## A-29 Exercise is Medicine/Poster - Body Composition, Diabetes, Cancer, Disease Management

May 30, 2012 7:30 AM - 12:30 PM

ROOM: Exhibit Hall

1220 Board #1 May 30 9:30 AM - 11:00 AM

### Sitting Time Was Highly Associated With Physical Activity Level And Obesity In Brazilian Public Employees

Luiz Guilherme G. Porto<sup>1</sup>, João Luis A. E. S. P. Leitão<sup>2</sup>, Évelin D. R. dos Santos<sup>2</sup>, Felipe F. Cavalcante<sup>2</sup>, Allan R. Mello<sup>2</sup>, Rayane G. A. Costa<sup>2</sup>, Leiriane V. Gregório<sup>2</sup>.  
<sup>1</sup>Brazilian Supreme Labor Court Health Service and University of Brasilia Faculty of Medicine - Cardiovascular Laboratory, Brasilia, Brazil. <sup>2</sup>Brazilian Supreme Labor Court Health Service, Brasilia, Brazil.

(No relationships reported)

Public health recommendations for physical activity (PA) have focused on the minimal PA that everyone should accumulate on a regular basis. Recently, studies have shown that sedentary behavior, as sitting time, could also be important in the public health context.

**PURPOSE:** To analyze the association between sitting time, PA level and body composition among Brazilian civil servants from the Superior Labour Court (TST).

**METHODS:** A cross-sectional study was done with a sample of 404 TST employees (189 women - 46.8%), aged 42.1±10.1 yrs and BMI: 26.0±4.3 kg/m<sup>2</sup>, randomly recruited and stratified by sex. Sitting time (ST) was assessed by questionnaire as proposed by Katzmarzyk et al (Med Sci Sports Exerc 41(5)), with data grouped in 2 categories: those who reported Longer ST Period (≥3/4 of day time - LSTP) and those who reported a Shorter ST Period (≤1/2 of day time - SSTP). PA level was characterized by the IPAQ Questionnaire, considering 2 PA categories: Insufficient Active group (IA - those who didn't met PA recommendations) and Active group (AT - those who met PA recommendations). Body composition was analyzed by BMI and obesity was considered when BMI≥30 kg/m<sup>2</sup>. Chi-square (X<sup>2</sup>) was used to analyze variable associations and Odds Ratio (95% CI) (OR) was calculated to evaluate the strength of the associations. Differences were considered statistically significant when p<0.05.

**RESULTS:** 181 volunteers (44.8%) reported a LSTP, 193 (47.8%) were IA and 68 (16.8%) were obese. ST frequencies and association analysis are shown on Table 1.

**CONCLUSIONS:** We observed a negative association between ST and PA level as for the body composition. Volunteers who reported a longer ST period showed a higher risk (estimated by OR) of been insufficiently active and obese.

Table 1: Absolute and relative frequencies of ST with Chi-square (X<sup>2</sup>) and OR analysis (n=404)

| Variables | LSTP        | SSTP        | X <sup>2</sup> | p       | OR (95% CI)        |
|-----------|-------------|-------------|----------------|---------|--------------------|
|           | n = 181     | n = 223     |                |         |                    |
| PA level  |             |             |                |         |                    |
| IA        | 110 (57.0%) | 83 (43.0%)  | 22.2           | <0.0001 | 2.61 (1.75 - 3.91) |
| AT        | 71 (33.6%)  | 140 (66.4%) |                |         |                    |
| BMI       |             |             |                |         |                    |
| ≥ 30      | 38 (55.9%)  | 30 (44.1%)  | 4.06           | = 0.04  | 1.71 (1.01 - 2.89) |
| < 30      | 143 (42.6%) | 193 (57.4%) |                |         |                    |

1221 Board #2 May 30 9:30 AM - 11:00 AM

### Body Mass Index of North American Participants at the World Masters Games

Mark DeBeliso<sup>1</sup>, Joe Walsh<sup>2</sup>, Kent J. Adams, FACSM<sup>3</sup>, Mike Climstein, FACSM<sup>4</sup>, Ian T. Heazlewood<sup>5</sup>, Stephen Burke<sup>2</sup>, Jyrki Kettunen<sup>6</sup>. <sup>1</sup>Southern Utah University, Cedar City, UT. <sup>2</sup>Australian Catholic University, Sydney, Australia. <sup>3</sup>California State University Monterey Bay, Seaside, CA. <sup>4</sup>Bond University, Gold Coast, Australia. <sup>5</sup>Charles Darwin University, Darwin, Australia. <sup>6</sup>Arcada University, Invalidisäätiö, Finland.

(No relationships reported)

World Masters Games (WMG) athletes have either pursued a physically active lifestyle for an extended period of time or have initiated exercise/sport in later life. This unique cohort of middle- to older-aged adults remains relatively uninvestigated with regards to various measures of health. With a need for multifaceted solutions to the obesity epidemic, investigating special populations such as those competing in sport at older ages may further the understanding of the nexus between aging, physical activity and obesity.

**PURPOSE:** To investigate the body mass index (BMI) of North American WMG competitors with respect to national health guidelines and demographics.

**METHODS:** An online survey was utilized to collect demographic information from athletes competing at the Sydney WMG. BMI was derived using the participant's height and body mass.

**RESULTS:** A total of 928 (46.7% male, 53.3% female) participants from Canada and the United States (age 52.6±9.8 yrs, range 27 to 87 yrs) completed the survey. The top 5 sports in which participants competed were football (25.6%), track/field (15.4%), swimming (8.4%), volleyball (8.2%), and softball (7.8%). Female and male BMI (kg/m<sup>2</sup>) across all sports were: >30 (obese-13.9%), 25-29.9 (overweight-34.1%), 18.5-24.9 (normal-50.3%), and <18.5 (underweight-1.7%). Data indicated that BMI was a health risk factor for 13.9% of the participants and a developing risk factor for 34.1% of the participants. Analysis demonstrated a significantly reduced (p<0.001) classification of obesity of the North American WMG competitors when compared to summary statistical values for the Canadian and United States national populations.

**CONCLUSIONS:** It is believed that adherence to exercise improves indices of general health. A key index of health (obesity) is significantly lower in incidence for North American WMG competitors when compared to Canadian and US populations.

1222 Board #3 May 30 9:30 AM - 11:00 AM

### The Health Benefits of Exercise are Independent of Weight Loss in Obese Men and Women.

Phillipa Caudwell<sup>1</sup>, Catherine Gibbons<sup>1</sup>, Mark Hopkins<sup>1</sup>, Neil King<sup>2</sup>, Erik Naslund<sup>3</sup>, Graham Finlayson<sup>1</sup>, John Blundell<sup>1</sup>. <sup>1</sup>University of Leeds, Leeds, United Kingdom. <sup>2</sup>Queensland University of Technology, Brisbane, Australia. <sup>3</sup>Karolinska Institute, Stockholm, Sweden.

(No relationships reported)

Exercise is often prescribed as a method of weight loss and weight management, whilst other health benefits of exercise are less emphasized. Weight loss is not the only benefit of exercise and may not be the most appropriate marker of health.

**PURPOSE:** To examine the relationship between weight change and changes in health parameters during a supervised exercise program.

**METHODS:** 107 overweight and obese men (n=35) and women (n=72) with a mean BMI=31.4±4.2kg/m<sup>2</sup> and age= 40.9±9.2years, completed a supervised 12 week exercise program designed to increase gross energy expenditure (EE) by 2500kcal/wk at an intensity of 70% of their maximum heart rate. Various health markers including blood pressure (BP), aerobic fitness (AF), resting heart rate (RHR), and body composition were measured at weeks 0 and 12.

**RESULTS:** There was a significant reduction in mean body mass ( $-3.2 \pm 3.2$  kg,  $p < 0.0001$ ), however, there was large individual variability (range:  $-14.7 - +3.7$  kg) and approximately half ( $n=59$ ) failed to change body composition as predicted - body mass ( $-0.81 \pm 2.11$  kg) and fat mass ( $-1.3 \pm 2.1$  kg). Despite this, their mean improvement in measured health markers was statistically significant: AF ( $+5.6 \pm 7.2$  ml/kg/min-1,  $p < 0.0001$ ) and fat free mass ( $+0.56 \pm 1.3$  kg,  $p = 0.002$ ) significantly increased, while RHR ( $-3.7 \pm 7.5$  bpm), Diastolic BP ( $-2.4 \pm 6.6$  mmHg,  $p = 0.008$ ), waist circumference ( $-3.2 \pm 2.7$  cm,  $p < 0.00001$ ) and % fat mass ( $-1.4 \pm 1.8$ ,  $p < 0.0001$ ) significantly decreased. Improvements in blood pressure changes were more marked when hypertensive (135/90 mmHg) individuals were examined separately. This group became normo-tensive by reductions in systolic ( $-13.0 \pm 10.1$  mmHg) and diastolic ( $-8.3 \pm 5.9$  mmHg) BP, which were independent of weight loss.

**CONCLUSIONS:** These data demonstrate that significant and meaningful exercise-induced health benefits can be achieved even with little or no weight loss. Therefore, the current public health focus on weight loss should be reduced and more attention focussed on improving general health. Supported by: Biotechnology and Biological Sciences Research Council (BB51/B/05079 and BB/G005524/1).

**1223** Board #4 May 30 9:30 AM - 11:00 AM

**Minimal Changes in Breathing Mechanics at Peak Exercise in Endurance-trained Obese Individuals**

Santiago Lorenzo<sup>1</sup>, J. Todd Basset<sup>2</sup>, Raksa B. Moran<sup>2</sup>, Jessica N. Pineda<sup>2</sup>, Tony G. Babb, FACSM<sup>3</sup>. <sup>1</sup>Texas Health Presbyterian Hospital Dallas and UT Southwestern Medical Center, Dallas, TX. <sup>2</sup>Texas Health Presbyterian Hospital Dallas, Dallas, TX. <sup>3</sup>UT Southwestern Medical Center, Dallas, TX.

(No relationships reported)

**PURPOSE:** Alterations in respiratory mechanics predisposes healthy obese individuals to low lung volume breathing at rest and during exercise, which places them at risk of developing expiratory flow limitation (EFL). The high ventilatory demand in endurance-trained obese adults further increases their risk of developing EFL as well as their work of breathing. Therefore, we measured breathing mechanics and ventilatory dynamics during exercise in endurance trained obese individuals.

**METHODS:** Seven (5W/2M) endurance-trained obese adults ( $35 \pm 3$  yr,  $37 \pm 5\%$  body fat,  $33 \pm 4$  BMI, mean  $\pm$  SD) underwent hydrostatic weighing, pulmonary function testing, submaximal and maximal cycle exercise testing, and the determination of the oxygen cost of breathing during eucapnic voluntary hyperpnea (EVH).

**RESULTS:** Pulmonary function was normal (FVC  $109 \pm 14\%$  predicted, FEV1  $108 \pm 11\%$  predicted, PEF  $119 \pm 13\%$  predicted, MVV  $129 \pm 6\%$  predicted, TLC  $101 \pm 13\%$  predicted, FRC  $45 \pm 6\%$  TLC). Peak  $\dot{V}O_2$  and work rate were  $135 \pm 16$  and  $133 \pm 9\%$  predicted, respectively. Peak ventilation, tidal volume, and breathing frequency were  $125 \pm 36$  L/min ( $77 \pm 11\%$  MVV),  $2.6 \pm 0.6$  L ( $56 \pm 5\%$  FVC), and  $49 \pm 8$  bpm, respectively. During submaximal exercise end-expiratory lung volume dropped slightly but it returned to resting levels at peak exercise (rest  $41.5 \pm 5.7$ , submaximal  $38.1 \pm 8.5$ , peak  $42.0 \pm 7.2\%$  TLC). Slight EFL at peak ( $16 \pm 5\%$  of tidal volume) without desaturation ( $98 \pm 1\%$ ) was observed in 6 subjects (5W/1M). During submaximal exercise the ventilatory response ( $\dot{V}E/\dot{V}CO_2$  slope) was  $25 \pm 1$ , and at peak exercise the rating of perceived breathlessness (Borg 0-10 scale) was  $7.7 \pm 1.6$ . The estimated oxygen cost of breathing during EVH was  $1.75 \pm 0.74$  ml/L and during peak exercise averaged  $7 \pm 3\%$  of peak  $\dot{V}O_2$ .

**CONCLUSIONS:** Fit obese individuals were able to adequately increase ventilation and match the elevated metabolic demand associated with high fitness without substantial alterations in breathing mechanics. We conclude that endurance-trained obese individuals with normal lung function are not limited by breathing mechanics, which is good news for otherwise healthy obese adults who wish to participate in vigorous exercise training.

**Fat Free Mass Response Of Overweight Males Following 12 Weeks Of High-intensity Intermittent Exercise**

Mehrdad Heydari<sup>1</sup>, Judith Freund<sup>2</sup>, Stephen H. Boutcher, FACSM<sup>1</sup>. <sup>1</sup>University of New South Wales, Sydney, Australia. <sup>2</sup>St Vincent's Hospital, Sydney, Australia.

(Sponsor: Stephen Boutcher, FACSM)

(No relationships reported)

The effect of high-intensity intermittent exercise (HIIE) on fat free mass (FFM) of overweight males is undetermined.

**PURPOSE:** To examine the effect of a 12-week HIIE intervention on FFM levels of sedentary overweight men.

**METHODS:** Thirty eight males aged  $24.9 \pm 4.3$  years, with a BMI of  $28.7 \pm 3.1$  kg/m<sup>2</sup>, and body mass of  $88.4 \pm 11.9$  kg underwent a  $\dot{V}O_{2max}$  test pre- and posttraining. Total body fat and FFM was assessed by dual energy x-ray absorptiometry. Subjects, who were randomly assigned to HIIE ( $n=20$ ) or control groups ( $n=18$ ), exercised three times a week for 12 weeks under supervision. The HIIE group completed 20 minutes of exercise (8 s sprint, 12 s recovery) each session, whereas controls performed no structured exercise for 12 weeks. Dietary intake was monitored through food diaries.

**RESULTS:**  $\dot{V}O_{2max}$  was significantly improved,  $P < 0.05$ , by an increase of 15% in the HIIE group ( $34.2 \pm 4.4$  to  $39.4 \pm 3.5$  ml.kg<sup>-1</sup>.min<sup>-1</sup>) and remained unchanged in the control group. Total FFM was significantly increased,  $P < 0.05$ , in the exercise group by 1.2 kg ( $54.3 \pm 6.5$  to  $55.5 \pm 6.1$  kg) and remained unchanged in controls ( $53.8 \pm 6.5$  to  $54.2 \pm 6.1$  kg). FFM increased by 0.4 kg in the leg ( $18.6 \pm 2.5$  to  $19.0 \pm 2.4$  kg) and 0.7 kg in the trunk ( $24.9 \pm 3.1$  to  $25.6 \pm 3.0$  kg) and was unchanged in the arm. Total fat mass in the HIIE group was significantly reduced ( $29.8 \pm 7.1$  to  $27.8 \pm 6.9$  kg;  $P < 0.05$ ) by 7%, whereas in the controls fat mass was unchanged ( $31.7 \pm 9.3$  to  $31.8 \pm 9.9$  kg).

**CONCLUSIONS:** Twenty minutes of HIIE, three times a week for 12 weeks, led to a significant decrease in fat mass and a significant increase in FFM in overweight, young males.

**A Multidisciplinary Intervention Results in Sustained Improvements in Fitness and Metabolic Profile in Overweight Youth**

Karissa L. Peyer<sup>1</sup>, R Randall Clark<sup>1</sup>, Jens Eickhoff<sup>2</sup>, Aaron L. Carrel<sup>2</sup>. <sup>1</sup>University of Wisconsin Hospital and Clinics, Madison, WI. <sup>2</sup>University of Wisconsin School of Medicine and Public Health, Madison, WI.

(No relationships reported)

**PURPOSE:** To evaluate the impact of a clinical intervention on body composition, aerobic fitness, cholesterol, and insulin sensitivity in a clinic for overweight children.

**METHODS:** 79 children (age  $10.56 \pm 3.24$  years, BMI z-score  $1.15 - 3.48$ ) were followed for 24 months at a Pediatric fitness clinic. All children were seen for initial visit (T0), at 12 months (T12), 24 months (T24), and often for addition follow-up visits between these time points. All children had height, weight, and blood pressure assessed and BMI z-score was computed. DXA and a submaximal treadmill test were used to assess body composition and aerobic fitness. Many children also had carbohydrate and lipid metabolism assessed. Children and parents attended appointments with physicians, registered dietitians, and exercise physiologists to assess lifestyle habits and establish goals for healthy change. Follow-up intervals were set on an individual basis and typically ranged from 6 weeks to 3 months. Changes from baseline were evaluated using the nonparametric Wilcoxon Signed Rank test. Spearman's rank correlations were also performed to assess relationships between variables.

**RESULTS:** At T12, significant changes (mean  $\pm$  SD) were seen in  $\dot{V}O_{2max}$  ( $1.39 \pm 3.25$  ml/kg/min,  $p = 0.001$ ), %fat ( $-2.18 \pm 2.79\%$ ,  $p < 0.001$ ), BMI z-score ( $-0.09 \pm 0.21$ ,  $p < 0.001$ ), and Total Cholesterol ( $-19.72 \pm 44.42$  mg/dL,  $p = 0.01$ ). There were no significant changes in fasting glucose, insulin or blood pressure. There were no significant differences between genders. All improvements remained significant at T24 [ $\dot{V}O_{2max}$  ( $1.32 \pm 3.98$  ml/kg/min,  $p = 0.006$ ), %fat ( $-1.25 \pm 2.87\%$ ,  $p = 0.006$ ), BMI z-score ( $-0.13 \pm 0.28$ ,  $p < 0.001$ ), and Total Cholesterol ( $-11.82 \pm 22.77$  mg/dL,  $0.025$ )]. Correlation analysis revealed a significant negative correlation ( $p < 0.001$ ) between changes in BMI z-score and  $\dot{V}O_{2max}$  levels from baseline to T12 ( $r = -0.67$ ) and T24 ( $r = -0.71$ ).

**CONCLUSIONS:** A personalized, multidisciplinary intervention focusing on lifestyle changes in nutrition and exercise for children yielded significant improvements in cholesterol measures, aerobic fitness, body composition and BMI for 2 years. Children who displayed positive changes in BMI z-score also saw the greatest improvement in  $\dot{V}O_{2max}$ . Further research should evaluate outcomes at longer follow-up intervals.

1226 Board #7 May 30 9:30 AM - 11:00 AM

**Body Mass Index and Parental Efficacy for Children's Exercise within a Youth Weight Management Program**

David Bellar<sup>1</sup>, Charly L. Bryan<sup>1</sup>, Lisa Broussard<sup>1</sup>, Holly Howat<sup>1</sup>, Lawrence W. Judge<sup>2</sup>. <sup>1</sup>University of Louisiana at Lafayette, Lafayette, LA. <sup>2</sup>Ball State University, Muncie, IN.

(No relationships reported)

Childhood obesity is an alarming trend within the United States and other areas of the world. Greater understanding of the predictors of childhood obesity and overweight are necessary to effectively combat this growing problem.

**PURPOSE:** The present investigation was designed assess the efficacy of parental provision of exercise for children and its relationship to health and fitness in a group of overweight and obese youth.

**METHODS:** Fourteen parents and children (Male n=5, Female n=9, Age: 11.0±2.0yrs, Height 152.5±12.3cm, BMI 34.75±10.3) volunteered to participate in the present investigation. The participants were selected from the population of a local youth weight management program. After consent and assent were collected, the parents were asked to fill out a modified version of the Self Efficacy Scale for Exercise. The youth were tested for cardiovascular fitness via a progressive 20 meter shuttle run, body composition via two site skinfold testing (calf and triceps), body mass index, muscular endurance via curl up and push up tests, and flexibility through back saver sit and reach as well as trunk lift and shoulder flexibility testing.

**RESULTS:** In general the youth in the study were classified in the healthy fitness zone for the flexibility assessments, however, for all body mass or body composition assessments and tests of muscular endurance or aerobic capacity participating youth were below the healthy fitness zone. There was a significant negative correlation between the reported efficacy of provision of exercise by the parents and the body mass index of the children ( $r=-0.522$ ,  $p=0.05$ ).

**CONCLUSIONS:** The results of this study suggest that parental efficacy may be a discriminating factor within a population of overweight and obese, low fitness level youth. As such, parental empowerment may be a key to health related fitness within this population.

1227 Board #8 May 30 9:30 AM - 11:00 AM

**Effects Of Family-based Behavioral Group Therapy And Exercise Training In Pre-pubertal Obese Children And Their Mother**

Nathalie J. Farpour-Lambert<sup>1</sup>, Albane M. Maggio<sup>1</sup>, Xavier E. Martin<sup>1</sup>, Sophie Bucher Della Torre<sup>2</sup>, Yacine Aggoun<sup>1</sup>, Maurice Beghetti<sup>1</sup>. <sup>1</sup>University Hospital of Geneva, Geneva<sup>14</sup>, Switzerland. <sup>2</sup>School of Dietetics HES, Geneva, Switzerland.

(No relationships reported)

**PURPOSE:** To determine the effects of a family-based behavioral group therapy combined with an exercise training program on body fat and cardio-respiratory fitness in pre-pubertal obese children and their mother.

**METHODS:** This was a 6-month RCT including 50 pre-pubertal obese children (mean age 9.7 years, 95% CI 9.1-10.1) and their mother (40.5 years, 38.2-43.0) were randomly assigned to an Intervention (I, n=25) or a Control group (C, n=25). The intervention consisted of 14 behavioral group therapy sessions (nutrition, physical activity, body image, motivation, positive reinforcement, social and parental skills) once a week for children and mothers separately. In addition, children exercised (swimming, ball games, resistance training) one hour twice a week, and mothers participated to a one-hour Nordic walking session per week. We assessed changes at 6 months in BMI, waist circumference (WC), total body and abdominal fat by dual-energy x-ray absorptiometry (DXA), and cardio-respiratory fitness (VO2max).

**RESULTS:** At baseline, children's characteristics were similar among groups. Mothers in the Intervention group had significantly ( $p<0.05$ ) higher WC, total body and abdominal fat than Controls. At 6 months, using mixed linear regression, we observed significant changes in children's BMI (I-C treatment effect -0.67 g.cm-2), BMI Z-score (-0.15), WC (-1.33 cm), total body fat (-0.94%), abdominal fat (-2.08%), and VO2max (83.7 ml.min-1). In mothers, significant changes in BMI (I-C treatment effect -0.85 kg.cm-2), WC (-9.24 cm), total body fat (-0.61%), and abdominal fat (-1.43%) were shown.Changes in VO2max were not significant in mothers.

**CONCLUSIONS:** Family-based behavioral therapy combined with exercise training significantly reduces BMI and body fat in both pre-pubertal obese children and their mother. This is an interesting public health approach to promote behavioral changes and reduce the degree of adiposity at the family level. This study was funded by the Swiss National Science Foundation (#3200B0-120437) and the Geneva University Hospital Research and Development Fund.

1228 Board #9 May 30 9:30 AM - 11:00 AM

**Examination of Modifiable Risk Factors for Obesity-Related Disease in African American College Students**

Brenda L. Swearingin<sup>1</sup>, Jamie E. Robbins<sup>2</sup>, Patricia A. Lynch<sup>1</sup>, Wi-Young So<sup>3</sup>, Brandon J. Crooms<sup>1</sup>. <sup>1</sup>North Carolina A&T State University, Greensboro, NC. <sup>2</sup>Winston Salem State University, Winston Salem, NC. <sup>3</sup>Seoul Women's University, Seoul, Korea, Republic of.

(No relationships reported)

The disparity in the prevalence of obesity and concomitant risk for cardiovascular disease in African Americans (AA) is a significant medical concern. Obesity-related chronic disease, associated with modifiable behaviors, is being diagnosed in younger AA populations.

**PURPOSE:** To examine relationships of the following variables in AA college students: 1) social support for healthy behaviors, 2) amount of physical activity (PA), 3) diet, 4) body mass index (BMI), 5) systolic (SBP) and diastolic (DBP) blood pressure, and 6) waist circumference (WC).

**METHODS:** 412 AA students completed a physical exam (BMI, SBP, DBP and WC) and a packet of surveys including the social support survey (SOC), a fruit and vegetable screener (FVS), a fat screener survey (FS), and the Paffenbarger PA questionnaire. Relationships were analyzed using one-way ANOVA, tukey post hoc comparisons and logistical regression.

**RESULTS:** The prevalence of overweight (OVW) and obesity (OB) was 28.3% and 30.3% respectively in males (N= 198, 20±1.5yrs) and 23.0% and 26.7% respectively in females (N=217, 19.8±1.6 yrs). In males, OVW subjects had WC ( $p < 0.01$ ) and SBP ( $p < 0.05$ ) indicating risk for cardiovascular disease (CVD) and low PA for recreational activities ( $p < 0.05$ ). The OB group was classified as increased risk for WC ( $p < 0.001$ ), SBP ( $p < 0.001$ ), and DBP ( $p < 0.001$ ) and lower than normal recreational activities ( $p < 0.05$ ). Female subjects in the OVW group met risk classification criteria for WC ( $p < 0.001$ ) and SBP ( $p < 0.05$ ). Female subjects in the OB group had CVD risk classifications for WC ( $p < 0.001$ ), SBP ( $p < 0.001$ ), and DBP ( $p < 0.001$ ) and lower than normal PA ( $p < 0.05$ ). Logistic regression showed, for both males and females, there was no statistical significance between OVW or OB and SOC, PA, FVS, and FS for males or females. When PA was increased by 1,000 kcal, the prevalence of OB decreased by 9.3% (OR = 0.907, CI = 0.834-0.986,  $p = 0.022$ ) in males and 9.0% (OR = 0.910, CI = 0.839-0.988,  $p = 0.025$ ) in females.

**CONCLUSIONS:** The only significantly different risk factor for obesity in college African Americans is PA. Differences in female PA for normal vs. overweight/obesity existed in total PA; however, males demonstrated significant differences in PA for recreational activities alone. Supported by USDA Grant 0204191.

**Student Athletes Have A More Favorable Body Composition And Bone Mineral Density Than Non-athletes**

Hattie H. Wright, Chrisna R. Botha, Lize Havemann-Nel. North-West University, Potchefstroom, South Africa.

(No relationships reported)

**PURPOSE** Data on the relative contribution of planned exercise to body composition and BMD of premenopausal black and white African women is scarce.

**METHODS:** Volunteer black and white University female students were recruited into groups according to exercise and race, namely white athletes (WA, n=117) and black athletes (BA, n=50), doing ≥5h/wk of planned weight bearing exercise, as well as white non-athletes (WNA, n=44) and black non-athletes (BNA, n=44) doing ≤1h/wk of planned exercise. Students with a body mass index (BMI) <28.0 and not pregnant were included. Exclusion criteria were use of corticosteroids/thiazides for ≥ 6 months and any known bone disease. Alpine spine (APS), femoral neck (FN), total hip (TH), and whole body (WB) BMD as well as body composition were measured with dual energy X-ray absorptiometry.

**RESULTS:** Mean age, weight, height, and BMI for the total group were 20.3±1.8yrs, 60.7±8.6kg, 1.65±0.1m, and 22.1±2.3kg/m<sup>2</sup>. WA were younger and heavier than both BNA and BA (p<0.05). Height differed significantly between all groups with WA the tallest and BNA the shortest [median = 1.67(1.64-1.72)m vs. 1.59(1.54-1.64)m, p<0.05]. After adjusting for age and weight BMD were similar between WNA and BNA, as well as WA and BA. WNA had lower BMD at all sites compared to WA (p<0.001). BNA had lower BMD at all sites compared to BA [APS= 0.969(0.912-1.028) vs. 1.087(0.991-1.148)g/cm<sup>2</sup>; FN=0.821(0.773-0.904) vs. 0.951(0.888-1.028)g/cm<sup>2</sup>; TH=0.926(0.872-1.012) vs. 1.028(0.959-1.099)g/cm<sup>2</sup>; and WB=1.072(1.003-1.108) vs. 1.129(1.074-1.180)g/cm<sup>2</sup>; p<0.001]. Body fat percentage (BF%) was similar between WNA and BNA as well as WA and BA. WNA had significantly higher BF% than WA, and BNA than BA (p<0.05). Fat-free mass was similar between WNA and BNA, but lower in BNA compared to both WA and BA [38.3(33.5-42.0)kg vs. 46.4(43.3-49.1)kg and 42.3(39.9-46.7)kg, p<0.001]. 36.4% WNA and 31.8% BNA had a Z-score between -1.0 and -2.0 at one or more BMD sites compared to 7.7% WA and 10% BA. Positive correlations were found between fat-free mass and height (r=0.7), weight (r=0.8), APS, FN, TH, and WB BMD (r=0.5 for all, p<0.05).

**CONCLUSIONS:** Exercise seemed to be the main contributing factor towards a higher BMD and a healthier body composition amongst this group of female students; ethnicity did not seem to play a role.

**1230**    *Board #11*    **May 30**    **9:30 AM - 11:00 AM**

**Effect Of Tai Chi During Dietary Weight Loss On Body Composition In Obese, Postmenopausal Women**

Lynn A. Katkowsk, Marisa C. Benson, Steven Magnanti, Matthew J. Delmonico, Ingrid E. Lofgren, Furong Xu. *University of Rhode Island, Kingston, RI.*

(No relationships reported)

Obesity is a growing problem for the aging population. Obesity, particularly in older women, is associated with increased risk for chronic disease, disability, and loss of physical functioning. Tai Chi, a low impact form of exercise, has been shown to be effective in improving outcomes including strength and balance in older adults. However, there is no published research examining the effect of Tai Chi during dietary weight loss on body composition in obese older women.

**PURPOSE:** To examine the additive effect of Tai Chi during dietary weight loss on body composition in obese, postmenopausal women.

**METHODS:** A 16-week trial was conducted with 27 obese women randomized to a Tai Chi plus weight loss group (TCWL, n=14, age 60.4 ± 5.9 years, BMI = 34.3 ± 5.1 kg/m<sup>2</sup>) or a weight loss only group (WL, n=13, age 62.7 ± 6.0 years, BMI = 34.8 ± 2.9 kg/m<sup>2</sup>). Body mass, height, and waist circumference were assessed using standard techniques. Total body mass, fat mass, and fat free mass were assessed using dual-energy x-ray absorptiometry. Thigh tissue composition was assessed using computed tomography. Both groups received a Dietary Approaches to Stop Hypertension-based weight loss program. The TCWL group also participated in three Tai Chi exercise sessions (~45 min) per week. Between-group comparisons were analyzed using an analysis of covariance adjusting for baseline values.

**RESULTS:** Both groups significantly lost body mass (TCWL, -2.2 ± 0.9 kg; WL, -3.7 ± 0.9 kg; both p < 0.05) with no between-group differences. The TCWL group had a borderline attenuation in fat-free mass change compared to the WL group (-0.2 kg vs. -1.2 kg, p = 0.056). There were significant between group differences in thigh high density muscle (-0.54 kg vs. -1.32 kg, p = 0.0311). There were no significant between group changes in BMI, total fat mass, percent body fat, waist circumference, fat area, normal density muscle, or muscle fat.

**CONCLUSIONS:** Tai Chi appears to aid in preservation of fat free mass but does not have significant additive effect on body fat measures during dietary weight loss in older, postmenopausal women.

**Effect Of Martial Arts Exercise On Body Composition, Bone Biomarkers, And Quality Of Life In Overweight Premenopausal Women**

Ming-Chien Chyu<sup>1</sup>, Raul Y. Dagda<sup>2</sup>, Susan Doctolero<sup>2</sup>, Eugene Chaung<sup>2</sup>, Vera Von Bergen<sup>2</sup>, Yan Zhang<sup>2</sup>, Michael Ragain<sup>2</sup>, Jean-Michel Brismée<sup>2</sup>, Chwan-Li Shen<sup>2</sup>.

<sup>1</sup>Texas Tech University, Lubbock, TX. <sup>2</sup>Texas Tech University Health Sciences Center, Lubbock, TX.

(No relationships reported)

**INTRODUCTION:** Various exercise interventions have been shown to benefit weight control and promote general health, including bone health. Bone mineral density at the spine and hips as well as bone formation markers were found to be significantly associated with the level of physical activity of healthy premenopausal women. However, there is no data on the effects of martial arts exercise (MAE) on body composition, bone biomarkers, and quality of life in overweight/obese premenopausal women.

**PURPOSE:** To evaluate the effects of 12 weeks of MAE intervention on body composition, bone biomarkers and quality of life in overweight/obese premenopausal women.

**METHODS:** After screening, qualified premenopausal women were randomized into two groups: MAE (1 hr/session, 3 sessions/week for 12 weeks) or control group. Body composition (Tanita Body Composition Monitor), serum biomarkers (osteocalcin, C-terminal telopeptide, insulin-like growth factor-I, leptin, and C-reactive protein), and quality of life (SF-36) were assessed at baseline, 6, and 12 weeks. Data were analyzed using paired t-tests.

**RESULTS:** Twenty-three subjects participated in the MAE group (40.2±5.7 yr, BMI: 36.0±5.4 kg/m<sup>2</sup>) and 24 in the control group (40.6±6.9 yr, BMI: 35.8±7.1 kg/m<sup>2</sup>). Fourteen subjects dropped out (7 in MAE, 7 in control) before completing the intervention due to issues such as family, job, personal, and schedule. Compared to the control group, MAE group tended to lose body weight (P=0.09) along with decreased fat-free mass (P=0.007) and muscle mass (P=0.022). The MAE group demonstrated an increase in serum insulin-like growth factor-I concentration (P=0.045), but no change in other serum biomarkers including osteocalcin (bone formation biomarker), C-terminal telopeptide (bone resorption biomarker), leptin and C-reactive protein. The results of SF-36 revealed that subjects in the MAE group reported a significant improvement in general health, vitality, role-emotional, and mental health as compared to those in the control group.

**CONCLUSIONS:** MAE may be a feasible, low-cost, and effective approach to improve body composition and quality of life in overweight/obese premenopausal women. Our study underscores the need for further long-term studies using larger sample size to establish the benefits of MAE in this/other populations.

**1232**    *Board #13*    **May 30**    **9:30 AM - 11:00 AM**

**Exercise Vital Sign Correlates with Diabetes Control**

Robert Sallis, FACSM<sup>1</sup>, Eunis Ngor<sup>2</sup>, Karen Coleman<sup>2</sup>. <sup>1</sup>Kaiser Permanente Medical Center, Fontana, CA. <sup>2</sup>Southern California Permanente Medical Group, Pasadena, CA.

(No relationships reported)

The Exercise is Medicine campaign calls for physicians to evaluate the exercise habits of their patients and Kaiser Permanente in Southern California (KPSC) was the first major healthcare system to begin using an exercise vital sign to record patient activity levels at every visit. Use of the "Exercise Vital Sign" (EVS) began in October of 2009, with every patient reporting the minutes per week of moderate or greater exercise they typically engage in. In addition, the role of physical activity in both the treatment and prevention of diabetes has been well established. It stands to reason that patients who report doing recommended amounts of regular exercise are likely to have improved control of their diabetes.

**PURPOSE:** To evaluate the correlation between self reported exercise level (using the EVS) and diabetes control as assessed by hemoglobin A1c (HbA1c) levels.

**METHODS:** Data were abstracted from the KPSC electronic medical records of 362,856 adults 18 years and older who had at least one HbA1c value during 4/1/2010 to 3/31/2011. Poisson regression analyses were done to determine the association of the following predictors with HbA1c values >= 7.0: age, gender, race/ethnicity, body mass index (BMI), Charlson comorbidity index, and median exercise min/wk.

**RESULTS:** Independent of all other predictors including BMI and disease burden, adults who were completely sedentary (0 min/wk) had 16% increased risk of HbA1c >= 7.0 as compared to adults who were regularly active (150 min/wk; p < .001).

**CONCLUSIONS:** Based on data from the EVS, we conclude that self reported physical activity is strongly correlated with improved diabetes control. It is well known that improved diabetes control is a major factor in reducing complications and costs associated with diabetes. For this reason, it seems logical that all diabetic patients who report they are not doing any exercise should be targeted with interventions designed to increase their weekly levels of physical activity.

1233 Board #14 May 30 9:30 AM - 11:00 AM

**Effect Of Exercise Training On Neuromuscular Function Of Arm And Leg Muscles Of Diabetic Patients**

Massimo Sacchetti<sup>1</sup>, Ilenia Bazzucchi<sup>1</sup>, Francesco Felici<sup>1</sup>, Susan Dewhurst<sup>1</sup>, Antonio Sgadani<sup>2</sup>, Giuseppe De Vito<sup>1</sup>. <sup>1</sup>University of Rome Foro Italico, Rome, Italy. <sup>2</sup>Università Cattolica del Sacro Cuore, Rome, Italy. (Sponsor: Carl Foster, FACSM)  
(No relationships reported)

Diabetes is associated to muscle weakness and physical disability. On the other hand, exercise training has the potential of counteracting the diabetes-associated derangement of neuromuscular function.

**PURPOSE:** To investigate the effect of exercise training on neuromuscular function of arm and leg muscles in type 2 diabetic patients.

**METHODS:** Eight type 2 sedentary diabetic patients (D, 61.0±2.3) and eight sedentary healthy matched control subjects (H, 63.9±3.8) underwent a 16-week supervised combined aerobic and resistance exercise training program. Before and after training, maximal isometric (MVC) and isokinetic (15, 30, 60, 120, 180 and 240°/s) muscle strength of the elbow flexors (EF) and knee extensors (KE) were assessed to investigate the torque-velocity relationship. Simultaneously, the EMG activity from the biceps brachii (BB) and the vastus lateralis (VL) muscles was recorded by means of array electrodes, in order to estimate the muscle fibre conduction velocity (MFCV).

**RESULTS:** After the training program, no significant changes in EF maximal torque values were noted in both groups. Differently, KE maximal torque values of D were significantly enhanced (p<0.05) during the MVC (+10.8%) and during isokinetic contractions at 15, 30 and 60 °s<sup>-1</sup> (+17.1% on average). EMG data mirrored what found for torque, with an increase in MFCV in VL in D during MVC and during isokinetic contractions at 15 and 30 °s<sup>-1</sup> (+ 11.2% on average; p<0.01).

**CONCLUSIONS:** Exercise training is more effective in KE than in EF muscles of diabetic patients, as shown by the shift toward higher values of the torque-velocity relationship and the enhancement of MFCV. This is in line with the more pronounced neuromuscular impairment of the lower than the upper extremities in type 2 diabetes.

1234 Board #15 May 30 9:30 AM - 11:00 AM

**Compliance, Safety And Utility Of Smartphone Indicators During A 52 Week Randomized Trial Of Prescriptive Exercise In Rural Patients With Metabolic Syndrome**

Robert J. Petrella, FACSM<sup>1</sup>, Melanie Stuckey<sup>1</sup>, Kristin Sabourin<sup>1</sup>, Sheree Shapiro<sup>1</sup>, Brittany Izanstadt<sup>2</sup>, John A. Petrella<sup>1</sup>, Claudio Munoz<sup>3</sup>, Robyn Fulkerson<sup>4</sup>. <sup>1</sup>U Western Ontario, London, ON, Canada. <sup>2</sup>U Waterloo, Waterloo, ON, Canada. <sup>3</sup>Gateway Rural Research Institute, Seaforth, ON, Canada. <sup>4</sup>Sykes Assistance Services, London, ON, Canada.  
(No relationships reported)

**PURPOSE:** To determine whether remote clinical monitoring technologies can provide markers of intervention compliance, safety and efficacy outside the clinic setting.

**METHODS:** In a 52 week randomized trial of lifestyle intervention to modify risk factors for metabolic syndrome (Artemis), we used a Smartphone technology- intensive monitoring system linked to a central database in an underserved rural setting. 75 participants were prescribed a lifestyle intervention and provided with Smartphones and Bluetooth-enabled blood pressure (BP) monitors, glucometers and pedometers. Smartphones transmitted pre-determined daily clinical data to a central database (Healthyanywhere™): BP twice daily; blood glucose (BG) twice daily and steps daily. A customized, proprietary decision support system (DSS) detected abnormal clinical data and life style patterns based on pre-determined clinical threshold algorithms. BP was grouped as normal, high-normal, pre-hypertensive, Stage 1, Stage 2; BG as normal, impaired glucose tolerance, diabetic; steps as sedentary, low active, somewhat active, active and highly active.

**RESULTS:** 68 participants (48 women) [56.8 (9.8)] years old completed the study and are reported 0-12, 13-24 and 25-52 weeks. No differences were observed for gender. Compliance with data transmission was high (81-94%) across all measures and did not change over time. Surprisingly, BP and BG were more compliant than daily steps transmission. Most clinical data were in the target therapeutic range over time. BP and BG highest 2 groups showed a decline (p<0.05) over the course of the study. 28-30% of patients achieved the target of 10,000 steps per day at each time point. % of patients in the sedentary, low and somewhat active groups declined with time (p<0.05).

**CONCLUSIONS:** These findings show that clinical data transmission compliance was high and few patients showed clinically relevant alerts during a 52 week lifestyle intervention. High threshold alerts decreased over time while more patients became active. Smartphone monitoring of lifestyle interventions appears to be an important tool for monitoring safety and utility of lifestyle interventions in primary care.

1235 Board #16 May 30 9:30 AM - 11:00 AM

**The Reliability of Behavioral Modification (Diet and Physical Exercises) on Metabolic Syndrome Primary Care**

Franz H P Burini<sup>1</sup>, Okesley Teixeira<sup>2</sup>, Fernando Moreto<sup>2</sup>, Erick P. de Oliveira<sup>2</sup>, Roberto C. Burini<sup>2</sup>. <sup>1</sup>USP - PRONUT, São Paulo, Brazil. <sup>2</sup>UNESP - Univ Estadual Paulista, Medical School, Botucatu, Brazil.  
(No relationships reported)

There is no curative model for the Metabolic Syndrome (MetS), being the primary prevention, such as the combat of sedentary behavior and food-intake inadequacy (lifestyle changes) the aim of the primary care system.

**PURPOSE:** To evaluate the effects of a protocol including dietary counseling and supervised physical exercises (LSMP) on MetS components.

**METHODS:** The longitudinal study included 131 subjects (55 ± 9 yrs old, 74% female and 68.7% under 60 yrs old) from a community-based sample that fulfilled the ethical and inclusion criteria of attending the 24 weeks LSMP and to all evaluations. The LSMP included a daily (5x/wk) sessions of supervised aerobic exercises (80 min, 65-80% VO2max), weekly dietary counseling and assessments (baseline and end-study) of treadmill cardiorespiratory fitness (CRF, Balke protocol), dietary intake, anthropometry and blood chemistry. The ATP-NCEP (2003) criteria was used for the MetS diagnosis and the Statistica 6.0 software for the analyses of the data (p=0.05).

**RESULTS:** At baseline the MetS group (MSG=50.3%) differed from the non-MS (NMS) by the higher body mass index (BMI) and plasma uric acid (UA) and lower in CRF. Both groups responded to LSMP by increasing CRF, health-eating index, lowering the food-energy intake and plasma high sensitive C-Reactive Protein (CRP-hs). The 24.2% MetS reduction with LSMP were due to waist circumference (WC), blood pressure (BP) and HDL-c normalization whereas the appearance of 10.8% MS in the NMS group during the LSMP was associate with the increased levels of plasma glucose and triglycerides (TG) along with a decreased dietary-fiber intake. The predictive variables for the MetS control with LSMP were the higher increasing of HDL-c and the decreasing of BP whereas the predictive risk factors for the MetS appearance with LSMP were the increasing of BMI, plasma glucose, TG and UA, and the lower consumption of dietary fibre.

**CONCLUSIONS:** These data lead to the conclusion that the MetS treatment by LSMP is primarily due to de lower energy intake (by increasing fibre consumption) and/or lower insulin resistance (by increasing CRF). Supported by CNPq and CAPES

1236 Board #17 May 30 9:30 AM - 11:00 AM

**Effect Of Regular Exercise Training On Cardiorespiratory Fitness In Diabetes Mellitus: Meta-analysis**

Juan Wang<sup>1</sup>, Zhengzhen Wang<sup>1</sup>, Xianbo Zhang<sup>2</sup>. <sup>1</sup>Beijing Sports University, Beijing, China. <sup>2</sup>Peking University, Beijing, China.  
(No relationships reported)

**PURPOSE:** Cardiorespiratory fitness is the core element of physical health, and it is not only closely related to the incidence but also directly associated with their mortality. Now there are many studies on exercise and Cardiorespiratory fitness in diabetes mellitus, but these studies had relatively small sample sizes and highly variable results. And few literature reviews focus on this. Therefore this article tries to find out the effect of regular exercise training on cardiorespiratory fitness in diabetes mellitus by using meta-analysis.

**METHODS:** Medline (1975 to Sep 2011) and SPORT Discus (1936 to Sep 2011) were searched for randomized, controlled trials evaluating effects of regular exercise interventions(not combined other intervention) of 4 weeks or more on cardiorespiratory fitness in diabetes mellitus. All satisfied trials were assessed by Jadad scales. And related data were extracted by two independent researchers. Then all the data were analyzed via software (Review Manage 5.0).

---

**RESULTS:** 1) there were 26 studies searched about exercise intervention on cardiorespiratory fitness in type 2 diabetes mellitus. Regular exercise can increase the VO<sub>2</sub>max about 14.1% in type 2 diabetes mellitus (SWD=1.01SD, p<.05). In the subgroups, Compared to the parallel controlled group, mellitus's VO<sub>2</sub>max was different only in 60-79%VO<sub>2</sub>max intensity exercise group(p<.05) while not occurred in 40-59%VO<sub>2</sub>max or ≥80%VO<sub>2</sub>max intensity exercise group(p>.05). The VO<sub>2</sub>max of type 2 diabetes mellitus both increased in moderate exercise group and moderate plus resistance exercise group, and the former is more effective (p<.05); 2) there were only 4 studies satisfied the criteria in type 1 diabetes mellitus. After regular exercise, VO<sub>2</sub>max increased 8.6%, no significantly (SWD=0.33SD, p>.05).

**CONCLUSIONS:** 1) for type 2 diabetes mellitus, regular exercise is benefit for improving cardiorespiratory fitness, both moderate exercise and moderate plus resistance exercise can, and it's sure about 60-79%VO<sub>2</sub>max intensity exercise can improve the VO<sub>2</sub>max. 2) It's not sure about regular exercise can improve cardiorespiratory fitness in type 1 diabetes mellitus.

---

**1237** Board #18 May 30 9:30 AM - 11:00 AM

**Additional Benefits of W-3 Oil Supplements on Metabolic Syndrome Care in Exercise Protocol Intervention**

Erick P. de Oliveira, Lidiana C. Talon, Fernando Moreto, Viviane M R Acerra, Katia C P McLellan, Roberto C. Burini. *UNESP - Univ Estadual Paulista, Medical School, Botucatu, Brazil.*

(No relationships reported)

Metabolic Syndrome (MetS) is a cluster of diseases associated with sedentary and food inadequacy. Lifestyle modification programs (LSMP) including physical activity and nutrition re-education are the aim of the primary care of MetS being the management of body adiposity and plasma lipids one of the goals. Dietary supplements of omega-3 polyunsaturated fatty acid (W-3 PUFA) have those properties.

**PURPOSE:** To compare the additional effect of dietary supplements of W-3 PUFA to a LSMP in treated MetS of free-living adults.

**METHODS:** In a prospective clinical trial, we studied 61 adults (50±13.8 years old), 85% of women, clinically screened to participate in a LSMP. The subjects were randomly assigned in two groups: LSMP (G1, n=26), including daily sessions (5x/wk) of supervised exercises of walking (3x/wk, 60-70% VO<sub>2</sub>max) and strength (2x/wk, 65-80% 1RM) along with a weekly dietary counseling. The other group (G2, n=35) also under LSMP received W-3 PUFA (3g/day). Anthropometric measurements (waist circumference, body mass index, body fat percentage), dietary intake (24-hour recall), cardiorespiratory fitness (Balke protocol in treadmill, CRF), blood pressure (BP), and plasma biomarkers for MetS were performed at baseline (M0), and after 20 weeks (M1) of intervention. For statistical analysis it was used anova-two way, adjusted for gender, age, BMI and total caloric intake, and significance when p<0.05.

**RESULTS:** After 20 weeks both groups increased the CRF, but only G2 showed significantly decrease in waist circumference (1.3%) followed by MetS reduction (29%) mainly due to the normalization of BP (33.3%) and triglycerides (27.3%).

**CONCLUSIONS:** The dietary-supplements of W-3 PUFA potentiated the MetS treatment effects of LSMP by its effects on abdominal fat and some blood markers. Supported by CNPq, CAPES and FUNDAP

**1238** Board #19 May 30 9:30 AM - 11:00 AM

**Effect Of Exercise Training On The Inflammation Status Among People With Metabolic Syndrome.**

dorthe Stensvold, Ulrik Wisløff, Stig A. Slørdahl. *Department of Circulation and Medical Imaging, Norwegian University of Science and Technology, Trondheim, Norway.*

(No relationships reported)

Metabolic syndrome is associated with chronic low-grade inflammation, a condition thought to play a key role in the pathogenesis of the syndrome. Among a number of pro-inflammatory cytokines, interleukin 18 (IL 18) seem to be the best marker for inflammation among people with metabolic syndrome.

**PURPOSE:** The aim of the study was to examine the effect of aerobic training versus strength training on circulating IL 18 and other pro-inflammatory markers in people with metabolic syndrome.

**METHODS:** Thirty-one inactive men and women (49.8 ± 9.1 years) with metabolic syndrome were randomized to either high intensity interval training (AIT, n=11), strength training (ST, n=10), or to a control group (n=10). Exercise training was carried out 3 times per week for 12 weeks. Serum insulin, high sensitive C-reactive protein (hs-CRP), interleukin 18 (IL 18), interleukin 6 (IL 6), and tumor necrosis factor-alpha (TNF-α) were measured before and after the intervention.

**RESULTS:** Serum IL 18 was reduced by 43% after AIT (p<0.001). Although AIT had no change in TNF-α from baseline, the levels were lower compared to ST (p=0.032) and control group (p=0.039) after the intervention. Total body fat was reduced after AIT (from 33.9 ± 7.3% to 32.2 ± 7.9%, p<0.001) and ST (from 31.2 ± 3.9% to 29.7 ± 3.4%, p=0.025). There were no changes in serum IL 6, insulin, or hs-CRP within or between the groups.

**CONCLUSIONS:** Both strength training and high intensity aerobic exercise reduces fat mass, however, only the latter intervention is associated with a more favourable inflammatory status among people with metabolic syndrome.

---

**1239** Board #20 May 30 9:30 AM - 11:00 AM

**Development of a Minimal Exercise Regimen With Maximal Benefits for Type 2 Diabetics**

Kathleen Broomall<sup>1</sup>, Avi Milgrom<sup>1</sup>, Dan Carl<sup>2</sup>. <sup>1</sup>Miami University, Hamilton, OH. <sup>2</sup>University of Cincinnati, Cincinnati, OH.

(No relationships reported)

**PURPOSE:** To examine the effectiveness of a novel, minimal exercise regimen based upon brief, strategically timed bouts of moderate intensity in attenuating postprandial glucose spikes as well its effectiveness in weight management over hours, days and years for type 2 diabetics. The regimen requires no exercise clothing or equipment; thus it can be readily integrated into a busy day in a "built environment" --unlike other brief-interval regimens The underlying premise, documented in the literature, is that muscle contractions can shunt blood glucose from the blood stream into muscle using interval style muscle work.

**METHODS:** Blood glucose levels were mapped over two time scales: hours and years. The short-term studies were to preliminarily explore how the exercise regimen attenuates blood glucose spikes; thus metabolic cart data was gathered in addition to blood glucose. Specifically, the short term studies mapped blood glucose curves as well as fat and carbohydrate utilization from repeated 2 minute bursts of physical activity in three scenarios: no exercise before or after eating (AUC 6095), exercise after eating but with diminished exercise frequency before the meal (AUC 5680), and normal frequency before and after the meal (AUC 1962). The long-term studies tracked daily blood glucose levels and appropriately timed HbA1C's over a 30-month period.

**RESULTS:** Short-term blood glucose attenuation was significantly more effective with the proposed exercise regimen using the third scenario. Additionally, carbohydrate utilization was significantly greater with the proposed regimen. Finally, glucose management yielded significantly improved A1C's as a clinical measure of glycemic control. Inhibition of weight regain with subsequent additive weight loss also seemed a long term trend of this regimen.

**CONCLUSIONS:** An exercise regimen of repeated brief bouts of moderate intensity executed after caloric intake can be effective in managing blood glucose and long term weight management in type 2 diabetics. Proposed research will map HbA1c values against degrees of adherence to the regimen and will identify psychological and physical factors moderating adherence. The ultimate goal is to deliver the regimen to clinicians with guidelines for the selection of viable candidates.

**1240** Board #21 May 30 9:30 AM - 11:00 AM

**Glucose Tolerance: A Comparison Of Sitting vs. 0.5 Mph Walk On The Active Workstation**

Ronald Cox, Christina Ohlinger. *Miami University, Oxford, OH.*

(No relationships reported)

A growing body of literature suggests that striking differences in metabolic responses to nutritional challenge can be demonstrated when the postural condition of the individual is changed from sitting to standing.

**PURPOSE:**To describe the possible differences in glucose clearance, in young healthy individuals, in response to a glucose tolerance test performed under standard sitting conditions or while using an Active Workstation at very low speeds.

**METHODS:** Nine students, eight females and one male (21±1 yrs) performed a series of glucose tolerance tests. After a minimum of an 8-hour fast a baseline glucose measurement (Accu-Chek®) was obtained. Subjects then ingested 75 gm of glucose solution (TruTol®75) within a ten-minute period. In a counterbalanced manner, subjects either spent the two hours sitting or walking at 0.5 mph on an Active Workstation. During the session, a blood sample (finger stick) was obtained every 30 min for the next two hours.

**RESULTS:** Table 1 shows the means ± SD for blood glucose for each time period under the two conditions. All subjects showed a lower blood glucose curve during walking. The levels at 90 and 120 min were significantly lower ( $p < 0.05$ ) in the walking condition.

**CONCLUSIONS:**These results support the impact of even very low levels of physical activity on metabolic response to glucose ingestion compared to sitting in healthy people. In fact, walking at a speed of 0.5 mph is a near proxy for standing. This result has implications for the standardization of glucose tolerance tests and reaffirms the potentially deleterious effects of sitting while offering support for the benefits of movement in normalizing blood glucose.

| Blood Glucose Levels: Sitting vs. Walk |          |          |          |          |          |
|--|----------|----------|----------|----------|----------|
| Condition                              | Baseline | 30 min   | 60 min   | 90 min   | 120 min  |
| Sitting                                | 85 ± 8   | 149 ± 27 | 156 ± 33 | 139 ± 22 | 124 ± 15 |
| Walk 0.5 mph                           | 86 ± 9   | 132 ± 23 | 116 ± 21 | 102 ± 18 | 106 ± 19 |

(No relationships reported)

Lifestyle modification focusing on dietary and exercise behaviors is the preferred first-line treatment for the management of metabolic syndrome (MetS), its components and co morbidities. However attempts to modify diet by reducing food intake are often unsuccessful due to the low compliance. Adequate-to-high fibre intake appears as an alternative for limiting energy intake in a society with high energy-dense food consumption.

**PURPOSE:** To investigate the effects of fibre intake on exercised-MetS patients in a prospective dynamic cohort study.

**METHODS:** The subjects that fulfilled all the inclusion criteria totaled 253 (mostly 35-60 years old and females). They all accomplished a protocol of lifestyle modification program (LSMP) including supervised physical exercise of walking (3 X/wk: 60-70% maximal heart rate) and strength (2 X/wk: 65-80% of one repetition maximal) along with a weekly dietary counseling. A group of 131 subjects was studied on traditional LSMP during 24 weeks (G1), another group of 72 subjects were randomized in either fibre (G2A = 25-30 g fibre/day) and non fibre (G2B) adequacy groups in a 20 weeks-lasting intervention, and the remainders 50 patients also received similar treatment of fibre intervention (G3A) or only LSMP (G3B) but in a shorter (10 weeks) experiment. The statistical analysis (paired Student's t test) were used to compare moments ( $p < 0.05$ ).

**RESULTS:** MetS varied from 40% to 50.4% (NCEP-ATP III, 2003 criteria) at the baseline and the recalled dietary fibre intake averaged  $16.0 \pm 7.1$  g/day. There was a decreasing in MetS with the LSMP alone lasting either 24 wks (-24.2%) or 20 wks (-11.5%) but not after 10 wks (+6%). These decreasing was optimized by dietary fibre interventions from 24% (G3A: 10 wks) to 36.4% (G2A: 20 wks). At the end of the experiment the increase of fibre intake varied from 7.2 g/d (G1) to 14.6 g/d (G2A) and 16.9 g/d (G3A), above the baseline values. The reduced obesity rate varied from 7% to 9% in the fibre-intervened groups.

**CONCLUSIONS:** The present data support the use of fibre adequacy as reducing factor for energy-dense food consumption and consequently body weight loss and then accelerating MetS decrease in a complementary physical exercise protocol. Supported by CNPq and FUNDAP

### The Impact Of Breaking Sitting Time On Postprandial Response To Three Separate Meal Replacement Beverages.

Meredith C. Peddie, Nancy J. Rehner, FACSM, Murray Skeaff, Tracy L. Perry. University of Otago, Dunedin, New Zealand.  
(No relationships reported)

**PURPOSE:** The purpose of this study was to compare the effects of breaking continuous sitting with short regular exercise breaks or one continuous bout of exercise on postprandial serum glucose, insulin, and triglyceride responses to three meal replacement beverages.

**METHODS:** Seventy participants (Mean (SD) VO<sub>2</sub>max 42.9 (10.3) ml·kg<sup>-1</sup>·min<sup>-1</sup>, Body mass index 23.6 (4.0)) completed three 9 h interventions. During the prolonged sitting intervention (SIT), participants sat continuously for 9 h; in the exercise intervention (EX) participants sat for 15 min, walked on the treadmill for 30 min, then sat continuously for 8 h and 15 min; in the breaking sitting time intervention (BRK) participants regularly interrupted their sitting with eighteen 1 min 40 s bouts (total of 30 min) of exercise. In each intervention participants were fed a MRB at 60, 240 and 420 min. Each MRB contained 31.4 ± 6.6 g fat, 36.8 ± 7.7 g protein 76.4 ± 16.1 g CHO and 3105 ± 652 kJ energy. Blood samples were obtained at baseline and hourly for 9 h, with additional samples collected 30 and 45 min after each feeding. Postprandial area under the curve (AUC) responses were calculated in response to the three separate MRB. Comparisons between interventions were made using mixed model regression.

**RESULTS:** The triglyceride AUC in BRK was 8% (95% CI 0.5 to 16.0%  $p=0.03$ ) greater compared to SIT in response to the 2nd MRB. There were no differences between conditions in response to the 1st or 3rd MRB. The glucose AUC in BRK was 5.8% (95% CI 2.5 to 9.1%  $p=0.04$ ) less than SIT in response to the 1st MRB. These differences were maintained in response to the 2nd MRB, but were no longer apparent in response to the 3rd MRB. The insulin AUC in BRK was 11.2% (95% CI 1.8 to 20.7%  $p=0.01$ ) less than SIT in response to the 1st MRB. In response to the 2nd MRB BRK was 41.9% (95% CI 15.4 to 68.3%  $p=0.02$ ) less than SIT. The response to the 3rd MRB was similar to the 1st MRB.

**CONCLUSIONS:** Breaking sitting time reduces postprandial insulin responses throughout the day. Health promotion guidelines should promote regular physical activity breaks during periods of prolonged sitting, particular for those at risk of insulin resistance.

**1243** Board #24 May 30 9:30 AM - 11:00 AM

### Chronic Exercise Training Effects on Fatigue in Multiple Sclerosis: A Meta-Analysis

Tina A. Mattila, Megan Nickrent, Lara A. Pilutti, Robert W. Motl, Steven J. Petruzzello, FACSM. University of Illinois at Urbana-Champaign, Urbana, IL.  
(No relationships reported)

Fatigue is a common, disabling, and poorly managed symptom of multiple sclerosis (MS). Chronic aerobic exercise training may be an effective behavioral strategy for reducing fatigue in persons with MS.

**PURPOSE:** Provide a quantitative review of research examining the effect of exercise training on fatigue in MS.

**METHODS:** Electronic databases (Web of Science, PubMed, PsycInfo, Medline, Google Scholar, and Current Contents Plus) were searched for articles published up to September 2011 by using the key words exercise, fatigue, tiredness, energy, mood, lassitude, physical activity, rehabilitation, and fitness in conjunction with MS. Manual search of bibliographies of the retrieved papers was also done and study authors were contacted about additional studies. Thirty-five journal articles were located and reviewed, and 25 provided enough data to compute effect sizes (ES) and include in the meta-analysis. The meta-analysis was conducted with Comprehensive Meta Analysis using a random effects model and the overall ES was expressed as Hedge's  $g$ .

**RESULTS:** Twenty-five ESs were retrieved from the 25 studies with 606 MS participants and yielded a weighted mean ES of 0.55 (95% CI = 0.37, 0.78). The weighted mean ES was heterogeneous,  $Q = 50.71$ ,  $df = 24$ ,  $P = 0.001$ , supporting a search for moderator variables.

**CONCLUSIONS:** The cumulative evidence supports that exercise training is associated with a fairly sizable reduction in fatigue among persons with MS.

**The Effect Of Aerobic Exercise On The Quality Of Life Amongst HIV Positive Persons**

Louis J. Holtzhausen, Sorita Viljoen, Marlene Schoeman. *University of the Free State, Bloemfontein, South Africa. (Sponsor: Jon Patricios, FACSM)*  
(No relationships reported)

The positive effects of regular exercise on the physiological well-being of HIV positive (+) persons have been well documented. Although evidence exist for HIV+ persons to retain muscular strength and improving work-related performance through regular exercise without compromising their immune capacities, limited research has been done to assess the effect of exercise on non-physiological parameters such as pain, functional limitations and social functioning which influence overall quality of life (QoL). Aerobic exercise results in several health benefits and consequent QoL improvements in HIV negative populations. However, it is uncertain how aerobic exercise would influence the QoL (self-perceived physical and mental well-being) of HIV+ persons.

**PURPOSE:** To determine the effect of an aerobic exercise intervention on the QoL in HIV+ persons.

**METHODS:** Twenty eight HIV+ persons were randomised into two groups (aerobic intervention and control, n=14 each). The intervention group was exposed to a 12 week supervised aerobic intervention, while the control group was exposed to a supervised stretching program to limit drop-out without inducing physiological adaptation. Participants were assessed for their aerobic capacity, immunological status (CD4 and viral load) and QoL score before and after the intervention. Significance between pre- and post intervention results were set at  $p < 0.05$ .

**RESULTS:** Following the intervention, a significant improvement ( $p = 0.02$ ) in aerobic capacity were seen for the intervention group, while their CD4 counts and viral loads remained unchanged. Interestingly, both groups displayed significant improvements in their self-perceived physical and mental well-being ( $p = 0.003$  and  $p = 0.002$  for the intervention and control group respectively). Based on research in other population groups, the improved QoL in the control group is speculatively attributed to a placebo effect achieved through the personal attention received during exercise supervision.

**CONCLUSIONS:** Aerobic exercise leads to an improved aerobic capacity without compromising the immune capacities of HIV+ persons. Supervised exercise seems to improve QoL for HIV+ persons, irrespective of the type and intensity of the exercise and should therefore be promoted in the holistic disease management of HIV+ persons.

**Effects of Self-Selected and Imposed Intensity Acute Exercise on Psychological and Cortisol Responses**

Kyoko K. Wardwell, Brian C. Focht, FACSM, Courtney A. DeVries, Ann A. O'Connell, Janet Buckworth, FACSM. *The Ohio State University, Columbus, OH.*  
(No relationships reported)

**PURPOSE:** The primary purpose was to examine psychological responses to self-selected and imposed-intensity acute exercise in inactive women with high levels of stress. The secondary purpose was to examine potential psychobiological mechanisms (HPA-axis response and self-efficacy) for changes in psychological states.

**METHODS:** Nineteen participants (age =  $23.58 \pm 5.30$  yr) completed 3 trials of treadmill exercise at self-selected intensity, 10% above and 10% below relative self-selected intensity. Exercise duration was determined to expend 150 kcal. Affective responses and salivary cortisol were measured prior to, during, and following exercise. Self-efficacy was also measured during and post-exercise. Future exercise intention was measured post exercise.

**RESULTS:** Affect and self-efficacy improved significantly over time at all exercise intensity conditions (all variables were  $p < .005$ ). Moreover, positive engagement was higher at self-selected than imposed intensity during and post exercise ( $p < .05$ ). No significant associations were observed between affect, self-efficacy and cortisol levels. However, affect and self-efficacy did significantly predict future exercise intentions.

**CONCLUSIONS:** Acute bouts of exercise at intensities proximal to and lower than ventilatory threshold are associated with positive affective responses during and after exercise in women with high levels of stress. Self-selected intensity may be effective for eliciting more favorable experiences during and following acute bouts of exercise, and promote future intentions for exercise. Findings provide partial support for self-efficacy during exercise as a potential mechanism for positive affective responses, especially at self-selected intensity.

1246 Board #27 May 30 9:30 AM - 11:00 AM

**Regular Exercise Attenuates Oxidative Stress in Aging Rat Liver : Apoptosis and Fibrosis Signal Pathway Toward Anti-Aging Medicine**

Kai-Wen Chang<sup>1</sup>, Chi-Chang Huang<sup>1</sup>, Wan-Teng Lin<sup>2</sup>. <sup>1</sup>National Taiwan Sport University, Taoyuan County, Taiwan. <sup>2</sup>Tunghai University, Taichung, Taiwan.  
(No relationships reported)

Regular exercise is known to exhibit various health benefits in reducing risks of age-related diseases such as cardiovascular diseases, type 2 diabetes and cancer. However, there is no report about the protective effects of exercise training on liver senescence.

**PURPOSE:** The purpose of this study was to investigate whether a 12-week swimming exercise training can suppress senescence-oxidative stress markers of liver tissues.

**METHODS:** Twenty-three male Sprague-Dawley rats were divided into the following four groups: (1) vehicle control (n = 6), (2) aging (n = 6), (3) swimming exercise (n = 5), and (4) aging with swimming exercise (n = 6). Rats in groups A and AS were intraperitoneal injection with D-galactose (150 mg/kg/day) for 12 weeks to induce aging. Rats in groups SE and ASE were subjected to swimming exercise for 60 min/day  $\times$  5 days/week for 12 weeks. Body weight, liver weight, epididymal fat mass, histopathological, TUNEL analysis and expressions of Cytochrome C, Bax, Bcl-2, Caspase 9, cleaved Caspase 3, cleaved PARP, MMP2 and MMP9 in liver apoptosis and fibrosis pathway are detected.

**RESULTS:** The results show that apoptosis index cleaved Caspase 3 and cleaved PARP were significantly lower in C and ASE than in A group ( $P < 0.05$ ); apoptosis protective protein Bcl-2 is significantly higher than A group ( $P < 0.05$ ). In ASE group through increasing PI3K-Akt signaling activities and inhibiting apoptosis and fibrosis pathway activities compared with aging group. be a major mechanism of anti-aging.

**CONCLUSIONS:** These results suggest that a 12-week swimming exercise may suppress apoptosis and fibrosis markers in the liver tissues of D-galactose induced aging rats. This study was supported by a research grant from the National Science Council, Taiwan (NSC99-2410-H029-059-MY2)

1247 Board #28 May 30 9:30 AM - 11:00 AM

**Exercise Training Counterbalances Chronotropic Incompetence and Delayed Heart Rate Recovery in Systemic Lupus Erythematosus**

Fabiana Benatti, Renata Miossi, Ana Lúcia de Sá Pinto, Fernanda Lima, Eduardo Borba, Danilo Prado, Bruno Gualano, Eloísa Bonfá, Hamilton Roschel. *University of São paulo, São Paulo, Brazil.*  
(No relationships reported)

**PURPOSE:** To evaluate the efficacy of a three-month exercise training program in counteracting the chronotropic incompetence and delayed heart rate recovery in patients with systemic lupus erythematosus.

**METHODS:** A 12-wk, randomized trial was conducted. Twenty four inactive SLE patients were randomly assigned into two groups: trained (T, n=14, three-month exercise program) and non-trained (NT, n=10). A gender-, BMI-, and age-matched healthy control group (C, n=8) also underwent the exercise program. Subjects were assessed at baseline (PRE) and 12 weeks after training (POST). Main measurements included the chronotropic reserve (CR) and the heart rate recovery ( $\Delta$ HRR) as defined by the difference between HR at peak exercise and at both first ( $\Delta$ HRR1) and second ( $\Delta$ HRR2) minutes after the exercise test.

**RESULTS:** Neither the non-trained SLE (NT) patients nor the healthy control group (C) presented any change in the chronotropic reserve (NT PRE:  $72.1 \pm 11.1$ , POST:  $75.6 \pm 19.2$  %,  $p=0.96$ ; C PRE:  $93.5 \pm 4.9$ , POST:  $95.9 \pm 10.4$  %;  $p=0.99$ ) or in  $\Delta$ HRR1 (NT PRE:  $26.6 \pm 11.8$ , POST:  $26.7 \pm 10.7$ ,  $p=1.0$ ; C PRE:  $33.8 \pm 6.6$ , POST:  $38.2 \pm 10.0$ ,  $p=0.95$ ) and  $\Delta$ HRR2 (NT PRE:  $38.8 \pm 13.5$ , POST:  $39.5 \pm 15.6$ ,  $p=1.0$ ; C PRE:  $52.0 \pm 5.7$ , POST:  $53.6 \pm 7.6$ ;  $p=0.99$ ). The exercise training program was effective in promoting significant increases in chronotropic reserve (T PRE:  $79.4 \pm 13.5$ , POST:  $95.4 \pm 9.6$  %,  $p=0.003$ ) (POST T vs. NT,  $p=0.0003$ ; ES=1.15), and in  $\Delta$ HRR1 (T PRE:  $23.1 \pm 9.6$ , POST:  $41.0 \pm 10.7$ ,  $p=0.0006$ ) (POST T vs. NT,  $p=0.02$ ; ES=1.12) and  $\Delta$ HRR2 (T PRE:  $39.0 \pm 10.5$ , POST:  $57.3 \pm 12.4$ ,  $p=0.0007$ ) (POST T vs. NT,  $p=0.01$ , ES=1.11) in the SLE trained group (T) when compared with the NT group. Moreover, the heart rate response in SLE patients after training achieved parameters comparable to the healthy control subjects, as evidenced by the ANOVA and by the Z-score analysis ( $p > 0.05$ , T vs. C). SLEDAI scores remained stable throughout the study.

**CONCLUSIONS:** A 3-month exercise training program was safe and capable of reducing the chronotropic incompetence and the delayed heart rate recovery observed in physically inactive SLE patients.

**1248** Board #29 May 30 9:30 AM - 11:00 AM

**Parasympathetic Tone And Its Adaptation To Aerobic Training (Fitwalking®) In HIV Patients On Anti-Retroviral Therapy**

Giampiero Merati<sup>1</sup>, Antonio La Torre<sup>1</sup>, Matteo Bonato<sup>1</sup>, Gaspare Pavei<sup>1</sup>, Simona Bossolasco<sup>2</sup>, Laura Galli<sup>2</sup>, Paola Cinque<sup>2</sup>. <sup>1</sup>University of Milan, Milan, Italy. <sup>2</sup>San Raffaele Scientific Institute, Milan, Italy.

(No relationships reported)

Recent evidences showed that in HIV patients Highly Active Antiretroviral Therapy (HAART) and HIV per se may affect parasympathetic tone; this may increase the cardiovascular risk and contribute to HIV associated lipodystrophy. Such impairment may be reversed by a regular physical activity, which is known to increase vagal tone. **PURPOSE:** To evaluate vagal tone and its change after 3 months of aerobic training in HIV patients on HAART.

**METHODS:** 12 non-hypertensive and non-smoker patients (F/M 2/10; 47±5 yrs; 71±14 kg) with HIV infection (H) on HAART were enrolled. A group of 12 control (C) subjects (F/M 3/9; 48±12 yrs; 76±13 kg), matched for gender, age and anthropometric features, was enrolled for baseline comparisons. Heart rate variability (HRV) indexes of parasympathetic tone in time (RMSSD, pNN50) and frequency (High Frequency [HF] in absolute and normalized units [nu]) domains, and a HRV index of sympathovagal balance (LF/HF ratio) were calculated in basal condition in H and C subjects, both in supine and standing position for 5 min each, by a HR monitor. The H group was then trained by walking at 60-70% of maximal HR 3 times/week for 12 weeks, and the HRV measures were repeated thereafter. A 6-min walking test (6MWT) was executed before and after the training.

**RESULTS:** In basal condition, despite similar values in supine position between H and C subjects, HIV patients showed a lower parasympathetic tone during standing, which was significant in the linear indexes (RMSSD: H 16.7±5.1 vs C 25.3±10.5 ms [p<0.05]; pNN50: H 1.4±1.3 vs C 5.4±5.3% [p<0.05]; HF: H 180±207 vs C 196±139 ms<sup>2</sup>; HFnu: H 21.6±23.5 vs C 27.0±16.2), and a higher sympathetic activation (LF/HF: H 9.2±7.0 vs C 4.1±2.7 [p=0.04]) compared to C subjects. Fitwalking® training significantly improved the distance covered by 6MWT (from 667±50 to 802±160 m, p=0.01) and the physical work done (from 451±96 to 538±132 J, p=0.01). However, standing values of HRV indexes did not significantly change after training in H patients (RMSSD 15.2±6.6 ms, pNN50 1.1±1.7%, HF 100±93 ms<sup>2</sup>, HFnu 11.5±6.7, LF/HF 9.7±7.5; p=ns vs pre-training for all comparisons).

**CONCLUSIONS:** 12-weeks aerobic training improved cardiovascular fitness in HIV patients, but did not affect the heart parasympathetic control, which remained reduced compared to healthy subjects.

**1249** Board #30 May 30 9:30 AM - 11:00 AM

**Oxidative Stress Biomarkers in HIV+ Sedentary Patients And Its Relation to HAART Administration Time**

Alesandro Garcia<sup>1</sup>, Géssica A. Fraga<sup>1</sup>, Fabiano Dmytro L. Pinto<sup>1</sup>, Gabriela G. Martins<sup>1</sup>, Carolina Mendes S. Silva<sup>1</sup>, Roberto Carlos V. Junior<sup>1</sup>, Adilson R. Filho<sup>1</sup>, Marisa C. Voltarelli<sup>1</sup>, Michel B. Araújo<sup>2</sup>, Flávia Carolina L. Melo<sup>1</sup>, Fabricio A. Voltarelli<sup>1</sup>. <sup>1</sup>Federal University of Mato Mato Grosso (UFMT), Cuiabá-MT, Brazil.

<sup>2</sup>Sao Paulo State University (UNESP), Rio Claro-SP, Brazil.

(No relationships reported)

**PURPOSE:** The goal of the present study was to analyze the antioxidant enzymes activities as well as a lipid peroxidation marker in the blood of HIV seropositive (HIV+) sedentary patients.

**METHODS:** This study assessed the effect of different Highly Active Antiretroviral Therapy (HAART) administration times on oxidative stress (OS) biomarkers of HIV+ sedentary patients. Twenty-two HIV+ subjects (Men n=11; 39.42±9.44 years old; Women n=11; 45.00±6.59 years old) were divided into 3 groups, according to the HAART administration time: from 0 to 5 years (0/5y; n=6); from 6 to 10 years (6/10y; n=7); and from 11 to 15 years (11/15y; n=9). The activity of catalase (CAT [U/mg Hbmin]), superoxide dismutase (SOD [U/mg Hbmin]) and glutathione peroxidase (GPx [U/mL]) enzymes as well as a lipid peroxidation marker (thiobarbituric acid reactant substances; TBARS [µmol/L]) were determined in the blood serum of patients by commercial kits (Cayman Chemical, Michigan, USA). The data were analyzed using Kruskal-Wallis test and Dunn *post hoc* test (p value of <0.05).

**RESULTS:** The mean values of SOD (2.67±0.41) and GPx (7.89±0.22) activities were lower in the 0/5y group when compared to 6/10y (SOD: 4.25±0.32; GPx: 9.57±0.66) and 11/15y (SOD: 5.91±0.34; GPx: 13.08±0.33) groups; if compared the 6/10y and 11/15y groups, the means values (SOD and GPx) were statistically different (11/15y > 6/10y). In relation to CAT activities and to TBARS concentrations, it were only observed significant differences when compared 0/5y (CAT: 2.39±0.36; TBARS: 4.14±0.35) and 11/15y (CAT: 4.37±0.24; TBARS: 6.08±0.44) groups. On the other hand, no differences were detected when these groups were compared to 5/6y group (CAT: 3.50±0.48; TBARS: 5.00±0.46).

**CONCLUSIONS:** The findings suggest that increased OS occurs additionally to persistent redox imbalance associated to HIV infection during apparently successfully HAART. In addition, the pro-oxidative responses seem to be related to HAART administration time. Finally, we believe that a physical exercise program would reverse, at least in part, this situation, once that regular physical exercise may protect the organism against the OS caused by the sedentarism condition. Supported by FAPEMAT (Brazilian Foundation; Process number: 512843/2009).

**1250** Board #31 May 30 9:30 AM - 11:00 AM

**Physical Training and Detraining and the Development of Nonalcoholic Hepatic Steatosis in Rats**

Leandro P. Moura, Amanda Christine S. Sponton, Michel B. Araújo, Rodrigo A. Dalia, Marcelo C. Junior, Maria Alice R. Mello, FACSM. UNESP, São Paulo State University, Rio Claro, Brazil.

(No relationships reported)

Nonalcoholic Hepatic Steatosis (NAHS) is a disease caused by fat accumulation in the liver that can lead to organ failure and, consequently, to death. This disease has been increasing alarmingly worldwide and still little is known about the influence of physical exercise training and subsequent detraining on preventing NAHS.

**PURPOSE:** Analyzes body weight, insulin sensitivity, fat tissue accumulation and triglyceride (TG) concentration in the mesenteric adipose tissue and fat accumulation in the liver of rats submitted to physical training and subsequent detraining.

**METHODS:** Thirty weanling Wistar rats were utilized and divided into three groups: Control sedentary rats (C), Trained rats (T) submitted to physical exercise throughout the experiment, and Detrained rats (D) submitted to physical exercise for half of the experimental period and kept sedentary until the end of the study. The training protocol began when the rats were 28 days old and consisted of swimming 1hr per day, 5 days per week, at 80% of their individual anaerobic threshold (LAN), as previously determined by a lactate minimum test. The physical training lasted 16 weeks for the T group and 8 weeks for the D group.

**RESULTS:** An insulin sensitivity test was performed and 48h after this, the animals were sacrificed to analyze total weight and total amount of TG of the mesenteric adipose tissue and liver TG concentration. It was shown that physical exercise performed throughout the experiment increased the sensitivity of insulin (%removal of serum glucose/min) (C: 3.67 ± 0.61; T: 6.36 ± 3.19; D: 4.69 ± 1.20) and decreased the body weight gain (g) (C: 527.13 ± 71.39; T: 453.14 ± 57.37; D: 522.21 ± 78.15), serum insulin concentration (ng/ml) (C: 1.72 ± 0.46; T: 1.39 ± 0.34; D: 1.65 ± 0.49), mesenteric adipose total weight (g) (C: 4.56 ± 1.60; T: 3.40 ± 1.20; D: 5.27 ± 1.94) and total TG amount (mg/total tissue weight-1) (C: 54.26 ± 5.03; T: 41.03 ± 2.27; D: 59.66 ± 3.99) as well as the TG concentration in the liver (mg/100mg) (C: 12.31 ± 3.07; T: 7.82 ± 2.14; CS: 11.94 ± 4.27).

**CONCLUSIONS:** In summary, physical exercise at 80% of LAN, attenuates the disorders that trigger fat accumulation in the liver and, consequently, counteracts NAHS development. Physical exercise cessation neutralizes all the beneficial effects of the physical training.

**Efficacy Of A Multifaceted Intervention Program To Increase Physical Activity In Patients With Parkinson'S Disease; The Parkfit Trial**

Marlies van Nimwegen<sup>1</sup>, Arlene D Speelman<sup>1</sup>, Sebastiaan Overeem<sup>1</sup>, Bart P. van de Warrenburg<sup>1</sup>, Katrijn Smulders<sup>1</sup>, Manon Dontje<sup>2</sup>, George F. Borm<sup>1</sup>, Frank J.G. Backx<sup>3</sup>, Bastiaan R. Bloem<sup>1</sup>, Marten Munneke<sup>1</sup>. <sup>1</sup>UMC St Radboud, Nijmegen, Netherlands. <sup>2</sup>Hanze University, Groningen, Netherlands. <sup>3</sup>University Medical Center Utrecht, Utrecht, Netherlands.

(No relationships reported)

**PURPOSE:** Many patients with Parkinson's disease (PD) lead a sedentary lifestyle. Simply informing patients about the health benefits of physical activity is insufficient to change their sedentary lifestyle. We developed and evaluated a multifaceted behavioural program (ParkFit) aiming to increase the level of physical activity undertaken by patients with PD.

**METHODS:** 586 PD patients were randomly assigned to the ParkFit Program or an active control group (ParkSafe Program). The level of physical activity was measured at baseline and at 6 months using a standardized interview-based 7-day recall (LAPAQ, primary endpoint), an ambulatory activity monitor (secondary endpoint) and an activity diary (secondary endpoint). Results were analysed according to the intention to treat concept.

**RESULTS:** 562 patients (96%) completed both baseline and 6 months assessments. In the ParkFit group, patients increased their time spent to physical activities with 7% as assessed with the LAPAQ; patients in the control group became 1% less active. The difference between both groups was not statistically significant. When we specified the nature of the activities, patients in the ParkFit group increased their 'outdoor and sports activities' (+32%), while their time spent to household activities decreased (-14%). In the control group these differences were less than 4%.

**CONCLUSIONS:** This short term outcome of the ParkFit trial suggests that patients with PD can increase their outdoor activities with a specific multifaceted program. This increase seems to be accompanied by a decrease in time spent to household activities. At the congress we will present the results of the ParkFit trial after 24 months intervention and the potential health consequences of a change in lifestyle. (Funded by ZonMw (The Netherlands Organization for Health Research and Development (75020012)); The Michael J Fox Foundation for Parkinson's research; VGZ; Glaxo Smith Kline; and National Parkinson Foundation; ClinicalTrials.gov number, NCT00748488.)

(No relationships reported)

**PURPOSE:** The purpose of this investigation was to identify changes in sedentary time (SED) and physical activity (PA) of cancer survivors enrolled in a post-treatment, 12 week, Livestrong® group exercise program.

**METHODS:** Eleven cancer survivors (1 Male and 10 Females; 51.8±9.27 yrs, BMI=26.6±4.1), representing a variety of cancer and treatment backgrounds, volunteered and wore armband activity monitors (BodyMedia® SenseWear) for seven consecutive days. Data collection occurred during the first and sixth week (midpoint) of the Livestrong® Program, and each minute of activity monitor wear time was classified as sedentary (SED), moderate (MOD), or vigorous (VIG). Minutes from MOD and VIG were then combined into a moderate-vigorous (MV) category. Linear mixed model analyses were used to compare weekly time spent in SED, MOD, VIG, and MV between weeks 1 and 6 with an adjustment for activity monitor wear time (time-varying covariate).

**RESULTS:** Across both assessment periods, participants averaged > 15 hr•day-1 of non-sleep activity monitor wear time with a weekly total of (mean ± SD) 6673.6 ± 734.8 min•week-1 (week 1 = 6853.8 ± 572.9, week 2 = 6493.4 ± 856.8). No significant differences were observed in weekly minutes (mean ± SE) from week 1 to week 6 for SED (6484.5 ± 155.6 vs. 6114.6 ± 246.3, respectively), MOD (366.5 ± 67.7 vs. 373.8 ± 51.4, respectively), MV (369.3 ± 68.6 vs. 378.7 ± 51.5, respectively) or VIG (2.7 ± 1.3 vs. 4.9 ± 1.9, respectively).

**CONCLUSIONS:** Results indicated no significant difference in weekly time spent in SED or any PA category between week 1 and week 6. Time spent in both MOD and MV was well above the 150 minutes per week CDC recommendation of PA for adults without chronic conditions. However, VIG activity averaged less than 5 minutes per week. Due to the short time span and small sample, it is difficult to evaluate the overall efficacy of the Livestrong program. However, these preliminary results are promising in that MOD PA is well above the national recommended threshold and SED time appears to be decreasing, though not significantly.

**The Effects Of Exercise Training From Different Cancer Treatments In Cancer Survivors**

City C. Hsieh<sup>1</sup>, Hsiao-Chuan Wen<sup>2</sup>, Chiuh-Chung Liu<sup>2</sup>, Chun-hong Lin<sup>2</sup>, Ling-Li Wang<sup>1</sup>. <sup>1</sup>Hsinchu University of Education, and Yuanpei University, Hsinchu, Taiwan. <sup>2</sup>Yuanpei University, Hsinchu, Taiwan.

(No relationships reported)

**PURPOSE:** The purpose of this study was to investigate the effects of exercise training on muscular fitness and quality of life in cancer survivors undergoing differing clinical treatments: surgery alone, chemotherapy following surgery, radiotherapy following surgery, or chemotherapy and radiotherapy following surgery.

**METHODS:** This study recruited four groups of female cancer survivors based on the type of clinical treatments they had received: surgery alone (S, n=10), surgery and chemotherapy (SC, n=10), surgery and radiotherapy (SR, n=10), surgery and chemotherapy and radiotherapy (SCR, n=10). The exercise sessions lasted for 60 minutes including a 10-minute warm-up, 40 minutes of aerobic exercise, resistance training, and 10 minutes cool-down, 3 days per week for 6 months. Exercise intensity ranged from 40% to 60% of heart rate reserve depending upon the participant's health status. The assessments and reassessments of muscular fitness (handgrip, peak torque of shoulder, elbow, and knee flexion and extension using Biodex S4 Pro) and quality of life were performed before and after the 6-month exercise training.

**RESULTS:** Cancer survivors in 4 groups following the 6-month exercise intervention showed significant (p < .05) improvements in shoulder flexibility (+22.6~38.0%) and extension (+26.6~35.0%), elbow flexibility (+16.7~43.0%) and extension (+20.7~35.1%), and knee flexibility (+12.2~27.5%) and extension (+8.6~33.0%). In addition, handgrip was improved significantly (p < .05) in SC (+6.3%), SR (+9.8%), and SCR (+7.7%) groups, but not in the S group. Psychologically, all 4 groups showed significant (p < .05) improvements in total (+9.6~18.8%), and in health (+13.8~21.3%), social (+7.9~20.5%), psychological (+9.3~11.3%), and family (+6.9~16.4%) quality of life. Moreover, no significant differences were observed between groups on any of the domains of muscular fitness and quality of life.

**CONCLUSIONS:** The current study suggested that moderate intensity exercise intervention is a safe and efficacious means to augment muscular fitness and improve the quality of life of cancer survivors. Moreover, the muscular fitness and quality of life of cancer survivors improved as a result of the exercise intervention in this study, regardless of the type of treatments.

**Randomized controlled trial Of Colorectal Cancer Exercise Program for Colorectal Cancer Patient After Surgery**

Ki-yong An<sup>1</sup>, Mi kyung Lee<sup>1</sup>, Dong il Kim<sup>1</sup>, Dong hyun Kim<sup>1</sup>, Ji hee Min<sup>1</sup>, Nam-kyu Kim<sup>2</sup>, Justin Y. Jeon<sup>1</sup>. <sup>1</sup>Yonsei University, Seoul, Korea, Republic of. <sup>2</sup>Yonsei University Severance Hospital, Seoul, Korea, Republic of.

(No relationships reported)

Recently, incidence of colorectal cancer is remarkably increasing in Korea.

Exercise and physical activity have positive effects in colorectal cancer patients and they are revealed in many previous studies. Specially, the patients in recovery after surgery need exercise, so many surgeons recommend to walk for patients after surgery. However, except walking, there is not detail exercise manual. Also, among many previous studies, there is no exercise intervention study has colorectal cancer patients immediately after surgery for subjects.

**PURPOSE:** The purpose of this study are to examine the effect of colorectal cancer exercise program on recovery and physiological and psychological variables in colorectal cancer inpatient after surgery.

**METHODS:** Subjects in exercise group participated supervised exercise program 1–2 times per day on colorectal patients undergoing laparoscopic surgery during hospitalization. Supervised exercise program is mainly composed of stretching, core exercise on the bed and walking. And subjects in conventional group used conventional protocol. Anthropometric measurements and fitness test assessed at pre-surgery, discharge from hospital.

**RESULTS:** The result showed that subjects in exercise group decreased hospital stay during hospitalization. Subjects between both group have no significant difference in anthropometric measurements and fitness level variation.

**CONCLUSIONS:** The finding demonstrated exercise program for colorectal cancer inpatients have a positive effect in recovery variables in colorectal cancer patients after surgery.

1255 Board #36 May 30 9:30 AM - 11:00 AM

**Effect Of Exercise On Bone Mass Density In Women With Postmenopausal Osteoporosis: A Case-control Study**

Marianna Broccatelli<sup>1</sup>, Antonio Sgadari<sup>2</sup>, Simona De Bellonia<sup>2</sup>, Roberto Bernabei<sup>2</sup>. <sup>1</sup>University of Study "Foro Italico", Rome, Italy. <sup>2</sup>Catholic University of Sacred Heart, Rome, Italy.

(No relationships reported)

Osteoporosis is a common disease with a spectrum ranging from asymptomatic bone loss to disabling hip fracture. Most guidelines suggest regular weight-bearing exercise, and combined (aerobic and resistance) training to prevent and treat osteoporosis. However, a recent review concluded that physical exercise (PE) slightly improves bone density and does not reduce the risk of having a fracture in postmenopausal women. It has been hypothesized that this paucity of effect may be due to relatively short duration of interventions, poorly standardized exercise protocols and high rate of loss to follow up.

**PURPOSE:** To assess whether a combined exercise program (2 times/week callisthenic exercises plus 3 times/week aerobic and resistance training) influenced BMD in 155 women with postmenopausal osteoporosis.

**METHODS:** Forty-seven women with either lumbar or femoral osteoporosis, exercising at the University Hospital Fitness Facility for at least one year were identified as cases (EXE). One hundred and eight sedentary controls, out from a pool of 5,434 attending the Osteoporosis Outpatient Clinic, were selected according to the following matching criteria: female gender, age  $\pm$  1.5 years, duration of the observation period  $\pm$  3 months, initial BMD value  $\pm$  5% (SED). Main outcome was percent change in BMD. Comorbidities, medications, risk factors for osteoporosis, level of physical activity, dietary intake of macronutrients as well as of Ca, K, P were recorded.

**RESULTS:** Baseline characteristics were similar between EXE and SED groups: mean ( $\pm$ s.d.) age was 64.4 $\pm$ 6.2 vs. 68.8 $\pm$ 6.4 years (n.s.), BMD at femoral neck 0.581 $\pm$ 0.067 vs. 0.598 $\pm$ 0.063 g $\cdot$ cm<sup>-2</sup> (n.s.), and BMD at lumbar spine 0.727 $\pm$ 0.067 vs. 0.732 $\pm$ 0.074 g $\cdot$ cm<sup>-2</sup> (n.s.). After an average follow-up of 36.5 $\pm$ 13.1 months, BMD was increased in the EXE group by 2.23% at the femoral neck and by 3.65% at the spine, while it was decreased in the SED group (2.59% and 0.65%, respectively) (p<0.01 at both sites).

**CONCLUSIONS:** Our results showed that sedentary postmenopausal women had a significant decline in BMD over a 3-year period, while women undergoing a combined PE program do increased their BMD both at the femoral neck and the lumbar level.

**Physical Exercise In Female Fibromyalgia Patients: Effects On Pain, Functional Capacity And Symptomatology.**

Ana Carbonell-Baeza<sup>1</sup>, Virginia A. Aparicio<sup>2</sup>, Inmaculada C. Alvarez-Gallardo<sup>2</sup>, Alejandro Romero<sup>2</sup>, Clelia M Martins-Pereira<sup>3</sup>, Ana M. Cuevas<sup>2</sup>, Pedro Femia<sup>2</sup>, Francisco B Ortega<sup>4</sup>, Pablo Tercedor<sup>2</sup>, Jonatan R. Ruiz<sup>4</sup>, Manuel Delgado-Fernández<sup>2</sup>. <sup>1</sup>University of Cadiz, Cadiz, Spain. <sup>2</sup>University of Granada, Granada, Spain. <sup>3</sup>Universidade Federal Da Paraíba, Joao Pessoa, Brazil. <sup>4</sup>University of Granada., Granada, Spain. Karolinska Institutet, Unit for Preventive Nutrition., Huddinge, Sweden.

(No relationships reported)

Exercise interventions have been extensively used for the management of fibromyalgia, but it is unclear which mode of exercise is more suitable for this population.

**PURPOSE:** To compare the effects of three different physical interventions (i.e. multidisciplinary, Biodanza and Taichi) on women with fibromyalgia.

**METHODS:** a total of 146 women (51.6 $\pm$ 7.0 years) volunteered to participate in the study and were allocated in 4 groups: control (n=34), multidisciplinary(n=41), Biodanza (n=37) and Taichi (n=34). Multidisciplinary and Taichi interventions were carried out 3 times/week and Biodanza 1 time/week over three months. The following variables were assessed before and after the interventions: tender points, functional capacity (i.e. the handgrip strength, 6 minutes walk, 8 feet up & go, chair sit and reach and chair stand tests) and the fibromyalgia impact questionnaire (FIQ). One-way analysis of covariance (group as fixed factor, change score (posttest-pretest) as dependent factor and pretest score as covariate) was performed.

**RESULTS:** The Taichi group presented greater improvements on the 8 feet up & go test than the multidisciplinary (Change score: -2.1 $\pm$ 0.2 vs. -1.1 $\pm$ 0.2, p=0.005), the Biodanza (-2.1 $\pm$ 0.2 vs. -1.1 $\pm$ 0.2, p=0.006) and the control groups (-2.1 $\pm$ 0.2 vs. -0.5 $\pm$ 0.2, p<0.001). The multidisciplinary and Taichi groups showed greater improvements than the control group on chair sit and reach test (7.4 $\pm$ 2.1 vs. -3.0 $\pm$ 2.2, p=0.005 and 9.9 $\pm$ 2.3 vs. -3.0 $\pm$ 2.2, p=0.001 respectively). The FIQ total score improved in the multidisciplinary (-8.8 $\pm$ 2.3 vs. 4.7 $\pm$ 2.3, p<0.001), the Biodanza (-12.7 $\pm$ 2.5 vs. 4.7 $\pm$ 2.3, p=0.001) and the Taichi (-7.4 $\pm$ 2.5 vs. 4.7 $\pm$ 2.3, p=0.003) groups compared with the control group. The Biodanza group presented a greater decrease on number of tender points than the Taichi group (-1.4 $\pm$ 0.4 vs. 0.1 $\pm$ 0.4, p=0.044).

**CONCLUSIONS:** The multidisciplinary, Biodanza and Taichi interventions improve the symptomatology in female patients. Taichi intervention improves the dynamic balance more than multidisciplinary and Biodanza interventions. Taichi and multidisciplinary interventions improve the lower body flexibility.

**Heavy, Explosive Strength Training For Postmenopausal Women With Osteoporosis: A Pilot Study**

Mats P. Mosti, Nils Kaehler, Astrid K. Stunes, Jan Hoff, Unni Syversen. Norwegian University of Science and Technology, Trondheim, Norway.

(No relationships reported)

Current exercise guidelines recommend weight-bearing activities and strength training for patients with osteoporosis. It is still unclear what type of strength training that is most beneficial for improving physical capacity and bone mass in these patients. **PURPOSE:** The present study investigated the effects of a heavy, explosive strength training programme on physical capacity, bone mineral density (BMD) and content (BMC) in postmenopausal women diagnosed with osteoporosis or osteopenia.

**METHODS:** Twentyone women with osteoporosis or osteopenia (t-score < -1.5 in hip or spine) were randomized to a training group (TG, n=10) or control group (CG, n=11). The TG underwent 12 weeks of supervised strength training in a squat machine, at an intensity of approximately five repetitions maximum, with emphasis on explosive initiation of the concentric part of movement. The CG was encouraged to do non-supervised training in line with current exercise guidelines. Measurements included one repetition maximum (1RM), rate of force development (RFD), serum markers of bone formation (procollagen type I N-terminal propeptide (P1NP)) and bone resorption (fragments of type I collagen C (CTX)), BMD, BMC and bone area measured by Dual X-ray absorptiometry. Nonparametric statistics were used. **RESULTS:** One participant was excluded in the TG and four participants withdrew (one in the TG and three in the CG). 1RM and RFD were significantly improved in the TG with 154 $\pm$ 75% and 52 $\pm$ 46%, respectively (p<0.05). BMC at the lumbar spine and femoral neck increased with 2.9 $\pm$ 2.8% and 4.9 $\pm$ 5.6%, respectively (p<0.05), while bone area increased with 2.4 $\pm$ 2.0% and 5.2 $\pm$ 5.1%, respectively (p<0.05). The 1RM and lumbar spine BMC improvements differed significantly from the CG (p<0.05). There was also a tendency to improved ratio of P1NP/CTX (21%, p=0.09) in the TG. No significant changes were observed in the CG.

**CONCLUSIONS:** Heavy, explosive strength training appears to be safe and give beneficial effects on muscle strength, RFD and BMC in postmenopausal women with osteoporosis. These findings should be further investigated in a larger trial of longer duration.

---

1258 Board #39 May 30 9:30 AM - 11:00 AM

**Effective Physical Activity Energy Expenditure Feature For Maintaining Bone Mass In Postmenopausal Women**

Zheng Lu, Zhi-xiong Zhou, Xiao-hong Chen, Xun Li, Yong-Sheng Wang. *Capital University of Physical Education and Sports, Beijing, China.*  
(No relationships reported)

Growing evidence indicates that physical exercise can prevent or improve bone loss. However, the standard of the deficient exercise is lacking.

**PURPOSE:** To observe the change of energy expenditure (EE), body composition (BC), BMD and muscle strength before and after 1y exercise in postmenopausal women, to explore the relationship between the indexes and bone mass, and to determine the best EE maintaining bone mass.

**METHODS:** 62 compliant women, aged 50-60y, with BMD T-score <-1, were divided into exercise group (EG, n=32) and control (CG, n=30). EG exercised 3-4 times weekly for 1y. PA and EE were determined by accelerometer. BMD and BC were measured by DXA. Hip's muscle strength was described by isokinetic peak-torque. Exercise intensity was assessed by portable metabolic test system. Paired and independent sample T tests were used within and between groups.

**RESULTS:** 1. EG were higher than CG in walking, physical activity(PA) and total diary energy expenditure (TDEE) (all p<0.01). And difference was mainly caused by walking EE, which should be considered effective PAEE.

2. PA time of 3-6MET in EG was more than CG (P<0.01). During the exercise, mean heart rate was 117.59±9.41bpm, maximum intensity 5.70±1.97MET, exercise time 50min, and EE 312.07±94.2Kcal. Moderate intensity exercise is adequate stimulus for maintaining EG bone mass.

3. After 1y, EG decreased in weight, BMI and F% (all p<0.01), and increased in LBM% (p<0.01). For both groups, weight, BMI, F%, muscle mass and TDEE was correlated with whole body BMD (r=-0.486, 0.475, 0.434, 0.386, 0.366, all P<0.01), and LBM% was negatively associated with BMD (r=-0.481, P<0.01). The BC optimization was important feature.

4. After 1y, peak-torque values for hip flexion (90°/s, 180°/s) and extension (180°/s) in EG observably elevated (all P<0.01). BMD at main sites in EG were higher than CG (p<0.01-0.05). For EG, 1y exercise effectively increased muscle strength, which was the primary cause of maintaining bone mass.

**CONCLUSIONS:** 1. Exercise can effectively maintain bone mass by improving muscle mass and strength.

2. Exercise of 3-4 times weekly, 50 min/time, and 3-6MET's moderate intensity is suitable for postmenopausal women to maintain bone mass.

3. Lower than 680 kcal PAEE can be considered as standard of deficient exercise for postmenopausal women maintaining bone mass.

---

1259 Board #40 May 30 9:30 AM - 11:00 AM

**Effects Of Exercise On Physical, Psychological, And Social Aspects Of Pain In Spinal Cord Injuries**

Carrie J. Yale, Petra B. Schuler, Ludmila Cosio Lima. *University of West Florida, Pensacola, FL.*  
(No relationships reported)

Individuals who suffer a spinal cord injury (SCI) experience pain as a secondary result of the injury. Pain can be difficult to treat as the experience is unique to each individual. If not treated effectively, pain can elevate levels of depression, anxiety, stress, and social isolation.

**PURPOSE:** To determine if exercise helps alleviate aspects of pain associated with SCI.

**METHODS:** Six subjects participated in 8 weeks of twice weekly exercise. Participants were required to complete 12 minutes of wheelchair propulsion and 50 minutes of resistance training. Resting heart rate (HR), blood pressure (BP), cardiorespiratory fitness, muscular strength, pain, depression, anxiety, stress, and perceived social support were assessed. Descriptive statistics were computed to determine changes in resting HR and BP. Subjects performed 6 minutes of arm ergometry and cardiorespiratory fitness was measured by changes in the rate of perceived exertion (RPE) and HR for the same workload. RPE and HR were taken each minute; a dependent t-test was used to determine changes in these variables. During the 12 minute bout, HR, number of completed laps, and the RPE given for each lap around the track were reported; repeated measures of analysis of variance was used to compare any change in these variables. Muscular strength was determined by the subject's one repetition maximum (1-RM). Self report questionnaires were used to measure pain, depression, anxiety, stress, and perceived social support. A dependent t-test was used to determine changes in the measures of the 1-RM and questionnaire scores. For all statistical analyses the confidence interval was set at p<0.05.

**RESULTS:** The group experienced improvement in measures of cardiorespiratory fitness as seen in a decreased resting HR (p = .043), lower RPE at the fifth and sixth minute of arm ergometry (p = .042), lower RPE between each minute of arm ergometry (p = .029), and a lower RPE observed during the 12 minutes of wheelchair propulsion (p = .010). An increase in muscular strength for the chest press (p = .047) and deltoid press (p = .03) was observed. No significant differences were observed in the measures of pain, depression, anxiety, stress, and perceived social support.

**CONCLUSIONS:** Participation in weekly exercise improves physical functioning among individuals with SCI.

**The Effect of Low Back Strengthening on Balance Performance in Patients with Lumbar Sacralization**

Yen-Ling Li<sup>1</sup>, Guo-Sheng Li<sup>1</sup>, Yu-Tsai Tu<sup>2</sup>, Wei-Han Chang<sup>3</sup>, Cheng-Hsiu Lai<sup>1</sup>, Shih-Wei Chou<sup>3</sup>. <sup>1</sup>Taipei Physical Education College, Taipei, Taiwan. <sup>2</sup>Chang Gung Memorial Hospital, Taipei, Taiwan. <sup>3</sup>Chang Gung Memorial Hospital, taipei, Taiwan. (Sponsor: Chia-Hua Kuo, FACSM)  
(No relationships reported)

Lumbosacral transitional vertebra (LSTV), commonly found between the fifth lumbar vertebra and the first sacral vertebra, of which the transverse processes fuse to different extent. The changes in spinal dynamics of LSTV may result in early disc degeneration, trunk instability and consequent low back pain (LBP). Patients with chronic LBP and lumbar degenerative disease are also characterized by an anterior sagittal imbalance. However, it is unclear whether low back strengthening exercise improve balance performance in LBP patients with LSTV.

**PURPOSE:** To investigate the low back strengthening effects in LBP patients with LSTV on balance performance.

**METHODS:** Thirty LBP patients with LSTV were recruited and divided into two group randomly assigned as Group A, the extensor-flexor group (age, 26.4 ± 11.2 years; body height, 171.9 ± 11.0 cm; body weight, 66.1 ± 13.5 kg) and group B, the flexor-extensor group (age, 26.1 ± 10.2 years; body height, 170.6 ± 8.4 cm; body weight, 66.0 ± 16.7 kg). Two session of the training program were prescribed including the extension session and the flexion session each for 3 weeks, and the order of the two training program was reversed between the two group. The results of the sensory organization test (SOT), Limits of St ability (LOS), and rhythmic weight shifting (RWS), measured by using the Smart Balance Master, lumbar ROM, measured by the microFET3, lumbar isometric strength, measured by the Cybex were compared between the two groups. LBP was evaluate by the visual analogus scale (VAS).

**RESULTS:** Irrespective to training group or modes, ROM, strength and VAS of low back were all improved significantly. Balance performance was in part improved significantly. Extensor training program seemed to be more effective than flexor training program in pain relief.

**CONCLUSIONS:** Low back strengthening for LBP patients with LSTV may improve balance performance in part. It also improves isometric strength, ROM and pain scale of low back. The extensor training session may outweigh flexor training session in pain relief for patients with LSTV.

---

1261 Board #42 May 30 9:30 AM - 11:00 AM

**Low Back Strengthening effects on Quadriceps Strength in Lumbago Patient with Lumbar Sacralization**

Yi-chen Lin<sup>1</sup>, Chi-Ping Lai<sup>1</sup>, Yu-Tsai Tu<sup>2</sup>, Yin-Chou Lin<sup>2</sup>, Cheng-Hsiu Lai<sup>1</sup>, Shih-Wei Chou<sup>2</sup>. <sup>1</sup>Taipei Physical Education College, Taipei, Taiwan. <sup>2</sup>Chang Gung Memorial Hospital, Taipei, Taiwan. (Sponsor: Chia-Hua Kuo, FACSM)  
(No relationships reported)

Lumbosacral transitional vertebra (LSTV), commonly found between the fifth lumbar vertebra and the first sacral vertebra, of which the transverse processes fuse to different extent. The changes in spinal dynamics of LSTV may result in early disc degeneration, trunk instability, and consequent low back pain (LBP). The patients with chronic LBP tend to show increased inhibition of quadriceps activity. However, it is unclear whether low back strengthening exercise improve the quadriceps strength in LBP patients with LSTV.

**PURPOSE:** To investigate the low back strengthening effects of the LBP patients with LSTV on quadriceps isokinetic strength.

**METHODS:** Thirty LBP patients with LSTV were recruited and divided into two groups randomly assigned as Group A, the extensor-flexor group (age, 26.4 ± 11.2 years; body height, 171.9 ± 11.0 cm; body weight, 66.1 ± 13.5 kg) and group B, the flexor-extensor group (age, 26.1 ± 10.2 years; body height, 170.6 ± 8.4 cm; body weight, 66.0 ± 16.7 kg). Two sessions of the training program were prescribed including the extension session and the flexion session each for 3 weeks, and the order of the two training program was reversed between the two group. The isokinetic strength of the knee extensor, measured by the Cybex, were compared between the two groups. Pain of low back and knee were evaluate by the visual analogous scale (VAS).

**RESULTS:** Quadriceps strengths were significantly improved in all 3 angular velocities of both right and left legs, particularly after extensor training. Low back extensor training was more efficient than flexor in pain control of the knee pain.

**CONCLUSIONS:** Low back strengthening training for LBP patients with lumbar sacralization may improve quadriceps isokinetic strength and low back/knee pain scale, particularly after extensor strengthening.

---

**1262** Board #43 May 30 9:30 AM - 11:00 AM

**Low Normalized Leg Strength in Obesity Predicts Habitual Physical Activity and Endurance in Knee Osteoarthritis**

Kevin R. Vincent, Cindy Montero, Amanda Seay, Heather K. Vincent. *University of Florida, Gainesville, FL.*

(No relationships reported)

Adults with knee osteoarthritis (OA) face multiple challenges with beginning exercise or participating in regular daily physical activity, especially if they are obese. It is unclear how normalized muscle strength relates to endurance time or habitual physical activity.

**PURPOSE:** To determine the associations between muscle strength, endurance time and habitual physical activity in obese and non-obese persons with knee OA.

**METHODS:** Participants with knee OA (68±7 yrs) who sought participation in an exercise program were stratified into obese (n=20; body mass index [BMI] 34±4 kg/m<sup>2</sup>, 49±9% body fat) and non-obese (n=20; BMI 25±3 kg/m<sup>2</sup>, 34±10% body fat). Maximal strength testing of the knee extensors and flexors, and maximal walking endurance tests were performed. Body fat was determined using the BODPOD. The Western Ontario McMaster Osteoarthritis (WOMAC) Index survey was administered to assess knee function with OA pain. Activity monitors were worn for 7 days to record daily activity. Regression analysis determined the contributions of normalized leg strength scores on treadmill endurance time, and average daily steps.

**RESULTS:** Walking endurance time was 31% lower in the obese group (p<0.0001). Average WOMAC knee pain was similar between groups (5.2-5.5 points). Average daily steps taken were 3246±1131 and 4248±1365 steps, in the obese and non-obese groups, respectively (p<0.005). The time spent performing moderate daily activity was 30 minutes less in the obese group (p=0.05). WOMAC scores were not different between groups (33.2 vs 28.8 points). Maximal normalized leg press, leg curl and leg extension strength values were less in the obese group (p<0.05). After accounting for age and sex, normalized leg strength values were contributors to the variance of the models predicting walking endurance time (model R<sup>2</sup>=0.514-0.561, R<sup>2</sup> change range 0.218-0.265) and in habitual physical activity (R<sup>2</sup>=0.198-0.230, change range 0.104-0.136; all p<.001).

**CONCLUSIONS:** Walking endurance and habitual physical activity were consistently predicted by leg strength in knee OA. Targeted resistance exercise may improve muscle strength and foster improvements in endurance and increased habitual physical activity in obese individuals, both of which would facilitate weight loss. Supported by NIH NIAMS RO3AR059786

**Efficacy And Effectiveness Of Exercise On Tender Points In Adults With Fibromyalgia: A Meta-analysis**

George A. Kelley, FACSM, Kristi S. Kelley. *West Virginia University, Morgantown, WV.*

(No relationships reported)

**PURPOSE:** Fibromyalgia is a major public health problem affecting an estimated 200 to 400 million people worldwide. The purpose of this study was to determine the efficacy and effectiveness of randomized controlled exercise intervention trials (aerobic, strength training or both) on tender points (TP) in adults with fibromyalgia.

**METHODS:** Meta-analysis using random effects models and 95% confidence intervals (CI) with results partitioned according to per-protocol and intention-to-treat analyses.

**RESULTS:** Statistically significant reductions in TP were observed based on per-protocol analyses (8 studies representing 322 participants) but not intention-to-treat analyses (5 studies representing 338 participants) (per-protocol, g, -0.68, 95% CI, -1.16, -0.20; intention-to-treat, g, -0.24, 95% CI, -0.62, 0.15). Changes were equivalent to relative reductions of 10.9% and 6.9%, respectively, for per-protocol and intention-to-treat analyses.

**CONCLUSIONS:** Exercise is efficacious for reducing TP in women with FM. However, a need exists for additional well-designed and reported studies on this topic.

**1264** Board #45 May 30 9:30 AM - 11:00 AM

**Case review for 12 Weeks Of High-intensity Interval Training (HIT) in a Spinal Cord Injured Man**

Christopher R. Harnish, Jonathan A. Daniels, Allison F. Keeley, David R. Gater. Hunter Holmes McGuire VAMC, *Richmond, VA.* (Sponsor: Edmond Acevedo, FACSM)

(No relationships reported)

Exercise may play an important role in managing the metabolic health consequences of SCI but little is known about the impact of arm crank ergometer (ACE) HIT or how to adapt it for individuals with SCI.

**PURPOSE:** To review the outcome of 12 weeks of periodized HIT in a man with chronic traumatic SCI.

**METHODS:** One 42 yo man (180 cm tall, 68.4 kg and 30.6% Fat) with C8/T1 AIS A SCI took part in 12 weeks of 3 days/week-1 ACE interval training. A continuous 2 min stage VO<sub>2</sub>Peak test was completed before, 6 and 13 weeks after training. During the first training session and at week 4, 8 and 12 a 30 min time trial (TT30) test was performed on a Monark 881E ACE to assess performance improvement; heart rate (HR) and mean power (W) were determined. Training was conducted on a LODE ACE and consisted of a combination of HIT that included three times 5 min at ~70% Peak Power (WPeak) and 5 min recovery (HIT5); four times 2.5 min at ~85% WPeak and 5 min recovery (HIT2.5); ten times 1 min at ~110% WPeak and 2 min recovery (HIT1). HR zones were set as <75% HRPeak (Z1), 75-89% (Z2), and 90+% (Z3) and HR was measured and stored for all training. HR training impulse (TRIMP) scores were calculated as: Z1 minutes + (Z2 minutes \* 2) + (Z3 minutes \* 3) and used to monitor overall training efficacy. DXA was used to estimate body fat pre and post training.

**RESULTS:** 35 sessions that included 8 HIT5, 10 HIT2.5, and 5 HIT1 sessions were completed. WPeak and VO<sub>2</sub>Peak improved about 45% and 52%, respectively, by week 6 without further improvement at week 12. TT30 wattage improved 32% at week 4, 47% at week 8, and 56% at week 12. HR TRIMP scores decreased in the first 6 weeks as mean session wattage increased before showing a parallel increase for the remaining 6 weeks.

**CONCLUSIONS:** Persons with SCI exhibit widely varying exercise responses, regardless of level of injury. This case report demonstrates that even high-level paraplegics can achieve exceptional training outcomes and that ACE HIT may provide an effective training method for SCI. As with able-bodied persons, maximal performance plateau early, while submaximal performance may show longer term improvement. The latter supports the use of submaximal training assessment important in the long-term training monitoring for SCI. HR TRIMP data provides a useful means for monitoring and periodizing training in paraplegia with a normal HR response.

