderate to vigorous physical activities ( $p > 0.05$ ). A1c was similar among H, O and OB, with 7.0±1.5, 6.6±1.2 and 6.6±1.4%, respectively ( $p > 0.05$ ).

**CONCLUSIONS:** Although there were differences in the considered variables among H, O and OB groups, these did not reach statistical significance. Leaner subjects showed a trend towards a higher number of daily steps and increased time spent on moderate to vigorous activities, but not in A1c levels. These results may be due to the relatively small sample size and diabetes related pharmacological therapy used by all subjects, which may attenuate differences among groups. Supported by PTDC/DES/104518/2008 (FCOMP-01-0124-FEDER-009599) and SFRH/PROTEC/50008/2009 grants.

**2005 Board #51 MAY 31 8:00 AM - 9:30 AM**

**Adiposity, Blood Pressure, And Glucose Metabolism Correlate Favorably With Higher Peak 30-minute Cadence**

Catrine Tudor-Locke, FACSM, Meghan M. Brashear, William D. Johnson. *Pennington Biomedical Research Center, Baton Rouge, LA.*  
(No relationships reported)

**PURPOSE:** Peak 30-minute cadence (defined as the average steps/min for the best 30, not necessarily consecutive, minutes in a day) has been introduced as an informative approach to describe accelerometry-determined intensity of best effort under free-living conditions. The purpose of this analysis of the 2005-2006 National Health and Nutrition Examination Survey (NHANES) accelerometer and health data was to determine the relationship between this objectively measured intensity parameter and directly measured indicators of adiposity (BMI, waist circumference), blood pressure (systolic and diastolic), and glucose metabolism (fasting glucose and insulin, HbA1c, and HOMA-IR).

**METHODS:** Accelerometer data were processed for 3522 NHANES adult participants (age= 47.5 (0.7), 47.7% male) who supplied 1-7 days of valid data (i.e., ≥10 hours of wear time/day). Minute-by-minute cadence data were ranked to identify and average the top 30 minutes each day, and then these were averaged across valid days. Spearman correlations were calculated to evaluate the relationships between peak 30-minute cadence and the specified health parameters.

**RESULTS:** All correlations with peak 30-minute cadence were statistically significant: BMI (-0.18), waist circumference (-0.25), systolic blood pressure (-0.21), diastolic blood pressure (0.05), glucose (-0.22), insulin (-0.18), HbA1c (-0.24), HOMA-IR (-0.22). Relationships were attenuated but still significant ( $p < .05$ ) when adjusted for age.

**CONCLUSIONS:** An indicator of natural best ambulatory effort in a day is significantly associated with measures of adiposity, blood pressure, and glucose metabolism. Peak 30-minute cadence is a continuous variable indicative of habitual intensity that may serve to expand upon volume-based estimates of ambulatory activity expressed only as steps/day.

**2006 Board #52 MAY 31 8:00 AM - 9:30 AM**

**The Efficacy of a Six Month Corporate Health Initiative Program**

Bethany Garner, Jennifer Patrick, John C. Garner, Melinda W. Valliant. *The University of Mississippi, University, MS.* (Sponsor: Mark Loftin, FACSM)  
(No relationships reported)

The fast-paced lifestyle of today's society often allows little time for attention to personal health and wellness. As a result, rising medical costs, insurance rates, and employee absenteeism leave employers searching for ways to improve the health of their workforce and company. Employers often struggle to find an affordable program for their employees. A well-designed worksite wellness program has the capacity to greatly improve the health and well-being of participants, thus improving their productivity.

**PURPOSE:** The purpose of this study was to evaluate six months of a corporate wellness program in a rural plant of a major manufacturing company.

**METHODS:** Data from program participants collected in January 2011 and July 2011 were compared to data from non participants collected during the same times. Data evaluated included waist circumference (WC), blood glucose (BG), triglycerides (TG), high density lipoprotein cholesterol (HDL), low density lipoprotein (LDL) and blood pressure (BP). To test for statistical significance of differences in biometrical outcomes, pair-t tests between pre and post assessments for both groups was utilized.

**RESULTS:** Data comparisons resulted in a statistically significant improvement ( $p < 0.01$ ) in WC, BG, TG, HDL, LDL of participants (individual coaching and group fitness) compared to non participants ( $p = 0.18$ ). Further evaluation of participation revealed that those who attended individual coaching sessions more frequently showed the greatest improvement in the analyzed biometrics (correlation 0.91) compared to group fitness participation (0.82). However, those who participated in both showed the greatest improvement and strongest correlation (0.95). Blood pressure comparisons did not result in a statistically significant difference although it did approach contribution to the regression equation.

**DISCUSSION:** Based on the results reported to the manufacturing plant, more new participants are joining the initiative. This may provide the opportunity to have a greater impact on employee health of the plant as a whole. Consideration should be made to encourage participation in both individual and group activities to facilitate improvement in overall health.

**2007 Board #53 MAY 31 8:00 AM - 9:30 AM**

**Food Consumption, Serum Vitamins, and Metabolic Syndrome Risk by Daily Steps in Middle Aged Men**

Jihyun E Choi, Barbara E Ainsworth, FACSM. *Arizona State University, Phoenix, AZ*  
(No relationships reported)

The purpose of this study was to examine metabolic syndrome risk and to find differences in food consumption and levels of serum vitamins by steps/day on the basis of data obtained from the 2005-2006 NHANES. The subjects were 948 men aged 40-70 years old. They were divided into three groups by tertiles of accelerometer-determined steps/day: G1 (n=313, <6,802 steps), G2 (n=322, 6,802 ~ 10,698 steps), and G3 (n=313, ≥10,699). Metabolic syndrome was defined as the presence of three or more of the following five components: waist circumference >40 inches; TG ≥150 mg/dL; HDL <40 mg/dL; blood pressure ≥130/85 mmHg, and fasting plasma glucose ≥100 mg/dL (NCEP ATP III). Logistic regression was used to estimate the odds ratios (ORs) and the 95% confidence intervals for the metabolic syndrome risk after adjustment for age. Univariate general linear model analysis of covariance (GLM-ANCOVA) adjusted for age and BMI,

and Bonferroni post-hoc test was used for multiple comparisons. G3 consumed significantly more "Fruits" and "Vegetables" than other groups, whereas G1 consumed significantly more "Milk and Milk Products" and less "Fruits" and "Vegetables" than other groups. The ratio of (Fruits+Vegetables) / (Eggs+Meats) was the highest in the G3 (2.46) and the lowest in the G1 (1.55). Serum levels of vitamin C, pyridoxal 5'-phosphate,  $\alpha$ -carotene, trans- $\beta$  carotene, cis- $\beta$  carotene, b-cryptoxanthin, lutein and zeaxanthin, trans-lycopene, retinyl pamate and vitamin D were the highest in the G3 and the lowest in the G1. There were no significant differences in the three groups in the levels of 4-pyridoxal acid, vitamin B<sub>12</sub>, retinal stearate, vitamin A and E. The OR of G1 to G3 (reference group) is 1.90 (1.89-1.90) for abdominal obesity, 2.46 (2.46-2.47) for fasting hyperglycemia, 1.97 (1.97-1.97) for hypertriglyceridemia, 2.07 (2.06-2.07) for low HDL, 1.96 (1.96-1.97) for hypertension, and 3.20 (3.20-3.21) for the metabolic syndrome. These results showed that middle aged men who do not walk much had the lowest levels of many serum vitamins and ate more milks, eggs and meats. Further, their daily steps and food intake are related to an increased risk of the metabolic syndrome.

**2008** Board #54 MAY 31 8:00 AM - 9:30 AM

**Relationship Between Physical Activity, Sitting Time and Metabolic Health**

Ketil Ostrem<sup>1</sup>, Sigurd Vik<sup>2</sup>, Sindre Mikal Dyrstad<sup>1</sup>. <sup>1</sup>University of Stavanger, Stavanger, Norway. <sup>2</sup>Enforme, Stavanger, Norway.

(No relationships reported)

**PURPOSE:** To study the relationship between sitting time and the metabolic health factors: total cholesterol (TCHO), low-density lipoprotein (LDL), high-density lipoprotein (HDL), triglycerides (TG) and blood glucose (GLU) in physical active and inactive individuals.

**METHODS:** Maximal oxygen uptake (VO<sub>2</sub> max) was measured in a cycle ergometer test (Astrand-Rhyming test). Level of GLU, cholesterol and TG was measured by Choletech LDX system. Activity habits and daily sitting time was self-reported. A sample of 1404 individuals (917 men), with a mean age of 41.8 (SD 11.0) participated in the study. A total of 1114 individuals completed all tests.

**RESULTS:** The participants were divided in six groups according to PA-level. VO<sub>2</sub> max increased according to PA (Tab 1). It was also found that the least active individuals had lower level of HDL (16,2%) and higher level of TG (34,3%), GLU (8,4%) and sitting time (31,5%) compared to the most active (p<.01). Among the physically inactive and among individuals who reported at least 90 min-wk<sup>-1</sup> with endurance training, there was a great variation of sitting time. However it was not found any significant correlations between sitting time and the metabolic health factors nor in the physically inactive or most active group.

**Table 1.** VO<sub>2</sub> max in different physical activity-levels.

|  | Number of times with moderate PA - minimum 30 min-day-1-wk-1 |               |              |              |                |               |
|--|--|---------------|--------------|--------------|----------------|---------------|
|  | 0<br>(n=258)   | 0,5<br>(n=62) | 1<br>(n=197) | 2<br>(n=279) | 3-4<br>(n=268) | 5+<br>(n=103) |
| VO <sub>2</sub> max<br>(ml·kg <sup>-1</sup> ·min <sup>-1</sup> ) | 31   | 32            | 35**         | 38*          | 40*            | 48*           |

\* Different from other PA-levels (p<.001).

\*\* Different from the least active (p<.001).

**CONCLUSION:** Even though there was a great variation in sitting time within the group of individuals who did not participate in endurance training, and the most active individuals, there were no significant correlations between metabolic health and sitting time. Activity level is according to our findings, a better indicator of metabolic health.

**2009** Board #55 MAY 31 8:00 AM - 9:30 AM

**Prevalence Of Obesity And Hypertension Among Senior Civil Servants In Lagos, Nigeria**

Oluwatoyosi Owoeye<sup>1</sup>, Oluwaseyi Osho<sup>1</sup>, Yejide Adeniji<sup>2</sup>, Adegoke Akinfeleye<sup>2</sup>, Oluwatobi Durowoju<sup>1</sup>, Oluwatosin Akinsola<sup>1</sup>. <sup>1</sup>College of Medicine, University of Lagos, Lagos, Nigeria. <sup>2</sup>Lagos University Teaching Hospital, Lagos, Nigeria.

(No relationships reported)

Weight has long been known to be a determinant of health and disease. Both overweight and underweight are associated with health consequences. Hypertension as well has been widely documented to be a major risk factor for heart attack, stroke, and kidney disease.

**PURPOSE:** To determine the prevalence of overweight, obesity and hypertension in Lagos State senior staff civil servants.

**METHODS:** A cross sectional cohort study of 305 (163 men, 142 women) senior civil servants in five ministries of the Lagos State civil service. Participants were aged 43.20 ± 7.37 years (range 25 to 65 years). The body mass index (BMI) and blood pressure (BP) of all participants were measured. The BMI and BP were stratified using acceptable international standards and data were analysed using descriptive statistics and Chi square. Level of significance was set at P < 0.05.

**RESULTS:** A prevalence of 47.9% and 30.8% were recorded for overweight and obesity respectively. Three (1.0%) participants were underweight while 62 (20.3%) had normal weight. Seventy-one (23.3%) of participants had hypertension (systolic blood pressure (SBP) ≥ 140 mmHg) while 161 (52.8%) had pre-hypertension (SBP of 120 - 139 mmHg) and 73 (23.9%) had normal BP (SBP < 120 mmHg). Gender and cadre were strongly significantly associated with BMI and SBP respectively (p = 0.000).

**CONCLUSIONS:** There is a high prevalence of overweight and obesity among senior staff of the Lagos State civil service. Majority of the workers were pre-hypertensive and a fair number of them were hypertensive. This study suggests that majority of the workers are at risk of cardiovascular diseases and other health related diseases. There is an urgent need for a public awareness on overweight, obesity and hypertension and appropriate measures for intervention and prevention in the studied population.

**2010** Board #56 MAY 31 8:00 AM - 9:30 AM

**Diabetes & Selected Components From Nhanes: Food Security, Ethnicity, Ses, Consumer Behavior, And Physical Activity**

M. Dot Fullwood, Pam Howard, Mi-Sook Kim, Marialice Kern, FACSM. San Francisco State University, San Francisco, CA. (Sponsor: Dr. Marialice Kern, FACSM)

(No relationships reported)

The primary aim of the present study was to examine predictabilities of socioeconomic status (SES) variables, food security, consumer behavior, and physical activity on the prevalence of type 2 diabetes (T2D) in ethnic groups. The first hypothesis was that all predictors would be negatively associated with T2D except poverty to income ratio. A second hypothesis was to examine ethnic group differences.

**METHODS:** Data from the 2007-2008 wave of NHANES was used for this study (n= 9,657 who responded to diabetes). Only selected NHANES instruments were used and select questions within the instruments were modified to capture consumer behavior, food security, and physical activity in relation to diabetes. Questions from the consumer behavior instrument were scaled and food security, physical activity, and SES markers were categorized into groups based on the literature.

**RESULTS:** Spearman's Rho correlations between all observed variables were not significant for the first hypothesis. No statistical relationship was identified at the p > 0.05 between the independent variables and the dependent variable diabetes. Ethnic group differences were found among four study variables using the Wilks Lambda at  $\Lambda = .746$ ,  $F(20, 500) = 3.95$ ,  $p < .000$ . The main effects were found in EatCook ( $F(2, 261) = 3.55$ ,  $p = .030$ ); Mexican American and Other Hispanic participants were different from the other two groups, HowOften ( $F(2, 261) = 14.43$ ,  $p = .000$ ); Mexican American and Other Hispanic non-White participants were different from non-Hispanic Black participants, LevOfEd ( $F(2, 261) = 13.91$ ,  $p = .000$ ); Mexican American and Other non-White Hispanic participants were different from the other two groups and PIR ( $F(2, 261) = 3.99$ ,  $p = .020$ ); Mexican American and Other non-White Hispanic participants were different from the other two groups.

**CONCLUSION:** Non-Hispanic Black and non-Hispanic White groups were more closely related for consumer behaviors in comparison to Mexican American and Other Hispanics. The current study's findings are in agreement with the breadth of knowledge suggesting that Mexican American and Other Hispanic, non-Hispanic White and non-Hispanic Black populations behave and operate in different manners with regard to the antecedents of T2D, this study could not demonstrate an association with the incidence of T2D.

**2011 Board #57 MAY 31 8:00 AM - 9:30 AM**  
**A Pareto Principle (20-80 Rule) Analysis of Daily Physical Activity and Diabetes Impact**

Weimo Zhu, FACSM, Elena Boiarskaia. *Univ. of Illinois, Urbana, IL*  
*(No relationships reported)*

Invented by Vilfredo Pareto, an Italian economist, the Pareto principle refers to a small number of causes is responsible for a large percentage of the effect and often a 20-percent to 80-percent ratio. While the principle has been applied to many different areas, the field of physical activity (PA) and health has not taken the advantage of this theory.

**PURPOSE:** To examine the most effective daily moderate and vigorous PA (MVPA) minutes (min) that may impact the diabetes population in the US according to the Pareto principle analysis.

**METHOD:** The National Health and Nutrition Examination Survey (NHANES) 2003-2004 data (N = 4,876, male = 2415 (mean age = 38 yr., SD = 24.32 yr.), female = 2451 (mean age = 38.3 yr., SD = 24.26 yr.)), were used for the analysis, in which diabetes were defined by subjects' responses to the question of "Doctor told you have diabetes" and plasma glucose levels using the cutoff " $\geq 110$ mg/dL". Daily MVPA min were determined using ActiGraph data (cutoff " $\geq 2020$  intensity counts per min"). Pareto diagrams, as well as corresponding statistics, were computed for both self-reported and glucose level-based diabetes rates by gender.

**RESULTS:** The impact of daily MVPA min on the US diabetes population (P = % of people who had diabetes and cumulative P) by gender (M/F) is summarized in the table below.

**CONCLUSION:** The increase in MVPA min at different levels had a nonlinear impact on the diabetes population. For males, the most effective minutes are between 30 and 60 min and for females, the most effective ones were between 20 and 30 min. Since these min were consistent to the recommended one by the US PA guideline, PA promotion, therefore, should focus on these min.

impact of daily MVPA min on the US Diabetes Population

**Alcohol Consumption Patterns And Metabolic Syndrome Criteria: 1999-2004 NHANES**

James R. Churilla, Tammie M. Johnson, Rebecca C. Curls. *University of North Florida, Jacksonville, FL*. (Sponsor: Scott Crouter, FACSM)  
*(No relationships reported)*

Several studies have examined the association between alcohol consumption patterns and metabolic syndrome (MetS) criteria, most of which used categorical dependent variables. Few studies have focused on the specific associations between alcohol consumption patterns and MetS criteria using linear modeling.

**PURPOSE:** To examine the linear relationship between alcohol consumption patterns and MetS criteria.

**METHODS:** Study sample (N=5,618) included adults, 21 years and older that participated in the 1999-2004 National Health and Nutrition Examination Survey.

**RESULTS:** The associations between moderate and above moderate alcohol consumption and MetS indicators varied by age group and indicator. The following findings control for race/ethnicity, gender, poverty level, smoking status, family history of diabetes, family history of heart disease, and physical activity level and use non-drinkers as the referent group. All reported findings have a p-value <0.05. Above moderate alcohol consumption was negatively associated with waist circumference among those in the 21-30 age group ( $\beta = -6.82$ ). Moderate alcohol consumption was negatively associated with waist circumference among those in the 31-40 and 41-50 age groups ( $\beta = -7.12$  and  $\beta = -4.27$ , respectively). Above moderate consumption was negatively associated with triglyceride levels among those in the 71-80 and 81+ age groups ( $\beta = -34.26$  and  $\beta = -49.89$ , respectively) and moderate consumption was negatively associated among those in the 41-50 and 61-70 age groups ( $\beta = -27.70$  and  $\beta = -15.96$ , respectively). Above moderate consumption was positively associated with HDL levels in all age groups ( $\beta$  range 9.44-14.98) except 81+ where it is negatively associated ( $\beta = -49.89$ ). Moderate consumption is positively associated with HDL in the age groups spanning 21-70 years ( $\beta$  range 3.86-6.03). Some statistically significant associations were observed between alcohol consumption level and blood pressure measures (systolic and diastolic), but these effects do not appear to be clinically relevant.

**CONCLUSION:** Moderate and above moderate alcohol consumption may favorable impact metabolic health risk, however, these finding need to be interpreted with caution.

**2013 Board #59 MAY 31 8:00 AM - 9:30 AM**  
**Effects of Kettlebell Training on Metabolic Syndrome in Women**

Karen I. Moreno, Peggy A. Plato. *San Jose State University, San Jose, CA*. (Sponsor: Craig Cisar, FACSM)  
*(No relationships reported)*

Metabolic syndrome (MetS) is a compilation of interrelated risk factors with the potential to significantly increase incidence of type 2 diabetes and cardiovascular disease. The prevalence of MetS is growing, with more women affected than men. Decreased physical activity and increased adiposity are contributing factors. Data support physical activity, primarily aerobic exercise, in the prevention of MetS. However, the prevalence of MetS in women increases with age, even among women with high cardiorespiratory fitness (Farrell et al., 2004). Thus, age-related physiological changes seem to result in unfavorable metabolic repercussions. Jurca et al. (2004) reported an independent and inverse relationship between muscular fitness and prevalence of MetS in men. The effect of increasing muscular fitness on MetS has not been explored in women.

**PURPOSE:** To examine the effects of a community-based, kettlebell resistance training program on the core components of MetS in women.

**METHODS:** Six physically inactive women ( $48.8 \pm 2.9$  years) with a BMI of  $31.8 \pm 2.4$  kg/m<sup>2</sup> and meeting at least two other components of MetS completed the training program. Strength and aerobic fitness, body composition, and risk factors for MetS were measured before and after the twice weekly, 10 week kettlebell program.

**RESULTS:** Upper and lower body muscular fitness increased 42% and 10%, respectively. Aerobic fitness increased 12%. Before training, fasting glucose was  $101.7 \pm 2.7$  mg/dl compared to  $94.4 \pm 1.3$  mg/dl after training. Body weight decreased 1 kg, but body fat decreased 3.8 kg ( $43.3 \pm 3.1\%$  pre vs.  $39.6 \pm 2.7\%$  post). Waist circumference decreased  $2.1 \pm 1.9$  cm. Systolic and diastolic pressures decreased  $1.8 \pm 2.4$  and  $1.2 \pm 2.1$  mm Hg, respectively. The training program did not favorably change triglycerides or HDL-C. Compliance was high; all participants completed 90-100% of the exercise sessions.

**CONCLUSION:** Although group changes were not statistically significant, individual improvements were encouraging, particularly in fasting glucose and body fat, and suggest that kettlebell training has potential for improving components of MetS in middle-aged women. Response to the training program was positive, indicating potential for kettlebell training to be effective within a community-based program.

**Supervised Exercise Interventions for Women at Risk for Heart Disease: Relationship Between Compliance and Outcomes**

Megan Donnelly, Scott S. Billecke, Pamela Marcovitz, Elizabeth Brown, Barry Franklin, FACSM. *William Beaumont Hospital, Royal Oak, MI.*  
(No relationships reported)

**BACKGROUND:** Structured exercise programs improve cardiac risk factors and quality of life (QOL) in men with and without cardiovascular disease (CVD). Few data are available regarding the responses and compliance to exercise interventions among women, and what quantity of exercise is necessary to elicit beneficial outcomes.

**PURPOSE:** To determine the cardiovascular and QOL benefits of a structured exercise program for women, with specific reference to the modulating impact of exercise compliance and/or concomitant dietary changes.

**METHODS:** Women age >18 years without known CVD but with  $\geq 1$  coronary risk factors were enrolled in a 6-month structured exercise program. Relationships between compliance (percent of weeks achieving target attendance,  $\geq 3$  times/wk for 30 min/session) and changes in anthropometric measures (weight, BMI, waist circumference), cardiorespiratory fitness (serial BP, heart rate, rating of perceived exertion during standardized submaximal exercise workload) and QOL (depression [PHQ-9], dietary fat intake [Fat Screener], self-reported physical activity [Duke Activity Status Index], sleepiness [Epworth]) were evaluated.

**RESULTS:** The program enrolled 117 women whose mean  $\pm$  SD age, weight and BMI were  $57 \pm 9$  years,  $202 \pm 48$  pounds and  $35 \pm 8$  kg/m<sup>2</sup>, respectively. Compliance (n = 49) was  $63 \pm 19\%$  and participants demonstrated significant improvements in all parameters tested after 6 months (P < 0.0001). Those in the top compliance tertile (mean  $82 \pm 19\%$ ,  $130 \pm 22$  min/wk) experienced significant reductions in weight, BMI and systolic BP and heart rate during standard submaximal exercise workloads (P < 0.05) compared with the middle tertile ( $63 \pm 6\%$ ,  $100 \pm 19$  min/wk). No such improvements were observed when comparing top and bottom ( $42 \pm 12\%$ ,  $82 \pm 20$  min/wk) tertiles, possibly due to the latter demonstrating significantly greater dietary fat restriction (Fat Screener  $8 \pm 7$  vs  $3 \pm 5$ ; P = 0.038). Only reductions in exercise systolic BP were significantly associated with compliance (Spearman correlation, r = 0.34, P = 0.026).

**CONCLUSIONS:** Women at risk for CVD demonstrated improvements in anthropometric measures, cardiorespiratory fitness and QOL following a 6-month exercise intervention. Improvements were influenced by exercise compliance but may have been modulated by reduced dietary fat intake.

**2015** Board #61 MAY 31 8:00 AM - 9:30 AM

**The Effect Of Weight Loss And Exercise On Cardiovascular Structure And Function In Class II And III Obese Women**

Steven D. Verba<sup>1</sup>, Blake D. Justice<sup>2</sup>, Lori Portzer<sup>3</sup>, Renee Ingel<sup>3</sup>, John M. Jakicic, FACSM<sup>3</sup>. <sup>1</sup>*Slippery Rock University, Slippery Rock, PA.* <sup>2</sup>*Pfeiffer University, Misenheimer, NC.* <sup>3</sup>*University of Pittsburgh, Pittsburgh, PA.*  
(No relationships reported)

**PURPOSE:** The purpose of this study was to examine effect of diet-induced or diet plus exercise-induced weight loss on cardiac structure and function in Class II and III obese women.

**METHODS:** 24 healthy, sedentary, obese women (BMI: 35.0 to <45 kg/m<sup>2</sup>; Age: 45.4  $\pm$  6.9 yrs.) underwent a 12-week diet and exercise intervention: caloric restriction alone (DIET), caloric restriction plus aerobic training (DIET+AT), and caloric restriction plus resistance training (DIET+RT). Subjects reported to UPMC Presbyterian Hospital to undergo Cardiac MRI to measure left ventricular mass (LVM), myocardial fibrosis (Ve), end diastolic volume (EDV), end systolic volume (ESV), and ejection fraction (EF).

**RESULTS:** 18 out of 24 subjects completed the intervention. 16 out of 24 completed 12 week Cardiac MRI at UPMC Presbyterian. Body weight significantly decreased across all treatment groups (~4.5kg lost, p=0.001). Subjects in the DIET group had significantly greater reduction in LVM (-7.2  $\pm$  3.9g) than the DIET+AT (2.3  $\pm$  4.7g) and DIET+RT (-0.2  $\pm$  3.5g) groups (p=0.007). Subjects in the DIET+RT group had a significantly higher Ve score at 12 weeks (27.9  $\pm$  1.5%) than subjects in the DIET+AT (26.5  $\pm$  1.4%) and DIET (24.0  $\pm$  0.8%) groups (p=0.010). There were no significant changes in EDV, ESV, or EF at 12 weeks between groups (p>0.159).

**CONCLUSIONS:** In conclusion, only LVM in the DIET group and Ve in the DIET+RT showed statistical changes from baseline. Further investigations into the effect of weight loss and exercise on cardiac structure and function in Class II and III obese adults are warranted to expand upon the results of this investigation.

**2016** Board #62 MAY 31 8:00 AM - 9:30 AM

**Chronic Physical Training Modulates Inflammatory Response In Healthy Adults Rats**

Luciana -, Nishimura, João Pedroso, Emidio Matos-Neto, Michele Trindade, Julio Tirapegui. *University of São Paulo, São Paulo, Brazil.*  
(No relationships reported)

Several studies have shown the effect of exercise in reducing the risk of developing chronic degenerative diseases and cardiovascular diseases. Although it is unclear in the literature, several authors suggest that this benefit is due to changes in the inflammatory responses caused by exercise.

**PURPOSE:** Thus, the objective of this study was to investigate the effect of endurance exercise training on inflammatory proteins.

**METHODS:** Fourteen (14) adult male Sprague Dawley rats were assigned into two groups: sedentary (SED) (n = 6) and trained group (Training) (n = 8), which was subjected to 1-hour training per day on a treadmill for 8 weeks, 50 -70% VO2max. Cytokine levels were measured by multiplex immunoassay using rat serum adipokine (panel kit 7 LINCplex) for simultaneous measurement of TNF- $\alpha$ , IL-1, IL-6, MCP1 and leptin, in the automatic Lincplex 200.

**RESULTS:** Trained group showed a higher concentration of IL-6 (880.36 276.09 pg / ml and 194.31 76.97 pg / ml) and IL-1alpha (203.47 49.16 pg / ml, 31, 29 4.7 pg / ml) compared to SED group (p < 0.05). There was no statistically significant difference on MCP1 and TNF-alpha levels between groups. We observed a higher leptin concentration in SED group (17.03 4.46 ng / ml) compared to trained group (6.44 1.06 ng / ml) (p < 0.05).

**CONCLUSION:** The results suggest that eight weeks of aerobic training was able to alter the production of some inflammatory proteins, exerting anti-inflammatory effects, and can provide several metabolic and hormonal improvements in different tissues, thus providing a powerful tool to control and / or reduce the risk of developing chronic degenerative disorders. Financial support: FAPESP and CNPq.

**2017** Board #63 MAY 31 8:00 AM - 9:30 AM

**Associations of Current Activity Level and Foot Peripheral Neuropathy (PN): The Framingham Foot Study (FFS)**

Jody L. Riskowski<sup>1</sup>, Alyssa B. Dufour<sup>2</sup>, Hylton B. Menz<sup>3</sup>, Virginia A. Casey<sup>4</sup>, Thomas J. Hagedorn<sup>4</sup>, Marian T. Hannan<sup>1</sup>. <sup>1</sup>*Institute for Aging Research, Harvard Medical School, Boston, MA.* <sup>2</sup>*Institute for Aging Research, Boston University, Boston, MA.* <sup>3</sup>*Institute for Aging Research, Harvard Medical School La Trobe University, Bundoora, Australia.* <sup>4</sup>*Institute for Aging Research, Boston, MA.*  
(No relationships reported)

Foot PN is often associated with diabetes, but many older adults have idiopathic PN, with age the main risk factor.

**PURPOSE:** To determine associations between current activity level and foot PN in the FFS by diabetes status.

**METHODS:** FFS members evaluated between 2002-08 for current activity level, foot PN and diabetes status were included. Individuals classified as having diabetes if fasting glucose  $\geq 126$  mg/dL or if taking oral hypoglycemic agent or insulin. A 128-Hz tuning fork assessed PN at: 1<sup>st</sup> and 5<sup>th</sup> metatarsal head and medial and lateral malleolus. Loss of vibrotactile sense at two or more sites on a foot defined foot PN. Current activity level computed by multiplying metabolic equivalent-hour (MET-hr) by self-reported hours sleeping (MET-hr: 0.9), sitting (1.0) and participating in light (3.0), moderate (4.5) and heavy (7.0) activity in a typical day. By tertile of METs, participants categorized as: high, low or moderate (referent) activity. Crude and adjusted (age, sex, body mass index [BMI], smoking, depression) logistic regression evaluated current activity level and foot PN associations.

**RESULTS:** There were 2090 FFS members included (Table 1). In individuals without diabetes, foot PN decreased 41% and increased 51% in the high and low activity groups, respectively, relative to the referent. With adjustment, associations persisted with wider confidence intervals. No significant associations noted between activity and foot PN in those with diabetes.

Table 1. Demographic information (reported as mean  $\pm$  standard deviation, unless otherwise noted) and odds ratios (OR) with 95% confidence intervals (95% CI) for current activity level and foot PN

|                        | FFS<br>(N=2090)     | No Diabetes<br>(N=1948) | Diabetes<br>(N=142) |

**A Prospective Population Study Of Resting Heart Rate And Peak Oxygen Uptake (the Hunt Study, Norway)**

Javaid Nauman<sup>1</sup>, Stian Thoresen Aspenes<sup>1</sup>, Tom Ivar Lund Nilsen<sup>2</sup>, Lars Johan Vatten<sup>3</sup>, Ulrik Wisløff<sup>1</sup>. <sup>1</sup>The K. G. Jebsen Center of Exercise in Medicine, Trondheim, Norway. <sup>2</sup>The human movement science programme, NTNU, Trondheim, Norway. <sup>3</sup>The K. G. Jebsen Center of Exercise in Medicine, and Department of Public Health, Faculty of Medicine, Trondheim, Norway.

(No relationships reported)

**PURPOSE:** Resting heart rate (RHR) and peak oxygen uptake ( $VO_{2peak}$ ) are strong and independent predictors of cardiovascular morbidity and mortality. Physical activity (PA) could modify the association of RHR with  $VO_{2peak}$ . However, the prospective association of RHR with  $VO_{2peak}$ , and combined effects of RHR and self-reported PA on later  $VO_{2peak}$  has not been assessed in population studies.

**METHODS:** In a prospective population study of 807 men and 810 women free from cardiovascular disease both at baseline (1984-86) and follow-up 23 years later, RHR was recorded at both occasions, and  $VO_{2peak}$  was measured by ergospirometry at follow-up. We used Generalized Linear Models to assess the association of baseline RHR with  $VO_{2peak}$ , and to study combined effects of baseline RHR and self-reported PA on  $VO_{2peak}$  at follow-up.

**RESULTS:** There was an inverse association of RHR at baseline with  $VO_{2peak}$  ( $p < 0.01$ ). Men and women with baseline RHR of 80 bpm or higher had 4.6 mL $\cdot$ kg<sup>-1</sup> $\cdot$ min<sup>-1</sup> (95% confidence interval [CI], 2.8 to 6.3) and 1.4 mL $\cdot$ kg<sup>-1</sup> $\cdot$ min<sup>-1</sup> (95% CI, 0.4 to 3.1) lower  $VO_{2peak}$  at follow-up compared to men and women with RHR below 60 bpm at baseline. Participants with relatively high RHR and high PA at baseline had a  $VO_{2peak}$  (0.7 mL $\cdot$ kg<sup>-1</sup> $\cdot$ min<sup>-1</sup>; 95% CI, -3.3 to 4.8) that was similar to inactive people with relatively low RHR (reference group). A combination of high PA and low RHR yielded highest  $VO_{2peak}$ .

**CONCLUSION:** A low RHR at baseline was a strong predictor of high  $VO_{2peak}$  23 years later. The results suggest that high levels of PA may compensate for the lower  $VO_{2peak}$  associated with a high RHR.

**Use of Heart Rate Index to Predict Maximal Oxygen Utilization Before and After Exercise Therapy in Pediatric Obese Patients**

Yvette M. Gerdes, Wayne Mays, Michelle Amos, Sandra Knecht, Randal Claytor, Timothy Knilans. *Cincinnati Children's Hospital, Cincinnati, OH.*

(No relationships reported)

**PURPOSE:** To evaluate the utility of heart rate index (HRindex) as a predictor of maximal oxygen utilization in pediatric obesity patients.

**METHODS:** We evaluated 299 pediatric obesity patients (mean age 12.0  $\pm$  2.8 years, 109 males) with a modified Balke treadmill protocol before and after a 16 week exercise program. HRindex was calculated by dividing the maximal heart rate by the sitting heart rate at rest. Predicted maximal METS (PMMETS) was generated by the line equation: 6 times HRindex minus 5.

**RESULTS:** There was a significant decrease in weight (88.4  $\pm$  28.6 vs 86.3  $\pm$  27.9 kilograms,  $p < 0.001$ ), a significant increase in absolute (MVO2) and indexed (MIVO2) maximal oxygen consumption, (2224  $\pm$  605 vs 2476  $\pm$  647 ml/min,  $p < 0.001$ , 26.0  $\pm$  4.7 vs 27.6  $\pm$  5.4 ml/kg/min,  $p < 0.001$ ) and a significant increase in maximal METS (MMETS) and energy expenditure (EE) (7.4  $\pm$  1.7 vs 8.5  $\pm$  1.6  $p < 0.0001$ , 25.0  $\pm$  10 vs 27.6  $\pm$  11.0 kcal,  $p < 0.001$ ) after exercise therapy. There was a significant correlation between MMETS and PMMETS before and after exercise therapy (7.4  $\pm$  1.4 vs 7.8  $\pm$  2.0  $r = 0.29$ ,  $p < 0.001$ , 8.5  $\pm$  1.6 vs 8.1  $\pm$  2.1  $r = 0.22$ ,  $p < 0.01$ ). However, METS and PMMETS were significantly different ( $p < 0.01$ ). Before and after exercise therapy HRindex was significantly correlated to MVO2 ( $r = 0.13$ ,  $p < 0.01$  and  $r = 0.12$ ,  $p < 0.01$ ), MIVO2 ( $r = 0.29$ ,  $p < 0.001$  and  $r = 0.22$ ,  $p < 0.001$ ) and MMETS ( $r = 0.29$ ,  $p < 0.001$  and  $r = 0.22$ ,  $p < 0.001$ ). HRindex was not significantly correlated with EE before and after exercise therapy.

**DISCUSSION:** There is a significant correlation between HR index and MVO2, MIVO2 and MMETS before and after exercise therapy. However, the correlation is weak and provides little

predictive value for MVO<sub>2</sub>, MIVO<sub>2</sub> and MMETS. This lack of predictive robustness is demonstrated by the significant difference seen in MMETS and PMMETS before and after exercise therapy.

**CONCLUSION:** The predictive power of the heart rate index is limited in pediatric obesity patients. Future research should focus on a multivariable predictive model that may include heart rate index.

---

**2020** Board #66 MAY 31 9:00 AM - 10:30 AM

### **Obesity Paradox and Cardiorespiratory Fitness in Women from the Veterans Exercise Testing Study (VETS)**

Ricardo B. Oliveira<sup>1</sup>, Paul A. McAuley<sup>2</sup>, Peter F. Kokkinos<sup>3</sup>, Paulo T.V. Farinatti<sup>1</sup>, Jonathan N. Myers, FACSM<sup>4</sup>. <sup>1</sup>Rio de Janeiro State University, Rio de Janeiro, Brazil. <sup>2</sup>Winston-Salem State Univ, Winston-Salem, NC. <sup>3</sup>VA Washington/Georgetown Univ, Northwest Washington, WA. <sup>4</sup>VA Palo Alto/Stanford Univ, Palo Alto, CA.

(No relationships reported)

Body mass index (BMI) has been inversely related to mortality in men from the Veterans Exercise Testing Study (VETS). Whether this “obesity paradox” occurs in women and how this is modified by cardiorespiratory fitness (CRF) has not been fully explored.

**PURPOSE:** To evaluate the relation of CRF and obesity to mortality in women.

**METHODS:** Subjects were 615 female veterans aged 20 to 83 (mean 53±12) years referred for exercise testing for clinical reasons at the Veterans Affairs Medical Centers in Washington D.C. and Palo Alto, CA during 1986-2008. Patients were grouped by BMI (kg/m<sup>2</sup>) according to three predetermined categories: normal weight (18.5-24.9), overweight (25.0-29.9) and obese (>=30.0). CRF was quantified as metabolic equivalents (METs) using final treadmill work rate and was categorized in tertiles. Associations of CRF (unfit - lowest third; fit - upper two-thirds) and BMI category with all-cause mortality were assessed by Kaplan Meier survival analysis and Cox proportional multivariate analysis adjusted for age, presence of diabetes, hypertension, smoking, and cardiovascular disease.

**RESULTS:** During a mean follow-up of 7.1 ± 4.9 years, a total of 55 patients (8.9%) died. Compared to the upper tertile of CRF, hazard ratios (HR) (95% confidence intervals [CI]) were 1.15 (0.47 - 2.80) and 2.31 (1.05 - 5.07) for middle and lowest tertiles, respectively. Survival rates did not differ significantly across BMI categories. In joint analysis, mortality risk was higher only for unfit-normal weight women (HR [95% CI] 4.48 [1.79-11.2]) (figure).

**CONCLUSIONS:** Although BMI was not predictive of mortality in this population of female veterans, our findings indicate that CRF is a more important predictor of outcomes than obesity in women.

### **Underwater Treadmill Training, Aerobic Fitness, and Leg Strength in Adults with Type 2 Diabetes**

Ryan T. Conners, Christina L. Aquila, Don W. Morgan, FACSM, Jennifer L. Caputo. Middle Tennessee State University, Murfreesboro, TN.

(No relationships reported)

Persons with Type 2 diabetes are often overweight and may experience accompanying health conditions such as diminished cardiovascular health, lower skeletal muscle strength, and osteoarthritis. While aquatic therapy enables endurance and resistance exercise to be performed simultaneously while generating reduced ground reaction forces, relatively little is known concerning the health benefits of water walking in this patient population.

**PURPOSE:** To document cardiovascular and strength adaptations in adults with Type 2 diabetes following an 8-week program of underwater treadmill training (UTT).

**METHODS:** Seven adults with physician-diagnosed Type 2 diabetes (age = 55 ± 8 yrs) completed 8 weeks of UTT. Before and after UTT, measures of seated resting heart rate (Polar heart rate monitor), estimated VO<sub>2max</sub> (single-stage, land-based treadmill protocol), and concentric peak torque of the dominant leg hamstrings and quadriceps at 60°/sec and 90°/sec (Biodex System 3) were obtained. During UTT, participants completed three training sessions per week, with each session featuring three walking bouts separated by 4 to 5 minutes of rest. Starting at a relative intensity of 40% of heart rate reserve (HRR), walking speed was gradually increased so that participants were exercising at 70% of HRR by the end of the training program. Likewise, the duration of each walking bout was systematically increased from 10 to 20 minutes as training progressed. Water height was maintained at 10 cm below the xyphoid process throughout the study.

**RESULTS:** Paired t-tests revealed that resting heart rate was lower (83 ± 14 vs. 75 ± 13 bpm) and estimated VO<sub>2max</sub> was higher (28.8 ± 3.9 vs. 31.0 ± 4.0 ml/kg/min) following UTT (p < .05). Moreover, peak torque of the hamstrings at 60°/sec (58.0 ± 21.0 vs. 67.0 ± 15.2 ft-lbs) and 90°/sec (48.1 ± 19.3 vs. 56.4 ± 13.3 ft-lbs), p < .05) was greater after training.

**CONCLUSION:** Underwater treadmill training featuring progressive increments in walking speed and duration appears to be a safe and effective training modality to improve cardiovascular fitness and leg strength in adults with Type 2 diabetes.

### **Cardiopulmonary Exercise Testing Predicts Hospital Length of Stay in Patients Undergoing Gastric Bypass Surgery**

Philip J. Hennis<sup>1</sup>, Paula M. Meale<sup>1</sup>, Rachel A. Hurst<sup>2</sup>, Alasdair F. O'Doherty<sup>1</sup>, James M. Otto<sup>1</sup>, Hugh E. Montgomery<sup>1</sup>, Martin Kuper<sup>3</sup>, Nick Harper<sup>3</sup>, Pratik Sufi<sup>3</sup>, Dugal Heath<sup>3</sup>, Michael P. W. Grocott<sup>4</sup>. <sup>1</sup>University College London, London, United Kingdom. <sup>2</sup>University of Hertfordshire, Hertfordshire, United Kingdom.

<sup>3</sup>Whittington Hospital NHS Trust, London, United Kingdom. <sup>4</sup>Southampton University Hospitals NHS Trust, Southampton, United Kingdom.

(No relationships reported)

Exertional peak oxygen consumption (Peak VO<sub>2</sub>) and anaerobic threshold (AT), determined by Cardiopulmonary Exercise Testing (CPET), can identify individuals at increased perioperative risk from non-cardiac surgery. In one study, this appears true for treadmill exercise-derived peak VO<sub>2</sub> in patients undergoing gastric bypass. We sought to confirm these findings, and to extend them to other exercise physiological variables using electronically-braked bicycle ergometry.

**PURPOSE:** To determine whether pre-operative physiological variables derived from CPET are associated with increased postoperative length of stay (LOS) following gastric bypass surgery.

**METHODS:** The study was approved by the hospital's audit department. All patients who completed CPET and underwent elective gastric bypass surgery at the Whittington Hospital NHS Trust between 01/09/09 - 25/02/11 were included in analysis. Subject age, sex, height, weight and Revised Cardiac Risk Index (RCRI) were recorded. From CPET, peak VO<sub>2</sub>, AT, and ventilatory equivalent for CO<sub>2</sub> (VE/VCO<sub>2</sub>) were derived. The primary outcome variables were hospital LOS (LOS) and critical care unit (CCU) LOS. CPET and non-CPET variables were separated according to postoperative LOS duration (LOS ≤ 3 vs LOS > 3, CCU LOS ≤ 1 vs CCU > 1) and compared using independent *t* tests. The capacity of CPET markers to predict LOS was determined using receiver operating characteristic (ROC) curves.

**RESULTS:** 106 patients (mean weight = 126 kg) were included in the study, 83 of whom were admitted to a CCU following surgery. Median LOS was 3 days and median CCU LOS was 1 day. AT was lower in patients with a LOS > 3 days compared to LOS ≤ 3 days (10.4 ± 1.4 vs 11.3 ± 1.8 ml·kg<sup>-1</sup>·min<sup>-1</sup>, P = 0.023). ROC curve analysis identified AT as a significant predictor of LOS > 3 day (AUC 0.640, P = 0.030), with an optimal AT to predict increased LOS of 11.4 ml·kg<sup>-1</sup>·min<sup>-1</sup> (sensitivity = 76%, specificity = 53%). AT was not different between those with a CCU LOS > 1 and those with a CCU LOS ≤ 1 day.

Peak VO<sub>2</sub>, VE/VCO<sub>2</sub>, weight, BMI and RCRI were not different between patients with a LOS ≤ 3 days compared to those with LOS > 3 days or between those with a CCU LOS ≤ 1 day compared to > 1 day.

**CONCLUSION:** In patients undergoing gastric bypass surgery, CPET-derived AT is predictive of prolonged hospital LOS.

2023 Board #69 MAY 31 9:00 AM - 10:30 AM

**Influence Of Measurement Location Of Visceral Adiposity On Hdl Cholesterol In Obese Japanese Men**

Rina So<sup>1</sup>, Takehiko Tsujimoto<sup>1</sup>, Miki Eto<sup>1</sup>, Tomoaki Matsuo<sup>1</sup>, Hiroyuki Sasai<sup>2</sup>, Kiyoji Tanaka, FACSM<sup>1</sup>. <sup>1</sup>University of Tsukuba, Tsukuba, Japan. <sup>2</sup>National Institutes of Health, Bethesda, MD.

(No relationships reported)

**BACKGROUND:** Obesity accounts for the majority of cases of low HDL cholesterol (HDL-C) levels and accumulation of visceral adipose tissue (VAT) at L4-L5 is frequently associated with a concentration of HDL-C. However, previous studies have indicated that the commonly used L4-L5 image level used to estimate VAT may not be the best level. Furthermore, it seems clear that the L4-L5 image of VAT may not be an appropriate level for assessing obesity-related health risks. Because VAT and HDL-C are important risk factors for cardiovascular disease in obese men, it is necessary to clarify an optimal measurement level of VAT as related to HDL-C.

**PURPOSE:** To determine the best image levels for VAT in relation to HDL-C and changes in their relationships after exercise training.

**METHODS:** Twenty-five middle-aged Japanese obese men (age: 45.0 ± 10.8 yr, BMI: 29.8 ± 4.3 kg/m<sup>2</sup>) participated in a 12-week (3 times/week, 90 min/each) exercise intervention. Body composition, VAT areas, VAT volume, blood samples and VO<sub>2</sub>max were obtained before and after the intervention. VAT areas and volume were determined by continuous T1-weighted abdominal magnetic resonance images from the ninth thoracic vertebra (T9) to the first sacral vertebra (S1) with a 1.5-T system.

**RESULTS:** With -1.8 ± 3.6 kg of significant weight loss, there were significant reductions in VAT (area at L4-L5: -20.6 ± 34.2 cm<sup>2</sup>, volume: -456 ± 557 cm<sup>3</sup>) after the exercise intervention. VO<sub>2</sub>max (7.6 ± 6.6 ml/kg/min) and HDL-C (4.5 ± 6.2 mg/dl) significantly increased. At baseline, VAT areas at 12-17 cm above L4-L5 showed significant correlations with HDL-C (r = 0.41 - 0.44, P < 0.05), while measurement at L4-L5 was not correlated (r = 0.01, P = 0.26). No correlations were found between changes in VAT areas and changes in HDL-C.

**CONCLUSION:** Our data show that measurement level of VAT may have an influence on the association with HDL-C. Measurement position at L4-L5 may not be the best for the prediction of obesity-related health risk. It is unclear if increases in HDL-C are associated with reduction in regional VAT.

2024 Board #70 MAY 31 9:00 AM - 10:30 AM

**Insulin Pump is Associated With Less Post-exercise Hyperglycemia Than Injected Insulin in Type 1 Diabetes**

Jane Yardley<sup>1</sup>, Katherine E. Iscoe<sup>2</sup>, Ronald J. Sigal<sup>3</sup>, Glen P. Kenny<sup>1</sup>, Michael C. Riddell<sup>4</sup>. <sup>1</sup>University of Ottawa, Ottawa, ON, Canada. <sup>2</sup>University of Western Australia, Perth, Australia. <sup>3</sup>University of Calgary, Calgary, AB, Canada. <sup>4</sup>York University, Toronto, ON, Canada.

(No relationships reported)

Previous studies have found little or no impact of aerobic exercise training on blood glucose control as measured by hemoglobin A<sub>1c</sub> (HbA<sub>1c</sub>) in people with type 1 diabetes (T1D). This failure to improve metabolic control may be due to frequent occurrence of exercise-associated hypo and hyperglycemia. The vast majority of these studies, however, either did not account for the method of insulin delivery, or were conducted before the use of continuous subcutaneous insulin infusion (CSII) became more frequent among individuals with T1D.

**PURPOSE:** To examine whether the blood glucose response to aerobic exercise differs between T1D individuals using CSII versus those receiving insulin by multiple daily injection (MDI).

**METHODS:** 19 active T1D individuals (10 CSII, 9 MDI) performed 45 minutes of aerobic exercise (either cycling or treadmill running) at 65% of their pre-determined VO<sub>2peak</sub>. Interstitial glucose levels were monitored during and after exercise by continuous glucose monitoring (CGM) in a double-blinded fashion. Data are reported as mean ± SD.

**RESULTS:** HbA<sub>1c</sub> (CSII=7.3±1.1; MDI=7.2±1.2, %), VO<sub>2peak</sub> (CSII=48±8; MDI=46±10, ml·kg<sup>-1</sup>·min<sup>-1</sup>) and pre exercise interstitial glucose (CSII=8.9±2.9; MDI=8.4±3.5, mmol/L) did not differ between groups. Although glucose levels decreased similarly in both groups during exercise (CSII=3.0±2.0; MDI= 3.3±2.7, mmol/L), post-exercise increases in glucose concentration were significantly greater in MDI than in CSII from 90 minutes post-exercise (CSII=0.7±2.5, MDI=2.0±2.2 mmol/L, p=0.037) to 270 minutes post-exercise (CSII=0.8±1.3, MDI=4.9±4.8 mmol/L, p=0.020) resulting in hyperglycemia (interstitial glucose > 10 mmol/L) in 6 out of 9 MDI participants.

**CONCLUSION:** The use of CSII is associated with a lower risk of post-exercise hyperglycemia as compared to MDI in active individuals with T1D. Future exercise intervention strategies in this population should consider insulin delivery methods in their design and analysis.

2025 Board #71 MAY 31 9:00 AM - 10:30 AM

**Relationship Between Body Composition and Oxygen Uptake Efficiency Slope in Heart Failure Patients**

Kelly Allsup<sup>1</sup>, Alexandra Zavin<sup>1</sup>, Ross Arena, FACSM<sup>2</sup>, Karla Daniels<sup>1</sup>, Samuel Davis<sup>1</sup>, Jacob Joseph<sup>1</sup>, Stewart Lecker<sup>3</sup>, Antonio Lazzari<sup>1</sup>, Daniel E. Forman<sup>1</sup>. <sup>1</sup>VA Boston Healthcare System, Boston, MA. <sup>2</sup>University of New Mexico, Albuquerque, NM. <sup>3</sup>Harvard Medical School, Boston, MA. (Sponsor: Ross Arena, FACSM)

(No relationships reported)

**INTRODUCTION:** Functional capacity is often diminished among patients with chronic heart failure (HF). Differences in body composition may underlie these functional consequences. Standard performance measures for HF patients provide little insight regarding body composition.

**PURPOSE:** To study functional capacity in relation to body composition in HF patients, with particular focus on a novel cardiopulmonary (CPX) index, Oxygen Uptake Efficiency Slope (OUES). We compared CPX indices (OUES, peak oxygen consumption [VO<sub>2</sub>], and ventilatory efficiency [VE/VCO<sub>2</sub>] slope) in HF patients and controls and studied the relative impact of lean vs. fat body tissue.

**METHODS:** 68 male subjects (mean age 66.2±9.7 years), 30 euvolemic, systolic HF patients (LVEF≤40%) and 38 age-matched controls. CPX was used to assess functional capacity. Dual-energy x-ray absorptiometry (DXA) was used to assess body composition (differences in lean and fat mass, and differences in distributions).

**RESULTS:** HF patients had relatively reduced aerobic capacity (Table 1a). Body composition was similar between groups (Table 1b). While peak VO<sub>2</sub> and VE/VCO<sub>2</sub> showed no associations with body composition, OUES showed significant correlations (Table 1c).

Table 1: Results

| Table 1a: Comparison of CPX Variables (expressed as mean±SD)        |            |          |           |          |              |          |
|---|------------|----------|-----------|----------|--------------|----------|
|   | HF         |          | Controls  |          | Significance |          |

| Legs Lean Mass  | 0.65***    | 0.69***  | -0.12     | 0.22     | -0.2         | 0.14     |
| Total Fat   | 0.67***    | 0.19     | -0.19     | -0.23    | -0.22        | 0.01     |
| Legs Fat  | 0.62***    | 0.14     | -0.21     | -0.12    | -0.18        | 0.22     |

R-values are indicated. \* p<0.05, \*\*p<0.01, \*\*\* p<0.001

**CONCLUSION:** OUES enhances CPX assessment as it provides perspective on performance capacity as well as body composition. OUES may better reflect peripheral contributors to functional capacity than standard CPX measures. Further analysis of OUES is warranted as it augments CPX assessment with unique diagnostic and management information.

**2026** Board #72 MAY 31 9:00 AM - 10:30 AM

**Effects of Aerobic Exercise on Serum Sex Hormone Binding Globulin and Metabolic Syndrome Factors in Obese Postmenopausal Women**

Do-Yeon Kim<sup>1</sup>, Jong-Won Kim<sup>2</sup>, Jeong-Ah Lee<sup>3</sup>, Chan-Ho Park<sup>4</sup>, Byung-Kon Yoon<sup>4</sup>. <sup>1</sup>Pusan National University, Kyungsoong University, Busan, Korea, Republic of. <sup>2</sup>Pusan National University, Busan, Korea, Republic of. <sup>3</sup>Kyungsoong University, Busan, Korea, Republic of. <sup>4</sup>Donggeui University, Busan, Korea, Republic of.

(No relationships reported)

Regular and continuous aerobic exercise is one of the most important nonpharmacologic methods in improving serum lipid concentrations, sex hormone-binding globulin (SHBG), and metabolic syndrome factors.

**PURPOSE:** We investigated the influence of aerobic exercise on SHBG and metabolic syndrome factors in obese postmenopausal Korean women.

**METHODS:** Twenty-six healthy postmenopausal, women aged 53.46 ± 2.74 years and with over 32 % body fat, were randomly assigned to an aerobic exercise group (EX; n = 13) or to a "non-exercise" control (Con; n = 13) group. The variables of body composition, visceral fat area, serum SHBG, lipid profiles, insulin levels, HOMA-IR, and metabolic syndrome factors were measured in all the participants before and after the 16-week study.

**RESULTS:** Post-training body weight and visceral fat area ( $p<0.05$ ), TC, glucose, and insulin levels ( $p<0.01$ ), and HOMA-IR ( $p<0.001$ ) decreased, whereas SHBG ( $p<0.001$ ) and metabolic syndrome factors ( $p<0.01$ ) increased in the exercise group but not in the control group. SHBG levels also showed a significant positive correlation with HDL-C and significant negative correlations with glucose, fat mass, and %BF ( $p<0.05$ ).

**CONCLUSION:** Our findings indicate that aerobic exercise improves body composition, SHBG, insulin levels, and metabolic syndrome factors. These findings suggest that in obese postmenopausal Korean women, 16 weeks of aerobic exercise is effective for preventing the metabolic syndrome caused by obesity.

**2027** Board #73 MAY 31 9:00 AM - 10:30 AM

**The Effect of Different Exercise Intensities on Blood Profiles and Body Composition for Type II Diabetes**

Byung-Kon Yoon, Se-Jung Park, Hye-Rym Cha. Dong-Eui University, Busan, Korea, Republic of.

(No relationships reported)

**PURPOSE:** To investigate the effect of different exercise intensities on blood profiles and body composition for type II diabetes.

**METHODS:** 40 type II diabetes patients (fasting glucose  $\geq 126$  mg/dl or 2-h glucose  $\geq 200$  mg/dl) with overweight (BMI  $> 25$  kg/m<sup>2</sup>) were divided into four groups (control, 40 of HRR; low intensity exercise, 60% of HRR; middle intensity exercise, 80 % of HRR; high intensity exercise group). The exercise groups participated in 60 min exercise program 3times a week for 12 weeks under the exercise director.

**RESULTS:** BMI was significantly decreased in middle and high intensity exercise groups. However, there was no different in control and low intensity exercise group. Waist circumference was significantly decreased in three exercise groups. The % of body fat was only decreased in high intensity exercise group. VO2max was higher in middle and high intensity exercise groups as compared with pre and post exercise program. There was no different in HbA1c. However, middle and high intensity exercise groups improved in HDL-C, TC/HDL-C ratio, triglycerides, fasting glucose, and HOMA-IR. The total cholesterol was significantly decreased in high intensity exercise group.

**CONCLUSION:** Over 60% of HRR intensity exercise may have positive effect on type II diabetes.

**2028** Board #74 MAY 31 9:00 AM - 10:30 AM

**Objectively Quantifying Physical Activity And Sedentary Behavior 10 Years Following Bariatric Surgery**

Olivier Babineau<sup>1</sup>, Tamara Carver<sup>1</sup>, Dr. Nicolas V. Christou<sup>2</sup>, Dr. Ross E. Andersen, FACSM<sup>1</sup>. <sup>1</sup>McGill University, Montreal, QC, Canada. <sup>2</sup>McGill University Health Center, Montreal, QC, Canada.

(No relationships reported)

Bariatric surgery is currently the preferred treatment for severe obesity. Little is known about long-term physical activity patterns in patients who have had surgery. The purpose of this investigation was to characterize the patterns of physical activity and hours spent sitting in 19 patients who underwent bariatric surgery 10 or more years earlier. ActivPal™ 3-dimensional accelerometers were attached to the patient's upper leg and were instructed to wear the device for 7 consecutive days. Mean steps per day, transitions from sitting to standing and minutes of sitting per day were measured. Patients were also asked to quantify the number of bouts of vigorous exercise performed weekly. At baseline, 72% of the patients were female, weighed 149±25 kg with a BMI of 53±8 kg/m<sup>2</sup>. They had surgery on average 13.3 years earlier and had lost 45.5±24 kg. Patients took on average 6,522±3,139 steps per day, made 53±20 transitions from sitting

to standing per day and spent 16.6±1.8 hours sitting or lying each day. Steps per day or sitting time was not significantly related to weight loss. Patients who reported doing more physical activity than before their surgery lost 61.2±10 kg which was significantly more ( $p<.001$ ) than those whose activity remained the same (32.0±26 kg) or those whose activity is now lower (20.0±21 kg). Only 21% of the participants reported doing three or more bouts of vigorous activity per week and 57% reported doing none. These data suggest that strategies to increase physical activity after bariatric surgery and reduce sitting time are needed for this population.

**Body Composition and Body Fat Distribution are Related With Cardiac Autonomic Control in NAFLD Patients**

Nuno M. Pimenta<sup>1</sup>, Helena Santa-Clara<sup>2</sup>, Helena Cortez-Pinto<sup>3</sup>, José Silva-Nunes<sup>4</sup>, Maria L. Rosado<sup>2</sup>, Pedro J. Sousa<sup>5</sup>, Rita Calé<sup>5</sup>, Xavier Melo<sup>2</sup>, Luis B. Sardinha<sup>2</sup>, Bo Fernhall, FACSM<sup>6</sup>. <sup>1</sup>ESDRM - IPS, Rio Maior, Portugal. <sup>2</sup>Faculty of Human Kinetics - Technical University of Lisbon, Lisbon, Portugal. <sup>3</sup>Hospital de Santa Maria, Lisbon, Portugal. <sup>4</sup>Hospital Curry Cabral, Lisbon, Portugal. <sup>5</sup>Hospital de Santa Cruz, Lisbon, Portugal. <sup>6</sup>University of Illinois - Chicago, Chicago, IL.  
(No relationships reported)

Body composition (BC), particularly central body fat (BF), is a major issue in Non-alcoholic Fatty Liver Disease (NAFLD). Decreased vagal activity is known to be a marker of imbalanced cardiac autonomic control (CAC) and a risk factor for death. It has been shown that BC, as well as BF distribution, are significantly related to CAC. To our knowledge this is the first study to address the relationship between BC or BF distribution and CAC in NAFLD patients.

**PURPOSE:** To determine if, and to what extent, specific markers of BC and BF distribution, are related to CAC, as assessed by heart rate recovery (HRR), in NAFLD patients.

**METHODS:** Total and regional BC were assessed with Dual Energy X-ray Densitometry (DXA) in 25 NAFLD patients (17 males, 50.0 ± 13.2 yrs, and 8 females, 47.2 ± 13.0 yrs), who were diagnosed through liver biopsy or ultrasound, after exclusion of other causes of liver disease. Ratios between specific BF depots were calculated to assess BF distribution. All subjects underwent a maximum graded exercise test (GXT) on a treadmill monitored by 12 lead ECG. HRR was measured as the difference between peak exercise heart rate and the heart rate recorded 1 (HRR1) and 2 minutes (HRR2) immediately after GXT end.

**RESULTS:** Simple linear regressions between BC or BF distribution and HRR showed that Trunk BF and Abdominal BF were the only BF depots significantly correlated with HRR1 ( $r=0.47$  and  $r=0.48$ ; respectively,  $p<0.05$ ). Trunk BF:Limbs BF ratio and Abdominal BF:Total BF ratio were the only BF distribution markers significantly correlated with HRR1 ( $r=0.70$  and  $r=0.47$ ;  $p<0.001$  and  $p<0.05$ ; respectively). Only Trunk BF:Limbs BF ratio was related with HRR2 ( $r=0.74$ ;  $p<0.001$ ). Total BF, as well as all fat free mass variables, was not correlated with HRR1 or HRR2. Step-wise multiple regressions with all BC and fat distribution markers, as independent variables to predict HRR1 and HRR2, displayed only one model for each dependent variable, using solely trunk BF:Limbs BF ratio as predictor for both HRR1 and HRR2.

**CONCLUSIONS:** Body fat distribution, more than body composition, seems to be related to CAC as assessed by HRR in NAFLD patients. Trunk BF:Limbs BF ratio was the best predictor of both HRR1 and HRR2 and may be a useful indicator in clinical setting.

2030 Board #76 MAY 31 9:00 AM - 10:30 AM

**Improving Body Composition With Taiji Quan: Differences Between Beginners And Experienced Post Menopausal Women.**

Marie-Eve Ringuet, Sébastien Barbat-Artigas, Marie-Eve Filion, Sophie Dupontgand, Karelis Antony, Mylène Aubertin-Leheudre. *Université du Québec à Montréal, Montréal, QC, Canada.* (Sponsor: Jean P. Boucher, FACSM)  
(No relationships reported)

**INTRODUCTION:** The physiological aging process leads to a loss of physical function. In women, aging, and especially the transition of menopause, leads to changes in the hormonal profile that generate body composition changes, more specifically an increased body weight, abdominal fat accumulation and decreased skeletal muscle mass and bone density. The feasibility and accessibility of Taiji training, as well as its beneficial health benefits recently attracted some attention in the scientific community. However, this new type of physical activity intervention still needs to be explored. Indeed, Taiji training has shown to be effective in improving health status in beginners, but we don't know to what extend this activity benefits to experienced individuals.

**OBJECTIVES:** Therefore, the aim of the present study was to investigate the effectiveness of a 12 weeks intervention in Taiji according to the participant's experience (beginners vs. experienced) on functional capacity and body composition.

**METHODS:** Sixty-two postmenopausal women were recruited and divided in two groups (beginners (BE) and intermediates (EX) in Taiji practice). Body composition and functional capacity were measured pre and post intervention.

**RESULTS:** Significant improvements were observed in the chair test score for both groups (BE:  $p<0.001$ ; EX:  $p=0.003$ ) and the perception of fatigue (BE:  $p=0.002$ ; EX:  $p=0.03$ ). Only the EX group showed a statistically significant improvement for the stair test ( $p=0.004$ ). Only the BE group demonstrated significant strength increases (Kincom;  $p=0.02$ ). Finally, we observed a significant decrease in BMI ( $p=0.03$ ) and waist circumference ( $p=0.007$ ) for the EX group.

**CONCLUSION:** Taiji training seems to be effective in improving body composition and functional capacity in postmenopausal women. Even if it is a soft method, and in spite of past experience in this practice, Taiji interventions still may lead to improvements in functional capacity and body composition. Therefore, it could be considered as an avenue in sports medicine for postmenopausal women in order to accomplish a successful aging.

2031 Board #77 MAY 31 9:00 AM - 10:30 AM

**Low Back Strength Adversely Affects Exercise Capacity in Obese, Older Adults with Chronic Back Pain**

Heather K. Vincent, Amanda N. Seay, Kevin R. Vincent, Cindy Montero, Bryan P. Conrad, Robert W. Hurley. *University of Florida, Gainesville, FL.*  
(No relationships reported)

Obese adults benefit from participation in regular exercise for weight loss and improved health. In older persons with chronic low back pain, however, avoidance of exercise may induce lumbar muscle weakness and subsequent lower exercise capacity.

**PURPOSE:** To determine the contribution of lumbar strength on maximal and functional exercise tolerance and physical function in obese older adults with chronic low back pain.

**METHODS:** Obese men and women ( $N=52$ ; 67±11 yrs, 65% women, body mass index [BMI] 32.2 ± 4.7 kg/m<sup>2</sup>) completed graded walking endurance treadmill tests, chair rise and stair climb tests and maximal strength testing of the lumbar muscles (MedX®, lumbar extension). Pain severity was assessed using a 0-10 numerical pain rating scale (NRS-pain) at rest and during each test. Fear of movement may impair exercise ability, and was measured with the Tampa Scale of Kinesiophobia (TSK). Hierarchical regression analysis was performed to determine the contribution of lumbar strength values on maximal and functional exercise capacity. In three separate models, treadmill endurance time, chair rise time and stair climb times were the dependent variables.

**RESULTS:** Mean back pain was 4.7±1.9 points, and lumbar extension strength was 199±115 Nm. Average endurance test time was 12.7±4.3 min, and chair rise and stair climb times averaged 1.1±0.5 sec and 5.9±2.2 sec, respectively. TSK scores averaged 23.4±6.5 points (range 13-40). After accounting for age, sex, BMI, pain and TSK scores, lumbar strength was a significant contributor to the variance in the model of walking endurance time (model  $R^2=0.501$ ,  $R^2$  change .091) but not chair rise or stair climb.

**CONCLUSION:** Lumbar strength appears more important for walking endurance than some specific functional exercise. Targeted lumbar exercise for strength improvement may facilitate longer participation in walking exercise, which is a critical component in weight loss and management in the obese older adult.

Supported by NIH NIAMS RO3 AR057552-01A1 and the US Bone and Joint Decade Scholar Program.

**2032** Board #78 MAY 31 9:00 AM - 10:30 AM  
**Relationships Between Physical Function, BMI, Fitness, And Activity Behaviors In An Obese Pediatric Clinic**

Renee Privette, Gary D. Miller, Sherry Frino, Joseph A. Skelton. *Wake Forest University, Winston Salem, NC.*  
(No relationships reported)

Recent data show that 16.9% of U.S. children and adolescents are obese and 32% are either overweight or obese. An often overlooked comorbidity of obesity is impairments in physical function and physical fitness. This has been targeted in older adults, but the implications of obesity on measures of fitness and function in children and adolescents have not been well described.

**PURPOSE:** This study examined correlates of physical function in overweight and obese patients attending a pediatric obesity clinic (Brenner FIT (Families in Training)). **METHODS:** 279 children (aged 2- 18) from the Brenner's FIT obesity management clinic were assessed for physical function, physical fitness, and activity behaviors by a physical therapist. Function and fitness measures included the 6-minute walk distance (6MWD), sit-up and pushup tests, hamstring flexibility and a balance test. Screen time hours and involvement in organized physical activity were self-reported. Spearman correlations and linear and logistic regression analyses examined relationships between the independent variables [BMI and behaviors (participation in organized physical activity and screen time)] with physical function and fitness variables.

**RESULTS:** As BMI z-score increased, physical function significantly decreased across all measured variables. Also, participation in organized sports was related to increased 6MWD. Males had lower flexibility than females and older children had worse balance and flexibility than younger children. Screen time was associated with both 6MWD and hamstring flexibility. Using linear regression, BMI z-score had the strongest association with 6MWD ( $R^2$  change of 0.30). From logistic regression, BMI z-score was significantly associated with balance with an odds ratio of 4.86, such that for each unit increase in BMI z-score there is nearly a 5 fold increase in risk for an abnormal balance assessment.

**CONCLUSIONS:** These data show that obesity and low amounts of participation in organized physical activity and high amounts of sedentary behaviors negatively impacts physical function in obese children. These findings highlight factors pediatric weight management interventions should target to maximize patient improvements in mobility disability.

**2033** Board #79 MAY 31 9:00 AM - 10:30 AM  
**Comparison of Exercise Test Responses Among Executives with and without Metabolic Syndrome**

Kirk D. Hendrickson, Allison Poremba, Barry Franklin, FACSM, Judith Boura, Joseph James, Lewis Rosenbaum. *William Beaumont Hospital, Royal Oak, MI.*  
(No relationships reported)

**BACKGROUND:** Executive physical exams are widely performed to screen for chronic diseases in asymptomatic individuals, including metabolic syndrome (MS). Individuals with MS have a 1.5 to 3-fold increased risk for developing coronary disease or stroke. This distinguishes the MS as a unique marker for increased cardiovascular risk, highlighting the need for aggressive risk factor reduction and treatment.

**PURPOSE:** To identify the incidence of MS in asymptomatic individuals undergoing executive physical examinations and to compare the exercise test responses among those with and without MS.

**METHODS:** We evaluated 299 asymptomatic executives (80.5% men, mean  $\pm$  SD age =  $53 \pm 6$  years) who underwent yearly physical examinations that included anthropometric measurements, peak or symptom-limited exercise testing, and blood chemistry studies to determine the incidence of persons who exhibited  $\geq 3$  risk factors for MS, including abdominal obesity, elevated triglycerides, low HDL-cholesterol, elevated blood pressure, and increased fasting glucose. Baseline evaluations included body mass index (BMI), waist circumference, resting and maximal heart rate, peak metabolic equivalents (METs), Duke treadmill score and heart rate recovery. Participants were divided into 2 groups based on presence or absence of MS.

**RESULTS:** Of 299 asymptomatic individuals, 7.4% were classified as having MS. The mean  $\pm$  SD age of individuals with ( $n = 22$ ) and without MS ( $n = 277$ ),  $54 \pm 6$  vs  $52 \pm 5$  years, was not significantly different. The cohort with MS had a significantly higher weight ( $104 \pm 6.4$  vs  $83 \pm 14$  kg;  $P < 0.0001$ ) and BMI ( $31.4 \pm 4.9$  vs  $26.4 \pm 3.3$  kg/m<sup>2</sup>;  $P < 0.0001$ ), and lower aerobic capacity ( $10.8 \pm 1.9$  vs  $12.5 \pm 2.1$  METs;  $P = 0.0003$ ), Duke treadmill score ( $10 \pm 2.4$  vs  $12 \pm 3.2$ ;  $P = 0.003$ ) and peak heart rate ( $158 \pm 12$  vs  $165 \pm 13$  bpm;  $P = 0.007$ ) than the group without MS. The incidence of arrhythmias and ischemic ST-segment depression between groups was not significantly different.

**CONCLUSION:** The present findings suggest that executives with MS were more likely to be overweight/obese, lower fit individuals with lower Duke treadmill scores and peak heart rates than their counterparts without MS. These data highlight the potential value of weight management and exercise interventions to prevent and treat MS.

**2034** Board #80 MAY 31 9:00 AM - 10:30 AM  
**Effect Of Yoga On Anxiety, Psychological Stress, And Cortisol Of Type 2 Diabetes Mellitus Patients**

Maricarmen Vizcaino, George A. King. *University of Texas at El Paso, El Paso, TX.*  
(No relationships reported)

The prevalence of anxiety and its subsequent implications on quality of life have been previously documented among individuals with Type 2 diabetes mellitus (T2DM). In addition, evidence suggests that psychological stress negatively impacts glycemic control, possibly through the disruption of adequate self-care behavior or directly altering metabolism by inducing chronic elevations of circulating cortisol levels. Yoga practice has been shown to reduce symptoms of stress and anxiety in a variety of populations; however, information on the effect of yoga among individuals with T2DM is limited.

**PURPOSE:** To investigate the effect of yoga practice on anxiety, psychological stress, and cortisol levels of T2DM patients.

**METHODS:** Ten non-insulin dependent diabetes mellitus patients (mean  $\pm$  SD age:  $61.4 \pm 6.7$  y; BMI:  $36.3 \pm 7.6$  kg/m<sup>2</sup>; years since diagnosis:  $6.1 \pm 6.3$  y) underwent a systematic 6-week yoga program (3d/week) with a registered yoga teacher. Psychological stress was assessed with the perceived stress scale (PSS) and anxiety with the State-Trait Anxiety Inventory (STAI). Physiological stress was estimated by salivary cortisol content at midnight. All data were obtained at baseline and post-intervention. A one-way within-subjects ANOVA model with Bonferroni adjusted post hoc analyses was used to analyze the yoga effect on psychological measures. Due to non-normality, changes in cortisol were assessed with the Wilcoxon Signed Rank Test.

**RESULTS:** Perceived stress scores ( $22.8 \pm 8.0$  vs.  $17.5 \pm 7.1$ ,  $P = 0.03$ ), state anxiety scores ( $39.8 \pm 13.3$  vs.  $29.2 \pm 8.6$ ,  $P = 0.01$ ), and salivary cortisol values ( $6.9 \pm 7.7$  vs.  $2.8 \pm 1.7$  nmol/L,  $P = 0.04$ ) significantly decreased following the intervention. Trait anxiety scores ( $36.8 \pm 11.2$  vs.  $31.1 \pm 8.1$ ,  $P = 0.09$ ) improved, but the change was non-significant.

**CONCLUSION:** Yoga practice appears to be an effective alternative therapy to reduce symptoms of anxiety and psychological stress among T2DM patients. The observed decrease in circulating cortisol levels likely resulted from the positive impact of yoga on stress and anxiety. Further studies are needed to determine the impact of cortisol reductions in glucose metabolism of T2DM and subsequent glycemic control.

This study was partially supported by: TACSM, UTEP CHS Graduate Enhancement Funds, and UTEP Graduate School.

**2035** Board #81 MAY 31 9:00 AM - 10:30 AM  
**Influence of Individual Metabolic Conditions on the Metabolic Syndrome in Southern Women**

L. Jerome Brandon, FACSM<sup>1</sup>, Larry Proctor<sup>2</sup>. <sup>1</sup>Georgia State University, Atlanta, GA. <sup>2</sup>B.E.A.M., LLC, Ruston, LA.  
(No relationships reported)

The metabolic syndrome (MetS) is the clustering of three metabolic conditions (elevated glucose, blood pressure, triglyceride and body fat (%fat), and depressed HDL-C) and is used to predict the development of cardiovascular disease (CVD).

**PURPOSE:** The purpose of this study was to determine if an abnormal level of each MetS conditions would be associated with similar levels of clustering with the other MetS conditions in obese southern women.

**METHODS:** One-hundred and thirteen obese southern women between the ages of 20 and 65 years participated in this hospital based study. All women were measured for blood pressure (BP), cholesterol (total (TC), HDL-C and LDL-C), triglyceride (TG), body mass index (BMI) percent %fat, waist circumference and glucose (Glu). Metabolic risk levels (example SBP  $\geq$  140 mmHg) of each condition were used to select subsamples and the subsamples were evaluated for abnormal values and subsequently MetS clustering. Analyses were completed using descriptive statistics and correlations.

**RESULTS:** The women were obese as their %fat was  $40.6 \pm 8.7\%$  and their BMI was  $31.2 \pm 7.8$  kg/m<sup>2</sup> and obesity was the only risk condition.

When risk values of each MetS condition were used for subsample

selection and the subsample was evaluated for MetS, only when Glu ( $\geq$  110 mg/dL) was the reference did the subsample have MetS (%fat 44.8; Glu 122.4; TG 206.0; HDL-C 41.5). No subsample for the other conditions had more than two abnormal MetS conditions and one of those was obesity.

**CONCLUSIONS:** These findings suggests that elevated glucose or insulin resistance is a more severe MetS condition as it is more likely to be clustered with two or more MetS conditions in southern women. This may partially explain why those living in the southern parts of the US are reported to have a higher prevalence of CVD.

---

**2036** Board #82 MAY 31 9:00 AM - 10:30 AM

**Impairment of Skeletal Muscle Oxidative Metabolism during Knee-Extension Exercise in Severely Obese Women**

Stefano Lazzar<sup>1</sup>, Desy Salvadego<sup>1</sup>, Simone Porcelli<sup>2</sup>, Enrico Rejc<sup>1</sup>, Carlo Busti<sup>3</sup>, Raffaella Galli<sup>3</sup>, Fiorenza Agosti<sup>3</sup>, Alessandro Sartorio<sup>3</sup>, Bruno Grassi<sup>1</sup>. <sup>1</sup>University of Udine, Udine, Italy. <sup>2</sup>National Research Council, Segrate (MI), Italy. <sup>3</sup>Italian Institute for Auxology, IRCCS, Piacavallo (VB), Italy.

(No relationships reported)

**PURPOSE:** During dynamic knee extension exercise the recruitment of a relatively small muscle mass, i.e. the *quadriceps femoris* of one leg, significantly reduces constraints to oxidative function deriving from cardiovascular O<sub>2</sub> delivery. We hypothesized, in a group of severely obese women (OB), a significant impairment of oxidative metabolism during KE, lending support to the role of skeletal muscles in limiting exercise tolerance in OB.

**METHODS:** 11 OB (age  $29.5 \pm 5.5$  yr, body mass  $112.9 \pm 17.7$  kg and body mass index  $43.2 \pm 5.4$  kg·m<sup>-2</sup>) and 10 non-obese (NOB) women were tested. Fat free mass (FFM) of a lower limb was assessed by a densitometer. Heart rate (HR) and O<sub>2</sub> uptake (VO<sub>2</sub>) were determined during an incremental exercise test to voluntary exhaustion on a custom-built KE ergometer.

**RESULTS:** Maximal isometric force of KE muscles was higher ( $p < 0.05$ ) in OB ( $522.3 \pm 149.4$  N) vs. NOB ( $357.2 \pm 66.9$  N). Peak HR was  $125 \pm 4$  b·min<sup>-1</sup> in OB and  $141.9 \pm 7.7$  b·min<sup>-1</sup> in NOB ( $p = 0.291$ ). Peak VO<sub>2</sub> normalized per unit of lower limb FFM was lower ( $p < 0.001$ ) in OB ( $99.2 \pm 3.7$  mL·min<sup>-1</sup>·kg<sup>-1</sup> FFM) vs. NOB ( $144.5 \pm 10.9$  mL·min<sup>-1</sup>·kg<sup>-1</sup> FFM), whereas peak work rate values were not different ( $p = 1.000$ ) in the two groups ( $24.0 \pm 3.1$  W in OB vs.  $25.0 \pm 2.0$  W in NOB). The slope of the VO<sub>2</sub>·FFM<sup>-1</sup> vs. work rate relationship was lower ( $p < 0.001$ ) in OB ( $2.09$  mL·min<sup>-1</sup>·kg<sup>-1</sup>·FFM·watt<sup>-1</sup>) vs. NOB ( $4.34$  mL·min<sup>-1</sup>·kg<sup>-1</sup>·FFM·watt<sup>-1</sup>).

**CONCLUSIONS:** After eliminating or significantly reducing, by the adopted KE exercise protocol, constraints related to cardiovascular O<sub>2</sub> delivery, skeletal muscle oxidative function at peak exercise was impaired in OB. On the other hand, at submaximal work rates an increased efficiency of contractions was observed in OB, which could be related to their higher maximal force, possibly deriving from the chronic "strength training" associated with the excessive body mass bearing.

Supported by Italian Institute for Auxology (Milan).

**2037** Board #83 MAY 31 9:00 AM - 10:30 AM

**Effect Of A Structured Exercise Program On Attitudes Toward Exercise In Post-bariatric Surgery Patients**

Paul G. Davis, FACSM<sup>1</sup>, Diane L. Gill<sup>1</sup>, Jeaneane C. Wilson<sup>2</sup>, Cody L. Sipe<sup>1</sup>, Maggie L. Roe<sup>1</sup>, Nicholas W. Justus<sup>1</sup>, Ryan W. Lepper<sup>1</sup>. <sup>1</sup>The University of North Carolina at Greensboro, Greensboro, NC. <sup>2</sup>Cone Health, Greensboro, NC.

(No relationships reported)

**PURPOSE:** Although exercise is generally advocated to assist patients with weight maintenance after bariatric surgery, little research on exercise adherence has been performed in this population. The purpose of this study was to examine the effects of a structured exercise program on factors related to exercise adherence in persons having undergone bariatric surgery.

**METHODS:** Eleven women (n=9) and men (n=2) (age:  $43 \pm 3$  y, BMI:  $38 \pm 2$  kg/m<sup>2</sup>; mean $\pm$ SE) having bariatric surgery in the past 6 weeks to 6 months were randomized to a 12-week group exercise program or a "usual care" (i.e., exercise encouraged with no formal instruction) wait list control group. The exercise program included three 1-hour exercise sessions per week (endurance and resistance exercise) and biweekly educational sessions (exercise, diet, and behavior change strategies). Participants completed a physical activity (PA) enjoyment Likert scale (1="I enjoy it", 5="I hate it") and a self-efficacy for exercise scale [possible scores range from 0 (lower self-efficacy) to 90 (higher self-efficacy)] at 0, 6, and 12 weeks. Since this was a pilot study, alpha was set at 0.10. Large effect sizes were defined by a partial eta squared ( $\eta^2$ )  $> 0.140$ .

**RESULTS:** Age was related to lack of PA enjoyment at baseline ( $r = 0.807$ ,  $p = 0.003$ ). A 2 (treatment) x 3 (time) ANCOVA with age entered as the covariate showed a significant time effect ( $p = 0.007$ ,  $\eta^2 = 0.463$ ) for PA enjoyment (Control - Pre:  $3.5 \pm 0.5$ , Mid:  $2.5 \pm 0.8$ , Post:  $2.6 \pm 0.5$ ; Exercise - Pre:  $3.9 \pm 0.4$ , Mid:  $3.4 \pm 0.7$ , Post:  $2.0 \pm 0.5$ ) with slightly greater improvement in the exercise group ( $p = N.S.$ ,  $\eta^2 = 0.183$ ). ANOVA showed a significant treatment x time effect ( $p = 0.096$ ,  $\eta^2 = 0.248$ ) for self-efficacy (Control - Pre:  $74 \pm 6$ , Mid:  $68 \pm 8$ , Post:  $69 \pm 8$ ; Exercise - Pre:  $49 \pm 6$ , Mid:  $54 \pm 7$ , Post:  $66 \pm 7$ ).

**CONCLUSIONS:** Results from this pilot study indicate that a 12-week structured exercise program may lead to enhanced physical activity enjoyment and exercise self-efficacy in patients recently having undergone bariatric surgery. Follow-up research is needed to determine if such changes can lead to longer-term physical activity adherence in this population.

Funded by a Regular Faculty Grant from UNC-Greensboro.

**2038** Board #84 MAY 31 9:00 AM - 10:30 AM

**Reliability of Paired Reflex Depression Protocol for Assessing Presynaptic Inhibition in Diabetic Neuropathy Patients**

Shannon J. Palmer, Junggi Hong, Willamette University, Salem, OR. (Sponsor: Peter Harmer, FACSM, FACSM)

(No relationships reported)

Considerable progress has been made in understanding the role of inhibitory systems in neurological conditions. While evidence suggests that presynaptic inhibition (PI) may be impaired under neuropathic conditions as a result of disinhibition in the spinal dorsal horn, no study has yet investigated the characteristics of spinal inhibition in diabetic peripheral neuropathy (DPN) patients. Paired reflex depression (PRD) is a protocol used to evaluate homosynaptic reflex activity at the spinal dorsal horn.

**PURPOSE:** To assess the intra- and inter-day reliability of the PRD protocol in assessing PI of DPN patients.

**METHODS:** Eight participants ( $58 \pm 6$  yrs.) diagnosed with either type I or II diabetes and peripheral neuropathy were recruited for the study. PRD values were derived from the average change of the second H-reflex relative to the first following stimulation of the posterior tibial nerve. For the intra-day reliability, PRD was measured an hour after baseline assessment. For the inter-day reliability, PRD was measured 2 weeks after the first day of testing. A total of 10 trials per session were recorded. Reliability was calculated via Intra Class Correlation Coefficients (ICCs) with a 95% confidence interval.

**RESULTS:** The ICCs for intra- and inter-day reliability were 0.94 and 0.88, respectively.

**CONCLUSION:** The PRD protocol with the posterior tibial nerve of DPN patients was reliable within and between days. The demonstrated reliability of the PRD protocol observed in the study will assist researchers in clinical intervention studies investigating the efficacy of various treatments for diabetic neuropathy patients.

2039 Board #85 MAY 31 9:00 AM - 10:30 AM

### Effect Of Aerobic Exercise On Protein Expression In Muscle Of Overweight Adolescents

Maciste H. Macias Cervantes, Francisco J. Diaz, Victoriano Perez-Vazquez, Katya Vargas-Ortiz, Juan M. Guazman-Flores. *Universidad de Guanajuato, Leon, Mexico.*  
(No relationships reported)

**PURPOSE:** To increase the cellular understanding of the molecular mechanisms that underlie the aerobic training and obesity in adolescents by proteomic analysis of skeletal muscle from obese adolescents.

**METHODS:** participated 4 sedentary, obese male adolescents (16years, BMI= 33.81Kg/M<sup>2</sup>). Previously the participants and their parents signed informed consent. All participants developed a treadmill stress test according Blake protocol, after them they engaged in 12 weeks of aerobic training (50min/3 times per week). Before and after training we taken a *vastus lateralis* muscle sample by needle biopsy, the specimen were put into a buffer with protease inhibitor and quickly frozen until the proteomic analysis. 2D-PAGE were stained with silver and spots with changes expression after training were compared with different data base to proteins identify.

**RESULTS:** clinical characteristics are shown in table 1. All participants decreased glucose, insulin, total cholesterol, BMI and waist circumference(p< 0.05 for all). Proteomic differential analysis revealed 9 overexpressed proteins after training, which corresponds to carbonic anhydrase III, beta enolase, creatine kinase, ATP synthase beta subunit, Aldolase A, Glyceraldehyde-3-phosphate dehydrogenase, triosephosphate isomerase, piruvate kinase and adenylate kinase.

**CONCLUSIONS:** These proteomic findings suggest that obese adolescent changes their BMI, waist circumference and serum glucose after aerobic training trough to improve protein expression pattern helping especially glucose metabolism.

This research was supported by: CONCYTEG 08-16k662-130 and PROMEP/103.5/08/3252.

2040 Board #86 MAY 31 9:00 AM - 10:30 AM

### Weight Management, Weight Loss and Bariatric Care: A Curricular Approach Model to Therapeutic Exercise

Laura A. Richardson, Judith A. Juvancic-Heltzel. *The University of Akron, Akron, OH.* (Sponsor: Ellen L. Glickman, FACSM)  
(No relationships reported)

**BACKGROUND:** The importance of implementing effective therapeutic exercise to clients/patients of size has never been more important. Body Mass Index rates nationwide, and across the lifespan, continue to rise. Review of literature is weak in this field. It is evident that caloric expenditure via exercise is a cornerstone but little research identifies specific guidelines, theories, and strategies that should be used with this population. It is paramount that the body of knowledge, guidelines, and resources be expanded. Numerous textbooks were reviewed and none adopted due to the scope of materials not meeting needs of exercise science students. A significant gap exists between current texts and the targeted clinician audience.

**PURPOSE:** To develop an exercise science curriculum to address the use of exercise as a therapeutic tool in the scope of weight management, weight loss, and bariatric care.

**METHODS:** A course was developed which included current literature and clinical guidelines regarding weight management, weight loss and bariatric care. The teaching model was created using course modules encompassing: Evolution & Prevalence of Obesity, Classification of Morbidity & Mortality, Pathophysiology of Excess Fat, Fat Metabolism, Assessment of the Obese Client, Exercise Prescription, Obesity Treatment, Genetic Influences on Obesity, Sleep and Weight Management. Modules are formatted to include basic definitions, history, application, clinical examples and questions related to each of the topics. Each semester the course is offered, content is reviewed and revised to reflect new findings.

**RESULTS:** Feedback from students has been positive. The curriculum has developed a greater awareness and confidence of future clinicians in the application of using exercise as one of the cornerstone therapeutic tools for this clinical population.

**CONCLUSION:** It is imperative that future exercise science professionals possess the knowledge, skills and abilities to implement current evidence based practices in treating this ever growing population. Future directions of the curriculum will add service learning to include students working with patients at a local bariatric center. Direct interactions with this population would enhance the application of the curricular content.

2041 Board #87 MAY 31 9:00 AM - 10:30 AM

### Effects of Whole Body Vibration on Pain, Hemodynamics and Nerve Conduction in Diabetic Peripheral Neuropathy

Nathan J. Kessler, Michael M. Lockard, Junggi Hong. *Willamette University, Salem, OR.* (Sponsor: Peter Harner, FACSM)  
(No relationships reported)

**BACKGROUND:** Whole Body Vibration (WBV) is an innovative therapy that preliminary research has indicated may be effective for reducing chronic pain associated with diabetic peripheral neuropathy (DPN), although no mechanism has been identified. Decreased blood flow has been cited as a risk factor for impaired nerve conduction which may be related to pain associated with DPN. Conditioning research has indicated that WBV facilitates blood flow to the leg. Therefore decreased DPN-associated pain may be related to maintaining nerve function through enhancing blood flow.

**PURPOSE:** To test the efficacy of WBV on pain associated with DPN, blood flow and nerve conduction velocity in the diabetic foot.

**METHODS:** 20 subjects (9 male, 11 female) with a mean age of 58.51± 10.69 yrs and a mean BMI of 33.60±8.20 kg/m<sup>2</sup> were assigned to a control (n=8) or treatment (n=12) group in a pre-post design. Pain was assessed with a 10 point visual analog pain scale (VAS). Motor nerve conduction velocity (MNCV) was measured at the posterior tibial nerve via electromyography using a surface stimulator probe. Blood flow in the foot was assessed via the toe-brachial index (TBI), which compares systolic pressure in the brachial artery and the great toe. Treatment consisted of six vibration sessions over two weeks. Each session consisted of 12 minutes of vibration (4 bouts of 3 minutes). The control protocol was identical but with sham vibration. All variables were analyzed with a 2 (group) x 2 (time) repeated measure ANOVA, alpha 0.05.

**RESULTS:** VAS scores of the treatment group decreased significantly pre-post ( p=0.001; 2.7±1.7 to 1.6 ±1.0) and were significantly different from control at post testing (p= 0.028). No significant differences were found for TBI or MNCV (p> 0.05)

**CONCLUSION:** WBV is effective for reducing DPN-associated pain. However, the reductions were not associated with changes in peripheral blood flow or in motor nerve conduction velocity as measured in this study. This indicates that the mechanism responsible for DPN-associated pain relief associated with WBV does not appear to involve changes in blood flow or motor nerve conduction to the foot.

2042 Board #88 MAY 31 9:00 AM - 10:30 AM

**Influence Of Objectively Measured Physical Activity On Change In Fitness In A Weight Loss Intervention**

Renee J. Rogers<sup>1</sup>, Kelli K. Davis<sup>1</sup>, Deborah F. Tate<sup>2</sup>, Kristen Polzien<sup>2</sup>, John M. Jakicic, FACSM<sup>1</sup>. <sup>1</sup>University of Pittsburgh, Pittsburgh, PA. <sup>2</sup>University of North Carolina-Chapel Hill, Chapel Hill, NC.  
(No relationships reported)

Moderate-to-vigorous physical activity (MVPA) accumulating to at least 1,000 kcal/wk or 150 min/wk is recommended to improve fitness in adults, and activity should be accumulated in bouts of at least 10 minutes. However, little is known about the contribution of shorter duration MVPA or lower intensity activity on change in fitness.

**PURPOSE:** To examine the pattern and intensity of objectively measured physical activity on change in fitness in obese adults across a behavioral weight loss intervention (BWL).

**METHODS:** Subjects were 216 adults (age: 42.8±9.2, BMI: 32.6±3.6 kg/m<sup>2</sup>) participating in an 18-month BWL. BWL includes prescription to decrease energy intake to 1200-1500 kcal/d, and increase PA to 300 min/wk. PA and fitness were assessed at 0, 6, and 18 months. PA was assessed objectively using an armband that provided minute-by-minute data for a period of 7 days (SenseWear Pro Armband™, BodyMedia, Inc). Fitness was assessed using a graded exercise test, with fitness defined as time to achieve 85% of age-predicted maximal heart rate (85%HRmax). MVPA was defined as bouts that were ≥10 minutes in duration and ≥3.0 METS. MVPA was also defined as total minutes ≥3.0 METS regardless of length of bout (MVPA-MIN). LPA was defined as minutes of activity between 1.5 to 2.9 METS.

**RESULTS:** Change in time to achieve 85%HRMAX from 0 to 6 months was correlated with MVPA-MIN (r=.29, p<.001) and MVPA (r=.36, p<.001), with LPA was not associated (r=.07). In regression analysis, MVPA was a significant predictor (β=.517, t=3.504, p=.001) of change in time to 85%HRmax, whereas neither MVPA-MIN nor LPA were not. At 18 months, change in time to 85%HRmax was correlated with LPA (r=.203, p=.003), MVPA-MIN (r=.374, p<.001) and MVPA (r=.426, p<.001). In regression analysis both MVPA (β=.604, t=4.078, p<.001) and LPA (β=.185, t=2.625, p=.009) were significant predictors of changes in time to 85%HRmax.

**CONCLUSIONS:** During the initial 6 months of BWL, total MVPA performed in bouts of at least 10 min in duration is associated with improvement in fitness. However, both MVPA and LPA contribute to improvement in fitness observed at 18 months. These findings suggest that need for BWL to include strategies to improve participation in both MVPA and LPA for overweight and obese adults.

**The Relationship Exercise Habits And Sleep In The Person Who Underwent The Health Checkup**

Yoshinori Kitabatake, Toshiya Nagamatsu, Tsutomu Kuchiki, Yasuo Suyama. *Meiji Yasuda Life Foundation of Health and Welfare, Shinjuku-ku, Tokyo, Japan.*  
(No relationships reported)

Recent reports produced in Europe and the United States show that physical activity may improve quality of sleep, especially sleep disorders such as insomnia. Exercise, however, has not yet met established efficacy standards although some studies have shown improvements in sleep disorders with exercise. In Japan, there is a lack of evidence regarding the effects of exercise on sleep disorder and insomnia. We need data examining whether physical exercise improves sleep disorders. The number of people suffering depression has increased in Japan and previous studies have reported that insomnia is considered to be a risk factor leading to depression. We hypothesize that physical exercise improves sleep quality and reduces sleep complaints.

**PURPOSE:** To explore the relationship between physical exercise habits and sleep patterns in people who underwent a health checkup.

**METHODS:** This study was cross-sectional with 15,590 subjects (male n= 8314, mean age 49 years, female n=7276, 47 years), all of whom underwent a medical checkup. The following information regarding exercise habits was gathered via a questionnaire: exercise timing, intensity, length, and frequency. The question, "Can you get rest by sleep?" was asked (Yes=1 or no=0). The subjects were asked about their smoking and drinking habits, and the number of meals eaten per day. Height and weight were also measured. To examine the association between exercise habits as the independent variable and status of sleep as the dependent variable, odds ratios (ORs) and 95% CIs were calculated using multilevel logistic regression analysis (Covariate: age, BMI, smoking, drinking and the number of times of a meal).

**RESULTS:** The exercise habit shows 70.1 in male and 64.4 % in female. The subjects who are satisfied with sleep were 75.3% in male and 79.0% in female. The exercise habit was related to satisfaction with sleep. Odds ratios (95% CI) were 1.66 (1.47-1.86) in male and 1.48 (1.31-1.66) in female.

**CONCLUSIONS:** These results suggest that exercise may be effective in producing sound sleep. We further posit that exercise may prevent depression via the improvement of sleep. However, this study data doesn't necessarily indicate a causal relationship. We must, therefore, conduct a data longitudinal study to confirm the relationship between sleep and depression.

**Physical Activity Preferences Among a Population-Based Sample of Colorectal Cancer Survivors**

Erin McGowan<sup>1</sup>, Amy Speed-Andrews<sup>1</sup>, Chris Blanchard<sup>2</sup>, Ryan Rhodes<sup>3</sup>, Christine Friedenreich<sup>4</sup>, Nicole Culos-Reed<sup>5</sup>, Kerry Courneya<sup>1</sup>. <sup>1</sup>University of Alberta, Edmonton, AB, Canada. <sup>2</sup>Dalhousie University, Halifax, NS, Canada. <sup>3</sup>University of Victoria, Victoria, BC, Canada. <sup>4</sup>Alberta Health Services, Calgary, AB, Canada. <sup>5</sup>University of Calgary, Calgary, AB, Canada.  
(No relationships reported)

Physical activity (PA) is associated with improvements in health in colorectal cancer (CRC) survivors, however participation rates are low. A better understanding of how to promote PA in this population is needed.

**PURPOSE:** The purpose of this study was to identify the key PA programming and counseling preferences of CRC survivors.

**METHODS:** Participants were 600 CRC survivors (34% response rate) identified through the Alberta Cancer Registry who returned completed mailed surveys that included measures of self-reported PA, medical and demographic variables, and PA preferences.

**RESULTS:** Most CRC survivors indicated that they were interested (78.3%) and able (81.4%) to participate in a PA program. The most common PA preferences of CRC survivors were to receive PA counseling from a fitness expert at a cancer centre (44.3%), receive PA information in the form of print materials (59.8%), start a PA program after cancer treatment (68.9%), do PA at home (53.3%), and walk in both the summer and winter (48.5% and 36.8% respectively). Chi-square analyses identified that age, education, annual family income, and current PA were the demographic variables most consistently associated with PA preferences.

**CONCLUSION:** The majority of CRC survivors expressed an interest in PA program participation and key PA preferences were identified. These preferences may be useful for developing and implementing successful PA interventions for CRC survivors.

Supported by CIHR Grant SPO-83173.

**Associations Between Stage Of Behavior Change, Physical Activity, And Self-efficacy In Prenatal Women**

Jacquelyn A. Nagle, Bridget Melton, Elaine Marshall, Helen Bland. *Georgia Southern University, Statesboro, GA.* (Sponsor: John M. Jakicic, FACSM)  
(No relationships reported)

Physical activity (PA) is an important component of health promotion, although most pregnant women do not meet the recommended levels. Consequently, there has been recent interest in developing intervention programs encouraging lifestyle behavior changes among pregnant women. Interventions tailored to an individual's readiness to change are known to be more effective than traditional approaches to physical activity and researchers have confirmed the application of the Transtheoretical Model of Behavior Change (TTM) to the uptake of physical activity among a variety of populations. However, the model has scarcely been examined among pregnant women in recent literature.

**PURPOSE:** To examine the relationships among stages of physical activity behavior change and self-reported physical activity behavior, as well as other TTM constructs such as self-efficacy.

**METHODS:** Participants included 88 women, primarily in the second or third trimester, from the southeastern United States recruited from regional obstetrical offices. Measures modified for pregnancy included stages of exercise adoption (SEA) and self-efficacy for exercise (SEE). PA was also assessed using the short-form of the IPAQ.

**RESULTS:** Based on the self-selected SEA, women were categorized into early (Precontemplation, Contemplation, and Preparation) or late (Action and Maintenance) stage groups. Results revealed statistically significant differences in PA ( $p = 0.03$ ) when categorized into levels (low, moderate, high) from the IPAQ, such that women in the late stages were more likely to be in the moderate PA category, and women in the early stages were more likely to be in the low physical activity group. Results also reveal significantly higher levels of SEE ( $p = 0.037$ ) in the late stage group than the early stage group, as well as significant differences among groups when stratified out to the original 6 SEA ( $p = 0.028$ ), with women in the Action stage ( $M = 41.8$ ,  $SD = 5.83$ ) having higher SEE than women in Precontemplation ( $M = 35.33$ ,  $SD = 5.85$ ).

**CONCLUSIONS:** Overall results indicate consistency with current evidence such that people at later stages of change are more physically active than those in the earlier stages. Furthermore, those who are more physically active have higher SEE, indicating that prenatal PA interventions ought to focus on improving SEE.

---

2046 Board #92 MAY 31 8:00 AM - 9:30 AM

**Peer Victimization and Physical Activity Attitudes and Behavior in Transgendered and Cisgendered Individuals.**

Megan M. Muchicko. *Kent State University, Kent, OH.* (Sponsor: Ellen Glickman, FACSM)  
(No relationships reported)

**BACKGROUND:** Transgendered (TG) individuals are more likely to be the targets of peer victimization than their cisgendered (CG, i.e., non-transgendered) counterparts. Emerging research has demonstrated a potential negative link between peer victimization and physical activity behavior. No studies that we are aware of have examined physical activity behavior of TG individuals much less its association with measures of peer victimization.

**PURPOSE:** To examine self-reported peer victimization, physical activity behavior and attitudes regarding physical activity in TG and CG adults.

**METHODS:** Thirty-five ( $N = 17$  TG, and 18 CG) adults ( $35.5 \pm 13.8$  years old) completed validated questionnaires assessing; peer victimization, physical activity behavior, social support for physical activity and self-efficacy for physical activity. Participants also self-reported height and weight and body mass index (BMI) was calculated. The peer victimization questionnaire asked participants about their peer interactions as children and contained the following sub-scales: Overt Victimization Subscale (OVS), Relational Subscale (RS) and Pro-social Receipt Subscale (PRS). The OVS assessed how frequently peers harmed or threatened to harm the individual's physical well-being. The RS assessed how often peers attempted to harm the individual's relationships with other peers. The PRS assessed how often the individual was the recipient of supportive acts by peers. Each of these subscales was summed individually.

**RESULTS:** TG individuals had a significantly ( $p \leq 0.05$ ) greater BMI ( $28 \pm 7$  TG,  $23 \pm 4$  CG), OVS ( $13 \pm 4$  TG,  $9 \pm 3$  CG) and RS ( $15 \pm 4$  TG,  $12 \pm 4$  CG) and lower PRS ( $12 \pm 3$  TG,  $17 \pm 3$  CG), physical activity ( $23 \pm 29$  TG,  $45 \pm 19$  CG), social support for physical activity ( $29 \pm 4$  TG,  $51 \pm 16$  CG) and self-efficacy for physical activity ( $31 \pm 14$  TG,  $41 \pm 8$  CG) than CG adults. Self efficacy ( $r = 0.6$ ), social support ( $r = 0.5$ ), PRS ( $r = 0.4$ ) and BMI ( $r = -0.4$ ) were significantly ( $p \leq 0.04$ ) correlated to physical activity. OVS ( $r = -0.3$ ) and RS ( $r = -0.1$ ) were not ( $p \geq 0.1$ ) correlated to physical activity.

**CONCLUSIONS:** TG individuals were less physically active, received less social support, had lower self-efficacy, were more victimized and had a greater average BMI than CG individuals. Additional research into physical activity behavior of TG individuals is very much needed.

---

2047 Board #93 MAY 31 8:00 AM - 9:30 AM

**Exercise Habits and Exercise Self-Efficacy among College Students Majoring in Exercise Science and Physical Education**

John McLester, FACSM<sup>1</sup>, Cherilyn N. Hultquist<sup>1</sup>, Virginia Frederick<sup>2</sup>, Jihan Williams<sup>1</sup>, Matthew Seitler<sup>1</sup>. <sup>1</sup>*Kennesaw State University, Kennesaw, GA.* <sup>2</sup>*The University of Tennessee, Knoxville, TN.*  
(No relationships reported)

The next generation of health and fitness professionals and educators has the responsibility to promote a healthy lifestyle to children and adults. Leading by example and having a favorable fitness profile are ways to be a positive influence. However, it is known that college students do not get adequate amounts of regular exercise and one of the variables strongly associated with long-term exercise adherence is exercise self-efficacy (ESE).

**PURPOSE:** To describe the current physical activity habits, body fat % (BF%), and ESE of a sample of college students majoring in Exercise Science (ES) and Physical Education (PE).

**METHODS:** Participants consisted of 132 students (ES = 99, PE = 31), (males = 67, females = 64) aged  $23.7 \pm 5.0$  yrs who volunteered to fill out questionnaires, the Barriers Specific Exercise Self-Efficacy Scale and have BF% measured with Dual Energy X-ray Absorptiometry.

**RESULTS:** Overall, 120 subjects self-identified as regular exercisers and 91 indicated that they were "fit." They engaged in  $4.0 \pm 3.7$  d/wk of aerobic exercise and  $2.6 \pm 1.7$  d/wk of strength training. This sample had a mean body mass index (BMI) of  $24.7 \pm 4.0$  kg/m<sup>2</sup> and a mean ESE score of  $61.5 \pm 19.9$ . When comparing self-estimated BF% to measured BF%, all subjects underestimated their BF% by  $4.0 \pm 5.6\%$  ( $P < 0.001$ ). When compared by sex, there was a difference for BMI with males falling into the overweight category ( $25.9 \pm 4.2$  kg/m<sup>2</sup>) and females into the normal category ( $23.5 \pm 3.5$  kg/m<sup>2</sup>) ( $P = 0.001$ ), for ESE males scored higher than females,  $68.7 \pm 15.8$  and  $54.9 \pm 20.14$  respectively ( $P < 0.001$ ) indicating that males were more confident in their ability to continue to exercise when faced with adverse situations. Males also engaged in strength training an average of  $3.0 \pm 1.5$  d/wk compared to females engaging  $2.2 \pm 1.7$  d/wk ( $P = 0.005$ ). When compared by major, PE was older than ES ( $26.4 \pm 8.5$  and  $22.9 \pm 2.9$  yrs, respectively) ( $P = 0.001$ ) but there were no differences in ESE, BMI, BF% or days participating in aerobic or strength exercises ( $P > 0.05$ ).

**CONCLUSION:** This sample of ES and PE majors did not exercise according to ACSM guidelines are equally challenged with their confidence to exercise in adverse situations indicating that exercise behavior management skills may be an important part of future curriculums to better prepare these students to be leaders in their field.

---

2048 Board #94 MAY 31 8:00 AM - 9:30 AM

**Posture Effects Energy Expenditure and Postural Preference when Playing Active and Non-active Video Games**

Gabriel J. Sanders<sup>1</sup>, Megan Williamson<sup>1</sup>, Antonia S. Santo<sup>2</sup>, Jacob E. Barkley<sup>1</sup>. <sup>1</sup>*Kent State University, Kent, OH.* <sup>2</sup>*University of Nevada Las Vegas, Las Vegas, NV.*  
(Sponsor: Ellen L. Glickman, FACSM)  
(No relationships reported)

Energy expenditure is greater when playing physically-active video games (AVG) than traditional, sedentary video games. In previous studies, these games are played per manufacturer instructions with participants standing during AVG play and seated during sedentary game play. It is not known if individuals prefer to play these games seated or standing and what the effect of these postural differences have on energy expenditure during game play.

**PURPOSE:** To assess energy expenditure during and preference for two different postural conditions (seated, standing) while playing two AVGs using the Nintendo Wii, a traditional sedentary video game using the Sony Playstation 2 (PS2) and a resting condition.

**METHODS:** Oxygen consumption ( $VO_2$ ) was assessed as the measure of energy expenditure in 25 participants ( $22.5 \pm 2.0$  years old,  $N = 11$  females) during four 20-minute conditions; resting, PS2 Madden Football 2011, Wii-Sports Boxing and Wii Madden Football 2011 completed in a random order. These 20-minute conditions were divided into two separate postural conditions (10 minutes seated and 10 minutes standing). After completion of each 20 minute condition, participants indicated if they preferred playing the game seated or standing.

**RESULTS:** Standing  $VO_2$  ( $4.1 \pm 0.7$  ml·kg<sup>-1</sup>·min<sup>-1</sup> rest,  $4.4 \pm 0.2$  ml·kg<sup>-1</sup>·min<sup>-1</sup> PS2,  $4.6 \pm 0.1$  ml·kg<sup>-1</sup>·min<sup>-1</sup> Wii Madden,  $6.8 \pm 0.3$  ml·kg<sup>-1</sup>·min<sup>-1</sup> Wii Boxing) was significantly ( $p \leq 0.001$ ) greater than seated  $VO_2$  ( $4.0 \pm 0.6$  ml·kg<sup>-1</sup>·min<sup>-1</sup> rest,  $4.0 \pm 0.1$  ml·kg<sup>-1</sup>·min<sup>-1</sup> PS2,  $4.2 \pm 0.1$  ml·kg<sup>-1</sup>·min<sup>-1</sup> Wii Madden,  $6.1 \pm 0.3$  ml·kg<sup>-1</sup>·min<sup>-1</sup> Wii Boxing) for the resting and gaming conditions. Mean  $VO_2$  was greater ( $p \leq 0.001$ ) during Wii Boxing ( $6.5 \pm 1.5$  ml·kg<sup>-1</sup>·min<sup>-1</sup>) than all other conditions. Mean  $VO_2$  was greater ( $p \leq 0.05$ ) during Wii Madden ( $4.4 \pm 0.6$  ml·kg<sup>-1</sup>·min<sup>-1</sup>) than PS2 Madden ( $4.2 \pm 0.7$  ml·kg<sup>-1</sup>·min<sup>-1</sup>) and rest ( $4.0 \pm 0.6$  ml·kg<sup>-1</sup>·min<sup>-1</sup>). Mean  $VO_2$  was not significantly different ( $p = 0.077$ ) between PS2 Madden and rest. Participants preferred ( $p \leq 0.001$ ) to stand while playing Wii Boxing but preferred to sit for all other conditions.

**CONCLUSIONS:** Playing video games while standing increases energy expenditure to a greater extent than playing the same games in a seated position. Participants preferred to sit for every condition except for Wii Boxing which was also the most physiologically challenging game.

**2049** Board #95 MAY 31 8:00 AM - 9:30 AM

### Determinants of Physical Activity in Physical Education Teacher Education Students

Carolyn Albright<sup>1</sup>, Alex Vigo<sup>2</sup>, Tabatha Uhrich<sup>2</sup>, Heather Crowe<sup>2</sup>. <sup>1</sup>Immaculata University, Immaculata, PA. <sup>2</sup>Towson University, Towson, MD.  
(No relationships reported)

The National Association of Sports and Physical Education has recently implemented program accreditation standards ensuring physical education teacher education (PETE) majors achieve and maintain healthy fitness standards throughout the program. However college students have found to be vulnerable to weight gain and a decrease in physical activity.

**PURPOSE:** To provide a descriptive analysis of determinants of physical activity in PETE majors.

**METHODS:** Seventy-nine PETE majors ( $22.5 \pm 3.8$  yrs) at Towson University completed the Social Support from Family and Friends for Physical Activity and Self-Efficacy for Physical Activity surveys. Students filled out a questionnaire providing demographic information and physical activity barrier and determinant feedback. Height and weight were also measured.

**RESULTS:** Factors most likely to motivate students to be physically active included improving physical fitness (87%) and enjoyment (74%). Factors least likely to affect motivation included social support (22%) and losing weight (39%). Students with a higher BMI were more motivated by losing weight ( $r = 0.38$ ,  $p = 0.001$ ). Major barriers to exercise included too much homework (53%) and not enough time (60%). Only 18% of students felt that economic inflation had impacted their ability to be physically active. Compared to other factors of self-efficacy, students were least confident they could motivate themselves to be physically active if they had to study less. Higher grade level was associated with being more confident they could study less to exercise ( $r = -0.26$ ,  $p = 0.02$ ). Social support for physical activity was higher from friends than family on questions regarding exercising with them and changing schedules to exercise together. Higher grade level was associated with being more likely to provide information to family and friends about physical activity ( $r = 0.25$ ,  $p = 0.028$ ). Students with a lower BMI felt their family was more likely to change their schedule to exercise with them ( $r = -0.23$ ,  $p = 0.04$ ).

**CONCLUSIONS:** New accreditation standards are making fitness and physical activity in PETE students a variable to be considered when designing curriculum. The following descriptive analysis was able to provide direction in terms of motivating factors and barriers to increasing physical activity levels in these students.

**2050** Board #96 MAY 31 8:00 AM - 9:30 AM

### Remembered Affect And Leisure Activity: Associations With Gender, Current Activity Level, And Type Of Activity

Courtney Stevens<sup>1</sup>, Tiffany J. Callahan<sup>1</sup>, Angela D. Bryan<sup>1</sup>, Rebecca Warner<sup>2</sup>. <sup>1</sup>University of Colorado Boulder, Boulder, CO. <sup>2</sup>University of New Hampshire, Durham, NH.  
(No relationships reported)

Prior work has found affective responses to exercise to be predictive of subsequent physical activity participation. However, the nature of this association has not been thoroughly explored in naturalistic settings.

**PURPOSE:** To assess the relationship between leisure activity (active vs. passive) and remembered energetic mood change using a modified Day Reconstruction Method. Method: Energetic mood ratings were compared for male ( $N = 87$ ) and female ( $N = 397$ ) participants who reported engaging in at least 20 minutes of physically active leisure ( $N = 201$ ), or at least 20 minutes of passive leisure ( $N = 284$ ). Participants were asked to rate how energetic they remembered feeling before and after a leisure activity using the energy sub-scale of the Thayer Activation/Deactivation Adjective Checklist. Participants also reported how frequently they engaged in physical activity using the Godin Leisure Time Questionnaire (GLTQ).

**RESULTS:** Interactions between type of leisure, GLTQ scores (zero centered), and gender, were explored in multiple regression analysis with change in energy pre- to post-activity as the dependent variable. The set of predictors accounted for a significant proportion of the variability in energy change scores  $R^2 = .101$ ,  $F(7, 421) = 6.374$ ,  $p < .001$ . Individual regression slopes revealed significant main effects of type of leisure,  $b = .442$ ,  $t(421) = 3.70$ ,  $p < .00$  and sex,  $b = -.383$ ,  $t(421) = -2.13$ ,  $p = .033$ ; however, these results were qualified by a significant three-way interaction between sex, type of leisure activity, and GLTQ scores,  $b = .019$ ,  $t(421) = 2.319$ ,  $p = .021$ . The two-way interaction between sex and type of leisure was non-significant at this centered level of the GLTQ. Two additional regression models were calculated to explore the sex by type of leisure interaction at one standard deviation (SD) above and below the mean on the GLTQ. At one SD above the mean on GLTQ, there was a significant sex by type of leisure interaction  $t(421) = 2.71$ ,  $p = .007$ ; however this relationship was not significant at one SD below the mean on the GLTQ.

**CONCLUSIONS:** Among individuals who exercise most frequently the pattern of remembered energy change from pre- to post activity differed across sex and across type of leisure activity. Frequent exercisers remember greater energetic mood boosts compared to those who exercise less.

**2051** Board #97 MAY 31 8:00 AM - 9:30 AM

### Exercise Barriers And Costs For Cancer Survivor: Two Distinct Elements Of Behavioral Change Process

Nathalie André. University of Poitiers, Poitiers, France. (Sponsor: Tomporowski Phillip, FACSM)  
(No relationships reported)

Although scientific evidence supports the role of physical activity as an effective intervention for improving health, the majority of cancer survivors do not comply with public health guidelines (i.e. at least 150 minutes per week of moderate-to-vigorous intensity). Among the determinants of non adherence, barriers to participation are a well-known problem (Brawley et al., 2002). However, the lack of consensus in the definitions and measurements of barriers led to puzzling interpretation. For instance, authors indifferently mentioned exercise barriers and exercise costs. Moreover, in a meta-analysis on exercise (Marshall & Biddle, 2001), the authors reported that the patterns of change in cons were more diverse than in pros. This instability can be explained by the conceptualization and methodology used to measure costs.

**PURPOSE:** The aim of this study was to distinguish between perceived barriers and perceived costs of exercise in cancer survivors.

**METHODS:** Two hundred and sixty one cancer survivors completed a series of questionnaires including decisional balance (DB), perceived barriers and stages of change.

**RESULTS:** Two ANOVAs were carried out with stages of change score as within-subject factor (Precontemplation PC, Contemplation C, Preparation PR, Action/Maintenance A/M) and barriers and costs as dependent variables. For each Anova, significant effect of stages of change was found on barriers and cons. For perceived barriers, post-hoc tests revealed significantly higher mean scores for PC ( $M = 2.76$ ), C ( $M = 2.83$ ) and PR ( $M = 2.46$ ) than for A/M ( $M = 1.58$ ) stage. For perceived costs, post-hoc tests showed significantly higher mean scores for PC ( $M = 3.21$ ) than for C ( $M = 3.82$ ), PR ( $M = 4.19$ ) and A/M stages ( $M = 4.26$ ).

**CONCLUSION:** Perceived barriers remain relatively high and stable from PC to PR compared to perceived costs that significantly decrease from PC to PR. These results suggest that to stimulate movement from the early stages of change, a greater emphasis may be needed on reducing perceptions of barriers. Whether interventions suggest increasing pros to get people to think about change, followed by decreasing cons to allow the behavior to change, decreasing the perceived barriers should be a first step to allow individuals to considering a given behavior, mainly with sedentary persons.

---

**2052**    *Board #98*    **MAY 31**    **8:00 AM - 9:30 AM**  
**Parental Style and Sedentary Behavior in Preschool-Aged Children**

David P. Schary<sup>1</sup>, Paul D. Loprinzi<sup>2</sup>, Bradley J. Cardinal, FACSM<sup>1</sup>. <sup>1</sup>Oregon State University, Corvallis, OR. <sup>2</sup>Bellarmine University, Louisville, KY.  
(No relationships reported)

Parents play an important role in their children's health behaviors. However, no studies have examined the association between parenting style and preschool children's sedentary behaviors. Given the reported high levels of sedentary behavior among preschool children, there is a need to examine the potential link between parenting style and sedentary behaviors within this age group.

**PURPOSE:** To examine the association of parenting style on sedentary behaviors among preschool-aged children.

**METHODS:** Two hundred and one parents completed an online survey assessing different parenting styles (i.e., neglectful, permissive, authoritarian, and authoritative) and they estimated the amount of time that their child (mean age: 3.9 yrs) spent in different sedentary activities (i.e., "screen time" and quiet play) during weekdays and weekends. Comparisons between sedentary activities and the four parenting styles were examined using one-way ANOVAs. Significant main effects were followed-up by Scheffe post-hoc tests and effect size ( $\eta^2$ ) was calculated to estimate the magnitude of the main effect.

**RESULTS:** Parents who employed a permissive parenting style reported that their child engaged in more screen time (i.e., sedentary behaviors; watching TV, playing videogames or on the computer) on weekdays compared to authoritative parents (1.78 hr/d vs. 1.26 hr/d, respectively;  $p = 0.006$ ). Authoritative parents also reported that their child engaged in less screen time on the weekends in comparison to neglectful and permissive parents (1.61 hr/d vs. 2.15 hr/d vs. 2.29 hr/d, respectively;  $p < 0.05$ ). The effect sizes for both weekdays and weekends was small ( $\eta^2 = 0.06$ ). Additionally, there were no detectable differences between quiet play and parental style for either weekdays or weekends.

**CONCLUSION:** Although additional research is needed, this set of observations suggests that parenting style may influence the amount of screen time preschool children engage in.

---

**2053**    *Board #99*    **MAY 31**    **8:00 AM - 9:30 AM**  
**Sports Participation in Young Adult Cancer Survivors**

Lisa J. Belanger<sup>1</sup>, Ronald C. Plotnikoff<sup>2</sup>, Alexander M. Clark<sup>1</sup>, Kerry S. Courneya<sup>1</sup>. <sup>1</sup>University of Alberta, Edmonton, AB, Canada. <sup>2</sup>University of Newcastle, Newcastle, Australia.  
(No relationships reported)

Physical activity improves health outcomes in young adult cancer survivors (YACS) but participation rates are low. Sport is an understudied strategy for increasing physical activity in cancer survivors.

**PURPOSE:** To examine the prevalence and correlates of sports participation in YACS. .

**METHODS:** A provincial, population-based mailed survey of YACS in Alberta, Canada, was completed in May, 2008 and included measures of sport participation, medical variables, and demographic variables.

**RESULTS:** A total of 588 YACS completed the survey. Almost a third (32.5%) of YACS reported participating in a sport in the past month with the most common sport being golf (40.8%) followed by hockey (8.3%), tennis (7.3%), soccer (5.7%) and swimming (5.2%). YACS reporting sport participation in the past month reported an average frequency of 1.7 (SD=1.0) days/week and an average duration of 140 minutes (SD=132) per session for a total weekly minutes of sport participation of 279 (SD=379). In multivariate regression analysis, 8.5% ( $p < 0.001$ ) of the variance in sport participation was explained by being male ( $\beta = .17$ ;  $p < 0.001$ ), Caucasian ( $\beta = .15$ ,  $p = 0.001$ ), in better general health ( $\beta = .15$   $p < 0.001$ ), and having a normal body mass index score ( $\beta = -.10$   $p = 0.024$ ).

**DISCUSSION/CONCLUSIONS:** Sport participation may be a useful strategy for increasing physical activity in YACS, however, some health conditions and demographic groups may warrant particular attention.

Funded by a Canadian Institutes of Health Research Seed Grant in Physical Activity, Sport, and Health CIHR SPO-83173.

**2054**    *Board #100*    **MAY 31**    **8:00 AM - 9:30 AM**  
**Treadmill Exerts Stronger Influence than Setting on Running Speed and Heart Rate in College Runners**

Michael T. Nodzenski, Elizabeth J. Queathem. Grinnell College, Grinnell, IA.  
(No relationships reported)

Exercisers in outdoor settings have been found to have significantly higher running speeds and heart rates than in indoor settings. To our knowledge, these studies have not separated the influences of treadmills and outdoor settings on response variables. This study sought to tease apart these conflated effects.

**PURPOSE:** Separate the influences of outdoor and treadmill settings on runners' heart rate, running speed, attention, affect, and activation.

**METHODS:** We used a fully factored 2x2 design with condition (treadmill, trail/track) and location (indoors, outdoors) as within group variables and average heart rate and running speed as dependent measures. We also included time after running (0, 10, 20, 30 minutes) as a within group variable when attention (association minus dissociation scores), affect, and activation (tranquility minus fatigue scores) were used as response variables.

**RESULTS:** Running speed was significantly higher in the non-treadmill ( $M = 11.335$ ,  $SE = 0.267$ ) than treadmill condition ( $M = 10.578$ ,  $SE = 0.225$ ; ANOVA,  $F = 17.62$ ,  $p < 0.001$ ), as was average heart rate (ANOVA,  $F = 9.37$ ,  $p = 0.003$ ) (Non-treadmill:  $M = 130.29$ ,  $SE = 1.63$ ; Treadmill:  $M = 125.03$ ,  $SE = 1.67$ ). Activation was significantly higher in treadmill sessions ( $M = 1.605$ ,  $SE = 0.315$ ) than non-treadmill sessions ( $M = 0.513$ ,  $SE = 0.346$ ; ANOVA,  $F = 9.61$ ,  $p = 0.002$ ), suggesting greater fatigue in non-treadmill sessions. Location did not significantly affect running speed, heart rate, or activation, but its effect on change in affect approached significance, with outdoor values ( $M = 0.934$ ,  $SE = 0.209$ ) higher than indoor values ( $M = 0.493$ ,  $SE = 2.72$ ; ANOVA,  $F = 3.62$ ,  $p = 0.058$ ). Attention was significantly more dissociative outdoors ( $M = -10.5$ ,  $SE = 2.01$ ) than indoors ( $M = -4.39$ ,  $SE = 1.98$ ; ANOVA,  $F = 5.87$ ,  $p = 0.019$ ).

**CONCLUSION:** Running speed and heart rate were significantly lowered by treadmill running compared to non-treadmill, but did not vary significantly by location. Outdoor locations yielded higher affective response values and corresponded to more dissociation. These findings suggest that the physiological aspects of running may be more strongly influenced by whether runners use a treadmill or track/trail, while the psychological aspects may be more strongly influenced by location.

---

**2055**    *Board #101*    **MAY 31**    **8:00 AM - 9:30 AM**  
**Effect Of Level Of Autonomy On The Amount Of Physical Activity In Young Children**

Judith A. Juvancic-Heltzel<sup>1</sup>, Gabriel J. Sanders<sup>2</sup>, Megan L. Williamson<sup>2</sup>, James N. Roemmich, FACSM<sup>3</sup>, Denise M. Feda<sup>4</sup>, Jacob E. Barkley<sup>2</sup>. <sup>1</sup>The University of Akron, Akron, OH. <sup>2</sup>Kent State University, Kent, OH. <sup>3</sup>Department of Agriculture, Northern Plains Area, Grand Forks, ND. <sup>4</sup>State University of New York University at Buffalo, Buffalo, NY.  
(No relationships reported)

Emerging research has indicated that providing choice of exercise options increases the amount of physical activity children perform. However, these studies have not yet assessed this effect using physical activities children typically have access to in a naturalistic setting.

**PURPOSE:** To assess physically active and sedentary behaviors of children in a naturalistic setting under two conditions: one that provided high autonomy through choice (HC) of eight physical activity options, and one that provided minimal autonomy by providing choice of two active options (LC).

**METHODS:** Ten boys (age  $6.3 \pm 1.6$  y) and seven girls (age  $5.7 \pm 1.3$  y) completed HC and LC conditions in a gymnasium. The order of the conditions was randomized. During HC participants had access to three obstacle courses, jump-rope, various balls and targets and a table of sedentary activities (games, toys, coloring sheets, books and crayons) for 30 minutes. During LC participants had access to two physical activity equipment options (one obstacle course, one ball with targets) and the same sedentary activities. During each condition participants

were free to participate in the physical and/or sedentary activities as they chose for the entire session. Physical activity intensity was monitored via accelerometer. Average per-minute accelerometer counts were converted to METs. The amount of time allocated to sedentary activity was monitored via observation and stopwatch. Participants reported their liking of each condition via a visual analog scale.

**RESULTS:** Mixed-model analysis of variance demonstrated a significant ( $p < 0.04$ ) sex (boys, girls) by condition (HC, LC) interaction for average physical activity intensity (METs). Boys increased ( $p = 0.002$ ) average physical activity intensity from the LC ( $5.8 \pm 3.3$  METs) to HC ( $6.9 \pm 2.8$  METs) condition. Girls did not alter ( $p \geq 0.6$ ) average physical activity intensity across conditions ( $5.8 \pm 4.7$  METs LC,  $5.5 \pm 4.4$  METs HC). There were no significant ( $p \geq 0.3$ ) main or interaction effects for differences in time allocated to sedentary activities or liking.

**CONCLUSIONS:** Increasing the variety of physical activity equipment options in a naturalistic setting increased average physical activity intensity in young boys but not young girls.

**2056** Board #102 MAY 31 8:00 AM - 9:30 AM

### Understanding Physical Activity in Kidney Cancer Survivors Using the Theory of Planned Behavior

Linda Trinh<sup>1</sup>, Ronald C. Plotnikoff<sup>2</sup>, Ryan E. Rhodes<sup>3</sup>, Scott A. North<sup>4</sup>, Kerry S. Courneya<sup>1</sup>. <sup>1</sup>University of Alberta, Edmonton, AB, Canada. <sup>2</sup>University of Newcastle, Callaghan, NSW, Australia. <sup>3</sup>University of Victoria, Victoria, BC, Canada. <sup>4</sup>Cross Cancer Institute, Edmonton, AB, Canada.  
(No relationships reported)

Physical activity (PA) improves quality of life, physical functioning, and fatigue in several cancer survivor groups including kidney cancer survivors (KCS). Despite the established benefits of PA, over half of KCS are completely sedentary and only a quarter are meeting PA guidelines. This highlights the need to identify and understand the determinants of PA in this understudied survivor population. To the best of our knowledge, no study to date has examined the determinants of PA in KCS.

**PURPOSE:** To determine the social cognitive correlates of PA intention and behaviour in KCS using the Theory of Planned Behaviour (TPB).

**METHODS:** All 1,985 KCS diagnosed between 1996 and 2010 identified through a Canadian provincial Registry in Alberta, Canada were mailed a self-report survey that consisted of the Godin Leisure Time Exercise Questionnaire and standard TPB items for intention, perceived behavioural control (PBC), affective and instrumental attitudes, and descriptive and injunctive norms. Standard demographic and medical variables were also collected.

**RESULTS:** Completed surveys were received from 703 of 1,654 (43%) eligible KCS. Briefly, the mean age was  $65.0 \pm 11.1$ , 62.9% were male, mean BMI was  $28.5 \pm 5.2$ , and mean number of months since diagnosis was  $69.0 \pm 55.5$ . The TPB was tested using structural equation modelling and demonstrated an adequate-to-good fit to the data [ $\chi^2 = 151.57$ ,  $p < 0.001$ ; TLI = 0.96; CFI = 0.98; RMSEA = 0.07, 90% CI = 0.06-0.08]. There were significant model pathways to intention from affective ( $\beta = 0.16$ ,  $p = 0.03$ ) and instrumental attitude ( $\beta = 0.24$ ,  $p = 0.03$ ), descriptive norm ( $\beta = 0.08$ ,  $p = 0.01$ ), and PBC ( $\beta = 0.51$ ,  $p = 0.02$ ). In addition, there were significant pathways to PA from PBC ( $\beta = 0.18$ ,  $p = 0.01$ ) and intention ( $\beta = 0.49$ ,  $p = 0.01$ ). Overall, the TPB accounted for 69% and 41% of the variance in intention and PA behaviour respectively.

**CONCLUSION:** The TPB appears to be a useful model for explaining PA in KCS. All TPB constructs except injunctive norm were useful for explaining intention with PBC emerging as the largest correlate. As expected, both PBC and intention were significant correlates of PA with intention emerging as the largest correlate. Developing PA behavior change interventions based on the TPB may be effective in promoting PA in KCS and may lead to important improvements in health.

### Psychosocial Mediators Of The Association Between Acculturation And Leisure-time Physical Activity Among Korean Americans

Hyo Lee, Bradley J. Cardinal, FACSM, Sombat Onsiri. Oregon State University, Corvallis, OR.  
(No relationships reported)

Ethnic minorities', including Korean Americans', leisure-time physical activity (LTPA) participation is less than ideal. Eliminating physical activity disparities in ethnic groups is important. Empirical studies suggested that acculturation may be an important factor explaining physical activity disparity, but there is a scarcity of studies testing psychosocial mediators by which the association between acculturation and leisure-time physical activity can be better understood.

**PURPOSE:** This study tested: 1) the theory of planned behavior's (Ajzen, 1991) four psychosocial constructs (attitude, subjective norm, perceived behavioral control, and behavioral intention) as potential mediators of the association between acculturation and LTPA in Korean Americans; and 2) whether the relationships among variables vary by gender.

**METHODS:** Four hundred forty nine Korean Americans (216 males and 223 females; age  $30.42 \pm 10.41$  years) participated in a survey for this study. A multiple-sample structural equation modeling was used to test gender invariance and associations among the constructs.

**RESULTS:** Factor structures and associations among the factors were invariant by gender. The final model fit to data well, CFI = .970, TLI = .969, RMSEA = .043. Acculturation was positively associated with perceived behavioral control (PBC;  $\beta = .31$ ,  $p < .001$ ), but inversely associated with subjective norm ( $\beta = -.23$ ,  $p < .001$ ). In turn, PBC ( $\beta = .46$ ,  $p < .001$ ), subjective norm ( $\beta = .15$ ,  $p < .001$ ), and attitude ( $\beta = .24$ ,  $p < .001$ ) were positively associated with behavioral intention ( $R^2 = .40$ ); and intention ( $\beta = .42$ ,  $p < .001$ ), perceived behavioral control ( $\beta = .22$ ,  $p < .01$ ), and acculturation ( $\beta = .11$ ,  $p < .05$ ) were significantly associated with LTPA ( $R^2 = .33$ ).

**CONCLUSIONS:** The association between acculturation and LTPA can be at least partially understood by the meditative effects of PBC, subjective norm, and behavioral intention. Korean Americans' cultural assimilation to the US mainstream enhance their belief about behavioral controllability and level of confidence, but decrease perception of social pressure to participate in LTPA. Practically, this study suggests that culturally relevant intervention programs to promote Korean Americans' LTPA should target to mitigate the negative impact of acculturation on subjective norm.

### Psychological Needs Mediate The Relationship Between Physical Exertion Barriers And Body Fat Percent In College-Aged Mexican-American Women

Vanessa Martinez, Jared Montoya, Murat Karabulut, Cody Cox, Alexis Martinez, David Wittenburg. University of Texas Brownsville, Brownsville, TX.  
(No relationships reported)

In the last several decades, there has been a wave of interest in the overweight/obese population in the United States. However, little research has focused on the association between exercise barriers and psychological needs in college-aged Mexican-American females.

**PURPOSE:** To investigate the relationships between exercise barriers, psychological needs for exercise, and obesity among college-aged Mexican-American females.

**METHODS:** Body fat measures were recorded on 91 female students ( $M = 22.8 \pm 5.1$ ). The Exercise Benefits and Barriers Scale (EBBS) was used to determine perceived barriers. The EBBS examined Exercise Milieu (EM), Time Expenditure (TEB), Physical Exertion (PEB), and Family Discouragement (FDB) for perceived barriers to exercise. The Psychological Need Satisfaction in Exercise Scale (PNSE) was used to examine the degrees of perceived Competence (PCo), Autonomy (PAu), and Relatedness (PR) as they pertain to an individual's motivation to exercise.

**RESULTS:** The mean body fat score indicated 28.6 % ( $n = 26$ ) of the sample were overweight, and 50.6 % ( $n = 46$ ) were obese. There were significant correlations observed between PCo ( $r = .35$ ,  $p = .00$ ) and PAu ( $r = -.25$ ,  $p = .02$ ) with reduced BF %. PCo ( $r = -.22$ ,  $p = .04$ ) and PAu ( $r = -.23$ ,  $p = .01$ ) negatively associated with PEB. PEB ( $r = .24$ ,  $p = .02$ ) significantly correlated with increased BF %. Mediation analysis indicated that PCo and PAu influenced the relationship between PEB and BF % in college-aged Mexican-American females.

**CONCLUSIONS:** The findings indicate that women who continue to perceive exercise as being strenuous lack intrinsic motivation which may lead to physical inactivity; thus unhealthy accumulation of BF is likely. In order to overcome such perceptions, practitioners should target the enhancement of psychological needs to reduce perceived barriers. Therefore, successful intervention programs need to focus on increasing competency and autonomy for exercise with the actual exercise program in Mexican-American women.

2059 Board #105 MAY 31 8:00 AM - 9:30 AM

**Self-reported Peer Victimization And Objectively Measured Physical Activity Behavior In Overweight/obese And Non-overweight Boys**

Jacob E. Barkley<sup>1</sup>, Melissa A. Rittenhouse<sup>2</sup>. <sup>1</sup>Kent State University, Kent, OH. <sup>2</sup>James Madison University, Harrisonburg, VA. (Sponsor: Ellen L. Glickman, FACSM)  
(No relationships reported)

**BACKGROUND:** Emerging evidence has indicated a negative association between self-reported peer victimization and physical activity behavior in youth. However, these previous studies have relied on survey instruments to assess physical activity and no studies have examined this relationship in a controlled environment.

**PURPOSE:** To assess peer victimization and its relationship to objectively-measured physical activity in boys in a controlled environment.

**METHODS:** Twenty-four overweight/obese (N=12) and non-overweight boys (10.4±1.5 years old) completed one experimental session. Children first completed a peer victimization questionnaire that included an overt victimization subscale (OVS) assessing how frequently other students have harmed or threatened to harm their physical well-being and a relational subscale (RS) assessing how often students have attempted to harm peer relationships. Children were then taken to a gymnasium where they had free-choice access to physical activities (e.g. balls and goals) and/or sedentary alternatives (e.g. crossword puzzles and magazines) for a period of 30-minutes. Children could participate in any of these activities, in any sequence they chose, for the entire 30-minute activity session. Physical activity during the activity session was assessed via accelerometry. A stop watch was used to record children's time allocation to sedentary activities.

**RESULTS:** Overweight/obese children (11.5 ± 3.9 OVS, 11.8 ± 4.7 RS) reported greater ( $p \leq 0.04$ ) scores in the OVS and RS subscales of the questionnaire than non-overweight children (7.6 ± 2.6 OVS, 8.2 ± 3.1 RS). Overweight/obese children (9.0e+4 ± 3.9e+4 counts, 7.7 ± 6.6 minutes) also accumulated fewer accelerometer counts and allocated more time ( $p \leq 0.01$  for all) to sedentary activity than non-overweight children (13.7e+4 ± 4.6e+4 counts, 1.2 ± 3.7 minutes) during the 30-minute activity session. The OVS and RS subscales were significantly and positively ( $r \geq 0.41$ ,  $p \leq 0.05$ ) correlated to sedentary activity time. There was a trend towards a negative ( $r \geq -0.36$ ,  $p \leq 0.07$ ) correlation between the two subscales and accelerometer counts.

**CONCLUSIONS:** These results support a potentially harmful link between peer victimization and decreased, objectively-measured physical activity behavior in boys.

**Gender, Weight Status And Socioeconomic Differences In Psychosocial Correlates Of Physical Activity In Schoolchildren**

Ana C. Seabra<sup>1</sup>, André Seabra<sup>1</sup>, Denisa Mendonça<sup>2</sup>, José Maia<sup>1</sup>, Gregory Welk, FACSM<sup>3</sup>, Robert Brustad<sup>4</sup>, António M. Fonseca<sup>1</sup>. <sup>1</sup>Research, Education, Innovation and Intervention in Sport, Faculty of Sport, University of Porto, Porto, Portugal. <sup>2</sup>Institute of Public Health (ISPUP), Institute of Biomedical Sciences Abel Salazar, University of Porto, Porto, Portugal. <sup>3</sup>Nutrition and Wellness Research Center, Iowa State University, Iowa, IA. <sup>4</sup>College of Natural & Health Sciences, Sport and Exercise Science, University of Northern Colorado, Greeley, CO.

(No relationships reported)

Childhood obesity is a major public health problem and a sedentary lifestyle is implicated in the development of this condition. Psychosocial factors are major correlates of children's participation in physical activity (PA). The number of studies that have examined demographic and biological differences in these psychosocial correlates is very limited.

**PURPOSE:** To assess differences in the attraction to PA, perceived physical competence and parental influences across gender, body mass index (BMI) and socioeconomic status (SES) in Portuguese primary school children.

**METHODS:** 683 children, 8-10 years of age, were surveyed. Attraction to PA, perceived physical competence and parental influences were assessed via standardized questionnaires. Family SES was estimated with a questionnaire. The prevalence of overweight and obesity was calculated using BMI, and the cut-off points suggested by Cole et al. Statistical procedures included three-way ANOVA.

**RESULTS:** (1) Normal-weight girls like more to participate in vigorous PA than overweight and obese girls ( $F=3.73$ ,  $p=0.025$ ). (2) High and medium SES children recognize more importance to PA than low SES children ( $F=4.97$ ,  $p=0.007$ ). (3) Boys enjoy more games and sports than girls ( $F=4.14$ ,  $p=0.042$ ). (4) Obese children consider to be less accepted by peers' in games and sports than normal-weight and overweight children ( $F=3.88$ ,  $p=0.021$ ). (5) High SES girls like more exertion aspects of PA than low SES girls ( $F=5.91$ ,  $p=0.003$ ). (6) Boys ( $F=19.18$ ,  $p<0.001$ ) and normal-weight ( $F=3.17$ ,  $p=0.043$ ) children perceiving themselves as being more successful and physically competent, than girls and obese children. (7) High SES children consider, more significantly, their parents as role models ( $F=4.55$ ,  $p=0.011$ ) and perceived them as having more fun ( $F=5.61$ ,  $p=0.004$ ) and enjoyment doing PA ( $F=8.42$ ,  $p<0.001$ ) than lower SES children.

**CONCLUSIONS:** These results suggest that intervention should focus on girls, obese and lower SES children who were less attracted to PA, perceived as less physical competent and less influenced by their parents which put them at higher risk for inactivity.

**C-29 Free Communication/Poster - Effects of Footwear on Gait**

MAY 31, 2012 7:30 AM - 12:30 PM

ROOM: Exhibit Hall

---

2061 Board #107 MAY 31 9:00 AM - 10:30 AM

**Effects Of Different Footwear On Peak Impact Force And Time During A Depth Drop**

Joe W. LaPorta, James J. Tufano, Vanessa L. Cazas, Jeremy G. Tan, Leah Truong, Lee E. Brown, FACSM. California State University, Fullerton, Fullerton, CA.

(No relationships reported)

**PURPOSE:** The purpose of this study was to determine the effects of different footwear on force absorption characteristics during a depth drop.

**METHODS:** Twenty seven female volunteers (23±2.2 yrs, 162.94±7.37 cm, and 62.02±8.79 kg) performed a five minute warm-up on a cycle ergometer and were then randomly assigned to one of two conditions (minimalist shoes, or barefeet). Subjects then performed three depth drops off an 18 inch box, then repeated the same protocol for the remaining condition. Peak S-gradient RFD, S-gradient force, and S-gradient time were measured on a force plate. A paired samples t-test compared the two conditions.

**RESULTS:** There was no significant ( $p>0.05$ ) difference in the peak S-gradient RFD (barefeet= 96427.3519 + 44785.139 N/s, minimalist shoe= 90916.5148 + 40157.80640 N/s) or peak S-gradient force (barefeet=1914.2616 + 764.18553 N, minimalist shoe=1806.6647 + 730.51036 N) between the two conditions. Peak S-gradient time was significantly ( $p<0.05$ ) longer in the minimalist footwear (0.0391 + 0.00851 sec) condition than in barefeet (0.0391 + 0.01058 sec).

**CONCLUSIONS:** It appears that during the depth drop neither rate of force development or peak force are affected by minimalist footwear. However, force absorption time is significantly longer in minimalist footwear. The minimalist footwear condition may allow individuals to reach the S-gradient over a slightly longer period of time, thus leading to greater force absorption. However, at this time, a change in footwear is not warranted to improve force absorption characteristics.

2062 Board #108 MAY 31 9:00 AM - 10:30 AM

**Four Weeks Familiarisation To Simulated Barefoot Running Significantly Improves Running Economy Compared To Shod Running**

Joe P. Warne, Giles D. Warrington, FACSM. Dublin City University, Dublin, Ireland.

(No relationships reported)

Despite the increased popularity of barefoot (BR) and simulated barefoot running (SBR), the physiological responses to different footwear conditions is largely unexplored and the process of adaptation and familiarisation to BR or minimalist SBR remains to be determined.

**PURPOSE:** The purpose of this study was to evaluate the effects of a 4 week familiarisation period of SBR (Vibram Five Fingers, VFF) on running economy (RE) and compare this to running in a traditionally shod (SR) condition.

**METHODS:** 15 male national level middle distance athletes (age:  $24 \pm 4$  yrs; stature:  $177.2 \pm 6.21$  cm; mass:  $67.99 \pm 7.36$  kg and  $VO_2$  max  $70.2 \pm 5.2$  ml/kg/min) were recruited to participate in the study. Subjects completed two RE tests; 24 hours apart, in both the VFF or SR condition, in a random order (pre-test) at 11 and 13km/h. Oxygen uptake ( $VO_2$ ), blood lactate (Bl<sub>a</sub>), heart rate (HR), and stride frequency (SF) were measured during each test. Subjects then completed a 4 week familiarisation period of running in VFF's, before repeating the 2 running economy tests in a random order (post-test).

**RESULTS:** Following the 4 week familiarisation a significant improvement in RE was observed at both velocities in the VFF condition ( $p=0.006$ ), the improvement in RE was 7.7% between the pre-test and post-test ( $46.34 \pm 1.29$  v  $43.02 \pm 1.1$  ml/kg/min;  $p=0.006$ ). There was also a non-significant improvement in RE of 2.4% in the SR condition between over time ( $47.52 \pm 0.94$  v  $46.43 \pm 0.88$  ml/kg/min;  $p=0.087$ ). At the pre-test, RE was 2.2% lower in the VFF compared to the SR condition but this was not found to be significant ( $p=0.231$ ). In contrast, following the familiarisation period (post-test), when compared to shod RE was significantly improved in the VFF condition ( $p=0.006$ :  $45.884 \pm 42.69$  v  $42.69 \pm 1.21$  ml/kg/min: 7.5% difference). SF was significantly higher (2.5%) in the VFF condition across both time points ( $p=0.01$ ).

**CONCLUSIONS:** The results of the current study support previous research suggesting that SBR improves running economy when compared to SR, which may in part be explained by a change in running mechanics associated with an increase in SF and consequent reduction in stride length. The study findings also suggest that being fully habituated to running in VFF's may further improve RE in the VFF condition and to a lesser extent the SR condition also.

**2063** Board #109 MAY 31 9:00 AM - 10:30 AM

**Comparison of Physiological Variables During Barefoot and Shod Treadmill Running in Inexperienced Barefoot Runners**

Joel R. De Paoli, Matt Lee, Marialice Kern, FACSM. *San Francisco State University, San Francisco, CA.*

*(No relationships reported)*

**PURPOSE:** To examine differences in physiological variables between barefoot (BF) and shod (SH) treadmill running in a group of inexperienced BF runners.

**METHODS:** Twelve participants with no previous BF running experience (mean age  $24.8 \pm 0.9$  yr; 6 males, 6 females) engaged in 6-minute running bouts of both BF and SH at 6 mph and 1% grade (randomly assigned). Oxygen consumption ( $VO_2$ ), heart rate (HR), respiratory exchange ratio (RER), pulmonary ventilation (VE), and Rating of Perceived Exertion (RPE) were recorded during both conditions. Video data was also collected to examine stride rate (SR) and stride length (SL). Data was averaged over the last 2 minutes of each condition. A 2 x 2 (sex x condition) repeated measures ANOVA was used to examine differences in variables between sex and conditions. A significance level of 0.05 was used for all tests.

**RESULTS:** The ANOVA revealed significant main effects of condition on  $VO_2$ , VE, RER, SL, and SR. This was such that  $VO_2$ , VE, and RER were lower during BF compared to SH ( $34.5 \pm 1.0$  vs.  $36.1 \pm 0.9$  ml/kg/min,  $55.3 \pm 4.0$  vs.  $58.8 \pm 4.2$  liters/min and  $0.92 \pm 0.1$  vs.  $0.94 \pm 0.02$ , respectively). Additionally, SL was lower ( $0.89 \pm 0.02$  vs.  $0.97 \pm 0.01$  m) and SR was greater ( $181.0 \pm 3.6$  vs.  $166.4 \pm 2.7$  strides/min) during BF compared to SH. Furthermore, there was a sex x condition interaction on HR such that HR was greater during BF in females ( $177.0 \pm 3.2$  vs.  $172 \pm 3.5$  bpm), while it was lower during BF in males ( $159.2 \pm 2.7$  vs.  $164 \pm 1.7$  bpm). Lastly, there was a trend for a main effect of condition on RPE such that it was lower during BF ( $11.6 \pm 0.3$  vs.  $12.3 \pm 0.4$ ;  $p=0.086$ ). Overall, the  $VO_2$  of running was 4.2% lower during BF compared to SH (males: 4.5%; females: 3.9%).

**CONCLUSIONS:** This data suggests that barefoot running is more economical than shod running in inexperienced barefoot runners. Additionally, BF results in shorter strides and a greater stride frequency, giving further merit to the notion that the economical differences, in part, result from the kinematic changes that occur when running barefoot. The different responses of HR between sexes during BF and SH warrants further investigation.

**2064** Board #110 MAY 31 9:00 AM - 10:30 AM

**A Comparison of 1-Mile Times in Experienced and Inexperienced Minimalist Footwear Runners**

Adam M. Coughlin, Allie Langwald. *Adrian College, Adrian, MI.*

*(No relationships reported)*

Minimalist footwear running, including barefoot running, has become increasingly popular as new technology and recent research has emerged. Research shows that traditional running footwear causes sudden loading of the lower extremities in contact with the weight bearing surface, producing an extremely sharp rise of vertically transmitted force impact. Barefoot running mechanics allows for adaptations that provide impact absorption. Little is known about running performance between shod and minimalist footwear.

**PURPOSE:** Determine the effects running in Vibram Five Finger (VFF) Bikilas on one-mile run times of both inexperienced and experienced barefoot runners on an indoor track.

**METHODS:** Twenty runners (8 experienced minimalist runners) conducted two separate one-mile time trials. Trials were performed in a traditional running shoe and another trial while running in VFF Bikilas. Weights of the shoes were also collected.

**RESULTS:** As a group, participants ran faster in VFF Bikilas (VFF  $7.17 \pm 1.04$  min, shod  $7.36 \pm 1.06$  min,  $p = 0.004$ ). Experienced minimalist participants also ran faster in VFF Bikilas (VFF  $6.63 \pm 1.20$  min, shod  $6.94 \pm 1.33$  min,  $p = 0.015$ ). Inexperienced minimalist participants ran an average of 6.4 seconds faster while wearing VFF Bikilas, but this was not statistically significant (VFF  $7.53 \pm 0.79$  min, shod  $7.63 \pm 0.78$  min,  $p = 0.12$ ). The difference in the weight of the shoe only accounted for 18% ( $R^2 = 0.1846$ ) of the variance between the difference two time trials.

**CONCLUSION:** As a whole, runners had significantly faster times in the VFF Bikilas. Experienced minimalist runners ran significantly faster in the VFF trial than the traditionally shod trial, while the inexperienced minimalist runners also ran faster in the VFF trial, although not statistically significant.

---

**2065** Board #111 MAY 31 9:00 AM - 10:30 AM

**Effect of Minimalist Shoes Versus Bare Feet on Deceleration from a Vertical Jump**

Vanessa L. Cazas, James J. Tufano, Joe LaPorta, Jeremy G. Tan, Leah Troung, Lee E. Brown, FACSM. *California State University Fullerton, Fullerton, CA.*

*(No relationships reported)*

Females have been shown to have a higher rate of ACL injuries in comparison to males. Newly developed footwear may alter deceleration during jump landings, thereby decreasing the risk of injury.

**PURPOSE:** The purpose of this study was to investigate the effect of minimalist shoes vs. bare feet on deceleration from a vertical jump.

**METHODS:** Twenty-seven recreationally trained females ( $23 \pm 2.2$  yrs,  $162.9 \pm 7.3$  cm, and  $62 \pm 8.7$  kg) performed a 5-minute cycling warm-up, then completed three vertical jumps while wearing either minimalist shoes (MS; Fila Skele-toes) or with bare feet (BF). All vertical jumps were performed on a force plate in a counter-movement fashion with hands placed on the hips. Deceleration time (DT), peak deceleration velocity (PDV) and deceleration (PDV/DT), were directly measured on an AMTI force plate sampling at 1000Hz.

**RESULTS:** Paired t-tests showed no significant ( $p > 0.05$ ) differences in deceleration between MS (mean:  $11.11$  m/s<sup>2</sup>, SD: 4.32) and BF (mean:  $11.02$  m/s<sup>2</sup>, SD: 4.51) or in DT MS (mean:  $0.25$  s, SD: 0.14) and BF (mean:  $0.23$  s, SD: 0.08) or in PDV MS (mean:  $-2.20$  m/s, SD:  $-0.21$ ) and BF (mean:  $-2.20$  m/s, SD:  $-0.20$ ).

**CONCLUSION:** Minimalist shoes do not appear to effect deceleration when compared to bare feet. This suggests that wearing minimalist shoes may not decrease the risk of injury when landing from a vertical jump.

2066 Board #112 MAY 31 9:00 AM - 10:30 AM

**Speed Dependent Changes In Emg Patterns In Minimalistic Footwear; Effects Of Footstrike Pattern: Preliminary Results**

Jasper Reenalda, Wiebe De Vries, Bart Freriks, Jaap Buurke. *Roessingh Research and Development, Enschede, Netherlands.*  
(No relationships reported)

There has been growing interest lately in barefoot running and many runners attempt to run barefoot or in new shoe concepts such as minimalistic footwear. It can be assumed that minimalistic footwear requires adaptation in running style mainly due to lack of cushioning. Especially of interest are effects of running speed, as ground reaction is known to increase with increasing running speed. Different adaptations in muscle activation patterns (EMG) can be expected between runners who are habitually running with a Rear Foot Strike (RFS) or with a Mid Foot or Fore Foot Strike (MFS/FFS).

**PURPOSE:** To investigate speed dependent changes in EMG patterns during running in minimalistic footwear in relation to foot strike pattern.

**METHODS:** 6 competitive runners ( $42 \pm 10$  years,  $183.8 \pm 1.2$  cm, and  $75.4 \pm 8.1$  kg), 3 of them were running with a RFS and 3 with a MFS/FFS, performed one minute trials at a treadmill at 6 different running speeds (10-15 km/h) while wearing minimal footwear. Surface EMG was measured at 1000 Hz according to the SENIAM protocol on the m. Tensor Fascia Latae (TF), m. Rectus Femoris (RF), m. Semitendinosus (ST), m. Tibialis anterior (TA), m. Peroneus longus (PL), m. Soleus (SL) and m. Gastrocnemius medialis (GM). Raw EMG data was filtered with a 3rd order high-pass filter with a cut-off frequency of 25 Hz. Smooth Rectified EMG (SRE) was filtered with a 3rd order low-pass filter with a cut-off frequency of 20 Hz. SRE was re-sampled to 100 HZ. Data was averaged over 10 gait cycles. SRE was integrated to obtain integrated-EMG (iEMG). 3-d Motion capturing was used to determine stance time as the time between initial contact and toe off.

**RESULTS:** Stance time decreased from 49 to 42% (mean  $45.5 \pm 2.6$ ) of gait cycle in RFS and from 44 to 38% (mean  $41 \pm 2.1$ ) in MFS/FFS with increasing speed. For maximal amplitude, highest increases of 46% were found for the RF in the RFS condition and of 32% for ST and SL in the MFS/FFS condition. iEMG increased 32% (range 17-55%) on average for all muscles in the RFS condition and 24% (range 16-37%) in the MFS/FFS condition.

**CONCLUSIONS:** Speed dependent changes in EMG patterns were found in runners who were novice to running in minimalistic footwear. Adaptation strategies were different between runners habitually running with a RFS or a MFS/FFS.

Supported by EC FP7 grant no. 222468

**Kinematic Comparison Of Treadmill Running While Barefoot And In Standard And Zero-drop Running Shoes**

Michael Bohne, Kelli Roach, Justin Tranchell, Jeff Wartena, Jason Slack, Andrew Creer. *Utah Valley University, Orem, UT.* (Sponsor: Scot Drum, FACSM)  
(No relationships reported)

**INTRODUCTION:** Evidence suggests that barefoot running may protect the feet and lower limbs from impact related injuries by producing a fore to mid-foot strike, which generate smaller collision forces with the ground. Barefoot running may protect feet from impact forces, running barefoot may not always be practical. Companies have developed shoes with minimal damping material in the heel of the shoe to decrease the offset between the heel and forefoot, resulting in a fore-foot to mid-foot strike. Although these designs are based on the benefits of barefoot running, no research has shown that running in this type of shoe is better than standard running shoes of a similar mass.

**PURPOSE:** Determine if a zero-offset shoe offers similar kinematics to running barefoot and different from standard running shoes.

**METHODS:** Nine well trained distance runners ( $25.7 \pm 3.5$  yrs,  $178.6 \pm 5.9$  cm,  $67.6 \pm 8.5$  kg,  $72.0 \pm 5.2$  ml/kg/min) Participants performed three, six minute run intervals on a treadmill at 16.0 km/hr at 1% grade. Three intervals were performed in standard running shoe (SR), zero-offset shoe (ZD), and barefoot (BF). The order of the intervals was randomized for each subject, and a rest period was provided between each interval to change shoes. During each interval joint kinematics were collected using reflective markers on the hip, knee, ankle, toe, heel, shoulder and head. Participants were filmed at 250 Hz using a Fastec Inline camera (Fastec Imaging, San Diego, CA). The video footage was digitized using MaxTraq software (Innovision Systems, Columbiaville, MI). Data were analyzed repeated measures ANOVA ( $\alpha=0.05$ ) **RESULTS:** There was a significant difference for the foot angle at touchdown between SR and both ZD and BF conditions. ( $p=0.07$ ). Additionally, there is an increase in the stance time between both shoe conditions and BF. ( $p=.040$ )

**CONCLUSIONS:** The ZD shoes showed a similar position at foot strike, leading to the belief that the ZD shoes may better mimic the "natural" running technique. It is believed that the increase in stance time will allow for greater absorption of the forces experienced during running, allowing for reduced injury rates in runners. Further research is needed to examine the joint characteristics of the lower extremity in the ZD condition to further illustrate the adaptations made during the running stride.

2068 Board #114 MAY 31 9:00 AM - 10:30 AM

**Running Injury & Adaptation to Footwear**

Stacey A. Meardon<sup>1</sup>, Alicia Deurst<sup>1</sup>, Timothy R. Derrick<sup>2</sup>. <sup>1</sup>University of Wisconsin - La Crosse, La Crosse, WI. <sup>2</sup>Iowa State University, Ames, IA. (Sponsor: Thomas Kemozek, FACSM)  
(No relationships reported)

Running in the real world requires runners to adapt to changing conditions. Injured runners have been reported to have decreased variability in running mechanics and therefore may lack adaptability. Failure to adapt to footwear or environmental conditions by making kinematic adjustments to attenuate impacts may result in elevated impacts or loading rates.

**PURPOSE:** to determine response to midsole hardness change in runners with a history of injury that has interrupted training for more than one week in duration **METHODS:** 20 injured (INJ) & 20 non-injured (CON) runners matched on gender, speed and limb dominance ran over a force platform at a self-selected pace in 3 randomized midsole hardness conditions: 45 (soft), 57 (medium) and 70 (hard) durometer. Force platform data were collected and synchronized with 3D motion capture data. The effects of group and condition on key biomechanical variables were assessed using ANOVA. The average loading rate of the vertical GRF in the first 20% of stance (VLR) served as the outcome variable and sagittal plane joint angles at contact served as the performance variables to determine responses to midsole hardness.

**RESULTS:** VLR differed between the three conditions ( $p<0.01$ ) but not between groups. No significant interaction was observed ( $p=.18$ ). VLR was lower in the soft condition ( $57.3 \pm 20.5$  BW/s) compared to the medium ( $60.6 \pm 20.4$  BW/s;  $p=0.03$ ) and hard conditions ( $60.3 \pm 20.6$  BW/s;  $p=.04$ ). A significant group X condition interaction was found for knee flexion angle ( $p=0.04$ ). CON runners adjusted knee angle across conditions whereas the INJ runners did not. Hip flexion and ankle flexion angles did not differ between groups or conditions ( $p>.05$ ).

**CONCLUSIONS:** CON runners made kinematic adjustments at the knee that may, in part, account for the observed reduction in VLR during the hard and soft conditions. On the contrary, INJ runners made little kinematic adjustment and displayed higher VLR in the hard condition and lower VLR in the soft condition suggesting that the cushioning properties of the shoe may have aided in the reduction in loading rates. However, since no significant condition X group interaction for VLR was observed, INJ may have made adaptations in other planes of motion. Overall, INJ runners appear to be less adaptable in the sagittal plane to acute changes in midsole hardness.

2069 Board #115 MAY 31 9:00 AM - 10:30 AM

**Walking On High-heels - A Challenge For Balance**

Tine Alkjaer, Peter Raffalt, Nicolas C. Petersen, Erik B. Simonsen. *University of Copenhagen, Copenhagen N, Denmark.*  
(No relationships reported)

Walking with high-heeled shoes constitutes an unstable condition, which can be hazardous to balance. The human locomotor system is flexible and enables humans to move without falling even under less optimal conditions. This property of the human locomotor control system can be explained by the principle of optimality in movement variability. In this model the movement variability has a deterministic structure reflecting the adaptability of the system to environmental stimuli.

**PURPOSE:** To explore the movement variability of high-heeled walking in order to investigate how the movement behavior of human walking is affected by the unstable condition created by

high-heeled shoes. We hypothesized that the movement variability of high-heeled walking would be characterized by a more complex and less predictable pattern than barefooted walking.

**METHODS:** Eleven female subjects (mean (SD): age: 27.5 (5.4) years, height: 1.70 (0.04) m, body mass: 58.1 (5.1) kg) were exposed to two different walking conditions while they walked at 4.0 km/h on a motor driven treadmill. One condition was barefooted walking while the other was high-heeled walking. In each condition the soleus (SO) H-reflex was elicited by stimulating the tibial nerve every two seconds. Surface EMG was recorded from the SO and tibialis anterior (TA) muscles and the ankle joint position was recorded by goniometry. The movement variability of the ankle joint angle was quantified by calculation of the approximate entropy (ApEn) in the angle joint signal obtained over 60 s of walking.

**RESULTS:** The ApEn of the ankle joint angle was significantly higher ( $p < 0.01$ ) during high-heeled ( $0.38 \pm 0.08$ ) than barefooted walking ( $0.28 \pm 0.07$ ). During high-heeled walking the EMG results showed increased coactivation between the SO and TA muscles prior to heel strike and the H-reflex was significantly increased prior to toe off and in terminal swing by 40% ( $p < 0.01$ ).

**CONCLUSION:** The results confirmed that high-heeled walking was characterized by a more complex and less predictable pattern than barefooted walking. The increase in movement variability during high-heeled walking may very likely reflect that the human locomotor system was more dependent on sensory feedback in the high-heeled condition in order to control balance.

2070 Board #116 MAY 31 9:00 AM - 10:30 AM

**Foot Orthoses Accelerate Muscle Onset Times In Chronic Ankle Instability Subjects**

Bart Dingenen<sup>1</sup>, Louis Peeraer<sup>2</sup>, Kevin Deschamps<sup>1</sup>, Luc Janssens<sup>3</sup>, Filip Staes<sup>1</sup>. <sup>1</sup>KU Leuven, Leuven, Belgium. <sup>2</sup>Katholieke Hogeschool Kempen, Geel, Belgium. <sup>3</sup>Groep T Leuven, Leuven, Belgium.

(No relationships reported)

**PURPOSE:** Foot orthoses (FO) are widely used to improve function in various lower extremity pathologies, including chronic ankle instability (CAI). The mechanism behind the clinical effectiveness remains unclear. Alterations in neuromuscular control might be important. The purpose of this study was to evaluate the influence of FO on lower extremity muscle activation onset times in subjects with CAI.

**METHODS:** Nine male and 6 female young adults with CAI wearing FO were recruited. Muscle activation onset times of 13 lower extremity muscles were recorded using surface electromyography during the transition from double-leg to single-leg stance, performed with eyes open (EO) and with eyes closed (EC). Both legs were tested in 4 experimental conditions: (1) barefoot (BF), (2) shoes only (SO), (3) shoes with standardized FO (SSFO), and (4) shoes with customized FO (SCFO).

**RESULTS:** Based on a full-factorial (condition-region-leg-vision) linear model for repeated measures, we found a significant condition effect ( $p < 0.0001$ ). Muscle activation onset times in SCFO were significant earlier compared to BF ( $p < 0.0001$ ), SO ( $p = 0.0188$ ) and SSFO ( $p = 0.0191$ ). Differences between conditions did not depend on the leg and/or the vision condition. Based on a two-way (condition-muscle) linear model within each region (ankle-knee-hip), we found significant differences between conditions for peroneus longus ( $p = 0.0001$ ), tibialis anterior ( $p = 0.0048$ ), vastus medialis ( $p = 0.0313$ ) and vastus lateralis ( $p = 0.0018$ ). No significant differences were found for the hip muscles.

**CONCLUSIONS:** Earlier muscle activation onset times were most apparent in the shoes with customized foot orthoses conditions for ankle and knee muscles, but not for hip muscles. These findings might help to better understand how foot orthoses can improve lower extremity function in subjects with chronic ankle instability.

**The Effects of Snowshoe Frame Shape on the Energetics and Kinematics of Snowshoe Walking**

Wayne J. Board, David I. Weber, Raymond C. Browning, FACSM. Colorado State University, Fort Collins, CO.

(No relationships reported)

Snowshoeing is an increasingly popular form of winter physical activity. Modern snowshoes are lightweight and provide traction, flotation and stability. The greater metabolic rate during snowshoeing vs. overground walking may be partly due to altered lower extremity kinematics associated with the extended tail of the snowshoe. Thus, snowshoe frame design may influence metabolic rate and kinematics. However, no studies have simultaneously quantified metabolic rate and biomechanics of snowshoeing to determine the effects of snowshoe frame design.

**PURPOSE:** To determine the effect of snowshoe frame shape on metabolic rate and lower extremity kinematics during level snowshoeing.

**METHODS:** Twelve healthy adult participants,  $26.5 \pm 5.3$  yrs,  $1.72 \pm 0.07$  m,  $67.9 \pm 10.4$  kg, with previous snowshoe experience participated in this study. We measured oxygen consumption via portable indirect calorimetry and lower extremity kinematics via inertial measurement units as participants walked with snowshoes on level packed snow. We tested five different snowshoe frame shapes of equivalent length and mass (1.0kg): one conventional (C) and four with varying degrees of rocker (frame curvature, R). Thus, participants completed five 6-minute trials at a set speed of 1.4m/s. We used a one-way repeated-measures ANOVA to determine if there were significant differences in metabolic rate or kinematics across snowshoe frame shapes.

**RESULTS:** Metabolic rate was similar across snowshoe frame shapes (overall mean  $6.8 \pm 0.7$  W/kg ( $p = 0.199$ )). Walking speed and stride characteristics were similar ( $p > 0.05$ ) across trials: speed,  $1.47 \pm 0.10$  m/s; stride frequency,  $0.93 \pm 0.04$  Hz; stride length,  $1.58 \pm 0.12$  m. When using R vs. C snowshoes, participants walked with greater hip flexion at heel-strike ( $53.9 \pm 1.0$  vs.  $45.4 \pm 0.9$ ,  $p < 0.05$ ) and throughout swing ( $45.1 \pm 0.8$  vs.  $37.8 \pm 0.8$ ,  $p < 0.05$ ), greater knee flexion throughout swing ( $64.2 \pm 1.4$  vs.  $57.1 \pm 1.1$ ,  $p < 0.05$ ), and more dorsiflexed ankle during stance ( $65.4 \pm 0.7$  vs.  $61.1 \pm 1.3$ ,  $p < 0.05$ ) and at toe-off ( $49.9 \pm 0.5$  vs.  $47.9 \pm 1.0$ ,  $p < 0.05$ ).

**CONCLUSION:** Snowshoe frame shape does not affect metabolic rate but does influence lower extremity kinematics. These results suggest that metabolic rate during snowshoeing may be more affected by the mass of the snowshoe than by the frame design.

**Reliability and Validity of the Velotron Racermate™ Cycle Ergometer to Measure Anaerobic Power**

Todd A. Astorino, Trisha A. Cottrell. California State University--San Marcos, San Marcos, CA.

(No relationships reported)

The Wingate Test is frequently used by sport scientists to assess anaerobic power using the Monark mechanically-braked cycle ergometer. However, the advent and popularity of electrically-braked cycle ergometers to administer the Wingate Test merits a comparison of Wingate-derived data across ergometers.

**PURPOSE:** This study assessed the reliability and validity of the Velotron Racermate™ cycle ergometer to assess anaerobic power.

**METHODS:** Men (9 cyclists and 13 recreationally-active) and women (17 recreationally-active and 1 cyclist) (age =  $24.7 \pm 4.2$  yr) performed two Wingate tests on the Velotron or three Wingate tests (two on the Velotron and one on the Monark Peak Bike) over a 7 - 14 d period. Peak power, mean power, minimum power, fatigue index, heart rate, and peak and minimum cadence were assessed. Intraclass correlation and coefficient of variation were used to assess test-retest reliability of data obtained on the Velotron, and standard error of measurement and minimum difference were calculated to obtain the typical error. Repeated measures ANOVA was used to identify differences in variables across all trials, and Bland-Altman plots were created to examine measurement agreement between ergometers.

**RESULTS:** Results revealed significant test-retest reliability for mean power ( $r = 0.90$ ,  $p < 0.01$ ), minimum power ( $r = 0.79$ ,  $p < 0.05$ ) and peak power ( $r = 0.70$ ,  $p < 0.05$ ) with repeated bouts on the Velotron. Peak power was significantly higher ( $p < 0.05$ ) on the Velotron ( $9.95 \pm 1.39$  W/kg) versus the Monark ( $9.13 \pm 1.26$  W/kg); however, mean power was higher ( $p < 0.05$ ) on the Monark ( $6.95 \pm 0.89$  W/kg) versus the Velotron ( $6.11 \pm 0.52$  W/kg and  $6.25 \pm 0.59$  W/kg). Although peak and minimum cadence differed ( $p < 0.05$ ), no differences ( $p > 0.05$ ) in fatigue index, heart rate, or minimum power were revealed between ergometers.

**CONCLUSIONS:** Data reveal significant test-retest reliability for Wingate-derived mean and peak power from the Velotron Racermate, yet multiple variables differ between the Velotron and the Monark mechanically-braked cycle ergometer. Overall, determinations of mean or peak power from the Velotron cannot be used interchangeably with those obtained from the Monark mechanically-braked ergometer.

**2073 Board #119 MAY 31 8:00 AM - 9:30 AM**

**Validation of Off-season Physiological Tests with Ski Ranking in Elite Male Junior Cross-Country Skiing**

Magnus Carlsson<sup>1</sup>, Tomas Carlsson<sup>1</sup>, Daniel Hammarström<sup>2</sup>, Johan Granath<sup>3</sup>, Jens Westergren<sup>2</sup>, Christer Malm<sup>1</sup>, Michail Tonkonogi<sup>2</sup>. <sup>1</sup>Dalarna University and Umeå University, Falun and Umeå, Sweden. <sup>2</sup>Dalarna University, Falun, Sweden. <sup>3</sup>Regional Sports Federation of Dalarna, Falun, Sweden. <sup>4</sup>Umeå University, Umeå, Sweden. (Sponsor: Carl Foster, FACSM)  
(No relationships reported)

Validated physiological test provides an important feedback for coaches and athletes. This information is of paramount importance for junior cross-country skiers' which are in an age-stage where the potential training adaptation is great. Physiological tests performed in sport science laboratories are often expensive and time consuming. Hence, there is a need for inexpensive validated off-season physiological tests which can be performed in the skier's daily training environment and therefore repeatable during the year.

**PURPOSE:** To validate off-season physiological test parameters with International Ski Federation's ranking points for distance (FISdist) and sprint (FISsprint) performances as well as create multiple regression models for FISdist and FISsprint.

**METHODS:** Twenty four elite male Swedish junior cross-country skiers (age: 18.5 ± 0.9 years [mean ± SD]) volunteered to the study. Ranking points FISdist and FISsprint were used as performance data (FISdist: 178 ± 90 points; FISsprint: 242 ± 105 points). During a period of three days (June 5-7th 2011) the subjects completed a test battery consisting of six physiological tests: 3 km flat running time trial (TTRun); 2 min all-out double poling on a ski ergometer (DP120); squat jump (SQJ); general strength (sum of completed repetitions for: chins, vertical sit-ups, and dips) (GS); 2 km moderate uphill double poling roller skiing time trial (TTDP) and 2 km uphill diagonal roller skiing time trial (TTDiag). Correlations were established using Pearson's correlation analysis with Bonferroni correction. Regression models were created using standard multiple linear regression analysis. Level of statistical significance was set at  $p < 0.05$ .

**RESULTS:** For FISdist and FISsprint significant correlations were found with TTRun, TTDP and TTDiag (all  $p < 0.05$ ). Regression models found for FISdist and FISsprint consist of TTRun combined with either TTDiag or TTDP explaining from 82 to 73 % of the variance in performance.

**CONCLUSIONS:** When evaluating junior cross-country skiers' performance capacity and training status; outside running and roller skiing time trials are adequate off-season tests. The regression models state that the running and roller skiing tests reflect different physiological abilities important for success in junior cross-country skiing.

**2074 Board #120 MAY 31 8:00 AM - 9:30 AM**

**Validation of a Snorkel Prototype for Measuring Gas Exchange Parameters during Swimming**

Carlo Baldari, FACSM<sup>1</sup>, Ricardo J. Fernandes<sup>2</sup>, João Ribeiro<sup>2</sup>, Marco Meucci<sup>1</sup>, João P. Vilas-Boas<sup>2</sup>, Laura Guidetti<sup>1</sup>. <sup>1</sup>University of Rome "Foro Italico", Rome, Italy. <sup>2</sup>CIF2D, Faculty of Sport, University of Porto, Porto, Portugal.  
(No relationships reported)

To assess  $\text{VO}_2$  in swimming a snorkel device is needed to convey gasses. Toussaint (1987) validated a snorkel device connected to Douglas bag. Conversely, when a snorkel was connected to K4b2 (Cosmed, Rome, IT), the validation studies (Keskinen 2003, Gayda 2010) reported some low systematic differences versus the use of K4b2 with the standard facemask (Mask).

**PURPOSES:** To find a possible explanation of these systematic errors, we detected the air temperature at the turbine to validate a snorkel prototype. Also, the snorkel prototype with 2 (SV2) and 4 (SV4) valves was compared with a Mask connected with K4b2.

**METHODS:** Nine subjects performed trails on a 25m swimming pool and on bike ergometer on separate days at 3 constant loads (low, medium, high). Trails were performed in random order: with SV2 and SV4 while swimming; with Mask, SV4, and SV2 while cycling. Air temperature at the turbine of the K4b2 system was measured at each condition.

**RESULTS:** Considering each parameter [ $\text{VO}_2$ ,  $\text{VCO}_2$ ,  $\text{V}_E$  (table) and also  $\text{V}_T$ ,  $\text{F}_{\text{E}}\text{O}_2$ ,  $\text{F}_{\text{E}}\text{CO}_2$ ] and comparing the different conditions [SV4 vs SV2 both in swimming (table) and cycling, Mask vs SV4, Mask vs SV2 (table)] by Passing-Bablok regression analysis, the 95% CI always contained the value 1 for the slope and the 0 for the intercept, thus rejecting the proportional and the systematic difference hypothesis.

| Parameters                                   | R2    | Slope [95% CI]         | Intercept [95% CI]           |
|--|-------|------------------------|------------------------------|
| <b>SV4 vs SV2 (N = 27, Swimming)</b>         |       |                        |                              |
| $\text{VO}_2$ (mL.min <sup>-1</sup> , STPD)  | 0.991 | 0.995 [0.950 to 1.040] | -12.705 [-119.201 to 81.186] |
| $\text{VCO}_2$ (mL.min <sup>-1</sup> , STPD) | 0.996 | 0.992 [0.965 to 1.022] | 8.227 [-53.300 to 61.519]    |
| $\text{V}_E$ (L.min <sup>-1</sup> , BTPS)    | 0.992 | 0.992 [0.957 to 1.023] | -0.514 [-2.382 to 1.817]     |
| <b>Mask vs SV2 (N = 27, Cycling)</b>         |       |                        |                              |
| $\text{VO}_2$ (mL.min <sup>-1</sup> , STPD)  | 0.994 | 1.001 [0.967 to 1.043] | -6.126 [-90.863 to 56.145]   |
| $\text{VCO}_2$ (mL.min <sup>-1</sup> , STPD) | 0.996 | 1.012 [0.978 to 1.044] | -42.292 [-104.030 to 23.499] |
| $\text{V}_E$ (L.min <sup>-1</sup> , BTPS)    | 0.992 | 1.008 [0.960 to 1.044] | -0.252 [-2.283 to 2.098]     |

**CONCLUSION:** Temperature measure at the turbine is needed since, as erroneously believed by others, the turbine do not have any temperature sensors so that the manufacturer recommends adjusting it to the ambient value when a snorkel is used. We prove that data must be adjusted to the real temperature of expired gases in order to have valid gas exchange values. Also, SV2 and SV4 snorkel were both valid, being the SV2 more comfortable.

**2075 Board #121 MAY 31 8:00 AM - 9:30 AM**

**Upper-body Work Capacity Assessed by Bench Press and Push-up Exercises.**

Alexander W. Purdy, William F. Brechue, FACSM. United States Military Academy, West Point, NY.  
(No relationships reported)

The bench press (BP) and push-up (PU) exercise are used to assess and develop upper-body muscular strength and work capacity.

**PURPOSE:** To compare the BP and PU for assessing upper-body work capacity during performance of repetitions-to-failure (RTF) tests.

**METHODS:** Subjects (n=10; age: 21±2 yr; ht: 177.3±3.4 cm; wt: 84.1±8.4 kg) performed BP one-repetition maximum (1RM) and RTF tests were performed at 0.9, 0.8, 0.7, 0.6 and 0.4 of 1RM BP and at 0.7 body mass (M) to simulate the load of the push-up test. Push-up RTF was also conducted; 2-min Army Physical Fitness Test). Work capacity (WC) was calculated as RTF x load.

**RESULTS:** 1-RM BP was 101±15 kg and 1.18±0.18 expressed per M. RTF and WC were 4.5±2.1 and 425±195 (0.9 RM), 9.5±2.5 and 767±215 (0.8 RM), 13.3±1.4 and 940±240 (0.7 RM), 21.4±2.5 and 1296±237 (0.6 RM), and 54.3±8.0 and 2137±327 (0.4 RM), respectively. At 0.7 M, which corresponded to 0.61±0.09 of 1RM, RTF was 17.3±4.9 and WC was 1039.8±321.1 kg reps. For push-ups, subjects completed 76±14 reps on the 2-min test; WC was 4282±1197 kg reps. There was an exponential relationship between BP RTF and %1RM ( $y=507.1e^{-0.053x}$ ;  $R^2=0.877$ ). WC increased linearly with %RM ( $y=-38.9x+3983$ ;  $R^2=0.772$ ). 1RM BP and push-up RTF were moderately correlated ( $r=0.783$ ).

**CONCLUSIONS:** The 2-min push-up test appears to represent upper-body muscular strength determined by the 1RM; however, WC at 40% 1RM BP appears to better indicate push-up WC than the 0.7 M model.

2076 Board #122 MAY 31 8:00 AM - 9:30 AM

**Intrasession Reliability and the Relationship Between the Explosive Bench Press and Medicine Ball Chest Pass Assessments of Upper Extremity Power**

Jayne D. Eitner, G Ken Limbaugh, George J. Davies, Bryan L. Riemann. *Armstrong Atlantic State University, Savannah, GA.* (Sponsor: T. Jeff Chandler, FACSM)  
(No relationships reported)

The bench press throw and explosive bench press (EBP) test have recently received increased attention; however, both of these tests require specialized apparatus and instrumentation which limits their utilization in many settings. Medicine ball chest pass (MBCP) distance is a field test that also attempts to measure upper extremity power, however the optimal load has not been established.

**PURPOSE:** To determine the relationship between EBP peak power and MBCP test distance using 2kg, 3kg and 4kg loads and to determine the intrasession reliability of both tests.

**METHODS:** Twenty-seven healthy collegiate-level baseball players (20.5±1.5yrs; 1.82±0.06m; 84.7±8.7kg) performed three MBCP trials using 2kg, 3kg, and 4kg MB loads. Instructions were given to hold medicine ball at shoulder level with feet shoulder width apart and knees straight, and to press the MB for maximal distance without countermovement. Initial impact sites of each trial determined distance. For the EBP trials, a standard 16kg barbell was loaded with and additional 14kg. Each subject was allowed a warm-up of 8 repetitions. Subjects then performed three maximum velocity bench press trials. An electromagnetic sensor (Motion Monitor, IST, Inc) offset from the bar with PVC pipe determined bar displacement. Displacement was then used to determine velocity, when coupled with the bar mass, provided power across each repetition. Both peak power and MBCP distance were averaged across three trials.

**RESULTS:** Strong intrasession reliability was revealed for the bench press and MBCP tests (ICC range=.933 to .977) Although correlational coefficients for 3kg (r=.647, 95% CI=.355 to .824) and 4kg (r=.612, 95% CI=.303 to .804) loads were slightly higher than 2kg (r=.482, 95% CI=.135 to .728) there was no significant difference between the three coefficients (P>.05).

**CONCLUSIONS:** Both the EBP and MBCP tests had strong intrasession reliability. If the EBP test is not feasible, then the slightly stronger relationships support using the 3kg or 4kg loads for the MBCP test as an alternative method of assessing upper extremity power. It should be recognized that although statistically significant, the relationships revealed were only moderate strength, suggesting that the tests may be measuring different aspects of upper extremity power.

2077 Board #123 MAY 31 8:00 AM - 9:30 AM

**Determination and Validation of Maximal Aerobic Speed**

Nidhi Gupta<sup>1</sup>, Govindasamy Balasekaran, FACSM<sup>1</sup>, Visvasuresh Victor Govindaswamy<sup>2</sup>, Naveen Agrawal<sup>3</sup>. <sup>1</sup>National Institute of Education, Nanyang Technological University, Singapore, Singapore. <sup>2</sup>Texas A&M University, Texarkana, TX. <sup>3</sup>GE Water & Process Technologies, John F. Welch Technology Centre, Bangalore, India.  
(No relationships reported)

Maximal aerobic speed (MAS) is usually determined at the velocity at VO<sub>2max</sub> (vVO<sub>2max</sub>). However the accuracy may be questioned since MAS at vVO<sub>2max</sub> elicits a higher amount of anaerobic energy.

**PURPOSE:** To determine and validate the criteria of MAS at a speed which elicits maximal and minimum contribution of aerobic and anaerobic energy.

**METHODS:** 9 sprint trained (ST) (age = 26.89±9.39 yrs, BMI = 23.09±2.07 kg•m<sup>-2</sup>) and 12 endurance trained (ET) (age = 31.67±7.24 yrs, BMI = 21.34±1.27 kg•m<sup>-2</sup>) athletes participated to determine MAS. 19 healthy participants (age = 29.74±8.31 yrs, BMI = 22.01±2.12 kg•m<sup>-2</sup>) were also selected to validate the criteria of MAS. To determine MAS, athletes performed four to five treadmill sessions as follows: Astrand modified running test, submaximal discontinuous test, VO<sub>2</sub> till exhaustion (T<sub>lim</sub>) test at vVO<sub>2max</sub> and Vsub%95 [vΔ50 (median of vVO<sub>2max</sub> and velocity at lactate threshold; vLT) or vΔ50+5%vVO<sub>2max</sub>]. To validate the criteria of MAS, participants also performed T<sub>lim</sub>MAS. Using the hyperbolic non linear relation, MAS was determined at its duration (MAS<sub>dur</sub>) which was calculated by eventually adding the T<sub>lim</sub>VO<sub>2max</sub> converted in T<sub>lim</sub>Vsub%95 using the following equations: T<sub>lim</sub>VO<sub>2max</sub> converted (s)=(T<sub>lim</sub>VO<sub>2max</sub>vVO<sub>2max</sub> \* vVO<sub>2max</sub>)/Vsub%95, MAS<sub>dur</sub>=T<sub>lim</sub>Vsub%95-(T<sub>lim</sub>VO<sub>2max</sub> converted).

**RESULTS:** The MAS was at 92.45±1.47%vVO<sub>2max</sub> and 89.27±3.56%vVO<sub>2max</sub> among ET and ST cohorts, respectively. The ET athletes achieved significantly (p<.001) higher MAS (16.07±1.58km•h<sup>-1</sup>) at shorter duration (MAS<sub>dur</sub> = 678.59±165.44s, p<.05) than ST athletes (MAS=12.77±.81km•h<sup>-1</sup>; MAS<sub>dur</sub>=840.28±164.97s). To validate the criteria of MAS, the oxygen uptake at MAS (50.69±4.69ml•kg<sup>-1</sup>•min<sup>-1</sup>; 96.08±2.51%VO<sub>2max</sub>) was not significantly (p≥.05) different from 95%VO<sub>2max</sub> among all participants. The blood lactate (mmol•L<sup>-1</sup>) at MAS (7.80±1.52) was significantly (p<.01) lower than at vVO<sub>2max</sub> (9.11±2.50) and VO<sub>2max</sub> (8.59±1.62).

**CONCLUSION:** The determination of MAS required a subtraction of T<sub>lim</sub>VO<sub>2max</sub> converted from T<sub>lim</sub>Vsub%95 as it eliminated some anaerobic energy contribution. In addition, MAS may be more accurate if measured at %vVO<sub>2max</sub> and not at vVO<sub>2max</sub>. The MAS at 91.08%vVO<sub>2max</sub> among athletes may be accurate as it represents maximal aerobic energy with minimal contribution from anaerobic energy sources.

2078 Board #124 MAY 31 8:00 AM - 9:30 AM

**Specific Critical Interval Test Can Determine The Aerobic Capacity In Karate**

Ramon M. Oliveira<sup>1</sup>, Cleiton A. Libardi<sup>2</sup>, Fúlvia B. Manchado-Gobatto<sup>1</sup>. <sup>1</sup>Methodist University of Piracicaba - UNIMEP, Piracicaba, Brazil. <sup>2</sup>University of Sao Paulo - USP, Sao Paulo, Brazil.  
(No relationships reported)

Karate training consists of many repetitions of short sequences (bursts techniques and hopping movement) interrupted by a recovery periods (Ravier et al., 2009) and depends to aerobic and anaerobic conditioning. The critical power model (Monod & Scherrer, 1965) was adapted for different sports to estimate the aerobic capacity, but still not was used in karate.

**PURPOSE:** To adapt the non-invasive critical power model to karate, using the interval recovery between punch sequences to determine the aerobic capacity of athletes (critical interval - CI) and compare these results to the maximal lactate steady state intensity (MLSSi).

**MATERIAL AND METHODS:** Twelve well trained karate athletes (6 men and 6 women; 26 ± 2 yrs) were submitted to five tests at different intensities, separated by 24 hrs. In each test, the athletes accomplished guyaku-zuki sequence until exhaustion, with active hopping movement between the sequences. The intensities were imposed based on interval recovery between punch sequences (2 to 6 seconds) expecting the exhaustion to occur between 1 and 10 min. The linear "interval versus 1/time to exhaustion" model was used to determine the CI (y-intercept). In order to verify the MLSS, the athletes were submitted to 30 min of continuous exercise at three random intensities (10% below of CI, CI and 10% above of CI), with blood lactate concentration (BLC) determined at each 5 min.

**RESULTS:** The results are expressed in mean ± SEM. The CI was obtained at 16.7±2.9s, with significant linear fit (R<sup>2</sup> = 0.95±0.01). In continuous exercise below CI (higher interval), all athletes presented BLC stabilization (2.24 ± 0.36 mM). The same results occurred at CI intensity. In higher intensity (shorter interval), there was a progressive increase in BLC. The MLSS was observed at CI for 75% of athletes, with BLC stable at 3.59 ± 0.44 mM.

**CONCLUSION:** The specific critical interval test can determine the aerobic capacity of karate athletes considering that there was MLSS at this intensity.

Monod H, Scherer J. (1965). *Ergonomics* 8, 329-38.

2079 Board #125 MAY 31 8:00 AM - 9:30 AM

**Validity of a Vertical Jump Mat for Determining Vertical Jump Height**

Charles M. Forsythe. *University of Kansas, Boise, ID.*  
(No relationships reported)

Vertical jump (VJ) height is related to athletic performance and is a common test for coaches and personal trainers. Several devices are available to measure VJ height.

**PURPOSE:** To determine the validity of a VJ mat used for measuring flight time, when compared to VJ heights using either a Vertec VJ tester or a force plate.

**METHODS:** 17 men and 18 women (age = 20.9±0.7 yrs., ht. = 176.1±0.9 cm, wt. = 72.6±13.5 kg) served as subjects. Subjects performed counter-movement vertical jumps (CMVJ) standing on a uni-directional force plate (Rough Deck, Rice Lake, WI) sampling at 1000 Hz (BioPac Systems, Goleta, CA), and a VJ mat (Probotics Inc., Huntsville, AL). Each subject reported for a familiarization session followed by one test session. Standing reach was assessed using a one-arm reach with both feet flat on the ground. During VJ testing session, subjects performed three to seven CMVJ, with the best jump recorded for statistical analysis. One-way ANOVAs with Scheffe post-hoc tests were used to determine differences between VJ measures (i.e., jump mat, force plate flight time). An independent t-test was used to compare flight times between the force plate and the VJ mat. Linear regression was used to establish explained variances ( $r^2$ ) and agreement between the VJ mat data and the criterion measures from the force plate ( $p < 0.05$ ).

**RESULTS:** A significant correlation was observed between flight time measured from the force plate and the VJ mat ( $r = 0.99$ ). When compared to the force plate, the VJ mat revealed greater values in VJ height (VJ mat = 0.50±0.12 m, force plate = 0.34±0.10 m) and flight time (VJ mat = 0.629±0.078 s, force plate = 0.524±0.077 s).

**CONCLUSION:** The VJ mat compared favorably with the Vertec but not the force plate. This is to be expected since the force plate determines changes in center of mass, not VJ reach. The resulting regression equations suggest further study on high performance athletes may be warranted since jump height may be underestimated at high performance.

### Accuracy, Validity And Reliability Of GPS-Technology Within Selected Sprint Running Speeds

Margot Niessen, Elisabeth Hohmann, Vanessa Martinez Lagunas, Mario Hermsdorf, Ulrich Hartmann. *Faculty of Sport Science, Universität Leipzig, Leipzig, Germany.* (Sponsor: Ralph Beneke, FACSM)

(No relationships reported)

During the last decade novel innovative technologies provide tools to monitor running velocity ( $v_{run}$ ) continuously. For outdoor running purposes light weight portable global positioning systems (GPS) have been developed.

**PURPOSE:** The study aimed to assess the accuracy of the GPS device and its reliability and validity under different sprint running speed conditions.

**METHODS:** Within a study relating GPS technology ( $n=10$  female competitive athletes (S1): 20±5 yrs, 162±5 cm, 59±6 kg;  $n=10$  male competitive athletes (S2): 25±3 yrs, 182±6 cm, 81±6 kg) the physical performance during altered running events on a track (S1: 3x70 m & 2x400 m, range  $v_{run}$ : 4.5-7.1 m/s; S2: selected sprints between 20-300 m ( $n=62$ ), range  $v_{run}$ : 6.4-9.3 m/s) was captured and analysed. Therefore the GPS sensor system, placed in the upper back, operated and collected the position data with 5 Hz, reaching 9.0±1.1 satellites simultaneously. Additionally a single light beam system and a digital measuring wheel were used as gold standard for completed distance and time. Descriptive and group-specific parametric statistical data analysis was applied.

**RESULTS:** The mean GPS distance divergence in S1 against reference constant value of the 70 m sprint was 67.8±2.1 m (-3.1 %;  $p \leq 0.001$ ), the reliability was good (coefficient of variation 3.1 %;  $p \leq 0.483$ ). Over sprint splits and 400 m in S1 the underestimation of GPS grows up to 3.5 % (-14.8 m). The non-linear curve error was less than 0.0003 m into 400 m and therefore negligible. In S2 mean GPS results showed distance deviations for short sprint runs (< 50 m,  $v_{run}$ : 7.5±0.6 m/s) of -0.7±2.2 % ( $n=20$ ), for sprints between 50 m and < 100 m ( $v_{run}$ : 8.4±0.4 m/s) of -0.2±1.0 % ( $n=19$ ) and for sprints  $\geq 100$  m until 300 m ( $v_{run}$ : 8.3±0.5 m/s) of -0.1±0.6 % ( $n=23$ ).

**CONCLUSIONS:** The GPS receivers are a valid and reliable method of measuring distance at sprinting intensities in both studied groups. The GPS device showed a good reproducibility (S1) and accuracy of measured distance for sprinting speeds (>6 m/s) in S2. Due to some weaknesses (e.g. quality and frequency of signal reception) the GPS-distance was underestimated in short sprints and somewhat less in longer sprints (> 100 m). Within exercise science, the use of GPS can assist field research even at higher movement intensities into exercise physiology, metabolism, and biomechanics.

### A New Utility Of Breath-holding Maneuver To Determine Resting Heart Rate

Flávio A. Lemos, Vanessa P. Frias, Tony M. Santos. *Gama Filho University, Rio de Janeiro, Brazil.*

(No relationships reported)

**PURPOSE:** The precise determination of resting heart rate (RHR) is very important for exercise testing and prescription based on reserve method. Traditionally, RHR is determined after a minimum of 5-min rest. Many researchers have investigated the heart rate variability under breath-holding maneuver. However, this procedure has not been used to determine RHR. The aim of this study was to use breath-holding maneuver to predict RHR with and without controlled breathing.

**METHODS:** Eighteen healthy subjects (nine male) 27.6 ± 5.0 year; 24.2 ± 2.9 kg·m<sup>-2</sup>; 43.3 ± 7.5 mL·kg<sup>-1</sup>·min<sup>-1</sup> (estimated) performed the breath-holding maneuver twice. The duration of maneuver was 10 s with a 1 min recovery between trials. After that, the subjects have been laying rest under two experimental situations: a) with respiratory controlled of 7.5 breaths·minute<sup>-1</sup> and b) without respiratory controlled. In both conditions, heart rate (HR) subjects were continuously monitored in milliseconds (POLAR RS800, USA). The lower HR observed at each experimental condition were utilized for further analysis (One-way ANOVA, Bland-Altman plot and regression analysis).

**RESULTS:** The subject's HR after breath-holding maneuver (57 ± 9 bpm) and rest laying with (54 ± 8 bpm) and without (56 ± 8 bpm) respiratory controlled has not been significant different ( $p < 0.05$ ). The Bland-Altman plot showed a 95% limit of agreement between -9.12 to 4.12 bpm and -8.89 to 8.89 when laying with and without respiratory controlled, respectively. The linear regression showed the high relationship between the RHR in respiratory controlled to breath-holding maneuver ( $r^2 = 0.848$ ; CI 95% 0.684 to 1.080, SEE 3 bpm) and lower relationship between the RHR without in respiratory controlled ( $r^2 = 0.684$ ; IC 95% 0.489 to 1.039 in 95%, 4 bpm).

**CONCLUSION:** Our results support the present approach as a substitute strategy to determine RHR in a procedure with 2 min long.

### Self- And Observer-rated Talk Test For Exercise Prescription Versus Free Exercise Training

Christian Thiel<sup>1</sup>, Carl Foster, FACSM<sup>2</sup>, Lutz Vogt<sup>1</sup>, Katharina Schmidt<sup>1</sup>, Andreas Bernardi<sup>1</sup>, Frieder Krause<sup>1</sup>, Winfried Banzer<sup>1</sup>. <sup>1</sup>Goethe-University, Frankfurt, Germany. <sup>2</sup>University of Wisconsin, La Crosse, WI.

(No relationships reported)

**PURPOSE:** Tools for exercise prescription need to be simple, economic and adequately precise to find widespread application. The Talk Test appears to be a simple way of achieving recommended exercise intensities. However, the relationship of Talk Test-based exercise prescription and intuitively selected exercise intensity has not been studied, and it is unclear whether instead of the subject, an outside observer could also rate appropriate intensity. The present study compared exercise intensities derived from an internal and an external rating of the Talk Test with self-selected exercise intensity and a reference intensity at the MaxLass.

**METHODS:** Fifteen well-trained subjects (5 f, 10 m; 24.9±2.4 yrs; 23.2±2.2 kg·m<sup>-2</sup>; VO2max 50.6±5.6 mL·kg<sup>-1</sup>·min<sup>-1</sup>; 7.1±4.1 hrs of exercise/wk) performed a self-paced training session for 30 minutes, a Talk Test incremental treadmill protocol, and separate MaxLass tests. During the last 20 seconds of each stage of the Talk Test, subjects recited a standard text and were asked if they could speak comfortably. Concomitantly, an observer recorded his impression of the subject's level of speech comfort.

**RESULTS:** Last positive Talk Test (LP TT), free pace, first equivalent TT (EQ TT) and first negative TT (N TT) equalled 82±14%, 92±10%, 94±13% and 109±14% of MaxLass (12.1±1.4 km/h), based on subject rating. Compared to free pace, 95%CI of differences indicated that LP TT tended to be slower (-19%;0%), while EQ TT was not different (-6%;+12%), and N TT was faster (+10%;+29%). Observer rating did not systematically differ from subject rating at LP TT (95% CI: -14%;+4%), at EQ TT (-11%;+3%) and at N TT (-6%;+4%).

**CONCLUSIONS:** When non-competitive athletes can speak comfortably, they are running well below MaxLass velocity, and still slower than in a short free-paced exercise bout. If they cannot speak comfortably, athletes are exercising slightly above MaxLass and far above intuitively-paced exercise. No consistent bias occurred whether the subject or an outside observer rated the Talk Test, suggesting that it may also be a useful tool for coaches to prescribe exercise intensity with minimal athlete burden. The Talk Test should be further tested in physically active and inactive healthy subjects, as well as in clinical populations.

**Ability of an Incremental Field Test to Evaluate Aerobic Capacity on Young Male Athletes**

Luis M. Gómez-Miranda<sup>1</sup>, Claudia E. Carrasco-Legleu<sup>2</sup>, Ofelia Urita<sup>2</sup>, Lidia G. De Leon<sup>2</sup>. <sup>1</sup>University of Baja California, Tijuana, B.C., Mexico. <sup>2</sup>University of Chihuahua, Chihuahua, Chih., Mexico.  
(No relationships reported)

Field tests have been recognized as an economical, practical and feasible way to determine performance in athletes; however, to be valid in terms of maximal aerobic capacity, workloads should be incremental and progressive, as ergometric tests. Maximal oxygen uptake (VO<sub>2</sub>max) is a widely used parameter to determine aerobic capacity and specific to validate field tests, but its direct measurement is difficult, unpractical and expensive. Heart rate maintains a direct relationship with oxygen uptake, is a very sensitive variable and technically easier and practical to evaluate the effort.

**PURPOSE:** To determine the ability of the 20-meters Multistage Shuttle Run field test (20mMST) to evaluate the aerobic capacity of elite male athletes, using the heart rate as an indicator of the performance.

**METHODS:** Ten male athletes 18 to 31 years old, from two elite aerobic sport groups, were measured by height, weight and body mass index (BMI). Each participant performed two different maximal stress tests: a progressive shuttle run field test and an ergometric treadmill test. Oxygen uptake (VO<sub>2</sub>) was directly obtained during treadmill protocol, or calculated from the charts provided by the field test. Heart rate (HR) was measured by a telemetric device in both tests. Parameters were recorded every minute. Descriptive statistics, linear regression and Pearson coefficient correlation at a p<0.05 significance level were used.

**RESULTS:** Athletes were 22.6 ± 4.3 years old and 21.2 ± 2.2 kg/m<sup>2</sup> of BMI. VO<sub>2</sub>max was higher in treadmill (65.4 ± 6.4 mL.kg<sup>-1</sup>.min<sup>-1</sup>) than in 20mMST (54.3 ± 5.9 mL.kg<sup>-1</sup>.min<sup>-1</sup>), p=0.002. Maximal HR was similar in ergometric than in field test (188.6 ± 9.3 vs 190.0 ± 9.0 beats/min respectively, p=0.743). Linear regression showed a different but directly proportional relationship of HR to VO<sub>2</sub> in treadmill (y = 2.332x + 43.07, R<sup>2</sup> = 0.874 P <0.001) compared with 20mMST (y = 1.339 + 115.7, R<sup>2</sup> = 0.987 P <0.001), evidencing a higher work in ergometric protocol. A high correlation of HR between tests was observed (r = 0.978, R<sup>2</sup> = 0.957, P <0.001).

**CONCLUSIONS:** 20mMST is a valid test to determine aerobic capacity in athletes demonstrated by the similar increment of HR in both protocols. Nevertheless, the higher work evidenced in ergometric test, may suggest that 20mMST underestimates the VO<sub>2</sub> value for each level of effort.

---

**2084** Board #130 MAY 31 8:00 AM - 9:30 AM

**Validity and Reliability of an Audio Headset Earbud Sensor for Heart Rate Measurements During Exercise**

Meir Magal, FACSM<sup>1</sup>, L Chris Eschbach<sup>1</sup>, Rebekah J. Cain<sup>1</sup>, Jen Bunn<sup>2</sup>. <sup>1</sup>North Carolina Wesleyan College, Rocky Mount, NC. <sup>2</sup>Campbell University, Buies Creek, NC.  
(No relationships reported)

Heart rate (HR) measurement during exercise plays a pivotal role in the determination of exercise intensity. Commonly, such a measure requires the use of a chest strap which could be perceived by some as uncomfortable and somewhat invasive. Earbud technology using light sensing algorithms (earbud sensor) for the measurement of HR would eliminate the need for the chest strap.

**PURPOSE:** To assess the validity and reliability of the earbud sensor for measurement of HR during indoor exercise.

**METHODS:** Forty participants (21 males, 19 females, age = 29.7 ± 10.6 yr, height = 171.8 ± 9.7 cm, weight = 76.5 ± 13.2 kg, BMI = 25.9 ± 3.7 kg·m<sup>-2</sup>) completed two identical trials, 14 days apart, consisting of a 15.5 minutes of sitting, standing, walking and running on the treadmill. Throughout the trials, HR was monitored and recorded using an earbud sensor and a twelve lead ECG. HR data was collected and computed at a recording interval of 5-seconds (7440 data points).

**RESULTS:** A significant positive correlation (P < 0.001) was observed between the earbud sensor and the twelve leads ECG. Bland-Altman analysis demonstrated that 7070 earbud data points (95.0%) were within a 95% confidence interval. The earbud sensor reliability was determined using 35 subjects by way of intraclass correlation coefficients (ICC([3,1]) >0.9) indicating a strong level of reliability.

**CONCLUSION:** The results of the study demonstrated that the earbud sensor is a valid and reliable instrument for the measurements of HR during various activities ranging from sitting quietly to jogging on the treadmill. Further, the earbud sensor may be used effectively during rest and exercise as an alternative to ECG or chest strap monitors.

**2085** Board #131 MAY 31 8:00 AM - 9:30 AM

**Intra-session And Inter-session Reliability Of A Modified Trunk Rotation Flexibility Test**

Laura H. Moore, Bryan L. Riemann, George J. Davies. *Armstrong Atlantic State University, Savannah, GA.*  
(No relationships reported)

While trunk rotational flexibility is an important measure of functional flexibility in active populations, many tests measuring rotational flexibility are hard to implement or require specialized instrumentation/training. Previous research established the reliability of a protocol to measure active rotation in standing using minimal instrumentation. To minimize contribution of hip rotation to rotational flexibility when standing, a seated protocol was developed to isolate and measure trunk rotation flexibility.

**PURPOSE:** To examine the intra- and inter-session reliability of a seated trunk rotation flexibility test and determine whether bilateral differences exist between rotation towards the dominant (D) and non-dominant (ND) limbs.

**METHODS:** 20 recreationally-active adults (10 males, 10 females; 33.4±8.3 yrs, 1.6±.1 m, 73.2±13.3 kg) performed three maximal seated trunk rotations each to D and ND sides. Subjects were seated on a backless chair with a metal rod held across the back of the shoulders. Subjects were encouraged to rotate as far as possible without shifting their hips. At maximal rotation, the rod was leveled and using a plumb bob, the location was marked on the floor. The angle of rotation was later measured using a long-arm goniometer. Subjects repeated the protocol 30 minutes later. Intraclass correlation coefficients (ICC, 2,k) and the standard error of measure (SEM) were calculated across the three repetitions in each direction for intra-session and across the average of the two sessions for intersession reliability. An independent t-test was used to compare D versus ND rotation.

**RESULTS:** Intra-session ICC and SEM were .960 and 2.32° for ND, and .950 and 2.41° for D, respectively. Inter-session ICC and SEM were .876 and 4.05° for ND and .922 and 3.02° for D, respectively. No significant differences were noted between D and ND rotation (P=.294) with additional analyses demonstrating equal numbers of subjects having greater rotation in each direction (D, ND).

**CONCLUSIONS:** The seated trunk rotation flexibility test is a reliable way to assess trunk rotational flexibility in an active population. Because minimal instrumentation or time is required, it is an ideal assessment for practitioners needing a reliable tool to assess isolated trunk rotational flexibility in patients or athletes.

---

**2086** Board #132 MAY 31 8:00 AM - 9:30 AM

**Intra- And Inter- Day Reliability Of Rasterstereography**

Valerio Bonavolontà, Alessandro Tito, Maria Chiara Gallotta, Carlo Baldari, FACSM, Laura Guidetti. *University of Rome "Foro Italico", Rome, Italy.*  
(No relationships reported)

The Formetric 4D allows the tridimensional evaluation of the spine through rasterstereographic analysis of the back surface. It is used in follow-up to verify the effectiveness of a therapy, allowing a reduction of x-ray exposition.

**PURPOSE:** To determine the intra-day and inter-day reliability of Formetric 4D with and without markers.

**METHODS:** 50 healthy volunteers (age 22 ± 2) were divided in two groups: one group (M, n= 26) had two markers manually placed by the same expert in correspondence of vertebra prominens (VP) and of the rima ani (SP), while the other group (NM, n=24) was assessed without markers. All participants were analyzed in Average 4D modality two times in the same day, two hours apart each other, and one more time on a separate day, one week apart. Subjects were asked to not perform any physical activity before the evaluations. The following parameters were measured: Trunk length VPDM, Kyphotic angle (ICT-ITL max), Lordotic angle (ITL-ILS max), Pelvic inclination, Kyphotic and Lordotic Apex, Right and Left Lateral deviation VPDM,

Cervical and Lumbar fleche, Trunk imbalance (° and mm), Pelvic tilt (° and mm), Pelvic inclination-dimples, Inflection point ITL and ILS, Rotation correction-pelvis, Right and Left Surface rotation, Pelvic torsion DL-DR (°), Trunk torsion. Intraclass correlation coefficient (ICC) and Cronbach  $\alpha$  were calculated.

**RESULTS:** In M group, for intra-, inter-day, and overall evaluations the higher reliability coefficients were 0.971, 0.963, 0.958 (for ICC) and 0.987, 0.983, 0.985 (for Cronbach  $\alpha$ ) respectively; while in NM group were 0.978, 0.982, 0.972 and 0.989, 0.991, 0.991; in M group ICC and Cronbach  $\alpha$  lower values were 0.958, 0.515, 0.534 and 0.742, 0.682, 0.784 respectively, while in NM group 0.561, 0.537, 0.461 and 0.731, 0.695, 0.729.

**CONCLUSION:** Highest values for both ICC and Cronbach  $\alpha$  were found for unvariant parameters i.e. not dependent on the subject's positioning respect to the machine. The reliability of most of parameters was excellent, it was also found an acceptable reliability even for the lowest values, both with and without markers.

**2087** Board #133 MAY 31 8:00 AM - 9:30 AM

**Validating The Adidas Micoach For Estimating Pace, Distance, And Energy Expenditure During Outdoor Over-ground Exercise**

Justin P. Porta, Angelica N. Lehker, Derek J. Acosta, Sean T. Miller, Joe Tomaka, George A. King. *The University of Texas at El Paso, El Paso, TX.*

(No relationships reported)

The Adidas miCoach was developed as a personal training system to estimate pace, distance and energy expenditure (EE) but has yet to be validated.

**PURPOSE:** To validate the Adidas miCoach for estimating pace (min/km), distance (km) and EE (kcal/min) during outdoor over-ground walking and running for two different sensor configurations.

**METHODS:** Six male and 8 female moderately endurance trained participants (mean  $\pm$  SD age: 28.2  $\pm$  8.5 y; height: 167.4  $\pm$  7.8 cm; mass: 60.9  $\pm$  11.1 kg; VO<sub>2max</sub>: 54.4  $\pm$  5.5 mL/kg/min) completed this validation study. The protocol consisted of walking at 53.6, 80.4, and 107.2 m/min and running at 134.0, 160.8, 187.6, and 214.0 m/min on an outdoor track while wearing a portable metabolic measurement unit (Cosmed K4b<sup>2</sup>). A miCoach sensor was attached to the right shoelaces (Laces) and a second miCoach sensor was inserted in the right insole of the shoe (Midsole). Estimated pace, distance and EE were compared to values determined by criterion methods (Actual). Data were analyzed using a repeated-measure ANOVA (pace, distance) or ANCOVA (EE) to evaluate significant differences.

**RESULTS:** A significant main effect ( $P < 0.035$ ) was observed for speed indicating an increase in measured values at each subsequent speed for pace, distance, and EE. For pace at all speeds, the laces and midsole miCoach estimated pace were significantly different from each other ( $P < 0.01$ ), and from actual pace ( $P < 0.02$ ). For distance, the laces and midsole miCoach estimates were similar for all speeds; however, significant differences were observed for the midsole at 53.6 m/min ( $P = 0.003$ ) and for both laces and midsole at 80.4 and 107.2 m/min ( $P \leq 0.05$ ) compared to actual distance. For walking speeds, miCoach estimated EE was significantly different between laces and midsole ( $P < 0.04$ ), and compared to actual EE ( $P < 0.001$ ); however, midsole at 160.8 m/min ( $P = 0.035$ ) and both laces and midsole at 187.6 and 214.4 m/min ( $P < 0.01$ ) were significantly different from actual EE.

**CONCLUSION:** These data indicate that the Adidas miCoach is accurate for estimating distance. However, it lacks the ability to accurately estimate pace and EE across a range of walking and running speeds. Additionally, it appears that the laces configuration produced more accurate estimates than the midsole.

Partially supported by UTEP CHS graduate enhancement funds.

**2088** Board #134 MAY 31 8:00 AM - 9:30 AM

**Validating The Nike+ Sport Kit For Estimating Pace, Distance, And Energy Expenditure During Treadmill Exercise**

Derek J. Acosta, Sean T. Miller, Justin P. Porta, Angelica N. Lehker, Joseph W. Tomaka, Rebecca J. Reed-Jones, George A. King. *The University of Texas, El Paso, TX.*

(No relationships reported)

The Nike+ Wireless Sport Kit was developed to allow athletes of all skill levels to observe their pace, distance, and energy expenditure during walking or running.

**PURPOSE:** To validate the accuracy of the Nike+ Wireless Sport Kit to estimate pace (min/km), distance (km), and energy expenditure (EE) (kcal/min) during treadmill walking and running, and for two different sensor configurations.

**METHODS:** Nine male and 9 female moderately endurance trained volunteers (mean  $\pm$  SD age: 28.83  $\pm$  1.90 y; height: 168.72  $\pm$  1.86 cm; body mass: 62.19  $\pm$  2.58 kg; VO<sub>2max</sub>: 54.36  $\pm$  1.15 mL/kg/min) completed a) a maximal oxygen consumption test and b) the Nike+ validation protocol comprised of level treadmill walking at 53.6, 80.4, and 107.2 m/min, and level treadmill running at 134.0, 160.8, 187.6, and 214.0 m/min. A Nike+ unit was attached to the left shoelaces and a second unit was placed within the left midsole of a compatible shoe. Nike+ estimated pace, distance, and EE were compared to actual values determined by criterion methods. Data were analyzed by conducting two repeated-measures ANOVAs, and one repeated-measures ANCOVA.

**RESULTS:** Each subsequent treadmill speed elicited a significant increase in pace ( $P \leq 0.037$ ), distance ( $P < 0.001$ ), and EE ( $P \leq 0.020$ ). The Nike+ significantly overestimated pace ( $P \leq 0.034$ ) and distance ( $P \leq 0.005$ ) at walking speeds (53.6 and 80.4 m/min) by 23% and 9%, respectively; and significantly underestimated pace ( $P \leq 0.034$ ) and distance ( $P \leq 0.005$ ) at higher running speeds (160.8, 187.6, and 214.0 m/min) by 6% (pace only - laces), 10% and 15%, respectively. Compared to the criterion indirect calorimetry, the Nike+ significantly underestimated EE ( $P \leq 0.022$ ) by 24%, 10%, and 12% for 107.2, 187.6 and 214.0 m/min, respectively. There appears to be no marked difference between the laces and midsole sensor configurations for pace, distance, or EE.

**CONCLUSION:** Compared to actual, estimates of EE were most accurate; speculating that the device's prediction equation is more suited for estimating EE. The sensor configuration affixed to the laces is a viable alternative to that of purchasing a Nike+ compatible shoe.

**Validating The Adidas miCoach For Estimating Pace, Distance, And Energy Expenditure During Treadmill Exercise**

Sean T. Miller, Derek Acosta, Angelica Lehker, Justin Porta, George King. *University of Texas at El Paso, El Paso, TX.*

(No relationships reported)

The use of accelerometry based physical activity monitors among recreational athletes to meet or exceed recommended physical activity guidelines has grown in popularity. In the interest of capitalizing on this demand, Adidas developed the miCoach Pacer System which allows the user to observe pace, distance, and energy expenditure during walking or running.

**PURPOSE:** To validate the accuracy of the Adidas miCoach activity monitor in estimating energy expenditure (EE) (kcal/min), pace (min/km), and distance (km) during treadmill walking and running, and for two different sensor configurations.

**METHODS:** Nine male and 9 female

moderately endurance trained volunteers (mean  $\pm$  SD age: 28.83  $\pm$  1.90 y; height: 168.72  $\pm$  1.86 cm; body mass: 62.19  $\pm$  2.58 kg; VO<sub>2max</sub>: 54.36  $\pm$  1.15 mL/kg/min) completed a maximal oxygen consumption test, and the miCoach validation protocol comprised of level treadmill walking at 53.6, 80.4, and 107.2 m/min, and level treadmill running at 134.0, 160.8, 187.6, and 214.0 m/min. A miCoach unit was attached to the right shoelaces (Laces) and a second unit was placed within the right midsole of a modified shoe (Midsole). MiCoach estimated pace, distance, and EE were compared to actual values determined by criterion methods (Actual). Data were analyzed using a repeated-measures ANCOVA (EE), or a repeated-measures ANOVA (pace, distance).

**RESULTS:** There was a significant increase in EE ( $P \leq 0.003$ ), pace ( $P \leq 0.001$ ), and distance ( $P < 0.001$ ) with each subsequent treadmill speed. The Adidas miCoach significantly overestimated actual EE for the midsole at 53.6 m/min ( $P = 0.045$ ), and for both laces and midsole at 80.4 and 107.2 m/min ( $P \leq .036$ ). No significant differences were observed for laces or midsole EE compared to actual EE at any running speeds. Further, no significant differences were observed for estimated pace or distance of laces or midsole compared to actual values.

**CONCLUSION:** The Adidas miCoach device appears to accurately estimate pace and distance across a range of treadmill walking and running speeds and accurately estimate EE during treadmill running. Additionally, these results suggest that either laces or midsole sensor configuration provides similar values. Partial support for this study was provided by UTEP CHS Graduate Enhancement Funds.

**2090 Board #136 MAY 31 8:00 AM - 9:30 AM**  
**Validating The Nike+ Sport Kit For Estimating Pace, Distance, And Energy Expenditure During Over-ground Exercise**

Angelica N. Lehker, Justin P. Porta, Derek J. Acosta, Sean T. Miller, George A. King. *The University of Texas at El Paso, El Paso, TX.*  
(No relationships reported)

The Nike+ Wireless Sport Kit was designed to estimate pace, distance, and energy expenditure (EE) during walking and running.

**PURPOSE:** To validate the Nike+ Wireless Sport Kit for estimating pace (min/km), distance (km), and EE (kcal/min) during walking and running on an outdoor track and to compare the accuracy of the Nike+ laces sensor to the midsole sensor configuration.

**METHODS:** The Nike+ was assessed for 6 male and 9 female moderately endurance trained participants (mean  $\pm$  SD age: 28.07  $\pm$  8.22 y; height: 167.13  $\pm$  7.62 cm; mass: 60.46  $\pm$  10.86 kg;  $VO_{2max}$ : 54.25  $\pm$  5.36 mL/kg/min) during walking at 53.6, 80.4, and 107.2 m/min and running at 134.0, 160.8, 187.6, and 214.0 m/min on an outdoor track. The Nike+ validation protocol involved wearing a portable metabolic measurement unit (Cosmed K4b<sup>2</sup>), one Nike+ sensor attached to the left shoelaces (Laces), and a second Nike+ sensor inserted in the left insole of a compatible shoe (Midsole). Pace, distance, and EE values estimated from the laces and midsole were compared to criterion measures (Actual). A repeated-measures ANOVA (pace, distance) or ANCOVA (EE) was used to evaluate data for statistical significance.

**RESULTS:** Each subsequent speed elicited a significant increase in pace ( $P < 0.005$ ), distance ( $P < 0.005$ ), and EE ( $P < 0.17$ ). However, compared to actual pace, both laces and midsole values were significantly different at 53.6, 80.4, 134.0 and 214.0 m/min ( $P < 0.03$ ), and midsole at 160.8 m/min ( $P < 0.001$ ). For distance, both laces and midsole values were significantly different at 53.6, 80.4, 134.0 and 160.8 m/min ( $P < 0.03$ ) and laces at 214.0 m/min ( $P = 0.002$ ). Significant differences were observed between estimated and actual EE for laces at 53.6 m/min ( $P = 0.043$ ), and for both laces and midsole at 80.4, 134.5, 160.8, and 187.6 m/min ( $P \leq 0.05$ ).

**CONCLUSIONS:** The Nike+ accurately distinguishes various intensities of walking and running on an outdoor track. Despite small but significant differences compared to actual values, these data indicate that the Nike+ provides similar estimates when mounted on the shoelaces as when inserted in a compatible shoe.

Partially supported by UTEP CHS graduate enhancement funds.

**2091 Board #137 MAY 31 8:00 AM - 9:30 AM**  
**Reliability Of The Actical Accelerometer As A Measure Of Activity During Front Crawl Swimming.**

Brian V. Wright<sup>1</sup>, Joel M. Stager<sup>2</sup>. <sup>1</sup>Austin College/Indiana University, Sherman, TX. <sup>2</sup>Indiana University, Bloomington, IN. (Sponsor: Joel M. Stager, FACSM)  
(No relationships reported)

**INTRODUCTION:** The use of accelerometers with competitive athletes provides a non-invasive, non-obtrusive method for monitoring training performance and adherence. For example, recent studies have utilized the Actical accelerometer to quantify swimming speed and distance in competitive swimmers (Wright et al., 2007, Hinman et al., 2008, Wright, Hinman, & Stager, 2010). These studies have shown the ability to use the Actical accelerometer to retrospectively quantify the swimming speed and swim distance of athletes during competitive training sessions.

**PURPOSE:** The purpose of this project was to assess the reliability of the Actical accelerometer during front crawl swimming in collegiate swimmers. More specifically, to examine the reliability in both the arm stroke and leg kicking motion during front crawl swimming when both swimming speed and swim distance are held constant.

**METHODS:** The Actical was assessed on 8 collegiate competitive swimmers (20.1  $\pm$  1.04 yrs.) during two 100 yard front crawl swims completed on separate days at the same swimming speed. Each subject wore an Actical accelerometer attached via watch strap to their right wrist and right ankle. Comparisons between the arm and between the leg Actical outputs (i.e. accelerometer counts) were examined using paired samples t-test.

**RESULTS:** The range of p-values from all sixteen comparisons was 0.49-0.98 (average 0.564). Only one case was shown to be significant different. Additional analysis using a One-way ANOVA comparing four separate swims within one subject displayed no significant difference between total (arm + leg) Actical output ( $F = 2.055$ ,  $p = .185$ ) or arm output ( $F = 0.562$ ,  $p = .655$ ). However, there was a significant difference between two of the four swims with regard to leg output (trial 2 = 1940.0 counts vs. trial 4 = 1217.3 counts;  $p = .029$ ).

**CONCLUSIONS:** The Actical accelerometer appears to have acceptable day to day reliability during front crawl swims. Furthermore, the Actical appeared to be most reliable when data was examined as the summated output (i.e. sum of arm and leg output) or arm output individually.

**2092 Board #138 MAY 31 8:00 AM - 9:30 AM**  
**Validation of Exercise Workloads on Two Lower Extremity Ergometers**

James H. Ross, Allison J. Silverman, Daniel S. Clevenger. *Wake Forest University, Winston-Salem, NC.* (Sponsor: Peter H. Brubaker, FACSM)  
(No relationships reported)

**PURPOSE:** The purpose of this study was to verify the accuracy of workloads during exercise at three levels on an Airdyne ergometer and a LifeFitness 9500 HR recumbent ergometer.

**METHODS:** Each of the seven recruited subjects completed in randomized order, 5-minutes at 45, 60, and 75 watts on both ergometers. Data was collected with a Medical Graphics CPX Ultima metabolic analyzer. Oxygen uptake ( $VO_2$ ), ratings of perceived exertion, heart rate, caloric expenditure and respiratory exchange ratios were recorded during each stage. Average  $VO_2$  obtained during the fifth minute of each workload on both ergometers was compared to the  $VO_2$  predicted using the ACSM equation for leg ergometers ( $VO_2 = [(10.8 \times \text{watts}) / (\text{wt. in kg})] + 7$ ). A t-test was used to determine if  $VO_2$  was significantly different for subjects at each workload on both modalities.

**RESULTS:**  $VO_2$  was significantly different for all workloads on the Lifefitness and at 60 and 75 watts on the Airdyne compared to the ACSM leg ergometer equation.

| Workloads | VO2 ACSM leg ergometer equation | VO2 AD (CPX) | VO2 LF-9500 (CPX) |
|-----------|---------------------------------|--------------|-------------------|
| 45 watts  | 14.23                           | 13.77        |                   |
| 60 watts  | 16.64                           | 15.02**      | 13.62**           |
| 75 watts  | 19.05                           | 16.44**      | 16.38**           |

$VO_2$  in  $\text{ml}\cdot\text{kg}^{-1}\cdot\text{min}^{-1}$

\*\*  $P < .05$

AD=Airdyne LF=Lifefitness 9500

**CONCLUSIONS:** These results suggest that the workloads provided by each ergometer during an exercise bout may not be accurate. When exercise is prescribed by MET level or  $VO_2$  the prescribed work rate may illicit a more variable physiological response than intended.

**2093 Board #139 MAY 31 8:00 AM - 9:30 AM**  
**Learning Effect With Repeated Use Of The Dynavision™ D2: Visual-motor Evaluation**

William P. McCormack, Nadia S. Emerson, David R. Williams, Adam J. Wells, Gerald T. Mangine, Adam M. Gonzalez, Maren S. Fragala, Jay R. Hoffman, FACSM.  
*University of Central Florida, Orlando, FL.*  
(No relationships reported)

**PURPOSE:** Recently a light-training reaction device has been developed to enhance sensory motor integration with the purpose of improving athletic performance. It has also been suggested that this system can serve as an evaluation tool for concussions and visual-field deficits that can provide information for a team's medical staff on issues related to return to play. However, in these circumstances it becomes critical to determine how many trials are needed to achieve a true baseline measure. Thus, the purpose of this study was to examine the effect of repeated trials on performance improvements using the Dynavision™ D2 reaction device.

**METHODS:** Twenty-one female division I college athletes (10 basketball and 11 volleyball) performed hand-eye reaction time tests of peripheral vision (PV), peripheral vision with number recall (PVNR), and visual-reaction (VR) on the Dynavision D2 (Dynavision, Ontario Canada). The PV and PVNR tests measured accuracy (hits) in reacting to light stimuli for one minute duration. The VR measured time in reacting to 5 separate visual stimuli with the dominant and non-dominant hands. Each volunteer completed four trials of each test. Differences between subsequent trials were analyzed with one-way repeated measures ANOVA.

**RESULTS:** Significant improvements in PV were seen between T1 ( $69.3 \pm 7.8$  hits) and T2 ( $77.3 \pm 12.5$  hits). No other significant differences were noted between testing sessions. Similarly, significant improvements were noted in PVNR between T1 ( $55.5 \pm 11.1$  hits) and T2 ( $65.6 \pm 10.9$  hits), but no additional improvements ( $p > 0.05$ ) were seen in subsequent testing sessions. No significant differences between trials were observed for VR in visual reaction time in dominant ( $0.40 \pm 0.07$  s) or non-dominant hands ( $0.41 \pm 0.10$  s), or in motor reaction time in dominant ( $0.37 \pm 0.14$  s) or non-dominant hands ( $0.38 \pm 0.13$  s). **CONCLUSIONS:**

Results indicate that competitive athletes should perform two trials to achieve baseline performance measures in PV or PVNR. In addition, both visual and motor reaction time does appear to be consistent with each testing trial, suggesting that there is a limited learning effect in VR observed during consecutive testing trials when assessing competitive athletes.

**2094 Board #140 MAY 31 8:00 AM - 9:30 AM**  
**Longitudinal Morphological and Performance Profiles for NCAA Division I Football Linemen**

Bert H. Jacobson, FACSM, Oklahoma State University, Stillwater, OK.  
(No relationships reported)

**PURPOSE:** A premium is placed on strength and speed of American college football players in order to be competitive on the playing field. All universities competing in football maintain well equipped weight training facilities and employ specialist in the area of strength and conditioning. Excelling in the weight room and in speed/agility drills often differentiates between starters and other squad members. Previous studies have been largely cross sectional, but the few existing studies suggest that athletes continue to improve in strength measures as they progress through their college playing career. The aim of this study was to compile and analyze data on incoming freshmen Division I football players and to longitudinally track their performance variables over their college career.

**METHODS:** Following IRB approval and athletic department approval, pre-existing data was obtained on 38 offensive and defensive linemen from 2005 to 2011. Only August preseason testing data was used because it was assumed that this was the point at which the participants reported in top playing condition. Physical measurements consisting of height, weight, body composition, vertical jump (VJ), IRM bench press (BP), power clean (PC), squat (SQ), 225 lb. maximum bench press repetitions (MBP), and the 40 yd. sprint were compared by year of participation.

**RESULTS:** Freshmen gained an average of 20.5 lbs or 7.2% in body mass (284.2 lbs to 304.7 lbs) with an average loss of 3.9% body fat (25.1% to 21.2%) between freshman and senior years. Greatest weight gain and fat decrease occurred between the first and second years. Significant ( $p < 0.05$ ) improvements were recorded for PB, PC, SQ, and MBP between freshman and senior years, but not for the VJ, or 40 yd. sprint.

**CONCLUSIONS:** Freshmen linemen reported with a body composition near the obese level (25.1%), but steadily reduced body fat while increasing in lean body mass over time. All strength measures improved most rapidly from year 1 to year 2 and continued to steadily improve over the participants' career. Conversely, while measures of strength improved significantly from year to year, the aspects of power (VJ) and speed (40 yd) did not. These results suggest that voluntary muscular strength will significantly improve by training and that measures of power and speed may improve, but to a much lesser degree.

**Influence of Autonomic Function and Exercise Training on C-Reactive Protein Levels in Obstructive Sleep Apnea**

Christopher E. Kline<sup>1</sup>, E. Patrick Crowley<sup>2</sup>, Gary B. Ewing<sup>2</sup>, James B. Burch<sup>2</sup>, Steven N. Blair, FACSM<sup>2</sup>, J. Larry Durstine, FACSM<sup>2</sup>, J. Mark Davis, FACSM<sup>2</sup>, Shawn D. Youngstedt<sup>2</sup>. <sup>1</sup>University of Pittsburgh School of Medicine, Pittsburgh, PA. <sup>2</sup>University of South Carolina, Columbia, SC.  
(No relationships reported)

Various studies have documented a link between autonomic function and inflammation. However, little is known regarding this association in adults with obstructive sleep apnea (OSA), who commonly have both altered autonomic function and elevated inflammation. Furthermore, it is unknown whether improved autonomic function can reduce inflammation in adults with OSA.

**PURPOSE:** To evaluate the effect of exercise training on C-reactive protein (CRP), a marker of systemic inflammation, and variables associated with CRP reduction among overweight/obese adults with OSA. The cross-sectional association between CRP and heart rate recovery at 1-min post-exercise (HRR, a marker of vagal tone) was also examined.

**METHODS:** 43 overweight/obese (BMI > 25) and sedentary adults aged 18-55 yr with at least moderate-severity OSA (apnea-hypopnea index [AHI]  $\geq 15$ ) were randomized to 12 wk of moderate-intensity exercise training (EX; n=27) or low-intensity stretching control (STR; n=16). Before and following the intervention, CRP was measured from plasma, body composition was assessed with dual x-ray absorptiometry (DXA), and cardiorespiratory fitness (VO<sub>2</sub>peak) and HRR were assessed with a maximal exercise test.

**RESULTS:** Of 37 participants with baseline CRP levels available ( $5.08 \pm 0.78$  mg/L), 17 had values associated with elevated cardiovascular risk (i.e.,  $> 3.0$  mg/L). Baseline CRP was correlated with DXA fat % ( $r = -0.71$ ,  $P < 0.01$ ), VO<sub>2</sub>peak ( $r = -0.55$ ,  $P < 0.01$ ), and HRR ( $r = -0.34$ ,  $P = 0.03$ ), but not OSA severity (e.g., AHI). Compared with participants with low CRP (n=20), those with elevated CRP had a significantly blunted HRR ( $20.45 \pm 1.61$  vs.  $13.59 \pm 1.50$ ;  $P = 0.02$ ) independent of age, sex, body fat, fitness, and AHI. For those who completed the intervention (n=32), there was a trend ( $F_{1,31} = 2.89$ ,  $P = 0.09$ ) for CRP reduction following EX ( $-1.18 \pm 0.52$  mg/L; n=21) versus STR ( $+0.32 \pm 0.71$  mg/L; n=11). Post-intervention CRP reduction was not correlated with change in body fat, VO<sub>2</sub>peak, HRR, or OSA severity. However, VO<sub>2</sub>peak change was greater among those with the greatest CRP reduction ( $P = 0.04$ ; n=16).

**CONCLUSIONS:** CRP was independently associated with impaired autonomic function in adults with OSA. Larger trials are needed to examine whether exercise can reduce CRP in OSA and the mechanisms by which this may occur.

**2096 Board #142 May 31 9:00 AM - 10:30 AM**  
**Body Warming Prior to Bedtime Fails to Affect Subjective Sleep Quality and Bedtime/Daytime Sleepiness**

Hermann J. Engels, FACSM, Jean E. Davis, Hossein N. Yarandi. Wayne State University, Detroit, MI.  
(No relationships reported)

The manipulation of body temperature prior to bedtime as a possible remedy to improve sleep-related problems in people with insomnia is receiving considerable research interest.

**PURPOSE:** This study served to examine the effects of acute endogenous and exogenous body warming interventions prior to sleep on subjective sleep quality, bedtime sleepiness, and daytime sleepiness throughout the following day.

**METHODS:** Eight postmenopausal women (age:  $55.3 \pm 5.9$  yrs; weight  $70.8 \pm 12.5$  kg; height  $160.4 \pm 6.0$  cm) who suffered from a sleep maintenance disorder completed an initial sleep adaptation and baseline sleep (BL) evaluation night. These were followed by three experimental treatment nights (spaced one week apart) in which they underwent three randomly assigned, 30-min body warming interventions prior to bedtime. Body warming treatments consisted of a moderate intensity (75% of HRmax) cycle ergometry exercise bout (EX), a 40°C seated whole body bath (WB), and a 40°C seated foot bath (FB). Changes in both core and skin (chest, foot) temperatures were measured using an ingestible core temperature capsule and dermal patches (Vitalsense, Mini-Mitter), respectively. Subjective sleep quality was assessed with the Subjective Sleep Quality Scale (SSQ; Davis, 1987) within 30 min of awakening. Sleepiness at bedtime and at four predetermined time points throughout the following day (10am, 1pm, 4pm, 7pm) were assessed with the Stanford Sleepiness Scale (SSS; Hoddes et al., 1973).

**RESULTS:** Pre-bedtime warming treatments were successful to produce significant intervention-specific changes in core and skin temperature recordings ( $p < 0.05$ ). However, repeated

measures MANOVA indicated no significant differences among trials for SSS scores (BL: 3.89±1.24; EX: 4.15±1.14; WB: 3.40±1.47; FB: 4.10±1.28), bedtime sleepiness (BL: 4.00±1.41; EX: 4.13±1.55; WB: 4.50±1.77; FB: 4.38±1.19), and the patterns of daytime sleepiness on the following day (BL: 2.81±0.58; EX: 2.84±1.32; WB: 2.75±1.04; FB: 2.72±0.89) (p>0.05).

**CONCLUSIONS:** These observations indicate no benefits of pre-bedtime endogenous (moderate intensity exercise) and exogenous (whole body and foot baths) body warming interventions on subjective sleep quality and bedtime/daytime sleepiness in postmenopausal women suffering from insomnia.