**1265** Board #46 May 30 9:30 AM - 11:00 AM

**Comparative Study Of The Effects Of Tai Chi And Strength Training On Osteoarthritis In Older Adults**

Abhinandan Batra, Yong Tai Wang, FACSM, Elisabeth Burgess, Ann Pearman. *Georgia State University, Atlanta, GA.*

(No relationships reported)

**PURPOSE:** Osteoarthritis (OA) is a degenerative joint disorder and one of the leading causes of disability in elderly. Tai Chi is seen to be effective in relieving symptoms of OA knee joint. The main aim of this study was to design a Tai Chi program and/or a strength training program for the older adults with knee OA and to compare the effects of these programs on the range of motion, gait, pain and balance.

**METHODS:** Twenty participants age 55 and over were divided into two groups (Tai Chi and Strength training) based on predetermined criteria (Age, Grade of OA, balance). Both groups received respective form of exercises twice a week for 2 months. Both groups were assessed before and after intervention on WOMAC, Berg balance scale, ROM and Manual muscle testing Independent and paired t test were employed to determine the differences within each group and between two groups with significance level at  $p < .05$ .

**RESULTS:** Mean ages of the participants in both strength training and Tai Chi group were  $82.8 \pm 10.6$  years and  $82 \pm 11.35$  years respectively. Both the groups showed statistical significant improvement in WOMAC scores and balance. WOMAC score decreased for strength training group (52 to 40.5) and Tai Chi group (52.28 to 38.57). Balance score on the Berg balance scale improved for strength training group (36.75 to 46 at  $p < .05$ ) and Tai Chi group (39.14 to 47.42 at  $p < .001$ ). Significant increase in strength of lower limb muscle was seen in strength training group with no change in Tai Chi group. Though significant changes were seen within the group analysis, no such difference was found on comparing strength group to Tai Chi group.

**CONCLUSIONS:** Both groups demonstrated improvement in symptoms related to OA showing that both forms of exercise are effective and safe in improving symptoms related to OA but no evidence was found depicting Tai Chi to be better form of exercise than strength training.

**1266**    *Board #47*    **May 30**    **9:30 AM - 11:00 AM**  
**Physical Activity, Sedentary Time, and Bone Health In Younger And Older Females**

Saori Ishikawa, Youngdeok Kim, Minsoo Kang, FACSM, Don Morgan, FACSM. *Middle Tennessee State University, Murfreesboro, TN.*  
(No relationships reported)

Recent studies have focused on the contribution of physical activity (PA) and sedentary behavior (SB) on metabolism and cardiovascular health in adults. Little is known, however, regarding the extent to which PA and SB impact bone mineral content (BMC) and bone mineral density (BMD) in females across the lifespan.

**PURPOSE:** To examine the impact of PA and SB on bone health in females from adolescence to old age.

**METHODS:** Data from 2,245 females aged 12 years and older collected as part of the 2007-2008 National Health and Nutrition Examination Survey (NHANES) were included in this analysis. Based on self-report, participants were categorized into three PA categories: sufficient moderate-to-vigorous recreational physical activity (S-MVRPA), insufficient MVRPA (I-MVRPA), and no MVRPA (N-MVRPA). S-MVRPA was defined as  $\geq 150$  minutes per week of moderate recreational PA (RPA) or an equivalent amount of vigorous RPA for adults ( $\geq 19$  years of age) or  $\geq 60$  minutes per day of MVRPA for adolescents (12 to 18 years of age). Values of BMC (g) and BMD (g/cm<sup>2</sup>) of total femur and total spine were measured by dual energy x-ray absorptiometry. Categories of PA and self-reported minutes of SB (i.e., sitting or reclining time, excluding sleeping) were used to predict BMC and BMD of the femoral and spinal regions in four age groups [i.e., adolescents (12-18 years), young adults (19-39 years), middle-aged adults (40-64 years), and older adults (>64 years)] after controlling for nutritional intake and body mass index (BMI). SAS 9.2 SURVEYREG procedures with ESTIMATE statement were used to account for the multistage and complex nature of the NHANES sampling scheme.

**RESULTS:** Female adolescents in the S-MVRPA category displayed significantly greater femoral BMC, femoral BMD, spinal BMC, and spinal BMD compared to those in N-MVRPA category ( $b = 3.01, 0.07, 4.72, \text{ and } 0.04$ , respectively,  $p < .05$ ). In older adults, SB was also a significant predictor of femoral BMC and BMD ( $b = -0.004$  and  $-0.0001$ , respectively,  $p < .05$ ), such that an increase in SB resulted in lower femoral BMC and BMD.

**CONCLUSIONS:** These findings suggest that engaging in S-MVRPA during adolescence and reducing sedentary time in the elderly may contribute to improved bone health in females.

**1267**    *Board #48*    **May 30**    **9:30 AM - 11:00 AM**  
**Pilates is More Effective than Common Exercise Program for Treatment of Forward Head Posture**

Sun-Myong Lee, Chang-Hyung Lee, Jung Jun Park. *Pusan National University, Busan, Korea, Republic of.*  
(No relationships reported)

**BACKGROUND:** Forward head posture (FHP) is defined as the anterior positioning of the cervical spine, which is one of the most common postural problems in modern society. Recently, Pilates has been reported to be effective exercise for correcting postural problems.

**PURPOSE:** To compare the effects of Pilates and common exercise program on improvements in craniocervical angle (CVA), cervical range of motion (cROM), pain, and muscle fatigue in FHP

**METHODS:** Twenty eight sedentary women with FHP, aged between 20 and 39, participated in this study. They were randomly divided into two groups; Pilates exercise group (PG,  $n = 14$ ) and common exercise group (CG,  $n = 14$ ). Pilates exercise program consisted of modern Pilates focused on FHP-related major muscle group. Common exercise program consisted of stretching and resistance exercise on the same muscle group as Pilates exercise program. Both group performed exercise 50 min/day, 3 days/week, intensity of 11-15 RPE for 10 weeks. CVA, indicating FHP degree, was measured by X-ray. cROM, representing cervical function, was measured by CROM device. Pain levels were assessed by visual analog scale (VAS) and neck disability index (NDI). Muscle fatigue was measured by surface electromyogram (sEMG) at median frequency. Statistical significance was  $p < .05$ .

**RESULTS:** PG significantly increased CVA ( $65.65 \pm 4.53^\circ$  vs.  $70.09 \pm 4.78^\circ$ ,  $p = .002$ ), but CG did not. PG also significantly increased 5 of 6 cROM items: flexion ( $35.11 \pm 6.39^\circ$  vs.  $46.64 \pm 8.83^\circ$ ,  $p = .004$ ), extension ( $50.14 \pm 11.76^\circ$  vs.  $57.05 \pm 9.3^\circ$ ,  $p = .037$ ), R. sideflexion ( $29.58 \pm 3.12^\circ$  vs.  $34.00 \pm 3.78^\circ$ ,  $p = .006$ ), R. rotation ( $51.5 \pm 10.63^\circ$  vs.  $57.81 \pm 5.81^\circ$ ,  $p = .045$ ), L. rotation ( $52.06 \pm 10.1^\circ$  vs.  $57.17 \pm 6.65^\circ$ ,  $p = .033$ ). However, CG did not change in CVA and cROM items. Among sEMG factors, only SCM was significantly increased in PG ( $27.27 \pm 11.26$  Hz vs.  $43.51 \pm 17.29$  Hz,  $p = .009$ ), but not in CG. VAS and NDI were significantly decreased in both groups.

**CONCLUSIONS:** These results indicate that Pilates is more effective to improve CVA, cROM, and, in part, muscle fatigue than common exercise (a combination of stretching and resistance exercise). It suggests that Pilates can be recommended as an appropriate exercise for FHP treatment, and may be extended for other patients with neuromusculoskeletal problems.

**1268**    *Board #49*    **May 30**    **9:30 AM - 11:00 AM**  
**Low Trunk Strengthening Effects on Patellofemoral Pain Syndrome**

Chiping Lai<sup>1</sup>, Guosheng Li<sup>1</sup>, Chingya Hung<sup>1</sup>, Joupin Li<sup>1</sup>, Chengshiu Lai<sup>1</sup>, Shihwei Chou<sup>2</sup>. <sup>1</sup>Taipei Physical Education College, Taipei, Taiwan. <sup>2</sup>Chang Gung Memorial Hospital, Taoyuan, Taiwan. (Sponsor: Chia-Hua Kuo, FACSM)  
(No relationships reported)

Patellofemoral pain syndrome (PFPS) is a common knee problem. Quadriceps strengthening has been suggested to treat patients with PFPS. The quadriceps muscle was inhibited after lumbar paraspinous fatiguing exercise in the absence of quadriceps fatigue.

**PURPOSE:** To investigate low back strengthening effects on the patients with PFPS in terms of (1) low trunk isometric strength, (2) quadriceps isokinetic strength, and (3) knee pain scale.

**METHODS:** Eighteen knees of sixteen patients with PFPS were randomly divided into two groups, group A (extensor-flexor, 9 knees of 8 patients) and group B (flexor-extensor, 9 knees of 8 patients). In the 1st 3-week session of training group A started low trunk extensors strengthening and group B did flexor and in the 2nd 3-week session, the training programs were shifted between groups. The visual analog scale (VAS) was used to scale knee pain. Cybex NORM was used to measure isometric strength of low back flexor, extensor and isokinetic strength of quadriceps at 60°/sec, 120°/sec and 180°/sec. Two-way ANOVA with repeated measures in the 1st session tested the significance of main and interaction effects between training group factor and pre-post training factor. The training effects in the 2nd session were analyzed by prescription.

**RESULTS:** After the 1st session of training, interaction effects were significant ( $p < .05$ ), indicating extensor training significantly increase low trunk extensor strength and vice versa. No interaction effects occur in isokinetic strength of the quadriceps between two groups at all three angular velocities. The VAS of knee pain appeared to be improved more in group A than B (51.83% vs. 36.07%). After the 2nd session, group B increased low trunk extensor strength and group A increased flexor strength. Isokinetic strength of the quadriceps in group B was improved more than group A at all three angular velocities. Extent of knee pain relief in group B seemed to be more than group A.

**CONCLUSIONS:** Low trunk strengthening training increases specific strength of either extensor or flexor muscles. However, extensor strengthening seemed to be more effective in patellofemoral pain relief and quadriceps strength enhancement.

**1269** Board #50 MAY 30 11:00 AM - 12:30 PM  
**Odds Ratios and Sex Differences in Staying in at-Risk Fitness Categories among Middle School Children**

Traci D. Zillifro, Wenhao Liu, Randall A. Nichols. *Slippery Rock University, Slippery Rock, PA.*  
(No relationships reported)

Fitness tracking statistics such as Pearson or Spearman rank correlations, kappa values, and percentage agreements in percentiles provide little guidance for intervention for adolescents because they just describe the stability of relative rank/position and fail to address the overall change in test scores relative to Fitnessgram Healthy Fitness Zone (HFZ). Fitness tracking studies providing more meaningful information are needed.

**PURPOSE:** To examine odds ratios and sex differences in staying in the at-risk groups among middle school children across a 31-month period.

**METHODS:** Fitnessgram battery was administered to 87 boys (mean age = 11.55 ± .54) and 107 girls (mean age = 11.34 ± .48) at baseline and a follow-up with a 31-month interval to assess percent body fat (%BF), BMI, Progressive Aerobic Cardiovascular Endurance Run (PACER), curl-up, push-up, and sit and reach. Based on sex- and age-specific criteria for Fitnessgram hfz, the participants were categorized into an at-risk group (not in HFZ) and a HFZ group (in HFZ) at the baseline and the follow-up for each fitness measure. Odds ratios and sex differences in staying in the at-risk groups across the 31-month period was examined with crosstabs.

**RESULTS:** Odds ratios of staying in the at-risk groups at the follow-up in fitness measures ranged from 2.6 (95% CI: 1.3-5.1) to 20.4 (95% CI: 7.7-84.7) for those initially in the at-risk groups relative to those who were in the HFZ groups at baseline. Across the 31 months the numbers or percentages of boys in the at-risk groups decreased in %BF (23 vs. 19, -17%), BMI (28 vs. 24, -14.3%), PACER (39 vs. 31, -20.5%), and curl-up (12 vs. 9, -25%); and remained no change in push-up (31 vs. 31, 0%) and sit and reach (15 vs. 15, 0%). In a sharp contrast with boys, the numbers of girls in the at-risk groups increased in %BF (18 vs. 23, +27%), BMI (29 vs. 35, +20.7%), PACER (24 vs. 39, +62.5%), and push-up (38 vs. 51, +34.2%); and decreased in curl-up (24 vs. 11, -54.2%) and sit and reach (47 vs. 29, -38.3%).

**CONCLUSIONS:** Children of roughly 11 years old who are at risk in fitness levels are much more likely to be in the at-risk groups later relative to those who are in the HFZ groups at baseline. In addition, during the middle school period more girls tend to become at risk in fitness levels, whereas numbers of boys in the at-risk groups tend to decrease.

---

**1270** Board #51 MAY 30 11:00 AM - 12:30 PM  
**Construction of Delayed Menarche Evaluation in Korean Female Athletes**

Katsunori Fujii, FACSM. *Aichi Institute of Technology, Toyota, Japan.*  
(No relationships reported)

**PURPOSE:** In the present study we conducted a regression analysis of age at menarche against age at maximum peak velocity (MPV) of height in non-athlete Korean girls (control group), and composed 1st to 3rd order regression polynomials to obtain the best regression polynomial. Author then applied the age at menarche and age at MPV of height of athletes to the best polynomial regression evaluation, and investigated the validity of a delayed menarche evaluation system that we constructed.

**Method:** The subjects were 150 second grade female students at a physical education high school in the suburbs of Pusan, South Korea. A questionnaire survey of these girls was conducted, from which their date of birth, age at menarche, and athletic activities in elementary, junior high school, and high school were obtained. In addition, health check records were examined retrospectively, and longitudinal growth data for height were obtained from the 1st grade of elementary school (7 years old) until the second year of high school (17 years old). One hundred twenty-four girls for whom all data were available were selected. Next, the same survey as above was also done for second grade students at a general high school in the same area, as a control group. Three hundred forty-five non-athletes for whom all data were available were selected. In the analysis, first the wavelet interpolation method was applied to the longitudinal height growth data for the athlete and control groups, and age at MPV was determined from the velocity curve.

**RESULTS:** The third order polynomial was found to be most suitable for the regression polynomial. When it was applied to individual female Korean athletes with respect to the regression evaluation, positive scores were obtained for nearly all athletes and an overall delay in menarche was seen. Delayed menarche was not seen, however, in archery athletes. A strong delay in menarche was thus found in Korean athletes.

**CONCLUSION:** it was found that 80% had moderate or greater menstrual pain and a close relation with menstrual abnormalities, suggesting that delayed menarche may be a barometer for menstrual abnormalities. The demonstration of delayed menarche in Korean female athletes from the above suggests the validity of the delayed menarche evaluation.

**1271** Board #52 MAY 30 11:00 AM - 12:30 PM  
**Cardiovascular Fitness and Bone Health of Adolescent Girls According to Age of Menarche**

Rebecca A. Battista, Lanay M. Mudd. *Appalachian State University, Boone, NC.* (Sponsor: Alan Utter, FACSM)  
(No relationships reported)

The teenage years are one of the most critical stages of bone mineral acquisition. Maturation may also be related to changes in cardiovascular fitness. However, little is known about the relations among menarcheal status, cardiovascular fitness and bone health during this timeframe.

**PURPOSE:** The purpose of this study was to determine relations among menarcheal status and cardiovascular fitness, bone mineral content (BMC) and bone mineral density (BMD) among teenage girls in the National Health and Nutrition Examination Survey (NHANES) 1999-2004.

**METHODS:** Participants included girls with complete dual-energy X-ray absorptiometry (DEXA) measures aged 12 to 18 years who had experienced menarche (N = 1458). Menarcheal status was defined as: early maturers (EM) with menarche < 12 years; average maturers (AM) with menarche 12-14 years (referent); and late maturers (LM) with menarche > 14 years. Self-reported demographics and physical activity (PA), measured height and weight (body mass index calculated), predicted VO<sub>2</sub>max from a cycle ergometer test, and BMC, BMD, and percent fat from a DEXA were obtained. SAS v9.2 used weighted analyses to account for the complex sampling frame of NHANES. Linear regression analyses were used to assess relations among menarcheal status, VO<sub>2</sub>max, BMC, and BMD.

**RESULTS:** EM were significantly (p<0.05) younger (mean ± standard error: 14.7±0.1, 15.4±0.1, 16.6±0.1 years), taller (160.7±0.4, 161.9±0.3, and 163.4±0.5 cm), and larger (24.1±0.4, 23.1±0.3, 22.1±0.5 kg/m<sup>2</sup>; 34.3±0.4, 33.2±0.5, 31.8±0.6 %fat) compared to the AM and LM, respectively. Menarcheal status was not related to VO<sub>2</sub>max in unadjusted or adjusted analyses. After adjustment for age, race and total minutes of PA, EM was significantly related to a higher mean BMC (beta estimate ± standard error: 51.8 ± 24.3 g, p<0.05) and tended to be related to slightly higher BMD (0.015 ± 0.007 g/cm<sup>2</sup>, p=0.054) compared to AM. LM was not related to any changes in BMC or BMD compared to AM.

**CONCLUSIONS:** EM have a larger body size than AM and LM, and slightly higher BMC and BMD. However, despite their larger body size, fitness levels are similar. Additional research is needed to determine if menarcheal status is related to cardiovascular fitness and bone health later in life.

---

**1272** Board #53 MAY 30 11:00 AM - 12:30 PM  
**Longitudinal Relationships Between Health-related Physical Fitness Test Item Performances In Elementary-aged Children**

Loran D. Erdmann, Cathy S. McMillan. *Western Illinois University, Macomb, IL.* (Sponsor: Michael P. Godard, FACSM)  
(No relationships reported)

Longitudinal study of health-related physical fitness (HRPF) in children is limited.

**PURPOSE:** To longitudinally examine relationships between HRPF tests in young children.

**METHODS:** HRRPF test data were collected annually from one school district, over an 18-yr period, and included: 1-mile run/walk (MR, in elapsed time); double-leg sit-and-reach (SR); pronated-grip pull-up (PU); and 1-min sit-up (SU). Data were retained from 167 boys and 165 girls who were (a) baseline tested as 5- or 6-yr-old kindergartners, (b) subsequently tested in each of grades 1, 2, 3, 4, and 5; and (c) had complete data at all grades. Pearson's *r* correlations were used to examine relations of MR to SR and SU performances, as well as relations of SR to SU performances. Spearman's *rho* correlations were used to examine relations of PU to MR, SR, and SU performances, as PU data were nonparametric. All analyses were sex-and-grade specific. *P* values < .05\*, .01\*\*, and .001\*\*\* are reported.

**RESULTS:** Correlations between HRRPF test items at grades K, 1, 2, 3, 4, and 5 respectively are as follows: MR/SR: Boys: -.03, -.08, -.13, -.19\*, -.08, -.13; Girls: -.09, .05, -.24\*\*, -.19\*, -.33\*\*\*, -.12; MR/SU: Boys: -.37\*\*\*, -.29\*\*\*, -.29\*\*\*, -.27\*\*\*, -.36\*\*\*, -.43\*\*\*; Girls: -.42\*\*\*, -.29\*\*\*, -.41\*\*\*, -.38\*\*\*, -.45\*\*\*, -.52\*\*\*; SR/SU: Boys: .08, .18\*, .13, .19\*, .30\*\*\*, .19\*; Girls: -.01, .20\*\*, .20\*\*, .15, .26\*\*, .29\*\*\*; Boys: PU/MR: -.28\*\*\*, -.34\*\*\*, -.44\*\*\*, -.29\*\*\*, -.40\*\*\*, -.53\*\*\*; Girls: -.25\*\*, -.28\*\*\*, -.26\*\*, -.27\*\*, -.42\*\*\*, -.39\*\*\*; PU/SR: Boys: .20\*, .21\*\*, .20\*, .11, .17\*, .14; Girls: .26\*\*, .02, .16\*, .21\*\*, .21\*\*, .06; PU/SU: Boys: .30\*\*\*, .38\*\*\*, .31\*\*, .43\*\*\*, .32\*\*\*, .41\*\*\*; Girls: .20\*\*, .27\*\*\*, .49\*\*\*, .35\*\*\*, .34\*\*\*, .32\*\*\*.

**CONCLUSION:** For boys and girls across the elementary grades, there are weak to moderate significant inverse relations of MR times to both SU and PU performances and weak to moderate positive relations of PU to SU performances. Although SR performance is significantly related to other HRRPF test performances at some grades for both genders, the strength of these relations is only very weak to weak. For these HRRPF test item pairs, generally the relational direction remains consistent and the relational strength changes little as young children progress through elementary school.

1273 Board #54 MAY 30 11:00 AM - 12:30 PM

### Physical Self-Perception and Physical Fitness in Adolescents With and Without Autism Spectrum Disorders

Chien-Yu Pan<sup>1</sup>, Chia-Hua Chu<sup>1</sup>, Chia-Liang Tsai<sup>2</sup>, Kai-Wen Hsieh<sup>1</sup>, Ya-Lin Li<sup>1</sup>, Shih-Tse Huang<sup>1</sup>. <sup>1</sup>National Kaohsiung Normal University, Kaohsiung, Taiwan.

<sup>2</sup>National Cheng Kung University, Tainan, Taiwan.

(No relationships reported)

Physical self-perception (PSP) exerts a crucial role during adolescence. Research has demonstrated that positive associations of PSP with physical fitness (PF) (Carraro, Scarpa, & Ventura, 2010). However, social and behavioral deficits and sometimes motor skill difficulties demonstrated by individuals with autism spectrum disorder (ASD) could limit opportunities for them to successfully participate in physical activity, and therefore, may put them at risk for being physically inactive and unfit.

**PURPOSE:** (a) To compare PSP and PF in adolescents with and without ASD, and (b) to assess the relationship of PSP with PF within each group.

**METHODS:** Thirty-one males with ASD and 36 males without ASD aged 12-18 (14.68±1.55 yrs) participated. The PSP was assessed with a questionnaire originally developed by Whitehead (1995) and translated into Chinese with a high degree of reliability and validity (Hagger, Biddle, Chow, Stambulova, & Kavussanu, 2003). The BROCKPORT Physical Fitness Test was used for PF measures. Independent *t* tests were used to compare group differences in PSP and PF. Pearson product-moment correlation coefficients were calculated to evaluate the relationships of PSP with PF within each group. Significance was set at *p*<0.05.

**RESULTS:** Findings indicate that (a) adolescents with ASD perceived significantly poor scores on physical condition (-2.47, *p*<0.05), sport competence (-2.05, *p*<0.05), and general self-worth (-1.53, *p*<0.05), (b) adolescents with ASD demonstrated significantly poor scores on 20-m PACER (-23.81, *p*<0.01), isometric push-up (-8.62, *p*<0.01), and back-saver sit-and-reach (-8.00, *p*<0.01), (c) for adolescents with ASD, physical condition was associated with 20-m PACER (*r*=0.58, *p*<0.01); sport competence was associated with sit-up (*r*=0.37, *p*<0.05), and (d) for adolescents without ASD, physical condition (*r*=0.51, *p*<0.01) and sport competence (*r*=0.41, *p*<0.05) were associated with 20-m PACER; attractive body was associated with sit-up (*r*=0.35, *p*<0.05); general self-worth was associated with sit-and-reach (*r*=0.39, *p*<0.05).

**CONCLUSION:** Adolescents with ASD perceived less favorable PSP than adolescents without ASD. PSP and PF indicators were related, despite incomplete overlap between the two variables in each group. Supported by Taiwan NSC grants 99-2410-H-017-036-MY2.

1274 Board #55 MAY 30 11:00 AM - 12:30 PM

### Faster Heart Rate Recovery and Higher Short-term Muscle Power in Physically Active Preschool Children

Leigh Gabel, Nicole A. Proudfoot, Joyce Obeid, Brian W. Timmons. McMaster University, Hamilton, ON, Canada.

(No relationships reported)

Aerobic fitness has a protective effect on metabolic and cardiovascular health and is positively related to physical activity in youth and adults. There is a paucity of literature examining fitness in preschool children (3- to 5-year olds); thus, little is known about the relationships between physical activity and fitness in this young age group.

**PURPOSE:** To investigate the relationships between physical activity patterns and fitness (aerobic and short-term muscle power) in a sample of preschool children.

**METHODS:** Ninety-six preschoolers (4.4 ± 0.9 years; 50 female) participated in the study. Children performed a maximal treadmill assessment (Bruce Protocol) with heart rate (HR) monitored throughout the test and into 1-min of recovery (HR60secpost). Aerobic fitness was assessed by heart rate recovery (HRR = HRmax - HR60secpost). Short-term muscle power was determined by peak power output using a modified 10-sec Wingate cycling protocol. Physical activity patterns were assessed by the duration and frequency of bouts of moderate-to-vigorous physical activity (MVPA) using accelerometry for seven consecutive days with 3-second epochs. Only children who achieved a HRmax of ≥180 bpm on the treadmill test and who wore the accelerometer for ≥3 days for ≥5 hours/day were included in analyses. Pearson correlation coefficients were used to assess the relationships between physical activity and fitness. Both physical activity and short-term muscle power were significantly related to age; thus, partial correlations controlling for age were used.

**RESULTS:** Average HRmax on the treadmill test was 195 ± 7 bpm with a HRR of 63 ± 14 bpm. HRR was positively related to the frequency of bouts of MVPA (*r*=0.29, *p*<0.01). Average peak power on the modified Wingate test was 4.6 ± 1.5 Watts/kg and was positively related to the duration of bouts of MVPA (*r*=0.23, *p*=0.03).

**CONCLUSIONS:** Preschool children who engage in more frequent bouts and longer duration of bouts of MVPA have faster HRR and higher short-term muscle power, respectively, compared to preschoolers who engage in less frequent and shorter duration of bouts of MVPA.

1275 Board #56 MAY 30 11:00 AM - 12:30 PM

### Characteristics of Physical Fitness According to the Level of Obesity Index among Young Children

Kosho Kasuga<sup>1</sup>, Takahiro Nakano<sup>2</sup>, Kazuo Oguri<sup>3</sup>, Keisuke Fukutomi<sup>4</sup>. <sup>1</sup>Gifu University, Gifu, Japan. <sup>2</sup>Nagoya Gakuin University, Seto, Japan. <sup>3</sup>Shizuoka Sangyo University, Iwata, Japan. <sup>4</sup>Gifu Sports Science Training Center, Gifu, Japan. (Sponsor: Kiyoji Tanaka, FACSM)

(No relationships reported)

Many reports have shown that the prevalence of obesity in Japanese children, including infants, has been increasing. The number of children diagnosed with infant metabolic syndrome is also on a rise. Moreover, in recent years, there has been an increase in the number of lean children in Japan.

**PURPOSE:** The purpose of this study is to examine the characteristic of physical fitness according to level of obesity index among young children (age, 3-6 years) by using a large dataset.

**METHODS:** This study included 5640 young children (2840 boys and 2800 girls). We administered physical fitness tests comprising 7 exercises to gauge the physical fitness status of these children. A T-score was calculated on the basis of the mean and standard deviation according to sex and age; this score was used as an individual score of physical fitness. The children were divided into 7 groups based on their obesity index. Further, the extent of differences among children with different obesity index was examined for each type of exercise. To conduct a statistical analysis of the data, one-way ANOVA and multiple comparisons (Tukey's HSD test) were employed.

**RESULTS:** Statistical analysis showed a significant difference among the groups for all the exercises. The children in the "+20% or more" group had the lowest scores in 25-m run, standing long jump, and upright hand standing time. The children in the "-15% or less" group had the lowest scores in softball throw, sitting trunk flexion, side-step, grip strength, and overall physical fitness.

**CONCLUSIONS:** The physical fitness of obese (+20% or more) and lean (-15% or less) children was found to be poor. The poor physical fitness in lean children may be due to low muscle mass and underdevelopment because of the lack of any physical activity. Moreover, their low energy expenditure may result in a low appetite, which can lead to poor nutrition. In contrast, the severely obese children (+20% or more) may be underdeveloped due to the lack of any physical activity and consumption of an excessive and unbalanced diet. However, the mildly obese (up to +15%) are not physically underdeveloped at infancy, and do not need extreme obesity prevention measures. It is important for them to adopt a "play a lot, eat a lot" lifestyle.

1276 Board #57 MAY 30 11:00 AM - 12:30 PM

**The Relationship Between The Development Of Physical Fitness And Lifestyle Behavior In Young Children**

Takahiro Nakano<sup>1</sup>, Kosho Kasuga<sup>2</sup>, Kazuo Oguri<sup>3</sup>. <sup>1</sup>Nagoya Gakuin University, Aichi, Japan. <sup>2</sup>Gifu University, Gifu, Japan. <sup>3</sup>Shizuoka Sangyo University, Shizuoka, Japan. (Sponsor: Kiyoji Tanaka, FACSM)  
(No relationships reported)

Recently, the decline in children's physical fitness has become a big problem in Japan for not only older children but also young children. Childhood is very important period for acquisition of basic lifestyle behavior. Many studies have shown a relationship between physical fitness and lifestyle behavior. However, few studies have examined the relationship between the development of physical fitness and lifestyle behavior. Such studies have been particularly rare in young children.

**PURPOSE:** The purpose of this study was to examine the relationship between the development of physical fitness and lifestyle behavior in young children using longitudinal data.

**METHODS:** The subjects of this study were 311 young children. We measured seven parameters related to physical fitness: grip strength, upright hand standing time, sitting trunk flexion, 25-meter run, standing long jump, side step, and softball throw. As well, we administered a questionnaire about daily lifestyle behavior. We calculated the development of physical fitness using two-years longitudinal data for the same young children, and calculated the correlation coefficient between the amount of development and daily lifestyle behavior. Further, we examined differences in lifestyle behavior between groups whose physical fitness developed well or did not, using a chi-square test and independent t-test.

**RESULTS:** The lifestyle behaviors related to several physical fitness items were "Bedtime," "TV viewing time," "video-game playing time," "active play with body movement" and "active play with family". Significant differences were confirmed between the high-development group and the low-development groups in 7 items, including "TV viewing time," "video-game playing time," "number of friends usually playing together," and "keeping a regular lifestyle".

**CONCLUSION:** Relationships between young children's physical fitness and several lifestyle behaviors were confirmed. It is suggested that physical fitness is easy to develop in children who have a regular lifestyle and a lot of friends to play with. In addition, it is suggested that the development of young children's physical fitness is promoted by improving lifestyle behaviors such as TV viewing time and video-game playing time.

1277 Board #58 MAY 30 11:00 AM - 12:30 PM

**Use Of Exergaming For Obtaining Moderate And Vigorous Physical Activity In Children**

Magdalene Horton, Larry Kennard, Scott E. Crouter, FACSM. *University of Massachusetts Boston, Boston, MA.*  
(No relationships reported)

There are a growing number of PA programs that now include interactive video games (exergames) as part of an activity routine; however, it is unclear, if these games are a viable alternative for children obtain moderate and vigorous PA (MVPA).

**PURPOSE:** The purpose of this study was to examine the energy cost of children playing exergames. A secondary purpose was to see how the energy cost of exergames compares to other commonly performed activities.

**METHODS:** Fifty-three boys and 50 girls (mean±SD; age 11.5±1.7 yrs; BMI%ile, 68.6±28.4 %) performed 30-min of lying rest. Each participant was then randomly assigned to perform one of three activity routines consisting of six activities. Participants were familiarized with all activities prior to testing. Exergames included were: Nintendo Wii, Floor-based LightSpace, Wall-based LightSpace, Dance Dance Revolution, SportWall, and Cybex Trazer. Oxygen consumption was measured using a Cosmed K4b<sup>2</sup>. Measured METs (measured activity VO<sub>2</sub>/measured resting VO<sub>2</sub>) were calculated for each activity. Data were also examined for differences between genders, age groups (8-9, 10-11, and 12-15 yrs) and BMI [normal weight (<85<sup>th</sup>% for age and sex), overweight (85<sup>th</sup>-95<sup>th</sup>% for age and sex), and obese (≥95<sup>th</sup>% for age and sex)].

**RESULTS:** On average, the mean METs for playing the Nintendo Wii were 2.5 METs. All other exergames had a mean MET value of at least moderate intensity (range; 3.4-5.3 METs). In general, there were no differences by gender, age, or BMI categories, except for; Nintendo Wii (overweight, 3.6 METs vs. normal weight and obese, 2.6 METs), Cybex Trazer (9 yrs, 2.5 METs vs. 10-11 yrs 3.9 METs vs. ≥12 yrs 5.0 METs) and SportWall (8-9 yrs, 2.7 METs vs. 10-11 yrs 4.5 METs vs. ≥12 yrs 6.9 METs). Playing exergames resulted in similar MET values as other commonly performed PA in children (e.g., slow and brisk track walking, track running, playing catch, and soccer).

**CONCLUSION:** The results of this study show that, in general, the energy cost to play exergames is at a moderate intensity or greater. Exergames could be an alternative way for children to obtain MVPA in addition to the use of more traditional activities. However, there may issues related to age and BMI that need to be further investigated as not all activities work equally well for all individuals.

1278 Board #59 MAY 30 11:00 AM - 12:30 PM

**Compliance with Physical Activity Recommendations and Blood Pressure In Preschool Children**

Jorge Mota, Sandra Santos, Rute Santos, Luisa Soares-Miranda, Carla Moreira, sandra Abreu, Susana Vale. *Research Centre in Physical Activity health and Leisure, Porto, Portugal.*  
(No relationships reported)

**PURPOSE:** Research suggests that moderate levels of PA are predictors of lower values of systolic and diastolic blood pressure (SBP and DBP). However, few studies addressed this issue in pre-school children. The purpose of this study was to analyse the associations between compliance of PA recommendations and SBP preschool children.

**METHODS:** The sample comprised 593 preschool children (48% female) with mean age of 5.3 years. Physical activity was assessed during 7 consecutive days by accelerometer (Actigraph GTM1). We analyzed the recommendation of at least one hour daily of moderate-vigorous PA (MVPA). Blood pressure was measured using the Colin monitor. The measurements were performed with each subject seated and rested for at least five minutes before the test. Percentage of fat (% MG) was calculated using the equation of Westraat and Durenberg. (1990).

**RESULTS:** The prevalence of BP above the 90th percentile (P90) was 7.8% and 1.3% respectively for SBP and DBP. We found that about 16.5% of the girls and 8.2% of the boys did not accomplish the recommended daily MVPA. Girls who did not meet the daily recommendations of MVPA were twice as much more likely to have SBP values above the P90 compared to those who meet the daily recommendations (OR: 2.6; CI 95%:1.0-6.6; p<0.05), even after adjustment to fat mass.

**CONCLUSION:** We found an association between the accomplishment of daily PA recommendations and SBP in pre-school children in girls.

1279 Board #60 MAY 30 11:00 AM - 12:30 PM

**After-School Exercise Increases Endothelial Progenitor Cells in Overweight and Obese Children**

Jong-Hwan Park<sup>1</sup>, Masashi Miyashita<sup>1</sup>, Yoshio Nakamura<sup>1</sup>, Hyun-Tae Park<sup>2</sup>, Yoo-Chan Kwon<sup>3</sup>, Eun-Hee Kim<sup>3</sup>, Jin-Kee Park<sup>3</sup>, Ki-Beam Park<sup>3</sup>, Sang-Kab Park<sup>3</sup>. <sup>1</sup>Waseda University, Saitama, Japan. <sup>2</sup>National Center for Geriatrics and Gerontology, Aichi, Japan. <sup>3</sup>Dong-A University, Busan, Korea, Republic of.  
(No relationships reported)

Obese children who are home alone after school have limited time to be active outdoors and unlimited access to junk food, video games and electronic devices which can lead to a more sedentary lifestyle. The role of bone marrow-derived circulating endothelial progenitor cells is to maintain endothelial function and organ perfusion. Endothelial dysfunction is associated with the childhood obesity and is closely linked to the amount and function of endothelial progenitor cells. However, it remains unclear whether endothelial progenitor cells increase with after-school exercise in overweight and obese children.

**PURPOSE:** The purpose of this study was to investigate the effects of an after-school exercise programme on endothelial progenitor cells in overweight and obese children.

**METHODS:** Total of 29 overweight/obese children were randomly divided into the control (i.e., no after-school exercise, n = 14) or after-school exercise (n = 15) groups. The 12-week after-school exercise intervention consisted of 3 days of combined aerobic and resistance exercise per week. Each 80-minute exercise programme included 10 minutes of warm-up and 10 minutes of cool-down after school. CD34+ (a cell surface marker on hematopoietic stem cells), CD133+ (a cell surface marker on hematopoietic progenitor cells) and CD34+/CD133+ (considered as endothelial progenitor cells) were measured at baseline and after 12 weeks using flow cytometry.

**RESULTS:** Increased percentages of CD34+, CD133+ and CD34+/CD133+ were observed in the after-school exercise group ( $p = 0.018$ ;  $p = 0.001$ ;  $p = 0.002$ , respectively) compared with the control group. Carotid intima-media thickness decreased after 12 weeks in the after-school exercise group ( $p = 0.020$ ) compared with the control group. Circulating concentrations of vascular endothelial growth factor and nitric oxide were increased in the after-school exercise group ( $p = 0.013$ ;  $p = 0.005$ , respectively) compared the control group.

**CONCLUSIONS:** This study provides preliminary evidence that an after-school exercise programme may represent an effective intervention strategy for improving vascular repair and endothelial function, leading to improved cardiovascular health in overweight and obese children.

**1280** Board #61 MAY 30 11:00 AM - 12:30 PM  
**Physical Activity, Focused Education and Endothelial Function in an Obese Teen: A Case Study**

Anna Gabbard, Nabil Boutagy, Elise Maniguet, Alison Peters, Shannon Isom, John W. Wygand, Robert M. Otto, FACSM. *Adelphi University, Garden City, NY.*  
(No relationships reported)

Endothelial function plays a significant role in vascular health. Normal endothelial function includes release of vasoactive substances and growth factors to maintain vascular homeostasis. Endothelial dysfunction (Reactive Hyperemia Index [RHI] < 1.67) can be defined as a loss of balance between vasoconstrictors vs vasodilators and other inflammatory factors. Endothelial dysfunction is precursor to atherosclerosis and is implicated in obesity, diabetes and hypertension. EndoPAT noninvasively assesses endothelial function by reactive hyperemia- pulse amplitude tonometry (RH-PAT). Endothelial function is calculated by measuring blood vessel diameter relative to resting, occluded and hyperemic conditions.

**PURPOSE:** To determine whether a combined education and physical activity program has an effect on endothelial function in an obese female (age 18 yr, wt 108 kg, ht 170 cm, BMI 37.4 m/kg<sup>2</sup>).

**METHODS:** EndoPAT was performed in a thermo-neutral environment with the subject supine and both index fingers in the EndoPAT probe. A blood pressure cuff (BPC) was placed on the subject's non-dominant arm. Baseline data were collected for 5 minutes. The BPC was inflated to  $\geq 200$  mmHg for complete occlusion for 5 minutes, rapidly released and post-occlusion data were collected. Body composition was measured by skinfolds & waist to hip (W/H) with Gulick tape. The intervention was a 12 week program of nutrition and physical activity education combined with twice weekly exercise sessions designed to reduce obesity and modify the participant's obesogenic environment. Each 60 minute exercise session, consisted of 20-35 minutes of aerobic interval cross training on 4-7 exercise machines at 65-85% HRR for 5 min. each. A circuit of resistance training was performed on 12 Nautilus resistance machines to an intensity of momentary muscular fatigue.

**RESULTS:** The subject reduced body mass 10.8%, BMI 10.9%, body fat 7.3%, W/H 2.5%, and improved muscular strength 79% (10 RM leg press). RHI improved from dysfunction of 1.46 at baseline to normal function of 2.61 following intervention.

**CONCLUSION:** A cardiovascular and resistance training intervention improved endothelial function, body composition and muscular strength in an obese teen and attenuated cardiovascular risk.

**1281** Board #62 MAY 30 11:00 AM - 12:30 PM  
**Comparison Between Individual And Averaged Methodologies For Anaerobic Threshold Assessment Of Age-group Swimmers**

Marisa Sousa, João Paulo Vilas-Boas, Ricardo Fernandes. *University of Porto, Faculty of Sports, Porto, Portugal.* (Sponsor: Carlo Baldari, FACSM)  
(No relationships reported)

The assessment of the velocity corresponding to anaerobic threshold ( $v_{AnT}$ ) is frequently part of elite swimmers training program in order to diagnosis their aerobic performance. However, the velocity corresponding to blood lactate concentration ( $[La^-]$ ) of 4 mmol/l ( $v_4$ ), an averaged value proposed for standard more than 30 years ago, is often used in detriment of individualized protocols; in addition, rarely swimmers of young ages are involved in training control.

**PURPOSE:** To compare the  $v_{AnT}$  of 10-11 years old swimmers assessed by individualized protocols (step and critical velocity tests) and by the traditional  $v_4$  value.

**METHODS:** Fifteen age-group swimmers ( $10.7 \pm 0.70$  years) performed a 5x200 m front crawl step test (increments of 0.05 m/s per step, and 1 min rest intervals), being capillary blood samples for  $[La^-]$  analysis collected from the earlobe at rest, after each step and at the end of the test, which allowed the assessment of the  $v_{AnTStep}$  through  $[La^-]$ /velocity curve modeling method, and  $v_4$  by linear interpolation. Critical velocity (CV) was obtained through the slope of the linear relationship of time versus distance based on the times of the 100 and 400m competitive events. Mean and SD were computed, as well as repeated measurements ANOVA (with Bonferroni post hoc test) and Pearson correlation coefficient ( $p \leq 0.05$ ).

**RESULTS:** Mean  $\pm$  SD values of  $v_{AnTStep}$ , CV and  $v_4$  were  $1.03 \pm 0.05$ ,  $1.03 \pm 0.07$  and  $1.08 \pm 0.06$  m/s, respectively, being the two former velocities significantly lower than  $v_4$ ; these differences corresponds to a 5 s gap in a 100m front crawl effort. The  $[La^-]$  corresponding to  $AnT$  obtained in the step test was  $2.3 \pm 0.59$  mmol/l.

**CONCLUSIONS:**  $v_4$  does not represent the individual  $v_{AnT}$  in children involved in competitive swimming, and both a 200 m step incremental protocol, with the later determination of the precise point of the rise in  $[La^-]$ , and CV, seems to be advised for individual anaerobic threshold assessment in young swimmers.

**1282** Board #63 MAY 30 11:00 AM - 12:30 PM  
**Validity of an Alternate Knee Raise Test for Assessing Aerobic Fitness of Adolescents**

Stanley Sai-chuen Hui, FACSM, Wing-luen Au, Lin Wang, Wing-ye Chan, Ka-wai Chan. *The Chinese University of Hong Kong, Shatin, Hong Kong, Hong Kong.*  
(No relationships reported)

**PURPOSE:** Simple but valid home-based aerobic fitness test that can be self-administered with minimal equipment is lacking. The purpose of this study was to examine the validity of an alternate knee raise test (AKR) for assessing aerobic fitness of adolescents.

**METHODS:** With informed consent form completed, 30 male adolescents age 12 to 18 yrs-old ( $14.63 \pm 1.56$  yrs-old) volunteered to participate in an AKR test and a grade maximal treadmill exercise (GXT) test. In the AKR test, participants were asked to perform alternate knee raise movement in place following a cadence of 96 beats/min for 3 mins continuously. In each knee raise motion the participants were required to lift up their leg until their thigh touched their palm which was placed in front of their waist at the same level of iliac crest and above their thigh. The movement was similar to a platform step test but no platform was required. At the end of the 3 min AKR test, the post-exercise heart rate (PHR) at 20 seconds after the test was recorded by a Polar heart rate monitor. For GXT test, criterion measure of  $VO_{2max}$  was examined by a portable COSMED K4b2 metabolic analyzing system. To evaluate the predictive validity of AKR test, independent variables of age, body weight, skinfolds, body mass index, resting heart rate, post-exercise heart rate were entered into stepwise regression procedures for predicting dependable variable of measured  $VO_{2max}$ .

**RESULTS:** Regression analysis revealed that the AKR test produced good predictive validity and acceptable standard error of estimates. Only two independent variables were needed which were age and PHR. The suggested equation was  $VO_{2max} \text{ (ml/kg/min)} = 52.168 - 0.25 \text{ (PHR)} + 1.568 \text{ (Age)}$ ,  $R=0.71$ ,  $SEE=5.17$  ml/kg/min.

**CONCLUSIONS:** The AKR Test was found to be a valid submaximal field test for assessing aerobic fitness of adolescents. It is a practical test due to its' simple procedure and can be self-administered at home with minimal equipment.

---

**1283** Board #64 MAY 30 11:00 AM - 12:30 PM  
**Body Perception: Parents' Poorly Perceive Children's Fitness Characteristics**

Elan J. Lieber, Carmen B. Swain. *The Ohio State University, Columbus, OH.*  
(No relationships reported)

At least 155 million school-age children worldwide are overweight or obese. Body Mass Index (BMI) as a measurement of parental recognition of child's overweight status ranges from 6-73%. When examining overweight children, less than 50% of parents identify their child as such.

**PURPOSE:** The purpose of this study was to examine parental ability to appropriately identify their child's BMI status and also measures of physical fitness (body composition, muscular strength, flexibility and aerobic fitness).

**METHODS:** Subjects consisted of 133 males (10.8±2.1 years), 110 females (11.4±2.4 years) and their maternal parent. Males and females scores were compared to maternal perception of score: BMI, body composition, and fitness characteristics (muscular strength, aerobic fitness and flexibility) were categorized according to normative rankings. The maternal perception questionnaire was administered while subject's fitness characteristics were evaluated. Data associations were examined using descriptive statistics and bivariate correlation.

**RESULTS:** BMI, body fat and fitness characteristics ranged categorically from poor to excellent. Maternal parents ability to correctly identify fitness characteristics by categorical selection were: BMI (72.8%), body composition (49.4%), flexibility (26.3%), muscular strength (32.5%) and aerobic fitness (39.5%). The relationship between subjects scores and parental perception of scores was considered weak to moderate, as determined by Pearson correlation (BMI:  $r=.618$ , body composition:  $r=.693$ , muscular strength:  $r=.268$ , aerobic fitness:  $r=.406$  and flexibility  $r=.435$ ).

**CONCLUSION:** In children ranging from under-weight to obese, parent's ability to predict characteristics relative to weight and body composition is substantially better than their ability to predict fitness characteristics. Parents have a strong influence on children's behavior and physical activity levels. Primary prevention is key in fighting the obesity epidemic, thus adult's awareness of their child's fitness status is imperative. As such, professional or school-based screening could be suggested as a necessary tool to identify children's fitness characteristics for parental informative purposes.

---

**1284 Board #65 MAY 30 11:00 AM - 12:30 PM**  
**Prevalence Of Obesity In Japanese Children Aged 3.5 Through 6.5 Years Old**

Kazuo Oguri<sup>1</sup>, Kosho Kasuga<sup>2</sup>, Takahiro Nakano<sup>3</sup>. <sup>1</sup>Shizuoka Sangyo University, Iwata, Shizuoka, Japan. <sup>2</sup>Gifu University, Gifu, Japan. <sup>3</sup>Nagoya Gakuin University, Aichi, Japan. (Sponsor: Kiyoji Tanaka, FACSM)  
(No relationships reported)

The prevalence of childhood obesity has risen progressively worldwide. It is said that obesity onsets in early childhood; however, factors not yet clarified include: age of obesity onset, and age when gender difference in obesity prevalence becomes apparent.

**PURPOSE:** The purpose of this study was to examine the prevalence of obesity and its development trends, such as differences with age and gender, in Japanese young children.

**METHODS:** This cross-sectional study analyzed height, weight and age data of 6,235 children (3,147 boys and 3,088 girls) aged 3.5 to 6.5 years old. Subjects were categorized into age groups in increments of 0.5 years, and prevalence of obesity was compared between gender and among groups. Obesity was defined according to the National Health and Nutrition Survey of Japan as 115% of the standard weight for an individual's height and gender. The chi-square test was used to compare differences in prevalence of obesity. Where appropriate, p values of the chi-square test were corrected according to Bonferroni inequalities.

**RESULTS:** Prevalence of obesity plateaued at 6.4 % to 6.7 % both in boys and girls, aged between 3.5 years and 4.5 years. However, it significantly decreased to 3.1 % and 3.0 % in boys and girls respectively, at age 5.0 years old ( $p<0.001$ ). Prevalence of obesity in boys and girls aged 5.5 years increased to 8.0 % and 6.8 % respectively, which was significantly higher than that in boys and girls at 5.0 years old, and the rate gradually increased with age thereafter ( $p<0.001$ ). No significant difference in prevalence of obesity was found between boys and girls in each group for ages 3.5 years to 6.0 years. However, the prevalence was significantly higher in boys than in girls at age 6.5 years ( $p<0.05$ ).

**CONCLUSIONS:** Our data suggest that prevalence of obesity temporarily decreases at age 5.0 years old, however, it markedly increases from age 5.5 years old. Prevalence of obesity among boys significantly increases relative to that among girls at age 6.5 years. These findings indicate that prevention and treatment of young childhood obesity is important for pediatric healthcare.

**1285 Board #66 MAY 30 11:00 AM - 12:30 PM**  
**Relationship of Body Mass Index to Exercise Participation and Adherence in Overweight Children and Adolescents**

Amanda Gier, Christopher Kist, Wayne A. Mays, Robert Siegel, Shelley Kirk. Cincinnati Children's Hospital Medical Center, Cincinnati, OH.  
(No relationships reported)

**PURPOSE:** To determine if body mass index (BMI) in overweight and obese children and adolescents is a barrier to participation in and adherence to an organized group exercise program.

**METHODS:** During medical visits for a clinical pediatric weight management program, height and weight was obtained on 603 overweight children and adolescents and used to calculate BMI. Patients were given information about the group exercise sessions available to them through the program. Group classes were offered five evenings per week, and participants could attend at their discretion. Classes were 1-hour long and consisted of strength training, cardiovascular activity and active games in a fun, non-competitive environment. Class attendance was tracked and duration of active participation was determined. Data was analyzed to determine if BMI was related to class attendance.

**RESULTS:** Active class attendance ranged from 0 to 182 weeks. There was no correlation between BMI ( $34.9 \pm 7.5$  kg/m<sup>2</sup>) and weeks attended ( $10.7 \pm 22.4$  weeks) ( $r = -0.054$ , NS) when looking at all participants. Within the group of participants that attended group exercise sessions,  $N=355$ , there was no correlation between BMI ( $34.4 \pm 7.8$  kg/m<sup>2</sup>) and total weeks of exercise class attendance ( $18.1 \pm 26.8$  weeks) ( $r = -0.03$ , NS). However, when comparing the participants that attended classes to those who did not attend any classes, the children who did attend classes had a significantly lower BMI ( $34.4 \pm 7.8$  vs  $35.6 \pm 7.1$  kg/m<sup>2</sup>) ( $p<0.05$ ), but were also significantly younger ( $11.2 \pm 3.3$  vs  $12.0 \pm 3.3$  years) ( $p<0.005$ ).

**CONCLUSION:** BMI was not related to the length of time that children actively participated in group exercise sessions. However, BMI and age were significantly lower in the group that attended classes. Younger children may have a lower BMI but still be in a higher BMI percentile for age than older children with a similar BMI. Therefore, BMI alone may not be helpful in determining which patients will participate in an exercise program. Future research should focus on a multivariate analysis of BMI percentile and age as indicators of participation in exercise classes. Further research into these variables could give healthcare providers insight into which patients may need additional support and encouragement when beginning structured exercise.

**1286 Board #67 MAY 30 11:00 AM - 12:30 PM**  
**Relationship between Health Status and Motor Ability among Young Children**

Keisuke Fukutomi<sup>1</sup>, Kosho Kasuga<sup>2</sup>, Katsunori Fujii<sup>3</sup>, Tohru Isigaki<sup>4</sup>. <sup>1</sup>Gifu Sports Science Training Center, Gifu, Japan. <sup>2</sup>Gifu University, Gifu, Japan. <sup>3</sup>Aichi Institute of Technology, Toyota, Japan. <sup>4</sup>Aichi Prefectural University of Fine Arts and Music, Nagakute, Japan. (Sponsor: Kiyoji Tanaka, FACSM)  
(No relationships reported)

It has been suspected that people with low motor ability are liable to have bad health status. However, less research has been performed on the motor ability of young children by using a large dataset.

**PURPOSE:** The purpose of this study is to examine the relationship between health status and motor ability among young children.

**METHODS:** The study included 2,431 young children (1,241 boys and 1,190 girls; age range: 4-6 years) and their parent. We administered motor ability tests comprising 10 exercises to gauge the motor ability status of these children. To obtain the overall motor ability parameter, the measurement items were summarized by using principal component analysis. And we concluded that the first principal component represented the overall motor ability. Further, the principal component score of the first principal component was divided by the number of subjects of each sex and 0.5 years to obtain the individual T-scores. These individual T-scores indicated the motor ability scores. Questionnaires comprising 13 items on health status\_frequent loose bowels, frequently catching cold, having a nosebleed, having eczema and suppuration, having car sickness, having no notable symptoms, allergy constitution, asthma, atopy, nasal catarrh, food allergy, drug allergy, and conjunctivitis\_were administered to their parent. Student's t-test was performed to determine the statistical differences in the motor ability scores between children who answered 'True' and those who answered 'False'. The level of significance was set at  $p < 0.05$ . The data were collected in 2009.

**RESULTS:** With respect to the health status, the motor ability scores of the group that answered 'True' were significantly lower than those of the group that answered 'False' for items under the category 'having no notable symptoms' (True: 50.7, False: 49.3) and 'frequently catching cold' (True: 47.9, False: 50.3). Particular attention was paid to allergy symptoms. Statistical analysis showed that there was no significant difference in the motor ability scores of young children who answered 'True' and those who answered 'False'.

**CONCLUSIONS:** The young children who caught cold frequently had low motor abilities. Moreover, 38% of the subjects had allergy constitution; however, presence of an allergy did not have any correlation with motor ability.

**Relations between Sedentary Behavior and FITNESSGRAM® Healthy Fitness Zone Achievement and Physical Activity**

Jacob S. Tucker, Scott B. Martin, Allen W. Jackson, FACSM, James R. Morrow, FACSM, Christy A. Greenleaf, Trent A. Petrie. *University of North Texas, Denton, TX.*

(No relationships reported)

Sedentary behaviors such as television viewing and video game playing increase the relative risk of morbidity and mortality independent of physical activity levels. Due to the direct relations between these sedentary behaviors and health risk, the American Academy of Pediatrics recommends no more than two hours of daily screen time for youth.

**PURPOSE:** To investigate the relations between sedentary behaviors and health-related physical fitness (PF) achievement and physical activity (PA) behaviors in middle school students.

**METHODS:** Students (N=1515) in grades 6-8 completed the FITNESSGRAM® PF items, and FITNESSGRAM PA questions in addition to Youth Risk Behavior Survey sedentary behavior questions as part of school activities.

**RESULTS:** Using logistic regression and controlling for gender, age, ethnicity, and economic status, we calculated odd ratios (OR) for all components of health-related fitness, aerobic capacity (OR=1.70, 95%CI = 1.30-2.34), muscular strength and endurance (OR = 1.87, 95%CI = 1.30-2.68), flexibility (OR = 1.54, 95%CI = 1.20-2.00), and body composition (OR = 1.71, 95%CI = 1.27-2.30). The odds of achieving the FITNESSGRAM Healthy Fitness Zone were higher when students reported  $\leq 2$  hours of sedentary behaviors per day. Similarly, the odds of achieving physical activity guidelines for aerobic (OR = 1.42, 95%CI = 1.09-1.84), muscular strengthening (OR = 1.77, 95%CI = 1.22-2.57), and flexibility (OR = 1.47, 95%CI = 1.15-1.88) activity were higher when students reported  $\leq 2$  hours per day of sedentary behaviors.

**CONCLUSION:** Results illustrate the importance of keeping sedentary behaviors to  $\leq 2$  hours per day in middle school students, thus increasing the odds that students will achieve sufficient health-related fitness for health benefits. Less screen time is related to achieving national physical activity guidelines.

Grant support from the National Association for Sport and Physical Education.

1288 Board #69 MAY 30 11:00 AM - 12:30 PM

**Associations Among Body Fat %, BMI, And Fitness Test Performance In School-Aged Children**

Ryan D. Burns<sup>1</sup>, James C. Hannon<sup>1</sup>, Brett Allen<sup>1</sup>, Pedro F. Saint-Maurice<sup>2</sup>, Gregory J. Welk, FACSM<sup>2</sup>. <sup>1</sup>University of Utah, Salt Lake City, UT. <sup>2</sup>Iowa State University, Ames, IA.

(No relationships reported)

**PURPOSE:** The purpose of this study was to examine associations among body fat % (BF%), BMI, and various fitness tests in school-aged children.

**METHODS:** The participants included male and female 4<sup>th</sup> through 10<sup>th</sup> grade students (n=376) recruited from three private schools from a metropolitan area in the southwestern United States. Participants completed assessments of body composition, aerobic fitness and muscular fitness on 4 separate testing days with at least 48 hours between sessions. On day 1 participants completed the BMI, BF% and PACER aerobic fitness test. On day 2 participants completed DYNAMIC CURL UPS and ROMAN CHAIR STATIC extension tests. On day 3 participants completed PLANKS, LATERAL STRENGTH, and ROMAN CHAIR DYNAMIC extensions. On day 4 participants completed any test that they may have missed on previous days. Pearson-Product Moment (PPM) correlations were used to assess the degree of association between body composition and fitness variables. Alpha level of 0.05 was set to determine significance for statistical analyses.

**RESULTS:** The BMI and BF% values were moderately correlated with each other ( $r=.51, p<.001$ ). BF% had higher correlations with the fitness variables than BMI (PACER:  $r=-.407$  vs.  $-.094$ ; CURL-UP:  $r=-.197$  vs.  $.108$ ; PLANK:  $r=-.311$  vs.  $-.06$ ; LATERAL STRENGTH:  $r=-.239$  vs.  $-.078$ ; ROMAN CHAIR DYNAMIC:  $r=-.142$  vs.  $-.128$ ; ROMAN CHAIR STATIC:  $r=-.149$  vs.  $-.133$ ). BF% correlations were significant among all fitness tests ( $p<.001$ ) while BMI correlations were only significant for both ROMAN CHAIR extensions ( $p<.05$ ).

**CONCLUSION:** The results suggest that BF% is negatively correlated with indicators of aerobic fitness and muscular fitness in youth. The moderate correlations between BF% and BMI and the weaker associations between BMI and fitness performance tests indicate that BMI may provide a less useful indicator of body composition for use in school health related fitness testing.

1289 Board #70 MAY 30 11:00 AM - 12:30 PM

**A Comparative Cross-cultural Comparison Of Posture, Core Strength, Height, Age And Body Mass Index**

Ulrike H. Mitchell, A Wayne Johnson, Barbara Simmons. *Brigham Young University, Provo, UT.*

(No relationships reported)

**PURPOSE:** High income countries around the world have experienced dramatic increases in obesity and sedentary behaviors in both genders, all income levels, ethnic groups, and all ages. We hypothesized that the lack of multiple TV channels or computers would have a positive impact on posture and fitness. This project was conducted in the rural villages outside of Irapuato, Mexico. The data were compared to similar studies conducted in Ghana, Australia and the United States.

**METHODS:** Intervention: 29 children, ages 10-12, performed 5 exercises indicative of core strength (plank, left and right bridge, left and right stork); the times of how long they were able to hold the positions were documented. With reflective markers placed on bony landmarks, the children had posture assessment photographs taken of their normal standing posture from a lateral view. A software program was used to mark and measure postural angles.

**RESULTS:** Height and weight (and their SD) were greater in Mexico (139.7cm SD9.6 and 35.1kg SD11.9) than in Australia (138.8cm SD5.8 and 32.4kg SD3.8). The gaze angle was greater in the Hispanic children (14.10 deg SD8.48) compared to the Australian's (10.3 deg SD7.6); this indicates a greater propensity towards a forward head posture.

The head on neck angle was greater in the Australian children (55.7deg SD8.7) compared to the Hispanics (50.3deg SD6.1); however, we believe that this is the result of a protruding C7 marker rather than an actual postural dysfunction.

Core strength: There were differences in exercise times for the side bridges and stork exercises between the children tested in Mexico and Utah County and for the left side bridge and stork exercises between the children tested in Mexico and Ghana (all with p-values  $<.05$ ); there was no difference in exercise times between children tested in Ghana and Utah County.

**CONCLUSIONS:** Our hypothesis was not supported by this study. While life in Irapuato, Mexico, is less influenced by computers and TV, it doesn't seem to have any impact on better posture or fitness. Reasons for this include widespread poverty which encourages consumption of cheaper high-calorie processed foods, culturally anchored sedentary lifestyle habits, lack of physical and health education and exercise-prohibitive living conditions.

1290 Board #71 MAY 30 11:00 AM - 12:30 PM

**Influence of BMI on Aerobic Fitness and Academic Performance in Middle School Students**

Guoyuan Huang<sup>1</sup>, Xiangrong Shi, FACSM<sup>2</sup>, Audra Offutt<sup>3</sup>. <sup>1</sup>University of Southern Indiana, Evansville, IN. <sup>2</sup>University of North Texas Health Science Center., Fort Worth, TX. <sup>3</sup>Thompson Middle School of EVSC, Evansville, IN.

(No relationships reported)

**PURPOSE:** Obesity is one of the most pressing health concerns for children. Could positive results presenting an academic advantage be due to children more fit in BMI? The current study was to explore if middle school students who are BMI fit are likely to have better aerobic fitness and stronger academic performance.

**METHODS:** The study sample included 146 middle school students (mean age: 11.9 $\pm$ 0.4 yrs). Subjects were administered physical fitness tests after first signing the informed consent. The study used standard physical fitness tests and was conducted in a controlled manner by the trained professionals. The academic performance information was collected, including previous and current semester GPA (P-GPA; C-GPA), and final GPA for the academic year (F-GPA). Only those students with complete sets of scores for both variables were included in the statistic analysis. SPSS for Windows 17.0 was used for statistical analysis.

**RESULTS:** The results showed a significant mean difference of aerobic fitness in terms of 1-mile running time (min) between normal-BMI and overweight-obese-BMI students (mean $\pm$ SD, 9.99 $\pm$ 2.67 vs. 13.51 $\pm$ 2.61;  $p<0.0001$ ), and between underweight-BMI and overweight-obese-BMI students (10.38 $\pm$ 2.52 vs. 13.51 $\pm$ 2.61;  $p<0.0001$ ). Students with normal-BMI tended having better academic performance than that of the overweight-obese-BMI students in terms of percentile rank for F-GPA (58.97 $\pm$ 26.47 vs. 46.27 $\pm$ 28.01;  $p=0.022$ ) and C-GPA (59.02 $\pm$ 26.05 vs.

47.56±26.91; p=0.041). Better GPAs were also found in normal-BMI students, compared to the underweight-BMI, in P-GPA (58.25±26.13 vs. 41.43±24.16; p=0.009), C-GPA (59.02±26.05 vs. 38.13±26.67; p=0.001), and F-GPA (58.97±26.47 vs. 40.50±26.09; p=0.004).

**CONCLUSIONS:** This study suggests that normal-BMI students are likely to have high level of cardiorespiratory fitness, compared to those students with underweight-BMI and overweight-obese-BMI. Students with healthy BMI tend to have higher GPAs, showing better academic performance.

---

**1291** Board #72 MAY 30 11:00 AM - 12:30 PM

**Relationship Of Exercise Class Participation and BMI Change In Pediatric Obesity Patients**

Christopher Kist, Amanda Gier, Wayne Mays, Bob Siegel, Shelley Kirk. *Cincinnati Children's Hospital, Cincinnati, OH.*

(No relationships reported)

**PURPOSE:** To evaluate the relationship of participation in a pediatric weight management program inclusive of exercise classes and family-oriented dietary counseling to body mass index (BMI) change pre and post participation.

**METHODS:** We evaluated 269 pediatric obesity patients (mean age 11.2 ± 3.0 years, 106 males) with a 400 meter walk test pre and post participation in the pediatric weight management program. There were 178 patients that participated in exercise classes (EC) and 91 patients that completed the program without participation in the exercise classes (NC). Heart rate difference (HRDiff) was calculated by subtracting the pre 400 meter walk heart rate (HR) from the post 400 meter walk HR.

**RESULTS:** For the total group, there was a significant correlation between the change in BMI (0.12 ± 2.13 kg) and the percentage of exercise classes attended (12.3 ± 16.2%, r=0.21, p<0.0005). Additionally, the initial BMI (34.7 ± 7.7 kg/m<sup>2</sup>) correlated with the pre and post HR Diff (30 ± 13 and 29 ± 13 BPM) (r=0.15, p<0.01 and r=0.16, p<0.01) Also, the post BMI was significantly correlated with the post HRDiff (r=0.14, p<0.05). The NC group showed no correlations with pre or post HRDiff. However, the EC group showed significant correlation between the change in BMI (0.43 ± 2.46 kg) and the percentage of exercise classes attended (18.6 ± 16.7%, r=0.25, p<0.0005). Additionally, the initial BMI (34.8 ± 7.9 kg/m<sup>2</sup>) correlated with the pre and post HR Diff (29 ± 13 and 28 ± 13 BPM) (r=0.20, p<0.005 and r=0.20, p<0.005) Also, the post BMI was significantly correlated with the post HRDiff (r=0.17, p<0.005). **DISCUSSION:** There was a significant correlation between the change in BMI pre and post exercise participation and the percentage of classes attended. This relationship was strengthened when patients that did not attend classes were removed from the analysis. Additionally, BMI was significantly correlated with HR difference from the 400 meter walk test indicating BMI relationship to the difficulty of the walk test.

**CONCLUSION:** There was a significant but weak correlation of BMI change to attendance to exercise classes in a pediatric weight management program. Further multivariate analysis may illuminate the relationship between attendance and BMI.

**1292** Board #73 MAY 30 11:00 AM - 12:30 PM

**Influence Of BMI On The New FITNESSGRAM® Aerobic Capacity Criteria Standards In Sixth-grade Children.**

Tinker D. Murray, FACSM<sup>1</sup>, John Walker, FACSM<sup>1</sup>, Pete Silvius<sup>2</sup>, Erik Silvius<sup>2</sup>, James Eldridge<sup>3</sup>, William G. Squires, Jr., FACSM<sup>4</sup>. <sup>1</sup>Texas State University, San Marcos, TX. <sup>2</sup>Seguin ISD, Seguin, TX. <sup>3</sup>University of Texas of the Permian Basin, Odessa, TX. <sup>4</sup>Texas Lutheran University, Seguin, TX.

(No relationships reported)

New criterion standards for percent body fat, body mass index (BMI), and aerobic capacity have been developed for the FITNESSGRAM®. Aerobic capacity is calculated based on 1-mile run, PACER, or 1-mile walk performances, as well as BMI values. Criterion standards for aerobic capacity include a healthy fitness zone (HFZ) and a categories for Needs Improvement - Some Risk (NI-SR) and Needs Improvement - High Risk (NI-HR).

**PURPOSE:** The purpose of this study was to examine the influence BMI has on the new FITNESSGRAM® criterion standards for aerobic capacity compared to the previous standards for one-mile run and PACER tests in sixth-grade children.

**METHODS:** Subjects were 439 sixth-grade boys and girls (61.3% Hispanic; 7.1% African-American) who completed each of the FITNESSGRAM® test components of their yearly physical education assessment. While, 60% of students met the previous FITNESSGRAM® age and gender criterion standards for BMI, only 43% met the new HFZ standards, and only 2% were in the very lean category. For the remaining students, 13% were classified as NI-SR, while 42% were classified as NI-HR.

**RESULTS:** The percent of these students meeting the previous criterion standards were 48% for the one-mile run, and 44% for the PACER test. The percent of these students meeting the new FITNESSGRAM® age and gender aerobic capacity standards calculated from one-mile run times were 55% for the HFZ, 19% for NI-SR, leaving 26% in the NI-HR category. The percent meeting the new aerobic capacity standards calculated from PACER performance were 50% for the HFZ, 19% for NI-SR, leaving 31% in the NI-HR category. Logistic regression revealed that compared to students who failed to meet the new HFZ standard for BMI, students who met the new HFZ standards for BMI were 42.6 times more likely to meet the aerobic capacity HFZ standard determined from one-mile times, and 57.1 times more likely to meet the aerobic capacity HFZ standard determined by PACER performance.

**CONCLUSIONS:** A decrease in BMI of one unit (based on weight loss only, -2.38 kilograms) would increase the probability of meeting HFZ criterion standards for aerobic capacity determined from the one-mile run by 45% and for aerobic capacity determined from PACER performance by 71%. This achievable (and safe) goal in similar youth populations remains to be tested in fitness interventions.

---

**1293** Board #74 MAY 30 11:00 AM - 12:30 PM

**The Effect of Waist Circumference on FITNESSGRAM® BMI and Aerobic Capacity Criterion Standards in Sixth-Grade Children.**

John L. Walker, FACSM<sup>1</sup>, Tinker D. Murray, FACSM<sup>1</sup>, James Eldridge<sup>2</sup>, Pete Silvius<sup>3</sup>, Erik Silvius<sup>3</sup>, William G. Squires, Jr., FACSM<sup>4</sup>. <sup>1</sup>Texas State University - San Marcos, San Marcos, TX. <sup>2</sup>University of the Permian Basin, Odessa, TX. <sup>3</sup>Seguin Independent School District, Seguin, TX. <sup>4</sup>Texas Lutheran University, Seguin, TX.

(No relationships reported)

Waist circumference has been identified as an indicator of metabolic syndrome. New FITNESSGRAM® health fitness zone (HFZ) standards for body composition and body mass index (BMI) have been established to identify students most at risk for metabolic syndrome. New HFZ standards have also been established for aerobic capacity (AC).

**PURPOSE:** The purpose of this study was to determine the effect of waist circumference (WC) on the new FITNESSGRAM® BMI and AC HFZ standards in sixth-grade children.

**METHODS:** Subjects were 528 sixth-grade boys and girls who completed each of the FITNESSGRAM® test components as a part of their yearly physical education assessment. AC was determined from one-mile run times. In addition to height and weight, subjects were also measured for WC. The percent of these students meeting the FITNESSGRAM® age and gender HFZ standards were 49% for BMI, and 59% for AC, compared to passing rates of 60% for BMI, and 35% for the one-mile run based on the previous FITNESSGRAM® standards.

**RESULTS:** The correlation between BMI and AC was .74. The correlation between WC and AC was .71. The correlation between BMI and WC was .94. Multiple regression indicated that BMI and gender accounted for 62% of the variation in AC. WC and gender accounted for 61% of the variation in AC. Logistic regression revealed that students who met the HFZ standards for BMI were 76.7 times more likely to meet the HFZ standards for AC than students who failed to meet the HFZ standards for BMI. A decrease in BMI by one unit would increase the probability of meeting the HFZ standards for AC by 41%. A decrease in WC by one inch would increase the probability of meeting the HFZ standards for AC by 37%.

**CONCLUSIONS:** The influence of BMI on AC is similar to that of WC. Receiver Operating Characteristic (ROC) analysis indicated that a waist circumference of 29 inches is the optimal cut-off score for determining successful completion for either BMI (AUC = .97) or AC (AUC = .93). These data suggest that interventions targeting a reduction in waist circumference or weight loss have the potential to improve performance on health-related fitness tests of aerobic capacity. Recent reports indicating an increase in overweight and obesity among children and adolescents make the development of such interventions even more meaningful for appropriate health-related fitness in youth.

**1294** Board #75 MAY 30 11:00 AM - 12:30 PM

**School Physical Education Programs And Children's Cardiovascular Fitness Tracking**

Randall A. Nichols, Traci D. Zillifro, Wenhao Liu. *Slippery Rock University, Slippery Rock, PA.*

(No relationships reported)

**PURPOSE:** To compare cardiovascular fitness tracking between children from two different PE programs.

**METHODS:** Participants were 176 children (85 girls) in a PE4life Academy middle school (S1), which was known for its high level of moderate and vigorous physical activity (MVPA) in the PE class, and 118 children (63 girls) in a same-area middle school with a traditional PE program (S2). Two schools were similar in socioeconomic status, race composition (white > 93%), and weekly PE class time (approximately 90 minutes per week). Progressive Aerobic Cardiovascular Endurance Run (PACER) was administered to the cohort at the beginning and end of their middle school period. Spearman rank correlation was used to examine stability of cardiovascular fitness. Further, based on the criteria of FITNESSGRAM Healthy Fitness Zone (HFZ), the cohort was categorized into either an at-risk group or HFZ group, and Chi-square test was used to examine differences in distribution changes in at risk and HFZ between S1 and S2 across the three years. Children's MVPA in the PE class were coded for 25 lessons in each school with System for Observing Fitness Instruction Time and analyzed with one-way MANOVA.

**RESULTS:** PACER correlations were .64 for S1 and .73 for S2 for boys, and were .77 for S1 and .49 for S2 for girls. Chi-square results for boys indicated similar distribution pattern in the two groups between S1 (49.1% in the at-risk group and 50.9% in the HFZ) and S2 (57.1% and 42.9%) at baseline. At the follow-up, however, the patterns became different between S1 (24.5% in the at-risk group and 75.5% in the HFZ) and S2 (81.0% and 19.0%), with  $\chi^2 = 19.86$  and  $p < .001$  in favor of S1. Results for girls were similar. At baseline S1 had 21.6% in the at-risk group and 78.4% in the HFZ, and S2 had 33.3% and 66.7%, respectively. At the follow-up S1 had 29.4% in the at-risk group and 70.6% in the HFZ, and S2 had 61.5% and 38.5%, respectively, with  $\chi^2 = 9.23$  and  $p < .01$  in favor of S1. Further, MANOVA results indicated that children in S1 had significantly larger percentage of PE class time in MVPA than those in S2 ( $p < .001$ ), with  $66.42 \pm 6.50$  vs.  $44.12 \pm 8.79$ .

**CONCLUSIONS:** The PE4life program has much more positive tracking results in children's cardiovascular fitness than traditional PE programs. But Spearman rank correlation alone could not identify or explain the differences.

---

**1295** Board #76 MAY 30 11:00 AM - 12:30 PM  
**Physical Activity Incorporated Within Head Start Curriculum Improves Early Literacy In African American Children**

Stacie M. Kirk, Erik P. Kirk. *Southern Illinois University Edwardsville, Edwardsville, IL.*  
(No relationships reported)

**PURPOSE:** To determine the effects of a low cost, teacher directed, minimal intervention program that delivered existing academic lessons taught through physical activity (PA) in Head Start preschools serving African American (AA) children.

**METHODS:** Seventy-two African American children (mean $\pm$ SE, age 3.8 $\pm$ 0.1y) from a low socioeconomic urban Head Start were randomized to Control (CON, n=3 classrooms, n=21, F, n=9 F, M, n=12) or PA (n=4 classrooms, n=51 F, n=29, M, n=22) groups for 6 mo. The PA program was designed to promote 150 min/wk of moderate to vigorous PA academic lessons (3.0-6.0 METS, ~15 min each, 2 lessons/day). Intensity of classroom PA was measured by a SOFIT. Height and weight to determine BMI were obtained using a stadiometer and digital scale. The Get It, Got It, Go Individual Growth and Development Indicators for children ages 3-5y was administered to assess early literacy and phonological awareness in the areas of alliteration and picture naming. All measures were assessed at baseline, 3 and 6 mo.

**RESULTS:** The PA protocol resulted in significantly ( $p < 0.05$ ) greater levels of PA in the classroom during free play at 3 (PA, 8.1 $\pm$ 2.1% vs. CON, -2.2 $\pm$ 2.1%) and 6 (PA, 20.1 $\pm$ 2.1% vs. C, -7.1 $\pm$ 2.1%) mo than children in the CON, resulting in between group differences at 3 and 6 mo,  $p < 0.01$ . The 6 mo change in BMI for the PA group was 2.0 $\pm$ 1.1% and CON 0.8 $\pm$ 0.9%, respectively (NS). Alliteration (letters sounds/two min) significantly ( $p < 0.01$ ) improved in the PA group from baseline (0.4 $\pm$ 0.1) to 3 mo (1.0 $\pm$ 0.4) and was maintained at 6 mo (1.0 $\pm$ 0.4) compared to no change in CON at 3 (0.1 $\pm$ 0.3) and 6 (0.2 $\pm$ 0.4) mo compared to baseline,  $p > 0.05$ , resulting in between group differences at 3 and 6 mo,  $p < 0.01$ . Picture naming (picture per minute) significantly ( $p < 0.01$ ) improved in the PA group from baseline (17.2 $\pm$ 3.5) to 3 (21.7 $\pm$ 5.0) and 6 (24.8 $\pm$ 5.4) mo compared to no improvement in the CON, resulting in between group differences at 3 and 6 mo,  $p < 0.01$ . Higher scores for alliteration and picture naming indicate greater early literacy skills and phonological awareness.

**CONCLUSION:** A low cost, teacher directed, minimal intervention program incorporating PA within Head Start curriculum promotes daily PA, increases early literacy, and attenuate increases in BMI in AA preschool children, a group at an increased risk for poor literacy development and obesity.

---

**1296** Board #77 MAY 30 11:00 AM - 12:30 PM  
**Effect of Exercise Training in the Cold on Regional Body Composition in Obese Boys**

Boguslaw Wilk, FACSM, Joyce Obeid, Raymond Trott, Oded Bar-Or, Brian W. Timmons. *McMaster University, Hamilton, ON, Canada.*  
(No relationships reported)

Exercise training in the cold reduces whole body fat mass in obese adolescent boys (Wilk et al 2006).

**PURPOSE:** To determine the effect of exercise training in the cold on regional body composition, substrate utilization, respiratory heat loss (RHL), and energy expenditure (EE) in obese adolescents.

**METHODS:** Twenty obese (>30% body fat) adolescent boys, ages 12 to 16 years, participated in a 6-week (3 times per week) exercise training program. Boys were randomly allocated to train in the cold (COLD; 5 °C, n=10) or a thermoneutral environment (NEUT; 24.5 °C, n=10). Each training session consisted of 3 x 20 min exercise bouts interspersed with 5 min rest performed in a climate chamber. The boys alternated between treadmill walking and cycling (both at 60 % VO<sub>2max</sub>) within each session. Regional body composition was measured before and after the 6-week training program using DXA. Volume, O<sub>2</sub>, CO<sub>2</sub>, and temperature of expired air were measured during exercise at the first (T1) and last (T18) training sessions to assess EE, substrate utilization (fat oxidation (FATox) and carbohydrate oxidation (CHOox)), and RHL. Two-way ANOVAs with between (COLD vs. NEUT) and within (pre- vs. post-training) factors were used ( $p < 0.05$ ).

**RESULTS:** Significant post-training %fat changes were observed for trunk (-1.6 %,  $P = 0.05$ ) and legs (-1.0%,  $P = 0.001$ ) in COLD and for arms in NEUT (-1.2%,  $P = 0.04$ ). Leg lean mass increased 4.6% ( $P = 0.001$ ) in COLD only. FATox was higher and CHOox lower at T18 compared with T1 ( $P < 0.05$ ), with no differences between groups. RHL were higher ( $P = 0.001$ ) in COLD at T1 (1.08 kcal/kg) and T18 (1.04 kcal/kg) compared with NEUT (0.61 and 0.57 kcal/kg at T1 and T18, respectively). Although EE was ~10% higher in COLD compared with NEUT at both T1 and T18, this difference was not statistically significant.

**CONCLUSIONS:** Six weeks of exercise training in the cold induces desirable changes in regional body composition, particularly central adiposity, of obese boys.

**Examining Elementary School Students' Motor Skills, Physical Activity, and Health-related Physical Fitness**

Tao Zhang<sup>1</sup>, Ping Xiang<sup>2</sup>. <sup>1</sup>University of North Texas, Denton, TX. <sup>2</sup>Texas A & M University, College Station, TX.  
(No relationships reported)

Promoting motor skills, physical activity (PA), and health-related physical fitness are all critical to our effort to help school-aged students live physically active lifestyles. Therefore, understanding their interrelationships is considered a research priority. While considerable research has examined PA in relation to students' health-related physical fitness, research on the relationships among students' motor skills, in-class PA and physical fitness has been scarce.

**PURPOSE:** The purpose of this study was to investigate the relationships among motor skills, in-class PA, and health-related physical fitness among elementary school students in physical education (PE).

**METHODS:** Participants were 104 fourth and fifth grade students (45 girls and 59 boys; M age = 11.0). They completed motor skills in basketball, overhand throwing, and striking assessed by PE Metrics TM (NASPE, 2010). Students' PA across three PE lessons was measured by Actical accelerometers (Mini-Mitter Co., Inc., Bend, OR). Health-related physical fitness was assessed by FITNESSGRAM® (Cooper Institute, 2007), including Progressive Aerobic Cardiovascular Endurance Run, curl-ups, push-ups, height and weight (calculating BMI), trunk lift, and sit-and-reach tests. The total number of fitness tests in which students achieved the Healthy Fitness Zone was calculated and used as an overall measure of physical fitness.

**RESULTS:** There were positive relationships among basketball, overhand throwing, and striking. Basketball was positively associated with in-class PA. Health-related physical fitness was positively correlated with basketball, striking, and in-class PA. Two regression analyses indicated basketball and overhand throwing were significant predictors of students' in-class PA ( $R^2 = 6.3\%$ ;  $\beta = .22, -.24$ , respectively, all  $p < 0.05$ ). The basketball skill emerged as a significant predictor of students' physical fitness ( $R^2 = 4.7\%$ ;  $\beta = .22, p < 0.05$ ).

**CONCLUSION:** These results provided empirical evidence on relationships among students' motor skills, PA, and health-related physical fitness. Given the small predictive strength of motor skills in this study, additional investigation is needed to further examine the dynamic relationships among motor skills, PA, and health-related physical fitness.

(No relationships reported)

**PURPOSE:** Although AT is a useful measure of exercise tolerance (ET), it has a drawback of requiring an evaluator, a source of subjectivity. This study was done to assess the AT by blind reading to detect changes in ET.

**METHODS:** The records of 166 patients who underwent cardiopulmonary exercise testing (CPX) during cardiac rehabilitation (CR) were retrospectively reviewed. CR was hospital (the mean of 3.1/mo) and home based. The mean time elapsed between the 1st and 2nd tests was 135(SD:29) days. The mean age was 64(11), with 143 males and 23 females. The underlying heart disease was mainly ischemic: post myocardial infarction in 95 and angina in 39. CPX was done using an upright bicycle with a breath-by-breath apparatus. The exercise was submaximal, which was mostly terminated with an appearance of AT or target heart rate. CPX records were erased of their ID's and coded by the controller. AT was read by 2 independent experienced investigators(A,B) based on the Wasserman's criteria.

**RESULTS:** The table below shows the mean(SD).

| CR   | Wt(kg)     | HR(b/min) at highest workload | Borg scale (/20) | VO2 at highest workload (ml/min/kg) | AT(ml/min, VO2) by A | AT(ml/min, VO2) by B |
|------|------------|-------------------------------|------------------|-------------------------------------|----------------------|----------------------|
| Pre  | 66.1(10.9) | 111(22)                       | 13.2(1.6)        | 14.6(3.5)                           | 670(217)             | 706(194)             |
| Post | 66.7(10.9) | 117(18)                       | 13.6(1.7)        | 17.0(4.1)                           | 721(251)             | 752(204)             |
| p    | 0.006      | 0.958                         | 0.012            | <0.0001                             | 0.0004               | 0.0001               |

The investigator A did not detect AT in 21.7% and B in 14.5%. About 2/3 of these cases had a R<1.0 at the highest workload, suggesting a workload below AT. Although the pre-and post-CR AT values read by the investigators A and B were clearly different (p<0.001), the mean pre-post difference in AT detected by each was remarkably similar (51(161) vs 46(140) ml/min in VO2, ns). We speculated that since the entire portion of the v-slope would shift to the right with training, any identifiable deflection point on it would equally shift in parallel

**CONCLUSIONS:** Despite differing AT readings at pre-and post-rehabilitation by the 2 independent investigators, the mean absolute difference (improvement) did not differ between the 2.

1299 Board #80 MAY 30 9:30 AM - 11:00 AM

### Effect Of An Exercise-based Cardiac Rehabilitation Program On Arterial Stiffness In Post Myocardial Infarction Patients

Norton Luis Oliveira<sup>1</sup>, Fernando Ribeiro<sup>2</sup>, Alberto Jorge Alves<sup>1</sup>, Fátima Miranda<sup>3</sup>, Marlene Fonseca<sup>3</sup>, Lilibeth Campos<sup>3</sup>, Madalena Teixeira<sup>3</sup>, José Oliveira<sup>1</sup>. <sup>1</sup>University of Porto, Faculty of Sport, Porto, Portugal. <sup>2</sup>CESPU, Polytechnic Health Institute of the North, Gandra PRD, Portugal. <sup>3</sup>Centro Hospitalar de Gaia/Espinho, Vila Nova de Gaia, Portugal.  
(No relationships reported)

The arterial stiffness, assessed by pulse wave velocity (PWV), has been showed to be an independent cardiovascular risk marker in several clinical conditions. Exercise seems to be an effective intervention in decreasing PWV in several chronic diseases, although few studies exist in post myocardial infarction (MI) patients

**PURPOSE:** To determine the effect of an exercise-based cardiac rehabilitation program on PWV in post MI patients.

**METHODS:** Twenty-four male and 2 female patients, mean (±SD) age 60.1 ± 10.5 years, after an acute myocardial infarction were randomized to either an 8-week exercise-based cardiac rehabilitation program (EG) or to a control group, which underwent only usual medical care (CG). Complete randomization was performed by choosing one of two sealed envelopes. The EG participated in an 8-week programme comprising 3 exercise sessions per week. Each exercise session included 10 minutes of warm-up, 35 minutes of aerobic exercise on a cycloergometer or treadmill, and 10 minutes of cool-down. The exercise intensity was calculated as 65-75% of maximal heart rate achieved in the exercise test. Outcome measures included changes in PWV, evaluated by applanation tonometry, and peak oxygen consumption (VO2). Group comparisons were made using two-way ANOVA with repeated measures.

**RESULTS:** Age (EG - 63 ± 9.4 vs. CG - 57 ± 11.2 years), PWV (EG - 9.2 ± 2.3 vs. CG - 8.2 ± 2.5 m/s) and VO2 (EG - 26.4 ± 6.6 vs. CG - 28.2 ± 5.4 ml/kg/min) were not significant different at baseline (p>0.05). Moreover, patients did not change their medication in the study period. The main effect of cardiac rehabilitation for PWV was significant (F 1.24 = 5.4) indicating a decrease in EG (8.2 ± 2.0 m/s, p0.05). The main effect was also significant for VO2 (F 1.24 = 6.6) with an average increase of 3.4 ml/kg/min in EG (29.8 ± 8.1 ml/kg/min, p<0.05) and no significant change in CG (28.5 ± 6.1 ml/kg/min).

**CONCLUSIONS:** Exercise-based cardiac rehabilitation decreases systemic arterial stiffness in post MI patients. Therefore, this could be one of the mechanisms associated with the positive outcome (i.e., mortality rates) on post MI patients who undergo rehabilitation.

### Double Product Based on Heart Sounds as a Marker of Catecholamines During Exercise

Takuro Matsuda<sup>1</sup>, Yasuki Higaki<sup>1</sup>, Akira Kiyonaga<sup>1</sup>, Shigeru Obara<sup>2</sup>, Hiroaki Tanaka<sup>1</sup>. <sup>1</sup>Fukuoka University, Fukuoka, Japan. <sup>2</sup>The University of Tokushima, Tokushima, Japan.  
(No relationships reported)

**PURPOSE:** It is well documented that exercise-induced adrenergic stimulation enhances myocardial contractility in healthy humans. The break-point of the double product of heart rate (HR) and systolic blood pressure, which is a marker of cardiac oxygen demands, is strongly correlated with the epinephrine (Ep) threshold. The amplitude of the first sound (HS1) is a marker of cardiac contractility, which is a major determinant of cardiac oxygen demand and is easy to determine continuously during exercise. This study investigated the relationship between the double product (DP) based on heart sounds and Ep level.

**METHODS:** Twelve subjects, with a mean±SD age of 22±3 years and a mean±SD BMI of 23.1±3.5 kg/m<sup>2</sup>, underwent graded cycle ergometer testing. The work rate started at 15 watts and then increased at 15 watts every 2 min until the heart rate reached 85% of its maximum expected for their age. The heart sounds were collected in a personal computer via an A/D converter throughout the exercise test. Blood from the antecubital vein was sampled and Ep levels were measured every 2 min during the test. Values of the DP were calculated by the formula HR×HS1. The break-point of DP (DPBP) and Ep threshold were determined based on a visual inspection three separate times and the mean value was calculated.

**RESULTS:** The DP was significantly correlated with Ep levels in all subjects during incremental exercise (r=0.97 to 0.99, p<0.001). A clear DPBP and Ep threshold were obtained in all subjects (DPBP: 84.6±13.9 watts; Ep threshold: 83.5 ±19.5 watts) and they were not statistically significant from each other (p=0.877).

**CONCLUSIONS:** The DP from heart sounds is a valid marker of the sympathetic nerve system during exercise stress. Monitoring heart sounds appears to provide valuable information related to the level of exercise stress. This information may be useful when determining an appropriate exercise prescription.

**Is Cardiorespiratory Fitness, Muscular Fitness or Physical Activity Related to Diabetes Risk in Postmenopausal Women?**

Judith A. Flohr, Elizabeth S. Edwards, Layne E. Eidemiller, Christine M. Nicewonger, Christopher J. Womack, FACSM. *James Madison University, Harrisonburg, VA.*

*(No relationships reported)*

**PURPOSE:** The purpose of this study was to examine the independent and joint associations of upper and lower body muscular strength (MS), cardiorespiratory fitness (CRF), and physical activity (PA) with the prevalence of Type 2 diabetes mellitus (T2DM) in a group of sedentary healthy postmenopausal women.

**METHODS:** Thirty-five postmenopausal (age  $57.9 \pm 4.7$  yrs.) women completed a graded exercise test on a treadmill to determine maximum relative oxygen consumption ( $VO_{2max}$ ) and the International Physical Activity Questionnaire (IPAQ) to estimate MET minutes/week of PA. Waist circumference (WC), body fat via DXA (BF), height, weight, 5RM leg press and chest press were measured and used to estimate 1RM. These 1RM values were then divided by body weight, yielding ratios for leg press (LP) and chest press (CP). All participants had blood drawn and analyzed for HbA1c (A1c). Bivariate Pearson's correlations were used to identify variables that were associated with A1c. Stepwise regression was then used to identify variables that significantly predicted A1c.

**RESULTS:** The average A1c was 5.9%. Both LP ( $r = -0.344, p = .043$ ) and CP ( $r = -0.414, p = .013$ ) were significantly associated with A1c, but neither  $VO_{2max}$  nor IPAQ were significantly correlated with A1c. In the regression model, only LP significantly predicted A1c,  $b = -0.57, t(33) = -2.61, p = .013$ . LP explained a significant proportion of the variance in A1c,  $R^2 = 0.17, F(1, 33) = 6.84, p = .013$ .

**CONCLUSIONS:** Previous studies have reported an inverse relationship among CRF, PA, MS and T2DM in men. There is limited data available describing the relationship between MS and A1c in postmenopausal women. However, recent reports suggest that muscle mass may play a significant role in glycemic control. The results of the present study indicate that muscular strength as measured by LP and CP were related to A1c. Therefore, efforts to increase muscle strength in postmenopausal women in an attempt to lower diabetes risk appear to be warranted.

**The Effects Of Aerobic Training In The Patients With Heart Failure**

Shang-Lin Chiang, Chinese. *Tri-Service General Hospital, National Defense Medical Center, Taipei, Taiwan.* (Sponsor: Wen-Hsu Sung, FACSM)

*(No relationships reported)*

**PURPOSE:** Aerobic training can improve not only aerobic capacity but also symptoms and survival rate in patients with heart failure (CHF). The purposes of our study will test the effects of exercise training on aerobic capacity, heart rate, blood pressure, cardioutput, body composition, serum lipid and NT-proBNP (aminoterminal fragment brain natriuretic peptide prohormone) in CHF patients, and examine the potential benefit of changes over time.

**METHODS:** The samples consisted of 13 eligible cases with heart failure. Seven of them completed 12-week exercise program (30 minutes a day, 3 days a week, at 60% peak oxygen uptake ( $VO_{2peak}$ )). Every 4 weeks training, heart rate, blood pressure, body composition, serum lipid and NT-proBNP were measured after an overnight fast. Besides,  $VO_{2peak}$  and cardioutput were measured at pre-training and post-training.

**RESULTS:** After 12-week exercise training program, seven cases completed the process. The results indicate that the parameters of cardiopulmonary capacity were all significant improved. The  $VO_{2peak}$  was improved from  $20.30 \pm 5.30$  to  $22.49 \pm 4.36$  ml/kg/min ( $p = .002$ ). The maximal metabolic equivalent (MET) was improved from  $5.76 \pm 1.55$  to  $6.37 \pm 1.31$  METs ( $p = .0001$ ). The maximal work load was improved from  $220.43 \pm 76.39$  to  $276.57 \pm 75.91$  Watt (W) ( $p = .029$ ). Although it was not significant, diastolic pressure and systolic pressure were improved over training time. Meanwhile, after 12-week training, static cardioutput was not significant changed, but dynamic cardioutput was significant improved (increased  $2.37$  ml/min  $p = .015$ ). However, total cholesterol and NT-proBNP did not decreased significantly. But the more time of exercise training they received, the more they improved.

**CONCLUSION:** It is concluded that aerobic exercise training could improve cardiopulmonary capacity, static heart rate, blood pressure, cardioutput, body composition, serum lipid and NT-proBNP in heart failure patients. The results also proved the effects of aerobic exercise for heart failure patients could be accumulated over time. Therefore, provide precise exercise prescriptions and educate them how to do the adequate aerobic exercise training are very important to patients with heart failure.

**Heart Rate Variability is Reduced at Peak Exercise in Individuals at Risk for Sleep Apnea**

Trent A. Hargens<sup>1</sup>, Amanda Mallory<sup>2</sup>, Steve Vesbach<sup>2</sup>. <sup>1</sup>*James Madison University, Harrisonburg, VA.* <sup>2</sup>*Ball State University, Muncie, IN.* (Sponsor: M. Kent Todd, FACSM)

*(No relationships reported)*

Obstructive sleep apnea (OSA) is a sleep disorder that significantly increases risk for hypertension, cardiovascular disease (CVD) and diabetes, among others. OSA leads to dysfunction in the autonomic regulation of the cardiovascular system, a primary mediating factor in the increased risk for chronic disease. Heart rate variability (HRV) has been widely used for assessing autonomic function, and has been shown to be predictive of CVD and all-cause mortality at rest and during exercise. HRV has been shown to be reduced in OSA at rest, but to date, no studies have examined exercise HRV in individuals diagnosed with, or at high risk for, OSA.

**PURPOSE:** To examine the HRV responses during exercise in individuals identified as high risk for OSA.

**METHODS:** Nine (6 male, 3 female) obese subjects (BMI: Mean SD =  $33.3 \pm 6.4$  kg/m<sup>2</sup>; age =  $47.4 \pm 8.2$  yr) at risk for OSA (OSA) and 16 (6 male, 9 female) obese subjects (BMI =  $32.5 \pm 4.9$ ; age =  $28.7 \pm 10.3$ ) at low risk for OSA (Control) performed maximal cycle ergometer exercise tests utilizing a 20 watts/min ramp protocol. HRV was assessed at rest, during exercise and immediately post-exercise. Measures of time and frequency domain HRV were obtained. HRV variables were log transformed and converted into normalized units for statistical analysis. Risk for OSA was established through a screening result from an at-home sleep assessment device (Embletta).

**RESULTS:** The OSA group was significantly older than the control group ( $P < 0.001$ ). Body mass index, blood pressure, resting heart rate, and  $VO_{2peak}$  did not differ between groups. After controlling for age and gender, peak exercise (last two minutes of exercise) log total power ( $0.74 \pm 0.2$  vs.  $1.5 \pm 0.2$  ms<sup>2</sup>), log low frequency ( $-0.47 \pm 0.3$  vs.  $0.31 \pm 0.2$ ), log high frequency ( $-0.92 \pm 0.3$  vs.  $0.27 \pm 0.2$ ), normalized low frequency ( $1.03 \pm 0.5$  vs.  $3.03 \pm 0.4$ ), and normalized high-frequency ( $0.60 \pm 0.5$  vs.  $3.00 \pm 0.4$ ) were reduced in the OSA group ( $P < 0.05$ ). No differences were noted in time domain variables at peak exercise. Resting, submaximal exercise or recovery HRV variables (time or frequency domain) did not differ.

**CONCLUSION:** Results suggest that individuals at high risk for probable OSA display abnormal autonomic modulation of heart rate during peak exercise. Exercise HRV may be a useful tool for improving risk assessment in OSA, but needs further examination.

**Early Oxygen Uptake Response to Constant Work Exercise and Mortality in Men**

Kai P. Savonen<sup>1</sup>, Vesa Kiviniemi<sup>2</sup>, Heikki Rajala<sup>1</sup>, Jari A. Laukkanen<sup>1</sup>, Timo A. Lakka<sup>1</sup>, Rainer Rauramaa, FACSM<sup>1</sup>. <sup>1</sup>*Kuopio Research Institute of Exercise Medicine, Kuopio, Finland.* <sup>2</sup>*Information Technology Center, University of Eastern Finland, Kuopio Campus, Kuopio, Finland.*

*(No relationships reported)*

The blunted pulmonary oxygen uptake ( $VO_2$ ) response to constant work exercise is associated with a poor prognosis in congestive heart failure patients but no previous study has addressed this issue in asymptomatic subjects.

**PURPOSE:** To study the association between a blunted VO<sub>2</sub> increase during the first 30 s of the constant work exercise in cycle ergometer and the risk of cardiovascular death in cardiovascularly healthy middle-aged men.

**METHODS:** The subjects were 484 men, 54-56 years of age, from eastern Finland without cardiovascular disease or cancer at baseline. VO<sub>2</sub> response to constant work exercise at 50 Watts in cycle ergometer was quantified by calculating the average net VO<sub>2</sub> during the first 30 s of exercise (VO<sub>2</sub>30) in proportion to the average net VO<sub>2</sub> at steady state (VO<sub>2</sub>ss, the average net VO<sub>2</sub> during the third minute of exercise). The association of VO<sub>2</sub> response with the risk of cardiovascular death was examined with multivariable Cox proportional hazards' regression model. A total of 52 cardiovascular deaths were observed during an average follow-up of 19.8 years.

**RESULTS:** The average net VO<sub>2</sub> during the first 30 s of exercise in proportion to the average net VO<sub>2</sub> at steady state was not related to the risk of cardiovascular death. In Cox-multivariable model, the risk of death increased 8% (95% CI -19-43, p=0.58) for a 1-SD (0.19) increment in VO<sub>2</sub>30/VO<sub>2</sub>ss after adjustment for myocardial ischaemia during exercise test, cigarette smoking, systolic blood pressure at rest, and body mass index.

**CONCLUSION:** An attenuated early VO<sub>2</sub> response during the first 30 s of constant work exercise does not predict cardiovascular death in cardiovascularly healthy middle-aged men. While submaximal testing itself offers certain advantages, the early VO<sub>2</sub> response can not be utilized for prognostic assessment in healthy men.

**Blood Flow Restriction Increases Angiogenic Gene Expression in Skeletal Muscle following Acute Resistance Exercise**

Kelly A. Larkin, Richard G. MacNeil, Launa Clough, Bhanupresad Sandesara, Todd M. Manini, Thomas W. Buford. *University of Florida, Gainesville, FL*

(No relationships reported)

Blood flow restriction (BFR) potentiates the effects of low-intensity resistance exercise on skeletal muscle size and strength. However, evidence is sparse regarding the effects of BFR exercise on vascular adaptations within the skeletal muscle.

**PURPOSE:** To evaluate the effects of BFR on post-exercise expression of angiogenesis-related mRNAs.

**METHODS:** Using a randomized cross-over design, six healthy young adults (n=3 men, n=3 women, 22±1 years) performed on separate occasions low-intensity exercise with and without BFR. Each exercise bout entailed 120 repetitions of single-limb knee extensor exercise at 40% of 1RM maximum. The BFR condition was performed with an external pressure cuff inflated to 220 mm Hg. Near-infrared spectroscopy (NIRS) was utilized to measure oxygenation of the vastus lateralis during exercise. Skeletal muscle samples were collected via percutaneous biopsy prior to, 4 hours following, and 24 hours following exercise. Skeletal muscle mRNA expression was determined using standard Q-PCR techniques and normalized to GAPDH. NIRS data were analyzed using paired Student's *t*-tests and Q-PCR data were analyzed using the Wilcoxon's test.

**RESULTS:** BFR (45.3±2.4%) decreased tissue oxygenation during the exercise bout compared to control exercise (59.7±2.9%, p=0.028). This was reflected in a significant increase in total Hb (14.4±2 vs. 0.9±2, p=0.010) that was driven largely by an increase in deoxygenated Hb. BFR increased (p<0.05) mRNA expression of vascular endothelial growth factor (VEGF), VEGF-R2, hypoxia inducible factor alpha (HIF1α), inducible nitric oxide synthase (NOS), and neuronal NOS. The most notable change in response to BFR was an increase in VEGF mRNA expression at 4 hours post-exercise (4.1±0.6 vs. 0.6±0.2 fold change, p=0.028). Muscle mRNA expression of endothelial NOS was not altered in response to BFR (p>0.05).

**CONCLUSIONS:** Acute BFR increases post-exercise expression of mRNA related to skeletal muscle angiogenesis.

**Effect Of Training With Blood Flow Restriction Of The Thigh Muscles In Men**

Hans-Christian C. Heitkamp, Beate Schiff, Walter Rapp, Andreas Niess. *Univ. of Tuebingen, Tuebingen, Germany.*

(No relationships reported)

Training with vascular restriction lately receives more attention since less percentage of 1 RPM seems necessary for gaining strength.

**PURPOSE:** The aim of this study was to find out whether training with 40 % of 1 RPM leads to more strength with blood flow restriction than without.

**METHODS:** 14 men aged 27 ± 2.8 years and a BMI of 26 kg/m<sup>2</sup> took part in this study. Initially, the strength of the quadriceps and the hamstrings was measured on an isokinetic system isometrically in 60° and 30° positions respectively, isokinetic strength at 60°/s and strength endurance at 120°/s with 25 maximal intensity movements.

Training was conducted for 8 weeks, twice a week for 35 minutes according to the endurance method with 3 sets and 20 repetitions. The right side was always trained under vascular occlusion and both sides at 40 % of 1 RPM. Each leg was trained separately in an alternating mode.

**RESULTS:** Maximal isometric force of flexion rose from 60 ± 26 to 70 ± 35 Nm (p < 0.001), while it remained constant in the control leg with 58 ± 27 and 57 ± 23 Nm. The extension rose from 82 ± 20 to 94 ± 19 Nm (p<0.001) and dropped in the control leg from 79 ± 21 to 78 ± 24 Nm. During isokinetic flexion, an increase from 106 ± 22 to 124 ± 24 Nm (p<0.01) occurred and in the control leg from 98 ± 22 to 114 ± 24 Nm. During isometric flexion an increase from 198 ± 27 to 219 ± 34 Nm (p < 0.001) and also in the control leg from 201 ± 30 to 210 ± 24 Nm (p < 0.005). The endurance measurement resulted in no increase. The compliance was 83 %.

**CONCLUSION:** Training with vascular restriction is especially effective for increasing the isometric maximal strength to a lesser degree for the isokinetic maximal strength and without an effect on the endurance of the quadriceps and the hamstrin

**Heart Rate Index Prediction Of Maximal Oxygen Consumption In Pediatrics During The James Cycle Protocol**

Wayne A. Mays, Yvette M. Gerdes, Michelle A. Wolfe, Sandra K. Knecht, Randall P. Claytor, Timothy K. Knilans. *Cincinnati Children's Hospital Medical Center, Cincinnati, OH.*

(No relationships reported)

**PURPOSE:** To evaluate the utility of two versions of heart rate index (HRindex) based on supine and sitting resting heart rates as predictors of maximal oxygen consumption in pediatric patients with structurally normal hearts.

**METHODS:** We evaluated 637 pediatric patients (mean age 13.8 ± 3.2 years, 354 males) with maximal graded exercise testing utilizing the James cycle ergometer protocol. Two versions of HRindex were calculated by dividing the maximal heart rate by the heart rate (HR) in the resting supine (SupHRindex) and sitting (SitHRindex) positions. Predicted maximal METS (EstMMETS) was generated by the line equation of 6 times the maximal HRindex minus 5 using both the supine HR(SupEstMMETS) and the sitting HR (SitEstMMETS) .

**RESULTS:** Both SupHRindex and SitHRindex were significantly correlated to maximal oxygen consumption (MVO<sub>2</sub>) (r=0.45 and r=0.43, p<0.0005), maximal indexed oxygen consumption (MIVO<sub>2</sub>) (r=0.25 and r=0.31, p<0.0005) and maximal metabolic equivalents (MaxMETs) (r=0.25 and r=0.31, p<0.0005). There was a significant correlation between MaxMETs and SupEstMMETS and SitEstMMETS (10.4 ± 2.2 vs 11.1 ± 3.0 r=0.25, p<0.0005 and 10.4 ± 2.2 vs 9.3 ± 2.6 r=0.31, p<0.0005, respectively). However, the absolute values of MaxMETs versus SupEstMMETS and MaxMETs versus SitEstMMETS were significantly different (p<0.0005).

**DISCUSSION:** There was a significant correlation between HR index calculated using either the supine or sitting resting heart rate and MVO<sub>2</sub>, MIVO<sub>2</sub> and MaxMETs. However, the correlation was weak and provided little predictive value for MVO<sub>2</sub>, MIVO<sub>2</sub> and MaxMETs. This lack of predictive robustness was demonstrated by the significant difference seen in absolute values for MaxMETs compared to both SupEstMMETS and SitEstMMETS.

**CONCLUSION:** The predictive power of the heart rate index utilizing either the supine or sitting resting heart rate for the calculation is limited in pediatric patients. Future research should focus on a multivariable predictive model that identifies the sources of variability in the correlational relationship of heart rate index and maximal oxygen consumption.

### Ventilatory Efficiency Is Not Associated With Acsm Heart Disease Risk Factors In Asymptomatic Obese Adults

Michael R. Holly, Bryan L. Smith, Erik P. Kirk, Kevin S. Chapman, Lucas M. Novotny, Ryan D. Beaty, Heather E. Garrett, Jeffrey E. Herrick. *Southern Illinois University Edwardsville, Edwardsville, IL.*  
(No relationships reported)

Graded exercise tests (GXT) are administered to symptomatic heart failure patients as a diagnostic and prognostic assessment of mortality. GXT's provide an assessment of functional capacity ( $VO_{2peak}$ ) and ventilatory efficiency ( $V_E/VCO_2$  slope) and both outcomes are predictive of patient mortality. However, the  $V_E/VCO_2$  slope has been shown to be a stronger predictor than  $VO_{2peak}$  for heart disease severity. The American College of Sports Medicine (ACSM) has established several cardiovascular disease risk factors for determining the risk for cardiac disease in asymptomatic adults.

**PURPOSE:** This study evaluated the relationship between the  $V_E/VCO_2$  slope,  $VO_{2peak}$ , and the total ACSM heart disease risk factors in asymptomatic obese adults.

**METHODS:** 29 obese adults free of heart disease (Mean  $\pm$  SE; Age  $46.5 \pm 2.6$  years; BMI  $35.9 \pm 1.1$  kg/m<sup>2</sup>) were stratified into low (LR <2 risk factor) or moderate risk (MR  $\geq 2$  risk factors) using ACSM's Logic Model from self reported health history questionnaires. Each subject performed a treadmill GXT at a constant speed of 3.5 mph with 2.5% grade increase every 2 minutes. LR exercised to volitional fatigue and MR until achieving 6 METS, or 76% predicted heart rate maximum.  $V_E/VCO_2$  slope was determined as the rise in  $V_E$  (L·min<sup>-1</sup>·BTSP) to the increase in  $VCO_2$  (L·min<sup>-1</sup>·STPD) throughout the entire exercise session.

**RESULTS:** There were no significant differences in ventilatory efficiency between risk groups (LR  $30.9 \pm 0.9$ , MR  $28.6 \pm 1.4$   $V_E/VCO_2$  slope). There were group differences in  $VO_{2peak}$  (LR  $33.9 \pm 3.4$ , MR  $19.7 \pm 0.9$  ml·kg<sup>-1</sup>·min<sup>-1</sup>) and total risk factors (LR  $1.0 \pm 0.0$ , MR  $3.0 \pm 0.25$ ).  $V_E/VCO_2$  slope was not associated with total risk factors ( $p = 0.12$ ,  $r = -0.288$ ) or final risk category ( $p = 0.17$ ,  $r = -0.258$ ).  $VO_{2peak}$  was associated with total risk factors ( $p = 0.00$ ,  $r = -0.614$ ) and final risk category ( $p = 0.00$ ,  $r = -0.665$ ). Exercise test and exercise duration were not associated with  $V_E/VCO_2$  slope.

**CONCLUSIONS:** Ventilatory efficiency, which has been shown to predict severity of heart disease in symptomatic adults, was not associated with total ACSM heart disease risk factors in this group of asymptomatic obese adults. Our results suggest that  $VO_{2peak}$  is inversely related to heart disease risk in asymptomatic obese adults.

1309 Board #90 MAY 30 9:30 AM - 11:00 AM

### Classical End-criteria With Impact On Maximal Oxygen Uptake In A Population

Elisabeth Edvardsen, Bjørge Herman Hansen, Sigmund Alfred Anderssen. *Norwegian School of Sport Sciences, Oslo, Norway.*  
(No relationships reported)

During a maximal exercise test, the subjects' motivation and effort are important requirements to ensure valid and reliable results. Classical end criteria are a plateau in  $VO_2$ , high RER, HR, [blood lactate] and ratings of perceived exertion. However, there is currently no consensus for the assessment of maximal effort and different end criteria may have an impact of the results.

**PURPOSE:** to describe classical end criteria during a maximal progressive exercise test in a random sample of 20 - 85 year old population, and to explore if changes in end criteria have an impact on  $VO_{2max}$ .

**METHODS:** A sample of 839 individuals (412 women), with a mean age of 51.0 (SD  $\pm 14.8$ ) performed a progressive exercise test on a treadmill to voluntary exhaustion. Gas exchange, heart rate, [blood lactate] and BORG scale<sub>6,20</sub> was measured. A plateau in  $VO_2$  was defined by levelling off despite increase in ventilation at maximal power. Different end criteria were used to study the impact on  $VO_{2max}$ , such as RER  $\geq 1.15$  and [blood lactate]  $\geq 8$  mmol·L<sup>-1</sup>.

**RESULTS:** There were no sex related differences in HR<sub>max</sub>, RER or BORG scale, while the [blood lactate] was significantly lower in women. When using RER  $\geq 1.15$  and [blood lactate]  $\geq 8.0$  mmol·L<sup>-1</sup>,  $VO_{2max}$  increased on average by 4.5 % and 11 %, respectively, compared to using only voluntary exhaustion. Furthermore, a [blood lactate]  $\geq 8.0$  mmol·L<sup>-1</sup> excluded 65 % of the participants in the 50 - 85 year cohort (424 vs 148 respectively).

**CONCLUSIONS:** A range of typically end criteria are presented in a healthy population. Choice of end criteria during exercise testing will have an impact on  $VO_{2max}$ . This shows the importance of maximal effort to ensure valid and reliable results.

| End criteria variables after voluntary exhaustion in healthy men and women age 20-85 years |            |            |            |            |            |            |

### Maximal Strength Training Enhances Functional Performance in Chronic Stroke Patients

Tor Ivar Gjellesvik<sup>1</sup>, Tessa R. Hill<sup>2</sup>, Per Marius R. Moen<sup>2</sup>, Tom Tørhaug<sup>2</sup>, Marius S. Fimland<sup>2</sup>, Jan Helgerud<sup>2</sup>, Jan Hoff<sup>2</sup>. <sup>1</sup>St.Olav University Hospital, Trondheim, Norway. <sup>2</sup>Norwegian University of Science and Technology, Trondheim, Norway.  
(No relationships reported)

Physical impairment after stroke has been shown to have an immense impact on the reintegration of patients into society and can affect their quality of life. Muscle strength has been shown to be a significant contributor to physical disability (more than the loss of dexterity) after stroke. It is therefore assumed that by increasing a patient's muscle strength, functional everyday tasks will become easier.

**PURPOSE:** This study aimed to demonstrate that maximal strength training improves muscle strength, and to assess the effect on functional measures and walking economy amongst chronic stroke survivors.

**METHODS:** Baseline control trial. 10 patients acted as their own controls for 4 weeks, prior to an 8-week training intervention. Patients trained 3 days/week, 4 sets of 4 repetitions at 85-95% one repetition maximum in unilateral leg press and plantarflexion with an emphasis on maximal mobilization of force in the concentric phase.

**RESULTS:** Post training, leg press strength improved by 30.6kg (75%) and 17.8kg (86%), and plantarflexion strength by 35.5kg (89%) and 28.5kg (223%) for the unaffected and affected limbs respectively (all  $p=0.005$ ). The 6-minute walk test improved by 13.9m ( $p=0.007$ ) and the Timed Up and Go test time by 0.6 seconds ( $p=0.028$ ). No changes were observed in the control period. There were no significant changes in walking economy, peak aerobic capacity, Four square step test or health related quality of life post training.

**CONCLUSIONS:** Chronic stroke patients could benefit from maximal strength training as it generates large increases in strength and some improvements in functional measures.

1311 Board #92 MAY 30 9:30 AM - 11:00 AM

**Enhanced External Counter Pulsation Improves Endothelial Function in Patients With Left Ventricular Dysfunction**

Randy W. Braith, FACSM, Darren P. Casey, C R. Conti, Wilmer W. Nichols, Calvin Y. Choi, Matheen A. Khuddus, Darren T. Beck. *University of Florida, Gainesville, FL.*  
(No relationships reported)

**PURPOSE:** Enhanced external counterpulsation (EECP) improves arterial function, exercise tolerance, and angina symptoms in patients with coronary artery disease (CAD) and normal LV function. To date, however, studies have not elucidated the mechanism of action and the overall effects of EECP therapy in patients with LV dysfunction. The purpose of this study was to investigate the effects of EECP on endothelial function in peripheral muscular conduit arteries in patients with LV dysfunction.

**METHODS:** Patients with ischemic etiology of LV dysfunction (EF < 40%; n = 9), and age-matched patients with symptomatic CAD and normal LV function (n = 13), were studied after 35 1-hr sessions of EECP. Flow-mediated dilation of the brachial (bFMD) and femoral (fFMD) arteries was performed using high-resolution ultrasound imaging.

**RESULTS:** EECP treatment improved comparably (p > 0.05 between groups) the following FMD parameters in both the CAD and LV dysfunction groups, respectively: absolute bFMD (0.213 to 0.325 and 0.226 to 0.385 mm); relative bFMD (4.12 to 6.16 and 4.18 to 7.26 %); bFMD normalized for shear during the first 10 sec after cuff release (0.185 to 0.313 and 0.191 to 0.307 mm); absolute fFMD (0.198 to 0.264 and 0.194 to 0.226 mm); relative fFMD (2.77 to 3.66 and 2.73 to 3.19 %); fFMD normalized for shear (0.198 to 0.264 and 0.194 to 0.226 mm). EECP treatment also improved comparably (p > 0.05 between groups) plasma levels of the stable nitric oxide metabolites nitrate and nitrite (NOx) in both the CAD (19.4 to 30.1 μmol/L) and LV dysfunction (22.0 to 28.2 μmol/L) groups.

**CONCLUSIONS:** EECP treatment improves brachial and femoral artery endothelial function, and NOx levels similarly in patients with CAD possessing normal LV function and in patients with LV dysfunction. Our data suggest that peripheral vascular adaptations may be the specific mechanisms responsible for the beneficial clinical effects of EECP in patients with LV dysfunction.

1312 Board #93 MAY 30 9:30 AM - 11:00 AM

**Evidence Of Reverse Left Ventricular Remodelling Following Exercise Training In Post-Myocardial Infarction Patients.**

Gordon S. McGregor<sup>1</sup>, David C. Gaze<sup>2</sup>, Rob E. Shave<sup>3</sup>. <sup>1</sup>*UHCW NHS Trust, Coventry, United Kingdom.* <sup>2</sup>*St George's Healthcare NHS Trust, London, United Kingdom.* <sup>3</sup>*Cardiff Metropolitan University, Cardiff, United Kingdom.* (Sponsor: Keith George, FACSM)  
(No relationships reported)

Raised serum NT-proBNP concentration is indicative of hemodynamic compromise following myocardial infarction (MI) and also in chronic heart failure (CHF). A reduction in NT-proBNP is evidence of successful treatment and may also indicate reverse left ventricular (LV) remodelling. Cardiac rehabilitation exercise training has been shown to reduce NT-proBNP in CHF, however, the effect of exercise training on resting and peak exercise NT-proBNP is less well characterised in post MI patients.

**PURPOSE:** To determine the effect of exercise training on resting and peak exercise NT-proBNP in post MI patients following successful percutaneous coronary intervention (PCI).

**METHODS:** Cardiopulmonary exercise testing (CPET) was undertaken in 31 male (56±10 yrs) clinically stable post MI (33±7 days) patients prior to (CPET1) and following (CPET 2) 10 weeks of exercise training. NT-proBNP measurements were determined from serum samples obtained at rest and at peak exercise via a peripheral venous cannula. Mixed modality (treadmill, cycle, rower, cross-trainer) supervised exercise training was conducted for 30-40 minutes twice weekly at 60-80% of VO<sub>2</sub> peak.

**RESULTS:** VO<sub>2</sub> peak significantly improved (3.1±2.6 ml.kg<sup>-1</sup>.min<sup>-1</sup>, P<0.0001) following 10 weeks of exercise training. Resting and peak NT-proBNP were significantly reduced by 178±419 ng/L (P<0.01) and 202±384 ng/L (P<0.001) respectively. NT-proBNP increased significantly (49±97 ng/L, P<0.001) from rest to peak exercise on CPET 1 but not on CPET 2 (25±77 ng/L, P>0.05) despite a greater exercise stimulus (147±26 vs 171±28 Watts, P<0.0001).

**CONCLUSION:** Consistent with findings in the HF population, exercise training improves VO<sub>2</sub> peak and lowers resting plasma NT-proBNP concentration in post MI patients. Furthermore, peak exercise NT-proBNP concentration is reduced. These reductions may potentially indicate reverse LV remodelling secondary to exercise training. However confirmation of this is required.

1313 Board #94 MAY 30 9:30 AM - 11:00 AM

**Improvement in Exercise Capacity after Cardiac Rehabilitation is Independent of Ejection Fraction in Patients With Coronary Heart Disease**

Aashish S. Contractor, Shraddha M. Khialani, Hetal D. Poptani, Anjali S. Zende, Priyanka M. Mehta. *Asian Heart Institute, Mumbai, India.*  
(No relationships reported)

**PURPOSE:** A low ejection fraction (EF- <35%) risk stratifies an individual in the high risk category for cardiac events. It is a wide spread belief that these patients should not engage in intense physical activity. The objective of this study is to determine safety and efficacy of exercise training in coronary heart disease patients (CHD) with low EF, and to evaluate whether cardiac rehabilitation (CR) outcomes differ in patients with normal or reduced EF.

**METHODS:** 454 patients who were diagnosed to have CHD and enrolled for a 4 week CR program at the Asian Heart Institute; Mumbai formed a part of this study. Based on the EF at enrolment patients were divided into three groups: EF (>55%- 240 patients), EF (35%-54% -154 patients) and EF <35%-60 patients. Exercise capacity was determined using the 6 minute walk test at baseline. Patients exercised under telemetry supervision for 13 sessions over 4 weeks. Exercise was prescribed at 60%- 80% of predicted maximum heart rate and a rating of perceived exertion of 11-13 on Borg's Scale. After 4 weeks the 6 minute walk test was repeated.

**RESULTS:** During the training period there were no adverse events reported. The results are tabulated as follows:

| EF      | 6 Minute    | Walk        | Distance    | (meters) | p value |
|---------|-------------|-------------|-------------|----------|---------|
|         | Pre-CR      | Post-CR     | Change      | %Change  |         |
| <35%    | 316.4±/58   | 401±/59.7   | 83±/32.3    | 20.7     | 0.0005  |
| 35%-55% | 306.2±/70.2 | 394.4±/76   | 87±/37.2    | 22.1     | 0.0005  |
| >55%    | 320.6±/75   | 405.2±/70.7 | 84.52±/48.5 | 21       | 0.0005  |

On comparing the change in the distance covered, no significant difference (p=0.694) was found between the three groups, indicating that improvement in the exercise capacity is independent of the EF.

**CONCLUSIONS:** Low EF patients with CHD can safely participate in a medically supervised exercise program and experience significant gains in exercise capacity equivalent to those with normal EF.

1314 Board #95 MAY 30 9:30 AM - 11:00 AM

**Enhanced External Counter Pulsation Improves Exercise Capacity in Patients With Left Ventricular Dysfunction**

Joseph C. Avery, Darren T. Beck, Darren P. Casey, C R. Conti, Wilmer W. Nichols, Calvin Y. Choi, Matheen A. Khuddus, Randy W. Braith, FACSM. *University of Florida, Gainesville, FL.*  
(No relationships reported)

**PURPOSE:** Enhanced external counterpulsation (EECP) improves peak oxygen uptake (VO<sub>2peak</sub>) and exercise time to angina symptoms in patients with coronary artery disease (CAD) and normal LV function. However, the efficacy of EECP in patients with LV dysfunction remains controversial. The purpose of this study was to investigate the effects of EECP on VO<sub>2peak</sub> and exercise time to angina symptoms in patients with LV dysfunction.

**METHODS:** Patients with ischemic etiology of LV dysfunction (EF < 40%; n = 9), and age-matched patients with symptomatic CAD and normal LV function (n = 13), performed symptom-limited treadmill tests using a modified Naughton protocol and metabolic cart to determine VO<sub>2peak</sub> before and after 35 1-hr sessions of EECP.

**RESULTS:** EECP treatment improved comparably (p > 0.05 between groups) the following exercise parameters in both the CAD and LV dysfunction groups, respectively: VO<sub>2peak</sub> (17.0 to 19.8 and 13.9 to 16.3 ml/kg/min); total exercise time (615 to 813 and 493 to 659 sec); exercise time to angina (421 to 686 and 345 to 528 sec); peak heart rate (112 to 116 and 113 to 118 beats per min); peak subjective angina rating (2.8 to 1.7 and 1.8 to 1.5). EECP treatment also improved comparably (p > 0.05 between groups) the Canadian Cardiovascular Society (CCS) angina classifications in both the CAD (3.17 to 1.17) and LV dysfunction (3.14 to 1.29) groups.

**CONCLUSIONS:** EECP treatment improves VO<sub>2peak</sub>, total exercise time, exercise time to angina, and CCS angina classification to the same magnitude in patients with CAD possessing normal LV function and in patients with LV dysfunction. Our data indicate that EECP serves as 'passive exercise' and may be a useful intervention in individual patients with LV dysfunction who are poor candidates for aerobic exercise training.

---

1315 Board #96 MAY 30 9:30 AM - 11:00 AM

**Field versus Laboratory Tests: Exercise Capacity Estimates in Elderly Patients with Coronary Artery Disease**

Sandra Mandic<sup>1</sup>, Rob Walker<sup>1</sup>, Emily Stevens<sup>1</sup>, Bridget McIlraith<sup>1</sup>, Sarah Featherston<sup>1</sup>, Edwin R. Nye<sup>1</sup>, Dianne Body<sup>2</sup>, Leanne Barclay<sup>2</sup>, Michael J A Williams<sup>1</sup>.

<sup>1</sup>University of Otago, Dunedin, New Zealand. <sup>2</sup>Dunedin Public Hospital, Dunedin, New Zealand. (Sponsor: Jonathan Myers, FACSM)

(No relationships reported)

Compared to conventional laboratory exercise tests, timed walking tests are cheaper and a more simple alternative for an assessment of exercise capacity in cardiac rehabilitation participants. It remains unknown whether these tests provide an adequate estimate of peak oxygen consumption (VO<sub>2peak</sub>) in elderly individuals with coronary artery disease (CAD).

**PURPOSE:** To compare measured VO<sub>2peak</sub> during symptom-limited exercise testing versus estimated VO<sub>2peak</sub> derived from 6-minute walk test and incremental shuttle walk test in elderly CAD patients.

**METHODS:** Fifty-one elderly individuals with CAD (age: 73±6 years (range: 60 to 89), 16 (31%) women) completed the following assessments: 1) symptom-limited graded exercise test with expired gas analysis on a cycle ergometer using a ramp protocol; 2) incremental 10-meter shuttle walk test and 3) two 6-minute walk tests. VO<sub>2peak</sub> was estimated based on maximal walking speed (shuttle walk test) and distance, age, height, weight and rate pressure product (6-minute walk test) using published equations. Data were analysed using Pearson Product Moment correlation and paired t-test.

**RESULTS:** Measured VO<sub>2peak</sub> obtained during symptom-limited exercise test was significantly related to distance covered during 6-minute walk test (r=0.71, p<0.001) and duration of the incremental shuttle walk test (r=0.75, p<0.001). Estimated VO<sub>2peak</sub> based on 6-minute walk test data (16.0±4.4 ml/kg/min) and maximum walking speed achieved during shuttle walk test (14.7±1.9 ml/kg/min) were significantly lower compared to VO<sub>2peak</sub> measured during a symptom-limited exercise test (19.9±0.7 ml/kg/min; p<0.001 for both comparisons).

**CONCLUSIONS:** Distance covered during 6-minute walk test and duration of incremental shuttle walk test can be used for an assessment of functional capacity and monitoring of cardiac rehabilitation progress in elderly CAD patients. Estimation of VO<sub>2peak</sub> based on these tests underestimates exercise capacity in elderly CAD patients.

**Coronary CT In Asymptomatic Subjects With Ventricular Repolarization Abnormalities During Maximal Exercise Test**

Andrea Ermolao, Fausto Roman, Andrea Gasperetti, Maurizio Varnier, Eleonora Zanella, Marco Zaccaria. *Università di Padova, Padova, Italy.*

(No relationships reported)

Specific data are still lacking about the significance of repolarization abnormalities observed during exercise test in physically active asymptomatic subjects. Coronary CT is a highly sensitive diagnostic procedure able to confirm or exclude a significant coronary artery disease (CAD).

**PURPOSE:** To evaluate if the occurrence in asymptomatic subjects of ECG repolarization abnormalities potentially suggesting a CAD, is confirmed by coronary CT. Further, clarify if the likelihood of detecting CAD or coronary anomalies was related to the degree of the ECG abnormalities and to the prevalence of cardiovascular risk factors.

**METHODS:** Among 940 athletes performing a maximal exercise test for sport eligibility (age 30-60yrs), 44 asymptomatic subjects (4,7%, 39 men and 5 females, 45,2±7,1yrs) demonstrated repolarization abnormalities requiring the completion of a coronary CT. The exercise tests were classified into two categories: suspicious and positive for CAD.

**RESULTS:** The average maximal heart rate at exhaustion was 170,4±11,9. Risk factors evaluation demonstrated 10 subjects with hypertension, 23 subjects with hypercholesterolemia, 5 smokers. Among the 44 subjects 23 had a suspicious while 21 had a positive exercise test. The coronary CT demonstrated 6 subjects (13,6%) with a clinically significant CAD, 8 non-significant CAD, while 7 showed various coronary abnormalities. Considering the coronary CT as "gold standard", the positive predictive value (PPV) of the exercise test for any coronary anomaly was 61,9% for positive exercise tests (47,7% including suspicious tests), while the PPV of positive tests for CAD was 47,6% (31,8% including suspicious tests). The association of late recovery abnormalities and cardiovascular risk factors improved the likelihood of CAD.

**CONCLUSION:** Our data suggest the clinical importance of slight repolarization abnormalities occurring at the peak of the exercise in asymptomatic middle-aged athletes, particularly when associated with the presence of cardiovascular risk factors. They also support the importance of a prolonged ECG monitoring during the late recovery phase. The PPV of a maximal exercise test in asymptomatic athletes appears lower than what observed in symptomatic subjects, however, about half of these subjects demonstrated some coronary anomalies.

1317 Board #98 MAY 30 9:30 AM - 11:00 AM

**Effects of Exercise Training on Objectively Measured Physical Activity Levels in Heart Failure Patients**

Daniel Clevenger, Peter H. Brubaker, FACSM, Joel Eggebeen, Dalane W. Kitzman. *Wake Forest University, Winston-Salem, NC.*

(No relationships reported)

Physical activity (PA) levels have not been quantified in the heart failure population, particularly heart failure patients with a preserved ejection fraction (HFpEF).

**PURPOSE:** To objectively measure PA in HFpEF patients and evaluate changes in levels after structured exercise training and weight loss interventions.

**METHODS:** Participants of this investigation were assessed at baseline and follow-up to an RCT of exercise and/or weight loss in HFpEF patients. Participants were randomized to one of four intervention groups for 20 weeks: Exercise Only (EO), Diet Only (DO), Exercise plus Diet (E+D), or Attention Control (AC). Participants were asked to wear an accelerometer for 7 continuous days at baseline and then again during the final week of the intervention. The data was included if the participant wore the accelerometer for > 10 hours, of which included activity > 80% of the wear time, and had > 3 days of activity recorded. Each participant's average steps/day, daily physical activity energy expenditure (PAEE) in kcal/min, minutes of light physical activity (LPA), and minutes of moderate/vigorous physical activity (MVPA) were analyzed.

**RESULTS:** Thirty-five subjects (77% female) with average age of 68.5±5.9 were included in the analysis. There were a significantly more steps per day in the E+D group compared to the AC group (6761 ± 2174 vs. 4052 ± 1083, respectively). There was a significant difference between the E+D, EO, DO, and AC, at follow-up for minutes of MVPA (31.0 ± 11.1, 11.6 ± 10.7, 14.2 ± 8.4, 9.9 ± 5.1, min/day respectively). There was also a significant difference for PAEE between the E+D and DO groups (280 ± 95 vs. 151 ± 52 kcal/day, respectively).

**CONCLUSIONS:** HFpEF patients randomized to the E+D group had significantly more minutes of MVPA compared to all of the other intervention groups and significantly greater number of steps/day than AC and more PAEE than DO. It appears that the weight loss, secondary to E+D, results in greater amounts of PA than EO and DO interventions for older HFpEF patients.

**1318** Board #99 MAY 30 9:30 AM - 11:00 AM  
**Safety Of Cardiopulmonary Stress Testing In Patients With A Broad Range Of Cardiovascular Disorders**

Erin West, Lora Raines, Daniel Forman, MD. *Brigham & Women's Hospital, Boston, MA.*  
(No relationships reported)

**PURPOSE:** While cardiopulmonary stress testing (CPX) has been well evaluated in heart failure patients, the utility and safety of these tests are not as well defined in other high-risk cardiovascular populations. The purpose of this study was to identify the rate of adverse outcomes during symptom limited CPX tests in a population of cardiovascular patients with a broad range of diagnoses.

**METHODS:** A retrospective data review was performed for CPX tests performed between July 2007 and July 2009. Patients with known cardiovascular disorders at the time of testing were included in the analysis. Peak functional capacity ( $\text{VO}_2$ ), peak respiratory exchange ratio (RER), and reason for test termination were collected. Adverse outcomes included significant hemodynamic abnormalities, arrhythmias, or ischemic changes.

**RESULTS:** The study population consisted of 815 patients (68% male) with the following cardiovascular diagnoses: dilated cardiomyopathy (41.8%), prior cardiac transplantation (25.2%), ischemic cardiomyopathy (12.3%), congenital/structural heart disease (3.9%), prior pulmonary embolism (3.4%), heart failure with preserved ejection fraction (2.9%), hypertrophic cardiomyopathy (1.8%), restrictive cardiomyopathy (1.7%), valvular disease (1.8%), and other cardiovascular disorders (5%). Mean peak  $\text{VO}_2$  was 15.9 ml/kg/min at a mean peak RER of 1.16. Eighty-three percent of patients achieved a peak RER  $\geq 1.05$ . Thirty-seven tests were terminated prematurely by the supervising exercise physiologist for the following reasons: hypotensive response (1.7%), hypertensive response (1.2%), and significant arrhythmia (1.6%). No myocardial infarctions, cardiac arrests, or deaths occurred.

**CONCLUSIONS:** Even amongst a population of patients with significant cardiovascular disorders, symptom limited CPX tests can be performed in a safe and effective manner with proper screening and test supervision.

**1319** Board #100 MAY 30 9:30 AM - 11:00 AM  
**Differences In Using The Same Supramaximal Verification Test Protocol For Treadmill And Cycle Ergometry**

Christoph Otto<sup>1</sup>, Friederike Scharhag-Rosenberger<sup>2</sup>, Anja Carlssohn<sup>1</sup>, Jürgen Scharhag, FACSM<sup>3</sup>, Frank Mayer<sup>1</sup>. <sup>1</sup>Potsdam University, Potsdam, Germany. <sup>2</sup>University of Applied Science for Prevention and Health Management, Saarbrücken, Germany. <sup>3</sup>University Hospital, Heidelberg, Germany.  
(No relationships reported)

Verification testing to validate maximum oxygen uptake ( $\text{VO}_{2\text{max}}$ ) is used increasingly in performance testing. Different verification test protocols are applied at different points of time after incremental tests.

**PURPOSE:** The aim of this study was to examine whether there are substantial differences in using the same verification test protocol for treadmill and cycle ergometry. Furthermore, verification tests subsequent to incremental tests and on separate days should be compared.

**METHODS:** 10 recreational runners ( $f=4$ ,  $m=6$ ,  $29 \pm 6$  y,  $1.74 \pm 0.06$  m,  $66 \pm 7$  kg,  $\text{VO}_{2\text{max}}$ :  $62 \pm 6$  ml/min/kg) and 10 male recreational cyclists ( $31 \pm 5$  y,  $1.82 \pm 0.05$  m,  $75 \pm 9$  kg,  $\text{VO}_{2\text{max}}$ :  $62 \pm 5$  ml/min/kg) underwent an incremental exercise test to exhaustion (E) either on the treadmill or the bicycle ergometer. After 10 min of rest a first verification test at 110% of  $\text{V}_{\text{max}}$  or  $\text{P}_{\text{max}}$  ( $\text{V}_1$ ) was performed to exhaustion. 24h later a second verification test ( $\text{V}_2$ ) similar to  $\text{V}_1$  followed. Breath by breath gas exchange data were measured continuously. Capillary blood samples were collected at the end of each stage and at the point of exhaustion. Differences in E,  $\text{V}_1$  and  $\text{V}_2$  were tested by using ANOVA for repeated measures.

**RESULTS:** Runners'  $\text{VO}_{2\text{max}}$  (E:  $62 \pm 6$  ml/min/kg,  $\text{V}_1$ :  $61 \pm 7$  ml/min/kg,  $\text{V}_2$ :  $60 \pm 6$  ml/min/kg) was not significantly different between E and  $\text{V}_1$ , while  $\text{V}_2$  was significantly lower than E ( $p<0.01$ ). There was no statistically significant difference in the runners' time to exhaustion (TTE;  $\text{V}_1$ :  $01:55 \pm 00:15$  min,  $\text{V}_2$ :  $02:05 \pm 00:30$  min). Cyclists'  $\text{VO}_{2\text{max}}$  (E:  $62 \pm 5$  ml/min/kg,  $\text{V}_1$ :  $61 \pm 6$  ml/min/kg,  $\text{V}_2$ :  $63 \pm 4$  ml/min/kg) was significantly lower in  $\text{V}_1$  than in E ( $p<0.05$ ) but there was no difference between E and  $\text{V}_2$ . Cyclists' TTE was significantly longer in  $\text{V}_2$  than in  $\text{V}_1$  ( $\text{V}_1$ :  $02:24 \pm 00:20$  min,  $\text{V}_2$ :  $03:23 \pm 00:25$  min,  $p<0.01$ ). TTE was significantly longer in cyclists than in runners in  $\text{V}_1$  and  $\text{V}_2$  ( $p<0.01$ ).

**CONCLUSION:** For recreational athletes, the time of verification testing seems less important since the observed differences in  $\text{VO}_{2\text{max}}$  were irrelevantly small. Therefore, verification tests can be performed directly after incremental tests to ensure validity of maximum values. Due to the longer TTE in cyclists it seems needful to examine different test protocols for different exercise modes.

**A-32** Free Communication/Poster - Diet and Exercise Interventions: Impact on Energy Balance

MAY 30, 2012 7:30 AM - 12:30 PM  
ROOM: Exhibit Hall

**1320** Board #101 MAY 30 11:00 AM - 12:30 PM  
**The Effect Of 2 Weeks Of Night Eating Restriction: A Randomized And Counter-balanced Study**

Ed Christensen, Bruce W. Bailey, Larry A. Tucker, FACSM, James D. LeCheminant, FACSM. *Brigham Young University, Provo, UT.*  
(No relationships reported)

**PURPOSE:** This study examined the effects of two weeks of night eating restriction on energy intake and body weight in young adult men.

**METHODS:** Eleven college-aged men were randomized to two weeks of normal eating (NE) and two weeks of night eating restriction (NER) in a counter-balanced fashion. There was a one week wash-out period between conditions. During NE, participants were asked to consume their normal diet, ad libitum. During NER, participants were asked to avoid all eating or kcal consumption from 7pm-6am but there were no restrictions on type or amount of food/beverage consumed. To assess diet, participants were asked to complete three randomly assigned dietary recalls during each week of the study. The National Cancer Institute's Automated Self-administered 24-hour Dietary Recall (ASA24) was used to collect and analyze energy and macronutrient intake. Body weight was measured using a digital scale before and after each condition (NE and NER). All participants were screened and excluded for Night Eating Syndrome.

**RESULTS:** During NE, participants consumed  $2,497 \pm 514$  kcal/d and during NER  $2,115 \pm 269$  kcal/d ( $F=7.89$ ;  $P=0.019$ ). Dietary fat intake during NE was  $105 \pm 27$  g/d and during NER was  $86 \pm 15$  g/d ( $F=7.05$ ;  $P=0.024$ ). Carbohydrate intake during NE was  $299 \pm 67$  g/d and during NER was  $258 \pm 64$  g/d ( $F=7.05$ ;  $P=0.024$ ). There were no differences between the two conditions in protein, alcohol, or fiber intake ( $P>0.05$ ). Body weight change during NE was  $0.81 \pm 0.87$  and during NER was  $-0.53 \pm 0.120$  ( $F=13.09$ ;  $P=0.005$ ). Additional data collection is ongoing.

**CONCLUSIONS:** Restricting energy intake after 7pm may result in lower energy intake and potentially better short-term weight management than not limiting night eating. The difference in energy intake resulted from lower fat and carbohydrate intake during NER.

**1321** Board #102 MAY 30 11:00 AM - 12:30 PM  
**Short Term Energy-Restricted Diets Improve Weight and Fat Loss Compared to Resistance Training**

Elizabeth J. Sussman, Carol S. Johnston, Pamela D. Swan, FACSM. *Arizona State University, Phoenix, AZ.* (Sponsor: Pamela D. Swan, FACSM)  
(No relationships reported)

Both energy expenditure and energy restriction are recommended for weight loss in obese populations.

**PURPOSE** This study examined the effects of energy restrictive diets (either high protein/low carbohydrate or high carbohydrate/low fat) or a resistance exercise training regimen on body weight, fat percentage and fasting resting metabolic rate (RMR) over a six week intervention.

**METHODS** Healthy adults ( $n = 25$ ), stratified by age (mean =  $37 \pm 11.5$  y), gender (4 M), and BMI (mean =  $29.6 \pm 5.6$  kg/m<sup>2</sup>), were randomly assigned to one of three groups: high protein (30% energy), low fat diet (PRO); high carbohydrate (60% energy), low fat diet (CHO); or resistance exercise training (EX). All foods consumed by the diet groups were prepared in a metabolic

kitchen and designed to achieve a 1-2 pound weight loss per week. The EX group followed their usual diet but attended three supervised weight training sessions per week. EX was comprised of eight exercises over 45 minutes designed to achieve similar calorie deficit as that computed for the diet groups. Body composition was assessed by bioelectrical impedance and RMR was measured during 40 minutes of supine rest in a fasted state following 24 hours of no exercise. Changes in body weight, RMR and %fat between groups were analyzed using ANOVA.

**RESULTS** There were no differences between groups at baseline. Change in body weight and %fat was significantly improved ( $p < 0.001$ ) for the PRO and CHO groups as compared to EX (Wt: -5.9%, -6.2%, -0.5%; Fat: -3.5%, -5.3%, + 1.2% respectively). There were no significant changes in RMR for any group.

**CONCLUSION** An energy-restricted caloric deficit produces greater weight loss and greater body fat loss in six weeks when compared to a resistance training exercise program inducing the same caloric deficit. It is possible that the EX group increased caloric intake during the intervention. Follow up is necessary to establish the long-term efficacy of these programs.

**Optimizing Fat Oxidation in Untrained Women: The Competing Indices of Fitness versus Fat Loss**

Harold C. Mayer, Deborah A. Beihl. *Southern Adventist University, Collegedale, TN.*

(No relationships reported)

Arresting the obesity epidemic is a high priority public health issue. This study explores factors affecting fat oxidation and resting metabolism in untrained overweight/obese women.

**PURPOSE:** The objective of this research was to explore the effects of a high fiber diet (*The Full Plate Diet* [FPD]) and exercise on resting metabolism, weight loss, and percent body fat loss.

**METHODS:** Overweight/obese (BMI between 25 -39), sedentary women (n=20) were recruited with a fiber intake <30g/day. Participants were randomized into three groups and followed for 8 weeks: FPD alone (FPD); FPD + continuous heart rate exercise (FPD+conEx); FPD + variable heart rate exercise (FPD+varEx). Pre- and post-study assessments included dietary analysis, resting metabolic rate,  $VO_2$  max treadmill test, and hydrostatic weight.

**RESULTS:** The high fiber FPD (consisting of 40 grams of whole food fiber daily) alone improved energy balance (from +339 to -226 kcals) without counting calories, but was inadequate to achieve fat (or weight) loss in the 8 weeks. The FPD+conEx group (training intensity  $56.8\% \pm 14.1$  verified via Polar heart rate monitors) saw a significant drop in (health measure) percent body fat (35.3% to 31.3%,  $p=.03$ ), but no significant change in weight or (fitness measure)  $VO_2$ max. The FPD+varEx group (training intensity =  $67.7\% \pm 5.8$  verified via Polar heart rate monitors) saw a significant drop in weight (3.7 lbs,  $p=.03$ ) and significant improvement in fitness measure Relative  $VO_2$  max (20.8 to 24.1,  $p=0.016$ ) and Absolute  $VO_2$  max (1.94 to 2.20,  $p=0.03$ ), but no significant drop in percent body fat (39.9% to 38.2%,  $p=0.06$ ). No group showed a statistically significant metabolic efficiency change in resting metabolic rate (RMR).

**CONCLUSION:** The Full Plate Diet helped participants to regulate energy balance without counting calories by reducing caloric intake, so they were more aligned with the resting energy expenditure (REE). Both increased fiber intake and low intensity exercise appear to be necessary to reduce percent body fat in untrained, overweight/obese participants. In fact, it appears that there is an inverse relationship between increased fitness and increased fat oxidation. Further research in a larger population over a longer period of time is needed to clarify this competing health - fitness relationship.

**1323** Board #104 MAY 30 11:00 AM - 12:30 PM

**Physiological and Psychosocial Benefits Associated with Weight Loss Programs: Changes in Body Weight, Social Physique Anxiety, and Exercise Enjoyment**

Lynn A. Darby, FACSM<sup>1</sup>, Bonnie G. Berger<sup>1</sup>, Rob A. Carels<sup>1</sup>, Roberta L. Pohlman<sup>2</sup>. <sup>1</sup>Bowling Green State University, Bowling Green, OH. <sup>2</sup>Wright State University, Dayton, OH.

(No relationships reported)

Weight loss has been correlated with changes in social psychic anxiety (SPA) and exercise enjoyment (PACES) after a behavioral weight loss program (BWLP) (Darby, Berger & Carels, 2011).

**PURPOSE:** To further explore relationships among psychophysiological variables and to assess changes from before to after two different weight loss programs.

**METHODS:** Thirty-six participants who were overweight or obese completed anthropometric assessments [visceral adipose tissue (VAT) determined from sagittal abdominal diameter (SAD) (Parr & Haight, 2006)], physiological tests (submax walking GXTs), and dietary and activity (accelerometer) reports. They also completed the psychological inventories of the PACES (Physical Activity Enjoyment Scale; Kendzierski & DeCarlo, 1991) and SPA (Social Physique Anxiety; Hart, Leary, & Rejeski, 1989). All measures were completed before and after weight loss programs (BWLP *LEARN*, Brownell, 2004 or *Transforming Your Life* (TYL), Carels et al., 2011).

**RESULTS:** Completers included 10 men and 26 women (Age =  $49 \pm 12$  yr). Body weight (BW), VAT, BMI, GXT time were significantly different ( $p < 0.05$ ) after 14-weeks. Mean scores pre- and post-program were as follows: BW ( $98.1 \pm 17.5$ ,  $93.3 \pm 18.2$  kg), VAT ( $10.6 \pm 2.5$ ,  $8.6 \pm 2.5$  lb), BMI ( $34.7 \pm 5.6$ ,  $32.3 \pm 5.6$  kg/m<sup>2</sup>), and GXT time ( $563 \pm 216$ ,  $673 \pm 216$  sec). Two-way ANOVAs (Time by Type of Program) indicated desirable changes in exercise enjoyment and social physique anxiety. Scores pre- and post-program were as follows: PACES ( $88.8 \pm 16.9$ ,  $97.7 \pm 14.1$ ), and SPA ( $41.8 \pm 8.4$ ,  $37.6 \pm 8.7$ ). There were no differences in PACES or SPA due to type of program, or sex. Not only did the PACES increase from beginning to end of the programs, pre- and post-values were significantly correlated with self-monitored average daily physical activity in minutes ( $r=.421$ ,  $p=.02$ ;  $r=.440$ ,  $p=.01$ ). Therefore, with participation in physical activity during the programs, there was a significant increase in exercise enjoyment and a decrease in anxiety. SPA scores at the beginning of the program were positively correlated with average energy intake during the program, however, lower SPA scores at the end of the program were not.

**CONCLUSION:** Weight loss programs, regardless of type, are associated with both desirable physiological and psychological changes.

**1324** Board #105 MAY 30 11:00 AM - 12:30 PM

**Weight Loss Induced by Exercise Preserves Resting Metabolic Rate: Midwest Exercise Trial II (MET II)**

Jeffery J. Honas<sup>1</sup>, Richard A. Washburn, FACSM<sup>1</sup>, Stephen D. Hermann<sup>1</sup>, Kate Lambourne<sup>1</sup>, Jaehoon Lee<sup>2</sup>, Joseph E. Donnelly, FACSM<sup>1</sup>. <sup>1</sup>University of Kansas Medical Center, Kansas City, KS. <sup>2</sup>University of Kansas, Lawrence, KS.

(No relationships reported)

Weight loss resulting from decreased energy intake has been associated with decreases in resting metabolic rate (RMR). The RMR response to weight loss by exercise without energy restriction is unclear. The inconsistent results on the effect of exercise induced weight loss on RMR may be due, in part, to variability in length, intensity, duration, and the level of supervision/verification of the exercise intervention.

**PURPOSE:** To evaluate the impact of weight loss induced by 2 levels of exercise energy expenditure (EEEx) on RMR.

**METHODS:** 91 sedentary, overweight/obese (BMI 25-39.9) young adults (18-30 yrs.; 55% female), were randomized to either 2,000 (N=36) or 3,000 (N=37) kcal/wk. of supervised treadmill exercise at 70-80% max heart rate (HR), or to a sedentary control group (N=18) for 10 mos. Participants were instructed not to alter energy intake. Exercise was progressed slowly in both exercise groups with participants reaching their target level at the end of mo. 4. The intensity and duration of all exercise sessions were verified by HR monitor. EEEx was assessed monthly by indirect calorimetry. RMR was assessed by indirect calorimetry at baseline and 10 mos. between the hrs. of 6-9 am, after a 12 hr. fast, and no exercise for 48 hrs.

**RESULTS:** Exercise at both 2000 or 3000 kcals/wk. resulted in clinically significant weight loss (2000 = - 4.2%, 3000 = - 5.3%) compared to the control group (+ 0.3%). Despite clinically significant weight loss, there were no significant decreases in RMR within or between exercise groups (2000 = -1.0%, 3000 = -1.6%;  $p=0.81$ ) or between exercise and control (Exercise = - 1.3%, Control = +1.1%;  $p=0.48$ ). The RMR response to exercise did not differ by gender ( $p=0.76$ ).

**CONCLUSIONS:** Weight loss induced by exercise without energy restriction prevents the decreases in RMR typically associated with weight loss by energy restriction alone. These results suggest that exercise may be the preferable mode of weight loss for the prevention of weight regain.

1325 Board #106 MAY 30 11:00 AM - 12:30 PM

**Self-reported Diet And Exercise Are Similar in Clinic And Phone Based Interventions**

Kate Lambourne, Stephen D. Herrmann, Jeffrey J. Honas, Richard A. Washburn, FACSM, Joseph E. Donnelly, FACSM. *University of Kansas Medical Center, Kansas City, KS.*  
(No relationships reported)

Self-monitoring is a crucial component of diet and exercise interventions and has been associated with greater amounts of weight loss. It is not known whether self-monitoring data reported for diet and exercise are different when participants are not seen directly by a health educator, such as in a phone-based intervention.

**PURPOSE:** To compare self-reported use of pre-packaged meals (PMs-shakes/entrees), fruit and vegetable (F/V) consumption, and physical activity (minutes, pedometer steps/day) between individuals receiving a group-based intervention delivered face-to-face (FTF) or by conference call, and to determine if these measures are predictive of weight loss.

**METHODS:** 395 overweight and obese adults (BMI 25-39.9, age 18-65) were randomly assigned to a 6-month weight loss intervention delivered by conference call or FTF clinic. The intervention targeted 300 min/week of moderate-to-vigorous exercise and 10,000 steps/day. Energy intake was reduced to ~1,200-1,500 kcal/day using PMs and F/V. Participants in both groups attended weekly clinics consisting of lessons on exercise, nutrition, and lifestyle modification. T-tests compared differences in the self-reported diet and exercise data between the phone and FTF groups. A regression analysis examined whether self-reported diet and physical activity data predicted weight loss after controlling for baseline weight and sex among the participants who completed the intervention.

**RESULTS:** No significant differences were observed in the self-reported diet and physical activity data between the phone and FTF group ( $p > 0.05$  for all comparisons). The number of pre-packaged shakes used ( $M = 2.6$ ,  $SD = 0.34$ ) and number of steps/day ( $M = 8485$ ,  $SD = 2508$ ) were significant predictors of weight loss ( $\beta = 0.14$ ,  $p = 0.02$ ;  $\beta = 0.17$ ,  $p < 0.01$ , respectively;  $R^2 = 0.28$ ). The reported number of pre-packaged entrees, F/V, and minutes of physical activity were not significant predictors of weight loss.

**CONCLUSION:** Changes in self-reported diet and physical activity were similar between weight loss interventions delivered FTF or by conference call. The use of pre-packaged shakes and a pedometer to monitor physical activity resulted in greater weight loss, independent of the clinic delivery method.

Supported by NIH DK076063 and Health Management Resources, Boston, MA.

1326 Board #107 MAY 30 11:00 AM - 12:30 PM

**Exercise Adherence By Energy Expenditure Level: Midwest Exercise Trial II (MET II)**

Stephen D. Herrmann, Jeffrey J. Honas, Richard A. Washburn, FACSM, Kate Lambourne, Joseph E. Donnelly, FACSM. *University of Kansas Medical Center, Kansas City, KS.*  
(No relationships reported)

The current ACSM position stand on exercise and weight management recommends > 250 min/wk. of moderate intensity physical activity (~1250-2450 kcal/wk. for a 100 kg individual at 3.0-5.9 METs) to achieve clinically significant weight loss. However, higher levels of exercise energy expenditure (EEEx) may have an adverse impact on adherence to an exercise protocol, and thus diminish the practicality of exercise recommendations for weight loss.

**PURPOSE:** To assess the effect of two levels of EEEx on adherence to 10 months of supervised exercise in sedentary, overweight/obese young adults.

**METHODS:** 115 sedentary, overweight/obese (BMI 25-39.9) young adults (18-30 yrs.; 55% female), were randomized to either 2,000 (N=53; 31 females) or 3,000 (N=62; 32 females) kcal/wk. of treadmill exercise at 70-80% max heart rate (HR), 5 days/wk. (supervised  $\geq 4$  days/wk.) over 10 months. Exercise was progressed slowly with participants reaching their target level at the end of month 4. EEEx was assessed monthly by indirect calorimetry to guide exercise prescription. The intensity and duration of all exercise sessions were verified by HR monitor. Compliance was assessed at 3 month intervals and defined as completing > 90% of scheduled exercise sessions at the target intensity and duration. Individuals falling below 90% compliance were dismissed from the study. Participants received \$2,000 at study completion.

**RESULTS:** Overall, 64.3% of the sample completed the study per protocol. The majority of attrition (> 95%;  $n = 39$ ) occurred during months 1-6. Those completing the study did not differ by EEEx (2,000 kcal/wk. = 69.8%, 3,000 kcal/wk. = 59.7%;  $\chi^2(1) = 1.28$ ,  $p = 0.26$ ), sex (males = 71.2%, females = 58.7%;  $\chi^2(1) = 1.92$ ,  $p = 0.17$ ); or baseline weight status (overweight = 64.9%, obese = 63.8%;  $\chi^2(1) = 0.02$ ,  $p = 0.90$ ). Logistic regression indicated no significant impact of EEEx on adherence ( $p = 0.31$ ) after controlling for sex, baseline weight and baseline fitness.

**CONCLUSIONS:** These results suggest that sedentary, overweight/obese young adults are capable of adhering to levels of EEEx associated with clinically significant weight loss. Additional studies to identify potential modifiable factors associated with improving adherence, particularly during the early months of an exercise intervention, are warranted.

Supported by NIH R01 DK49181

1327 Board #108 MAY 30 11:00 AM - 12:30 PM

**Insulin Resistance and Body Fat Gains in Non-Diabetic Women: A Prospective Study**

Jared M. Tucker<sup>1</sup>, Larry A. Tucker<sup>2</sup>. <sup>1</sup>North Dakota State University, Fargo, ND. <sup>2</sup>Brigham Young University, Provo, UT.  
(No relationships reported)

**PURPOSE:** To determine the effect of insulin resistance (IR) on risk of gaining body fat (BF) over time in women, and to examine the potential confounding effects of age, education, initial BF, objectively measured physical activity, and energy intake.

**METHODS:** A prospective cohort study was conducted with 226 women completing the assessments at baseline and follow-up, 18 months later. IR was assessed using fasting blood insulin and glucose levels to calculate HOMA. Participants were divided into High IR (4th quartile) Moderate IR (2nd and 3rd quartiles) and Low IR (1st quartile) categories. BF was estimated using plethysmography (Bod Pod) at baseline and follow-up. Participants wore accelerometers and completed weighed food logs for 7 consecutive days to objectively index physical activity and energy intake, respectively.

**RESULTS:** On average, women in the High IR group decreased in BF ( $-0.48 \pm 3.60$ ) from baseline to follow-up, whereas those in the Moderate ( $0.40 \pm 3.66$ ) and Low IR ( $1.17 \pm 3.15$ ) groups gained in BF in a dose-response manner over the 18 months ( $F = 5.4$ ,  $p = 0.0211$ ). Controlling for differences in age, education, physical activity, and energy intake had little impact on changes in BF across the insulin resistance groups, but adjusting for baseline BF nullified differences in body fat changes across the IR groups.

**CONCLUSIONS:** Women with High IR have less than half the risk of gaining substantial BF (>5%) over 18 months compared to women with low or moderate levels of IR. The decreased risk appears independent of potential confounders except for initial body fat levels, which seem to play a key role in the relationship.

1328 Board #109 MAY 30 11:00 AM - 12:30 PM

**Changes In Physical Fitness And Body Composition During Inpatient Treatment Of Longstanding Eating Disorders**

Eva M. Støa, Solfrid Bratland-Sanda. *Telemark University College, Norway, Telemark, Norway.*  
(No relationships reported)

**PURPOSE:** The purpose of this study was to examine changes in aerobic fitness, muscular strength and body composition during inpatient treatment of underweight and normal weight patients with longstanding eating disorders (ED).

**METHODS:** Twenty-nine underweight (BMI < 18.5,  $n = 7$ ) and normal weight (BMI  $\geq 18.5$ ,  $n = 22$ ) inpatients meeting the DSM-IV criteria for anorexia nervosa, bulimia nervosa or eating disorders not otherwise specified (mean (SD) age: 31.0 (9.0) yrs, ED duration: 14.9 (8.8) yrs, duration of treatment: 16.6 (5.5) weeks) completed this prospective naturalistic study. The treatment consisted of nutritional counseling, two weekly sessions of 60 min moderate intensive physical activity, and psychotherapy. Patients with BMI < 18.5 aimed to increase body weight with 0.5 kg/week until BMI  $\geq 18.5$ . Aerobic fitness, muscular strength (1RM) in lower and upper body and body composition were measured at admission and discharge.

**RESULTS:** There was a 28.5% increase in lower body muscular strength among the underweight patients, and 18.9% increase in upper body muscular strength among the normal weight patients from admission to discharge. No changes were detected in aerobic capacity. Total body mass increased with 7% among the underweight patients (from 46.2 to 49.5 kg,  $p < 0.001$ ), although three out of seven underweight patients were still underweight at discharge. No significant changes in total body mass were observed among the normal weight patients. Altering in

body composition was observed, with an increase of 36% and 6% in fat mass among underweight and normal weight patients, respectively. Lean body mass increased among underweight, but not normal weight patients. Nine of the 29 patients had a body fat percentage exceeding healthy limits at admission; none of these showed decrease in body fat percentage at discharge.

**CONCLUSIONS:** Several underweight patients were still underweight at discharge, whereas none of the patients with excess amounts of body fat managed to reduce body fat percentage. Increase in aerobic capacity would have been beneficial to especially patients with excess body fat. These results call for a more individualized treatment approach to achieve a more optimal body composition among both underweight and normal weight patients with longstanding ED.

**1329** Board #110 MAY 30 11:00 AM - 12:30 PM

**Systemic Inflammation and Disease Risk Factors in Mexican-American Children after an Intensive Lifestyle Intervention**

Whitney L. Breslin<sup>1</sup>, Craig A. Johnston<sup>2</sup>, Jennette P. Moreno<sup>2</sup>, Kelley Strohacker<sup>1</sup>, Katie C. Carpenter<sup>1</sup>, John P. Foreyt<sup>2</sup>, Brian K. McFarlin, FACS<sup>1</sup>. <sup>1</sup>University of Houston, Houston, TX. <sup>2</sup>Baylor College of Medicine, Houston, TX. (Sponsor: Brian K McFarlin, FACS)  
(No relationships reported)

**PURPOSE:** Obesity is an independent risk factor for chronic disease. The prevalence of obesity is especially high among Mexican-American children. Peripheral blood monocytes are altered with obesity and may contribute to systemic inflammation that mediates the relationship between obesity and chronic disease. In addition, obesity alters the circulating levels of cytokines/chemokines that influence monocyte behavior. To evaluate the effects of a 6-month school-based healthy lifestyle program on systemic inflammation and disease risk markers in healthy weight (zBMI  $\leq$  85th percentile), overweight (zBMI=85th-95th percentile), and obese (zBMI  $\geq$  95th percentile) Mexican-American children.

**METHODS:** Participants were randomized to either a 6-month intensive intervention or self-help group. Pre- and post-intervention blood samples were analyzed for total monocyte concentration, pro-inflammatory monocyte concentration, and classic monocyte concentration via flow cytometry. Serum MCP-1, Fractalkine, IL-8, and TNF- $\alpha$  were measured using a Milliplex MagPix assay. Serum cholesterol, HDL, triglycerides, and glucose were measured using an enzymatic reagent kit.

**RESULTS:** At baseline, Total monocyte concentration (P=0.012), classic monocyte concentration (P=0.045), MCP-1 (P=0.015), and TNF- $\alpha$  (P=0.002) were significantly greater in obese children compared to healthy weight children. Also, overweight and obese children had elevated triglycerides (P=0.001) and reduced HDL (P=0.033) compared to healthy weight children. Post-intervention samples will be analyzed to determine the effect of the intervention on these markers of systemic inflammation and disease risk.

**CONCLUSIONS:** Elevations in circulating monocytes, MCP-1, and TNF- $\alpha$  have been implicated in the development of obesity-related chronic disease in adults. School-based healthy lifestyle interventions that promote zBMI reduction may reduce systemic inflammation and prevent the future development of obesity-related chronic diseases.

**1330** Board #111 MAY 30 11:00 AM - 12:30 PM

**Daily Exercise and Caloric Restriction Impact Fibroblast Growth Factor-21 in Hyperphagic OLETF Rats**

Justin A. Fletcher, Grace M. Meers, Jamal A. Ibdah, John P. Thyfault, R. Scott Rector. University of Missouri, Columbia, MO.  
(No relationships reported)

**PURPOSE:** Chronic treatment with fibroblast growth factor-21 (FGF-21) favorably improves obesity and nonalcoholic fatty liver disease (NAFLD) outcomes; however, FGF-21 expression is paradoxically elevated in obese conditions. Here, we sought to determine the effects of obesity prevention by daily exercise (EX) vs. caloric restriction (CR) on hepatic FGF-21 in the hyperphagic, Otsuka Long-Evans Tokushima Fatty (OLETF) rat.

**METHODS:** At 4 wks of age, male OLETF rats (n=7-8/group) were randomized to groups of ad libitum fed, sedentary (OLETF-SED), voluntary wheel running exercise (OLETF-EX), or CR (OLETF-CR; 70% of SED) until 40 wks of age. Nonhyperphagic, Long-Evans Tokushima Otsuka (LETO-SED) rats served as controls.

**RESULTS:** Both daily EX and CR prevented obesity and NAFLD development observed in the OLETF-SED animals. This was associated with significantly (p<0.01) lower serum FGF-21 (~80% lower) and hepatic FGF-21 mRNA expression (~65% lower) in the OLETF-EX and OLETF-CR rats compared with OLETF-SED. However, hepatic FGF-21 protein content was reduced to the greatest extent in the OLETF-EX animals (50% of OLETF-SED) and did not differ between OLETF-SED and OLETF-CR. Further examination of hepatic FGF-21 signaling mediators revealed that the protein content of the hepatic co-factor of FGF-21 ( $\beta$ -Klotho), hepatic FGF-21 receptor 2 (FGFR2) mRNA expression, and hepatic FGF-21 receptor substrate 2 (FRS2) protein content were elevated (+30-50%, 60-100%, and ~40%, respectively) in the OLETF-EX and OLETF-CR compared with OLETF-SED animals.

**CONCLUSIONS:** Daily exercise and caloric restriction modulate hepatic FGF-21 and its primary signaling mediators in the hyperphagic OLETF rat. Enhanced metabolic action of FGF-21 may partially explain the benefits of exercise and caloric restriction on NAFLD outcomes. Supported by NIH grant T32 AR 048523-07 and VHA-CDA2 IK2BX001299-01.

**Effects of Obesity and Exercise Training on Regional Adipose Tissue VEGF Production in Rats**

Tongjian You, FACS<sup>1</sup>, Beth Disanzo<sup>2</sup>. <sup>1</sup>University of Massachusetts Boston, Boston, MA. <sup>2</sup>State University of New York at Buffalo, Buffalo, NY.  
(No relationships reported)

Vascular endothelial growth factor (VEGF) plays an important role in angiogenesis within adipose tissue. However, the effects of obesity and chronic exercise on regional adipose tissue VEGF production are still not well known.

**PURPOSE:** To compare the regional differences in VEGF production in subcutaneous and intra-abdominal adipose tissue, and investigate the effects of obesity and chronic exercise on adipose tissue VEGF production in rats.

**METHODS:** Lean (Fa/Fa) and obese (fa/fa) male Zucker rats at 2 months of age were randomly assigned to a sedentary and an exercise training group (lean sedentary: n=7, lean exercise: n=8, obese sedentary, n=7, obese exercise: n=8). The exercise group walked on a rat treadmill at 20 m/min for 60 min, 5 times per week for 8 weeks. Inguinal and epididymal adipose tissue samples were collected and in vitro VEGF secretion levels were determined.

**RESULTS:** In the whole cohort, VEGF secretion levels were higher in epididymal (13.20 $\pm$ 3.93 ng/g protein) compared to inguinal (6.41 $\pm$ 1.18 ng/g) adipose tissue (P<0.01). There were significant main effects of obesity on inguinal (lean: 2.66 $\pm$ 0.23 ng/g, obese: 10.17 $\pm$ 1.93 ng/g, P<0.01) and epididymal (lean: 6.92 $\pm$ 1.85 ng/g, obese: 19.48 $\pm$ 7.42 ng/g, P<0.05) adipose tissue VEGF secretion, and significant main effects of exercise training on epididymal adipose tissue VEGF secretion (sedentary: 5.80  $\pm$ 0.77 ng/g, exercise: 19.68 $\pm$ 7.05 ng/g, P<0.05). There were no obesity-exercise interactions on the variables.

**CONCLUSIONS:** Our results support that intra-abdominal adipose tissue releases more VEGF than subcutaneous adipose tissue, and both obesity and exercise training increase adipose tissue VEGF production in rats. Future studies are needed to identify the role of VEGF in angiogenesis in response to chronic exercise in obesity.

**The Supplement Of A-keto Acids Supports Diabetes Patients To Do Physical Exercise**

Yuefei Liu, Tamara Spreng, Jürgen M. Steinacker, FACS<sup>1</sup>. Sports and Rehabilitation Medicine, Ulm, Germany.  
(No relationships reported)

**PURPOSE:** Type 2 diabetes mellitus (DM) is one of the most important epidemic diseases that threaten the public health, and physical inactivity plays an important role in the development of DM. Therefore, to improve physical activity is of critical significance for dealing with DM. However, to do physical exercise brings about a variety of physiological changes including metabolic challenges that can reduce exercise tolerance. The aim of this study was to investigate supportive effects of nutritional supplement of a-keto acids (KAS) in patients with DM doing physical training.

**METHODS:** In the double-blinded, placebo-controlled study 30 patients with DM (non-insulin-dependent) were recruited (60  $\pm$  10 yrs, 173  $\pm$  8 cm, 91  $\pm$  16 kg) and randomized into two groups (placebo and KAS, respectively). The subjects underwent 6 weeks of physical training on cycle-ergometers supervised by a professional assistant. The training program was composed of 3 obligatory sessions (3 x 15 min endurance training followed by 5 min high intensity strength training each) and voluntarily additional training. The agents with placebo or 0.2 g/kg/d a-keto acids (0.1g a-ketoglutarate and 0.1g branched-chain keto acids) were supplemented during the training phase and one following recovery week.

**RESULTS:** In the placebo group only 28 min/week voluntary training were performed while in the KAS group 78 min ( $P < 0.05$ ). With KAS the subjects attained higher maximum power output (224 vs 193 watts,  $P < 0.05$ ). A greater improvement in glucose control and Quantitative Insulin Sensitivity Check-Index was achieved in the KAS group.

**CONCLUSIONS:** The supplement with  $\alpha$ -keto acids in patients with DM during physical training could improve exercise tolerance and training effect along with beneficial effect on glucose control and insulin sensitivity. Thus, KAS supports patients with DM to do physical exercise.

**Similar Metabolite Shifts Following 75-Km Cycling Time Trials When Ingesting Bananas Or a Carbohydrate Beverage**

David C. Nieman, FACSM<sup>1</sup>, Nicholas Gillitt<sup>2</sup>, Wei Sha<sup>3</sup>, Andrew Shanely<sup>1</sup>, Amy Knab<sup>1</sup>, Lynn Kam<sup>1</sup>. <sup>1</sup>Appalachian State University, Kannapolis, NC. <sup>2</sup>Dole Nutrition Research Institute, Kannapolis, NC. <sup>3</sup>UNC-Charlotte, Bioinformatics Research Center, Kannapolis, NC.

(D.C. Nieman: Contracted Research - Including Principle Investigator; Dole Foods.)

**PURPOSE:** This study compared the acute effect of ingesting bananas (BAN) versus a 6% carbohydrate sports drink (CHO) on 75-km cycling performance and shifts in metabolites using metabolomics-based profiling.

**DESIGN:** Trained cyclists ( $N=14$ , age  $37 \pm 1.9$  y,  $Watts_{max}$   $379 \pm 12.5$ ) completed two 75-km cycling time trials (3 weeks apart, randomized, crossover) while ingesting BAN or CHO. Subjects cycled on CompuTrainers for 75-km at the fastest pace possible while ingesting 0.2 gm/kg carbohydrate from BAN or CHO every 15 min. Blood samples were taken pre-exercise, immediately following, and 1-h post-exercise, and analyzed for metabolic profiles using gas chromatography-mass spectrometry (GC-MS).

**RESULTS:** Performance time did not differ between BAN and CHO ( $2.41 \pm 0.06$ ,  $2.36 \pm 0.05$  h, respectively,  $P=0.258$ ). Of 103 metabolites detected, 56 had significant time effects following the 75-km cycling bouts, and only one (dopamine) had a pattern of change that differed between BAN and CHO. Score plots from the partial least squares discriminant analysis (PLS-DA) model visualized the global metabolic differences between pre-exercise, immediately post-exercise, and 1-h post-exercise, indicating a distinct separation between time points [ $R^2 Y(cum) = 0.869$ ,  $Q^2(cum) = 0.766$ ]. Of the top 15 metabolites (ranked by both variable influence on the projection, VIP, and FDR adjusted  $p$ -values), five (2-hydroxybutyric acid, 2-aminobutyric acid, L-glutamic acid, L-methionine, and L-proline) were related to liver glutathione production, four (palmitoleic acid, palmitic acid, oleic acid, and heptadecanoic acid) to lipid metabolism, three (2,3,4-trihydroxybutanoic acid, D-fructose, and pyruvic acid) to carbohydrate metabolism, two (malic acid and succinic acid) were intermediates in the tricarboxylic acid cycle (TCA cycle), and one (L-isoleucine) was involved in branched chain amino acid metabolism.

**CONCLUSIONS:** With the exception of higher dopamine in BAN (a polyphenolic found in bananas), shifts in metabolites following BAN and CHO 75-km cycling time trials indicate a similar pattern of heightened production of glutathione and utilization of fuel substrates in several pathways including glycolysis, lipolysis, and amino acid catabolism.

**High Physical Activity Counteracts the Altered Incretin Response to High Fructose Consumption**

Jill A. Kanaley, FACSM<sup>1</sup>, Amy Bidwell<sup>2</sup>, Timothy Fairchild<sup>3</sup>. <sup>1</sup>University of Missouri, Columbia, MO. <sup>2</sup>Syracuse University, Syracuse, NY. <sup>3</sup>Murdoch University, Perth, Australia.

(No relationships reported)

Fructose consumption has increased substantially in the past few decades and has been linked with metabolic maladaptations. Whether increased physical activity (PA) may confer protection against these maladaptations is yet to be determined. Although the glucose and insulin response to fructose ingestion has been well studied, the incretin response is not well understood.

**PURPOSE:** The purpose of this study was to determine the interaction between high fructose consumption and PA levels on the incretin response to a fructose rich meal in normal weight individuals.

**METHODS:** Twenty normal weight men and women (age: 21-30 yr) consumed an additional 64 g high fructose corn syrup for 14 days on 2 occasions. During these 14 days, subjects maintained either low PA (4,500 steps/day) or high PA (12,500 steps/day). Each condition was followed by a study day where subjects were given a fructose-rich meal (600 calorie mixed meal (45% carbohydrate [7.3% fructose], 40% fat, and 15% protein)) in the morning after a 12 h overnight fast, and blood was sampled at baseline and for 6 h after the meal. Samples were analyzed for glucagon-like peptide 1 (GLP-1), glucose-dependent insulinotropic peptide (GIP) and insulin concentrations. The incremental area under the curve (iAUC) was calculated to quantify the postprandial responses.

**RESULTS:** GIP concentrations showed a significant PA by fructose loading interaction ( $P=0.00$ ) such that fructose increased the GIP iAUC levels from pre to post-loading more so in the physically inactive condition (pre  $14,575 \pm 2339$ ; post  $30,431 \pm 3502$  pg/ml) than in the high PA condition (pre  $12,812 \pm 1303$ ; post  $14,938 \pm 1834$  pg/ml). GLP-1 concentrations also demonstrated a significant interaction ( $P=0.05$ ,  $n=13$ ) such that high PA lowered the GLP-1 levels (pre  $8203 \pm 1484$ ; post  $6248 \pm 1678$  pg/ml) during fructose loading, while low PA resulted in an increase in GLP-1 levels (pre  $6977 \pm 1508$ ; post  $8432 \pm 1539$  pg/ml). The glucose and insulin response to the fructose challenge showed no changes with the loading or PA changes. There were no sex differences.

**CONCLUSIONS:** The combination of high fructose intake in conjunction with more sedentary behavior results a larger incretin response to a fructose-rich meal, while glucose levels are maintained. High PA appears to protect the incretin response to increased fructose loading.

**The Influence of Aerobic Fitness on the Recovery of Peak Power Output**

Mark Glaister, John R. Pattison, Bernadette Dancy, Gillian McInnes. *St Mary's University College, Twickenham, United Kingdom.* (Sponsor: Gregory B Dwyer, FACSM)

(No relationships reported)

**PURPOSE:** The aim of this study was to evaluate the influence of aerobic fitness on the recovery of peak power output (PPO) following a maximal 30 s sprint.

**METHODS:** On separate occasions, 16 well-trained men (age:  $21 \pm 3$  years; height:  $1.84 \pm 0.05$  m; body mass:  $78.8 \pm 7.8$  kg; and  $VO_{2max}$ :  $4.28 \pm 0.54$  L $\cdot$ min<sup>-1</sup>) performed a 30 s maximal sprint on a cycle ergometer, followed by a predetermined stationary rest period (5, 10, 20, 40, 80, or 160 s) and a subsequent 5 s sprint to determine the kinetics of PPO during recovery. On another occasion, oxygen uptake ( $VO_2$ ) was monitored during recovery from a 30 s sprint to enable the recovery kinetics of  $VO_2$  and PPO to be compared. In addition, subjects completed a  $VO_{2max}$  test to evaluate the influence of this parameter on the recovery of PPO.

**RESULTS:** Comparison of the recovery kinetics of PPO and  $VO_2$  revealed no significant difference between the variables ( $F_{(1,15)} = 3.16$ ,  $p = 0.096$ ); there was, however, a significant effect of time ( $F_{(5,75)} = 374.44$ ,  $p < 0.001$ ), and a significant variable  $\times$  time interaction ( $F_{(5,75)} = 3.86$ ,  $p = 0.004$ ). Post hoc tests detected differences between the two variables at 20 s only ( $p < 0.05$ ). Time constants for the kinetics of PPO and  $VO_2$  ( $54.0 \pm 19.1$  s and  $51.8 \pm 11.0$  s, respectively) were poorly correlated ( $r = -0.17$ ;  $p = 0.541$ ), but were not significantly different ( $t_{(15)} = 0.385$ ,  $p = 0.705$ ). There were no significant correlations between  $VO_{2max}$  and the time constants of either PPO ( $r = 0.20$ ;  $p = 0.455$ ) or  $VO_2$  ( $r = -0.13$ ;  $p = 0.641$ ).

**CONCLUSION:** Despite many similarities, the results of this study suggest that the recovery of PPO may be faster than that of  $VO_2$  in the early phase of recovery following a maximal sprint; moreover, the speed of that recovery does not appear to be related to  $VO_{2max}$ .

1336 Board #117 MAY 30 9:30 AM - 11:00 AM

**The Effect of Short and Long Recovery Periods on the Contribution of Oxidative Processes to Energy Expenditure During Multiple Bouts of Supramaximal Exercise**

Eric C. Olson<sup>1</sup>, Kenneth V. Christensen<sup>2</sup>, Adam Jajtner<sup>2</sup>, Jen Copeland<sup>2</sup>, Matt Unthank<sup>2</sup>, Joel B. Mitchell, FACSM<sup>2</sup>. <sup>1</sup>Texas Christian University, Dallas, TX. <sup>2</sup>Texas Christian University, Fort Worth, TX.

(No relationships reported)

The contribution of oxidative energy to multiple sprint exercise is of interest due to implications for the training needs of people engaging in anaerobic activities.

**PURPOSE:** The purpose of this study was to examine the effect of short and long active recovery durations on oxidative and anaerobic energy contributions during maximal intensity cycle ergometry.

**METHODS:** Six male subjects completed the study. After a VO<sub>2</sub>max test on the bicycle ergometer, each subject completed 2 conditions: a short recovery condition (SRC) and a long recovery condition (LRC). The SRC consisted of 10, 10-sec. supramaximal sprints with 30-sec. recovery periods. The LRC consisted of 10, 10-sec supramaximal sprints with 3-min. recovery periods. The load applied to the ergometer was 1.2 g/kg and the RPM during the sprints varied based on the maximal output. During recovery, no load was applied and subjects maintained a cadence of 80 RPM. VO<sub>2</sub> was measured throughout both conditions and peak power and total work were calculated from two, 5-sec RPM averages generated during the sprints. Blood samples were taken pre-exercise, after sprints 4, 7, and 10, and 3 minutes post-exercise.

**RESULTS:** Peak power and total work were significantly greater ( $p < 0.05$ ) in the LRC (1091.3 + 88.7 W and 1363.6 + 34.6 kg-m) compared to the SRC (915.3 + 109.2 W and 1161.6 + 33.9 kg-m). In addition, peak power decayed by 21.7% over the 10 sprints in the SRC compared to no decay in the LRC. Oxygen uptake averaged 28.3 + 0.9 ml/kg/min for the entirety of the LRC; whereas, in the SRC there was a large increase in oxygen uptake during the second sprint that remained elevated and averaged 47 + 1.5 ml/kg/min for the remaining sprints. There was no difference in blood lactate between conditions.

**CONCLUSION:** The heightened aerobic response and the lower work and power outputs seen in the SRC are suggestive of a decrement in both anaerobic glycolysis and phosphocreatine activity as successive sprints were completed. After repeated bouts of explosive exercise with short rest periods, oxidative processes play a more important role in energy production, most likely due to fatigue occurring in the anaerobic energy producing systems. These findings point to the need for enhancing the aerobic capacity of athletes engaging in consecutive high intensity bouts of exercise when rest intervals are short.

**Post-match Recovery In Elite Soccer Referees**

Matthew Weston, Alan M. Batterham, FACSM. Teesside University, Middlesbrough, United Kingdom.

(No relationships reported)

The measurement of recovery following competition is required to facilitate the effective planning and timing of subsequent training sessions. Soccer refereeing at the elite-level represents a significant physical challenge. The effect of match intensity on post-match recovery, however, has yet to be investigated.

**PURPOSE:** To examine the effect of match intensity on recovery in elite soccer referees.

**METHODS:** Data were collected from 14 elite soccer referees for 194 English Premier and Football League matches (range: 5 to 21 matches). Internal match loads were RPE (CR-10 scale) and heart rate (HR) load, computed by multiplying the accumulated duration in each of five different HR zones by a multiplier for each zone and summing the results. Each match was analysed using a semi-automated match-analysis system. External match loads were the referees' total distance covered (m) and the total high-speed running distance (m; running speed >19.8 km·h<sup>-1</sup>). The referees' recovery was recorded 30-min after waking on the day following their match, with a score of 0 representing poor recovery and 10 representing full recovery. A within-referee design was used to determine if high internal and external match loads were associated with low post-match recovery scores. Within-subject correlations between the referees' measures of external and internal match load and post-match recovery ( $n=194$ ) were examined, with 90% confidence intervals (CI) and effect sizes (Cohen's  $d$ ) also presented.

**RESULTS:** Match internal loads were  $6.7 \pm 1.5$  and  $304 \pm 47$  au for RPE and HR load, respectively. Match external loads were  $11648 \pm 609$  and  $1025 \pm 338$  m for total distance and high-speed running, respectively. Post-match recovery was  $6.7 \pm 1.2$  au. There was a small correlation between post-match recovery and match RPE ( $r = -0.24$ ; 90% CI -0.36 to -0.12,  $d = 0.49$ ) and trivial correlations between recovery and total distance ( $r = 0.10$ ; -0.02 to 0.22,  $d = 0.20$ ), high-speed running ( $r = -0.03$ ; -0.15 to 0.09,  $d = 0.06$ ) and HR load ( $r = 0.06$ ; -0.07 to 0.18,  $d = 0.11$ ).

**CONCLUSION:** Elite soccer referees' post-match psychophysiological recovery was influenced by the perceived exertion of their matches but not by their match running distances or match heart rates. Future research should investigate the effect of fitness levels and age on the post-match recovery process.

1338 Board #119 MAY 30 9:30 AM - 11:00 AM

**Effects of Recovery Duration from Prior Heavy Exercise on VO<sub>2</sub> Kinetics and Performance**

Glen R. Belfry, Seung-Jun Park, William J. Karelson, Juan M. Murias, Matthew D. Spencer, John M. Kowalchuk, Donald H. Paterson, FACSM. University of Western Ontario, London, ON, Canada.

(No relationships reported)

**PURPOSE:** To examine the effect of recovery duration (R) to heavy-intensity priming exercise (HVY1) on i) O<sub>2</sub> uptake (VO<sub>2</sub>) kinetics during a subsequent HVY exercise bout (HVY2), and ii) VO<sub>2</sub> kinetics and endurance time (TTF) during a subsequent maximal exercise bout (VHVY) performed to fatigue. It was hypothesized that VO<sub>2</sub> kinetics would be faster in HVY2 than in HVY1, and that the TTF would be longer after priming exercise.

**METHODS:** Nine (22±2 yrs (mean±SD)) healthy and active males ( $n=4$ ) and females ( $n=5$ ) volunteered to participate. A ramp (25 W/min) test to fatigue was performed on a cycle ergometer on Day 1 to determine estimated lactate threshold ( $\theta_L$ ) and peak VO<sub>2</sub> (VO<sub>2</sub>peak). Subjects returned on 8 separate occasions to perform the exercise protocols. These included transitions from 20 W to HVY1, HVY2 and VHVY. Each transition was separated by the same recovery period lasting 5 (R5), 12 (R12) or 25 min (R25) that were randomly assigned for each visit. The power outputs (PO) for HVY1 and HVY2 corresponded to 50% of the difference between the VO<sub>2</sub> at  $\theta_L$  and VO<sub>2</sub>peak ( $\Delta 50\%$ ); the PO for the VHVY endurance test was 92% of peak VO<sub>2</sub> (271±77 W). Two repetitions of the protocol were performed for each of R5, R12 and R25. Two TTF tests with no priming exercise were also performed.

**RESULTS:** Peak VO<sub>2</sub> and  $\theta_L$  were  $3.02 \pm 1.09$  L·min<sup>-1</sup> (at 293±97 W) and  $2.08 \pm 1.02$  L·min<sup>-1</sup> (at 164±44 W), while  $\Delta 50\%$  was  $2.68 \pm 0.94$  L·min<sup>-1</sup> (at 228±69 W). With R5, VO<sub>2</sub> kinetics (Mean Response Time) were faster ( $p < 0.05$ ) in HVY2 (49±10 s) and VHVY (47±13 s) compared to HVY1 (63±10 s); additionally, with R12, VO<sub>2</sub> kinetics were faster ( $p < 0.05$ ) during VHVY (57±8 s) than in HVY1 (64±14 s). TTF was greater ( $P < 0.05$ ) after R25 (323±94 s) than no priming exercise (245±61 s), R5 (226±62 s), and 12 min R (255±65 s).

**CONCLUSION:** This study suggests after HVY priming exercise VO<sub>2</sub> kinetics during a subsequent HVY exercise is faster when the R time is shorter (R5 vs R12 and R25). Improvements in TTF during very heavy-intensity exercise are observed with longer recovery (R25 vs R5 and R12), when enhanced VO<sub>2</sub> kinetics are not seen. These data suggest that at exercise intensities above the lactate threshold, benefits of faster VO<sub>2</sub> kinetics are attenuated by the production of fatigue-inducing metabolites that may require a longer recovery time to resolve.

1339 Board #120 MAY 30 9:30 AM - 11:00 AM

**Recovery Of Heart Rate Variability Immediately After Endurance Exercises On Trained And Non-trained Individuals**

Piia Kaikkonen<sup>1</sup>, Ari Nummela<sup>2</sup>, Heikki Rusko<sup>3</sup>. <sup>1</sup>Tampere Research Center of Sports Medicine, Tampere, Finland. <sup>2</sup>KIHU-Research Institute for Olympic Sports, Jyväskylä, Finland. <sup>3</sup>University of Jyväskylä, Jyväskylä, Finland.

(No relationships reported)

**PURPOSE:** The goal of endurance training is to disturb homeostasis of the body to induce a training effect. Heart rate variability (HRV) has been used as a non-invasive technique to assess modulations in autonomic nervous system, regulating homeostasis. This study investigated the effects of different running exercises on immediate post-exercise HRV in individuals with different training backgrounds, to find out if immediate HRV recovery could offer additional information on disturbance of homeostasis, the training load and training effect of different exercises.

**METHODS:** Non-trained females (NT, n = 13, age 35 ± 3 years, VO<sub>2max</sub> 36 ± 3 ml/kg/min) and recreational trained males (T, n = 13, age 35 ± 5 years, VO<sub>2max</sub> 54 ± 4 ml/kg/min) performed three running exercises on a treadmill, separated at least by two days. In both group, the effects of increased intensity (NT from 50 to 74 %, T from 60 to 85 % of vVO<sub>2max</sub>) or the duration (NT from 3.5 to 7 km, T from 3 to 14 km) of the typical control exercise of the group was investigated. HRV data was collected during pre-exercise baseline, exercise and controlled recovery of 1 minute and analyzed with STFT method. The decrease in high frequency power, as an indicator of changes in vagal activation, from the baseline (HFP<sub>bl</sub>) to the first minute of the recovery (HFP<sub>rec1</sub>, % HFP<sub>bl</sub>) was investigated.

**RESULTS:** HFP<sub>bl</sub> in NT and T were 6.6 ± 1.1 and 7.8 ± 0.9 ln ms<sup>2</sup>, respectively. When compared to HFP<sub>bl</sub>, HFP<sub>rec1</sub> varied from 41 ± 17 % (NT, 3.5 km at 74 % of vVO<sub>2max</sub>) to 83 ± 20 % (NT, 3.5 km at 50 % of vVO<sub>2max</sub>) after different exercises. Increased intensity of the typical exercise resulted in further decreased (P < 0.05) HFP<sub>rec1</sub> in both NT (from 83 ± 20 to 41 ± 17 %) and T (from 60 ± 15 to 46 ± 18 %). Increased duration of typical exercise resulted in lower HFP<sub>rec1</sub> in T (from 60 ± 15 to 47 ± 18 %, P < 0.05) while no change was seen in NT (83 ± 20 vs. 76 ± 26 %).

**CONCLUSION:** The effects of increased exercise intensity or duration, i.e. increased training load, of typical endurance exercises could be detected by HRV during the first recovery minute. However, small changes in duration or intensity may not necessarily induce changes on immediate HRV recovery. HRV during the first recovery minute seems to reflect training load of different exercises, and may be useful in evaluating the physiological training effects.

---

**1340** Board #121 MAY 30 9:30 AM - 11:00 AM

**Effects of Two-Minutes Active Recovery On A “Booster” VO<sub>2max</sub> Test Using Collegiate Female Soccer Players**

Andy Bosak<sup>1</sup>, Matt Hawkey<sup>2</sup>, Thomas Andre<sup>1</sup>, Nathan Winn<sup>1</sup>. <sup>1</sup>Georgia Southwestern State University, Americus, GA. <sup>2</sup>Oklahoma State University, Stillwater, OK.  
(No relationships reported)

Maximal oxygen consumption (VO<sub>2max</sub>) tests typically end at the point of volitional exhaustion. However, previous research with averagely fit individuals and highly fit NCAA Division II female athletes suggest that concluding a maximal treadmill test with 2min active recovery and allowing subjects to exercise a second time at the workload eliciting volitional exhaustion results in significantly greater VO<sub>2</sub> max values (1.4% and 4.2% mean increase, respectively). The potential effects of this testing sequence (2min recovery) on VO<sub>2max</sub> treadmill tests has not been evaluated utilizing highly fit NCAA Division I elite female soccer players.

**PURPOSE:** To examine changes in VO<sub>2max</sub> values, in elite collegiate female soccer players, following 2min of active recovery at the conclusion of a treadmill GXT to volitional exhaustion.

**METHODS:** Twelve NCAA Division I female soccer players completed a max treadmill GXT until reaching volitional exhaustion (MAX1). Immediately following 2min active recovery (at 0% grade & 2.5 mph), each subject exercised to volitional exhaustion a second time (MAX2). MAX1 and MAX2 were compared using a paired T-test. Differences were considered significant at p ≤ 0.05.

**RESULTS:** No significant differences (p = 0.15) occurred between MAX1 (47.4 ± 4.7 ml/kg/min) and MAX2 (48.0 ± 5.3 ml/kg/min). Yet, the mean change from MAX1 to MAX2 following 2min active recovery was +1.3% with individual values ranging from -4.2% to +5.9%. Also, 66.7% of the subjects benefited (+3.3% mean increase) from the booster test with individual increases of +0.5% up to +5.9%.

**CONCLUSION:** Mean results suggest that 2min active recovery may not allow significantly greater VO<sub>2</sub> max values to be achieved by highly fit NCAA Division I elite female soccer players during treadmill testing, yet 66.7% of the subjects increased their VO<sub>2max</sub> during the “booster max” treadmill protocol. Further research is needed to determine if fitness level, training experience, age, sport specificity, or other variables might affect this exercise testing protocol.

**In Vs. Out Of Water Recovery Methods, Performance And Inflammation Response: A Comparative Study**

Mahdi Hosseini Zadeh<sup>1</sup>, Valiollah Dabidi Roshan<sup>2</sup>, Hosein Babaei<sup>3</sup>, Vahid Shirinbayan<sup>2</sup>, Lars Arendt-Nielsen<sup>1</sup>. <sup>1</sup>Aalborg University, Center for Sensory-Motor Interaction (SMI), Aalborg, Denmark. <sup>2</sup>College of Physical Education and Sport Sciences, University of Mazandaran, Babolsar, Iran, Babolsar, Iran, Islamic Republic of. <sup>3</sup>Islamic Azad University, Branch Sari, Sari, Iran, Sari, Iran, Islamic Republic of. (Sponsor: Jonathan Myers, FACSM)  
(No relationships reported)

**BACKGROUND:** Repeated swimming sprints are commonly used to develop anaerobic performance in swimmers. The ability to recover from each high intensity sprint bout is an important factor for eliciting the best neuromuscular adaptations in order to attain the highest possible speed for each repetition, and therefore the best performance.

**PURPOSE:** To compare the effect of in (IN) vs. out of water (OUT) active recovery on cytokines (IL-6 and CRP), CK, lactate, and mean repeated sprint time (RSm).

**METHODS:** 16 volunteer male swimmers (age:19±4years; weight:75±12kg) were assigned to either IN vs. OUT recovery methods. Six 50-m sprint swimming bouts were performed with a 120-second interval of either IN or OUT recovery in between. Measurements were done at baseline and after third and sixth sprint swimming bout.

**RESULTS:** Serum IL-6, CRP and lactate levels (mg/dl) increased from baseline to the third and sixth bouts in both groups (IL-6: from 1.69±.78 to 2.40±1.047 and 3.86±1.81 vs. 1.84±.7 to 3.76±2.2 and 4.99±2.5, P<0.05, IN vs. OUT respectively); (CRP: from 0.39±0.21 to 1.26±0.69 and 1.95±1.14 vs. 0.37±0.25 to 1.29±0.42 and 1.75±0.56, P<0.05 IN vs. OUT respectively); and (Lactate: from 18.21±2 to 50.32±13 and 57.13±10 vs. 19.80±4 to 57.02±14 and 55.03±8, P<0.05 IN vs. OUT respectively). The CK level (U/l) and the RSm time (s) only increased in OUT (CK: from 245±109 to 294±117 and 302±121, P<0.05), (RSm: from 4.56±2.06 to 5.18±2.24 and 6.48±2.28, P<0.05).

**CONCLUSION:** Inflammatory and muscle damage markers are not affected by the IN vs. OUT recovery methods; however, out of water recovery might be associated with higher inflammatory responses. In-water recovery can improve performance compared with out-water recovery at the same intensity.

**1342** Board #123 MAY 30 9:30 AM - 11:00 AM

**Establishing An Active Recovery Protocol For Paralympic-level Swimming**

Shane P. Esau, Jared R. Fletcher, Brian R. MacIntosh, FACSM. University of Calgary, Calgary, AB, Canada.  
(No relationships reported)

Following a competitive event, subsequent performance is thought to be enhanced by an active recovery. In competitive Paralympic-level swimming, the athletes compete twice a day for 4-8 consecutive days. Blood lactate concentration ([BLa]) has been used as a measure of the effectiveness of an active recovery. With this in mind, an active recovery protocol was investigated which could allow individualized prescribed active recovery.

**PURPOSE:** To determine [BLa] clearance during warm-down of elite Paralympic swimmers and test this in competition circumstances.

**METHOD:** 29 elite Paralympic swimmers (age = 20±3 years) completed either a 150 or 300 meter time trial in the shortest time possible, five days before the IPC Swimming World Championships. The distance covered was based on the athlete's main event at the World Championships. Post event [BLa] was determined 5 minutes after the completion of the event. Subsequently, the athletes swam 1000 meters at a heart rate between 140-150 bpm as an active recovery. [BLa] was measured every 200 meters of the active recovery. Individual [BLa] clearance rates were determined from the half-life in exponential decay (t<sub>1/2</sub>). The following week, individual [BLa] clearance rates were used to determine active recovery distance after each event during the IPC World Championships (WC).

**RESULTS:** Mean post time-trial [BLa] was 9.3±3.4 mM. The mean [BLa] t<sub>1/2</sub> was 399.2±121 m. The distance required for the athletes [BLa] to return to 4.0 mM and 2.0 mM based on the t<sub>1/2</sub> was 470±190 m and 799±239 m, respectively. During the IPC WC, the distance required to return [BLa] to at least 4.0 mM was 543±157 m. This distance was not significantly different than the active recovery distance calculated from the t<sub>1/2</sub> and was significantly shorter than the athletes traditional active recovery distance (P<0.05).

**CONCLUSION:** The results suggest that determining [BLa] t<sub>1/2</sub> could be an effective method to determine an appropriate active recovery distance in elite Paralympic swimmers. Next it will be necessary to determine the appropriate target lactate for an active recovery.

---

**1343** Board #124 MAY 30 9:30 AM - 11:00 AM  
**Weight Lifting Performance And Heart Rate Variability During A Training Recovery**  
Mu-Tsung Chen<sup>1</sup>, Jui-Lien Chen<sup>2</sup>, Chung-Yu Chen<sup>2</sup>. <sup>1</sup>*Shih-Chien University, Taipei, Taiwan.* <sup>2</sup>*Taipei Physical Education College, Taipei, Taiwan.* (Sponsor: Chia-Hua Kuo, FACSM)  
(No relationships reported)

Weight training can cause muscle damage, which elicits a protracted repair process and resulted in greater muscle strength following approximately 48-72 h of recovery. It is currently unknown how the autonomic nervous system is modulated in relation to the strength training recovery.

**PURPOSE:** This study determined heart rate variability (HRV) during a 72-h recovery following a weight training bout for elite weight lifters, and its links to muscle strength, pain feeling and plasma creatine kinase level.

**METHODS:** After a 10-d detraining period, seven weight lifters performed a 2-h strength training program including back squat, seated shoulder press, dead lifts, and front squat. Weight lifting performance was evaluated at baseline (before training) and 3, 24, 48, 72 h following training. Electrocardiogram was continuously recorded for 5 min at rest in seated positions immediately before each strength performance measurement.

**RESULTS:** Weight lifting performance was recovered to baseline in approximately 24 h following training. Plasma creatine kinase level was peaked at 3 h following training and gradually decline for 72 h. Weight lifting performances were maximally increased above baseline at 72 h of recovery. Although the subjective pain feeling was not completely vanished, vagal activity (mirrored by natural log HF) was maximal at 72 h after training.

**CONCLUSIONS:** After an acute weight lifting training program, vagal activity dropped significantly and gradually elevated above baseline at 72 hour post training while the weight lifting performance was recovered to highest level.

**1344** Board #125 MAY 30 9:30 AM - 11:00 AM  
**The Influence Of Recovery Time Following A Dynamic Warmup On Lower Body Balance And Flexibility**  
Lee Everett, Matt Beekley, FACSM. *University of Indianapolis, Indianapolis, IN.*  
(No relationships reported)

Previous studies have reported improvements in flexibility following dynamic warm-ups. However, it is possible that the recovery period may influence subsequent performance changes.

**PURPOSE:** The purpose of this study was to examine the influence of recovery time following a dynamic warm up on lower body flexibility and balance.

**METHODS:** Twenty-eight healthy, recreationally active males [(mean  $\pm$  SD) age, 21.3  $\pm$  1.4 years; height, 178.0  $\pm$  6.3 cm; weight, 80.9  $\pm$  10.7 kg] volunteered for this study. The 28 participants reported engaging in a total of 6.9  $\pm$  2.9 h $\cdot$ wk<sup>-1</sup> of exercise. Each subject performed a dynamic warm-up which included an exercise routine that gradually progressed in intensity. Furthermore, each participant performed a pretest, and three post tests (0 min, 10 min, and 20 min). Flexibility was measured using both a straight leg raise test (SLR) for hamstring flexibility and Thomas test for hip flexor flexibility. Balance was measured in the number of ground contacts and balance time during a 30 second balance test using a balance wobble board. A one-way repeated measures ANOVA was used to analyze all dependent variables. Bonferonni adjusted pairwise comparisons were used as post hoc analysis. An alpha level of  $P \leq 0.05$  was set for statistical significance.

**RESULTS:** There was a significant decrease in hip flexor flexibility from 0 min post to 10 min ( $p = .015$ ) and 20 min ( $p = .010$ ) post warm up while also being significantly lower ( $p = 0.16$ ) at 20 min post warm up compared to pre warm up values. Hamstring flexibility significantly increased from pre to 0 min post warm up ( $p < .001$ ) while also significantly decreasing from 0 min post to both 10 min ( $p = .003$ ) and 20 min ( $p < .001$ ) post warm up. Hamstring flexibility was also significantly higher at 10 min post warm up ( $p = .006$ ) when compared to pre warm up values. Balance contacts significantly decreased from pre to 10 min post warm up ( $p = .026$ ), while balance time also significantly increased from pre to 10 min post warm up ( $p = .009$ ).

**CONCLUSION:** A dynamic warm up may influence hamstring flexibility, however a longer recovery time following the warm up is less effective in maintaining hamstring and hip flexor flexibility improvements. Furthermore, the influence a dynamic warm up may have on balance may be minimal.

**1345** Board #126 MAY 30 9:30 AM - 11:00 AM  
**Recovery And Soreness In Trained Females After An Exhaustive Resistance Training Protocol**  
Jason A. Campbell<sup>1</sup>, Phillip A. Bishop<sup>2</sup>. <sup>1</sup>*Murray State University, Murray, KY.* <sup>2</sup>*The University of Alabama, Tuscaloosa, AL.*  
(No relationships reported)

**PURPOSE:** To examine the recovery capabilities and soreness profiles of 10 resistance-trained females (ages 19-35) following three sets to failure for eight resistance exercises.

**METHODS:** The intensity used to elicit responses was the participants' 10-repetition maximum for each lift. Recovery was measured as the ability to replicate the total number of repetitions performed in the first set of the baseline workout compared to the first set total in subsequent workouts. Participants repeated the baseline session following 24, 48, 72, or 96 hours of passive recovery.

**RESULTS:** After 24 hours, the group mean for repetitions (10.0  $\pm$  1.1 reps) was similar to baseline (10.7  $\pm$  0.5 reps;  $p > 0.05$ ). But at 48 hours and 72 hours, the group performed significantly better (11.5  $\pm$  1.3  $p = 0.01$  and 11.4  $\pm$  1.2,  $p = 0.004$  reps for 48 and 72 hours, respectively) than at 24 hours. Soreness was also measured using a 100-mm visual analog scale (VAS). Soreness peaked at 24h and was significantly higher than baseline for all recovery periods (all  $p < 0.05$ ). Additionally, at 48 hours, soreness was significantly correlated to the number of repetitions ( $r = -0.77$ ,  $p = 0.01$ ). Large inter-subject variability existed across all recovery periods for all variables.

**CONCLUSIONS:** These findings suggest that trained females can recover within 24 hours following an exhaustive resistance training protocol. Women were able to perform similarly to baseline at all time points despite experiencing a significant level of soreness.

**1346** Board #127 MAY 30 9:30 AM - 11:00 AM  
**Examining Racial Differences in Sympathetic Overactivity Assessed During Recovery from Exercise in Obese Female Adolescents**  
Stacey L. Hall, R. Lee Franco, Mary K. Bowen, Ronald K. Evans, Edmond P. Wickham. *Virginia Commonwealth University, Richmond, VA.* (Sponsor: Edmund O Acevedo, FACSM)  
(No relationships reported)

Sympathetic overactivity (SO) is associated with several disease states including type 2 diabetes, obesity, and hypertension. Black Americans have the highest risk for hypertension and black females have a greater prevalence in hypertension and obesity compared to white females.

**PURPOSE:** To evaluate differences in SO, as assessed by an exercise recovery index (ERI; heart rate/VO<sub>2</sub> plateau), between black (BOA) and white obese female adolescents (WOA). An additional aim was to determine the association of ERI with insulin resistance (HOMA-IR), cardiovascular fitness (VO<sub>2</sub>peak) per fat free mass (FFM), systolic blood pressure (SBP), and percent body fat (%FAT) in both BOA and WOA.

**METHODS:** Fifty-six obese females volunteered to participate in this study. HOMA-IR, SBP and %FAT were assessed during resting conditions in BOA ( $n=45$ , 13.7 $\pm$ 1.6 yrs, 38.1 $\pm$ 6.1 kg/m<sup>2</sup>) and WOA ( $n=11$ , 13.3 $\pm$ 2.2 yrs, 34.3 $\pm$ 4.9 kg/m<sup>2</sup>). An ERI was calculated during a 5-minute passive recovery period immediately following a graded treadmill exercise test to exhaustion.

**RESULTS:** The ERI was significantly greater (29.7 $\pm$ 6.1 vs. 23.9 $\pm$ 3.1,  $P=0.004$ ) in BOA compared to WOA females. Using multiple linear regression modeling, there was a significant independent association between ERI and VO<sub>2</sub>peak per FFM ( $r = -0.317$ ,  $P=0.049$ ) in BOA after controlling for HOMA-IR, SBP, and %FAT. HOMA-IR ( $r=0.232$ ,  $P=0.155$ ), SBP ( $r = -0.237$ ,  $P=0.146$ ), and %FAT ( $r=0.178$ ,  $P=0.280$ ) were not independently associated with ERI in BOA. Additionally, VO<sub>2</sub>peak per FFM ( $r = -0.075$ ,  $P=0.860$ ), HOMA-IR ( $r=0.112$ ,  $P=0.792$ ), SBP ( $r=0.060$ ,  $P=0.887$ ), and %FAT ( $r = -0.026$ ,  $P=0.951$ ) were not independently associated with ERI in WOA.

**CONCLUSIONS:** These results suggest that BOA females have greater SO, as assessed by an ERI, than WOA females. Understanding racial differences can contribute to both prevention and treatment of hypertension in obese female adolescents.

### Load Carriage Increases Exposure Time during Tactical Combat Movements

Andrew P. Hunt<sup>1</sup>, Aaron J. Silk<sup>2</sup>, Paul J. Tofani<sup>2</sup>. <sup>1</sup>Defence Science and Technology Organisation, Melbourne, Australia. <sup>2</sup>University of Wollongong, Wollongong, Australia. (Sponsor: Christopher Gore, FACSM)  
(No relationships reported)

Dismounted combatants engaging an enemy force are required to move tactically between points of cover, involving repeated high-intensity short duration bounds.

**PURPOSE:** To quantify the effect of external load carriage on exposure time, the period of vulnerability to enemy fire as the combatant moves between points of cover, during a tactical combat movement simulation.

**METHODS:** Nineteen qualified Airfield Defence Guards (age 21.7±2.4 years, height 181.4±8.0 cm, body mass 81.0±9.0 kg) provided written informed consent to participate. Experimental procedures were approved by the Australian Defence Human Research Ethics Committee. The tactical movement simulation involved sixteen 6-m bounds commencing every 20 s, each starting from a prone position and ending in a kneeling position. The simulation was performed in five load conditions (A - E) ranging between 10-30 kg (5 kg increments) and comprised a replica weapon, chest webbing, protective vest, and helmet. During all trials participants were fitted with a global positioning device which contained a 10 Hz global positioning chip and nine inertial sensors. The data were analysed by custom software algorithms that were developed to objectively identify the start and end points of each bound. Repeated measures ANOVA assessed statistical differences between the load conditions.

**RESULTS:** Exposure time significantly increased as a function of external load (A 3.72±0.26 s, B 3.86 ±0.29 s, C 4.09 ±0.31 s, D 4.32 ±0.43 s, E 4.53 ±0.41 s, p<0.001). Peak velocity tended to decrease with increasing load, but this was not significant (A 2.65±0.26 m·s<sup>-1</sup>, B 2.67±0.26 m·s<sup>-1</sup>, C 2.58±0.30 m·s<sup>-1</sup>, D 2.51±0.30 m·s<sup>-1</sup>, E 2.42±0.25 m·s<sup>-1</sup>, p=0.095). However, a significantly greater time was required to reach peak velocity as external load increased (A 2.16±0.33, B 2.25±0.31, C 2.47±0.37, D 2.65±0.45, E 2.82±0.36, p<0.001). When normalised to exposure time, time to peak velocity did not differ, averaging 60% of the exposure duration.

**CONCLUSION:** Load carriage significantly impairs the ability to move between points of cover during tactical movement simulations. With technology advancing and dismounted combatants being required to carry increasing amounts of equipment, these findings highlight how additional load may impact survivability and ultimately mission outcomes.

---

1348 Board #129 MAY 30 11:00 AM - 12:30 PM

### Foot Trajectory and Swing Time changes with Soldier Borne Loads in Walking and Running

Kari Loverro<sup>1</sup>, Leif Hasselquist<sup>2</sup>, Michael Brown<sup>2</sup>. <sup>1</sup>Oakridge Institute for Science and Engineering, Belcamp, MD. <sup>2</sup>Natick Soldier Research, Development, and Engineering Center, Natick, MA.  
(No relationships reported)

Soldiers are often tasked with carry heavy loads. Little is known on how these loads affect trip avoidance. Previous researchers have used foot trajectory and swing time as predictors of tripping in the young and elderly adults.

**PURPOSE:** To compare foot trajectory and swing time of Soldiers during walking and running while carrying loads.

**METHODS:** Eight male soldiers walked (1.34m/s) or ran (2.24m/s) for 10 minutes on the treadmill with torso armor only (No RUCK: 17kg) and with a rucksack (RUCK: 40kg). Kinematic data was collected for 20s per condition; five strides from each trial were analyzed. Three landmarks on each foot (toe, 5th metatarsal head, and heel) were used to calculate foot trajectory and swing time. Foot trajectory variables were defined using minimum toe clearance (MTC), first and second peak in toe trajectory (TOE1 and TOE2), first peak in 5th metatarsal trajectory (MET5) and first peak in the heel trajectory (HEEL). Swing time was examined as percent stride time. Two-way repeated measures ANOVA were performed for each variable.

**RESULTS:** At both speeds, increased load significantly decreased swing time (walk: No RUCK: 37.7±0.3% RUCK: 35.9±0.5% p=0.005; run: No RUCK: 58.2±1.0% RUCK: 48.3±0.3% p<0.001). Increased speed for all load conditions significantly increased HEEL (No RUCK: walk: 31.7±0.4cm run: 36.3±0.7cm p<0.001, RUCK: walk: 31.8±0.5cm run: 34.8±0.5cm p<0.001) and MET5 (No RUCK: walk: 15.7±0.4cm run: 19.2±0.4cm p=0.001, RUCK: walk: 15.5±0.3cm run: 17.3±0.5cm p=0.011); but significantly decreased TOE2 (No RUCK: walk: 18.2±0.4cm run: 15.0±0.4cm p<0.001, RUCK: walk: 17.7±0.5cm run: 14.9±0.5cm p=0.006). During running, increased load significantly decreased HEEL (p=0.012) and MET5 (p=0.010). However, MTC (p=0.085) was not significantly affected by load or speed.

**CONCLUSIONS:** When carrying a load while ambulating, toe clearance appears to be preserved while swing time and other foot trajectory variables change. This implies that toe clearance is a crucial factor to keep consistent and Soldiers attempt to do this to prevent tripping while running with heavy loads. However, the decrease of the heel and 5th metatarsal head peaks; and reduction of swing time during running with heavy loads will decrease the ability of the Soldier to adjust their gait to prevent trips and falls on varied terrains.

1349 Board #130 MAY 30 11:00 AM - 12:30 PM

### Improving Estimation of Energy Expenditure with Accelerometers during Military Training using a Field-Based Calibration Procedure

Sam D. Blacker, Fleur E. Horner, David M. Wilkinson, Denise M. Linnane, Peter I. Brown, Mark P. Rayson. *Optimal Performance Ltd, Bristol, United Kingdom.*  
(No relationships reported)

Estimation of physical activity energy expenditure (PAEE) in military populations is an important measurement. The gold standard for estimating PAEE is doubly labelled water (DLW). However it is expensive and can only be used following observation periods greater than seven days. Accelerometers are low cost and their output (Physical Activity Counts; PAC) is often used in linear prediction models. However, the contribution of PAC in predicting PAEE can be low unless individual calibration is performed.

**PURPOSE:** To determine if simple field-based individual user calibrations could improve the relationship between accelerometer PAC and PAEE.

**METHODS:** Following ethical approval, 32 participants (16 female and 16 male, body mass 67.9 ± 12.4 kg, stature 1.71 ± 0.10 m, estimated VO<sub>2</sub>max 44.3 ± 8.5 mL·kg<sup>-1</sup>·min<sup>-1</sup>) volunteered for the study. During 10 days of military training, PAC were measured using a 3-dimensional accelerometer device worn around participants' waist and PAEE was measured using DLW. Participants completed a multistage fitness test (MSFT) to estimate VO<sub>2</sub>max while wearing the accelerometers. Daily PAC were divided by PAC recorded during the first six levels of the MSFT (PAC<sub>MSFT</sub>) to calibrate the outputs to individual participants' movement patterns during the walking and running shuttles. Relationships between PAC and PAC<sub>MSFT</sub> with PAEE were established using Pearson bivariate correlations. Linear regression was used to develop multivariable models to predict PAEE from body mass and PAC or PAC<sub>MSFT</sub>. All data are expressed as mean ± one standard deviation and priori  $\alpha$  was set at p<0.05.

**RESULTS:** Mean 10 day PAC and PAEE were 536,341 ± 55,143 counts·day<sup>-1</sup> and 1,600 ± 386 kcal·day<sup>-1</sup>, respectively. PAEE showed a moderate relationship with PAC (r=0.44, p=0.02) and a stronger relationship with PAC<sub>MSFT</sub> (r=0.71, p<0.01). PAC did not contribute (p=0.10) to a multivariable model that included body mass to predict PAEE. However, PAC<sub>MSFT</sub> contributed (p<0.01) to the multivariable model [PAEE= 505.48 - (body mass x 14.53) + (PAC<sub>MSFT</sub> x 1.29), R<sup>2</sup>=0.68, SEE=227].

**CONCLUSION:** Calibrating accelerometer PAC to sub-maximal individual participant movements using a field-based fitness test provides a simple method for improving the prediction of PAEE during military training.

1350 Board #131 MAY 30 11:00 AM - 12:30 PM

**Injuries among Army Recruits during Occupational Training for Military Police and Combat Engineers**

Elizabeth Clearfield, Keith G. Hauret, Phillip Garrett, Ashly Westrick, Joseph J. Knapik, FACSM. *Army Institute of Public Health, Edgewood, MD.*  
(No relationships reported)

New Army recruits who enlist as combat engineers (Engs) and military police (MPs) train 14 weeks and 19 weeks, respectively, at Fort Leonard Wood, MO. Training includes both physically demanding basic combat and occupational skill training. Injury incidence and rates among Eng and MP students have not been reported previously.

**PURPOSE:** To determine and compare demographics and injury rates for male students enrolled in 14-week Eng and 19-week MP occupational training courses that began between 1 October 2009 - 30 September 2010.

**METHODS:** Electronic rosters with demographics (age, height, weight) were obtained from the Army Training and Doctrine Command for all males who entered Eng and MP training during the survey period. Records for Eng and MP students were linked to injury data from the Defense Medical Surveillance System. Injuries were identified based on specific diagnostic (ICD-9) codes. Body mass index (BMI) was calculated as weight/height<sup>2</sup>. Demographics were compared by independent sample t-tests. Injury incidences (recruits with  $\geq 1$  injury/total recruits X 100%) and injury rates (injured/100 person-months [p-mos]) for Engs and MPs were compared using  $\chi^2$  tests; rate ratios (RR) with 95% confidence intervals (CI) were calculated. All students were assumed to have completed the full training and to be at risk for injury for the full time.

**RESULTS:** There were 4,523 Engs and 4,090 MPs. Mean  $\pm$  SD age, height, weight and BMI for Eng and MPs were, respectively, 21.2  $\pm$  3.8 and 25.3  $\pm$  3.4 years ( $p < 0.01$ ), 175.5  $\pm$  7.0 and 175.8  $\pm$  6.8 cm ( $p = 0.02$ ), 77.9  $\pm$  14.2 and 78.7  $\pm$  14.2 kg ( $p = 0.02$ ), and 25.3  $\pm$  4.1 and 25.4  $\pm$  4.1 kg/m<sup>2</sup> ( $p = 0.13$ ). Injury incidence for Engs was 41.7% and for MPs, 33.6% ( $p < 0.01$ ). The overall injury rate was 14.0/100 p-mos for Engs and 8.5/100 p-mos for MPs (RR [Eng/MPs] = 1.65, 95% CI: 1.54 to 1.77). Lower extremity overuse injury rate among Engs was 10.6/100 p-mos and among MPs was 5.7/100 p-mos (RR [Eng/MPs] = 1.86, 95% CI: 1.71 to 2.02).

**CONCLUSION:** MP students were younger, taller and heavier than Eng students. Students in Eng training had higher overall injury and lower extremity overuse injury rates compared with MPs in training. Risk factors for injuries among Engs and MPs should be determined and injury prevention efforts focused on identified risk factors for students in these occupational training programs.

1351 Board #132 MAY 30 11:00 AM - 12:30 PM

**Sleep and Activity Measurement in Search and Rescue Aircraft Crews Using Novel Sensing Technologies.**

Gregory C. May, Giles Warrington, FACSM, John Burke, Sarah Colclough, Brendan Maloney, Ciaran O' Cathain, Shauna O' Connor O' Connor, Stephen Ryan.  
*Dublin City University, Glasnevin, Ireland.*  
(No relationships reported)

Helicopter search and rescue crews (SARC) remain on 24 hour alert. This requires the SARC to remain in a state of readiness and maximise sleep opportunities. When on duty, depending on their proximity to the SAR base, crew members may either sleep on-base or at home. These factors may lead to possible variations in the level of physical activity (PA), sleep duration ( $S_{dur}$ ) and sleep efficiency ( $S_{ef}$ ).

**PURPOSE:** To investigate the levels of PA,  $S_{dur}$ , and  $S_{ef}$  of members of the SARC during a 24 hour on-call shift using several novel sensing technologies. **Method:** Ten members of the Dublin SARC (mean  $\pm$  SD: age 40  $\pm$  5 years; height 1.76  $\pm$  0.06m; mass 89.2  $\pm$  14 kg; 5 on-base, 5 off-base) were instrumented with 2 tri-axial accelerometers (XL) and a Sensewear armband (SW) with an internal accelerometer (SW<sub>XL</sub>). The XL were placed on the right ankle and right hip with the SW placed on the left triceps. Data was recorded for a 26 hour period during which the subjects kept a written record of their activity. Total estimated energy expenditure ( $\dot{E}_{EE}$ ),  $S_{ef}$  and  $S_{dur}$  were calculated for each sensor during the 24 hour period. Sleep periods were verified for each subject using a written activity log.

**RESULTS:** *Group:* Based on the placement location of the sensors (ankle; waist; triceps) significant differences were observed for  $\dot{E}_{EE}$  (1093.9kcal  $\pm$  329.8kcal; 502kcal  $\pm$  211.5 kcal; 2371.1kcal  $\pm$  838.2kcal,  $p < 0.01$ ). Sleep indices calculated from the SW were seen to be significantly different to the XL data, but not between the XL units themselves (triceps vs. ankle; waist):  $S_{ef}$  (72.8%  $\pm$  18.5% vs. 96.3%  $\pm$  2.6%; 97.3%  $\pm$  1.9%,  $p < 0.01$ ) and  $S_{dur}$  (257.9mins  $\pm$  80.1mins vs. 371.3mins  $\pm$  49.0mins; 379.6mins  $\pm$  53.9mins,  $p < 0.01$ ). *Home vs Base:* Significant differences were seen for  $\dot{E}_{EE}$  for the SW (1907.0kcal  $\pm$  397.3kcal vs. 2835.2kcal  $\pm$  940.4kcal,  $p < 0.01$ ) and SW<sub>XL</sub> (193.8kcal  $\pm$  63.2kcal vs. 893.2kcal  $\pm$  564.2kcal,  $p < 0.01$ ). Similarly a significant difference was observed for  $S_{dur}$  (231.4mins  $\pm$  82.1mins; vs. 284.4mins  $\pm$  77mins,  $p < 0.01$ ) on the SW.

**CONCLUSION:** The location of the sensor utilised to measure PA and sleep indices in SARC members appears to play a vital role in determining the accuracy of measurement. The SW recorded significant differences in PA levels and  $S_{dur}$  between SARC on-base and off-base. Further research is required to determine if this holds true for a larger sample size.

1352 Board #133 MAY 30 11:00 AM - 12:30 PM

**The Metabolic Cost of Walking and Running while Wearing Standard Military Gear or Running Shoes**

Shannon R. Isom, Mariel Wenzel, Cory Whitmer, Michele Aquino, Nabil Boutagy, John W. Wygand, Robert M. Otto, FACSM. *Adelphi University, Garden City, NY.*  
(No relationships reported)

Military personnel wear official military issue boots when deployed, however during non-combat base related activity, military personnel are permitted to wear "go fasters" (running shoes) during their physical training. The military perception of using "go fasters" is based on empirical evidence from training exercises, but the energy cost of using either footwear has not been quantified.

**PURPOSE:** The purpose of this study is to measure the energy cost of walking and running in military boots and running shoes under conditions of no load and of simulated combat load (~29.5kg).

**METHODS:** 6 current or veteran US Marines volunteered to participate in 8 randomly assigned steady state treadmill trials walking [W] (80.4 m/min 5% grade) and running [R] (160.8 m/min 0% grade), while oxygen consumption was obtained by open circuit spirometry. Data were collected at W and R in trials of unloaded with boots (UB), loaded state with boots (LB), unloaded with running shoes (US), & loaded with running shoes (LS). The loaded trial requires each subject to wear their own military issued boots (~1.7 kg), a flak jacket without plates (~4.0 kg), a pack (20.5 kg) and carry a rubber rifle (3.5 kg). During the last minute of each stage, rating of perceived exertion was obtained. A lactate (LA) sample was obtained at 3 minutes post exercise.

**RESULTS:** The mean energy cost for WUS, WUB, WLS & WLB trials: 17.4, 18.6, 22.8 & 23.9 mL O<sub>2</sub>/kg-min, HR: 101, 114, 132 & 138 bpm, and LA: 2.9, 2.5, 2.4 & 2.3 mmol, respectively. The mean energy cost for RUS, RUB, RLS & RLB trials: 31.9, 32.2, 40.3 & 41.0 mL O<sub>2</sub>/kg/min, HR: 150, 164, 172 & 181 bpm, and LA: .4, 4.2, 5.7 & 7.5 mmol, respectively. Statistical analysis by ANOVA ( $p < .05$ ) revealed no significant difference between footwear trials. However, the additional load of 29.7 kg required a significantly greater metabolic and cardiovascular response at both W and R trials.

**CONCLUSIONS:** The use of running shoes during non-combat physical training elicits a similar metabolic demand as the use of military boots. Therefore, the use of running shoes during physical training may be advantageous if injury potential is reduced.

1353 Board #134 MAY 30 11:00 AM - 12:30 PM

**A Physiological Comparison of Three Backpack Frames During Treadmill Walking**

Jana E. Hollins<sup>1</sup>, Kimberly A. Pribanic<sup>2</sup>, Brian Higginson<sup>3</sup>, Daniel P. Heil, FACSM<sup>1</sup>. <sup>1</sup>Montana State University, Bozeman, MT. <sup>2</sup>Mystery Ranch, LTD, Bozeman, MT. <sup>3</sup>Gonzaga University, Spokane, WA.  
(No relationships reported)

It is well known how heavy load positioning can influence cardiorespiratory (CR) responses when walking, but few studies have focused on how backpack frame design may impact these same parameters.

**PURPOSE:** This study compared CR variables for three backpack frames during treadmill walking, all of which are commonly used the U.S. Armed Forces.

**METHODS:** Backpack-experienced subjects (18 men, 4 women; Mean  $\pm$  SD: 32 $\pm$ 8 yrs, 79.7 $\pm$ 7.7 kg) completed 4 successive 15-min walking trials at a fixed treadmill speed (80.5 m/min)

and grade (2%). The Control trial (walking without a backpack) was always tested first, while the order of backpack frames tested were counterbalanced. Trials 2-4 corresponded to wearing one of 3 military backpack frames (MOLLE, FILBE, NICE), each of which was loaded with a 26.6 kg bag load. Subjects wore a portable metabolic measurement system for measuring oxygen uptake (VO<sub>2</sub>) and heart rate (HR), as well as carried a Rubber Ducky rifle in front, the total of which weighed another 4.1 kg (30.7 kg total load). CR variables were summarized at two time points (mins 6 and 13) for each trial, while blood lactate (BL) was measured during min 15. Data were evaluated using multivariate 2-factor RM ANOVA and Sheffe's post-hoc ( $\alpha=0.05$ ).

**RESULTS:** Mean VO<sub>2</sub> and HR values for the Control trial (Mean±SE: 13.7±0.4 ml/kg/min; 97±2 BPM) were significantly lower ( $P<0.05$ ) than those for the MOLLE (16.5±0.3; 128±3), FILBE (16.6±0.4; 128±3), or NICE frames (15.9±0.4; 125±4), while there were no differences between frames. Mean BL for the FILBE trial (1.5±0.1 mmol/L) was significantly higher ( $P<0.05$ ) than the Control (1.1±0.1) but not from either the MOLLE (1.3±0.1) or NICE (1.3±0.1) frames. The percent differences in VO<sub>2</sub> of both FILBE (+4.4%) and MOLLE (+3.8%) frames from the NICE frame were practically significant.

**CONCLUSION:** The influence of backpack frame designs on CR and BL responses were generally small and non-significant. However, the FILBE frame trial elicited a slightly higher BL than the Control trial, and the difference in walking economy (i.e., VO<sub>2</sub>) between the NICE frame and the other frames (+3.8-4.4%) was greater than the 2.5% practical significance threshold. This suggests that both practical and statistical significance are most likely observed when these frames are worn for longer rather than shorter walking bouts.

**1354 Board #135 MAY 30 11:00 AM - 12:30 PM**

**The Effects Of Wearing A Weighted Vest On Aerobic Efficiency, Muscular Strength and Body Composition: A Case Study**

John W. Wygand, Raymond Peralta, Michele Aquino, Cory Whitmer, Mariel Wenzel, Shannon Isom, Anthony Lucic, Nabil Boutagy, Robert M. Otto, FACSM.  
*Adelphi University, Garden City, NY.*  
*(No relationships reported)*

Operation Heavy Heart is a philanthropic effort by US Marine veterans in support of The Wounded Warrior Project. The objectives are to raise awareness and support for injured U.S. service members. Active duty military personnel are subject to unique and prolonged physiological stress. This includes chronic musculoskeletal loading with heavy combat gear for extended periods of time. Loading periods and subsequent unloading may be associated with specific physiological adaptations and may include alterations in body composition, energy expenditure, muscular strength and cardiovascular responses to exercise.

**PURPOSE:** To evaluate the effects of long term musculoskeletal loading on muscular strength, aerobic efficiency and body composition.

**METHODS:** Two US Marine veterans (Age 26.5 yr, Ht. 170 cm, Wt 76.5 kg) volunteered to participate in this nine month trial. Aerobic efficiency was measured by open circuit spirometry and heart rate by telemetry during steady state trials at 93.8 m/min and 10% grade. Body composition was measured by DEXA. Pull ups were performed to repetition max. with palms facing at shoulder width to a 3-1-3 cadence. Squats were performed to repetition max, on a Smith machine, with a load of 97.8 kg at a 3-1-3 cadence and a range of motion of 70-180 degrees of knee flexion. Each subject wore a 9.1 kg weighted vest during all daily activities except sleeping. All parameters were measured monthly during the nine months of weighted vest application and one month after they stopped wearing the vests.

**RESULTS:**

|                           | VO <sub>2</sub><br>(ml/min) | HR<br>(beats/min) | %HRR | PULL UPS | SQUATS | BMD<br>(g/cm <sup>2</sup> ) | MASS<br>(kg) | FFM<br>(kg) | %FAT |
|---------------------------|-----------------------------|-------------------|------|----------|--------|-----------------------------|--------------|-------------|------|
| PRE                       | 2376                        | 145               | 61   | 7.5      | 6.5    | 1.295                       | 76.5         | 63.9        | 16.4 |
| NINE MONTHS               | 2355                        | 136               | 53.5 | 11       | 5      | 1.328                       | 75.6         | 66.2        | 13.1 |
| 1 MONTH<br>POST UNLOADING | 2345                        | 137               | 54.5 | 11       | 6.5    | 1.33                        | 76.7         | 65          | 13.3 |

**CONCLUSION:** Chronic, long term musculoskeletal loading is associated with improvements in body composition, upperbody strength and cardiovascular efficiency that persist for at least four weeks after the loading period.

**1355 Board #136 MAY 30 11:00 AM - 12:30 PM**

**Effects of 4-Month Heat Exposure on Body Composition, Physical Performance and Serum Hormone Concentrations**

Heikki Kyröläinen<sup>1</sup>, Matti Santtilä<sup>2</sup>, Harri Lindholm<sup>3</sup>, Keijo Häkkinen<sup>1</sup>, Hanna Seikola<sup>1</sup>, Hannu Rintamäki<sup>3</sup>. <sup>1</sup>University of Jyväskylä, Jyväskylä, Finland. <sup>2</sup>Finnish Defence Forces, Helsinki, Finland. <sup>3</sup>Finnish Institute of Occupational Health, Helsinki, Finland. (Sponsor: Paavo V. Komi, FACSM)  
*(No relationships reported)*

Military operations in a hot environment together with body armor and helmet increase dramatically soldiers' heat strain, which may decrease the operational readiness.

**PURPOSE:** To investigate changes in body composition, physical performance and serum hormone concentrations of soldiers during a 4-month deployment in physically demanding a high ambient air temperature environment (range from 18.1 to 37.7 °C, in vehicles even 57.0°C).