**2097** Board #143 May 31 9:00 AM - 10:30 AM

**Level Evolution Of Physical Activity After Six Months Of Monitoring In Sedentary Individuals Through Emails**

Carolina Vicaria Rodrigues D'Aurea<sup>1</sup>, Carla Giuliano de Sá Pinto<sup>1</sup>, Marcio Marega<sup>1</sup>, Felipe Gambetta Carmona<sup>1</sup>, Aylton Figueira Júnior<sup>2</sup>, José Antônio Maluf de Carvalho<sup>1</sup>. <sup>1</sup>Hospital Israelita Albert Einstein, São Paulo, Brazil. <sup>2</sup>Universidade São Judas Tadeu, São Paulo, Brazil.

(No relationships reported)

Physical activity is an important intervention to the prevention, and treatment of cardiovascular diseases, hypertension, diabetes mellitus, stroke, some kinds of cancers, osteoporosis, depression and imbalance in the lipid profile. Counseling for physical activity has been poorly applied for the needs of individuals who should be encouraged to develop healthier lifestyle habits.

**PURPOSE:** To investigate the effect of counseling, for 6 months, through emails, on the level of physical activity in sedentary adults.

**METHODS:** The study sample consisted of 104 adults of both sexes who completed the protocol for Continuing Health Revision at the Center for Preventive Medicine of the Albert Einstein Hospital. To participate in this study, the clients should be defined as sedentary, considering the physical activity level (IPAQ), signing the informed consent and having participated in the monitoring program and answered the three IPAQs applied: on the day of RCS, after 3 months and 6 months follow-up. The monitoring was done by physical education teachers through periodic e-mails, sent at weeks 1, 2, 3, 4, 6, 8, 10, 12, 16, 20 and 24. Statistical analysis was performed, using the Statistical Package for Social Sciences (SPSS) v.15.0.

**RESULTS:** After 3 months of follow-up, 29.8% of this sample, began to be lazy and at the end of 6 months follow-up, 67.3% became active and 9.6% became very active (p <0.0001). After 6 months, compared with the initial physical activity level, there was a considerable increase in the number of active individuals, reaching the necessary recommendations to achieve a healthier lifestyle.

**CONCLUSIONS:** The counseling and monitoring conducted through periodic and individualized e-mails, proved to be very motivating and effective for sedentary individuals, which contribute to a change in their lifestyles, making them more active for the encouragement of regular physical activity practice.

**Comparison Of Awareness Of ACSM Physical Activity Recommendations Between College Students And Other Population**

Luis Leite<sup>1</sup>, Dulce Leal Esteves<sup>2</sup>, Paulo Gonçalves Pinheiro<sup>3</sup>, Sérgio Vieira<sup>1</sup>, Kelly O'Hara<sup>2</sup>, Rui Brás<sup>2</sup>. <sup>1</sup>Beira Interior University, Covilha, Portugal. <sup>2</sup>Beira Interior University & CIDESD, Covilha, Portugal. <sup>3</sup>Beira Interior University - Research Unit in Business Sciences, Covilha, Portugal.

(No relationships reported)

Many health behaviors are established during late adolescence and early adulthood, when many attend college, so the decline in physical activity (PA) during college is a disturbing trend. Increasing efforts to promote college students PA have been made, but is not clear if college students have a better knowledge on adequate PA characteristics for health improvement than other population.

**PURPOSE:** This study aims to examine the extent to which knowledge of the ACSM PA recommendations has diffused through college students and compare with recommendations knowledge of the rest of population.

**METHODS:** The study included a randomly recruited sample of 848 subjects (54.5% M; 45.5% F), 42.0±19.6 y; and 200 undergraduate college students (31.0% M; 69.0%F) age 20.42±3.3. The awareness of ACSM PA Recommendations was assessed as indicated by Bennett et al., 2009.

**RESULTS:** There is not widespread knowledge of the ACSM PA recommendations neither for college students (only 28.5% know the recommendations) nor for the rest of population (26.3%). No statistic differences were found (p<.05) between these two groups.

**CONCLUSIONS:** Despite efforts to widespread knowledge on ACSM recommendations on college students, their knowledge is similar to the rest of population. This finding should highlight the limited ability to enhance knowledge from existing campaigns designed to college students and the need for more effective strategies to widespread

accurate information both for college students and for the rest of population. REFERENCE: Bennett, G., Wolin, K. et al. (2009) Awareness of National Physical Activity Recommendations for Health Promotion among US Adults. Med Sci Sports Exerc. 41(10), pp. 1849-1855.

**Awareness Of ACSM Physical Activity Recommendations For Health Promotion: Assessing BMI And METS Differences**

Sergio Vieira<sup>1</sup>, Paulo Gonçalves Pinheiro<sup>2</sup>, Rui Brás<sup>3</sup>, Kelly O'Hara<sup>3</sup>, Ricardo Gouveia Rodrigues<sup>2</sup>, Dulce Leal Esteves<sup>3</sup>. <sup>1</sup>Beira Interior University, Covilha, Portugal. <sup>2</sup>Beira Interior University - Research Unit in Business Sciences, Covilha, Portugal. <sup>3</sup>Beira Interior University & CIDESD, Covilha, Portugal.

(No relationships reported)

Regular moderate physical activity (PA) has an important influence on health and well-being, but is not clear if adult population knows the adequate PA characteristics for health improvement.

**PURPOSE:** This study aims to examine whether knowledge of the American College of Sports Medicine (ACSM) physical activity recommendations varies with BMI and METS.

**METHODS:** The study included a randomly recruited sample of 848 subjects (54.5% M; 45.5% F), 42.0±19.6 years. The awareness of ACSM PA Recommendations for Health Promotion was assessed as indicated by Bennett et al., 2009. METS were estimated using IPAQ, validated to Portugal.

**RESULTS:** PA evaluation revealed 40.6% of low; 9.2% moderate and 50.2% high PA level. BMI (Kg/m<sup>2</sup>) assessment found 2.48% underweight (BMI< 18.5); 51.59% normal (18.5<BMI<24.99); 36.95% overweight (25<BMI<29.99) and 8.98% obese (BMI>=30). Less than a third of respondents (26.3%) were accurately knowledgeable of the ACSM PA recommendations. Recommendations knowledge increases with PA level (22.1%, 25.6% and 30.0% for low, average and high PA level, respectively) and with BMI (14.3%, 23.3%, 39.1% and 35.5% for underweight, normal, overweight and obese, respectively).

**CONCLUSIONS:** For almost three quarters of interviewed population there is not widespread knowledge of ACSM PA recommendations. Knowledge augments with PA level, what is an expected finding, and also with BMI: obese have a better knowledge of ACSM PA recommendations than underweight and normal weight. This unexpected result may be related with people with higher BMI could be alerted to the need of physical exercise to lose weight, so, their knowledge on exercise recommendations is better. **Longitudinal Non-exercise Models For Estimating Cardiorespiratory Fitness Of Men And Women**

Andrew S. Jackson, FACSM<sup>1</sup>, Xuemei Sui<sup>2</sup>, Daniel P. O'Connor<sup>3</sup>, Duck-chul Lee<sup>2</sup>, Enrique G. Artero<sup>2</sup>, Timothy S. Church, FACSM<sup>4</sup>, Steven N. Blair, FACSM<sup>2</sup>.

<sup>1</sup>University of Houston, Onalaska, TX. <sup>2</sup>University of South Carolina, Columbia, SC. <sup>3</sup>University of Houston, Houston, TX. <sup>4</sup>Pennington Biomedical Research Center, Baton Rouge, LA.

(No relationships reported)

Low cardiorespiratory fitness (CRF) is associated with high risk of chronic diseases and mortality. CRF measured with a maximal or sub-maximal exercise test has limited application in clinical and public health settings due to time constraints and the need for specialized test equipment and trained administrators. Published cross-sectional, non-exercise (Non-Ex) models show that CRF can be estimated with reasonable accuracy, but cannot be generalized to changes in CRF associated with aging.

**PURPOSE:** To develop longitudinal Non-Ex models for men and women that accurately estimate CRF and changes in CRF associated with aging.

**METHODS:** The sample included 1,325 women (age range 20-78 y) and 10,040 men (age range 20-86 y) who completed from 2 to 21 maximum treadmill exercise tests from 1977 to 2005. The number of observations was: women, 3,816; and men, 38,716. The dependent variable was CRF measured with a maximal Balke treadmill test. The independent variables were age, body composition (body mass index and waist circumference), self-report physical activity (SR-PA), smoking behavior and resting heart rate. Linear mixed levels regression (LML) modeled the data and the standard error of estimate defined model accuracy.

**RESULTS:** the LML analyses found that all variables were independently related with CRF ( $p < 0.001$ ) and were used to construct the longitudinal models. The longitudinal model error estimates (95% CI) were: women, 1.51 METs (1.45, 1.58); and men, 1.66 METs (1.63, 1.68). These error estimates are congruent with published cross-sectional error estimates.

**CONCLUSIONS:** The longitudinal models provide accurate Non-Ex equations for estimating CRF with data routinely collected in public health settings. These results can be generalized to assessing changes in CRF associated with aging.

**Individuals With Physical Limitations Can Benefit From Training On A Motorized Elliptical For Community-based Exercise**

Judith M. Burnfield<sup>1</sup>, Marie C. Yeseta<sup>2</sup>, Thad W. Buster<sup>1</sup>, Adam P. Taylor<sup>1</sup>, Yu Shu<sup>1</sup>. <sup>1</sup>Madonna Rehabilitation Hospital, Lincoln, NE. <sup>2</sup>University of Southern California, Los Angeles, CA.

(J.M. Burnfield: Intellectual Property; Judith M. Burnfield, Yu Shu, Adam P. Taylor, and Thad W. Buster are co-inventors of the ICARE trainer (U.S. Patent 8,007,405). Remaining authors do not have a conflict of interest.)

The ICARE, an Intelligently Controlled Assistive Rehabilitation Elliptical, was developed to address barriers to physical activity that individuals with motor control, strength, and endurance limitations face. An elliptical trainer was adapted with a body weight support (BWS) system, ramp, steps, safety rails, footplate straps, and an adjustable seat to enhance access. A sensor controlled motor was integrated to initiate and sustain pedal motion for continuous training up to 65+ revolutions per minute (rpm). For community members with movement limitations who cannot use traditional equipment, the ICARE provides an option for engaging in meaningful exercise.

**PURPOSE:** This study assessed use of the ICARE trainer in a community-based fitness facility for individuals with chronic medical conditions.

**METHODS:** Ten community fitness facility members (ages 42-80) with varying neurologic, cardiovascular, and orthopedic diagnoses ICARE trained with a fitness instructor for 12 sessions. Velocity (VEL), stride length (SL), and BWS progressions were customized based on participant performance, with session duration (DUR) determined by their perceived exertion (RPE) and heart rate (HR) and blood pressure (BP). Paired t-tests (significance set at  $p < 0.05$ ) evaluated changes across the training program in VEL, SL, DUR, BWS, strides/session, vital signs (HR, BP), RPE, and functional measures of walking velocity (6 meter Walk Test), endurance (5-Minute Walk Test-5MWT), and balance (Timed Up and Go-TUG; Berg Balance Scale-BBS).

**RESULTS:** ICARE training performance improved from pre to post as evidenced by increases in VEL (34 vs. 39 rpm;  $p = 0.020$ ), DUR (15.4 vs. 18.8 min;  $p = 0.013$ ), SL (20 vs. 22 in;  $p = 0.014$ ), and strides/session (540 vs. 765;  $p = 0.012$ ) without significant changes in RPE (13 vs. 12). Improvements in fast walking velocity (43.5 vs. 48.1 m/min;  $p = 0.048$ ) and the 5MWT (710 vs. 798 ft;  $p = 0.013$ ) also were identified. Comfortable walking speed and BBS improvements were not significant.

**CONCLUSIONS:** The ICARE is a promising fitness modality for individuals in the community with activity limitations, as evidenced by increases in exercise tolerance and corresponding improvements in fast walking speed and endurance with training.

Supported by Department of Education, NIDRR grant #H133G070209

**Effects of a Desk Treadmill on Physical Activity in a Counseling Observation Room**

Michelle Dell'Orto, David Weber, Toni Zimmerman, Raymond C. Browning, FACSM. Colorado State University, Fort Collins, CO.

(No relationships reported)

The workplace environment can have a significant impact on the prevalence of obesity as well as the ability of individuals to obtain the recommended daily levels of physical activity (PA). One potentially feasible way to decrease sedentary time and increase overall physical activity levels is the introduction of a desk treadmill into a generally sedentary work environment.

**PURPOSE:** To determine whether the introduction of desk treadmills into a counseling observation room would lead to increases in objectively measured (via accelerometry) physical activity.

**METHODS:** Eight female, Center for Family Therapy counseling supervisors and assistant supervisors were asked to wear hip mounted Actical accelerometers during four study periods, baseline, Tm1, Tm2, and Tm3, from November 2010 until March 2011. Counseling observation periods occurred three times weekly for a period of four hours. After the three week baseline period, two desk treadmills were placed in the counseling observation room and PA was measured in two week intervals. Individuals were instructed in the use of the desk treadmill but were not required to use it. Accelerometer data were analyzed using cut-point values and divided into percent time in sedentary, light, and moderate-vigorous PA (MVPA). A comparison of percent time in different PA intensities was made with one-way repeated measures ANOVA.

**RESULTS:** No significant changes were seen in sedentary time or time engaged in PA between the four time periods. While not significant, percent time in sedentary activity decreased from 86% to 80% between baseline and Tm1, but returned to base line levels during Tm2 and Tm3. Conversely, percent time in MVPA increased slightly from 5% to 9% between baseline and Tm1, and remained above baseline for Tm2 and Tm3, 9% and 7%, respectively. Difficulties with noise level and a treadmill user interface were cited as potential barriers to treadmill use. In particular, participants cited that treadmill noise interfered with their ability to hear and concentrate on counseling sessions.

**CONCLUSIONS:** While the results did not demonstrate a significant increase in PA from the addition of two desk treadmills into an otherwise sedentary environment, the trend toward an increase in percent MVPA suggests that this type of intervention could help individuals increase daily PA.

**2103 Board #149 May 31 9:00 AM - 10:30 AM**

**Musculoskeletal Injuries And Healthcare Needs Among Women With Or At-Risk For Breast-Cancer-Related Lymphedema In A Weight Lifting Exercise Trial**

Justin C. Brown, Andrea B. Troxel, Kathryn H. Schmitz, FACSM. University of Pennsylvania, Philadelphia, PA.

(No relationships reported)

**PURPOSE:** The purpose of our study was three-fold: 1) quantify and compare the incidence of musculoskeletal injury in a large cohort of BrCa survivors with or at-risk for developing breast cancer related lymphedema randomized to twice-weekly weight lifting or standard care for one-year; 2) compare the risk of musculoskeletal injury among BrCa survivors to apparently healthy women engaging in a similar weight lifting protocol and; 3) qualitatively identify the frequency and severity of healthcare needs that may require dose modification of weight lifting or medical referral.

**METHODS:** BrCa survivors with (n=141) or at-risk for (n=154) lymphedema were randomized to twice weekly weight lifting or standard care for one year. An injury survey and healthcare evaluation were

administered after one year, and in three-month intervals, respectively.

**RESULTS:** The cumulative incidence and rate of injury was higher in the weight lifting compared to the control group. The injury rates were 2.3 (95% CI: 2.0-2.6) and 0.3 (95% CI: 0.2-0.5) per 1000 bouts of weight lifting among BrCa survivors with versus at-risk for lymphedema, respectively. Among BrCa survivors with or at-risk for lymphedema, 19.6% in the weight lifting group had an encounter with a healthcare provider that required cessation or dose modification of weight lifting exercise.

**CONCLUSIONS:** Despite the demonstrated efficacy of weight lifting among BrCa survivors with or at-risk for lymphedema, musculoskeletal injuries, and other health needs do occur.

Health-fitness professionals working with BrCa survivors need the knowledge, skills, and abilities to encounter these healthcare needs and implement a system of referral to appropriate clinical experts for medical evaluation for healthcare events falling outside their scope of practice.

2104 Board #150 May 31 9:00 AM - 10:30 AM

**Obesity and Mobility: Outcomes From a Multidisciplinary Team Weight Management Program**

Mary E. Sanders, FACSM, Katie Lyons, Quang Nguyen, Maureen Blanford, Stacey Frattinger, Karmella Thomas, Ray Plodkowski, Hu Shien, Aimee Brock.  
University of Nevada, Reno, Reno, NV.  
(No relationships reported)

Mobility disability is prevalent in obese older populations, yet little is known about the effect of obesity and weight loss on mobility in younger populations.

**PURPOSE:** To determine the effect of a clinical weight loss program conducted by an integrated multidisciplinary team including physicians, registered dietitians, and clinical exercise physiologists on selected anthropometrics and mobility in obese patients.

**METHODS:** Program evaluation of patients (n=66); 46.6±8.3 y; 114kg ± 22; BMI= 41.3 kg/m<sup>2</sup>, enrolled in a 12 week weight loss program. Integrated team visits included medical, nutrition and physical activity assessments; weekly follow-ups included weight loss behavior education, lifestyle strategies, tracking and guidance. Physical activity visits included functional field assessments, pre-exercise screening, medical and current activity status. Patients received a pedometer with step tracking instructions and a First Step to Active Health® kit. An individualized home/gym exercise program based on ACSM guidelines was designed and progressed over time. Dietitians reviewed patient's food and step log/activity records. Physicians reviewed patient's health status, with intervention as needed.

**RESULTS:** The following table summarizes results.

| Assessment                         | Baseline  | 12 week    | Change (%) |
|------------------------------------|-----------|------------|------------|
| Weight (kg)                        | 114±21.8  | 107± 18**  | -6         |
| BMI (kg/m <sup>2</sup> )           | 41.3±18.2 | 38.9±16**  | -5.8       |
| Percent body fat (%)               | 43.8±7.1  | 41.9±5.8** | -4.3       |
| Muscle mass (kg)                   | 58.8±5.1  | 57.8±5.6** | -1.62      |
| Walking: Pedometer steps           | 5100±1574 | 8040±773** | +57.6      |
| Strength/lower: Sit to stands      | 11.6±4.9  | 14.7±5.8** | +26.7      |
| Strength/upper: Arm curls          | 17.3±4.6  | 20.4±5.2** | +17.9      |
| Balance (seconds)                  |           |            |            |
| Left leg                           | 26.4±9.3  | 27.8±5.8   | +5.3       |
| Right leg                          | 24.1±9.3  | 26.7±7.3*  | +10.7      |
| Flexibility: Back Scratch (inches) |           |            |            |
| Right arm                          | -7.0±5.1  | -5.1±4.6** | +28        |
| Left arm                           | -8.6±5.4  | -6.6±4.6** | +23        |

\* p<.05, \*\*p<0.0001

Measures revealed significant improvements in all areas except balance of the left leg. Baseline scores were below older adult (60-94 y) normative mobility scores and by 12 weeks, our patients exceeded all older adult normative mobility scores except for flexibility.

**CONCLUSIONS:** This multidisciplinary team weight management program is an approach that can help young obese patients lose weight and improve mobility.

2105 Board #151 May 31 9:00 AM - 10:30 AM

**Efficacy of the Walk for Health Program: A Physical Activity Intervention for Adults with Blindness**

Elizabeth A. Holbrook<sup>1</sup>, Joel Reece<sup>2</sup>, Minsoo Kang<sup>2</sup>, Don W. Morgan, FACSM<sup>2</sup>. <sup>1</sup>Roanoke College, Salem, VA. <sup>2</sup>Middle Tennessee State University, Murfreesboro, TN.  
(No relationships reported)

It has been hypothesized that the pervasive comorbidity documented in adults with visual impairment (VI) may be largely attributable to physical inactivity. Nonetheless, relatively little is known concerning the extent to which physical activity (PA) level and health status can be improved in persons with VI.

**PURPOSE:** To document the effectiveness of Walk for Health, an adaptive community-based walking program, on daily step activity (DSA) and profiles of body composition (BC; body mass, body fat, waist circumference), cardiovascular health (CV; resting heart rate and blood pressure), and lipid function (LIP; triglycerides and total, HDL-, and LDL-cholesterol) in adults with blindness.

**METHODS:** Twenty-two adults (age = 46.7 ± 11.9 years) completed eight weeks of guided PA intervention (INT; n = 15) or served as control subjects (CON; n = 7). INT participants were provided with individually-tailored feedback designed to increase DSA by approximately 1,000 steps every two weeks and maintain these gains in PA during the final two weeks of the program.

**RESULTS:** Participants in the INT group displayed a mean increase of 73% in DSA (p< .01; 4,925 + 2,234 steps to 8,506 + 3,063 steps), while no changes in DSA were observed in the CON group (p = .90). No group-by-time effects were noted for BC (p = .10), CV (p = .07), or LIP (p = .56) variables.

**CONCLUSIONS:** The Walk for Health program was successful in substantially improving walking behavior in adults with VI, but health profiles remained unaltered. Future research should examine the impact of walking intensity and program length on physical health and quality of life in persons with varying levels of vision loss.

2106 Board #152 May 31 9:00 AM - 10:30 AM

**Upper-spinal Postural Alignment With Behavioral Modification (Dietary and Physical Exercises) Protocol**

Thomas F C Pesavento, Isabela M. Paixão, Reinaldo C. Dalanesi, Rodrigo M. Manda, Viviane M R Acerra, Natasha A G França, Livia S. Gonçalves, Roberto C. Burini. UNESP - Univ Estadual Paulista, Botucatu, Brazil.  
(No relationships reported)

Sedentary behavior and related overweight and sarcopenia are the major causes of postural alteration. Lifestyle changes with physical exercises and nutritional re-education are tools either for prevention and/or therapeutic care of these postural misalignments.

**PURPOSE:** To evaluate the effects of a protocol including supervised combined physical exercises and dietary counseling (lifestyle modification program; LSMP) on postural alterations in adults.

**METHODS:** From a community-based sample of 363 subjects (40-75 years old, most females) having thoracic kyphosis (148.3° ± 7.3°) as the main postural problem, 49 subjects fulfilled the ethical and inclusion criteria of attending the 24 weeks LSMP and to all evaluations. The LSMP included monthly dietary counseling and daily (5 X/wk) session of supervised physical exercises of walking (3 X/wk, 80 min, 60-70% VO<sub>2</sub>max) and strength (2 X/wk, 65-80% of one repetition maximal, 1RM) and assessments (baseline and end-study). Anthropometric assessment included waist circumference (WC), body weight and height for body mass index (BMI, kg/m<sup>2</sup>) calculation. Physical fitness tests included flexibility (sit and reach test) and 1RM exercises for seated bench press, pec deck flies, seated rows, back lat pulldowns, leg extensions and seated leg curls. The postural assessments by computerized photogrammetry (ALC image 2.1) were taken for cervical lordosis, thoracic kyphosis, lumbar lordosis and Q angle. The comparison between moments was analyzed by Student's t paired test and the correlation between variables through the Pearson's test, both in software Statistica 6.0 considering p<0.05.

**RESULTS:** The most prominent improvements with LSMP were observed in thoracic kyphosis (-7.98°) and lumbar lordosis (4.49°). Cervical (CL) and lumbar lordosis (LL) variations reversely correlated with WC loss and gained strength in the leg extensions. A significant reverse relationship between changes were observed for WC x CL (r=-0.320) and leg extensions x LL (r=-0.318).

2107 Board #153 May 31 9:00 AM - 10:30 AM

**Relationship between Body Mass Index and Percent Body Fat: Preliminary results from the Energy Balance Study.**

Vivek K. Prasad, Gregory A. Hand, FACSM, E Patrick Crowley, Kelly Kavanaugh, Jason R. Jagers, Robin P. Shook, Steven N. Blair, FACSM. *University of South Carolina, Columbia, SC.*  
(No relationships reported)

**PURPOSE:** The CDC has stated that "BMI provides a reliable indicator of body fatness for most people and is used to screen for weight categories that may lead to health problems." However, previous work has shown that BMI is not a reliable indicator in special populations including children, elderly, and some minorities. The purpose of this study was to examine in a healthy group of men and women the relationship between the BMI and body fat "cut points" for overweight and obesity.

**METHODS:** A group of healthy women and men were assessed for BMI and body fat percent (BF). BMI was calculated as weight in KG/ht in meters<sup>2</sup>. BF percentage was calculated as the percentage of total weight identified as fat tissue by dual x-ray absorptiometry (DXA). Descriptive statistics were calculated and a Pearson correlation was determined for BMI and BF percent by gender. BMI overweight and obese cut points were 25.0 to 29.9 and 30.0 and above, respectively. Obesity cut points for BF percent were 25 and 32 percent for men and women, respectively.

**RESULTS:** The population consisted of 55 healthy adults (22 men and 33 women; aged 21 to 35 years). Body weight ranged from 53.7 to 110.8 kgs (men: 83.66±14.55 kgs; women: 72.53±13.29 kgs) with a BMI range of 19.3 to 35.0 for men (26.7±4.14) and a range for women of 19.8 to 35.1 (26.45±4.46). BF percent for men ranged from 7.83 to 39.55 (24.72±7.36) and for women ranged from 16.39 to 50.54 (35.63±7.67). Pearson correlations were 0.816 (p<0.0001) and 0.793 (p<0.0001) for men and women, respectively. Of the 6 men in the BMI overweight range of 25 to 29.9, all were in the obese BF range of over 25%. Eleven women were in the BMI overweight range of 25 to 29.9, and 9 of those were in the obese range of over 32% BF.

**CONCLUSIONS:** These results indicate that the majority of men and women (100% and 82%, respectively) who were categorized as overweight by BMI cut points were in the obese BF range. The findings suggest that the correlation between BMI and percent BF is high, but nearly all individuals classified as overweight by BMI were obese by percent BF standards. The range of BF percentage is significantly higher than would be expected by BMI classification of the individuals. In this population, BMI does not accurately categorize individuals as overweight or obese. Supported by the Coca Cola Corporation and the NINR/NIH.

2108 Board #154 May 31 9:00 AM - 10:30 AM

**Effect Of Overestimated Resting Metabolic Rate (rnr): Preliminary Results From The Energy Balance Study**

Gregory A. Hand, FACSM, John C. Sieverdes, Kelly Kavanaugh, Madison DeMello, E. Patrick Crowley, Vivek K. Prasad, Jason R. Jagers, Robin P. Shook, Steven N. Blair, FACSM. *University of South Carolina, Columbia, SC.*  
(No relationships reported)

**PURPOSE:** Body weight control requires a balance of energy intake and energy expenditure (EE) that is regulated by physiological, behavioral, environmental, and genetic components. The largest portion of EE is resting metabolic rate (RMR). RMR has been defined as 1 MET and an oxygen consumption of 3.5 ml/kg body weight/minute. As energy requirements for activity are calculated as multiples of METs, an overestimation of RMR will result in greater error in estimating EE as intensity or duration increases. The purpose of this study was to determine the RMR of a group of healthy adults, and calculate the effect of overestimating EE.

**METHODS:** RMR was measured in 55 healthy adults. Participants arrived fasted for at least 12 hrs. and having refrained from alcohol or exercise for at least 24 hrs. Participants rested in a supine position under a ventilated hood for 15 minutes, followed by a 30 minute RMR gas collection period in which inflow and outflow of oxygen and carbon dioxide was measured. Height and weight were measured and BMI calculated as body weight (kgs)/height (meters)<sup>2</sup>. Descriptive statistics were calculated and a Pearson Correlation of BMI to RMR was determined.

**RESULTS:** The population consisted of 22 men and 33 women (aged 21 to 35 years). Body weight ranged from 53.7 to 110.8 kgs (men: 83.66±14.55 kgs; women: 72.53±13.29 kgs) with a BMI range of 19.3 to 35.4 (men: 26.7±4.14; women: 26.45±4.46). The RMR ranged from 0.15 to 0.32 L/min (men: 0.25±0.037; women: 0.21±0.03) resulting in a RMR per body weight range of 2.25 to 3.58 ml/kg/min (men: 2.99±0.33; women: 2.89±0.36). The Pearson Correlation analysis of BMI to RMR for men was -0.443 (p=0.039) and for women was -0.71 (p<0.001).

**CONCLUSIONS:** These results indicate that the inverse relationship between BMI and RMR is stronger in women than men. Further, both genders showed a significantly lower RMR than the standard estimate of 3.5 ml/kg/min. The findings suggest that using the standard RMR estimate would have overestimated EE of 1 MET by approximately 0.55 ml/kg/min. This error would overestimate resting energy consumption for this population by approximately 2.5 L oxygen/hr, or by 2134 kcal per week. This error would dramatically increase as MET minutes of activity, calculated as multiples of RMR, were added to the total EE. Supported by the Coca Cola Corporation and NINR/NIH.

2109 Board #155 May 31 9:00 AM - 10:30 AM

**Exercise is Medicine with Altitude**

Rachel Cline, Rebekah Lauersdorf, Jeff Bakke, Tim Behrens, FACSM. *University of Colorado Colorado Springs, Colorado Springs, CO.*  
(No relationships reported)

The Exercise is Medicine on Campus campaign was adapted for the University of Colorado Colorado Springs (UCCS) and was titled Exercise is Medicine with Altitude (EIMA).

**PURPOSE:** To increase physical activity and its health benefits at UCCS through the implementation of EIMA.

**METHODS:** Students were recruited to participate in this descriptive study through flyers posted around campus, the student health center (SHC), the student recreation center (SRC), and social networking. The planning phase began in fall 2010 and included recruiting departments and developing implementation strategies. The campaign and data collection began February 1, 2011, consisting of a physical activity screening and referral process, health education flyers posted around campus, an EIMA team for a campus 5K, health and fitness assessments at the campus health fair, and a campaign mascot with his own Facebook page. The Physical Activity Vital Signs (PAVS) tool was used to screen for physical activity at the SHC. If the PAVS score resulted in a physical activity level below federal recommendations, a referral was made to the SRC for a free gym orientation, fitness assessment, and semester group fitness pass. To determine the effectiveness of the screening and referral process, PAVS scores and referral coupons were collected. The following ratios were calculated: patients screened/total number of SHC patients, patients referred/patients screened, and referrals used/referrals given. The number of Facebook friends and 5K EIMA team members were also collected.

**RESULTS:** 7.4% of SHC patients were screened, 81.4% of patients screened were referred to the SRC, and 8.6% of referrals made were used at the SRC. The campaign's mascot obtained 30 Facebook friends and the 5K team had 14 members.

**CONCLUSIONS:** This pilot study proved effective in collaborating with departments and gaining interest through the Facebook page and mascot. Although the campaign only reached a small portion of students, it still increased physical activity and increased awareness of physical activity benefits. The results from the screening and referral process highlighted the importance of communication between researchers and departments. Future efforts should aim for greater participation and more consistent implementation to help the campaign reach its full potential.

2110 Board #156 May 31 9:00 AM - 10:30 AM

**Venice Maps-s ( Measuring Activity Patterns Study - In Students)**

Robert V. Musci<sup>1</sup>, Peter H. Brubaker, FACSM<sup>1</sup>, Makoto Ayabe<sup>2</sup>, Hiroaki Tanaka<sup>2</sup>. <sup>1</sup>Wake Forest University, Winston-Salem, NC. <sup>2</sup>Fukuoka University, Fukuoka, Japan.  
(No relationships reported)

**PURPOSE:** Most Americans do not accumulate the amount of physical activity (>300 kcal/day) associated with a reduced risk of cardiovascular disease (CVD). The lower prevalence of CVD observed in the Mediterranean Region is generally attributed to a healthier diet, but the contribution of increased PA cannot be discounted. This study examined the effects of the built environment of Venice, Italy (a city with minimal automotive transportation) on PA levels in college students.

**METHODS:** This study compared the physical activity levels of 18 American students from Wake Forest University (WFU) before (AS@WFU) and during the semester they spent abroad in Venice, Italy (AS@VEN). A matched group of 12 Italian university students (IS@VEN) were recruited for comparison. Participants were instructed to wear a Lifecorder (Kenz) accelerometer

continuously for ten days. Daily physical activity energy expenditure (PAEE) and minutes of light (LPA), moderate (MPA), and vigorous (VPA) PA were determined for each group. T-tests, with a  $p < .05$  level of significance, were used to compare PA levels between groups.

**RESULTS:** Although not significantly different, daily PAEE levels were higher in AS@VEN (423.2 + 187.4 kcal) and IS@VEN (408.8 + 113.8 kcal) than AS@WFU (329.3 + 217.2 kcal). Furthermore, daily minutes of LPA (72.5 + 27.6 min, 66.5 + 21.5 min, 36.9 + 10.8, respectively) and MPA (57.3 + 25.8 min, 58.3 + 23.6 min, 34.0 + 14.0, respectively) were significantly higher in AS@VEN and IS@VEN vs. AS@WFU. There were no significant differences between AS@VEN and IS@VEN for LPA, MPA or VPA. In contrast, minutes of VPA were significantly higher in AS@WFU than AS@VEN or IS@VEN (17.8 + 26.1, 7.3 + 12.5, 3.9 + 3.8, respectively).

**CONCLUSIONS:** American students, while in Venice, achieved a PAEE level of  $>300$  kcal/day by adopting a similar pattern of PA, with greater reliance on LPA and MPA and less on VPA, as their Italian counterparts. In contrast, American students (at WFU) relied more on vigorous (i.e. structured bouts of exercise) than lifestyle PA and expended ~100 fewer kcal/day than VEN. These findings suggest that lifestyle PA (i.e. LPA and MPA) can produce a PAEE level that may contribute to the reduced prevalence of CVD observed in the Mediterranean region.

---

**2111** Board #157 May 31 9:00 AM - 10:30 AM

**Risk Prediction to Graded Exercise Test in 40-49yr Chinese Men**

hao Su<sup>1</sup>, Minhao Xie<sup>1</sup>, Hui Wang<sup>2</sup>, Xintang Wang<sup>1</sup>, Jianmin Cao<sup>1</sup>, Liang Li<sup>3</sup>, Wengfei Zhu<sup>1</sup>, Tingting Li<sup>1</sup>, Yi Yan<sup>1</sup>. <sup>1</sup>Beijing Sport University, Beijing, China. <sup>2</sup>Jinggangshan University, Ji'an Jiang Xi Province, China. <sup>3</sup>Chinese University of Hong Kong, Hong Kong, China. (Sponsor: Lili Ji, FACSM)

(No relationships reported)

**PURPOSE:** To observe the relationships between the ECG and quiet biochemical, heart rate variability and EEG indicators, also to establish the Index system for the risk prediction to GXT in men from 40 to 49yr.

**METHODS:** 173 men from 40-49 year (44.0±3.5yr) without cardiovascular disease, diabetes and other diseases. They answered their PA by IPAQ. To test their BP, HR, PWV, TC, TG, HDL-c, LDL-c, myocardium enzymes, hCRP, OP of EEG and LF/HF of heart rate variability in the quiet and fasting state before the GXT at the same day. The GXT was performed on a cycle ergometer of Custo-med with incremental work loads starting with 25 w and adding 25 w at 2 min intervals until the subject reached the Vo<sub>2</sub>max or abnormal change in ST. The performance of GXT, ECG and Vo<sub>2</sub> were recorded. To analyze the relationships between indicators of ECG and other indicators by multiple regression analysis; To build the regression equations by stepwise regression. The significance was  $p < .05$ ; The highly significance was  $p < .01$ .

**RESULTS:** 28 men had abnormal change in ST; 145 men had normal change in ST during GXT. For the normal men, LDH1, LDH1/LDH, OP of EEG and PA in the quiet and fasting state had closed relationships to change in ST of ECG,  $p < .05$ . The risk prediction equation for the men of normal change in ST was  $Y = 0.022 - 0.001X_1 - 0.147X_2 + 0X_3 + 4.53 * 10^{-6}X_4$ . Y was the change of ST, X<sub>1</sub> was LDH1, X<sub>2</sub> was LDH1/LDH, X<sub>3</sub> was OP, X<sub>4</sub> was PA.  $R = 0.496, R^2 = 0.246$ . The forecast range of ST was -0.07-0.08mv. The correlation between the real values and the predictive value was 0.471( $p = 0.000$ ).

For the abnormal men, HDL-c, OP of EEG and DBP in the quiet and fasting state had closed relationships to change in ST of ECG,  $p < .05$ . The risk prediction equation for the men of abnormal change in ST was  $Y = 0.446 + 0.004X_1 - 0.042X_2 + 0.002X_3$ . Y was the change of ST, X<sub>1</sub> was DBP, X<sub>2</sub> was HDL-c, X<sub>3</sub> was OP.  $R = 0.733, R^2 = 0.538$ . The forecast range of ST was -0.24--0.1 mv. The correlation between the real values and the predictive value was 0.643( $p = 0.045$ ). We used the equation to predict the men of normal change of ST, the forecast range of ST was -0.1-0.14 mv.

**CONCLUSIONS:** The values of LDH1, LDH1/LDH, OP of EEG, PA in the quiet and fasting state can be used to predict the normal change of ST in 40-49yr Chinese men in GXT; 2. The values of HDL-c, DBP and OP of EEG can be used to predict the abnormal change of ST in 40-49yr Chinese men in GXT.

**2112** Board #158 May 31 9:00 AM - 10:30 AM

**Aerobic Exercise Training Conserves Insulin Sensitivity for One Year Following Weight Loss in Overweight Women**

Gordon Fisher, Gary R. Hunter, FACSM, Barbara A. Gower. University of Alabama at Birmingham, Birmingham, AL.

(No relationships reported)

The objectives of this study were to: (i) identify the independent effects of exercise (aerobic or resistance training) and weight loss (WL) on whole body insulin sensitivity (SI) and (ii) determine if aerobic or resistance training would be more successful for maintaining improved SI one-year following WL. Subjects were 97 healthy, premenopausal women, BMI 27-30 kg/m<sup>2</sup>. Following randomized assignment to one of three groups (diet only, diet + aerobic-, or diet + resistance training) until a BMI  $< 25$  kg/m<sup>2</sup> was achieved. They continued their assigned exercise regimen, and participated in diet counseling sessions aimed at maintaining WL. Body composition, fat distribution, and SI were determined at baseline, in the weight reduced state, and at one-year follow up. The whole body insulin sensitivity index (SI) was determined using a frequently sampled intravenous glucose tolerance test. Results of repeated-measures ANOVA indicated a significant improvement in SI following WL. However there were no effects of group or group\*time. During the one-year follow-up period, the women showed an average weight change of +5.5 kg (range -3.3 kg to +23.7 kg). At one-year follow up, there were no significant main effects of time or group for SI, however there was a significant group\*time interaction. Post hoc analysis revealed that women in the aerobic training group showed a significant increase in SI from weight-reduced to one-year follow up ( $P < 0.05$ ), which was independent of intra-abdominal adipose tissue and % fat. No significant differences in SI from weight-reduced to one year follow up were observed for diet only or diet + resistance groups. These results suggest that long term aerobic exercise training may conserve improvements in SI following WL.

---

**2113** Board #159 May 31 9:00 AM - 10:30 AM

**Using Digital Music Technology To Promote Healthy Walking In Non-traumatic Trans-tibial Amputees**

David A. Rowe, FACSM<sup>1</sup>, David McMinn<sup>2</sup>, Leslie Peacock<sup>1</sup>, Arjan W P Buis<sup>1</sup>, Rona Sutherland<sup>1</sup>, Emma Henderson<sup>1</sup>, Allan Hewitt<sup>1</sup>. <sup>1</sup>University of Strathclyde, Glasgow, United Kingdom. <sup>2</sup>University of Aberdeen, Aberdeen, United Kingdom.

(No relationships reported)

Non-traumatic lower limb amputees have elevated health risks due to pre-existing morbidity, and the potential effect of lower limb amputation on subsequent physical activity levels. A few studies have investigated walking pace of lower-limb amputees during short (10-60 meters) walk tests. Very limited evidence is available on typical walking pace or the ability to match walking cadence (step rate) to the beat of auditory stimuli (e.g., metronome or music) in this population, over longer distances. **PURPOSE:** To investigate self-selected and music-paced cadence in unilateral non-traumatic trans-tibial amputees.

**METHODS:** 17 participants (age=52±13 yr; height=1.66±0.16 m; weight=85.0±20.2 kg; BMI=31.5±9.6 kg/m<sup>2</sup>; 88% male) completed two treadmill walking trials, during which steady-state VO<sub>2</sub> was measured. They then completed two overground walking trials of at least 4 min. The first trial was self-paced following instructions to "walk briskly". The second trial was paced using a digital music track which was individually determined from the treadmill trials to be at a moderate cadence (≈3MET). Data were analyzed using RM t-test, Cohen's d, and Bland-Altman plot.

**RESULTS:** During the self-selected brisk walking trial (5.33±0.28 min), participants walked at a cadence of 113±13.5 steps/min (range = 88-139). Cadence during the music-paced walking trial (5.37±0.28 min) was significantly slower (104±13.2 steps/min; range = 80-122;  $p < .05$ ,  $d = 0.69$ ). This pattern occurred for all participants (range = 1 to 23 steps/min slower). From the Bland-Altman plots, 12 of 17 (71%) participants walked within 10 steps/min of the prescribed cadence. No participants walked slower than the prescribed cadence.

**CONCLUSIONS:** Non-traumatic trans-tibial amputees walk faster during self-selected "brisk" walking than during music-guided moderate intensity walking. Additionally, they are able to match a prescribed cadence by following an auditory stimulus relatively well. The use of auditory stimuli is therefore an effective way to prompt walking of a health-enhancing pace in this population, and they appear to be quite capable of walking above moderate intensity.

---

2114 Board #160 May 31 9:00 AM - 10:30 AM

**Perceived Barriers To Physical Activity And Program Incentives In A University Wellness Program**

Elizabeth G. Groendal<sup>1</sup>, Samantha J. Danbert<sup>2</sup>, Jeremy L. Knous<sup>1</sup>, Joshua J. Ode<sup>1</sup>. <sup>1</sup>Saginaw Valley State University, University Center, MI. <sup>2</sup>Michigan State University, East Lansing, MI.  
(No relationships reported)

Exercise is Medicine on Campus (EIMC) is a national initiative aimed at improving physical activity (PA) and health on college campuses. One way to promote EIMC is through the development of a university employee wellness program, which can potentially lead to individual improvements in health and fitness. In order to enhance the effectiveness of a wellness program, both barriers to PA participation and appropriate program incentives for the participants should be evaluated.

**PURPOSE:** Therefore, the purpose was to evaluate fitness, perceived barriers to PA and appropriate program incentive levels among university employee wellness program participants.

**METHODS:** Participants included 150 employees enrolled in a wellness program. Fitness assessments included anthropometrics, body composition, flexibility, muscular endurance, muscular strength, and aerobic capacity. Survey evaluation included perceptions of PA barriers and program incentives. Perceived barriers to PA were assessed using a 5 point Likert scale and dichotomized for analysis. Program incentives were categorized as least, moderately, or most appealing. Descriptive data (mean±SD) were reported for fitness data. Barrier and program incentive prevalence was reported. Chi-square and T-test were used to assess gender differences.

**RESULTS:** Mean (±SD) age was 44.4±12 years with 63% of participants being female. 55% of the participants were considered overweight or obese by BMI, with a statistical difference ( $p \leq 0.05$ ) between males and females. Mean (±SD) for estimated VO<sub>2</sub>max was 35±9 ml/kg/min, percent fat 25±8, curl-ups 26±13, push-ups 26±14, grip strength 77±28kg, sit-and-reach 32±9cm. Estimated VO<sub>2</sub>max and grip strength values were higher in males than females, while percent fat and sit-and-reach values were lower. Lack of time due to work (46%) and feeling tired (27%) were the most common barriers. The greatest perceived program incentive was cash (36%) while additional vacation time was the least (14%).

**CONCLUSIONS:** Participants in this wellness program have a high prevalence of overweight/obesity and low aerobic fitness highlighting the need for university wellness programs. In order to maximize the effectiveness of these programs, lack of time as a barrier to physical activity and cash incentives for participation should be considered.

---

2115 Board #161 May 31 9:00 AM - 10:30 AM

**Achieving Recommended Physical Activity Requirements For Elementary Aged Children In New Jersey**

M. Alysia Mastrangelo, FACSM<sup>1</sup>, Patrick Lesniak<sup>1</sup>, Edward C. Chaloupka, FACSM<sup>2</sup>, Lisa Scheetz<sup>3</sup>. <sup>1</sup>Richard Stockton College of New Jersey, Galloway, NJ. <sup>2</sup>Rowan University, Glassboro, NJ. <sup>3</sup>Cumberland Cape Atlantic YMCA, Vineland, NJ.  
(No relationships reported)

**PURPOSE:** Childhood obesity has become a national issue. Over the past three decades, obesity has dramatically increased. Childhood obesity has been linked to a decrease in physical activity (PA) among children. The purpose of this study was to increase vigorous to moderate physical activity (VMPPA) into the school day in an attempt to meet the state mandated 150 minutes of required physical activity.

**METHODS:** Students in kindergarten and 1st grade participated in the program. They were surveyed on the amount of physical activity they participated in during five data collection weeks; baseline, first, second, third and fourth quarter. Following the baseline data collection week, the students began an eight month physical activity program. The program, structured recess was designed to infuse VMPPA into recess by providing a fun and age-appropriate program instructed by certified fitness instructors. The Coordinated Approach to Child Health (CATCH) was utilized for the structured recess. The program 30 min/ day provided 150 min/ wk of VMPPA.

**RESULTS:** A total of 909 students participated in the eight month program. At baseline, 890 students participated and achieved 49.98 min of PA. At the first quarter data collection week, 887 students participated for a mean of 203.62 min of PA per student. During the second quarter data collection week, 882 students participated for a mean of 211.06 min of PA per student. In the third quarter, 884 students participated for a mean 229.44 min of PA per student. The fourth quarter had 880 students participating for a mean of 240.28 min of PA per student. There was an increase in PA from baseline to the end of the fourth quarter of 79.58%.

**CONCLUSIONS:** Infusing structured PA into the school day ensured that the students received more than the 150 min state requirement for PA. The students also demonstrated a progressive increase in the amount of PA they were performing outside of the school day during the eight month program.

2116 Board #162 May 31 9:00 AM - 10:30 AM

**Relationships Among Participation In A Worksite Wellness Program, Leisure-time Physical Activity, And Aerobic Capacity**

Samantha J. Danbert<sup>1</sup>, Jeremy L. Knous<sup>2</sup>, Joshua J. Ode<sup>2</sup>, Rebecca A. Schlafli<sup>1</sup>, James M. Pivarnik, FACSM<sup>1</sup>. <sup>1</sup>Michigan State University, East Lansing, MI. <sup>2</sup>Saginaw Valley State University, Saginaw, MI.  
(No relationships reported)

Studies have found worksite wellness programs to improve biometrics and employee behaviors, however their effect on aerobic capacity (VO<sub>2</sub>max) and leisure-time physical activity (LTPA) levels is not well established.

**PURPOSE:** Our purposes were to 1) describe active University worksite wellness participants and 2) determine the relationships between time spent in a worksite wellness program, LTPA levels, and fitness.

**METHODS:** Participants included faculty/staff enrolled in a worksite wellness program ranging from 1 to 72 months (n=68). Each received a fitness assessment (anthropometry, body composition, aerobic capacity, muscular strength, muscular endurance, and flexibility). In addition, participants' self-reported LTPA was assessed via the Global Physical Activity Questionnaire (MET.min/wk). Descriptive statistics were calculated using means and standard deviations. The sample was split into three groups based on time spent in the program (1-20, 21-36, >36 months). Relationships between time spent in the wellness program and 1) LTPA levels and 2) fitness measures were assessed via a one-way ANOVA.

**RESULTS:** Mean(±SD) age was 43.6 ± 10.3 years and 66% of participants were female. Participants reported engaging in strength and flexibility training an average of 2.2 ± 1.9 and 2.2 ± 2.0 times per week, respectively. Mean(±SD) BMI was 25.9 ± 5.1 kg/m<sup>2</sup>, % fat was 28.5 ± 8.1, VO<sub>2</sub>max averaged 34.7 ± 8.2 ml/kg/min, and MET.min/wk was 2103 ± 1769. VO<sub>2</sub>max of participants enrolled for 21-36 months was significantly lower (30.8 ml/kg/min;  $p \leq .05$ ) than those enrolled for 1-20 months (36.0 ml/kg/min) and >36 months (36.9 ml/kg/min). No significant differences were found in BMI, %fat, muscular strength, muscular endurance, flexibility, or MET.min/wk.

**CONCLUSIONS:** Knowing health and fitness characteristics of active worksite wellness participants may help to create effective programming to improve participation and fitness measures. Our results suggest that length of time spent in a worksite wellness program is not related to LTPA levels, but may have a relationship with aerobic capacity. Longitudinal data collected at consistent time points might help explain the observed differences in aerobic capacity.

---

2117 Board #163 May 31 9:00 AM - 10:30 AM

**Physical Fitness Comparisons of Safety-Net Community Health Center and Medically Affiliated Fitness Center Older Adults**

Stephanie Greer, Anthony S. Kalesh, FACSM, Kyle McIlrath, NiCole R. Keith, FACSM. IUPUI, Indianapolis, IN.  
(No relationships reported)

Health outcome disparities may occur when socially disadvantaged populations experience differences in opportunities to achieve optimal health and fitness. Safety net community health centers (CHC) are community-based providers that offer health services to vulnerable populations. However, health disparities go beyond access to health care services and include limited opportunities and access for improving physical fitness (PF).

**PURPOSE:** To compare PF measures in adults who are members of a medically affiliated fitness center (FC) with patients of a safety net CHC.

**METHODS:** Males and females (aged >40 yr) who expressed interest in learning more about their PF were invited to participate. Each participant completed the Rikli and Jones Senior Fitness Test (SFT), which included assessments of: 1) upper-body endurance (UBE, mean number of arm curls); 2) lower-body endurance (LBE, mean number of chair stands); 3) aerobic endurance (AE, distance walked, yd); 4) lower body flexibility (LBF, mean distance reached, cm); 5) upper body flexibility (UBF, distance between finger tips, cm); and 6) percent body fat

(%BF).

**RESULTS:** There were 101 CHC participants (50 female, 51 male, mean education 12.14 + 2.5yr, mean age 53.9 + 8.1yr) and 100 FC participants (50 female, 50 male, mean education 16.34 + 2.6yr education, mean age 55.5 + 16.8yr). Multiple comparisons (mean±SD) showed that FC female participants performed significantly better on each PF measure compared to female CHC: UBE (CHC=13.6±4.2, FC=20.1±5.6, p<0.001); LBE (CHC=9.8±3.2, FC=17.1±3.1, p<0.001); AE (CHC=409.7±177.5, FC= 692.6 + 95.6, p<0.001); LBF (CHC=3.2±5.6, FC=2.3±4.6, p<0.001); UBF (CHC=-6.6±6.3, FC=0.7±0.7, p<0.001); and %BF (CHC=43.6±11.6, FC=32.1±10.0, p<0.001). Except for LBF (CHC=-1.5±5.6, FC=-0.4±5.6, p=0.7), FC men performed significantly better on all PF measures compared to CHC: UBE (CHC=17.6±6.6, FC=21.5±4.7, p<0.01); LBE (CHC=11.6±4.5, FC=17.3±4.6, p<0.001); AE (CHC=482.7±191.7, FC=698.9±89.2, p<0.001); UBF (CHC=-8.9±6.9, FC=-2.8±5.6, p<0.001); and %BF (CHC= 29.3±10.0, FC=24.0±8.0, p=0.05).

**CONCLUSIONS:** FC adults were more physically fit than CHC adults. Results support the need for access to fitness centers and professionals in disadvantaged populations in order to more completely address health disparities.

---

**2118 Board #164 May 31 9:00 AM - 10:30 AM**  
**Engaging and Enabling Rural Communities in Chronic Disease Prevention: The HealthSteps Program**

Lyndsay Foisey<sup>1</sup>, Sheila Cook<sup>1</sup>, Brittany Intzand<sup>2</sup>, Melanie Stuckey<sup>3</sup>, Robert Petrella, FACSM<sup>1</sup>. <sup>1</sup>Lawson Health Research Institute, London, ON, Canada. <sup>2</sup>The University of Waterloo, Waterloo, ON, Canada. <sup>3</sup>The University of Western Ontario, London, ON, Canada.  
(No relationships reported)

Heart disease and type II diabetes are on the rise, and more than half of Canadian adults are classified as overweight or obese. Rural communities have a higher prevalence of heart disease and diabetes while they face additional barriers to performing regular exercise compared to their urban counterparts. Our previous research has demonstrated that tailored exercise prescription in the family health team setting is feasible and effective, as at-risk patients improved cardiovascular fitness, reduced waist circumference, normalized blood pressure and increased energy expenditure.

**PURPOSE:** To implement a post-research study program to enable and engage communities in sustainable lifestyle change for individuals at-risk of developing type II diabetes.

**METHODS:** The HealthSteps program is the knowledge translation phase following a 12-month randomized controlled trial to determine the efficacy of a prescriptive exercise intervention in patients with cardiovascular risk factors of type II diabetes (ARTEMIS). The HealthSteps program consists of group lifestyle prescription sessions led by healthcare professionals in the family health team (FHT) setting. Program components include a comprehensive, community-sensitive program of training and support for healthy lifestyle change delivered by the family health team.

**RESULTS:** Conceptualization and then construction of the program was informed by knowledge brokering stakeholders and users in focus group sessions. The HealthSteps pilot program was launched in September 2011 in a rural Southwestern Ontario FHT comprised of 8 physicians and 10 healthcare professionals serving a population of 59,325. Analysis revealed that participants found the program suitable to their needs to continue a healthy lifestyle and 100% would continue the program and recommend it to others. In addition, participants noted that the support of a program after the initial study was essential to their continuing motivation for a healthy lifestyle.

**CONCLUSIONS:** The HealthSteps program is the knowledge to action outcome of an evidence-based research program that has demonstrated feasibility and utility in the FHT setting. Next steps will include implementation in a range of rural and urban community family health teams to demonstrate generalizability and fidelity of the program.

**2119 Board #165 May 31 9:00 AM - 10:30 AM**  
**Atherosclerotic Cardiovascular Risk and Aerobic Fitness in Paralympic Athletes with Locomotor Impairments**

Marco Bernardi<sup>1</sup>, Paolo Emilio Adami<sup>2</sup>, Silvia Carucci<sup>2</sup>, Emanuele Guerra<sup>3</sup>, Antonio Spataro<sup>4</sup>, Carlo Tranquilli<sup>4</sup>, Alessandro Biffi<sup>4</sup>, Antonio Pelliccia<sup>4</sup>. <sup>1</sup>School of Specialization in Sports Medicine, Sapienza University of Rome; Italian Paralympic Committee, Rome, Italy. <sup>2</sup>School of Specialization in Sports Medicine, Sapienza University of Rome, Rome, Italy. <sup>3</sup>Italian Paralympic Committee, Rome, Italy. <sup>4</sup>Institute of Sports Medicine and Science of the Italian Olympic Committee, Rome, Italy.  
(No relationships reported)

Atherosclerotic cardiovascular disease (ACVD) represents a leading cause of morbidity and mortality in locomotor impaired (LI) individuals. A sedentary habit has been established as main risk factor (RF) in this population.

**PURPOSE:** We evaluated the hypotheses that (1) in LI athletes (LIA) aerobic fitness (oxygen uptake peak - VO<sub>2</sub>peak) was inversely related to ACVD RF and (2) the prevalence for each RF was higher in LIA with spinal cord injury (SCI) than in LIA with other locomotor impairments.

**METHODS:** A total of 70 male LIA, who competed in the last two summer and winter Paralympic Games (36 with SCI, 18 lower limb amputees, 3 with cerebral palsy, 5 with poliomyelitis and 8 with other locomotor disorders) were screened through anthropometric and blood pressure (BP) measurements, laboratory blood tests and graded maximal arm cranking exercise tests, to estimate both an ACVD RF score and VO<sub>2</sub>peak. The ACVD risk score was assessed summing 1 point for each of the following RF, potentially modifiable by fitness and evaluated in accordance with the ACSM recommendations: obesity, hypertension, dyslipidemia, impaired fasting glucose and subtracting 1 point when serum HDL cholesterol was higher than 60 mg-dl<sup>-1</sup>.

**RESULTS:** Prevalence of hypertension, obesity, total cholesterol, LDL cholesterol, HDL cholesterol and impaired fasting glucose were equal to 13.9% and 17.6%, 13.9% and 5.9%, 47.2% and 32.3%, 50% and 41.2%, 38.9% and 44.1%, 30.6% and 23.5%, respectively in LIA with SCI and LIA with other impairments. Based on the number of ACVD RF, 4 groups were formed: group 1 (RF=0, N=26), group 2 (RF=1, N=25), group 3 (RF=2, N=9), group 4 (RF=≥3, N=10). VO<sub>2</sub>peak values were equal to 36±8.8 ml·kg<sup>-1</sup>·min<sup>-1</sup>, 32±8.6 ml·kg<sup>-1</sup>·min<sup>-1</sup>, 27±5.5 ml·kg<sup>-1</sup>·min<sup>-1</sup>, 18±4.3 ml·kg<sup>-1</sup>·min<sup>-1</sup> in group 1, group 2, group 3 and group 4, respectively.

**CONCLUSIONS:** ACVD risk was higher in LIA with SCI than in other LIA. VO<sub>2</sub>peak is inversely associated with ACDR RF. High aerobic fitness, which has been demonstrated correlated with energy expenditure of some continuous and intermittent sports, provides a protective effect on the ACVD risk.

Funding from Italian Paralympic Committee and Sapienza, University of Rome.

**2120 Board #166 May 31 9:00 AM - 10:30 AM**  
**Objectively Measured Physical Activity And Health-related Quality Of Life: The Hong Kong Family Project**

Paul H. Lee<sup>1</sup>, Hairong Nan<sup>1</sup>, Brandford H. Y. Chan<sup>1</sup>, Ian McDowell<sup>2</sup>, Gabriel M. Leung<sup>1</sup>, Tai Hing Lam<sup>1</sup>. <sup>1</sup>University of Hong Kong, Hong Kong, Hong Kong. <sup>2</sup>University of Ottawa, Ottawa, ON, Canada.  
(No relationships reported)

The association between physical activity (PA) and health-related quality of life / well-being has been well established. However, most previous studies used self-reported questionnaire data with uncertain validity. Accelerometers offer an objective measurement of motion, and are becoming popular in PA monitoring, but the relationship between accelerometer-measured PA and health-related quality of life is unclear.

**PURPOSE:** To examine the relationship between PA, measured objectively both by time spent and by number of steps, and health-related quality of life, measured by the physical component subscale (PCS) and mental component subscale (MCS) of the Medical Outcome Study Short Form - 12 (SF-12) in Hong Kong.

**METHODS:** In the Hong Kong Jockey Club FAMILY Project Cohort Study household survey, 2,138 adults (aged 44.5 ±SD 17.6 years, 46.3% male) wore an ActiGraph accelerometer for four days and completed the SF-12 at baseline (March - October 2009). In the follow up surveys, the SF-12 questionnaire was repeated 3, 9 and 15 months later.

**RESULTS:** The follow-up rates were 64% at 3 months, 75% at 9 months, and 68% at 15 months. Of all the participants, 40.9% had at least 150 minutes of moderate-to-vigorous physical activity (MVPA) in the four-day observation period, and 48.9% accumulated ≥8,000 steps per day. Adjusting for age, sex, income, education, marital status, smoking and drinking habits, multilevel regression for repeated measure showed that participants who had at least 150 minutes of MVPA per week over the 4-day had a higher PCS (difference = 0.71, Cohen's d effect size = 0.10, p < 0.05) than those who did not, but there was no difference in MCS (p > 0.05). Participants who walked at least 8,000 steps per day had a higher PCS (difference = 0.89, Cohen's d effect size = 0.12, p < 0.01) than those who did not, but there was no difference in MCS (p > 0.05).

**CONCLUSIONS:** Both MVPA and number of steps were associated with physical ability but not with mental aspects of health-related quality of life.

Supported by the Hong Kong Jockey Club Charities Trust.

**2121 Board #167 May 31 9:00 AM - 10:30 AM**  
**Analysis Of Physical Activity Participation, Attitude, Barrier Factors Of Patients With Colorectal Cancer In Korea**

Jae Youn Chung, Ji Hye Park, Justin Y. Jeon. *Yonsei University, Seoul, Korea, Republic of.*  
(No relationships reported)

Colorectal cancer is the third most commonly diagnosed cancer in the United States and also in Korea. Although the effects of physical activity on prevention and prognosis of colorectal cancer have been reported previously, the amount of physical activity participation and barrier factors affecting physical activity in colorectal cancer patients, have not been fully elucidated.

**PURPOSE:** This study was to examine the level of physical activity participation, barrier factors affecting physical activity participating and attitude toward exercise in colorectal cancer patients in Korea.

**METHODS:** A total of 431 patients (male:271, female:160, aged:59.69 ±10.86), diagnosed with colorectal cancer, were recruited for this study. Data collection is accomplished through a structured interview.

**RESULTS:** The level of physical activity participation increased significantly after patients were diagnosed with colorectal cancer. The subjects showed higher level of physical activity participation after the completion of cancer treatment compare to the level of physical activity participation during cancer treatment ( $p < 0.05$ ). A 68.8% of patients believed that the exercise is beneficial for the prevention of cancer recurrence and 66.5% of patients were willing to participate in some kind of physical activity programs. However, only 34.9% of patients participated in more than 18 MET-hours per week of physical activity, which is known to have beneficial effects in the prevention of colorectal cancer recurrence. The major barriers in participating in physical activity experienced by colorectal cancer patients were fatigue, lack of fitness and not feeling well.

**CONCLUSIONS:** Interestingly, the colorectal cancer patients participate more physical activity after the cancer diagnosis with expectation that the exercise is helpful for them. Although most of colon cancer patients had an positive attitude toward physical activity and exercise, only one third of them participated in enough physical activity known to prevent cancer recurrence. Therefore, a strategy to increase the physical activity for colorectal cancer patients is required.

**2122 Board #168 May 31 9:00 AM - 10:30 AM**  
**Free Choice Access to Wellness Education and Services Positively Impact Employee Wellness**

Gary A. Sforzo, FACSM<sup>1</sup>, Mirandi P. Kaye<sup>1</sup>, David Calleri<sup>2</sup>, Nancy Ngai<sup>2</sup>. <sup>1</sup>*Ithaca College, Ithaca, NY.* <sup>2</sup>*Plus One Health Management, New York, NY.*  
(G.A. Sforzo: Contracted Research - Including Principle Investigator; Plus One Health Management.)

The effects of wellness and exercise programming are usually studied in subjects agreeing to a minimal level of participation. This removes a normal degree of free choice from these studies. In the present study we recruited subjects to partake in wellness programming but did not dictate a minimum level of involvement but instead simply made healthful services available to them. The most prominent services provided were wellness education, access to a fitness facility, and healthy cafeteria meals. The only obligation participants had was to complete outcome measures. **PURPOSE:** Examine effects of voluntary participation in employer-sponsored, multi-point wellness education programming on employee wellness.

**METHODS:** A randomized and controlled design was used to organize 96 participants into three groups: education+access; access-only; and control. Those receiving education were offered health promoting: email messages three times weekly; lectures once per week; and web portal entry. Those receiving access were offered use of a corporate fitness facility and discounted healthy cafeteria meals. Outcome measures included biometrics, fitness, psychological, and health knowledge variables and were made at start and end of a 12-week intervention period. ANOVA and path analysis were used to inspect these data.

**RESULTS:** Education+Access improved wellness knowledge (pre: .50+.14; post: .69+.14;  $p < .05$ ) which led to improvements in life satisfaction ( $r = .27$ ;  $p < .05$ ), employee morale ( $r = .29$ ;  $p < .05$ ), energy ( $r = .25$ ;  $p < .05$ ), and nearly in stress level ( $r = .24$ ;  $p = .06$ ). Those who received facility access without educational programming did not reap health benefits. Employees voluntarily used the fitness facility and healthy meal cards only 1.3 and 1.5 times/week, respectively.

**CONCLUSIONS:** Participants made limited and likely inadequate use of wellness opportunities when given access but free choice. As a result, physical health benefits (e.g., fitness parameters, blood pressure) were not seen. It is evident that motivation to participate, and determining obstacles that limit participation, is of great concern for employee wellness programs. However, wellness education, delivered in a multi-point fashion was effective and resulted in psychosocial health benefits in just 12 weeks.

**2123 Board #169 May 31 9:00 AM - 10:30 AM**  
**Reaching Targeted Participants In An Urban Ciclovía: The Case Of Sunday Streets San Francisco**

Susan G. Zieff, Mi-Sook Kim. *San Francisco State University, San Francisco, CA.* (Sponsor: Marialice Kern, FACSM)  
(No relationships reported)

Community-based events that use public spaces such as city streets for physical recreation have the potential to influence population-wide health behavior. The rotating routes used for an urban, monthly "street opening" event, Sunday Streets SF (SS), purposely include neighborhoods that lack recreational resources.

**PURPOSE:** Previous studies showed that convenient access to physical activity (PA) influences participation of residents living on or near SS routes. The purpose of this study first examined the extent to which SS attracts participants who reside in neighborhoods that are underserved for PA resources but are outside of route boundaries. Second, the study explored these participants' experiences while at SS.

**METHODS:** A total of 626 participants (mean age: 39.51 years, SD=10.8) from three SS events were recruited to complete a 24-item survey in 2010. The participants reported demographic information, their residential zipcodes, reasons to attend and return to the event, and their experience while attending SS. Using residential zipcodes of participants, the target group for the present study was selected from a list of zipcodes identifying neighborhoods lacking recreational facilities using a park assessment report, city government website zipcode data, and a city Planning Department map.

**RESULTS:** A total of 17.3% of participants were classified as the targeted group (n=108). The participants traveled an average of 7.3 miles (SD=5.9 miles) to attend SS and 67% reported attending multiple SS events. Biking (20.4%) and walking (19.4%) were the most commonly reported activities and participants indicated an average of 57 minutes engaged in PA of their total average time of 168 minutes at the event. The most important reasons to attend and return were for the safe environment and the opportunity for outdoor PA. Printed advertisements (billboards and buses) (22.2%) and word of mouth (22.2%) were the most common ways that participants learned of the event.

**CONCLUSIONS:** Public streets offer a unique and effective strategy for increasing PA among underserved populations. This study suggests that community events successfully attract a substantial group of participants from distant neighborhoods with low-access to recreational opportunities thereby reducing the need for separate events in each location.

**2124 Board #170 May 31 9:00 AM - 10:30 AM**  
**Exercise Is Medicine On Campus: Participation Rates In A University Employee Wellness Program.**

Jeremy L. Knous, Joshua Ode. *Saginaw Valley State University, Saginaw, MI.*  
(No relationships reported)

Exercise is Medicine on Campus (EIMC) is a national initiative aimed at improving physical activity (PA) and health on college campuses. One way to promote EIMC is through the development of a university employee wellness program, which can potentially lead to individual improvements in health and fitness. Employee wellness programs may offer a variety of structured opportunities for participants to improve health. In order to maximize participation it is important to evaluate participation within all components of the wellness program.

**PURPOSE:** Therefore, the purpose of this study was to assess participation rates of university employees in each component of a university worksite wellness program.

**METHODS:** Participants included all eligible university employees who participated in at least on component of the university wellness program. Participation was tracked for the following components of the wellness program: 1) logging of exercise, 2) strength training, 3) annual physical exams, 4) lunch and learns, and 5) fitness testing. Maximal monthly participation and mean yearly participation rates, along with percentage of each as a function of active program participants and total eligible participants, are reported for the various components of the wellness program.

**RESULTS:** Over a three year period, participation in the university wellness program have slowly increased from 40% to 49% of the eligible participants. The average number of participants using the exercise log to record physical activity has increased from 43% of active and 18% of eligible participants in year 1 to 54% and 22% in year 3, respectively. Participation in lunch and learns has remained steady over the 3 year period at 18% of active and 7% of eligible employees. Only 9% of the active participants participated in fitness testing this past year.

**CONCLUSIONS:** While university wellness program participation has increased over the past 3 years, less than half of the eligible participants are taking advantage of the opportunity. Of the various components offered through the program, tracking of exercise using the exercise log is the most often utilized (54%) by active participants. These findings highlight a need for greater EIMC promotion and increased employee participation in an already established university wellness program.

**2125** Board #171 May 31 9:00 AM - 10:30 AM

**Health Clinic Staff do not Increase Physical Activity One Year After a Brief Intervention**

Janet M. Shaw, FACSM<sup>1</sup>, Trever Ball<sup>1</sup>, Jessica Greenwood<sup>1</sup>, Elizabeth A. Joy, FACSM<sup>2</sup>. <sup>1</sup>University of Utah, Salt Lake City, UT. <sup>2</sup>Intermountain Healthcare, Salt Lake City, UT.

(No relationships reported)

Staff workers in primary health care settings have potential for impacting physical activity (PA) levels in patients.

**PURPOSE:** We sought to measure PA levels of health clinic staff and to determine whether a brief intervention would result in higher PA levels after one year of follow-up.

**METHODS:** Apparently healthy clinic staff  $\geq 18$  yrs were recruited. Exclusion criteria included unmanaged chronic disease and pregnancy. Self-reported age, height and weight were assessed by medical history. PA was assessed by accelerometry (accel) and two self-report assessments designed for primary care. At least 4 valid days of accel were required for analysis. After baseline PA assessment, staff were asked to choose a goal to improve diet or PA. Guidance of 1-3 minutes on desired behavior change and a tip sheet, on which the goal was indicated, were provided. The suggested PA goal was to do 30 minutes of moderate to vigorous (MV) PA on 5 days of the week. Staff were told that follow-up would occur about 12 months later without contact from researchers in the interim. The intervention was meant to mimic the time between typical primary care visits in patients without chronic disease. Change in PA variables was assessed by repeated measures ANOVA.

**RESULTS:** 85 staff workers were recruited at baseline; 62 had valid accel data. 40 staff completed follow-up testing; 30 had valid accel data. Those with complete PA data were mostly women, were  $39.4 \pm 11.9$  yrs, and had a BMI of  $28.5 \pm 3.0$  kg/m<sup>2</sup>. Weekly minutes of MVPA by accel at baseline were not statistically different between staff who did ( $95.1 \pm 71.5$ ) or did not ( $89.5 \pm 44.4$ ) choose to improve PA. Self-reported PA was also similar between groups. At follow-up, weekly minutes of MVPA by accel was  $96.9 \pm 71.3$  in those who chose a PA goal ( $n=20$ ) and was  $77.1 \pm 44.4$  in those who chose a diet goal ( $n=10$ ). There were no group or time differences in any PA measures at follow-up. These results were not altered when body weight or age were considered as covariates.

**CONCLUSIONS:** Very few staff achieved the goal of 150 minutes per week of MVPA at baseline or at follow-up. More intensive intervention strategies and cultural change may be necessary in order to improve PA in this group. Funded in part by DHHS Office on Women's Health (Asist2010: ASTWH070006-01-00) and the University of Utah Department of Family and Preventive Medicine.

**2126** Board #172 May 31 9:00 AM - 10:30 AM

**Body Weight And Smoking Modifications After An Exercise Program On Female Young Smokers**

Jacqueline Torres<sup>1</sup>, Andrea Avila<sup>2</sup>, Camilo Povea<sup>3</sup>. <sup>1</sup>Indeportes Cundinamarca, bogotá, Colombia. <sup>2</sup>CMD Bodytech, bogotá, Colombia. <sup>3</sup>Fundacion Cardio Infantil, bogotá, Colombia.

(No relationships reported)

Weight gain is a factor on smoking cessation because it has been seen as a problem that may influence the cessation attempts among smokers.

**PURPOSE:** To establish the effects of a supervised aerobic program on body weight and number of smoking cigarettes of 15 sedentary young female smokers on pre contemplative stage.

**METHODS:** Through a case control study, fifteen sedentary young smokers were placed on two groups. Nine women were part of the Control Group (COG) and had no intervention. Six women belonged to the case group (CG) and participated on an aerobic exercise program during 8 weeks. Each session lasted 35 to 40 minutes 3 days a week, at 65 to 75% HRmax, with a Borg scale intensity of 13-14 and an average caloric expenditure of 242.2 per session. Bodyweight, BMI and fat percentage were measured at the beginning and the end of training period.

**RESULTS:** At the end of the supervised aerobic program, the CG group had a lower number of cigarettes smoked by day compared to COG group ( $0.66 \pm 0.5$  vs.  $3.11 \pm 1.61$ ;  $p < 0.05$ ), BMI changed from  $23.02 \pm 3.9$  to  $23.2 \pm 4.05$  ( $p > 0.05$ ) and body fat percentage  $24.8 \pm 7.01$  to  $26.03 \pm 4.8$  ( $p > 0.05$ ). As for the CG, body weight changed from  $57.3 \text{ Kg} \pm 6.7$  to  $56.9 \text{ Kg} \pm 7.3$  ( $p > 0.05$ ), BMI changed from  $22.01 \pm 2.3$  to  $21.8 \pm 2.5$  ( $p > 0.05$ ) and body fat percentage  $25.4 \pm 7.1$  to  $24.3 \pm 6.1$  ( $p > 0.05$ ).

**CONCLUSIONS:** After eight weeks of training there were no differences on body composition (weight, BMI or body fat percentage) between the groups but a supervised aerobic program decrease the number of cigarettes smoked by day on a group of habitual female cigarette smokers on pre contemplative stage. According to these data, a supervised aerobic program might prevent the increased in body weight after smoking cessation.

**2127** Board #173 May 31 9:00 AM - 10:30 AM

**Behavioural Outcomes Using Smartphone Technology Versus Paper-based Logs In The Prevention Of Cardiovascular Risk**

Brittany Intzandt<sup>1</sup>, Kristin J. Sabourin<sup>1</sup>, Sheree Shapiro<sup>1</sup>, Melanie I. Stuckey<sup>1</sup>, Lyndsay Foisey<sup>1</sup>, Claudio Munoz<sup>2</sup>, Robert J. Petrella, FACSM<sup>1</sup>. <sup>1</sup>Lawson Health Research Institute, London, ON, Canada. <sup>2</sup>Gateway Rural Health Research Institute, Seaforth, ON, Canada.

(No relationships reported)

**PURPOSE:** This study investigated the potential behavioural influence of a physical activity (PA) intervention for participants in rural Southwestern Ontario who are at risk for type II diabetes and cardiovascular disease.

**METHODS:** Participants were  $57.8 \pm 9.2$  y and had at least two of the following criteria: abdominal obesity, high blood pressure (BP), low high density lipoproteins (HDL), elevated triglycerides, and increased blood glucose (BG) levels. Intervention participants ( $N=63$ ) received a Step Test and Exercise Prescription (STEP), home monitoring BG and BP systems, a Smartphone, and a pedometer. Participants documented BG and BP three times per week, as well as daily PA through an online health monitoring system. Control participants ( $N=45$ ) also received STEP but used only paper-based logs to record daily PA and did not have BG or BP home monitoring. At baseline (V0), 12 (V1)- and 24-week (V2) visits, participants completed two behavioural questionnaires: Decisional Balance (DB), and Health-related Quality of Life (SF-36).

**RESULTS:** Analysis of variance revealed no changes in the perceived pros or cons of PA ( $p > 0.05$ ) as determined by DB for either group. The intervention group's general ( $71.4 \pm 15.6$  at V0 to  $75.2 \pm 14.4$  at V1 and  $76.6 \pm 13.9$  at V2;  $p < 0.05$ ) and mental health improved ( $78 \pm 14.7$  at V0 to  $82.3 \pm 12.6$  for V1 and to  $82.8 \pm 11.3$  for V2;  $p < 0.05$ ). The intervention group also demonstrated changes in vitality from  $58.7 \pm 19$  V0 to  $63.7 \pm 17.5$  at V1 and  $65.9 \pm 17.1$  at V2 ( $p < 0.05$ ). The control group showed improvements in general ( $71.1 \pm 18.1$  at V0 to  $76.4 \pm 16.5$  at V2;  $p < 0.05$ ) and mental health ( $78.4 \pm 14.2$  at V0 to  $81.6 \pm 13.7$  at V2;  $p < 0.05$ ). Vitality also improved for controls from  $59.2 \pm 18.8$  at V0 to  $65.2 \pm 16$  at V1 to  $65 \pm 17$  at V2 ( $p < 0.05$ ).

**CONCLUSIONS:** Based on these findings, exercise prescription, along with tracking PA may have a positive effect on the quality of life amongst at-risk individuals residing in rural areas. Aspects of quality of life increased at a greater for the intervention group than the controls.

2128 Board #174 May 31 9:00 AM - 10:30 AM

**Lifestyle Intervention For The Management Of Type 2 Diabetes Mellitus In African-americans**

Raya Kheirbek, Lauren Korshak, Helen Sheriff, Justin Kotler, Monica Aiken, Shikha Khosla, Eric Nylen, Charles Faselis, Peter Kokkinos, FACSM. *Veterans Affairs Medical Center, Washington, DC. (Sponsor: Peter Kokkinos, FACSM)*  
(No relationships reported)

The prevalence of Diabetes Mellitus (DM) in African-Americans

(AA) is higher than Caucasians. The Lifestyle Intervention for Veterans (LIVE) Program was developed to provide intensive diabetes management through lifestyle interventions as an adjunct to traditional medication therapy.

**PURPOSE:** To assess metabolic and cardiovascular changes following a 12-week supervised exercise and dietary intervention in AA diabetic veterans.

**METHODS:** Individuals from our Primary Care and Diabetes clinics were referred to the program. Baseline exercise capacity was assessed by a peak exercise test. Blood chemistries, blood pressure and exercise parameters were recorded at baseline and after 12 weeks of individualized dietary counseling provided by a registered dietician and a supervised cardiovascular and resistance exercise training. Exercise intensity was maintained at 50% to 80% of heart rate reserve. In addition to the supervised, participants were instructed to supplement their exercise by daily brisk walks aiming to accumulate at least 150 minutes of exercise per week.

**RESULTS:** The average weekly time spent in supervised exercise sessions was 72 minutes. There were significant improvements noted in exercise capacity (8.5±1.8 to 10.1±2.1 METs), body weight, and waist circumference, cardiovascular and metabolic parameters (Table).

**CONCLUSIONS:** Supervised exercise program and dietary interventions were effective in improving cardiovascular and metabolic parameters in AA with Type 2 DM.

| VARIABLES           | BASELINE | POST-EXERCISE | P-values |
|---------------------|----------|---------------|----------|
| Wt (lbs)            | 230±42   | 224±39        | 0.001    |
| Waist (inches)      | 45.2±5   | 44.2±5        | 0.009    |
| Rest SBP (mm Hg)    | 125±17   | 120±14        | 0.07     |
| Rest DBP (mm Hg)    | 71±9     | 68±8          | 0.08     |
| HR @ 3 min (bpm)    | 107±13   | 104±14        | 0.02     |
| SBP @ 3 min (mm Hg) | 158±20   | 147±20        | <0.001   |
| DBP @ 3 min (mm Hg) | 79±17    | 73±10         | 0.02     |
| Peak HR (bpm)       | 137±19   | 139±21        | 0.8      |
| Peak SBP (mm Hg)    | 187±25   | 181±26        | 0.9      |
| Peak DBP (mm Hg)    | 84±14    | 77±11         | 0.003    |

2129 Board #175 May 31 9:00 AM - 10:30 AM

**Long-Term Physical Activity Vs. Inactivity And Health: A Co-twin Control Study**

Tuija Leskinen, Urho M. Kujala. *University of Jyväskylä, University of Jyväskylä, Finland.*  
(No relationships reported)

When studying the associations between physical (in)activity and health outcomes we are faced with two specific issues: genetic selection may explain some of the associations in observational follow-up studies, and RCTs that investigate the effects of exercise on health outcomes are usually of a too short duration to document the long-term effects on health.

**PURPOSE:** To tackle these limitations, we have investigated 7 monozygotic (MZ) and 9 dizygotic (DZ) twin pairs (50-74 yrs), discordant for leisure-time physical activity habits during their adult life, to document the specific effects of long-term physical activity on fitness and obesity status while controlling for genes and childhood family environment.

**METHODS:** Twin pairs were comprehensively identified from the Finnish Twin Cohort. Discordance was initially defined in 1975 and the same co-twin remained more active during the 32-year-long follow-up. Symptom-limited maximal clinical exercise test with cycle ergometer was performed for the assessment of cardiorespiratory fitness. Maximal isometric left knee extensor force was measured in a sitting position using an adjustable dynamometer chair. Body composition was measured using bioimpedance technique (InBody 720) after a 10-h fast. T1-weighted MRI axial scans were acquired from the abdomen and mid thigh with 1.5T GE-Signa Excite HD CVI.

**RESULTS:** Estimated peak oxygen uptake was 6.1 ml/kg/min lower (p<0.001) in inactive compared to the active co-twins, the difference being 4.8 ml/kg/min between inactive and active MZ co-twins. Compared to their inactive co-twins, maximal knee extension force was 20% higher among the active twins (p=0.006) and 26% higher among the active MZ twins. The fat percent was lower among all active (21.5 vs 27.0 kg/m<sup>2</sup>, p=0.004) and active MZ twins (22.9 vs 27.9 kg/m<sup>2</sup>, p=0.10). The area of visceral fat at the level of L4-L5+5cm was 1.5 times greater among the inactive twins (p=0.01) and 1.3 times greater among the inactive MZ twins (p=0.18). Mid thigh intramuscular fat area was 1.5 times greater among the inactive twins (p=0.002), being also 1.5 times greater among the inactive MZ twins (p=0.028).

**CONCLUSIONS:** Physically active lifestyle maintains fitness and lowers the rate of in particular ectopic fat accumulation even after taken into account the genetic background.

2130 Board #176 May 31 9:00 AM - 10:30 AM

**Prescribed Exercise Dose and Associated Physiological Outcome Changes in the TIGER Study**

Matthew P. Herring<sup>1</sup>, Daniel P. O'Connor<sup>2</sup>, Andrew S. Jackson, FACSM<sup>2</sup>, Danielle N. Hessong<sup>1</sup>, Jennifer L. Williams<sup>1</sup>, Molly S. Bray<sup>1</sup>. <sup>1</sup>University of Alabama at Birmingham, Birmingham, AL. <sup>2</sup>University of Houston, Houston, TX.  
(No relationships reported)

Accumulating recommended levels of moderate and vigorous physical activity is associated with health benefits including reduced all-cause mortality and risk of chronic illness. Exercise dose is a complex stimulus involving intensity and duration of exercise accumulated across multiple sessions, and there is continued interest in examining health benefits associated with cumulative exercise dose.

**PURPOSE:** To examine the association of total aerobic exercise dose, quantified by a heart rate physical activity score (HRPAS), and changes in physiological outcomes across a 15-week intervention.

**METHODS:** Data from 1,285 ethnically-diverse participants (507 men, 778 women), age 17-35 y, from the Training Interventions and Genetics of Exercise Response (TIGER) Study were included in the present analyses. Exercise training was comprised of three 30-min sessions of aerobic exercise at 65%-85% maximum heart rate reserve (HRR) weekly for 15 weeks. Exercise intensity and duration were recorded using computerized HR monitors during each session. HRPAS was calculated by summing the product of relative exercise intensity (%HRR) and duration (min) across all sessions. Regression models adjusted for age, gender, race and baseline values were used to regress each outcome on HRPAS score. Partial t-test and p values are provided for each model.

**RESULTS:** Exercise dose, as defined by HRPAS, was significantly associated with improvements in BMI (t(1062) = -5.19, p< 0.001), waist (t(1048) = -4.16, p< 0.001) and hip (t(1047) = -3.57, p< 0.001) circumferences, %BF (t(998) = -2.66, p = 0.008), resting HR (t(1049) = -3.46, p = 0.001), estimated aerobic capacity (t(980) = 4.10, p< 0.001), DXA fat mass (t(636) = -3.84, p< 0.001), and DXA percent fat (t(636) = -4.16, p< 0.001). Systolic and diastolic blood pressure and DXA total lean mass were not associated with HRPAS. In TIGER, the minimum

cumulative dose needed to meet ACSM vigorous activity guidelines (i.e., 75 min/wk,  $\geq 60\%$ HRR, HRPAS = 675) was associated with a 1.3% decrease in percent body fat, a 4.0 b-min<sup>-1</sup> decrease in resting HR, and a 2 cm decrease in waist and hip circumferences independent of age, gender and race.

**CONCLUSIONS:** Cumulative aerobic exercise dose is associated with improved physiological outcomes including measures of body composition, resting HR, and estimated fitness.

---

**2131** Board #177 May 31 9:00 AM - 10:30 AM

**Aerobic Exercise Training Improves Heart Rate Recovery Activity In Sedentary African Americans With Abnormal Diastolic Function**

Jan Kretzschmar<sup>1</sup>, Deborah Crabbe<sup>1</sup>, Deborah Fearheller<sup>2</sup>, Kathleen Sturgeon<sup>1</sup>, Keith Diaz<sup>1</sup>, Sheara Williamson<sup>1</sup>, Praveen Veerabhadrapa<sup>1</sup>, Chenyi Ling<sup>1</sup>, Amanda Perkins<sup>1</sup>, Kassandra McGlenn<sup>1</sup>, Olivia Menardy<sup>1</sup>, Michael Brown, FACSM<sup>1</sup>. <sup>1</sup>Temple University, Philadelphia, PA. <sup>2</sup>University of California Los Angeles, Los Angeles, CA.

(No relationships reported)

**PURPOSE:** African Americans are an at risk population for diastolic heart failure (DHF). Increased Sympathetic Nervous System Activity (SNSa) is strongly associated with DHF. Abnormal diastolic function (ADF) is a precursor to DHF and manifests itself early in the disease process without any other apparent signs or symptoms. Like DHF, ADF is often accompanied by increased SNSa. Heart Rate Recovery (HRR) obtained from a graded exercise test is thought to be an indicator of SNSa. Aerobic exercise training has been shown to decrease SNSa and improve HRR, therefore presenting a potential tool for early intervention for people with ADF. Thus, the purpose of this preliminary study was to investigate the effects of aerobic exercise training on HRR in African Americans with abnormal diastolic function.

**METHODS:** AA subjects (n=9) ages 45-62, who were sedentary, non-diabetic, non-smoking, and had abnormal diastolic function, but were free of cardiovascular disease, underwent 6 months of aerobic exercise training (3days/week, 65% of VO<sub>2</sub>max, 40 minutes/day). E' was measured by Doppler ultrasound during an echocardiographic stress test, and abnormal diastolic function was defined as having an E' value less than 10 cm/sec. HRR (maximum heart rate obtained during the test minus 4 min heart rate of passive recovery) determined from a sub-maximal graded exercise stress test was used as a surrogate measure for SNS activity.

**RESULTS:** HRR significantly ( $p<0.029$ ) increased ( $60.22\pm 3.58$  bpm vs.  $70.22\pm 2.55$  bpm) with 6 months of aerobic exercise training. However, aerobic fitness measured via VO<sub>2</sub>max did not ( $p<0.176$ ) change ( $28.07\pm 2.76$  ml/kg/min vs.  $30.57\pm 2.94$  ml/kg/min).

**CONCLUSIONS:** Although no improvements in aerobic fitness were observed, likely due to the small sample size, a significant improvement in HRR was seen, which might indicate an improvement in SNSa. Therefore, among individuals at risk for the development of DHF, aerobic training may be a useful tool at altering one associated abnormality associated with its progression, increased SNS activity.

---

**2132** Board #178 May 31 9:00 AM - 10:30 AM

**Aerobic Gait Training in Older Adults With Mild Cognitive Impairment and Hypertension: Preliminary Results.**

Noah Koblinsky<sup>1</sup>, Joseph DeCaria<sup>2</sup>, Manuel Montero-Odasso<sup>3</sup>, Robert Petrella, FACSM<sup>1</sup>. <sup>1</sup>University of Western Ontario, London, ON, Canada. <sup>2</sup>Lawson Health Research Institute, London, ON, Canada. <sup>3</sup>Parkwood Hospital, London, ON, Canada.

(No relationships reported)

Executive dysfunction and gait disability are commonly associated with aging and have shown to be accentuated by hypertension. There is sufficient evidence that warrants the treatment of hypertension in order to slow cognitive and functional decline in at risk older adults.

**PURPOSE:** To determine the effect of aerobic exercise combined with step length feedback on blood pressure (BP), executive function (EF), and gait in hypertensive older adults with signs of mild cognitive impairment (MCI) and hypertension.

**METHODS:** Eleven community dwelling older adults (72.5 $\pm$ 6.3 years) with hypertension and objective signs of MCI completed 12 weeks of an aerobic gait-training intervention. The participants exercised at a moderate to vigorous intensity for 30 minutes, 3 times a week on a treadmill that provided real time visual feedback about their step length. BP was measured over 24 hours by ambulatory monitoring and EF was measured using the Trail Making Test (TMT) and the Digit Symbol Substitution Test (DSST). An electronic walkway measured gait under single and dual task conditions. Paired samples t-tests were used to detect changes between baseline and 12 weeks.

**RESULTS:** Baseline 24-hour mean systolic and diastolic BP was 125.73 $\pm$ 12.31 and 74.27 $\pm$ 8.63 mmHg respectively. Mean baseline TMTa time was 39.57 $\pm$ 18.92 seconds and mean DSST score was 52.91 $\pm$ 11.20 items. Baseline single and dual task (naming animals) step length was 65.04 $\pm$ 8.21 cm, and 61.30 $\pm$ 11.32 cm respectively, while baseline single and dual task (serial 7's) gait velocity averaged 121.22 $\pm$ 17.25 cm and 85.05 $\pm$ 34.98 cm respectively. Following the intervention, 24-hour mean systolic and diastolic BP decreased by [mean difference (95%CI)] 1.09 (1.95; -4.13) mmHg ( $p=0.443$ ) and 2.18 (-0.43; -3.93) mmHg ( $p=0.019$ ). Mean TMTa scores improved by 4.55 (1.04; 8.06) seconds ( $p=0.016$ ) while improvements in DSST scores were not significant ( $p=0.120$ ). Dual task step length increased by 3.74 (1.47; 6.01) cm ( $p=0.004$ ) and dual task velocity increased by 9.85 (0.12; 19.59) cm/s ( $p=0.048$ ).

**CONCLUSIONS:** Our 12-week aerobic gait training intervention was feasible in our sample and the significant improvements observed warrant a larger trial to evaluate the impact of this intervention in at risk older adults. Supported by the St. Joseph's healthcare foundation

**2133** Board #179 May 31 9:00 AM - 10:30 AM

**The POTS Registry: Treatment of Patients with the Postural Orthostatic Tachycardia Syndrome with Exercise Training**

Tiffany B. Bivens<sup>1</sup>, M. Melyn Galbreath<sup>1</sup>, Dianne Hendrickson<sup>1</sup>, Sheryl Livingston<sup>1</sup>, Qi Fu<sup>2</sup>, Benjamin D. Levine, FACSM<sup>2</sup>. <sup>1</sup>Institute for Exercise and Environmental Medicine, Dallas, TX. <sup>2</sup>University of Texas Southwestern Medical Center, Dallas, TX.

(No relationships reported)

The Postural Orthostatic Tachycardia Syndrome (POTS) is characterized by chronic orthostatic intolerance resulting in upright tachycardia ( $\geq 120$  bpm or  $>30$  bpm over supine heart rate (HR) at 10-min standing), with lightheadedness, fatigue, and reduced quality of life. Our prior research has shown that "cardiovascular deconditioning" (i.e., cardiac atrophy and hypovolemia) is a significant underlying mechanism, and that an "optimized" 3 month exercise training program improved or even cured POTS (53% "cure" rate, i.e. they no longer meet heart rate criteria) as well as improved patient quality of life.

**PURPOSE:** To determine the effectiveness of this program in the community setting in POTS patients.

**METHODS:** We established a World-wide POTS registry and enrolled 111 patients from five countries [12 M, 99 F, 26  $\pm$  11 (mean  $\pm$  SD) years old]. Before and after use of the program, a 10-min stand test was performed to obtain heart rate (HR) and blood pressure (BP), and patient quality of life was assessed using the Short-Form 36 Health Survey. The program begins with semi-recumbent exercise and progresses to upright modes while encouraging adherence in the face of likely increased fatigue in the first 4-6 weeks. Weight training focused on leg and core muscles. In addition, water and salt intake were increased.

**RESULTS:** Forty patients completed the program to date. Fourteen patients dropped out (12.6% drop out rate). Thirty-six are still pending due to lack of follow up data, and twenty-one are still training. The HR response to 10-min standing was significantly reduced after training ( $\Delta$ HR 40.9  $\pm$  14.8 bpm pre vs. 21  $\pm$  9.3 post,  $p<0.001$ ). Mean BP was not different before and after training (Supine: 85.8  $\pm$  9.3 mm Hg pre vs. 85.1  $\pm$  16.3 post; at 10-min standing: 84.3  $\pm$  8.8 vs. 89.1  $\pm$  12.2,  $p=0.129$  for interaction). Patients' physical (27.3  $\pm$  7.3 pre vs. 35.2  $\pm$  6.5 post,  $p<0.001$ ), mental (42.5  $\pm$  9.6 vs. 46.5  $\pm$  6.4,  $p=0.026$ ), and social function (36.6  $\pm$  5.9 vs. 44.7  $\pm$  6.5,  $p<0.001$ ) scores were significantly improved. Twenty-five out of forty patients were "cured" (63% "cure" rate).

**CONCLUSIONS:** These results suggest this unique training program is effective in the community setting, and thus, can be used as a non-drug treatment for POTS patients. However, it remains to be determined if maintaining exercise is an effective life-long treatment strategy.

2134 Board #180 May 31 9:00 AM - 10:30 AM

**Hemodynamic, Cardiorespiratory, and Perceived Exertion Responses To Low-impact Exercise In Coronary Patients**

Roger L. Sacks, Barry Franklin, FACSM, Adam deJong, FACSM, Jenna Brinks, Brad Gliha, Kirk Hendrickson, Lindsey Krajewski, Amy Fowler, Lisa Schornak, Judy Boura. *William Beaumont Hospital, Royal Oak, MI.*

(No relationships reported)

**PURPOSE:** Cardiac exercise programs use varied forms of exercise equipment. For patients with orthopedic limitations, low or non-impact equipment, including the elliptical trainer (ET), is commonly recommended to minimize musculoskeletal discomfort. We compared hemodynamic cardiorespiratory and perceived exertion (RPE) responses to the ET and the Cybex Arc Trainer (AT) in clinically stable patients with coronary disease.

**METHODS:** Ten low risk cardiac men (mean  $\pm$  SD age = 58  $\pm$  11 years) satisfying inclusion criteria (functional capacity  $\geq$  7 metabolic equivalents [METs] without evidence of impaired left ventricular function, signs/symptoms of myocardial ischemia or significant dysrhythmias) were monitored for heart rate (HR), blood pressure (BP), and oxygen consumption ( $\text{VO}_2$ ) responses at rest and during submaximal exercise bouts on the AT and traditional ET using legs-only at 50 and 70% heart rate reserve (HRR). Data were obtained for each piece of equipment on 2 non-consecutive days at the same time of day. Metabolic data were directly obtained using breath-by-breath measurements of  $\text{VO}_2$ , adjusted for body weight (kg). RPE was assessed using the category Borg Scale (6-20), as was pain/discomfort using the 0-4 Scale.

**RESULTS:** Mean  $\pm$  SD aerobic requirements at 50% HRR on the AT and ET were 17.8  $\pm$  4.8 and 18.5  $\pm$  5.1 ml/kg/min (NSD), respectively. Exercise BP responses at 50% HRR during AT and ET were 158  $\pm$  26 and 151  $\pm$  27 mmHg (NSD), respectively. RPE responses at 50% HRR on the AT and ET were 11  $\pm$  1 and 12  $\pm$  2 (NSD), respectively. At 50% HRR subjects reported no pain/discomfort on either device. Aerobic requirements at 70% HRR using the AT and ET were 21.8  $\pm$  6.5 and 21.8  $\pm$  6.9 ml/kg/min (NSD), respectively. Exercise BP responses at 70% HRR on AT and ET were 178  $\pm$  22 and 173  $\pm$  26 mmHg (NSD), respectively. RPE responses at 70% HRR on the AT and ET were 13  $\pm$  1 and 13  $\pm$  1 (NSD), respectively. At 70% HRR, 3 subjects reported 1/4 (mild) leg pain on the AT whereas 2 subjects reported comparable discomfort on the ET.

**CONCLUSIONS:** Our findings suggest the AT is a viable alternative to the ET, with comparable hemodynamic, cardiorespiratory and perceived exertion responses at either 50 or 70% HRR.

---

2135 Board #181 May 31 9:00 AM - 10:30 AM

**Exercise Training Increased SOD Activity in Liver of NASH Rats**

Shen Ken Hung<sup>1</sup>, Chan Che-Chang<sup>2</sup>, Wei-Chih Huang<sup>1</sup>, Shioh-Chwen Tsai<sup>1</sup>. <sup>1</sup>Taipei Physical Education College, Taipei, Taiwan. <sup>2</sup>National Yang-Ming University, Taipei, Taiwan. (Sponsor: Chia-hua Kuo, FACSM)

(No relationships reported)

**PURPOSE:** To investigate the interaction of exercise training and MCD diet on steatosis and oxidative stress in liver.

**METHODS:** In this study, 8-week-old male Sprague Dawley rats were randomly divided into 5 groups: control (fed normal diet, W0), MCD diet fed for 9 weeks or 14 weeks combined without (W9, W14) or with exercise training (W9+Ex, W14+Ex). The exercise training was treated for 4 weeks on a motorized treadmill before sacrifice. The blood were collected and analyzed for AST. The liver tissues were collected, extracted and assayed for the production of glutathione (GSH) and lipid peroxidation and the activities of superoxide dismutase (SOD), catalase, glutathione peroxidase (GPx), and glutathione reductase (GR) by using commercial kits. The hematoxylin-eosin staining was used to determine the degree of lobular inflammation and fibrosis in liver. The degree of fibrosis and inflammation were evaluated by METAVIR score. The statistical analysis was done using the one-way ANOVA for independent samples, with significance level of 5%.

**RESULTS:** Rat fed with the MCD diet showed a rapid induction of AST and hepatic steatosis, loss of body weight and liver weight, but increased the ratio of liver and body weight. Compared with W14, the W14+Ex significantly decreased steatosis ( $p < 0.05$ ) and fibrosis ( $p < 0.05$ ). The production of lipid peroxidation in liver increased significantly in W14 (24.0  $\pm$  6.9 vs 0.40  $\pm$  0.05 nmole/min/ $\mu$ g protein,  $p < 0.05$ ) but not in W14+Ex compared with W0 group. The activity of SOD in W14 and W14 +Ex were increased compared with W0. Feeding with MCD diet for 14 weeks significantly decreased the activities of catalase ( $p < 0.01$ ), GPx ( $p < 0.05$ ), and GR ( $p < 0.05$ ). Exercise training did not alter MCD diet abolished activities of antioxidant enzymes.

**CONCLUSIONS:** Exercise training improves NAFLD through increased activity of SOD in liver.

2136 Board #182 May 31 9:00 AM - 10:30 AM

**Lead, Exercise Training and Herbal Supplementation: Concomitant Neuroprotective Effects of Endurance Exercise Training and Curcumin**

Valiollah Dabidi Roshan<sup>1</sup>, Mahdi Hossein Zadeh<sup>2</sup>, Somayeh Hosseinzadeh<sup>3</sup>, Jonathan Myers, FACSM<sup>4</sup>. <sup>1</sup>University of Mazandaran, Babolsar, Iran, Islamic Republic of. <sup>2</sup>Center for Sensory-Motor Interaction (SMI), Aalborg University, Denmark, Aalborg, Denmark. <sup>3</sup>University of Mazandaran, Babol, Iran, Islamic Republic of. <sup>4</sup>Cardiology Division, VA Palo Alto Health Care System, Stanford University, Palo Alto, CA, USA, Palo Alto, CA.

(No relationships reported)

**BACKGROUND:** Lead as an air pollutant is a life-threatening metal that has been associated with several conditions including degenerative disease of the nervous system.

**PURPOSE:** To investigate neuroprotective effects of treadmill running (TR) and/or Curcuma Longa (CCML) on lead -induced neurotoxicity in the hippocampus and cortex of rats.

**METHODS:** 40 male rats were randomly divided into 5 groups: (1) lead acetate; (2) CCML; (3) TR; (4) TR+CCML; and (5) a sham-treated group. The rats in groups 1 to 4 received lead acetate (20 mg/kg). In addition, groups 3 and 4 underwent TR, 15 to 22 m/min for 25 to 64 minutes, 5 times a week for 8 weeks, while groups 2 and 4 received CCML (30 mg/kg) intraperitoneally. Rats in group 5 received CCML solvent (ethyl oleat), only.

**RESULTS:** Chronic administration of lead increased lipid peroxidation as measured by malondialdehyde (MDA) in the plasma (72%), hippocampus (59%), and cortex (96%) in comparison to the sham group. In addition, lead decreased brain-derived neurotrophic factor (BDNF) in the hippocampus and cortex (17% and 10% respectively), nerve growth factor (NGF) levels in the cortex (39%), and total antioxidant capacity (TAC) levels in the hippocampus (27%), and the cortex (38%), as compared to the sham-treated group ( $P \leq 0.05$ ). Both training and supplementation treatment alone ameliorated the adverse effects of lead; however, the combination of them was more effective. Treadmill+CCML treatment resulted in a significant decrease in MDA levels in plasma and hippocampus (60% and 22%, respectively). However, it increased BDNF in the plasma, hippocampus, and cortex (45%, 76% and 113%, respectively), NGF in the cortex (149%), and TAC levels in plasma (62%) in comparison to the lead only group.

**CONCLUSIONS:** These results provide a rationale for an inhibitory role of CCML and regular exercise in the attenuation of lead-induced neurotoxicity.

**Estimating Fitness Improvements After Phase II Cardiac Rehabilitation: Comparison of Three Methodologies**

Susan S. Haapaniemi, Lindsey Krajewski, Amy L. Fowler, Barry A. Franklin, FACSM, Judith Boura, Brenda White. *Beaumont Hospital, Royal Oak, MI.*

(No relationships reported)

A recent review of modulators of coronary patient outcomes suggests that each 1-metabolic equivalent (MET) increase in functional capacity (FC) appears to confer an 8% to 35% reduction in mortality. The Duke Activity Status Index (DASI) is a self-administered questionnaire that has been shown to accurately estimate FC, expressed as METs. Other widely used methods for estimating fitness improvements in phase II cardiac rehabilitation (PII CR) include the increase in training workload (Train WL) and the decrease in heart rate (HR) at a fixed workload, where a 10 bpm decrease  $\sim$  1 MET.

**PURPOSE:** The present study compared the change ( $\Delta$ ) in METs following PII CR using the DASI questionnaire with the  $\Delta$  in METs via the Train WL and HR at a fixed WL.

**METHODS:** Patients (157 men, 41 women) who completed  $>18$  PII CR sessions were evaluated. A comparison of the improvement in METs ( $\Delta$  METs) according to the 3 methodologies is shown in the table, with specific reference to gender and to patients on versus off beta-blocker (BB) therapy.

|              | DASI |      |      | Train WL |      |      | HR-Fixed WL |      |      |
|--------------|------|------|------|----------|------|------|-------------|------|------|
|              | N    | Mean | SD   | N        | Mean | SD   | N           | Mean | SD   |
| All Patients | 194  | 0.89 | 1.49 | 193      | 1.28 | 1.03 | 184         | 0.80 | 1.23 |
| Women        | 41   | 0.89 | 1.23 | 40       | 0.73 | 0.64 | 37          | 0.61 | 1.03 |
| Men          | 153  | 0.90 | 1.55 | 153      | 1.43 | 1.06 | 147         | 0.85 | 1.27 |
| BB -Yes      | 154  | 0.89 | 1.51 | 151      | 1.29 | 1.01 | 144         | 0.70 | 1.00 |
| BB -No       | 38   | 0.97 | 1.37 | 39       | 1.27 | 1.10 | 38          | 1.19 | 1.84 |

**RESULTS:** Correlation coefficients comparing the 3 methodologies for all patients (n = 194), and for the varied population subsets, were nonsignificant (P = 0.12 - 0.58). Nevertheless, on average, FC increased by ~ 1 MET, regardless of the methodology employed. Women tended to demonstrate slightly lower absolute improvements in  $\Delta$  METs, using the Train WL or HR-fixed WL estimates. The HR at a fixed WL methodology appeared to underestimate fitness improvements in patients taking  $\beta$ B.

**CONCLUSIONS:** The present findings suggest that a brief PII CR program results in ~ 1 MET improvement in FC, and may help to explain the reduced mortality associated with exercise-based CR programs.

**2138** Board #184 May 31 9:00 AM - 10:30 AM

**Quality Coding Of Meta-analyses Of The Blood Pressure Response To Exercise: A Systematic Review**

Blair T. Johnson<sup>1</sup>, Hayley V. MacDonald<sup>1</sup>, Michael L. Bruneau, Jr.<sup>1</sup>, TaShauna U. Goldsby<sup>1</sup>, Justin C. Brown<sup>2</sup>, Tania B. Huedo-Medina<sup>1</sup>, Linda S. Pescatello, FACSM<sup>1</sup>.  
<sup>1</sup>University of Connecticut, Storrs, CT. <sup>2</sup>University of Pennsylvania, Philadelphia, PA.

(No relationships reported)

**PURPOSE:** Many meta-analyses have been conducted to summarize the growing numbers of controlled trials addressing the blood pressure (BP) response to exercise. The methods involved in meta-analysis have improved across science, but it is not known to what extent meta-analyses on exercise and BP exhibit high quality among all of the steps required in conducting meta-analyses. This study addressed this gap.

**METHODS:** Meta-analyses were retrieved from electronic databases (PubMed, Biosis, Scopus, and Web of Science) with pre-established inclusion criteria: 1) applied meta-analytic procedures; 2) to controlled exercise trials; and 3) that had systolic BP (SBP) or diastolic (DBP) as endpoints. The AMSTAR questionnaire (Shea et al., 2007) and several customized items quantified the quality of the procedures in the meta-analyses. Across the 17 dimensions, two trained coders exhibited high reliability (mean agreement=87%; mean kappa=0.80).

**RESULTS:** The 22 meta-analyses that qualified for this review were published between 1993 and 2011 and reviewed widely varying exercise modalities and populations. Total methodological quality ranged from 13.33% to 76.47% of the total points possible (Mean 46.72±20.22%), with more recent meta-analyses scoring significantly higher, r(21)=0.59, p<.01, and with higher quality meta-analyses being more cited per year in the Web of Knowledge, in a non-significant trend, r(21)=0.30, p=.17. Nearly all meta-analyses (95%) satisfactorily followed a priori design, but they tended not to satisfy quality criteria related to literature search and duplicate effort (46%); coding of studies (44%); analysis and interpretation (36%); and 5) reporting potential conflicts of interest (41%). Criteria that were the least likely to be met satisfactorily were with regard to documenting the quality of studies included in the meta-analytic sample (0%) and interpretation of results relative to the quality of studies (5%).

**CONCLUSIONS:** Meta-analyses may provide insights into the BP response to exercise but to date none have achieved contemporary quality standards. Our results offer some guidance as to whether new meta-analyses are needed to address particular problems and help readers of these meta-analyses to realize what constitutes a high-quality review.

**2139** Board #185 May 31 9:00 AM - 10:30 AM

**Single Session of Exercise Ameliorates Differences in Insulin Resistance Between Active and Inactive Overweight Adults**

Rachael K. Nelson, Jeffrey F. Horowitz, FACSM. University of Michigan, Ann Arbor, MI.

(No relationships reported)

Regular physical activity (PA) is an essential component of lifestyle programs targeting the prevention and/or treatment of obesity-related metabolic complications, such as insulin resistance. However, the contribution of adaptations resulting from a habitually active lifestyle compared with the effects of the most recent session of exercise on improvements in insulin resistance remains unclear.

**PURPOSE:** To determine the influence of habitual PA level and a single session of exercise on insulin resistance in overweight-to-mildly obese adults.

**METHODS:** A total of 22 overweight-to-mildly obese men and women (BMI: 27-34 kg/m<sup>2</sup>) were divided into 2 cohorts based on their self-reported PA. Five men and 7 women were classified as ACTIVE (>2.5h moderate-to-vigorous PA/week), while 5 men and 5 women were INACTIVE (<30min PA/week). Participants reported to the laboratory after an overnight fast for an oral glucose tolerance test (OGTT), and insulin resistance was assessed using the Matsuda Insulin Sensitivity Index (ISI). ACTIVE participants refrained from exercising for exactly 3 days before the OGTT. After completing the OGTT, participants performed a single session of exercise for 1h at an intensity of ~70% of their age-predicted HRmax, and they returned to the laboratory the next morning for a second OGTT.

**RESULTS:** Despite similar body weight (89±3 vs. 91±3 kg) and %body fat (34±2 vs. 36±2%) in ACTIVE vs. INACTIVE, ISI tended to be greater in ACTIVE (measured 3 days after their last exercise session) compared with INACTIVE (4.0±0.6 vs. 2.5±0.3), but this difference did not reach statistical significance (P=0.09). A single session of exercise increased ISI the next morning in INACTIVE (P=0.03), but interestingly the exercise session did not increase ISI the next day in our ACTIVE subjects (P=0.89). As a result, ISI was similar between ACTIVE and INACTIVE subjects in the morning after a single session of exercise (3.9±0.7 vs. 3.2±0.4; P=0.49).

**CONCLUSIONS:** A single session of moderate exercise was sufficient to increase ISI the next day in our INACTIVE participants, which ameliorated the difference in insulin resistance between habitually active and habitually inactive overweight adults.

**2140** Board #186 May 31 9:00 AM - 10:30 AM

**Effects of Accumulated Short and Very Short Bouts of Exercise on Cardiovascular Fitness: A Meta-Analysis**

Joel D. Reece, Youngdeok Kim, Minsoo Kang, FACSM. Middle Tennessee State University, Murfreesboro, TN.

(No relationships reported)

The American College of Sports Medicine recommends 30 minutes of moderate exercise most days of the week, which can be accumulated in short bouts of as little as 10 minutes. A number of studies have also examined the effect of very short bouts of exercise (< 10 minutes), yet this effect is uncertain.

**PURPOSE:** To determine the effect of accumulated short and very short bouts of exercise on cardiovascular fitness and to examine the difference in effect size (ES) between accumulated short (10-15 minutes) and very short bouts (< 10 minutes).

**METHODS:** Multiple online databases (i.e. Medline, Web of Science, EBSCO Host, Science Direct, Pubmed, Google Scholar, and Oregon PDF in Health and Performance) were used to identify applicable articles. Search terms included the following words: accumulate, exercise, physical activity, short bouts, intermittent, and health benefits. In addition, extensive cross-referencing from review and original articles was conducted. Only articles that were randomized, trained for at least 4 weeks (not sport specific), measured cardiovascular fitness, and included an experimental group with well-defined or well-estimated accumulated short or very short bouts of exercise (2-15 minutes) were included. Comprehensive Meta-Analysis software was used for the analysis.

**RESULTS:** A total of 51 articles were collected in the initial searches. After further review, 14 ES values from 12 articles and 5 ES values from 5 articles were calculated using a random effect model for accumulated short and very short bouts, respectively. Overall, all accumulated bouts of exercise yielded a moderate ES of 0.43 (95% CI = 0.30, 0.57). No significant difference

was identified between accumulating short and very short bouts of exercise ( $Q = 0.41$ ,  $df = 1$ ,  $p = 0.52$ ). Accumulating short (10-15 minutes) and very short bouts (< 10 minutes) of exercise yielded moderate effects of 0.41 (0.25, 0.56) and 0.51 (0.24, 0.78), respectively.

**CONCLUSIONS:** The accumulation of short and very short bouts of moderate-to-vigorous exercise has a moderate and positive effect on cardiorespiratory fitness. In addition, evidence from this study suggests the effects of exercise accumulated in as short as 2-minute bouts are homogeneous to those accumulated in 10- to 15-minute bouts of exercise.

---

**2141 Board #187 May 31 9:00 AM - 10:30 AM**

**Effect Of A 14-week Group Exercise Class On Various Health Measures Among College-age Women.**

Stephanie M. Otto, Shanda Kirkeidi, Kelly Maloney, Dain Clausen, Sandie Walker, Rochelle L. Quam. *Gustavus Adolphus College, St. Peter, MN.*

(No relationships reported)

Group exercise is a popular form of activity and is often taught using a combination of weight bearing exercise and resistance training, resulting in positive health outcomes. However, there is still much to learn about the impact of group exercise participation on specific health measures.

**PURPOSE:** The purpose of this study was to monitor changes in body mass index (BMI), body fat percentage (BF%), mean arterial blood pressure (MAP), calcium intake, and bone stiffness index (BSI) among college age females for the duration of a 14-week group exercise course.

**METHODS:** Pre-menopausal, non-athlete women ( $n = 16$ , age  $20.44 \pm 0.89$ ) elected to participate in a 14-week group exercise class that met three days per week for 50 minutes each day. Activity included step, kickboxing, floor aerobics, and some resistance training. Height, weight, BMI, BF%, MAP, and BSI were measured during week two, week 8, and week 14.

**RESULTS:** Repeated measures analysis of variance ( $p < .05$ ) was used to evaluate change over the three measurement periods. Results indicated no significant change in any of the variables of interest except BF% ( $F = 11.33$ ,  $p = .00$ ) and calcium intake ( $F = 6.55$ ,  $p = .01$ ). Multiple paired sample t-tests ( $p < .016$ ) were used to identify where significant differences appeared. Results indicated an increase in BF% between week 2 and week 8 ( $t = -4.65$ ,  $p = .00$ ). Significantly higher calcium intake was identified at week 8 compared to week 14 ( $t = 3.07$ ,  $p = .01$ ).

**CONCLUSIONS:** Participants in this study exhibited significant increases in BF% at week 8 compared to week 2. In addition, a significant increase in calcium intake was seen at week 8 compared to week 14. There is some evidence suggesting that novice exercisers report decreases in additional leisure time activity and increases in dietary intake upon the initiation of an exercise program (Church, Martin, Thompson, Earnest, Mikus, & Blair, 2009), which may have contributed to the results seen in this study. It appears that among this group of non-athlete, college age women, group exercise participation was associated with dietary adjustments that may have contributed to changes in body composition throughout this 14-week period.

**2142 Board #188 May 31 9:00 AM - 10:30 AM**

**Effects of Neck Muscle Training On Body Weight Shifting Ability In Patients With Chronic Neck Pain**

Yi-Jia Lin<sup>1</sup>, Shih-Wei Chou<sup>2</sup>, Cheng-Hsiu Lai<sup>1</sup>, Chia-Hua Kuo<sup>1</sup>, Alice May-kuen Wong<sup>2</sup>. <sup>1</sup>Taipei Physical Education College, Taipei, Taiwan. <sup>2</sup>Chang Gung Memorial Hospital, Taipei, Taiwan.

(No relationships reported)

Through cervical mechanoreceptors and their central and reflexive connections to the vestibular and visual systems, the neck plays an important role in providing various inputs which are responsible to body weight shifting. Although patients with chronic neck pain demonstrate impaired balance performance and also degraded neck fitness, the effectiveness of the neck strengthening program on body weight shifting ability remained unclear.

**PURPOSE:** To evaluate the effects of neck muscle training on body weight shifting.

**METHODS:** We recruited thirty patients (Age:  $55.3 \pm 6.4$  year-old) with chronic neck pain and 19 healthy adults (Age:  $53.7 \pm 3.9$  year-old). We gave neck exercise of which each training session includes warm-up, stretching, strengthening and neuromuscular control exercise. Seventeen patients completed 18 training sessions. Before and after the whole course, we assessed visual analogue scale (VAS), active range of motion (ROM), maximal isometric strength of the neck and dynamic balance by target reaching test using SMART Balance Master System. The parameters of Rhythmic Weight Shifting (RWS) including on-axis velocity and directional control were recorded. Changes in all parameters pre- and post-training were compared by the paired t-test (SPSS 15.0).

**RESULTS:** For the between group comparison before training, in the balance test of RWS, significant differences were detected at the on-axis velocity (deg/sec) in Front/Back -slow Speed (healthy subjects:  $2.6 \pm 0.2$  vs. patients:  $2.4 \pm 0.3$ ,  $p = 0.046$ ); and at the directional control 1 (%) in Left/Right -Medium Speed (healthy subjects:  $86.8 \pm 3.6$  vs. patients:  $83.0 \pm 6.6$ ,  $p = 0.038$ ). After training, significant differences were detected at the on-axis velocity (deg/sec) in Front/Back -fast Speed (Pre-Training:  $5.3 \pm 1.0$  vs. post-training:  $6.1 \pm 0.8$ ,  $p = 0.012$ ); and at the directional control (%) in Left/Right -Medium Speed (Pre-Training:  $83.0 \pm 6.6$  vs. post-training:  $86.7 \pm 3.8$ ,  $p = 0.022$ ).

**CONCLUSIONS:** The patient with chronic neck pain showed worse body weight shifting than healthy subjects in terms of body weight shifting ability. Neck muscle training seems have significant influence in neck fitness and body weight shifting ability. Our study shows the importance of the neck training in weight shifting ability which plays essential role in ADL activities.

**2143 Board #189 May 31 9:00 AM - 10:30 AM**

**Resistance Training Effect's on Anthropometric, Aerobic Capacity and Muscle Strength in Women Who Underwent Bariatric Surgery**

Ricardo A. Simões<sup>1</sup>, Marcelo C. Cesar<sup>1</sup>, Adalberto V. Oliveira Jr.<sup>1</sup>, Fernanda Torques<sup>1</sup>, Silvia C.C. Alves<sup>1</sup>, Maria I.L. Montebello<sup>1</sup>, Irineu Rasera Jr.<sup>2</sup>. <sup>1</sup>Universidade Metodista de Piracicaba, Piracicaba, Brazil. <sup>2</sup>Bariatric Clinic of Piracicaba - Center Gastroenterology and Obesity Surgery, Piracicaba, Brazil.

(No relationships reported)

Bariatric surgery (BS) has proven an effective method for weight loss and reduction of comorbidities in individuals with morbid obesity. To avoid weight regain is necessary to modify sedentary lifestyle. Resistance training (RT) is part of the ACSM recommendations for promoting health.

**PURPOSE:** To evaluate the effects of a RT program on anthropometric, aerobic capacity and muscle strength in women who underwent BS.

**METHODS:** Subjects were 15 women with 30 to 180 days after BS separated into two groups: Control (CG;  $n = 6$ ;  $35.3 \pm 3.3$  yrs;  $80.4 \pm 4.9$  kg;  $157.0 \pm 3.0$  cm;  $32.6 \pm 1.3$  kg/m<sup>2</sup>), who did not perform any type of exercise and Training (TG;  $n = 9$ ;  $30.7 \pm 1.5$  yrs;  $92.4 \pm 6.7$  kg;  $162.0 \pm 1.0$  cm;  $35.3 \pm 2.6$  kg/m<sup>2</sup>) who performed a 8 weeks of RT program. The subjects followed the following protocol evaluations: 1) Anthropometric measures (AM) - weight, height, BMI and waist circumference. 2) Six minute walk test (W6M) - aerobic capacity and 3) 10RM test in bench press machine (BPM), leg-press 45° (Leg) and lat pull down (LPd) - muscle strength tests. The RT sessions lasted about 60 minutes with 3 sets of 15RM, 60s rest between sets following ACSM guidelines with one exercise for the major muscle groups for a total of 13 exercises. Normal distribution of the data was checked by Kolmogorov-Smirnov test. Student's t-test and Mann Whitney was used for the comparison between the variables

**RESULTS:** There were no significant differences between CG and TG at baseline (W0) for all measured variables. After 8 weeks (W8) AM decreased significantly ( $p < 0.05$ ) in all collected variables for CG and TG, not showing difference between groups ( $\Delta CG$  vs  $\Delta TG = -8.2 \pm 0.5$  vs  $-8.4 \pm 1.4$  kg;  $-3.3 \pm 0.2$  vs  $-3.2 \pm 0.5$  kg/m<sup>2</sup>;  $-4.9 \pm 1.0$  vs  $-7.1 \pm 1.0$  cm;  $p > 0.05$ ). The same was observed in the W6M, both groups increased the distance traveled at W8 compared to W0 with no significant difference between then ( $\Delta GC = +37.5 \pm 2.0$  vs  $\Delta TG = +63.4 \pm 25.7$  m;  $p > 0.05$ ). 10RM increased significantly the load lifted only on the BPM for the GC. GT increase 10RM for all exercises compared both to WO and GC ( $\Delta CG$  vs  $\Delta TG$ : BPM:  $+3.0 \pm 0.8$  vs  $+7.7 \pm 1.4$ ; LPd:  $+1.5 \pm 1.0$  vs  $+5.7 \pm 2.0$ ; Leg:  $+4.0 \pm 3.6$  vs  $+17.6 \pm 2.9$  kg;  $p < 0.05$ ).

**CONCLUSIONS:** RT program may contribute to increase the muscular strength, without affect the decrease of AS and improve of aerobic capacity, in women after BS.

2144 Board #190 May 31 9:00 AM - 10:30 AM

**Training Using Single Versus Multiple Intermittent Bouts Of High-intensity Exercise Training Are Equally Effective For Increasing Maximal Oxygen Uptake**

Amt E. Tjønnå<sup>1</sup>, Ingeborg M. Leinan<sup>1</sup>, Anette T. Bartnes<sup>1</sup>, Bjørn M. Jenssen<sup>1</sup>, Richard A. Winett<sup>2</sup>, Martin Gibala<sup>3</sup>, Ulrik Wisløff<sup>1</sup>. <sup>1</sup>Norwegian University of Science and Technology, Trondheim, Norway. <sup>2</sup>Virginia Tech, Blacksburg, VA. <sup>3</sup>McMaster University, Hamilton, ON, Canada.  
(No relationships reported)

**PURPOSE:** Regular exercise training improves maximal aerobic capacity (VO<sub>2</sub>max) and reduces all-cause mortality risk, but the influence of intensity and volume remains to be clearly established. Public health guidelines generally advocate a relatively high-volume of moderate-intensity exercise, but a growing body of evidence suggests that low-volume, high-intensity training may be a time-efficient means to achieve health benefits. In the present study, we measured changes in health status markers after 10 wk of training using an established, efficacious high-intensity interval training protocol [4 x 4 min at 90% of maximal heart rate (HRmax) interspersed with 3 min active recovery at 70% HRmax; 4-BOUT], or a novel single bout protocol that requires a markedly lower time commitment (1 x 4 min at 90% HRmax; 1 BOUT)

**METHODS:** Twenty six healthy, sedentary overweight men (BMI: 25-30, age: 35-45 y) were randomized to either 1-BOUT (n=13) or 4-BOUT (n=13).

**RESULTS:** After 10 wk of training, VO<sub>2</sub>max increased by 10% (~5.0 mL\*kg<sup>-1</sup>\*min<sup>-1</sup>) and 13% (~6.5 mL\*kg<sup>-1</sup>\*min<sup>-1</sup>) in 1-BOUT and 4-BOUT, respectively, with no group difference (P=0.22). Work economy also improved in both groups after training, as evidenced by lower oxygen cost during running at a sub-maximal work load (14% and 13%, respectively, in 1-BOUT and 4-BOUT; with no group difference P=0.40). Systolic blood pressure decreased 7.1 and 2.6 mmHg in 1-BOUT and 4-BOUT respectively, no group difference (P=0.3), and diastolic pressure decreased 7.7 and 6.1 mmHg in 1-BOUT and 4-BOUT respectively (no group difference P=0.74). Both groups had a decrease in fasting glucose (-6% and -5% in 1 and 4-BOUT respectively, no group difference (P=0.30). 4-BOUT improved blood-profile to a larger extent than 1-BOUT, although without any group difference.

**CONCLUSIONS:** These preliminary data suggest that training using a relatively brief, single bout of vigorous exercise three times per week may be a time-efficient strategy to improve health in previously sedentary but otherwise healthy middle-aged individuals. Such brief bouts of exercise could be translated into public health policies and programs.

2145 Board #191 MAY 31 8:00 AM - 9:30 AM

**Climbing Mount Rainier: Water Turnover and Core Temperature**

Walter Hailes<sup>1</sup>, John S. Cuddy<sup>1</sup>, Dustin S. Slivka<sup>2</sup>, Brent R. Ruby, FACSM<sup>1</sup>. <sup>1</sup>University of Montana, Missoula, MT. <sup>2</sup>University of Nebraska at Omaha, Omaha, NE.  
(No relationships reported)

**PURPOSE:** Hydration is an important logistical consideration for individuals performing in austere environments because water demands must be balanced with the burden of carrying the water. Therefore investigation into the water turnover of individuals climbing Mount Rainier can provide insight into the hydration demands of high altitude activity in cool to cold environments.

**METHODS:** Seven novice climbers participated in a study to determine the hydration kinetics and core temperatures associated with a successful summit of Mt Rainier. Ingestible, radio equipped thermometers were ingested to monitor core temperature and a dose of deuterium was administered to determine hydration kinetics via stable isotope dilution.

**RESULTS:** Mean core temperature was 37.6 ± 0.3°C, water turnover was 95.0 ± 17.5 mL\*kg<sup>-1</sup>\*24H<sup>-1</sup>, body mass was not different from pre (75.9 ± 13.0 kg) to post (74.8 ± 12.5 kg) climb (p=0.06), but urine specific gravity increased from pre (1.013 ± 0.002) to post (1.022 ± 0.006) climb (p=0.004).

**CONCLUSIONS:** Hydration demands of climbing Mt Rainier are highly elevated despite modest fluctuations in core temperature. Participants were able to maintain sufficient hydration with limited access to water over the course of the approximately 30 hour climb.

2146 Board #192 MAY 31 8:00 AM - 9:30 AM

**OUES And VE/VCO<sub>2</sub> Slope, At Sea Level And 3600 Meters, In Professional Soccer Player**

Galo E. Narvaez<sup>1</sup>, Enrique Vargas<sup>2</sup>, Galo E. Narvaez Alban<sup>1</sup>. <sup>1</sup>Comite Olimpico Ecuatoriano, Guayaquil, Ecuador. <sup>2</sup>Instituto Boliviano De Biologia De Altura, La Paz, Bolivia, Plurinational State of. (Sponsor: George Brooks, FACSM)  
(No relationships reported)

**PURPOSE:** In previous works [1, 2], we analyzed VE/VCO<sub>2</sub> Slope and Oxygen Uptake Efficiency Slope OUES, during a soccer-specific test. In this paper we are comparing VE/VCO<sub>2</sub> Slope and OUES vs. traditional parameters (tp): VE, VO<sub>2</sub>, VE/VO<sub>2</sub>, VE/VCO<sub>2</sub>, VO<sub>2</sub>/HR, under laborator conditions.

**METHODS:** 53 professional soccer players, not native high; 43 at sea level in Guayaquil (GYE) and 10 from La Paz Bolivia (LPB) at 3600 m. All underwent maximum treadmill ramp (MXRT). Expired gas samples were taken with an automatic analyzer K4b2. All variables are representative of the total test time.

**RESULTS:** (X±DS) VO<sub>2</sub> 3.044±82.5 vs 3232±66.2 L.min<sup>-1</sup>; OUES 21.8±4.3 vs 21.5±3.3; VO<sub>2</sub>/HR 21.1 ± 2.1 vs 20.5 ± 2.8 ml.beat<sup>-1</sup> NS. VE 109.4±2.7 vs 84.8±1.8 L.min<sup>-1</sup> t=6.2 p<0.0001; VE/VCO<sub>2</sub> Slope 40.9±3.3 vs 25.4±4.4 t=10.1 p<0.0001; VE/VO<sub>2</sub> 34.2±0.5 vs 25.1±0.4 t=9.5 p<0.0001; VE/VCO<sub>2</sub> 35.8±0.5 vs 25.1±0.6 t=8.8 p<0.0001 for LPB vs GYE respectively.

**CONCLUSIONS:** Hyperventilation at altitude is a good argument. However, this study shows its influence on VE/VCO<sub>2</sub> Slope and other tp. The OUES and VO<sub>2</sub>/HR are remaining stable, independent of altitude, due in part to reduce variability in VO<sub>2</sub> at sea level and LPB. The stability of the oxygen uptake efficiency and O<sub>2</sub> Pulse could be good indicators of adaptation to altitude, during physical exercise in trained subjects.

2147 Board #193 MAY 31 8:00 AM - 9:30 AM

**Effects of Garlic Consumption on Exercise in Hypoxia**

David Morris, Reid Beloni, Hannah Wheeler, Collier Scott. *Appalachian State University, Boone, NC.*  
(No relationships reported)

Effects of Garlic Consumption on Exercise in Hypoxia

David M. Morris, Reid K. Beloni, Hannah Wheeler, & Scott R. Collier, FACSM

Appalachian State University, Boone, NC 28608

Hypoxia can induce pulmonary vasoconstriction (HPV) and ventilatory shunt. The reduced interface between alveoli and vasculature contributes to reductions in blood oxygenation and aerobic

exercise performance. Reduction in HPV via pharmacological vasodilators reduces pulmonary hypertension and improves blood oxygenation and exercise performance. Garlic administration to rats has also been shown to reduce HPV.

**PURPOSE:** To investigate the effects of garlic supplementation on blood oxygen saturation and aerobic exercise performance during exercise in acute hypoxia.

**METHODS:** Ten male subjects ( $21 \pm 3$  yr,  $70.7 \pm 5.0$  kg) completed an initial graded exercise test to exhaustion (GXTE) on an electronically braked cycle ergometer under normoxia (N) ( $P_{iO_2} = 144$  Torr) to assess time to exhaustion (TTE),  $VO_{2max}$ , and  $SaO_2$  at exhaustion. Subjects then consumed  $4650 \text{ mg} \cdot \text{d}^{-1}$  garlic (H+G) or equal volume of placebo (H-G) for 1 wk. Following supplementation, subjects performed an identical GXTE under hypoxic conditions ( $P_{iO_2} = 90$  Torr). After a 1-week washout period the remaining supplement was consumed followed by a second hypoxic GXTE. Dependent variables were compared across the 3 treatments using repeated measures ANOVA and Bonferroni post-hoc analyses.

**RESULTS:**  $VO_{2max}$  in N ( $4.24 \pm 0.27 \text{ l} \cdot \text{min}^{-1}$ ) was significantly higher ( $P < 0.01$ ) compared to H+G ( $2.94 \pm 0.32 \text{ l} \cdot \text{min}^{-1}$ ) and H-G ( $2.99 \pm 0.24 \text{ l} \cdot \text{min}^{-1}$ ), but did not differ between H+G and H-G ( $P = 0.67$ ).  $SaO_2$  was significantly higher ( $P < 0.01$ ) in N ( $91 \pm 4\%$ ) than H+G ( $71 \pm 2\%$ ) and H-G ( $71 \pm 6\%$ ), but did not differ between H+G and H-G ( $P = 0.80$ ). TTE in N ( $570 \pm 84$  s), was significantly greater ( $P < 0.01$ ) than H+G ( $330 \pm 60$  s) and H-G ( $334 \pm 82$  s), but did not differ between H+G and H-G ( $P = 0.91$ ).

**CONCLUSION:** Garlic supplementation for one week does not improve blood oxygen saturation, maximal oxygen consumption, or time to exhaustion in a progressive exercise test to exhaustion performed in acute hypoxia.

Supported by a Grant from the Gatorade Sport Science Institute.

2148 Board #194 MAY 31 8:00 AM - 9:30 AM

**Effect Of Post-exercise Oxygen Supply On Heart Rate Variability And Hemodynamic Change**

Wen-Chih Lee<sup>1</sup>, Hung-Ling Wang<sup>2</sup>, Sun-Chin Yang<sup>1</sup>, Cheng-Feng Ho<sup>1</sup>. <sup>1</sup>Shih Hsin University, Taipei, Taiwan. <sup>2</sup>Buddhist Tzu Chi General Hospital, Taipei, Taiwan. (Sponsor: Chia-Hua Kuo, FACSM)

(No relationships reported)

**PURPOSE:** Glucose and insulin are delivered by blood to peripheral tissues via blood vessel, which is largely controlled by autonomic nervous system (can be reflected by heart rate variability or HRV). Under this condition, the role of autonomic nervous activity in blood flow regulation has not yet been elucidated previously.

**METHODS:** In the proposed study, 8 youth swimmers (N=10,  $14.8 \pm 0.5$  years) will be recruited for a counterbalanced design. In particular, 2 different concentrations of oxygen will be delivered (21%, 16% O<sub>2</sub>) following a training protocol with 1 week separation period among trials. Muscle tissue oxygenation will be monitored by Near Infrared Spectroscopy (NIRS) on arm and leg. Oxygen saturation, oxyhemoglobin, deoxyhemoglobin, total hemoglobin, sympathetic power and vagal power will be measured under each experimental condition for all subjects.

**RESULTS:** After training, hypoxia exposure significantly increased total hemoglobin and oxygen saturation on triceps and quadriceps muscles above normoxic level. This increase was paralleled with oxy-hemoglobin elevation. Furthermore, hypoxia did not cause differences in deoxy-hemoglobin levels. Hypoxia did not affect vagal activity but significantly increased sympathetic power.

**CONCLUSION:** This study demonstrated that hypoxia can increase total hemoglobin and oxygen saturation on triceps and quadriceps muscles. This effect may be due to increased sympathetic power during recovery.

2149 Board #195 MAY 31 8:00 AM - 9:30 AM

**The Effect Of Exercise On Cerebral Oxygenation And Cognitive Performance During Normobaric Hypoxia.**

Chul-Ho Kim, Edward J. Ryan, Corey A. Peacock, Yongsuk Seo, John Gunstad, Ellen L. Glickman, FACSM. Kent State University, Kent, OH.

(No relationships reported)

Exposure to the reduced oxygen (i.e. hypoxia) is associated with cognitive impairment, largely mediated by reduced cerebral oxygenation. Physical activity during hypoxia is common, though its effects on cerebral oxygenation and cognitive function are poorly understood.

**PURPOSE:** The purpose of present investigation was to determine the effect of normobaric hypoxia and low intensity exercise on cerebral oxygenation and cognitive function in middle-aged males.

**METHODS:** Eight apparently healthy ( $35.9 \pm 5.7 \text{ ml} \cdot \text{kg}^{-1} \cdot \text{min}^{-1}$ ), middle-aged ( $40.5 \pm 2$  yr) males participated in the present investigation. Prior to experimental trials, participants completed a graded exercise test (Excalibur 1300W cycle ergometer) to estimate  $VO_{2max}$ . Following pre-experimental testing, participants underwent two experimental trials, hypoxia (H) and hypoxia with exercise (HE), including 2-h resting, 1-h exercise (cycling with 50% of hypoxic  $VO_{2max}$ ) and 2-h recovery. Both trials were accomplished in a normobaric hypoxia (12.5% O<sub>2</sub>) chamber (Colorado Altitude Training, Louisville, CO). Arterial oxygen saturation ( $SaO_2$ ) was measured by Pulse-oximeter (Oxi-Go, Roslyn, NY), and cerebral oxygenation ( $rSO_2$ ) were measured by Near-Infrared Spectroscopy (Somanetics, Troy, MI) every 30-min. Computerized versions of the Trail Making Test (TMT) A and B were administered at baseline, 30-min, pre-exercise, post-exercise, 4-h and 5-h during all experimental trials. The ratio of TMTA to TMTB was used as the dependent variable.

**RESULT:** Repeated measures ANOVA revealed a trial (H and HE) by time interaction in both  $SaO_2$  and  $rSO_2$  ( $p < 0.01$ );  $SaO_2$  and  $rSO_2$  were lower during exercise in hypoxia. In terms of cognitive function, there were no significant main effect of time ( $p > 0.05$ ) and time by trial interaction ( $p > 0.05$ ) for TMTA. For TMTB, there was a significant main effect of time ( $p < 0.01$ ), but no time by trial interaction emerged ( $p > 0.05$ ). Follow-up, a test (of the ratio) revealed a main effect of time ( $p < 0.01$ ), but no time by trial interaction emerged ( $p > 0.05$ ).

**CONCLUSION:** There was a differential response following exercise with respect to oxygen saturation and cerebral oxygenation. In addition, cognitive performance was declined over time during hypoxia, but low intensity exercise did not impact cognitive performance in middle-aged males.

2150 Board #196 MAY 31 8:00 AM - 9:30 AM

**Weight and Body Composition Changes in Mountaineers Following an Ascent of Denali**

Dale R. Wagner. Utah State University, Logan, UT. (Sponsor: Gerald Smith & Edward Heath, FACSM)

(No relationships reported)

Sojourns to both hypobaric and cold environments have been associated with weight loss. Denali (Mt. McKinley) in Alaska, at a height of 6194 m and latitude of 63°N, combines these environmental stressors.

**PURPOSE:** To determine the weight and body composition changes that occur in mountaineers during a commercial climbing expedition on Denali.

**METHODS:** Eleven mountaineers began the expedition, and 8 (5 clients, 3 guides; 7 males, 1 female; age:  $39.2 \pm 9.6$  yr) completed the study; all 8 reached the summit. Pre- and post-data, spanning 21 days, was collected in Talkeetna, AK (105 m). Height was self-reported; weight and body fat percentage (%BF) were obtained with a full-body bioelectrical impedance (BIA) scale. Urine specific gravity was assessed with a digital refractometer to ensure that participants were euhydrated at the time of the BIA measurements. Only 10 of the 21 days involved ascending or descending. Typical loads carried were approximately 40 kg, distributed between packs and sleds. Calorie intake was unrestricted, and food was available ad libitum throughout the expedition.

**RESULTS:** Every participant lost weight ( $0.8$  to  $5.2$  kg;  $2.9 \pm 1.4$  kg,  $p = .001$ ), and on average there was a significant drop in %BF ( $3.0 \pm 3.1\%$  BF,  $p = .029$ ). There was a tendency for the clients to lose more weight ( $3.5 \pm 1.1$  kg vs  $2.0 \pm 1.5$  kg,  $p = .149$ ) and %BF ( $4.8 \pm 1.4\%$  BF vs  $0.1 \pm 3.1\%$  BF,  $p = .024$ ) than the guides. Neither the pre-expedition weight nor the pre-expedition %BF were significantly correlated with the losses.

**CONCLUSIONS:** Despite sleeping only 3 nights above 5000 m and having no food restrictions, mountaineers lost a significant amount of weight and %BF during a 3-wk expedition on Denali. Additional research is needed with a larger sample to make more definitive comparisons among groups of mountaineers (e.g., commercial vs non-commercial expeditions, clients vs guides, males vs females).

2151 Board #197 MAY 31 8:00 AM - 9:30 AM

**N-acetyl-cysteine Does Not Improve Cerebral Blood Flow Or Cerebral Oxygenation At An Altitude Of 3500m.**

Marie R. Grunbeck, Beth A. Beidleman, Stephen R. Muza, FACSM, Sean P. Andrew, Janet E. Staab, Charles S. Fulco. *U. S. Army Research Institute of Environmental Medicine, Natick, MA.*  
(No relationships reported)

Altitude exposure increases the concentration of reactive oxygen species (ROS) in the brain, which may impair cerebral vascular auto-regulation and result in reduced cerebral oxygenation. Whether minimizing ROS accumulation would benefit vascular function to improve oxygenation has not been determined.

**HYPOTHESIS:** N-acetyl-cysteine (NAC), a product that minimizes ROS accumulation, will increase cerebral blood flow (CBF) and cerebral oxygenation during exposure to 3500 m.

**METHODS:** Seventeen unacclimatized men and two women (mean  $\pm$  SD; 22  $\pm$  3 yr; 77  $\pm$  12 kg; 176  $\pm$  9 cm) were divided into two groups who were treated *t.i.d.* with either 800 mg of NAC (n=10, FDA-approved oral suspension) in 240 ml of diet soda or placebo (PLA, n=9, 240 ml of diet soda only) for 2 days prior to and during a 24 hr exposure to 3500 m. Near infrared spectroscopy estimated cerebral oxygenation and CBF via relative concentration changes in oxy- ( $\Delta$ [O<sub>2</sub>Hb]) and total ( $\Delta$ [Hb<sub>tot</sub>]) hemoglobin, respectively, in the mornings at sea level (SL) and following 2 hr (ALT2) and 24 hr (ALT24) of altitude exposure. Delta values were calculated as the difference between breathing 100% O<sub>2</sub> and 20.9% O<sub>2</sub> (room air).

**RESULTS:** For both groups at ALT compared to SL,  $\Delta$ [O<sub>2</sub>Hb] was higher (P<0.05), indicating decreased cerebral oxygenation at ALT2 and ALT24 while  $\Delta$ [Hb<sub>tot</sub>] did not change at ALT2 but was lower (P<0.05) at ALT24, indicating an increase in cerebral blood flow. There were no differences (P>0.05) between PLA and NAC groups at ALT for either  $\Delta$ [O<sub>2</sub>Hb] at ALT2 (2.96  $\pm$  0.6 vs 3.64  $\pm$  0.5) and ALT24 (2.71  $\pm$  0.4 vs 2.04  $\pm$  0.4) or for  $\Delta$ [Hb<sub>tot</sub>] at ALT2 (-0.64  $\pm$  0.4 vs 0.02  $\pm$  0.4) and ALT24 (-0.84  $\pm$  0.5 vs -1.46  $\pm$  0.5).

**CONCLUSION:** Results suggest that administering NAC to reduce ROS accumulation does not alter CBF and cerebral oxygenation at 3500 m.

This does not reflect the views of the U.S. Army. Funding provided by the Defense Medical Research and Development Program (D10\_I\_AR\_J5\_419).

2152 Board #198 MAY 31 8:00 AM - 9:30 AM

**Prediction of Susceptibility to Acute Mountain Sickness by Baseline Physiological Measurements Obtained at Sea Level**

Justin P. Waxman, Erin N. Harper, Rose M. Ward, Mark S. Walsh. *Miami University, Oxford, OH.* (Sponsor: Helaine Alessio, FACSM)  
(No relationships reported)

High altitude illness describes several syndromes, ranging from mild to life threatening, which can occur in unacclimatized individuals shortly after ascending to altitudes of greater than 2500 meters. Acute Mountain Sickness (AMS) includes a constellation of symptoms and is the most common (and most mild) altitude related illness, affecting approximately 40-50% of individuals ascending from sea level to high altitude each year. While the cause of AMS is well established, just what causes some people to suffer from AMS but not others is still undetermined. The only treatment for individuals suffering with symptoms of AMS is to let the individual spend more time acclimatizing or descend to lower elevation, however sometimes these options are not feasible. If susceptible individuals could be identified prior to ascending to high altitude, precautionary measures could be taken to reduce or eliminate the risk of developing AMS.

**PURPOSE:** The purpose of this study was to determine if one or more physiological variables measured at sea level could predict the occurrence of AMS at high altitude (5140 m).

**METHODS:** Twenty college students participating in a study abroad trip to the Himalayas volunteered for this study. Before leaving for Nepal, 15 sea level measurements were obtained for each participant (e.g., blood parameters, body composition, VO<sub>2</sub>max). On the trek, evaluation of AMS symptoms was obtained through the administration of the Lake Louise Questionnaire. Multiple regression analysis was used to determine whether any of the baseline values obtained predicted AMS.

**RESULTS:** A series of multiple linear regression analyses evaluated how well baseline physiological measurements predicted AMS scores at the highest elevation of the trek. Of the 15 physiological measurements, only Red Blood Cell (RBC;  $\beta$  = .47) count was found to be significantly related to the AMS score, F (1, 19) = 4.975, p < .05. The sample multiple correlation coefficient of .47, indicated approximately 17% of the variance of the AMS score in the sample was accounted for by RBC.

**CONCLUSIONS:** Results of this study suggest that a pre-trek evaluation of RBC count can help to identify a subpopulation at risk of developing AMS at high altitude. This laboratory measurement may prove to be a useful screening tool for a trek leader when creating a high-altitude protocol.

---

2153 Board #199 MAY 31 8:00 AM - 9:30 AM

**Male Gendered and Lower Arterial Oxygen Saturation are Associated with Acute Mountain Sickness**

Janet E. Staab<sup>1</sup>, Beth A. Beidleman<sup>1</sup>, Charles S. Fulco<sup>1</sup>, Allen Cymerman<sup>1</sup>, Paul B. Rock<sup>2</sup>, Stephen R. Muza, FACSM<sup>1</sup>. <sup>1</sup>*U.S. Army Research Institute of Environmental Medicine, Natick, MA.* <sup>2</sup>*Oklahoma State University, Tulsa, OK.*  
(No relationships reported)

Although the ultimate cause of acute mountain sickness (AMS) is thought to be hypoxia, arterial oxygen saturation (SaO<sub>2</sub>) has not been consistently related to AMS. The lack of a clear association may be due to measurements having been made under diverse altitudes, time points and experimental conditions (i.e., field environment with no control for hydration, medication usage, or acclimatization status).

**PURPOSE:** Assess the relationship of AMS to SaO<sub>2</sub> and demographic data in a large sample collected under well-controlled experimental conditions at 4300 m.

**METHODS:** Seven prior USARIEM studies on the summit of Pikes Peak, CO (4300 m, P<sub>B</sub> 460 $\pm$ 2mmHg) were retrospectively analyzed for AMS prevalence, resting SaO<sub>2</sub> and heart rate (HR) in 60 men (mean $\pm$ SD: 26 $\pm$ 5 yr, 79 $\pm$ 10 kg, 54 $\pm$ 7ml/kg/min) and 25 women (23 $\pm$ 4 yr, 65 $\pm$ 11 kg, 42 $\pm$ 8ml/kg/min) in the morning after rapid passive ascent the previous day. The AMS cerebral factor score (AMS-C) was calculated from the Environmental Symptoms Questionnaire and an AMS-C  $\geq$  0.7 indicated the presence of AMS. Resting SaO<sub>2</sub> and HR were measured at the same time as AMS. Independent t-tests were utilized to analyze differences in SaO<sub>2</sub> and HR between AMS sick and AMS non-sick groups while multiple logistic regression was utilized to examine the relationship between SaO<sub>2</sub>, HR, and demographic data with the presence of AMS.

**RESULTS:** Fifty-two subjects (62%) had AMS and SaO<sub>2</sub> (%) was lower (p=0.05) in sick compared to non-sick subjects (81 $\pm$ 6 vs. 83 $\pm$ 6) but HR (bpm) did not differ between groups (80 $\pm$ 15 vs. 80 $\pm$ 14). A lower SaO<sub>2</sub> was associated with AMS (OR: 1.15, 95% CI: 1.03 to 1.29; p=0.02) and men demonstrated increased odds of experiencing AMS (OR: 3.37, 95% CI: 1.05 to 10.82; p=0.02). Heart rate was not associated with AMS.

**CONCLUSION:** Under well-controlled experimental conditions male gender and a lower resting SaO<sub>2</sub> was associated with the presence of AMS.

**Acid-base Balance During Moderate Altitude Exposure Under Acid Or Alkaline Forming Nutrition**

Petra Platen, FACSM, Mirjam Limmer. *Ruhr-University Bochum, Bochum, Germany.*  
(No relationships reported)

**PURPOSE:** The present pilot study was conducted to examine the effects of moderate altitude exposure in combination with acid or alkaline forming nutrition on blood and urinary acid-base parameters.

**METHODS:** 12 healthy physical education students (n=10 males; n=2 females) were randomized into 2 groups according to the acid/alkaline load of their nutrition: the alkaline forming (ALK; n=6) and acid forming (ACID; n=6) group. 7 days of moderate hypobaric altitude exposure were obtained in the European Alps while living and hiking at an altitude level of 2434 m to 3772 m. During altitude exposure, ALK mainly consumed alkaline forming nutrients while ACID mainly consumed acid forming nutrients. Blood acid-base parameters (pH, oxygen saturation, bicarbonate, oxygen and carbon dioxide partial pressure, active/standard base excess and standard bicarbonate) were determined in capillary blood samples taken daily or every other day from the earlobe in the morning prior to breakfast. Furthermore, urinary pH values were determined daily in spontaneous early morning urine samples. All parameters were analyzed directly after sampling (blood acid-base-status: Radiometer system, urinary pH-values: pH-paper-sticks). Data were analyzed with repeated measures ANOVA.

**RESULTS:** We could not find any significant differences of the blood parameters in ALK and ACID. Urinary pH values, however, significantly declined over time in ACID (from 6.18 to 5.57) while it remained nearly constant in ALK (from 6.18 to 6.08).

**CONCLUSIONS:** The results indicate that nutritional acid/alkaline load influenced urinary acid excretion during moderate altitude exposure, while blood acid-base-balance remained more stable under these conditions. Further studies with longer or higher altitude exposure are needed to demonstrate chronic effects of nutritional manipulation on acid-base balance.

**2155** Board #201 MAY 31 8:00 AM - 9:30 AM

**Time-trial Performance Is Impaired To A Greater Degree In Hypobaric Versus Normobaric Hypoxia At The Same Ambient PO<sub>2</sub>**

Beth A. Beidleman, Janet E. Staab, Charles S. Fulco, Allen Cymerman, Stephen R. Muza, FACSM. *USARIEM, Natick, MA.*

(No relationships reported)

Previous research has suggested differences in pulmonary ventilation, arterial oxygen saturation (SaO<sub>2</sub>) and heart rate (HR) in hypobaric hypoxia (HH) versus normobaric hypoxia (NH) at the same ambient PO<sub>2</sub>.

**PURPOSE:** To determine whether time-trial (TT) performance also differs between HH and NH at the same ambient PO<sub>2</sub> (92 mmHg, 4300 m equivalent).

**METHODS:** Seventeen volunteers (21±3 yr, 79.0±11.7 kg, 48.7±4.2 ml/kg/min) exposed to HH and six volunteers (21±3 yr; 77.4±8.8 kg, 49.9±5.1 ml/kg/min) exposed to NH completed a 720-kJ TT on a cycle ergometer both at sea level (SL) and following ~1 h of exposure to the same ambient PO<sub>2</sub> (92 mmHg, 4300 m equivalent) in either HH or NH. Volunteers were free to manually increase or decrease the work rate on the cycle ergometer by 5 watt increments. Heart rate, SaO<sub>2</sub> and rating of perceived exertion (RPE) were collected every 5 min during the TT and mean values were calculated.

**RESULTS:** Five volunteers (29%) were unable to complete the 720-kJ TT in HH so only the remaining 12 volunteers were utilized for data analysis. Both groups exhibited nearly identical TT performance (min) at SL (73.3±12.2 vs. 73.2±8.2) but TT performance was longer (p=0.05) in HH (120.4±20.6) compared to NH (99.5±18.1). Similarly, the % decrement in TT performance from SL to HH (65.4±23.5) was greater (p=0.01) than the % decrement from SL to NH (35.5±13.7). In HH, the HR (bpm) and SaO<sub>2</sub> (%) (148±9; 74±4) tended (p=0.09) to be lower than in NH (157±13; 77±3). There were no differences in RPE during the TT in HH or NH.

**CONCLUSION:** Time-trial performance is impaired to a greater degree in hypobaric compared to normobaric hypoxia at the same ambient PO<sub>2</sub> equivalent to 4300 m despite similar cardiorespiratory responses. Funding provided by US Army MRCM ATO. Authors' views not official US Army or DoD policy.

**2156** Board #202 MAY 31 8:00 AM - 9:30 AM

**The Ergogenic Effect Of Oxygenation At Exhaustion In Severe Acute Hypoxia: A Placebo Effect?**

José Losa-Reyna, Jesús Gustavo Ponce-González, Rafael S. de Torres-Peralta, Ismael Pérez-Suárez, David Feijóo, Pedro J. Martínez-Muñoz, Lorena Rodríguez-García, Jaime Calle-Herrero, José A. L. Calbet. *Universidad de Las Palmas de Gran Canaria, Las Palmas de Gran Canaria, Spain.*

(No relationships reported)

At exhaustion in hypoxia (FIO<sub>2</sub>≤0.115) administration of an O<sub>2</sub>-enriched gas mixture relieves fatigue swiftly. It is unknown what minimal level of oxygenation improvement is required for this ergogenic effect. This question requires an experimental design ruling out a potential placebo effect avoiding experimental bias due to lack of concealment and deception.

**PURPOSE:** To determine what is the minimal level of oxygenation required to swiftly relieve fatigue in hypoxic exercised humans.

**METHODS:** Ten men (21.7±2.2 years; VO<sub>2</sub> max 53.0±4.4 ml·kg<sup>-1</sup>·min<sup>-1</sup>, mean±SD) performed five randomized incremental exercise tests (cycle ergometer, 80 rpm) to exhaustion on different days. One test was carried out in normoxia (Δ30w/2 min) (Nx). The other four tests started in severe hypoxia (P<sub>i</sub>O<sub>2</sub>=74 mmHg; Δ20w/2min) (HYP1). At exhaustion (inability to maintain a pedalling rate above 50 rpm despite strong verbal encouragement for 5 seconds) the breathing gas mixture was swiftly changed and subjects requested to try overcome fatigue. After two minutes the intensity was increased (Δ20w/2min) until exhaustion (HYP2). Four different gas mixtures were randomly administered in HYP2 (P<sub>i</sub>O<sub>2</sub>= 74 (placebo), 83, 91, 99 mmHg). At exhaustion, subjects were again requested to overcome fatigue when swiftly switched to breathe normoxia (NX3, P<sub>i</sub>O<sub>2</sub> 143 mmHg) and after 2 min the exercise intensity was increased (Δ20w/2min) until termination.

**RESULTS:** Similar VO<sub>2</sub>max were achieved in NX3 and in the control incremental test in Nx (3.54±0.17; 3.63±0.17, 3.66±0.16, 3.68±0.13, and 3.63±0.12). The transition to HYP2 resulted in significantly increased work (P<0.05) only for the 99 mmHg P<sub>i</sub>O<sub>2</sub>. A placebo effect accounted for 25% of the extra work performed with oxygenation in HYP2. The transition to NX3 allowed continuing the incremental exercise in all conditions. The work performed in NX3 was significantly lower when the preceding P<sub>i</sub>O<sub>2</sub> was 99 mmHg compared to the other conditions.

**CONCLUSION:** Fatigue during incremental exercise to exhaustion in severe acute hypoxia is swiftly relieved by even small increases in oxygenation. The latter combined with the existence of a placebo effect is compatible with central fatigue as the main mechanism causing exhaustion during exercise in either moderate or severe acute hypoxia.

Supported by MEC, Spain (DEP2009-11638).

**Ischemic Preconditioning Does Not Improve Cycling Capacity at Sea Level or During Acute Normobaric Hypoxia**

Elizabeth A. Hittinger, Amanda A. Price, Jochen Kressler, Kevin A. Jacobs. *University of Miami, Coral Gables, FL.*

(No relationships reported)

Ischemic preconditioning (IPC), a technique involving brief episodes of occlusion-derived ischemia followed by reperfusion, has been shown to improve outcomes from surgical procedures that necessitate prolonged ischemia. IPC may also benefit exercise performance that is limited by arterial hypoxemia, but little is known of this effect to date.

**PURPOSE:** To examine the effect of IPC of the arm on pulmonary function and peak cycling capacity at sea level (SL) and acute normobaric hypoxia (NH).

**METHODS:** Nine highly, male, trained cyclists and triathletes (32.1 ± 5.8 yr, 56.1 ± 7.0 ml/kg/min VO<sub>2peak</sub>, mean ± SD) performed four experimental exercise trials at least 48 h apart at SL and NH (12.8% F<sub>i</sub>O<sub>2</sub>, ~3900 m) with or without IPC before exercise in randomized and counterbalanced fashion. Each trial consisted of pulmonary function measurements at rest, IPC or no IPC, and a continuous progressive cycling capacity test. Pulmonary function (FVC, FEV<sub>1</sub>, FEV<sub>1</sub>/FVC, FEF<sub>25-75%</sub>, PEF) was measured using an online open-circuit metabolic cart. The IPC protocol was 4 cycles of 5 min of occlusion of one arm to 200-220 mm Hg followed by 5 min of reperfusion. The cycling capacity test started 10-15 minutes after the end of the IPC cycles and consisted of 2 min at 50 W and increases in workload by 50 W every 2 min until 150 W, and then by 20 W every 2 minutes until volitional exhaustion on an electromagnetically braked cycle ergometer. Heart rate measured by telemetry and RPE were assessed at the end of every stage and arterial oxygen saturation was measured continuously by pulse oximetry.

**RESULTS:** IPC of one arm did not significantly change peak cycling capacity at either SL (316 ± 20 vs. 323 ± 43 W, control vs. IPC) or NH (253 ± 24 vs. 251 ± 21 W). IPC also did not significantly change arterial oxygen saturation at either SL (91 ± 4 vs. 90 ± 4%, control vs. IPC) or NH (70 ± 5 vs. 68 ± 5%) or any other variable measured.

**CONCLUSION:** IPC of the arm does not positively affect pulmonary function or peak cycling capacity at SL or NH, but these results may be limited by the small amount of musculature made ischemic by the IPC procedure.

**Time-course Of Changes In Cardiorespiratory Measures Post-altitude Training: Implications For Competitive Endurance Performance**

Abigail S. Laymon, Daniel P. Wilhite, Joseph W. Duke, Jonathon L. Stickford, Joel M. Stager, Timothy D. Mickleborough, FACSM, Robert F. Chapman, FACSM. *Indiana University, Bloomington, IN.*

(No relationships reported)

Coaches have anecdotally noted that best performances following altitude training occur either: a) very early after return from an altitude training camp, or b) after a period of 10-25 days of post-altitude sea level training. However, there is little scientific evidence to support these "ideal" times for post-altitude competition.

**PURPOSE:** To describe serial changes in cardiorespiratory measures related to performance in elite distance runners over three weeks at sea-level (SL), immediately following return from a "live high - train low" (LHTL) altitude camp.

**METHODS:** Six elite male distance runners completed a 28d altitude training intervention at 2150m, following a LHTL training model. Isocapnic hypoxic ventilatory response (HVR), submaximal and maximal exercise ventilation (VE), oxygen uptake (VO<sub>2</sub>), heart rate (HR), and respiratory muscle VO<sub>2</sub> (VO<sub>2</sub>RM) were measured in the one week prior to and within 24h upon return (D1) from altitude. Additional SL measures of HVR and submaximal VE, VO<sub>2</sub>, HR, and VO<sub>2</sub>RM were taken on days 5-6 (D5), 12-13 (D12), and 20-21 (D20) post-alt. Competitive performance was assessed via race times at SL over 26d post-alt.

**RESULTS:** HVR was significantly elevated above pre-alt levels on D1 post-alt and declined back to pre-alt levels over the ensuing three weeks. There were no significant differences between any cardiorespiratory measures during maximal exercise pre- to D1 post-alt. During submaximal exercise, VO<sub>2</sub> tended to be lower at all speeds and all days post-alt as compared to pre-alt. HR was significantly lower D1, D5, and D20 at all speeds compared to pre-alt, but not at D12. Following a similar pattern, the VO<sub>2</sub>RM was less than pre-alt measures at D1 post-alt and rose to a peak at D12 before declining again at D20. Average race time in competition on days 9-10 post-alt was 0.4% slower than the athlete's pre-alt personal best; results from competition on day 26 showed an average time of 0.6% faster than pre-alt best.

**CONCLUSION:** The time course of changes in cardiorespiratory measures post-altitude training appears to follow a pattern that matches the anecdotally noted timing of best competitive performances. Whether post-altitude variations in competitive performance are explained by physiological de-acclimatization effects or post-altitude training effects has yet to be determined.

**Effects of Normobaric Hypoxia Training with Different Durations on Metabolic Risk Markers in Sedentary Men**

Takuma Morishima, Yuta Hasegawa, Hiroto Sasaki, Toshiyuki Kurihara, Takafumi Hamaoka, FACSM, Kazushige Goto. *Ritsumeikan University, Kusatsu, Japan.*

(Sponsor: Takafumi Hamaoka, FACSM)

(No relationships reported)

**PURPOSE:** To investigate the effects of normobaric hypoxia training with different durations (2wk or 4wk) on metabolic risk markers in sedentary men.

**METHODS:** Twenty one healthy men (25 ± 6 yrs, BMI: 25 ± 0.6) were divided into either 2-wk training group (2wk group; n = 11) or 4-wk training group (4wk group; n = 10). Each group conducted 12 training sessions at 65% of maximal oxygen uptake (VO<sub>2max</sub>) under normobaric hypoxia condition (FiO<sub>2</sub> = 0.15) during either 2wk (6 days per week) or 4wk (3days per week). Before and after each training period, body composition (measured by DXA), VO<sub>2max</sub>, glucose tolerance (measured by OGTT) were determined. Arterial stiffness was evaluated by brachial-ankle pulse wave velocity (baPWV).

**RESULTS:** After each training period, body fat mass and percent body fat did not change significantly in both groups. In the 2wk group, a significant increase in VO<sub>2max</sub> was observed after the training period ( $P < 0.05$ ). Although 4wk group showed increase in VO<sub>2max</sub> with training, it did not reach statistical difference ( $P = 0.056$ ). Both groups revealed significant increase in time to exhaustion during VO<sub>2max</sub> test ( $P < 0.05$ ). The 2wk and 4wk groups did not show significant change in fasting blood glucose and serum insulin concentrations. In the OGTT test, no change was observed in area under the curve (AUC) of blood glucose concentration in both groups. However, the AUC of serum insulin concentration was significantly reduced only in the 4wk group ( $P < 0.05$ ). Arterial stiffness did not change significantly in both groups.

**CONCLUSIONS:** These results indicate that hypoxia training with longer duration (4wk) causes greater improvement of insulin sensitivity compared with equivalent training with shorter duration (2wk). Although we did not find significant improvement of glucose tolerance in 2wk group, a possible reason may be marked inter-individual variation for adaptation of insulin sensitivity.

**The Association Of C-reactive Protein Level With Muscle Strength In Japanese Adult**

Lei Guan, Kaijun Niu, Yoritoshi Kobayashi, Haruki Momma, Hui Guo, Masahiko Chujo, Atsushi Otomo, Yufei Cui, Cong Huang, Ryoichi Nagatomi. *Graduate School of Medicine, Tohoku University, Sendai, Japan.*

(No relationships reported)

**BACKGROUND:** Chronic inflammation impairs muscle function. Serum C-reactive protein (CRP) level is considered to represent the grade of chronic inflammation. Even at a very low range, a cross-sectional study showed that serum CRP concentration showed an inverse relationship with muscle strength in an elderly population. We hypothesized that such association should be present at younger population group who have lower levels of CRP within the normal range (1mg/L).

**PURPOSE:** To determine the association between serum CRP level and muscle strength in Japanese middle-age male and female.

**METHODS:** We designed a cross-sectional study for 1405 (mean age and standard deviation: 45.2 ± 11.0 years) Japanese adults employees. Subjects participated in annual health check-up examination in Sendai Oroshisho Center, and the examination results for serum high-sensitivity CRP concentration (hs-CRP) and muscle strength such as grip strength and leg extension power from 2008 to 2010 were used for current study.

**RESULTS:** After adjustment for potential confounders, the adjusted mean values of grip strength (kg; mean, 95% confidence interval [CI]) across the tertile of serum CRP concentration 1.0mg/l in 1,073 male subjects were 42.9 (42.1, 43.6), 42.1 (41.4, 42.7), 41.9 (41.2, 42.6), and 41.2 (40.4, 42.1), respectively and in 332 female subjects were 26.5 (25.6, 27.4), 24.9 (24.0, 25.7), 24.5 (23.6, 25.4), and 24.0 (22.4, 25.7), respectively. (P for trend = 0.03 and 0.01, respectively). In the subgroup of 825 males subjects, leg extension power (W/kg BW) were 18.7 (18.1, 19.4), 18.2 (17.6, 18.8), 17.9 (17.3, 18.5), and 17.4 (16.7, 18.2), respectively, and in the 332 female subjects for leg extension power (W/kg; mean, 95% confidence interval [CI]) were 9.9 (9.1, 10.7), 9.8 (9.0, 10.6), 8.6 (7.7, 9.4), and 8.5 (6.7, 10.3) respectively. (P for trend <0.01 and 0.04, respectively).

**CONCLUSION:** Serum CRP concentration was found to be inversely associated with muscle strength, even within a very low range (<1.0mg/l). This finding may together with further follow up study may rationalize earlier risk stratification and subsequent exercise recommendation. This work is supported by a Grant-in-Aid under the "Knowledge Cluster Initiative" from the Ministry of Education, Culture, Sports, Science and Technology of Japan.

**The Association Of C reactive Protein Level With Muscle Strength In Japanese Adult**

Lei Guan. *Tohoku University, Sendai, Japan.*

(No relationships reported)

**BACKGROUND:** Chronic inflammation impairs muscle function. Serum C-reactive protein (CRP) level is considered to represent the grade of chronic inflammation and generally, one cross-sectional study show that serum CRP concentration is favorably related to muscle strength, even within a very low range in the elderly population. However, this association is also unclear in the Japanese adult. In this paper, we investigated the associations of muscle strength with the levels of CRP of Japanese adults who have lower levels of CRP within the normal range (1mg/L).

**PURPOSE:** To determine the association relationships between serum CRP level and muscle strength and its gain or loss in Japanese adult male and female.

**METHODS:** We designed a cross-sectional study for Japanese employees 1405 (45.2 ± 11.0 years) in their annual health check-up examination for hsCRP concentration (± mg/L) and muscle strength measured that grip strength and leg extension power measured in 2008 to 2010.

**RESULTS:** Our result show that after adjustment for potential confounders, the adjusted mean values (95% confidence interval [CI]) for the tertile of serum CRP concentration <1.0mg/l or >1.0mg/l in subjects of grip strength were In the 1,073 males subjects for grip strength measurement (kg) were 42.9 (42.1, 43.6), 42.1 (41.4, 42.7), 41.9 (41.2, 42.6), and 41.2 (40.4, 42.1),

respectively and in the 332 female subjects were 26.5 (25.6, 27.4), 24.9 (24.0, 25.7), 24.5 (23.6, 25.4), and 24.0 (22.4, 25.7), respectively. (P for trend 0.03 and 0.01). In the 825 males subjects for leg extension power measurement (age 45.0 ± 11.0) were 18.7 (18.1, 19.4), 18.2 (17.6, 18.8), 17.9 (17.3, 18.5), and 17.4 (16.7, 18.2), respectively, and in the 332 female subjects for grip strength measurement (age 42.9 ± 10.7) were 26.5 (25.6, 27.4), 24.9 (24.0, 25.7), 24.5 (23.6, 25.4), and 24.0 (22.4, 25.7), respectively (p for trend <0.01 and 0.04).

**CONCLUSION:** A lower serum CRP concentration is found to be favorably related to muscle strength, even within a very low range (<1.0mg/l). The findings suggest that maintaining CRP levels as low as possible may potentially maintain a better muscle strength.

2162 Board #208 MAY 31 9:00 AM - 10:30 AM

**Clinically Significant Side-to-Side Lower Extremity Strength Asymmetries in US Army 101st Airborne Soldiers**

Nicholas C. Clark<sup>1</sup>, Karen A. Keenan<sup>1</sup>, John P. Abt<sup>1</sup>, Timothy C. Sell<sup>1</sup>, Takashi Nagai<sup>1</sup>, Jennifer B. Deluzio<sup>1</sup>, Mita T. Lovalekar<sup>1</sup>, Larry J. McCord<sup>2</sup>, Michael D. Wirt<sup>2</sup>, Scott M. Lephart<sup>1</sup>. <sup>1</sup>University of Pittsburgh, Pittsburgh, PA. <sup>2</sup>101st Airborne Division (Air Assault), Fort Campbell, KY.

(No relationships reported)

Side-to-side (S-S) symmetry of lower extremity (LE) muscle strength is important for preventing between-limb compensations that overload one side and increase injury risk. As such, S-S comparisons in LE strength are frequently made in injury prevention and rehabilitation contexts. Past work consistently shows S-S LE strength differences <10% are normal in athletes. However, S-S LE strength differences in large military samples have not been previously reported. Considering the healthcare burden of unintentional musculoskeletal injuries, characterizing the S-S LE strength differences in Soldiers will give data of the frequency of potentially dangerous S-S muscle imbalance. This data can then be used to screen for future risk of new LE injury or re-injury.

**PURPOSE:** To describe the prevalence of clinically significant S-S asymmetry (S-S difference >10%) in LE strength of Soldiers.

**METHODS:** Fully operational male US Army 101st Airborne Soldiers (n=402; age 28.1 ± 6.6yr; height 177.7 ± 7.1cm; mass 84.1 ± 12.5kg) were tested. An isokinetic dynamometer measured concentric quadriceps (QUAD) and hamstring (HAM) mean peak torque (Nm/kg, 5 reciprocal repetitions, 60°/sec), and isometric hip abductor (ABD) mean peak force (N/kg, 3 reciprocal repetitions, 5 sec/effort). A handheld dynamometer measured isometric ankle eversion (EV) and inversion (INV) mean peak force (kg, 3 repetitions, 5 secs/effort). Counts were made of Soldiers with S-S differences >10% (designated 'suprathreshold' (ST)) and proportions calculated.

**RESULTS:** For QUAD and HAM strength, 41% had S-S differences >10% (ST range=11-50%). For ABD strength, 38% had S-S differences >10% (ST range=11-53%). For EV strength, 34% had S-S differences >10% (ST range=11-37.5%). For INV strength, 37% had S-S differences >10% (ST range=11-40%).

**CONCLUSION:** A large proportion of Soldiers (>33%) had S-S leg strength differences >10% (maximum S-S difference=53%). Consideration should be given to correction of S-S imbalances via targeted training programs. Such intervention may contribute to reducing the risk of sustaining new unintentional LE injury or re-injury, and enhance Soldiers' ability to safely and effectively execute mission essential tasks.

**Concurrent Inspiratory-Expiratory And Aerobic Training Effects On Respiratory Muscle Strength In Asthmatics**

Brandon S. Shaw<sup>1</sup>, Ina Shaw<sup>2</sup>, Gregory A. Brown, FACSM<sup>3</sup>. <sup>1</sup>Tshwane University of Technology, Johannesburg, South Africa. <sup>2</sup>Monash South Africa, Johannesburg, South Africa. <sup>3</sup>University of Nebraska at Kearney, Kearney, NE.

(No relationships reported)

The evaluation of respiratory muscle strength can prove useful to determine the severity and progress of asthma and is an appropriate indicator of an increased use of health care resources and survival in hospitalized patients with respiratory disease.

**PURPOSE:** The purpose was to evaluate and compare the effects of eight weeks of aerobic, inspiratory-expiratory training and concurrent inspiratory-expiratory and aerobic training on respiratory muscle strength.

**METHODS:** Previously sedentary, moderate-persistent asthmatics (n = 88) were divided into a non-exercising control (NOEX), aerobic trained (AERT), inspiratory-expiratory trained (IET) or endurance trained combined with inspiratory and expiratory trained (CONC) group. AERT, IET and CONC subjects exercised three times weekly over eight weeks with the AERT program (n = 22) consisting of walking/jogging at 60% of individual age-predicted maximum heart rate, the IET program (n = 22) of inspiratory and expiratory training in a semi-recumbent position at varying inspiration, expiration ratios while the CONC program (n = 22) utilized a combination of the AERT and IET programs. NOEX subjects (n = 22) were instructed to continue their usual activities and received no prescribed exercise.

**RESULTS:** While there were no significant changes in any of the measured variables in the NOEX group. AERT, IET and CONC resulted in significant (p ≤ 0.05) strength improvements in eleven of the thirteen measured inspiratory muscles. AERT and CONC resulted in significant strength improvements in all seven of the measured expiratory muscles, while IET improved the strength of five of the seven measured expiratory muscles, excluding left latissimus dorsi and left quadratus lumborum.

**CONCLUSIONS:** Programs utilizing aerobic and inspiratory-expiratory training can improve respiratory muscle strength in moderate-persistent asthmatics and are essential to the asthmatic to ensure ventilation by adapting to the increasing workloads of the disease.

2164 Board #210 MAY 31 9:00 AM - 10:30 AM

**Effects Of Muscle Strengthening Activities And Protein Intake On Fat-free Mass Percentage In Us Adults**

Jonathan Kurka<sup>1</sup>, Kelly Laurson<sup>2</sup>, Robert Cullen<sup>2</sup>, Dale Brown, FACSM<sup>2</sup>, Julie Schumacher<sup>2</sup>. <sup>1</sup>Arizona State University, Phoenix, AZ. <sup>2</sup>Illinois State University, Normal, IL.

(No relationships reported)

**PURPOSE:** The study examined the independent and dependent effects of grams of protein intake per kilogram body weight per day (PI) and frequency of participation in muscle strengthening activities per week (MSF) on fat-free mass percentage (FFM%) estimated by bioelectrical impedance analysis.

**METHODS:** The sample consisted of males (n=2,499) and females (n=2,373) aged 20-49 years from the National Health and Nutrition Examination Survey (NHANES, 2001-2004). PI and MSF were divided into three groups based on American College of Sports Medicine (ACSM) guidelines and prior research. Multiple regression was used to determine the association between varying levels of PI, MSF and FFM%, while stratifying by sex and controlling for age, race, socio-economic status, standing height, and total caloric intake.

**RESULTS:** There was a significant association between FFM% and MSF in males (0.6±0.1% per unit MSF) and females (0.4±0.1 FFM% per unit MSF). The same was true for the association between FFM% and PI in males (3.5±0.4% per unit PI) and females (5.9±0.4% per unit PI). Using MSF=0 and PI 1.4 categories respectively, compared to referent groups. It was significantly observed that the MSF=0 and PI 1.4 group interaction.

**CONCLUSIONS:** Results of the study showed that MSF and PI significantly predict FFM% increases in males and females, even when controlling for covariates. From a nationally representative sample, results indicated that higher PI was a stronger predictor of FFM% in females, while MSF was more predictive in males. Meeting ACSM guidelines of ≥2 MSF per week and the PI recommended dietary allowance (RDA) of >0.8 showed significant increases in FFM% in males and females.

### Asymmetry In Parkinson's Disease Is Reflected In The Timed Up And Go Test

Kyle M. Rose, Arend W. A. Van Gemmert, Jan M. Hondzinski, Li Li, FACSM. *Louisiana State University, Baton Rouge, LA.*  
(No relationships reported)

The cardinal symptoms of Parkinson's disease (PD) are movement related. The severity and effects of the disease, along with the effectiveness of rehabilitation within this population, can be measured using the Timed Up and Go (TUG). Since PD manifests itself typically with asymmetrical symptoms, we reasoned that asymmetry might influence performance of the TUG test in this population. We investigated whether TUG scores were influenced by turning direction congruent with the most affected side of PD patients.

**PURPOSE:** To determine if asymmetry observed in PD influences TUG scores when turning toward or away from the most affected side.

**METHODS:** Performance of the TUG test by people with PD was measured electronically in three segments: approaching the turn (approach), turning (turn), and returning back to the chair (return). Each patient completed the course a total of six times, turning different directions three times each. The segments collected in each trial were analyzed relative to the total time in seconds. Mean and standard deviations of the relative approach, turn, and return segments, in addition to total time for the most vs. least affected sides were analyzed using one-tailed, paired T-Tests. The most affected side was determined by leg rigidity on the United Parkinson's Disease Rating Scale (UPDRS).

**RESULTS:** The relative approach, turn, and return percentages and the total mean times (seconds) and standard deviations on turns toward the most affected side were  $2.26\% \pm 0.52$  ( $P < .05$ ),  $2.17\% \pm 0.61$  ( $P < .05$ ), and  $5.35(s) \pm 1.98$  ( $P < .05$ ), respectively. P-values less than .05 indicated that approach and turn segments as well as total times differed between most and least affected sides.

**CONCLUSIONS:** Our results indicate directional turning to the most affected side vs. the least affected side can produce different TUG scores in PD patients. This difference can be primarily attributed to the relative timing of the turn segment. This outcome offers greater insight into asymmetrical movement patterns for people with PD that should be considered when designing training interventions for this population.

### Emergency Brake Response Time after Stroke

Hui Yu Shih<sup>1</sup>, Chih Chung Wang<sup>2</sup>, Jing Min Liang<sup>1</sup>, Wei Tso Hung<sup>1</sup>, Ying Yi Chen<sup>1</sup>, Jia Hroung Wu<sup>3</sup>, Wen Lan Wu<sup>1</sup>. <sup>1</sup>*Kaohsiung Medical University, kaohsiung, Taiwan.* <sup>2</sup>*Kaohsiung Medical University Hospital, kaohsiung, Taiwan.* <sup>3</sup>*Hsiuping Institute of Technology, Taichung, Taiwan.*  
(No relationships reported)

**INTRODUCTION:** Previous research has shown that most of stroke patients didn't obtain enough information about resuming driving during their hospital stay and nearly half of them would like to have driving training to help them drive safely.

**PURPOSE:** For assessing the driving capabilities, 3 stroke patients (mean age=48.33±4.04) with right hemiplegia and 10 healthy controls (mean age=22.80±2.39) were included in this study to investigate whether their ability was sufficient for the emergency braking function.

**METHODS:** The driving simulator was used in this study. This simulator consisting of actual brake and accelerator pedal assemblies attached to an automobile steering column was constructed. A 17-in color monitor that displayed a driving simulation was placed in front of the steering wheel. The monitor was positioned at the subject's eye level, and the steering wheel was placed at a height to represent his or her normal driving position. An automobile seat is adjustable for the patient's height. Subjects were instructed to drive in the city condition, the average speeds ranged from 45 to 55 km/hr. The machine recorded the time taken from the appearance of the walker to brake until the moment the patient began to lift the foot from the accelerator pedal; this was recorded as the reaction time. The machine also calculated the time taken from the moment the patient began to release the accelerator pedal to the moment the patient depressed the brake pedal; this was recorded as the brake time. Totally, each subject was required to apply the brake pedal five times during a 100-second trial.

**RESULTS:** On the braking task, normal controls and 1 of 3 patients (brunnstrom stage 6) were able to completely avoid a collision with the walker. However, the collision occurred once during their 5 trials for the other 2 patients (brunnstrom stage 5 and 6), respectively. The mean reaction time of the patients was 983.67±322.41 ms, which was significantly longer than that of healthy volunteers (643.00±78.72 ms). The mean brake time of patients and controls was 374.33±157.51 ms and 206.90±37.17 ms, respectively.

**CONCLUSION:** The braking time of the patients remained higher than the controls. The results suggested that not only "reaction time" but also the "brake time" were the important factors determining the ability to drive again.

### Interval Active Assisted Cycling Improves Balance in Individuals with Parkinson's disease

Angela L. Ridgel, Emily J. Fickes, Corey A. Peacock, Kayla A. Wilson, Megan L. Williamson. *Kent State University, Kent, OH.* (Sponsor: Ellen L. Glickman, FACSM)  
(No relationships reported)

Parkinson's disease (PD) is a progressive neurodegenerative disorder that results in tremor, rigidity, bradykinesia and postural instability. As PD progresses, balance impairment can lead to increases in falling and decreases in quality of life. With the progressive nature of PD and the short term effect of medication on balance it is critical to identify rehabilitative interventions that minimize disease-related impairments.

**PURPOSE:** To determine the effects of a four week interval active-assisted cycling program on balance in individuals with Parkinson's disease.

**METHODS:** Individuals were counterbalanced into two groups: a non-exercise control group and an exercise group. Participants in the exercise group completed 30 minutes of interval active-assisted high-rate cycling with 5 minutes of warm-up and cool-down, three times a week for four weeks. Balance was assessed by testing postural stability, Clinical Test of Sensory Integration of Balance/Clinical Test of Sensory Integration of Balance/fall risk and sensory integration of balance (m-CTSIB) using the Biodex Balance System SD. The Biodex Balance System quantifies the ability to maintain postural stability on an unstable surface and the ability to move the centre of mass within the limits of stability utilizing a circular platform that moves in the anterior-posterior and medial-lateral axes. Balance was also assessed using the Berg balance scale. All participants (exercise and control groups) were tested at baseline, 2 weeks and 4 weeks.

**RESULTS:** Repeated-measures ANOVA analysis demonstrated a significant ( $p = 0.025$ ) improvement in postural stability in the exercise group ( $1.66 \pm 1.7$  pre,  $1.30 \pm 1.0$  post). Although there was no significant change in fall risk ( $p = 0.371$ ;  $2.0 \pm 1.1$  pre,  $1.74 \pm 0.76$  post) and m-CTSIB ( $p \leq 0.088$ ;  $1.11 \pm 0.51$  pre,  $0.86 \pm 0.41$  post), there was improvement in both scores. Furthermore, slight, but non-significant, improvements were also present in the Berg balance scale scores after 4 weeks ( $p = 0.239$ ;  $38.8 \pm 11.1$  pre,  $42.6 \pm 13.9$  post). However, this slight difference moves this group from the medium fall risk to the low fall risk category.

**CONCLUSION:** A four week interval active-assisted cycling intervention leads to improvements in some measures of balance in individuals with PD.

### Electromyographic Responses Across Repeated Maximal Isometric And Concentric Muscle Actions

Clayton L. Camic<sup>1</sup>, Marcia L. Taddy<sup>1</sup>, Jorge M. Zuniga<sup>2</sup>, Terry J. Housh, FACSM<sup>3</sup>, Daniel A. Traylor<sup>3</sup>, Haley C. Bergstrom<sup>3</sup>, Richard J. Schmidt<sup>3</sup>, Glen O. Johnson<sup>3</sup>.  
<sup>1</sup>University of Wisconsin-Platteville, Platteville, WI. <sup>2</sup>Western New Mexico University, Silver City, NM. <sup>3</sup>University of Nebraska-Lincoln, Lincoln, NE.  
(No relationships reported)

**PURPOSE:** To examine the pattern of electromyographic (EMG) responses associated with fatigue across repeated maximal isometric (ISO) and concentric (CON) muscle actions.

**METHODS:** Twelve female subjects (mean age  $\pm$  SD = 21.1  $\pm$  1.4 yrs; BW = 63.3  $\pm$  7.4 kg) volunteered to perform ISO and CON muscle actions of the leg extensors on a Cybex 6000 isokinetic dynamometer on three separate days. The first visit was structured as an orientation session to familiarize the subjects with the testing protocols. During the second and third visits, the subjects performed randomly ordered ISO and CON fatigue protocols separated by 72 hours. The intermittent ISO fatigue protocol involved 30 maximal ISO muscle actions that were sustained for 3 seconds followed by 3 seconds of rest. The CON fatigue protocol involved 30 consecutive maximal CON muscle actions at 30°·s<sup>-1</sup>. In addition, EMG signals were recorded from the vastus lateralis during the ISO and CON fatigue protocols. The relationships for torque, EMG amplitude, and EMG mean power frequency (MPF) versus repetition number were examined using polynomial regression analysis.

**RESULTS:** There were significant ( $p < 0.05$ ) decreases across the 30 repeated maximal ISO muscle actions for torque (linear,  $r^2 = 0.95$ ), EMG amplitude (quadratic,  $R^2 = 0.44$ ), and EMG MPF (linear,  $r^2 = 0.62$ ). In addition, there were significant decreases across the 30 repeated maximal CON muscle actions for torque (quadratic,  $R^2 = 0.97$ ), EMG amplitude (quadratic,  $R^2 = 0.46$ ), and EMG MPF (quadratic,  $R^2 = 0.86$ ).

**CONCLUSIONS:** The pattern of responses for EMG amplitude indicated that both the ISO (quadratic,  $R^2 = 0.44$ ) and CON (quadratic,  $R^2 = 0.46$ ) muscle actions led to a fatigue-induced de-recruitment of activated motor units and/or a reduction in the global firing rate that occurred after 10 - 15 maximal repetitions. These findings also suggested that complete muscle activation during the maximal ISO and CON muscle actions required multiple repetitions. Furthermore, the decreases in EMG MPF during both the ISO (linear,  $r^2 = 0.62$ ) and CON (quadratic,  $R^2 = 0.86$ ) muscle actions were parallel to the linear ( $r^2 = 0.95$ ) and quadratic ( $R^2 = 0.97$ ) decreases in torque, respectively. Thus, the present findings suggested that the mechanisms of fatigue responsible for decreases in torque were consistent between the ISO and CON muscle actions.

2169 Board #215 MAY 31 8:00 AM - 9:30 AM

### Trunk Kinematics Analysis during Acute Loading Before and After Prolonged Loading of the Paraspinal Tissues

Michael W. Olson. Southern Illinois University Carbondale, Carbondale, IL. (Sponsor: M. Daniel Becque, FACSM)  
(No relationships reported)

Continuous loading of the low back tissues results in modified neuromuscular output to external perturbations, and influences temporal and spatial movement variables. It is believed that these movement outcomes provide evidence to support hypotheses related to movement disorders.

**PURPOSE:** To observe trunk kinematics parameters after introduction of an acute load before and after passive cyclic trunk flexion-extension exercise.

**METHODS:** Fifteen healthy volunteers (7 males, 8 females; 21.3  $\pm$  2.1 yrs, 1.74  $\pm$  0.08 m, 70.8  $\pm$  11.8 kg) participated. Reflective markers were adhered to the skin over bony landmarks at C7, L1, L3, and S1 for kinematics analysis. An isokinetic dynamometer was used in performing two, five min sets of cyclic trunk flexion-extension conditions at a preset velocity of 10°/s through the subjects' range of trunk motion from seated upright position at a: 1) passive and 2) active. Blocks of three trials were performed before and after (3 blocks, B) each trunk cyclic loading period as subjects stood on a platform while holding a crate affixed to a pulley system with a 9 kg mass attached. A triaxial accelerometer affixed to the crate was used to determine the onset time of trunk perturbation. Kinematics dependent variables included trunk displacement (Dis\_T), peak trunk velocity (PV\_T), rate of trunk displacement (SLOPE), and SLOPE to PV\_T ratio (VR). A 2 x 3 x 2 (condition x block x gender) repeated measures ANOVA was performed on the kinematics data. Alpha was set at 0.05.

**RESULTS:** A significant difference for Dis\_T between blocks was present (B1: 10.13  $\pm$  5.0°, B2: 8.24  $\pm$  4.8°, B3: 8.11  $\pm$  5.0°,  $p < 0.01$ ). Gender difference were present for PV\_T (males: 49.47  $\pm$  22.0°·s<sup>-1</sup> vs. females: 60.85  $\pm$  38.1°·s<sup>-1</sup>,  $p < 0.01$ ) and SLOPE (males: 26.4  $\pm$  13.1°·s<sup>-1</sup> vs. females: 30.1  $\pm$  16.7°·s<sup>-1</sup>,  $p < 0.032$ ). A non-significant trend ( $p = 0.0518$ ) was present for VR between B (B1: 0.501  $\pm$  0.16, B2: 0.539  $\pm$  0.13, B3: 0.539  $\pm$  0.10). All other variables were not significantly different.

**CONCLUSIONS:** Kinematic differences were not apparent between conditions, which may or may not agree with neuromuscular response of the system to these protocols. However, there is evidence present to indicate a time-dependent modified kinematics response to these protocols.

2170 Board #216 MAY 31 8:00 AM - 9:30 AM

### Effect Of Coffee On Dual-task Performance

Mojdeh Baniasadi, Nassim Nadji, Jeremy A. Patterson, FACSM, Douglas F. Parham. Wichita State University, Wichita, KS.  
(No relationships reported)

**PURPOSE:** To assess the effects of coffee on dual-task performance (DtP).

**METHODS:** 23 college-aged individuals (15/8 m/f; 25 $\pm$ 3.4 yrs) participated in this study. Each participant attended 3 sessions (Familiarization, Baseline, and Experimental). Before each session, participants were asked to abstain from consuming caffeinated beverages the night before testing. The DtP assessment was completed during all three visits, this consisted of testing cognition (Stroop color-word test/ N-back test) while measuring balance (modified CTSIB) at the same time. The modified CTSIB test consist of four, 30-second tests; Condition 1; eyes open on a firm surface, Condition 2; eyes closed on a firm surface, Condition 3; eyes open on a foam surface, Condition 4; eyes closed on a foam surface reporting the Stability Index as the average position of the participant's body from center. In Conditions 1 and 3, subjects were asked to stand on the balance machine with eyes open and respond to the Stroop color-word test by naming the color of a word that appears on the screen in front of them in a color different from its name. In Conditions 2 and 4 of balance test, the N-back test was completed with eyes closed and participants responded by saying 'yes' when a word read had already been read aloud two words previously. Additionally, on the Experimental visit participants were asked to consume one cup of brewed coffee (12 oz) that contain 240 mg caffeine, and after 30 minutes the DtP assessment was repeated. Statistical analysis was performed using paired sample t-test, with significance set at  $p \leq 0.05$ .

**RESULTS:** Outcomes suggest that the DtP assessment showed significant differences between Condition 1 ( $p = 0.018$ ) and Condition 3 ( $p = 0.013$ ) at Baseline compared to Familiarization. Moreover, after receiving coffee the results of all DtP assessments indicated no significant difference between Baseline and Experimental ( $p = 0.063$ ;  $p = 0.390$ ;  $p = 0.992$ ;  $p = 0.204$ ).

**CONCLUSION:** The data of this study suggests that the DtP assessment requires a Familiarization visit. In addition, significant improvement appears on DtP in Condition 1 and 3, but it does not report any significant effect on DtP after consuming coffee.

2171 Board #217 MAY 31 8:00 AM - 9:30 AM

### Gaze Behavior In Response To A Dynamic Obstacle With Time Delays In Young Adults

Fabricio Saucedo<sup>1</sup>, Emily McIntosh<sup>2</sup>, Lori Vallis<sup>2</sup>, Rebecca Reed-Jones<sup>1</sup>. <sup>1</sup>The Univ. Of Texas at El Paso, El Paso, TX. <sup>2</sup>University of Guelph, Guelph, ON, Canada.  
(No relationships reported)

Dynamic obstacles pose a unique challenge to the motor control system. On-going locomotor patterns must be quickly adapted to changes in obstacle height and position in order to successfully avoid collision. Adaptations of motor patterns are based on available visual information regarding the obstacle and body position in space. Thus how vision is being directed (gaze behavior) may be critical to successful obstacle avoidance and have important implications for falls in older adults.

**PURPOSE:** To examine the gaze behavior of healthy young adults as they negotiate a dynamic obstacle with varying time delays.

**METHODS:** Six young adults performed 36 walking trials over an obstacle that, following trigger of a laser beam, moved (with a zero, short or long delay) and ended in either a high (45% of leg length) or low (10 cm lower) position. Gaze behavior was measured using a head mounted eye tracking system (ISCAN, MA, USA; 60 Hz). Six possible points of interest (POI) within the movement environment were identified (wall ahead, travel path pre obstacle, foot position pre obstacle, obstacle, foot position post obstacle, and travel path post obstacle). Movement trials were windowed three steps before obstacle crossing and two steps afterwards. Fixation of gaze with respect to each of the POIs was coded for the windowed trials and converted to a % of trial

time. Repeated measures ANOVA was conducted on the fixation data with obstacle height and time delay as independent factors.

**RESULTS:** A significant interaction between obstacle height\*POI was found ( $p = .024$ ). Participants directed gaze to the obstacle itself when the obstacle moved from a low position to a high position. In contrast, gaze was directed to the post foot position when the obstacle moved from a high position to a low position. Overall, young adults directed their gaze to either the obstacle or the post foot position on all trials with little fixation spent pre obstacle. No significant effect of time delay was found for gaze behavior.

**CONCLUSION:** The results indicate that obstacle height rather than time-delays change where young adults direct their gaze. Future research will examine the gaze behavior of older adults to assess whether there are differences in gaze behavior and whether this contributes fall risk.

---

2172 Board #218 MAY 31 8:00 AM - 9:30 AM

**Assessment Of Oculomotor Control And Balance In Concussed And Non-concussed Individuals**

Nicholas Murray, Pradeep V.N Ambati, Fabricio Saucedo, Monica Contreras, Anthony Salvatore, Rebecca Reed-Jones. *The Univ. Of Texas at El Paso, El Paso, TX.*  
(No relationships reported)

Damage sustained from a concussion can result in lingering balance disturbances and vertigo. Rehabilitation focused on the vestibular system has shown to improve balance performance post concussion. However the role of the vestibular system in oculomotor control (stabilization and tracking) has been generally overlooked. Investigating oculomotor control post concussion could provide valuable scientific information regarding vestibular function post concussion.

**PURPOSE:** The purpose of this research is to study oculomotor function during concussion recovery. The goal is to provide evidence for the use of oculomotor assessment in addition to balance assessment post concussion.

**METHODS:** Nine post concussion athletes and nine non-concussed athletes performed 3 balance trials while wearing a head mounted eye tracking system (Applied Science Laboratories, MA, USA). Balance performance was measured using the Nintendo WiiFit® soccer heading game. This test assesses combined oculomotor control and balance as it incorporates directing center of pressure in response to visual stimuli. Gaze stabilization was used as the measure of oculomotor control and coded as the percent of time fixed on the center of the game screen. Between subjects ANOVA and Pearson Product correlations were performed for gaze time on center and soccer game score.

**RESULTS:** A significant correlation between gaze time on center and soccer game score was found, however; these were different between the concussed and non-concussed groups. Non-concussed individuals had a positive correlation ( $r = .792$ ,  $p = .011$ ) between gaze and soccer variables. In contrast, concussion subjects showed a significant negative correlation ( $r = -.846$ ,  $p = .004$ ). No significant between group differences in Wii score or time on center were found. However, soccer score was lower in the concussed ( $94.90 \pm 21.80$ ) versus non-concussed group ( $132.2 \pm 25.57$ ), while time on center was similar between the groups (63.5% non-concussed versus 64.2% concussed).

**CONCLUSION:** Results indicate deficits in visually driven balance responses in concussed athletes. Concussed athletes directed gaze to the center however balance responses were reduced. Further research will examine the association of these measures with the vestibular system.

2173 Board #219 MAY 31 8:00 AM - 9:30 AM

**Changes in Kinematic Sequence with Fatigue: A Comparison of Female Dancers and Female Athletes**

Karl F. Orishimo<sup>1</sup>, Ian J. Kremenic<sup>1</sup>, Evangelos Pappas<sup>2</sup>, Marshall Hagins<sup>2</sup>, Marijeanne Liederbach<sup>3</sup>. <sup>1</sup>Lenox Hill Hospital, New York, NY. <sup>2</sup>Long Island University, Brooklyn, NY. <sup>3</sup>NYU Langone Medical Center Hospital for Joint Diseases, New York, NY. (Sponsor: Malachy McHugh, FACSM)  
(No relationships reported)

The propulsive phase of a stretch-shortening cycle movement is characterized by a proximal to distal transfer of joint velocities, with peak hip velocity preceding peak knee velocity, which in turn precedes peak ankle velocity. Due to their extensive training in jumping activities, dancers are considered experts in these tasks. While fatigue affects jump biomechanics, it is not known how it alters the kinematic sequence or if fatigue-induced changes are different between dancers and athletes.

**PURPOSE:** To compare the effects of fatigue on kinematic sequence of female dancers and female athletes during the propulsive phase of a single-leg countermovement jump.

**METHODS:** Twenty female dancers and twenty female athletes performed single-leg countermovement jumps to 50% of their maximum jump height before and after a lower extremity fatigue protocol. Joint kinematics were measured with eight infrared cameras and 22 markers. For each subject, the velocity profile of each joint was normalized to the maximum velocity achieved by that joint. Repeated-measures ANOVA (Group x Joint x Fatigue) were used to compare the timing of peak joint velocities as well as the percentage of peak velocity of each joint when the other two were maximal.

**RESULTS:** As documented elsewhere, dancers achieved peak joint velocities later in the propulsive phase compared to the athletes (Group:  $P = 0.044$ ). With fatigue, peak hip and knee velocities were delayed while ankle timing was unchanged.

**CONCLUSIONS:** Fatigue affected the kinematic sequence in both groups similarly by shifting the timing of peak hip and knee velocities closer to that of peak ankle velocity. This could be to compensate for the changes in muscle mechanics following fatigue in order to maintain jump height.

Percent of propulsive phase at which peak joint velocities occurred; \* = Effect of Fatigue  $P < 0.05$

|              | Hip          | Knee         | Ankle      |
|--------------|--------------|--------------|------------|
| Pre-Fatigue  | 69.0 ± 7.1   | 74.8 ± 6.0   | 84.1 ± 3.9 |
| Post-Fatigue | 71.8 ± 7.1 * | 77.1 ± 6.0 * | 84.6 ± 3.9 |

2174 Board #220 MAY 31 8:00 AM - 9:30 AM

**Assessment Of Prediction And Learning Effect On Dynamic Postural Stability In Single Leg Landing Task**

Issei Ogasawara<sup>1</sup>, Yoshio Koyanagi<sup>1</sup>, Ken Nakata<sup>2</sup>. <sup>1</sup>Mukogawa Women's University, Nishinomiya, Japan. <sup>2</sup>Osaka University, Suita, Japan.  
(No relationships reported)

**PURPOSE:** The purpose of this study is to investigate the effect of prediction for the postural demands after single legged landing and to elucidate whether human can learn how to stabilize their posture even in the unpredictable condition.

**METHODS:** 12 subjects with no histories of lower limb surgery or neurological disorder participated in this study. The subjects were asked to land on the target with their dominant leg from the 30 cm high box. The length of the center of pressure (CoP) trajectory from 0 to 100 ms after foot impact was compared between following two conditions. In the normal condition (NC), the target was displayed before the trial to allow the subjects to predict the postural demands after the foot impact. In perturbation condition (PC), the target was displayed beforehand, however, when the subject started their landing, it was moved to another position (10 cm apart from the initial position) in order to interfere with the subjects' prediction for postural adjustment.

**RESULTS:** Figure compares the trial-by-trial change for the CoP trajectory length between NC and PC from a representative subject. The white circle denotes NC and the gray dose PC. In NC, the length gradually decreased as the subject adopted to stabilize the post landing posture, however, in PC, the length was entirely longer than that of NC ( $NC 0.25 \pm 0.69$  cm vs  $PC 0.32 \pm 0.56$  cm,  $p < 0.05$ ) and the obvious adaptation was not observed. Similar results were also obtained in CoP velocity.

**CONCLUSIONS:** Our findings suggest that it is difficult to learn the postural stabilization skill in unpredictable condition. Difficulty in predictive postural adjustment may contribute to develop the sports injury, such as knee ligament injury, which occurs in unpredictable situation.

---

2175 Board #221 MAY 31 8:00 AM - 9:30 AM

**Assessment Of Muscle Use With Surface Electromyography And Positron Emission Tomography**

Jens Bojsen-Møller<sup>1</sup>, Thomas Losnegard<sup>1</sup>, Jostein Hallén<sup>1</sup>, Per Aagaard<sup>2</sup>, Inge-Lis Kanstrup<sup>3</sup>, Kari Kalliokoski<sup>4</sup>, S Peter Magnusson<sup>5</sup>. <sup>1</sup>Norwegian School of Sport Sciences, Oslo, Norway. <sup>2</sup>University of Southern Denmark, Odense, Denmark. <sup>3</sup>Herlev Hospital, University of Copenhagen, Copenhagen, Denmark. <sup>4</sup>University of Turku, Turku, Finland. <sup>5</sup>Bispebjerg Hospital, University of Copenhagen, Copenhagen, Denmark.  
(No relationships reported)

Surface EMG (SEMG) has certain inherent limitations when applied during dynamic human movements. By quantifying exercise induced glucose uptake, positron emission tomography (PET) presents an alternative method to acquire detailed 3D information about muscle use during complex human movement. PET and SEMG have not previously been combined.

**PURPOSE:** To compare PET and SEMG obtained during different contractile tasks.

**METHODS:** In total 12 subjects participated: 6 subjects performed concentric vs. eccentric plantarflexor (PFLX) contractions on separate days with similar load (30%MVC) and duration (6 contractions/min for 30 min). 6 other subjects performed aerobic whole body exercise in a skiing ergometer (20 min bouts, intensity: 55-75% of VO<sub>2</sub>max). Prior to exercise, a tracer ([18F]FDG) was injected, during exercise EMG was sampled, and after exercise the subjects underwent a PET scanning. An MRI scan was performed for anatomical reference. Muscle activation/use during exercise was quantified by 1) peakEMG (%MVC) and 2) by a glucose uptake index (GUI) for each muscle based on PET scans. To determine associations between the two methods, linear regression analyses was performed, and Pearson product-moment correlations were computed.

**RESULTS:** Two PFLX muscles were examined in eccentric/concentric conditions and 10 muscles for the aerobic exercise trial. For the PFLX exercise average GUI of all muscles (related to passive muscle) was 161±59%, while EMG was 32±18% MVC. A positive, weak but significant (r=0.45, P<0.05) correlation was seen for this condition. For the aerobic exercise, average GUI of all muscles (related to bone tissue) was 1641±1184%, while EMG was 37±18 %MVC with a positive moderate correlation (r=0.85, P<0.01).

**CONCLUSIONS:** The two methods are highly different with respect to time/spatial resolution, to actual measurement (electrical voltage vs. glucose uptake) and to normalization method (EMG is related to maximal contraction, PET is normalized to passive tissue uptake). Nonetheless, a reasonable relation exists between the outcomes suggesting certain compatibility. Depending on the research question, PET may be an alternative or supplementary method when high spatial resolution is required and further when muscles that can not be accessed by EMG (surface or indwelling) are examined.

---

2176 Board #222 MAY 31 8:00 AM - 9:30 AM

**Heterogenic Effect of Exercise Induced Quadriceps Muscle Damage on Ankle Kinematics and Step Cycle Timing During Slope Walking**

Manning Sabatier<sup>1</sup>, Chris Black<sup>2</sup>, Megan Luallen<sup>1</sup>, Kourtney Aylor<sup>1</sup>, Samantha Drew<sup>1</sup>. <sup>1</sup>Clayton State University, Morrow, GA. <sup>2</sup>University of Mississippi, University, MS. (Sponsor: Melanie Poudevigne, FACSM)  
(No relationships reported)

It is currently not clear how exercise induced muscle damage (EIMD) affects heterogenic proprioception in the lower extremities.

**PURPOSE:** To determine whether EIMD in one muscle could affect lower limb function. It was hypothesized that quadriceps EIMD would affect ankle angle trajectories and step cycle timing during walking.

**METHODS:** Eight subjects (age: 24+/-2, height: 64+/-5 in, mass: 60+/-5 kg) were tested. Electrogoniometers were used to monitor ankle angle during slope walking (-10, 0 and 10 degrees) at 2.5 mph. Maximal isometric (IM) strength was measured with the knee at 75 degrees of flexion. EIMD was induced with 60 repetitions of eccentric-only quadriceps muscle contractions with 110% of 1RM, then walking and IM strength were evaluated again.

**RESULTS:** EIMD resulted in a 22% loss of IM strength (p<0.01). Ankle angle kinematics vary greatly with slope before EIMD. The most significant differences are much larger stance phase 1) passive ankle flexion during downslope (Ds) walking (30 degrees vs 20 and 13 degrees for Lv and Us, p<=0.01) and 2) active ankle extension associated with thrust during upslope (Us) walking (35 degrees vs 28 and 18 degrees for Us and Lv, respectively, p<=0.05). There was a loss of the slope effect on excursion during the thrust period of stance after injury and more time was allocated to the swing phase during downslope walking after the EIMD protocol (p=0.04).

**CONCLUSION:** Quadriceps EIMD alters slope-related ankle kinematics and step cycle timing, especially during Ds walking. Since the quadriceps undergoes large excursions of loaded muscle lengthening during the stance phase of Ds walking, these results support the idea that the distribution of proprioceptive feedback related to stretch emanating from the quadriceps is important for normal control of downslope walking.

**Head and Trunk Coordination in Turning between Young and Old Adults**

V. N. Pradeep Ambati<sup>1</sup>, Nicholas Murray<sup>1</sup>, Fabricio Saucedo<sup>1</sup>, Douglas Powell<sup>2</sup>, Rebecca Reed-Jones<sup>1</sup>. <sup>1</sup>The Univ. Of Texas at El Paso, El Paso, TX. <sup>2</sup>Fairmont State University, Fairmont, WV.  
(No relationships reported)

Turning is a task critical to everyday life. Without the ability to turn people cannot navigate in a crowded market or safely turn down a hallway in their home. Unfortunately, turning is a movement that is significantly interrupted by aging and by neurological deficits such as Parkinson's disease. Currently, there is limited research regarding this important movement and the motor control associated with it.

**PURPOSE:** In previous work using virtual reality, it was found that the initial eye movement made prior to redirecting the body may be a critical trigger for releasing a coordinated turning response (head leads the trunk). The purpose of the current study was to translate these previous findings to real world walking. Therefore, the current study examined segment coordination during a 90° turn in healthy young and older adults under two visual conditions: Free Gaze and Fixed Gaze.

**METHODS:** Whole body kinematics were recorded using a Vicon motion capture system. Participants performed walking trials (straight, right turn, and left turn) randomly presented in two experimental conditions (Free Gaze and Fixed Gaze). In addition, eye movement was recorded using a head mounted eye tracking system (Applied Science Laboratories). Repeated measures ANOVAs for each group (young and older adults) were performed on the time between segment reorientation.

**RESULTS:** Young adults showed a significant (p < .05) difference in the relative head and trunk reorientation time between Free Gaze (255 ± 72 ms) and Fixed Gaze (54 ± 81 ms) conditions. In contrast, older adults showed similar relative head and trunk orientation between Free Gaze (68 ± 31 ms) and Fixed Gaze (86 ± 93 ms).

**CONCLUSION:** Results in young adults support previous findings that when visual redirection is constrained segment reorientation is altered and segments move together in an 'en bloc' movement strategy. More interestingly, older adults did not show a head leading strategy during the turn in either visual condition; the relative time between head and trunk was similar between Free and Fixed Gaze conditions. These findings indicate that older adults may have compromised turning coordination. Further investigation of the eye movement data will determine whether this is a result of lack of eye movement in the Free Gaze condition.

---

2178 Board #224 MAY 31 8:00 AM - 9:30 AM

**The Effects Of Additional Load On The Occurrence Of Bilateral-Deficit: Mechanical Or Neural Factors?**

Kevin D. Wright<sup>1</sup>, Scott M. Graham<sup>2</sup>, Gavin L. Moir<sup>3</sup>, Chris Connaboy<sup>1</sup>. <sup>1</sup>Edinburgh Napier University, Edinburgh, United Kingdom. <sup>2</sup>University of the West of Scotland, Glasgow, United Kingdom. <sup>3</sup>East Stroudsburg University, Stroudsburg, PA.  
(No relationships reported)

Bilateral deficit (BD) is the reduction in the maximal voluntary force output from a synchronous bilateral contraction, when compared to the combined force outputs in biomechanically similar unilateral contractions (Bobbert et al., 2006). A number of theories for the occurrence of BD have been suggested; (1) an inhibition in neural drive or (2) differences in the mechanics between bilateral and unilateral jumping. If BD is principally a neural phenomenon, then a change in load should not affect the relative magnitude of BD observed. However, if there is a mechanical basis for BD then a difference will present in the observed BD between unloaded and loaded conditions.

**PURPOSE:** Examine the effects of an additional load of 10% body-weight (BW) on the occurrence of bilateral deficit.

**METHODS:** A group of 26 physically active students (22.3±4yrs, 22 male, 4 female) performed a series of counter-movement jumps under both unloaded (BW) and loaded (BW+10%) conditions: 3 x unilateral left leg jumps (UL), 3 x unilateral right leg jumps (UR) and 3 x bilateral jumps (BL). A period of 30-s rest was taken between jumps, with 5-min between sets of jumps. Participants were randomly assigned to 1 of 2 groups. Group 1 performed unloaded followed by loaded condition. Group 2 performed loaded followed by unloaded condition. Vertical jump height was determined using a jump mat with the percentage difference (%diff) in jump height between the combined unilateral jumps (UL + UR) and BL for the unloaded and loaded conditions being analyzed.

**RESULTS:** No effect for jump order was observed ( $p > 0.05$ ). A significant reduction in BD was observed in the jump heights recorded during the unloaded and loaded conditions (unloaded %diff:  $81.1 \pm 6.7\%$ ; loaded %diff:  $82.8 \pm 7.9\%$ ;  $p < 0.05$ )

**CONCLUSION:** A significant reduction in the difference between unilateral and bilateral vertical jumps resulting from the addition of extra load suggests that mechanical factors may predominate in BD, with the additional load causing a shift in the force-speed continuum of the active musculature.

**Neural Drive during Explosive Force Production exceeds that at Maximum Force**

Jonathan P. Folland, Adam Fry. *Loughborough University, Leics, United Kingdom.* (Sponsor: Glyn Howatson, FACSM)

(No relationships reported)

Anecdotal observations suggest that the neural drive during explosive force production may exceed that achieved at maximum voluntary force (MVF) i.e. the rising vs plateau phase of contraction, and these high levels of neural drive may be followed by an immediate decline. However, these phenomena have not been documented.

**PURPOSE:** To compare the magnitude and pattern of neural drive during explosive force production to neural drive at MVF.

**METHODS:** Following familiarisation, 27 healthy, untrained, young men performed two identical trials of isometric contractions of the knee extensors at a knee joint angle of 120°, 7 days apart, with data averaged across both trials. Force was measured by a strain gauge perpendicular to the tibia and double differential surface EMG recorded from two sites over each of the three superficial quadriceps muscles (RF, VM, VL). Participants performed: two series of four maximum voluntary contractions of 3-s duration in order to measure MVF and EMG amplitude (RMS of a 500-ms epoch around MVF,  $EMG_{@MVF}$ ); and 10 explosive contractions of ~1-s duration. For the explosive contractions, force was assessed for 200-ms after force onset, and EMG RMS amplitude measured in four successive 50-ms time periods after signal onset and the highest value from these time periods ( $EMG_{EXP-MAX}$ ).

**RESULTS:** Whole quadriceps  $EMG_{EXP-MAX}$  exceeded  $EMG_{@MVF}$  ( $206 \pm 119$  vs  $181 \pm 0.084 \mu V$ ;  $P < 0.01$ ), reaching  $112 \pm 16 \%EMG_{@MVF}$ , and this was also the case for all three individual muscles (All,  $P < 0.02$ ; VM  $115$ , VL  $112$  and RF  $113 \%EMG_{@MVF}$ ). Participants were divided into two groups according to relative explosive force after 100 ms (HIGH,  $59 \pm 6 \%MVF$ ,  $n=14$ ; LOW,  $45 \pm 5 \%MVF$ ,  $n=13$ ;  $P=0.02$ ) with HIGH recording greater quadriceps  $EMG_{50-100}$  ( $115 \pm 17$  vs  $99.4 \pm 14 \%EMG_{@MVF}$ ;  $P=0.01$ ) and this elevated neural drive was followed by a decline in EMG that was not the case for LOW ( $-20 \pm 19$  vs  $-3 \pm 20 \%$ ,  $P=0.03$ ). Furthermore, for individuals with high quadriceps  $EMG_{50-100}$  ( $>100 \%EMG_{@MVF}$ ,  $n=19$ ) this value was correlated with the subsequent decline in neural drive ( $R=-0.51$ ;  $P=0.03$ ).

**CONCLUSIONS:** In these untrained individuals neural drive during explosive force production was greater than at MVF, indicating that activation at MVF may be sub-maximal, and very high values of neural drive were associated with a subsequent decline indicating an inhibitory response.

**2180** Board #226 MAY 31 8:00 AM - 9:30 AM

**Effect of Cycling Training with Foot External Rotation on Electromyographic Activity of the Vasti**

Wei-Gang Chang, Li-Lan Fu. *National Taiwan Sport University, Taoyuan, Taiwan.*

(No relationships reported)

Previous researches demonstrate that neuromuscular training can decrease the risk of knee injuries. Cycling exercise is one of the neuromuscular training strategies for knee joints. Recently, it was found that cycling exercise with foot external rotation (ER) could induce more vastus medialis oblique (VMO) activation than neutral position. Although neuromuscular function of the knee could be improved by the continuous training, the effect of cycling is still remained unknown.

**PURPOSE:** To determine the effect of the continuous cycling training with foot ER on electromyographic activity of the vasti.

**METHODS:** Twenty-seven healthy young male ( $21 \pm 1$  yrs) were randomly allocated into one of 3 groups, namely, neutral (N), ER 45°, and the control group (C). All subjects were trained 3 times per week for 8 weeks. Each session lasted 20 min on cycling. The foot position in the C was decided by themselves. The difference of electromyographic onset time and activities of the VMO and vastus lateralis (VL) were collected during step up (concentric contraction) and step down (eccentric contraction) that were performed before and after training. Statistical analysis using a 2-way ANOVA based on group and training was performed.

**RESULTS:** Between pre- and post-test, only subjects in the ER 45° group was significantly decreased in the difference of VMO-VL onset time ( $29 \pm 46$  vs.  $-92 \pm 54$  ms,  $p < 0.05$ ) during the descend stepping, and was significantly different compared to N and C ( $-92 \pm 54$  vs.  $-8 \pm 38$  vs.  $-7 \pm 32$  ms,  $p < 0.05$ ) after training. No significant differences in the VMO/VL ratio were found among 3 groups or between pre- and post-test.

**CONCLUSION:** The knee neuromuscular function during eccentric contraction might be enhanced after cycling training with foot ER in healthy young male.

**2181** Board #227 MAY 31 8:00 AM - 9:30 AM

**DtP Score Method for Assessing Dual-task Performance Using Stability and Cognition Measures**

Nassim Nadji<sup>1</sup>, Mojdeh Baniasadi<sup>2</sup>, Jeremy A. Patterson, FACSM<sup>2</sup>, Douglas F. Parham<sup>2</sup>. <sup>1</sup>Wichita State University, Wichita, KS. <sup>2</sup>Wichita State University, wichita, KS.

(No relationships reported)

**PURPOSE:** To design a method assessing dual-task performance (DtP) using balance and cognition measures.

**METHODS:** 23 (15/8 m/f;  $25 \pm 3.4$  yrs) college-aged individuals participated in this study. Each participant attended two sessions which consisted of testing cognition by combining the Stroop color-word and N-back test, while measuring balance at the same time. The balance test consisted of two 30-second tests. Test 1 was completed with eyes open on a firm surface and Test 2 with eyes closed on a firm surface, values were recorded as Stability Index. During Test 1, participants were asked to stand on the balance machine and respond to the Stroop color-word test by naming the color of a word that appears on the screen in front of them in a color different from its name. During Test 2, participants completed the N-back test with eyes closed by saying 'yes' when a word read aloud had already been read aloud two words previously. The scores of the cognitive tests were divided by the results of the Stability Index to create a single score (DtP Score = Cognition Score / Stability Index).

**RESULTS:** Study results suggest that individuals who achieved a higher DtP Score had a greater capacity to complete the dual-task assessment and likewise, a low DtP Score suggested a poor ability to perform dual-tasks.

**Mean of DtP Score Test 1 and 2**

|           |        | Cognition Score  | Stability Index | DtP Score        |
|-----------|--------|------------------|-----------------|------------------|
| Session 1 | Test 1 | $16.83 \pm 2.83$ | $2.7 \pm 2.35$  | $9.79 \pm 5.76$  |
|           | Test 2 | $4.4 \pm 0.88$   | $2.7 \pm 2.35$  | $3.41 \pm 3.74$  |
| Session 2 | Test 1 | $18.25 \pm 2.32$ | $1.99 \pm 1.95$ | $13.82 \pm 7.51$ |
|           | Test 2 | $4.83 \pm 0.38$  | $2.42 \pm 2.29$ | $3.86 \pm 3.22$  |

**CONCLUSION:** The DtP Score presented here, provides a single score assessment value to measuring two tests completed at the same time. Preliminary results suggest that the DtP Scoring has consistent reproducibility and represents a unique scoring scale for evaluating DtP. Further studies with larger sample sizes and including populations with balance and/or cognitive deficits need to be completed to assess the effectiveness of the DtP Score.

**2182 Board #228 MAY 31 8:00 AM - 9:30 AM**

**Fatigue-Induced Median Frequency Shifts in Healthy Aging and Parkinson's Disease**

Julia Falkenklaus<sup>1</sup>, Amanda Morgan<sup>1</sup>, Nicholas J. Hanson<sup>2</sup>, Michael J. Ryan<sup>1</sup>, Paul D. Reneau<sup>1</sup>, Douglas W. Powell<sup>1</sup>. <sup>1</sup>Fairmont State University, Fairmont, WV. <sup>2</sup>The Ohio State University, Columbus, OH.

(No relationships reported)

Parkinson's disease (PD) is a neurodegenerative disease of the basal ganglia that is associated with the perception of fatigue. Muscular fatigue is associated with a reduction in the number, average size and firing rate of activated motor units resulting in a shift in median frequency (Mdf).

**PURPOSE:** The nature of PD-related fatigue is not well understood; therefore, the purpose of this study was to compare changes in Mdf in people with PD to healthy young (YA) and healthy old adults (OA). We hypothesized that people with PD would exhibit less muscular fatigue than YA and OA.

**METHODS:** 16 people participated in the current study (6PD, 5YA, 5OA). Surface EMG was recorded from the vastus lateralis. An isokinetic dynamometer (Biodex System 3) was used to record isometric knee extension torques (MVIC) at 60° of knee flexion before (pre-) and after (post-) an isokinetic fatiguing knee extension protocol. The fatiguing protocol consisted of repetitions of maximal knee extension contractions at 60°/sec until peak torque was reduced by 50% for three consecutive contractions. After fatigue was reached, the MVIC was repeated (post-). Torque and surface EMG data were recorded using Datapac 2K2 software (1000 Hz, RunTech). EMG signals were smoothed using the root mean squared with a 20 ms window. Mean EMG data were calculated during a 200 ms window (100 ms pre- and post-) surrounding the peak knee extension torque. EMG amplitude was normalized to peak mean EMG of the MVIC contraction. EMG median frequency (Mdf) from the pre- and post-fatigue MVICs was calculated using customized software (MatLab 2010a). A repeated measures analysis of variance was used to determine the effect of fatigue on Mdf. Alpha level was set at  $p < 0.05$ .

**RESULTS:** YA produced significantly less torque after the fatiguing protocol (Pre-:  $118.9 \pm 15.7$ ; Post-:  $96.9 \pm 13.5$ ;  $p = 0.040$ ) while reductions in torque were not significant in OA (Pre-:  $83.9 \pm 9.0$ ; Post-:  $80.2 \pm 9.1$ ;  $p = 0.16$ ) or PD (Pre-:  $69.2 \pm 14.9$ ; Post-:  $70.5 \pm 17.6$ ;  $p = 0.726$ ). YA had a significantly greater decrease in median frequency (39 Hz) than OA (25 Hz;  $p = 0.027$ ) or PD (26Hz;  $p = 0.028$ ) groups with fatigue.

**CONCLUSIONS:** These data suggest that PD and OA do not deplete the muscle substrate and experience greater levels of central fatigue, while younger adults experience peripheral muscular fatigue due to substrate depletion.

---

**Analysis Of Eeg In Movement Sciences: An Example On Treadmill Walking**

Kristel Knaepen, Vinciane Fontenelle, Helio Fernandez, Romain Meeusen, FACSM. *Vrije Universiteit Brussel, Brussels, Belgium.*

(No relationships reported)

Recent advances in technology offer the possibility to record electroencephalograms (EEG) not only during rest, but also during exercise. The use of active EEG electrodes combined with new decomposition and source localization techniques should allow for the assessment of brain activity during complex movements and moderate exercise.

**PURPOSE:** This study will give an overview of 2 new analysis techniques for EEG data, i.e., independent component analysis (ICA) and standardized low resolution electromagnetic tomography (sLORETA), recorded during exercise, in this case treadmill walking.

**METHODS:** Ten volunteers ( $28.2 \pm 4.1$  years) participated in this study. Thirty-two channel EEG data were recorded with active electrodes during 20 minutes of treadmill walking. EEG data were segmented into epochs of 1 gait cycle based on left heelstrike. ICA was used to unmix the EEG signal in its constituent components and remove artifacts. Next, data were averaged to 1 movement-related cortical potential (MRCP) for each subject. The component and channel cross spectra of the MRCPs were also calculated. The averaged MRCPs and cross spectra for each subject were imported into sLORETA software in order to compute intracerebral sources of activity.

**RESULTS:** Artifactual components due to movement can successfully be removed through ICA. It also reveals the different components that constitute the MRCP. When comparing with seated rest, sLORETA shows the visual, prefrontal and premotor cortex, the supplementary motor area, the cingulate cortex, the primary somatosensory, somatosensory association and primary motor cortex to be significant sources ( $p < 0.05$ ) that contribute to the MRCP. Gait ERSPs (event-related spectral perturbations) revealed significant modulations of spectral power in the alpha, beta and gamma frequency bands ( $p < 0.05$ ) which seem to correspond to the phases of a gait cycle.

**CONCLUSION:** Techniques such as ICA and sLORETA offer the opportunity to study brain activity during moderate exercise. In this study, these techniques revealed a specific pattern of brain activity inherent to treadmill walking (i.e., MRCP), the sources underlying this MRCP (through sLORETA), the different components (through ICA) and the corresponding perturbations in spectral power.

**Acute Muscle Damage Induced by Eccentric Contractions Increases Corticospinal Excitability**

Takashi Endoh<sup>1</sup>, Tsuyoshi Nakajima<sup>2</sup>, Azusa Uematsu<sup>3</sup>, Tetsuya Ogawa<sup>2</sup>, Kimitaka Nakazawa<sup>4</sup>. <sup>1</sup>Uekusa Gakuen University, Chiba, Japan. <sup>2</sup>Research institute, National Rehabilitation Center for Persons with Disabilities, Saitama, Japan. <sup>3</sup>Osaka University of Health and Sport sciences, Osaka, Japan. <sup>4</sup>University of Tokyo, Tokyo, Japan.

(No relationships reported)

Acute muscle damage induced by intense eccentric exercise affects not only muscle structure but also the central nervous system. For example, electromyographic (EMG) activity and force fluctuation increase immediately after eccentric exercise. However, the mechanisms that underlie this increased EMG activity and force fluctuation after eccentric exercise are unclear.

**PURPOSE:** The purpose of this study was to clarify the effects of muscle damage induced by eccentric contractions on corticospinal tract excitability.

**METHODS:** Eight healthy male volunteers (age range, 21-33 yrs) performed submaximal voluntary pincer grip contractions (5, 10, and 20% of maximal voluntary contraction [MVC]) before and 3 hours after eccentric exercise (ECC). ECC was performed using hand grip and continued until MVC decreased to 50%. Force fluctuation and background EMG activities in the first dorsal interosseous muscle (FDI) were measured during these voluntary contractions. To obtain a recruitment curve for the motor evoked potentials (MEP) in the left FDI, transcranial magnetic stimulation at a wide range of intensities (0.8-2.0 x threshold) was applied to the contralateral motor cortex innervating the left FDI during 10% maximal EMG before and 3 hours after ECC. The maximum MEP value, slope, and calculated threshold were assessed using the Boltzmann sigmoid function. Indirect markers of muscle damage, such as MVC and pressure-pain threshold, were measured before and after ECC.

**RESULTS:** Following ECC, MVC decreased to 75% of the pre-exercise value without muscle soreness. During submaximal voluntary contractions, EMG activity and force fluctuation were significantly higher after ECC than before ECC ( $p < 0.05$ ). Maximum MEP and slope values increased significantly after ECC compared with those before ECC ( $p < 0.05$ ). The calculated MEP threshold did not change before or after ECC. Discussion: These results suggest that muscle damage induced by ECC increased corticospinal excitability, which was seen at high stimulator output levels. This could be attributed to increased EMG activities and force fluctuation during voluntary contractions of damaged muscle.

**2185** Board #231 MAY 31 8:00 AM - 9:30 AM  
**A Dynamic Systems Analysis of Phase Shift Identification in Long Jump Performance: A Longitudinal Study**  
David A. Kinnunen, Dawn K. Lewis. *CSU Fresno, Fresno, CA.* (Sponsor: Catherine G. R. Jackson, FACSM)  
(No relationships reported)

Dynamic systems theory predicts shifts in skill performance when one or more control parameters is altered. Kinnunen & Lewis (2006) identified structural-maturational variables (SM) that predict standing long jump (SLJ) performance in children age 7, at peak height velocity (PHV) (12 f, 14 m), and two years post PHV (14 f, 16 m). Shifts in SLJ performance have not yet been described along with associated rate attractors and limiters.

**PURPOSE:** To identify phase shifts in SLJ performance at age 7, age at peak height velocity and 2 years post PHV and to identify rate attractors and limiters associated with peaks and deep wells in performance.

**METHODS:** Participants (N = 487; 234 males, 258 females) were recruited at 40 months of age and were assessed until 6 months post-peak height. Thirteen SM measures and SLJ distance were collected semi-annually until participants reached adult height. Graph analyses, ANOVA and Pearson correlations identified phase shifts and associated control parameters.

**RESULTS:** Significant phase shifts in SLJ performance were identified over time. SM control factors include: Radio-styloid length, various skinfolds, standing and sitting height and biacromial width. SM included in the analyses explained between 9.5% and 25.9% of the performance variance. SM identified as driving or limiting SLJ performance varied by age and sex.

**CONCLUSION:** Improvement in motor skill performance from toddler to early adulthood occurs in progressive phases consisting of observable peaks and deep wells. Identifying SM associated with shifts in motor skill performance may modify motor development theory and pedagogy beyond identifying age-related characteristics of motor skill stages in the design of instructional plans for skill improvement across the lifespan.

**2186** Board #232 MAY 31 8:00 AM - 9:30 AM  
**Effect of Body Position and Isometric Quadriceps Activation on Q-Angle**  
Rumit S. Kakar<sup>1</sup>, Kathy J. Simpson<sup>1</sup>, Sumit Kalra<sup>2</sup>. <sup>1</sup>University of Georgia, Athens, Athens, GA. <sup>2</sup>Banarsidas Chandiwala Institute of Physiotherapy, GGSIPU, New Delhi, India.  
(No relationships reported)

An abnormal Q angle is associated with an increased risk for developing patellar problems, e.g., patellar subluxation and chondromalacia patella. Moreover, females involved in activities that create high quadriceps force are more prone to lateral patellar dislocation than their male counterparts. Therefore, using the most valid and standardized measurement protocol is crucial to clinicians. However, factors that influence Q-angle outcomes are not well understood, potentially affecting values among differing protocols used.

**PURPOSE:** To determine if isometric quadriceps activation (QA) and body position (BP) affect Q angle.

**METHODS:** 60 subjects (30 females, 30 males), 23 ± 3 yr participated. Q angle was measured in standing and supine during quadriceps relaxed and isometric quadriceps contraction (100% maximum effort) conditions. 2 QA x 2 BP RM ANOVA for each gender were used to test Q-angle ( $p < .05$ ).

**RESULTS:** Q angle decreased when standing and during maximum effort QA. Posthoc analyses of the QA X BP interaction for Q-angle of both genders revealed that the greatest difference among mean Q angles (females and males, respectively: 7.62°, 4.79°) occurred between standing-relaxed (17.8 ± 3.5°, 11.38 ± 1.6°) and supine-maximum QA (10.2 ± 2.5°, 6.59 ± 0.9°).

**CONCLUSION:** Regardless of gender, Q angle is affected by an interactive effect of BP with QA. Females were comparatively more sensitive to the interaction than males. Therefore, it is recommended that a standardized protocol for measuring Q-angle should take into account the QA and BP. Separate Q-angle norms may be needed for standing and supine testing protocols.

**2187** Board #233 MAY 31 8:00 AM - 9:30 AM  
**The Effects of Visual-perception on Evasive Sidestepping: Implications for Anterior Cruciate Ligament Injury Prevention**  
Marcus Lee, Brendan Lay, David Lloyd, Paul Bourke, Jacqueline Alderson. *The University of Western Australia, Perth, Australia.* (Sponsor: Sports Medicine Australia, FACSM)  
(No relationships reported)

**PURPOSE:** Sidestepping (SS) to evade opponents in sports can result in non-contact anterior cruciate ligament (ACL) injuries. Although SS in response to different simple visual stimuli has been studied previously, it has never been investigated using "game-realistic" visual conditions. This study compared the biomechanics of high-level (HL) and low-level (LL) soccer players when SS to evade projected, three-dimensional (3D) defender(s). Further comparisons were made with sidesteps performed in response to traditionally employed planned and unplanned arrow stimuli.

**METHODS:** A 3D motion analysis system captured the trunk and lower limb kinematics, ground reaction forces and activation of 8 knee muscles, of 15 HL and 15 LL soccer players performing the SS tasks. Participants sidestepped in response to an arrow-planned condition (AP), arrow-unplanned condition (AUNP), one-defender scenario (1DS) and two-defender scenario (2DS). Temporal constraints imposed by the stimuli conditions increased in difficulty from the AP, 1DS, 2DS to the AUNP. A biomechanical model was used to investigate peak lateral trunk flexion and knee valgus loading during stance phase of the sidestep. Knee muscle activation measured during pre-contact and weight-acceptance phase was used to create flexor-extensor co-contraction ratios. Dependent variables were submitted to a 4 x 2 (stimulus x skill) mixed design ANOVA.

**RESULTS:** Stimuli significantly affected all measurements ( $p < 0.05$ ). The trunk was most upright in the AP and approximately 4° more laterally flexed in the other conditions. Knee valgus moments were lowest in the AP, increased by 40% in the defender scenarios and 70% in the AUNP. In the 2DS, the shift from a flexor dominant co-contraction strategy in pre-contact toward extensor dominance in weight-acceptance commenced earlier for the HL players compared with the LL players. HL players also exhibited lower knee valgus moments in the 2DS.

**CONCLUSION:** Compared with the arrow conditions, SS in response to the game-realistic defender scenarios resulted in different mechanics, which further differentiated between HL and LL players in the complex 2DS. These findings highlight the importance of stimuli realism and complexity, and the visual-perceptual contribution toward SS, which has implications for ACL injury prevention.

**2188** Board #234 MAY 31 8:00 AM - 9:30 AM  
**The Relationship Between Ankle Laxity and Fibularis Longus Spinal Reflex Excitability**  
Michelle M. McLeod, Brian G. Pietrosimone, Phillip A. Gribble. *University of Toledo, Toledo, OH.*  
(No relationships reported)

Ankle sprains are the most prevalent lower extremity injury in sport, and a risk factor for the development of chronic ankle instability (CAI). CAI is contributed to by mechanical and functional factors, such as ligamentous laxity, and neuromuscular alterations, respectively. While mechanical and functional factors individually contribute to CAI, the extent of their influence on each other is not well understood. The relationship between neuromuscular function and ankle laxity has not been determined in patients with CAI.

**PURPOSE:** Determine the relationship between mechanical and functional contributions to CAI measured through inversion-eversion (IE) laxity and spinal reflexive excitability (SRE) of the fibularis longus (FL) muscle.

**METHODS:** Twenty individuals with CAI (13F, 7M, 20.9±1.5 yrs, 171.0±11.23 cm, 67.9±11.6 kg) and 15 healthy individuals (11F, 4M, 21.4±2.6 yrs, 169.8±9.8 cm, 70.2±12.3 kg) participated. IE laxity was quantified using an ankle arthrometer. SRE was assessed via the Hoffmann reflex (H-reflex). Maximum H-reflex was determined by peak-to-peak amplitude. The stimulus was increased until a maximal muscle response (M-wave) was elicited. H-reflexes were normalized to the M-wave (H:M ratio), which has been reported to denote SRE of the motor neuron pool, with larger values indicating greater excitability. A separate nonparametric Spearman rank order correlation was used to determine the relationship between laxity and excitability. Alpha level was set a-priori  $P \leq 0.05$ .

**RESULTS:** The CAI group displayed a significant moderate correlation between laxity ( $44.24^\circ \pm 15.97^\circ$ ) and SRE ( $29.8 \pm 19.3$ ;  $\rho=0.463$ ,  $P=0.040$ ). No significant correlation was found in the healthy group ( $43.27^\circ \pm 20.17^\circ$ ,  $26.1 \pm 20.4$ ;  $\rho=-0.032$ ,  $P=0.909$ ).

**CONCLUSION:** The positive moderate correlation between laxity and SRE indicates that FL SRE is increased in patients with greater IE laxity. It is possible that as IE laxity increases, reflexive excitability of the FL is up-regulated in an attempt to prevent an inversion injury. Continued research should examine if increased SRE may be part of a more sophisticated motor control strategy attempting to compensate for increased IE ankle laxity. **ACKNOWLEDGEMENTS:** The authors would like to acknowledge the University of Toledo Interdisciplinary Grant for funding this project.

**2189** Board #235 MAY 31 8:00 AM - 9:30 AM  
**Within And Between Session Reliability Of The Maximal Voluntary Knee Extension Torque And Activation**

Adam C. Squires, Jihong Park, David H. Chinn, Dennis L. Eggett, J Ty Hopkins, FACSM. *Brigham Young University, Provo, UT.*  
(No relationships reported)

**PURPOSE:** Calculation of central activation ratio (CAR) has been widely used to assess central activation failure. To date no data exist regarding the intersession reliability of this measurement. To report within and between session reliability and the standard error of measurement (SEM) of quadriceps maximal voluntary knee extension torque and activation.

**METHODS:** Thirteen, neurologically sound volunteers (9 males and 4 females, age:  $21.9 \pm 3.2$  year, height:  $1.7 \pm 3.1$  m, mass:  $76.6 \pm 10.1$  kg) underwent three testing sessions with 48 hours between sessions. To obtain knee extension torque, subjects performed maximal voluntary isometric contraction (MVIC) of the quadriceps with the knee locked at  $90^\circ$  flexion and the hip at  $85^\circ$ . Once the knee extension torque reached a plateau, an electrical stimulation (100 pulses/s, 600  $\mu$ s pulse duration, 10 train in 100 ms duration, 125 V with peak output current 450 mA) was manually delivered and transmitted directly to the quadriceps via stimulating electrodes. This stimulation caused a transient increase of torque by recruiting any remaining muscle fibers or maximizing the firing frequency of the quadriceps. CAR was calculated by dividing the MVIC by the sum of the torque generated by the MVIC and the superimposed burst (SIB) technique ( $CAR = MVIC / (MVIC + SIB \text{ torque})$ ). Subjects performed three trials in each session. Means were calculated from three trials of each measurement. Intraclass correlation coefficient (ICC) within a session and between sessions were calculated using maximal MVIC torques and CAR values.

**RESULTS:** We found strong reliability in MVIC both within ( $ICC_{(1,1)}=0.96$ ,  $ICC_{(2,1)}=0.97$ ) and between session ( $ICC_{(1,1)}=0.91$ ). CAR had moderate to weak reliability within a session ( $ICC_{(1,1)}=0.78$ ,  $ICC_{(2,1)}=0.67$ ) and weak in between session ( $ICC_{(1,1)}=0.63$ ). SEM for MVIC and CAR within a session was 11.9 N-m and 0.03, respectively. SEM for MVIC and CAR between sessions was 17.7 N-m and 0.04, respectively.

**CONCLUSIONS:** Knee extension MVIC torque is very reliable both within and between measurement sessions. CAR had lower reliability within a session and between sessions compared with knee extension MVIC.

---

**2190** Board #236 MAY 31 8:00 AM - 9:30 AM  
**Changes in Movement Patterns Following a Fatiguing Resistance Training Protocol**

David R. Hooper, Tunde K. Szivak, Brett A. Comstock, Courtenay Dunn-Lewis, Jenna M. Apicella, Neil A. Kelly, Brent C. Creighton, Lindsay J. DiStefano, Jeff Volek, Carl M. Maresh, FACSM, William J. Kraemer, FACSM. *University of Connecticut, Storrs, CT.*  
(No relationships reported)

**PURPOSE:** Resistance training has been found to have a multitude of benefits. However, when performed with short rest, resistance training can result in substantial fatigue, which may have a negative impact on exercise technique. The purpose of this study was to establish the effects that fatigue from resistance exercise has on joint biomechanics and therefore assess the potential consequences these changes might have.

**METHODS:** 14 men underwent a 3 dimensional analysis of 5 bodyweight squats using the flock of birds electromagnetic motion analysis system (Ascension technologies, Inc., Burlington, VT) before and after a highly fatiguing resistance training workout. The workout included barbell squat, barbell bench press and barbell deadlift performed at 75% 1RM with a descending pyramid of repetitions beginning at 10 and ending at 1 for all lifts. Peak angle, total angular displacement and displacement rate were assessed for knee flexion, trunk flexion, hip flexion, hip rotation and hip adduction.

**RESULTS:** Following a fatiguing resistance training workout, independent t-tests showed a significant decrease in peak angle for knee flexion (Pre:  $120.28 \pm 11.93^\circ$ , Post:  $104.46 \pm 9.85^\circ$ ), hip flexion (Pre:  $-109.42 \pm 12.49^\circ$ , Post:  $-95.8 \pm 12.30^\circ$ ) and hip adduction (Pre:  $-23.32 \pm 7.04^\circ$ , Post:  $-17.30 \pm 8.79^\circ$ ). There was a significant reduction in angular displacement for knee flexion (Pre:  $115.56 \pm 10.55^\circ$ , Post:  $103.35 \pm 10.49^\circ$ ), hip flexion (Pre:  $97.94 \pm 10.69^\circ$ , Post:  $90.51 \pm 13.22^\circ$ ), hip adduction (Pre:  $17.79 \pm 7.36^\circ$ , Post:  $11.89 \pm 4.34^\circ$ ) and hip rotation (Pre:  $30.72 \pm 12.28^\circ$ , Post:  $20.48 \pm 10.12^\circ$ ). There was also a significant reduction in displacement rate for knee flexion (Pre:  $2.20 \pm 0.20$ , Post:  $1.98 \pm 0.20$ ), hip flexion (Pre:  $1.92 \pm 0.20$ , Post:  $1.76 \pm 0.27$ ), hip adduction (Pre:  $-0.44 \pm 0.17$ , Post:  $-0.31 \pm 0.17$ ) and hip rotation (Pre:  $0.59 \pm 0.23$ , Post:  $0.38 \pm 0.21$ ).

**CONCLUSIONS:** These findings indicate that resistance training combining high loads and short rest produce a substantial fatigue that results in significant changes in movement technique. Changes in movement technique have been associated with injury, therefore it is important for strength coaches to consider the effects that fatigue has on joint biomechanics to prevent possible injury.

**2191** Board #237 MAY 31 8:00 AM - 9:30 AM  
**Effects Of Visual Biofeedback On Bilateral Force Symmetry In Sling Exercise Training**

Yu-Lin You<sup>1</sup>, Shih-Ting Wang<sup>1</sup>, Chich-Huang Yang<sup>2</sup>, Lan-Yuen Guo<sup>1</sup>. <sup>1</sup>*Kaohsiung Medical University, Kaohsiung, Taiwan.* <sup>2</sup>*Tzu-Chi University, Hualien, Taiwan.*  
(No relationships reported)

Deterioration of bilateral muscle activation symmetry may affect spinal stability, which has been associated with low back pain (LBP). Sling exercise training (SET) was often used to improve spinal stability; however the effect of visual biofeedback (VB) on bilateral force symmetry (BFS) still remained unknown.

**PURPOSE:** To confer the effects of the SET combined with VB on BFS between the LBP and control (CON) groups.

**METHODS:** 12 LBP ( $22.6 \pm 2.3$  yrs) and 11 CON ( $22.6 \pm 2.1$  yrs) subjects were recruited in this study. Two load cells were installed for quantifying the forces applied bilaterally accompanying with custom-designed VB software for BFS were added to the SET equipments. This study contained four movements (M1 to M4), and the test sequence of movements was randomized. M1 is knelt on the bed with hands in the straps. M2 is lay supine with two legs in the straps and proceeded bridge exercise. M3 is lay prone with two legs in the straps and use the forearms to support the body. M4 is similar to M3, but it combined the knee flexion. 4 trails were collected in each movement, including two without visual biofeedback (NVB) and two with visual biofeedback (VB). Each movement was held for 15 seconds for each trial. The left-side applied force was divided by right-side to represent BFS, thus the ratio more close to 1 represent the better bilateral force symmetry.

**RESULTS:** In NVB condition, CON group (ranged from 1.10 to 1.20) had better BFS than LBP group (range from 1.12 to 1.27) for all 4 movements, but did not show the statistical difference. Comparing the difference in BFS between VB and NVB conditions, CON group exercise in M2 ( $1.10 \pm 0.03$  vs.  $1.06 \pm 0.02$ ) and LBP group exercise in M1 ( $1.04 \pm 0.01$  vs.  $1.12 \pm 0.06$ ), M2 ( $1.05 \pm 0.01$  vs.  $1.13 \pm 0.09$ ) and M4 ( $1.10 \pm 0.08$  vs.  $1.19 \pm 0.11$ ) showed significant improvement ( $P < .05$ ).

**CONCLUSION:** The CON group had a trend of better FS than LBP group. Exercising with VB improved BFS for LBP group significantly. **ACKNOWLEDGE:** This study was supported by NSC 99-2622-B-037-001-CC3

2192 Board #238 MAY 31 8:00 AM - 9:30 AM

**Effect of Acute Feedback on Landing Patterns in a Horizontal Land and Cut Maneuver**

Sarah K. Leissing<sup>1</sup>, Mitchell L. Stephenson<sup>1</sup>, Erich J. Petushek<sup>2</sup>, Bryanne Bellovary<sup>1</sup>, Alexander R. Wolfe<sup>1</sup>, Caitlin Glendenning<sup>1</sup>, Erika Purdy<sup>1</sup>, Bailey M. Hagner<sup>1</sup>, Randall L. Jensen, FACSM<sup>1</sup>. <sup>1</sup>Northern Michigan University, Marquette, MI. <sup>2</sup>Michigan Technological University, Houghton, MI.

(No relationships reported)

Anterior Cruciate Ligament (ACL) Injury prevention programs have assessed the effects of acute feedback on valgus angle and peak GRF in drop landing tasks. Knee valgus angle and peak ground reaction force (GRF) are two variables important to the mechanism and prevention of ACL injury. However, although studies have assessed effects of acute feedback on these two variables during drop jumps, studies have failed to study them during a cutting maneuver.

**PURPOSE:** To assess the effects of acute feedback on valgus angle and peak GRF during a horizontal land and cut maneuver.

**METHODS:** Nine division II women soccer players (Mean  $\pm$  SD Age = 19.80  $\pm$  0.63 years; Height = 163.86  $\pm$  7.42 cm; Weight = 60.71  $\pm$  6.88 kg) randomly performed 12 horizontal land and cut maneuvers, with 3 left cuts and 3 right cuts pre- and post-feedback. Feedback was based on script from previous studies as well as results from studies using the Landing Error Scoring System. A three-way repeated measures ANOVA was used to compare the differences in knee valgus angle and peak GRF. The independent variables were leg (preferred plant leg/preferred kicking leg), feedback (pre/post), and trial. Significance was set at  $p < 0.05$ .

**RESULTS:** Results of the three-way repeated measures ANOVA indicated significant main effects for valgus angle between the preferred plant leg/preferred kicking leg and pre/post feedback. Values for the conditions were 13.80°  $\pm$  4.76° pre and 12.52°  $\pm$  4.79° post feedback for cuts on the preferred plant leg and 19.75°  $\pm$  4.07° pre and 18.34°  $\pm$  3.05° post feedback for cuts on the preferred kicking leg. There were no significant differences between trials and no significant interactions across conditions. There were no significant differences or interactions in GRF between legs, pre- and post-feedback, or trials. Values of GRF were 1068.25N  $\pm$  181.85N and 986.20N  $\pm$  159.32N pre- and post-feedback respectively for cuts on the preferred plant leg and 1126.81N  $\pm$  187.68N and 1073.76N  $\pm$  154.97N pre- and post-feedback respectively for cuts on the preferred kicking leg.

**CONCLUSIONS:** Knee valgus angle decreased with acute feedback while GRF were not affected by the same acute feedback given during a horizontal land and cut task. Therefore, acute feedback may be a useful tool for decreasing knee valgus angle during cutting tasks in ACL injury prevention programs.

2193 Board #239 MAY 31 8:00 AM - 9:30 AM

**The Effects of Verbal Cueing on Muscle Coordination Patterns in the Step Up Exercise**

Mischa U. Harris<sup>1</sup>, Darren E.R. Warburton<sup>1</sup>, James M. Wakeling<sup>2</sup>. <sup>1</sup>University of British Columbia, Vancouver, BC, Canada. <sup>2</sup>Simon Fraser University, Burnaby, BC, Canada.

(No relationships reported)

In an effort to improve dysfunctional muscle activation patterns, clinicians often use verbal cues to guide differential muscle activation and joint positioning during rehabilitation. While verbal cuing has been shown to elicit changes in muscle recruitment patterns during single joint, open kinetic chain exercises, it is unknown what effect verbal cuing has on a multi-joint movement with increased degrees of freedom.

**PURPOSE:** To determine the effects of three different clinically common verbal instructions on lower extremity muscle activation and coordination patterns during a step up exercise.

**METHODS:** Seven healthy males completed 1 un-cued control trial and 8 randomly assigned experimental trials after receiving cues to either preferentially recruit gluteal muscles, preferentially recruit vastus medialis, maintain hip and knee alignment or count backwards from a high number (distraction). Surface electromyograms (EMG) were recorded from the surface of seven muscles: vastus medialis (VM), vastus lateralis (VL), rectus femoris (RF), semitendinosus, (ST) biceps femoris (BF), gluteus maximus (GMx), gluteus medius (GMd). EMG intensities were calculated using wavelet techniques. Muscle coordination patterns were then compared across trials using principal component analysis and repeated measures ANOVA with Tukey's Post-hoc comparisons.

**RESULTS:** The gluteal and VM cue conditions were significantly different in comparison to the control, alignment and distraction conditions and also to each other ( $p < 0.05$ ). Both gluteal cues and VM cues elicited greater overall muscle activation and in particular greater ST and BF activity than the other conditions. The VM cues condition also showed greater VM, VL, RF, GMx and GMd activity and less ST and BF activity than the gluteal cues condition.

**CONCLUSION:** Our results indicate that verbal cuing for preferential muscle recruitment can alter muscle coordination patterns in a step up exercise, but that the resulting changes do not represent the pattern that was cued. Verbal instructions to modify lower extremity alignment did not significantly change the coordination patterns compared to an un-cued control trial. Caution should be taken when attempting to use verbal cues to change muscle activation patterns. Supported by the BC Sports Med Research Foundation.

**Effect of Feedback on Peak Torque in a Female Population**

Barbara L. Warren, FACSM, Nika Evans. University of Puget Sound, Tacoma, WA.

(No relationships reported)

**PURPOSE:** The purpose of the study was to assess the effect of feedback on peak torque during isokinetic testing.

**METHODS:** Fourteen (7 athletes: mean age=20.7 years, height=178.5 cm, weight=74.7 kg; 7 non-athletes: mean age 20.0 years, height 168 cm, weight=64.1 kg) apparently healthy college-age females participated in the study. Each subject performed 2 familiarization and 4 experimental trials on a Cybex NORM isokinetic dynamometer. Each subject executed 10 reciprocal knee flexion/extension maximal contractions at velocities of 60 deg/s, 180 deg/s and 300 deg/sec with a 1 minute rest between velocity sets. Subjects were randomly assigned feedback conditions: none, visual, verbal, visual and verbal. A 2 (athlete or not) X 3 (velocities) X 4 (feedback conditions) repeated measures ANOVA ( $\alpha < .05$ ) was used to analyze the data.

**RESULTS:** For knee extension there were no significant interaction effects, but there were significant differences in the peak torque between velocities ( $F=574.8$ ,  $p < .0005$ ). There were no significant differences in peak torque regardless of the feedback condition and no significant differences between athletes and non-athletes. For knee flexion, there was a significant interaction between velocity and athlete ( $F=6.755$ ,  $p < .002$ ), and a significant difference in peak torque by velocity ( $F=284$ ,  $P < .0005$ ). Additionally, there was a significant difference in knee flexion peak torque between athletes and non-athletes ( $F=4.882$ ,  $p < .032$ ), but no significant difference in peak torque by feedback condition.

**CONCLUSIONS:** Feedback conditions did not affect peak torque in this population of females.

**Impact of Instructor Cues on Changes in Cycling Form during a Spin Class**

Jacilyn Olson, Ashley Binns, Jennifer Bliss, Addie Swyden, Michelle Gray, Ro Di Brezzo. University of Arkansas, Fayetteville, AR. (Sponsor: Barry Brown, FACSM)

(No relationships reported)

Many people attend group fitness classes as their regular mode of exercise; however, proper form may not be consistently emphasized in these classes. In spin classes, form is especially important due to the repetitive nature of the movement putting those with improper technique at increased risk of injury.

**PURPOSE:** The purpose of this study was to examine the impact of instructor cues on joint angle changes and rating of perceived exertion (RPE) during a spin class.

**METHODS:** Fifteen participants (8M, 7F) of various cycling backgrounds participated with mean ( $\pm$  SD) age, height, and weight of 22.6  $\pm$  5.07 yr., 1.73  $\pm$  0.10 m, and 66.94  $\pm$  12.03 kg, respectively. Informed consent was obtained and reflective markers placed on the right and left sides of the body over anatomical landmarks aligned with lower and upper limb joint centers. The spin bike was set for individual comfort and was consistent for each trial. Each participant completed two testing sessions at least one week apart; order was randomized. During each session participants cycled following instructions from a recorded spin class (55 minutes). The two testing videos were exactly the same, except one version included instructor cues about proper form, while the other did not. Two video cameras were used to observe sagittal and frontal angles. Video of each participant was recorded at three 10-second periods during the class; the

beginning, middle, and end. Joint angles of interest were elbow, hip, knee, ankle, spine, and shoulders. Motion analysis software was used to calculate joint angles via inverse dynamics. A repeated measures MANOVA was used to analyze joint angles and RPE.

**RESULTS:** The MANOVA revealed a significant change in the group of variables throughout the course of the spin class ( $F = 843.52, p < .001$ ). The overall measures of interest were not influenced by instructor cues ( $F = 0.00, p = .99$ ). Significant joint angle changes were found at the hip ( $F = 7.30, p = .02$ ) and left shoulder ( $F = 7.40, p = .02$ ). RPE significantly increased as the class progressed ( $F = 41.11, p < .001$ ).

**CONCLUSIONS:** Contrary to our hypothesis, instructor cues did not influence changes in joint angles during a spin class; class duration appeared to be more influential. The biomechanics of spin classes should continue to be studied, especially in regards to maintaining form throughout the classes.

**2196** Board #242 MAY 31 8:00 AM - 9:30 AM

**The Reliability Of Percent Voluntary Activation During Submaximal And Maximal Isometric Muscle Actions.**

Michael Cooper<sup>1</sup>, Ashley Walter<sup>2</sup>, Pablo Costa<sup>3</sup>, Eric Ryan<sup>4</sup>, Joel T. Cramer, FACSM<sup>5</sup>, Trent Herda<sup>1</sup>. <sup>1</sup>University of Kansas, Lawrence, KS. <sup>2</sup>University of Oklahoma, Norman, OK. <sup>3</sup>California State University, San Bernardino, CA. <sup>4</sup>University of North Carolina, Chapel Hill, NC. <sup>5</sup>Oklahoma State University, Stillwater, OK.

(Sponsor: Joel T. Cramer, FACSM)

(No relationships reported)

The interpolated twitch technique is a popular method used to assess percent voluntary activation (%VA) during submaximal and maximal isometric muscle actions, however, there is limited knowledge on the reliability of this technique at different contraction intensities.

**PURPOSE:** The purpose of this study was to examine the test-retest reliability of the %VA versus force relationships.

**METHODS:** 14 healthy men (mean±SD age=21±2.6 yrs) and 8 women (age=21±1.8 yrs) completed four maximal voluntary contractions and nine randomly-ordered submaximal isometric plantar flexions from 10 to 90% of the MVC. Transcutaneous electrical stimuli were delivered to the tibial nerve using a high-voltage constant-current stimulator (Digitimer DS7AH, Herthfordshire, UK) during two of the four MVC's and during all submaximal isometric plantar flexions. Submaximal isometric step contraction percentages were calculated from the higher of the two initial MVCs that were performed without the transcutaneous electrical stimuli. Doublets were administered at a supramaximal stimulus intensity during the maximal and submaximal MVC plateau and then again 3-5 s after the maximal and submaximal MVC at rest. %VA was calculated for each maximal and submaximal MVC. The intraclass correlation coefficients (ICCs) and standard errors of measurements expressed as a percentage of the mean (%SEMs) were used for test-retest reliability, while paired samples *t* tests were used to quantify systematic variability. Model "2,1" from Shrout and Fleiss (1979) was used to calculate the ICCs.

**RESULTS:** Systematic variability was not present at any of the contraction intensities ( $P > 0.05$ ). The ICCs ranged from 0.52 to 0.84, while the %SEM ranged from 6.75 to 38.45%. The ICCs were  $\geq 0.74$  at contraction intensities ranging from 40 to 100% MVC (6.75 to 16.78% SEM), while the ICCs were  $\leq 0.65$  (20.95 to 38.45% SEM) for the contraction intensities  $\leq 30\%$  MVC.

**CONCLUSIONS:** Although not statistically tested, the ICCs tended to be higher, while the %SEMs lower for contractions  $\geq 40\%$  MVC (Table 1). Future research in assessing muscle activation or predicting the true maximal force from the %VA versus force relationships may want to exclude contractions intensities below 40% MVC.

---

**2197** Board #243 MAY 31 8:00 AM - 9:30 AM

**Quadriceps Strength and Corticospinal Excitability as Predictors of Disability Following Anterior Cruciate Ligament Reconstruction**

Adam S. Lepley, Hayley M. Ericksen, Jason Levine, Phillip A. Gribble, Brian G. Pietrosimone. University of Toledo, Toledo, OH.

(No relationships reported)

Disability is common in a proportion of patients following anterior cruciate ligament reconstruction (ACLR). Neuromuscular quadriceps deficits are a hallmark impairment following ACLR, yet the link between self-reported disability and quadriceps muscle dysfunction is not clearly understood.

**PURPOSE:** To evaluate the ability of a clinical measure of neuromuscular function, quadriceps strength, and corticospinal excitability to predict self-reported disability in patients with ACLR.

**METHODS:** Fifteen participants with a history of ACLR (11 Female, 4 Male; 172±9.8cm, 70.4±17.5kgs, 54.4±40.9 months post-surgery) whom had been medically cleared to fully participate in physical activity were examined. Quadriceps strength was assessed via maximal voluntary isometric contractions (MVIC) performed at 90° of knee flexion. Corticospinal excitability was assessed with active motor thresholds (AMT), which were elicited by stimulating specific areas on the motor cortex using Transcranial Magnetic Stimulation (TMS). AMT's were measured during a standardized contraction at 5% of an MVIC. A multiple linear regression model was used to determine the ability of strength and corticospinal excitability of the involved limb to predict disability measured with the International Knee Documentation Committee (IKDC) index score. The change in R<sup>2</sup> to the model from the addition of each predictor variable was also analyzed.

**RESULTS:** The overall multiple regression model significantly predicted 66% of the variance in self-reported disability as measured by the IKDC (R<sup>2</sup> = 0.66, P=0.01; IKDC= .78MVIC - .24AMT +58.89). Initial imputation of MVIC into the model accounted for 61% (R<sup>2</sup>=0.61, P=0.01) of the variance in IKDC. The subsequent addition of AMT in the model accounted for an insignificant increase of 5% ( $\Delta R^2 = 0.05, P=0.19$ ) in the prediction capability of the model.

**CONCLUSION:** Quadriceps strength and corticospinal excitability predicted two-thirds of the variance in disability of patients with ACLR, yet, strength solely accounted for a significant portion of the predictive capability of the model. Maintaining quadriceps strength following ACLR may substantially influence patient's perception of disability, however the impact of corticospinal excitability on both strength and disability remains unclear.

**2198** Board #244 MAY 31 8:00 AM - 9:30 AM

**Does Gait Retraining To Decrease Vertical Loads Reduce Bony Loads In Runners?**

Rebecca E. Fellin<sup>1</sup>, Irene S. Davis, FACSM<sup>2</sup>. <sup>1</sup>University of Delaware, Newark, DE. <sup>2</sup>Harvard Medical School, Boston, MA.

(No relationships reported)

In runners, tibial stress fractures (TSF) most often occur between the midshaft and distal third of the tibia. TSF incidence has been linked to excessive impact loads including tibial shock (TS) and vertical load rate (VALR). Gait retraining to decrease initial impacts has been demonstrated to reduce TS, as well as the VALR of the ground reaction force. However, external loads do not directly indicate loads within the tibia. These bony loads are the ones that need to be decreased to reduce injury risk.

**PURPOSE:** To assess tensile strain rates (TSR) and compressive strain rates (CSR) from the midshaft to the distal third of the tibia following gait retraining. We hypothesized that these tibial strain rates would decrease following gait retraining.

**METHODS:** To date, 5 subjects (32.2 ± 2.9 yr), running > 10 mi/wk, with high TS (>8 g's) were recruited. They completed 8 sessions of gait retraining, which consisted of real-time visual feedback of their TS. Tibial joint contact force was calculated from a musculoskeletal model and input into a finite element model. Tibial peak principal strain rates were then calculated. VALR, TS, TSR and CSR were compared pre and post retraining. Due to the small n, data were analyzed descriptively.

**RESULTS:** TS decreased by 23-65% (Fig 1) and all values of TS were within the normal range following gait retraining. 4/5 runners decreased TSR and CSR in the region of interest by 4-45% (Fig 1). Although bony loads generally decreased, the changes were not tightly coupled with external load reductions.

**CONCLUSION:** External and bony loads appeared to decrease post gait retraining. These preliminary results suggest that reducing excessive external vertical loads may result in decreased tibial strain rates and TSF risk in runners.

**Relationship between Lean Mass and Coactivation during Downward Stepping with Advancing Age**

Heidi Bastin<sup>1</sup>, Douglas Renshaw<sup>1</sup>, Nicholas J. Hanson<sup>2</sup>, Matthew R. Bice<sup>3</sup>, Michael J. Ryan<sup>1</sup>, Paul D. Reneau<sup>1</sup>, James Eldridge<sup>4</sup>, Douglas W. Powell<sup>1</sup>. <sup>1</sup>Fairmont State University, Fairmont, WV. <sup>2</sup>The Ohio State University, Columbus, OH. <sup>3</sup>Southern Illinois University, Carbondale, IL. <sup>4</sup>University of Texas of the Permian Basin, Odessa, TX.

(No relationships reported)

Older adults adopt altered neuromuscular strategies to complete activities of daily living. One adaptation includes increased levels of agonist-antagonist muscle coactivation. It has been proposed that older adults increase coactivation to improve stability in response to losses in muscle mass associated with advancing age. However, no previous investigation has directly assessed the relationship between muscle mass and coactivation ratios (CAR).

**PURPOSE:** The purpose of this study was to examine the relationship between lean mass (LM) and muscle coactivation ratio. It was hypothesized that a negative correlation would exist between LM and CAR for the young adults (YA) and old adults (OA).

**METHODS:** Ten YA and 10 OA participated in this study. Age (YA: 22.9±1.4 yrs; OA: 80.9±3.1 yrs), height, mass, and LM (YA: 59.3±14.2 kg; OA: 40.7±6.6 kg) were recorded from each participant. Five downward stepping trials were performed by each participant while surface EMG (2000Hz) was collected from the vastus lateralis (VL), biceps femoris (BF), tibialis anterior (TA) and the gastrocnemius (LG) of the right lower extremity. EMG data were then smoothed and rectified using root mean squared (RMS) with a 20ms smoothing window. The mean RMS value over the stance phase was calculated for each muscle and normalized to the peak value for each muscle across all trials of that subject. CAR at the knee and ankle were calculated as the quotient of the BF divided by the VL and the TA divided by the GM, respectively. A correlation analysis was conducted to examine the relationship between lean mass and CAR. An analysis of variance (ANOVA) was used to determine differences in CAR, total mass and LM. Alpha level was set at p<0.05.

**RESULTS:** OA had significantly less LM than YA (OA: 40.7±6.6; YA: 59.3±14.2; p=0.001). YA and OA adults exhibited similar CARs at the knee (OA: 0.80±0.28; YA: 0.71±0.16; p=0.399) but young adults had a significantly lower CAR at the ankle (OA: 0.61±0.21; YA: 0.38±0.21; p=0.025). Though no statistical comparison was made in the correlation analysis, young and old adults exhibited opposite relationships between LM and CAR at the knee.

**CONCLUSIONS:** These data suggest that the altered neuromuscular activation patterns in old adults are not solely the result of declines in the mechanical capacity for movement.

**Eccentric Muscle Activation Patterns During a Five-time-sit-to-stand Movement**

Bradley S. Davidson<sup>1</sup>, Dana L. Judd<sup>2</sup>, Abbey C. Thomas<sup>2</sup>, Jennifer E. Stevens-Lapsley<sup>2</sup>. <sup>1</sup>University of Denver, Denver, CO. <sup>2</sup>University of Colorado Anschutz Medical Campus, Aurora, CO. (Sponsor: Catherine M. Jankowski, FACSMS)

(No relationships reported)

Muscle dysfunction is common in patients with end-stage osteoarthritis (OA) and is exacerbated following total knee arthroplasty (TKA). This dysfunction may be problematic during eccentric tasks in which the knee extensors encounter compound duties: absorbing force and maintaining knee stability.

**PURPOSE:** To examine knee muscle coactivation, individual muscle activity, and associated ground reaction force (GRF) production in healthy participants and TKA patients during the eccentric phases of a five-time-sit-to-stand movement (FTSTS).

**METHODS:** Patients with end-stage OA (n=14; age 63.9±9.3 years) performed FTSTS before and one month after TKA. Healthy participants (HP; n=9; age 61.6±9.9 years) performed FTSTS on one occasion. Electromyography (EMG) from *vastus lateralis* (QUAD) and *biceps femoris* (HAM) and vertical GRF were recorded from each limb. Ensemble averages taken from the eccentric phases were used to calculate coactivation index, normalized integrated EMG (iEMG), and normalized GRF impulse (iGRF) for each condition (HP, PreTKA, PostTKA) and limb (Surgical, NonSurgical). Data were analyzed with two-way ANOVAs and Tukey HSD for *post hoc* comparisons.

**RESULTS:** Coactivation index PreTKA (mean±sd: 61.6±15.1) and PostTKA (64.5±17.2) were higher than HP (49.1±15.8; p=0.011). PostTKA iGRF was lower in the Surgical (0.38±0.08) versus NonSurgical limb (0.62±0.08; p=0.009). QUAD iEMG PostTKA (81.1±24.1) was higher than PreTKA (62.7±19.4) and HP (51.6±19.1; p=0.001). QUAD iEMG was higher in the Surgical (71.4±27.4) versus NonSurgical limb (58.2±16.3; p=0.010). PostTKA HAM iEMG trended higher in the Surgical (85.1±18.0) versus NonSurgical limb (60.3±12.3; p=0.059).

**CONCLUSION:** Patients produced higher levels of coactivation than HP in both limbs before and after TKA, which suggests a protective strategy against knee instability. This strategy included greater QUAD and HAM activity in the Surgical limb, and reducing load absorption demands by shifting GRF to the NonSurgical limb. Despite these protective advantages, chronic movement asymmetry may impede post-surgical rehabilitation and accelerate NonSurgical joint degeneration. As such, patients may benefit from rehabilitation strategies to restore normal muscle activity and load absorption, especially during eccentric movements.

**Power And Fatigue Index Differ Between Sitting And Standing During The Wingate Test In Women**

Donald L. Hoover, Benjamin Lemon, Jessica Rolf, Angela Schleeper, Brooke Stoppel, Nathan Carlson, Jessica Karlson. *Rockhurst University, Kansas City, MO.*

(No relationships reported)

The Wingate Anaerobic Test (WAnT) is widely used to assess anaerobic performance. Yet, while this test has been studied in multiple contexts and populations, little is known about how the performance on this test is influenced by changes in cycling position, particularly in women. Deeper understanding of this issue has clinical implications, as cycling position is itself a form of exercise specificity, which is an important consideration in training and rehabilitation.

**PURPOSE:** The goal of this study was to explore the effects of seated and standing pedaling position on measures of peak power (PP) mean power (MP) and fatigue index (FI) during maximal cycling.

**METHODS:** Thirty two women (24.14±1.62 yr, 167.77±7.52 cm, 64.13±8.55 kg) completed this study. Criteria was used to 1) include subjects who exercise at least 30 minutes 3 or more days per week and 2) exclude individuals a) who possess any type of pathology which would, by itself, alter gross motor performance, or b) who regularly cycle. Participants visited the laboratory on two occasions, in which they completed the WAnT under seated and standing conditions. The trial order was randomized. Following a standardized warm up, each rode an electronically-braked cycle ergometer at maximal intensity for 30 seconds. Conditions were controlled and measured by computer. The following variables were assessed continuously during each trial: speed, watts, cadence, and measures of cycling efficiency (SpinScanTM, and average torque angle (ATA) throughout the 360° of pedal travel). Indices of PP, MP, and FI were calculated using 5 second time periods. Paired t-tests were used for statistical analysis.

**RESULTS:** Significant differences were found between the conditions for PP (t(31)= -2.46, p=0.02), MP (t(31)= -8.66, p=0.000), and FI (t(31)= 2.42, p=0.021). Power values were significantly higher - and the fatigue index was significantly lower - during the seated condition.

**CONCLUSIONS:** Lesser PP and MP were found for the WAnT in the standing position, compared to sitting. The FI was also more evident during the standing condition. The motor performance of the participants was clearly influenced by the cycling positions used in this study, suggesting that position-based neuromuscular coordination patterns contribute greatly to cycling performance in women.

### A Dynamic Overshoot In Skeletal Muscle Deoxygenation Is Not Evidence Of A VO<sub>2</sub> Kinetic Limitation

T Scott Bowen<sup>1</sup>, Harry B. Rossiter, FACSM<sup>1</sup>, Alan P. Benson<sup>1</sup>, Tatsuro Amano<sup>2</sup>, Narihiko Kondo<sup>2</sup>, John M. Kowalchuk<sup>3</sup>, Shunsaku Koga<sup>4</sup>. <sup>1</sup>University of Leeds, Leeds, United Kingdom. <sup>2</sup>Kobe University, Kobe, Japan. <sup>3</sup>The University of Western Ontario, London, ON, Canada. <sup>4</sup>Kobe Design University, Kobe, Japan.  
(No relationships reported)

An overshoot (OS) in skeletal muscle deoxygenation dynamics during constant work-rate exercise is seen in pathologies where O<sub>2</sub> delivery is limited (Diederich et al., *Cardiovasc Res*, 2002). Such a transient reduction in PO<sub>2</sub> is expected to limit the maximum rate of capillary-to-myocyte O<sub>2</sub> diffusion. Whether this limitation is sufficient to slow O<sub>2</sub> uptake (VO<sub>2</sub>) kinetics, however, is currently unclear.

**PURPOSE:** To determine the relationship between VO<sub>2</sub> kinetics and absolute skeletal muscle deoxygenation during reductions of inspired O<sub>2</sub> to attenuate O<sub>2</sub> delivery.

**METHODS:** Seven healthy males performed repeats of 8 min cycle ergometry from 5 W to 80 % lactate threshold in normoxia (N, F<sub>i</sub>O<sub>2</sub> = 0.21), moderate hypoxia (MH, 0.16) and severe hypoxia (SH, 0.12). VO<sub>2</sub> was measured breath-by-breath (Minato Medical AE-300S). Deoxy-(hemoglobin+myoglobin) (HHb) dynamics were measured from *rectus femoris* and *vastus lateralis* using quantitative, time-resolved, near-infrared spectroscopy (Hamamatsu TRS-20), and corrected for adipose thickness.

**RESULTS:** The phase II VO<sub>2</sub> time constant ( $\tau$ ) was slowed ( $p = 0.02$ ) as F<sub>i</sub>O<sub>2</sub> decreased (N,  $17 \pm 3$  (mean  $\pm$  SD); MH,  $22 \pm 4$ ; SH,  $29 \pm 9$  s). The resting and baseline HHb increased ( $p = 0.01$ ) as F<sub>i</sub>O<sub>2</sub> decreased, and  $\Delta$ HHb (end-exercise - baseline) was greater ( $p = 0.01$ ) in SH ( $24 \pm 13$   $\mu$ M) than N ( $16 \pm 8$   $\mu$ M) and MH ( $18 \pm 10$   $\mu$ M). There was no relationship between the increase in  $\tau$ VO<sub>2</sub> in hypoxia and relative OS incidence (N, 38 %; MH, 52 %; SH, 43 %;  $r^2 < 0.01$ ;  $p = 0.95$ ), or OS area ( $r^2 = 0.04$ ;  $p = 0.49$ ), but the increase in  $\tau$ VO<sub>2</sub> was positively related to the increase in peak HHb ( $r^2 = 0.46$ ;  $p < 0.01$ ).

**CONCLUSIONS:** An overshoot in muscle deoxygenation in heart failure (Sperandio et al., *AJP*, 2009) or pulmonary arterial hypertension (Barbosa et al., *EJAP*, 2011) is suggested to reflect a mismatch in O<sub>2</sub> delivery-to-utilization that contributes to slowing VO<sub>2</sub> kinetics. While the peak HHb during the transient was related to slowed VO<sub>2</sub> kinetics in hypoxia, the OS incidence and OS area were not. This suggests that an overshoot in HHb *per se* is not evidence of a capillary-myocyte O<sub>2</sub> diffusion limitation to VO<sub>2</sub> kinetics. Rather, the absolute peak HHb (specifically, a reflection of a low capillary PO<sub>2</sub>) during the transient determined by quantitative NIRS may be a better index of an O<sub>2</sub> delivery limitation to VO<sub>2</sub> kinetics.

### Physiological Responses to an Acute Bout of Sprint Interval Cycling

Eric C. Freese, Nicholas H. Gist, Kirk J. Cureton, FACSM. University of Georgia, Athens, GA.  
(No relationships reported)

Sprint interval training has been shown to improve skeletal muscle oxidative capacity, maximal oxygen uptake and insulin sensitivity, and reduce postprandial triglycerides.

**PURPOSE:** To determine the oxygen uptake and related cardiorespiratory responses and associated energy expenditure during an acute bout of sprint interval cycling (SIC).

**METHODS:** Twelve healthy, college-aged subjects, 6 men and 6 women, completed 2 SIC sessions with at least 7 d between trials. SIC was performed on a mechanically-braked cycle ergometer and involved a 5-min warm-up followed by four 30-s all-out sprints with 4 min active recovery. Work performed was quantified using an optical sensor to measure flywheel revolutions. Oxygen uptake was measured continuously by open-circuit spirometry during the last minute of warm-up and throughout the SIC session. The energy expenditure during each sprint was based on the estimated anaerobic energy contribution to the sprints and the net aerobic energy calculated from measured oxygen uptake above rest.

**RESULTS:** The average work performed decreased during the four sprints for males ( $19.3 \pm 2.7$ ,  $17.5 \pm 3.5$ ,  $16.2 \pm 4.0$ , and  $14.3 \pm 6.0$  kJ) and females ( $11.6 \pm 1.4$ ,  $11.1 \pm 1.5$ ,  $10.6 \pm 1.5$ , and  $10.6 \pm 1.9$  kJ). Percent fatigue increased from sprint 1 to sprint 4 ( $29.8 \pm 11.8$ ,  $34.6 \pm 15.8$ ,  $38.5 \pm 17.7$ , and  $38.5 \pm 15.4$ ). Average aerobic, anaerobic, and total energy expended during the 18 min necessary to complete the SIC session were  $130.8 \pm 31.5$ ,  $72.6 \pm 8.3$ , and  $203.4 \pm 38.2$  kcal for males and  $108.1 \pm 16.9$ ,  $47.6 \pm 6.4$ , and  $155.7 \pm 21.3$  kcal for females. Peak oxygen uptake (ml/kg/min) during the 4 sprints was 35.3, 38.8, 38.8, and 36.8. Peak heart rate (bpm) during the 4 sprints was 164, 172, 177, and 175. Peak minute ventilation (L/min) during the 4 sprints was 75, 102, 107, and 101.

**CONCLUSIONS:** An acute bout of SIC elicits submaximal oxygen uptake and cardiorespiratory responses during each interval that approximates ~80% of estimated maximal values. The energy expended is much lower than that expended in moderate-intensity aerobic exercise training programs shown to improve aerobic capacity and insulin sensitivity, and reduce postprandial triglycerides, signifying the importance of the high-intensity nature of the exercise.

### Optimising And Validating A Computational Model Of The Influence Of Circulatory Dynamics On VO<sub>2</sub> Kinetics

Alan P. Benson<sup>1</sup>, Bruno Grassi<sup>2</sup>, Harry B. Rossiter, FACSM<sup>1</sup>. <sup>1</sup>University of Leeds, Leeds, United Kingdom. <sup>2</sup>Università degli Studi di Udine, Udine, Italy.  
(No relationships reported)

The dynamics of the circulation can dissociate muscle (VO<sub>2m</sub>) and alveolar (VO<sub>2A</sub>) O<sub>2</sub> uptake kinetics. Computational models to investigate this (e.g. Rossiter & Benson, *MSSE* 42:25-, 2010) are yet to be directly validated against experimental data, and the influence of the structural organisation of the venous vascular compartments on these kinetics has yet to be determined.

**PURPOSE:** To optimise and validate a computational model linking muscle and lung gas exchange kinetics, using simultaneously-measured VO<sub>2m</sub>, muscle blood flow (Q<sub>m</sub>) and VO<sub>2A</sub> from six healthy male subjects during moderate-intensity exercise.

**METHODS:** VO<sub>2m</sub> (by direct Fick) and Q<sub>m</sub> (by thermodilution) were measured on transition from unloaded to  $183 \pm 20$  W cycle ergometry (published in Grassi et al, *JAP* 80:988-, 1996). Baselines, steady-states and time constants ( $\tau$ ) for VO<sub>2m</sub> and Q<sub>m</sub> were used as inputs for a model with a single 3 L venous volume (SCM; as in Barstow et al, *JAP* 68:979-, 1990) and an optimised multi-compartment model (MCM) with volumes draining the exercising muscle, the rest of the body, and a volume carrying mixed-venous blood to the lung. Error between model-predicted and experimental breath-by-breath VO<sub>2A</sub> was calculated as the sum of absolute differences in time delay (TD) and phase II  $\tau$ .

**RESULTS:** Experimentally-measured VO<sub>2A</sub> kinetics were (mean  $\pm$  SD): TD =  $17.5 \pm 1.8$  s;  $\tau$  =  $18.7 \pm 4.2$  s. The SCM gave an error of  $8.2 \pm 9.6$  s (TD =  $16.6 \pm 0.9$  s;  $\tau$  =  $21.4 \pm 12.2$  s). With the MCM, separate muscle, body and mixed-venous volumes of  $0.8 \pm 0.7$ ,  $0.6 \pm 1.1$  and  $1.7 \pm 1.0$  L respectively (total venous volume =  $3.1 \pm 1.0$  L) improved predictions for TD ( $17.4 \pm 1.9$  s) and  $\tau$  ( $20.5 \pm 10.0$  s) and significantly reduced error to  $5.1 \pm 7.6$  s compared to SCM (paired *t*-test,  $p = 0.02$ ).

**CONCLUSIONS:** These data validate a computational model linking the kinetics of VO<sub>2m</sub> and VO<sub>2A</sub> against experimental measurements. Distributing blood between three venous vascular compartments significantly improved the accuracy with which the model reproduced experimentally-determined VO<sub>2A</sub> kinetics, suggesting that both the structure and dynamics of the circulation should be accounted for when interpreting the pulmonary expression of VO<sub>2m</sub> dynamics.

### Helium Breathing Abolishes The Slow Component Of Pulmonary Oxygen Uptake Kinetics In Obese Adolescents

Bruno Grassi<sup>1</sup>, Desy Salvadego<sup>1</sup>, Alessandra Patrizi<sup>2</sup>, Gabriella Tringali<sup>2</sup>, Fiorenza Agosti<sup>2</sup>, Alessandro Sartorio<sup>2</sup>. <sup>1</sup>University of Udine, Udine, Italy. <sup>2</sup>Italian Institute of Auxology, Piancavallo (VB), Italy.  
(No relationships reported)

**BACKGROUND:** Ventilatory dynamics during exercise are modified by obesity. Replacement of nitrogen by helium in inspired gas reduces the work of breathing.

**PURPOSE:** To determine, in obese adolescents (OB), if respiratory muscles unloading via helium-O<sub>2</sub> breathing would reduce the amplitude of the "slow component" of pulmonary O<sub>2</sub> uptake (VO<sub>2</sub>) kinetics and increase exercise tolerance.

**METHODS:** Seven male OB (age 16.7 ± 1.4 [x ± SD] years, body mass 101.5 ± 9.0 kg, body mass index 32.4 ± 4.7 kg/m<sup>2</sup>) were evaluated. Experiments were conducted with subjects inspiring room air (CTRL) and a 21% O<sub>2</sub>-79% helium mixture (HE). Two exercise protocols were performed on a cycle ergometer: an incremental exercise (for the determination of maximal VO<sub>2</sub> and the gas exchange threshold [GET]), and a 12-min constant-load exercise (for VO<sub>2</sub> kinetics analysis) at a work rate (122.6 ± 18.4 watt) corresponding to 120% of GET determined in CTRL.

**RESULTS:** A slow component of VO<sub>2</sub> kinetics, with an amplitude corresponding to 10.2 ± 3.5% of the total amplitude of the VO<sub>2</sub> response, was observed in CTRL; the amplitude was significantly lower in HE (1.3 ± 3.4%). The lower amplitude of the slow component in HE was associated with: lower heart rate (165.0 ± 13.5 b/min in CTRL vs. 158.0 ± 14.5 in HE); lower "gain" of the VO<sub>2</sub> response (Delta VO<sub>2</sub>/Delta work rate: 16.1 ± 1.0 mL/min/watt in CTRL vs. 14.2 ± 1.3 in HE); lower gas exchange ratio (0.93 ± 0.05 in CTRL vs. 0.89 ± 0.09 in HE); lower values of rate of perceived exertion for dyspnea/respiratory discomfort (6.4 ± 1.0 in CTRL vs. 3.9 ± 0.7 in HE) and for "leg effort" (7.5 ± 1.6 in CTRL vs. 5.4 ± 1.3 in HE).

**CONCLUSION:** Respiratory muscles unloading via helium-O<sub>2</sub> breathing determined, in obese adolescents, the virtual abolishment of the slow component of pulmonary VO<sub>2</sub> kinetics during constant work rate exercise at 120% of GET, and clear signs of increased exercise tolerance. Respiratory muscles training may represent an option for increasing exercise tolerance in obese patients.

Supported by: Progetti di Ricerca Corrente, Italian Institute for Auxology (Milan).

### ATP Turnover And The Coupling Of Mitochondrial Oxidative Phosphorylation During Dynamic Exercise In Humans

Daniel T. Cannon<sup>1</sup>, T Scott Bowen<sup>1</sup>, Scott R. Murgatroyd<sup>1</sup>, William E. Bimson<sup>2</sup>, Graham J. Kemp<sup>2</sup>, Harry B. Rossiter, FACSM<sup>1</sup>. <sup>1</sup>University of Leeds, Leeds, United Kingdom. <sup>2</sup>University of Liverpool, Liverpool, United Kingdom.  
(No relationships reported)

During constant work rate (CWR) exercise above the lactate threshold (LT), the kinetics of oxygen uptake (VO<sub>2</sub>) are supplemented by the VO<sub>2</sub> slow component (VO<sub>2sc</sub>), reflecting reduced work efficiency. The majority of the VO<sub>2sc</sub> originates from the active locomotor muscles, yet the intracellular source of inefficiency is less clear. An increase in the ATP cost of power production (P:W) has been postulated, rather than a change in the O<sub>2</sub> cost of ATP resynthesis (P:O).

**PURPOSE:** To determine ATP turnover rate during sub- and supra-LT CWR exercise in humans.

**METHODS:** Seven healthy participants completed a series of prone, knee-extension, rest-exercise-rest protocols using a computer-controlled ergometer in a 3T superconducting magnet. <sup>31</sup>P spectra (3200 Hz bandwidth; 1024 data points; 2 s TR) were collected from the quadriceps throughout using a dual-tuned (<sup>1</sup>H and <sup>31</sup>P) surface coil. Moderate (MOD; sub-LT) and heavy (HVY; supra-LT) CWR exercise was completed for 3 and 8 min allowing total ATP turnover (ATP<sub>tot</sub>) to be estimated at cessation from the dynamics of phosphocreatine (PCr) and proton handling. Pulmonary VO<sub>2</sub> was measured breath-by-breath using a mass spectrometer and turbine.

**RESULTS:** During MOD there was no discernable VO<sub>2sc</sub> (0.07 ± 0.15 L.min<sup>-1</sup>). Conversely, during HVY the VO<sub>2sc</sub> was larger ( $p < 0.05$ ) at 0.32 ± 0.11 L.min<sup>-1</sup> or 20 ± 6 % of the fundamental VO<sub>2</sub> amplitude. Similarly, the difference in PCr between 3 and 8 min of MOD was minimal (-2.8 ± 4.0 mM), whereas this difference was larger ( $p < 0.05$ ) during HVY (2.1 ± 1.5 mM or 17 ± 13 % of the fundamental amplitude). ATP<sub>tot</sub> was constant during MOD (18.6 ± 11.7 vs. 15.3 ± 8.02 mM.min<sup>-1</sup>;  $p > 0.21$ ), but increased between 3 and 8 min of HVY (24.1 ± 13.1 vs. 28.3 ± 9.46 mM.min<sup>-1</sup>;  $p < 0.098$ ; 17.0 ± 22.0 %Δ). However, ΔATP<sub>tot</sub> was not related to the VO<sub>2sc</sub> during HVY ( $r = 0.2$ ;  $p > 0.6$ ). Three of seven participants exhibited a non-linear PCr/VO<sub>2</sub> relationship.

**CONCLUSIONS:** The rate of ATP turnover increased between 3 and 8 min of supra-LT, but not sub-LT, exercise. Importantly, this conclusion was reached without assumptions of intramuscular PCr/VO<sub>2</sub> or ADP/VO<sub>2</sub> relationships. However, the poor correlation between ΔATP<sub>tot</sub> and the VO<sub>2sc</sub> suggests that reduced work efficiency in HVY exercise is not wholly consequent to augmented P:W, but that reductions in P:O may also contribute.

Supported by the BBSRC UK BB/100162X/1

2207 Board #253 MAY 31 9:00 AM - 10:30 AM

### Acute Metabolic Responses during Postprandial Exercise of Incremental Intensity

Jie Kang, FACSM, Joseph Rosenberg, Emily Raines, Nicholas Ratamess, Fernando Naclerio, Avery Faigenbaum, FACSM. The College of New Jersey, Ewing, NJ.  
(No relationships reported)

**PURPOSE:** Exercise and digestive processes are known to elevate the metabolic rate independently. However, it remains equivocal whether these two events are additive when taking place simultaneously. The present investigation was to examine metabolic cost and substrate utilization during exercise that occurred shortly after the consumption of a meal.

**METHODS:** Twenty healthy volunteers including 10 men and 10 women completed a VO<sub>2</sub> peak test and three experimental trials: 1) consumption of a test meal (M), 2) exercise only (E), and 3) consumption of a test meal followed by exercise (M+E). All trials commenced in the morning after an overnight fasting and were preceded by a 10-min rest period (R) during which resting VO<sub>2</sub>, heart rate (HR), and respiratory exchange ratio (RER) were determined. Exercise protocol consisted of three successive 10-minute cycle exercises at 50, 60, and 70% VO<sub>2</sub> peak in an ascending order. The test meal contained 725 kilocalories composed of 40%, 35% and 25% of carbohydrate, lipids and protein, respectively. Data collection including VO<sub>2</sub>, HR, and RER began immediately after the rest period in E and 45 min after the start of the test meal in M and M+E. Delta efficiency was calculated as the ratio of the increment of power output to the increment of energy expenditure.

**RESULTS:** Resting oxygen uptake (VO<sub>2</sub>) in l.min<sup>-1</sup> was higher ( $p < 0.05$ ) in M than R (0.28 ± 0.09 vs. 0.22 ± 0.06). Exercising VO<sub>2</sub> in l.min<sup>-1</sup> was lower ( $p < 0.05$ ) at 50% VO<sub>2</sub> peak in E than M+E (1.38 ± 0.08 vs. 1.51 ± 0.08), while no differences between E and E+M were seen at higher intensities. Respiratory exchange ratio was lower ( $p < 0.05$ ) in E than E+M at 50% (0.89 ± 0.04 vs. 0.94 ± 0.04), 60% (0.92 ± 0.05 vs. 0.96 ± 0.04) and 70% VO<sub>2</sub> peak (0.95 ± 0.04 vs. 0.98 ± 0.04). No differences in delta efficiency were observed between M+E and E.

**CONCLUSION:** Exercise during postprandial period elicits a greater increase in energy expenditure than exercise in a fasted state. However, this additive effect of meal and exercise seems intensity-dependent and is not caused by a decrease in metabolic efficiency of the exercising muscle. Postprandial exercise also results in a greater percentage of energy derived from carbohydrate regardless of exercise intensity.

2208 Board #254 MAY 31 9:00 AM - 10:30 AM

### The Effect Of Work Rate On Oxygen Uptake Kinetics During Exhaustive Severe Intensity Cycling Exercise

Jennifer L. Sylvester, Samantha D. Burdette, Steven W. Cross, Nosa O. Idemudia, John H. Curtis, Jakob L. Vingren, David W. Hill, FACSM. University of North Texas, Denton, TX.  
(No relationships reported)

During exhaustive severe intensity exercise, the oxygen uptake (VO<sub>2</sub>) increases exponentially, with a time constant of ~30 s. After ~1 to 2 min, a slow component emerges and drives the VO<sub>2</sub> to its maximum. There are clear differences in the VO<sub>2</sub> response profile across exercise intensity domains. These disparities might not be attributable to metabolic demand but, rather, to characteristics of the various intensity domains, such as the consequences of lactic acid production.

**PURPOSE:** To investigate the role of exercise intensity on the VO<sub>2</sub> response profile at intensities wholly within the severe domain.

**METHODS:** Four women (mean  $\pm$  SD: age  $22 \pm 2$  years, height  $167 \pm 7$  cm, mass  $66 \pm 5$  kg) and eight men (age  $23 \pm 2$  yr, height  $179 \pm 9$  cm, mass  $78 \pm 10$  kg) performed exhaustive constant-power cycle ergometer tests at two different severe intensity work rates ( $263 \pm 78$  W and  $214 \pm 64$  W). Smoothed breath-by-breath  $\text{VO}_2$  data were fitted to a two-component (primary response and slow component) model using iterative regression.

**RESULTS:** Times to exhaustion were  $217 \pm 27$  s and  $590 \pm 82$  s, respectively. The  $\text{VO}_{2\text{max}}$  values were the same at the two different work rates ( $2973 \pm 691$  ml $\cdot$ min $^{-1}$  and  $3011 \pm 728$  ml $\cdot$ min $^{-1}$ ). The amplitude of the primary response was greater ( $p < 0.05$ ) at the higher work rate ( $2095 \pm 716$  ml $\cdot$ min $^{-1}$ ) than at the lower work rate ( $1857 \pm 618$  ml $\cdot$ min $^{-1}$ ) and the amplitude of the slow component was smaller ( $367 \pm 177$  ml $\cdot$ min $^{-1}$  vs  $645 \pm 347$  ml $\cdot$ min $^{-1}$ ). In addition, the time delay before the emergence of the slow component was shorter at the higher work rate ( $92 \pm 22$  s vs  $116 \pm 42$  s).

**CONCLUSION:** The results show that exercise intensity *per se* affects the  $\text{VO}_2$  response profile within the severe intensity domain and suggest that metabolic demand drives the primary response of  $\text{VO}_2$  kinetics within this domain.

**2209** Board #255 MAY 31 9:00 AM - 10:30 AM  
**Heart Rate and Oxygen Uptake Kinetics Before and After Prolonged Spaceflight**

Uwe Drescher<sup>1</sup>, Alan Moore, FACSM<sup>2</sup>, Dieter Essfeld<sup>1</sup>, Uwe Hoffmann<sup>1</sup>. <sup>1</sup>German Sport University Cologne, Cologne, Germany. <sup>2</sup>Wyle Integrated Science and Engineering Group, Houston, TX.  
(No relationships reported)

Routine assessments of the cardiovascular training state of the International Space Station (ISS) astronauts following flight have been limited to heart rate (HR) measurements during submaximal exercise tests. The kinetic responses to work rate change of HR and both respiratory and muscular oxygen uptake (RVO<sub>2</sub> and MVO<sub>2</sub>, respectively) may be used to more accurately evaluate the efficiency and regulation of the cardiorespiratory system than simple examination of HR during steady-state work stages.

**PURPOSE:** To examine the influence of long-duration spaceflight on the kinetic responses of HR (Hpeak), RVO<sub>2</sub> (Rpeak), and MVO<sub>2</sub> (Mpeak).

**METHODS:** Seven astronauts (age:  $48 \pm 4$  yr; ht:  $172 \pm 7$  cm; wt:  $73 \pm 18$  kg; ISS stay:  $154 \pm 27$  d; preflight workload (WLpeak):  $221 \pm 64$  W; preflight  $\text{VO}_2$ peak:  $2.6 \pm 0.9$  L/min) [means  $\pm$  SD] performed exercise tests comprised of dynamic workload changes between 30-80 W on a cycle ergometer (Lode). These tests were performed before (L-170  $\pm$  59 d) and twice after (early R+6  $\pm$  3 d; late R+20  $\pm$  4 d) spaceflight. Breath-by-breath gas exchange was measured using the ISS Portable Pulmonary Function System. HR was determined by measuring ECG. Mpeak was computed using a 2-compartment model comprised of exercising and non-exercising parts. Time-series analysis was applied to determine the maximal cross-correlation function as indicators for the kinetic responses of Hpeak, Rpeak, as well as Mpeak. Friedman test for related samples was used to analyze for differences across the time.

**RESULTS:** The kinetic responses for Hpeak were calculated as  $0.497 \pm 0.095$  (L-170),  $0.494 \pm 0.119$  (R+6) and  $0.524 \pm 0.098$  (R+20), respectively. Rpeak was estimated as  $0.432 \pm 0.061$ ,  $0.371 \pm 0.077$ ,  $0.365 \pm 0.054$ , and Mpeak as  $0.451 \pm 0.091$ ,  $0.373 \pm 0.087$  and  $0.401 \pm 0.091$ , respectively. No significant differences in Hpeak ( $P = 0.37$ ) were observed. Rpeak ( $P = 0.05$ ), and Mpeak ( $P = 0.05$ ) both bordered on significance.

**CONCLUSIONS:** Hpeak seems uninfluenced by long-duration spaceflight. Rpeak and Mpeak seem reduced postflight by trend. Thus, prolonged spaceflight may alter both Rpeak and Mpeak. The influence of other factors, such as the individual exercise training of the astronauts during weightlessness on these parameters, remains to be clarified.

The study was funded by the DLR (Deutsches Zentrum für Luft- und Raumfahrt), Germany (FKZ 50WB0726).

**2210** Board #256 MAY 31 9:00 AM - 10:30 AM  
**Effects Of Caffeine On VO2 And VCO2 Kinetics During Supramaximal Cycling**

Kenneth R. Dragoo<sup>1</sup>, Kelly E. Johnson<sup>2</sup>, Eliseo A. Gonzalez<sup>1</sup>. <sup>1</sup>Eastern Washington University, Cheney, WA. <sup>2</sup>The University of Akron, Akron, OH.  
(No relationships reported)

The time course change in oxygen consumption ( $\text{VO}_2$ ) has been shown to remain unaltered following caffeine ingestion for moderate, heavy and severe domain exercise. However, carbon dioxide production ( $\text{VCO}_2$ ) kinetics remain unclear.

**PURPOSE:** To determine the effects of caffeine on  $\text{VO}_2$  and  $\text{VCO}_2$  kinetics during supramaximal cycling time-to-exhaustion (TTE) at 120% maximal oxygen consumption ( $\text{VO}_{2\text{max}}$ ).

**METHODS:** Seventeen subjects ( $23.3 \pm 3.4$  y,  $1.71 \pm 0.12$  m and  $75.3 \pm 13.8$  kg) voluntarily participated. A maximal graded exercise test and two submaximal cycling tests were used to determine the TTE intensity. A familiarization session was completed prior to the TTE with identical procedures. All subjects refrained from caffeine for 48h and vigorous exercise for 24h. The caffeine (C; spearmint flavored caffeinated gum) or placebo (P; spearmint flavored gum) was given in a double blind fashion for 5min followed by 20min seated rest and 10min warm up. Subjects then cycled at an unloaded resistance at 70revolutions per minute. The 120%  $\text{VO}_{2\text{max}}$  intensity was applied without notice. Subjects cycled until exhaustion. Breath-by-breath data for  $\text{VO}_2$  and  $\text{VCO}_2$  were fitted to the model  $X(t) = SS + A \{1 - \exp[-(t - TD)/\tau]\}$  where  $X(t)$  is  $\text{VO}_2$  or  $\text{VCO}_2$  at time  $t$ ,  $SS$  is the steady state at unloaded cycling,  $A$  is the amplitude,  $TD$  is the time delay, and  $\tau$  is the time constant. Mean reaction time (MRT) was calculated as  $MRT = TD + \tau$ . Full factorial analyses of variance were used to compare means.

**RESULTS:**  $\text{VO}_2$   $\tau$  ( $P = 52.8 \pm 16.1$  s,  $C = 59.6 \pm 11.7$  s),  $\text{VCO}_2$   $\tau$  ( $P = 70.7 \pm 14.5$  s,  $C = 79.9 \pm 18.1$  s) and  $\text{VCO}_2$  MRT ( $P = 79.3 \pm 16.8$  s,  $C = 87.4 \pm 18.0$  s) were significantly different ( $p < 0.05$ ).  $\text{VO}_2$  MRT ( $P = 55.9 \pm 16.7$  s,  $C = 61.8 \pm 11.0$  s) approached significance ( $p = 0.059$ ).

**CONCLUSIONS:** Caffeine may delay  $\text{VO}_2$  and  $\text{VCO}_2$  kinetics. Future research should study minute ventilation to determine if caffeine alters bodily  $\text{CO}_2$  stores, thereby delaying  $\text{VCO}_2$  kinetics.

**2211** Board #257 MAY 31 9:00 AM - 10:30 AM  
**Slowed Muscle Vo2 Kinetics With Raised Metabolism: Not Dependent On Blood Flow Or Recruitment Dynamics**

Rob C.I. Wüst<sup>1</sup>, James R. McDonald<sup>2</sup>, Brian S. Ferguson<sup>2</sup>, Yi Sun<sup>2</sup>, Matthew J. Rogatzki<sup>2</sup>, Jessica Spires<sup>3</sup>, John M. Kowalchuk<sup>4</sup>, L. Bruce Gladden, FACSM<sup>2</sup>, Harry B. Rossiter, FACSM<sup>1</sup>. <sup>1</sup>University of Leeds, Leeds, United Kingdom. <sup>2</sup>Auburn University, Auburn, AL. <sup>3</sup>Case Western Reserve University, Cleveland, OH. <sup>4</sup>The University of Western Ontario, London, ON, Canada.  
(No relationships reported)

The rate of adjustment ( $\tau$ ) of pulmonary oxygen uptake ( $\text{VO}_2$ ) is slowed when initiated from a higher versus lower metabolic rate (Bowen et al., Exp Physiol 96: 1049-61, 2011). Whether this is consequent to the intrinsic properties of newly recruited muscle fibers, slowed circulatory dynamics or the effects of a raised metabolism is currently unclear.

**PURPOSE:** To determine muscle  $\text{VO}_2$  kinetics in canine muscle in situ, with independent experimental control over muscle recruitment, blood flow and metabolic rate.

**METHODS:** The gastrocnemius complex of 6 anaesthetized, ventilated dogs was surgically isolated and the tendon attached to a force transducer. Blood flow through the popliteal artery was pump-controlled at a constant flow ( $1.09 \pm 0.25$  L $\cdot$ kg $^{-1}$  $\cdot$ min $^{-1}$ ; mean  $\pm$  SD). Isometric tetanic contractions (50 Hz; 200 ms duration) were elicited via supramaximal sciatic nerve stimulation to recruit all muscle fibers. Metabolic rate was manipulated using 3 min of stimulation at 0.33 Hz (S1) followed by 3 min at 0.67 Hz (S2). Muscle  $\text{VO}_2$  was determined contraction-by-contraction using an ultrasonic flowmeter and inline venous oximetry. Tissue deoxygenation (HHbMb) was measured using near-infrared spectroscopy. Phase II  $\text{VO}_2$  and HHbMb dynamics were fitted to a mono-exponential model to give a time delay (TD),  $\tau$  and amplitude.

**RESULTS:** Upon stimulation onset, the TD for  $\text{VO}_2$  was greater ( $p < 0.05$ ) in S1 than in S2:  $7 \pm 1$  vs.  $4 \pm 2$  s. Similarly, TD for HHbMb ( $3 \pm 2$  s) in S1 was shorter ( $p < 0.002$ ) than for  $\text{VO}_2$ , but greater ( $p < 0.05$ ) than 0 s in all cases. However,  $\tau\text{VO}_2$  and  $\tau\text{HHbMb}$  were both smaller ( $p < 0.05$ ) in S1 ( $12 \pm 2$  s and  $11 \pm 4$  s, respectively) as compared to S2 ( $18 \pm 3$  s and  $21 \pm 5$  s, respectively). The  $\text{VO}_2$  amplitude was larger ( $p < 0.01$ ) in S1 than S2:  $70 \pm 15$  vs.  $43 \pm 13$  ml $\cdot$ kg $^{-1}$  $\cdot$ min $^{-1}$ .

**CONCLUSIONS:** Under conditions in which all muscle fibers were recruited and blood flow was maintained at the S2 steady-state value throughout, muscle  $\text{VO}_2$  kinetics were slower on transition from a raised metabolic rate; consistent with the proposal by Bowen et al. (2011) in humans. Despite increased mitochondrial enzyme activity following S1, the present data suggest that  $\text{VO}_2$  takes longer to achieve its steady state when contractions are initiated from a raised metabolic rate, where the muscle energetic state may be less favorable (i.e. less negative  $\Delta G_{\text{ATP}}$ ).

**High-Intensity Interval Training Speeds VO<sub>2</sub> Kinetics In Moderate-Intensity Exercise Transitions Initiated From Elevated Metabolic Rates**

Alexandra M. Williams, Donald H. Paterson, FACSM, John M. Kowalchuk. *University of Western Ontario, London, ON, Canada.*

(No relationships reported)

During step-transitions in work rate (WR) within the moderate-intensity (MOD) exercise domain, pulmonary O<sub>2</sub> uptake (VO<sub>2p</sub>) kinetics are slowed and VO<sub>2p</sub> gain ( $\Delta$ VO<sub>2p</sub>/ΔWR) is greater when exercise is initiated from an elevated metabolic rate. High-intensity interval training (HIT) has been shown to speed VO<sub>2p</sub> kinetics, without affecting kinetics of local muscle deoxygenation ([HHbMb]), when step-transitions to MOD exercise are initiated from lower, light-intensity baseline metabolic rates. The effects of HIT on step-transitions initiated from elevated metabolic rates have not been established.

**PURPOSE:** To investigate the effects HIT on VO<sub>2p</sub> and muscle deoxygenation kinetics during transitions from low and elevated metabolic rates, within the MOD domain.

**METHODS:** Eight untrained young men (27±6 yrs; mean±SD) completed 12 sessions of HIT (spanning 4 weeks). HIT consisted of 8-12 1-min intervals on a cycle ergometer, at a WR corresponding to 110% of pre-training WR<sub>max</sub> (established during ramp incremental (RI) exercise testing). Pre-, mid- and post-training, subjects completed a RI test to determine VO<sub>2max</sub>, WR<sub>max</sub> and estimated lactate threshold (LT). Participants additionally completed double-step constant-load tests, consisting of step transitions from 20W→Δ45%LT (LS) and Δ45→90%LT (US). VO<sub>2p</sub> was measured breath-by-breath using mass spectrometry and volume turbine, and the [HHbMb] profile was monitored using near-infrared spectroscopy. The ensemble-averaged VO<sub>2p</sub> and [HHbMb] profiles for each transition were modeled as mono-exponential responses using non-linear regression techniques. The time constant ( $\tau$ VO<sub>2p</sub>) and amplitude of the fundamental, phase II VO<sub>2p</sub> response were estimated for each subject and transition.

**RESULTS:** HIT led to a greater VO<sub>2max</sub> (43ml/kg/min→ 50ml/kg/min, p<0.05), and lower  $\tau$ VO<sub>2</sub> for both the lower (LS: 24s→ 15s, p<0.05) and upper steps (US: 45s→ 25s, p<0.05). However, mean response time of [HHbMb] was unchanged in the lower (LS: 18s vs. 21s) and upper steps (US: 32s vs. 28s).

**CONCLUSIONS:** These results indicate that the speeding of VO<sub>2p</sub> kinetics in both the LS and US may be due, in part, to better matching of the muscle O<sub>2</sub> utilization-to-microvascular O<sub>2</sub> delivery relationship within the working muscle following 12 sessions of HIT.

**Moderate Hypoxia Does Not Slow Muscular Oxygen Uptake At The Onset Of Intense Exercise**

Peter M. Christensen, Nikolai Nordsborg, Lars Nybo, Niels Secher, Mikael Sander, Jens Bangsbo. *University of Copenhagen, KBH O, Denmark.*

(No relationships reported)

Several studies have reported slower oxygen uptake (VO<sub>2</sub>) kinetics measured at the pulmonary level in response to hypoxia during cycling supporting the concept of an O<sub>2</sub> delivery limitation to the rise in VO<sub>2</sub> at the onset of exercise. However the response to hypoxia at the onset of exercise with regards to VO<sub>2</sub> at the muscular level and O<sub>2</sub> delivery has not been measured.

**PURPOSE:** To investigate whether a reduction in oxygen delivery through inspiring of hypoxic gas causes lower oxygen uptake of the contracting muscles during intense exercise.

**METHODS:** 6 healthy young male subjects performed intense 2-legged knee-extensor exercise (100±6 W, mean±SE) for 2 min in hypoxia (FiO<sub>2</sub>=0.13; H) and normoxia (N) on separate days. Catheters were placed in the femoral artery and vein allowing for blood samples and blood flow measurements at rest, just prior to exercise and after 3, 6, 9, 12, 15, 20, 40, 60 & 120 s of exercise. A 2-way ANOVA test for repeated measures using sampling time and condition (N or H) as factors was used for the statistical analysis.

**RESULTS:** Blood flow was not different between N and H, however arterial O<sub>2</sub> content was lowered (P<0.05) from 191±1 ml/l in N to 181±1 ml/l in H, resulting in a ~20-30% reduction in O<sub>2</sub> delivery in H (P<0.01). The arterial-venous O<sub>2</sub> difference was not different between conditions, thus muscular VO<sub>2</sub> was not affected by the reduced O<sub>2</sub> delivery. Lactate release and pH was not different between N and H.

**CONCLUSION:** The present study shows that muscular VO<sub>2</sub> and anaerobic lactic metabolism during intense two-legged knee-extensor exercise is unaffected despite a 20-30% reduction in O<sub>2</sub> delivery caused by inspiring hypoxic air, suggesting that in normoxia O<sub>2</sub> delivery does not limit muscle VO<sub>2</sub> during intense exercise.

2214 Board #260 MAY 31 9:00 AM - 10:30 AM

**A Measurement of the Energy Cost of Resistance Training Activities in Young Men**

Jesse W. Vezina, Nathanael Meckes, Cheryl A. Der Ananian, Kathryn D. Campbell, Barbara E. Ainsworth, FACSM. *Arizona State University, Phoenix, AZ.*

(No relationships reported)

Many studies have been conducted to evaluate the energy expenditure of various types of physical activity. Very few however, have focused on the energy expenditure of resistance training. Moreover; the studies that have examined resistance training often report energy expenditure for an entire resistance training session, rather than for individual activities.

**PURPOSE:** To determine the energy cost of four modes of resistance training (push-ups, curl-ups, pull-ups, and lunges) in young men.

**METHODS:** Twelve well trained men (minimum three days per week of resistance training over the past year), aged 23.6 (SD=2.84) years were recruited to participate in the study. Each of the 12 men completed three trials of each of the four exercises, in a randomly assigned order, on one visit to the laboratory which lasted slightly longer than one hour (M=72 min, SD=5.9 min). Each activity was performed to the beat of a metronome set at 40 beats per minute. Participants were asked to complete repetitions of the exercises at this rate for 60 seconds. A total of 20 repetitions were completed if the subject was able to complete the activity for the entire duration. Average time spent in push-ups (M=59.4 sec, SD=1.5), curl-ups (M=60.0 sec, SD=0.0), pull-ups (M=29.3 sec, SD=6.7), and lunges (M=60.0 sec, SD=0.0) was recorded. The oxygen consumption of the men was monitored constantly throughout the trial by indirect calorimetry, and data were recorded every five seconds. Mean VO<sub>2</sub> values were calculated for each exercise by averaging the VO<sub>2</sub>, in ml/kg/min, over the final two trials of each activity. These VO<sub>2</sub> values were converted to metabolic equivalents (METs) to express energy expenditure.

**RESULTS:** The mean VO<sub>2</sub> values obtained for the four resistance activities were as follows: push-ups (M=11.57 ml/kg/min, SD=1.99), curl-ups (M=10.99 ml/kg/min, SD=1.48), pull-ups (M=10.87 ml/kg/min, SD=2.51), and lunges (M=14.18 ml/kg/min, SD=1.78). The corresponding MET values (push-ups: 3.31, curl-ups: 3.14, pull-ups: 3.11, and lunges: 4.05 respectively) were all within the range of moderate intensity activity.

**CONCLUSIONS:** The findings of this study indicate that a single set of any of the above exercises will qualify as a moderate intensity activity and can be used to meet recommendations on daily physical activity.

2215 Board #261 MAY 31 9:00 AM - 10:30 AM

**Metabolic Comparison Between Barefoot, Zero-drop Shoe, And Standard Shoe Running In Well-trained Runners**

Andrew Creer, Kelli Roach, Nicholas Rust, Jason Slack, Michael Bohne. *Utah Valley University, Orem, UT.* (Sponsor: Allen Parcell, FACSM)

(No relationships reported)

Barefoot running has been touted as metabolically superior to running shod. In an effort to mimic barefoot running (a more mid to forefoot foot strike), while protecting the foot, shoe manufacturers have begun developing low mass shoes with minimal damping material in the heel. This process minimizes offset between the heel and forefoot and is referred to as zero-drop.

**PURPOSE:** The purpose of this study was to determine if running in zero-drop shoes (261g; size 43cm) is metabolically similar to running barefoot in well-trained runners, as well as to compare metabolic differences between zero-drop and standard, low mass running shoes (286g; size 43cm).

**METHODS:** Nine well-trained distance runners (25.7±3.5 yrs, 178.6±5.9 cm, 67.6±8.5 kg, 72.0±5.2 ml/kg/min) participated in this study. Runners completed two bouts of treadmill running separated by 48 hrs to 7 days. The first bout included a graded exercise test to exhaustion to determine maximal O<sub>2</sub> consumption (VO<sub>2max</sub>). The second bout involved running on a treadmill at 16 km/hr and a 1% grade. Runners ran 6 min in zero-drop shoes (ZD), standard low mass shoes (ST), or barefoot (BF), in a randomized order. Expired gases were collected throughout each 6 min interval, and VO<sub>2</sub>, respiratory exchange ratio (RER), and heart rate (HR) values were averaged over the last two min of each interval. A two min break was allowed between intervals for shoe changes. Comparisons were made using a repeated measures ANOVA.

**RESULTS:** There were no significant differences in  $\text{VO}_2$  ( $57.8 \pm 3.7$ ;  $58.0 \pm 3.1$ ;  $57.5 \pm 3.1$  ml/kg/min), RER ( $.88 \pm .03$ ;  $.89 \pm .04$ ;  $.87 \pm .03$ ), or HR ( $169.1 \pm 14.8$ ;  $171.6 \pm 13.4$ ;  $170.1 \pm 14.9$  bpm) between ZD, ST, and BF conditions.

**CONCLUSION:** Interestingly, there were no differences in the selected metabolic variables between the conditions. At 16 km/hr and a 1% grade, subjects were running at ~80% of their  $\text{VO}_{2\text{max}}$  in each condition. Although the intensity utilized during this investigation may have reduced the ability to detect metabolic differences between conditions, it may also indicate that well-trained runners may spontaneously adapt to the most efficient running style regardless of shod or barefoot condition as a result of years of consistent training.

---

**2216** Board #262 MAY 31 9:00 AM - 10:30 AM  
**Running Economy Differences in Shod and Barefoot States**

Nicholas R. Klug, Sarah Jarvis, Bryan Haddock, FACSM. *California State University, San Bernardino, San Bernardino, CA.*  
(No relationships reported)

**Abstract:** Running with minimalist footwear or barefoot has become a popular alternative to traditional shod running. The promoted benefits of barefoot running (BFR) range from biomechanical improvements to economic enhancements during competition.

**PURPOSE:** The purpose of this study was to examine running economy differences in the shod and barefoot states; the running economy protocol included flat and inclined modes. In addition, the mass affect of shoes on running economy was examined.

**METHODS:** Six males and 7 females participated in the study. The mean age was  $22.2 \pm 3.1$  years, the average height was  $167.2 \pm 7.3$  cm, the average mass was  $59.5 \pm 7.88$  kg, and the average BMI was  $21.2 \pm 1.5$  kg/m<sup>2</sup>. Self-reported competitive runners were recruited. All participants underwent baseline  $\text{VO}_2$  max tests. After at least 24 hours post max test, participants underwent standardized running economy protocol that randomized four stages: running flat shod (FS), running flat barefoot (FBF), running inclined shod (IS) at, and running inclined barefoot (IBF); flat stages were performed at 7 mi/hr with no incline and inclined stages were performed at 6 mi/hr at 5% incline. Flat and inclined stages were compared independently of each other. Expired gasses were measured and analyzed by a Medgraphics Ultima CPX metabolic cart.

**RESULTS:** The average  $\text{VO}_2$  for the economy tests were,  $35.3 \pm 3.2$  ml/kg/min,  $35.2 \pm 3.2$  ml/kg/min, and  $37.1 \pm 2.8$  ml/kg/min for FS, FBF, IS, and IBF respectively. An independent sample t-test showed no significant difference between barefoot and shod running economy at a flat or an incline state ( $p = \text{NS}$ ). No relationship between shoe weight and differences in running economy was observed ( $p = \text{NS}$ ). **CONCLUSION:** Previous research looking at the affect of shoe mass would suggest that  $\text{VO}_2$  differences would occur between shod and barefoot states; however, this was not observed in the current study. In addition, inclined running was performed in an attempt to correct for differences in strike pattern, and observe mass affects of the shoe. Nonetheless, no differences or relationships due to shoe mass were observed.

**2217** Board #263 MAY 31 9:00 AM - 10:30 AM  
**Sex Differences In The Oxygen Uptake Kinetic Response To Moderate Intensity Exercise In Obese Adolescents**

Mary K. Bowen<sup>1</sup>, R. Lee Franco<sup>1</sup>, Stacey L. Hall<sup>1</sup>, Ross A. Arena, FACSM<sup>2</sup>, Ronald K. Evans<sup>1</sup>, Edmond P. Wickham<sup>1</sup>. <sup>1</sup>*Virginia Commonwealth University, Richmond, VA.* <sup>2</sup>*The University of New Mexico, Albuquerque, NM.* (Sponsor: Edmund O Acevedo, FACSM)  
(No relationships reported)

The pulmonary oxygen uptake ( $\text{VO}_2$ ) kinetic response to exercise provides insight into aerobic performance and overall efficiency of the cardiovascular, pulmonary, and muscular systems to meet oxygen demand upon initiation of exercise. Previously, investigators have reported no significant differences in the  $\text{VO}_2$  kinetic response to moderate intensity exercise in normal weight male and female children. However, the small sample size in conjunction with a large effect size may have confounded the interpretation of the time constant. Additionally, few studies have been devoted to investigating the  $\text{VO}_2$  kinetic response in obese adolescents.

**PURPOSE:** To determine if sex differences exist in the  $\text{VO}_2$  kinetic response to moderate intensity exercise in obese male and female adolescents.

**METHODS:** 102 obese subjects volunteered to participate. Male ( $n=25$ ,  $13.5 \pm 1.6$  yrs,  $40.6 \pm 6.1$  %FAT) and female ( $n=77$ ,  $14.1 \pm 1.8$  yrs,  $41.5 \pm 3.8$  %FAT) adolescents completed a graded exercise test to exhaustion on a treadmill. Breath by breath data from the first 4-min of treadmill walking (2.5 mph, 0% grade) at moderate intensity (<60% of  $\text{VO}_2\text{peak}$ ) was averaged into 10s intervals and fit with a monoexponential equation to determine the phase II time constant.

**RESULTS:** The phase II time constant was significantly different ( $P=0.014$ ) between obese male and female adolescents ( $16.8 \pm 7.8$  s vs.  $21.8 \pm 8.9$  s, respectively). Additionally,  $\text{VO}_2\text{peak}$  was significantly greater ( $P<0.001$ ) in males compared to females ( $2.7 \pm 0.4$  vs.  $2.4 \pm 0.3$ ; L/min). The initial 4-min walking stage during the graded exercise test elicited a similar relative exercise intensity between the two groups ( $P=0.118$ ; male,  $47.4 \pm 6.7\%$  vs. female,  $49.8 \pm 6.4\%$ ). A weak, but significant relationship between the time constant and  $\text{VO}_2\text{peak}$  was found only in females ( $r=0.233$ ,  $P=0.041$ ).

**CONCLUSIONS:** In the current study, sex differences were observed in the  $\text{VO}_2$  kinetic response to moderate intensity exercise, which is indicative of a greater ability for obese adolescent males to intake, transport and/or utilize oxygen as compared to their female counterparts. A longer time constant may reflect a greater dependency upon anaerobic energy sources, therefore the initiation and maintenance of functional exercise may be more difficult in obese female adolescents.

---

**2218** Board #264 MAY 31 9:00 AM - 10:30 AM  
**Pulmonary O<sub>2</sub> Uptake and Muscle Deoxygenation Responses to Repeated Bouts of Fast Ramp Exercise**

Nicholas T. Kruse, Trent E. Cayot, Aaron G. Fosnaugh, Erin C. Garmyn, Sarah A. McGlinchy, Barry W. Scheuermann. *The University of Toledo, Toledo, OH.*  
(No relationships reported)

Results of previous studies using a prior "priming" exercise to examine pulmonary (and muscle)  $\text{O}_2$  uptake ( $\text{VO}_2$ ) at the onset of a subsequent bout of exercise have provided considerable insight into metabolic regulation. While most studies use constant load exercise to examine  $\text{VO}_2$  kinetics, relatively few studies have examined  $\text{VO}_2$  kinetics during ramp exercise where the relationship between muscle perfusion and  $\text{O}_2$  uptake appear to be nonlinear; even fewer studies have examined  $\text{VO}_2$  responses to repeated bouts of ramp exercise. The use of near infrared spectroscopy (NIRS) to measure changes in muscle oxygenation during exercise has provided important mechanistic insight into the matching between  $\text{O}_2$  supply-to- $\text{O}_2$  utilization.

**PURPOSE:** To determine  $\text{VO}_2$  and muscle deoxygenation (HHb) responses to repeated bouts of fast ramp exercise.

**METHODS:** Pulmonary  $\text{VO}_2$  and HHb of the vastus lateralis muscle was recorded on five ( $28.8 \pm 9.4$  yrs,  $\pm$  SD) healthy males during successive bouts of a fast ramp exercise ( $F_1$ ;  $F_2$ ) where the forcing function was increased by 64 W/min. The "priming" bout ( $F_1$ ) was initiated from a baseline of 20 W cycling and continued to fatigue.  $F_2$  was initiated following 6 min of recovery cycling at 20W and continued to fatigue.  $\text{VO}_2$  and HHb were continuously measured during exercise and recovery.

**RESULTS:** Baseline  $\text{VO}_2$  was higher in  $F_2$  compared to  $F_1$  ( $F_1$ :  $1153 \pm 0.205$ ;  $F_2$ :  $1495 \pm 247$  ml/min,  $p<0.05$ ). Although there was no difference in peak work rate between  $F_1$  and  $F_2$ ,  $\text{VO}_2\text{PEAK}$  was higher in  $F_2$  versus  $F_1$  ( $F_1$ :  $4114 \pm 497$ ;  $F_2$ :  $4352 \pm 599$  ml/min,  $p<0.05$ ). Results of linear regression analysis of the  $\Delta\text{VO}_2/\Delta\text{WR}$  relationship revealed no difference between  $F_1$  ( $8.8 \pm 0.8$  ml/min/W) and  $F_2$  ( $9.0 \pm 0.4$  ml/min/W). Compared to  $F_1$ , the increase in HHb from baseline to end exercise (i.e.  $\Delta\text{HHb}$ ) was greater during  $F_2$  than  $F_1$  ( $F_1$ :  $11.2 \pm 7.7$ ;  $F_2$ :  $16.3 \pm 11.1$   $\mu\text{M}$ ,  $p<0.05$ ). Analysis of the HHb response (normalized for differences in amplitude) using a sigmoid function indicated that the time to achieve 50% of the total amplitude was not significantly different between  $F_1$  and  $F_2$ .

**CONCLUSIONS:** A prior bout of priming exercise resulted in a higher peak  $\text{VO}_2$  during a subsequent bout of exercise, which may be associated with altered HHb responses. However, priming exercise did not lead to an appreciable change in either  $\text{VO}_2$  or HHb during submaximal exercise.

**Power and VO<sub>2</sub> During Three Consecutive Wingates in Untrained Individuals Compared to Trained Cyclists**

Stephen J. McGregor, Jason R. Boynton, Lynne Shetron-Rama, Chris Herman, Andrea D. Workman, Tim Muth, Josh Gordon, Ian Ratz, Zach Maino. *Eastern Michigan University, Ypsilanti, MI.*

(No relationships reported)

The multiple Wingate protocol has previously been used to elucidate physiological responses to multiple supra-maximal efforts. To our knowledge though, it has not been used to contrast responses between trained and untrained individuals.

**PURPOSE:** To compare changes in power output and VO<sub>2</sub> over the course of multiple consecutive Wingate efforts in untrained individuals (UT) and trained cyclists (T). We hypothesized that T would produce more power and consume more oxygen, both in absolute terms and relative to power, than UT.

**METHODS:** All procedures were approved by the EMU-CHHS Human Subjects Review Committee. 11 UT (age 22.4 yr, weight 83.8 ± 11.8 kg, VO<sub>2peak</sub> = 40.05 ± 6.96 ml/kg/min) and 9 T (age 25.4 yr, weight 77.8 ± 9.26 kg, VO<sub>2peak</sub> = 59.56 ± 5.66) performed three consecutive Wingates with 4 min of rest between each bout. Exercise was performed on an electronically braked ergometer (Velotron, Racermate WA) with a sampling rate of 10 Hz. Breath-by-breath metabolic gasses were recorded using an Oxycon Mobile (Viasys, CA) and averaged over 5 s. Peak power (best 1 sec), average power, VO<sub>2</sub> and VO<sub>2</sub>/Watt were analyzed for statistical differences between groups using 2-way ANOVA, and when appropriate, within groups by Wingate using ANOVA (SPSS 19.0; IBM, NY).

**RESULTS:** As anticipated, numerous variables were higher in T vs UT including, relative peak power (10.39 ± 0.87 W/kg vs. 8.80 ± 1.44 W/kg; *p* < .001), relative average power (8.36 ± 0.54 W/kg vs. 6.38 ± 0.84 W/kg; *p* < .001), relative VO<sub>2</sub> (42.38 ± 9.32 mL/kg/min vs. 23.96 ± 7.18 mL/kg/min; *p* < .001) and VO<sub>2</sub>/Watt (5.02 ± 1.02 mL/min/W vs. 3.83 ± 0.81 mL/min/W; *p* < .001). Within groups, by Wingate, average power (absolute and relative) was significantly lower in UT by the third Wingate (*p* = .011), while average power in T tended to be lower (*p* = .14) and no interaction was observed. VO<sub>2</sub>/Watt was significantly lower in the first bout for both the untrained and trained group (VALUES; *p* = .001, *p* = .002) compared to the second and third bouts.

**CONCLUSION:** During MWE, trained cyclists produce more power and consume more oxygen relative to power than untrained individuals. Despite these distinct differences between groups, there did not seem to be an interaction between training status and number of Wingates that would signify differential rates of fatigue.

**Competitive Sport Attrition: A Retrospective Analysis Of The Trois-Rivieres Study**

François Trudeau, FACSM<sup>1</sup>, Louis Laurencelle<sup>1</sup>, Roy J. Shephard, FACSM<sup>2</sup>, Richard Larouche<sup>1</sup>. <sup>1</sup>Université du Québec à Trois-Rivières, Trois-Rivières, QC, Canada. <sup>2</sup>University of Toronto, Toronto, QC, Canada.

(No relationships reported)

**PURPOSE:** Our aim was to gain a better understanding of attrition from competitive sports and its effect on subsequent participation.

**METHODS:** Subjects (aged 44.0 ± 1.2 years; 42 previously involved (18 females and 24 males) and 23 never involved (17 females and 6 males) in sport) were a sub sample from the Trois-Rivières Growth and Development Study who participated in a semi-structured retrospective interview that revolved around two main themes: 1) attrition from competitive sport and its associated life events; and 2) participation in physical activity and/or another competitive sport after leaving their first sport.

**RESULTS:** Of the 42 subjects previously involved in competitive sport, attrition occurred in most individuals (32 of 42) during their school years

(including higher education). Only 5 of the 42 became inactive after dropping out of competitive sport; 10 remained slightly active, (0 to 150 min weekly), 9 moderately active (150 to 300 min weekly) and 8 very active (more than 300 min per week). Of the 23 subjects who had never practiced a competitive sport, 10 individuals became sedentary or rarely active. The content analysis indicated 3 principal reasons motivating subjects to quit competitive sports: 1) lack of time, conflict with work, social and familial life, and school requirements, 2) lack of or loss of interest for the sport that was dropped, and 3) excessive competition (stressful, difficult to maintain competitive level).

**CONCLUSIONS:** Our results suggest that attrition from competitive sports happened mainly during schooling; nevertheless, former participation in competitive sport translated into a lower risk of sedentary behaviour during middle age. Supported by a grant from CRSH/SSHRC

**Comparison of Physical Activity Performed at Two U.S. Army Basic Combat Training Sites**

Kathleen Simpson<sup>1</sup>, Nathan R. Hendrickson<sup>1</sup>, Jan E. Redmond<sup>1</sup>, Bruce S. Cohen<sup>1</sup>, Barry A. Spiering<sup>1</sup>, Joseph J. Knapik, FACSM<sup>2</sup>, Marilyn A. Sharp<sup>1</sup>. <sup>1</sup>U.S. Army Research Institute of Environmental Medicine, Natick, MA. <sup>2</sup>U.S. Army Institute of Public Health, Aberdeen Proving Ground, MD.

(No relationships reported)

**PURPOSE:** During Army Basic Combat Training (BCT), there are extensive physical demands placed upon recruits, including fitness training and other activities. There are concerns that total physical activity (PA) at various BCT sites may differ and result in different injury rates. The purpose of this study was to measure and compare PA performed during 10 weeks of BCT at two training sites.

**METHODS:** Data were collected from 11 companies (Ft Jackson, SC and Ft Sill, OK). Trained observers (n=5-6) performed continuous observation of these companies during waking hours with novel Smartphone-based PA tracking software. Each activity was coded for type and load carried. Intensity was rated as resting, light, moderate, vigorous, or maximum. Percent time (%T) recruits spent in each activity type, load, and intensity were calculated. T-tests were used to determine whether PA differed between the BCT sites.

**RESULTS:** Recruits were followed 13.2 ± 0.1 hr/d for 49.5 ± 2.2 days at Ft Jackson and 11.8 ± 0.1 hr/d for 46.6 ± 2.2 days at Ft Sill. %T recruits from Ft Jackson and Ft Sill spent in each activity and load category is shown in Table 1. Recruits at Ft Sill spent more time cadence marching, running, doing menial tasks, obstacles/climbing, and carrying 11-34kg (*p* < 0.05). Conversely, recruits at Ft Jackson spent more time stationary and engaging in combatives training (*p* < 0.05). There were no differences in %T spent in each intensity between soldiers at Ft Jackson and Ft Sill (*p* > 0.05).

**CONCLUSIONS:** We observed differences in the %T spent in various types of activities and load carried between the BCT sites, but no differences in activity intensity.

---

**Leisure Time Physical Activity and Health-Related Quality of Life in Women**

Mary K. Dinger, FACSM, Danielle R. Brittain. *University of Northern Colorado, Greeley, CO.*  
*(No relationships reported)*

A positive relationship between health-related quality of life (HRQoL) and physical activity has been fairly well established in clinical populations. However, less is known about this relationship among healthy adults.

**PURPOSE:** The purpose of this study was to examine HRQoL among sufficiently and insufficiently physically active community dwelling women aged 50-75 years.

**METHODS:** Participants were 118 healthy women [age = 60.0 ± 6.9 years, Body Mass Index (BMI) = 26.1 ± 4.1 kg/m<sup>2</sup>, body fat percent (%fat) = 35.0 ± 7.2%, 91% Caucasian] recruited from the Oklahoma City metropolitan area. They completed the long version of the International Physical Activity Questionnaire (IPAQ) and the Medical Outcomes Survey Short Form 36 (SF-36v2). Sufficiently active women accumulated ≥ 150 minutes of walking, moderate, or vigorous physical activity during leisure time the previous week; whereas, insufficiently active women accumulated < 150 minutes of these activities during their leisure time. HRQoL norm-based subscale scores were compared between the two groups.

**RESULTS:** Sufficiently active participants (n = 57, age = 59.6 ± 7.0 years, BMI = 25.3 ± 3.3 kg/m<sup>2</sup>, %fat = 33.9 ± 7.2%) accumulated 399.6 ± 304.8 minutes of leisure time physical activity during the previous week; whereas, insufficiently active participants (n = 61, age = 60.4 ± 6.8 years, BMI = 27.0 ± 4.7 kg/m<sup>2</sup>, %fat = 36.1 ± 7.2%) accumulated 42.2 ± 47.8 minutes. Sufficiently active women scored significantly higher on role-physical (t = 2.7, p = .009) and social functioning (t = 2.36, p = .02) subscales than those who were insufficiently active. The two groups did not differ significantly on physical functioning (p = .08), bodily pain (p = .35), general health (p = .40), vitality (p = .12), role-emotional (p = .81), or mental health (p = .80) subscales.

**CONCLUSIONS:** Two of eight HRQoL norm-based subscales differed between sufficiently and insufficiently physically active women. Additional research is needed to continue examining the relationship between HRQoL and physical activity among healthy women.

**2223 Board #269 MAY 31 8:00 AM - 9:30 AM**  
**Quantitative Genetic Analysis Of Sports Participation In Portuguese Nuclear Families**

Denisa Mendonça<sup>1</sup>, André Seabra<sup>2</sup>, Michele Souza<sup>2</sup>, Raquel Chaves<sup>2</sup>, Ana Seabra<sup>2</sup>, Daniel Santos<sup>2</sup>, Fernanda Santos<sup>2</sup>, Thayse Gomes<sup>2</sup>, Rojapon Buranarugs<sup>2</sup>, Rui Garganta<sup>2</sup>, José Maia<sup>2</sup>. <sup>1</sup>*Institute of Public Health (ISPUP), Institute of Biomedical Sciences Abel Salazar, University of Porto, Porto, Portugal.* <sup>2</sup>*Research, Education, Innovation and Intervention in Sport, Faculty of Sport, University of Porto, Portugal (CIFID2), Faculty of Sport, University of Porto, Porto, Portugal.*  
*(No relationships reported)*

The number of studies that focus on familial aggregation and genetic contribution in the variation of the sport participation (SP) habits is very limited.

**PURPOSE:** To estimate familial aggregation and quantify the genetic and environmental contributions to the phenotypic variation on SP among Portuguese families.

**METHODS:** The sample consisted of 2375 nuclear families (parents and two offspring each) from different regions of Portugal with a total of 9500 subjects. SP assessment was based on a psychometrically established questionnaire. Phenotypes used were based on the participation in sports (yes/no), intensity of sport, weekly amount of time in SP and the proportion of the year in which a sport was regularly played. Familial correlations were calculated using FCOR in the SAGE 6.0 software. Heritability was estimated using variance-components methods implemented in SOLAR 4.0 software.

**RESULTS:** (1) Subjects of the same generation tend to be more similar in their SP habits than subjects of different generations. (2) All familial correlations (father, mother, and their different off-spring) were significantly greater than zero, ranging from 0.12 to 0.48. (3) In all SP phenotypes studied, adjusted for the effects of multiple covariates (age, sex and their interactions), the proportion of phenotypic variance due to additive genetic factors ranged between 40% and 50% (SP: h<sup>2</sup>= 50%; intensity of sport: h<sup>2</sup>= 40%; weekly amount of time: h<sup>2</sup>= 46%; proportion of the year: h<sup>2</sup>= 49%). (4) The proportion of variance attributable to environmental factors ranged from 50% for the participation in sports to 60% for intensity of sport.

**CONCLUSIONS:** In this large population-based family study, there was significant familial aggregation on SP. These results highlight that the variation on SP phenotypes have a significant genetic contribution although environmental factors are also important in the familial resemblance of SP, which points out the likely success of both individual and family-based lifestyle interventions in the promotion of SP.

**2224 Board #270 MAY 31 8:00 AM - 9:30 AM**  
**Do Kinesiology Majors Practice What They Preach?**

Renee Zeltwanger, Mindy Mayol, Matthew D. Beekley, FACSM. *University of Indianapolis, Indianapolis, IN.*  
*(No relationships reported)*

Kinesiology students should score better on indicators of health and fitness compared to other majors.

**PURPOSE:** The purpose of this study was to compare the health-and fitness results of Kinesiology majors to other non-Kinesiology majors.

**METHODS:** Kinesiology students (KINS, N=109, 52 female, 57 male; majors: Physical Education and Health, Exercise Science, Sport Management, Community Health Education, Athletic Training) were age, gender, race, and height matched to non-Kinesiology majors (non-KINS, n=109) and tested in a wellness class. VO2max was predicted by Rockport walk test. Body fat was predicted by electrical impedance. Flexibility was determined by sit and reach box. Handgrip strength, number of push-ups and curl-ups in one minute were determined by ACSM guidelines. Blood lipids and fasting glucose were determined (not all students completed the blood draw; KINS N=62, non-KINS N=57).

**RESULTS:**

| Measure                       | KINS         | Non-KINS    |
|-------------------------------|--------------|-------------|
| Age (y)                       | 19.3+ 1.2    | 20.1+ 4.1   |
| Height (cm)                   | 173.3+ 10.7  | 174.0+ 11.0 |
| Weight (kg)                   | 76.3+ 15.9   | 78.5+ 20.2  |
| BMI                           | 19.3+ 7.7    | 21.2+ 8.9   |
| Blood Pressure (mm Hg)        | 122/73+14/12 | 123/76+11/8 |
| Predicted Body Fat            | 21.2+ 8.9    | 23.4+ 7.9   |
| Predicted VO2 Max (ml.kg.min) | 38.3+ 7.9    | 38.7+ 9.8   |
| Sit and Reach (cm)            | 23.4+ 7.9    | 21.8+ 8.0   |
| Grip Strength (lb; R + L)     | 72.9+ 27.8   | 73.7+ 26.5  |
| Push-ups (1 min)              | 41.6+ 14.3   | 39.6+ 15.5  |
| Curl-ups (1 min)              | 58.7+ 19.6   | 53.9+ 16.9  |

| Blood measure         | KINS       | Non-KINS   |
|-----------------------|------------|------------|
| Glucose (mg/dL)       | 59.2+31.9  | 64.3+32.1  |
| Triglyceride (mg/dL)  | 76.1+56.7  | 85.6+69.9  |
| Cholesterol (mg/dL)   | 137.1+75.2 | 133.5+73.1 |
| HDL (mg/dL)           | 43.9+25.4  | 45.8+29.9  |
| LDL (mg/dL)           | 76.3+48.6  | 71.3+42.9  |
| Cholesterol/LDL ratio | 2.61+1.71  | 2.52+1.41  |
| LDL/HDL ratio         | 1.51+1.21  | 1.39+0.87  |

Via t-test, no measure was significantly different between KINS and non-KINS majors; p > 0.05

**CONCLUSIONS:** Kinesiology students did not differ from non-Kinesiology majors for all major health and fitness-related parameters.

**2225 Board #271 MAY 31 8:00 AM - 9:30 AM**

**Relationships Between Perceived Health and Objective Health Status of Rural Appalachian Adults**

Wayne C. Miller, FACSM, Brian N. Griffith, Timothy O. Leonard, Gretchen D. Lovett, Jill D. Cochran, Haylee B. Heinsberg. *West Virginia School of Osteopathic Medicine, Lewisburg, WV.*  
(No relationships reported)

Appalachia is characterized by poor health behaviors, poor health status, and health disparities. Recent interventions have not demonstrated success in improving health status or reducing health disparities in the Appalachian region.

**PURPOSE:** Since one's perception of personal health precedes his or her health behaviors, the purpose of this project was to evaluate the self-rated health of Appalachian adults in relation to objective health status and current health behaviors.

**METHODS:** Appalachian adults (n = 616) were surveyed regarding health behaviors - sugared drink consumer (drink ≥ 12 oz/d), or non-consumer (drink < 12 oz/d), fast food consumer (eating fast food ≥ 1 time/wk) or non-fast food consumer (eating fast food < 1 time/wk), smoking (smoker or non-smoker), exercise (exerciser > 30 min > 1d/wk) and sedentary (exercise < 30 min 1 d/wk), blood pressure medication (yes, no), and self-rated health (0-100 scale). Blood pressure was measured through brachial artery auscultation and serum cholesterol measured via needle prick. Weight status was based on BMI: normal weight (NW ≥ 18.5 and < 25.0), overweight (OW ≥ 25.0 and < 30.0), and obese (OB ≥ 30.0). Jaccard Binary Similarity coefficients, odds ratios, chi-square, and prevalence ratios were calculated to evaluate the relationships among self-rated health, objective health status, and health behaviors. Significance was set at p < 0.05.

**RESULTS:** Respondents reported being healthy, while being sedentary (56%), hypertensive (84%), OW (67%), or hyperlipidemic (79%). Between 55% and 99% of the respondents who considered themselves healthy had at least two disease conditions or poor health behaviors. Jaccard Binary Similarity coefficients showed the chance of somebody perceiving themselves as healthy when they were sedentary was (0.58), OW (0.47), OB (0.33), eating fast food often (0.32), rarely eating fruit (0.30), taking blood pressure medication (0.29), taking cholesterol medication (0.20) and depressed (0.23).

**CONCLUSION:** The association between perceived health and actual health in Appalachian adults is distorted. The public health challenge is to formulate messages and programs about health and health needs which take into account the current distortion about health in Appalachia and the cultural context in which this distortion was shaped.

**2226 Board #272 MAY 31 8:00 AM - 9:30 AM**

**Physical Activity, Walking And Leanness: Analysis Of The Northern Ireland Sport And Physical Activity Survey**

Marie H. Murphy, FACSM<sup>1</sup>, Paul Donnelly<sup>2</sup>, Simon Shibli<sup>3</sup>, Charlie Foster<sup>4</sup>, Alan Nevill<sup>5</sup>. <sup>1</sup>University of Ulster, Co Antrim, United Kingdom. <sup>2</sup>Sport Northern Ireland, Belfast, United Kingdom. <sup>3</sup>Sheffield Hallam University, Co Antrim, United Kingdom. <sup>4</sup>University of Oxford, Oxford, United Kingdom. <sup>5</sup>University of Wolverhampton, Wolverhampton, United Kingdom.  
(No relationships reported)

**PURPOSE:** Walking is a popular form of physical activity shown to be associated with indicators of health. The purpose of this study was to determine the contribution walking makes to total weekly physical activity and the relationship between the volume and intensity of walking and leanness in the Northern Ireland population.

**METHODS:** 4563 adults participated in this cross-sectional survey of physical activity behaviour. Data was collected through face-to-face interviews using computer assisted personal interviewing. Self-reported height and weight was used to determine inverse body mass index (iBMI) as a measure of leanness. Data across all domains of physical activity including self-reported volume and intensity of walking (in bouts of 10 minutes or more) were analysed to determine their contribution to inverse BMI as our measure of leanness using an ANCOVA, having controlled for age, gender, socio-economic and smoking status.

**RESULTS:** Over 68% of the participants reported walking >10 minutes during the previous week but only 24% report walking at a brisk or fast pace. Time walking at a brisk or fast pace to get somewhere was identified as having the strongest positive association with being lean (F<sub>1,4256</sub>=10.45, β=0.051 cm<sup>2</sup>.kg<sup>-1</sup>.min<sup>-1</sup> (SE=0.016),P=0.001).

**CONCLUSION:** In addition to increasing the amount of walking and the percentage of people walking regularly, public health messages encouraging an increase in walking pace may be valuable to increase in the proportion of the population meeting physical activity guidelines and gaining associated health benefits.

**2227** Board #273 **MAY 31** **8:00 AM - 9:30 AM**

**Motor Skill Competence and Physical Activity: Perceived Competence as a Mediator**

Tao Zhang<sup>1</sup>, Zan Gao<sup>2</sup>. <sup>1</sup>University of North Texas, Denton, TX. <sup>2</sup>Texas Tech University, Lubbock, TX.  
(No relationships reported)

It has been well documented that the development of motor skill competence is a major correlate in promoting physical activity (PA) and perceived competence in middle to late childhood (Stodden et al., 2008). However, limited empirical evidence has supported the mediating effect of perceived competence on relationships between motor skill competence and PA among US children. Examining these relationships is necessary to develop effective strategies to promote students' PA.

**PURPOSE:** To test a hypothesized mediating effect of perceived competence on relationships between motor skill competence and PA among a sample of elementary school students.

**METHODS:** 294 students (152 boys, 142 girls, M<sub>age</sub> = 11.0 years) from three elementary school completed validated questionnaires assessing their perceived competence and self-report PA (William et al., 1998; Kowalski et al., 1997). Students' motor skill competence in overhand throwing, basketball, and striking were assessed by PE Metrics™ (NASPE, 2010). After examining the correlations among the variables, the hypothesized model was tested using structural equation modeling (SEM; AMOS 16, Arbuckle, 2007).

**RESULTS:** Correlation analyses revealed a pattern of positive relationships among the study variables (*r* ranging from .12 to .40). The SEM analyses indicated that the hypothesized model produces a good fit to the data according to the various indices of fit:  $\chi^2/df = 1.93 < 5$ ; CFI = .97; NFI = .94; RMSEA = .056 (Hu & Bentler, 1999). Specifically, the model accounted for 10.2 % and 14.1 % of the variances in perceived competence and PA, respectively. Path coefficients suggested that overhand throwing ( $\beta = .23$ ) was directly and positively associated with perceived competence, which in turn significantly predicted PA ( $\beta = .38$ ). The effect of overhand throwing on PA was mediated fully through perceived competence. No direct effect was found between basketball, striking and students' PA.

**CONCLUSIONS:** The results highlight that overhand throwing significantly predicted students' perceived competence, which in turn positively predicted their PA. However, basketball and striking didn't emerge as predictors of students' perceived competence and PA. The findings have practical implications for intervention strategies aimed at promoting students' PA.

**Likelihood of Meeting Physical Activity Guidelines Comparing those Who Walk Dogs and Those That Don't**

Jesus Soares, Chantelle Owens, Jacqueline Epping, David R. Brown, FACSM, Tina Lankford. CDC, Atlanta, GA. (Sponsor: David R. Brown, FACSM)  
(No relationships reported)

Little evidence exists on whether dog walkers are more likely to gain health benefits through physical activity (PA) than persons who do not walk dogs.

**PURPOSE:** To determine the likelihood of meeting the aerobic component of the 2008 Physical Activity Guidelines (PAGs) for adults when comparing dog owners who walk their dogs versus those who do not.

**METHODS:** Abstracts were retrieved through a systematic search of 10 databases from 1990 to 2011 and hand searching of reference lists. The primary inclusion criterion for review was having published data for total time spent in PA to compare dog owners who walk their dogs versus those who do not walk their dogs with the goal being to identify those who met recommended levels of PA (at least 150 minutes of moderate-vigorous PA per week). We used a random effects model to estimate the unadjusted odds ratio and corresponding 95% confidence interval (CI) of persons who met PAGs when comparing dog owners who walk dogs versus those that do not. We used Comprehensive Meta Analysis Software for calculations.

**RESULTS:** Among 236 relevant articles (including 2 under review) there were eight cross-sectional studies and one cohort study that met the inclusion criterion and which allowed calculation of odds ratios. For these studies there were 6980 dog owners aged 18 to 81 years old, with 41% being male, and among whom 63.9% (n=4463) actually reported walking their dogs. All the studies, except one, relied on self-reported PA measures. Based on total weekly time spent in PA, 2710 (60.7%) met the recommended PA guidelines among those who walked their dogs, and 950 (37.7%) among those who did not walk their dogs. The random effects estimated odds ratio was 2.74 with a 95% CI: 2.16-4.22.

**CONCLUSION:** Our systematic review of published articles revealed that across 9 published studies almost 2 in 3 dog owners report walking their dogs, and they are more than two and one-half times more likely to have met recommended levels of PA when considering total weekly PA. Further research need to consider whether adjustment for covariates affects this association. However, dog walking may be a viable strategy for dog owners to help reach recommended levels of PA to enhance their health.

**2229** Board #275 **MAY 31** **8:00 AM - 9:30 AM**

**Initial Effects of a National Men's Health Programme Delivered in English Premier League Football Clubs**

Andy Pringle, Stephen Zwolinsky, Andy Daly-Smith, James McKenna, Steven Robertson, Alan White. Leeds Metropolitan University, Leeds, United Kingdom.  
(A. Pringle: Contracted Research - Including Principle Investigator; contracted research was undertaken for the Football Foundation.)

In the UK, men not only have an increased risk of cardio-vascular diseases, fat related cancers and poor mental health, but also a low uptake of primary health care (PHC) services. Sporting settings offer health professionals a potentially exclusive channel to reach men, including those hard-to-reach-men (HTRM) not using PHC, with interventions designed to improve health. The English Premier (soccer) League (EPL) is attended by 11 million male fans and the basis for Premier League Health (PLH), the first nationally evaluated programme of health promotion for men in EPL clubs.

**PURPOSE:** To examine the initial reach and impact of PLH on the health behaviour of men.

**METHODS:** Health interventions delivered in clubs (N=16) including, educational activities on match days for fans and weekly lifestyle classes. Interventions were delivered at soccer stadia/training venues and community facilities and led by health professionals who received specific training on men's health activities. After ethics/consent, men completed validated self-report measures for demographics and health behaviours. Differences in measures were identified pre vs post-intervention (3 months).

**RESULTS:** Among PLH recruits, 2214 provided pre-intervention data; 84% (1714/2214) were white British aged 18-44. 78% (n=909/1159) did not see themselves as unhealthy, but only 6% (n=58/1044) used PHC regularly. In a sub-sample providing lifestyle data, the percentage failing to meet recommendations for healthy behaviours was: physical activity, 85% (n=1106/1301); daily consumption of fruit/vegetables, 88% (n=948/1072); weekly alcohol units, 29.9% (n=203/679); body-mass-index (BMI), 63% (n=570/893) and smoking, 33.4% (n=422/1262). Significant increases were found for mean sessions of physical activity pre (2.06±1.52) v post-intervention (3.06±1.28), p=0.000 (n=185); daily consumption of fruit/vegetables pre (2.06±1.44) v post (2.97±1.20), p=0.000 (n=154); mean weekly decreases in alcohol units pre (17.41±14.18) v post (12.69±9.94), p=0.000 (n=105); and BMI pre (27.27±4.37) v post (26.65±4.03), p=0.0039 (n=91).

**CONCLUSIONS:** A national programme of men's health delivered in EPL soccer clubs reached men not meeting health guidelines and HTRM not using PHC regularly. Positive change was found for men's selected health behaviours.

**2230** Board #276 **MAY 31** **8:00 AM - 9:30 AM**

**Adaptation Of The Academia Da Cidade Program (acp) For Implementation In The United States: Academia Fit**

Elizabeth Mejia, Simon J. Marshall, Ermilia Medina, Megan Duesterhaus, Humberto Parada, Guadalupe X. Ayala, John P. Elder, Elva Arredondo, Thomas L. McKenzie, FACSM, Ming Ji. San Diego State University Research Foundation, San Deigo, CA.

(No relationships reported)

In Latin America, the widespread popularity of community physical activity (PA) classes provides evidence that free group exercise classes have potential to yield substantial public health benefit.

**PURPOSE:** To describe translation science methodology in adapting ACP, an evidence-based community PA program in Brazil, for implementation with Latino communities in the US.

**METHODS:** An assets-based community engagement model was used to identify key partnerships, including the American Council on Exercise (ACE®) and local parks and recreation departments. Guided by socio-ecological framework, a community-based participatory research model was used to create a sustainable community program through which free PA classes could be taught in public spaces by Spanish-speaking instructors. A program logic model was used to identify inputs and activities that would contribute to successful program implementation and the building of community capacity to support long-term program maintenance. The RE-AIM framework is being used to evaluate reach and the public health impact of the program.

**RESULTS:** Key informant interviews (n=16) conducted with local stakeholders identified needs, facilitators, and barriers to offering a free Spanish-language community PA program. A fitness advisory panel (n=9) was established to provide input on program development, sustainability, and cultural appropriateness. ACE education materials were translated into Spanish, culturally adapted, and delivered as part of a 14-week program to 25 Spanish-speaking community members recruited to a newly established Academia (Academia Fit). Environmental audits were conducted in 70 public sites to assess their suitability for hosting free PA classes; 23 were selected as meeting criteria. To date, 10 newly certified instructors have taught free PA classes in 9 public settings averaging 17 hours per week; and 553 community residents have participated in the classes, with 123 participants enrolled in a year-long evaluation study. Complete data on the public health impact of Academia Fit will be available in Fall 2012.

**CONCLUSION:** Through leveraging existing local resources, ACP has been successfully translated to a Mexico-US border community. Funded by a research grant (1R18DP002138-01) from the Centers for Disease Control and Prevention.

---

**2231 Board #277 MAY 31 8:00 AM - 9:30 AM**  
**Physically Active Residential Communities And Schools (parcs) - A Service-learning University-community Partnership To Promote Health**

Sarah N. Herrerah, Stephanie Greer, Rachel Swinford, Brian Culp, NiCole R. Keith, FACSM. *IUPUI, Indianapolis, IN.*  
(No relationships reported)

Physically Active Residential Communities and Schools (PARCS) is a 9-year-old community-based exercise partnership between an urban university and public school community. Exercise Science and Fitness Studies majors deliver exercise options to adult participants as part of service learning required throughout the curriculum. Participants with physician referrals attend for free and others attend at a membership price of \$20/year. Public schools are host sites.

**PURPOSE:** To describe the experiences of university students who have completed one semester of service learning at a PARCS site and the demographics of adult participants who received exercise programming from students.

**METHODS:** A team comprised of student research assistants, a behavioral scientist, an exercise physiologist, and a physical educator reviewed de-identified student reflections to find common themes and created a system that was used to code each reflection. We conducted the coding by hand, individually reading reflections to identify themes and then discussed themes for each reflection at team meetings. Two varying team members coded each reflection and all members discussed results. This process occurred for 3 months until all transcripts were coded and discussed. We coded 120 student reflections. Identified student themes included pre-conceptions, contextual comparisons, first impressions, influence on learning, academic understanding, professional development, and change recommendations. IBM SPSS Statistics 19 was used to describe PARCS participants' demographic characteristics.

**RESULTS:** Students pre-conceptions included descriptions of people who were unhealthy, uneducated, and unlike themselves. Students found PARCS participants to be informative sources of learning. Students discussed personal strengths and weaknesses within the framework of their academic and professional preparation. Future recommendations were similar. Of the PARCS participants (N=1352), 74% were female, 38% were white, 51% were black, 79% had a household income of < \$40,000 per year, and 89% had a high school diploma or higher.

**CONCLUSION:** Results show partnerships such as PARCS provide students with the opportunity to have practical experiences, work with a diverse population and give exercise opportunities to a community in need.

**Walking To Meet The 2008 Physical Activity Guidelines In Knee OA: The MOST Study**

Daniel K. White<sup>1</sup>, Catrine Tudor-Locke, FACSM<sup>2</sup>, David Felson<sup>1</sup>, K.Doug Gross<sup>3</sup>, C.Elizabeth Lewis<sup>4</sup>, James Torner<sup>5</sup>, Michael Nevitt<sup>6</sup>, Tuhina Neogi<sup>1</sup>. <sup>1</sup>*Boston University, Boston, MA.* <sup>2</sup>*Pennington Biomedical Reserach Center, Baton Rouge, LA.* <sup>3</sup>*MGH Institute of Health Professions, Boston, MA.* <sup>4</sup>*University of Alabama Brimingham, Brimingham, AL.* <sup>5</sup>*University of Iowa, Iowa City, IA.* <sup>6</sup>*University of California San Francisco, San Francisco, CA.* (Sponsor: Catrine Tudor-Locke, FACSM)  
(No relationships reported)

**PURPOSE:** Physical activity (PA) provides health benefits even to those with knee osteoarthritis (OA) and therefore national organizations promote PA, and specifically walking for this population. However, PA guidelines include minimal intensity and duration requirements, and it is unknown whether people meet these specific parameters by walking.

**METHODS:** The Multicenter Osteoarthritis Study (MOST) is a cohort of older adults who have or who are at high risk of knee OA. Participants wore a StepWatch activity monitor to record steps/day over 7 days. Proportions were calculated for 1) walking a single minute  $\geq$  100 steps/min (indicative of minimally moderate intensity), 2) walking a single minimal bout duration of  $\geq$  10 minutes at this intensity, and 3) attaining 150 minutes/week accumulated with these intensity and bout duration requirements.

**RESULTS:** Of 1795 participants who wore the monitor for at least 3 days (age  $67 \pm 8$  yrs, BMI  $31 \pm 6$  kg/m<sup>2</sup>, 60% women), over 90% walked at minimal intensity, however only 33% met a single minimal duration bout. PA guidelines were fully met by 7% of men and 5% of women.

**CONCLUSIONS:** An overwhelming majority of people with or at high risk of knee OA appear capable of walking at minimal intensity to meet PA guidelines, however, only a third walked at a minimal duration, and few met PA guidelines by walking. Since intensity does not seem to be a limiting factor, promotion efforts should focus on accumulating more bouts at a minimal duration to facilitate achievement of PA guidelines by walking.

**2233 Board #279 MAY 31 8:00 AM - 9:30 AM**  
**Potential for Enhanced Safety to Stimulate More Bicycling**

James F. Sallis, FACSM<sup>1</sup>, Lianne Dillon<sup>2</sup>, Terry L. Conway<sup>1</sup>, Lawrence D. Frank<sup>3</sup>, Brian E. Saelens<sup>4</sup>, Kelli Cain<sup>1</sup>, James E. Chapman<sup>5</sup>, Joni Mayer<sup>6</sup>. <sup>1</sup>*University of California, San Diego, San Diego, CA.* <sup>2</sup>*California Department of Public Health, Sacramento, CA.* <sup>3</sup>*University of British Columbia, Vancouver, BC, Canada.* <sup>4</sup>*University of Washington, Seattle, WA.* <sup>5</sup>*Urban Design for Health, Seattle, WA.* <sup>6</sup>*San Diego State University, San Diego, CA.*  
(No relationships reported)

About half of all trips in the US are 2 miles or less, a feasible distance for bicycling. Bicycling for leisure or transportation can increase physical activity, reduce chronic disease, improve air quality, and reduce greenhouse gas emissions. Yet, fewer than 1% of trips are taken by bicycle in the US. Many studies show that concern about traffic dangers is the primary barrier to bicycling, and US investments in safe bicycling infrastructure are minimal compared to other countries.

**PURPOSE:** The present study examined correlates of projected increases in cycling if perceived safety from cars was improved.

**METHODS:** Participants were 1780 adults aged 20-65 recruited from the Seattle, WA and Baltimore, MD regions (48% female; 25% ethnic/racial minority). The outcome variable was based on this item: "How often would you bike if you thought it was safe from cars?". The difference between current and projected bicycling frequency is the estimated impact of improving safety from cars. Multivariate mixed models were conducted to examine demographic and built environment correlates of projected cycling increases.

**RESULTS:** For the whole sample, bicycling at least once per week was projected to increase from 9% to 39% if bicycling was safe from cars. Ethnic/racial minority groups reported greater projected increases ( $p < .009$ ) in cycling compared to whites. Scores on the item "safe to ride bike in neighborhood" were inversely related ( $p < .001$ ) to projected increases in cycling. Street connectivity was positively related ( $p < .007$ ) to projected increases in cycling.

**CONCLUSION:** Implementing measures used widely outside the US to improve bicyclists' safety from cars would primarily benefit minority groups who cycle less but have higher rates of chronic diseases, as well as those who currently feel least safe. Bicycling improvements are also projected to be largest in areas with connected streets that provide many alternative routes so bicyclists can avoid busy streets. Improving bicycle safety appears to target subgroups who could benefit most.

Supported by NIH grant HL67350.

**2234** Board #280 **MAY 31** **8:00 AM - 9:30 AM**  
**Examination of the Physical and Social Environments Effect on Health Promotion Program and Exercise Participation**

Lisa J. Leininger, Debra Harris, Susan M. Tracz, James E. Marshall. *CSU Fresno, Fresno, CA.*  
(No relationships reported)

**PURPOSE:** The purpose of this study was to examine if the social and physical environment is associated with participation in university worksite health promotion programs and self initiated physical activity.

**METHODS:** Three state university campuses without health promotion programs and four campuses with a health promotion program participated in this study. Physical activity participation was assessed via survey to all campus employees. Physical activity was compared for those with (N=426) and without a program (N=371). In addition, the campuses with a program were classified as high, medium or low social and physical support as indicated on the Environmental Assessment Tool (EAT). Program participation and amount of physical activity were compared between employees on campuses designated as high (N=76), medium (N=187) and low (N=167) support campuses.

**RESULTS:** The results indicated that there was no significant difference ( $p > .05$ ) in the amount of vigorous physical activity between those with ( $M = 1.87 \pm 2.29$ ) and without a program ( $M = 1.6 \pm 1.87$ ). In addition, there was no significant difference ( $p > .05$ ) in the amount of moderate physical activity between those with ( $M = 2.18 \pm 2.43$ ) and without a program ( $M = 1.88 \pm 2.03$ ). There were significant differences ( $p < .05$ ) for walking days per week, with the employees with a program having the highest number of days ( $M = 4.06 \pm 3.57$ ) compared to those without a program ( $M = 3.38 \pm 2.28$ ). Program participation was influenced by support level, with the high support campus reporting the highest percentage of employees participating in health promotion activities (76.5%), followed by the medium support campuses (41%) and low support campus (20.7%).

**CONCLUSIONS:** Overall findings indicate that support was highly related to program participation, and increased levels of walking. Despite the differences, employees were not meeting minimum requirements for weekly physical activity. Therefore, health promotion directors on university campuses should strive to increase physical and social support and implement best practices to increase physical activity among employees to improve health outcomes, reduce absenteeism and increase productivity.

**Acute Protection Against Hyperpnoea-Induced Bronchoconstriction By Terbutaline In Athletes**

Pascale Kippelen<sup>1</sup>, Aldona S. Greenwood<sup>1</sup>, Andrew J. Simpson<sup>1</sup>, Lee M. Romer, FACSM<sup>1</sup>, Sandra D. Anderson<sup>2</sup>. <sup>1</sup>Brunel University, Uxbridge, United Kingdom.  
<sup>2</sup>Royal Prince Alfred Hospital, Camperdown, NSW, Australia.  
(No relationships reported)

Exercise-induced bronchoconstriction (EIB) is highly prevalent in elite athletes. Short-acting inhaled beta2-agonists are widely prescribed to prevent EIB in asthmatic patients. The pathophysiology of EIB, however, seems to differ between asthmatic patients with EIB and otherwise healthy athletes with EIB.

**PURPOSE:** We aimed to test the efficacy of a single-dose of the inhaled short-acting beta2-agonist terbutaline in preventing EIB in athletes.

**METHODS:** We conducted a randomized double-blind placebo-controlled study of the effects of inhaled terbutaline (0.5 mg) and placebo administered as dry powder at different study days in 11 summer sports recreational athletes (age range 19-33 years) with documented EIB. Forced expiratory volume in 1 sec (FEV<sub>1</sub>) was measured at baseline, 15 min after inhaling terbutaline or placebo, and at intervals up to 30 min after an 8 min eucapnic voluntary hyperpnoea (EVH) test (a surrogate for exercise). Data were analysed with repeated measures ANOVA and paired t-tests.

**RESULTS:** Terbutaline induced a slight but significant bronchodilation at rest (mean  $\pm$  SD FEV<sub>1</sub> increase  $0.24 \pm 0.15$  L,  $p < 0.001$ ) and fully prevented hyperpnoea-induced bronchoconstriction in 7 out of 11 (64%) subjects. The percentage protection afforded by terbutaline was  $36 \pm 22\%$  (range 0-88%), with a mean FEV<sub>1</sub> fall post-EVH of  $14 \pm 4\%$  in the placebo condition versus  $9 \pm 5\%$  in the terbutaline condition ( $p < 0.05$ ).

**CONCLUSIONS:** Pre-treatment with inhaled terbutaline prevents hyperpnoea-induced bronchoconstriction in a majority of recreational summer sports athletes. However, the degree of bronchoprotection afforded by terbutaline is lower in athletes than previously reported in asthmatic patients with EIB.

Funded by the World Anti-Doping Agency.

**2236** Board #282 **MAY 31** **8:00 AM - 9:30 AM**  
**Docosahexaenoic Acid Does Not Attenuate Hyperpnea-Induced Bronchoconstriction in Adults With Asthma**

Sally K. Head<sup>1</sup>, Timothy D. Mickleborough, FACSM<sup>2</sup>. <sup>1</sup>Indiana University School of Medicine, Indianapolis, IN. <sup>2</sup>Indiana University, Bloomington, IN.  
(No relationships reported)

**BACKGROUND:** Hyperpnea, or rapid breathing, can be used to identify exercise-induced bronchoconstriction, which is a complication of asthma that has been shown to be attenuated by supplementation with fish oil. An optimal formula for fish oil has not been determined, although previous *in vitro* studies have suggested that, in terms of reducing inflammation, docosahexaenoic acid (DHA) may be the more potent omega-3 fatty acid in fish oil.

**PURPOSE:** Determine whether supplementation with DHA can attenuate hyperpnea-induced bronchoconstriction (HIB) in adults with asthma as compared to placebo.

**METHODS:** Nine subjects (18-30 years; 6 males, 3 females) with asthma and HIB participated in a randomized, double-blind, placebo-controlled crossover trial where they received either DHA or placebo capsules for 3 weeks. Following a 2-week washout, subjects received the opposite supplement for 3 weeks. Subjects were tested in a laboratory following an initial 2-week run-in phase and after each supplementation phase. At each test, bronchoprovocation was elicited with eucapnic voluntary hyperventilation (EVH), a surrogate exercise challenge involving rapid breathing. Prior to and following the EVH challenge, the forced expiratory volume in one second (FEV<sub>1</sub>) and concentrations of 8-isoprostane and the DHA metabolite protectin D1 in exhaled breath condensate were measured. Repeated measures ANOVA assessed differences among the study phases; significance was held at  $p < 0.05$ .

**RESULTS:** There were no significant changes ( $p > 0.05$ ) in the maximum drop in FEV<sub>1</sub> among the pre-supplementation ( $21.07 \pm 2.65\%$ ), placebo ( $17.20 \pm 3.27\%$ ), and DHA supplementation ( $17.27 \pm 3.73\%$ ) phases. The pre-EVH concentration of 8-isoprostane was not significantly different ( $p > 0.05$ ) among the pre-supplementation ( $3.08 \pm 1.50$  pg/ $\mu$ L), placebo ( $6.16 \pm 2.12$  pg/ $\mu$ L), and DHA supplementation ( $4.48 \pm 1.20$  pg/ $\mu$ L) phases. The concentration of protectin D1 was undetectable ( $< 0$  pg/ $\mu$ L) at each laboratory test.

**CONCLUSION:** The data indicate that supplementation with 4.0 g DHA for 3 weeks does not significantly attenuate HIB in adult asthmatic subjects compared to baseline or placebo.

Supplementation with the omega-3 fatty acid eicosapentaenoic acid should be similarly tested to determine if it is the more effective component of fish oil for attenuating HIB.

---

**2237** Board #283 **MAY 31** **8:00 AM - 9:30 AM**  
**Post-Exercise Airway Response To Atropine In Healthy Elite Swimmers**

Mona Luke-Zeitoun, Ben Wildman-Tobriner, Emily Ghio, Nicolas Hatamiya, Anthony Luke, FACSM, Dennis Nielson, Stephen Lazarus, Warren Gold. *University of California San Francisco, San Francisco, CA.*  
(No relationships reported)

**PURPOSE:** There is a high prevalence of airway hyperresponsiveness (AHR) in endurance athletes, particularly in elite swimmers. Athletes develop exercise-induced bronchoconstriction at a

higher rate than the general population. Vagal activity has been shown to be increased in high level athletes and is known to promote bronchoconstriction. The goal of this study was to determine the direct effects of parasympathetic tone on airway responsiveness in healthy elite swimmers.

**METHODS:** Bronchial response to exercise was measured in 7 healthy collegiate swimmers from a local NCAA Division 1 University team (4 males, 3 females) on 2 different occasions. To provoke EIB, the athletes exercised for 8 minutes on a cycle ergometer at 90% of their maximal heart rate while breathing dry air. In one of the visits, the athletes received intravenous saline (placebo). In the other visit, they received intravenous atropine (0.04 mg/kg), given in divided doses (0.01 mg/kg every 30 seconds) between minutes 8 and 10 of exercise to selectively achieve parasympathetic blockade by the end of the exercise challenge. Airway conductance was measured by body plethysmography before and after 3, 6, 10, 15, 20 and 30 minutes after the exercise challenge. A one-way repeated measures ANOVA was used to identify differences in bronchial response after exercise with and without parasympathetic blockade.

**RESULTS:** Postexercise airway conductance as percent of pre-exercise values showed significant changes over time ( $p < 0.05$ ), significant differences among the 2 experimental conditions ( $p < 0.05$ ) and a significant condition  $\times$  time interaction ( $p < 0.05$ ). Airway conductance was significantly lower for placebo, as compared with atropine at 6, 10, and 30 minutes post-exercise ( $p < 0.05$ ). The lowest values for airway conductance occurred during the placebo trial at 3 minutes post-exercise (88% pre-exercise). The highest values for airway conductance occurred during the atropine trial at 30 minutes post-exercise (173% pre-exercise).

**CONCLUSION:** Parasympathetic blockade results in airway dilation in healthy elite swimmers. These data suggest that vagal mechanisms play a major role in post-exercise airway response and possibly the development of exercise-induced bronchoconstriction in competitive swimmers.

---

**2238** Board #284 MAY 31 8:00 AM - 9:30 AM

**Respiratory Muscle O<sub>2</sub> Uptake and Deoxygenation During Incremental Exercise to Fatigue: Is There a “Steal”?**

Andrea D. Marjerrison, Mark A. Babcock, Donald H. Paterson, FACSM, John M. Kowalchuk. *The University of Western Ontario, London, ON, Canada.*

(No relationships reported)

Muscle deoxygenation reflects the relationship between O<sub>2</sub> utilization (VO<sub>2</sub>) and (microvascular) perfusion (Q). During incremental exercise, O<sub>2</sub> requirement for muscle work occurs in active “locomotor” muscles and in respiratory muscles (RM), and competition for Q and O<sub>2</sub> delivery impacts local deoxygenation. During incremental exercise (IE) involving only increases in RM work, the relationship between muscle VO<sub>2</sub>-to-Q may differ compared to cycling exercise.

**PURPOSE:** To examine RM deoxygenation using near-infrared spectroscopy (NIRS) during incremental RM-specific exercise to fatigue (IE<sub>RM</sub>) and compare deoxygenation changes to those seen with incremental leg cycling exercise to fatigue (IE<sub>LC</sub>).

**METHODS:** Healthy men (n, 6; age, 29  $\pm$  6 yrs (mean  $\pm$  SD); ht, 184  $\pm$  9 cm; mass, 89  $\pm$  10 kg) performed 4 IE<sub>RM</sub> and 1 IE<sub>LC</sub>. The IE<sub>RM</sub> was performed seated, at a breathing frequency of 15 br/min; after 5-min breathing without resistance, inspiratory resistance increased by 50 g every 2-min until the subject was unable to generate the required inspiratory pressure to overcome the added resistance. For the IE<sub>LC</sub>, subjects sat at rest for 5-min, and began cycling at 20 W for 2-min after which power output increased by 40 W every 2-min until volitional fatigue. During IE, V<sub>E</sub> and VO<sub>2</sub> were measured breath-by-breath using a volume turbine and mass spectrometer. Deoxygenation (tissue %O<sub>2</sub>sat) of the intercostal (IC) and vastus lateralis (VL) muscle groups was monitored using NIRS.

**RESULTS:** Peak VO<sub>2</sub> in IE<sub>RM</sub> was 1.06 L/min ( $\Delta$  = 0.58 L/min) and in IE<sub>LC</sub> was 4.3 L/min ( $\Delta$  = 3.6 L/min). Compared to baseline (BL), peak V<sub>E</sub> decreased ( $p < 0.05$ ) during IE<sub>RM</sub> (24  $\pm$  6 to 17  $\pm$  2 L/min) and increased ( $p < 0.05$ ) during IE<sub>LC</sub> (15  $\pm$  3 to 155  $\pm$  27 L/min). During IE<sub>RM</sub>, tissue %O<sub>2</sub>sat increased ( $p < 0.05$ ) from BL to mid-exercise (73  $\pm$  6 to 76  $\pm$  4 %) and returned to BL values at peak; deoxygenation was not seen in VL during IE<sub>RM</sub>. During the IE<sub>LC</sub>, tissue %O<sub>2</sub>sat decreased ( $p < 0.05$ ) from BL to peak (69  $\pm$  2 to 59  $\pm$  6 %) in IC and in VL (71  $\pm$  5 to 62  $\pm$  7 %) ( $p < 0.05$ ).

**CONCLUSIONS:** The increase in RM VO<sub>2</sub> during IE<sub>RM</sub> represented ~ 16% of the whole body VO<sub>2</sub> observed in IE<sub>LC</sub>. At the peak exercise, the increase in RM deoxygenation during IE<sub>LC</sub> but not IE<sub>RM</sub> is consistent with a redistribution of Q away from the RM (and higher VO<sub>2</sub>-to-Q) during IE<sub>LC</sub> compared to IE<sub>RM</sub>.

Supported by NSERC and UWO ADF

**2239** Board #285 MAY 31 8:00 AM - 9:30 AM

**Does Deoxygenation Of The Intercostals Reflect On That Of The Accessory Respiratory Muscle?**

Takuya Osawa<sup>1</sup>, Ryotaro Kime<sup>2</sup>, Masako Fujioka<sup>3</sup>, Takuya Osada<sup>2</sup>, Norio Murase<sup>2</sup>, Toshihito Katsumura<sup>2</sup>. *Japan Institute of Sports Sciences, Tokyo, Japan.* <sup>2</sup>Tokyo Medical University, Tokyo, Japan. <sup>3</sup>Ritsumeikan University, Shiga, Japan.

(No relationships reported)

Deoxygenation, measured by near-infrared spectroscopy (NIRS), in the intercostals is increased during high intensity exercise. Although previous studies have reported that this phenomenon was induced by an increase in the accessory respiratory muscle O<sub>2</sub> consumption, it was possible that sympathetic nerve activity-induced vasoconstriction decreased the O<sub>2</sub> supply in the muscle and increased the deoxygenation level, similar to non-active muscles. Additionally, it was unclear if the relationship between minute ventilation (VE) and deoxygenation in the intercostals during incremental exercise would be similar to that in other exercise protocols.

**PURPOSE:** To compare deoxygenation between the intercostals and non-active (the biceps brachii) muscle during incremental and decremental bicycle exercise, and to investigate the relationship between VE and deoxygenation in the intercostals.

**METHODS:** Seven male subjects (age; 23  $\pm$  2 yr) performed a ramp incremental bicycle exercise test (20 W $\cdot$ min<sup>-1</sup>) to exhaustion, and the peak power output (PPO) was determined. After 48 h, they performed a ramp decremental bicycle exercise test (-20 W $\cdot$ min<sup>-1</sup>) from 90-95% of PPO. Pulmonary O<sub>2</sub> uptake (VO<sub>2</sub>) and VE were calculated by breath-by-breath methods, and muscle O<sub>2</sub> saturation in the intercostals (SO<sub>2IM</sub>) and the biceps brachii (SO<sub>2BB</sub>) were evaluated by NIRS.

**RESULTS:** The peaks of VO<sub>2</sub> and VE during incremental exercise were 63.5  $\pm$  6.3 mL $\cdot$ kg<sup>-1</sup> $\cdot$ min<sup>-1</sup> and 146  $\pm$  19 L $\cdot$ min<sup>-1</sup>, respectively. SO<sub>2IM</sub> and SO<sub>2BB</sub> decreased during incremental exercise, and these values at PPO were 34.2  $\pm$  7.2% and 26.5  $\pm$  12.8%. The two changes did not differ significantly throughout the test. During decremental exercise, both SO<sub>2IM</sub> and SO<sub>2BB</sub> were acutely decreased at the onset of exercise, and these minimum values occurred at the 75 to 80% of PPO. These values were also similar throughout the test. The relationship between VE and SO<sub>2IM</sub> was not significantly different between both protocols. However, in hyperventilation (at ~80% of PPO), SO<sub>2IM</sub> tended to be higher during decremental exercise than during incremental exercise.

**CONCLUSIONS:** It is likely that deoxygenation in the intercostals during high intensity exercise was induced by low O<sub>2</sub> supply, similar to non-active muscle.

---

**2240** Board #286 MAY 31 8:00 AM - 9:30 AM

**The Effect of IMT on Muscle Deoxygenation during Exercise with Resistive Inspiratory Loading**

Louise A. Turner<sup>1</sup>, Sandra Tecklenburg-Lund<sup>2</sup>, Robert F. Chapman<sup>3</sup>, Joel M. Stager<sup>3</sup>, Joseph W. Duke<sup>3</sup>, Timothy D. Mickleborough, FACSM<sup>3</sup>. <sup>1</sup>Northumbria University, Newcastle Upon Tyne, United Kingdom. <sup>2</sup>Nebraska Wesleyan University, Lincoln, NE. <sup>3</sup>Indiana University, Bloomington, IN.

(No relationships reported)

High levels of respiratory muscle work during exercise have been shown to increase the metabolic demands of the respiratory musculature and increase limb and respiratory muscle deoxygenation, however, the role of inspiratory muscle training (IMT) on these parameters remains unclear.

**PURPOSE:** To determine the effect of IMT on respiratory (RM) and limb locomotor (LM) muscle deoxygenation during exercise while undergoing periods of increased inspiratory loading.

**METHODS:** Using a double blind, placebo controlled design, 16 male cyclists completed 6-wk of inspiratory muscle training (IMT) using an inspiratory load of 50% (IMT; n=8) or 15% [placebo] (CON; n=8) of maximal inspiratory pressure (P<sub>I,max</sub>). Pre- and post-training all subjects completed three, 6-min experimental trials in a randomized order, separated by 20-min. The exercise intensity of each trial was performed at a workload equivalent to ~80% VO<sub>2max</sub> (EX<sub>80%</sub>); during the final 3-min of each trial each subject received an intervention consisting of; (1) moderate resistive inspiratory loading, (2) heavy resistive inspiratory loading, or (3) maximal exercise. LM and RM oxy- ([HbO<sub>2</sub>]), deoxy- ([HHb]) and total- ([THC]) hemoglobin concentration was continuously monitored using near-infrared spectroscopy. Statistical significance was accepted when  $p < 0.05$ .

**RESULTS:** P<sub>I,max</sub> was significantly increased from pre- to post- training by 26  $\pm$  19% (114  $\pm$  12 to 142  $\pm$  19 cmH<sub>2</sub>O) in the IMT group and remained unchanged in the CON group. Following IMT, a significant reduction in the change in VO<sub>2</sub> (96 ml/min), LM [HHb] (1.7  $\pm$  1.3  $\mu$ m) and RM [HHb] (2.8  $\pm$  2.6  $\mu$ m) from EX<sub>80%</sub> to heavy inspiratory loading was observed during submaximal exercise. There was no significant difference in [HHb], [HbO<sub>2</sub>], [THC] during any of the other loading trials, from pre- to post- training, in either the IMT or CON group.

**CONCLUSION:** After IMT, highly-trained competitive cyclists demonstrate decreased whole-body VO<sub>2</sub>, and LM and RM deoxygenation during exercise with heavy inspiratory loading.

These data suggest that IMT reduces respiratory muscle demand and decreases oxygen extraction by the active muscles, which may reflect IMT-induced changes in respiratory and limb locomotor muscle oxygen delivery.

**2241** Board #287 MAY 31 8:00 AM - 9:30 AM

**Effects of Inspiratory Muscle Training on 15-Km Time Trial Physiological Responses in Trained Cyclists**

Courtenay McFadden<sup>1</sup>, Lorrie R. Brilla, FACSM<sup>1</sup>, David N. Suprak<sup>1</sup>, Kathleen M. Knutzen, FACSM<sup>2</sup>. <sup>1</sup>Western Washington University, Bellingham, WA. <sup>2</sup>University of California at Bakersfield, Bakersfield, CA.

(No relationships reported)

**PURPOSE:** Inspiratory muscle training (IMT) has shown some performance improvements in athletes. The effects of IMT on peak anaerobic power and mean anaerobic power in bicycle racers, specifically during the last 30 seconds of a simulated 15-km time trial were examined. Physiological responses and time were monitored during the time trial to determine IMT influence.

**METHODS:** Eighteen males and eight females were randomly divided into a training (T) or placebo (P) group and had testing of maximal inspiratory pressure (MIP) to set IMT workloads. T performed each set at 85% of their MIP while P performed each set at 15% of their MIP. Each group performed 5 sets of 12 repetitions of IMT for 6 weeks, 5 days per week, using a spring loaded resistive device. A 15-km time trial, with the last 30 seconds of the time trial being a 30 second Wingate Anaerobic Test was performed pre and post IMT. Every five minutes during the time trial, heart rate (HR), arterial oxygen-hemoglobin saturation (SaO<sub>2</sub>) via pulse oximeter, and ratings of perceived exertion (RPE) were measured. Overall 15-km time was also collected. A repeated measures ANOVA group by time was applied.

**RESULTS:** There were no significant interaction effects (P>0.05). Mean anaerobic power increased in both groups (P<0.05; P: 529.6 ± 124.6 watts to 574.4 ± 99.3 watts T: 612.3 ± 81.7 watts to 632 ± 81.7 watts), SaO<sub>2</sub> values increased in both groups (P<0.05; P: 94.8 ± 2.1% to 95.3 ± 1.8% T: 93.8 ± 1.9% to 95.1 ± 1.6%), and MIP increased (P<0.05) in both the P (110 ± 40cmH<sub>2</sub>O to 150 ± 40 cmH<sub>2</sub>O) and T (130 ± 30 cmH<sub>2</sub>O to 160 ± 20 cmH<sub>2</sub>O). There were no significant main effects for RPE, HR, or time trial.

**CONCLUSIONS:** Since both groups showed improvements in mean anaerobic power, MIP, and SaO<sub>2</sub>, it cannot be concluded that IMT helped the subjects improve these factors. However, the placebo condition may not have been a true placebo effect since the subjects improved their MIP, as well as the higher intensity training group.

**2242** Board #288 MAY 31 8:00 AM - 9:30 AM

**Effects of an Inspiratory Muscle Training Program on Cardiopulmonary Capacity of Collegiate Cross-Country Runners**

Justin Severance, Stephen Lux, Marlene Wentz. *Alma College, Alma, MI.*

(No relationships reported)

The issue has been raised that the effectiveness of the ventilatory system during maximal exercise in elite runners may be a limiting factor to performance. Research on this topic has been variable, thus no conclusive evidence has been found to support respiratory muscle fatigue in highly trained athletes.

**PURPOSE:** The purpose of this study was to investigate the effects of inspiratory muscle training (IMT) on VO<sub>2</sub>max, Maximum Voluntary Ventilation (MVV), Vital Capacity (VC), Inspiratory Capacity (IC), and Expiratory Reserve Volume (ERV) on highly trained endurance athletes.

**METHODS:** Eight (3 female, 5 male) Division III collegiate cross-country runners (mean age = 20 years) participated in the study. Baseline measurements were taken for VO<sub>2</sub>max and MVV, VC, IC, and ERV using a maximal graded exercise test and spirometry, respectively. Four subjects were randomly chosen to undergo IMT in conjunction with standard cross-country conditioning, with the remaining 4 subjects comprising the control group with no IMT. The training regimen consisted of 6-weeks of progressive inspiratory muscle training using a Smith's Inspiratory Muscle Trainer. VO<sub>2</sub> and pulmonary function measurements were taken pre-IMT training, mid-IMT training (2 weeks) and post-training.

**RESULTS:** Pre-test results indicated a mean VO<sub>2</sub>max of 66.5 ml/kg/min for the experiment group and 61.0 ml/kg/min for the control group. Average pulmonary function results for the experimental and control groups were; MVV of 157.3L/min v 150.7L/min, VC of 4.87L v 4.82L, IC of 2.93L v 2.88L, ERV of 1.93L v 1.95L, respectively. Post-test results showed a mean VO<sub>2</sub>max of 61.15 ml/kg/min for the experimental group and 65.7 ml/kg/min for the control group. The average pulmonary function post-test results for the experimental and control groups were; MVV of 165.1L/min v 167.3L/min, IC of 2.93L v 2.70L, VC of 4.87L v 4.75L, ERV of 1.97L v 2.05L, respectively.

**CONCLUSIONS:** There was no significant difference (p>.05) in cardiopulmonary capacity measures between the experimental and control group. Similar results have been reported in previous research on this topic, which supports the necessity for further investigation into cardiopulmonary limitations during exercise in elite, endurance-trained athletes.

---

**2243** Board #289 MAY 31 8:00 AM - 9:30 AM

**Pulmonary Adaptations To Swim And Inspiratory Muscle Training In Sub-elite Swimmers**

Joshua Weavil<sup>1</sup>, Ren-Jay Shei<sup>1</sup>, Martin Lindley<sup>2</sup>, Timothy D. Mickleborough, FACSM<sup>1</sup>. <sup>1</sup>Indiana University, Bloomington, IN. <sup>2</sup>Loughborough University, Loughborough, United Kingdom.

(No relationships reported)

**PURPOSE:** We have previously shown that there are no significant differences in respiratory changes between elite swimmers undergoing a 12 week swim training (ST) program and those undergoing the same ST program and flow-resistive inspiratory muscle training (IMT). The aim of this study was to assess respiratory muscle and pulmonary function of 24 competitively trained sub-elite swimmers assessed at the beginning and end of an intensive 12-week ST program using the same IMT device we used previously (RT2 trainer, DeVilbiss).

**METHODS:** Swimmers (n=8) combined ST with either IMT set

at 80% sustained maximal inspiratory pressure with progressively increased work-rest ratios until task failure for 3 d/wk. (ST + IMT), or ST with sham-IMT (ST + SHAM-IMT, n=8), or acted as controls (ST only, n=8). Measures of pulmonary and respiratory muscle function were assessed at the beginning and end of the 12-week study period.

**RESULTS:** There were no significant differences (p>0.05) in

respiratory muscle and pulmonary function between groups at baseline, or at the end of the 12-week study for the ST + SHAM-IMT and ST group only. However, while no significant changes (p>0.05) in pulmonary function, except for forced inspiratory time in 1-sec (%Δ, +15%), were observed within the ST + IMT group at the end of the 12 week study compared to baseline, significant increases (p<0.05) were observed in a number of respiratory muscle function variables at the end of the 12-week study, such as maximal inspiratory pressure (%Δ, +90%), sustained maximal inspiratory pressure (%Δ, +42%), maximal inspiratory muscle power output (%Δ, +61%), inspiratory time of contraction (%Δ, +34%), and maximal voluntary ventilation in 12-sec (%Δ, +39%).

**CONCLUSIONS:** This study has demonstrated that there are substantial differences in respiratory muscle function between sub-elite swimmers undergoing a competitive ST program only and those undergoing IMT in conjunction with the same ST program. This is in contrast to our previous study which showed no appreciable differences between ST + IMT and ST only in elite swimmers. Whether the enhanced respiratory muscle function in the ST + IMT group in the present study translates into improved swimming performance using this specific inspiratory muscle trainer has yet to be determined.

**2244** Board #290 MAY 31 8:00 AM - 9:30 AM

**Ventilatory Efficiency, Body Composition, Dyspnea, And Exercise Mode In Lean And Obese Females**

Jeffrey E. Herrick, Erik P. Kirk, Curt L. Lox, Brandon L. Sharp. *Southern Illinois University Edwardsville, Edwardsville, IL.*

(No relationships reported)

Obesity reduces ventilatory efficiency (V<sub>E</sub>/VCO<sub>2</sub>) during exercise through a combination of increased metabolic cost of breathing and reduced pulmonary capacity. An elevated V<sub>E</sub>/VCO<sub>2</sub> slope may suggest the presence of exercise induced dyspnea, which is the most commonly reported physiologically barrier of exercise adherence. Little research has investigated the relationship between ventilatory efficiency, regional adiposity, exercise mode, and dyspnea in females.

**PURPOSE:** This study compared ventilatory efficiency and perceived dyspnea between lean (LN) and obese (OB) females during randomized sub-maximal cycle ergometer (CE) and treadmill (TM) exercise. We also investigated the relationships between total (BF) and truncal adiposity (TA), truncal lean (TL), and cardiopulmonary outcomes.

**METHODS:** Twenty females participated (Mean  $\pm$ SE: LN n=10, BMI=22.8 $\pm$ 0.6, OB n=10, BMI=38.6 $\pm$ 1.4 kg/m<sup>2</sup>). BF, TA, and TL were assessed via iDXA. Subjects completed randomized sub-maximal TM and CE exercise to 6 METS or 75% of predicted HR<sub>max</sub>, the termination point of the first randomized test was utilized for the second. V<sub>E</sub>/VCO<sub>2</sub> slope was determined as the slope of the rise in V<sub>E</sub> (L·min<sup>-1</sup> BTPS) to the increase in VCO<sub>2</sub> (L·min<sup>-1</sup> STPD).

**RESULTS:** There were between group differences ( $p \leq 0.05$ ) in BF (LN 29.6 $\pm$ 1.7, OB 46.4 $\pm$ 1.4 %Fat), TA (LN 8.5 $\pm$ 0.8, OB 25.6 $\pm$ 2.6 kg), and TL (LN 20.7 $\pm$ 0.6, OB 24.6 $\pm$ 1.0 kg). There were no differences in exercise durations or VO<sub>2peak</sub> between group or mode. V<sub>E</sub>/VCO<sub>2</sub> was different between groups on the bike and between modes within OB (CE LN 23.6 $\pm$ 1.2, OB 27.8 $\pm$ 0.5; TM LN 23.8 $\pm$ 0.5, OB 25.9 $\pm$ 0.7 V<sub>E</sub>/VCO<sub>2</sub>). OB minute ventilation (LN 37.8 $\pm$ 3.5, OB 61.3 $\pm$ 1.8 L·min<sup>-1</sup>) and respiratory rate (RR LN 27.2 $\pm$ 2.2; OB 32.9 $\pm$ 1.5 breaths·min<sup>-1</sup>) was greater during CE. OB reported greater exercise dyspnea than LN during CE (LN 1.6 $\pm$ .36, OB 3.2 $\pm$ .38 Borg Dyspnea Scale) which was associated with TA ( $p \leq 0.00$ ,  $r=0.796$ ), BF ( $p \leq 0.00$ ,  $r=0.781$ ), and TL ( $p \leq 0.00$ ,  $r=0.731$ ).

**CONCLUSIONS:** Our results suggest that weight bearing exercise (treadmill walking) supported an increased ventilatory efficiency over non-weight bearing exercise (cycle ergometer) which our obese female group perceived as lower exercise induced dyspnea. Thus, prescribing weight bearing exercise to obese females may limit dyspnea and in turn support greater exercise adherence.

**2245 Board #291 MAY 31 8:00 AM - 9:30 AM**  
**Prevalence And Determination Of Expiratory Flow Limitation During Exercise In Men And Women**

Joshua R. Smith, Craig A. Harms, FACSM. *Kansas State University, Manhattan, KS.*  
(No relationships reported)

Expiratory flow limitation (EFL) can occur in healthy young women and men during exercise. Women, however have been reported to have smaller lungs and airways than height and aged matched men potentially leaving them more susceptible to EFL.

**PURPOSE:** We questioned whether the prevalence of EFL during exercise was greater in women compared to men.

**METHODS:** Data from healthy men (n=74, 23.3 $\pm$ 4.4 yrs) and women (n=76; 21.8 $\pm$ 3.7 yrs) were examined from previously published studies from our lab. All subjects completed either a progressive treadmill or cycle test to exhaustion. Subject's maximal flow volume loop (MFVL) was compiled from several effort graded vital capacity maneuvers before and after exercise. The MFVL, along with inspiratory capacity maneuvers was used to determine lung volumes, expiratory flows and to quantify EFL. To determine relative airway size, we used a ratio sensitive to both airway size and lung volume; referred to as the dysanapsis ratio (DR). The subjects were divided into groups based upon the appearance of  $\geq 5\%$  EFL at max exercise.

**RESULTS:** EFL was present in significantly more women (60/76, 79%) than men (18/74, 24%). Both women with EFL (W-EFL) and with no EFL (W-NEFL) had significantly lower VO<sub>2max</sub>, forced vital capacity (FVC), and DR (indicating smaller airways) than men with EFL (M-EFL) or with no EFL (M-NEFL). W-EFL had similar ( $p > 0.05$ ) VO<sub>2max</sub> as W-NEFL, but significantly lower FVC (3.93 $\pm$ 0.56 vs 4.23 $\pm$ 0.32 l) and DR (0.19 $\pm$ 0.04 vs 0.23 $\pm$ 0.02). M-EFL had higher ( $p < 0.05$ ) VO<sub>2max</sub> (57.4 $\pm$ 4.0 vs 49.7 $\pm$ 7.3 ml/kg/min) than M-NEFL but similar ( $p > 0.05$ ) FVC, and DR.

**CONCLUSION:** EFL during exercise is more prevalent in women compared to men and can largely be explained by smaller lung volumes and airways in women. In women, EFL is largely due to smaller airways; while in men, EFL is likely due to higher ventilation associated with greater aerobic capacity.

---

**2246 Board #292 MAY 31 8:00 AM - 9:30 AM**  
**Expiratory Flow Limitation during Maximal Exercise in Young Competitive Swimmers Following One-Year of Swim Training**

Kosuke Kojima, Daniel P. Wilhite, Masataka Ishimatsu, Brian V. Wright, Joel M. Stager. *Indiana University, Bloomington, IN.*  
(No relationships reported)

Expiratory flow limitation (EFL) during maximal exercise in prepubescent children has been principally explained by disproportionate growth of the lung-airway system and a conflict between ventilatory demand and capacity. Previous research comparing prepubescent swimmers and controls has shown that swim training improves the conductive properties of the airways independent of growth (Courteix et al., 1997).

**PURPOSE:** To examine how an additional 1-year of swim training influences pulmonary function and metabolic demands of maximal exercise, and consequently the degree and prevalence of EFL in young children.

**METHODS:** Ten healthy young competitive swimmers (5 boys and 5 girls; 10.3  $\pm$  1.1 years; 145.0  $\pm$  7.3 cm; 39.3  $\pm$  8.8 kg, an average of two years of competitive swimming experience) performed pulmonary function and VO<sub>2max</sub> tests before and after the 2010/2011 season. Pulmonary function values were collected during a set of maximal inspiratory and expiratory maneuvers for the determination of the maximal flow-volume loop (MFVL). Metabolic variables and minute ventilation were collected each minute during an incremental exercise test to exhaustion on a cycle ergometer. The degree of EFL was determined by the percentage of the exercise tidal flow-volume loop that overlapped the expiratory portion of the MFVL. In order to compare pre- and post-training data (boys and girls were combined due to no sex-based differences), a paired two-sample t-test was used.

**RESULTS:** After an additional 1-year of swim training, absolute VO<sub>2max</sub> (L·min<sup>-1</sup>) increased by 13.2% ( $P < 0.05$ ). Peak expiratory flow (PEF) increased by 13.7% ( $P = 0.01$ ). There were no significant increases in any other resting pulmonary function variables. At maximal exercise, PEF of tidal volume was increased by 10.6% ( $P < 0.01$ ), while expiratory and inspiratory reserve volumes did not change. The degree of EFL did not differ ( $P > 0.05$ ) although its prevalence altered from 6 to 7 out of 10 young swimmers.

**CONCLUSION:** Despite an increase in demand during maximal exercise and an additional year of swim training, pulmonary function was similar in these children to our prior measures. When compared to previous data and sedentary control values from the literature, young swimmers continue to show unique adaptations to swim training.

**2247 Board #293 MAY 31 8:00 AM - 9:30 AM**  
**Assessment of Pulmonary Restriction in Athletes with Cervical Spinal Cord Injury: a Method Comparison**

Lee M. Romer, FACSM<sup>1</sup>, Christopher R. West<sup>2</sup>, Ian G. Campbell<sup>1</sup>. <sup>1</sup>*Brunel University, Uxbridge, United Kingdom.* <sup>2</sup>*University of British Columbia, Vancouver, BC, Canada.*  
(No relationships reported)

Pulmonary restriction is rarely assessed by the criterion standard method of total lung capacity (TLC) below the lower 5<sup>th</sup> percentile of the able-bodied (AB) predicted value (lower limit of normal; LLN). More often, restriction is inferred using a vital capacity (VC) below the LLN and a normal-to-high forced expiratory volume in 1 second (FEV<sub>1</sub>)-to-VC ratio. SCI causes a greater loss of expiratory relative to inspiratory muscle strength, and therefore a disproportionate reduction in VC compared to TLC. Accordingly, there may be a greater chance of misclassifying pulmonary restriction in individuals with SCI.

**PURPOSE:** To determine whether the VC method results in a greater misclassification of pulmonary restriction in SCI vs. AB.

**METHODS:** Twelve Paralympic athletes with cervical SCI (injury level, C5-C7) and twelve AB controls matched for age, stature, and body-mass were assessed for TLC (body-plethysmography), FEV<sub>1</sub> and VC (spirometry), and maximal inspiratory and expiratory mouth pressures (P<sub>L,max</sub> and P<sub>E,max</sub>).

**RESULTS:** All participants with SCI exhibited a VC < LLN, whereas significantly fewer (8 of 12) participants with SCI exhibited a TLC < LLN ( $p=0.046$ ) and a normal-to-high FEV<sub>1</sub>-to-VC ratio. For the AB group, no participant exhibited a VC or TLC < LLN. Percent-predicted VC was lower than percent predicted TLC in SCI ( $p=0.013$ ), whereas percent predicted VC was higher than percent-predicted TLC in AB ( $p=0.001$ ). Percent-predicted P<sub>L,max</sub> was higher than P<sub>E,max</sub> in SCI ( $p=0.001$ ) but not AB ( $p=0.146$ ).

**CONCLUSION:** A VC < LLN with normal-to-high FEV<sub>1</sub>/VC does not accurately predict pulmonary restriction in athletes with cervical SCI. When using spirometry to infer pulmonary restriction in athletes with cervical SCI we recommend using a VC below 60% of the AB predicted value.

2248 Board #294 MAY 31 8:00 AM - 9:30 AM

### Measurement of Ventilatory Parameters During Voluntary Wheel Running in Mice

Takashi Sonobe<sup>1</sup>, Hirotsugu Tsuchimochi<sup>1</sup>, Daryl O. Schwenke<sup>2</sup>, Mikiyasu Shirai<sup>1</sup>. <sup>1</sup>National Cerebral and Cardiovascular Center Research Institute, Suita, Japan. <sup>2</sup>University of Otago, Dunedin, New Zealand.  
(No relationships reported)

Ventilation and metabolism, i.e. oxygen consumption (VO<sub>2</sub>), are coordinated with fine precision to regulate the physiological demands during exercise. Although several reports have described the regulation of either ventilation or VO<sub>2</sub>, the regulatory link between the two variables has not yet been fully elucidated.

**PURPOSE:** The aim of present study was to investigate the interaction in the dynamic changes in ventilatory parameters and VO<sub>2</sub> during exercise in mice.

**METHODS:** C57BL/6 mice (n=5, 26 ± 1 g) were anesthetized for implantation of a telemetric ECG transmitter for monitoring heart rate (HR) and body temperature (T<sub>B</sub>). Following 3 days of recovery, the mouse was placed into the plethysmograph equipped with a running wheel and rotation counter. Using whole-body plethysmography and a high-resolution O<sub>2</sub>-CO<sub>2</sub> analyzer, we monitored respiratory waveform and the inspired and mixed expired O<sub>2</sub>-CO<sub>2</sub> concentrations simultaneously. Tidal volume (V<sub>T</sub>), ventilatory frequency (V<sub>f</sub>), minute ventilation (V<sub>E</sub>) and VO<sub>2</sub> were calculated and corrected for changes of T<sub>B</sub>. Each variable was analyzed from the mean of a 10-sec data block under resting or running conditions.

**RESULTS:** Mice performed intermittent voluntary running at a speed of ~20-25 m/min in the wheel chamber. Resting values for each variable were, HR: 502 ± 14 bpm, T<sub>B</sub>: 36.5 ± 0.2 °C, V<sub>T</sub>: 6.2 ± 0.3 ml/kg, V<sub>f</sub>: 196 ± 8 bpm, V<sub>E</sub>: 1218 ± 69 ml/kg/min, VO<sub>2</sub>: 2822 ± 228 ml/kg/h. Importantly, running significantly increased HR (Δ169 ± 14 bpm), T<sub>B</sub> (Δ1.2 ± 0.1 °C), V<sub>T</sub> (Δ2.5 ± 0.3 ml/kg), V<sub>f</sub> (Δ230 ± 17 bpm), V<sub>E</sub> (Δ2443 ± 137 ml/kg/min), and VO<sub>2</sub> (Δ2220 ± 187 ml/kg/h).

**CONCLUSION:** In conclusion, dynamic responses of ventilation and oxygen consumption during voluntary exercise were evaluated in the present mice model. This experimental model has the potential to uncover the mechanism(s) underlying the link between ventilatory responses to exercise using specific genetic knock-out mice in future studies.

2249 Board #295 MAY 31 8:00 AM - 9:30 AM

### The Effects of Voluntary Hyperventilation on Performance of Intermittent Intense Exercise

Frank J. Bosso<sup>1</sup>, Rick L. Sharp, FACSM<sup>2</sup>. <sup>1</sup>Youngstown State University, Youngstown, OH. <sup>2</sup>Iowa State University, Ames, IA.  
(No relationships reported)

**PURPOSE:** To determine if voluntary hyperventilation between short bouts of intermittent, intense exercise would affect acid-base status resulting in an increased work capacity.

**METHODS:** Seven males (VO<sub>2</sub>max 55 ± 5 ml/kg/min) volunteered (age: 21 - 28). The exercise trials were three 30sec Wingate anaerobic tests (B1,B2,B3) with 4 min recovery. Pedal resistance was set at .075kg/kg body wt. Each subject performed two trials separated by one week, one trial with normal breathing (NB), and one with voluntary hyperventilation (VH). Blood was drawn from a heated forearm vein at rest, immediately post (IP) each exercise bout, and each min of recovery. Blood acid-base variables were measured on a Radiometer BMS3. VE, VO<sub>2</sub>, VCO<sub>2</sub>, RER, f, and ECG were monitored continuously.

#### RESULTS:

|       |       | VE      | VA      | VCO2      | VO2      | PCO2  | [H+]  |
|-------|-------|---------|---------|-----------|----------|-------|-------|
| Trial | Bout  | L/4min  | L/4min  | L/4min    | L/4min   | mm Hg | nM    |
| NB    | PreB2 | 243±43  | 226±44  | 9.8±1.6   | 6.7±0.7  | 36±7  | 62±4  |
| NB    | PreB3 | 265±46  | 244±46  | 8.2±.8    | 6.8±0.9  | 28±5  | 74±7  |
| VH    | PreB2 | 320±49* | 301±49* | 10.8±1.6* | 7.0±1.1* | 33±4  | 57±4  |
| VH    | PreB3 | 372±45* | 350±46* | 9.4±1.3*  | 8.0±1.1* | 26±6  | 72±10 |

NB mean power output was significantly higher during B2(600 ± 61W) and B3(521 ± 59W) when compared to B2(552 ± 58W) and B3(490 ± 55W) of VH. Despite a significant increase in estimated VA (calculated from VT & f with an assumed VD), VE and VCO<sub>2</sub>, no significant differences was obtained in PCO<sub>2</sub> (and consequently pH) immediately prior to B2 and B3.

**CONCLUSION:** Possibly the intensity of the exercise was severe enough to stimulate involuntary ventilation to near maximum, as indicated by the low mean PCO<sub>2</sub> immediately prior B3 with NB. The increased ventilatory cost during VH trial may help to explain the decreased power output during this trial.

Supported by the Research Institute, Iowa State University

2250 Board #296 MAY 31 8:00 AM - 9:30 AM

### Electrical Activity of the Diaphragm in Trained Subjects During Progressive Cycling to Exhaustion Trials

Dan S. Karbing, Nicolai L. Mifsud, René M. Jørgensen, Mathias K. Poulsen, Niels-Peter B. Nielsen, Lars P. Thomsen. Aalborg University, Aalborg, Denmark.  
(No relationships reported)

Previous studies of the dynamics of transdiaphragmatic pressure have shown progressive increase in diaphragmatic strength with workload (WL). Esophageal measurement of electrical activity of the diaphragm (EA<sub>di</sub>) may elucidate whether neural respiratory drive follows a similar pattern or is adapted differently to the changing ventilatory demands during exercise.

**PURPOSE:** To measure EA<sub>di</sub> changes during cycling to exhaustion and determine whether measured EA<sub>di</sub> is reproducible within subjects.

**METHODS:** 7 trained male subjects (Mean ±SD Age: 28 ±6 yrs; VO<sub>2</sub>max: 59.1 ±3.9 ml.min<sup>-1</sup>.kg<sup>-1</sup>) performed progressive cycling to exhaustion trials on a cycle ergometer. Trials consisted of 4 min warmup at 0 W, then 4 min segments at WL of 40, 55, 70 and 85%, ended by 100% WL until exhaustion, 100% WL estimating VO<sub>2</sub>max. WL from previous trial. Crural EA<sub>di</sub> was measured using a commercial esophageal probe with 9 electrodes. Each subject repeated the trial after 6-24 days. Median maximal breath EA<sub>di</sub> recorded during the last 25 s at 40, 55, 70 and 85% WL were used for analysis.

**RESULTS:** Trial 1 mean ±SD EA<sub>di</sub> were 39 ±22 μV, 55 ±17 μV, 64 ±18 μV and 67 ±13 μV for WL of 40, 55, 70 and 85%, respectively. For trial 2, these were 40 ±19 μV, 50 ±21 μV, 60 ±19 μV and 60 ±6 μV for 40, 55, 70 and 85% WL. Bland-Altman plots of EA<sub>di</sub> within subject differences between trials showed bias of 13 μV and limits of agreement of -30 - 56 μV, largest relative differences being for EA<sub>di,40%.</sub> Patterns of changes were similar within subjects, and repeated measures ANOVA showed EA<sub>di</sub> differences among WL for both trials (P<0.05), with Bonferroni adjusted post hoc tests showing EA<sub>di,40%<EA<sub>di,70%</sub> and EA<sub>di,40%<EA<sub>di,85%</sub> for trial 1, and EA<sub>di,40%<EA<sub>di,70%</sub> for trial 2 (P<0.05).</sub></sub></sub>

**CONCLUSIONS:** Results showed poor within subject agreement over time for EA<sub>di</sub>. Possible causes include probe placement and subject variation over time. In contrast, trends in EA<sub>di</sub> changes with workload were similar within subjects. In general, EA<sub>di</sub> increased from WL of 40% to 55% and 70%. On average, a plateau at 85% WL was indicated in agreement with previous studies of EA<sub>di</sub>, but individual subjects showed no clear pattern of changes in EA<sub>di</sub> from 70 to 85% WL. Esophageal EA<sub>di</sub> measurement equipment was sponsored by the manufacturer.

2251 Board #297 MAY 31 8:00 AM - 9:30 AM

### Fitness Levels In Smokers And Healthy Controls: Predictability By Carbon Monoxide And Fagerström Test

Christopher S. Oh, Michael K. Chronley, Brian K. Le, Christian K. Roberts, FACSM. University of California, Los Angeles (UCLA), Los Angeles, CA.  
(No relationships reported)

**PURPOSE:** Cigarette smoking affects human metabolism and exercise capacity, but these relationships are not fully understood. This study aims to compare: 1) cardiorespiratory fitness (CRF) and muscle strength in chronic smokers and recreationally-active, non-smoking young adults as part of a randomized-controlled trial to investigate the effects of resistance training on vascular function and; 2) the effectiveness of self-reported number of cigarettes smoked per day (CPD), Fagerström Test for Nicotine Dependence (FTND), and breath carbon monoxide (CO) levels to assess predictability of exercise capacity markers and arterial stiffness in young adult chronic smokers.

**METHODS:** 26 young adult male smokers (age  $25.1 \pm 4.5$  yr, BMI  $25.4 \pm 5.9$ ) were assessed for breath CO concentration, CPD, and by FTND. Smokers and 25 non-smokers (age  $23.8 \pm 4.1$  yr, BMI  $24.5 \pm 2.6$ ) were assessed for CRF by  $\text{VO}_{2\text{max}}$ , composite 1-repetition maximum (1RM) strength by bench press, leg press and machine row, and arterial stiffness by arterial tonometry.

**RESULTS:** Smokers exhibited lower absolute ( $2.39 \pm 0.49$  vs.  $2.97 \pm 0.67$  L/min,  $p = 0.004$ ) and relative ( $29.1 \pm 1.2$  vs.  $40.4 \pm 2.0$  ml/kg/min,  $p < 0.0001$ )  $\text{VO}_{2\text{max}}$  and total ( $825 \pm 39.5$  vs.  $989 \pm 49.6$  lbs,  $p = 0.01$ ) and relative ( $4.6 \pm 0.1$  vs.  $6.1 \pm 1.0$  lbs/lbs body weight,  $p < 0.0001$ ) 1RM. CO was highly related to FTND ( $R = 0.62$ ,  $p = 0.0003$ ) and CPD ( $R = 0.56$ ,  $p = 0.0006$ ). CO significantly predicted total 1RM ( $R = -0.51$ ,  $p = 0.009$ ),  $\text{VCO}_2$  ( $R = 0.55$ ,  $p = 0.033$ ), subendocardial viability ratio ( $R = 0.44$ ,  $p = 0.02$ ),  $\text{HR}_{\text{rest}}$  ( $R = -0.39$ ,  $p = 0.047$ ). FTND significantly predicted  $\text{VT}_{\text{max}}$  ( $R = -0.46$ ,  $p = 0.03$ ), aortic augmentation index ( $R = -0.35$ ,  $p = 0.048$ ), aortic systolic pressure ( $R = 0.36$ ,  $p = 0.03$ ), and central pulse height ( $R = -0.35$ ,  $p = 0.049$ ). Both CO and FTND predicted  $\text{HR}_{\text{max}}$  (CO:  $R = -0.61$ ,  $p = 0.007$ ; FTND:  $R = -0.65$ ,  $p = 0.036$ ) and  $\text{VE}_{\text{max}}$  (CO:  $R = -0.52$ ,  $p = 0.023$ ; FTND:  $R = -0.50$ ,  $p = 0.03$ ). CPD showed no significant predictions.

**CONCLUSION:** Preliminary results suggest that cigarette smoking negatively impacts CRF and strength fitness in young adult males. Additionally, higher CO levels are associated with lower muscle strength. CO and FTND are associated with both complementary and unique indices of exercise capacity and vascular function, suggesting studies would benefit most from determining CO levels and administering FTND tests.

**2252 Board #298 MAY 31 8:00 AM - 9:30 AM**  
**Compensation for Breathing Valve Leak during Pneumotachograph Calibration**

Erik M. Groves, Rosie Neil, David J. Smith. *University of Calgary, Calgary, AB, Canada.*  
(No relationships reported)

Metabolic carts are often used with a two-way, non-rebreathing mouthpiece (NRB) connected to a pneumotachograph (PNT) to measure expiratory flow rates. In order to calibrate this flow measurement system, a number of strokes of varying flow rates from a 3L calibrated syringe are used to generate a conductance curve for the PNT. The algorithm developed by Yeh et al. (1982) achieved an accuracy  $\pm 1\%$  based upon a direct connection between the syringe and PNT. In a clinical setting, calibration of the flow measurement system, including a NRB, assumes that all 3L passes through the expired PNT.

**PURPOSE:** To assess NRB valve leak (i.e. flow out the inspiratory (INSP) port during an EXP syringe stroke) and develop an algorithm to account for volume discrepancies in determination of PNT calibration conductance curves. **METHOD:** Unheated screen PNTs were connected directly to the INSP and EXP ports of a standard NRB. A minimum of 100 strokes of varying flow rates were used ( $0.3\text{--}15\text{L}\cdot\text{s}^{-1}$ ). Two calibration conditions were used: unplugged (UNP) (i.e. standard setup) and opposing port plugged (PLU). In the latter, the INSP and EXP ports were alternately blocked to ensure no leak during each stroke. Conductance curves were generated for both PNT's and conditions.

**RESULTS:** Mean volume for INSP and EXP in the PLU condition was  $3.001 \pm 0.024\text{L}$  and not different from 3L. The difference in total measured volume (systematic error) between INSP and EXP was  $< 0.1\text{mL}\cdot\text{stroke}^{-1}$ . The systematic error between INSP and EXP, when the PLU calibration was applied to the stroke data from the UNP condition was  $18.9\text{mL}\cdot\text{stroke}^{-1}$ . A novel algorithm was used to estimate the volume of the leak and offset the assumed volume passing through the PNT (i.e. 3L) in UNP. Calculated leak volume was maximal ( $\sim 80\text{mL}$ ) at the slowest flows and varied inversely with flow rate stopping by  $\sim 3\text{L}\cdot\text{s}^{-1}$ . The mean INSP and EXP volumes were  $3.001 \pm 0.022\text{L}$ . Importantly, there was low systematic error ( $< 0.9\text{mL}\cdot\text{stroke}^{-1}$ ) between INSP and EXP using this correction.

**CONCLUSION:** The use of an INSP PNT attached to a NRB-EXP PNT setup has demonstrated systematic error in standard EXP flow calibration and volume measurement resulting from valve leak. This effect is prominent at lower flow rates. A known syringe volume does not necessarily result in that volume passing through a PNT during calibration with a NRB.

**C-38 Free Communication/Poster - Sports Science II: Team Sports**

MAY 31, 2012 7:30 AM - 12:30 PM  
ROOM: Exhibit Hall

**GPS Technology In Team Sports**

Cloe Janine Cummins. *The University of Sydney, Sydney, Australia.* (Sponsor: Michael Climstein, FACSM)  
(No relationships reported)

Global Positioning System (GPS) technology is a satellite-based navigation system widely used for navigation, vehicle or personal tracking, robotics and surveying. GPS use in team sport is still relatively novel but permits quantitative assessment of player position, velocity, heart rate, and movement patterns through traditional GPS triangulation methods and accelerometer and heart rate monitoring software. GPS provides scope for better understanding the positional and specific physiological demands of team sport.

**PURPOSE:** A systematic review of GPS technology applied in team sports.

**METHODS:** A Systematic search of electronic databases (Medline, SPORTdiscus, CINAHL, Web of Science, Scopus, Embase and Cochrane) was performed from earliest record to September 2011. Permutations of key words included Global Positioning System, able-bodied male and female, age 15-50 years, recreational to elite competitive team sports.

**RESULTS:** There were 21 eligible papers reporting on Rugby League (2), Australian Football (AFL) (7), Rugby Union (3), Netball (1), Lacrosse (1), Hockey (1) and Soccer (6). Manuscripts reported the GPS variables of heart rate demands (maximum, minimum and mean heart rate, time and exertions) and movement demands (speed, distance, time, accelerations, maximum and mean speed). In most papers, movement demands were further categorised into six zones comprised of speeds (0 to 36 km/h) and descriptions (from walking to sprinting). Except for cricket, speed zones and descriptors were inconsistent and not standardized within sports, eg in AFL, Zone 3 speeds varied from 7 to 16 km/h whilst Zone 4 definitions ranged from jog, run, high velocity to high intensity run. Variations were also observed between sports eg Zone 4 speeds spanned hockey and soccer (7-18 km/h), cricket (13-14 km/h), rugby union and rugby league (12-21 km/h) and AFL (14-20 km/h).

**CONCLUSIONS:** This systematic review highlights the variability of movement demand associated with GPS application in team sports. There is a need for within sport standardization of speed zones attached to clearly defined movement patterns. Clarity and consistency of speed zones and movement pattern definitions within a team sport facilitates precise comparison and analysis of performance between players, teams and competitive seasons.

**2254 Board #300 MAY 31 9:00 AM - 10:30 AM**  
**Testosterone, Not Dietary Composition, Predicts Power in Elite Soccer Players**

Vittorio E. Bianchi, FACSM<sup>1</sup>, Roberto C. Burini<sup>2</sup>. <sup>1</sup>Laboratory of Physiology of Exercise and Human Performance, Rimini, Italy. <sup>2</sup>UNESP - Univ Estadual Paulista, Botucatu, Brazil.  
(No relationships reported)

**BACKGROUND:** Dietary composition has been widely studied as factor

influencing endurance performance. Less is known regarding hormonal influences, particularly in short-term performance requiring power. We assessed detailed hormonal and dietary influences on a novel sprint test in elite soccer players.

**METHODS:** Eighteen professional soccer players were studied using a 10-meter sprint test (10-MST) involving the chronometric evaluation with photocells (Globus Italia, Codognè, Italy). Dietary composition was determined by 7-day food records by self-reported food questionnaire, while resting energy expenditure (REE) and RQ were measured by indirect calorimetry ( $\text{Vmax}29$ , Sensormedics, Yorba Linda, CA, USA). Oxygen consumption and carbon dioxide production were measured for 20 minutes continuously. Blood samples were taken after a 12 hr fast for basal biochemistry and hormones. The following hormones were evaluated: Insulin-like Growth Factor-1 (IGF-1), total testosterone, and free testosterone.

**RESULTS:** Resting metabolic rate, indices of body dimensions, and dietary factors were poorly related to 10-MST performance (see table). Total and free testosterone were strongly associated with 10MST,  $r=0.80$   $P<0.001$  (see figure), but no correlation was found between IGF1 and 10MST. IGF1 is correlated to Kcal ( $r=0.39$   $p<0.01$ ) and carbohydrates ingested ( $r=0.40$   $p<0.001$ ). RQ has negative correlation with CHO ( $r=-0.39$ ) and lipids ( $r=-0.38$ ).

**CONCLUSION.** Testosterone levels, rather than dietary factors, predict sprint performance in elite soccer players, but not IGF1 and RQ that are related only to the macronutrients ingested. Then further the physical testing the hormonal evaluation is fundamental to predict the performance in soccer.

**2255 Board #301 MAY 31 9:00 AM - 10:30 AM**  
**Correlation Of VO<sub>2max</sub> Between The Bruce Protocol And Yo-yo Test In Mexican Professional Soccer Players**

Alejandro Soria-Contreras<sup>1</sup>, Johanna Yvette Silva-Laguna<sup>1</sup>, Angélica Becerra-Magaña<sup>1</sup>, Juan Ricardo López y Taylor<sup>1</sup>, Juan Antonio Jiménez-Alvarado<sup>1</sup>, Rubens Valenzuela-Lazo<sup>2</sup>, Edna Jáuregui-Ulloa<sup>1</sup>. <sup>1</sup>Universidad de Guadalajara, Guadalajara, Mexico. <sup>2</sup>Club Deportivo Leones Negros, Guadalajara, Mexico.  
(No relationships reported)

The maximal oxygen uptake (VO<sub>2max</sub>) has been considered the most important determinant of aerobic endurance in soccer players. On the other hand, Bangsbo in 1994, using the Yo-Yo Test, assessed the maximum aerobic capacity in professional soccer teams, demonstrating the importance of intermittent resistance in soccer players.

**PURPOSE:** To evaluate the results of VO<sub>2max</sub> in soccer players with two different indirect test and analyze the correlation between them

**METHODS:** A total of 54 Mexican professional soccer players aged 26 years (SD= 2.12) were evaluated. Weight was 74.5 Kg. (SD=2.5) and height 177.3 cms. (SD=6.68). Each player was submitted to a VO<sub>2max</sub> test using the Bruce protocol and the Yo-Yo intermittent endurance Level 2 test.

**RESULTS:** The mean VO<sub>2max</sub> obtained by treadmill running was 55.0 ml / kg / min (SD = 4.6). VO<sub>2max</sub> obtained by Yo-Yo test was 55.1 ml / kg / min (SD = 2.9). We found a  $r = 0.297$  and a  $p < 0.25$ .

**CONCLUSIONS:** This study reports that the average VO<sub>2max</sub> level of players was found in the lower limit (Reilly 1993, 56 to 69 ml/kg/min). By comparing the average data from the Bruce protocol with the Yo-Yo test, the results were similar, however there was no correlation between both tests. This study shows that the aerobic capacity of these players was deficient and need more aerobic training. We found that both tests are useful for the assessment of football because they measure different characteristics of the cardio respiratory fitness. More research and evaluations regarding this issue are suggested in order to increase the performance of the players.

**2256 Board #302 MAY 31 9:00 AM - 10:30 AM**  
**Relation Between The H:Q Ratio And Age And Lower Limb Dominance In Young Soccer Players**

Tomas Maly, Frantisek Zahalka, Lucia Mala. Charles University, FPES, Prague, Czech Republic.  
(No relationships reported)

During the game, strength and power movements are accumulated on both lower extremities (LE). This occurs in an asymmetrical manner and may gradually leads to higher shifts of myodynamic characteristics and strength asymmetries of LE. The hamstring to quadriceps (H:Q) ratio has been used in several studies to examine the similarity between H:Q moment-velocity patterns and to assess knee functional ability and muscle balance, but mainly in adults players. However, less is known about the bilateral difference in H:Q ratio among different age groups.

**PURPOSE:** The purpose of the study was to find out the level of H:Q ratio and differences in terms of age and limb dominance.

**METHODS:** Elite players of 4 age categories (U16=16, U17=18, U18=17 and U19=19) were tested on the isokinetic dynamometer Cybex at three velocities (60, 180, 300 °.s<sup>-1</sup>) for the dominant (DL) and non-dominant leg (NL) during the knee flexion and extension. The ratio between peak muscle torque of hamstring to quadriceps for both legs (H<sub>D</sub>:Q<sub>D</sub>; H<sub>N</sub>:Q<sub>N</sub>) was evaluated. Three-way Mixed-design ANOVA with two between subject effect (age (A), laterality (L)) and one within subject effect (velocity) was used for evaluation of H:Q differences between the factors.

**RESULTS:** The factors of A and L do not significantly influence the level of H:Q in young elite players (age:  $F_{(3,132)} = 1.07$ ,  $p > 0.05$ ,  $\eta^2 = 0.024$ , laterality:  $F_{(1,132)} = 0.278$ ,  $p > 0.05$ ,  $\eta^2 = 0.002$ ). Similarly, the effect of interaction between A and L was not significant ( $p > 0.05$ ). With increasing angular velocity, significant changes in H:Q ratio appeared (H:Q<sub>60</sub> = 56.80, HQ<sub>180</sub> = 60.83, HQ<sub>300</sub> = 61.75,  $F_{(1,132)} = 32.71$ ,  $p < 0.001$ ,  $\eta^2 = 0.199$ ). Post-hoc analysis showed a significant difference in H:Q<sub>60</sub> compared to H:Q<sub>180</sub> or H:Q<sub>300</sub> ( $p < 0.001$ ), while no significant difference was found between H:Q<sub>180</sub> and H:Q<sub>300</sub> ( $p > 0.05$ ). Totally, 44 risk results of H:Q (24 for DL and 20 for NL) were identified in 23 players (32.9%).

**CONCLUSIONS:** Neither calendar age, nor limb dominance have significant impact on the level of H:Q ratio in young elite players, on the contrary, the speed of the movement during knee flexion and extension has a significant effect. In the individual assessment, we have revealed strength asymmetries that should be eliminated by means of appropriate sports training.

Supported by GACR P407/11/P784 and MSM 0021620864.

**2257 Board #303 MAY 31 9:00 AM - 10:30 AM**  
**Effects of a Water Exercise Training Program on Biochemical Parameters and Aerobic Fitness in Indoor Soccer Players**

Dalila Tusset<sup>1</sup>, Mabel Olkoski<sup>2</sup>, Kenji Fuke<sup>3</sup>, Silvana Matheus<sup>4</sup>, Félix Soares<sup>2</sup>, Rafael Portella<sup>2</sup>, Edovando da Rosa<sup>2</sup>, Rômulo Barcelos<sup>2</sup>. <sup>1</sup>University of Brasilia, Brasilia, Brazil. <sup>2</sup>Federal University of Santa Maria, Santa Maria, Brazil. <sup>3</sup>Federal University of Santa Maria, Santa Maria, Brazil. <sup>4</sup>Federal University of Brasilia, Santa Maria, Brazil. (Sponsor: Lee E. Brown, FACSM)  
(No relationships reported)

Studies have shown that chronic dry land and chronic water exercise training improves oxygen uptake. Furthermore, studies have reported that acute levels of creatine kinase (CK) after water exercise are less when compared to performing dry land exercise. However, it is unclear if the water exercise training affects physical fitness, muscle oxidative stress, or indirect markers of muscle damage.

**PURPOSE:** To compare the effects of dry land and water exercise training programs on oxidative stress, indirect markers of muscle damage, and aerobic fitness of indoor college soccer players.

**METHODS:** Twelve university indoor soccer players were randomly divided into two training groups: 1) 6 subjects performed on dry land (LG), and 2) 6 subjects performed water exercise (WG), twice a week for 5 weeks. Aerobic fitness (Yo-Yo Intermittent Test) was evaluated before and after 10 training sessions. Muscle damage (CK) and oxidative stress (catalyze [CAT] activity) markers were analyzed at rest [R-1<sup>st</sup>] before the first session, immediately after the first session [A-1<sup>st</sup>], 24 hours [24h-1<sup>st</sup>] and 48 hours after [48h-1<sup>st</sup>]. Also, CK and CAT were analyzed at rest [R-10<sup>th</sup>] before the 10<sup>th</sup> training session, immediately after session [A-10<sup>th</sup>], 24 hours [24h-10<sup>th</sup>] and 48 hours after [48h-10<sup>th</sup>].

**RESULTS:** Both groups increased their aerobic fitness ( $p \leq 0.05$ ; LG 1104.29 to 1294.29 m; WG 970.00 to 1214.00 m) after the training program but no differences were found between groups. Also, no significant changes were observed in CK or CAT for the LG after the training program. However, WG showed greater CAT activity at R-10<sup>th</sup> (28  $\mu\text{molH}_2\text{O}_2/\text{min}/\mu\text{L}$ ) in relation to R-1<sup>st</sup> (23  $\mu\text{molH}_2\text{O}_2/\text{min}/\mu\text{L}$ ;  $p \leq 0.05$ ). By comparing both groups, WG presented lower levels of CK ( $p \leq 0.05$ ) at R-10<sup>th</sup> (93 vs 127 U.I./L), A-10<sup>th</sup> (101 vs 168 U.I./L) and 24h-10<sup>th</sup> (80 vs 125 U.I./L).

**CONCLUSION:** These data suggest that water exercise training increases soccer players' aerobic fitness, antioxidant markers in addition to a minor muscle damage level. Thus, water exercise can be useful as an alternative method for indoor soccer players during their training and recovery periods due to its low potential to generate muscle injury.

**2258 Board #304 MAY 31 9:00 AM - 10:30 AM**  
**Effects of Season-Long High-Intensity Interval Training on Conditioning of High School Soccer Players**

Neal F. Howard, Stasinios Stavrianeas. Willamette University, Salem, OR.  
(No relationships reported)

High-intensity interval training (HIIT) has been put forth as a viable alternative to more traditional endurance conditioning for the improvement of aerobic conditioning.

**PURPOSE:** We hypothesized that HIIT will compare favorably to traditional soccer conditioning over the course of a high school soccer season.

**METHODS:** High school junior varsity soccer players were split into control (n=17) and experimental (n=17) groups during the 10-week study. The HIIT consisted of 4-6 30 second "all-out" sprint efforts with 4.5 minute recovery, 3 times a week. The control group performed endurance training for the same duration. The groups did not differ in any other aspect of their training. Participants completed the yo-yo intermittent recovery test level 1 (IR1), a 40-yard dash, vertical jump, agility test, and a sit-and-reach test, in 2 different testing sessions (pre and post season).

**RESULTS:** Both control (n=10 at post) and experimental groups (n=6 at post) showed significant increase in IR1 test performance pre and post training (720±99.6m vs. 1196±80.0m,  $p<0.000$  and 480±67.6m vs. 860±161.6m,  $p<0.045$  respectively), with no significant difference between groups ( $p<0.854$ ). Both experimental (n=5) and control (n=9) groups showed a significant difference in the 40-yard dash between pre and post training (5.48s vs. 5.17s, (5.6%)  $p<0.005$  and 5.73s vs. 5.36s (6.4%),  $p<0.001$  respectively). There was no difference between experimental and control groups between pre ( $p<0.550$ ) and post ( $p<0.089$ ). There was no difference in vertical jump between experimental (n=7,  $p<0.803$ ) and control (n=12,  $p<0.954$ ) groups pre and post testing. Similarly, there was no difference in the agility test between the experimental (n=7,  $p<0.683$ ) and control (n=12,  $p<0.094$ ) groups pre and post test. Finally, there was no difference in the sit-and-reach test for the experimental group pre to post (n=7,  $p<0.798$ ). There was, however, a significant decrease in the control group (n=12, 29.13 cm vs. 27.75 cm,  $p<0.024$ ).

**CONCLUSION:** Our results indicate that HIIT is an adequate training stimulus offering similar endurance improvements to more traditional soccer training.

**Short Duration High-Intensity Interval Training Improves Aerobic Conditioning of Female College Soccer Players**

Tannin Kueffner, Andrea Rowan, Stasinios Stavrianeas. *Willamette University, Salem, OR.*

(No relationships reported)

High-intensity interval training (HIIT) has been shown to improve aerobic conditioning at a considerable savings in time compared to the more traditional endurance training.

**PURPOSE:** We hypothesized that maximal oxygen consumption ( $VO_{2max}$ ) and performance in the Yo-Yo Intermittent Recovery Test 1 (IRT1) between the HIIT group and the endurance training group (END) would be similar between over a short 4-week spring training period.

**METHODS:** Following a valid  $VO_{2max}$  test and the IRT1, female Division III college soccer players were matched and randomly assigned to the HIIT (n=7) or the END (n=6). The HIIT consisted of 5 30-second "all-out" sprint efforts with a 4.5 minute active recovery, twice per week. The END completed a 40-min run at 80% of  $VO_{2max}$  twice per week. All other aspects of the training were identical for the two groups. Comparisons of  $VO_{2max}$  and IRT1 test data between groups (END vs. HIIT) or between conditions (pre- vs. post-training) were made using Student's t-test and ANOVA ( $\alpha=0.05$ ).

**RESULTS:** The distance covered during the IRT1 test was significantly different between the pre- and post-tests (1680±480 m vs. 1895±524 m respectively,  $p=0.002$ ). The differences were true for the HIIT group (pre-test: 1857±423 m vs. post-test: 2131±436 m,  $p=0.001$ ) and END group (pre-test: 1473±494 m vs. post-test: 1613±510 m,  $p=0.042$ ). There were no significant differences between the HIIT and END groups for the pre-test ( $p=0.108$ ) or the post-test ( $p=0.076$ ). The 4-week training program resulted in significant improvements in team  $VO_{2max}$  values between the pre- and post-training tests (50.66±3.52  $ml\cdot kg^{-1}\cdot min^{-1}$  vs. 52.71±3.24  $ml\cdot kg^{-1}\cdot min^{-1}$  respectively,  $p=0.002$ ). There were no differences in  $VO_{2max}$  between the SPR and END groups for the pre-test ( $p=0.493$ ) and the post-test ( $p=0.362$ ). Improvements in  $VO_{2max}$  between the pre- and post- tests were 2.36  $ml\cdot kg^{-1}\cdot min^{-1}$  (4.73%) for the HIIT group and 1.66  $ml\cdot kg^{-1}\cdot min^{-1}$  (3.42%) for the END group.

**CONCLUSIONS:** Our results indicate that HIIT as little as twice per week offers an adequate aerobic training stimulus at considerable time savings.

**Response of Plasma Creatine Kinase After Pre Season Compared with an Official Soccer Game**

Luciano Capelli<sup>1</sup>, Leandro Dias<sup>1</sup>, Júlio Tadao Murakawa<sup>2</sup>. <sup>1</sup>São Bernardo Futebol Clube, São Bernardo do Campo, Brazil. <sup>2</sup>Cemafé, São Paulo, Brazil.

(No relationships reported)

Plasma creatine kinase (CK) concentration has been widely used as an indicator of skeletal muscle damage in sports. The increase of CK concentration occurs 4 hours after the exercise, reaching the peak after 48-72 hours.

**PURPOSE:** The aim of this study was to evaluate serum CK concentration in professional soccer players after ten days of intense physical training compared with an official soccer game.

**METHODS:** Ten professional soccer players (25 ± 3.63 yrs, 78.52 ± 6.97 kg and 8.18 ± 2.95 % fat) participated in this study. Plasma CK concentration was measured in three moments, at the beginning of pre season (baseline), after ten days of intense physical training (780 minutes) with aerobic and anaerobic resistance exercises (post-training) and 48 hours after an official soccer game (post-game). CK was checked using Reflotron Plus (Roche). Data were analyzed by one way ANOVA and Tukey's post hoc test.

**RESULTS:** The values of plasma CK was significant higher ( $p<0.05$ ) comparing the baseline (177.83 ± 70.46 U/l) with post-training (542.40 ± 224.35 U/l) and post-game (627.40 ± 399.10 U/l). No significant differences were found between post-training and post-game.

**CONCLUSIONS:** The training routine of the soccer players on the pre season has the same physical stress as an official soccer game, the variability of response plasma CK concentration is individual both in rest and workout. This procedure can be used to monitor the intensity of training and games.

**2261** Board #307 MAY 31 9:00 AM - 10:30 AM

**The Influence of Acute Exercise on Torque Decline Between Positions in Collegiate Female Soccer Players**

Matthew J. Hawkey, Brennan J. Thompson, Eric C. Conchola, Ryan E. Fiddler, Nathaniel D.M Jenkins, Douglas B. Smith, Eric J. Sobolewski, Eric D. Ryan, Mallory L. Craig, K. Lee Everett, Jennifer, L. Klufa, Aric J. Warren, Matthew D. O'Brien, Kazuma Akehi, Jennifer L. Volberding, Crishel Kline. *Oklahoma State University, Stillwater, OK.*

(No relationships reported)

The ability among players to sustain muscular activity following intense bouts of muscular exertion that may frequently occur during soccer match play may play an important role in successful performance and injury prevention. Muscular fatigue results in decreased muscular torque production and consequently may hinder playing performance. Research findings have suggested that various positions in elite level soccer players may be functionally unique in regards to the distances covered and metabolic demands imposed during match play

**PURPOSE:** To examine the effects of a fatigue inducing bout of isokinetic exercise on peak torque decline for the leg flexor and leg extensor muscle groups between playing positions in Division I collegiate female soccer players.

**METHODS:** Eighteen healthy female individuals (seven defenders: mean ± age= 19.86 ± 0.83; seven midfielders: mean ± age= 20.57 ± 1.59; four forwards: mean ± age= 20 ± 0) volunteered to participate in the study. Peak torque of the right leg extensors and flexors was assessed on a Biodex System 3 dynamometer (Biodex Medical Systems, Inc., Shirley, NY USA) at 180° s-1. Following a general warm-up, participants performed 50 consecutive maximal leg extensions and leg flexions in tandem. Peak torque and least torque values across the 50 repetitions for both leg flexors and leg extensors were used to calculate the percent of torque decline. Percent decline values were calculated by taking the highest peak torque minus the least torque divided by peak torque and multiplying by 100. A one-way analysis of variance (ANOVA) was used to analyze the peak torque percent decline values. An alpha level of  $p \leq 0.05$  was used to determine statistical significance.

**RESULTS:** There was no significant difference ( $p = 0.78$ ) for peak torque percent decline for any of the player position groups.

**CONCLUSIONS:** These findings indicated that there appears to be no difference in leg flexor or leg extensor peak torque decline between playing positions during a repeated bout of fatigue inducing isokinetic exercise in Division I collegiate female soccer players. Thus, strength and conditioning professionals may choose to develop muscle endurance conditioning programs to maximize time and efficiency given the similarity of lower body muscle endurance capacities among player positions.

---

**2262** Board #308 MAY 31 9:00 AM - 10:30 AM

**The Level, Dependence And Structure Of Speed Indicators In Young Elite Soccer Players**

Tomas Maly, Frantisek Zahalka, Lucia Mala, Mario Buzek, Jaroslav Teplan, Tomas Gryc. *Charles University, FPES, Prague, Czech Republic.*

(No relationships reported)

In-game analysis of professional soccer players showed that players perform a high intensity activity which lasts for 2-4 seconds every 90 seconds during a game. These activities occur at irregular intervals, across unequally covered distances and with different types of player's movement (running sideways, backwards, with the ball, without the ball, acceleration, deceleration, etc.). It is believed that, in adult players, acceleration speed, maximum speed and agility are independent components.

**PURPOSE:** To determine the level, dependence and structure of speed indicators in young elite soccer players.

**METHODS:** The screened sample consisted of players from the U16 Czech national team (n = 22, age = 15.6 ± 0.4 years, body height = 177.7 ± 6.9 cm, body weight = 67.9 ± 8.7 kg). Speed indicators were detected in the following tests: sprint at 5 and 10 m (S5, S10), maximum speed at 20 m flying sprint (MS20), agility test 505 with turns for the dominant (A5D) and non-dominant lower limb (A5N), agility K-test (AK), the speed of instep kick for the dominant (SKD) and non-dominant lower limb (SKN). Photocell gates (Brower Timing System) were used for speed diagnostics and radar gun STALKER ATS was used for the measuring of ball speed. Pearson's correlation coefficient and factor analysis (Extraction method: Principal component analysis with Varimax rotation) were applied to detect dependence and structure of the variables

**RESULTS:** Players' speed in the tests was as follows: S5 = 1.09 ± 0.06 s, S10 = 1.85 ± 0.08 s, MS20 = 2.48 ± 0.09 s, A5D and A5N = 2.42 ± 0.09 s, AK = 10.65 ± 0.37 s, SKD = 102.89 ± 4.45 km·h<sup>-1</sup>, SKN = 90.50 ± 7.71 km·h<sup>-1</sup>. A significant correlation was found between these parameters: S5 vs. S10 (p < 0.01), S10 vs. MS20 (p < 0.05), MS20 vs. A5N (p < 0.01), A5N vs. AK (p < 0.01) and SKD vs. SKN (p < 0.01). Factor analysis revealed 3 speed components with the following proportion of variance explained (% of total variance explained): acceleration and maximum speed (27.5%), agility and maximum speed (21%) and acyclic speed (16.8%).

**CONCLUSIONS:** Results indicated 3 speed components in the soccer players. Acceleration speed, agility and acyclic speed form independent speed components. This knowledge should be respected when stimulating speed abilities in sports training. Supported by GACR P407/11/P784 and MSM 0021620864

2263 Board #309 MAY 31 9:00 AM - 10:30 AM

**Changes In Peak Oxygen Uptake And Substrate Utilization In Male Collegiate Soccer Players**

Shannon R. Siegel<sup>1</sup>, Dorothy Chen-Maynard<sup>1</sup>, Martin R. Lindley<sup>2</sup>, Sarah Jarvis<sup>1</sup>, Gracie Almanza<sup>1</sup>, Floyd Chavez<sup>1</sup>, Ryan Hollingshead<sup>3</sup>, Anthony Menacho<sup>1</sup>, Eddie Menacho<sup>1</sup>, Martina Turcato<sup>4</sup>. <sup>1</sup>California State University San Bernardino, San Bernardino, CA. <sup>2</sup>Loughborough University, Loughborough, United Kingdom.

<sup>3</sup>Wichita State University, Wichita, KS. <sup>4</sup>University of Bologna, Bologna, Italy. (Sponsor: Bryan L Haddock, FACSM)

(No relationships reported)

It is accepted that some sports (cycling/endurance running) have demonstrable changes in energy substrate utilization in training and competition phases. However, less is known about team sports.

**PURPOSE:** To assess changes in energy substrate utilization in a group of well-trained college soccer players pre and post competitive season.

**METHODS:** Participants for this study were 20 male soccer players, 19.2 ± 1.5 years of age; all were members of an NCAA Division II soccer team. Average height for field players was 175.6 ± 4.9 cm, weight was 71.8 ± 7.9 kg, Body Mass Index (BMI) was 23.3 ± 2.3 kg/m<sup>2</sup>, and body fat, assessed with the 7-site skinfold test, was 10.3 ± 4.4%. For physiological testing, participants ran the Yo-Yo Intermittent Recovery Test (YIRT) while wearing a portable metabolic cart (Viasys, Oxycon) to measure oxygen use. The YIRT is a 20-metre shuttle test with a progressively increasing pace. Athletes start out at a relatively slow pace and then quickly increase their speed according to the pace set by the beeps. Each bout of intense running (a 2x20m shuttle) is followed by 10 seconds of active recovery prior to the athlete resuming a sprint (Bangsbo et al.) Substrate utilization was estimated using indirect calorimetry methodology, and values for fat, carbohydrate, and protein use were calculated as absolute units (grams per test). Dependent samples t-tests were used to determine whether physiological parameters changed from Time 1 (T1-pre-season) to Time 2 (T2-end of season).

**RESULTS:** The majority of parameters did not significantly differ from T1 to T2. Average number of shuttles was 12 ± 3 at T1 and 13 ± 3 at T2 (p > 0.05). Average heart rate (171 ± 11 bpm vs. 173 ± 10 bpm), protein use, fat use, and carbohydrate use did not differ from T1 to T2 (p > 0.05). Energy expenditure (16.6 ± 1.9 vs 17.4 ± 2.2 kcal/min) approached a significant difference (p = 0.09). Peak VO<sub>2</sub> was the only parameter that differed significantly between T1 and T2 (57.6 ± 6.7 ml/kg/min vs 62.3 ± 6.2 ml/kg/min); the athletes had a higher VO<sub>2</sub> at T2 (p < 0.01).

**CONCLUSIONS:** No differences in energy substrate use were found during field based VO<sub>2</sub> peak testing in male collegiate soccer players across a competitive season, despite changes in absolute VO<sub>2</sub> peak.

---

2264 Board #310 Abstract Withdrawn

2265 Board #311 MAY 31 9:00 AM - 10:30 AM

**Match Demands of professional Futsal Players**

Carles Tur<sup>1</sup>, Carlos González-Haro<sup>1</sup>, Jordi Ferré<sup>2</sup>. <sup>1</sup>School of Medicine, University of Zaragoza, Zaragoza, Spain. <sup>2</sup>Faculty of Sport, Education and Social Sciences, University of Chichester, Chichester, United Kingdom.

(No relationships reported)

Futsal is a professional sport that is played in many countries around the world; nonetheless there is scarce information in literature about the demands of professional Futsal players during competition. To our knowledge it is important to know the specific demands of this sport to build up specific training programs for these kinds of players in the best way possible.

**PURPOSE:** To describe the physical characteristics and the physiological demands of Futsal professional players during matches.

**METHODS:** 10 elite Spanish Futsal players (Age: 30.1 ± 2.8 yrs, experience: 11.1 ± 3.0 yrs, BMI: 23.9 ± 1.4 kg·m<sup>-2</sup>) carried out some physical tests during the second week of the 2008-2009 training pre-season, to assess the aerobic metabolism (Probst test to measure the maximal aerobic speed (MAS), total distance covered (TDC), and maximum heart rate (HR<sub>max</sub>)) during a first day; and to measure some strength qualities (peak power in ½ squat (PO<sub>peak</sub>), height in a Squat Jump (SJ), and in a Counter Movement Jump (CMJ)) a second day. After that, some physiological and physical parameters during 8 consecutive matches were recorded (Activity periods (rotations): Number of rotations (NRot), average time (RotTime<sub>avg</sub>), heart rate peak (HR<sub>peak</sub>), heart rate average (HR<sub>avg</sub>), and percentage of maximum heart rate (%HR<sub>max</sub>) of HR<sub>peak</sub> and HR<sub>avg</sub>; recovery periods: Number of recovery periods (NRec), and average time (RecTime<sub>avg</sub>). It was performed a descriptive analysis of all data, and it was expressed as mean ± SD.

**RESULTS:** Physical profile of Futsal players was: MAS: 13.7 ± 0.5 km·h<sup>-1</sup>, TDC: 1,372 ± 77 m, HR<sub>max</sub>: 190 ± 7 bpm, PO<sub>peak</sub>: 806 ± 213 W, SJ: 39.8 ± 4.9 cm, CMJ: 42.7 ± 7.2 cm. Physiological and physical demands during matches were: NRot: 2.8 ± 0.9, RotTime<sub>avg</sub>: 4:37 ± 2:06 min, HR<sub>peak</sub>: 185 ± 4 bpm corresponding to %HR<sub>max</sub>: 96 ± 2 %, HR<sub>avg</sub>: 168 ± 6 bpm corresponding to %HR<sub>max</sub>: 88 ± 4 %, NRec: 1.8 ± 0.9 with a RecTime<sub>avg</sub>: 13:18 ± 17:12 min.

**CONCLUSION:** These results show that professional Futsal players have moderate endurance, power and explosive strength levels, moreover Futsal played at professional level have to develop high-intensity exercise during short and moderate periods of time, although they provide of few periods of rest to recover moderately the fatigue accumulated during rotations or periods of exercise.

2266 Board #312 MAY 31 9:00 AM - 10:30 AM

**Comparison Of Fitness Characteristics Between Men's And Women's Rugby Sevens Players**

David B. Pyne, FACSM<sup>1</sup>, Dean G. Higham<sup>1</sup>, Anthea Clarke<sup>1</sup>, John Mitchell<sup>2</sup>, Anthony Eddy<sup>2</sup>. <sup>1</sup>Australian Institute of Sport, Belconnen, Australia. <sup>2</sup>Australian Rugby Union, St Leonards, Australia.

(No relationships reported)

Both Men's and Women's Rugby Sevens have been added to the program for the 2016 Olympic Games in Rio de Janeiro, Brazil, but little is known about the comparative fitness requirements.

**PURPOSE:** To determine magnitudes of difference, and degree of variability, in standard anthropometric and fitness characteristics of national level men and women Rugby Sevens players.

**METHODS:** National Sevens squad players (males n=32, age 22 ± 3 years; height 1.82 ± 0.06 m; mass 90 ± 8 kg; females n=32, age 25 ± 6 years, height 1.68 ± 0.06 m; mass 70 ± 9 kg; mean ± SD) age were tested during routine training camps. All testing was conducted indoors on a synthetic running track after instruction, warm-up and familiarization with each test protocol. Each player completed a 40 m maximal sprint test, standing vertical jump and the YoYo Intermittent Recovery Level 1 (YoYo-IRL1) tests. Difference in mean scores between male and female players were expressed as a percentage, and variability as a ratio of the coefficients of variation (CV).

**RESULTS:** Male players had ~40% more lean mass and 40% lower skinfolds than the women. Speed (40 m sprint time and maximal running velocity V<sub>max</sub>) was only ~10-20% faster for the Men, while lower body power and momentum (mass x V<sub>max</sub>) were 40-50% higher in Men. The most marked difference was in endurance capacity (YoYo distance covered) where the Men

(2260 ± 270 m; mean ± SD) were ~two-fold better on the YoYo-IRL1 than Women (990 ± 320 m; mean difference ± 90% confidence limits of 1234 ± 184 m). The Women were more than twice as variable (ratio of CV <0.4) in endurance fitness than the Men.

**CONCLUSION:** Women Rugby Sevens players should focus conditioning programs on power, size and endurance to improve these aspects of fitness.

**2267** Board #313 MAY 31 9:00 AM - 10:30 AM

**The Influence of Different Weighted Warm-up Bats on Swinging Performance**

Nicole C. Dabbs, John C. Garner, Robert C. Ricks, Harish Chander, Cade Wilderson, Jordan Young. *The University of Mississippi, University, MS.* (Sponsor: Mark Loftin, FACSM)

(No relationships reported)

In sport performance today it is vital to maximize performance to stay a top competitive athlete. In softball, this is very prevalent and is seen through a variety of hitting performance enhancements. Implementing a weighted bat prior to maximum swinging performance has traditionally been utilized but recent research has shown a decrease in bat swing velocity.

**PURPOSE:** The purpose of this study was to determine the influence of different weighted warm-up bats on swinging performance in varsity softball players.

**METHODS:** Ten active participating Division I female softball athletes volunteered to participate. The order of the three warm-ups were randomized at the beginning of testing session and all conditions were completed in one visit. Subjects performed a self-selected warm up (instructed to simulate their on-deck warm up routine) with a normal weight (NW); 29oz, heavy (HW); 45oz or light-weight (LW); 13oz bat immediately following 5 maximal bat swings using a normal weight bat. Following each condition a 3mins washout/rest period was given prior to the following condition. This wash out/rest period allows adequate time decreased fatigue between conditions. Each swing in conditions was analyzed to assess swing kinematics and bat speed using Vicon Nexus Software. The swing with the highest motion capture clarity was used for analysis of the trajectory and velocity of a marker placed on the most distal portion of the bat.

**RESULTS:** A 1x3 repeated measures analysis of variance was used to analyze mean differences. There were no significant ( $p > .1$ ) differences in maximal bat swing velocity following NW (56.97 ± 14.82mph), LW (48.34 ± 20.47mph) and HW (51.22 ± 22.70mph).

**CONCLUSIONS:** These results indicate that warming up with different weighted bats has no effect on bat swing velocity. However, there is a practical trend that supports previous research that HW warm-up demonstrates a decreased bat velocity compared to NW warm-up. Considering the current data is 3D, it may be considered to be a more precise estimate of bat swing velocity, which also supports the 2D linear velocity that has previously been investigated. Further research investigating the time point of maximum bat swing velocity during the swing should be performed to see if the warm-up bat has any influence on the joint mechanics rather than just bat velocity.

**Influence of Twelve Second Pitching Interval Time on Muscle Damage and Inflammation in Baseball Pitcher**

Sun Chin Yang<sup>1</sup>, Chia-Chi Wang<sup>2</sup>, Yu-Chung Lee<sup>3</sup>, Kuei Hui Chan<sup>4</sup>, Chia-Hua Kuo, FACSM<sup>5</sup>. <sup>1</sup>Shih-Hsin university, Taipei, Taiwan. <sup>2</sup>National Taiwan Sport University, Tao-Yuan county, Taiwan. <sup>3</sup>Vanung University, Tao Yuan County, Taiwan. <sup>4</sup>National Taiwan Sport University, Tao Yuan County, Taiwan. <sup>5</sup>Taipei Physical Education College, Taipei, Taiwan. (Sponsor: Chia-Hua Kuo, FACSM)

(No relationships reported)

**PURPOSE:** To investigate the reaction of 12 sec pitching interval on baseball pitcher's muscle damage and inflammatory cytokine markers in a simulate game.

**METHODS:** Eight baseball pitchers were recruited form an excellent university baseball team. Subjects participated a simulate game that pitching interval time was 12 sec, 15 pitching per inning for 7 innings and the rest time between inning was 5 minutes. Venous blood were drawn on pre-game, post-game and days 1, 2, and 3 after-game to measure the activity of CK, LDH as well as the concentration of IL-1 $\beta$ , IL-6, TNF- $\alpha$  and IL-10. Parametric data were analyzed using repeated-measures ANOVA.

**RESULTS:** Activity of CK was elevated significantly on post-game (205.75±23.05 U/l) ( $p < .05$ ) and peaked value was on day 1 (348.87±83.59) after-game ( $p < .05$ ) and then gradually decreased on days 2 and 3, but day 2 was still significant higher than pre-game. Activity of LDH was elevated significantly on day 1 (185.38±32.74 U/l) and then close to value of pre-game on day 2 and 3. IL-1 $\beta$  reminded steady during post-game period. In contrast, IL-6 was elevated significantly on the end of post-game (3.30±1.61 pg/ml) ( $p < .05$ ) and had no significant difference on day 2 and 3. TNF- $\alpha$  was elevated significantly on day 1 (4.05±0.29 pg/ml) and 2 (3.90±0.26 pg/ml) after-game ( $p < .05$ ) and then close to value of pre-game on day 3. IL-10 was elevated significantly on post-game (6.67±0.88 pg/ml) and days 1 (7.15±1.18 pg/ml) and 2 (6.14±0.99 pg/ml) after-game ( $p < .05$ ).

**CONCLUSION:** Twelve sec pitching interval for 7 innings induced significant muscle damage and inflammation reaction, but returned the baseline on days 3 after-game.

**Physiological Indexes of Fitness between Aboriginal and non-Aboriginal College Baseball Players**

Yi-Tzu Chen, Li-Lan Fu, Pei-Fan Wang, jung-Tang Kung. *National Taiwan Sport University, Taoyuan, Taiwan.*

(No relationships reported)

**PURPOSE:** The purpose of this study was to compare various physiological indexes of fitness between aboriginal and non-aboriginal college baseball players of a treadmill incremental maximal test.

**METHOD:** Ten aboriginal (Ab) (ht: 180.40 ± 3.13 cm, wt: 81.70 ± 10.85 kg, age: 19.20 ± 1.13 yrs) and 27 non-aboriginal (nAb) (ht: 177.97 ± 4.79 cm, wt: 77.07 ± 10.08 kg, age: 19.69 ± 1.13 yrs) healthy college baseball players participated in this study. Treadmill (COSMED) and indirect calorimetry (SensorMedics, Vmas 29) were used during maximal exercise test and calculation of physiological indexes of fitness. Finger-tip blood samples were collected right before and after exercise, and then analyzed (Biosen C\_Line Analysers). Unpaired t-test and two-way ANOVA were used for significant differences calculation ( $\alpha = 0.05$ ).

**RESULTS:** Ab have significantly lower  $VO_{2Max}$  (Ab: 48.53 ± 5.62 mL·min<sup>-1</sup>·kg<sup>-1</sup>; nAb: 54.21 ± 4.82 mL min<sup>-1</sup>·kg<sup>-1</sup>,  $p = 0.00$ ) and significantly higher post-exercise Lac (Ab: 14.33 ± 3.31 mmol·L<sup>-1</sup>; nAb: 11.35 ± 2.24 mmol·L<sup>-1</sup>,  $p = 0.00$ ) compared to nAb. But total exercise time, HR<sub>Max</sub>, VE, and post-exercise Glu were not significantly different between Ab and nAb.

**CONCLUSION:** Ab group have significantly lower  $VO_{2Max}$  and higher post-exercise Lac than nAb. Possible underlining mechanism could be related to the different performance of anaerobic metabolic pathway, which caused the higher post-exercise Lac after exercise test.

**2270** Board #316 MAY 31 9:00 AM - 10:30 AM

**Total Touch Height in Football Performance Testing: A Case for Practicality**

Cole M. Thompson, Brian J. Campbell. *University of Louisiana at Lafayette, Lafayette, LA.*

(No relationships reported)

Performance testing in football might suggest how fast a player can run (40-yard dash), the upper/lower body strength (1 rep max), or the agility of a player (pro-agility test). Most coaches would assume that traditional vertical jump (TVJ) testing suggest how high a player can jump. TVJ assesses the relative power of an athlete, but does not measure how high a player can reach. Thus total touch height (TTH) is a more practical test for coaches to assess how high an athlete can jump. If a football is thrown up in the air, it's the player with the highest TTH that has the best chance to catch the ball, not necessarily the player with the best vertical jump.

**PURPOSE:** To determine a more practical test for assessing jumping ability in athletes.

**METHODS:** 58 college level football players (Age= 20.75± 1.13 years) served as subjects. Athletes were tested by an NSCA certified strenght coach and performed TVJ protocol using a Vertec<sup>TM</sup> apparatus. No step was given to the jumpers and the top score out of three trials was used for data collection. TTH data were calculated by adding the TVJ measure to the maximum standing reach measure. Peak anaerobic power (PAP) calculated from the TVJ test was then correlated to the more functional TTH measure.

**RESULTS:** PAP and TTH have a moderate correlation of (Pearson's  $r = .469$ ,  $p < .001$ ).

**CONCLUSIONS:** The 78% unexplained relationship of PAP to TTH confirmed that TVJ does not sufficiently explain how high a player can jump. The lack of a strong correlation confirmed the use of separate tests for either TVJ Power or TTH. TTH does not only prove to be more practical, but also more cost efficient. Measuring how high an athletic can jump can simply be done with a pre-measured wall and chalk on the subjects' finger tips.

---

2271 Board #317 MAY 31 9:00 AM - 10:30 AM

**Changes in Body Mass and Absolute and Relative Bench Press, Squat and Leg Press Strength in NCAA Division I Football players**

Jerrold C. Grace<sup>1</sup>, Ali Boolani<sup>2</sup>. <sup>1</sup>Tennessee State University, Nashville, TN. <sup>2</sup>Oklahoma City University, Oklahoma City, OK.

(No relationships reported)

**PURPOSE:** The purpose of this study was to determine whether there were changes in body mass (BM) and absolute and relative bench press (BP), squat (SQ), and leg press (LP) strength over the course of 3 years in NCAA Division I football players. **METHODOLOGY:** Collegiate football players (N=29, age= 18-24) were tested yearly for BW, 1 repetition max (RM) on BP, SQ and LP. Data was collected over 3 years in March, approximately 3 months after the end of the college football season. A Repeated Measures ANOVA was used to analyze results. Post-hoc data was analyzed using paired t-tests.

**RESULTS:** Repeated measures ANOVA indicated significant differences in BW (p<.001), BP (p<.001), BP/BM ratio (p<.001), SQ (p<.003), SQ/BM ratio (p<.017), LP (p<.001), LP/BM ratio (p<.001). Post-hoc analysis yielded a significant increase from year 1 to 2 in BM (p<.001), BP (p<.001), SQ (p<.001), SQ/WT (p<.001), LP (p<.001), LP/WT (p<.001). There was no significant increase in BP/WT from year 1 to 2 (p=.280). There was a significant decrease in BM from year 2 to 3, but there was a significant increase in BP (p<.001), BP/WT (p<.001), SQ (p<.001), SQ/WT (p<.001), LP (p<.001), LP/WT (p<.001).

**CONCLUSION:** Significant increases in BM, absolute BP, SQ and LP and relative in SQ and LP in the first year indicate increased muscle mass and an adaptation to the strength and conditioning program at the university. This may be attributed to a change in diet, increased muscle mass and increased neural adaptation to strength training. Second year decrease in BM and increase in absolute and relative BP, SQ and LP might be attributed to decreased body fat percentages and improved tissue quality.

---

2272 Board #318 MAY 31 9:00 AM - 10:30 AM

**Testosterone And Cortisol With Relation To Mood State In Professional Spanish Basketballers**

Xavi Schelling i del Alcázar<sup>1</sup>, Julio Calleja-González<sup>2</sup>, Nicolás Terrados Cepeda<sup>3</sup>, Jeffrey M. Mjaanes<sup>4</sup>, Holly J. Benjamin, FACSM<sup>5</sup>. <sup>1</sup>Basquet Manresa, Barcelone, Spain. <sup>2</sup>Faculty of Physical Activity and Sport Sciences. UPV-EHU, Vitoria, Spain. <sup>3</sup>University of Oviedo, Oviedo, Spain. <sup>4</sup>Rush University Medical Center, Chicago, IL. <sup>5</sup>University of Chicago, Chicago, IL.

(No relationships reported)

**PURPOSE:** To describe the trends in Total Testosterone (TT) and Cortisol (C) and their relation to mood state during a complete season in elite Spanish basketball players.

**METHODS:** We studied eleven male players of a professional basketball team (n=11; 27.4±6.3 years; 92±9.9 kg; 23.9±1.1 BMI). Samples were taken in the morning, in fasting state, every 4-6 weeks, after a 24-36 hour break following the last game played. Seven samples were collected since August to April from each player. Blood samples of preseason's 1<sup>st</sup> day was considered as baseline. POMS (*Profile of Mood States*) test was performed at the laboratory waiting room before every blood extraction.

**RESULTS:** TT concentration showed significant variations between blood samples: September Vs. August (+2.6 nMol/l, p=0.027). In October TT correlated with POMS' s Total Punctuation (PT) (R=0.685; p=0.029), Tension (R=0.634; p=0.049) and Aggressivity (R=0.669; p=0.034). C concentration and TT/C ratio did not show significant variations during the season. In November C correlated with PT (R=-0.846; p=0.001), Tension (R=-0.676; p=0.022), Depression (R=-0.814; p=0.002) and Confusion (R=-0.715; p=0.013). TT/C ratio correlated in October with PT (R=0.765; p=0.010), Tension (R=0.817; p=0.004), Depression (R=0.709; p=0.022) and Aggressivity (R=0.843; p=0.002); and in November with PT (R=0.685; p=0.020), Tension (R=0.611; p=0.046) and Depression (R=0.745; p=0.008).

**CONCLUSIONS:** The physiologic effect of playing professional level basketball is reflected by total testosterone concentrations and mood state. Preseason phase is the one which implies the most significant hormonal and psychological variations, where the total testosterone increases may show an anabolic state. POMS reflects better current stress than fatigue state. Therefore, testosterone could be an indicator of the athlete's physiologic state and may serve as a future clinical marker for preventing overload or overtraining states. POMS, on the other hand, can help to evaluate the psychological stress level of players.

---

2273 Board #319 MAY 31 9:00 AM - 10:30 AM

**Comparison of Physical Performance and Muscle Imbalances of First and Second Division Spanish Basketball Teams**

Valter Di Salvo<sup>1</sup>, Carlos González-Haro<sup>2</sup>, Mattia Modonutti<sup>3</sup>. <sup>1</sup>University of Rome "Foro Italico", Rome, Italy. <sup>2</sup>School of Medicine. University of Zaragoza, Zaragoza, Spain. <sup>3</sup>ASPIRE, Academy of Sports Excellence, Doha, Qatar.

(No relationships reported)

Many basketball teams coach their young players with the aim that some of them will play on the first league's team. There is little information in the literature that compares muscular imbalances and physical performance between 1<sup>st</sup> and 2<sup>nd</sup> division leagues.

**PURPOSE:** To describe the differences in physical performance and muscular imbalances of male basketball players of 1<sup>st</sup> and 2<sup>nd</sup> division Spanish leagues.

**METHODS:** Twelve 1<sup>st</sup> division and twelve 2<sup>nd</sup> division Spanish professional basketball players (age: 30.2 ± 3.1 and 22.7 ± 5.1 yr, BMI: 24.1 ± 1.3 and 23.3 ± 1.4 m·kg<sup>-2</sup>) carried out muscular imbalance and physical performance tests. Stabilometry (normality <20% error) and Isokinetic knee (high imbalance: H<sub>CON</sub>/Q<sub>CON</sub> and H<sub>ECC</sub>/Q<sub>CON</sub> = mean-1SD, bilateral imbalance = mean+1SD) tests were measured on the first day. Peak power in leg press and jump tests (CMJ, CMJas, 3-CMJ and 5-RJ) were measured on the second day. Results were compared by an equal or unequal variance Student's t-test for unpaired data after a F-test. Statistical significance was set at p<0.05.

**RESULTS:** No differences were observed neither in Stabilometry for both right and left legs nor in the Isokinetic test (concentric and eccentric peak force, H<sub>CON</sub>/Q<sub>CON</sub> and H<sub>ECC</sub>/Q<sub>CON</sub>) within and between teams. A higher H<sub>CON</sub>/Q<sub>CON</sub> (61.8 ± 12.2 vs. 50.8 ± 7.9%, p<0.05) and H<sub>ECC</sub>/Q<sub>CON</sub> (91.0 ± 15.9 vs. 66.0 ± 7.8%, p<0.001) in right leg for 2<sup>nd</sup> vs. 1<sup>st</sup> team was observed. Players' frequency in high levels of imbalance was similar on 1<sup>st</sup> vs. 2<sup>nd</sup> team (H<sub>CON</sub>/Q<sub>CON</sub>, H<sub>ECC</sub>/Q<sub>CON</sub> and bilateral deficit). Force and load to achieve peak power in leg press were higher on 1<sup>st</sup> vs. 2<sup>nd</sup> team (2986 ± 382 vs. 2270 ± 332 N, 276 ± 36 vs. 212 ± 29 kg, p<0.01). There were not significant differences neither in speed nor in power although the latter one was higher for 1<sup>st</sup> team (1235 ± 122 vs. 1046 ± 207 W). There were no differences in height neither CMJ nor CMJas between teams; peak power and force on 1<sup>st</sup> team were higher than on 2<sup>nd</sup> team for both CMJ (4747 ± 130 vs. 4224 ± 582 W, p<0.05; 2538 ± 313 vs. 1897 ± 380 N, p<0.01) and CMJas (8625 ± 786 vs. 5083 ± 1007 W, p<0.001; 2682 ± 342 vs. 2048 ± 464 N, p<0.05), despite no differences in body mass. There were no significant differences in 3-CMJ and 5-RJ between teams.

**CONCLUSION:** Muscular imbalances were similar between both teams. 1<sup>st</sup> team showed higher levels of strength and power than 2<sup>nd</sup> team.

---

2274 Board #320 MAY 31 9:00 AM - 10:30 AM

**Seasonal Progression in Fitness Variables in Elite Junior Basketball Players**

Julio Calleja-Gonzalez. Faculty of Sport Sciences. University of the Basque Country, Vitoria, Spain. (Sponsor: Holly Benjamin, FACSM)

(No relationships reported)

**PURPOSE:** Tests of athletic performance are widely used in team sports to assess the progression of various fitness characteristics in players over the course of a season. However, no scientific data exists analyzing these parameters in top level junior players.

The aim of the present study was to evaluate seasonal variation in anthropometric and physiological variables, and identify differences between the first and reserve team in the elite Spanish junior basketball players.

**METHODS:** Fifteen top-level junior male players (Spanish National Junior team) (mean  $\pm$  SD), age ( $17 \pm 0$  years), height ( $197.0 \pm 4.4$  cm), body mass ( $88.9 \pm 8.3$  kg) participated in this study. All the players completed the same training program (5 h per day, four years). The subjects were divided into two different categories: first team player (FT) ( $n=7$ ) and reserve team player (RT) ( $n=8$ ). Four times during the season (Sep., Dec., March and June) each player performed lower-limb power test, course Navette (60 yard shuttle run) test (CN) and explosive arm strength test (SEAT). In addition anthropometrical data were recorded.

**RESULTS:** No significant changes were observed in body composition. At the end of the training program the values were: [ABK:  $49.2 \pm 7.5$  Vs.  $57.7 \pm 6.5$  cm;  $46.3 \pm 10.0$  Vs.  $56.1 \pm 4.4$  cm]; [HJ:  $2.14 \pm 0.3$  Vs.  $2.18 \pm 0.4$  m;  $2.01 \pm 0.3$  Vs.  $2.59 \pm 0.4$  m]; [CN:  $11.9 \pm 1.6$  Vs.  $12.5 \pm 1.4$  ppliers;  $11.6 \pm 1.6$  Vs.  $12.9 \pm 1.4$  ppliers]; [SEAT:  $7.0 \pm 0.7$  Vs.  $7.6 \pm 0.8$  m;  $7.3 \pm 0.7$  Vs.  $7.8 \pm 1.2$  m], FT and RT respectively. Significant pre- and post-training intra-group increases in maximum speed, strength and endurance were noted ( $P<0.05$ ).

**CONCLUSIONS:** The progression of both groups during the season was quite similar, with no significant differences in any anthropometric or physiological variables between them. At the end of the season and close to the international championship all players got the best results. All players obtained the best results towards the end of the season.

---

**2275** Board #321 MAY 31 9:00 AM - 10:30 AM  
**Specific Short-sprint Assessment For Beach Volley Defensive Actions**

Bernat Buscà<sup>1</sup>, David Alique<sup>2</sup>, Cristofol Salas<sup>3</sup>, Raül Hileno<sup>3</sup>. <sup>1</sup>Ramon Llull University, Barcelona, Spain. <sup>2</sup>National Institute of Physical Education of Catalonia, Barcelona, Spain. <sup>3</sup>National Institute of Physical Education of Catalonia, Lleida, Spain.  
(No relationships reported)

Defensive actions are one of the most important phases for scoring in beach volleyball. Team tactics and individual decision making are both decisive to get advantage in the rally but these decisions are conditioned for short-sprint ability on the sand. The specificity of these movements in this particular surface requires an appropriated assessment method.

**PURPOSE:** To design and report reliability and validity of a new method for assessing defensive displacements called Short-Sprint Ability Beach Volleyball Test (SSABVT).

**METHODS:** Seventeen sub-elite beach volleyball players ( $29 \pm 6$  yrs;  $1.85 \pm 0.09$  m height;  $78.56 \pm 13.44$  kg weight) were assessed for short-sprint and jump ability on the beach volleyball court (three trials each test). The sprint test consisted in sprinting to the net in diagonal, departing from the center of the court (Velleman PMD10 @ light gates were used to switch on the timing Chronojump Bosco System ®), touch a contact sensor situated at 4 m in diagonal, coming back to the starting point and continue sprinting to the other touch sensor located on the opposite corner, and finally return to the starting point (final test time). The jump test consisted in performing a counter movement jump (CMJ) on a rigid surface. Coefficient of variation (CV) was calculated and Pearson product-moment correlation was used to compare short-sprint ability and jump ability. We also used a t-test to determine the difference of the mean between regional (RP) and national (NP) ranked players.

**RESULTS:** CV was less than 2% in both tests. Significant correlations were found between SSABVT time and CMJ flight time ( $r=-0.81$ ;  $p<0.05$ ). The NR players needed 0.26 sec less ( $p<0.01$ ) than RP in SSABVT and jumped 0.036 sec more ( $p>0.05$ ) than RP.

**CONCLUSION:** SSABVT constitute a reliable and valid test for short-sprint ability assessment on the sand court. NR players perform significantly better the specific sprints on the sand than RP, but not the CMJ.

---

**2276** Board #322 MAY 31 9:00 AM - 10:30 AM  
**Load On Lower Extremities During Landing After An Offensive Stroke In Volleyball (case Study).**

David Zahradnik<sup>1</sup>, Dan Jandacka<sup>1</sup>, Jaroslav Uchytíl<sup>1</sup>, Roman Farana<sup>1</sup>, Martin Zvonar<sup>2</sup>. <sup>1</sup>Pedagogická fakulta Univerzita Ostrava, Ostrava, Czech Republic. <sup>2</sup>Fakulta sportovních studií Masarykova univerzita, Brno, Czech Republic.  
(No relationships reported)

**PURPOSE:** The knee joint is the most overloaded joint in volleyball where the number of landings and the magnitude of the reaction force of the pad represent limitary factors in the occurrence of knee injuries. The aim of the study was to compare the reaction force of the pad and the loading rate generated during a bilateral landing after an offensive stroke in relation to the type of the pass.

**METHODS:** One highest-level male volleyball player (aged 38; height 194 cm; weight 94 kg; 20 years experiences of playing highest-level volleyball) from the Czech Republic participated in this study. The experimental positioning was based on a real situation of an offensive stroke in a match. Two dynamometric platforms were built in the floor in the area of the landing and eight infrared cameras for kinematic analysis were installed in a circle around the net. Mean values and standard deviations of selected dynamic and kinematic movement parameters were calculated. Subsequently, the pairing T-test was used. The objective significance was evaluated according to the index of effect of size.

**RESULTS:** Statistically significant differences were found in the length of the last step before the bounce (m) and the horizontal movement of the left leg after the bounce (m), in the maximum values of the anteroposterior reaction force of the pad (BW), in the times for reaching the maximum values of the reaction forces of the pad (s), in the loading rate in the vertical and sagittal direction (BW/s) on the right lower extremity in favor of the landing after a quick pass ( $P \leq 0.05$ ).

**CONCLUSIONS:** The load on lower extremities from the point of the reaction forces of the pad and the loading rate was greater in the quick pass.

---

**2277** Board #323 MAY 31 9:00 AM - 10:30 AM  
**Using a Vertical Jump as Monitoring Purpose of Resistance Training Progress for Women's Volleyball**

Chieh-Ying Chiang, Timothy McInnis, Kimitake Sato. East Tennessee State University, Johnson city, TN.  
(No relationships reported)

Strength is the ability to generate muscle force. Athletes who have higher strength generate higher power output. Intensive resistance training can improve strength and power, and monitoring progression is a vital component of the athletes' development. The efficacy of measuring force output as part of a monitoring program during intensive resistance training period needs to be established.