**METHODS:** 20 voluntary male soldiers (age 23 ± 1 yrs, height 1.80 ± 0.06 m, body mass 78.4 ± 11.5 kg) participated in the study. Whole body composition was measured by bioimpedance device and the cross-sectional area (CSA) of the thigh by magnetic resonance imaging. Physical performance was measured before and after the mission, which resulted in the energy deficit was 677 ± 1023 kcal/day. Basal serum hormone concentrations were measured before, middle and after of the deployment.

**RESULTS:** Body mass decreased by 3.5 % ( $p<0.05$ ) but no changes were observed in fat % and CSA (subcutaneous fat and muscle) of the thigh. The mission did not cause any changes in the 12-min running distance (2785 ± 238 vs. 2749 ± 237 m,  $p=0.276$ ) but increased MVC of the leg extensors (3042 ± 614 vs. 3277 ± 706 N,  $p<0.05$ ). No changes were noticed in repeated squats and push-ups, while sit-ups and vertical jump improved ( $p<0.01-0.001$ ). No significant alterations in basal cortisol (COR) or testosterone (TES) concentrations were observed but sex hormone-binding globulin (SHBG) concentration was higher ( $p < 0.05$ ) at 2 (33 ± 10.2 nmol/L) and 4 months (31.2 ± 10.3 nmol/L) compared with the initial values (25.5 ± 9.1 nmol/L). Insulin-like growth factor I (IGF-I) concentration was lower ( $p < 0.05$ ) at 4 months (29.6 ± 6.5 nmol/L) compared with initial (33.1 ± 5.9 nmol/L) and middle (33.8 ± 5.1 nmol/L) concentrations.

**CONCLUSIONS:** Despite the heat stress and energy deficit, it seems that soldiers managed to retain their physical performance and basal COR and TES concentrations. Thus, it can be concluded that the overall stress during the mission was not very severe despite a decrease of the biomarker IGF-1. In addition, the type of physical activity, including strength training that soldiers often performed during the deployment might have played an important role in individual sustainability of the operational readiness.

**A-35 Free Communication/Poster - Motor Control**

**An Investigation Of Age, Task Complexity, And Gender As Potential Moderators Of Attentional Focus Effects.**

Peter J. Smith<sup>1</sup>, Kevin Becker<sup>2</sup>. <sup>1</sup>Illinois State University, Normal, IL. <sup>2</sup>University of Tennessee, Knoxville, TN. (Sponsor: Kristen Lagally, FACSM)  
*(No relationships reported)*

A large body of research has suggested that focusing on the effects of a movement (external focus) is more effective than focusing on the movement itself (internal focus) for learning and performing motor skills (for reviews see Wulf, 2007; Wulf and Prinz, 2001). Recent research has suggested that age and task complexity may moderate this attentional focus effect.

**PURPOSE:** The present study examined the effectiveness of internal and external attentional foci for learning two novel locomotor skills varying in complexity.

**METHODS:** 48 children (ages 8-10) and 48 adults (ages 19-26) learned to ride a Double Pedalo either with or without stability handles while adopting either an internal or external focus of attention. Participants were instructed to either push their feet (internal focus) or the boards of the Pedalo (external focus) forward to make the Pedalo move. The dependent measure used was time to travel 7 meters.

**RESULTS:** For the simpler task, no attentional focus effects were elicited during either acquisition or retention. With the complex task, there were no significant attentional focus effects in acquisition, but in retention, an external focus of attention resulted in faster times than an internal focus, but only in males.

**CONCLUSIONS:** These findings further support the findings of Wulf, Toellner, and Shea (2007), suggesting that a certain degree of instability or error is necessary to elicit external focus benefits. In addition, they corroborate the findings of Wulf, Wächter, & Wortmann (2003) which suggested females and males may be differentially affected by attentional focus instructions.

**1357** Board #138 **MAY 30 9:30 AM - 11:00 AM**  
**The Development Of General And Soccer-specific Perceptual Motor Skills During Adolescence**  
 Tomi Vanttinen. *Research Institute for Olympic Sports, Jyväskylä, Finland.*  
 (No relationships reported)

Expert-novice comparisons have indicated that perceptual motor skills are sport-specific. That is, the level of expertise is more important than the age itself in sports. However, it is not clear what is the dynamics of development of sport-specific perceptual skills compared to the development of general perceptual motor skills.

**PURPOSE:** To examine how general and soccer-specific perceptual motor skills develop during adolescence.

**METHODS:** The subjects of the present study were four age groups (10y, 12y, 14y and 16y) from a club team (n=74). Subject's simple reaction time was measured with Wayne Membrane Saccadic Fixator and peripheral reaction time with Wayne Peripheral Awareness Trainer. A specific laboratory test was used to measure soccer-specific decision making time and choice reaction time during simultaneous ball handling. Age comparisons were made using one-way ANOVA with Tukey's post hoc.

**RESULTS:** All perceptual motor skills improved with age (Table 1) from 10 to 16y but improvement was greater in soccer-specific perceptual skills (decision making time 79.0%,  $F_{73}=49.315$ ,  $p<0.001$ ; choice reaction time 27.7%,  $F_{73}=16.725$ ,  $p<0.001$ ) than in general perceptual motor skills (simple reaction time 17.6%,  $F_{73}=6.371$ ,  $p<0.01$ ; peripheral reaction time 26.1%,  $F_{73}=6.808$ ,  $p<0.001$ ).

**CONCLUSIONS:** These results suggest that soccer training provides training stimulus for soccer-specific perceptual skills that is beyond to be expected from the normal development of general perceptual skills. Decision making time was less than simple reaction time which means that the players ability to anticipate, not just react, is a key factor for success in soccer already at a young age.

Table 1. Mean  $\pm$  SD of the measured variables in the different age groups.

|     | Simple Reaction Time (ms)        | Peripheral Reaction Time (ms) | Choice Reaction Time with Ball Handling (ms) | Soccer-specific Decision Making Time (ms) |
|-----|----------------------------------|-------------------------------|--|---|
| 10y | 250 $\pm$ 34 <sup>12,14,16</sup> | 348 $\pm$ 54 <sup>16</sup>    | 336 $\pm$ 24 <sup>14,16</sup>                | 181 $\pm$ 39 <sup>14,16</sup>             |
| 12y | 224 $\pm$ 27 <sup>10</sup>       | 328 $\pm$ 58 <sup>16</sup>    | 329 $\pm$ 42 <sup>14,16</sup>                | 161 $\pm$ 33 <sup>14,16</sup>             |

**1358** Board #139 **MAY 30 9:30 AM - 11:00 AM**  
**Analysis Of Inter-limb Force Coordination During Isometric Bilateral Grip Control Task**  
 Chueh-Ho Lin, Wen-Hsu Sung, Li-Wei Chou, Shun-Hwa Wei. *National Yang-Ming University, Taipei, Taiwan.*  
 (No relationships reported)

Interhemisphere interaction plays an important role in motor performances, especially during inter-limb force control and coordination during exercise and activity of daily life. Simultaneous bilateral movement training can improve functional performance of the affected limb after CNS lesion. However, the effect of interhemisphere interactions on bilateral force control was still unclear.

**PURPOSE:** The aim of the preliminary study was to analyze interhemisphere interaction by investigating inter-limb force control and coordination during force-maintenance task.

**METHODS:** Seven female and seventeen male healthy adults participated in this study (mean age = 23.3 $\pm$ 3.4y/o). Subjects were asked to hold hand grip force of one hand at a given force level, then gradually decrease hand grip force of that hand while the other hand gradually increase hand grip force so that the sum of the total force from two hands maintained at the given force level. This task was performed at 10, 20 and 40% maximal force levels and was repeated in different order (right to left hand and left to right hand). The force outputs of the participant's hands were recorded and analyzed. The timing of grip force cross point between two hands during force generating process was used to evaluate the force balance between both hands. Two-way analysis of variance was performed to determine the timing differences in handgrip force control under different conditions.

**RESULTS:** The results demonstrated that the force modulation timing in right to left hand was longer than in left to right hand condition at 10% (46.2 $\pm$ 17.6% vs. 33.1 $\pm$ 14.7%,  $p=.005$ ), 20% (40.4 $\pm$ 11.3% vs. 29.8 $\pm$ 11.3%,  $p=.002$ ) and 40% (40.7 $\pm$ 13.7% vs. 27.9 $\pm$ 14.6%,  $p=.002$ ) isometric force-maintain tasks. The timing difference of target force-maintain task for both hands at 3 force levels was not significant different (18.9 $\pm$ 14.6% vs. 13.1 $\pm$ 11.6% vs. 17.6 $\pm$ 9.5%,  $p=.229$ ).

**CONCLUSIONS:** We concluded that left brain controlling right hand has greater control ability than right brain during bilateral force modulation. This finding could indicate interhemispheric interactions during bilateral limb control, which provide new information with implications for clinicians and therapists an evaluation parameter for inter-limbs coordination. Supported by the Taiwan NSC grant (NSC99-2221-E-010-002).

**1359** Board #140 **MAY 30 9:30 AM - 11:00 AM**  
**Visuospatial Working Memory in Children with Poor Motor Coordination as Revealed by Event-Related Potential**  
 Ming-Wei Chen<sup>1</sup>, Chia-Liang Tsai<sup>1</sup>, Chien-Yu Pan<sup>2</sup>, Tzu-Chi Chen<sup>1</sup>, Feng-Ying Chou<sup>3</sup>. <sup>1</sup>National Cheng Kung University, Tainan, Taiwan. <sup>2</sup>National Kaohsiung Normal University, Kaohsiung, Taiwan. <sup>3</sup>Chi Mei Medical Center, Tainan, Taiwan.  
 (No relationships reported)

Children with poor motor coordination have been demonstrated to show an impairment in working memory in visuospatial domains. However, no studies have yet been conducted on the mechanisms of deficits of visuospatial working memory (VSWM) in children with poor motor coordination as revealed by event-related potential (ERP).

**PURPOSE:** The present study aimed to investigate the mechanisms of motor processing in brain activity underlying behavioral anomalies in children with poor motor coordination, and to compare them with those found in children with normal motor coordination when performing the VSWM task. **METHOD:** Twenty-five children with poor motor coordination and 25 age- and sex-matched children with normal motor coordination were identified with the Movement Assessment Battery for Children-Second Edition test. Each child simultaneously performed one spatial non-delay and two time-delayed spatial memory tasks (i.e., 3s-dealy and 6s-delay) with concomitant ERP recording. Behavioral and ERP data were statistically analyzed using repeated measures ANOVA.

**RESULTS:** Children with poor motor coordination had a significantly longer reaction time (879.93 $\pm$ 67.13 vs. 829.07 $\pm$ 52.43ms in 3s-delay task; 864.84 $\pm$ 64.53 vs. 820.81 $\pm$ 50.22ms in 6s-delay task; both  $p<.05$ ) and lower accuracy rates (0.79 $\pm$ 0.08 vs. 0.87 $\pm$ 0.05 in 3s-delay task; 0.72 $\pm$ 0.08 vs. 0.82 $\pm$ 0.07 in 6s-delay task; both  $p<.05$ ) than children with normal motor coordination in the

two spatial memory tasks. With respect to the ERP components, children with poor motor coordination, as compared to children with normal motor coordination, showed smaller P3 (13.55±5.93 vs. 19.61±6.44µV in 3s-delay task; 16.54±7.83 vs. 21.05±7.59µV in 6s-delay task; both p<.05) and pSW (i.e., positive slow wave) (14.41±4.56 vs. 20.17±5.47µV in 3s-delay task; 15.40±5.75 vs. 19.38±7.93µV in 6s-delay task; both p<.05) amplitudes during the retrieval-process phase for later remembered items.

**CONCLUSION:** Children with poor motor coordination showed impairment when performing VSWM task and the mechanisms could allocate less resources and less effort for comparison of spatial locations and response selection.

**Key words:** motor coordination, visuospatial working memory, event-related potential, neuropsychology

---

**1360** Board #141 MAY 30 9:30 AM - 11:00 AM

**Effects of Exercise Intervention on Attention Networks in Children with Poor Motor Coordination: ERP Evidences**

Tz-Chi Chen<sup>1</sup>, Chia-Liang Tsai<sup>1</sup>, Feng-Ying Chou<sup>1</sup>, Chien-Yu Pan<sup>2</sup>, Yu-Ting Tseng<sup>1</sup>. <sup>1</sup>National Cheng Kung University, Tainan, Taiwan. <sup>2</sup>National Kaohsiung Normal University, Tainan, Taiwan.

(No relationships reported)

Children with poor motor coordination (PMC) have been demonstrated to exhibit impaired inhibitory control capacity. However, no studies have been undertaken on the potential effects of exercise intervention on the attention networks of such individuals.

**PURPOSE:** The aim of the present study was to investigate the effects of soccer training on the inhibitory control of children with PMC, focusing on the event-related potential (ERP) components regarding early modality specific inhibition (N2) and late general inhibition (P3).

**METHODS:** Forty-two children were screened with the Movement Assessment Battery for Children test and categorized into those with normal motor coordination (n=14, control group) and those with PMC (n=28). Children with PMC were then quasi-randomly subdivided into either an exercise-intervention (EI) group (n=14) or a non-exercise-intervention (NEI) group (n=14). Before and after a ten-week training program (50-minute sessions, five times a week), all children performed the visuospatial attention task with centrally non-predictive gaze-directed cues with the lower extremities, while brain ERP were concurrently recorded. Repeated measure analysis of variance was used to analyze the training effect.

**RESULTS:** Before training, although the N2 component did not have any significant differences among the three groups, children with PMC, when compared to the control group, showed an impaired inhibitory control capacity (NEI: 49.15±37.99, EI: 43.04±23.80, Control: 10.00±17.99ms, p<.05), smaller P3 amplitude (NEI: 11.94±2.64, EI: 12.14±3.12, Control: 15.34±3.21µV, p<.05) and slower P3 latency (NEI: 335.73±30.34, EI: 332.37±36.28, Control: 300.12±26.30ms, p<.05) across conditions of the visuospatial attention orienting task. After training, beneficial effects emerged with regard to the strength of inhibitory control (NEI: 34.12±28.61 vs. EI: 11.62±16.83 and Control: 10.46±10.43ms, p<.05) and the P3 latency (NEI: 323.24±21.45 vs. EI: 292.89±24.43, Control: 299.96±24.43ms, p<.05) in the EI group.

**CONCLUSION:** The execution and acquisition of compound lower-limb motor skills during extensive soccer training for children with PMC seems to induce reinforced neuronal networks that enable faster cognitive processing.

**1361** Board #142 MAY 30 9:30 AM - 11:00 AM

**Changes In Mental Simulation Of Goal-directed Movements In Healthy Adults Aged 20- 89**

Bouwien C. Smits-Engelsman. *KULeuven, Leuven, Belgium.*

(No relationships reported)

Mental simulation or imagery is a common mental training technique in sports and is gradually introduced for rehabilitation purposes in patient populations. Imagery research has demonstrated that motor imagery and motor execution share similar neural representations. However little is known about changes in the relation between the duration of actual and mental movements. We have recently shown that motor imagery training from a first person perspective in young healthy adults leads to improvements in performance of the executed movements (Herremans et al, 2011). However little is known about changes in the ability to represent actions during normal aging.

**PURPOSE:** To examine age-related similarities and differences in duration of mental and actual goal directed upper limb movements using a Fitts paradigm.

**METHODS:** 3 groups of adults performed the Radial Fitts Task with 5 Indexes of Difficulty (2.91-6.91) on a digitizer [young (20-29; n=39), senior (50-65; n=23) and elderly individuals (70-89 n=29); 97% right handed and 69% female].

**RESULTS:** Overall, the elderly group was significantly slower on the mental and executed tasks (F(1,2) 9.36, p<0.001, means 8.1, 7.5 and 12.7 seconds, respectively). However, no interaction with task condition (mental and executed) emerged, indicating that the mental and actual tasks slowed down comparably. In the second analysis the goodness of fit for the Index of Difficulty was determined. Here a highly significant group effect was found for the goodness of fit, testing for the adherence to Fitts' Law, (F(1,2) 15.92, p<0.001; mean R2 was 0.70, 0.65 and 0.43, respectively). Elderly adapted their movement time less to the task difficulty. Again no interaction with task (mental and executed) was found.

**CONCLUSIONS:** The oldest group had a clear idea of their movement durations: they knew they were slow. However when they imagined to move they were also very slow, leading to good correlations between motor imagery and motor execution duration. Therefore we conclude that the ability to mentally represent goal directed actions is still intact.

**Ankle Movement Discrimination Is Correlated with Sports Performance Levels**

Jia Han<sup>1</sup>, Gordon Waddington<sup>2</sup>, Judith Anson<sup>2</sup>, Roger Adams<sup>3</sup>. <sup>1</sup>University of Canberra; *Shanghai University of Sport, ACT, Australia.* <sup>2</sup>University of Canberra, ACT, Australia. <sup>3</sup>University of Sydney, Sydney, Australia.

(No relationships reported)

Numerous studies have tried to find evidence to suggest athletes specialized in particular sports have better ankle proprioceptive ability than athletes in other sports or non-athletes. However, the results in the literature are inconsistent. Although different testing methods and the diversity of testing range and planes of movement may account for this variability, other possible confounding variables such as years of training and sports performance levels have not been systematically investigated.

**PURPOSE:** To determine the relationship between ankle movement discrimination ability and years of training and sports performance levels.

**METHODS:** One hundred and twenty right handed, healthy young Chinese athletes (handedness was determined by the Edinburgh Handedness Test), without significant injuries during the past 6 months, mean 20.5 years, (range 18-25) and mean 8.2 years of current professional training, (range 2-15) across 6 sports (aerobic gymnastics (12F, 8 M), hand ball (9F, 11M), swimming (10F, 10M), soccer (7F, 13M), sports dancing (13F, 7M), badminton (8F, 12M)) were tested with a purpose-built ankle Active Movement Extent Discrimination Apparatus (AMEDA). Sports performance levels were determined by the athletes' best record within the past year (level 3: national top 6 and above; level 2: national top 16; and level 1: national top 32 or regional top 3; mean level 1.7, range 1-3). Participants were tested in standing position with bare feet and undertook 50 trials (10 for each of 5 different inversion displacements) presented at random to the right ankle. Pearson correlations, with statistical significance at p<0.05, were calculated to estimate the relationship between movement discrimination scores and years of training and sports performance levels.

**RESULTS:** Enhanced ankle movement discrimination was positively correlated with higher levels of sports performance (p<0.001), but not with years of training (p>0.05).

**CONCLUSION:** These results are consistent with Ericsson's (2006) hypothesis about deliberate practice underpinning high level sport performance. Given that higher level athletes have better ankle movement discrimination ability, ankle proprioception could possibly be considered as one of the measures used in sports talent identification testing.

**“Return To Driving”; Examining Driving Performance After Concussion**

Maria T. Schultheis<sup>1</sup>, Preeti Sunderaraman<sup>1</sup>, Bradley J. Sandella<sup>2</sup>, Taylor Blake<sup>1</sup>, Jocelyn Ang<sup>1</sup>, Nazaneen Zahedi<sup>1</sup>, Danielle Martin<sup>1</sup>, Joy Ricasa<sup>2</sup>, Eugene S. Hong<sup>2</sup>.  
<sup>1</sup>Drexel University, Philadelphia, PA. <sup>2</sup>Drexel University College of Medicine, Philadelphia, PA.  
(No relationships reported)

Management of concussions is commonly focused on “return to play” decision for athletes; however concussion may impact other activities, such as the ability to drive an automobile. Findings from other neurologically compromised populations have shown that deficits in information processing speed, working memory and executive functioning are related to changes in driving performance. Concussion research has implicated deficits in these same domains, yet little to no research has been done to examine the relationship between driving and concussion.

**PURPOSE** The current study compares driving performance (using a virtual reality driving simulator; VRDS) between individuals recently concussed (RC) and an age and gender-matched healthy control (HC) group.

**METHODS** Participants were recruited from consecutive referrals from 2 universities. Concussion was diagnosed by treating sports physician using the Zurich Concussion Consensus guidelines. Participants were seen for a 2.5 hr. testing session within the first 72 hours post-concussion. Testing included VRDS administration and a series of cognitive measures. The current findings are a part of a larger ongoing study. Sixteen individuals (11m, 5f; M=20 yrs old) were included. All participants were licensed, active drivers with greater than 2 years driving experience.

**OUTCOME MEASURES** The VRDS generates a variety of driving performance measures. For the current analysis, 2 driving variables; 1) center lane deviation and 2) mean speed were examined across 3 environments; 1) straight lane segment, 2) curve lane segments and 3) a complex driving task of following a truck. **RESULTS** Paired sample T-tests were used to compare group differences. In the straight driving task, the RC group spent more time outside their designated lane compared to HC ( $p = 0.005$ ). In the curved driving task, the RC group drove significantly slower than the HC group ( $p = 0.02$ ). During driving while following a truck, speed was significantly reduced for the RC group ( $p = 0.001$ ). Exploratory correlational analysis between cognitive and VRDS measures revealed some significant relationships.

**CONCLUSIONS** These preliminary findings suggest that changes in driving behaviors may exist at 72 hours post-concussions and this may be related to cognitive performance. Supported by NIH Grant # 1R03HD064847

1364 Board #145 MAY 30 9:30 AM - 11:00 AM

**Changes in Target Displacement and the Effects on Quiet Eye Duration**

Michelle S. Okumura<sup>1</sup>, Robert R. Horn<sup>2</sup>, Michele M. Fisher<sup>2</sup>, Melissa G.F. Alexander<sup>2</sup>, Curtis T. Sylvester<sup>2</sup>. <sup>1</sup>University of Georgia, Athens, GA. <sup>2</sup>Montclair State University, Montclair, NJ.  
(No relationships reported)

The role of gaze in aiming tasks (e.g., throwing a ball or shooting a gun) is an important characteristic of human performance, including certain aspects of sport and military performance. In aiming tasks, the final fixation of the eye before the initiation of a movement is called the quiet eye (QE) period. The location-suppression hypothesis proposes that the QE period is used to program the movement parameters (e.g., force, velocity, angle of release) during execution of an aiming task.

**PURPOSE:** To examine QE duration in response to directional and displacement-based changes in target location using a sky dart aiming task.

**METHODS:** 11 male participants (22.91±3.39 yrs) completed two sets of 46 throws to targets located on a grid on the floor. Each throw resulted in changes in target displacement in terms of direction (X-, Y-, or Z-axis) and distance (1-, 2-, or 3-increment changes on the grid). Changes in target displacement required the participant to scale the movement parameters on successive trials. The duration of the QE period was assessed on each trial using the vision-in-action approach.

**RESULTS:** A two-way ANOVA with repeated measures revealed a main effect for both direction,  $F(1.30, 13.05) = 204.85, p \leq .001$ , and displacement,  $F(1.16, 11.61) = 21.20, p \leq .001$ . An interaction effect was also observed between target direction and target distance. For Y-axis changes, 3-increment changes resulted in longer QE duration (+0.039 s) than 1-increment changes. For Z-axis changes, 3-increment changes resulted in longer QE duration than both 1- and 2-increment changes (+0.144 s; +0.041 s), and 2-increment changes resulted in longer QE duration than 1-increment changes (+0.073 s).

**CONCLUSION:** Larger target displacements result in longer QE duration compared to smaller target displacements. Therefore, when throws require greater reprogramming of movement parameters, the QE period will be longer.

1365 Board #146 MAY 30 9:30 AM - 11:00 AM

**Gross Motor Skills of Children and Adolescents with Mental Health Problems: a Pilot Study**

Alain S. Comtois<sup>1</sup>, Claudia Verret<sup>1</sup>, Tommy Chevrette<sup>2</sup>, Jean P. Boucher, FACSMT<sup>1</sup>, Jordan Lefebvre<sup>1</sup>, Émilie Kalinova<sup>1</sup>, Mario Leone<sup>2</sup>. <sup>1</sup>University of Quebec in Montreal, Montreal, QC, Canada. <sup>2</sup>University of Quebec in Chicoutimi, Chicoutimi, QC, Canada.  
(No relationships reported)

**PURPOSE:** There is a growing body of literature providing evidence on the gross motor (GM) deficit of children having internalised or externalised mental health problems. Despite this, motor troubles are rarely reported in the primary diagnosis, and the impact of motor difficulties are not well documented. Thus, the goal was to evaluate the GM skills of children and adolescents having a mental health problem.

**METHODS:** Twenty-four boys and girls were divided into children and adolescents (n=11, n=5, n=6 and n=2, respectively). All participants had a primary diagnosis of mental health problem using DSM-IV and were referred into the study by a paediatrician. GM performance was evaluated with the UQAC-UQAM GM skills test battery comprising 12 items that assesses 5 GM qualities: Upper and Lower limb speed; Agility; Static and Dynamic Balance; Simple Reaction Time; and Coordination. Results were compared to percentile ratings gathered from 1494 boys and 1551 girls across 5 regions in Quebec all ranging in age 6.0 to 12.9 years.

**RESULTS:** The mean age of the children and adolescents, boys and girls, was 10.6±1.0 and 9.2±2.6, and 13.3±0.5 and 14.0±1.4 years, respectively. The children boys and girls were compared to their respective age groups (11.0 to 11.9 and 9.0 to 9.9 years, respectively), while both adolescent groups were compared to their gender respective 12.0 to 12.9 year age group. The children and adolescent boys and girls for weight, height and BMI scored in the 50<sup>th</sup> to 80<sup>th</sup> percentile. The upper and lower limb speed revealed that all boys and girls scored below the 20<sup>th</sup> percentile. The agility test percentile scores for children boys and adolescent girls was all within median range (40<sup>th</sup> to 70<sup>th</sup> percentile) while for the adolescent boys and children girls the range was within the 10 to 40<sup>th</sup> percentile. Static and dynamic balance indicated that all participants scored in the 10<sup>th</sup> to 30<sup>th</sup> percentile range. All participants scored in the 20<sup>th</sup> to 50<sup>th</sup> percentile range for the simple reaction time test, while for coordination the range was in the 10<sup>th</sup> to 50<sup>th</sup> percentile.

**CONCLUSIONS:** In this limited number of participants GM skills were all within the median range or lower (10<sup>th</sup> percentile) suggesting that mental health problems may lead to impaired GM skills development.

1366 Board #147 MAY 30 9:30 AM - 11:00 AM

**Video Feedback on Advanced Wheelchair Skills Training for Individuals with Spinal Cord Injury**

Xiang Ke<sup>1</sup>, Li-Shan Chang<sup>1</sup>, Michelle Nemeth<sup>2</sup>, Abhinandan Batra<sup>1</sup>, Weerawat Limroongreungrat<sup>3</sup>, Yong Tai Wang, FACSMT<sup>1</sup>. <sup>1</sup>Georgia State University, Atlanta, GA. <sup>2</sup>Shepherd Center, Atlanta, GA. <sup>3</sup>Mahido University, Salaya, Thailand.  
(No relationships reported)

**PURPOSE:** This study was to investigate the effectiveness of the implementation of immediate video feedback on advanced manual wheelchair skills training for individuals with spinal cord injury (SCI)

**METHODS:** Twenty-one manual wheelchair users with SCI level between T1 and L1 were recruited. Participants signed informed consent forms were matched (9 pairs) on gender and motor function level and randomized to the control group (using conventional training) or experimental group (using immediate video feedback training). Twelve participants were in the control

group (33.22±11.33 yrs) and 9 in the experimental group (34.50±12.69 yrs). Each participant was expected to learn three advanced wheelchair skills (wheelie, ramping, and curbing) through four sessions: training session, competence test, retention test, and transfer test. The paired t-test was employed to determine the differences of learning and performing time (minutes), spotter intervention (times), occurrence of tip (times) and successful rate of performance between the two groups. A mixed-model ANOVA and Bonferroni post hoc test were used to compare mean differences between the two groups on three wheelchair skills and four sessions

**RESULTS:** In the pair t-test, out of the 51 comparisons, only three comparisons were significantly different between the two groups. The experimental group had a significantly less performing time in wheelie competence test (1.33±.17 minutes vs. 2.05±.76 minutes,  $p<.05$ ), a significantly more spotter intervention in curbing transfer test (6.15±1.3 times vs. 4.35±1.7 times,  $p<.05$ ), and a significantly lower successful rate in curbing transfer test (33.5% vs. 81.5%,  $p<.05$ ). In the mixed-model ANOVA analysis, no significant differences on ramping and wheelie skills across the four sessions were found between the two groups, except a significantly higher successful rate on the curbing in the control group than experimental group (81.4% vs. 56.7%,  $p<.05$ ).

**CONCLUSIONS:** This study didn't demonstrate the superiority of video feedback to conventional training for advanced manual wheelchair skills training for individuals with SCI. However, the immediate video feedback might be used to assist the conventional training for advanced wheelchair skills.

#### Effects of Three Weeks of Carnitine Supplementation and High-intensity Interval Training on Endurance Performance

Kuei-Hui Chan, Shao-Zeng Hu, Kang-Hao Lu, Chun-Yi Shih. *National Taiwan Sport University, Taoyuan, Taiwan.*  
(No relationships reported)

Carnitine has been presented to have the benefits on anti-oxidative and endurance capacity. High-intensity interval training (HIT) was demonstrated to increase the endurance capacity and oxidative stress.

**PURPOSE:** To investigate the effects of three weeks of carnitine supplementation and HIT combination on aerobic capacity and oxidative stress.

**METHODS:** Ten untrained healthy males were recruited and randomly assigned into carnitine group (25.0±4.4 yr, 80.3±8.5 kg, 170.2±4.3 kg) or placebo group (22.4±3.3 yr, 69.1±11.2 kg, 172.2±6.3 kg). Subjects received carnitine or placebo supplementation 2 g per day for 3 weeks. All subjects also performed the HIT three per week. The HIT protocol contains 10 bouts of cycling trail at 90%VO<sub>2</sub>max, with each bout lasting 2 min and separated by 1 min of rest. The increment running tests and high-intensity interval exercise tests were conducted before and after supplementation. The VO<sub>2</sub>max and time to fatigue were measured by the increment running test. Blood samples were drawn before test, immediately after test, 1 h and 3 h after test of high-intensity interval exercise test to determine the activities or concentrations of creatine kinase (CK) and uric acid.

**RESULTS:** After 3 week of supplementation, VO<sub>2</sub>max (43.0±2.4 vs. 37.6±5.0 mL/min/kg) and time to fatigue (1563.0±221.0 vs. 1496.0±207.6 sec) significantly increased ( $p<.05$ ) in carnitine group. However, there were no differences in placebo group. In carnitine group, the values of blood CK and uric acid in high-intensity interval exercise test before supplementation still elevated at 3 h after test (170.0±44.6 vs. 160.8±32.8 U/L for CK and 8.88±2.16 vs. 7.88±2.0 mg/dL for uric acid,  $p<.05$ ). But the values returned to baseline after 3 weeks of supplementation (184.8±48.7 vs. 174.6±43.5 U/L for CK and 7.82±1.98 vs. 7.74±1.95 mg/dL for uric acid).

**CONCLUSION:** Carnitine supplementation during HIT is benefit to aerobic capacity and recovery of high-intensity interval exercise.

Supported by NTSU Grant 99D014.

#### Effects Of Chronic Green Tea Extract Supplementation On Substrate Utilization And Time-trial Performance

Brian J. Martin, J. Albert Bartolini, Taylor S. Thurston, Nicholas W. Aguirre, Benjamin M. Kamel, Jared W. Coburn, FACSM, Lee E. Brown, FACSM, Daniela A. Rubin, Daniel A. Judelson, FACSM. *California State University, Fullerton, Fullerton, CA.*  
(No relationships reported)

Supplementation with green tea extract (GTE) has been shown to increase fat oxidation at rest and during moderate intensity exercise. Despite its potential ergogenic utility, little work examines if or how GTE supplementation influences metabolic function and performance during time-trial exercise in humans.

**PURPOSE:** To examine the effects of chronic GTE supplementation on markers of substrate oxidation and physiological stress during 1 h constant load submaximal exercise and performance during a subsequent 10 km time-trial.

**METHODS:** Nine male participants with previous 10 km or half-marathon race experience volunteered (age = 27 ± 5 y, height = 174.8 ± 7.2 cm, mass = 71.6 ± 6.1 kg, body fat = 10.3 ± 2.7%, and VO<sub>2</sub>max = 64.2 ± 6.0 ml·kg<sup>-1</sup>·min<sup>-1</sup>). In a double-blind crossover design, subjects supplemented with GTE (725 mg) or placebo for 14 days then performed 1 h of treadmill running at 50% VO<sub>2</sub>max immediately followed by a 10 km time-trial. Investigators collected 1) expired gasses during the constant load exercise only, and 2) heart rate (HR) and ratings of perceived exertion (RPE) throughout both bouts. A 14 day washout separated supplementation periods.

**RESULTS:** No significant differences existed between trials in VO<sub>2</sub> or respiratory exchange ratio during constant load exercise. GTE supplementation also failed to affect HR and RPE during either constant load exercise or time-trial. Time-trial performance was similar between trials (placebo = 47.9 ± 6.7 min, GTE = 46.6 ± 5.8 min).

**CONCLUSIONS:** Supplementation with GTE did not affect metabolic, physiological or perceptual variables during moderate intensity exercise. Additionally, no differences were observed in performance during a 10 km time-trial. These data suggest chronic GTE supplementation does not alter substrate utilization or increase endurance exercise performance in trained individuals.

### 1369 Board #150 MAY 30 11:00 AM - 12:30 PM

#### Green Tea Consumption And Risk Of Prostate Cancer: Meta-analysis Of Epidemiologic Studies

Byungjung Kim, Seunghyun Lee. *Kyunghee University, Seoul, Korea, Republic of.*  
(No relationships reported)

**PURPOSE** Worldwide, prostate cancer has the second highest incidence of all male cancers. Prostate cancer incidence and mortality varies widely between geographic regions, with overall rates in USA being nearly six-times higher than that of Asian countries. This variation suggests that prostate cancer may be linked to lifestyle-related factors, particularly dietary factors. Several epidemiologic studies have focused on the lower incidence of prostate cancer in Asian countries where green tea consumption is high. We undertook a meta-analysis to verify the relation between green tea consumption and prostate cancer.

**METHODS** We performed meta-analysis with the search of MEDLINE (PubMed), EMBASE and Cochrane Library, using the keywords "green tea" or "polyphenols" or "catechins" for the exposure factors, and "prostate cancer" for the outcome factors. Studies included in this review are prospective cohort and case-control studies published between 1966 and July 2010. The search was limited to English language.

**RESULTS** A total of 20 articles were identified for this review. Only 6 studies met the inclusion criteria. When using all the case-control and cohort studies, the pooled RR of prostate cancer for the highest vs lowest category of green tea consumption was 0.82 (95% CI, 0.75-1.07). In case-control studies, green tea drinking habit showed preventive effect on prostate cancer with the odds ratio of 0.40 (95% CI, 0.17-0.92). When cohort studies were pooled, no significant association was seen between green tea consumption and prostate cancer. (RR, 1.08 CI, 0.89-1.32)

**CONCLUSION** Green tea consumption was not associated with the risk of prostate cancer in this meta-analysis. Further cohort studies are needed.

1370 Board #151 Abstract Withdrawn

1371 Board #152 MAY 30 11:00 AM - 12:30 PM

**American Ginseng And Swimming Combined Effect On Glucose Tolerance In Fructose-Fed Rats**

HUNG-MIN TSENG<sup>1</sup>, Chung-hsiang Yang<sup>1</sup>, Kuei-yu Chien<sup>2</sup>, Mei-chich Hsu<sup>2</sup>. <sup>1</sup>National Taipei University of Education, Taipei, Taiwan. <sup>2</sup>National Taiwan Sport University, Taoyuan, Taiwan. (Sponsor: Chia-Hua Kuo, FACSM)  
(No relationships reported)

**PURPOSE:** The purpose of the present study was to investigate the combined effect of American ginseng and swimming on regulation of blood glucose homeostasis in fructose-fed insulin resistance rats.

**METHODS:** Seventy Wistar male rats were divided into ten groups. First group served as control, and remaining nine groups treated with 21% fructose water for 8 weeks to induce insulin resistance and hyperglycemia. After 8 weeks, oral glucose tolerance test (OGTT) was performed to confirm the insulin resistance (IR). Then, we treated rats with different doses of American ginseng and combined with swimming exercise for 28 days (low-dose, low-dose and exercise, medium-dose and exercise, high-dose, high-dose and exercise, placebo, placebo and exercise, metformin). Second time OGTT was performed to know American ginseng and swimming effects.

**RESULTS:** In our study, we found that fasting blood glucose was significantly increased in fructose-fed groups. After 8 weeks, the insulin resistance was markedly increased in fructose groups compare to control group ( $p < .05$ ). Calculated glucose area under curve (GAUC) was significantly decreased in both high-dose of ginseng and medium-dose of ginseng combined with exercise compared to placebo group. The HOMA (homeostasis model assessment of IR), an indicator of insulin sensitivity, was significantly increased in placebo, low-dose and medium-dose groups ( $p < .05$ ) compared to control group. This elevation was attenuated by exercise in placebo and low-dose groups. High-dose intake of ginseng also decreased the HOMA compare to placebo ( $p < .05$ ) group.

**CONCLUSIONS:** Our study concludes that high-dose of American ginseng can control the blood glucose levels in hyperglycemia rats. Furthermore, medium-dose of American ginseng combined with swimming exercise also able control the blood glucose in hyperglycemia rats.

1372 Board #153 MAY 30 11:00 AM - 12:30 PM

**Panax ginseng Extracts Suppress Hepatic Oxidative Damage in Exhaustive Exercised Rats**

Ming-Fen Hsu<sup>1</sup>, Hsin-Yi Hsu<sup>2</sup>, Szu-Hsien Yu<sup>1</sup>, Mallikarjuna Korivi<sup>1</sup>. <sup>1</sup>Taipei Physical Education College, Taipei, Taiwan. <sup>2</sup>Aletheia University, Taipei, Taiwan. (Sponsor: Chia-Hua Kuo, FACSM)  
(No relationships reported)

**PURPOSE:** Chinese herbal medicine is most popular in the world, and ginseng is widely used herb in that traditional medicine. Previous studies showed divergent results from ginseng extracts. This study was aimed to examine the effects of purified ginseng extract on oxidative damage in liver of rats.

**METHODS:** In the present study, 80 male Sprague Dawley (SD) rats were equally divided into four groups, including placebo (0.9% saline), DS-20 (Dammarane oligo-saponins 20 mg/kg), DS-60 (60 mg/kg) and DS-120 (120 mg/kg bodyweight) groups. DS was orally administered for a period of 10 weeks. After completion of the last treatment half number of rats ( $n=10$ ) from each group performed exhaustive swimming exercise.

**RESULTS:** A significant ( $p < .05$ ) decrease in hepatic glutathione peroxidase (GSH-Px) activity after exhaustive exercise in placebo group was ameliorated in DS pretreated rats. Glutathione S-transferase (GST) and glutathione reductase (GR) activities were not significantly altered after exhaustive exercise in placebo. Interestingly, DS pretreatment for 10 weeks significantly increased GST activity. The activity of free radical source enzyme, xanthine oxidase (XO) was significantly elevated after exhaustive swimming and abolished in DS pretreated rats. In addition, the lipid peroxidation marker, thiobarbituric acid reactive substance (TBARS) was dramatically raised after exhaustive performance in placebo group and attenuated in DS pre-treated group.

**CONCLUSIONS:** Administration of Panax ginseng extract, Dammarane oligo-saponins can protect liver from oxidative damage by suppressing free radical production and increasing antioxidant status after exhaustive exercise.

1373 Board #154 MAY 30 11:00 AM - 12:30 PM

**Dose Dependant Studies of Panagin DS-1227 on Free Radical Scavenging System in the Liver of Exhaustive Exercise Rats**

Mallikarjuna Korivi<sup>1</sup>, Hsin-Yi Hsu<sup>2</sup>, Ming-Fen Hsu<sup>1</sup>, Szu-Hsien Yu<sup>1</sup>, Feng-Chih Hsu<sup>3</sup>, Chih-Yang Huang<sup>4</sup>. <sup>1</sup>Taipei Physical Education College, Taipei, Taiwan. <sup>2</sup>Aletheia University, Taipei, Taiwan. <sup>3</sup>National Taoyuan Agricultural & Industrial Vocational High School, Taoyuan, Taiwan. <sup>4</sup>China Medical University, Taichung, Taiwan. (Sponsor: Kuo Chia-Hua, FACSM)  
(No relationships reported)

**PURPOSE:** Ginseng extracts are able to cope against oxidative stress condition; however it is limited to emphasize the therapeutic application of specific compounds with specific dose. This study was designed to explore the therapeutic properties of Panagin DS-1227 (HPLC-grade extract of ginseng stem and leaves), against exhaustive exercise-induced oxidative stress in rats.

**METHODS:** Rats ( $n=120$ ) were evenly divided into four groups such as, control, P-20, P-60 and P-120. Panagin DS-1227 (P) extracts were orally administered to respective groups at 20 (low), 60 (medium) and 120 (high) mg/kg bodyweight for 10-week. Half number of rats from each group performed exhaustive exercise in a swimming pool and sacrificed along with their unexercised rats immediately after exercise.

**RESULTS:** Exhaustive exercise-induced drastic ( $P < .001$ ) drop in liver glutathione (GSH) content was significantly restored in P-20 and P-60 groups, while unable to restore in DS-120 group. Oxidative damage to proteins was evidenced by increased protein carbonyl (PC) levels in control exercised rats. Interestingly, low dose was marginally, and medium dose was completely decreased the PC levels, whereas, no change with high dose of Panagin. In addition, high dose significantly increased the PC levels at resting condition. Nitric oxide (NO) levels were increased in control group after exhaustive exercise, nevertheless, no change with all doses of Panagin. Superoxide dismutase (SOD) and catalase (CAT) activities were significantly decreased as a result of exercise in control group, and also with high dose of Panagin treatment at resting condition. In contrast, glutathione S-transferase (GST) activity was increased with all doses of Panagin.

**CONCLUSIONS:** Our findings elucidate that purified ginseng extract, Panagin DS-1227 attenuates the oxidative damage in liver of exhaustive exercised rats. Interestingly, low and medium doses of Panagin showed better results than the high dose.

1374 Board #155 MAY 30 11:00 AM - 12:30 PM

**Effect of Dammarane Oligo-Saponins on Selected Biochemical Parameters in Blood of Rats after Exhaustive Exercise**

Yi-Ting Lin<sup>1</sup>, Szu-Hsien Yu<sup>1</sup>, Ming-Fen Hsu<sup>1</sup>, Feng-Chih Hsu<sup>2</sup>, Mallikarjuna Korivi<sup>1</sup>. <sup>1</sup>Taipei Physical Education College, Taipei, Taiwan. <sup>2</sup>National Taoyuan Agricultural & Industrial Vocational High School, Taoyuan, Taiwan. (Sponsor: Chia-Hua Kuo, FACSM)  
(No relationships reported)

**PURPOSE:** Therapeutic applications of ginseng extracts are controversial due to inconsistency in ginsenoside profile. In this study we investigated the beneficial effects of Dammarane Oligo-Saponins (DS) and their dose response on selected biochemical parameters in the blood of exhaustive exercised rats.

**METHODS:** Total sixty Sprague Dawley rats were evenly divided into four groups, including control, DS-20, DS-60 and DS-120. DS extract was orally administered to respective groups at the dose of 20, 60, 120 mg/kg bodyweight for a period of 8-week. All the rats were performed exhaustive swimming exercise after the last treatment. Blood samples were collected from the tail vein before exercise, immediately, 1-h and 3-h after exercise.

**RESULTS:** Recorded average swimming duration seems higher in DS treated groups, but statistically not reached the significant level. Baseline blood glucose, lactate, glutamic-oxaloacetic transaminases (GOT), blood urea nitrogen (BUN) and creatine kinase (CK) were not significantly different among groups. Blood glucose levels were significantly ( $P < .05$ ) higher in DS-60 and DS-120 groups compared to control group immediately after exercise, and 1-h after exercise. Contrary to other doses, high dose (DS-120) group showed significantly lower GOT levels 1-h

after exercise. BUN levels were significantly lower 3-h after exercise in DS-60 group compared to control group at same time point. Interesting finding of the present study is that increased CK levels after exercise were decreased in all DS treated groups 3-h after exercise compared to control group.

**CONCLUSIONS:** The data of the present study concludes that purified ginseng extracts, Dammarane Oligo-Saponins possesses beneficial effects against exhaustive exercise challenge. Further detailed investigations are under progress to suggest the DS as nutraceutical substance.

**1375** Board #156 MAY 30 11:00 AM - 12:30 PM

**Coffee Reduces Liver Damage through Increased SOD Activity in Liver of NASH Rats**

Yi-Tse Wang<sup>1</sup>, Che-Chang Chan<sup>2</sup>, Shan-Ken Hung<sup>1</sup>, Shioh-Chwen Tsai<sup>1</sup>. <sup>1</sup>Taipei Physical Education College, Taipei, Taiwan. <sup>2</sup>Division of Gastroenterology, Department of Internal Medicine, Taipei Veterans General Hospital, Shih-Pai, Taipei 11217, Taiwan, R.O.C., Taipei, Taiwan. (Sponsor: Chia-Hua Kuo, FACSM)  
(No relationships reported)

**PURPOSE:** Non-alcoholic fatty liver diseases (NAFLD) are wide spectrum diseases ranging from simple steatosis, non-alcoholic steatohepatitis (NASH) to liver cirrhosis, and induce hepatocellular carcinoma. Coffee has been reported to reduce the risk of advanced liver disease and its complications as well as hepatocellular carcinoma. To investigate whether coffee improved MCD diet induced steatosis and oxidative stress in liver.

**METHODS:** In this study, 8-week-old male Sprague Dawley rats were randomly divided into 5 groups: control (fed normal diet, W0), methionine-choline-deficient (MCD) diet fed for 9 weeks or 14 weeks combined fed with water (W9, W14) or fed with coffee (W9+Co, W14+Co). Coffee (corresponding to approximately 6 cups of espresso coffee or 2 cups of filtered coffee for a person weighing 70 kg) was fed daily for 4 weeks to the rats who were being fed a MCD diet for the previous 5 or 10 weeks. The blood were collected and analyzed for AST. The liver tissues were collected, extracted and assayed for the production of glutathione (GSH) and lipid peroxidation and the activities of antioxidant enzymes by using commercial kits. The hematoxylin-eosin staining was used to determine the degree of lobular inflammation and fibrosis in liver. The degree of fibrosis and inflammation were evaluated by METAVIR score. The statistical analysis was done using the one-way ANOVA for independent samples, with significance level of 5%.

**RESULTS:** Rat fed with the MCD diet showed a rapid induction of AST and hepatic steatosis, loss of body weight and liver weight, but increased the ratio of liver and body weight. Coffee significantly decreased steatosis of W9 ( $p<0.05$ ) and fibrosis of W14 ( $p<0.05$ ). The production of lipid peroxidation in liver increased significantly in W14 ( $24.0\pm 6.9$  vs  $0.40\pm 0.05$  nmole/min/ $\mu$ g protein,  $p<0.05$ ) but not in W14+Co compared with W0 group. The activity of superoxide dismutase (SOD) in W14 and W14+Co were increased compared with W0. Feeding with MCD diet for 14 weeks significantly decreased the activities of catalase ( $p<0.01$ ), glutathione peroxidase (GPx) ( $p<0.05$ ), and glutathione reductase (GR) ( $p<0.05$ ). Administration of coffee did not alter MCD diet abolished activities of antioxidant enzymes.

**CONCLUSIONS:** Administration of coffee improves NAFLD through increased activity of SOD in liver.

**1376** Board #157 MAY 30 11:00 AM - 12:30 PM

**Baker's Yeast Beta Glucan Supplementation Reduces The Number Of Cold/Flu Symptomatic Days After Completing A Marathon**

James A. Navalta<sup>1</sup>, Katie C. Carpenter<sup>2</sup>, Whitney L. Breslin<sup>2</sup>, Tiffany Davidson<sup>2</sup>, Brian K. McFarlin, FACSM<sup>2</sup>. <sup>1</sup>Western Kentucky University, Bowling Green, KY. <sup>2</sup>University of Houston, Houston, TX. (Sponsor: Brian K McFarlin, FACSM)  
(No relationships reported)

**PURPOSE:** Marathon running places a profound stress on one's body. Such stress manifests itself in the form of muscle soreness, fatigue, and a weakened immune system. It is common for marathon runners to develop an upper respiratory tract infection in the days and weeks following completion of a marathon. The present study sought to examine a commercially available form of Baker's yeast  $\beta$ -glucan (BG); this form of BG has been previously demonstrated to boost immune system function in marathon runners and in laboratory studies where subjects completed a defined exercise stimulus.

**METHODS:** We recruited 324 subjects who were completing in the 2011 Austin Livestrong Marathon (Austin, TX). Upon enrolling in the study, subjects completed a demographics question designed to provide information about their exercise training patterns and health status. Subjects were also provided either a BG (250 mg/d) or placebo (sugar pill, PL) supplement. Double-blind administration of the supplement was used to reduce bias. Subjects were also given 2 packets of surveys that were returned at 2 and 4 weeks post marathon. Of the 324 enrolled, only 182 subjects completed and returned both sets of surveys. The set of surveys included were the Profile of Mood States (POMS), the Wisconsin Upper Respiratory Tract Symptom Survey (WURSS), and a daily health/exercise log. Survey data was entered into a database using a custom scanning solution. Data were analyzed for significance using separate repeated measures ANOVAs with a  $P<0.05$ .

**RESULTS:** BG supplementation significantly reduced both the number of days that subjects reported both general health problems as well as cold/flu symptoms. We did not find any significant differences in either POMS or WURSS scores between groups.

**CONCLUSIONS:** The key finding of the present study was that BG supplementation post-marathon reduced the number of symptomatic days experienced by a subject. Based on previous studies from our lab and others, it is reasonable to speculate that the improvements associated with BG were likely due to alterations in monocytes, plasma cytokines, and improved mucosal immunity. This study was funded by Biothera, The Immune Health Company.

---

**1377** Board #158 MAY 30 11:00 AM - 12:30 PM

**Supplementation With Baker's Yeast Beta Glucan Improves Mucosal Immunoglobulin Profile After Exercise In A Hot, Humid Environment**

Brian K. McFarlin, FACSM, Whitney L. Breslin, Katie C. Carpenter, Tiffany Davidson, Amy Adams. University of Houston, Houston, TX.  
(No relationships reported)

**PURPOSE:** Strenuous exercise is known to suppress mucosal immunity for up to 24-h, which can increase the risk of developing an upper respiratory tract infection. While many dietary interventions have been used to combat post-exercise immune suppression, most have been ineffective. Recent evidence has suggested that a commercially-available form of baker's yeast  $\beta$ -glucan may be useful as an immune-booster. The purpose of this study was to determine if 10-d of supplementation with baker's yeast  $\beta$ -glucan (BG) prior to a bout of exercise in a hot ( $37\pm 2^\circ\text{C}$ ), humid ( $45\pm 5\%$  relative humidity) environment improves mucosal immunity during recovery from exercise in recreationally active subjects (29 men, 31 women,  $22\pm 4$  y).

**METHODS:** Subjects completed  $49\pm 6$  min of cycling after consuming either BG (250 mg/d) or a placebo (sugar pill, PL) for 10-d prior to each exercise session. The investigators were blinded to the supplement conditions until all data was collected and analyzed. Saliva was collected using a salivette placed under the tongue at baseline (BASE), before exercise (PRE), immediately after (POST), and two-hours after (2H) exercise. The salivette was kept in the mouth for 10-min and then transferred to a specially designed freezer tube and frozen ( $-80^\circ\text{C}$ ) until analysis for salivary IgA, IgM, IgG1, and IgG2 using a multiplex kit (MagPix). Data were analyzed using separate repeated measures ANOVAs and significance was set at  $P<0.05$ .

**RESULTS:** BG supplementation was associated with an increase in salivary IgA ( $P=0.048$ ) and a decrease in salivary IgM ( $P=0.029$ ) at 2H compared to placebo. In the placebo condition, there was a progressive decline in IgA and an increase in IgM, with the most pronounced changes occurring at 2H. Also, in the BG condition, IgA was increased and IgM was decreased at 2H compared to PRE and the placebo 2H samples. We did not find any significant differences for either salivary IgG1 or IgG2.

**CONCLUSIONS:** These findings suggest that supplementation with baker's yeast  $\beta$ -glucan may improve mucosal immunity following a strenuous bout of exercise. While previous research is not conclusive, a boost to mucosal immunity may reduce susceptibility to upper respiratory tract infection. This study was funded by Biothera, The Immune Health Company.

**1378** Board #159 MAY 30 11:00 AM - 12:30 PM

**Baker's Yeast  $\beta$ -glucan Supplementation Improves Monocyte And Cytokine Responses Following Exercise In A Hot, Humid Environment**

Katie C. Carpenter, Whitney L. Breslin, Tiffany Davidson, Amy Adams, Brian K. McFarlin, FACSM. University of Houston, Houston, TX. (Sponsor: Brian K McFarlin, FACSM)  
(No relationships reported)

**PURPOSE:** Strenuous exercise is known to suppress the immune system, which can increase the chances of getting sick in the hours after exercise. The purpose of this study was to determine if 10-d of supplementation with yeast  $\beta$ -glucan alters monocyte concentration, LPS-stimulated cytokine production, and plasma cytokine concentration in recreationally active subjects.

**METHODS:** Recreationally active subjects (29 men, 31 women, 22±4 y) completed 49±6 min of cycling (37±2°C, 45±5% relative humidity) after consuming either yeast β-glucan (250 mg/d, BG) or a placebo (sugar pill, PL) for 10-days prior to each exercise session. The investigators were blinded to the supplement conditions until all data was collected and analyzed. Venous blood was collected at baseline (prior to supplement), pre-, post-, and 2-hours (2H) post exercise. Total and subset monocyte concentration was measured by flow cytometry. LPS-stimulated production of 12 cytokines was measured using a whole blood assay. Plasma concentration of 13 cytokines was measured using a high-sensitivity MagPlex assay.

**RESULTS:** Monocyte (CD14+) concentration was significantly greater at 2H (P=0.05) with BG. Also, compared to PL, BG boosted LPS-stimulated production IL-2, IL-4, IL-5, and IFN-γ at PRE and POST (P<0.05). Plasma concentration of IL-2, IL-4, IL-5, IL-7, IL-10, and IFN-γ were significantly greater at 2H in the BG compared to PL. In the placebo condition we observed the traditional response to strenuous exercise (rise at POST and suppression at 2H). It appears that 10-days of supplementation with BG primed blood leukocytes for the production of IL-2, IL-4, IL-5, and IFN-γ. These cytokines were elevated prior to and immediately after exercise in LPS-stimulated cultures and subsequent elevation were observed at 2H with unstimulated plasma measures. In addition to cytokine changes, BG appeared to blunt post-exercise reduction in blood monocyte concentration, which may have implication of immune-surveillance.

**CONCLUSIONS:** The key findings of the present study demonstrate that BG may be a suitable countermeasure to protect and boost the immune system following stressful exercise. Such boost is likely to lower the duration of the “open window” response. This study was funded by Biothera, The Immune Health Company.

1379 Board #160 MAY 30 11:00 AM - 12:30 PM

**Effect of Six Weeks of Oral Echinacea Purpurea Supplementation on Erythropoiesis**

Tyler D. Martin<sup>1</sup>, Michael S. Green<sup>1</sup>, Malcolm T. Whitehead<sup>2</sup>, Timothy P. Scheett<sup>3</sup>, Michael J. Webster, FACSM<sup>1</sup>, <sup>1</sup>Troy University, Troy, AL, <sup>2</sup>Arkansas State University, State University, AR, <sup>3</sup>College of Charleston, Charleston, SC, <sup>4</sup>The University of Southern Mississippi, Hattiesburg, MS.

(No relationships reported)

*Echinacea purpurea*, a purple coneflower plant of the compositae family (Asteraceae), is native to North America and commonly used as an herbal supplement to enhance immune function. Recent research has demonstrated that four weeks of oral *Echinacea purpurea* supplementation (8,000 mg·d<sup>-1</sup>) in untrained males (42.5 ± 1.6 mL·kg<sup>-1</sup>·min<sup>-1</sup>) significantly increased serum erythropoietin (EPO). The increase in EPO was not accompanied by a significant increase in the number of red blood cells (RBCs) or hemoglobin concentration [Hb]; however, there were non-significant increases in the erythropoietic status by the end of the four week study (% change in RBC, hematocrit (Hct), [Hb], mean corpuscular volume (MCV)), suggesting the initiation of erythropoiesis.

**PURPOSE:** To investigate the effect of six weeks of oral *Echinacea purpurea* supplementation on serum EPO and erythropoietic status.

**METHODS:** Twenty-four males (mean ± SE): age = 25.2 ± 1.4 yr, height = 178.1 ± 1.4 cm, mass = 78.1 ± 1.6 kg, percent body fat = 12.7 ± 0.9 %, VO<sub>2max</sub> = 52.9 ± 0.9 mL·kg<sup>-1</sup>·min<sup>-1</sup> were randomly grouped using a matched-pair, double-blind design and self-administered 8,000 mg·d<sup>-1</sup> (5 × 400 mg × 4 times·d<sup>-1</sup>) of either *Echinacea purpurea* (ECH) (n=12) or placebo (PLA) (n=12) for 42 consecutive days. Blood samples were collected and analyzed for EPO, RBCs, Hb, Hct, MCV, and mean corpuscular hemoglobin concentration (MCHC). Separate 2 × 4 (Group × Time) factorial ANOVA with repeated measures were used to determine statistical differences with significance set at p ≤ 0.05.

**RESULTS:** There were no statistically significant (p > 0.05) interaction, group or time effects observed for EPO or erythropoietic status markers.

**CONCLUSION:** Six weeks of oral ECH supplementation in apparently healthy, recreationally active, males with above average fitness status (VO<sub>2max</sub> = 52.9 ± 0.9 mL·kg<sup>-1</sup>·min<sup>-1</sup>), does not enhance EPO or erythropoietic status. These findings are in contrast with previous reports of *Echinacea* supplementation. Any explanation for these differences, including the role that training and/or physical fitness level of participants, is unclear and speculative.

Supported by Troy University Faculty Development Research Grant.

1380 Board #161 MAY 30 11:00 AM - 12:30 PM

**Effects of 16wk Fucoxanthin and Punicic Acid Supplementation I: Body Composition and Hemodynamic Changes**

Geoffrey M. Hudson, Lisa A. Knecht, Cody J. Tullos, Emily R. Buras, Bethany L. Boleware, James T. Goetz, David E. Krzeminski, Alicia D. Sample, Michael J. Webster, FACSM. *The University of Southern Mississippi, Hattiesburg, MS.*

(No relationships reported)

Supplementation with 100 mg brown seaweed extract (0.8 % fucoxanthin) and 100 mg pomegranate seed oil (70 % punicic acid), abbreviated as Xan, has been shown to significantly reduce body fat, liver fat, and blood pressure (BP) in obese females.

**PURPOSE:** To determine the effects of Xan supplementation on body composition, heart rate, and BP in obese men and women.

**METHODS:** Twenty-nine obese men and women (29±8 y; 36.50±5.39 kg/m<sup>2</sup>; 43.8±8.0 % body fat) were matched on gender, age, and body fat percentage and randomized to either a Xan (n=14) or olive oil placebo (Pla; n=15) group. This study was double-blind and placebo-controlled. Participants were instructed to ingest 200 mg capsules of their given supplement three times per day (prior to meals) for 16 weeks while consuming a reduced calorie diet (equivalent to their resting energy expenditure). The 2011 ACSM physical activity guidelines were also recommended. Data were analyzed with repeated measures ANOVA and presented as means ± SD changes from baseline.

**RESULTS:** Analysis of the data demonstrated that body mass (Xan:-1.83±3.48 kg; Pla:-3.17±3.42 kg) and body mass index (Xan:-0.64±1.19 kg/m<sup>2</sup>; Pla:-1.14±1.21 kg/m<sup>2</sup>) were significantly reduced over the 16 weeks (p=0.001; p=0.001) with no group differences. Diastolic BP was significantly reduced (Xan:-6±9 mmHg; Pla:-2±9 mmHg; p=0.021), while there was a trend for a reduction of systolic BP (Xan:-10±10 mmHg; Pla:-3±13 mmHg; p=0.059). No significant within- or between-group effects were observed in body fat percentage or lean body mass.

**CONCLUSION:** The 16 weeks of Xan supplementation (600 mg/d) did not augment the effects of exercise and a reduced calorie diet on weight and BP in this obese population.

Supported by a grant from P.L. Thomas & Co., Inc.

1381 Board #162 MAY 30 11:00 AM - 12:30 PM

**Effects of 16wk Fucoxanthin and Punicic Acid Supplementation II: Metabolism**

Bethany L. Boleware, Lisa A. Knecht, Geoffrey M. Hudson, Cody J. Tullos, Emily R. Buras, David E. Krzeminski, James T. Goetz, Alicia D. Sample, Michael J. Webster, FACSM. *The University of Southern Mississippi, Hattiesburg, MS.*

(No relationships reported)

Supplementation with 100 mg brown seaweed extract (0.8 % fucoxanthin) and 100 mg pomegranate seed oil (70 % punicic acid), abbreviated as Xan, has been shown to significantly reduce body fat and liver fat assumedly by increasing metabolism.

**PURPOSE:** To determine the effects of Xan supplementation on resting energy expenditure (REE) and respiratory quotient (RQ) in obese men and women.

**METHODS:** Twenty-nine obese men and women (29±8 y; 36.50±5.39 kg/m<sup>2</sup>; 43.8±8.0 % body fat) were matched on gender, age, and body fat percentage and randomized to either a Xan (n=14) or olive oil placebo (Pla; n=15) group. This study was double-blind and placebo-controlled. Participants were instructed to ingest 200 mg capsules of their given supplement three times per day (prior to meals) for 16 weeks while consuming a reduced calorie diet (equivalent to their resting energy expenditure). The 2011 ACSM physical activity guidelines were also recommended. Data were analyzed with repeated measures ANOVA and presented as means ± SD changes from baseline.

**RESULTS:** Analysis of the data demonstrated significant reductions in REE (Xan:-38±140 kcal·d<sup>-1</sup>; Pla:-59±153 kcal·d<sup>-1</sup>) and absolute VO<sub>2</sub> (Xan:-0.003±0.021 L·min<sup>-1</sup>; Pla:-0.008±0.021 L·min<sup>-1</sup>) over the 16 weeks (p=0.007; p=0.001) with no between-group effects. No within- or between-group effects were observed with relative VO<sub>2</sub>, VCO<sub>2</sub>, or RQ.

**CONCLUSION:** As expected, weight loss resulted in a reduced REE; however, 16 weeks of Xan supplementation (600 mg/d) did not prevent reductions in REE typically occurring with weight loss.

Supported by a grant from P.L. Thomas & Co., Inc.

1382 Board #163 MAY 30 11:00 AM - 12:30 PM

**Effects of 16wk Fucoxanthin and Punicic Acid Supplementation III: Serum Lipids Changes**

Cody J. Tullios, Lisa A. Knecht, Geoffrey M. Hudson, Bethany L. Boleware, Emily R. Buras, Alicia D. Sample, Michael J. Webster, FACSM. *The University of Southern Mississippi, Hattiesburg, MS.*  
(No relationships reported)

Supplementation with 100 mg brown seaweed extract (0.8 % fucoxanthin) and 100 mg pomegranate seed oil (70 % punicic acid), abbreviated as Xan, has been shown to significantly reduce body fat, liver fat, and serum lipids in obese females.

**PURPOSE:** To determine the effects of Xan supplementation on serum lipid levels [i.e. high-density lipoprotein (HDL), low-density lipoprotein (LDL), total cholesterol, triglycerides] in obese men and women.

**METHODS:** Twenty-nine obese men and women (29±8 y; 36.50±5.39 kg/m<sup>2</sup>; 43.8±8.0 % body fat) were matched on gender, age, and body fat percentage and randomized to either a Xan (n=14) or olive oil placebo (Pla; n=15) group. This study was double-blind and placebo-controlled. Participants were instructed to ingest 200 mg capsules of their given supplement three times per day (prior to meals) for 16 weeks while consuming a reduced calorie diet (equivalent to their resting energy expenditure). The 2011 ACSM physical activity guidelines were also recommended. Data were analyzed with repeated measures ANOVA and presented as means ± SD changes from baseline.

**RESULTS:** Data analysis demonstrated that there was a trend for a reduction in serum triglycerides (Xan:-31±45 mg-dl-1; Pla:-5±66 mg-dl-1; p=0.071) and a trend for an interaction effect (p=0.088). No significant within- or between-group effects were observed in serum total cholesterol, HDL, or LDL levels.

**CONCLUSION:** The 16 weeks of Xan supplementation (600 mg/d) did not significantly augment the beneficial effects of exercise and a reduced calorie diet on serum cholesterol and triglyceride levels in this obese population. However, a larger decrease in serum triglyceride levels was observed in the Xan group, which may be of clinical significance. Supported by a grant from P.L. Thomas & Co., Inc.

**Effects of 16wk Fucoxanthin and Punicic Acid Supplementation IV: Markers of Liver and Kidney Function**

Emily R. Buras, Geoffrey M. Hudson, Lisa A. Knecht, Bethany L. Boleware, Cody J. Tullios, Alicia D. Sample, Michael J. Webster, FACSM. *The University of Southern Mississippi, Hattiesburg, MS.*  
(No relationships reported)

Supplementation with 100 mg brown seaweed extract (0.8 % fucoxanthin) and 100 mg pomegranate seed oil (70 % punicic acid), abbreviated as Xan, has been shown to significantly reduce body fat, liver fat, and improve serum markers of liver function in obese females.

**PURPOSE:** To determine the effects of Xan supplementation on serum markers of liver and kidney function in obese men and women.

**METHODS:** Twenty-nine obese men and women (29±8 y; 36.50±5.39 kg/m<sup>2</sup>; 43.8±8.0 % body fat) were matched on gender, age, and body fat percentage and randomized to either a Xan (n=14) or olive oil placebo (Pla; n=15) group. This study was double-blind and placebo-controlled. Participants were instructed to ingest 200 mg capsules of their given supplement three times per day for 16 weeks while consuming a reduced calorie diet (equivalent to their resting energy expenditure). The 2011 ACSM physical activity guidelines were also recommended. Data were analyzed with repeated measures ANOVA and presented as means ± SD changes from baseline.

**RESULTS:** Data analysis demonstrated that significant reductions in serum levels of alkaline phosphatase (ALP; Xan:-5±6 U-L-1; Pla:-3±9 U-L-1; p=0.001), alanine aminotransferase (ALT; Xan:-12±22 U-L-1; Pla:-4±7 U-L-1; p=0.021), total protein (Xan:-0.3±0.3 g-dl-1; Pla:-0.2±0.3 g-dl-1; p<0.001), and creatinine (Xan:-0.11±0.15 mg-dl-1; Pla: X:-0.08±0.13 mg-dl-1; p<0.001) were observed over the 16 weeks with a trend for an interaction effect for ALT (p=0.101), but no other between-group effects. Blood urea nitrogen (BUN) levels did not change over time, but there was a significant between-group effect (Xan:14±4 mg-dl-1; Pla:11±3 mg-dl-1; p=0.018). No within- or between-group effects were observed in serum aspartate aminotransferase, total bilirubin, or albumin.

**CONCLUSION:** The 16 weeks of Xan supplementation (600 mg/d) did not affect these liver and kidney function markers in this obese population.

Supported by a grant from P.L. Thomas & Co., Inc.

**The Effect of Yoga Exercise and Ascorbic acid Supplementation on Stress Hormones in Korean Young Females**

Malryun Shin<sup>1</sup>, Jungho Cho<sup>1</sup>, Ikwon Kang<sup>2</sup>, Jihyun Lee<sup>1</sup>, Jaehyun Jung<sup>1</sup>, Sunmin Kim<sup>1</sup>, Myungjoo Yang<sup>1</sup>, Sooyoun Kim<sup>1</sup>. <sup>1</sup>*Sookmyung Women's University, Seoul, Korea, Republic of.* <sup>2</sup>*Hongik University, Seoul, Korea, Republic of.*  
(No relationships reported)

**PURPOSE:** The purpose of this study was to investigate the effects of 8 weeks of ascorbic acid supplementation and yoga exercise on epinephrine, norepinephrine, glucagon and cortisol.

**METHODS:** Thirty young females were randomly assigned to one of three group. I.e., Group I(n=10): placebo(1000mg/day); GroupII(n=10): ascorbic acid(500mg/day) and placebo(500mg/day); Group III(n=10): ascorbic acid(1000mg/day) with yoga exercise(55-75% of HRmax, 3-4 d/w, 60-90min/d). The following measurements were made on all subjects before and after 8 week of experiment. Analysis of covariance and bonferroni test were used to determine the statistical significance.

**RESULTS:** There were no significant differences in epinephrine, norepinephrine and glucagon but cortisol were significantly changed(p<.05).

**CONCLUSIONS:** 8 week's ascorbic acid supplementation with yoga exercise was effective for epinephrine, norepinephrine, glucagon and cortisol in Korean young females. Determination of which exercise types, ascorbic acid dosage and fitness status of individuals would produce reproducible ergogenic effects is a logical extension of current research.

1385 Board #166 MAY 30 11:00 AM - 12:30 PM

**Vitamin C Does Not Prevent Endurance Training-induced Improvement Of Glucose Tolerance And Insulin Sensitivity**

Ayuko Nii, Koichi Yada, Shigeru Obara, Hideki Matoba. *The University of Tokushima, Tokushima, Japan.*  
(No relationships reported)

Conflicting results have been reported concerning the involvement of reactive oxygen species (ROS) in endurance training-induced improvement of glucose tolerance and insulin sensitivity.

**PURPOSE:** The purpose of this study was to determine whether vitamin C supplementation prevented the training-induced improvement of glucose tolerance and insulin sensitivity in rats.

**METHODS:** Twenty male rats, 4-week of age, were assigned to four groups: sedentary control, sedentary with vitamin C supplementation, trained control, trained with vitamin C supplementation (n=5 each). The rats of vitamin C supplemented groups were administered 500mg per kg body weight of vitamin C from 12 days before the start of the training until the end of the training period. The rats of the trained groups swam 6h/day with two 3h sessions separated by 45 min of rest. The training lasted for 2 weeks with a frequency of 5 days per week. After the training period, the rats underwent intraperitoneal glucose tolerance test (IPGTT). Glucose and insulin responses during IPGTT were assessed by the area under the curve (AUC). Insulin resistance was evaluated using homeostasis model assessment as an index of insulin resistance (HOMA-R). Insulin sensitivity was evaluated using composite whole-body insulin sensitivity index (ISI (comp)).

**RESULTS:** The training significantly suppressed body weight gain (P<0.01). There was no difference in fasting glucose levels and fasting insulin levels among the groups. There was also no significant difference in the HOMA-R indices among the groups. On the other hand, the training significantly lowered the AUC for glucose and insulin (P<0.05). The training significantly increased ISI (comp) (P<0.05). The vitamin C supplementation did not alter the AUC for glucose, the AUC for insulin and ISI (comp).

**CUNCLUSION:** This study suggests that the vitamin C supplementation does not prevent the training-induced improvement of glucose tolerance and insulin sensitivity in rats.

**Effects of Quercetin Supplementation on Physical Function in Older Adults**

Stephen C. Chen<sup>1</sup>, J. Mark Davis, FACSM<sup>1</sup>, E. Angela Murphy<sup>1</sup>, Michele Neese<sup>2</sup>, Matthew Kostek<sup>1</sup>, Kei Lam<sup>1</sup>, John Sieverdes<sup>1</sup>, Victor Hirth<sup>2</sup>, Andres Leone<sup>2</sup>, Seung H. Jung<sup>1</sup>, Benjamin Gordon<sup>1</sup>, Katie Becofsky<sup>1</sup>, Toni Torres-McGehee<sup>1</sup>, Steve Blair, FACSM<sup>1</sup>, J. Larry Durstine, FACSM<sup>1</sup>. <sup>1</sup>University of South Carolina, Columbia, SC. <sup>2</sup>Palmetto Health Senior Primary Care, Columbia, SC. (Sponsor: Mark Davis, FACSM)  
(No relationships reported)

Fatigue is a common complaint among older adults and is associated with functional decline and multiple adverse health outcomes. Previous studies in our laboratory have shown that the dietary flavonoid quercetin can enhance voluntary activity and endurance performance in mice as well as aerobic capacity in young adults. However, the benefits of quercetin on physical function in older adults has not yet been evaluated.

**PURPOSE:** To determine the effects of short-term quercetin (QUE) versus placebo (PLA) supplementation on habitual physical activity ( $N=10$ ), physical performance ( $N=18$ ) as well as markers of mitochondrial biogenesis ( $N=4$ ) in healthy older adults (61 to 89 years).

**METHODS:** Subjects were randomized to receive QUE (1000 mg-day<sup>-1</sup>) or PLA for 14 days using a double-blind, placebo controlled, crossover study design with a 2-week washout period. Physical activity patterns were assessed by accelerometry daily throughout the study. After completion of treatments, physical performance including VO<sub>2</sub> peak, Short Physical Performance Battery (SPPB) and 6-minute walk (6MW) were determined, and muscle biopsies acquired from the vastus lateralis were analyzed for mRNA gene expression of PGC-1 $\alpha$ , citrate synthase and cytochrome c using RT-PCR.

**RESULTS:** QUE feedings significantly increased daily steps count by 16.7% compared with PLA (4811.7  $\pm$  778.5 vs. 5614.9  $\pm$  993.3 steps-day<sup>-1</sup>, respectively,  $P=0.02$ ), along with a trend for increased minutes of moderate intensity of physical activity (10.5  $\pm$  3.9 vs. 7.6  $\pm$  2.6 min-day<sup>-1</sup>,  $P=0.11$ ). QUE increased mRNA gene expression of PGC-1 $\alpha$ , citrate synthase and cytochrome c by 49%, 26% and 32%, respectively, although these did not reach statistical significance which is likely due to the small sample size that was used in this analysis. No differences were found between QUE and PLA conditions for VO<sub>2 peak</sub>, SPPB score, and 6MW distance.

**CONCLUSION:** These novel data suggest that short-duration QUE feedings can promote physical activity in older adults, and that these effects may be partially attributed to the increased muscle mitochondrial biogenesis which plays a role in fatigue development. Overall, the results of this study provide evidence in support of dietary QUE as a possible safe and effective nutritional strategy for disease prevention and health promotion in the elderly.

**Effect Of Resveratrol On Oxidative Stress And Skeletal Muscle Oxygenation With NIRS In Trained Cyclists**

Claude Lajoie, Sana Driss, Maria-Grazia Martinoli, Simon Bergeron-Vaillancourt, Louis Laurencelle, Fanny Longpré. UQTR, Trois-Rivieres, QC, Canada. (Sponsor: Francois Trudeau, FACSM)  
(No relationships reported)

During strenuous exercise, there is a dramatic increase in oxygen consumption that leads to an increased oxygen species (ROS) production. This increase in ROS results in oxidative stress, which has been associated with muscle fatigue and impaired recovery following high-intensity aerobic exercise.

**PURPOSE:** The purpose of the present study was to evaluate the effects of a Resveratrol supplementation on protein blood markers of oxidative stress and blood antioxidant capacity during a single bout of intermittent exercise and recovery in trained cyclists. A second purpose was to measure vastus lateralis muscle oxygenation, using near infrared spectroscopy (NIRS), blood lactate concentration and whole body oxygen consumption under the Resveratrol condition.

**METHODS:** A double-blind study was conducted with 7 male trained cyclists, aged 37.3  $\pm$  11.7 years. The participants completed two sessions high intensity interval training (HIT) in two conditions, with and without Resveratrol supplementation (1000 mg daily) in orange juice, 7 consecutive days before the experiment, with partially counterbalanced conditions across subgroups. Blood sampling was collected pre- and post-exercise for the determination of protein carbonyls (PC) and total antioxidant capacity (TAC).

**RESULTS:** Resveratrol supplementation did not improve organism's antioxidant defence and protein carbonyl blood concentrations following HIT. Under Resveratrol supplementation, tissue saturation index in oxygen (TSI%) in vastus lateralis was slightly less attenuated ( $p<0.05$ ) at the end of HIT ( $\Delta = -1.3\%$ ) as compared to placebo condition ( $\Delta = -2.0\%$ ). Resveratrol had no effect on skeletal muscle oxyhemoglobin (O<sub>2</sub>Hb) deoxyhemoglobin (HHb) and total hemoglobin (THb). Heart rate and blood lactate concentration recovery both showed a tendency ( $p 0.10$ ) to decrease following 15 min passive recovery under the Resveratrol condition. However, a positive correlation trend ( $r = 0.72$ ,  $p = 0.07$ ) was observed between THb and TAC.

**CONCLUSION:** This study did not show an effect of Resveratrol on protein carbonyl and antioxidant capacity. However, Resveratrol improved tissue saturation index (TSI%) in vastus lateralis during the HIT.

1388 Board #169 MAY 30 11:00 AM - 12:30 PM

**Involvement of PI3K/Akt/mTOR Pathway in Angelica sinensis Induced Myotube Hypertrophy.**

Tzu-Shao Yeh, FACSM<sup>1</sup>, Jen-Fang Liu<sup>1</sup>, Mei-Chieh Hsu, FACSM<sup>2</sup>. <sup>1</sup>Taipei Medical University, Taipei, Taiwan. <sup>2</sup>National Taiwan Sport University, Taoyuan, Taiwan.  
(No relationships reported)

**PURPOSE:** Herbal medicine has long been used in ergogenic aids for athletes but there is little scientific evidence for their actions. To investigate whether Angelica sinensis increases hypertrophy of myotubes through activating the PI3K/Akt/mTOR pathway, have been proposed to promote skeletal muscle hypertrophy and prevent muscle atrophy.

**METHODS:** We examined the PI3K/Akt/mTOR pathway in C2C12 myotubes, a well-established in vitro model of skeletal muscle hypertrophy, with or without Angelica sinensis extract for 72 hours.

**RESULTS:** In Angelica sinensis extract treated, the average myotube diameter was 1.34 $\pm$ 0.13 fold to normal, which is significantly larger than the diameter in non-herbal supplements cultures. This indicates clearly that myotubes were hypertrophied by Angelica sinensis extract. Hypertrophy was largely suppressed by wortmannin or rapamycin, inhibitors of PI3K or mTOR, respectively. The PI3K inhibitor, wortmannin, decreased the diameter of Angelica sinensis extract treated myotubes by 25%, as well as that of positive controls by approximately 30%. The mTOR inhibitor, rapamycin behaved similarly to wortmannin. These results indicate that the PI3K/Akt/mTOR pathway plays an important role in Angelica sinensis-induced myotube hypertrophy.

**CONCLUSIONS:** Angelica sinensis promotes hypertrophy in cultured skeletal myotubes through activating the PI3K/Akt/mTOR pathway. Furthermore, phosphorylation of Akt was enhanced by Angelica sinensis treatment and suppressed by wortmannin. Angelica sinensis and its derivatives may be promising candidates for the treatment of muscular dystrophy.

1389 Board #170 MAY 30 11:00 AM - 12:30 PM

**Efficacy of Tart Cherry Juice to Reduce Inflammation Among Patients with Osteoarthritis**

Adriana E. Sleight, Kerry S. Kuehl, Diane L. Elliot, FACSM. Oregon Health & Science University, Portland, OR.  
(No relationships reported)

**PURPOSE:** Osteoarthritis (OA) is a common syndrome affecting 65 million Americans characterized by joint pain, limitation of movement, crepitus, occasional effusion, and variable degrees of local inflammation. Up to 40% of OA patients have inflammation. Numerous antioxidant and anti-inflammatory agents have been identified in tart cherries and may be beneficial for the treatment of pain and inflammation. This study assessed the effects of tart cherry juice on serum inflammation biomarkers among women with inflammatory OA.

**METHODS:** We used a three week, randomized, placebo controlled design among twenty 40-70 year old females with inflammatory OA. All subjects fulfilled the 1990 American College of Rheumatology classification guidelines for the diagnosis of osteoarthritis with evidence of swelling in at least one joint in the past year. For 21 days, subjects ingested 10.5 fl oz of tart cherry juice or a placebo beverage twice a day. Pre and post drink intervention blood measurements included IL-6, IL-10, TNF- $\alpha$ , and CRP.

**RESULTS:** Among the subjects who consumed tart cherry juice, all serum biomarkers showed evidence of decreased inflammation, however the only statistically significant change was observed in TNF- $\alpha$  ( $P < 0.05$ ). In addition, a subset analysis was performed on those subjects with active inflammation as defined by CRP  $> 3.0$  mg/L. Within the high inflammation subset ( $n = 12$ ), there was a statistically significant decrease in TNF- $\alpha$  and CRP for subjects on the tart cherry juice as compared to placebo.

**CONCLUSIONS:** Tart cherries have the highest antioxidant and anti-inflammatory content of any food. This study suggests a benefit of tart cherry juice in reducing inflammation as measured by certain serum inflammatory biomarkers among women with OA. Pain relief and improvement of functional disability are the main goals of OA treatment and it is important to look at healthy alternative therapies to conventional methods in the treatment and management of inflammatory osteoarthritis. Tart cherries may provide beneficial anti-inflammatory activity helping OA patients manage their disease.

**1390** Board #171 MAY 30 11:00 AM - 12:30 PM

**Melatonin And Sleep Quality Are Increased Following Tart Cherry Juice Consumption**

Glyn Howatson, FACSM<sup>1</sup>, Phillip G. Bell<sup>1</sup>, Jamie Tallent<sup>1</sup>, Benita Middleton<sup>2</sup>, Malachy P. McHugh, FACSM<sup>3</sup>, Jason Ellis<sup>1</sup>. <sup>1</sup>Northumbria University, Newcastle-upon-Tyne, United Kingdom. <sup>2</sup>University of Surrey, Guildford, United Kingdom. <sup>3</sup>Nicholas Institute of Sports Medicine and Athletic Trauma, NY, NY.  
(No relationships reported)

Tart Montmorency cherries contain high levels of phytochemicals that include melatonin. Considering the alleged rampant use of prescription sleep medications in professional sports with a lot of travel (e.g. NHL), cherry juice might be a viable non-pharmacological alternative. We hypothesized that consumption of a tart cherry juice concentrate would provide an exogenous supply of melatonin and have a positive influence on sleep.

**PURPOSE:** The aim of our investigation was to examine the effect of tart cherry juice on melatonin metabolism and the subsequent influence on sleep quality in healthy asymptomatic adults.

**METHODS:** Twenty volunteers participated in this randomized, double-blind, placebo controlled, cross-over trial. Cherry juice or a placebo was administered for 7 days following a 48 h baseline period. Measures of sleep quality were determined with actigraphy (sleep onset latency, time in bed, fragmentation index, total sleep time and sleep efficiency) and urinary 6-sulfatoxymelatonin (aMT6); these were recorded for both baseline periods and the final 48 h of each supplement period. Determination of the circadian rhythm (amplitude, acrophase and mesor of aMT6) was determined using cosinor analysis. In addition, total aMT6 was also determined for the aforementioned epoch.

**RESULTS:** Total sleep time was significantly greater with cherry juice than baseline and placebo trials ( $P = 0.003$ ; 95% CI = 14.7 - 63.6 min). Sleep efficiency also showed improvements with the cherry juice over placebo trials ( $P = 0.017$ ; 95% CI = 0.5 - 9.4%). Although circadian rhythm measures were not different, total aMT6 was greater with cherry juice ( $P < 0.001$ ; 95% CI = 2519 - 5450 ng).

**CONCLUSIONS:** Tart cherry juice provides an increase in exogenous melatonin, improves sleep indices and hence the propensity for improved sleep quality in healthy adults. These findings present athletic and clinical populations with an alternative and viable solution for managing disturbed sleep.

---

**1391** Board #172 MAY 30 11:00 AM - 12:30 PM

**Dose Response Effects of Pomegranate Juice Concentrate Supplementation on DOMS**

Daniel R. Machin, Kevin M. Christmas, Ting-Heng Chou, Sarah C. Hill, Douglas Van Pelt, Justin R. Trombold, Edward F. Coyle, FACSM. *The University of Texas at Austin, Austin, TX.*  
(No relationships reported)

An acute bout of unaccustomed eccentric exercise causes prolonged strength loss and delayed onset muscle soreness (DOMS) for several days. Chronic dietary supplementation with polyphenols, from pomegranates, has been shown to accelerate recovery following eccentric exercise (Trombold et al. MSSE 42 (3) 493-498, 2010), however the optimal dose is unknown.

**PURPOSE:** To determine the effect of dietary supplementation with different doses of pomegranate juice concentrate (PJC) on isometric strength and soreness throughout a 96-hour period following an acute bout of eccentric exercise.

**METHODS:** Forty-five healthy, recreationally active males (22.3  $\pm$  4.0 y, 73.8  $\pm$  11.5 kg, 174.9  $\pm$  6.2 cm) were assigned to one of three treatment groups: Once-daily PJC (1x), twice-daily PJC (2x), or placebo (PLA) supplementation over a period of eight days. A 1x dose of PJC provided approximately 650 mg GAE. On day four of each treatment, subjects performed downhill running intervals (-10% decline) over a 40 minute period followed by 40 repetitions of eccentric elbow flexion at 100% of concentric 1-RM. Muscle soreness and maximal isometric strength of the elbow flexor and knee extensor muscles were assessed pre-exercise, 2, 24, 48, 72, and 96 hours post-exercise. Treatment comparisons were made using a one-way ANOVA with  $p < 0.05$ . Values were reported as mean  $\pm$  SD.

**RESULTS:** Throughout the 96-hour period after exercise, isometric elbow flexor strength was significantly higher in 1x and 2x groups as compared to PLA (main treatment effect, 83.6  $\pm$  2.7%, 85.6  $\pm$  1.9%, and 78.4  $\pm$  1.8%, respectively;  $p < 0.001$ ). Isometric knee extensor strength was significantly higher in 1x and 2x groups as compared to PLA (main treatment effect, 93.9  $\pm$  1.5%, 91.6  $\pm$  1.5%, and 87.1  $\pm$  1.8%, respectively;  $p < 0.001$ ). Muscle soreness peaked 24-48 hours following exercise, but was not different between treatments.

**CONCLUSION:** Dietary supplementation with 1x or 2x PJC results in higher isometric strength values compared to placebo for elbow flexor and knee extensor muscles during the 96-hour period after an acute bout of eccentric exercise. Once per day supplementation of PJC is equally effective as twice per day for recovery of isometric strength in the four days after downhill running or eccentric elbow flexion exercise.

**1392** Board #173 MAY 30 11:00 AM - 12:30 PM

**Effects Of A Botanical Supplement On Recovery From Delayed Onset Muscle Soreness**

Corey A. Rynders, Judy Y. Weltman, Chelsea Williams, Frank I. Katch, FACSM, Jay Hertel, FACSM, Arthur Weltman, FACSM. *University of Virginia, Charlottesville, VA.*  
(No relationships reported)

**PURPOSE:** We examined the effects of a supplement containing a proprietary blend of botanical concentrates of Aphanizomenon flos-aquae (blue-green algae), antioxidants, enzymes, and D-Ribose (StemSport, Stemtech HealthSciences, Inc., San Clemente, CA) suggested to increase circulating stem cells, decrease local muscle inflammation, and attenuate exercise induced muscle damage on recovery from delayed onset muscle soreness (DOMS).

**METHODS:** Fifteen males ( $N = 7$ ) and females ( $N = 8$ ); age  $24.4 \pm 4.8$  years; stature  $171.9 \pm 10.0$  cm, mass  $72.2 \pm 14.7$  kg) were randomized in a crossover, double-blind, placebo controlled trial to receive a placebo or supplement (4050 mg/day) for 14 days. DOMS was induced on day 7 for both placebo and active conditions in the non-dominant elbow flexor group with repeated eccentric contractions. Muscle swelling (biceps girth), elbow flexor isometric strength (hand held dynamometer), muscle pain/tenderness (visual analog scale), and range of motion (active elbow flexion and extension) were measured at baseline and at 24, 48, and 72 h post eccentric exercise. The crossover washout period was  $\geq 14$  days.

**RESULTS:** No significant condition-by-time interactions occurred between placebo and supplementation for the criterion measures of muscle swelling ( $p = 0.59$ ), elbow flexion ( $p = 0.27$ ), isometric strength ( $p = 0.74$ ), pain ( $p = 0.16$ ), or tenderness ( $p = 0.53$ ). Decrements in elbow extension range of motion between 24 and 48 h post-exercise were less following supplementation ( $\Delta$  elbow extension 24-48h post; supplement,  $-0.04 \pm 5.0$  deg; placebo,  $-2.8 \pm 5.5$  deg;  $p = 0.04$ ).

**CONCLUSIONS:** Compared to placebo, supplementation did not significantly improve recovery outcome measures related to muscle recovery after upper-arm induced DOMS.

Supported in part by an unrestricted gift from Stemtech HealthSciences, Inc., San Clemente, CA. 92673. F.I. Katch, J. Hertel, and A. Weltman serve as scientific advisors to Stemtech HealthSciences.

**1393** Board #174 MAY 30 11:00 AM - 12:30 PM  
**Can Therapeutic Use Of Terbutaline Be Distinguished From Doping Use With A Urine Sample**

Jimmi Elers. *Copenhagen University Hospital: Bispebjerg, Copenhagen, Denmark.*  
(No relationships reported)

**PURPOSE:** We examined urine and serum concentrations after therapeutic use of single and repetitive doses of inhaled terbutaline and suprathreshold use of a single oral dose of terbutaline.

**METHODS:** We compared the concentrations in asthmatics with regular use of beta2-agonists prior to study and healthy subjects with no previous use of beta2-agonists. We enrolled 10 asthmatics and 10 controls in an open-label, cross-over study in which subjects were administered 2 mg inhaled and 10 mg oral terbutaline on two study days. Further 10 healthy subjects were administered 1 mg inhaled terbutaline every second hour (total 4 mg), which is the maximum permitted daily dose by the World Anti-Doping Agency (WADA). Blood samples were collected at baseline, 30 min, 1, 2, 3, 4, and 6 h after the first inhalations. Urine samples were collected at baseline, 0-4 h, 4-8 h, and 8-12 h after the first inhalations.

**RESULTS:** Median (IQR) urine concentrations peaked in the period 0-4 h after inhalation with Cmax 472 (324) ng x mL<sup>-1</sup> in asthmatics and 661 (517) ng x mL<sup>-1</sup> in healthy subjects, and 4-8 h after oral use with Cmax 666 (877) ng x mL<sup>-1</sup> in asthmatic and 402 (663) ng x mL<sup>-1</sup> in healthy subjects. All urine concentrations were corrected for the urine specific gravity.

**CONCLUSION:** In conclusion we found no significant differences in urine and serum concentrations between asthmatic and healthy subjects. We compared urine and serum concentrations after therapeutic inhaled doses and suprathreshold oral doses and observed significant statistical differences in both groups. We found high variability in urine concentrations between subjects in both groups. The variability between subjects was still present after the samples were corrected for urine specific gravity. When evaluating our results we found it impossible to distinguish between permitted therapeutic use and prohibited suprathreshold use based on doping tests with urine and blood samples.

**1394** Board #175 MAY 30 11:00 AM - 12:30 PM  
**Effect of Exercise and Aged Garlic Extract on Metabolic Parameters in High-Fat Diet-Induced Obese Rats**

Dae Yun Seo<sup>1</sup>, Sung Ryul Lee<sup>1</sup>, Yeong Ho Baek<sup>2</sup>, Yi Sub Kwak<sup>3</sup>, Arturo Figueroa<sup>4</sup>, Nari Kim<sup>1</sup>, Byoung Doo Lee<sup>1</sup>, Kyueng Soo Ko<sup>1</sup>, Tae Hee Ko<sup>1</sup>, Jin Han<sup>1</sup>. <sup>1</sup>Inje University, Busan, Korea, Republic of. <sup>2</sup>Pusan National University, Busan, Korea, Republic of. <sup>3</sup>Dong Eui University, Busan, Korea, Republic of. <sup>4</sup>Florida State University, Tallahassee, FL.  
(No relationships reported)

The worldwide prevalence of obesity is increasing at an alarming rate, with major adverse consequences for human health. Aged garlic extract (AGE) is widely promoted as a cholesterol-lowering agent and exercise alone is widely perceived to be beneficial for improving metabolic function in high fat diet (HFD) induced obese rats through reducing metabolic parameters.

**PURPOSE:** The purpose of this study was to investigate the effect of exercise and/or AGE on body weight, lipid profiles, inflammatory and oxidative stress markers in HFD induced obese rats.

**METHODS:** Forty Sprague Dawley rats were switched to HFD diet for 6 week and randomized into five groups: HFD (n=10), HFD with exercise (n=10), HFD with AGE (n=10), and HFD with exercise and AGE (n=10) for 4 weeks. AGE was administered orally at a dose of 2.86 g/kg. Exercise consisted of 15-60 min of running 5 times/day with gradually increasing intensity.

**RESULTS:** AGE (p<0.01), Exercise, and Exercise with AGE (p<0.001) significantly decreased body weight gain, average weight gain and food efficiency rate compared to HFD. AGE significantly decreased visceral fat (p<0.05), and liver (p<0.01). Exercise significantly decreased visceral fat, and liver (p<0.01). In reducing visceral fat (p<0.001), epididymal fat (p<0.01) and liver weight (p<0.001), Exercise with AGE was effective but exercise showed stronger suppressing effect than AGE admin. Consumption of AGE significantly inhibited the increase in total cholesterol (65.1±10.0 vs HFD: 92.64±2.9) and low density lipoprotein-cholesterol (37.4±8.1 vs HFD: 52.1±18.6). C-reactive protein (CRP) and malondialdehyde (MDA) were significantly decreased compared to HFD (p<0.05).

**CONCLUSION:** AGE supplementation and exercise alone have anti-obesity effects AGE with exercise result in improvements of inflammatory and oxidative stress markers independently of changes in adiposity and lipids.

**1395** Board #176 MAY 30 11:00 AM - 12:30 PM  
**Effects of Oxygenated Water on Aerobic Performance in Division II Collegiate Male Soccer Players**

Tina M. Manos, Peter J. Fuller, Thomas J. Koesterer. *Humboldt State University, Arcata, CA.*  
(No relationships reported)

Supplemental oxygen (O<sub>2</sub>), ingested in commercially-available "oxygenated water" preparations, has not been shown to have consistent effects on aerobic performance measures. Most researchers have found no significant differences in oxygen saturation of hemoglobin, VO<sub>2</sub> max, and time to exhaustion when comparing the effects of oxygenated water to placebo; yet, in some studies, highly-fit subjects ingesting oxygenated water were found to have significantly higher values for these measures.

**PURPOSE:** To determine the effects of oxygenated water on aerobic performance in Division II male soccer players.

**METHODS:** A randomized, double-blind, cross-over design was used to study 12 Division II soccer players (age = 20.1 ± 1.4 years; mass = 73.3 ± 10.6 kg; height = 176.0 ± 6.9 cm) with the fastest two-mile run times (12:34 ± 0:19 min:sec) of their team (n = 20). Two maximal tests were conducted (8 mph, 2.5% grade initially, with increments of 2.5% grade every two minutes until volitional exhaustion) approximately 1 week apart; conditions were 500 ml of bottled water (placebo) or commercial "activated stabilized oxygen" water taken 15 min prior to the test. Time to exhaustion, oxygen saturation of hemoglobin (SpO<sub>2</sub>; via pulse oximetry), heart rate (HR), and expired gases were measured.

**RESULTS:** The SpO<sub>2</sub> (95.58 ± 3.05 vs. 96.08 ± 2.46%; p = .497), HR (187.00 ± 8.66 vs. 187.16 ± 7.73 bpm; p = .942), and VO<sub>2</sub> (57.26 ± 4.93 vs. 58.15 ± 3.87 ml/kg/min; p = .351) at the highest common workload achieved on both trials were not different between the placebo and oxygenated water conditions, respectively. The SpO<sub>2</sub> at the lowest point during the maximal testing (94.58 ± 2.90 vs. 94.92 ± 2.06%; p = .732) and the SpO<sub>2</sub> at exhaustion (94.75 ± 3.01 vs. 95.16 ± 2.24%; p = .610) were not different between conditions. VO<sub>2</sub> max (59.97 ± 4.24 vs. 60.92 ± 3.51 ml/kg/min; p = .247) and maximum HR (192.08 ± 7.69 vs. 191.08 ± 7.63 bpm; p = .597) also were not significantly different between the conditions. Although the time to exhaustion (428.83 ± 62.54 vs. 451.17 ± 57.05 sec; p = .072) was longer by 22.34 seconds for oxygenated water versus placebo, the difference did not reach statistical significance.

**CONCLUSION:** Ingestion of oxygenated water did not result in any changes in aerobic performance measurements in Division II male soccer players.

**1396** Board #177 MAY 30 11:00 AM - 12:30 PM  
**Polyphenol Rich Juice Supplementation in Olympic Swimmers does not alter Inflammation or Immune Biomarkers**

Amy M. Knab<sup>1</sup>, Nicholas D. Gillitt<sup>2</sup>, Lynn Ciadella-Kam<sup>1</sup>, David C. Nieman, FACSM<sup>1</sup>, R. Andrew Shanelly<sup>1</sup>. <sup>1</sup>Appalachian State University, Kannapolis, NC. <sup>2</sup>Dole Nutrition Research Institute, Kannapolis, NC.  
(No relationships reported)

**PURPOSE:** This study investigated the effects of consumption of a juice blend made from whole fruits and vegetables on innate immunity, and chronic and acute inflammation in elite swimmers training three hours per day, compared to non-athletic controls.

**METHODS:** Nine male swimmers and seven controls were recruited and compared before and after a 10-day study period. Swimmers were randomized, and completed 10 days supplementation with or without 16 fl oz of the juice ingested pre- and post-workout, with a three week wash out period between supplementation periods. Blood samples were taken pre-supplementation, post-10 days supplementation, and immediately post-exercise on the 10<sup>th</sup> day.

**RESULTS:** Age was not different between swimmers (24.6 ± 0.7 y) and controls (25.7 ± 1.3 y). Swimmers were significantly fitter (VO<sub>2max</sub> = 53.1 ± 1.4 ml·kg<sup>-1</sup>·min<sup>-1</sup>, body fat = 11.7 ± 0.8%) compared to controls (VO<sub>2max</sub> = 39.9 ± 2.7 ml·kg<sup>-1</sup>·min<sup>-1</sup>, body fat = 19.6 ± 1.6 %). All pre-exercise measures of inflammation and immune function were not different between swimmers and controls. The patterns of change (chronic) in inflammatory cytokines (IFN-γ, IL-1β, IL-6, IL-10, IL-8, IL-12p70, and TNF-α) and innate immune function (granulocyte and monocyte phagocytosis/oxidative burst activity) were not different between juice and non-juice conditions over the 10-day study period. A single training bout at the end of the 10-day supplementation period caused a small but significant increase in plasma IL-6 (0.3 ± 0.1 to 0.8 ± 0.1 pg·ml with juice, and 0.5 ± 0.1 to 0.8 ± 0.1 pg·ml with no juice) and IL-10 (but not other cytokines), with no

differences between juice and non-juice conditions. The training bout caused a small but significant increase in phagocytosis and oxidative burst activity, with no differences between juice and non-juice conditions.

**CONCLUSIONS:** Contrary to expectations, high-level training in elite swimmers was not associated with chronic inflammation or dysfunctional innate immunity, and acute changes post-3-h aerobic/anaerobic training bouts were mild or indicative of immune stimulation. The mixed fruit-vegetable juice supplement (~9500 ORAC units) is a nutritious addition to the training diet, but has no influence on inflammation and innate immune measures that could be considered already at favorable levels. (Funded by Dole Foods Inc.)

**1397** Board #178 MAY 30 11:00 AM - 12:30 PM

**Effect of 4 Weeks Resveratrol Supplementation on Body Composition in Healthy Adults**

Sarah J. Wherry<sup>1</sup>, James M. Smoliga<sup>2</sup>. <sup>1</sup>Arizona State University, Phoenix, AZ. <sup>2</sup>High Point University, High Point, NC.

(No relationships reported)

Resveratrol, a polyphenol found in grapes and other plants, has been demonstrated to have a number of beneficial health effects in laboratory models. Current evidence suggests there is much potential for resveratrol to decrease fat mass and increase muscle mass and bone mass. However, no human clinical trials have examined the effects of resveratrol supplementation on body composition.

**PURPOSE:** To evaluate the effects of 4 weeks oral supplementation of a resveratrol mixture (400mg 98% pure *trans*-resveratrol, 400mg grape extract, 100mg quercetin) on body composition parameters in healthy individuals, including total mass, fat mass, lean mass, and bone mass.

**METHODS:** 41 healthy adults (13 male, 28 female) between the ages of 18-75 were randomized to either the resveratrol (RES, n = 21) or placebo (PLA, n = 20) groups. Individuals participated in two testing visits: baseline (Pre) and post-supplementation (Post). Each visit included a fasting Dual-Energy X-ray Absorptiometry (DEXA) scan during which total body mass, fat mass, lean mass, and bone mass were measured. Following Pre, participants self-administered their respective supplement once daily for 4 weeks. Participants then underwent their Post DEXA scan. Data were analyzed using Repeated Measures ANOVA to determine if a significant ( $p \leq 0.05$ ) Group x Visit effect existed.

**RESULTS:** Total body mass was unchanged between groups (mean  $\pm$  sd; PLA: Pre = 70.4  $\pm$  14.1kg, Post = 70.2  $\pm$  13.9kg; RES: Pre = 74.7  $\pm$  14.7kg, Post = 74.8  $\pm$  14.8kg;  $p = 0.317$ , power = 0.167). There were no significant Group x Visit effects for fat mass (PLA: Pre = 24.2  $\pm$  9.5kg, Post = 24.3  $\pm$  9.6kg; RES: Pre = 23.7  $\pm$  9.3kg, Post = 23.7  $\pm$  9.3kg;  $p = 0.664$ , power = 0.071), lean mass (PLA: Pre = 46.4  $\pm$  10.3kg, Post = 46.1  $\pm$  9.9kg; RES: Pre = 48.1  $\pm$  10.2kg, Post = 48.3  $\pm$  10.0kg,  $p = 0.195$ , power = 0.251), or bone mass (PLA: Pre = 2.83  $\pm$  0.62kg, Post = 2.84  $\pm$  0.63kg; RES: Pre = 2.87  $\pm$  0.62kg, Post = 2.87  $\pm$  0.63kg;  $p = 0.435$ , power = 0.120). **DISCUSSION:** It appears that short-term resveratrol supplementation does not alter body composition parameters in healthy adults. Further research using larger sample sizes, longer supplementation periods, and concurrent exercise in a variety of populations should be performed to better evaluate resveratrol's efficacy.

---

(No relationships reported)

**PURPOSE:** Resveratrol is one of many phenolic compounds that have been suggested as having potential applications in chronic disease prevention, however, most of the current evidence is based on in vitro findings. Given the potential benefits of resveratrol for combating chronic inflammatory diseases, it is important to evaluate the bioavailability of resveratrol especially as it has been suggested that the compound is rapidly metabolized and eliminated in humans.

**METHODS:** Twelve healthy, young males completed the study. Blood samples were collected at 30, 60 and 90 min following ingestion of a 1 g oral resveratrol dose (Transmax, Biotivia Biocenticals, Vienna, Austria). Plasma samples were analyzed using high performance liquid chromatography and eluted resveratrol and metabolite peaks identified by mass spectrometry. The identity of resveratrol was confirmed by MS in plasma samples containing a standard at 100 ng/mL and 200 ng/mL concentrations with retention time identified by spikingOut of six peaks appearing on the HPLC chromatogram, the identities of resveratrol, and two metabolites were confirmed by MS (Metabolite B - mono-glucuronide; metabolite C- mono-sulfate conjugate).

**RESULTS:** The concentration of resveratrol (ng/mL) and metabolites (resveratrol equivalents in ng/mL) showed an increasing trend over time following ingestion. Plasma concentrations of resveratrol and metabolites at 30, 60 and 90 min post-dose were different from baseline ( $p < 0.008$ ) except for metabolites C and E. There was an increase in the concentration of metabolite D: 181.3 ng/mL  $\pm$  284.4, 1325.9 ng/mL  $\pm$  1425.3, ( $p = 0.005$ ) and metabolite F: 155.0 ng/mL  $\pm$  311.4, 1926.5 ng/mL  $\pm$  2365.9 ( $p = 0.005$ ) between 30 and 60 minutes. Significant increases from 30 to 90 min were seen for metabolite B (438.4 ng/mL  $\pm$  756.3 to 1634.1ng/mL  $\pm$  1327.4,  $p = 0.006$ ), metabolite D (181.3 ng/mL  $\pm$  284.4 to 1748.1 ng/mL  $\pm$  1578.0,  $p = 0.005$ ), metabolite F (155.0 ng/mL  $\pm$  311.4 to 2783.7 ng/mL  $\pm$  2174.3,  $p < 0.001$ ) and resveratrol ( $p < 0.001$ ). No differences were seen in resveratrol or any of its metabolites from 60 to 90 minutes ( $p > 0.008$ ).

**CONCLUSIONS:** Resveratrol has been shown to have low bioavailability as well as being lower than its metabolites and as such future research should focus not only on resveratrol bioavailability but also that of its metabolites.

**Effects of High Antioxidant Foods on Antioxidant Capacity in Post-Menopausal Women**

Shelby Kloiber<sup>1</sup>, Robert Sawyer<sup>2</sup>, Melanie Hart<sup>1</sup>, Jacalyn McComb<sup>1</sup>. <sup>1</sup>Texas Tech University, Lubbock, TX. <sup>2</sup>Utah Valley University, Orem, UT.

(No relationships reported)

Oxidative stress brought on by free radicals can lead to an increased risk of certain diseases such as heart disease and some cancers. Oxidative stress mediated damage can be reduced by scavengers, or antioxidants that can eliminate the high reactivity of free radicals by turning them into non-radical and nontoxic metabolites. Many scientists have investigated the effects of different kinds of foods (whole, liquid, or supplement) to measure the change in oxidative damage and antioxidant capacity.

**PURPOSE:** To examine the effects of two types of foods high in antioxidants on antioxidant capacity in postmenopausal women.

**METHODS:** Healthy post-menopausal women without hormone replacement, (N=16) were randomly divided into four groups: fruits (F), soymilk (S), fruits and soymilk (S+F) and control (C). The intervention included a one week wash-out period where participants refrained from a list of foods high in antioxidants. The next four weeks involved a diet intervention. The S group was instructed to consume a total of 706 ml of approved soymilk throughout the day. The F group was instructed to consume 5 or more servings of fruit per day. The S+F group followed both the soymilk and fruit instructions. Subjects in the C group were instructed to maintain their normal diet. Fasting blood samples were drawn before and after the intervention. Spectrophotometric assays were conducted for antioxidant capacity by SOD (Cayman Chemical).

**RESULTS:** SOD showed a significant main effect for Test with the mean for the pre-test (M = 0.28 units/ml, SD = 0.15) being significantly lower than the mean for the post-test (M = 0.39 units/ml, SD = 0.23). There were no significant between group differences in SOD.

**CONCLUSION:** The results of a diet high in antioxidant rich food, specifically fruits and/or soymilk, after a 4 week time period, did significantly increase antioxidant levels. Both diets appear effective in increasing antioxidant capacity, with no diet being more effective than the other.

**1400** Board #181 MAY 30 11:00 AM - 12:30 PM

**Impact Of Intermittent And Continuous Physical Exercise On Endothelial Function And Oxidative Stress Postprandially**

Robinson Ramirez-Velez<sup>1</sup>, Jose G. Ortega<sup>1</sup>, Ana C. de Plata Aguilar<sup>1</sup>, Cristina Araujo, Nut<sup>1</sup>, Celia Escobar Hurtado<sup>1</sup>, Ricardo A. Agredo Zuñiga<sup>1</sup>, Jorge H. Ramirez<sup>2</sup>.

<sup>1</sup>University of Valle, Cali, Colombia. <sup>2</sup>University ICESI, Cali, Colombia.

(No relationships reported)

**PURPOSE:** To evaluate the impact of intermittent and continuous physical exercise on endothelial function and blood oxidative stress postprandially after a high-fat meal.

**METHODS:** Crossover trial in 14 healthy male subjects, 20 years of age, randomized to three experimental groups: (i) no exercise, (ii) 1 hour of moderate intensity continuous physical exercise, and (iii) 1 hour of moderate intensity intermittent physical exercise. Endothelium dependent flow mediated dilatation (FMD%) and plasmatic levels of nitrites and nitrates (NO<sub>2</sub>/NO<sub>3</sub>) were used to assess vascular endothelial function. Oxidative stress was evaluated using the total antioxidant capacity (TAC) test. Endothelial function and oxidative stress were assessed after 14 to 18 hours of physical inactivity (baseline); posterior measurements were performed 1h and 2h after the consumption of a high-fat meal.

**RESULTS:** No statistically significant differences were found on baseline FMD% in the three experimental groups. However, NO<sub>2</sub>/NO<sub>3</sub> levels were significantly higher in the intermittent and continuous exercise groups compared to the control group (P<0.01). After the high-fat meal ingestion the FMD% decreased in the no-exercise and continuous exercise group but significantly increased in the intermittent exercise group. Furthermore, intermittent exercise was associated with increased TAC compared to no exercise and continuous exercise.

**CONCLUSIONS:** Moderate intensity intermittent physical exercise was found to be associated with beneficial effects on endothelial function and oxidative stress in the postprandial state. Randomized clinical trials assessing the effect of intermittent versus continuous physical exercise on hard outcomes of cardiovascular disease and metabolic syndrome are warranted.

**Antioxidant Supplementation To Prevent The Progression Of Microangiopathy In Hindlimb Unloading-induced Atrophied Soleus Muscle In Rats**

Hidemi Fujino<sup>1</sup>, Miho Kanazashi<sup>1</sup>, Hiroyo Kondo<sup>2</sup>, Shinichiro Murakami<sup>1</sup>, Naoto Fujita<sup>1</sup>, Fumiko Nagatomo<sup>3</sup>, Akihiko Ishihara<sup>3</sup>. <sup>1</sup>Kobe University Graduate School of Health Sciences, Kobe, Japan. <sup>2</sup>Nagoya Women's University, Nagoya, Japan. <sup>3</sup>Kyoto University, Kyoto, Japan.

(No relationships reported)

**PURPOSE:** Exposure of skeletal muscle to oxidative stress increases the expression of important components of the proteasome proteolytic system and induces the damage of endothelial cell. The aim of this study was to explore the effects of the antioxidant supplementation during the phase of unloading on capillary regression in atrophied soleus muscle.

**METHODS:** Four groups of Wistar rats were studied: control (Con), control with ASX (Con+ASX), hindlimb unloading (HU), hindlimb unloading with astaxanthin (HU+ASX) groups. In the Con+ASX and HU+ASX groups, astaxanthin (ASX) was orally administered twice in a day for seven consecutive days (50mg/kg). Hindlimb unloading was applied to animals by suspending their tails for seven days. Intracellular ROS generation was determined by use of the redox-sensitive probe dihydroethidium. The capillary network of the soleus muscle was visualized using confocal laser microscopy. The expression levels of SOD-1 and VEGF protein were measured by immunoblotting and the mRNA expression levels of angiogenic factors (VEGF, KDR, Flt-1, Ang-1, Ang-2, Tie-2, and HIF-1 alpha) in the soleus muscle were determined by TaqMan probe-based real-time PCR.

**RESULTS:** HU resulted in an increase of ROS and a decrease of the number of capillaries, capillary volume, and capillary luminal diameter. Namely, the capillary network of the soleus muscle regressed in HU. In addition, HU caused the overexpression of SOD-1 and decreased the expression level of VEGF. However, the capillary network of the soleus muscle prevented disuse-induced capillary regression in HU+ASX. Furthermore, ASX supplementation abolished the unloading-induced overexpression in SOD-1 and attenuated the decrease in VEGF expression, and other angiogenic factors.

**CONCLUSIONS:** These results revealed that astaxanthin is effective to attenuate the development of oxidative stress and maintain the architecture of capillary network in disused skeletal muscle.

**Uric Acid Is A Key Antioxidant Against Iron-mediated Oxidative Stress In Resistance/power Exercise.**

Marcelo P. Barros<sup>1</sup>, Leandro Lorenço-Lima<sup>1</sup>, Douglas Ganini<sup>2</sup>, Cristina V. Vardaris<sup>1</sup>, Etelvino J.H. Bechara<sup>3</sup>, Rui Curi<sup>4</sup>, Tacito P. Souza-Junior<sup>5</sup>. <sup>1</sup>Universidade Cruzeiro do Sul, Sao Paulo, SP, Brazil. <sup>2</sup>National Institute of Environmental Health Sciences, NIH, Research Triangle Park, NC 27709, NC. <sup>3</sup>Universidade Federal de Sao Paulo (UNIFESP), Diadema, SP, Brazil. <sup>4</sup>Universidade de Sao Paulo, Sao Paulo, SP, Brazil. <sup>5</sup>Universidade Federal do Parana, Curitiba, PR, Brazil. (Sponsor: Tania Pithon-Curi, FACSM)

(No relationships reported)

Reactive oxygen species (ROS) are normally produced in humans during endurance (mainly by mitochondrial electron transport system) or resistance exercise (augmented xanthine oxidase activity in cytosol). Drastic drops in performance, precocious fatigue, exacerbated inflammation processes, and injury risk are regular outcomes of the excessive production of ROS in athletes. Paradoxically, balanced ROS production is also essential to provide the desired physiological adaptations of training and also the health benefits from exercise. Furthermore, iron homeostasis is recognized as a key factor in controlling oxidative stress during exercise.

**PURPOSE:** This work aims to evaluate key biomarkers of iron-related oxidative stress in plasma of young athletes after an anaerobic power test.