**PURPOSE:** To monitor women's volleyball team's off-season strength training protocol by periodically measuring the peak force output during squat jumps.

**METHODS:** Nine collegiate women's volleyball players participated in the study during their off-season (age:  $21.3 \pm 1.4$  yrs, height:  $179.4 \pm 8.6$  cm, mass:  $67.4 \pm 4.6$  kg). They reported to the laboratory for initial squat jump (SJ) test to measure peak force output prior to their off-season resistance training program. Then they underwent a 4 days/wk resistance training program for 10 weeks. To monitor progress, the athletes performed SJ bi-weekly to measure the peak force (total 5 tests). The statistical analysis was performed to identify whether the peak forces over 6 testing sessions to be similar or not. The peak force output from each player was tracked and analyzed using repeated-measure ANOVA to see if there is any difference ( $p = 0.05$ ).

**RESULTS:** The repeated-measures ANOVA was calculated comparing peak force output over six times: from initial test to the 10th week. A significant difference was found ( $F(5,40)=3.52$ ,  $p < 0.01$ ) with effect size of .301. Follow-up t tests revealed that the peak force output increased significantly from initial test to week 6, week 8, week 10, and from week 2 to week 8.

**CONCLUSION:** The peak force value increased gradually to show some improvement from the resistance training. Monitoring athlete performance is essential to maximize performance and prevent excessive fatigue or overtraining. Peak force output from SJ on a force plate is a quick and seemingly relevant test to monitor athletes' physical status. Although this study was based around off season training, this monitoring program could also be employed during in-season training when fatigue management and performance maintenance is the most important. Monitoring data could also be used by strength and conditioning professionals to design periodized programs.

**2278** Board #324 MAY 31 9:00 AM - 10:30 AM  
**Evaluating Division I Collegiate Ice Hockey Players Using Preseason Fitness Characteristics and Game Performance**

Christopher P. Connolly, James M. Pivarnik, FACSM, Kimberly Maier, Adam Nightingale, Michael Vorkapich. Michigan State University, East Lansing, MI.  
(No relationships reported)

Preseason fitness testing has been shown to predict game performance in Division I collegiate ice hockey players. Although the plus/minus (+/-) system has been examined previously as a measure of game performance, individualized scoring chance assessments have not been investigated.

**PURPOSE:** To determine whether preseason fitness predicts game performance among collegiate hockey players.

**METHODS:** Testing was performed on members of a Division I collegiate men's ice hockey team over two consecutive seasons (season 1, n=19; season 2, n=20). Overall team performance resulted in 7 wins, 17 losses, and 4 overtime losses for the first season and 14 wins, 8 losses, and 6 overtime losses for the second season. Participants included forwards and defensemen who played at least half (14) the conference games each season. Preseason fitness variables consisted of % body fat, chin-ups, bench press, leg press, off-ice sprinting, and treadmill aerobic capacity. Game performance was assessed for each athlete in the form of +/- score and primary scoring chances, which were determined by a member of the hockey coaching staff. Median split was used to categorize players into high and low performance groups by both +/- score and scoring chances. Differences in preseason values between the performance groups were analyzed using one-way analysis of variance.

**RESULTS:** The median +/- scores for season 1 and season 2 were -9.5 (range -22 to +2) and -1 (range -5 to +11). Median scoring chances for season 1 and season 2 were 10 (range 2 to 28) and 15.5 (range 0 to 41). In season one, chin-up score was significantly higher ( $p=0.01$ ,  $ES=0.26$ ) in the high performance group as determined by scoring chances. In season two, the percentage of maximum blood lactate at the fourth stage of the incremental treadmill test was significantly lower in the low performance group as determined by scoring chances ( $p=0.021$ ,  $ES=0.23$ ). No other significant differences were found in preseason fitness measures between performance groups.

**CONCLUSIONS:** Further testing is needed to determine how overall team performance affects the relationship between preseason exercise and fitness testing and game performance among Division I collegiate hockey players.

---

**2279** Board #325 **MAY 31** **9:00 AM - 10:30 AM**  
**Time Motion Analysis of Varsity Ice Hockey**

Gordon J. Bell, Alex Game, Jessie Gill, Ben Davis, Pierre Gervais, Gary Snyder. *University of Alberta, Edmonton, AB, Canada.* (Sponsor: Darren Delorey, FACSM)  
(No relationships reported)

Ice hockey has evolved to become more physically demanding and played at a higher intensity than in the past. However, a time motion analysis (TMA) of various movements performed during a varsity ice hockey game has not been reported.

**PURPOSE:** The purpose of this study was to determine the frequency and time spent performing different movement patterns during an ice hockey game.

**METHODS:** A convenient sample of 18 male varsity ice hockey players belonging to the same team agreed to participate. The mean ( $\pm$ SD) age, height and body mass of the players was:  $22\pm 1$  yrs;  $179.7\pm 6.3$  cm; and,  $84.3\pm 6.7$  kg, respectively. A digital camera (GoPro<sup>®</sup> Hero; 720p, 60fps) was mounted to the arena wall and was used to videotape an in-season game. The video files were downloaded and analyzed using Dartfish computer software. Three categories of movements (forward, backward and other) were separated into 9 different movement activities.

**RESULTS:** Forwards and defensemen had a mean shift time of 53 and 54s, respectively. The mean frequency of movements per shift and mean time per movement (in brackets;  $\pm$ SD) during a complete ice hockey game for centers was: forward gliding = 7.7 (4.9 $\pm$ 3.6s); moderate intensity forward skating = 4.7 (1.6 $\pm$ 1.0s); high intensity forward skating = 0.2 (3.4 $\pm$ 1.5s); backward gliding = 0.6 (1.5 $\pm$ 1.2s); struggling for the puck or position = 1.2 (1.7 $\pm$ 0.8s); and standing occurred 1.9 (1.8 $\pm$ 1.4s) times per shift. Forwards: forward gliding = 7.3 (4.3 $\pm$ 3.3s); moderate intensity forward skating = 4.6 (1.8 $\pm$ 1.0s); high intensity forward skating = 0.2 (3.3 $\pm$ 1.2s); backward gliding = 0.8 (1.9 $\pm$ 1.0s); backward moderate skating = 0.1 (1.9 $\pm$ 0.3s); struggling for the puck or position = 0.6 (1.6 $\pm$ 1.0s); and standing occurred 1.4 (2.1 $\pm$ 1.6s) times per shift. Defense: forward gliding = 6.9 (4.1 $\pm$ 2.9s); moderate intensity forward skating = 2.3 (1.5 $\pm$ 0.6s); high intensity forward skating = 0.1 (3.2 $\pm$ 1.0s); backward gliding = 3.4 (2.8 $\pm$ 1.7s); backward moderate skating = 0.1 (1.8 $\pm$ 0.7s); struggling for the puck or position = 0.5 (1.3 $\pm$ 0.7s); and standing occurred 2.9 (2.2 $\pm$ 2.0s) time per shift.

**CONCLUSION:** Time motion analysis of a varsity ice hockey game revealed that the movement activities performed by players varied in time and depended on player positions. High intensity movements were least frequently performed and for shorter periods of time.

---

**2280** Board #326 **MAY 31** **9:00 AM - 10:30 AM**  
**Fitness Level of Professional Hockey Players**

Paul Hafen, Cody Bremner, Jon Garcia, Tedd Girouard, Lawrence A. Golding, FACSM, Stephen Harris, Michael Jarrett, Hanaa Shaheen, Kimberly Trocio, Antonio S. Santo. *University of Nevada, Las Vegas, Las Vegas, NV.*  
(No relationships reported)

**PURPOSE:** The primary purpose of this study was to describe the physiological profile of members of the same professional hockey team.

**METHODS:** 21 professional hockey players (mean age =  $25.15 \pm 1.49$  years) reported to our laboratory in order to test body composition, VO<sub>2</sub>max, and heart rate data.

**RESULTS:** The mean height, weight, body fat percent and lean body mass (LBM) of the hockey players was  $181.85 \pm 5.79$ cm,  $88.99 \pm 6.43$ kg,  $13.19 \pm 4.12\%$ , and  $75.13 \pm 14.98$ kg, respectively. The VO<sub>2</sub>max running test resulted in an observed mean of  $61.55 \pm 6.7$  ml/kg/min. Resting Heart Rate for the group was  $68.28 \pm 9.97$  beats per minute (bpm), with a maximum recorded heart rate during the VO<sub>2</sub>max test of  $188.14 \pm 6.81$ bpm.

**CONCLUSION:** This study provides an interesting view into the profile of an entire, professional hockey team. Because the team is divided drastically based upon position played, it would be valuable insight to those interested in athletic profiles to also seek out possible studies involving positional profiling and perhaps data throughout the different training cycles.

---

**2281** Board #327 **MAY 31** **9:00 AM - 10:30 AM**  
**Isokinetic Strength and Anaerobic Capacity in Collegiate Male Lacrosse Players**

Yosuke Tsuchiya, MSc<sup>1</sup>, Keishoku Sakuraba, MD, PhD<sup>2</sup>, Kenta Wakamatsu, MSc<sup>2</sup>, Eisuke Ochi, PhD<sup>3</sup>, Inkwan Hwang, PhD<sup>1</sup>. <sup>1</sup>*Nippon Sport Science University, Tokyo, Japan.* <sup>2</sup>*Graduate School of Medicine, Juntendo University, Tokyo, Japan.* <sup>3</sup>*Meiji Gakuin University, Tokyo, Japan.*  
(No relationships reported)

Although previous studies have shown to investigate physiological characteristics of major sports players such as soccer and football, those of lacrosse players are limited. Since lacrosse includes three playing positions, position-specific characteristics of players need to be explored for their training and conditioning.

**PURPOSE:** The purpose of this study was to investigate isokinetic strength and anaerobic capacity in collegiate male lacrosse players.

**METHODS:** Subjects were 33 male Japanese lacrosse players (age:  $21.5 \pm 1.3$  years, height:  $173.1 \pm 5.1$  cm, body mass:  $65.6 \pm 6.5$  kg). They were divided into three groups on the basis of their positions: attacker (AT; n = 11), defender (DF; n = 10), and midfielder (MF; n = 12). All subjects were measured in body composition (height, body mass, body fat, and lean body mass), isokinetic strength (elbow/knee extension and flexion), and cycling power output (peak power, PP; 30-sec Wingate anaerobic power, WAnP; intermittent power, IP).

**RESULTS:** No significant difference in height, body mass, body fat and lean body mass was found between the three groups. The isokinetic strength of knee flexion was significantly higher in the DF (60 deg/sec:  $1.62 \pm 0.20$  vs.  $1.35 \pm 0.20$  Nm/kg,  $p < 0.05$ ; 180 deg/sec:  $1.31 \pm 0.31$  vs.  $1.10 \pm 0.17$  Nm/kg,  $p < 0.05$ ) and MF groups (300 deg/sec:  $1.18 \pm 0.23$  vs.  $0.96 \pm 0.15$  Nm/kg,  $p < 0.05$ ) than in the AT group. PP was significantly higher in the MF group than in the AT group ( $13.51 \pm 1.31$  vs.  $12.40 \pm 0.76$  watts/kg,  $p < 0.05$ ), and cycling power output was significantly higher in the MF group than in the AT (WAnP:  $9.36 \pm 0.35$  vs.  $8.75 \pm 0.39$  watts/kg,  $p < 0.01$ ; IP:  $102.9 \pm 4.4$  vs.  $97.2 \pm 4.4$  watts/kg,  $p < 0.01$ ) and DF groups (WAnP:  $9.36 \pm 0.35$  vs.  $8.79 \pm 0.52$  watts/kg,  $p < 0.01$ ; IP:  $102.9 \pm 4.4$  vs.  $96.0 \pm 6.6$  watts/kg,  $p < 0.01$ ).

**CONCLUSIONS:** The present results suggest that players at the MF position have better anaerobic capacity than those at the DF and AT positions. In addition, players at the MF and DF positions have better muscle strength than those at the AT position. On the basis of these findings, we conclude that lacrosse players require different physiological abilities depending on their position.

---

2282 Board #328 MAY 31 9:00 AM - 10:30 AM

**Physiologic Profile of National Champion Cheerleaders**

Judy R. Wilson, FACSM, Rolando J. Aviles, Angela Dougall. *University of Texas @ Arlington, Arlington, TX.*

*(No relationships reported)*

**INTRODUCTION:** Cheerleading involves the performance of skills requiring a high degree of muscular strength, endurance, flexibility, balance, and determination. Despite the trend of cheerleaders performing increasingly difficult and athletic skills, very little is known about their physiological fitness levels.

**PURPOSE:** The purpose of the study was to create a physiologic profile of the fitness status of male and female collegiate cheerleaders.

**METHODS:** Eight females (age:  $19.4 \pm 1.1$  yrs; ht:  $156.3 \pm 6.9$  cm; wt:  $55.3 \pm 8.6$  kg) and four males (age:  $24.2 \pm 2.6$  yrs; ht:  $182.8 \pm 9.9$  cm; wt:  $83.4 \pm 10.6$  kg) volunteered to participate in this study. Each subject completed a treadmill test to maximal oxygen levels using the Bruce Protocol, Hydrostatic weighing, and a Wingate Anaerobic Test (WAnT) on a cycle ergometer.

**RESULTS:** Maximal oxygen consumption for the males was  $47.9 (\pm 1.1)$  ml/kg/min and  $40.9 (\pm 6.1)$  ml/kg/min for the females. Absolute values were  $4.3 (\pm 0.1)$  L/min for males and  $2.3 (\pm 0.4)$  L/min for the females. The maximal heart rates achieved were  $204.7 (\pm 13.6)$  bpm for the males and  $191.2 (\pm 4.9)$  bpm for females. It was determined that the percent body fat for the males was  $9.2 (\pm 5.8\%)$  and  $16.0 (\pm 4.6\%)$  for the females. The findings for the WAnT indicated a mean power of  $8.625 (\pm 0.8)$  W/kg for the males and  $7.23 (\pm 0.69)$  W/kg for the females with peak power of  $14.9 (\pm 2.57)$  W/kg and  $11.34 (\pm 2.18)$  W/kg, respectively.

**CONCLUSION:** When compared to norms from the ACSM's Guidelines for Exercise Testing and Prescription 8th ed (2010), the relative maximal oxygen consumption was above the 70th percentile for males and above the 65th percentile for females for the 20 to 24 year old. According to norms for 18-25 year old (Nieman, 2007) the results for the WAnT placed 10 of 12 subjects in this group of cheerleaders in the elite category for both peak and mean power/kg. This physiological profile of the fitness level of cheerleaders suggests that the ability to generate power is developed to a greater extent than aerobic fitness.

2283 Board #329 MAY 31 9:00 AM - 10:30 AM

**The Effects of Vision Training on Softball Performance**

Britany Tallhammer<sup>1</sup>, Michael J. Ryan<sup>1</sup>, Katie Burgess<sup>1</sup>, Paul Reneau<sup>1</sup>, Randy Bryner<sup>2</sup>. <sup>1</sup>*Fairmont State University, Fairmont, WV.* <sup>2</sup>*West Virginia University, Morgantown, WV.* (Sponsor: Stephen Alway, FACSM)

*(No relationships reported)*

While it is consistently agreed upon that superior vision is desirable for sports participation, the efficacy of vision training continues to be debated.

**PURPOSE:** The purpose of this study was to determine if a 5-week program of vision training, designed to train saccades, accommodation, vergence of the eye, hand eye coordination and peripheral vision, enhanced skills related to softball in a group of female collegiate softball players.

**METHODS:** Sixteen healthy softball athlete's age (18-22 years), from a Division II collegiate setting were randomly assigned into treatment or control groups. Treatment consisted of 20 sessions of vision training conducted over five weeks. Eye training was conducted following a specific program using equipment from the Eye Metrix, Inc (Maryland Heights, MO, USA) with exercises changing every session. The subjects from the control group did not participate in any vision training. All subjects maintained their usually softball practice schedule. Study design was a 2 x 2 factorial with group (experimental group and control group), and time (pre- and post- testing). The dependent variables included colored line perception test and background alteration, vertical saccades, horizontal saccades and hand eye coordination/peripheral vision assessment. The testing and training occurred at Fairmont State University in the Feaster Center.

**RESULTS:** There was a significant group by test interaction for all measures involving saccades and accommodation and vergence with the experimental group improving on all visual dependent variables. There were no significant differences between groups in the ability of players to hit balls colored with different lines. Softball players scored significantly higher ( $p \leq 0.05$ ) in their ability to hit balls coming at them with a red background. However, no difference was observed using either a black or green background.

**CONCLUSIONS:** Although eye training significantly improved visual characteristics in a group of collegiate female softball players, this improvement did not appear to translate into enhanced batting capabilities within laboratory conditions.

*(No relationships reported)*

Since it has been considered that prolonged fatigue has negative influence on maintaining physical condition, it would be essential for athletes to continuously monitor their state of physical fatigue. Although resting heart rate (HR) has long been recognized as an objective index of physical fatigue, recent studies suggest that heart rate variability (HRV) would be a better tool for monitoring a state of physical fatigue. To date, however, little is known whether measuring HRV would be efficient for elite athletes to monitor their state of physical fatigue.

**PURPOSE:** To examine the relationships between HRV indices and physical fatigue in elite athletes.

**METHODS:** Sixteen Japanese national badminton team players ( $23.2 \pm 2.9$  yrs) volunteered to participate in the study. Measurements were carried out during the national team training camps on two different days, each separated by three months. In each measurement, all data were collected in the morning just after the players' waking time. Beat-to-beat heart rate was recorded for five minutes under the controlled breathing of 15 breaths per minute. Frequency domain heart rate variability indices were obtained using spectral analysis. The spectral power in the low-frequency (LF: 0.04-0.15Hz) and the high-frequency (HF: 0.15-0.40Hz) bands were calculated. In addition, normalized units (LFnu and HFnu) were obtained. Whereas HF is known to represent parasympathetic activity, LFnu and HFnu represent an evaluation of the autonomic nervous system balance. The subjects were also asked to fill in a questionnaire in which they estimated their subjective feeling of fatigue on a visual analog scale.

**RESULTS:** There was a significant difference in subjective feeling of fatigue between the measurements ( $54.7 \pm 4.8$  vs.  $62.6 \pm 3.8$  mm,  $p < 0.05$ ). The changes in subjective feeling of fatigue between the measurements were significantly correlated with the changes in HFnu ( $r = -0.70$ ,  $p < 0.01$ ). In contrast, no significant correlation were observed between the changes in subjective feeling of fatigue and the changes in HR ( $r = 0.06$ ,  $P > 0.05$ ).

**CONCLUSION:** These results suggest that measuring changes in HRV indices such as HFnu might be more efficient than measuring changes in HR for elite athletes to objectively monitor their state of physical fatigue.

#### Age-related Changes In Hydration Status During Intermittent Exercise In The Heat

Heather E. Wright<sup>1</sup>, Joanie Larose<sup>1</sup>, Stephen G. Hardcastle<sup>2</sup>, Ronald J. Sigal<sup>3</sup>, Pierre Boulay<sup>4</sup>, Glen P. Kenny<sup>1</sup>. <sup>1</sup>University of Ottawa, Ottawa, ON, Canada. <sup>2</sup>CANMET Natural Resources Canada, Sudbury, ON, Canada. <sup>3</sup>University of Calgary, Calgary, AB, Canada. <sup>4</sup>Champlain Diabetes Regional Coordination Centre, Ottawa, ON, Canada.

(No relationships reported)

Ageing is associated with a progressive decrease in thermoregulatory and cardiovascular function. When combined, these age-related changes are thought to decrease the body's ability to maintain core temperature at safe levels, during heat exposure. This can be exacerbated by reductions in hydration. However, the differences in hydration between young and older individuals during exercise in the heat and how this may affect core temperature are unclear.

**PURPOSE:** To examine the effects of intermittent exercise in a hot/dry environment on the changes in hydration status in healthy young, middle-aged, and older males.

**METHODS:** Five young (Mean±SD; Y: 27.6±4.4 yrs), five middle-aged (M: 45.2±3.0 yrs), and five older (O: 61.2±4.3 yrs) healthy males, matched for weight and body composition, performed four successive bouts of 15-min cycling at a constant rate of metabolic heat production (400 W) in dry heat (35°C, 20% relative humidity). Each exercise bout was separated by 15 minutes of rest with a final rest period of 60 minutes. Rectal temperature (T<sub>re</sub>) was measured continuously. Blood and urine samples were obtained prior to exercise (PRE) and following the final recovery for the analysis of hematological parameters (e.g., hemoglobin, hematocrit) and osmolality, and urine specific gravity (USG), respectively.

**RESULTS:** The change in T<sub>re</sub> from PRE to the end of exercise (Y: 0.36±0.15, M: 0.55±0.21, O: 0.58±0.23°C) and final recovery was similar between age groups. Similar hydration status measures, including changes in weight (Y: -1.2±0.1, M: -1.2±0.2, O: -1.2±0.1 kg), plasma (Y: -6.1±2.8, M: -7.8±2.5, O: -7.1±4.0%) and blood volumes (Y: -2.8±2.4, M: -3.8±1.5, O: -4.0±1.8%), plasma osmolality (Y: +4.5±5.7, M: +3.7±2.6, O: +3.8±2.5 mOsm/kgH<sub>2</sub>O), and USG (Y: +0.006±0.007, M: +0.007±0.005, O: +0.005±0.007), were observed between groups.

**CONCLUSION:** Preliminary data indicate that young, middle-aged, and older male adults show similar changes in hydration status following intermittent exercise in the heat. Support: Workplace Safety and Insurance Board of Ontario and Canada Foundation for Innovation-Leaders Opportunity Fund (held by G.P. Kenny).

#### Predetermined Drinking Plans Impact Blood Sodium Concentration And Body Weight During A Half Marathon

Nicole Mitchell<sup>1</sup>, James Winger<sup>1</sup>, Jonathan Dugas<sup>2</sup>, Amy Luke<sup>1</sup>, Lara Dugas<sup>1</sup>. <sup>1</sup>Loyola University Chicago, Maywood, IL. <sup>2</sup>The Vitality Group, Chicago, IL.

(No relationships reported)

**PURPOSE:** Exercise-associated hyponatremia (EAH) is caused by ingesting fluids beyond thirst, resulting in dilution of blood sodium concentrations ([Na<sup>+</sup>]). Runners can decrease the likelihood of EAH by following their bodies' natural drive to drink, commonly known as drinking to thirst<sup>®</sup>. ACSM recommends that runners lose no more than 2% of their starting body mass, to protect them from dehydration and poor performance. We sought to investigate the relationships between predetermined drinking plans, body mass changes and changes in blood sodium levels during a half marathon race.

**METHODS:** 94 runners completed a pre-race drinking plan survey, 67 runners completed both pre and post-race body mass and blood sample measurements. Blood samples were used to determine serum [Na<sup>+</sup>].

**RESULTS:** No runners finished the race hyponatremic. The majority of runners (52%) indicated that they planned to drink according to a predetermined schedule (SCHED), 37% of runners planned to drink only when thirsty (DTT), with 11% of runners planning to drink as much as possible (AMAP). The DTT group was significantly younger (p<0.001), predominantly female (58%) and had the least running experience (5.5 yrs vs. 12.5 yrs, p<0.05). Runners in these three groups differed in their [Na<sup>+</sup>] change during the race (DTT; 2.7±2.7 mmol/L, SCHED; 1.4±2.0 mmol/L, AMAP; 0.8±4.5 mmol/L; p = 0.08) but did not exhibit statistical difference in their race times (DTT; 121.3±22.2 min, SCHED; 124.8±20.2 min, AMAP; 139.4±22.6 min; p = 0.14). However the running time for the DTT group represents almost 11 min faster than the combined mean race time of the other 2 groups. Alternatively runners losing ≥2% of starting body mass on average ran 10 min faster (p = 0.06) compared to runners with a more modest body mass loss and experienced greater differences in their [Na<sup>+</sup>] (3.2 mEq/L in [Na<sup>+</sup>] vs. 1.1 mEq/L for group losing <2% body mass, p = 0.002).

**CONCLUSIONS:** Pre-race hydration plan has a measurable effect on post-race parameters of fluid and electrolyte balance. Drinking to thirst or losing ≥2% of starting body mass may protect runners from EAH through favorable [Na<sup>+</sup>] changes and may have favorable outcomes on running performance. These findings bring into question current drinking recommendations and advice given to recreational runners. No external funding.

### 2287 Board #333 MAY 31 9:00 AM - 10:30 AM

#### Hydration Status, Perceived Thirst and RPE of South-East Asian Soccer Players during Consecutive Days Training

John O'Reilly, Stephen H. Wong, FACSM, Feng Hua Sun. The Chinese University of Hong Kong, Shatin, NT, Hong Kong.

(No relationships reported)

There is little, if any, data published in the literature on the hydration status and sweat rate of South-East Asian soccer players during consecutive days of regular season training. Furthermore, the relationship between heart-rate and self-perception measures for exercise and thirst has not been well established in soccer players.

**PURPOSE:** (1) To assess the sweat rate (SR) and hydration status of South-East Asian professional soccer players during consecutive days of in-season training. (2) To investigate the relationship between rate of perceived exertion (RPE), heart-rate (HR) & perceived thirst (PT) amongst South-East Asian soccer players.

**METHODS:** 14 healthy, male professional soccer players from the Hong Kong football league (mean ± SD: age 24.1 ± 3.5 years, height 1.78 ± 0.07 m, body mass (BM) 72.6 ± 12.1 kg) took part in two soccer-specific, in-season training sessions of similar intensity on consecutive days (T1 & T2). Environmental conditions (Temp: 27 °C, RH: 85%, Wind speed: 1.03 - 1.20 m/sec) were similar on both occasions. Ad libitum drinking was permitted at all times. Each participant was individually assessed to establish their pre- and post-training hydration status by urine specific gravity (USG), as well as their fluid consumption (FC) and SR for each training session. RPE and PT were measured periodically during both training sessions.

**RESULTS:** Although the mean percentage BM losses were within recommended ranges (i.e. < 2%) on both days, 5 players began T1 in a dehydrated condition (USG > 1.020), while 7 players commenced T2 dehydrated. The relationship between SR and FC was significant in T1 (SR vs. FC: 1.39 ± 0.54 L/h vs. 0.85 ± 0.20 L/h, p<0.01), but not in T2 (SR vs. FC: 1.54 ± 0.46 L/h vs. 1.02 ± 0.23 L/h, p>0.05). There were no significant differences observed in USG either between or within training sessions (p<0.05). A positive correlation was observed between PT and RPE during both training sessions (T1: r = 0.986, T2: r = 0.988, p<0.01).

**CONCLUSIONS:** RPE provides an accurate estimate of PT and work intensity during soccer specific exercise. Not all South-East Asian soccer players commence training in a euhydrated condition. Training on consecutive days in a hot and humid environment does not significantly alter USG in South-East Asian professional soccer players.

2288 Board #334 MAY 31 9:00 AM - 10:30 AM

**Male and Female Runners Underestimate Sweat Losses during 1 h Summer Run**

Eric K. O'Neal<sup>1</sup>, Brett A. Davis<sup>1</sup>, Lauren K. Thigpen<sup>1</sup>, Christina R. Caufield<sup>1</sup>, Joyce R. McIntosh<sup>1</sup>, Anthony D. Horton<sup>1</sup>, Rebecca L. Keating<sup>1</sup>, Jared H. Hornsby<sup>2</sup>, James M. Green, FACSM<sup>1</sup>. <sup>1</sup>University of North Alabama, Florence, AL. <sup>2</sup>University of Alabama, Tuscaloosa, AL.  
(No relationships reported)

A key tenant in adherence to ACSM fluid intake guidelines is accurate assessment of fluid volume lost during exercise.

**PURPOSE:** To determine how accurately runners estimate their sweat losses.

**METHODS:** Twenty heat-acclimated female (age = 41 ± 9 y, VO<sub>2</sub>max = 52 ± 8 ml/kg/min, body fat = 23 ± 4%) and 19 male (41 ± 12 y, VO<sub>2</sub>max = 61 ± 9 ml/kg/min, body fat = 14 ± 5%) runners from the southeastern US completed a challenging outdoor road run between August and early September (WBGT = 24.1 ± 1.5 °C) that allowed a finishing time of approximately 1 h. Runs began at approximately 06:45 or 18:45. Runners filled 8 oz race aid station paper cups with a volume of fluid they felt would be equivalent to their sweat losses before and after running.

**RESULTS:** Total sweat losses and losses by percent body were significantly greater ( $p < 0.01$ ) for men (1797 ± 449 mL, 2.3 ± 0.6%) than women (1155 ± 258 mL, 1.9 ± 0.4%), but post-run sweat loss estimation accuracy did not differ between males (underestimation = 46.9 ± 27.3%; 95% CI = 33.8-60.0%) and females (underestimation = 52.1 ± 18.4%; CI = 43.5-60.7%). Collectively, runners' predictions (738 ± 470 mL) were less than half of actual sweat losses (1468 ± 484;  $p < 0.001$ ). Pre- and post-run sweat loss estimations did not differ and were strongly correlated ( $r = 0.88$ ). Nine runners (5 female and 4 male) reported they had assessed their pre- and post-run body weights in the previous month. However, there was no difference ( $p = 0.55$ ) in the accuracy of runners who had assessed body weight change before and after a run (underestimations = 53.6 ± 18.2%) and those who had not (underestimations = 48.3 ± 24.4%).

**CONCLUSIONS:** These results suggest inadequate fluid intake during runs or between runs may stem from underestimations of sweat losses. Further, runners who attempt to assess sweat losses through changes in body weight may be making sweat loss calculation errors or do not accurately translate changes in body weight on a scale to physical volumes of water in race aid station cups.

2289 Board #335 MAY 31 9:00 AM - 10:30 AM

**Drinking According to Thirst does not Prevent Dehydration in Sub-optimally Hydrated Young Soccer Players**

Giannis Arnaoutis, Stavros A. Kavouras, FACSM, Yiannis P. Kotsis, Costas N. Bardis. Harokopio University, Athens, Greece.  
(No relationships reported)

Maintenance of fluid balance is essential for health, athletic performance and thermoregulation. Although there are a lot of studies evaluating hydration status in adults, limited data concerning hydration levels in athletic youth exists.

**PURPOSE:** To assess hydration status in male young soccer players during a summer sports camp and to investigate if ad libitum water intake will prevent further dehydration in the hypohydrated children.

**METHODS:** Initial hydration status was assessed in 107 young soccer players (age: 13±2 y, weight: 52.2±8.5 kg, height: 1.58±0.08 m). Seventy-two out of the 107 children agreed to undergo additional testing for two more separate training days, in order to calculate dehydration via changes in body weight, while water drinking was allowed ad libitum. Hydration status of the participants was assessed in the morning and after the training session, via urine specific gravity (USG), urine color and changes in total body weight. Mean environmental temperature and humidity was 27.2±2°C and 57±9% respectively.

**RESULTS:** According to USG values ( $\geq 1.020$ ), 95 out of 107 of the children (88.7%) were dehydrated prior to practice. Likewise, according to the urine color chart, 93.7% (100 out of 107) were also classified as dehydrated. The prevalence of dehydration was maintained in both training days, with 95.8% and 97.2% of the children being dehydrated (USG  $\geq 1.020$ ) after the end of the 1st and the 2nd training session respectively. Remarkably, despite fluid availability, mean weight loss of -0.35±0.04 kg after the 1st practice and -0.22±0.03 kg after the 2nd practice was observed among the subjects. Specifically, 54 out of the 66 children (81.8%) with pre-exercise USG > 1.020 reduced their body weight after 1st training session, while similarly, 47 out of the 63 dehydrated children (74.6%) also further reduced their body weight after the end of the 2nd training session. Correlation between pre-exercise USG values and changes in body weight failed to reveal any relationship ( $p > 0.05$ ).

**CONCLUSION:** Approximately 80% of the dehydrated soccer players dehydrated more during soccer practice, regardless of fluid availability. These findings indicate that drinking according to thirst during practice, did not prevent further dehydration in sub-optimally hydrated young soccer players.

2290 Board #336 MAY 31 9:00 AM - 10:30 AM

**Are All Milks Equal? Comparing The Rehydration Potential Of Popular Milk Based Beverages.**

Sarah Jansen, Christopher Irwin, Michael Leveritt, Ben Desbrow. Griffith University, Gold Coast, Australia. (Sponsor: Louise Burke, FACSM)  
(No relationships reported)

**PURPOSE:** To examine several varieties of milk regarding their ability to rehydrate following exercise-induced fluid losses.

**METHODS:** Six male participants (age 25.7 ± 5.9y, height 178.9cm ± 6.3cm, body mass 75.2kg ± 5.5kg (mean±SD)) lost 2.1 ± 0.3% body weight through intermittent cycle exercise before consuming a different beverage on four separate occasions. Drinks included Cow's milk (0.6cal·mL<sup>-1</sup>), Soy milk (0.6cal·mL<sup>-1</sup>), a milk based liquid meal replacement - Sustagen - (1.1cal·mL<sup>-1</sup>) and a Sports Drink (0.3cal·mL<sup>-1</sup>). Beverages were consumed over 1h in total volumes equivalent to 150% of body weight loss during exercise. Body weight, blood and urine samples and measures of gastrointestinal tolerance were obtained before and for 4h after beverage consumption.

**RESULTS:** Net fluid balance at conclusion of the trial was significantly enhanced on the Sustagen trial compared to the Sports Drink (Sustagen = -0.59±0.36 kg vs Sports Drink = -1.25±0.44kg,  $p=0.039$ ), which was largely a result of significant differences in total urine output ( $p < 0.01$ ) between treatments. There was a tendency for improved fluid retention with the Soy (-0.83±0.39kg) and Cow's (-0.85±0.41kg) milk treatments relative to the Sports Drink trial however this was not statistically significant. Overall measures of gastrointestinal tolerance and haematological markers exhibited no difference between milk-based trials.

**CONCLUSION:** Milk-based drinks are more effective rehydration options compared to traditional sports drinks. The consumption of a high calorie milk-based liquid meal replacement maximises the recovery of fluid losses following exercise and should be recommended to individuals requiring rapid fluid restoration.

---

2291 Board #337 MAY 31 9:00 AM - 10:30 AM

**Voluntary Fluid Intake With Milk Or Chocolate Milk In Boys Exercising In The Heat**

Alheli MateosRoman<sup>1</sup>, Luis F. Aragon-Vargas, FACSM<sup>2</sup>. <sup>1</sup>Club Deportivo Saprissa, San José, Costa Rica. <sup>2</sup>UNIVERSIDAD DE COSTA RICA, San José, Costa Rica.  
(No relationships reported)

**PURPOSE:** To compare fluid balance (FB) and voluntary intake (VI) in 10-to-14-year-old boys, when they combine milk or chocolate milk with water during exercise in the heat. In addition, palatability and gastrointestinal (GI) symptoms were assessed.

**METHODS:** Thirty-one boys from a junior soccer team (12.6±1.4 y.o., 42.69±2.09 kg and 147.8±10.0 cm) (Mean ± S.D.), exercised in a controlled environment chamber (31.6±0.36°C dry bulb and 47.3±2% relative humidity), at 67.4±4.1% HRmax, using a cycle ergometer and a treadmill. They alternated 20 min of exercise with 10 min of rest on four consecutive times, for a total of 2h in the chamber. Ad libitum fluid intake was monitored from the simultaneous presentation of water and partially skimmed milk (session A), or water and partially skimmed chocolate milk (session B); the drinks had a temperature of 15.9±0.12°C. Fluid balance was calculated from differences in nude body weight. Palatability and GI symptoms were reported upon arrival, and before, during, and at the end of the exercise session.

**RESULTS:** Initial conditions were the same for sessions A and B ( $p > 0.05$ ). No significant difference was found between sweat rates during session A (460.8±217.4 mL·h<sup>-1</sup>) and session B (459.8±229.4 mL·h<sup>-1</sup>) ( $p=0.98$ ). FB was the same for both sessions (0.76±0.80%BW vs. 0.77±0.76%BW,  $p=0.94$ ). A significant difference was found for time: a positive FB was observed during the first hour of exercise, but not during the second hour. VI was the same for both sessions ( $p = 0.87$ ), but different over time: boys drank more fluid during the first hour (573±213 mL and 526±203 mL for sessions A and B, respectively) than during the second hour (307±137 mL and 343±138 mL for A and B, respectively) ( $p < 0.001$ ). Chocolate milk showed the highest

palatability scores and water showed the lowest. GI symptoms were low (session A= 0.8±1.4, 1.5±1.7, 0.7±1.3; session B=0.8±1.9, 1.6±1.9, 0.8±1.4 for abdominal pain, fullness, and side stitch, respectively).

**CONCLUSION:** When presented simultaneously with water, both partially skimmed milk and chocolate milk were effective in preventing voluntary dehydration in boys exercising in the heat. Palatability scores were favorable and GI symptoms presented were not clinically relevant.

Supported by Cooperativa de Productores de Leche Dos Pinos R.L<sup>®</sup> and UCR-VI-245-B0-315.

**2292** Board #338 **MAY 31 9:00 AM - 10:30 AM**  
**Hydration Status Influenced by Gender but not Environment**

Namrita K. O'Dea, Deborah M. Wendland, Tracy Norman, Michael L. Jones, Jochen Kressler, Maxime E. Buyckx, Mindy Millard-Stafford, FACSM. *Georgia Institute of Technology, Atlanta, GA.*

(No relationships reported)

Optimal hydration is important for health in daily living, including for individuals who are not engaging in exercise.

**PURPOSE:** To compare the impact of gender and environment (hot vs. temperate) on hydration status during free-living (FL) and 24 hr fluid restriction (FR) conditions.

**METHODS:** Female and male subjects (n=46, 24 ± 6 yrs) participated in morning (AM) and afternoon (PM) laboratory visits while otherwise maintaining activities of daily living without exercise over three days. After the first day of FL, 24 hr of euhydration was followed by 24 hr dehydration via FR. Mean ± SD peak outdoor temperature was 32 ± 4°C and 18 ± 13.5°C during hot and temperate conditions, respectively. Body mass (BM), perceived thirst, urine osmolality (UOsm), urine color (UC), urine specific gravity (USG), and plasma osmolality (POsm) were measured.

**RESULTS:** The frequency distribution for FL subjects with UOsm >700 mOsm/kg during hot weather was 55%, 59% (for AM, PM) and 75%, 63% (for AM, PM) during temperate conditions. Mean ± SD UOsm was not different in hot vs. temperate (783 ± 119 vs. 805 ± 119 mOsm/kg) and no differences were observed in other hydration status biomarkers during FL and FR. Males had significantly higher UOsm (818 ± 117 vs. 733 ± 117 mOsm/kg in females, p < .02) and POsm (291 ± 4 vs. 287 ± 4 mOsm/kg in females, p < .001) across all time points and environmental conditions. During 24 hr FR, males lost a greater %BM compared to females (-2.3 ± 0.6 vs. -1.9 ± 0.7 %, p < 0.05) but thirst, UC, and USG were not different by gender. From 16 to 24 hr of FR, thirst rating, UOsm, POsm, and %BM loss increased significantly (p < 0.001) in all subjects while UC and USG did not change.

**CONCLUSIONS:** Hydration status in young adults suggests no greater incidence of dehydration during daily living when weather conditions are hot vs. temperate. However, men exhibit greater hypertonicity of urine and plasma compared to women.

**2293** Board #339 **MAY 31 9:00 AM - 10:30 AM**  
**Effect Of Milk Intake On Electrolyte Balance In Children After Exercise In The Heat**

Kim Volterman, Joyce Obeid, Boguslaw Wilk, FACSM, Brian W. Timmons. *McMaster University, Hamilton, ON, Canada.*

(No relationships reported)

The use of low-fat milk as a safe and effective post-exercise rehydration beverage has been recently investigated in the adult population; however, there is a paucity of information on milk's rehydration ability in children after exercising in the heat.

**PURPOSE:** This study tested the hypothesis that due to higher electrolyte content, milk will be more effective than both water and a carbohydrate/electrolyte solution (CES) in replacing electrolyte losses in children following exercise in the heat.

**METHODS:** Fourteen 8- to 10-year old heat-acclimated children (8 girls, 6 boys) performed three exercise trials in a warm environment (35°C, 50% relative humidity) consisting of two 20-min cycling bouts at 60% VO<sub>2peak</sub> followed by consumption of either water (W), CES, or skim milk (SM). Each beverage was consumed in a volume equal to 100% of their body weight losses and beginning immediately after exercise. Urine samples were collected before, during, and after exercise, as well as during the 120 min following drink consumption.

**RESULTS:** Participants ingested 399 ± 97 mL of fluid. Children remained in a net negative balance for Na<sup>+</sup> and Cl<sup>-</sup> at the end of the 120 min recovery period for all beverages. No difference was found between beverages for Na<sup>+</sup> balance; however, children maintained a more positive Cl<sup>-</sup> following the consumption of SM (-1059 ± 575 mg) compared with both W (-1530 ± 561 mg; p < 0.01) and CES (-1412 ± 484 mg; p < 0.05). Similarly, K<sup>+</sup> balance was significantly greater in the SM trial compared with both the W (p < 0.001) and CES (p < 0.001) trials; no significant difference between the W and CES trials. Children were able to return to a net positive K<sup>+</sup> balance following the consumption of SM (182 ± 170 mg), whereas they remained in a net negative K<sup>+</sup> balance during the CES (-270 ± 179 mg) and W (-399 ± 228 mg) trials.

**CONCLUSIONS:** SM was effective at maintaining a more positive electrolyte balance for both K<sup>+</sup> and Cl<sup>-</sup> in comparison to W and a C.

**Lack of an Effect of Venous Occlusion on Reactive Hyperemia During Three Different Types of Contractions**

Morgan Bauman, Hannah Stone, Maurie J. Luetkemeier, John E. Davis. *Alma College, Alma, MI.*

(No relationships reported)

Previous studies have examined handgrip strength and brachial artery dilation as a result of venous occlusion while strength training with solely a concentric contraction. However, few studies have looked at the vascular response as a result of different types of muscular contractions with and without venous restriction.

**PURPOSE:** The purpose of this study was to investigate the effects of different types of muscular contractions, with and without venous restriction, on reactive hyperemia.

**METHODS:** Nine participants (mean ± 1 SD: age 19 ± 8.5 years, males = 4, females = 5) performed 15 repetitions of three types of forearm muscular contractions: concentric (CON), eccentric (ECC), and isometric (ISO) on an isokinetic dynamometer (Cybex Norm) using right wrist flexion. Each type of contraction was performed once with venous restriction induced by a pneumatic cuff inflated to 80 mmHg on the upper arm and once without venous occlusion for a total of six trials on six different days. All trials were randomized. Reactive hyperemia was measured before and after each exercise condition using venous-occlusion plethysmography following a 250mmHg occlusion in the same arm as the exercise. From the reactive hyperemia data, area under the curve, time to return to baseline, and peak blood flow were determined. An analysis of variance was used to compare the previously mentioned variables following exercise with and without venous restriction and also to compare them during the CON, ECC, and ISO contractions.

**RESULTS:** While area under the curve was significantly greater after each type of exercise (Pre-CON = 62.1 ± 23, Post-CON = 114.2 ± 27.7; Pre-ECC = 45.9 ± 23.3, Post-ECC = 112.5 ± 47.9; Pre-ISO = 45.2 ± 19.3, Post-ISO = 95.7 ± 46.3), there were no significant differences either between contraction types or with or without occlusion (P > 0.05).

**CONCLUSION:** These data suggest that the active hyperemia induced by exercise is so great that it masks any reactive hyperemia differences that may be present due to contraction type or venous occlusion.

**The Effect of Eccentric Exercise-Induced Muscle Injury on Vascular Function**

Mitchel R. Stacy, Jennifer L. Lawrence, Sarah A. McGlinchy, Barry W. Scheuermann. *The University of Toledo, Toledo, OH.*

(No relationships reported)

Pro-inflammatory conditions associated with aging, poor dietary habits, obesity and increased levels of oxidative stress have been linked to endothelial dysfunction. While the long-term benefits of exercise on vascular function are well known, muscle injury is often a consequence of performing exercise. Post-injury inflammatory responses may contribute to vascular dysfunction, as markers of inflammation have been shown to increase arterial stiffness, impair endothelial-dependent vasodilatation, and decrease the expression of endothelial nitric oxide synthase.

**PURPOSE:** To examine the effect of eccentric exercise-induced injury on endothelial dependent and independent vascular responses.

**METHODS:** Ten healthy male subjects ( $26.6 \pm 1.2$  yrs,  $\pm$  SD) performed 50 maximal eccentric contractions to induce injury to the biceps brachii. Subsequent changes in maximal isometric strength and vascular responses were assessed at 1, 24, 48, and 96 hrs post injury. Endothelial-dependent and -independent vasodilatation were measured in the brachial artery using the flow-mediated dilation (FMD) approach and sublingual NTG (0.4 mg) administration, respectively. Mean blood velocity was measured by Doppler ultrasound and subsequently used to calculate muscle blood flow and shear stress (expressed as the area under the curve,  $SS_{AUC}$ ).

**RESULTS:** Eccentric exercise resulted in impaired maximal isometric strength for up to 96 hours ( $p < 0.05$ ). Compared to pre-injury values, FMD decreased within 1 hr of injury (Pre;  $8.4 \pm 0.9$ ; 1 hr post;  $5.12 \pm 0.7$  %FMD,  $p < 0.05$ ) and remained lower ( $p < 0.05$ ) for up to 96 hrs. Similarly, the vasodilatory response to NTG was also impaired for 96 hours following eccentric-induced muscle injury (Pre;  $26.3 \pm 2.1$ ; 1 hr post;  $20.7 \pm 1.5$  %,  $p < 0.05$ ). Injury resulted in a decrease ( $p < 0.05$ ) in  $SS_{AUC}$  immediately following exercise which remained impaired for 48 hrs. Resting blood pressure and muscle blood flow remained similar throughout the duration of the study.

**CONCLUSIONS:** These results suggest that muscle injury leads to impaired local endothelial and vascular smooth muscle function. The lower shear stress following injury may contribute to the reduced FMD response but the mechanism responsible for the attenuated endothelial-independent vasodilatation requires further investigation.

**Influence of Self-reported Physical Activity on Arterial Stiffness in Adolescents**

Megumi Sugino, Hajime Miura, Saori Maruoka, Yukimi Maki. *Univ. of Tokushima, Tokushima, Japan.*

(No relationships reported)

Insufficient physical activity may play a pathophysiological role in the development of atherosclerosis in middle-aged to older men. However, few attempts have so far been made to identify the role of physical activity on arterial function in adolescents.

**PURPOSE:** The aim of this study was to explore the effect of current life style of physical activity on arterial stiffness in adolescents.

**METHODS:** 183 healthy male high school students were divided into two groups: 83 were in the active group who participated in sports or athletic clubs in addition to physical education class and 100 were in the control group who took only physical education class. The brachial systolic and diastolic blood pressure (SBP, DBP), heart rate (HR) and brachial to ankle pulse wave velocity (baPWV) were measured using a volume-plethysmographic apparatus while the subjects were in the supine position. In order to estimate the energy expenditure of physical activity (PA), the International Physical Activity Questionnaire with the short format was adopted.

**RESULTS:** In the active group, both baPWV and PA significantly differed from those in the control group ( $p < 0.001$ ). However, no significant differences in age, height, weight, body mass index (BMI), %fat, SBP, DBP, or HR were found between two groups. The 9 independent variables that had correlations with selected variables (age, height, weight, BMI, %fat, SBP, DBP, HR, and PA) were examined by regression modeling to determine their relative influence on the baPWV. In the final model, SBP, PA, weight, and age accounted for 43.5% of the variation in baPWV. The standardized beta estimates were  $\beta = 0.544$  ( $p < 0.0001$ ) for SBP,  $\beta = -0.371$  ( $p < 0.0001$ ) for PA,  $\beta = -0.145$  ( $p < 0.05$ ) for weight, and  $\beta = 0.129$  ( $p < 0.05$ ) for age.

**CONCLUSIONS:** These results suggested that spending more time engaging in physical activity has a favorable effect on arterial stiffness in adolescents as well as middle-aged to older men.

2297 Board #343 MAY 31 8:00 AM - 9:30 AM

**Acute Effect of Moderate and High Intensity Resistance Exercise on Arterial Stiffness**

Thomas Black. *Springfield College, Springfield, MA.*

(No relationships reported)

**INTRODUCTION:** Cardiovascular disease is the leading cause of death in the western world. The stiffness of large arteries has been identified as a major independent risk factor for cardiovascular disease. Resistance exercise (RE) is included in a well-rounded exercise prescription for the general public and for persons with a variety of diseases in accordance with ACSM guidelines. However, researchers have found evidence indicating that RE may increase arterial stiffness.

**PURPOSE:** The current study was designed to determine the effect on moderate and high intensity RE on arterial stiffness (AS).

**METHODS:** Twelve young healthy males, age ( $21.5$  yr  $\pm$  1.5), training age ( $6$  yr  $\pm$  1.8), weight ( $88.5$  kg  $\pm$  7.9), height ( $177.2$  cm  $\pm$  3.3), and % body fat ( $15.9$  %  $\pm$  5.3), who regularly resistance trained were recruited for the study. Each subject completed both the moderate and high intensity bout on two separate occasions in a randomized order. Pulse wave velocity (PWV) was used to estimate AS and was measured at baseline, 10 min post, 20 min post, and 30 min post. Heart rate was measured during each bout and was used as a marker of sympathetic nervous system activity. A total body RE workout was completed during each bout and consisted of four free weight exercises.

**RESULTS:** Significant increases ( $p < .05$ ) in PWV were observed up to 30 min following RE, however, no significant differences ( $p < .05$ ) were found between the two intensities. The differences in PWV observed are as follows: BL ( $M = 5.66$ ,  $SD = .82$ ), 10 min post ( $p = .00$ ;  $M = 6.17$ ,  $SD = .94$ ), 20 min post ( $p = .04$ ;  $M = 5.95$ ,  $SD = .89$ ) and 30 min post ( $p = .04$ ;  $M = 5.93$ ,  $SD = 1.01$ ). The moderate intensity RE ( $M = 156.65$  bpm,  $SD = 12.08$ ) produced a significantly higher ( $p < .05$ ) HR as compared to the high intensity RE ( $M = 143.17$  bpm,  $SD = 11.53$ ).

**CONCLUSION:** AS was elevated for up to 30 min following a bout of RE and is not dependent on intensity. Whether or not the AS elevation is pathologic and identifying the mechanisms involved warrants further investigation.

**Effects of School-Based Exercise Training on Endothelial Function and Pulse Wave Velocity in Obese Adolescents**

Soo-Hyun Park, Eun-Sun Yoon, Yong Jin Lee, Ki Won Lee, Yong Hee Lee, Sae Young Jae. *University of Seoul, Seoul, Korea, Republic of.*

(No relationships reported)

Vascular endothelial dysfunction and increased arterial stiffness are associated with early atherosclerosis in obese adolescents.

**PURPOSE:** The purpose of the study was to assess the effects of school-based exercise training on endothelial function and pulse wave velocity in obese adolescents.

**METHODS:** Twenty one obese adolescents ( $13 \pm 1$ yr) were randomly assigned to a school based exercise training (ET)(12weeks, 50 minutes, 5day/week) group ( $n=11$ ) and a non exercise control (CON) group ( $n=10$ ). Cardiorespiratory fitness was measured using maximal oxygen uptake with metabolic gas analysis and body composition was determined by bioelectrical impedance. We measured carotid-femoral pulse wave velocity and reactive hyperemia index as indices of vascular function.

**RESULTS:** Waist girth was significantly decreased in ET group than CON group (ET  $94.41 \pm 6.17$  to  $92.62 \pm 6.13$  vs. CON  $92.62 \pm 7.80$  to  $94.27 \pm 9.23$ cm,  $p < 0.05$ ). Cardiorespiratory fitness was significantly increased in ET group than CON group (ET  $32.35 \pm 6.49$  to  $39.24 \pm 6.63$  vs. CON  $34.59 \pm 5.47$  to  $38.36 \pm 6.54$ ml/kg/min,  $p < 0.05$ ). Body mass index and selected CVD risk factors were not improved in ET group. Reactive hyperemia index was significantly increased in ET group (ET  $1.60 \pm 0.45$  to  $1.87 \pm 0.58$  vs. CON  $1.73 \pm 0.39$  to  $1.43 \pm 0.26$ %,  $p < 0.05$ ) but carotid-femoral pulse wave velocity did not significantly decrease in ET group (ET  $5.77 \pm 5.40$  to  $5.40 \pm 0.53$  vs. CON  $5.12 \pm 0.53$  to  $5.05 \pm 0.54$ m/s, NS). Change in cardiorespiratory fitness was associated with change in reactive hyperemia index after adjusted for changes in waist ( $r=0.469$ ,  $p < 0.05$ ).

**CONCLUSIONS:** These results show that school-based exercise training improved endothelial function, and this was associated with improved cardiorespiratory fitness in obese adolescents.

2299 Board #345 MAY 31 8:00 AM - 9:30 AM

**Physical Activity, Age, And Arterial Compliance**

A. Maleah Holland, Joel M. Stager, David A. Tanner, Colleen M. McCracken, Hao Guo, Peter R. Finn. *Indiana University, Bloomington, IN.*  
(No relationships reported)

A reduction in large arterial compliance has been shown to occur with age and physical inactivity and is considered an independent risk factor of cardiovascular disease. Low compliance is associated with various pathological states such as hypertension, left ventricular hypertrophy, and congestive heart failure. The relationship between sex, aging, and physical activity remains unclear.

**PURPOSE:** The purpose of this study is to determine if high levels of physical activity influence arterial compliance similarly in men and women.

**METHODS:** Thirty-six subjects, 16 men (M), 20 women (W), were categorized as younger (Y, 40-59yrs old) or older (O, 60-79yrs old). Nineteen subjects (6 YM, age= 46.8±2.6yrs, 2 OM, age= 61±1.4yrs; 9 YW, age= 48 ± 4.1yrs, 3 OW, age= 67.3±8.4) were considered highly active based on self-reported vigorous physical activity > 200 min/wk and 17 subjects (4 YM, age=50.5 ± 4yrs, 4 OM, age= 70.5±7.4yrs; 4 YW, age 54.3±5.6, 5 OW, age=65.6±5.9yrs) were considered sedentary to moderately active- with activity confirmed by an activity monitor worn for 7 days. Resting cardiovascular measurements including large arterial compliance, blood pressure, and heart rate were recorded. Statistical analysis included a 2x2x2 Analysis of Variance with p<0.05.

**RESULTS:** Compliance was greater in highly active subjects compared to the sedentary or moderately active subjects (18.2 ± 4.2 vs. 13.5 ± 3.8 mL/mmHg<sup>10</sup>) and it was greater in men when compared to women (17.9 ± 4.4 vs. 14.6 ± 4.3 mL/mmHg<sup>10</sup>). There was no difference in compliance between age groups though power was low due to a small n. There were no significant interactions between activity, sex, and age on compliance. There was a significant simple effect for sex by activity in women, as compliance was greater in active women compared to inactive women (16.9 ± 3.9 vs. 11.6 ± 2.6 mL/mmHg<sup>10</sup>).

**CONCLUSIONS:** Arterial compliance differs as a function of physical activity in an aging population demonstrating the highly active to be at a reduced risk of cardiovascular disease. Oddly, women, particularly the inactive women show the greatest risk for cardiovascular disease as compared with other groups. Thus, the converse, habitually high levels of physical activity may pose a greater benefit for women than for men.

2300 Board #346 MAY 31 8:00 AM - 9:30 AM

**Effects of Group Training on Arterial Stiffness in Elderly Hypertensive Women**

Hajime Miura<sup>1</sup>, Yoshinori Takahashi<sup>2</sup>, Yukimi Maki<sup>1</sup>, Megumi Sugino<sup>1</sup>. <sup>1</sup>University of Tokushima, Tokushima, Japan. <sup>2</sup>Institute of Tohigi Health & Wellness Foundation, Tohigi, Japan.  
(No relationships reported)

Regular physical exercise is recommended for the prevention and treatment of cardiovascular diseases. However, few attempts have so far been made to identify the role of exercise training in arterial function in elderly hypertensive people.

**PURPOSE:** The aim of this study was to evaluate the effects of group training on arterial stiffness in elderly hypertensive women.

**METHODS:** According to their systolic blood pressure (SBP) and diastolic blood pressure (DBP), 153 elderly women were assigned to 4 groups; hypertensive training (HT) group (n=35), normal BP training (NT) group (n=42), hypertensive control (HC) group (n=37), and normal BP control (NC) group (n=39). In the training group, subjects participated in 90-min group training twice a week for 12 weeks. Each training program included recreational activities, six to eight resistance exercise for circuit training, leg exercises for chair-based exercise. Before and after training, SBP, DBP and brachial to ankle pulse wave velocity (baPWV) were obtained in the supine position using an automatic pulse wave form analyzer.

**RESULTS:** Changes ratio ( $\Delta$ ) of baPWV, SBP and DBP between before and after training were -4.3±3.3%, -4.6±4.3%, -4.4±5.5% for HT, -4.1±6.9%, -3.5±6.9%, -8.1±5.9% for NT, -0.6±3.4%, -0.3±3.9%, 0.5±4.4% for HC, and 0.8±5.5%, 0.4±5.9%, 0.2±5.7% for NC, respectively. Compared with control (HC and NC) groups, a greater reduction in  $\Delta$ PWV,  $\Delta$ SBP and  $\Delta$ DBP were observed in training (HT and NT) groups (p<0.05). The difference of  $\Delta$ PWV between HT and NT was also significant (p<0.05).

**CONCLUSIONS:** These data indicate that short term group training

produces less improvement of arterial stiffness in elderly hypertensive women compared with healthy elderly. Different training effect of arterial stiffness might be explained by the structural changes such as increased fragmentation, collagen content, or cross-linking of collagen molecules in hypertensive elderly.

2301 Board #347 MAY 31 8:00 AM - 9:30 AM

**The Effect Of Acute Aerobic Exercise On Arterial Stiffness Of Overweight Males**

David Chandrakumar, Stephen H. Boutcher, FACSM, Yati N. Boutcher. *University of New South Wales, Sydney, Australia.*  
(No relationships reported)

Overweight and obese individuals have been shown to possess early stiffening of the arteries and abnormal lipid profiles. To date, no studies have examined the effect of one single bout of aerobic exercise on arterial stiffness in young overweight males.

**PURPOSE:** To determine the acute effect of a single bout of exercise on arterial stiffness assessed by an augmentation index (AIx) and pulse wave velocity (PWV) in young overweight males.

**METHODS:** Twenty young healthy males aged 18-30 yrs with a body mass index (BMI) of between 18-35 kg.m<sup>2</sup> were recruited. They comprised of normal weight (n=12; BMI=18-25 kg.m<sup>2</sup>) and overweight (n=8; BMI>25 kg.m<sup>2</sup>) males. All subjects underwent one single bout of cycle exercise at 65% of their maximal oxygen uptake. Cardiovascular function such as resting heart rate, blood pressure, AIx, and PWV were assessed pre and post acute exercise. Lipid profiles and body composition were also recorded. AIx, a measure of wave reflection and a surrogate measure of arterial stiffness, was assessed using applanation tonometry, and was calculated as the ratio of augmented pressure and pulse pressure. Carotid-radial PWV (PWV<sub>cr</sub>) and carotid-femoral PWV (PWV<sub>cf</sub>) were also measured using applanation tonometry. PWV velocity is determined from the time taken for the arterial pulse to propagate from the carotid to the femoral/radial artery. AIx was assessed at pre, 10, 20, 30, and 60 min post acute exercise, whereas PWV was assessed at pre and 60 min post acute exercise.

**RESULTS:** There was no significant change in PWV<sub>cr</sub> and PWV<sub>cf</sub> following acute exercise, however, AIx at pre and throughout post acute exercise was significantly higher (P<0.05) in overweight compared to normal weight males. Resting blood pressure and total cholesterol levels (P<0.05) were also higher in overweight than that of normal weight males.

**CONCLUSION:** The high AIx levels after acute exercise of the overweight males is possibly associated with their high resting blood pressure and abnormal lipid levels.

2302 Board #348 MAY 31 8:00 AM - 9:30 AM

**Endothelial Dysfunction In Polycystic Ovarian Syndrome Is Not Explained By Poor Fitness Or Increased Fatness**

Victoria S. Sprung<sup>1</sup>, Daniel J. Cuthbertson<sup>2</sup>, Christopher JA Pugh<sup>1</sup>, Nabil Aziz<sup>3</sup>, Graham J. Kemp<sup>2</sup>, Daniel J. Green<sup>4</sup>, Greg Atkinson<sup>1</sup>, Tim Cable<sup>1</sup>, Helen Jones<sup>1</sup>. <sup>1</sup>Liverpool John Moores University, Liverpool, United Kingdom. <sup>2</sup>University of Liverpool, Liverpool, United Kingdom. <sup>3</sup>Liverpool Women's Hospital, Liverpool, United Kingdom. <sup>4</sup>University of Western Australia, Crawley, Australia. (Sponsor: Professor Keith Geroge, FACSM)  
(No relationships reported)

**PURPOSE:** Polycystic ovarian syndrome (PCOS) has an adverse cardiovascular disease (CVD) risk profile which infers a ~2 fold increased risk of coronary artery disease. It remains unclear as to whether endothelial dysfunction is evident in PCOS independently, or if co-existing morbidities are independent risk factors for endothelial function in this population. The aim of this study was to investigate the relationship between endothelial function, adiposity and fitness in PCOS patients compared with matched control women.

**METHODS:** PCOS (n=35, age 27±1 yrs, BMI 32±1 kg/m<sup>2</sup>) and control women (n=15, age 31±1 yrs, BMI 29±2 kg/m<sup>2</sup>) were matched for age and BMI. Brachial artery endothelial function was assessed using flow mediated dilation (FMD). Visceral (VAT) and subcutaneous fat (SAT) was quantified using whole body magnetic resonance imaging. Cardiorespiratory fitness was also determined by a VO<sub>2peak</sub> test. Differences between PCOS and control women were analysed using independent t-tests and analysis of covariance. Data are presented as mean±SE.

**RESULTS:** FMD was impaired in PCOS when compared to matched control women ( $6.2 \pm 0.4$  vs.  $10.5 \pm 1.0\%$ ;  $P < 0.0005$ ). When FMD was adjusted for individual differences in BMI, VAT, SAT and cardiorespiratory fitness, the difference in FMD between groups remained ( $6.4 \pm 0.5$  vs.  $9.4 \pm 1.0\%$ ;  $P = 0.01$ ).

**CONCLUSION:** These findings indicate that FMD is impaired in PCOS women independent of global adiposity, specific fat deposition or volume, or cardiorespiratory fitness. Endothelial dysfunction is likely directly mediated by PCOS and further exploration of potential moderators of endothelial function associated with the PCOS is warranted.

**2303 Board #349 MAY 31 8:00 AM - 9:30 AM**

**Exercise Training Reduces Peripheral Pulse Wave Velocity in Young Prehypertensives**

Darren T. Beck<sup>1</sup>, Jeffrey S. Martin<sup>2</sup>, Darren P. Casey<sup>3</sup>, Randy W. Braith, FACSM<sup>1</sup>. <sup>1</sup>University of Florida, Gainesville, FL. <sup>2</sup>University of Missouri, Columbia, MO. <sup>3</sup>Mayo Clinic, Rochester, MN.

(No relationships reported)

**PURPOSE:** To determine the separate effects of resistance and endurance exercise training on arterial function in young prehypertensives.

**METHODS:** Forty-three prehypertensive subjects were recruited and randomly assigned to either a resistance training (n=15), endurance training (n=13), or control group (n=15). Additionally, fifteen sedentary matched normotensive time controls were studied. Training groups completed an eight week exercise training regimen. Carotid to Femoral (C-F), Carotid to Radial (C-R), and Femoral to Dorsalis Pedis (F-D) pulse wave velocity (PWV) were measured via electrocardiogram gated applanation tonometry before and after exercise training or time matched control.

**RESULTS:** Pulse wave velocity before and after exercise training and time control

| C-R, msec | 8.81±0.30*  | 7.81±0.30† | 8.63±0.36*  | 7.71±0.35† | 8.78±0.28*  | 8.75±0.27*  | 7.92±0.31   | 7.90±0.31 |
| F-D, msec | 10.41±0.25* | 9.39±0.36† | 10.27±0.27* | 8.93±0.39  | 10.43±0.23* | 10.19±0.33* | 8.60±0.25   | 8.62±0.36 |

Values are mean±SEM. Significance values are reported from between group and between timepoint repeated measures ANOVA and Tukey post hoc analysis. \* $P < 0.05$  baseline versus normotensive control values; † $P < 0.05$  versus pretreatment values.

**CONCLUSIONS**

Young prehypertensives increased peripheral pulse wave velocity when compared to matched normotensives. Additionally, both resistance and endurance exercise training reduced peripheral pulse wave velocity in young prehypertensives.

**2304 Board #350 MAY 31 8:00 AM - 9:30 AM**

**Effect of Resistance Training and/or a Hypocaloric Diet on Endothelial Function in Hypercholesterolemic Obese Women**

Javier Ibáñez Santos<sup>1</sup>, Irene Madariaga<sup>2</sup>, Ana Grijalba<sup>3</sup>, Marisol García-Unciti<sup>4</sup>, Mikel Izquierdo<sup>1</sup>, Esteban Gorostiaga<sup>1</sup>. <sup>1</sup>CEIMD, Pamplona, Spain. <sup>2</sup>Hospital of Navarra, Pamplona, Spain. <sup>3</sup>Hospital of Navarra., Pamplona, Spain. <sup>4</sup>Universidad de Navarra., Pamplona, Spain.

(No relationships reported)

The pathogenesis of endothelial dysfunction in obesity remains uncertain; the relative roles of insulin resistance, circulating NEFA, or adipocyte-associated cytokines are being delineated. In this context, the effects of resistance training (RT) and/or a hypocaloric diet on the relationship between those metabolic variables and the endothelial function of obese women with hypercholesterolemia remain to be elucidated.

**PURPOSE:** To evaluate the effect of a twice-weekly RT program and/or a hypocaloric diet on the endothelial function in hypercholesterolemic obese women.

**METHODS:** The design was a 16 week randomized controlled trial. Thirty three participants were assigned to 3 groups: Control group (C, n= 8); Diet group (D, n= 12) with a caloric restriction of 500 Kcal/day; and Diet + RT group (D+RT, n= 13) with a caloric restriction as diet group and a 16- week supervised RT program of 2 sessions/ week. Endothelial function (measured by high-frequency ultrasonography), and basal circulating levels of insulin, glucose, NEFA, leptin, adiponectin and IL- 1Ra were measured baseline and at week 16.

**RESULTS:** Body weight reduction was similar in both D and D+RT groups (6.3 vs. 7.1 Kg). No significant change was observed in plasma NEFA levels. Insulin sensitivity (HOMA index) improved ( $P < .01$ ) and plasma leptin decreased ( $P < .001$ ) in both D and D+RT groups. In contrast, while no significant change was observed in plasma adiponectin levels in women of diet group, in the trained group adiponectin levels decreased significantly (from  $13.8 \pm 4.3$  to  $12.4 \pm 3.5$ ;  $P < .05$ ). As to the endothelial function, an amelioration in the endothelium-independent vasodilatation was observed only in D+RT group (from  $0.41 \pm 0.05$  to  $0.48 \pm 0.04$ ;  $P < .001$ ). IL- 1Ra also increased only in D+RT group ( $P < .05$ ), and in all the three groups a significant correlation was observed between the evolution of the endothelium-independent vasodilatation and the percentage variation of IL- 1Ra ( $r = .348$ ;  $P < .05$ ).

**CONCLUSIONS:** Two sessions/ week of RT, with a concomitant weight loss diet, improves endothelium-independent vasodilatation associated to IL- 1Ra.

Supported in part by grants of Spanish Ministry of Health, Institute Carlos III, Dept. of Health of the Government of Navarra and Government of Spain (CSD) RD06/013/1003 and 87/2010 and 008/EPB10/11, respectively.

**Exercise Training and Skeletal Muscle Blood Flow: Functional Role of Neuronal Nitric Oxide Synthase (nNOS)**

Daniel M. Hirai, Steven W. Copp, Scott K. Ferguson, Clark T. Holdsworth, David C. Poole, FACSM, Timothy I. Musch, FACSM. Kansas State University, Manhattan, KS.

(No relationships reported)

Exercise training induces multiple adaptations within skeletal muscle which enhance hemodynamic control. Increased nitric oxide (NO) bioavailability via upregulation of endothelial NO synthase (eNOS) function is intrinsic in this process. However, it is also possible that training-induced upregulation of nNOS function contributes importantly to the NO-mediated training response.

**PURPOSE:** To test the hypothesis that selective nNOS inhibition would reduce blood flow and vascular conductance (VC) in hindlimb skeletal muscle of exercise trained rats during submaximal treadmill running.

**METHODS:** Male Sprague-Dawley rats (4-5 mo;  $456 \pm 5$  g) were assigned randomly to either sedentary (S; n=8) or exercise trained (ET; n=8) groups. ET rats performed treadmill exercise 60 min/day, 5 days/wk for 6-8 wks at a speed of up to 35 m/min. Blood flow and VC were determined during submaximal treadmill running at 20 m/min via radiolabeled microspheres before and after administration of the selective nNOS inhibitor S-methyl-L-thiocitrulline (SMTC,  $2.1 \mu\text{mol/kg}$  i.a.).

**RESULTS:** ET rats had greater  $\text{VO}_2$  peak ( $82.4 \pm 2.3$  ml/kg/min) than S rats ( $76.9 \pm 1.3$  ml/kg/min;  $p < 0.05$ ). During submaximal whole-body exercise, ET rats had lower blood lactate concentration during control (S:  $4.4 \pm 0.4$ ; ET:  $1.4 \pm 0.2$  mM;  $p < 0.05$ ) and SMTC (S:  $5.7 \pm 0.5$ ; ET:  $2.0 \pm 0.3$  mM;  $p < 0.05$ ) conditions. Consistent with previous reports, SMTC had no effects on total hindlimb muscle blood flow (control:  $104 \pm 12$ ; SMTC:  $102 \pm 13$  ml/min/100g;  $p > 0.05$ ) and VC (control:  $0.74 \pm 0.07$ ; SMTC:  $0.72 \pm 0.09$  ml/min/100g/mmHg;  $p > 0.05$ ) in S rats. Contrary to our hypothesis, no changes in total hindlimb muscle blood flow (control:  $98 \pm 6$ ; SMTC:  $95 \pm 6$  ml/min/100g;  $p > 0.05$ ) and VC (control:  $0.72 \pm 0.03$ ; SMTC:  $0.66 \pm 0.02$  ml/min/100g/mmHg;  $p > 0.05$ ) were observed in ET rats. Individual hindlimb muscle blood flow and VC were not significantly different following SMTC in S rats. Similarly, the great majority of the individual hindlimb muscles from ET rats exhibited no significant differences in blood flow (27 out of 28) and VC (25 out of 28) between control and SMTC.

**CONCLUSIONS:** Upregulation of nNOS function does not appear to play an obligatory role in muscle hyperemia during submaximal treadmill running in exercise trained rats.

**Effect of Aging and Indomethacin on Forearm Reactive Hyperemia in Healthy Adults.**

Jill N. Barnes, Jennifer L. Taylor, Casey N. Hines, Michael J. Joyner, FACSM. *Mayo Clinic, Rochester, MN.*

*(No relationships reported)*

Prostaglandins contribute to peripheral vasodilatory responses and this contribution may vary with age. There are conflicting reports on the extent to which post-ischemic hyperemic flow is influenced by the cyclooxygenase inhibitor indomethacin in young adults, with both increased and decreased flow reported. Despite these discrepancies in young adults, the effect of indomethacin on reactive hyperemia in older adults has not been evaluated.

**PURPOSE:** To evaluate the effect of cyclooxygenase inhibition on forearm reactive hyperemia, in young and old adults. Because aging is associated with a shift from vasodilating to vasoconstricting prostaglandins, we hypothesized that indomethacin would augment forearm vascular conductance during reactive hyperemia in older adults.

**METHODS:** Forearm blood flow (FBF) responses to 5 minutes of forearm ischemia were measured in 20 healthy subjects, including 10 young (26±5 yr) and 10 older (65±6 yr) adults using venous occlusion plethysmography before (CON) and after cyclooxygenase inhibition with oral indomethacin (INDO).

**RESULTS:** Baseline MAP, FBF, and forearm vascular conductance (FVC) were not different between young and old adults during either trial. During the INDO trial, MAP increased during reactive hyperemia in the old (+7±7 mmHg) but not young adults (-1±3 mmHg). Peak FVC was similar between young and old adults during the CON trial (p=0.59), but tended to be lower in older adults during INDO (26±5 AU vs. 37±5 AU; p=0.06). The magnitude of change in FVC peak between the CON and INDO trials was significantly different between groups with increased FVC peak in young (+9±4 AU) and decreased FVC peak in old (-5±6 AU). Similarly, the change in FVC area under the curve (AUC) between CON and INDO trials was increased in young (+1±1 AU) and decreased in old (-2±2 AU). **CONCLUSIONS:** There were no age-related differences in post-ischemic vascular conductance prior to cyclooxygenase inhibition. Contrary to our hypothesis, peak vascular conductance after indomethacin was lower in older adults compared with younger adults. These results suggest that aging alters the effect of cyclooxygenase inhibition on forearm vasodilator responses to reactive hyperemia. **Independent Relationship Between Flexibility And Arterial Stiffness In Patients With Stroke**

Yong-Hee Lee, Soo-Hyun Park, Eun-Sun Yoon, Ki Won Lee, Sae Young Jae. *University of Seoul, Seoul, Korea, Republic of.*

*(No relationships reported)*

Increased arterial stiffness is a strong predictor of future cardiovascular events and mortality. Flexibility is associated with arterial stiffness in healthy populations, but it is unclear if this is also the case in patients with stroke.

**PURPOSE:** We investigate the relationship between flexibility and arterial stiffness in patients with stroke.

**METHODS:** Ninety four patients with stroke (male n=68, female n=26, 61±9 years) were recruited in the study. We measured a modified sit and reach test on chair as an index of flexibility. Arterial stiffness was assessed by carotid-femoral pulse wave velocity using applanation tonometry.

**RESULTS:** There was a significant inversely association between flexibility and pulse wave velocity (r=-0.48, p<0.001). In multivariable linear regression models that adjusted for age, gender, body mass index, duration of stroke, systolic blood pressure, heart rate, medication, an cardiorespiratory fitness, flexibility was an independent associated with pulse wave velocity (β=-0.19, p<0.05). Patients with high flexibility had significantly lower pulse wave velocity than patients with low flexibility (8.9m/s vs. 11.8m/s, p<0.001).

**CONCLUSIONS:** These findings demonstrate that high flexibility was associated with low arterial stiffness independent of risk factors and cardiorespiratory fitness in patients with stroke.

**Aerobic Exercise Training Improves Arterial Stiffness in Relation to the Reduction of Visceral Adiposity in Middle-Aged Men with Abdominal Obesity**

Yoshikazu Takanami<sup>1</sup>, Yukari Kawai<sup>2</sup>, Wataru Aoi<sup>3</sup>, Yuko Tanimura<sup>2</sup>, Hiroshi Ichikawa<sup>4</sup>, Yukari Furukawa<sup>1</sup>, Toshikazu Yoshikawa<sup>3</sup>. <sup>1</sup>*Otsu Women's University, Tokyo, Japan.* <sup>2</sup>*Kyoto Prefectural University of Medicine, Kyoto, Japan.* <sup>3</sup>*Kyoto Prefectural University, Kyoto, Japan.* <sup>4</sup>*Doshisha University, Kyoto, Japan.*

*(No relationships reported)*

**PURPOSE:** To elucidate whether regular aerobic exercise reduces visceral adiposity and arterial stiffness in middle-aged men with abdominal obesity.

**METHODS:** We assigned forty-six sedentary subjects (51.0±0.9 y; mean±SE) to two groups: one that engaged in 30-60 minutes of aerobic exercise/day at least 2 times/week for 16 weeks (Ex, n=36), and one age-matched sedentary control group (C, n=10). Body fat indices and brachial-ankle pulse wave velocity (baPWV) were measured at baseline and after 16 weeks. Visceral fat area (VFA) and subcutaneous fat area (SFA) at the umbilical level was determined by computed tomographic scanning (CT).

**RESULTS:** According to the baseline CT examination, there were 16 subjects with abdominal obesity (VFA≤100cm<sup>2</sup>; Ob) in Ex (Ex-Ob), and 5 in C (C-Ob). Twenty subjects were not abdominally obese in Ex (Ex-N). Exercise training reduced VFA in Ex-Ob (139.6±7.3cm<sup>2</sup> to 113.4±7.9cm<sup>2</sup>; p<0.001) and also in Ex-N (58.0±3.9cm<sup>2</sup> to 48.6±3.7cm<sup>2</sup>; p<0.001). baPWV of Ex-Ob decreased from 1340.9±39.3cm/sec to 1281.6±39.1cm/sec (p<0.05) through exercise training. However, no significant change of baPWV was detected in Ex-N and in C-Ob after 16 weeks period. There was a significant correlation between the changes in VFA and the changes in baPWV in Ex (r=0.338, p<0.05).

**CONCLUSIONS:** Regular aerobic exercise reduced visceral adiposity and arterial stiffness in abdominal obesity. This reduction of arterial stiffness through aerobic exercise training may be partially caused by the reduction of visceral fat.

**Measurement Of Peak-flow To Rest-flow Ratio In Children After Aerobic Exercise Using Laser Doppler Fluximetry**

Goutham Ganesan, Diana Vigil, Scott Graf, Shlomit Aizik, Dan Cooper, Pietro Galassetti. *UC Irvine, Irvine, CA.*

*(No relationships reported)*

**PURPOSE:** The non-invasive assessment of endothelial function has become a key part of the study of the progression of dysmetabolic states (obesity, diabetes). Reliable measurements have however proven challenging during metabolic perturbations (i.e. physical exercise, invoked in these conditions both as a therapeutic and as a testing tool), and in vulnerable populations such as obese and diabetic children. We sought to optimize the use of an established technique measuring skin microcirculation reactivity, Laser Doppler Fluximetry (LDF), in the post-exercise state in healthy and obese children, and to determine a reproducible method for analyzing and reporting measurements of reactive hyperemia.

**METHODS:** Ten children (13.3±1.1 years, 3 f; 5 obese, 5 healthy weight) completed standard incremental maximal exercise tests. Post-Occlusive Reactive Hyperemia (PORH) testing (1 min occlusion, >280 mm Hg at wrist, probe placed over middle phalanx of third digit, recumbent position) was conducted 5 min before, and 5 and 15 min post-exercise (Periflux 5000, Perimed, Sweden). Perfusion index (PI) and temperature were continuously measured. Data taken one minute before and two minutes after occlusion was analyzed with PSW software, provided by manufacturer, yielding calculations of time to maximum PI (TM), rest, or baseline pre-occlusion PI (RF), peak post-occlusion PI (PF), and biological zero (BZ).

**RESULTS:** We observed that the ratio of peak flow to rest flow (PF/RF) was very consistent within and across subjects, showing a clear post-exercise vasodilatory effect (pre-exercise: 1.59±.08; 5 min post, 1.75±.18; 15 min post 1.85±.18). As a relative index, PF/RF prevented imprecision due to varying baseline values, changes in probe positioning, and inaccuracies in determination of PI absolute values, and could therefore be used as reliable index of maximal hyperemic response in our study group.

**CONCLUSIONS:** Our data suggests that post-occlusive PF/RF ratio may be a reproducible index of both resting vascular function, and of post-exercise vasodilation in children with a wide range of BMI values. Broader application of this variable may help standardize prior non-homogeneous findings of altered post-occlusive hyperemic response in pediatric obese populations, often reported in arbitrary perfusion units.

**Brachial Artery Low Flow-Mediated Constriction in Individuals with Increased Cardiovascular Risk**

Kunihiko Aizawa, Salim Elyas, Damilola D. Adingupu, Angela C. Shore, W David Strain, Phillip E. Gates. *Peninsula Medical School, Exeter, United Kingdom.*  
(No relationships reported)

Low flow-mediated constriction (LFMC) is a recently introduced technique that has been proposed to provide additional and complementary information to "traditional" flow-mediated dilation (FMD). However, whether LFMC occurs when the test is performed in the brachial artery remains controversial and LFMC has not been well studied in older individuals with increased cardiovascular (CV) risk.

**PURPOSE:** The purpose of this study was 1) to determine whether LFMC would differ between older individuals with increased CV risk and healthy older individuals, and 2) to examine relationships between LFMC and estimated shear rate (SR).

**METHODS:** Data from 2 groups [56 individuals with increased CV risk (history of recent stroke or transient ischemic attack, presence of hypertension and/or type2 diabetes, 67.5±9.2yrs, 12F), and 20 individuals with no clinically manifest CV disease (65.8±4.3yrs, 16F)] were compared. FMD and LFMC were assessed using a 5-min forearm cuff occlusion technique. Diameter and blood velocity data obtained by a Doppler ultrasound machine were used for the calculation of FMD, LFMC, and SR indices using a semi-automated edge detection software. Two indices of SR were calculated: SR during LFMC (SRlow) and the differences in SR between baseline and LFMC (SRdiff).

**RESULTS:** The prevalence of LFMC was 60.7% in the increased CV risk group and 45.0% in the healthy group. LFMC tended to be greater in the increased CV risk group (-0.63±1.64%) than the healthy group (0.24±2.04%, p=0.058). In the healthy group, LFMC was significantly correlated with FMD (r=0.55, p<0.05), whereas no association was observed in the increased CV risk group. Neither SRlow nor SRdiff was correlated with LFMC.

**CONCLUSION:** These results suggest that LFMC is independent of SR during cuff occlusion in our populations. Whereas greater LFMC may lead to a lower FMD in healthy older individuals, the FMD response may be independent of LFMC in older individuals with increased CV risk. The trend for a difference in LFMC between the groups requires further investigation. Supported in part by Peninsula NIHR Clinical Research Facility.

**Responsiveness of the Popliteal Artery in Older Trained and Untrained Women**

Kaitlin M. McLay<sup>1</sup>, Shilpa Dogra<sup>2</sup>, Donald H. Paterson, FACSM<sup>1</sup>. <sup>1</sup>University of Western Ontario, London, ON, Canada. <sup>2</sup>Acadia University, Wolfville, NS, Canada.  
(No relationships reported)

Age and sex are two major determinants of the flow-mediated dilation (FMD) response. Advancing age is associated with endothelial dysfunction, with older women displaying a more prominent decline. The role of aerobic fitness on preserving endothelial function in post-menopausal women is not well understood. Further, the response of the popliteal artery among older women is not well documented.

**PURPOSE:** To determine whether there are differences between the FMD response of the popliteal artery between older women (ages 60-85 years) who are endurance trained compared to older women who are not endurance trained.

**METHODS:** Ultrasound-derived arterial diameter and Doppler mean blood velocity (MBV) of the popliteal artery were measured in 10 trained (age: 62.6 ± 3.3 yrs, VO2max : 39.5 ± 8.7 ml·kg<sup>-1</sup>·min<sup>-1</sup>) and 11 untrained (age: 68.7 ± 6.0 yrs, VO2max: 24.0 ± 2.6 ml·kg<sup>-1</sup>·min<sup>-1</sup>) healthy post-menopausal women at rest and after 5 min of distal cuff occlusion. Blood flow (BF) and shear rate (SR) were calculated as 60×MBV×3.14r<sup>2</sup> and MBV/diameter respectively. Multivariate analysis of variance was conducted to determine between group differences and linear regression analyses were conducted with FMD, MBV, BF and SR as outcomes.

**RESULTS:** No significant differences between peak diameter, MBV, BF and SR were noted between groups. The percent change in diameter following cuff release was 5.6% in the trained group and 4.8% in the untrained group. Age was a significant predictor of MBV, BF and SR such that older women were more likely to have higher MBV and SR.

**CONCLUSIONS:** A greater MBV, BF and SR are required to induce the same change in diameter of the popliteal artery as post-menopausal women age, regardless of their aerobic fitness level. This has implications for the utility of FMD as a measure of exercise training related endothelial function improvements.

2312 Board #358 MAY 31 8:00 AM - 9:30 AM

**The Effect of High-Dose Atorvastatin Therapy on Peripheral Arterial Stiffness in Healthy Adults**

Jeffrey A. Capizzi, Amanda L. Augeri, Adam S. Grimaldi, Michael C. White, Paul D. Thompson, FACSM, Beth A. Parker. *Hartford Hospital, Hartford, CT.*  
(No relationships reported)

**PURPOSE:** Statin therapy has been shown to improve peripheral arterial stiffness in clinical populations. The purpose of this study was to examine the effect of high dose atorvastatin therapy on peripheral arterial stiffness in healthy adults.

**METHODS:** Healthy, statin naïve adults (20-76 years old) were randomized to either 80mg atorvastatin (ATOR: n=17) or placebo (PL: n=22) for 6 months. Peripheral (femoral-tibial) pulse wave velocity (PWV) was measured before and after drug treatment. Change in PWV ( $\Delta$  PWV) was calculated as the difference between baseline and post treatment values. Repeated measures ANCOVA tested differences in PWV over 6 months by drug treatment group, investigating potential covariates such as baseline age, fitness (VO2max), body mass index, blood pressure, blood lipids and physical activity (Actical accelerometer) as well as changes in these parameters over the trial.

**RESULTS:** Baseline characteristics were similar between statin and placebo groups including PWV (p=0.62). Low density lipoprotein (LDL) cholesterol decreased significantly (-49.8 ± 16.6%; p<0.01) in the ATOR group with no change in LDL for the PL group (0.3 ± 14.6% ; p=0.92). There was no difference in  $\Delta$  PWV between ATOR and PL groups (p=0.52). However, there was a significant interaction between time spent in moderate and vigorous physical activity at baseline and drug treatment (both p < 0.05) such that in the ATOR group only,  $\Delta$  PWV with statin treatment (0.12 ± 1.95 m/s) was directly related to baseline levels of moderate activity (Pearson coefficient = 0.55; p = 0.02) and inversely related to baseline levels of vigorous activity (Pearson coefficient = -0.56; p = 0.02).

**CONCLUSIONS:** Healthy adults with high levels of moderate physical activity and low levels of vigorous physical activity at the beginning of the trial exhibited reduced peripheral arterial stiffness with statin therapy. The interaction between atorvastatin and baseline physical activity level suggests that direct effects of statin therapy on the peripheral vasculature may be influenced by exposure to chronic physical activity. Resultantly, physical activity levels should be monitored in clinical trials assessing vascular effects of statins.

---

2313 Board #359 MAY 31 8:00 AM - 9:30 AM

**The Effect Of An Acute Bout Of Exercise On Endothelial Function Following Ischemic-reperfusion Injury**

Jennifer L. Lawrence, Mitchell R. Stacy, Sarah A. McGlinchey, Erin C. Garmyn, Barry W. Scheuermann. *The University of Toledo, Toledo, OH.*  
(No relationships reported)

Previous studies have shown that ischemic-reperfusion injury (IRI) leads to endothelial dysfunction, a hallmark of poor vascular health. It has been established that endothelial dysfunction is one of the first markers of atherosclerosis and thus, identifying conditions that lead to endothelial dysfunction have important clinical implications. Participation in regular physical activity can provide some protection against IRI through a preconditioning mechanism as well as improve endothelial function. However, it is not currently known if an acute bout of exercise performed prior to IRI can lead to a protective condition whereby endothelial dysfunction is prevented or reduced.

**PURPOSE:** To determine if an acute bout of moderate intensity exercise can provide an alternative method of preconditioning to either prevent or attenuate the effects of IRI on endothelial function.

**METHODS:** Nine healthy subjects (6 males; 3 females, 21.7 ± 3.2 yrs, ± SD) participated in three protocols including, ischemic-reperfusion injury (IRI), exercise only (EXER), and preconditioning (COND). IRI was induced by inflating a cuff placed around the upper arm to 200 mm Hg for 20 minutes. The COND protocol involved running on a treadmill at a moderate intensity (60% APMHR) for 45 min prior to application of IRI. Endothelial function in the brachial artery was assessed using flow-mediated dilation (FMD) before and at 120, 140 and 160 min after the initial FMD measurement.

**RESULTS:** Compared to pre-injury FMD, both IRI (Pre;  $7.56 \pm 1.04$ ; Post  $2.57 \pm 1.07$  %FMD,  $p < 0.05$ ) and COND (Pre;  $7.23 \pm 0.94$ ; Post  $2.34 \pm 1.05$  %FMD,  $p < 0.05$ ) resulted in a decrease in vascular response at 120 min. The FMD at 140 min remained blunted ( $p < 0.05$ ) for IRI but returned to pre-injury values by 160 min. The FMD for COND returned to pre-injury values by 140 min with no further change at 160 min. The EXER only intervention did not result in a significant change in %FMD at any time points.

**CONCLUSIONS:** Ischemic-reperfusion resulted in a significant decrease in endothelial function during the IRI and COND protocols but %FMD returned to pre-injury values by 140 for COND and not until 160 min for IRI. An acute bout of moderate intensity exercise performed prior to IRI may not attenuate the magnitude of endothelial dysfunction but recovery from IRI may be speeded by exercise.

**2314** Board #360 MAY 31 8:00 AM - 9:30 AM  
**50%vo2max-Arm-Crank Exercise May Not Improve Arterial Stiffness**

Yukimi Maki, Hajime Miura, Megumi Sugino. *Univ. of Tokushima, Tokushima, Japan.*  
(No relationships reported)

The endurance exercise such as cycling, walking, or running is useful for improving arterial stiffness. Subjects suffering from partial paralysis or arthritis, however, are not able to conduct these kinds of lower-limb exercise. Previous research suggested that 60-70%VO<sub>2</sub>max-arm-crank exercise increased arterial stiffness. Therefore, in order to improve arterial stiffness by arm-exercise, lower exercise intensity might be needed.

**PURPOSE:** We tried to identify the acute effect of 50%VO<sub>2</sub>max-arm-crank exercise on arterial stiffness determined by pulse wave velocity.

**METHODS:** Six healthy recreationally active adult men were studied under two experimental trials on 2 separate days. The order of experiments was randomized among 30min-arm-crank exercises at 50%VO<sub>2</sub>max (50%-Arm) and control (C; seated rest while reading). Before and for 45min at 15min intervals after each trial, brachial to ankle pulse wave velocity (baPWV), brachial systolic and diastolic blood pressure (SBP, DBP) and heart rate (HR) were obtained while in the supine position.

**RESULTS:** Baseline hemodynamic values were not different among two trials. In 50%-Arm trials, SBP, DBP, and HR returned to baseline at 15-min recovery. Compared with rest value ( $999.5 \pm 26.4 \text{ cm} \cdot \text{sec}^{-1}$ ), baPWV was significantly elevated after 15-min recovery ( $1083.0 \pm 38.8 \text{ cm} \cdot \text{sec}^{-1}$ ), 30-min recovery ( $1047.7 \pm 34.3 \text{ cm} \cdot \text{sec}^{-1}$ ), 45-min recovery ( $1016.0 \pm 64.6 \text{ cm} \cdot \text{sec}^{-1}$ ). In C trial, however, there were no changes in SBP, DBP, HR, and baPWV through the trial.

**CONCLUSIONS:** These results indicate that acute 50%VO<sub>2</sub>max-arm-crank exercise increased baPWV, which was the opposite reaction of lower-limb exercise. Therefore, in order to improve arterial stiffness by arm-crank exercise, less than 50%VO<sub>2</sub>max should be recommended.

---

**2315** Board #361 MAY 31 8:00 AM - 9:30 AM  
**Systemic Vascular Resistance Response to Exercise in Morbidly Obese College-Aged Mexican-American Females**

David Wittenburg, Jared Montoya, Vanessa Martinez, Stephanie Rodriguez, Idalia Obregon, Alexis Martinez. *University of Texas at Brownsville, Brownsville, TX.*  
(No relationships reported)

Systemic vascular resistance response (SVRR) to exercise provides insight into potential cardiovascular disease. However, one potential risk factor that may contribute to reduction of the SVRR may be the over accumulation of adipose tissue. Research in obesity-related reduction of SVRR in Mexican-American females is lacking.

**PURPOSE:** The purpose of this study was to examine the SVRR to exercise of morbidly obese Mexican-American college-aged females compared to non-morbidly obese females.

**METHODS:** Subjects (N=79) were limited to Mexican-American females of college age (mean =  $23.59 \pm 5.85$  yrs) recruited across campus. Body fat percent (BF%) was recorded by air plethysmography. Radial pulse wave contour tonometry was used to determine large artery elasticity index (LAEI) and small artery elasticity index (SAEI) and systemic vascular resistance (SVR). Pulse wave contour analysis was recorded prior to a multistage submaximal treadmill exercise test and within 5 minutes after completing the submaximal test. Predicted VO<sub>2</sub> was calculated from the submaximal test. Subjects were categorized by BF% and VO<sub>2</sub>. The SVRR was calculated as the difference between the exercise pretest SVR and posttest SVR.

**RESULTS:** The non-morbidly obese group had significantly greater predicted VO<sub>2</sub> ( $35.05 \pm 5.9 \text{ ml/kg/min}^{-1}$ ) than the morbidly obese group ( $28.25 \pm 5.9 \text{ ml/kg/min}^{-1}$ ,  $p < 0.05$ ). The mean SVRR for non-morbidly obese fit subjects ( $120.72 \pm 205.17 \text{ dynes/sec/cm}^2$ ) was significantly greater than for the morbidly obese unfit subjects ( $37.21 \pm 133.83 \text{ dynes/sec/cm}^2$ ,  $p < 0.05$ ). To determine if fitness was a factor for SVRR a one-way ANOVA was conducted that excluded the independent variable of obesity. The results of the ANOVA indicated no significant differences for SVRR between the fitness groups. No significant differences between the LAEI and the SAEI were observed between the groups.

**CONCLUSIONS:** The mediation of morbid obesity attributes to the loss of SVRR in this sample of Mexican-American females; placing them at greater risk for CVD. One possible explanation is that obese individuals typically have less circulating adiponectin. Other research indicates that Mexican-American populations have reduced levels of adiponectin than other population groups.

**2316** Board #362 MAY 31 8:00 AM - 9:30 AM  
**Acute Effects of Stretching Exercise on Arterial Stiffness**

Yuko Gando<sup>1</sup>, Kenta Yamamoto<sup>2</sup>, Hiroshi Kawano<sup>1</sup>, Isao Muraoka<sup>1</sup>. <sup>1</sup>Waseda University, Saitama, Japan. <sup>2</sup>University of North Texas Health Science Center, Fort Worth, TX. (Sponsor: Mitsuru Higuchi, FACSM)  
(No relationships reported)

Increased arterial stiffness is a risk factor for cardiovascular diseases. Poor flexibility is associated with arterial stiffening. Currently, it is unknown whether stretching exercise induces favorable changes in the arterial stiffness.

**PURPOSE:** To determine the acute effects of stretching exercise on arterial stiffness.

**METHODS:** Seven healthy adults (2 men and 5 women, age  $24 \pm 1$  yrs) were studied separately under parallel experimental trials on two days. The order of experiments was performed randomly between stretching exercise (40 stretching exercises for whole body at maximum range of motion) and sham control (seated rest in the exercise room). Arterial stiffness (baPWV; brachial-ankle pulse wave velocity) was measured before and immediately after the stretching exercise as well as 15, 30, 45, 60 minutes after the stretching exercise.

**RESULTS:** Baseline baPWV was not different between the two experimental trials (Stretching;  $1011 \pm 55$  vs. Control;  $992 \pm 55 \text{ cm/s}$ ,  $P > 0.05$ ). The baPWV significantly decreased 45 and 60 minutes after stretching exercise (45 min;  $958 \pm 46$ , 60 min;  $951 \pm 42 \text{ cm/s}$ ,  $P < 0.05$  respectively). In contrast, during the sham control trial, no significant changes in baPWV were observed. Systolic blood pressure, mean arterial pressure, and diastolic blood pressure were not significantly different from baseline values at any time point in both experimental trials.

**CONCLUSIONS:** These results indicated that stretching exercise decreases acutely arterial stiffness, suggesting that to improve flexibility induced by stretching exercise may be capable of modifying arterial stiffening. This study was supported by a Grant-in-Aid for Research Activity Start-up (#23800060, Y.Gando).

**2317** Board #363 MAY 31 8:00 AM - 9:30 AM  
**Vitamin C Prevents Attenuation of Flow-mediated Dilation Following Exercise with Augmented Oscillatory and Retrograde Shear**

Blair D. Johnson<sup>1</sup>, Kieren J. Mather<sup>2</sup>, Sean C. Newcomer<sup>3</sup>, Timothy D. Mickleborough<sup>1</sup>, Janet P. Wallace, FACSM<sup>1</sup>. <sup>1</sup>Indiana University, Bloomington, IN. <sup>2</sup>Indiana University, Indianapolis, IN. <sup>3</sup>Purdue University, West Lafayette, IN.  
(No relationships reported)

Elevated oscillatory and retrograde shear rate (SR) reduces flow-mediated dilation (FMD) possibly due to oxidative stress.

**PURPOSE:** We tested the hypothesis that the antioxidant vitamin C would prevent the attenuation of FMD following exercise with elevated oscillatory and retrograde SR.

**METHODS:** Twelve lean healthy men ( $26.3 \pm 0.9$  years) ingested 1 g of vitamin C or placebo (1 g sucrose) before undergoing two supine cycle ergometer exercise trials (20 min at 90 W). A forearm blood pressure cuff was inflated to 60 mm Hg during exercise to increase oscillatory and retrograde SR in one arm. The contralateral arm served as the control. Brachial artery FMD was assessed in both arms before and promptly after exercise. SR profiles were assessed at baseline and during exercise. The oscillatory shear index (OSI) was determined as:  $(\text{retrograde} / (\text{retrograde} + \text{lantegrade}))$ .

**RESULTS:** Baseline FMD was not different between arms or trials ( $P > 0.52$  for both) (placebo: cuffed  $4.9 \pm 2.4\%$ , control  $4.4 \pm 1.5\%$ ; vitamin C: cuffed  $4.9 \pm 3.0\%$ , control  $4.5 \pm 2.4\%$ ). Antegrade SR increased during exercise ( $P < 0.01$ ), was not different between trials ( $P = 0.37$ ) but was greater in the cuffed arm ( $P = 0.01$ ) (placebo: cuffed  $52.8 \pm 13.0 \text{ s}^{-1}$ , control  $49.6 \pm 12.5 \text{ s}^{-1}$ ; vitamin C: cuffed  $53.2 \pm 13.0 \text{ s}^{-1}$ , control  $45.4 \pm 9.0 \text{ s}^{-1}$ ). Retrograde SR increased in both arms during exercise ( $P < 0.01$ ) and was greater in the cuffed arm in both trials ( $P < 0.01$ ) (placebo: cuffed  $36.7 \pm 10.8 \text{ s}^{-1}$ , control  $27.9 \pm 9.7 \text{ s}^{-1}$ ; vitamin C: cuffed  $35.6 \pm 10.3 \text{ s}^{-1}$ , control  $26.1 \pm 6.7 \text{ s}^{-1}$ ). Mean SR was not different between arms or trials ( $P > 0.10$  for both) (placebo: cuffed  $16.1 \pm 14.7 \text{ s}^{-1}$ , control  $21.7 \pm 15.9 \text{ s}^{-1}$ ; vitamin C: cuffed  $17.6 \pm 11.9 \text{ s}^{-1}$ , control  $19.2 \pm 9.5 \text{ s}^{-1}$ ). The OSI was greater in the cuffed arm vs. control ( $P = 0.02$ ) and was not different between trials ( $P = 0.88$ ) (placebo: cuffed  $0.40 \pm 0.1$ , control  $0.36 \pm 0.1$ ; vitamin C: cuffed  $0.40 \pm 0.1$ , control  $0.37 \pm 0.1$ ). Postexercise FMD in the control arms increased ( $P < 0.01$ ) but were not different between trials ( $P > 0.05$ ) (placebo  $7.7 \pm 2.8\%$  vs. vitamin C  $7.1 \pm 3.5\%$ ). FMD in the cuffed arm was unchanged in the placebo trial ( $5.4 \pm 2.4\%$ ,  $P = 0.52$ ). FMD increased in the vitamin C trial ( $6.6 \pm 3.3\%$ ,  $P = 0.03$ ).

**CONCLUSIONS:** Vitamin C prevents the attenuation of FMD after exercise with elevated oscillatory and retrograde SR through an apparent reduction of oxidative stress.

**2318** Board #364 MAY 31 8:00 AM - 9:30 AM

**Effects of Cigarette Smoking on Endothelial Function in Chronic Smokers Compared with Healthy Young Adults**

Marvin T. Dang<sup>1</sup>, Deborah L. Fearheller<sup>1</sup>, Ryan A. Harris<sup>2</sup>, Christian K. Roberts, FACSM<sup>1</sup>. <sup>1</sup>University of California, Los Angeles, Los Angeles, CA. <sup>2</sup>Georgia Health Sciences University, Augusta, GA.  
(No relationships reported)

**PURPOSE:** Previous studies have suggested endothelial dysfunction as a predictor of adverse cardiovascular events, and cigarette smoking impairs endothelial function. To examine the degree to which smoking cigarettes affects endothelial function in individuals, we compared brachial artery flow-mediated dilation (FMD) between young adult smokers (100 cigarette lifetime minimum, and 15 per month) and non-smoking recreationally-active young adults.

**METHODS:** The FMD test was performed on 30 young adult smokers (26 M, 4 F, age  $25.2 \pm 4.6$  yrs) and 28 non-smokers (19 M, 9 F age  $24.2 \pm 3.7$  yrs). Parameters of the FMD test include, baseline and peak diameter, FMD (% and absolute change), shear rate area under the curve ( $\text{s}^{-1}$ , AUC), normalized FMD response (FMD (%)/Shear rate ( $\text{s}^{-1}$ , AUC). Smoking status was verified via breath carbon monoxide (CO) concentration.

**RESULTS:** FMD ( $5.6 \pm 3.8\%$  vs.  $7.6 \pm 3.1\%$ ,  $p = 0.05$ ) and the normalized FMD response ( $0.41 \pm 0.35$  vs.  $0.73 \pm 0.52$ ,  $p = 0.01$ ) were both lower in smokers compared to non-smokers. There were sex differences in baseline diameter ( $0.35 \pm 0.03$  cm vs.  $0.41 \pm 0.06$  cm;  $p = 0.001$ ) and peak diameter ( $0.37 \pm 0.01$  cm vs.  $0.43 \pm 0.06$  cm  $p = 0.001$ ), with men exhibiting higher for both measures. No differences ( $p > 0.05$ ) between smokers and non-smokers were observed for baseline diameter ( $0.38 \pm 0.06$  cm vs.  $0.41 \pm 0.06$  cm), peak diameter ( $0.41 \pm 0.06$  cm vs.  $0.43 \pm 0.06$  cm), absolute change in diameter ( $0.03 \pm 0.01$  cm vs.  $0.02 \pm 0.02$  cm), and shear rate ( $14011.98 \pm 10.456.17 \text{ s}^{-1}$ , AUC vs.  $16714.42 \pm 8128.99 \text{ s}^{-1}$ , AUC). Further, there was no correlation with breath CO concentration and any FMD variable in smokers.

**CONCLUSION:** These data support previous studies which indicate that chronic smoking results in endothelial dysfunction. Our ongoing randomized-controlled trial will determine if resistance training can improve endothelial function in chronic smokers and whether the levels after training will be similar to those in non-smokers before training.

**2319** Board #365 MAY 31 8:00 AM - 9:30 AM

**Cross-Sectional Analysis of Arterial Stiffness in Chronic Smokers Compared with Physically-Active Young Adults**

Michelle L. LaFranchi, Sang Moon, Christian K. Roberts, FACSM. UCLA, Los Angeles, CA.  
(No relationships reported)

**PURPOSE:** Previous studies have demonstrated the beneficial effect of exercise on arterial stiffness, an independent predictor of cardiovascular disease risk, in healthy, young adults. However, the effects of exercise on chronic smokers are not known. The present study compared baseline arterial stiffness measurements between smoking and non-smoking, recreationally-active, young adults as part of a randomized-controlled trial (RCT) to investigate the effects of resistance training (RT) and smoking cessation on vascular function in young adult, chronic smokers.

**METHODS:** Brachial blood pressure and arterial tonometry measurements were performed on 30 young adult smokers (26 men, 4 women, age  $25 \pm 4.6$  yr) and 28 non-smokers (19 men, 9 women, age  $24 \pm 3.7$  yr). Smokers reported the number of cigarettes smoked/day over the past 30 days. Arterial stiffness was assessed in duplicate via measurements of cPWV and radial artery pulse wave analysis (PWA) using applanation tonometry (Sphygmocor) to derive augmentation index (AIx), sub-endocardial viability ratio (SEVR, an index of cardiac perfusion), pulse pressure amplification (PPA), and mean aortic pressure (aMAP). Results are reported as mean  $\pm$  standard deviation.

**RESULTS:** Despite no significant differences in brachial blood pressures, compared with healthy, recreationally-active control subjects, smokers exhibited higher cPWV ( $6.6 \pm 1.1 \text{ m/s}$  vs.  $5.9 \pm 0.8 \text{ m/s}$ ,  $p < 0.01$ ) and AIx ( $-2.6 \pm 12.4\%$  vs.  $-11.2 \pm 12.4\%$ ,  $p < 0.05$ ). Additionally, SEVR ( $189.4 \pm 32.8$  vs.  $212.9 \pm 42.7$ ,  $p < 0.05$ ) and PPA ( $1.6 \pm 0.1$  vs.  $1.5 \pm 0.1$ ,  $p < 0.005$ ) were lower in smokers. No difference in aMAP was noted ( $93.8 \pm 9.5 \text{ mmHg}$  vs.  $93.6 \pm 9.6 \text{ mmHg}$ ). In smokers, there was a significant difference in cPWV between less frequent (6 cigarettes/day) ( $6.0 \pm 0.9 \text{ m/s}$  vs.  $6.9 \pm 1.1 \text{ m/s}$ ,  $p < 0.05$ ).

**CONCLUSIONS:** Chronic smokers exhibit higher arterial stiffness and lower cardiac perfusion, even at a young age. Furthermore, individuals who smoke more cigarettes per day present higher cPWV. These results agree with prior studies that cigarette smoking increases arterial stiffness. Our ongoing RCT will determine if RT can improve arterial stiffness and induce smoking cessation in chronic smokers.

**2320** Board #366 MAY 31 8:00 AM - 9:30 AM

**Blood Flow Regulation is Blunted during Exercise in Patients with Cystic Fibrosis**

Ryan A. Harris<sup>1</sup>, Breana Berry<sup>1</sup>, Spencer Poore<sup>1</sup>, Dabney Eidson<sup>1</sup>, Gareth W. Davison, FACSM<sup>2</sup>, Katie T. McKie<sup>1</sup>. <sup>1</sup>Georgia Health Sciences University, Augusta, GA. <sup>2</sup>University of Ulster, Jordanstown, Ireland.  
(No relationships reported)

Cystic fibrosis (CF) is an autosomal recessive genetic disorder that affects multiple organ systems. The non-functional CFTR protein channel characteristic in patients with CF has recently been discovered in skeletal muscle and vascular endothelium and may be linked to observed exercise intolerance in these patients.

**PURPOSE:** To examine the peripheral hemodynamic response during exercise in children with CF compared to matched controls.

**METHODS:** 14 patients with CF and 14 demographically matched controls underwent pulmonary function tests and a maximal cycle exercise test. Brachial artery diameter and blood flow were measured at baseline and during progressive submaximal exercise; 20%, 40% and 60% of maximal work load. Blood samples were taken at baseline and during 60% of maximal workload for the detection of ascorbyl free radicals.

**RESULTS:** All subject characteristics were similar between CF and control groups (all  $p > 0.05$ ) except for lung function ( $\text{FEV}_1/\text{FVC}$ ,  $\text{FEV}_1\%$  of predicted, and  $\text{FEF}_{25-75}$ ; all  $p < 0.05$ ). Although not significant, exercise capacity was lower in patients with CF compared to controls ( $\text{VO}_2 = 34.5 \pm 6.7$  vs.  $37.8 \pm 9.2 \text{ ml}\cdot\text{kg}^{-1}\cdot\text{min}^{-1}$ ;  $p = 0.287$ ). During submaximal exercise, all subjects exhibited an increase in blood flow and blood velocity ( $p < 0.001$ ) with increased exertion. However, patients with CF exhibited a blunted retrograde blood velocity ( $3.1 \pm 0.9$  vs.  $5.9 \pm 0.8 \text{ cm/s}$ ;  $p = 0.013$ ) and retrograde blood flow ( $14.3 \pm 7.7$  vs.  $23.6 \pm 4.6 \text{ l/min}$ ;  $p = 0.095$ ) during 60% exercise compared to the controls, indicating an impaired blood flow regulation during exercise. No differences ( $p = 0.894$ ) in ascorbyl free radical concentration was observed between patients ( $5.23 \times 10^5 \text{ A.U}$ ) and controls ( $6.01 \times 10^5 \text{ A.U}$ ) at baseline, however, patients with CF appear to have an exaggerated ( $p = 0.179$ ) free radical response to exercise compared to controls ( $\Delta 1.47 \times 10^6$  vs.  $4.25 \times 10^5 \text{ A.U.}$ , respectively).

**CONCLUSION:** These data are the first to identify an impaired blood flow regulation during exercise in patients with CF compared to controls, which may, in part, be explained by the greater free radical response to exercise in these patients compared to controls. This work was supported in part by grants from the American Heart Association (R.A.H) and Child Health Discovery Institute (R.A.H).

2321 Board #367 MAY 31 8:00 AM - 9:30 AM

**Effect of Maximal Exercise on Carotid Artery Stiffness in African-American and Caucasian Men and Women**

Bo Fernhall, FACSM<sup>1</sup>, Sushant Randive<sup>2</sup>, Huimin Yan<sup>2</sup>, Abbi Lane<sup>1</sup>, Rebecca Kappus<sup>1</sup>, Marc Cook<sup>2</sup>, Peng Sun<sup>2</sup>, Shevon Harvey<sup>2</sup>, Kenneth Wilund<sup>2</sup>, Jeffrey Woods, FACSM<sup>2</sup>. <sup>1</sup>University of Illinois at Chicago, Chicago, IL. <sup>2</sup>University of Illinois at Urbana-Champaign, Urbana, IL.  
(No relationships reported)

**PURPOSE:** Arterial stiffness is higher in young African-Americans (AA) vs Caucasians (CA). It has also been suggested that peripheral, but not central arterial stiffness changes differentially after maximal exercise in AA, but only in a select small sample of AA men. The purpose of this study was to compare the arterial response to maximal exercise in AA and CA men and women.

**METHODS:** 36 AA (17 men and 19 women) and 34 CA (18 men and 16 women) between the ages of 18-35 volunteered for the study. Women were tested during menses. Carotid, brachial and femoral artery stiffness were assessed using high resolution ultrasonography. Subjects completed a maximal exercise test with maximal oxygen uptake (VO<sub>2</sub>max) measurements. All arterial measures were conducted in a supine position, at rest and then at 15 and 30 minutes after the maximal exercise.

**RESULTS:** AA exhibited lower VO<sub>2</sub>max (31.8 ± 7.5 vs 37.1 ± 7.8 ml/kg/min) but slightly higher body mass index (27.1 ± 5.2 vs 24.6 ± 3.6) than CA (p<.05). Consequently, all arterial and blood pressure exercise responses were adjusted for VO<sub>2</sub>max and BMI, and the adjusted means are presented. CA increased carotid beta stiffness more following exercise than AA (5.4 ± 0.2 to 6.6 ± 0.3 to 5.9 ± 0.3 vs 5.7 ± 0.2 to 5.9 ± 0.2 to 5.5 ± 0.2; p<.01 for interaction). There was no significant change in brachial or femoral artery stiffness following maximal exercise for either group (data not shown; p>.05). However, aortic SBP significantly decreased in CA but did not change in AA following exercise (105 to 102 to 100 mmHg vs 103 to 105 to 105 mmHg; p<.001 for interaction) and carotid SBP showed a similar response, and approached significance (117 to 117 to 113 vs 113 to 121 to 116 for CA vs AA respectively; p=.07 for interaction).

**CONCLUSION:** These data show that AA exhibited lower changes in carotid artery stiffness following maximal exercise compared to CA despite maintaining higher BP, suggesting an uncoupling of changes in stiffness and blood pressure following exercise. Future work is needed to determine if the differential responses between AA and CA translates to differences in CVD risk.

2322 Board #368 MAY 31 8:00 AM - 9:30 AM

**The Associations Between Aerobic Capacity and Arterial Stiffness in People with Chronic Spinal Cord Injury**

Masae Miyatani<sup>1</sup>, Cameron Moore<sup>1</sup>, Kei Masani<sup>1</sup>, Paul I. Oh<sup>1</sup>, Milos R. Popovic<sup>2</sup>, B Cathy Craven<sup>1</sup>. <sup>1</sup>Toronto Rehabilitation Institute, Toronto, ON, Canada. <sup>2</sup>University of Toronto, Toronto, ON, Canada. (Sponsor: Mitsuru Higuchi, FACSM)  
(No relationships reported)

People living with spinal cord injury (SCI) are a vulnerable population prone to coronary artery disease (CAD) resulting in high morbidity and mortality. Arterial stiffness assessed by pulse wave velocity measured between the common carotid and femoral arteries (cfPWV) is an established independent predictor of CAD morbidity and mortality in the able-bodied population. The European Society of Hypertension and the European Society of Cardiology have defined cfPWV values ≥1200 cm/s as a diagnostic threshold for subclinical vascular end-organ damage. We have previously reported that average cfPWV values among people with chronic SCI above this diagnostic threshold. Prior studies have demonstrated that aerobic capacity is inversely associated with arterial stiffness in able-bodied people. However, the relationship between arterial stiffness, particularly elevated cfPWV values (≥1200 cm/s), and aerobic capacity in people with SCI has not been described.

**PURPOSE:** To explore the associations between aerobic capacity (VO<sub>2</sub>peak) and elevated cfPWV values (≥1200 cm/s) among adults with chronic SCI.

**METHODS:** Thirty men and women with chronic SCI (C2-T12; AIS A-D; 11 paraplegics and 19 tetraplegics; time post injury: 14.3±11.7 yrs; Age: 50.6±11.8 yrs; Height: 175.9 ± 9.4cm; and Weight: 85.7 ± 19.1 kg) participated in the study. cfPWV was measured using two Doppler flowmeters and VO<sub>2</sub>peak was measured by arm ergometry. Subjects were stratified into two groups according to cfPWV values (<1200 cm/sec: low cfPWV, ≥1200 cm/sec: high cfPWV). Logistic regression analysis was used to determine the contribution of aerobic capacity after adjustment for confounders (age, level of injury, and gender) to high cfPWV.

**RESULTS:** Aerobic capacity was significantly and negatively associated with cfPWV (r=-0.459, p<0.045). After correction for other confounding parameters, low aerobic capacity was an independent predictor for high cfPWV (odds ratio = 2.04, 95% CI=1.07- 3.87, p<0.029).

**CONCLUSIONS:** Aerobic capacity is an independent predictor of high cfPWV values (≥1200 cm/sec) among people with chronic SCI. Further research is needed to explore whether improvements in aerobic capacity will reduce arterial stiffness and adverse cardiac outcomes among people with chronic SCI.

2323 Board #369 MAY 31 8:00 AM - 9:30 AM

**Six Weeks of Sprint Interval Training Speeds Flow-Mediated Dilation in Women**

Stephanie M. Reid<sup>1</sup>, Alan R. Smith<sup>1</sup>, T. Dylan Olver<sup>1</sup>, J. Kevin Shoemaker<sup>2</sup>, Peter W.R. Lemon, FACSM<sup>3</sup>. <sup>1</sup>The University of Western Ontario, London, N6A 3K7, ON, Canada. <sup>2</sup>(The Neurovascular Research Laboratory) The University of Western Ontario, London, ON, Canada. <sup>3</sup>(The Exercise and Nutrition Laboratory) The University of Western Ontario, London, ON, Canada.  
(No relationships reported)

The effects of sprint interval training (SIT; 4-7 x 30-45 s all out exercise efforts separated by 4 min of recovery, repeated 3-4 times/wk over 4-6 wk) on endothelial function in the superficial femoral artery (SFA) remains to be elucidated fully.

**PURPOSE:** To assess the effects of 18 sessions of SIT (3 sessions/wk X 6 wk) on flow mediated SFA dilation (FMD) in young women.

**METHODS:** Five women (lean mass=64.7±3.7 kg, fat mass=17.6±3.9 kg, height=163±4 cm, age=24±4 y; mean±SD) arrived at the laboratory after a 12 h overnight fast. SFA diameter and blood velocity (BV) were assessed with ultrasound imaging (4 MHz Doppler ultrasound, 10 MHz Doppler ultrasound imaging, GE Vivid 7) before and after 5 min of suprasystolic cuff inflation of the lower leg. Blood pressure was measured using a Finometer on the right hand. Normalized FMD was analyzed as the maximal Δ in SFA diameter (%) ÷ shear rate (mean BV x 8 ÷ diameter: s-1) measured every 30 s for 5 min following cuff release. This was assessed pre- and 6 weeks post SIT.

**RESULTS:** After training, no changes in baseline SFA diameter (Pre- = 0.61±0.04 vs Post = 0.61±0.04 cm; P=0.80), mean arterial pressure (Pre- = 86.5±8.3 vs Post = 84.9± 4.3 mmHg; P=0.64), peak shear rate (30 s average) after cuff release (Pre- = 390±124 vs Post = 418±125 s-1; P=0.64) or peak flow after cuff release (Pre- = 559±211 vs Post = 666±277 ml-min-1; P=0.41) or normalized FMD (Pre- = 0.014±0.010 vs Post = 0.017±0.006 s-1; P=0.54), were observed. However, time to peak dilation decreased significantly (Pre- = 150±60 vs Post = 54±25 s; P=0.03).

**CONCLUSION:** Six weeks of SIT reduces SFA response time to peak dilation despite a similar shear stimulus suggesting an alteration in shear-induced vasodilation.

**Effects of Diet and/or Low-intensity Resistance Training on Arterial Stiffness and Body Composition in Women**

Arturo Figueroa, Bruce Daggy, Florence Vicil, Alexei Wong, Marcos A. Sanchez-Gonzalez, Bahram H. Arjmandi. Florida State University, Tallahassee, FL.  
(Sponsor: Bo Fernhall, FACSM)  
(No relationships reported)

Arterial stiffness (pulse wave velocity, PWV) is inversely related to muscle strength and mass. High-intensity resistance exercise training (RET) preserves lean soft tissue mass (LSTM) during weight loss, but it may increase PWV. Although low-intensity RET with slow movement (LIRET) may improve LSTM and PWV, its effects on PWV and LSTM during weight loss are unknown.

**PURPOSE:** To determine the effect of diet-induced weight loss and/or LIRET on arterial function and body composition in obese women.

**METHODS:** Forty five postmenopausal obese women (54.3±0.9 years; 33.7±0.9 kg/m<sup>2</sup>) were randomized to LIRET (n=12), diet (n=14) or diet+LIRET (n=14) for 12 weeks. The data of 40

women who have completed the study are shown. LIRET consisted of four leg exercises at 40% of maximal strength (1RM). Brachial-ankle PWV (baPWV), aortic systolic blood pressure (aSBP), leg strength, body weight, and DEXA-measured body fat mass (FM), trunk FM, and leg LSTM were collected before and after the interventions.

**RESULTS:** BaPWV, a marker of systemic arterial stiffness, was significantly decreased after diet ( $-1.2 \pm 0.7$  m/s,  $p < 0.05$ ) compared with after LIRET ( $0.2 \pm 0.5$  m/s,  $p > 0.05$ ) but not after diet+LIRET ( $-0.5 \pm 0.5$  m/s,  $p > 0.05$ ). ASBP significantly ( $p < 0.05$ ) decreased after LIRET ( $-7 \pm 4$  mmHg), diet ( $-5 \pm 3$  mmHg), and diet+LIRET ( $-9 \pm 3$  mmHg). Leg strength increased after LIRET ( $27 \pm 8\%$ ,  $p < 0.05$ ) and diet+LIRET ( $28 \pm 7\%$ ,  $p < 0.05$ ) compared to diet ( $-4 \pm 5\%$ ,  $p > 0.05$ ). Leg LSTM was significantly decreased after diet ( $-0.7 \pm 0.0$  kg,  $p < 0.05$ ) compared to after LIRET ( $0.4 \pm 0.0$  kg,  $p > 0.05$ ) but not after diet+LIRET ( $-0.3 \pm 0.2$  kg,  $p > 0.05$ ). Weight and body FM decreased after diet ( $-7 \pm 1$  and  $-5 \pm 4$  kg,  $p < 0.01$ ) and diet+LIRET ( $-5 \pm 1$  and  $4 \pm 1$  kg,  $p < 0.01$ ) compared to LIRET ( $-1 \pm 1$  and  $-3 \pm 3$  kg,  $p > 0.05$ ). Trunk FM significantly ( $p < 0.05$ ) decreased after LIRET ( $-2.6 \pm 2.6$  kg), diet ( $-3.2 \pm 3.4$  kg), and diet+LIRET ( $-2.1 \pm 1.5$  kg).

**CONCLUSIONS:** A weight loss diet improved arterial stiffness, blood pressure, and FM but resulted in leg LSTM loss. LIRET and diet+LIRET improved trunk FM, muscle strength, and blood pressure independently of baPWV; however, LIRET did not affect body weight and body FM. Our findings suggest that addition of LIRET to a weight loss program would be recommended to improve aortic blood pressure and body composition since prevents the loss of leg LSTM induced by hypocaloric diet.

**Distensibility But Not Compliance Is Augmented In Spinal Cord Injury When Matched For Physical Activity**

Aaron A. Phillips, Anita T. Cote, Shannon S.D. Bredin, Andrei Krassioukov, Darren E.R. Warburton, FACSM. *University of British Columbia, Vancouver, BC, Canada.*

(No relationships reported)

**PURPOSE:** To compare arterial stiffness between those with spinal cord injury (SCI) and able bodied (AB) individuals when matched for habitual level of physical activity.

**METHODS:** A total of 17 SCI and 17 AB were matched for gender, age, weight, blood pressure and levels of self reported habitual physical activity (Godin-Shephard). Measures included central (cfPWV) and lower limb (flPWV) pulse wave velocity and large and small arterial compliance.

**RESULTS:** The cfPWV was significantly elevated ( $726 \pm 206$  vs.  $570 \pm 135$  cm/s, respectively) in the SCI in comparison to AB. No other measures of arterial stiffness were different between groups. Moderate to vigorous physical activity was significantly correlated with both large ( $r = 0.48$ ) and small ( $r = 0.65$ ) artery compliance, but not cfPWV or flPWV.

**CONCLUSIONS:** Both large and small artery compliance appear to be affected highly by habitual physical activity in active individuals with SCI. However, physical activity does not appear to influence PWV in physically active individuals with SCI. These findings suggest that factors other than physical inactivity may mediate the increase in central arterial stiffness seen in the SCI population.

**Inflammation, Glucose and Insulin Changes with a High Carbohydrate Diet After Downhill Running in Normal and Overweight Women**

Colleen P. Miller, Katherine A.M. McNulty, Gregory N. Ruegsegger, Peter Stordahl, Mary P. Miles, FACSM. *Montana State University, Bozeman, MT.*

(No relationships reported)

Hyperglycemia amplifies inflammation and insulin resistance in obese women. Thus, a high carbohydrate intake following muscle damaging exercise may increase the magnitude of inflammation and insulin resistance.

**PURPOSE:** To determine whether the magnitude of the inflammatory response and related changes in glucose and insulin differ between normal and overweight women after downhill running with a high carbohydrate recovery diet.

**METHODS:** Normal (BMI  $< 25$  kg/m<sup>2</sup>, n=8) and overweight (BMI  $> 25$  kg/m<sup>2</sup>, n=7) women (age 20-37 y) performed an aerobically based eccentric, downhill, running exercise to induce an inflammation. The exercise was followed by a controlled diet for the first 24 hours post-exercise consisting of 71% carbohydrate, 11% protein, and 18% fat with kilocalories proportional to body mass (31 kcal/kg). Blood collected under fasting conditions pre-exercise, 0, 24, and 48 hours post-exercise and analyzed for tumor necrosis factors- $\alpha$  (TNF- $\alpha$ ), interleukin (IL)-6, IL-18, C-reactive protein (CRP), glucose, insulin, and creatine kinase (CK) activity.

**RESULTS:** Pre-exercise values were similar between groups for TNF- $\alpha$ , IL-18, glucose, insulin, and CK; higher in the overweight group for IL-6 (2.5-fold) and CRP (3.8-fold). Average downhill run distances ( $3.4 \pm 0.5$  and  $3.1 \pm 0.5$  miles), exercise HR ( $152.9 \pm 8.1$  and  $152.4 \pm 15.1$  bpm), and post-exercise increases in CK activity were similar between normal and overweight groups, suggesting that the exercise stress and muscle damage responses were similar. There were no changes over time or differences between groups for TNF- $\alpha$ , IL-18, CRP, and insulin. IL-6 was lower 0 h ( $0.94 \pm 0.36$  vs  $2.32 \pm 1.45$  pg/ml) and 24 h ( $0.39 \pm 0.20$  vs  $0.78 \pm 0.42$  pg/ml) post-exercise in the normal compared to overweight group. Glucose increased 0 h post-exercise and decreased 48 h post-exercise, but was similar between groups. Insulin was lower 0 h ( $7.12 \pm 2.87$  vs  $11.36 \pm 3.60$   $\mu$ U/ml) and 24 h ( $5.28 \pm 1.82$  vs  $9.68 \pm 4.83$   $\mu$ U/ml) post-exercise in the normal compared to overweight group.

**CONCLUSION:** Compared to normal weight women, overweight women have a greater inflammation (IL-6) and insulin increase following downhill running with a high carbohydrate recovery diet.

**Under Insulin-Mediated Conditions, Resveratrol Restores Glucose Uptake but not Fatty Acid Oxidation in Skeletal Muscle Cells made Insulin Resistant by Treatment with Protease Inhibitors**

Lorraine P. Turcotte, FACSM, Lindsey D. Bogachus. *University of Southern California, Los Angeles, CA.*

(No relationships reported)

Protease inhibitors (PI) such as atazanavir (A) and ritonavir (R) used in antiretroviral therapy (HAART) for HIV patients are known to induce insulin resistance possibly via activation of the pro-inflammatory signaling intermediate JNK1/2. Resveratrol has been shown to improve insulin action in some insulin-resistant states.

**PURPOSE:** To determine the efficiency of resveratrol to blunt PI-induced insulin resistance in skeletal muscle cells.

**METHODS:** L6 muscle cells were treated with A (100 $\mu$ M) and R (25 $\mu$ M)  $\pm$  resveratrol (100 $\mu$ M) or  $\pm$  the JNK inhibitor SP600125 (5 $\mu$ M) and incubated  $\pm$  insulin (100nM). After treatment(s), glucose uptake (GU) and fatty acid uptake (FAU) and oxidation (FAO) as well as JNK1/2 and AKT2 phosphorylation were measured. Treatment effects were statistically assessed with ANOVA.

**RESULTS:** A/R led to the development of insulin resistance as seen by the absence of an insulin-mediated increase in GU and FAU and of an insulin-mediated decrease in FAO. A/R was also accompanied by a rise ( $P < 0.05$ ) in pJNK1/2 that was accompanied by a decrease ( $P < 0.05$ ) in insulin-induced pAKT. In A/R-treated cells, resveratrol and JNK inhibition decreased ( $P < 0.05$ ) basal GU (51-55%) and restored the insulin-sensitive increase (31-62%) in GU ( $P < 0.05$ ). Resveratrol and JNK inhibition decreased ( $P < 0.05$ ) basal FAU (44-55%) but only JNK inhibition reduced ( $P < 0.05$ ) FAO (28%). In contrast to their effects on insulin-mediated GU, neither resveratrol nor JNK inhibition restored the effects of insulin on FAU and FAO in PI-treated cells ( $P > 0.05$ ). In line with the GU data, resveratrol and JNK inhibition reduced ( $P < 0.05$ ) pJNK1/2 (67-86%) but only resveratrol restored the insulin-mediated increase ( $P < 0.05$ ) in pAKT (461%) measured in control cells.

**CONCLUSION:** In L6 myotubes made insulin-resistant by treatment with protease inhibitors, the effects of resveratrol and JNK inhibition on insulin-sensitive muscle metabolism are selective and with resveratrol may occur in part via a restoration of insulin-induced AKT phosphorylation.

2328 Board #3 MAY 31 2:00 PM - 3:30 PM

**Pre-exercise Ingestion of Amylo maize Decreases Hypoglycemia Risk During High Intensity Cycling**

Rachel Bell, Douglas S. King, Mike E. Spurlock, Rick L. Sharp, FACSM. *Iowa State University, Ames, IA.*

(No relationships reported)

Modified amylo maize-7 was previously shown to be 92% digestible but is digested slowly enough that hyperinsulinemia is avoided (Zhou et al. *J Nutr*, 127:1997).

**PURPOSE:** To assess the effect of a carbohydrate pre-load on performance of a brief high-intensity cycling trial, and to compare the metabolic response when amylo maize-7 versus dextrose was consumed in the hour before exercise.

**METHODS:** Ten trained cyclists ( $\text{VO}_{2\text{max}} 64.6 \pm 1.8 \text{ mL}\cdot\text{kg}^{-1}\cdot\text{min}^{-1}$ ) were given 1 g $\cdot\text{kg}^{-1}$  body mass of either dextrose (DEX) or amylo maize-7 (AMY-7) or a flavored water placebo (PL) 45 min prior to exercise on a cycle ergometer. A 15 min ride at 60%  $\text{W}_{\text{max}}$  was immediately followed by a self-paced time trial (TT) equivalent to 15 min at 80%  $\text{W}_{\text{max}}$  ( $264 \pm 12 \text{ KJ}$ ). Blood samples were taken at baseline, pre-exercise, pre-TT, post-TT and 30 min post-exercise.

**RESULTS:** When cyclists consumed the DEX preload, mean serum glucose concentration increased by  $3.3 \text{ mM} \pm 2.1$  before exercise, compared to AMY-7 or PL ( $0.2 \pm 0.5$ ,  $0.1 \pm 0.8$ , respectively,  $p < 0.001$ ). Glucose concentrations returned to baseline by pre-TT in all treatments. However, the mean post-TT glucose concentration of  $5.5 \pm 0.4 \text{ mM}$  in the DEX group was significantly lower than baseline, AMY-7 or PL ( $5.8 \pm 0.4$ ,  $6.8 \pm 0.8$ ,  $6.8 \pm 1.5$ , respectively,  $p < 0.05$ ). Serum insulin concentration increased nine-fold from baseline to pre-exercise in the DEX trial ( $1.3 \pm 0.1$  to  $11.7 \pm 10.1$ ), whereas PL or AMY-7 remained unchanged ( $p < 0.05$ ). Time (s) required to complete the performance trial was not significantly different between DEX, AMY-7 or PL ( $1091 \pm 71$ ,  $1054 \pm 66$ ,  $1078 \pm 59$ , respectively,  $p = 0.209$ ).

**CONCLUSIONS:** Pre-exercise ingestion of amylo maize-7 compared to dextrose resulted in a more stable serum glucose concentration, but did not offer an additional performance advantage in a high-intensity cycling time trial.

2329 Board #4 MAY 31 2:00 PM - 3:30 PM

**Insulin, Glucose, and Blood Lipid Responses with a High Glycemic Index Diet Following Downhill Running in Normal and Overweight Women**

Katherine A.M. McNulty, Colleen P. Miller, Gregory N. Rueggsegger, Peter Stordahl, Mary P. Miles, FACSM. *Montana State University, Bozeman, MT.*

(No relationships reported)

A chronic, low-grade level of inflammation occurs with increases in adiposity. This inflammation is implicated in development of insulin resistance (IR) and cardiovascular disease (CVD). Hyperglycemia intensifies both IR and inflammation.

**PURPOSE:** To determine if insulin, glucose, homeostatic model assessments (HOMA) of IR (HOMA-IR),  $\beta$ -cell function (HOMA-B), insulin sensitivity (HOMA-S), cholesterol, triglycerides (TG), HDL, and LDL responses differ in normal vs. overweight women consuming a high glycemic index (GI) diet following downhill running.

**METHODS:** Normal weight (BMI  $< 25 \text{ kg}/\text{m}^2$ ,  $n = 7$ ) and overweight (BMI  $> 25 \text{ kg}/\text{m}^2$ ,  $n = 7$ ) women (20-37 y) performed 30 minutes of downhill running with their heart rate (HR) at 65% of predicted maximal oxygen consumption ( $\text{VO}_{2\text{max}}$ ). Participants ate a high GI diet consisting of a carbohydrate/protein/fat ratio of 71%/11%/18%, with kilocalories relative to participant's body mass (31 kcal/kg) for 24 hours post-exercise. Blood was drawn from participants in fasting conditions immediately prior to downhill running, and at 0 h, 24 h, and 48 h following exercise.

**RESULTS:** There were no significant differences between groups at baseline. HOMA-S was higher in normal compared to overweight women and increased from  $109.7 \pm 51.4$  pre-exercise to  $127.0 \pm 57.6$  24 h post-exercise in both groups. HOMA-B and IR responses did not differ between groups. Cholesterol decreased from  $183.0 \pm 27.5$  at pre-exercise to  $177.8 \pm 25.1 \text{ mg}/\text{dl}$  24 h post-exercise. There was a trend ( $P = 0.06$ ) towards higher TG in the overweight group vs. normal weight group ( $110 \pm 69$  vs.  $55 \pm 28 \text{ mg}/\text{dl}$ ), and TG increased from pre-exercise ( $82.2 \pm 58.1 \text{ mg}/\text{dl}$ ) to 0 h ( $91.3 \pm 55.8 \text{ mg}/\text{dl}$ ), while there was a trend ( $P = 0.08$ ) to decrease 24 h post-exercise ( $63.2 \pm 36.7 \text{ mg}/\text{dl}$ ). HDL decreased ( $P < 0.05$ ) from pre-exercise ( $61.4 \pm 12.3$ ) to 24 h post-exercise ( $58.4 \pm 10.7 \text{ mg}/\text{dl}$ ). Magnitude of change ( $\Delta$ ) associated with BMI for  $\Delta$  insulin at 24 h,  $\Delta$ HOMA-B at 24 h ( $r = 0.55$ ) and  $\Delta$ TG at 48 h ( $r = -0.625$ ).

**CONCLUSION:** The combination of inflammation and high GI diet elicited changes in insulin (+), HOMA-B (+), and TG (-) that associated with BMI. While both groups had decreased cholesterol at 24 h, the overweight group had greater decreases in TG after consuming a high GI diet for 24 h after 30 minutes of downhill running.

2330 Board #5 MAY 31 2:00 PM - 3:30 PM

**Effects of Impaired Glucose Metabolism-induced Inflammation on the Joint Function in Current and Retired Athletes**

Ching-Hung Lin<sup>1</sup>, Li-Yuan Tsao<sup>2</sup>, Chu-Chun Fang<sup>2</sup>, Chi-Chang Huang<sup>3</sup>, Mei-Chich Hsu<sup>3</sup>. <sup>1</sup>*Yuan Ze University, Chung-Li, Taiwan.* <sup>2</sup>*National Taipei College of Business, Taipei, Taiwan.* <sup>3</sup>*National Taiwan Sport University, Taoyuan, Taiwan.* (Sponsor: Chia-Hua Kuo, FACSM)

(No relationships reported)

**PURPOSE:** This study aims to investigate the differences of metabolic fitness, inflammatory response and joint condition between current and retired female athletes, as well as the correlation between inflammation and joint function.

**METHODS:** The subjects of this study are all female basketball players. They are divided into two groups based on their status: (1) current group ( $n = 12$ ,  $18.2 \pm 0.9$  yr, height  $166 \pm 0$  cm, weight  $59.6 \pm 2.7$  kg) and (2) retired group ( $n = 19$ ,  $56.1 \pm 1.0$  yr, height  $171 \pm 0$  cm and weight  $73.1 \pm 2.7$  kg). Analysis of a representative sample of all subjects for whom data on body mass index (BMI), waist circumference (WR), Western Ontario and McMaster Universities (WOMAC) index of osteoarthritis, and fasting glucose (FG), hemoglobin A1c (HbA1c), C-reactive protein (CRP), and 2-h plasma glucose during an OGTT and blood glucose area under the curve (GAUC) were determined after a 12-hour period of fasting.

**RESULTS:** The current group had significantly lower BMI, WR, GAUC, FG, HbA1c and WOMAC scores than the retired group ( $P < 0.05$ ). The score of functional evaluation in WOMAC for current group was significantly lower than retired group ( $6.9 \pm 2.8$  vs  $19.4 \pm 3.2$ ,  $P < 0.05$ ). There was a significantly positive correlation between CRP and FG ( $r = 0.504$ ), and CRP and HbA1c ( $r = 0.498$ ), respectively ( $P < 0.05$ ). However, there was no difference in the CRP levels between the two groups and no significant correlation existed between age and CRP.

**CONCLUSION:** The main finding of this study is that the metabolic fitness, the function of knee and HbA1c were impaired in the retired female athletes. Although impaired metabolic fitness-induced inflammatory status in the retired athletes, the deterioration of joint function in the retired subject group was not induced by inflammation.

2331 Board #6 MAY 31 2:00 PM - 3:30 PM

**A Single Exercise Bout Does Not Improve Glycemic Control In Individuals With Type 2 Diabetes**

Douglas J. Oberlin, Catherine R. Mikus, Monica L. Kearney, Justin A. Fletcher, Pam S. Hinton, Jill A. Kanaley, FACSM, Randy Scott Rector, Heather J. Leidy, John P. Thyfault. *University of Missouri, Columbia, MO.*

(No relationships reported)

Type 2 diabetes (T2D) and the associated impaired glycemic control greatly increases the risk of cardiovascular disease mortality.

**PURPOSE:** Our lab previously has shown that seven consecutive days of aerobic exercise can effectively reduce the amplitude of postprandial glycemic excursions ( $\Delta\text{PPG}$ ; = post meal glucose - pre meal glucose) in previously sedentary individuals with T2D measured by continuous glucose monitors (CGMS). It is unknown if or for how long a single bout of exercise will reduce  $\Delta\text{PPG}$  in individuals with T2D.

**METHODS:** We recruited 7 individuals with T2D (BMI:  $38 \pm 1 \text{ kg}/\text{m}^2$ ; age  $59 \pm 2$  years; HbA1c:  $6.49 \pm 0.34$  %) who were not using exogenous insulin and sedentary ( $< 30$  minutes/week of exercise). The subjects consumed a eucaloric diet (51% carbohydrate, 31% fat, 18% protein) containing identical food components at each meal during two separate 3 day trials while wearing CGMS monitors to continually monitor blood glucose. During one 3 day trial the subjects performed one 60 minute, supervised exercise bout (EX; 60-75% of heart rate reserve) prior to breakfast on the morning of the first day. During the second 3 day trial, the subjects maintained their sedentary lifestyle (SED). The order of the SED and EX trials was randomly assigned.

**RESULTS:** A comparison of the 2 trials revealed that one bout of exercise did not significantly change  $\Delta\text{PPG}$  averaged across all meals (EX:  $1.6 \pm 0.1$  vs. SED  $1.1 \pm 0.1 \text{ mmol}/\text{l}$ ), percent of time spent within normal glucose ranges (EX:  $86.1 \pm 2.0$  vs. SED:  $92.7 \pm 0.4$ %), or mean blood glucose (EX:  $6.3 \pm 0.1$  vs. SED:  $6.4 \pm 0.2 \text{ mmol}/\text{l}$ ) throughout the day.

**CONCLUSION:** These preliminary results suggest that more than one moderate-intensity bout of aerobic exercise is needed to significantly improve glycemic control in subjects with T2D.

2332 Board #7 MAY 31 2:00 PM - 3:30 PM

**Immediate Energy Signaling During Physical Activity**

Nicholas Gant, Clare E. Turner, Cathy M. Stinear, Winston D. Byblow. *The University of Auckland, Auckland, New Zealand.*

(No relationships reported)

The presence of carbohydrate in the mouth has been associated with immediate improvements in human performance and the facilitation of neural drive to muscle. Oral energy receptors may be involved in a novel form of sensorimotor integration, capable of regulating motor output during exercise.

**PURPOSE:** This study used neuroimaging to examine central influences of oral carbohydrate during a motor task, identifying areas of the brain involved in immediate energy signalling.

**Method:** Carbohydrate (CHO) and Placebo (PLA) solutions with identical perceptual qualities but variable energy content were infused and recovered from the mouth in a double-blind, counterbalanced fashion. Functional Magnetic Resonance Imaging was used to measure blood oxygen level-dependent contrast in the brain whilst participants generated isometric force during a handgrip task.

**RESULTS:** The main finding of this study was an increase in the motor cortex activation network with CHO compared to PLA during the handgrip task. Additional areas of activation with CHO were seen in left insular cortex and left central operculum (primary taste areas), and regions of the frontal cortex associated with rewarding sensory stimuli.

**CONCLUSION:** This is the first demonstration of oral CHO exposure enhancing the extent of a neural activation network during a motor task. The increased activity within motor cortex and regions involved in reward processing provides a neural basis for enhancements in force production and motor output observed with oral exposure to carbohydrate.

2333 Board #8 MAY 31 2:00 PM - 3:30 PM

**Short-Term Aerobic Exercise Training Beneficially Alters PYY and GLP-1 in Impaired Glucose Tolerant Individuals**

Emily S. Louis<sup>1</sup>, Karen R. Kelly<sup>2</sup>, Jacob M. Haus<sup>3</sup>, Ciaran E. Fealy<sup>1</sup>, Amanda R. Scelsi<sup>1</sup>, Mangesh R. Pagadala<sup>1</sup>, John P. Kirwan, FACSM<sup>1</sup>. <sup>1</sup>Cleveland Clinic, Cleveland, OH. <sup>2</sup>Naval Health Research Center, San Diego, CA. <sup>3</sup>University of Illinois at Chicago, Chicago, IL. (Sponsor: John P. Kirwan, FACSM)

(No relationships reported)

**PURPOSE:** PYY and GLP-1 are potent inducers of satiety, and GLP-1 is also an important mediator of insulin secretion. The purpose of this investigation was to investigate the effect of short-term aerobic exercise training on basal and glucose stimulated PYY and GLP-1 release among overweight and obese individuals with varying glucose tolerance.

**METHODS:** Seven impaired glucose tolerant (IGT; BMI=33), and five normal glucose tolerant (NGT; BMI=31) subjects performed a 3-h oral glucose tolerance test (OGTT) before and one day after a 7-day aerobic exercise program. Subjects performed 60 min. of supervised aerobic exercise training at 80-85% of HRmax for seven consecutive days. Blood was collected before (0 min.) and at 30, 60, 90, 120 and 180 min. during the OGTT. Plasma was analyzed for PYYTotal, active GLP-1, and insulin, at each time point.

**RESULTS:** Before exercise training, IGT tended to have higher basal GLP-1 ( $p=0.09$ ) than NGT. In response to glucose ingestion, IGT tended to have a higher insulin response (AUC120;  $p=0.06$ ) compared to NGT, and only NGT showed a trend ( $p=0.07$ ) for increased PYY in response to glucose ingestion. After exercise training, IGT decreased basal and OGTT GLP-1 ( $p<0.05$ ), decreased the insulin response to glucose (AUC120;  $p<0.01$ ), and significantly increased the PYY response to glucose ( $p<0.01$ ) from pre-exercise training. NGT maintained the trend ( $p=0.08$ ) for a glucose-induced increase in PYY. Furthermore, in the IGT group, basal PYY tended to be elevated ( $p=0.08$ ) relative to NGT, and was significantly higher than that of NGT following glucose ingestion ( $p<0.05$ ).

**CONCLUSIONS:** Short-term moderate- to high-intensity aerobic exercise was effective at beneficially altering gut peptides and the insulin response to glucose in IGT individuals. Increased basal and glucose-induced PYY indicates that exercise may be effective at lowering appetite and increasing satiety in response to food intake, leading to improved weight control. Additionally, decreased basal and OGTT GLP-1 indicates a mechanism of improved insulin regulation following exercise training in IGT individuals. Supported by NIH grants R01 AG12834 and T32DK007319.

2334 Board #9 MAY 31 2:00 PM - 3:30 PM

**Hepatic Glycogen And Serum Triglycerides Of Diabetic Rats Submitted To Aerobic Training**

Natalia Oliveira Bertolini, Luciana Mendonça Arantes, Rodrigo Ferreira de Moura, Maria Alice Rostom de Mello, Eliete Luciano. *São Paulo State University, Rio Claro, Brazil.*

(No relationships reported)

Diabetes mellitus type 1 is an autoimmune disease characterized by chronic hyperglycemia resulting of impaired insulin secretion. Characteristic symptoms are thirst, polyuria, etc. Metabolic alterations include hepatic impairment of glycogen storage and hypertriglyceridemia, a risk factor of cardiovascular diseases. By the other hand, physical activity is prescribed to improve the metabolic control in diabetic subjects.

**PURPOSE:** To evaluate the effects of aerobic training on serum triglycerides and hepatic glycogen content in diabetic rats.

**METHODS:** Forty-five Wistar male rats were randomly allocated into four different groups: sedentary control (SC), trained control (TC), sedentary diabetic (SD) and trained diabetic (TD). Experimental diabetes was induced by an intravenous single dose injection of alloxan monohydrate (32 mg/kg bw dissolved in citrate buffer 0.01M, pH 4.5). For diabetic status checking, a fasting blood glucose test was performed seven days after the induction. Only rats exhibiting glycemia higher than 250mg/dL were considered diabetic. After group allocation, the animals were submitted to water adaptation for 5 days. The training was set at 90% of the maximum lactate steady state. There were seven weeks of swimming training constituted by five sessions/week lasting one hour each. The animals were killed 48 hours after the last training session. Liver samples were collected for glycogen content determination by phenol sulfuric method and blood samples were used for serum triglycerides dosage by commercial kit. One-way ANOVA followed by Bonferroni post test were applied for statistical analysis, the significance level was preset to  $p<0.05$ , data are presented as mean  $\pm$  standard deviation.

**RESULTS:** Liver glycogen content were diminished in the diabetic groups compared to SC, but TD was not different from TC (SC:  $73.4 \pm 20.6$ ; TC:  $72.0 \pm 24.9$ ; SD:  $37.2 \pm 9.2$ ; TD:  $46.1 \pm 14.3$  mg/100mg). Regarding the serum triglycerides concentration an increase related to diabetes was observed in SD group, however TD showed no difference compared to the control groups (SC:  $253.7 \pm 98.9$ ; TC:  $199.1 \pm 54.6$ ; SD:  $459.6 \pm 187.0$ ; TD:  $358.1 \pm 244.4$  mg/dL).

**CONCLUSIONS:** Endurance training improves the serum triglycerides profile but elicits no changes in hepatic glycogen content of diabetic rats.

**Physical Activity And Metabolic Characteristics For Politicians In Taiwan**

Chien-Te Ho<sup>1</sup>, Chih-Ling Su<sup>2</sup>, Kuei-Yu Chien<sup>3</sup>. <sup>1</sup>Tatung Institute of Commerce and Technology, Chiayi City, Taiwan. <sup>2</sup>Taiwan Shou Fu University, Tainan City, Taiwan. <sup>3</sup>National Taiwan Sport University, Taoyuan County, Taiwan. (Sponsor: Chia-Hua Kuo, FACSM)

(No relationships reported)

**PURPOSE:** Taiwan politician is having unique social lifestyle aimed to recruit voters, characterized by greater walking activity but high frequency in alcohol drinking. Thus, purpose of the study was to determine metabolic characteristic for Taiwan politician in contrast to their first order adult relatives.

**METHODS:** Oral glucose tolerance test (OGTT), insulin, triglyceride, cholesterol, and inflammatory markers (C-reactive protein and interleukin-6) were measured among 8 parliamentary politician (age  $50.9 \pm 2.2$ ) in Taiwan and their first order descendants (age  $25.5 \pm 3.5$ ) as genetic controls.

**RESULTS:** Politicians had more alcohol consumption and restaurant dining than controls. All politicians were substantially insulin resistant compared with their young descendants, evidenced by exaggerated high glucose and insulin levels ( $>100\%$  greater in area under curve) under oral glucose challenged condition. Although none of the politicians was clinically diabetic, their waist circumference, diastolic blood pressure, and cholesterol levels were significantly greater than controls. Furthermore, C-reactive protein (CRP) of the politicians was approximately 2.3 folds of the control value.

**CONCLUSIONS:** This study presents a potential metabolic risk for the politicians, despite more weekly walking distance was performed during their voter visit. The insulin resistance state of this group appears to be associated with substantially greater baseline inflammation level.

**2336** Board #11 MAY 31 2:00 PM - 3:30 PM

**The Characteristic Of Metabolism In Young Boxing Athletes**

Ta-Cheng Hung<sup>1</sup>, Ming-Chia Lin<sup>2</sup>, Kun-Fu Liao<sup>2</sup>, Chien-Wen Hou<sup>2</sup>, Chung-Yu Chen<sup>2</sup>. <sup>1</sup>Shih-Chien University, Taipei Physical Education College, Taipei, Taiwan. <sup>2</sup>Taipei Physical Education College, Taipei, Taiwan. (Sponsor: Chia-Hua Kuo, FACSM)  
(No relationships reported)

Previous study has shown that the former elite power sports (boxing, wrestling, weight lifting) athletes exhibited higher relative risk in insulin resistance and hypertension than elite endurance (long-distance running) athletes in elder age.

**PURPOSE:** To investigate that whether this metabolic deterioration already occurred in the young boxing athletes.

**METHODS:** A total of 563 college students were divided into two groups: physical active control (n=538, aged 21.58±.07) and boxing athletes (n=25, aged 20.96±.25). The boxing athlete regularly participated in boxing training program and competition. Physical active control attended to routine physical education (PE) courses and work out more than 160 min/wk. The resting blood pressure included the systolic blood pressure (SBP) and diastolic blood pressure (DBP) was determined. All plasma samples were collected for measuring the glucose, insulin and cholesterol after an overnight fasting.

**RESULTS:** The BMI value of boxing athlete was significantly higher than those of control group. Boxing athlete presented significantly greater systolic blood pressure (SBP) and diastolic blood pressure (DBP) than in control group. No significant difference was observed in the levels of fasting glucose, insulin and cholesterol between in control and boxing athlete.

**CONCLUSIONS:** Our study showed significantly greater value of BMI, SBP and DBP in boxing athlete than in control group. The higher SBP and DBP in boxing athlete were appeared to relate to greater BMI value rather than increased the insulin and glucose level; suggest that well weight management needs to be more concerned in these young power sports athletes.

**2337** Board #12 MAY 31 2:00 PM - 3:30 PM

**Interactive Effect Of Igf-1 And Exercise Training On Muscle Glut4 Protein Expression**

Chung-Yu Chen, Yu-Chiang Lai, Chien-Wen Hou, Mallikarjuna Korivi. Taipei Physical Education College, Taipei, Taiwan. (Sponsor: Chia-Hua Kuo, FACSM)  
(No relationships reported)

Exercise transiently elevates the IGF-I (insulin-like growth factor 1) level, but whether exogenous IGF-I administration can reproduce exercise training benefit in glycemic control is currently unknown.

**PURPOSE:** This study compared the effect of IGF-1 administration and exercise training on glycogen storage, glucose tolerance, and muscle GLUT4 protein expression in normal rats.

**METHODS:** Forty rats were weight matched and evenly assigned to the following 4 groups: control (C), exercise trained (E), IGF-1 treated (I), and exercise-trained + IGF-1 (EI). Same volume of saline or IGF-1 (2 µg/kg BW) was injected daily to rats. Exercise training consisted of 90 min swimming for the first week and gradually increased to 180 min twice for the third week. Oral glucose tolerance test (OGTT) was performed in all rats under fasted condition. Muscle tissues were removed at the end of the 3-week treatments (3 days after OGTT). The levels of GLUT4 protein and mRNA were determined in red and white portions of the quadriceps muscle (RQ and WQ).

**RESULTS:** Both exercise training and chronic IGF-1 administration increased GLUT4 expression and improved glucose tolerance without an observed additive effect. Exercise training increased glycogen level in RQ and WQ above control level. Despite chronic IGF-1 administration increased muscle GLUT4 expression above control level, glycogen increase was not observed.

**CONCLUSIONS:** Our data suggests that IGF-1 can partially reproduce exercise training effect on improving glycemic control.

**2338** Board #13 MAY 31 2:00 PM - 3:30 PM

**Effect of Glycemic Index of Snack Bars on Substrate Utilization during Subsequent Moderate Intensity Exercise**

Wendy Y. Huang, Stephen H. Wong, FACSM, Feng Hua Sun, Ka Fai Tsang. The Chinese University of Hong Kong, Hong Kong, China.  
(No relationships reported)

**PURPOSE:** To investigate whether the glycemic index (GI) of pre-exercise snack bars will affect substrate utilization during subsequent moderate intensity exercise.

**METHODS:** Seven young physically active male subjects (age: 21.0 ± 0.7 yr, BMI: 22.7 ± 2.1 kg·m<sup>-2</sup>, VO<sub>2max</sub>: 51.2 ± 4.6 mL·kg<sup>-1</sup>·min<sup>-1</sup>) volunteered to participate in the study. All subjects completed two main trials in a counterbalanced crossover design with seven days interval. In the main trials, all subjects reported to the lab after an overnight fast. Then they ate one of two snack bars: a low-GI snack bar (LGI) and a moderate-GI snack bar (MGI). The estimated GI values for the two snack bars were 28 and 68, respectively. All snack bars provided similar energy and carbohydrate (CHO) content (1 g CHO/kg body mass). However, the energy percentages of fat and protein were different (LGI vs. MGI: fat, 30% vs. 24%; protein, 9% vs. 16%). After 90-min resting, all subjects completed 45-min cycling at 60% VO<sub>2max</sub>. Substrate utilization was measured using indirect respiratory calorimetry every 30 minutes during the postprandial period and every 15 minutes during exercise. Blood glucose and lactate concentrations were measured every 15 minutes.

**RESULTS:** Blood glucose concentrations peaked at 30 min and returned to baseline level at the end of postprandial period in both trials. During exercise, blood glucose concentrations were suppressed in the MGI trial than those at the onset of exercise, but not in the LGI trial. During the postprandial period, blood glucose was higher at 60 min in the MGI trial compared with that in the LGI trial (5.74 ± 0.83 vs. 4.67 ± 4.06 mmol·L<sup>-1</sup>, P<0.05). The incremental area under the blood response curve of glucose (IAUC) value was also higher in the MGI trial than that in the LGI trial (MGI vs LGI: 206 ± 39 vs 136 ± 28 mmol·min·L<sup>-1</sup>; P<0.05). No differences were observed in blood lactate concentrations, fat and CHO oxidation amounts between the two trials both during the postprandial and exercise periods.

**CONCLUSIONS:** The results suggest that substrate utilization during the 45-min moderate intensity exercise was not affected by the pre-exercise LGI or MGI snack bars consumption.

**2339** Board #14 MAY 31 2:00 PM - 3:30 PM

**Subcellular Localization-dependent Skeletal Muscle Glycogen Content in the Recovery Period After a High-level Soccer Match**

Joachim Nielsen<sup>1</sup>, Peter Krstrup<sup>2</sup>, Lars Nybo<sup>2</sup>, Thomas P. Gunnarsson<sup>2</sup>, Klavs Madsen<sup>3</sup>, Henrik Daa Schrøder<sup>1</sup>, Jens Bangsbo<sup>2</sup>, Niels Ørtenblad<sup>1</sup>. <sup>1</sup>University of Southern Denmark, Odense M, Denmark. <sup>2</sup>University of Copenhagen, Copenhagen, Denmark. <sup>3</sup>Aarhus University, Aarhus, Denmark.  
(No relationships reported)

**PURPOSE:** Whole muscle glycogen levels are deteriorated for a prolonged period following a soccer match. The present study was conducted to investigate how this relates to glycogen content in distinct subcellular localizations. Thus, subcellular localizations of glycogen may be regulated differently and be of distinct importance for muscle performance and recovery.

**METHODS:** Seven high-level male soccer players had a vastus lateralis muscle biopsy collected immediately after and 24, 48, 72 and 120 h after a competitive soccer match. Transmission electron microscopy was used to estimate the glycogen volume in subsarcolemmal (SS), intermyofibrillar (IMF) and intramyofibrillar (Intra) localizations. Two-way interactions or main effects were tested using linear mixed-effect model with subject, time and fibre as random effects and with time and localization as fixed effects. Values were log-transformed before analysis and presented as geometric means and 95% confidence intervals.

**RESULTS:** During the first day of recovery, glycogen content increased by ~60% in all defined subcellular localizations (SS, 0.029 (0.024-0.035) vs 0.046 (0.038-0.057) µm<sup>3</sup> µm<sup>-2</sup>; IMF, 0.014 (0.012-0.017) vs 0.022 (0.020-0.025) µm<sup>3</sup> µm<sup>-3</sup>; Intra, 0.0016 (0.0012-0.0020) vs 0.0026 (0.0022-0.0032) µm<sup>3</sup> µm<sup>-3</sup>), but during the subsequent second day of recovery Intra glycogen content did not increase further (48 h, 0.0025 (0.0020-0.0030) µm<sup>3</sup> µm<sup>-3</sup>) compared with an increase of 25% in subsarcolemmal glycogen (48 h, 0.058 (0.048-0.069) µm<sup>3</sup> µm<sup>-2</sup>) (P = 0.047). Conversely, from the second to the fifth day of recovery, Intra glycogen content exclusively increased (53%) (120 h, 0.0037 (0.0029-0.0048) µm<sup>3</sup> µm<sup>-3</sup>) compared to no change in subsarcolemmal (120 h, 0.048 (0.037-0.063) µm<sup>3</sup> µm<sup>-2</sup>) or intermyofibrillar glycogen (120 h, 0.027 (0.023-0.031) µm<sup>3</sup> µm<sup>-3</sup>) (P < 0.005).

**CONCLUSION:** In the recovery period after a soccer match, the increase in glycogen content is dependent on its subcellular localization. These results indicate that spatial distinct depositions of glycogen may have differential regulatory mechanisms, which might be influenced by the type of prior exercise.:

**Intake of Dammarane Oligo-Saponins Improves Glycogen Resynthesis in Human Skeletal Muscle after Exercise**

Szu-Hsien Yu<sup>1</sup>, Hsin-Yi Hsu<sup>2</sup>, I-Shiung Cheng<sup>3</sup>, Feng-Chih Hsu<sup>4</sup>, Mallikarjuna Korivi<sup>1</sup>. <sup>1</sup>Taipei Physical Education College, Taipei, Taiwan. <sup>2</sup>Aletheia University, Taipei, Taiwan. <sup>3</sup>National Taichung University of Education, Taichung, Taiwan. <sup>4</sup>National Taoyuan Agricultural & Industrial Vocational High School, Taoyuan, Taiwan. (Sponsor: Chia-Hua Kuo, FACSM)  
(No relationships reported)

**PURPOSE:** Glycogen is the major energy source in the skeletal muscle for physical activities. Ginseng extracts shown to enhance the exercise performance, but no study demonstrated the effect of purified ginseng extracts and their dose response on glycogen metabolism in human skeletal muscle after exercise. The present study was aimed to investigate the impact of different doses of Dammarane Oligo-Saponins (DS), a purified ginseng extract on glycogen re-synthesis in exercised human skeletal muscle.

**METHODS:** Twelve physically active male college students were considered as placebo and DS trials. DS trials received three different doses of DS substance (low-240, medium-480, high-960 mg/day) for one-month, and all subjects performed an acute bout of cycling exercise for 1-h at 75%  $\dot{V}O_{2max}$ . Muscle samples from vastus lateralis were collected by needle biopsy immediately and 3-h after exercise. Blood glucose, insulin and lactate levels were estimated before exercise, immediately and 3-h after exercise. Crossover trials were performed ones after every dose with 4-week washout interval.

**RESULTS:** We found glycogen resynthesis rate was significantly higher in DS-240 trial ( $2.15 \pm 0.66 \mu\text{moles/mg tissue/h}$ ) than that in placebo trial. The protein levels of glycogen synthase (GS) were significantly ( $P < 0.05$ ) elevated immediately after exercise, and continued until 3-h after exercise in all DS trials. Phospho-GS levels were also increased immediately after exercise in low to high dose of DS. However, lower pGS/GS ratio was found in DS240 trial 3-h after exercise compared to placebo trial. Estimated Akt protein levels in muscle samples were not significantly altered. Nevertheless, phospho-Akt was significantly increased immediately after exercise in all 3 trials, while, DS-240 trial showed 3-h after exercise. Blood lactate levels with medium and high DS dose was higher 3-h after exercise, while blood glucose levels were lower with low dose (DS-240) 3-h after exercise. No significant change in insulin levels were noticed among groups after exercise.

**CONCLUSIONS:** Our findings clearly demonstrating that one-month Dammarane oligosaponins supplementation improved the glycogen resynthesis in skeletal muscle, and this was more prominent with moderate dose of DS.

**2341** Board #16 MAY 31 2:00 PM - 3:30 PM

**Exercise Training Improves Glucose Tolerance In Type 2 Diabetic Rats Regardless Elevation Of Body Temperature**

Takamasa Tsuzuki<sup>1</sup>, Hiroyuki Kobayashi<sup>2</sup>, Toshinori Yoshihara<sup>1</sup>, Ryo Kakigi<sup>1</sup>, Noriko Ichinoseki-Sekine<sup>1</sup>, Hisashi Naito<sup>1</sup>, Shizuo Katamoto<sup>1</sup>. <sup>1</sup>Juntendo University, Inzai, Japan. <sup>2</sup>Tsukuba University Hospital, Mito, Japan.  
(No relationships reported)

Exercise has been shown to improve impaired glucose tolerance and type 2 diabetes. Exercise elevates body temperature, resulting in increased heat shock protein (HSP) expressions in skeletal muscle. This increase of HSP expression has been suggested to contribute to the improvement of glucose tolerance. However, it is unclear whether exercise alone without raising body temperature can improve glucose tolerance.

**PURPOSE:** To examine the effects of exercise training with and without elevation of body temperature on glucose tolerance in type 2 diabetic rats.

**METHODS:** Otsuka Long-Evans Tokushima Fatty (OLETF) rats, which are type 2 diabetes models, were randomly divided into a sedentary (Sed-OLETF; n=9), trained under cold environment (CTr-OLETF; n=9), or trained under ordinary environment group (OTr-OLETF; n=9). OTr- and CTr-OLETF were trained five days a week for 10 weeks on a treadmill under ordinary (25°C) and cold (4°C) temperatures, respectively. The rectum temperature was measured to verify the rise of body temperature during exercise. An intraperitoneal glucose tolerance test (IPGTT) was performed for each group before and after the training period. Soleus and plantaris muscles were sampled under anesthesia 48 hours after the last exercise session. HSP72 expressions were measured using western blot analysis.

**RESULTS:** Body temperature significantly increased in OTr-OLETF ( $40.65 \pm 0.41^\circ\text{C}$ ), whereas body temperature in CTr-OLETF ( $38.01 \pm 0.35^\circ\text{C}$ ) remained similar after exercise. No significant differences in HSP72 expressions were observed among the three OLETF groups in soleus muscle. In plantaris however both CTr- and OTr-OLETF induced higher HSP72 expressions than Sed-OLETF, with the increase in HSP72 expression being greater for OTr-OLETF. The area under the curve of IPGTT was smaller for CTr- and OTr-OLETF than Sed-OLETF, indicating improved glucose tolerance after training. The values were however similar between CTr- and OTr-OLETF.

**CONCLUSION:** Preventing the rise in body temperature during exercise did not preclude the increase of HSP expression. Regardless of different expression levels of HSP72 induced by exercise training, exercise training with and without elevation of body temperature improved glucose tolerance in type 2 diabetic rats by similar degrees.

**2342** Board #17 MAY 31 2:00 PM - 3:30 PM

**High Physical Activity Attenuates The Hyperlipidemic Effect Of A Fructose-rich Meal**

Amy Bidwell<sup>1</sup>, Timothy Fairchild<sup>2</sup>, Jill Kanaley, FACSM<sup>3</sup>. <sup>1</sup>Syracuse University, Syracuse, NY. <sup>2</sup>Murdoch University, Perth, Australia. <sup>3</sup>University of Missouri, Columbia, MO.  
(No relationships reported)

The hyperlipidemic effect of a chronic high fructose diet has been well documented, however, whether increased physical activity (PA) may confer protection against these effects is yet to be determined.

**PURPOSE:** The purpose of this study was to determine the interaction between chronic high fructose consumption and PA levels on post-prandial lipemia in normal weight, recreationally active individuals.

**METHODS:** Twenty-two normal weight men and women (age:  $21.18 \pm .61$ , BMI =  $22.54 \pm .60 \text{ kg/m}^2$ ) consumed an ad libitum diet while ingesting an additional 75g of fructose for 14 days on 2 occasions. During the 14 days, subjects maintained either low PA (4500steps/day) or high PA (12,500 steps/day). Prior to and at the conclusion of the intervention, subjects underwent a study day in which they were given a fructose-rich meal (600 calorie mixed meal (45% carbohydrate [7.3% fructose], 40% fat, and 15% protein)) in the morning after a 12 h overnight fast. Blood was sampled at baseline and for 6 h after the meal and analyzed for triglycerides (TG), very-low density lipoproteins (VLDL), and total cholesterol (TC). The postprandial effect of a high fructose diet was determined by calculating total area under the curve (AUC) for TC, VLDL and TG.

**RESULTS:** VLDL AUC significantly increased by  $773.7 \pm 372.9 \text{ mg/dL} \times 6\text{hr}$  from pre to post intervention in the inactive group while the active group increased by only  $265.8 \pm 314 \text{ mg/dL} \times 6\text{hr}$  ( $p=0.015$ ). The inactive, fructose-fed group increased TC AUC by  $2598.16 \pm 1162 \text{ mg/dL} \times 6\text{hr}$  from pre to post intervention compared to the active group which TC AUC increase by  $598.421 \pm 1520 \text{ mg/dL} \times 6\text{hr}$ , however, this was not significant ( $p=.228$ ). There were no significant differences in TG AUC levels.

**CONCLUSIONS:** Physical activity seems to be protective against increases in post-prandial lipemia when fed a diet high in fructose.

**2343** Board #18 MAY 31 2:00 PM - 3:30 PM

**Effects of Moderate Swim Exercise on Adiposity and Metabolic Function in Mice**

Roberta L. Pohlman<sup>1</sup>, Ana Carneiro<sup>1</sup>, Vera Farah<sup>2</sup>, Lynn Hartzler<sup>1</sup>, Mariana Morris<sup>1</sup>. <sup>1</sup>Wright State University, Dayton, OH. <sup>2</sup>Universidade Presbiteriana Mackenzie, São Paulo, Brazil. (Sponsor: Lynn Darby, FACSM)  
(No relationships reported)

Chronic exercise has been recommended for diabetics as a way to attenuate metabolic changes and prevent obesity.

**PURPOSE:** This study was undertaken to determine the effects of swim training on the metabolic and anthropomorphic response to a high fat (60%) and fructose (10% liquid) diet in C57BL male mice.

**METHODS:** Mice were randomly assigned to one of three groups: Control (CON, Standard Chow & Water, n=10); Sedentary (SED, High Fat Chow & Fructose Water, n=9); and Exercise (EX, High Fat Chow & Fructose Water, n=9). EX mice swam 1 hr/day, 3 days/week, for 8 weeks. SED and CON did not participate in the exercise program. Caloric consumption and body composition were measured weekly (ECHO-MRI). A glucose tolerance test (GTT) was conducted at week 7. Plasma glucose, insulin, leptin, and corticosterone were measured at week 8. Epididymal white adipose tissue (WAT) was analyzed histologically to determine fat cell size. Data were analyzed using ANOVA and *post hoc* tests.

**RESULTS:** Exercise did not improve body fat or fat cell size. Body fat was as high as ~40% in the SED and EX groups as compared to 18% in CON. The increased levels of corticosterone, insulin, and glucose in the fat/fructose groups were reduced by exercise. Corticosterone: CON,  $211 \pm 1.6$  ng/ml; SED,  $571 \pm 0.9$  ng/ml; EX,  $257 \pm 1.6$  ng/ml (SED>ED,  $p < 0.01$ ). Insulin: CON,  $1.2 \pm 0.2$  ng/ml; SED,  $8.3 \pm 2.3$  ng/ml; EX,  $3.8 \pm 0.5$  ng/ml (SED>EX,  $p < 0.05$ ). Glucose: CON,  $136.2 \pm 4.7$  mg/dl; SED,  $153.9 \pm 5.5$  mg/dl; EX,  $126.2 \pm 6.2$  mg/dl (SED>EX  $p < 0.01$ ). GTT was impaired by the fat/fructose diet with levels corrected by exercise ( $p < 0.05$ ).

**CONCLUSION:** These results document the beneficial effects of even moderate exercise on key metabolic parameters in dietary-induced diabetes.

This study was supported by NIH R01 HL093567

**2344** Board #19 MAY 31 2:00 PM - 3:30 PM

**Time Trial Performance 4 h following Glycogen-Depleting Exercise is Enhanced Similarly with Recovery Non-dairy Chocolate Beverages vs Chocolate Milk**

Adam N. Upshaw, Tiffany Lam, Arash Bandegan, Peter W.R. Lemon, FACSM. *University of Western Ontario, London, ON, Canada.*

(No relationships reported)

Post exercise chocolate milk ingestion has been shown to enhance both glycogen resynthesis and subsequent exercise performance.

**PURPOSE:** To assess whether non-dairy chocolate beverage ingestion post glycogen-depleting exercise can enhance 20km time trial performance 4 h later.

**METHODS:** Ten healthy trained male cyclists ( $21 \pm 2$  y,  $VO_{2max} = 60 \pm 5.2$  ml $\cdot$ kg $^{-1}$  $\cdot$ min $^{-1}$ ; mean $\pm$ SD) completed a series of intense cycling intervals designed to lower muscle glycogen (Jentgens & Jeukendrup, 2003) followed by 4h of recovery and a subsequent 20km cycling time trial. During the first 2h of recovery, participants ingested chocolate dairy (DAIRYCHOC), chocolate soy milk (SOYCHOC), chocolate hemp milk (HEMPCHOC), low fat dairy milk (MILK), or a 0 kcal artificially sweetened, flavored beverage (PLACEBO) at 30min intervals in a double blind, counterbalanced repeated measure design. All drinks, except the PLACEBO were isoenergetic (1010  $\pm$  148 kcal) and provided 1g CHO $\cdot$ kg body mass $^{-1}$  $\cdot$ h $^{-1}$ . Fluid intake across CHOC treatments was equalized (1796  $\pm$  498 ml) by ingesting appropriate quantities of water based on MILK intake. The CHO:PRO ratio was 4:1, 1.5:1, 4:1, and 5:1, for DAIRYCHOC, MILK, SOYCHOC, and HEMPCHOC, respectively.

**RESULTS:** Time trial performance (DAIRYCHOC 34.58  $\pm$  2.5 min, SOYCHOC 34.83  $\pm$  2.2 min, HEMPCHOC 34.88  $\pm$  1.1 min, MILK 34.47  $\pm$  1.7 min) was enhanced similarly vs PLACEBO (37.85  $\pm$  2.1) for all treatments ( $P = 0.019$ ).

**CONCLUSION:** These data suggest that post exercise macronutrient and total energy intake are more important for 20 km time trial performance following glycogen-depleting exercise than protein type or protein: carbohydrate ratio.

**The Effect Sweet Cassava Polysaccharide (SCP) on Exhaustive Running Performance**

Te Hung Tsao<sup>1</sup>, C. H. Yen<sup>2</sup>, C. U. Huang<sup>2</sup>. <sup>1</sup>National Sun Yat-Sen University, Kaohsiung, Taiwan. <sup>2</sup>National Pingtung University Science and Technology, Pingtung, Taiwan.

(No relationships reported)

**PURPOSE:** This study was to examine the effect of sweet cassava polysaccharide (SCP) on endurance performance.

**METHODS:** Thirty male SD rats (7-week old) were divided into three groups: control (C), exercise (E) and exercise with SCP administration (ESCP) at the dosage of 500mg/kg body weight by gastric-intubation for 6 days in addition to standard rat food and plain water. Exercise training was performed in the E and ESCP groups for 5 days (no exercise in the 6th day), and then all rats were sacrificed for determining the levels of gastrocnemius and soleus glycogen content and blood metabolites such as blood glucose, free fatty acid and insulin after the ESCP and E groups completed the exhaustive running. **RESULTS:**

The running time to exhaustion was significantly longer in ESCP group than in E group- (63 vs. 45 minutes,  $p < 0.05$ ). Both gastrocnemius (C, ESCP, and E for  $2.10 \pm 0.51$ ,  $1.70 \pm 0.25$ , and  $1.00 \pm 0.28$  mg/g, respectively,  $p < 0.05$ ) and soleus (C, ESCP, and E for  $3.15 \pm 0.92$ ,  $2.23 \pm 0.44$ , and  $1.09 \pm 0.59$  mg/g, respectively,  $p < 0.05$ ) glycogen content of ESCP and C groups were significantly greater than those of E group, but, only significantly higher in the C group than in the ESCP group for soleus was found. In addition, free fatty acid (C, ESCP, and E for  $1.21 \pm 0.13$ ,  $1.25 \pm 0.12$ , and  $0.84 \pm 0.14$  mEq/L, respectively,  $p < 0.05$ ) and blood glucose (C, ESCP, and E for  $111.4 \pm 5.56$ ,  $109.1 \pm 4.68$ , and  $100.1 \pm 1.91$  mg/dL, respectively,  $p < 0.05$ ) concentrations were significantly higher in the ESCP and C groups than in the E group. **CONCLUSIONS:** A 5-day supplementation of SCP can extend the running time to exhaustion, which might be attributed to elevated muscle glycogen content and free fatty acid levels in blood.

**2346** Board #21 MAY 31 2:00 PM - 3:30 PM

**Carbohydrate Attenuates Central Fatigue in Cyclists**

Beth W. Glace, Ian J. Kremeric, Malachy P. McHugh, FACSM. *Lenox Hill Hospital, New York, NY.*

(No relationships reported)

**PURPOSE:** Carbohydrate ingestion prolongs fixed-intensity, submaximal exercise. The purpose of this study was to identify the mechanism [peripheral vs. central] by which carbohydrate ingestion delays fatigue after exhaustive cycling.

**METHODS:** 4 men [ $35 \pm 5$  yrs;  $VO_{2peak}$   $66 \pm 4$  ml/Kg/min] were assigned, in a double-blind crossover design, to an artificially sweetened, non-caloric, electrolyte beverage ["Placebo", 4C Totally Light 2 Go] and to a commercially available sports drink ["Carbohydrate", Gatorade] at a rate of 1% of body weight each hour. Subjects cycled for 2 hours at their ventilatory threshold, approximately 66% of  $VO_{2peak}$ , with 5, 1-minute sprints interspersed, followed by a 3-Km time trial. Intensity was then increased to the workload at their respiratory compensation threshold [approx. 85%  $VO_{2peak}$ ] and subjects were encouraged to pedal for as long as possible. Ratings of perceived exertion [RPE] were measured throughout using the Borg scale. Blood glucose, lactate and quadriceps strength were measured pre-exercise, post-3K time trial and post-exhaustion. Isometric strength testing was performed in a semi-reclined position: 1) MVC; 2) MVC with superimposed femoral nerve magnetic stimulation to measure central activation ratio [CAR]; 3) femoral nerve stimulation [PMS] in a 4-second pulse train on a relaxed muscle. Changes in metabolic and strength measurements were analyzed with repeated measures ANOVA.

**RESULTS:** Post-exercise strength was 92% of baseline in the Carbohydrate trial vs. 75% in the Placebo trial [ $p = 0.002$ ]. Preservation of strength with Carbohydrate was due to better maintenance of central activation [Carbohydrate CAR after fatigue was 91% of baseline vs. Placebo CAR 80% of baseline,  $p = 0.036$ ], since there was no evidence of peripheral fatigue based on maintenance of PMS-elicited force [effect of time,  $p = 0.869$ ; time x drink,  $p = 0.938$ ]. Carbohydrate intake tended to improve time trial and ride to exhaustion performance. There was no effect of drink on blood glucose or lactate.

**CONCLUSION:** Carbohydrate ingestion preserves performance via a central mechanism during exhaustive cycling.

2347 Board #22 MAY 31 2:00 PM - 3:30 PM

**Effects of Carbohydrate Supplementation on Human Growth Hormone and Cytokine Responses during Resistance Exercise**

Pan Soo Kim, Ying Chang, Hyun Lyung Jung, Jun Gu Jung, Ho Youl Kang. *Kyungpook National University, Daegu, Korea, Republic of.*  
(No relationships reported)

**PURPOSE:** This study was to investigate the effects of carbohydrate consumption on human growth hormone (hGH) and cytokine responses during resistance exercise

**METHODS:** Ten male students (Age;  $23.2 \pm 0.4$  yr, Height;  $174.1 \pm 2.0$  cm, Body Weight;  $68.4 \pm 1.7$  kg) were randomly received to the exercise treatment (8RM 3sets) and exercise/carbohydrate (8RM 3sets/CHO). The 8RM 3sets/CHO ingested the carbohydrate ( $1.2$  g/kg bw) during and after resistance exercise which consisted of leg press exercise with three sets using eight repetition maximum (8 RM) load. Blood samples were drawn immediately before (pre) and at 15, 30, 45, 60, 75, 90, 105, and 120 min after exercise. Plasma hGH, total testosterone, cortisol, insulin and glucose levels were determined and Interleukin 1, interleukin  $1\beta$  and interleukin 10 levels were also measured.

**RESULTS:** Plasma hGH level in 8RM 3sets/CHO was significantly decreased at 30, 45, 60, 75, 90 min during exercise compared with the 8RM 3sets ( $p < 0.05$ ). Plasma glucose in 8RM 3sets/CHO was significantly increased at 15, 30, 45, 60, 90 min during exercise compared with the 8RM 3sets and plasma insulin responses in 8RM 3sets/CHO was significantly increased at all times (15–120 min) compared to those of 8RM 3sets ( $p < 0.05$ ). The cortisol level was significantly increased in 8RM 3sets/CHO at 120min after (0) exercise than 8RM 3sets ( $p < 0.05$ ). Testosterone level was significantly reduced at 45, 60, 75, 90, 105, 120 min compared to those of CON ( $p < 0.05$ ). Plasma CK activity and cytokines (IL-6, IL- $1\beta$ , IL-10) were no significantly different between two treatments.

**CONCLUSIONS:** The data of this study indicate that carbohydrate supplementation during resistance exercise could suppress the elevation of plasma growth hormone, but did not affect the concentrations of plasma cortisol and testosterone. In addition, carbohydrate consumption during resistance exercise did not cause the changes of plasma IL-6, IL- $1\beta$ , and IL-10 levels

2348 Board #23 MAY 31 2:00 PM - 3:30 PM

**Consumption Of A Novel, Carbohydrate-free Recovery Beverage Reduces Muscle Damage And Improves Recovery Post-exercise**

Paul A. Borsa, FACSM<sup>1</sup>, Kelly A. Larkin<sup>1</sup>, Jeffrey S. Martin<sup>2</sup>. <sup>1</sup>University of Florida, Gainesville, FL. <sup>2</sup>University of Missouri-Columbia, Columbia, MO.  
(P.A. Borsa: Contracted Research - Including Principle Investigator; Revalerio Corporation.)

**PURPOSE:** To assess the effects of consuming a novel carbohydrate-free recovery beverage on muscle damage, inflammation and functional recovery following a single bout of isokinetic resistance exercise for the biceps brachii muscle.

**METHODS:** Subjects were blinded and randomly assigned to a beverage (BEV; n=20) or placebo control (PLA; n=20) group. Subjects consumed 2-6 500ml bottles of the BEV or PLA daily, as determined by weight categories, for 23 days. On day 19 subjects completed a fatigue protocol for the biceps in order to induce muscle damage. The fatigue protocol consisted of 3 sets of 20 repetitions using concentric and eccentric contractions of the elbow flexors. Blood draw and clinical measurements were performed pre-exercise and 24, 48, and 96-hrs post-exercise. Clinical measures included maximal isometric arm strength, pain with elbow extension, resting arm angle (RANG) and self-report arm disability. Pain was quantified using a visual analog scale and RANG was measured in degrees. Disability was measured using the QuickDASH self-report questionnaire. Plasma samples were analyzed to determine concentrations of creatine kinase (CK), myoglobin (Mb) and C-reactive protein (CRP).

**RESULTS:** There was no significant difference in maximal isometric arm strength between BEV and PLA pre-exercise and at 48-hr and 96-hr post-exercise. Pain with elbow extension and self-report arm disability were significantly higher in the PLA compared to the BEV group at 48-hr [ $39.2 \pm 16$  v.  $25.4 \pm 13$ ,  $p < 0.01$ ;  $25 \pm 9$  v.  $19.8 \pm 3$ ,  $p < 0.01$ ] and 96-hr [ $17.8 \pm 13$  v.  $7.7 \pm 8$ ,  $p < 0.01$ ;  $11.9 \pm 3$  v.  $16.8 \pm 5$ ,  $p < 0.01$ ] after exercise, while RANG was significantly higher in the BEV group compared to PLA at 48-hr [ $159.2 \pm 7$  v.  $150 \pm 11$ ;  $p < 0.01$ ] and 96-hr [ $163.4 \pm 5$  v.  $158.9 \pm 4$ ,  $p < 0.01$ ] after exercise. Similarly, plasma concentrations for CK (IU/L) and CRP (mg/L) were significantly lower in the BEV group compared to PLA at 48-hr [ $235.6 \pm 280$  v.  $770.6 \pm 934$ ,  $p < 0.05$ ;  $3.1 \pm 2$  v.  $5.4 \pm 4$ ,  $p < 0.05$ ] and 96-hr [ $364 \pm 247$  v.  $948 \pm 1098$ ,  $p < 0.05$ ;  $2.64 \pm 2$  v.  $5.8 \pm 5$ ,  $p < 0.01$ ] after exercise.

**CONCLUSIONS:** Consuming a novel, carbohydrate-free recovery beverage significantly reduced exercise-induced muscle damage and inflammation, and improved biochemical and functional recovery.

---

2349 Board #24 MAY 31 2:00 PM - 3:30 PM

**Consumption Of A Novel, Carbohydrate-free Recovery Beverage Attenuates Strength Loss After High Intensity Resistance Exercise**

Kelly A. Larkin, Paul A. Borsa, FACSM. *University of Florida, Gainesville, FL*

(K.A. Larkin: Contracted Research - Including Principle Investigator; Revalerio Corporation.)

**PURPOSE:** To assess the effects of consuming a novel, carbohydrate-free recovery beverage on strength loss and ratings of perceived exertion (RPE) following isokinetic exercise.

**METHODS:** Subjects were blinded and randomly assigned to either a beverage (BEV; n=20) or placebo control (PLA; n=20) group. Subjects consumed 2 to 6 500ml bottles of the BEV or PLA daily, as determined by weight categories, for 18 days. On day 19 subjects completed a fatigue protocol for the elbow flexors. The fatigue protocol consisted of a single bout of isokinetic resistance exercise using 3 sets of 20 repetitions of concentric and eccentric contractions of the biceps brachii. Subjects were tested for isometric strength pre-exercise and again immediately following exercise. The maximal voluntary contraction (MVC) was used as the criterion measure for isometric strength and was recorded in N-m. Ratings of perceived exertion were also assessed following the exercise bout using a modified Borg scale. Borg scale ratings ranged from 6 (no exertion) to 20 (maximal exertion). Strength loss indices were calculated for each subject by dividing the post-exercise strength value with the pre-exercise value multiplied by 100.

**RESULTS:** The BEV group had a smaller decrease in MVC post-exercise than the PLA control group [BEV: pre-ex =  $38.4 \pm 19$ , post-ex =  $19.1 \pm 10$ ; PLA: pre-ex =  $46.5 \pm 26$ , post-ex =  $22.4 \pm 14$ ]. The strength loss index was also significantly lower for the BEV group compared to PLA control [BEV: 0.505, PLA: 0.527;  $p < 0.01$ ]. In addition, the exercise protocol was perceived as less strenuous by the BEV group [BEV: 16.5, PLA: 17.8;  $p < 0.05$ ].

**CONCLUSIONS:** Consuming a novel, carbohydrate-free recovery beverage for 18 days prior to high intensity resistance exercise can significantly reduce muscular fatigue and ratings of perceived exertion.

---

2350 Board #25 MAY 31 2:00 PM - 3:30 PM

**Effects Of Carbohydrate And Electrolyte Supplementation On Processing Speed, Selective Attention And Vo2max**

Ali Boolani<sup>1</sup>, Kumar Tammareddi<sup>2</sup>, Bert Jacobson, FACSM<sup>3</sup>, Will Roszel<sup>1</sup>. <sup>1</sup>Oklahoma City University, Oklahoma City, OK. <sup>2</sup>Alvin C. York VA Hospital, Nashville, TN. <sup>3</sup>Oklahoma State University, Stillwater, OK.

(No relationships reported)

**PURPOSE:** The purpose of this study was to evaluate performance on cognitive post sub-maximal VO2Max testing using the Bruce protocol after consumption of water or a carbohydrate-electrolyte solution (CE).

**METHODS:** Volunteers (N=12, age= $21.42 \pm 2.43$ , weight=  $82.34 \pm 33.44$ ; height=  $175$ cm  $\pm$  12.8) from a Historically Black College and University (HBCU) were issued a Stroops task (ST) and Random Numbers (RN) test at baseline. The ST congruent (STC) and incongruent (STI) words were timed and number incorrect was identified. The RN was a one minute timed test with numbers 0-99 randomized in a 10x10 grid. Subjects circled numbers as they were identified. Subjects were given water at the start of their warm-up on a Bruce Protocol (BP) VO2Max test and were asked consume it prior to the end of the first level of the BP. Subjects were administered the test until they reached a perceived exertion of 20 on a Borg rating of perceived exertion (RPE) scale. When a subject reached a RPE of 20, the test was stopped and without rest subjects were re-administered a ST and RN. Subjects were asked to complete the same protocol one week later however, they were administered 400ml of Gatorade G2 fruit punch. Data was analyzed using paired t-tests and test scores were analyzed for pre- and post-test data for both days. Changes in test scores were evaluated using paired t-tests.

**RESULTS:** Analysis yielded significant difference in pre and post-test STI ( $p=.010$ ) and RN ( $p=.006$ ) for water. There was no significant difference in STC ( $p=.613$ ) for water. There was a significant difference in pre and post-test STI ( $p<.001$ ), STC ( $p=.002$ ), but no significant difference in RN ( $p=.587$ ) for CE. No significant differences in changes in STC ( $p=.975$ ), STI ( $p=.181$ ), RN ( $p=.690$ ) for both protocol were identified. A significant difference in VO2Max was also noted ( $p=.002$ )

**CONCLUSIONS:** Significant decreases in STI and an increase score on RN may be attributed to increased cognitive function post-exercise. However no significant difference was found between the changes in of STC, STI and RN may lead us to assume that CE supplementation during exercise does not improve cognitive function more than water. The increase in VO2Max during may be attributed to increased blood glucose post supplementation giving the subject more time before they reached their lactic threshold.

**CHO Mouth-rinse Improves 16 Km Time Trial Cycling Performance In A Glycogen Depleted State**

Alexis R. Mauger<sup>1</sup>, Harry McGonagle<sup>2</sup>, Lee Taylor<sup>2</sup>, Paul C. Castle<sup>2</sup>. <sup>1</sup>University of Kent, Chatham, United Kingdom. <sup>2</sup>University of Bedfordshire, Bedford, United Kingdom.

(No relationships reported)

Rinsing of carbohydrate (CHO) solutions during exercise can improve performance in fixed work-amount cycle time trials (TT) and automated treadmill running of ~45-60 min duration. Mechanisms responsible for this improved performance have been attributed to a reduced perceived exertion, activation of reward centres in the brain and/or increased cortical excitability. However, this phenomena has never been demonstrated in distance-based TT cycling, or when exercise is performed in a glycogen depleted state.

**PURPOSE:** To determine whether the central effect of CHO mouth-rinse during a 16 km cycling TT improves performance when muscle glycogen has been previously depleted.

**METHODS:** Eight recreationally active subjects completed a VO2max test, a 16 km familiarisation TT and four performance 16 km TT. The evening before each performance TT, subjects completed a previously described muscle glycogen depletion protocol (Van Den Bergh et al. 1996) and only ate a low-CHO evening meal before the subsequent performance TT. During the performance TT, in a double-blind, randomised fashion, subjects either ingested (GluI) or rinsed (GluR) 150 mL of 6.4% glucose solution every 2 km, or ingested (PlaI) or rinsed (PlaR) 150 mL of commercially available non-caloric concentrate sweetened with aspartame and saccharin. Subjects received no feedback during the TT other than distance completed. Measures of blood lactate B[La], blood glucose B[Glu], heart rate (HR), RPE and power output (PO) were recorded during each TT.

**RESULTS:** Time to complete the TT was significantly reduced ( $F_{2,5,17.2} = 4.3, p = 0.02$ ) in the GluR ( $29:53 \pm 2:56$  min) vs. PlaR ( $31:16 \pm 3:15$ ) ( $p = 0.05$ ). The 5% performance improvement in the GluR (compared with PlaR) was accompanied by a mean 21 W higher PO in the first 12 km ( $F_{3,21} = 3.4, p = 0.03$ ) and a mean 8 bpm higher HR ( $F_{3,21} = 3.1, p = 0.04$ ) throughout the TT. No changes in B[La], B[Glu] or RPE across the TT ( $p > 0.05$ ) were observed. No significant differences were observed between the GluI, PlaR and PlaI conditions.

**CONCLUSIONS:** The proposed central changes and subsequent exercise performance improvement accompanying CHO mouth-rinsing during exercise are apparent even when muscle glycogen levels have been previously depleted.

**Effect Of Carbohydrate Mouth Rinse And/or Ingestion On High-intensity Exercise Performance**

Ajmol Ali, Catherine Moss, Ji Y. Yoo, Bernhard Breier. Massey University, Auckland, New Zealand.

(No relationships reported)

There is equivocal data regarding mouth rinsing with carbohydrate (CHO) and exercise performance. It has been suggested that in a fed state, where muscle and liver glycogen stores are not compromised, glucose levels are maintained and hence mouth rinsing will not affect performance.

**PURPOSE:** To examine effects of fluid intake, CHO mouth rinse, and CHO ingestion on cycling performance under glycogen-compromised conditions.

**METHODS:** Nine recreationally trained cyclists volunteered for this randomised, counterbalanced, double-blind study. Four main trials were performed on an electronically braked cycle ergometer; each trial, separated by 7 days, took place over 2 days. On Day 1 the participants underwent a 90 min glycogen-reducing exercise protocol, immediately followed by a low-carbohydrate meal and then a subsequent overnight fast. The following morning a 1-h time trial performance test was conducted. Subjects performed a certain amount of work as fast as possible for the performance test. For the main trials subjects either a) mouth rinsed with a 15% CHO solution (CHOR), b) ingested 7.5% CHO solution (CHOI), c) mouth rinsed with a taste-matched placebo (PLAR), or d) ingested taste-matched placebo (PLAI); solutions were administered every 12.5% of exercise completed. Blood samples were taken every 25% of exercise.

**RESULTS:** There were no significant differences in performance time between treatments (CHOI  $3927 \pm 288$  s; CHOR  $4101 \pm 236$  s; PLAI  $4125 \pm 316$ ; 4097  $\pm 310$  s; mean  $\pm$  SD;  $P=0.22$ ). However, mean power output was higher in CHOI ( $231 \pm 33$  W) relative to other trials ( $221-223$  W;  $P<0.05$ ). There was a main effect of treatment ( $P<0.001$ ) and interaction of treatment x time for plasma glucose ( $P<0.001$ ); values were similar at the start of exercise ( $4.2-4.9$  mM) but were higher in CHOI at 75% ( $5.4 \pm 0.7$  mM) and 100% ( $5.9 \pm 1.2$  mM) of exercise relative to other trials ( $3.9-4.7$  mM;  $P<0.05$ ). There were treatment ( $P<0.001$ ) and interaction ( $P=0.015$ ) effects for insulin; levels were higher in CHOI between 50-100% of exercise ( $2.8-2.0$  mU/L) relative to other trials ( $1.5-0.4$  mU/L;  $P<0.05$ ).

**CONCLUSIONS:** Mouth rinsing with a CHO solution in a glycogen-compromised condition did not affect exercise performance. CHO ingestion increased glucose concentrations and improved performance relative to fluid ingestion and CHO mouth rinse trials.

**Pre-exercise Carbohydrate Supplementation Does Not Suppress Rate Of Fatigue During Resistance Exercise In Trained Females.**

Bill I. Campbell<sup>1</sup>, Kelly A. Raposo<sup>1</sup>, Ashley Bullion<sup>1</sup>, Amber Petchonka<sup>1</sup>, Nina Pannoni<sup>1</sup>, Brad Cloer<sup>1</sup>, Shawn Deignan<sup>1</sup>, Tina Vyas<sup>1</sup>, Richard Kreider, FACSM<sup>2</sup>.

<sup>1</sup>University of South Florida, Tampa, FL. <sup>2</sup>Texas A&M University, College Station, TX.

(No relationships reported)

**PURPOSE:** To investigate the effects of ingesting pre-exercise waxy maize carbohydrate on the rate fatigue (as measured by total repetitions performed) during an acute bout of resistance exercise.

**METHODS:** 13 resistance-trained females ( $21.9 \pm 4.8$  yrs;  $163.8 \pm 7.6$  cm;  $62.1 \pm 6.7$  kg) participated in 2 separate resistance exercise sessions separated by seven days. During a familiarization trial, each participant's 1RM for the bench press and leg press was determined. Next, the participants were randomly assigned to either the carbohydrate or placebo treatment session using a double blind, counterbalanced, cross-over design with each participant consuming 1.0g carbohydrate/kg of body mass or a non-caloric placebo beverage 60 minutes before exercise. The source of carbohydrate was waxy maize carbohydrate. The resistance exercise workout required each participant to perform 5 sets of bench press at 75% 1RM followed by 5 sets of leg press at 85% of 1RM performed to muscular failure, with 3 minutes of rest between each set and 5 minutes of rest between the two exercises. The rate of fatigue was calculated as the percentage decline (in repetitions completed) from the first set to the fifth (and final) set in both the bench press and leg press. Data were analyzed by a paired samples t-test ( $p < .05$ ).

**RESULTS:** No statistically significant differences existed between treatments in the rate of fatigue in relation to bench press and leg press. Rate of fatigue for bench press in the carbohydrate group was  $54 \pm 14\%$  and was  $57 \pm 8\%$  in the placebo group. There were no significant differences ( $p = 0.420$ ) between these two groups in relation to rate of fatigue in the bench press. Rate of fatigue for leg press in the carbohydrate group was  $29 \pm 22\%$  and was  $22 \pm 24\%$  in the placebo group. There were no significant differences ( $p = 0.144$ ) between these two groups in relation to rate of fatigue in the leg press.

**CONCLUSIONS:** Pre-exercise carbohydrate supplementation (in the form of waxy maize carbohydrate) does not impact the rate of fatigue during an acute bout of resistance exercise in resistance-trained females.

2354 Board #29 MAY 31 2:00 PM - 3:30 PM

**Fasting Blood Glucose is Significantly Associated with Metabolic Inflexibility in Hispanic Women**

Sarah E. Deemer<sup>1</sup>, George A. King<sup>2</sup>, Valorie Castro<sup>2</sup>, Fabiola Ibarra<sup>2</sup>, Alexandra Jacquez<sup>2</sup>, Diana Ponce<sup>2</sup>, Mariana Rodriguez<sup>2</sup>, Elizabeth Venegas<sup>2</sup>, Chris L. Melby<sup>1</sup>, Matthew S. Hickey, FACSM<sup>1</sup>. <sup>1</sup>Colorado State University, Fort Collins, CO. <sup>2</sup>University of Texas at El Paso, El Paso, TX.

(No relationships reported)

Metabolic inflexibility is characterized by an attenuated ability to increase CHO oxidation in response to increased circulating glucose and insulin. Such inflexibility is found in type 2 diabetes, and may also be associated with increased diabetes risk in individuals with normal blood glucose concentrations. This link has not been studied in normoglycemic Hispanic women, a group known to be at higher risk for diabetes.

**PURPOSE:** To determine if fasting blood glucose and insulin sensitivity are related to the magnitude of metabolic inflexibility in non-diabetic Hispanic women.

**METHODS:** Insulin sensitivity was assessed using the euglycemic hyperinsulinemic clamp (EHC) technique and changes in substrate oxidation, i.e. metabolic flexibility, were measured by the respiratory exchange ratio (RER) in 23 non-diabetic Hispanic women (mean  $\pm$  SD: age (y): 35.7  $\pm$  13.2; BMI (kg/m<sup>2</sup>): 29.8  $\pm$  6.1; % body fat: 45.9  $\pm$  5.9). Metabolic flexibility was calculated as the RER under insulin-stimulated (EHC) conditions - fasting RER. Fasting glucose (X=80.6 mg/dL) was measured using enzyme electrode technology (YSI 2300 Stat Plus). Data were analyzed using paired *t*-tests and Pearson's Product-Moment Correlation. Significance was set at  $\alpha = 0.05$ .

**RESULTS:** Mean fasting RER (0.82) increased to 0.93 during the clamp ( $P < 0.001$ ), indicative of metabolic flexibility in these women. However, there was a significant inverse correlation between fasting blood glucose and metabolic flexibility ( $r = -0.431$ ,  $P = 0.040$ ) and insulin sensitivity as determined by the glucose-infusion rate was positively correlated with metabolic flexibility ( $r = 0.553$ ,  $P = 0.006$ ). **DISCUSSION:** These data indicate that even in normoglycemic Hispanic women, fasting blood glucose and insulin sensitivity may be predictive of early impairments in metabolic flexibility. Future studies should be undertaken to determine the time-course of development of metabolic inflexibility and risk of diabetes in Hispanic women.

**Effects of a Carbohydrate Containing Beverage on Thermoregulatory Parameters During Endurance Exercise in a Thermoneutral Environment**

Nicole E. Pollard, Jessica C. Brown, Lindsay R. Laamann, RYanne D. Carmichael, Tracey D. Matthews, Vincent J. Paolone, FACSM. *Springfield College, Springfield, MA.*

(No relationships reported)

**PURPOSE:** The investigation was designed to determine if a 7% carbohydrate containing beverage ingested throughout a high intensity (80-85% of VO<sub>2peak</sub>) cycling bout lasting 45 min would have an effect on thermoregulatory parameters.

**METHODS:** Female subjects with a mean age of 29.9 $\pm$ 5.22 years (N = 10) performed two separate trials of a 45 min cycling session at 80-85% VO<sub>2peak</sub>. In one trial subjects consumed 2 ml·kg<sup>-1</sup> of body weight of a 7% carbohydrate containing beverage 30 min and 15 min before the 45 min cycling session began. The same amount of beverage was consumed during the cycling bout at 15, 30, and 45 min into the exercise session. In the second trial, subjects were given 2 ml·kg<sup>-1</sup> of body weight of a placebo beverage at the same time points. The study was conducted in a crossover design, and the variables included VO<sub>2</sub>, RER, heart rate, core temperature, skin temperature, core to shell gradient, blood pressure, RPE, thermal sensation, blood hemoglobin and blood hematocrit. Variables were measured every 5 min and blood data every 15 min.

**RESULTS:** No significant interaction ( $p > .05$ ) was found between the carbohydrate beverage and placebo beverage ingestion across time in heart rate, core temperature, RPE, RER, thermal sensation or pre and post measures of mean body temperature, mean skin temperature, and core to shell gradient. In addition, no significant main effect for the treatments was found for all of the dependent variables. Significant time effects were found for heart rate, core temperature, RPE, RER, thermal sensation, mean skin temperature, and core to shell gradient. No significant differences were found ( $p > .05$ ) between the ingestion of a carbohydrate and placebo drink before and after an acute exercise bout in the thermoregulatory parameters. A non-statistically significant but possibly physiologically significant percent change in pre and post core to shell gradient was observed. A 69.3% decrease in the width occurred between pre and post core to shell gradient measures for the carbohydrate beverage and a 76.04% decrease in the width occurred for the placebo beverage.

**CONCLUSIONS:** The ingestion of carbohydrate beverages during endurance exercise had no significant effect on thermoregulatory parameters ( $p > .05$ ).

2356 Board #31 MAY 31 2:00 PM - 3:30 PM

**The Addition of Protein to a Carbohydrate Supplement Enhances Fluid Retention But Not Running Performance**

Craig O. Mattern<sup>1</sup>, Brian Campbell<sup>2</sup>, Tina Carson<sup>1</sup>, Justin Charland<sup>2</sup>, Sam Craven<sup>3</sup>, Natalia Filip<sup>2</sup>, Celia Watt<sup>1</sup>, Ryan Yapple<sup>1</sup>, Byrne K. Heidi<sup>1</sup>. <sup>1</sup>The College at Brockport, SUNY, Brockport, NY. <sup>2</sup>Upstate Medical University, SUNY, Syracuse, NY. <sup>3</sup>Ball State University, Muncie, IN.

(No relationships reported)

**INTRODUCTION:** It is unclear whether or not the isocaloric addition of protein (PRO) to a carbohydrate (CHO) endurance exercise supplement improves exercise performance, recovery, and/or fluid retention.

**PURPOSE:** 1) to determine if a PRO+CHO beverage during and/or after endurance exercise improves performance in a subsequent exercise bout compared to CHO alone, 2) to measure fluid retention as a possible mechanism for enhanced performance.

**METHODS:** Using a randomized crossover design, nine endurance trained subjects (age=33 $\pm$ 4.2 yrs; VO<sub>2max</sub>=65.1 $\pm$ 1.47 ml/kg/min, body fat=7.9 $\pm$ 1.0%) received a beverage containing CHO (0.65g of CHO/kg) or CHO + PRO (0.52g of CHO/kg plus 0.13g of protein/kg) during a one hour run at 68% of VO<sub>2max</sub>. During a 7 hour recovery period subjects then received beverages containing either CHO (1.0g of CHO/kg) or CHO+PRO (0.80g of CHO/kg plus 0.20g of protein/kg) immediately post-exercise, at 1 and 4 hours of recovery. Urine volume and body weight were measured post-exercise, during recovery at hours 3, 5, and 7 to calculate fluid retention. Subjects then ran a 10-km time trial.

**RESULTS:** There were no statistical differences in 10-km running times or measures of blood glucose or insulin during or after exercise among the four nutritional conditions. However fluid retention was significantly higher at hour 5 of recovery in both conditions in which CHO+PRO (37.2 $\pm$ 18.0% and 34.9 $\pm$ 19.3%) was provided during recovery as compared to those in which CHO alone (19.7 $\pm$ 18.0%) was given.

**CONCLUSION:** While a 4:1 ratio of CHO:PRO provided in recovery may enhance fluid retention compared to CHO alone, this did not lead to improved 10-km running performance.

This project was supported by Infinit Nutrition.

**Effects Of A Whey-carbohydrate Supplement On Markers Of Muscle Damage After Concurrent Exercise In Men**

Catherine Saenz, Jenna M. Apicella, Brooke L. Bailey, William J. Kraemer, FACSM, Carl M. Maresh, FACSM, Jeff S. Volek. *University of Connecticut, Storrs, CT.*

(No relationships reported)

Effects of a whey-carbohydrate supplement on markers of muscle damage after concurrent exercise in men

Catherine Saenz, Jenna M. Apicella, Brooke L. Bailey, William J. Kraemer, FACSM, Carl M. Maresh, FACSM, Jeff S. Volek. University of Connecticut, Storrs, CT

Ingestion of whey protein and carbohydrate after varying types of resistance exercise rapidly increase plasma levels of essential amino acids and insulin which has been shown to positively affect muscle protein balance, but its effect on markers of muscle damage remains unclear.

**PURPOSE:** To examine the effects of a whey-carbohydrate supplement ingested mid-workout on exercise-induced muscle damage (EIMD) as determined by blood levels of creatine kinase (CK), myoglobin and fast-twitch skeletal muscle troponin-I (sTnI).

**METHODS:** Eight competitive “Crossfit” men (age,  $27.4 \pm 1.9$  yrs; height,  $180.4 \pm 2.4$  cm; weight,  $92.7 \pm 3.9$  kg; body fat,  $15.8 \pm 1.9$  %) participated in a randomized, placebo-controlled, crossover study. Subjects performed two identical acute exercise trials (AET) held 7 days apart. AET consisted of a resistance exercise portion (5x5 front barbell squat, 80% 1RM, with 2 min rest), a 15 minute rest interval where either water or protein-carbohydrate supplement (28g whey protein isolate, 15g carbohydrate) was consumed, followed by 8X10sec maximal sprints with 45sec rest between bouts. Serum measurements were obtained pre AET and immediately post (IP), 30min post, 60min post, and 180min post AET. CK and myoglobin were analyzed using commercially available assays and sTnI was analyzed by SDS-PAGE under denaturing conditions.

**RESULTS:** CK and myoglobin significantly increased over time indicating that the protocol induced muscle damage. CK levels peaked IP AET (mean  $\pm$  SE, percent change from pre AET, Water:  $42 \pm 4$ ; Supplement:  $44 \pm 9$ ,  $p < 0.05$ ). Myoglobin levels peaked 60min post AET (mean  $\pm$  SE, percent change from pre AET, Water:  $293 \pm 36$ ; Supplement:  $303 \pm 37$ ,  $p < 0.05$ ). sTnI positively correlated with CK ( $r = 0.434$ ;  $p < 0.001$ ). There was no significant difference in CK, myoglobin, or sTnI between supplementation conditions.

**CONCLUSION:** A whey- carbohydrate beverage consumed mid-workout did not attenuate the initial elevation in blood levels of muscle damage in “Crossfit”- trained men after an acute bout of concurrent exercise.

**2358** Board #33 MAY 31 2:00 PM - 3:30 PM

**Dietary Fiber Does Not Attenuate Postprandial Glycemic Responses Following A High-carbohydrate Meal Adults And Children**

Siddhartha Angadi<sup>1</sup>, Nathan Weltman<sup>2</sup>, Arthur Weltman, FACSM<sup>3</sup>, Jessica Rodriguez<sup>3</sup>, James Patrie<sup>3</sup>, Glenn Gaesser, FACSM<sup>1</sup>. <sup>1</sup>Arizona State University, Phoenix, AZ. <sup>2</sup>University of South Dakota, Sioux Falls, SD. <sup>3</sup>University of Virginia, Charlottesville, VA.

(No relationships reported)

Postprandial hyperglycemia and hyperinsulinemia are both direct and independent risk factors for the development of atherosclerotic cardiovascular disease. Dietary fiber has been previously shown to reduce postprandial glycemic and insulin excursions. We hypothesized that addition of a high-fiber breakfast cereal to a high-carbohydrate meal would blunt postprandial glycemic and insulin excursions.

**PURPOSE:** We examined the effects of dietary fiber (mostly insoluble) on postprandial blood glucose and insulin responses in youth, adults and seniors.

**METHODS:** To assess the effect of dietary fiber on postprandial glycemia, 10 youth (ages 10-17), 12 adults (ages 19-63), and 13 seniors (ages 65-75) completed two meal trials on separate days, following an overnight fast. The high-carbohydrate, low-fiber (HCLF) meal contained 95.7 g carbohydrate, 11.4 g fat, 16.7 g protein, and 3.0 g fiber. The high-carbohydrate, high-fiber (HCHF) meal contained 103.7 g carbohydrate, 12.2 g fat, 21.8 g protein, and 19.3 g fiber (mainly from All-Bran cereal). Blood was drawn at baseline and hourly for 4 hours following meal ingestion. Area under the curve for postprandial glucose and insulin was computed via the trapezoidal rule. Linear contrasts of ANOVA least-squares means were constructed to evaluate differences in postprandial glucose and insulin.

**RESULTS:** Four-hour blood glucose area under the curve (AUC;  $\text{mg} \cdot \text{dl}^{-1} \cdot \text{hour}^{-1}$ ) following both meals was not significantly different ( $p > 0.05$ ) in youth (HCLF =  $390 \pm 36$ , HCHF =  $400 \pm 22$ ), adults (HCLF =  $409 \pm 59$ , HCHF =  $406 \pm 52$ ) and seniors (HCLF =  $426 \pm 52$ , HCHF =  $430 \pm 61$ ). No significant differences between peak postprandial glucose were noted across all 3 age groups. Similarly 4-hour plasma insulin AUC ( $\text{uIU} \cdot \text{ml}^{-1} \cdot \text{hour}^{-1}$ ) following both meals was not significantly different in youth (HCLF =  $97 \pm 46$ , HCHF =  $119 \pm 47$ ), adults (HCLF =  $147 \pm 113$ , HCHF =  $139 \pm 93$ ) and seniors (HCLF =  $170 \pm 124$ , HCHF =  $129 \pm 72$ ). No significant differences between peak postprandial insulin were noted across all 3 age groups.

**CONCLUSIONS:** The addition of dietary fiber (primarily insoluble) to a high-carbohydrate meal failed to attenuate the postprandial glucose and insulin responses in children and young and older adults. Supported by NIH RR00847 and a grant from the Wheat Foods Council.

**2359** Board #34 MAY 31 2:00 PM - 3:30 PM

**Methylglyoxal And Glyoxal-derived Hydroimidazolone-AGEs Are Reduced When Exercise Training Is Combined With Low-glycemic Index Diet**

Jacob M. Haus<sup>1</sup>, Jacob T. Mey<sup>2</sup>, Thomas P.J. Solomon<sup>3</sup>, Takhar Kasumov<sup>2</sup>, Renliang Zhang<sup>2</sup>, John P. Kirwan, FACSM<sup>2</sup>. <sup>1</sup>University of Illinois at Chicago, Chicago, IL. <sup>2</sup>Cleveland Clinic, Cleveland, OH. <sup>3</sup>Centre of Inflammation and Metabolism, Copenhagen, Denmark.

(No relationships reported)

Aldehydes derived from glucose, such as methylglyoxal (MG-H1) and glyoxal-derived hydroimidazolone (G-H1), react with proteins resulting in glycation that can yield advanced glycation end products (AGEs). AGEs are present at elevated levels in plasma and atherosclerotic lesions from people with diabetes.

**PURPOSE:** We sought to examine the effects of aerobic exercise training combined with either a low- or high-glycemic index (GI) diet on insulin sensitivity and free circulating MG-H1 and G-H1.

**METHODS:** Twenty-seven obese subjects with impaired glucose tolerance (IGT), (mean  $\pm$  SEM age:  $65 \pm 1$  y; BMI:  $35.3 \pm 0.8$   $\text{kg}/\text{m}^2$ ), underwent a 12-wk aerobic exercise-training intervention (1 h/d, 5 d/wk, 85% of  $\text{HR}_{\text{max}}$ ) while randomly assigned to receive either a low-GI diet (LoGIX;  $n = 13$ ,  $40 \pm 0.3$  Units) or a high-GI diet (HiGIX;  $n = 14$ ,  $80 \pm 0.6$  Units). Free plasma MG-H1 and G-H1 (measured by liquid chromatography tandem mass spectrometry), insulin sensitivity (measured by  $40 \text{ mU}/\text{m}^2/\text{min}$  hyperinsulinemic euglycemic clamp), fasting plasma glucose (FPG), glycated hemoglobin (HbA1c), body composition and  $\text{VO}_{2\text{max}}$  were examined.

**RESULTS:** Both groups lost equal amounts of body weight ( $-7.9 \pm 1.6$  kg) and adiposity ( $-4.4 \pm 0.5\%$  body fat) and showed similar improvements in peripheral tissue insulin sensitivity ( $+87.8 \pm 13.3\%$ ) and  $\text{VO}_{2\text{max}}$  ( $+5.9 \pm 0.7$   $\text{ml}/\text{kg}/\text{min}$ ; all  $P < 0.05$ ). FPG was reduced following the lifestyle intervention ( $p = 0.003$ ) and a significant group effect was observed in the LoGIX group ( $p < 0.001$ ). HbA1c was also reduced ( $-0.07 \pm 0.08\%$ ,  $p > 0.05$ ) by the lifestyle intervention but did not reach significance. MG-H1 was reduced in both groups ( $\Delta$ , LoGIX:  $-9.9 \pm 7.5$ ; HiGIX:  $-13.0 \pm 16.3$   $\text{ng}/\text{mL}$ ), however the HiGIX group demonstrated greater reductions in G-H1 compared to LoGIX ( $\Delta$ , LoGIX:  $+1.1 \pm 1.1$ ; HiGIX:  $-0.4 \pm 0.8$   $\text{ng}/\text{mL}$ ,  $p = 0.04$ ).

**CONCLUSION:** The combined aerobic exercise and glycemic index diet lifestyle intervention was successful in improving body composition, aerobic fitness, glycemic control and reactive precursors to AGEs in obese adults with IGT. These data suggest that regular aerobic exercise and a controlled diet can reverse the formation of AGEs which may lead to reduced risk of future diabetes and diabetic complications.

**Post-Exercise Chocolate Milk and Cycling Performance Following 30 Hours of Recovery**

Hsuan-Yu Wan, Jonathon L. Stickford, Emily J. Dawkins, Alice K. Lindeman, Timothy D. Mickleborough, FACSM, Joel M. Stager, FACSM. Indiana University, Bloomington, IN.

(No relationships reported)

**INTRODUCTION:** Post-exercise chocolate milk consumption has been shown to improve subsequent endurance exercise performance following a four-hour recovery period, presumably due to added carbohydrate (CHO). It is unknown whether or not similar findings will extend following a longer recovery period.

**PURPOSE:** To examine the influence of post-exercise chocolate milk consumption on 1) subsequent cycling time trial performance following and 2) macronutrient intake during a 30-h recovery period.

**METHODS:** Twelve trained, male cyclists ( $21.7 \pm 1.8$  y,  $63.0 \pm 4.1$   $\text{ml}\cdot\text{kg}^{-1}\cdot\text{min}^{-1}$ ) performed a glycogen-depleting exercise bout followed by a 2-h supplementation period, 28 h of free-living recovery, and a subsequent 40 km cycling time trial on two separate occasions. During the supplementation period, subjects consumed an equal volume of chocolate milk (CM;  $2.0$  g  $\text{CHO}\cdot\text{kg}^{-1}$ ) or a sports drink (SD;  $0.8$  g  $\text{CHO}\cdot\text{kg}^{-1}$ ) in a single-blind, randomized design. Following the supplementation, individuals' food log was recorded during the remaining 28-h recovery period. Performance time ( $T_{\text{TT}}$ ), average power output ( $P_{\text{TT}}$ ), interval heart rates (HR), ratings of perceived exertion (RPE) and voluntary food intake were compared between the treatments using 1- or 2-tailed paired t-tests.

**RESULTS:** No difference in  $T_{\text{TT}}$  (CM:  $4016.1 \pm 71.2$  sec, SD:  $4015.1 \pm 64.1$  sec),  $P_{\text{TT}}$  (CM:  $247.5 \pm 11.6$  W, SD:  $247.5 \pm 11.1$  W), HR, or average RPE (CM:  $16.6 \pm 0.3$ , SD:  $16.7 \pm 0.3$ ) was observed between the CM and SD trials. Thirty-hour total calorie, fat and protein (PRO) intakes were significantly greater in CM compared to SD (CM:  $73.8 \pm 3.4$   $\text{kcal}\cdot\text{kg}^{-1}$ ,  $9.5 \pm 0.6$  g  $\text{CHO}\cdot\text{kg}^{-1}$ ,  $2.9 \pm 0.3$  g  $\text{fat}\cdot\text{kg}^{-1}$ ,  $2.9 \pm 0.2$  g  $\text{PRO}\cdot\text{kg}^{-1}$ , SD:  $60.3 \pm 2.6$   $\text{kcal}\cdot\text{kg}^{-1}$ ,  $8.2 \pm 0.4$  g  $\text{CHO}\cdot\text{kg}^{-1}$ ,  $2.0 \pm 0.2$  g  $\text{fat}\cdot\text{kg}^{-1}$ ,  $2.4 \pm 0.2$  g  $\text{PRO}\cdot\text{kg}^{-1}$ ). However, 28-h free-living food intake did not differ (CM:  $63.0 \pm 3.4$   $\text{kcal}\cdot\text{kg}^{-1}$ ,  $7.5 \pm 0.6$  g  $\text{CHO}\cdot\text{kg}^{-1}$ ,  $2.7 \pm 0.3$  g  $\text{fat}\cdot\text{kg}^{-1}$ ,  $2.4 \pm 0.2$  g  $\text{PRO}\cdot\text{kg}^{-1}$ , SD:  $57.3 \pm 2.6$   $\text{kcal}\cdot\text{kg}^{-1}$ ,  $7.4 \pm 0.4$  g  $\text{CHO}\cdot\text{kg}^{-1}$ ,  $2.0 \pm 0.2$  g  $\text{fat}\cdot\text{kg}^{-1}$ ,  $2.4 \pm 0.2$  g  $\text{PRO}\cdot\text{kg}^{-1}$ ).

**CONCLUSIONS:** Ingestion of CM immediately following exhaustive exercise did not represent an advantage to cyclists performing ~ 1 h of exercise following a day of free-living recovery. The athletes' dietary choices during the free-living period appeared sufficient to replenish muscle glycogen such that it washed out the expected macronutrient benefits of CM.

**Effect Of A Natural Versus Commercial Product On Running Performance And Gastrointestinal Tolerance**

Brandon W. Too, Sarah Cicai, Kali R. Hockett, Elizabeth Applegate, FACSM, Brian A. Davis, FACSM, Gretchen A. Casazza. *University of California at Davis, Davis, CA.*

(No relationships reported)

**PURPOSE:** To examine the effects of raisins and chews on running performance and gastrointestinal (GI) tolerance. **METHOD:** Eleven male ( $29.3 \pm 2.4$  yrs) runners completed three randomized trials (raisins, chews and water only) separated by 7 days apart. Each trial consisted of 80-min submaximal (75%VO<sub>2</sub>max) running followed by a 5-km time trial (TT). Heart rate (HR), respiratory exchange ratio (RER), glucose, lactate, free fatty acids, glycerol, insulin, electrolytes, creatine kinase, GI symptoms and rating of perceived exertion (RPE) were recorded every 20-min during the submaximal trial and at the end of the TT. Whole body muscle soreness and fatigue were also measured.

**RESULTS:** VO<sub>2</sub>, HR, muscle soreness and fatigue, electrolytes, lactate and RPE did not differ due to treatment. RER was significantly higher during the carbohydrate treatments, as was blood glucose ( $104.9 \pm 3.6$ ,  $107.0 \pm 2.5$ ,  $98.0 \pm 2.9$  mg-dl<sup>-1</sup> for raisin, chews and water respectively). Plasma creatine kinase was higher with raisins ( $466.6 \pm 101.7$ ,  $308.2 \pm 58.5$ ,  $321.5 \pm 48.3$  U-L<sup>-1</sup> for raisin, chews and water respectively). Time to complete the TT was shorter for both carbohydrate treatments ( $20.6 \pm 0.8$ ,  $20.7 \pm 0.8$ ,  $21.6 \pm 0.8$  min for raisin, chews and water respectively). GI disturbance was mild for all treatments.

**CONCLUSION:** Both the raisins and chews maintained high blood glucose levels and improved running performance compared to water only. Running performance between the raisins and chews were similar with no significant GI differences. Key words: blood glucose, time trial, respiratory exchange ratio, creatine kinase, carbohydrate, fiber

**Efficacy of Chocolate Lactaid Milk as a Recovery Supplement on Cycling and Strength Performance in Young, Active Women**

Heather A. Flores, Ryan Schmitt, Rachel Shull, Todd A. Astorino. *California State University San Marcos, San Marcos, CA.*

(No relationships reported)

Recovery after intense exercise is vital for optimizing subsequent performance. Nutritional supplements containing carbohydrate (CHO) and protein (PRO) are the primary constituents in recovery drinks. Recently, chocolate milk (CM) has been identified as a potent recovery beverage, although results are equivocal regarding its efficacy.

**PURPOSE:** The aim of the study was to examine the effects of CM on subsequent cycling and strength performance in active women. **METHOD:** Eight active women (age:  $22.3 \pm 3.8$  yr, physical activity:  $9.5 \pm 1.5$  h/wk, and %BF:  $17.5 \pm 3.4$  %) completed familiarization trials including a VO<sub>2</sub>max test, 5 interval training bouts, a 12.9 km cycling time trial (TT), and 10 repetitions of knee extension/flexion (KE/KF) at 60°/s on an isokinetic dynamometer (IKD) over 2 d. At the same time 3 d later, subjects cycled for 30 min at 50 %Wmax followed by eight 60 s bouts at 100 %Wmax to deplete muscle glycogen. Immediately post exercise and 2 h later (50% Kcal), subjects ingested an isocaloric, randomly assigned meal, CHO (Bagel + Gatorade = 370 Kcal, 77 g of CHO) or CM (370 Kcal, 53 g CHO, 6 g fat, and 18 g PRO). The next day, subjects completed a 16.6 km TT followed by 3 bouts of 10 maximal repetitions on the IKD. Three days later, subjects repeated the 2-day exercise protocol and ingested the other recovery beverage after day 1. Subjects standardized dietary intake and refrained from intense exercise for 48 h pre-trial, and all testing was conducted during the follicular phase. Paired t-test and repeated measures ANOVA were used to examine differences in TT performance and peak/average KE/KF torque across time and/or treatment.

**RESULTS:** In response to the TT, mean power ( $157.9 \pm 24.4$  W vs.  $157.3 \pm 29.4$  W), average speed ( $18.8 \pm 1.2$  mi/h vs.  $18.7 \pm 1.4$  mi/h), and overall time ( $32.4 \pm 2.8$  min vs.  $32.0 \pm 2.6$  min) were similar between CM and CHO. There was no change ( $P > 0.05$ ) in muscle force between CM and CHO across bouts ( $P > 0.05$ ). Peak KE torque was similar ( $P > 0.05$ ) with CM ( $88.8 \pm 19.8$  ft/lb,  $89.3 \pm 21.8$  ft/lb, and  $90.4 \pm 18.4$  ft/lb) compared to CHO ( $92.2 \pm 20.6$  ft/lb,  $89.0 \pm 20.3$  ft/lb, and  $91.0 \pm 18.5$  ft/lb) in bouts 1 - 3.

**CONCLUSION:** In active women, there was no difference in subsequent exercise performance after ingesting CM or CHO post glycogen-depleting exercise. Thirty min of cycling may have been inadequate to fully exhaust glycogen stores.

**2363 Board #38 MAY 31 2:00 PM - 3:30 PM**  
**Understanding The Role Of Lactate And Its Transporters In Cancer**

Rajaa Hussien, George A. Brooks. *University of California, Berkeley, Berkeley, CA.*

(No relationships reported)

The role of lactate and its transporters in healthy muscle tissue is well known, while their role in cancer is still debated. The MDA-MB-231 is a mesenchymal breast-cancer cell line that has high MCT4 expression, lactate production, glycolytic rate, and invasive cancer growth in vivo. Previously, we have shown that the oxygen consumption and expression of MCT1 protein in MDA-MB-231 cell line is very low compared to normal breast cell lines. MCT1 was reported by others to be deleted in MDA-MB-231 cells by promoter hypermethylation. The role of MCT1 deletion in this cell line is not clear.

**PURPOSE:** To determine the role of MCT1 deletion on the proliferation rate of MDA-MB-231 cells.

**METHODS:** MDA-MB-231 cells were transfected with MCT1-CMV7S plasmid or a control CMV7S plasmid. The CMV7S plasmid contains the G148 resistant (neo) gene, which allowed us to generate stable cancer cell lines expressing either a high level of MCT1 or empty vector. Cells were fixed and stained with antibodies to the lactate transporter (MCT1), the mitochondrial marker (Cytochrome, Cyc C), and the proliferation marker (Ki-67), and then visualized using confocal microscopy.

**RESULTS:** Transfected MDA-MB-231 cells expressed MCT1 protein in the plasma membrane and also in concentrated vesicles throughout the cells.

**CONCLUSION:** By various combinations of knocking in MCT1, and/or deleting MCT4 we hope to be able to affect the proliferation rate of MDA-MB-231 cancer cells.

**The Influence Of Nutritional Interventions On The Measurement Of Gross Efficiency During Cycling**

Matthew Cole, Damian A. Coleman, Jonathan D. Wiles. *Canterbury Christ Church University, Canterbury, United Kingdom.*

(No relationships reported)

Many research studies report and monitor cycling efficiency over a sustained period of time. None of these studies report that the nutritional intake was controlled or recorded across the period of assessment.

**PURPOSE:** To determine whether manipulation of nutritional intake before, during and after cycling exercise could influence subsequent gross efficiency measurement.

**METHODS:** Thirty six cyclists were split into three groups and undertook one of three studies. All studies involved repeated 2-hour cycling tests at submaximal exercise intensity (60% of Power at VO<sub>2</sub>max) in a randomised, crossover design. During study A, carbohydrate (CHO) intake was manipulated in the 3-days preceding cycling trials. Participants consumed isocaloric diets (~4000kcal) that contained a high (70%), moderate (45%) or low (20%) proportion of CHO, with the remaining proportions derived from fat and protein (10%) intake. For study B, cyclists consumed a standard 3-day pre-exercise diet and conducted four exercise tests where they consumed either water (600ml.h<sup>-1</sup>), CHO (36g.h<sup>-1</sup>), caffeine (5mg.kg<sup>-1</sup>) or both CHO and caffeine in combination during the test. During study C, cyclists undertook four exercise trials. Following a standard 3-day pre-exercise diet, participants completed the first two tests on consecutive days and consumed either a high or a low CHO diet (identical to study A) in the 24-h period between tests. A week later, this was repeated with the alternative diet ingested in the recovery period between trials. During all tests, expired air was measured at 30 min intervals in order to calculate gross efficiency (GE).

**RESULTS:** A - GE was significantly greater following the High CHO diet than the Mod CHO diet. (HighCHO=20.1 ± 0.5%, ModCHO=19.3 ± 0.6%, mean ± SD; P<0.05). B - The decline in GE over time was significantly attenuated after the ingestion of CHO (Water=-1.8 ± 1.1%, CHO=-0.7 ± 0.1%; P<0.05). C - Dietary intervention did not alter GE (HighCHO =19.5± 0.2%, LowCHO 19.2± 0.4%; P>0.05).

**CONCLUSIONS:** Significant differences in gross efficiency were obtained following alteration of nutritional intake in the 3-days preceding and during exercise. This suggests that nutritional intake should be carefully controlled and monitored to ensure the validity of gross efficiency measurements.

### Positives of Negative Work: Eccentric Cycling Effects on Skeletal Muscle in Chronic Obstructive Pulmonary Disease

Norah J. MacMillan<sup>1</sup>, Sophia Kapchinsky<sup>1</sup>, Fennigie M. Purves-Smith<sup>1</sup>, Nicolas Sgarioto<sup>1</sup>, Jacinthe Baril<sup>1</sup>, Riany de Sousa Sena<sup>2</sup>, Russell T. Hepple<sup>1</sup>, Ruddy Richard<sup>3</sup>, Helene Perrault<sup>1</sup>, Jean Bourbeau<sup>2</sup>, Tanja Taivassalo<sup>1</sup>. <sup>1</sup>McGill University, Montreal, QC, Canada. <sup>2</sup>Respiratory Epidemiology and Clinical Research Unit, Montreal Chest Institute, Montreal, QC, Canada. <sup>3</sup>Department of Sport Medicine and Functional Explorations, Clermont-Ferrand, France.

(No relationships reported)

Studies in healthy individuals have shown that for the same metabolic cost, significantly greater muscle forces are produced during negative (eccentric) compared to positive (concentric) work. Accordingly, eccentric endurance exercise has been proposed as a feasible approach to enhance exercise intolerance in patients with chronic obstructive pulmonary disease (COPD), particularly as they present with reduced muscle endurance and strength that relate to fiber atrophy and Type 2 fiber predominance.

**PURPOSE:** To elucidate the effects of eccentric endurance training on muscle structure, composition and function in COPD patients.

**METHODS:** 3 of 10 male (65±1.2 yrs) severe COPD patients (FEV1=37.7±2 %predicted) completed 10 weeks of eccentric cycle training. Pre and post testing included assessment of quadriceps muscle: 1) structure determined through a needle biopsy to quantify fiber cross sectional area and type using immunofluorescent labeling of myosin-heavy chain Type 1 and 2 isoforms; 2) composition using DEXA reflected as lean and fat tissue mass; 3) function determined by peak strength and endurance using the isokinetic Biodex dynamometer. The muscle biopsy analyses were done with the investigator blinded to training status (pre versus post).

**RESULTS:** Cross-sectional area increased in Type 1 fibers by 76% (4570±1733 to 9048±3241µm<sup>2</sup>, p=0.06), with little (7.6%) change in Type 2 fibers (5916±594 to 6221±979µm<sup>2</sup>) after training. The proportion of Type 1 fibers increased by 7% (28.6±6.6 to 36.1±21.5%) and Type 2 fibers decreased proportionally (71.4±6.6 to 63.9±21.5%). Thigh lean tissue mass increased (6.43±0.88 to 6.54±0.89kg, p<0.05) and fat mass decreased (2.82±0.65 vs. 2.68±0.59, p<0.05) after training. Muscle endurance power increased by 35% in two patients and there were no changes in peak isokinetic torque.

**CONCLUSIONS:** This randomized clinical trial examining eccentric cycling as a novel training modality for COPD is ongoing. Preliminary findings suggest eccentric cycling induces marked fiber hypertrophy and fiber shift specific to Type 1 fibers in COPD muscle. These cellular changes are associated with improved lean and fat tissue mass of the thigh and improved muscle endurance. Eccentric cycling appears effective in inducing structural and functional adaptations within COPD muscle.

### Severity of Exercise Intolerance and Functional Aerobic Impairment in Patients with Pulmonary Hypertension

Lisa M. K. Chin<sup>1</sup>, Randall E. Keyser, FACS<sup>2</sup>, Joshua Woolstenhulme<sup>1</sup>, Michelle Kennedy<sup>1</sup>, Bart Drinkard<sup>1</sup>, Gerilynn Connors<sup>3</sup>, Steven D. Nathan<sup>3</sup>, Leighton Chan<sup>1</sup>. <sup>1</sup>National Institutes of Health, Bethesda, MD. <sup>2</sup>George Mason University, Fairfax, VA. <sup>3</sup>Inova Fairfax Hospital, Falls Church, VA.

(No relationships reported)

Pulmonary hypertension (PH) is known to restrict functional capacity, exercise tolerance, and the ability to carry out routine physical activities. However, PH has been understudied and the severity of associated physical limitations is not fully understood.

**PURPOSE:** To examine cardiorespiratory capacity and exercise tolerance in patients with PH.

**METHODS:** Twenty-three patients with PH (Age: 52 ± 11 yrs; BMI: 31 ± 7 kg/m<sup>2</sup>; mean ± SD) and nine sedentary healthy controls (CON; 48 ± 9 yrs; 30 ± 9 kg/m<sup>2</sup>) completed symptom-limited treadmill cardiopulmonary exercise tests (CPET) and 6-minute walk tests (6MWT) as part of the NIH Exercise Therapy for Advanced Lung Disease Trial. Functional aerobic impairment (FAI) was calculated as a percent deviation in peak VO<sub>2</sub> measured by CPET, from an algorithmically predicted peak VO<sub>2</sub> based on age and gender for persons with a sedentary lifestyle (Bruce et al., 1973).

**RESULTS:** Compared to CON, patients with PH had significantly lower peak VO<sub>2</sub> (14.0 ± 4.7 vs. 23.9 ± 6.5 ml/min/kg; P = 0.002), time to peak exercise (630 ± 192 vs. 1144 ± 393 s; P = 0.002), peak work rate (93 ± 48 vs. 228 ± 61 W; P <= 0.001) and VO<sub>2</sub> at anaerobic threshold (9.3 ± 5.0 vs. 13.2 ± 3.7 ml/kg/min; P = 0.015). 6MWT distance was also shorter (P = 0.006) in PH (409 ± 81 m) than in CON (553 ± 130 m). Moderate FAI was observed in patients with PH (41 ± 22 %), while as expected, FAI was not observed in CON.

**CONCLUSIONS:** Overall exercise tolerance was substantially diminished in patients with PH compared to sedentary controls. Observation of FAI in this group reflects the effect of pathomechanisms on cardiorespiratory function. Instrumental activities of daily living (IADL) fall within a range of VO<sub>2</sub> demands between 10.5 and 17.5 ml/kg/min. In patients with PH, cardiorespiratory capacity was determined to be functionally impaired and insufficient for sustaining even low intensity IADL. As such, these patients may greatly benefit from a medically supervised exercise rehabilitation program.

### Quantifying Physiological Benefit from Improvements in Exercise Tolerance

Scott R. Murgatroyd<sup>1</sup>, Carrie Ferguson<sup>1</sup>, Daniel T. Cannon<sup>1</sup>, T Scott Bowen<sup>1</sup>, Lindsey A. Wylde<sup>1</sup>, Janos Porszasz<sup>2</sup>, Harry B. Rossiter, FACS<sup>1</sup>. <sup>1</sup>University of Leeds, Leeds, United Kingdom. <sup>2</sup>Harbor-UCLA Medical Center, Los Angeles, CA.

(No relationships reported)

The efficacy of a therapeutic intervention to ameliorate physiological impairments is reflected in improvements in exercise tolerance ( $t_{lim}$ ); however a standardized method for evaluating  $t_{lim}$  change is lacking (Whipp & Ward, *ERJ* 2009). Constant work rate (CWR) testing is said to be more sensitive to changes in exercise tolerance than ramp-incremental (RI) peak work rate ( $WR_{peak}$ ), oxygen uptake ( $VO_{2peak}$ ) or 6 min walk distance. However,  $t_{lim}$  distribution at any fraction of  $WR_{peak}$  is non-normal invalidating standard statistical tests. Accurate interpretation of a physiological benefit should, therefore, estimate the change in WR at a given  $t_{lim}$ .

**PURPOSE** To determine whether a novel algorithm accounts for inter-individual differences in the relationship between physiological and mechanical responses to RI exercise, thus accurately estimating a CWR corresponding to a 6 min  $t_{lim}$  ( $WR_6$ ).

**METHODS** 60 men (mean ± SD: 23 ± 4 yr, 179 ± 7 cm, 78 ± 11 kg) performed 3 protocols to intolerance using electromagnetically-braked cycle ergometry: 1) RI test (15 to 30 W/min) for  $WR_{peak}$  and  $VO_{2peak}$ ; 2) CWR test at  $WR_6$  estimated using the algorithm:  $WR_{peak} - (2 * RI \text{ rate})$ ; 3) Series of CWR tests to determine critical power (CP), the curvature constant (W'), and interpolate 'true'  $WR_6$ .  $VO_2$  was measured breath-by-breath (mass spectrometer, turbine).

**RESULTS** Fitness varied widely among participants: lactate threshold 25 ± 5 (range: 16 - 37) mL/min/kg; CP 3.0 ± 0.5 (1.5 - 4.8) W/kg; W' 239 ± 49 (136 - 360) J/kg;  $VO_{2max}$  51 ± 7 (36 - 75)

mL/min/kg. RI duration was  $16 \pm 4$  (10 - 23) min, and  $WR_{peak}$  was  $329 \pm 38$  (242 - 420) W. Estimated  $WR_6$  ( $288 \pm 37$  (212 - 364) W) resulted in a  $t_{im}$  of  $6.0 \pm 0.3$  (5.1 - 6.9) min, and did not differ ( $p = 0.88$ ;  $R^2 = 0.97$ ) from the 'true'  $WR_6$  ( $287 \pm 36$  (210 - 360) W). Mean bias  $\pm$  95% LoA were  $-2 \pm 13$  W ( $m = -0.04$ ).

**CONCLUSION** The simple algorithm closely estimated  $WR_6$ , predicting the 'true'  $WR_6$  to within 6% in all cases. The algorithm appeared to effectively account for inter-individual variations in common fitness parameters in a diverse group of participants, thus providing a standardized method for determining changes in  $WR_6$ . As such, this approach has the potential to facilitate interpretation of the physiological benefit(s) accrued from exercise training, therapeutic and/or experimental interventions in health and disease.

**Effects of a 10-week Aerobic Exercise Program on Cardiorespiratory Function in Patients with Interstitial Lung Disease**

Joshua G. Woolstenhulme<sup>1</sup>, Randall E. Keyser, FACSM<sup>2</sup>, Bart E. Drinkard<sup>1</sup>, Lisa Chin<sup>1</sup>, Michelle Kennedy<sup>1</sup>, Steven D. Nathan<sup>3</sup>, Gerilynn Connors<sup>3</sup>, Leighton Chan<sup>1</sup>.  
<sup>1</sup>National Institutes of Health, Bethesda, MD. <sup>2</sup>George Mason University, Fairfax, VA. <sup>3</sup>Inova Fairfax Hospital, Falls Church, VA.

(No relationships reported)

Interstitial lung disease (ILD) is a debilitating condition that limits functional capacity and cardiorespiratory function. Patients with ILD often experience severe exercise intolerance which can limit participation in daily activities. Little is known about the effects of aerobic exercise on cardiorespiratory function and exercise capacity in populations with ILD.

**PURPOSE:** To examine the effects of a 10-week aerobic exercise program on measures of functional capacity and cardiorespiratory function in patients with ILD.

**METHODS:** Six patients with ILD (3 males, 3 females; Age:  $61 \pm 7$  yrs; BMI:  $30 \pm 5$  kg/m<sup>2</sup>; mean  $\pm$  SD) completed treadmill cardiopulmonary exercise tests (CPET) and 6-minute walk tests (6MWT) before and after a 10-week aerobic exercise training program (AET). The AET was comprised of treadmill walking at an intensity of 70-80% of heart rate reserve determined from the initial CPET, for 30-45 minutes, 3 times per week on non-consecutive days.

**RESULTS:** The AET resulted in significant increases in peak VO<sub>2</sub> (from  $17.93 \pm 6.29$  to  $19.93 \pm 5.31$  ml/kg/min;  $p = 0.029$ ), anaerobic threshold (from  $10.2 \pm 2.0$  to  $13.4 \pm 2.4$  ml/kg/min;  $p = 0.002$ ), 6MWT (from  $456 \pm 67$  to  $494 \pm 48$  m;  $p = 0.022$ ), and CPET duration (from  $711 \pm 93$  to  $837 \pm 110$  s;  $p = 0.002$ ).

**CONCLUSIONS:** These are results from the NIH Exercise Therapy for Advanced Lung Disease Trial. Following an intensive 10-week aerobic exercise training regimen, significant improvements in cardiorespiratory function and exercise tolerance were observed. These results suggest that patients with ILD may respond well to an intensive aerobic exercise training program and could possibly benefit from participation in an exercise-based pulmonary rehabilitation program.

**Many College Women Are Not Aware That They Are Over-fat Or Obese**

Aubriane E. Rote, Lori A. Klos, Lynn A. Wheeler, Ann M. Swartz. *University of Wisconsin-Milwaukee, Milwaukee, WI.*

(No relationships reported)

Because awareness of one's own body weight is a key motivator in weight reduction efforts, lack of knowledge of being over-fat or obese poses a challenge for interventions aimed at reducing obesity rates. Previous studies have examined women's ability to self-classify their weight status in comparison with their actual body mass index (BMI). However, little is known about the alignment of perceived weight status and measured percent body fat (%BF).

**PURPOSE:** The purpose of this study was to examine the alignment among perceived weight status, weight status based on BMI, and measured fat status.

**METHODS:** A total of 120 college-aged women ( $19.5 \pm 1.2$  yrs,  $23.4 \pm 3.4$  kg/m<sup>2</sup>,  $31.9 \pm 6.8$  %BF) completed this cross-sectional investigation. Participants self-classified their body weight status on a scale from 1 (very underweight) to 5 (very overweight). BMI was calculated from measured height and weight, and %BF was assessed using dual-energy x-ray absorptiometry (DXA): 21-32% was considered normal fat, 33-39% was considered over-fat, and >39% was obese. Kappa statistics were conducted to examine the alignment among these variables.

**RESULTS:** The alignment between self-classified weight status and measured fat status was poor ( $\kappa = 0.343$ ), while the alignment between perceived weight status and weight status based on BMI was slightly better ( $\kappa = 0.515$ ). The agreement between women's %BF and BMI classifications was poor ( $\kappa = 0.299$ ). Of the 84 women who self-classified their weight as "Normal", results of the DXA scan showed 61(73%) were in fact normal fat, while 16 (19%) women were over-fat and 6 (7%) were obese. When examining BMI results of those same women who self-classified their body weight as "Normal" ( $n=84$ ), 75 (89%) were in fact normal BMI, while 6 (7%) women were overweight and 1 (1%) was considered obese by BMI.

**CONCLUSION:** Results from this analysis provide evidence that many college women are not aware that they are over-fat or obese. Previous studies demonstrate that women struggle to accurately estimate weight status, and results from this investigation demonstrate that this accuracy may be worse when comparing estimations to measured fat status. Efforts to educate college women on body fat and weight status may be part of an effective weight management and obesity prevention strategy.

**Effects Of Six-month Trunk Stability Exercises On Low Back Pain Prevalence In Young Athletes**

Juliane Mueller, Josefine Weber, Christoph Otto, Steffen Mueller, Frank Mayer. *University of Potsdam, Potsdam, Germany.*

(No relationships reported)

The six-month prevalence of low back pain in young athletes is reported to be about 20%. In prevention and rehabilitation exercise is supposed to be evident. However, it is not clear if a regular 15-minute-exercise is efficient in highly trained athletes.

**PURPOSE:** To examine the effects of trunk stability exercises on low back pain prevalence in young athletes.

**METHODS:** 140 athletes from four elite schools of sport (85 male/ 55 female;  $13 \pm 0.5$  yrs;  $50 \pm 9$  kg;  $14 \pm 5$  h training per week;  $13 \pm 4$  competitions last season) were included in a six-month controlled intervention trial. Subjects were assigned to an intervention (IG;  $n=43$ ) and control (CG;  $n=97$ ) group. The intervention included a progressive trunk exercise program (minimum of thrice a week in the warm-up-phase of normal training). The program was structured into three levels and consisted of four exercises (side-stabilization, pelvis lift, side-jumps, two-legged jump). At baseline and after six month subjective low back pain was assessed (LBP; six-month-prevalence; numeric rating scale). Furthermore, jumping performance (counter movement jump (CMJ): force plate; maximum peak force [Nm], PF<sub>abs</sub>: jumping height [m], JH) was analyzed to control if athletic capability is effected due to intervention. Descriptive analysis was followed by two-way ANOVA (dependent samples) to calculate effects of interaction ( $\alpha=0.05$ ).

**RESULTS:** Athletic capability, controlled by jumping performance, increased in both groups (pre-PF<sub>abs</sub>/post-PF<sub>abs</sub>: IG:  $1132 \pm 237$  Nm /  $1193 \pm 220$  Nm, CG:  $1079 \pm 240$  Nm /  $1135 \pm 238$  Nm; JH<sub>pre</sub>/JH<sub>post</sub>: IG:  $0.24 \pm 0.04$  m /  $0.26 \pm 0.04$  m, CG:  $0.24 \pm 0.04$  m /  $0.26 \pm 0.04$  m). Coaches gave a gapless training documentation for 86% of athletes (IG). IG implemented the program  $2.1 \pm 0.5$  times a week. During the six-month LBP decreased (LBP<sub>pre</sub>/LBP<sub>post</sub>: IG: 28% / 26%; CG: 20% / 16%) ( $p < 0.01$ ). Moreover, there were no interaction-effects between the two groups (LBP:  $p=0.78$ ; PF<sub>abs</sub>:  $p=0.85$ ; JH:  $p=0.62$ ).

**CONCLUSION:** Reduction of LBP and improvement of jumping performance could not be assigned to the effect of the trunk stability program applied. Efficacy of the additional trunk stability exercises as conducted have therefore to be considered critically, mainly due to low compliance of IG. Further studies need to focus on improvement of compliance.

**Impact Of A Modified School Lunch Program On Weight Loss In A Middle School Cohort**

Katalin Skelton. *Marquette University, Milwaukee, WI.* (Sponsor: Paula E Papanek, FACSM)  
(No relationships reported)

The obesity crisis is striking at younger ages with alarming rates in Latino youth. Over 50% of students in grades 1-8 in our charter school are overweight/obese (> 85 percentile). An intervention: Youth Empowered to Succeed (YES) targets 50 middle school students and provides daily fitness & college peer mentoring. Despite almost daily exercise for 1 year, several continue to increase bodyweight (BW). **PURPOSES:** to determine the impact of a one-month intervention of a healthier school lunch on weight loss in a subset and determine the impact on attitudes, self-image and well being.

**METHODS:** Ten students regularly participating in YES were selected because of their difficulty in maintaining their BW, increasing BW in 4 consecutive quarters, despite regular exercise (3x/wk 50 mins). All exercise and afterschool programming remained constant during the intervention. Dietary intervention was created by a registered dietician and developed specifically for Latino children. The meals (27 lunches) were served to small groups in a separate dining hall during which nutritional information was provided including lessons on calorie balance, general nutrition, and tips on healthy eating. No changes to family meals or other programming occurred.

**RESULTS:** Significant weight loss over 1 month (paired t-test  $p < 0.05$ ). On average BW decreased by 3 pounds with a maximum loss of 7. Previously all 10 students had gained BW each quarter and this was the first time any of them lost weight. All students reported more energy, better concentration and attitude post intervention.

**CONCLUSION:** Substitution of a healthy lunch successfully changed a habitual pattern of weight gain in Latino youth engaged in a prescribed fitness program. 9 of 10 lost a significant amount of weight and self-reported feeling better about themselves and their bodies. This study supports the important and long-term implications of providing a healthy lunch in terms of stemming the obesity epidemic in Latino middle school students. Supported by DHHS/OMH grant 1 YEPMP090044-02

**2372**    *Board #47*    **MAY 31**    **3:30 PM - 5:00 PM**  
**Effects of a Conceptually and Activities Based Course on Health and Fitness Variables among College Students**

Wendy S. Bjerke. *Sacred Heart University, Fairfield, CT.* (Sponsor: Peter Ronai, FACSM)  
(No relationships reported)

**PURPOSE:**

The prevalence of overweight and obesity among 18-24 year olds has increased with overweight status exceeding 20% of the population and 20% of this age group meeting criteria for obesity. The majority of 18-24 year olds in the United States are enrolled part or full time in colleges and universities which suggests that the higher education environment is appropriate for health promotion and education programs targeting young adults. Historically health and fitness courses in higher education have consisted of activities based education courses (APE's) with a shift towards conceptually based courses (CPE's). Short term and longitudinal health related outcomes have been observed for both APE and CPE courses. The purpose of this study is to compare health and behavioral outcomes associated with a combination of these approaches in an APE/CPE course.

**METHODS:** Twenty college students with a mean age of 20 years included 12 males and 8 females who participated in a 14 week APE/CPE course at a University in New England. Body mass index (BMI), body composition, hand grip dynamometry, vertical jump and health behaviors were examined pre and post. Physical fitness and activity associated behaviors were assessed via the International Physical Activity Questionnaire (IPAQ) and included frequency of days and time spent in the last seven days participating in vigorous and moderate physical activity, walking, and sitting.

**RESULTS:** Physical activity behavior associated variables; specifically the number of days and the duration of time spent performing vigorous physical activity increased significantly (from 3.5 to 4.4 days per week,  $p = .005$  and from .7 to 1.4 hours per session,  $p = .02$ ) with no other behavioral or physical variables achieving statistically significant changes during this time period.

**CONCLUSION:** Higher education health and fitness courses for young adults have the potential to impact physical and behavioral health and fitness variables and may provide effective strategies for the reduction of overweight and obesity in young adults. These findings suggest that longitudinal studies and studies comparing APE/CPE courses to other health promotion programs are indicated.

**2373**    *Board #48*    **MAY 31**    **3:30 PM - 5:00 PM**  
**Campus and Community Safety and Physical Activity Participation Among College Students**

Zi Yan, Patricia L. Ketcham, Bradley J. Cardinal, FACSM. *Oregon State University, corvallis, OR.*  
(No relationships reported)

The Exercise is Medicine<sup>®</sup> on Campus initiative of the American College of Sports Medicine seeks to encourage physical activity participation among college and university students. Campus and community safety may be a factor affecting said behavior.

**PURPOSE:** To examine the relationship between perception of campus and community safety and physical activity participation among college students. **METHOD.** College students ( $N=1366$ , age=21.7±4.1) from a large university in Oregon participated in the study. Self-report data were collected through the *American College Health Association Assessment* in 2010. Perceptions of campus and community safety during the day and night were assessed using a 4-item Likert-scale. Participants were classified as meeting or not meeting the physical activity recommendation (i.e., 5 or more days a week of 30 minutes or more of moderate-intensity physical activity, or 3 or more days a week of 20 minutes or more of vigorous intensity physical activity) on the basis of their responses to two questions.

**RESULTS.** A slight majority of males (55.5%) and females (56.5%) met the physical activity recommendation. Those who met the physical activity recommendation perceived both the campus and community to be safer at night compared to those who did not (For campus: Females,  $M=2.85$  vs.  $M=2.78$ ,  $p < 0.05$ , Cohen's  $d=0.18$ ; Males,  $M=3.62$  vs.  $M=3.48$ ,  $p < 0.01$ , Cohen's  $d=0.23$ ; For community: Females:  $M=2.70$  vs.  $M=2.57$ ,  $p < 0.05$ , Cohen's  $d=0.17$ ; Males,  $M=3.43$  vs.  $M=3.26$ ;  $p < 0.01$ ; Cohen's  $d=0.24$ ). No differences were observed for daytime ( $p > 0.05$ ).

**CONCLUSION.** Increasing campus and community safety at night may positively influence the physical activity behavior of college and university students.

---

**2374**    *Board #49*    **MAY 31**    **3:30 PM - 5:00 PM**  
**Relationship Of Waist Circumference, Fitness, And Walking In Male And Female College Students**

Rickie Lee Marker-Hoffman, Matthew G. Hinman, Daniel Chi Shing Yeung, Jeanne D. Johnston. *Indiana University, Bloomington, IN.* (Sponsor: Georgia C. Frey, FACSM)  
(No relationships reported)

Previous research has examined weight (WT) and physical activity (PA) in the college students demonstrating an increase in WT over the college years and a decrease in PA. The relationship between waist circumference (WC), fitness (FIT), and walking may offer additional insight.

**PURPOSE:** To examine the relationship between WC, FIT, and walking in college students.

**METHODS:** Participants were recruited from a mid-Western University via face-to-face contact, email, and fliers. FIT was assessed with three measures: PACER multi stage 20-meter shuttle run (PACER), modified pull-up (MPU), and one-minute sit-up (SU). Anthropometric assessment included height, WT, and average of 3 WC measurements. Body fat (BF) was assessed using bioelectrical impedance. Self-reported PA was assessed with the International Physical Activity Questionnaire (IPAQ) to determine minutes of walking and PA per week. Descriptive statistics, independent t-test (by sex), ANOVA (by class), and Pearson's Correlation were utilized to determine differences and relationships for PA, FIT, and WC.

**RESULTS:** The sample included 149 male (mean age 20.2, SD 1.5) and 203 females (mean age 19.9, SD 1.4), with 46.8 % residing in dorms/residence halls. There was a significant difference between weight (WT) and WC by class ( $p < 0.001$ ). However, when examined by sex, only men had a significant difference by class for WT, BF, and WC ( $p < 0.005$ ). A non-significant but decreasing trend in moderate, vigorous, and walking (TPA) by class was found. Furthermore, there was a non-significant but decreasing trend for men's walking and TPA by class, whereas vigorous and moderate PA appeared to remain more constant. WC was correlated with moderate PA for freshman only ( $p < 0.005$ ). For men, WC was significantly correlated with PACER

( $r = -.290, p < 0.001$ ). WC was correlated with PACER ( $r = -.279, p < 0.001$ ) and MPU ( $r = -.258, p < 0.001$ ) in women. Furthermore, walking was correlated with PACER ( $r = -.165, p < 0.05$ ) and SU ( $r = -.206, p < 0.001$ ).

**CONCLUSION:** Overall, there was a decrease in TPA for this sample and significant increase in WT and WC by class, which is consistent with previous research. The relationship between PA, FIT, and body composition differed by sex and should be examined in greater detail.

---

**2375** Board #50 MAY 31 3:30 PM - 5:00 PM

**Changes In Physical Activity And Body Composition In Female Freshmen During Their First Academic Year**

Michael V. Fedewa<sup>1</sup>, Matthew P. Thorpe<sup>2</sup>, Mina C. Mojtahedi<sup>2</sup>, Dolores D. Guest<sup>2</sup>, Bhibha M. Das<sup>1</sup>, Emily M. Mailey<sup>2</sup>, Michael D. Schmidt<sup>1</sup>, Ellen M. Evans, FACSM<sup>1</sup>. <sup>1</sup>University of Georgia, Athens, GA. <sup>2</sup>University of Illinois, Urbana-Champaign, IL.  
(No relationships reported)

The transition to college often invokes changes in physical activity (PA) behaviors that may alter weight status in young adults. Contemporary studies indicate that in addition to moderate to vigorous physical activity (MVPA), sedentary (SED) time may also have implications for health.

**PURPOSE:** The aim of this study was to assess changes in weight status and physical activity in female freshmen in a university setting their first academic year.

**METHODS:** Female freshmen ( $n=162; 18.0 \pm 0.3$  y) were assessed for height and weight to determine body mass index (BMI) and waist circumference (WC). Physical activity was assessed via accelerometer in minutes of SED, light (LPA), moderate (MPA), vigorous (VPA), and moderate + vigorous (MVPA) at the beginning and end of the academic year.

**RESULTS:** At baseline, females had normal weight status ( $62.7 \pm 8.7$  kg, BMI  $22.9 \pm 3.1$  kg/m<sup>2</sup>, WC  $82.6 \pm 8.7$  cm). Over the academic year weight, WC, and SED increased ( $1.6 \pm 2.6$  kg,  $0.8 \pm 4.2$  cm,  $29.9 \pm 103.9$  min); while LPA and MVPA decreased ( $26.9 \pm 71.0$  min,  $9.1 \pm 34.1$  min, respectively, all  $p < 0.05$ ). Subjects were further classified as Gainers (>3% weight gain), Maintainers (<3% weight change), and Losers (weight loss >3%). No changes in SED, LPA, or MVPA were observed among Losers, although few freshman lost weight ( $n = 13$ ). In Maintainers ( $n = 77$ ), LPA and MPA decreased ( $28.7 \pm 62.6$  min and  $7.9 \pm 33.8$  min respectively). However, Gainers ( $n = 72$ ) experienced a reduction in LPA and MVPA ( $29.2 \pm 78.4$  min and  $11.0 \pm 33.9$  min respectively), while SED increased ( $47.7 \pm 111.5$  min) (all  $p < 0.05$ ).

**CONCLUSION:** Unfavorable changes in weight status among female freshman may be related to decreased physical activity and increased sedentary time during their first year on a college campus. On-going analysis is exploring the implications for changes in weight due to changes in PA, dietary intake, stress, sleep and medications (i.e. oral contraceptives).

**2376** Board #51 MAY 31 3:30 PM - 5:00 PM

**Still Active In College ? The Contribution Of College Physical Education On Exercise And Physical Active Behaviors.**

Jean Lemoyne<sup>1</sup>, Pierre Valois<sup>2</sup>. <sup>1</sup>Université du Québec à Trois-Rivières, Trois-Rivières, QC, Canada. <sup>2</sup>Université Laval, Quebec city, QC, Canada. (Sponsor: François Trudeau, FACSM)  
(No relationships reported)

Most epidemiological studies demonstrated an important decline in physical activity between teenage years and the young adulthood. However, few longitudinal data is available regarding the influences of physical education during transition between high school and college.

**PURPOSE:** The objective of this study is to analyze the evolution of physical activity behaviors during college, among a sample of Quebec's college students where it is compulsory. We also wanted to verify the contribution of physical education on the maintenance of physical activity.

**METHODS:** Data was drawn from an initial sample of 417 college students (275 females, 142 males) participating in mandatory physical education classes. Mean age of the participants was  $17.8 \pm 2.4$  years. A longitudinal design was conducted over a 2 year period, involving 6 waves of assessment, measuring self-reported physical activity. Latent growth analysis was conducted, first to analyze the rate of change for physical activity and then to observe the potential influences of physical education on the maintenance of physical activity. **RESULTS:** Results revealed excellent fit indices for each models (CFI > 0.97, RMSEA > 0.03). During the college years, there is a slight but significant increase in physical activity, suggesting a direct influence of physical education ( $p < 0.05$ ). The best fit for the rate of change trajectory was following a cubic function, suggesting substantial influences of the physical education program on active behaviors. Further analysis revealed a significant decrease ( $p < 0.05$ ) of physical activity between each trimester, suggesting little influence of the program. The most important influences of physical education were observed among the less active groups.

**CONCLUSIONS:** Physical education permits and encourages the maintenance of a minimal level of physical activity. Over a 2 year physical education program, less predisposed groups at the initial level seemed to be more influenced towards the adoption of physical activity. However, influences of physical education seemed to disappear between each trimesters, suggesting a minimal influence from the program. Further research is needed to better understand the influences of the physical education program. Funded by the Ministère de l'Éducation du Loisir et du Sport, Quebec.

**2377** Board #52 MAY 31 3:30 PM - 5:00 PM

**Faster Rate of Weight-loss Associated with Female Athlete Triad Components in Youth**

Sheng-An Lo<sup>1</sup>, Chieh-Ling Wang<sup>2</sup>, Shu-Chich Chen<sup>1</sup>, Kuei-Hui Chan<sup>1</sup>. <sup>1</sup>National Taiwan Sport University, Taoyuan, Taiwan. <sup>2</sup>Shih Hsin University, Taipei, Taiwan.  
(No relationships reported)

The female triad (triad) is an interrelated condition of low energy availability, amenorrhea, and osteoporosis. A large body of evidence suggests that the populations who suffer from the triad components are mainly athletic and physically active women. Inappropriate weight-loss behaviors are one of the main factors causing the triad. However, weight-loss attempts are common in young women. They may be susceptible to the triad components regardless of physical activity levels.

**PURPOSE:** To determine the prevalence of the triad in athletes and non-athletes with weight-loss attempts.

**METHODS:** One hundred thirty-four female competitive athletes ( $20.1 \pm 1.5$  yrs) and 144 healthy female non-athletes ( $20.1 \pm 1.1$  yrs) were recruited from 2 colleges. Each subject completed screening questionnaires assessing eating disorders (EDs), menstrual status, weight-loss experience, and physical activity levels. The EDs were assessed by 26-item eating attitudes test (EAT-26). The physical activity levels were assessed by the short version of International Physical Activity Questionnaire. The body fat percentage (%BF) and bone strength (bone mineral density and bone quality) were also measured by eight-polar tactile-electrode impedance meter and ultrasoundometer, respectively.

**RESULTS:** The %BF of non-athletes were significantly higher than athletes ( $28.3 \pm 5.6\%$  vs.  $25.3 \pm 5.8\%$ ,  $p < 0.05$ ). Subjects with EDs, menstrual dysfunction (MD), or both reported they lost  $1.9 \pm 0.5$ ,  $1.6 \pm 0.7$ , or  $1.7 \pm 0.8$  kg per wk during the past year. Therefore, the definition of faster rate was weight-loss >1.5 kg/wk in this study. Between subjects with faster and slower rate of weight-loss, significant differences were found in the rate of weight-loss ( $2.1 \pm 0.7$  vs.  $0.9 \pm 0.6$  kg/wk,  $p < 0.05$ ), EAT-26 score ( $18.8 \pm 6.2$  vs.  $12.2 \pm 9.3$ ,  $p < 0.05$ ), and the prevalence of MD (32 vs. 0%,  $p < 0.05$ ). No significant differences were found in Z-scores [bone mineral density ( $0.7 \pm 0.8$  vs.  $1.0 \pm 0.4$ ,  $p < 0.05$ )] and stiffness index [bone quality ( $108.2 \pm 14.4$  vs.  $111.5 \pm 15.3$ ,  $p < 0.05$ )] between 2 groups.

**CONCLUSIONS:** Our study suggests weight-loss >1.5 kg/wk is associated with the developments of EDs and MD in youth.

---

**2378** Board #53 MAY 31 3:30 PM - 5:00 PM

**Coronary Heart Disease Risk Factors and Knowledge in a Young Adult Subpopulation**

Nicholas F. Boer, Gregory Heath, FACSM. Univ. of Tennessee, Chattanooga, TN.  
(No relationships reported)

Risk factors for coronary heart disease (CHD) are common among young adults aged 20-30 years, however there are no established guidelines within the U.S. for when to begin screening for CHD risk among this population

**PURPOSE:** To determine if young adults know their risk for CHD, specifically values for fasting blood glucose (gluc) and cholesterol (chol), and examination of prevalence of CHD risk factors among young adults attending a medium-sized university in the Southeast U.S. was carried out.

**METHODS:** 60 female college students ( $21.7 \pm 2.4$  years) and 40 male students ( $21.4 \pm 1.7$ ) completed a survey to assess health habits and CHD risk factors prior to completing a fitness testing battery. The exam included measured blood pressure, maximal aerobic fitness, strength measures, body composition, flexibility and balance.

**RESULTS:** None of the women or men reported knowing their fasting chol or gluc concentrations. The proportion of the other risk factors included the following: 1.7% of women and 0% of men reported a family history of heart disease; 3.4% of women and 15% of men reported being inactive; 3.4% of women and 10% of men were regular smokers; 60% of women and 55% of men had a body mass index (BMI) 25 but less than 30; with 3.4% of women and 15% of men having a BMI >30; there were no reports of hypertension among the women or men; 17.5% of women had one CHD risk factor and 37.5% of men had at least one risk factor for CHD.

**CONCLUSIONS:** Risk factor levels are low in this group of exercise science students (for whom the survey and fitness tests were compulsory) and students who chose to undergo a fitness battery. Neither healthy individuals with no risk factors nor individuals with one or more risk factors knew their fasting chol and gluc levels. Therefore, they did not know their personal risk for CHD.

ROOM: Exhibit Hall

---

### 2379 Board #54 MAY 31 2:00 PM - 3:30 PM

#### Oxidative Stress In The Serum Of Exercised Rats Supplemented With Creatine

Michel B. Araújo<sup>1</sup>, Leandro P. Moura<sup>1</sup>, Marcelo C. Junior<sup>1</sup>, Rodrigo A. Dalia<sup>1</sup>, Fabricio A. Voltarelli<sup>2</sup>, Amanda C. Sponton<sup>1</sup>, Maria Alice R. Mello<sup>1</sup>. <sup>1</sup>São Paulo State University, Rio Claro, Brazil. <sup>2</sup>Mato Grosso Federal University, Rio Claro, Brazil.

(No relationships reported)

**PURPOSE:** There is evidence that creatine may exert antioxidant activities. This study analyzes the effects of aerobic training and creatine supplementation on biomarkers of oxidative stress in the serum of rats.

**METHODS:** Adults male wistar (90 day old) rats were submitted to a Maximal Lactate Steady State (MLSS) test in order to identify the aerobic/anaerobic metabolic transition during treadmill running. Soon afterwards, the rats were divided into 6 groups: Trained Creatine (TCr), Trained (T), Trained Maltodextrin (TM), Control Creatine (CCr), Control Maltodextrin (CM) and Control (C). Trained rats ran on a treadmill for 40 minutes per day, 5 days per week for 8 weeks, at a speed equivalent to per individual MLSS. Creatine supplemented rats received creatine monohydrate per 5 days per week (0.107g/kg body weight (b.w)) and maltodextrin (0.160g/kg b.w), by gavage during the 8 weeks. The maltodextrin supplemented rats received maltodextrin (0.160g/kg b.w) by gavage. At the end of the experiment, all the rats were sacrificed and the amount of the substances that reacted with thiobarbituric acid (TBARs) and catalase (CAT), superoxide dismutase (SOD) and glutathione peroxidase (GSH-GPx) activities in the serum were analyzed.

**RESULTS:** The amount of TBARs was not different among the groups. There also were no significant differences between the groups in relationship to CAT and SOD activities. On the other hand, GSH-GPx activity was lower in the TM group (2.24+1.75) group than other groups (TCr 3.87+1.47; T 2.85+1.63; CCr 5.60+1.73; CM 4.28+2.32 and C 2.85+1.06).

**CONCLUSION:** These results suggest that neither exercise or supplementation did not affect the redox state of the animals.

---

### 2380 Board #55 MAY 31 2:00 PM - 3:30 PM

#### Thermoregulatory And Cardiovascular Responses To Creatine, Glycerol And Alpha Lipoic Acid In Trained Cyclists

Thelma P. Polyviou, Takas Pantazis, Wu Chean Lee, Dalia Malkova, Yannis P. Pitsiladis, FACSM. University of Glasgow, Glasgow, United Kingdom.

(No relationships reported)

It has been shown that supplementation with creatine (Cr) and glycerol (Gly), when combined with glucose (Glu) necessary for the enhancement of Cr uptake by the muscle, induces significant improvements in thermoregulatory and cardiovascular responses during exercise in the heat.

**PURPOSE:** To determine whether Cr/Gly-induced thermoregulatory and cardiovascular responses are maintained or even enhanced when the majority (~75%) of the Glu in the Cr/Gly supplement is replaced with the insulinotropic agent alpha lipoic acid (Ala).

**METHODS:** 22 healthy endurance trained cyclists were randomly assigned to receive either 11.4 g of Cr-H<sub>2</sub>O, 1 g of Gly/kg body mass (BM) and 150 g of Glu (Cr/Gly/Glu) or 11.4 g of Cr-H<sub>2</sub>O, 1 g of Gly/kg BM, 100 g of Glu and 1000 mg Ala (Cr/Gly/Glu/Ala) for 7 days. Exercise trials were conducted pre- and post-supplementation and involved 40 min of constant-load cycling exercise at 70% VO<sub>2</sub>max followed by a self-paced 16.1 km time trial at 30 °C and 70% relative humidity.

**RESULTS:** BM increase, although not statistically significant ( $p=0.056$ ), was noted in most individuals: 1.75(0.1-3.0) kg and 0.9(0.0-2.1) kg (median (range) in the Cr/Gly/Glu and in the Cr/Gly/Glu/Ala, respectively. Heart rate (HR) and core temperature ( $T_{core}$ ) were significantly lower post-supplementation: HR was reduced on average by  $3.0 \pm 1.2$  beats/min and by  $1.8 \pm 1.4$  beats/min (mean  $\pm$  SD) in the Cr/Gly/Glu and Cr/Gly/Glu/Ala trials, respectively while  $T_{core}$  was reduced by  $0.2 \pm 0.1$  on both trials; the reduction in HR and  $T_{core}$  was not different between the two supplementation groups.

**CONCLUSION:** Cr/Gly-induced improvements in thermoregulatory and cardiovascular responses during exercise in heat were not affected with part replacement of Glu with Ala.

### 2381 Board #56 MAY 31 2:00 PM - 3:30 PM

#### The Effects of Creatine Supplementation and Plyometric Training on Vertical Jump and Sprint Performance

Solomon H. Young, David L. Gee, Kelly L. Pritchett, Robert C. Pritchett. Central Washington University, Ellensburg, WA.

(No relationships reported)

Creatine (Cr) supplementation is associated with improving measurements of maximal strength. However, since Cr supplementation is also associated with weight gain, this may impair weight impacted exercises like jumping and sprinting.

**PURPOSE:** The purpose of this study was to determine the effects of Cr supplementation on vertical jump and sprint performance during 4 weeks of plyometric training.

**METHODS:** Using a randomized, double-blind design, subjects were assigned to receive either Cr or placebo (Pl) for 4-weeks. A total of 13 subjects completed the study (6 = Pl, 7 = Cr). Data was collected at baseline (T0), post-loading (T1), and post-maintenance (T2). Measures included body weight, height, bioelectrical impedance analysis (BIA), single and multiple vertical jump performance, (4 x 10m) shuttle sprint time, and anaerobic power using a 30-s Wingate trial. BIA was used to determine total body water (TBW). Subjects were instructed to maintain a normal diet and to follow a training program designed for this study. Data was analyzed using repeated measures two-way ANOVA for differences (time x treatment) and *t*-tests to assess the absolute change in values for all measures.

**RESULTS:** The interaction over time between treatment groups revealed significantly greater increases in body weight, body mass index (BMI), and average Wingate power ( $p < 0.05$ ) for the Cr group. Using the absolute change in values, *t*-tests revealed significant increases in body weight (mean gain = 1.0 kg,  $p = 0.003$ ) and TBW (mean gain = 0.4 kg,  $p = 0.03$ ) in the Cr group compared to Pl after T1. No significant changes in single jump height or shuttle sprint time were seen with either Cr or Pl groups. Average Wingate power tended to increase from T0 to T2 in the Cr group (mean % change = +5.9%) with no change in the Pl group ( $p = 0.06$ ). Average repeated vertical jump height from T0 to T2 tended to decline in the Pl (mean change = -7.5%) compared to Cr (mean change = -0.2%,  $p = 0.07$ ).

**CONCLUSION:** Although weight increased with Cr supplementation, it did not impede sprint and jump performance. Cr supplementation did tend to increase power as measured using the non-weight impacted Wingate test. Cr supplementation can be recommended to athletes wishing to increase power and weight without negatively affecting sprint and vertical jump performance.

---

**2382** Board #57 MAY 31 2:00 PM - 3:30 PM

**Magnesium Creatine Chelate and Whey Protein Supplementation Effects Combined with Periodized Training on Body Water**

Lorrie R. Brilla, FACSM, David N. Suprak, Rory Callahan. *Western Washington University, Bellingham, WA.*

(L.R. Brilla: Contracted Research - Including Principle Investigator; Albion Laboratories.)

**Creatine is often “stacked” with protein supplementation to enhance performance. Magnesium augments creatine absorption. The efficacy of these supplements in combination with a superimposed training program has not been well established.**

**PURPOSE:** To compare the effects of supplementation with magnesium-creatine chelate (C), C with whey protein stack (W), and a placebo (P), combined with periodized resistance training (RT), on total and compartmentalized body water.

**METHODS:** Healthy, recreationally active subjects (n=23) completed the study. Subjects were randomly assigned, in a double-blind format, to C (400-mg magnesium with 5-g creatine per day), W (35 g of whey protein, in addition to C supplement), and P (dextran). The 8-week RT progressively increased strength and power in a linearly periodized fashion. Testing was conducted pre and post RT and supplementation program. Strength testing was 1-repetition maximum (1RM) bench press (BP) and back squat (BS). Total body water (TBW) and both intracellular (ICF) and extracellular (ECF) fluid compartments were determined with bioimpedance. The effects of time and group were assessed with a two-way repeated measures ANOVA

**RESULTS:** There were no group by time interactions or group effects for any of the performance variables ( $P > 0.05$  for each). Significant increases in strength were observed for both 1RM BP and BS ( $P < 0.001$  for each) over time for all groups (BP  $\Delta$ kg: P 4.83, C 6.82, W 5.81; BS  $\Delta$ kg: P 12.78, C 7.42, W 13.13). There were no significant changes in TBW ( $P > 0.05$ ). ICF had a significant time by group interaction ( $P < 0.05$ ), and subsequent simple effects analysis showed C (+1.5%) and W (+1.26%) increased and P (-0.34%) decreased. ECF had a significant time by group interaction ( $P < 0.05$ ), and subsequent simple effects analysis reflected the shifts from the ICF.

**CONCLUSIONS:** In healthy, recreationally active individuals, participation in periodized RT has a greater effect on improving strength than superimposed supplementation with either C or W. No significant changes in TBW were noted. However, ICF and ECF were significantly affected by supplementation showing a shift to increased ICF, with magnesium creatine chelate increasing to a greater extent than the whey stack group.

**2383** Board #58 MAY 31 2:00 PM - 3:30 PM

**No Adverse Effects Associated with Low-Dose Longer-Duration Creatine Supplementation in Older Adults**

Eric S. Rawson, FACSM<sup>1</sup>, Andrew C. Venezia<sup>1</sup>, Christopher D. Still<sup>2</sup>. <sup>1</sup>Bloomsburg University, Bloomsburg, PA. <sup>2</sup>Geisinger Medical Center, Danville, PA.

(No relationships reported)

The effects of low dose, longer-term creatine supplementation on kidney function and reported adverse events in older men and women have not been described.

**PURPOSE:** The purpose of this study was to assess the effects of low-dose, longer-duration creatine supplementation on makers of health in older adults.

**METHODS:** Thirty-five older men and women (mean age 71 yr) ingested 2.3 g of creatine (n=18) or placebo (n=17) per day for six weeks. A renal function test consisting of blood levels of Potassium, Chloride, CO<sub>2</sub>, Anion Gap, Glucose, Blood Urea Nitrogen, Creatinine, Calcium, Phosphorous, and Albumin were assessed pre- and post-supplementation. Reported frequency of adverse events related to muscle, gastrointestinal, and kidney function was collected at baseline, and at 3 and 6 weeks post-supplementation. Renal function between groups was assessed with an ANOVA, and frequency of adverse events was assessed with a Chi square analysis.

**RESULTS:** Creatine supplementation had no effect on any measured marker of renal function from pre- to post-supplementation (mean change score creatine vs. placebo) Sodium (-0.2 vs. -0.3 mmol/L), Potassium (0.1 vs. -0.1 mmol/L), Chloride (-0.7 vs. 0.1 mmol/L), CO<sub>2</sub> (1.6 vs. 0.2 mmol/L), Anion Gap (-1.0 vs. -0.6 mEq/L), Glucose (-6.1 vs. 7.1 mg/dL), Blood Urea Nitrogen (-0.2 vs. 1.0 mg/dL), Creatinine (-0.1 vs. 0.01 mg/dL), Calcium (0.1 vs. -0.05 mg/dL), Phosphorous (0.2 vs. 0.02 mg/dL), and Albumin (0.02 vs. 0.00 g/dL) (all  $p > 0.05$ ). Additionally, there were no differences in the frequency of reported adverse events between creatine and placebo supplemented groups pre-supplementation, or at 3 or 6 weeks post-supplementation (all  $p > 0.05$ ).

**CONCLUSIONS:** Low dose, longer-duration creatine supplementation is not associated with increased risk of adverse events in older adults. It may be unnecessary for older adults who have normal kidney function to have a renal panel prior to low-dose creatine supplementation. Also, these data support the findings of previous studies that showed no adverse effects associated with creatine supplementation. **FUNDING:** National Institutes of Health National Center for Complementary and Alternative Medicine (1R15 AT003938-01).

**2384** Board #59 MAY 31 2:00 PM - 3:30 PM

**Combined Ergogenic Effects Of Creatine Added To Different Types Of Carbohydrates, Maltodextrin And Ribose**

Carlos Eduardo Costa<sup>1</sup>, Helena Angélica P. Batatinha<sup>1</sup>, Erico C. Capetuto<sup>2</sup>. <sup>1</sup>Mackenzie Presbyterian University, São Paulo, Brazil. <sup>2</sup>Mackenzie Presbyterian University and São Judas Tadeu University, São Paulo, Brazil.

(No relationships reported)

Creatine supplementation is a resource that assists in training to increase lean mass and strength by promoting ATP resynthesis and consequently protein synthesis. Ribose is a pentose that is involved in the resynthesis of adenosine nucleotides, providing more ATP and prolonging anaerobic activity. Maltodextrin is a complex carbohydrate that helps spare glucose for muscle and central nervous system delaying the state of fatigue.

**PURPOSE:** We investigated the effects of creatine supplementation alone and combined with 2 types of carbohydrates (ribose and maltodextrin).

**METHODS:** We had 20 subjects divided into 4 groups: CrG (Creatine Group), CrMG (Creatine and Maltodextrin Group), CrRG (Creatine and Ribose Group), CrRMG (Creatine, Ribose and Maltodextrin Group), all groups did 1MR test at bench press exercise and 3 sets of maximum repetitions with 3 minutes interval between each set. All groups did one week load of 10g of creatine, 10g of Ribose and 20g of Maltodextrin every day according to each group. 7 days later they repeated the same tests. Data were analyzed using one way ANOVA test,  $p < 0.05$  was adopted.

**RESULTS:** on the 1MR test significant difference was observed between CrG ( $3.4 \pm 2.3$ ) e CrRMG ( $11.6 \pm 4.9$ ), the CrRG e CrMG wasn't show significant differences compared to the others, suggesting that combined supplementation promotes strength gains. Maximum repetitions test showed no statistical differences. CrRMG however presented a trend to sustain the number of maximum repetitions throughout the 3 sets.

**CONCLUSIONS:** We can conclude that the use of 1 type of carbohydrate combined with creatine wasn't able to improve 1MR test. However when we combined ribose and maltodextrin with creatine significant increases were detected.

**Creatine Supplementation Increases Physical Function And Lower-limb Lean Mass In Osteoarthritis: A Role For Myostatin?**

MARINA Y. SOLIS<sup>1</sup>, Manoel Neves Jr<sup>1</sup>, Guilherme Giannini Artioli<sup>2</sup>, Hamilton Rochel<sup>2</sup>, Ricardo Fuller<sup>1</sup>, Fabiana Braga Benatti<sup>2</sup>, Ana Lucia De Sá Pinto<sup>1</sup>, Fernanda Rodrigues Lima<sup>1</sup>, Antonio Herbert Lancha Jr<sup>2</sup>, Eloísa Bonfá<sup>1</sup>, Bruno Gualano<sup>2</sup>. <sup>1</sup>School of Medicine - University Of São Paulo, São Paulo, Brazil. <sup>2</sup>School of Physical Education and Sport - University Of São Paulo, São Paulo, Brazil.

(No relationships reported)

Creatine monohydrate (CrM) supplementation has been suggested as a therapeutic intervention in some chronic disabilities, including knee osteoarthritis (OA). However, little is known about the molecular mechanism underlying the beneficial response to CrM. In this respect, a few studies have suggested that chronic CrM supplementation could increase lean mass partially by

modulating myostatin (MSTN) pathway **PURPOSE:** To assess the effects of CrM supplementation combined with resistance training on muscle function, lower-limb lean mass, and MSTN pathway in women with knee OA.

**METHODS:** A 12-week randomized, double-blind, placebo-controlled clinical trial was performed. Twenty-three postmenopausal women with knee OA were submitted to lower-limb resistance training (3 times a week) and randomly assigned to either CrM supplementation (20 g/d for 1 week and 5 g/d thereafter) or placebo (PL). Physical function (as assessed by timed-stands test) and lower-limb lean mass (as assessed by DXA) were assessed at baseline (PRE) and after 12 wk (POST). Additionally, muscle samples were taken at PRE and POST and MSTN pathway was assessed by quantitative real-time (qPCR).

**RESULTS:** Physical function and lower-limb lean mass were significantly improved only in the CrM group (PRE:  $15.7 \pm 1.4$ , POST:  $18.1 \pm 1.8$ ,  $p = 0.006$ ; PRE:  $13.3 \pm 2.3$ ; POST:  $13.8 \pm 2.0$ ,  $p = 0.04$ ; respectively). qPCR revealed no alteration in MSTN expression and MSTN binding proteins, i.e., SMAD-7, follistatin, follistatin-like 3 (FSTL3), activin receptor IIb (ACTV-IIb) and growth and differentiation factor-associated serum protein (GASP-1) ( $p > 0.05$ ) as a consequence of CrM combined with exercise.

**CONCLUSION:** CrM supplementation improves physical function and lower-limb lean mass in postmenopausal women with knee OA who underwent resistance training. However, MSTN pathway seems not be implicated in these beneficial adaptations. Further studies should investigate other molecular mechanisms behind CrM-induced lean mass accretion. Supported by Fundação de Amparo à Pesquisa do Estado de São Paulo (FAPESP) - Grant #2010/15450-3.

**2386** Board #61 MAY 31 2:00 PM - 3:30 PM

**Creatine Supplementation Does Not Affect Measured Renal Function In Resistance Trained Subjects: A Pilot Study**

Rebeca Lugaresi<sup>1</sup>, Marco Leme<sup>1</sup>, Vitor de Sales Painelli<sup>1</sup>, Marcelo Tatit Sapienza<sup>2</sup>, Fabiana Braga Benatti<sup>1</sup>, Hamilton Roschel<sup>1</sup>, Carlos Ugrinowitsch<sup>1</sup>, Antonio Carlos Seguro<sup>2</sup>, Ana Lucia Pinto<sup>2</sup>, Fernanda Rodrigues Lima<sup>2</sup>, Antonio Herbert Lancha Jr<sup>1</sup>, Bruno Gualano<sup>1</sup>. <sup>1</sup>School of Physical Education and Sports University of Sao Paulo, Sao Paulo, Brazil. <sup>2</sup>Medicine School University of Sao Paulo, Sao Paulo, Brazil.

(No relationships reported)

A growing number of human studies have reported the safety of creatine supplementation on estimated glomerular filtration rate (GFR) (e.g., creatinine clearance). However, there is a paucity of data on the effect of creatine supplementation in measured GFR in subjects ingesting a high-protein intake.

**PURPOSE:** To investigate the effects of creatine supplementation on measured GFR in resistance trained subjects ingesting a high-protein diet (ranging from 1.2 to 10.7 g/Kg BW/day).

**METHODS:** A 12-week randomized, double-blind, placebo-controlled

trial was conducted. Fifteen resistance trained males were randomly assigned to either the creatine (CR) or the placebo (PL) group. The CR group (n=8) received 20g/day of creatine for five days followed by

5g/day throughout the study. The PL group (n=7) received the same amount of dextrose. At baseline (PRE) and after 12 weeks of intervention (POST), 51Cr-EDTA clearance, creatinine clearance, serum and urinary sodium and potassium, urea urinary, albuminuria and proteinuria were assessed. Food intake was assessed by a 7-day food record.

**RESULTS:** 51Cr-EDTA clearance was unchanged within and between groups (PRE

CR:  $101.31 \pm 14.37$ , PL:  $106.51 \pm 20.57$ ; POST CR:  $104.61 \pm 14.45$ , PL:  $97.3 \pm 17.05$  mL/min/1.733). Protein intake was similar between groups and did not change throughout the study (PRE CR:  $1.8 \pm 0.8$ , PL:  $1.7 \pm 0.3$ ; POST CR:  $1.6 \pm 0.9$ , PL:  $1.4 \pm 0.6$  g/kg bw/day). Creatinine clearance was also comparable between groups before and after the supplementation (PRE CR:  $2.2 \pm 0.5$  PL:  $1.6 \pm 0.7$ , POST CR:  $2.41 \pm 0.33$ , PL:  $2.1 \pm 0.6$  g/vol 24h). Additionally, serum creatinine, proteinuria, urinary and serum sodium and potassium, urea urinary and albuminuria remained stable and within normal range in both groups.

**CONCLUSION:** Creatine supplementation did not affect measured GFR or any other parameter of kidney function in resistance-trained subjects ingesting a high-protein diet, further confirming that this supplement is safe to the kidneys. Future studies should investigate whether this holds true in a long-term basis.

**2387** Board #62 MAY 31 2:00 PM - 3:30 PM

**Creatine Monohydrate: Daily Blood Pressure Monitoring During the Loading Phase of Supplementation**

Gary M. Castello, Emily J. L. Asuncion, Michael S. Boyd, Natalie A. Exsted, Sawyer A. Hildebrandt, Ryan R. Reidt, Ashley M. Rundle, Paul T. Verschaetse. Winona State University, Winona, MN. (Sponsor: Mark Sothmann, FACSM)

(No relationships reported)

Creatine monohydrate (CM) is considered to be a safe nutritional supplement. The loading phase of CM supplementation is associated with shifts in total body water and plasma volume that may affect blood pressure. However, few studies have measured blood pressure during the loading phase of CM supplementation.

**PURPOSE:** The aim of this study was to determine if CM supplementation in normotensive college-aged males induces a daily blood pressure increase during the supplementation-loading phase.

**METHODS:** Participants' blood pressure, shoulder extension active range of motion (AROM), arm girth, arm volume, plasma volume, blood volume, hematocrit, and hemoglobin were measured daily for five days of supplementation (4x5gxd<sup>1</sup>x5d) of either CM (n=12) or placebo (P; n=12).

**RESULTS:** The CM group did not experience significant changes in systolic blood pressure (mmHg) (CM  $126.7 \pm 1.9$  Day 5; P  $125.5 \pm 2.6$  Day 5) or diastolic blood pressure (mmHg) (CM  $83.8 \pm 2.2$  Day 5; P  $82.3 \pm 2.1$  Day 5) compared to P. There were significant time x treatment interaction ( $p = 0.001$ ) and treatment effect ( $p = 0.03$ ) supporting a decline in AROM (cm) in the CM group compared to P (CM  $38.3 \pm 2.2$  Day 1, CM  $34.0 \pm 2.0$  Day 5; P  $41.0 \pm 2.5$  Day 1, P  $43.2 \pm 2.5$  Day 5). There was a significant time x treatment interaction ( $p = 0.026$ ) supporting an increase in arm volume (ml) in the CM group compared to P (CM  $2443 \pm 99$  Day 1, CM  $2470 \pm 92$  Day 5; P  $2372 \pm 74$  Day 1, P  $2374 \pm 75$  Day 5). An increase in plasma volume (%Δ from baseline) ( $p = 0.014$ ) (CM  $1.48 \pm 2.6$  Day 2, CM  $6.03 \pm 4.0$  Day 5; P  $3.25 \pm 2.7$  Day 2, P  $5.05 \pm 2.9$  Day 5) and a decrease in hematocrit (%) ( $p = 0.026$ ) (CM  $0.47 \pm 0.014$  Day 1,  $0.45 \pm 0.008$  Day 5; P  $0.46 \pm 0.012$  Day 1,  $0.45 \pm 0.006$  Day 5) were observed.

**CONCLUSION:** These findings suggest that CM supplementation in the loading phase does not affect blood pressure in normotensive college-aged males, and in regards to blood pressure is considered safe in this population. CM reduces shoulder extension AROM presumably due to increased tissue volume secondary to fluid shifts.

---

**2388** Board #63 MAY 31 2:00 PM - 3:30 PM

**Creatine Supplementation plus Strength Training on Cognition and Depression in Elderly Women: A Pilot Study**

Christiano R. Alves, Fabiana Braga Benatti, Aline Cristina Trito, Ana Lúcia de Sá Pinto, Hamilton Roschel, Fernanda Rodrigues Lima, Rosa Maria Pereira, Antonio Herbert Lancha Junior, Bruno Gualano. University of São Paulo, São Paulo, Brazil.

(No relationships reported)

It has been suggested that both strength training and creatine supplementation alone may ameliorate depression and improve a variety of cognition performance measures.

**PURPOSE:** to investigate the possible combined effect of these strategies on depression and cognitive function in elderly people.

**METHODS:** we performed a 12-week randomized double-blind placebo-controlled pilot-study to explore the possible synergic effect of creatine supplementation and strength training on depression and cognition function in elderly women. Participants (n=34) aged  $\geq 60$  years were randomly assigned into one of the four groups: 1) placebo (Pl), 2) strength training plus placebo (Pl-Tr), 3) creatine (Cr), and 4) strength training plus creatine (Cr-Tr). The Pl-Tr and Cr-Tr were submitted to strength training twice a week throughout the study. The Cr and Cr-Tr groups received 20 g/day of creatine for 5 days followed by 5g/day for 12 weeks. The Pl and Pl-Tr groups received exactly the same dose of dextrose. At baseline (PRE) and after 12 weeks (POST 12), a geriatric depression scale and a battery of cognitive tests were applied to the volunteers. Data were expressed as percent changes from POST to PRE and tested by one-way ANOVA.

**RESULTS:** Neither creatine supplementation nor strength training nor the combination of both were able to improve cognition, as assessed by Mini Mental State Examination (Pl: + 1.4%, Pl-Tr: + 1.6%, Cr: + 3.1%, Cr-Tr: + 3.7%,  $p = 0.56$ ), Digit Span Forward (Pl: + 0.0%, Pl-Tr: - 6.5%, Cr: - 4.0 %, Cr-Tr: + 15%,  $p = 0.50$ ), Digit Span Backward (Pl: + 8.6%, Pl-Tr: - 3.4%, Cr: +

0.0%, Cr-Tr: + 6.8%,  $p = 0.46$ ), Stroop Test Color, Non-Color and Word-Color conditions (Pl: - 8.3%, Pl-Tr: + 0.0%, Cr: - 3.4%, Cr-Tr: - 8.2%,  $p = 0.13$ ; Pl: - 8.9%, Pl-Tr: - 12.0%, Cr: - 15.2%, Cr-Tr: - 5.1,  $p = 0.88$ ; and Pl: - 9.6%, Pl-Tr: - 3.9%, Cr: + 1.0%, Cr-Tr: + 2.1%,  $p = 0.02$ ) and Trail Making Test A (Pl: - 2.6%, Pl-Tr: - 11.9%, Cr: - 0.3%, Cr-Tr: + 7.6%,  $p = 0.10$ ). The geriatric depression scale was also unchanged among the groups (Pl: - 4.7%, Pl-Tr: - 29.2%, Cr: - 13.3%, Cr-Tr: - 23.8%,  $p = 0.64$ ).

**CONCLUSION:** 12 weeks of creatine supplementation associated or not with resistance training was unable to improve cognitive function and depression in mentally healthy elderly women. The longer-term follow-up of this study with a larger sample will confirm the veracity of this conclusion.

---

## D-20 Free Communication/Poster - Energy Balance and Metabolic Responses

#### Differential Responses of Metabolic Syndrome Components to Tumor Necrosis Factor- $\alpha$ Levels over 16-Weeks

Mary P. Miles, FACSM, Colleen P. Miller, Amy C. Hartz, Gregory N. Rueggesser, Katherine A.M. McNulty, John C. Christopher. *Montana State University, Bozeman, MT.*

(No relationships reported)

Tumor necrosis factor- $\alpha$  (TNF) is an inflammatory cytokine that interferes with insulin signaling and associates with risk for development of insulin resistance and related metabolic problems. It is important to know whether elevations in TNF are an early indication of accelerated progression of the metabolic syndrome components.

**PURPOSE:** To determine whether healthy, overweight adults with lower versus higher basal levels of TNF have measurable changes in variables related to metabolic syndrome over a 16-week time period.

**METHODS:** Adults ( $n=40$ ) were measured pre- (INITIAL) and post-16 weeks (FINAL) for BMI, waist circumference, blood pressure, and fasting glucose, insulin, triglycerides (TG), HDL, TNF, interleukin (IL)-6, C-reactive protein (CRP), and homeostatic model assessment of insulin resistance (HOMA-IR). Participants were ranked by INITIAL TNF concentrations, and the lowest 15 and highest 15 were placed in LOW and HIGH TNF groups. There were 11/4 and 13/2 women/men in the LOW and HIGH groups, respectively.

**RESULTS:** INITIAL values were similar between groups with the exceptions of a trend ( $P=0.09$ ) for higher CRP ( $1.53 \pm 0.53$  vs  $2.29 \pm 0.83$  mg/l) and a trend ( $P=0.07$ ) for greater waist circumference ( $88.5 \pm 6.5$  vs  $93.6 \pm 8.1$  cm) in the HIGH compared to LOW TNF group. HDL increased ( $P<0.05$ ) over time with no difference between groups. There was a trend for decreased systolic and diastolic blood pressure ( $P=0.08$  for both), an increase in insulin ( $P=0.08$ ) and HOMA-IR ( $P=0.09$ ). Group by time interactions ( $P<0.05$ ) were measured for IL-6 and TG. Post-hoc analysis identified trends for IL-6 to decrease ( $P=0.10$ ) and for TG to increase ( $P=0.06$ , from  $95.7 \pm 36.4$  to  $114.7 \pm 48.5$  mg/dl) in the HIGH TNF group.

**CONCLUSION:** These findings provide preliminary evidence that insulin levels and HOMA-IR increase over time in overweight individuals, independent of TNF levels. Fasting insulin and HOMA-IR primarily reflect insulin sensitivity of liver and beta-cell activity. However, an increase in TG, an occurrence linked to insulin resistance in adipose tissue, was more pronounced in the HIGH TNF group. Thus, the effect of higher plasma TNF levels in overweight individuals may vary by tissue.

This study was funded by a grant from the American Heart Association Western States Affiliate.

### 2390 Board #65 MAY 31 3:30 PM - 5:00 PM

#### Energy Expenditure During and After Standard Exercise While on a Carbohydrate or Fat Restriction Diet

Rachel M. Perron, Robert J. Brychta, Kong Y. Chen, Carla M.M. Prado, Mario Siervo, Laura Musse, Kevin D. Hall. *National Institutes of Diabetes Digestive and Kidney Disease, Bethesda, MD.*

(No relationships reported)

**PURPOSE:** As different dietary interventions may lead to variable energy expenditure and weight loss, we aimed to measure exercise and post-exercise energy expenditure during calorically equal dietary restrictions of carbohydrate versus fat.

**METHODS:** Eight obese subjects (4 male, 4 female; BMI  $\geq 30$  kg/m<sup>2</sup>) were fed a low carbohydrate (LC) or a low fat (LF) diet in a randomized, crossover design. Subjects spent 5 days on a baseline (weight-maintenance) diet and 6 days on either an LC or LF diet (30% caloric reduction) with a 2-10 week washout period between diets. During both baseline and diet conditions, subjects spent 60 minutes daily walking at a consistent, self-selected pace on a treadmill. Oxygen consumption (VO<sub>2</sub>) and carbon dioxide production (VCO<sub>2</sub>) were measured in a metabolic chamber. Energy expenditure (EE) and respiratory quotient (RQ) were calculated during exercise and for 30 minutes post-exercise. Pairwise t-test was used to compare changes in metabolic parameters on each diet relative to baseline. P value was set at  $<0.05$ .

**RESULTS:** A comparable negative energy balance was achieved during the LC ( $-634 \pm 213$  kcal/day) and LF ( $-592 \pm 148$  kcal/day) caloric restricted periods, which induced at the end of each period a weight loss of  $-1.5 \pm 0.3$  kg ( $p<0.05$ ) and  $-1.2 \pm 0.3$  kg ( $p<0.05$ ), respectively. Exercise EE and post-exercise EE did not change during the two dietary interventions. However, exercise and post-exercise RQ values significantly decreased during the LC diet whereas RQ values did not change during the LF diet.

**CONCLUSION:** Exercise and post-exercise respiratory quotient, but not energy expenditure, responded to a significant restriction of dietary carbohydrate, but not dietary fat.

---

### 2391 Board #66 MAY 31 3:30 PM - 5:00 PM

#### Post-exercise Growth Hormone Kinetics Differ Between Assay Methods During Energy Balance

Dennis E. Scofield, David W. DeGroot, FACSM, Matthew R. Ely, J Philip Karl, Andrew J. Young, FACSM, Bradley C. Nindl, FACSM. *U.S. Army Research Institute of Environmental Medicine, Natick, MA.*

(No relationships reported)

The secretion of growth hormone (GH)--characterized by molecular heterogeneity that includes molecular weight variants and aggregates--is modulated in part by both changes in nutritional status and exercise. Treating serum samples with glutathione prior to assay is a method used to break disulfide-linked GH aggregates and potentially increase GH assay signal. The effect of this method on samples obtained during periods of energy imbalance is unknown.

**PURPOSE:** To determine the effect of glutathione (GSH) treatment on serum GH samples obtained during energy balance (EB), underfeeding (UF) and overfeeding (OF).

**METHODS:** 10 men ( $22 \pm 2$  yrs) were assigned to 3 interventions over 12 days: 4 days each of EB, UF (60% of EB), and OF (150% of EB). Subjects exercised on a cycle ergometer at 50% VO<sub>2peak</sub> for 20 min on the 4th day of each intervention. Blood samples were obtained pre-, post- and 30 min post-exercise. Serum GH concentrations were determined in reduced (+GSH) and non-reduced (-GSH) states using a commercially available IRMA assay. Data were analyzed using RM ANOVA ( $P \leq 0.05$ ) with a Tukey HSD post-hoc test when appropriate.

**RESULTS:** During all feeding conditions the mean GH signal was significantly increased in the +GSH samples (EB: +GSH:  $2.2 \pm 0.07$  vs. -GSH:  $1.8 \pm 0.7$  ng/mL;  $P < 0.01$ ; UF: +GSH:  $1.3 \pm 0.3$  vs.  $1.0 \pm 0.3$  ng/mL;  $P = 0.04$ ; OF: +GSH:  $0.8 \pm 0.2$  vs. -GSH:  $0.6 \pm 0.2$  ng/mL;  $P < 0.01$ ). During EB, *post hoc* testing indicated a greater GH assay signal in +GSH ( $3.0 \pm 0.8$  ng/mL) vs. -GSH ( $2.4 \pm 0.6$  ng/mL) at post-exercise ( $P < 0.01$ ).

**CONCLUSION:** These data demonstrate that compared to untreated serum samples, the addition of GSH to serum prior to assay allows for the detection of significant alterations in post-exercise GH concentrations due to the detection of disulfide-linked GH aggregates. The mechanism by which nutritional status affects the differential response of GH aggregates to aerobic exercise and their influence on post-exercise homeostasis remains to be determined.

---

**2392** Board #67 MAY 31 3:30 PM - 5:00 PM  
**The Metabolic Responses Of Work Load Matched High Intensity Intermittent Exercise**  
Tracey Gerber, Alan Hayes, Christos G. Stathis. *Victoria University, Melbourne, Australia.* (Sponsor: David Bishop, FACSM)  
(No relationships reported)

**While high intensity intermittent exercise (HIIE) training programs show greater decreases in indirect measures of adiposity (skinfold and dual x-ray absorptiometry) than continuous exercise training programs, there is limited information about potential mechanisms.**

**PURPOSE:** The aim of this study was to elucidate reasons behind this finding and to examine the influence of exercise intensity during HIIE on potential fat loss.

**METHODS:** Healthy, untrained males completed a  $\text{VO}_{2\text{max}}$  test and 2 HIIE protocols a) 20s cycling at 150%  $\text{VO}_{2\text{peak}}$ , with 40s rest (20:40 HIIE), and b) 10s cycling at 300%  $\text{VO}_{2\text{peak}}$ , with 50s rest (10:50 HIIE); both were followed by a 90-min recovery. Blood and respiratory gases were collected and heart rate and rating of perceived exertion (RPE) monitored. Student T test, 2 way repeated measures ANOVA and Tukey's post hoc analysis were used to identify significant differences ( $p < 0.05$ ). All procedures were approved by the Victoria University Human Research Ethics Committee.

**RESULTS:** On completion of the two HIIE no differences were observed in heart rate, oxygen consumption ( $\text{VO}_2$ ), carbon dioxide production ( $\text{VCO}_2$ ) and RPE. While plasma lactate increased during both HIIE protocols, the decline in the recovery period was significantly higher following the 10:50 HIIE ( $p < 0.05$ ). No group differences were seen in plasma glucose, however at the end of HIIE plasma insulin was significantly elevated from rest 15 min post the HIIE ( $p < 0.05$ ). During HIIE and recovery, plasma glycerol increased significantly more with 20:40 HIIE compared to the 10:50 HIIE bout. Excess post exercise oxygen consumption (EPOC) was significantly greater in the 10:50 HIIE compared to the 20:40 HIIE bout ( $P < 0.05$ ).

**CONCLUSIONS:** During HIIE, physiological responses to the 2 protocols were not different demonstrating the effectiveness of the workload matched design. Plasma markers of fat metabolism indicate 20:40 HIIE utilises relatively greater fat than 10:50 HIIE ( $p < 0.05$ ), while the greater plasma lactate during HIIE and the recovery period are indicative of an increased glycolysis during the 10:50 bout ( $p < 0.05$ ). The elevated EPOC following both bouts of HIIE provides a potential mechanism for enhanced energy utilisation with bouts of higher workloads.

---

**2393** Board #68 MAY 31 3:30 PM - 5:00 PM  
**Acute Effects of Resistance Exercise vs. Endurance Exercise on Postprandial Fuel Partitioning**  
Patrick M. Davitt, Gregory C. Henderson, Shawn M. Arent, FACSM. *Rutgers University, New Brunswick, NJ.*  
(No relationships reported)

The ability to alter postprandial metabolism in favor of increased energy expenditure and fatty acid (FA) oxidation could help attenuate the retention of body fat.

**PURPOSE:** To compare acute effects of resistance exercise (RE) and endurance exercise (EE) to a resting control (C) for effects upon subsequent postprandial energy substrate partitioning in obese women.

**METHODS:** Sedentary, obese women ( $n=10$ ; Body weight =  $101.0 \pm 8.0$  kg; BMI =  $37.1 \pm 2.3$ ) participated in a crossover designed study. Each subject was studied on 3 occasions: RE, EE, and C. Subjects completed a body composition, 10-repetition maximum (10RM), and aerobic capacity test ( $\text{VO}_{2\text{peak}}$ ). A 1 h total body high intensity RE workout consisted of 3 sets of 10 repetitions for 8 exercises at a load of 90% the 10RM. EE consisted of walking on a treadmill at 65%  $\text{VO}_{2\text{peak}}$  for 1 h. A standardized meal of 20 kcal/kg FFM (CHO-48%, Fat-36%, Protein-16%) was administered 30 min after exercise. Pulmonary gas exchange was assessed immediately before the meal and at 40, 80, 160, 240, 320, and 400 min afterwards in order to assess changes in metabolic rate, fat oxidation, and carbohydrate oxidation. RM ANOVAs were used for statistical analysis. Values were calculated as averages over the 400 min assessment period.

**RESULTS:** In comparison to C, both RE and EE led to an increased rate of fat oxidation (RE,  $0.58 \pm 0.07$  kcal/min; EE,  $0.54 \pm 0.06$  kcal/min; C,  $0.41 \pm 0.03$  kcal/min,  $P < 0.05$ ) with no significant difference between RE and EE. There was no significant difference in carbohydrate oxidation between any conditions (RE,  $0.85 \pm 0.05$  kcal/min; EE,  $0.88 \pm 0.06$  kcal/min; C,  $0.94 \pm 0.06$  kcal/min). Postexercise increase in % energy from fat was significant in RE ( $P < 0.05$ ) and approached significance in EE ( $P = 0.05$ ) (RE,  $41.4 \pm 3.6$  %; EE  $39.1 \pm 3.3$  %; C,  $32.3 \pm 1.9$  %). Postexercise decrease in % energy from carbohydrate was significant in RE ( $P < 0.05$ ) and approached significance in EE ( $P = 0.05$ ) (RE,  $58.6 \pm 3.6$  %; EE,  $60.9 \pm 3.3$  %; C,  $67.7 \pm 1.9$  %).

**CONCLUSION:** Acute, moderate intensity EE and high intensity RE both enhance the rate of fat oxidation in the postprandial period in obese women when compared to a sedentary control. The results indicate that RE and EE may be equally effective in altering postprandial energy substrate partitioning, and the findings may have implications for designing weight loss programs.

**2394** Board #69 MAY 31 3:30 PM - 5:00 PM  
**The Effects Of Resistance Exercise Training On Food Intake In Young Rats**  
Fábio M. Lorenzetti, Daniela Fojo Seixas Chaves, Guilherme Giannini Artioli, Juliana Leandro da Silva, Antonio Herbert Lancha Junior. *University of Sao Paulo, São Paulo, Brazil.*  
(No relationships reported)

**INTRODUCTION:** Physical exercise is responsible for altering various physiological parameters. Although several studies report a phenomenon known as "anorexia induced by exercise" in response to endurance exercise, little is known about the effects of resistance exercise on food intake.

**PURPOSE:** To verify the patterns of food intake of young rats (~4 months) in response to a 12-week resistance training protocol.

**METHODS:** The rats were kept in individual cages in inverted light/dark cycle and had free access to food and water. They were divided in two groups: a sedentary control group (CON) and a trained group (TR). The training consisted of 35 sessions, one session a day, 3 days a week. In each session rats performed a total of 30 repetitions at 80% of the previously established maximum force. This protocol has been successfully used in our lab to induce muscle hypertrophy. Food intake was measured in a daily basis every morning. To compare the difference between treatments at each time point, we used analysis of variance (ANOVA) for repeated measures.

**RESULTS:** No significant differences between groups were found for body weight at both PRE (CON= $401.38 \pm 1.06$ g; TR= $402.13 \pm 1.46$ g) and POST intervention (CON= $500.38 \pm 48.64$ g; TR= $507.63 \pm 24.12$ g). Likewise, there was no significant difference between groups for food intake, at any time of the study (PRE: CON= $30.00 \pm 0.00$ g; TR= $29.00 \pm 1.07$ g; POST: CON= $29.00 \pm 3.21$ g; TR= $29.00 \pm 3.21$ g).

**CONCLUSIONS:** According to the data obtained, we can conclude that 35 sessions of strength training with 80% of maximum load does not affect the voluntary food intake and weight in an animal model for resistance exercise training. Supported by FAPESP: 2010/08329-3 and 2010/10852-6.

**2395** Board #70 MAY 31 3:30 PM - 5:00 PM  
**Effects Of Different Modes Of Exercise On Appetite In Young Men**  
Hiroshi Kawano, Mayuko Mineta, Meiko Asaka, Masashi Miyashita, Yuko Gando, Takafumi Ando, Shigeharu Numao, Shizuo Sakamoto, Mitsuru Higuchi, FACSM. *Waseda University, Tokorozawa, Japan.*  
(No relationships reported)

It is known that an acute bout of high-intensity exercise induces appetite suppression. Recent research suggests that the appetite stimulating hormone secreted from the gut, acylated ghrelin, mediates exercise-induced appetite changes. However, it remains unclear whether there are differences in appetite and acylated ghrelin responses to different modes of exercise (i.e. weight bearing exercise versus non-weight bearing exercise). Rope skipping exercise is traditional exercise modality that everyone who had experienced during elementary school years in Japan, and it has characteristic exercise modality that it has a great up-and-down motions of the center of mass.

**PURPOSE:** This study was to examine the effects of exercise mode on appetite and plasma acylated ghrelin.

**METHODS:** Sixteen healthy young men (age  $24.6 \pm 0.5$  yrs, body mass  $65.7 \pm 1.6$  kg, maximal oxygen uptake  $46.6 \pm 1.6$  ml/kg/min) participated in this study. After 12-h fasting, all subjects undertook three, 160 min trials, 1) rope skipping exercise ( $291 \pm 9$  kcal, 3 sets x 10 min with 5 min interval, then rested for 120 min), 2) bicycle ergometer exercise ( $298 \pm 10$  kcal, 3 sets x 10 min with 5 min interval, then rested for 120 min), 3) control (rested for 160 min). Plasma concentration of acylated ghrelin and hunger evaluated by visual-analog scale (0 mm Not Hungry - 100 mm Very Hungry) were measured throughout.

**RESULTS:** Two-way ANOVA revealed significant ( $P < 0.05$ ) interaction effects for hunger and acylated ghrelin, indicating suppressed hunger and acylated ghrelin during rope skipping and

bicycle ergometer exercises. There were no significant trial effects for hunger and acylated ghrelin. The amount of change in appetite from baseline during exercise was greater in the rope skipping trial ( $-30 \pm 7$  mm) than both bicycle ergometer ( $-9 \pm 5$  mm) and control trials ( $3 \pm 3$  mm) by one-way ANOVA ( $P < 0.05$ ). However, there was no difference of change in plasma concentration of acylated ghrelin from baseline between in rope skipping and bicycle ergometer exercise trials.

**CONCLUSION:** These results suggest that rope skipping exercise with dramatic ups and downs in center of mass may have greater effect of exercise-induced suppression of appetite but not of acylated ghrelin compared with bicycle ergometer exercise without ups and downs.

**2396** Board #71 MAY 31 3:30 PM - 5:00 PM

**Effects Of Exercise On Appetite And Ad Libitum Energy Intake In Men And Women**

Megan M. Yamashiro, Jake Hinkel-Lipsker, Hanne Wolff, Katherine Stredler, Nero Evero, Terry Hackney, Todd A. Hagobian. *California Polytechnic State University San Luis Obispo, San Luis Obispo, CA.* (Sponsor: Barry Braun, FACSM)  
(No relationships reported)

Short-term aerobic exercise suppresses appetite and subsequent energy intake in men, however it remains unclear whether this occurs in women.

**PURPOSE:** To determine whether exercise alters subjective appetite ratings, appetite hormones and ad libitum energy intake differently in men and women.

**METHODS:** 11 healthy men ( $22 \pm 2$  yrs;  $16 \pm 6$  %BF;  $42.9 \pm 6.5$  ml/kg-min) and 10 healthy women ( $21 \pm 2$  yrs;  $23 \pm 3$  %BF;  $39.9 \pm 5.5$  ml/kg-min) completed a no-exercise and exercise condition in a counterbalanced, cross-over fashion. Subjects either rested for 60 minutes (no-exercise) or exercised on a cycle ergometer at  $\sim 70\%$  VO<sub>2</sub> max until 30% of their total daily energy expenditure was expended (Men; exercise expenditure =  $975 \pm 195$  kcal; Women; exercise expenditure =  $713 \pm 86$  kcal). Hunger and satiety ratings and insulin concentrations were assessed before and up to 30 minutes post each condition using a repeated measure ANOVA. Forty minutes after completion of both conditions, subjects were given an ad libitum buffet meal and relative energy intake was calculated as energy intake minus exercise expenditure.

**RESULTS:** There was no significant sex or condition effect in appetite ratings (i.e., hunger and satiety) and insulin concentrations. Absolute energy intake was significantly higher ( $P < 0.05$ ) in the exercise and no-exercise conditions in men ( $1648 \pm 950$ ,  $1216 \pm 633$  kcal, respectively) compared to women ( $591 \pm 183$ ,  $590 \pm 231$  kcal, respectively). Relative energy intake was significantly lower ( $P < 0.05$ ) after exercise compared to no-exercise in men ( $558 \pm 813$ ,  $1133 \pm 619$  kcal, respectively) and women ( $-205 \pm 248$ ,  $530 \pm 233$  kcal, respectively). However, relative energy intake was highly variable as 12 out of 21 subjects had lower energy intake after exercise, whereas 9 subjects had higher relative energy intake.

**CONCLUSIONS:** We observed no change in appetite ratings or insulin concentrations in either sex. However, ad libitum relative energy intake was lower after exercise in both men and women. Other key hormones (e.g. peptide-YY, acylated ghrelin) may have a more profound role in appetite regulation and may explain the lower relative energy intake.

**2397** Board #72 MAY 31 3:30 PM - 5:00 PM

**Fetuin-A Responses to Incremental Weight Loss**

Peter W. Grandjean, FACSM<sup>1</sup>, Guang Ren<sup>2</sup>, Xiaoming He<sup>2</sup>, Teayoun Kim<sup>2</sup>, Laurel A. Littlefield<sup>1</sup>, Robert L. Bowers<sup>2</sup>, Felipe Araya-Ramirez<sup>2</sup>, A Jack Mahurin, FACSM<sup>3</sup>, Suresh T. Mathews<sup>2</sup>. <sup>1</sup>Baylor University, Waco, TX. <sup>2</sup>Auburn University, Auburn, AL. <sup>3</sup>Baptist Hospital, Montgomery, AL  
(No relationships reported)

Fetuin-A is a hepatokine known to attenuate insulin action by suppressing insulin receptor tyrosine kinase activity. Fetuin-A concentrations are elevated in obesity, insulin resistance and type 2 diabetes and can be reduced with weight loss. Dose-response relationships between changes in fetuin-A concentrations and incremental weight loss and changes in body composition have not been characterized.

**PURPOSE:** The objectives of this investigation were to characterize the effects of incremental weight loss on circulating concentrations of fetuin-A and to determine relationships between fetuin-A and changes in body composition in obese men.

**METHODS:** Sixteen obese men (age =  $43.3 \pm 9.0$ ; weight =  $106.5 \pm 17.8$  kg; BMI =  $33.4 \pm 4.4$  kg/m<sup>2</sup>; body fat =  $36 \pm 4\%$ ) were assigned to regularly-practiced exercise and dietary restriction in order to reach a targeted weight loss of 8 to 10% of initial body weight over a 6 to 10-month period. Fasting blood samples were analyzed for fetuin-A concentrations and clinical markers of insulin sensitivity and changes in body fat and body fat distribution were measured at regular weight loss intervals (2-4%, 4-6%, 6-8% and target weight loss).

**RESULTS:** Fetuin-A was significantly reduced with 2-4% weight loss (83 mg/mL or 18.7%) and decreased by 126 mg/mL or 28.5% with target weight loss ( $p = 0.0002$ ). Body fat decreased by 4% ( $p < 0.0001$ ) and lean mass decreased by 3% ( $p < 0.0001$ ) with the targeted weight loss. Markers of insulin sensitivity [HOMA and glucose/insulin ratio, reported previously: MSSE Vol. 43 (5) No. 2462, 2011] were improved with as little as 4-6% weight-loss ( $p < 0.05$ ). Reductions in fetuin-A were correlated with the decrease in total fat mass measured after reaching target weight (0.67,  $p = 0.0045$ ).

**CONCLUSIONS:** As little as 2-4% weight loss resulted a decrease in fetuin-A concentrations. Continued weight and body fat loss resulted in further decrements in fetuin-A and improved insulin sensitivity. The decrease in fetuin-A was associated with a reduction in fat mass that occurred with 6-8% weight loss in obese men.

**Effects Of Visfatin Rs4730153 Snps On Exercise-induced Weight Loss Of Chinese Obese Children And Adolescents**

aiping lai<sup>1</sup>, wenhe chen<sup>2</sup>, Kelly Helm<sup>3</sup>. <sup>1</sup>Zhejiang College of Sports, HangZhou, China. <sup>2</sup>Shanghai University of Sport, Shanghai, China. <sup>3</sup>Valparaiso University, Valparaiso, IN.  
(No relationships reported)

**PURPOSE:** To investigate the effects of Visfatin gene polymorphism RS4730153 on exercise-induced weight loss.

**METHODS:** 88 obese children and adolescents of Han Chinese were subjected to 4 weeks of aerobic exercise to lose weight. By using ligase detection-polymerase chain reaction(LDR-PCR) sequence typing techniques,RS4730153 polymorphism of Visfatin gene of individual subject was determined, physical shape, functions, quality and metabolic indicators of glucose and lipid metabolism before and after exercise intervention were measured.

**RESULTS:** AG genotype frequency was 15.9% among subjects. Significant changes were found when indicators of all genotypes were compared before and after aerobic exercise. Compared indicators of all genotypes before with after aerobic exercise, there were significant changes. Pre-exercise triglyceride (TG) levels were significantly different between two genotypes (GG:  $1.40 \pm 0.74$  mmol/L; AG:  $1.86 \pm 1.11$  mmol/L;  $P = .050$ ). Exercise-induced changes of HOMA- $\beta$  level between two genotypes were significantly different (GG:  $220.50 \pm 178.81$ ; AG:  $332.23 \pm 207.90$ ;  $P = .050$ ). Gender also influenced changes of various metabolic indicators by exercise.

**CONCLUSIONS:** Visfatin single nucleotide variants RS4730153 exist in obese Han Chinese children and adolescents. Weight loss via exercise may be improved by reducing TG levels or by increasing insulin sensitivity of obese children with homozygous Visfatin RS4730153.

**2399** Board #74 MAY 31 3:30 PM - 5:00 PM

**Is there Longitudinal Agreement between Methods to Estimate Total Body Water on Adolescents?**

José Ramón Alvero Cruz<sup>1</sup>, Elvis Camero<sup>2</sup>, Jesús Barrera Expósito<sup>1</sup>, José Carlos Fernández García<sup>2</sup>, Luis B Sardinha<sup>3</sup>. <sup>1</sup>Faculty of Medicine. University of Málaga, Málaga, Spain. <sup>2</sup>Faculty of Education Sciences. University of Málaga, Málaga, Spain. <sup>3</sup>Technical University of Lisbon, Lisbon, Portugal.  
(No relationships reported)

Accurate estimation of total body water (TBW) is a cornerstone of the body composition assessment, since it is used to estimate fat-free mass and fat mass. Also, TBW changes have several implications on performance and health. However, there is a lack of knowledge about the agreement between gold standard and field methods to assess longitudinal changes of TBW, mainly on adolescents.

**PURPOSE:** The aim of this study was to explore the agreement between deuterium dilution method and whole-body bioelectrical impedance analysis (BIA) before and after 2 years of follow-up on adolescents.

**METHODS:** 73 adolescents (36 girls and 35 boys) were assessed (age= 13.6 ±1.2 yr, BMI= 22.0 ±3.2 kg/m<sup>2</sup>) during a 2-years follow-up period (2YFU) which was between October 2006 and 2008. TBW was determined by the isotope (deuterium oxide (<sup>2</sup>DO)) dilution technique using an isotope-ratio mass-spectrometer and a BIA by the traditional protocol. Paired sample T-test was performed to compare differences between TBW estimated by BIA and deuterium before (DifB-<sup>2</sup>DO<sub>1</sub>) and after (DifB-<sup>2</sup>DO<sub>2</sub>) 2YFU. Bland and Altman plot (B&A) and Kendall's Tau were carried out in order to analyze the agreement and bias between methods. Differences between TBW by <sup>2</sup>DO and BIA were calculated (DifB-<sup>2</sup>DO). Independent sample T-test between DifB-<sup>2</sup>DO<sub>2</sub> and DifB-<sup>2</sup>DO<sub>1</sub> was used in order to analyze if the magnitude of differences was statistically significant between moments.

**RESULTS:** Paired sample T-test did not show significant differences between methods either before (31.9 ±4.5 vs. 32.1 ±4.8 kg, BIA and <sup>2</sup>DO respectively; *p*>0.05) or after 2YFU (33.6 ±4.3 vs. 35.1 ±5.4 kg, BIA and <sup>2</sup>DO respectively; *p*>0.05). The B&A showed that DifB-<sup>2</sup>DO<sub>2</sub> had large confidence intervals (CI= -8.70 to 5.62 kg) and a significant proportional bias (Kendall's Tau = 0.31, *p*<0.001). Independent sample T-test between DifB-<sup>2</sup>DO before and after was statistically significant (-1.36 kg, *p*<0.001).

**CONCLUSION:** The main finding of this study was that after a 2YFU, BIA underestimated the TBW larger than before the follow up period. Also, DifB-<sup>2</sup>DO<sub>2</sub> had more variability and a great negative tendency than DifB-<sup>2</sup>DO<sub>1</sub>. So, our data indicate that higher TBW values greater underestimating by BIA. These results must be taken in consideration when TBW changes are assessed by BIA, mainly during maturation periods.

---

**2400** Board #75 MAY 31 3:30 PM - 5:00 PM

### Adult-Child Differences in Substrate Utilization Following Moderate and Vigorous Intensity Cycle Ergometer Exercise

Justin R. Bland<sup>1</sup>, Karin A. Pfeiffer, FACSM<sup>1</sup>, Joey C. Eisenmann<sup>2</sup>, Lorraine Weatherspoon<sup>1</sup>, Kimberly S. Maier<sup>1</sup>. <sup>1</sup>Michigan State University, East Lansing, MI. <sup>2</sup>Helen DeVos Children's Hospital, Grand Rapids, MI.

(No relationships reported)

**INTRODUCTION:** Previous research has shown fat oxidation, measured by respiratory exchange ratio (RER), to be greater in children than in adults at rest and during exercise. Few studies have investigated substrate utilization post-exercise in children.

**PURPOSE:** To examine adult-child differences in substrate utilization following moderate and vigorous intensity exercise performed on the cycle ergometer.

**METHODS:** 20 children and 23 adults visited the laboratory on three separate occasions and completed an exercise trial each day: VO<sub>2</sub>max test, moderate exercise (MOD), and vigorous exercise (VIG). Maximum power output (MaxPO) during the VO<sub>2</sub>max test was used to determine workload for MOD (35% MaxPO) and VIG (70% MaxPO) exercise. MOD and VIG trials were randomized and counterbalanced. Participants rested for 30 minutes (min) prior to exercise; the last 20 min were used for baseline VO<sub>2</sub> measures. In order to mimic child physical activity patterns, tests were 2-min square-wave intervals lasting 1 hour for the MOD trial and 30 min for the VIG trial. Expired gas measurements began 10 min prior to the cessation of exercise and continued for 30 min. Substrate utilization was examined using multivariate analysis of variance (ANOVA) for RER at minutes 1, 5, 10, 15, and 20 post-exercise. Another ANOVA model statistically controlling for caloric intake and gender was also performed.

**RESULTS:** After MOD, children's RER was significantly lower than adults at 1, 5, and 10 min (0.84 ± 0.05 vs. 0.90 ± 0.05; 0.93 ± 0.05 vs. 1.00 ± 0.08; and 0.86 ± 0.03 vs. 0.91 ± 0.05, respectively; all *p* < 0.01; effect sizes of 0.61, 0.26, and 0.29, respectively). After VIG, RER was similar in children and adults at min 1 and 10; however, children's RER in min 5 was significantly lower than adults (1.02 ± 0.06 vs. 1.15 ± 0.11, *p* = 0.001; effect size of 0.60). Children's RER in min 15 and 20 was significantly higher than adults' (0.83 ± 0.05 vs. 0.77 ± 0.06; 0.83 ± 0.05 vs. 0.75 ± 0.06, respectively; *p* ≤ 0.001; effect sizes of 1.66 and 2.12, respectively).

**CONCLUSIONS:** Children had lower RER than adults after MOD, but higher RER 15 and 20 min after VIG. Children rely more on fat oxidation at rest and during exercise than adults. This study observed children to utilize a greater proportion of carbohydrates than adults after VIG.

### Using the Bite Counter Device to Measure Energy Intake in Overweight African Americans

Phillip W. Jasper, Jenna L. Scisco, Veronica G. Parker, Adam W. Hoover, Eric R. Muth. Clemson University, Clemson, SC.

(No relationships reported)

Energy intake can be measured using tools such as paper-and-pencil and electronic food diaries, dietary recalls, food frequency questionnaires, and food history questionnaires (Thompson & Subar, 2008). Energy intake estimation with these tools can be challenging, and none of these methods allow the individual to measure their energy intake automatically and in real time. The Bite Counter is a watch-like device that can measure bites of food taken during a meal. This study was the first observational study using the Bite Counter in free-living humans.

**PURPOSE:** To determine the relationship between the numbers of bites taken during meals and three variables: kilocalories, meal duration, and meal location.

**METHODS:** Bite Counter devices were worn by 13 African-American participants (7 females, mean age = 55.5 (SD = 9.1), mean BMI = 36.8 (SD = 7.4)). Participants wore the Bite Counter on their dominant wrist for one week. Participants recorded bites of food by turning the device on when they began eating a meal and off when they finished eating a meal. Participants also completed daily dietary recalls using the Internet-based Automated Self-Administered 24-Hour Recall (ASA24 Beta version, National Cancer Institute, Bethesda, MD, 2009). Kilocalories for each meal and meal location were obtained from the ASA24. Bites for each meal and meal duration were obtained from the Bite Counters.

**RESULTS:** 147 meals were included in the analysis. Participants took an average of 42 bites (SD = 26) per meal, ate an average of 549 kilocalories (SD = 379) per meal, and ate for an average of 15 minutes (SD = 10) at each meal. 101 meals were eaten at home, and 46 meals were eaten outside of the home (e.g., work, restaurants). Correlational analyses indicated positive relationships between kilocalories and bites, *r*(145) = .31, *p* < .01, and meal duration and bites, *r*(145) = .87, *p* < .01. Significantly more bites were taken during meals eaten outside of the home (*M* = 51, *SD* = 35) compared to those eaten at home (*M* = 38, *SD* = 20, *t*(145) = 2.80, *p* < .05).

**CONCLUSIONS:** This small-scale study in African-American, overweight adults indicated that bites may serve as a measure of energy intake and meal duration. Additionally, bite count could be used to help individuals identify locations where their energy intake may increase.

### The Effects of Massage Therapy on Weight Management

Mark Blegen, FACSM<sup>1</sup>, Hannan Hassan<sup>1</sup>, Megan Gosselin<sup>1</sup>, Alisse Indrellie<sup>1</sup>, Heidi Sande<sup>1</sup>, Tracey Matthews<sup>2</sup>. <sup>1</sup>St. Catherine University, St. Paul, MN. <sup>2</sup>Springfield College, Springfield, MA.

(No relationships reported)

Cortisol is an adrenal cortex hormone and is released in response to stress. Massage has been shown to lower cortisol levels in individuals. High levels of cortisol in the body are associated with increases in fat mass and distribution.

**PURPOSE:** To examine if receiving weekly massages would influence salivary cortisol, bodyweight, blood pressure, and heart rate.

**METHODS:** Blood pressure, heart rate and salivary cortisol were measured pre-massage, post-massage, 15 min post-massage and 30 min post-massage. In the control setting, variables were measured at the same time point. For body weight a 2 X 2 repeated measures factorial ANOVA was computed to examine body weight. Measures were taken pre- and post-massage and pre- and post-control. In addition, 2 X 4 Repeated Measures ANOVAs were conducted for HR, SBP, DBP and salivary cortisol with an alpha level of 0.05.

**RESULTS:** A significant difference (*p* < 0.05) between the control and massage conditions was found for body weight. No significant difference (*p* > 0.05) between the two groups existed for body weight at pre-test (massage: 189.75 ± 24.15 lbs, control: 190.81 ± 24.60 lbs). Subjects weighed significantly less (*p* < 0.05) after massage than during the control session (massage: 186.94 ± 24.50 lbs, control 190.94 ± 23.71 lbs). For SBP, a significant interaction between time and condition existed. At baseline and the end of the condition, the massage group had significantly lower mean SBP (118.00 ± 11.39; 118.25 ± 6.50) than the control condition (128.5 ± 16.50, 127.63 ± 10.30). For heart rate, significant differences (*p* < 0.05) were found for the condition. Subjects had a significantly lower (*p* < 0.05) mean heart rate during the massage condition (67.38 ± 3.59) than the control condition (75.56 ± 3.39). For DBP, the massage condition had a

significantly lower mean DBP ( $78.13 \pm 3.28$ ) than the control condition ( $86.13 \pm 2.45$ ). For salivary cortisol the massage condition exhibited a significantly lower value ( $1.15 \pm 0.08$ ,  $1.42 \pm 0.07$ ).

**CONCLUSION:** Receiving weekly massages may be an adjunct to a weight management plan by reducing cortisol and thereby influencing body weight.

### Gender Differences in Isokinetic Strength and Endurance among Division II Athletes

Elizabeth Mathews, Kara Feller, Robert S. Van Zant. *The University of Findlay, Findlay, OH.*  
(No relationships reported)

**PURPOSE:** Gender disparity is noted in ACL injury. Muscles acting on the knee provide dynamic stabilization to the joint. The purpose of this study was to identify the gender differences in isokinetic muscular strength and endurance among Division II athletes in sports (soccer, basketball, volleyball) most susceptible to ACL injury.

**METHODS:** 33 Division II athletes (15 female, 18 male) provided informed consent for participation. Prior to their competitive season, athletes were tested for knee flexion and extension muscular strength and endurance in both dominant (D) and non-dominant (ND) legs using a Biodex 3 isokinetic dynamometer. Once seated and stabilized, subjects first performed 6 maximal repetitions at 1.04 and 4.19 radians per second (rad/sec). To test muscular endurance, subjects then performed 60 maximal repetitions at 3.14 rad/sec. Peak torque (PT), time to PT, PT to body weight ratio (PT/BW), and agonist/antagonist ratio (AGON/ANTAG) were determined at all 3 test speeds. In the endurance set, percent total work performed in the first third and final third of the set, as well as 30 and 60 sec recovery percentage of PT were assessed. All tests were conducted by the same investigator, providing standardized verbal feedback. All parameters were analyzed for group (gender) differences via independent t-test using SPSS statistical software.

**RESULTS:** Males were significantly ( $p < 0.05$ ) taller, heavier and leaner than females. In D and ND knee extension at all test speeds, males generated significantly greater PT and PT/BW. No gender differences were noted in time to PT, AGON/ANTAG, or any of the muscular endurance parameters. In D and ND knee flexion at all test speeds, males generated significantly greater PT and, with the exception of D leg at all speeds, PT/BW. No differences were noted in time to PT, AGON/ANTAG, or any of the endurance measures.

**CONCLUSIONS:** Even when corrected for body weight differences, Division II male athletes generate significantly greater knee extension torque and, in the ND leg, knee flexion torque. No gender differences were noted regarding muscular endurance in knee extension and flexion. Female Division II athletes may lack comparable dynamic knee joint stability relative to their male peers due to their reduced ability to generate maximal muscular strength.

### Heart Rate Variability and Maximal Oxygen Consumption in Healthy College Students

Andrew G. Thompson<sup>1</sup>, Carmine Grieco<sup>1</sup>, David Swain, FACSM<sup>1</sup>, James Onate<sup>2</sup>, Nelson Cortes<sup>3</sup>. <sup>1</sup>Old Dominion University, Norfolk, VA. <sup>2</sup>The Ohio State University, Columbus, OH. <sup>3</sup>George Mason University, Fairfax, VA.  
(No relationships reported)

The relationship between heart rate variability (HRV) and maximal oxygen consumption (VO<sub>2</sub>max) is equivocal. Results from recent studies suggest the relationship between HRV and VO<sub>2</sub>max is inconclusive.

**PURPOSE:** To examine possible correlations between resting HRV and VO<sub>2</sub>max in twenty-four healthy college students ( $22 \pm 3.7$  yr).

**METHODS:** HRV time and frequency-domain measures were calculated from electrocardiogram (ECG) recordings taken by a BioHarness during supine metronomic breathing (6 bpm). Five minutes of recumbent rested breathing was performed prior to five minutes of ECG recording. An incremental, maximal treadmill test and closed circuit spirometry was used to determine VO<sub>2</sub>max ( $51.6 \pm 11.1$  mL·min<sup>-1</sup>·kg<sup>-1</sup>).

**RESULTS:** Several significant inverse correlations between HRV indices and resting heart rate were found in both time and frequency-domain measures: Standard Deviation of Normal R-R intervals ( $r = -0.876$ ,  $p < 0.001$ ), Root Mean Squared of the Standard Deviation ( $r = -0.827$ ,  $p < 0.001$ ), HRV Triangular Index ( $r = -0.789$ ,  $p < 0.001$ ), Low Frequency (LF) in milliseconds ( $r = -0.758$ ,  $p < 0.001$ ), and High Frequency (HF) in milliseconds ( $r = -0.725$ ,  $p < 0.001$ ). There were, however, no significant correlations between HRV indices and VO<sub>2</sub>max.

**CONCLUSIONS:** These findings suggest that in a healthy college-aged population HRV and VO<sub>2</sub>max are independent of one another. Future research should examine the differences in athletic performance of equally fit individuals with different HRV profiles.

**2405** Board #80 MAY 31 2:00 PM - 3:30 PM

### The Effect Of Bio-feedback Manipulation On Incidence Of Plateau At VO<sub>2</sub>max.

Oliver Caddy<sup>1</sup>, Paul Bond<sup>1</sup>, Dan Gordon<sup>1</sup>, Richard Barnes<sup>2</sup>, Marie Gernigon<sup>3</sup>. <sup>1</sup>Anglia Ruskin University, Cambridge, United Kingdom. <sup>2</sup>Cambridge University, Cambridge, United Kingdom. <sup>3</sup>University of Angers, Angers, France.  
(No relationships reported)

**PURPOSE:** The purpose of this study was to determine the effects of altering the perception of effort, for the duration of a maximal oxygen uptake (VO<sub>2</sub>max) trial, through bio-feedback on the incidence of plateau at VO<sub>2</sub>max.

**METHOD:** Following Local University Institutional ethical approval, 7 active male participants volunteered to participate (age  $23.9$  yrs  $\pm 5.0$ ; mass  $82.8$  kg  $\pm 9.4$ ; stature  $180.9$  cm  $\pm 9.4$ ; VO<sub>2</sub>max  $49.19$  ml·kg<sup>-1</sup>·min<sup>-1</sup>  $\pm 5.41$ ). All participants completed four gradient-based VO<sub>2</sub>max trials on a treadmill using a ramp of 0.5%·30s<sup>-1</sup> at a constant speed of 10kph  $\pm 1$ . The initial trial served as a familiarisation. During the remaining three trials, which were completed in a randomised order, heart rate was displayed to the participants as the actual value (HR-A) and with variation of -10 b·min<sup>-1</sup> (HR-L) and +10 b·min<sup>-1</sup> (HR-H). Throughout all four trials VO<sub>2</sub> was recorded on a breath by breath basis using a pre-calibrated metabolic cart. The chosen criterion for attainment of a plateau response was a  $\Delta VO_2 \leq 50$  ml·min<sup>-1</sup> between the final two consecutive 30s sampling periods. At least one secondary criterion for the attainment of VO<sub>2</sub>max was employed: RER  $> 1.15$ ;  $\Delta RER \geq 0.4$ ; HR<sub>max</sub> 220-age  $\pm 10$  b·min<sup>-1</sup>; RPE  $> 19$ .

**RESULTS:** Across all three conditions there was no significant difference in VO<sub>2</sub>max and end workload ( $p > 0.05$ ). The  $\Delta VO_2$  values (ml·kg<sup>-1</sup>·min<sup>-1</sup>) between the final two consecutive 30s samples were HR-L  $68.95 \pm 46.42$ ; HR-A  $23.78 \pm 24.15$ ; HR-H  $55.27 \pm 61.29$ .  $\Delta VO_2$  was significantly lower in HR-A than HR-L ( $p = 0.04$ ) but there was no significant difference between HR-L and HR-H or HR-H and HR-A ( $p > 0.05$ ). The incidence of plateau varied across trials, HR-L 43%, HR-A 86%, HR-H 57%. RPE remained statistically unchanged ( $p > 0.05$ ) HR-L  $18.5 \pm 1.6$ ; HR-A  $18.7 \pm 1.8$ ; HR-H  $19 \pm 1.2$ .

**CONCLUSION:** These data are implicit of a detrimental effect on the attainment of a plateau in VO<sub>2</sub>max, with manipulation of biofeedback. Given the disassociation between RPE and the behaviour of  $\Delta VO_2$  at exhaustion, it is conceivable that differences in plateau attainment are instead related to a deviation from the mental map set during the familiarisation trial. Such a divergence may detract from the efficacy of a teleoanticipatory pacing strategy and, in turn, influence the central regulatory command at the end of a VO<sub>2</sub>max trial.

2406 Board #81 MAY 31 2:00 PM - 3:30 PM

**Impact Of K4b2 Calibration Drift On Respiratory Measurements During Walking And Running**

Chris Easton<sup>1</sup>, Chris C.F. Howe<sup>1</sup>, Richard O. Matzko<sup>1</sup>, Fabio Piaser<sup>2</sup>, Yannis P. Pitsiladis, FACSM<sup>2</sup>. <sup>1</sup>Kingston University, Kingston upon Thames, United Kingdom. <sup>2</sup>University of Glasgow, Glasgow, United Kingdom.  
(No relationships reported)

The K4b<sup>2</sup> (COSMED s.r.l, Rome, Italy) is a portable metabolic analyser designed to measure breath-by-breath respiratory variables in the field. While the majority of published evidence suggests that the K4b<sup>2</sup> is valid and reliable during rest and exercise, it has been previously demonstrated that the accuracy of the %O<sub>2</sub> and %CO<sub>2</sub> measurements can drift over time (McLaughlin *et al.* 2001. *Int J Sports Med* 22(4): 280-284). However, the effect of K4b<sup>2</sup> calibration drift on respiratory variables during prolonged exercise tests is presently unclear.

**PURPOSE:** To examine the accuracy of K4b<sup>2</sup> measurements of VO<sub>2</sub>, VCO<sub>2</sub> and V<sub>E</sub> following a one hour delay between calibration and measurement.

**METHODS:** Ten male participants (age: 31 ± 11 years, height: 181 ± 3 cm and body mass: 84.1 ± 10.0 kg) completed three maximal discontinuous incremental exercise tests on a motorized treadmill at speeds corresponding to 4, 5, 6, 8, 10, 12, 14 and 16 km·hr<sup>-1</sup>, or until volitional exhaustion. Participants completed 3 min of exercise at each speed, followed by 3 min active recovery for all speeds above 10 km·hr<sup>-1</sup>. Respiratory variables were measured continuously using either a laboratory based metabolic cart (Oxycon Pro, Carefusion, Germany) (OP), a K4b<sup>2</sup> calibrated immediately before use (K4b<sup>2</sup>) or a K4b<sup>2</sup> calibrated one hour prior to the test (K4b<sup>2</sup>DEL).

**RESULTS:** VCO<sub>2</sub> and V<sub>E</sub> were not different when measured by K4b<sup>2</sup> ( $P=0.27$ ,  $P=0.53$  respectively) or K4b<sup>2</sup>DEL ( $P=0.14$ ,  $P=0.39$  respectively) compared to the OP. VO<sub>2</sub> was not different between OP and K4b<sup>2</sup> ( $P=0.19$ ) but K4b<sup>2</sup>DEL overestimated VO<sub>2</sub> compared to the OP at faster running speeds ( $P=0.05$ ). Bland and Altman analysis indicated good agreement in the measurement of VO<sub>2</sub> between OP and K4b<sup>2</sup> with a mean difference of 38 ml·min<sup>-1</sup> and limits of agreement between -285 and 208 ml·min<sup>-1</sup>. The mean difference between K4b<sup>2</sup>DEL and OP was 84 ml·min<sup>-1</sup> with limits of agreement between -469 and 302 ml·min<sup>-1</sup>.

**CONCLUSIONS:** The K4b<sup>2</sup> overestimated VO<sub>2</sub> during faster running speeds following a one hour delay between calibration and measurement. Whilst care should be taken when using this device for longer duration exercise tests, the extent of the differences were small and newer models of the K4b<sup>2</sup> are fitted with a periodical recalibration mechanism which may eliminate this issue.

---

2407 Board #82 MAY 31 2:00 PM - 3:30 PM

**Gas Exchange Fatigue Thresholds From Ramp Versus Step Incremental Cycle Ergometer Tests**

Miranda T. Goodman, Jorge M. Zuniga, Chad Harris, FACSM. *Western New Mexico University, Silver City, NM.* (Sponsor: Chad Harris, FACSM)  
(No relationships reported)

**PURPOSE:** The purpose of this study was to compare the VO<sub>2</sub> (L·min<sup>-1</sup>) associated with the gas exchange threshold (GET) and respiratory compensation point (RCP) for ramp versus step incremental cycle ergometer tests.

**METHODS:** Seven male and seven female subjects (age = 23.36 ± 3.34 years; body mass = 71.65 ± 11.10 kg) performed a ramp (15 W·min<sup>-1</sup>) and step (30 W every 2 min) incremental cycle ergometer tests to exhaustion (in random order) to determine VO<sub>2</sub> max (L·min<sup>-1</sup>) RCP (VO<sub>2</sub> L·min<sup>-1</sup>), and GET (VO<sub>2</sub> min<sup>-1</sup>). The values GET and RCP were determined using the V-slope method. GET and RCP were defined as the VO<sub>2</sub> values corresponding to the intersection of 2 linear regression lines derived separately from the data points below and above the breakpoints for VCO<sub>2</sub> vs. VO<sub>2</sub> (GET) and V<sub>E</sub> vs. VCO<sub>2</sub> (RCP). In addition, the total work performed (kJ) during each protocol was calculated from the integral of power output versus time. Paired *t*-tests were used to analyze the mean differences between the ramp and step protocols.

**RESULTS:** The results showed no significant differences in VO<sub>2</sub> (L·min<sup>-1</sup>) between ramp and step incremental cycle ergometer tests for VO<sub>2</sub> max (ramp = 2.94 ± 0.74 L·min<sup>-1</sup> and step = 2.91 ± 0.70 L·min<sup>-1</sup>,  $p = 0.91$ ), GET (ramp = 1.86 ± 0.51 L·min<sup>-1</sup> and step = 1.90 ± 0.57 L·min<sup>-1</sup>,  $p = 0.83$ ) and RCP (ramp = 2.46 ± 0.63 L·min<sup>-1</sup> and step = 2.47 ± 0.56 L·min<sup>-1</sup>,  $p = 0.95$ ). A significantly greater ( $p = 0.01$ ) amount of total work was performed for the step (118.27 ± 45.51 kJ) versus the ramp (108.12 ± 39.70 kJ) test.

**CONCLUSION:** The results of the present study indicate that despite the increased amount of work performed for the step versus the ramp incremental cycle ergometer test, there were no significant differences in the VO<sub>2</sub> (L·min<sup>-1</sup>) associated to the gas exchange fatigue thresholds that demarcate the moderate from heavy (i.e., GET) and heavy from severe (i.e., RCP) exercise intensity domains.

2408 Board #83 MAY 31 2:00 PM - 3:30 PM

**Metabolic Responses When Jogging on an Anti-Gravity Treadmill**

Michael A. Figueroa<sup>1</sup>, James Manning, FACSM<sup>1</sup>, John M. Wolkstein<sup>2</sup>, Patricia Escamilla<sup>1</sup>. <sup>1</sup>William Paterson University, Wayne, NJ. <sup>2</sup>MCRC Physical Therapy, West Orange, NJ.  
(No relationships reported)

**PURPOSE:** To determine whether there would be any significant differences in metabolic work when jogging to maximal aerobic capacity on an anti-gravity treadmill, using differential air pressure, at different percentages of body weight (100%, 90% and 80% BW).

**METHODS:** Metabolic data were collected on 10 subjects (5 males, 5 females) on three separate days, which were separated by two weeks. The order in which body weight was manipulated was randomized on each day of testing. Maximal oxygen consumption was assessed using the Bruce Protocol and a metabolic cart.

**RESULTS:** Absolute VO<sub>2</sub>max values (L/min) were significantly different between, but not within genders, at each percent of body weight (100%BW: males = 3.4 ± 1.1 vs. females = 2.4 ± 0.25; 90%BW: males = 3.3 ± 1.1 vs. females = 2.4 ± 0.4; 80%BW: males = 3.4 ± 0.9 vs. females = 2.3 ± 0.3,  $p < 0.05$ ). Relative VO<sub>2</sub>max (ml/kg/min) was not found to be significantly different at 100%, 90% or 80% BW (42 ± 8 vs. 43 ± 9 vs. 42 ± 7,  $p = 0.99$ ). Heart rate (HR), respiratory exchange ratio (RER) values and substrate utilization were also not found to be significantly different between body weight percentages during any stage of testing.

**CONCLUSION:** Removal of up to 20% bodyweight did not alter metabolic responses (VO<sub>2</sub>, HR, RER, substrate utilization) during jogging to maximal aerobic capacity. Prescribed cardiovascular training intensities can be achieved with a reduction in ground reaction forces. This type of weight-assisted device may be an effective alternative during rehabilitation or recovery after an event in order to maintain cardiovascular fitness.

2409 Board #84 MAY 31 2:00 PM - 3:30 PM

**Exercise Tolerance During Cardiopulmonary Exercise Testing**

Adrian Midgley<sup>1</sup>, Peter Clough<sup>1</sup>, Fiona Earle<sup>1</sup>, Earle Keith<sup>1</sup>, Jason Siegler, FACSM<sup>2</sup>. <sup>1</sup>University of Hull, Hull, United Kingdom. <sup>2</sup>University of Western Sydney, Sydney, Australia.  
(No relationships reported)

**PURPOSE:** Subjects are expected to continue exercising to their limit of tolerance during a cardiopulmonary exercise test (CPET), since a maximal or near maximal effort is generally considered necessary for valid test results. However, very little is known about exercise tolerance during CPET.

**METHODS:** Fifty apparently healthy men visited the laboratory on two occasions. The first visit was mainly to familiarise the subjects with the equipment and test procedures and to complete questionnaires and a pain threshold test. On the second visit, subjects performed a maximal incremental treadmill test. After the test they completed a questionnaire to establish why they terminated the test when they did, to rate how helpful they found the verbal encouragement given during the test, how long they estimated it would have been before they would have collapsed on the treadmill or fell off the back if they did not terminate the test at the moment they did (time to collapse), and whether they set themselves any performance goals. Maximum jump height and lung function were measured before and after the CPET.

**RESULTS:** Twenty-three men terminated the test mainly due to leg fatigue and discomfort, 11 due to breathing discomfort, 2 due to safety concerns, and 14 because of other reasons. The mode for the total number of reasons that subjects stated influenced why they terminated the test when they did was six (range = 12). The median (IQR) estimated time to collapse was 45 (60) s. Correlates of time to collapse were perceived pre-exercise mental and physical readiness ( $r_s = -0.32$ ,  $p = 0.024$ ), self-reported preference for ( $r_s = -0.41$ ,  $p = 0.011$ ) and tolerance to ( $r_s = -$

0.35,  $p = 0.031$ ) high-intensity exercise, and change in maximal voluntary ventilation ( $r_s = -0.37$ ,  $p = 0.011$ ). The change in maximal jump height ( $r = 0.17$ ,  $p = 0.26$ ) and pain threshold ( $r_s = -0.19$ ,  $p = 0.20$ ) were not significantly correlated to time to collapse. The median (IQR) perception of the usefulness of verbal encouragement was 70 (37), where zero was 'not at all helpful' and 100 was 'extremely useful'. Thirty-nine of the subjects set themselves some sort of performance goals before or during the CPET.

**CONCLUSIONS:** The present study indicates that psychological factors result in termination of a CPET a relatively long before any physiological catastrophe occurs.

---

**2410 Board #85 MAY 31 2:00 PM - 3:30 PM**

**Influence Of Endurance Training On The Development Of Hemoglobin Mass During Adolescence**

Jon P. Wehrlin, Thomas Steiner. *Swiss Federal Institute of Sport, Magglingen, Switzerland.* (Sponsor: Ben Levine, FACSM)

(No relationships reported)

It is well known, that adult elite endurance athletes are characterized by about 30% higher hemoglobin mass ( $Hb_{mass}$ ) than untrained subjects. However, it is unclear, if this is due to endurance training, a better genetic predisposition of the athletes combined with a selection process, or other factors. Interestingly,  $Hb_{mass}$  at age 16 yrs is reported to be not different between endurance athletes and untrained subjects.

**PURPOSE:** To study the development of  $Hb_{mass}$  in elite endurance athletes and age matched untrained controls during adolescence with a longitudinal approach.

**METHODS:** We measured  $Hb_{mass}$  in 10 Swiss national team endurance athletes (AG: cross-country skiers and triathletes) as well as in 12 age matched non endurance training controls (CG) every 0.5 yrs from age 16 to age 18.5 yrs (T1 - T6) with the optimized carbon monoxide re-breathing technique.

**RESULTS:**  $Hb_{mass}$  increased ( $p < 0.001$ ) in the AG and was  $797 \pm 96$  g (T1),  $826 \pm 110$  g (T2),  $852 \pm 114$  g (T3),  $876 \pm 120$  g (T4),  $897 \pm 116$  g (T5) and  $902 \pm 123$  g (T6) as well as in the CG ( $p < 0.001$ ) from  $766 \pm 95$  g (T1) to  $797 \pm 90$  g (T2),  $833 \pm 100$  g (T3),  $845 \pm 94$  g (T4),  $855 \pm 95$  g (T5) and  $868 \pm 98$  g (T6). There were no differences between the groups in the initial  $Hb_{mass}$  level and in the rate of increase per year between the AG (5.2 $\pm$ 2.1%) and the CG (5.6 $\pm$ 4.7%). These rates of increase were individually highly different and ranged between 2.5 and 9.3% in the AG and between 1.2 and 16.9% in the CG. The correlation between the increase in  $Hb_{mass}$  and the increase in body weight was  $r = 0.81$  ( $p < 0.01$ ). Body weight related  $Hb_{mass}$  increased ( $p < 0.05$ ) during the measurement period from  $12.7 \pm 1.0$  g/kg (T1) to  $13.1 \pm 1.3$  g/kg (T6) in the AG as well as from  $12.1 \pm 0.9$  g/kg (T1) to  $12.6 \pm 0.7$  g/kg (T6) in the CG ( $p < 0.05$ ).

**CONCLUSION:**  $Hb_{mass}$  increases during adolescence, but there is no difference in increase rates between national team endurance athletes and untrained subjects. The amount of endurance training seems, therefore, not to influence the development of  $Hb_{mass}$  in adolescent subjects. The increase in  $Hb_{mass}$  is strongly correlated with the increase in bodyweight and increase rates are highly individually different. Other unknown factors may be responsible for these different increase rates in  $Hb_{mass}$  during adolescence.

---

**2411 Board #86 MAY 31 2:00 PM - 3:30 PM**

**All-out Critical Power Test Predicts Time-to-exhaustion During Ramp Incremental And Constant-work-rate Exercise**

Weerapong Chidnok<sup>1</sup>, Fred J DiMenna<sup>2</sup>, Stephen J Bailey<sup>1</sup>, Daryl P Wilkerson<sup>1</sup>, Anni Vanhatalo<sup>1</sup>, Andrew M Jones, FACSM<sup>1</sup>. <sup>1</sup>University of Exeter, Devon, United Kingdom. <sup>2</sup>Adelphi University, Garden City, NY.

(No relationships reported)

The power-duration relationship for severe-intensity exercise is defined by two parameters: the critical power (CP) and the  $W'$  which represents a fixed amount of work that can be performed above CP. These parameters can be established in a 3-min all-out cycling test, where the end-test power represents the CP and the work done above CP represents the  $W'$ . According to the power-duration principle, the total work done  $>CP$  ( $W_{>CP}$ ) during exhaustive exercise is the same irrespective of the work-rate forcing function, provided that the work-rate does not fall below CP.

**PURPOSE:** To test the hypothesis that the CP and  $W'$  derived from the 3-min all-out test accurately predict time-to-exhaustion ( $T_{lim}$ ) during ramp incremental and constant-work-rate (CWR) exercise  $>CP$ .

**METHODS:** Following ethical approval, seven recreationally-active male subjects (mean  $\pm$  SD: age  $21 \pm 4$  years) completed a ramp incremental test, a 3-min all-out test for the determination of CP and  $W'$ , and a CWR test until exhaustion on a cycle ergometer. The CWR was predicted to result in exhaustion in 3 min using the power-duration equation [ $P = (W'/180 \text{ s}) + CP$ ] and the predicted  $T_{lim}$  in the ramp test ( $T_p$ ) was calculated as:  $T_{lim} = CP/S + \sqrt{(2W'/S)}$ , where S is the ramp slope (0.5 Watts/s). Data were analyzed using paired samples  $t$ -tests and Pearson correlation coefficients. Significance was accepted at  $P < 0.05$ .

**RESULTS:** The CP and  $W'$  estimated in the 3-min all-out test were  $260 \pm 60$  W and  $16.5 \pm 4.0$  kJ. The  $W_{>CP}$  during the CWR ( $16.5 \pm 7.4$  kJ) and the ramp incremental test ( $16.4 \pm 8.4$  kJ) were not different from the  $W'$  measured in the all-out test ( $P > 0.05$ ). The predicted  $T_{lim}$  ( $754 \pm 122$  s) for the ramp incremental test was not different from ( $P > 0.05$ ), and was highly correlated with, the actual  $T_{lim}$  ( $753 \pm 121$  s;  $r = 0.92$ ,  $P < 0.01$ ). The predicted  $T_{lim}$  in the CWR test of 180 s was not different from ( $P > 0.05$ ), and was highly correlated with, the actual  $T_{lim}$  ( $185 \pm 24$  s;  $r = 0.99$ ;  $P < 0.01$ ).

**CONCLUSION:** The 3-min all-out test accurately predicted the  $T_{lim}$  during both ramp incremental and CWR exercise. These results provide further evidence that the power-duration parameters estimated in a single-visit all-out protocol provide meaningful predictions of exercise tolerance, and support the notion that only a finite amount of work is achievable above CP before exhaustion.

---

**2412 Board #87 MAY 31 2:00 PM - 3:30 PM**

**The Effect of a Priming Exercise on Cardiac Output Kinetics**

Ryan A. Seeto, Greg D. Wells, Scott G. Thomas. *University of Toronto, Toronto, ON, Canada.*

(No relationships reported)

A priming or warm-up exercise has been shown to accelerate oxygen uptake kinetics in a subsequent exercise; however, the mechanisms in which these changes occur is not well understood. One possible explanation for the accelerated oxygen uptake kinetics following a priming exercise may be due to adaptations in cardiac output (Q).

**PURPOSE:** To determine the effects of a priming exercise on Q kinetics.

**METHODS:** Following an assessment day to determine  $VO_{2max}$  and lactate threshold, seven moderately trained cyclists ( $VO_{2max}$ :  $58.4 \pm 11.6$  mL $\cdot$ min $^{-1}$  $\cdot$ kg $^{-1}$ ; height:  $1.75 \pm 0.07$  m; weight:  $73.9 \pm 14.1$  kg; age:  $29 \pm 6$  yrs) performed 6 minutes of cycling at a work rate equal to 10% above lactate threshold (unprimed; U) followed by a 3 minutes of no cycling and 6 minutes of cycling at an equivalent work rate to U (primed; P). Bioelectrical impedance was used to determine Q. Kinetics were modeled using a monoexponential equation and comparison between U and P trials were made using ANOVA.

**RESULTS:** While the Q time constant ( $\tau$ ) was not significantly different between U and P trials ( $42.3 \pm 9.6$  vs.  $39.7 \pm 10.7$  s,  $p = 0.62$ ), baseline Q was trended higher in the P trial ( $5.1 \pm 0.8$  vs.  $6.6 \pm 1.9$  L $\cdot$ min $^{-1}$ ,  $p = 0.06$ ). The absolute asymptotic Q value was significantly higher in the P trial ( $15.9 \pm 2.1$  vs.  $16.7 \pm 2.1$  L $\cdot$ min $^{-1}$ ,  $p < 0.05$ ). Heart rate (HR) kinetics shared a similar trend with Q. The HR  $\tau$  was not significantly different between U and P ( $41.1 \pm 7.2$  vs.  $40.9 \pm 9.1$  s.,  $p = 0.95$ ) while baseline HR ( $68.9 \pm 8.8$  vs.  $83.7 \pm 14.0$  beats $\cdot$ min $^{-1}$ ,  $p < 0.025$ ) and absolute asymptotic HR ( $152.8 \pm 13.3$  vs.  $159.7 \pm 14.3$  beats $\cdot$ min $^{-1}$ ,  $p < 0.005$ ) were significantly higher in the P trial.

**CONCLUSIONS:** There was no significant difference between the HR and Q  $\tau$  of the U and P trial and there is significant increase in baseline HR and close to a significant increase in baseline Q in the P trial. Differences in Q response with priming may be due to absolute stroke volume. Faster  $VO_2$  kinetics with priming does not reflect a faster rate of Q adjustment.

---

**2413 Board #88 MAY 31 2:00 PM - 3:30 PM**

**Changes of Incremental Exercise VO2 Kinetics between Different Fitness Levels**

Pei-Fan Wang, Li-Lan Fu, Yi-Tzu Chen. *National Taiwan Sports University, Taoyuan, Taiwan.*

(No relationships reported)

The analysis of  $VO_2$  kinetics in the previous studies focused more often in continuous exercise test. However, incremental exercise as an evaluation test or prescription raised clinical attention recently, but research evidence is still scant.

**PURPOSE:** The purpose of this study was to investigate the changes of incremental exercise VO<sub>2</sub> kinetics between people with different fitness level.

**METHODS:** Physically active college male students were recruited into this study. There were two groups of subjects, high-fitness (HF: 20.22 ± 2.11 yr, 177.89 ± 4.48cm, 72.06 ± 10.88 kg, VO<sub>2max</sub>: 58.87 ± 1.62 ml.kg<sup>-1</sup>.min<sup>-1</sup>; n=9) and low-fitness (LF: 19.33 ± 1.12 yr, 177.78 ± 5.95 cm, 79.82 ± 13.34 kg, VO<sub>2max</sub>: 44.10 ± 2.31 ml.kg<sup>-1</sup>.min<sup>-1</sup>; n=9). All subjects completed two 6-min bouts of moderate-intensity (63%VO<sub>2max</sub>) and severe-intensity(95%VO<sub>2max</sub>) running incremental exercise test (separated by 10 min of rest). Breath-by-breath pulmonary gas exchange (SensorMedics, Vmax 29) and HR were measured. One-way repeated-measure ANOVA was used to compare the ΔVO<sub>2</sub> of each minutes between the 2 groups under different intensity.

**RESULTS:** TheΔVO<sub>2</sub> during SI exercise [HF: ΔVO<sub>2(2-1), (3-2), (4-3), (5-4), (6-5)</sub>:11.48, 6.65, 0.49, 0.73, -0.73ml.kg<sup>-1</sup>.min<sup>-1</sup>; LF: ΔVO<sub>2(2-1), (3-2), (4-3), (5-4), (6-5)</sub>: 6.0, 6.49, 1.31, 0.54, -0.54 ml.kg<sup>-1</sup>.min<sup>-1</sup>, respectively] was plateaued at third minute for both groups (VO<sub>2</sub> between 3 and 4 min, HF: p = .15, LF: p = .26). TheΔVO<sub>2</sub> during MI exercise [HF: ΔVO<sub>2(2-1), (3-2), (4-3), (5-4), (6-5)</sub>: 9.51, 3.11, 0.48, -0.30, 0.30 ml.kg<sup>-1</sup>.min<sup>-1</sup>; LF: ΔVO<sub>2(2-1), (3-2), (4-3), (5-4), (6-5)</sub>: 6.41, 3.4, 0.98, 0.27, -0.27 ml.kg<sup>-1</sup>.min<sup>-1</sup>, respectively] was plateaued at third minute for LF groups (VO<sub>2</sub> between 3 and 4 min, p = .87), but at second minute for the HF group (VO<sub>2</sub> between 2 and 3 min, p = 1.5).

**CONCLUSIONS:** Under moderate-intensity exercise, subjects at different fitness level achieved stages of stable VO<sub>2</sub> at different timing. HF participants can reach stable VO<sub>2</sub> earlier than participants in LF.

**2414** Board #89 MAY 31 2:00 PM - 3:30 PM

**Effect Of Exercise Order On Cardiorespiratory And Perceptual Responses To Concurrent Exercise**

Nicholas W. Aguirre<sup>1</sup>, Jeremy G. Tan<sup>1</sup>, Daniel R. Coats<sup>1</sup>, Barry A. Spiering<sup>2</sup>, Lee E. Brown, FACSM<sup>1</sup>, Jared W. Coburn, FACSM<sup>1</sup>, Daniela A. Rubin<sup>1</sup>, Daniel A. Judelson, FACSM<sup>1</sup>. <sup>1</sup>California State University, Fullerton, Fullerton, CA. <sup>2</sup>United States Army Research Institute of Environmental Medicine, Natick, MA.  
(No relationships reported)

A training bout combining resistance (RE) and endurance exercise (EE) in a single session is termed concurrent exercise (CE). To date, few investigations have characterized the acute physiological and perceptual responses to CE order despite its popularity of its use for sport, recreational and health reasons. Since exercise order might influence RE and/or EE quality (and thereby overall training adaptations), elucidating these acute responses is integral for optimizing program design.

**PURPOSE:** To examine the effects of CE order on cardiorespiratory and perceptual responses.

**METHODS:** Nine healthy, concurrently trained subjects (age = 22.7 ± 1.7 y; mass = 84.8 ± 11.9 kg; height = 176.1 ± 7.4 cm) performed two CE trials: one in which RE (squat, bench press, lat pulldown: 60% 1-RM, 4 sets x 10 reps, 90-s rest) preceded EE (RE-EE) and one in which EE (cycling: 80% ventilatory threshold for 30-min) preceded RE (EE-RE). Heart rate (HR) and rating of perceived exertion (RPE) were recorded following each set of RE and every five minutes during EE. In addition, VO<sub>2</sub> and respiratory exchange ratio (RER) were recorded every 2.5 minutes during EE.

**RESULTS:** Subjects experienced significantly greater HR throughout RE in EE-RE (151 ± 5 bpm) compared to RE-EE (136 ± 5 bpm), concomitant with increased RPE during the squat exercise (EE-RE = 15 ± 2; RE-EE = 13 ± 1). Similarly, the HR and RPE elicited by EE during EE-RE significantly exceeded RE-EE for the first 10 and 15 min of exercise, respectively. Finally, VO<sub>2</sub> significantly increased and RER significantly decreased periodically during EE in RE-EE compared to EE-RE.

**CONCLUSIONS:** In conclusion, 1) preceding RE with EE increases RE cardiovascular and perceptual demands, and 2) preceding EE with RE increases EE caloric expenditure, fat oxidation, HR and RPE. This study supports performing RE before EE if superior caloric expenditure and fat oxidation is desired during EE, albeit at a higher physiological and perceptual cost.

**2415** Board #90 MAY 31 2:00 PM - 3:30 PM

**Strength And Cardiovascular Fitness Measures Over Time Regarding Sex, Age, And Season Of Testing**

Katherine E. LaBarbera<sup>1</sup>, Justin Keadle<sup>1</sup>, Kevin S. O'Fallon<sup>1</sup>, Priscilla M. Clarkson, FACSM<sup>1</sup>, Linda S. Pescatello, FACSM<sup>2</sup>, Beth A. Parker<sup>3</sup>, Paul D. Thompson, FACSM<sup>3</sup>. <sup>1</sup>University of Massachusetts Amherst, Amherst, MA. <sup>2</sup>University of Connecticut, Storrs, CT. <sup>3</sup>Hartford Hospital, Hartford, CT.  
(No relationships reported)

Muscular strength and cardiovascular fitness are often assessed during short- and long-term research studies. Familiarization sessions are intended to habituate participants with testing procedures, but they are typically used before initial data collection and not prior to follow-up testing.

**PURPOSE:** To examine the repeatability of muscular strength and VO<sub>2max</sub> measures over 6 months regarding age, sex, and season of initial testing, and to determine if repeating a familiarization session after a 6 month time period is necessary.

**METHODS:** 208 participants (100 men and 108 women, aged 20-76 yr) completed a familiarization session at visit 1 consisting of all strength assessments. Baseline testing occurred 3 days later and consisted of handgrip, isometric, and isokinetic strength measures of the dominant arm and leg at visit 2 and visit 3, which were also separated by 3 days; VO<sub>2max</sub> was assessed only at visit 2. After 6 months, participants completed the same strength assessments at visit 4 and 5; VO<sub>2max</sub> was assessed only at visit 4. A second familiarization visit was not performed prior to visit 4 or 5. Data were analyzed using a repeated measures analysis of variance (ANOVA). Significant interactions were investigated *post hoc* using a Tukey's HSD test.

**RESULTS:** No changes in strength over time with regard to sex, age cohort, or season were observed in grip strength, isometric elbow flexor and knee extensor strength, and isokinetic elbow flexor strength at 60 and 180 deg.sec<sup>-1</sup>. For example, isometric elbow flexor strength was similar at baseline (51.5 ± 1.4 Nm) and 6 months (52.0 ± 1.4 Nm), and VO<sub>2max</sub> did not change from baseline (33.3 ± 0.7 ml.kg<sup>-1</sup>.min<sup>-1</sup>) to 6 months (33.0 ± 0.7 ml.kg<sup>-1</sup>.min<sup>-1</sup>). A Time X Age Cohort interaction was observed for isokinetic knee extensor strength at 60 and 180 deg.sec<sup>-1</sup> (p<0.01), and further analysis showed that younger adults increased in strength over time for isokinetic knee extensor exercise at 180 deg.sec<sup>-1</sup> (118.6 ± 4.8 Nm to 127.0 ± 4.8 Nm).

**CONCLUSIONS:** Remarkable stability in strength and VO<sub>2max</sub> measures was observed over time for both sexes across the lifetime, and season of testing did not affect changes in strength from baseline to 6 month testing. Repeating a second familiarization after a 6-month time period may not be necessary.

**2416** Board #91 MAY 31 2:00 PM - 3:30 PM

**A Simplified Approach For Estimating VT And RCT**

Giancarlo Condello, Ezekiel Reynolds, Aimee Schneider, Erica Wherry, Megan Knutson, Erika Casolino, Scott Doberstein, Mark Gibson, Jos J. de Koning, FACSM, Carl Foster, FACSM. University of Wisconsin-La Crosse, La Crosse, WI.  
(No relationships reported)

Determining absolute values for training intensity (e.g. running speed) often requires extensive laboratory evaluation that is not widely available or practical beyond the setting of elite athletes.

**PURPOSE:** This study evaluates whether physiologic thresholds, useful for training prescription (ventilatory threshold (VT) & respiratory compensation threshold (RCT)), can be determined as simple percentages of maximal running velocity during an incremental treadmill test.

**METHODS:** Thirty-one physically active students (16 male: age 22.5 ± 2.2y, height 183 ± 5cm, weight 81.9 ± 11.1kg, VO<sub>2max</sub> 59.3 ± 8 ml\*kg<sup>-1</sup>\*min<sup>-1</sup>; 15 female: age 21.8 ± 2.5y, height 163 ± 6cm, weight 61.8 ± 7.8kg, VO<sub>2max</sub> 50.6 ± 4.4 ml\*kg<sup>-1</sup>\*min<sup>-1</sup>) performed incremental, maximal treadmill running (1% grade, start @ 5 km\*h<sup>-1</sup> for 3 min + 0.8 km\*h<sup>-1</sup> every minute) with respiratory metabolism measured using open circuit spirometry. In stages where 1 min was not completed, maximal speed was interpolated based on proportional stage time. The speed at VT and RCT were determined by visual inspection of each individual test.

**RESULTS:** The mean ± sd maximal running speed for all subjects combined was 15.4 ± 2.1 km\*h<sup>-1</sup>. The mean ± sd running speed at VT (10.1 ± 1.6 km\*h<sup>-1</sup>) and RCT (12.9 ± 1.8 km\*h<sup>-1</sup>) represented 67 ± 9 and 84 ± 6 % of maximal running speed, respectively. Using lower and upper 95% confidence intervals for VT and RCT, respectively, ≤64% and ≥86% of maximal speed should produce conditions consistent with <VT and >RCT.

**CONCLUSION:** The VT and RCT can be predicted from simple percentages of the maximal running speed with reasonably accuracy, and may provide a simplified method of training prescription.

**2417** Board #92 **MAY 31 2:00 PM - 3:30 PM**  
**Physiological and Perceptual Responses to Inclined Walking With and Without Handrail Support**  
 John D. Smith, Kevin H. Kendrick. *Texas A&M University-San Antonio, San Antonio, TX.* (Sponsor: David Nichols, FACSM)  
 (No relationships reported)

Level and inclined treadmill walking is a common form of exercise in the home and at fitness centers. While rails (handrails) are available for balance purposes when walking on a treadmill, exercisers will often use the rails as supports, most noticeably when walking on an incline.

**PURPOSE:** To examine the effect of handrail holding on physiological and perceptual responses while walking on an inclined treadmill.

**METHODS:** Thirty-eight participants (33.9±9.1 yrs, 169.5±10.2 cm, 78.2±24.2 kg) walked at 4.8 kph (3 mph) for 3 minutes under 3 conditions in this continuous protocol in the following order: 1) level without the use of the rails, 2) at 10% grade while holding onto the handrail, and 3) at 10% grade without the use of the handrail. Metabolic measurements were recorded using a ParvoMedics TrueOne 2400 metabolic system (Sandy Lake, UT) interfaced with a Polar heart rate monitor and averaged for one minute during the final minute of each stage. Rating of perceived exertion (RPE) was measured with the Borg's 6-20 scale during the last 10 seconds of each stage. Data were analyzed using repeated measures ANOVA and are presented as mean ± SD.

**RESULTS:** Level walking resulted in significantly lower responses compared to graded walking while holding the rails for heart rate (104.5±18.0 vs 119.6±20.6 b/min, p<.05), VO<sub>2</sub> (14.3±3.3 vs 19.6±3.6 ml/kg/min, p<.05), and RPE (7.8±1.7 vs 9.6±2.1, p<.05). Likewise, graded walking while holding the rails resulted in significantly lower responses compared to graded walking without holding the rails for heart rate (119.6±20.6 vs 140.6±22.9 b/min, p<.05), VO<sub>2</sub> (19.6±3.6 vs 25.6±3.5 ml/kg/min, p<.05), and RPE (9.6±2.1 vs 11.9±2.4, p<.05).

**CONCLUSION:** Using the rail as a support may be beneficial with the use of an incline when greater workloads are warranted and an increase in speed is not desired. Handrail use while walking on an incline will result in a lowered metabolic response compared to not holding the rail. While greater intensity can be achieved with holding the handrail during incline walking compared to level walking, the intensity when holding the rails on an incline is not as great compared to incline walking without the rails.

**2418** Board #93 **MAY 31 2:00 PM - 3:30 PM**  
**Effect of Intermittent Capillary Blood Sampling on Physiological Responses During Load Incremented Cycle Ergometry**  
 Monica Taylor. *University of Pittsburgh, Pittsburgh, PA.*  
 (No relationships reported)

Effect of intermittent capillary blood sampling on physiological responses during load incremented cycle ergometry.

Taylor, M., Shafer, A., Wisniewski, K., Haile, L., Panzak, G., Nagle, E., FACSM, L., Goss, F., FACSM, and Robertson, R., FACSM. University of Pittsburgh, Pittsburgh, PA

The measurement of capillary blood to assess the lactate inflection point is used for health-fitness and performance applications. However it is unknown if capillary blood sampling impacts physiological responses during exercise testing.

**PURPOSE:** To compare the effect of capillary blood sampling on peak oxygen consumption (VO<sub>2</sub> peak; l·min<sup>-1</sup>), heart rate at VO<sub>2</sub> peak (HR<sub>p</sub>; b·min<sup>-1</sup>), Total Cycle Time (TCT; min), and Ventilatory breakpoint (V<sub>pt</sub>) during a load incremented cycle protocol.

**METHODS:** Eleven males (22.9±3.4 years), and ten females (22.1±2.7 years) performed two load incremented cycle ergometer tests (Trial A and Trial B) to obtain VO<sub>2</sub> peak (l·min<sup>-1</sup>), Ventilation (V<sub>e</sub>; l·min<sup>-1</sup>), VCO<sub>2</sub> (l·min<sup>-1</sup>), VO<sub>2</sub> (l·min<sup>-1</sup>), and HR (b·min<sup>-1</sup>) were recorded each min. The V<sub>pt</sub> was determined as the %VO<sub>2</sub>peak at which V<sub>e</sub>:VO<sub>2</sub> increased without an accompanying increase in V<sub>e</sub>:VCO<sub>2</sub>. TCT was recorded at test termination. Trial A included capillary blood lactate (BLa) measures taken during the last min of each stage. Trial B used an identical protocol without BLa measures. The order of administration of Trial A and Trial B was counter-balanced. **RESULTS:** There were no differences in VO<sub>2</sub> peak, HR<sub>p</sub>, TCT, and V<sub>pt</sub> between Trial A and Trial B (p>0.05).

**CONCLUSION:** Capillary blood sampling does not appear to adversely influence aerobic fitness variables during exercise testing. This finding supports incorporating capillary blood sampling into exercise testing protocols.

**Aerobic Performance Recovers Within One Week After Blood Donation, With or Without Iron Supplementation**  
 Joel R. Krentz, Tyler B. Judd, Philip D. Chilibeck. *University of Saskatchewan, Saskatoon, SK, Canada.*  
 (No relationships reported)

Recently, our lab has shown that the time course for recovery of peak aerobic power after blood donation is between 2-3 weeks. Supplementation of iron may improve this recovery as iron is a constituent of hemoglobin.

**PURPOSE:** To examine the effects of iron supplementation on recovery of aerobic performance and red blood cell components after blood donation.

**METHODS:** 8 subjects (6 males, 2 females, 36 y, peak aerobic power 52.7 ml/kg/min) participated in the study. In a counter-balanced double-blind design subjects were randomized to receive either iron (65 mg) or placebo daily after donating blood. Subjects underwent 2 baseline testing days prior to donation. Recovery was monitored 24 hours post-donation and then weekly thereafter for 5 weeks. Exercise consisted of 45 minutes of cycle ergometry at ~50% peak work rate immediately followed by a 5 km time trial. At each time point pre-exercise hemoglobin and hematocrit levels were measured and ratings of perceived exertion (RPE) were taken at the 15, 30, 45 minute points of the pre-time trial exercise bout.

**RESULTS:** There were time main effects for both time trial performance and hemoglobin values (p<0.05). Post hoc analysis revealed that performance of the time trial was 5.5% slower the day after donation compared to baseline (417 SD 42 s vs. 395 SD 31 s; p<0.01) but then recovered by week 1 (406 SD 37 s). Hemoglobin decreased after donation (baseline = 15.4 SD 0.9 g/dL; 1 day after donation = 13.8 SD 1.1 g/dL p<0.05) and never recovered to pre-donation levels (13.3 SD 1.4 g/dL at 5 weeks). There was a time main effect of "time of exercise" for RPE with values increasing as exercise duration increased (p<0.001). No significant group by time interactions were observed for any of the measures.

**CONCLUSION:** Aerobic performance is significantly reduced the day after blood donation but recovers within one week, even in the absence of hemoglobin recovery. Iron supplementation does not affect aerobic performance or blood component recovery after donation.

Funded by the Saskatchewan Academy of Sports Medicine and NSERC

2420 Board #95 MAY 31 2:00 PM - 3:30 PM

**Total Hemoglobin Mass, Erythrocyte Volume and VO<sub>2</sub>max in Overweight and Normal Weight Healthy Subjects**

Trine Karlsen, Ingeborg M. Leinan, Fredrik Bækkerud, Frederic Solberg, Asbjørn Støylen, Ulrik Wisløff, Øivind Rognmo. *Norwegian University of Science and Technology, Trondheim, Norway.*

(No relationships reported)

Endurance athletes have significantly higher hemoglobin mass than recreational athletes and total hemoglobin mass correlates well with maximal oxygen uptake (VO<sub>2</sub>max). Less data is available on total hemoglobin mass in inactive overweight subjects.

**PURPOSE:** In a cross sectional study compare total hemoglobin mass, erythrocyte volume and VO<sub>2</sub>max between overweight and normal weight subjects.

**METHODS:** In 20 physically inactive overweight subjects (12 women/8men, age 41 ± 9 Yr, BMI 30 ± 3), and 20 normal weigh subjects (12 women/8 men, age 40 ± 15 Yr, BMI 23 ± 3), total hemoglobin mass and erythrocyte volume was measured with the improved CO-rebreathing method. Maximal oxygen consumption was measured in all subjects with an individualized ramp protocol to exhaustion.

**RESULTS:** Total hemoglobin mass was 758 ± 159 g and 736 ± 199 g in overweight compared to normal weight subjects respectively (n.s). Total erythrocyte volume was 2.24 ± 0.44 L and 2.16 ± 0.56 L in overweight compared to normal weight subjects respectively (n.s). Relative haemoglobin mass and erythrocyte volume was significantly reduced in overweight subjects compared with normal weight subjects. As the mean body weight in the overweight group was 20 kg greater than in the normal weight group relative hemoglobin mass was lower in overweight versus normal weight subjects (8.5 ± 1.5 g · kg<sup>-1</sup> and 10.4 ± 1.5 g · kg<sup>-1</sup>) (p = 0.001), and relative erythrocyte volume was lower in overweight versus normal weight subjects (25.1 ± 4.0 ml · kg<sup>-1</sup> and 30.8 ± 3.7 ml · kg<sup>-1</sup>) (p = 0.001). Absolute VO<sub>2</sub>max (L · min<sup>-1</sup>) was not significantly different between the two groups, while relative VO<sub>2</sub>max was significantly reduced in the overweight subjects versus in the normal weight subjects (36.3 ± 6.9 ml · kg<sup>-1</sup> · min<sup>-1</sup> and 50.0 ± 9.0 ml · kg<sup>-1</sup> · min<sup>-1</sup>). Total hemoglobin mass was significantly correlated with absolute VO<sub>2</sub>max (r = 0.807, p = 0.001) in the measured subjects.

**CONCLUSIONS:** Total hemoglobin mass and erythrocyte volume was identical in overweight and normal weigh subjects, and was within the expected range for untrained subjects. Relative hemoglobin mass, erythrocyte volume and VO<sub>2</sub>max was reduced in the overweight subjects due to 20 kg larger body weight compared to the normal weight subjects. Reduced relative VO<sub>2</sub>max is unrelated to total haemoglobin mass in overweight inactive subjects.

2421 Board #96 MAY 31 2:00 PM - 3:30 PM

**Maximal Physiologic And Kinematic Parameters During Partial Weight Unloading Treadmill Testing**

Boris Gojanovic, Phil Cutti, Rebecca Shultz, Gordon O. Matheson. *Stanford University, Stanford, CA.*

(No relationships reported)

**PURPOSE:** This study investigated maximal cardio-metabolic stimulation while running in a lower body positive pressure treadmill (AG), that reduces body weight (BW) and impact. The AG allows reduction of BW down to 20% and is used in rehabilitation of musculoskeletal injuries, but could have potential for high speed running in healthy athletes, especially if workload can remain maximally elevated at high speeds.

**METHODS:** 14 trained (9 male) runners (age 27 (5), 10k personal best 38.1 (1.1) min) completed a classical short 10 to 15 minutes treadmill incremental test (CON) to measure aerobic capacity and heart rate (VO<sub>2</sub>max and HRmax). They completed 4 identical tests (48 hours apart) on the AG at BW of 100%, 95%, 90% and 85% (AG100 to AG85). Stride length (SL) and rate (SR) were measured at peak velocities (V<sub>peak</sub>) by high-speed video analysis.

**RESULTS:** VO<sub>2</sub>max (ml·kg<sup>-1</sup>·min<sup>-1</sup>) was similar across all conditions (Men: CON=66.6 (3.0), AG100=65.5 (4.0), AG95=65.0 (5.4), AG90=65.6 (4.5) and AG85=65.0 (4.8). Women: CON=63.0 (4.6), AG100=61.5 (4.3), AG95=60.6 (4.7), AG90=61.4 (3.3) and AG85=62.8 (3.9)). Similar results were found for HRmax, excepted AG85 in men, AG100 and AG90 in women which were lower than CON. V<sub>peak</sub> (km·h<sup>-1</sup>) in men was 19.7 (0.9) in CON, which was lower than every other condition: AG100=21.0 (1.9) (p<0.05), AG95=21.4 (1.8) (p<0.01), AG90=22.3 (2.1) (p<0.01) and AG85=22.6 (1.6) (p<0.001). In women V<sub>peak</sub> (km·h<sup>-1</sup>) was similar between CON (17.8 (1.1)) and AG100 (19.3 (1.0)), but higher at AG95=19.5 (0.4) (p<0.05), AG90=19.5 (0.8) (p<0.05) and AG85=21.2 (0.9) (p<0.01). SL increased with the higher speeds in men, from CON=96.8 (5.8), AG100=99.6(6.5), AG95=99.6(6.2), AG90=99.1(4.9) and AG85=100.8(4.9). Only SL increased in women with higher speeds.

**CONCLUSIONS:** The AG can be used to elicit maximal exercise intensities at BW of 85 to 95%, reaching faster running speeds than normally feasible, and higher stride rate in men only. This could be potentially used for overspeed training in distance runners. The AG can help maintain aerobic conditioning during rehabilitation at lower BW.

2422 Board #97 MAY 31 2:00 PM - 3:30 PM

**Assessment Of Carotid Versus Radial Heart Rate Palpation Accuracy Following A Submaximal 3-min Step Test**

Nathan C. Winn, Andy Bosak, Thomas Andre, Felisa Glover, David Porley. *Georgia Southwestern State University, Americus, GA.*

(No relationships reported)

Previous studies have evaluated the accuracy of subjects palpating their carotid heart rate (HR) post-submaximal exercise. But, very few studies have assessed the accuracy of palpating HR at different artery sites. Post-exercise recovery HR has a critical and symbiotic relationship with step tests and accurate palpation of post-exercise recovery HR is extremely important for more precise exercise prescription.

**PURPOSE:** To evaluate subjects' ability to accurately palpate their step test post-exercise recovery HR at the carotid and radial sites.

**METHODS:** Above averagely fit male subjects (n = 31) were connected to an Electrocardiogram (EKG) and completed two 3-min step tests at a cadence of 24 steps/min, separated by 48-72 hours, in a counterbalanced order. Upon completion of stepping activity, subjects palpated their HR at the carotid and/or radial sites within 5 secs and then counted their post-exercise recovery HR for the next 15 secs.

**RESULTS:** The post-exercise recovery EKG HR (CAREkg and RADEkg) was compared with their respective post-exercise recovery palpated carotid (CARpal) and radial (RADpal) HR using MANOVA statistical methods with significant differences considered at p ≤ 0.05. Differences between CAREkg vs CARpal and RADEkg vs RADpal were significant.

**CONCLUSIONS:** Despite the results suggesting that subjects palpated their CARpal (± 2.48 bts off) more accurately than RADpal (± 4.12 bts off), subjects were not 100% accurate at palpating their post-exercise recovery HR when compared to the post-exercise recovery HR EKG recording. Future research may be required to determine whether longer familiarization trials of pre-exercise HR palpation are needed to ensure greater accuracy in palpating post exercise recovery HR.

2423 Board #98 MAY 31 2:00 PM - 3:30 PM

**Metabolic And Hormonal Responses to Modality Of Exercise and Sequence of Aerobic and Resistance Exercise in College Aged-women**

Dong-Ho Park<sup>1</sup>, Do-Yun Kim<sup>1</sup>, Chang-Sun Kim<sup>2</sup>. <sup>1</sup>Inha University, Incheon, Korea, Republic of. <sup>2</sup>Dongduk Women's University, Seoul, Korea, Republic of.

(No relationships reported)

**PURPOSE:** This study compared the effects of 4 different exercise programs [Aerobic exercise only (A), Resistance exercise only (R), Aerobic-Resistance exercise (A-R), and Resistance-Aerobic exercise (R-A)] on metabolic factors and hormones in untrained college aged-women.

**METHODS:** Eight females (18.5±0.76 years) completed Aerobic exercise Only (A, 65% VO<sub>2</sub>max), Resistance exercise only (R, 65% of 1-RM with an interset rest period of 105s), Aerobic-Resistance exercise (A-R), and Resistance-Aerobic exercise (R-A) experimental conditions. Aerobic exercise consisted of 25 minutes of treadmill exercise. VO<sub>2</sub> was determined during treadmill exercise and after each exercise treatment. Resistance exercise consisted of 7 lifts with 3 sets. Blood was obtained pre-, post-, 30 min after- and 60 min after exercise.

**RESULTS:** There were significant interaction effects on Growth hormone (p=.030), cortisol (p=.021) and testosterone (p=.007) by exercise mode (R and A) and exercise sequence (A-R and R-A). No significant difference was seen in the levels of estradiol between exercise mode (p=.071), but just showed the significant increase after R-A exercise (time, p=.001) which maintained

the highest concentration among the exercises mode and sequence. Glucose( $p=0.007$ ), free fatty acids( $p=0.000$ ) and lactic acid( $p=0.000$ ) had significant interaction effect by exercise mode and sequence respectively, especially glucose showed higher concentration of R-A than A-R, but lower than R only at post-exercise. EPOC and RER had significant interaction effects by exercise mode and sequence ( $p=0.000$  and  $p=0.000$ , respectively), particularly EPOC in R-A was higher than R only and A-R ( $p=0.014$ ,  $p=0.000$ , respectively). During R-A, rating of perceived exertion (RPE) during treadmill exercise was significantly increased ( $p=0.001$ ) above that of A-R and A only.

**CONCLUSIONS:** Either aerobic or resistance exercise alone increases the levels of estradiol and testosterone, but the increases are greatest with R-A exercise. Therefore, the R-A exercise might be more beneficial to increase bone density by the secretions of estradiol and testosterone, whereas the A-R exercise might be suitable for elderly people or a beginner because of relatively lower exercise intensity in regard to the RPE.

**Combining Heart Rate And Accelerometer Data To Estimate Physical Fitness**

Thijs M. Tönis, Miriam M.R. Vollenbroek-Hutten, Hermie Hermens. *Roessingh Research and Development, Enschede, Netherlands.*

(No relationships reported)

Monitoring changes in physical fitness is relevant in many conditions and groups of patients, but its estimation demands substantial effort from the person, personnel and equipment. Besides that, present (sub) maximal exercise tests give a momentary fitness score, which depends on many (external) factors. Obtaining a fitness score based on measures gathered during longer periods of time and in natural conditions, like in daily life, would be an attractive alternative for the present methods. We performed an explorative lab-experiment to study the feasibility of fitness estimation during an activity commonly encountered in daily life; walking.

**PURPOSE:** To investigate the feasibility of physical fitness estimation from combined heart rate and accelerometer data obtained during treadmill walking.

**METHODS:** Forty-one subjects (23m, 18f) aged between 21 and 29 walked at three speeds on a treadmill (4, 5.5 and 6  $\text{kmh}^{-1}$ ) wearing a heart rate monitor and a hip mounted 3D accelerometer. The acceleration signal was converted into activity counts per 10 seconds. Stepwise linear regression analysis to estimate  $\text{VO}_{2\text{max}}$  was performed on the *slope* and *intercept* of the linear relation between heart rate and activity counts during steady state exercise ( $> 3\text{min}$ ), together with *age*, *gender*, *weight*, *length* and *BMI*. Reference  $\text{VO}_{2\text{max}}$  was obtained by performing a sub-maximal single stage treadmill walking test.

**RESULTS:** The model with the highest percentage of explained variance ( $R^2=0.93$ ) combined the slope and intercept parameter of the relation between heart rate and activity counts, together with gender. The model had a standard error of the estimate of  $1.78 \text{ ml O}_2\text{kg}^{-1}\text{min}^{-1}$ .

**CONCLUSION:** Results of the model are comparable with commonly used sub-maximal laboratory tests to estimate  $\text{VO}_{2\text{max}}$ . Fusing heart rate and accelerometer data during steady state activities seems promising for ambulant estimation of  $\text{VO}_{2\text{max}}$  and would not require the subject to carry out a high performance test.

This research was supported by the Dutch Alpe d'HuZes foundation.

**2425** Board #100 MAY 31 2:00 PM - 3:30 PM

**Effects of Time of Day for Exercise on 24-hour Ambulatory Blood Pressure in Normotensive Female Adults**

Chia-Hua Chu, Chien-Yu Pan. *National Kaohsiung Normal University, Kaohsiung, Taiwan.*

(No relationships reported)

Time of day for exercise may influence blood pressure reduction in hypertension because of the diurnal variation of blood pressure and the duration of blood pressure reduction following a single bout of exercise (Park, Jastremski, & Wallace, 2005). However, knowledge about the response of blood pressure following at different time of day for exercise is limited and often were not be disclosed by study investigators.

**PURPOSE:** To compare different time of day for aerobic exercise on 24-hour ambulatory blood pressure (ABP) in normotensive female adults.

**METHODS:** Fifteen nonobese ( $\text{BMI } 23.07 \pm 3.38 \text{ kg}\cdot\text{m}^{-2}$ ) and normotensive middle-aged women ( $45.40 \pm 5.40$  years) volunteered to participate. They underwent a single bout of aerobic exercise (30 min, 60% heart rate reserve) 2 times in random fashion on separate days: (a) in the morning (between 0630-0800 hours, AMex), (b) in the afternoon (between 1630-1800 hours, PMex), and (c) a control (no exercise) session. Each participant's 24-hour ABP was measured after AMex, PMex, and control treatments using SpaceLabs model 90217. The dependent variables used for analysis were average 24-hour, daytime, and night time blood pressure. A repeated measure analysis of variance (ANOVA) was used to assess the effect of varied time of day for aerobic exercise on 24-hour ABP. In the case of a significant F-value, a Tukey *post hoc* test was used to identify differences under various time of day.

**RESULTS:** The 24-hour systolic (SBP), diastolic (DBP), mean arterial blood pressure (MAP) and daytime SBP were significantly lower after PMex than after AMex and control sessions (all  $p<0.05$ ). After PMex, 24-hour SBP was reduced an average of  $4.46 \pm 2.86$  and DBP by  $2.6 \pm 0.4 \text{ mmHg}$ ; and daytime SBP by  $3.1 \pm 0.2 \text{ mmHg}$ .

**CONCLUSION:** The post-exercise ABP reduction observed in normotensive middle-aged women depends on time of day for exercise; that is, the PMex significantly decreased daytime and 24-hour ABP. Supported by Taiwan NSC grants 99-2410-H-017-035.

**2426** Board #101 MAY 31 2:00 PM - 3:30 PM

**A New Method For Determining Exercise Intensity To Meet Cardiovascular Needs**

Ronald Garner<sup>1</sup>, Jessica Gengler<sup>2</sup>, Brandon Lynn<sup>2</sup>, Jeremy Rindlisbacher<sup>2</sup>, Cassidy Robertson<sup>2</sup>, Natalie Schreher<sup>2</sup>, Eli Lankford<sup>2</sup>. <sup>1</sup>Utah State University, Logan, UT.

<sup>2</sup>BYU-Idaho, Rexburg, ID.

(No relationships reported)

**PURPOSE:** The purpose of the study was to determine whether work at lactate threshold (LT) or ventilatory threshold (VT) is optimal for improvements in cardiovascular fitness.

**METHODS:** 27 college-aged students (7 females, 20 males) participated in the study. Subjects were separated into groups based on fitness levels, sedentary (SED), average (AVG) and fit (FIT). Subjects participated in a graded exercise test (GXT) to determine LT followed by a  $\text{VO}_{2\text{max}}$  test.  $\text{VO}_2$  at LT was used to determine work rate for a final run where time to exhaustion (TTE) was recorded.

**RESULTS:** No differences ( $p = 0.079$ ) in TTE were found between groups SED, AVG, and FIT, therefore all groups were combined for further analysis. TTE =  $33.96 \pm 10.97 \text{ min}$ ; HR at LT =  $167.77 \pm 9.12 \text{ bpm}$ ; RPE at LT =  $13.19 \pm 1.36$ ;  $\text{VO}_{2\text{max}} = 53.35 \pm 7.67 \text{ ml/kg/min-1}$ ;  $\text{VO}_2$  at LT =  $39.46 \pm 6.02$ ;  $\text{ml/kg/min-1}$ . Percent  $\text{VO}_{2\text{max}}$  at LT =  $74.04 \pm 5.26\%$  TTE was not related to  $\text{VO}_{2\text{max}}$  ( $p=0.9$ ;  $r = -0.009$ ). Additionally, TTE was not related to  $\text{VO}_2$  at LT ( $p = 0.24$ ;  $r = .06$ ). The study determined no correlation between TTE and fitness level measured as both  $\text{VO}_{2\text{max}}$ , and  $\text{VO}_2$  at LT.

**CONCLUSIONS:** General guidelines typically recommend between 30-60 min of exercise most days of the week. Other guidelines use RPE, %  $\text{VO}_{2\text{max}}$ , or HR to determine exercise intensity. The varying recommendations can cause confusion as to proper exercise prescription. We found that by exercising at LT, total exercise time fell within the recommended guidelines of the ACSM and the CDC for both duration and intensity. Exercise at LT or VT fell within the recommended guidelines for duration of exercise regardless of fitness level. We recommend using LT or VT as the guideline for determining exercise intensity.

**2427** Board #102 MAY 31 2:00 PM - 3:30 PM

**Relationship Of Vo2 Max And Ratio Of Total Co2 And O2 During Testing**

Keisuke Ida<sup>1</sup>, David Bellar<sup>2</sup>, Ellen L. Glickman, FACSM<sup>3</sup>. <sup>1</sup>Active Recovery, Sacramento, CA. <sup>2</sup>University of Louisiana at Lafayette, Lafayette, LA. <sup>3</sup>Kent State University, Kent, OH.

(No relationships reported)

Maximum oxygen uptake ( $\text{VO}_2 \text{max}$ ) is commonly studied among both recreational and athletic populations and is widely held to be the criterion measure by which to judge cardiovascular fitness. Although the results of a high level of fitness after a  $\text{VO}_2 \text{max}$  test are complete, there is little information about differences that explain fitness outcomes during the assessment other than the termination point.

**PURPOSE:** The purpose of the present investigation was to examine the ratio between total accumulated CO<sub>2</sub> expiration and O<sub>2</sub> consumption and examine the relationship to VO<sub>2</sub> at the point of test termination or oxygen consumption plateau.

**METHODS:** Twenty male (age: 20.0±1.0yrs, weight: 71.3±9.7kg, VO<sub>2</sub> max: 56.6± 8.6 ml O<sub>2</sub>/kg\*min) and eighteen female male (age: 21.1± 0.6yrs, weight: 55.8±7.2kg, VO<sub>2</sub> max: 44.8± 9.9 ml O<sub>2</sub>/kg\*min) college aged students who were recreationally active volunteered for the present investigation. The participant underwent a custom ramped treadmill protocol with expiratory gases monitored via computerized metabolic measurement system. After the testing third order polynomial regression was undertaken for the VO<sub>2</sub> and VCO<sub>2</sub> by time ( $r>0.950$ ). Regression equations were then integrated from 60seconds after the start of the test (to negate any initial hyperventilation) until the point at which maximum oxygen consumption was determined to have occurred. This area under the curve calculation was equal to the total accumulated expired CO<sub>2</sub> and consumed O<sub>2</sub> during this time period. The values for carbon dioxide were then divided by the values for Oxygen and a ratio score was created (AOC ratio). This ratio was then compared against the results of the VO<sub>2</sub> max test.

**RESULTS:** Data analysis examining the relationship between the AOC ratio and VO<sub>2</sub> max was undertaken utilizing partial correlation analysis (controlled for gender). The results of the analysis showed a significant negative correlation between AOC ratio and VO<sub>2</sub> max ( $r=-0.602$ ,  $p<0.001$ ).

**CONCLUSION:** Based upon these results it would appear that during the course of the test of maximum aerobic capacity, individual who are more fit produce less carbon dioxide over the course of the test per unit of oxygen utilized.

### Does Physical Activity Explain Racial/Ethnic Differences in Cardiorespiratory Fitness among Young U.S. Adults?

Tyrone Ceaser, Eugene Fitzhugh, Dixie Thompson, FACSM. *University of Tennessee-Knoxville, Knoxville, TN.*

(No relationships reported)

**PURPOSE:** Cardiorespiratory fitness (CRF), an outcome of regular physical activity (PA), decreases the risk of heart disease in adults. Expressed as maximal oxygen uptake (VO<sub>2</sub>max), previous research has shown differences in CRF levels among racial groups. However, it is unclear how much of these differences in fitness can be explained by physical activity. Thus, we sought to answer this question.

**METHODS:** A total of 3115 adults (18-49 years) completed a submaximal graded treadmill exercise test from NHANES (1999-2004) to estimate VO<sub>2</sub>max, the dependent measure. Independent variables included demographics (race, education, gender, partner status, and waist circumference), behavioral measures (smoking and alcohol consumption), self-reported PA from three different domains: leisure-time, domestic, and transportation PA (MET-min/week), and the proportion of PA of a vigorous intensity (VMET). Multiple linear regression was performed using SUDDAN statistical software.

**RESULTS:** Results indicated that VO<sub>2</sub>max was significantly higher for Mexican Americans (40.9 ± 0.5 ml/kg/min), and Non-Hispanic Whites (40.2 ± 0.3 ml/kg/min) compared to non-Hispanic Blacks (37.9 ± 0.6 ml/kg/min) ( $P = 0.01$ ). Demographics including race explained 18.5% of the variance in VO<sub>2</sub>max, with race being significant ( $P < 0.01$ ) in the model. When PA was added to the model, the variance in VO<sub>2</sub>max explained increased by 0.8% to 19.3% ( $P = 0.001$ ). VMET was more predictive of VO<sub>2</sub>max than overall PA, and the model including VMET explained 20.5% of the variance in VO<sub>2</sub>max. Race remained a significant, independent predictor of VO<sub>2</sub>max after VMET and overall PA were added to the model.

**CONCLUSIONS:** Race and VMET are important factors in explaining differences in CRF. However, after accounting for demographics, PA, and VMET, a large proportion of the variance in CRF remains unexplained by the models. This suggests that other factors should also be considered when examining racial/ethnic differences in CRF.

### Comparing Levels of Anti-Fat Bias Between Mexican and American Athletes and Undergraduate Physical Education and Exercise Science Students

Miriam M. Wood, James R. Whitehead, FACSM, Sandra E. Short, Martin Short. *University of North Dakota, Grand Forks, ND.*

(No relationships reported)

Anti-fat bias is "an obesity prejudice in which the attribute of being obese influences the expectations about the individuals, often in terms of negative character assessment such as laziness, lack of discipline, and incompetence" (Puhl & Brownell, 2001) displayed either in an implicit or explicit way.

**PURPOSE:** this study compared anti-fat bias ratings between American and Mexican athletes and undergraduate physical education and exercise science students (a replication and extension of Chambliss et al., 2004). It also investigated the possible that socially desirable response tendencies are threat to the validity of the explicit anti-fat bias measure.

**METHODS:** undergraduate students from the US ( $n = 63$ ) and Mexico ( $n = 40$ ) and Mexican athletes ( $n = 15$ ) filled out questionnaires to investigate their levels of anti-fat bias (Implicit Association Test (IAT) and Anti-fat Attitudes Test (AFAT). The BIDR-6 was used to measure socially desirable response tendencies.

**RESULTS:** for the AFAT, there were no statistically significant differences between the American and Mexican samples. On the IAT, when *good vs. bad* was paired with *thin vs. fat*, there was an effect revealing that American students scored higher than Mexican students ( $M = 4.68$  vs.  $2.63$ ,  $p < .01$ ). Similarly, when *smart vs. stupid* was linked to *thin vs. fat* the results revealed that the Mexican students ( $M = 6.76$ ) scored higher ( $p < .001$ ) than the Mexican athletes ( $M = 4.08$ ) and significantly higher ( $p < .05$ ) than the American students ( $M = 3.62$ ), and when *motivated-lazy* was paired with *fat vs. thin*, there was a significant interaction effect ( $F [2, 111] = 3.66$ ,  $p < .05$ ). Most IAT sub-sample scores were significantly different from zero indicating implicit anti-fat bias. There were no significant correlations between the BIDR-6 scales and the AFAT. Only 6% of the variance in the AFAT items was explained by socially desirable response tendency, indicating no substantive threat to validity.

**CONCLUSION:** the results suggested that anti-fat bias is an issue with future exercise science professionals, and thus, further research on incidence levels and prevention strategies is warranted. Also, given the lack of association between measurement methods, further research should investigate if implicit bias does, or does not affect an individual's explicit bias.

### Understanding Cultural Perspectives On Physical Activity Among Older Mexican Women Through Visual Research Methods

Andiara Schwingel, Wojtek Chodzko-Zajko, FACSM, Salva Najib. *University of Illinois at Urbana Champaign, Champaign, IL.*

(No relationships reported)

Older Latina women are a particularly vulnerable group for physical inactivity for whom public health messages and interventions appear to be less effective.

**PURPOSE:** The purpose of this study was to evaluate the benefits of using visual and participatory research techniques with this population.

**METHODS:** Perceptions of physical activity were assessed using a visual research method known as photo-elicitation from a sample of 37 older women of Mexican background living in Illinois.

**RESULTS:** Following analyses of photographs and interviews, we collected a number of prominent themes emerging from the qualitative data. Categorized according to the Social Ecological Model, major themes representing factors that may influence physical activity choices were: (1) Individual Level: health status; beliefs about physical activity, health and wellness; previous physical activity behavior (2) Social Environment: family influence and support; support from social networks and friends; community involvement and activity (3) Physical Environment: availability of physical activity resources and opportunities; weather; neighborhood safety (4) Cultural and Social Norms: cultural values and perceptions on physical activity and being healthy; perceptions on the role of women in the household; the role of religion in everyday life.

**CONCLUSIONS:** Findings suggest that this method may be a valuable tool in extracting rich and meaningful data from target audiences while fostering a sense of partnership between researchers and community members. Innovative interdisciplinary research techniques may present improved ways to reach and impact underserved populations.

**Development And Evaluation Of A Culturally-responsive Fitness Instructor Training Program For Underserved Latinos.**

Ermilia Medina, Elizabeth Booen-Mejia, Megan P. Duesterhaus, Susana Moral Gonzalez, Jeanne Nichols, FACSM, Todd Galati, Simon Marshall. *San Diego State University, San Diego, CA.*

(No relationships reported)

Few opportunities exist for Spanish-speaking community members to become certified exercise and fitness professionals.

**PURPOSE:** Adapt, implement and evaluate a culturally-responsive, Spanish-language training program for community members to become certified fitness instructors.

**METHODS:** A print-based English-language self study course for group fitness instructors (the ACE® Group Fitness Instructor self study course) was culturally adapted using principles of Culturally Responsive Teaching for delivery as a Spanish-language, 14-week face-to-face course. Bilingual, bicultural exercise scientists and group fitness instructors were part of the expert panel that completed the cultural adaptation of the curriculum. Live training was delivered by public health background certified fitness professionals.

**RESULTS:** The 14-week training program comprised of 4 distinct modules with pedagogical emphasis on diverse instructional strategies such as lecture, small class discussion, case studies, role playing, peer mentoring, and shadowing. Twenty-seven Spanish-speaking community members were recruited to a training Academy (Academia Fit) for Latino fitness professionals. Twenty-six participants (mean age = 40 yr, 70% female) completed the 14-week course with a mean training exposure of 104.5 hours ( $\pm 35.97$ ) per candidate (54% in class). Eighteen candidates sat the certification exam, with a pass-rate of 61% (37% first time). Adherence to training was 87% (% classes attended), and a mean of 3.57 ( $\pm 2.8$ ) hours per week was reported as self-study outside of class, 60% of that recommended by the instructor. After adjusting for age and education level, the correlation between attendance (# classes attended) and out-of-class study time with exam score was  $r = 0.19$  and  $r = 0.63$ , respectively.

**CONCLUSION:** A culturally responsive Spanish-language training program that helps Latino community members become certified fitness professionals helps build capacity to offer culturally sensitive quality opportunities for physical activity.

Funded by research grant (1R18DP002138-01) from Centers for Disease Control and Prevention.

**The Effects of Hydration and Fatigue in Mild and Hot Environments on Landing Technique**

Jessica C. Martinez, Lindsay J. DiStefano, Rachel Karslo, Megan VanSumeren, Robert A. Huggins, Rebecca L. Stearns, Julie K. DeMartini, Carl M. Maresh, FACSM, Douglas J. Casa, FACSM. *University of Connecticut, Storrs, CT.*

(No relationships reported)

Improper landing technique increases the risk of lower extremity injury. Fatigue has been shown to impair landing technique but it is unknown if hypohydration and hyperthermia have a similar negative effect.

**PURPOSE:** To examine the effects of hydration and fatigue in mild and hot environments on landing technique.

**METHODS:** Twelve healthy, physically active males (age=20 $\pm$ 2 yrs, height =182 $\pm$ 8 cm, body mass=74.0 $\pm$ 8.2 kg, body fat=9 $\pm$ 3%, VO<sub>2</sub>max = 57.0  $\pm$  6.0 mL·kg<sup>-1</sup>·min<sup>-1</sup>) completed 4 test sessions in randomized hydration and environmental conditions: Euhydrated Temperate (EUT), Euhydrated Hot (EUH), Hypohydrated Temperate (HYT), Hypohydrated Hot (HYH). Temperate and hot condition sessions were performed in 18 $\pm$ 0.2°C, 50 $\pm$ 3.5% relative humidity (RH), and 34  $\pm$ 0.3°C, 45 $\pm$ 4.5% RH, respectively. Subjects completed a 90-min treadmill exercise protocol wearing a 20.5 kg backpack (5% incline, 1.34-1.78 m·s<sup>-1</sup>). Landing technique was evaluated 3 times a session (before exercise (PRE), after exercise (POST), after 60-min recovery session (REC)). One rater evaluated the landings using the Landing Error Scoring System (LESS), which is a valid and reliable movement screening tool. A high LESS score indicates a greater number of errors committed and poor technique. Change scores between time points (PRE, POST, REC) were calculated. Separate within-subjects ANOVAs evaluated differences in LESS change scores (POST-PRE, REC-PRE, REC-POST) between conditions.

**RESULTS:** Body mass loss differed across sessions (HYT:-3.80  $\pm$  1.22%, HYH:-5.66  $\pm$  1.57%, EUT:0.10  $\pm$  0.90%, EUH:-1.30  $\pm$  0.85%). HYH (POST-PRE Change Score: 0.69, 95% CI: 0.13, 1.26)) resulted in a greater increase in LESS scores between PRE and POST than HYT (-0.19, 95% CI: -0.55, 0.16), EUH (-0.56, 95%CI: -1.15, 0.02), EUT (-0.03, 95%CI: -0.60, 0.54)( $p=0.002$ ). HYH (REC-PRE Change Score: 0.67, 95%CI: 0.21, 1.13) also resulted in a greater increase in LESS scores between PRE and REC than HYT (-0.03, 95%CI: -0.53, 0.48), EUH (-0.31, 95% CI: -0.93, 0.31), EUT (-0.67, 95% CI: -1.08, -0.25)( $p=0.001$ ).

**CONCLUSION:** Landing technique is impaired when an individual is hypohydrated and in a hyperthermic environment, regardless of acute fatigue. Hypohydration in hot environments needs to be prevented to protect individuals from a possible increase in lower extremity injury risk.

**2433** Board #108 MAY 31 3:30 PM - 5:00 PM

**Leg Extension Strength Effects Plantar Loads While Landing from a Drop Jump**

David Hudson, Chris Wilson, Lauren Parker, Mary Ann Pascutti. *Western Carolina University, Cullowhee, NC.*

(No relationships reported)

**PURPOSE:** To determine if there are differences in structure and function in the lower limb among groups that load plantar force more medially, centrally, or laterally when landing from a drop jump.

**METHODS:** A pedobarograph mat measured the force under the right foot of thirty-three subjects when landing from a 30cm drop jump. Proprietary software was used to extract data for 15 frames before and 15 frames after the peak vertical force. The pressure map was then divided into medial and lateral halves; a Plantar Force Index (PFI) was calculated from the ratio: medial force / whole force. Each subject was also measured for the following structural and functional measurements: calcaneal eversion excursion (subtalar joint neutral to relaxed standing); navicular drop normalized to foot length; knee valgus; hip depth normalized to body height; repetitions of single leg squats and calf raises performed in 30 seconds. Subject data were stratified into three groups based on PFI (lateral pressure, mid-pressure, and medial pressure). A MANOVA with Tukey's post-hoc test was used to determine if differences existed among the three groups for the variables measured.

**RESULTS:** Significant differences were found in the PFI among all three groups (lateral pressure; 46.3%; mid-pressure 53.1%; medial pressure 60.2%;  $p \leq 0.001$ ). Compared to subjects that landed with more medial pressure, subjects that loaded the foot more laterally had significantly greater normalized hip depth (13.2% vs. 10.6%;  $p < 0.03$ ) and were able to perform significantly more repetitions of squats (38.6 vs. 31.2;  $p < 0.03$ ).

**CONCLUSIONS:** Subjects with greater strength in the large lower limb extensors and greater gluteal size landed more laterally on the foot, which was interpreted as a more stable landing pattern than landing those that landed more medially. These results indicate that proximal strengthening should be part of the management of hyperpronation.

2434 Board #109 MAY 31 3:30 PM - 5:00 PM

**Knee Position And Loading Is Influenced By Foot-Landing Technique**

Nelson Cortes<sup>1</sup>, Steven Morrison<sup>2</sup>, Bonnie Van Lunen<sup>2</sup>, Eric Greska<sup>2</sup>, James Onate<sup>3</sup>. <sup>1</sup>George Mason University, Fairfax, VA. <sup>2</sup>Old Dominion University, Norfolk, VA. <sup>3</sup>The Ohio State University, Columbus, OH.  
(No relationships reported)

Noncontact anterior cruciate ligament (ACL) injuries have been reported to occur with the ankle in a dorsiflexed position (rearfoot landing) during cutting maneuvers. Few studies have attempted to quantify the knee position and loading during a cutting task when performed with different landing techniques.

**PURPOSE:** To evaluate the effects of two landing techniques (rearfoot and forefoot) on lower extremity biomechanics while performing a sidestep cutting task (SS).

**METHODS:** Lower extremity biomechanics of nineteen healthy female collegiate soccer athletes (20±0.9 years; 1.67±0.1m; 63.2±10.1kg) were obtained while performing a SS with forefoot (FF) and rearfoot (RF) landing techniques. Subjects performed five trials of each landing technique which were verified by video and counterbalanced between subjects. Kinematic measures of the lower extremity were captured using an eight-camera high-speed motion capture system, and ground reaction force data were obtained through two force plates sampling at 500 Hz. Repeated measures ANOVAs were conducted to assess differences between foot-landing techniques in knee flexion and abduction angles and moments at initial contact and peak stance. Alpha level set *a priori* at  $p \leq .05$ .

**RESULTS:** Knee flexion (KF) angle at initial contact was higher for FF (-42±10°) than RF (-33±6°,  $p < 0.05$ ). The knee was in a more abducted position with the RF (-3±9°) than with the FF (-0.6±11°,  $p < 0.05$ ), and had a higher adductor moment with the FF (0.034±0.06Nm/kgm) than with the RF (0.0013±0.03Nm/kgm). At peak stance, KF was significantly higher for the RF than FF (-56±5° vs. -53.7±7°,  $p < 0.05$ ). No significant difference was found for knee abduction angle and adductor moment at peak stance between landing techniques ( $p > 0.05$ ).

**CONCLUSION:** There are essential differences in lower extremity biomechanics between landing techniques. The rearfoot landing technique increasingly affects knee position and loading at initial contact (e.g., less flexion, greater abduction angle and moment), which can potentially place a higher strain on the ACL. This study supports the observational findings that rearfoot landing technique may increase the likelihood of ACL injury. Intervention programs should address foot-landing technique as a preventive measure to decrease ACL loading.

2435 Board #110 MAY 31 3:30 PM - 5:00 PM

**Influence of Hip Strength and Flexibility on Qualitative Jump-Landing Performance in Adolescent Males and Females**

Michelle C. Boling<sup>1</sup>, Anh-Dung Nguyen<sup>2</sup>, Bernadette Buckley<sup>1</sup>, Lindsay J. DiStefano<sup>3</sup>. <sup>1</sup>University of North Florida, Jacksonville, FL. <sup>2</sup>College of Charleston, Charleston, SC. <sup>3</sup>University of Connecticut, Storrs, CT. (Sponsor: Kevin Guskiewicz, FACSM)  
(No relationships reported)

Strength and flexibility of the hip musculature are thought to influence lower extremity movement patterns that potentially increase the risk of knee injury in adolescent athletes. A method to identify faulty movement patterns is through the use of qualitative lower extremity movement screens. Understanding the influence of hip strength and flexibility on lower extremity motion is needed to appropriately develop effective injury prevention strategies.

**PURPOSE:** To determine the influence of hip muscle strength and flexibility on qualitative jump-landing performance in adolescent males and females.

**METHODS:** Fifty-four (27 females, 27 males; 16±1yrs, 64±12kg, 172±11cm) adolescent athletes participated in this investigation. Frontal and sagittal plane views were recorded with video cameras as participants performed three trials of a jump-landing task. Isometric strength of the hip abductors, extensors, internal rotators, and external rotators was assessed over two trials using a hand-held dynamometer. Hip abduction, internal rotation, and external rotation range of motions (ROM) were assessed with a digital inclinometer over three trials. Jump-landing trials were later evaluated by a trained rater using the Landing Error Scoring System (LESS), a valid and reliable tool for assessing lower extremity movement patterns. The average of total LESS scores (higher score indicates poor jump-landing performance), hip strength (normalized to body mass (%BM)), and hip ROM were used for data analysis. Separate regression analyses were performed to determine the influence of hip strength and ROM on total LESS score in males and females.

**RESULTS:** Strength and flexibility of the hip musculature did not influence total LESS score in females ( $P > 0.05$ ). In males, strength of the hip extensors (0.37±0.09%BM) significantly influenced total LESS score (4.53±1.20) ( $R^2 = 0.16$ ,  $P = 0.04$ ). No other strength or flexibility measures were found to influence total LESS score in males ( $P > 0.05$ ).

**CONCLUSION:** Decreased strength of the hip extensors appears to influence poor jump-landing performance in adolescent males. The lack of additional significant findings indicates that more research needs to be performed to understand the intrinsic factors influencing lower extremity movement patterns in adolescent males and females.

**Residual Compromised Knee Performance During Single Leg Landings in People with ACL Reconstruction**

Maggie Dewitz, Caitlin Gollehon, Jenna Kokes, Ryan Mizner. University of Montana, Missoula, MT.  
(No relationships reported)

Patients with ACL reconstruction are at above normal risk for development of early knee osteoarthritis and re-injury. A growing body of evidence suggests that the ACL reconstructed knee exhibits compromised ability to accept weight during demanding activities. Diminished ability to flex under load may be a contributing factor etiology of early knee OA and re-injury. The performance of the ACLR knee during a single leg land (SLL) is still relatively under studied. Single leg lands are interesting as most ACL injuries occur during deceleration of SLL.

**PURPOSE:** To identify significant differences between limbs during SLL in active patients who have had unilateral ACLR.

**METHODS:** Participants included 17 subjects with unilateral ACLR (age= 22±4 years, BMI=24.6 ± 2.5, 7 males) who were physically active ( $\geq 4$  on the Tegner Physical Activity Scale) and good clinical results (IKDC score =85% ± 0.10). Subjects participated in a onetime session where each limb's performance was analyzed using a 3D Vicon system with force plates during a SLL off a 20 cm platform. The variables of interest included peak knee flexion angle and moment during weight acceptance of landing, peak vertical ground reaction force (VGRF), and the knee's contribution to the total support moment. The VGRF and joint moments were normalized to body weight. We compared the mean values between limbs using paired t-tests ( $\alpha = 0.05$ ).

**RESULTS:** Peak knee moments were statistically less in the involved ( $p = 0.004$ , mean=2.53±0.47) compared to the uninvolved limb (mean= 2.81±0.31). The knee's percentage of the total support moment was significantly less ( $p = 0.003$ ) in the involved limb as well (mean inv=36% ± 5%, mean unin= 40% ± 5%). No significant differences were found between limbs in VGRF ( $p = 0.192$ , mean inv= 3.55±0.29, mean unin= 3.49±0.33) or in peak knee flexion ( $p = 0.081$ , mean unin=56.61 ± 13.03 mean inv=53.23 ±12.43).

**CONCLUSION:** There were significant deficits in weight acceptance between limbs during a SLL task in an active population with good clinical outcome scores. Compromised ability to utilize the operated knee to decelerate body weight is concerning in light of the repetitive stresses placed on the limb during these patients' daily life. The findings of this study have potential implications for the high risk for early degeneration and re-injury.

**Hip Abduction Strength and Its Relationship with Landing Mechanics**

Alyssa Romasco, Kelley MacDonald, Jessica A. Cohen, Gretchen D. Oliver. University of Arkansas, Fayetteville, AR. (Sponsor: Heidi Kluess, FACSM)  
(No relationships reported)

Lower extremity neuromuscular training programs are effective in improving performance and biomechanics, and it is known that increased knee valgus increases the risk of ACL injury. With hip abduction strength being of neuromuscular concern, it is questioned if hip abduction strength would affect landing mechanics?

**PURPOSE:** To examine the relationship between hip abduction strength and landing mechanics.

**METHODS:** Sixteen, graduate students (23.1 ± 1.1 years; 169.8 ± 9.1 cm; 69.5 ± 15.9 kg) volunteered. Kinematic data were collected using electromagnetic sensors attached to the following locations: (1) S1; (2-3) bilateral distal/posterior upper leg; (4-5) bilateral proximal/posterior lower leg; and (6-7) superior proximal foot bilaterally. Participants performed 5 drop jump landings (47cm) onto a force plate. Following drop landings, hip abduction strength was measured with a hand held dynamometer.

**RESULTS:** Pearson correlation revealed a significant relationship between hip strength and knee abduction,  $r = -.513$ ,  $p < .05$ , and ground reaction forces,  $r = .636$ ,  $p < 0.01$ . [Table 1].

**CONCLUSIONS:** These data suggest greater hip strength may decrease knee valgus, but does not contribute to decreased ground reaction forces. Thus other components in landing mechanics may have an effect on ground reaction forces. However, improved hip strength incorporated with neuromuscular training programs may decrease knee valgus loads and likely decrease the risk of ACL injury resulting from poor landing mechanics. Programs emphasizing hip strength should be examined in future research to determine the effect on landing mechanics.

**Relationship Between Knee Extensor Strength And Knee Angle At Landing: Implications For ACL Injury Risk**

Zachary J. Domire, Dmitry Okorokov, Katie Hughes. *Texas Tech University, Lubbock, TX.*

*(No relationships reported)*

Anterior cruciate ligament (ACL) injury is common, costly, requires a lengthy rehabilitation, and results in increased risk of osteoarthritis. For these reasons, prevention of ACL injury is critical. While the mechanism for non-contact ACL injury is unclear, injuries normally occur with the knee near full extension. Therefore, increasing knee flexion at ground contact may dramatically reduce ACL injury rates. One factor that may contribute to landing with an extended knee is knee extensor weakness, as an extended knee reduces demand on knee extensors.

**PURPOSE:** To determine the relationship between knee extensor strength and knee flexion angle at landing.

**METHODS:** Healthy, active participants (10M 11F) were asked to perform landings from 64cm. 3D kinematic data was recorded and knee flexion angle was calculated at the instant of ground contact. Knee extensor strength was measured during maximum, 60°/s isokinetic contractions. Correlations were calculated between strength and knee angle at landing.

**RESULTS:** Strength was significantly related ( $p < 0.05$ ) to knee angle at landing in male subjects. In female subjects a similar trend existed between the two variables. However, the relationship was not significant.

**CONCLUSION:** A relationship exists between knee extensor strength and knee flexion angle at landing in male subjects. Additional testing is needed to confirm this finding in female subjects. A significant relationship between these variables does not prove a causal relationship. However, knee extensor weakness is a logical cause for landing with an extended knee. If additional testing confirms this relationship, knee extensor strengthening should be tested as a simple intervention for ACL injury prevention.

**2439** Board #114 MAY 31 3:30 PM - 5:00 PM

**Fear and Muscle Strength are Correlated to Knee Kinetics During Jump Landings after ACL Reconstruction**

Jenna Kokes, Caitlin Gollehon, Maggie Dewitz, Alessander D. Santos, Ryan Mizner. *University of Montana, Missoula, MT.*

*(No relationships reported)*

Patients with unilateral anterior cruciate ligament reconstruction (ACLR) can exhibit a hesitancy to accept load through the involved limb that could impact long-term outcomes. Impaired thigh muscle strength, high fear of re-injury, and decreased standing balance can also linger after surgery.

**PURPOSE:** To assess the interaction between the independent variables of muscle strength, fear of re-injury, and diminished standing balance to the performance variables of the operated knee kinetics during a single leg landing (SLL).

**METHODS:** Seventeen (7 males) physically active ( $\geq 4$  on Tegner Physical Activity Scale) subjects, ages 16-31 with unilateral ACLR participated. A one-time testing session was used to assess peak knee flexion moment and the knee's contributions to the total support moment during the weight acceptance phase of a SLL off a 20 cm platform. A Kin Com dynamometer assessed quadriceps and hamstring strength (MVIC). The ACL-Return to Sport Index (ACL-RSI) questionnaire was completed which quantifies the emotional response to injury (e.g. fear), confidence in the operated knee, and re-injury risk appraisal. Standing balance was quantified using the area contained by sway of the center of pressure during unilateral standing balance. The relationship between the impairments and landing performance was assessed using Pearson Correlation Coefficients (alpha: 0.05).

**RESULTS:** Quadriceps strength was related to both the knee flexion moment ( $r = 0.57, p = 0.018$ ) and the knee's contribution to the total support moment ( $r = 0.74, p = 0.001$ ). The ACL-RSI questionnaire score was significantly correlated to both peak knee flexion moment ( $r = 0.70, p = 0.002$ ) and the knee's contribution to the total support moment ( $r = 0.68, p = 0.002$ ). The hamstring muscle strength was only related to the knee's contribution to the support moment ( $r = 0.69, p = 0.002$ ) and the standing balance assessment was not significantly correlated to either knee kinetic assessment ( $\leq 0.398, p > 0.114$ ).

**CONCLUSION:** Muscle strength along with fear and a lack of confidence in the operated knee were related to a reduced amount of knee loading during the weight acceptance phase of jump landing. Future assessments should consider both of these variables as part of post-operative care to insure optimal knee performance during jump landing tasks.

**2440** Board #115 MAY 31 3:30 PM - 5:00 PM

**Landing Patterns in Subjects with Chronic Ankle Instability**

Chai-Hsien Yu, Kuo-Wei Tseng, Hui-mei Lin, Yu-Hua Tseng. *Taipei Physical Education College, Taipei, Taiwan.*

*(No relationships reported)*

The most common symptoms after ankle sprains were chronic ankle instability, proprioception defect and probable neuromuscular adaptation.

**PURPOSE:** The purpose of this study was to identify the normal landing pattern using detailed biomechanical analysis including analysis of the kinematics and ground reaction force, and to compare the landing pattern in the subjects with recurrent ankle sprain and normal subjects.

**METHODS:** 20 male adults were recruited in this study (10 subjects with recurrent lateral ankle sprains group, 10 subjects with normal control group). All subjects would be asked to perform maximal standing jumps and drop landing from 3 platforms with different heights (0.37 m, 0.67 m, & 0.97 m, respectively). Those movements were collected by VICON 512 (Oxford Metrics, UK) motion analysis system and the kinematics was analyzed using self making software with MATLAB. The ground reaction force of both lower limbs was recorded by two AMTI force platforms, and the kinetic data were calculated with inverse dynamics.

**RESULTS:** In the different landing height, the main differences of kinematics were the maximum flexion angles of hip and knee joints in normal landing patterns and the flexion angles increased with the landing height, as well as the flexion of pelvis, hip abduction, and knee external rotation in the subjects with recurrent ankle sprains. When compare those two groups, the landing pattern in the subjects with recurrent ankle sprain was significant smaller than normal subjects in knee flexion ( $65.71^\circ \pm 6.43^\circ$  vs.  $70.19^\circ \pm 13.76^\circ$ ) and hip flexion ( $34.15^\circ \pm 5.42^\circ$  vs.  $42.54^\circ \pm 10.07^\circ$ ). The time to maximum angles in ankle dorsiflexion and foot pronation were also quite different between these two groups. The maximum vertical ground reaction force in sprain group was significant smaller than normal group.

**CONCLUSION:** In this study, we have revealed the adaptation of performing drop landing in the individuals with recurrent ankle sprains. It could be considered as a recommendation of the rehabilitation.

**Landing on Inverted Surface Increased Frontal Plane Loading to Ankle and Knee Joints**

Songning Zhang, FACSM<sup>1</sup>, Qingjian Chen<sup>2</sup>. <sup>1</sup>The University of Tennessee, Knoxville, TN. <sup>2</sup>University of Maryland, Maryland, MD.

*(No relationships reported)*

Landing on inverted surface (IS) has been shown to introduce smaller medial ground reaction force (GRF) and greater ankle inversion compared to normal landing on flat surface (FS). It is, however, still unknown if the surface would also introduce greater mechanical loading to the ankle and more proximal lower extremity joints.

**PURPOSE:** To examine effects of inverted surface and ankle brace on lower extremity joint kinetics during a drop landing movement.

**METHODS:** Eleven healthy subjects performed five drop landing trials from a 0.45m on FS and IS without (NB) and with (BR) a semi-rigid ankle brace. Simultaneous collection of three-dimensional kinematic and GRF data were performed. The internal moments were computed and normalized to body mass (Nm/kg) using Visual 3D. A 2 x 2 (brace x surface) repeated measures ANOVA was used ( $p < 0.05$ ).

**RESULTS:** In sagittal plane, the peak ankle plantarflexion moment was smaller in IS (-1.28 vs -1.46 Nm/kg,  $p = 0.045$ ) and NB (-1.22 vs -1.52 Nm/kg,  $p = 0.012$ ) landing conditions compared to FS and BR conditions, respectively. The peak knee extension moment for the IS landing was also increased compared to FS (2.50 vs 2.75 Nm/kg,  $p = 0.001$ ) but no brace effect was observed. For peak hip extension moment, it was smaller in IS landing compared to FS ( $p = 0.001$ ) but greater in BR compared to NB ( $p = 0.001$ ). The peak eversion moment was significantly increased only in IS (-0.92 vs -0.28 Nm/kg,  $p = 0.001$ ) conditions compared to FS. The peak knee adduction moment (0.93 vs 0.27 Nm/kg,  $p = 0.001$ ) was increased while the peak hip abduction moment (-0.92 vs -0.44 Nm/kg,  $p = 0.01$ ) were reduced in IS landing only.

**CONCLUSION:** The results indicate that the landing on IS reduced the extensor's effort of ankle, knee and hip. This is in line with the reduced vertical GRF previously reported for IS landing and increased lateral GRF. In the frontal plane, the IS landing increases loading on ankle and knee joints reflecting increased frontal plane demands, due to the increased peak lateral GRF and downward momentum in IS landing. This contradiction may be related to the increased friction in IS landing, which in turn requires greater ankle eversion and knee adduction moments to prevent the body from moving more laterally. The ankle brace application does not seem to cause any significant changes of frontal plane loading to the lower limb joints.

**2442** Board #117 MAY 31 3:30 PM - 5:00 PM

**The Different Landing Strategy in Chronic Isolated Posterior Cruciate Ligament Injury Patients**

Fan Tsang-Yu, F, Paul Pei-Hsi Chou, M. *Kaohsiung Medical University, Department of Sports Medicine, Kaohsiung, Taiwan, Taiwan.*

(No relationships reported)

**PURPOSE:** After Posterior Cruciate Ligament (PCL) injuries, some patients, copers, are capable of returning to normal activities. Other patients, non-copers, remain symptomatic and often require surgeries. The purpose of this study is to investigate the landing strategy between copers and non-copers, in order to have a better understanding of the functional adaptation strategy in asymptomatic PCL injured patients.

**METHODS:** Twenty isolated posterior cruciate ligament injured patients and ten normal subjects were recruited in this study. These subjects were divided into three groups, copers, non-coper and control group respectively. The kinematic and kinetic parameters of landing were recorded. One-way analysis of variance was used to compare the differences between three groups.

**RESULTS:** There were no significant differences in age, height, and weight between three groups. The average injury time were 23.36 and 35.80 months for copers and non-copers respectively. At the moment of landing, there were no significant differences in joint angle and moment between the three groups, neither than two limbs of copers and non-copers. The loading rate and ground reaction force (GRF) were significantly different among the three groups. Copers had greater loading rate and ground reaction force than non-copers. (Table 1.) There were also significantly lesser loading rate ( $p=0.0079$ ) and ground reaction force ( $p=0.0117$ ) of the involved side in non-coper group.

**CONCLUSIONS:** Non-copers attempted to decrease the impact when landing by lower loading rate and GRF to protect the injury limb. These findings may be helpful for clinicians to design a proper rehabilitation program for patients with PCL deficiencies.

Table 1. Landing rate and ground reaction force among the three groups.

|                     | coper                   | non-coper               | control                 | p value | post hoc                   |
|---------------------|-------------------------|-------------------------|-------------------------|---------|----------------------------|
| loading rate (BW/s) | 22.30<br>( $\pm 2.18$ ) | 18.91<br>( $\pm 2.11$ ) | 19.80<br>( $\pm 3.10$ ) | 0.0413* | coper > non-coper          |
| MaxGRF (Nm/kg)      | 31.63<br>( $\pm 2.45$ ) | 24.45<br>( $\pm 4.64$ ) | 30.15<br>( $\pm 4.85$ ) | 0.0139* | control, coper > non-coper |

**2443** Board #118 MAY 31 3:30 PM - 5:00 PM

**Effect of Decision Making on Frontal Plane Hip Muscle Co-activation Patterns During Landing**

Melissa A. Mache<sup>1</sup>, Mark A. Hoffman, FACSM<sup>2</sup>, Michael J. Pavol<sup>2</sup>. <sup>1</sup>CSU, Chico, Chico, CA. <sup>2</sup>Oregon State University, Corvallis, OR.

(No relationships reported)

ACL injuries pose serious concerns and one possible contributor to these injuries is the use of more generalized muscle activation patterns when decision making (DM) is required, as is seen during cutting tasks. Whether DM similarly affects muscle activation during 2-footed landing tasks is unknown.

**PURPOSE:** To examine the effects of DM during 2-footed landing tasks on muscle co-activation at the hip as a function of task and sex.

**METHODS:** Twenty-nine young adults (22+3 years; 13 women) with no history of knee injury completed 3 randomized blocks of trials: 7 preplanned (PP) drop landings (DL), 7 PP drop-jumps (DJ), and 14 randomized DM trials consisting of 7 DL and 7 DJ. Surface EMG activity of the gluteus medius and adductor longus was sampled at 1080 Hz. From the rectified, normalized EMG, average proactive and reactive activation of each muscle was computed over 100 ms before and 120 ms after ground contact, respectively. Proactive and reactive co-contraction ratios (CCR) were computed, as was average activation of the less active muscle. Comparisons were made using 3-way, condition x task x sex, repeated-measures ANOVA.

**RESULTS:** Despite a significant 3-way interaction ( $p = .046$ ), post hoc analysis revealed no effect of condition, task, or sex on the proactive CCR (0.54+0.17). However, the reactive CCR was greater under DM than under PP conditions (0.65+0.17 vs. 0.60+0.18,  $p < .001$ ), independent of task and sex. This increase in reactive CCR was not due to greater activation of the less active muscle. In the post-hoc analysis of a significant 3-way interaction ( $p = .006$ ), men were found to perform DJ with lesser reactive activation of the less active muscle under DM than under PP conditions (6.5+2.0 vs. 9.0+3.0 %MVIC,  $p = .002$ ), whereas reactive activation of the less active muscle did not differ between conditions for DL or in women.

**CONCLUSIONS:** During 2-footed landing tasks, both women and men exhibit greater hip muscle co-activation in the frontal plane after ground contact under DM compared to PP conditions. This appears to be due to lesser activation of the more active muscle under DM conditions. These findings suggest a more generalized muscle activation strategy, that may provide lesser control of hip and knee frontal-plane motion, is used when DM is required. These results could have implications for ACL injury during landing.

**2444** Board #119 MAY 31 3:30 PM - 5:00 PM

**Electromyography Analysis Of Lower Body Muscle Mechanics During Maximal Vertical Jumps On Rigid and Sand Surface**

James Guerrero<sup>1</sup>, Robert B. Pankey<sup>1</sup>, Kevin McCurdy<sup>1</sup>, John Walker, FACSM<sup>1</sup>, Tim Henrich<sup>2</sup>. <sup>1</sup>Texas State University, San Marcos, TX. <sup>2</sup>University of the Incarnate Word, San Antonio, TX.

(No relationships reported)

**PURPOSE:** The aim of this study was to analyze electromyography activity of lower extremity muscles while jumping on rigid versus sand surfaces.

**METHODS:** Healthy, physically active males and females ( $n=26$ ) (age=26.9 $\pm$ 6.5 yr., ht. 177.2 $\pm$ 10.6, cm, wt.=79.1 $\pm$ 15.1kg) participated in this study. All subjects performed three short step countermovement jumps on a sand and rigid surface. A 4-channel electromyography (EMG) system recorded output from the rectus femoris (RF), vastus lateralis (VL), biceps femoris (BF) and gastrocnemius (GN) muscles of the right leg. A wireless waist belt accelerometer obtained subject jump height. Mean peak EMG data from lower extremity muscles were compared between the two surfaces.

**RESULTS:** Repeated measures ANOVA was conducted between the two surfaces. Males jumped significantly higher than females on both sand (35.3 $\pm$ 7.6cm; 24.9 $\pm$ 3.4cm) and rigid (34.8 $\pm$ 7.2cm; 23.5 $\pm$ 3.9cm) surfaces respectively ( $F=21.1$ ,  $p \leq .05$ ). There was no significant difference in jump height between sand (31.3+8.1cm) and rigid (30.5+8.3cm) jumping conditions for male and females combined ( $F=1.1$ ,  $p \geq .05$ ). There was a significant difference between jumping surfaces on normalized mean peak percentage EMG output measures with subjects RF (62.99 $\pm$ 16.91Hz; F12.7,  $p \leq .05$ ) and VL (62.76 $\pm$ 16.88 Hz; F4.6,  $p \leq .05$ ) from a sand surface. The BF (60.89 $\pm$ 9.76Hz; F4.7,  $p \leq .05$ ) and GN muscles (62.63 $\pm$ 11.41Hz; F=9.4,  $p \leq .05$ ) were significantly higher on a rigid surface for normalized mean peak percentage EMG output measures.

**CONCLUSIONS:** Jumping from a sand surface requires more output from the RF and VL of the quadriceps muscles than jumping from a rigid surface. This may be due to a longer duration of activity from knee extensor muscles that are stabilizing the center of mass prior to jump takeoff. The results from this study demonstrate that jumping in sand is not as mechanically efficient for lower extremity muscles as jumping on a rigid surface.

2445 Board #120 MAY 31 3:30 PM - 5:00 PM

**The Single-Leg Squat: Kinematics of Good and Poor Performance in Healthy Young Adults**

Christopher P. Carty<sup>1</sup>, Sean A. Horan<sup>1</sup>, Massimo Sartori<sup>2</sup>, Benjamin K. Weeks<sup>3</sup>. <sup>1</sup>Griffith Health Institute, Griffith University, Gold Coast Campus, Australia. <sup>2</sup>Georg-August University, Göttingen, Germany. <sup>3</sup>Griffith Health Institute, Griffith University, Gold Coast campus, Australia. (Sponsor: Belinda R. Beck, FACSM)  
(No relationships reported)

Poor lower limb stability during dynamic movement is thought to increase the risk of musculoskeletal injury. Biomechanically, stability is determined by a number of factors including the external load and contributions from passive and active tissues. One approach for studying lower limb stability is the single leg squat (SLS) test, which requires coordinated lower limb movement across a range of joint motions under external load. Although clinicians typically assess SLS quality from a single point of view (i.e. frontal plane), a 3D investigation of SLS kinematics would help to determine factors that differentiate clinician-defined "good" from "poor" quality performance.

**PURPOSE:** To determine the kinematic parameters that characterise a good or a poor SLS performance in young adults.

**METHODS:** 22 healthy young adults (13 male, 9 female; age: 23.8 ±3.1 years; height: 1.73 ±0.07 m; mass: 69.4 ±12.7 kg) free from musculoskeletal impairment were recruited. Video footage was collected in the frontal plane as participants performed three SLSs on each leg. SLS quality was assessed by a panel of physiotherapists using a ten-point ordinal scale. Performances were subsequently divided into tertiles corresponding to poor, intermediate and good SLS technique. 3D trajectories of 28 reflective markers attached to the pelvis, and lower limbs were simultaneously recorded at 200 Hz using a 10-camera, motion capture system (Vicon Motion Systems, Oxford, UK). Pelvis, hip and knee angles were calculated using a validated lower limb biomechanical model that incorporated functional identification of hip and knee joint centres.

**RESULTS:** Mean rating of SLS quality as assessed by the panel of physiotherapists was 6.3±1.9 (range: 2.4 - 9.1). 3D analysis of SLS performance revealed that poor squatters had increased hip adduction (22.4 ±6.1 vs 14.7 ±4.7 deg, *p*<0.01), reduced knee flexion (73.1 ±8.7 vs 90.1 ±12.1 deg, *p*<0.01) and increased medial-lateral displacement of the knee joint centre (53.7 ±16.8 vs 38.4 ±14.3 mm, *p*=0.02) compared to good squatters.

**CONCLUSION:** In healthy young adults a poor SLS is characterised by inadequate knee flexion and excessive frontal plane motion at the knee and hip. It is recommended that clinicians standardise knee flexion angle when using the SLS test as it might confound the perception of SLS quality.

2446 Board #121 MAY 31 3:30 PM - 5:00 PM

**A Comparison of Lower Extremity Kinematic Sequence between Female Dancers and Female Athletes**

Ian J. Kremenich<sup>1</sup>, Karl F. Orishimo<sup>1</sup>, Evangelos Pappas<sup>2</sup>, Marshall Hagins<sup>2</sup>, Marijeanne Liederbach<sup>3</sup>. <sup>1</sup>Lenox Hill Hospital, New York, NY. <sup>2</sup>Long Island University, Brooklyn, NY. <sup>3</sup>NYU Langone Medical Center Hospital for Joint Diseases, New York, NY. (Sponsor: Malachy McHugh, FACSM)  
(No relationships reported)

The propulsive phase of a stretch-shortening cycle movement is characterized by a proximal to distal transfer of joint velocities, with peak hip velocity preceding peak knee velocity, which in turn precedes peak ankle velocity. Due to their extensive training in jumping activities, dancers are considered experts in these tasks. Analysis of their performance of such tasks may give insight into optimization of jumping technique.

**PURPOSE:** To compare lower extremity kinematic sequence during a single-leg countermovement jump between female dancers and female athletes.

**METHODS:** Twenty female dancers and twenty female athletes performed single-leg countermovement jumps to 50% of their max height. Joint kinematics were measured with eight infrared cameras and 22 markers. For each subject, the velocity profile of each joint was normalized to the maximum velocity achieved by that joint. Repeated-measures ANOVA (Group x Joint) were used to compare the timing of peak joint velocities as well as the percentage of peak velocity of each joint when the other two were maximal.

**RESULTS:** Peak joint velocities occurred later in the dancers compared to the athletes (Main Effect: Group, *P* = 0.037) (see table). Additionally, a Joint by Group interaction was found for hip and knee velocities at peak ankle velocity (*P* = 0.024). Post-hoc t-test revealed that dancers had lower relative hip velocities at peak ankle velocity than the athletes (72% vs. 79%, *P* = 0.031).

**CONCLUSIONS:** The delayed peak velocities seen in female dancers may indicate a strategy to maximize storage of elastic energy prior to takeoff and result in a less ballistic, more esthetically pleasing takeoff. It also appears that dancers utilize the ankle more than the hip at the final phase of takeoff.

Percent of propulsive phase at which peak joint velocities occurred. \* = grp diff, *P* < 0.05

|                | Hip        | Knee         | Ankle        |
|----------------|------------|--------------|--------------|
| Female Dancer  | 70.3 ± 5.3 | 77.0 ± 4.0   | 86.1 ± 2.6   |
| Female Athlete | 67.7 ± 8.6 | 72.6 ± 7.5 * | 82.0 ± 4.8 * |

2447 Board #122 MAY 31 3:30 PM - 5:00 PM

**Analysis Of Jumping Technique Via Functional Principal Components Data Analysis Versus Peak Ground Reaction Force**

Randall L. Jensen, FACSM<sup>1</sup>, Sarah K. Leissing<sup>1</sup>, Erich J. Petushek<sup>2</sup>, William P. Ebben<sup>3</sup>, Chris Richter<sup>4</sup>. <sup>1</sup>Northern Michigan University, Marquette, MI. <sup>2</sup>Michigan Technological University, Houghton, MI. <sup>3</sup>University of Wisconsin-Parkside, Kenosha, WI. <sup>4</sup>CLARITY: Centre for Sensor Web Technologies, Dublin, Ireland.  
(No relationships reported)

Analysis of the force curves during jumping is typically done using a single point, often the peak of the ground reaction force (GRF), or rate of force development to describe the performance. A weakness of this discrete data point (DPA) technique is that changes in the entire curve are not analyzed. Conversely techniques using functional principal component analysis (FPCA) assess differences throughout the entire curve.

**PURPOSE:** To evaluate jump technique by assessing GRF via DPA and FPCA.

**METHODS:** Twenty recreationally active college students (Mean ± SD Age = 23.1 ± 4.8 years; Height = 1.76 ± .09 m; Weight = 72.1 ± 13.6 kg) performed a maximal counter-movement jump, with arm swing, from a force platform sampling at 1000 Hz. The jumps studied were single leg jumps using the left leg (LCMJ), right leg (RCMJ), and a jump with both legs simultaneously (BCMJ). GRF curves were analyzed via Repeated Measures ANOVA using DPA of the peak GRF and via FPCA to analyze the entire curve and test for differences between jump conditions. Steps to identify FPC were continued until they described 95 % of the variability in the data set and were VARIMAX rotated to increase reliability. The resulting FPCA scores were then compared between the jump conditions via ANOVA.

**RESULTS:** Peak GRF did not differ (*p*= 0.126) between the three jump conditions: BCMJ = 2533 ± 466 N; LCMJ = 2193 ± 593 N; RCMJ = 2158 ± 603 N. Seven functional principal components were needed to describe 95% of the variability in the data; of these, FPC scores of components 1, 2, and 4 differed between the jump conditions (BCMJ < LCMJ, RCMJ; *p* < 0.05). Principal component 1 explained 40% of the variability while components 2 and 4 explained 24% and 8% respectively.

**CONCLUSION:** FPCA identified differences in the curves of the three jump conditions that were not apparent when comparing peak GRF. Specifically, statistical analyses of the functional principal component scores showed that components 1, 2, and 4 for the BCMJ were different from either of the single leg jumps. These components were analogous to the following temporal aspects of the force curve: 1) the rapid increase in force, 2) just after the minimal force during the counter-movement, and 4) the rapid drop in force just prior to takeoff from the ground.

2448 Board #123 MAY 31 3:30 PM - 5:00 PM

**Hip and Knee Mechanics During a Sidestep Cutting Task Unaffected by Limb Dominance**

Eric Greska<sup>1</sup>, Nelson Cortes<sup>2</sup>, Stacie Ringleb<sup>1</sup>, Ashley Spear<sup>1</sup>, Alysia Jordan<sup>1</sup>, Bonnie Van Lunen<sup>1</sup>. <sup>1</sup>Old Dominion University, Norfolk, VA. <sup>2</sup>George Mason University, Fairfax, VA.

(No relationships reported)

Previous studies have demonstrated that dissimilarity between the dominant and non-dominant legs with relation to noncontact anterior cruciate ligament injuries; the non-dominant leg being the involved side in 48-67% of reported incidents.

**PURPOSE:** To evaluate lower extremity biomechanical differences in leg dominance during an unanticipated sidestep cutting task.

**METHODS:** Twenty-nine female collegiate soccer players (19.3±1.0 years, 1.66±0.1m, 63.2±6.3Kg) completed trials of an unanticipated sidestep cutting task. Subjects were required to complete three valid trials for both the dominant and non-dominant leg, with the dominant leg being defined as the leg the subject would use to kick a soccer ball furthest. Trials were performed in a randomized order, with task cues graphically projected in front of the subject through a custom-designed computer program. An 8-camera motion capture system, and two force plates, captured data at rates of 250Hz and 2000Hz, respectively. A MANOVA was used to determine the effect of leg dominance on hip and knee mechanics at initial contact (IC) and peak knee abduction moment (PKABM). Dependent variables consisted of hip and knee flexion, abduction, and rotation joint angles and moments. The alpha level was set *a priori* at 0.05, with a Bonferroni adjustment applied.

**RESULTS:** No significant differences ( $p < 0.05$ ) were found at initial contact or peak knee abduction moment for joint angles and moments of the hip and knee. Though not significant ( $p > 0.05$ ), at IC the knee abduction angle was comparable between the dominant and non-dominant legs (-1.35±4.23 and -1.86±4.21), yet demonstrated a divergence at PKABM (-0.88±4.84° and -2.10±4.42°), with the non-dominant leg shifting to a more abducted position.

**CONCLUSION:** As no significant differences for the biomechanics of the hip and knee were demonstrated between limbs at IC or PKABM, it is believed that the discrepancy between involved limbs in noncontact anterior cruciate ligament injuries may stem from other neuromechanical characteristics. Such neuromechanical characteristics can include muscular strength, rate of force development, muscular activation amplitude and timing, and cortical activation patterns that can differ between limbs, yet still demonstrate similar mechanical outcomes.

---

2449 Board #124 MAY 31 3:30 PM - 5:00 PM

**Assessing Single-Leg Squat Quality: Kinematic Predictors for Experienced and Inexperienced Clinicians**

Sean A. Horan, Benjamin K. Weeks. Griffith Health Institute, Griffith University, Gold Coast campus, Australia. (Sponsor: Belinda R. Beck, FACSM)

(No relationships reported)

The single-leg squat (SLS) is commonly used by physical therapists (PTs) in the clinical assessment of the lower limb. SLS performance is associated with hip muscle function, knee loading patterns and risk of musculoskeletal injury. The kinematic parameters relating to clinician observations of SLS quality, however, are yet to be illuminated. Furthermore, it is unknown if such parameters are related to clinician experience.

**PURPOSE:** To reveal the pelvis, hip and knee kinematic parameters used to determine SLS quality by experienced and inexperienced clinicians.

**METHODS:** Eight student and eight post-graduate level musculoskeletal PTs agreed to rate each SLS. Twenty-two healthy, young adults (23.8 ± 3.1 years) were videoed while performing three SLSs on each leg. 3D motion of the pelvis, hip and knee was recorded using a 10-camera optical motion analysis system (Vicon, Oxford, UK). Quality of each SLS performance was rated from video data using a 10-point ordinal scale (i.e. 1 = lowest, 10 = highest). SLSs were re-scored two weeks later by all assessors. Stepwise multiple regression analysis was performed to determine kinematic predictors of stability scores for experienced PTs and student PTs. Inter- and intra-rater reliability was determined using a two-way mixed model to generate intra-class correlation coefficients (ICC) of consistency.

**RESULTS:** The second SLS on each side was analyzed for each participant, providing 44 SLSs for analysis. Experienced PT scores were greater than student PT scores (6.4 ± 1.8 vs 6.1 ± 1.5;  $p = 0.02$ ). Variance in experienced PT scores was predicted by peak knee flexion, peak hip adduction, and knee medio-lateral displacement ( $R^2 = 0.64$ ,  $p = 0.01$ ). Variance in student PT scores was predicted by peak knee flexion, and knee medio-lateral displacement ( $R^2 = 0.57$ ,  $p = 0.01$ ). Inter-rater reliability was good for PTs (ICC = 0.71) and students (ICC = 0.60). Intra-rater reliability was excellent for PTs (ICC = 0.81) and good for PT students (ICC = 0.71).

**CONCLUSION:** Experienced PTs and student PTs are both capable of reliable assessment of SLS stability; however experienced PT assessments bear somewhat stronger relationships to lower limb kinematics. PT ratings were related to hip and knee motion, while student PT ratings were specific to the knee.

2450 Board #125 MAY 31 3:30 PM - 5:00 PM

**Differences in Muscle Activation Following Drop Jump Landing Biofeedback Intervention**

Hillary Plummer, Gretchen D. Oliver, Alyssa Romasco, Taylor Holt. University of Arkansas, Fayetteville, AR. (Sponsor: Heidi Kluess, FACSM)

(No relationships reported)

Neuromuscular training has been proven effective in injury prevention, however it has yet to be determined if immediate landing feedback interventions are effective.

**PURPOSE:** The purpose of this study was to examine the effects of a landing intervention program on lower extremity muscle activation.

**METHODS:** Eighteen (12 females, 6 males) graduate students volunteered to participate (22.94 ± 1.03 years; 169.47 ± 8.78 cm; 69.31 ± 15.13 kg). Surface electrodes were placed on gluteus medius, gluteus maximus, rectus femoris, and biceps femoris. sEMG data were collected and expressed as percent maximum voluntary isometric contraction (%MVIC). Participants were instructed to perform three drop jump landings from a height of 47 cm. Following the initial landings participants were given a 5 minute intervention that included verbal and visual feedback on landing strategies. Immediately following the intervention, they performed three more drop landings.

**RESULTS:** Paired samples t test revealed significantly greater activation, post intervention, of the biceps femoris ( $p = 0.047$ ) and the gluteus maximus ( $p = 0.001$ ). Biceps femoris activity increased by 52.11 %MVIC and the gluteus maximus by 73.57 %MVIC. No statistically significant differences were observed in the gluteus medius and rectus femoris muscles. However, while not significantly different, the gluteus medius decreased by 14.9 %MVIC and the rectus femoris by 8.23 %MVIC.

**CONCLUSIONS:** The biceps femoris and gluteus maximus function to flex the knee and extend the hip respectively. The intervention focused on increasing posterior chain activation by increasing knee flexion in order to land softly. Further analysis is needed to understand the kinematics utilized post intervention.

2451 Board #126 MAY 31 3:30 PM - 5:00 PM

**Intra-rater Reliability and Between-leg Deficits in Unilateral Jump Performance and Muscle Strength in Healthy Controls**

Anders Holsgaard-Larsen<sup>1</sup>, Tanja Andersen<sup>1</sup>, Carsten Jensen<sup>1</sup>, Per Aagaard<sup>2</sup>. <sup>1</sup>Orthopaedic Research Unit, Institute of Clinical Research, Odense C, Denmark.

<sup>2</sup>Institute of Sports Science and Clinical Biomechanics, Odense C, Denmark.

(No relationships reported)

Assessing the ratio between the affected and unaffected leg is traditionally used in the clinical setting to distinguish between normal or abnormal test scores (1,2). Knowledge about the reliability in outcome measures and the extent of asymmetry in healthy subjects is crucial.

**PURPOSE:** To investigate *i*) intra-rater reliability of unilateral jump performance and isometric knee extensor and flexor strength (MVC) and *ii*) between-leg asymmetry in healthy men.

**METHODS:** Test-retest measurements were performed in 13 healthy men (mean age: 27.1 ± 6.1 years, BMI: 24.5 ± 2) separated by ~7 days. Subjects performed maximal counter movement jumps (CMJ) with each leg positioned on a separate force plate. Kinematic data were recorded using a 6 camera Vicon<sup>MX</sup> system. Subsequently, center of mass jump height (JH), unilateral range of motion (ROM), and unilateral peak and mean sagittal knee moment in the concentric phase were analyzed. Also, one-legged maximal hop for distance (HD) was recorded (1), along with unilateral knee extensor and flexor MVC (3). Within-subject coefficient of variation (CV<sub>ws</sub>), 95% confidence interval for test-retest differences, and asymmetry ratios were calculated according to previous procedures (1,4,5).

**RESULTS:** **CMI:**  $CV_{ws}$  was 4.8% for center of mass JH. For unilateral measures,  $CV_{ws}$  was 8.7%-12.6%. **Hop for distance:**  $CV_{ws}$  was 3.1% - 4.3%. **MVC:**  $CV_{ws}$  was 7.7%-14.1%. HD increased at retest (95% CI: [-8.1 ; -0.1] and [-11.5 ; -2.0]) in both legs. Asymmetry ratios in unilateral CMJ were 100%, 80%, 80% for ROM, peak and mean knee moment, respectively, and 96% for HD and 73% and 85% for isometric knee flexor and extensor MVC, respectively.

**CONCLUSION:** Good to moderate reliability was observed for all measured variables. However, a small but systematic increase was observed for hop for distance. Signs of between-leg asymmetry were observed in healthy males. Future research should investigate accuracy before this test battery can be applied to determine when/if an injured subject is fully recovered.

**2452** Board #127 MAY 31 3:30 PM - 5:00 PM

**Electromyographic Analysis of the Biceps Femoris During Conventional and Rubber-Based Band Squats**

Ty B. Palmer<sup>1</sup>, Kevin W. McCurdy<sup>2</sup>, James S. Williams, FACSM<sup>2</sup>, John L. Walker, FACSM<sup>2</sup>. <sup>1</sup>Oklahoma State University, Stillwater, OK. <sup>2</sup>Texas State University, San Marcos, TX.

(No relationships reported)

Recently, several variable resistance methods of attaching bands to the power rack during the back squat exercise have been established.

**PURPOSE:** To compare the electromyographic (EMG) output of the long head of the biceps femoris (BF) muscle amongst 3 resistance conditions on the back squat exercise. The no band (NB) condition used only the barbell plus weighted-plates. The bottom band (BB) and top band (TB) conditions combined weighted-plates with bands attached to the barbell originating from the bottom and tops of the power rack, respectively.

**METHODS:** Twenty-two healthy, physically active collegiate males volunteered to participate (age =  $22.4 \pm 2.6$  yr; height =  $177.8 \pm 9.7$  cm; weight =  $87.0 \pm 19.0$  kg). Initial 1-repetition maximum (1RM) testing was conducted in order to assess each subject's maximal strength for each resistance condition. Eighty percent (%) of each 1RM was used as the external load during EMG testing. To compare EMG activity across the entire range of motion (ROM), both the eccentric and concentric phases of movement were divided into % intervals based upon the time it took each subject to complete the measured repetition. A pair of disposable bipolar surface electrodes (2-cm interelectrode distance, 1-cm<sup>2</sup> circular conductive area) was placed along the longitudinal axis of the BF (50% of the distance from the ischial tuberosity to the lateral epicondyle of the tibia), connected to an amplifier, and continuously streamed through an analog to digital converter using an EMG telemetry system. The EMG signals (gain = 500, bandwidth frequency = 10-500 Hz, CMRR = 110 dB) were sampled at 1000 Hz, smoothed using root mean square, and averaged in millivolts (mV) over the durations of the 90 and 10% intervals (top and bottom portions of the ROM, respectively).

**RESULTS:** At the 90% interval there was significantly higher EMG output in the TB ( $0.039 \pm 0.029$  mV) condition than the NB condition ( $0.033 \pm 0.023$  mV,  $p < 0.05$ ). At the 10% interval there was significantly higher EMG output in the NB condition ( $0.020 \pm 0.013$  mV) than both the BB ( $0.016 \pm 0.008$  mV) and TB ( $0.017 \pm 0.010$  mV) conditions ( $p < 0.05$ ).

**CONCLUSION:** The TB condition elicited greater BF EMG activity at the top of the ROM when compared with the NB condition. However, at the bottom of the ROM, the NB condition elicited greater BF EMG activity than both the BB and TB conditions.

**2453** Board #128 MAY 31 3:30 PM - 5:00 PM

**Gender Differences in Lower Extremity Kinematics during an Unanticipated Side-Cut**

Donald E. Fowler, III, Robert J. Butler, Wesley Oglesby, Claude T. Moorman, III, William E. Garrett, Jr, FACSM, Robin M. Queen. *Duke University, Durham, NC.*

(No relationships reported)

Female athletes have a higher incidence of anterior cruciate ligament (ACL) injury compared to men playing the same sports. The majority of these injuries are attributed to a non-contact pivoting mechanism, as seen in cutting and jumping tasks. Gender differences in lower extremity kinematics are documented in the literature, with most of these studies being conducted in the laboratory setting, which do not simulate in-game competition.

**PURPOSE:** To compare differences in lower extremity kinematics between males and females when completing an unanticipated side-cut on FieldTurf, wearing a firm ground cleat.

**METHODS:** Twenty-nine subjects (13 males, 16 females) were included in the study. All participants were skilled soccer players with no history of lower extremity or ACL injury within the last 6 months. Eight infrared cameras (Motion Analysis, Inc) were positioned around the FieldTurf field and used to record the trajectories of the retro-reflective markers. A single firm ground cleat was used for every trial. Each subject completed 45 degree unanticipated cuts to the right or left depending on which light flashed in front of them while running until 7 acceptable trials were recorded.

**RESULTS:** Males demonstrated larger peak hip abduction at 25.71 degrees, versus 20.23 degrees in females ( $p < 0.03$ ). Females exhibited greater peak hip adduction ( $p < 0.03$ ). No other dependent variables were statistically different. Females had greater hip flexion at heel-strike when cutting compared to males (57.4 vs. 51.4 degrees). Men demonstrated larger peak knee flexion (54.2 vs. 51.8 degrees). Women had slight knee abduction (2.0 degrees) at heel-strike when cutting, compared to men who exhibited slight knee adduction (1.3 degrees).

**CONCLUSIONS:** Minor gender differences in joint kinematics were demonstrated during an unanticipated side-cut on FieldTurf in cleats, which better recreates in-game activity. The lack of statistically significant differences similar to those that have been reported between genders in recreational athletes is most likely the result of testing highly skilled soccer players. As a result of this study it appears that assessing multiple domains of movement may be important in examining an individual's injury risk.

**2454** Board #129 MAY 31 3:30 PM - 5:00 PM

**Discrete Vs. Functional Based Data To Analyze Countermovement Jump Performance**

Chris Richter, Noel E. O'Connor, Kieran Moran. *Dublin City University, Dublin, Ireland.* (Sponsor: Randall Jensen, FACSM)

(No relationships reported)

While discrete point analysis (DPA) (e.g. peak power) is by far the most common method of analyzing movement data, it may have significant limitations because it ignores the vast majority of a signal's data. In response, there has been a small but growing use of methods, such as functional data analysis (FDA), which allow an investigation of the underlying structure of the continuous signal and may therefore provide a more powerful analysis. However, a direct comparison between DPA and FDA has not been previously reported.

**PURPOSE:** To directly compare DPA and FDA for the identification of performance determining factors for the countermovement jump (CMJ).

**METHODS:** Twenty-five male participants performed 15 CMJs, and the highest jump was selected for further analysis. Joint and whole body kinematic and kinetic measures were determined using position data (Vicon, 250 Hz) and force plate data (AMTI, 1000Hz). Participants were divided into good (n=10) and poor (n=10) groups based on jump height. A t-test ( $\alpha = 0.05$ ) was performed on the timing and magnitude of key variables (DPA) and functional derived points (FDA) during the propulsion phase to examine differences between the groups.

**RESULTS:** Both techniques found differences ( $p < 0.05$ ) in knee angular peak velocity, CoM peak velocity, CoM peak power and CoM work done. However, the FDA alone found significant higher ( $p < 0.05$ ) ankle moment (79 - 83%, peak at 67%), ankle power (54 - 67%, peak at 81%), knee angular velocity (28 - 100%), CoM velocity (56 - 100%), CoM power (49 - 91%) and a delay in CoM position (10 - 90%) and CoM velocity (10 - 60%) for the good performance group. Finally, the DPA alone found differences in ankle peak moment, ankle peak power and hip peak angular velocity.

**CONCLUSIONS:** In contrast to FDA, DPA found three events which were not detected by FDA. However, only FDA was able to identify important differences in phases of the CMJ and explains differences between good and poor performance better than DPA. Finally, the ability to examine data with continuous techniques appears to provide a deeper insight into human movement than DPA.

2455 Board #130 MAY 31 3:30 PM - 5:00 PM

**Assessing Muscular Power with a Portable Device in a Clinical Setting**

Cengiz Akalan<sup>1</sup>, Robert Scales<sup>2</sup>, Kathryn A. Cornella<sup>2</sup>, Susan Halli<sup>2</sup>, Robert T. Hurst<sup>2</sup>. <sup>1</sup>Ankara University, ANKARA, Turkey. <sup>2</sup>Mayo Clinic, Phoenix, AZ  
(No relationships reported)

**PURPOSE:** An age-related decline in muscular power may have a detrimental effect on sports performance and tasks of daily living. This study assessed lower extremity muscular power in a group of middle-aged adults (40-59 yrs) who elected to participate in a cardiology-based prevention program.

**METHODS:** The study involved a single visit observation of the participants. Ninety-nine apparently healthy adults (70% male) were assessed for lower extremity muscular power with the Counter Movement Jump (CMJ) Test. Participants performed 5 consecutive vertical counter movement jumps with the hands on the hips. The jumps were performed in a medical exam room on a hard carpeted surface while wearing shoes. None of the participants reported a physical limitation or injury at the time of testing. A Myotest accelerometer was attached to the waist and it instantly calculated the average height jumped, force produced, velocity and power from the best 3 jumps.

**RESULTS:** The mean age of the participants was 50.8 yrs (SD= 5.4). The overall mean height, force, velocity and power scores for men (n=69) and women (n=30) were 24.2 cm (SD= 5.8) Vs 15.0 cm (SD= 4.1), 19.3 N/Kg (SD= 2.2) Vs 17.5 N/Kg (SD= 1.9), 162.6 cm/s (SD= 31.1) Vs 142.4 cm/s (SD= 25.3) and 25.6 W/Kg (SD= 7.4) Vs 20.6 W/Kg (SD= 5.0) respectively. The mean scores on the same measures for men 40-49 yrs (n=30) and 50-59 yrs (n=39) were 26.3 cm (SD= 6.4) Vs 22.6 cm (SD= 4.8), 20.1 N/Kg (SD= 2.1) Vs 18.7 N/Kg (SD= 2.2), 169.6 cm/s (SD= 35.4) Vs 157.1 cm/s (SD=26.6) and 27.6 W/Kg (SD= 8.6) Vs 24.0 W/Kg (SD= 6.1) respectively. The mean scores for women 40-49 yrs (n=9) and 50-59 yrs (n=21) were 17.7 cm (SD= 4.1) Vs 13.8 cm (SD= 3.7), 17.4 N/Kg (SD= 1.1) Vs 17.5 N/Kg (SD= 2.1), 153.2 cm/s (SD=18.1) Vs 137.7 cm/s (SD=26.9), 22.2 W/Kg (SD= 3.2) Vs 19.9 W/Kg (SD= 5.5) respectively.

**CONCLUSIONS:** The Myotest accelerometer is a small user friendly portable device that can be used to assess muscular power in a clinical setting. This type of technology may assist in the design of exercise programs to improve muscular fitness. A larger, more representative sample is needed to determine age, gender and race norms for CMJ Test scores using the Myotest accelerometer.

2456 Board #131 MAY 31 3:30 PM - 5:00 PM

**Does Higher Anterior Knee Joint Laxity Alter Landing Biomechanics in Pubescent Girls?**

Catherine Y. Wild, Julie R. Steele, Bridget J. Munro. University Of Wollongong, Wollongong, Australia.  
(No relationships reported)

From the onset of puberty females are at a greater risk of sustaining a non-contact anterior cruciate ligament (ACL) rupture compared to males. Increased anterior knee laxity (AKL) in females has been proposed as a possible mechanism for increased ACL injury risk, due to the associated decrease in knee joint stability during landing movements. Despite this association, there is a dearth of literature investigating the effects of increased AKL on lower limb landing biomechanics in adolescent girls.

**PURPOSE:** To investigate whether adolescent girls with higher AKL displayed altered landing biomechanics compared to adolescent girls with lower AKL.

**METHODS:** Forty-six healthy girls (10-13 yr), confirmed as Tanner stage II-III, were recruited and tested at their time of peak height velocity (PHV; peak growth in height). Passive AKL was quantified and used to classify participants into a higher (peak displacement > 4 mm) and a lower (peak displacement < 3 mm) AKL group (n = 15/group), with the 16 middle participants removed to ensure a significant between-group difference in AKL. Strength testing of the quadriceps and hamstring muscles was carried out using an isokinetic dynamometer. Participants then performed a functional, single-limb landing movement, during which three-dimensional lower limb kinematics (100 Hz), ground reaction forces and muscle activation patterns (1,000 Hz) were assessed. Independent samples t-tests were applied to the data to determine any significant ( $p \leq 0.05$ ) differences in lower limb landing biomechanics displayed by the higher AKL group relative to their lower AKL counterparts.

**RESULTS:** Girls with higher AKL displayed significantly ( $p = 0.018$ ) greater height velocity compared to girls with lower AKL ( $12.3 \text{ cm}\cdot\text{y}^{-1}$  vs  $9.5 \text{ cm}\cdot\text{y}^{-1}$ ), as well as similar leg strength, thought to decrease knee joint stability. However, girls with higher AKL demonstrated significantly earlier hamstring muscle activation ( $p < 0.05$ ) compared to girls with lower AKL.

**CONCLUSION:** We speculate that earlier hamstring activation displayed by girls with higher AKL may be an attempt to impart sufficient posterior tibial drawer to protect the ACL upon landing, due to their decreased knee joint stability. Further research, however, is warranted to longitudinally track landing mechanics throughout the adolescent growth spurt.

**The Three-Dimensional Passive Support Characteristics of Ankle Braces on Combined Talocrural-Subtalar Joint Motions**

John E. Kovaleski<sup>1</sup>, Larry R. Gurchiek<sup>1</sup>, Robert J. Heitman<sup>1</sup>, Wei Liu<sup>1</sup>, J. Marcus Hollis<sup>2</sup>, Mitchell L. Cordova, FACSM<sup>3</sup>. <sup>1</sup>University of South Alabama, Mobile, AL. <sup>2</sup>Blue Bay Research, Navarre, FL. <sup>3</sup>Florida Gulf Coast University, Fort Myers, FL.  
(No relationships reported)

Studies of the passive support provided by ankle braces have focused primarily on inversion motion. Our goal was to develop a technique to measure support provided by ankle braces in all rotational directions and to use this technique to compare two common braces. Brace effectiveness in combination with a shoe has never been evaluated in vitro.

**PURPOSE:** To compare the effects of a rigid-hinge brace (Active Ankle™) and a lace-up brace (ASO™) on rotary foot displacement.