**METHODS:** Young male college athletes (n = 17; age, 23.1 ± 5.8 years; height, 175.4 ± 2.3 cm; weight, 81.1 ± 9.3 kg; from Universidade Metodista de Santos, Brazil) were selected. A Wingate Test was carried out using a Cybex cycle ergometer with increasing loads up to 10% BW (after familiarization and pre-heat procedure for 5 min). Blood samples (5 mL) were collected before (t0) and 5/60 min after (t5 and t60) the Wingate test, and total iron, heme-iron, uric acid, xanthine oxidase activity (XO), ferric-reducing activity (FRAP), and malondialdehyde (MDA, biomarker of lipid oxidation) were measured in plasma. **RESULTS:** Plasma iron content was increased immediately after Wingate (up to 3-fold, at t5), whereas heme-iron content only varied slightly (25% maximum). However, total FRAP levels varied consistently with total iron (R<sup>2</sup> = 0.939) in order to limit iron-mediated lipid oxidation in plasma. Remarkably, uric acid - a major purine catabolite from energy(ATP)-depleted muscles - accumulated in plasma lately (25% higher at t60) to adequately provide an extended antioxidant capacity, as shown by its high correlation with FRAP (R<sup>2</sup> = 0.788).

**CONCLUSIONS:** Even under exhaustive conditions, there is a tight control of iron homeostasis in plasma of athletes, and uric acid, massively produced by exhausting muscles during resistance/power exercise, contributes to restrain oxidative stress in plasma based mostly on its iron-chelating capacity, identified here by FRAP activity. Financial support: FAPESP, CAPES & CNPq (Brazil).

**The Effect of Quercetin Supplementation on Volitional Fatigue and Skeletal Muscle Mass Retention During Cancer Cachexia**

Justin P. Hardee, Kandy T. Velazquez, Melissa J. Puppa, Johannes D. Aartun, Aditi A. Narsale, Shuichi Sato, J Mark Davis, FACSM, James A. Carson, FACSM. University of South Carolina, Columbia, SC.

(No relationships reported)

Cancer cachexia (CC) has been defined as an unintentional 10% loss of body weight (BW) over a 12-month period that occurs in the presence of an underlying disease. Two common hallmarks of CC are decreased muscle mass and hypogonadism. The APC<sup>Min/+</sup> mouse is an IL-6 dependent model of CC.

**PURPOSE:** To determine the effects of quercetin supplementation on volitional grip strength, muscle mass, and testes size during the progression of CC.

**METHODS:** At 15 weeks of age, male C57BL/6 and APC<sup>Min/+</sup> mice were randomly assigned to vehicle (B6 and Min-V) or quercetin supplementation (Min-Q) for 3 weeks. Quercetin was administered via oral gavage daily at a dose of 25 mg/kg of BW. Grip strength was measured pre- and post-supplementation.

**RESULTS:** Cachexia decreased grip strength 19% (B6: 2.42 ± 0.07 N vs Min: 2.01 ± 0.08 N; p < 0.001); however, quercetin maintained grip strength over 3 weeks (Min-V: 1.67 ± 0.08 N vs Min-Q: 2.09 ± 0.13 N). Bodyweight decreased 13% (p < 0.001) with cachexia; while quercetin attenuated BW loss (Min-Q: -7%). Cachexia decreased gastrocnemius (GAS) muscle mass 33% and rectus femoris (RF) muscle mass 37% (p < 0.05); whereas quercetin attenuated muscle mass loss. Cachexia reduced testes size 29% (p < 0.01) and quercetin attenuated the loss (Min-Q: 12%). Min GAS and RF muscle mass were correlated with testes size (R<sup>2</sup> = 0.68 and 0.62, p < 0.05, respectively).

**CONCLUSION:** Quercetin supplementation for 3 weeks maintained volitional grip strength in mice undergoing cachexia, which may be due to the retention of muscle mass and testes size. Funded by NCI R01-CA121249

#### Daily Aspirin Therapy Does Not Increase Body Core Temperature Responses in Firefighters During Exertion in Thermal Protective Clothing

Serina J. McEntire, Steven E. Reis, Diane Comer, Charity G. Moore, Riana R. Pryor, Jennifer Erin, Priya Khorana, Joe Suyama, Francis X. Guyette, David Hostler.  
*University of Pittsburgh, Pittsburgh, PA.* (Sponsor: Robert Robertson, PhD, FACSM)  
(No relationships reported)

Heart attack is the most common cause of line-of-duty deaths in the fire service. Daily aspirin therapy is a common preventative measure used to reduce the morbidity of heart attacks in the general population. However, the mechanism of aspirin can hypothetically impair thermoregulation and anecdotal reports have suggested aspirin use increases the risk of heat illness. In spite of these observations, the safety profile of aspirin during uncompensable heat stress has not been well described.

**PURPOSE:** Determine if fourteen days of daily aspirin therapy (81mg PO) alters body core temperature responses during exertion in the heat while wearing thermal protective clothing (TPC).

**METHODS:** In this double-blind, placebo controlled study, 102 firefighters were randomized to receive either 14 days of aspirin (N=54) or a placebo (N=48) prior to completing a 50 minute bout of treadmill exercise in the heat (38.9±1.1°C; 24±7% RH) while wearing TPC and self contained breathing apparatus. Heart rate, weighted mean skin temperature, and body core temperature were monitored throughout the 50 minutes of exercise.

**RESULTS:** There were no differences in age, height, mass, BMI, or VO<sub>2</sub>max between groups. Heart rate at the end of exercise did not differ between aspirin and placebo groups (174±17 vs. 171±17 bpm, respectively). In the aspirin group, baseline core body temperature was 37.1±0.3°C, which was similar to the placebo group (37.2±0.5°C; p=0.55). Maximal body core temperature was 38.7±0.5°C in the aspirin group and 38.6±0.5°C in the placebo group (p=0.39). The percent change in core temperature from baseline was 4.3±1.2% in the aspirin group and 3.9±1.6% in the placebo group (p=0.20). Upon completion of exercise, maximal weighted skin temperature was 38.3±0.5°C in the aspirin group and 38.1±0.6°C in the placebo groups. Skin temperature rose 12.5±2.3% from baseline in the aspirin group and 12.2±2.6% with the placebo (p=0.55).

**CONCLUSIONS:** Fourteen days of aspirin therapy does not alter temperature responses among firefighters performing exertion in the heat.

### 1405 Board #186 MAY 30 11:00 AM - 12:30 PM

#### Physiological and Thermoregulatory Responses to Wearing N95 Filtering Facepiece Respirators

Jung-Hyun Kim, Raymond J. Roberge, Stacey M. Benson. *CDC/NIOSH/NPPTL, Pittsburgh, PA.*  
(No relationships reported)

The use of filtering facepiece respirators (FFR) has increased enormously in both public and occupational sectors for respiratory protection from infectious airborne particles. The N95 class of FFR, which filters out at least 95% of airborne particles >0.3 µm, is the most common type of FFR; however, there has been a lack of scientific information on physiological and thermal burdens of wearing N95 FFR.

**PURPOSE:** To investigate physiological and thermoregulatory responses to wearing N95 FFRs while performing low-moderate intensity exercise.

**METHODS:** Twenty healthy subjects (13 men, 7 women), who passed a physical examination and a respirator quantitative fit test, performed three trials of treadmill exercise (5.6 km/h, 0% grade, 60min duration) in a thermoneutral environment (21.4±0.7°C, 23.5±7.9%) while wearing two popular styles (cup-shaped and flat fold) of N95 FFR or not wearing FFR for control (CON). Study variables included core body temperature (T<sub>co</sub>), skin temperature at the cheek (T<sub>cheek</sub>) and abdomen (T<sub>abdomen</sub>), heart rate (HR), respiratory rate (RR), transcutaneous carbon dioxide (tcPCO<sub>2</sub>), and oxygen saturation (SpO<sub>2</sub>). Dead-space microclimate temperature and humidity were also measured in FFR trials. Data were analyzed by two-way (Trials × Time) repeated measures ANOVA.

**RESULTS:** T<sub>co</sub>, T<sub>cheek</sub>, and T<sub>abdomen</sub> rose significantly by time in all trials (p<0.001) and the final dead-space microclimate temperature and humidity reached up to 33°C and 90%, respectively. However, there was no statistical difference in these temperature variables between CON and the FFR trials. HR and RR increased significantly by time in all trials (p<0.001), but at a greater rate in the FFR trials than in CON (HR; P<0.001, RR; P<0.01). There was no statistical difference in SpO<sub>2</sub> levels between CON and FFR trials, however, tcPCO<sub>2</sub> levels were significantly higher in the FFR trials than in CON (p<0.001).

**CONCLUSION:** Wearing N95 FFR while performing low-moderate work for 60 min in a thermoneutral environment did not impose a significant thermal burden on the wearer. However, significantly elevated HR and RR in the FFR trials indicated that wearing N95 FFR may add additional metabolic demands. Also, breathing through N95 FFR did not interfere with SpO<sub>2</sub>, but caused some mild degree of CO<sub>2</sub> retention (tcPCO<sub>2</sub> ≥ 45 mmHg).

### 1406 Board #187 MAY 30 11:00 AM - 12:30 PM

#### Increased Salivary Cortisol and State Anxiety Levels in Firefighter Candidates during Repeated Fire Suppression Tasks

Deena Campbell<sup>1</sup>, Heather E. Webb<sup>2</sup>, Christopher J. Jackson<sup>1</sup>, Daniel Cross<sup>3</sup>. <sup>1</sup>University of New South Wales, Sydney, Australia. <sup>2</sup>Mississippi State University, Starkville, MS. <sup>3</sup>Mississippi State Fire Academy, Jackson, MS.  
(No relationships reported)

Research suggests that the combined psychological and physiological stress load of firefighting may contribute to an exacerbated cortisol response during fire suppression.

**PURPOSE:** The purpose of this study was to examine the salivary cortisol (SCORT) response in firefighter candidates during simulated fire suppression tasks.

**METHODS:** Twelve firefighter candidates (age = 25.25 ± 5.69) participated in two research sessions, an informational session during which consent and demographic/psychometric data were obtained, and a second session in which the candidates completed two fire suppression evolutions. In each evolution, the participants entered the burn building in pairs and undertook fire suppression tasks. Baseline measures of SCORT and state anxiety (SAI) were collected immediately prior to each evolution, and collected again within 5 minutes of completion of each evolution.

**RESULTS:** The fire suppression tasks resulted in elevated SCORT levels (when controlling for participant order) compared to baseline in both evolution 1 and 2 (t = 11.27, p = 0.004 and t = 44.07, p = 0.000 respectively). Anxiety levels also increased but did not reach significance in evolution 1, and increased significantly in evolution 2 (t = -2.66, p = 0.026).

**CONCLUSIONS:** These findings suggest that the candidates experienced both physical and psychological stress in both evolutions. Further, findings suggest that the experience of the first evolution did not reduce the psychological stress and the resultant physiological load of the second evolution.

### 1407 Board #188 MAY 30 11:00 AM - 12:30 PM

#### Review of Current Minimum Riding Weights in Australian Horse Racing - Implications for Jockey Health and Wellbeing

Caron B. Jander<sup>1</sup>, David A. Greene<sup>2</sup>, Helen O'Connor<sup>3</sup>, Giles D. Warrington, FACSM<sup>4</sup>. <sup>1</sup>Australian Racing Board, Freshwater, Australia. <sup>2</sup>Australian Catholic University, Strathfield, NSW, Australia. <sup>3</sup>University of Sydney, Lidcombe, NSW, Australia. <sup>4</sup>Dublin City University, Dublin, Ireland.  
(No relationships reported)

Despite the international popularity of horse racing there is a dearth of population specific research available describing the physiological demands and health and lifestyle characteristics of jockeys. Given the weight-restricted nature of horse racing, jockeys often engage in extreme and unhealthy weight-loss practices, which are likely to place riders at an increased risk of injury. As a consequence, the Australian Racing Board (ARB) commissioned a scientific review of the minimum riding weight for flat jockeys.

**PURPOSE:** The purpose of this review was to identify potential health issues associated with jockeys complying with current stipulated weight standards operating in Australian horse racing. **METHODS:** The review comprised (i) a comprehensive review of national height and weight statistics, (ii) a review of the international scientific literature on population specific normative data, (iii) evaluations of race-day jockey urine samples collected on 875 jockeys over the past 3 years in New South Wales for determination of urine specific gravity (Usg) (iv) and the comparison of the results of Usg samples collected for the purpose of drug testing in the work place in the state of Victoria on 452 petrochemical workers (control group) and 305 jockeys at the race course.

**RESULTS:** Jockeys were found to have 8 key health issues associated with race riding. Issues included: 'Making weight'; poor dietary practices; compromised bone health; dehydration; smoking; engaging in a high risk sport; lifestyle challenges; and mood disorders. Disturbing levels of consistent and pervasive dehydration were found in jockeys both on race day and non-race days. Results indicate that on race day 48.4% of 875 samples indicated significant dehydration, (Usg  $\leq 1.025$ ), 27% had moderate to high levels of dehydration (Usg  $\leq 1.025$  and  $\geq 1.02$ ), 24.5% within the dehydration threshold as defined by Sawka et al., 2007 (Usg  $\leq 1.020$ )

**CONCLUSION:** Based on these findings, the following recommendations were presented to the ARB: (i) increase the minimum riding weight by 1 kg to 54 kg; and (ii) increase the median and maximum riding weight by 1 kg. It is anticipated that immediate health outcomes will result in a decrease in the extreme dehydrating practices currently employed by many jockeys.

**1408** Board #189 MAY 30 11:00 AM - 12:30 PM

**Anthropometric Measurements of Obesity and Their Link to Lifestyle and Cardiovascular Risk in Colorado Firefighters**

Tiffany Lipsey, Lorin O'Toole, Tracy Nelson, Jennifer Peel, Richard G. Israel, FACSM. *Colorado State University, Fort Collins, CO.*

(No relationships reported)

Cardiovascular disease (CVD) is the leading cause of death in firefighters as it is in the general population. Despite data promoting Colorado as the leanest state in the nation and the image of firefighters as healthy and physically fit, obesity is evident in Colorado firefighters and continues to be an important CVD risk factor. Job performance and health outcomes among those in public safety are greatly impacted by obesity despite the perception of the general public that firefighters are healthy and fit.

**PURPOSE:** To determine obesity prevalence, depending on measurement and classification, and its association with lifestyle factors and cardiovascular (CV) risk in a cohort of Colorado firefighters.

**METHODS:** Analyses were conducted on data from 466 Colorado firefighters (41 females; 425 males; mean age 38 y). Using standard classification cut-points, rates of obesity were determined using body mass index (BMI), waist circumference (WC), sagittal abdominal diameter (SAD), and percent body fat (%BF) from skin fold (SF) and hydrodensitometry (H) measurements. Lifestyle factors used in the analysis included diet, physical activity, sleep, and stress. Lipids, C-reactive protein (CRP), predicted maximal oxygen consumption and strength measures were also included. CV risk was also assessed using the Cooper Risk Profile. Correlation statistics were run for each anthropometric measure with the above variables.

**RESULTS:** Obesity prevalence varied by measurement in females and males respectively: BMI=9.8%, 19.1%; WC=19.5%, 19.8%; SAD=31.6%, 43.5%; %BF(SF)=17.1%, 15.1%; and %BF(H)=23.7%, 28.6%. In both sexes, anthropometric measures were positively correlated with triglycerides and CRP but inversely associated with high-density lipoprotein cholesterol, sit & reach, and estimated maximal oxygen consumption ( $VO_{2max}$ ) (besides BMI in females) ( $p \leq 0.05$ ). All anthropometric measures were significantly correlated with CV risk ( $p \leq 0.05$ ) except WHR in females. The strongest link to CV risk was %BF(SF) in females and WHR in males.

**CONCLUSIONS:** The rate of obesity in Colorado firefighters varies depending on the measure used. There are significant associations between obesity, lifestyle factors and CV risk that should be further explored in light of the already increased risk for CVD in firefighters.

---

**1409** Board #190 MAY 30 11:00 AM - 12:30 PM

**The Beneficial Effects Of Walking Following Repeated Bouts Of Sustained Static Postures**

François Taillefer, Jean P. Boucher, FACSM, M Zummo, R Savard, A S. Comtois. *University of Quebec in Montreal, Montreal, QC, Canada.*

(No relationships reported)

**PURPOSE:** We have shown that 20 min of various sit, sit-stand and stand static postures interspersed by 5 min walking periods was beneficial for lower limb muscle blood flow and oxygenation (Taillefer et al., 2011). However, the physiological impact of walking on the lower limbs following static postures remains to be shown, especially in individuals confronted with varicose veins. Thus, the present study measured the physiological effects of a 5' walk following repeated bouts of 20' static periods.

**METHODS:** Two groups (n = 10 per group) of women (without varicose veins, C0 and with varicose veins, C2) were studied during the maintenance of 6 twenty minute periods of different static postures all interspersed by 5 min walking periods. The following measurements were continuously recorded on the left lower limb during each static and walking periods: blood perfusion (foot), transcutaneous partial pressure (TcP) of O<sub>2</sub> and CO<sub>2</sub> (foot), cutaneous temperature (Ct, medial malleola), EMG of the gastrocnemius muscle, VO<sub>2</sub>, and heart rate (HR).

**RESULTS:** Physiological variables were pooled since no significant differences were observed between both groups (C0 vs C2). The variables were significantly ( $p < 0.05$ ) modified during walking when compared to the static postures (blood perfusion,  $120.0 \pm 35.31$  vs  $5.7 \pm 1.79$  perfusion units; TcPO<sub>2</sub>,  $75.7 \pm 19.56$  vs  $59.4 \pm 16.77$  mmHg; TcPCO<sub>2</sub>,  $27.48 \pm 5.83$  vs  $33.1 \pm 5.82$  mmHg; Ct,  $28.4 \pm 1.60$  vs  $27.8 \pm 1.34$ ; EMG,  $23.4 \pm 9.50$  vs  $2.3 \pm 2.50$  mV; VO<sub>2</sub>,  $629.9 \pm 195.50$  vs  $219.9 \pm 40.10$  ml\*min<sup>-1</sup>; HR,  $84.7 \pm 10.40$  vs  $72.5 \pm 10.60$  b\*min<sup>-1</sup>, respectively).

**CONCLUSIONS:** The varicose vein group (C2) responded very similarly to the non varicose vein group (C0) during walking. These results indicate the importance of walking to maintain lower limb oxygenation to possibly minimize the cascade of physiological events leading to the appearance of varicose veins, especially when these individuals have to maintain prolonged static postures.

---

**1410** Board #191 MAY 30 11:00 AM - 12:30 PM

**The Effect of Pre-cooling on Cardiovascular and Metabolic Strain During Incremental Exercise**

Eric M. Hultquist<sup>1</sup>, Logan Arena<sup>1</sup>, Welsey K. Lefferts<sup>1</sup>, Thomas W. Storer<sup>2</sup>, Christopher B. Cooper, FACSM<sup>2</sup>, Patricia C. Fehling, FACSM<sup>1</sup>, Denise L. Smith, FACSM<sup>1</sup>. <sup>1</sup>Skidmore College, Saratoga Springs, NY. <sup>2</sup>UCLA, Los Angeles, CA.

(No relationships reported)

Pre-cooling has been shown to improve endurance performance and to lessen heart rate (HR) for a given level of work. However, the effect of pre-cooling on the relationship between HR and oxygen uptake (VO<sub>2</sub>) has not been well studied.

**PURPOSE:** To investigate the relationship between cardiovascular and metabolic responses during maximal exercise performed at either normal or depressed core temperature (T<sub>co</sub>).

**METHODS:** Ten men (age,  $21 \pm 1$  yr; VO<sub>2max</sub>,  $60.2 \pm 6.9$  ml·kg<sup>-1</sup>·min<sup>-1</sup>) performed a maximal treadmill test following two conditions: (a) control (CON), in which participants rested in a thermoneutral laboratory ( $21.6 \pm 4.8$  °C), and (b) pre-cooling (PC), during which participants were submerged up to their armpits in  $23.1 \pm 0.2$  °C water for 24 min. The chronotropic index (CI) was derived from the slope of the regression line between HR and VO<sub>2</sub>. A repeated measures ANOVA was employed to examine differences in T<sub>co</sub>, HR, and VO<sub>2</sub> and the CI. Significance was set at  $P < 0.05$ .

**RESULTS:** Prior to the onset of exercise T<sub>co</sub> was significantly lower for PC ( $36.69 \pm 0.32$  °C) compared to CON ( $37.12 \pm 0.39$  °C;  $P < 0.05$ ). Time to fatigue was significantly longer in the CON ( $914 \pm 97$  s) compared to the PC condition ( $889 \pm 97$  s). T<sub>co</sub> during exercise remained consistently lower for PC compared to CON ( $P < 0.05$ ). Furthermore, there was a significant condition x time interaction for T<sub>co</sub> between conditions ( $P < 0.05$ ). VO<sub>2</sub> was not significantly different between conditions. PC resulted in an  $8-10$  b·min<sup>-1</sup> lower HR than the CON condition at any given time point during the exercise protocol and at peak (PC,  $178 \pm 9$  b·min<sup>-1</sup>; CON,  $188 \pm 6$  b·min<sup>-1</sup>). The CI did not differ between conditions; however, the y-intercept was significantly lower for PC compared to CON (PC,  $53.6 \pm 11.0$ ; CON,  $67.3 \pm 11.0$ ).

**CONCLUSION:** Reductions in T<sub>co</sub> significantly reduced cardiovascular strain (HR) at any given workload and decreased time to fatigue. However, pre-cooling did not change VO<sub>2</sub> or alter the relationship between HR and VO<sub>2</sub> (CI). Although there was no change in the CI, pre-cooling decreased the HR response, shifting the regression line down. These results suggest potential use of pre-cooling to mitigate cardiovascular strain in firefighters.

Supported by contract from DHS Science and Technology (UCLA contractor).

1411 Board #192 MAY 30 11:00 AM - 12:30 PM

**Cardiovascular and Metabolic Responses During Maximal Incremental Exercise in Firefighter's Personal Protective Equipment**

Wesley K. Lefferts<sup>1</sup>, Eric M. Hultquist<sup>1</sup>, David A. Barr<sup>1</sup>, Thomas W. Storer<sup>2</sup>, Christopher B. Cooper, FACSM<sup>2</sup>, Patricia C. Fehling, FACSM<sup>1</sup>, Denise L. Smith, FACSM<sup>1</sup>. <sup>1</sup>Skidmore College, Saratoga Springs, NY. <sup>2</sup>UCLA, Los Angeles, CA.  
(No relationships reported)

Personal protective equipment (PPE) is worn by firefighters to protect them from work related hazards. Work in PPE increases the metabolic cost of a given work load. Due to added weight, restrictive properties and the circulatory effects of full encapsulation, working in PPE may affect the relationship between heart rate (HR) and oxygen uptake (VO<sub>2</sub>) as expressed as the chronotropic index (CI) (slope of the regression line for HR vs. VO<sub>2</sub>); however, the extent to which the physiological stress imposed by PPE impacts the CI is unknown.

**PURPOSE:** To investigate the effects of PPE on cardiovascular and metabolic responses during incremental exercise and to determine if PPE affects the CI.

**METHODS:** HR and VO<sub>2</sub> were measured in 10 male participants (age, 21 ± 2 yr; height, 178 ± 8 cm; weight, 76.2 ± 3.1 kg; VO<sub>2max</sub>, 51.9 ± 5.0 ml·kg<sup>-1</sup>·min<sup>-1</sup>) when performing graded exercise tests across 3 conditions: control (CON; wearing athletic attire), wearing PPE (PPE) and weighted vest (WV) (weight equal to PPE).

**RESULTS:** Time to exhaustion was significantly different across all 3 conditions (CON, 866 ± 121 s; PPE, 582 ± 92 s; WV, 671 ± 105 s; (P < 0.01). Over time, submaximal VO<sub>2</sub> and HR were significantly lower in the CON condition (P < 0.01) compared to the PPE and WV conditions, which were similar to each other. Peak HR was significantly higher in the CON (191 ± 11 b·min<sup>-1</sup>) condition compared to the WV (187 ± 10 b·min<sup>-1</sup>) and PPE (183 ± 9 b·min<sup>-1</sup>) conditions (P < 0.01). There was a tendency for peak HR in the PPE condition to be lower than the WV condition (P = 0.07). VO<sub>2max</sub> was significantly different among all 3 conditions (P < 0.01). VO<sub>2max</sub> was 9.4% higher in the CON (3.96 ± 0.5 l·min<sup>-1</sup>) condition compared to the PPE (3.62 ± 0.4 l·min<sup>-1</sup>) condition (P < 0.01). VO<sub>2max</sub> was 4.8% higher in the CON condition compared to the WV (3.78 ± 0.4 l·min<sup>-1</sup>) condition; however, this was not statistically significant (P = 0.07). The CI (CON, 31.8 ± 4.4; PPE, 31.7 ± 5.4; WV, 32.6 ± 4.6) and y-intercept (CON, 72.1 ± 20.7; PPE, 74.6 ± 23.8; WV, 72.0 ± 18.8) were similar across all conditions.

**CONCLUSION:** The present study has shown that increasing the physiological strain with PPE or equivalent weight increases HR and VO<sub>2</sub>; however, the tight linear relationship between HR and VO<sub>2</sub> (CI) remains unaffected.

Supported by contract from DHS Science and Technology (UCLA contractor).

1412 Board #193 MAY 30 11:00 AM - 12:30 PM

**The Relationship Between Bmi And A Graded Maximal CPR Compression Test**

Patrick W. Davidson<sup>1</sup>, Christopher C. Dunbar, FACSM<sup>2</sup>, Robert Curran<sup>3</sup>, Paul F. Martinowicz<sup>2</sup>. <sup>1</sup>Springfield College, Springfield, MA. <sup>2</sup>Brooklyn College, Brooklyn, NY. <sup>3</sup>Brooklyn College, Brooklyn College, NY.  
(No relationships reported)

**PURPOSE:** To determine if there was a relationship between subject BMI and VO<sub>2peak</sub> during an Incremental Work Test using a CPR simulator (IWT)

**METHODS:** Eleven male subjects (age: 23 ± 4 yrs; body mass: 81.06 ± 11.40 kg; BMI: 25.86 ± 3.03 kg/m<sup>2</sup>) underwent the following conditions: 1) Incremental Work Test (IWT): using a CPR simulator where the cadence of CPR compressions increased every 30 sec to volitional fatigue 2) Treadmill VO<sub>2max</sub> (TM): incremental oxygen consumption (VO<sub>2</sub>) test using the Bruce Protocol. During all conditions VO<sub>2</sub> and Heart Rate (HR) were measured using a Parvo-Medics True One 2400 Metabolic Measurement System (Sandy, Utah).

**RESULTS:** The VO<sub>2peak</sub> measured during maximal graded treadmill testing using the Bruce Protocol averaged 38.13 mL/kg/min ± 5.98. The VO<sub>2peak</sub> measured during maximal graded CPR compression testing averaged 14.76 mL/kg/min ± 3.46. There was no relationship found between subject BMI and TM; however, a significant (p < .05) inverse relationship was found between subject BMI and IWT

**CONCLUSION:** A significant inverse relationship was found between BMI and IWT. The results indicate that the larger an individual is relative to height, the poorer the performance during repeated CPR compressions irrespective of cardiorespiratory fitness as measured by treadmill exercise.

1413 Board #194 MAY 30 11:00 AM - 12:30 PM

**Changes in Physical Fitness and Anthropometry of Police Academy Cadets During a 16-Week Physical Training Program**

Ross A. Sherman, Amy A. Crawley, William R. Crawley, William J. Burgess, III. Grand Valley State University, Allendale, MI. (Sponsor: Jeffrey A. Potteiger, FACSM)  
(No relationships reported)

Law-enforcement organizations require their employees to attain and maintain a threshold level of physical fitness so they are 'fit to work'. As part of a college-run police academy, cadets undertake a structured 16-week physical training program.

**PURPOSE:** To describe changes in physical fitness and anthropometry of police academy cadets during their 16-wk physical training program.

**METHODS:** 15 cadets (24±4 yrs; 1.80±0.08 m), thirteen males and two females, were tested in Wks 1, 8, and 16 of their 3-day per wk police academy training program. A battery of tests was used to assess physical fitness (flexibility, vertical jump, grip strength, sprint speed, and agility) and anthropometrical characteristics (body mass and body fat) and . Time-related changes in each test are shown as mean difference and 95% confidence interval (CI).

**RESULTS:** Only 40-yd sprint time substantially improved during the 16-wk program; specifically between Wk 1 and Wk 8 (-0.45 [-0.78 to -0.12] s). However, flexibility was found to marginally decrease during the 16-wk program (Wk 1-16: -5.4 [-10.9 to 0.1] cm). The remaining markers of physical fitness did not change (see Table 1.).

**Table 1. Mean differences (95% CI) in police cadet physical fitness during a 16-wk academy.**

|                               | Wk 1-8                | Wk 8-16               |
|-------------------------------|-----------------------|-----------------------|
| T-test run time (s)           | -0.18 (-0.93 to 0.58) | -0.21 (-0.98 to 0.56) |
| 1-rep max bench press (kg)    | 7.8 (-19.7 to 35.2)   | 3.2 (-30.1 to 23.8)   |
| Left hand grip strength (kg)  | 8.2 (-0.4 to 16.8)    | -3.2 (-11.8 to 5.4)   |
| Right hand grip strength (kg) | 7.5 (-1.1 to 16.2)    | -5.2 (-13.9 to 3.4)   |
| Vertical jump (cm)            | 1.0 (-6.3 to 8.4)     | 2.4 (-5.0 to 9.7)     |

Neither body mass (Wk 1-16: -1.9 [-15.0 to 11.1] kg) nor body fat (Wk 1-16: -0.6 [-4.6 to 3.3]%) changed during the course of the 16-wk training program.

**CONCLUSION:** The 16-wk physical training program currently used had little or no impact on pre-academy physical fitness or anthropometric characteristics. Only 40-yd sprint performance improving during the first eight week block, and there were no improvements in any test during the second eight week block.

1414 Board #195 MAY 30 11:00 AM - 12:30 PM

**Wildland Firefighters Demonstrate Seasonal Acclimatization to the Heat Despite No Changes in Aerobic Fitness**

Brianna Lui, Walter S. Hailes, John S. Cuddy, Brent C. Ruby, FACSM. Montana Center for Work Physiology and Exercise Metabolism, The University of Montana, Missoula, MT.  
(No relationships reported)

Wildland fire suppression involves long hours of strenuous work across rugged terrain with frequent exposure to high ambient temperatures. These physical demands of the job, coupled with the environmental conditions, increase the probability of heat related injury (HRI). Although heat acclimatization may mitigate the risk of HRI, the degree to which wildland firefighter's (WLF) demonstrate seasonal acclimatization is unknown.

**PURPOSE:** To determine the physiological changes associated with heat acclimatization across the 4-month fire season in the western United States.

**METHODS:** (n=26 males) 12 WLFF (27 ± 7 yrs; 179 ± 7 cm; 79 ± 10 kg) and a comparison group of 14 non-WLFF (25 ± 4 yrs; 180 ± 7 cm; 77.7 ± 8.8 kg) completed a 60-min heat stress trial (treadmill walking at 50% VO<sub>2</sub>max) in a climate controlled chamber (43.3°C, 33% RH) prior to and following the western Montana fire season (May and September, respectively). VO<sub>2</sub>max and body composition was also measured pre- and post-season. Core temperature, heart rate, and physiological stress index (PSI) was continuously monitored and analyzed using repeated measures ANOVA. A significance level was set at p<0.05.

**RESULTS:** VO<sub>2</sub>max did not change for the WLFF across the season. In contrast, non-WLFF demonstrated a significant increase in VO<sub>2</sub> max (55.9 ± 7.8 ml/kg/min vs. 58.7 ± 8.6 ml/kg/min pre and post season, respectively, p<0.05). Neither group demonstrated significant seasonal differences in the heart rate response to the heat stress trials. In contrast, WLFF demonstrated a significant seasonal reduction in core temperature during the heat stress trials at 45-min (38.1 ± 0.31°C vs. 38.2 ± 0.30°C, p=0.032) and 60-min (38.2 ± 0.39°C vs. 38.5 ± 0.34°C, p=0.022). WLFF PSI also demonstrated a significant seasonal decrease from 5.84 ± 1.3 to 5.13 ± 1.2 (p<0.05, main effect of season). There were no differences in core temperature or PSI for the non-WLFF.

**CONCLUSIONS:** WLFF demonstrate significant changes in seasonal acclimatization to exercising in the heat independent of changes in aerobic capacity. This suggests that long-term exposure to the environment strongly drives adaptation to hot environments.

---

1415 Board #196 MAY 30 11:00 AM - 12:30 PM

**Deployment of an Advanced Electrocardiographic Analysis (A-ECG) to Detect Cardiovascular Risk in Career Firefighters**

Brett A. Dolezal<sup>1</sup>, Tom Storer<sup>1</sup>, Marlon Abrizado<sup>1</sup>, Reed Watne<sup>1</sup>, Todd Schlegel<sup>2</sup>, Maxim Batalin<sup>1</sup>, William Kaiser<sup>1</sup>, Denise Smith, FACSM<sup>3</sup>, Christ Cooper, FACSM<sup>1</sup>. <sup>1</sup>UCLA, Los Angeles, CA. <sup>2</sup>NASA Johnson Space Center, Houston, TX. <sup>3</sup>Skidmore College, Saratoga Springs, NY.

(No relationships reported)

**INTRODUCTION:** Sudden cardiac death is the leading cause of line of duty death among firefighters, accounting for approximately 45% of fatalities annually. Firefighters perform strenuous muscular work while wearing heavy, encapsulating personal protective equipment in high ambient temperatures, under chaotic and emotionally stressful conditions. These factors can precipitate sudden cardiac events like myocardial infarction, serious dysrhythmias, or cerebrovascular accidents in firefighters with underlying cardiovascular disease.

**PURPOSE:** The purpose of this study was to deploy and then evaluate the contribution of resting advanced ECG (A-ECG) in addition to other screening tools (family history, lipid profiles, and cardiopulmonary exercise tests, XT) in assessment of an individual's cardiac risk profile.

**METHODS:** Forty-four career firefighters were recruited to perform comprehensive baseline assessments including tests of aerobic performance, fasting lipids and glucose. Five-min resting 12-lead A-ECGs were obtained in a subset of firefighters (n=21) and transmitted over a secure networked system to a NASA physician collaborator. Using myocardial perfusion and other imaging as the gold standard, A-ECG scoring has been proven useful in accurately identifying a number of cardiac pathologies including coronary artery disease (CAD), left ventricular hypertrophy, hypertrophic cardiomyopathy, and non-ischemic and ischemic cardiomyopathy.

**RESULTS:** Subjects' mean (SD) age was 43 (8) years, weight 91 (13) kg, and BMI 28 (3) kg/m<sup>2</sup>. Fifty-one percent of subjects had ≥3 cardiovascular risk factors. One subject had ST depression on XT ECG, at least one positive A-ECG score for CAD, and documented CAD based on cardiology referral. While all other subjects, including those with fewer risk factors, higher aerobic fitness, and normal exercise ECGs, were classified as healthy by A-ECG, there was no trend for association between risk factors and any of 20 A-ECG parameters in the grouped data.

**CONCLUSIONS:** We have demonstrated that remote capture of a standard resting 12-lead ECG analyzed with advanced algorithms is a simple, time and cost-effective approach that offers the prospect of early identification of individuals potentially at risk for line-of-duty death from cardiovascular incidents.

**The Practice of Physical Exercise is a Modifiable Factor for Urge Urinary Incontinence in Older**

Giovana Zarpellon Mazo, Virtuoso Franck Janeisa. UDESC, Florianópolis, Brazil.

(No relationships reported)

The symptoms of urinary urgency tend to increase with advancing age. The literature suggests a number of risk factors that can be modified by an active lifestyle through healthy eating and physical exercise.

**PURPOSE:** To examine the modifiable risk factors of urge urinary incontinence (UUI) in older women.

**METHODS:** The sample consisted of 200 elderly (60 years or older) with a mean age of 69.06 ± 6.26 years. We identified the presence of UUI and behavioral risk factors (consumption of coffee, alcohol consumption, smoking and presence of constipation). Was also applied to the Domain 4 for International Physical Activity Questionnaire (IPAQ) to identify the level of physical activity and measured body mass index and waist circumference. The data were processed using descriptive and inferential statistics with a significance level of 5%.

**RESULTS:** The prevalence of UUI in the sample was 15.5%. Among the modifiable factors, only the level of physical activity was associated with the occurrence of UUI, and the physical exercise appeared as a protective factor among very active women (OR = 0.288) and less active (OR = 0.356).

**CONCLUSIONS:** The symptoms of urgency can be softened by regular physical exercise. Through a healthy lifestyle can minimize a number of modifiable factors in the genesis of urge urinary incontinence.

1417 Board #198 MAY 30 9:30 AM - 11:00 AM

**Intermuscular Adipose Tissue Change is Related to Improved Physical Performance in Older Adults**

Adam J. Santanasto, Anne B. Newman, Robert M. Boudreau, Mark A. Newman, Bret H. Goodpaster, Nancy W. Glynn. University of Pittsburgh, Pittsburgh, PA.

(No relationships reported)

Obesity exacerbates age-related declines in physical function, but there is controversy about the whether older adults should lose weight and whether weight or particular aspects of body composition should be targeted.

**PURPOSE:** To determine the relationship between changes in body composition and physical function in older adults, who participated in a 1 yr intervention study of physical activity + weight loss (PA+WL) compared to physical activity (PA).

**METHODS:** Thirty-six overweight to moderately obese (body mass index (BMI) 28-39.9 kg/m<sup>2</sup>) sedentary older adults mean age 70.3±5.9 yrs were randomized (GRP) to a 12 month program. PA program had a goal of 150 min/wk treadmill walking plus lower limb resistance and balance. The PA+WL group also underwent a weight loss intervention promoting 7% weight loss. Calorie and fat gram goals were based on the Diabetes Prevention Program. At baseline (BL) and 12-months (12) computerized tomography (CT) for intermuscular adipose tissue (IMAT) area of the thigh, visceral adipose tissue (VAT) area, thigh muscle area, muscle density, an indirect measure of intramuscular fat, in Hounsfield units (HU), subcutaneous adipose tissue area, BMI and short physical performance battery (SPPB) were assessed. The relationship between concurrent changes in body composition and physical function were determined using multivariate linear regression. Intervention groups were combined in these analyses.

**RESULTS:** SPPB score increased by an average of 0.53 ± 1.52 in both groups combined. Changes (BL-12) in several fat depots were associated with change in function. Change in IMAT was significantly related to change in SPPB after adjusting for BL IMAT, GRP and BL SPPB score,  $\beta_{adj} = -0.29$ , SE = 0.12, p=0.02; this was not explained by adjustment for change in BMI ( $\beta_{adj-bmi} = -0.24$ , SE = 0.12, p=0.05). HU and VAT were each associated with change in SPPB after adjusting for GRP and BL HU or VAT (p=0.06 and 0.05), respectively but these associations were completely attenuated by change in BMI. Change in muscle area was not related to change in SPPB.

**CONCLUSION:** Change in IMAT was the body composition parameter most strongly related to change in function. Interventions that target IMAT in older adults may be of particular importance for improving function.

**1418**    *Board #199*    **MAY 30**    **9:30 AM - 11:00 AM**  
**Association Between Sociodemographic, Neighborhood Environment And Domain Of Physical Activity Among Middle-aged And Elderly Japanese.**  
Yoshinobu Saito<sup>1</sup>, Yuko Oguma<sup>2</sup>, Shigeru Inoue<sup>3</sup>, Ayumi Tanaka<sup>4</sup>, Yoshitaka Kobori<sup>4</sup>. <sup>1</sup>Fujisawa City Health and Medical Center, Fujisawa, Kanagawa, Japan. <sup>2</sup>Keio University, Yokohama, Japan. <sup>3</sup>Tokyo Medical University, Shinjuku, Japan. <sup>4</sup>Fujisawa City Health and Medical Center, Fujisawa, Japan.  
(No relationships reported)

Recent studies suggested the importance of neighborhood environment as physical activity determinants. However, few studies have been investigated in Japan.

**PURPOSE:** To examine the association of moderate-to-vigorous intensity leisure-time physical activity (LTPA), walking for recreation, walking for transportation with sociodemographic/health and neighborhood environmental factors among community dwelling middle-aged and elderly Japanese.

**METHODS:** The study included 2,449 adults aged 40-69 years living in Fujisawa city, located at 40km southwest of Tokyo, who had taken the Specific Health Checkups in 2009 and responded to the additional survey by mail in 2010. Sociodemographic/health factors (gender, age, education, working, economic, children in household, self-rated health, orthopedic disorders, body mass index), the long version of International Physical Activity Questionnaire and its Environmental Module were obtained. The adjusted odds ratios (OR) of high levels of LTPA, walking for active transportation/recreation were calculated in relation to these sociodemographic/health and neighborhood environmental factors using multiple logistic regression models.

**RESULTS:** Higher age and good self-rated health were significantly associated with high level of each physical activity outcome ( $P < 0.05$ ). Having work (OR=0.74), presence of children in household (OR=0.65), higher educational attainment (OR=1.58), higher economic status (OR=1.38), good access to recreational facilities (OR=1.26), and not owing household motor vehicles (OR=0.65) were associated with longer LTPA time. Women (OR=0.68), having work (OR=0.52), presence of children in household (OR=0.62), not having strong pain by orthopedic disorders (OR=1.58), seeing people being active (OR=1.41), and good aesthetics (OR=1.37) were associated with longer walking time for recreation. Higher economic status (OR=0.81), not owing household motor vehicles (OR=2.18), good access to shops (OR=1.35), and presence of sidewalks (OR=1.24) were associated with longer walking time for transportation.

**CONCLUSION:** The results suggest that different individual and neighborhood environmental variables are associated with different physical activity outcomes among community-dwelling middle-aged and elderly Japanese.

**Assessment of a Physical Activity Program in Low-Income Seniors Living in Independent Community Residences**  
Leticia Malavasi, Cathy Inouye. *California State University, East Bay, Hayward, CA.* (Sponsor: Calvin Caplan, FACSM)  
(No relationships reported)

The Nutrition and Fitness program offered through the Senior Support Program of the Tri-Valley provides on-site free of charge physical activity classes for low-income seniors living in community residences. Their primary goal is to improve the quality of life in part by helping participants maintain their independence, of which fitness is a pivotal component. The following analysis of senior fitness assessments was conducted on data gathered from five community sites over a 9-18 month time period. Based on those findings, recommendations for programmatic changes will be implemented with oversight from the investigators and following the securement of grant funding.

**PURPOSE:** To analyze the effect of an on-site physical activity program for independent-living seniors and implement subsequent programmatic changes.

**METHODS:** Forty-two female (75±4.6 years) and 9 male (81±4 years) participants attended two 60-minute exercise classes per week. Classes were led by 3 different instructors and followed a program template that included a 5-10 min warm-up, 20-30 min aerobic, strength, and balance exercises, 5-10 min cool-down, and 5 min relaxation session. Pre to post-fitness assessments of balance, strength, muscular endurance, agility, and flexibility were analyzed using dependent t-tests. Post-test scores between sites was analyzed using independent t-tests.

**RESULTS:** Pre to post-strength (bicep curls/30 sec, 16.7±4.9 vs. 19.8±5.1 repetitions,  $p < 0.05$ ) and agility (8' Up & Go, 7.3±2.2 vs. 7.8±2.6 seconds,  $p = 0.05$ ) increased when data was combined for all sites. Comparison of post-strength scores between one versus multi-instructor sites was also significant (22.6±5.8 vs. 18.8±4.6 repetitions,  $p = 0.02$ )

**CONCLUSION:** The lack of change in several fitness parameters and on-site observation of individual classes has led to a number of programmatic recommendations including standardization of instruction, implementation of balance courses, incorporation of activities that utilize large muscle groups, and closer monitoring of exercise intensity.

**1420**    *Board #201*    **MAY 30**    **9:30 AM - 11:00 AM**  
**Habitual Physical Activity is Associated With Cognitive Function And The Risk Factors For Hip Fracture In Older Adults**  
Hyuntae Park<sup>1</sup>, Youchan Kwon<sup>2</sup>, Eunhee Kim<sup>2</sup>, Jinkee Park<sup>2</sup>, Sangkab Park<sup>2</sup>. <sup>1</sup>National Center for Geriatrics and Gerontology, Aichi, Japan. <sup>2</sup>Dong-A University, Busan, Korea, Republic of.  
(No relationships reported)

Regular physical activity is an important component of a healthy lifestyle, conferring many physical health benefits, including protection against, osteoporosis, sarcopenia and cognitive impairment. However, only a few studies have reported actual daily physical activity levels in relation to the reduction of cognitive function and risk factors of hip fracture.

**PURPOSE:** In this prospective study, we examined the association between baseline physical activity and cognitive decline and risk factor for hip fracture in order adults.

**METHODS:** Using the KMMSE, we tested the cognitive function, and participants reported all previous hip fracture with circumstances leading to fracture between baseline and 2 year follow-up. Using an electronic accelerometer calculated total number of steps during a month. Body sway was measured by using the Dynamic Posturography (AMTI OR 6-7-2000, Massachusetts, U.S.A.). Each subject performed 10 m maximal walk speed, maximal step length, one-legged-stand, 40cm step up and down test, and functional reach and trunk flexion tests.

**RESULTS:** The risk of cognitive decline in the lowest two quartiles (lowest and low activity group, with respectively means of counts of about 3400 and 6800 steps/day) was 1.6-2.6 times higher than in the top quartile (highest group, taking means of about >10000 steps/day). We founded significant lineal associations between physical activity levels and the gait velocity.

Compared with a lowest and low activity group, older adults reporting a high activity group (> 7000 steps/day) had a significantly lower risk of hip fractures such as a lateral body sway, functional reach and maximal step length.

**CONCLUSIONS:** In this study, we suggest that to improve cognitive decline and the risks of hip fracture older adults should be encouraged to undertake > 7000 steps/day.

---

**1421**    *Board #202*    **MAY 30**    **9:30 AM - 11:00 AM**  
**Evaluating Moderate Intensity Walking With A Hip-worn Accelerometer In Elders**  
Todd Manini, Jeff Knaggs. *University of Florida, Gainesville, FL.*  
(No relationships reported)

**PURPOSE:** The National Health and Nutrition Examination Survey (NHANES) uses activity counts from accelerometers to objectively categorize the population's physical activity level. It is unclear activity counts correspond to metabolic effort in older adults. This study set out to examine the association between activity counts derived from a hip-worn accelerometer and metabolic effort in older adults performing usual and rapid paced walking.

**METHODS:** Forty-five community-dwelling older adults (70-90 years) performed long-distance walking tasks at a self-selected usual and rapid pace in a laboratory setting. During each walking test, participants wore a portable metabolic unit to measure pulmonary gas exchange and a hip-worn accelerometer (Actigraph GT1M) to measure activity counts. Metabolic equivalents (MET) were calculated as ventilation of oxygen (VO<sub>2</sub>) / 3.5 ml·kg<sup>-1</sup>·min<sup>-1</sup>. Values that surpassed 3.0 METs and 2020 counts/min were considered walking at or greater than moderate intensity. Participants were categorized as a "slow walker" if they had a usual pace < 1.0 meters/sec\_ a common cutoff used to designate an older person with functional impairments.

**RESULTS:** Activity counts recorded while walking at rapid ( $r = 0.62$ ,  $p < 0.01$ ), but not usual pace ( $r = 0.24$ ,  $p = 0.11$ ) was significantly associated with METs. Slow walkers attained only half the amount of activity counts during each walk condition (usual: 1125 ± 132 vs. 2242 ± 121; rapid: 1534 ± 214 vs. 3117 ± 219 counts/min,  $p < 0.01$ ) while at the same time achieving between 82-

90% of MET level of individuals who walked  $\geq 1.0$  m/sec. When using the NANES cutoff of 2020 counts/min, 75% of slow walkers were misclassified as not achieving a moderate intensity MET level (18 out of 24 occurrences,  $p = 0.09$ ). Walking above 1.0 m/sec misclassified 25% of the individuals as not achieving a moderate intensity MET level (13 out of 52 occurrences,  $p < 0.01$ ).

**CONCLUSIONS:** Activity counts from a hip-worn accelerometer are marginally correlated with walking metabolic rate in older adults. Accelerometers might misclassify functionally impaired older adults with slow walking speed as not achieving the recommended physical activity intensity to produce health benefits. Additional research is needed to derive better accelerometer activity count thresholds for older adults.

**1422** Board #203 MAY 30 9:30 AM - 11:00 AM  
**Exploring Physical Activity Patterns on Body Composition Phenotypes of Sarcopenia and Obesity in Older Adults**

Mi-Ji Kim, Hunkyung Kim, Narumi Kojima. *Tokyo Metropolitan Institute of Gerontology, Tokyo, Japan.*  
(No relationships reported)

Along with sarcopenia, obesity is an important cause of the development of functional impairment and frailty in older adults. Physical inactivity or low physical activity (PA) has been reported to be independently associated with sarcopenia and obesity. However, little is known about the impact of PA patterns on body composition phenotypes based on sarcopenia and obesity in older adults.

**PURPOSE:** This study examined the association between objectively measured PA patterns and body composition phenotypes based on sarcopenia and obesity in frail older women.

**METHODS:** A cross-sectional analysis was conducted on 109 community-dwelling frail older women with a mean age of 80.3 years (SD = 2.7, range = 75-88). Measurements of appendicular skeletal muscle mass and body fat percentage were assessed by dual energy X-ray absorptiometry, which were used to characterize normal (N), sarcopenic (S), obese (O), and sarcopenic/obese (SO) body composition phenotypes. The objective assessment of physical activity was obtained for a 1-week period using a triaxial accelerometer (Activity Style pro). With intensity as sedentary (1.0-1.5 metabolic equivalent units, METs), light PA (1.6-2.9 METs), and moderate to vigorous PA (MVPA,  $\geq 3$  METs), average daily time spent being each PA was examined.

**RESULTS:** The O group was the most prevalent 36.7% in frail older women, followed by the S (29.4%), N (22.0%), and SO (11.9%) groups. On average, participants wore the accelerometer for  $766.3 \pm 102.8$  min/day. Overall, participants spent 57.6% of their daily time being sedentary behavior, 39.7% in light PA, and 2.7% in MVPA. The time spent in sedentary behavior was significantly more in the O and SO groups than the normal group ( $p < 0.05$ ). Time spent in light PA was similar between the O ( $292.7 \pm 91.8$  min/day) and SO ( $243.6 \pm 88.1$  min/day) groups but significantly less than the N ( $357.5 \pm 97.1$  min/day) group ( $p < 0.05$ ), but not the S group. There was no difference in time spent in MVPA among body composition phenotypes.

**CONCLUSIONS:** These findings suggest that majority of daily time in frail older women spend being sedentary lifestyle, and obesity phenotypes are more strongly related to the light PA level, independent of sarcopenia.

**1423** Board #204 MAY 30 9:30 AM - 11:00 AM  
**5-year Changes In Functional Fitness of Brazilian Elderly Women**

Maressa P. Krause<sup>1</sup>, Hassan M. Elsangedy<sup>2</sup>, Kleverton Krinski<sup>2</sup>, Fredric L. Goss, FACSM<sup>3</sup>, Sergio G. DaSilva<sup>2</sup>. <sup>1</sup>Universidade Tecnológica Federal do Parana, Curitiba, Brazil. <sup>2</sup>Universidade Federal do Parana, Curitiba, Brazil. <sup>3</sup>University of Pittsburgh, Pittsburgh, PA.  
(No relationships reported)

Functional fitness tests have been used to evaluate functional components associated with physiological parameters, which are necessary for older adults to perform activities of daily living independently. Aging can decrease functional fitness; however, evidence had indicated that exercise can reverse or attenuate this process.

**PURPOSE:** To verify changes on functional fitness of Brazilian elderly women, classified according to their physical activity status.

**METHODS:** On 2011, 78 women (mean: 73.2yrs) were evaluated with the same procedures of the first assessment, conducted on 2005-2006. Functional fitness components were evaluated by body mass index (BMI), cardiorespiratory fitness (CRF) using the 6-min walk test (6WT), flexibility using the chair sit-and-reach (CSR), strength using the arm curl (AC) and chair stand (CS), and dynamic balance and agility using the 8-ft up-and-go (8ft). Regular physical activity was evaluated by the *Modified Baecke Questionnaire for older adults*.

**RESULTS:** MANOVA determined time ( $F_{1,140}=5.950$ ;  $p<0.05$ ) and groups main effect ( $F_{2,140}=1.850$ ;  $p0.05$ ). There was a significant decrease on CRF over time in the active group (-9.2%); on muscle strength of upper body in the inactive (-35.2%) and active (-25.5%) groups; and, on muscle strength of lower body in the active group (-11.8%). Active women had a greater CRF ( $480.3 \pm 72.3$ m) than inactive women ( $409.5 \pm 119.9$ m) on the second assessment; also, active women had a better performance on the dynamic balance and agility test ( $5.86 \pm 0.98$ s) than inactive women ( $7.11 \pm 1.41$ s) on the first assessment, and on the second assessment ( $5.91 \pm 1.01$ s; and  $7.50 \pm 2.80$ s, respectively) (all  $p<0.05$ ).

**CONCLUSIONS:** Active elderly women showed a lower decrease on functional fitness than inactive women. Also, the active group had a better cardiorespiratory fitness and dynamic balance and agility than inactive women. These results highlight the benefits of regular exercise practice on functional fitness of older women.

**1424** Board #205 MAY 30 9:30 AM - 11:00 AM  
**Recruitment Of Frail Older Adults Residing At Assisted Living Facilities Into An Exercise-nutrition Field Trial.**

Michael P. Corcoran, Miriam E. Nelson, FACSM, Roger A. Fielding, Jennifer M. Sacheck, Sara C. Folta. *Tufts University, Boston, MA.*  
(No relationships reported)

Exercise-nutrition programs designed to improve functional mobility in older adults are essential. Researching the efficacy of such programs in this population presents unique challenges, particularly with respect to study recruitment.

**PURPOSE:** To describe the challenges to recruitment of mobility limited older adults in assisted living facilities, and to compare the relative resource requirements and efficacy of two recruitment methods.

**METHODS:** Fifteen facilities in the greater Boston area were selected for this study. Residents were eligible if they were  $\geq 65$  years old, exhibited moderate mobility limitations, no severe memory impairment, and were not severely obese. At eight sites, "informational sessions", which were heavily advertised through facility channels and included a brief presentation about the study, were the only type of recruitment activity conducted. At seven sites, informational sessions were preceded by a researcher attending an activity offered by the facility ("activity attendance"), such as dances and bingo games. Staff time for both recruitment types was documented, as was number screened, number eligible, and number enrolled (eligible minus withdrawals) for each facility.

**RESULTS:** Severe memory impairment (38.7%) followed by severe mobility limitations (14.5%) were the leading causes of ineligibility, indicating the population was more functionally limited than anticipated. Other challenges included apathy due to institutionalized status and high facility staff turnover making it difficult to obtain support for recruitment activities. The addition of activity attendance resulted in 4-11 additional research staff hours spent on recruitment per facility. Compared with an informational session alone, attendance at activities resulted in better targeting: slightly more of those screened were eligible (51.7% vs 43.9% respectively), and significantly more of those who were eligible remained in the study (70.0% vs 12.0%,  $p<0.01$ ). The two leading causes of withdrawal overall were loss of interest and/or time constraints (40%) and illness (40%).

**CONCLUSION:** Increased interaction with older adults residing at assisted living facilities results in improved recruitment and retention in an exercise-nutrition study, and is likely worth the additional resources required.

---

**1425** Board #206 MAY 30 9:30 AM - 11:00 AM  
**Prediction of Maximal Oxygen Pulse without Exercise Testing in Older Adults**

Geraldo A. Maranhao Neto<sup>1</sup>, Ricardo B. Oliveira<sup>2</sup>, Paulo T.V. Farinatti<sup>2</sup>, Jonathan N. Myers, FACSM<sup>3</sup>. <sup>1</sup>Gama Filho University, Rio de Janeiro, Brazil. <sup>2</sup>Rio de Janeiro State University, Rio de Janeiro, Brazil. <sup>3</sup>Palo Alto/Stanford University, Palo Alto, CA. (Sponsor: Jonathan N. Myers, FACSM)  
(No relationships reported)

Maximal Oxygen Pulse ( $O_2P_{max}$ ) has been considered a surrogate for cardiovascular function and has demonstrated to be an independent predictor of all cause mortality in healthy subjects

and patients with cardiovascular disease. Although readily available from cardiopulmonary exercise testing, the O<sub>2</sub>Pmax depends on maximal volitional effort which may limit its measurement in older subjects with physical limitations.

**PURPOSE:** The aim of this study was to develop a model to estimate the maximal O<sub>2</sub> pulse without exercise in elderly subjects.

**METHODS:** The equation was derived from a sample of 67 older adults (69.4 ± 7.1 yrs; 41 men) through a hierarchical linear regression that included body weight, Veterans Specific Activity Questionnaire (VSAQ) score, gender, beta-blocker usage and resting heart rate. The model was cross-validated against an independent sample (67.7 ± 6.4 years; N=30; 17 men). In order to detect the classification accuracy of the model, the estimated and actual O<sub>2</sub>Pmax were ranked in tertiles and treated by the gamma (γ) nonparametric correlation in both groups (validation and cross-validation).

**RESULTS:** The model resulted in a R<sup>2</sup>=0.83 and standard error of estimate=1.68ml/beat. The comparison of the estimated against the actual O<sub>2</sub>Pmax in the independent sample was r=0.80. A high probability for the model to rank the values in the same tertile in both validation and cross-validation groups was observed (γ=0.98; γ=0.92, respectively).

**CONCLUSION:** Our findings suggest that O<sub>2</sub>Pmax can be estimated with reasonable precision without aerobic effort, being an alternative option for older subjects not able to perform maximal exercise testing.

**Commercial Relationship:** Paulo T.V. Farinatti, CNPq Research Grant Recipient.

**1426** Board #207 **MAY 30 9:30 AM - 11:00 AM**

**Group Pilates Program And Muscular Strength And Endurance Among Elderly Woman**

Ina Shaw<sup>1</sup>, Marinda Fourie<sup>2</sup>, Gertrude M. Gildenhuis<sup>2</sup>, Brandon S. Shaw<sup>2</sup>, Gregory A. Brown, FACSM<sup>3</sup>. <sup>1</sup>Monash South Africa, Johannesburg, South Africa. <sup>2</sup>Tshwane University of Technology, Pretoria, South Africa. <sup>3</sup>University of Nebraska at Kearney, Kearney, NE.  
(No relationships reported)

Muscular strength and peak power output substantially decline with age and can lead to impairments in neuromuscular function, degradation of the hormonal system and intrinsic factors such as age-related alterations in calcium homeostasis.

**PURPOSE:** The purpose was to determine the effects of mat Pilates on muscular strength using dumbbell biceps curls and squats, and muscular endurance using chair squats in elderly woman.

**METHODS:** Fifty sedentary, apparently healthy females aged 60 and older were randomly assigned into a control (CON, n = 25) or an intervention (INT, n = 25) group. The INT took part in an eight-week supervised progressive Pilates exercise program with sessions being conducted by a qualified Pilates instructor. The programme consisted of three non-consecutive 60 minute sessions that were repeated for the eight-week period only increasing in intensity. All sessions commenced with breathing, followed by a flowing system from standing, to sitting, to lying down exercises and ended in the rest position. The CON did not take part in any structured exercises throughout the eight-week period and were instructed to continue their usual activities.

**RESULTS:** Significant (p ≤ 0.05) improvements in upper-body muscular strength (19.12 ± 5.13 repetitions (reps) - 27.84 ± 5.68 reps; p = 0.000), lower-body muscular strength (13.24 ± 3.23 reps - 7.52 ± 3.81 reps; p = 0.000) and muscular endurance (24.48 ± 11.62 reps to 44.16 ± 18.97 reps; p = 0.000) were observed following Pilates training.

**CONCLUSIONS:** Programs utilizing Pilates can improve muscular strength and endurance in the elderly and may assist in decreasing dependency and possibly lead to an improved quality of life in the elderly.

**1427** Board #208 **MAY 30 9:30 AM - 11:00 AM**

**Past Year Leisure Moderate to Vigorous Physical Activity is Associated with Calcaneal Bone Density and Stiffness in Perimenopausal and Postmenopausal Women**

Heather C. Medema-Johnson<sup>1</sup>, Kathleen F. Janz, FACSM<sup>2</sup>. <sup>1</sup>St. Ambrose University, Davenport, IA. <sup>2</sup>University of Iowa, Iowa City, IA.  
(No relationships reported)

Along with calcium intake, weight-bearing moderate to vigorous physical activity (MVPA) has been shown to decrease the rate of bone loss in peri- and postmenopausal women. However, the importance of domain- and time-specific characteristics of MVPA to bone remains unclear.

**PURPOSE:** To evaluate relationships among domain-specific long term (past year) and short term (past week) MVPA, calcium and vitamin D intakes, and calcaneal BMD and stiffness (QUI).

**METHODS:** For this cross-sectional-study, 87 peri- and postmenopausal women (43-65 years) completed demographic/health questionnaires and the Block calcium and vitamin D screener. Participants wore a NL-1000 pedometer for one week to assess short-term MVPA (total steps/day and MVPA-min/day). Past year MVPA, past year leisure MVPA, past year occupational/household MVPA, past week leisure MVPA, and past week occupational/household MVPA were assessed with the Modifiable Activity Questionnaire. Calcaneal BMD and QUI were measured with a Sahara Quantitative Ultrasound (Hologic, Inc.). Pearson correlation coefficients and stepwise linear regression analyses were used to examine the relationships among measures of MVPA, calcium and vitamin D intakes, calcaneal BMD and QUI. Income and education entered as control variables in stepwise regression analyses.

**RESULTS:** Bivariate analyses revealed significant relationships between BMD and pedometer-measured MVPA-min/day (r = 0.23, p < 0.05). Past year MVPA (r = .25, p < 0.05), and past year leisure MVPA (r = 0.35, p < 0.01) measured via survey were associated with BMD. Significant relationships were found between QUI and past year MVPA (r = 0.23, p < 0.05) and past year leisure MVPA (r = 0.34, p < 0.01). For stepwise linear regression analyses, income, education, and past year leisure MVPA entered the models, collectively explaining 19% and 18% of the variance in BMD and QUI.

**CONCLUSION:** Past year MVPA performed in the leisure domain is associated with calcaneal BMD and QUI in peri- and postmenopausal women. Our results suggest the value of long-term measures of PA when considering bone health and the likelihood that women engage in more osteogenic activity during leisure when compared to other domains. These findings can be used to support future interventions and the continued need for multi-dimensional PA measures.

**1428** Board #209 **MAY 30 9:30 AM - 11:00 AM**

**Lumbar Lordosis Angle Predicts Walking Ability In Community-dwelling Elderly Men**

Junya Miyazaki<sup>1</sup>, Shin Murata<sup>2</sup>, Jun Horie<sup>1</sup>, Tibor Hortobagyi, FACSM<sup>3</sup>, Shuji Suzuki<sup>4</sup>. <sup>1</sup>Kobe International University, Kobe, Japan. <sup>2</sup>Nishikyushu University, Kanzaki, Japan. <sup>3</sup>University of Groningen, Groningen, Netherlands. <sup>4</sup>Waseda University, Tokorozawa, Japan.  
(No relationships reported)

**PURPOSE:** Aging modifies the sagittal plane structural alignment of the human spine as measured with the gravity line method (Schwab F et al., 2006). At the 2010 ACSM meeting we reported that the physical function of elderly males correlated with the lumbar lordosis angle (LLA) but not with the thoracic kyphosis angle (TKA) measured in the sagittal plane. Here we examine the possibility that a structural measure of the spine, the LLA, predicts gait speed and distance in old adults.

**METHODS:** Subjects were 103 elderly male community residents (72.9 ± 7.2 yr, 1.59 ± 0.15m, 59.4 ± 8.7 kg). To characterize sagittal plane spinal alignment, we measured LLA in all participants using the Spinal Mouse (Idiag AG, Switzerland). The LLA (deg) was measured as the sum of the angles between each of the five lumbar vertebral bodies relative to the 1st sacral vertebral body. We also measured quadriceps femoris muscle strength (QMF) with a hand-held dynamometer (Anima Corp., Japan), one-leg standing (OLS) time with eyes open, maximum walking speed (MWS), and distance in the 6-min walking test (6MWT). In regression analyses we predicted MWS and 6MWT from LLA, QMS and OLS and used p < 0.05 for all analyses.

**RESULTS:** Mean (± SD) LLA was -13.1° (± 9.2). Mean QMF, OLS time, MWS, and 6MWT distance was, respectively, 39.9 kg (± 11.6), 34.1 s (± 36.8), 2.6 m/s (± 1.0), and 477.4 m (± 90.2). The regression analysis showed that LLA (p < 0.01, β = -0.43) and QMF (p < 0.01, β = 0.46) predicted strongly MWS. QMF (p < 0.01, β = 0.63) was also a strong predictor of walking distance.

**CONCLUSION:** Gait speed predicts mortality (Studenski et al., 2011)

and here we show that not only a functional (muscle strength) but a structural factor (LLA) may also play a role in the regulation of gait in old age. Thus, interventions should target muscle strength and postural alignment to be most effective in preserving gait speed in old adults.

**Effects of Fall Prevention PNF Program on Body Function and Fall Efficacy in Elderly Women**

Seokhwan Kim<sup>1</sup>, Michael G. Bembem, FACSM<sup>2</sup>, Daeyeol Kim<sup>2</sup>, Donghee Kim<sup>3</sup>, Youngkwan Kim<sup>3</sup>, Hayan Lee<sup>3</sup>, Doohong Kuk<sup>3</sup>, Meehyun Yang<sup>4</sup>, Gieun Jang<sup>5</sup>.  
<sup>1</sup>Seoyeong University, Gwangju, Korea, Republic of. <sup>2</sup>University of Oklahoma, Oklahoma, OK. <sup>3</sup>Chonnam National University, Gwangju, Korea, Republic of.  
<sup>4</sup>University of Gwangju Women's, Gwangju, Korea, Republic of. <sup>5</sup>Dongshin University, Naju, Korea, Republic of. (Sponsor: Michael G. Bembem, FACSM)  
(No relationships reported)

**PURPOSE:** To investigate the effects of a fall prevention program with proprioceptive neuromuscular facilitation (PNF) on body functions (gait, balance, lower extremity power and instrumental activities daily living) and fall efficacy in elderly women.

**METHODS:** Subjects (n = 38, 65 - 70 years) participated in this study and were randomly assigned to an experimental (n = 18, EXP) or a control (n = 20, CON) group. The subjects in both EXP and CON performed the fall prevention training three times at pre, 6<sup>th</sup> and 12<sup>th</sup> week. Only subjects in the EXP completed PNF sprint & skate program (40 - 60 min, 60 - 80% HR<sub>max</sub>) three times per week for 12 weeks. The body function (Time up & go test, 2 min step test, balance by TetraX and Berg balance scale, sit to stand test, one leg standing test, and instrumental activities of daily living) and fall efficacy (fall efficacy scale) were determined at pre, 6<sup>th</sup> and 12<sup>th</sup> week. Two-way repeated measure ANOVA was utilized to compare groups and times with statistical significance set at p<0.05.

**RESULTS:** The Gait, balance, lower extremity power functions in the EXP were significantly higher than CON. The balance function in the EXP was significantly higher than CON. Also, the Instrumental activities of daily and fall efficacy in the EXP were significantly greater than CON.

**CONCLUSIONS:** These results indicate that the fall prevention program with PNF was effective to prevent fall and to increase fall efficacy. Thus, the fall prevention program with PNF is considered to be helpful to prevent fall and the quality of life for elderly people by strengthening their body functions and fall efficacy.

---

1430 Board #211 MAY 30 9:30 AM - 11:00 AM

**Increased Sitting Time is an Independent Risk Factor for All-cause Mortality in Community-Dwelling Older Adults**

Steven N. Blair, FACSM<sup>1</sup>, Xuemei Sui<sup>1</sup>, Ali Ahmed<sup>2</sup>. <sup>1</sup>University of South Carolina, Columbia, SC. <sup>2</sup>University of Alabama at Birmingham, Birmingham, AL.  
(No relationships reported)

**PURPOSE:** Older adults often assume a sedentary lifestyle and spend more time sitting or lying, than younger adults. Sedentary lifestyle has been shown to be associated with increased risk of poor clinical outcomes. However, the association of sedentary lifestyle as measured by time spent sitting and lying with mortality has not been well studied in community-dwelling older adults.

**METHODS:** Participants were 5060 community-dwelling older adults from the Cardiovascular Health Study, age ≥65 years, with data on baseline history of hours spent sitting or lying. Participants were categorized into tertiles of hours per day spent sitting or lying: <11, 11-13, and ≥14 (reference). Cox regression models were used to estimate association of the 2 lower tertiles with all-cause mortality adjusting for other confounders. To study association with incident heart failure, a second cohort of 4833 participants free of prevalent heart failure at baseline was assembled.

**RESULTS:** Participants had a mean (±SD) age of 73 (±6) years; 58% were women; and 16% were African American. Unadjusted, age-sex-race-adjusted, and multivariable-adjusted associations of the 2 lower tertiles of hours spent sitting or lying with all-cause mortality and incident HF during over 13 years of follow-up are displayed in the **Table** below.

**CONCLUSIONS:** Among community-dwelling older adults, those spending <14 hours sitting and lying, had lower risk of all-cause mortality but had no significant independent association with incident HF after multivariable adjustment for confounders.

---

1431 Board #212 MAY 30 9:30 AM - 11:00 AM

**Development and Evaluation of a Health Empowerment Program to Improve Depression and Meaning in Life**

Sherry A. Barkley<sup>1</sup>, Tracey Hughes<sup>2</sup>, Nancy L. Fahrenwald<sup>3</sup>, Angie L. Larson<sup>3</sup>, Joyce Fjelland<sup>3</sup>, Patricia Shaver<sup>3</sup>, Mary Minton<sup>3</sup>, Jane Mort<sup>3</sup>. <sup>1</sup>Augustana College, Sioux Falls, SD. <sup>2</sup>Dow Rummel Village, Sioux Falls, SD. <sup>3</sup>South Dakota State University, Brookings, SD. (Sponsor: Matthew D. Vukovich, FACSM)  
(No relationships reported)

Older adults in residential settings are at risk for depression. Health empowerment, a dynamic process wherein residents purposefully connect to create environmental change and personal meaning, may help control depression and quality of life.

**PURPOSE:** To develop and evaluate Project MILE: Meaning in Life Enrichment for Older Adults, a theory-based program using resident-driven activities intended to decrease depression and increase quality of life.

**METHODS:** Residents and selected staff at a residential living community partnered with researchers in exercise science and healthcare to develop and implement Project MILE. A random sample of 20 older adult residents (16 female, 4 male), mean age = 86.7 years, participated in this pilot study. Needs assessment, conducted through structured interviews between residents and exercise science students, was used to inform Project MILE activities. A descriptive-correlational study was used to evaluate reliability of measurement instruments and to determine cross-sectional relationships between multi-item measures of depression (Geriatric Depression Scale [GDS]) and meaning in life (Personal Meaning Index [PMI]). A paired samples t-test was used to compare baseline and follow up scores in these measures. Feasibility and acceptability of the intervention was evaluated through written/oral review of strengths, weaknesses, and suggestions by and with residents.

**RESULTS:** Needs analysis identified themes that contribute to meaning and quality of life: learning new skills, volunteering, meaningful social engagement, and aesthetic experiences. Participants selected and planned weekly activities (e.g., computer class, reading to children, Mexican Day, cycling, going fishing) based on identified themes. GDS and PMI met acceptability criteria for reliability ( $\alpha > .70$ ) and construct validity. Baseline scores (mean + SD) for GDS and PMI (6.8 + 5.4, 86.2 + 10.3) respectively were not significantly different (p > .05) at follow up (7.7 + 5.1, 86.2 + 10.3). Intervention strategies (i.e., activities and measurement instruments) were found acceptable to residents.

**CONCLUSIONS:** Although we saw no significant change in GDS and PMI scores, evaluation of this pilot study generated evidence to support the use of this health empowerment approach in a future randomized trial.

1432 Board #213 MAY 30 9:30 AM - 11:00 AM

**An Examination of the Survivability of Professional Wrestlers**

Christopher W. Herman<sup>1</sup>, Anna S.C. Conlon<sup>2</sup>, Andrew R. Burghardt<sup>1</sup>, Stephen J. McGregor<sup>1</sup>. <sup>1</sup>Eastern Michigan University, Ypsilanti, MI. <sup>2</sup>The University of Michigan, Ann Arbor, MI. (Sponsor: Christopher J. Womack, FACSM)  
(No relationships reported)

In recent years, much attention has been given to the occurrence of premature deaths in professional wrestling.

**PURPOSE:** The purpose of this study was to determine the survival estimates for professional wrestlers active between 1985 and 2011.

**METHODS:** Data required for this study was collected using public records and wrestling company publications. A comprehensive review of age, race, sex, BMI, cause of death (if applicable) and age at death (if applicable) of 625 wrestlers who were active between January 1, 1985 and September 30, 2011 was completed. Specifically, 557 males and 68 females were considered consistently active wrestlers during this time period. 2007 published mortality rates from the CDC were used to compare the general population to the wrestlers by age, race, BMI, time period, and cause of death for both males and females. Additionally, a Kaplan-Meier survival analysis and Cox Proportional Hazards Models for survival data were performed using the R statistical software package (Vienna, AT) to determine the degree of professional wrestlers' premature death.

**RESULTS:** 65 wrestlers (61 males and 4 females) died during the observation period. Wrestler mortality rates calculated for age groups 25-34, 35-44 and 45-54 were approximately 22.9, 16.5 and 7.6 times greater than the mortality rates for the same three age groups of the general population. After controlling for age at which the wrestlers started wrestling and number of years wrestled prior to 1985, survival estimates and 95% confidence limits from the Cox hazard regression models indicated that sex and BMI are significantly associated with the hazard of death

---

from the time someone starts wrestling (Sex:  $p = 0.02$ ; BMI:  $p < 0.0001$ ). Specifically, the hazard of death for women was only 30% that of men and the hazard of death increased by 80% for each increase in BMI category. Kaplan-Meier survival estimates and Cox hazard estimates indicated that there was no significant difference in time to death between wrestler starting age groups ( $p = 0.31$ ).

**CONCLUSION:** Professional wrestlers are more likely to die prematurely compared to the general population. Morbidly obese and male wrestlers are especially at risk for premature death. Results from this study may be useful for future corporate wellness policy implementation among professional wrestling companies.

#### Accumulated Rpe: A Distance Independent Marker Of Effort During Cycle Time Trials

Carl Foster, FACSM, Jose Rodríguez-Marroyo, Annabel Splinter, Joyce van Tunen, Corey Speaker, Jana Hagen, Kayla Henslin, Blair Johnson, Trent Joseph, John P. Porcari, FACSM, Jos J. de Koning, FACSM. *University of Wisconsin-La Crosse, La Crosse, WI.*

(No relationships reported)

Decisions about whether to accelerate or decelerate during competitions are based on the Rating of Perceived Exertion in relation to the % distance remaining (e.g. the Hazard Score). However, the percent of distance remaining may not be an accurate representation of the % effort expended by the athlete (e.g. the classic expression that a marathon (42km) is 50% over at 32km (~75% distance)).

**PURPOSE:** This study compares the accumulated RPE during cycle time trials of different distances, to determine whether  $\Sigma$ RPE would be independent of distance.

**METHODS:** Well-trained and task habituated cyclists performed freely paced (FP) time trials (2.5km, n=9, 3km, n=10, 5km, n=17, 10km, n=50) on a Velotron cycle ergometer. RPE was measured every 5% of the total distance, summated and normalized to the maximum value.

**RESULTS:** The  $\Sigma$ RPE increased in a regular, but non-linear, fashion during all races, and the pattern of increase amongst distances was overlapping. The relationship between % distance completed and  $\Sigma$ RPE was well explained with a 2<sup>nd</sup> order polynomial ( $R^2=0.9881$ ).

**CONCLUSIONS:** The  $\Sigma$ RPE may provide a tool for measuring the relative effort expended during competitive effort that is superior to the % distance completed, with 50% effort being completed at ~60% distance.

---

### 1434 Board #215 MAY 30 11:00 AM - 12:30 PM

#### The Effect of Music on Cycle Time Trial Performance

Jana Hagen, Carl Foster, FACSM, Jos J. deKoning, FACSM, Charles R. Hendrix, Richard P. Mikat, FACSM, Jose Rodriguez-Marroyo, John P. Porcari, FACSM. *University of Wisconsin-La Crosse, La Crosse, WI.*

(No relationships reported)

High intensity competitive exercise depends on the interaction of a pre-exercise template with feedback from the body. In well-trained people the interaction between template and feedback is complex and can be understood in terms of comparisons between expected and experienced Rating of Perceived Exertion (RPE) at each point in the trial. Motivational music generally augments exercise performance, potentially by the arousal from music changing the template or by suppression of feedback from homeostatic disturbance.

**PURPOSE:** This study compared both the level of performance and the pattern of PO during a 10km cycle time trial in relation to the presence of motivational music.

**METHODS:** Well-trained, task habituated cyclists (n=18) performed two randomly ordered time trials, listening either to self-selected motivational music or no music (control). Performance markers including PO, HR, blood lactate [BL] & RPE were monitored.

**RESULTS:** Music had no effect on maximal HR  $174 \pm 11$  vs  $172 \pm 10$ , mean PO  $222 \pm 66$  vs  $220 \pm 65$  W, maximal RPE  $8.4 \pm 1.5$  vs  $8.5 \pm 1.6$ , maximal [BL]  $8.2 \pm 3.6$  vs  $8.2 \pm 3.5$  mmol $\cdot$ l $^{-1}$  or time  $17.7 \pm 2.1$  and  $17.8 \pm 2.1$  min ( $p > .05$ ). Further, the pattern of PO during the trial did not suggest a change in pacing pattern consistent with arousal related template modification (e.g. increased early PO) or suppression of feedback (e.g. higher mid-trial PO).

**CONCLUSIONS:** The results show that, despite the subjects preferring the time trial with music, there were no significant differences in time trial responses relative to the presence of music.

### 1435 Board #216 MAY 30 11:00 AM - 12:30 PM

#### Effects of Warm-up Duration on Vo2 Kinematics and Lactate During a Cycling Time Trial

Jennifer Bunn. *Campbell University, Buies Creek, NC.*

(No relationships reported)

#### Effects of Warm-up Duration on VO<sub>2</sub> Kinematics and Lactate during a Cycling Time Trial

J. Bunn<sup>1</sup>, M. Magal (FACSM)<sup>2</sup>, L.C. Eschbach<sup>2</sup>, R. Vogel<sup>3</sup>, and R. Yow<sup>3</sup>

1) Campbell University, Buies Creek, NC; 2) NC Wesleyan

A warm-up prior to long-duration exercise has been shown to be effective during the initial phase of the activity, but may not have a significant impact on performance for the entire activity.

**PURPOSE:** The purpose of this study was to evaluate if the duration of a warm-up affects VO<sub>2</sub> kinematics and lactate during a 5K cycling time trial (TT).

**METHODS:** Sixteen trained cyclists ( $41.0 \pm 7.7$  years,  $76.5 \pm 13.5$  kg,  $1.75 \pm 0.11$  m,  $50.5 \pm 11.7$  ml/kg/min) completed a cycling graded exercise test to measured maximum oxygen consumption (VO<sub>2</sub>max) and lactate threshold, followed by an orientation session the TT. At subsequent visits, participants completed one of three warm-up protocols, in randomized order, and the TT. The warm-up protocols included: 1) a short duration three-minute warm-up at 60% max power (SW), 2) a long duration warm-up of 10 minutes at 60% max power (LW), and 3) no warm-up (NW). All cycle testing was completed using a stationary cycle simulator and the participant provided their own bicycle, and testing sessions were completed approximately one week apart. Data were analyzed to address differences amongst type of warm-up for VO<sub>2</sub>, TT time, and lactate at the 1K split and the entire 5K.

**RESULTS:** There was no difference between type of warm-up ( $p > 0.05$ ) for VO<sub>2</sub> (SW:  $50.1 \pm 9.0$ , LW:  $49.5 \pm 9.4$ , NW:  $50.6 \pm 9.0$  ml/kg/min), post-TT lactate levels (SW:  $9.0 \pm 2.9$ , LW:  $7.9 \pm 3.2$ , NW:  $8.0 \pm 3.2$  mmol/l), or TT completion time. There was also no difference between warm-ups ( $p > 0.05$ ) after completion of 1K for VO<sub>2</sub> (SW:  $41.5 \pm 7.6$ , LW:  $46.1 \pm 10.3$ , NW:  $37.4 \pm 5.2$  ml/kg/min) or 1K split time.

**CONCLUSION:** This data conflicts current evidence that a warm-up may be beneficial during the initial phase of an endurance activity, but agrees with research that indicates no difference amongst warm-up types for the entire performance. This study limited the warm-up sessions to steady state exercise, but future research should address variations in intensity during the warm-up in addition to the duration.

---

**1436** Board #217 **MAY 30 11:00 AM - 12:30 PM**  
**Physiological And Performance Comparisons Between A Simulated Time Trial And The Respiratory Compensation Point In Well-Trained Cyclists**  
Rick T. Bradley, Jamie L. Donkin, Raymond Martinez, Jr., Roberto Quintana, Daryl L. Parker. *Irvin Faria Exercise Physiology Laboratory CSUS, Sacramento, CA.*  
(No relationships reported)

Graded exercise test (GXT) results are commonly used to prescribe exercise. However, investigators have found that GXT power overestimates submaximal steady-state (SS) power.

**PURPOSE:** This study evaluated the physiological and performance values from a simulated 576 kJ (~20 km) time trial (TT) in comparison to the values at the respiratory compensation point (RCP) from a GXT.

**METHODS:** Eight (female n=1) well-trained cyclists [ $VO_{2max}$ :  $62.3 \pm 7.16$  ml·kg<sup>-1</sup>·min<sup>-1</sup>, maximal power ( $W_{max}$ ):  $374 \pm 54.5$  W, BMI:  $23.5 \pm 4.5$  kg·(m<sup>2</sup>)<sup>-1</sup>, Age:  $32.8 \pm 7.5$  years] served as volunteer participants for this investigation. Each volunteer first underwent a GXT on a cycle ergometer to exhaustion beginning at 70 W (female=50 W) and increasing at a rate of 35 W·min<sup>-1</sup> (female=25 W·min<sup>-1</sup>) to determine RCP and  $VO_{2max}$ . On a separate day, a self-paced 576 kJ (~20 kilometer) TT was performed at an "all-out" effort, with only simulated distance revealed. A one-way ANOVA for RCP and TT variables; heart rate (HR), power, respiratory exchange ratio (RER), ventilation (Ve) and  $VO_2$  at 144 kJ (~5 K), 288 kJ (~10K), 432 kJ (~15K) and 576 kJ (~20K) was used to detect differences. Relationships between RCP and TT variables were assessed with Pearson's r.

**RESULTS:** RCP values were; HR ( $178 \pm 8.32$  bpm), power ( $317 \pm 47.2$  W, 85% of  $W_{max}$ ), RER ( $1.07 \pm 0.06$ ), Ve ( $100 \pm 19.2$  l·min<sup>-1</sup>) and  $VO_2$  ( $3.81 \pm 0.56$  l·min<sup>-1</sup>, 91% of  $VO_{2max}$ ). No significant difference was found over the course of the TT for any variable ( $p > 0.05$ ). HR, Ve and  $VO_2$  were not different between the TT and RCP ( $p > 0.05$ ), but power ( $249 \pm 55$  W) and RER ( $0.96 \pm 0.05$ ) from the TT were significantly less than RCP ( $p < 0.05$ ,  $p < 0.01$ ). RCP HR, power and  $VO_2$  were significantly correlated to TT HR ( $r = 0.92$ ,  $p < 0.05$ ), power ( $r = 0.90$ ,  $p < 0.05$ ) and  $VO_2$  ( $r = 0.93$ ,  $p < 0.05$ ).

**CONCLUSION:** The RCP HR, Ve and  $VO_2$  from a GXT are similar to TT responses in well-trained cyclists, but RCP power and RER are overestimated compared to the TT. As expected, strong correlations were found between RCP and TT HR, power and  $VO_2$ ; and RCP power and  $VO_2$  from this study are similar to others' findings as a percentage of maximum (~85-90%). Interestingly, we found the RCP power to be much greater than TT power ( $67.8 \pm 23.6$  W), with the difference being greater than that found between the ventilation threshold and equivalent sub-maximal SS exercise by previous investigators ( $45 \pm 12$  W).

**1437** Board #218 **MAY 30 11:00 AM - 12:30 PM**  
**Decision Making Relative To Pacing Strategy: Test Of The Hazard Score Hypothesis**  
Katherine R. Malterer, Carl Foster, FACSM, Jos J. de Koning, FACSM, Samantha Bischel, Frieder Krause, Miranda Menke, Jose Rodriguez-Marroyo, Christian Thiel, John P. Porcari, FACSM. *University of Wisconsin-La Crosse, La Crosse, WI.*  
(No relationships reported)

Performance in any physically demanding task depends on a motor template and feedback regarding how the task is affecting the body. The 'language' of this feedback is the rating of perceived exertion (RPE). Previous evidence from our laboratory suggests that RPE x the % of distance remaining, the Hazard Score (HS), determines whether the athlete speeds up or slows down.

**PURPOSE:** This study tested if the HS will predict changes in running velocity during individual 3km time trials.

**METHODS:** Well-trained, task-habituated subjects (N=12), completed three 3km running time trials with individual starting times to discourage drafting/pacing off other runners. Changes in momentary running velocity vs. HS were computed every 200m by comparing the running velocity immediately (100m) before providing a RPE score vs the running velocity immediately (100m) after the RPE score, to test the hypothesis that HS > 3 yields deceleration & < 1.5 yields acceleration.

**RESULTS:** Regression analysis ( $R^2 = 0.16$ ) of a total of thirty-four 3km time trials, yielding 469 observations, revealed a regression curve predicting acceleration with HS < 1.5 and deceleration with HS > 3.5, which substantially supports the experimental hypothesis.

**CONCLUSION:** HS may be a tool for understanding how humans regulate energy expenditure during exercise.

---

**1438** Board #219 **MAY 30 11:00 AM - 12:30 PM**  
**Long Range Correlations And Complex Regulatory Control Of Pacing In Half Marathon Racing**  
Olaf Hoos<sup>1</sup>, Tobias Boeselt<sup>1</sup>, Martin Steiner<sup>1</sup>, Kuno Hottenrott<sup>2</sup>, Ralph Beneke, FACSM<sup>1</sup>. <sup>1</sup>Philipps-University Marburg, Institute of Sports Science, Marburg, Germany. <sup>2</sup>Martin-Luther-University Halle-Wittenberg, Institute for Media, Communication and Sports, Halle, Germany.  
(No relationships reported)

Fractal scaling properties serve as evidence of complex regulatory controlling. Recent studies on prolonged, self-paced laboratory and field time trials have shown substantial variability and suggest fractal scaling in speed or power output. High resolution data on speed (S) reflecting stride frequency (SF) and stride length (SL) during real-world endurance competition are lacking.

**PURPOSE:** To determine and classify spectral and fractal properties of S, SF and SL fluctuations and interrelationships with half-marathon running performance.

**METHODS:** High-resolution (1 Hz) data on S (m/s), SF (Hz) and SL (m) were assessed during half-marathon (21,098 m) competition using a miniaturized accelerometric device in 21 male experienced runners ( $38 \pm 11$  yrs, BMI:  $23 \pm 2$  kg·m<sup>-2</sup>). Performance times, coefficient of variation (CV), spectral powers (TP) and peaks (PP), fractal scaling exponent (beta) and fractal dimension (FD) of S, SF and SL were computed.

**RESULTS:** S, SF, SL were  $3.65 \pm 0.41$  m/s,  $1.41 \pm 0.05$  Hz and  $2.58 \pm 0.25$  m, respectively. Variability of SF (CV:  $1.7 \pm 0.4$  %; TP:  $0.0004 \pm 0.0002$  n.u.) was lower ( $p < 0.05$ ) than that of S (CV:  $4.5 \pm 1.3$  %; TP:  $0.0260 \pm 0.0195$  n.u.) and SL (CV:  $4.4 \pm 1.4$  %; TP:  $0.0116 \pm 0.0081$ ). Non-stationary fractional Brownian motion (fBm) was found in SF (beta:  $1.35 \pm 0.16$ ; FD:  $1.82 \pm 0.08$ ), SL (beta:  $1.45 \pm 0.19$ ; FD:  $1.77 \pm 0.10$ ) and S (beta:  $1.57 \pm 0.20$ ; FD:  $1.71 \pm 0.10$ ) with similar PP-values (S:  $0.00156 \pm 0.00109$  Hz; SF:  $0.00170 \pm 0.00099$  Hz; SL:  $0.00150 \pm 0.00108$  Hz). Fractal and spectral variability measures were independent of performance. The semi-partial explanation of S variation was  $84 \pm 6$  % for SL and  $16 \pm 6$  % for SF. PP ( $r = 0.56$ ) and beta ( $r = 0.91$ ) were interrelated for S and SL.

**CONCLUSIONS:** fBm in SL, SF and S indicate long range correlations and complex regulatory control of pacing in real-world half marathon running. In experienced runners this control mechanism is independent of performance.

**1439** Board #220 **MAY 30 11:00 AM - 12:30 PM**  
**Incidence Of Plateau At VO2max Is Influenced By Prior Knowledge Of Trial Number**  
Dan A. Gordon<sup>1</sup>, Oliver Caddy<sup>1</sup>, Rutendo Ganyani<sup>1</sup>, Marie Gemigon<sup>2</sup>, Nicolas Buttinger<sup>3</sup>, James Latchford<sup>3</sup>, Don Keiller<sup>1</sup>, Richard Barnes<sup>3</sup>. <sup>1</sup>Anglia Ruskin University, Cambridge, United Kingdom. <sup>2</sup>University of Angers, Angers, France. <sup>3</sup>University of Cambridge, Cambridge, United Kingdom.  
(No relationships reported)

**PURPOSE:** The purpose of this study was to examine the  $VO_2$  plateau response during a series of  $VO_{2max}$  trials in a group of well-trained an un-trained individuals who had no prior experience of completing incremental tests to exhaustion.

**METHOD:** Following University Institutional ethical approval, n=10 well-trained male athletes (WT) (age,  $23.0 \pm 3.16$  yrs; height,  $183.3 \pm 5.5$  cm; weight,  $77.5 \pm 11.1$  kg;  $VO_{2max}$ ,  $66.3 \pm 5.7$  ml·kg<sup>-1</sup>·min<sup>-1</sup>) and n=7 un-trained male subjects (UT) (age,  $20.1 \pm 0.9$  yrs; height,  $181.6 \pm 6.2$  cm; weight,  $72.9 \pm 10.0$  kg;  $VO_{2max}$ ,  $48.8 \pm 5.3$  ml·kg<sup>-1</sup>·min<sup>-1</sup>) volunteered and agreed to participate. The subjects completed four  $VO_{2max}$  trials (Tr 1-4) at the same time of day, each trial being separated by 72 h. For each trial the subject completed a cycle-based incremental ramp starting at 100 W. After 60 s of cycling the workrate increased by  $0.42$  W·s<sup>-1</sup> while maintaining a constant cadence of 60 rpm (UT) and 80-90 rpm (WT). The incremental ramp test was terminated either when the cadence decreased by <10 rpm or when the subject stopped due to volitional exhaustion. Verbal encouragement was initiated after 360 s of cycling and re-introduced continuously once VE displayed a significant break from linearity. Throughout all trials, the  $VO_2$  response to exercise was recorded on a breath-by-breath basis using a pre-calibrated metabolic cart. The first criterion for a plateau in  $VO_2$  was determined according to a  $\Delta VO_2 < 1.5$  ml kg<sup>-1</sup>·min<sup>-1</sup> over the final two consecutive 30 s sampling periods. Secondary criteria were RER  $\geq 1.15$ ,  $\Delta RER \geq 0.4$ , peak blood lactate  $\geq 8.0$  mM·l<sup>-1</sup>, HR $_{max} \geq 220$ -age  $\pm 10$  b·min<sup>-1</sup> and an RPE > 19.

**RESULTS:** In the WT group the  $\Delta\text{VO}_2$  ( $\text{ml}\cdot\text{kg}^{-1}\cdot\text{min}^{-1}$ ) during the final two consecutive 30 s sampling periods was  $2.52 \pm 1.63$  for Tr1,  $1.68 \pm 1.05$  for Tr2,  $1.68 \pm 1.19$  for Tr3 and  $1.28 \pm 0.87$  for Tr4 ( $P=0.083$ ), there was no-significant difference across trials for UT ( $P=0.699$ ). Plateau incidence for WT was 20% Tr1, 50% Tr 2-3 and 70% Tr4, while for UT incidence it was 7% across Tr 1-4. For both WT ( $P=0.295$ ) and UT ( $P=0.694$ ) there was no-significant difference in  $\text{VO}_{2\text{max}}$  across Tr 1-4.

**CONCLUSION:** The data suggests that the incidence of plateau at  $\text{VO}_{2\text{max}}$  is influenced by other factors aside from anaerobic substrate metabolism. The results suggest that a form of pacing occurs in WT based on the prior knowledge and anticipation of the number of trials.

---

**1440** Board #221 **MAY 30** **11:00 AM - 12:30 PM**

**Racing the Favourite: Effects of Competition During Laboratory Based 4,000-m Cycling Time Trials**

Mark R. Stone<sup>1</sup>, Kevin Thomas<sup>2</sup>, Alan St Clair Gibson<sup>2</sup>, Michael Wilkinson<sup>2</sup>, Kevin G. Thompson<sup>2</sup>. <sup>1</sup>Buckinghamshire New University, High Wycombe, United Kingdom. <sup>2</sup>The University of Northumbria at Newcastle, Newcastle upon Tyne, United Kingdom.  
(No relationships reported)

Cyclists can achieve marginal reductions in the time taken to complete a time trial (TT) whilst racing against a simulated opponent compared with riding alone. However, in previous studies the opponent has typically mirrored the participants own previous performance. It is not known whether a simulated opponent whose exercise intensity is known to be greater than that previously achieved could 'push' participants to realise meaningful reductions in performance time.

**PURPOSE:** To assess whether trained cyclists could reduce the amount of time taken to complete a 4,000-m TT during head-to-head competition against a simulated opponent who they understood to be performing at a higher power output than their own previous performance.

**METHODS:** Ten trained male cyclists each performed four, 4,000-m TT with between three and seven days separating each trial. The first TT served to acclimatise participants and the second was used to form a baseline condition (BL). During TT three and four, two avatars were displayed on a video screen; one of these represented the progress of the participant and the other represented the progress of the simulated opponent. The power output of the simulated opponent was set at either 102% or 105% of the participants mean BL power output in a randomised and counter balanced order. Participants were briefed about the nature of the experiment and encouraged to try to beat their opponent. Heart rate was monitored continuously and session RPE was recorded on completion of each trial.

**RESULTS:** There were no significant differences between BL and either the 102% or 105% TT for time taken [( $F = 1.201_2$ ,  $p = 0.3$ ), ( $359.4 \pm 11.1$ ,  $360 \pm 11.7$  and  $361.2 \pm 12.8$  s, respectively)]; mean heart rate [( $F = 0.468_2$ ,  $p = 0.6$ ), ( $180 \pm 15$ ,  $180 \pm 13$  and  $179 \pm 12$  bpm, respectively)] or session RPE [( $F = 0.536_2$ ,  $p = 0.6$ ), ( $18 \pm 1$ ,  $18 \pm 1$  and  $19 \pm 1$ , respectively)].

**CONCLUSION:** The presence of a simulated opponent, known to be exercising at an intensity which was greater than participants achieved during BL, did not affect performance time or the physiological or perceptual responses during a 4,000-m TT. These findings indicate that the regulation of self paced exercise is a robust mechanism which is not readily influenced by the presence of a simulated opponent designed to 'push' the athlete to reduce the amount of time taken to perform a TT.

**A-40** Free Communication/Poster - Posture/Balance

MAY 30, 2012 7:30 AM - 12:30 PM

ROOM: Exhibit Hall

---

**1441** Board #222 **MAY 30** **11:00 AM - 12:30 PM**

**The Influence of Occupational Footwear on Balance**

John C. Garner, III<sup>1</sup>, Harish Chander<sup>1</sup>, Nicole C. Dabbs<sup>1</sup>, Jennica Roche<sup>2</sup>, Chip Wade<sup>3</sup>. <sup>1</sup>University of Mississippi, University, MS. <sup>2</sup>University of Pittsburgh, Pittsburgh, PA. <sup>3</sup>Auburn University, Auburn, AL. (Sponsor: Mark Lofitin, FACSM)  
(No relationships reported)

There is a wealth of research investigating human balance following exposure to smooth, level surfaces, with recent investigations examining posture following exposure to ramps, stairs, steps, and uneven terrain. Occupational footwear worn for a work setting are often designed for safety and stability, rather than comfort or aesthetics. As such the functionality of occupational footwear may impact balance characteristics over time.

**PURPOSE:** The purpose of the study was to examine balance while wearing different types of occupational footwear for extended durations.

**METHODS:** 14 adult males (age: 22-26yrs, ht:  $181 \pm 5.32\text{cm}$ , wt:  $197 \pm 32.14\text{lbs}$ ) with no vestibular, neurological, or gait related problems were selected for this study. The experimental session included an extended duration of walking (4hours) with balance testing done at 30min intervals (Pre, 30, 60, 90, 120, 150, 180, 210 & 240min). The standing balance protocol was assessed in the eyes open condition with sway velocities in the A/P and M/L directions (APVELO & MLVELO) and RMS Sway in the A/P and M/L directions (APRMS & MLRMS). Participants were randomly assigned 3 different types of occupational footwear: Work Boots (WB), Tactical Boots (TB) and Low Top Boots (LB) with a minimum of 72 hours of rest between conditions.

**RESULTS:** Balance related dependent variables were evaluated using a  $3 \times 9$  (Boot)  $\times$  (Extended duration of walking intervals) RMANOVA for each dependent variable,  $p = 0.1$ . Significant difference over time was seen only in MLRMS ( $p=0.063$ ), with a main effect for boot type seen in APRMS ( $p=0.025$ ).

**CONCLUSIONS:** These results indicate that balance; with reliable sensory inputs from each of the 3 systems (i.e. visual, somatosensory, vestibular) was not influenced over time during the extended duration of walking on a hard flat surface except for MLRMS. Further these results suggest that the fatigue level due to extended duration walking was not enough to alter sway parameters when tested with eyes open on a stable platform and visual environment. Significance found between LB and TB, where LB had a higher APRMS sway, despite having a greater mass, suggests the increased boot shaft height of TB may be the reason for greater stability. Results from this data suggest that the high boot shaft supports the ankle, resulting in decreased fatigue, thus better balance.

---

**1442** Board #223 **MAY 30** **11:00 AM - 12:30 PM**

**Mediolateral Control Of The Center Of Pressure During Quiet Stance Is Altered In Parkinson's Disease**

Ryan T. Roemmich<sup>1</sup>, Joe R. Nocera<sup>2</sup>, Shinichi Amano<sup>1</sup>, Chris J. Hass, FACSM<sup>1</sup>. <sup>1</sup>University of Florida, Gainesville, FL. <sup>2</sup>Department of Veteran Affairs, Gainesville, FL. (Sponsor: Chris J. Hass, FACSM)  
(No relationships reported)

Presentation of unilateral motor symptoms is a hallmark of early Parkinson's disease (PD). While unilateral deficits in appendicular motor function have been studied in PD, influence of unilateral symptoms on postural control has remained relatively ignored.

**PURPOSE:** To examine whether unilateral symptoms affect postural control in persons with PD.

**METHODS:** Twenty persons with PD ( $64 \pm 11$  y) and six healthy older adults (HOA,  $72 \pm 10$  y) stood in a quiet stance on a single force plate with their eyes open for two two-minute trials. Kinematic and kinetic data were collected using a 12-camera Vicon Nexus motion capture system (120 Hz; Vicon Nexus, Oxford, UK) and a Bertec force plate (360 Hz; Bertec Corporation, Columbus, OH). The participants with PD completed the Unified Parkinson's Disease Rating Scale (UPDRS), which was subsequently scored by an independent rater. The participants' more-affected side (MAS) and less-affected side (LAS) were defined based on their subscores on UPDRS items 20-26. Of the 20 participants with PD, 13 performed the static balance trials with their center of pressure (COP) displaced toward their MAS relative to their center of mass (COM) for at least 50% of each trial (PD MAS). The remaining 7 PD participants displaced their COP toward their LAS relative to their COM (PD LAS). For each participant, we calculated the average anterior-posterior (AP) and medial-lateral (ML) velocities of the COP. We also calculated the average root mean square error (RMSE) of the COP position relative to COM position. A one-way ANOVA with Bonferroni post-hoc corrections for pairwise comparisons was performed to compare each variable across the three groups.

**RESULTS:** HOA demonstrated significantly lower ML COP velocity than the PD MAS and PD LAS groups (10.22 vs. 20.18 and 19.27 mm/sec, respectively;  $p = .011$ ,  $p = .014$ ). HOA also demonstrated higher RMSE values when compared to the PD LAS group but not the PD MAS group (33.49 vs. 14.62 and 22.00 mm, respectively;  $p = .016$ ,  $p = .138$ ). There were no significant differences between the PD MAS and PD LAS groups in any of the measures.

**CONCLUSIONS:** When compared to HOA, persons with PD exhibit higher ML COP velocity when the COP is displaced laterally from the COM during quiet stance. However, we did not observe an effect of leaning toward the MAS on postural control in persons with PD.

**1443** Board #224 MAY 30 11:00 AM - 12:30 PM  
**Static And Dynamic Weight Shifting Ability In Children With Adolescence Idiopathic Scoliosis**

Gozde Gur, Songul Aksoy, Fatma Uygur, Yavuz Yakut. *Hacettepe University, Ankara, Turkey.*  
(No relationships reported)

It is well known that postural control and balance is adversely affected in children with idiopathic scoliosis. Adequate weight shifting is an important element of postural control. Most studies have focused on the evaluation of somatosensory organisation and these studies have shown that there is an increase in lateral and sagittal and postural sway during still standing activities. We have not come across a study measuring the ability to shift weight in these children.

**PURPOSE:** To investigate static and dynamic weight shifting abilities of children with adolescence idiopathic scoliosis.

**METHODS:** Twenty six patients (17 girls 9 boys) with adolescence idiopathic scoliosis with a mean age of  $14 \pm 3.4$  years were included in the study. The mean weight mass index of the subjects was  $18.59 \text{ kg/m}^2$ . The demographic characteristics of the subjects and characteristics of the scoliotic curve were recorded. The ability of the patients to bear weight in their right and left lower extremities during weight bearing squat was measured by means of "Neurocom Computerized Dynamic Posturography" at 0, 30, 60, 90 degrees of knee flexion. Also rhythmic weight shifting to the right and left, anterior and posterior directions was used to measure the centre of gravity by means of "Neurocom Computerized Dynamic Posturography". The results were evaluated according to on-axis velocity and directional control.

**RESULTS:** The Cobb angle was found to be a mean of 21 degrees for thoracic curves and 24 degrees for lumbar curves. The most common curves were right thoracic left lumbar. In weight bearing squat test, no difference was found between the right and left extremities in the positions of 0, 30, 60 and 90 degrees knee flexion. During rhythmic weight shifting test, there was 30% decrease in on-axis velocity and 27% decrease in directional control ability.

**CONCLUSION:** While adolescence idiopathic scoliosis did not affect static weight shifting ability, there was a decrease in dynamic weight bearing ability. This result can be interpreted as an adverse effect of scoliosis.

Tibor Hortobagyi, FACSM<sup>1</sup>, Caitlin Pearl<sup>2</sup>, Olivia Ratcliff<sup>2</sup>, Jennifer Streeter<sup>2</sup>, Patrick Rider<sup>2</sup>, Paul DeVita, FACSM<sup>2</sup>. <sup>1</sup>University of Groningen, Groningen, Netherlands. <sup>2</sup>East Carolina University, Greenville, NC.  
(No relationships reported)

One cause for weight gain may be due to the increase in sedentary time leading to reduced energy expenditure, especially in the workplace. A preventative measure could be to perform clerical work in different postures that would increase the amount of active muscle such as sitting on a therapy ball or standing and accumulate excess energy expenditure throughout the day.

**PURPOSE:** We examined the hypotheses that the energy cost while performing clerical work standing or sitting on a therapy ball is higher than when sitting on a chair and this increase in energy cost is associated by an increase in muscle activation.

**METHODS:** Subjects ( $n = 10$ , mean age 21.2) copied printed text into a Word document under three randomized and standardized conditions: sitting on a chair, sitting on a therapy ball, and standing. EMG activation in two upper extremity muscles, four lower extremity muscles, and two trunk muscles, in addition to passive energy expenditure were recorded for 15 minutes during each condition. A basal measurement was taken while lying down for 15 minutes. Quality of typing was calculated by assessing correct word count.

**RESULTS:** Average  $\text{VO}_2$  was  $3.70 \text{ ml/kg/min}$  (SD  $\pm 0.23$ , lying) and lower ( $p < 0.05$ ) than  $4.40 (\pm 0.88, \text{ chair})$  and both lower ( $p < 0.05$ ) than  $4.57 (\pm 1.02, \text{ ball})$  and  $4.60 (\pm 0.58, \text{ standing})$ . Average EMG in 8 muscles was  $0.007 \text{ mV}$  ( $\pm 0.001$ , lying), lower ( $p < 0.05$ ) than  $0.022 \text{ mV}$  ( $\pm 0.006, \text{ chair}$ ), both lower ( $p < 0.05$ ) than  $0.034 \text{ mV}$  ( $\pm 0.009, \text{ ball}$ ) and  $0.030 \text{ mV}$  ( $\pm 0.001, \text{ standing}$ ). Increase in EMG activity explained 52% of variance in increase in oxygen uptake. Average word count per minute was  $48.5 (\pm 9.7, \text{ ball})$ ,  $46.5 (\pm 12.4, \text{ chair})$ , and  $49.6 (\pm 12.5, \text{ standing})$  ( $p > 0.05$ ).

**CONCLUSION:** These preliminary data suggest that there is a parallel and correlated increase in energy expenditure and muscle activation while performing clerical work in non-standard postures.

**1445** Board #226 MAY 30 11:00 AM - 12:30 PM  
**Balance Control During Transition From Double To Single-leg Stance In Subjects With Chronic Ankle Instability**

Jacques Duysens, Adriaan Van Nevel, Colin Malone, Sara Van Deun, Oron Levin, Filip Staes. *KU-Leuven, Heverlee, Belgium.*  
(No relationships reported)

Subjects with CAI (chronic ankle instability) are slower in activating their leg muscles when shifting weight from double to single leg stance (DLS and SLS, Van Deun et al., 2007).

**PURPOSE:** Based on these results, the hypotheses tested were: (1) that in CAI the shift of the COP takes longer, (2) that this delay is associated with longer stabilization times when standing on one leg is achieved, and (3) that the largest delays in EMG onset are correlated with the slowest transfer in weight and/or greater instability in the SLS.

**METHODS:** 20 subjects with CAI and 20 controls were tested. A single force platform was used to monitor the anteroposterior (AP), mediolateral (ML) and vertical components of the foot-ground reaction (FGR) forces before during and after transition (TR) from DLS to SLS, either with the eyes open (EO) or closed (EC). Trajectory of the center of pressure (COP) was calculated to determine TTR (time of TR) and TTS (time to stabilization). TTR is the time from the onset of TR until the second zero crossing of ML COP velocity time series. TTS was estimated with the method of sequential estimation by taking a cumulative average of the ML COP displacement time series (Colby et al, 1999). The quasi-stable (QS) phase started at the end of TR and finished at the point of TTS. Electromyography (EMG) signals were recorded from ankle, knee and hip muscles.

**RESULTS:** The TTS was longer for the CAI than for controls (3.25 vs. 2.28 s in EO and 3.41 vs. 2.51 s in EC;  $P < 0.01$ ). Similarly, the TTR was prolonged in CAI (1.48 vs. 1.14 s in EO and 1.53 vs. 1.20 s in EC;  $P < 0.05$ ). These prolonged periods came in parallel with an increase in the ML sway in the QS period (mean displacement 2.20 vs. 1.75 cm in EO; 3.37 vs. 2.62 cm in EC; significant for EC,  $P < 0.01$ ). The TTR in CAIs was positively correlated with time onset of the Adductor Longus during transitions with EC ( $R = 0.51$ ,  $P = 0.03$ ).

**CONCLUSIONS:** CAIs made slower transitions as indicated by longer TTR. These slower transitions in CAIs were associated with later onset time in the hip muscles and with larger instability in the ML direction in the period just after weight transfer (QS). The latter could indicate that for CAI the transfer was delayed because of anticipated instability. The present data support the use of a weight-shifting paradigm for the discrimination of stable and unstable ankles.

**1446** Board #227 MAY 30 11:00 AM - 12:30 PM  
**Influence Of Visual Conditions And Leg Dominance On Balance Performance On Unstable Surfaces**

Alison B. Regal, Karen Roemer, Erich J. Petushek, Louisa Raisbeck. *Michigan Technological University, Houghton, MI.*  
(No relationships reported)

Maintaining stability on unstable surfaces in a quiet stance depends on the integration of afferent information (Peterka, 2002). It has been well documented how dynamic balance is affected by vision (Day et al., 1993), however the effect of vision impairment on dynamic balance is inconclusive (Houwen et al., 2009). Leg dominance has been reported to have no effect on full vision and no vision conditions (Hoffman et al., 1998). However, the research on impaired vision and balance performance is limited and inconclusive.

**PURPOSE:** To investigate the influence of vision and leg dominance for balance performance on an unstable surface.

**METHODS:** Twenty four females (Mean + SD; Age= 19.2 + 1.2; Wt= 72.1 + 13.45 kg; Ht = 166.0 + 6.3 cm) who were considered healthy with no previous injuries performed a dynamic balance task on a balance pad under three different vision conditions; full vision open, no vision, and impaired vision, on the dominant leg (dl) and non-dominant leg (ndl). Leg dominance was assessed using the recovery balance test. Sway velocity was the dependent variable. A 3x2 Repeated Measures ANOVA was used to compare differences between the vision conditions and dominant leg on dynamic balance.

**RESULTS:** Significance between full vision compared (dl: 9.7± 2.6m/s, ndl: 9.0± 1.6m/s) to no vision (dl: 12.8± 3.1m/s, ndl: 12.5± 2.5m/s) and impaired vision (dl: 10.8± 3.5m/s, ndl: 13.4± 4.5m/s), with  $p < 0.001$  were found. Significant differences between no vision and impaired vision ( $p = 0.925$ ) were not observed. The dominant leg showed significantly reduced sway velocities compared to the non-dominant leg ( $p = 0.012$ ) for impaired vision.

**CONCLUSION:** Leg dominance influenced balance performance for impaired vision. These findings imply that with impaired vision the non-dominant leg may cause instability, which can lead to fall related injuries.

**1447** Board #228 MAY 30 11:00 AM - 12:30 PM

**Is the Activities-Specific Balance Confidence Scale Appropriate for Fall Screenings in Active Older Men?**

Gregory F. Martel<sup>1</sup>, John F. Yannessa<sup>1</sup>, Michael C. Rabel<sup>2</sup>, George W. Lyerly<sup>1</sup>, Dennis W. Klima<sup>2</sup>. <sup>1</sup>Coastal Carolina University, Conway, SC. <sup>2</sup>University of Maryland Eastern Shore, Princess Anne, MD.

(No relationships reported)

Although frequently used for fall risk screenings, the Activities-Specific Balance Confidence Scale (ABC) lacks data regarding the relationships between the ABC and factors affecting balance confidence in active older men. Previous work from our laboratory, which included a population of 59% women, indicated significant relationships between the ABC and fall history, physical activity status, 1-RM leg strength, and isokinetic peak torque (PT).

**PURPOSE:** 1) To compare differences in balance confidence among male fallers (F) and non-fallers (NF) and 2) examine relationships between the ABC and age, PT, body mass index (BMI), and medication use.

**METHODS:** Seventy-one physically active, community dwelling men were recruited (67±7 yr, 84±15 kg, 27.1±4.1 BMI) to complete the ABC, a health history, and testing for concentric PT for knee extensors and knee flexors. Data were then dichotomized based on fall history.

**RESULTS:** When comparing F (n=14, 69±6 yr, 27.8±3.3 BMI) to NF (n=57, 67±7 yr, 27.0±4.3 BMI), independent t-tests revealed significantly higher ABC scores for NF (94±7 vs. 87±12;  $p < 0.01$ ), but no group differences for age, BMI, or PT. A Spearman nonparametric test revealed that ABC significantly correlated with fall history ( $\rho = -0.264$ ;  $p < 0.05$ ) and left knee extension PT ( $\rho = -0.434$ ;  $p < 0.05$ ), but did not significantly correlate with age, BMI, or medication use.

**CONCLUSIONS:** ABC scores correlated with fall history and left knee extension PT, and were significantly lower among active older men who had recently fallen. However, typical balance confidence correlates (age, BMI, and polypharmacy) were not observed. Clinicians should be cautious when interpreting male balance confidence profiles in gender-mixed studies.

**1448** Board #229 MAY 30 11:00 AM - 12:30 PM

**Changes in Plantar Loading During the Lower Quarter Y Balance Test**

Mary E. Russell<sup>1</sup>, Boyi Dai<sup>2</sup>, Robert J. Butler<sup>1</sup>, Robin M. Queen<sup>1</sup>. <sup>1</sup>Duke University, Durham, NC. <sup>2</sup>University of North Carolina, Chapel Hill, NC. (Sponsor: Donald T. Kirkendall, FACSM)

(No relationships reported)

Dynamic balance has previously been established as a risk factor for lower extremity injury during sport. One way to measure dynamic balance is by using the Lower Quarter Y-Balance Test (YBT-LQ), however, there is currently no research on how loading of the foot is altered for the three different reach directions that are part of this test.

**PURPOSE:** To determine if total foot, rear foot (RF), medial midfoot (MMF), lateral midfoot (LMF), medial forefoot (MFF), middle forefoot (MidFF), lateral forefoot (LFF), hallux, and the lesser toes (LT) loading (defined by maximum force (MF)) were significantly different when performing the different reach directions of the YBT-LQ. The effect of gender on this outcome was also examined.