**METHODS:** A 6 degrees-of-freedom linkage was used to measure ankle-complex rotation in 6 cadaver ankles. Each ankle was mounted to a jig proximally via a tibial rod cemented into the tibial medullary cavity and distally via an athletic shoe fixed to a mounting plate of the testing machine. The specimens were loaded to 2 Nm in internal-external rotation at 0° plantar-flexion (PF), as well as 4 Nm inversion-eversion (I-E) rotation at 15° PF. Exercise consisted of dorsi-plantar flexion cycling to  $\pm 1.5$  Nm for 10 minutes. Ankles were tested with no brace (NB) and both pre- and post-exercise braced. Comparisons of total ankle-complex internal-external rotation and I-E rotation (degrees ROM) were made using separate two-way ANOVA with repeated measures.

**RESULTS:** A significant condition main effect was found for I-E rotation ( $P < .001$ ). Before exercise, application of either brace produced a significant reduction in I-E ROM (rigid:  $37.9 \pm 8.4^\circ$ ,  $P = .002$ ; lace-up:  $39.5 \pm 10.3^\circ$ ,  $P = .006$ ) when compared to NB ( $62.5 \pm 17.4^\circ$ ). No I-E ROM differences ( $P > .05$ ) were found between pre-post exercise for either the rigid ( $39.7 \pm 7.9^\circ$ ) or lace-up ( $43.8 \pm 12.8^\circ$ ), despite the rigid brace demonstrating greater restriction ( $-4.1^\circ$ ). A significant condition main effect ( $P < .044$ ) was found for internal-external rotation. Brace application showed no significant rotation decrease ( $P > .05$ ) for either the lace-up ( $36.2 \pm 13.3^\circ$ ) or rigid brace ( $33.5 \pm 14.6^\circ$ ) from the NB condition ( $43.1 \pm 18.4^\circ$ ). Pre-post exercise comparisons showed internal-external rotation significantly increased  $1.4^\circ$  for the lace-up ( $37.6 \pm 13.9^\circ$ ,  $P = .007$ ) but not for the rigid brace ( $34.3 \pm 14.4^\circ$ ,  $P = .11$ ).

**CONCLUSION:** Data indicate that both braces are similarly effective in restricting inversion-eversion rotation before and after exercise but neither was significantly effective in restricting internal-external rotation.

**The Effect of Serial Acupuncture Treatment on Hamstring Muscle Flexibility and Strength**

Kevin J. Curley, MD<sup>1</sup>, Mariel Wenzel<sup>2</sup>, Karl Zierman, DO<sup>1</sup>, Cory Whitmer<sup>2</sup>, Michele Aquino<sup>2</sup>, Raymond Peralta<sup>2</sup>, Shannon Isom<sup>2</sup>, Robert M. Otto, FACSM<sup>2</sup>, John W. Wygand<sup>2</sup>. <sup>1</sup>Winthrop University Hospital, Mineola, NY. <sup>2</sup>Adelphi University, Garden City, NY.

(No relationships reported)

Modern acupuncture is a technique of inserting small, thin, thread-like (filiform), single use needles into specific points (acupoints or energy meridians) on the body for therapeutic purposes. The use of acupuncture is known to reduce discomfort/pain sensation and may permit improvements in strength or flexibility.

**PURPOSE:** This study was designed to evaluate the effect of serial acupuncture treatment (8 treatments) on hamstring strength and flexibility.

**METHODS:** 15 subjects (7 male, 8 female, age 21.9±1.6 yr, ht 173±9.9 cm, body mass 74.9±13.7 kg) volunteered to perform a unilateral hamstring strength assessment (Cybex 6000 isokinetic seated knee flexion) and a unilateral flexibility assessment (modified Wells Sit and Reach test). Following the baseline trials, subjects served as their own control with one leg assigned as the placebo (P) and the other leg as the acupuncture intervention (A). In this double blind design, subjects entered the lab blindfolded, assumed a prone position on a plinth, and eight acupuncture needles were inserted inferior to the gluteal fold and superior to the popliteal fossa in the intervention leg. In addition, needles were inserted at the same locations and removed within 2 sec in the control leg. The points in the intervention leg included UB36, UB37, UB38 and UB40, as well as 5 additional Ashi points that were placed at areas of particular tightness in the hamstring muscle. The thirty minute treatments were separated by a minimum of 48 hours and conducted twice each week for four weeks. Statistical analysis by paired t test was applied to these data (p<.05).

**RESULTS:** The following data were obtained for treatment A and P, pre- and post-treatment, respectively: Peak Torque 118.5 & 114.2 vs 119.4 & 112.4 ft/lbs, mean work/rep 128.1 & 122.2 vs 128.2 & 122.1 ft/lbs, and hamstring flexibility 46.2 & 48.5 vs 46.7 & 47.9 cm, respectively. Hamstring flexibility evidenced significant improvement in the treated limb.

**CONCLUSION:** Four hours of accumulated acupuncture treatment significantly improved limb flexibility, which may, in part, be attributed to change in tension within the muscle, allowing for relaxation and elongation.

2459 Board #134 MAY 31 3:30 PM - 5:00 PM

**The Effect of a Strength-training Prehabilitation Intervention on Postoperative Outcomes of Total Knee Arthroplasty**

Carly McKay<sup>1</sup>, Harry Prapavessis<sup>2</sup>. <sup>1</sup>University of Calgary, Calgary, AB, Canada. <sup>2</sup>University of Western Ontario, London, ON, Canada.

(No relationships reported)

Pre-operative function has been shown to be the greatest overall predictor of post-operative function for those undergoing total knee arthroplasty (TKA), and quadriceps strength is one of the greatest contributors to function in this population. Although pre-surgical interventions (prehabilitation) aiming to increase quadriceps strength have recently been investigated, their effects on post-operative outcomes are not clear.

**PURPOSE:** This pilot study aimed to examine the effect of a six-week, pre-surgical strength training program on post-operative quadriceps strength, mobility, pain, self-reported function, health-related quality of life, and arthritis self-efficacy for patients undergoing TKA.

**METHODS:** Participants who were booked for TKA (n = 22) were randomized to either a lower body strength-training program or a placebo upper body strength-training program for six weeks before TKA. Measures included the Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC), Medical Outcomes Study Short Form 36 (SF-36), Arthritis Self Efficacy Scale, a flat surface walking test, a stair ascent/descent test, and an isometric quadriceps strength assessment. Measures were taken at baseline, before surgery, and 6 and 12 weeks post-operatively. Between-group comparisons were made using repeated measures ANOVAs.

**RESULTS:** The effect sizes associated with the lower body training program were large for quadriceps strength,  $F(3,18) = 0.89$ ,  $p = 0.47$ ,  $\eta^2 = 0.13$ , and walking speed,  $F(3,18) = 1.47$ ,  $p = 0.26$ ,  $\eta^2 = 0.20$ , with clinically meaningful differences emerging before TKA. These benefits were not evident after surgery, however. Although there were no significant time x treatment interactions for pain  $F(3,18) = .35$ ,  $p = 0.54$ ,  $\eta^2 = .054$ , self-reported function  $F(3,18) = .52$ ,  $p = 0.67$ ,  $\eta^2 = 0.08$ , or self efficacy  $F(3,18) = .51$ ,  $p = 0.08$ ,  $\eta^2 = 0.08$ , the effect sizes were in the moderate to large range, and in the expected direction.

**CONCLUSIONS:** The intervention was effective at increasing pre-operative strength and walking speed, but this study was underpowered to detect statistically significant benefits after surgery. Replication with a larger sample size is recommended.

2460 Board #135 MAY 31 3:30 PM - 5:00 PM

**Muscle Imbalance, Functional Loading and Cartilage Composition at the Knee**

Deepak Kumar, Subburaj Karupppasamy, Wilson Lin, Hamza Alizai, Samuel Wu, Kelly Bauer, Nishant Neel, Anthony Luke, FACSM, Xiajuan Li, Sharmila Majumdar, Thomas Link, Richard Souza. University of CA San Francisco, San Francisco, CA.

(No relationships reported)

Functional muscle imbalance at the knee is a cause and consequence of numerous injuries and diseases. Coordinated muscular contraction is critical to dynamic control of knee segments during functional activities and loading during functional activities impacts cartilage morphology and composition. Relationship of muscle imbalance with functional loading and cartilage composition is unknown.

**PURPOSE:** To investigate the relationship between muscle imbalance, functional loading and cartilage composition in young healthy adults using quantitative MRI.

**METHODS:** 33 young healthy subjects (20-35 years, BMI < 28 kg/m<sup>2</sup>) had 3-T knee MRI to calculate T1 $\rho$ - and T2 relaxation times for articular and meniscal cartilage. T1W MRI was used to calculate mid-thigh muscle cross-sectional area (CSA) for the quadriceps (Q) and hamstrings (H). 3-D motion analysis during self-selected walking speed was used to calculate peak kinetic and kinematic variables during stance phase in sagittal and frontal planes. Pearson's correlations were used to correlate medio-lateral (M:L) and Q:H muscle CSA ratios with qMRI and gait variables followed by multiple linear regression.

**RESULTS:** Greater Q:H ratio was related with greater Tibiofemoral T1 $\rho$  ( $r = 0.327$ ,  $p = 0.035$ ) and T2 ( $r = 0.401$ ,  $p = 0.009$ ). Greater M:L Q ratio was associated with greater M:L ratio of meniscus T1 $\rho$  ( $r = 0.337$ ,  $p = 0.029$ ). Greater M: L Q ratio was associated with greater knee adduction moment (KAM) peaks ( $r = 0.357$ ,  $p = 0.024$ ) and impulse ( $r = 0.461$ ,  $p = 0.003$ ), and greater frontal rate of loading ( $r = 0.303$ ,  $p = 0.057$ ). Greater Q:H ratio was associated with greater peak frontal ( $r = 0.645$ ,  $p = 0.000$ ) and sagittal moments ( $r = 0.360$ ,  $p = 0.023$ ) and greater dynamic frontal malalignment ( $r = 0.330$ ,  $p = 0.038$ ).

**CONCLUSION:** Results show for the 1st time that muscle imbalance (high Q:H and M:L CSA ratios), is related to high T1 $\rho$ - and T2 relaxation times for articular and meniscal cartilage indicating loss of proteoglycans and collagen disruption. Muscle imbalance is also related to high KAM peak/ impulse, high dynamic varus, all of which are known risk factors for cartilage degeneration. These novel findings suggest that people with greater muscle imbalance might be at risk for developing knee degeneration. Hence, muscle balance training would be a critical component of preventive programs.

2461 Board #136 MAY 31 3:30 PM - 5:00 PM

**EMG And MMG Responses In Individuals With A History Of ACL Injury**

Kyle T. Ebersole<sup>1</sup>, Kimberly Zbella<sup>2</sup>, Jacob J. Sosnoff<sup>2</sup>, Stefani J. Voudrie<sup>2</sup>. <sup>1</sup>University of Wisconsin-Milwaukee, Milwaukee, WI. <sup>2</sup>University of Illinois, Urbana, IL. (Sponsor: Terry J. Housh, FACSM)

(No relationships reported)

It has been suggested that residual quadriceps femoris weakness may continue to exist following completion of prescribed rehabilitation for anterior cruciate ligament (ACL) surgery. The

underlying, if any, impact that this residual weakness has on submaximal electrical and mechanical aspects of function, as measured by electromyography (EMG) and mechanomyography (MMG), has not been previously investigated.

**PURPOSE:** To examine the EMG and MMG responses of the vastus lateralis (VL) during isometric muscle actions in individuals with a history of ACL surgery.

**METHODS:** The participants included 6 healthy individuals (control) with no history of ACL injury (age  $21.8 \pm 1.3$  yrs, BW  $73.5 \pm 12.1$  kg) and 6 individuals who were post ACL reconstruction from 6 months to 18 months (age  $20.2 \pm 1.2$  yrs, BW  $66.2 \pm 6.0$  kg) and fully cleared to return to recreational activities. Each participant performed three, 6-second maximal and three, 20-second sub-maximal (15%, 30%, 45 %MVC) isometric leg extensions at angles of 15° and 60° below the horizontal plane on a Humac Dynamometer. EMG ( $\mu$ V) and MMG (mV) amplitude was measured from the VL. Independent T-tests examined group (control, ACL) differences in maximal torque and EMG and MMG amplitude at each %MVC for both angles. An alpha of 0.05 was used to determine statistical significance.

**RESULTS:** The ACL group was weaker than then control group at 15° ( $50.8 \pm 25.7$  Nm vs.  $76.1 \pm 25.1$  Nm) and significantly weaker at 60° ( $106.8 \pm 36.9$  Nm vs.  $190.8 \pm 61.0$  Nm). In comparison to the control group at 15 and 60°, the EMG amplitude for the ACL group was greater at 100%MVC and less at each submaximal level, but these differences were not significant. The MMG amplitude at 15° was similar for each group. At 60°, however, the MMG amplitude for the ACL group was greater at 100%MVC and significantly less than that of the control group at each submaximal %MVC.

**CONCLUSION:** The group differences in EMG and MMG amplitudes suggested that the apparent strength deficit the ACL group may manifest in the inability to control submaximal force outputs, particularly at the larger joint angle of 60°. These findings indicate that residual strength deficits in individuals who have recently undergone ACL reconstruction may be associated differences in motor unit recruitment strategies to control a submaximal force.

2462 Board #137 MAY 31 3:30 PM - 5:00 PM

**Proprioceptive And Strength Comparison Of Remnant Preserved Versus Conventional Anterior Cruciate Ligament Reconstruction.**

Do Kyung Kim, Won Hah Park, FACSM. *Samsung Medical Center, seoul, Korea, Republic of.*

(No relationships reported)

**PURPOSE:** Reconstruction of the anterior cruciate ligament (ACL) restores knee stability. The remnant preserving technique was developed to preserve mechanoreceptor function, promote revascularization and facilitate ligamentation. The purpose of this study was to analyze the clinical results of ACL reconstruction with remnant preserving.

**METHODS:** From August in 2009 to July in 2010, 40 patients underwent ACL reconstruction using auto graft-hamstring tendon. On the basis of the ACL's condition patients were divided into 2 groups. In the trial group (preserved remnant group; PRG, n=20), there were 20 males with an average age of 26.2 years. In the control group (no remnant group; NRG, n=20) were 20 males with an average of age 27.1 years. We measured concentric peak torque measurements of the knee extensors and flexors at 60°/sec and 180°/sec on an Isokinetic dynamometry. Proprioceptive functions has been assessed using Joint position sense and threshold to detection of passive motion. Dynamic postural stability was measured as a stability index in the anterior-posterior and medial-lateral planes with the Biodex Stability System. All tests were measured post-operative 1year.

**RESULTS:** We found significant difference between the PRG and NRG for Joint position sense at 15° ( $2.40 \pm 1.00^\circ$  vs  $3.36 \pm 0.95^\circ$ ,  $p=0.0145$ ) and threshold to detect passive motion at 45° ( $2.02 \pm 0.59^\circ$  vs  $3.12 \pm 0.94^\circ$ ,  $p=0.0213$ ). But, we found no significant difference between the groups for the test results of the dynamic postural stability and knee strength.

**CONCLUSIONS:** We thought that the presence of the proprioceptive nerve fibers in the remnant of the ACL may provide a source for the reinnervation of the graft and restoration of normal proprioception. Therefore, preservation of the remnant ACL reconstruction is helpful in preserving the proprioception and function to stabilize the knee.

2463 Board #138 MAY 31 3:30 PM - 5:00 PM

**Infrapatellar Strap Reduces Pain In Athletes With Patellar Tendinopathy (Jumper's Knee)**

Johannes Zwerver, Jolanda Boetje, Inge van den Akker-Scheek. *University Medical Center Groningen, University of Groningen, Groningen, Netherlands.*

(J. Zwerver: Contracted Research - Including Principle Investigator; NEA International, The Netherlands provided the straps for this study but was not involved in study design and analysis.)

Athletes with patellar tendinopathy (jumper's knee) often use an infrapatellar strap to reduce their pain during knee loading activities like jumping and landing. However, no studies have been performed to investigate the effectiveness of this orthosis.

**PURPOSE:** To determine if an infrapatellar strap reduces pain in athletes with patellar tendinopathy during functional loading of the patellar tendon.

**METHODS:** 47 adult male (n=33) and female (n=14) athletes (mean age 28.0 (range 18-48) years) with patellar tendinopathy (mean VISA-P  $52.7 \pm 19.6$ ; median duration of symptoms 24 (range 3-300) months) performed ten single leg decline squats with and without an infrapatellar strap. Pain during this functional patellar tendon loading test was recorded on a visual analogue scale. The athletes also practiced one training session without and one with the strap and were asked for satisfaction with and side effects of the strap.

**RESULTS:** Pain reported by the athletes differed significantly when performing ten single leg decline squats without and with a strap,  $4.0 \pm 2.3$  and  $3.1 \pm 2.1$  respectively ( $p < 0.001$ ). Two thirds of the athletes reported that the strap was beneficial in reducing the pain during their sporting activities. 30% of the athletes reported a feeling of compression in the popliteal fossa and/or at the painful spot in the patellar tendon.

**CONCLUSION:** An infrapatellar strap can reduce pain experienced by athletes with patellar tendinopathy who perform patellar tendon loading activities.

**The Effects Of Therapeutic Modalities On Hamstring Range Of Motion And Flexibility**

Christina Padron, Jennifer Bolton, Alisha Reid, Ludmila Cosio-Lima. *The University of West Florida, Pensacola, FL.*

(No relationships reported)

Adequate hamstring flexibility is important for athletic performance. Healthcare professionals are always searching for innovative methods to increase flexibility. This study compares the changes in hamstring length after the use of three different therapeutic modalities (ice bag, heat pack, and therapeutic massage).

**METHODS:** Six female University of West Florida softball players (18-21 years) were tested on three non-consecutive days. The players' right leg was passively stretched into hip flexion three times, each stretch was held for 30 seconds, and a fourth passive stretch was measured with a goniometer. A therapeutic modality was given randomly (ice pack, heat pack, or massage) for 15 minutes. A final measurement was then taken with a goniometer after the use of the therapeutic modality.

**RESULTS:** The results were assessed using repeated measures ANOVA (pretest and posttest x 3 therapeutic modalities: ice bag, heat pack, and therapeutic massage). The ice bag modality had a mean increase of  $7.7^\circ$  ( $115.3^\circ \pm 7.1^\circ$  vs.  $123.0^\circ \pm 5.1^\circ$ ). The heat pack modality had a mean increase of  $1.3^\circ$  ( $199.8^\circ \pm 6.9^\circ$  vs.  $121.1^\circ \pm 7.1^\circ$ ). Therapeutic massage had a mean increase of  $10.1^\circ$  ( $115.5^\circ \pm 4.0^\circ$  vs.  $125.6^\circ \pm 2.3^\circ$ ).

**CONCLUSION:** Therapeutic massage was significantly greater in each participant with one athlete having a 19 point increase in their flexibility. The heat pack modality gave the participants the least amount of increase in their flexibility.

**Standing Flexion Angle Characteristics in Patients Following Ipsilateral Hamstring Tendons Autograft Anterior Cruciate Ligament Reconstruction**

Giampietro L. Vairo<sup>1</sup>, Sayers J. Miller<sup>1</sup>, Nicole M. McBrier<sup>2</sup>, Wayne J. Sebastianelli<sup>1</sup>, Paul S. Sherbondy<sup>1</sup>, William E. Buckley<sup>1</sup>. <sup>1</sup>The Pennsylvania State University, University Park, PA. <sup>2</sup>Lock Haven University of Pennsylvania, Clearfield Campus, Clearfield, PA.

(No relationships reported)

Standing flexion angle is used to assess joint excursion following ipsilateral hamstring tendons anterior cruciate ligament (ACL) reconstruction. However, limited evidence exists detailing clinical implications for this measure pertaining to knee health-related quality of life (HRQL).

**PURPOSE:** Our primary aim was to profile standing flexion angle responses to ipsilateral hamstrings tendons autograft ACL reconstruction in physically active patients. We hypothesized autograft harvest would yield related deficits. A secondary aim was to explore associations among subjective outcome measures and standing knee flexion angle.

**METHODS:** A retrospective cohort of 15 patients (age =  $21.2 \pm 2.6$  years, height =  $1.7 \pm 0.1$  m, mass =  $68.7 \pm 12.6$  kg, Tegner =  $6.9 \pm 1.6$ ) 27.5  $\pm$  10.9 months post-surgery were matched to 15 healthy control participants (age =  $21 \pm 1.1$  years, height =  $1.6 \pm 0.1$  m, mass =  $67.4 \pm 10.3$  kg, Tegner =  $6.3 \pm 1.3$ ) and assessed in a laboratory setting. The independent variable was the operative technique. Dependent variables included standing flexion angle, using a reliable technique, and subjective subscale scores for the reliable Knee Outcome Survey (KOS) and Knee Injury and Osteoarthritis Outcome Score (KOOS). Group means and standard deviations were calculated. Respective one-tail dependent and independent t-tests were calculated. Correlation coefficients were computed among the KOS and KOOS to standing flexion angle.  $P < 0.05$  denoted statistical significance.

**RESULTS:** Data were normally distributed. A lesser standing flexion angle was demonstrated for the involved ( $113.3 \pm 7.0^\circ$ ) compared to uninjured ( $116.7 \pm 6.7^\circ$ ) leg ( $P = 0.019$ ). Significant correlations existed among subjective subscale scores and standing flexion angle (KOS-ADLS Symptoms:  $r = 0.578$ ,  $P = 0.024$ ; KOS-ADLS Function:  $r = 0.578$ ,  $P = 0.024$ ; KOOS Symptoms:  $r = 0.553$ ,  $P = 0.033$ ; KOOS Pain:  $r = 0.785$ ,  $P = 0.001$ ; KOOS Function:  $r = 0.683$ ;  $P = 0.005$ ; KOOS Sports:  $r = 0.520$ ;  $P = 0.047$ ) for the involved leg.

**CONCLUSIONS:** Decreased standing knee flexion angle may be attributed to hamstrings deficits. Linear associations among subjective and objective data indicate better clinical outcomes with greater standing knee flexion angle. Our findings advocate continued investigation for determining factors associated with knee HRQL post-ACL-reconstruction.

---

2466 Board #141 MAY 31 3:30 PM - 5:00 PM

**Normative Serum Cartilage Oligomeric Matrix Protein (sCOMP) Levels in an Uninjured, Physically Active Population**

Johanna M. Hoch, Jessica L. Mateer, Carl G. Mattacola, Christian Lattermann. *University of Kentucky, Lexington, KY.*

(No relationships reported)

Serum cartilage oligomeric matrix protein (sCOMP) is a biomarker primarily associated with cartilage degradation. Elevations in sCOMP have been exhibited following acute knee injury and bouts of exercise. To further explore and better understand sCOMP elevations following acute knee injury and exercise, baseline values for an uninjured, physically active cohort are necessary.

**PURPOSE:** To establish normative sCOMP values for physically active patients ages 18-40 with no reported history of lower extremity surgery and to determine if differences exist between males and females.

**METHODS:** A total of 70 physically active subjects (28 males age:  $21.1 \pm 4.0$  years, height:  $178.2 \pm 7.3$  cms, weight:  $77.7 \pm 12.1$  kgs and 42 females age:  $22.1 \pm 4.9$  years, height:  $168.3 \pm 6.4$  cms, weight:  $65.4 \pm 8.6$  kgs) with no history of lower extremity surgery participated. Following 30 minutes of seated rest, a maximum of 10cc of blood was collected from the antecubital vein. Once the serum was collected the samples were centrifuged, separated, and placed into a  $-80^\circ\text{C}$  freezer. Once all samples were collected, ELISA tests were run (IBL Euro-Diagnostica, Malmo, Sweden) for human sCOMP. The average sCOMP value and associated standard deviation (SD) was calculated. In addition, the average sCOMP value and SD were calculated for each sex and an independent samples t-test was employed to determine if a significant difference was present. Serum COMP values are expressed as ng/mL.

**RESULTS:** The average normative sCOMP value for all participants was  $1493.3 \pm 409.1$  ng/mL. A statistical difference between sexes was determined, with males having higher baseline levels ( $1767.5 \pm 479$  ng/mL) when compared to females ( $1317.1 \pm 225.4$ ,  $p < 0.0001$ ).

**CONCLUSIONS:** The results indicate normative sCOMP values for a physically active cohort ages 18-40 with no history of lower extremity surgery are  $1493.3 \pm 409.1$  ng/mL, and that males have higher levels than females. These normative values are important in understanding differences following acute knee injury or bouts of exercise for future research investigations.

2467 Board #142 MAY 31 3:30 PM - 5:00 PM

**Preoperative Quadriceps Strength is Associated with Postoperative Quadriceps Strength Following Anterior Cruciate Ligament Reconstruction**

Lindsey Lepley, Riann Palmieri-Smith. *University of Michigan, Ann Arbor, MI.*

(No relationships reported)

Quadriceps activation failure is considered, in part, to contribute to the quadriceps weakness that lingers following anterior cruciate ligament reconstruction (ACLR). Higher levels of preoperative quadriceps activation, therefore, may be associated with improved recovery of quadriceps strength following ACLR. Understanding this association could help improve ACL rehabilitation programs.

**PURPOSE:** To determine if quadriceps activation and strength prior to ACLR are related to postoperative quadriceps strength.

**METHODS:** Twenty-eight individuals post-ACL injury (12 male, 16 female; age  $18.46 \pm 4.2$  yrs; height  $1.72 \pm 0.01$  m; mass  $70.32 \pm 13.33$  kg) reported for testing on two occasions: prior to ACLR ( $2.14 \pm 2.34$  mo) and upon return to activity post-ACLR ( $7.23 \pm 0.44$  mo). Quadriceps activation was assessed preoperatively using the burst superimposition technique and quantified via the central activation ratio (CAR). Quadriceps strength was assessed at both time points and quantified via an isokinetic dynamometer at  $60^\circ/\text{second}$ . Three maximal knee extension trials were averaged and normalized to subject body mass (Nm/kg). Linear regressions were used to examine the relationship between preoperative CAR and postoperative quadriceps strength and preoperative strength and postoperative strength.

**RESULTS:** Greater preoperative quadriceps strength was associated with greater postoperative quadriceps strength ( $R^2 = 0.157$ ,  $P = 0.037$ ). Preoperative quadriceps activation was not associated with postoperative quadriceps strength ( $R^2 = 0.032$ ,  $P = 0.363$ ).

**CONCLUSION:** These results suggest that ACLR patients with better preoperative strength recover quadriceps strength better than those with lower preoperative strength. Preoperative quadriceps activation failure may be mediated by other factors such as pain and effusion. Rehabilitation programs for ACL patients should focus on maximizing quadriceps strength prior to surgery.

Supported by NIH Grant K08 AR053152-01A2 and the University of Michigan's Rackham School of Graduate Studies.

2468 Board #143 MAY 31 3:30 PM - 5:00 PM

**Back To Competitive Soccer After ACL Surgery: Functional Tests Are Needed For Safe Medical Consensus**

Furio Danelon<sup>1</sup>, Lorenzo Boldrini<sup>1</sup>, Davide Pisoni<sup>1</sup>, Giulio S. Roi<sup>2</sup>. <sup>1</sup>Isokinetic Medical Group, Milan, Italy. <sup>2</sup>Isokinetic Medical Group, Bologna, Italy. (Sponsor: Jeff G Konin, FACSM)

(No relationships reported)

Return to full sport activity after Anterior Cruciate Ligament (ACL) reconstruction is a controversial topic. As suggested by many studies, allowance to full return should be given after functional assessment tests.

**PURPOSE:** Aim of the study is to evaluate some functional and technical aspects of performance of reconstructed-ACL soccer players once the orthopaedic surgeon gave them consensus for going back to play

**METHODS:** We evaluated 28 consecutive male soccer players after ACL reconstruction, 15 with hamstring graft (HG) and 13 with bone patellar tendon bone graft (BPTB) once they return to full playing, through functional tests on the soccer field. Players returned to sport  $168 \pm 69$  days after surgery, after a sport-specific rehabilitation protocol. We measured lengths of single (SHT) and triple (THT) one leg hop test, speed of shuttle run test (SRT), and soccer skill based on score in the long passing test (LPT). We compared results with those obtained in the same tests by 108 healthy soccer players of same level. Differences between groups and between HG and BPTB were assessed by Student's T-test assuming  $P < 0.05$  as significance value.

**RESULTS:** When compared to healthy players, operated players showed significant strength deficit of the operated limb in both leg hop tests (SHT:  $179 \pm 21$  vs  $192 \pm 15$  cm,  $P < 0.001$ ; THT:  $567 \pm 70$  vs  $627 \pm 49$  cm,  $P < 0.001$ ). Comparing the performances of both limbs, BPTB patients showed a significant deficit of the operated limb in SHT ( $-9\%$ ,  $P < 0.05$ ) and THT ( $-9\%$ ,  $P < 0.05$ ), while HG did not ( $-6\%$  and  $-3\%$  respectively, N.S.). Performance times in SRT did not show any significant difference between operated and healthy players, being respectively  $6.70 \pm 0.41$  and  $6.79 \pm 0.51$  s (N.S.). The scores in the LPT were significantly better ( $P < 0.05$ ) in the operated players compared to the control group ( $5.93 \pm 2.85$  pts vs  $4.75 \pm 2.52$  pts, respectively).

**CONCLUSIONS:** When soccer players with reconstructed ACL are allowed to return to play at competitive level on subjective basis, they seem to have gained full recovery of technique and shuttle run, but they did not completely recover strength of the operated limb. We suggest that clinicians should measure strength through field tests and should improve rehabilitation protocol to strengthen the injured limb in order to ensure safe return to competitive level.

2469 Board #144 MAY 31 3:30 PM - 5:00 PM

**Biomechanical Characteristics Of The Jump And Change Direction In Women's With A History Of Stress Fracture Of The Tibia**

Fabio R. Jose, Bruno Mezencio, Daniel Lopes Capua, Alberto Carlos Amadio, Julio Cerca Serrao. *São Paulo University, São Paulo, Brazil.*

(No relationships reported)

**PURPOSE:** Data available in literature about stress fractures are scarce, even though it is often disabling and presents a high recurrence rate. These conditions can cause disruption of activity and total involvement of bone cortical structure. The aim of this study was to analyze the biomechanical characteristics of locomotion of volunteers with history of tibial fracture caused by stress.

**METHODS:** In this study we analyzed 24 volunteers, professional athletes aged  $18 \pm 1$ . The experimental group was formed by 7 professional athletes who had previous primary or relapsed stress fractures. The control group was formed by 17 professional athletes who had not had any type of musculoskeletal injury in the last 6 months. The volunteers were evaluated in terms of specific movements of the practiced sport (basketball or volleyball) such as: vertical jump, horizontal jump, and changes of direction. The volunteers were monitored bilaterally by surface electromyography on the medial gastrocnemius and anterior tibial muscles. The electromyography rated RMS with 50ms windows before and after the subject had contact with the force platform in conditions of anterior-posterior displacement, medial-lateral displacement and horizontal and vertical jumps. The piezoelectric platform rated the peak force, time to peak, growth gradient and momentum in 50ms during mass transition, load control, propulsion control and charge.

**RESULTS:** The results showed statistically significant differences between groups under conditions of anteroposterior displacement. In this condition, the experimental group showed a decreased time to peak force ( $0.20 \pm 0.09$ s -  $0.15 \pm 0.09$ s) and an increased growth gradient ( $12.63 \pm 10.04$ s to  $20.7 \pm 18.31$ s) when compared to the control group. The parameters related to muscle activation in the same condition were different for the control and experimental groups. At the time of transition from anterior to posterior displacement, the medial gastrocnemius muscle's electromyographic activity showed a greater than 50 ms window prior to contact with the ground ( $1.19 \pm 0.84$  -  $1.43 \pm 0.62$ ).

**CONCLUSIONS:** The results show that there were significant changes in muscle activation of the volunteers with history of stress fracture, these changes may explain the dynamic behavior observed in the group.

2470 Board #145 MAY 31 3:30 PM - 5:00 PM

**Anterior Cruciate Ligament (ACL) Reconstruction in Obese Patients**

Michael J. Chambers, Tigran Garabekyan, Stephanie Zimmeck, John Jasko, Charles Giangarra. *Marshall University, Huntington, WV.*

(No relationships reported)

**PURPOSE:** To characterize the unique features of ACL injury and reconstruction in obese patients.

**METHODS:** We conducted a retrospective cohort analysis of 131 patients with an ACL injury treated with ACL reconstruction at a single university-affiliated hospital from November, 2007 to March, 2011. Thirty-two obese patients (BMI greater than or equal to 30) were identified (Group 1) and compared with 99 non-obese control patients (Group 2). Fisher's exact test, Wilcoxon test, and multivariate logistic regression analyses were performed with respect to various parameters including mechanism of injury, frequency of instability prior to reconstruction, and incidence of osteochondral injury.

**RESULTS:** The mean BMI was 35 (range 30 - 54) in Group 1 vs 24 (range 16 - 29) in Group 2. Forty percent of patients in Group 1 sustained a low energy mechanism of injury compared with 14% in Group 2 (OR = 4,  $p = 0.004$ ). Fifty-six percent of patients in Group 1 experienced at least two episodes of symptomatic instability prior to undergoing ACL reconstruction vs 32% of patients in Group 2 ( $p = 0.02$ ). The diagnosis of osteochondral injury (Outerbridge grade greater than or equal to 3) on arthroscopic evaluation was 56% in Group 1 vs 16% in Group 2 ( $p = 0.0001$ ).

**CONCLUSIONS:** Anterior cruciate ligament injury in obese patients is characterized by a lower-energy mechanism of injury, a greater degree of symptomatic instability with non-operative management, and a higher incidence of high-grade osteochondral lesions on arthroscopic evaluation. Although these individuals do not match the current or desired future activity level profile of the typical patient undergoing ACL reconstruction, we challenge the bias toward non-operative treatment and recommend surgical consideration providing other medical comorbidities are stable. In our experience, non-operative management in this sedentary cohort often leads to episodes of instability with activities of daily living and may predispose to the earlier onset of degenerative joint disease.

**Association Between The Stress Fracture And Bone Metabolism/quality Markers In Lacrosse Players**

Kenta Wakamatsu<sup>1</sup>, Keishoku Sakuraba<sup>1</sup>, Yoshio Suzuki<sup>1</sup>, Yosuke Tsuchiya<sup>2</sup>, Eisuke Ochi<sup>3</sup>. <sup>1</sup>Graduate School of Medicine, Juntendo University, Tokyo, Japan.

<sup>2</sup>Nippon Sport Science University, Tokyo, Japan. <sup>3</sup>Meiji Gakuin University, Tokyo, Japan.

(No relationships reported)

Overuse injury of the bone including stress fracture is a serious problem for athletes. Female athletes with low bone mineral density (BMD), an indicator of bone strength, and amenorrhea have a high risk of stress fracture. However, some athletes have achieved superior results in competitions without experiencing stress fractures despite low BMD, suggesting that it is difficult to predict the occurrence of stress fractures based on BMD alone. Recently, the importance of bone metabolism and quality is increasingly recognized as factors influencing bone strength. We sought to evaluate not only BMD but also bone metabolism and quality in overuse injury of the bone.

**PURPOSE:** This study was conducted to clarify the association of bone metabolism and quality markers with overuse injury of the bone in university lacrosse players.

**METHODS:** The subjects, elite university lacrosse players (35 males and 49 females), were divided into a stress fracture group and a control group. After the measurement of BMD, BAP, NTx, TRAP-5b, homocysteine, and pentosidine in blood samples were measured in both groups.

**RESULTS:** No significant differences were observed in the levels of BAP, NTx, and TRAP 5b between the stress fracture and control groups in all or male subjects. In the female players, no significant differences were observed in the levels of BMD, BAP, NTx, homocysteine, and pentosidine. On the other hand, TRAP 5b levels were  $409.9 \pm 209.3$  and  $318.6 \pm 81.6$  mU/dL in the stress fracture and control groups, respectively. A significant increase in TRAP 5b in female group levels was observed in the stress fracture group ( $p < 0.05$ ).

**CONCLUSION:** We suggest that TRAP 5b is a useful bone metabolism marker that reflects the dynamics of bone condition, particularly in female athletes.

**Differences between Attending and Resident Management of Acute Ankle Injuries in a Tertiary Care Emergency Department**

Karen Gustafson, James Borchers. *The Ohio State University, Columbus, OH.*

(No relationships reported)

**Objectives:** Management of acute ankle injury in the Emergency Department can vary by level of physician training. Variations occur in radiologic evaluation, documentation, medications given, immobilization techniques and follow up. This study evaluates the differences in care between Resident and Attending physicians with regards to acute ankle injury management.

**METHODS:** Retrospective chart review of all ankle injuries during a one year period at a tertiary care Emergency Department (January 1, 2010 through December 31, 2010). A sample of 637 patients greater than 18 years old presenting with acute ankle injury was included. Descriptive statistics and Chi-Square Tests were used in data analysis. Variables analyzed include narcotic medications, radiographs, immobilization, follow-up and documentation of Ottawa Ankle Rules.

**RESULTS:** Of the 637 patients evaluated with ankle injury, 55% were primarily cared for by a Resident with Attending supervision, with the remaining 45% cared for by an Attending only. 600 patients received x-rays, 283 were ordered by a registered nurse, 274 were ordered by a physician and 43 had multiple x-rays ordered by both a registered nurse and physician. Residents accounted for 69% of all x-rays ordered by a physician, however results were not statistically significant. Both Attendings and Residents were more likely to document incomplete Ottawa Ankle Rules as opposed to complete ( $p < 0.001$ ) and immobilize with an Aircast as opposed to an ACE wrap ( $p < 0.001$ ). Residents were more likely to provide narcotic pain medication in the ED ( $p < 0.001$ ) and write a prescription for narcotic pain medication ( $p < 0.003$ ).

**CONCLUSIONS:** Ankle injuries are a common ED presentation. In an academic medical center, variances in management between Residents and Attendings were identified specifically

related to medication choices. Residents were more likely to order and prescribe narcotic pain medications for ankle sprains in comparison to Attendings alone. Residents were also more likely to obtain radiographic confirmation, although not statistically significant. This study suggests Residents are less strictly supervised in the management of acute ankle injury as evidenced by statistically significant variations in practice from that of Attending physicians.

---

**2473** Board #148 MAY 31 3:30 PM - 5:00 PM

**Risk Factors Of Stress Fracture Of The Fifth Metatarsal Bone In University Soccer Players**

Kohei Fujitaka<sup>1</sup>, Shingo Otuki<sup>2</sup>, Mamoru Okubo<sup>3</sup>, Masasjo Hashimoto<sup>4</sup>, Keiichi Kishimoto<sup>5</sup>, Shunsuke Fujitake<sup>6</sup>, Teruyuki Kita<sup>7</sup>. <sup>1</sup>Osaka Sangyo university of Graduate School, Osaka, Japan. <sup>2</sup>Osaka Sangyo university, Osaka, Japan. <sup>3</sup>Biwako Seikei Sports College, Shiga, Japan. <sup>4</sup>Yukioka School of Allied Health Professions, Osaka, Japan. <sup>5</sup>Graduate School of Human Development and Environment, Kobe University, Hyogo, Japan. <sup>6</sup>Department of Rehabilitation, Tachiiri Orthopedics, Kyoto, Japan. <sup>7</sup>Department of Rehabilitation, Toyonakawanabe Hospital, Osaka, Japan.

(No relationships reported)

**PURPOSE:** The purpose of this study was to investigate university soccer players with stress fracture of the fifth metatarsal bone regarding their physical factor, the relationship of such fracture with a history of sporting injuries, and the ground surfaces as well as shoes used.

**METHODS:** A total of 154 male soccer players from one university were evaluated between 2004 and 2010. The foot arch ratio, toe flexor muscle strength, Q-angle, leg-heel angle, one-leg standing time with eyes closed, range of motion (ROM) of the ankle joint, and general joint laxity were measured, and the Functional Reach Test was conducted at the time of admission to the university. We also evaluated the subjects' histories of sporting injuries to the foot and ankle joint, ground surfaces and shoes used at the time of injury, and whether tapes or supporters were used for the ankle joint. All subjects who developed a stress fracture of the fifth metatarsal bone during the investigation period presented to one of our medical centers. The subjects were divided into those with and without stress fracture of the 5th metatarsal bone (injured (11 players, 12 feet) and non-injured (143 players, 296 feet) groups), and each measurement as well as other investigated items were compared between the groups at the time of admission to the university.

**RESULTS:** The toe flexor muscle strength tended to be weaker in the injured (16.4±1.9 kg) than in the non-injured (17.3±4.9 kg) group (p=0.06). The Q-angle also tended to be smaller in the injured (13.9±2.0 degrees) than in the non-injured (15.1±4.9 degrees) group (p=0.07). The rate of using elastic bandages for the foot joint was higher in the injured group (p<0.05). There were no significant difference in any other measurement and survey items.

**CONCLUSIONS:** Stress fracture of the fifth metatarsal bone was suggested to be caused by excessive weight-bearing on the fifth metatarsal bone, which resulted from the difficulty of shifting the body weight to the hallux side due to a small Q-angle and toe flexor muscle strength. As the rate of using elastic bandages for the foot joint was higher in those with such fracture, the influence of elastic bandages on the fifth metatarsal bone needs to be evaluated.

**2474** Board #149 MAY 31 3:30 PM - 5:00 PM

**Groin Wrapping And Its Effects On Skating Performance In Ice Hockey Players**

Howard W. Theberge, Julie Bigelow, Stacie Lee, Brittany Pelkey, Lara A. Carlson, FACSM. University of New England, Biddeford, ME.

(No relationships reported)

Groin injuries are a common overuse injury in ice hockey. Preventative groin wrapping is a technique that is used to accelerate return to play in the rehabilitative stage of injury treatment. However, it is unknown whether this treatment negatively impacts skating performance.

**PURPOSE:** To examine the effect of standard groin wrapping on sprint and agility performance in collegiate ice hockey players.

**METHODS:** Seven healthy male NCAA ice hockey players without lower limb pathology participated in this study (age, 25.7 ± 3.9 yr; weight, 85.2 ± 8.9 kg; height, 174.5 ± 10.0 cm; body fat, 14.3 ± 3.5%). Subjects took part in on-ice familiarization of tests 48 hours prior to data collection and were instructed not to engage in exercise 24 h prior to testing. Subjects then performed two on-ice skating testing sessions (randomly controlled) where either the dominant leg of each player was wrapped (TAPE) or not wrapped (CON). Testing sessions were separated by 24 hrs. During each testing session subjects performed 3 trials of both 40-yd sprint and agility tests while wearing full uniform and equipment. Mean sprint and mean agility times were compared via paired t-tests.

**RESULTS:** The % CV for both the sprint and agility tests were under 4%. There were no differences (p > 0.05) in mean 40-yd sprint times between TAPE (5.34 ± 0.23 s) and CON (5.25 ± 0.23 s). Mean times for the agility test were also not different (p > 0.05) between TAPE (38.74 ± 5.17 s) and CON (37.61 ± 3.43 s).

**CONCLUSION:** Findings suggest that preventative groin wrapping does not appear to negatively alter on-ice sprint and agility performance and may be considered an efficacious treatment for groin injuries that does not affect overall skating performance.

**2475** Board #150 MAY 31 3:30 PM - 5:00 PM

**Developing a Functional Test for Athletes Following a Lower Extremity Injuries**

Rebecca K. Shultz, Melissa Hodgins, Karyn Haitz, Jessica Popish, Gordon O. Matheson. Stanford University, Stanford, CA.

(No relationships reported)

Knowing when to return an athlete to sport following an injury is a complex decision and should involve a standardized testing protocol. Few such protocols exist.

**PURPOSE:** To develop a lower extremity injury function evaluation and to assess its face validity.

**METHODS:** The Functional Lower Extremity Evaluation (FLEE) is a battery of 8 tests, including single leg (SL) squat, box jump and SL hop for distance, purported to assess an athlete's functional ability post injury. FLEE was developed by a committee of sports medicine clinicians based on their clinical experience and using data from a literature review. A survey distributed to Pac-12 physicians, physical therapists, and athletic trainers (over 200 recipients) assessed the face validity of the test. Respondents were asked to evaluate the level of importance (0-4, 4 being very important), frequency of clinical usage (0-100%), and the ability of a test to measure the clinical components of functional performance (0-4, with 4 being significant), such as balance and strength, for each test. The test's importance was calculated as the number of respondents who rated the test a 3 or 4 divided by the total number of respondents. The test was considered frequent if the respondent stated they used the test 70-100% of the time.

**RESULTS:** 73 clinicians with an average of 13 years and 30 hours per week of sports medicine experience responded. The top five sports for which respondents made return to play decisions were football, basketball, soccer, baseball, and volleyball. Given that lower extremity injuries are most common in field and court sports, this population was considered appropriate for assessing FLEE. 80% of respondents used functional testing (FT) as part of their RTP decision "Often" or "Always" and 70% used FT to follow an athlete through rehabilitation "Often" or "Always". The results of the survey showed that the level of importance for each test was rated considerably higher than the clinical usage. Sports medicine clinicians also agreed that FLEE assesses each of the 11 clinical components of FT, except for Range of Motion.

**CONCLUSION:** Results show that the FLEE is considered relevant and an important part of clinical decision making. Future research should assess the reliability and content validity of the FLEE and why the usage of the tests is lower than the relevance.

**Effects Of Short-term Resistance Training And Subsequent Detraining On The Electromechanical Delay**

Pablo B. Costa<sup>1</sup>, Eric D. Ryan<sup>2</sup>, Trent J. Herda<sup>3</sup>, Ashley A. Walter<sup>4</sup>, Andrea M. Valdez<sup>4</sup>, Joel T. Cramer, FACSM<sup>5</sup>. <sup>1</sup>California State University – San Bernardino, San Bernardino, CA. <sup>2</sup>University of North Carolina – Chapel Hill, Chapel Hill, NC. <sup>3</sup>University of Kansas, Lawrence, KS. <sup>4</sup>University of Oklahoma, Norman, OK. <sup>5</sup>Oklahoma State University, Stillwater, OK.

(No relationships reported)

The time elapsed between the onset of electrical muscle activation and the onset of force development is termed the electrical mechanical delay (EMD). Resistance training adaptations can affect musculotendinous stiffness and force transmittal, possibly altering EMD.

**PURPOSE:** To examine and compare the effects of three days of dynamic constant external resistance (DCER) and isokinetic (ISOK) training and subsequent detraining on EMD.

**METHODS:** Thirty-one apparently-healthy untrained men (mean  $\pm$  SD age = 22.2  $\pm$  4.2 yrs; body mass = 77.9  $\pm$  12.9 kg; height = 173.9  $\pm$  5.4 cm) were randomly assigned to a DCER training group, ISOK training group, or control (CONT) group. Subjects visited the laboratory eight times, the first visit was a familiarization session, the second visit was a pre-training assessment, the subsequent three visits were for training (if assigned to a training group), and the last three visits were the post-training assessments (48 hrs, 1 wk, and 2 wks after the final training session). One training group performed ISOK leg extension exercise and the other performed DCER leg extension exercise for three sets of ten repetitions in each of the three days of training. A third group took part in a CONT condition and did not train. In each testing assessment visit, five, single, 200- $\mu$ s duration, square-wave, supramaximal transcutaneous electrical stimuli (each separated by 5 seconds) were delivered to the femoral nerve at rest in order to examine the EMD.

**RESULTS:** No significant changes were found for EMD from pre- to post-training assessments 1, 2, and 3 (mean SE = 4.5  $\pm$  0.2 ms, 4.7  $\pm$  0.2, 4.5  $\pm$  0.1, 4.5  $\pm$  0.2, respectively) ( $p > 0.05$ ). There was no significant interaction for time  $\times$  group (Table 1) ( $p > 0.05$ ). In addition, there were no significant main effects for time or group ( $p > 0.05$ ).

**CONCLUSION:** To our knowledge, this was the first study to investigate the effects of short-term resistance training on EMD. It can be hypothesized that increases in strength observed following a short-term resistance training program may not be attributed to stiffness changes in the series elastic component. Future studies should investigate the precise physiological components responsible for short-term training strength gains.

**The Effect Of Graft Type On Joint Loading Following Acl Reconstruction**

Kurt Manal, Emily Gardinier, Lynn Snyder-Mackler, Thomas S. Buchanan, FACSM. University of Delaware, Newark, DE.

(No relationships reported)

The risk of developing knee osteoarthritis (OA) increases greatly after sustaining an anterior cruciate ligament (ACL) injury. Two common reconstruction procedures include the quadruple-bundled semitendinosus, gracilis (STG) autograft, and harvesting of cadaveric tissue (ie., allograft). In previous work we have shown the STG autograft results in profound morphological changes to the hamstrings muscle group, while minimal changes are seen in those after allograft reconstruction. This is relevant in the context of OA as muscle forces are the dominant contributor to joint loading, and altered loading is believed to be associated with the onset and progression of knee OA. These findings lead us to believe there will be differences in joint loading depending on graft type.

**PURPOSE:** To investigate if there is a differential effect in joint loading associated with graft type in a group of healthy, young active patients during natural cadence walking.

**METHODS:** Medial and lateral compartment contact forces for 5 individuals after STG autograft reconstruction and 5 subjects who had the allograft procedure were compared six months after surgery. EMG and motion analysis data were used as inputs to an EMG-driven musculoskeletal model to predict knee joint loading. The model included 10 lower extremity muscles crossing the knee, and all forces were normalized to bodyweight (BW). The interval of interest was limited to the stance phase of natural cadence walking.

**RESULTS:** Peak medial contact force for subjects with an allograft was 2.05 BW's (SD=0.25), while peak loading for the STG autograft group was 2.49 BW's (SD=0.37). Peak loading occurred at 24% and 22% of stance respectively. Peak lateral contact force for the autograft group (mean = 1.25 BW; SD = 0.44) coincided with the timing of peak medial loading; in contrast the allograft group had smaller lateral loading (1.09 BW's; SD=0.34) reaching a peak value earlier during stance (12%).

**CONCLUSION:** It is premature to draw strong conclusions given our small sample size, however our preliminary data suggest disrupting the hamstrings during the reconstructive process impacts joint loading in patients undergoing reconstruction.

**2478** Board #153 MAY 31 2:00 PM - 3:30 PM

**Are The Patellar Tendon Stiffness And Joint Proprioception Of The Badminton Player Better Than Normal?**

Shao Ming Wu. Kaohsiung Medical University, Kaohsiung, Taiwan.

(No relationships reported)

As we know, most of the badminton players have better muscle strengths, agility, suddenly stop, and intermittent running abilities than the normal people. The resistance training of badminton players also focuses on the lower limb. Are the mechanical properties of the tendon and joint proprioception of the badminton players better than the normal?

**PURPOSE:** The purpose of this research is to investigate the difference of patellar tendon stiffness and knee joint proprioception between badminton players and normal subjects with similar age.

**METHODS:** Fourteen university badminton players and twelve university students without training were recruited in this study. All of them are healthy and without any lower extremity injuries within one year. Following the warm-up, the dynamometer was used for patella tendon stiffness and knee joint proprioception measurement. In the patellar stiffness measurement, the patella tendon length elongation at 100%, 75%, 50% 25%, and 0% (rest) of maximum isometric torque was detected by the ultrasound image. The slope of regression between tendon force and tendon elongation is defined as tendon stiffness. Joint position sense (JPS) was used as the index of joint proprioception in both passive and active movements. Two sample t-test was used to detect the difference of tendon stiffness and joint proprioception between players and normal.

**RESULTS:** In the knee joint proprioception test, badminton players have better performance than normal in the active JPS (8.58+5.85 degrees vs. 4.90+2.37 degrees,  $p < 0.05$ ). However, the tendon stiffness between badminton players and normal did not show significant difference (669.11+345.82 N/mm vs. 805.46+223.51 N/mm,  $p > 0.05$ ).

**CONCLUSIONS:** According to this study, the stiffness of patellar tendon in badminton players is not stronger than normal university students as expected. We also found that the badminton players have better joint proprioception than the normal university students. That may be the reason the players have better agility and movement ability. Moreover, the poor proprioception may also lead to injuries easily during exercise in untrained people.

2479 Board #154 MAY 31 2:00 PM - 3:30 PM

**Automatic Determination Of A Morphology-based Anatomical Coordinate System Of The Human Patella**

Michael J. Rainbow<sup>1</sup>, Daniel L. Miranda<sup>2</sup>, Roy T.H. Cheung<sup>1</sup>, Braden C. Fleming<sup>2</sup>, Irene S. Davis, FACSM<sup>1</sup>. <sup>1</sup>Harvard Medical School, Cambridge, MA. <sup>2</sup>Brown University, Providence, RI  
(No relationships reported)

*In vivo* patellar kinematics can be determined using biplanar videoradiography. However, the proper interpretation of patellar kinematics requires a coordinate system that is both anatomically meaningful and repeatable.

**PURPOSE:** To determine an anatomical coordinate system (ACS) using the morphology of the patella.

**METHODS:** 3D patella surface models (PSM) were isolated from CT images (512x512, 0.625 slice thickness) of 10 subjects' knees (5 M, 25±4.2 yrs; 5 F, 26±2.3 yrs). The center of mass of the PSM defined the origin of the ACS. The 3rd principal axis of inertia served as the anterior/posterior (AP) axis. The proximal/distal (PD) axis was aligned with the posterior vertical ridge by rotating the 1st and 2nd inertial axes about the AP axis until the variation in the medial/lateral (ML) location of the ridge was minimized. We determined inter-subject ACS repeatability by registering all PSM's and their associated ACS to a single PSM, using a best-fit alignment algorithm. We computed a resultant AP, ML, and PD axis from the vector sum of all AP, ML, and PD axes. We then calculated the centroid (CO) from all ACS origins. We quantified differences between whole bone morphology and the ACS by computing the angle between the resultant axis and each subject's axis, and the distance between the CO and each origin.

**RESULTS:** The mean angle and 95% CI between the resultant AP, ML, and PD axis and each subject's axis was 1.3° (CI: 0.9° - 1.7°), 3.0° (CI: 1.8° - 4.2°), and 3.2° (CI: 2.1° - 4.3°) respectively. The mean distance between the CO and individual origins was 0.7 mm (CI: 0.5 mm - 0.9 mm).

**CONCLUSION:** The low inter-subject variability of the ACS suggests that this patellar morphology based method is robust.

---

2480 Board #155 MAY 31 2:00 PM - 3:30 PM

**Estimating Anterior Cruciate Ligament Loading During a Randomly Cued Cutting Task Using a Musculoskeletal Model**

Joshua T. Weinhandl<sup>1</sup>, Jennifer E. Earl-Boehm<sup>2</sup>, Kyle T. Ebersole<sup>2</sup>, Wendy E. Huddleston<sup>2</sup>, Brian S.R. Armstrong<sup>2</sup>, Kristian M. O'Connor<sup>2</sup>. <sup>1</sup>Old Dominion University, Norfolk, VA. <sup>2</sup>University of Wisconsin-Milwaukee, Milwaukee, WI. (Sponsor: Robert Spina, FACSM)  
(No relationships reported)

To assess anterior cruciate ligament (ACL) injury risk, researchers commonly quantify kinematic, kinetic variables and muscle activation variables during cutting maneuvers. In an effort to more accurately represent typical sporting maneuvers, anticipatory actions have been included in many studies. Yet previous research has been unable to study the actual loading of the ACL during athletic maneuvers, making the identification of ACL injury mechanisms virtually impossible.

**PURPOSE:** To determine the influence of movement anticipation on ACL loading using a musculoskeletal model.

**METHODS:** Twenty healthy recreationally active females (21 ± 1 years, 61.8 ± 6.4 kg, 1.66 ± 0.05 m) completed a cutting tasks that consisted of four conditions: anticipated (AC) and unanticipated (UC) cutting, a straight run, and a stop. Three-dimensional kinematic and kinetic data were then input into a subject-specific musculoskeletal model created using OpenSim to estimate muscle forces during the AC and UC trials. The musculoskeletal model outputs were used in a three-dimensional model of the knee to calculate ACL force. Dependent t-tests were used to assess differences in ACL force between AC and UC trials. Other variables of interest included the timing peak ACL force, as well as the planar components (sagittal, frontal and transverse) of ACL loading. Significance for all tests was set at p<0.05.

**RESULTS:** Peak ACL loading significantly increased during UC trials (AC: 11.02 ± 4.65 N·kg<sup>-1</sup>, UC: 12.40 ± 3.79 N·kg<sup>-1</sup>, p=0.001). However, there was no difference in the timing of this peak. The sagittal plane component of ACL loading was significantly greater during UC trials (AC: 6.79 ± 3.43 N·kg<sup>-1</sup>, UC: 8.27 ± 2.68 N·kg<sup>-1</sup>, p<0.001) but there were no differences in frontal plane (AC: 2.89 ± 1.13 N·kg<sup>-1</sup>, UC: 2.96 ± 1.25 N·kg<sup>-1</sup>, p=0.059) or transverse plane (AC: 1.35 ± 1.19 N·kg<sup>-1</sup>, UC: 1.17 ± 0.84 N·kg<sup>-1</sup>, p=0.719) loading of the ACL.

**CONCLUSION:** The results of this study suggest that increases in ACL loading during UC maneuvers is primarily due to changes in sagittal plane loading. Furthermore, while peak knee adduction moment has been prospectively identified as an ACL injury risk factor, the current model supports the hypothesis that knee adduction loads in isolation may not large enough to injure the ACL.

---

2481 Board #156 MAY 31 2:00 PM - 3:30 PM

**Muscle Damage And Sex: Implications of Rate of Torque Development on Velocity-dependent Power Loss**

Geoffrey A. Power, Brian H. Dalton, William J. Booth, Charles L. Rice, FACSM, Anthony A. Vandervoort, FACSM. *The University of Western Ontario, London, ON, Canada.*  
(No relationships reported)

Unaccustomed lengthening contractions result in muscle damage and velocity-dependent power loss (Power et al. 2010).

**PURPOSE:** This study investigated changes in neuromuscular properties of the dorsiflexors following high intensity lengthening contractions in men and women. We hypothesized a preferential loss of velocity-dependent power when tested at high versus low loads owing to strength loss via impaired rate of torque development (RTD) and a shift to longer muscle lengths for optimal angle of torque production (OPT<sub>TORQUE</sub>). We also investigated whether power loss was affected by an impaired rate of neural activation.

**METHODS:** In 8 men (27±3y) and 8 women (26±4y) we studied the dorsiflexors during and following 5 sets of 30 lengthening contractions performed on a Biodex. A 30°/s isokinetic shortening contraction was used to determine OPT<sub>TORQUE</sub>, and neural activation was calculated as the rate of rise in RMS of the EMG from onset to peak RTD of the dynamic contractions. Force-velocity and power relationships were determined from 8 shortening contractions (1Nm to 70% MVC) performed before and up to 48 h post task.

**RESULTS:** Men were stronger (~35%), faster (~13%), and more powerful (~48%) than women. Markers of muscle damage included a prolonged reduction in MVC torque, an increase in muscle soreness, and a shift in OPT<sub>TORQUE</sub> (2-8°) (p < 0.05) towards longer muscle lengths without changes in voluntary activation or rate of neural activation. Maximal RTD was impaired ~20% more in women than men during recovery (p < 0.05). Both groups had similar impairments in maximal shortening velocity (~4%) and peak power (~10%). However, women had a larger reduction in MVC than men throughout recovery (p < 0.05). Power was reduced preferentially at higher loads (i.e. ≥50%MVC) with a greater loss (~20-40%) in women than men (p < 0.05), whereas maximal shortening velocity was minimally affected in both groups.

**CONCLUSION:** Greater impairments in isometric RTD following muscle damage can explain the greater loss of power at higher loads in women than men. However, the similar change in OPT<sub>TORQUE</sub> and neural activation cannot explain the power loss difference between men and women. Thus, it seems, following muscle damage RTD is a critical component for dynamic muscle performance and the disparity between the sexes needs further elucidation.

---

2482 Board #157 MAY 31 2:00 PM - 3:30 PM

**The Influence Of Hamstring Musculotendinous Stiffness On Biomechanical Mechanisms Of Anterior Cruciate Ligament Loading**

Troy Blackburn<sup>1</sup>, Marc Norcross<sup>2</sup>. <sup>1</sup>University of North Carolina at Chapel Hill, Chapel Hill, NC. <sup>2</sup>Oregon State University, Corvallis, OR. (Sponsor: Kevin M. Guskiewicz, FACSM)  
(No relationships reported)

Greater hamstring stiffness is associated with lesser anterior cruciate ligament (ACL) loading during controlled perturbations. However, it is unknown if hamstring stiffness influences ACL loading during dynamic tasks in which ACL injury commonly occurs. Landing biomechanics discriminate high vs. low ACL injury risk, thus an influence of hamstring stiffness on these factors may infer an influence on ACL injury risk.

**PURPOSE:** To evaluate the influence of hamstring stiffness on landing biomechanics.

**METHODS:** Thirty-six healthy volunteers (18 males, 18 females) participated in this investigation. Stiffness was assessed from the damping effect imposed by the hamstrings on oscillatory knee flexion-extension. Lower extremity biomechanics were captured during a double leg landing task via a motion capture system interfaced with a force plate. Simple bivariate correlations were used to evaluate relationships between hamstring stiffness and landing biomechanics. Stiffness data were also arranged into tertiles, and landing biomechanics were compared between the highest and lowest tertiles (i.e. High vs. Low stiffness groups) via independent t-tests.

**RESULTS:** Peak internal knee varus moment was negatively correlated with hamstring stiffness ( $r = -0.414, p = 0.006$ ) and was 4x smaller in the High stiffness group ( $0.049\text{WxH}$  vs.  $0.014\text{WxH}$ ;  $p = 0.019$ ). The High stiffness group also demonstrated greater knee flexion at the instants of peak anterior tibial shear force (62 vs. 77;  $p = 0.049$ ) and internal knee extension (56 vs. 69;  $p = 0.048$ ) and varus (45 vs. 62;  $p = 0.018$ ) moments.

**CONCLUSION:** Large frontal plane knee loading increases ACL injury risk. Additionally, greater knee flexion reduces ACL loading for given joint kinetics. Our data indicate that individuals with greater hamstring stiffness display landing biomechanics consistent with lesser ACL loading and injury risk. As muscle stiffness can be modified via training, exercises which enhance hamstring stiffness may be important additions to future ACL injury prevention programs.

---

**Uniquely Processed Titanium Permeated Tape Increases Achilles Tendon Compliance and Short Latency Response following Running**

David S. Rowlands, *Massey University, Wellington, New Zealand.*

(D.S. Rowlands: *Contracted Research - Including Principle Investigator; Phiten Co Ltd, Japan.*)

Wadsworth *et al.* (MSSE, 2010, 42(12):2273) previously reported a small increase in joint range of motion (ROM) and a possible enhancement of running economy during recovery from simulated soccer play in response to wearing garments processed with microscopic titanium particles (Aquatitan). Possible mechanisms are increased tendon compliance or modulated peripheral nervous-system activity.

**PURPOSE:** To determine the magnitude of increase in ankle joint ROM, Achilles tendon compliance, and reflex response with Aquatitan tape 48-h following a 40-min intermittent treadmill run.

**METHODS:** In a double-blind crossover, 10 males performed two 3-d trials comprising: 1) baseline measures, randomly-allocated Aquatitan- or placebo-treated tape covering the triceps surae, treadmill run; 2), recovery; 3), post-treatment outcomes. Compliance was determined by isometric dynamometry during plantarflexion, utilising simultaneous real-time ultrasound imaging of the Achilles-medial-gastrocnemius muscle-tendon junction, and motion analysis of landmarks. Motor reflex latency was determined using tendon tap and electromyography. An exponential curve was fitted to force-length data to model tendon compliance. Data were log-transformed prior to mixed modelling and magnitude-based inference.

**RESULTS:** The application of Aquatitan tape during recovery resulted in a small 5.1% (90% CL:  $\pm 4.5\%$ ) increase in plantar-flexor ROM relative to placebo tape, but the impact on dorsiflexion ROM was unclear ( $-1.6\% \pm 15.2\%$ ). Placebo tape application had trivial impact on Achilles compliance ( $-5.8\% \pm 19.5\%$ ), but Aquatitan tape increased compliance ( $22\% \pm 25\%$ ) with the difference small ( $23\% \pm 18\%$ ). In the tendon-tap experiment, placebo tape had trivial impact ( $0.2\% \pm 3.0\%$ ) on reflex latency, while Aquatitan tape reduced latency ( $-6.7\% \pm 2.8\%$ ) with a moderate difference ( $-7.3\% \pm 4.6\%$ ).

**CONCLUSIONS:** Increased plantarflexor ROM and Achilles tendon compliance suggests that the application of Aquatitan tape to primary movers during and after high-intensity running reduces tendon stiffness and improves reflex reaction time. Increased compliance may enhance tendon function warranting further investigation on the effect of Aquatitan on running economy and to explore therapeutic applications relating to reduced tendon stiffness.

**2484** Board #159 MAY 31 2:00 PM - 3:30 PM

**Reliability Of Transcranial Magnetic Stimulation-related Measurements Of Plantar Flexor Muscles In Healthy Subjects**

Olivier Girard, Sébastien Racinais, Abdulaziz Farooq, *ASPETAR - Qatar Orthopaedic and Sports Medicine Hospital, Doha, Qatar.*

(No relationships reported)

Despite the widespread use of transcranial magnetic stimulation (TMS), only few studies focusing on the elbow, wrist and quadriceps muscles have described the reliability of the measure(s) being used. To date, the applicability and reliability of a TMS twitch interpolation technique for measuring cortical voluntary activation of the plantar flexors is unknown.

**PURPOSE:** This study aimed at comprehensively evaluating the test-retest reliability of TMS-related measurements linked to the cortico-spinal control of the plantar flexor muscles in healthy subjects.

**METHODS:** Cortico-spinal responsiveness and cortical voluntary activation were assessed from the plantar-flexor muscle group in 15 healthy adults ( $32 \pm 4$  years) on two visits separated by 4 weeks - i.e. where they maintained their normal lifestyle - by measuring motor evoked potentials produced in the soleus, gastrocnemius medialis and gastrocnemius lateralis muscles, and the superimposed twitch torques evoked by TMS during isometric plantar flexions of varying intensity (50, 75 and 100% of maximal voluntary contraction). Reliability (average of three trials per session) was assessed using the intraclass correlation coefficient (ICC) with its 95% confidence interval (95% CI), along with standard error of measurement and minimal detectable difference.

**RESULTS:** We observed moderate to substantial-levels of between-sessions reliability (ICC range 0.41-0.88) in majority of the normalized motor evoked potential responses. The amplitude of TMS-evoked twitch forces decreased linearly between 50% and 100% of mean maximal torque ( $R^2 > 0.9$ ), and produced substantially reliable estimations of resting twitch ( $17.8 \pm 1.4$  versus  $17.0 \pm 1.2$  Nm; ICC = 0.74 with 95% CI: 0.50-0.89) and cortical voluntary activation ( $87.6 \pm 2.7$  versus  $89.2 \pm 2.5\%$ ; ICC = 0.68 with 95% CI: 0.39-0.86).

**CONCLUSIONS:** Assessment of cortico-spinal responsiveness and measurement of cortical voluntary activation of the plantar flexors using TMS present substantial levels of reliability when the testing sessions are separated by a relatively long duration of time (4 weeks). Reliability scores are generally lower than those obtained for elbow, wrist or quadriceps muscles with test sessions spaced 5-7 days apart.

**2485** Board #160 MAY 31 2:00 PM - 3:30 PM

**Reliability of Cortical and Spinal Excitability During Muscle Lengthening and Shortening Contractions in Healthy Humans**

Jamie Tallent<sup>1</sup>, Stuart Goodall<sup>1</sup>, Tibor Hortobágyi, FACS<sup>2</sup>, Duncan N. French<sup>1</sup>, Alan St Clair Gibson<sup>1</sup>, Glyn Howatson, FACS<sup>1</sup>. <sup>1</sup>*Northumbria University, Newcastle, United Kingdom.* <sup>2</sup>*University of Groningen Medical Centre, Groningen, Netherlands.* (Sponsor: Glyn Howatson, FACS)

(No relationships reported)

Transcranial magnetic stimulation (TMS) and peripheral nerve stimulation (PNS) are methods commonly used in combination to assess plasticity of the central and peripheral nervous systems, respectively. Despite the continuous fluctuations within the central nervous system, studies using TMS and PNS have reported reliable cortical and spinal responses during isometric contractions. Plastic changes rapidly occur, even after one practice session (Selvanayagam *et al.*, 2011), thus, it is critical to assess the stability of such measures during dynamic contractions.

**PURPOSE:** To investigate the repeatability of corticospinal excitatory and inhibitory measures during muscle lengthening and shortening at a range of contraction intensities in the tibialis anterior (TA).

**METHODS:** 20 healthy males performed lengthening and shortening contractions of the TA at 15, 25, 50 and 80% of maximum voluntary contraction (MVC) over 3 consecutive days. Motor evoked potentials (MEPs) were recorded at rest and during the 4 contraction intensities. The corticospinal silent period was also analyzed during 80% MVC. PNS was used to evoke the H-reflex during an isometric (10% MVC) and at 25% of shortening and lengthening MVC. V-waves were also evoked during MVCs on each of the 3 days.

**RESULTS:** No significant differences were found between days for any of the variables, with the exception of MEPs at rest and during a 25% shortening MVC. MEPs significantly increased during a 25% shortening MVC from days 1 to 2 ( $P = 0.001$ ; 95% CI 0.05 - 0.15) and at rest from days 1 to 2 ( $P = 0.016$ ; 95% CI 0.00 - 0.04) and days 1 to 3 ( $P = 0.046$ ; 95% CI = 0.01 - 0.02). Confidence intervals revealed less variability between days 2 and 3 when compared to days 1 and 2. The H-reflex during dynamic contractions showed good reliability across the 3 days (ICC = 0.76-0.84), as did V-waves during shortening (ICC = 0.77). Conversely, isometric H-reflex (ICC = 0.66) and V-waves during lengthening (ICC = 0.54) was more variable.

**CONCLUSION:** Cortical and spinal excitability can be measured reliably during dynamic contractions of healthy young humans' TA. Cortical and spinal excitability associated with motor tasks can be highly variable after a single session; therefore, it may be more difficult to reliably detect rapid plastic changes, necessitating an initial familiarisation session.

2486 Board #161 MAY 31 2:00 PM - 3:30 PM

**Influence of Lean Mass on Lower Extremity Biomechanics during a Prolonged Exercise Bout**

Melissa M. Montgomery<sup>1</sup>, Randy J. Schmitz<sup>2</sup>, Sandra J. Shultz, FACSM<sup>2</sup>. <sup>1</sup>California State University, Northridge, Northridge, CA. <sup>2</sup>University of North Carolina at Greensboro, Greensboro, NC.  
(No relationships reported)

The ability of the lower extremity (LE) musculature to maintain proper function and provide dynamic joint stability is likely a crucial factor in reducing injury risk during exercise. Possessing a greater relative proportion of LE lean mass (LELM) may delay the adoption of high risk biomechanics. However, little is known regarding the influence of body composition, specifically available LELM relative to total body mass, on resistance to deleterious changes in biomechanics during a prolonged exercise bout.

**PURPOSE:** To investigate the influence of LELM on LE biomechanics during a prolonged exercise bout designed to simulate a soccer match. We expected that a lower relative amount of LELM would predict high risk frontal and transverse hip and knee motions linked to ACL injury risk; further, that the strength of these relationships would increase with greater exercise duration.

**METHODS:** 26 females (1.7±0.1m, 61.7±9.5kg, 20.7±2.5yrs) and 28 males (1.8±0.1m, 75.1±7.1kg, 20.3±2.0yrs) were assessed for LELM using dual-energy x-ray absorptiometry (DXA) and completed a 90 minute intermittent over ground running protocol that was individualized to his/her fitness level to control for exercise intensity across participants. 3D biomechanical data were collected during drop jump landings performed every 15 minutes during the protocol. Linear regressions examined the extent to which LELM predicted frontal and transverse hip and knee kinematics collected at 4 time points during the exercise protocol (T1, T2, T3, T4), corresponding to measurements taken immediately before and after two 45-minute running intervals.

**RESULTS:** LELM was a significant negative predictor ( $p<0.05$ ) of peak hip adduction ( $R^2=0.08, 0.12, 0.10, 0.08$ ) and knee valgus ( $R^2=0.12, 0.11, 0.09, 0.12$ ) angles at T1-T4 and for knee valgus excursion at T2-T4 ( $R^2=0.13, 0.12, 0.08$ , respectively). LELM predicted increased knee external rotation excursion at T4 only ( $R^2=0.07$ ).

**CONCLUSIONS:** Lower amounts of LELM were related to various "at-risk" landing variables and in the case of knee rotation, became apparent as exercise duration increased. This implies that greater amounts of LELM may aid in avoidance of high risk LE mechanics, thus potentially reducing increased injury risk documented with longer exercise duration.

**Unchanged Anconeus Motor Unit Recruitment Thresholds At Maximal Velocity In Response To Submaximal Velocity-dependent Fatigue**

Brad Harwood, In H. Choi, Charles L. Rice, FACSM. *The University of Western Ontario, London, ON, Canada.*  
(No relationships reported)

Motor unit (MU) discharge rates of the anconeus decrease during maximal velocities in response to submaximal velocity-dependent fatiguing elbow extensions, but the relative change of MU recruitment thresholds in this paradigm is undefined.

**PURPOSE:** To determine the effect of submaximal velocity-dependent fatiguing elbow extensions on anconeus MU recruitment thresholds recorded during a maximal velocity-dependent elbow extension.

**METHODS:** Motor units ( $n=5$ ) of the anconeus from 5 healthy young men were tracked throughout a series of submaximal and maximal velocity-dependent fatiguing elbow extensions performed over 60° joint range of motion. Subjects first performed 3 maximal voluntary contractions (MVCs) followed by 3-5 maximal velocity-dependent elbow extensions at a load of 40%MVC ( $V_{max40}$ ), each separated by 2 minutes rest. Subjects then performed a submaximal fatiguing task comprised of sets of 10 submaximal (60% $V_{max40}$ ) elbow extensions followed by 2 maximal ( $V_{max40}$ ) elbow extensions. The protocol continued until subjects failed to reach 60% $V_{max40}$ , and a single MVC was performed immediately following task failure. Motor unit recruitment thresholds were determined for each submaximal and maximal contraction as the relative force at which the first MU action potential began discharging consistently. The inclusion criteria required a MU to be active for greater than 90% of all contractions. Recruitment thresholds were expressed relative to MVC for individual comparison, and relative to the highest recorded threshold for group comparisons.

**RESULTS:** Recruitment thresholds ranged from 0%MVC to 65%MVC, with average thresholds of 13.0%, 15.1%, 13.1%, and 11.9%MVC at 25%, 50%, 75%, and 100% of time to task failure, respectively. When expressed relative to the highest recorded MU recruitment threshold for each subject, there was no change in recruitment threshold as subjects progressed to task failure for both submaximal and maximal elbow extensions. However, there were tendencies ( $p=0.07$ ) for an approximate 30% reduction in MU recruitment threshold for  $V_{max40}$  and for 60% $V_{max40}$  at task failure.

**CONCLUSIONS:** results support a maintenance of anconeus MU recruitment thresholds in response to submaximal fatiguing velocity-dependent elbow extensions when recorded at  $V_{max40}$ .

**Anconeus Discharge Rates Are Associated With Recovery Of Velocity Following A Submaximal Velocity-dependent Fatiguing Protocol**

In Ho Choi, Brad Harwood, Charles L. Rice, FACSM. *University of Western Ontario, London, ON, Canada.*  
(No relationships reported)

In response to submaximal velocity-dependent fatigue, motor unit discharge rates (MUDRs) decline concurrently with the fatigue-induced reduction of power and velocity.

**PURPOSE:** To assess the short-term (10 mins) recovery profile of anconeus MUDRs following submaximal velocity-dependent fatiguing elbow extensions.

**METHODS:** Motor unit (MU) action potentials of the anconeus were tracked continuously in 5 healthy young men during baseline, fatiguing and recovery contractions using indwelling EMG wire electrodes. Subjects performed 3 maximal voluntary elbow extensions (MVCs) on a Biodex, followed by 3-5 maximal-effort velocity-dependent contractions at a load of 40%MVC ( $V_{max40}$ ). Subjects then performed a fatiguing protocol comprised of 10 submaximal contractions per set at a speed of 60% $V_{max40}$  followed by 2 elbow extensions at  $V_{max40}$  at the end of each set. Task failure occurred when the subjects could not reach 60% $V_{max40}$  at the end of a set. Subjects also performed a single MVC immediately following task failure, and a MVC and two  $V_{max40}$  elbow extensions were performed at 30s, 2min, 5min, and 10min post task failure. Global EMG signals were sampled from the inserted wires in the long and lateral heads of the triceps brachii and MU trains were recorded using more selective wires from the anconeus. Elbow extensor power, contraction velocity, root mean square (RMS) of the long and lateral heads of the triceps brachii and anconeus, and individual MUDRs were determined at six time points (pre- and post-fatigue; and at 30s, 2min, 5min, and 10min recovery).

**RESULTS:** Torque, power and contraction velocity were reduced to 55%, 75% and 65%, respectively, at task failure ( $p<0.05$ ). No significant differences in the global EMG of the long and lateral heads of the anconeus were observed during fatigue and recovery. Power and contraction velocity recovered within 5 min, but torque did not recover. Reduced (25%) MUDRs post-fatigue were restored to pre-fatigue MUDRs within 5 min ( $p>0.01$ ). Regression analysis determined the greatest amount of shared variance to be between MUDR and velocity ( $R^2=0.62$ ), and MUDR and power ( $R^2=0.58$ ).

**CONCLUSION:** Results indicate that the reduced anconeus MUDRs recorded at  $V_{max40}$  following submaximal velocity-dependent fatigue recover at a similar rate to that of velocity and power. Supported by NSERC

**Effects of Isometric Contraction on Stress Relaxation of the Plantar Flexors**

Andrew M. Stewart<sup>1</sup>, Ilze R. Jacobs<sup>2</sup>. <sup>1</sup>Victoria University, Melbourne, Australia. <sup>2</sup>Unitec, Auckland, New Zealand.  
(No relationships reported)

Muscle Energy Technique and Proprioceptive Neuromuscular Facilitation are techniques employed to increase flexibility. While these techniques are similar, they typically employ different contraction forces (% maximum). Previous studies have mainly investigated outcomes such as range of motion, but there has been little emphasis on physiological mechanisms of change.

**PURPOSE:** To explore the viscoelastic response (stress relaxation) during sub-maximal isometric contractions.

**METHODS:** Twenty-seven females (18-25y) began this study. The data from 13 subjects were used for final analysis. All subjects acted as their own control. Subjects attended a familiarization session and two test sessions (each two weeks apart). A Kin-Com dynamometer was used to maintain subjects' ankle at 80% of maximum dorsiflexion throughout the protocols. Subjects performed, in randomized order, either a sub-maximal protocol (20% MVIC) that consisted of three isometric contractions of five seconds, with five seconds rest between contractions, or a static stretch protocol in either test session. Stress (force) relaxation of the plantar flexor muscle-tendon unit and EMG activity were continuously recorded throughout both protocols.

**RESULTS:** A paired t-test between the initial peak passive force and final force indicated a substantial decline in both protocols (19.1%  $\pm$  5.5%,  $p = 0.002$ ; and 14.8%  $\pm$  4.1%,  $p = 0.002$  in the sub-maximal protocol and static stretch protocol respectively). The probability that the estimated difference between the protocols was clinically negative, trivial, or positive was 1%, 5%, and 93% respectively. Mean EMG activity was < 1% of maximum throughout.

**CONCLUSIONS:** Total stress relaxation revealed a trend towards greater decline in force during the sub-maximal protocol compared with the static stretch protocol. Negligible EMG activity lends support to a prominent viscoelastic adaptation.

### **Near-Infrared Spectroscopic Measurement of the Effect of Leg Dominance on Muscle Oxygen Saturation during Cycling**

Gwenn E.C. Ellerby<sup>1</sup>, Stuart M.C. Lee<sup>2</sup>, Lelia Adelina Paunescu<sup>1</sup>, Chelsea Pereira<sup>1</sup>, Charles P. Smith<sup>1</sup>, Babs R. Soller<sup>1</sup>. <sup>1</sup>Reflectance Medical, Westborough, MA. <sup>2</sup>Wyle Integrated Science and Engineering, Houston, TX.

(No relationships reported)

The effect of leg dominance on the symmetry of the biomechanics during cycling remains uncertain. Asymmetries have been observed in kinematics and kinetics, while symmetries were found in muscle activation. No studies have yet investigated the symmetry of muscle metabolism during cycling. Near-infrared spectroscopy (NIRS) provides a non-invasive method to investigate the metabolic responses of specific muscles during cycling.

**PURPOSE:** To determine whether there was an effect of leg dominance on thigh muscle oxygen saturation (SmO<sub>2</sub>) during incrementally loaded submaximal cycling using NIRS.

**METHODS:** Eight right leg dominant, untrained subjects (5 men, 3 women; 31 $\pm$ 2 yrs; 168.6 $\pm$ 1.0 cm; 67.2 $\pm$ 1.8 kg, mean  $\pm$  SE) volunteered to participate. Spectra were collected bilaterally from the vastus lateralis (VL) during supine rest and cycling. SmO<sub>2</sub> was calculated using previously published methods (Zou et al. 2010 Biomed. Opt. Express). Subjects pedaled at 65 rpm while resistance to pedaling was increased in 0.5 kp increments from 0.5 kp every 3 min until the subject reached 80% of age-predicted maximal heart rate. SmO<sub>2</sub> was averaged over 3 min for each completed stage. A two-way ANOVA was performed to test for leg differences. A priori contrasts were used to compare work levels to rest.

**RESULTS:** VL SmO<sub>2</sub> was not different between the dominant and non-dominant legs at rest and during exercise ( $p=0.57$ ). How SmO<sub>2</sub> changed with workload was also not different between legs ( $p=0.32$ ). SmO<sub>2</sub> at 0.5 kp (60.3 $\pm$ 4.0,  $p=0.12$ ) and 1.0 kp (59.5 $\pm$ 4.0,  $p=0.10$ ) was not different from rest (69.1 $\pm$ 4.0). SmO<sub>2</sub> at 1.5 kp (55.4 $\pm$ 4.0,  $p=0.02$ ), 2.0 kp (55.7 $\pm$ 5.0,  $p=0.04$ ), and 2.5 kp (43.4 $\pm$ 7.9,  $p=0.01$ ) was significantly lower than rest.

**CONCLUSIONS:** VL SmO<sub>2</sub> during cycling is not different between dominant and non-dominant legs and decreases with moderate workload in untrained cyclists. Assuming blood flow is directed equally to both legs, similar levels of oxygen extraction (as indicated by SmO<sub>2</sub>) suggests the metabolic load of cycling is not different between legs. This is in agreement with a recent study demonstrating symmetrical increase of muscle activation of the VL during cycling. Leg dominance did not influence VL SmO<sub>2</sub> during submaximal cycling, but may have an effect at higher loads or during other forms of exercise, such as walking and running.

### **Reliability Of Intensity Analysis Of MMG And EMG During Incremental Stimulation Of The Triceps Surae.**

W. Jeffrey Armstrong. Western Oregon University, Monmouth, OR.

(No relationships reported)

**PURPOSE:** The reliability of mechanomyography (MMG) and electromyography (EMG) during electrically-evoked muscle contraction was examined using the von Tscharnar "intensity analysis," which describes the power of a non-stationary signal as a function of both frequency and time. **METHOD:** Data for 9 college-aged participants (5 males; 4 females) with measurable H-reflexes were analyzed. MMG and EMG for the medial gastrocnemius (MG), lateral gastrocnemius (LG), and soleus (SOL) muscles of the dominant leg were elicited via percutaneous stimulation of the tibial nerve. Signals were sampled 5 times for each stimulus strength, recorded and later analyzed to determine total intensity (P). Peak total intensity (Pmax) and the time delay to Pmax (TTmax) were measured and analyzed for test-retest reliability (intraclass correlation coefficient, ICC). Repeated measures ANOVA analyzed for time effects (systematic error).

**RESULTS:** RM-ANOVA revealed no significant effects for time ( $p > 0.79, 0.99, 0.98, \text{ and } 0.99$  for EMG TTmax, EMG Pmax, MMG TTmax, and MMG Pmax, respectively). For EMG, ICC (range) for TTmax was 0.98 (0.97-0.98), 0.41 (0.31-0.51), and 0.96 (0.94-0.97); and ICC (range) for Pmax was 0.98 (0.98-0.99), 0.97 (0.96-0.98), and 0.97 (0.97-0.98) for MG, LG, and SOL, respectively ( $p < 0.001$ ). For MMG, ICC (range) for TTmax was 0.91 (0.88-0.93), 0.91 (0.88-0.94), and 0.95 (0.94-0.97); and ICC (range) for Pmax was 0.99 (0.99-0.99), 0.99 (0.99-0.99), and 1.00 (0.99-1.00) for MG, LG, and SOL, respectively ( $p < 0.001$ ).

**CONCLUSIONS:** Overall, reliability of Pmax and TTmax was strong. Lower reliability in the LG may have been due to electrode placement, as the location of the innervation zone was not determined. The intensity analysis provides insight into the frequency characteristics of the muscle responses not seen in traditional analysis of the H-reflex and may be a useful tool in studying individual variations and changes in the conduction and contraction velocities of skeletal muscle.

### **The Influence Of Aging On The Stretching-induced Force Deficit**

Eric D. Ryan<sup>1</sup>, Trent J. Herda<sup>2</sup>, Pablo B. Costa<sup>3</sup>, Ashley A. Walter<sup>4</sup>, Joel T. Cramer, FACSM<sup>5</sup>. <sup>1</sup>University of North Carolina at Chapel Hill, Chapel Hill, NC.

<sup>2</sup>University of Kansas, Lawrence, KS. <sup>3</sup>California State University - San Bernardino, San Bernardino, CA. <sup>4</sup>University of Oklahoma, Norman, OK. <sup>5</sup>Oklahoma State University, Stillwater, OK.

(No relationships reported)

**INTRODUCTION:** If a disrupted functional gamma loop is the cause of the neural decreases seen after prolonged passive stretching, it is possible that these decreases are not seen in the elderly who often exhibit a dysfunctional gamma loop.

**PURPOSE:** To examine the influence of aging on the stretching-induced force deficit.

**METHODS:** Twenty-one healthy young (22  $\pm$  2 yrs) and 21 healthy elderly (70  $\pm$  7 yrs) men performed an isometric maximal voluntary contraction (MVC) of the plantar flexor muscles on a modified custom-built load-cell apparatus connected to a calibrated Biodex System 3 dynamometer prior to and following nine 135-s passive stretches. Isometric force (N) values were sampled from the load cell, while electromyographic (EMG) amplitude values ( $\mu$ V) were recorded from the soleus (SOL) and medial gastrocnemius (MG) muscles. Percent voluntary activation (%VA) was assessed by tibial nerve stimulation and the twitch interpolation technique. A two-way mixed factorial ANOVA was used to analyze the MVC force, %VA, normalized EMG SOL, and normalized EMG MG. An ANCOVA was used to analyze the magnitude of change when baseline values were different. An alpha of  $P < 0.05$  was used to determine statistical significance.

**RESULTS:** Isometric MVC force decreased from pre- to post-stretching for the young group ( $P < 0.001$ ) but did not change in the elderly group ( $P = 0.193$ ). MVC force was also greater for the young compared to the elderly at both time points ( $P < 0.018$ ) and decreased significantly more for the young group when baseline values were adjusted ( $P = 0.006$ ). There was a non-significant decrease in %VA for the young group (-3.9%) and no change (0.02%) for the elderly group ( $P = 0.139$ ). There was no aging or stretching induced changes in EMG SOL ( $P > 0.05$ ). However, normalized post-stretching EMG MG values were significantly different ( $P = 0.043$ ) between the young (92.8%) and elderly group (104.0%).

**CONCLUSIONS:** These findings demonstrate that prolonged passive stretching results in significant decreases in MVC strength and are accompanied by changes in muscle activation (%VA and EMG MG amplitude) for the young group only. The lack of changes in MVC strength and muscle activation for the elderly group may suggest that the neural mechanism for the stretching-induced force deficit is gamma loop mediated.

2493 Board #168 MAY 31 2:00 PM - 3:30 PM

**Influence Of Intensity Of Conditioning Contraction On The Extent Of Postactivation Potentiation Is Muscle Dependent**

Atsuki Fukutani<sup>1</sup>, Kosuke Hirata<sup>1</sup>, Naokazu Miyamoto<sup>1</sup>, Hiroaki Kanehisa<sup>2</sup>, Toshimasa Yanai<sup>1</sup>, Yasuo Kawakami<sup>1</sup>. <sup>1</sup>Waseda University, Tokorozawa, Japan. <sup>2</sup>National Institute of Fitness and Sports in Kanoya, Kanoya, Japan.  
(No relationships reported)

Twitch torque is increased after a high intensity voluntary contraction (conditioning contraction). This phenomenon is called postactivation potentiation (PAP). Because PAP occurs only in the muscle fibers that are activated by the conditioning contraction, it is likely that the extent of PAP is affected by the number of recruited muscle fibers. It is hypothesized therefore that the extent of PAP differs between muscles with different strategy of force increment (recruitment of muscle fibers and increasing firing frequency).

**PURPOSE:** To test the above hypothesis by comparing muscles with different recruitment patterns of muscle fibers (plantar flexor and adductor pollicis muscles).

**METHODS:** Eleven young adults (24.0 ± 1.4 years, 1.68 ± 0.08 m, 62.1 ± 8.8 kg) voluntarily participated in this study. Subjects performed plantar flexion and thumb adduction for 10-s as a conditioning contraction with an intensity set at each of 20, 40, 60, 80, and 100% of the maximal voluntary isometric contraction (MVC). Before and after each conditioning contraction, twitch torque was measured to evaluate the extent of PAP. The extent of PAP of each muscle was expressed with the normalized value with respect to the value of 100% MVC condition of each muscle.

**RESULTS:** For the plantar flexor muscles, the extent of PAP was significantly increased as the intensity of the conditioning contraction became higher (20% MVC: 6.7 ± 8.8%, 40% MVC: 20.4 ± 8.8%, 60% MVC: 44.8 ± 18.9%, 80% MVC: 81.4 ± 19.5%) (p < 0.05). For the adductor pollicis, while the extent of PAP was significantly increased up to 60% MVC condition (20% MVC: 25.6 ± 16.2%, 40% MVC: 63.1 ± 31.0%, 60% MVC: 111.0 ± 36.8%) (p < 0.05), there were no significant differences among 60%, 80% and 100% MVC conditions (80% MVC: 101.9 ± 34.5%).

**CONCLUSIONS:** The present study shows that the influence of intensity of conditioning contraction on the extent of PAP is different between plantar flexor and adductor pollicis muscles, suggesting that the extent of PAP is related to the amount of muscle fibers being recruited.

This study was supported by the Waseda University GCOE program.

**The Influence Of Stiffness And Stretch Tolerance On The Viscoelastic Responses To Stretch**

Eric Sobolewski<sup>1</sup>, Eric D. Ryan<sup>1</sup>, Brennan J. Thompson<sup>2</sup>, Doug B. Smith<sup>2</sup>. <sup>1</sup>University of North Carolina- Chapel Hill, Chapel Hill, NC. <sup>2</sup>Oklahoma State University, Stillwater, OK. (Sponsor: Joel T Cramer, FACSM)  
(No relationships reported)

**INTRODUCTION:** Skeletal muscle demonstrates properties of viscoelastic creep and stress-relaxation (SR) during passive stretching protocols and may be influenced by initial levels of passive stiffness and stretch tolerance.

**PURPOSE:** To examine the influence of passive stiffness and stretch tolerance on SR and creep during repeated passive stretching.

**METHODS:** Thirty-eight healthy participants (age = 24±3 yr) performed four 30-s constant torque passive stretches of their right plantar flexors on a calibrated Biodex System 4 dynamometer. All passive stretches were performed at a pre-determined torque threshold for the entire 30-s stretch. Prior to the 4 stretches, a maximal stretch tolerance test was performed to determine: (1) terminal passive stiffness, (2) common passive stiffness, and (3) maximal stretch tolerance. Position (°) and torque (Nm) signals were sampled at 2 KHz during each stretch and stretch tolerance assessment. Stress-relaxation was examined from the torque responses at 5-s intervals and creep was measured from the changes in position during subsequent stretches. Passive stiffness values were calculated from the slope of the angle-torque curve that was fit with a 4th order polynomial and normalized to corrected calf girth. The participants were then ranked by each of the three measures and the 10 highest and lowest participants were examined separately. A 4×2 mixed factorial ANOVA and independent t-test were used to examine the rate and relative change of SR and creep, respectively.

**RESULTS:** There was no difference (P>0.05) in the rate or relative change in SR between groups when ranked by terminal and common passive stiffness, except for stretch 3 (least stiff < most stiff) when ranked by common passive stiffness (P=0.005). There was also a main effect for stretch (1<2) when ranked by terminal stiffness (P=0.022). The group with the greatest stretch tolerance demonstrated a greater rate of change in SR (P=0.041), however the relative change in SR was similar between groups (P=0.576). There were no differences among any of the ranked groups (P>0.05) for the rate and relative change in creep.

**CONCLUSIONS:** These results indicated that differences in terminal stiffness, common passive stiffness, and stretch tolerance have little influence on the viscoelastic response to stretch.

**Physical Activity is Related to Pain Sensitivity in Healthy Women**

Laura D. Ellingson, Lisa H. Colbert, FACSM, Dane B. Cook, FACSM. University of Wisconsin-Madison, Madison, WI.  
(No relationships reported)

There are many benefits associated with meeting current physical activity recommendations. At present, it is unknown whether a reduced sensitivity to pain is included among these benefits.

**PURPOSE:** To assess the relationship between pain sensitivity and physical activity and sedentary behaviors in a sample of healthy women.

**METHODS:** Self-reported and accelerometer measures of physical activity and sedentary behavior were collected and compared with pain intensity and unpleasantness ratings to noxious thermal stimuli in a sample of twenty-one healthy women (age 30.0 ± 5.8). Based on accelerometer data, participants were classified into two groups: meets recommendations (n=12) and insufficiently active (n=9). Independent samples t-tests were conducted to compare pain ratings and physical activity behaviors between groups and correlation coefficients (Spearman's ρ) were calculated between average minutes per day spent in moderate, vigorous, and sedentary behaviors and average intensity and unpleasantness ratings.

**RESULTS:** Participants who met physical activity recommendations had significantly lower unpleasantness ratings than their insufficiently active peers. Correlational analyses demonstrated a significant relationship between minutes spent in vigorous physical activity and both pain intensity and pain unpleasantness ratings. Relationships were not significant for moderate activity or sedentary behavior.

**CONCLUSIONS:** These results provide preliminary evidence that meeting current physical activity recommendations may be beneficial for pain in women. Moreover, participation in vigorous activity appears to account for the decreased pain sensitivity. In our sample, sedentary behavior did not appear to have a deleterious effect on pain. Results from this study have a number of potential applications including aiding our understanding of why exercise functions as a treatment for those with chronic pain conditions, and providing a rationale for including physical activity assessment in pain research.

2496 Board #171 MAY 31 3:30 PM - 5:00 PM

**Pain Relief in Older Adults Following Static Contractions is Not Task-Dependent**

Kathy J. Lemley, Breanna Drewek, Lauren Miller, Sandra K. Hunter, FACSM, Marie Hoeger Bement. *Marquette University, Milwaukee, WI.*  
(No relationships reported)

Pain complaints increase with age. Exercise is frequently utilized for pain relief but the optimal exercise prescription to relieve pain is not clear. Following static contractions, young adults experience the greatest pain relief with low intensity, long duration contractions. The pain response to static contractions in older adults however is unknown.

**PURPOSE:** To compare pain reports in healthy older adults before and after static contractions of varying intensity and duration.

**METHODS:** Pain perception was assessed in 23 healthy older adults (11 men, 12 women;  $72.0 \pm 6.3$  yrs) using a pressure pain device consisting of a 10 N force applied to the right index finger through a Lucite edge (8 x 1.5mm) for two minutes. Subjects pushed a timing device when they first felt pain (i.e., pain threshold) and rated their pain intensity every 20 seconds using a 0-10 numerical rating scale. Pain threshold and pain ratings were measured before and immediately after static contractions of the left elbow flexors at the following three doses: 1) three brief maximal voluntary contractions (MVC); 2) 25% MVC sustained for 2 minutes; and 3) 25% MVC sustained until task failure. Experimental sessions were randomized and separated by one week.

**RESULTS:** Time to task failure for the 25% MVC contraction was  $11.8 \pm 5.1$  minutes. A reduction in pain was found following all three tasks with no difference between tasks (trial x task effect:  $p > 0.05$ ), despite the duration of the 2 minute low-intensity contraction being ~17% of the contraction held to task failure. Pain thresholds for all doses increased 20% from  $51 \pm 33$  to  $61 \pm 37$  seconds and pain ratings averaged over the six time points decreased 20% from  $3.3 \pm 2.8$  to  $2.6 \pm 2.5$  following static contractions (trial effect:  $p < 0.001$  and  $p < 0.001$ , respectively).

**CONCLUSION:** Low and high intensity static contractions of both long and short duration produce similar levels of pain reduction in older adults. These preliminary data suggest that several different types of static contractions can induce significant pain relief in older adults. Age-related changes in the pain response to static contractions must be taken into account when prescribing static exercise for the management of pain.

**Robustness of Pain Catastrophizing Scores During Isokinetic Testing of Anterior Cruciate Ligament Deficient Patients**

Elena D. Diaconescu, Sivan Almosnino, Dean Tripp, Davide D. Bardana, Joan M. Stevenson. *Queen's University, Kingston, ON, Canada.*  
(No relationships reported)

Measurements of isokinetic knee musculature strength and pain catastrophizing behavior prior to Anterior Cruciate Ligament (ACL) reconstruction may serve as a baseline to which post-operative patient status may be compared. To attain maximal voluntary contractions during isokinetic testing, clinicians routinely employ various patient targeted psychological interventions with the purpose of enhancing motivation as well as reducing apprehension. However, these regular clinical practices may also influence immediate pain catastrophizing behavior, and hence confound baseline measurements of this psychological construct.

**PURPOSE:** To assess the robustness of pain catastrophizing scores obtained during knee strength testing of unilateral ACL deficient patients.

**METHODS:** 12 men ( $26 \pm 4$  yrs) and 10 women ( $25 \pm 5$  yrs) with unilateral ACL deficiency performed bilateral isokinetic knee musculature strength testing. The healthy knee was tested first, and testing of each leg encompassed 2 sets of 6 concentric extension-flexion repetitions at angular velocities of  $60^\circ\text{sec}^{-1}$  and  $180^\circ\text{sec}^{-1}$ . During the warm-up phase and during testing, the examiner attempted to increase confidence and reduce possible fear of pain, or injury aggravation by providing targeted verbal and visual feedback on performance. Pain catastrophizing scores were obtained using the pain catastrophizing scale questionnaire prior to testing, between testing of the healthy and injured leg, and at completion of all efforts. Differences in pain catastrophizing scores within the testing session were assessed using one-way ANOVA with repeated measures.

**RESULTS:** Omnibus test results indicate nonsignificant statistical differences in pain catastrophizing scores as a function of questionnaire administration occurrence (mean pain catastrophizing scores 12.5, 11.9, and 11.2 for pre, mid, and post test occasions, respectively,  $p = 0.26$ ).

**CONCLUSION:** The construct of pain catastrophizing was not affected by psychological interventions regularly employed during muscle strength testing. From a practical perspective, the pain catastrophizing scale questionnaire can be administered at a time of convenience during pre-operative isokinetic testing in this specific patient population.

2498 Board #173 MAY 31 3:30 PM - 5:00 PM

**Biopsychosocial Factors Influencing Physical Activity Participation Among People With Chronic Pain**

Jennifer Hulbert<sup>1</sup>, Angela Loucks-Atkinson<sup>1</sup>, Sandra LeFort<sup>1</sup>, LeAnne Petherick<sup>2</sup>. <sup>1</sup>Memorial University of Newfoundland, St. John's, NL, Canada. <sup>2</sup>University of Manitoba, Winnipeg, MB, Canada.  
(No relationships reported)

While it is known that a range of biological, psychological and sociological factors such as pain, perceived stress and exercise self-efficacy are associated with physical activity participation among people with chronic pain (CP), little is understood about the relationships among these variables and how they might impact physical activity participation in younger versus older adults with CP.

**PURPOSE:** To explore the relationships between pain, stress, exercise self-efficacy and physical activity participation among people with CP, and to examine the differences between older adults (50 years and older), and younger adults (under 50 years) in terms of the study variables.

**METHODS:** Self-administered surveys were collected from adults ranging in age from 19-79 years ( $N = 99$ ). The Brief Pain Inventory (Cleeland & Ryan, 1994), Perceived Stress Scale (Cohen, Kamarck, & Mermelstein, 1983), Baecke Questionnaire of Physical Activity (Baecke, Burema, Fritjers, 1982), and Exercise Self-Efficacy Scale (McAuley, 1993) were used to examine the relationships among pain (pain severity and pain interference), stress, physical activity (PA) participation (Sport PA, Work PA, and Leisure PA), and exercise self-efficacy. Hierarchical regression, mediation analyses, and independent t-tests were used to test the hypothesis that greater stress prompts people to be more physically active because it helps them to cope with stress, and that those who are more physically active experience less pain.

**RESULTS:** Pain interference was more significantly associated with Sport PA, stress, and exercise self-efficacy than pain severity. Mediation analyses confirmed the buffer effect of physical activity participation on the association between stress and pain among the oldest adults (i.e. 70+ years). More active participants versus less active participants reported lower pain severity, lower pain interference, and higher levels of exercise self-efficacy.

**CONCLUSION:** An individual's perception of the way pain interferes with their life and activities (e.g. mood, exercise, social relations, and work) is associated with their level of physical activity. People with CP, especially older adults, may reduce stress and pain in their lives by being more physically active.

**Physical Activity, Pain, And Functional Limitations In Older, Overweight And Obese Knee Osteoarthritis Patients**

Matthew J. Garver<sup>1</sup>, Brian C. Focht, FACSM<sup>2</sup>, Steven T. Devor, FACSM<sup>2</sup>, Justin Dials<sup>2</sup>, Charles F. Emery<sup>2</sup>, Alexander R. Lucas<sup>2</sup>, Kevin Hackshaw<sup>2</sup>. <sup>1</sup>Abilene Christian University, Abilene, TX. <sup>2</sup>The Ohio State University, Columbus, OH.  
(No relationships reported)

The pain and functional limitations accompanying knee osteoarthritis (KOA) are primary causes of age-related activity restriction and disability. Although it is well established that overweight individuals have significantly greater risk of developing KOA, it remains unclear if self-reported symptoms differ as a function of weight status among older KOA patients.

**PURPOSE:** The purpose of this investigation was to examine differences in pain and self-reported physical function in overweight, obese, and morbidly obese older adults with symptomatic KOA. A secondary purpose was to examine the relationship between physical activity (PA) participation, pain, and self-reported physical function.

**METHODS:** Seventy-one (58 women and 13 men;  $M$  age = 63 years) KOA patients classified as overweight ( $n=22$ ), obese ( $n=36$ ) or morbidly obese ( $n=13$ ) completed assessments of the WOMAC pain and physical function subscales and pedometer-determined PA.

**RESULTS:** Results of univariate ANCOVA analyses controlling for age revealed that morbidly obese participants reported significantly greater pain symptoms ( $p < 0.01$ ) and worse physical function ( $p < 0.01$ ) relative to overweight or obese participants. No differences in pain or self-reported physical function were observed between the overweight and obese participants ( $p > 0.05$ ). Results of partial correlation analyses controlling for age also revealed that pedometer-determined PA was inversely correlated with pain ( $r = -.31$ ;  $p < 0.01$ ) and physical function ( $r = -.30$ ;  $p < 0.01$ ).

**CONCLUSIONS:** The present results suggest that morbidly obese KOA patients report the highest pain symptoms and functional limitations. Additionally, higher levels of PA participation are associated with more favorable self-reported KOA symptoms. These findings underscore the potential importance of promoting successful weight management in the treatment of older KOA patients.

#### Session RPE Is Not Different When Estimated 15 Minutes Vs 30 Minutes Post-exercise.

Kyle R. Thompson<sup>1</sup>, Justin A. Kraft<sup>1</sup>, James M. Green, FACSM<sup>2</sup>. <sup>1</sup>Missouri Western State University, Saint Joseph, MO. <sup>2</sup>University of North Alabama, Florence, AL. (No relationships reported)

Session RPE is considered a valid and reliable measure at a period of 30 minutes (min) post exercise. Recent research which recorded session RPE every 5 min for a 30 min post-exercise period showed the possibility of session RPE's validity at all intervals 15 min through 30 min post exercise. However, the session RPE may have been influenced by the proximity of the previous rating.

**PURPOSE:** The purpose of this study was to corroborate previous research in order to confirm 15 min as an acceptable time for session RPE estimation.

**METHODS:** Participants performed three resistance training sessions (at 60% of their predetermined 1RM) consisting of the bench press, lat pull down, overhead press, upright row, triceps extension, and biceps curl according to the following protocols: a) 3 sets x 8 reps x 1.5 min rest, b) 3 sets x 8 reps x 3 min rest, c) 2 sets x 12 reps x 3 min rest. A standard 2 min rest was provided between all exercises. Session RPE and recovery HR were recorded 15 min and 30 min after exercise. Session RPE was gathered by asking the question "How difficult was the overall workout?" according to the 10-point omni scale for resistance training. Session RPE was analyzed with a 3 condition x 2 time point repeated measures ANOVA.

**RESULTS:** No significant difference was observed in session RPE based on time recorded 15 min post exercise ( $5.1 \pm 1.5$ ) vs. 30 min post exercise ( $5.2 \pm 1.6$ ). However, mean recovery HR was significantly higher ( $81 \pm 6$  bpm) at 15 min post exercise than 30 min post exercise ( $74 \pm 5$  bpm).

**CONCLUSIONS:** No observed difference in session RPE when recorded 15 min post exercise vs. 30 min post exercise confirms the results of Singh et al., 2007 indicating that 15 min after exercise is a sufficient passage of time for accurate measurement of session RPE. No change in session RPE despite a significant decrease in recovery HR indicated recovery HR had no effect on session RPE at 15 min post exercise.

---

### 2501 Board #176 MAY 31 2:00 PM - 3:30 PM

#### Relative Intensity Oxygen Consumption at Criterion RPE in Trained and Untrained Men following Memory Anchoring

Randall F. Gearhart, Jr., FACSM<sup>1</sup>, Beth J. Patton<sup>1</sup>, David F. Vanata<sup>1</sup>, Bruce Mason<sup>2</sup>. <sup>1</sup>Ashland University, Ashland, OH. <sup>2</sup>University of Akron, Akron, OH. (No relationships reported)

It has been shown that memory anchoring is sufficient for monitoring ratings of perceived exertion (RPE) in recreationally trained men and women. It is unclear if memory anchoring would also be appropriate for those that may not be as familiar with sensations experienced during exercise and their placement in the effort-perceptual response continuum.

**PURPOSE:** The current investigation compared percent of maximal oxygen uptake in recreationally trained (RT) versus untrained (UT) men at selected criterion RPE during graded, treadmill exercise following memory anchoring to the Borg 15-category scale.

**METHODS:** Eight men were assigned to each group. The RT ( $23.88 \pm 6.03$  yrs.) and UT groups ( $19.5 \pm 1.77$  yrs.) each received memory anchoring instructions. The experimental trial consisted of a graded, treadmill exercise test with small increases in intensity between stages. Linear regression with RPE as the independent variable and oxygen consumption as the dependent variable was used to calculate percent  $\dot{V}O_{2max}$  for each criterion RPE (7, 9, 11, 13, 15, 17, and 19). An independent samples t-test was used to compare percent  $\dot{V}O_{2max}$  between RT and UT at each criterion RPE.

**RESULTS:** As expected,  $\dot{V}O_{2max}$  was higher for the RT than the UT. All other descriptive variables were similar between groups. Relative oxygen uptake at each criterion RPE was also similar.

**CONCLUSION:** The current results are similar to a previous investigation using trained and untrained young adult women. Memory anchoring saves time in estimation-production designs by allowing examiners to anchor participants and have them perform a follow-up experimental trial in a single laboratory session. Also, in the attempt to construct a prediction model using RPE as the independent variable, it is critical that memory anchoring instructions be presented before exercise. Pre-exercise memory anchoring yields similar relative  $\dot{V}O_2$  for young men independent of training status, further validating Borg's assumption for the application of a category scale that the perceptual range may be set equal for all individuals.

---

### 2502 Board #177 MAY 31 2:00 PM - 3:30 PM

#### Accuracy Of Perceived Exertion In Older Adults Performing Common Daily Tasks

Torrance J. Higgins, Jeffrey Knaggs, Christopher M. Janelle, Todd M. Manini. University of Florida, Gainesville, FL. (No relationships reported)

**PURPOSE:** To examine the relationship between ratings of perceived exertion (RPE) and metabolic effort in older adults performing common daily tasks. Though metabolic responses to physical activity explain the majority of RPE variance among young adults, few studies have evaluated whether metabolic effort is associated with RPE in older adults.

**METHODS.** Forty-five community-dwelling older adults (70-90 years) performed 14 daily tasks in a laboratory setting at a self-selected pace. During testing, participants wore a portable metabolic unit to measure pulmonary gas exchange. Metabolic equivalents (MET) were calculated as ventilation of oxygen ( $\dot{V}O_2$ ) /  $3.5 \text{ mlkg}^{-1}\text{min}^{-1}$ . Each task was performed for 9.1 1.8 min to allow for a steady state metabolic rate to be reached. The RPE scale (CR-10) was administered using standardized instructions following the completion of each task.

**RESULTS.** Correlational analysis revealed a significant but weak association between RPE and METs ( $R^2 = 0.07$ ,  $p < 0.01$ ), indicating that physiological responses to physical activity only explains 7% of the variance in perceived exertion among older adults. Analyses to establish the directionality of the error revealed that of the 38% of participants demonstrating exertional error, 21% overestimated and 17% underestimated moderate/vigorous intensity exertion ( $>3$  METs). Polytomous logistic regression indicated that higher MET cost of activity [Odds Ratio (OR): 0.38, 95% Confidence Interval (CI): 0.22-0.64], lower physical function (OR: 0.78, 95% CI: 0.67-0.91), older age (OR: 0.77, 95% CI: 0.63-0.94), exercising 30 minutes per day (OR: 0.70, 95% CI: 0.51-0.97), and lower cognitive function (OR: 0.66, 95% CI: 0.53-0.84) were associated with underestimating RPE compared to measured MET level. Higher body mass index (OR: 1.28, 95% CI: 1.05-1.54) and experiencing non-exertion related fatigue (OR: 1.77, 95% CI: 1.15-2.71) were associated with overestimating RPE.

**CONCLUSION.** Older adults inaccurately estimate their exertion while performing daily tasks. Physiological, psychological, and demographic factors differentially affect the magnitude and direction of RPE error in rating moderate intensity physical activity. These inaccuracies might complicate prescribing the recommended physical activity intensity to older adults.

---

2503 Board #178 MAY 31 2:00 PM - 3:30 PM

**Exertional Responses To Sprint Interval Training: A Comparison Of 30-Second and 60-Second Conditions**

Marcus Kilpatrick<sup>1</sup>, Samuel J. Greeley<sup>1</sup>, Elizabeth A. Hubbard<sup>1</sup>, Larry H. Collins<sup>1</sup>, Jamie L. Ohara<sup>2</sup>. <sup>1</sup>University of South Florida, Tampa, FL. <sup>2</sup>Villanova University, Villanova, PA. (Sponsor: John Bartholomew, FACSM)  
(No relationships reported)

Research investigating exertional responses to continuous aerobic exercise suggests that RPE increases over time during constant load work. Recent studies comparing predicted, momentary, and session RPE in response to continuous aerobic exercise suggest that RPE taken before and after exercise do not always match in-task assessments of effort. Predicted and session RPE values typically match peak exertion or exertion observed near the conclusion of the exercise session. One area not yet adequately addressed by the research literature relates to how sprint interval training impacts exertion.

**PURPOSE:** Determine the impact of sprint interval training on RPE responses obtained pre-exercise, during exercise (for work and recovery phases), and upon completion of exercise.

**METHODS:** Sixteen healthy participants (9 male, 7 female; mean age = 23 years) completed a maximal cycle ergometer test and two counterbalanced sprint interval training sessions. Each session utilized the same work-to-rest ratio (1:1), work intensity (90% max), recovery intensity (10% max), and session duration (16 minutes). Trials differed on work duration, with a 30-sec trial and a 60-sec trial. RPE was assessed before, during, and after sessions. Sessions required the same amount of total work over the duration of the trial, but the manner in which the effort was distributed varied.

**RESULTS:** Data were analyzed using ANOVA and pairwise comparisons. Predicted, momentary, and session RPE were higher for the 60-sec trial than the 30-sec trial ( $p < 0.05$ ) despite no difference in total work. Analyses also revealed that RPE increased significantly over time in the work and recovery phases of the interval, with greater increases occurring in the 60-sec trial ( $p < 0.05$ ).

**CONCLUSIONS:** Findings suggest that sprint interval trials utilizing the same total external work and work-to-recovery ratio but differing on interval length produce significantly different RPE responses. RPE is significantly greater for sessions of exercise that utilize longer work intervals. These findings have implications for individuals who utilize interval training as part of their fitness program and suggest that shorter intervals may produce less fatigue and exertional discomfort.

---

2504 Board #179 MAY 31 2:00 PM - 3:30 PM

**Perception of Exercise Intensity Level in Recreationally Active Young Adults**

Kristofer Wisniewski, Alex Shafer, Monica Taylor, Elizabeth Nagle, FACSM, Robert Robertson, FACSM, Fredric Goss, FACSM. University of Pittsburgh, Pittsburgh, PA.  
(No relationships reported)

The American College of Sports Medicine (ACSM) defines moderate exercise intensity as 40% to < 60% oxygen uptake reserve ( $VO_2R$ ) that noticeably increases heart rate (HR) and breathing, and vigorous exercise intensity as  $\geq 60\%$   $VO_2R$  that results in substantial increases in HR and breathing. However, no previous studies have examined if individuals can identify these intensities as feeling moderate or vigorous.

**PURPOSE:** To determine how physically active young adults perceive moderate and vigorous exercise intensity based on ACSM definitions.

**METHODS:** Twenty (males,  $n=10$ ; females,  $n=10$ ) recreationally active adults ( $22.2 \pm 3.0$  yrs) performed a peak load-incremented cycle ergometer test. Subjects used a Perceived Intensity Level (PIL) scale with the following categories: 1-Light, 2-Light/Moderate, 3-Moderate, 4-Moderate/Vigorous, and 5-Vigorous. Subjects rated their PIL at the end of each 3 min stage. 40% and 60%  $VO_2R$  ( $l \cdot min^{-1}$ ) were calculated for each subject, and the stages these intensities occurred were identified. The PIL rated during the stages that 40% and 60%  $VO_2R$  occurred were taken as the subject's PIL at those intensities.

**RESULTS:** Paired Samples t-test showed the mean  $\pm$  SD PIL ratings at 60%  $VO_2R$  ( $2.7 \pm 0.7$ ) were significantly greater ( $p < 0.05$ ) than the ratings at 40%  $VO_2R$  ( $1.4 \pm 0.6$ ). At 40%  $VO_2R$ , 65% of subjects reported the intensity as Light, 30% reported the intensity as Light/Moderate, and 5% of subjects reported the intensity as Moderate. At 60%  $VO_2R$ , 45% of subjects reported the intensity as Light/Moderate, 40% reported the intensity as Moderate, and 15% reported the intensity as Moderate/Vigorous.

**CONCLUSION:** ACSM guidelines state individuals should exercise at a moderate and/or vigorous intensity for health benefits. The majority of subjects in this study perceived moderate intensity as Light to Light/Moderate, and only 15% perceived the border between moderate and vigorous intensity (60%  $VO_2R$ ) as Moderate/Vigorous. These results suggest that the majority of recreationally active young adults underestimate their exercise intensity. Therefore, when prescribing exercise intensity it is important that clear definitions of moderate and vigorous intensity be described to individuals who are currently active or wish to become physically active.

---

2505 Board #180 MAY 31 2:00 PM - 3:30 PM

**Influence of Work Rate on Session RPE During Resistance Training.**

Justin A. Krafi<sup>1</sup>, James M. Green, FACSM<sup>2</sup>, Kyle R. Thompson<sup>1</sup>. <sup>1</sup>Missouri Western State University, St. Joseph, MO. <sup>2</sup>University of North Alabama, Florence, AL.  
(No relationships reported)

Estimating workload during weight training presents a challenge as traditional markers such as heart rate (HR) increase disproportionately to intensity. Session RPE is a global marker, integrating multiple perceptual and physiological cues, but may be mitigated by specific exercise parameters (i.e. intensity, volume (total work), average HR, and work rate).

**PURPOSE:** This study examined the influence of work rate (total work/unit time) on session RPE.

**METHODS:** Participants performed three resistance protocols at 60% of their predetermined 1RM with all trials equated for total work volume. Participants performed bench press, lat pull down, overhead press, upright row, triceps extension, and biceps curl according to the following protocols: a) 3 sets x 8 reps x 1.5 minute (min) rest, b) 3 sets x 8 reps x 3 min rest, c) 2 sets x 12 reps x 3 min rest. A standard 2 min rest separated each exercise. Session RPE was recorded 30 min after exercise.

**RESULTS:** Pre-set RPE was significantly lower with extended rest period when doing the same number of sets and repetitions per set ( $2.5 \pm 1.6$  vs.  $3.1 \pm 1.6$ ). Post-set RPE was significantly higher for the 2 x 12 x 3 min rest trial ( $5.9 \pm 1.4$ ) vs. 3 x 8 x 1.5 min rest trial ( $4.8 \pm 1.2$ ) despite matched work rates. Post-set RPE was significantly lower for 3 x 8 x 3 min rest trial ( $4.0 \pm 1.6$ ) vs. the 2 x 12 x 3 min rest trial and the difference approached significance ( $p = 0.07$ ) vs. 3 x 8 x 1.5 min rest trial. Pre-set HR for the 3 x 8 x 1.5 min rest trial ( $95 \pm 10$  bpm) was significantly higher than the 3 x 8 x 3 min rest trial ( $89 \pm 10$  bpm). No other significant differences in pre-set or post-set HR were observed. Session RPE results indicate the 3 x 8 x 3 min rest trial was perceived as significantly easier ( $4.2 \pm 1.8$ ) vs. 3 x 8 x 1.5 min rest ( $5.3 \pm 1.8$ ) and 2 x 12 x 3 min rest trials ( $6.2 \pm 1.7$ ). The difference approached significance for the 3 x 8 x 1.5 min rest vs. the 2 x 12 x 3 min rest trial ( $p = 0.08$ ) despite matched work rates.

**CONCLUSIONS:** Session RPE was responsive to changes in work rate. No difference was observed when work rate was matched indicating that session RPE may be linked more tightly with work rate than the number of sets or repetitions per set. However, the difference in session RPE approached significance ( $p = 0.08$ ) between work rate matched protocols indicating that potential mediating effects of this variable warrant further investigation.

---

2506 Board #181 MAY 31 2:00 PM - 3:30 PM

**Validity of Three Alternative Versions of the Original OMNI Cycle Scale of Perceived Exertion**

George L. Panzak, Robert J. Robertson, FACSM, Fredric L. Goss, FACSM, Elizabeth F. Nagle, FACSM, Elaine N. Rubinstein, Tanya Shyrchenko, Alex B. Shafer. University of Pittsburgh, Pittsburgh, PA.  
(No relationships reported)

**PURPOSE:** To examine both the concurrent and construct validity of three Alternative Adult OMNI-Cycle Scale formats that eliminate the zero rating category.

**METHODS:** Sixteen young adult males performed four load incremented cycle ergometer tests. Concurrent validity was established by correlating RPE from the three alternative scales with corresponding  $VO_2$  and HR responses. Construct validity was established by correlating RPE from the three alternative scales with RPE from the original scale. Perceptual signal dominance and signal integration were examined by a within subjects three factor ANOVA.

**RESULTS:** Listed in Table 1 are the correlation/regression analyses for Concurrent Validity. Listed in Table 2 are the correlation/regression analyses for Construct Validity. ANOVA indicated signal dominance and signal integration for each of the three alternative scales.

**CONCLUSION:** Findings supported concurrent and construct validity of the three Alternative Adult OMNI-Cycle Scale formats where the zero category represented a resting state and not an exercise response.

TABLE 1. Concurrent Validity: RPE expressed as a function VO2 and HR.

|           |               | Alternative Scale I | Alternative Scale II | Alternative Scale III |
|-----------|---------------|---------------------|----------------------|-----------------------|
| Criterion | RPE Predictor | r*                  | r*                   | r*                    |

**Validity of Borg Ratings of Perceived Exertion During Active Video Game Play**

Brandon S. Pollock<sup>1</sup>, Jacob E. Barkley<sup>1</sup>, Nick Potenzini<sup>2</sup>, Renee M. DeSalvo<sup>2</sup>, Stacey L. Buser<sup>2</sup>, Ronald Otterstetter<sup>2</sup>, Judith A. Juvancic-Heltzel<sup>2</sup>. <sup>1</sup>Kent State University, Kent, OH. <sup>2</sup>The University of Akron, Akron, OH. (Sponsor: Ellen L. Glickman, FACSM)

(No relationships reported)

**BACKGROUND:** Borg's rating of perceived exertion (RPE) scale has been shown to be a valid tool for predicting physiologic effort during differing modes of exercise (e.g. walking, running and cycling). However, an individuals' perception of their effort at a given exercise intensity can be altered with distracters such as listening to music while exercising. Increasingly, physically interactive video games (e.g. Nintendo Wii) have been studied as potential modes of exercise. RPE during game play is often assessed in these studies. However, during game play the user will be exposed to multiple potential distracters: the video of their interactive computer avatar, music and sound effects. These factors may reduce an individual's ability to accurately predict their physiologic effort during game play.

**PURPOSE:** To determine the association between RPE scores and heart rate during physically-interactive video game play.

**METHODS:** Thirteen healthy adults (51.5 ± 11.5 years old) participated in two separate, 40-minute exercise sessions using the Nintendo Wii Fit Plus on non-consecutive days. During each session participants underwent a five-minute warm-up (running in place as part of the Basic Run game), played two separate Wii Fit Plus games (Yoga, Strength Training, Aerobics or Balance Training) for fifteen minutes each and then completed a five-minute cool down (identical to the warm up). Borg RPE and heart rate were assessed during the final 30 seconds of the warm up and cool down, as well as the final 30 seconds of minutes 15 and 30 of Wii Fit Plus play.

**RESULTS:** Correlation analysis combining data from both exercise sessions indicated a moderate positive relationship between heart rate and RPE (r = 0.32). Mixed-effects model regression analyses demonstrated that RPE scores were significantly associated with heart rate (p < 0.001). The average percentage of age-predicted heart rate maximum achieved (58 ± 6%) was significantly greater (p = 0.001) than the percentage of maximum RPE indicated (43 ± 11%)

**CONCLUSIONS:** Borg RPE scores were found to be positively associated with heart rate in adults during exercise sessions using the Wii Fit Plus. However, this relationship was lower than observed in past research that assessed RPE validity during different modes of exercise (e.g. walking, running and cycling) without distracters.

**Accuracy of Self-Reported Height and Weight among Basic Combat Trainees**

Ryan Steelman<sup>1</sup>, Joseph J. Knapik, FACSM<sup>1</sup>, Marilyn Sharp<sup>2</sup>, Nathan Hendrickson<sup>2</sup>, Jan Redmond<sup>2</sup>, Bruce Cohen<sup>2</sup>, Bruce H. Jones, FACSM<sup>1</sup>. <sup>1</sup>Army Institute of Public Health, Aberdeen Proving Ground, MD. <sup>2</sup>US Army Research Institute of Environmental Medicine, Natick, MA.

(No relationships reported)

Height (H) and weight (W) measurements are used to calculate body mass index (BMI) to indicate overweight and obese status. Studies looking at the relationship between self-reported and measured H and W have been mostly conducted using middle-aged men and women (Niedhammer, Int J Obesity, 2000;24:1111-18.; Spencer, Public Health Nutr, 2002;5:561-65). Few studies have specifically looked at the relationship of these measures in younger adults, the age group of basic combat trainees. If self-reported H and W are similar to measured values then self-reports may be adequate for epidemiological uses.

**PURPOSE:** To compare the accuracy of self-reported height, weight and resulting BMI among recruits entering Basic Combat Training (BCT).

**METHODS:** Participants were 539 recruits entering BCT at Fort Jackson, South Carolina. They completed a questionnaire asking them to report their H and W. Immediately afterwards, H and W was measured with a stadiometer and digital scale, respectively. Age was calculated from the day of questionnaire administration to their date of birth obtained from the Defense Medical Surveillance System. BMI was calculated as  $W/H^2$ . Pearson correlations examined the relationship between self-reports and measured H, W, and BMI; t-tests examined the differences between the two values. Mean  $\pm$  standard deviation (SD) differences were calculated by subtracting each recruit's measured H, W, and BMI from their respective self-reported H, W, and BMI.

**RESULTS:** Participants were  $20.7 \pm 3.8$  years old. Average  $\pm$  SD measured and self reported H, W, and BMI were, respectively,  $172.5 \pm 9.4$  and  $173.7 \pm 10.0$  cm ( $p < 0.01$ ),  $73.9 \pm 13.8$  and  $72.8 \pm 13.9$  kg ( $p < 0.01$ ) and  $24.73 \pm 3.51$  and  $24.00 \pm 3.39$  kg/m<sup>2</sup> ( $p < 0.01$ ). Correlations between self-reported and measured H, W, and BMI were 0.97, 0.99, and 0.97, respectively. Trainees over-reported their height by an average of  $1.2 \pm 2.5$  cm and under-reported their weight by an average of  $1.2 \pm 2.0$  kg. The calculated BMI was under-reported by  $0.72 \pm 0.92$  kg/m<sup>2</sup>.

**CONCLUSIONS:** Among BCT recruits, there was a close relationship between self-reported and measured H, W, and BMI. Self-reported H and W appears adequately valid for use in epidemiological studies involving large numbers of basic trainees, although the direction of the biases should be considered in drawing conclusions from self-reports.

**Validation of a Previous Day Recall Measuring Time Spent in Physically Active and Sedentary Behaviors**

Charles E. Matthews, FACSM<sup>1</sup>, Sarah Keadle<sup>2</sup>, Joshua Sampson<sup>1</sup>, Kate Lyden<sup>2</sup>, Amanda Libertine<sup>2</sup>, Heather R. Bowles<sup>1</sup>, Patty S. Freedson, FACSM<sup>2</sup>, Jay H. Fowke<sup>3</sup>.  
<sup>1</sup>National Cancer Institute, Bethesda, MD. <sup>2</sup>University of Massachusetts, Amherst, MA. <sup>3</sup>Vanderbilt University, Nashville, TN.  
(No relationships reported)

Previous-day recalls (PDR) can collect detailed information about time spent in specific active and sedentary behaviors, as well as contextual information often missing from other measures.

**PURPOSE:** Test the validity of a PDR administered by phone against a valid reference measure.

**METHODS:** Adolescents ( $n=91$ ; 12-17 yrs; 53% female) and adults ( $n=88$ ; 18-71 yrs; 55% female) wore an activPAL (aPAL) for 7 days to measure sedentary (sit/lie) and active time (standing/stepping) and completed up to three PDRs. Interviewers conducted PDRs eliciting open-ended reports of time spent sleeping and in specific active and sedentary behaviors at home, work/school and in the community. Bland-Altman methods and measurement error models evaluated PDR validity versus aPAL on days matched by date and observation time.

**RESULTS:** Adolescents and adults reported 10.0 (SD=2.2) and 9.9 (SD=2.8) hr/d of sedentary time, and 4.2 (SD=1.8) and 5.2 (SD=2.6) hr/d of active time, respectively. Total PDR active and sedentary time was greater than aPAL wear time (difference=0.58 hr/d,  $p < 0.01$ ). Bland-Altman analysis of differences between measures (bias=PDR-aPAL) revealed a non-significant ( $p > 0.05$ ) negative bias for active time in adolescents (bias=-0.27 (SD=1.37) hr/d) and adults (bias=-0.13 (SD=1.44) hr/d). In contrast, a significant positive bias in PDR sedentary time was evident ( $p < 0.01$ ) in adolescents (bias=0.81 (SD=1.52) hr/d) and adults (bias=0.74 (SD=1.59) hr/d), in part due to greater PDR observation time. Measurement error models indicated: (1) only modest systematic error over the range of sedentary ( $B_{QI}=0.90$  to 1.00) and active time ( $B_{QI}=0.70$  to 0.95); (2) random reporting error was greater than systematic reporting error; and (3) correlations between measures were relatively high (Active:  $r_{QI}=0.54$  to 0.73; Sedentary:  $r_{QI}=0.62$  to 0.80). Reporting error was higher for adolescent females, but similar for adolescent males and all adults.

**CONCLUSION:** PDRs measuring active and sedentary behaviors can provide useful estimates of population means, can rank-order individuals on the day observed, and systematic reporting errors were low. PDRs may have value in future epidemiological research, particularly for studies testing hypotheses about specific behaviors and the context within which behavior occurs.

**Moderate Intensity Cutpoints for Vertical Axis and Triaxial Vector Magnitude in Simulated Lifestyle Physical Activities**

Liane B. Azevedo, Kathryn L. Taylor, Alison L. Innerd, Alan M. Batterham, FACSM. Teesside University, Middlesbrough, United Kingdom.  
(No relationships reported)

Men and women engage in 30 and 23 minutes, respectively, of daily moderate intensity physical activity, but in just one minute of vigorous intensity physical activity (Health Survey for England, 2008). Therefore, the point differentiating light from moderate intensity is most relevant from a public health perspective.

**PURPOSE:** To derive cutpoints for the vertical axis and triaxial vector magnitude for demarcating the light and moderate physical activity intensity domains (3 standard metabolic equivalents; METs).

**METHODS:** Forty-nine participants (21 male) volunteered to participate. Guided by the Compendium of Physical Activities, we selected 5 'lifestyle' activities intended to hover around the 3 METs threshold. These activities comprised one 'lawn and garden' (Code 08135, 2.0 METs), three 'home activities' (05090, 2.0 METs; 05148, 2.5 METs; 05140, 4.0 METs), and one 'walking' activity (17190, 3.5 METs). Simultaneously, participants wore a portable indirect calorimeter and a triaxial accelerometer (Actigraph GT3X) while performing each activity for a period of 5 minutes with 5 minutes rest between each bout. We excluded the first 2 minutes and the last 15 s of each bout and derived mean counts per 10 s epoch for both the vertical axis and vector magnitude. Classification as either 'light' or 'moderate' was in agreement with the Compendium for all activities bar one ('home activities' code 05090; measured mean energy expenditure of 3.1 METs). We used Receiver Operating Characteristic curve analysis to derive optimum cutpoints for vertical and vector magnitude counts (sensitivity and specificity weighted equally).

**RESULTS:** For vector magnitude, the area under the curve (AUC) was 0.914 (90% confidence interval, 0.885 to 0.943). The optimum cutpoint was  $>275$  counts/10 s (Sensitivity: 74.6% [67.9 to 80.6%]; Specificity: 94.8% [89.5 to 97.9%]). For the vertical axis, the AUC was 0.757 (0.118 to 0.196). The optimum cutpoint was  $>98$  counts/10 s (Sensitivity: 57.0% [49.8 to 64.1%]; Specificity: 91.8% [85.6 to 95.8%]). There was a substantial difference for the AUC between the vector magnitude versus vertical axis markers of 0.157 (0.118 to 0.196).

**CONCLUSION:** The vector magnitude is clearly superior to the vertical axis marker in discriminating between light and moderate intensity lifestyle physical activities.

**2511** Board #186 MAY 31 3:30 PM - 5:00 PM

**Validity of the Global Physical Activity Questionnaire (GPAQ) for Measuring Physical Activity**

Humberto Parada, Jr., Elizabeth Mejia, Ermilia Medina, Megan Dueterhaus, Thomas L. McKenzie, FACSM, Simon J. Marshall. San Diego State University Research Foundation, San Diego, CA.  
(No relationships reported)

**PURPOSE:** To evaluate the convergent validity of the Spanish and English versions of the GPAQ for estimating time spent in moderate to vigorous physical activity (MVPA).

**METHODS:** A community sample of 88 participants (mean age = 41y, SD = 9y; mean BMI = 30, SD = 5) completed an English ( $n = 64$ , 73%) or Spanish ( $n = 24$ , 27%) language GPAQ and wore an ActiGraph GT3X accelerometer for 7 days. The majority of participants were women (90%), self-identified as Latino (83%), born in Mexico (52%), married (64%), and employed at least part time (76%). Outcome variables from the GPAQ were computed as Weekly Minutes of MVPA (WM-MVPA) during work, transportation, leisure, and total (work + transportation + leisure). Participants who did not wear the accelerometer for  $>600$  min per day for 5 days, or  $\geq 3,000$  min in 5 days or less were asked to re-wear the device. Data were scored using a 60s epoch with Freedson cut points being used to classify intensity levels. Outcome variables from the accelerometer were minutes spent in sedentary, light, moderate, and vigorous PA. For both measures, participants with  $\geq 150$  WM-MVPA were identified as meeting national PA guidelines.

**RESULTS:** 100% of participants who completed the Spanish language GPAQ reported meeting PA guidelines; however, only 77% met guidelines when objective data were used. 79% of participants who completed the English-language GPAQ reported meeting PA guidelines, but only 68% met guidelines based on accelerometer data. Levels of MVPA varied substantially between the two measures for both languages (878 vs 227 median WM-MVPA for the Spanish GPAQ and ActiGraph, respectively; 300 vs 176 median WM-MVPA, for the English GPAQ and ActiGraph, respectively). Correlations between the individual indicators from GPAQ (weekly minutes of moderate and vigorous work-, leisure-, and travel-related PA) and accelerometer (moderate and vigorous WM-PA) ranged from 0.02 to 0.32.

**CONCLUSIONS:** Compared to ActiGraph data, the GPAQ leads to greater reporting of time spent in MVPA, especially in the Spanish-language version. Comparison of the levels of MVPA estimated by the two measures suggests that the English language version but not the Spanish-language version appears to be a valid measure of PA in this sample.

**Reliability And Validity Of Two Physical Activity Surveys In Spanish-Speaking Mexican Americans**

Adrian Chavez, Barbara Ainsworth, FACSM, Kristin J. Farr, Sonia Vega-López. *Arizona State University, Phoenix, AZ*

(No relationships reported)

The accurate assessment of physical activity (PA) is important to understand the relationship that exists between PA and chronic disease. There is a need for reliable and valid measures of PA in the Spanish-speaking population.

**PURPOSE:** The purpose of this study was to assess the test-retest reliability and criterion validity of the Spanish translation of two physical activity surveys, the Stanford Brief Activity Survey (SBAS), and Rapid Assessment of Physical Activity (RAPA), in a Spanish-speaking, Mexican-American population.

**METHODS:** A total of 31 participants (male=12, female=19, age=37.5±9.8y) completed all or part of the study. The responses to the SBAS were placed into three categories (score 1=Inactive, 2=Light/Moderate, and 3=Hard/Very Hard) and the RAPA scores were placed into four categories (1=Sedentary, 2=Underactive/Underactive regular/light, 3=Underactive regular, and 4=Active). Chi-squared correlations were performed to determine one week, test-retest reliability for each survey. Criterion validity was assessed by having the participants wear an Actigraph GT1M accelerometer for one week to objectively measure activity levels. The minutes of moderate- and vigorous-intensity physical activity were determined using Freedson cut-points. A Spearman rank order correlation was performed to determine the association between objectively measured PA and responses on the two surveys.

**RESULTS:** Test-retest reliability for the SBAS and RAPA were .62 ( $p < 0.01$ ) and .40 ( $p < 0.01$ ), respectively. The SBAS and RAPA both demonstrated criterion validity ( $r = .45$ ,  $p < 0.05$  for both) with minutes of moderate- and vigorous-intensity physical activity.

**CONCLUSION:** In this sample, the SBAS was a more reliable measure of physical activity than the RAPA. Both surveys are sufficiently valid against accelerometry. The SBAS shows acceptable validity and reliability for use in the Spanish-speaking, Mexican-American population.

2513 Board #188 MAY 31 3:30 PM - 5:00 PM

**Validity And Accuracy Of Physical Activity Monitors For Estimating Energy Expenditure During Wheelchair Locomotion**

Scott A. Conger<sup>1</sup>, Stacy N. Scott<sup>1</sup>, Jennifer I. Flynn<sup>1</sup>, Brian M. Tयो<sup>2</sup>, David R. Bassett, Jr., FACSM<sup>1</sup>. <sup>1</sup>*University of Tennessee, Knoxville, TN.* <sup>2</sup>*Columbus State University, Columbus, GA.*

(No relationships reported)

**PURPOSE:** To compare energy expenditure (EE) estimates of two physical activity monitors with measured EE during wheelchair locomotion.

**METHODS:** Participants were fourteen individuals who used manual wheelchairs. Each participant performed five different locomotion activities in a manual wheelchair. These activities included wheeling on a level surface that elicited a low rolling resistance at three different speeds (4.5, 5.5, and 6.5 km·hr<sup>-1</sup>), wheeling on a rubberized 400m track that elicited a higher rolling resistance at one speed (5.5 km·hr<sup>-1</sup>), and wheeling on sidewalk course that included uphill and downhill segments at the participants self-selected speed. EE was measured using a portable indirect calorimetry system (Oxycon Mobile, Viasys Healthcare). Each subject wore an Actical (AC) and a SenseWear (SW) activity monitor on the right wrist and upper arm, respectively. A repeated measures ANOVA was used to compare measured EE to the estimates from the AC and the SW. Additionally, EE estimates from a wheelchair specific prediction equation using the SW data (Hiremath and Ding, 2011) was also compared. Bland-Altman plots were used to assess the agreement between the criterion values and the predicted values.

**RESULTS:** A repeated measures ANOVA demonstrated a significant main effect between measured EE and estimated EE ( $p < 0.01$ ). There were no significant differences between the criterion method and the AC ( $\pm 9$  to 25%,  $p > 0.05$ ). The SW significantly overestimated EE when wheeling at 4.5 km·hr<sup>-1</sup>, 5.5 km·hr<sup>-1</sup>, 6.5 km·hr<sup>-1</sup>, and during self-paced sidewalk wheeling (+30 to 80%,  $p < 0.05$ ). The Hiremath and Ding SW equation on average improved in the EE prediction during low intensity activities, but error progressively increased during higher intensity activities (+27 to 43%).

**CONCLUSION:** Overall, the wrist-mounted AC can accurately estimate EE ( $\pm 9$  to 25%) whereas the SW tends to overestimate EE during wheelchair locomotion. The wrist-mounted accelerometer is a viable option for physical activity assessment during wheelchair propulsion.

**Comparison of New Wristband Type Activity Monitor and Accelerometer**

Shinji Takahashi<sup>1</sup>, Koya Suzuki<sup>1</sup>, Kanzo Okazaki<sup>1</sup>, Keiji Sasaki<sup>1</sup>, Tomohiro Kizuka<sup>2</sup>, Yosuke Sakairi<sup>2</sup>. <sup>1</sup>*Tohoku Gakuin University, Sendai, Japan.* <sup>2</sup>*University of Tsukuba, Tsukuba, Japan.*

(No relationships reported)

To simplify the objective assessment of physical activity during daily activity, many accelerometers have been used. The accelerometers generally underestimate the physical activity energy expenditure during vertical work, arm activity, and carrying a baggage. The ViM sports memory wristband (ViM), using a uniaxial accelerometer and a gyro-sensor, was designed to classify activity patterns and estimate energy expenditure in daily activity.

**PURPOSE:** To assess the accuracy of the ViM during various activities compared with an indirect calorimeter (IC) and an accelerometer (Kenz Lifecorder EX: KL).

**METHODS:** Eight men (20.8 ± 0.4 yrs) and Seven women (20.6 ± 0.6 yrs) performed each 10 min of 15 type activities (Kendama, active video games [Wii Sports tennis, baseball, boxing], static and dynamic stretch, jump-rope, step exercise, table tennis, darts, ball juggling, balance ball, golf putting, walking, and dumbbell exercise). The ViM was placed on non-dominant wrist position. The KL was placed on waist. During all activities, the IC (MetaMax-3B) measured energy expenditure (MET). The ViM and the KL recorded body motion, we then calculated MET by using outputs of both the ViM and the KL. Estimated MET by the KL and the ViM and the IC measured MET were analyzed with two-way ANOVA model in mixed models. We also calculated correlation coefficients of the KL and the ViM to the IC measurements.

**RESULTS:** Two-way ANOVA model results showed significant interaction ( $F(14, 492.5) = 12.4$ ,  $p < 0.05$ ). The KL estimates significantly underestimated (-62 to -9%) measured MET during all 15 activities. The ViM estimates significantly underestimated (-56 to -24%) measured MET during Kendama, active video games (tennis and boxing), static stretch, jump-rope, step exercise, table tennis, ball juggling, balance ball, golf putting, and dumbbell exercise. No significant differences were found between the IC and the ViM of MET during dynamic stretch, darts, active video game (boxing), and walking (-11 to 7%). Correlation coefficient of the KL to the IC ( $r = 0.80$ ,  $p < 0.05$ ) was higher than it of the ViM ( $r = 0.63$ ,  $p < 0.05$ ).

**CONCLUSIONS:** The ViM can provide more accurate estimates of MET than the KL during non-regulated activities; however, large errors are found in the ViM estimates. The validity of the ViM is lower than the KL's validity.

---

2515 Board #190 MAY 31 3:30 PM - 5:00 PM

**Comparison of the New and Old Compendium of Physical Activities to Predict Energy Expenditure in Pregnant Women.**

Christina G. Campbell, Katie M. Smith, Lorraine M. Lanningham-Foster, Gregory J. Welk, FACSM, Randal C. Foster. *Iowa State University, Ames, IA.*

(No relationships reported)

The Compendium of Physical Activities (CPA) provides the energy expenditure (EE) for hundreds of daily activities reported in metabolic equivalents (MET). An updated version of the CPA was published in June 2011. The CPA has been used to quantify the EE of activities in pregnant women although metabolic changes associated with pregnancy may render the CPA values invalid.

**PURPOSE:** This study compares the METs measured via indirect calorimetry (IC) in pregnant women to the METs published in the 2011 (CPA<sub>new</sub>) and the 2000 (CPA<sub>old</sub>) CPA.

**METHODS:** EE was measured in 23 pregnant women during their 1<sup>st</sup>, 2<sup>nd</sup> and 3<sup>rd</sup> trimester. Each woman completed a series of activities consisting of typing, folding laundry while standing, sweeping (household activities), and treadmill walking at speeds of 2.0, 2.5, 3.0 mph, 0% incline and 3.0 mph, 3% incline. METs were defined two ways: absolute method (1 MET = 3.5 mL O<sub>2</sub>/kg/min or 1 kcal/kg/h) and ratio method (EE<sub>activity</sub>/EE<sub>rest</sub>). Data were compared across pregnancy using repeated measures ANOVA. Observed METs were compared the CPA<sub>new</sub> and CPA<sub>old</sub> with t-tests. A Bonferroni-corrected P-value was used to test significance.

**RESULTS:** Data across all trimesters were not significantly different, thus 2<sup>nd</sup> trimester data is presented. CPA<sub>old</sub> vs. observed METs: For the absolute definition, all activities were

significantly different ( $P < 0.005$ ) except for level walking at 2.0 and 2.5 mph; household activities were overestimated by CPA<sub>old</sub> ( $P < 0.001$ ). With the ratio definition, all activities were significantly different than observed METs ( $P < 0.005$ ); household activities were overestimated whereas all walking was underestimated by the CPA<sub>old</sub>. CPA<sub>new</sub> vs. observed METs: Using the absolute definition, all activities except level walking at 2.5 and 3.0 mph were significantly overestimated ( $P < 0.0001$ ). Using the ratio definition, only folding and sweeping were significantly different ( $P < 0.005$ ) however walking at a level grade was significantly underestimated ( $P < 0.001$ ).

**CONCLUSION:** Using either version of the CPA, the ratio definition significantly overestimates household activities and underestimates walking. The 2011 CPA minimizes the error associated with assessing energy expenditure; the CPA METs still provide a significantly different MET than what is measured in pregnant women.

**2516** Board #191 MAY 31 3:30 PM - 5:00 PM

**Agreement of Hip and Ankle Worn Activity Monitors for Measurement of Physical Activity**

Matthew T. Mahar, FACSM, Mallory Peavler, Grace Anne Edwards, Nicholas A. Boerio, Lucas J. Carr. *East Carolina University, Greenville, NC.*

(No relationships reported)

**PURPOSE:** To examine agreement among three activity monitors for assessment of moderate and vigorous physical activity.

**METHODS:** Participants ( $N = 39$ ) wore three activity monitors for 48 hours. The monitors included the ActiGraph GT1M accelerometer, the three-dimensional GT3X+ accelerometer, both worn at the hip, and the ankle-worn StepWatch activity monitor. Moderate-to-vigorous physical activity (MVPA) was calculated for the ActiGraph monitors using previously published cut points. MVPA was calculated from the StepWatch steps per minute output based upon previously published moderate intensity cut points relative to height. Average minutes of MVPA were compared with repeated measures ANOVA. Effect sizes ( $ES$ ) were estimated with Cohen's delta and Pearson correlations were calculated. Participants were then categorized as either meeting or not meeting the recommendation for 30 min of MVPA per day. Criterion-referenced agreement between different monitors was examined with proportion of agreement ( $Pa$ ) and modified kappa ( $kq$ ).

**RESULTS:** The GT3X+ produced significantly ( $p < .05$ ) more daily minutes of MVPA ( $69.5 \pm 42.9$  min) than the GT1M ( $47.8 \pm 35.8$  min;  $ES = 0.55$ ;  $r = .70$ ) and StepWatch ( $48.4 \pm 32.6$  min;  $ES = 0.56$ ;  $r = .75$ ). The difference in mean daily minutes of MVPA between the GT1M and StepWatch was not significant ( $p = .89$ ;  $ES = 0.02$ ;  $r = .58$ ). Criterion-referenced agreement was high between the GT1M and StepWatch on day 1 ( $Pa = .90$ ,  $kq = .79$ ), but lower on day 2 ( $Pa = .74$ ,  $kq = .49$ ). Agreement between the GT3X+ and GT1M was moderate ( $Pa = .77$ ,  $kq = .54$  [day 1],  $Pa = .79$ ,  $kq = .59$  [day 2]). Similar moderate levels of agreement were found between the GT3X+ and StepWatch ( $Pa = .77$ ,  $kq = .54$  [day 1],  $Pa = .74$ ,  $kq = .49$  [day 2]).

**CONCLUSIONS:** The three-dimensional accelerometer (GT3X+) produced approximately 20 more minutes of MVPA per day than the GT1M or StepWatch. Although average number of daily minutes of MVPA was similar for the GT1M and StepWatch, agreement between these monitors for categorizing participants as meeting or not meeting physical activity recommendations was only of moderate accuracy on day 2. The cut points used in this study for the GT3X+ monitor do not provide high levels of agreement with the other monitors studied for daily minutes of MVPA or for categorization for meeting or not meeting physical activity recommendations.

**2517** Board #192 MAY 31 3:30 PM - 5:00 PM

**Perceptions of Objective and Self-Report Methods for Monitoring Sedentary and Physical Activity Behaviors**

Lucas J. Carr, Mallory Peavler, Grace Anne Edwards, Nicholas Boerio, Matthew T. Mahar, FACSM. *East Carolina University, Greenville, NC.*

(No relationships reported)

While many studies have examined the accuracy, validity, and reliability of physical activity measures, little is known about individual perceptions of the monitoring process. Such information could provide researchers insight to assist in reducing non-compliance when assessing physical activity.

**PURPOSE:** To identify participant perceptions of two objective (hip-worn ActiGraph accelerometer, ankle-worn StepWatch monitor) and two self-report methods (online 48 hour recall questionnaire, 48 hour activity log) of measuring sedentary and physical activity behaviors.

**METHODS:** A convenience sample of 53 college-aged students wore two objective monitors for 48 hours during all non-bathing hours including sleep time. Participants documented their sedentary/active time in 15 minute blocks using a 48 hour behavioral log. Participants completed a four-item, online 48 hour sedentary/activity recall survey. Participants rated the objective monitors (e.g., comfort during day, comfort while sleeping, ease of wear during exercise, awareness of monitor, intrusiveness, responsiveness to device for engaging in physical activity) and self-report surveys (e.g., difficulty to complete, perceived accuracy) using a five-point Likert Scale (strongly disagree=1; disagree=2; neutral=3; agree=4; strongly agree=5).

**RESULTS:** Participants rated the ankle-worn StepWatch significantly more comfortable to wear during the day ( $3.6 \pm 1.0$  vs.  $2.8 \pm 1.1$ ;  $P < 0.001$ ), more comfortable while sleeping ( $3.1 \pm 1.3$  vs.  $1.9 \pm 1.0$ ;  $P < 0.001$ ), easier to wear during exercise ( $3.6 \pm 1.1$  vs.  $2.8 \pm 1.1$ ;  $P < 0.001$ ) and less intrusive/interfering ( $2.2 \pm 0.8$  vs.  $2.8 \pm 1.0$ ;  $P < 0.001$ ) than the ActiGraph accelerometer. Participants also reported being more aware of the hip-worn ActiGraph than the StepWatch ( $3.1 \pm 1.0$  vs.  $2.9 \pm 1.1$ ;  $P = 0.008$ ). No differences were observed between the self-report assessment tools.

**CONCLUSIONS:** Participants found the ankle-worn StepWatch to be more agreeable to wear during the assessment process than the hip worn ActiGraph monitor. These findings support future studies that explore individual perceptions of assessment tools to ensure maximum compliance.

**2518** Board #193 MAY 31 3:30 PM - 5:00 PM

**The Utility of a Simple Physical Activity Screener to Differentiate Cardiometabolic Risk in Latino Youth**

Joon Young Kim, Justin R. Ryder, Rocio Ortega, Hillary Burks, Gabriel Q. Shaibi. *Arizona State University, Phoenix, AZ.*

(No relationships reported)

**PURPOSE:** Latino youth are disproportionately impacted by obesity and type 2 diabetes, therefore early identification of high-risk youth is an essential step for closing the obesity-related health disparity gap. As researchers develop and implement sophisticated approaches to objectively quantify physical activity (PA), clinicians struggle to translate these approaches into real-world settings. Therefore, the purpose of this study was to examine the utility of a simple PA screener for differentiating cardiometabolic disease risk in Latino youth.

**METHODS:** 151 non-diabetic Latino adolescents (age  $16.6 \pm 2.7$  yrs, 70 male /81 female) were assessed for fasting: Triglycerides (TG), HDL-cholesterol (HDL), LDL-cholesterol (LDL), VLDL-cholesterol (VLDL), and plasma glucose and insulin. In addition, participants underwent a 2-hour Oral Glucose Tolerance Test to assess insulin sensitivity (Matsuda index) and glucose tolerance. Prior to testing, participants completed a questionnaire which asked whether or not they engage in regular PA (yes or no).

**RESULTS:** 100 youth answered "yes" and 51 answered "no" to the single-question PA screener with a significantly greater proportion of males answering yes than females (84.3% vs. 50.6%,  $p < 0.0001$ ). After adjusting for age and gender, those responding "yes" had significantly lower TG ( $92.3 \pm 47.1$  vs.  $113.5 \pm 59.6$  mg/dl), VLDL ( $15.5 \pm 7.9$  vs.  $19.0 \pm 9.9$  mg/dl), fasting and 2-hour glucose ( $90.7 \pm 6.3$  vs.  $91.4 \pm 7.0$  mg/dl,  $112.4 \pm 24.3$  vs.  $122.5 \pm 21.8$  mg/dl), 2-hour insulin ( $69.7 \pm 66.2$  vs.  $108.1 \pm 78.2$   $\mu$ U/ml), and total glucose AUC ( $15123.0 \pm 2465.2$  vs.  $16386.2 \pm 2685.4$   $\text{mg} \cdot \text{dl}^{-1} \cdot \text{h}^{-1}$ ), all  $p < 0.05$ . Participants responding yes also had significantly higher HDL ( $44.5 \pm 8.2$  vs.  $41.9 \pm 11.6$  mg/dl) and insulin sensitivity ( $5.2 \pm 3.4$  vs.  $4.5 \pm 3.6$ ) (both  $p < 0.05$ ). In multiple regression analysis controlling for age, gender, and BMI, a yes response was a significant and independent predictor of higher insulin sensitivity ( $\beta = 0.112$ ,  $p < 0.05$ ) and lower 2-hour glucose levels ( $\beta = -0.038$ ,  $p < 0.05$ ).

**CONCLUSIONS:** These data suggest that a simple PA screener may differentiate risk for cardiometabolic disease in Latino youth. Given that obesity and type 2 diabetes disproportionately impact Latino youth, simple PA screeners may provide clinicians with a useful tool when caring for this vulnerable population.

**2519** Board #194 MAY 31 3:30 PM - 5:00 PM

**Validity Of A Direct Observation Measure To Evaluate Group Exercise Classes**

Megan P. Duesterhaus<sup>1</sup>, Thomas L. McKenzie, FACSM<sup>1</sup>, Simon J. Marshall<sup>2</sup>. <sup>1</sup>San Diego State University, San Diego, CA. <sup>2</sup>San Diego State Research Foundation, San Diego, CA.

(No relationships reported)

Group exercise classes are a common physical activity modality but there is currently no validated objective measure to assess class content, instructor quality, or participant activity levels.

**PURPOSE:** To adapt and validate the System for Observing Fitness Instruction Time (SOFIT) for use in adult group exercise classes (SOFIT-X).

**METHODS.** Three sequential studies were used to adapt and validate a new direct observation measure. Study 1 used a nominal group technique with subject-matter experts to modify and content-validate the target behaviors of the SOFIT-X. Study 2 used behavioral assessment experts to establish criterion codes across seven types of group-exercise classes through iterative cycles of pilot testing and measure revision. Study 3 assessed ecological validity and inter-rater reliability via data collected by trained observers on 36 live group exercise classes.

**RESULTS.** Seven subject-matter experts developed four coding categories (posture, intensity, class context, and instructor behavior), 22 sub codes (observable behaviors within each coding category) with definitions, and 23 instructor behavior criteria to yield a face- and content-valid version of the new measure. Three trained observers then established criterion codes for 140 minutes of video-taped group exercise classes which were used subsequently for observer training. Interobserver agreement (IOA) among any two of three observers was 97%, 100%, 99%, and 100% on posture, intensity, class context, and instructor behavior. Agreement for all three observers ranged from 76% (intensity) to 87% (posture). Data collected on 36 live classes using SOFIT-X revealed that participants were predominantly ambulatory (49.4%) at light intensity (43.1%), designed to promote cardiovascular fitness (39.2%). Instructors mainly 'promoted and demonstrated' fitness (59.7%). IOA during live observation was 91%, 76%, 92%, and 86% for posture, intensity, class context, and instructor behavior, respectively.

**CONCLUSIONS.** SOFIT-X is a content- and criterion-valid measure that can be used to evaluate the quality of adult group exercise classes. Further research should attempt to improve the validity of coding exercise intensity. Funded by a research grant (1R18DP0021380-01) from the Centers for Disease Control and Prevention.

**2520** Board #195 MAY 31 3:30 PM - 5:00 PM  
**Validation Of New Sensewear Mini Armband Algorithms (version 5.2) In Children**

Jung-Min Lee<sup>1</sup>, YoungWon Kim<sup>1</sup>, Yang Bai<sup>1</sup>, Gregory J. Welk, FACSM<sup>1</sup>, Glenn A. Gaesser, FACSM<sup>2</sup>. <sup>1</sup>Iowa State University, Ames, IA. <sup>2</sup>Arizona State University, Phoenix, AZ. (Sponsor: Gregory J Welk, FACSM)  
(No relationships reported)

The SenseWear Mini Armband (SWM) has been shown to provide valid estimates of energy expenditure (EE) in adults and children. A new set of pattern recognition algorithms version (v) 5.2 has recently been developed to further improve precision for assessing free-living activities, particularly for non-locomotor activities.

**PURPOSE:** The purpose of the study was to evaluate the new v8.0 software (algorithm v5.2) compared to the previous v7.0 software (algorithm v2.2) in a sample of children performing a range of lifestyle activities ranging from sedentary to vigorous.

**METHODS:** Forty five boys (n=34) and girls (11) ages 7 to 13 years performed 12 randomly assigned activities (out of a set of 24) while wearing a SWM with simultaneous indirect calorimetry monitoring using a portable metabolic analyzer (Oxycon Mobile, OM). Each activity lasted 5 minutes with a 1 minute break in between. Data from minute 3 and minute 4 were utilized to obtain steady-state EE values from both OM and SWM. The SWM data were processed with both the v2.2 and v5.2 (pre-release version) algorithms.

**RESULTS:** Pearson product-moment correlations (r) with OM were similar for both algorithms (v5.2: r = 0.91; v2.2: r = 0.90). However, the absolute error rates (computed as average absolute value of the individual errors) were considerably lower for the new v5.2 algorithm (6.7%) compared with the v2.2 algorithm (30.1%). The v5.2 algorithms yielded non-significant (p>.05) differences in EE estimates for most of the walking related activities as well as for stationary cycling at moderate intensity (absolute error = 3.13%). Significant differences were found for vigorous cycling (absolute error = 20.46%).

**CONCLUSIONS:** The newly developed SenseWear v5.2 (pre-release) algorithms yielded more accurate estimates of EE than the v2.2 algorithms for monitoring lifestyle activities in children. The result for moderate intensity cycling is particularly noteworthy since this activity has proven difficult to assess with traditional accelerometry-based monitors.

**2521** Board #196 MAY 31 3:30 PM - 5:00 PM  
**Does Changing Firmware Affect Actigraph Gt1m And Gt3x Monitor Output?**

Jeffer E. Sasaki, Dinesh John, Amanda Libertine, Marianna Mavilia, Patty Freedson, FACSM. *University of Massachusetts, Amherst, MA.*  
(No relationships reported)

The flash-memory within ActiGraph GT1M and GT3X monitors contains software code (firmware) that performs various functions including signal filtering. ActiGraph frequently update firmware for these monitors. A recent study attributed significant differences between GT1M and GT3X activity counts to firmware differences.

**PURPOSE:** To compare vector magnitude (VM) activity counts from GT1M and GT3X monitors programmed with different firmware versions.

**METHODS:** Five GT3X and 7 GT1M firmware versions were selected for comparison. Each activity monitors was programmed with one of the 12 firmware versions. These GT1M and GT3X monitors were worn at the hip by 10 participants (age=25.5 ± 5.0, BMI= 23.3 ± 2.2 kg m<sup>-2</sup>) who performed treadmill (walking at 1.5, 3 and 4.5 mph and running at 6 mph) and simulated free-living (sitting, self-paced walking, filing papers, dusting, vacuuming, and cleaning the room) activities during two lab visits. Two-way ANOVAs (p<0.05) were used to compare VM activity counts from monitors with different firmware versions.

**RESULTS:** There were no significant differences in VM activity counts from monitors with different firmware versions during all activities. For treadmill activities, the smallest inter-firmware percent difference in activity counts was less than 1% between the GT3X with firmware 2.1.0 and the GT1M with firmware 5.1.0 during running at 6 mph. The largest difference was 19% between the GT3X with firmware 1.0.0 and the GT1M with firmware 4.3.0 during walking at 1.5 mph. For simulated free-living activities, the smallest inter-firmware percent difference in activity counts was less than 1% between the GT3X with 2.1.0 and the GT3X with 4.1.0 during self-paced walking. The largest difference was 41% between the GT3X with firmware 2.1.0 and the GT1M updated with firmware 4.1.0 during filing papers.

**CONCLUSION:** All firmware versions used in this study produced consistent results and seemed free of errors. Previously reported inconsistencies in firmware version 4.1.0 for the GT1M have been corrected. It is recommended that prior to a firmware release, the manufacturer should verify consistency in output with previous firmware releases by conducting both mechanical and human testing and provide these results to the end-user.

**2522** Board #197 MAY 31 3:30 PM - 5:00 PM  
**Calibration Method for Accelerometer-Based Physical Activity Monitors**

Crystal Coolbaugh, David Hawkins. *University of California, Davis, Davis, CA.*  
(No relationships reported)

Accelerometer-based physical activity monitors (PAMs) have recently been used to estimate ground reaction forces (GRFs) during gait. However, to estimate GRFs, the accelerometer must be properly calibrated and its amplitude range must match the site where the PAM will be worn (e.g. the hip). Currently, no standard PAM calibration methods exist.

**PURPOSE:** Develop and test a standardized PAM accelerometer calibration method.

**METHODS:** A PAM calibration system was developed and its utility demonstrated by calibrating a hip-PAM. Hip accelerations during gait can reach 6 g; therefore, the calibration system must provide accelerations over a range of at least 0 to 6 g. A calibration system capable of producing this acceleration range was constructed using a 122 cm long aluminum frame with its center mounted to the shaft of a variable speed motor (0-110 rpm). Custom fixtures were built to mount a PAM in 3 orthogonal orientations anywhere along the length of the frame (r). During a constant angular velocity ( $\omega$ ), the PAM axis aligned with the radial axis of the frame experiences a constant radial acceleration ( $a_r = \omega^2 r$ ). For the system characteristics defined,  $a_r$  can be varied between 0.3 and 8g. To illustrate the utility of this calibration system, 30 custom PAMS (±8g amplitude range) were calibrated. Each sensitive axis (±X, ±Y, and ±Z) was tested at 3  $a_r$  settings (18 total trials). A least squares solution was used to find accelerometer calibration factors from theoretical and raw acceleration values. To test the validity of the calibration, 2 intermediate  $a_r$  settings were tested. Applied and calibrated  $a_r$  values were compared. Percent error (normalized to amplitude) and Pearson correlations were calculated and results for the 30 PAMs were averaged.

**RESULTS:** PAMs were accelerated up to 7g without saturation indicating sufficient range for hip mounted applications. Normalized % error (mean ± standard deviation) averaged for the  $a_r$  validation settings were 2.6 ± 0.5, 2.2 ± 0.7 and 1.1 ± 0.2 for the X, Y, and Z axes respectively. Pearson correlations were excellent for 12 validation conditions (r = 1.0, p < 0.001).

**CONCLUSIONS:** A simple, inexpensive PAM calibration method was developed and shown to accurately find calibration factors for custom PAMs. Calibrated accelerations had less than 3% normalized error and did not saturate.

2523 Board #198 MAY 31 3:30 PM - 5:00 PM

**Validity Of The PAtacker Device For Observational Quantification Of Physical Activity**

Bruce S. Cohen<sup>1</sup>, Peter N. Frykman<sup>1</sup>, Kathleen Simpson<sup>1</sup>, Nathan R. Hendrickson<sup>1</sup>, Jan E. Redmond<sup>1</sup>, Barry A. Spiering<sup>1</sup>, Charles H. Negus<sup>2</sup>, Marilyn A. Sharp<sup>1</sup>.  
<sup>1</sup>USARIEM, Natick, MA. <sup>2</sup>L-3 Communications, San Diego, CA. (Sponsor: Dr Edward Zambraski, FACSM)  
(No relationships reported)

Most pedometer or accelerometer-based methods for tracking physical activity (PA) cannot assess body posture, external loads carried, activity intensity and type. Direct observation, by trained observers (OBS), can be used to capture this information. Custom software (PAtacker) has been developed for use on an Android smart phone to observe PA.

**PURPOSE:** To determine the validity of a direct observational method using the PAtacker software that quantifies (in seconds) and characterizes PA over extended periods of time.

**METHODS:** PA was classified into body positions, activity types, intensities and external loads carried. To establish a criterion score (CRIT), expert observers agreed on the scoring of a 30-min video. To determine validity, 6 trained observers (OBS), who were actively using the device, watched and scored this video immediately following training and again after 5 and 9 weeks. Agreement between OBS and the CRIT were analyzed. Mean % of the CRIT = OBS score - CRIT/CRIT x 100.

**RESULTS:** Agreement between OBS and CRIT, as measured by mean percent (SD) of the CRIT, is displayed in Table 1.

**CONCLUSIONS:** The PAtacker provides a valid method by which to classify body positions and activity types. While the load and intensity categories do not appear to be valid measures, they may be improved upon with additional training or redefining the operational definitions.

Table 1. Mean Percent Agreement (MPA) between OBS and CRIT (SD).

| Body Position | MPA       | PA Type      | MPA      | PA Type    | MPA       | Load (lbs) | MPA      | PA Intensity | MPA      |
|---------------|-----------|--------------|----------|------------|-----------|------------|----------|--------------|----------|
| Kneeling      | 101 (14)* | Calisthenics | 55 (10)  | Climbing   | 40 (51)   | 0-10       | 130 (45) | Rest         | 159 (32) |
| Lying         | 116 (17)* | Combatives   | 98 (16)* | Running    | 78 (39)   | 11-25      | 16 (90)  | Light        | 36 (50)  |
| Sitting       | 49 (29)   | Crawling     | 90 (14)* | Stationary | 118 (27)* | 51-75      | 171 (34) | Mod          | 58 (55)  |
| Standing      | 91 (10)*  | Lift/Carry   | 91 (13)* | Walking    | 107 (29)* |            |          | High         | 147 (56) |

\*Indicates 80-120% acceptable level of agreement. If MPA = 100 then CRIT values = Observed Values. If MPA < 100 then Observed values underestimated CRIT values. If MPA > 100 then Observed values overestimated CRIT values.

2524 Board #199 MAY 31 3:30 PM - 5:00 PM

**Evaluation Of The ActiGraph's 'low Frequency Extension' - A Pilot Study**

Yuri Feito, Heather Garner. Barry University, Miami Shores, FL  
(No relationships reported)

The accuracy of the ActiGraph accelerometer has been widely established. However, the effect of its 'low-frequency extension' (LFE) during treadmill walking and the free-living environment has not been studied.

**PURPOSE:** To determine the accuracy of the ActiGraph's LFE during treadmill walking and the free-living environment.

**METHODS:** Participants wore the StepWatch (SW) and the ActiGraph with and without the LFE activated (GT3X-LFE and GT3X-N). They walked on a treadmill at five different speeds (1.5, 2.0, 2.5, 3.0, and 3.5 mph) and wore the devices in the free-living environment for an entire day. The hand-tally counter and the SW served as the criterion method for the treadmill and free-living condition, respectively.

**RESULTS:** Repeated measures ANOVA showed the GT3X-N significantly underestimating step counts at speeds less than 2.5 mph. During the free-living condition, significant differences ( $P < 0.001$ ) were observed between the GT3X-LFE (overestimated), GT3X-N (underestimated) and the criterion method.

**CONCLUSIONS:** Repeated measures ANOVA showed the GT3X-N significantly underestimating step counts at speeds less than 2.5 mph. During the free-living condition, significant differences ( $P < 0.001$ ) were observed between the GT3X-LFE (overestimated), GT3X-N (underestimated) and the criterion method.

2525 Board #200 MAY 31 3:30 PM - 5:00 PM

**Validation of the Actical Step Count Function in Older Adults**

Marquell J. Johnson, Amanda Shelton, Justina Malin, Amber Schulzetenberge, Alyssa Hopfensperger. University of Wisconsin - Eau Claire, Eau Claire, WI. (Sponsor: David R. Bassett, Jr., FACSM)  
(No relationships reported)

**PURPOSE:** To assess the validity of the Actical accelerometer step count function in older adults.

**METHODS:** Twenty-nine participants aged  $67.70 \pm 6.07$  participated in the study. Actical step counts were compared to actual steps taken and those recorded by three pedometers (Yamax, Omron, & Walk4Life). Participants walked around a 200-m indoor track at a self-selected pace and performed treadmill walking at different speeds (40.2 m/min, 53.64 m/min, and 67.2 m/min) for 5 minutes at each speed. Two trained observers counted steps using hand tally counters for all walking activities. Paired t-tests were used to assess significant differences between actual steps taken and step counts registered by the activity monitors for all walking activities. Mean absolute percent error (MAPE) was also determined for all walking activities.

**RESULTS:** There was no statistical difference between Actical step counts and actual steps taken during self-paced walking ( $p = .50$ ; MAPE = .44%). During treadmill walking at 40.2 m/min speed, the Actical step counts were significantly different from actual steps taken ( $p < .01$ ; MAPE = 57%). During treadmill walking at 53.64 m/min, the Actical step counts were significantly different from actual steps taken ( $p < .01$ ; MAPE = 17%). During treadmill walking at 67.2 m/min, the Actical step counts were significantly different from actual steps taken ( $p < .05$ ) but had an acceptable MAPE value (1.51%). Overall, MAPE values were acceptable for all activity monitors during self-paced walking (< 3%). MAPE values were acceptable for the Omron and Walk4Life pedometers during treadmill walking at 67.2 m/min speeds (< 3%).

**CONCLUSIONS:** The Actical step count function provides valid estimates of step counts during self-paced walking and walking at constant speeds of  $\geq 67.2$  m/min in older adults.

2526 Board #201 MAY 31 3:30 PM - 5:00 PM

**Accuracy Of Sensewear® Pro Armband In Estimating Energy Expenditure During Steady-state And Non-steady-state Physical Activity**

Dharini M. Bhammar, Brandon J. Sawyer, Siddhartha A. Angadi, Glenn A. Gaesser, FACSM. Arizona State University, Phoenix, AZ  
(No relationships reported)

The SenseWear® Pro Armband (SWA) estimates energy expenditure (EE) for facilitation of physical activity and weight goals.

**PURPOSE:** We compared EE estimates from the SWA to indirect calorimetry-derived EE during physical activity.

**METHODS:** 17 men ages  $61 \pm 16$  years (BMI:  $29.1 \pm 4.6$  kg/m<sup>2</sup>) and 28 women ages  $48 \pm 20$  years (BMI:  $26.5 \pm 6.1$  kg/m<sup>2</sup>) performed 90-min and 65-min physical activity routines on separate days. The 90-min routine (steady-state: SS) routine consisted of 8-min bouts of 8 different activities including rest, walking, cycling, arm cranking, and simulated activities of daily living (ADL), performed in a random order, with a 4-min rest period between each activity (only steady-state data during min 4-7 were analyzed). The 65-min routine (non-steady-state: Non-SS) consisted of 5-min bouts of 12 different randomly assigned activities performed in one continuous routine, after an initial 5-min rest period, and included walking, jogging, cycling, rowing,

simulated sports, and ADL (all 65 min were analyzed). EE was measured by indirect calorimetry using the Oxycon™ Mobile (OM) and predicted using the SWA (Version 7.0). Pearson correlations, paired t-tests, intraclass correlation coefficients (ICC) and Bland-Altman plots were used for the analysis.

**RESULTS:** EE from SWA and OM were moderately correlated for both SS and Non-SS routines ( $r = 0.75$  and  $0.63$  respectively,  $p < 0.01$ ). SWA overestimated total EE (TEE) compared to OM for SS ( $337 \pm 80$  kcal vs  $252 \pm 59$  kcal,  $p < 0.01$ ) and Non-SS ( $293 \pm 80$  kcal vs  $212 \pm 62$  kcal,  $p < 0.01$ ) routines. For TEE, Bland-Altman analysis showed wide limits of agreement for SS (85 kcal, 95% CI: -14 to 181 kcal) and Non-SS (86 kcal, 95% CI: -3 to 175 kcal) routines. In the SS routine, strong ICC values were observed for walking at 4 mph (0.95) and jogging at 5 mph (0.95), and moderate ICCs were observed for rest and walking at 2.0 and 2.5 mph (0.75 to 0.77). Lower ICCs were obtained for the remaining activities, ranging from 0.35 (cycling) to 0.58 (walking at 3 mph). ICCs for each activity in the Non-SS routine ranged from 0.21 (arm cranking) to 0.85 (jogging at 5.5 mph).

**CONCLUSIONS:** Our results indicate that the SWA overestimates EE across a variety of low- and moderate-intensity activities, but produces better estimates of EE during high-intensity activities.

Supported by NIH grant R01 HL091006

**Physical Activity Scale for Elderly (PASE): A Cross-validation study for Chinese Older Adults**

Hongjun Yu<sup>1</sup>, Weimo Zhu, FACSM<sup>2</sup>, Jun Qiu<sup>1</sup>, Chenggang Zhang<sup>1</sup>. <sup>1</sup>Tsinghua University, Beijing, China. <sup>2</sup>University of Illinois at Urbana-Champaign, Champaign, IL.

(No relationships reported)

**PURPOSE:** To cross-validate PASE, a valid and reliable physical activity (PA) recall questionnaire, for the Chinese older adults.

**METHODS:** 66 (41 males & 25 females; aged  $70.0 \pm 7.1$ , Height =  $165.6 \pm 9.4$  cm, Weight =  $65.1 \pm 16.0$  kg, BMI =  $23.5 \pm 4.22$ ) Chinese older adults' 7-day energy expenditures (EE) were collected using Armband Pro 3. They were then asked to recall their PA using PASE before and after the Armband data collection. Total EE, average METs, steps, Measured EE, Measured Active EE by Armband Pro 3 were computed and compared with EE derived from PASE and test-retest reliability was computed also for PASE.

**RESULTS:** 77% of the subjects wore the armband for 24 hr. a day. The correlation between the Armband Measured Active EE and that reported by PASE is 0.58, which moderately supported the validity of PASE when applying it to the Chinese sample. The test-retest reliability coefficient of PASE is 0.87. In average, the Chinese older adults' daily PA are: Total EE =  $2088.92 \pm 539.86$  (METs), Average METs =  $1.62 \pm 0.35$ , Measured EE =  $1751.58 \pm 507.21$  METs, Measured Active EE  $502.52 \pm 288.26$  METs, according to the Armband.

**CONCLUSIONS:** PASE's validity and reliability was confirmed for the Chinese older adult sample and the Chinese older adults spent most of their time at low and light PA.

2528 Board #203 MAY 31 3:30 PM - 5:00 PM

**Validation Of The Mywellness Key In Walking And Running Speed**

Marco Bergamin<sup>1</sup>, Andrea Ermolao<sup>1</sup>, John C. Sieverdes<sup>2</sup>, Marco Zaccaria<sup>1</sup>, Silvano Zanuso<sup>3</sup>. <sup>1</sup>University of Padova, Padova, Italy. <sup>2</sup>University of South Carolina, Columbia, SC. <sup>3</sup>University of Greenwich, London, United Kingdom.

(No relationships reported)

**PURPOSE:** This study was performed to assess the validity of the MyWellness Key (MWK) accelerometer during a treadmill-based protocol. The identification of different exercise intensities is imperative to objectively measure time spent at a specified exercise intensity.

**METHODS:** Thirty subjects (age =  $24.5 \pm 2.6$  years; body mass index =  $22.5 \pm 2.5$  kg·m<sup>-2</sup>) participated in a treadmill protocol using three different walking velocities (3, 4.5, and 6 km·h<sup>-1</sup>) and run (8 km·h<sup>-1</sup>) while outfitted with a MWK. Exercise intensity was measured by indirect calorimetry (ICVO2).

**RESULTS:** The relationship between exercise intensity predicted from MWK (MWKVO2) and oxygen consumption (VO2), yielded a high and significant correlation ( $r = 0.944$ ;  $P < .001$ ) with standard error of estimate =  $2.42$  ml·kg<sup>-1</sup>·min<sup>-1</sup>. The average differences between the two methods (MWKVO2-ICVO2) were  $-0.79$  (-8.0%),  $-0.02$  (-0.02%),  $0.51$  (3.26%) and  $-0.74$  (-2.7%) ml·kg<sup>-1</sup>·min<sup>-1</sup> at 3, 4.5, 6, and 8 km·h<sup>-1</sup> respectively. Only the 3 km·h<sup>-1</sup> speed showed a difference when compared to the criterion measure ( $p < .001$ ). Bland and Altman analysis revealed less than a 1 MET difference in the mean at each point estimate and relatively tight distribution with the standard errors, especially with the 2 moderate walking speeds.

**CONCLUSIONS:** We found a high correlation between oxygen utilization and the MWK with low standard errors estimates. This indicates that this accelerometer can be used to accurately identify exercise intensities that are related to walking and running.

2529 Board #204 MAY 31 3:30 PM - 5:00 PM

**Validating GPS Data With The PALMS System To Detect Different Active Transportation Modes**

Jacqueline Kerr, Gregory Norman, Suneeta Godbole, Frederick Raab, Barry Demchak, Kevin Patrick. UCSD, San Diego, CA.

(No relationships reported)

Active transportation e.g. walking and cycling can contribute to overall physical activity levels. Travel diaries are often used to measure active transportation but are prone to self-report bias and individuals often round travel times to the nearest 5 minutes causing error. Hip worn accelerometers do not provide information on travel mode and do not detect cycling behavior. GPS devices that record speed of travel may improve assessment of active transportation. While GPS devices have become cheaper, smaller and more accurate, methods to process the data are not widely available.

**PURPOSE:** To test the validity of web-based GPS processing software to detect transportation mode.

**METHODS:** A total of 714 protocolized travel trips were made by trained researchers. They carried 2 GPS models set to collect data every 30 seconds. Trips across four transportation modes (bus, car, walk, cycle) were made in open space locations or downtown corridors (with more signal interference from buildings) with either continuous transitions across modes or with planned pauses. Start and end times of the journeys were noted to provide an annotated "truth" file to match to the processed GPS data. The GPS data were processed in the Personal Activity Location Measurement Software (PALMS). Sensitivity and specificity were tested and algorithm classification was considered correct if transportation mode was correct for 85% of the trip.

**RESULTS:** There were no significant differences by device model. Across conditions sensitivity ranged from .38-.64 and specificity ranged from .44-.59. Under the best conditions (i.e., pause between trips, open space location) sensitivity ranged from .73-1.0 and specificity ranged from .12-.25 for both device models.

**CONCLUSIONS:** Validation studies using field based trials of naturally occurring travel modes have not been reported before. Validation studies to date have not tested different conditions for algorithm specificity and sensitivity. Under optimal conditions the algorithm demonstrated good sensitivity but poor specificity, suggesting that further algorithm refinement is needed to improve accuracy of transportation classification. Our validation and processing protocols are available for researchers to use to test the conditions under which GPS may function best in their region.

2530 Board #205 MAY 31 3:30 PM - 5:00 PM

**Validity of the Bouchard Activity Record in Free-Living Older Adults**

Nora E. Miller<sup>1</sup>, Ann M. Swartz<sup>1</sup>, Teresa L. Hart<sup>2</sup>, John M. Hawkins, Jr.<sup>1</sup>, Scott J. Strath<sup>1</sup>. <sup>1</sup>University of Wisconsin - Milwaukee, Milwaukee, WI. <sup>2</sup>Arizona State University, Phoenix, AZ.

(No relationships reported)

Current literature supports a growing interest in identifying accurate and feasible assessment tools of sedentary and physical activity (PA) behaviors in older adults. The Bouchard Activity Record (BAR) represents a self-report PA assessment tool that could practically and feasibly be employed in field-based studies. To date, limited evidence exists on the validity of the BAR within older adults.

**PURPOSE:** To assess the validity of the BAR against accelerometry in an older adult population in a free-living environment.

**METHODS:** Forty-nine healthy participants (33 females,  $65.6 \pm 7.8$  yrs,  $25.6 \pm 4.3$  kg/m<sup>2</sup>; 16 males,  $68.6 \pm 8.1$  yrs,  $26.7 \pm 3.0$  kg/m<sup>2</sup>) completed a 1-day BAR while wearing the

activPAL™ (Glasgow, Scotland, UK) affixed to the right anterior thigh. For comparison purposes, the nine PA intensity categories from BAR were collapsed into three sedentary/activity categories (categories one & two=sedentary time; three=standing time; four-nine=walking time), and total time (hrs) spent in each category was calculated. Spearman's rho correlation coefficients and Wilcoxon signed rank tests were conducted to compare total sedentary, standing, and walking time between BAR and activPAL™.

**RESULTS:** Data from this study show that older adults self-reported 17.53 hours sedentary, 3.18 hours standing, and 3.27 hours walking on the BAR, compared with 17.28 hours, 3.94 hours, and 2.70 hours, recorded via activPAL™, for sedentary, standing, and walking respectively. Significant and moderately strong correlations were found between BAR and activPAL™ for time spent in sedentary ( $r=0.44$ ,  $p=0.002$ ) and walking ( $r=0.50$ ,  $p<0.001$ ) behavior. There were no significant mean differences reported between BAR and activPAL™ for time spent in sedentary, standing, or walking behaviors.

**CONCLUSION:** The BAR and activPAL™ provide similar results for sedentary behavior and PA time in this older adult sample with reported sedentary, standing, and walking time differing from objective measurement by 1%, 19%, and 21%, respectively over a 24-hour period of time. The BAR, therefore, represents a viable pen-and-paper option for those interested in assessing sedentary behavior and PA profiles in an older adult free-living population.

This work was supported by funding sources K01-AG025962 and UWM Research Growth Initiative.

**2531 Board #206 MAY 31 3:30 PM - 5:00 PM**  
**Accuracy Of The Fitbit Pedometer For Self-paced And Prescribed Physical Activity**

Ernesto R. Ramirez, Carlyn Peterson, Wanmin Wu, Gregory J. Norman. *University Of California, San Diego, La Jolla, CA.* (Sponsor: Jeanne Nichols, FACSM)  
(No relationships reported)

**PURPOSE:** The purpose of this study was to examine the validity of the FitBit pedometer (FB; FitBit Inc.) for measuring steps taken during self-paced and prescribed physical activity.

**METHODS:** A total of 17 adults (8 males, 9 females; age = 41.19, BMI = 28.82 kg/m<sup>2</sup>) participated in this study. Participants completed four to eight bouts of physical activities in a laboratory condition and in a simulated free-living condition. During the laboratory (treadmill) condition participants completed walking bouts at a slow pace (1.5 mph), a normal pace (3.0 mph), a brisk pace (4.0 mph) and one jogging bout (5.5 mph). Each bout lasted three minutes. Participants then completed 400m self-paced walking bouts at slow, normal, and brisk paces as well as one 400m jog on an outdoor track. Male participants wore one FB and one Omron HJ-720IT (OM) on the right hip attached to an elastic belt and one FB in the right front pocket. Female participants wore the devices in the same configuration but also wore an additional FB attached to the front/center of the sports bra. Absolute and percent differences were calculated for FB vs. directly observed (DO) steps. Linear mixed models were determined effects of body location, speed, condition (laboratory vs. free-living) on FB accuracy.

**RESULTS:** The magnitude of the difference between DO and the FB devices (M(SD); range) across all activities was small for both the FB-waist (2.0%(4.7%); -6 - 23%) and FB-br (0.8%(4.3%); -11 - 15%) and moderate for the FB-pocket (8.8%(16.8%); 4 - 74%). Model parameter estimates from the full factorial mixed-model indicated the FB under estimated by 24 (SE = 2.83) steps across all conditions compared to direct observation. Significant parameter estimates for body location, speed and the body location x speed interaction (all  $p < .001$ ) indicated that the FB in the pocket underestimated steps more than on the waist, both devices underestimated steps more as speed increased, and the magnitude of the underestimation increased more for the pocket compared to the waist as speed increased.

**CONCLUSIONS:** The FB appears to be a valid device for assessing step counts in adults when worn on the waist. Caution should be taken when assessing activities at higher ambulatory speeds. Further research is needed to better understand the validity of the FB in free-living conditions.

---

**2532 Board #207 MAY 31 3:30 PM - 5:00 PM**  
**Determinants of Variance in Habitual Total and Moderate-to-Vigorous Physical Activity in Overweight Adults**

David Paul<sup>1</sup>, Matthew Kramer<sup>2</sup>, William Rumpel<sup>2</sup>, Kim Stote<sup>2</sup>, Beverly Clevidence<sup>2</sup>, G. Keith Harris<sup>2</sup>, David Baer<sup>2</sup>. <sup>1</sup>University of Idaho, Moscow, ID. <sup>2</sup>US Department of Agriculture, Beltsville, MD. (Sponsor: Justin Moore, FACSM)  
(No relationships reported)

**PURPOSE:** To determine the number of days of data and number of subjects necessary to accurately represent habitual total physical activity (TPA) and moderate-to-vigorous physical activity (MVPA).

**METHODS:** Seventy-one women and men wore accelerometers for seven day intervals, one week-on and one-week off, for 6 consecutive months. Daily counts were log transformed before analysis in a mixed model.

**RESULTS:** TPA was 195.2±63.1 counts/min/day, while subjects averaged 27.1±16.4 minutes of MVPA per day. Day of week effects were present (Sundays lower than the other days), but no monthly effects were found. Percent body fat was inversely related to log counts for both TPA and MVPA; women had significantly higher log counts for TPA, but not MVPA; and age was not a significant factor. The principle source of subject related variation (after accounting for fixed effects) in TPA was within-subject (day-to-day) (57.2%); the other two components were between-subject (33.3%) and week-to-week (9.4%). Based on within-subject variances, only 5 days of data are required to represent habitual TPA, with coefficients of variation (CV) of 5%. Similar percentages were obtained for MVPA: 57.0%, 35.0%, and 7.9%. Estimates of habitual

MVPA were twice as variable (based on CVs): therefore 8 and 30 days of data are necessary to represent habitual MVPA, with resulting CVs of 10 and 5%, respectively. Based on between-subject variances, to detect a 10% difference between two groups at a power of 85% requires approximately 125 and 450 subjects per group for TPA and MVPA, respectively.

**CONCLUSIONS:** TPA and MVPA counts are influenced by factors

such as day of the week, body composition, and gender. Estimates of MVPA are more variable than TPA in free-living adults, therefore more days of data are required to estimate habitual physical activity. The large variances translate into requiring large sample sizes to detect treatment differences, as measured by TPA and MVPA counts.

**Mass Media Campaigns: Outcomes Vary by Degree to Which Self-Reported Measures Assess Weekly Physical Activity**

David R. Brown, FACSM, Jesus Soares, Jacqueline Epping, Tina Lankford. *Centers for Disease Control and Prevention, Atlanta, GA.*  
(No relationships reported)

The Task Force on Community Preventive Services concluded that there is insufficient evidence to determine the effectiveness of stand alone mass media campaigns to increase physical activity (PA) at the population level. Findings were based on self-reported PA and varied in consistency and magnitude.

**PURPOSE:** Determine if self-report measures of PA used in stand alone mass media studies that provide an estimate of the weekly volume of physical activity (wVPA), i.e., frequency [F], intensity [I], and duration [D], lead to greater magnitude of PA behavior change compared to measures that do not provide indepth estimates of the wVPA.

**METHODS:** Relying on a qualitative assessment of self-report measures in 13 mass media studies, 2 authors independently ranked the measures high, medium, or low based on each measures ability to estimate wVPA. Measures asking respondents to report their F, I, and D of weekly activity were ranked high. Measures that obtained information on 2 of the 3 indicators of wVPA were rated medium. Measures based on a single item (more active? yes or no) or on 1 indicator were ranked low. Differences between rankings of the 2 raters were discussed until agreement was obtained. A Kappa coefficient was calculated to determine interrater agreement of the raters' initial assessments. The median relative % change in PA outcomes by rankings of the measures were calculated.

**RESULTS:** The Kappa coefficient among the 2 raters was 0.77 (adequate agreement). Studies (n=5) possessing high potential to provide information about wVPA resulted in a median relative increase in PA of 3.1% (interquartile range = -31.2%, 56.5%), studies (n=2) having medium potential to yield information about respondents' wVPA lead to a median relative increase in PA of 1.4% (interquartile range = -1.6%, 4.4%), and studies (n=6) having low potential to yield information about respondents' wVPA resulted in a median relative increase in PA of 12.2% (interquartile range = 5.4%, 18.2%).

**CONCLUSION:** Numerous factors may have influenced outcomes in the stand alone mass media studies reviewed. Our findings highlight just one of these factors and reinforces the need to consider PA measurement in the evaluation of community- or population- based interventions.

2534 Board #209 MAY 31 3:30 PM - 5:00 PM

**Agreement of a Repeated Primary Care Physical Activity Measure with Accelerometry**

Trevar Ball<sup>1</sup>, Janet M. Shaw, FACSM<sup>1</sup>, Elizabeth A. Joy, FACSM<sup>2</sup>, Jessica Greenwood<sup>1</sup>. <sup>1</sup>University of Utah, Salt Lake City, UT. <sup>2</sup>Intermountain Healthcare, University of Utah, Salt Lake City, UT.  
(No relationships reported)

Repeatability has not been estimated simultaneously with agreement in self-report physical activity (PA) methods comparison studies.

**PURPOSE:** To apply the Bland-Altman limits of agreement method (LoA) to repeated measures (RM) of a self-report PA measure designed for primary care.

**METHODS:** 45 clinic staff wore an accelerometer (accel) for 7 days and then self-reported days they acquired  $\geq 30$  bout-mins of moderate to vigorous PA (MVPA). 11 of these 45 staff repeated this procedure 18 months later. Both accel-PA and self-report PA were recorded as number of days with  $\geq 30$  mins MVPA. The LoA method was applied by estimating the mean difference of days with  $\geq 30$  mins MVPA between measures, and the standard deviation (SD) of differences about the mean, i.e. 95% LoA. 95% LoA were estimated by within and between-subject variances from ANOVA, with the subject as the factor. A 95% repeatability coefficient for each method was estimated by  $1.96\sqrt{2}$  within-subject SD between RM.

**RESULTS:** Staff ( $38.3 \pm 9.6$  yr) were mostly female (91%) and Caucasian. The self-report PA measure overestimated days  $\geq 30$  mins MVPA by a mean of 1.86 days. 95% of the differences in days  $\geq 30$  mins MVPA between RM of accel-PA and self-report PA were between -1.22 and 4.95 days (see Figure). The repeatability coefficient of the self-report PA was 71% greater than the coefficient of accel-PA.

**CONCLUSIONS:** Agreement of self-report PA with a criterion PA measure is most useful when self-report PA also agrees with itself - that is, it's repeatable. This small sample had poor agreement with one repeated measure of self-report PA, with 95% LoA between -1.22 and 4.95 days.

Funded in part by DHHS Office on Women's Health (ASTWH070006-01-00); University of Utah Department of Family and Preventive Medicine.

2535 Board #210 MAY 31 3:30 PM - 5:00 PM

**The Influence of Body Mass Index on Physical Activity Level and Recall Accuracy**

Katrina D. DuBose, FACSM, Brooke Graves, Thomas D. Raedeke, Lucas Carr, Lesley Lutes. East Carolina University, Greenville, NC.  
(No relationships reported)

**PURPOSE:** To evaluate whether normal weight and overweight/obese college students differ on physical activity level and self-reported physical activity recall accuracy.

**METHODS:** On day one, 52 college students ( $18.7 \pm 0.85$  years) had height and weight measured and received an ActiGraph GT1M accelerometer to wear for 7 consecutive days. After wearing the GT1M, participants completed self-report physical activity questions on the Behavior Risk Factor Surveillance Survey (BRFSS) and the International Physical Activity Questionnaire (IPAQ). Body mass index (BMI) was classified as either normal weight  $<25.0$  kg/m<sup>2</sup> ( $n=30$ ;  $21.08 \pm 2.01$  kg/m<sup>2</sup>) or overweight/obese:  $\geq 25.0$  kg/m<sup>2</sup> ( $n=22$ ;  $29.57 \pm 4.76$  kg/m<sup>2</sup>). Recall accuracy was calculated by self-reported minutes in moderate and vigorous physical activity minus minutes in moderate and vigorous physical activity measured by the GT1M. Independent *t*-tests compared the time spent in moderate and vigorous physical activity on the BRFSS, IPAQ, and GT1M by BMI group. The independent *t*-tests compared differences between the BMI groups and the level of recall accuracy on the BRFSS and IPAQ questionnaires for moderate and vigorous physical activity.

**RESULTS:** No significant differences were found between normal and overweight/obese participants on the average minutes per day spent in moderate and vigorous physical activity based on the BRFSS, IPAQ, and ActiGraph GT1M ( $p>.05$ ). Recall accuracy was similar between the normal weight and overweight/obese groups on the BRFSS (Moderate: normal= $104.29 \pm 116.9$  min/d, overweight/obese= $88.56 \pm 106.96$  min/d; Vigorous: normal= $24.43 \pm 25.28$  min/d, overweight/obese= $44.28 \pm 47.33$  min/d) and IPAQ questionnaires (Moderate: normal= $108.14 \pm 139.26$  min/d, overweight/obese= $89.42 \pm 116.81$  min/d; Vigorous: normal= $34.15 \pm 40.08$  min/d, overweight/obese= $38.09 \pm 46.03$  min/d).

**CONCLUSIONS:** These results suggest that in college students physical activity levels and recall accuracy are similar regardless of BMI.

2536 Board #211 MAY 31 3:30 PM - 5:00 PM

**Validity Of Actigraphs Uniaxial And Triaxial Accelerometers For Assessment Of Physical Activity In Adults**

Duncan GE McMillan, Alexandra Alexandra, Morgan Fippinger, Gunnar Fillerup, Louise A. Kelly. California Lutheran University, Thousand Oaks, CA.  
(No relationships reported)

**PURPOSE:** To assess the validity of the uniaxial GT1M and the triaxial GT3X Actigraph accelerometers against oxygen consumption

**METHODS:** Thirty-four participants aged 18 to 30 years performed three 6-minute bouts of exercise on a treadmill at 4.8, 6.4, and 9.7 km.h-1. Oxygen consumption was measured minute-by-minute using a metabolic system.

**RESULTS:** The GT3X had significant higher counts at all speeds as compared with the GT1M accelerometer ( $p<0.001$ ). Mean error for the GT1M at 4.8 km.h-1 was +2862 cpm (limits of agreement +1897 to +3828), at 6.4 km.h-1 was +4852 cpm (limits of agreement +3616 to +6088), and at 9.7 km.h-1 was +9369 cpm (limits of agreement +6589 to +12148). Whereas, mean error for the GT3X at 4.8 km.h-1 was +5716 cpm (limits of agreement +3589 to +7843), at 6.4 km.h-1 was +13142 cpm (limits of agreement +8329 to +17954), and at 9.7 km.h-1 was +8580 cpm (limits of agreement +5846 to +11314).

**CONCLUSIONS:** These data suggest that the uniaxial GT1M and the triaxial GT3X Actigraph accelerometers are valid tools for measuring treadmill walking and jogging.

2537 Board #212 MAY 31 3:30 PM - 5:00 PM

**Distributional Characteristics of Athletic Performance**

Andrew C. Cornett<sup>1</sup>, Joel M. Stager<sup>2</sup>, Karen Kafadar<sup>2</sup>. <sup>1</sup>Eastern Michigan University, Ypsilanti, MI. <sup>2</sup>Indiana University, Bloomington, IN.  
(No relationships reported)

**INTRODUCTION:** It is difficult to characterize the distribution shape for an athletic performance variable, due largely to unavailable data. On the rare occasions when an adequate data set is available, discussion typically focuses on measures of location and dispersion and ignores skewness of the data and elongation (or heaviness) of the tails.

**PURPOSE:** This study characterizes the skewness and elongation parameters for an athletic performance variable (swim times) and assesses the effects of age and sex on these distribution parameters.

**METHODS:** Data for this project was provided by USA Swimming (USAS) and consisted of the best 50-yard Freestyle performance for all USAS registered male and female swimmers from 6-19 years of age that competed in the event from 2005-2010 ( $N = 1,193,362$ ). First, the distribution skewness and elongation parameters were assessed using methods previously described (Hoaglin, 2006). Then, MANOVA was conducted to test for differences in the parameters for age, sex, and competition year.

**RESULTS:** MANOVA revealed a highly significant effect of age on both the skewness and elongation parameters ( $V = 1.59$ ,  $F(26, 130) = 19.27$ ,  $p < .001$ ), a result that was confirmed by separate univariate ANOVAs. There was significantly greater positive skew (0.44-0.49) for the middle ages (9-15 years) as compared to the skewness (0.37-0.42) for the youngest and oldest ages (6-7 and 16-18 years). The elongation parameter was positively correlated with age with the smallest value (-0.02) occurring for 6 year old swimmers and the greatest values (0.10-0.11) occurring for the oldest swimmers (17-19 years).

**CONCLUSIONS:** Positive skewness was confirmed for all combinations of age, sex, and competition year. The degree of skewness appears to be influenced by the number of swimmers of a given age. The positive correlation between age and elongation is a novel finding. Whether or not a similar relationship exists for variables such as height and muscle mass is unclear and could aid in a better understanding of the elongation parameter for this particular athletic performance variable.

2538 Board #213 MAY 31 3:30 PM - 5:00 PM

**Estimation Of Energy Expenditure Using Heart Rate And Triaxial Accelerometry In Overweight And Obese Adults**

Christopher C. Howe, Chris Easton. *Kingston University, Kingston upon Thames, United Kingdom.* (Sponsor: Dr Yannis Pitsiladis, FACSM)  
(No relationships reported)

To date, no study has examined the validity of the Actitrainer tri-axial accelerometer (AT) (Actigraph, Florida, USA) in combination with heart rate (HR) for prediction of energy expenditure (EE) during walking in overweight and obese adults.

**PURPOSE:** To examine the validity of existing regression equations (Freedson and vector magnitude equations (VM)) based on accelerometer counts (AC) from the AT for predicting EE in overweight and obese adults during treadmill and outdoor walking. Further, to examine whether novel gender-specific equations combining AC, HR and body mass (BM) can enhance the accuracy of the EE prediction.

**METHODS:** Twenty overweight or obese adults (eight males and twelve females, age  $43 \pm 11$  years, BMI  $30.5 \pm 4.9$  kg/m<sup>2</sup>) completed a 30 min incremental walking protocol on a treadmill in a laboratory setting (4-6.5 km·h<sup>-1</sup>). VO<sub>2</sub> and VCO<sub>2</sub> were measured throughout via breath-by-breath indirect calorimetry (IC) and EE for each stage was calculated using the Weir equation. AC and HR were continuously measured using the AT and Polar HR monitor. Novel gender-specific EE prediction equations were generated by multiple linear regression using AC, HR and BM. In a separate study, ten overweight and obese adults (five males and five females, age  $44 \pm 13$  years, BMI  $30.4 \pm 4.0$  kg/m<sup>2</sup>) conducted a self-paced three kilometre external walk during which EE, AC and HR were measured as before. EE was estimated using existing and novel prediction equations for both treadmill and external walks and compared to IC.

**RESULTS:** The Freedson equation overestimated EE ( $7.9 \pm 1.3$  kcal·min<sup>-1</sup> vs. IC:  $5.5 \pm 1.1$  kcal·min<sup>-1</sup>,  $P < 0.01$ ) during treadmill walking as did the VM equation ( $7.1 \pm 1.1$  kcal·min<sup>-1</sup>,  $P < 0.01$ ). There was no difference between EE estimated using the novel gender specific prediction equations and EE measured by IC during either treadmill ( $P = 0.993$ , standard error of estimate (SEE)  $0.17$  kcal·min<sup>-1</sup>) or outdoor walking ( $P = 0.114$ , SEE  $0.77$  kcal·min<sup>-1</sup>).

**CONCLUSIONS:** The Freedson and VM equation significantly overestimated EE in overweight and obese adults during walking exercise. However, novel gender specific prediction equations based on VM, HR and BM appear to provide valid estimations of EE in this population during both treadmill and self-paced external walking.

2539 Board #214 MAY 31 3:30 PM - 5:00 PM

**Physical Activity Pattern Complexity Reveals Associations between Pattern, Health and Socio-Demographic Determinants**

Oleksii Mandrychenko, Malcolm Howard Granat, Sebastien François Martin Chastin. *Glasgow Caledonian University, Glasgow, United Kingdom.*

(O. Mandrychenko: Salary; PhD research scholarship provided by the Glasgow Research Partnership in Engineering, Scottish Overseas Research Student Award Scheme.)

**PURPOSE:** Free-living physical activity is comprised of complex patterns of activity periods and sedentary behaviour. Recent studies have suggested that these patterns have an impact on health. Currently, there is no methodology available that can robustly quantify the patterns of physical activity. However, complexity theory provides an analytical framework to develop such a measure. The aim of this study was to investigate the relationship between the complexity of patterns of physical activity, health and socio-demographics (such as complexity of patterns and BMI, age, gender, socioeconomic deprivation, and occupation).

**METHODS:** Data was obtained from 120 adults who wore a physical activity monitor for 5 to 7 continuous days. The complexity of patterns of physical activity was quantified using a robust method based on GZIP compression. Regression models were developed to investigate the relationship between common physical activity determinants and the complexity of the patterns.

**RESULTS:** The regression model for the complexity of patterns of physical activity adjusted for the volume of physical activity was significant ( $p < .001$ ). The model explained 52% of the variance in the dataset. All regression coefficients were significant: BMI ( $p < .001$ ), age ( $p = .004$ ), socioeconomic deprivation ( $p = .043$ ), occupation ( $p = .002$ ), interaction of socioeconomic deprivation and occupation ( $p = .002$ ), interaction of gender and occupation ( $p = .017$ ).

**CONCLUSIONS:** Complexity of patterns of physical activity reveals that only 50% of the variance in physical activity can be explained. The complexity has a clear association with the determinants of physical activity independently of the amount of physical activity. Quantifying complexity of the pattern provides important added information to inform the design, and monitor the impact of interventions.

**Role Of The Playground Environment On Levels Of Physical Activity In Elementary School Children**

Heidi J. Nace<sup>1</sup>, Christine A. Schaefer<sup>1</sup>, Eve M. Kutchman<sup>2</sup>, Claudio R. Nigg<sup>3</sup>, Lois A. Brink<sup>2</sup>, James O. Hill<sup>2</sup>, Raymond C. Browning, FACSM<sup>1</sup>. <sup>1</sup>Colorado State University, Fort Collins, CO. <sup>2</sup>University of Colorado Denver, Denver, CO. <sup>3</sup>University of Hawaii at Manoa, Honolulu, HI.

(No relationships reported)

The school environment offers opportunities for children to be active, particularly during recess. Yet the influence of the playground on levels of daily physical activity (PA) has not been well described.

**PURPOSE:** To determine the role of renovated (Learning Landscapes, LL) vs. non-renovated playgrounds on levels of recess, school day and after school PA in elementary school children. Data collected serve as baseline for the Intervention of Physical Activity in Youth (IPLAY) Study.

**METHODS:** We measured 5-6 days of free-living PA via wrist-mounted Actical accelerometers in 277 low socioeconomic status elementary school children in metropolitan Denver, CO. We applied age specific cutpoints to the data to determine minutes and percent time spent in moderate-vigorous PA (MVPA). Univariate ANOVA was conducted to determine between-subject effects of weight status, presence of LL and sex on recess, school day, after school (end of school day-5PM) PA, and likelihood of meeting the PA guideline.

**RESULTS:** During recess (see figure) and the school day, but not after school, children in LL accumulated more PA than their non-LL counterparts (school day mins MVPA: 35.7 (LL) vs. 25.5 (non-LL)). Boys were significantly more active than girls at all time points. Normal weight children were more active than overweight children over the course of the school day. Children in LL were no more likely than their non-LL counterparts to meet the guideline for daily MVPA.

**CONCLUSIONS:** In LL schools, normal weight girls and all boys participate in greater levels of recess PA compared to non-LL. However, overweight girls' levels of PA are not different between playground conditions, signifying the need for additional approaches to encourage them to be more active.

---

2541 Board #216 MAY 31 3:30 PM - 5:00 PM

**Objectively Measured Physical Activity, Sedentary Behavior and Academic Performance in Finnish School-Aged Children**

Heidi Syväoja<sup>1</sup>, Marko Kantomaa<sup>2</sup>, Timo Ahonen<sup>3</sup>, Tuija Tammelin<sup>1</sup>. <sup>1</sup>LJKES- Research Center for Sport and Health Sciences, Jyväskylä, Finland. <sup>2</sup>Imperial College London, London, United Kingdom. <sup>3</sup>University of Jyväskylä, Jyväskylä, Finland.

(No relationships reported)

**PURPOSE:** To provide basic data of objectively measured physical activity and sedentary behavior of Finnish school-aged children, and determine the relationships between objectively and subjectively measured physical activity and sedentary behavior and academic performance.

---

**METHODS:** 278 children from five schools in the Jyväskylä school district in Finland (59% of the 475 eligible students; their mean age was 12.2 years; 55% were girls) participated in the study in the spring of 2011. Self-reported physical activity and screen time were evaluated by questions used in the WHO Health Behavior in School-aged Children (HBSC) study. Children's physical activity and sedentary time were measured objectively by using an ActiGraph GT1M/ GT3X accelerometer for seven consecutive days. A cut-off value of 2,000 counts per minute was used for moderate to vigorous physical activity (MVPA) and 100 counts per minute for sedentary time. Schools' grade averages were provided by the education services of the city of Jyväskylä. Cross-tabling and the analysis of variance were used to analyze the relationships between physical activity, sedentary behavior and academic performance.

**RESULTS:** Based on objective measurements, 59% of the children met the recommended level of 60 minutes of MVPA per day. Children were sedentary 59% of their waking hours. Children's self-reported screen time was 3.6 hours per day on average. Objectively measured physical activity ( $p=0.595$ ) and sedentary time ( $p=0.551$ ) were not associated with the schools' grade average. However, high levels of self-reported physical activity ( $p=0.001$ ) and low levels of self-reported screen time ( $p<0.001$ ) were associated with the high average of school grades.

**CONCLUSIONS:** The level of physical activity and sedentary behavior of Finnish school-aged children is comparable with that reported in international results. In this study, self-reported physical activity was directly, and screen time inversely, associated with academic performance. Objectively measured physical activity and sedentary time were not associated with academic performance. Objective and subjective measures may reflect different constructs and contexts of physical activity and sedentary behavior in association with academic outcomes.

---

**2542** Board #217 MAY 31 3:30 PM - 5:00 PM

**Factors Associated With Children's Walking Or Biking To School**

Robin DeWeese, Punam Ohri-Vachaspati. *Arizona State University, Phoenix, AZ.*

*(No relationships reported)*

The percentage of trips youth made to and/or from school every day using active transport (e.g., walking or biking) declined from almost 50% of all trips in 1969, to approximately 13% of trips in 2009. The daily commute to and from school accounts for 22% of both total trips and time spent traveling by 5-18 year-olds. These facts, coupled with the nation's childhood obesity epidemic, led the 2010 White House Task Force on Childhood Obesity to recommend a goal of increasing by 50% active transport to school among 5-18 year-old youth.

**PURPOSE:** To determine the prevalence of and factors associated with walking or biking to school in four low-income urban communities with large Hispanic and black populations.

**METHODS:** A random digit-dial survey of 1400 households was conducted in 2009-10. Survey questions included information about active transport to school for one randomly selected child in the household, parental perceptions of the neighborhood physical environment, and household demographic characteristics. Objective data on neighborhood physical activity facilities was collected as well. Geographic location of households and physical activity facilities were geocoded to calculate proximity measures. Descriptive statistics and bivariate relationships were investigated using SPSS.

**RESULTS:** 39% percent of all children walked to school on a regular basis. Factors associated with walking to school included income level (45% of students  $\leq 200\%$  of poverty walked to school vs 32% of those at  $>200\%$  of poverty), presence of sidewalks (43% of children living in communities with sidewalks walked to school vs 18% living in communities with no sidewalks), and perceived neighborhood pleasantness (44% of children living in neighborhoods perceived as pleasant walked to school vs 33% living in unpleasant neighborhoods).

**CONCLUSION:** Physical environment plays a critical role in whether children use active transport such as walking or biking to get to school.

---

**2543** Board #218 MAY 31 3:30 PM - 5:00 PM

**Correlates of Physical Fitness in Children. A Multilevel Analysis**

Thayse Natacha Q F Gomes<sup>1</sup>, Fernanda K. Santos<sup>2</sup>, Raquel N. Chaves<sup>2</sup>, Michele C. Souza<sup>2</sup>, Daniel Santos<sup>1</sup>, Rojapon Buranarugsa<sup>1</sup>, André Seabra<sup>1</sup>, Rui Garganta<sup>1</sup>, José A R Maia<sup>1</sup>. <sup>1</sup>CIF12D, Faculty of Sport, University of Porto, Porto, Portugal. <sup>2</sup>CAPEs Foundation, Ministry of Education of Brazil, Brasília – DF, Brazil and CIF12D, Faculty of Sport, University of Porto, Porto, Portugal.

*(No relationships reported)*

In the last decade, children physical fitness (PF) levels have declined. School conditions and/or environmental characteristics may be of great help in promoting increases in PF among children.

**PURPOSE:** To identify student- and school-level correlates responsible for inter-individual variability in PF levels of Portuguese children.

**METHODS:** PF levels and school characteristics were collected in 2801 children (aged 6 to 10 years) of both gender (1342 girls and 1460 boys) in 75 primary schools from North of Portugal. PF was assessed with Fitnessgram test battery, and physical activity with the Godin & Shephard questionnaire; body mass index (BMI) was also computed. School characteristic included socio-geographical localization (rural, urban and suburban area), frequency of physical education (PE) classes, professional qualification of PE teachers, and student participation in swimming classes. Results from each PF test were transformed in a z-score and then summed, creating an overall PF-score. Multilevel modeling was used to examine individual and school characteristics related to the overall PF-score. HLM 6.0 software was used in all analysis.

**RESULTS:** School-effects explain only 14% of the total variance of PF in children. Fitter children are more physically active ( $\beta=0.017$ ,  $p<0.05$ ) and older ( $\beta=0.708$ ,  $p<0.05$ ); and boys showed higher PF levels than girls ( $\beta=0.530$ ,  $p<0.05$ ); on the other hand, heavier children had a lower PF-score ( $\beta=-0.193$ ,  $p<0.05$ ). At the school-level, only school setting was related to children's PF-score, where rural children ( $\beta=0.626$ ,  $p<0.05$ ) were fitter than urban or suburban.

**CONCLUSIONS:** At the individual level, age, gender, physical activity, and BMI are relevant correlates of PF; at the school level the socio-geographical school localization was a significant predictor of PF levels among Portuguese children.

Supported by Fundação para Ciência e Tecnologia (FCT). Contract PTDC/DES/67569/2006 FCOMP-01-0124-FEDEB-09608.

**2544** Board #219 MAY 31 3:30 PM - 5:00 PM

**Assessing Physical Activity in Children - a Comparison: Parental Questionnaire versus Objective Measurement with Accelerometry**

Susanne Kobel, Sarah K. Kettner, Benjamin Koch, Jens Dreyhaupt, Nanette Fischbach, Rainer Mueche, Juergen M. Steinacker, FACSM. *Ulm University, Ulm, Germany.*

*(No relationships reported)*

Assessing physical activity (PA), especially in young children has become to play an important role but can be challenging. According to recent studies (e.g. Andersen et al, 2011), only a minority of children reach the current recommendations on health-enhancing PA. Many of these results are based on self-report questionnaires and parental accounts.

**PURPOSE:** This study therefore aims to compare an objective assessment method with a subjective one in order to gain a better understanding whether parental report data can be used to determine daily PA in children.

**METHODS:** PA was measured in 374 children (7.1 $\pm$ 0.7yrs; 50% male, 16.1 $\pm$ 2.4 BMI) over four consecutive days using accelerometry combined with heart rate (Actiheart; CamNtech, UK). Parents were asked to estimate the number of days a week their child is moderately to vigorously active (MVPA); so they would start sweating or breathing heavily and therefore equating to current guidelines) for a minimum of 60 minutes. Measured daily MVPA was defined as activity with a heart rate above 140bpm and compared with parental responses. Kendall's correlation coefficients are reported, based on the total measured and reported PA.

**RESULTS:** Over a period of four consecutive days, the children spent an average of 55 min ( $\pm 27.2$ ) at MVPA and 36.7% managed to achieve a mean of 60 min/day. 69.1% of parents reported 60 min/day of MVPA of their child on 0-3 days/week, 24.4% on 4-5 days/week and 6.5% on 6-7 days/week. No correlation was found between parental responses to the question if their child is physically active for at least 60 minutes daily and PA objectively measured by Actiheart. This non-existing correlation also applies for those children who reached the 60 minutes MVPA per day as well as for those whose parents categorise their children as active. No gender difference was found.

**CONCLUSION:** This study shows that in order to obtain reliable information about children's daily PA, parental estimation of PA in a structured questionnaire is not sufficient. Therefore, objective measurements such as accelerometry and heart rate are needed. However, it might be discussed whether more or more specific questions about PA would overcome this problem.

2545 Board #220 MAY 31 3:30 PM - 5:00 PM

**Impact of Physical Activity Breaks on Healthy Activity Children Policy (HSP-S-000) Adherence in Middle Schools**

Ramine C. Alexander<sup>1</sup>, Melicia C. Whitt-Glover, PhD, FACSM<sup>2</sup>, Sandra Ham<sup>3</sup>, Nancy P. Sutton<sup>4</sup>, Joan M. Belnap<sup>5</sup>, Toni (Antronette) Yancey, MD, MPH<sup>6</sup>. <sup>1</sup>Virginia Polytechnic Institute and State University, Blacksburg, VA. <sup>2</sup>Gramercy Research Group, Winston-Salem, NC. <sup>3</sup>Sandra Ham Consulting, Chicago, IL. <sup>4</sup>Winston-Salem/Forsyth County Schools, Winston-Salem, NC. <sup>5</sup>YMCA of Northwest North Carolina, Winston-Salem, NC. <sup>6</sup>UCLA School of Public Health, Los Angeles, CA. (No relationships reported)

In North Carolina, a statewide policy mandates that schools provide at least 30 minutes of daily PA for children in grades K-8, over and above PE requirements (HSP-S-000). To assist middle schools with policy adherence we provided 16 middle schools in suburban NC with Instant Recess® (IR), which provides 10-minute classroom-based PA breaks, available on CD or DVD.

**PURPOSE:** This study evaluated the impact of IR in 16 middle schools in Winston-Salem Forsyth County Schools (WS/FCS).

**METHODS:** The WS/FCS Superintendent implemented a requirement for middle school students to engage in at least one IR break daily. Study staff trained middle school staff on IR use. School staff determined when IR would be implemented. IR videos were loaded on a central server that could be accessed through a networked computer in each classroom. Schools implemented IR for 8 weeks in Spring 2011. Students completed a pre-post online survey to assess health-related behaviors and attitudes toward IR. Teachers maintained a daily log of IR use. After 4 weeks, trained volunteers and study staff conducted direct classroom observations of IR, on/off task behavior of students, and teacher engagement. Teachers and students also provided qualitative feedback about IR.

**RESULTS:** Pre-post online surveys were completed by 1,553 middle school students (26.3% 6<sup>th</sup> graders, 37.4% 7<sup>th</sup> graders, and 35.4% 8<sup>th</sup> graders; 43% white, 25% black, and 32% other). Seventy-seven percent of students reported participating in an IR at any time during the evaluation period and 56% of students reported doing IR daily. Most students (73%) reported that they did IR first thing in the morning. Students participated in 8.0±3.4 IR minutes per classroom (n=75 classrooms), of which 3.9±3.0 minutes were spent in moderate to vigorous-intensity PA (MVPA). There was a significant association between teacher engagement ( $p = 0.03$ ), teacher activity level ( $p < 0.0001$ ), and student IR MVPA minutes. Students indicated that they would prefer alternative types of activities and to have activity breaks at different times during the school day.

**CONCLUSION:** Policies for daily activity breaks can facilitate increased school day PA. Student and staff input is critical when developing and implementing policies and programs to increase school day PA. Further research is needed to confirm these findings.

2546 Board #221 MAY 31 3:30 PM - 5:00 PM

**Back Tracking Of Growth, Motor Coordination And Physical Fitness Of Primary School Children**

Michele C. Souza<sup>1</sup>, Raquel N. Chaves<sup>1</sup>, Fernanda K. Santos<sup>1</sup>, Thayse Gomes<sup>2</sup>, Daniel Santos<sup>2</sup>, Rojapon Buranarugsa<sup>2</sup>, André Seabra<sup>2</sup>, Rui Garganta<sup>2</sup>, Gaston Beunen<sup>3</sup>, Robert M. Malina, FACSM<sup>4</sup>, José Maia<sup>2</sup>. <sup>1</sup>CAPES Foundation, Ministry of Education of Brazil, Brasília – DF, Brazil and CIFI2D, Faculty of Sport, University of Porto, Porto, Portugal. <sup>2</sup>CIFI2D, Faculty of Sport, University of Porto, Porto, Portugal. <sup>3</sup>Katholieke Universiteit Leuven, Leuven, Belgium. <sup>4</sup>Tarleton State University, Stephenville, TX. (No relationships reported)

Gross motor coordination (GMC) and physical fitness (PF) are related, in part, to growth status during childhood. GMC and PF influence physical activity (PA) and can also be influenced by PA.

**PURPOSE:** to describe antecedents of growth, GMC, PA and health- and performance-related PF of children at 6 years of age relative to level of PA at 10 years of age.

**METHODS:** 285 primary school children (142 girls, 143 boys) from the Azores islands, Portugal, were measured annually (in the Fall) from 6 to 10 years. PA was assessed with personal interview using the Godin and Shephard questionnaire. Tertiles for PA (sedentary, moderate, very active) at 10 years of age were calculated. Then, growth status, health and performance-related PF (Fitnessgram and AAHPERD) and GMC of the children in each tertile at 10 years were tracked back to 6 years of age. ANOVA models were computed with SPSS 18.

**RESULTS:** Sedentary and high active girls at 10 years of age differed in GMC ( $F=4.23$ ,  $p=0.016$ ) and had poorer performances in the curl-up ( $F=3.57$ ,  $p=0.028$ ), push-up ( $F=1.14$ ,  $p<0.001$ ) and 50 yard dash ( $F=9.40$ ,  $p<0.001$ ) at 6 years; sedentary girls had poorer scores on all variables. Sedentary and moderately active girls at 10 years differed only in 50 yard dash test ( $F=9.40$ ,  $p=0.003$ ) at 6 years, while moderately and very active girls at 10 years differed only in push up test ( $F=1.14$ ,  $p<0.001$ ) at 6 years. Sedentary boys at 10 years of age had a higher fatness ( $F=3.28$ ,  $p=0.038$ ) and lower GMC ( $F=3.35$ ,  $p=0.035$ ) and did not perform as well in push-ups ( $F=3.44$ ,  $p<0.001$ ) compared to high active boys at 6 years. Sedentary and moderately active boys, and moderately and very active boys at 10 years differed only in push-ups ( $F=3.44$ ,  $p<0.001$  and  $F=3.44$ ,  $p<0.001$ , respectively) at 6 years.

**CONCLUSIONS:** Children with high level of PA at 10 years tended to have a better profile of GMC and health and performance-related PF at 6 years of age compared to those with low PA. The findings highlight a need to incorporate GMC into PA intervention programs.

Study funded by the Fundação para a Ciência e a Tecnologia (FCT). Contract PTDC/DES/67569/2006 FCOMP-01-0124-FEDEB-09608.

2547 Board #222 MAY 31 3:30 PM - 5:00 PM

**Physical Activity And Clustered Metabolic Risk Score In Young Children: A Cross-sectional Study (the Idefics Study)**

David Jimenez-Pavon<sup>1</sup>, Ken Konstabel<sup>2</sup>, Patrick Bermang<sup>3</sup>, Wolfgang Ahrens<sup>4</sup>, Hermann Pohlbeln<sup>4</sup>, Charis Hadjigeorgiou<sup>5</sup>, Denes Molnar<sup>6</sup>, Stefaan De Henauw<sup>7</sup>, Yanis Pitsiladis<sup>8</sup>, Luis A Moreno<sup>1</sup>. <sup>1</sup>University of Zaragoza, Zaragoza, Spain. <sup>2</sup>National Institute for Health Development, Estonia, Estonia. <sup>3</sup>Göteborg University, Sweden, Sweden. <sup>4</sup>University of Bremen, Bremen, Germany. <sup>5</sup>Research & Education Institute of Child Health, Cyprus, Cyprus. <sup>6</sup>University of Pécs, Pécs, Hungary. <sup>7</sup>Ghent University, Ghent, Belgium. <sup>8</sup>University of Glasgow, Glasgow, United Kingdom. (No relationships reported)

The relevance of physical activity (PA) as the main therapeutic tool for combating cardiovascular risk and metabolic syndrome in children has been highlighted.

**PURPOSE:** To study the association between objectively measured PA intensities and clustered metabolic risk score (MRS) in a large sample of European children aged 2<10 years.

**METHODS:** We conducted a cross sectional study (the IDEFICS) which comprised 5548 children (2863 boys; 2<10 years) from eight European countries with complete measurements. Triglycerides, total cholesterol (TC), high-density lipoprotein cholesterol (HDL-c), glucose, insulin, systolic blood pressure, sum of two skinfold thickness and cardiorespiratory fitness were measured. The ratio TC/HDL-c and the homeostasis model assessment were calculated. Z-scores were calculated for each risk factor variable by age group and sex, and then all individual Z-scores were summed to create a continuous score clustering metabolic risk factors. Since cardiorespiratory fitness was only available in children older than 6 years old, a second clustered metabolic risk score was obtained only for older children. Physical activity (PA) was assessed by accelerometry and minutes spent at the follow intensities were calculated; low PA, moderate PA, vigorous PA and average physical PA.

**RESULTS:** In pre-school boys (2<6 yrs), the odds ratio for having high MRS in the least active quintile compared with the most active quintile of average PA was 2.79 (1.23 - 6.32). Odds ratios, in pre-school girls, compared with the most active quintile were raised in the second and least active quintiles for vigorous PA (4.55 and 5.34, respectively) and in the second quintile for moderate PA (2.87). The logistic regression analysis were repeated for the MRS including cardiorespiratory fitness only available for older children (6 < 10 yrs), and the results show that the strongest associations were found with moderate PA, where the least active quintiles had an odds ratios of MRS around 5 compared with the most active quintile in both sexes.

**CONCLUSIONS:** Our results suggest that those children who are less active have a higher risk score compared to those who are in the highest quintile of PA in both sexes aged from 2 to 10 years. Special focus on moderate and vigorous PA and to start at earlier age (2 yrs) should be provided.

---

2548 Board #223 MAY 31 3:30 PM - 5:00 PM

**Factors Associated with Physical Activity in Children Attending Family Child Care Homes**

Katherine B. Gunter<sup>1</sup>, Kelly R. Rice<sup>1</sup>, Dianne S. Ward, FACSM<sup>2</sup>, Stewart G. Trost, FACSM<sup>1</sup>. <sup>1</sup>Oregon State University, Corvallis, OR. <sup>2</sup>University of North Carolina, Chapel Hill, NC.

(No relationships reported)

Family Child Care Homes (FCCHs) are among the largest providers of non-relative care for young children in the U.S. However, little is known about physical activity (PA) levels of children attending FCCHs. The available, limited evidence suggests these children spend most of their time engaging in sedentary behavior, and the factors which influence children's PA in this setting are unknown.

**PURPOSE:** To determine the relationship between FCCH characteristics and practices and objectively measured PA in 2- to 5-year old children attending FCCHs.

**METHODS:** FCCH practices and characteristics were assessed in 45 FCCHs using the Nutrition and Physical Activity Self-Assessment for Child Care Instrument (NAP SACC-SA). Within the 45 FCCHs, 136 children (ages 2 to 5 yrs) wore an accelerometer during childcare attendance over one-week. Time spent in light, moderate, and vigorous PA per hour was calculated using intensity-related cut-points. For each NAPSACC-SA item, FCCHs were divided into two groups: Promoting PA (PPA) or not promoting PA (Non-PPA). Mixed model analysis of variance was used to evaluate differences in total activity between groups. Models included FCCH as a random effect to control for the clustering of children within FCCHs. Age, sex, and BMI z-score were included as child-level covariates.

**RESULTS:** FCCH characteristics and practices associated with higher levels of PA (min/hr;  $p < 0.05$ ) included provision of sufficient outdoor active play ( $32.2 \pm 1.0$  vs.  $28.6 \pm 1.3$ ), active play using portable play equipment ( $31.7 \pm 1.0$  vs.  $29.3 \pm 1.4$ ), the presence of a variety of fixed play equipment ( $32.2 \pm 1.0$  vs.  $28.9 \pm 1.3$ ), suitable indoor play space ( $32.2 \pm 1.0$  vs.  $28.6 \pm 1.3$ ), engaging in active play with children ( $32.1 \pm 1.1$  vs.  $29.6 \pm 1.2$ ), and receiving activity-related training ( $33.1 \pm 1.2$  vs.  $30.3 \pm 1.1$ ). Children were most active in FCCHs with  $\geq 4$  significant PPA characteristics/practices compared to children in FCCHs with  $< 4$  significant PPA characteristics/practices.

**CONCLUSIONS:** This is the first study to identify specific practices and characteristics of FCCHs that influence children's PA. These data should be considered when developing programs and policies to promote PA in FCCHs.

Supported by USDA-NIFA Grant 2008-04423

2549 Board #224 MAY 31 3:30 PM - 5:00 PM

**Biological and Behavioral Predictors of Cardiometabolic Risk in 6th Graders: The Cardiovascular Health Intervention Program.**

Mark D. Peterson<sup>1</sup>, Dongmei Liu<sup>1</sup>, Heidi IglayReger<sup>1</sup>, William Saltarelli<sup>2</sup>, Paul Visich<sup>2</sup>, Paul M. Gordon, FACSM<sup>1</sup>. <sup>1</sup>University of Michigan, Ann Arbor, MI. <sup>2</sup>Central Michigan University, Mt. Pleasant, MI.

(No relationships reported)

**PURPOSE:** The prevalence of obesity has increased significantly among adolescents, and is now considered to be the primary cause of various cardiometabolic comorbid conditions. The purpose of this study was to determine the biological and behavioral variables associated with cardiometabolic disease risk among adolescents, and to assess the pattern of risk component clustering.

**METHODS:** A large cohort ( $n=2886$ ) of 6<sup>th</sup> grade students was assessed for cardiometabolic profiles. Risk components included waist circumference, fasting glucose, blood pressure, plasma triglycerides levels and HDL-cholesterol. Principal components analysis was used to determine the pattern of risk clustering and to derive a continuous aggregate score (MetScore). Individual risk components and MetScore were analyzed for association with age, adiposity (BMI), cardiorespiratory fitness (CRF), physical activity (PA), and parental factors (i.e. age, adiposity, family history of CVD, etc.).

**RESULTS:** BMI was associated with multiple risk factors, and overall MetScore among boys and girls. CRF was a strong negative predictor, such that greater CRF conferred less risk. Maternal smoking was associated with multiple risk factors in girls and boys, even after controlling for children's BMI. Paternal family history of early CVD and parental age were associated with increased blood pressure and MetScore for girls. Children's PA levels, maternal history of early CVD, and paternal BMI were also indicative for various risk components, but not MetScore in girls or boys.

**CONCLUSIONS:** Several biological and behavioral factors are independently associated with children's cardiometabolic disease risk. These findings serve to bolster the value of fitness, PA, and family-oriented healthy lifestyles for improving children's cardiometabolic health.

---

2550 Board #225 MAY 31 3:30 PM - 5:00 PM

**Objectively Measured Sedentary Time Among Finnish Students Aged 7 To 15 Years**

Tuija Tammelin, Harto Hakonen, Kirsti Siekkinen, Janne Kulmala, Kaarlo Laine. *LIKES - Research Center for Sport and Health Sciences, Jyväskylä, Finland.*

(No relationships reported)

**PURPOSE:** Accumulating evidence suggests that, independent of physical activity levels, sedentary behaviours are associated with increased health risk. The purpose of this study was to evaluate the differences in sedentary time among Finnish school-aged children of different ages and to compare the results with recently published international data.

**METHODS:** The study population consisted of 218 boys and girls from grades 1 to 9 (ages 7 to 15), from 6 schools who were involved in the baseline measurements of the "Finnish Schools on the Move" program in 2010-2011. Sedentary time and physical activity were measured objectively by an ActiGraph accelerometer for 7 consecutive days. A cut-off value of 100 counts per minute for sedentary time and 2000 counts per minute for moderate to vigorous physical activity (MVPA) was used. Analysis of variance was used for group comparisons.

**RESULTS:** Total sedentary time was 4.4, 5.6, and 8.0 h/day for students in grades 1-3, 4-6 and 7-9, respectively ( $p < 0.001$  for group differences). Mean sedentary time was 35.7, 38.5, and 46.0 min/h during the school day, and 33.2, 37.7, and 42.8 min/h outside school hours for students in grades 1-3, 4-6, and 7-9, respectively ( $p < 0.001$ ). Mean MVPA time was 69, 61, and 45 min/day for these age groups, respectively ( $p < 0.001$ ); and boys had on average 13 min/day more MVPA than girls ( $p < 0.001$ ). No gender difference was observed in total sedentary time among younger students, but girls in grades 7-9 had 0.9 h/day more sedentary time than boys ( $p < 0.001$ ).

**CONCLUSION:** Total sedentary time, as well as sedentary time during and outside the school-day, was directly associated with increasing age. Gender difference in sedentary time was observed in grades 7-9, where girls had more sedentary time than boys. Among Finnish students, total sedentary time was 1.3 h/day lower in grade 1-6 students and 0.6 h/day higher in grade 7-9 students than recently published data for children of the same ages from USA and Europe (Pate et al., 2011). Results raise concern about extensive sedentary time among young people, especially among older students in grades 7 to 9.

REFERENCE: Pate et al. Sedentary behavior in youth. *Br J Sports Med* 2011 45: 906-913.

2551 Board #226 MAY 31 3:30 PM - 5:00 PM

**Reducing Obesity Trends in Secondary Public School Physical Education Classrooms through Innovative Technology**

Dr. Jean Ann Hargreaves<sup>1</sup>, Chelsea Foster<sup>2</sup>, Dr. Larry Nelson<sup>1</sup>, Dr. John Buckwalter, FACSM<sup>1</sup>. <sup>1</sup>University of Texas at Arlington, Arlington, TX. <sup>2</sup>The Ohio State University, Columbus, OH.

(No relationships reported)

Currently 1 in 3 Americans are classified as being overweight or obese and the obesity rate continues to rise. The impact of physical activity on obesity and overall physical fitness has been widely accepted. Dramatic declines in physical activity have been observed across a person's life with a dramatic decline occurring as they enter high school.

**PURPOSE:** To assess the difference in physical activity levels in students enrolled in secondary physical education classes and other programs that are "approved" by the state of Texas to substitute for physical education classes.

**METHODS:** High school students enrolled in drill team (n=33), band (n=33) (both are approved substitutes for physical education credits), and physical education (n=36) were recruited for participation in this study. Participants completed a brief survey, physical measurements, and wore an ActiTrainer Accelerometer, which is a valid and objective method of continuously recording physical activity, for a seven-day period. The groups were compared in two areas: 1) total time spent in moderate to vigorous physical activity (MVPA) and 2) time spent in MVPA during class (in minutes).

**RESULTS:** The drill team group (180.64 ± 87.77) participated in a significantly (P<0.01) greater amount of MVPA during class than both the band (95.30 ± 56.41) and PE groups (71.28 ± 39.06) which were not significantly different from each other. The overall weekly MVPA for the band group (743.64 ± 304.25) was significantly greater than the PE group (533.67 ± 242.00) while neither were significantly different from the drill team group (677.39 ± 265.99).

**CONCLUSION:** These findings suggest that a significantly greater amount of moderate to vigorous physical activity occurs in the drill team classes compared to the physical education and band classes that were examined in this study. The findings of this study suggest that approved substitutes for physical education that result in increases in physical activity should be encouraged as options for students to enroll in as a means of combating the prevalence of sedentary behavior in high school students. Further research is needed to examine other extracurricular activities' impact on physical activity in students.

2552 Board #227 MAY 31 3:30 PM - 5:00 PM

**Evaluation of an After School Physical Activity Program for Disadvantaged Youth**

Timothy K. Behrens, FACSM<sup>1</sup>, John M. Schuna, Jr<sup>2</sup>, Rebekah L. Lauersdorf<sup>1</sup>, Gary Liguori<sup>2</sup>, Mina L. Liebert<sup>3</sup>. <sup>1</sup>University of Colorado Colorado Springs, Colorado Springs, CO. <sup>2</sup>North Dakota State University, Fargo, ND. <sup>3</sup>LiveWell Colorado Springs, Colorado Springs, CO.  
(No relationships reported)

**PURPOSE:** To evaluate the effectiveness of "Keep It Moving" (KIM), an afterschool physical activity program in Colorado Springs, CO designed to encourage healthy movement outside of the formal school setting.

**METHODS:** Children at four disadvantaged elementary schools (87-93% free and reduced lunches) were assessed using an accelerometer along with the SOFIT observation method at two different time points during spring 2011. Standard data reduction processes for accelerometer and SOFIT data were used to determine time spent participating in physical activity. KIM facilitators were also observed using SOFIT to evaluate their interaction with participants during the program.

**RESULTS:** Among the entire sample (N=119) an average of 20.8 ± 9.5 minutes of moderate physical activity and 2.9 ± 3.9 minutes of vigorous physical activity was accumulated during the 45 minute KIM sessions, resulting in a combined 23.7 ± 11.3 minutes of moderate to vigorous physical activity (MVPA). Data from the SOFIT observation demonstrated that participants in the KIM program spent 12.3% of the session being "very active." (i.e. MVPA), with the majority of time spent "standing" (40.3%) and "walking" (36.0%). Only a small portion of the KIM sessions were devoted to sitting (10.5%) or lying down (0.8%). SOFIT data for facilitators indicated the majority of time was spent "managing" (40.6%), "observing" (33.3%), "promoting fitness" (10.1%) and in "general instruction" (9.2%), while lesser time was spent "demonstrating fitness" (2.6%) and on non-codifiable tasks (4.3%).

**CONCLUSIONS:** The KIM afterschool program succeeded at engaging participants in approximately 24 minutes of MVPA per session. The SOFIT observation results also suggest that participants spent a large portion of each KIM session being physically active. In addition to other activity accumulated throughout the day, the program could potentially assist children in reaching the recommended levels of PA, thus aiding them in achieving the benefits of a healthy lifestyle.

2553 Board #228 MAY 31 3:30 PM - 5:00 PM

**Is Maintained Pattern of Physical Activity from Adolescence to Adulthood Associated with Reduced CVD-risk? HUNT-Study, Norway**

Vegar Rangul<sup>1</sup>, Turid Lingaas Holmen<sup>2</sup>, Kristian Midthjell<sup>2</sup>, Adrian Bauman<sup>3</sup>. <sup>1</sup>Nord-Trøndelag University College, Levanger, Norway. <sup>2</sup>HUNT Research Centre, Faculty of Medicine, Norwegian University of Science and Technology, Levanger, Norway. <sup>3</sup>Prevention Research Collaboration, School of Public Health, University of Sydney, Sydney, Australia.  
(No relationships reported)

Little is known about the effect of adolescent physical activity on later health status, and few studies have examined physical activity patterns from adolescence to young adulthood as predictors of subsequent risk of cardiovascular disease (CVD).

**PURPOSE:** In a prospective longitudinal design we examined how different physical activity patterns from adolescence to young adulthood associated with CVD risk factors in young adulthood.

**METHODS:** Data were from the Nord-Trøndelag Health Study (HUNT2, 1995-97 and HUNT3, 2006-08), Norway. In the present 10-year longitudinal study we included 1869 individuals (males n=838) who participated in both the youth part of HUNT2, aged 13-19 years old (baseline) and the follow-up HUNT3, aged 23-31. Measurements included self-reported physical activity, body mass index (BMI), waist circumference (WC), total cholesterol (TC), high-density lipoprotein cholesterol (HDL-C), glucose, triglycerides, resting heart rate (HR), and blood pressure. We used separate linear regressions models to investigate associations between physical activity patterns and each CVD risk factor. Physical active maintainers (physical active defined as ≥2-3 days/wk) were compared to inactive maintainers (IM). Adopters (those who were inactive (<2 days/wk) as adolescents (baseline) and physical active as young adults, follow-up) were compared to IMs and to those who discontinued activity (relapsers).

**RESULTS:** AMs had significantly lower HR, compared to all other PA patterns. Men who were AMs had significantly lower WC than relapsers and IMs. In unadjusted analyses, AMs had significantly lower WC, BMI, HR, diastolic blood pressure, TC, triglycerides and higher HDL-C compared to IMs. When adjusted for age and gender, WC BMI, HR, diastolic blood pressure and HDL-C remained significant. When comparing IMs against adopters, only HR was significant lower. In gender specific analysis, male adopters had no different CVD risk compared to inactive maintainers. Among females, adopting was associated with lower HR and TC compared to IMs.

**CONCLUSIONS:** Active maintainers had the best profile, with significantly lower CVD risks compared to inactive maintainers. Adopting physical activity between adolescence and young adulthood may not confer a lowered CVD risk, compared to inactive maintainers.

2554 Board #229 MAY 31 3:30 PM - 5:00 PM

**Physical Activity And Its Association With Academic Performance In Korean Adolescents**

Jung-woo Oh, Hyun-jin Kwon, Yeon-soo Kim. Seoul National University, Seoul, Korea, Republic of.  
(No relationships reported)

**PURPOSE:** The purpose of this study was to investigate the association between PA and AP, as well as between media time (MT) and AP.

**METHODS:** This study used cross-sectional data included 75,066 (39,612 male students, 35,454 female students) middle and high school students from Korea Youth Risk Behavior Web-based Survey (KYRBWS, 2009). Logistic regression performed to analyze the association between PA, MT, and AP.

**RESULTS:** From an analysis of Odds Ratio (OR), male students who achieved lower AP showed a significant decline in PA participatory rate compared to those who reported higher AP. For the high AP groups' PA participatory rate, the reference value was 1. The middle AP group showed an OR value of 0.92(95% CI 0.87-0.96), and the low group showed an OR value of 0.86(95% CI 0.82-0.90). In the case of female students, OR values were 0.92(95% CI 0.87-0.98), 0.99(95% CI 0.93-1.04), respectively. Male students who achieved lower AP showed a significant decline in MT guideline practical rate compared to those who reported higher AP. For the high AP groups' MT guideline practical rate, the reference value was 1. The middle AP group showed an OR value of 0.78(95% CI 0.73-0.83), and the low group showed an OR value of 0.49(95% CI 0.46-0.51). In the case of female students, OR values were 0.83(95% CI 0.77-0.88), 0.53(95% CI 0.50-0.56), respectively.

**CONCLUSIONS:** Our results show a correlation between practical rate of PA and MT guideline with AP. Therefore, to improve AP of Korean youth, there is a need for encouraging a regular PA participation and MT guideline practice.

**2555** Board #230 **MAY 31 3:30 PM - 5:00 PM**  
**Examining Girls' Physical Activity Levels in Organized Sports**

Justin M. Guagliano<sup>1</sup>, Richard R. Rosenkranz<sup>2</sup>, Gregory S. Kolt<sup>1</sup>. <sup>1</sup>University of Western Sydney, Sydney, Australia. <sup>2</sup>Kansas State University, Manhattan, KS.  
(Sponsor: Karen Croteau, FACSM)  
(No relationships reported)

Many children do not meet recommended levels of physical activity (PA). This is particularly evident for girls in adolescence, when PA declines sharply. Organized sports (OS) may have potential to increase girls' likelihood of meeting PA recommendations, but little research has focused on girls' PA within OS.

**PURPOSE:** The purpose of this study was to describe the amount of PA that girls accumulate during games and practices within three OS, and to compare the levels between games and practices.

**METHODS:** A cross-sectional design was used. Participants were 94 girls, aged 10 to 17 yr, mean ( $\pm$ SD) = 13.4  $\pm$  2.2 yr, recruited from 10 teams in three OS (netball, basketball, soccer) in Sydney's Western Suburbs. Each participant wore one ActiGraph GT3X monitor, placed on the right hip via elastic belt, for the duration of one practice and one game. Accelerometers were initialized to record counts and steps, using 5 s epochs. Freedson's cut-points were used to determine PA intensity.

**RESULTS:** Across OS, the mean ( $\pm$ SD) for percent time in moderate-to-vigorous PA (MVPA) during games (30.1  $\pm$  10.2%) was significantly lower ( $r = -5.27$ ,  $P < 0.001$ ) than during practices (36.4  $\pm$  8.3%). In games (mean duration = 90.8  $\pm$  13.7 min), OS featured similar proportions of MVPA (netball = 30.9  $\pm$  9.1%; basketball = 29.9  $\pm$  8.5%; soccer = 29.1  $\pm$  8.5%). In OS practices (mean duration = 82.6  $\pm$  22.6 min), MVPA was more heterogeneous (netball = 39.4  $\pm$  4.7%; basketball = 35.5  $\pm$  8.1%; soccer = 32.6  $\pm$  11.2%). Overall, steps/h for games (OS = 2,702  $\pm$  960; netball = 2,543  $\pm$  699; basketball = 2,349  $\pm$  660; soccer = 3,340  $\pm$  1267) was significantly lower ( $r = -5.05$ ,  $P < 0.001$ ) than during practices (OS = 3,234  $\pm$  743; netball = 3,430  $\pm$  432; basketball = 2,753  $\pm$  767; soccer = 3,602  $\pm$  916).

**CONCLUSION:** Our observations of the three sports showed that participants achieved significantly higher levels of MVPA and steps during OS practices, compared to OS games. Girls spent 21.8 min/h in MVPA during practices and 18.1 min/h in MVPA during games. For this population, OS appears to make a substantial contribution to the PA of participating girls. OS alone, however, does not provide amounts of PA sufficient to meet daily recommendations for adolescent girls. This information on OS can be used as a platform from which to inform policies, and to develop strategies to increase adolescent girls' PA levels through sport.

**2556** Board #231 **MAY 31 3:30 PM - 5:00 PM**  
**Physical Activity Tracking in Iowa Bone Development Study Youth: Alignment by Biological versus Chronological Age**

Shelby L. Francis, Joanna L. Morrissey, Elena M. Letuchy, Steven M. Levy, Kathleen F. Janz, FACSM. University of Iowa, Iowa City, IA.  
(No relationships reported)

**PURPOSE:** To compare the tracking of childhood and adolescent objectively-measured physical activity (PA) using peak height velocity (PHV) as a predicted measure of biological age (BA) versus chronological age (CA, yr). To investigate whether known gender differences in PA trajectories were altered after aligning by BA instead of CA.

**METHODS:** The Iowa Bone Development Study has collected longitudinal ActiGraph data at ages 5, 9, 11, 13, and 15 yr. To be included in this analysis, participants had to have worn an accelerometer at least two measurement periods (N = 112 girls; N = 96 boys). Spearman correlation coefficients were used to determine two-year intervals of tracking of moderate to vigorous PA (MVPA) before and after maturity (PHV). Gender-specific MVPA trajectories were compared using mixed models with autoregressive residual covariance.

**RESULTS:** Moderate two-year tracking associations were present, except the -1 yr PHV to +1 yr PHV in boys. The mixed models indicate MVPA was highest at age 5 and then declined in girls. Boys' MVPA increased until 9 yr and then decreased at a faster rate than girls. A significant interaction between age and gender confirmed the different trajectories. By 2.5 to 3 yr post PHV girls and boys had similar levels of MVPA.

**CONCLUSIONS:** Exploring opportunity, availability, and support of MVPA in boys and girls may help explain why levels are decreasing with age. Further research into the immediate time period surrounding PHV appears warranted in boys.

Supported by the National Institute of Dental and Craniofacial Research (R01-DE12101, R01-DE09551); General Clinical Research Centers Program (M01-RR00059); National Center for Research Resources (UL1 RR024979).

**2557** Board #232 **MAY 31 3:30 PM - 5:00 PM**  
**Comparison Of Adolescents Risk Factors Prevalence To Chronic Disease Development In Urban Regions In Brazil**

raquel sapone ceschini, Fabio Luis Ceschini, Aylton Figueira Júnior. São Judas Tadeu University - São Paulo - Brazil, São Paulo, Brazil.  
(No relationships reported)

**PURPOSE:** This paper compared both sex adolescents' risk factors to chronic diseases development living at four distinct areas in developing country. Sample: We evaluated 1.442 adolescents [710 (49.2%) girls and 732 (50.8%) boys] from 14 to 19 years of age living in São Paulo State-Brazil. We selected three regions in countryside and one in central area. The sample distribution was at countryside regions: North (n=355) and East (n=366) side in Sao Paulo State. Both cities presented as main activity the rural profile (rural-non-urban cities) while in the West area (n=42), the city presented urban profile (rural-urban city). The city at Central (n=379) area presented urban profile (central-urban city).

**METHODS:** All adolescents were surveyed by cross sectional evaluation answering the Youth Behavior Risk Questionnaire and the International Physical Activity Questionnaire (IPAQ-short version). Four behavioral risks were assessed: 1) physical inactivity (PI): adolescents that reported less than 300 minutes/week of moderate-vigorous physical activity in the previous evaluation week; 2) alcohol intake (AI): drink at least one dose of any kind of alcohol beverage in the previous evaluation week; 3) cigarette smoking (CS): smoke at least once in the previous evaluation week; 4) overweight indicator (OW): present at least 21.66 (Kg/m<sup>2</sup>) body mass index value. Data Analysis: Qui-Square test (p<.05 as significance level).

**RESULTS:** Data analysis evidenced significant differences in risk factors prevalence by gender. Boys presented higher behavior risk for AI as well CS than girls. On the other hand, female group presented higher prevalence value for PI and OW. IN general, more than 2 risks factors were higher in girls than boys. The analysis by regions, showd different physical inactivity prevalence. Rural non-urban cities (Norths = 56.7% and East = 64.6%) presented more active adolescents than rural-urban city ( West = 39.2%) and central-urban city (Central = 35.4%). Similar trend was found for AI, CS and OW by region.

**CONCLUSION:** This paper allow us to conclude that: 1- distint regional development may influence the amount behavior risk prevalence in adolescents; 2- prevalence of risk factors were different in boys and girls; 3- the comparison among the four studied risk factors, PI presented the highest prevalence,

**2558** Board #233 **MAY 31 3:30 PM - 5:00 PM**  
**Metabolic Syndrome and Lifestyle Behaviors in Adolescents**

Ana J A Rodrigues, Andreia G. Luis, Candida J. Sousa, G. Marlene Silva, Joao F. Ferreira, Maria Joao B. Rodrigues, Lucia R. Carvalho, M Joao C A Almeida.  
University of Madeira, Funchal, Portugal.  
(No relationships reported)

Research about metabolic syndrome and the relationship with lifestyle behaviors in youth is crucial in the design of intervention strategies.

**PURPOSE:** The objective of this study was to examine the differences between adolescents with Metabolic Syndrome (MetS) and without MetS (w/MetS) in physical activity (PA) levels, sedentary behaviors and consumption of processed foods and sugary drinks.

**METHODS:** A total of 468 adolescents (247 boys and 215 girls), between 10 and 15 years of age, participated this study. Participants were measured for height, weight, waist circumference, triceps and calf skinfolds, and blood pressure. Measures of triglycerides, glucose and C-HDL were taken by blood draw, and MetS diagnosis was done according to the IDF et al. (2008) criteria. Percent body fat (%BF) was estimated according to Slaughter et al. (1988), and participants classified according to Lohman's (1987) categories. Abdominal obesity (AOB) classification was defined according to Katzmarzyk et al. (2004), and the prevalence of the MetS was determined with the IDF (2008) criteria. PA and sport participation were assessed by the

PAQ-C questionnaire and PA general scores (PAgS) estimated according to Crocker et al. (1997). Sedentary behavior, consumption of processed foods and sugary drinks (Wilson et al., 2008) were assessed by self-report.

**RESULTS:** The prevalence of MetS was 3.5%. Significant differences were found between participants w/MetS and with MetS in PAgS ( $2.56 \pm 0.71$  vs  $2.1 \pm 0.67$ , respectively), and participants with MetS had a significantly lower mean score ( $p=0.012$ ). Regarding the risk factors for MetS (HDL, LDL, WACL, blood pressure and triglycerides), significant differences were found between subjects with AOb and without AOb (w/AOb) ( $2.43 \pm 0.64$  vs  $2.66 \pm 0.70$ , respectively). Those with AOb also had lower scores in PAgS ( $p<0.001$ ). There were no differences between subjects with MetS and wMetS for sedentary behaviors ( $1.77 \pm 1.69$  vs  $1.79 \pm 2.30$  hrs/wk, respectively), and scores of processed foods and sugary drinks consumption ( $5.56 \pm 3.78$  vs  $5.73 \pm 5.23$ ).

**CONCLUSION:** A physically active lifestyle may prevent the diagnosis of metabolic syndrome in adolescents.

**2559** Board #234 MAY 31 3:30 PM - 5:00 PM  
**Physical Activity Levels of Elementary School Students during Physical Education and Recess.**

Kerry L. McIver, Russell R. Pate, FACSM. *University of South Carolina, Columbia, SC.*  
(No relationships reported)

Physical education class (PE) and recess are the two main opportunities that children have to be physically active during the school day. However, no study has directly observed the exact time spent, by children, in these settings, while using accelerometry for the purpose of quantifying physical activity in these settings.

**PURPOSE:** The purpose of this study was to precisely document time spent in PE and recess and to describe the physical activity levels of elementary school children in those settings.

**METHODS:** One-hundred and forty-one 1st and 5th graders, attending 10 elementary schools, participated in the study. Participants wore Actigraph accelerometers for one-week, and during that period the precise times spent in PE and recess each day were documented for each participant. Accelerometer counts per 30-seconds were categorized as sedentary, light, moderate-to-vigorous (MVPA) and vigorous physical activity (VPA). Minutes spent in these categories were calculated for PE and recess periods for each day and across the week.

**RESULTS:** Participants attended PE once per week for an average of 48 minutes. Percent of time spent in MVPA during PE was approximately 30%, except for 5th grade girls, who spent 23% of PE class in MVPA. First graders spent significantly more time in recess compared to 5th graders (24 minutes per day vs. 17 minutes per day), and more of that time was spent in MVPA (65% vs. 48%).

**CONCLUSION:** The results suggest lower than recommended levels of MVPA during PE for both grades. Proportion of time spent in MVPA during recess was higher than PE. Physical activity during PE and recess, as determined by close observation of times spent in these settings, was variable based on grade and gender. PE, as an active opportunity for children, warrants continued examination. While activity levels were higher in recess, modifications of active opportunities may be necessary especially for older girls.

**2560** Board #235 MAY 31 3:30 PM - 5:00 PM  
**Breaks in Sedentary Time during Childhood and Adolescence: Iowa Bone Development Study**

Kathleen F. Janz, FACSM<sup>1</sup>, Soyang Kwon<sup>2</sup>, Trudy L. Burns<sup>1</sup>, Steven M. Levy<sup>1</sup>. <sup>1</sup>University of Iowa, Iowa City, IA. <sup>2</sup>Consortium to Lower Obesity in Chicago Children, Chicago, IL  
(No relationships reported)

**PURPOSE:** The frequency of interruptions in sedentary time (sedentary

breaks) is an aspect of sedentary behaviors which may be associated with metabolic health outcomes. The aim of this study was to describe the change in the frequency of sedentary breaks over a 10-year period from ages 5 to 15 yr.

**METHODS:** The longitudinal Iowa Bone Development Study has collected accelerometry data at approximately 5, 8, 11, 13, and 15 years of age. Data from participants who wore an accelerometer at least 10 hours per day and three days per data collection episode were used (423 children at age 5, 550 at age 8, 520 at age 11, 454 at age 13, and 344 at age 15). The frequency of sedentary breaks was determined based on accelerometry data and compared by weekday/weekend, time period during the day, gender, and data collection episode.

**RESULTS:** The frequency of sedentary breaks decreased by > 200 times/day over a 10-year period from ages 5 to 15. Linear regression models estimated a 1.8 times/hour decrease per year for boys and a 2.0 times/hour decrease per year for girls ( $P_s < 0.0001$ ). Both boys and girls showed significantly fewer breaks on weekdays from morning to 3:00 PM than on weekends from morning to 3:00 PM ( $P_s < 0.0001$ ). The frequency of sedentary breaks was slightly higher among boys than girls (gender difference  $\leq 2$  times/hour;  $P_s < 0.01$  at ages 11, 13, and 15).

**CONCLUSIONS:** Breaks in sedentary time notably decrease during childhood and adolescence. During school hours, boys and girls have fewer breaks in sedentary time than during any other time period of weekday or weekend day. If health effects of sedentary breaks are proven, schools may be a potential intervention setting for increasing the frequency of sedentary breaks. School policy interventions such as increasing recess time and activity breaks during class time may have an impact on students' sedentary break behaviors.

Supported by the National Institute of Dental and Craniofacial Research (R01-DE12101, R01-DE09551); General Clinical Research Centers Program (M01-RR00059); National Center for Research Resources (UL1 RR024979).

**Is Physical Activity Set in Stone? Tracking of Accelerometer-measured Activity in Early Childhood**

Nicholas M. Edwards<sup>1</sup>, Philip R. Khoury<sup>2</sup>, Heidi J. Kalkwarf<sup>1</sup>, Randal P. Clayton<sup>3</sup>, Stephen R. Daniels<sup>4</sup>. <sup>1</sup>Cincinnati Children's Hospital Medical Center & University of Cincinnati, Cincinnati, OH. <sup>2</sup>Cincinnati Children's Hospital Medical Center, Cincinnati, OH. <sup>3</sup>Miami University, Oxford, OH. <sup>4</sup>University of Colorado School of Medicine & Children's Hospital Colorado, Aurora, CO. (Sponsor: Gregory D. Myer, FACSM)  
(No relationships reported)

**PURPOSE:** To determine whether relative physical activity (PA) levels at age 3 years are sustained in subsequent years during early childhood.

**METHODS:** This study enrolled 372 children. Objective measures of PA (RT3, triaxial accelerometer) were collected for 3 days every 4 mo from age 3 to age 7 y. Non-wear time was defined as 60 min with consecutive zero vector magnitudes per min (vpm) allowing up to 3 min with vector magnitudes  $\leq 100$ . Valid days were defined as 8 to 18 h wear time. PA for each year of age (e.g. 3.0-3.99 y) was calculated as mean daily vpm averaged across valid days ( $\geq 1$ ). Spearman rank correlation coefficients between PA at age 3 y and ages 4 through 7 y were calculated. Participants were categorized into gender-specific tertiles of PA at each age. Differences in PA throughout the study between sexes and between the High PA tertile and Middle/Low PA tertile at age 3 y were tested using t-tests.

**RESULTS:** At age 3, PA was  $613 \pm 201$  vpm (mean  $\pm$  SD) in boys and  $564 \pm 199$  vpm in girls; boys' PA remained higher at each age ( $P < 0.01$ ). PA at age 3 y was significantly correlated with PA levels at ages 4 through 7 y ( $P < 0.015$ ; Table). Participants in the highest tertile of PA at age 3 y were approximately twice as likely to remain in the highest tertile in subsequent years compared with those not in the highest tertile at age 3 (50% vs. 26%;  $P < 0.001$ ).

**CONCLUSIONS:** Boys are more active than girls at ages 3 through 7 y. Children who are relatively more physically active at age 3 y have a significantly greater likelihood of maintaining higher PA levels from age 4 to 7 y than their peers. These findings highlight the importance of establishing healthy PA levels early in life.

**Correlates Of Physical Fitness Among Secondary School Students**

Adilson Marques<sup>1</sup>, João Martins<sup>1</sup>, Hugo Sarmento<sup>2</sup>, José Diniz<sup>1</sup>, Francisco Carreiro da Costa<sup>3</sup>. <sup>1</sup>Faculty of Human Kinetics, Technical University of Lisbon, Lisbon, Portugal. <sup>2</sup>University of Trás-os-Montes and Alto Douro, Vila Real, Portugal. <sup>3</sup>Lusophone University of Humanities and Technologies, Lisbon, Portugal.  
 (No relationships reported)

Physical fitness is an important health correlate. In Portugal the FitnessGram tests have been distributed to schools and physical education teachers are asked to apply it in order to assess the physical fitness levels of students.

**PURPOSE:** This cross-sectional study examined the patterns and factors related to adolescents' physical fitness in Portuguese high school students.

**METHODS:** A total of 387 healthy students (150 boys, 237 girls) age 14 to 18 years (16±1.2 years) participated in the study. In the total sample, leisure time physical activity was assessed using a questionnaire and physical fitness were measured utilizing the FitnessGram tests. Students' aerobic capacity, muscular strength, muscular endurance, flexibility, and body composition were assessed. Scores from these assessments were compared to Healthy Fitness Zone standards and students were labeled as not fit or fit according to the Pacer test results. The correlates of physical fitness were assessed using log-binominal regression analysis separately for boys and girls.

**RESULTS:** Overall, 51% (66% of boys and 41% of girls) were considered fit, according to Pacer test adjusted to the age of the students. Those who reported participation in organized youth sport on a regular basis (boys: OR=1.86, 95% CI: 1.31-2.64, p=0.001; girls: OR=1.66, 95% CI: 1.20-2.29, p=0.002) were more likely to have a better performance on Pacer test in both genders. On the other hand, body mass index for boys (OR=0.728, 95% IC: 0.62-0.86, p<0.001), and age for girls (OR=0.60, 95% CI: 0.46-0.78, p<0.001) were negatively associated with being considered physically fit. The total amount of physical activity practice and the practice of non-organize physical activity during the week were not significant correlates of physical fitness.

**CONCLUSION:** The figures of physically fit students are low, and a cause of concern, especially among girls, because physical fitness is a health correlate. It was concluded that adolescents' regular participation in formal sport activities is an important factor in increasing the likelihood of being physically fit.

**2563 Board #238 MAY 31 3:30 PM - 5:00 PM**  
**Pedometer Determined Physical Activity of Azores Youth and Psychosocial Correlates.**

Pedro Silva, Rute Santos, Carla Moreira, Susana Vale, Pedro Moreira, Jorge Mota. *CIAFEL, FADE-University of Porto, Porto, Portugal.* (Sponsor: Gregory Welk, FACSM)  
 (No relationships reported)

Pedometers have the potential to become effective youth physical activity surveillance tools because they are inexpensive, easy to use and provide objective measures of PA (physical activity). Psychosocial correlates such as enjoyment and self-efficacy have been reported as factors influencing the amount of PA among youth.

**PURPOSE:** To determine the PA amount of Azores adolescents using pedometers and assess the impact of individual and psychosocial correlates.

**METHODS:** A cross-sectional school-based study - The Azorean Physical Activity and Health Study II, of 799 adolescents (446 girls) aged 15-18y from Azorean Islands was conducted. PA was assessed by pedometer for 7 consecutive days. Psychosocial correlates, enjoyment and self-efficacy, were determined by established questionnaires. The impact of the different variables on the amount of PA (steps/day) was assessed by regression analysis (p<.05).

**RESULTS:** Steps per day were significantly (p<.001) higher in males than females, 8776.59 ± 3430.28 vs 7895.63 ± 2900.64, respectively. Males also had higher values in self-efficacy index 2.51 ± .32 vs 2.43 ± .38 (p<.001), and enjoyment index 4.54 ± .69 vs 4.39 ± .74 (p<.004). There was no significant effect for age and BMI on steps/day. The final model included the effect in steps/day of gender β= 810.45 (p<.001), self-efficacy β= 731.38 (p<.035) and enjoyment β= 355.57 (p<.036).

**CONCLUSION:** Results are consistent with other objective assessments of youth PA indicating that males are typically more active than females. Psychosocial correlates, such as self-efficacy and enjoyment are significant factors in adolescents PA.

**KEYWORDS:** Adolescents, Pedometers, Psychosocial correlates

**Cross-cultural Differences In Physical Activity, Sedentary Behaviour And Obesity Of British And Saudi Youth**

Yahya Al-Nakeeb<sup>1</sup>, Mark Lyons<sup>1</sup>, Hazzaa M. Al-Hazzaa, FACSM<sup>2</sup>, Anwar Al-Nuaim<sup>1</sup>, Peter Collins<sup>1</sup>, Michael Duncan<sup>3</sup>, Alan Nevill<sup>4</sup>. <sup>1</sup>Newman University College, Birmingham, Birmingham, United Kingdom. <sup>2</sup>King Saud University, Riyadh, Saudi Arabia. <sup>3</sup>Coventry University, Coventry, United Kingdom. <sup>4</sup>University of Wolverhampton, Birmingham, United Kingdom.  
 (No relationships reported)

While there is a general decline in levels of physical activity (PA) and prevalence of sedentary activities across various populations due to mechanisation and modernisation, obesity seems to rise concurrently in almost all parts of the world coupled with changes in the global food system, which is characterized by caloric dense, more processed, affordable and effectively marketed foods. Although the rise of the global obesity epidemic during the past few decades is substantial, there are wide variations in obesity prevalence across countries and populations due to socioeconomic, cultural and transport differences in national and local environments.

**PURPOSE:** 1) to explore the lifestyle of youth from culturally and environmentally diverse cities, two in Central England (Birmingham & Coventry) and one in the Eastern Province of Saudi Arabia (Al-Ahsa); 2) to examine differences due to gender, age and geographical location.

**METHODS:** 2290 volunteered youth (15-17 years) from the three cities completed a self-report questionnaire that contained 47 items relating to patterns of physical activity, sedentary behaviours and eating habits. The questionnaire allows the calculation of total energy expenditure in METs-min per week based on reported metabolic equivalent values.

**RESULTS:** The univariate ANOVA revealed highly significant differences in levels of PA of youth across the three cities ( $p < .001$ ). Youth from Al-Ahsa were less active than youth in Birmingham and Coventry (1495, 3627 & 3949 METs-min/wk respectively). Using Chi-square analysis, frequency data revealed a significant difference in PA levels between youth in Birmingham, Coventry and Al-Ahsa ( $\chi^2 = 653.85, p < 0.001$ ), with 72.3%, 77.2% and 26% of youth being 'active' respectively. Also, ANOVA revealed highly significant differences ( $p < .001$ ) in the proportions of overweight/obese participants based on IOTF BMI classification, with males and females from Al-Ahsa exhibiting a higher prevalence of overweight/obesity (36.4% and 36.6%, respectively).

**CONCLUSIONS:** Youth from Birmingham and Coventry are more physically active than their counterparts living in Al-Ahsa. Males are generally more physically active than females. Additionally, youth with higher BMI reported lower levels of physical activity and higher amounts of sedentary time.

**2565 Board #240 MAY 31 3:30 PM - 5:00 PM**

**Longitudinal Investigation Of Daily And Yearly Physical Activity In Australian Children**

Rohan M. Telford<sup>1</sup>, Richard D. Telford, FACSM<sup>2</sup>, Ross B. Cunningham<sup>3</sup>, Rachel C. Davey<sup>1</sup>, Gordon Waddington<sup>1</sup>, Thomas Cochrane<sup>1</sup>. <sup>1</sup>Canberra University, Canberra, Australia. <sup>2</sup>Canberra Hospital, Canberra, Australia. <sup>3</sup>Australian National University, Canberra, Australia.  
(No relationships reported)

Longitudinal studies of the daily and yearly physical activity (PA) patterns in young children may provide valuable information for intervention strategies aiming to promote and increase PA in youth.

**PURPOSE:** To contribute to our understanding of the patterns of PA which may exist on a yearly and daily basis within a cohort of boys and girls as they progress through elementary school.

**METHODS:** Participants were initially 775 children (394 boys and 381 girls, mean age 8.0 ± 0.3) recruited from 29 elementary schools in suburbs where the household income was similar to the Australian average. Pedometers were worn annually for a 7 day period over five consecutive years and step counts were converted to a physical activity index (PAI, approximately the square root of steps) to satisfy requirements for statistical analysis. In the final two years accelerometers were worn to assess PA intensity.

**RESULTS:** Overall, the PAI of boys was higher than girls, the respective means and standard errors being 102.5, 0.76 v 93.5, 0.77 ( $p < 0.001$ ). Boys spent more time per day (values expressed as the means of the sqrt of minutes and standard errors) in moderate (5.71, 0.10 v 4.7, 0.11,  $p < 0.001$ ) and vigorous (2.8, 0.09 v 2.4, 0.09,  $p < 0.001$ ) intensity activity, while girls spent more time in sedentary classified activities (20.4, 0.12 v 19.9, 0.12  $p < 0.01$ ). There were changes in the average daily step count from year to year ( $p < 0.001$ ), but these changes fluctuated, providing little evidence of any systematic changes in total PA between the ages of 8 and 12 years. On the other hand, a systematic pattern of step counts did emerge according to day of the week ( $p < 0.001$ ). This was characterized by a gradual build up of daily steps from Monday to Friday followed by a decline over the weekend, with Sunday being the least active day. This pattern persisted from year to year in both genders and a corresponding pattern was found for time spent in moderate, vigorous and light intensity activity.

**CONCLUSION:** Whilst there was little evidence of any systematic changes in step-counts within this cohort over the final four years of elementary school, there were systematic day by day changes during the week which persisted from year to year. These data suggest that strategies to increase PA in elementary school children might benefit from targeting specific days of the week.

**2566 Board #241 MAY 31 3:30 PM - 5:00 PM**

**Physical Activity and Motor Skill Development in Young Children**

Jennifer I. Flynn, Dawn P. Coe, Jeffrey T. Fairbrother, R. Sean Durham. *The University of Tennessee, Knoxville, TN.* (Sponsor: Dixie Lee Thompson, FACSM)  
(No relationships reported)

Young children should accumulate at least 60 minutes of moderate-to-vigorous physical activity (MVPA) daily. Physical activity (PA) contributes to motor skill development, particularly for tasks requiring complex movement patterns thought to underlie skill-related activity and PA later in life (e.g., sport and dance).

**PURPOSE:** To assess the association between MVPA and motor skill development in young children.

**METHODS:** Participants were 40 children (4.8 ± 0.8 years) enrolled in a university research laboratory school. MVPA was assessed using an accelerometer (Actigraph GT3X) set to collect data at 15 s epochs. These data were used to calculate average daily time (min) spent in MVPA for one week (Pate et al., 2006). The Tests of Gross Motor Development-2 (TGMD2) was used to assess 8 gross motor skills that were considered to represent complex skills (CS). CS tests were TGMD2 subtests that show the lowest percentage of mastery for 3-5 year old children. The CS tests were 4 locomotor (galloping, unipedal hopping, leaping, and horizontal jumping) and 4 object control (stationary basketball dribble, catching, kicking, and underhand rolling) skills. Relationships between MVPA and CS scores were examined using Pearson correlations.

**RESULTS:** There were significant correlations between MVPA and galloping ( $r = 0.372$ ;  $P = 0.028$ ), hopping ( $r = 0.471$ ;  $P = 0.004$ ), dribbling ( $r = 0.393$ ;  $P = 0.020$ ), and catching ( $r = 0.337$ ;  $P = 0.048$ ).

**CONCLUSIONS:** These correlations indicate that further research is warranted to determine a causal link between MVPA and CS competency. It is important to determine if PA drives CS competency or if CS competency supports PA efforts. This relationship is important given the recognition that motor skill development and CS competency are critical to success in lifetime PA. This study was funded by a grant from the University of Tennessee Korn Learning, Assessment, and Social Skills (KLASS) Center.

**2567 Board #242 MAY 31 3:30 PM - 5:00 PM**

**Types of Physical Activities Among High School Students - United States, 2010**

MinKyoung Song, Dianna D. Carroll, Sarah M. Lee, Janet E. Fulton, FACSM. *Centers for Disease Control and Prevention, Atlanta, GA.*  
(No relationships reported)

There are no recent nationally-representative studies on participation in types of physical activity among U.S. high school students.

**PURPOSE:** Describe the most frequently reported types of leisure-time physical activities among U.S. high school students overall, and by sex and body mass index (BMI).

**METHODS:** We analyzed data from the 2010 National Youth Physical Activity and Nutrition Survey among 8,895 U.S. high school students in grades 9-12 who completed a self-administered questionnaire. A total of 35 different physical activities were listed in the questionnaire. Students were classified as participating in a specified activity if they reported that activity ≥ 1 days/week. Weighted prevalence estimates and 95% confidence interval (CI)s were compared by sex and BMI (normal, overweight, obese).

**RESULTS:** Overall, walking was the most frequently reported physical activity among U.S. high school students (80.4%, 95% CI [79.1, 81.6]) followed by running/jogging (70.0%, [68.0, 71.9]), weight-lifting (44.1%, [41.8, 46.5]), basketball (43.5%, [41.5, 45.6]), and active video-games (39.8%, [37.7, 42.0]). Four of the top five reported activities were the same between boys and girls (Table). Stratified by sex and BMI, four of the top five activities in each sex group were also reported the top five in all BMI categories for that sex.

**CONCLUSIONS:** Walking and running/jogging were the most frequently reported activities among U.S. high school students for all sex and BMI groups. Knowledge of the types of activities in which youth engage may inform public health professionals to develop targeted strategies to improve participation in physical activities among U.S. youth.

| Male               |      |            | Female             |      |            |
|--------------------|------|------------|--------------------|------|------------|
| Activity           | %    | 95% CI     | Activity           | %    | 95% CI     |
| Walking            | 77.3 | 75.4, 79.1 | Walking            | 83.6 | 81.8, 85.3 |
| Running/Jogging    | 72.0 | 69.5, 74.4 | Running/Jogging    | 68.0 | 65.3, 70.5 |
| Weight-lifting     | 61.1 | 58.6, 63.5 | Dance              | 50.8 | 47.8, 53.7 |
| Basketball         | 56.7 | 53.8, 59.5 | Active video-games | 39.3 | 36.9, 41.8 |
| Active video-games | 40.3 | 37.5, 43.2 | Basketball         | 30.2 | 27.7, 32.7 |

2568 Board #243 MAY 31 3:30 PM - 5:00 PM

**Outside of School Physical Activity Participation in Children and Adolescents from the Urban Core**

Savannah J. Maxwell<sup>1</sup>, Guoyuan Huang<sup>2</sup>, Cheryl A. Gibson<sup>1</sup>. <sup>1</sup>University of Kansas Medical Center, Kansas City, KS. <sup>2</sup>University of Southern Indiana, Evansville, IN. (No relationships reported)

Although 60 minutes of physical activity (PA) per day are recommended for children and adolescents, many schools have physical education (PE) class 1 to 2 times per week for 30 minutes to 1 hour per class. It is unknown whether, despite the lack of opportunity for PA in PE, students from a multi-ethnic, low income, urban setting meet the recommendations for PA through participation in outside of school activities, and in what types of PA students most often engage.

**PURPOSE:** To determine the number and types of PA children and adolescents from an urban core area participate in outside of school.

**METHODS:** The Physical Activity Checklist Interview (PACI) was administered to students (n= 1332; age 9-15 years; grades 4-8) in the school setting. Students were asked to circle activities in which they had participated before or after school on the previous day. Students were instructed to include only activities in which they had participated for at least 15 minutes. Students could indicate as many activities as appropriate and report additional activities that were not included on the form (PA and sedentary activities (SA)).

**RESULTS:** Ninety-two percent of students reported participating in  $\geq 1$  PA with an overall average of 2.8 activities before or after school. The most common out of school activities reported were walking (55% of students), running/jogging (30%), dance (29%), basketball (26%), and football (23%). However, 55% of students also reported participating in  $\geq 1$  SA. The majority of SA (46% of students) reported were technology based (screen time) such as TV, non-active video games, and computer use. Twenty-two percent of students also reported participating in other SA which included activities such as reading, doing homework, and talking on the phone.

**CONCLUSION:** Although they indicated a range of PA types, the majority of students were not participating in the recommended amount of PA. Because PA has a beneficial effect on physical and mental health, and patterns of health-related behaviors are often established in childhood, strategies to increase PA outside of school are needed. Additionally, because PA levels begin to decline during adolescence, health care providers, school personnel, community leaders and families should work to develop PA programs appropriate to students' interests.

2569 Board #244 MAY 31 3:30 PM - 5:00 PM

**Screen-based Entertainment Time And Physical Fitness In School-aged Children And Youth**

Leandro F6mias Machado de Rezende, Gerson Ferrari, Sandra Mahecha Matsudo, Victor Keihan Matsudo. *Celafiscs, S6o Caetano do Sul, Brazil.* (No relationships reported)

**INTRODUCTION:** Accumulated evidences suggest that, independent of physical activity level, sedentary behaviors are associated to high body composition in youth.

**PURPOSE:** to associate the computer time with physical fitness variables in children and youth from a low socioeconomic region.

**METHODS:** cross-sectional study from the "Longitudinal Project of Growth, Development and Physical Fitness in Children from Ilhabela", Brazil. The sample consisted of 191 youth aged 10-15 years-old, male (n=99) and female (n=92), living in a low socioeconomic status island in Brazil. The sedentary time was measured by interviewed-administered proxy-reported about screen time of: a- computer (1.34 $\pm$ 0.96 hours/day); b- videogame (1.01 $\pm$ 1.96 hours/day); c- TV (3.06 $\pm$ 2.39 hours/day); d- total-time (amount of computer, videogame and TV time) (5.09 $\pm$ 3.97 hours/day). Exposure was dichotomized as more than 2 hours and less than two hours. The physical fitness variables measured were: body weight, body height, adiposity (mean of 7 skinfolds) and waist circumference. The neuromotor variables included flexibility (sit and reach test), agility (shuttle run test), lower and upper-limb muscle strength (vertical jump test and handgrip, respectively), speed (50 meters dash test). All results from physical fitness variables were divided in tertile. The Logistic Regression was performed by unadjusted and adjusted (sex and gender) with confidence intervals of 95%.

**RESULTS:** The analysis showed that computer time was associated, in an adjusted odds ratios in the third tertile for vertical jump 4.22 (CI 95% 1.55-1.52) and agility 0.35 (CI 95% 0.12-1.02). Videogame time was associated with the third tertile of waist circumference 0.29 (CI 95% 0.09-0.97), adiposity 3.68 (CI 95% 1.17-11.58) vertical jump test 3.16 (CI 95% 1.19-8.38). Television viewing time was associated with vertical jump 3.86 (CI 95% 1.29-11.55) and agility 0.19 (CI 95% 0.68-0.54).

**CONCLUSION:** Screen based entertainment time was associated with low-performance in neuromotor variables as agility and lower-limb muscle strength as well with high adiposity in school-aged children from a low socioeconomic level living in an island in Brazil.

2570 Board #245 MAY 31 3:30 PM - 5:00 PM

**Is Active Transport to/from School Important to Improve Metabolic Health in Adolescents?**

Andreia N. Pizarro, Clarice Martins, Joana Teixeira, Jos6 Ribeiro, Jorge Mota, Maria Paula Santos. *Porto University - Sports faculty, Porto, Portugal.* (No relationships reported)

Active transport (AT) should be consider a major key factor to reduce important negative health outcomes as it has been identified as an important source of physical activity (PA) for young people. However, it is still unclear whether this type of PA has enough potential to reduce the metabolic risk factors by improving lipid profile, glucose and blood pressure, reducing obesity or help achieving physical activity recommendations.

**PURPOSE:** to determine associations between active transport and metabolic risk factors.

**METHODS:** Participants were 230 adolescents (122 girls) with mean age of 11.7 ( $\pm$ 0.8) years old from Porto, Portugal. AT was accessed by questionnaire. Physical activity was obtained with Actigraph accelerometer Model GT1. Lipid profile measurements were conducted with Cholestech LDX<sup>®</sup> analyser. Waist circumference (WC) was measured midway between the lower rib margin and the iliac crest at the end of normal expiration. Blood pressure was obtained with Dinamap model BP 8800 according to standard procedures. Metabolic risk factors included HDL-C <40 mg/dL, triglycerides (TG)  $\geq$ 150 mg/dL, Glucose (GLU)  $\geq$ 100mg/dL, systolic/diastolic blood pressure  $\geq$ 130/85 mm hg, WC  $\geq$ 90th percentile.

**RESULTS:** Binary logistics regression showed that adolescents who reported active transport to/from school had a significantly higher likelihood of having a better HDL-C levels (OR=2.64, 1.27 to 5.48, p<.01) and achieving PA recommendations (OR=3.82, 1.09 to 13.33, p<.05) compared to those who reported passive transport. No significant associations were observed for TG, GLU, BP and WC.

**CONCLUSION:** Active transport to/from school appears to improve HDL-C; however more interventions and longitudinal studies are needed to investigate the nature of this relationship.

**Syndrome Metabolic Risk, Physical Activity And Overweight In Children Of Rural Communities.**

Jose G. Montano Corona<sup>1</sup>, Ma. Teresa Melchor-Moreno<sup>1</sup>, Fernando Cervantes<sup>1</sup>, Roberto Caffo<sup>2</sup>. <sup>1</sup>Universidad de Guanajuato, Leon, Guanajuato, Mexico. <sup>2</sup>Universidad Nacional de Trujillo, Trujillo, Peru. (Sponsor: Universidad de Guanajuato, FACSM) (No relationships reported)

**PURPOSE:** Identify the level of physical activity, dietary habits and metabolic syndrome in rural children.

**METHODS:** 5 boys and 9 girls 10 years of age. They were measured, weight, height and calculated the body mass index (BMI), waist circumference and blood pressure. In addition, we applied the lifestyle survey, Survey Food and blood sample to determine fasting conditions, glucose, HDL, triglycerides. Was implemented with a physical activity monitor and energy expenditure.

**RESULTS:** In men and women body weight was found in 33.0 and 34.0 $\pm$ 4 $\pm$ 2 kg, height 134 $\pm$ 4 and 135 $\pm$ 2 cm and BMI 17.5 $\pm$ 0.4 and 18.6 $\pm$ 0.3 respectively. In addition, physical activity in men and women registered was 45 and 60% (light), 40 and 30% (moderate) and 15 and 5% (intense), respectively. The results in blood was observed that significant differences existed between gender p<0.05=0.0014 and only triglycerides showed values [Unsupported Character - &#8203;] [Unsupported Character - &#8203;] for SM in children.

**CONCLUSIONS:** 100% of the children do daily physical activity, foods high in energy content will increase. There are significant differences in SM variables except abdominal circumference and triglycerides in children only qualified for metabolic syndrome.

---

**2572** Board #247 **MAY 31 3:30 PM - 5:00 PM**  
**Eating Behaviors And Fitness Scores Differ By Socio-economic Status In Elementary School Students**  
Mariane M. Fahlman, FACS<sup>1</sup>, Heather L. Hall<sup>2</sup>. <sup>1</sup>Wayne State University, Detroit, MI. <sup>2</sup>Elmhurst College, Detroit, MI.  
(No relationships reported)

There is a clear disparity in health in the United States such that groups of lower socioeconomic status (SES) (L) are more likely to suffer from morbidity and mortality related to chronic disease than those of higher SES (H). While chronic disease does not manifest itself until late in life, the health behaviors that contribute to it begin in childhood and have a cumulative effect. Thus, direct intervention strategies aimed at high risk populations are appropriate.

**PURPOSE:** To determine if fitness levels and eating behaviors differ by SES as early as elementary school.

**METHODS:** The study population consisted of 1064 elementary school students from urban and suburban schools in the Midwest. Students completed the Fitnessgram® fitness test which measured aerobic fitness, abdominal and upper body muscular endurance, back and hamstring flexibility, and body mass index (BMI); and the Eating Behavior Survey which measured intake of fruits, vegetables, meats, grains and non-nutritious foods. Comparisons between SES were conducted using analysis of variance with a Tukey post hoc.

**RESULTS:** Significant differences between H SES and L SES students were found on the following dependent variables in both males and females. ( $p < 0.05$ ). Sample data for females: BMI (L = 20.1 + 1.2; H = 18.5 + 0.5); mile run in seconds (L = 834 + 30.7; H = 626 + 18.5); curl-ups (L = 20.8 + 3.3; H = 35.0 + 2.7); and push-ups (L = 8.7 + 1.3; H = 15.1 + 0.7). Eating behaviors showed similar trends. Fruits (L = 0.8 + 0.3; H = 3.0 + 0.7); vegetables (L = 0.9 + 1.0; H = 2.9 + 1.5); grains (L = 4.8 + 2.3; H = 6.3 + 3.7); and non-nutritious foods (L = 9.2 + 7.3; H = 4.5 + 2.5).

**CONCLUSIONS:** L SES students have lower fitness scores and poorer eating behaviors than H SES students. Recent research indicates that improvements in fitness reduce the risk of becoming overweight across puberty. Targeting these students for interventions at an early age may decrease their risk of obesity related disorders in adulthood.

---

**2573** Board #248 **MAY 31 3:30 PM - 5:00 PM**  
**Change in School Choice Policy and Active Commuting to Elementary School**  
John R. Sirard<sup>1</sup>, J. Michael Oakes<sup>2</sup>, Kelsey McDonald<sup>2</sup>. <sup>1</sup>University of Virginia, Charlottesville, VA. <sup>2</sup>University of Minnesota, Minneapolis, MN.  
(No relationships reported)

The strongest and most consistent correlate of whether a child will walk to school is the commute distance. In existing urban areas, restricting school choice, which forces more children to attend their neighborhood school, may reduce this distance barrier to actively commuting to school.

**PURPOSE:** The purposes of this study were to assess the effect of a new, more restrictive school choice policy, which separated the city into three geographical transportation zones, on changes in 1) travel distance to school for students in Minneapolis K-5 and K-8 schools and 2) prevalence of active commuting to Minneapolis K-5 and K-8 schools. We hypothesized that travel distance to school would decrease and the proportion of students actively commuting would increase.

**METHODS:** Baseline data were collected in spring 2010 and follow-up data in fall 2010 after the policy went into effect. School district transportation data were used to determine distance to school for the approximately 20,500 enrolled students across 39 schools. Direct observations of student travel modes (i.e., walking, bicycling, auto) during morning and afternoon commute times were used to assess changes in active and automobile commuting for school. Each school was observed by trained research staff on 2 morning and 2 afternoon commutes at each time point. A transportation survey was completed by the transportation coordinator at each school to control for any new active commuting programs or infrastructure projects.

**RESULTS:** Across all schools, distance to school significantly decreased from spring to fall 2010 (1.83+0.48 miles vs. 1.74+0.46 miles;  $p=0.002$ ). From spring to fall, there was a statistically significant 1% increase in the proportion of students actively commuting (about 205 students;  $p=0.024$ ) that was seen for the morning ( $p=0.033$ ) and afternoon commuting times ( $p=0.018$ ).

**CONCLUSIONS:** We observed a significant increase in active commuting to and from school after implementation of a restricted school choice policy, which was similar across the transportation zones. These findings indicate that reducing school choice options may decrease travel distance and increase active commuting to school.

Supported by a grant from Active Living Research #67295.

**2574** Board #249 **MAY 31 3:30 PM - 5:00 PM**  
**A Survey of Sports Health and Nutrition in Urban High School Athletes**  
Brian Y. Kim<sup>1</sup>, David Kruse<sup>2</sup>. <sup>1</sup>University of California Los Angeles, Santa Monica, CA. <sup>2</sup>University of California Irvine, Irvine, CA.  
(No relationships reported)

**PURPOSE:** To survey the baseline knowledge of sports health and nutrition in urban high school athletes and identify areas that can be targeted for education.

**METHODS:** Student-athletes enrolled in grades 9-12 at an urban, Title I-funded, public high school were asked to submit self-reported age, height, and weight, and complete a 23-item multiple-choice questionnaire covering various topics in sports nutrition and health. CDC criteria were used to determine BMI %ile, underweight, overweight, and obesity. Comparisons of means and proportions were made using two-tailed t-tests and confidence intervals, respectively.

**RESULTS:** 424 students (304 M, 120 F) completed the survey. Mean age was 16 y (M 15.8 y, F 15.9 y;  $p = 0.76$ ). Mean BMI %ile was 68.9, (M 69.9, F 66.1;  $p = 0.15$ ). 32% were overweight (M 34%, F 24%; CI 0.003-0.2) and 15% were obese (M 19%, F 4%; CI 0.09-0.21). 1 boy and 1 girl were underweight. Overall, 44% were happy with their bodies (M 47%, F 38%; CI -0.02-0.19). Girls more frequently reported a desire to lose weight (M 37%, F 67%; CI 0.2-0.4) and endorsed planning to lose weight (M 14%, F 25%; CI 0.02-0.19). Boys were more likely to desire gaining weight (M 32%, F 7%; CI 0.18-0.32). 9% of athletes reported current dieting to lose weight (M 9%, F 11%; CI -0.09-0.04) and 15% admitted to dieting to lose weight in the past (M 14%, F 18%; CI -0.12-0.04) with no significant differences between sexes. 76% identified carbohydrates (CHO) as an important source of fuel during exercise, but only 48% and 58% correctly identified cereals and fruit, respectively, as good sources of CHO. Girls were more likely to consider nuts a good source of CHO (M 55%, F 69%; CI 0.05-0.25), whereas boys were more likely to consider steak a good source of CHO (M 36%, F 26%; CI 0.01-0.2). 59% of athletes considered a high protein diet the ideal diet for teenage athletes and 56% considered protein an important source of fuel during exercise. 60% believed that all athletes should be taking a daily multivitamin. Boys were more likely to agree with the statement that B vitamins improve exercise performance (M 14.5%, F 5.8%; CI 0.14-0.03). 57% of girls were able to identify the female athlete triad.

**CONCLUSIONS:** High school athletes display deficits in several areas of knowledge related to sports health and nutrition, and may benefit from targeted education addressing these topics.

---

**2575** Board #250 **MAY 31 3:30 PM - 5:00 PM**  
**The Relationship Between Active Travel to School, Sports Participation and Obesity in Young People**  
M. Joao C A Almeida, Marlene M. Rodrigues, Ana J A Rodrigues, Mario A. Botelho, Diogo J. Neves, Fatima J. Goncalves, Marco Fernandes. *University of Madeira, Funchal, Portugal.*  
(No relationships reported)

Informal physical activity (PA) such as active travel to school (ATS) is an important source of physical activity for children and adolescents. However, more research is needed for better understanding the relationship between ATS and parameters of health-related fitness.

**PURPOSE:** The purpose of this study is to investigate the relationship between ATS and, % body fat (%BF) and estimates of  $VO_2$ max.

**METHODS:** Participants in this study were 1329 adolescents (630 boys and 699 girls), between 10 and 17 years of age ( $x=11.7\pm 1.6$  yrs), from 4 schools in Madeira Island, Portugal. Participants completed the PAQ-C questionnaire (Crocker et al., 1997), and answered questions about transport to and from school as well as sport participation. Measures for height, weight, waist circumference, triceps and calf skinfolds were taken, % BF was estimated according to Slaughter et al. (1988), and participants classified in health risk categories (Lohman, 1987).

**RESULTS:** Of all participants, only 10% walked daily to and from school, with a duration of at least 20 minutes. About 53.1% of participants did not participate in any organized activities

apart from PE classes, and 41% had a high or very high %BF. Results showed significant differences between boys and girls ( $p < 0.05$ ), with boys reporting higher mean levels in the PA score ( $2.73 \pm 0.71$  vs.  $2.23 \pm 0.51$  for boys and girls, respectively), with a significant decrease in the PA scores, as age increased. Students who went to school by car or bus (non-ATS) had a significantly higher %BF ( $p < 0.05$ ), compared to those who use ATS (26.7% vs. 22.2%, respectively). Three predictors for high or very high % BF were identified: being younger (OR=1.136; 95%IC: 1.036-1.246), using non-ATS (OR=1.002; 95%IC: 1.000-1.005), and not participating in organized sports and activities (OR = 1.212; 95%IC: 1.034-1.421).

**CONCLUSION:** Strategies to promote PA in youth should target active travel to school, younger ages and opportunities for participating in organized physical activities.

**Screening for Risk of the Female Athlete Triad Among High School Athletes**

Katie N. Brown<sup>1</sup>, Heidi J. Wengreen<sup>1</sup>, Katherine A. Beals, FACSM<sup>2</sup>. <sup>1</sup>Utah State University, Logan, UT. <sup>2</sup>University of Utah, Salt Lake City, UT.

(No relationships reported)

Screening to identify high school athletes at risk for the Female Athlete Triad (Triad) would allow for intervention to prevent deleterious effects of the Triad. Currently there are no screening tools that are brief and easy to administer to large numbers of athletes in a high school setting.

**PURPOSE:** To develop and explore the use of a brief survey to assess knowledge and prevalence of Triad risk factors among female high school athletes so as to guide the development of future screening and intervention programs.

**METHODS:** Female high school athletes (n=163) representing a variety of sports completed a brief questionnaire that assessed knowledge of the components of the Triad as well as Triad risk factors including eating behaviors, body weight beliefs, menstrual history and history of stress fracture. Triad knowledge questions were piloted among 52 athletes, and formally assessed in the remaining 91. Descriptive statistics were calculated and differences between athlete groups were examined using analysis of variance and chi squared distributions.

**RESULTS:** None of the athletes had heard of the Triad and few answered the Triad knowledge questions correctly. Only 31% knew that skipping a period during training was not normal; 30% knew that not eating enough could influence menstrual dysfunction; 13% knew that stress fractures occurred more frequently in girls who skip their period; and 23% knew that skipping periods could cause their bones to become weak. Cheerleaders had more correct answers (53%) than the other athlete groups ( $p = .006$ ). Nineteen percent of athletes reported having suffered a stress fracture, although this was more common among drill team members (59%,  $p < .0001$ ). A history of amenorrhea was reported by 24% of athletes. Seventeen percent of the athletes had a BMI  $< 18.5$  kg/m<sup>2</sup>, 79% had a BMI between 18.5 kg/m<sup>2</sup> and 25 kg/m<sup>2</sup>, and 4% had a BMI greater than 25 kg/m<sup>2</sup>. The average desired weight change was -4.0 lbs. Of the 46 athletes (28%) who reported wanting to lose more than 10 lbs, 92% had a BMI less than 25 kg/m<sup>2</sup>. Fifty-nine percent of the athletes reported feeling pressure to be a certain weight; for most (80%) the pressure was self-imposed.

**CONCLUSIONS:** Knowledge of the Triad among this group of female high school athletes was poor and many were demonstrating behaviors and attitudes that placed them at risk for the Triad.

2577 Board #252 MAY 31 3:30 PM - 5:00 PM

**Physical Activity In Adolescents In An Olympic Borough Prior To The London 2012 Olympic Games**

Zoe Hudson, Stephanie JC Taylor, Eoin McNamara. *Barts and The London School of Medicine and Dentistry, Queen Mary University of London, London, United Kingdom.*

(No relationships reported)

Overweight and obesity continues to escalate in children. Tower Hamlets (TH) is multi ethnic, socio-economically deprived and one of the five Olympic boroughs for the Olympic Games in London 2012.

**PURPOSE:** To evaluate current pedometer determined physical activity and body composition in 11-12 yr olds in TH.

**METHODS:** All secondary schools were invited to participate. A sealed pedometer was worn for 7 days. Internationally recognised mean daily step count cut-offs (boys = 15000, girls = 12000) were used to define activity level. BMI, BIA-determined % body fat (BF) and waist circumference (WC) were all measured. Children were classified as normal weight, overweight or obese according to international cut-off points. A questionnaire was also administered to establish socioeconomic status and ethnicity.

**RESULTS:** 452 boys and 229 girls took part, 69 and 62% were South Asian, respectively. Boys were more active than girls (mean daily steps  $11,580 \pm 3560$  vs  $10,062 \pm 3239$ ) ( $p < 0.001$ ). Activity was greater during the week compared to the weekend (mean step counts of 11,297 and 10,080, respectively). There was no significant difference by ethnicity or socioeconomic status. Overweight/obesity ranged from 33.5%, 53.2% and 61.5% for BMI, % BF and WC, respectively (Table 1). BMI cut-offs may under-estimate overweight/obesity in a South Asian population.

Table 1 Percentage body composition according to 3 different measures

|            | BMI  | WC   | % BF |
|------------|------|------|------|
| Normal     | 66.0 | 46.8 | 38.5 |
| Overweight | 20.5 | 23.8 | 16.5 |
| Obese      | 13.5 | 29.4 | 45.0 |

There was no significant interaction between activity and body composition in this cohort.

**CONCLUSION:** Over 50% were overweight or obese according to % BF and WC. Only 16.6 % of boys and 27.9 % of girls achieved the minimum recommended daily step counts. Intervention strategies are required.

Supported by an Icebreaker grant

**Physical Activity, Bmi Percentile, And Vascular Health In U.s. Children And Adolescents: Nhanes 2003-2006**

Heather H. Betz<sup>1</sup>, Joey C. Eisenmann<sup>2</sup>, Kelly R. Laurson<sup>3</sup>, Katrina D. DuBose, FACSM<sup>4</sup>, James M. Pivarnik, FACSM<sup>5</sup>, Mathew J. Reeves<sup>5</sup>, Joseph J. Carlson<sup>5</sup>, Karin A. Pfeiffer, FACSM<sup>6</sup>. <sup>1</sup>Albion College, Albion, MI. <sup>2</sup>Helen DeVos Children's Hospital, Grand Rapids, MI. <sup>3</sup>Illinois State University, Normal, IL. <sup>4</sup>East Carolina University, Greenville, NC. <sup>5</sup>Michigan State University, East Lansing, MI.

(No relationships reported)

**PURPOSE:** To examine the main effects and combined association of physical activity (PA) and body mass index (BMI) percentile on resting blood pressure (BP) and C-reactive protein (CRP) in a nationally representative sample of United States (U.S.) children and adolescents from the National Health and Nutrition Examination Survey (NHANES).

**METHODS:** Cross-sectional analysis of the 2003-2004 and 2005-2006 NHANES was performed. Inclusion criteria included children and adolescents 8 to 18 years of age (1303 boys, 1282 girls) with BMI, BP, CRP, and PA data. BMI was calculated from measured height and weight (kg/m<sup>2</sup>). BMI percentiles were determined from Centers for Disease Control and Prevention growth charts. Resting BP was measured by standard procedure and mean arterial pressure (MAP) was calculated. CRP was analyzed from venous blood samples and log transformed for analysis. Subjects with CRP values greater than 10mg/L were excluded due to possibility of infection. PA [defined as minutes of moderate-to-vigorous PA (MVPA)] was assessed by accelerometry.

Subjects who wore the accelerometers  $> 10$  hours/day for  $> 4$  of the 7 measurement days were included in the analysis. Independent main and interaction effects of PA (MVPA minutes) and BMI percentiles with BP and CRP were analyzed separately using multivariate linear regression analysis. Separate analyses were undertaken in girls and boys.

**RESULTS:** A significant main effect for BMI percentiles was found in both boys and girls when examining CRP ( $\beta = 0.02$ ,  $p < 0.0001$ , boys;  $\beta = 0.02$ ,  $p < 0.001$ , girls) and systolic BP ( $\beta = 0.07$ ,  $p = 0.002$ , boys;  $\beta = 0.09$ ,  $p < 0.0001$ , girls). No main effect was found for PA. In either gender, there were no significant interactions between PA and BMI percentile on either BP (MAP, systolic BP, or diastolic BP) ( $p = 0.22-0.76$ , boys;  $p = 0.18-0.92$ , girls) or CRP ( $p = 0.96$ , boys;  $0.50$ , girls).

**CONCLUSION:** BMI percentile, but not MVPA minutes, was directly associated with CRP and systolic BP in a nationally representative sample of U.S. children and adolescents. No combined association was seen between PA and BMI percentile when examining BP or CRP. Our data suggest that a public health focus should be reducing fatness in children and adolescents with elevated BP and CRP.

**Validity of Accelerometry During Free-Living Activity In Children**

Scott E. Crouter, FACSM<sup>1</sup>, Magdalene Horton<sup>1</sup>, David R. Bassett, Jr, FACSM<sup>2</sup>. <sup>1</sup>University of Massachusetts Boston, Boston, MA. <sup>2</sup>The University of Tennessee Knoxville, Knoxville, TN.

(No relationships reported)

Accelerometers are commonly used to assess free-living physical activity (PA). Most validation studies with accelerometers focus on structured activities; however it has not been determined how well they work under free-living conditions.

**PURPOSE:** The primary purpose of this study was to examine the validity of the Crouter vector magnitude 2-regression model (Cvm2RM) and the Crouter vertical axis 2RM (Cva2RM) for children, to estimate energy expenditure (EE) and time spent in sedentary behaviors (SB), light PA (LPA), moderate PA (MPA), and vigorous PA (VPA) during a 2-hr free-living measurement. A secondary purpose was to examine single linear regression equations for children under the same conditions.

**METHODS:** Twenty-seven boys and 15 girls (mean±SD; age, 12±0.8 yrs; BMI percentile, 73.1±28.4%) were monitored for 2-hrs of free-living activity. Activity data was collected using an ActiGraph GT3X+, positioned on the right hip, and measured EE (METs) was obtained using a Cosmed K4b<sup>2</sup>. ActiGraph prediction equations for children (Cvm2RM, Cva2RM, Freedson, Treuth, Trost, and Puyau) were compared against the Cosmed for mean METs and time spent in LPA, MPA, and VPA. Measured METs were calculated as measured activity VO<sub>2</sub> divided by measured resting VO<sub>2</sub>. For comparability all prediction equations were converted to METs using measured resting VO<sub>2</sub>.

**RESULTS:** On average, participants were monitored for 95.0±36.5 minutes. The Puyau equation was within 0.1±1.8 METs of measured METs; all other methods significantly underestimated measured METs (P<0.05). For SB, the Cvm2RM, Treuth and Trost equations were all within 7-min of measured values (P>0.05), the other equations overestimated measured SB time (P<0.05). Measured time spent in LPA and MPA was overestimated by the Cvm2RM (11.0 min) and Puyau (25.2 min) equations, respectively (P<0.05). All prediction equations significantly underestimated measured time spent in VPA. The Cvm2RM and Cva2RM had 95% prediction intervals that were 20-50% lower than the other equations for time spent in SB, LPA, and MPA.

**CONCLUSION:** Compared to the Cosmed, all prediction equations were significantly different from at least one PA intensity category, however the use of a 2RM in children reduced the individual errors compared to other equations.

**2580** Board #255 MAY 31 3:30 PM - 5:00 PM

**Actigraph Cut-Points for Sedentary Behaviour and Moderate-to-Vigorous Intensity Physical Activity in 2-3 Year Old Children**

Silvia S. N. Costa<sup>1</sup>, Stacy A. Clemes<sup>1</sup>, Sally Barber<sup>2</sup>, Paula Griffiths<sup>1</sup>, Noël Cameron<sup>1</sup>. <sup>1</sup>Loughborough University, Loughborough, United Kingdom. <sup>2</sup>Bradford Institute for Health Research, Bradford, United Kingdom.

(No relationships reported)

Whilst accelerometers have become the preferred instruments for objectively measuring physical activity (PA), the short/sporadic nature of young children's PA patterns requires the use of short (<15 seconds) sampling periods (epochs). There are currently no accepted cut-points for determining time spent in sedentary behaviour and time spent in moderate-to-vigorous intensity PA (MVPA) in toddlers, for epochs shorter than 15 seconds.

**PURPOSE:** To determine Actigraph cut-points for defining sedentary behaviour and MVPA in 2-3 year old children, for 5 and 10 second epochs.

**METHODS:** Twenty-two toddlers (age: 2.92 ± 0.55 years) were video recorded during a 25 minute structured activity session, whilst wearing an Actigraph GT3X+ accelerometer positioned on the right hip with an elastic belt. Children's PA was coded second-by-second using the Children's Activity Rating Scale (CARS). Receiver Operating Characteristic curve analysis was used to determine the sedentary behaviour and MVPA cut-points for accelerometer counts derived from the vertical axis at 5 and 10 second epochs, using the average CARS score per epoch. Epochs with an average CARS score ≤2 were classified as sedentary behaviour, while epochs with an average CARS score ≥4 were classified as MVPA.

**RESULTS:** The sedentary behaviour and MVPA cut-points for 5 second epochs are ≤29 counts/epoch (Se: 82.1%; Spec: 84.0%; Area under the curve (AUC): 0.914) and ≥178 counts/epoch (Se: 86.4%; Sp: 85.3%; AUC: 0.926), respectively.

For 10 second epochs, the sedentary behaviour and MVPA cut-points are ≤85 counts/epoch (Se: 81.9%; Sp: 82.2%; AUC: 0.894) and ≥365 counts/epoch (Se: 84.6%; Sp: 82.6%; AUC: 0.917), respectively.

**CONCLUSIONS:** To our knowledge, this is the first study to develop cut-points at shorter epochs for use in toddlers, using the new ActiGraph GT3X+. The proposed cut-points show high Se and Sp, and can be used to estimate time spent in sedentary behaviour, light and MVPA in 2-3 year old children, for the Actigraph GT3X+.

**Active Commuting to School Predicts One-year Changes in Children's Physical Activity**

Stephen H. Wong, FACSM, Wendy Y. Huang, Gang He. *The Chinese University of Hong Kong, Hong Kong, China.*

(No relationships reported)

It has been suggested that children who actively commute to school tend to be more physically active than passive commuters. However, the longitudinal association of active commuting with overall physical activity (PA) has not been well established.

**PURPOSE:** To determine the one-year PA changes among 6-10 years old Chinese children and to examine whether PA levels in active commuters at baseline were less likely to decline than those in passive commuters.

**METHODS:** Participants were a subsample of a cohort in a longitudinal study Understanding Children's Activity and Nutrition (UCAN). PA was assessed by Actigraph accelerometers for 8 consecutive days at baseline and one year follow up. Time spent in moderate-to-vigorous PA (MVPA) was estimated based on the age- and gender-specific cut-off points. Children's usual travel mode to/from school was reported by their parents at baseline. Children were then categorized on the number of active commuting trips to and from school per week, i.e. active, ≥5; passive, 0-5. Changes in PA between baseline and one-year later were assessed using paired *t* test. The association between active commuting on changes in PA was determined using a generalized estimating equations adjusting for gender, age, parental education and baseline body mass index (BMI).

**RESULTS:** A final sample of 166 children (42.2% boys, 7.6 ± 1.0 yr) recorded sufficient ActiGraph data for both assessments, i.e. 10 hours per day during at least 3 weekdays, whilst their parents provided the complete information on the frequency of travel mode to school. MVPA on weekdays decreased at follow-up among 54% of the girls and 60% of the boys. On average, the girls reduced MVPA by 11.8 minutes (95%CI: 1.6, 21.9, P<0.05) while the boys reduced by 3.9 minutes (95%CI: -10.3, 18.1, NS). The active commuters at baseline were more likely to increase their PA participation at follow up compared with the passive commuters (B=19.5, 95%CI: 1.5, 37.4, P<0.05) after adjusting for gender, age, parental education, and baseline BMI.

**CONCLUSIONS:** PA participation decreased over a one year period among Chinese girls. Children who actively commuted to school at baseline were less likely to decrease the PA participation compared with the passive commuters.

2582 Board #257 MAY 31 3:30 PM - 5:00 PM

**Reliability Of Free-living Physical Activity Using Hip- And Wrist-worn Activity Monitors In Adolescents**

Katelyn J. Taylor, Daniel P. Heil, FACSM. *Montana State University Movement Science / Human Performance Lab, Bozeman, MT.*  
(No relationships reported)

While stability reliability of hip-worn accelerometry-based activity monitors (HAM) has been reported in adolescents, currently there has been no research into the stability reliability of wrist-worn AMs (WAM).

**PURPOSE:** This study examined the stability reliability of physical activity (PA) variables measured by HAM and WAM in adolescents under free-living conditions.

**METHODS:** Eleven girls (Mean  $\pm$  SD: 14  $\pm$  2 yrs) and 10 boys (15  $\pm$  2 yrs) wore a HAM and WAM for 14 consecutive days. The PA variables included: total time (min/day) occurring at a sedentary ( $T_S$ ), light ( $T_L$ ) and  $\geq$  moderate ( $T_{MV}$ ) intensity PA, and the sum of activity energy expenditure (AEE; kcal/day) occurring at a light ( $AEE_L$ ) and  $\geq$  moderate intensity ( $AEE_{MV}$ ), and total AEE ( $AEE_T$ ). Stability reliability was assessed with intraclass correlation coefficients specific to a single day within the monitoring period ( $ICC_{DAY}$ ) calculated using variance values from a RM ANOVA, for all variables for both AM locations and minimum bout durations (BD) of 1-, 5-, and 10-min. The  $ICC_{DAY}$  values allowed for the necessary number of monitoring days to reliably measure ( $ICC_{DAY} \geq 0.80$ ) each variable to be determined. Additionally, 95% confidence intervals (CI) were calculated for all  $ICC_{DAY}$  values to determine if any significant differences existed between variables by AM location.

**RESULTS:** No significant differences in  $ICC_{DAY}$  values were found between HAM and WAM for any variable (i.e., overlapping CIs), however distinct trends were observed. Excluding  $T_L$  measured by the WAM,  $ICC_{DAY}$  values for all variables decreased as BD increased from 1- to 10-min. The number of monitoring days necessary to reliably measure  $AEE_L$ ,  $AEE_{MV}$ ,  $AEE_T$ ,  $T_L$ , and  $T_{MV}$  was greater for HAM versus WAM across BD, ranging from 2-26 versus 2-10 days, respectively. Conversely, the number of monitoring days to reliably measure  $T_S$  was lower for HAM (4-5 days) versus WAM (6-8 days). Among all variables,  $T_L$  measured by both HAM and WAM had the largest range of days necessary to reach an  $ICC_{DAY} \geq 0.80$  across all BDs, 6-26 and 7-10 days, respectively.

**CONCLUSION:** Reliability of PA variables changed with BD and AM location, and was generally higher for WAM. Practically, the results of the study suggest that a monitoring period of 7 consecutive days allows for WAM to reliably measure a variety of free-living PA variables in adolescents.

2583 Board #258 MAY 31 3:30 PM - 5:00 PM

**Comparison Between Sensewear Mini Armband And Actigraph Accelerometers In Classifying Physical Activity Intensities In Youth.**

Youngwon Kim<sup>1</sup>, Jungmin Lee<sup>1</sup>, Yang Bai<sup>1</sup>, Glenn A. Gaesser<sup>2</sup>, Gregory J. Welk, FACSM<sup>1</sup>. <sup>1</sup>Iowa State University, Ames, IA. <sup>2</sup>Arizona State University, Phoenix, AZ  
(Sponsor: Gregory J. Welk, FACSM)  
(No relationships reported)

**PURPOSE:** The purpose of this study was to compare the accuracy of SMA and Actigraph in classifying youth MVPA in relation to a criterion measure.

**METHODS:** A total of 42 youth ages 7 - 13 (male: 31, female: 11) performed a set of 12 different free living activities while wearing the SMA, an Actigraph and while being monitored with an Oxycon Mobile (OM) metabolic analyzer. The 12 activities (randomly selected from a set of 25) were of varying intensity (i.e. sedentary, light, moderate and vigorous) and were completed in a random order to simulate real world conditions. Each activity lasted 5 minutes, with 1 minute between activities. Six different Actigraph cut-points were applied to estimate MVPA from the Actigraph activity counts [Freedson/Trost (FT), Puyau (PU), Vanhelst (VH), Treuth (TH), Evenson (EV), Mattocks (MT)]. The SMA data were processed using the latest software (version 8.0, pre-released algorithm 5.2e). A metabolic equivalent (MET) of 4 was used to differentiate MVPA from non-MVPA for the OM and SMA. Weighted Cohen's kappa coefficient ( $\kappa$ ), sensitivity (Se) and specificity (Sp) were used to determine classification accuracy compared to the OM. The total recorded minutes of MVPA from OM, SMA and the Actigraph cut-points were also directly compared to one another.

**RESULTS:** SMA showed substantially better classification agreement ( $\kappa = .64$ ) than the various Actigraph cut-points (FT = .34; PU = .18; VH = .34; TH = .20; EV = .28; MT = .16). The Se for OM (.89) was greater than the 6 sets of Actigraph cut-points (range from .24 - .49). The Sp for OM (.75) was smaller than the Actigraph values (range from .97 - .99) but still acceptable. The estimated minutes of MVPA from SMA (48.4 $\pm$ 7.8min) were nearly identical to those from OM (48.7 $\pm$ 9.1min). In contrast, the 6 Actigraph cut-points all underestimated the OM values (FT = 23.5 $\pm$ 8.0min; PU = 13.3 $\pm$ 5.9min; VH = 23.5 $\pm$ 6.8min; TH = 14.3 $\pm$ 6.1min; EV = 19.7 $\pm$ 6.7min; MT = 11.6 $\pm$ 5.5min).

**CONCLUSION:** The SenseWear Mini Armband yielded better classification agreement for monitoring youth physical activity. The high specificity of the various Actigraph cut-points appears to underestimate the actual activity levels of children in simulated free living conditions.

2584 Board #259 MAY 31 3:30 PM - 5:00 PM

**A Comparison Of Weight Status And Health-related Fitness Between Canadian And English 10-yr Olds**

Christine Voss<sup>1</sup>, Heather Macdonald<sup>1</sup>, Lindsay Nettlefold<sup>1</sup>, Gavin Sandercock<sup>2</sup>, Heather McKay<sup>1</sup>. <sup>1</sup>University of British Columbia, Vancouver, BC, Canada.  
<sup>2</sup>University of Essex, Colchester, Essex, United Kingdom.  
(No relationships reported)

Over the last few decades, Canada and England have witnessed accelerated increases in childhood obesity and have independently documented secular declines in health-related fitness. No study has directly compared these outcomes between contemporary samples of Canadian and English children.

**PURPOSE:** First, to describe the prevalence of overweight and obesity; and second, to compare health-related fitness - between Canadian and English 10-yr old boys and girls.

**METHODS:** We obtained institutional ethics approval and parental consent to assess Canadian (n = 771, 49% boys; 10.7 $\pm$ 0.6 yrs; Fall 2008) and English children (n = 1030, 51% boys; 10.7 $\pm$ 0.6 yrs; Fall 2008). Measures were: stature (cm), body mass (kg), BMI (kg $\cdot$ m<sup>-2</sup>), aerobic fitness (20 metre shuttle run; laps) and upper body strength (dominant arm hand grip; kg). BMI was used to classify children as overweight or obese as per International Obesity Task Force (IOTF) criteria. We conducted analyses by sex to determine between-cohort differences (Pearson's chi-square, independent t-tests or ANCOVA; PASW v. 18.0; significance set at p < 0.05).

**RESULTS:** Compared with English children, Canadians were significantly taller (boys: 145.8 $\pm$ 7.9 vs. 143.4 $\pm$ 7.5; girls: 146.1 $\pm$ 8.0 vs. 143.9 $\pm$ 7.7) and heavier (boys: 41.8 $\pm$ 11.4 vs. 38.7 $\pm$ 9.2; girls: 40.7 $\pm$ 10.0 vs. 39.1 $\pm$ 9.0); however, prevalence of IOTF weight categories did not differ significantly between countries. More than a quarter of children in Canada and England were overweight (22% vs. 20%) or obese (7% vs. 5%). English children completed significantly more laps in the shuttle run compared with their Canadian peers (boys: 40 $\pm$ 21 vs. 35 $\pm$ 17; girls: 30 $\pm$ 15 vs. 27 $\pm$ 13; respectively). Results did not change after adjusting for age and BMI. Canadian children were significantly stronger than their English counterparts (boys: 21.5 $\pm$ 4.8 vs. 16.8 $\pm$ 3.8; girls: 19.2 $\pm$ 4.7 vs. 15.8 $\pm$ 3.8; respectively). Results did not change after adjusting for age and body mass.

**CONCLUSION:** This is the first study to compare overweight/obesity patterns and fitness levels of Canadian versus English children. Importantly, health-related fitness differed between groups that had a comparable obesity burden. Research into the underlying mechanisms, which are likely to include differences in physical activity patterns, is warranted.

**Comparison Of Accelerometer Cut-points In Physical Activity Assessment Of Rural South African Children And Adolescents**

Eva Craig<sup>1</sup>, Ruth Bland<sup>2</sup>, John Reilly<sup>3</sup>. <sup>1</sup>University of Glasgow, Glasgow, United Kingdom. <sup>2</sup>Africa Centre for Health and Population Studies, KwaZulu-Natal, South Africa. <sup>3</sup>University of Strathclyde, Glasgow, United Kingdom. (Sponsor: David Rowe, FACSM)  
(No relationships reported)

Objective physical activity assessment is novel in rural Africa, little is known regarding volume or intensity of physical activity in this population and no studies have compared accelerometer cut-points.

**PURPOSE:** To compare accelerometer cut-points for assessing physical activity levels in South African children/adolescents.

**METHODS:** The study took place within the Africa Centre for Health and Population Studies surveillance area in rural KwaZulu-Natal, South Africa. 150 participants; 50 from each school

grade 1, 5 and 9 (7, 11 and 15 years) were randomly selected from a previous cross-sectional study of 1519 and invited to take part in 7 days objectively measured physical activity using ActigraphGT3X accelerometers. Data were analysed using Puyau and Evenson cut-points; levels of moderate to vigorous physical activity (MVPA) were compared between the methods. Data were analysed for participants who had at least 3 days accelerometry with a minimum of 6 hours each day.

**RESULTS:** Of 150 approached, 38 chose not to take part and 23 provided incomplete accelerometer data, therefore, data from 89 participants were available for analysis.

Comparison of levels of MVPA using two different accelerometer cut-points

|                    | School Grade 1 |         | School Grade 5 |         | School Grade 9 |         |
|--------------------|----------------|---------|----------------|---------|----------------|---------|
|                    | Puyau          | Evenson | Puyau          | Evenson | Puyau          | Evenson |
| n                  | 26             |         | 33             |         | 30             |         |
| Mean % MVPA        | 1.6            | 8.0*    | 1.5            | 5.1*    | 0.8            | 2.8*    |
| Mean MVPA Mins/day | 17             | 61*     | 11             | 39*     | 5              | 20*     |

\* significantly different to Puyau, in same grade  $p < .01$

Levels of MVPA were significantly higher using Evenson compared to Puyau cut-points, however compliance with international recommendations (60 minutes MVPA on most days) was extremely low irrespective of cut-point used. Applying Puyau cut-points no participants met the recommendations, for Evenson cut-points 7(27%) in grade 1, 2(6%) in grade 5 and 0(0%) in grade 9 met recommendations.

**CONCLUSION:** These results reveal an urgent need to determine which Actigraph cut-point is most accurate. However, using both cut-points, levels of engagement in MVPA were low in this sample.

**2586 Board #261 MAY 31 3:30 PM - 5:00 PM**  
**Establishing Wrist-based Cutpoints for the Actical Accelerometer in Elementary School Aged Children**

Christine A. Schaefer, Heidi J. Nace, Raymond C. Browning, FACSM. *Colorado State University, Fort Collins, CO.*  
*(No relationships reported)*

Accurate physical activity (PA) monitoring is crucial to understand the effectiveness of PA interventions. Wrist-mounted accelerometer (ACC) use is appealing, particularly in children for whom compliance is challenging. The Actical ACC has been validated and cutpoints established for wrist placement in 8-17 year-old children, but no study has validated its use in younger children performing typical activities.

**PURPOSE:** To establish wrist-based cutpoints for the Actical ACC in elementary aged children and to compare PA estimated by cutpoints using linear regression (LR) and Receiver Operator Characteristics, (ROC) curves.

**METHODS:** Metabolic and ACC data were collected in 6-11 year olds (n=22, mean age (SD), 8.73 (1.70) years, 55% female). Subjects completed 8 activities for 6 minutes each. METs were calculated by dividing measured  $\text{VO}_2$  by estimated resting values from Schofield's equation. LR and ROC were used to examine the relationship between METs and ACC counts. Cutpoints were established at 1.5, 3, 6 and  $\geq 6$  METs for sedentary (sed), light, moderate (mod) and vigorous (vig) activity, respectively. Each set of cutpoints was then applied to a large, multi-day sample (n=269, mean age (SD), 8.7 (1.8) years, 49% female) to examine differences in cutpoints on minutes of PA at each intensity.

**RESULTS:** LR yielded an  $r^2$  value of 0.83 ( $p < .001$ ). Cutpoints for sed, light, mod and vig activity using LR were 21, 2479, 7267, and  $\geq 7268$ , respectively. Cutpoints for sed, light, mod and vig activity using ROC were 208, 1551, 4843, and  $\geq 4844$ , respectively. ROC yielded areas under the curve of 0.95, 0.94 and 0.97 for sed, mod and vig intensities. When applied to a large multi-day sample, LR yielded 75 minutes of mod-vig PA (MVPA) and 63% of the sample met the guideline of 60 minutes of daily MVPA. ROC yielded 140 minutes of MVPA and 98% of the sample met the guideline.

**CONCLUSION:** In light of national data reporting children accumulate ~85 minutes of MVPA/day we recommend researchers use the LR cutpoints for the wrist-mounted Actical. These differences support adopting standardized methods for establishing cutpoints. Until then, within subjects and longitudinal study designs are most appropriate. A move toward collecting raw acceleration data is critical to improve estimates of PA.

**2587 Board #262 MAY 31 3:30 PM - 5:00 PM**  
**Sedentary Behavior And Overweight In Children And Adolescents**

Elin Kolle, Jostein Steene-Johannessen, Lars Bo Andersen, Sigmund A. Anderssen. *Norwegian School of Sport Sciences, Oslo, Norway.*  
*(No relationships reported)*

Evidence on the harmful effect of sedentary behaviour on health is emerging. Further, sedentary behaviour in children and youth is a concern as it tracks from childhood into adulthood. Previous studies of sedentary behavior have often relied on self-reported measures of the behavior, such as time spent watching TV. More studies using objective methods to measure sedentary behavior are needed to further explore the association between sedentary behavior and health indicators, such as body mass index (BMI).

**PURPOSE:** The purpose of this study was to determine time spent in sedentary behaviour using accelerometers, and to study the association between time spent in sedentary behaviour and BMI in a population based sample of 9- and 15-year-olds.

**METHODS:** This is a part of the Physical Activity among Norwegian Children Study (PANCS). A total of 2299 9- and 15-year-olds participated in the study, giving a participation rate of 82%. Sedentary behaviour was measured using the Actigraph accelerometer. The sum of minutes at  $< 100$  cpm was used to define time spent at sedentary behavior. Differences between groups were analysed using independent-sample T-test.

**RESULTS:** Nine-year-old boys and girls spent 6.9 h/day and 7.1 h/day, respectively, in sedentary behaviour. The corresponding numbers in 15-year-old boys and girls were 8.8 h/day and 9.0 h/day, respectively. In both age groups, girls spent more time in sedentary behaviour than boys ( $p \leq 0.026$ ), and 15-year-olds spent 2h more per day in sedentary behaviour than 9-year-olds ( $p < 0.001$ ). There was no association between time spent in sedentary behaviour and BMI, with the exception of 9-year-old boys where a weak correlation was observed ( $r = 0.1$ ,  $p = 0.04$ ).

**CONCLUSIONS:** Both 9- and 15-year olds spend a large proportion of the day being sedentary. Girls were more sedentary than boys, and time spent in sedentary behaviour increased with increasing age. The latter suggest that early intervention may be needed to prevent this increase. An association was found between sedentary behaviour in 9-year-old boys only, suggesting that more research is needed.

**2588 Board #263 MAY 31 3:30 PM - 5:00 PM**  
**How Many Days of Accelerometry Monitoring Predict Sedentary Behavior in Preschool Children?**

Wonwoo Byun, Steven N. Blair, FACSM, Michael W. Beets, Marsha Dowda, FACSM, Russell R. Pate, FACSM. *U of South Carolina, Columbia, SC.*  
*(No relationships reported)*

Accelerometry is emerging as the device of choice for the objective measure of habitual activity in children. However, little research has been conducted to understand the reliability of accelerometry in measuring sedentary behavior in preschool children.

**PURPOSE:** To determine: (1) how many days of accelerometry monitoring are necessary to reliably estimate sedentary behavior in preschool children, and (2) whether the number of days necessary to reliably estimate sedentary behavior differs by application of different cutpoints.

**METHODS:** The participants of this study were preschool children who were enrolled in the Children's Activity and Movement in Preschool Study. We included a total of 212 children who had  $\geq 4$  days of in-school accelerometry data and 150 children who had  $\geq 6$  days (including weekend) of total day data. Sedentary behavior was measured using ActiGraph accelerometers. Accelerometry data were summarized as time spent in sedentary behavior (min/hr of observation) using three different cutpoints developed specifically for 3- to 5-year old children ( $< 37.5$  cts/15s,  $< 200$  cts/15s, and  $< 373$  cts/15s). PROC MIXED procedure was used to determine if the amount of time spent in sedentary behavior is different across days of the week. The ICCs and

95% confidence intervals (CIs) were calculated using variance estimates from repeated ANOVA model. The number of days of accelerometry monitoring required to reliably estimate sedentary was estimated using the Spearman-Brown prophecy formula.

**RESULTS:** On average, the children wore the accelerometers for a total of 12.1 hrs/d and 8.4 hrs/d while in school. Preschool children spent less time in sedentary behavior on weekend days compared to weekdays ( $P < .05$ ). Across different cutpoints, the ICCs ranged from 0.75 to 0.81 for total sedentary behavior, and from 0.81 to 0.92 for in-school sedentary behavior, respectively. To achieve the ICC of  $\geq 0.8$ , between 6.4 and 8.6 days, and between 1.8 and 4.4 days of monitoring was needed for total sedentary behavior, and in-school sedentary behavior, respectively.

**CONCLUSIONS:** The greatest reliability, and hence the lowest number of days needed for the ICC of  $\geq 0.8$ , was obtained using the cutpoints of  $<373$  cts /15s for total daily sedentary behavior (6.4 days), and  $<200$  cts /15s for in-school sedentary behavior (1.8 days) respectively.

**2589** Board #264 MAY 31 3:30 PM - 5:00 PM

**Do Physically Active Young Children Maintain Their Activity Levels After The Preschool Day?**

Jennifer R. O'Neill<sup>1</sup>, Marsha Dowda, FACSM<sup>1</sup>, Karin A. Pfeiffer, FACSM<sup>2</sup>, Russell R. Pate, FACSM<sup>1</sup>. <sup>1</sup>University of South Carolina, Columbia, SC. <sup>2</sup>Michigan State University, East Lansing, MI.

(No relationships reported)

Increasing attention on young children's low levels of physical activity (PA) from expert panels and policy makers has highlighted the need to understand young children's PA, both in school and out of school.

**PURPOSE:** To determine if the most active children during the preschool day are the most active children outside of preschool.

**METHODS:** Participants were 351 children, mean age  $4.6 \pm 0.3$  years (50% male, 49% African American), from 16 preschools in central South Carolina. Children wore accelerometers for 5 consecutive weekdays. School day was defined by each preschool as the period of instruction. In-school and out-of-school min-hr<sup>-1</sup> of moderate to vigorous physical activity (MVPA) were calculated. Children in the highest quartile of in-school MVPA (*High Active*) were compared to those in the lower 3 quartiles of in-school MVPA (*Low Active*) using mixed model ANOVA, separately for males and females. Models controlled for race/ethnicity, and parental education; preschool was a random variable.

**RESULTS:** Children wore accelerometers for an average of 6.0 and 6.5 h-d<sup>-1</sup> in school and out-of-school, respectively. Children engaged in MVPA for  $6.9 \pm 2.6$  min-hr<sup>-1</sup> in school and  $8.7 \pm 3.3$  min-hr<sup>-1</sup> out-of-school. Males were more active than females during preschool ( $7.4 \pm 2.6$  vs.  $6.3 \pm 2.5$  min-hr<sup>-1</sup>;  $p < .05$ ) and outside preschool ( $9.0 \pm 3.3$  vs.  $8.3 \pm 3.2$  min-hr<sup>-1</sup>;  $p < .05$ ). *High Active* males obtained more in-school MVPA ( $10.5 \pm 0.5$  min-hr<sup>-1</sup>) than *Low Active* males ( $6.1 \pm 0.3$  min-hr<sup>-1</sup>;  $p < .05$ ). For out-of-school MVPA, there was no difference between *High Active* males ( $9.6 \pm 0.5$  min-hr<sup>-1</sup>) and *Low Active* males ( $8.7 \pm 0.3$  min-hr<sup>-1</sup>;  $p = .06$ ). *High Active* females accumulated more in-school MVPA ( $9.5 \pm 0.4$  min-hr<sup>-1</sup>) than *Low Active* females ( $5.3 \pm 0.3$  min-hr<sup>-1</sup>;  $p < .05$ ). *High Active* females obtained more out-of-school MVPA ( $9.5 \pm 0.4$  min-hr<sup>-1</sup>) than *Low Active* females ( $8.5 \pm 0.3$  min-hr<sup>-1</sup>;  $p < .05$ ).

**CONCLUSIONS:** The most active males in preschool had similar out-of-school MVPA compared to the least active males in preschool. The most active females during the preschool day were the most active females outside of preschool.

**Parental Perception of Neighborhood Environments and Children's Physical Activity in Hong Kong**

Gang He, Wendy Y. Huang, Stephen H. Wong, FACSM. *The Chinese University of Hong Kong, Hong Kong, China.*

(No relationships reported)

**PURPOSE:** Examining neighborhood environments is important to explain and promote physical activity (PA) of children, but it is under-investigated among Chinese population. Therefore, the purpose of this study was to investigate the association between parental perception of neighborhood environments and PA in Hong Kong children.

**METHODS:** 280 children (143 boys) aged 6-10 years and their parents were recruited from 14 local schools. Children were instructed to wear an ActiGraph GT3X accelerometer for 8 consecutive days to determine their PA level. Average time (minutes/day) spent on moderate to vigorous PA (MVPA) was calculated based on Freedson's age-specific cut-off counts. Parental perceived neighborhood environments, namely supervision, safety, facilities and climate, were determined by a valid questionnaire. Data were collected as part of a longitudinal study; Understanding Children's Activity and Nutrition (UCAN). Gender differences in MVPA minutes were determined using independent samples T test. Association between neighborhood environmental variables and PA was determined by Pearson correlations. Variables with significant associations were further examined using multiple regression analyses adjusting for age and parental education.

**RESULTS:** Boys were more physically active than girls (MVPA:  $142 \pm 47$  vs.  $112 \pm 41$  minutes/day,  $P < 0.05$ ). No associations were found in any neighborhood environmental variables with boys' MVPA. For girls, supervision, facilities and climate were significantly related to PA level ( $P < 0.05$ ). Multiple regression analyses revealed that after controlling for age and parental education, supervision ( $b = 10.12$ ; 95%CI = 3.52 to 16.73) and climate ( $b = -9.47$ ; 95%CI = -17.13 to -1.81) were associated with girls' MVPA ( $P < 0.05$ ).

**CONCLUSIONS:** Parental perception of supervision and climates might influence PA participation amongst girls in Hong Kong.

---

**2591** Board #266 MAY 31 3:30 PM - 5:00 PM

**Establishing Wrist-based Cutpoints For The GeneActiv Accelerometer In Elementary School Aged Children**

Raymond C. Browning, FACSM, Christine A. Schaefer, Heidi J. Nace, Paige E. Kyle. *Colorado State University, Fort Collins, CO.*

(No relationships reported)

Accurate physical activity (PA) monitoring is necessary to evaluate PA interventions. Wrist-mounted accelerometer (ACC) use is appealing, particularly in children for whom compliance is challenging. However, concern exists regarding the accuracy of the monitor at the wrist. The GeneActiv ACC has been validated and intensity cutpoints established for wrist placement in adults, but no study has validated its use in children performing typical activities.

**PURPOSE:** To establish wrist-based intensity cutpoints for the GeneActiv ACC in children performing typical activities.

**METHODS:** Metabolic and ACC data was collected in 6-11 year olds ( $n = 18$ , mean age (SD), 9.33 (1.0) years, 67% female) while they performed 9 activities for 6 minutes each. METs were calculated by dividing measured  $\text{VO}_2$  by estimated resting values. ACC data was collected at 75Hz and gravity subtracted summed vector magnitudes (SVM) were calculated for each second. Linear regression was used to examine the relationship between METs and SVM using all activities (AA) as well as after removing active gaming (NG). Cutpoints were established at 1.5, 3, 6 and  $\geq 6$  METs for sedentary (sed), light, moderate (mod) and vigorous (vig) activity, respectively.

**RESULTS:** AA and NG yielded  $R^2$  values of 0.73 and 0.88, respectively ( $p < .001$ ). Cutpoints for sed, light, mod and vig activity using AA were 5.2, 20.9, 52.4 and  $\geq 52.4$ , respectively. Cutpoints for sed, light, mod and vig for NG were 2.1, 17.4, 48.1 and  $\geq 48.1$ , respectively.

**CONCLUSION:** Active gaming involving significant wrist movement decreases the strength of the relationship between SVM and METs using LR. This highlights the need for activity specific intensity classification, particularly for activities involving wrist movement.

**2592** Board #267 MAY 31 3:30 PM - 5:00 PM

**Relationship between Moderate-to-Vigorous Physical Activity and Daily Step Counts in Elementary School Children**

Chiaki Tanaka<sup>1</sup>, Maki Tanaka<sup>2</sup>, Shigeho Tanaka<sup>3</sup>. <sup>1</sup>J. F. Oberlin University, Tokyo, Japan. <sup>2</sup>Kyoto Seibo College, Kyoto, Japan. <sup>3</sup>National Institute of Health and Nutrition, Tokyo, Japan.

(No relationships reported)

Locomotion is one of the important parts of physical activity in free living conditions and daily step counts have been used as an index of physical activity in many studies. However, data on the relationship between total steps and minutes of engagement in moderate-to-vigorous physical activity including non-locomotive activities are lacking for elementary school children.

**PURPOSE:** The purpose of the present study was to evaluate moderate-to-vigorous physical activity using triaxial accelerometry in Japanese elementary school children. The relationship between daily step counts as a convenient measure of physical activity and minutes of engagement in moderate-to-vigorous physical activity was also examined.

**METHODS:** Physical activity was assessed using a triaxial accelerometer (Active style Pro : HJA-350IT, Omron Health Care) and daily steps for 6 consecutive days, including weekdays and weekend days, in 223 six- to twelve-year-old Japanese children attending elementary school. The algorithm for the classification of locomotive and non-locomotive activities and physical activity intensity (metabolic equivalents) of these activities has been developed for adults (Oshima, 2010; Ohkawara, 2011) and modified for elementary school children. Using the triaxial accelerometer, minutes of locomotive and non-locomotive activities and step counts for children can be evaluated, respectively.

**RESULTS:** Average daily moderate-to-vigorous physical activity (metabolic equivalents $\geq$ 3) and step counts were 60 ( $\pm$ 27) min/day and 11,814 ( $\pm$ 2,866) steps/day, respectively. A strong and significant correlation was observed between minutes of moderate-to-vigorous physical activity and step counts ( $r=0.83$ ,  $p<0.001$ ). The daily step counts corresponding to 60 min, 100 min, and 120 min of moderate-to-vigorous physical activity were 11,843, 15,362, and 17,121 steps/day, respectively.

**CONCLUSIONS:** These results suggest that approximately 12,000 steps/day are required for elementary school children to engage in more than 60 min of moderate-to-vigorous physical activity. Supported by Health Sciences Research Grants (Research on Health Science) from the Ministry of Health, Labor and Welfare (to C. Tanaka) and a grant from Sumitomo Life Health Foundation in 2010 (to C. Tanaka).

**2593** Board #268 MAY 31 3:30 PM - 5:00 PM

**Associations between After-School Settings with Physical Activity and Sedentary Behavior in 5th Grade Children**

Sharon Ross<sup>1</sup>, Marsha Dowda, FACSM<sup>1</sup>, Natalie Colabianchi<sup>2</sup>, Ruth Saunders<sup>1</sup>, Russell Pate, FACSM<sup>1</sup>. <sup>1</sup>University of South Carolina, Columbia, SC. <sup>2</sup>University of Michigan, Ann Arbor, MI.

(No relationships reported)

**PURPOSE:** Amid a childhood obesity and inactivity epidemic, the after-school context has been identified as one setting that can be modified to increase children's physical activity (PA); however, little is known about how PA and sedentary behavior (SB) vary by after-school setting for children of different race/ethnicities. This study aims to determine the relative influence of time spent at home vs. in after-school programs on children's PA and SB during after-school hours (3-6pm), and differences by race/ethnicity.

**METHODS:** A total of 662 5th graders (n=297 boys, n=365 girls) participating in the Transitions and Activity Changes in Kids (TRACK) study provided accelerometer data for 5 weekdays; parents reported their child's location after school (i.e., home [with supervision or at a relative/friend's home] or after-school program [at school or other location]). Unadjusted and adjusted mixed-model ANOVA was used to test for mean differences in PA and SB by after-school setting, including interactions by race/ethnicity.

**RESULTS:** Boys who attended an after-school program (16.2%) spent less time in SB and had higher levels of moderate-to-vigorous (MVPA) and total PA (all  $p<0.05$ ) compared with those who were at home during after-school hours. A significant interaction effect was found for race and after-school setting for females; non-white (black and Hispanic) females who attended after-school programs (21.9%) accrued an additional 15 minutes of total PA and reduced their SB by 15 minutes per day compared to those who stayed at home during after school hours (3-6pm) ( $p<0.01$ ). Further, non-white females attending after-school programs engaged in an additional 7 minutes of MET-weighted MVPA and 3 minutes of MVPA per day compared to non-white females who stayed at home after-school ( $p<0.05$ ). There was no difference for White girls in the amount of time spent in SB, MVPA or total PA by after-school setting.

**CONCLUSIONS:** Boys and black and Hispanic girls attending after-school programs were more physically active than those who stayed at home during after-school hours. Efforts should focus on recruiting children into after-school programs, as well as examining the characteristics of after-school programs that promote physical activity in this group.

**2594** Board #269 MAY 31 3:30 PM - 5:00 PM

**Validity of Family Day Care Providers' Proxy Reports on Children's Physical Activity**

Kelly R. Rice, Kathy Gunter, Stewart Trost, FACSM. Oregon State University, Corvallis, OR.

(No relationships reported)

Interventions to promote physical activity (PA) in children attending Family Day Care require valid, yet practical measurement tools. Among preschool-aged children, PA is typically measured using direct observation or motion sensors; however, the cost and participant burden associated with these methods make them difficult to implement in large surveillance studies and/or community-level program evaluations. For these scenarios, proxy-reports completed by Family Day Care Providers (FDCPs) may be a viable option; however, the validity of this approach has not been evaluated.

**PURPOSE:** To assess the concurrent validity of a brief caregiver proxy report instrument designed to measure PA in 2- to 5-year old children attending Family Day Care.

**METHODS:** FDCPs (N=39) completed a modification of the Burdette et al. (2004) parental proxy report. For each child under their care, FDCPs recalled the usual duration of outdoor play time from arrival to lunchtime and from lunchtime to departure. Responses were recorded on a 5-point scale consisting of 0 = 0 min, 1 = 1-15 min, 2 = 16-30 min, 3 = 31-60 min, and 4 = over 60 min. A single PA score was calculated by averaging the responses. 107 children (53.2% male) between the ages of 2 and 5 y (mean age = 3.4  $\pm$  1.2 yrs) wore the ActiGraph GT1M accelerometer for the duration of child care attendance during a single week. Time spent in moderate-to-vigorous PA (MVPA), and light- moderate-vigorous PA (LMVPA) was calculated using the intensity-related cut-points developed by Pate et al. (2006). Associations between FDCP-reported PA and objectively measured MVPA and LMVPA were assessed using Pearson product moment correlations. Additionally, one-way ANOVA was used to evaluate differences in objectively measured PA across levels of FDCP-reported PA.

**RESULTS:** Significant positive correlations were observed between FDCP-reported PA and objectively measured LMVPA ( $r = 0.31$ ,  $p < 0.01$ ) and MVPA ( $r = 0.33$ ,  $p < 0.01$ ). Across levels of FDCP-reported PA, both LMVPA ( $F(2, 104) = 7.82$ ,  $p = .009$ ) and MVPA ( $F(2, 104) = 8.71$ ,  $p = .0003$ ) increased significantly in a linear dose-response fashion.

**CONCLUSIONS:** Proxy PA reports completed by FDCPs were significantly correlated with objectively measured PA, and may be a valid assessment option in studies where more burdensome objective measures are not feasible.

**Associations Of Physical Activity, Screen Time, And Bmi With Quality Of Life In Urban Children**

Joseph T. Warning<sup>1</sup>, Karin A. Pfeiffer, FACSM<sup>1</sup>, Joey C. Eisenmann<sup>2</sup>, James M. Pivarnik, FACSM<sup>1</sup>, Joseph J. Carlson<sup>1</sup>, Kimberly S. Maier<sup>1</sup>, Erin Lamb<sup>3</sup>. <sup>1</sup>Michigan State University, East Lansing, MI. <sup>2</sup>Helen DeVos Children's Hospital, Grand Rapids, MI. <sup>3</sup>Crim Fitness Foundation, Flint, MI.

(No relationships reported)

Health-related quality of life (HRQoL) includes measures of physical health, emotional functioning, and social functioning. Previous studies have shown that overweight children have lower quality of life scores when compared to healthy-weight children. However, limited research is available regarding the potential associations of HRQoL with physical activity (PA) and screen time (ST) in low socioeconomic children.

**PURPOSE:** The purpose of this study was to examine the associations of physical activity, screen time, and BMI with HRQoL in children from a racially diverse, low socioeconomic status area.

**METHODS:** Participants were 197 children (50% males, 64% African American) from four elementary schools (~80% eligible to receive free/reduced lunch) in/near Flint, Michigan. PA was assessed using pedometers (New Lifestyles, SW-200) and a survey question. ST was assessed using children's self-report for viewing television, playing video games, and online computer use. Quality of life was assessed using the Pediatric Quality of Life (PedsQL) inventory. Mann Whitney U tests were used to assess differences between sexes and/or weight status for HRQoL, PA, ST, and BMI. Spearman correlations were used to assess the relationships between HRQoL and physical activity (separately for pedometer and survey question), screen time and BMI.

**RESULTS:** Approximately 27% and 5% met guidelines for PA and ST, respectively, while 45% were overweight or obese. Approximately 33% did not meet the cut-off score for HRQoL (impaired HRQoL). No differences were found for PA, ST, BMI or HRQoL between sexes and/or weight status. No significant associations were found between HRQoL (76.0  $\pm$  15.9) and PA (4.0  $\pm$  2.0 days/week,  $r = -0.07$ ; 8848  $\pm$  399 steps/day,  $r = -0.02$ ), between HRQoL and screen time (19.1  $\pm$  13.9 hours/week,  $r = -0.01$ ), or between HRQoL and BMI (21.6  $\pm$  6.0  $r = -0.04$ ).

**CONCLUSION:** There were no associations between quality of life scores with physical activity, total screen time, or BMI. Results also did not show differences between overweight and normal weight children in HRQoL, which was contrary to existing literature (Williams et al., 2005; Riazzi et al., 2010). It is likely that variables aside from PA, ST and BMI are more relevant to minority/low-SES populations with regard to HRQoL.

This study was funded by the Crim Fitness Foundation

2596 Board #271 MAY 31 3:30 PM - 5:00 PM

**Association Between Serum Sex Hormone and Obesity Status in Pubertal Chinese Boys**

Liang Li<sup>1</sup>, Minhao Xie<sup>2</sup>, Yi Yan<sup>2</sup>, Stephen H. Wong, FACSM<sup>1</sup>. <sup>1</sup>The Chinese University of Hong Kong, Hong Kong, China. <sup>2</sup>Beijing Sport University, Beijing, China.  
(No relationships reported)

Over the past decades, the prevalence of obesity in children and adolescents has increased dramatically. However, it is not clear whether sex hormone profiles are associated with obesity status in pubertal Chinese boys.

**PURPOSE:** To evaluate the association between sex hormone profiles and obesity status in pubertal Chinese boys.

**METHODS:** A total of 30 pubertal Chinese boys aged 13-15 years were recruited in this study, including 15 obese boys (obese group, BMI: 29.8 ± 2.4 kg/m<sup>2</sup>, age: 14.2 ± 0.8 years), and 15 normal weight boys (control group, BMI: 19.4 ± 2.0 kg/m<sup>2</sup>, age: 14.7 ± 1.0 years). Venous blood samples were collected in the morning after an overnight fast. Body fat (BF) and weight were measured using a body composition instrument (Model InBody 230, Biospace, Korea). Height was measured to the nearest 0.1 cm using a stadiometer. Serum sex hormones, i.e., testosterone (T) and estradiol (E<sub>2</sub>) were assessed through chemiluminescence immunoassay method.

**RESULTS:** The obese group had a higher BF than control group (30.4 ± 4.6 % vs. 15.6 ± 5.4 %, p<0.01). The serum T level was lower in the obese group compared with that in control group (2.8 ± 1.1 vs. 4.2 ± 1.8 ng/ml, p<0.05). There was no statistical difference between the two groups in E<sub>2</sub> level (obese group vs. control group: 26.5 ± 13.4 vs. 20.3 ± 9.4 pg/ml, NS). However, a higher ratio of E<sub>2</sub>/T was found in obese group compared with control group (9.7 ± 3.7 vs. 5.2 ± 2.3, p<0.01). BF was negatively associated with T level (r = -0.386, p<0.05), and positively associated with E<sub>2</sub> level (r = 0.439, p<0.05).

**CONCLUSIONS:** The results suggest that the 13-15 years old obese Chinese boys expressed lower serum T level and higher E<sub>2</sub>/T ratio compared with normal weight boys. The amount of adipose tissue may correlate with sex hormone metabolisms in Chinese boys. Future studies are needed to illustrate the possible mechanisms behind this.

Supported by National Natural Science Foundation of China, NO.: 30800541.

2597 Board #272 MAY 31 3:30 PM - 5:00 PM

**Comparison of Peer and Instructor Assessment in a Physical Education Teacher Education Program**

Melissa M. Snyder, Beth J. Patton. Ashland University, Ashland, OH. (Sponsor: Randall F. Gearhart Jr., FACSM)  
(No relationships reported)

Peer assessment (PA) occurs in many higher education programs. However, there is no known research examining PA in physical education teacher education (PETE) in regards to student teaching experiences. PA may be a method to better prepare PETE students to assess their future students.

**PURPOSE:** The current observational investigation compared PETE students' assessment of a peer teaching to the instructor's assessment using a 13 item written tool.

**METHODS:** Subjects included nine sophomore PETE students completing their first field experience, five male and four female. The subjects were assigned in groups of two or three to a school. Subjects assessed one another teaching a physical education skill to various age groups. Two sessions for each subject were also assessed by the university instructor using the same 5-point Likert-type scale (excellent, very good, satisfactory, needs improvement, unacceptable). Each assessment consisted of 13 items. Frequencies of each assessment were compared for the student and university supervisor assessment.

**RESULTS:** There were a total of 468 items assessed over both teaching sessions (234 by the subjects, 234 by the instructor). Subjects were much more likely to assess a student as excellent (n = 93, 39.74%) or very good (n = 98, 41.88%) than the university instructor (n = 3, 1.28% and n = 89, 38.03%, respectively). The subjects infrequently assessed the student teacher as needing improvement (n = 1, 0.43%) as compared to the instructor (n = 5, 2.14%).

**CONCLUSIONS:** Subjects tended to assess their peers performance higher than the instructor. Further research is needed to determine how peer assessment can be improved. Factors such as training, previous experiences and interpersonal issues can affect the assessments peers provide. Teacher education students are required to learn numerous skills during their educational preparation and will be required to assess their students as a professional. Assessing others as a student may better prepare them to evaluate their students in the future. This, in turn, may help the students to become more competent teachers and benefit society.

2598 Board #273 MAY 31 3:30 PM - 5:00 PM

**Youth Soccer Participation History in NCAA Division 1 Athletes**

Aaron Gray<sup>1</sup>, John DiFiori, FACSM<sup>2</sup>, Ryan Baker<sup>2</sup>. <sup>1</sup>University of Missouri, Columbia, MO. <sup>2</sup>University of California - Los Angeles, Los Angeles, CA.  
(No relationships reported)

**PURPOSE:** To investigate the youth soccer participation history of intercollegiate athletes across all sports at the University of California - Los Angeles.

**METHODS:** Observational survey of NCAA Division 1 intercollegiate athletes listed on the 2010-12 rosters. Data collected included sport participation history for subjects, levels of participation, and reasons for sport discontinuation.

**RESULTS:** 296 subjects (162 women, 134 men) from 12 different sports completed surveys. Included within this group were 26 athletes (9 women, 17 men) participating in collegiate soccer. Excluding those collegiate soccer athletes, 41.8% of females and 54.7% of males played soccer from the ages of 6 to 9. From the ages of 10 to 11, 35.9% of these women and 33.3% of the men participated in soccer. When evaluating those currently competing in individual sports (golf, gymnastics, tennis, swimming) compared to team sports (baseball, basketball, football, rowing, softball, volleyball, water polo), 36% of those competing in individual sports played soccer from the ages of 6 to 9 compared to 56.4% of those in team sports. Within the group of those competing in collegiate soccer, 34.4% of the women and 41.2% of the men did not participate on a travel/club soccer team prior to the age of 10.

**CONCLUSIONS:** 47% of non-collegiate soccer athletes participated in soccer as a child with 35% continuing until the ages of 10 to 11. Those currently participating in team sports were more likely to have been involved with youth soccer compared to those currently competing in individual sports. Over 40% of NCAA Division 1 soccer players surveyed were not involved in travel/club soccer until the age of 10.

2599 Board #274 MAY 31 3:30 PM - 5:00 PM

**Landscape: Learning About The Needs And Desires Of A School And Community-based Activity Program Evaluation**

Kisha Virgil, Mary de Groot, Stephanie Greer, Sarah Herrera, NiCole Keith, FACSM. IUPUI, Indianapolis, IN.  
(No relationships reported)

Physical inactivity disproportionately affects low-income and ethnic minority urban residents. PARCS is a 9-year-old community-based exercise partnership between IUPUI and Indianapolis Public Schools (IPS) that strives to increase regular physical activity in urban residents at a membership price of \$20/year. Costs remain low by employing university exercise science and fitness studies majors as facility staff for academic credit. This model could be duplicated with other community and academic partners across the US.

**PURPOSE:** To characterize program participants, LANDSCAPE describes adult PARCS members who have enrolled in this study. Data describe the sociodemographic, health, attitudinal, quality of life and physical attributes of the LANDSCAPE sample.

**METHODS:** Our study sample consists of 154 adult PARCS members of Black or White race. Four questionnaires were completed by study participants. Anthropometric measures were collected as well as resting heart rate (RHR) and resting blood pressure (BP).

**RESULTS:** Data show that 68% of the study participants were Black, 48% had a household income of < \$40,000 per year, 48% found it financially difficult to make ends meet, while 43% reported making ends meet to be "not hard, not easy," 41% of the respondents owned a home and 56% worked outside of the home. Forty percent reported having hypertension, 31% high cholesterol, 19% diabetes, 18% physically inactive, and 15% smoked. Measured mean resting SBP and DBP were 125 ± 13 mmHg and 77 ± 8 mmHg, respectively. Mean RHR was 76 ± 12 BPM and the average BMI was 34.6. Resting SBP and BMI in study participants were higher than national recommendations of <120 mmHg and <25, respectively, while, resting DBP and RHR of study participants fell within recommended ranges of <80 mmHg and 60-100 BPM, respectively.

**CONCLUSION:** Results show that LANDSCAPE participants have limited discretionary income and several risk factors and/or comorbidities that could be managed by participating in

regular exercise. Community-based partnerships such as PARCS reduce financial barriers and could improve the exercise opportunities for populations with limited resources. Study data collection will continue in order to inform strategies to improve the existing PARCS program and potentially replicate similar partnerships locally and nationally.

**2600** Board #275 MAY 31 3:30 PM - 5:00 PM

**Association Between Total Energy Expenditure And Body Kinematics During Active Video Gaming**

Lau Yuen Yan<sup>1</sup>, Pui Lam Wong<sup>2</sup>, Andrew W. Smith<sup>2</sup>, Lynda B. Ransdell, FACSM<sup>3</sup>. <sup>1</sup>University of South Carolina, Columbia, SC. <sup>2</sup>The Hong Kong Institution of Education, Hong Kong, Hong Kong. <sup>3</sup>Boise State University, Boise State, ID.

(No relationships reported)

Active video gaming (AVG) has been suggested as an alternative for increasing total daily energy expenditure among adolescents. One of the challenges of using AVG to promote a physically active lifestyle is the selection of appropriate AVG with moderate-intensity level (3.0-5.9 METs) that produces sufficient energy cost for obtaining health-related benefits. There are many AVGs available in the market but their energy cost demand varies widely. However, very few studies have identified the factors contributing to this variation.

**PURPOSE:** To examine the association between total energy expenditure and body kinematics while playing the selected AVG.

**METHODS:** Sixty Hong Kong Chinese adolescents aged 15 to 17 years old, without physical and psychological illness, enrolled in the present within-subject study. Participants attended three AVG experimental sessions in a randomized fashion to perform AVG using: i) lower limb movement (soccer) ii) upper limb movement (table tennis) and iii) whole body movement (adventure), respectively. During the AVG sessions, participant's in-game metabolic energy expenditure (kcal/min) was measured using portable indirect calorimetry, and mechanical energy expenditure and in-game 3D motion were measured using a 14-camera motion capture system. Repeated measures ANOVA was used to examine the differences between the selected AVGs in terms of energy expenditure. Multiple regression analysis was conducted to examine the contribution of the movement of different body segments in predicting energy expenditure after adjusting for gender, age and maturation status.

**RESULTS:** The findings of the present study will provide empirical data concerning the contribution of the movement of different body segments (head, sacrum, foot, shoulder and wrist) to the variation in energy expenditure among the selected AVGs.

**CONCLUSIONS:** These results will be able to inform the choice on AVGs to meet the desired intensity for future AVG intervention studies.

**2601** Board #276 MAY 31 3:30 PM - 5:00 PM

**Children's Physical Activity Levels and Their Psychological Correlates in Interactive Dance Versus Aerobic Dance**

Zan Gao<sup>1</sup>, Tao Zhang<sup>2</sup>. <sup>1</sup>Texas Tech University, Lubbock, TX. <sup>2</sup>University of North Texas, Denton, TX. (Sponsor: Li Li, FACSM)

(No relationships reported)

**PURPOSE:** Comparisons on children's physical activity (PA) levels and PA psychological correlates (e.g., self-efficacy and enjoyment) between interactive video games and the corresponding traditional activities remain unanswered. Therefore, the purpose of this study was to examine differences in children's PA levels and PA correlates in interactive dance games (Dance Dance Revolution [DDR]) and aerobic dance.

**METHODS:** A total of 53 urban fourth grade children (29 girls;  $M_{age}=10.3$  yrs) participated in a year-long DDR-based exercise program. During each 30-min. session, participants were divided into two groups, with one group playing DDR and the other playing aerobic dance for 15 minutes. The groups then switched activities in the second 15 minutes. Participants wore NL-1000 pedometers in four consecutive sessions; and sequences for playing were count-ordered. They also responded to a questionnaire measuring their self-efficacy and enjoyment toward two dance activities (DDR and aerobic dance) at the end of each session. Outcome variables were children's moderate-to-vigorous physical activity time (MVPA), self-efficacy and enjoyment.

**RESULTS:** ANOVA with repeated measures for MVPA yielded a significant main effect for dance activity, Wilks' lambda = .51,  $F(1, 52) = 50.26$ ,  $p < .01$ . Specifically, children spent more MVPA time in performing aerobic dance ( $M_{time}=4.66$ ) than they did in playing DDR ( $M_{time}=3.16$ ). MANOVA with repeated measures for PA correlates also revealed a significant main effect for dance activity, Wilks' lambda = .70,  $F(2, 47) = 10.12$ ,  $p < .01$ . Follow-up univariate tests suggested children had significant higher self-efficacy in DDR ( $M=4.22$ ) than they had in aerobic dance ( $M=3.53$ ),  $F(1, 49) = 18.81$ ,  $p < .01$ . Similarly, they also reported significant higher enjoyment toward DDR ( $M=3.42$ ) than they did toward aerobic dance ( $M=2.96$ ),  $F(1, 49) = 10.57$ ,  $p < .01$ .

**CONCLUSIONS:** The findings indicated children had more MVPA time in aerobic dance. However, children demonstrated higher self-efficacy and enjoyment toward DDR as compared to aerobic dance. Thus, professionals may not replace the traditional physical activities and sports with interactive video games. Meanwhile, interactive video games (e.g., DDR) can be an excellent addition to promote PA.

---

**2602** Board #277 MAY 31 3:30 PM - 5:00 PM

**Daily Physical Activity Levels of Young Adults with Autism Spectrum Disorder Who Are Low-Expressive**

John T. Foley<sup>1</sup>, Matthew F. Moran<sup>2</sup>, Mary E. Parker<sup>3</sup>, Michael J. Weiss<sup>4</sup>. <sup>1</sup>SUNY Cortland, Cortland, NY. <sup>2</sup>Sacred Heart University, Fairfield, CT. <sup>3</sup>Texas State University - San Marcos, San Marcos, TX. <sup>4</sup>Fairfield University, Fairfield, CT.

(No relationships reported)

The U.S. Department of Health and Human Services in 2008 released the Physical Activity Guidelines Advisory Committee Report that indicated that health benefits for adults can be achieved with 150 minutes a week of moderate-intensity physical activity (MPA). However, the literature suggest that individuals with disabilities may not be reaching that threshold and tend to engage in less activity than their peers without disabilities. There is also data to indicate that physical activity levels vary by type of disability. However, there is little information on physical activity patterns of individuals with the autism spectrum disorder, and even less on individuals with autism spectrum disorder who are low expressive in verbally (ASD-LE).

**PURPOSE:** To investigate physical activity levels of young adults with ASD-LE.

**METHODS:** Participants were 12 young adults without physical impairments: 6 (5M 1F, Age  $18.8 \pm 1.7$  yrs, Ht.  $70.8 \pm 2.1$  in, Wt.  $187.0 \pm 33.8$  lbs) with ASD-LE and 6 matched peers without disability (5M 1F, Age  $19.7 \pm .5$  yrs, Ht.  $70.4 \pm 2.6$  in, Wt.  $169 \pm 23.7$  lbs). There were no significant differences between matching variables (Age, Ht. & Wt.). Participants with ASD-LE were selected if they met two criteria on the Childhood Autism Rating Scale: 1) rating of "severely autistic" and 2) at least 3 out of 4 on Verbal Sub-Scale, which indicates a severe verbal disorder. Participants wore an omnidirectional accelerometer on the wrist for 6 continuous days. Prior to the study individuals were given time to become desensitized to the accelerometers on the wrist. Data were recorded into 1 minute epochs and raw counts were converted to MET values. Values of  $\geq 3$  METs were classified as MPA. An independent T-test, adjusted for unequal variances, in PASW Statistics 18 was used for the comparison between the two groups.

**RESULTS:** Individuals with ASD-LE had significantly lower minutes of MPA per day (78 mins) than their peers without disability (153 mins) ( $t=3.4, df 7.6, p=.01$ ). However, both groups were above the daily amount of MPA for health benefits.

**CONCLUSIONS:** This study indicates that young adults with ASD-LE may be getting enough MPA to receive a substantial health benefit. Unfortunately, there is a disparity in the amount of physical activity between the two groups. Because of the small sample size further research is needed.

---

**2603** Board #278 MAY 31 3:30 PM - 5:00 PM

**Overweight and Central Obesity and its Association to Physical Activity in German Primary School Children**

Anja Schreiber, Susanne Kobel, Benjamin Koch, Dorothea Kesztyues, Verena Hundsdoerfer, Olivia Wartha, Tamara Wirt, Rainer Muehe, Tina Seufert, Juergen M. Steinacker, FACSM. University Ulm, Ulm, Germany.

(No relationships reported)

Recent studies suggesting relations between overweight and cardiovascular risk factors imply a strong correlation with central body fat mass, even in children. For an appraisal of a child's body weight status it is therefore advised to not only rely on Body-Mass-Index (BMI) but also consider measures of central obesity like the weight-to-height-ratio (WHtR).

**PURPOSE:** This study therefore aimed at assessing the prevalence of overweight and obesity in German primary school children on the basis of BMI as well as WHtR (central obesity). Furthermore, the prevalence of central obesity in active vs. less active children is determined.

**METHODS:** 157 classes took part in the evaluation of the school-based health promotion programme "Join the Healthy Boat" in south-west Germany. Written, parental consent for examination and data collection was obtained of 1968 children. Body weight and height, as well as waist circumference of 1892 children ( $7.1 \pm 0.6$  yrs; 50.3% male) were measured. In a subsample of 294 children physical activity was measured for 4 consecutive days using accelerometry combined with heart rate (Actiheart; CamNtech, UK).

**RESULTS:** An average BMI of  $16.0 \pm 2.2$  kg/sqm and a mean WHtR of  $0.45 \pm 0.04$  could be observed. On basis of German BMI classifications (Kromeyer-Hauschild et al, 2001) 7.8% of the examined children were underweight, 82.3% normal weight, 5.5% overweight and a further 4.4% obese. Central obesity (WHtR  $\geq 0.5$ ) was established at 9.5% of children. Also, 2.8% of normal weight children (based on BMI) showed a WHtR  $\geq 0.5$ , as well as 55.8% of overweight and 94.0% of obese children. In the subsample 10.5% are central obese. Of the 109 children achieving the guideline of 60 min moderately to vigorously physical activity (MVPA) only 6.4% are central obese compared to 13% of those not achieving the guideline.

**CONCLUSIONS:** These baseline data show an unusual high percentage of obese children within an otherwise rather small portion of overweight children compared to other German studies (9.9% including obesity). Nearly all obese children are affected by central obesity, which applies to just about half of overweight children and at least a small proportion of normal weight children. Moderate to vigorously active children show a slightly smaller prevalence of central obesity.

---

**2604 Board #279 MAY 31 3:30 PM - 5:00 PM**

**Prevalence of Biomarkers of Vascular Disease in Young Adults**

Matt Feigenbaum, PhD, FACS, Andy O'Neill, Vincent Marsh. *Furman University, Greenville, SC.*

*(No relationships reported)*

**BACKGROUND:** Atherosclerotic vascular disease remains the leading cause of morbidity and mortality in the U.S. and is largely influenced by lifestyle choices. Detection and treatment of controllable risk factors (RFs) can prevent or deter the progression of vascular disease.

**PURPOSE:** To determine the prevalence of biomarkers and RFs of vascular disease in young adults.

**METHODS:** Biomarkers and RFs of vascular disease were assessed in undergraduates (N=416; age=19.3±0.9yrs; Caucasian=95.1%) enrolled in a required Wellness Concepts course. Students were risk stratified as low (0-2 RFs), moderate (3-5 RFs), or high risk (6+ RFs) according to AHA Guidelines (2009).

**RESULTS:** Data indicated that 93.7% and 6.3% are Low and Moderate Risk, respectively. Only 5.4% of the students have elevated LDL-C, 1.2% have hypertension, 1.3% have type 2 diabetes, and 2.6% indicate tobacco use. Gender differences exist ( $p \leq 0.05$ ) in HDL-C (mg/dL) (M=48.5±11.0; F=57.0±11.2), SBP (mmHg) (M=118.7±8.9; F=104.9±14.4), and BMI (kg/m<sup>2</sup>) (25-29.9: M=25.4%; F=17.7%; >30: M=8.3%; F=5.4%). When grouped by BMI categories, data indicate differences ( $p \leq 0.01$ ) in C-RP levels (mg/L) (acute phase protein associated with vascular inflammation) between underweight ( $0.04 \pm 0.59$ ), healthy weight ( $0.96 \pm 1.18$ ), overweight ( $1.17 \pm 0.79$ ), and obese students ( $2.88 \pm 2.30$ ).

**CONCLUSION:** While few young adults (in the population studied) are at increased risk for vascular disease, they should be aware that increases in BMI are accompanied by increases in biomarkers of vascular inflammation known to contribute to atherosclerotic lesions.

---

**2605 Board #280 MAY 31 3:30 PM - 5:00 PM**

**7-day Physical Activity And Self-efficacy Toward Physical Activity Of Children With Developmental Coordination Disorder**

Sheng K. Wu<sup>1</sup>, Tsung-Yi Wu<sup>1</sup>, Hsien-Hui Lin<sup>1</sup>, Fu-Chen Chen<sup>2</sup>. <sup>1</sup>National Taiwan College of Physical Education, Taichung, Taiwan. <sup>2</sup>University of Minnesota, Minneapolis, MN.

*(No relationships reported)*

**PURPOSE:** To analyze the motor coordination and physical activity of school-aged children with and without developmental coordination disorder (DCD) in Taiwan.

**METHODS:** Participants including 34 children without DCD and 20 children with DCD aged 9-11 years old, were examined by the Movement Assessment Battery for Children (MABC) test, and measured and recorded their total physical activities within 7-day by the RT3 accelerometer. Children's Self-Perception of Adequacy in and Predisposition for Physical Activity Scale (CSAPPA scale) was used to measure the generalized self-efficacy toward physical activity of children.

**RESULTS:** Children with DCD scored higher in MABC test than children without DCD (18.5 vs. 7.0,  $p < 0.001$ ). The amounts of total physical activity and moderate to vigorous physical activities (MVPA) in 7-day were higher in the non-DCD group than the DCD group ( $p < 0.05$ ). Children with DCD had significantly lower scores in CSAPPA scale than children without DCD (47.9 vs. 56.2,  $p < 0.01$ ).

**CONCLUSIONS:** This study confirmed that children without DCD participated in more physical activities in 7 days and had higher MVPA and generalized self-efficacy toward physical activity than children with DCD in Taiwan. Comparing to children without DCD, it is essential to encourage children with DCD to participate in more physical activities and MVPA and concern their physical fitness and health.

**Acute Physiological Effects of Different Circuit Training Protocols in Young Adults**

Myosotis Massidda, Alessandra Caria, Lucia Cugusi, Carla M. Calò. *University of Cagliari, Cagliari, Italy.*

*(No relationships reported)*

Circuit training (CT) effectively reduces the time devoted to strength training. Nonetheless, few studies have focused on the differences in the acute physiological strain produced by free weight CT and weight CT compounded with aerobic exercise.

**PURPOSE:** The purpose of this study was to perform a comparison of 3 different training protocols (TP): Circuit Weight Training (CWT), Compounded Circuit Weight Training (weight CT and cycling) (CCWT) and Compounded Circuit Free Weight Training. (free weight CT and running) (CCFWT) in order to determine which of the 3 programs provides the best acute physiological responses in a young adult population.

**METHODS:** The sample consisted of 21 healthy sedentary individuals, 12 males and 9 females (age range 20-30 years). We have developed 3 CT Protocols. Sixty seconds (sec) sets of resistance exercises (30% of 1RM) for CWT have been established. Whereas in the CCWT, the subjects spent 30 sec on the same resistance exercises and 30 sec cycling on a bike (60%HRmax). Finally in the CCFWT, the subjects spent 30 sec on the free weight exercises and 30 sec running on a treadmill (60%HRmax). Each TP were on 3 separate days at least 48 hours apart. The rest intervals between the sets lasted 20 sec and the exercises rhythm were fixed at 60 beats per minute (bpm).

**RESULTS:** The CCFWT elicited a higher average HR response than CWT and CCWT for both genders (F=9.88;  $P < 0.001$ ). However, when males and females performed the CCFWT they spent a greater percent of training time within a high HR training zones (70-79% and 80-89% of HRmax) than CWT and CCWT (F=5.58;  $P < 0.001$ ). Similarly, the CCFWT required a greater training load than CWT and CCWT for both sexes (F=7.33;  $P > 0.001$ ). Moreover, the CCWT elicited a lower average HR response and training load than CWT and CCWT for both genders ( $P < 0.001$ ). Regarding inter-gender comparison, we did not find any significant differences ( $P > 0.05$ ) in energy expenditure, blood lactate concentration and cardiac response between males and females for all the TP.

**CONCLUSIONS:** CFWT produces measures that provided a significantly greater benefit of exercise for the 3 programs of interest and seems adequate to produce good training load and cardiovascular improvements for both genders, while CCWT seems not to produce sufficient responses for cardiovascular fitness improvement in both sexes.

---

**2607** Board #282 MAY 31 2:00 PM - 3:30 PM  
**>Body Weight Resistance Training Improves Body Composition in Overweight Men and Women**

Brian Wu, USC, Los Angeles, CA.  
(No relationships reported)

Improving body composition and fitness is important in reducing the increased risk of obesity and associated diseases. Body weight resistance training (BWRT) may constitute a convenient, economical, and effective method to improve body composition and fitness for those who do not have access to traditional resistance training equipment.

**PURPOSE:** To examine the effects of a 10-week BWRT program with caloric restriction on body weight and composition.

**METHODS:** Twenty-six sedentary adults were assigned to one of two groups: exercise (n=14, 9 women, 5 men) or control (n=12, 8 women, 4 men). Exercising subjects were on average 34±4 years of age, weighed 91.3±32.0 kg, with a mean BMI of 32.1±8.9. Control subjects were 36±7 years of age, weighed 92.2±16.1 kg, with a mean BMI of 33.9±6.1. The exercise group completed 3 training sessions per week using the TotalGym XLS while reducing caloric intake by 500 kcal/day for 10 weeks. The training sessions followed a progression protocol to maintain appropriate intensities. The control group maintained a sedentary lifestyle with no change in caloric intake. Baseline and post-intervention anthropometric measurements and body composition were assessed. Body composition was evaluated in each subject by bioelectrical impedance using the InBody 520 (Biospace Co. Ltd, Los Angeles, CA.) Data was analyzed using the Statistical Package for Social Sciences (SPSS 16.0 Inc.).

**RESULTS:** Significant decreases in body weight (-3.4±4.1kg, p=0.013) and BMI (-1.2 index points, p=0.013) were observed in the exercise group, while the control group demonstrated no changes from baseline (p>0.05). Participants had a mean reduction of 472 kcal per day. Neck, waist, hip, thigh, relaxed biceps (arm), and flexed biceps (elbow flexed) circumference significantly decreased in the exercise group (p=0.003) while neck, waist, relaxed biceps, and flexed biceps circumference significantly increased in the control group (p=0.02). Between-group analyses revealed that decreases in the exercise group were significantly larger than the increases in the control group (p=0.001).

**CONCLUSION:** 10 weeks of body weight resistance training with the commercially available, home use Total Gym XLS, in combination with reduced caloric intake may promote weight loss and improve body composition.

**2608** Board #283 MAY 31 2:00 PM - 3:30 PM  
**Effect of Resistance Training Programs on Body Composition and Local Subcutaneous Fat in Young Women**

Jason White, Christa Cocumelli, Sharon Rana. Ohio University, Athens, OH. (Sponsor: Fredrick C. Hagerman, FACSM)  
(No relationships reported)

It is not well understood if localized changes in subcutaneous (SC) fat occur due to resistance training (RT). It is also not known if different methods of RT have differing effects on localized SC fat loss.

**PURPOSE:** To compare the effects of 12-weeks of compound superset (CS) RT to traditional strength (TS) RT on body composition (BC) and localized SC fat.

**METHODS:** 20 untrained women (20.8±2.69 y) were randomly placed into two groups: TS RT or CS RT. All subjects were pre- and post-tested for SC fat via ultrasound (US), SC fat via skinfold (SF) calipers for the triceps (TRI), suprailiac (SI), and thigh (TH), percent body fat (FAT) via SF, fat mass (FM), lean body mass (LBM), total body mass (TBM), and body mass index (BMI). The CS and TS groups performed back squats (SQ) and leg press (LP) at matched intensities, volumes and cumulative rest time per session. The CS group's sets were SQ followed by LP and then rest. The TS group performed SQ with 1min rest between sets, and then LP with 1min rest between sets. Comparisons of all variables were made using repeated measures mixed model ANOVAs.

**RESULTS:** 2x2 mixed model ANOVAs showed no significant interactions or main effects for FM, TBM, FAT, TRI SF or SI SF. A main effect for BMI and LBM showed a significant (p<0.05) increase due to training (mean±SE) (BMI: 22.764±0.583 vs. 23.128±0.477 kg/m<sup>2</sup> and LBM: 44.126±1.172 vs. 45.617±1.021 kg) but no difference between groups. There was a significant interaction for TH SF, which was further analyzed via paired t-test for both groups, showing a significant (p<0.05) decrease in the TS group (mean±SD) (29.9583±2.90927 mm pre vs 24.4167±1.54826 mm post), but not the CS group. A 2 (group) x 2 (site) x 2 (time) ANOVA was used to compare the US SC fat thickness, which was measured at 2 sites on the thigh. There were no significant 3-way or 2-way interactions, and the only significant main effect was a significant (p<0.05) difference between the 2 measured sites (0.721±0.057 vs 1.043±0.078 cm).

**CONCLUSION:** There is little evidence to support a 12-week lower body RT effect on percent body fat or localized SC fat with the possible exception of the TH SF when using traditional strength training. The change in LBM demonstrates any body composition changes due to 12-week RT may be due to increases in muscle mass, not fat loss.

---

**2609** Board #284 MAY 31 2:00 PM - 3:30 PM  
**Resistance Training Increases SHBG and Improves Glucose Tolerance in Overweight Sedentary Young Men**

Christian K. Roberts, FACSM, Nina Brandt, Daniel M. Croymans. University of California, Los Angeles, Los Angeles, CA.  
(No relationships reported)

**PURPOSE:** The prevalence of type 2 diabetes (T2D) in the US has rapidly increased in recent decades, with an estimated 26 million Americans being diagnosed. Recent evidence suggests that sex hormone-binding globulin (SHBG) independently predicts risk of T2D. Previously we demonstrated that a 12-week periodized resistance training (RT) program results in improvements in body composition, independent of weight loss in overweight, sedentary young adult men. In this randomized controlled trial, we investigated the effects RT on SHBG, testosterone, cortisol and glucose tolerance.

**METHODS:** 33 overweight, sedentary young adult males (BMI=31.8±0.5 kg/m<sup>2</sup>) were randomized in a 3:1 fashion to RT (12 wks training at 3 sessions/wk) or control (C, 12 weeks of no training) group. After an overnight fast and abstaining for exercise for 72 hrs, pre- and post-intervention whole body glucose tolerance was assessed during an oral glucose tolerance test (OGTT) and serum levels of testosterone, cortisol and sex hormone-binding globulin (SHBG) was determined. Subsequently, levels of free testosterone and free androgen index (FAI) were calculated.

**RESULTS:** In the RT group, SHBG increased by ~ 25% (16.09 ± 1.38 vs. 20.28 ± 1.74, P < 0.001). Levels of free testosterone (125.5 ± 6.5 vs. 106.0 ± 5.3 pg\*mL<sup>-1</sup>, P < 0.001) as well as FAI (1.19 ± 0.10 vs. 0.90 ± 0.07, P < 0.001) decreased in the RT group, while serum total testosterone (488 ± 21 vs. 468 ± 26 ng\*dl<sup>-1</sup>, P = 0.35) and cortisol (15.42 ± 1.08 vs. 13.78 ± 0.87 µg\*dL<sup>-1</sup>, P = 0.17) did not change. Additionally, the RT group exhibited a significant decrease in 2-hr glucose area under the curve (AUC) (4290.58 ± 427.35 vs. 3042.19 ± 394.65 mMol\*min, P < 0.01) and mean insulin (57.50 ± 5.86 vs. 49.87 ± 5.21 µU\*ml<sup>-1</sup>, P < 0.05) during the OGTT. Apart from serum cortisol levels, which increased by ~ 20% (15.06 ± 1.38 vs. 17.92 ± 0.88 87 µg\*dl<sup>-1</sup>, P < 0.05) none of the above mentioned variables changed in the C group.

**CONCLUSION:** Chronic RT increases SHBG in overweight, sedentary young men in concert with improved glucose tolerance. The improvement in whole body glucose tolerance by RT may be mediated, in part, by an increase in SHBG. Whether RT may decrease risk for T2D via increased SHBG requires further study.

---

**2610** Board #285 MAY 31 2:00 PM - 3:30 PM  
**Changes in Muscular Strength and Endurance After 10 Weeks of Body Weight Resistance Training**

Tanya J. Gupta, Alberto F. Vallejo, Lindsey J. Anderson, Alan Gurler, Jesus Dominguez, Brian Wu, E. Todd Schroeder. University of Southern California, Los Angeles, CA.  
(No relationships reported)

Improving strength and muscular endurance promotes vitality and may protect against functional decline in late adulthood. However, research concerning the effects of resistance training has mainly been restricted to exercise protocols utilizing standard training equipment found in fitness facilities. Body-weight resistance training (BWRT) is a cost-effective, home-based exercise modality that may constitute a viable alternative to such traditional exercise protocols.

**PURPOSE:** To examine the effects of a 10-week BWRT program using the TotalGym XL S with caloric restriction on muscular strength and muscular endurance.

**METHODS:** Twenty-six sedentary adults were assigned to one of two groups: exercise and diet (n=14, 9 women, 5 men) or control (n=12, 8 women, 4 men). Exercising subjects were on average 34±4 years of age, weighed 91.3±32.0 kg, with a mean BMI of 32.1±8.9. Control subjects were 36±7 years of age, weighed 92.2±16.1 kg, with a mean BMI of 33.9±6.1. The exercise

group completed 3 training sessions per week using the TotalGym XLS while reducing caloric intake by 500 kcal per day for 10 weeks. Subjects performed two sets of 15 repetitions for each of the 18 exercises with 30 seconds of rest between sets. The Borg Rating of Perceived Exertion (RPE) scale was used to monitor and adjust resistance settings, ensuring continuous progression over the entire training period. Baseline and post-intervention maximal strength and muscular endurance were assessed via 1-RM testing and maximum repetitions to fatigue at 60% of 1-RM, respectively.

**RESULTS:** Exercising subjects demonstrated significant increases in maximal voluntary strength for the chest press ( $8.9 \pm 13.8\%$ ,  $p=0.014$ ), leg flexion ( $11.5 \pm 11.7\%$ ,  $p=0.003$ ), and latissimus dorsi pull-down exercises ( $10.1 \pm 5.2\%$ ,  $p=0.002$ ). The exercise group also demonstrated substantial increases in muscular endurance for the chest press ( $57.4 \pm 33.6\%$ ,  $p<0.001$ ), leg extension ( $43.5 \pm 16.9\%$ ,  $p<0.001$ ), leg flexion ( $25.1 \pm 9.3\%$ ,  $p<0.001$ ), and latissimus dorsi pull-down exercises ( $47.2 \pm 24.9\%$ ,  $p<0.001$ ). No significant changes were detected in the control group.

**CONCLUSIONS:** Body weight resistance training with the Total Gym XLS combined with a 500 kcal per day restrictive diet may enhance muscular strength and endurance.

**2611** Board #286 MAY 31 2:00 PM - 3:30 PM

**Effect Of Free-weight And Machine-weight Training On Upper-body Strength Gains In Low- And High-strength College Women**

Thomas J. Pujol, FACSM<sup>1</sup>, Jerry L. Mayhew<sup>2</sup>, William F. Brechue<sup>3</sup>, Paul Reneau<sup>4</sup>. <sup>1</sup>*Southeast Missouri State University, Cape Girardeau, MO.* <sup>2</sup>*Truman State University, Kirksville, MO.* <sup>3</sup>*United States Military Academy, West Point, NY.* <sup>4</sup>*Fairmont State University, Fairmont, WV.*

(No relationships reported)

Anecdotal evidence suggests that women prefer to perform resistance exercises using machine weights as opposed to free weights. However, few studies have compared free weights and machine weights for women. Furthermore, little evidence is available relative to the effect of initial strength level on strength gain in women.

**PURPOSE:** To compare the effect of training modes on upper-body strength development in low- and high-strength women.

**METHODS:** Untrained women ( $n = 217$ , age =  $19.2 \pm 1.0$  y, body mass =  $64.6 \pm 15.6$  kg, %fat =  $23.0 \pm 5.3\%$ ) were selected from a larger cohort based on initial 1RM bench press performance on either free weights (FW,  $n = 69$ ), seated horizontal press machine (SHP,  $n = 81$ ), and supine vertical press machine (SVP,  $n = 67$ ). Body fat (%fat) and lean body mass (LBM) were estimated from skinfolds using a generalized equation. Subjects were matched for low-strength (LS;  $n = 106$ ; 1RM =  $27.8 \pm 2.1$  kg) and high-strength (HS;  $n = 111$ ; 1RM =  $45.6 \pm 6.1$  kg) on their specific training mode. Each subject completed a 12-wk linear periodization resistance training program (Wk 1-5: 3 x 10-12-RM; Wk 6-9: 3 x 6-8-RM; Wk 10-12: 3 x 3-5-RM) using either free weights or mode-specific weights.

**RESULTS:** Pre-training mode x strength level ANOVA indicated that HS had significantly greater body mass ( $72.8 \pm 17.9$  kg), LBM ( $54.0 \pm 10.0$  kg), and %fat ( $24.9 \pm 5.8\%$ ) than LS ( $56.8 \pm 6.7$  kg,  $44.7 \pm 4.5$  kg, and  $21.1 \pm 3.8\%$ , respectively). Following training, mode x strength level ANOVA on strength gain (Post 1RM - Pre 1RM) indicated SHP ( $10.1 \pm 4.2$  kg) was significantly greater than SVP ( $6.5 \pm 4.2$  kg;  $p<0.001$ ) which was greater than FW ( $4.5 \pm 4.3$  kg;  $p<0.001$ ). There was no significant difference ( $p>0.99$ ) in strength gain between strength groups (LS =  $7.2 \pm 4.3$ ; HS =  $7.2 \pm 5.3$  kg); however, the LS groups made a significantly greater percent gain ( $25.9 \pm 5.6\%$ ) compared to the HS groups ( $16.0 \pm 11.3\%$ ). None of the body composition parameters made significant changes following training.

**CONCLUSIONS:** Changes in muscular strength following resistance training in college women is likely to be greater for machine weights than for free weights and may differ between machine weight types. However, absolute strength gains will be similar between low- and high-strength women regardless of training mode.

**2612** Board #287 MAY 31 2:00 PM - 3:30 PM

**The Effects Of Four Weeks Home-Based Isometric Exercise Training On Resting Blood Pressure**

Natalie Goldring, Jonathan D. Wiles, Damian A. Coleman. *Canterbury Christ Church University, Canterbury, United Kingdom.*

(No relationships reported)

Research demonstrates that isometric exercise training can reduce resting blood pressure (BP). However, most training studies involve the use of expensive laboratory-based equipment to complete the training, which is ultimately neither cost nor time effective as a treatment method for hypertension. A home-based isometric exercise program would be cheaper and simpler to perform, and could potentially make this form of exercise more accessible to the general population.

**PURPOSE:** The aim of this study was to assess whether resting BP (systolic - SBP, diastolic - DBP, and mean arterial pressure - MAP) could be reduced after 4 weeks of home-based isometric wall squat exercise (IWSE) training.

**METHODS:** Thirty healthy normotensive males were examined using a crossover study design. Participants were initially randomly assigned to either an IWSE training group or a control group for a 4 week period. After a 4 week 'washout' period, participants then changed to the other condition. The IWSE training consisted of 3 exercise sessions per week performing 4 x 2 minute wall squat exercises in each session. Before training, all participants performed a continuous incremental IWSE test to determine training intensity (equivalent to 95% peak heart rate (HR)). The control period required participants to maintain a normal daily routine for the 4 week period. BP and HR were measured 48 hours pre- and post- both conditions. Resting BP was measured using a non-invasive hemodynamic monitor and HR was measured via ECG using a bipolar lead II configuration.

**RESULTS:** During training, participants exercised at a HR of  $121.2 \pm 24.5$  beats·min<sup>-1</sup> (mean  $\pm$  SD). After 4 weeks of IWSE training, significant reductions in resting SBP  $-3.5 \pm 3.7$ , DBP  $-4.0 \pm 2.7$  and MAP  $-3.8 \pm 2.7$  mmHg were demonstrated ( $P<0.05$ ) when compared to the control period (SBP  $0.7 \pm 1.1$ , DBP  $0.7 \pm 1.8$  and MAP  $0.7 \pm 1.3$  mmHg). Resting HR also reduced significantly ( $P<0.05$ ) with training ( $-8.9 \pm 6.7$  beats·min<sup>-1</sup>) compared to the control period ( $-0.1 \pm 6.0$  beats·min<sup>-1</sup>).

**CONCLUSION:** 4 weeks of home-based IWSE training can reduce resting BP in a simple, cost and time effective way, allowing an individual to exercise privately, in familiar surroundings and at their own convenience. This novel method of exercise prescription should be investigated further with borderline hypertensive participants.

**2613** Board #288 MAY 31 2:00 PM - 3:30 PM

**Unilateral Strength Training With Maximal Velocity Improves Lower Body Power Outcome And Movement Velocity**

Johan Petersson<sup>1</sup>, Kenneth Riggberger<sup>2</sup>, Sofia Brorsson<sup>1</sup>, M. Charlotte Olsson<sup>1</sup>. <sup>1</sup>*School of Business and Engineering, Halmstad University, Sweden.* <sup>2</sup>*Malmö Sports Academy, Stadionkontoret, Malmö, Sweden.*

(No relationships reported)

In many sports development of power is considered to be one of the most important physiological qualities for success. Despite many studies in the area, research investigating unilateral power training methods for elite athletes is lacking.

**PURPOSE:** The purpose of this study was to examine the effects of unilateral explosive strength training on lower body power output and movement velocity after six weeks of training.

**METHODS:** 17 elite male handball players (age  $22 \pm 4$ ), experienced in resistance training, participated in a six week intervention study. The players were divided into a training group (TR)  $n=11$ , and control group (CTL)  $n=6$ . The TR group performed 15 supervised training sessions during six weeks, involving ballistic weightlifting exercises performed unilateral with heavy loads ( $>80\%$  1RM) and maximal intended movement velocity in both the concentric and eccentric phases of the lifts. The CTL group performed bilateral strength training with heavy loads without movement velocity consideration. Loaded vertical squat jumps with absolute loads of 20, 40, 60, 80 and 100 kg were made before and after the training period. A linear encoder attached to the barbell measured average concentric power (APc), average eccentric power (APe), peak velocity and time to peak velocity (tpV) to evaluate power output and movement velocity. To keep results brief but clear, average load was calculated as the mean change of all five loads from pre- to post intervention. T-tests were used to analyze differences between the two groups.

**RESULTS:** The unilateral power training improved APc ( $p<0,05$ ) on average with  $3 \pm 1$  W/kg (18%) in TR vs.  $-1 \pm 2$  W/kg (-3%) in CTL. Similarly, for APe, average load increased significantly ( $p<0,05$ ) in TR  $3 \pm 2$  W/kg (36%) compared to  $-1 \pm 1$  W/kg (-1%) in CTL. Moreover, TR decreased their tpV with  $-0,18 \pm 0,08$  ms (-40%), compared to CTL  $0,01 \pm 0,06$  ms (2%:  $p<0,05$ ).

**CONCLUSION:** The TR group showed improvements after only a short period of structured unilateral maximal velocity training which indicates that unilateral training principles could be effective for improving lower body power output in elite athletes involved in sports where unilateral movements predominate. Longer studies are needed to evaluate further potential benefits of unilateral strength training.

2614 Board #289 MAY 31 2:00 PM - 3:30 PM

**Comparison of Shoulder Training Techniques for Strength Improvements in Collegiate Volleyball Players**

Anthony Clapp<sup>1</sup>, Emilee Traxler<sup>1</sup>, John L. Walker, FACSM<sup>2</sup>. <sup>1</sup>Augsburg College, Minneapolis, MN. <sup>2</sup>Texas State University, San Marcos, TX.  
(No relationships reported)

Shoulder strength is frequently touted as a key factor for volleyball performance. Although resistance bands are often employed in rehabilitating athletes, their use for the purpose of making significant strength gains is viewed as tributary compared to that of weight training.

**PURPOSE:** The purpose of this study was to compare the level of strength gains in the female collegiate volleyball player employing either a resistance training protocol with free weights or resistance bands, to determine which training technique would be most beneficial for shoulder strength.

**METHODS:** Eight intercollegiate athletes from a NCAA Division III Women's Volleyball team (Age=19.3 ± 1.3 yrs, Ht. = 177.0± 8.8 cm, Wt.=71.8 ± 9.0 Kg) were matched by position and then randomly assigned to either a resistance band strength training group (RB, n=4) or a free weight strength training group (FW, n=4). The participants' shoulder strength was measured with a Chattanooga Hydraulic Push-Pull Dynamometer with a digital gauge, in four different shoulder positions: flexion, extension, abduction, and adduction. After the completion of the measurements, the athletes completed a six week training program consisting of four different training exercises; flexion, extension, abduction, and adduction. All athletes performed these exercises 20 min/day, three times a week. Following six weeks of training, the participants' shoulder strength was measured again.

**RESULTS:** All of the athletes improved their shoulder strength over the length of the exercise program. Mean(x) strength was calculated from the four measurements and the average strength score for the FW group improved from 14.55 ± 2.3 lb. to 18.33 ± 1.9 lb. The average strength score for the RB improved from 15.18 ± 2.9 lb. to 18.67 ± 2.4 lb. Both groups were significantly stronger than the initial measurements ( $p < 0.05$ ). There were no differences between the groups.

**CONCLUSIONS:** This study revealed that participation in a shoulder strengthening program, using either elastic bands or free weights, can significantly improve the athlete's shoulder strength. Ultimately, this should lead to an increase in performance and a decrease in the risk of injury to the shoulder.

2615 Board #290 MAY 31 2:00 PM - 3:30 PM

**Effects of Magnesium-Creatine Chelate and Protein Supplementation on Strength and Power Measures in Recreationally Trained Individuals**

David N. Suprak, Rory Callahan, Lorrie R. Brilla, FACSM. Western Washington University, Bellingham, WA.  
(No relationships reported)

Creatine is the most effective supplement available for increasing high-intensity exercise capacity and muscle mass, and is often "stacked" with protein supplementation. Magnesium enhances creatine absorption into muscle. The efficacy of these supplements in combination has not been established.

**PURPOSE:** To compare the effects of supplementation with magnesium-creatine chelate (C), C with whey protein stack (W), and placebo (P), combined with resistance training (RT), on measures of strength, power and acceleration.

**METHODS:** Twenty-three healthy, recreationally active participants completed the study. Strength and power testing was conducted before and after an 8-week RT and supplementation program. Strength testing consisted of 1-repetition maximum (1RM) bench press (BP) and back squat (BS). Power testing included the standing broad jump (SBJ), vertical jump (VJ), and seated medicine ball (MB) chest throw. Acceleration was tested via a 10-m sprint. Participants were randomly assigned to one of three supplementation groups, in a double-blind format. The C group was given 5-g creatine chelate equivalent and 400-mg magnesium equivalent per day. The W group received 35 g of whey protein per day, in addition to that given to the C group. The P group received dextran. The eight-week RT was designed to progressively increase strength and power in the major muscle groups involved in movements being tested in a linearly periodized fashion. The effects of time and group were assessed with a two-way repeated measures ANOVA for each outcome measure.

**RESULTS:** There were no group by time interactions or group effects for any outcome measure ( $p > .05$  for each). Across groups, the following changes were observed. 1RM BS increased by 13.64 kg, while BP increased by 5.74 kg ( $p < .001$  for each) over time. MB throw increased by .21 m, while SBJ increased by .11 m ( $p < .001$  for each). 10-m sprint time decreased by .04 s ( $p = .005$ ), while VJ did not change ( $p = .828$ ).

**CONCLUSION:** In healthy, recreationally active individuals, participation in periodized RT to improve strength and power of major muscle groups has a greater effect on improving strength, power, and acceleration than does supplementation with either C or W.

---

2616 Board #291 MAY 31 2:00 PM - 3:30 PM

**Timed Protein Supplementation Following Resistance Training in Young Women**

Heather C. Heidebreicht, Jessica Stallings, Jennifer L. Caputo, Richard S. Farley, Don W. Morgan, FACSM. Middle Tennessee State University, Murfreesboro, TN.  
(No relationships reported)

The combination of resistance training (RT) and appropriately-timed protein supplementation yields additional gains in lean body mass, muscular strength, and muscular endurance in adult males compared to RT alone. However, limited research is available concerning the effects of timed protein supplementation among young adult females who engage in RT.

**PURPOSE:** To determine the effects of timed protein supplementation immediately post-RT and 1-hour post-RT on lean body mass and muscle strength in young adult women.

**METHODS:** Females (N = 29; age = 21.6 ± 2.1 yrs; body mass = 63.5 ± 7.4 kg; protein intake = 1.10 ± 0.23 g/kg) participated in a 10-week RT program featuring exercises targeting upper- and lower-body muscle groups. Participants were randomly assigned to one of three groups: immediate post-RT supplementation (IMPRT), 1-hour post-RT supplementation (1HPRT), or a control group (RT only; CTLRT). RT was conducted three days per week in a supervised environment. Lean body mass (LBM) was assessed using dual-energy x-ray absorptiometry (DEXA) and muscle strength was assessed using a 1-repetition maximum bench press (1RMBP) and leg press (1RLMP). Intake of dietary protein was assessed through 24-hour diet recall. The IMPRT group consumed the protein supplement immediately post-RT, the 1HPRT group returned one hour after RT to consume the protein supplement, and the CTLRT group consumed water immediately following RT. Participants in the IMPRT and 1HPRT groups were given 24 grams of a whey isolate protein mixed with water, irrespective of body mass.

**RESULTS:** When participant data from the three RT groups were combined, significant ( $p < .05$ ) increases in LBM (2.3%) and 1RMBP and 1RLMP (21% and 20%, respectively) were observed following RT. However, no group-by-time interaction was detected for LBM, 1RMBP, or 1RLMP.

**CONCLUSION:** Ten weeks of resistance training increases lean body mass and upper- and lower-body muscle strength in women, regardless of whether a protein supplement is ingested within one hour following RT workouts.

---

2617 Board #292 MAY 31 2:00 PM - 3:30 PM

**The Effects of Protein and Carbohydrate Supplementation on Resistance Training Induced Gains in Fat Free Mass and Strength**

Robert S. Santana, Ralph E. Graham, Michael P. Godard, FACSM, Timothy J. Piper, Loran D. Erdmann. Western Illinois University, Macomb, IL.  
(No relationships reported)

**PURPOSE:** The purpose of this study was to compare the gains in strength and fat-free mass achieved by novice weight lifters who participated in a 9-week resistance training program, and who consumed either a protein and carbohydrate supplement drink or a non-caloric placebo drink immediately after each resistance training bout.

**METHODS:** Twenty-one participants (Supplement: 12, Placebo: 9) completed the 9-week resistance-training program. Body fat percentage (BF%) and fat-free mass (FFM) were assessed via air displacement plethysmography at baseline and again at the end of the 9-week training period. Pre- and post-training strength was also assessed via 1-repetition maximum tests on three different lifts.

**RESULTS:** Food diaries collected and analyzed at 3 time points during the study indicated that the protein intake (without post-exercise supplementation) of the subjects in both groups exceeded the RDA for protein of 0.8 g/kg. Both groups exhibited significant increases in FFM and strength over the 9-week training period (FFM increased from 66.0 kg to 67.9 kg and from 62.8 kg to 64.4 kg, and total 1-rep max increased from 359.1 kg to 455.3 kg and from 356.3 kg to 458.1 kg in the Supplement and Placebo groups, respectively). However, no significant between-group differences in FFM or strength gains were observed.

---

**CONCLUSIONS:** The results of this study suggest that if protein intake is already adequate to meet daily protein requirements, post-exercise protein supplementation may not be associated with additional training-induced improvements in FFM and strength in novice lifters participating in a relatively short-term program of resistance training. (The whey protein and dextrose used in this study were provided by Bioplex Nutrition and NOW Foods respectively.)

**2618** Board #293 **MAY 31 2:00 PM - 3:30 PM**

**Effects Of Strength Training On Parameters Of The Power-Duration Relationship Using Linear And Non-linear Models**

Brandon J. Sawyer<sup>1</sup>, David G. Stokes<sup>2</sup>, R Hugh Morton<sup>3</sup>, Arthur Weltman, FACSM<sup>2</sup>, Glenn A. Gaesser, FACSM<sup>1</sup>. <sup>1</sup>Arizona State University, Phoenix, AZ. <sup>2</sup>University of Virginia, Charlottesville, VA. <sup>3</sup>Massey University, Palmerston North, New Zealand.  
(No relationships reported)

**PURPOSE:** Strength training has been shown to improve the capacity for high-intensity exercise, but it is uncertain whether it can improve critical power (CP). The purpose of this study was to determine the effects of strength training on CP and the curvature constant ( $W'$ , or Anaerobic Work Capacity) of the hyperbolic power-duration relationship using linear and non-linear models.

**METHODS:** Before and after 8 weeks of whole-body strength training, 14 males (age  $20.6 \pm 2.0$  years; weight:  $78.2 \pm 15.9$  kg) performed an incremental exercise test on a cycle ergometer for determination of  $VO_{2peak}$  and lactate threshold. In addition, on separate days each subject performed 4 randomly assigned constant-power exercise bouts (P1-P4, lowest to highest) to exhaustion on a cycle ergometer. CP and  $W'$  were estimated using nonlinear 2-parameter [ $t = W'/(P-CP)$ ] and 3-parameter [ $t = (W'/(P-CP)) - k$ ] models, and two linear models [Work (W):  $W = W' + CP(t)$ ; Power:  $P = W'/t + CP$ ].

**RESULTS:** Significant ( $p < 0.05$ ) improvements were found for upper and lower body strength (mean increase = 20%), power output at peak lactate (218 to 235 W), and time to exhaustion (TTE) during all 4 constant-power tests (P1: 17.9 to 21.0 min; P2: 9.1 to 13.4 min; P3: 4.4 to 6.1 min; P4: 1.9 to 2.8 min). Parameter estimates for CP and  $W'$  could not be obtained with the 3-parameter model.  $W'$  significantly ( $p < 0.001$ ) improved with the other 3 models (2-parameter nonlinear: 20.1 to 32.5 kJ; W: 16.7 to 24.0 kJ; P: 13.8 to 19.3 kJ). By contrast, CP showed a significant decrease with the 2-parameter nonlinear model (162 to 157 W,  $p = 0.023$ ) and no change ( $p > 0.05$ ) with the 2 linear models (W: 167 to 166 W; P: 175 to 175 W).

**CONCLUSIONS:** The improvement in  $W'$  is consistent with previous findings of increased capacity for high-intensity exercise after strength training. However, CP was not improved, and paradoxically decreased as estimated from the nonlinear 2-parameter model. These results suggest that strength training alters the power-duration hyperbola such that  $W'$  is enhanced at the (apparent) expense of CP. Because significant increases in exercise tolerance within the severe exercise intensity domain were observed, our results suggest that current models of the power-duration hyperbola cannot reliably estimate changes in CP after strength training.

**2619** Board #294 **MAY 31 2:00 PM - 3:30 PM**

**Effect Of Core Strength and Endurance Training On Performance In College Students: Randomized Pilot Study**

Jim Schilling, Jeff Murphy, John Bonney, Jacob Thich. *University of Southern Maine, Gorham, ME.* (Sponsor: Karen Croteau, FACSM)  
(No relationships reported)

The evidence is inconsistent regarding benefits in performance acquired through core muscle training. Few investigators have considered utilizing nonathletes and none have compared the effects of core strength training with core endurance training and their influence on various functional measures.

**PURPOSE:** To examine the effectiveness of a core endurance and a core strength training protocol on endurance, basic strength, and specific performance measures.

**METHODS:** Ten college students (age  $21 \pm 7.0$ ) were randomly assigned to either a core endurance trained group ( $n = 5$ ) or a core strength trained group ( $n = 5$ ). Training consisted of 3 specific exercises and training protocols for each group which took place 2 days per week for 6 weeks. Core muscle endurance was assessed using flexion, extension, and lateral tests. Strength tests were a back squat and bench press conducted on a smith machine. Performance tests consisted of a vertical jump, 10 yard sprint, and pro agility test.

**RESULTS:** A significant improvement in flexor ( $153.40$  sec.  $\pm 91.31$  to  $175.60$  sec.  $\pm 94.45$ ,  $p < 0.05$ ) and back extensor ( $124.80$  sec.  $\pm 42.72$  to  $151.40$  sec.  $\pm 40.40$ ,  $p < 0.05$ ) endurance times along with strength values with both the back squat ( $54.99$  kg.  $\pm 27.34$  to  $62.27$  kg.  $\pm 25.14$ ,  $p < 0.05$ ) and bench press ( $34.09$  kg.  $\pm 14.82$  to  $37.73$  kg.  $\pm 15.63$ ,  $p < 0.05$ ) occurred with the strength trained group. Also, a significant improvement in flexor ( $87.40$  sec.  $\pm 37.25$  to  $150.20$  sec.  $\pm 53.62$ ,  $p < 0.05$ ) and right lateral ( $65.40$  sec.  $\pm 35.68$  to  $104.60$  sec.  $\pm 45.37$ ,  $p < 0.05$ ) endurance times along with strength values in the back squat ( $61.82$  kg.  $\pm 32.83$  to  $72.73$  kg.  $\pm 32.42$ ,  $p < 0.05$ ) were found with the endurance trained group. No significant differences were discovered with either group in functional performance measures.

**CONCLUSION:** Although the results from this limited sample cannot be considered conclusive, they suggest that both core endurance and strength training may improve selected core muscle endurance parameters and possibly assist in increasing strength with specific movements. Also, the endurance training protocol was not superior to the strength training protocol, and they both lacked effectiveness in improving functional performance.

**2620** Board #295 **MAY 31 2:00 PM - 3:30 PM**

**Effects of Short-term Core Endurance Training on Running Economy**

Kelsey Figg, Colleen Kirk, Kelcie Wittman, Kathryn Appel, Ashleigh Handorff, Gary Van Guilder, Jeffrey Janot. *University of Wisconsin-Eau Claire, Eau Claire, WI.* (Sponsor: Mark Blegen, FACSM)  
(No relationships reported)

The core musculature assists in stabilizing the spine during dynamic movement. Poor core endurance has been shown to increase the risk of spinal injury and may be linked to movement inefficiency. Therefore, improving core endurance may produce favorable changes in body posture and stability leading to improved health and exercise performance. With respect to performance, previous research has produced conflicting results regarding the potential benefits of core training on running economy (RE).

**PURPOSE:** The aim was to determine if short-term, core endurance training improves RE in healthy young adults.

**METHODS:** Three males and 13 females, age 18-25 years, participated in a 4-wk (30-min, 3 days/wk) core training program (12 sessions total). A total of 13 exercises were employed to train the anterior, lateral, and posterior core musculature. Measurements of anthropometry, core endurance, and RE were performed prior to and following the 4-wk program. Dependent t-tests were used to compare outcome variables pre- and post-training.

**RESULTS:** Right and left side bridge, flexor, and back extensor endurance times were significantly ( $p < .05$ ) increased following training. Interestingly, despite increases in core endurance, a significant ( $p < .05$ ) decrease in RE was observed.

| Variables  | Pre-training      | Post-training      |
|--|-------------------|--------------------|
| Left side bridge (s)   | 56.7 $\pm$ 13.3   | 86.6 $\pm$ 21.6*   |
| Right side bridge (s)  | 56.0 $\pm$ 11.3   | 86.8 $\pm$ 24.1*   |
| Flexor endurance (s)   | 152.9 $\pm$ 118.6 | 318.8 $\pm$ 258.2* |
| Back extensor (s)  | 110.3 $\pm$ 24.6  | 151.1 $\pm$ 30.1*  |
| Oxygen consumption (ml·kg <sup>-1</sup> ·min <sup>-1</sup> ) | 14.3 $\pm$ 2.2    | 15.2 $\pm$ 2.6*    |

\*Post-training significantly ( $p < .05$ ) greater than pre-training

**CONCLUSION:** These results showed that an inverse relationship between improvements in core endurance and oxygen uptake may exist during a given submaximal running workload. Further research is warranted to examine the impact of endurance training on RE with and without core training and the overall impact of core endurance improvements on energy expenditure.

2621 Board #296 MAY 31 2:00 PM - 3:30 PM

### Impact of 6 Months Intervention Program on Cardiovascular Fitness in Overweight and Obese People

Ana B. Peinado, Miguel A. Rojo-Tirado, Pedro J. Benito, on behalf of the PRONAF Study Group. *Technical University of Madrid, Madrid, Spain.*  
(No relationships reported)

The effects of diet and exercise on physical capacity in weight loss programs (WLP) for overweight (W) and obese (O) people has been studied in few studies, concluding that physical capacity measures improve after intervention, although it is unknown the most effective exercise training.

**PURPOSE:** To determine which protocol is the most effective to improve the cardiovascular fitness in W and O in WLP.

**METHODS:** One hundred eighty-nine W and O (body mass index [BMI] 25-34.9 kg/m<sup>2</sup>), aged from 18 to 50 years, performed an incremental test until exhaustion on a treadmill, using a modified Bruce protocol, before (pre) and after (post) the 24 weeks intervention. Subjects were randomized to one of the following training groups: strength training (S), endurance training (E), a combination of S and E (SE) (Training frequency: 3 times per week) and control group (C). All of them in combination with a 25 % calorie restriction diet. Two-way ANOVA with repeated measures was used to determine differences between pre and post intervention in each training group. The significant level was set at 0.05.

**RESULTS:** Maximum oxygen uptake (VO<sub>2max</sub>) increased significantly in all groups in W (Pre and post values, respectively; S: 2466.1 ± 728.6 vs. 2742.5 ± 921.1; E: 2420.9 ± 635.7 vs. 2745.6 ± 655.3; SE: 2725.1 ± 802.7 vs. 3134.7 ± 888.1; C: 2447.1 ± 704.6 vs. 2735.8 ± 753.9 mL·min<sup>-1</sup>), although in O the increase was only significant in SE (3102.8 ± 691.8 vs. 3405.2 ± 906.7 mL·min<sup>-1</sup>). The position of aerobic threshold respect to VO<sub>2max</sub> changed in all groups in W (S: 44.6 ± 7.1 vs. 49.5 ± 7.6; E: 41.2 ± 7.5 vs. 55.1 ± 11.3; SE: 43.3 ± 8.7 vs. 48.6 ± 8.6; C: 44.3 ± 6.2 vs. 52.3 ± 7.8 %, p<0.05), although in O the change was only significant in E (48.1 ± 7.6 vs. 52.7 ± 8.1 %) and C (47.9 ± 10.7 vs. 52.4 ± 8.4 %). There were no significant changes in the position of anaerobic threshold respect to VO<sub>2max</sub>, only E in O showed a significant increase (81.7 ± 7.9 vs. 85.7 ± 7.8 %).

**CONCLUSION:** The proposed protocols improved the cardiovascular fitness in W while in O only SE increased VO<sub>2max</sub> and E changed the thresholds position.

The PRONAF Study takes place with the financial support of the *Ministerio de Ciencia e Innovación, Convocatoria de Ayudas I+D 2008, Proyectos de Investigación Fundamental No Orientada, del VI Plan de Investigación Nacional 2008-2011.*

### Effects Of A Training Program On Sedentary Graphic Arts Workers

Andre Luiz Mores<sup>1</sup>, Felipe Borges Trama<sup>2</sup>, Laurinda Abreu<sup>3</sup>, Daniel Alexandre Boulosa Alvarez<sup>1</sup>. <sup>1</sup>Universidade Catolica De Brasilia, Brasilia, Brazil. <sup>2</sup>Universidade Catolica De Brasilia, Sao Paulo, Brazil. <sup>3</sup>Lavadores, Vigo, Spain.  
(No relationships reported)

**PURPOSE:** The aim of this study was to evaluate the changes in physical and anthropometric parameters in a group of sedentary workers after joining a physical training program.

**METHODS:** Fifty graphic arts workers (37.7 ± 8.6 yrs; 82.1 ± 15.3 kg) volunteered for participation on this study. The training program consisted of concurrent strength and endurance training sessions of moderate intensity (i.e. 70% RM and 70% HR reserve, for strength and endurance exercises, respectively) that were performed 2-3 times a week. The workers were divided into four groups depending on the number of sessions completed: G1 (n=12) ~ 10-21 sessions; G2 (n=14) ~ 22-35 sessions; G3 (n=14) > 36 sessions; and control group (n= 10). Handgrip dynamometry, scapular dynamometry, shoulder abduction strength, shoulder flexion strength, and anthropometric measures (i.e. % body fat, and excess of weight) were evaluated before and after the completion of each training period.

**RESULTS:** G1, G2, and G3 showed significant improvements (from -45% to +114%; p=0.000-0.041) in all physical tests parameters (except for scapular dynamometry in G2, p=0.104-0.186) and anthropometric measures over the training period. Analysis of variance showed that only G3 demonstrated significant percentage changes in physical performance parameters with respect to the control group (p values ranged from 0.001 to 0.045). In contrast, there were no differences among experimental groups with respect to the control group in any anthropometric variable (p > 0.05).

**CONCLUSION:** Few sessions (i.e. 10-21) of regular moderate resistance and aerobic training could rapidly improve health-related parameters in a group of sedentary graphic arts workers, with more than 36 sessions being necessary for experiencing the greater benefits. Implementation of a training program in graphic arts workers could be effective for a greater fitness which may improve employees' productivity and quality of life.

2623 Board #298 MAY 31 2:00 PM - 3:30 PM

### Association of IPAQ-S, Body Composition, and Lipid Profile Response To Exercise

William W. Edwards<sup>1</sup>, Shyam S. Mali<sup>2</sup>, D. Drew Pringle, FACSM<sup>3</sup>. <sup>1</sup>Lander University, Greenwood, SC. <sup>2</sup>Texas A & M University - Kingsville, Kingsville, TX. <sup>3</sup>Wright State University, Dayton, OH.  
(No relationships reported)

The International Physical Activity Questionnaire-Short Form (IPAQ-S), a non-invasive seven-question assessment of physical activity, has received considerable recent international attention. The reliability and validity of the individual IPAQ-S questions with body composition and the lipid profile response to exercise are unclear.

**PURPOSE:** To determine the association of the individual IPAQ-S components with body composition and the blood lipid profile response to exercise in young adults.

**METHODS:** Twenty healthy recreationally trained college students (13M, 7F; 20.1±1.3 yr; 82.0±24.4 kg; BMI 27.4±6.7, respectively) enrolled in a resistance training activity class participated. All were free of any illness or medication that might affect lipid profile. Total body water (TBW), extracellular water (ECW), intracellular water (ICW), basal metabolic rate (BMR), BF %, fat-free mass (FFM) and fat mass (FM) were obtained via bioelectrical impedance analysis. Fasting seated blood samples were taken immediately before (pre) and after (post) a class exercise session and measured for total cholesterol (TC), high-density lipoproteins (HDL), low-density lipoproteins (LDL), triglycerides (TG) and TC/HDL ratio.

**RESULTS:** Correlations between the IPAQ-S, body composition, and lipid profile were generally weak to moderate. The strongest correlations for body composition and IPAQ-S were FFM vs. IPAQ-5 (r = -0.65), and TBW vs. IPAQ-5 (r = -0.64); weakest were ECW vs. IPAQ-3 (r = -0.01), and BMR vs. IPAQ-7 (r = 0.07). Strongest correlations for lipid profile and IPAQ-S were post TC vs. IPAQ-3 (r = 0.46), and post LDL vs. IPAQ-3 (r = 0.45). Strongest negative correlations were post TC/HDL ratio vs. IPAQ-5 (r = -0.36), and post TC vs. IPAQ-6 (r = -0.34).

**CONCLUSION:** Our data suggest that the strongest correlations for IPAQ-S and body composition were with IPAQ-5, while for lipid profile and IPAQ-S were post-exercise with IPAQ-3, IPAQ-5, and IPAQ-6. To better understand the association and validity of the individual IPAQ-S questions, future research may associate these with body composition and lipid profile response across age, gender, ethnicity, and training status.

### The Effects of Short-Term Power Training on Vertical Jump Performance

Matthew Miltenberger<sup>1</sup>, Todd Miller<sup>2</sup>, Shala Davis, FACSM<sup>1</sup>, Frank Pullo<sup>1</sup>. <sup>1</sup>East Stroudsburg University, East Stroudsburg, PA. <sup>2</sup>George Washington University, Washington, DC.  
(No relationships reported)

It has been well established that power is a major distinguishing factor in the ability to be successful in athletics. Olympic lifts are common techniques that are employed by exercise professionals; the question of specificity arises when determining the use of push vs. pull exercises.

**PURPOSE:** To assess the effects of short term power training using the power clean (PC) and the ground base jammer (GBJ) on vertical jump performance.

**METHODS:** After familiarization of exercises, the experimental protocol consisted of a 2 group design (PC and GBJ). Each group trained for 10 sessions over a 20 day period with 5 sets of 3 repetitions at approximately 85-90% of calculated 1RM. Subjects (n=9) were college age males defined as untrained and free from injury that would prevent or inhibit participation. Vertical jump height was assessed using the Vertec® system for both the countermovement vertical jump (VJCM) and the non-countermovement vertical jump (VJNCM). The VJCM consisted of the subject quickly squatting to 90° of knee flexion followed by an explosive upward movement. The VJNCM consisted of a 3 second pause at 90° of knee flexion before the concentric phase of

the jump was initiated. Each subject performed 3 jumps; maximal jump height was recorded and converted to watts for comparison. Descriptive statistics were used to illustrate emerging trends within the data.

**RESULTS:** The findings of this study suggest that the PC training group increased their VJCM and VJNCM performances by 231 watts or 4.6% and 29 watts or .6% respectively. The GBJ group also increased their performances in both the VJCM and VJNCM by 92 watts or 2% and 124 watts or 3% respectively.

**CONCLUSIONS:** Although a small sample was used, data suggests a trend toward specificity of push vs. pull exercises. The push (GBJ) appeared to affect the VJNCM while the pull (PC) affected the VJCM. In the perspective of specificity, sports involving movement without a countermovement (football lineman) may benefit more from training with the GBJ while sports involving countermovement ability (volleyball) may benefit more from training with the PC. In addition, the data also suggests that short term power training in general may be enough to elicit some adaptation increasing performance across conditions.

### The Importance Of Sitting Time And Physical Activity On BMI In Hard To Reach Men

Andy J.W Smith, Stephen Zwolinsky, Andy Pringle, Jim Mckenna, Steve Robertson, Alan White. *Leeds Metropolitan University, Leeds, United Kingdom.*

(A.J. Smith: Contracted Research - Including Principle Investigator; contracted research was undertaken for the Football Foundation.)

Both physical inactivity and sedentary time are important risk factors for obesity in men. Recent UK activity guidelines have stated the importance of minimising time men spend being sedentary while also undertaking enough health-enhancing physical activity. Within interventions for hard-to-reach men it is vital that there is clear advice on the importance of each behaviour.

**PURPOSE:** To investigate the relevant importance of the amount of physical activity and time spent sitting on the risk of being overweight or obese in hard-to-reach men.

**METHODS:** Data were collected from the Mens' Premier League Health Programme delivered through soccer stadia, club training venues and community facilities in England. After providing ethical clearance and consent, participants completed validated, population-specific, self-report measures for height, weight, total daily time spent sitting and levels of physical activity (number of 30+ minutes sessions of MVPA per week). Based on established cut points individuals' sitting risk was classed as low (<4.7 hours per day, coded '1'), moderate (4.7 to 7.4 hours, '2') or high (>7.4 hours per day, '3').

**RESULTS:** A total of n=2214 participants engaged the evaluation; 574 contributed data for time spent sitting, levels of physical activity and BMI. Of these men, 224 were classed as healthy weight (BMI 18.5-24.9, coded '0'), with 344 identified as overweight/obese (BMI $\geq$  25, coded '1'). Six participants were excluded from the analysis due to being underweight (BMI <18.5). A binary logistic regression found no effect on weight classification according to the number of physical activity sessions completed per week (OR=0.99, 95% CI 0.89 to 1.12). Risk for being classified as overweight/ obese increases by 33% for each increment of additional sitting behaviour (OR=1.33, 95% CI 1.06 to 1.66).

**CONCLUSION:** Self-reported sitting time is a better predictor of overweight/obesity than physical activity. Prospective studies are needed to establish the value of focussing on reducing sitting time to manage weight status in programmes delivered to hard-to-reach men.

2626 Board #301 MAY 31 3:30 PM - 5:00 PM

### Daytime Patterns Of Time Spent In Sedentary Behaviors Among Us Middle-aged Adults

Youngdeok Kim, Saori Ishikawa, Anah R. Smith, Joel D. Reece, Ryan T. Connors, Rose M. Carter, Minsoo Kang, FACSM. *Middle Tennessee State University, Murfreesboro, TN.*

(No relationships reported)

**PURPOSE:** Sedentary behaviors (SBs) have been recognized as an independent risk factor of chronic diseases in the adult population. Despite of the increasing importance of SBs for maintaining healthy life in later years, few studies have explored the trajectory of time spent in SBs throughout a day. The purpose of this study, therefore, was to examine the patterns and changes in time spent in SBs during the day among US middle-aged adults.

**METHODS:** Data from the 2003 to 2006 National Health and Nutrition Examination Survey (NHANES) were analyzed for this study. A total of 1,038 middle-aged adults (40-60 years of age) who provided valid data of accelerometer activity counts for at least three days of weekdays and a day of weekend days were included. The average minutes of SBs (<100counts/min) for each time block of the 11-hour daytime period (8:00am-6:59pm) was calculated for a weekday and a weekend. The exploratory factor analyses (EFA) and the piecewise latent growth models (LGM) were employed using Mplus v6.11 to examine the patterns and changes in minutes of SBs during the daytime.

**RESULTS:** For both weekday and weekend day, four latent factors (i.e., time periods) were extracted by EFAs (8:00am-10:59am, 11:00am-12:59pm, 1:00pm-3:59pm, and 4:00pm-6:59pm for weekday; 8:00am-11:59am, 12:00pm-1:59pm, 2:00pm-4:59pm and 5:00pm-6:59pm for weekend). The four-piecewise LGMs for both weekday and weekend day were all well fitted. For weekday, the initial minute of SBs at 8:00am was 33.13. Decreasing trends were found with slope estimates of -0.78 and -0.14 in the first two time periods, while increasing trends were found in the third and fourth time periods with slope estimates of 0.28 and 0.93, respectively. For weekend day, the initial minute of SBs at 8:00am was 36.44. The minutes of SBs was decreased in the first time period with the slope estimates of -1.80 and increased throughout the last three time periods with the slope estimates of 0.27, 0.45, and 1.88, respectively.

**CONCLUSIONS:** This study investigates the patterns of SBs during daytime among US middle-aged adults. Those transition points where the minutes of SBs increase should be targeted in future research in order to reduce the total amount of SBs among middle-aged adults.

2627 Board #302 MAY 31 3:30 PM - 5:00 PM

### Physical Activity Level According to Sitting Time in Adults

Timoteo L. Araujo<sup>1</sup>, Victor KR Matsudo<sup>2</sup>, Sandra MM Matsudo<sup>1</sup>. <sup>1</sup>CELAFISCS - Agita São Paulo Program, São Paulo, Brazil. <sup>2</sup>CELAFISCS - Agita São Paulo Program, São Paulo - SCS, Brazil.

(No relationships reported)

**PURPOSE:** to determine physical activity level according to the sitting time in Brazilian adults.

**METHODS:** Representative population samples from 3 cities of Metropolitan region of São Paulo were collected. Physical activity (PA) level and sitting time (ST) was determined using the IPAQ, short version, last week form, obtained by a home-based interview. Sample consisted of 1066 subjects, 524 men and 543 women, over 18 yrs-old. Sample was randomized according to gender, age, socio-economic, and educational status. 1- Insufficient active (IS): those who were: Sedentary: no report of PA for more than 10 minutes during last week; or Irregularly active: subjects below the current PA recommendation; 2- Sufficient active (SA): people who met the: moderate activity (MPA): 5d.wk-1 30 min per day; or vigorous physical activity (VPA): 3d.wk-1, 25 min per day; or walking 150 min.wk-1; or any accumulation of 150 min.wk-1, 5 times per week of VPA, MPA and/or walking. The sitting time during the week day was analyzed in the four groups (Bauman A et al 2011) in minutes/wk, with an range of 0-179, 180-240, 241-360 and >360 minutes/wk. Statistical analysis used was a t-test for comparing two proportions, and the level of significance adopted was p<.05.

**RESULTS:** sitting time mean was significantly (p<.01) higher (271.9 + 177.6) in the IS group than in the SA one (236.7 + 153.2 minutes/wk). Similar trend was observed when it was compared the percentage of the IA (42.3%) that stayed more than 4 hours sitting to the SA group (30.4%). The Q square analysis found a significant association between lower prevalence of IA people and higher values of sitting time.

**CONCLUSION:** Data clearly showed an inverse relationship between physical activity level and sitting time.

2628 Board #303 MAY 31 3:30 PM - 5:00 PM

**Objective Assessment Of Sedentary Behaviour And Light Physical Activity In Free Living Activities**

Sveinung Berntsen<sup>1</sup>, Rune Hageberg<sup>2</sup>, Anders Aandstad<sup>2</sup>, Sigmund Alfred Anderssen<sup>2</sup>, Lars Bo Andersen<sup>3</sup>. <sup>1</sup>University of Agder, Kristiansand, Norway. <sup>2</sup>Norwegian School of Sport Sciences, Oslo, Norway. <sup>3</sup>University of Southern Denmark, Odense, Denmark.  
(No relationships reported)

Sedentary behaviours, those that involve sitting and low levels of energy expenditure, have emerged as a new focus for research on physical activity and health. Therefore, there is the need to identify the validity of objective measures of sedentary behaviour for epidemiological, genetic, behavioural and population health studies.

**PURPOSE:** To examine the validity of SenseWear™ Pro2 Armband (Armband) in assessing sedentary behaviour and light physical activity in free living activities in adults.

**METHODS:** 14 men and six women (19-56 yrs) with Body Mass Index of 20-36 kg-m<sup>-2</sup> wore Armband (BodyMedia Inc., Pittsburgh, PA, USA) and a portable oxygen analyser (Metamax II, Cortex Biophysic, Leipzig, Germany) for 120 minutes doing various activities including sitting activities. Resting metabolic rate (RMR) was measured with indirect calorimetry according to international guidelines. The cut off points defining sedentary behaviour and light physical activity were 1.0-1.5 and 1.6-2.9 times RMR, respectively. The data from the Armband was downloaded and analysed with software developed by the manufacturer (SenseWear Professional Research Software v.6.1). Bland-Altman plots were constructed and limits of agreements were calculated. Intra class correlation analyses were performed to evaluate the extent of agreement.

**RESULTS:** Mean differences and limits of agreement from the Bland-Altman plots were 40.3 ±51.5 and -28.4 ±43.4 min for sedentary behaviour and light physical activity, respectively. Armband significantly overestimated sedentary behaviour by 134% (p<0.0001) and underestimated light physical activity by 83% (p<0.0001). Several minutes in light physical activity (according to indirect calorimetry) were classified as "sedentary behaviour" by Armband. There was no statistical agreement (35 (-10, 68) %) in sedentary behaviour assessed with Armband vs. indirect calorimetry. 48 (6, 76) % of the variation in light physical activity was explained by differences among individuals.

**CONCLUSION:** Compared to indirect calorimetry in a free living situation, the use of Armband to assess sedentary behaviour in adults is not recommended using the existing algorithms.

2629 Board #304 MAY 31 3:30 PM - 5:00 PM

**Dietary Quality And TV Viewing In Adults And Children In The U.S.**

Susan B. Sisson<sup>1</sup>, Christina Shay<sup>1</sup>, Stephanie T. Broyles<sup>2</sup>, Misti Leyva<sup>1</sup>. <sup>1</sup>University of Oklahoma Health Sciences Center, Oklahoma City, OK. <sup>2</sup>Pennington Biomedical Research Center, Baton Rouge, LA.  
(No relationships reported)

Higher TV viewing (TVV) is generally associated with unhealthy dietary behaviors. Few studies have examined TVV and composite measures of dietary quality.

**PURPOSE:** To examine the relationship between TVV and dietary quality.

**METHODS:** Participants in the 2003-06 National Health and Nutrition Examination Survey were included (analyses conducted in fall 2011). Dietary quality was determined by Healthy Eating Index (HEI)-2005 calculated from two 24-hour recalls. TVV was reported as low (≤1hr/day), middle (2-3 hr/day), and high (≥4 hr/day; referent). Multivariate linear regression models were used to analyze TVV and HEI-2005, adjusted for body mass index (percentile for children 2-18 years), age, ethnicity and physical activity. Analyses were conducted separately for sex and age [preschool=2-5 years (n=1423), school-age=6-11 years (n=1749), adolescent=12-18 years (n=3343), and adult≥19 years (n=8222)].

**RESULTS:** Lower volumes of TVV were significantly associated with healthier HEI for all age groups including preschool boys (low β=3.85, p=0.04) preschool girls (low β=4.08, p=0.003, middle 2.75, p=0.01), school-age boys (low β=3.39, p=0.02), school-age girls (low β=3.65, p=0.002), adolescent boys (low β=2.28, p=0.004, middle β=1.04, p=0.004) and adolescent girls (low β=2.41, p=0.03) as well as adult men (low β=1.89, p=0.003, middle β=1.73, p<0.0001) and women (low β=3.17, p<0.0001).

**CONCLUSIONS:** Excessive TVV (≥4 hr/day) is associated with a less healthy diet determined by a composite dietary formula for each age and sex group. Research is needed to determine the most effective interventions to target both behaviors as well as the combined effect of poor diet and excessive TVV on disease risk.

2630 Board #305 MAY 31 3:30 PM - 5:00 PM

**Physical Activity and Screen Time in Relation to BMI and Cardiometabolic Risk Among U.S. Adolescents**

Sarah M. Camhi<sup>1</sup>, Molly E. Waring<sup>2</sup>, Ling Shi<sup>1</sup>, Laura Hayman<sup>1</sup>. <sup>1</sup>University of Massachusetts Boston, Boston, MA. <sup>2</sup>University of Massachusetts Medical School, Worcester, MA.  
(No relationships reported)

**PURPOSE:** Previous research with adults demonstrate differences in physical activity (PA) and sedentary behaviors (SB) between BMI-cardiometabolic risk (CR) groups (normal weight normal, NWN; metabolically obese normal weight MONW; metabolically healthy obese, MHO; obese abnormal, OA). Available data indicate less SB and more moderate and vigorous physical activity (MVPA) in NWN and greater MVPA in MHO than OA, suggesting possible intervention strategies to reduce chronic disease risk even within BMI groups. In this report, we compare PA and SB by BMI and CR among adolescents.

**METHODS:** Data from the National Health and Nutrition Examination Survey (2003-2004 and 2005-2006) were analyzed; participation was limited to 12-18 year olds, without diabetes, pregnancy or non-fasting blood analysis. Abnormal CR was identified as top 10% of homeostasis model of insulin resistance or ≥2 risk factors (triglycerides ≥150mg/dL; HDL-C <40/50mg/dL for boys/girls; blood pressure ≥90<sup>th</sup> %ile for age, gender, and height; glucose ≥100mg/dL). BMI (kg/m<sup>2</sup>) was classified as normal weight (15-85<sup>th</sup> %ile) or overweight/obese (>85<sup>th</sup> %ile). Youth self-reported MVPA, strength training, and screen time (computer and television/videos). Adjusting for age, sex, race, smoking, and total kilocalories of dietary intake, PA and SB differences by BMI and CR were analyzed with ANOVA. All analyses were weighted to represent adolescents nationally.

**RESULTS:** Adolescents (n=1024) were 50% male, 64% non-Hispanic white, and age (mean±SE) 14.9±0.1 years. Fifty-nine percent were NWN, 4% were MONW, 24% were MHO, and 12% were OA. Overall mean MVPA was 70.3±4.5 mins/day, screen time was 3.4±0.1 hrs/day, and strength training was 9.8±0.6 times/30days. After adjustment, MHO and OA adolescents reported more screen time than NWN adolescents (3.6±0.2 and 3.9±0.3 respectively, vs. 3.0±0.2; p<0.01). However, no differences were found between CR groups within BMI group for screen time, MVPA or strength training.

**CONCLUSION:** Overweight/obese adolescents spend more time viewing TV/video/computer than NWN, but unlike adults, MVPA, screen time and strength training did not differ by CR within BMI. Thus, targeting SB may be a useful strategy for obesity reduction in adolescence, but modifying PA or SB may not be sufficient to alter CR within BMI group.

2631 Board #306 MAY 31 3:30 PM - 5:00 PM

**Associations Between Sitting Time And The Prevalence And Clustering Of Lifestyle Risk Factors In Men**

Stephen Zwolinsky, Andy Pringle, Jim McKenna, Andy Smith, Steve Robertson, Alan White. Leeds Metropolitan University, Leeds, United Kingdom.  
(S. Zwolinsky: Contracted Research - Including Principle Investigator; Contracted research was undertaken for the Football Foundation.)

Men's health is adversely influenced by the amplification effect of multiple problematic lifestyle risk factors (LRFs), including smoking, poor diet, inactivity and excessive alcohol consumption. Further, too much sitting, independent of time spent in physical activity (PA), is linked to all-cause mortality, CVD, obesity, type 2 diabetes and the metabolic syndrome.

**PURPOSE:** To determine associations between sitting time and the prevalence of LRFs.

**METHODS:** Men aged 18+ (n=584) provided data for analysis. Data was collected prior to engagement in interventions at professional UK soccer clubs. Analysis identified LRFs totals; men sitting <4.7 hours (classified as low risk sitting, LRS), are compared with those spending >4.7 hours sitting daily (higher risk sitting, HRS). LRFs were recorded for men who did not achieve (i) 30+ minutes of MVPA five days per week, (ii) ate less than 5+ portions of fruit/vegetables daily, (iii) drank ≥21 units of alcohol weekly and (iv) were current smokers. Associations between LRS and HRS groups were examined by calculating odds ratios (OR, 95% CI). Statistical differences in LFR prevalence were identified using independent t-tests.

**RESULTS:** HRS men (n=375) were almost twice as likely to report all four LFRs (OR=1.94, 95% CI=1.06-3.56) than men in LRS; 10.9% of all men self-reported all four LRFs, while the most prevalent combination of LRFs was under consumption of fruit/vegetables and too few weekly PA sessions (n=219, 37.5%); this was linked to both sitting risk groups (Table 1). Men at HRS reported significantly more LFRs (2.41 ±0.92) than those at LRS (2.21 ±0.89) p<0.05.

Table 1

| Number of LRFs | Identified LFRs |          |         |         | Sitting Category |       |
|----------------|-----------------|----------|---------|---------|------------------|-------|
|                | Diet            | Activity | Smoking | Alcohol | LRS %            | HRS % |
| 4              | +               | +        | +       | +       | 7.2              | 13.2  |
|                |                 |          |         |         | Total 7.2        | 13.2  |
| 3              | +               | +        | +       | -       | 15.3             | 14.9  |
|                | +               | +        | -       | +       | 10.5             | 13.3  |
|                | +               | -        | +       | +       | 1.9              | 1.6   |
|                | -               | +        | +       | +       | 0.0              | 0.3   |
|                |                 |          |         | Total   | 27.7             | 30.1  |
| 2              | +               | +        | -       | -       | 36.3             | 38.2  |
|                | +               | -        | +       | -       | 2.4              | 1.1   |
|                | +               | -        | -       | +       | 5.3              | 2.1   |
|                | -               | +        | +       | -       | 2.4              | 0.8   |
|                | -               | +        | -       | +       | 1.0              | 1.3   |

|                |                 |          |         | Total   | 47.8             | 44.0  |
| 1              | +               | -        | -       | -       | 7.7              | 3.7   |
|                | -               | +        | -       | -       | 5.3              | 6.1   |
|                | -               | -        | +       | -       | 1.0              | 0.5   |
|                | -               | -        | -       | +       | 0.0              | 0.0   |
|                |                 |          |         | Total   | 14.0             | 10.3  |
| 0              | -               | -        | -       | -       | 3.3              | 2.4   |
|                |                 |          |         |         | Total            | 3.3   |

+ = RF present, - = RF absent

**CONCLUSIONS:** HRS time was significantly associated with increased LRFs in men engaging the intervention.

**2632 Board #307 MAY 31 3:30 PM - 5:00 PM**  
**Time Spent In Sedentary/Light Activities Reported By Adolescent Girls Between 6th, 8th, And 11th Grades**

Brit I. Saksvig, JoAnn Kuo, Deborah Rohm Young, FACSM. *University of Maryland SPH, College Park, MD.*  
*(No relationships reported)*

Reducing sedentary/light behaviors (SLB) is a recommended obesity prevention strategy. Understanding the types of SLB that adolescent girls participate in over time may help to target obesity prevention interventions.

**PURPOSE:** To examine time spent in SLB among two cohorts of adolescent girls between 6th and 8th grade and 8th and 11th grade.

**METHODS:** Three random samples of girls participated in the Trial of Activity in Adolescent Girls (TAAG) in the 6th grade (2003) and 8th grade (2005 and 2006). In 2010 Maryland TAAG girls participated in TAAG II in 11th grade. Girls completed a modified version of the 3-Day Physical Activity Recall (3DPAR). The number of 30-minute blocks over 3 days spent in the following activities was calculated and expressed as a percentage of awake time: 8 SLBs (personal care, eating, screen time, riding in a vehicle, socializing, homework, listening to music/reading, and attending church), physical activity (PA), school, and work (e.g. part-time job, babysitting).

**RESULTS:** 1,362 girls completed the 3DPAR in both the 6th and 8th grade and 587 did so at both 8th and 11th grade. The percent of awake time spent in SLB decreased from 58.2% in 6th grade, 59.1% in 8th grade, and 55.1% in 11th grade. The percent of awake time spent in PA also decreased: 15.6% in 6th grade, 12.5% in 8th grade, and 11.2% in 11th grade. Time in school and riding in a vehicle remained stable while time at work increased (6th: 0.5%; 8th grade: 0.6%; 11th grade 4.8%). Among the 8 SLBs, awake time spent in screen time decreased (6th: 15.7%; 8th: 14.9%; and 11th: 10.1%). Time socializing increased (6th: 10.3%; 8th: 13.1%; 11th: 13.2%), as did time spent doing homework (6th: 4.2%, 8th: 5.1%; 11th: 7.9%). Percent of time in all other SLB activities remained relatively stable.

**CONCLUSIONS:** Overall, time spent in sedentary and light behaviors as well as physical activity decrease between 6th and 11th grade, however, time spent in some individual SLBs increases over time.

**Is Sedentary Behavior Associated With Metabolic Syndrome In Adults? The Cardiovascular Risk In Young Finns Study.**

Hari Helajarvi<sup>1</sup>, Katja Pahkala<sup>1</sup>, Olli J. Heinonen<sup>1</sup>, Heinonen Ilkka<sup>2</sup>, Tuija Tammelin<sup>3</sup>, Mirja Hirvensalo<sup>4</sup>, Kristiina Mansikkaniemi<sup>5</sup>, Jorma Viikari<sup>2</sup>, Olli Raitakari<sup>2</sup>.  
<sup>1</sup>Paavo Nurmi Centre, University of Turku, Turku, Finland. <sup>2</sup>University of Turku, Turku, Finland. <sup>3</sup>LIKES Research Centre, Jyväskylä, Finland. <sup>4</sup>University of Jyväskylä, Jyväskylä, Finland. <sup>5</sup>University of Helsinki, Helsinki, Finland. (Sponsor: Raija Laukkanen, FACSM)  
*(No relationships reported)*

**PURPOSE:** We have shown that sitting (sedentary behavior) per se increases BMI and waist circumference, and that it is associated with individual cardiometabolic risk markers in adults. This study investigated, how leisure-time sedentary behavior in adults is associated with metabolic syndrome (MetS), defined by different criteria.

**METHODS:** In the Cardiovascular Risk in Young Finns study, MetS was defined by: 1) EGIR (European Group for the Study of Insulin Resistance), 2) IDF (International Diabetes Federation), and 3) HARM (according to harmonized criteria, Alberti et al. 2009) in 1084 women and 909 men aged 30-45. Data on total leisure-time sedentary behavior (i.e. time spent watching TV, computing, reading, listening to music/radio, etc), physical activity (leisure-time physical activity and active commuting), occupational physical activity, and smoking were collected with a questionnaire. Food frequency questionnaire was used to study diet composition, energy intake, and alcohol consumption. Linear regression analysis was used to study the association of leisure-time sedentary behavior with MetS.

**RESULTS:** Increased total leisure-time sedentary behavior was independently associated with increased prevalence of MetS in males (EGIR  $p < 0.02$ , IDF  $p < 0.008$ , HARM  $p < 0.009$ ), but not in females. Adjustment with physical activity, occupational physical activity, energy intake, diet composition, alcohol, smoking, BMI, and age did not affect the result.

**CONCLUSIONS:** Leisure-time sedentary behaviour is directly associated with MetS among men, as defined by three different MetS criteria. Reduction of sedentary behavior can be one important clinical tool in preventing metabolic syndrome.

**Relation between Physical Activity, Sedentary Behaviour and Selected Cardiovascular Disease Risk Factors in Adolescent Female**

Kieran P. Dowd<sup>1</sup>, Sarah M. Hughes<sup>2</sup>, Steven Gastinger<sup>3</sup>, Grainne Hayes<sup>1</sup>, Michael Harrison<sup>4</sup>, Alan P. Macken<sup>1</sup>, Clodagh S. O'Gorman<sup>1</sup>, Niall M. Moyna, FACSM<sup>2</sup>, Alan E. Donnelly<sup>1</sup>. <sup>1</sup>University of Limerick, Limerick, Ireland. <sup>2</sup>Dublin City University, Dublin, Ireland. <sup>3</sup>University of Rennes 2, Rennes, France. <sup>4</sup>Waterford Institute of Technology, Waterford, Ireland.  
(No relationships reported)

**BACKGROUND:** Cardiovascular disease risk factor (CVRF) levels for an individual tend to track over time in a given rank within the distribution of the population. Long term exposure to multiple CVRF and lifestyle behaviours confers a lifelong burden of CVD risk resulting in the development of early systemic atherosclerosis. Measurement of carotid intima-media thickness (CIMT) and large artery stiffness (LAS) are commonly used to determine the extensiveness and severity of asymptomatic disease and potential future risk.

**PURPOSE:** To examine the relation between both physical activity (PA) and sedentary behaviour (SB) and i) selected CVRF and ii) subclinical disease in adolescent females.

**METHODS:** Data are presented as mean  $\pm$  standard deviation, except where otherwise indicated. Participants ( $n=35$ ; age =  $14.4 \pm 1.1$  yrs.; BMI =  $22.6 \pm 2.9$  kg/m<sup>2</sup>; percentage body fat  $31.2 \pm 3.0$ ; mean arterial pressure (MAP) =  $85.0 \pm 8.3$  mmHg) were randomly selected from 4 high-schools in Ireland. Height, weight, percentage body fat, blood pressure, CIMT, and LAS data was obtained for each participant. SB and PA were recorded for 4-6 days using an ActivPAL<sup>TM</sup> physical activity monitor. The amount of time spent sedentary, standing, and in both light and moderate to vigorous PA (MVPA) was calculated. Sedentary data was also examined to identify sedentary bouts of specific duration.

**RESULTS:** The mean left and right-sided CIMT score was  $0.47 \pm 0.0$  cm and the mean LAS index was  $5.20 \pm 0.58$ . Participants spent  $19.42 \pm 0.94$  h/d in sedentary activities ( $9.93 \pm 1.03$  waking sedentary h/d),  $3.08 \pm 0.74$  h/d standing,  $0.73 \pm 0.17$  h/d in light activity and  $0.78 \pm 0.26$  h/d in MVPA. There was a significant inverse relation between light physical activity levels (independent of standing time) and mean arterial pressure (MAP), ( $r = -0.5$ ;  $p < 0.05$ ), BMI ( $r = -0.5$ ;  $p < 0.01$ ) and percentage body fat ( $r = -0.4$ ;  $p < 0.05$ ). There was no relation between other PA variables and CIMT or LAS. There was no significant relation between SB and CVRF, CIMT or LAS.

**CONCLUSIONS:** Objectively measured light PA (independent of standing time) is correlated with MAP, BMI and percentage body fat, but not CIMT or LAS in this population of adolescent females. Although a large amount of time was spent sedentary (9.93 hr), SB were not related to CVRF, CIMT or LAS in this population of adolescent females.

**2635** Board #310 MAY 31 3:30 PM - 5:00 PM

**Associations Between Physical Activity, Sedentary Behavior, Waist Circumference And Alanine Aminotransferase In Youth: NHANES 2003-2006**

Jennifer L. Trilk<sup>1</sup>, Russell R. Pate, FACSM<sup>1</sup>, Andrew Ortoglia<sup>1</sup>, Marsha Dowda, FACSM<sup>1</sup>, Steven N. Blair, FACSM<sup>1</sup>, Timothy S. Church<sup>2</sup>, Matteo Bottai<sup>3</sup>. <sup>1</sup>University of South Carolina, Columbia, SC. <sup>2</sup>Pennington Biomedical Research Center, Baton Rouge, LA. <sup>3</sup>Karolinska Institutet, Stockholm, Sweden. (Sponsor: Russell R. Pate, FACSM)  
(No relationships reported)

Pediatric non-alcoholic fatty liver disease (NAFLD) is a significant public health issue, as NAFLD leads to cirrhosis, hepatocellular carcinoma, and cardiovascular disease in adults. At least 8% of U.S. youth have elevated alanine aminotransferase levels (ALT), a biomarker for NAFLD. Regular physical activity (PA) improves ALT in adults with NAFLD, but information is scarce for youth.

**PURPOSE:** To examine associations between PA, sedentary behavior (SED), waist circumference (WC) and ALT in youth.

**METHODS:** Data were obtained from youth ( $N=2088$ , aged 12-19 years) in the National Health and Nutrition Examination Survey (NHANES) 2003-2006. Traditional statistical methods (linear and logistic regression) were compared with quantile regression to examine associations between accelerometer-measured moderate-to-vigorous physical activity (MVPA), vigorous physical activity (VPA), SED, and ALT. Variables with previously reported associations to ALT (age, race, gender, WC) were *a priori* included in all models as covariates, along with SED (for PA models) or MVPA (for SED models). WC also was examined after adjusting for all other variables.

**RESULTS:** The results of the linear regression showed a small positive ( $\beta=0.001$ ) significant association between MVPA and log transformed ALT ( $p=0.02$ ). For the logistic regression, each observation was dichotomized and the odds of observing ALT  $\geq 30$  U/L was modeled. Results of the logistic regression suggested that a 1 minute increase in VPA results in the odds of ALT  $\geq 30$  changing by a factor of 1.02 ( $p=0.04$ ). No other PA or SED associations were found for the linear or logistic regression models ( $p > 0.05$ ). The results of the quantile regression suggest significant, positive, but clinically-negligible associations between the 40<sup>th</sup>, 50<sup>th</sup>, and 60<sup>th</sup> adjusted ALT percentiles and MVPA ( $\beta=0.02$ , 0.03, and 0.03, respectively). No significant associations were found for VPA or SED across adjusted ALT percentiles. A strong positive association was found for all three models between WC and ALT.

**CONCLUSION:** Neither PA nor SED were clinically associated in NHANES youth of whom the majority (92%) were within normal ALT levels. Further studies need to examine whether PA or SED affects above normal ALT levels in larger samples of youth with NAFLD.

Supported by NIH Grant F32 HD066924/NICHD.

**2636** Board #311 MAY 31 3:30 PM - 5:00 PM

**A Comparison Of Sedentary Behavior Between A Self-report Diary And Accelerometers**

Elizabeth K. Lenz<sup>1</sup>, Ann M. Swartz<sup>2</sup>, Amy E. Harley<sup>2</sup>, Nancy A. Mathiowetz<sup>2</sup>, Scott J. Strath<sup>2</sup>. <sup>1</sup>The College at Brockport-SUNY, Brockport, NY. <sup>2</sup>University of Wisconsin-Milwaukee, Milwaukee, WI.  
(No relationships reported)

Research has demonstrated negative impacts on health related to increased time spent engaging in sedentary behavior (SB). Older adults engage in significantly more SB than other age groups. Currently there are a few methods being used to assess SB but little research has examined these methodologies in older adults.

**PURPOSE:** The purpose of this project was to compare three SB assessment methods in a sample of older adults.

**METHODS.** Seventy-three older adults (73.5 $\pm$ 6years) participated in this study. Concurrently, each participant completed a previously piloted self-report diary over a three-day period (one weekend day and two weekdays) and wore two triaxial accelerometers (AG; Actigraph GT3X, Pensacola, FL; AP, activPal<sup>TM</sup>, Glasgow, Scotland). Sedentary behavior was classified as minutes per day (mins/d) of activities that are done while sitting/lying down in the diary and SB was classified in mins/d with accelerometry (AG =  $\leq 50$  cts/min; AP = sitting/lying posture). Means  $\pm$  SD is presented for all measures of time spent in SB. Pearson correlation coefficients between methods were determined. Two-tailed paired sample t-tests were conducted.

**RESULTS.** Participants self-reported engaging in 618.2 $\pm$ 90.5 mins/d of SB, the AG and AP recorded 613.1 $\pm$ 86.6 mins/d and 603.9 $\pm$ 110 mins/d, respectively. The SB recorded by the AG and the diary ( $r=-0.02$ ,  $p=0.87$ ) or the AG and AP ( $r=-0.19$ ,  $p=0.12$ ) was not significantly correlated. However, the SB recorded by the AP was significantly correlated to the SB reported in the diary ( $r=0.62$ ,  $p<0.05$ ). There were no significant differences in SB recorded with the AG and AP [ $t(70)=-0.52$ ,  $p=0.61$ ], the AG and diary [ $t(71)=-0.36$ ,  $p=0.72$ ], or the AP and the diary [ $t(71)=1.25$ ,  $p=0.22$ ].

**CONCLUSION.** The older adults in this sample engaged in approximately 10.1-10.3 hours of SB when reporting their behavior in a diary or when it was objectively measured with accelerometry. Upon examining the relationship between methods, only the SB measured with the AP and diary were significantly related however there were no difference in mins/d of SB when examined between methods. These results suggest that a diary can capture SB similarly to accelerometry in older adults.

2637 Board #312 MAY 31 3:30 PM - 5:00 PM

**Sedentary Marathoners: The Multi-context Sitting Time Questionnaire and Reported Sitting among Highly Active Runners**

Geoffrey P. Whitfield, Kelley K. Pettee Gabriel, Harold W. Kohl, III, FACSM. *University of Texas School of Public Health, Austin, TX.*

(No relationships reported)

Interest in the health effects of excessive sitting has increased in recent years. Recent evidence suggests that participation in vigorous or moderate-intensity physical activity (PA) may not fully protect against the risks of prolonged sitting. Unfortunately, existing instruments to assess sitting are often single-item or proxy-based measures which may introduce misclassification.

**PURPOSE:** To develop and validate the Multi-context Sitting Time Questionnaire (MSTQ) and use the new instrument to describe usual sitting behavior of recreational runners.

**METHODS:** 25 volunteers were recruited for the questionnaire validation (Phase 1) and twice completed the on-line MSTQ, separated by one week. Participants wore an accelerometer on a workday and non-workday. Test-retest reliability was assessed with intra-class correlation coefficients (ICCs). Convergent validity (accelerometry as standard) was assessed with correlation coefficients ( $\rho$ ). In Phase 2, 199 participants in the 2011 Livestrong<sup>™</sup> Austin Marathon and Half-Marathon were recruited to complete the new questionnaire.

**RESULTS:** In Phase 1, the MSTQ demonstrated good reliability with ICCs of 0.76 and 0.72 for workday and non-workday total sitting, respectively. Only two sitting contexts had ICCs <0.60. Convergent validity was strongest with accelerometry adjusted for accelerometer wear time ( $\rho = 0.34$  and  $0.61$  for

workday and non-workday respectively). In Phase 2, 195 and 199 participants reported workday and non-workday sitting time, respectively. Total sitting did not differ between marathon and half-marathon participants, but was significantly higher on workdays than non workdays (645 and 480 min respectively,  $p < 0.0001$ ). Most workday sitting was done during work activities while most non-workday sitting was composed of TV/movie watching. Median reported training time was  $6.5 \text{ h-wk}^{-1}$  and was higher in marathoners.

**CONCLUSIONS:** Preliminary validation of the MSTQ indicates good potential for assessing usual sitting across several contexts. Despite far exceeding PA guidelines, this sample of recreational runners reported sitting over 10 hr on workdays and 8 hr on non-workdays, suggesting endurance athletes may be an appropriate population for investigating the interaction between PA and sedentary behavior on health.

**Reliability And Validity Of A Self-report Scale Of Sedentary Time In Children**

Sara K. Rosenkranz<sup>1</sup>, Richard R. Rosenkranz<sup>1</sup>, Tanis J. Hastmann<sup>2</sup>, Craig A. Harms, FACSM<sup>1</sup>. <sup>1</sup>*Kansas State University, Manhattan, KS.* <sup>2</sup>*Oakland University, Rochester, MI.*

(No relationships reported)

**PURPOSE:** Sedentary behavior (SB) is an independent risk factor for negative health consequences. The most common self-report SB instruments are based on screen time, which is not sufficient for capturing most SB in youth. Therefore, the purpose of this study was to determine the reliability and validity of a comprehensive self-report SB scale.

**METHODS:** A convenience sample included 18 children (16 girls, 2 boys) aged 7-11 years from an ongoing training study. The self-report SB scale was administered on days one and eight, encompassing one week of Actical accelerometer-based monitoring. Identical scale administration and Actical monitoring were repeated after eight weeks. Twelve items from the SMART Student Questionnaire were used to assess six SB components at the four time points: watching TV, playing video games, computer use, homework, art, and quiet games indoors. The Heil (2006) equation for Actical was used to derive the accelerometer-based SB criterion measure. Comparisons were made between the SB criterion measure, SB scale, and time spent in very light intensity free-time activity from the Previous Day Physical Activity Recall (PDPAR). Cronbach's alpha was used to assess SB scale internal consistency. Intraclass correlations (ICC) were used for test-retest reliability. Spearman's rho was used to determine convergent and discriminant validity.

**RESULTS:** Internal consistency for the 12-item SB scale ranged from  $\alpha = 0.392 - 0.711$  across the four time points. The two assessments of one-week test-retest reliability showed ICC =  $-0.02$ , 95% CI =  $-1.73 - 0.62$  and ICC =  $0.77$ , 95% CI =  $0.37 - 0.92$ . For convergent validity, the SB scale correlations ranged from  $\rho = 0.18$  ( $p = 0.58$ ) to  $\rho = 0.19$  ( $p = 0.49$ ) with Actical, and  $\rho = 0.11$  ( $p = 0.68$ ) to  $\rho = 0.44$  ( $p = 0.09$ ) with the PDPAR. For discriminant validity, the SB scale correlations were  $\rho = -0.52$  ( $p = 0.04$ ) to  $\rho = -0.42$  ( $p = 0.09$ ) with time spent outside.

**CONCLUSION:** Our findings showed that the internal consistency, test-retest reliability, and convergent validity ranged widely, and for the most part, were not acceptable. These findings suggest that the 12-item scale has limited reliability and validity as a measure of sedentary behavior in school-aged children. Further research is needed to develop a more reliable and valid self-report scale for sedentary behavior.

**Validity Of Accelerometer-derived Estimates Of Sedentary Behaviour**

Stacy A. Cledes<sup>1</sup>, Jennifer Connelly<sup>1</sup>, Theodoros Konstantinidis<sup>1</sup>, Robert Koivula<sup>1</sup>, Charlotte Edwardson<sup>2</sup>, Thomas Yates<sup>2</sup>, Trish Gorely<sup>1</sup>, Stuart JH Biddle<sup>1</sup>.

<sup>1</sup>*Loughborough University, Loughborough, United Kingdom.* <sup>2</sup>*University of Leicester, Leicester, United Kingdom.*

(No relationships reported)

Accelerometers are gaining popularity as an objective measure of sedentary behaviour. Limited evidence exists however on the validity of different cut points used to define sedentary time, or on the inclinometer function seen in newer models of the ActiGraph accelerometer.

**PURPOSE:** To determine the concurrent validity of the ActiGraph GT3X+ inclinometer and different counts per minute (cpm) cut points for detecting sedentary behaviour in free-living adults.

**METHODS:** 52 participants (54% male, age =  $26.3 \pm 6.2$  years) wore an activPAL3 inclinometer (the criterion) and an ActiGraph GT3X+ accelerometer whilst continuing with their normal routine for 1 day. The activPAL3 was attached to the right thigh, whilst the ActiGraph was positioned on the right hip using an elastic belt. Both devices displayed data in 15-second epochs. Accelerometer-determined sedentary time was calculated using the inclinometer function of the ActiGraph, and by multiple cut points (<50, 100, 150 and 200 cpm) applied to activity counts derived from the vertical axis. Accelerometer-determined sedentary times were compared to sedentary time measured by the activPAL3 using a repeated measures ANOVA and Bland-Altman plots. Associations between the different measures were examined using Pearson correlation coefficients.

**RESULTS:** Time spent sedentary did not differ significantly between the ActiGraph inclinometer function and the activPAL3 ( $532 \pm 95$  vs  $522 \pm 125$  mins,  $p = 0.51$ ). There was a significant moderate correlation between these measures ( $r = 0.52$ ), however the limits of agreement were large ( $-207 - 227$  mins). Sedentary time was significantly overestimated, relative to the activPAL3, when calculated using the four cut points ( $p < 0.001$ ). The <50 cpm cut point provided the closest estimate of sedentary time ( $582 \pm 86$  mins). This cut point had a stronger correlation ( $r = 0.60$ ) and narrower limits of agreement ( $-137 - 258$  mins) relative to the criterion, when compared to data derived from the ActiGraph inclinometer.

**CONCLUSION:** The findings suggest that the inclinometer function of the ActiGraph GT3X+ provides a good overall estimate of sedentary time when compared to the activPAL3. The present findings also suggest that the <50 cpm cut point may provide a better estimate of sedentary behaviour in comparison to the widely used <100 cpm cut point.

**Convergent Validity Of Self-report Sedentary Behavior And Accelerometry: Comparing Multiple Cut Points**

Gina Merchant, Humberto Parada, Simon J. Marshall. *San Diego State University, San Diego, CA.*

(No relationships reported)

Sedentary behavior (SB) is related to obesity, chronic disease, and adverse metabolic profiles independent of physical activity, but assessment methods of SBs are not well developed, particularly for Spanish speaking individuals.

**PURPOSE:** To (i) evaluate the convergent validity of a Spanish language self-report measure of SB (SBSR) compared to an objective measure (ActiGraph GT3X accelerometer) of sedentary time, and (ii) examine how associations between self reports of SB and objective data vary as a function of the accelerometer cut point used to define sedentary time.

**METHODS:** A community sample of 71 female participants ( $M_{age} = 41.61$ ;  $SD = 9.28$ ;  $M_{BMI} = 30.07$ ;  $SD = 5.60$ ) recruited to a PA intervention completed a 12 item SBSR and wore an accelerometer for 600 minutes/day for 5 days or 3000 minutes total. Data presented here were collected prior to the start of the intervention. Almost half of the participants were born in Mexico (47%) and the majority of participants self-identified as Latino (79%), was married (62%), and employed for wages (75%). A total SBSR score was computed as mean SB minutes per day

across transportation, television, computer, and 'Other' domains during work and non-work days. SBSR domain scores were log transformed to approximate normality. Objective sedentary time was computed as the average number of minutes per day (i) <50 counts/minute (SB50), (ii) <100 counts/minute (SB100), and (iii) <150 counts/minute (SB150).

**RESULTS:** Mean SB min.dy<sup>-1</sup> was 374 (±72) for SB50, 443 (±74) for SB100, and 486 (±72) for SB150. SBSR total time was marginally correlated with SB50 ( $r=.22$ ;  $p=.07$ ). Correlations between total SBSR and SB100 and SB150 were ( $r=.19$ ;  $p=.12$ ) and ( $r=.20$ ;  $p=.10$ ), respectively. The only SBSR domain significantly correlated with accelerometer min.dy<sup>-1</sup> was computer time ( $r$ 's range 0.24-0.29 across cut points,  $p<.05$ ). Accelerometer sedentary time was not related to BMI whereas total SBSR was marginally related ( $r=.22$ ,  $p=.07$ ). TV viewing was the only SBSR domain related to BMI ( $r=.35$ ,  $p<.01$ ).

**CONCLUSION:** Self-reported SB showed poor convergent validity with objective accelerometry. Total self-reported SB was most closely linked to SB50, the lowest cut point of objective SB tested.

Funded by a research grant (1R18DP002138-01) from the Centers for Disease Control and Prevention.

**2641 Board #316 MAY 31 3:30 PM - 5:00 PM**

**Effects Of Sedentary Behavior And Steps/day On Insulin Sensitivity**

Corianne Oliver, Sarah Kozey-Keadle, Richard Viskochil, Barry Braun, FACSM, Patty S. Freedson, FACSM. *University of Massachusetts Amherst, Amherst, MA.*  
(No relationships reported)

The benefits of physical activity (PA) on insulin sensitivity have been previously established. However, the effects of sedentary behavior (SB) on insulin sensitivity are not well understood.

**PURPOSE:** To determine the association between habitual SB, steps/day, and insulin sensitivity in non-exercising, overweight/obese individuals.

**METHODS:** Fifty-seven non-exercising, overweight/obese (mean ± SD: BMI = 35.1 ± 4.6 kg·m<sup>-2</sup>) participants 43.6 ± 9.9 yrs wore an inclinometer to measure free-living SB (time sitting/lying, expressed as % of wear time [%sed]) and steps for 7-days. Plasma insulin and glucose concentrations were measured during a 2-hour oral glucose tolerance test following the wear time and the composite insulin sensitivity index (CISI) was calculated. The independent effects of SB and steps overall, on weekdays and weekends on CISI were evaluated using linear regression. Correlations ( $r$ ) between SB and steps/day with CISI were also calculated.

**RESULTS:** SB was not associated with CISI. Steps/day on the weekend, controlling for SB and BMI, was positively associated with CISI ( $p<0.05$ ).

|           | % Sed Overall | % Sed Weekday | % Sed Weekend | Steps Overall   | Steps Weekday   | Steps Weekend   |
|-----------|---------------|---------------|---------------|-----------------|-----------------|-----------------|
| Mean ± SD | 68.6 ± 8.0    | 70.8 ± 7.8    | 64.2 ± 12.2   | 5987.8 ± 1998.8 | 6011.8 ± 2135.6 | 5905.8 ± 2711.6 |
| $r$       | 0.181         | 0.284         | 0.157         | 0.393*          | 0.283           | 0.486*          |
| $p$       | 0.748         | 0.322         | 0.164         | 0.070           | 0.184           | 0.009^          |

\*  $p<0.01$ ; ^  $p<0.05$  controlling for % Sed and BMI

**CONCLUSION:** In a group of overweight/obese men and women who do not exercise, SB was not related to insulin sensitivity. However, steps/day, particularly on the weekend, was significantly associated with insulin sensitivity. Both SB and steps were more variable on the weekend compared to weekdays, which may play a role in the sensitivity differences observed.

**NAD(P)H Kinetics At Onset Of Contractions In Single Myofibers: Effect Of Prior Contractions**

Paulo Gandra, Leonardo Nogueira, Amy A. Shiah, Michael C. Hogan, FACSM. *UCSD, La Jolla, CA.*  
(No relationships reported)

**INTRODUCTION -** Evidence supports the notion of delayed respiratory activation occurring in skeletal muscle mitochondria during the transition from rest to exercise. NAD(P)H autofluorescence can be used to measure changes in mitochondrial activity since it reflects the mitochondrial potential energy status.

**PURPOSE:** Determine the changes in NAD(P)H fluorescence in single myocytes at the onset of successive contractile bouts and in the absence of the cross-bridges cycling.

**METHODS:** Intact *Xenopus* single fibers were stimulated to contract repetitively at maximal tetanic tension (1 contraction/2 sec) for 2 min and both isometric tension and NAD(P)H autofluorescence were measured ( $n=7$  fibers). A second bout of contractions was performed 5 min (5-min rest) after the first bout. In a different set of fibers ( $n=4$  fibers), a contractile bout was performed in the presence and in the absence of the specific cross-bridge inhibitor N-benzyl-p-toluene sulfonamide (BTS, 15 μM) with a 60 min interval between each bout.

**RESULTS:** For the first bout of contractions, the NAD(P)H autofluorescence demonstrated a decrease during stimulation after a time delay of 14.1 ± 1.3 sec. In the second contraction period (after 5 min of rest), NAD(P)H decreased immediately after the first contraction. The time constant of the NAD(P)H kinetics was shorter during the second contractile period (3.3 ± 0.3 sec) vs the first period (5.0 ± 0.3 sec;  $P<0.05$ ). Interestingly, when cross-bridge cycling was inhibited by BTS, the time-delay of NAD(P)H fluorescence kinetics at the onset of contractions was slightly increased in 3 of the 4 fibers compared to control (i.e., no BTS) while the time constant of NAD(P)H fluorescence was significantly increased with BTS (8.1 ± 0.7 sec) compared to control (3.5 ± 0.8 sec  $P<0.05$ ).

**CONCLUSION:** Priming skeletal muscle by a previous contractile activity results in a faster adjustment of NAD(P)H oxidation at the onset of contractions. In addition, reduction of the energy cost by the inhibition of cross-bridges cycling resulted in a slower rate of NAD(P)H oxidation. Thus, mechanisms directly related to the mitochondrial potential energy as well as other mechanisms, such as a regulation parallel to the cross-bridge cycling regulate mitochondrial activity at the onset of contractions.

Supported by NIH grant 5R01AR040155-17.

**Influence of MHC Hybrid Isoform Protein Proportions on Single Muscle Fiber Function in Humans**

James R. Bagley, Kevin A. Murach, Kiril Minchev, Robert A. Standley, Todd A. Trappe, Scott W. Trappe, FACSM. *Human Performance Laboratory, Ball State University, Muncie, IN.*  
(No relationships reported)

Human skeletal muscle contains pure myosin heavy chain (MHC) fiber types (I, IIa, and IIx) along with hybrid fibers expressing multiple MHC isoforms (I/IIa, IIa/IIx, and I/IIa/IIx). Although hybrid fibers represent a common component of human muscle, little research exists on their relative MHC protein distribution or single fiber functional profiles.

**PURPOSE:** Quantify the proportion of co-expressed MHC isoforms in hybrid fibers and determine its influence on single muscle fiber function.

**METHODS:** Human muscle fibers (n=68) were isolated from vastus lateralis biopsies, analyzed for single fiber physiology (size, strength, speed, power), typed electrophoretically, digitally imaged, and identified as one of three hybrid fiber types [MHC I/IIa (n=47), MHC IIa/IIx (n=20), and MHC I/IIa/IIx (n=1)]. Two researchers independently quantified (in duplicate) the proportion of MHC isoforms expressed in these fibers via densitometry.

**RESULTS:** Significant correlations in densitometry measures existed between observations from the same researcher ( $r \geq 0.995$ ) and different researchers ( $r = 0.998$ ,  $ICC = 0.997$ ), indicating strong test-retest and inter-rater reliability. Proportions of MHC IIa isoform expressed in I/IIa and IIa/IIx hybrid fibers ranged between 7-94% and 28-83% of total MHC protein, respectively. MHC IIa isoform percentage positively correlated with strength ( $P_0$ ,  $R^2 = 0.40$ ), speed ( $V_0$ ,  $R^2 = 0.78$ ), and normalized power ( $R^2 = 0.76$ ) in MHC I/IIa fibers. No significant correlations were observed between MHC isoform proportions and IIa/IIx hybrid fiber function.

**CONCLUSION:** These initial results indicate hybrid fibers exist on a morphological and functional continuum. More research is needed to elucidate the physiological significance of hybrid muscle fibers in humans and their adaptability with changes in physical activity patterns.

**Severe Atrophy of Slow Fibers in Aging Muscle is Masked by Myosin Heavy Chain Co-expression**

Fennigie M. Purves-Smith<sup>1</sup>, Nathan M. Solbak<sup>2</sup>, Sharon L. Rowan<sup>2</sup>, Russell T. Hepple<sup>1</sup>. <sup>1</sup>McGill University, Montreal, QC, Canada. <sup>2</sup>University of Calgary, Calgary, AB, Canada.

(No relationships reported)

Although it is widely considered a fact that slow twitch muscle fibers are less susceptible to atrophy in aging muscle, two key points raise the possibility that atrophy of slow twitch fibers has been underestimated in the past. Firstly, the marked atrophy of the aging rat soleus (Sol) muscle cannot be explained by atrophy and loss of only the fast fibers, due to their very low abundance in this muscle. Secondly, recent immunolabeling evidence reveals a high abundance of small fibers co-expressing both fast and slow myosin heavy chain (MHC) isoforms in the aging rat Sol, and that their accumulation occurs at the expense of the pure MHC slow fiber population.

**PURPOSE:** To determine whether slow twitch muscle fibers are less susceptible to atrophy in aging muscle, after accounting for the size and proportion of MHC co-expressing fibers that derived from formerly pure MHC slow fibers.

**METHODS:** Young adult (YA) and senescent (SEN) rat Sol muscles were immunolabeled for MHC slow and MHC fast expression. We then examined the size and proportion of MHC slow, MHC fast, and MHC fast-slow co-expressing fibers. To explain the atrophy behavior, we also probed *in situ* for MAFbx, a protein involved in protein degradation by the proteasome machinery and necessary for muscle atrophy under a variety of conditions.

**RESULTS:** In the Sol, whereas the abundance of pure MHC fast fibers was unchanged between YA ( $1.3 \pm 0.2\%$ ) and SEN ( $2.9 \pm 1.3\%$ ;  $P = 0.10$ ), there was a marked increase in MHC co-expressing fibers from  $3.9 \pm 0.9\%$  in YA to  $46.8 \pm 5.3\%$  in SEN, and this was accompanied by a proportional decline in pure MHC slow fibers between YA ( $94.7 \pm 0.9\%$ ) and SEN ( $50.3 \pm 4.9\%$ ). This suggests that MHC co-expressing fibers represent a subclass of formerly MHC slow fibers. Strikingly, the co-expressing fibers exhibited a marked amount of atrophy (58%) when compared to the size of MHC slow fibers in YA, and this was coincident with an increase in MAFbx expression.

**CONCLUSIONS:** Our results indicate that MHC co-expressing fibers represent a population of formerly pure MHC slow fibers in the SEN Sol muscle that exhibit a marked amount of atrophy with aging. These results redefine the impact of aging on slow fiber atrophy, and emphasize the necessity of addressing the atrophy potential of both fast and slow fibers in seeking treatments for aging muscle atrophy.

**Small Angular Mhc Co-expressing Fibers In Copd Muscle: Evidence Of Premature Aging?**

Sophia Kapchinsky<sup>1</sup>, Norah J. MacMillan<sup>1</sup>, Fennigie M. Purves-Smith<sup>1</sup>, Nicolas Sgarito<sup>1</sup>, Jacinthe Baril<sup>1</sup>, Vincent Mainguy<sup>2</sup>, Steve Provencher<sup>2</sup>, Thomas Jagoe<sup>1</sup>, Tanja Taiavassalo<sup>1</sup>, Russell Hepple<sup>1</sup>. <sup>1</sup>McGill University, Montreal, QC, Canada. <sup>2</sup>Universite Laval, Quebec, QC, Canada.

(No relationships reported)

Exercise intolerance in Chronic Obstructive Pulmonary Disease (COPD) results from a complex interplay of a shift to less aerobic fiber types, fiber atrophy, and other peripheral muscle disturbances, superimposed on the primary ventilatory limitation seen in this population. While the root cause of the muscle dysfunction is unclear, several of the phenotypes reported resemble those seen with normal aging, albeit on an accelerated time-course. In this respect, another interesting feature reported in COPD muscle is an elevated abundance of fibers expressing more than one myosin heavy chain (MHC) isoform (co-expressing fibers). Although MHC co-expressing fibers which are very small in size and having angular shape have recently been shown to result from long-term denervation in aging muscle, whether denervation is the cause of MHC co-expression in COPD muscle has not been examined.

**PURPOSE:** To investigate whether MHC co-expressing fibers in peripheral muscle of COPD patients exhibit features of long-term denervation.

**METHODS:** A muscle biopsy of the vastus lateralis was collected from three severe COPD patients ( $65 \pm 1$  y,  $FEV_1 = 37.7 \pm 1.5\%$  pred) to investigate fiber size, fiber circularity (calculated as  $4\pi \times \text{area}/\text{perimeter}^2$ , where a perfect circle = 1.0), and fiber type using immunolabelling for type I, IIa, and IIx MHC isoforms. For comparison, a biopsy was also collected from a healthy age-matched subject (CTRL; 64 y).

**RESULTS:** Fiber size distribution in COPD muscle showed a pronounced leftward shift towards an increased abundance of smaller fibers compared to CTRL. Similarly, COPD patients also exhibited a leftward shift towards less circular fibers, and in contrast to the CTRL subject, exhibited several very angular fibers (circularity  $\leq 0.4$ ) with a very low cross-sectional area ( $\leq 2000 \mu\text{m}^2$ ). All but one of these small angular fibers was co-expressing MHC IIa and IIx.

**CONCLUSIONS:** The presence of small, severely angular MHC co-expressing fibers in COPD muscle suggests these are the result of long-term denervation. Since these fibers were exclusive to COPD, but are also known to accumulate with more advanced age, our results are consistent with other evidence suggesting that COPD may accelerate key aspects of aging. Additional markers of denervation are currently being investigated to support these findings.

**High-Frequency Acupuncture Represses the Atrophy of Fast-Fiber Rich Skeletal Muscle**

Shin Fujimaki, Masanao Machida, Kohei Takeda, Tohru Takemasa. University of Tsukuba, Ibaraki, Japan.