**METHODS:** Plantar loading in 40 (20 men, 20 women) healthy, recreational athletes were evaluated using the Pedar-X in-shoe system collecting at 100Hz. Exclusion included any history of lower extremity injuries in the past 6 months. Subjects completed 3 trials bilaterally for each of the 3 reach directions of the YBT-LQ. Subjects were asked to reach as far as possible in the anterior (A), posteromedial (PM), and posteriolateral (PL) directions. 6 practice trials on each leg in each of the 3 reach directions were executed prior to formal testing. Repeated measures ANOVAs (gender by reach directions) examining the MF were used to determine statistical differences ( $\alpha = 0.05$ ). All MF measures were normalized to body weight.

**RESULTS:** The total foot MF in the A ( $1.16 \pm 0.10$ BW) direction was smaller than the PL ( $1.19 \pm 0.09$ BW) and PM ( $1.19 \pm 0.11$ BW) directions in males only ( $P < 0.001$ ). The LMF MF was highest in the PL direction, whereas MF in the MFF, MidFF, LFF, hallux and LT were all significantly higher in the A direction ( $P < 0.001$ ). MF in the RF, MidFF, and total foot were significantly higher in females than males overall ( $P < 0.001$ ).

**CONCLUSIONS:** Overall, the anterior direction had the highest load in the forefoot, hallux and LT while the PL direction was associated with higher loads beneath the lateral midfoot. During testing women exhibited increased loads in the RF and MMF, and LMF for all reach directions. These results may indicate that the three reach directions of the YBT-LQ load the foot differently and thus may have an application for various types of lower extremity injuries that have specific foot loading patterns.

**1449** Board #230 MAY 30 11:00 AM - 12:30 PM

**Effects of Ankle Instability on Ground Reaction Forces during a Landing with Sidestep**

Matt Denning, Mark Coglianese, Matthew K. Seeley, J. Ty Hopkins, FACSM. Brigham Young University, Provo, UT.

(No relationships reported)

Ankle instability is associated with mechanical and functional deficits. Appropriate foot position during functional, stressful movement is important to avoid dangerous loads on the ankle. Whole-body center of mass motion, which is reflected by the ground reaction force, influences how loads are applied to the foot during movement.

**PURPOSE:** Compare certain ground reaction force characteristics between individuals who have functional ankle instability (ankle group) and those who do not (control group) during a functional, stressful movement.

**METHODS:** 20 functionally unstable subjects were matched with 20 control subjects (gender, height, and weight). Subjects jumped forward (1m) and upward ( $\pm 5\%$  of their averaged maximal height), landed on one leg on a force platform, and then quickly jumped laterally. Two-sample t-tests ( $\alpha = 0.05$ ) were used to evaluate the effect of ankle instability on peak vertical ground reaction force and loading rate, peak medial ground reaction force and loading rate, and average center of pressure distance from the midline of the foot while the subject contacted the plate.

**RESULTS:** No significant between-group differences were detected ( $p < 0.05$ ). Peak vertical ground reaction force and loading rates for the ankle and control group were  $2.86 \pm 0.44$  BW,  $6.83 \pm 1.53$  BW/s,  $2.91 \pm 0.45$  BW, and  $7.2 \pm 1.99$  BW/s, respectively. Peak medial ground reaction force and loading rates for the ankle and control group were  $0.44 \pm 0.29$  BW,  $1.06 \pm 0.75$  BW/s,  $0.31 \pm 0.32$  BW, and  $0.78 \pm 0.84$  BW/s, respectively. Center of pressure distances from the midline of the foot for the ankle and control groups were  $0.007 \pm 0.009$  m and  $0.007 \pm 0.004$  m, respectively.

**CONCLUSIONS:** No observed ground reaction force characteristic was different between groups, suggesting that certain characteristics of whole-body center of mass motion are not affected by ankle instability during this dynamic task. This lack of significance may be due to variability of the landing strategies used by the ankle group, or the nature of the jumping and landing task.

**Is Four Weeks Enough To Improve Balance And Mobility Function Of Older Adults Who Are Already Physically Active?**

Kali J. Tupper, Brandi S. Row. *Western Washington University, Bellingham, WA.*  
(No relationships reported)

**PURPOSE:** To determine the effectiveness of a brief balance-training (BT) program to improve the balance of physically active older adults.

**METHODS:** A 4-week BT program was conducted with physically active older men and women (Exercise [EX] group, n = 10, mean age [standard deviation, SD]: 77.2 [8.9] yr; waitlist control (EX2) group, n = 9, mean age [SD]: 75.8 [6.0] yr). The BT program focused on the multisensory, motor, and cognitive contributors to dynamic postural control & gait. During the EX2 group's waitlisted participation phase, fewer seated balance ball multisensory exercises were included, replaced instead by more weight-bearing balance, stepping, & gait exercises.

Outcome measures included a modified Fullerton Advanced Balance Scale (modFAB), including three items from the Community Balance & Mobility Scale. Additionally, gait speed & Gait Stability Ratio (GSR) of cadence to velocity, Trail Making Test, the Activities-Specific Balance Confidence Scale, & Stair Climb power. Acceleration measurements were made & are reported in a separate presentation.

For the initial 4-week intervention phase, repeated measures ANOVA (with factors Time [pre, post], Group [EX, EX2]) were conducted for measures that were suitable for parametric tests, otherwise, the Wilcoxon rank-sum (between groups) or Wilcoxon matched pairs (within group) tests were used. For the EX2 group's waitlisted intervention analysis, a one-way ANOVA (with factor Time [pre, post, EX2-post]) was used for variables suitable for parametric tests; otherwise, the Friedman's test was conducted.

**RESULTS:** Following BT, GSR decreased significantly during maximum gait speed trial for the EX group (EX: pre = 1.41 [SD 0.32], post = 1.32 [0.27]; EX2: pre = 1.18 [0.15], post = 1.21 [0.12]; p = 0.01). The EX2 group did not improve on GSR at EX2-post, but secondary analysis on each item of the modFAB revealed evidence of improvement in reactive postural control in this group at EX2-post. No differences on the other measures resulted.

**CONCLUSIONS:** Overall scores on the modFAB did not improve, but even in this small sample & brief intervention, there were some indications of a benefit of four weeks of BT regarding dynamic walking pattern (GSR) & reactive postural control. Evidence of improved frontal plane control is presented in an accompanying abstract from our lab.

---

1451 Board #232 MAY 30 11:00 AM - 12:30 PM

**Effects Of Hyperthermia, Hypohydration And Fatigue On Balance**

Lindsay J. DiStefano, Megan VanSumeren, Rachel Karslo, Julie K. DeMartini, Rebecca L. Stearns, Robert Huggins, Lawrence Armstrong, FACSM, Carl Maresh, FACSM, Douglas J. Casa, FACSM. *University of Connecticut, Storrs, CT.*  
(No relationships reported)

Poor balance increases lower extremity injury risk. Fatigue, dehydration, and hyperthermia may impair balance, which could increase an individual's injury risk.

**PURPOSE:** To evaluate the effects of hyperthermia, dehydration, and fatigue on balance ability.

**METHODS:** Twelve trained healthy male subjects (age=20±2 yrs, height=182±8 cm, body mass=74.0±8.2 kg, body fat=9±3%, VO<sub>2</sub>max = 57.0 ± 6.0 mL·kg<sup>-1</sup>·min<sup>-1</sup>) completed four randomized test sessions in a climate controlled chamber. Sessions varied based on environmental conditions and hydration status (Euhydrated Temperate (EUT), Euhydrated Hot (EUH), Hypohydrated Temperate (HYT), Hypohydrated Hot (HYH). Temperate and hot conditions were performed in 18±0.2°C, 50±3.5% relative humidity (RH), and 34 ±0.3°C, 45±4.5% RH, respectively. Dynamic balance during a 10-second unilateral landing task was assessed three times per session: before exercise (PRE), after exercise (POST), and after recovery (REC). The 90-minute treadmill exercise protocol required subjects to walk carrying a 20.5 kg backpack (1.34-1.78 m-s<sup>-1</sup>; 5% grade). Subjects sat quietly in the test environment during a 60-minute recovery period. Mean sway velocity and elliptical sway area were calculated from force plate data (4060-NC Bertec Corporation). A repeated measures analysis of variance with a Tukey HSD post hoc test evaluated differences between time and condition for all dependent variables.

**RESULTS:** Body mass loss differed across sessions (HYT:-3.80 ± 1.22%, HYH:-5.66 ± 1.57%, EUT:0.10 ± 0.90%, EUH:-1.30 ± 0.85%). Regardless of time, HYH resulted in the highest values for sway velocity (p=.024, 6.62±0.28 vs. 6.06±0.16 (HYT), 6.16±0.25 (EUH), 6.19±0.26 (EUT) m/s) and sway area (p=.048, 3.40±0.35 vs. 2.71±0.19 (HYT), 2.65±0.21 (EUH), 2.72±0.24 (EUT) cm<sup>2</sup>). POST sway velocity (PRE: 5.89±0.21, POST: 6.53±0.27, REC: 6.35±0.21) was higher than PRE and REC, regardless of condition (p=.003).

**CONCLUSION:** Regardless of hydration status and environmental conditions, fatigue appears to decrease balance ability. Dehydration in a hot environment also impairs balance ability. These findings suggest that hydration during physical activity in the heat may be critical to alleviate an increased risk of injury.

---

1452 Board #233 MAY 30 11:00 AM - 12:30 PM

**The Relationship Between Dynamic Balance and Isokinetic Ankle Strength in College Female Athletes**

Danika Evans, Barbara Warren, FACSM. *University of Puget Sound, Tacoma, WA.*  
(No relationships reported)

Conflicting results have been found between dynamic balance and isokinetic ankle strength as measured by peak torque.

**PURPOSE:** To investigate the relationship between ankle joint peak torque and dynamic balance. **METHOD:** Fifteen healthy female Division III varsity athletes (mean (SD) age = 20.53 yrs (.743), height = 170.02 cm (4.962), weight = 67.27 kg (9.183)) were tested on a Cybex NORM isokinetic dynamometer performing maximal ankle plantar and dorsiflexion for both right and left ankles. Dynamic balance was assessed using the Star Excursion Balance Test (SEBT). Isokinetic strength was assessed through 8 reciprocal maximal contractions of plantar and dorsiflexion at 60, 120, and 180°/s with a 60 second rest between each velocity set. Pearson's correlations were used to assess the relationship between the dynamic balance score and peak torque at each velocity for each muscle group (alpha < 0.05).

**RESULTS:** Moderate correlations were found between right ankle dorsiflexor peak torque and dynamic balance (60°/s: r = .476, 120°/s: r = .608, and 180°/s: r = .667), left dorsiflexor peak torque and dynamic balance at all velocities (60°/s: r = .499, 120°/s: r = .488, 180°/s: r = .445), and between right and left ankle plantarflexor peak torque and dynamic balance (60°/s: r = .520, 60°/s: r = .454). Weak correlations were found between right ankle plantarflexor peak torque and dynamic balance at 120°/s and 180°/s (120°/s: r = .362, 180°/s: r = .274) and left plantarflexor peak torque and dynamic balance at 120°/s and 180°/s (120°/s: r = .237, 180°/s: r = -.037).

**CONCLUSION:** In this population of female athletes, these results suggest that dynamic balance may be related more to dorsiflexion strength than plantarflexion strength.

---

1453 Board #234 MAY 30 11:00 AM - 12:30 PM

**Heart Rate and Postural Stability Recovery are Similar after Aerobic and Anaerobic Exercise**

Katelyn Fleishman Allison, Jonathan S. Akins, Timothy C. Sell, John P. Abt, Mita T. Lovalekar, Kim Crawford, Scott M. Lephart. *University of Pittsburgh, Pittsburgh, PA.*  
(No relationships reported)

Postural stability (PS) assessment is an important component of sideline concussion testing and fatigue may influence PS independent of neurological insult. While studies found that PS is disrupted after both anaerobic (ANA) and aerobic (AER) exercise, the relationship between heart rate (HR) and PS recovery following exercise has not been determined.

**PURPOSE:** To compare PS and HR following maximal ANA and AER exercise using a cross-over study design.

**METHODS:** Physically active subjects (M=8, F=5, 23.5±3.5 yrs, 173.7±9.5 cm, 72.7±15.0 kg) participated in two test sessions, where PS and HR were assessed utilizing a single-leg balance task prior to and following ANA or AER exercise every 2-min for 20 min. Dominant-leg balance was measured with eyes open while standing on a foam pad on top of a force plate. A Wingate cycle power test induced ANA fatigue and a graded treadmill exercise test induced AER fatigue. Separate one-way repeated measures ANOVA with simple contrast compared standard deviations of ground reaction forces in the anterior-posterior (AP), medial-lateral (ML) and vertical (V) directions during post-fatigue time intervals to baseline in order to determine PS recovery for each condition (α=0.05). Paired t-tests compared % of max HR achieved during ANA and AER (%HRmax) between conditions at each post-fatigue time interval; adjustment for multiple comparisons set α=0.0045.

**RESULTS:** AP was greater than baseline up to 8-min post-fatigue for ANA (7.2±2.9 vs 5.5±2.0 N) and AER (6.8±2.3 vs 5.5±2.1 N); ML and V were greater than baseline at 0-min post-fatigue for ANA (ML: 6.1±2.9 vs 4.0±1.4 N, V: 23.3±22.2 vs 11.0±5.2 N) and AER (ML: 6.8±3.1 vs 3.7±1.2 N, V: 24.3±17.5 vs 12.1±3.4 N) ( $p<0.05$ ). While max HR achieved during AER was significantly greater than ANA (193.4±10.6 vs 174.8±17.6 bpm,  $p<0.001$ ), no significant differences in %HRmax were found between ANA and AER at any post-fatigue time interval ( $p>0.0045$ ).

**CONCLUSION:** PS and HR recovered similarly following ANA and AER fatigue. Since PS recovered by 10-min post-fatigue with %HRmax at ~52.7%, future research should investigate the potential of using %HRmax to determine when fatigue may be ruled out as a confounding factor during sideline concussion PS assessment following intense sporting activities.

**1454** Board #235 MAY 30 11:00 AM - 12:30 PM  
**The Effects of Core Strength Training on Static and Dynamic Balance in Female Collegiate Athletes**

Kathryn E. Kramer, Sheila K. Kelly, Tina M. Manos, Justus D. Ortega. *Humboldt State University, Arcata, CA.*

(No relationships reported)

The core muscles of the body are essential components to most kinetic chains in sport activities; therefore, control of core strength should improve controlled motion during dynamic and static balance tasks. Although it is well established that core strength training (CST) improves balance in untrained adults, it is unknown whether CST improves balance in trained athletes.

**PURPOSE:** To determine if a 6-week core strength-training program improves dynamic and static balance in Division II female athletes with prior core strength training experience.

**METHODS:** The Experimental (EXP) and Control (CON) groups were comprised of 33 Division II female athletes (19 softball, 2 basketball, 7 crew, and 5 cross-country); age 19±3.5 yrs, mass 72.3±12.3 kg, height 167.6±7.0 cm. Both EXP and CON groups performed baseline core strength tests [60-second max sit up, max time held in side plank (sec), and max number of medicine-ball twists] and balance tests [Functional Reach (FR), Single-Limb Dynamic Balance (SLDB), Single-Limb Eyes Closed (SLEC), and Single-Limb Eyes Open (SLEO) performed on a force platform and Star Excursion Balance Test (SEBT)]. For the core strength tests, T-scores were calculated for each test and then summed, resulting in a composite core strength score for each athlete (CS-T). For the four tests on the force platform, average CoP velocity (AveVel in cm/s) and 95% of the total area ellipse (95%TAE in cm<sup>2</sup>) were calculated in addition to the maximum reach (cm) of the FR test and the combined maximum reach (sum of three directions) for the SEBT (cm). The EXP group completed a training program consisting of ten core strength exercises performed three times per week for 6 weeks. After the training, the EXP and CON groups performed the core strength and balance testing.

**RESULTS:** Prior to the core strength training there was no difference in strength or balance between the EXP and CON groups. After 6 weeks of core strength training, the EXP group improved in core strength (CS-T: 594.60% increase,  $p=0.0001$ ) and dynamic balance (SLDB: 95%TAE decreased 30.82%,  $p=0.049$  and AveVel decreased 9.76%,  $p=0.005$ ; SEBT: combined maximum reach increased 6.94%,  $p=0.0001$ ). Maximum functional reach (sum of three directions) for the SEBT did not change. Although the CON showed a modest improvement in core strength measures (10.76%,  $p=0.001$ ), there was no improvement in balance except for a 10% decrease in the average CoP velocity during the SLDB test ( $p=0.027$ ).

**CONCLUSION:** Six weeks of supplemental core strength training improves core strength and dynamic balance but does not significantly affect static balance or functional reach in Division II, collegiate female athletes.

---

**1455** Board #236 MAY 30 11:00 AM - 12:30 PM  
**Effect of a Lower Extremity Fatigue Protocol on the Balance Error Scoring System**

Rose L. Smith, Jessica Murphy, Kirk Rhein, Melissa Smith, Emanuel Werner, Daniel L. Carl. *University of Cincinnati, Cincinnati, OH.*

(No relationships reported)

Concussion is one of the most common sports-related head injuries accounting for approximately 300,000 diagnosed cases yearly and with as many as 15% of those resulting in persistent long term symptoms. Current concussion assessment and return-to-play decisions rely on the athlete's willingness to share self-reported symptoms. Missed diagnosis due to relying on subjective symptoms from athletes could lead to future complications, such as second impact syndrome. The Balance Error Scoring System (BESS) was developed in order to provide a cost-effective sideline assessment tool for evaluating deficits in postural stability following a concussion. To date the role of the athlete's level of fatigue and how it may interact with BESS scoring is unclear.

**PURPOSE:** To determine if lower extremity (LE) exercise induced fatigue will result in elevated BESS scores.

**METHODS:** 28 subjects (20M, 8F; 18-25 yo) participated in the study. Each subject completed an informed consent and was familiarized with the error measurements of the BESS protocol. Subjects were tested (Pre), LE fatigued, tested immediate post (Post I) and tested 20min post exercise (Post II). The LE fatigue protocol consisted of in order a 1.5 mile run/walk, a Queen's College step test, and 4 sets of squats based on the DAPRE technique. The BESS protocol consisted of a 20s trial for single leg stance, double leg stance and tandem leg stance. In addition each stance was conducted on a firm surface and a medium density (60 kg.m<sup>3</sup>) foam block. The BESS performance score was a compilation of the total errors committed. A paired t-test was conducted to determine differences in Pre, Post I and Post II BESS scores.

**RESULTS:** BESS scores were significantly elevated immediate post fatiguing exercise (Pre 38.4 + 10.2 vs. Post I 54.3 + 12;  $p<0.01$ ) and returned to statistical baseline by 20 min. post exercise (Pre 38.4 + 10.2 vs. Post II 38.1 + 7.0). No statistical differences were identified between M & F or with regard to subject's level of conditioning.

**CONCLUSIONS:** Fatigue adversely affected BESS scoring immediately post exercise. Although a return to statistical baseline was observed at 20 min post exercise, as many as 21% of the participants had not fully recovered. Additional studies are warranted to further elucidate the role of BESS in return-to-play decision making.

---

**1456** Board #237 MAY 30 11:00 AM - 12:30 PM  
**Integrative Training Of Strength And Sensorimotor Control Enhances Vestibular And Proprioceptive Activation During Postural Challenges**

Henrike Fischer, Hans Martin Sommer, Olaf Hoos, Ralph Beneke, FACSM. *Philipps University of Marburg, Marburg, Germany.*

(No relationships reported)

Postural control depends on visual (VI), vestibular (VE) and proprioceptive (PR) feedback. Corresponding treatment effects usually do not discriminate between underlying sensory mechanisms.

**PURPOSE:** To discriminate between different adaptations of somatosensory control of a combined strength and sensorimotor intervention (EG) and a classical back school training (CG) in physically active subjects.

**METHODS:** EG (n=17, 25.9 yrs, 61.8kg, 1.70m) joined a specifically designed integrative strength and coordination program to promote joint extensions in supine and upright position (1h weekly for three months). CG (n=13, 26.5 yrs, 63.9kg, 1.75m) performed an identical volume of trunk muscle strength training and balance exercises on stable and unstable surfaces. Postural sway was assessed in barefooted single-leg stance with eyes open on a force platform (1 kHz). Center of pressure sway area (COPA) and spectral powers of Fast Fourier transformation distinguishing between VI (0.1-0.3 Hz), VE (0.3-1 Hz) and PR (1-3Hz) frequency bands were computed for anterior-posterior (AP) and medio-lateral (ML) directions.

**RESULTS:** COPA were unchanged in EG (pre: 1.02±0.37cm<sup>2</sup>, post 0.89±0.24cm<sup>2</sup>; ns) and in CG (pre 1.17±0.48cm<sup>2</sup>, post 1.32±0.86cm<sup>2</sup>; ns). In CG the distribution of spectral powers remained constant in ML (VI: pre 86.4±12.4%, post 88.9±15.6%; ns; VE: pre 10.0±8.8%, post 8.5±11.7%; ns; PR: pre 3.6±3.7%, post 2.6±3.9%; ns) and AP (VI: pre 95.4±1.2%, post 95.3±0.9%; ns; VE: pre 3.5±0.9%, post 3.6±0.7%; ns; PR: pre 1.1±0.3%, post 1.1±0.3%; ns). In EG the COP-powers shifted in terms of a reduction in VI (ML: pre 86.6±8.9%, post 77.8±13.7%;  $p<0.05$ ; AP: pre 96.0±0.6%, post 93.8±1.8%;  $p<0.001$ ) and an increase in VE (ML: pre 10.4±7.4%, post 16.6±10.6%,  $p<0.01$ ; AP: pre 3.1±0.5%, post 4.8±1.4%;  $p<0.001$ ) and AP component of PR (ML: pre 3.0±2.0%, post 5.6±4.5%; ns; AP: pre 0.9±0.2%, post 1.4±0.4%,  $p<0.001$ ).

**CONCLUSIONS:** Both interventions had no effect on COPA. However, the integrative strength and coordination program to promote joint extensions in supine and upright position reduced dependency of the VI system in favour of increased VE and PR control during postural challenges.

**1457 Board #238 MAY 30 11:00 AM - 12:30 PM**  
**Association of Dynamic Postural Stability Index Scores and Clinical Impairments: A Preliminary Analysis**

Timothy J. Gilleran, Anthony Luke, FACSM, Richard B. Souza. *UCSF, San Francisco, CA.*  
*(No relationships reported)*

Recurrent lateral ankle sprains (RLAS) are common injuries which may lead to impairments in postural control. A measure of *dynamic* postural stability was recently developed by Wikstrom. The relationships between the Dynamic Postural Stability Index (DPSI) and physical/functional impairments are currently unknown.

**PURPOSE:** To examine the relationships between the DPSI and selected clinical measurements.

**METHODS:** DPSI and clinical tests (questionnaires, ankle ROM and joint stability/mobility, hip and ankle strength, Y Balance and Lateral Hop tests) were performed on 15 subjects (3 male, 14 female, age: 28 ± 4.5) with RLAS. Forward, diagonal and lateral jumps were examined using GRF data acquired by a force platform (1000 Hz). Three successful trials averaged for DPSI calculations (described by Wikstrom) and clinical measures were entered into a correlation matrix (p<0.05).

**RESULTS:** Moderate correlations were observed between all DPSI scores and the FADI Sports questionnaire and ankle dorsiflexion ROM scores (Table 1); whereas, ankle mobility/stability and inversion ROM, ankle and hip strength, Lateral Hop tests and DPSI scores were non-significant and weakly correlated.

**CONCLUSION:** These data suggest DPSI scores are related to self-reported activity limitations and physical/functional impairments. The moderate association between FDPSI and Y Balance scores may provide insight into dynamic postural stability in clinical situations where force plate data is not available. Supported by **NIH/NCRR/OD UCSF-CTSI Grant Number TL1 RR024129.**

**Impaired Standing Balance Performance After Maximal And Submaximal Endurance Exercise In Healthy Seniors**

Oliver Faude, Lars Donath, Mareike Cordes, Livia Fricker, Ralf Roth, Henner Hanssen, Arno Schmidt-Trucksäss, Lukas Zahner. *University of Basel, Institute of Exercise and Health Sciences, Basel, Switzerland.*  
*(No relationships reported)*

Impaired standing balance performance (SBP) is a relevant intrinsic fall risk factor in seniors. Acute effects of endurance exercise (maximal and submaximal) on SBP have not yet been studied in elderly.

**PURPOSE:** To evaluate the acute effects of an exhaustive maximal exercise test and 2 km walking at moderate intensity on single and double limb SBP.

**METHODS:** 19 healthy seniors (10 women, 9 men, age = 64.6 (SD 3.2) yrs, height = 1.70 (0.10) m, weight = 69.6 (11.2) kg) completed 3 experimental conditions on separate days one week apart. After a maximal ramp-like treadmill test (duration = 23.1 (3.1) min, maximal oxygen uptake (VO2max) = 32.3 (4.8) mL/min/kg, maximal heart rate = 165 (9) /min) participants randomly completed a 2 km walking test on a treadmill at moderate intensity (27.5 (3.6) min at CR-10 Borg level 4 corresponding to 76 (8)% VO2max) and a resting control condition. During exercise tests heart rate and gas exchange data were continuously recorded. Ratings of perceived exertion (CR-10 scale) were assessed every minute (ramp test) as well as every 5 minutes (2 km walking test). Directly before and after maximal and submaximal exercise and the control condition, SBP was assessed by double leg stance with closed eyes (DLEC) and single leg stance with open eyes (SLEO) on a force platform. Total path length of center of pressure (COP) displacement was determined over 30 s (DLEC) and 10 s (SLEO).

**RESULTS:** A significant condition x time interaction in COP path length data for both standing balance tests was observed (p < 0.001). Whereas COP path length during DLEC slightly decreased from pre to post test on the control day (-8%, effect size (d) = 0.21, p = 0.60), a small (+18%, d = 0.42, p = 0.05) and large (+52%, d = 1.04, p < 0.001) increase was observed after the 2 km and the ramp test, respectively. Similarly, COP path length during SLEO was reduced on the control day (-22%, d = 0.47, p = 0.04), whereas it was slightly increased (+15%, d = 0.29, p = 0.65) after the 2 km test. A large significant increase was observed after the maximal exercise test (+88%, d = 1.24, p < 0.001).

**CONCLUSIONS:** SBP was considerably deteriorated after maximal exhaustive treadmill exercise in healthy seniors. The small changes after walking 2 km at moderate intensity (typical endurance tasks of everyday life or health-oriented cardiovascular training) were of minor relevance.

**1459 Board #240 MAY 30 11:00 AM - 12:30 PM**  
**Progression Of Ankle Muscle Activation Performing Exercises With Different Types Of Body Stability**

Victor Tella, Julio Martin, Sebastian Borreani, Juan Carlos Colado, Fernando Martin, Joao Alves. *University of Valencia, Valencia, Spain.*  
*(No relationships reported)*

Ankle injury is one of the most prevalent in athletics. Rehabilitation protocol must include proprioception to improve the ankle stability and thus to the return to the functional status. Proprioception and balance training equipments are used despite the insufficient knowledge about a proper progression with these devices.

**PURPOSE:** To compare ankle muscular activity performing 4 exercises performed in stable and unstable conditions using Thera-Band® devices.

**METHODS:** 18 physically fit and healthy male subjects took part in a randomized, within-subject design assessment. The maximum isometric voluntary contraction (MIVC) was evaluated for the normalization. Peroneus longus (PL), tibialis anterior (TA) and soleus (S) muscular activities were recorded, and then the average root mean square values of all of them were calculated. Surface electromyography activity was analyzed during the central 16 seconds of 20 of 4 isometric unipodal postures: Sitting on swissball and foot over the floor (SF), standing up on the floor (UF), standing up on a Rocker Board (UR) and standing up on a Stability Soft (US). All values, expressed as the mean of the 5 muscles %MIVC, were compared using a mixed-model MANOVA with a post-hoc analysis of Bonferroni. Significance level was set at p≤0.05.

**RESULTS:**

|    | Peroneus Longus | Tibialis Anterior | Soleus        | Total Mean    |
|----|-----------------|-------------------|---------------|---------------|
| SF | 36.22 (5.04)    | 4.30 (0.54)       | 15.71 (1.91)  | 18.74 (2.24)  |
| UF | 45.05 (6.56)*   | 11.79 (2.10)*     | 27.83 (3.04)* | 28.22 (2.97)* |
| UR | 46.39 (6.80)*   | 18.49 (3.38)†     | 28.62 (3.26)* | 31.16 (3.24)† |
| US | 49.12 (6.11)*   | 19.38 (3.12)†     | 30.35 (2.75)† | 32.95 (2.68)† |

Data is expressed as a mean (SEM) in percentage of the MIVC.  
\* indicates significant differences ( $p \leq 0.05$ ) related to SF  
† indicates significant differences ( $p \leq 0.05$ ) related to SF and UF  
SF= sitting on swissball and foot on the floor, UF= standing up on the floor, UR= standing up on a Rocker Board, US= standing up on a Stability Soft.

**CONCLUSION:** Unipodal exercise performed sitting on the swissball generates the lower ankle muscles activation. Rocker Board and Soft Stability are unstable surfaces which increase significantly ankle muscle activity in comparison with stable surface. US provokes greater but not significant activation of all ankle muscles in comparison with the UR probably due to the direction of the unbalance which is multidirectional and unidirectional respectively.

**1460 Board #241 MAY 30 11:00 AM - 12:30 PM**  
**Changes In Functional Balance Among Firefighters Following Live Fire Training**

Deanna Colburn, Serina J. McEntire, Joe Suyama, Steven E. Reis, Riana R. Pryor, Priya Khorana, Jennifer Erin, Francis X. Guyette, David Hostler. *University of Pittsburgh, Pittsburgh, PA.* (Sponsor: Fredric Goss, FACSM)  
(No relationships reported)

Slips, trips, and falls are a common cause of injury and disability among firefighters. Little is known about the relative contribution of protective clothing, physical fitness, and body composition on functional balance following fire suppression.

**PURPOSE:** Determine if the time to complete a test of functional balance or the number of errors committed during the test changes after fire suppression and if these variables are related to maximal oxygen consumption or body composition.

**METHODS:** 31 firefighters (90% male) had maximal oxygen consumption and body fat ( $18.4 \pm 5.3\%$  male,  $17.5 \pm 4.4\%$  female) measured prior to participating in a 20-minute live fire exercise at a county fire academy. Subjects completed a test of functional balance at a baseline assessment in shorts and athletic shoes and immediately before and after fire suppression while wearing thermal protective clothing and breathing apparatus. Subjects completed three trials of the task at each assessment. Time to complete the task and the number of errors committed were recorded. Repeated measures ANOVA was performed to identify changes in time and errors. Correlations were calculated between VO<sub>2</sub>max and body fat against the change in time to complete the task and change in errors committed.

**RESULTS:** Body core temperature following fire suppression was  $38.5 \pm 0.5^\circ\text{C}$  and heart rate after exiting the fire was  $152 \pm 28$  bpm. Time to complete the task did not differ between baseline in normal clothing ( $12.3 \pm 4.4$  sec), compared to pre- ( $12.1 \pm 4.0$ ), and post- ( $12.2 \pm 3.9$ ) fire in protective clothing ( $p = 0.84$ ). There was a trend ( $p = 0.056$ ) towards more errors committed after fire suppression (1.4) when compared to baseline (0.9). A correlation was identified ( $r = -0.41$ ,  $p = 0.04$ ) between VO<sub>2</sub>max and time to complete the task with high VO<sub>2</sub>max associated with faster completion times. No significant correlations were identified between VO<sub>2</sub>max and errors or between body fat (%) and either time to complete or errors committed.

**CONCLUSIONS:** Time to complete a test of functional balance and the number of errors committed during the task did not differ either between normal clothing and protective clothing conditions or after a single 20-minute bout of fire suppression. Maximal oxygen consumption, but not percent body fat, was correlated with time to complete the task.

**1461 Board #242 MAY 30 11:00 AM - 12:30 PM**  
**The Role of Foot Type in Dynamic Balance Performance**

Anat Lubetzky-Vilnai, Patricia Ann Kramer. *University of Washington, Seattle, WA.*  
(No relationships reported)

The Star Excursion Balance Test (SEBT) is a simple clinical test designed to measure dynamic balance. Determining which parameters are associated with SEBT performance can help therapists understand potential underlying impairments that lead to decreased or enhanced dynamic balance performance. Specifically, the association between SEBT performance and foot type is yet to be determined. The Arch Index (defined as the ratio between midfoot and total foot area) is a simple and reliable measure used to quantify foot type.

**PURPOSE:** Our primary purpose was to investigate the association between foot morphology and Star Excursion Balance Test (SEBT) performance in recreational runners. The secondary purposes were to explore the association between the severity of past injuries and SEBT performance and to test the hypothesis that increased severity of past injuries will be correlated with flatter feet among recreational runners.

**METHODS:** 20 healthy recreational runners (15 women, 5 men, aged 23 -58 years) participated in this cross-sectional study. We interviewed the participants about their running habits and history of injuries. A pressure sensitive mat and associated software (Footscan USB plate, RSScan International, Olen, Belgium) was used to obtain the static footprints of all participants. Arch indexes were calculated from the footprints. Participants performed the SEBT.

**RESULTS:** Participants with lower medial longitudinal foot arch reached significantly farther on all SEBT directions except for anterolateral. The Spearman correlation coefficient between arch index and the SEBT composite score was 0.55 and the  $R^2$  was 0.31 ( $p = 0.02$ ) indicating that arch index explained 31% of the variance in SEBT performance. Severity of injuries in the past was not associated with SEBT performance ( $p > 0.1$ ) and was significantly associated with arch index ( $R_s = 0.54$ ,  $p = 0.02$ ).

**CONCLUSION:** When using the SEBT to measure dynamic balance, researchers and clinicians need to be aware of potential differences in performance with different foot types. In the clinic, asymmetry in arch index may affect symmetry in SEBT performance. In the research setting, arch index may need to be adjusted for when comparing SEBT performance between groups.

**1462 Board #243 MAY 30 11:00 AM - 12:30 PM**  
**Reliability Investigation of A Novel Custom-made Body Posture and Spinal Curve Measurement System**

Shih-Ting Wang<sup>1</sup>, Yu-Chi Hsu<sup>1</sup>, Yi-Hsuan Yeh<sup>1</sup>, Yu-Lin Yu<sup>1</sup>, Chich-Haung Yang<sup>2</sup>, Lan-Yuen Guo<sup>1</sup>. <sup>1</sup>*Kaohsiung Medical University, Kaohsiung, Taiwan.* <sup>2</sup>*TzuChi University, Hualien, Taiwan.*  
(No relationships reported)

Poor posture may not only induce musculoskeletal pain, but also related to dysfunction in cardiopulmonary system. Measuring posture and spinal curve can be as a reference for clinical decision. Few instruments can assess both posture and spinal curve simultaneously.

**PURPOSE:** This study was to develop a custom-made body posture and spinal curve measurement system and to examine its with-day and between-days reliability while measuring both in sagittal and frontal planes.

**METHODS:** Five healthy subjects (two male and three female, mean age 20.2 years old) were recruited. The measurement system included three encoders for measuring the distance of moved and representing the relative positions of the subjects' anatomic makers in the three dimensional space. For measuring the spinal curve, those makers included the spinal process of the 1<sup>st</sup> and 12<sup>th</sup> thoracic (T1, T12) and of the 1<sup>st</sup> and 5<sup>th</sup> lumbar (L1, L5). Thoracic kyphosis was defined as the angle projected in sagittal plane between the intersections of the tangents at the T1 and the T12, meanwhile the lumbar lordosis was defined by using the tangents at the L1 and the L5. For measuring the body posture in sagittal plane, the craniocervical (CVA) angle was determined by the measured positions of the ear canal and the spinal process of the 7<sup>th</sup> cervical and trunk forward lean (TFL) angle was determined by the measured positions of acromioclavicular joint and greater trochanter of femur. For measuring the body posture in coronal plane, back symmetry variables was calculated through measuring the positions of the following markers (shoulder, axilla and trunk) bilaterally. With-day and between-days reliability were determined using statistical analysis by intraclass correlation coefficient (ICC).

**RESULTS:** For both with-day and between-days measurements, the ICC values of the thoracic kyphosis and lumbar lordosis were between 0.77-0.98. For measuring the body posture in sagittal plane, ICC values of the CVA and TFL were between 0.90-0.95. For measuring the body posture in coronal plane, ICC values of the back symmetry variables were between 0.78-0.93.

**CONCLUSION:** Body posture and spinal curves measurement using this custom-made system demonstrated a good reliability.

**ACKNOWLEDGEMENTS:** This study was supported by NSC 99-2410-H-037-009-MY2

1463 Board #244 MAY 30 11:00 AM - 12:30 PM

**A History of Multiple Concussions Does Not Alter Dual Task Gait Stepping Characteristics**

Thomas A. Buckley<sup>1</sup>, David A. Krazeise<sup>2</sup>, Barry A. Munkasy<sup>1</sup>. <sup>1</sup>Georgia Southern University, Statesboro, GA. <sup>2</sup>Webber International University, Babson Park, FL.  
(Sponsor: Chris Hass, FACSM)  
(No relationships reported)

Recent investigations have suggested that multiple concussions, typically identified as three or more, may have serious long term consequences including multiple cognitive and neurological pathologies resulting in impaired quality of life. A recent investigation identified alterations in gait performance in individuals with a concussion history; however, the specific threshold of three or more concussions has not been assessed.

**PURPOSE:** The purpose of this study was to identify changes in gait spatial and temporal characteristics in individuals with a history of at least 3 concussions.

**METHODS:** Ten individuals (age: 20.6 ± 1.2 years, ht: 1.76 ± 0.12m, wt: 83.8 ± 24.8kg) with a history of at least three concussions (3.5 ± 0.9), CONC group, were matched to ten individuals with no history of concussions (age: 20.5 ± 1.6 years, ht: 1.75 ± 0.11m, wt: 83.6 ± 22.9kg), No CONC group. All participants performed 5 trials of self-selected single task gait (ST) and dual task gait (DT) on a 4.9m instrumented walkway, previously identified as valid and reliable. The dual task group answered working memory challenges while walking. Stepping characteristics were compared using a 2 (group) x 2 (task) repeated measures ANOVA.

**RESULTS:** There were no interaction (p=0.243) or group effect (p=0.495) for gait velocity (CONC: ST: 1.30 ± 0.12m/s, DT: 1.18 ± 0.11m/s and No CONC: ST: 1.31 ± 0.08, DT: 1.27 ± 0.26m/s). Similarly, there was no interaction (p=0.230) or group effect (p=0.967) for stride length (CONC: ST: 1.36 ± 0.07m, DT: 1.31 ± 0.09m and No CONC: ST: 1.34 ± 0.7m, DT: 1.34 ± 0.15m). Further, there was no interaction (p=0.838) or group effect (p=0.986) in double support phase (CONC: ST: 23.8 ± 1.9%, DT: 24.7 ± 1.9% and No CONC: ST: 23.8 ± 2.0%, DT: 24.6 ± 2.6%). Finally, there was no difference between groups for the number of dual task challenges successfully completed.

**CONCLUSION:** The results of this study suggest there are no differences in gait spatial and temporal characteristics between individuals with a history of multiple concussions and those with no history of concussion when performing working memory dual task challenges during normal overground walking. This population of otherwise young healthy adults appeared to possess sufficient supraspinal compensatory resources to accomplish both a cognitive and postural task simultaneously.

1464 Board #245 MAY 30 11:00 AM - 12:30 PM

**Accelerometry Reveals Improvements In Frontal Plane Control After Only Four-weeks Of Balance And Mobility Training**

Brandi S. Row, Kali J. Tupper. Western Washington University, Bellingham, WA.  
(No relationships reported)

**PURPOSE:** To study the effects of balance-training (BT) on frontal plane control during gait.

**METHODS:** A 4-week BT program was conducted with physically active older men & women (Exercise group [EX], n = 10, mean age [standard deviation, SD]: 77.2 [8.9] yr; waitlist control group [EX2], n = 9, 75.8 [6.0] yr). The BT program focused on multisensory, motor, & cognitive contributors to postural control & gait. EX2's training had less seated training & more weight-bearing exercise.

Four gait trials included: Normal (NORM) & Maximal (MAX) speed, and NORM & MAX speed with a cognitive distraction (COG). Average per-step peak medial-lateral (M-L) trunk acceleration (ACC) magnitude & variability (SD) were calculated.

For the initial 4-week intervention phase, repeated measures ANOVA (with factors Time [pre, post], Group [EX, EX2]) were conducted for measures appropriate for parametric tests, otherwise, the Wilcoxon rank-sum (between groups) or Wilcoxon matched pairs (within group) tests were used. For EX2's waitlisted intervention analysis, a one-way ANOVA (with factor Time [pre, post, EX2-post]) was used for variables suitable for parametric tests; otherwise, the Friedman's test was used.

**RESULTS:** No M-L trunk ACC changes occurred for EX or EX2 from pre to post. Though no changes occurred in gait speed, the waitlisted EX2 group had significant reductions in M-L ACC variables following their BT phase between post- & EX2-post (Table 1).

**Table 1:** Mean [SD] of acceleration results.

| ACC VARIABLE (m/s <sup>2</sup> )                | PRE                                 | POST                                | EX2-POST                    |
|---|-------------------------------------|-------------------------------------|-----------------------------|
| NORM, mean per-step peak M-L ACC                | EX: 3.23 [0.87]<br>EX2: 2.87 [0.66] | EX: 3.00 [0.74]<br>EX2: 2.77 [0.57] | EX: N/A<br>EX2: 2.41 [0.37] |
| MAX, mean per-step peak M-L ACC                 | EX: 6.13 [2.19]<br>EX2: 5.31 [1.13] | EX: 6.87 [3.05]<br>EX2: 5.62 [1.74] | EX: N/A<br>EX2: 4.37 [1.44] |
| MAX, mean per-step M-L ACC variability (SD)     | EX: 1.96 [0.64]<br>EX2: 1.66 [0.36] | EX: 2.16 [0.99]<br>EX2: 1.81 [0.61] | EX: N/A<br>EX2: 1.43 [0.46] |
| MAX COG, mean per-step M-L ACC variability (SD) | EX: 1.34 [0.45]<br>EX2: 1.24 [0.27] | EX: 1.22 [0.48]<br>EX2: 1.17 [0.24] | EX: N/A<br>EX2: 1.02 [0.33] |

**CONCLUSIONS:** Reduced magnitude & variability of per-step M-L ACC following BT indicate improved frontal plane control during NORM & MAX walking & MAX COG gait. The latter result may also represent an improved ability to switch attention between walking & the cognitive task.

1465 Board #246 MAY 30 11:00 AM - 12:30 PM

**Differential Effects Of Foot Sole Sensory Impairment On Balance And Gait**

Shuqi Zhang, Li Li, FACSM. Louisiana State University, Baton Rouge, LA.  
(No relationships reported)

Foot somatosensation provides valuable feedback information to central nervous system to maintain balance. Acute reduced foot sensation would change the plantar pressure distribution during standing and gaits. However, the effect of long-term foot sole sensory impairment on plantar pressure distribution is unclear.

**PURPOSE:** this study was to examine the effects of chronic sensory loss due to peripheral neuropathy (PN) on plantar pressure distribution during walking and standing.

**METHODS:** Twenty-four elderly PN suffers (7 male, 17 female) participated the study (average age/standard deviation = 73.0/6.9). The foot sole sensitivity was tested at big toe (BT), 1<sup>st</sup> and 5<sup>th</sup> metatarsal (M1 and M5), mid-foot (MF) and med-heel (MH) with a 5.07 monofilament and sties was divided into sensitive and insensitive groups based on test score. Relative peak pressure (RPP) of the five tested sites collected according to sensitivity of each of the five sites via an in-shoe pressure system during walking and standing. Walking was conducted on a treadmill at 0.45 m/s (1 mile / hour) for 20 seconds, while standing data was collected during a 30 seconds quiet standing with eyes open. Five-way MANOVA examined the association between dependent variables as a group, RPP of BT, M1, M5, MF and HL, and the sensitivity (sensitive versus insensitive groups) of BT, M1, M5, MF and HL as independent variables during standing and walking separately. Significant associations were examined further using Tukey's test.

**RESULTS:** during standing, the sensitivity of BT affected average RPP at BT significantly (P < .05), where RPP associated with insensitive BT (8.1% ± 5.7%) was greater than with sensitive BT (4.5% ± 4.9%). Furthermore, the RPP at HL was greater for insensitive MF (36.1% ± 17.9%) than sensitive MF (23.6% ± 7.4%) (P < .05). No pressure distribution change observed due to insensitivity of other sites during standing. No pressure distribution changes observed during walking.

**CONCLUSION:** These results indicate feedback from foot sole sensation in gait is not as important as in standing. It suggests maintaining standing balance is more reliance on the feedback control mechanism, while gait control is more reliance on the feedforward control mechanism.

---

**1466** Board #247 **MAY 30 11:00 AM - 12:30 PM**  
**Relationships Between Presynaptic Inhibition and Static Postural Sway in Subjects With and Without Diabetic Neuropathy**

Kevin G. Burfeind, Junggi Hong. *Willamette University, Salem, OR.*  
(No relationships reported)

Nearly 50% of diabetic patients also suffer from neuropathy, the most common form being diabetic peripheral neuropathy (DPN). DPN affects men and women with equal frequency, and symmetrically damages nerves of the limbs, especially the foot, leading to balance impairment. One mechanism that has been reported to be important for balance, yet has not been investigated in DPN patients, is the spinal reflex. The inhibitory or facilitatory behavior of the spinal reflex plays an important role in controlling static postural sway by filtering afferent nerve signals.

**PURPOSE:** To compare the differences in spinal reflex and balance in subjects with and without DPN to determine the influence of the spinal reflex on balance in DPN patients.

**METHODS:** Eight DPN patients (58+6 yrs) and eight normal subjects (59+7 yrs) participated in this study. Presynaptic inhibition (PI) and static postural sway were tested for each subject. The mean percent difference of the conditioned relative to the unconditioned spinal reflex amplitude was assessed to calculate PI. To quantify static postural sway, a balance index was determined for each subject from a single-leg balance assessment on a computerized balance-measuring device.

**RESULTS:** DPN patients showed less PI than the normal group (47+30% vs. 87+17%,  $p < 0.05$ ), as well as increased balance index (0.65+0.24 vs. 0.38+0.06,  $p < 0.05$ ) indicating increased postural sway. No significant correlation was found between PI and balance index ( $R = 0.37$ ,  $p = 0.15$ ).

**CONCLUSION:** DPN patients demonstrated decreased spinal reflex inhibition accompanied by a decrease in static balance compared to normal age-matched controls. Further research is necessary to explore the role of PI in the decreased balance seen in DPN patients.

**1467** Board #248 **MAY 30 11:00 AM - 12:30 PM**  
**Human Motion Differentiation Based on Inertial Parameters**

Chao-Ping Chi<sup>1</sup>, Kuo-Wei Tseng<sup>1</sup>, Wen-Ting Tei<sup>2</sup>, Yi-Pin Wang<sup>3</sup>. <sup>1</sup>Taipei Physical Education College, Taipei City, Taiwan. <sup>2</sup>Cheng Hsin General Hospital, Taipei City, Taiwan. <sup>3</sup>Power & Health Rehabilitation Clinic, Taipei City, Taiwan.  
(No relationships reported)

**PURPOSE:** This project plans to develop an alert system based on inertial parameters with human motion differentiation, high-risk movement detection, and fall detection.

**METHODS:** 90 subjects volunteered to participate in this study. The Xbus Master (Xsens Technologies B.V., The Netherlands) inertial parameter detector were carried by the subjects during various movements, including standing, sitting, supine, prone, lying, up/down stairs, sit-to-stand, stand-to-sit, running, jumping and walking.

**RESULTS:** An algorithm was developed for each decision node with hierarchy structure as binary tree method. A human motion classifier was constructed with best basis feature extraction, maximal likelihood classifier and the accuracy tested. Half of the sample data were used as the released-set and applied in constructing individual classifiers. The other half will be used as the withhold-set and employed in testing reliability of the individual classifiers. The results have shown that the level 3 static and transfer action have high sensitivity (95.6%-100%) and level 4 static and transfer action have well sensitivity (84.4%-93.3%). (Tab. 1)

**CONCLUSION:** The method has potential applications to apply in telemedicine and fall-risk analysis for the elderly, and long-distance monitoring and behavioral pattern analysis for daily activities modern of elderly people. There are clear limits in the calculation time on what can be achieved in a free-living monitoring environment.

**1468** Board #249 **MAY 30 11:00 AM - 12:30 PM**  
**Postural Control, Knee Alignment, And Self-reported Function In Patients With Symptomatic Knee Osteoarthritis And Normal Control Subjects**

Carrie L. Silkman, Jennifer M. Medina McKeon. *University of Kentucky, Lexington, KY.*  
(No relationships reported)

**PURPOSE:** Declining levels of function are associated with osteoarthritis (OA); however it is unknown to what degree balance deficits occur. The purpose was to evaluate differences between healthy individuals and those with OA on subjective measures of pain and disability, and objective measures of structure, balance, and clinical measures of function.

**METHODS:** Ten subjects (1 male, 9 females, age = 40.4 ± 11.7 yrs, ht = 166 ± 9 cm, mass = 82.6 ± 14 kg) with OA were matched by sex, height and mass with 10 healthy subjects (1 male, 9 female, age = 41.6 ± 11.9 yrs, ht = 166 ± 9 cm, mass = 81.9 ± 15 kg). The subjects completed the Knee injury Osteoarthritis Outcome Survey (KOOS), which consists of 5 subscales (Pain, Symptom, Activities of Daily Living (ADL), Sports and Recreation (Sport/Rec), and Quality of Life (QOL). Subjects underwent functional testing including the 15m Timed Up and Go (TUG), 15.24m walk test, timed stair ascent, and stair descent. Balance was measured using the step test as a dynamic balance task, and force plate static balance as measured by time to boundary (TTB). Additionally, knee varus alignment was measured bilaterally. Hedge's g effect sizes [95% confidence intervals] were calculated to assess the difference between the affected limb of the OA group compared to the matched limb of the control group for each outcome.

**RESULTS:** The OA group demonstrated worse scores for all subscales of the KOOS (pain 5.2 [1.8]; KOOS symptom 5.7 [2.0]; KOOS ADL 2.1 [1.1]; KOOS sport/rec 3.8 [1.5]; KOOS QOL 3.9 [1.5]), increased knee varus (1.0 [0.9]), and slower stair ascent (1.0 [0.9]) than the healthy group. For other functional tests (TUG 0.5 [0.9]; Walk test 0.5 [0.9]; Stair descent 0.8 [0.9]), confidence intervals encompassed zero, indicating a need for caution when interpreting results. Lastly, there was no difference in balance between groups for either measure (Step Test 0.2 [0.9]; TTB mean of minima in the medial-lateral direction 0.6 [0.9]; TTB mean of minima in the anterior-posterior direction 0.1 [0.9])

**CONCLUSION:** Patient reports of functional deficits as a result of OA were not substantiated by laboratory testing of balance, and not well-associated with functional, clinical tests. Other objective methods for determining the extent in OA, which are also highly correlated with patient reports, are needed.

---

**1469** Board #250 **MAY 30 11:00 AM - 12:30 PM**  
**Post Nuchal Icing Effect On Neck Fitness And Balance Performance Between Boxers And Non-boxers**

Shih-Wei Chou<sup>1</sup>, Cheng-Hsiu Lai<sup>2</sup>, Yu-Tsai Tu<sup>1</sup>, Yin-Chou Lin<sup>1</sup>, Yi-Liang Cheng<sup>2</sup>, Ching-Ya Huang<sup>2</sup>. <sup>1</sup>Chang Gung Memorial Hospital, Taoyuan, Taiwan. <sup>2</sup>Taipei Physical Education College, Taipei City, Taiwan. (Sponsor: Chia-Hua Kuo, FACSM)  
(No relationships reported)

Boxing involves impacts to the head, potentially resulting in acute or chronic head and neck injuries. Objective: To evaluate post nuchal icing effect on the neck fitness and balance performance between the boxer and the age-matched non-boxers who had not been specialized in any specific sport.

**METHODS:** A 2 x 2 factorial design between the boxing and the icing pre-post factors was conducted. Twenty five boxers from the Taipei Physical Education College (20.92 ± 1.35 years of age; 169.32 ± 9.86 cm; 64.84 ± 13.24 kg) and 11 students of non-sport majors (21.55 ± 1.51 years of age; 169.55 ± 6.15 cm; 65.10 ± 8.41 kg) were enrolled as the boxer group and the non-boxer group, respectively. Their balance performance were assessed by the sensory organization test (SOT) with the Smart Balance Master (Neurocom International Inc., USA) and then the microFET3 (Hoggan Health Industries, USA) was used to measure neck maximal isometric strength and active range of motion (ROM) in six directions. After icing intervention, the boxers and the control group were measured again for their balance performance and neck fitness.

**RESULTS:** Statistic significance was shown in the more challenging conditions, i.e., conditions 5 and 6 of the SOT for the main icing pre-post effect, and condition 5 for the interaction effect. In sensory analysis, statistic significance was shown in the visual and vestibular ratios only for the main icing pre-post effect. In neck fitness with respect to maximal isometric strength and active ROM, the main effects of boxing and icing pre-post factors and their interaction effect were almost all statistically significant.

**CONCLUSION:** In balance, icing may be effective of both the boxer and non-boxer groups, but more in the boxers. In general, maximal isometric strength scored higher but active ROM scored lower in the boxers than in the non-boxers. Icing may be also effective in both strength and flexibility of both groups, but more in the boxers. As a result, the detrimental effect in boxing and the beneficial effect of icing were demonstrated in terms of neck fitness and balance performance.

**Relationship Between Anthropometric And Postural Balance In Semi-static Upright Posture**

Angelica Castilho Alonso, Luciana Baltazar Dias, Emmanuel Gomes Ciolac, Fábio Brabieri, Júlia MD<sup>1</sup> Andréa Greve. *faculdade de medicina da universidade de são paulo, São Paulo, Brazil.*  
(No relationships reported)

**INTRODUCTION:** The maintenance of posture is a constant contest for the human body, because it demands a system capable of responding quickly and efficiently, even in unstable situations, avoiding falls and maintaining balance. Objectives: to assess the influence of anthropometric characteristics and gender on postural balance of irregularly active adults in the upright, bipedal and semi-static posture, with eyes open and closed.

**METHODS:** 100 individuals of both genders were assessed, with age between 20 and 40 years, through an anthropometric measurements, bone densitometry (lean and fat mass, composition and bone mineral density), BMI, height, body mass, lower and head length limb and upper torso length, waist and hip, support base and postural balance test performed on a force platform.

**RESULTS:** The correlation analysis showed weak correlations between the postural balance and anthropometric measure. The multiple linear regression analysis demonstrated that in the whole group (female and male) height explained 12% of the medial-lateral displacement, 10% of the speed of oscillation and 11% of the scroll area. The torso circumference length explained 6% of the shift from anterior to posterior. In the eyes closed condition, height and base of support explained 18% of the medial lateral displacement, height explained 10% of the speed displacement and 5% of the scroll area.

**CONCLUSION:** Postural balance measured by posturography is little influenced by anthropometric variables with eyes open and closed. Postural balance is more influenced by anthropometric factors in the men than those of women. Height is the anthropometric variable that most influenced the postural balance among the three groups, with eyes open and closed. The balance between men and women measured by posturography is equal, except for the lateral displacement and average speed of oscillation, which are larger in women.

**The Effect Of Exercise During Early Lactation On Bone Mineral Density At 1 Year Postpartum**

Andrea Sorvillo, Heather Colleran, Laurie Wideman, Cheryl Lovelady. *The University of NC at Greensboro, Greensboro, NC.* (Sponsor: Allan Goldfarb, FACSM)  
(No relationships reported)

**PURPOSE:** Hyperprolactemia, which results in increased bone turnover, causes breastfeeding women to lose 1 to 10% of bone mineral density (BMD) by 6 mo postpartum (PP). BMD usually returns to prepregnancy levels with weaning; however, not in all women. Exercise, particularly resistance training, prevents the loss of BMD. We hypothesized that exercise may slow bone loss during early lactation, resulting in higher BMD at 1 yr PP. Therefore, the purpose of this study was to determine the effects of a 16 wk exercise program, beginning 4 wks PP, on BMD at 20 wks and 1 yr PP.

**METHODS:** At 4 wks PP, fully breastfeeding women were randomized to either exercise group [EG, n=18, aerobic and resistance exercise (3d/wk)] or control group [CG, n=18] for 16 wks. Exercises included bench press, bent over row, deadlift, military press, pushups, squats and walking 30-40 min/d, 4d/wk or 10,000 steps/d. Measurements were made at baseline (4 wks PP), end of intervention (20 wks PP), and 1 yr PP. Maximal strength and predicted maximal oxygen consumption (VO<sub>2</sub> max) were determined by 1-rep max and submax treadmill test. BMD was measured by DXA at lumbar spine (LS), hip and total body. Prolactin levels (analyzed by ELISA) and calcium intake (24-hr diet recalls) were measured in a subsample of 20 women. Repeated measures ANOVA was used to test for time and group differences.

**RESULTS:** At 20 wks PP, strength increased significantly more in EG compared to CG; with no differences in VO<sub>2</sub> max. LS BMD decreased in both groups; however, EG decreased less (EG = 3.59 ± 2.12% vs. CG = 5.17 ± 3.28%, p = 0.10). Results were similar for hip and total body. At 1 yr PP, LS, hip, and total body BMD changed significantly over time (p < 0.001) but not by group. When controlling for calcium intake and prolactin levels, EG lost less LS BMD from 4 to 20 wks PP and gained slightly more from 20 wks to 1 yr PP (EG 1.114 ± 0.128 to 1.070 ± 0.130 to 1.107 ± 0.127 vs. CG 1.105 ± 0.139 to 1.031 ± 0.135 to 1.065 ± 0.137, p = .02). The overall change in the EG group was -0.67 ± 2.23%, while the change in the CG was -3.65 ± 2.41%; a 5.4 fold difference in LS BMD change. Hip and total body BMD did not change significantly over time or by group.

**CONCLUSIONS:** These results suggest that resistance exercise slows LS BMD losses during early lactation, resulting in higher BMD levels at 1 yr PP. This may result in a decreased risk for fracture as women age.

**Fat Tissue Inflammation, Sedentary Time, and Light Daily Activity among Postpartum Latinas**

Paska Permana<sup>1</sup>, Barbara Ainsworth, FACSM<sup>2</sup>, Michael Belyea<sup>2</sup>, Kathie Records<sup>2</sup>, Sonia Vega-López<sup>2</sup>, Allison Nagle-Williams<sup>2</sup>, Dean V. Coonrod<sup>3</sup>, Colleen Keller<sup>2</sup>.  
<sup>1</sup>Phoenix Veterans Affairs Health Care System, Phoenix, AZ <sup>2</sup>Arizona State University, Phoenix, AZ <sup>3</sup>Maricopa Integrated Health System, Phoenix, AZ  
(No relationships reported)

Postpartum Latinas have high rates of obesity and are at risk for obesity-related metabolic disorders, yet their physical activity (PA) rates are often quite low. Chronic sub-clinical inflammation associated with obesity may exacerbate risk for metabolic disorders and pro-inflammatory cytokines released by fat tissue contribute to systemic inflammation.

**PURPOSE:** To determine if fat tissue inflammation correlates with daily PA in postpartum Latinas.

**METHODS:** *Madres para la Salud* is a prospective, randomized trial exploring the effectiveness of a culturally specific social support intervention using moderate-intensity PA to reduce body fat, systemic and fat tissue inflammation, and depression symptoms in postpartum Latinas. PA was assessed at baseline with the ActiGraph GT3X accelerometer, worn for 7 days. PA intensities were determined from sedentary to vigorous using Freedson's and Matthews' cut-points. A subcutaneous abdominal fat biopsy and a blood draw were performed on a subset (n=15) of participants. We determined mRNA expression levels of inflammatory markers Interleukin-6 (IL-6), Interleukin-8 (IL-8), and Tumor Necrosis Factor  $\alpha$  (TNF- $\alpha$ ) in fat tissue using Real Time PCR. Plasma concentrations of IL-6 and IL-8 were measured using Enzyme Linked Immunosorbent Assay. Data are presented as Mean $\pm$ SD.

**RESULTS:** Daily proportion of light PA (39 $\pm$ 9%) correlated negatively (r=-0.98, p<0.001) with sedentary time (58 $\pm$ 10%). Fat tissue mRNA expression levels, but not plasma concentrations, of IL-6 (3.8 $\pm$ 6.8 Relative Units), IL-8 (1.7 $\pm$ 1.6), and TNF- $\alpha$  (0.9 $\pm$ 0.2) correlated with sedentary time (r=0.47, p=0.08; r=0.7, p=0.004; r=0.55, p=0.04, respectively) and inversely with light PA (r=-0.51, p=0.05; r=-0.75, p<0.001; r=-0.59, p=0.02, respectively).

**CONCLUSION:** The correlation between the mRNA expression levels of inflammatory markers in fat tissue with sedentary time and, inversely, with light PA is strengthened by the inverse correlation between the two types of activity. These results indicate that even light PA incorporated in daily routine, independent of more intense PA, may already reduce inflammation in fat tissue in postpartum Latinas. Moderate-intensity intervention will likely further reduce fat tissue and systemic inflammation, thus minimize risk for obesity-related diseases.

1473 Board #254 MAY 30 9:30 AM - 11:00 AM

**Healthcare Providers' Beliefs And Practices Related To Antenatal Physical Activity For Sedentary And Overweight Women**

Margaret J. Gutilla, Jenn A. Leiferman. *University of Colorado, Aurora, CO.* (Sponsor: John B. Bartholomew, FACSM)  
(No relationships reported)

Despite the fact that the American Congress of Obstetricians and Gynecologists recommends pregnant women who are free of obstetrical complications engage in regular leisure physical

activity, women who are pregnant engage in less physical activity than their nonpregnant counterparts. Pregnant women often report a lack of knowledge concerning the safety of exercising during pregnancy and believe that if they received information related to how to safely and effectively exercise during pregnancy it would facilitate their engagement in physical activity.

**PURPOSE:** To explore the relationship between healthcare providers' beliefs that sedentary and/or overweight pregnant women should begin exercise and their current practices regarding exercise counseling.

**METHODS:** Obstetricians and certified nurse midwives who provide obstetric care for women residing in Denver-Aurora completed a cross-sectional survey, containing a total of 48 items, assessing their current beliefs and practices pertaining to antenatal physical activity.

**RESULTS:** The sample included 102 healthcare providers (HCPs) with the majority of respondents being obstetricians (70.6%), female (79.4%), non-Hispanic white (87%) and reporting an average of 18.7 years of healthcare experience (SD=10.2 years, range=3-41 years). Overall, HCPs reported that they discuss exercise with approximately 73% (SD=26.8%) of their patients. The majority of HCPs (92%) also believe that sedentary patients should begin an exercise program during pregnancy; however only 47% reported that they always or often discuss physical activity with their sedentary patients. Further, HCPs more strongly believed that overweight and sedentary patients should begin an exercise program, compared to only sedentary patients ( $p=0.0042$ ).

**CONCLUSIONS:** These data suggest that, in general, HCPs believe that women who are free of obstetric complications should engage in regular physical activity during pregnancy. However, many HCPs are not currently providing antenatal physical activity anticipatory guidance. Further analysis is warranted to determine other factors (e.g. perceived provider, practice, and patient level barriers) that may be influencing providers' ability or decision to deliver physical activity counseling. Supported by AHRQ #1R03HS018595-01A1.

1474 Board #255 MAY 30 9:30 AM - 11:00 AM

**The Effects of Supervised Exercise and Telehealth Support on Postpartum Health-Related Physical Fitness**

Katie L. Chapman, Darren ER Warburton, Shannon SD Bredin. *University of British Columbia, Vancouver, BC, Canada.*

(No relationships reported)

Excessive gestational weight gain and failure to return to a healthy body weight within one year postpartum heightens a woman's risk for obesity and related co-morbidities. Moreover, the transition to motherhood (including various barriers to physical activity participation) often leads to a decline in health-related physical fitness. Therefore, physical activity interventions tailored to the unique needs of postpartum women are needed.

**PURPOSE:** This prospective randomized intervention study examined changes in health-related physical fitness after participation in either supervised mom-and-baby fitness classes (Fit 4 Two) or telehealth physical activity support (the Physical Activity Line) versus control.

**METHODS:** Thirty-three women (6 wks to 11 mo postpartum) were assigned randomly to one of three conditions for 10 wks: 1) the Fit 4 Two group (twice/wk,  $n = 11$ ), 2) the Physical Activity Line group (twice/wk,  $n = 11$ ), or 3) a usual activity control group ( $n = 11$ ). Health-related physical fitness (BMI, grip strength, push-ups, flexibility, and aerobic fitness) was measured pre- and post-intervention.

**RESULTS:** In both the Fit 4 Two and the Physical Activity Line group, key changes included a similar reduction in BMI ( $-2.1 \pm 2.4\%$  and  $1.6 \pm 2.2\%$ , respectively), greater change in flexibility ( $8 \pm 9\%$  and  $9 \pm 9\%$ , respectively), significant increases in aerobic capacity ( $4 \pm 5\%$  and  $3 \pm 5\%$ , respectively), and an increase in number of push-ups completed in comparison to the control group. There was no significant change in grip strength in the three conditions.

**CONCLUSION:** Fit 4 Two and telehealth physical activity support are effective at improving health-related physical fitness in postpartum women. A novel telehealth program can lead to similar changes in various indicators of health-related physical fitness versus supervised exercise.

1475 Board #256 MAY 30 9:30 AM - 11:00 AM

**Exercise During Pregnancy Decreases Cesarean Rate In Nulliparous Women**

Katrine M. Owe<sup>1</sup>, Wenche Nystad<sup>2</sup>, Hein Stigum<sup>2</sup>, Siri Vangen<sup>3</sup>, Kari Bø<sup>1</sup>. <sup>1</sup>Norwegian School of Sport Sciences, Oslo, Norway. <sup>2</sup>Norwegian Institute of Public Health, Oslo, Norway. <sup>3</sup>Norwegian Resource Center for Women's Health, Oslo University Hospital, Oslo, Norway.

(No relationships reported)

Exercise during pregnancy may influence the course of labor and mode of delivery by affecting metabolic and hormonal changes, uterine contractility, endurance, and muscle strength. Given the worldwide rising cesarean delivery (CD) rates over the past decades, the search for modifiable factors associated with CD is needed.

**PURPOSE:** To investigate the association between exercise during pregnancy and CD, both acute and elective, in nulliparous women.

**METHODS:** We used data from a population based pregnancy cohort study, involving 25,160 nulliparous women with a singleton pregnancy who were enrolled in the Norwegian Mother and Child Cohort Study (MoBa) between 2000 and 2006. Acute and elective Cesarean deliveries obtained from the Medical Birth Registry of Norway were the main outcome variables. Information on exercise frequency and type was assessed by two questionnaires in pregnancy weeks 17 and 30. From the generalized linear model, adjusted risk differences (RD) with 95% CI for different frequencies and types of exercise during pregnancy were reported.

**RESULTS:** The total CD rate was 15.6% ( $n=3928$ ), in which 67.8% ( $n=2663$ ) was acute CD. CD rates, both acute and elective type, were reduced in women exercising during pregnancy compared to non-exercisers. The greatest risk reduction was observed for acute CD among women reporting a high weekly frequency of exercise ( $\geq 6$  times per week) during pregnancy weeks 17 and 30 ( $-3.8\%$ , 95% CI  $-5.7$ ;  $-2$ , and  $-4.5\%$ , 95% CI  $-6.5$ ;  $-2.4$ , respectively). Participation in high impact exercises such as jogging, running, ballgames orienteering or high-impact aerobics in weeks 17 and 30, was associated with the largest reductions in risk ( $-5.1\%$ , 95% CI  $-6.9$ ;  $-3.3$ , and  $-6.2\%$ ,  $-9.4$ ;  $-3.0$ , respectively) compared to non-exercisers. For elective CD, exercising 1-2 per week in week 17 showed the greatest RD ( $-2.2\%$ ,  $-3.0$ ;  $-1.4$ ), whereas women had to exercise at least 6 times a week in week 30 to reach comparable risk reductions ( $-2.1\%$ ,  $-3.3$ ;  $-0.9$ ).

**CONCLUSIONS:** Nulliparous women exercising during pregnancy had a substantially reduced risk of having a CD, in particular acute CD. A "can do" attitude towards labor and self-efficacy may also play a role here.

1476 Board #257 MAY 30 9:30 AM - 11:00 AM

**Comparison of Two BodyMedia Algorithms for Estimating Energy Expenditure During Mid-Pregnancy.**

Katie M. Smith, Lorraine M. Lanningham-Foster, Gregory J. Welk, FACSM, Christina G. Campbell. *Iowa State University, Ames, IA.*

(No relationships reported)

Excessive gestational weight gain (GWW) is an independent risk factor for future maternal chronic disease. Accurate assessment of physical activity (PA) is required to appropriately control for energy expenditure (EE) when evaluating GWW. Metabolic alterations during pregnancy complicate the assessment of PA and EE in pregnant women. The BodyMedia SenseWear® Mini armband monitor has been shown to provide accurate estimates of EE in adults but has not been tested in pregnancy.

**PURPOSE:** The purpose of the study was to evaluate the accuracy of the SenseWear® Mini physical activity armband (SWA) in predicting EE in pregnant women performing activities of daily living (ADLs). A secondary aim was to assess how a new proprietary algorithm (v5.2) performed relative to an older algorithm (v2.2).

**METHODS:** Twenty-three women completed a series of ADLs between 22-24 weeks of pregnancy. Activities included typing, folding laundry while standing, sweeping, and treadmill walking at speeds of 2.0, 2.5, 3.0 mph, 0% incline and 3.0 mph, 3% incline. Participants wore the SWA on their left arm and had oxygen consumption measured by indirect calorimetry (IC). Data from both IC and SWA were processed on a minute-by-minute basis. Correlation analyses and a mixed model analysis of variance were used to examine agreement between the measures.

**RESULTS:** Average individual correlations between IC and SWA were 0.857 and 0.865 for the old and new algorithm respectively. The model analysis showed significant main effects for the algorithm (F-Value 6.98,  $P < 0.01$ ) and activity (F-Value 21.5,  $P < 0.0001$ ). Both algorithms significantly overestimated EE for all activities except walking at 3.0 mph, 3% incline; however, follow-up tests showed that the new algorithm had significantly less error than the old algorithm (0.594 kcal/min vs 0.804 kcal/min, respectively). Post-hoc analysis for the activities showed non-significant differences between algorithms for all activities except sweeping ( $P = 0.0304$ ).

**CONCLUSION:** Both algorithms significantly overestimated EE compared to IC but the newer algorithm had less error. Additional training of the algorithms with pregnancy-specific data could minimize the overestimation of EE for this population.

---

1477 Board #258 MAY 30 9:30 AM - 11:00 AM

**Measurement of Energy Expenditure During Pregnancy and Postpartum**

Rebecca A. Schlaff, Alaina K. Vince, Karin A. Pfeiffer, FACSM, Kimberly Maier, James M. Pivarnik, FACSM. *Michigan State University, East Lansing, MI.*  
(No relationships reported)

Recall questionnaires use MET values from the Compendium of Physical Activities (Compendium: Ainsworth, et al. 2011) to assess energy expenditure (EE) for pregnant women, but the validity of this practice has not been well-established.

**PURPOSE:** The purposes of this study were 1) to compare actual EE in pregnant women to MET values listed in the Compendium, and 2) to evaluate EE longitudinally across pregnancy and postpartum periods.

**METHODS:** Fifteen pregnant women were tested at 20 and 32 weeks gestation, seven of whom were also evaluated at 12 weeks postpartum. Participants were 18-35 years old, nonsmokers, and considered low-risk by their health care providers. Each participant was tested in our laboratory, and equipped with a portable gas analyzer to measure EE via indirect calorimetry. Resting EE was determined during ten minutes of left lateral/supine rest. Women performed a series of five-minute activities ranging from light to vigorous. MET values were calculated for each activity by dividing steady state relative  $\dot{V}O_2$  by actual resting EE measured at each time point. MET values for each activity at 20 and 32 weeks gestation were compared to MET values listed in the Compendium using a one sample t-test. For the seven women with postpartum data, EE across the three time points were evaluated using repeated measures ANOVA.

**RESULTS:** Compared to the Compendium, observed MET values for laundry, dusting, sweeping, and aerobics were lower (range= -0.2 to -2.8 METS, effect sizes (ES)= 0.6 to 4.1;  $p<0.05$ ) at both pregnancy time points, while child care and walking were higher (range=0.4 to 1.1 METS; ES=0.6 to 1.9;  $p<0.05$ ). Longitudinal analysis revealed that resting EE was significantly higher (0.2 METS; ES=0.55) and dusting was significantly lower (-0.5 METS; ES=0.75) at 32 weeks gestation compared to 12 weeks postpartum ( $p<0.05$ ). Average MET values for all other activities were lower at 32 weeks gestation than at 12 weeks postpartum, however these differences were not statistically significant.

**CONCLUSION:** Compendium MET values may not be accurate during pregnancy, and the direction of measurement errors do not appear consistent. Future research with larger samples is needed to corroborate these results.

**Physical Activity And Lipid Levels During Pregnancy: Results For 1999-2006 NHANES Data**

Lanay M. Mudd<sup>1</sup>, Rebecca A. Battista<sup>1</sup>, Jean Kerver<sup>2</sup>. <sup>1</sup>*Appalachian State University, Boone, NC.* <sup>2</sup>*Michigan State University, East Lansing, MI.* (Sponsor: Alan Utter, FACSM)

(No relationships reported)

Physical activity (PA) is related to higher high-density-lipoprotein cholesterol (HDLc) and modestly lower total cholesterol (TC) among non-pregnant adults. One study found similar relations among pregnant women in the 1st trimester; however, PA and lipid relations later in pregnancy, when lipids rise dramatically, have not been studied.

**PURPOSE:** To determine trimester-specific relations between PA and lipids among pregnant women in the National Health and Nutrition Examination Survey (NHANES).

**METHODS:** In this cross-sectional study design, we analyzed self-reported demographics, PA, trimester of gestation, diet, and measured serum TC and HDLc, for pregnant women in NHANES 1999-2006 (n=995 with complete PA and lipid values: 193 in 1st, 418 in 2nd, and 384 in 3rd trimester). PA was categorized as none (referent), less than recommended (LT Recs: 1- <150 min/wk), meets U.S. recommendations (Meets Recs: 150-300 min/wk), and far exceeds recommended (FE Recs: 300+ min/wk). SAS v9.2 used weighted analyses to account for the complex sampling frame of NHANES. Linear regression analyses assessed relations among mean lipids and PA within trimesters.

**RESULTS:** Mean  $\pm$  standard error for 1st, 2nd, and 3rd trimester, TC (171.5 $\pm$ 2.9, 218.7 $\pm$ 3.8, and 247.6 $\pm$ 4.6 mg/dl) and HDLc (59.3 $\pm$  1.7, 68.5 $\pm$  1.6, and 67.6 $\pm$  1.9 mg/dl) differed ( $p<0.05$ ). PA participation was higher in the 1st (36.1% Meets/FE Recs) vs. the 3rd trimester (24.3%,  $p>0.05$ ). All regression models adjusted for body mass index, total caloric intake, race, and marital status. In the 1st trimester, compared to no PA, LT Recs was significantly related (adjusted beta, 95% confidence interval: -15.0, -28.5 to -1.4 mg/dl) and Meets Recs was borderline ( $p=0.06$ ) related (-15.4, -32.7 to 2.0 mg/dl) to reduced mean TC, but FE Recs was not (6.3, -17.3 to 29.9). FE Recs was related to significantly higher HDLc in the 1st trimester (10.9, 1.8 to 20.0 mg/dl) compared to no PA, but lower amounts of PA were not significant. PA was not related to lipids in either the 2nd or 3rd trimesters.

**CONCLUSIONS:** Relations among PA and lipids within the 1st trimester are similar to, if not stronger than, those seen in non-pregnant adults. Physiological changes to lipids in later gestation may overpower effects of PA. More work is needed to examine these relations prospectively throughout pregnancy.

**Arterial Stiffness in Patients with Chronic Kidney Disease: Correlations at Different Level of Physical Function**

Pei-Tzu Wu<sup>1</sup>, Emily J. Tomayko<sup>1</sup>, Hae Ryong Chung<sup>1</sup>, Brandon M. Kistler<sup>1</sup>, Jin Hee Jeong<sup>1</sup>, Peter J. Fitchen<sup>1</sup>, Bo Femhall, FACSM<sup>2</sup>, Kenneth R. Wilund<sup>1</sup>. <sup>1</sup>*University of Illinois at Urbana Champaign, Urbana, IL.* <sup>2</sup>*University of Illinois at Chicago, Chicago, IL.*

(No relationships reported)

Studies have shown that exercise training improves arterial stiffness in healthy populations, but there is little research investigating the relationship between physical function and arterial health in hemodialysis patients. The few studies that have assessed this relationship have used indirect measures of arterial stiffness, such as central pulse wave velocity and augmentation index, and the results from these studies have been equivocal.

**PURPOSE:** The purpose of this study was to evaluate the relationship between physical function and arterial stiffness in hemodialysis patients using  $\beta$ -stiffness via ultrasound, which is a direct measure of arterial stiffness.

**METHODS:** Forty-nine hemodialysis patients were recruited (29 men, 20 women; 54.7 $\pm$ 1.9 years). Arterial stiffness index ( $\beta$ ) was measured by applanation tonometry and ultrasound. Physical function was measured by a validated shuttle walk test and a battery of objective physical performance tests. Patients were divided into high function (HF; n=26) and low function (LF; n=23) groups according to the scores of the physical function tests. One-way analysis of variance (ANOVA) was used to evaluate the difference between groups. Bivariate analyses were performed to assess the associations between  $\beta$ -stiffness and physical function tests.

**RESULTS:** Among 49 subjects,  $\beta$ -stiffness was significantly correlated with physical function tests, including gait speed, shuttle walk distance, and time on 8-foot up-and-go test ( $r=0.33$ , -0.30, and 0.34, respectively;  $p<0.05$ ), but not with repetitions of arm-curl and chair-stand.  $\beta$ -stiffness was greater in the LF group (13.9 $\pm$ 1.2) compared to the HF group (10.1 $\pm$ 0.9;  $p<0.05$ ).

**CONCLUSION:** In contrast to previous studies showing equivocal evidence that exercise training improves arterial stiffness, we found a close relationship between reduced physical function and increased arterial stiffness in hemodialysis patients. The increased arterial stiffness observed in the LF group suggests that the patients with lower fitness level may have increased cardiovascular disease risk. We have an ongoing longitudinal clinical trial to confirm these findings, and assess if exercise training improves  $\beta$ -stiffness in hemodialysis patients.

**Body Composition is Associated with Arterial Stiffness and Physical Function in Chronic Kidney Disease Patients**

Jin H. Jeong<sup>1</sup>, Pei-Tzu Wu<sup>1</sup>, Emily J. Tomayko<sup>1</sup>, Hae R. Chung<sup>1</sup>, Brandon M. Kistler<sup>1</sup>, Peter M. Fitchen<sup>1</sup>, Bo Fernhall, FACSM<sup>2</sup>, Kenneth R. Wilund<sup>1</sup>. <sup>1</sup>University of Illinois at Urbana-Champaign, Urbana, IL. <sup>2</sup>University of Illinois at Chicago, Chicago, IL.  
(No relationships reported)

Patients with renal failure requiring hemodialysis experience a reversal in the relative risk of death from many traditional risk factors including the Body Mass Index (BMI). This phenomenon is often referred to as a reverse epidemiology. While many studies have demonstrated survival benefits with increasing BMI, few studies have differentiated between the components of BMI, fat mass and lean mass.

**PURPOSE:** To determine the association of fat mass and lean mass with cardiovascular disease (CVD) risk factors and physical function in a cross-sectional analysis of patients undergoing maintenance hemodialysis.

**METHODS:** Sixty-five hemodialysis patients were recruited (men=41, women=24; 54.2±11.8). Whole body lean mass (LM) and fat mass (FM) were measured using dual-energy X-ray absorptiometry (DXA). Augmentation index (AIx), a measure of arterial stiffness, was assessed by applanation tonometry. Physical function was measured by a validated shuttle walk test and a battery of objective physical performance tests. Linear regression was used to determine predictors of arterial stiffness.

**RESULTS:** Among 65 subjects, AIx was significantly correlated with BMI ( $r=-.25$ ,  $p<.05$ ); however, this was primarily due to a correlation between AIx and LM ( $r=-.34$ ,  $p<.01$ ), while there was no correlation between AIx and FM. AIx decreased 3% for each 10g increase of LM ( $F(2, 62)=5.1$ ;  $p<.01$ ). Percent body fat was associated with worse performance on several metrics of physical function, including gait speed, shuttle walk distance, time on 8-foot up-and-go, and repetitions of chair-stand ( $r=.32$ ,  $-.45$ ,  $.34$ , and  $-.36$  respectively;  $p<.05$ ). By contrast, percent lean mass was associated with better performance in gait speed, shuttle walk distance, time on 8-foot up-and-go, and repetitions of chair-stand ( $r=-.32$ ,  $.46$ ,  $-.32$ , and  $.32$ , respectively,  $p<.05$ ).

**CONCLUSION:** Although higher BMI is associated with lower mortality in patients undergoing hemodialysis, this study differentiated the contributions of BMI, LM and FM to CVD risk in this population. We found that increased LM is a predictor of reduced arterial stiffness, and higher percent body fat is associated with declined physical function in hemodialysis patients. However, longitudinal studies are needed to confirm these findings.

1481 Board #262 MAY 30 11:00 AM - 12:30 PM

**Exercise Capacity Is Associated With Myocardial And Vascular Function In Patients With Chronic Kidney Disease**

Erin J. Howden<sup>1</sup>, Nicole M. Isbel<sup>2</sup>, Thomas H. Marwick<sup>3</sup>, Jeff S. Coombes, FACSM<sup>1</sup>. <sup>1</sup>University of Queensland, St Lucia, Australia. <sup>2</sup>Princess Alexandra Hospital, Woollongabba, Australia. <sup>3</sup>Cleveland Clinic, Cleveland, OH.  
(No relationships reported)

**BACKGROUND:** Understanding the correlates of exercise capacity may help to explain the poor prognosis observed in patients with chronic kidney disease (CKD).

**PURPOSE:** To determine the relationship between exercise capacity (VO<sub>2</sub> peak), clinical factors and myocardial and vascular parameters in patients with CKD.

**METHODS:** 115 patients with stage 3 and 4 CKD performed a graded exercise test to exhaustion for determination of VO<sub>2</sub> peak. Myocardial function was assessed using two dimensional echocardiography and tissue Doppler imaging. Vascular function and structure were assessed using ultrasound to measure brachial artery reactivity and carotid intima-media thickness (cIMT). Central arterial stiffness was assessed by aortic pulse wave velocity (aPWV) and systemic arterial stiffness by augmentation index (AIx). Demographics were recorded and standard biochemistry performed. Patients were categorized by tertiles of fitness.

**RESULTS:** The lowest fitness group (VO<sub>2</sub> peak 19.4±4.6) had worse diastolic function (E/e' 16.0±10.0 vs. 11.5±5.2), central (aPWV 11.1±3.5 vs. 8.5±1.8) and systemic arterial stiffness (AIx 22.2±7.8 vs. 17.2±8.2) than the highest fitness group (VO<sub>2</sub> peak 28.2±7.7) ( $p<.05$ ). Whilst the middle fitness group (VO<sub>2</sub> 21.7±4.2) had significantly worse central (aPWV 10.2±2.5) and systemic arterial stiffness (AIx 23.6±7.8) compared to the highest fitness group ( $p<.05$ ). Patients who achieved age predicted VO<sub>2</sub> peak had significantly lower cIMT, reduced aPWV and were less likely to have myocardial ischaemia ( $p<.05$ ). Clinical associates of VO<sub>2</sub> peak were BMI ( $r=-.343$ ,  $p<.001$ ), diabetes ( $r=-.380$ ,  $p<.001$ ), phosphate ( $r=-.343$ ,  $p<.001$ ), HbA1c ( $r=-.306$ ,  $p<.001$ ), physical activity ( $r=.219$ ,  $p=.026$ ) and LDL cholesterol ( $r=.239$ ,  $p=.016$ ). VO<sub>2</sub> peak was negatively associated with outcome; atheroma (cIMT,  $r=-.219$ ,  $p=.028$ ), diastolic function (E/e',  $r=-.283$ ,  $p=.004$ ), arterial stiffness (aPWV,  $r=-.373$ ,  $p<.001$ ) and (AIx,  $r=-.373$ ,  $p<.001$ ).

**CONCLUSION:** Low exercise capacity is associated with poor myocardial and vascular function in patients with CKD.

**Effects of Intradialyze Resistance Exercise in Chronic Kidney Disease Patients**

Bruna S. Lourenço, Marcos A. Nascimento, Thiago S. Rosa, Anderson S. Haro, Vicente N. Siqueira, Sergio Tufik, Marco T. Mello, Maria E. Canziani, Elisa S. Higa. Universidade Federal de São Paulo, São Paulo, Brazil.  
(No relationships reported)

The loss of body mass is common in chronic kidney disease (CKD) patients, and it is a great predictor of mortality in this population. Around 91% of the patients with CKD need hemodialysis as substitutive renal therapy (SRT). In Brazil the number of patients utilizing this treatment in 2009 was 77,589. The decrease of life quality in this population can also be attribute to other factors as psychological alterations, comorbidities, biological aging, malnutrition, oxidative stress, use of corticosteroids and the hemodialysis process itself. Studies show that resistance training (RT) can be efficient on power gain and improve to life quality in CKD patients, analyzed by questionnaires and functional capacity tests.

**PURPOSE:** Evaluate the strength values before and after RT, made intradialysis in CKD patients.

**METHODS:** There were recruited 11 patients in hemodialysis clinic Oswaldo Ramos (UNIFESP), we included both male and female patients with age between 20 and 76 yrs and dialysis treatment > 3 months. The body mass index (BMI) was 25.2± 5.2 characterizing overweight. Previous RT, the patients were submitted to exercise test, echocardiography and physical evaluation. Then, it was realized the 1 maximum repetition test (1MR), during the hemodialysis, before and after the training, in order to obtain strength values and exercise load estimative for each exercise. The RT was constituted of seven exercises, being: 3 to upper limb and 4 to lower limb realized on 6 weeks period, with exercise intensity of 40% of 1MR on the first 3 weeks and 60% of 1MR in the other weeks. Each session was composed of 3 series of 12 repetitions with two minutes resting intervals between the exercises. For data analysis (mean± standard error) it was utilized the t student test with value of  $P<.05$ .

**RESULTS:** On the 1MR tests we found strength increase (kg) after training, on the following exercises: shoulder press 8± 0.55 vs 7± 0.51; biceps 8±0.47 vs 7±0.61, triceps 5±0.56 vs 4±0.82 and leg extension 10± 1.32 vs 7± 0.70.

**CONCLUSIONS:** Intradialysis resistance exercise promotes power increase in CKD patients which may improve their life quality.

**Intradialytic Protein Supplementation Reduces Inflammation and Improves Physical Function**

Brandon M. Kistler<sup>1</sup>, Emily J. Tomayko<sup>1</sup>, Pei-Tzu Wu<sup>1</sup>, Peter J. Fitchen<sup>1</sup>, Hae Ryoung Chung<sup>1</sup>, Jin Hee Jeong<sup>1</sup>, Barbara Yudell<sup>1</sup>, Elizabeth Jeanes<sup>2</sup>, Shane A. Phillips<sup>2</sup>, Bo Fernhall, FACSM<sup>2</sup>, Kenneth R. Wilund<sup>1</sup>. <sup>1</sup>University of Illinois, Urbana, IL. <sup>2</sup>University of Illinois at Chicago, Chicago, IL.  
(No relationships reported)

In maintenance hemodialysis patients (MHD), high inflammation contributes to muscle wasting, cardiovascular disease, and bone-mineral disorders. Inflammation and poor nutrition status often occur in unison and therefore improving nutrition status may reduce inflammation and improve dialysis comorbidities.

**PURPOSE:** To determine the effects of intradialytic protein supplementation on markers of inflammation and physical function in MHD patients.

**METHODS:** Sixty MHD patients were randomly assigned to receive whey protein, soy protein, or placebo. On days separated by one week, blood was drawn both immediately after initiation of dialysis and again three hours later and analyzed for serum Interleukin-6 (IL-6). For the first day, subjects received no study beverage to measure baseline response to a single dialysis session. One week later, the subject consumed their study beverage immediately prior to the start of dialysis and blood was again collected as described. A subset of subjects (n=29) continued

to receive their respective study beverage during dialysis sessions for six months. Standard clinical laboratories were drawn monthly and High Sensitivity C - reactive protein (CRP), IL-6, and measures of physical function were measured at baseline and six months.

**RESULTS:** When no study beverage was provided, IL-6 increased during a single dialysis session in all groups. The rise in IL-6 was attenuated by intradialytic protein supplementation ( $p < 0.05$ ). At six months, repeated measures ANOVA revealed a time by treatment effect for reduced IL-6 with protein supplementation in relation to the control group ( $p < 0.05$ ). A similar but non-significant trend was observed for CRP ( $p > 0.089$ ). For functional measures, there was an interaction effect for shuttle walk with the whey group improving over six months ( $p < 0.05$ ).

**CONCLUSION:** Intradialytic protein supplementation attenuates the rise in inflammation during an individual dialysis session. Chronic supplementation reduces inflammation and improves physical function, suggesting intradialytic protein supplementation may represent a low-cost intervention to reduce inflammation and improve function in MHD patients.

**1484** Board #265 MAY 30 11:00 AM - 12:30 PM

**Physical Inactivity Causes Differential Changes in Vascular Gene Expression in Rat Iliac and Renal Arteries**

Jaume Padilla, Nathan T. Jenkins, Michael D. Roberts, M Harold Laughlin, FACSM, Frank W. Booth, FACSM. *University of Missouri, Columbia, MO.*

(No relationships reported)

It is now well established that local factors such as hemodynamic forces (e.g. shear stress) can modulate the susceptibility of the vasculature to dysfunction. In vivo, conduit arteries are constantly exposed to alterations in wall shear stress as a result of changes in blood flow demands in downstream tissues and/or changes in vasoconstriction tone. During running, blood flow is prominently increased in skeletal muscles of the rat hindlimb, but decreased in organs that are metabolically less active (e.g. kidney).

**PURPOSE:** Using our "rodent wheel lock (WL) model", we tested the hypothesis that the influence of short-term physical inactivity on vascular gene expression in the iliac and renal arteries would be divergent as a result of removal of episodic bouts of increased iliac artery blood flow and decreased renal artery blood flow associated with exercise.

**METHODS:** We used generation 4-5 female Wistar rats selectively bred to voluntarily run long distances. Following 23 days of access to voluntary running wheels (average distance of ~16 km/night), rats were rapidly transitioned to a sedentary state by locking the wheels for 7 days (WL 7 days;  $n=9$ ) or remained active (WL 0 days;  $n=9$ ) for 7 days. Real-time PCR was conducted on total RNA isolated from iliac and renal arteries to evaluate expression of 22 genes selected for their involvement in preservation of vascular health.

**RESULTS:** Compared to iliac arteries of WL 0-day rats, iliac arteries of WL 7-day rats exhibited increased expression of TNFR1 (1.2-fold), ET1 (1.6-fold), and LOX-1 (1.3-fold) (all  $p < 0.05$ ). Moreover, compared to renal arteries of WL 0-day rats, renal arteries of WL 7-day rats exhibited decreased expression of ETb (0.77-fold), p47phox (0.68-fold), and p67phox (0.81-fold) (all  $p < 0.05$ ).

**CONCLUSIONS:** These data provide evidence that changes in the expression of vascular cell genes with cessation of physical activity are artery-specific, and suggest that differential alterations in exercise-induced blood flow signals between the iliac and renal arteries may contribute to the heterogeneous influence of short-term physical inactivity on vascular gene expression. Support: NIH RO1HL036088, AHA 11POST5080002

**Focal Adhesion Kinase Expression in Heat-shocked Rat Soleus Muscle Following Eccentric Exercise**

Zachary A. Graham<sup>1</sup>, Chad Touchberry<sup>2</sup>, Paige Geiger<sup>3</sup>, Anishe Gupta<sup>3</sup>, Gregory Bumhoff<sup>3</sup>, Phil Gallagher<sup>1</sup>. <sup>1</sup>University of Kansas, Lawrence, KS. <sup>2</sup>University of Missouri, Kansas City, Kansas City, MO. <sup>3</sup>University of Kansas Medical Center, Kansas City, MO.

(No relationships reported)

Integrins are heterodimeric proteins that span the cell surface. They also detect stretch and coordinate intracellular protein signaling. One of these principal proteins, focal adhesion kinase (FAK), has been shown to coordinate hypertrophic and protective signaling in skeletal muscle. It has also been demonstrated that inducing heat shock protein 70 (Hsp70) prevents caspase-mediated degradation of FAK, possibly allowing it to maintain pro-survival signaling and providing an overall protective mechanism for the cell.

**PURPOSE:** The purpose of this study was to compare total and phosphorylated FAK in the soleus (SOL) muscle of rats following exercise-induced muscle damage.

**METHODS:** Male Wistar rats were randomly assigned to either a control group (CON), an eccentric exercise group (EE) (downhill running), or a heat shock (core temp 41°C for 20 min) + EE group (HS). SOL muscles were removed at 2h and 48h following exercise. Protein expression of FAK was determined using western immunoblotting and spot densitometry. A multivariate analysis of variance (MANOVA) was used to determine significance. Follow-up tests were conducted using one way ANOVAs and a Bonferroni test was used to adjust the level of significance.

**RESULTS:** Total FAK was significantly lower in the EE and HS groups when compared to CON 2h post-exercise. There were no significant differences in total FAK in the 48hr group. There were also no differences in phosphorylated FAK at either 2hr or 48hr post-exercise.

**CONCLUSION:** Eccentric exercise, regardless of heat treatment, causes a decrease in total FAK expression in rat soleus muscle two hours post-exercise.

Research supported, in part, by a University of Kansas General Research Fund grant (P. Gallagher).

**Strain-Dependent Protein Metabolism and Muscle Hypertrophy under Chronic Isometric Training of Rat Gastrocnemius Muscle**

Koji Kobayashi<sup>1</sup>, Riki Ogasawara<sup>2</sup>, Arata Tsutaki<sup>1</sup>, Kihyuk Lee<sup>1</sup>, Eisuke Ochi<sup>3</sup>, Koichi Nakazato<sup>1</sup>. <sup>1</sup>Nippon Sport Science University, Tokyo, Japan. <sup>2</sup>The University of Tokyo, Tokyo, Japan. <sup>3</sup>Meiji Gakuin University, Kanagawa, Japan.

(No relationships reported)

Skeletal muscle size is regulated by both protein synthesis and degradation. Appropriate mechanical stimulation of skeletal muscles induces muscle hypertrophy characterized by enhanced protein synthesis. Conversely, muscle unloading induces atrophy characterized by increased protein degradation. Because several studies have shown the presence of strain-dependent differences in rat skeletal muscles (i.e., myosin heavy chain [MHC] composition), we hypothesized that muscle responses to resistance training (RT) might be strain dependent.

**PURPOSE:** We examined the levels of molecules related to protein synthesis/degradation to elucidate strain-dependent responses to isometric RT in 2 rat strains.

**METHODS:** Isometric resistance exercise involving only the right legs of male Sprague-Dawley (SD) ( $n = 5$ ) and Wistar rats ( $n = 6$ ) was performed for 2 days (2 sessions) followed by rest for 1 day (Total 12 sessions). Twenty-four hours after the last session, the gastrocnemius (GST) muscles were harvested. The levels of target proteins were analyzed by western blotting. Paired t-test was used to evaluate differences between the trained leg (TRN) and control leg (CON). GST mass, GST mass relative to body mass, MHC isoform, and the levels of proteins involved in protein synthesis/degradation (Akt, mTOR, p70<sup>S6k</sup>, FOXO1, FOXO3a, MuRF1, and MAFbx/atrogen-1) were measured.

**RESULTS:** After RT, fast (IIB) to slow (IIX) MHC isoform transition was observed in the 2 strains. In the case of the SD rats, muscle mass and muscle mass relative to body mass in the TRN group were significantly higher than those in the CON group (8.5% and 8.6%, respectively,  $p < 0.05$ ). In the case of the Wistar rats, the 2 groups did not differ significantly. In the case of the SD rats, the level of p70<sup>S6k</sup> (2.9-fold,  $p < 0.05$ ) and FOXO3a (2.2-fold,  $p < 0.05$ ) phosphorylation increased in the TRN group, compared to the CON group. Further, decreased expressions of MuRF-1 (0.6-fold,  $p < 0.05$ ) and MAFbx/atrogen-1 (0.7-fold,  $p < 0.05$ ) were observed in the TRN group of SD rats. In the case of the Wistar rats, the 2 groups did not differ significantly with regard to protein levels.

**CONCLUSIONS:** Strain-dependent protein metabolism and hypertrophy exists in rat skeletal muscles. This phenomenon may be useful for studying individual differences in response to RT.

**The Effect Of High Intensive Physical Exercise In Expression Of Myostatin And Smad7 In Skeletal Muscle**

Hakan C. Rundqvist, Mona Esbjörnsson, Ted Österlund, Eva Jansson. *Clinical Physiology, Laboratory Medicin, Karolinska Institutet, Stockholm, Sweden.*  
(No relationships reported)

Myostatin is a negative regulator of muscle growth and a member of the transforming growth factor- $\beta$  family partly by being a negative regulator of satellite cells proliferation and differentiation and plays thereby a critical role in development, repair and regeneration of 'adult' muscle. It is produced within the muscle cell thereafter transported out of the cell and binds to the activin receptor 2b, which is located in the cell membrane. The binding to act2b receptor activates the type 1 receptor enhancing SMAD-signaling. Myostatin gene expression has been shown, by others, to increase following periods of muscle inactivity and decrease following acute resistance training. We have found that myostatin also decreases after sprint exercise (unpublished observation). How the myostatin gene expression is regulated in these situations is not known. From cell studies, it has been shown that myostatin auto-regulates its own expression through a SMAD7-dependent negative feedback loop.

**PURPOSE:** To test the hypothesis that SMAD7 is involved in the regulation of the gene expression of myostatin in human skeletal muscle after sprint exercise.

**METHODS:** Healthy, physically active and young men and women (n=17) performed three bouts of sprint exercise with 20 minutes rest in between. Muscle biopsies were obtained from quadriceps femoris vastus lateralis at rest and 140 minutes after third bout of exercise. The gene expression of myostatin and SMAD7 was related to rps18 (housekeeping gene) and analyzed by real time-PCR technique. The myostatin at the protein level was analyzed by Western blot technique.

**RESULTS:** Gene expression of SMAD7 increased by 53 % (p<0.0006) and gene expression of myostatin decreased by 52 % (p<0.013). Myostatin at the protein level, did not change by sprint exercise.

**CONCLUSION:** This is, to our knowledge, the first study analyzing SMAD7 in human skeletal muscle after exercise. The increased SMAD7 together with the decreased myostatin gene expression in skeletal muscle after sprint exercise support earlier cell studies showing that SMAD7 is involved in the auto regulation (feed-back regulation) of myostatin gene expression.

**Temporal Resolution of PGC-1 $\alpha$  Splice Variants in Human Skeletal Muscle After One Bout of Exercise**

Eva-karin Sällstedt, Mia Ydfors, Jessica Norrbom. *Karolinska Institutet, Department of Physiology & Pharmacology, Stockholm, Sweden.*  
(No relationships reported)

Increased mitochondrial and capillary densities are central components of skeletal muscle remodeling in response to exercise. The transcription co-activator peroxisome proliferator-activated receptor  $\gamma$  coactivator-1 $\alpha$  (PGC-1 $\alpha$ ) has been shown to be important for this coordination of multiple processes in training-induced skeletal muscle remodeling. Recently, our lab showed for the first time that at least two splice variants of PGC-1 $\alpha$  (PGC-1 $\alpha$ -a and PGC-1 $\alpha$ -b) exist in human skeletal muscle and that they are highly regulated with exercise.

**PURPOSE:** To investigate the temporal resolution of PGC-1 $\alpha$  and its splice variants after one acute bout of cycle exercise. Also, to study transcription factors important for mitochondrial biogenesis regulated by PGC-1 $\alpha$ , namely NRF-1, Tfam and TFB1M.

**METHODS:** Healthy men (n=4) and women (n=3) performed one hour of cycling exercise at 70 % of their VO<sub>2</sub>max. Skeletal muscle biopsies were obtained before and after exercise (pre, 30', 2h, 6h and 24h).

**RESULTS:** PGC-1 $\alpha$ -b mRNA increased significantly at 2h and 6 h after exercise compared to pre-values (p<0.01), and had returned to baseline levels at 24 h after the exercise bout. Neither PGC-1 $\alpha$ -a nor total PGC-1 $\alpha$  showed a significant change in mRNA levels in response to exercise. There was no significant change in NRF-1, Tfam or TFB1M mRNA levels after one bout of cycle exercise.

**CONCLUSIONS:** This study shows that an upstream promoter of PGC-1 $\alpha$  (PGC-1 $\alpha$ -b) is massively induced up to 6 h after exercise by a single exercise bout, and that the levels were back to baseline at 24 h after exercise. This implies that the exercise-induced PGC-1 $\alpha$  response is more complex than previously suggested. The lack of significant change in PGC-1 $\alpha$ -a and total PGC-1 $\alpha$  levels is likely due to the low number of subjects.

**mTORC2 Is Activated In Muscle During Exercise And Regulates Contraction Induced Glucose Uptake**

Maximilian Kleinert, Lykke Sylow, Erik A. Richter. *University of Copenhagen, Copenhagen, Denmark.*  
(No relationships reported)

**PURPOSE:** Two distinct mTOR complexes (mTORCs) have been defined. While mTORC1 serves as a regulator of protein synthesis, mTORC2 has been found to be downstream of PI3K and to phosphorylate Akt on Ser 473. However, little is known about the physiological importance of mTORC2 in skeletal muscle during muscle contractions. Here we test the hypothesis that mTORC2 is activated during exercise and might be involved in contraction-induced glucose uptake in skeletal muscle.

**METHODS:** mTORC2 activity was judged by phosphorylation of its downstream target N-myc downregulated gene 1 (NDRG1) on the Thr346 residue. Mice ran for 30 min on a treadmill at 70% of their individual maximal running capacity, or EDL and soleus muscles were incubated in vitro and stimulated with insulin or contracted in the presence or absence of pharmaceutical inhibitors. Radioactive tracers were used to estimate glucose uptake.

**RESULTS:** In vivo running increased NDRG1 Thr346 phosphorylation by 60% (p < 0.05) compared to resting controls in gastrocnemius muscle. To test whether the running induced increase in mTORC2 activity was dependent upon AMPK activity, NDRG1 Thr346 phosphorylation was measured in mice that overexpress a kinase-dead alpha 2 subunit of the AMPK protein in skeletal muscle (AMPK-KD). In these mice NDRG1 Thr346 phosphorylation increased significantly to the same extent as in WT mice. Treatment of mouse soleus muscles with the total mTOR inhibitor, AZD8055, blocked basal and insulin stimulated NDRG1 Thr346 phosphorylation (p < 0.001) and inhibited Akt phosphorylation and glucose uptake, while rapamycin (a mTORC1 specific blocker) treatment had no effect. In EDL muscle AZD8055 had no effect on insulin stimulated glucose uptake despite ablation of Akt and NDRG1 phosphorylation. During in vitro contractions AZD8055 reduced contraction induced glucose uptake by 23% (p < 0.05) in EDL. In soleus the inhibitor had no effect on contraction induced glucose uptake. While AZD8055 reduced NDRG1 Thr346 phosphorylation to almost undetectable levels, AMPK Thr172 phosphorylation was unaffected by the blocker and increased about 2-fold with contractions in both EDL and soleus (p < 0.05).

**CONCLUSIONS:** It is concluded that mTORC2 is activated in muscle during exercise and has muscle specific effects on insulin and contraction induced glucose uptake.

**Enhanced As160 Phosphorylation In Response To Sprint Exercise In Severe Acute Hypoxia**

David Morales-Alamo, Amelia Guadalupe-Grau, Jesús Gustavo Ponce-González, Ismael Pérez-Suárez, David Feijoo-Díez, Jaime Calle-Herrero, Alfredo Santana, Cecilia Dorado, Jose A L Calbet, Borja Guerra. *Universidad De Las Palmas De Gran Canaria, Las Palmas, Spain.*  
(No relationships reported)

Muscle glucose uptake is increased during exercise in hypoxia. Akt is activated through phosphorylation on Ser<sup>473</sup> and Thr<sup>308</sup>. Although Akt phosphorylation in these residues could be regulated independently, a higher Akt activity has been reported when both sites are phosphorylated. Acute sprint exercise elicits Ser<sup>473</sup> Akt phosphorylation that subsequently induces AS160 phosphorylation, which may facilitate muscle glucose uptake.

**PURPOSE:** To determine if severe acute hypoxia enhances the skeletal muscle Akt/AS160 phosphorylation response to sprint exercise.

**METHODS:** Ten healthy physical males (age: 25±5 yrs; VO<sub>2</sub>max: 51±6 ml.kg<sup>-1</sup>.min<sup>-1</sup>; means ± SD) performed on separate days and random order two 30s-isokinetic Wingate test at 100 rpm in normoxia and hypoxia (F<sub>I</sub>O<sub>2</sub>=0.10). Blood samples and muscle biopsies were obtained before, at the end of the test, and at 30 and 120 min into the recovery period. Akt, p38-MAPK, ERK1/2, and AS160 phosphorylation levels and the protein expression of the total form of these kinases was determined by western blot.

**RESULTS:** Peak power output and peak blood lactate were similar, but mean power output was 6% and VO<sub>2</sub> 37% lower in hypoxia than in normoxia (P<0.05). At the end, and thirty minutes after the Wingate test, insulin and glucose serum concentrations were increased by a 10-24% (P<0.05). Compared to rest, thirty and 120 minutes after the Wingate tests, Ser<sup>473</sup>-Akt

phosphorylation was increased by 117% and a 14%, respectively, ( $P < 0.05$ ). Thr<sup>308</sup>-Akt phosphorylation was elevated 1.4-fold just after the Wingate test and remained elevated during the first 2 hours after the test ( $P < 0.05$ ). p38-MAPK and ERK1/2 phosphorylations did not change significantly after the sprints. Compared to rest, AS160 phosphorylation was 50% greater 30 minutes after Wingate performed in hypoxia ( $P < 0.05$ ).

**CONCLUSIONS:** Isokinetic sprint exercise in severe acute hypoxia elicits an essentially similar signaling response to that observed in normoxia, with the exception of a slightly higher AS160 phosphorylation.

### Molecular Responses in Skeletal Muscle to Resistance Training in Older Men

Juha P. Ahtiainen<sup>1</sup>, Juha J. Hulmi<sup>1</sup>, Maarit Lehti<sup>2</sup>, William J. Kraemer<sup>3</sup>, Kai Nyman<sup>4</sup>, Harri Selänne<sup>2</sup>, Markku Alen<sup>5</sup>, Jyrki Komulainen<sup>2</sup>, Vuokko Kovanen<sup>1</sup>, Antti A. Mero<sup>1</sup>, Keijo Häkkinen<sup>1</sup>. <sup>1</sup>University of Jyväskylä, Jyväskylä, Finland. <sup>2</sup>LIKES Research Center for Sport and Health Sciences, Jyväskylä, Finland. <sup>3</sup>University of Connecticut, Storrs, CT. <sup>4</sup>Jyväskylä Central Hospital, Jyväskylä, Finland. <sup>5</sup>University of Oulu, Oulu, Finland.

(No relationships reported)

IGF-I and its splice variant mechano growth factor (MGF) has been suggested to be involved in skeletal muscle regeneration via Erk and/or Akt pathways. Both of these pathways can control protein translation by p70S6K1. Effects of heavy resistance training (RT) on these regulating proteins are still, however, mostly unknown.

**PURPOSE:** To determine changes in skeletal muscle MGF, Erk, Akt and p70S6K1 protein concentrations and IGF-IEa and MGF mRNA expression following RT, and their associations with RT-induced changes in muscle strength and mass.

**METHODS:** Healthy untrained older men ( $61 \pm 5$  yrs,  $177 \pm 3$  cm,  $80 \pm 5$  kg,  $24 \pm 3$  fat%) were recruited for the study. RT comprised whole body resistance exercises twice a week with a progressively increased training load for 21 weeks. Maximal concentric strength of leg extensors (1RM), fat free mass (FFM; by bioimpedance) and m.vastus lateralis (VL) thickness (by ultrasound) were measured pre- and post-RT. Experimental heavy resistance exercises (RE; 5 x 10RM leg presses with 2-minute recovery periods) were performed pre- and post-RT. Muscle biopsies were obtained before and 48h after the REs from VL to determine molecular responses during the regeneration phase after RE.

**RESULTS:** RT led to increases in 1RM ( $20.8 \pm 8.7$  %,  $p < 0.001$ ), FFM ( $1.6 \pm 2.0$  %,  $p < 0.05$ ) and VL thickness ( $13.6 \pm 5.0$  %,  $p < 0.001$ ). Present muscle proteins or mRNAs were not systematically influenced by the REs or RT, except MGF mRNA expression was increased ( $p < 0.01$ ) after RE before the RT. Changes in 1RM correlated with changes in VL thickness ( $r = 0.74$ ,  $p < 0.05$ ). When RE-induced changes at pre- and post-RT were averaged, MGF protein ( $r = 0.70$ ,  $p < 0.05$ ) and Erk ( $r = 0.67$ ,  $p < 0.05$ ) were related to changes in 1RM. Changes in pre- to post-RE responses in p70S6K1 were related to changes in FFM ( $r = 0.71$ ,  $p < 0.05$ ). Changes in Akt from pre- to post-RT were related to changes in FFM ( $r = 0.72$ ,  $p < 0.05$ ).

**CONCLUSIONS:** Present study demonstrated that the basal levels or RE-induced responses in skeletal muscle MGF, Erk, Akt and p70S6K1 protein concentrations or IGF-IEa and MGF mRNA expression did not change systematically due to RT in older men. However, individual changes in MGF and Erk protein concentrations may be related to RT-induced changes in muscle strength, and changes in Akt and p70S6K1 may be associated with RT-induced changes in lean body mass.

### Contraction-Induced rpS6 Phosphorylation Is Attenuated After Chronic Resistance Training But Recovered After Short-Term Detraining

Riki Ogasawara<sup>1</sup>, Koji Kobayashi<sup>2</sup>, Arata Tsutaki<sup>2</sup>, Kihyuk Lee<sup>3</sup>, Takashi Abe<sup>3</sup>, Satoshi Fujita<sup>4</sup>, Koichi Nakazato<sup>2</sup>, Naokata Ishii<sup>1</sup>. <sup>1</sup>University of Tokyo, Tokyo, Japan. <sup>2</sup>Nippon Sport Science University, Tokyo, Japan. <sup>3</sup>University of Oklahoma, Norman, OK. <sup>4</sup>Ritsumeikan University, Shiga, Japan.

(No relationships reported)

Resistance training-induced muscle anabolism and subsequent hypertrophy is most rapid during early phase of training, and it becomes progressively slower with time. However, little is known about the intracellular signaling mechanisms underlying such changes in sensitivity of muscle to training stimulus.

**PURPOSE:** To investigate the changes in exercise-induced activation (phosphorylation) of signaling proteins associated with muscle protein anabolism during chronic resistance training and subsequent detraining.

**METHODS:** Twenty male SD rats were divided into 4 groups: one bout group (1B), 12 bouts group (12B), 18 bouts group (18B), and detraining group (DT). In the DT group, rats were detrained for 12 days after completion of 12 exercise sessions and then completed one exercise session before sacrificed. The right gastrocnemius muscle was isometrically trained (maximum isometric contraction was produced via percutaneous electrical stimulation) every other day, whereas the left gastrocnemius muscle served as an internal control (CON). Muscles were removed 24 h after the last exercise session. Phosphorylation and total protein levels of p70S6K, 4E-BP1, rpS6, and p90RSK were determined by Western blotting.

**RESULTS:** The wet weight of exercised muscle increased by 8.6% in 12B and 10.7% in 18B group ( $P < 0.05$  vs CON). Twelve days of detraining did not decrease muscle wet weight (8.8% above the weight of CON;  $P < 0.05$  vs CON,  $P > 0.1$  vs 12B) in DT group. Acute exercise increased p70S6K (1.3-fold), 4E-BP1 (1.8-fold), rpS6 (3.1-fold), and p90RSK (1.8-fold) phosphorylation 24 h after exercise in 1B group (all  $P < 0.05$  vs CON). However, repeated bouts of exercise blunted the phosphorylation of rpS6 and p90RSK in 12B or 18B groups (rpS6: 0.9- and 1.8-fold, p90RSK: 1.0- and 1.0-fold, all  $P > 0.1$  vs CON). Interestingly, the phosphorylation of rpS6 and p90RSK were restored following 12 days of detraining in DT group (rpS6: 2.6-fold, p90RSK: 2.0-fold, both  $P < 0.05$  vs CON). Phosphorylation of p70S6K and 4E-BP1 were not altered with chronic training and detraining.

**CONCLUSION:** These results suggest that with chronic resistance training, specific signaling become less sensitive to resistance exercise stimulus even muscle is contracted maximally but those are restored after a short detraining period without attenuation of muscle mass.

### Botanical Supplement Effects On Nuclear Factor Kappa B (NF-κB) DNA-binding Activity Following Eccentric Exercise

Ling Xin<sup>1</sup>, Shyam Ramakrishnan<sup>2</sup>, Robert D. Hyldahl<sup>1</sup>, Karen L. Riska<sup>1</sup>, Stuart Chipkin<sup>1</sup>, Monica J. Hubal, FACSM<sup>3</sup>, Mary A. Murray<sup>2</sup>, Valerie Greger<sup>4</sup>, Prakash Prabhakar<sup>4</sup>, Karen Shaver<sup>4</sup>, Priscilla M. Clarkson, FACSM<sup>1</sup>. <sup>1</sup>UMass at Amherst, Amherst, MA. <sup>2</sup>Nutrilite Health Institute, Buena Park, CA. <sup>3</sup>Children's National Medical Center, Washington, DC. <sup>4</sup>Interleukin Genetics, Inc., Waltham, MA.

(No relationships reported)

Inflammation and oxidative stress contribute to exercise-induced muscle damage (EIMD). NF-κB is an important redox-sensitive molecule that increases gene expression of many pro-inflammatory mediators. Because evidence has shown that NF-κB signaling pathway is activated after exercise, antioxidant supplements may exert beneficial effects against EIMD via inhibiting NF-κB activation.

**PURPOSE:** To examine the effects of two novel botanical supplements containing mixtures of plant extracts with anti-inflammatory and antioxidant properties on NF-κB DNA-binding activity following eccentric exercise.

**METHODS:** 26 healthy men (18-30yrs) were randomly assigned to receive the placebo (N=8), Supplement 1 (N=10), or Supplement 2 (N=8) for 35d. Stage 1 - subjects exercised one leg (knee extensors) and a muscle biopsy of both legs (vastus lateralis) was taken at ~3.5h post-exercise; Stage 2 - subjects took supplements or placebo for 28d; Stage 3 - subjects repeated the exercise and tests with the contralateral leg. NF-κB DNA-binding activity of biopsy samples was measured using ELISA-based TransAM NF-κB p65 assay kit (Active Motif, Carlsbad, CA). Data were expressed as either absorbance at 450 nm or the percentage of p65 DNA-binding activity of eccentric exercised (ECC) leg relative to control (CON) leg. Paired t-test and repeated measures ANOVA were performed to analyze the data.

**RESULTS:** p65 DNA-binding activity was increased following eccentric exercise in both Stage 1 (ECC  $0.24 \pm 0.01$  vs. CON  $0.20 \pm 0.01$  (Mean  $\pm$  SE);  $p < 0.001$ ) and Stage 3 (EC  $0.22 \pm 0.01$  vs. CON  $0.21 \pm 0.01$ ;  $p < 0.05$ ). Compared with Stage 1 (122.9%  $\pm$  2.6%), NF-κB DNA-binding activity was significantly decreased in Stage 3 (109.1%  $\pm$  3.0%;  $p = 0.002$ ). There was no significant Treatment effect or Treatment X Stage interaction.

**CONCLUSION:** The botanical supplements had no effect on changes in NF-κB DNA-binding activity following eccentric exercise. However, the increased response of NF-κB DNA-binding activity post-exercise was attenuated in Stage 3. This attenuation effect may be due to a blunted systemic inflammatory response following a repeated bout of eccentric exercise with the contralateral leg.

1494 Board #275 MAY 30 11:00 AM - 12:30 PM

**Rapid Ryanodine Receptor-1 Phosphorylation In Response To High Intense Resistance Exercise In Human Skeletal Muscle**

Frank Suhr<sup>1</sup>, Sebastian Gehler<sup>1</sup>, Lena Willkomm<sup>1</sup>, Yüksel Korkmaz<sup>2</sup>, Kurt Pfannkuche<sup>3</sup>, Wilhelm Bloch<sup>1</sup>. <sup>1</sup>German Sport University Cologne, Cologne, Germany. <sup>2</sup>Heinrich Heine University Duesseldorf, Duesseldorf, Germany. <sup>3</sup>University of Cologne, Cologne, Germany.  
(No relationships reported)

**BACKGROUND:** Resistance exercise is a common mode to increase muscle strength. However, severe resistance exercise leads to rapid and enduring muscle fatiguing which functional mechanisms have not been fully resolved, yet. One candidate involved in the regulation of myocellular fatigue is calcium (Ca<sup>2+</sup>) which is vital for electromechanical coupling of myofilaments. Rapid Ca<sup>2+</sup> modulation is mediated by ryanodine receptor-1 (RyR1), which, when phosphorylated at serine<sup>2844</sup> (pRyR1Ser<sup>2844</sup>) results in leaky ryanodine calcium channels, impaired calcium homeostasis and thus decreased abilities to sustain the molecular basis of electromechanical coupling. However, little is known about the time course and magnitude of acute exercise on pRyR1Ser<sup>2844</sup> phosphorylation in human skeletal muscle.

**PURPOSE:** It was aimed to investigate the effect of acute resistance exercise (EX) on pRyR1Ser<sup>2844</sup> phosphorylation (phosph.) in human type I and II myofibers.

**METHODS:** Six healthy male subjects (age: 23 ± 2 years, height: 185 ± 7 cm, and weight: 82 ± 5 kg) performed 3 sets with 8 repetitions of maximum eccentric knee extensions. Muscle biopsies were taken PRE exercise, 15 min, 30 min, and 60 min post EX. Immunohistochemistry, western blots and confocal microscopy were used to determine pRyR1Ser<sup>2844</sup> and pAMPK<sup>Thr172</sup> phosph. levels at the respective time points.

**RESULTS:** pRyR1Ser<sup>2844</sup> phosph. increased rapidly at 15 min in both type I and II myofibers (p<0.01) and further showing a sustained phosph. pattern up to 30 min (p<0.01) post EX. Compared to baseline levels, type I fibers showed higher increases in phosph. levels of RyR1 up to 60 min post EX (p<0.05) than type II myofibers. pAMPK<sup>Thr172</sup> phosph. showed significant increases 15 to 30 min post EX (p<0.01) in type I and II myofibers with a higher increase in phosph. levels in Type I myofibers.

**CONCLUSION:** Severe resistance exercise contributes to temporarily increased phosph. of RyR1 and AMPK due to active recruitment of myofibers. This result supports the hypothesis that RyR1 can be rapidly phosphorylated by resistance exercise and very likely contributes to muscle fatiguing by a decline in calcium handling properties. Enhanced phosph. of RYR1 is sustained up to 60 min post EX in both myofibers what may contribute up to this time point to impaired skeletal muscle contraction abilities.

**Ryr-1 Phosphorylation Responds Differently Between Concentric And Eccentric Workload In Rat Skeletal Muscle**

Kristina Braun, Sebastian Gehler, Wilhelm Bloch, Lena Willkomm, Frank Suhr. German Sport University Cologne, Cologne, Germany.  
(No relationships reported)

**BACKGROUND:** Calcium (Ca<sup>2+</sup>) handling in skeletal muscle regulates to diverse pathologies and performance capacities as Ca<sup>2+</sup> is involved in muscle contraction machinery. Ca<sup>2+</sup> homeostasis is mainly regulated by transmembrane channel complexes of sarcoplasmic reticule, called ryanodine receptor-1 (RyR1). RyR1 associates to many regulatory proteins, of which calstabin-1 plays a key role. It was described that long-lasting exercise models hyperphosphorylate RyR1 at Ser2843 and thus induce a leaky channel leading to impaired muscle function by dissociating calstabin-1 from RyR1. However, time patterns of RyR1 hyperphosphorylation (pRyR1) is unknown wherefore short-term exercise stimuli and their effects on pRyR1 were investigated.

**PURPOSE:** It was aimed to investigate whether concentric and eccentric exercise offers a different impact on ryanodine receptor phosphorylation in loaded rat skeletal muscle.

**METHODS:** 32 Sprague-Dawley rats were assigned to one of following groups: age-matched control (AC, sedentary), concentric (Conc, 0° decline) or eccentric (Ecc, -20° decline) exercise (each exercise lasted 15 min). pRyR1 was investigated by immunohistochemistry in both medial gastrocnemius and vastus lateralis.

**RESULTS:** In lateralis muscle 15 min of either concentric or eccentric led to markedly increased levels of pRyR1 compared to AC. Furthermore, concentric led to significantly higher amounts of pRyR1 compared to eccentric exercise. In gastrocnemius muscle a similar pattern was observed. However, there was no difference between concentric and eccentric stimuli. Discussion: The present results demonstrate that RyR1 is hyperphosphorylated very fast, which is an additional finding compared to data from the literature. Importantly, different muscle types react in a comparable manner. Interestingly, concentric exercise seems to exert a more severe effect on RyR1 hyperphosphorylation, at least in lateralis. These findings give new insights into RyR1 regulation by exercise.

**Igf-1 Downstream Signaling Response To Protein Rich Supplementation During Hindlimb Suspension**

Taejeong Song. University of Texas at Austin, Austin, TX.  
(No relationships reported)

It was known that anabolic signals were suppressed and catabolic signals were activated during prolonged muscle disuse, but the exact underlying molecular mechanisms are unclear. High protein supplementation has been recognized to increase the rate of muscle protein synthesis and activate anabolic signaling pathways (ex. IGF-1) and was employed in this study.

**PURPOSE:** To examine whether high protein supplementation would elevate phosphorylation of Akt and downstream pathways and maintain muscle function during hindlimb suspension (HS).

**METHODS:** Lower limbs of female rats were subjected to be unloaded by tail suspension for 28 days. During this period, one group (HS-PRO) was provided high protein supplementation (5ml/kg body weight), but others (HS) was received water via gavage twice per day, and ambulatory rats were served as control group (CON). After 28 days, contractile function of lateral gastrocnemius (LGAS) was evaluated, and both LGAS were excised and stored at -80°C. Total and phosphorylated levels of Akt, mTOR, p70S6K, and FOXO3a were measured from the sampled muscle by Western blot analysis.

**RESULTS:** LGAS weight was significantly decreased in HS and HS-PRO compared to that of CON at 28 days after HS, -19 and -22.5% respectively (P <0.01). However, in-situ peak tetanic force (Po) of HS-PRO was significantly higher than HS by 12% (P<0.05) but lower than CON by 25% (P<0.01). Phosphorylation of Akt in HS-PRO was significantly increased to CON, and pFOXO3a was also elevated in HS-PRO compared to CON and HS (P<0.05 and P<0.01 respectively). In addition, the supplementation prevented the reduction of mTOR phosphorylation during HS, -31 and -34% compared to CON and HS-PRO respectively (P <0.05), but there was no difference in p70S6K phosphorylation between groups. Total protein contents of all detected signals were not changed.

**CONCLUSION:** Although protein rich supplementation was not able to prevent the loss of muscle mass during prolonged HS, it reduced the decrease of contractile function, and elevated pAkt and pFOXO3a while maintained pmTOR .

---

1497 Board #278 MAY 30 11:00 AM - 12:30 PM

**Influence Of Age On Leptin Induced Skeletal Muscle Signalling**

Amelia Guadalupe-Grau<sup>1</sup>, Steen Larsen<sup>2</sup>, Borja Guerra<sup>1</sup>, Flemming Dela<sup>3</sup>, Jørn W Helge<sup>3</sup>. <sup>1</sup>University of Las Palmas de Gran Canaria, Las Palmas de Gran Canaria, Spain. <sup>2</sup>Copenhagen University, Copenhagen, Denmark. <sup>3</sup>University of Copenhagen, Copenhagen, Denmark.  
(No relationships reported)

Aging is a multifactorial process that is characterized by decreased physical activity, low fat-free mass and reduced ability to mobilize fat. Leptin is an adipocyte-derived hormone where systemic levels increases in proportion with adiposity. Chronic hyperleptinemia leads to leptin resistance, as indicated by a lower abundance of leptin receptors (OBRb), and reduced phosphorylation of STAT3 and AMPK in human skeletal muscle. The potential contribution of leptin resistance to the increase of fat mass with aging has not yet been elucidated.

**PURPOSE:** To determine if there is indication of increased skeletal muscle leptin resistance with aging, the basal amount of leptin receptors and the phosphorylation levels of STAT3 and AMPK, as well as the protein amount of SOCS3 and PTP1B (the last two leptin signalling inhibitors) was assessed in healthy young and aged non-obese adults.

---

**METHODS.** Muscle biopsies were obtained in fourteen young (YG), seventeen middle-aged (MG), and eight aged (AG) healthy lean men (age:  $25 \pm 2$ ,  $46 \pm 1$ ,  $62 \pm 2$  yrs, and BMI:  $24.3 \pm 0.5$ ,  $25.5 \pm 0.3$ ,  $25.0 \pm 0.7$  kg/m<sup>2</sup>, respectively). Protein expression of OBRb, STAT3, AMPK, PTP1B and SOCS3 was measured by Western Blot. Plasma leptin, glucose, insulin and FFA were measured by conventional assays. Insulin sensitivity was estimated by HOMA. Body composition was measured by DXA.

**RESULTS.** Fat mass, FFA and leptin plasma concentrations were higher in MG and AG group than YG ( $P < 0.05$ ), whereas HOMA values did not differ between the groups. OBRb protein abundance was similar among groups; however, Thy705STAT3 phosphorylation was lower in AG and MG compared to YG ( $0.29 \pm 0.05$ ;  $0.32 \pm 0.11$  and  $0.63 \pm 0.20$  a.u., respectively,  $P < 0.05$ ). Surprisingly, Thr172AMPK $\alpha$  phosphorylation was 2-fold higher in AG than in MA and YG groups ( $2.94 \pm 0.05$ ;  $1.32 \pm 0.29$  and  $1.74 \pm 0.17$  a.u., respectively,  $P < 0.05$ ). SOCS3 expression remained unchanged, whereas PTP1B expression was higher in the AG compared with MG and YG ( $P < 0.05$ ).

**CONCLUSION.** Skeletal muscle 170 KDa OBRb protein amount is not affected by aging. However, a lower basal phosphorylation of Thy705STAT3 and a higher abundance of PTP1B suggest that leptin resistance is increased with aging in healthy lean males. It is possible that increased phosphorylation of Thr172AMPK $\alpha$  is a compensatory mechanism to attenuate this.

---

**1498** Board #279 **MAY 30** **11:00 AM - 12:30 PM**

**Short-Term Unloading and Exercise Effects on Mechanical Stress-Sensitive Structural and Sensor Proteins in Human Soleus**

Clay E. Pandorf, Fadia Haddad, Joshua A. Cotter, Kenneth M. Baldwin, FACSM, Vincent J. Caiozzo, FACSM, Gegory R. Adams. *University of California, Irvine, Irvine, CA.*

(No relationships reported)

Loading forces are critical to maintaining homeostasis in the muscle cell. Perturbations, such as unloading/disuse, upset the normal gene expression of structural and signaling proteins. Exercise countermeasures can offset these alterations.

**PURPOSE:** To examine gene expression of several large sarcomeric proteins that provide structural support to the myofilament (titin, nebulin and  $\alpha$ -actin) and converge at the Z-disc. Since evidence suggests that loading forces in the muscle may be transmitted by structural support proteins that integrate mechanical stress at the Z-disc, we also examined several signaling proteins that reside in this region (STARS, atrogin-1, and calcineurin via its modulator MCIP1) and can in-turn regulate the expression of sarcomeric genes.

**METHODS:** Two groups of healthy inactive human subjects participated in unilateral lower limb suspension (ULLS; male N=5; female N=4) for 10 days alone or with a combination of aerobic and resistance exercise training (ULLS+T; male N=5; female N=5). Soleus biopsies were obtained before and after ULLS; ULLS+T biopsies were obtained ~24 hrs after the last training session. RT-PCR was used to quantify pre-mRNA and mRNA levels of select genes (arbitrary units/mg).

**RESULTS:** Nebulin, titin and  $\alpha$ -actin RNA levels changed pre to post by -11%, +26% and +7% with ULLS, and by +25%\*, +56%\* and +16% with ULLS+T, respectively (\* $p < 0.05$  pre to post). STARS, atrogin1 and MCIP1 mRNA levels changed pre to post by -75%\*, +77%\* and -40%\* with ULLS, and by -63%\*, +30%\* and -26%\* with ULLS+T, respectively (\* $p < 0.05$  pre to post).

**CONCLUSIONS:** While changes in transcription of the Z-disc associated structural proteins nebulin and titin following 10d unloading was not statistically significant, there was significant upregulation with unloading + training stimuli. The unfavorable unloading-induced signaling response was ameliorated when combined with training as suggested by differential mRNA levels of mechano-sensitive Z-disc factors that can promote atrophy (atrogin) and fiber-type shifts (calcineurin/MCIP1). These data suggest that exercise countermeasures to short-term unloading of the loading-sensitive slow soleus muscle can promote favorable transcriptional responses of proteins associated with the stress-sensitive Z-disc. (Supported by NSBRI-NASA NCC 9-58)

**Sumo-1 Rapidly Translocates In Human Skeletal Muscle Myonuclei In Response To High Intense Resistance Exercise**

Sebastian Gehlert<sup>1</sup>, Suhr Frank<sup>1</sup>, Lena Willkomm<sup>1</sup>, Franz-Josef Klimz<sup>2</sup>, Wilhelm Bloch<sup>1</sup>. <sup>1</sup>German Sport University Cologne, Cologne, Germany. <sup>2</sup>University of Cologne, Cologne, Germany.

(No relationships reported)

**INTRODUCTION:** The small ubiquitin-like modifier "SUMO" regulates target protein functions via post-translational modification and regulates cellular integrity. Sumoylation is triggered in vivo by stressors like oxidative stress but also acute hypoxia. Exercise induced myocellular adaptation requires a complex network of nuclear protein shuttling as well as post-translational modification of proteins and thus may include also the SUMO system as acute modulator of loaded skeletal muscle.

**PURPOSE:** It was aimed to investigate whether SUMO-1 is involved in the early response towards exercise in sarcoplasmatic and myonuclear compartments of loaded skeletal muscle myofibers.

**METHODS:** 6 healthy male subjects (age:  $23 \pm 4$  years; height:  $180 \pm 8$  cm; weight:  $79 \pm 10$  kg) performed 1 single set of 20 maximum eccentric and concentric isokinetic knee extensions. PRE, 15, 30, 60, 240 min and 24h after exercise (EX) muscle biopsies were taken from vastus lateralis muscle. DAB and Fluorescence staining was performed on  $7 \mu\text{m}$  cross-sections of skeletal muscle. The density and sub-cellular localization of SUMO-1 in sarcoplasmatic and nuclear compartments of type I and II myofibers were determined via optical densitometry and confocal laser microscopy as well as in whole skeletal muscle lysates by western blotting.

**RESULTS:** Sarcoplasmatic SUMO-1 density was higher in type I than in type II myofibers ( $p < 0.05$ ) PRE exercise, increased 15 to 30 min POST EX significantly ( $p < 0.01$ ) in both fiber types but returning to PRE levels within 60 min. SUMO-1 positive nuclear areas increased significant ( $p < 0.01$ ) from PRE values within 15 min up to 60 min post EX but returning below PRE levels within 24 hours. Confocal microscopy offered a predominant sub cellular localization of SUMO-1 towards the nuclear envelope at baseline and 24h post EX. Western blotting offered substantial changes in the pattern of SUMO-1 positive bands within the first hour POST EX.

**CONCLUSION:** The present investigation reveals time dependent changes in SUMO-1 density in nuclear and sarcoplasmatic compartments of human skeletal muscle fibers as early response towards high intense resistance exercise. This modulation offers a potential role of the SUMO system in myocellular adaptation towards acute exercise induced stress but also in recurring homeostasis.

**Novel Transcriptional Changes Associated with Age-related Muscle Insulin Resistance**

Dongmei Liu<sup>1</sup>, Maureen Sartor<sup>1</sup>, Heidi IglayReger<sup>1</sup>, Emidio Pistilli<sup>2</sup>, Laurie Gutmann<sup>3</sup>, Gustavo Nader<sup>4</sup>, Eric Hoffman<sup>5</sup>, Paul Gordon, FACSM<sup>1</sup>. <sup>1</sup>University of Michigan, Ann Arbor, MI. <sup>2</sup>University of Pennsylvania, Philadelphia, PA. <sup>3</sup>West Virginia University, Morgantown, WV. <sup>4</sup>Karolinski Institute, Stockholm, Sweden. <sup>5</sup>Children's National Medical Center, Washington, DC.

(No relationships reported)

Skeletal muscle insulin resistance is a characteristic feature of the normal aging process and plays a key role in the pathogenesis of age-related type II diabetes mellitus and Alzheimer's disease. However the mechanisms associated with age-related muscle insulin resistance are not completely understood.

**PURPOSE:** Through a global view of transcriptional changes in young and older skeletal muscle, we sought to identify the molecular mechanisms underlying age-associated insulin resistance.

**METHODS:** Muscle biopsies were obtained basally from young (19-28yrs) and older (65-76 yrs) men (7 young, 4 older) and women (8 young, 4 older). Gene expression profiling was performed using the Affymetrix Human Genome U133 Plus 2 chip. Differential gene expression between older and young muscle was analyzed, separately for men and women, using an intensity-based Bayesian moderated t-test (IBMT). A logistic regression-based method (LRpath) was used to test for significant (FDR $< 0.01$ ) enrichment of biological functions based on Gene Ontology (GO) terms and KEGG pathways.

**RESULTS:** LRpath analysis in combination with IBMT revealed different patterns of transcriptional changes with aging in men and women. A much greater number of GO and KEGG were found to be significantly enriched with differentially expressed genes in older women than in older men (259 vs. 57). Transcriptional changes in older women presented a coordinated up-regulation of immune activation (e.g., *FABP4*, *LOX*, *C1R*), extracellular matrix (ECM) remodeling (e.g., *COL6A2*, *COL8A2*), lipids storage (e.g., *CD36*, *SCD*); and down-regulation of mitochondrial biogenesis and function (e.g., *PPARGC1*, *CS*), muscle regeneration (e.g., *MYF6*, *AKT2*). In contrast, no consistent biological themes can be inferred based on the limited number of significant GO/KEGG in older men.

**CONCLUSION:** Sex-based differences exist in skeletal muscle transcriptional regulation that may play a major role in the muscle's aging process in women but not in men. Moreover, given that immune activation, ECM remodeling, lipids storage, mitochondrial dysfunction, and muscle atrophy have all been implicated in muscle insulin resistance, altered transcriptional regulation in these biological pathways may represent novel mechanisms for age-associated insulin resistance, especially in women.

**Erk and p38 Phosphorylation Following Three Different Maximal Velocity Squat Protocols**

Rebecca Kudrna<sup>1</sup>, Nicole Moodie<sup>2</sup>, Michael Prewitt<sup>3</sup>, Andrew Fry<sup>3</sup>, Phillip Gallagher<sup>2</sup>. <sup>1</sup>DeSales University, Center Valley, PA. <sup>2</sup>Rockhurst University, Kansas City, MO. <sup>3</sup>University of Kansas, Lawrence, KS.

(No relationships reported)

Changes in the cellular signaling molecules within skeletal muscle are believed to account for the specific adaptations that occur following various types of exercise. Mitogen activated protein kinases (MAPKs) including extracellular regulated kinase 1/2 (ERK1/2) and stress-activated kinase (p38) that likely play a role in muscle adaptation. While it has been shown that these kinases are affected by aerobic and anaerobic exercise, less is known about how these molecules are affected by different resistance training protocols.

**PURPOSE:** The purpose of this study was to determine the effect of low, moderate, and high intensity exercise protocols as are commonly used by athletes on the phosphorylation of ERK1/2 and p38 MAPKs.

**METHODS:** Nine recreationally trained males ( $21.4 \pm 1.67$  yrs,  $92.23 \pm 9.72$  kg), completed each of three speed squat (emphasizing speed of the concentric phase) protocols in randomized order and on non-consecutive days. The three testing protocols consisted of a low relative intensity (LI; 5 sets of 10 repetitions at 30% 1RM); moderate intensity (MI; 5 sets of 5 repetitions at 70% 1RM); and high intensity (HI; 5 sets of 3 repetitions at 90% 1RM). Muscle biopsies were taken before and after each exercise bout and examined by western blot analysis. Separate 3x2 repeated measures ANOVAs compared differences between the ratio of phosphorylation among the three protocols and at the pre- and post- exercise time points for ERK1/2 and p38 respectively.

**RESULTS:** For ERK1/2, there was a significant main effect for time ( $F_{(1,8)} = 6.86, p = 0.031$ ). Ratio of phosphorylated to total ERK1/2 increased by 33%, 56%, and 43% for the HI, MI, and LI respectively but was not significantly different between protocols ( $F_{(2,16)} = 0.186, p > 0.05$ ). There was no interaction between protocol and timepoint for ERK1/2. There were no significant main effects or interactions for p38 phosphorylation ( $p > 0.05$ ).

**CONCLUSIONS:** ERK1/2 phosphorylation was equally elevated following each of the three lower body resistance training protocols examined. Though not measured in this study, force production under these three different circumstances may have been more similar than the external exercise load indicates due to the maximal velocity contraction. p38 phosphorylation did not change following the short bouts of exercise in this study.

**A Polymorphism Of Angiotensin-converting Enzyme Gene Does Not Affect Exercise-induced Muscle Damage Following Eccentric Muscle Contractions**

Jooyoung Kim<sup>1</sup>, Kyu-Wan Lee<sup>1</sup>, Changsun Kim<sup>2</sup>, Joohyung Lee<sup>1</sup>. <sup>1</sup>Kookmin University, Seoul, Korea, Republic of. <sup>2</sup>Dongduk Women's University, Seoul, Korea, Republic of.

(No relationships reported)

It is well demonstrated that angiotensin-converting enzyme (ACE) is one of the critical factors for renin-angiotensin system leading to vasoconstriction. It is also known to be related to exercise metabolism and performance including muscle strength and endurance. A recent study showed that ACE genotype may be related to creatine kinase activity following eccentric exercise but other muscle damage markers were not compared.

**PURPOSE:** To investigate whether ACE genotype can affect exercise-induced muscle damage to explain a large inter-subject variability shown after eccentric muscle contractions.

**METHODS:** Total 80 male subjects who had not participated in any exercise program in the past six months were recruited. A polymorphism of ACE gene was determined using real-time polymerase chain reaction. Each subject performed 2 sets of 25 eccentric contractions of the elbow flexors in the non-dominant arm. Maximal isometric force (MVC), muscle soreness (SOR), and blood markers including creatine kinase (CK) activity and myoglobin (Mb) were measured at pre, immediately after, 24, 48, 72 and 96 hours after exercise.

**RESULTS:** The frequency distribution of I allele and D allele was 62(78%) and 18(23%) respectively corresponding to Hardy Weinberg's equilibrium ( $p = 0.887$ ). There were no significant group by time effects in MVC ( $p = 0.399$ ), SOR ( $p = 0.644$ ), CK activity ( $p = 0.199$ ) and Mb levels ( $p = 0.399$ ) following eccentric muscle contractions.

**CONCLUSIONS:** Our data showed that there is no effect of ACE gene polymorphism on exercise-induced muscle damage suggesting that ACE may not be the factor to explain inter-subject variability of muscle damage markers.

**Small Differences in Exercise Intensity May Impact Muscle Glycogen Without Concurrent Changes in Metabolic Gene Expression.**

Matt Heesch<sup>1</sup>, Dustin Slivka<sup>1</sup>, Charles Dumke, FACSM<sup>2</sup>, John Cuddy<sup>2</sup>, Walter Hailes<sup>2</sup>, Brent Ruby, FACSM<sup>2</sup>. <sup>1</sup>University of Nebraska at Omaha, Omaha, NE. <sup>2</sup>University of Montana, Missoula, MT.

(No relationships reported)

Intensity in exercise studies is often established relative to VO<sub>2</sub> peak. However, when there is an experimental manipulation of altitude, the intensity may be different depending on the altitude at which VO<sub>2</sub> peak is measured.

**PURPOSE:** To determine the impact of different absolute intensities associated with 60% VO<sub>2</sub> peak, when VO<sub>2</sub> peak is measured at 975 m or at a simulated altitude of 3000 m on metabolic gene expression.

**METHODS:** Twelve recreationally trained males (age  $23.8 \pm 3.8$  y, mass  $81.6 \pm 11.6$  kg, body fat  $14.6 \pm 7\%$ ) had their VO<sub>2</sub> peak measured on a cycle ergometer at 975 m and 3000 m. Participants then completed two trials consisting of cycling at 965 m elevation for 60 min at 60% VO<sub>2</sub> peak as measured at (A) 975 m and (B) 3000 m. Skeletal muscle biopsies were obtained from the vastus lateralis before exercise (PRE) and after 4 hours of recovery (POST4). Gene expression was measured using real-time RT PCR and expressed using the  $\Delta\Delta$  CT method.

**RESULTS:** VO<sub>2</sub> peak was statistically similar when measured at 975 m and 3000 m ( $p = 0.139$ ;  $4.24 \pm 0.89$  L·min<sup>-1</sup> and  $4.03 \pm 0.60$  L·min<sup>-1</sup>). The absolute intensities were  $174 \pm 33$  watts for trial A and  $158 \pm 23$  watts for trial B ( $p > 0.05$ ). The VO<sub>2</sub> during trial A ( $2.48 \pm 0.40$  L·min<sup>-1</sup>) was not significantly different than during trial B ( $2.43 \pm 0.56$  L·min<sup>-1</sup>). Skeletal muscle glycogen was similar between trials at PRE but at was 37.6% higher in trial B at POST4 ( $p < 0.05$ ). There were no differences between trials for COX, HIF, PGC1, FIS, MFN, OPA, HK or PFK ( $p > 0.05$ ) gene expression. However, COX, HIF, PGC1, FIS, MFN, HK and PFK increased as a result of exercise regardless of trial ( $p < 0.05$ ) while OPA did not.

**CONCLUSION:** These data indicate that small differences in exercise intensity created by completing initial VO<sub>2</sub> peak tests at 975 m versus 3000 m environment have an effect on muscle glycogen but not on select metabolic genes.

**Alterations in the Exercise-Induced Transcriptional Response Following Short-Term Aerobic Exercise Training**

J. Matthew Hinkley, Adam R. Konopka, Miranda K. Udem, Bozena Jemiolo, Todd A. Trappe, Scott W. Trappe, FACSM, Matthew P. Harber. Human Performance Laboratory, Ball State University, Muncie, IN.

(No relationships reported)

An acute bout of exercise induces transient changes in mRNA expression that, with training, lead to specific adaptations. Interestingly, little is known about the effects of short-term training on the exercise-induced transcriptional response of markers associated with skeletal muscle adaptation.

**PURPOSE:** To examine the effects of short-term training on whole body performance and associated exercise-induced molecular adaptations in skeletal muscle.

---

**METHODS:** Ten recreationally active subjects ( $25 \pm 2$  yr,  $79 \pm 3$  kg) were studied before and after a ten day cycling protocol consisting of both steady state and interval days. Prior to training and 24 hours after the last exercise bout, subjects completed a 20 km cycle time trial. Skeletal muscle biopsies were taken from the vastus lateralis at rest and 3h following the time trial in both conditions to measure mRNA expression.

**RESULTS:** Time trial performance improved ( $P < 0.05$ ) by  $5 \pm 1\%$  following training, which was associated with an enhanced power output ( $P < 0.05$ ). MuRF-1 and PGC-1 $\alpha$  mRNA were elevated ( $P < 0.05$ ) after exercise before and after training, with an attenuated response ( $P < 0.05$ ) following training (11-fold vs. 3-fold and 33-fold vs. 12-fold for MuRF-1 and PGC-1 $\alpha$ , respectively). NF $\kappa$ B was elevated ( $P < 0.05$ ) 2-fold following the pre-training time trial, and unaltered after the post-training time trial. A significant interaction ( $P < 0.05$ ) was found for the exercise-induced mRNA expression of myostatin and TNF- $\alpha$ , suggesting a greater reduction in myostatin after training and a greater response in TNF- $\alpha$  prior to training.

**CONCLUSION:** These data suggest that short-term high-intensity aerobic exercise training alters the exercise-induced transcriptional response of genes involved in the regulation of skeletal muscle. Specifically, markers of myofibrillar degradation were attenuated, suggesting less susceptibility to post-exercise protein breakdown after training.

### **DNA Methylation is Altered in Human Skeletal Muscle in Response to Exercise Training**

Shlomit Radom-Aizik<sup>\*1</sup>, Fadia Haddad<sup>\*1</sup>, Tomasz Owerkovicz<sup>2</sup>, Joseph M. Devaney<sup>3</sup>, Eric P. Hoffman<sup>3</sup>, Per A. Tesch<sup>4</sup>, Gregory R. Adams<sup>1</sup>\*These 2 individuals are joint first authors<sup>1</sup>. <sup>1</sup>University of California Irvine, Irvine, CA. <sup>2</sup>California State University, San Bernardino, CA. <sup>3</sup>Children National Medical Center, George Washington University, Washington, DC. <sup>4</sup>Mid Sweden University, Ostersund, Sweden. (Sponsor: Kenneth M. Baldwin, FACSM)

(No relationships reported)

DNA methylation is an epigenetic modification, which is influenced by environmental stimuli (e.g., exercise), and can play an important role in the adaptive process involving altered gene expression. Currently, little is known on DNA methylation status in muscle undergoing remodeling in response to exercise training.

**PURPOSE:** To determine if exercise training would induce alteration in DNA methylation in human skeletal muscle.

**METHODS:** Thirty three subjects, 20-26 y/o, were assigned to one of two 5-week exercise protocols: a) Resistance Exercise (RE), 4x7 squats, 2 days a week, or b) Combined Aerobic and RE (AE+RE), 5 days a week: 3 days of AE: 4, 4-min bouts of rowing at  $\sim 90\%$   $\dot{V}O_{2\max}$  interspersed with 4, 4-min bouts of rowing at  $\sim 50\%$   $\dot{V}O_{2\max}$ , and 2 days of RE. DNA was extracted from the vastus lateralis muscle, treated with sodium bisulfite, and analyzed for methylation using the Infinium HumanMethylation450 BeadChip (Illumina). Statistical analysis was done using Partek Genomics Suite (version 6.6).

**RESULTS:** Both exercise protocols altered the methylation status in the vastus lateralis muscle, however the AE+RE protocol had a greater effect (6976 CpG sites compared to 970 CpG sites in the RE only ( $P < 0.0005$ )). These altered CpG sites correspond to 3323 and 692 genes respectively. Of these, only 197 genes were common in both paradigms. In the AE+RE group we identified Kegg pathways that were enriched with genes with altered methylation; e.g., insulin signaling, focal adhesion, phosphatidylinositol, MAPK, Notch signaling, and regulation of actin cytoskeleton ( $EASE < 0.05$ ). We scanned for 1000bp regions that were enriched with  $\geq 2$  CpG altered methylation sites ( $P < 0.005$ ) and found 47 regions in the AE+RE group and only 3 regions in the RE group.

**CONCLUSION:** Two different exercise protocols generated differential response in DNA methylation. The altered genes are part of important signaling and structural pathways that are involved in muscle plasticity. This is the first study demonstrating that only five weeks of training can alter DNA methylation in human skeletal muscle. This information can enhance our understanding of complex molecular mechanisms leading to muscle plasticity in response to exercise stimulus. Supported by NSBRI NCC 9-58-7, and by NIH grants #2R24HD050846-06 and UL1RR031985

**1506** Board #287 **MAY 30** **11:00 AM - 12:30 PM**

### **The Effect Of Lactate On Primary Human Myoblasts And Potential Signalling Pathways**

Raphael Jung, Lena Willkomm, Sebastian Borosch, Sebastian Gehlert, Frank Suhr, Wilhelm Bloch. *Institute of cardiovascular research and sports medicine, Cologne, Germany.*

(No relationships reported)

Satellite cells (SCs) play a crucial role in embryonic myogenesis and skeletal muscle regeneration and adaptation. SCs can be activated by different stimuli and underlie a number of regulatory factors and proteins. In the past decades lactate (La) has been considered as a metabolic waste product, being responsible for the decrease in muscle pH and hence causing muscle fatigue. Nowadays La is better known as an intermediate of glucose metabolism and its ability to stimulate molecular pathways essential for skeletal muscle adaptation.

**PURPOSE:** The aim of this study was to analyse to what extent and how La can influence myoblast behaviour.

**METHODS:** Human myoblasts (HMB) were isolated from muscle biopsies, cultured and incubated with different La concentrations (0, 10, and 20 mM). Immunostainings and Western Blots were carried out for Ki67 (proliferation), activated Caspase-3 (apoptosis), Myogenin (early differentiation) and Myosin Heavy Chain (MHC; late differentiation). To investigate which signalling pathways are involved, activated beta-catenin, a molecule important in Wnt-mediated signalling, has also been analysed.

**RESULTS:** The results showed significant changes in proliferation and differentiation behaviour of the La treated cells. Regarding proliferation, La reduced the activity in a dose-dependent manner. Differentiation of primary HMB seemed to be timely delayed by La. Analysis of beta-catenin showed a decrease in its activation if cells were treated with La in a dose-dependent manner.

**CONCLUSIONS:** La has a negative or time-delaying influence on proliferation and differentiation of HMB. Although the literature suggests a strong involvement of redox signalling pathways, activated by La-dependent reactive oxygen species (ROS) production, beta-catenin could also play an influential role in the observed effects. However, further investigations are necessary to allow for a more precise estimation of La-induced regulation of proliferation, apoptosis, and differentiation in myogenic cell culture.

### **Skeletal Muscle Mitochondrial Respiration And Type 2 Diabetes Duration**

T P. Gavin, FACSM, J M. Ernst, S E. Kehe, M A. Reed, A H. Clark, R D. McKernie, M Dar, W E. Pofahl, G L. Dohm, H B. Kwak. *East Carolina University, Greenville, NC.*

(No relationships reported)

Type 2 diabetes (T2DM) resolution following Roux-en Y gastric bypass (RYGB) surgery is poorer in patients with longer duration T2DM and lower pre-RYGB insulin sensitivity. Skeletal muscle mitochondrial function is impaired in T2DM.

**PURPOSE:** It was hypothesized that skeletal muscle mitochondrial respiration (JO2) would be lowest in T2DM patients with long-duration (LD;  $\geq 8$  y) compared to medium-duration (MD; 4-7) and short-duration (SD;  $\leq 3$  y).

**METHODS:** Vastus lateralis biopsies were obtained from T2DM patients ( $N = 12$ ). Muscle mitochondrial JO2 was measured using the permeabilized fiber technique under basal (State 2) and ADP stimulated (State 3) conditions with glutamate+malate (GM) or palmitoylcarnitine+malate (PM) as substrate. Respiratory control index (RCI), an index of mitochondrial coupling, was calculated as State 3/State 2 JO2.

**RESULTS:** There was a non-significant ( $p = 0.10$ ) trend of lower GM State 2 JO2 with longer T2DM duration (LD:  $9.7 \pm 1.7$ ; MD:  $13.5 \pm 1.0$ ; SD:  $17.8 \pm 4.7$  pmol/sec/mg dry wt.). GM RCI was greater in LD than MD or SD (LD:  $21.3 \pm 1.8$ ; MD:  $12.6 \pm 2.4$ ; SD:  $13.8 \pm 1.3$ ). There was a significant correlation between T2DM duration and GM RCI ( $r = 0.59$ ;  $p \leq 0.05$ ). There was no difference in JO2 or RCI for PM conditions between groups.

**CONCLUSIONS:** Skeletal muscle mitochondrial coupling is higher in longer compared to shorter duration T2DM patients. Also, there may be a trend toward lower basal skeletal muscle mitochondrial respiration in patients with longer compared to shorter duration T2DM.

Supported by a Grant from the East Carolina Diabetes and Obesity Institute (ECDOI).

**Age-associated Declines In Mitochondrial Biogenesis And Protein Quality Control Are Minimized By Exercise Training**

Erika Koltai<sup>1</sup>, Nikolett Hart<sup>1</sup>, Albert W. Taylor<sup>1</sup>, Sataro Goto<sup>1</sup>, Jenny K. Ngo<sup>2</sup>, Kelvin J A Davies<sup>2</sup>, Zsolt Radak<sup>1</sup>. <sup>1</sup>*Semmelweis University, Budapest, Hungary.*  
<sup>2</sup>*University of Southern California, Los Angeles, CA.* (Sponsor: L. L. Ji., FACSM)  
(No relationships reported)

Impairments of the mitochondrial reticulum or network, and its function have often been associated with aging. A decline in mitochondrial biogenesis and mitochondrial protein quality control in skeletal muscle, directly contributes to this problem, but exercise training has been suggested as a possible cure.

**PURPOSE:** In this report, we tested the effects of moderate intensity exercise training on young and old rats, and assessed mitochondrial biogenesis and mitochondrial protein quality control.

**METHODS:** Twelve young (three mo) and twelve old (26 mo) male Wistar rats were used in the study and grouped into young control (YC), young exercised (YE), old control (OC) and old exercised (OE). The investigation was carried out according to the requirements of The Guiding Principles for Care and Use of Animals, EU. Exercised rats were trained on treadmill for 6 weeks, 5 times per week, where the running speed and duration of the exercise were gradually increased. We examined in this study the gastrocnemius muscle by Western blot and fluorometric assays. Statistical significance was assessed by one-way ANOVA, followed by Tukey's post hoc test.

**RESULTS:** Exercise training prevented or attenuated significant age-associated (detrimental) declines in SIRT1 activity (437±174 v. 1166±109 rel. act. p<0.05), AMPK (0.21±0.11 v. 1.05±0.29 rel.dens. p<0.01), peroxisome proliferator-activated receptor gamma coactivator 1-alpha (PGC-1alpha) (0.35±0.04 v. 0.87±0.08 rel.dens. p<0.01) and the Lon protease, in the gastrocnemius muscle of rats. Exercise training also prevented the age-related (detrimental) increases in NRF1 (1.11±0.17 v. 0.67±0.1 rel.dens. p<0.01), TFAM, Mfn1 (0.98±0.31 v. 0.48±0.16 rel.dens. p<0.01), Fis1 and polynucleotide phosphorylase (PNPase) (1.52±0.42 v. 1.05±0.25 rel.dens. p<0.01) levels.

**CONCLUSION:** Our data suggest that regular exercise training can help minimize detrimental skeletal muscle aging deficits stimulating mitochondrial biogenesis through the PGC1[Unsuported Character - Symbol Font α] system, a rejuvenating the mitochondrial network via fission and fusion, and improving quality control of mitochondrial proteins by the Lon protease. All of these properties, working in conjunction with one another, would improve the overall functionality of mitochondria in aged cells.

**Interaction Of Mitochondria And Oxygen Binding Protein In L6, Rat Skeletal Muscle Cell Line**

Tatsuya Yamada<sup>1</sup>, Nobumasa Iwanaka<sup>1</sup>, Yasuro Furuichi<sup>1</sup>, Yukio Kato<sup>1</sup>, Takeshi Hashimoto<sup>2</sup>, Thomas Jue<sup>3</sup>, Kazumi Masuda<sup>1</sup>. <sup>1</sup>*Kanazawa University, Ishikawa, Japan.* <sup>2</sup>*Ritsumeikan University, Shiga, Japan.* <sup>3</sup>*University of California Davis, Davis, CA.*  
(No relationships reported)

**PURPOSE:** It has been for a long time believed that myoglobin (Mb), muscle specific oxygen binding protein, is a cytosolic protein. However, our recent immunohistochemical and biochemical analyses showed that Mb located not only in cytosol but also in mitochondria and that the mitochondrial Mb content was positively related to muscle oxidative potential. These results led us the hypothesis that mitochondrial Mb has a pivotal role in the regulation of mitochondrial respiration. In order to assess this idea, we determined protein-protein interaction between Mb and mitochondrial proteins in L6 skeletal myocytes in the present study.

**METHODS:** The recombinant pcDNA3-Myc tagged Mb was transfected to L6 myoblast. The myoblasts were cultured in the presence of G418 and a single colony was isolated, proliferated and differentiated. The expression of Myc-Mb was screened by Western blotting (WB). Cellular subfractions were separated by serial centrifugation, and WB assessed the presence of Mb protein in each fraction. Co-immunoprecipitation (Co-IP) was performed to confirm protein-protein interactions of Mb with mitochondrial proteins. Silver staining of the Co-IP samples was also performed to assess the existence of putative proteins that interact with mitochondrial Mb.

**RESULTS:** WB confirmed the presence of Mb protein in mitochondrial fraction in normal and Mb-overexpressed L6 myotube. Both VDAC and COX-IV, mitochondrial outer and inner membrane proteins, respectively, were detected from mitochondrial fraction but not from cytosolic fraction. COX-IV was co-precipitated with Myc-Mb by Co-IP, suggesting a protein-protein interaction between Mb and COX-IV in L6 myotube. On the other hand, VDAC-I was not co-precipitated with Myc-Mb. Thus, Myc-Mb did not have interaction with VDAC-I. Silver staining revealed several proteins might interact with mitochondrial Mb.

**CONCLUSIONS:** The present results suggested the possibility of the interaction of mitochondrial respiratory chain with Mb in skeletal myocytes. Further study including proteome analysis is necessary to determine the specific mechanism for the interaction between mitochondrial proteins and Mb.

**Effects Of Endurance Training And Immobilization On The Localization Of Myoglobin In Skeletal Muscle**

Hisashi Takakura<sup>1</sup>, Tatsuya Yamada<sup>1</sup>, Yasuro Furuichi<sup>1</sup>, Minoru Ojino<sup>1</sup>, Nobumasa Iwanaka<sup>1</sup>, Thomas Jue<sup>2</sup>, Kazumi Masuda<sup>1</sup>. <sup>1</sup>*Kanazawa University, Kanazawa City, Japan.* <sup>2</sup>*University of California Davis, Davis, CA.*  
(No relationships reported)

Myoglobin (Mb) supplies O<sub>2</sub> to mitochondria immediately at the onset of muscle contraction. The release rate of O<sub>2</sub> from Mb increases progressively with the rate of increase in muscle O<sub>2</sub> consumption and fluctuates in accordance with the level of physical activity. We recently reported the novel localization of Mb to mitochondria, suggesting a possible mechanism that Mb supplied O<sub>2</sub> to mitochondria immediately with the increase in mitochondrial O<sub>2</sub> demand, because Mb translational diffusion in the cell appears too low to have a significant role for O<sub>2</sub> transport in the basal PO<sub>2</sub> (above 10 mmHg). However, it remains unknown whether the localization of Mb to mitochondria is involved in the changed release rate of O<sub>2</sub> from Mb to the modulated physical activity level.

**PURPOSE:** The purpose of this study was to determine the effect of swimming endurance training (eTR) and hindlimb immobilization (IM) on the localization of Mb to mitochondria.

**METHODS:** Male Wistar rats were randomly assigned to the eTR, IM, or Control (Con) group. Rats in the eTR group underwent a 4-week swimming eTR (6 days/week, 30 min × 4 sets/day) with a weight of 2% body mass. Rats in the IM group had their left hindlimb immobilized at the full plantar flexion with a thermoplastic cast for 3 weeks. Citrate synthase (CS) activity and Mb concentration ([Mb]) in the hindlimb muscle were measured spectrometrically. Western blotting was performed to evaluate the amount of Mb in mitochondrial fraction of the m. gastrocnemius. Expression of Mb in the mitochondrial fraction was normalized by the amount of the voltage dependent anion channel (VDAC-I), which was mitochondrial protein.

**RESULTS:** 4-weeks eTR significantly increased [Mb], CS activity and Mb/VDAC-I (p < 0.05), while 3-weeks IM did not show any change in [Mb], CS activity and Mb/VDAC-I.

**CONCLUSIONS:** The eTR increased the expression of Mb in the mitochondrial fraction in the skeletal muscle, suggesting the formation of more efficient O<sub>2</sub> transport mechanism at the onset of muscle contraction. On the contrary, the IM did not change the co-localization of Mb with mitochondria. In order to clarify the interaction of Mb with mitochondria, it is necessary to measure the changes in the mitochondrial respiration in response to changes in physical activity.

---

**Effect of Hydrogen Peroxide on Mitochondrial Motility Protein Miro1 in C2C12 Cells**

Yong Zhang<sup>1</sup>, Huijun Liu<sup>1</sup>, Ning Jiang<sup>1</sup>, Fei Zhao<sup>1</sup>, Hu Ding<sup>1</sup>, Li Li Ji, FACSM<sup>2</sup>. <sup>1</sup>*Tianjin University of Sport, Tianjin, China.* <sup>2</sup>*University of Minnesota, Minneapolis, MN.* (Sponsor: Li Li Ji, FACSM)  
(No relationships reported)

**OBJECTIVE:** The dynamic changes of mitochondria morphology and distribution have a profound influence on mitochondrial function. The mitochondria movement and distribution is still unclear. It was studied that mitochondrial motility and its regulation mechanism with moderate oxidative stress caused by exogenous H<sub>2</sub>O<sub>2</sub> in present research.

**METHODS:** C2C12 myoblast model of mild oxidative stress was induced by exogenous H<sub>2</sub>O<sub>2</sub>. Cell survival rate was detected by MTT. The colorimetry was used for measure of MDA. Oxygen consumption rate and ATP content were detected by using Oxytherm liquid oxygen electrode and fluorospectrophotometer. The western blotting and realtime-PCR were used to measure the contents of Miro1 protein and mRNA express in C2C12 myoblast. EGTA was used as chelator for Ca<sup>2+</sup>. **RESULTS:** 1) Cell survival rate of myoblast stimulated by low concentration (1-100μM) H<sub>2</sub>O<sub>2</sub> had no obvious change, and showed significantly low level when stimulated by higher concentrations of H<sub>2</sub>O<sub>2</sub> (1 mM or 10mM). The MDA level showed the

same trend. 2) The rates of respiration of myoblast cells were transient reversibly inhibited when stimulated by low concentrations of H<sub>2</sub>O<sub>2</sub> (100nM-1mM). H<sub>2</sub>O<sub>2</sub> of 100µM-10mM decreased the ATP content, nevertheless there were no significant effects when myoblasts were treated with 1µM or 10µM H<sub>2</sub>O<sub>2</sub>. 3) Miro1 mRNA of C2C12 cells treated with 10µmol / L H<sub>2</sub>O<sub>2</sub> for 0.5h, 1h, 1.5h increased by 44.1%, 49.0%, 54.9% respectively compared with the control group. The Miro1 protein expression increased 26.7% (P<0.05) after the treatment with the 10µmol / L H<sub>2</sub>O<sub>2</sub> for 1h. But the miro1 mRNA and protein expression in the EGTA+H<sub>2</sub>O<sub>2</sub> treated group decreased significantly (P<0.05) compared with the H<sub>2</sub>O<sub>2</sub> treated group.

**CONCLUSIONS:** H<sub>2</sub>O<sub>2</sub> had bidirectional for mitochondrial motility in myoblast. Lower H<sub>2</sub>O<sub>2</sub> promoted mitochondrial motility, high H<sub>2</sub>O<sub>2</sub> inhibited those. Ca<sup>2+</sup> involved in mitochondrial motility induced by H<sub>2</sub>O<sub>2</sub>. Supported by NSFC(No. 31071040)

**Reactive Oxygen Species Markers After Multiple Wingate Bouts in Trained and Untrained Subjects**

Jason R. Boynton, Lynn Shetron-Rama, Chris Herman, Andrea D. Workman, Tim Muth, Josh Gordon, Ian Ratz, Zack Maino, Stephen J. McGregor. *Eastern Michigan University, Ypsilanti, MI.*  
(No relationships reported)

Reactive oxygen species (ROS) are reactive molecules in the body that contain oxygen and unpaired valence electrons. Previous research has shown that ROS increase with acute exercise, but levels in untrained (UT) vs. trained (T) subjects vary in the literature in cross sectional vs. longitudinal studies.

**PURPOSE:** To study changes in ROS markers over time following multiple 30 s supra-maximal efforts in UT and T subjects.

**METHODS:** All procedures were approved by the Eastern Michigan University Human Subjects Review Committee. 11 UT subjects (22 ± 4 yr, weight 83.8 ± 11.8 kg, VO<sub>2peak</sub> = 40.05 ± 6.96 ml/kg/min) and 9 T cyclists (age 25 ± 4 yr, weight 77.8 ± 9.26 kg, VO<sub>2peak</sub> = 59.56 ± 5.66) performed three consecutive Wingates with 4 min of rest between each bout (MW). Exercise was performed on an electronically braked ergometer (Velotron, Racermate WA). Blood was collected by antecubital venipuncture: pre, immediate, 1 hr, 24 hr & 48 hr post MW. Samples were quantitatively analyzed for malondialdehyde (MDA) and 4-hydroxynonenal (4-HNE) with enzyme-linked immunosorbent assays (ELISAs; Cell Biolabs, inc., CA). Differences between the blood draw timepoints were analyzed using ANOVA. MDA and 4-HNE concentrations for all timepoints were compared using a 2 x 5 analysis of variance (ANOVA) to account for differences by training status as well as time (SPSS, IBM, NY).

**RESULTS:** Lactate values were higher on average in T vs UT, but increased significantly and similarly between groups immediately post for both the UT and T groups (1.14 ± 0.78 to 12.58 ± 1.75 mmol, 1.34 ± 0.54 to 12.62 ± 0.95 mmol, respectively; p<.05). There was a significant difference in MDA and 4-HNE levels between the UT group (7.45 ± 1.66 µg/mL, 6.73 ± 2.83 µg/mL) and T group (17.32 ± 2.07 µg/mL, 7.88 ± 0.81 µg/mL) at basal and across all the time points (p=.001; p=.015). There was no significant change from basal MDA and 4-HNE levels over the course of the blood draws in either the UT or T group. There was no significant interaction between the groups.

**CONCLUSION:** MDA and 4-HNE blood serum levels do not change acutely after multiple Wingate efforts, but are higher in T subjects than UT subjects at basal levels and after exercise. This indicates that ROS levels may change with chronic training over longer time frames than were examined in this study.

**Aged Skeletal Muscle Inflammation Susceptibility**

Edward K. Merritt, Anna Thalacker-Mercer, Michael J. Stec, David P. Shelley, Marcos M. Bamman, FACSM. *University of Alabama at Birmingham, Birmingham, AL.*  
(No relationships reported)

**BACKGROUND:** The regenerative response of skeletal muscle to mechanically induced damage is impaired with age. Previous work in our laboratory indicates that the impairment likely results from a differential inflammatory response in old relative to young, although the specific signaling mechanisms and their magnitudes are unknown.

**PURPOSE:** To examine the effects of age on the mRNA expression and protein signaling of putative pro-inflammatory and catabolic pathways in skeletal muscle at rest and after mechanically induced damage.

**METHODS:** Young (40.4 ± 1.1 y), older (61.2 ± 0.6 y), and old (75.5 ± 0.7 y) adults performed nine sets x 10 repetitions of unaccustomed, high-intensity leg extensions to induce modest muscle damage. A blood sample and a biopsy of the vastus lateralis muscle were obtained before and 24 h after the bout. Muscle mRNA expression and protein signaling within the interleukin-6 (IL-6) and tumor necrosis factor-α (TNF-α) pathways were determined by qPCR and Western blot analysis.

**RESULTS:** All subjects experienced similar levels of muscle damage as indicated by serum creatine kinase levels. Baseline expression of several analyzed genes was higher in older and old adults relative to young: IL-6 (1.64 - 2.70 fold higher); TNF-α (1.38 - 4.06 fold higher); and TWEAK (1.30 - 1.74 fold higher). TWEAK receptor expression was significantly increased in all groups after muscle damage and tended to be higher in older and old. STAT3 and NFκB protein expression were 17% and 35% higher in the old at baseline. Of all of the markers of inflammation, none were higher in young adults at baseline or after muscle damage.

**CONCLUSION:** The overall lower inflammatory state of skeletal muscle before and after muscle damage in young adults indicates that a higher sensitivity to inflammation signaling occurs in the muscle with age. Higher muscle inflammation susceptibility likely contributes to the impaired regenerative capacity of skeletal muscle in the older population, and should be considered when designing exercise programs to promote skeletal muscle recovery following damage or surgery.

**1514** Board #295 **MAY 30 11:00 AM - 12:30 PM**

**Effects Of H2O2 On Oxidant Generation And NF-κB Pathway Activity In C2C12 Muscle Cells**

Kevin S. O'Fallon, Lawrence M. Schwartz, Priscilla M. Clarkson, FACSM. *University of Massachusetts, Amherst, MA.*  
(No relationships reported)

Reactive oxygen and nitrogen species (RONS) production increases during exercise and following muscle injury. In vitro studies have shown that H<sub>2</sub>O<sub>2</sub> activates the canonical NF-κB pathway involved in transcription of antioxidant defenses in response to exercise. However, the effects of RONS on the alternative NF-κB pathway, which is involved in mitochondrial biogenesis, are currently unknown. Understanding the mechanisms of RONS-induced NF-κB activation will elucidate how NF-κB regulates the responses to exercise and muscle injury.

**PURPOSE:** To test the hypothesis that elevated RONS by H<sub>2</sub>O<sub>2</sub> induces changes in alternative NF-κB pathway activation in cultured muscle cells.

**METHODS:** C<sub>2</sub>C<sub>12</sub> myotubes were loaded with a fluorescent probe to quantify intracellular RONS levels. Culture media was supplemented with 100µM H<sub>2</sub>O<sub>2</sub> and fluorescence was measured hourly for 1-4 hrs, then again at 24 hrs. In a separate experiment, myotubes were exposed to H<sub>2</sub>O<sub>2</sub> for 1, 5 and 24 hrs and then harvested for total nuclear protein. Changes in the DNA binding activity of canonical (via the p65 subunit) and alternative (via the Rel B subunit) NF-κB pathways were quantified via ELISA assay.

**RESULTS:** Myotubes treated with H<sub>2</sub>O<sub>2</sub> showed higher RONS levels at 1 hr (42%), 2 hrs (33%), 3 hrs (30%), 4 hrs (28%), and 24 hrs (14%) relative to untreated controls (p<0.05). Fold changes in DNA binding activity of p65 (1.96 fold at 1 hr) and Rel B (0.71 fold at 1 hr and 0.61 fold at 5 hrs) were observed relative to controls (p<0.05).

**CONCLUSIONS:** H<sub>2</sub>O<sub>2</sub> stimulates RONS production in cultured muscle cells and alters the DNA binding activities of canonical and alternative NF-κB complexes within 5 hrs of exposure. The decrease in Rel B DNA binding indicates that elevated RONS reduces the transcriptional activity of the alternative NF-κB complex, which may be intended to temporarily restrict processes involved in mitochondrial biogenesis while intracellular redox homeostasis is being restored.

**Age- And Load-dependent Variations In Apoptotic Quantification And Localization With Skeletal Muscle Adaptation And Maladaptation**

Brent A. Baker<sup>1</sup>, Melinda S. Hollander<sup>2</sup>, Robert G. Cutlip<sup>2</sup>. <sup>1</sup>NIOSH, Morgantown, WV. <sup>2</sup>West Virginia University, Morgantown, WV. (Sponsor: Stephen E. Alway, Ph.D., FACSM)

(No relationships reported)

Increased skeletal muscle nuclear apoptosis has been suggested to be involved with age-related pathological remodeling that contributes to sarcopenic states.

**PURPOSE:** The purpose of this study was to determine if apoptosis plays a role in age-dependent adaptation and maladaptation in young and old skeletal muscle of rats, respectively, following chronic high-intensity mechanical loading via stretch-shortening contractions (SSCs).

**METHODS:** Left dorsiflexor muscles of young (3 mo, N=6) and old (30 mo, N=6) Fischer 344 x BN rats, were loaded 3 times/week for 4.5-weeks using a protocol of 80 maximal SSCs per exposure *in vivo*. Twenty-four hours after the last training session, tibialis anterior (TA) muscles were harvested and individual muscle regions were allocated for biochemical or histological analyses. TA muscle was homogenized and prepared for cell death enzyme-linked immunosorbent assay (ELISA), while histomorphology was conducted on transverse sections of the TA muscle mid-belly prepared for terminal dUTP nick-end labeling (TUNEL) and laminin dual immunofluorescence and quantified via standard stereology.

**RESULTS:** Cell death was increased in both old control (~50%) and old SSC-loaded (~105%) skeletal muscle versus young muscle, as quantified by ELISA ( $p < 0.05$ ). Moreover, ELISA data revealed chronic SSC-loading increased cell death ~95% in young rats' skeletal muscle, while old rats' cell death significantly increased ~105% ( $p < 0.05$ ), compared with control muscle. Additionally, aging increased the volume density of TUNEL-positive myonuclei in both control (~125%) and SSC-loaded (~200%) TA muscles compared with young rats ( $p < 0.05$ ). Interestingly, no increase in TUNEL-positive myonuclei was observed following chronic SSC loading in young or old rats.

**CONCLUSION:** Our data suggest that adaptation and maladaptation following chronic SSC loading is significantly impacted by apoptosis; however apparent differences exist with the individual cell types undergoing apoptosis; specifically, nuclei distinct from skeletal muscle may contribute to these findings. Collectively, these results indicate that apoptotic-related events contribute significantly to age-dependent adaptive and maladaptive remodeling in young and old soft tissue, respectively, following chronic mechanical loading.

**The Role Of Wound Healing Macrophages In Acute Muscle Injury**

Gina M. Many<sup>1</sup>, Tanya V. Cohen<sup>1</sup>, Bryan D. Flemming<sup>2</sup>, Po Zhao<sup>1</sup>, Terrence Partridge<sup>1</sup>, David M. Mosser<sup>2</sup>, Eric P. Hoffman<sup>1</sup>. <sup>1</sup>Children's National Medical Center, Washington, DC. <sup>2</sup>University of Maryland, College Park, MD. (Sponsor: Joseph A. Houmar, FACSM)

(No relationships reported)

Macrophages are recruited to sites of acute skeletal muscle injury and depletion of macrophages has been shown to hinder muscle regeneration. The mechanisms by which macrophages promote muscle regeneration remain to be elucidated.

**PURPOSE:** To investigate temporal changes in the expression of transcripts indicative of macrophage phenotypic specialization in response to cardiotoxin-induced acute myonecrosis.

**METHODS:** Cardiotoxin (CTX) was injected into the gastrocnemius of 8-wk old C57BL/10 mice on day 0. Bilateral sections of the belly of the gastrocnemius were taken at 27-time points (0-40d) for RNA extraction and profiling using murine U74A Ver. 2 chips. Expression profiling data were analyzed via the dChip differential algorithms. To assess the effects of differential macrophage activation on myogenesis, an *in vitro* co-culture system was used. Bone marrow-derived macrophages (M $\phi$ ) were stimulated with IL-4 or LPS to promote a wound healing (M2a) or classical activation phenotype (M1), respectively. M $\phi$  were plated onto transwells on top of myoblasts. Myoblasts were then induced to differentiate and myotube formation was compared between co-culture conditions.

**RESULTS:** M2a and M1 M $\phi$  markers were upregulated 1-3 days following CTX-induced injury. The increased expression of M1 M $\phi$  markers (CD11b: 3.6-fold, 1d; IFN $\gamma$ : 2.9-fold, 1d; CXCL9: 4.4-fold, 1d; CD68: 13.8-24.2-fold, 1-3d) and M2a M $\phi$  markers (arginase-1: 4800-fold, 1d; YM-1: 37-fold, 1d; STAT6: 5-6.8-fold, 1-2d; RELM $\alpha$ : 46.9-fold, 2d) was observed. Myogenic markers were upregulated following increases in M2a and M1 M $\phi$  transcripts (MyoD: 4.9-fold, 3d; myogenin: 12.0-12.5-fold, 3-3.5d; Myf5: 4.0-4.5-fold, 3.5-5d). Co-culture of H2K cells with M2a M $\phi$  resulted in a myotube fusion index of 13% vs. 5% in M1 co-cultures.

**CONCLUSIONS:** Our findings suggest that muscle injury by CTX results in the acute upregulation of M1 and M2a M $\phi$  transcripts. Our *in vivo* findings suggest a complex interplay of Th1 and Th2 immunological responses promote myogenesis following acute muscle injury. Additionally, our *in vitro* findings suggest that M2a macrophages are capable of potentiating myotube formation. Further research is needed to elucidate mechanisms by which acute adaptive immune responses promote myogenesis following acute muscle injury.

1517 Board #298 MAY 30 11:00 AM - 12:30 PM

**The Effect Of Myosin Light Chain 3f On Inactivity-induced Decline In Contractile Velocity In Type II Single Muscle Fibers**

Jong-Hee Kim, Ted G. Graber, Lisa F. Stegall, Haiming Liu, Atsushi Asakura, LaDora V. Thompson. University of Minnesota, Minneapolis, MN.

(No relationships reported)

A period of inactivity is associated with muscle atrophy and impaired contractility (e.g., power, force, velocity); however, the mechanism that underlies inactivity-induced changes in contractile velocity is unknown. Recent evidence suggests that inactivity-induced decline in contractile velocity is related with a decrease in the relative content of essential myosin light chain 3f (MLC3f) isoform.

**PURPOSE:** The purpose of this study was to examine whether 1) inactivity-induced decline in contractile velocity in type II single muscle fibers is associated with a decreased relative MLC3f content, 2) increased MLC3f via recombinant adenovirus gene (rAd) transfer technology can ameliorate inactivity-induced decrease in contractile velocity, 3) MLC3f-induced changes in  $V_o$  are dose and time dependent.

**METHODS:** F344 rats (10 mo. old) were randomly assigned to one of experimental groups: weight-bearing control (CON), hindlimb suspension (HS), and hindlimb suspension plus rAd-MLC3f (HSM). Rats were hindlimb-suspended for 7 days. The rAd-MLC3f ( $1 \times 10^{11}$ - $1 \times 10^{12}$  ifu/ml) was injected into semimembranosus (SM) muscles with different timing (one day before HS, 2<sup>nd</sup> day of HS, 4<sup>th</sup> day of HS) and volume (250, 375, 500 $\mu$ l). The fiber size, isometric maximal force ( $P_o$ ), and shortening velocity ( $V_o$ ) were determined using single fiber physiology test. Myosin heavy chain (MHC) and MLC isoforms were determined by SDS-PAGE gel electrophoresis and silver staining. Densitometry using molecular multi-imaging system (GS-800) was used to determine the relative content of MLC1f, MLC2f, and MLC3f in MHC type II fibers.

**RESULTS:** HS resulted in a significant decline in fiber size (-17%) and  $P_o$  (-51%). The rAd-MLC3f injection did not affect fiber size and  $P_o$ . HS significantly decreased relative MLC3f content [%MLC3f (-4.2%), MLC3f/MLC2f (-27%), and MLC3f/(MLC1f+MLC3f) (-39%)]. The rAd-MLC3f injection significantly increased MLC3f content dependant on injection timing and. HS significantly decreased  $V_o$  (-27%). The rAd-MLC3f injection increased  $V_o$  and the increase was associated with rAd-MLC3f injection timing and volume.

**CONCLUSIONS:** Increasing MLC3f content provided significant protection against inactivity-induced decline in  $V_o$  of type II single muscle fibers.

1518 Board #299 MAY 30 11:00 AM - 12:30 PM

**Fiber Type Conversion *in vivo*: The Effects of Six1 Gene Expression in Murine Skeletal Muscle**

Kimbell L. Hetzler, Matthew C. Kostek. University of South Carolina, Columbia, SC. (Sponsor: James Carson, FACSM)

(No relationships reported)

Six1 is a gene necessary for the development of several tissues, but in adults is expressed solely in skeletal muscle. Six1 gene and protein levels decrease in response to acute exercise in humans and mice. Overexpression of Six1 can cause a slow-to-fast fiber type transition, but the effect of Six1 decrease on fiber type proportion and size is unknown.

**PURPOSE:** To determine the effect of Six1 overexpression and knockdown on muscle fiber type in mice.

**METHODS:** The tibialis anterior muscles of 30 mice were transfected with vectors to increase or knockdown Six1 gene expression, or empty vector control. Muscles were collected at 2 and 14 days after transfection (n=4 or 6 mice per group at each time point). Six1 gene expression was quantified by qRT-PCR. Number of fibers and total cross-sectional area are being calculated using fluorescent microscopy for Type I, IIA, and IIB fibers.

**RESULTS:** Electroporation efficiency was >50% (green fluorescent protein). The Six1 vector increased Six1 mRNA expression 11.2-fold ( $\pm 2.7$ ,  $p < .01$ ) compared to control, and the siRNA vector decreased Six1 mRNA expression 1.37-fold ( $\pm .09$ ,  $p = .04$ ). Preliminary analysis suggests that the proportion and cross-sectional area of IIB fibers decrease in response to decreased Six1.  
**CONCLUSIONS:** A decrease in Six1 expression affects the expression of different muscle fiber types and may be responsible for fiber type conversions after exercise.

---

**1519 Board #300 MAY 30 11:00 AM - 12:30 PM**  
**Fast-To-Slow: Muscle Fiber Type Transformation In Response To Altered Six1 Gene Expression**

Brittany C. Collins, Bradley S. Gordon, Matthew C. Kostek. *University of South Carolina, Columbia, SC.* (Sponsor: James Carson, FACSM)  
(No relationships reported)

Muscle activation patterns, like exercise and disuse, can cause alterations in muscle fiber type proportions in skeletal muscle. However, little is known of the molecular events that cause this shift. Six1 is a developmental gene that has been shown to be altered by exercise in humans. Further, Six1 causes a fiber type shift in mice. Yet, little is known of how it functions.

**PURPOSE:** Examine the effect of Six1 expression on the myosin heavy chain (MyHC) genes during muscle fiber formation.

**METHODS:** C2C12 mouse myoblasts were grown in standard conditions. When cells reached 80% confluence, they were transfected with Six1 expression vectors, to increase Six1 expression, or empty vector control. 24 hours later, cells were switched to differentiation medium. After four days, cells were harvested. Six1 and MyHC gene expression was analyzed by qRT-PCR.

**RESULTS:** Six1 expression vector (A) increased Six1 expression  $700 \pm 243.4$  fold ( $p = 0.02$ ) and Six1 expression vector (B) increased Six1 expression  $875 \pm 83.7$  fold ( $p < 0.01$ ). MyHC-IIB expression decreased 2.02 fold ( $p = 0.01$ ) and 3.02 fold ( $p < 0.01$ ) by vectors (A) and (B) respectively. MyHC-IIx decreased 1.50 fold ( $p = 0.05$ ) and 1.50 fold ( $p = 0.02$ ) by vectors (A) and (B) respectively. MyHC-I increased 2.24 fold ( $p = 0.03$ ) and 1.50 fold ( $p = 0.05$ ) by vectors (A) and (B) respectively. MyHC-IIa expression was not affected.

**CONCLUSION:** Six1 overexpression alters the muscle fiber-type gene program during the formation of a muscle fiber. This suggests that altered Six1 expression, in response to exercise, controls muscle fiber-type in humans.

---

**1520 Board #301 MAY 30 11:00 AM - 12:30 PM**  
**Modification Of Skeletal Muscle Fiber Type Induced By Aerobic Exercise. Proposal Of A Peripheral Marker**

Paula Tavares. *Faculty of Sport Science and Physical Education, University of Coimbra, Coimbra, Portugal.*  
(No relationships reported)

It is known that exercise has the ability to change the skeletal muscle fiber type. In sport these changes may result from the applied training, which brings athletic advantage. However, the only technique available for fiber type monitoring is the muscle biopsy. In addition to the ethical issues, we also believe that this invasive method has a low accuracy in certain types of muscle evaluation.

**PURPOSE:** The aim of this work is to propose a peripheral marker that can show the skeletal muscle fiber type dominance in a subject. In order to achieve our goal we looked for changes in the nitric oxide synthase (NOS) that is expressed in skeletal muscle fibers and platelets.

**METHODS:** We used male Wistar adult rats that were trained during 8 weeks with a treadmill aerobic protocol. The animals were divided in two groups: exercise and control. The control group was submitted to a slight exercise just to maintain motor skills and avoid central nervous system interferences. Platelets were isolated from blood collected in the jugular vein (after anaesthesia) before and at the end of the exercise protocol. At the end of the experiments the animals were sacrificed by anaesthetic overdose, and the skeletal muscles (soleus and gastrocnemium) were removed for histological analysis and determination of NOS expression. The histological analysis included a hematoxylin-eosin staining and an ATPase staining to identify and measure the different fiber types. The expression of both NOS isoforms, in skeletal muscle and platelets, was determined by Western-blot with NOS specific antibodies.

**RESULTS:** The results showed that aerobic exercise changes the muscle fiber type. These changes were more evident in the soleus muscle which is mainly composed by type I muscle fibers. Moreover, our results also suggest that exercise induces muscle fibre necrosis and the consequent formation of new fibers through satellite cells division. This stimulation is induced by exercise, and allows the replacement of the damaged fibres.

**CONCLUSIONS:** The result stresses the correlation between NOS expression in muscle and platelets, suggesting the usefulness of cNOS in platelets for the study of exercise induced fibre change without the need for muscle biopsy. Other studies are needed to confirm our findings. This project was partially financed by FCT.

---

**1521 Board #302 MAY 30 11:00 AM - 12:30 PM**  
**Satellite Cell And Myonuclear Content In Older Adults Following 7 Days Of Inactivity**

Dillon Walker, Micah Drummond, Jared Dickinson, Elena Volpi, Blake Rasmussen. *UTMB, Galveston, TX.* (Sponsor: Elizabeth Protas, FACSM)  
(No relationships reported)

Skeletal muscle atrophy is linked to a number of pathological and physiological conditions and is characterized by a loss of protein and muscle nuclei. However, it is not known if changes in satellite cell and myonuclear content occur as early as 7 days following inactivity in older adults.

**PURPOSE:** To determine if changes occur in satellite cell (SC) and myonuclear content following 7 days of physical inactivity in older adults.

**METHODS:** Healthy, older adults participated in a strict best rest model for 7 days. Muscle biopsies were collected from the vastus lateralis before and after best rest. Immunohistochemical analysis was used to assess satellite cell content (anti-Pax7), muscle nuclei (Hoechst 33342), basal lamina (anti-laminin), and slow twitch fibers (anti-MHC type I).

**RESULTS:** In slow twitch fibers, we observed no change in SC/fiber, % SC, and myonuclear domain after 7 days of inactivity; however, myonuclei/fiber decreased by 18% and the % of fibers with centrally located nuclei decreased by 69%. In fast twitch fibers, SC/fiber increased by 50% and % SC increased by 79% whereas % fibers with centrally located nuclei, myonuclei/fiber, and myonuclear domain were unaffected after 7 days of inactivity.

**CONCLUSIONS:** Short-term physical inactivity results in the loss of muscle nuclei and appears to impair ongoing regeneration as indicated by a reduction in the % of fibers with centrally located nuclei in slow twitch muscle fibers. On the other hand, in fast twitch muscle fibers, an increase in satellite cell content may play a role in the bed rest induced transition of slow to fast twitch fibers. Future studies are warranted to determine the role of satellite cells in the regulation of physical inactivity induced muscle atrophy.

Supported by NIAMS R01 AR049877, NIA P30 AG024832 and R01 AG018311, NIH AG030070, NCRRI 1UL1R029876 and K01 AG038556

**1522 Board #303 MAY 30 11:00 AM - 12:30 PM**  
**Training Effect on Satellite Cell Response after Exhaustive Exercise in Thoroughbred Horses**

Minako Kawai<sup>1</sup>, Atsushi Hiraga<sup>2</sup>, Hiroko Aida<sup>2</sup>, Hirofumi Miyata<sup>1</sup>. <sup>1</sup>*Yamaguchi Univ., Yamaguchi, Japan.* <sup>2</sup>*Japan Racing Association, Utsunomiya, Japan.*  
(No relationships reported)

**PURPOSE:** Satellite cells are muscle stem cells capable of increasing myonuclear number during repair from injury and hypertrophy. The purpose of this study was to investigate the training effect on the short-term response of satellite cell activation in thoroughbred horse muscles.

**METHODS:** Six horses (3 years old) had acclimatized to exercise on a treadmill before experiments and then were subjected to conventional training for 10 weeks. Before (PRE) and after (POST) training, an incremental exercise test (IET) was performed on a 6% inclined treadmill to measure maximum oxygen consumption ( $VO_{2max}$ ) and the velocity at a plasma lactate of 4 mmol/l (VLA4). Biopsy samples from gluteus medius muscle was obtained before and at 1 min, 3 (3h), 6 (6h) and 24 hours (24h) after each IET. Total RNA was extracted from each muscle sample and the levels of SDHa, Pax7, MyoD, myogenin, PCNA, IGF-1 and HGF mRNA expression were determined using real time RT-PCR.

**RESULTS:** Ten-week training increased the mean values of  $VO_{2max}$  (from 144 to 168 ml/min/kg,  $P < 0.05$ ) and VLA4 (from 7.3 to 8.5 m/s). IL-6 mRNA expression increased remarkably at 6h after IET ( $P < 0.05$ ) in both PRE and POST. Unexpectedly, MyoD mRNA was significantly decreased at 6h after IET in both PRE and POST ( $P < 0.05$ ), and myogenin mRNA was also decreased at 3h after IET in POST ( $P < 0.05$ ). PCNA mRNA was increased at 24h ( $P < 0.05$ ) in both PRE and POST. In addition this mRNA in POST was also increased at an earlier point (3h) than that in PRE. When the correlations between performance level ( $VO_{2max}$  and VLA4) and mRNA expressions of each horse was investigated in PRE, the horses with higher  $VO_{2max}$  had

higher expression levels of MyoD and myogenin mRNAs ( $r = 0.97$  and  $0.85$ ,  $P < 0.05$ , respectively). In addition, the horses with higher VLA4 had higher expression level of IGF-I mRNA ( $r = 0.85$ ,  $P < 0.05$ ). After the 10-week training, interestingly, the horses with a greater  $\text{VO}_{2\text{max}}$  improvement had a greater increase in the expression level of IL-6 mRNA ( $r = 0.82$ ,  $P < 0.05$ ) at 1d after IET.

**CONCLUSIONS:** The activation and proliferation of satellite cells in response to exhaustive exercise were slightly different between pre and post training. There were significant correlations between the performance level of each horse and these mRNA expression patterns in response to exhaustive exercise.

---

**1523** Board #304 MAY 30 11:00 AM - 12:30 PM  
**Transient Satellite Cell Response to Acute 'Non-Injurious' Resistance Exercise in MHC I and MHC II Skeletal Muscle Fibers**

Nicholas Luden, Lyle Babcock, Matt Escano, Andrew D'Lugos, Kent Todd, FACSM, Kevin Murach. *James Madison University, Harrisonburg, VA.*  
(No relationships reported)

Skeletal muscle satellite cells (SC) have been implicated in the hypertrophic response to resistance training. Satellite cell proliferation is also likely involved in repair processes following skeletal muscle injury. Elevated satellite cell counts have been documented as early as 6 hours and as late as 8 days following acute resistance exercise. However, these studies have exclusively utilized exercise protocols characterized by a high volume of supramaximal eccentric muscle contractions.

**PURPOSE:** To assess the general and fiber-type specific [Myosin Heavy Chain (MHC I and II)] SC response to a more conventional, 'non-injurious', exercise protocol at 4 and 10 days following exercise.

**METHODS:** Immediately following one-repetition max (1RM) testing, eight recreationally active college-aged males ( $23 \pm 1$  yr,  $83 \pm 4$  kg,  $49 \pm 2$  ml/kg/min) performed 4 sets of unilateral leg-extensions and presses (4 sets of 10 repetitions at 75% 1RM). Skeletal muscle biopsies were obtained from the vastus lateralis immediately before, 4 days, and 10 days following exercise. Muscle samples were cross-sectioned, stained with NCAM, Ki-67, and MHC I antibodies, counterstained with DAPI, and analyzed via immunohistochemistry to determine SC density (SC per muscle fiber), satellite cell activation and muscle fiber type.

**RESULTS:** SC density (not fiber type specific) was elevated 4 days following exercise but returned to baseline at 10 days post-exercise. MHC I muscle fiber SC density remained unaltered with exercise when compared across all three time points, whereas MHC II muscle fiber SC density tended to be elevated at 4 days ( $p = 0.09$ ), but not 10 days post-exercise. No alterations in the quantity of activated SC were observed.

**CONCLUSIONS:** Our data indicate that a single session of one-legged resistance exercise increases the SC population at 4 but not 10 days following exercise. Further, this response seems to be primarily manifested in MHC II muscle fibers. These data have implications for future satellite cell research, as the SC proliferative response to acute exercise is not detectable 10 days following a relatively conventional exercise protocol.

**1524** Board #305 MAY 30 11:00 AM - 12:30 PM  
**Concurrent Aerobic Exercise Interferes With the Satellite Cell Response to Acute Resistance Exercise in MHC I Muscle Fibers**

Lyle Babcock, Matt Escano, Andrew D'Lugos, Kent Todd, (FACSM), Kevin Murach, Nicholas Luden. *James Madison University, Harrisonburg, VA.*  
(No relationships reported)

The addition of aerobic exercise (AE) to a resistance exercise program (RE) (concurrent exercise; CON) can interfere with maximum muscle fiber size gains achieved with RE alone. Further, CON appears to interfere with myosin heavy chain (MHC) I, but not MHC IIa muscle fibers. The underlying mechanism responsible for this 'interference' is unknown. The magnitude of satellite cell (SC) proliferation following exercise has been shown to influence muscle adaptation, but these dynamics have not been examined following acute concurrent exercise.

**PURPOSE:** To assess the fiber-type specific SC response to RE, AE, and CON exercise.

**METHODS:** Eight recreationally active college-aged males completed the following two exercise trials separated by a 10-day washout: RE -unilateral leg-extensions and presses (4 sets of  $\geq 10$  repetitions at 75% 1RM); AE/CON - immediately following an identical RE protocol with the opposite leg, subjects completed 90 min of cycling (60%  $\text{VO}_{2\text{max}}$ ). Skeletal muscle biopsies were obtained from the exercised vastus lateralis immediately before and 4 days after each session. Muscle samples were cross-sectioned, stained with NCAM, Ki-67, MHC I antibodies, counterstained with DAPI, and analyzed via immunohistochemistry to determine SC density (SC per muscle fiber), satellite cell activation and muscle fiber type.

**RESULTS:** SC density increased to a greater extent ( $p < 0.05$ ) following RE ( $38 \pm 10\%$ ), compared to AE ( $10 \pm 10\%$ ) and CON ( $-9 \pm 10\%$ ). Similarly, MHC I muscle fiber SC density displayed a greater increase following RE ( $46 \pm 16\%$ ), compared to AE ( $-22 \pm 10\%$ ) and CON ( $-7 \pm 17\%$ ). No exercise mode differences were observed among MHC IIa fibers.

**CONCLUSIONS:** Our data indicate that CON blunts the SC response to RE, specifically in MHC I muscle fibers. The satellite cell response observed here mimics the fiber type growth response to RE and CON training. This suggests that SC physiology contributes to the interference effect that concurrent AE has on MHC I fiber growth.

**1525** Board #306 MAY 30 11:00 AM - 12:30 PM  
**Therapeutic Ultrasound Affects Muscle Cell Proliferation: Implications For Muscle Rehabilitation**

Diana C. Delgado-Diaz<sup>1</sup>, Matthew C. Kostek<sup>2</sup>. <sup>1</sup>University of South Carolina, Columbia, SC. <sup>2</sup>University of South Carolina, Columbia, SC.  
(No relationships reported)

Therapeutic ultrasound (TUS) is a common modality in the rehabilitation of muscle injuries. In-vivo models of skeletal muscle have demonstrated that TUS increases satellite cell proliferation, a requirement for skeletal muscle repair. Current studies have attempted to determine the autonomous response of muscle cells to TUS; however their results are controversial due to the diversity of techniques and parameter used to deliver TUS (indirect sonification).

**PURPOSE:** To examine the dose-response of muscle cell proliferation due to TUS.

**METHODS:**  $\text{C}_2\text{C}_{12}$  cells were propagated in 10% FBS growth medium and incubated under sterile standard conditions. Equal numbers of cells were seeded in 100-mm culture dishes. Once cells achieved 50% confluence, TUS was delivered for 5 consecutive days. 24-h after the last treatment, cells were collected and counted with a hemocytometer. TUS delivery (continuous; 3MHz) was performed under sterile conditions; the ultrasound probe was positioned perpendicular to the dish and lowered to full contact with the medium (distance between the probe and the bottom of the dish = 4-5 mm). Nine combinations of output intensities and treatment durations were studied. Intensities: 0.2, 0.5 and 1.0W/cm<sup>2</sup>. Treatment durations: 2, 5, and 10 min. The sham cells was exposed to TUS as described with output intensity of 0W/cm<sup>2</sup> for 5min and control cells were untreated. Media temperature was measured immediately before and after each TUS exposure.

**RESULTS:** Temperature increased only in response to the highest intensity (1.0W/cm<sup>2</sup>) when delivered for 5 or 10 min. TUS increased cell proliferation when compared to Sham and control in all groups, being greater at lower output intensities (0.2 and 0.5W/cm<sup>2</sup>).

**CONCLUSION:** These data demonstrate that the direct delivery of ultrasonic waves to muscle cells in culture is feasible and produces positive effects. TUS enhances muscle cell proliferation in an autonomous manner by a mechanism other than heating. Our results support an evidence-based mechanism for the use of TUS for the treatment of skeletal muscle injuries.

**1526** Board #307 MAY 30 11:00 AM - 12:30 PM  
**Essential Amino Acid Ingestion After Exercise Enhances Amino Acid Transporter Expression In Human Skeletal Muscle**

Jared M. Dickinson, Micah J. Drummond, Jennifer R. Coben, Elena Volpi, Blake B. Rasmussen. *University of Texas Medical Branch, Galveston, TX.* (Sponsor: Elizabeth Protas, FACSM)  
(No relationships reported)

An increase in amino acid transporter expression is a proposed mechanism contributing to increases in muscle protein synthesis following essential amino acid ingestion (EAA) or resistance exercise (RE).

**PURPOSE:** To determine whether the expression of amino acid transporters in human skeletal muscle is increased in response to the combination of RE and EAA ingestion, and whether a differential response occurs with aging.

**METHODS:** Young (n=7, 30±2yr) and older males (n=6, 70±2yr) ingested 20g of EAA 1 h after performing a single bout of leg extension RE (8 sets, 10 reps, ~70% 1RM). Muscle biopsies (*vastus lateralis*) were obtained at rest and at 3 and 6h postexercise for examination of amino acid transporter mRNA and protein expression via qPCR and immunoblotting, respectively.

**RESULTS:** In both young and older males, the combination of RE+EAA elicited an increase in mRNA expression (fold change) of L-type amino acid transporter 1 (LAT1)/solute linked carrier (SLC)7A5 (Y: 3h, 4.0±0.8; 6h, 3.7±0.9; O: 3h, 3.9±1.4; 6h, 5.9±2.3) sodium-coupled neutral amino acid transporter 2 (SNAT2)/SLC38A2 (Y: 3h, 2.0±0.4; O: 3h, 1.79±0.5), and cationic amino acid transporter 1 (CAT1)/SLC7A1 (Y: 6h, 3.9±0.9; O: 3h, 3.5±0.9; 6h, 5.0±1.2) (P<0.05), whereas no changes were observed for proton-assisted amino acid transporter 1 (PAT1)/SLC36A1 or CD98/SLC3A2 in either group (P>0.05). Additionally, SNAT2/SLC38A2 protein was increased only in young adults at 3 and 6h postexercise (P<0.05), whereas older adults maintained higher LAT1/SLC7A5 protein expression compared to young following exercise (P<0.05).

**CONCLUSION:** These results suggest that both young and older males experience an increase in skeletal muscle amino acid transporter expression following the combination of RE+EAA, however, there appears to be a differential response with aging for SNAT2/SLC38A2 and LAT1/SLC7A5. These data support the hypothesis that amino acid transporters are involved in the regulation of human skeletal muscle protein synthesis in young and older adults.

1527 Board #308 MAY 30 11:00 AM - 12:30 PM

**Low Magnitude Vibration To Improve Musculoskeletal Health In A Mouse Model Of Muscle Disease**

Susan A. Novotny, Brian C. Eby, David J. Nuckley, Jarrod A. Call, Michael D. Eckhoff, Dawn A. Lowe, FACSM. *University of Minnesota, Minneapolis, MN.*

(Sponsor: Dawn Lowe, FACSM)

(No relationships reported)

Low-magnitude, high-frequency vibration (VIB) can benefit bone and skeletal muscle. These beneficial effects arise from the application of mechanical loads equivalent to those produced during postural muscle contraction. Therefore, VIB is particularly attractive as a therapeutic modality in diseases such as Duchenne muscular dystrophy (DMD) to preserve muscle and bone strength, as patients are often advised to minimize exercise.

**PURPOSE:** We devised and constructed a vibration platform for mice and using the mdx model of DMD, our initial experiments were aimed to: 1) select the frequency and acceleration of VIB that provoked an osteogenic response, 2) determine if three bouts of VIB are injurious to diseased muscle and 3) assess the myogenic potential of 7d VIB.

**METHODS:** Mdx mice were exposed to VIB for 15min/d for 7d at either 30, 45, or 90 Hz with an acceleration of either 0.3 or 0.6 g. Tibial bone RNA was extracted and compared to non-vibrated mice for genes along the osteoblast lineage. To assess if VIB was injurious, muscle strength and markers of inflammation (CCL2 and Itgam by RTPCR) were compared between mdx mice that received three bouts of VIB (45 Hz, 0.6 g), non-VIB mice, and eccentrically-injured mdx mice. The myogenic potential of VIB was assessed by RTPCR (MyoD, myogenin, and Pax7) following 7d of VIB (45 Hz, 0.6 g).

**RESULTS:** VIB at 45 Hz and 0.6 g had the largest effect in stimulating an osteogenic response; collagen type 1 mRNA was upregulated 31%, and alkaline phosphatase mRNA trended toward upregulation (p=0.09). Following three VIB bouts, muscle strength was equivalent to non-VIB mice (p=0.94) and significantly greater than eccentrically-injured mice (p>0.65), indicating that VIB is not injurious to diseased muscle. Following 7d of VIB, MyoD expression was elevated 7% (p<0.05).

**CONCLUSIONS:** These data highlight that VIB exposure at 45 Hz and 0.6 g in the mdx mouse is not injurious to muscle and has the modest potential to elevate the expression of genes involved in osteogenesis and myogenesis. Chronic studies of VIB in mdx mice are in progress to further determine the therapeutic potential of VIB for musculoskeletal health.

1528 Board #309 MAY 30 11:00 AM - 12:30 PM

**Effects Of Pre-habilitative Conditioning On Unloading-induced Remodeling Of Young And Aged Neuromuscular Systems.**

Michael R. Deschenes, FACSM, Emily K. Glass, Elizabeth G. Sherman. *College of William & Mary, Williamsburg, VA.*

(No relationships reported)

**PURPOSE:** To determine if pre-habilitative conditioning effectively mitigates adaptations to muscle unloading in young and aged neuromuscular systems.

**METHODS:** Forty young (9 mo), and 40 aged (25 mo) male rats were randomly assigned to one of four treatment groups within each age category (N=10/group). Treatment groups were: 1) hindlimb suspension for 2 wks (HS); 2) pre-habilitative exercise (i.e. treadmill running) for 2 wks prior to 2 wks of hindlimb suspension (PH-HS); 3) 2 wks of treadmill running without hindlimb suspension (PH), or 4) no intervention (CTL). Neuromuscular junctions (NMJs) of soleus muscles were stained with Bungaroxin (postsynaptic acetylcholine receptors) and RT 97 (presynaptic nerve terminals), and fluorescently stained images were captured with confocal microscopy. Myofiber profiles of those same muscles were assessed with histochemical staining for ATPase activity.

**RESULTS:** In neither age group did NMJ morphology differ (P>0.05) among the 4 treatment groups. However, young and aged rats displayed different patterns of myofiber remodeling as a result of the various experimental treatments. Among young rats, HS resulted in a 22% decline (P<0.05) in myofiber cross-sectional area; this atrophy was significantly exacerbated in the PH-HS group (40% decrease), while PH training alone had no significant effect on myofiber size. But among aged rats, PH training significantly attenuated unloading-induced myofiber atrophy (32% vs. 45%), and average myofiber size of PH rats was 14% larger than the CTL group (P<0.05).

**CONCLUSIONS:** Two weeks was too brief a period to elicit reconfiguration of the NMJ regardless of age, or treatment. In contrast, myofibers were significantly remodeled following the 2 wk intervention, with age significantly influencing those adaptations. Among young rats, pre-habilitative endurance training exaggerated unloading-induced fiber atrophy, but among aged rats - where sarcopenia was evident - the same pre-habilitative protocol significantly abated unloading-induced atrophy. We conclude that not all components of the neuromuscular system (NMJs and myofibers) are equally sensitive to unloading, and that among myofibers, aging impacts the value of pre-habilitative conditioning prior to muscle unloading.

**Nuclear Factor-KappaB Activity in Human Primary Pericytes Affects Proliferation and Differentiation of Co-Cultured Skeletal Muscle Myoblasts**

Robert D. Hylldahl<sup>1</sup>, Lawrence M. Schwartz<sup>2</sup>, Priscilla M. Clarkson, FACSM<sup>2</sup>. <sup>1</sup>University of Massachusetts Amherst, Sunderland, MA. <sup>2</sup>University of Massachusetts Amherst, Amherst, MA.

(No relationships reported)

Skeletal muscle regeneration following damage relies on the activation, proliferation and differentiation of muscle precursor cells. We recently observed altered NF-kB signaling in human skeletal muscle-resident pericyte cells following eccentric contractions, a stimulus known to induce a muscle regenerative response.

**PURPOSE:** This study determined how alterations in pericyte NF-kB activity affected the proliferation and differentiation response of local muscle precursor cells (myoblasts) in an in vitro co-culture system.

**METHODS:** Human primary pericytes (HPPs) were transiently induced to express DNA vectors designed to both increase and decrease NF-kB activity. An empty vector was used as a control. HPPs expressing the NF-kB DNA vectors were then co-cultured with C2C12 myoblasts for 4 days in a culture medium designed to promote the differentiation of myoblasts into mature muscle fibers (myotubes). Myoblast proliferation and differentiation were measured using immunocytochemistry and Western blot.

**RESULTS:** The DNA vectors were effective at both increasing and decreasing NF-kB activity in HPPs. When HPPs with increased NF-kB activity were co-cultured with myoblasts, we observed a 50% increase in myoblast proliferation (p<0.001), and inhibition of myoblast differentiation, evidenced by a 32% reduction in myotube diameter (p<0.001) and a decrease in myotube nuclei. Western blot also showed a decrease in the expression of the muscle specific marker myosin heavy chain when HPPs with increased NF-kB activity were co-cultured with myoblasts.

**CONCLUSIONS:** Taken together, these data suggest that NF-kB dependent signaling in pericytes may indirectly regulate the regenerative response following damage by promoting proliferation of muscle precursor cells.

1530 Board #311 MAY 30 11:00 AM - 12:30 PM

**Cyclooxygenase-Inhibiting Drug Effects on Skeletal Muscle Exercise Adaptations in Older Adults: Potential Mechanisms of Action**

Robert A. Standley, Bozena Jemioło, Chad C. Carroll, Scott W. Trappe, FACSM, Todd A. Trappe. *Human Performance Laboratory, Ball State University, Muncie, IN.*

(No relationships reported)

We recently reported that 12 weeks of knee extensor resistance training (3d/wk) combined with daily consumption of the cyclooxygenase (COX) inhibiting drugs acetaminophen (4.0g/d; n=11, 64±1y) or ibuprofen (1.2g/d; n=13, 64±1y) unexpectedly promoted muscle mass and strength gains 25-50% above those obtained on placebo (n=12, 67±2y).

**PURPOSE:** To further investigate the mechanism of action of these drugs.

**METHODS:** Vastus lateralis biopsies obtained before and ~72h following the last training bout were analyzed for mRNA levels of components of the COX pathway (arachidonic acid synthesis: cPLA<sub>2</sub> and sPLA<sub>2</sub>-X; prostaglandin (PG)F<sub>2α</sub> synthesis: AKR1C3 and CBR1; PGE<sub>2</sub> synthesis: PTGES, PTGES-2; PGF<sub>2α</sub> and PGE<sub>2</sub> receptors: FP and EP4), regulators of muscle proteolysis (MuRF-1, Atrogin-1, FOXO3A, IKKβ) and growth (Myogenin, MRF4, myostatin), and cytokines involved in skeletal muscle adaptation (TNF-α, IL-1β, IL-6, IL-8, IL-10).

**RESULTS:** Several components were increased with training (cPLA<sub>2</sub>, AKR1C3, CBR1, EP4, IKKβ, TNF-α, IL-1β, IL-8). However, IL-6, IL-10, and MuRF-1 were differentially upregulated (P<0.05) in the placebo group compared to both drug groups, and FP was upregulated (P<0.05) only in the drug groups.

**CONCLUSION:** Considering PGE<sub>2</sub> stimulates the production of IL-6, which has been shown to promote muscle atrophy, suppression of IL-6 and MuRF-1 in both drug groups support our previous hypothesis that inhibition of COX-derived PGE<sub>2</sub> and muscle proteolysis following the repeated exercise bouts may have been the basis for the additional muscle mass gains. Thus, we extend our hypothesis to suggest acetaminophen and ibuprofen suppression of PGE<sub>2</sub>-induced IL-6 production contributed to the additional muscle mass gains in the drug groups. Finally, the drug-induced PGF<sub>2α</sub> receptor upregulation may have restored or enhanced the protein synthesis response after each exercise bout and influenced the muscle mass gains in the drug groups.

**Effect of Prior Physical Exercise on Autophagy During MPTP-Induced Parkinson's Disease in Mice**

Ning Jiang<sup>1</sup>, Wei Cao<sup>1</sup>, Chao Song<sup>1</sup>, Jing Jing Guo<sup>1</sup>, Yong Zhang<sup>1</sup>, Li Li Ji, FACSM<sup>2</sup>. <sup>1</sup>Tianjin University of Sport, Tianjin, China. <sup>2</sup>University of Minnesota, Minneapolis, MN. (Sponsor: Li Li Ji, FACSM)

(No relationships reported)

**OBJECTIVE:** To investigate if prior chronic treadmill running could be a protective way in delaying the procedure of PD in mice. And to find the corresponding mechanism(s) about autophagy and mitochondrial fusion and fission.

**METHODS:** 40 C57BL/6 (6-8weeks) mice were randomly divided into sedentary or exercise group (12m/min, 20 minutes/day, running on treadmill for 6 weeks). After 6 weeks each group were divided into two groups which were injected with moderate dose of 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP) (30mg/kgx2, ip, 16 hr apart) or saline. Finally mice were divided into the following groups: (1) saline injected (N); (2) exercise and saline injected (NE); (3) MPTP injected (M); (4) exercise and MPTP injected (ME). Behavioral tests (pole climbing, hanging and swimming) were conducted in succession 1 day before MPTP injection, and 2, 5, 8 day after MPTP injection. Then all animal was sacrificed. Brain mitochondrial respiratory capacity (state3, state4, RCR) was measured. The expression of proteins (LC3, Beclin1, Drp1, Fis1, OPA1) were detected by western-blotting. TEM was used to observe the autophagic vacuole in brain. Two-way ANOVA with repeated measures was used for statistics.

**RESULTS:** The behavioral outcomes showed from the second day after MPTP injection, M got the lower score compared with N (p<0.05) and the figures showed a continuous rising. ME got higher score than M. Mice brain mitochondrial RCR attenuated in ME compared with M (p<0.05). Drp1 protein expression elevated notably in exercise groups compared with non-exercise groups (increasing 13% for NE vs. N and 11% for ME vs. M, p<0.05), which was similar with Fis1, whereas OPA1 indicated an opposite pattern (reducing 37% for NE vs. N and 39% for ME vs. M, p<0.01). LC3 and Beclin1 Protein increased without significance in NE vs. N. But they increased 13% (p<0.05) and 30% (p<0.01) respectively in ME vs. M. No typical autophagic vacuole was found in each group.

**CONCLUSIONS:** Prior moderate exercise may delay the development of PD by enhancing the mice brain mitochondrial respiration capacity in PD mice, which may due to exercise up-regulate the abilities of autophagy accompanied with the higher level of mitochondrial fission and lower fusion level.

**MARCH-V: A Possible Regulator of Mitochondrial Fusion and Fission in Aerobic Training Reducing Insulin Resistance?**

Fei Zhao<sup>1</sup>, Qingxun Jin<sup>1</sup>, Hairong Qiao<sup>1</sup>, Yong Zhang<sup>1</sup>, Lili Ji, FACSM<sup>2</sup>. <sup>1</sup>Tianjin University of Sport, Tianjin, China. <sup>2</sup>University of Minnesota, Minneapolis, MN.

(No relationships reported)

**PURPOSE:** To explore the MARCH-V gene expression changes in long-term aerobic training improving insulin resistance induced by high fat diet. It might have an essential role in the control of mitochondrial dynamics as a dual modulator of MFN2 and DRP1 which regulate mitochondrial dynamics and function.

**METHODS:** 40 mice were randomly divided into normal chow and high-fat diet group. After 8 weeks, each group was divided into 2 groups: normal diet control (NC), normal diet plus exercise (NE), high-fat diet control (HC) and high-fat diet plus exercise (HE). Mice were fed and/or trained for another 8 weeks. Respiratory control ratio and ATP synthesis activity in isolated skeletal muscle mitochondria were detected. Skeletal muscle mRNA and Protein levels of MARCH-V, MFN2 and DRP1 were measured by Realtime PCR and Westernblot respectively.

**RESULTS:** 1) The Fins, HOMA-IR of HC group mice were significantly lower than NC group, HE group were significantly lower than HC and significantly higher than NC (p<0.01). 2) Skeletal muscle mitochondria in HC group mice showed lower state 3 respiration and higher state 4 respiration with lower RCR than NC group (p<0.01), HE group had higher state 3 respiration and RCR than HC group (p<0.05, p<0.01), and had no difference with NC (p>0.05). 3) The size and number of mitochondria are decreased in HC group and increased in NE, HE group. 4) MFN2 mRNA and protein in NE group were higher than that of NC group (p<0.05, p<0.01). HC group were lower than NC and NE group (p<0.01). HE group were higher than the HC and NC group (p<0.01). 5) DRP1 mRNA and protein in NE group were higher than the NC group (p<0.05, p<0.01), HC were also higher than NC (p<0.05, p<0.01), HE were significantly higher than HC and NC group (p<0.01). 6) MARCH-V mRNA and protein expression in NE group were significantly higher than NC group (p<0.01), HE group were higher than NC and HC group (p<0.01).

**CONCLUSIONS:** MARCH-V may be one of the regulators for mitochondrial dynamics and function in the mechanism of aerobic training reducing IR. But it may not participate in the regulation the mitochondrial fusion and fission during development of diet induced IR.

**The Effect Of Aerobic And Resistance Exercise On Cardiac And Mitochondrial Function In Oletf Rats**

Tae hee Ko, Dae Yun Seo, Sung Ryul Lee, Hyoung kyu Kim, Na ri Kim, Byoung Doo Lee, Kyung Soo Ko, Jin Han. *Inje University, Busan, Korea, Republic of.*

(No relationships reported)

Type 2 diabetes (T2DM) is the metabolic disease from the failure of insulin secretion and accompanied by obesity and hyperlipidemia, cause cardiovascular disease. To prevent or cure, exercise helps regulate blood sugar and also significantly reduced the risk of cardiovascular disease (CVD).

**PURPOSE:** The purpose of this study was to investigate the effect of aerobic and resistance exercise on cardiac and mitochondrial function in OLETF rats.

**METHODS:** OLETF (Otsuka Long-Evans Tokushima Fatty) rats, an animal model of T2DM are occurred at 25 weeks. Twenty four OLETF rats were divided into treadmill exercise (EXT, n=8), resistance exercise (EXR, n=8) and control (SED, n=8) groups after 25weeks. EXT and EXR groups were exercised 5 day/week for 12 weeks. EXT groups were exercised at 5m/min for 10minutes as adaptation for 2 weeks. And then, speed and duration were increased gradually. EXR groups were climbed ladder 5 repetition without weight as adaptation for 2 weeks. And then, repetition and weight were increased gradually.

**RESULTS:** The left ventricular (LV) function of diastolic in echocardiogram, EXT groups are improved EDV (End of Diastolic Volume, EXT: 1.24±0.06 vs SED: 0.68±0.05, p<0.005), LVIDd (Left Ventricular Internal Dimension, diastolic, EXT: 8.28±0.16 vs SED: 6.65±0.19, p<0.005) and SV (stroke volume, EXT: 1.09±0.04 vs SED: 0.6±0.04, p<0.005) compared with SED rats. In EXR, LVPWD (Left Ventricular Posterior Wall Thickness, diastolic, EXR: 1.48±0.09 vs SED: 2.02±0.05, p<0.05) was decreased, and EDV (EXR: 0.99±0.04 vs SED: 0.68±0.05, p<0.005), LVIDd (EXR: 7.41±0.26 vs SED: 6.65±0.19, p<0.05) and SV (EXR: 0.86±0.08 vs SED: 0.6±0.04, p<0.05) were increased compared with SED rats. In mitochondria function, oxygen consumption was higher in EXT and EXR without significance. In ROS production, there was no significant change. Mitochondria membrane potential was not significantly different among OLETF groups.

**CONCLUSION:** We are suggested that improved by aerobic and resistance exercise may be positive effects on inhibiting aberrant morphological change of diabetic heart. Different function in echocardiogram between aerobic and resistance exercise, it may be different function physiologically in T2DM. However, more precise evaluations on change in cardiac mitochondria will be required.

**Exercise Enhances Myogenic Differentiation through Regulating Reactive Oxygen Species Mediated Mitochondrial Fusion**

Hai Bo<sup>1</sup>, Xun Wang<sup>1</sup>, Qixiang Chen<sup>1</sup>, Yong Zhang<sup>1</sup>, Li Li Ji, FACSM<sup>2</sup>. <sup>1</sup>Tianjin University of Sport, Tianjin, China. <sup>2</sup>University of Minnesota, Minneapolis. (Sponsor: Li Li Ji, FACSM)

(No relationships reported)

Muscle precursor cell (MPC) proliferation and differentiation has been shown to play a key role in muscle plasticity following exercise. During myogenic differentiation the short mitochondria of myoblasts change into the extensively elongated network observed in myotubes, suggesting that mitochondrial fusion may have a role in myogenesis.

**PURPOSE:** To determine the functional relevance and the molecular mechanisms driving the formation of this mitochondrial network.

**METHODS:** MPC were isolated from both trained (T) and sedentary (S) mouse skeletal muscle with a high degree of myogenic purity. Mitochondrial membrane potential, ROS generation, ATP amount, fusion protein (OPA1 and Mfn2), p-mTOR and mitochondrial prohibitin2 expression were measured. We also examined the effects of exogenous low doses H<sub>2</sub>O<sub>2</sub> (100 μM) exposure for 1h on differentiation of cultured MPC isolated from 3-month-old C57BL/6J mouse.

**RESULTS:** MPCs isolated from T mouse exhibited increased differentiation into myotubes and demonstrated increased myosin heavy chain (+117%, p<0.01) and creatine kinase (+135%, p<0.01) expression compared with S mouse. Mitochondrial membrane potential (+18%, p<0.05), ROS generation (+41%, p<0.05), ATP amount (+65%, p<0.05), OPA1 (+68%, p<0.05), p-mTOR (+34%, p<0.05) and mitochondrial prohibitin2 (+85%, p<0.01) were higher in MPC isolated from T mouse than from S mouse. We also demonstrated that H<sub>2</sub>O<sub>2</sub> enhanced MPC differentiation, while treatment with a ROS trapping agent (N-acetyl-L-cysteine, NAC) slowed MPC differentiation. H<sub>2</sub>O<sub>2</sub> exposure increased mTOR phosphorylation (+75%, p<0.01), mitochondrial membrane potential (+19%, p<0.05), ROS generation (+169%, p<0.01), ATP amount (+53%, p<0.05) and OPA1 expression (+51%, p<0.05). mTOR antagonist (Rapamycin) inhibits H<sub>2</sub>O<sub>2</sub>-induced mTOR phosphorylation (185.6±17.6% vs. 95.9±11.2, p<0.01), MPC differentiation and OPA1 expression (142.4±15.4 vs. 110.6±13.3%, p<0.05).

**CONCLUSION:** OPA1-mediated mitochondria fusion is required for exercise induced myogenic differentiation, and this event depends on generation of ROS and mTOR activation.

Supported by NSFC(No. 31071040, 31110103919).

**NAD-Linked Isocitrate Dehydrogenase Activity is Phosphate Dependent in Sparrow Mitochondria**

Doree Lynn Gardner, Sarah Kuzmiak, Wayne T. Willis. Arizona State University, Tempe, AZ.

(No relationships reported)

Flying birds are highly aerobic athletes, yet literature values indicate low activities of NAD-linked isocitrate dehydrogenase (IDH) in avian flight muscle. IDH is an important locus of rate control in the citric acid cycle (CAC) in most species, but calculations revealed that literature values of avian IDH V<sub>max</sub> could account for < 5% of the oxygen consumed by avian mitochondria oxidizing pyruvate + malate. Therefore carbon flux through the CAC might fundamentally differ in avian compared to mammalian mitochondria. It is conceivable that NADP-linked IDH plays a more important role in the routine flux of the avian CAC or that NAD-linked IDH of avian flight muscle may have different kinetic requirements than its mammalian counterpart.

**PURPOSE:** To determine physiologic co-factors which might influence NAD-IDH activity in avian skeletal muscle and to assess NAD- and NADP-IDH activity in whole muscle homogenate and isolated mitochondria from avian and mammalian locomotory muscles.

**METHODS:** Rat mixed hindlimb and English sparrow pectoralis muscle were excised and mitochondria were isolated. A 10% muscle homogenate in 10 mM KPO<sub>4</sub> (pH 7.4) was made from a second tissue sample. IDH activity was spectrophotometrically assayed in whole muscle homogenate and mitochondrial fractions following NAD(P)H appearance at 340 nm. Cofactor additions included MnCl<sub>2</sub> (1.3mM), MgCl<sub>2</sub> (10mM), K<sub>2</sub>PO<sub>4</sub> (10mM), ADP (100 mM), and dithiothreitol (DTT) (1mM).

**RESULTS:** The highest NAD-IDH activity was observed when MnCl<sub>2</sub>, K<sub>2</sub>PO<sub>4</sub>, ADP, and DTT were included in the assay medium. NAD-IDH activity was higher in sparrow than rat muscle homogenate (10.1 ± 1.4 vs. 2.9 ± 0.4 μmol/g/min), while NADP-IDH activity was higher in rat than in sparrow (20.9 ± 4.2 vs. 11.4 ± 1.4 μmol/g/min). Rat mitochondrial NAD and NADP-IDH activities were 208.0 ± 17.0 and 1105 ± 152.7 nmol/mg/min, respectively, while sparrow mitochondrial NAD and NADP-IDH values were 389.6 ± 74.4 and 152.5 ± 27.9 nmol/mg/min.

**CONCLUSIONS:** While rodent muscle NAD-IDH exhibits no phosphate dependence, sparrow IDH activity was highly dependent upon K<sub>2</sub>PO<sub>4</sub>, revealing a different metabolic control mechanism in the avian system. In the presence of phosphate, avian NAD-IDH was fully competent to account for the apparent CAC flux during pyruvate + malate oxidation by flight muscle mitochondria.

**Electron Conductance in Rat and Sparrow Skeletal Muscle Mitochondrial Electron Transport Chain**

Sarah Kuzmiak, Wayne T. Willis. Arizona State University, Tempe, AZ.

(No relationships reported)

Flying birds utilize fat for fuel during flight, a moderate-high intensity exercise, while mammalian reliance on carbohydrate increases with increasing exercise intensity. Previous investigations in our lab have shown this pattern of fuel selection persists even when saturating fuels are provided to the inner membrane transporters of intact respiring mitochondria, suggesting a fuel selection mechanism at the level of the matrix.

**PURPOSE:** To compare the maximal rates of complete substrate oxidation to the oxidation of electrons as well as electron conductance in rat and sparrow mitochondria to elucidate differences between the species in the ability to produce electrons (via dehydrogenase enzymes, β-oxidation, and the citric acid cycle) and the capacity for these electrons be consumed (via travel down the electron transport chain (ETC)).

**METHODS:** Intact mitochondria were isolated, provided saturating fuels (pyruvate, glutamate, and malate), and the maximal rate of oxygen consumption (J<sub>o</sub>) was determined. Mitochondria were then sonicated and maximum NADH oxidation was measured following the rate of oxygen reduction to water. The slope of the oxidation:reduction (redox) potential difference (ΔEh):J<sub>o</sub> relationship, a measure of the conductance of electron flow down the ETC, was also determined.

**RESULTS:** Intact maximal J<sub>o</sub> were 636 ± 87 and 641 ± 83 nmol·mg<sup>-1</sup>·min<sup>-1</sup> in rat and sparrow, respectively, while the ETC V<sub>max</sub> were 731 ± 76 and 1020 ± 108 nmol·mg<sup>-1</sup>·min<sup>-1</sup>. Combined, these data indicate greater relative ETC activity in the sparrow; the (intact oxidase pathway)/(ETC only) ratio was .86 ± .04 in the rat and .65 ± .07 in the sparrow. Additionally, the slope of the ΔEh: J<sub>o</sub> relationship was 1.7x greater in sparrow than the rat mitochondria, 12306 ± 1538 and 7196 ± 924, respectively.

**CONCLUSIONS:** These data indicate avian mitochondria have greater ETC “excess capacity” as well as greater conductance down the ETC compared to mammalian mitochondria. As a high reduction level of the mitochondrial matrix has been associated with an inhibition of β-oxidation, we posit rat fatty acid oxidation is inhibited by high reduction in the mitochondrial matrix while birds, via a high ETC conductance, are able to maintain lower matrix reduction, allowing fatty acid oxidation to proceed.

1537 Board #318 MAY 30 11:00 AM - 12:30 PM

**Endurance Training and Chronic Intermittent Hypobaric-Hypoxia Modulate Liver Mitochondrial Bioenergetics. Role Against Salicylate-Induced Mitochondrial Dysfunction**

Antonio A. Ascensao<sup>1</sup>, Ines O. Goncalves<sup>1</sup>, Jose Lumini-Oliveira<sup>1</sup>, Ines M. Aleixo<sup>1</sup>, Emanuel Passos<sup>1</sup>, Silvia Rodrigues<sup>1</sup>, Nuno G. Machado<sup>2</sup>, Ana C. Moreira<sup>2</sup>, Paulo J. Oliveira<sup>2</sup>, Juan R. Torrella<sup>3</sup>, Jose Magalhaes<sup>1</sup>. <sup>1</sup>CIAFEL, Faculty of Sport, University of Porto, Porto, Portugal. <sup>2</sup>CNC, Coimbra, Portugal. <sup>3</sup>Faculty of Biology, University of Barcelona, Barcelona, Spain.  
(No relationships reported)

Endurance-training (ET) and chronic intermittent hypobaric-hypoxia (CIHH) are strategies for preventing and treating metabolic and cardiovascular diseases. Salicylate is an anti-inflammatory metabolite that causes liver injury by mitochondrial-mediated mechanisms. Whether ET and CIHH modulate liver mitochondrial (LM) bioenergetics altering the resistance against toxic conditions is not known.