(No relationships reported)

**PURPOSE:** Electroacupuncture has been utilized for preventing skeletal muscle atrophy. The target muscle of previous studies was slow-fiber rich soleus muscle, so effects have not been elucidated on fast-fiber rich gastrocnemius and plantaris muscles. The atrophy of fast fibers is great loss for power-athletes specializing in sprint, throwing and so on. This study aimed to investigate the effects of electroacupuncture on these muscles controlling the stimulus frequencies of electroacupuncture.

**METHODS:** Eight-week-old male ICR mice were randomly divided in four groups; Con (Control), Den (Denervation), Den-H (Denervation + High-frequency electroacupuncture) and Den-L (Denervation + Low-frequency electroacupuncture). Den, Den-H and Den-L mice were subjected to surgical removal of the sciatic nerves and Den-H and Den-L mice received electroacupuncture for 15 min per day, twice in the experimental period (5days), with high- (100Hz; Den-H) or low (10Hz; Den-L) frequency waves.

**RESULTS:** Sciatic denervation significantly reduced muscle mass of gastrocnemius and plantaris muscles. The denervation-induced reduction of gastrocnemius muscles was repressed in Den-H and Den-L mice, whereas that of plantaris muscles was only repressed in Den-H mice. We found that the phosphorylation levels of mTOR signaling proteins, which accelerates to muscle hypertrophy, were unchanged by denervation. We also found that the expressions of E3 ubiquitin ligases, which accelerate to muscle atrophy, were significantly increased by denervation. However, the redundant expressions of E3 ubiquitin ligases by denervation were repressed in Den-H mice.

**CONCLUSIONS:** Therefore, it is suggested that electroacupuncture stimulation with high frequency waves represses the atrophy of fast-fiber rich gastrocnemius and plantaris muscles, via downregulation of E3 ubiquitin ligases.

**Selective Embedding of Capillaries within Murine Slow Twitch Skeletal Muscle Fibers Visualized Using In Vivo Microscopy**

Brian Glancy, Li-Yueh Hsu, Lam Dao, Matthew Bakalar, Stephanie French, David J. Chess, Joni L. Taylor, Mathew P. Daniels, Shervin Esfahani, Robert S. Balaban.  
*National Institutes of Health, Bethesda, MD.*  
(No relationships reported)

Maximal aerobic energy production is limited by the ability to deliver and transfer oxygen (O<sub>2</sub>) to mitochondria (MITO) within skeletal muscle. As such, the spatial relationship between capillaries (CAP), MITO, and the muscle fiber plays an important role in determining the aerobic capacity of a muscle. Most skeletal muscle morphology knowledge comes from electron (EM) and/or light microscopy studies and show that both MITO content and CAP density increase with the aerobic capacity of a muscle. However, these studies are typically done by analyzing single 2D slices of muscle fibers and require a fixative which can alter morphology.

**PURPOSE:** Evaluate the *in vivo*, 3D spatial relationship between CAP, MITO, and three fiber types within murine Tibialis anterior (TA) muscle.

**METHODS:** Two photon excitation microscopy was utilized for simultaneous imaging of MITO (NADH autofluorescence), vasculature, and interstitial space using selective dyes. ~825 x 825 x 280 μm volumes of the TA were analyzed *in vivo* with flowing blood. A custom contour drawing and analysis program was used to trace fiber boundaries and determine the contact and volume ratios between CAP and muscle fibers for 98 fibers. Fiber type (slow (ST), intermediate (IT), fast-twitch (FT)) was determined based on the relative intensity of the NADH signal and fiber size. EM was performed on cross-sections and longitudinal slices of fixed TA samples for further validation.

**RESULTS:** Microscopy revealed that a significant fraction of ST fiber CAP (51.7 ± 4.0%) had at least 50% of their circumference embedded in a groove in the sarcolemma, *in vivo*. Embedded CAP were tightly associated with dense MITO populations lateral to the CAP grooves and nearly absent below the groove where fibrils dominated. CAP embedding was significantly lower in IT (25.7 ± 4.5%) and FT (14.1 ± 2.1%). EM images confirmed ST embedded CAP and MITO localization. 35.1 ± 1.5% of ST fiber surface area (SA) was in contact with CAP, whereas IT and FT fiber SA contact was only 13.2 ± 1.4% and 8.4 ± 0.7%, respectively.

**CONCLUSIONS:** A specialized sarcolemma/CAP groove is present in murine ST fibers resulting in the embedding of CAP in a MITO rich region of the cell. This structure optimizes the CAP O<sub>2</sub> delivery to highly aerobic ST fibers as well as selectively restricts the O<sub>2</sub> delivery to FT fibers in these mixed fiber muscles.

**Fiber Type Comparison Between Wild-type And Desmin Knock-out Mice**

Allen C. Parcell, FACSM, Brenda Benson, Michael Leavitt, Daniel Nelson, Derek Stewart. *Brigham Young University, Provo, UT.*  
(No relationships reported)

Proteins of the muscle cytoskeleton are important for the transmission of forces and appear to be a component of the adaptive response to chronic overload. Questions remain as to how cytoskeletal proteins may mediate the translation of a contractile stimulus to an adaptive response.

**PURPOSE:** As an initial phase to approach these questions the purpose of this research was to conduct a contemporary examination of muscle morphology in a desmin knockout mouse with regard to muscle fiber-type composition.

**METHODS:** The gastrocnemius and tibialis anterior muscles were dissected from wild-type and desmin knockout mice. Tissue cross-sections were stained for myosin ATPase with an acid preincubation pH of 4.45. Sections were assessed for type I and type II cells by two independent evaluators after which fiber counts and distributions were calculated.

**RESULTS:** Wild type (WT) mice possessed and fiber-type distribution in the gastrocnemius of 7% type I, 7% type IIa/IIx, and 86% type IIb cells. WT tibialis anterior muscle was composed of 34% type I, 11% type IIa/IIx, and 55% type IIb cells. Desmin knockout (KO) mice had a gastrocnemius muscle composition of 11, 7, and 82% type I, IIa/IIx, and type IIb fibers, respectively. KO tibialis anterior muscle was composed of 40% type I, 10% type IIa/IIx, and 50% type IIb cells. Fiber type composition values were not different between WT and KO.

**CONCLUSIONS:** The absence of the protein desmin appears to have no impact on fiber type distribution in the gastrocnemius or tibialis anterior muscle of mice.

**A Model For Understanding Eccentric Contractions-induced Muscle Damage: Bupivacaine-induced Elevations In Intramyocyte Ca<sup>2+</sup>**

Tadakatsu Inagaki<sup>1</sup>, Takashi Sonobe<sup>2</sup>, David C. Poole, FACSM<sup>3</sup>, Yutaka Kano<sup>1</sup>. <sup>1</sup>University of Electro-Communications, Chofu, Japan. <sup>2</sup>National Cerebral and Cardiovascular Center Research Institute, Suita, Japan. <sup>3</sup>Kansas State University, Manhattan, KS.  
(No relationships reported)

The mechanistic bases for eccentric exercise (ECC)-induced muscle damage is thought to involve dysregulation of stretch-activated channels leading to loss of intramyocyte Ca<sup>2+</sup> homeostasis and elevated intramyocyte Ca<sup>2+</sup> concentration ([Ca<sup>2+</sup>]<sub>i</sub>) which induces muscle damage via calpain activation (Sonobe et al. *Am J Physiol* 294:R1329-37, 2008). However, to determine the effects of elevated [Ca<sup>2+</sup>]<sub>i</sub> in separtum from the mechanical stress of ECC a pharmacological means of perturbing [Ca<sup>2+</sup>]<sub>i</sub> would be valuable.

**PURPOSE:** To test the hypothesis that the anesthetic bupivacaine (BPV) would cause prolonged elevation of [Ca<sup>2+</sup>]<sub>i</sub> in "whole" muscle and single fibers of rat spinotrapezius muscle.

**METHODS:** Adult male Wistar rats (n=12) were divided randomly into 1) ECC (500 contractions in 10 sets, 100 Hz, 700 ms duration, 20/min) and 2) BPV treatment (1 mg/0.2 ml, 5 min exposure) groups. Contractions induced by surface electrode stimulation during synchronized muscle stretch of 10% resting length. The spinotrapezius muscle was exteriorized with vascular and neural connections intact for intravital microscopic observations and incubated with FURA2-AM (20 μM) to estimate [Ca<sup>2+</sup>]<sub>i</sub> and changes thereof. Before and following each set of ECC or BPV treatment the fluorescence ratio (F340/F380 nm) was resolved for ~ 1 hour to determine [Ca<sup>2+</sup>]<sub>i</sub>.

**RESULTS:** Following ECC and BPV "whole" muscle [Ca<sup>2+</sup>]<sub>i</sub> increased significantly and to a similar magnitude (ECC, 22.0±6.7%; BPV, 19.0±4.9%, p<0.05 vs. baseline for both) and this remained true for the 1 hour post-treatment recovery period. However, there was substantial heterogeneity of the [Ca<sup>2+</sup>]<sub>i</sub> and its subsequent time course within and among individual muscle fibers during recovery.

**CONCLUSIONS:** Bupivacaine-induced [Ca<sup>2+</sup>]<sub>i</sub> elevations offer a potentially powerful mechanistic tool to determine the precise linkage (e.g., degree of perturbation of [Ca<sup>2+</sup>]<sub>i</sub> and the duration necessary) between [Ca<sup>2+</sup>]<sub>i</sub> and damage within individual myocytes. These are key steps to resolving the mechanisms responsible for ECC-induced muscle damage.

**Sources of Variation in Maximal Dorsiflexor Muscle Strength in Young and Older Adults**

Stephen A. Foulis, Anita Christie, Logan Maynard, Jane A. Kent-Braun, FACSM. *University of Massachusetts- Amherst, Amherst, MA.*  
(No relationships reported)

Muscle specific strength (voluntary torque per unit muscle) is determined by a number of factors. On the neural side, recruitment of muscle fibers and the rate at which fibers are active play a key role in torque generation. At the level of the muscle, variations in size have been shown to account for ~2/3 of the variations in strength. Given the changes that occur in the neuromuscular system in old age, it is possible that there are differences in the sources of specific strength variation in young and older adults.

**PURPOSE:** To investigate whether there is a relative difference in neural and muscular contributions to variations in strength in young (Y) and older (O) adults.

**METHODS:** Eight Y (5F, 3M, 23±1 yr, mean±SE) and 11 O (4F, 7M, 73±2 yr) healthy, sedentary adults performed maximal isometric contractions of the ankle dorsiflexor muscles. Full voluntary activation of the muscle was determined using the central activation ratio. MRI was used to calculate maximal fat-free muscle cross-sectional area (mCSA). Specific strength was calculated as peak isometric torque / maximal mCSA (Nm·cm<sup>-2</sup>). Maximal motor unit discharge rates (MUDR) were measured using four-wire, needle electromyography.

**RESULTS:** There were no differences between Y and O in specific strength (p=0.56) or MUDR (p=0.36), and all participants had complete voluntary activation. Size and strength were linearly related in both Y (r=0.87, p<0.01) and O (r=0.58, p=0.06). There was no association between specific strength and maximal MUDR in either group (Y: r=0.02, p=0.96; O: r=0.08, p=0.81).

**CONCLUSIONS:** Specific strength, voluntary activation, and MUDR were similar in Y & O, indicating no impairment in isometric torque generation with old age. The observation that 76% of the variation in muscle strength was accounted for variation in muscle size in Y, but only 34% in O, suggest that the sources of strength variation do vary by age, but are independent of activation and rate coding. The remaining variation may be due to differences fiber type or muscle architecture.

**Evidence for PGC-1 Mediated Angiogenesis in Human Muscle: Insights from Energetic Deficiency in Mitochondrial Myopathy**

Gilles Gouspillou<sup>1</sup>, Katrina Dutkiewicz<sup>1</sup>, Nicolas Sgarioto<sup>1</sup>, Martin Picard<sup>1</sup>, Ronald Haller<sup>2</sup>, Russell T. Hepple<sup>1</sup>, Tanja Taivassalo<sup>1</sup>. <sup>1</sup>McGill University, Montreal, QC, Canada. <sup>2</sup>University of Texas, Dallas, TX.

(No relationships reported)

Human mitochondrial myopathy (MM) can result from inborn mutations of mitochondrial (mt)-DNA, impairing respiratory chain function and energy production. Patients with high levels of mutation in skeletal muscle present with debilitating exercise intolerance and an exaggerated cardiopulmonary response to exercise. Recently, abnormally high levels of capillaries - the interface for oxygen delivery and utilization in muscle - have been reported in MM, particularly around respiratory-deficient fibers, despite normal muscle levels of oxygen delivery and low capacity for oxygen extraction. This is surprising given that a low cellular oxygen level, through the stabilization of Hypoxia Inducible Factor 1 $\alpha$  (HIF-1 $\alpha$ ), is considered the main driver of new capillary growth in skeletal muscle. Interestingly, recent findings from transgenic animals have indicated that fluctuation in cellular energy intermediates could induce angiogenesis through the metabolic regulator PGC-1 $\alpha$ , independently of the canonical HIF-1 $\alpha$  pathway.

**PURPOSE:** To evaluate the hypothesis that elevated PGC-1 $\alpha$  in response to a myofiber energy deficit is the mechanism leading to capillary proliferation surrounding fibers containing oxidatively impaired mitochondria in MM muscle.

**METHODS:** A 52 y old male with a single, large-scale mt-DNA deletion causing Cytochrome C Oxidase (COX)-deficiency was studied. In-situ labeling was performed in serial cross-sections obtained from a vastus lateralis muscle biopsy to identify at the single cell level: oxidatively-deficient fibers (histochemical stain for COX); capillary number around a fiber ( $N_{CAF}$ ; lead-ATPase); PGC-1 content; and fiber type (based on myosin heavy chain protein expression)

**RESULTS:** Findings revealed that COX-deficient fibers were exclusively type IIa. Interestingly, both  $N_{CAF}$  ( $5.70 \pm 1.5$  vs.  $4.1 \pm 0.8$ ,  $p < 0.05$ ) and PGC-1 content ( $2628 \pm 563$  vs.  $2122 \pm 98$  AU,  $p < 0.05$ ) were significantly increased in COX-deficient compared to COX normal myofibers.

**CONCLUSIONS:** These results suggest that enhanced myofiber angiogenesis in MM patients is mediated by an increase in PGC-1 expression secondary to energy insufficiency resulting from the severe mt-DNA defect. As such, they provide the first experimental support for the non-canonical regulation of angiogenesis via PGC-1 in humans.

**Stimulation Current Does Not Influence NIRS Measured Metabolic Rate**

Hillary B. Liken, Jared T. Brizendine, Kevin K. McCully, FACSM. University of Georgia, Athens, GA.

(No relationships reported)

Near infrared spectroscopy (NIRS) has been used to evaluate skeletal muscle oxygen levels and metabolic rates.

**PURPOSE:** This study tested the effect of different electrical stimulation current levels on NIRS measured metabolic rate.

**METHODS:** Healthy subjects (7 F, 1 M, ages 23-32) were tested. A dual channel NIRS device (Oxymon, Artinis) was used with separation distances between 3.0 and 4.5 cm, placed over either the medial gastrocnemius or vastus lateralis. Surface electrical stimulation produced muscle activation. Each subject was stimulated for three 2 minute stimulation periods at 4 Hz with randomized current levels (for example: 40, 50, 60 mAmps). Between levels, a 10 second ischemic period was used to measure metabolic rate. A 5 minute duration ischemic cuff with reactive hyperemia was used to calibrate NIRS signals.

**RESULTS:** Oxygen saturation during stimulation was not different between current levels ( $69.8 \pm 9.0\%$ ,  $68.6 \pm 9.8\%$ ,  $69.6 \pm 8.2\%$  low, med, high current) and was similar to resting oxygen saturation ( $69.3 \pm 10.2\%$ ). Metabolic rate was not significantly different between current levels (96%, 107%, 117% of resting metabolic rate for low, med, high current). Longer separation distances gave results similar to those reported for shorter separation distances. In conclusion small differences in current levels at or above 50 mA did not influence, on average, muscle oxygen saturation or metabolic rate following electrical stimulation. Separation distance also did not influence these measurements.

**CONCLUSIONS:** This suggests that electrical stimulation is a feasible method of activating skeletal muscle for NIRS-based measurements of muscle metabolism.

**Effects of FES-Cycling Parameters on Oxygen Uptake after Spinal Cord Injury**

Ashraf S. Gorgey, FACSM, Hunter J. Poarch, David R. Dolbow, David R. Gater. Hunter Holmes McGuire VA Medical Center, Richmond, VA.

(No relationships reported)

Functional electrical stimulation (FES) cycling is an effective therapeutic intervention in attenuating skeletal muscle atrophy and cardiovascular de-conditioning after spinal cord injury (SCI). Previously it was shown that lengthening the pulse duration increases skeletal muscle activation during isometric actions. However, it is not known whether adjusting the stimulation parameters could influence oxygen uptake to match the metabolic needs of increasing skeletal muscle activation during FES-cycling.

**PURPOSE:** To determine the effects of different pulse durations (P200, P350 and P500  $\mu$ s) on oxygen uptake during FES-cycling in men with SCI

**METHODS:** Ten (9 men and 1 woman) individuals with motor complete SCI ( $44 \pm 10$  years,  $25 \pm 4$  Kg/m<sup>2</sup>) participated in three cross-over randomized visits separated by a week. The FES cycling (RT300 bike) parameters were kept constant (33 Hz, amplitude of the current to maintain cycling at 40-45 RPM, resistance at 1Nm) across the three visits and the participants cycled until fatigued. Pulse durations (P200, P350 and P500  $\mu$ s) were randomized across the three visits. Bilateral surface adhesive electrodes were placed on knee extensor, flexor and hip extensor muscle groups. Oxygen uptake was measured using COSMED K4b2 (COSMED USA, Chicago, IL) portable metabolic unit. A repeated measure ANOVA (within and between designs) was used to analyze the data.

**RESULTS:** Across the three visits, absolute and relative oxygen uptake significantly ( $P < 0.001$ ) increased during the warm up period ( $3.17 \pm 0.95$  ml/kg/min) and exercise ( $4.9 \pm 1.8$  ml/kg/min) compared to the rest ( $2.7 \pm 0.85$  ml/kg/min) period. Both absolute and relative oxygen uptake remained higher in the recovery period ( $3.8 \pm 1.12$  ml/kg/min) compared to both rest and warm-up periods but lower than the exercise period ( $P < 0.0001$ ). The relative oxygen uptake was not statistically different among the P200 ( $4.5 \pm 1.8$  ml/kg/min), P350 ( $5.2 \pm 1.9$  ml/kg/min) and P500 ( $4.9 \pm 1.8$  ml/kg/min) cycling protocols ( $P = 0.7$ ).

**CONCLUSION:** Administering different pulse durations did not influence oxygen uptake during FES-cycling in men with SCI. Clinicians may likely use 200 or 350  $\mu$ s, because there are no additional benefits from using 500  $\mu$ s on oxygen uptake.

**Effect of Body Composition on Electromyography Using a Vibration Platform**

Bruce W. Mason<sup>1</sup>, Ronald Otterstetter<sup>1</sup>, Randall F. Gearhart, FACSM<sup>2</sup>, Beth Patton<sup>2</sup>. <sup>1</sup>The University of Akron, Akron, OH. <sup>2</sup>Ashland University, Ashland, OH.

(No relationships reported)

**PURPOSE:** Previous research has demonstrated that excess sub-cutaneous adipose tissue muscles could act as an insulator to electrical signatures. Electromyography (EMG) is used to record and evaluate electrical signals produced by skeletal muscles measured in microvolts. However, it is unclear whether excess adipose will cause a discrepancy in results of the biofeedback from EMG. This investigation used EMG to compare the biofeedback throughout exercise of recreationally trained women with different body composition while exercising on a vibration platform.

**METHODS:** Twenty women (mean age  $20 \pm 1.04$  yrs; body fat  $21.95 \pm 4.418\%$ ) volunteered to participate in this study. The group was divided evenly based on the average % BF for the whole group (lower % BF (L%BF) and higher % BF (H%BF)). The experimental trial consisted of dynamic squat exercise on the vibration platform at three different vibration frequencies (i.e.

Hz = 20, 30, 40) on a stable surface in two groups for 30 seconds per trial. The resistance used during the three different vibration frequencies or on stable ground was the individual's body weight. The EMG electrodes were placed on the Vastus Medialis to measure biofeedback during all trials. The conditions were presented in counterbalanced order and a rest period of three minutes occurred between each trial. A T-test was used to compare the three conditions in relation to body composition.

**RESULTS:** L%BF's mean body fat percentage was  $18.5 \pm 2.79\%$  and H%BFs body fat percentage was  $25.4 \pm 2.63\%$ . The biofeedback was slightly higher with resistance training on the platform in H%BF compared to L%BF in all trials. Standard deviation of H%BF in all trials had a greater range and mean compared to L%BF but was not significant. At 20 Hz ( $p < .69$ ), 30 Hz ( $p < .71$ ) and 40 Hz ( $p < .83$ ).

**CONCLUSIONS:** Electromyography in relation to body composition of young recreational trained women was not significantly different during a vibration platform training program.

#### Neuromuscular Parameters For Ramp And Step Incremental Cycle Ergometer Tests

Jorge M. Zuniga<sup>1</sup>, Chad Harris, FACSM<sup>1</sup>, Clayton L. Camic<sup>2</sup>, Terry J. Zuniga, FACSM<sup>3</sup>, Haley C. Bergstrom<sup>3</sup>, Daniel A. Traylor<sup>3</sup>, Miranda T. Goodman<sup>1</sup>, Richard J. Schmidt<sup>3</sup>, Glen O. Johnson<sup>3</sup>. <sup>1</sup>Western New Mexico University, Silver City, NM. <sup>2</sup>University of Wisconsin-Platteville, Platteville, WI. <sup>3</sup>University of Nebraska-Lincoln, Lincoln, NE. (Sponsor: Chad Harris, FACSM)  
(No relationships reported)

**PURPOSE:** The purpose of the study was to examine the patterns of electrical (EMG) and mechanical (MMG) responses, as well as submaximal mean values for step (30 W increments every two min) versus ramp ( $15 \text{ W} \cdot \text{min}^{-1}$ ) incremental cycle ergometer tests.

**METHODS:** Seven male and seven female (age and body mass =  $23.36 \pm 3.34$  years and  $71.65 \pm 11.10$  kg) visited the laboratory on three separate occasions. The initial visit was an orientation session and the next two visits were randomly ordered step (30 W increments every 2 min) and ramp ( $15 \text{ W} \cdot \text{min}^{-1}$  increments, 1 W increase every 4 s) incremental cycle ergometer tests. The EMG and MMG signals were collected from the vastus lateralis of the dominant leg. In addition, the work performed (kJ) during each protocol was calculated. Two-way repeated measures ANOVAs were used to analyze the data. Polynomial regression analyses were used to determine the patterns of responses for the EMG and MMG signals. A paired t-test was used to analyze the difference in the work performed (kJ) during each protocol. All the data was analyzed using the common power outputs (i.e., 30, 60, 90, 120, and 150 W).

**RESULTS:** The polynomial regression analyses showed that most subjects had the same patterns of responses for the ramp and step incremental tests for EMG amplitude (79%), but different patterns for MMG amplitude (57%). The ramp incremental cycle ergometer test resulted in significantly ( $p = 0.03$ ) lower mean (ramp =  $127.2 \pm 45.1 \mu\text{Vrms}$  and step =  $137.5 \pm 39.9 \mu\text{Vrms}$ ) EMG amplitude values (collapsed across power output) than the step protocol. Furthermore, there was a significantly ( $p = 0.001$ ) greater amount of work performed at the common power outputs for the step ( $54.20 \pm 0.08$  kJ) vs. the ramp ( $45.66 \pm 0.06$  kJ) incremental cycle ergometer test.

**CONCLUSION:** The results of the present study indicated that the different pattern of responses for MMG amplitude associated with changes in motor unit recruitment may be due to the different workload increments (step vs. ramp). Furthermore, the greater mean EMG amplitude values for the step than the ramp protocols suggest that there was an increase in motor unit activation (i.e., recruitment and firing rate) in response to the greater work performed for the step vs. ramp incremental cycle ergometer test.

**2656** Board #331 MAY 31 2:00 PM - 3:30 PM

#### Effects Of Superoxide, Nitric Oxide And Peroxynitrite On Skeletal Muscle Mitochondrial Function

Chris J. Lancaster, Rob C.I. Wüst, William D. Fish, Harry B. Rossiter, FACSM. University of Leeds, Leeds, United Kingdom.  
(No relationships reported)

The intramuscular accumulation of nitric oxide (NO) and reactive oxygen species (ROS) can lead to reactive nitrogen species formation (RNS; peroxynitrite). NO is a competitive inhibitor of mitochondrial complex IV, and ROS can oxidize complex I, III or outer membrane proteins; each of which can limit ATP provision and impair muscle function. RNS, however, causes complex I nitrosation and widespread cytotoxicity that may exaggerate mitochondrial dysfunction. How the combination of these inhibitors affects mitochondrial respiration in intact skeletal muscle is currently unknown.

**PURPOSE:** To determine the effects of NO, ROS, and their combination (RNS) on skeletal muscle mitochondrial respiration *in situ*.

**METHODS:** Oxygen consumption ( $\text{JO}_2$ ) of ~8 mg soleus muscle from 8, 2-month-old, rats was measured by high-resolution respirometry (Oroboros). Respiratory state 3 (RS3) was measured after the addition of Krebs cycle substrates and 2.5 mM ADP. Outer-membrane integrity was assessed by 10  $\mu\text{M}$  cytochrome c.  $\text{JO}_{2\text{max}}$  was measured after 10 mM succinate, and complex II-IV function by FCCP and rotenone.  $\text{JO}_2$  values in this protocol (CON) were compared to those measured after the addition of 100  $\mu\text{M}$  pyrogallol (ROS), 100  $\mu\text{M}$  S-nitroso-N-acetyl penicillamine (NO) or both (RNS).

**RESULTS:** ADP-stimulated  $\text{JO}_2$  was lower in NO, ROS and RNS ( $15.4 \pm 9.0$ ,  $18.3 \pm 7.5$  and  $12.7 \pm 3.7$  nmol $\text{O}_2$ /s/mg; mean  $\pm$  SD) than CON ( $48.5 \pm 14.2$  nmol $\text{O}_2$ /s/mg;  $p < 0.05$ ).  $\text{JO}_{2\text{max}}$  was lower in ROS than CON ( $p < 0.05$ ), but both were greater than NO and RNS ( $p < 0.05$ ). The ADP flux control ratio ( $\text{RS3}/\text{JO}_{2\text{max}}$ ) was not different between NO ( $0.45 \pm 0.15$ ) and CON ( $0.46 \pm 0.11$ ), but was lower ( $p < 0.05$ ) in ROS ( $0.25 \pm 0.14$ ) and RNS ( $0.32 \pm 0.13$ ).  $\text{JO}_2$  increased by 75  $\pm$  49% and 51  $\pm$  44% after cytochrome c addition in ROS and RNS ( $p < 0.01$ ), suggesting outer-membrane damage. The flux control ratio for rotenone was higher for ROS and RNS compared to CON and NO ( $p = 0.052$ ).

**CONCLUSION:** As expected, NO resulted in a proportional reduction in  $\text{JO}_2$  across all titration steps. ROS and RNS exposure resulted in complex I dysfunction and outer-membrane damage. However, RNS did not result in an exacerbated mitochondrial dysfunction compared to NO and ROS alone. It remains to be determined whether the effect of the combination of NO and ROS on mitochondrial function *in situ* is reversible.

#### Child-adult Differences In The Variability Of Torque Kinetics

Bareket Falk<sup>1</sup>, Cameron Mitchell<sup>2</sup>, Rotem Cohen<sup>3</sup>, David Gabriel<sup>1</sup>, Panagiota Klentrou<sup>1</sup>, Raffy Dotan<sup>1</sup>. <sup>1</sup>Brock University, St Catharines, ON, Canada. <sup>2</sup>McMaster University, Hamilton, ON, Canada. <sup>3</sup>Wingate Institute, Netanya, Israel.  
(No relationships reported)

Boys demonstrate slower torque kinetics than men. Correspondingly, boys typically have lower agility, speed, and power capacities, although their performance appears to be more widely varied than men's.

**PURPOSE:** To examine whether torque-kinetics variability is likewise greater in boys than in men, and whether differences, if any, can be attributed to age or maturity level.

**METHODS:** Participants included minimally active boys ( $n=20$ ;  $10.1 \pm 1.3$  yrs) and men ( $n=19$ ;  $22.9 \pm 4.4$  yrs). Tanner stage and years from peak height velocity ( $\text{YRS}_{\text{PHV}}$ ) were determined for the boys. All subjects performed maximal, explosive, isometric knee extensions (Biodes System-3 dynamometer). Filtered traces of best 5 contractions were averaged and peak torque (MVC), elapsed time to 30% MVC ( $T_{30}$ ), %MVC at 100ms (%MVC<sub>100</sub>), normalized peak rate of torque development ( $\text{RTD}_{\text{pk}}$ ), and time to  $\text{RTD}_{\text{pk}}$  ( $T_{\text{RTDpk}}$ ) were determined.

**RESULTS:** Body-mass-normalized MVC was lower in the boys and all kinetics parameters were consistent with the boys' slower torque kinetics ( $p < 0.02$ ). Notably, the coefficients of variation in all kinetics parameters ( $T_{30}$ , %MVC<sub>100</sub>,  $\text{RTD}_{\text{pk}}$ ,  $T_{\text{RTDpk}}$ ) were, respectively, 43, 45, 37, and 56% larger in the boys compared with the men. When boys were divided into fast and slow groups (based on  $T_{30}$ ), torque kinetics of the faster group was similar to the men's. The groups did not differ in age or in sexual or somatic maturity (Tanner stage,  $\text{YRS}_{\text{PHV}}$ ).

**CONCLUSIONS:** In addition to being slower than men, boys' force kinetics is highly variable. This variability cannot be explained by age or the standard measures of biological maturity.

2658 Board #333 MAY 31 2:00 PM - 3:30 PM

**Anti-catabolic Effects Of Cla/n-3 In Resting And Loaded Muscles Of A High Fat Diet-fed Mice**

Sang-Rok Lee, Andy V. Khamoui, Edward Jo, Bong-Sup Park, Michael C. Zourdos, Neema Bakhshalian, Samuel C. Grant, Bahram H. Arjmandi, Michael J. Ormsbee, Jeong-Su Kim. *The Florida State University, Tallahassee, FL.* (Sponsor: Lynn B. Panton, FACSM)  
(No relationships reported)

Conjugated Linoleic Acid (CLA) and Omega-3 polyunsaturated fatty acids (n-3) have attracted interest due to their health enhancing benefits. However, their efficacy in attenuating high fat diet (HFD)-induced impairments in skeletal muscle remains poorly understood.

**PURPOSE:** To determine the combined effects of CLA and n-3 intake on muscle morphology as well as transcript levels of catabolic factors in resting and loaded muscle during 20 wks of a HFD.

**METHODS:** After sacrificing eight randomly selected C57BL/6 male mice (age= 9 mo.) for baseline *in vitro* tissue, the remaining animals were randomly allocated to five experimental groups (n=10/group): 1) normal diet (CON), 2) high fat diet (HFD), 3) HFD + resistance training (HFD/RT), 4) HFD + CLA/n-3 (HFD/CN), or 5) HFD + RT + CLA/n-3 (HFD/RT/CN). Progressive RT was administered on a ladder climbing device 3d/wk for 20 wks. The supplement consisted of 1% CLA (0.5% of c9, t11 and 0.5% of t10, c12) and 1% n-3. Muscle wet weight, myofiber dimensions [eigen values and fractional anisotropy (FA) determined from diffusion tensor imaging (DTI)] and transcript levels of catabolic factors were assessed. Data were analyzed with ANOVAs, and significance was set at p<0.05.

**RESULTS:** There were significant group effects in wet weight. Gastrocnemius wet weight significantly decreased in CON (-27%), HFD (-37%) and HFD/CN (-25%) from baseline while remaining in HFD/RT and HFD/RT/CN. Soleus wet weight significantly decreased in HFD (-21%) but was maintained in CON, HFD/CN, and HFD/RT. In contrast, soleus wet weight increased in HFD/RT/CN (+19%). While no changes in DTI eigen values were observed, FA was significantly decreased in HFD/RT/CN (-21%). This indicates a positive effect of CLA/n-3 administration on myofiber hypertrophy as FA is inversely correlated with cross-sectional area. Interestingly, there were trends for greater mRNA expression associated with muscle wasting (i.e. Atrogin-1, MURF1, Cap-3, and Cap-9) in HFD/CN compared to baseline with no change in HFD/RT/CN.

**CONCLUSION:** Twenty-wks of HFD-induced muscle wasting. However, daily CLA/n-3 intake partially attenuated HFD-induced impairments while facilitating RT-induced muscle hypertrophy.

**Association Between Knee Extension Power and Functional Performance in Patients After Total Knee Arthroplasty**

Adam R. Marmon, Lynn Snyder-Mackler. *University of Delaware, Newark, DE.*  
(No relationships reported)

Lower extremity functional ability in patients after total knee arthroplasty (TKA) is largely attributed to quadriceps strength, which is generally obtained during isometric tests. However, during functional tasks knee extension contractions are not static, but dynamic and require muscle power, as can be tested with isokinetic contractions.

**PURPOSE:** The aims of this study were; 1) to compare peak knee extension power during isokinetic contractions between the surgical (SL) and non-surgical limbs (NSL) of patients' six-months after undergoing TKA, and 2) to evaluate the associations between tests of lower extremity performance and peak knee extension power of the SL.

**METHODS:** Performance-based tests and knee extension power during isokinetic contractions were assessed in patients, six-months after undergoing unilateral TKA. Paired t-tests were used to compare peak knee extension power of the SL and NSL (normalized to body mass) at three isokinetic speeds (60, 90, 120 deg/s). The functional relevance of knee extension power was assessed with Pearson's correlation analyses between peak knee extension power by the SL and performance measures.

**RESULTS:** Preliminary data are presented (N=4). Peak normalized knee extension power was not significantly different between the limbs of patients 6-months after TKA (60 deg/s SL 2.3 ± 1.0 vs NSL 2.3 ± 0.9; 90 deg/s SL 3.0 ± 1.5 vs NSL 2.9 ± 1.3; 120 deg/s SL 3.4 ± 1.1 vs NSL 3.4 ± 1.6 W/kg). Peak knee extension power was strongly associated with performance measures (Table 1).

**CONCLUSION:** Understanding the functional relevance of dynamic knee extension strength may have implications on the treatment of patients after TKA and serve as a useful assessment tool for evaluating post-surgical interventions.

Table 1. Correlation coefficients between power and performance measures. \*P<0.05; \*\*P<0.01

|           | Timed Up-and-Go | Stair Climbing Test | 6-Minute Walk |
|-----------|-----------------|---------------------|---------------|
| 60 deg/s  | -0.926          | -.944               | 0.998**       |
| 90 deg/s  | -0.924          | -0.928              | 0.999**       |

**Insulated Athletic Pants Do Not Prevent Muscle Temperature Decline Following Warm Up Nor Benefit Performance**

Steve H. Faulkner<sup>1</sup>, Richard A. Ferguson<sup>1</sup>, Nicola Gerrett<sup>1</sup>, Simon G. Hodder<sup>1</sup>, Maarten Hupperets<sup>2</sup>, George Havenith<sup>1</sup>. <sup>1</sup>Loughborough University, Loughborough, United Kingdom. <sup>2</sup>Adidas AG, Herzogenaurach, Germany.  
(No relationships reported)

Elevations in muscle temperature (T<sub>m</sub>) have been shown to be important for enhancing maximal muscle power output during short duration, sprint based activities, hence the completion of a warm up prior to many exercise types. However, in many sporting activities and competition it is not uncommon for there to be delays between warm up completion and performance execution, during which time activity levels may be insufficient to maintain elevations in T<sub>m</sub>. Excessive decline in T<sub>m</sub> may lead to sub-optimal contractile conditions and impaired exercise performance.

**PURPOSE:** To determine whether a delay between warm up and competition may influence T<sub>m</sub> and performance and whether this may be attenuated using an insulated athletic pant.

**METHODS:** On two separate occasions, 11 male cyclists (24±5 yrs; 182.4±7.6cm; 77.4±10.0 Kg) completed a standardized 15 min intermittent sprint-based warm up on a cycle ergometer, followed by a 30 min passive recovery period before completing a 30 sec maximal sprint test. T<sub>m</sub> of the vastus lateralis was measured at depths of 1, 2 and 3 cm prior to and following the warm up and immediately before the sprint test. Measures of absolute and relative peak power output and blood lactate were taken. During the recovery period subjects wore a tracksuit top and either i) a standard tracksuit ensemble (CONT) or ii) a pair of insulated athletic pants (INS).

**RESULTS:** The warm up increased T<sub>m</sub> at all depths by ~2.5°C, with no differences between conditions. During the recovery period INS T<sub>m</sub> declined to similar values to CONT at 1cm (36.5±0.6°C vs. 36.3±0.4°C, INS vs. CONT), 2cm (36.7 ±0.4 vs. 36.6±0.3°C) and 3cm (37.0 ±0.3°C vs. 36.9±0.2°C). There were no differences for INS vs. CONT in absolute (1545.1 ± 338.0W vs. 1468.2 ± 260.2 W), relative (20.3 ± 2.3 ± 19.2 ± 1.7 W/kg) and mean power output (707.8 ± 127.9 Vs. 711.4 ± 153.1W) nor in Δblood lactate concentration following the sprint test (4.8 ± 2.3 vs. 4.1 ± 1.9mmol/L).

**CONCLUSION:** The use of an insulated athletic trouser has little benefit at reducing the decline in T<sub>m</sub> that is associated with forced periods of inactivity between warm up completion and competition.

**Acute Exercise And Starvation-induced Insulin Resistance**

Per Berthelson. *GIH - the Swedish school of sport and health sciences, Stockholm, Sweden.*  
(No relationships reported)

It is well known that starvation causes insulin resistance. The mechanism is unclear but may relate disturbances in lipid metabolism i.e. incomplete mitochondrial FA oxidation and/or accumulation of lipid intermediates. Exercise results in increased substrate oxidation and may thus remove interfering lipid metabolites and reverse starvation-induced insulin resistance. However, the effect of acute exercise and starvation on insulin sensitivity is not known.

**PURPOSE:** The aim of this study was to investigate the effect of exercise on starvation-induced insulin resistance and to elucidate potential mechanisms.

**METHODS:** Nine healthy lean subjects underwent 84h starvation on two occasions separated by at least 2 weeks. The starvation period was followed by either exercise (EX; 5x10 min intervals with 2-4 min rest, starting at 70 %VO<sub>2</sub> max) or an equal period of rest (NE). Before and after the starvation period (3h after exercise/rest) subjects were investigated with muscle biopsies, blood samples and an intravenous glucose tolerance test. Muscle samples were used for measurements of mitochondrial respiration in permeabilized muscle fibers (Oroboros oxygraph), glycogen content and activation of signaling proteins.

**RESULTS:** Insulin sensitivity was significantly higher in the EX group compared to the NE group (p<0.05). After starvation mitochondrial respiration was lower in both groups with complex I substrates whereas respiration with complex I+II substrates was higher in EX (p<0.05 vs. basal and NE). Muscle glycogen was decreased to 73% (NE) and 31% (EX) of the basal values. The EX group had a significant increased activation of AS160. Plasma FA was increased 3-4 fold after starvation to 1.39±0.32 (NE) and 1.80±0.49 (EX) (mmol/l) and plasma beta-hydroxybutyrate increased about 50-fold to 6.43±2.01 (NE) and 7.12±1.59 (EX)(mmol/l).

**CONCLUSION:** Acute exercise reverses starvation-induced insulin resistance. Plasma FA and BOH were increased to similar extent after NE and EX and cannot explain the changes in insulin sensitivity. However, an increased substrate oxidation together with the observed increased capacity for mitochondrial FA oxidation after EX may be involved in the activation of AS160 and the reversal of starvation-induced insulin resistance.

**2662** Board #337 **MAY 31** **2:00 PM - 3:30 PM**  
**Effect Of Calf Raise Exercise On Electromechanical Delay Of Ankle Plantar Flexion In Older Adults**

Koichi Takase<sup>1</sup>, Masahiro Taguchi<sup>2</sup>, Mayumi Kakimoto<sup>2</sup>, Ryoji Tahara<sup>2</sup>. <sup>1</sup>Meio University, Nago Okinawa, Japan. <sup>2</sup>Fukuoka University, Fukuoka, Japan.  
(No relationships reported)

Ankle plantar flexion is important in phase of mid stance and terminal stance in the walk. But those functions are thought to decrease with aging.

**PURPOSE:** The purpose of this study is, by intervening calf raise exercise for the older adults, to investigate the effect that the calf raise exercise has on older adult's electromechanical delay (EMD) and muscle strength of ankle plantar flexion and walking functions.

**METHODS:** A group of 25 healthy older women (mean age: 75.2±5.6years) subject gave informed consent for participating in this experiment. Intervention of calf raise exercise is performed for eight weeks (10 × three sets per day until the three weeks, four-six weeks is 10 × four sets, seventh weeks after the 10 × five sets, and each of the intervention three times a week). The measurements of EMD and muscle strength in ankle plantar flexion are performed by using a dynamometer (KinCom 500H). Moreover, they are performed under the condition of eccentric muscle actions. The start of reaction in measurement of EMD is performed the proprio-ceptor response of plantar part. The walk function performed two-dimensional photography from the side.

**RESULTS:** The main results are as follows: In the EMD, total reaction time, and peak torque value, there was significantly improved than the pre (EMD: pre 69.9±10.5msec, post 63.1±7.1msec; total reaction time: pre 300.1±56.7msec, post 264.8±38.2msec; peak torque value: pre 50.0±18.9 Nm, post 62.9±12.2 Nm). However, Stride, pitch, maximum walking velocity, and normal walking velocity parameters, no significant changes observed in between the pre and post.

**CONCLUSION:** These results suggest that the following. Calf raise exercise, the functional recovery of the triceps surae was revealed to be effective. But, it was ineffective to the walk functions can consider a possibility of having been controlled by the function of the knee or hip joint.

---

**2663** Board #338 **MAY 31** **2:00 PM - 3:30 PM**  
**No Differences in Wrist Flexion Strength for Isometric, Eccentric, and Concentric Contractions With and Without Venous Occlusion**

Hannah A. Stone, Morgan Bauman, Maurie Luetkemeier, John E. Davis. *Alma College, Alma, MI.*  
(No relationships reported)

Several recent studies have reported greater strength gains with handgrip training in an occluded versus a non-occluded arm. However, few if any prior studies have compared muscular strength for different contractions with and without occlusion.

**PURPOSE:** The purpose of this study was to determine muscle strength in an occluded and non-occluded arm with exercise using concentric (CON), eccentric (ECC), and isometric (ISO) muscle contractions.

**METHODS:** Nine subjects (Men=4 Women=5, mean age ± 1 SD = 19 ± 8.5 years) completed 6 trials each using a randomized design. Each subject did one trial each of concentric (at a speed of 90° per second), eccentric (at a speed of 90° per second) and isometric (held contraction for 5 seconds) wrist flexion both occluded (OCC) and non-occluded (NO-OCC). All testing was done on a Cybex isokinetic dynamometer using the subject's right arm. For the occluded condition, the cuff was placed on the upper arm and inflated to 80 mmHg for the duration of the exercise. The subject performed 15 repetitions of the assigned condition. The cuff was released as soon as the subject finished the exercise. Initial peak torque for the first muscle contraction and the total work done for the 15 repetitions of the exercise was recorded.

**RESULTS:** Peak torques were not significantly different (P>0.05) between contraction type with or without occlusion (CON-NO-OCC= 14.1 + 7 n-m, CON-OCC = 14.3+ 6.8 n-m; ISO- NO-OCC = 18.3 + 4.5 n, ISO-OCC = 17.2 + 4.3 n ; ECC-NO-OCC = 18.8+ 8.6 n-m, ECC-OCC = 19.1 +7.6 n-m ). There were no differences in total work done between CON or ECC with or without occlusion (CON-NO-OCC= 178 + 87 n-m, CON-OCC = 158.1+ 80.3 n-m ; ECC-NO-OCC = 192.4+ 99.6 n-m, ECC-OCC = 228.0+106.6).

**CONCLUSION:** These data suggest that moderate occlusion does not result in differences in wrist flexion strength for concentric, eccentric or isometric contractions. It is possible that the lack of differences is due to the small muscle mass involved with this type of exercise.

**2664** Board #339 **MAY 31** **2:00 PM - 3:30 PM**  
**The Acute Effects of Stretching on Pennation Angle, and Force Production**

Ryan Miskowicz, Arnold Nelson, FACSM, Michael Welsch, FACSM, Laura Stewart. *LSU, Baton Rouge, LA.*  
(No relationships reported)

Stretching has been found to acutely reduce maximal voluntary contraction force (MVC). While there are several potential mechanisms which may influence MVC following stretching their roles are unclear. Pennation angle (PA) should have a mathematical relationship to MVC, as the PA of muscles describe what portion of the muscle fibers' force production is being applied to its deep aponeurosis. If stretching results in a change in PA, then this may aid in explaining the reduction in MVC commonly observed.

**PURPOSE:** To examine changes in pennation angle as a result of stretching, and its relationship with reduced in force production.

**METHODS:** Using a randomized crossover design, 24 subjects (10 male, 14 female, ages 19-30) were treated with either stretching (S) or mock stretching (MS) during each of four trials (2 S, 2 MS). The S treatment consisted of four 30 second passive calf stretches with 15 seconds of rest in-between, while the MS treatment served as a control. PA was assessed on the medial gastrocnemius using ultrasonography before, during, and after each treatment. A single repetition maximal isotonic plantar flexion protocol was employed to measure MVC before and after each treatment. Changes in PA and MVC were analyzed using paired T-tests, while the relationship between change in PA and MVC was analyzed using a one-way ANOVA.

**RESULTS:** Significant reductions in MVC were noted following the S treatment ( $-5.30 \pm 2.40$  kg,  $p < 0.01$ ), but not for the MS treatment ( $+0.52 \pm 0.26$  kg,  $p = 0.06$ ). No significant changes in PA were observed for either the S ( $+0.31 \pm 1.33^\circ$ ,  $p = 0.27$ ) or MS ( $+0.41 \pm 1.12^\circ$ ,  $p = 0.09$ ) treatments. The relationship between PA and MVC was found to be insignificant ( $p = 0.948$ ).

**CONCLUSION:** PA change was not a mechanism which contributed to the reduction in MVC due to stretching.

**Relationship Between Oxidative Capacity And Work Capacity With 3-week Upper Limb Immobilization**

Shinsuke Nirengi, Toshiyuki Kurihara, Masako Fujioka, Takeshi Saiki, Takafumi Hamaoka, FACSM. *Ritsumeikan University, Shiga, Japan.* (Sponsor: Takafumi Hamaoka, FACSM)

(No relationships reported)

It is well known that muscle disuse causes decreased muscle mass, muscle strength, and muscle oxidative capacity. On the other hand, the change in work capacity following muscle disuse and its mechanism remain to be conclusive. We have chosen a 3-week upper limb immobilization that created only muscle functional decline without muscle mass reduction (Homma et al., 2009).

**PURPOSE:** To investigate whether the 3-week immobilization reduces muscle functions and to clarify the relationship between oxidative capacity and work capacity with the 3-week upper limb immobilization.

**METHODS:** Eight healthy men ( $19.5 \pm 0.9$  years, mean  $\pm$  SD) were participated in this study. For all subjects non-dominant arm was immobilized for 3 weeks with a cast (IMM) and the dominant arm was measured as control (CON). We measured the following parameters for participant pre- and post-immobilization: maximal voluntary contraction (MVC) of the grip, forearm cross-sectional area (CSA), work capacity per CSA (dynamic handgrip exercise at 30% of MVC of the day, 1 Hz until exhaustion). The oxidative capacity was evaluated by the time constant for the recovery of phosphocreatine (PCrTC) using  $^{31}$ P-phosphorus-magnetic resonance spectroscopy ( $^{31}$ P-MRS).

**RESULTS:** There is no significant change in CSA (pre:  $3604 \pm 662$  mm<sup>2</sup>, post:  $3568 \pm 607$  mm<sup>2</sup>) pre- and post-immobilization. MVC (pre:  $415.5 \pm 72.4$  N, post:  $305.9 \pm 80.5$  N), PCrTC ( $39.6 \pm 10.6$  s,  $58.4 \pm 14.4$  s), and work capacity ( $0.55 \pm 0.18$  N $\cdot$ m / mm<sup>2</sup>,  $0.42 \pm 0.16$  N $\cdot$ m / mm<sup>2</sup>) were significantly decreased post-immobilization. A negative correlation was found between work capacity and PCrTC ( $r = -0.62$ ,  $p < 0.01$ ) pre-immobilization, but no correlation was observed between the change (post - pre) in PCrTC and work capacity pre- and post-immobilization. For all the measurements there was no significant difference observed between pre- and post- intervention in the CON.

**CONCLUSIONS:** The work capacity and the oxidative capacity were decreased, but the decrease in the work capacity showed no relationship with the decrease in oxidative capacity post-immobilization.

**The Effect of Low-Pressure Functional Elastic-Property Tights on Reoxygenation Recovery Following Exhaustive Knee Extension Exercise**

Kohei Kido<sup>1</sup>, Shinsuke Nirengi<sup>1</sup>, Yuko Kurosawa<sup>1</sup>, Masako Fujioka<sup>1</sup>, Tetsuya Kimura<sup>1</sup>, Toshiyuki Kurihara<sup>1</sup>, Keita Sato<sup>1</sup>, Yutaka Ishida<sup>1</sup>, Fumiko Nakamura<sup>2</sup>, Junko Deguchi<sup>3</sup>, Shoichi Akita<sup>3</sup>, Takafumi Hamaoka, FACSM<sup>1</sup>. <sup>1</sup>*Ritsumeikan University, Shiga, Japan.* <sup>2</sup>*Kokugakuin University, Tokyo, Japan.* <sup>3</sup>*Asahi Kasei Fibers Corporation, Shiga, Japan.* (Sponsor: Takafumi Hamaoka, FACSM)

(No relationships reported)

In recent years, various types of functional tights such as graduated compression tights have been used to aim at enhancing athletic performance. However, there is limited information about the effect of low-pressure functional elastic-property tights (Tights<sub>LP</sub>) on physical performance and muscle metabolism.

**PURPOSE:** To clarify the effects of Tights<sub>LP</sub> on muscle oxygenation in the rectus femoris (RF) and vastus lateralis (VL) muscles during exhaustive knee extension exercise.

**METHODS:** Six subjects performed knee extension exercise on the dominant leg using isokinetic ergometer (Biodes). The maximal load torque (W<sub>max</sub>) for each subject was determined using the ramp exercise test (20 Nm increment per a stage from 20 Nm until exhaustion). The subjects performed three sets of exhaustive exercise at W<sub>max</sub>, with one contraction every 2.5 s, followed by the active recovery (30% W<sub>max</sub> each for 5 min). The subjects performed the knee extension exercise with or without Tights<sub>LP</sub> (Elacion PRO, soft type, Asahi Kasei Fibers Corporation). Muscle deoxygenation using near infrared spectroscopy and electromyography (EMG) activity in the RF and VL were simultaneously measured during both the W<sub>max</sub> and the active recovery. The muscle fatigue index was defined as the ratio between the root mean square (RMS) of the last 36 s (RMS<sub>E</sub>) and the RMS of the initial 36 s (RMS<sub>I</sub>) during 30% W<sub>max</sub>. Leg blood flow was measured using ultrasonic Doppler in the femoral artery during the active recovery.

**RESULTS:** The recovery half time of muscle reoxygenation was significantly shortened with the Tights<sub>LP</sub> for the second set in the RF ( $P < 0.05$ ) and the VL ( $P < 0.05$ ) and, although it did not reach statistical significance, for the third set in the VL ( $P = 0.06$ ). The muscle fatigue index showed a decrease tendency for the third set in the RF ( $P = 0.08$ ). Blood flow during 30% W<sub>max</sub> showed a increase tendency with the Tights<sub>LP</sub>.

**CONCLUSIONS:** We found that Tights<sub>LP</sub> was effective for the faster recovery from muscle deoxygenation and gradual decline in muscle fatigue index during 30% W<sub>max</sub>, suggesting an enhancement of blood flow (venous return) in the lower limb during low-intensity active recovery.

**2667** Board #342 MAY 31 2:00 PM - 3:30 PM

**Regulators of Muscle Hypertrophy are Unaffected by Free Leucine Supplementation in Older Individuals**

Matthew Cooke<sup>1</sup>, Annie Allison<sup>2</sup>, Clayton Dorsa<sup>2</sup>, Carrie Nix<sup>2</sup>, Jorge Raudales<sup>2</sup>, Brian Shelmadine<sup>2</sup>, Matthew McPheeters<sup>2</sup>, Paul La Bounty<sup>2</sup>, Mike Greenwood, FACSM<sup>3</sup>, Darryn Willoughby, FACSM<sup>2</sup>. <sup>1</sup>*Victoria University, Melbourne, Australia.* <sup>2</sup>*Baylor University, Waco, TX.* <sup>3</sup>*Texas A&M, College Station, TX.*

(No relationships reported)

**PURPOSE:** To examine the effects of ingesting free leucine on serum insulin-like growth factor 1 (IGF-1), free testosterone and hepatocyte growth factor (HGF) levels and muscle tissue phosphorylated mesenchymal-epithelial transition factor (c-Met) concentrations compared to isoenergetic placebo during a 12 week resistance training program in older males.

**METHODS:** Twenty three non-resistance trained males ( $61.22 \pm 7.13$  yrs,  $176.93 \pm 5.99$  cm,  $92.59 \pm 14.59$  kg) were randomized in a double blind manner. Participants ingested either leucine (LEU) [3.6g/d LEU + 5g carbohydrate (CHO)] or maltodextrine (CHO) (5g/d CHO) while participating in a supervised high intensity resistance training program (3 sets  $\times$  10 repetitions at 75% of 1RM), 3 days per week for 12 weeks. Testing sessions were completed prior to (0 weeks), 4 weeks, 8 weeks and 12 weeks post resistance training and supplementation. Each testing session included blood collection and vastus lateralis muscle biopsy. The blood serum was analyzed for IGF-1, free testosterone and HGF and the muscle tissue for phosphorylated c-Met. Data was analyzed using repeated measures ANOVA.

**RESULTS:** No significant time effects were observed for serum free testosterone (0 weeks:  $18.79 \pm 11.2$  pg/ml vs. 12 weeks:  $18.19 \pm 12.9$  pg/ml,  $p = 0.862$ ), IGF-1 (0 weeks:  $0.686 \pm 0.503$  pg/ml vs. 12 weeks:  $0.685 \pm 0.585$  pg/ml,  $p = 0.809$ ), HGF (0 weeks:  $267.28 \pm 289.14$  pg/ml vs. 12 weeks:  $173.32 \pm 177.04$  pg/ml,  $p = 0.192$ ), or phosphorylated c-Met (0 weeks:  $0.105 \pm 0.185$  ng/mg vs. 12 weeks:  $0.230 \pm 0.239$  ng/mg,  $p = 0.09$ ). Furthermore, no significant group or group by time interactions were observed.

**CONCLUSIONS:** The ingestion of free leucine with carbohydrate, as compared to carbohydrate alone, when combined with 12-weeks of high intensity resistance training was unable to enhance serum IGF-1 and testosterone levels and/or indirect markers of satellite cell activation in older males.

---

**2668** Board #343 MAY 31 2:00 PM - 3:30 PM

**Effect Of Regular Exercise On Different Tissues Oxygenation In Retired Female Athletes**

Li-Yen Tsao<sup>1</sup>, Chu-Chun Fang<sup>1</sup>, Ching-Hung Lin<sup>2</sup>. <sup>1</sup>*National Taipei College of Business, Taipei, Taiwan.* <sup>2</sup>*Yuan Ze University, Zhongli City, Taiwan.* (Sponsor: Chia-Hua Kuo, FACSM)

(No relationships reported)

Regular exercise has been shown to improve the ability of the tissue oxygenation. However, no study has been done on different tissues oxygenation on elder athletes, who were not participating in regular exercise after retirement.

**PURPOSE:** This study was aimed to examine the effect of regular exercise on different tissues oxygenation in retired female basketball players.

**METHODS:** In this study, retired domestic A-class female basketball players were recruited. All subjects were categorized into two groups as non-exercise (n=6, aged 56.7±2.14) and regular exercise (n=6, aged 57.2±1.6) groups. Each subject's oxygenation for different tissues including left and right side of forehead, upper triceps and lower gastrocnemius muscle. Oxygenation include total hemoglobin, oxyhemoglobin, de-oxyhemoglobin and oxygen saturation were determined by using near infrared spectroscopy (NIRS) at sitting position in a quite environment.

**RESULTS:** We found muscle total hemoglobin, oxyhemoglobin, deoxyhemoglobin and oxygen saturation was not significantly different for brain, triceps and gastrocnemius muscle. We speculate that retired athletes who participated in regular exercise may have better oxygenation. However our data didn't show this trend.

**CONCLUSIONS:** The reason behind no changes in oxygenation levels between non-exercise and exercise elder athletes might be the measurement of oxygenation at sitting position. Hence, we recommend further studies to measure the oxygenation levels during dynamic process.

**2669** Board #344 MAY 31 2:00 PM - 3:30 PM

**Comparison Of Post-tetanic To Postactivation Potentiation In Human Tibialis Anterior**

Cameron B. Smith, Matti D. Allen, Charles L. Rice (FACSM), FACSM. *The University of Western Ontario, London, ON, Canada.*

(No relationships reported)

**INTRODUCTION:** Potentiation may be induced following a conditioning contraction which can either be evoked (post-tetanus (PT)) or voluntary (postactivation (PA)). However, these conditioning contractions activate the muscle fibers using dissimilar combinations of motor unit discharge rate and recruitment pattern. Additionally, evoked contractions exclude the central nervous system, which is active during a voluntary contraction.

**PURPOSE:** To explore whether PT potentiation of contractile properties differs from PA potentiation, in the human tibialis anterior.

**METHODS:** In 8 recreationally active male subjects (age ~26.0 y), we assessed potentiation of isometric contractile properties by comparing baseline contractions to PT and PA contractions. In the following order, baseline measurements were: maximal twitch torque and peak rate of twitch torque development, maximal evoked 50Hz torque, and maximal voluntary (ballistic) peak rate of torque development. In random order, potentiation was induced by either a 10s 50Hz evoked contraction, or a torque-matched 10s voluntary contraction (~76% MVC torque). Immediately following the conditioning contraction, two twitches were evoked followed by two maximal voluntary ballistic contractions. Prior to all conditioning contractions, subjects rested for a minimum of 6 min, and twitch torque had returned to baseline.

**RESULTS:** Baseline twitch torque was 5.7±1.9 Nm, which was potentiated equally (P<0.05) for PT (9.5±2.4 Nm), and PA (9.3±3.4 Nm) contractions. Peak rate of twitch torque development at baseline was 182.1±44.9 Nm/s, and was increased equally (P<0.05) for PT (305.8±65.2 Nm/s), and PA (290.9±89.1 Nm/s) contractions. Ballistic rate of torque development was not different between baseline, PT, or PA (P = 0.07).

**CONCLUSIONS:** For this experimental paradigm, PT and PA have similar potentiating effects on twitch contractile properties, and neither significantly potentiates voluntary rate of torque development immediately following either tetanus or voluntary activation.

**Skeletal Muscle Metabolism and Glucose Tolerance after Spinal Cord Injury: Influence of Intramuscular Fat and Injury Duration**

Terence E. Ryan, Jared T. Brizendine, Hui-Ju Young, Melissa L. Erickson, Kevin K. McCully, FACSM. *The University of Georgia, Athens, GA.*

(No relationships reported)

Spinal cord injury (SCI) represents one of the most extreme health conditions resulting in physical inactivity, especially in the paralyzed musculature. This lack of muscle activity results in muscle atrophy, increases in intramuscular fat, and reduced mitochondrial function.

**PURPOSE:** To examine the relationships between injury duration and intramuscular fat (IMF), mitochondrial function, and glucose tolerance in individuals with complete (AIS-A) SCI.

**METHODS:** Eleven individuals (2 female) with chronic (1.7-22.1 years post-injury) SCI gave informed consent prior to testing. All subjects completed a standard 75-gram oral glucose tolerance test at the Shepherd Hospital (Atlanta, GA). Blood samples were taken and analyzed for glucose and insulin. Magnetic resonance testing was performed in a 3 Tesla magnet. Axial T1-weighted magnetic resonance images of the thighs were collected to assess muscle volume and IMF. Muscle metabolism of the m. vastus lateralis was measured as the rate of phosphocreatine recovery after electrical stimulation using 31P MRS. Statistical significance was tested using a one-tailed t-test.

**RESULTS:** The results showed relationships between the duration of injury and mitochondrial impairment (r=0.58, p=0.03), IMF and mitochondrial impairment (r=0.58, p=0.03), and IMF and glucose tolerance (r=0.59, p=0.028). In this study we found no relationship between mitochondrial function and glucose tolerance.

**CONCLUSIONS:** The duration of spinal cord injury appears to be related to the degree of mitochondrial dysfunction and level of intramuscular fat. Intramuscular fat may be a predictor of glucose tolerance; while the role of mitochondrial function in glucose tolerance is still being investigated. Future studies will help guide the development of effective interventions to improve the health of individuals with spinal cord injury.

**Skeletal Muscle Mitochondrial and Lipid Droplet Volume Density: Validity of Electron Microscopy Point-counting Measurements**

Nicholas T. Broskey, Jean Daraspe, Bruno M. Humbel, Francesca Amati. *University of Lausanne, Lausanne, Switzerland.* (Sponsor: Elizabeth F. Nagle, FACSM)

(No relationships reported)

Mitochondrial (M) and lipid droplet (L) volume density (vd) are often used in exercise research. Vd is the volume of muscle occupied by M and L. The means of calculating these percents are accomplished by applying a grid to a 2D image taken with transmission electron microscopy; however, it is not known which grid best predicts these values.

**PURPOSE:** To determine the grid with the least variability of Mvd and Lvd in human skeletal muscle.

**METHODS:** Muscle biopsies were taken from *vastus lateralis* of 10 healthy adults, trained (N=6) and untrained (N=4). Samples of 5-10mg were fixed in 2.5% glutaraldehyde and embedded in EPON. Longitudinal sections of 60 nm were cut and 20 images were taken at random at 33,000x magnification. Vd was calculated as the number of times M or L touched two intersecting grid lines (called a point) divided by the total number of points using 3 different sizes of grids with squares of 1000x1000nm sides (corresponding to 1µm<sup>2</sup>), 500x500nm (0.25µm<sup>2</sup>) and 250x250nm (0.0625µm<sup>2</sup>). Statistics included coefficient of variation (CV), 1 way-BS ANOVA and spearman correlations.

**RESULTS:** Mean age was 67 ± 4 yo, mean VO<sub>2peak</sub> 2.29 ± 0.70 L/min and mean BMI 25.1 ± 3.7 kg/m<sup>2</sup>. Mean Mvd was 6.39% ± 0.71 for the 1000nm squares, 6.01% ± 0.70 for the 500nm and 6.37% ± 0.80 for the 250nm. Lvd was 1.28% ± 0.03 for the 1000nm, 1.41% ± 0.02 for the 500nm and 1.38% ± 0.02 for the 250nm. The mean CV of the three grids was 6.65% ± 1.15 for Mvd with no significant differences between grids (P>0.05). Mean CV for Lvd was 13.83% ± 3.51, with a significant difference between the 1000nm squares and the two other grids (P<0.05). The 500nm squares grid showed the least variability between subjects. Mvd showed a positive correlation with VO<sub>2peak</sub> (r = 0.89, p < 0.05) but not with weight, height, or age. No correlations were found with Lvd.

**CONCLUSION:** Different size grids have different variability in assessing skeletal muscle Mvd and Lvd. The grid size of 500x500nm (240 points) was more reliable than 1000x1000nm (56 points). 250x250nm (1023 points) did not show better reliability compared with the 500x500nm, but was more time consuming. Thus, choosing a grid with square size of 500x500nm seems the best option. This is particularly relevant as most grids used in the literature are either 100 points or 400 points without clear information on their square size.

(Sponsor: Ed McFarland, FACSM)  
(No relationships reported)

A variety of *in vivo* imaging techniques are being developed to assess changes in whole muscle structure and/or function. The ability to view individual myofibers is possible with many histological techniques, but not yet with standard *in vivo* imaging, such as MRI. Optical coherence tomography (OCT) is an emerging medical imaging technology that can generate high resolution 1-10  $\mu\text{m}$  cross-sectional imaging (1-2 mm in depth) of tissue microstructure *in vivo* and in real time.

**PURPOSE:** OCT has recently been used in dystrophic skeletal muscle to identify necrosis and changes after exercise. We used *in vivo* OCT to determine architectural differences of whole muscles of healthy (wild-type, or WT) and dystrophic (mdx) muscle.

**METHODS:** We examined the tibialis anterior muscles (TA) of WT mice (n=3) and mdx mice (n=3). Before OCT, high resolution T1 and T2-weighted structural MRI (100 $\mu\text{m}$  x 100 $\mu\text{m}$  x 750  $\mu\text{m}$ ) including diffusion tensor imaging (DTI, 150 $\mu\text{m}$  x 150 $\mu\text{m}$  x 750  $\mu\text{m}$  x 12 directions) were acquired on a 7T MRI system. The OCT system utilized a wavelength-swept laser source. It generates a broadband spectrum of ~100 nm FWHM centered at 1310 nm, which provides an axial resolution of 10  $\mu\text{m}$  in the tissue. Laser sweep rate was 16 kHz. A Michelson interferometer composed of one circulator, and a fiber-optic 50/50 splitter is used to generate the Fourier-domain OCT interference signal. Immediately after OCT, muscles were harvested, snap frozen in pentane-cooled liquid nitrogen, and sectioned (longitudinally) for H&E staining.

**RESULTS:** DTI was used for 3D reconstruction of fiber tracks (fascicles) and showed an increase in isotropy of mdx compared to WT TAs. OCT indicated a shorter intramuscular tendon (WT/mdx ratio of 1.5) and a 10 % higher degree of pennation in mdx. H&E staining confirmed these architectural changes.

**CONCLUSIONS:** The increase in isotropy suggested differences in pennation angles and OCT was used to confirm this supposition by imaging of individual myofibers. Because physiological cross-sectional area (PCSA) is proportional to the cosine of the pennation angle and muscle mass, the increase in pennation alone in mdx TAs would result in a corresponding reduction in stress (force/PCSA) of 10%, assuming similar fiber lengths. This reduction would be even more dramatic given the apparent increase in muscle size.

### In Vivo Imaging Of Intramyocyte Sodium Following Eccentric Contractions In Rat Skeletal Muscle

Takuma Kimura<sup>1</sup>, Tdakatsu Inagaki<sup>1</sup>, Yoshinori Tanaka<sup>1</sup>, David C. Poole, FACSM<sup>2</sup>, Yutaka Kano<sup>1</sup>. <sup>1</sup>University of Electro-Communications, Tokyo, Japan. <sup>2</sup>Kansas State University, Manhattan, KS.  
(No relationships reported)

Intramyocyte ionic balance controls various muscle functions. The primary cause of muscle fatigue and damage are believed to be induced, in part, by failure to maintain intramyocyte ionic homeostasis. Eccentric contractions (ECC) facilitate intramyocyte influx of ions such as Na<sup>+</sup> and Ca<sup>2+</sup> by operation of stretch-activated channels (SAC). We have recently shown that ECC induce prolonged elevation of myocyte Ca<sup>2+</sup> using an *in vivo* imaging model. However, little is known regarding intramyocyte Na<sup>+</sup> regulation after ECC under *in vivo* conditions

**PURPOSE:** We tested the hypothesis that ECC-induced damage and fatigue would be associated with intramyocyte Na<sup>+</sup> accumulation.

**METHODS:** For *in vivo* microscopic observation, adult male Wistar rats (n = 8) were anesthetized and the spinotrapezius muscle exteriorized maintaining principal blood vessels and neural pathways intact. Tetanic eccentric contractions (100 Hz, 700 ms duration, 20 contractions per minute for a total of 10 sets of 50 contractions) were elicited by electrical stimulation during synchronized muscle stretch of 10% resting muscle length. The fluorescence ratio (F340/F380 nm) was determined from images captured following each set of contractions, and SBFI-AM was used to estimate intracellular Na<sup>+</sup> and changes thereof.

**RESULTS:** Isometrically-evoked active force was decreased significantly with each set of ECC (-76.8  $\pm$  0.9 % at end of 10th set vs. initial force). Morphological features of muscle damage such as extreme sarcomeric disruption and hypercontracted fibers were clearly evident. However, there was no significant change of intracellular Na<sup>+</sup> level over the 10 sets of ECC (pre-contraction : 1.68  $\pm$  0.03, 1 set : 1.66  $\pm$  0.03, 5 set : 1.66  $\pm$  0.03, 10 set : 1.62  $\pm$  0.03, 340/380 ratio value, p >0.05).

**CONCLUSIONS:** These results demonstrate that intracellular Na<sup>+</sup> homeostasis is maintained following ECC. Therefore muscle damage and fatigue after ECC are not associated with lack of Na<sup>+</sup> homeostasis *per se*.

2674 Board #349 MAY 31 2:00 PM - 3:30 PM

### Muscle Adaptations Following Short-Duration Bed Rest with Integrated Resistance, Interval, and Aerobic Exercise

Kyle J. Hackney<sup>1</sup>, Jessica M. Scott<sup>2</sup>, Roxanne Buxton<sup>3</sup>, Elizabeth Redd-Goetchius<sup>3</sup>, J. Brent Crowell<sup>4</sup>, Meghan E. Everett<sup>3</sup>, Jason Wickwire<sup>1</sup>, Jeffrey Ryder<sup>2</sup>, Jacob J. Bloomberg<sup>5</sup>, Lori L. Ploutz-Snyder, FACSM<sup>2</sup>. <sup>1</sup>Wyle Integrated Science & Engineering Group, Houston, TX. <sup>2</sup>Universities Space Research Association, Houston, TX. <sup>3</sup>University of Houston, Houston, TX. <sup>4</sup>MEI Technologies, Houston, TX. <sup>5</sup>National Aeronautics and Space Administration, Houston, TX. (Sponsor: Lori Ploutz-Snyder, FACSM)  
(No relationships reported)

Exercise countermeasures have been frequently tested during bed rest (BR) and limb suspension; however, high-intensity, short-duration exercise prescriptions have not been explored.

**PURPOSE:** To determine if a high intensity resistance, interval, and aerobic exercise program could protect against muscle atrophy and dysfunction when performed during short duration BR.

**METHODS:** Nine subjects (1F,8M) performed a combination of supine exercises during 2 weeks of BR. Resistance exercise (3 d  $\cdot$  wk<sup>-1</sup>) consisted of squat, leg press, hamstring curl, and heel raise (3 sets, 12 repetitions). Aerobic (6 d  $\cdot$  wk<sup>-1</sup>) sessions alternated continuous (75% VO<sub>2</sub> peak) and interval exercise (30s, 2 & 4min) and were completed on a supine cycle ergometer and vertical treadmill. Muscle volumes were calculated pre, mid, and post-BR using magnetic resonance imaging. Maximal isometric force (MIF), rate of force development (RFD), and peak power were measured twice before BR (averaged to represent pre) and once post BR. ANOVA with repeated measures and *a priori* planned contrasts tested differences.

**RESULTS:** There were no changes to quadriceps, hamstring, and adductor muscle volumes at mid and post BR compared to pre BR (Table 1). Peak power increased significantly from 1614  $\pm$  372 W to 1739  $\pm$  359 W post BR (+7.7%, p = 0.035). Neither MIF (pre: 1676  $\pm$  320 N vs. post: 1711  $\pm$  250 N, +2.1%, p = 0.333) nor RFD (pre: 7534  $\pm$  1265 N $\cdot$ ms<sup>-1</sup> vs. post: 6951  $\pm$  1241 N $\cdot$ ms<sup>-1</sup>, -7.7%, p = 0.136) were significantly impaired post BR.

Table 1.

| Muscle Group    | Pre           | Mid           | Post          | % change <sup>^</sup> | p-value <sup>†</sup> |
|-----------------|---------------|---------------|---------------|-----------------------|----------------------|
| Quadriceps (mL) | 974 $\pm$ 104 | 989 $\pm$ 104 | 992 $\pm$ 109 | +1.84%                | 0.083                |
| Hamstrings (mL) | 466 $\pm$ 76  | 468 $\pm$ 82  | 471 $\pm$ 83  | +1.07%                | 0.662                |
| Adductors (mL)  | 386 $\pm$ 57  | 382 $\pm$ 67  | 377 $\pm$ 63  | -1.03%                | 0.321                |

Mean  $\pm$  SD; <sup>^</sup>Pre to Post; <sup>†</sup>ANOVA time effect

**CONCLUSION:** A combination of high intensity, short duration exercise countermeasures performed during 2 weeks of BR increased concentric power and protected muscle from unloading induced atrophy and dysfunction.

**2675** Board #350 **MAY 31 2:00 PM - 3:30 PM**  
**Pgc-1 $\alpha$  Enhances Skeletal Muscle Recovery From Disuse Atrophy**

Choung-Hun Kang, Craig Goodman, Troy Hornberger, Li Li Ji, FACSM. *University of Wisconsin-Madison, Madison, WI.*  
(No relationships reported)

Prolonged inactivity results in skeletal muscle atrophy including increased reactive oxygen species generation, inflammation, protein degradation, and weight loss. Over-expression of peroxisome proliferator-activated receptor- $\gamma$  coactivator-1 $\alpha$  (PGC-1 $\alpha$ ) has been shown to increase mitochondria biogenesis and reduce oxidative stress. **PURPOSE:** Thus, we hypothesize that PGC-1 $\alpha$  over-expression may ameliorate skeletal muscle atrophy caused by immobilization in rats.

**METHODS:** FVB/N mice (Age 8 mo, N=20) were randomly divided into four groups; (1) control and injected with empty vehicle (GFP) transfection (Con-GFP); (2) control and injected with Flag-PGC-1 (Con-PGC-1); (3) five days remobilization after 2 weeks of immobilization with hindlimb banding and injected with GFP (RM-GFP); and (4) RM and injected with PGC-1 (RM-PGC-1). GFP or PGC-1 was injected to tibialis anterior (TA) muscle of one of the hindlimbs with a skeletal muscle gene electroporation.

**RESULTS:** There was a decrease in Cytochrome C (Cyt C) expression after 2 weeks immobilization, whereas Cyt C was significantly increased by ~3.9-fold in both Con and RM groups with PGC-1 in vivo transfection. RM mediated ~20% decrease in Tfam expression (p<0.05), however, its level was restored by PGC-1 overexpression in RM group (p<0.01). mtDNA:nDNA ratio was decreased by 72% in RM groups (p<0.01), whereas PGC-1 increased the mtDNA significantly (p<0.05). PGC-1 increased cytochrome c oxidase (COX) activity by 55% in CON (p<0.05) and by 29% in RM and mitochondrial ATP production rate (MAPR) was increased by 18% in RM-PGC-1 (p<0.05).

**CONCLUSIONS:** PGC-1 enhanced mitochondrial biogenesis and oxidative capacity in the recovery of skeletal muscle from disuse atrophy.

**2676** Board #351 **MAY 31 2:00 PM - 3:30 PM**  
**Sex-Related Difference in Muscle Oxygenation Kinetics during Isometrics Contraction in Older Adults**

Tai -You Lin, Linda L. Lin, Jia-Jin J. Chen. *National Cheng Kung University, Tainan, Taiwan.*  
(No relationships reported)

**PURPOSE:** The aim of this study was to investigate the effect of sex-related on local muscle oxygenation kinetics and oxygen desaturation through relative intensity exercise.

**METHODS:** Nine male (M) (aged 65  $\pm$  2.2 yr) and seven female (F) (aged 60  $\pm$  5.7yr) were recruited. All subjects performed 20, 30, 40, 50 and 60% maximum voluntary contraction (MVC) of knee extension exercise by a custom-made isometrics strength device. Local muscle oxygenation was recorded by a frequency-domain Near-infrared spectroscopy (Imagent, ISS Inc.). Infrared light of 690 and 830 nm wavelengths were applied to estimate hemodynamic parameters of vastus lateralis obliquus muscle. Outcome measures derived from oxy-hemoglobin (Hb), deoxy-Hb, total Hb (Hbt) and oxygen saturation using a hyperbolic tangent equation to fit the oxygen saturation curves of exercise phase and recovery phase. Inflection time (time to reach 50 % of the change range) represents the efficiency of reaching steady-state level. Time constant (the changing rate of oxygen desaturation) was used to represent the characteristic of oxygenation adjustment during isometrics contraction. The minimum and maximum values of each phase will be found to estimate the change volume. The dependent variables both groups were compared by Mann-Whitney U test.

**RESULTS:** In exercise phase, phase, the inflection time in M was longer than F at 60% MVC (41.66  $\pm$  2.52s vs. 38.71  $\pm$  2.75s, p<0.05). Time constant was significantly lower in F than M at 20% MVC (4.2  $\pm$  2.21 vs. 6.92  $\pm$  2.17, p<0.05) and a larger time constant in W at 40% MVC (7.99  $\pm$  1.53 vs. 5.16  $\pm$  1.36, p<0.05). A great oxygen desaturation in man at 20% MVC (8.51  $\pm$  5.79% vs. 2.17  $\pm$  1.32%, p<0.05), 30% MVC (11.51  $\pm$  7.26% vs. 4.18  $\pm$  2.18%, p<0.05), 50% MVC (14.96  $\pm$  7.82% vs. 7.92  $\pm$  4.02%, p<0.05) and 60% MVC (15.75  $\pm$  8.23% vs. 8.64  $\pm$  2.46%, p<0.05) than Female (p< 0.05).

**CONCLUSIONS:** At the same relative exercise intensity, female reduce oxygen consumption which can support energy demand during muscle contraction. The results suggest that sex-related difference in muscle oxygenation can be observed in exercise phase. Future, it is important to find the sex-related difference in muscle oxygenation at other age levels to get a better understanding on sex-related factor.

**2677** Board #352 **MAY 31 2:00 PM - 3:30 PM**  
**Protein Expression and Activity of Antioxidant Enzymes in the Muscle of Rats Subjected to Exercise**

Roberto Carlos Vieira Junior<sup>1</sup>, Carolina Mendes S. Silva<sup>1</sup>, Marisa C. Voltarelli<sup>1</sup>, Alesandro Garcia<sup>1</sup>, Michel B. Araújo<sup>2</sup>, Vanessa A. Voltarelli<sup>3</sup>, Fabricio A. Voltarelli<sup>1</sup>.  
<sup>1</sup>Federal University of Mato Grosso (UFMT), Cuiabá-MT, Brazil. <sup>2</sup>Sao Paulo State University (UNESP), Rio Claro-SP, Brazil. <sup>3</sup>University of Sao Paulo (USP), São Paulo-SP, Brazil.  
(No relationships reported)

**PURPOSE:** The goal of the present study was to analyze the activity and protein expression of the antioxidant enzymes catalase (CAT), superoxide dismutase (SOD) and glutathione peroxidase (GPx) as well as a lipid peroxidation biomarker (thiobarbituric acid reactant substances; TBARs) in the skeletal muscle of rats subjected to swimming exercise.

**METHODS:** Eighteen male Wistar rats were used. With 90 days of age, the animals were divided into 2 groups: Control Group (C: n=10): rats maintained as sedentary controls; Trained Group (T: n=8): rats subjected to swimming exercise. The exercise protocol consisted of 1h/day of swimming exercise, 5x/week, during 8 weeks. The animals carried out overload equivalent to 5% of body weight. At the end of the experiment, the rats were killed by CO<sub>2</sub> inhalation and cervical dislocation; samples of gastrocnemius muscles (200mg) of all rats were collected for antioxidant enzymes activities (Cayman Chemical, Michigan, USA) as well as protein expression (western blotting; Primary and secondary antibodies Santa Cruz Biotechnology, inc.) determinations; the lipid peroxidation biomarker (Cayman Chemical, Michigan, USA) was also determined. The data were analyzed using Student t-test (p value of <0.05).

**RESULTS:** The antioxidant enzymes activities levels were significantly higher in the skeletal muscle of T group [CAT (Umol/min.mg.protein): 0.87 $\pm$ 0.04; SOD (U/ml): 6.49 $\pm$ 0.04; GPx (nmol/min.protein): 6.57 $\pm$ 0.52] if compared to C group (CAT: 0.51 $\pm$ 0.03; SOD: 4.01 $\pm$ 0.37; GPx: 2.94 $\pm$ 0.56). On the other hand, the TBARs levels (nmol/mg.protein) were significantly lower in the skeletal muscle of T group (2.34 $\pm$ 0.41) when compared to C group (8.94 $\pm$ 0.56). In addition, the protein expression of antioxidant enzymes were found increased (CAT: 25%; SOD: 33%; GPx: 23%) in the gastrocnemius muscle of rats belonging to T group if compared to C Group.

**CONCLUSIONS:** The antioxidant mechanisms were improved (increased protein expressions and activities of the antioxidant enzymes and decreased lipid peroxidation) in the skeletal muscle of rats subjected to chronic swimming exercise. Such results indicated that regular physical exercise may protect the organism against the oxidative stress caused by the sedentarism condition.

**Aging is Associated with Increased Skeletal Muscle Type IV Collagen Content and Decreased MMP-2 Expression in Mice**

Ryan S. Mehan, Molly C. Madden, Brooke J. Greybeck, Cameron R. Niswander, David L. Allen. *University of Colorado - Boulder, Boulder, CO.* (Sponsor: William C. Byrnes, FACSM)  
(No relationships reported)

Aging is associated with decreases in muscle size and force production and increased connective tissue content. However, the role of matrix metalloproteinases (MMPs) in aging related changes in muscle collagen content is not clear.

**PURPOSE:** To examine the expression of type IV collagen and its degrading enzymes MMP-2 and MMP-9 in slow and fast-twitch muscles of younger (3 month old) and older (22 month old) mice.

**METHODS:** Younger and older WT mice were run on a rodent treadmill at a 17% downhill gradient at 15meters/min for 3 bouts of 30min. Blood was taken pre, immediately post, and 1 day post-exercise. Gastrocnemius (GAST) and soleus (SOL) muscles were isolated and trunk blood collected 1 day post-exercise. Semi-quantitative PCR was performed to determine levels of MMP-2, MMP-9, and TIMP-1 mRNA. Plasma MMP-2, pro-MMP-9, total MMP-9, and TIMP-1 protein levels were determined by ELISA assay. Type IV collagen immunohistochemistry was performed on 10um-thick serial cross sections of GAST and SOL. Threshold analysis using ImageJ64 was performed to determine collagen-staining quantity.

**RESULTS:** The relative percentage of type IV collagen immunostaining was significantly greater in muscle sections from older GAST and SOL compared to younger muscle. Plasma levels of MMP-2 were significantly lower in older compared to younger mice, while neither pro- nor total plasma MMP-9 levels differed between younger and older mice. MMP-2 mRNA levels were significantly lower in both GAST and SOL of older mice compared to younger mice. Plasma TIMP-1 levels were significantly higher in older compared to younger mice, however TIMP-1 mRNA levels did not differ between the two age groups but were greater in the SOL compared to the GAST.

**CONCLUSION:** Age-related changes in systemic and/or muscle MMP-2 expression may contribute to the accumulation of type IV collagen observed in aging muscle.

**Intramuscular Doxorubicin Accumulation and Skeletal Muscle Function**

Eric C. Bredahl, Noah M. Gibson, Stephanie E. Greufe, Keith B. Pfannenstiel, Traci L. Parry, Carole M. Schneider, FACSM, Reid Hayward, David S. Hydock.

University of Northern Colorado, Greeley, CO.

(No relationships reported)

Doxorubicin (DOX) is powerful anthracycline antibiotic used to treat a wide variety of cancers. DOX has been linked to debilitating side effects, and recent studies have reported a DOX-induced decline in skeletal muscle function. However, the connection between intramuscular DOX accumulation and muscle dysfunction has yet to be determined.

**PURPOSE:** To evaluate the effects of DOX on type I and type II muscle function and DOX accumulation.

**METHODS:** Male Sprague-Dawley rats received 15 g/kg DOX i.p. (n=27) or an equivalent volume of saline i.p. as a control (CON, n=11). Soleus (SOL) and extensor digitorum longus (EDL) function was assessed *ex vivo* 1 day (n=9), 3 days (n=10), or 5 days (n=8) post DOX injections. DOX accumulation in skeletal muscle was then assessed using high performance liquid chromatography.

**RESULTS:** No significant SOL or EDL maximal twitch force differences were observed 1 day or 3 days post DOX when compared to CON (p>0.05). However, SOL maximal twitch force 5 days post DOX was significantly lower than CON (19±5 mN vs. 39±3 mN, respectively, p<0.01), and EDL maximal twitch force 5 days post DOX was significantly lower than CON (34±4 mN vs. 76±8 mN, respectively, p<0.01). SOL DOX accumulation at 1, 3, and 5 days post injection was (in ng DOX/g of tissue) 269±35, 147±29, and 166±45, respectively. The only significant DOX accumulation difference observed between SOL and EDL was at day 1 (p<0.01). Significant reductions in intramuscular DOX levels were observed in SOL between days 1 and 5 (p<0.01) and days 3 and 5 (p<0.05), but significant reductions in intramuscular DOX levels were not observed between days 1, 3, or 5 in the EDL (p>0.05).

**CONCLUSIONS:** Although DOX treatment resulted in depressed skeletal muscle function in both the SOL and EDL, differences in intramuscular DOX accumulation and clearance were observed between the SOL and EDL. DOX levels were higher in the SOL when compared to EDL, but this elevated level also declined significantly over time in the SOL suggesting differential accumulation and clearance of DOX in type I and type II muscle.

**Skeletal Muscle Quality Is Associated With Physical Function In People With COPD**

Priscila Robles<sup>1</sup>, Dina Brooks<sup>1</sup>, Roger Goldstein<sup>1</sup>, Ali Naraghi<sup>2</sup>, Marshall Sussman<sup>2</sup>, Larry White<sup>2</sup>, Sunita Mathur<sup>1</sup>. <sup>1</sup>University of Toronto, West Park Healthcare Centre, Toronto, ON, Canada. <sup>2</sup>University of Toronto, University Health Network, Toronto, ON, Canada.

(No relationships reported)

The loss of muscle mass and muscle strength observed in people with chronic obstructive pulmonary disease (COPD) has been associated with impaired mobility and lower physical activity levels. However, muscle atrophy alone does not fully explain the loss of function. Changes in muscle quality (e.g. fatty infiltration) may also account for impaired functional performance.

**PURPOSE:** To compare skeletal muscle quality in people with COPD to controls using magnetic resonance imaging and proton spectroscopy (MRI/1H-MRS) and to correlate it with measures of muscle function and physical activity.

**METHODS:** Seven individuals with moderate to severe COPD and seven control subjects underwent T1-weighted MRI at 1.5T to obtain maximal muscle cross-sectional area (CSA<sub>max</sub>) of the quadriceps, hamstrings, dorsi- and plantar-flexors; and 1H-MRS of the vastus lateralis and soleus muscles to obtain lipid:water ratio. Isometric and isokinetic peak torque of the same muscle groups, six-minute walk distance (6MWD) and physical activity levels using a questionnaire (PASE score) were also assessed.

**RESULTS:** People with COPD and controls were matched for age (72±6.7 vs 69±9.3 yrs), sex (3 males, 4 females) and body mass index (25±6.2 vs 25±4.6 kg/m<sup>2</sup>). Compared with controls, people with COPD had ~30% lower CSA<sub>max</sub> of their quadriceps, hamstrings and plantarflexors (p<0.05); whereas muscle strength of the same muscle groups was ~60% lower in people with COPD (p<0.05). Lipid:water ratio was ~55% higher in COPD vs controls for the vastus lateralis and soleus (p=0.003; p=0.02). 6MWD was lower in people with COPD (248 m vs 639 m; p=0.02); however, no difference was observed between groups for PASE score. CSA<sub>max</sub> of the quadriceps and plantarflexors were correlated with peak torque (r=0.87; r=0.83). Correlations were also observed between lipid:water ratio and peak torque (r=-0.93), 6MWD (r=-0.91) and PASE scores (r=-0.89). **CONCLUSION:** Muscle atrophy and greater fatty infiltration was observed across thigh and calf muscles of people with COPD and was associated with muscle strength, 6MWD and physical activity. Functional impairments in muscle strength were more profound than muscle atrophy and highly associated with poor muscle quality in people with COPD.

**Prevalence of Mitochondrial Respiratory Chain Deficiency in Skeletal Muscle of Chronic Obstructive Pulmonary Disease Patients**

Yana Konokhova, Martin Picard, Gilles Gouspillou, Sophia Kapchinsky, Jacinthe Baril, Thomas Jagoe, Tanja Taivassalo. McGill University, Montreal, QC, Canada.

(No relationships reported)

Chronic obstructive pulmonary disease (COPD) is characterized by exercise intolerance and peripheral muscle weakness and dysfunction. Alterations in skeletal muscle structure and metabolic properties are common and include fiber atrophy, type II fiber predominance and decreased mitochondrial content and oxidative capacity. Interestingly, these cellular characteristics are also common features of healthy aging muscle. Consequently, it has been suggested that COPD pathophysiology is characterized by a premature aging phenotype. A major marker of age-related cellular muscle damage is the focal loss of cytochrome c oxidase (COX, a respiratory chain enzyme encoded by mitochondrial DNA) activity, which arises secondary to mitochondrial DNA damage from oxidative stress, resulting in compromised mitochondrial respiratory capacity. However, the prevalence of this COX deficiency in COPD has not previously been investigated.

**PURPOSE:** To quantify the levels of COX deficient myofibers in patients with COPD.

**METHODS:** Histochemistry using combined COX and succinate dehydrogenase (SDH, a respiratory system enzyme encoded by nuclear DNA) stains was used to identify respiratory deficient myofibers in quadriceps of 12 COPD patients (mean age 68±5yr, FEV1=48±15% predicted). The proportions of COX normal and deficient fibers, as well as fiber cross-sectional area, were determined using Image J software by two independent investigators.

**RESULTS:** Muscle sections from 9 patients had COX deficient myofibers. On average, 0.37% of all myofibers analyzed (n=10,945) were COX deficient, a proportion exceeding over 7-fold the established standard values for that age group (-0.05%, Sleight et al. Muscle and Nerve 2011). Compared to COX normal, COX deficient fibers were not significantly different in size.

**CONCLUSION:** The higher proportion of COX-deficient myofibers in our participants support the notion that COPD is characterized by an accelerated aging phenotype. Biochemical and molecular genetic analyses are currently underway to determine if the COX deficient fibers identified in these patients contain age-related clonally-expanded mitochondrial DNA deletions and greater oxidative stress compared to COX normal fibers, which would provide a molecular basis for this age-related biochemical defect.

**In Vivo Measurement of Intercellular pH and Contractile Performance During Repetitive Stimulation in Rat Skeletal Muscle**

Yoshinori Tanaka<sup>1</sup>, Tadakatsu Inagaki<sup>1</sup>, Takuma Kimura<sup>1</sup>, David C. Poole, FACSM<sup>2</sup>, Yutaka Kano<sup>1</sup>. <sup>1</sup>University of Electro-Communications, Tokyo, Japan. <sup>2</sup>Kansas State University, Manhattan, KS.  
(No relationships reported)

Homeostasis of intracellular pH (pHi) serves a crucial role for maintenance of cellular function. However, the relationship between muscle force/fatigue and pHi under physiological (circulation intact) conditions remains unclear.

**PURPOSE:** Using an in vivo bioimaging model, we tested the hypothesis that muscle fatigue would be associated closely with a reduction in pHi during tetanic muscle contractions.

**METHODS:** The intact spinotrapezius muscle of adult Wistar rats (n = 7) was exteriorized and loaded with the fluorescent probe BCECF-AM (10 μM). Tetanic isometric contractions (20 contractions/min for a total of 10 sets of 50 contractions) were elicited by electrical stimulation (100 Hz, 4-7 V). The fluorescence ratio (F500 nm/F445 nm) was determined from images captured following each set of contractions was used to estimate pHi and changes thereof.

**RESULTS:** Tetanic force at the end of set 3 was decreased significantly to  $-54.7 \pm 2.3\%$  of initial force ( $P < 0.01$ ). On the other hand, there was no significant change of pHi throughout this period. Subsequently, tetanic force declined gradually until set 10 ( $-38.3 \pm 3.2\%$  of initial force at set 1) by which time pHi was reduced substantially (set 5:  $-10.0 \pm 2.7\%$ , set 10:  $-19.9 \pm 3.9\%$  vs. pre-contractions). Below  $\sim 55\%$  initial force further reductions in force and pHi correlated tightly ( $r = 0.97$ ,  $P < 0.001$ ).

**CONCLUSIONS:** These results demonstrate two distinctly different profiles of pHi during fatiguing stimulation protocol. Although initial muscle fatigue is independent of the pHi, decline of pHi during sequential bouts of muscle contractions is associated closely with fatigue. This model offers a unique opportunity to investigate the consequences of experimental manipulations of pH on muscle fatigue under close-to-physiological conditions.

**Effect Of Aging On The Relationship Between Knee Angle And Triceps Surae Power Output**

Matti D. Allen, Brian H. Dalton, Geoff A. Power, Charles L. Rice, FACSM. The University of Western Ontario, London, ON, Canada.  
(No relationships reported)

**INTRODUCTION:** Human adult aging is associated with a loss of strength, contractile velocity and power of the plantar flexors, but the effect of knee joint angle on the force-velocity relationship and hence power is unknown. As the dominant plantar flexor (PF), the triceps surae is comprised of the bi-articular gastrocnemii and the mono-articular soleus, and in young men isometric PF torque and power are reduced in knee flexion compared with extension. In addition to mechanical differences in these muscles there are dissimilar histochemical and electrophysiological properties; but it is unknown how changes in these may alter torque and power with aging.

**PURPOSE:** To assess the effects of adult aging and knee angle on PF performance.

**METHODS:** Neuromuscular properties were recorded from 11 young ( $\sim 25$  y) and 11 old ( $\sim 78$  y) men with either the knee extended ( $170^\circ$ ) or flexed ( $90^\circ$ ). Participants performed isometric maximal voluntary contractions (MVCs), followed by maximal dynamic shortening contractions using the isotonic mode of a Biodex at loads from 15%, 20%, 30%, 45%, 60% and 75% of MVC; applied in random order.

**RESULTS:** The young were stronger ( $\sim 25\%$ ), faster ( $\sim 13\%$ ) and more powerful ( $\sim 30\%$ ) than the old in all static and dynamic contractions. In both young (170 Nm vs 203 Nm) and old (128 Nm vs 154 Nm), MVC was greater in the extended than flexed position, respectively, with no difference in voluntary activation ( $\sim 96\%$ ). There was no difference between age groups in the degree of strength decrement from the extended (young  $\sim 17\%$ , old  $\sim 15\%$ ) to the flexed position. The young men produced (7-10%) faster shortening velocities with their knee extended for the 15%, 20% and 30% of MVC contractions, but no differences for higher loads; whereas there were no differences in shortening velocity between knee positions in the old group across all relative loads. In the young, power production was  $\sim 20$ - $25\%$  greater in the extended knee across all loads, whereas the old had greater power at lower loads, but similar power in both knee positions at  $> 45\%$  of MVC.

**CONCLUSION:** Results indicate that the presumed age-related preferential loss of Type II muscle fibers may lead to impairment in gastrocnemius function, causing an age-related attenuation of differences in plantar flexion function between extended and flexed knee angles.

**Median Power Frequency As A Parameter To Measure Muscle Fatigue During Intense Exercise**

Gustavo Sierra. UACJ, Cd Juarez, Mexico.  
(No relationships reported)

Fatigue may be explained as a task dependent multifactorial phenomenon. Alterations in muscle performance, especially during muscle fatigue may be analyzed through the use of surface electromyography (sEMG). Changes in sEMG during muscle contraction can be observed and have been used to describe various aspects of motor unit activation.

**PURPOSE:** The purpose of the study was to quantify the level of muscle fatigue at the end of a VO<sub>2max</sub> test in comparison with an anaerobic test (AnT). To assess muscle fatigue, the median power frequency (MPF) of the sEMG signals was computed before, during and after the two tests.

**METHODS:** Six aerobically conditioned men ( $28 \pm 6.5$  yr;  $60.9 \pm 9.7$  mL/kg/min) performed two cycle ergometry tests on different days. VO<sub>2max</sub> testing began at 15% of peak watts (previously determined) and every minute an increment of 11% was added until exhaustion. AnT began at 100% of peak watts and continued until exhaustion. Six bipolar channels continuously assessed sEMG of the rectus femoris (RF), vastus medialis (VM) and vastus lateralis (VL) for both legs. Raw data segments of 20% of the total test time were further analyzed. MPF values were normalized to the maximal voluntary contraction (MVC) preceding each test. Data were analyzed using separate muscle- and leg-specific 2 (test type) by 2 (pre-, post-test) ANOVAs with repeated measurement and  $\alpha = .05$  to observe differences in the MPF during the last 20% segment of the tests.

**RESULTS:** The interaction effect was significant for the left VM (VO<sub>2max</sub>= $79.39 \pm 11.26\%$  vs anaerobic test =  $88.28 \pm 9.6\%$ ):  $F(1,6) = 8.517$ ,  $p = .027$ ; the right RF (VO<sub>2max</sub>= $92.91 \pm 8.85\%$  vs anaerobic test =  $82.82 \pm 10.51\%$ ):  $F(1,5) = 12.608$ ,  $p = .016$ ; and the right VL (VO<sub>2max</sub>=  $93.46 \pm 8.78$  vs anaerobic test =  $80.54 \pm 13.17$ ):  $F(1,5) = 7.583$   $p = .033$ .

**CONCLUSION:** For our sample, muscle fatigue at the end of a VO<sub>2max</sub> was not maximal; there was a reserve of muscle fiber recruitment mainly from the slow-twitch fiber type. EMG signals may be used to evaluate muscle fatigue during intense exercise. We found the median frequency to be the most sensitive signal.

**Mechanomyographic Frequency Domain Responses During Fatiguing Concentric Isokinetic Leg Extensions**

Trent J. Herda<sup>1</sup>, Eric D. Ryan<sup>2</sup>, Michael A. Cooper<sup>1</sup>, Joel T. Cramer, FACSM<sup>3</sup>. <sup>1</sup>University of Kansas, Lawrence, KS. <sup>2</sup>University of North Carolina - Chapel Hill, Chapel Hill, NC. <sup>3</sup>Oklahoma State University, Stillwater, OK.  
(No relationships reported)

The mechanomyographic (MMG) represents a summation of the mechanical activity from individual motor units. During voluntary contractions, it has been suggested that the frequency domain parameters may reflect the firing rate. Furthermore, during fatiguing concentric isokinetic muscle actions it is believed that the median frequency may reflect the decrease in recruitment of fast-twitch muscle fibers.

**PURPOSE:** The purpose of the present study was to examine the MMG median frequency (MDF) responses of the vastus lateralis (VL) and rectus femoris (RF) during concentric isokinetic leg extension endurance tests.

**METHODS:** Twenty-four healthy men (mean  $\pm$  SD, age =  $23 \pm 4$  yrs, body mass  $82 \pm 12$  kg) volunteered for this investigation. The MMG sensor (EGAS-FS-10/V05; Measurement Specialties, Inc., Hampton, VA) was placed over the VL and RF of the muscle at 50% of the distance between the greater trochanter and lateral condyle of the femur. Each participant completed the leg extension endurance test on the Biodex System 3 isokinetic dynamometer. Three to five submaximal trials preceded 50 consecutive maximal concentric isokinetic leg

extension muscle actions performed at  $180^{\circ}\text{s}^{-1}$  with the right leg. Not all subjects were able to complete all 50 repetitions; however, all subjects did complete at least 48 repetitions. Therefore, the first 48 repetitions were analyzed. Percent decline calculations were used to measure the changes in  $\text{MMG}_{\text{MDF}}$  during the endurance tests (percent decline = initial  $\text{MMG}_{\text{MDF}}$  - final  $\text{MMG}_{\text{MDF}} \div$  initial  $\text{MMG}_{\text{MDF}} \times 100$ ). The initial  $\text{MMG}_{\text{MDF}}$  was calculated as the average of the 3 highest values, whereas the final  $\text{MMG}_{\text{MDF}}$  represented the average of the 3 lowest values during the endurance test. A paired-samples *t* test was used to examine if there was a difference between the VL and RF on percent decline of  $\text{MMG}_{\text{MDF}}$ .

**RESULTS:** There was a greater ( $P < 0.001$ ) percent decline in  $\text{MMG}_{\text{MDF}}$  for the RF ( $59.52 \pm 4.85\%$ ) than the VL ( $50.95 \pm 7.38\%$ ) during the fatiguing leg extension tests.

**CONCLUSION:** The results of the present study indicated that the  $\text{MMG}_{\text{MDF}}$  responses during the fatiguing concentric isokinetic leg extensions reflected the differences between fiber type compositions of RF and VL muscles.  $\text{MMG}_{\text{MDF}}$  may have reflected a fatigue-induced "dropout from recruitment" of fast-twitch fibers, which are more abundant in RF than the VL.

**Creatine Kinase Inhibition with Iodoacetamide Does Not Alter Microvascular PO<sub>2</sub> On-kinetics and Twitch Tension in the Rat EDL**

R. Reed Lambert, Tyler G. Robertson, William L. Sexton, FACSM. *A.T. Still University, Kirksville, MO.*

(No relationships reported)

Creatine kinase (CK) catalyzes the reversible reaction in which high-energy phosphates are shuttled between phosphocreatine and ADP. Thus, CK is a pivotal regulator of energy flux in skeletal muscle at the onset of contractions when the metabolic demand increases. The microvascular PO<sub>2</sub> (PO<sub>2mv</sub>) reflects the dynamic relationship between oxygen delivery (QO<sub>2</sub>) and oxygen consumption (VO<sub>2</sub>). Inhibition of CK with iodoacetamide (IA) has recently been shown to slow VO<sub>2</sub> on-kinetics and to impair force production in vasodilated canine muscle.

**PURPOSE:** The purpose of this study was to determine the impact of CK inhibition on PO<sub>2mv</sub> on-kinetics and muscle twitch tension in the auto-perfused rat extensor digitorum longus muscle (EDL).

**METHODS:** The predominantly fast-twitch, EDL of female Sprague Dawley rats (n=20) was isolated and the distal tendon was attached to load cell interfaced with a Muscle Tension Analyzer. PO<sub>2m</sub> was measured with the phosphorescence quenching method using Oxyphor G2. All animals first completed a 3 min electrical stimulation (1 Hz, 6V) during which PO<sub>2m</sub> and twitch tension were measured continuously. After recovery the rats were randomly assigned to either a IA treatment group (46 mg/kg) or a saline vehicle control (C). The stimulation bout was repeated 10 min later to assess the effect of CK inhibition.

**RESULTS:** Baseline PO<sub>2m</sub>, PO<sub>2m</sub> on-kinetics, and EDL twitch tension for IA and C groups were not different during the initial contraction bout. During the second contraction bout (after IA), there was no difference in pre-stimulation PO<sub>2m</sub> in IA and C rats ( $25 \pm 1$  and  $23 \pm 1$  mmHg) or on-kinetics as reflected in similar time delay (IA  $4 \pm 1$ ; C,  $3 \pm 1$  s) and time constant (IA,  $15 \pm 2$  s; C,  $15 \pm 2$  s). Twitch tension was not different between IA and C revealing only minimal fatigue (IA,  $-5 \pm 2$ ; C,  $-8 \pm 2\%$ ) over the 3 min bout.

**CONCLUSIONS:** Contrary to expectations, IA did not alter PO<sub>2m</sub> on-kinetics or muscle contractile function. The reason for the lack of effect of IA in the present study is unclear, however, they may reflect differences in the experimental preparation (i.e., twitch contractions in an auto-perfused, predominantly fast-twitch muscle in rats) or that the dose of iodoacetamide was insufficient. **Resveratrol Improves Muscle Function, Increases Utrophin Expression, And Decreases Inflammation In The Mdx Mouse**

Bradley S. Gordon, Diana C. Delgado Diaz, Matthew C. Kostek. *University of South Carolina, Columbia, SC.* (Sponsor: James A. Carson, FACSM)

(No relationships reported)

Duchenne Muscular Dystrophy (DMD) is fatal X-linked genetic muscle disease characterized by reduced muscle function, increased oxidative stress, and inflammation for which there is no good treatment. Resveratrol is a compound found in various foods that has anti-inflammatory and antioxidant effects.

**PURPOSE:** Examine the effect of resveratrol in the mdx mouse model of DMD on muscle function and pathology.

**METHODS:** Mice were given resveratrol (100 mg/kg) via oral gavage everyday for 10 days or every other day for 8 weeks. Rotarod performance and in-situ muscle function were examined before and after 8 weeks of treatment. Inflammation was quantified from H&E stained gastrocnemius muscle samples after 10 days of treatment. PGC-1 $\alpha$  and utrophin mRNA expression, and total utrophin protein were analyzed by qRT-PCR and western blot respectively after 10 days of treatment.

**RESULTS:** Resveratrol treatment increased Rotarod performance  $53 \pm 15\%$  ( $p < 0.05$ ). In-situ peak tension of the triceps surae muscle complex increased  $9.5 \pm 2\%$  with resveratrol treatment ( $p < 0.05$ ). Time to fatigue during a tetanic contraction of the triceps surae muscle complex increased  $44 \pm 18\%$  with resveratrol treatment ( $p < 0.05$ ). Overall inflammation was reduced  $20.7 \pm 6\%$  after 10 days of resveratrol treatment ( $p < 0.05$ ). PGC-1 $\alpha$  and utrophin mRNA expression increased  $1.4 \pm 0.2$  fold and  $1.7 \pm 0.2$  fold respectively after 10 days of resveratrol treatment ( $p < 0.05$ ).

**DISCUSSION:** We conclude that resveratrol improves muscle function and decreases muscle pathology in the mdx mouse. The improvement is likely due to increases in oxidative capacity, improved membrane integrity (utrophin), and decreased inflammation.

**Morphological Characteristics of Deep Aponeurosis of Pennate Muscle in Men and Women**

Kenya Kumagai<sup>1</sup>, Takashi Abe<sup>2</sup>. <sup>1</sup>Nagasaki International University, Nagasaki, Japan. <sup>2</sup>University of Oklahoma, Norman, OK.

(No relationships reported)

Aponeurosis is a broad tendinous sheet that attaches to pennate muscle and is known to be an important component that affects muscle function. Sex differences in muscle contractile properties and fatigue resistance have previously been reported. However, it is unknown if a morphological difference in the aponeurosis exists between men and women.

**PURPOSE:** To compare the morphological characteristics of deep aponeurosis in young recreationally active men and women.

**METHODS:** Eight young men (mean age, 19 [SD 1] yr; height, 1.73 [SD 0.06] m; weight, 60.2 [SD 7.5] kg) and 8 young women (mean age, 19 [SD 1] yr; height, 1.60 [SD 0.04] m; weight, 50.1 [SD 4.8] kg) volunteered. Continuous cross-sectional images of the thigh were obtained using magnetic resonance imaging (MRI). In each slice, anatomical muscle cross-sectional area (CSA) was measured, and muscle length, muscle volume and mean muscle CSA (muscle volume divided by muscle length) of quadriceps muscle (QF) were calculated. For aponeurosis of vastus lateralis muscle (VL), width of the aponeurosis (aponeurosis width) was measured in each slice, and aponeurosis length and aponeurosis area were determined.

**RESULTS:** Muscle length (men, 39.4 [SD 1.6] cm; women, 35.1 [SD 1.4] cm), muscle volume (men, 1792 [SD 382] cm<sup>3</sup>; women, 978 [SD 84] cm<sup>3</sup>), and mean muscle CSA (men, 45.2 [SD 8.0] cm<sup>2</sup>; women, 27.8 [SD 1.9] cm<sup>2</sup>) of the QF were greater ( $p < 0.01$ ) in men than in women (12%, 83%, and 63%, respectively). Maximal aponeurosis width (men, 9.7 [SD 0.9] cm; women, 7.8 [SD 1.2] cm), aponeurosis length (men, 22.8 [SD 3.0] cm; women, 18.8 [SD 1.7] cm), and aponeurosis area (men, 150 [SD 15] cm<sup>2</sup>; women, 111 [SD 20] cm<sup>2</sup>) of the VL were also greater ( $p < 0.01$ ) in men than in women (25%, 21%, and 35%, respectively). However, the ratio of aponeurosis maximal width to length of the VL was quite similar between men (0.43 [SD 0.08]) and women (0.42 [SD 0.07]). There was a significant correlation between VL aponeurosis area and QF mean muscle CSA in women ( $r = 0.87$ ,  $p < 0.01$ ), but not in men ( $r = 0.52$ ). QF muscle length was correlated to VL aponeurosis length in men ( $r = 0.84$ ,  $p < 0.01$ ), but not in women ( $r = 0.14$ ). VL maximal aponeurosis width did not associate with QF muscle length in either sex.

**CONCLUSIONS:** Our results suggest that there are morphological differences in the deep aponeurosis of the VL muscle between young men and women.

**Fatty Acid Intake and Exercise Improve Body Composition and Functionality in High Fat Diet-Fed Mice**

Jeong-Su Kim, Sang-Rok Lee, Samuel C. Grant, Edward Jo, Andy V. Khamoui, Bong-Sup Park, Michael C. Zourdos, Shirin Hooshmand, Michael J. Ormsbee,

Bahram H. Arjmandi. *The Florida State University, Tallahassee, FL.* (Sponsor: Lynn B. Pantone, FACSM)

(No relationships reported)

Conjugated Linoleic Acid (CLA) and Omega-3 polyunsaturated fatty acids (n-3) have received attention due to their health benefits; however, their potential synergistic effects with resistance training (RT) during a high fat diet are not well established.

**PURPOSE:** To determine the effects of combined CLA and n-3 administration independently or with RT on body composition, strength, and sensorimotor function in middle aged male mice during 20 wks of a high fat diet.

**METHODS:** Nine-month old C57BL/6 male mice were randomly assigned to five groups (n=10/group): 1) normal diet (CON), 2) High fat diet (HFD), 3) HFD+RT (HFD/RT), 4) HFD+CLA/n-3 (HFD/CN), and 5) HFD+RT+CLA/n-3 (HFD/RT/CN). Progressive RT (4 sets of 3 repetitions with 1-min inter-set rest) was conducted using a ladder climbing device 3x/wk for 20 wks. The combined supplement was comprised of 1% CLA (0.5% of c9, t11 and 0.5% of t10, c12) and 1% n-3. Lean (LM) and fat mass (FM) were determined using dual energy x-ray absorptiometry while grip strength and sensorimotor function were evaluated with a strain gauge and the incline-plane test, respectively. All measures were obtained pre- and post-intervention. Data were analyzed with a group x time repeated measures ANOVA, and significance was set at  $p < 0.05$ .

**RESULTS:** There were significant group x time interactions for LM, FM, grip strength, and sensorimotor function. FM increased in HFD (+30%) and HFD/RT (+34%), while LM decreased in HFD (-32%) and HFD/RT (-55%). No significant changes in LM or FM were observed for CON, HFD/CN, and HFD/RT/CN. Strength significantly declined in HFD (-15%) and HFD/CN (-17%) but was maintained in both CON and HFD/RT. Sensorimotor function declined significantly in HFD (-11%) with no change in CON, HFD/CN and HFD/RT. Interestingly, CLA/n-3 administration appeared to facilitate greater RT-mediated improvements in strength (+22%) and sensorimotor coordination (+17%).

**CONCLUSION:** Body composition and functionality were negatively altered following 20 wks of high fat diet. Daily CLA/n-3 intake appears to attenuate these negative alterations while even facilitating RT-induced improvements in body composition and functionality.

### Muscle Regeneration: Impact of Mast Cells on Inflammatory Cell Recruitment and Muscle Cell Proliferation

Elise Duchesne, Marie-Pier Roussel, Claude H. Côté. *CHUQ Research Center, Université Laval, Québec, QC, Canada.*

(No relationships reported)

Inflammatory cells are traditionally associated with pain, heat, redness and swelling. However, accumulating studies have shown that some of these cells can also contribute to tissue repair. Indeed, neutrophils and macrophages can contribute to the resolution of inflammation and to skeletal muscle regeneration via the release of cytokines and growth factors. We recently showed that tryptase, the most abundant mediator in mast cell granules, could potentially support muscle regeneration by increasing skeletal muscle cell proliferation.

**PURPOSE:** To evaluate if mast cells can stimulate skeletal muscle cell proliferation.

**METHODS:** In vitro: mast cells were isolated from peritoneal cavity of female Wistar rats. L6 muscle cells were cultured with either mast cells activated with compound 48/80 or mast cell-derived conditioned media. L6 cell number was determined with CellTiter assay 24h post-seeding. In vivo: muscle injury was induced through a bupivacain injection into the right EDL muscle. Rats received a daily intra-peritoneal injection of 5 bromo-2' deoxyuridine (BrdU) and were treated or not with the mast cell stabilizer cromolyn from 24h before injury. Rats were sacrificed 48 h post injury and immunohistochemistry analyzes were performed.

**RESULTS:** In vitro proliferation of L6 cells cultured with either activated mast cells or mast cell-conditioned media was significantly increased above control (1.30±0.08 fold and 1.24±0.04 fold), respectively. The proliferative effect of conditioned media was lost when APC-366, a tryptase inhibitor, was added. In vivo results shown that, compared to control, mast cell stabilization increased the density of proliferating cells (109,033±8,186 vs 79,678±10,833 cells/mm<sup>3</sup>), neutrophils (34,116±6,167 vs 15,636±4,201 cells/mm<sup>3</sup>), macrophages ED1 (35,426±7,517 vs 13,075±4,108 cells/mm<sup>3</sup>) and macrophages ED2 (21,671±1,676 vs 16,922±715 cells/mm<sup>3</sup>), respectively.  $P < 0.05$ .

**CONCLUSION:** Activated mast cells can stimulate skeletal muscle cell proliferation via tryptase release in vitro. However, in vivo this effect was masked by the influence of mast cells on the recruitment of other mitogenic cells such as neutrophils and macrophages.

### Signaling Responses In Unloaded Rat Soleus Muscle To Combination Of Heat Stress And Intermittent Reloading

Toshinori Yoshihara<sup>1</sup>, Takao Sugiura<sup>2</sup>, Hisashi Naito<sup>3</sup>. <sup>1</sup>Juntendo University, *JSPS Research Fellow., Inzai, Japan.* <sup>2</sup>Yamaguchi University, *Yamaguchi, Japan.*

<sup>3</sup>Juntendo University, *Inzai, Japan.*

(No relationships reported)

Heat stress and intermittent reloading are known as the effective countermeasure for skeletal muscle atrophy. However, it remains unclear whether the combination of heat stress and intermittent reloading are effective to attenuate muscle atrophy.

**PURPOSE:** To examine the effect of the combination of heat stress and intermittent reloading on signaling responses in unloaded rat soleus muscle induced by hindlimb unloading.

**METHODS:** Forty male Wistar rats (10wk of age, 261.7±1.17 g) were randomly divided into four groups: control (CON, n=10), hindlimb unloading (HU, n=10), hindlimb unloading with intermittent reloading (IR, n=10), hindlimb unloading with intermittent reloading and heat stress (IR+H, n=10). The HU, IR and IR+H group were unloaded for seven days. IR and IR+H group were released from unweighting for 1h every second days. During this time, IR+H group was exposed to environmental heat stress (41.5-42°C for 30 min) in a heat chamber without anesthesia. After seven days unloading, the soleus muscle were removed and analyzed by western blotting.

**RESULTS:** Seven-days unloading resulted in a 31% reduction in the soleus muscle mass, but only IR+H significantly prevented the reduction (CON; 168.2±6.7, HU; 116.3±3.7, IR; 121.0±3.7, IR+H; 131.1±2.4 mg). In soluble fraction, although 80-kDa form of calpain 1 was significantly increased in IR+H group compared to CON and HU group (HU; 102, IR; 132 and IR+H; 147% of CON), the autolyzed form of IR+H group was lower than CON group. Moreover, autolyzed form of calpain 2 (HU; 267, IR; 236 and IR+H; 105% of CON) and ubiquitinated protein (HU; 164, IR; 140 and IR+H; 112% of CON) in particulate fraction was significantly increased in HU group, but IR+H group prevented the increase. There were no significant changes in the phosphorylation of Akt, mTOR, S6K1 and eIF-4E.

**CONCLUSION:** The combination of heat stress and intermittent reloading attenuates soleus muscle atrophy through the prevention of calpain autolysis and protein ubiquitination, but independent of Akt/mTOR pathway.

### Developmental Change in Domain Size of Endplate Nucleus in the Rat Diaphragm

Hirofumi Miyata, Maiko Tanaka, Akane Yamaguchi. *Yamaguchi Univ., Yamaguchi, Japan.*

(No relationships reported)

**PURPOSE:** Nuclei around the neuromuscular junction play an important role for the maintenance of motor endplate morphology and function in skeletal muscle. In this study, we examined the number of endplate nuclei, 3-dimensional morphological properties of the motor endplate, and the expression level of muscle-specific kinase (MuSK) in rat muscles during the postnatal development.

**METHODS:** Segments of the mid-costal diaphragm (DIA) and sternocleidomastoideus (STM) muscles were removed at 1, 2, 3, 4, 11 and 25 weeks after birth (n=7 in each age group). Motor endplates were labeled with a-bungarotoxin conjugated tetramethylrhodamine. Then, several single muscle fibers with labeled endplate were isolated from the segments under fluorescent microscopy, and myonuclei, including endplate nuclei, were stained with DAPI (4', 6-diamino-2-phenylindole) to examine the space distribution of these nuclei. Thirty to fifty single fibers from each muscle segment were imaged using a laser-scanning confocal system, and the domain sizes of endplate nuclei were calculated from endplate volume and number of endplate nuclei. Furthermore, total RNA was extracted from the remains of muscle segments and the level of Pax7 mRNA expression was determined using real time RT-PCR analysis system.

**RESULTS:** In DIA collected during the developmental period (1 to 25 weeks after birth), the mean values of muscle fiber diameter and endplate volume were significantly increased from 24±6µm to 60±15µm and from 451 ± 304µm<sup>3</sup> to 1045 ± 781µm<sup>3</sup>, respectively. The mean values of the number of endplate nuclei were increased from 3.9±1.2 at 1 week to 10.2±7.8 at 25 weeks; therefore, domain sizes of endplate nuclei were identical during the developmental period (115±77µm<sup>3</sup> at 1 week and 102.5±75µm<sup>3</sup> at 25 weeks). The level of MuSK mRNA expression was dramatically decreased by 60% during this period. There were no obvious differences in the above data between DIA and STM muscles.

**CONCLUSIONS:** The domain sizes of endplate nuclei were speculated to be constant during postnatal development and between muscles, indicating that a regulation mechanism of the domain size exists in the neuromuscular junction. It was also speculated that the domain size was not directly regulated by the expression of MuSK.

**Exercise Performance And Muscle Metabolic Response In Endurance Trained, Strength Trained And Untrained Elderly Men**

Magni Mohr<sup>1</sup>, Peter Krstrup<sup>1</sup>, Carsten Juel<sup>2</sup>, Henriette Pilegaard<sup>2</sup>, Bengt Saltin<sup>3</sup>. <sup>1</sup>University of Exeter, Exeter, United Kingdom. <sup>2</sup>University of Copenhagen, Copenhagen, Denmark. <sup>3</sup>Rigshospitalet, Copenhagen, Denmark.  
(No relationships reported)

Ageing is accompanied by gradual deterioration of exercise performance and skeletal muscle oxidative capacity. However, information on effects of different life-long training regimes is sparse.

**PURPOSE:** To study performance, muscle metabolic capacity and response to exhaustive sub-maximal cycle exercise in lifetime endurance trained, strength trained and untrained +70 yrs old men.

**METHODS:** Life-time endurance trained (ET, n=8), strength training (ST, n=7) and untrained (UT, n=7) elderly men cycled at 75% VO<sub>2</sub>max until exhaustion. M. Vastus Lateralis biopsies were collected prior to and after exercise and antecubital vein blood samples were frequently drawn.

**RESULTS:** Exercise time was 87±8 min for ET which was 42 and 56% longer than for ST and UT, respectively. Power output was 34 and 32% higher (p<0.05) in ET than in ST and UT. Glycogen utilization per work unit was 41% lower (p<0.05) in ET than ST. Muscle lactate at exhaustion was lower (p<0.05) for ET than ST (14.1 vs 28.9 mmol kg<sup>-1</sup> d.w.) and blood lactate was lower (p<0.05) for ET than UT from 15 min of exercise with an intermediary response for ST (15 min: 2.2, 3.8 and 3.0 mM, respectively). VO<sub>2</sub>max, CS activity and capillaries per fibre, respectively, were higher (p<0.05) for ET than for ST (39, 24 and 19%) and UT (46, 53 and 35%). The MCT1 content in ET was 49% higher (p<0.05) than in UT, but not different from ST (22%, NS). No differences were evident in exercise performance, oxidative capacity or muscle metabolic response between ST and UT, except that ST had a 23% higher (p<0.05) CS activity. Exhaustion time correlated with the fraction of ST fibres (r=0.41, p<0.05) and negatively with blood lactate at exhaustion (r=-0.51, p<0.05). Muscle lactate at exhaustion correlated negatively with muscle HAD activity (r=-0.62) and positively with glycogen utilization (r=0.51) and type IIX fibres (r=0.54).

**CONCLUSIONS:** Life-long endurance trained elderly had a markedly higher endurance performance and muscle aerobic capacity compared to untrained and strength trained master athletes resulting in attenuated muscle lactate production and glycogen utilization during continuous exhaustive cycle exercise. Exercise performance and muscle metabolite exercise response did not differ between strength trained and untrained elderly men. The Danish Ministry of Culture funded the study.

2694 Board #369 MAY 31 2:00 PM - 3:30 PM

**Plasma Matrix Metalloproteinase-9 (MMP-9) is Increased Following Downhill Running in Sedentary Individuals**

Molly C. (Madden) Welsh, David L. Allen, FACSM, William C. Byrnes, FACSM. University of Colorado at Boulder, Boulder, CO.  
(No relationships reported)

Our lab has investigated the utility of plasma MMP-9 as a potential systemic indicator of muscle damage in humans. We have previously reported that the systemic response is variable and unchanged in the week following an eccentric arm task in sedentary subjects, and a downhill run in concentrically-trained subjects. Although concentrically-dominated training has been associated with increased susceptibility to muscle damage, subjects may not have experienced the degree of damage that might ensue in a sedentary population. Sedentary subjects did not have a systemic MMP-9 response after completing an eccentric arm task, but the volume of muscle damaged may have been too small to detect a response. Thus, it is still not clear whether plasma MMP-9 or its inhibitor, tissue inhibitor of metalloproteinase-1 (TIMP-1), change following a downhill run in sedentary subjects.

**PURPOSE:** To quantify systemic changes in MMP-9, TIMP-1, and other muscle damage indices following a downhill run in sedentary subjects.

**METHODS:** 8 sedentary males (n=3) and females (n=5) ran downhill (-10°) for 30 minutes. Plasma creatine kinase (CK) activity, MMP-9 and TIMP-1 concentrations, soreness ratings, and leg strength were collected pre-exercise (pre-ex), immediately post-, 1-, 2-, 4-, and 7-days post-exercise (post-ex). Trends were analyzed with a linear mixed model approach. Means ±SE are presented with p<0.05 considered significant.

**RESULTS:** Soreness significantly increased (p=0.013) from 4.1 ±2.3 mm pre-ex to a peak of 44.0 ±7.5 mm at 1-day post-ex (p=0.003). Values returned to baseline by 4-days post-ex. Plasma CK activity was significantly increased (p=0.005) from 74.5 ±29.4 U/L pre-ex to a peak of 102.7 ±25.2 U/L at 1-day post-ex. Plasma MMP-9 was significantly increased (p=0.009) from 25.4 ±2.4 ng/ml pre-ex to 35.8 ±4.1 ng/ml at 4-days post-ex. Plasma TIMP-1 levels were unchanged throughout the time course.

**CONCLUSIONS:** Plasma MMP-9 levels are increased at 4-days post-downhill running in sedentary individuals. These results, along with our previous results, suggest that the plasma MMP-9 response to exercise may be related to either physical training history or the severity of an exercise task. We plan to follow-up on this by examining the tissue response to either concentric or eccentric exercise in sedentary human muscle biopsies.

2695 Board #370 MAY 31 2:00 PM - 3:30 PM

**Comparison of Skeletal Muscle Tissue Oxygen Saturation Responses between Genders**

Sonio D. Garcia<sup>1</sup>, Jose A. Leal Jr.<sup>1</sup>, Yoshiaki Sato<sup>2</sup>, Michael G. Bembien, FACSM<sup>3</sup>, Murat Karabulut<sup>1</sup>. <sup>1</sup>University of Texas at Brownsville, Brownsville, TX. <sup>2</sup>University of Tokyo, Tokyo, Japan. <sup>3</sup>University of Oklahoma, Norman, OK.  
(No relationships reported)

Special attention should be given to subcutaneous thigh fat accrual and its impact on the amount of skeletal muscle blood flow and accumulation when using different initial restrictive pressure (IRP) during blood flow restriction (BFR) training. Due to different patterns of fat distribution and deposition in males and females, it is important to test the effects of subcutaneous fat on tissue oxygenation and lactate production during exercises with BFR.

**PURPOSE:** The present study investigated the importance of thigh subcutaneous fat as a variable that may be associated with affecting the magnitude of initial pressure (tightness of cuffs before inflation with air) on skeletal muscle tissue oxygen saturation and lactate between males and females.

**METHODS:** Twenty healthy volunteers, 10 males (25 ± 4.83 yr) and 10 females (20.7 ± 1.06 yr), performed exercises with an IRP of 40mmHg. The following procedures were performed in order: a) subcutaneous fat thickness, b) pre-maximal isometric force (MVC), c) 4 sets (1 × 30 reps and 3 × 15 reps) of dynamic knee extension exercises performed at 20% MVC, d) post-MVC. Skeletal muscle tissue oxygen saturation was continuously monitored before, during, and after exercises with near-infrared spectroscopy placed to a mark that was made at 50% on the line from the anterior superior iliac spine to the superior part of the patella. Plasma lactate levels were assessed prior to, in between the first and second set, immediately after post MVC, 5min-post, 10 min-post, and 20 min-post.

**RESULTS:** Thigh subcutaneous fat thickness was significantly greater in females than males (p<0.01). Tissue oxygenation significantly decreased (p<0.03) throughout exercise in both genders with an observed significant time × gender interaction (p<0.01). Both male and females responded to the BFR similarly with a significant decrease (p<0.01) in peak force production from pre to post exercise, while plasma lactate levels significantly differed (p<0.01) throughout the exercise with no time × gender interaction (p<0.3).

**CONCLUSIONS:** The observed gender difference in tissue oxygenation in response to BFR with an IRP of 40mmHg underline the necessity for future studies to consider subcutaneous fat as a variable to influence the magnitude of physiological adaptations between genders and adjust the IRP accordingly.

2696 Board #371 MAY 31 2:00 PM - 3:30 PM

**A Computational Model of Neuromuscular Function That Predicts Age-Related Fatigue Resistance**

Damien M. Callahan, Brian R. Umberger, Jane A. Kent-Braun, FACSM. University of Massachusetts, Amherst MA, MA.  
(No relationships reported)

Numerous studies indicate that the muscles of older individuals fatigue relatively less than younger individuals during isometric contractions. Due to the many differences in neuromuscular function between young and old, it is difficult to ascertain with precision the physiological mechanisms of age-related fatigue resistance. While computational models have been developed that predict muscle fatigue, and others have been designed to predict altered neuromuscular function with old age, no integrative model has been presented that examines age-related changes of the neuromuscular system in the context of fatigue.

**PURPOSE:** To develop a comprehensive computational model that evaluates the effects of old age on neuromuscular function during fatiguing voluntary contractions.

**METHODS:** We combined de novo experimental data and literature values to derive functions that describe multiple components of neuromuscular function (motor unit recruitment, excitation-contraction coupling, force generation, bioenergetics, and ankle dorsiflexion torque) during voluntary activation. These functions were parameterized in two versions; one to represent the neuromuscular function of younger men (YM) and the other to characterize older men (OM). Separate forward dynamics simulations were run using each model to predict isometric torque-generating capacity during repeated, maximal voluntary activations. We tested the validity of this model to predict fatigue, defined as a relative decline in maximal torque, by comparing model estimates of torque to values from the literature.

**RESULTS:** The model simulated contractions of similar duration and duty cycle to an example from the literature, and less fatigue was predicted by OM (84.4% initial) than YM (79.1%). These values are highly consistent with those reported in vivo for younger and older men (Root mean square difference [RMSD] = 6.6% and 0.11% respectively).

**CONCLUSIONS:** By simulating contraction protocols from the literature, we have demonstrated sensitivity of the present model to age-related differences in neuromuscular function and fatigue. These findings validate the present model as a unique and powerful tool for testing hypotheses related to the phenomenon of age-related fatigue resistance.

**Estrogen Receptor (ER) Mediated Recovery Of Atrophic Muscle Following Hind Limb Unweighting (HLU)**

Andries J. Ferreira, Madoka Spence, Andrew J. Dunn, James R. Langworthy, Marybeth Brown. *University of Missouri, Columbia, MO.*

(No relationships reported)

Estrogen (E2) is necessary for normal muscle function.

Genomic E2 effects are mediated through two ER, alpha and beta but whether they are important for the recovery of atrophic muscle has not been identified.

**PURPOSE:** to determine if the recovery of atrophic muscle (mass and contractile function) is ER mediated.

**METHODS:** Mature 4 mos old female C57/BL6 mice (n=70) were divided into sham ovariectomy (OVX) and OVX groups. All but 10 sham controls were HLU for 4 wks. One third of the HLU mice were studied immediately after unweighting, one third were studied after 3 days of recovery following HLU and the final third were studied after 3 days of recovery and 3 days of injections with ICI 182780, an E2 antagonist that blocks both ER alpha and beta. Contractile tension was determined in soleus, plantaris, gastrocnemius and tibialis anterior. Muscle mass and fiber cross-sectional area (CSA) were also determined for each muscle. **RESULTS:** HLU significantly reduced muscle mass and contractile force in all 4 muscles studied. In Sham OVX, recovery resulted in a significant (p<0.05) return toward baseline for muscle mass; recovery in mass was barely apparent in OVX mice. ICI attenuated recovery in Sham OVX and blocked recovery in OVX females. Evidence of recovery in muscle force (Po) was evident in Sham OVX but not in OVX with the exception of the soleus (e.g., sham Con 9.0 + 3.1, OVX HLU 5.0 + 2.7, OVX HLU + recovery 5.6 + 1.0 and OVX HLU + recovery + ICI 6.7 + 1.5). Values for CSA mirrored those of mass.

**CONCLUSIONS:** Without ER, recovery is attenuated suggesting an alternative but slower route mediating E2 effects. Without E2 or ER, recovery of atrophic muscle is compromised but effects are muscle specific. Supported by NIH HD 058834 and the MO Spinal Injuries Research Board.

2698 Board #373 MAY 31 2:00 PM - 3:30 PM

**Effect of Exercise Order on Testosterone Availability in Post-exercise Recovery**

Daniel W.D. West, Lisa M. Cotie, Cameron J. Mitchell, Tyler A. Churchward-Venne, Maureen J. MacDonald, Stuart M. Phillips, FACSM. *McMaster University, Hamilton, ON, Canada.*

(No relationships reported)

It has been suggested that performing arm prior to lower-body resistance exercise could reduce testosterone-rich blood delivery to the arm in recovery, thereby hampering potential hypertrophy over time.

**PURPOSE:** To determine the availability of testosterone to the arm, after arm exercise performed before or after intense lower-body resistance exercise.

**METHODS:** In a randomized cross-over design, four men (28 ± 5 y, BMI = 25.8 ± 2.0 kg m<sup>-2</sup>; means ± SD) performed 4 sets of isotonic arm exercise on a Biodex before (A-L) or after (L-A) intense bilateral leg resistance exercise. Blood samples for hormone analysis as well as brachial artery blood flow measures (Doppler ultrasound) were obtained immediately after arm and leg exercise and at intervals for 75 min of post-exercise recovery. Testosterone and growth hormone (GH) 'delivery' were calculated as the product of blood flow and hormone concentration.

**RESULTS:** There was a 3-fold increase in brachial artery blood flow after exercise by either legs or arm alone, followed by a further 1.5-fold increase after subsequent leg or arm exercise; consequently, there were no overall differences between exercise order for brachial artery blood flow. Testosterone and GH increased similarly with both A-L and L-A, each peaking 15 min after leg exercise. After A-L and L-A (respectively), testosterone delivery (AUC, arbitrary units) was 159 ± 26 and 141 ± 58 and GH delivery was 454 ± 111 and 462 ± 128. Total work output across 4 sets of arm exercise was higher in A-L (162 ± 35 kJ) than L-A (131 ± 50 kJ; P = 0.03).

**CONCLUSIONS:** Exercising the legs after arm exercise enhances rather than impairs blood flow to the exercised arm. Total testosterone and GH availability to the arm is not different depending on whether arm exercise is performed before or after intense leg exercise and so would not impair hypertrophy. Supported by CIHR and NSERC.

2699 Board #374 MAY 31 2:00 PM - 3:30 PM

**A Description of the Relationship between Straight Leg Raise (SLR) Test and Muscle Hardness**

Susumu Iwasaki<sup>1</sup>, Akitoshi Sogabe<sup>2</sup>, Andrew C. Fry<sup>1</sup>, Philip M. Gallagher<sup>1</sup>, Erik Christensen<sup>3</sup>. <sup>1</sup>The University of Kansas, Lawrence, KS. <sup>2</sup>Konan University, Kobe, Japan. <sup>3</sup>The Ohio State University, Columbus, OH.

(No relationships reported)

**PURPOSE:** The two purposes of this study are to: 1) describe the participants' results of SLR and muscle hardness statistically, and 2) identify any significant linear regression relationship between the SLR results and the muscle hardness as the preliminary study for upcoming analysis with the EMG data from the identical participants.

**METHODS:** Participants, the SRL of 23 males (age, 23.22±10.78 yrs; height, 174.67±12.83 cm; weight, 82.98±23.29 kg) were measured for both legs, and the muscle hardness for five different conditions: relaxed, voluntarily SLR, passively SLR, forcedly SRL, and maximal voluntary contraction with four different muscles: vastus medialis, vastus lateralis, rectus femoris, and biceps femoris. As the statistical data analysis, the descriptive statistics such as means and SDs for each variable were calculated. Also, linear regression and correlation analyses were conducted in order to identify any significant relationship. In order to judge collinearity, tolerance and VIF coefficients were calculated for each predictor.

**RESULTS:** The linear regression analysis revealed a set of significant regression coefficients that the SLR for left leg is predicted by all the muscle hardness scores (5 conditions \* 4 muscles = 20 predictors), (F=35.01; p<.028; df=20).

**CONCLUSION:** Even though there is only one statistically significant regression relationship, it may be possible to identify other significant pathways by such as collecting a larger sample. However, the description of dispersion with the participants' SLR and muscle hardness scores is beneficial for the future study.

---

2700 Board #375 MAY 31 2:00 PM - 3:30 PM

**Gender Differences in Leg Length, Q-Angle, Navicular Drop, and Tibial Torsion of College Age Subjects**

Mark Walker<sup>1</sup>, Ali Boolani<sup>2</sup>, A. Warren<sup>3</sup>, C. Kline<sup>3</sup>, J. Guerrero<sup>4</sup>. <sup>1</sup>Tennessee State University, Nashville, TN. <sup>2</sup>Oklahoma City University, Oklahoma, OK. <sup>3</sup>Oklahoma State University, Stillwater, OK. <sup>4</sup>Texas A&M University, College Station, TX.

(No relationships reported)

**PURPOSE:** The objective of this study was determine whether gender differences exist in skeletal structures. **Methodology:** A convenience sample of 24 males (age=22.46yrs ±2.41; height (HT)= 68.06in ±3.50; weight (WT)=186.75lbs±49.84) and 34 females (age=21.50yrs ±1.73; HT=66.05in ±2.61; WT=138.98lbs ±20.98) was chosen from a large Midwestern university in the United States. Leg length (LL), Q-Angle, Navicular Drop (ND) and Tibial Torsion (TT) were measured for each subject. Data was analyzed using a one-way ANOVA.

**RESULTS:** Analysis yielded significant differences between TT ( $p<.001$ ), LL ( $p=.001$ ) and Q-Angle ( $p=.005$ ), however no significant difference was found in ND ( $p=.189$ ) and LL/HT ratio ( $p=.601$ ). Males had significantly longer LL ( $94.68\text{cm} \pm 6.37$ ) and TT ( $19.79$ [[Unsupported Character - &#7506;]]  $\pm 5.74$ ) compared to females (LL= $89.72\text{cm} \pm 4.56$ ; TT=  $13.29$ [[Unsupported Character - &#7506;]]  $\pm 4.29$ ), however women had significantly large Q-angles ( $9.03$ [[Unsupported Character - &#7506;]] than males ( $7.50$ [[Unsupported Character - &#7506;]]).

**CONCLUSION:** This study validated studies that have stated that females have larger Q-angles than males. While lateral rotation of the tibia occurs at sexual maturation, males tend to have a great rotation of the tibia than females. Leg length was also significantly greater in males than females ( $p=0.001$ ), however this may be attributed to the males in this study being taller than females since LL/HT ratio was not significantly different ( $p=.601$ ). Inter-tester reliability may also be in question, as inter-tester reliability at 99% confidence indicated high correlation ( $R>0.85$ ) between TT and LL measurements, however lower correlations ( $R=0.65-0.85$ ) for Q-Angle and ND. Further investigation is required to determine why males have greater lateral rotation than females.

---

**2701** Board #376 MAY 31 2:00 PM - 3:30 PM

**Aging-related Changes In Isokinetic Torque Generation Capacities Of Knee Extensor**

kyung jae yoon<sup>1</sup>, Ho Jun Lee<sup>2</sup>, Min-Kyun Oh<sup>3</sup>, Dong Yeon Cha<sup>2</sup>, Yong-Taek Lee<sup>1</sup>. <sup>1</sup>Kangbuk Samsung Hospital, Sungkyunkwan University, School of Medicine, Seoul, Korea, Republic of. <sup>2</sup>Dongguk University, College of medicine, Goyang, Korea, Republic of. <sup>3</sup>Gyeongsang National University Hospital, Jin-ju, Korea, Republic of. (No relationships reported)

The purpose of this study was to investigate the effect of aging on the concentric and eccentric peak torque (PT) generation capacities of knee extensors in three different angular velocities (30, 60, and 180°/s). Concentric and eccentric PTs were measured in 130 healthy men (27-76 years). PT was compared between three age groups (young: 20 - 39 years, intermediate: 40 - 59 years, and old: 60 years and older). Concentric quadriceps PT at all angular velocities in intermediate and old group was significantly lower than that in young group ( $p<0.01$ ). Further regression analysis showed that the decrement of the PT explained by aging was larger in higher angular velocities than the lower (concentric PTs of old group were 82.8%, 80.4%, and 72.2% of the young group at angular velocity of 30°/s, 60°/s, and 180°/s, respectively). However, the eccentric PT did not demonstrate any significant differences among the three age groups ( $p>0.05$ ). These findings suggest that the neuromuscular aging not only diminishes the concentric peak torque generation but also impedes the rate of torque generation capacities of knee extensors. In eccentric contraction, the torque generation capacities might be influenced more by non-contractile, passive properties of muscles than in the concentric contraction.

---

**2702** Board #377 MAY 31 2:00 PM - 3:30 PM

**Asymmetry joint loading of Temporomandibular Joint During Clenching in Patients with Temporomandibular Joint Disorders**

Han-Yi Cheng<sup>1</sup>, Shin-Tsu Chang<sup>2</sup>, Pei-Wen Pon<sup>3</sup>, Wei-Chun Hsu<sup>4</sup>, Yuan-hsiang Lin<sup>4</sup>, Keng-Liang Ou<sup>5</sup>, Wan-Ju Hsu<sup>4</sup>, Shih-Chi Lee<sup>4</sup>, Yu-An Hu<sup>4</sup>. <sup>1</sup>National Taiwan University, Taipei, Taiwan. <sup>2</sup>Tri-Service General Hospital, Taipei, Taiwan. <sup>3</sup>College of Oral Medicine, Taipei, Taiwan. <sup>4</sup>National Taiwan University of Science and Technology, Taipei, Taiwan. <sup>5</sup>Taipei Medical University, Taipei, Taiwan. (No relationships reported)

To examine the causal relationship between pain and joint loading at temporomandibular joint (TMJ), one must focus on the magnitude and location of the maximum stresses under physiological loading during functional oral activities such as clenching. However, the asymmetry nature of left and right sides joint loading was not fully addressed using finite element analysis (FEA).

**PURPOSE:** To quantify the stress distribution in the mandibular condyle, disc and articular eminence, and to compare the joint loading revealed by von Mises' and shear stresses on the models of normal young adults and patients with TMJ disorders.

**METHODS:** The CT images of TMJ of three healthy adult female volunteer and three patients with TMJ disorders were used to build the models for FEA. As loading condition, 290N for masseter, 140N for temporalis, and 143N for medial pterygoid were introduced bilaterally. For each subject, the highest von Mises' stresses and highest shear stresses at TMJ during clenching were calculated

**RESULTS:** For the comparison of joint loading at right and left sides, all the normal young adults manifest symmetry joint loading in terms of their highest von Mises' stresses (Y: 2.321-2.855 MPa at the mandibular condyle, 0.634-0.957 MPa at articular disc, and 1.743-1.976 MPa at articular eminence; TMJ: 2.652-3.717 MPa at the mandibular condyle, 0.620-1.789 MPa at articular disc, and 1.632-2.010 MPa at articular eminence) and of highest shear stresses (Y: 3.023-3.725 MPa at the mandibular condyle, 0.815-1.291 MPa at articular disc, and 2.289-2.518 MPa at articular eminence; TMJ: 0.840-2.317 MPa at articular disc, and 2.196 -2.650 MPa at articular eminence).

**CONCLUSION:** All the patients with TMJ disorders manifest asymmetry joint loading revealed by von Mises' stresses at the mandibular condyle, by von Mises' stresses at the articular disc, by shear stresses at the mandibular condyle, and by shear stresses at the articular disc; while these asymmetry findings were not shown neither by the von Mises' stresses nor by the shear stresses at the articular eminence. Both the von Mises and shear stress during clenching was higher in patient with TMJ disorder than that in healthy subjects. Trends of the asymmetry loading have been observed in the patients with TMJ but not in the normal young adults.

**Do Sleep Problems Mediate Development of Mental Health Symptoms After Deployment?**

Caroline A. Macera, FACSM, Hilary J. Aralis, Mitchell J. Rauh, FACSM, Andrew J. MacGregor. Naval Health Research Center, San Diego, CA. (No relationships reported)

**PURPOSE:** Many military members who are exposed to combat-related blasts and screen for traumatic brain injury (TBI) subsequently develop mental health symptoms suggesting posttraumatic stress disorder (PTSD) or depression. One common symptom reported after deployment is difficulty falling or staying asleep. The role of sleep in the development of mental health symptoms is unclear.

**METHODS:** We prospectively followed 29,640 U.S. Navy and Marine Corps men who completed health assessments immediately upon return from deployment in Kuwait, Iraq, or Afghanistan during 2008 and 2009. Among those who did not screen positive for PTSD ( $n = 29,019$ ), self-reported sleep problems and TBI screening results were obtained and related to PTSD screening results from a separate health assessment administered several months later. After establishing a significant association between TBI and sleep problems, the association of TBI and PTSD was independently tested and retested while controlling for sleep problems. Similar methods were used for the alternative outcome of a positive depression screen ( $n = 27,702$ ).

**RESULTS:** After controlling for sleep problems, the odds of receiving a positive PTSD screen decreased from 1.61 (confidence interval [CI]: 1.21-2.14) to 1.32 (CI: 0.99-1.77) for a subject screening positive for TBI relative to a subject screening negative. Sleep problems mediated 26% of TBI's effect on development of PTSD. After controlling for sleep problems, the odds of receiving a positive depression screen for a subject screening positive for TBI relative to a subject screening negative decreased from 1.41 (CI: 1.11-1.80) to 1.15 (CI: 0.90-1.47), and the ratio became nonsignificant. Sleep problems mediated 41% of the effect of TBI on development of depression.

**CONCLUSIONS:** We found the effect of a positive TBI screen on the development of PTSD or depression is mediated by sleep problems. The results of our study suggest that sleep problems may be an early indicator of risk for PTSD or depression, and immediate treatment of self-reported sleep problems could mitigate the risk for development of mental health disorders, although future (intervention) studies are needed. This work was supported by the U.S. Navy Bureau of Medicine and Surgery under Work Unit No. 60818.

2704 Board #379 MAY 31 3:30 PM - 5:00 PM

**Objectively Measured Sleep is Predictive of Adiposity in Young Adult Women**

Bruce W. Bailey, Matthew Allen, Marshall Hill, James D. LeCheminant, FACSM. *Brigham Young University, Provo, UT.*

(No relationships reported)

**PURPOSE:** Over the past several decades, the prevalence of obesity has risen at an alarming rate. One of the critical times for developing excess body weight is during the college years. The reason for this weight gain is not completely clear, but one factor that has not been well examined is the role of sleep. The purpose of this study is to examine the relationship between sleep and adiposity in 199 college women.

**METHODS:** The study was cross-sectional. Participants were recruited from October 2009 to August 2011 from a Mountain West University. Participants wore an accelerometer for seven consecutive nights to assess sleep duration and quality. Participants also kept a sleep log to verify sleep time. Height and weight were assessed following a three-hour fast and in a standard one-piece swimsuit. Body composition was assessed using the BOD POD.

**RESULTS:** The women in the study slept an average of  $7.41 \pm 0.82$  hours per night. There was a negative relationship between total minutes in bed and BMI; this correlation was strengthened when controlling for average number of awakenings per night ( $P \leq 0.05$ ). It was also found that percent body fat was trending in the same direction as BMI, but was not significant ( $P = 0.07$ ). There was a 72% reduction in the odds of being overweight for those who slept more than 6.5 hours per night ( $P \leq 0.05$ ).

**CONCLUSIONS:** Total sleep time is related to BMI in college women; this relationship was strengthened when controlling for number of awakening per night. More than 6.5 hours of sleep per night seems to be a reasonable recommendation for sleep time in college women and is related with the lowest BMIs.

---

2705 Board #380 MAY 31 3:30 PM - 5:00 PM

**Associations Between Objectively-Measured Physical Activity and Sleep**

Liana L. Suhadolnik<sup>1</sup>, Kelly R. Laurson<sup>1</sup>, Miguel A. Calabro<sup>2</sup>, Greg J. Welk, FACSM<sup>2</sup>. <sup>1</sup>Illinois State University, Normal, IL. <sup>2</sup>Iowa State University, Ames, IA.

(No relationships reported)

Adequate sleep is vital to achieve proper health and well-being; however, millions of U.S. adults are not getting enough sleep, nor are they getting quality sleep. Physical activity may be an important tool in combating sleep inadequacy, although prior research is unclear on any potential associations between these two behaviors.

**PURPOSE:** To compare various measures of physical activity with sleep duration and sleep quality.

**METHODS:** Subjects ( $n=58$ , mean age = 54 years) wore the SenseWear Armband for approximately 12 consecutive days. Duration and intensity of physical activity, steps per day, minutes of sleep, and sleep quality were recorded and averaged over the monitoring period. Pearson correlations were used to examine the association between measures of physical activity and sleep duration and quality. Sleep duration was categorized into tertiles ("high" >409.7 minutes, "moderate" 355.9 - 409.7 minutes, and "low" <355.9 minutes) and physical activity was compared between the three groups using an ANOVA.

**RESULTS:** There was a consistent trend for measures of physical activity (steps per day, and minutes of moderate and vigorous physical activity) to be negatively correlated with sleep duration and quality, however all correlations were non-significant. The results of the ANOVA indicated that the low sleep group took significantly more steps per day (12,952 steps/day) than the high sleep group (9,207 steps/day;  $p < 0.05$ ). Also, there were significant differences in sleep quality between the high and low sleep groups and the moderate and low sleep groups (both  $p < 0.05$ ). Those that slept for shorter durations generally had a lower sleep quality. Minutes of moderate and vigorous activity were not statistically different between tertiles of sleep duration.

**CONCLUSION:** The findings indicate that aggregate measures of sleep duration and quality are related to physical activity. Overall, subjects that slept a greater duration were less physically active and had a higher quality of sleep.

2706 Board #381 MAY 31 3:30 PM - 5:00 PM

**Association Of Poor Food Choices With Sleep And Performance Among Qatar STARS League Football Players**

Abdulaziz Farooq, Rita Mansour, Christopher P. Herrera, Rodney Whiteley, Bruce Hamilton. *ASPETAR, Qatar Orthopaedic and Sports Medicine Hospital, Doha, Qatar.*

(No relationships reported)

Healthy eating and sleeping habits are associated with better athletic performance. Additionally, sleeping habits can be altered by dietary intake. These modifiable factors have not been documented in Arab footballers.

**PURPOSE:** To determine the dietary habits of professional football players and study their association with sleep and physical performance.

**METHODS:** A cross-sectional study of 111 athletes (age  $23.6 \pm 4.7$  y) were randomly recruited from eight different clubs from the STARS league. Each completed a culture-specific, structured questionnaire to quantify both frequency and preferences of food intake. All participants underwent body composition analysis by DXA, haematological investigations for lipid profile and vitamin D concentration. Sleep was assessed using the Arabic version of the Pittsburgh Sleep Quality Index (PSQI) and Insomnia Severity Index (ISI). Physical performance was evaluated based on isokinetic dynamometer (Biodex 3.0).

**RESULTS:** A large proportion of the athletes did not consume fruits (74.3%), vegetables (59.8%) or milk (67.6%) as a part of their regular diet. Players consumed fried chips (33.6%), chocolate bars (40.4%) and sweets (44.2%) at least twice daily and 79.6% do not hydrate adequately. Participants that consumed chocolate 2-3 times a day were younger ( $-4.6 \pm 1.6$  y,  $P=0.009$ ) and had high triglyceride ( $+0.3 \pm 0.1$  mmol/L,  $P=0.026$ ) compared to those who did not. Frequent chocolate snacks were also associated with poor sleep quality ( $P=0.029$ ) and insomnia severity ( $P=0.013$ ). After adjusting for age and lean mass of the limb, subjects who never consumed sweet snacks showed better eccentric hamstring performance on left ( $+24.5 \pm 9.3$  Nm,  $P=0.010$ ) and right ( $+16.7 \pm 8.8$  Nm,  $P=0.063$ ) legs.

**CONCLUSIONS:** This study documents dietary inadequacies in Arab footballers, and their association with poor sleep quality, and reductions in a measure of performance. Further research is needed using controlled trials to establish better relationship of diet on sleep and performance in this population.

**Variability in Simulated Hemorrhagic Challenge Tolerance is not Explained By Differences in Body Temperature**

Matt S. Ganio<sup>1</sup>, Kimberly Ganio<sup>2</sup>, James Pearson<sup>2</sup>, Rebekah Lucas<sup>3</sup>, Robert Matthews Brother<sup>4</sup>, Craig G. Crandall, FACSM<sup>3</sup>. <sup>1</sup>University of Georgia, Athens, GA. <sup>2</sup>Texas Health Presbyterian Hospital, Dallas, TX. <sup>3</sup>Texas Health Presbyterian Hospital, Dallas, TX. <sup>4</sup>University of Texas Austin, Austin, TX.

(No relationships reported)

**PURPOSE:** To examine if body temperature variations in normothermic and heat stressed conditions explain the variability in tolerance to simulated hemorrhage within each thermal condition.

**METHODS:** Data were retrospectively examined in individuals who underwent a simulated hemorrhagic challenge to pre-syncope (onset of syncopal symptoms) via lower body negative pressure (LBNP). The correlation between mean body temperature (T<sub>body</sub>, calculated from core and skin temperatures) and LBNP tolerance time while normothermic (n=45) and passively heat stressed (n=90) was examined. Second, LBNP time while normothermic and heat stressed in the 15 lowest T<sub>body</sub> was compared to the 15 highest T<sub>body</sub> within each thermal condition. Third, for subjects tested in both thermal conditions (n=33), the correlation between the increase in T<sub>body</sub> and the decrease in LBNP time was examined, as was LBNP times of the 10 smallest T<sub>body</sub> increases relative to the 10 largest T<sub>body</sub> increases.

**RESULTS:** LBNP time while normothermic (1237 ± 240 sec) and heat stressed (635 ± 275 sec) was not correlated to T<sub>body</sub> within each condition (normothermic range = 36.21-37.24°C, r = -0.15, p=0.33; heat stress range = 37.69-39.46°C, r=-0.12, p=0.28). Normothermic LBNP times of those with the lowest (36.35 ± 0.07°C) and highest (36.87 ± 0.15°C) T<sub>body</sub> were not different (1241 ± 256 and 1233 ± 294 sec, respectively; p=0.94). Similarly, heat stressed LBNP times of those with the lowest (37.86 ± 0.09°C) and highest (38.82 ± 0.20°C) T<sub>body</sub> were not different (690 ± 266 and 559 ± 282 sec; p=0.20). For subjects tested in both thermal conditions, decreases in heat stressed LBNP time (606 ± 218 sec) were not correlated to the magnitude of T<sub>body</sub> elevation (1.64 ± 0.23°C; r=0.04; p=0.83); moreover LBNP time of those with the smallest T<sub>body</sub> increase (664 ± 231 sec, 1.38 ± 0.14°C) was not different than those with the largest T<sub>body</sub> increase (611 ± 212 sec, 1.91 ± 0.07°C; p=0.60).

**CONCLUSIONS:** Between subject variations in T<sub>body</sub> while normothermic and heat stressed do not explain the within-condition variability in tolerance to a simulated hemorrhagic challenge. Although heat stress compromises blood pressure control, differences (1.1-2.0°C) in the magnitude of body temperature increase during a heat stress do not explain the variability in tolerance.

**mTORC2 Is Activated In Muscle During Exercise And Regulates Contraction Induced Glucose Uptake**

Maximilian Kleinert, Lykke Sylow, Erik Richter. *University of Copenhagen, Copenhagen, Denmark.*

(No relationships reported)

**PURPOSE:** Two distinct mTOR complexes (mTORCs) have been defined. While mTORC1 serves as a regulator of protein synthesis, mTORC2 has been found to be downstream of PI3K and to phosphorylate Akt on Ser 473. However, little is known about the physiological importance of mTORC2 in skeletal muscle during muscle contractions. Here we test the hypothesis that mTORC2 is activated during exercise and might be involved in contraction-induced glucose uptake in skeletal muscle.

**METHODS:** mTORC2 activity was judged by phosphorylation of its downstream target N-myc downregulated gene 1 (NDRG1) on the Thr346 residue. Mice ran for 30 min on a treadmill at 70% of their individual maximal running capacity, or EDL and soleus muscles were incubated in vitro and stimulated with insulin or contracted in the presence or absence of pharmaceutical inhibitors. Radioactive tracers were used to estimate glucose uptake.

**RESULTS:** In vivo running increased NDRG1 Thr346 phosphorylation by 60% (p < 0.05) compared to resting controls in gastrocnemius muscle. To test whether the running induced increase in mTORC2 activity was dependent upon AMPK activity, NDRG1 Thr346 phosphorylation was measured in mice that overexpress a kinase-dead alpha 2 subunit of the AMPK protein in skeletal muscle (AMPK-KD). In these mice NDRG1 Thr346 phosphorylation increased significantly to the same extent as in WT mice. Treatment of mouse soleus muscles with the total mTOR inhibitor, AZD8055, blocked basal and insulin stimulated NDRG1 Thr346 phosphorylation (p < 0.001) and inhibited Akt phosphorylation and glucose uptake, while rapamycin (a mTORC1 specific blocker) treatment had no effect. In EDL muscle AZD8055 had no effect on insulin stimulated glucose uptake despite ablation of Akt and NDRG1 phosphorylation. During in vitro contractions AZD8055 reduced contraction induced glucose uptake by 23% (p < 0.05) in EDL. In soleus the inhibitor had no effect on contraction induced glucose uptake. While AZD8055 reduced NDRG1 Thr346 phosphorylation to almost undetectable levels, AMPK Thr172 phosphorylation was unaffected by the blocker and increased about 2-fold with contractions in both EDL and soleus (p < 0.05).

**CONCLUSIONS:** It is concluded that mTORC2 is activated in muscle during exercise and has muscle specific effects on insulin and contraction induced glucose uptake.

 **$\alpha$ -adrenergic Vasoconstriction Contributes To The Age-related Increase In Conduit Artery Retrograde And Oscillatory Shear**

Darren P. Casey<sup>1</sup>, Jaume Padilla<sup>2</sup>, Branton G. Walker<sup>1</sup>, Essa A. Mohamed<sup>1</sup>, Michael Joyner, FACSM<sup>1</sup>. <sup>1</sup>Mayo Clinic, Rochester, MN. <sup>2</sup>University of Missouri, Columbia, MO.

(No relationships reported)

Aging is associated with greater presence of retrograde and oscillatory shear in peripheral conduit arteries of humans. We previously demonstrated that reduced nitric oxide bioavailability in the resistance vessels contributes, in part, to the age-related alterations in shear rate patterns.

**PURPOSE:** To further elucidate the potential mechanisms for age-related discrepancies in shear patterns, we examined the contribution of  $\alpha$ -adrenergic vasoconstriction in resistance vessels on shear rate patterns in upstream conduit arteries of younger (n=8; 5M/3F, age 27 ± 2 years) and older (n=11; 6M/5F, age 68 ± 2 years) healthy adults.

**METHODS:** Brachial artery diameter and velocities were measured via Doppler ultrasound during 1) rest (control), 2) sympathetic activation via lower body negative pressure (LBNP; -20 mmHg), and 3) intra-arterial administration of phentolamine (non-specific  $\alpha$ -adrenergic antagonist).

**RESULTS:** At rest older adults exhibited greater brachial artery retrograde and oscillatory shear (-9.9 ± 2.7 s<sup>-1</sup> and 0.11 ± 0.03 arbitrary units, respectively) compared with younger adults (-3.1 ± 1.0 s<sup>-1</sup> and 0.05 ± 0.02 arbitrary units, respectively; P < 0.05 for both). LBNP increased brachial artery retrograde and oscillatory shear in young (-6.7 ± 2.1 s<sup>-1</sup> and 0.10 ± 0.02 arbitrary units, respectively, respectively; P < 0.05 vs. control) but not older adults (-9.1 ± 2.4 s<sup>-1</sup> and 0.12 ± 0.02 arbitrary units, respectively; P = 0.85-0.97 vs. control). With phentolamine retrograde and oscillatory shear were abolished in young adults (-0.2 ± 0.2 s<sup>-1</sup> and 0.00 ± 0.00 arbitrary units, respectively; P < 0.05 vs. control) and markedly reduced, however still persistent, in older adults (-3.8 ± 0.9 s<sup>-1</sup> and 0.02 ± 0.01 arbitrary units, respectively; P < 0.001 vs. control).

**CONCLUSIONS:** Our data indicate that  $\alpha$ -adrenergic vasoconstriction substantially contributes to age-related discrepancies in conduit artery shear rate patterns at rest.

**High Fat Diet Enhances Tumorigenesis And Pro-tumoral Factors in the C3(1)SV40Tag Breast Cancer Mouse Model**

Jennifer Steiner<sup>1</sup>, J. Mark Davis, FACSM<sup>1</sup>, Jamie McClellan<sup>1</sup>, Jeffrey Green<sup>2</sup>, E. Angela Murphy<sup>1</sup>. <sup>1</sup>University of South Carolina, Columbia, SD. <sup>2</sup>National Cancer Institute, Bethesda, MD.

(No relationships reported)

High fat diet (HFD) induced obesity increases the risk for breast cancer (BrCa); obese women have a greater risk of developing breast cancer and of dying from the disease than healthy women. However, few well supported mechanistic explanations in regards to the relationship between HFD induced obesity and BrCa exist.

**PURPOSE:** The purpose of this study was to determine the effects of HFD feedings on tumorigenesis in the C3(1)SV40Tag mouse model of BrCa and further to relate this to pro-tumoral factors expressed in the tumor microenvironment.

**METHODS:** Female C3(1)SV40Tag mice were assigned to a dietary treatment group (n=14-15), beginning at 4 wks of age: control (CON) diet (AIN76A), or high fat diet (HFD). The CON diet contained 11.5% kcal fat while the HFD diet had 41% kcal fat. All diets were identical in vitamin and mineral content. Body weight (BW) was measured weekly, and mice were examined bi-weekly for palpable tumors, from which tumor number and volume was recorded. At 18wks of age mice were sacrificed and all visible tumors were counted, measured, and excised. Tumor tissue was analyzed for pro-tumoral factors including mRNA gene expression of CD206 (a marker for pro-tumor M2 macrophage phenotype), VEGF (a mediator of angiogenesis) and TNF- $\alpha$  & IL-6 (pro-inflammatory cytokines) using RT-PCR. Tumor number and volume as well as BW were analyzed using a one-way repeated measures ANOVA and pro-tumoral factors were analyzed using Student's T-Tests. Significance was set at P<0.05.

**RESULTS:** HFD feedings significantly increased BW (wks 8-18), and body fat percentage (~70%) (P<0.05). Tumorigenesis was greatly enhanced by HFD; tumor volume in HFD was ~50% greater than CON at 18wks (P<0.05). HFD consumption increased tumor expression of CD206 (1.4 fold), VEGF (1.5 fold), IL-6 (~3 fold), and TNF- $\alpha$  (1.2 fold) compared to CON.

**CONCLUSIONS:** These data confirm the negative influence of HFD consumption on breast cancer in a transgenic mouse model and further provide evidence of a relationship between HFD and pro-tumoral factors related to tumor associated macrophages, angiogenesis and inflammation within the tumor microenvironment.

2712 Board #5 May 31 5:45 PM - 7:00 PM

**Vascular Dysfunction with Age: Evidence from Upright and Supine Passive Limb Movement**

Jon Groot<sup>1</sup>, Joel D. Trinity<sup>2</sup>, Gwenael Layec<sup>2</sup>, Matthew J. Rossman<sup>1</sup>, Stephen J. Ives<sup>2</sup>, Russell S. Richardson<sup>2</sup>. <sup>1</sup>University of Utah, Salt Lake City, UT. <sup>2</sup>Salt Lake City VAMC, Salt Lake City, UT.  
(No relationships reported)

Aging attenuates the hyperemic response to supine passive limb movement. In the young, increased perfusion pressure evoked by an upright-seated posture augmented the hyperemic response, however, whether this increase is consistent with age is unknown.

**PURPOSE:** Utilizing a model devoid of exercise-induced increases in metabolism, this study sought to elucidate the impact of age on central and peripheral contributors to movement-induced hyperemia to better understand the mechanisms contributing to reduced blood flow with age.

**METHODS:** Passive leg movement was performed in 20 young (21±2 yrs) and 20 old (72±6 yrs) healthy participants for 3 min in both the supine and upright-seated position. Second-by-second measurements of central and peripheral hemodynamic responses were noninvasively performed (Finometer and Doppler Ultrasound), while femoral perfusion pressure (FPP) was directly measured via catheter in a subset of 10 participants.

**RESULTS:** The young exhibited a 25% increase in movement-induced peak leg blood flow in the upright-seated position (supine: 942±67; upright: 1189±89 mL/min), while in the old, leg blood flow failed to increase (supine: 737±65; upright: 649±50 mL/min), despite a similar increase in FPP (5±1 mmHg). Changes to central hemodynamic responses in the supine and upright-seated position were unremarkable between groups.

**CONCLUSIONS:** In light of similar central hemodynamic changes with posture, this study reveals attenuated movement-induced hyperemia in the elderly. This observation appears to be independent of both metabolism and perfusion pressure, implying that local vascular phenomena, such as endothelial function and vascular stiffness, likely play a major role in vascular dysfunction with age.

2713 Board #6 May 31 5:45 PM - 7:00 PM

**Peripheral MCP-1 Induces Fatigue and Modulates Central Fatigue-Associated Neural Factors in the Brainstem and Cerebellum**

Seung H. Jung, E Angela Murphy, Raja Fayad, Maria Pena, Benjamin T. Gordon, Martin Carmichael, J Mark Davis, FACSM. University of South Carolina, Columbia, SC.  
(No relationships reported)

An increased concentration of peripheral monocyte chemoattractant protein-1 (pMCP-1) has been reported in people with diseases, such as cancers and Alzheimer's disease, with which central fatigue often occurs and has a negative impact on these people, but no study has been done to evaluate a role of pMCP-1 in fatigue.

**PURPOSE:** To investigate pMCP-1 effects on occurrence of fatigue and central fatigue-associated neural factors in the brain.

**METHODS:** Voluntary wheel running activities of male C57/BL6 mice during 19:00 - 07:00 were collected to investigate the effects of daily, intraperitoneal injections (ip) of MCP-1 for 3 continuous days on the occurrence of fatigue. Another set of male C57/BL6 mice were used to investigate the effects of the pMCP-1 on the central fatigue-associated neural factors in the brainstem and cerebellum.

**RESULTS:** Compared with the mean baseline, the MCP-1 treatments induced a significant reduction in relative running distance (% change from the mean baseline) on days after 2nd injection (2nd mid), 3rd injection (1st post day) and 4th post day; a significant reduction in relative total running time (%) on 2nd mid and 1st, 4th, 6th and 7th post days; and a significant reduction in relative average running speed on the 4th post day. When compared with the placebo group, mRNA expression of cytokine IL-1β was 28% and 24% increases in the brainstem and cerebellum (p < 0.05) in MCP-1 group 12 hours after the 3rd injection. Our data showed 25% and 24% increases in mRNA expression of 5-HT1B receptors in the brainstem and a 19% increase in mRNA expression of 5-HT1A receptor in the cerebellum. No effect was found on the dopamine D2 receptor.

**CONCLUSIONS:** These data suggest for the first time that pMCP-1 induces fatigue that is associated with changes in CNS fatigue-associated neural factors, including IL-1β, 5-HT1A, and 5-HT1B receptor subtypes in the brainstem and/or cerebellum. The results are important to elucidate the central mechanisms of fatigue, which occurs with a certain diseases or disorders, such as cancer and infection where elevated levels of pMCP-1 are common.

---

2714 Board #7 May 31 5:45 PM - 7:00 PM

**Short-Term Unloading and Exercise Effects on Mechanical Stress-Sensitive Structural and Sensor Proteins in Human Soleus**

Clay E. Pandorf, Fadia Haddad, Joshua Cotter, Kenneth Baldwin, FACSM, Vincent J. Caiozzo, FACSM, Gegory R. Adams. University of California, Irvine, Irvine, CA.  
(No relationships reported)

Loading forces are critical to maintaining homeostasis in the muscle cell. Perturbations, such as unloading/disuse, upset the normal gene expression of structural and signaling proteins. Exercise countermeasures can offset these alterations.

**PURPOSE:** To examine gene expression of several large sarcomeric proteins that provide structural support to the myofibril (titin, nebulin and α-actin) and converge at the Z-disc. Since evidence suggests that loading forces in the muscle may be transmitted by structural support proteins that integrate mechanical stress at the Z-disc, we also examined several signaling proteins that reside in this region (STARS, atrogin-1, and calcineurin via its modulator MCIP1) and can in-turn regulate the expression of sarcomeric genes.

**METHODS:** Two groups of healthy inactive human subjects participated in unilateral lower limb suspension (ULLS; male N=5; female N=4) for 10 days alone or with a combination of aerobic and resistance exercise training (ULLS+T; male N=5; female N=5). Soleus biopsies were obtained before and after ULLS; ULLS+T biopsies were obtained ~24 hrs after the last training session. RT-PCR was used to quantify pre-mRNA and mRNA levels of select genes (arbitrary units/mg).

**RESULTS:** Nebulin, titin and α-actin RNA levels changed pre to post by -11%, +26% and +7% with ULLS, and by +25%\*, +56%\* and +16% with ULLS+T, respectively (\*p<0.05 pre to post). STARS, atrogin1 and MCIP1 mRNA levels changed pre to post by -75%\*, +77%\* and -40%\* with ULLS, and by -63%\*, +30%\* and -26%\* with ULLS+T, respectively (\*p<0.05 pre to post).

**CONCLUSIONS:** While changes in transcription of the Z-disc associated structural proteins nebulin and titin following 10d unloading was not statistically significant, there was significant upregulation with unloading + training stimuli. The unfavorable unloading-induced signaling response was ameliorated when combined with training as suggested by differential mRNA levels of mechano-sensitive Z-disc factors that can promote atrophy (atrogin) and fiber-type shifts (calcineurin/MCIP1). These data suggest that exercise countermeasures to short-term unloading of the loading-sensitive slow soleus muscle can promote favorable transcriptional responses of proteins associated with the stress-sensitive Z-disc. (Supported by NSBRI-NASA NCC 9-58)

2715 Board #8 May 31 5:45 PM - 7:00 PM

**Role of Dietary Leucine on Amino Acid Transporter mRNA Expression Following Resistance Exercise**

Tyler A. Churchward-Venne<sup>1</sup>, Andrew Philp<sup>2</sup>, George R. Marcotte<sup>1</sup>, Cameron J. Mitchell<sup>1</sup>, Daniel W.d West<sup>1</sup>, Leigh Breen<sup>1</sup>, Steven K. Baker<sup>1</sup>, Keith Baar, FACSM<sup>2</sup>, Stuart M. Phillips, FACSM<sup>1</sup>. <sup>1</sup>McMaster University, Hamilton, ON, Canada. <sup>2</sup>University of California, Davis, CA.  
(No relationships reported)

Skeletal muscle amino acid transporters (AAT) may play a key role in the regulation of muscle protein metabolism via their ability to transport amino acids (AA) across the sarcolemma and relay signals to downstream protein targets. The mRNA expression of some AAT is increased after essential amino acid (EAA) intake and resistance exercise (RE); however, the combined effect of AA and RE on AAT mRNA expression and whether greater leucine intake alters the response is unknown.

**PURPOSE:** To examine the effect of AA/whey protein intake (with high and low leucine content) after RE on the mRNA expression of select AAT in human skeletal muscle.

**METHODS:** 24 adult men (22±1 y) completed unilateral knee-extensor RE before consuming one of the following: WHEY (25 g whey protein); LEU (6.25 g whey protein supplemented with leucine to be iso-leucine with WHEY); and EAA-LEU (6.25 g whey protein supplemented with EAA except leucine to be iso-EAA with WHEY for each EAA except for leucine). Muscle

biopsies were obtained before RE and 1, 3, and 5h after from both rested-fed (FED) and exercise-fed legs (EX-FED). qRT-PCR was used to determine changes in mRNA expression of LAT-1, CD-98, and PAT-1 AAT and members of the general AA control pathway GCN-2 and ATF-4.

**RESULTS:** mRNA expression of CD-98 and LAT-1 (fold-change from basal) increased in FED and EX-FED, however the response at 5h was greater in EX-FED (CD-98 FED = 2.17 vs. EX-FED = 3.52 (P=0.003); LAT-1 FED = 3.58 vs. EX-FED = 5.18 (P=0.025)). PAT-1 increased in FED and EX-FED, however EX-FED was greater in WHEY vs. EAA-LEU (WHEY = 3.26 vs. EAA-LEU = 1.89 (P=0.031)). ATF-4 showed time dependent changes in all treatments while the FED response of GCN-2 was greater in LEU vs. WHEY and EAA-LEU at 5h (LEU = 2.07 vs. WHEY = 1.44 vs. EAA-LEU = 1.02 (P=0.004)).

**CONCLUSIONS:** RE prior to whey protein/AA intake increases the mRNA expression of select AAT above feeding alone at 5h post RE. WHEY induced greater changes in PAT-1 vs. EAA-LEU suggesting unique benefits of whey protein that extend beyond total leucine content. EAA-LEU resulted in robust increases in select AAT comparable to LEU despite containing ~75% less leucine, suggesting that a high leucine content is not critical in increasing AAT expression after AA intake. The functional physiological significance of these changes remains to be elucidated. Supported by NSERC.

**2716 Board #9 May 31 5:45 PM - 7:00 PM**  
**Electron Conductance in Rat and Sparrow Skeletal Muscle Mitochondrial Electron Transport Chain**

Sarah Kuzmiak, Wayne T. Willis. *Arizona State University, Tempe, AZ*  
(No relationships reported)

Flying birds utilize fat for fuel during flight, a moderate-high intensity exercise, while mammalian reliance on carbohydrate increases with increasing exercise intensity. Previous investigations in our lab have shown this pattern of fuel selection persists even when saturating fuels are provided to the inner membrane transporters of intact respiring mitochondria, suggesting a fuel selection mechanism at the level of the matrix.

**PURPOSE:** To compare the maximal rates of complete substrate oxidation to the oxidation of electrons as well as electron conductance in rat and sparrow mitochondria to elucidate differences between the species in the ability to produce electrons (via dehydrogenase enzymes,  $\beta$ -oxidation, and the citric acid cycle) and the capacity for these electrons to be consumed (via travel down the electron transport chain (ETC)).

**METHODS:** Intact mitochondria were isolated, provided saturating fuels (pyruvate, glutamate, and malate), and the maximal rate of oxygen consumption ( $J_o$ ) was determined. Mitochondria were then sonicated and maximum NADH oxidation was measured following the rate of oxygen reduction to water. The slope of the oxidation:reduction (redox) potential difference ( $\Delta E_h$ ): $J_o$  relationship, a measure of the conductance of electron flow down the ETC, was also determined.

**RESULTS:** Intact maximal  $J_o$  were  $636 \pm 87$  and  $641 \pm 83$  nmol-mg<sup>-1</sup>-min<sup>-1</sup> in rat and sparrow, respectively, while the ETC  $V_{max}$  were  $731 \pm 76$  and  $1020 \pm 108$  nmol-mg<sup>-1</sup>-min<sup>-1</sup>. Combined, these data indicate greater relative ETC activity in the sparrow; the (intact oxidase pathway)/(ETC only) ratio was  $.86 \pm .04$  in the rat and  $.65 \pm .07$  in the sparrow. Additionally, the slope of the  $\Delta E_h$ :  $J_o$  relationship was 1.7x greater in sparrow than the rat mitochondria,  $12306 \pm 1538$  and  $7196 \pm 924$ , respectively.

**CONCLUSIONS:** These data indicate avian mitochondria have greater ETC "excess capacity" as well as greater conductance down the ETC compared to mammalian mitochondria. As a high reduction level of the mitochondrial matrix has been associated with an inhibition of  $\beta$ -oxidation, we posit rat fatty acid oxidation is inhibited by high reduction in the mitochondrial matrix while birds, via a high ETC conductance, are able to maintain lower matrix reduction, allowing fatty acid oxidation to proceed.

**2717 Board #10 May 31 5:45 PM - 7:00 PM**  
**Fat Tissue Inflammation, Sedentary Time, and Light Daily Activity among Postpartum Latinas**

Paska Permana<sup>1</sup>, Barbara Ainsworth, FACSM<sup>2</sup>, Michael Belyea<sup>2</sup>, Kathie Records<sup>2</sup>, Sonia Vega-López<sup>2</sup>, Allison Nagle-Williams<sup>2</sup>, Dean V. Coonrod<sup>3</sup>, Colleen Keller<sup>2</sup>.  
<sup>1</sup>Phoenix Veterans Affairs Health Care System, Phoenix, AZ. <sup>2</sup>Arizona State University, Phoenix, AZ. <sup>3</sup>Maricopa Integrated Health System, Phoenix, AZ.  
(No relationships reported)

Postpartum Latinas have high rates of obesity and are at risk for obesity-related metabolic disorders, yet their physical activity (PA) rates are often quite low. Chronic sub-clinical inflammation associated with obesity may exacerbate risk for metabolic disorders and pro-inflammatory cytokines released by fat tissue contribute to systemic inflammation.

**PURPOSE:** To determine if fat tissue inflammation correlates with daily PA in postpartum Latinas.

**METHODS:** Madres para la Salud is a prospective, randomized trial exploring the effectiveness of a culturally specific social support intervention using moderate-intensity PA to reduce body fat, systemic and fat tissue inflammation, and depression symptoms in postpartum Latinas. PA was assessed at baseline with the ActiGraph GT3X accelerometer, worn for 7 days. PA intensities were determined from sedentary to vigorous using Freedson's and Matthews' cut-points. A subcutaneous abdominal fat biopsy and a blood draw were performed on a subset (n=15) of participants. We determined mRNA expression levels of inflammatory markers Interleukin-6 (IL-6), Interleukin-8 (IL-8), and Tumor Necrosis Factor  $\alpha$  (TNF- $\alpha$ ) in fat tissue using Real Time PCR. Plasma concentrations of IL-6 and IL-8 were measured using Enzyme Linked Immunosorbent Assay. Data are presented as Mean $\pm$ SD.

**RESULTS:** Daily proportion of light PA (39 $\pm$ 9%) correlated negatively ( $r=-0.98$ ,  $p<0.001$ ) with sedentary time (58 $\pm$ 10%). Fat tissue mRNA expression levels, but not plasma concentrations, of IL-6 (3.8 $\pm$ 6.8 Relative Units), IL-8 (1.7 $\pm$ 1.6), and TNF- $\alpha$  (0.9 $\pm$ 0.2) correlated with sedentary time ( $r=0.47$ ,  $p=0.08$ ;  $r=0.7$ ,  $p=0.004$ ;  $r=0.55$ ,  $p=0.04$ , respectively) and inversely with light PA ( $r=-0.51$ ,  $p=0.05$ ;  $r=-0.75$ ,  $p<0.001$ ;  $r=-0.59$ ,  $p=0.02$ , respectively).

**CONCLUSIONS:** The correlation between the mRNA expression levels of inflammatory markers in fat tissue with sedentary time and, inversely, with light PA is strengthened by the inverse correlation between the two types of activity. These results indicate that even light PA incorporated in daily routine, independent of more intense PA, may already reduce inflammation in fat tissue in postpartum Latinas. Moderate-intensity intervention will likely further reduce fat tissue and systemic inflammation, thus minimize risk for obesity-related diseases.

**Associations Between Abnormal Ultrasound Color Doppler Measures and Pain Symptoms In Badminton Players During a Season: A Prospective Cohort Study**

Anders P. Boesen<sup>1</sup>, Morten Ilum Boesen<sup>2</sup>, Soren Torp-Pedersen<sup>2</sup>, Robin Christensen<sup>2</sup>, Karen Ellegaard<sup>2</sup>, Henning Bliddal<sup>2</sup>, Lars Boesen<sup>2</sup>, Hölmich Per<sup>3</sup>, Michael Bachmann Nielsen<sup>4</sup>, Andreas Hartkopp<sup>5</sup>, Henning Langberg<sup>1</sup>. <sup>1</sup>Institute of Sportsmedicine, Bispebjerg Hospital, Copenhagen, Denmark. <sup>2</sup>Parker Institute, Frederiksberg Hospital, Copenhagen, Denmark. <sup>3</sup>Amager Hospital, Copenhagen, Denmark. <sup>4</sup>Department of Radiology, Rigshospital, Copenhagen, Denmark. <sup>5</sup>A2, Hillerød Hospital, Copenhagen, Denmark.  
(No relationships reported)

Color Doppler ultrasound is widely used to examine intra-tendinous flow in individuals with overused tendon problems but the association between color Doppler and pain is still unclear.

**PURPOSE:** To find out if intra-tendinous flow is present and associated with complaints in badminton players and if intra-tendinous flow and pain increase during a badminton season.

**METHODS:** Ninety-five semi-professional badminton players were included in the study at a tournament at the start of the badminton season. All players were interviewed regarding pain. Each tendon was scored using a quantitative grading system (grade 0 to 5) and a qualitative scoring system (color fraction) using color Doppler ultrasound. Eight months later, 86 of the players (91%) were re-tested by the same investigators during an equivalent badminton tournament (incl. 1032 tendon regions - 86 players with 4 tendons each with 3 regions), forming the study group.

**RESULTS:** At start of the season 24 players (28%) experienced pain in 37 tendons (11%) and at the end of the season 31 players (36%) experienced pain in 51 tendons (15%), which was a statistically significant increase ( $P = 0.0002$ ). Abnormal flow was found in 230 tendon regions in 71 players (83%) at start season compared to 78 tendon regions in 41 players (48%) at the follow-up. The decrease in abnormal flow was statistically significant ( $P < 0.0001$ ). Of the 37 painful tendons at the start of the season 25 had abnormal flow (68%). In contrast 131 tendons (85%) with abnormal flow start season were pain-free. At the end of the season 18 of the 51 painful tendons (35%) had abnormal flow. Ninety-six of the 131 pain-free tendons (73%) with abnormal flow at start season were normalized (no pain and normal flow) at end season.

**CONCLUSIONS:** It was not possible to verify any association between intra-tendinous flow and pain at start season or at the follow-up (end season). Intra-tendinous flow at the start of the season could not predict symptomatic outcome at the end of the season. The decrease in Doppler flow during season might suggest that intra-tendinous flow could be part of a physiological adaptive response to loading and that intra-tendinous flow as previously believed is not always a sign of pathology.

---

**2720** Board #2 May 31 5:45 PM - 7:00 PM  
**Investigating the Participation in Level I/II Activities by Potential Copers and Non-Copers 12 Months after Anterior Cruciate Ligament Reconstruction**

Victoria Allen, Andrew Lynch, Stephanie DiStasi, Lynn Snyder-Mackler. *University of Delaware, Newark, DE.*  
(No relationships reported)

Ability to return to sport (RTS) activity is a common success measure for athletes who sustain an anterior cruciate ligament (ACL) injury. The University of Delaware uses a functional test battery to determine a minimum state of readiness for RTS. Patients complete questionnaires about their perceived knee function, current activity, and what limits their ability to return to their previous level of athletic activity. Recent work showed 78% of non-copers passed Delaware's RTS criteria 12 months after surgery, but the rate of athletes who return to their previous activity level is still unknown.

**PURPOSE:** Athletes were examined 12 months after ACL reconstruction (ACLR). The purpose was to (1) evaluate the rate of athletes returning to activity; (2) evaluate activity level based on the Marx Activity Rating Scale (MARS); (3) investigate reasons for not returning to the same level of activity, despite meeting clinical RTS criteria.

**METHODS:** Data were collected from a total of 88 non-copers ( $n=52$ ) and potential copers ( $n=36$ ); subjects were high-level athletes involved in Level I/II activities. The MARS specifically evaluates the frequency that athletes are running, cutting, jumping and pivoting. Two supplemental questions were used, asking athletes to list reasons why they have not returned to all pre-injury sports and why they have not returned to the same level of competition within the sport.

**RESULTS:** The total pass rate for RTS criteria of 87.5%. However, overall return to activity rate was 65.9%, with 77.3% of potential copers and 45.3% of non-copers returning to pre-injury levels. MARS scores frequently indicated higher activity level than the patient-reported, creating an inconsistency. "Fear of re-injury", "too little time to participate" and "not yet cleared from doctor", were listed as predominant reasons for not returning to the same level of activity, despite clinical clearance for RTS.

**CONCLUSIONS:** Although athletes pass RTS criteria, they may not return to same level of activity. Non-copers demonstrate the need for additional evaluation and education to increase their likelihood of participating in higher-level activities. The outcomes reveal the need to intervene with athletes' activity level after injury to increase the percentage of individuals who engage in at least fifty hours of level I/II sports/year.

---

**2721** Board #3 May 31 5:45 PM - 7:00 PM  
**Dogs and Docs - Getting Patients More Active**

Jacqueline N. Epping. *CDC, Atlanta, GA. (Sponsor: Robert E. Sallis, FACSM)*  
(No relationships reported)

**PURPOSE:** To examine and describe the role that dogs and dog walking may play in initiating, increasing and maintaining physical activity and improving health in patients.

**METHODS:** The relationship of dog ownership to a variety of health outcomes was examined. Dog walking as a mechanism to increase physical activity, in particular was examined. A rationale was provided for the potential effectiveness of dog walking as a population-based intervention strategy that could be utilized by health care providers.

**RESULTS:** A growing body of literature was reviewed which demonstrates the relationship of dogs, dog ownership, and dog walking to a wide variety of health outcomes, including increased physical activity and the likelihood of meeting physical activity guidelines and recommendations. For example, a recent review of the literature found that, among dog owners, those owners who walked their dogs were 2.7 times as likely to meet U.S. guidelines for physical activity as owners who do not walk their dogs.

**CONCLUSIONS:** Recommending dog walking to patients can be a strategy that health care professionals can use to encourage and motivate patients to initiate, increase, and sustain health-enhancing levels of physical activity.

---

**2722** Board #4 May 31 5:45 PM - 7:00 PM  
**Primary Prevention of the Female Athlete Triad in College Athletics**

Jill W. Lassiter<sup>1</sup>, Don Sabo<sup>2</sup>, Celia A. Watt<sup>3</sup>. <sup>1</sup>Bridgewater College, Bridgewater, VA. <sup>2</sup>D'Youville College, Buffalo, NY. <sup>3</sup>The College at Brockport, Brockport, NY.  
(No relationships reported)

Primary prevention of the female athlete triad is recommended by numerous athletic organizations as a primary means to address health risks among female athletes. Collegiate athletic departments can play a role in prevention.

**PURPOSE:** To describe current triad-related preventative practices of college sports medicine departments, and identify characteristics associated with prevention.

**METHODS:** Surveyed all NCAA member institutions with on-line questionnaire that measured the extent of screening and educational practices for each component of the triad. The sampling procedure generated a 37% response rate ( $N = 327$ ), representing all NCAA athletic divisions (32.5% DI, 8.0% DIAA, 5.5% DIIAA, 26.0% DII, 41.5% DIII). ANOVA and independent-t tests were used to compare differences across institutional characteristics.

**RESULTS:** At least half of the institutions did not screen for the components of the triad (disordered eating 52.9%, menstrual dysfunction 49.5%, osteoporosis 61.2%). Screening most often occurred reactively, when athletes presented with signs and symptoms. Almost half of the institutions (48.6%) provided no education to athletes regarding the triad, and 55.4% provided no education to coaches. Division IA institutions were significantly more likely to implement preventative screenings ( $F=5.601$ ,  $p<0.001$ ) and to educate athletes and coaches ( $F=6.921$ ,  $p<0.001$ ,  $F=2.916$ ,  $p<0.05$ , respectively) than lower division institutions. Other institutional correlates of preventative practices included participation in the NCAA CHAMPS program, regular presence of a team physician, and larger athletic training staffs ( $\geq 3$  ATC's).

**CONCLUSIONS:** Primary preventative practices related to the female athlete triad are not common within college athletics. Comprehensive prevention is minimal, however, Division IA institutions with larger healthcare staffs are significantly more likely to engage in preventative practices. Further steps are needed to encourage implementation of triad related preventative practices within collegiate athletic departments.

---

2723 Board #5 May 31 5:45 PM - 7:00 PM

**Diclofenac Sodium 1% Gel for Relief of Osteoarthritis Pain in the Finger Joints**

Roy D. Altman<sup>1</sup>, John H. Peniston<sup>2</sup>, Morris S. Gold<sup>3</sup>, Matthew S. Wieman<sup>4</sup>. <sup>1</sup>David Geffen School of Medicine, Los Angeles, CA. <sup>2</sup>Feasterville Family Health Care Center, Feasterville, PA. <sup>3</sup>Novartis Consumer Health, Inc., Parsippany, NJ. <sup>4</sup>Endo Pharmaceuticals Inc, Chadds Ford, PA.

(R.D. Altman: Consulting Fee; Endo, Novartis, Abbott, Ferring, AstraZeneca, and Rottapharm. Contracted Research - Including Principle Investigator; Novartis and Ferring.)

**PURPOSE:** To compare the relative efficacy of diclofenac sodium 1% gel (DSG) to treat osteoarthritis (OA) pain in the first carpometacarpal (CMC1) and intraphalangeal (IP) joints of the hand. OA of the IP and CMC1 joints may occur in participants of sports that require exceptional grip strength (eg, climbing) or have a high risk for thumb and finger injuries (eg, basketball, boxing). Patients with OA limited to a few finger joints may prefer topical treatments to minimize systemic nonsteroidal anti-inflammatory drug (NSAID) exposure.

**METHODS:** Patients (aged  $\geq 40$  y) with hand OA applied DSG or vehicle gel, 2 g per hand, 4 times daily for 8 weeks. Assessments at 6 weeks included pain intensity (100-mm Visual Analog Scale [VAS]) and Australian/Canadian Osteoarthritis Hand Index (AUSCAN) subscales for pain, stiffness, and function. Efficacy was compared in patients with OA in CMC1 only (n=34), CMC1 plus  $\geq 1$  IP joint (CMC1+; n=241), and IP joints only (no CMC1; n=110). Institutional review board approval and patient informed consent were obtained.

**RESULTS:** In adults with OA of the hand, DSG was superior to vehicle for relieving pain to a similar degree in all finger joints (IP and CMC1). VAS pain intensity improved by 40%-49% with DSG compared with 34%-37% for vehicle. AUSCAN pain improved by 30%-43% with DSG compared with 28%-30% for vehicle. A general trend for mild to moderate improvement in stiffness and function was observed.

**CONCLUSIONS:** DSG was superior to vehicle for reducing OA pain in hand joints, with a trend toward improvement in stiffness and function. Limiting OA treatment to the affected finger joints with topical DSG may be preferable for patients wishing to minimize systemic NSAID exposure.

This study was funded by Endo Pharmaceuticals Inc., Chadds Ford, PA.

---

2724 Board #6 May 31 5:45 PM - 7:00 PM

**Barriers to Intake Assessment in Women Referred for Cardiac Rehabilitation**

Mireille Landry, Jennifer A.D. Price, Paula J. Harvey. *Women's College Hospital, Toronto, ON, Canada.*

(No relationships reported)

The benefits of exercise-based cardiac rehabilitation (CR) are well-documented in the literature. CR is underutilized, particularly in women. Once referred to CR, women are less likely to attend the first appointment or intake assessment (IA) compared to male counterparts. Previous studies have investigated barriers to attendance or completion of CR once enrolled, but little attention has been paid to barriers that affect attendance to IA.

**PURPOSE:** To describe women referred to CR but who fail to attend an IA, and their barriers to IA.

**METHODS:** Women referred to CR from 2008-2010 but did not attend an IA completed a telephone survey. Telephone interviews included a demographics questionnaire, open-ended questions regarding perceived barriers to attending IA, the Cardiac Exercise Self-Efficacy Instrument (CESEI) and Cardiac Rehabilitation Barriers Scale (CRBS). Descriptive statistics were generated on the collected variables, and compared to women who attended IA. The content of the participant responses to the open-ended questions was analyzed through categorization, coding of data, and frequency counts.

**RESULTS:** Of the 671 referrals received from 2008-2010, 169 (25%) did not attend an IA, and were eligible to participate in this study. A total of 53 (mean age= 56.6 yrs, +/-12.2 yrs) consented to participate. Depression (n=22, 42%) and arthritis (n=29, 55%) were most frequently cited comorbidities among participants. The presence of arthritis was significantly different in attendees to IA vs. nonattendees (p<0.001). Mean scores on the CRBS and CESEI were 2.37 +/- .55 and 3.35 +/- .88 respectively. Distance to CR was significantly greater for the nonattendees (p< 0.001). Distance and transportation issues were also cited by 26% (n=14) of respondents as a specific challenge to attending CR. 15 participants (28%) went on to attend CR closer to home.

**CONCLUSIONS:** Improved participation in CR by women can be effected through careful evaluation of factors that influence access to care. Addressing transportation issues at onset of referral may improve attendance to IA in women referred to CR.

---

2725 Board #7 May 31 5:45 PM - 7:00 PM

**Female Former Elite Athletes Suffering From Eating Disorders During Their Career. A 15-20 Year Follow-up**

Jorunn Sundgot-Borgen<sup>1</sup>, Kjersti K. Danielsen<sup>1</sup>, Monica K. Torstveit<sup>2</sup>. <sup>1</sup>The Norwegian School of Sport Sciences, Oslo, Norway. <sup>2</sup>University of Agder, Kristiansand, Norway.

(No relationships reported)

Longitudinal follow up studies on female former elite athletes and knowledge regarding the recovery rate of eating disorders (EDs) is lacking.

**PURPOSE:** To examine whether female former elite athletes diagnosed with an eating disorder (ED) during their athletic career recover from EDs and whether long term health variables differ from former elite athletes with no history of EDs.

**METHODS:** In 1989, 18% of the total population of female elite athletes in Norway (n=522) met the criteria for a clinical ED. During the period from 2005-2010 we managed to get hold of 417 (80%) of these 522 athletes. In addition, a bureau of statistics picked a randomly selected sample of controls from the total population of female citizens in Norway aged 30-50 years and a total of 640 females volunteered to participate. In phase I, all subjects replied to a postal questionnaire including questions related to training and competitive history, health history including questions about dieting and EDs and validated questions on ED behaviour (Eating Disorders Inventory, EDI), and mental health (WHO-QOL). In phase II, all athletes and non-athlete controls with a total EDI > 40 and/or a self-reported history or present ED, as well as 20 athletes and 20 non-athletes with EDI <40 and no self-reported history of EDs (a total of 130 athletes and 110 controls) participated in a telephone interview in which the Eating Disorder Examination (EDE) was used to diagnose possible EDs.

**RESULTS:** Seventy (72%) out of those 97 athletes who met the criteria for an ED during their athletic career had recovered, and three new cases of athletes had developed an ED after they stopped competing. Out of the athletes and non-athletes who were interviewed, 30 (23%) athletes and 22 (20%) non-athletes met the DSM-IV criteria for EDs. Athletes with a history of EDs reported more present menstrual dysfunction and lower score on the WHO-QOL than former athletes with no ED history, and controls.

**CONCLUSIONS:** Most former elite athletes with a history of EDs recover, however more than one out of four are still struggling with their ED 15-20 years after they finished their sport career.

2726 Board #8 May 31 5:45 PM - 7:00 PM

**Variability In Hallux Pressures With Cam Walker Boot And Rigid Sandal: Implications For Post-operative Mobilization**

Kenneth J. Hunt<sup>1</sup>, Rebecca Shultz<sup>2</sup>, Maria Malone<sup>2</sup>, Alex Sox-Harris<sup>1</sup>, Daniel Garza, FACS<sup>2</sup>, Gordon O. Matheson<sup>2</sup>. <sup>1</sup>Stanford, Redwood City, CA. <sup>2</sup>Stanford, Stanford, CA.

(No relationships reported)

There are numerous surgical procedures for pathologies affecting the hallux metatarsophalangeal (MTP) joint, including arthrodesis, osteotomies, bunionectomies, and soft tissue reconstructions. While early protected weight bearing (WB) has been shown to be safe for some procedures, higher failure rates have been reported for hallux MTP arthrodesis with early WB. Post-operative protocols usually include transition to WB in a short CAM walker boot device or rigid post-operative sandal. The pressures exerted at the great toe (GT) and the hallux metatarsal head (MTH) in these devices are unknown.

**PURPOSE:** To compare the contact peak pressure and impulse at the great toe and hallux MTH with three different movement tasks during ambulation in each of three foot devices.

**METHODS:** 20 healthy subjects (age 25-37) performed three movement tasks (normal walking, heel WB, 90 deg pivot turn), while wearing each of three different footwear devices: CAM walker boot, hard-sole post-operative sandal, and running shoes. Insole pressure measurements were collected using Tekscan (South Boston, MA) insoles. Contact pressures, peak pressures

and impulse (Force x time) were collected at GT and MTH during stance phase for each subject for three trials during each of the nine conditions (3 movement tasks and 3 shoe devices). Mixed-effects regression models were used to estimate mean simultaneous pairwise differences and (95%CI) between the nine conditions.

**RESULTS:** The boot resulted in lower MTH contact pressure than both other devices during all three conditions, with a significant difference occurring between the boot and the sandal during heel walking ( $p < 0.01$ ). MTH impulse was significantly lower with the boot compared to the other devices during pivot, but only versus shoe during walking, with no difference between boot and sandal during walking. The lowest peak pressure occurred during heel walking at both MTH and GT independent of the device; this was significantly lower than the other two movement tasks.

**CONCLUSIONS:** As safe, early mobilization is often the goal for patients following hallux procedures and during recovery from hallux injuries, it appears a short CAM walker boot may be superior to a rigid sandal in terms of pressures at the hallux MTH and GT.

---

**2727 Board #9 May 31 5:45 PM - 7:00 PM**  
**Recurrent Syncope in an Adolescent Football Player**

Mark Riederer, Prince Kannankeril, Monroe Carell Jr. Children's Hospital at Vanderbilt, Nashville, TN.  
(No relationships reported)

**HISTORY:** A 17-year-old high school athlete adolescent male is hospitalized overnight after having a syncopal episode. He was "roughhousing" with a few of his friends when he suddenly didn't feel well and then proceeded to pass out. Two of his friends, trained in cardiopulmonary resuscitation, felt no pulse and performed chest compressions and breaths for about 1 minute until he regained consciousness.

He had two prior episodes of syncope, the first when he was 13-years-old when he collided with another boy while playing lacrosse. He had a very brief loss of consciousness after the hit, and then felt well when he awoke. The second episode occurred one year later while lifting weights he suddenly stood up and lost consciousness. Again after he awoke, he felt relatively well.

He has no other past medical history or surgical history. He plays high school football and club rugby. There is no family history of sudden death or arrhythmia. His mother has had several episodes of syncope with "stress."

**PHYSICAL EXAMINATION:** Vital signs: Heart rate 47, blood pressure 122/62. In general, he is awake, alert and well appearing. His breath sounds are symmetric, and clear to auscultation. His heart is regular in rate and rhythm, normal S1 and S2 without murmur or gallop. His abdomen is soft, nontender and nondistended. His strength is normal. There is no clubbing, edema, or cyanosis. He has a nonfocal neurologic examination.

**DIFFERENTIAL DIAGNOSIS:**

Neurocardiogenic syncope

Long QT Syndrome

Hypertrophic cardiomyopathy

Aortic stenosis

Arrhythmogenic right ventricular cardiomyopathy

Catecholaminergic polymorphic ventricular tachycardia

**TEST AND RESULTS:** He had a normal resting electrocardiogram, with a normal QT interval, and normal echocardiogram. An exercise stress test showed bidirectional ventricular tachycardia. An intracardiac electrophysiology study was normal, with no inducible arrhythmias. Resequencing of the cardiac ryanodine receptor (RYR2) gene revealed a nonsynonymous mutation in RYR2 (Arg 15 Pro), a rare variant not previously described in the literature.

**FINAL WORKING DIAGNOSIS:** Catecholaminergic polymorphic ventricular tachycardia

**TREATMENT AND OUTCOMES:** He did well on high dose beta-blocker therapy, was restricted from strenuous activity, and is doing well without any further episodes of syncope.

---

**2728 Board #10 May 31 5:45 PM - 7:00 PM**  
**Infectious Disease - Swimming**

Kari Taggart<sup>1</sup>, Sherrie Ballantine-Talmdage<sup>2</sup>. <sup>1</sup>AthletiCo/Northwestern University, Evanston, IL. <sup>2</sup>Northwestern University, Evanston, IL.  
(No relationships reported)

**HISTORY** 18-year-old female Division I swimmer presented to athletic training room with sore throat, bilateral tonsillar exudates and painful swallowing. She was referred to team physician for further evaluation and treated with Penicillin. Patient improved symptomatically, but returned 13 days later with sore throat, subjective fever, body aches, headache, and muffled voice. She was treated for mono and placed on Prednisone. In four days her condition drastically changed. She called ATC with fever, difficulty breathing, and sharp, constant back/abdominal pain so was sent to ER

**PHYSICAL EXAMINATION**

VS: BP 96/55 HR 102 Temp 97.8 RR24

Gen: uncomfortable w/ breathing

HEENT: wnl

CV: S1S2 w/o murmur; tachy rate; regular rhythm

Chest: decreased and course BS at RLL; breath sounds throughout

Abd: ttp in RUQ with no guarding or rebound; (-) Murphy's sign; ttp along mid thoracic spine, in mid line, radiating around to LUQ

Ext: no clubbing, cyanosis or edema (-) Homan's B

**DIFFERENTIAL DIAGNOSIS**

1. Mononucleosis
2. Strep throat/pneumonia
3. Community-Acquired Pneumonia
4. Sepsis
5. Pulmonary Embolism
6. Endocarditis/pericarditis
7. Peritonsillar abscess

**TESTS/RESULTS**

At Hospital

CXR for B infiltrates (+)

Elevated WBC

Blood cultures: Fusobacterium necrophorum & Streptococcus dysgalactiae

Elevated LFTs

**TREATMENT/OUTCOMES**

Began Unasyn at hospital for presumed CAP with sepsis

Continued to spike fevers and had persistent RUQ pain; Ultrasound showed mildly enlarged spleen  
Thoracentesis performed and chest tubes placed bilaterally  
Patient underwent empyema treatment w/ multiple rounds of tPa  
Neck CT reviewed again and R IJ thrombus found  
Cardiothoracic surgery consulted and decortication of B lungs performed, revealing significant pus throughout RLL and under diaphragm  
Patient improved post-op (week 3), but became anemic; transfused prior to discharge  
Began light cardiovascular exercise in spring and had tonsillectomy in summer due to persistent tonsillar pain  
Progression back to swimming following tonsillectomy and return to pre-illness levels of training in the fall  
**FINAL/WORKING DIAGNOSIS** Lemierre Syndrome; Mononucleosis; Anemia

---

## E-20 Free Communication/Poster - Bone Mineral Density

JUNE 1, 2012 7:30 AM - 12:30 PM  
ROOM: Exhibit Hall

---

### 2729 Board #1 June 1 9:30 AM - 11:00 AM

#### Reduced Bone mineralization in Elite Male Lightweight Rowers Compared to Elite Rowers Without Weight Restriction

Anders Vinther<sup>1</sup>, Tine Alkjær<sup>2</sup>, Inge-Lis Kanstrup<sup>3</sup>, Bo Zerahn<sup>3</sup>, Charlotte Ekdahl<sup>4</sup>, Per Aagaard<sup>5</sup>. <sup>1</sup>Herlev Hospital and Lund University, Herlev and Lund, Denmark. <sup>2</sup>Panum Institute, University of Copenhagen, Copenhagen, Denmark. <sup>3</sup>Herlev Hospital, Herlev, Denmark. <sup>4</sup>Lund University, Lund, Sweden. <sup>5</sup>University of Southern Denmark, Odense, Denmark.  
(No relationships reported)

During the last decades an increased incidence of exercise-induced rib stress fractures has been observed among rowers at the international elite level. In Denmark, male lightweight rowers have demonstrated a particularly high frequency of injury. Sufficient energy intake is important to ensure optimal bone adaptation, and since lightweight rowers need to comply with strict weight limits, insufficient energy intake could potentially lead to impaired bone strength. Bone Mineral Density (BMD) is closely correlated with bone strength and rowers with previous rib stress fractures have exhibited reduced BMD compared to uninjured rowers.

**PURPOSE:** To investigate if lightweight rowers were characterized by reduced BMD compared to heavyweight rowers.

**METHODS:** Total body BMD was measured in male (ML, n=20) and female (FL, n=9) lightweight rowers, and male (MH, n=10) and female (FH, n=10) heavyweight rowers (Danish National Team) by dual energy X-ray absorptiometry (DXA-scan). To enable comparisons between the four groups of rowers BMD was expressed in % of a young adult reference population (20-40 years of age). Statistical analysis was performed using one-way ANOVA with Bonferroni corrected post hoc comparisons.

**RESULTS:** Total body BMD was reduced in ML (99.9 ± 5.0 %) (mean ± SD) compared to MH (111.0 ± 5.2 %, p<0.001), FH (111.1 ± 7.2 %, p<0.001) and FL (107.2 ± 5.4 %, p<0.05). No other group differences were observed.

**CONCLUSION:** Total body BMD was reduced in male National Team lightweight rowers compared to male heavyweight rowers, whereas no difference was observed between lightweight and heavyweight female rowers. Thus, internationally competitive male National Team lightweight rowers seem to demonstrate an attenuated adaptive skeletal response compared to that observed in National Team rowers without weight restriction, which expose male lightweight rowers to an increased risk of exercise-induced rib stress fracture injury.

---

### 2730 Board #2 June 1 9:30 AM - 11:00 AM

#### The Evaluation of Forearm Muscles Strength and Bone Mineral Density of Archers

Nisa Zekiye Özberk<sup>1</sup>, Özlem Öner Coşkun<sup>1</sup>, Sabire Akın<sup>2</sup>, Hayri Ertan<sup>3</sup>, Feza Korkusuz<sup>1</sup>. <sup>1</sup>Middle East Technical University Medical Center, Ankara, Turkey. <sup>2</sup>Medicana Hospital, Ankara, Turkey. <sup>3</sup>Anadolu University, Eskişehir, Turkey.  
(No relationships reported)

**PURPOSE:** Archery can be described as a static sport requiring strength and endurance of the upper body, in particular the forearm and shoulder girdle. The discipline is described as a three-phase (the stance, the drawing and the sighting) movement. Shooting the high number arrows during both training and competition, a repeated contraction-relaxation strategy by both drawing and bow hand forearm muscles should be developed. The studies that have been done on forearm muscles proved that muscular strength imbalance cause uncoordinated shooting and may impair with wrist injuries. This study investigated the effects of long-term archery training on the forearm isokinetic muscular strength and bone mineral density (BMD).

**METHODS:** 10 male and 3 female totally 13 high level archers volunteered into the study. Concentric strength of wrist extensor and flexor in both forearms was measured by using Biodex System 3 isokinetic dynamometer. Both forearms were measured at speed of 60°/s and in the distal and total radius-ulna by dual energy x-ray absorptiometry (DEXA).

To evaluate the relationship between muscle strength and bone mineral density Wilcoxon t-test in IBM SPSS 20 was used to determine whether there exist differences between the dominant and non-dominant arm. A criterion level of p<.05 was selected.

**RESULTS:** Distal radius BMD (0.42±0.06 vs. 0.39±0.05, p=.002), both of distal radius and ulna BMD (0.40±0.06 vs. 0.37±0.06, p=.011), total ulna BMD (0.61±0.05 vs. 0.59±0.05, p=.019) and both of total radius and ulna BMD (0.60±0.05 vs. 0.58±0.04, p=.017) values of dominant arm were higher than the values of non-dominant arm. Flexion Peak torque (12.26±9.25 vs. 8.35±5.55, p=.023), extension Peak torque/body weight (28.83±10.60 vs. 23.81±10.48, p=.021) and flexion Peak torque/body weight (18.58±12.35 vs. 11.72±8.79, p=.002) values of dominant arm were higher than non-dominant arm.

**CONCLUSIONS:** Dominant forearm BMD and muscle strength values were significantly higher than non-dominant forearm values. These strength and BMD relations indicate sport specific skeletal and muscular adaptations. As a result of sports-specific movement pattern and training programs, the dominant forearm muscle strength is expectedly higher than non-dominant forearm. The results of this study can guide clinicians, coaches and archers.

---

### 2731 Board #3 June 1 9:30 AM - 11:00 AM

#### Cortisol and Bone Mineral Density in Competitive Male Cyclists

Shannon L. Mathis, Richard S. Farley, Dana K. Fuller, Amy E. Jetton, Jennifer L. Caputo. Middle Tennessee State University, Murfreesboro, TN. (Sponsor: Don W. Morgan, FACSM)  
(No relationships reported)

Elevated cortisol is linked to a high prevalence of osteoporosis. The etiology of low bone mineral density (BMD) in male cyclists may be partially due to elevations in cortisol, which increases during physiological and psychological stress.

**PURPOSE:** To determine whether pre- and post-competition cortisol levels, pre-race competitive state anxiety, daily calcium intake, and training history were related to lumbar spine and hip BMD in male cyclists.

**METHODS:** Lumbar spine (L1 - L4), total hip, femoral neck, and trochanter BMD were measured with dual x-ray absorptiometry in 33 male cyclists who competed in a state championship time trial event. Calcium intake was measured using a 1 day dietary recall. On a survey, participants reported age, years of bike-specific training, number of races per season, and minutes per week riding a bike, weight training, and running. On race day, a competitive state anxiety questionnaire was used to measure pre-race nervousness. Salivary cortisol was measured within 10 minutes of racing and within 5 minutes of race finish.

**RESULTS:** Low BMD of the lumbar spine or hip was found in 50% of the cyclists. Total hip BMD of cyclists over the age of 40 years was significantly correlated with post-race cortisol ( $r = .72, p = .03$ ), but cortisol was not significantly correlated with BMD in the full sample. Cortisol level increased significantly ( $p = .004$ ) from pre- ( $9.4 \pm 4.1$  nmol/L) to post-competition ( $20.8 \pm 14.5$  nmol/L). No correlation existed between pre-race nervousness and pre- or post-race cortisol. Weight training was associated with higher BMD of the lumbar spine ( $\beta = 0.61, t = 4.03, p < .001$ ), total hip ( $\beta = 0.62, t = 4.16, p < .001$ ), femoral neck ( $\beta = 0.70, t = 5.72, p < .001$ ), and trochanter ( $\beta = 0.68, t = 4.86, p < .001$ ). Increased number of years of cycling experience was associated with lower BMD of the femoral neck ( $\beta = -0.26, t = -2.15, p = .04$ ). Higher daily calcium intake was associated with higher BMD of the lumbar spine ( $\beta = 0.40, t = 2.30, p = .03$ ) and femoral neck ( $\beta = 0.38, t = 2.19, p = .04$ ).

**CONCLUSION:** Findings support the recommendation that cyclists should participate in weight training and increase calcium intake in order to increase or maintain BMD.

---

2732 Board #4 June 1 9:30 AM - 11:00 AM

**Bone Mineral Density In Female Players: Comparisons Among Sports**

Duckhyun Nam, Seungyun Shin, Mihyun Lee, Yoonho Nam. *Yong in University, Yongin, Korea, Republic of.* (Sponsor: Zhu, Weimo, FACSM)  
(No relationships reported)

**PURPOSE:** The purpose of this study was to examine the bone mineral density (BMD) of female college athletes by sports and the relationship between BMD and body composition in an attempt to provide some information on how to improve their athletic performance.

**METHOD:** The subjects of this study were 73 female college athletes who had exercised for five or more years and had ever won a prize in national competitions: 21 taekwondo, 25 judo, 6 kendo, 9 table tennis and 12 basketball. Their body composition, spinal BMD, femur BMD and total BMD were measured by using Dual Energy X-ray Absorptiometry (GE Medical System Lunar, USA).

**RESULTS:** It was found that the judo players were the highest in spinal BMD, followed by the basketball, kendo, table tennis and taekwondo. In terms of femur BMD, judo players were the highest, followed by the basketball, kendo, taekwondo and table tennis. Comparison of the total BMD among sports, the judo players were the highest, followed by the basketball, kendo, table tennis and taekwondo. Low to moderately high correlations were found among BMD and body composition, weight and lean body mass index (BMI). Spinal BMD had highest correlation with BMI ( $r=.510$ ), followed by weight ( $r=.361$ ) and lean body mass ( $r=.305$ ); femur BMD had the highest correlation with BMI ( $r=.403$ ), followed by weight ( $r=.323$ ) and lean body mass ( $r=.322$ ); finally, total BMD had the highest correlation with BMI ( $r=.547$ ), followed by weight ( $r=.492$ ) and lean body mass ( $r=.431$ ).

**CONCLUSIONS:** It seems that characteristics of the sports exerted a different influence on BMD, and the sports with weight class such as Taekwondo had the lowest BMD, which may result from excessive weight control and accumulated training. Low to moderately high correlations were found between BMD and body composition.

**Bone Mineral Density and Fracture Risk in Young Competitive Female Cyclists**

Emily F. Foxman<sup>1</sup>, Marta Van Loan<sup>2</sup>, Caitlin Campbell<sup>2</sup>, Christina Lozada<sup>3</sup>, Gretchen Casazza<sup>4</sup>. <sup>1</sup>University of California, Davis, Davis, CA. <sup>2</sup>USDA Western Human Nutrition Research Center, Davis, CA. <sup>3</sup>University of California Davis Medical Center, Sports Medicine Program, Sacramento, CA. <sup>4</sup>Sports Performance Laboratory, University of California Davis Medical Center, Sports Medicine Program, Sacramento, CA.  
(No relationships reported)

**PURPOSE:** To determine if bone mineral density (BMD) and bone strength of competitive female cyclists is lower than the average population due to the low impact nature of their training.

**METHODS:** Eight competitive female cyclists (Age =  $26 \pm 4$  yrs) completed a maximal cycle ergometer exercise test and dual X-ray absorptiometry (DXA) and peripheral quantitative computed tomography (pQCT) scans to assess body composition, bone mineral density, bone strength and fracture risk. Serum samples for bone-specific alkaline phosphatase (BAP), carboxyterminal cross-linked telopeptide of type I collagen (CTX), parathyroid hormone (PTH), serum 25-hydroxy-vitamin D levels and estrogen were also collected. Summary of Results. Characteristics of the group included a  $VO_{2max}$  of  $53.7 \pm 5.5$  ml·kg<sup>-1</sup>·min<sup>-1</sup>, body fat of  $20.2 \pm 3.8\%$  and a total volume of training of  $10.5 \pm 3.3$  hrs per week. Total BMD was  $1.2 \pm 0.09$ , AP Spine was  $0.93 \pm 0.12$  and Femur was  $0.89 \pm 0.08$  g/cm<sup>2</sup>. Average z scores for total BMD was  $0.1 \pm 1.1$ , AP Spine was  $-1.1 \pm 1.1$  and Femur was  $-0.19 \pm 0.06$ .

**CONCLUSION:** Our results demonstrate that despite normal total body BMD, competitive cyclists had AP spine Z scores in the osteopenic range. This is especially significant in that athletes usually have higher than average BMD. Recommendations to add weight bearing cross training into the training regimens of cyclists may be warranted.

**Muscular Strength, Bone Mineral Content And Bone Metabolism In Female Adolescents**

Romulo M. Fonseca<sup>1</sup>, Ricardo J. Oliveira<sup>1</sup>, Nanci M. França<sup>2</sup>, Rinaldo W. Pereira<sup>2</sup>. <sup>1</sup>Universidade de Brasilia, Brasilia, Brazil. <sup>2</sup>Universidade Católica de Brasilia, Brasilia, Brazil.  
(No relationships reported)

Throughout life, bones adapt their strength parameters (size, shape and mass) through process of bone modeling and remodeling, in response to mechanical loading, which arises mainly from muscle contractions. However bone turnover markers and muscular strength have been poorly studied in the non-athletes growing skeleton.

**PURPOSE:** To investigate relationships among muscular strength and bone mineral content and metabolism in non-athletes female adolescents

**METHODS:** 148 post-pubertal (Tanner 4-5) healthy female adolescents were evaluated in this study (age:  $15.9 \pm 1.9$  years; body weight:  $52.7 \pm 8.2$  Kg; height:  $160.4 \pm 6.03$  cm). Muscular strength was evaluated by handgrip dynamometer. The average of the best scores of each hand was used. Arm bone mineral content was derived from total body exam in dual-energy x-ray absorptiometry. Blood serum osteocalcin (OC) and C-terminal telopeptide of type I collagen (CTX) were assessed by Elisa (Biosource hOST-EASIA kit and Serum CrossLaps® ELISA - ids, respectively). Pearson's correlation coefficient was used ( $p \leq 0.05$ ).

**RESULTS:** Muscular strength was associated to arm bone mineral content ( $r=0.55, p<0.01$ ), and it was negative associated to OC ( $r=-0.18, p<0.05$ ).

**CONCLUSIONS:** Arm muscular strength can influence local mineral content, however this influence seems to be too weak to modify bone turnover in healthy non-athletes female adolescents.

**Muscle Strength of Hip and Trunk and Bone Mineral Density in Postmenopausal Women**

Zhixiong Zhou, Lu Zheng, Fang Gu, Xun Li. *Capital University of Physical Education and Sports, Beijing, China.*  
(No relationships reported)

Few studies currently demonstrated the relationship between muscle strength (MS) of hip, trunk and adjacent bone mineral density (BMD) sites.

**PURPOSE:** To investigate the relationship between muscle strength and BMD in postmenopausal women with different age groups.

**METHODS:** 293 healthy postmenopausal women aged 44-64 ys ( $54.1 \pm 4.08$ ) were classified into five subgroups: 44-50ys(G1), 51-53ys(G2), 54-56ys(G3), 57-59ys(G4), 60-64ys(G5). BMD of lumbar (L2-4BMD), femur neck(FNBMD) and total body(TBMD) were measured by dual-energy X-ray absorptiometry (DXA). Muscle strength of hip and trunk were measured using an isokinetic dynamometer. Multiple linear regression was performed using all variables.

**RESULTS:** Regional and TBMD gradually decreased with age in postmenopausal women. MS of hip and trunk did not show a decreasing trend with age. The relation between MS at different degree and BMD associated with the different age groups, there was higher correlation coefficients between TBMD and MS ( $r=0.40-0.56, P<0.05$ ) at lower speed (hip at 120°/s, trunk at 30°/s) than between TBMD and MS ( $r=0.29-0.44, P<0.05$ ) at high speed (hip at 180°/s, trunk at 60°/s and 120°/s) in G1, G3, G4. Significant relationships were drastically reduced after adjusting for lean mass in G1-G4, but significant relationships between MS and BMD were found. After controlling for lean mass the relation between MS and BMD had no significance in G5. Significant correlation coefficients were observed between MS of hip flexor at 120°/s and L2-4BMD ( $r=0.285-0.606, P<0.05-0.01$ ), and MS of trunk extensor at 30°/s and FNBMD ( $r=0.296-0.406, P<0.05-$

0.01) in five subgroups. MS of hip extensor at 90° accounted for 18.8% of the variance of TBMD in G1 and 29.10% in G2, and accounted for 27.4% of the variance of L2-4 BMD in G3. MS of trunk flexor at 120°/s accounted for 23.4% of the variance of FNBMD in G5. Body weight was an independent predictor of TBMD accounting for 53.7% of the variance, and lean mass accounted for 33.2% of the variance of L2-4BMD in G5.

**CONCLUSION:** In postmenopausal women, muscle strength of hip and trunk did not show a decreasing trend with age and significant correlation were observed between BMD and MS of hip, trunk. Lean mass is an important determinant of BMD.

**2736** Board #8 June 1 9:30 AM - 11:00 AM

**Body Composition and Bone Mineral Density Responses to Different Intensity Resistance Training in Postmenopausal Women**

Linda Lin<sup>1</sup>, Michael Lo<sup>2</sup>, Min- Huei Hsieh<sup>1</sup>, Wei-Jen Yao<sup>1</sup>, Yi-Ju Chen<sup>1</sup>. <sup>1</sup>National Cheng Kung University, Tainan, Taiwan. <sup>2</sup>Kun Shan University, Tainan, Taiwan.  
(No relationships reported)

**PURPOSE:** The purpose of this study was to compare the effects of 24 weeks high- and medium-intensity resistance training (RT) on bone mineral density (BMD), body composition(BC), and muscular isokinetic strength in postmenopausal women.

**METHODS:** Thirty -two volunteers (50–67 years) matched for strength and randomly assigned to either the high-intensity (80% 1RM, 8 reps; HI, N = 11), medium-intensity (50% 1RM, 13reps; MI, N = 11) and control group (CG, N = 10). The exercise program consisted of using 9 resistance machines under supervised progressive resistance training two sessions per week for 24 weeks. Dual-energy X-ray absorptiometry (DXA) was used to measure subjects' body composition and total bone mineral density. Isokinetic knee and elbow extension/flexion (180°/s) performances were measured by the Biodex System 4 PRO. Total bone mineral density, body fat, lean body mass, and peak torque were measured at baseline and after 24 weeks training. The statistical comparisons for the different variables among the three groups were performed by applying one-way ANCOVA.

**RESULTS:** At baseline, the three groups had similar BMD, BC, and strength characteristics. After 24 weeks training, there were no differences between the three groups in the total bone mineral density and total body fat. HI increased significantly(3.5%) more than CG(-11%) in lean mass of arm( $p < .05$ ). The peak torque in biceps(27-29%) and quadriceps(15-22%) of both groups were also significantly higher than the control group (-2-4%)( $p < .05$ ), but there was no significant differences between three groups in triceps' peak torque.

**CONCLUSIONS:** These findings suggest that high- and medium-intensity resistance training effectively increase muscular strength and have equally beneficial effects in postmenopausal women. However, RT with higher intensity might have greater response at the upper body lean mass.

**2737** Board #9 June 1 9:30 AM - 11:00 AM

**The Relationship Between Protein Consumption And Bone Mineral Density In Postmenopausal Breast Cancer Survivors**

Emily Page, Emily Simonavice, Michael J. Ormsbee, Pei-Yang Liu, Jasminka Z. Ilich-Ernst, Jeong-Su Kim, Bahram H. Arjmandi, Lynn B. Pantan, FACSM. Florida State University, Tallahassee, FL.  
(No relationships reported)

Breast cancer survivors (BCS) encounter many side effects from cancer treatments that negatively affect body composition. Specifically, postmenopausal BCS have increased rates of bone turnover, leading to loss of bone mineral density (BMD). There is evidence to suggest a higher level of protein in the diet may be beneficial for bones in older adults. It has not been investigated whether higher protein consumption in BCS can lead to improved BMD.

**PURPOSE:** To evaluate the relationship between protein intake and BMD of various skeletal sites in postmenopausal BCS.

**METHODS:** Twenty seven BCS (age: 64±7yrs; BMI:27.7±5.5kg/m<sup>2</sup>) completed a 24-hour dietary recall to assess nutritional intake. Total body and regional (lumbar spine, femur, and forearm) BMD were measured via dual energy X-ray absorptiometry. One way analysis of variance was used to determine if BCS consuming greater than 20% protein (>20%) in diet differed in total and regional BMD compared to those consuming less than 20% (<20%). Multiple regression models (controlled for total lean mass, fat mass, vitamin D intake) were developed to examine the influence of protein intake on various BMD sites.

**RESULTS:** The BCS consumed on average 1920±783 kcal/day with 49±13% from carbohydrates, 34±9% from fat, and 17±7% from protein. Average calcium and vitamin D intake (from food and supplements) were 1846±746 mg/day and 1218±1408 IU/day, respectively. Protein intake was 1.06±0.54 g/kg of body weight per day. BCS consuming >20% protein had significantly higher total BMD (>20%: 1.252±0.124 vs <20%: 1.118±0.120 g/cm<sup>2</sup>) and femur BMD (>20%: 1.020±0.128 vs <20%: 0.900±0.107 g/cm<sup>2</sup>). There were no differences between the two groups in BMD of other skeletal regions, body weight, lean mass, fat mass, energy intake, calcium or vitamin D intake. In multiple regression models, controlled for total lean mass, fat mass, vitamin D intake, protein intake was a significant determinant of total body and femoral neck BMD.

**CONCLUSIONS:** Our findings indicate that BCS with greater than 20% daily protein consumption exhibit higher total BMD regardless of calcium, vitamin D, or energy intake. Further research in larger samples is needed to elucidate potential benefits of protein or other dietary regimens on BMD and body composition in postmenopausal BCS.

**2738** Board #10 June 1 9:30 AM - 11:00 AM

**High Impact Unilateral Exercise Increased Femoral Neck Bone Mineral Density in Older Men**

Sarah J. Allison<sup>1</sup>, Jonathan P. Folland<sup>1</sup>, Winston J. Rennie<sup>2</sup>, Greg D. Summers<sup>3</sup>, Katherine Brooke-Wavell<sup>1</sup>. <sup>1</sup>Loughborough University, Leicestershire, United Kingdom. <sup>2</sup>University Hospitals of Leicester, Leicester, United Kingdom. <sup>3</sup>Royal Derby Hospital, Derby, United Kingdom.  
(No relationships reported)

High impact exercise is effective for improving bone mineral density (BMD) in children and young adults, although the few studies in older adults have yielded mixed results. Older men are at risk of osteoporotic fractures but the feasibility of high impact exercise and its influence on BMD in this population is unknown. Age-related changes and lifestyle modification may confound exercise intervention trials in older people. The effect of these confounders can be minimised using a within-subjects unilateral design (exercise vs. control limb) that has greater statistical power.

**PURPOSE:** To investigate the influence of a 12 month high impact unilateral exercise intervention on femoral neck BMD in older men.

**METHODS:** Healthy community-dwelling older men completed a 12 month high impact unilateral exercise intervention which progressed to 50 multidirectional (vertical, anteroposterior, mediolateral, rotational) hops, 7 days a week on one randomly allocated leg. BMD of both femurs was measured using dual energy X-ray absorptiometry (DXA) at baseline and after 12 months of exercise, by an observer blind to the leg allocation. Two-way repeated measures ANOVA was used to identify leg (exercise leg [EL] vs. control leg [CL]) x time (pre vs. post) interactions.

**RESULTS:** Thirty-five men (mean ± SD, age 69.9 ± 4.0 yrs) exercised for 12 months and intervention adherence was 90.9 ± 9.1% (305 ± 30.5 sessions completed out of 336 prescribed sessions). Fourteen men did not complete the 12 month exercise intervention due to: health problems or injuries unrelated to the intervention (n=9), time commitments (n=2), or discomfort during exercise (n=3). Femoral neck BMD increased in the EL relative to the CL (mean ± SEM: EL 0.948 ± 0.018 to 0.954 ± 0.017g/cm<sup>2</sup>; CL 0.954 ± 0.018 to 0.945 ± 0.018 g/cm<sup>2</sup>; ANOVA leg x time  $P = 0.003$ ) as did femoral neck BMC (EL 5.50 ± 0.13 to 5.54 ± 0.12g; CL 5.51 ± 0.13 to 5.50 ± 0.13g; ANOVA leg x time  $P = 0.024$ ).

**CONCLUSION:** A 12 month high impact unilateral exercise intervention was feasible and effective for inducing modest increases in femoral neck BMD and BMC in older men. Carefully targeted high impact exercises may be suitable for incorporation into exercise interventions aimed at preventing fractures in healthy community-dwelling older men.

**2739** Board #11 June 1 9:30 AM - 11:00 AM

**Risk Factors for Low Bone Mineral Density in Institutionalized Individuals with Developmental Disabilities**

Michael A. Vice, Vinayak K. Nahar, Martha Bass, Allison Ford-Wade. The University of Mississippi, university, MS. (Sponsor: Mark Loftin, FACSM)  
(No relationships reported)

Persons with developmental disabilities are exposed to several factors which have been determined as risks for osteoporosis. Many of these individuals are non-ambulatory, resulting in lack of weight bearing activity which is well established as a major contributor to bone loss. It is suspected that low bone mineral density (BMD) and related fractures are more prevalent in non-ambulatory persons and persons with developmental disabilities. It is also suspected that low BMD in this population is due to the presence of multiple risk factors.

**PURPOSE:** The purpose of this study was to investigate risk factors for low bone mineral density in persons with developmental disabilities who reside in an institutional setting. With the assessment of risk factors we hope to establish protocol for 1) identifying high risk persons and 2) prevention of low BMD.

**METHODS:** A cross-sectional study was conducted to gather data from client charts, pharmacy records, dietary records,

**RESULTS:** Data were collected on 69 participants. Thirty-nine were male and 30 were female. Ages ranged from 19 to 67 years with only 10 of the participants being over 55 years old (mean age = 45.58, SD = 11.52). Sixty-six of the participants were ambulatory. All were diagnosed with varying levels of intellectual disability, with 35 being classified with Profound Mental Retardation. Ultrasound BMD measures ranged from a t score of 2.0 to -3.0. Thirty-six participants (52.2%) were classified as healthy BMD, 22 (31.9%) as osteopenic, and 11 (15.9%) as osteoporotic. BMD measures were not significantly associated with age, gender, height, weight, or BMI for this population ( $p > .05$ ). When BMD was categorized as healthy, osteopenia, or osteoporosis the association with classification of intellectual disability approached significance ( $X^2 = 14.83, p = .063$ ). A significant association was also found with anti-seizure medication use ( $X^2 = 23.62, p = .009$ ).

**CONCLUSIONS:** Risk factors for low BMD have been identified for the healthy, normal population. Data collected in this study indicate that institutionalized individuals, with varying diagnosis of intellectual disability, do not share these risk factors. Studies investigating risk factors and determinants of low BMD in this population are warranted.

**2740** Board #12 June 1 9:30 AM - 11:00 AM

**Effects of Exercise Training on Bone Mineral Density, Inflammatory Cytokines, and Biochemical Bone Markers**

Elisa A. Marques<sup>1</sup>, Jorge Mota<sup>1</sup>, Diana Tuna<sup>2</sup>, Tiago Guimarães<sup>3</sup>, Joana Carvalho<sup>1</sup>. <sup>1</sup>University of Porto - Faculty of Sport, CIAFEL, Porto, Portugal. <sup>2</sup>Hospital of S. João, Porto, Portugal. <sup>3</sup>University of Porto - Faculty of Medicine, Porto, Portugal.  
(No relationships reported)

Skeletal response to long-term exercise training is reduced in older adults; although most of the literature supports the notion that greater strain magnitudes and unusual strain distributions provide the most effective stimuli for bone formation, bone's response to exercise have produced inconsistent results. Moreover, experimental studies have recently implicated inflammation in the pathogenesis of osteoporosis.

**PURPOSE:** To determine the effects of 32-week exercise training on bone mineral density (BMD), biochemical markers of bone metabolism, and inflammatory cytokines concentrations.

**METHODS:** 47 healthy older adults (61-84 years) participated in a exercise training intervention that included resistance exercise training (2 days/week) plus a multicomponent weight-bearing impact exercise training (1 day/week) for 32 weeks. Outcome measures included lumbar spine (LS) and proximal femoral BMD (by dual X-ray absorptiometry), dynamic balance, serum osteocalcin (OC), C-terminal telopeptide of Type I collagen (CTX), osteoprotegerin (OPG), receptor activator of nuclear factor kappa B ligand (RANKL), high sensitive (hs)-CRP, and the inflammatory cytokines [interleukin (IL)-6, tumor necrosis factor (TNF- $\alpha$ ), and interferon (IFN)- $\gamma$ ] pre- and post-intervention. A two-way factorial ANOVA, with repeated measures on one factor (time), was performed for differences in main effects and time by group interactions for each dependent variable.

**RESULTS:** After 32 weeks, both men and women significantly increased trochanter ( $0.7 \pm 2.1\%$ ), intertrochanter ( $0.7 \pm 2.0\%$ ), total hip ( $0.6 \pm 1.7\%$ ), and LS BMD ( $1.7 \pm 2.3\%$ ), while OC, CTX, OPG and RANKL remained unchanged. In addition, IFN- $\gamma$  significantly decreased by 15.6% ( $p=0.002$ ), while there were no significant group or time effects in TNF- $\alpha$ . A significant decrease in IL-6 was observed only in men ( $9.0\%$ ,  $p=0.002$ ). The change in TNF- $\alpha$  was negatively correlated with the change in lumbar spine BMD ( $r=-0.30, p=0.047$ ).

**CONCLUSIONS:** Despite the lack of a significant change on bone turnover markers, our combined impact protocol decreased inflammation, and increased BMD in older adults. Results further support the beneficial role of long-term exercise on bone mass and low-grade inflammation.

**2741** Board #13 June 1 9:30 AM - 11:00 AM

**College-age Dancers Have Greater Bone Mass than Runners and Controls Despite Low Energy Availability**

Hawley C. Almstedt, Zakkoyya H. Lewis-Powell. Loyola Marymount University, Los Angeles, CA.  
(No relationships reported)

The Female Athlete Triad is a syndrome comprised of three inter-related conditions: menstrual dysfunction, suboptimal bone health, and poor energy availability (EA). EA is calculated as kilocalorie intake minus energy expended through activity.

**PURPOSE:** The goal of this research was to evaluate the relationship between EA and bone mineral density (BMD) in runners, dancers, and controls.

**METHODS:** Runners ( $n=13$ ), dancers ( $n=11$ ), and controls ( $n=15$ ) between the ages of 18-22 (mean= $19.8 \pm 1.1$  years) underwent BMD testing at the hip, spine, and whole body using dual-energy x-ray absorptiometry (DXA, Hologic Explorer, Waltham, MA). Dietary intake was assessed using the Block 2005 Food Frequency Questionnaire (Nutrition Quest, Berkeley, CA). Average daily energy expenditure was measured via an accelerometer (Philips Respironics Actical, Bend, OR) worn by participants at the right hip for an average of four days.