**PURPOSE:** To analyze the effects of ET and CIHH on LM bioenergetics under basal conditions and with salicylate.

**METHODS:** Twenty-eight young-adult male rats were divided into normoxic-sedentary (NS), normoxic-exercised (NE), hypoxic-sedentary (HS) and hypoxic-exercised (HE). ET consisted of 1h/d of treadmill running and CIHH of 5wks, 5h/d simulated atmospheric pressure of 49.3kPa. Oxygen consumption, transmembrane potential and calcium-induced mitochondrial permeability transition pore (MPTP) were evaluated in isolated LM in the presence and absence of salicylate (0.5mM). Aconitase, MnSOD, -SH, MDA, SIRT3, Cyp D, HSP70, OXPHOS subunits, caspase 3 and 8 were assessed. Group comparisons were made using one-way ANOVA.

**RESULTS:** ET and CIHH decreased basal state 3 (NS-249 vs. NE-161, HS-168, HE-170 natomsO/min/mg,p<0.05) and state 4 (NS-74 vs. NE-46, HS-33, HE-45 natomsO/min/mg,p<0.05). No alterations were observed in membrane potential endpoints evaluated under basal conditions. In the presence of salicylate, ET and CIHH decreased state 4 and lag phase of ADP phosphorylation (NS-105 vs. NE-56, HS-62, HE-66 natomsO/min/mg; NS-151 vs. NE-130, HS-107, HE-105 sec,p<0.05). Neither ET nor CIHH altered the susceptibility to calcium-induced MPTP. CIHH lowered MnSOD (NS-12 vs. NE-11, HS-8, HE-8 U/mg,p<0.05) and increased aconitase (NS-0.63 vs. NE-0.24, HS-0.85, HE-0.80 U/mg,p<0.05) activities. ET and CIHH decreased caspase 8 activity (NS-1150 vs. NE-864, HS-545, HE-537 pNa/ug,p<0.05) whereas no effect was observed on caspase 3. The levels of SIRT3 increased with ET and CIHH (NS-100 vs. NE-150, HS-128, HE-151%,p<0.05) and Cyp D decreased with CIHH per se (NS-100 vs. HS-83%,p<0.05). No differences were observed in HSP70 and OXPHOS subunits.

**CONCLUSION:** ET and CIHH modulate basal LM bioenergetics and may antagonize some adverse effects of salicylate. Supported by FCT grant PTDC/DES/113580/2009.

**Seven Weeks Of 10-20-30 Running Effectively Improves Health Profile And Performance In Trained Runners**

Thomas P. Gunnarsson, Stine S. Johansen, Rasmus Jørgensen, Jacob Vorup, Jonas T. Nielsen, Martin R. Krisitansen, Jens Bangsbo, Professor. *University of Copenhagen, Copenhagen, Denmark.*  
(No relationships reported)

An intense training regime ( $\geq 100\%$  of maximal oxygen uptake ( $VO_2$ -max)) is known to be an effective way to improve performance in already trained subjects. However little is known about how such training affects the health profile of trained subjects.

**PURPOSE:** To examine whether an intensified training regime (10-20-30 training) can improve the health profile and performance in moderately trained runners.

**METHODS:** Eighteen trained runners (6 females and 12 males with  $VO_2$ -max of  $50.9 \pm 2.0$  and  $52.4 \pm 1.6$  ml·kg<sup>-1</sup>·min<sup>-1</sup>, respectively) were divided into two matched groups; an intermittent training group (INT; n=10) and a control group (CON; n=8). INT replaced all regular training sessions with 3 weekly sessions of 10-20-30 training reducing training volume by 54% (from  $30.4 \pm 2.3$  to  $14 \pm 0.9$  km per week) while CON continued the normal training. The 10-20-30 training consisted of 3-4 5-min blocks interspersed by 2 min of rest per training session. Each 5-min block consisted of 30 seconds of jogging followed by 20 seconds of normal running and 10 seconds of sprinting. The training progressed from 3 blocks during the first 4 weeks to 4 blocks in the last 3 weeks per training session. All tests were preceded by at least 36-h of rest and the subjects were familiarized to testing procedures. On a separate day, in the morning after an overnight fasting, blood pressure (BP) was measured after 10 min of supine resting and blood samples were drawn from v. brachialis. Data are presented as means $\pm$ SE and data are compared pre vs. post using a students paired t-test.

**RESULTS:** After 7 weeks of 10-20-30 training total and LDL cholesterol were lowered (p<0.05) in INT ( $4.8 \pm 0.4$  vs.  $4.3 \pm 0.3$  and  $2.7 \pm 0.3$  vs.  $2.3 \pm 0.3$  mmol·l<sup>-1</sup>, respectively) as well as systolic BP ( $125 \pm 3$  vs.  $120 \pm 4$  mmHg p<0.05). In CON, BP and LDL cholesterol were unaltered, but total cholesterol was higher (p<0.05) after the training period ( $5.0 \pm 0.4$  vs.  $5.4 \pm 0.4$  mmol·l<sup>-1</sup>). In INT,  $VO_2$ -max and 5-K performance was improved (p<0.05) by 4% ( $51.6$  vs.  $53.8$  ml·kg<sup>-1</sup>·min<sup>-1</sup>) and 3% ( $23:22 \pm 1:04$  vs.  $22:40 \pm 0:54$  min:s), respectively, whereas no changes were observed for CON.

**CONCLUSION:** Seven weeks of 10-20-30 training enhanced the health profile and improved performance in moderately trained male and female runners, despite a marked reduction in training volume.

Supported by Nordea-fonden, Denmark.

1539 Board #320 MAY 30 9:30 AM - 11:00 AM

**A Harness Safety Spotting System During Treadmill Vo2max testing in collegiate runners**

Micah Zuhl, Ailish C. White, Roy M. Salgado, Jason R. Beam, M. Virginia Wilmerding, Christine M. Mermier. *University of New Mexico, Albuquerque, NM.*  
(No relationships reported)

A maximal exercise test on a treadmill is commonly used to assess aerobic capacity ( $VO_2$ max), maximal running velocity ( $vVO_2$ max), and either ventilatory (VT) or lactate threshold (LT). As the speed and grade of the treadmill increase during the test, there is an increased risk of a falling injury. The termination of a maximal treadmill exercise test may be due to the subject's concern for safety while running at high velocities. The premature termination may result in an inaccurate assessment of maximal exercise capacity.

**PURPOSE:** To compare the results of maximal treadmill testing with and without a safety harness system in collegiate middle and long distance runners.

**METHODS:** Eighteen (n = 10 M, n = 8 F) collegiate runners completed two randomly selected maximal treadmill tests: one trial using a safety harness (SH) and one trial without a safety harness (NSH), all tests were separated by at least 48 h. The subjects began the test at a velocity of 14.5 km/hr or 12 km/hr with 1% grade for men and women, respectively. Speed increased by 0.806 km/hr per minute until volitional fatigue.  $VO_2$ max,  $vVO_2$ max, VT, test time (TT), RPE, HR, and  $VO_2$  plateau were measured for each trial. A questionnaire was administered after each trial to assess safety.

**RESULTS:** No significant difference was found for  $VO_2$ max,  $vVO_2$ max, RPE, and HR between trials. TT was significantly longer in the NSH trial (NSH = 590s vs. SH = 536s, p< 0.05). Questionnaire responses showed a significantly higher feeling of safety during the SH trial (p< 0.05).

**CONCLUSION:** A safety harness system increases the safety of subjects without affecting the results of a maximal exercise test. Therefore, safety is not a limitation during a maximal exercise test for collegiate middle and long distance runners.

1540 Board #321 MAY 30 9:30 AM - 11:00 AM

**An Examination of Stretching Practices and Perceptions within US Collegiate Cross Country and Distance Programs**

Lawrence Judge<sup>1</sup>, David Bellar<sup>2</sup>, Jeffrey Petersen<sup>3</sup>, Bruce Craig<sup>1</sup>, Kimberly Bodey<sup>4</sup>, Erin Gilreath<sup>4</sup>, Laura Simon<sup>1</sup>, Matt Benner<sup>1</sup>. <sup>1</sup>Ball State University, Muncie, IN. <sup>2</sup>University of Louisiana at Lafayette, Lafayette, LA. <sup>3</sup>Baylor University, Waco, TX. <sup>4</sup>Indiana State University, Terre Haute, IN.  
(No relationships reported)

Research pertaining to pre-activity and post-activity stretching continues to expand in varied sport settings along with related best practice recommendations.

**PURPOSE:** This study was designed to determine if the pre- and post-activity stretching practices and perceptions of college cross country and track and field distance programs are aligned with the current recommendations.

**METHODS:** A total of 770 questionnaires were distributed to NCAA Division I, Division II, and Division III coaches in the United States. The demographic characteristics for participants in the investigation were as follows: n = 111, 78.2% male, 21.8% female, and age 41.31±12.0 years. The questionnaire was designed to gather demographic, professional, and educational information, as well as specific pre- and post-activity stretching usage by the coaches. The responses were examined by computing frequency counts and means where applicable. Pearson's chi-square tests were utilized to determine differences in stretching modality usage.

**RESULTS:** Chi square analyses revealed a significantly greater usage of static stretching alone as a pre-activity modality ( $\chi^2 = 21.582$ ,  $p = 0.0174$ ) by non-certified coaches (18.9%, n = 9) versus their certified counterparts (1.8%, n = 1). In addition, certified coaches reported higher usage of dynamic flexibility only during the pre-activity period (47.4%, n = 27) versus non-certified peers (32.4%, n = 16). Coaches were also asked if they allowed for static stretching between interval work and competitive efforts, and similarly a significant difference ( $\chi^2 = 11.948$ ,  $p = 0.0177$ ) was noted with a higher percentage of non-certified coaches (45.5%, n = 23) allowing athletes to perform static stretches during these situations than certified peers (37.9%, n = 22).

**CONCLUSION:** When comparing coaching specific certification to pre-activity flexibility practices, it is clear not all coaches are in compliance with suggested pre-activity flexibility recommendations. These significant differences help demonstrate coaching certification courses as an effective tool for communicating current information about effective stretching modalities. However, the results also revealed that there are still many certified coaches who are not implementing best practices into athlete stretching routines.

1541 Board #322 MAY 30 9:30 AM - 11:00 AM

**Effects Of 8-week Whole-body Vibration Training On Running Economy**

Ching-Feng Cheng, Kuo-Hui Cheng, Yu-Ming Lee, Hsin-Wei Huang, Yu-Hsuan Kuo, Heng-Ju Lee. National Taiwan Normal University, Taipei, Taiwan.  
(No relationships reported)

Running economy (RE), one of the critical physiological factors related to running performance, can be improved by explosive training. Whole-body vibration (WBV) has been used as an exercise modality to enhance explosive performance. However, there are no studies to demonstrate if the WBV training could be used to improve the RE.

**PURPOSE:** The purpose of this study is to investigate the effects of 8-week WBV training on power performance and RE.

**METHODS:** Twenty-four male collegiate athletes were recruited and randomly assigned to experimental (WBV, n=12) and placebo (PL, n=12) groups. The WBV participants performed semi-squat vibration training (30 Hz, ± 1–2 mm, 3 times per week), while PL participants performed identical training without vibration. The isometric maximum voluntary contraction test was used to evaluate the maximal isometric force ( $F_{max}$ ) and the rate of force development (RFD) of the lower extremities, and RE was measured on a level treadmill at 3 different velocities (2.68, 3.13, and 3.58 m·s<sup>-1</sup>), before and after the intervention.

**RESULTS:** There were no significant improvements on the  $F_{max}$  of the knee extensors and flexors in the both groups after training. The  $F_{max}$  of the lower leg (plantar flexion, from 80.8 ± 24.5 to 99.0 ± 33.9 N·m,  $p < 0.05$ ,  $\eta^2 = 0.567$ ; dorsiflexion, from 38.1 ± 6.5 to 43.0 ± 7.7 N·m,  $p < 0.05$ ,  $\eta^2 = 0.415$ ), and the RFD of 0–200 ms during plantar flexion (from 186.0 ± 69.2 to 264.6 ± 87.2 N·m·s<sup>-1</sup>,  $p < 0.05$ ,  $\eta^2 = 0.184$ ) were significantly increased in the WBV group after training. No significant differences were observed on the  $F_{max}$  of the dorsiflexors and the RFD of 0–200 ms during plantar flexion after PL intervention. The averaged RE values for the 3 running velocities were significantly improved after WBV training (pre- vs. post-training, 4.31 ± 0.33 vs. 4.65 ± 0.34 m·ml<sup>-1</sup>·kg<sup>-1</sup>,  $p = 0.001$ ,  $\eta^2 = 0.654$ ); however, no significant differences were found in the PL group (pre- vs. post-training, 4.18 ± 0.26 vs. 4.26 ± 0.44 m·ml<sup>-1</sup>·kg<sup>-1</sup>,  $p = 0.476$ ). The WBV training significantly improved RE at selected speeds (~5.0–6.2 % in caloric unit cost, and ~7.2–8.5 % in distance unit cost,  $p < 0.05$ ).

**CONCLUSION:** These results indicate that short-term WBV training may improve RE and power performance in competitive athletes.

Supported by grants from National Taiwan Normal University, Taipei, Taiwan.

**Manipulation of Training Regimen and Dietary Pattern Enhanced Submaximal Performance in Ramadan Fasting Distance Runners**

Ali M. Al Nawaiseh<sup>1</sup>, Mo'ath F. Bataineh<sup>1</sup>, Matt Green<sup>2</sup>. <sup>1</sup>The Hashemite University, Zarqa, Jordan. <sup>2</sup>University of North Alabama, Alabama, AL. (Sponsor: Matt Green, FACSM)  
(No relationships reported)

Muslim athletes are obligated to abstain from eating and drinking from dawn to dusk during the whole lunar month of Ramadan, this religious practice has been reported by many to interrupt regular training schedules and therefore influence performance.

**PURPOSE:** We investigated the effects of modified training protocols and altered dietary intake on the performance of Ramadan (daytime) fasting on distance running performance.

**METHODS:** Fourteen competitive distance male runners (23.9 ± 3.1 yrs) who observed Ramadan participated in this study after signing an IRB-approved Informed consent. Participants reported to the lab at 10:00 am and rested for 30 minutes. A graded treadmill exercise protocol (Conconi) was conducted to assess oxygen consumption (VO<sub>2</sub>), rating of perceived exertion (RPE), heart rate (HR), and time to exhaustion on 3 separate occasions (3 days before Ramadan, at day 14 and day 28 of Ramadan). Subjects maintained their free living style for the first two weeks of Ramadan. For the second half of Ramadan participants were randomly divided into two groups (control and treatment). Treatment included training (modified schedule & increased load) and dietary (increased caloric and fluid intake and modified timing of intake).

**RESULTS:** Ramadan decreased energy intake ( $p < 0.0001$ ), number of meals ( $p < 0.0001$ ), and training loads ( $p < 0.0001$ ). HR and VO<sub>2</sub> at sub maximal speeds tended to decrease while RPE increased ( $p = 0.046$ ) during Ramadan. Time to exhaustion tended to increase during Ramadan for both groups. However, the treatment group took longer to reach exhaustion ( $p = 0.021$ ) and tended to have lower HR and VO<sub>2</sub> compared to control group at the end of Ramadan. Body weight and body fluids were not affected by fasting.

**CONCLUSIONS:** Despite increasing RPE during exercise, Ramadan enhanced performance and this effect could be augmented by manipulating dietary behavior (mainly timing of intake) and training protocol.

**Case-Study: Individualized Training and Nutrition Periodizations in Three Elite Marathoners**

Trent Stellingwerff. Canadian Sport Centre - Pacific, Victoria, BC, Canada. (Sponsor: Lawrence L. Spriet, FACSM)  
(No relationships reported)

Recent studies have begun to examine how the implementation of individualized fueling (i.e. a periodic lack of carbohydrate (CHO) availability during training) and fluid strategies, can enhance training effectiveness and adaptations that ultimately translates into optimal race-day performance in endurance athletes.

**PURPOSE:** To characterize periodized training and nutrition interventions leading to individualized race-day fluid and fueling plans for three world-class marathoners.

**METHODS:** This case-study involved 16 wks of nutrition and training periodization in 3 elite male runners (28.3±2.3 yrs; 67.3±3.3 kg) with >9yrs of elite training (>125km/wk) prior to a target marathon. Athletes kept detailed training logs including information on training volume (min; km) and interval splits, body weight and subjective ratings of perceived exertion (RPE) for each training session. RPE based training impulse calculations (TRIMP; i.e. training volume x intensity = load) were undertaken as a measure of training "load". Two main nutritional interventions were implemented: periodic low-CHO availability training, and individualized targeted CHO and fluid intake interventions. Interventions were fully described to each athlete/coach and continuous interaction and individual feedback were provided with alterations implemented, where needed, throughout the 16 wk period.

**RESULTS:** Athletes averaged 12.6±2.1 training sessions/wk for a total of 202±22 sessions over 16 wks. Average weekly training volumes were 173.6±32.5, 213.3±41.2 and 159.6±27.0 km/week for marathoner 1, 2 and 3, respectively. There was a weekly high TRIMP of 4437 AU (wk 9) and low of 1887 AU (wk 16), and an average of 3082±646 AU. Of the 606 total training sessions, on average ~74, 11 and 15% were completed at an intensity in zone 1 (very easy to somewhat hard), zone 2 (at lactate threshold) and zone 3 (very hard to maximal). There was 2.5±2.3 low energy training bouts per week. On race day athletes consumed 61±15g CHO in 604±156 ml per hour (10.1±0.3% CHO solution). Athletes improved their marathon race times from 2:16:53 to 2:11:23, a debut at 2:16:17 and 2:15:15 to 2:12:39, respectively.

**CONCLUSIONS:** These unique periodized training and nutrition approaches in preparation for competition allowed for enhanced individual marathon performance.

**1544 Board #325 MAY 30 9:30 AM - 11:00 AM**  
**Body Composition and Weight Changes Based on Sex During a 15-Week Marathon Training Program**

Scott R. Brown, Stacy J. Ingraham, Jane R. Yank, Jordan M. Langen. *University of Minnesota, Minneapolis, MN.*  
(No relationships reported)

Exercise and nutritional interventions have been at the forefront to produce positive health changes and reduce obesity. The general public often views the effectiveness of an exercise program solely on changes in weight, especially females. This research demonstrates weight loss may not occur with months of an endurance training intervention and weight loss may be a poor assessment to quantify immediate positive results. This study also gives evidence that the public needs a practical way to assess body composition changes through intervention programs designed to lower body weight. Finally, there appears to be a difference between males and females in regards to weight loss during the marathon training.

**PURPOSE:** To determine if a 15-week marathon training program is successful for lowering body weight and improving body composition without a subsequent diet intervention.

**METHODS:** Eighty-five students (30 males, 55 females) were recruited from a marathon- training course offered by the Physical Activity Program at the University of Minnesota. Testing included VO<sub>2</sub>max, body composition, and anthropometric measures. Testing was done prior to the marathon training and two weeks prior to the marathon. Percentage of body fat was assessed using a BodPod. Independent t-tests were used to compare males and females on two dependent variables: (a) change of weight (kg), and (b) change in percentage of body fat after 15 weeks of marathon training. Differences between pre- and post-test measurements of weight and percentage of body fat were assessed using dependent t-tests for paired samples.

**RESULTS:** There was a not a weight change for females (0.21 +/- 0.22 kg p=0.346), and men trended to lose weight (-0.74 +/- 0.39 kg, p=0.75). Percent body fat did decline for females (-1.04 +/- 0.35%, p=0.004) and males (-1.26 +/- 0.46%, p=0.10) trended toward a decline also. Men lost more weight (0.95 +/- 0.441 p=0.027) than females and men also trended towards lowering percent body fat (0.258 +/- 0.14, p=0.073) when compared to females.

**CONCLUSIONS:** There is a tendency for males to lose more weight and have larger changes in body fat percentages than females following a 15-week marathon-training program and changes in percent body fat may be the best way to monitor body compositional changes during an endurance training protocol.

**Maintenance of Increased Step Frequency Training in Female Runners Following Period of No Training**

Timothy J. Quinn, FACSM, Sara E. Hourihan, Shauna L. Dempsey. *University of New Hampshire, Durham, NH.*  
(No relationships reported)

Running economy (RE) is the steady-state VO<sub>2</sub> for a given submaximal running velocity and accounts for up to 65% of the variability in performance time. Increased step frequency (SF) training has been previously shown to improve running economy (RE). Whether an increased SF can be maintained following this type of training is unknown.

**PURPOSE:** The purpose of the study was to determine if a runner could retain an increased step frequency and improved RE after 12 days of structured training followed by 14 days with no learning stimulus.

**METHODS:** Ten female runners were recruited from local races and track clubs that had 5K times between 17-22 mins within the past year and a SF <175 s/min. Day 1 involved subjects running for 5 mins on the treadmill at 3.4 and 3.8 m/sec at their preferred SF (PSF) and at an optimal SF (OSF) of 180 s/min. VO<sub>2</sub> was measured at the two speed and SF conditions. VO<sub>2</sub>max was measured after the submaximal runs. Days 2-11 involved training on the treadmill for 15 mins each day at the OSF of 180 s/min. A metronome was used to help subjects maintain the increased SF and SF was monitored using a footswitch and a BIOPAC MP100 Data Acquisition System. Days 12 and 26 involved post-training treadmill VO<sub>2</sub> testing with no step training between days. Subjects were encouraged to train at the recently learned, faster SF. A repeated-measures ANOVA was used to detect significant differences at the p<0.05 level.

**RESULTS:** Following the training and on average, submaximal VO<sub>2</sub> decreased by 3.0% (p=NS), HR dropped 4.0% (p<0.05), and SF was 4.0% (p<0.05) higher across both speeds and conditions. Following two weeks of no structured SF training, the VO<sub>2</sub> reduction was maintained (2.9%; p=NS) as were the reduced HR (4.0%; p<0.05) and increased SF (3.7%; p<0.05) compared to the pre-training measurements and these findings were not different from post-training measurements.

**CONCLUSIONS:** The results from this study suggest that an increased SF can be maintained following a short SF training program resulting in a lower VO<sub>2</sub> and HR and therefore, an improved RE in well-trained female runners.

**1546 Board #327 MAY 30 9:30 AM - 11:00 AM**  
**The Effect of Stride Frequency on Running Economy**

Robert M. Otto, FACSM, Michele Aquino, John W. Wygand, Raymond Peralta, Mariel Wenzel, Cory Whitmer, Shannon Isom. *Adelphi University, Garden City, NY.*  
(No relationships reported)

Run economy is closely allied with both stride frequency and stride length, which are inversely proportional at a fixed speed. It is believed that veteran runners gravitate to a specific stride frequency, which may coincide with optimal efficiency. Often acute fatigue during a race attenuates both run performance and efficiency through changes in stride frequency and length. If an optimal stride frequency can be identified, then the seasoned athlete can strive to retain the optimal stride frequency during all efforts.

**PURPOSE:** To determine the effects of three different stride frequencies on energy cost at a fixed speed.

**METHODS:** 12 intercollegiate athletes (9 male, 3 females, ht. 173.3 ± 8.9 cm, body mass 66.9 ± 10 kg) volunteered to run at a steady state level which corresponded to their 10K race pace. A baseline trial was conducted at 214.4 (n=2), 241.2 (n=3) or 268 (n=7) m/min and 1% grade at the participants self-selected stride frequency (SS), while metabolic energy cost (oxygen consumption) and stride frequency were obtained. Subjects practiced running at the initial fixed speed with a stride frequency of 5 steps/min above (A) and 5 steps/min below (B) their self-selected stride frequency. After a minimum of four practice sessions, subjects performed trials A and B with open circuit spirometry in a randomized design.

**RESULTS:** Mean SS stride frequency was 89 ± 6.7 with a range of 81-102. The mean energy cost at a fixed speed and a stride frequency of SS, A, and B were 51.5 ± 5.7, 51.2 ± 5.6 and 51.4 ± 5.0 mL<sub>O</sub><sub>2</sub>/kg-min, and .204, .203, and .204 mL<sub>O</sub><sub>2</sub>/kg-meter, respectively, with a mean range of less than 39 mL<sub>O</sub><sub>2</sub>/min among all trials. Stride length and stride length/leg length ratio were 1.43, 1.35, and 1.51 meters/stride and 1.70, 1.62, and 1.81, for SS, A, and B trials, respectively. Statistical analysis by ANOVA at p<.05 revealed no significant difference among the three trials, even though eight subjects displayed the lowest energy cost at a stride frequency greater than their SS frequency.

**CONCLUSION:** The lack of statistical significance among various stride frequencies does not preclude the possibility of an improved run efficiency and/or performance of specific individuals with an alteration in stride frequency.

**1547 Board #328 MAY 30 9:30 AM - 11:00 AM**  
**Running Economy Is Not Related To Jumping Performance**

James M. Smoliga<sup>1</sup>, Josh J. Fleming<sup>2</sup>, Michael S. Hux<sup>2</sup>, Andrea J. Fradkin<sup>2</sup>. <sup>1</sup>Marywood University, Scranton, PA. <sup>2</sup>Bloomsburg University, Bloomsburg, PA.  
(No relationships reported)

Previous research has shown that plyometric training is an effective way of improving running economy (RE). Yet it is unknown whether certain jump types have larger running-specific components associated with them.

**PURPOSE:** To determine the relationship between eight different jump types and RE.

**METHODS:** Ten recreationally active college students (six males, four females) participated in two days of testing separated by 48 hours. On Day 1, participants ran for five minutes on a treadmill at four submaximal speeds with three minutes rest between speeds. Metabolic data was collected continuously and RE for each speed was computed as  $\text{VO}_2$  required to run 1km. On Day 2, participants performed a series of eight randomized jumps including a single-legged vertical jump (VJ), broad jump (BJ), and contralateral jump (CJ) on both right (R) and left (L) legs, as well as a double-legged (2L) VJ and BJ. Participants performed three repetitions of each jump, with 45 seconds rest between repetitions and a three minute rest between jump types. A repeated measures ANOVA was performed to compute differences in metabolic data and RE between speeds. Pearson's product moment correlations were performed to determine the relationship between the best jump performance for each condition and RE.

**RESULTS:** There were significant differences in heart rate and  $\text{VO}_2$  between all speeds ( $p \leq 0.001$ ), yet there were no significant differences in RE between all speeds ( $p = 0.938$ ). Very poor, non-significant, negative relationships were found between mean RE ( $218.2 \pm 27.2 \text{ mL O}_2 \cdot \text{kg}^{-1} \cdot \text{km}^{-1}$ ) and both double-legged jumps ( $\text{VJ}_{2L}$ ,  $0.52 \pm 0.16\text{m}$ ,  $r = -0.015$ ,  $p = 0.967$ );  $\text{BJ}_{2L}$  ( $2.22 \pm 0.50\text{m}$ ,  $r = -0.055$ ,  $p = 0.880$ ), as well as  $\text{VJ}_L$  ( $0.39 \pm 0.14\text{m}$ ,  $r = -0.028$ ,  $p = 0.938$ ). Very poor, non-significant, positive relationships were found between RE and all right-legged jumps ( $\text{VJ}_R$  ( $0.37 \pm 0.13\text{m}$ ,  $r = 0.059$ ,  $p = 0.872$ );  $\text{BJ}_R$  ( $1.77 \pm 0.43\text{m}$ ,  $r = 0.248$ ,  $p = 0.489$ );  $\text{CJ}_R$  ( $2.02 \pm 0.33\text{m}$ ,  $r = 0.159$ ,  $p = 0.662$ ), as well as  $\text{BJ}_L$  ( $1.82 \pm 0.35\text{m}$ ,  $r = 0.218$ ,  $p = 0.546$ ) and  $\text{CJ}_L$  ( $2.01 \pm 0.34\text{m}$ ,  $r = 0.175$ ,  $p = 0.629$ ).

**CONCLUSION:** All jump types examined in this study had very poor relationships to RE, suggesting that there must be alternate explanations for the improved RE seen after plyometric training. Future research should explore other jump types, as well as other mechanisms that may account for this.

**1548** Board #329 MAY 30 9:30 AM - 11:00 AM

**Effects of Unweighting on Heart Rate Response and Speed/Incline Adjustments Necessary in Elite Runners**

Robert G. LeFavi, Aubrey G. Morris, Jayme Eitner, Ernest Ledesma, Bryan L. Riemann. *Armstrong Atlantic State University, Savannah, GA.* (Sponsor: T. Jeff Chandler, FACSM)

(No relationships reported)

The AlterG Treadmill, which makes use of lower body positive pressure (LBPP), enables runners to train at race-pace speeds yet with variable body weights (BW) and resultant ground reaction forces. The AlterG is marketed as an "unweighting" tool useful during lower body injury. There is lack of research investigating the additional speed and/or incline necessary at lower BW to achieve the equivalent intensity possible at 100% BW.

**PURPOSE:** To quantify AlterG speed and incline adjustments necessary at two levels of unweighting in order to achieve intensities equivalent to those at 100% BW running.

**METHODS:** Following an initial  $\text{VO}_{2\text{max}}$  test, seven elite male runners (average age = 30.1 yrs; ht = 177.4 cm; wt = 77.1 kg;  $\text{VO}_{2\text{max}}$  = 64.1 ml/kg/min) underwent two unweighted running trials (75% BW and 50% BW). The trials ended when subjects reached their heart rate at 90%  $\text{VO}_{2\text{max}}$ . Heart rate, speed, and incline were recorded throughout each trial.

**RESULTS:** When subjects were unweighted to 75% BW and ran at their heart rate equivalent of 70%  $\text{VO}_{2\text{max}}$ , they required an average speed increase of 1.7 mph and an average incline increase of 4.3%; at 80%  $\text{VO}_{2\text{max}}$ , 2.8 mph and 3.1% incline, respectively; at 90%  $\text{VO}_{2\text{max}}$ , 3.4 mph and 2.0% incline, respectively. When subjects were unweighted to 50% BW and ran at their heart rate equivalent of 70%  $\text{VO}_{2\text{max}}$ , they required an average speed increase of 2.7 mph and an average incline increase of 5.1%; at 80%  $\text{VO}_{2\text{max}}$ , 4.1 mph and 4.7% incline, respectively; at 90%  $\text{VO}_{2\text{max}}$ , 3.9 mph and 4.1% incline, respectively. Further, the average speed increase at 75% BW across all target intensities to reach the equivalent heart rate at 100% BW was 3.1 mph, yet there was only a 0.8 mph additional increase necessary when BW dropped from 75% to 50%. Likewise, the average incline increase at 75% BW relative to 100% BW was 3.1%, while the decrease from 75% BW to 50% BW required only an additional 1.9% incline.

**CONCLUSION:** Unweighting due to LBPP requires an increase in running speed and incline in order to maintain training intensity levels in elite male runners. Since the increases in speed and incline necessary to achieve target intensities do not appear to be linearly related to the level of unweighting, further research is necessary to identify the variables at which maximum intensity can be achieved while ground reaction forces are minimal.

**1549** Board #330 MAY 30 9:30 AM - 11:00 AM

**Physiological Characteristics of a Co-ed Cross Country Running Team Living and Training at Altitude**

Scott N. Drum, FACSM, Sarah Baysden, Meta Haley. *Western State College of Colorado, Gunnison, CO.*

(No relationships reported)

The literature is limited related to characterizing the traits of successful college cross country (XC) running programs, especially ones where athletes live and train at altitude (7,700 ft or 2,350 m) while competing frequently at or near sea level.

**PURPOSE:** To determine the physiological characteristics of a national caliber, college XC running team residing at altitude with an established tradition of winning men's and women's NCAA Division II (D-II) national championships.

**METHODS:** Maximal treadmill testing records in reference to 14 men ( $21 \pm 2.2$  yrs) and 10 women ( $20 \pm 1.1$  yrs) were retrospectively analyzed for maximal oxygen uptake ( $\text{VO}_{2\text{max}}$ ), heart rate max ( $\text{HR}_{\text{max}}$ ), pulmonary ventilation at max ( $\text{V}_E@_{\text{max}}$ ), ventilatory threshold (VT), and heart rate at VT ( $\text{HR}@_{\text{VT}}$ ). All subjects had been living and training consistently with their college-based XC program for at least one year and were tested at 7,700 ft in Gunnison, Colorado.

**RESULTS:** Men and women, respectively, exhibited an average (mean  $\pm$  SD)  $\text{VO}_{2\text{max}}$ ,  $\text{HR}_{\text{max}}$ ,  $\text{V}_E@_{\text{max}}$ , VT, and  $\text{HR}@_{\text{VT}}$  of  $63 \pm 2.8$  and  $50 \pm 3.4 \text{ mL} \cdot \text{kg}^{-1} \cdot \text{min}^{-1}$ ,  $191 \pm 6.1$  and  $186 \pm 10.1$  bpm,  $168 \pm 17.9$  and  $124 \pm 13.4 \text{ L} \cdot \text{min}^{-1}$ ,  $3.7 \pm .3$  and  $2.6 \pm .3 \text{ L} \cdot \text{min}^{-1}$ , and  $178 \pm 6.7$  and  $174 \pm 8.8$  bpm, respectively. Interestingly, with regard to  $\text{VO}_{2\text{max}}$ , the men and women were about 7.6% and 15.5%, respectively, decremented versus trained sea level, college runners found in the literature. Furthermore,  $\text{HR}_{\text{max}}$  was reduced by about 4% and 7% in men and women, respectively, in comparison to the standard sea level  $\text{HR}_{\text{max}}$  formula of 220-age (noting that this formula maintains a large SD).

**CONCLUSION:** Well-trained male and female college XC runners living and training at altitude may exhibit some decrements in physiological performance attributes when compared to sea level trained competitors. However, despite potential physiological decrements at altitude, upon return to sea level for racing, both genders in the current study seem to benefit from training and living high within the context of competing in the NCAA D-II ranks. Potentially, controlled studies should be conducted on this particular team and others that reside at altitude to fully discover the supposed sea level racing advantages of living and training at a moderate elevation (i.e., between about 7,000 and 8,000 ft) and competing in the NCAA D-II classification.

**1550** Board #331 MAY 30 9:30 AM - 11:00 AM

**Age, Gender, and Mode Considerations in Elite Ultra-endurance Triathlete Performances**

Vincent Nethery, Travis Hudon, Tim Burnham, Robert Pritchett. *Central Washington University, Ellensburg, WA.*

(No relationships reported)

Participation in World Championship events through invitation via qualification represents the ultimate in competition for age group competitors. The ultra-endurance Ironman 70.3 World Championships, held over consecutive years in Clearwater Florida, represents one such venue.

**PURPOSE:** To compare overall as well as swimming (1.9 km), cycling (91 km), and running (21.2 km) performances across a 20-70yr age-span in males and females.

**METHODS:** Times for the top 20 male and female competitors each year (2006-2009) were extracted from WTC 70.3® World Championship race results and compared across age groups (ANOVA-Bonferroni post-hoc). Absolute and relative differences among age groups were calculated and compared.

**RESULTS:** Overall performance for males was maintained through age group 45-49 with progressively greater declines ( $P < 0.05$ ) noted for older age categories. Declines of 4.09%, 7.63%, and 10.57% were observed for the 50-54, 55-59, and 60-64 age groups relative to their immediate preceding group. Females followed a similar pattern, except that diminished overall performance was noted after the 40-44 age group with declines of 3.66%, 8.44%, and 13.88% for the 45-49, 50-54, and 55-59 age groups relative to the immediate preceding category. In males, swim and run performances diminished after age 50 whereas cycling performance was maintained until age 55. In contrast, all female sub-discipline performances declined beyond age 50.

**CONCLUSIONS:** The threshold for age related diminishments in high-level ultra-endurance triathlon performances are related to both gender and specific event sub-discipline. Such performance-based analyses of world-class age-group athletes, provides unique insight into the relationships between aging, functional ability, and task mode.

1551 Board #332 MAY 30 9:30 AM - 11:00 AM

**Training, Nutrition, Injury and Lifestyle Characteristics of Shorter Distance Triathletes**

Loren E. Johnson<sup>1</sup>, Alexandra L. Braud<sup>1</sup>, Laura A. Forney<sup>1</sup>, Conrad P. Earnest, FACSM<sup>2</sup>, Laura K. Stewart<sup>1</sup>. <sup>1</sup>Louisiana State University, Baton Rouge, LA. <sup>2</sup>Pennington Biomedical Research Center, Baton Rouge, LA.  
(No relationships reported)

The triathlon is a popular sport which consists of swimming, biking and running; however, there is little descriptive data about individuals participating in this event.

**PURPOSE:** To provide information about the training, nutrition and overall health of triathletes.

**METHODS:** Athletes participating in shorter distance (Sprint or Olympic distance) triathlons in the Southern region of the US during the 2011 season completed a 30 question survey examining training habits, nutritional supplementation, lifestyle characteristics, injury occurrence and overall health status. Data are presented as mean  $\pm$  standard error.

**RESULTS:** Male and female triathletes (N = 277) ranged in age from 18 - 66 yrs (38.7  $\pm$  0.61 years). Average height was 175.9  $\pm$  0.81 cm and weight was 74.3  $\pm$  0.15 kg. Athletes had 4 years of previous race experience and typically finished in the upper 50% of their age group by gender. Training consisted of 3.2  $\pm$  .21 hours swimming, 6.2  $\pm$  .39 hours biking, 5.1  $\pm$  .41 hours running, 1.3  $\pm$  .10 hours weight lifting, and .97  $\pm$  .19 hours of cross training per week. Triathletes reported consuming 3.5  $\pm$  .09 servings of carbohydrates, 3.0  $\pm$  .06 servings of fruits, 3.1  $\pm$  .08 servings of vegetables, 2.3  $\pm$  .08 servings of dairy products, 2.3  $\pm$  .08 servings of fat rich foods and 3.1  $\pm$  .08 servings of protein rich foods on a daily basis. The most commonly used nutritional supplements were bars (92%) followed by liquids (91%). Triathletes (n = 71) reported average energy consumption 2322  $\pm$  51.5 kcal, with 2473.9  $\pm$  72.9 kcal and 2072  $\pm$  57.6 kcal in men and women respectively. Knee (34%), foot (31%), back (24%) and shoulder (18%) injuries were the most common, but the majority of athletes reported that their health (89%) and quality of life (86%) was very good or excellent. Lastly, most triathletes (88%) reported no problems with work or other daily activities as a result of emotional problems.

**CONCLUSION:** Overall, triathletes cycle more than run and spend the least time swimming. Triathletes reported eating more carbohydrates than other food groups and regularly use liquids and bars as supplements. While most triathletes experience a higher quality of life, a number of them tend to experience injuries to the lower extremity.

---

1552 Board #333 MAY 30 9:30 AM - 11:00 AM

**Recovery Heart Rates in Trained Recreational Cyclists and Runners**

Silvie Grote<sup>1</sup>, Herman L. Falsetti<sup>2</sup>, William C. Beam, FACSM<sup>3</sup>, Kelia G. McDonald<sup>1</sup>, John F. Sanguedolce<sup>1</sup>. <sup>1</sup>Loyola Marymount University, Los Angeles, CA. <sup>2</sup>Health Corp., Laguna Niguel, CA. <sup>3</sup>California State University, Fullerton, Fullerton, CA.  
(No relationships reported)

Cardiovascular disease is the leading cause of death in the United States. Recovery heart rates have been studied in diseased populations in order to establish a marker for increased risk of mortality from cardiovascular disease. Abnormal 1-minute heart rate recovery (<13 bpm) is significantly associated with greater mortality. Recovery heart rates of highly trained recreational athletes have not been studied to the same degree.

**PURPOSE:** The purpose of this study was to investigate the effect of age and mode on heart rate recovery in trained recreational athletes.

**METHODS:** Forty-four recreational athletes were studied including 21 cyclists and 23 runners. The participants, who were considered trained (training at least 6 hours per week), had a mean maximal oxygen consumption of 50.5 $\pm$ 9.0 ml kg<sup>-1</sup> min<sup>-1</sup> and mean resting heart rate of 50 $\pm$ 7 bpm. The sample was divided into 3 different age groups - young (n=5, age=22 $\pm$  4), middle-age (n=14, age= 35 $\pm$  3), and masters (n=25, age=51 $\pm$  8) Following completion of maximal exercise, recovery heart rate at 1 minute (HRR1) and 2 minutes (HRR2) was determined by HR<sub>max</sub>-HR<sub>min</sub>. ANOVA was used to test for main effects due to age and mode with follow up using an independent t test to examine differences between the modes.

**RESULTS:** Heart rate recovery at 1 and 2 minutes, respectively, for young (31 $\pm$  13, 78 $\pm$ 11), middle age (36 $\pm$ 17, 84 $\pm$ 22), and masters (31 $\pm$ 11, 71 $\pm$ 19) were not significantly different. Training mode did have an impact on recovery heart rate. Heart rate recovery in runners was significantly faster (p<0.05) with HRR1 (39 $\pm$ 13) and HRR2 (87 $\pm$ 16) than recovery in cyclists with HRR1 (25 $\pm$ 10) and HRR2 (64 $\pm$ 16).

**CONCLUSION:** This study describes the effect of age and mode on heart rate recovery in trained recreational athletes. Runners exhibit faster recovery than cyclists regardless of age.

1553 Board #334 MAY 30 9:30 AM - 11:00 AM

**Upper Body Training And Exercise According To ACSM Guidelines: Effects On Handcycling And Cycling Capacity.**

Florentina J. Hettinga, Mark Hoogwerf, Ben Sijtsma, Marloes van Ballegooijen, Faes Kerkhof, Lucas H.V. van der Woude. *Center for Human Movement Sciences, University Medical Center Groningen, University of Groningen, Groningen, Netherlands.* (Sponsor: Thomas Janssen, FACSM)  
(No relationships reported)

**PURPOSE:** Studies on optimal training are mostly aimed at training the large muscle groups of the lower body. 'How can we optimally train the upper body' is a particularly relevant question for those in a wheelchair. To develop a knowledge base on upper body training, it is important to use available knowledge on training in general, and adapt this to the rehabilitation context. The present study aims to study effects of training the upper body according to the ACSM guidelines and to determine if training adaptations are exercise specific.

**METHODS:** 22 Female able-bodied participants, non-experienced to upper body exercise, were randomly divided in a handcycling training (TG: 7-weeks, 3 times a week at 65% heart rate reserve for 30 minutes) and control group (CG). Peak physiological capacity was evaluated pre- and post-training with an incremental handcycling exercise test to determine local, exercise specific adaptations. A matched incremental test on a bicycle ergometer was performed, to determine non exercise specific central/cardiovascular adaptations. Oxygen uptake (VO<sub>2</sub>), heart rate (HR), ventilation (VE), power output (PO) and rate of perceived exertion (RPE) were compared between TG and CG before and after training on both handcycling and cycling performance.

**RESULTS:** TG improved significantly on peak VO<sub>2</sub> (+18.1%), peak PO (+31.9%), peak VE (+31.4%) and peak HR (+4.0%) during handcycling compared to CG. No improvements were found in the incremental cycling test, thus differences in peak capacity between cycling and handcycling decreased after training.

**CONCLUSIONS:** Handcycling is an effective training mode for upper body exercise capacity. A training schedule based on ACSM guidelines (though designed for exercising the large muscle masses of the lower body) leads to exercise specific improvements in handcycling performance on peak VO<sub>2</sub>, peak PO and peak HR. In this way, it seems that ACSM guidelines can be used as a general basis to determine training frequency, intensity and duration for upper body exercise in healthy able-bodied subjects. Future research must focus on transferability of these results to different patient groups and persons with different impairments and physiological capacities. In particular those with a low physical capacity must receive special attention.

---

1554 Board #335 MAY 30 9:30 AM - 11:00 AM

**Effects Of Low Intensity Cycling With Blood Flow Restriction On Body Composition, Strength, And Vo2max**

Daeyeol Kim, Harshvardhan Singh, Kaelin Young, Christopher A. Fahs, Lindy M. Rossow, Jeremy P. Loenneke, Robert S. Thiebaut, Eonho Kim, Kyle Sherk, Xin Ye, Debra A. Bemben, FACSM, Michael G. Bemben, FACSM. *University of Oklahoma, Norman, OK.*  
(No relationships reported)

Traditional high-intensity cycle training (HI) has been shown to improve muscular responses and aerobic capacity, however, recent research indicates that low-intensity cycle training with blood flow restriction (LI) can have similar effects.

**PURPOSE:** To compare the effects of 6 weeks high-intensity cycle training to low-intensity cycle training with blood flow restriction on body composition, muscle hypertrophy, muscle strength, and aerobic capacity.

**METHODS:** Subjects (31 males, 18-30 yrs) were assigned to one of three groups: HI (n=10, 60-70% Heart Rate Reserve (HRR)), LI (n=11, 30% HRR with BFR at 160-180 mmHg), and CON (n=10, no exercise). Subjects in HI and LI exercised 3 sessions (5 min warm-up & 20 min cycling)/week for 6 weeks. Body composition (fat %, total fat mass, and total lean mass by DXA), muscle hypertrophy (leg fat and lean mass by DXA, and muscle CSA by pQCT), muscle strength (1-RM leg extension and flexion), and aerobic capacity (VO<sub>2max</sub>) were measured pre and post training. A two-way repeated measure ANOVA was utilized to compare groups and times with statistical significance set at p<0.05.

**RESULTS:** There were no significant differences between groups for any of the outcome variables but a number of trends were noted. Fat %, fat mass, and lean mass changed by -4.7%, -4.3%, and 2.1% in LI, -0.4%, -0.1%, and 0.7% in HI, and -1.1%, -1.1%, and 0.0%, respectively in CON. Additionally, leg fat mass decreased by 3.1% in LI, but only 1.3% in HI and 0.4% in

CON. Leg flexion strength was significantly different between HI and CON ( $P = 0.035$ ), however, % changes for leg extension and flexion strength were 5.2% and 7.2% in HI, 5.7% and 6.3% in LI, respectively. Finally, % change for  $VO_{2max}$  was 5.7% in HI, 2.1% in LI, and -1.4% in CON.  $VO_{2max}$  was significantly different between HI and CON ( $P = 0.029$ ).

**CONCLUSIONS:** Even though low-intensity cycle training with blood flow restriction did not statistically improve body composition, muscle hypertrophy, muscle strength, and  $VO_{2max}$ , decreases for fat in the LI group were greater than the HI, and the other changes for LI were similar to the changes for the HI group.

---

**1555** Board #336 MAY 30 9:30 AM - 11:00 AM  
**The Effect Of Endurance Cycling Training On Cross-sectional Area And Strength Of Thigh Muscles In Human**  
Hidetoshi Hoshikawa, Saori Yoshida, Tsukasa Miyamura. *Hamamatsu University, Shizuoka, Japan.*  
(No relationships reported)

Although endurance training has been shown to markedly affect the oxidative capacity of the skeletal muscle, there is limited information about the effect of on the skeletal muscle morphological property and strength.

**PURPOSE:** To investigate the effect of endurance cycling training on cross-sectional area of and isokinetic strength of thigh muscles.

**METHODS:** Four male ( $20.8 \pm 0.5$  yr,  $171.9 \pm 1.5$  cm,  $63.5 \pm 2.2$  kg) and four female ( $20.5 \pm 0.5$  yr,  $164.5 \pm 4.5$  cm,  $52.9 \pm 7.6$  kg) university students were participated in this study. They trained for 7 weeks on a bicycle ergometer for 30 min/day, three times a week at a work load requiring 60 % of oxygen uptake reserve ( $VO_{2R}$ ) at 90 rpm. Before and after training, isokinetic knee extension and flexion moment (60, 150, and 240 deg/s) were measured and cross-sectional areas (CSAs) of quadriceps femoris and hamstrings at 30, 50, and 70 % of the femur bone length, and psoas major muscle at the center of the L4-L5 transverse level were determined by magnetic resonance imaging.

**RESULTS:**  $VO_{2max}$  was significantly increased by  $10.1 \pm 6.6$  % after training ( $p < 0.01$ ). By the end of the training period, peak knee extension moment at 60, 150 and 240 deg/s ( $10.3 \pm 7.2$ ,  $9.6 \pm 8.8$ , and  $18.2 \pm 14$  %, respectively,  $p < 0.05$ ) and flexion moment at 60deg/s ( $8.7 \pm 8.1$  %,  $p < 0.05$ ) were significantly increased. CSA of quadriceps femoris was significantly increased at 30, 50, and 70 % of the femur bone length after training ( $5.8 \pm 5.9$ ,  $4.5 \pm 3.9$ ,  $5.1 \pm 4.4$  %, respectively,  $p < 0.05$ ). Significant increase in CSA of hamstrings was observed at 70 % of the femur bone length after training ( $5.1 \pm 4.0$  %,  $p < 0.05$ ). Although CSA of psoas major was not statistically significance, the value tended to be higher after training ( $p = 0.06$ ).

**CONCLUSIONS:** These results suggest that moderate endurance cycling training induce muscle hypertrophy and increase muscle strength in the thigh.

---

**1556** Board #337 MAY 30 9:30 AM - 11:00 AM  
**Comparison Of Different Exercise Tests For Predicting Endurance Performance In Moderately Trained Cyclists**  
Niklas Psilander<sup>1</sup>, Mikael Flockhart<sup>2</sup>, Kent Sahlin<sup>1</sup>. <sup>1</sup>Karolinska Institutet, Stockholm, Sweden. <sup>2</sup>Swedish School of Sport and Health Sciences (GIH), Stockholm, Sweden.  
(No relationships reported)

Laboratory exercise tests are important for evaluating training adaptations and to predict endurance performance. The most frequently used test parameters are  $VO_{2max}$  and power output at the 4 mmol L<sup>-1</sup> blood lactate threshold ( $W_{LT4}$ ). However, alternative test parameters might provide improved precision and/or reduce the need of expensive laboratory equipment.

**PURPOSE:** To investigate how different test parameters correlates with endurance performance in moderately trained cyclists.

**METHODS:** Eighteen cyclists ( $VO_{2max}$  (mean  $\pm$  SEM)  $56 \pm 1$  mL  $kg^{-1}$   $min^{-1}$ ) completed two tests on separate days; a 40 min time trial (TT40) on a SRM cycle ergometer for assessment of endurance performance and an incremental ergometer test for assessment of maximal oxygen consumption ( $VO_{2max}$ ; mL  $kg^{-1}$   $min^{-1}$ ) and maximal power output at exhaustion ( $W_{max}$ ; W  $kg^{-1}$ ). Lactate was measured in capillary blood taken during and after the incremental test and used for calculation of the power output at the 4 mmol L<sup>-1</sup> ( $W_{LT4}$ ; W  $kg^{-1}$ ) and modified  $D_{max}$  ( $W_{Dmax}$ ; W  $kg^{-1}$ ) lactate threshold.

**RESULTS:** Endurance performance, calculated as the average power output during the TT40 (W  $kg^{-1}$ ), was correlated with the conventionally used test parameters  $VO_{2max}$  ( $r = 0.81$ ,  $p < 0.01$ ) and  $W_{LT4}$  ( $r = 0.78$ ,  $p < 0.01$ ). However, higher correlation coefficients were observed between TT40 and the alternative test parameters  $W_{max}$  ( $r = 0.90$ ,  $p < 0.01$ ) and  $W_{Dmax}$  ( $r = 0.87$ ,  $p < 0.01$ ). Further, multiple regression analysis shows that  $W_{max} + W_{Dmax}$  can explain 80 % (adjusted  $r^2$ -value) of the variance in endurance performance whereas  $VO_{2max} + W_{LT4}$  can explain 73 %.

**CONCLUSION:** Compared to traditional test parameters, our results indicate that both  $W_{max}$  and  $W_{Dmax}$  are suitable test parameters to predict endurance performance in moderately trained cyclists. However,  $W_{max}$  is to be preferred due to high precision in combination with relatively low laboratory costs.

**1557** Board #338 MAY 30 9:30 AM - 11:00 AM  
**Gender Differences In Training Load Guided Cycling Training**  
Andreas Bruch, Bjoern Stapelfeldt. *Albert-Ludwigs Universität Freiburg, Germany, Freiburg, Germany.*  
(No relationships reported)

A novel approach for guiding endurance training is the Training Load (TL) concept. TL aims to make different exercise sessions comparable in terms of adaptive or exhausting characteristics. Input information for TL include gender, weight,  $VO_{2max}$ , HR<sub>max</sub>, HR<sub>rest</sub>, lactate threshold (LT), anaerobic threshold (IAT), heart rate and training time. It has been shown that using TL results in significantly less intense training with equal performance improvements in cycling training (Bruch et al., ECSS 2011). The question remains whether gender has an impact on TL guided vs. non-guided training in cyclists.

**PURPOSE:** To document and analyze gender differences in TL guided and non-guided training in well-trained cyclists.

**METHODS:** 22 competitive level German cyclists and triathletes (11 males, 11 females) with 15 h/week cycling training and  $VO_{2peak}$  values between 50-60 ml/min/kg trained for 8 weeks, study group guided by TL, control group without guiding. At the beginning and end of the study a standardized incremental exercise test (IET) was completed starting with 100 W for males and 80 W for females with 20 W increase every 3rd minute. Lab-test measurements included weight related power at LT, IAT and maximum power. During study time the TL-values of all subjects were calculated before and after every training session. In addition the training starting and ending times, the minutes of training over 100 bpm and the average HR of each session were documented.

**RESULTS:** TL guided cycling training decreased intensity in training and led to equal performance increase in women and men. Women completed an average of 53,45 training session, men 50,36 training sessions ( $p = 0.41$ ). TL-values before training were on average 87,39 in women, 91,49 in men ( $p = 0.83$ ). TL-values after training range from 152,65 in women to 159,23 in men ( $p = 0.83$ ). Women and men achieved similar performance increase (no significant differences in any relevant marker).

**CONCLUSION:** TL guiding in cycling training seems to be effective in both genders. It leads to a less intense training while achieving the same performance increase. Positive implications include optimizing training intensity and recovery times. These may prevent overtraining and reducing the risk of illness and injury in women and men.

**VO<sub>2</sub> Kinetics in Uphill Cycling**  
Andrew Gai. *University of Central Missouri, Warrensburg, MO.*  
(No relationships reported)

**PURPOSE:** The objective of this study was to test for differences in oxygen consumption during a cycling hill climb based on whether the subject was seated or standing while pedaling.

**METHODS:** Eight male trained cyclists began by having DEXA scan to determine body comp and a preliminary  $VO_{2max}$  test on an electronic bike ergometer. The  $VO_{2}$  data was used to set the ergometer wattage levels and determine cardio-respiratory fitness. Subjects returned on a separate day to do a simulated climb portion of the research. The exercise began with cycling at a light pace to warm up. After warm-up, the intensity was increased to a wattage equal to 60% of  $VO_{2max}$  to simulate a moderate hill climb. The subject pedaled in a standing position for 3 minutes while  $VO_{2}$  data and heart rate were monitored and collected. After the 3 minute climb, the wattage was lowered to allow the subject to recover. After 3 min recovery, a second climb using seated

pedaling method for 3 minutes at 60% was completed. The subject was then allowed to recover and a second more difficult simulated climb was performed at 85% of  $\text{VO}_2\text{max}$  for 3 minutes seated and standing. Data was collected for  $\text{VO}_2$  consumption, wattage and heart rate for all 3-minute sessions. The  $\text{VO}_2$  data used for comparison was an average of the last minute of each 3 minute "climb" session.

**RESULTS:** The hypothesis was that the seated hill climb would require more oxygen consumption compared to the standing climb. Results for the 60% intensity were  $3.376 \pm 0.58$  L/min standing and  $2.967 \pm 0.31$  L/min seated ( $p < 0.05$ ). The values for the 85% intensity were  $3.993 \pm 0.52$  L/min standing and  $3.904 \pm .32$  L/min for seated ( $p > 0.05$ ).

**CONCLUSION:** Based on the current data at lower wattage levels seated cycling is more efficient, while higher wattage levels were equal seated or standing. [[Unsupported Character - &#8194;]] [[Unsupported Character - &#8194;]]

**1559**    *Board #340*    **MAY 30**    **9:30 AM - 11:00 AM**  
**Range of Motion is Not Related to Cycling Performance**

Daryl L. Parker, Jamie L. Donkin, Rick T. Bradley, Raymond Martinez, Jr, Max Polin, Roberto Quintana. *Irvin Faria Exercise Physiology Research Laboratory, CSU Sacramento, Sacramento, CA.*  
(No relationships reported)

Over the past several year a number of research studies have evolved indicating that pre-exercise static stretching can reduce muscular performance. This has lead to the recommendation that static stretching should be completed during the post-exercise period. However, it is unclear whether improving range of motion in a joint provides a benefit or detriment to performance.

**PURPOSE:** This investigation was conducted to examine the range of motion (ROM) in the major muscle groups of cycling exercise and determine if there is a relationship between ROM and performance.

**METHODS:** Nine competitive cyclists [(female n=1) age:  $23.8 \pm 4.37$  yrs, mass:  $69.8 \pm 9.72$  kg,  $\text{VO}_2\text{max}$ :  $61.3 \pm 7.28$  ml/kg/min] served as subjects for this investigation. All had been competing for over a year and ranged in ability from category 5 to 2 (USA cycling). Upon arrival to the lab each subject completed a graded exercise test (GXT) on a cycle ergometer (male= $35 \text{ W min}^{-1}$ , or female= $25 \text{ W min}^{-1}$ ) to determine  $\text{Wmax}$  and  $\text{VO}_2\text{max}$ . Following the GXT, range of motion (ROM) was assessed using a Leighton flexometer. Hip flexion (HF), hip extension (HE), knee flexion (KF), knee extension (KE), and plantar flexion (PF) were all measured in triplicate. Following the ROM assessment, each subject completed a Wingate test for the determination of peak power (PP). The rest period between the GXT and the Wingate test was 30 minutes minimum. Thirty minutes was the minimum amount of time required for the GXT to not interfere with the outcome of the Wingate test during our pilot testing. Relationships between ROM and PP as well as ROM and  $\text{Wmax}$  were assessed using Pearson's r. An alpha level 0.05 was used to assess significance in this sample.

**RESULTS:** The average  $\text{Wmax}$  and PP for the sample was consistent with competitive cyclists ( $\text{Wmax}$   $5.41 \pm 0.58$  W/kg, PP  $13.6 \pm 1.31$ , respectively). None of the ROMs assessed had a significant relationship with  $\text{Wmax}$  (HF  $r=0.32$   $p=0.40$ , HE  $r=0.20$   $p=0.61$ , KF  $r=0.40$   $p=0.28$ , KE  $r=0.10$   $p=0.79$ , PF  $r=0.40$   $p=0.29$ ) or PP (HF  $r=0.37$   $p=0.33$ , HE  $r=0.36$   $p=0.33$ , KF  $r=0.004$   $p=0.99$ , KE  $r=0.04$   $p=0.91$ , PF  $r=0.34$   $p=0.38$ ).

**CONCLUSIONS:** The data from this investigation seem to suggest that poor ROM is not a detriment to the motion of cycling. The data also seem to suggest that good range of motion is not a benefit in the motion of cycling. A larger sample may elucidate a different relationship.

**1560**    *Board #341*    **MAY 30**    **9:30 AM - 11:00 AM**  
**Comparison Of Vo2 For Three Cycling Modes**

Andrew I. Miller, Edward M. Heath, FACSM, Eadric Bressel, Gerald A. Smith, FACSM. *Utah State University, Logan, UT.* (Sponsor: Edward M. Heath, FACSM)  
(No relationships reported)

Bicycling research in a laboratory has an advantage of being more tightly controlled compared to field studies; however, consideration must be given to ecological validity for the study's results to be best applied to its target population and environment. A stationary cycle ergometer is often the default instrumentation for lab data collections, but results may not generalize well to target populations or environments for two key reasons: (1) a cycle ergometer is not what a cyclist is accustomed to riding and will usually have a geometry different from an individually-fitted cycle, and (2) there is no balance requirement on a cycle ergometer. Rollers or a stationary trainer can be used to partially address these concerns.

**PURPOSE:** To compare oxygen uptake ( $\text{VO}_2$ ) at a similar power level during cycling on an ergometer, a stationary trainer, and rollers.

**METHODS:** Highly-trained cyclists ( $n = 5$ , age =  $34.0 \pm 8.9$  yr,  $\text{VO}_2$  peak =  $63.7 \pm 4.8$  ml/kg/min) performed a ramped  $\text{VO}_2$  peak test with 50 W increase per min on a stationary trainer using their own bicycle. This was followed by 4 min sub-max tests at a power corresponding to 70% of  $\text{VO}_2$  peak on each of three modes in randomized order (modified Monark ergometer, CycleOps Supermagneto trainer, CycleOps aluminum rollers with magnetic resistance). Testing was performed at an altitude of 1382 m. Power on the bicycle (rollers and trainer) was measured via a Power Tap SL+ hub, and by way of resistance on the ergometer. Because power could not be exactly matched across the 3 modes, a regression based on the  $\text{VO}_2$  peak test was used to adjust  $\text{VO}_2$  values to corresponding values at a constant mechanical power.

**RESULTS:** Mean  $\text{VO}_2$  values at constant power levels were: rollers =  $48.2 \pm 5.2$ , trainer =  $46.9 \pm 5.1$ , and ergometer =  $46.9 \pm 4.1$  ml/kg/min.

**CONCLUSION:** Riding on rollers required a 2.8% increase in oxygen uptake (10.2 W) compared to riding a stationary trainer or ergometer at the same mechanical power level ( $p < 0.05$ ). This increased cost was likely due to the metabolic cost of balance associated with cycling on rollers, and suggests that rollers may better simulate the metabolic cost of natural cycling.

**Effect Of An 11-week Strength Core-training Program On Lumbar Range Of Movement In Swimmers**

Monica Solana-Tramunt<sup>1</sup>, Josep Cabedo<sup>1</sup>, Ana M. Bofill-Rodenas<sup>2</sup>, Josep Morales<sup>1</sup>. <sup>1</sup>*FPCEE Blanquerna Ramon Llull University, Barcelona, Spain.* <sup>2</sup>*GISEAFE INEFC Barcelona, Barcelona, Spain.*  
(No relationships reported)

Lumbar range of movement (ROM) is essential to develop effective movements during underwater undulatory swimming technique. Core exercises are used to improve the strength of the muscles that participate on that technique but they are not designed to improve lumbar ROM.

**PURPOSE:** To examine the effects of an 11-week core training program on lumbar ROM after lumbar flexion and extension exercises on underwater gliding body position.

**METHODS:** A sample of 37 professional swimmers, 21 males and 16 females ( $20.7 \pm 3.3$  yrs), participated in the study. They were randomly divided in 21 swimmers for the experimental group (EG) and 16 swimmers for the control group (CG). EG fulfilled 3 core exercises, 6 days a week during 11-weeks. All subjects underwent the same type of training in parallel with the experimental group intervention and signed informed consent.

The exercises consisted of performing maximum lumbar extension and recover underwater gliding body position, repeated at slow pace of 10 breaths. ROM was measured by an electrogoniometer attached on the skin, its cranial arm over T12-L1 spinous process, line up to L3 level, and lower arm over S1-S3 surface. The evaluation consist of measuring lumbar ROM from maximal flexion to maximal extension degrees, in 3 consecutive trials separated by 20s, sitting over a Swiss ball keeping hips and knees between 80° and 90° of flexion, the back straight, the sight to the front and both hands over the knees on a relaxed position. The test position allowed easy lumbar movements on sagittal plane.

It has been measured the mean of each flexion and extension trial and calculated the total ROM from the maximal extension mean to maximum flexion mean degrees. ROM comparisons between pre-test and post-test were made using paired samples t -Test. The results are expressed by the mean, SD and significant differences ( $p < 0.05$ ) before and after the experimental period.

**RESULTS:** Lumbar ROM changed on EG from  $34.4 \pm 12.9^\circ$  to  $44.7 \pm 14.3^\circ$  ( $p=0.000$ ) and on CG from  $34.7 \pm 11.9^\circ$  to  $35.9 \pm 12.5^\circ$  ( $p=0.22$ ).

**CONCLUSIONS:** The results suggest that to repeat maximal lumbar extension positions at breathing pace without holding them, can increase lumbar range of movement in sagittal plane. It could be important to consider this on future ROM exercises programs.

---

1562 Board #343 MAY 30 9:30 AM - 11:00 AM

**Effects of Altitude Training on Heart Rate Variability in Orthostatic Test in Elite Swimmers**

Ferran A. Rodriguez, FACSM<sup>1</sup>, Xavier Iglesias<sup>1</sup>, Belén Feriche<sup>2</sup>, Carmen Calderón<sup>3</sup>, Xavier Ábalos<sup>1</sup>, Jairo Vázquez<sup>1</sup>, Anna Barrero<sup>1</sup>, Lara Rodríguez<sup>1</sup>, Esa Hynnenen<sup>4</sup>, Benjamin D. Levine, FACSM<sup>5</sup>. <sup>1</sup>INEFC, University of Barcelona, Barcelona, Spain. <sup>2</sup>FCAFD, University of Granada, Granada, Spain. <sup>3</sup>Sierra Nevada High Altitude Training Center, Granada, Spain. <sup>4</sup>KIHU – Research Institute for Olympic Sports, Jyväskylä, Finland. <sup>5</sup>IEEM/UT Southwestern, Dallas, TX.  
(No relationships reported)

Different stressors, like athletic training, can change the autonomic modulation of the heart. This can be evaluated with heart rate variability (HRV) analysis. Acute hypoxia is also known to attenuate parasympathetic activity and accentuate the sympathetic activity. Whether these changes in autonomic modulation will disappear with altitude acclimatization remains unclear.

**PURPOSE:** This study was made to investigate the effects of 3-week moderate altitude training on HRV in elite swimmers.

**METHODS:** 9 elite swimmers (Hi) of international level (5 women and 4 men, age  $19.4 \pm 1.6$  years) lived and trained 3 weeks at Sierra Nevada, Spain (2,320 m). Control group (Lo) consisted of 11 swimmers of similar level (7 women and 4 men, age  $17.9 \pm 1.9$  years), who lived and trained at sea level. RR-intervals were recorded every morning in supine (8-min) and orthostatic (6-min) positions with beat-by-beat heart monitors. Breathing was paced to 12 breaths/min. Recordings were done during the 3-week intervention period and one week before and after. HRV was analyzed from the last 5-min period of both positions with FFT spectral power analysis. TRIMPs of every training session were calculated to estimate training load. HRV results are averaged over every week and presented as relative percentage changes.

**RESULTS:** The training load was similar in both groups during the 3-week intervention but was lower during the week after in Hi-group when compared to Lo-group ( $P=0.003$ ). An interaction of group, time and TRIMPs was found in change in spectral power of supine LF (-40% vs. +36%,  $P=0.02$ ) and HF (-46% vs. +55%,  $P=0.01$ ) during the intervention period showing increased HRV in Lo group and decreased HRV in Hi-group. Also LF (+93% vs. +12%,  $P=0.01$ ) and LF/HF ratio (+79% vs. -2%,  $P=0.01$ ) during standing increased more in Hi-group than in Lo-group in the end of the intervention.

**CONCLUSION:** The present findings of lower HRV in Hi-group than in Lo-group suggest that the physiological stress of training at moderate altitude leads to parasympathetic withdrawal and possibly increased sympathetic activity even after night rest. These changes in autonomic modulation seem to last longer than for the first week after altitude training camp.

**An Ultraendurance Swimming Event From Italy To Albany: A Case Study**

Giulia De Ioannon<sup>1</sup>, Giuseppe Cibelli<sup>2</sup>, Sergio Mignardi<sup>3</sup>, Agnese Antonelli<sup>1</sup>, Laura Capranica<sup>1</sup>, Maria Francesca Piacentini<sup>1</sup>. <sup>1</sup>University of Rome "Foro Italico", Rome, Italy. <sup>2</sup>University of Foggia, Foggia, Italy. <sup>3</sup>Scuola dello Sport CONI, Rome, Italy. (Sponsor: Carl Foster, FACSM)  
(No relationships reported)

**PURPOSE:** To investigate pacing strategy, average swimming speed (ASS), stroke rate (SR), and stroke length (SL) during a 42 nm (78.154 km) ultra-endurance swimming in open water.

**METHODS:** One male athlete (age: 48 yr, body mass: 68 kg, height: 172 cm) participated in the study. Anthropometric parameters were measured before and after the event. Water temperature (WT), ASS, SR, SL, rating of perceived exertion (RPE) were monitored every three hours during swimming. Hazard score (HS) was calculated as the product of the momentary RPE and the fraction of the event remaining at the same point. The profile of mood state (POMS) questionnaire was filled in at baseline (6 months before), immediately before swimming, and at 90 min post-event. The energy index (POMS vigour/fatigue) was calculated. Swimming velocity was expressed as % change every 3-hour period compared to the first split time.

**RESULTS:** The athlete completed the event in 23:44 hr:min. Body mass and skinfolds did not change after swimming, probably due to previous feeding (every 15 min). Despite WT remained constant ( $28 \pm 2^\circ\text{C}$ ), body temperature increased by 2.9%. ASS, average SR and SL were  $3.3 \text{ km} \cdot \text{hr}^{-1}$ ,  $58.6 \text{ strokes} \cdot \text{min}^{-1}$  and  $0.93 \text{ cm}$ , respectively. A positive relationship ( $r^2 = 0.84$ ,  $p < 0.05$ ) between SL and speed was found. Compared to the first 3 hours, between 18 hr and 21 hr the greatest decreases in speed (-36%) and in SL (-25%) were observed. Thereafter, the athlete increased speed (+26%) and in SL (+17%) between 21 hr and 23:44 hr:min compared to the previous three hours. RPE steadily increased from the beginning (5 pt) to the last 6-hour of swimming (10 pt). Pacing strategy varied, with a negative trend observed between 12 hr and 15 hr associated with high HS values (>3), and a positive trend was found from 21 hr to the end of the event (HS < 1.5). Compared to baseline, before the event the energy index showed a 33% increase, whereas after swimming a 65% decrease emerged.

**CONCLUSIONS:** For the first time an athlete crossed the Adriatic sea. Findings support SL as the most critical factor influencing speed in ultraendurance swimming. Despite the athlete perceived his effort at maximum during the last 6 hours, the decrease in HS and increases of swimming speed and SL might substantiate his determination to accomplish the challenging event. However, this aspect needs further investigation.

---

1564 Board #345 MAY 30 9:30 AM - 11:00 AM

**The Role of High Volume Endurance Training in Competitive Swimming**

Masaru MATSUNAMI<sup>1</sup>, Akihiro TAIMURA<sup>2</sup>. <sup>1</sup>Beppu Mizobe Gakuen College, Beppu, OITA, Japan. <sup>2</sup>Nagasaki University, Nagasaki, Japan.  
(No relationships reported)

In competitive swimming, more than 80% of competitive swimming events are less than 2 minutes in duration. Therefore, it is shown that high volume training, which is aerobic training of low intensity, is not advantageous. However, the improvement of aerobic capacity is related to competitive performance, and in specificity principle, it is considered essential to perform endurance training in the early stages of an annual swimming training program.

**PURPOSE:** To examine the role of high volume endurance training which aimed at the improvement of aerobic capacity.

**METHODS:** Five competitive female swimmers (height,  $159.8 \pm 3.1 \text{ cm}$ ; body weight,  $52.3 \pm 3.9 \text{ kg}$ ) had taken a one-month break after the intercollege swimming championship in Japan, and then had trained in high volume endurance swimming for eight weeks. The swimming performance tests (200 m x 4t, 3t, 2t) were conducted before the training period (T1) and after the first (T2) and the second (T3) four weeks. Swimming velocity and heart rate (HR) after each trial were measured. Aerobic capacity was evaluated from the relation between swimming velocity (V) and HR. Moreover, subjects took part in swimming competitions in the 4th week (COMP1) and the 8th week (COMP2) of a training period.

**RESULTS:** V and HR of each set in T1 and T2 were 1.261 m/s, 144.0 bpm; 1.321 m/s, 163.2 bpm; 1.355 m/s, 180.0 bpm and 1.297 m/s, 141.6 bpm; 1.365 m/s, 162.0 bpm; 1.409 m/s, 177.6 bpm. After the training for the first four weeks (T2) the V-HR line was shifted to the right of T1, and the fall of HR in the same V was observed. However, change of the V-HR line was not observed after the training for the second four weeks (from T2 to T3). In COMP1, personal best times were improved at two out of ten races. In COMP2 of four weeks later, exceeding personal best times occurred at five out of ten races. A significant difference was observed in the %personal best between COMP1 (98.2%) and COMP2 (100.4%) ( $p < .05$ ).

**CONCLUSIONS:** It is suggested that high volume endurance training recovers the lowered cardiopulmonary function by detraining, and there is the possibility of a competitive performance improvement. Therefore, in view of progressive strengthening of swimming training, it seems that high volume endurance training has a role to play and should be arranged in the early stages of annual training.

### Heat Acclimation In Skin Graft Patients

Rebekah A. I. Lucas, Matthew S. Gano, James Pearson, Craig G. Crandall, FACSM. *Institute for Exercise and Environmental Medicine, Dallas, TX.*  
(No relationships reported)

**PURPOSE:** This project tested the hypothesis that skin graft patients have the capacity to heat acclimate.

**METHODS:** Twenty burn survivors (age range: 22-54 years) with well-healed split thickness grafts (16±14 years post-injury) were stratified into two groups: 20-40% body surface area (BSA) grafted (N=13) and 45-75% BSA grafted (N=7). Six similarly aged, non-injured subjects served as controls. Subjects exercised for 90 min (the first 45 min at 1 l/min oxygen uptake followed by 45 min at a workload equivalent to 45% maximal oxygen uptake) in an environmental chamber (40° C, 30% relative humidity) on the first and final day of a 7 day heat acclimation regimen. Local sweat rate (from non-grafted skin), whole body sweat rate (pre/post weight), and change in body core temperature (intestinal) and heart rate responses were measured.

**RESULTS:** See Table. Five grafted subjects (one 20-40%, four 45-75% BSA) were unable to complete the second 45 min bout of exercise on Day 1; therefore, Day 7 comparisons were time matched.

**CONCLUSIONS:** 7 days of heat acclimation attenuated the increase in body core temperature and heart rate in both the 20-40% and 45-75% BSA groups, indicating that these individuals are able to heat acclimate and thus improve heat tolerance. Local and whole body sweat rates were not improved by the heat acclimation regime; though this may be because the central drive for sweating (i.e., body core temperature) was reduced following the acclimation regime.

**Grant:** NIH GM068865.

(No relationships reported)

It has been reported that exercise-trained animals have lower mortality rate against heat stress than sedentary animals, implicating a cross-adaptation in physiological components central to heat tolerance.

**PURPOSE:** This study was aimed to investigate that whether heat preconditioning can protect humans from exercise-induced muscle damage and inflammation.

**METHODS:** Using a balanced crossover design with one month separation, 16 active young male subjects voluntarily participated in a heat preconditioning program before exercise challenge, which includes 4 sessions of 30-min hot water immersions at 41 °C every 72 h.

**RESULTS:** Three days after last immersion, circulating muscle creatine kinase (CK) and thiobarbituric acid-reactive substances (TBARS) were slightly elevated by 27% and 21%, respectively (P< 0.05). This was concurrent with increased heart rate variability (HRV) (P< 0.05). After an acute bout of eccentric exercise challenge with 6 squats at 85% maximal voluntary effort for 6 sets, interleukin-6 (IL-6) and CK levels increased significantly by 120% and 34% (P< 0.05). However, this normal exercise response was completely eliminated following heat preconditioning. Post-exercise HRV and vagal power in the heat preconditioning trial were significantly greater than those in the control trial.

**CONCLUSIONS:** The results of the study suggest a hormetic effect of heat preconditioning, which can attenuate eccentric exercise-induced muscle damage and inflammatory response.

### Effects Of Heat Acclimatization On Work Tolerance And Thermoregulation In Trained Tropical Natives

Jason K W Lee, Amanda Q X Nio, David C Y Fun, Ya Shi Teo, Ee Von Chia, Chin Leong Lim. *Defence Medical and Environmental Research Institute, DSO National Laboratories, Singapore, Singapore.*  
(No relationships reported)

**PURPOSE:** This study aimed to investigate the effects of standard heat acclimatization in trained individuals residing in the tropics.

**METHODS:** Eighteen male trained soldiers, who are native to a warm and humid climate, performed a total of four heat stress tests donning the Skeletal Battle Order (SBO, 20.5 kg) and Full Battle Order (FBO, 24.7 kg) before (PRE) and after (POST) a 10-day heat acclimatization programme. Each heat stress test comprised three cycles of 60-min marches on a treadmill at 4 km/h, separated by 15-min seated rest. The trials were conducted in an environmental chamber (dry bulb temperature: 32°C, relative humidity: 70%, solar radiation: 400 W/m<sup>2</sup>). Work tolerance, body core (via ingestible temperature capsules) and skin (chest, triceps, thigh and calf) temperatures, heart rate, sweat rate and subjective responses were measured.

**RESULTS:** Excluding the data sets of which participants fully completed the heat stress tests (210 min) before and after heat acclimatization, work tolerance was improved from 173±30 to 201±18 min (~21%, p<0.05, n=9) following heat acclimatization. Heat acclimatization had no effects on baseline body core temperature across trials (37.1±0.3°C, p>0.05). After heat acclimatization, chest skin temperature during exercise was lowered in SBO (PRE=36.7±0.3 vs. POST=36.5±0.3°C, p<0.01) and FBO (PRE=36.8±0.4 vs. POST=36.6±0.3°C, p<0.01). Mean heart rate was similar with SBO (115±17 beats/min, p=0.44) and FBO (PRE=120±16 beats/min, p=0.70) following heat acclimatization. Heat acclimatization did not affect sweat rate in SBO (0.6±0.2 l/h, p=0.91) and FBO (0.6±0.2 l/h, p=0.54). After heat acclimatization, ratings of perceived exertion were decreased (PRE=11±2 vs. POST=10±2, p<0.05). Thermal sensation was reduced after heat acclimatization with SBO (PRE=1.2±0.7 vs. POST=0.9±0.7, p<0.05), but was similar with FBO (PRE=1.2±0.6 vs. POST=1.0±0.5, p=0.06).

**CONCLUSIONS:** A standard heat acclimatization programme improves work tolerance with negligible effects on thermoregulation in trained tropical natives. These findings are important for recommending appropriate heat acclimatization guidelines to tropical native athletes and military personnel undergoing physical training and competition/operation in a warm and humid environment.

### Core Temperature During Training In The Heat: Comparison Between Athletes In Continuous And Intermittent Sports

Jessica A. Frontanés, Raúl A. Rosario, Farah A. Ramírez-Marrero, FACSM, Osvaldo Hernández, Walter R. Frontera, FACSM, Anita M. Rivera-Brown, FACSM. *Center for Sports Health and Exercise Sciences, University of Puerto Rico School of Medicine, San Juan, Puerto Rico.*  
(No relationships reported)

Few field data are available on core temperature responses in elite athletes exercising in the heat in sports of intermittent nature in which the decreased exercise intensity is expected to facilitate heat dissipation.

**PURPOSE:** To compare the core body temperature responses between athletes in continuous (CON) and intermittent (INT) sports during a training session of prolonged duration in the heat.

**METHODS:** Sixty two elite athletes (runners, cyclists, and triathletes [CON]=23, mean age= 26.6 ± 6.9 yr; judo, soccer, tennis, basketball and handball players [INT]= 39, mean age=20.8 ± 3.3 yr) were tested during a typical training session for their sport. Heat exposure time in the last month was higher in CON (3,000.9 ± 1,738.2 min) compared to INT (796.9 ± 903.1 min), P < 0.05. Core temperature (T<sub>c</sub>) was measured pre, every 10 min and at the end of training using an ingestible temperature sensor. Acute changes in body weight were used to assess dehydration level (% of the pre-training BW). Exercise intensity was estimated using an accelerometer worn by the athletes during training. **RESULTS:** The duration of the training session was: CON= 75.8 ± 18.1 min; INT= 95.4 ± 16.9 min, P < 0.05. The WBGT was 30.3 ± 1.1 °C and 29.1 ± 1.3 °C for CON and INT, respectively (P < 0.05). Average exercise intensity was three times higher in CON (7,748.8 ± 1,307.3 activity counts/min) compared to INT (2,506.3 ± 504.6 activity counts/min), P < 0.05. Sweat rate and dehydration were higher for CON (1.6 ± 0.4 L/h and 2.0 ± 0.8%) compared to INT (1.0 ± 0.4 L/h and 1.0 ± 0.4%), both P < 0.05. Pre-exercise T<sub>c</sub> was higher in INT (37.4 ± 0.3 °C) compared to CON (37.2 ± 0.3 °C), P < 0.05. A steady increase in T<sub>c</sub> was observed throughout the exercise session for both CON and INT. The highest T<sub>c</sub> was similar for CON (38.8 ± 0.4 °C) compared to INT (38.7 ± 0.4 °C) and was not related to % dehydration in either group (P > 0.05). The change in T<sub>c</sub> (highest-pre exercise) was higher in CON (1.6 ± 0.6 °C) compared to INT (1.3 ± 0.4 °C), (P < 0.05).

**CONCLUSIONS:** In comparison to athletes in continuous sports, athletes in intermittent sports do not show the expected thermoregulatory response during training in a high heat stress environment possibly due to their lower level of heat acclimatization.

**1569** Board #350 MAY 30 9:30 AM - 11:00 AM

**Heat Tolerance Testing: Physiologic Responses of Men and Women**

Josh B. Kazman<sup>1</sup>, Francis O'Connor<sup>1</sup>, Patricia Deuster<sup>1</sup>, Stacey Zeno<sup>1</sup>, Yuval Heled, FACSM<sup>2</sup>. <sup>1</sup>USUHS, Bethesda, MD. <sup>2</sup>Heller Institute, Tel Aviv, Israel.  
(No relationships reported)

**PURPOSE:** Heat tolerance testing (HTT) is used by the Israeli Defense Force for managing exertional heat stroke (EHS) and when heat intolerance (HI) is suspected. We compared physiologic responses to the HTT as a function of gender and aerobic capacity.

**METHODS:** Men (n=16) and women (n=7) underwent maximal aerobic power testing (VO<sub>2</sub>max) and a HTT (walking at 5kph on a 2% grade for 120 minutes in a chamber set at 40°C/40% relative humidity). Heart rate, blood pressure, core and skin temperatures (T<sub>core</sub>/T<sub>skin</sub>) were measured and sweat rate was determined by pre and post weight. The physiological strain index (PSI) was determined from heart rate and temperature. HI was determined by heart rate (>145 bpm) and T<sub>core</sub> (>38.5°C).

**RESULTS:** Maximal T<sub>core</sub> (Men: 38.2±0.3 vs. Women: 38.4±0.3°C), T<sub>skin</sub> (Men: 36.8±0.6 vs. Women: 37.2 ± 0.3°C), and PSI (Men: 5.0±1.3 vs. Women: 5.9±1.4) did not differ significantly by gender, whereas heart rate was lower (Men: 127±21 vs. Women: 146±18 bpm; p=0.055) and VO<sub>2</sub>max (Men: 51.9±7.5 vs. Women: 43.8±5.9 ml/kg/min; p=0.02) and sweat rate (Men: 1.09±0.29 vs. Women: 0.72±0.26 L/h; p=0.02) higher in men than women. Four men and 3 women were HI (30.4%). Persons with VO<sub>2</sub>max <50 ml/kg/min were 2.2 times more likely to be HI compared to ≥50 ml/kg/min.

**CONCLUSIONS:** The HTT does not appear to be biased against women, unless one considers VO<sub>2</sub>max, which is typically lower in women. Although different criteria could be set, it would not alter responses in a warm environment. Improving VO<sub>2</sub>max may be of primary importance.

**Perceptual Responses of Obese and Lean Girls during Cycling under Thermoneutral and Heat Conditions**

Gabriela Tomedi Leites, Paulo Lague Sehl, Giovanni dos Santos Cunha, Adriano Detoni Filho, Flavia Meyer. Federal University of Rio Grande do Sul, Porto Alegre, Brazil.  
(No relationships reported)

Obese girls appear to subjectively perceive a greater discomfort during exercise in the heat compared to lean girls, indicating that ambient conditions could affect their adherence to an exercise program.

**PURPOSE:** To compare the perceptual responses of obese and lean pre-pubertal girls during exercise under thermoneutral and heat conditions.

**METHODS:** Twenty-seven girls (9.3±1.2 yrs old), 14 of whom were lean and 13 obese according to their % fat (<25 and >30%) measured by DXA, participated in the study. The girls completed two sessions (2-3 days apart) that, in a randomized order, differed only with respect to the thermal condition of the environmental chamber: neutral (23.9±0.9°C, 50.0±5.6% RH) and heat (35.2±0.9°C, 38.4±3.9% RH). Sessions consisted of 30-min of cycling at ~55% of their individual pre-determined VO<sub>2peak</sub>. Perceptual measurements consisted of four scales: 1) rate of perceived exertion (RPE Borg scale) 2) thermal sensation (9-point scale, from very cold to very hot); 3) thermal comfort (6-point scale, from very comfortable to very uncomfortable); 4) irritability (5-point scale, from nothing noticeable to very strong). RPE was recorded every five minutes of exercise, while the other responses were recorded at 0, 10, 20, and 30 minutes.

**RESULTS:** The RPE and thermal sensation were similar between groups and did not demonstrate a group × time interaction. Mean RPEs under the heat condition ranged from 8.0±2.0 to 12.0±6.0 and from 8.0±1.0 to 14.0±6.0, and under the thermoneutral condition from 8.0±1.7 to 11.0±4.0 and 8.0±0.7 to 12.0±4.0 in the lean and obese girls, respectively. Mean thermal sensation under the heat condition ranged from 6.0±1.3 to 7.5±2.2 in the lean and 6.0±1.2 to 7.0±1.5 in the obese, and under the thermoneutral condition, from 3.9±0.9 to 5.0±0.9 and from 3.8±1.5 to 5.0±2.0, respectively. In the lean girls, the thermal comfort decreased from 2.1±0.5 to 3.1±1.2 (p=0.009) and irritation increased from 1.3±0.4 to 2.0±1.0 (p=0.02) during the exercise in heat condition, while no change was observed in the obese girls.

**CONCLUSION:** Obese girls did not seem to experience a greater discomfort or heat sensation during cycling based on these exercise and environmental conditions.

**Sweating Of Obese And Lean Prepubescent Boys During Cycling In The Heat**

Jocelito B. Martins, Paulo L. Sehl, Flávia Meyer. Universidade Federal do Rio Grande do Sul - ESEF/UFRGS, Porto Alegre, Brazil.  
(No relationships reported)

Obese children are considered to be at a greater risk for exertional heat-illness during exercise in the heat, however, it is unclear whether their sweating characteristics or body water balance are different from those of lean children.

**PURPOSE:** To compare sweat volume (SV), water balance, and sweat electrolyte concentration and losses in obese and lean boys after cycling in the heat.

**METHODS:** Thirty physically active prepubescent boys (age 9.3±1.1 years) participated in the study. Fifteen were obese (OB) and 15 lean (LB) with respective body mass, height, IMC, %fat and VO<sub>2peak</sub> of: 48.1±8.3 and 30.3±4.7 kg, 141±6.2 and 135±7.1 cm, 24.9±3 and 16.1±1 kg.m<sup>-2</sup>, 46.4±14.3 and 15.7±3.6 %, and 34±5.8 and 43.1±6.2 ml.kg<sup>-1</sup>.min<sup>-1</sup>). After a preliminary session whereby a physical evaluation and a VO<sub>2peak</sub> assessment were conducted, the boys came to an experimental session which consisted of 30-min of cycling (50-60% of their predetermined VO<sub>2peak</sub>) in the heat (35°C, 40-45% RH). SV was calculated from change in body mass plus the voluntary fluid intake of a commercially available sports drink. Sweat was collected using adhesives for [Na<sup>+</sup>], [Cl<sup>-</sup>] and [K<sup>+</sup>] analysis in duplicates (AVL 9180, Roche). Independent T-test were used to compare groups.

**RESULTS:** The SV after the 30-min of cycling was similar between OB and LB, with respective means±SD of 280 ± 50 and 255 ± 110 ml. When corrected for body mass, SV was lower in OB than LB (5.9 ± 0.9 vs 8.6 ± 4.3 ml.kg<sup>-1</sup>, p=0.035) but when corrected for body surface area SV remained similar between groups (208 ± 33.8 vs 244 ± 116 ml.m<sup>-2</sup>, p=0.064). Sweat [Na<sup>+</sup>] and [Cl<sup>-</sup>] were higher (p=0.005) in OB, whereas [K<sup>+</sup>] was similar between groups. OB and LB showed no difference both in water balance in ml (-131 ± 170 and -189 ± 132, p=0.234) or in the resultant electrolyte losses in mmol (Na<sup>+</sup>= 12.0 ± 6.31 and 10.6 ± 4.24, p= 0.463; Cl<sup>-</sup>= 14.55 ± 5.23 and 10.9 ± 3.73, p= 0.054, and K<sup>+</sup>=2.84 ± 2.27 and 2.44 ± 1.98, p=0.638).

**CONCLUSION:** Prepubescent OB had similar SV both in absolute amount or when corrected for body surface area; however, they presented a higher sweat [Na<sup>+</sup>] and [Cl<sup>-</sup>]. Both groups ended the 30-min cycling in similar body water deficits and sweat electrolyte losses.

1572 Board #353 MAY 30 9:30 AM - 11:00 AM

### Differences In Self-generated Convection And Heat Balance Status In NCAA Linemen And Backs

Tomasz M. Deren<sup>1</sup>, Eric E. Coris<sup>2</sup>, Douglas J. Casa<sup>3</sup>, Julie K. DeMartini<sup>3</sup>, Anthony R. Bain<sup>1</sup>, Steve M. Walz<sup>2</sup>, Ollie Jay<sup>1</sup>. <sup>1</sup>University of Ottawa, Ottawa, ON, Canada. <sup>2</sup>University of South Florida, Tampa, FL. <sup>3</sup>University of Connecticut, Storrs, CT.

(No relationships reported)

Greater core temperature elevations in linemen compared to backs during summer training camps may be due to the stationary nature of linemen-specific activities resulting in a lower self-generated air velocity and a lower attendant convective and evaporative heat transfer.

**PURPOSE:** To compare the influence of self-generated convection on heat balance status between American football linemen (L) and backs (B) during preseason summer training camp.

**METHODS:** Ten NCAA D1 American football players 5 linemen (mass: 128±21 kg, BSA: 2.53±0.22 m<sup>2</sup>) and 5 backs (mass: 82±8 kg BSA: 2.02±0.12 m<sup>2</sup>) took part in on-field measurements at the start of summer training camp in southern Florida (T<sub>db</sub>:31.2±1.6°C, T<sub>wb</sub>:27.0±0.7°C, T<sub>re</sub>:38.4±2.8°C). Mean skin temperature (T<sub>sk</sub>) and self-generated air velocities (v<sub>self</sub>) were measured throughout practice. Self-generated convective (h<sub>c</sub>) and evaporative (h<sub>e</sub>) heat transfer coefficients and resultant sensible heat losses (C+R) and maximum rate of evaporative heat loss (E<sub>max</sub>) were calculated. Values were also combined to derive the maximum rate of metabolic heat production that is physiologically compensable (M<sub>max</sub>).

**RESULTS:** Values for T<sub>sk</sub> were similar between L (35.4±0.8°C) and B (35.4±0.4°C) (p>0.05). However, v<sub>self</sub> (L:0.23±0.06 m/s, B:0.37±0.10 m/s) and the resultant h<sub>c</sub> and h<sub>e</sub> values were greater in B compared to L (p<0.05). Nonetheless, no significant differences in C+R (L:-4±15 W/m<sup>2</sup>, B:+9±9 W/m<sup>2</sup>) or E<sub>max</sub> (L:70±8 W/m<sup>2</sup>, B:81±7 W/m<sup>2</sup>) were found between L and B over the course of practice (p>0.05). However since L had a lower BSA-to-mass ratio (L:199±16 cm<sup>2</sup>/kg, B:248±12 cm<sup>2</sup>/kg) M<sub>max</sub> per unit mass was lower in L (1.6±0.3 W/kg) compared to B (2.8±0.2 W/kg) (p<0.05).

**CONCLUSION:** The greater v<sub>self</sub>, h<sub>c</sub> and h<sub>e</sub> in B did not result in different C+R or E<sub>max</sub> values between positions. However, due to differences in body morphology a greater metabolic rate can be sustained in linemen before physiological compensability is reached in a summer training camp environment.

1573 Board #354 MAY 30 9:30 AM - 11:00 AM

### Effects of Heat Acclimation, With or Without Simulated Hypoxic Living, on Exercise Performance

Erik D. Hanson<sup>1</sup>, Tracey Gerber<sup>1</sup>, Mitchell Anderson<sup>2</sup>, David J. Bishop, FACSM<sup>1</sup>, Christos G. Stathis<sup>1</sup>. <sup>1</sup>Victoria University, Melbourne, Australia. <sup>2</sup>Baker IDI Heart and Diabetes Institute, Melbourne, Australia.

(No relationships reported)

**PURPOSE:** This project aimed to investigate the effect of 12 days of heat acclimation, with or without simulated hypoxic living, on physiological perturbations and performance during submaximal and maximal efforts.

**METHODS:** Well-trained men and women (age 35±2 yrs, VO<sub>2max</sub> 60.2±1.6 mL.kg<sup>-1</sup>.min<sup>-1</sup>) were allocated to either: heat exposure (H, N=7), heat + altitude exposure (H+A, N=7), or controls (CON, N=7). All participants completed a heat stress test (30°C, 80% humidity), which consisted of a 75 min submaximal effort at ~63% of the peak power output achieved in a pre trial VO<sub>2max</sub> test followed immediately by a 15 min maximal effort time trial. H and H+A then completed normoxic heat training sessions (1 h at 58% of peak power output at 30°C, 80% humidity) for 12 consecutive days. The H+A group was also exposed to 2500 m of altitude for an average of ~12 h per night. Blood and respiratory gas were collected during the experimental period and all tests were repeated post intervention. Differences between groups were determined using mixed model, repeated measures ANOVA.

**RESULTS:** There were no differences between groups at baseline. There were several group x trial interactions during the submaximal effort such that daily heat exposure tended to decrease heart rate in both H and H+A (P=0.08), but temperature decreased only in H (-1.1 ± 0.3°C, P=0.03) whilst respiratory exchange ratio was lower only in H+A (-0.08 ± 0.01, P<0.01). Heat exposure also produced lower lactate responses in the H and H+A compared with CON (2.07 ± 0.24 vs. 2.27 ± 0.19 vs. 3.10 ± 0.39 mmol/L, P=0.05). For the time trial, there was a trend for improved performance in both the H and H+A for total distance (P=0.06) and average wattage (P=0.07). As there was no difference between H and H+A, these groups were pooled. Compared to CON, daily heat exposure, with or without altitude exposure, produced greater improvements during the time trial (0.53 ± 0.13 vs. 0.01 ± 0.11 km, P=0.02; 35.1 ± 9.4, vs. -1.7 ± 8.5 watts, P=0.02).

**CONCLUSIONS:** Heat exposure improved time trial performance and tended to reduce physiological demands during submaximal workloads. However, concurrent exposure to altitude may impair or alter heat acclimation. Future studies should consider the timing of the altitude exposure in relationship to heat exposure to optimize performance.

1574 Board #355 MAY 30 9:30 AM - 11:00 AM

### Heat Induces An Overload During Complex Cognitive Performance

Nadia Gaoua<sup>1</sup>, Christopher P Herrera<sup>1</sup>, Sebastien Racinais<sup>1</sup>, Farid El Massioui<sup>2</sup>. <sup>1</sup>ASPETAR - Qatar Orthopaedic and Sports Medicine Hospital, doha, Qatar. <sup>2</sup>Universite Paris 8, Paris, France.

(No relationships reported)

**PURPOSE:** To investigate the modifications in brain electrical activity (EEG) when performing a cognitive task in the heat.

**METHODS:** 10 subjects performed a planning task (OTS: One Touch Stockings of Cambridge) with two levels of complexity: simple (OTS-4) and complex (OTS-6) after 2 hours of rest in hot (HOT, WBGT =40.2 ±0.6°C.) and neutral (CON, WBGT =21.1 ± 0.4°C) environments. EEG was recorded over the frontal lobe and theta power (4-8 Hz) and total alpha power (8-12 Hz) were analyzed.

**RESULTS:** Central temperature, was significantly higher in HOT (39.0 ± 0.2) than in CON (37.0 ± 0.2) condition. Independent of conditions, total alpha power (p<0.005) decreased from baseline to task engagement and theta power increased linearly comparing baseline to OTS-4 and OTS-6, respectively (p<0.05), suggesting theta activity increases with memory load and is a good indicator of working memory task demand. Prior to task engagement, theta power was higher in HOT (2.08) than in CON (1.68). During OTS-4, theta power in HOT (2.19) remained higher than in CON (1.97), however during OTS-6 theta power in HOT (2.27) was similar in CON (2.24). Performance on OTS-4 was similar in HOT and CON, whereas performance on OTS-6 was significantly lower in HOT than in CON (P<0.005).

**CONCLUSIONS:** The present changes in theta and alpha power suggest the existence of a load on working memory capacity prior to task engagement in response to heat exposure. Despite the difference in theta power during OTS-4, performance remained the same. However, no difference in theta power was observed between conditions during OTS-6, suggesting that it had reached a critical threshold that explains the decrements in cognitive performance in the heat. Thus, the present study demonstrates that additional cognitive resources for complex cognitive task are unavailable given the allostatic load imposed by passive hyperthermia leading to decrements in performance.

1575 Board #356 MAY 30 9:30 AM - 11:00 AM

### Heat Stress Does Not Augment Ventilatory Responses To Pre-Syncopal Limited Lower-Body Negative Pressure

James Pearson, Matt S. Ganio, Rebekah AI Lucas, Craig G. Crandall, FACSM. *IEEM, Presbyterian Hospital Dallas, Dallas, TX.*

(No relationships reported)

**INTRODUCTION:** Simulated hemorrhage reduces central blood volume and mean arterial pressure (MAP), while ventilation increases possibly to attenuate reductions in venous return via the respiratory pump. Whole-body heat stress can also cause hyperventilation.

**PURPOSE:** To test the hypothesis that ventilatory responses to reductions in central blood volume and arterial pressure during simulated hemorrhage are greater when individuals are exposed to a hyperthermic challenge comparable to that experienced by soldiers (Buller et al. 2008).

**METHODS:** 8 healthy males ( $34 \pm 9$  years,  $176 \pm 6$  cm,  $80.2 \pm 4.2$  kg) underwent a simulated hemorrhagic challenge, using lower body negative pressure (LBNP) until the development of pre-syncope symptoms, on two separate occasions: normothermic control and during whole body heat stress. Heat stress was induced using a water perfused suit sufficient to raise core body temperature  $\sim 1.2^\circ\text{C}$ . Core body temperature (CorTemp, intestinal pill), ventilation ( $V_E$ , Parvo Metabolic Cart) and MAP (Finometer) were measured throughout.

**RESULTS:** Prior to LBNP, MAP was reduced from baseline values in the heat stress trial ( $89 \pm 6$  vs.  $80 \pm 6$  mmHg;  $P = 0.001$ ) but was unchanged in the time control period in the normothermic trial ( $95 \pm 13$  vs.  $97 \pm 12$  mmHg;  $P = 0.51$ ). In the heat stress trial  $V_E$  increased from baseline values ( $8.3 \pm 3.6$  to  $11.7 \pm 4.6$  l/min;  $P < 0.001$ ). There was no change in  $V_E$  in the normothermic trial at similar time points ( $7.5 \pm 1.3$  to  $7.8 \pm 1.7$  l/min;  $P = 0.56$ ). At pre-syncope, neither absolute MAP (heat stress trial:  $59 \pm 14$ ; normothermic trial:  $69 \pm 14$  mmHg; mmHg;  $P = 0.20$ ) nor the reduction in MAP from pre-LBNP (heat stress trial:  $21 \pm 10$ ; normothermic trial:  $28 \pm 16$  mmHg;  $P = 0.28$ ) were different between heat stress and normothermic trials. At pre syncope,  $V_E$  increased to  $19.7 \pm 8.6$  l/min ( $P < 0.001$ ) and  $24.0 \pm 8.8$  l/min ( $P < 0.001$ ) in the normothermic and heat stress trials, respectively. However, the increases in  $V_E$  from pre-LBNP were not different between trials ( $P = 0.10$ ).

**CONCLUSION:** Despite similar reductions in MAP in response to simulated hemorrhage, the increase in  $V_E$  was not greater when individuals were hyperthermic. These data suggest that the central drive to increase  $V_E$  during simulated hemorrhage is not altered by hyperthermia.

**Extracellular Hsp72 Is Both Duration- And Intensity-dependent During Moderate And Intense Exercise-heat Stress To Exhaustion**

Julien D. Périard<sup>1</sup>, Patricia Ruell<sup>2</sup>, Corinne Caillaud<sup>2</sup>, Martin W. Thompson<sup>2</sup>. <sup>1</sup>Aspetar - Qatar Orthopaedic and Sports Medicine Hospital, Doha, Qatar. <sup>2</sup>University of Sydney, Lidcombe, Australia.

(No relationships reported)

The extracellular expression of heat shock protein 72 (eHsp72) during exercise-heat stress is suggested to increase as a function of the core temperature attained. However, whether this relationship is also influenced by exercise intensity remains unclear.

**PURPOSE:** This study investigated the relationship between eHsp72 expression and exercise to exhaustion in the heat at moderate and high intensities to determine the role of exercise intensity in mediating eHsp72 release.

**METHODS:** Sixteen male subjects cycled to exhaustion at 60% and 75% of maximal oxygen uptake in hot conditions ( $40^\circ\text{C}$ , 50% relative humidity). eHsp72 expression was measured prior to exercise, on reaching exhaustion, and 24 h following exercise cessation. Heart rate, core temperature, oxidative stress (malondialdehyde; MDA), and blood lactate and glucose concentration were measured to determine the predictor variables associated with eHsp72 expression.

**RESULTS:** The expression of eHsp72 increased similarly from pre-exercise baseline to exhaustion in the 60% and 75% trials ( $P < 0.001$ ). During the following 24 h, eHsp72 expression decreased to levels below baseline in both trials ( $P < 0.05$ ). Core temperature was significantly different at exhaustion, reaching  $39.7^\circ\text{C}$  in the 60% trial (58.9 min) and  $39.0^\circ\text{C}$  in the 75% trial (27.2 min) ( $P < 0.001$ ). The rate of rise in core temperature ( $2.1^\circ\text{C}\cdot\text{h}^{-1}$ ) was significantly greater in the 75% trial ( $P < 0.001$ ). Heart rate exceeded 96% of maximum on reaching exhaustion in both trials. A significant decline in MDA was observed 24 h after exercise compared with pre-exercise baseline and exhaustion ( $P < 0.001$ ). eHsp72 expression was highly correlated with the core temperature attained in the 60% trial and the rate of increase in core temperature in the 75% trial ( $P < 0.05$ ).

**CONCLUSION:** The similarity in expression of eHsp72 during moderate and high intensity exercise may relate to the duration (i.e. core temperature attained) and intensity (i.e. rate of increase in core temperature) of exercise. Therefore, the immuno-inflammatory release of eHsp72 in response to exercise in the heat appears to be duration- and intensity-dependent.

---

**1577** Board #358 MAY 30 9:30 AM - 11:00 AM

**Platelet Inhibition Attenuates Skin Blood Flow During Exercise in the Heat Without Impairing Thermoregulation**

Rebecca S. Bruning, Jessica D. Dahmus, W. Larry Kenney, FACSM, Lacy A. Holowatz. *The Pennsylvania State University, University Park, PA.*

(No relationships reported)

During passive heating (water-perfused suit), chronic low-dose aspirin and clopidogrel (Plavix®) treatment each result in a lower skin blood flow response and a greater rate of rise in core temperature in healthy, middle-aged individuals. If similar results occur during exercise in hot environments this would have widespread health implications, as these are the top anti-thrombotic agents used worldwide.

**PURPOSE:** The present double-blind, placebo control, crossover study examined the effects of seven days of systemic low-dose aspirin (81 mg/day) and clopidogrel (75 mg/day) treatment on physiological responses of healthy, middle-aged (50-65 years old) men and women during exercise in a hot environment ( $30^\circ\text{C}$ , 40% rh).

**METHODS:** Four men and three women exercised at 60%  $\text{VO}_{2\text{max}}$  on a cycle ergometer for up to 60 minutes. Esophageal temperature and skin temperatures at six sites were measured. Cutaneous vascular conductance was calculated as skin blood flow (laser Doppler Flowmetry) divided by mean arterial pressure (MAP) and normalized as a percentage of maximum vasodilation (elicited via local heating to  $43^\circ\text{C}$ ; %CVC<sub>max</sub>). Heart rate and blood pressure were also recorded.

**RESULTS:** Control of skin blood flow was altered by both low-dose aspirin and clopidogrel treatments. Both treatments increased the threshold for reflex vasodilation (aspirin  $37.29 \pm 0.03^\circ\text{C}$  and clopidogrel  $37.45 \pm 0.04^\circ\text{C}$  versus control  $37.07 \pm 0.02^\circ\text{C}$   $p < 0.001$ ). Aspirin treatment resulted in lower plateau skin blood flow versus control ( $45 \pm 3$  versus  $56 \pm 3$  %CVC<sub>max</sub> at 40 minutes of exercise;  $p = 0.03$ ). Despite altered thermoregulatory skin blood flow effector mechanisms; there was no difference in esophageal or body temperatures from control.

**CONCLUSION:** Platelet COX inhibition (low-dose aspirin) attenuates the plateau in skin blood flow during exercise, while both COX and platelet  $\text{P}_2\text{Y}_{12}$  ADP receptor inhibition (clopidogrel) increase the threshold for reflex vasodilation without impairing thermoregulation.

**FUNDING:** Supported by NIH grant R21 HL098645-01

**Sex-differences In Whole-body Sudomotor Activity Are Only Evidenced At High Requirements For Heat Loss**

Daniel Gagnon, Glen P. Kenny. *University of Ottawa, Ottawa, ON, Canada.*

(No relationships reported)

A lower whole-body sudomotor activity has recently been observed in females, paralleled by a lower thermosensitivity of the response. Although evidence suggests that these differences only occur at higher exercise intensities, no study has examined potential sex-differences in sudomotor activity at increasing requirements for heat loss.

**PURPOSE:** To examine sex-related differences in whole-body sudomotor activity during progressive increases in the requirement for heat loss.

**METHODS:** Eight males (M) and eight females (F, follicular phase) performed three successive 30 min exercise bouts at fixed rates of metabolic heat production equal to 200, 250, and 300  $\text{W}\cdot\text{m}^{-2}$ . Air temperature and humidity were set at  $40^\circ\text{C}$  and 20%. Whole-body sudomotor activity (evaporative heat loss, EHL) was measured by direct calorimetry. Mean body temperature ( $T_b$ ) was calculated from esophageal and mean skin temperatures.

**RESULTS:** By design, metabolic heat production did not differ between groups during the exercise bouts ( $p > 0.05$ ). Nonetheless, changes over time in EHL significantly differed between sex ( $p = 0.002$ ). Although EHL did not differ between groups during the first (M:  $228 \pm 5$  vs. F:  $220 \pm 7$   $\text{W}\cdot\text{m}^{-2}$ ,  $p = 0.418$ ) and second (M:  $284 \pm 9$  vs. F:  $273 \pm 7$   $\text{W}\cdot\text{m}^{-2}$ ,  $p = 0.394$ ) exercise bouts, it became significantly greater in males during the third exercise bout ( $348 \pm 13$  vs.  $305 \pm 8$   $\text{W}\cdot\text{m}^{-2}$ ,  $p = 0.015$ ). The greater EHL observed in males was paralleled by a greater thermosensitivity of the response compared to females ( $296 \pm 27$  vs.  $195 \pm 21$   $\text{W}\cdot\text{m}^{-2}\cdot^\circ\text{C}^{-1}$ ,  $p = 0.011$ ). In contrast, no differences in the mean  $T_b$  onset threshold for EHL were observed ( $p = 0.224$ ).

**CONCLUSION:** Sex-differences in whole-body sudomotor activity are only evidenced at high requirements for heat loss. These results suggest that the lower sudomotor thermosensitivity observed in females is due to sex-differences in the properties of the thermoeffector organ (sweat gland). Supported by NSERC grant RGPIN-298159-2009.

1579 Board #360 MAY 30 9:30 AM - 11:00 AM

**Aspirin Prevents Hyperthermic Platelet Activation in Firefighters During Exertion in Thermal Protective Clothing**

David Hostler, Serina J. McEntire, Steven E. Reis, Diane Comer, Charity G. Moore, Riana R. Pryor, Jennifer Erin, Priya Khorana, Francis X. Guyette, Joe Suyama. *University of Pittsburgh, Pittsburgh, PA.* (Sponsor: Robert Robertson, FACS) (No relationships reported)

Platelet aggregation is enhanced in firefighters following relatively short bouts of work in thermal protective clothing (TPC). Additionally, platelets may be directly activated by heat resulting in faster clot formation. It is important to understand if heat mediated platelet activation can be blunted or prevented given the high proportion of line of duty heart attacks in the fire service.

**PURPOSE:** Determine if aspirin therapy before and/or immediately following exertion in TPC prevents platelet activation.

**METHODS:** In this double-blind, placebo controlled study, 102 firefighters were randomized to receive daily therapy (81 mg aspirin or placebo) for 14d before and a single dose (325 mg aspirin or placebo) immediately following 50 minutes of treadmill exercise in TPC. The design used random assignment of aspirin before and after exercise (AA), placebo before and after exercise (PP), daily aspirin before and placebo following exercise (AP), and placebo before and aspirin following exercise (PA) conditions. Heart rate and core temperature were monitored during and for 90 minutes following exercise. Platelet closure time (PCT) was measured with a platelet function analyzer with an upper limit of detection of 300 sec before initial drug treatment, before exercise, immediately post exercise and 30, 60, and 90 minutes later. A random effects tobit model was used to test the effects of drug prior to exercise and during recovery controlling for the baseline platelet closure time.

**RESULTS:** Maximum heart rate and core temperature during exercise did not differ between groups with means exceeding 170 bpm and 38.6°C. Baseline median PCT did not differ between groups ranging from 112-124 sec and did not change after two weeks of placebo. PCT differed over time for the four groups ( $p < 0.001$ ) rising to a median of 300 sec [IQR 99, 300] in AA and 300 [92, 300] in AP prior to exercise. Following exercise, median PCT decreased to 275.5 [62, 300] (AA), 207 [55, 300] (AP), 95 [71, 182] (PA), and 90 [58, 201] (PP) sec. Median PCT returned to 300 sec 30 min after exercise in AA and AP and rose to 300 sec in PA 60 min after exercise.

**CONCLUSIONS:** Daily aspirin therapy blunts platelet activation during exertional heat stress. Furthermore, single dose aspirin therapy following exertional heat stress reverses platelet activation within 60 minutes.

**Interindividual Variability in Orthostatic Tolerance during Heat Stress: Role of Reductions in Cerebral Perfusion**

R. Matthew Brothers, Joshua F. Lee, Michelle L. Harrison, Skyler Brown. *University of Texas at Austin, Austin, TX.* (No relationships reported)

**PURPOSE:** Heat stress compromises orthostatic tolerance relative to normothermic conditions. However, the extent to which heat stress compromises orthostatic tolerance differs amongst individuals with some being more affected than others. While the exact mechanism(s) responsible for this interindividual variability in orthostatic tolerance during heat stress remain unknown, syncope will always occur when cerebral perfusion is not adequately maintained. This study tested the hypothesis that the individuals with the greatest heat-stress induced reduction in orthostatic tolerance would have the largest reduction in cerebral perfusion in this thermal condition.

**METHODS:** 15 individuals performed a maximal simulated hemorrhage challenge (lower body negative pressure; LBNP) during normothermia and following a whole-body heat stress on separate days. Tolerance during each condition was quantified as cumulative stress index (CSI) and the difference in CSI between thermal conditions was used to categorize individuals as HighDif (most affected by heat) and LowDif (least affected by heat). The effect of heat stress (prior to LBNP) on internal temperature (telemetry pill), cerebral perfusion ( $MCAV_{mean}$ : indexed by middle cerebral artery blood velocity), cerebral vascular conductance (CVC;  $MCAV_{mean} / \text{mean arterial pressure}$ ), and end-tidal carbon dioxide tension ( $PETCO_2$ ) was assessed in each group.

**RESULTS:** The difference in CSI was larger in the HighDif group relative to the LowDif group (HighDif:  $1243 \pm 135$  mmHg  $\times$  min; LowDif:  $605 \pm 311$  mmHg  $\times$  min,  $P < 0.01$ ). The increase in internal temperature was similar between groups (HighDif:  $1.47 \pm 0.15$  °C; LowDif:  $1.50 \pm 0.13$  °C,  $P = 0.70$ ). Heat stress reduced  $PETCO_2$ ,  $MCAV_{mean}$ , and CVC relative to normothermia in both groups ( $P < 0.05$  for each variable), however, the magnitude of the reduction in  $PETCO_2$  (HighDif:  $7.2 \pm 5.7$  Torr; LowDif:  $5.5 \pm 2.7$  Torr,  $P = 0.56$ ),  $MCAV_{mean}$  (HighDif:  $21.9 \pm 14.7$  cm $\cdot$ s $^{-1}$ ; LowDif:  $10.7 \pm 10.9$  cm $\cdot$ s $^{-1}$ ,  $P = 0.23$ ), and CVC (HighDif:  $31.3 \pm 24.9$  cm $\cdot$ s $^{-1}$ ·mmHg $^{-1}$ ; LowDif:  $11.4 \pm 19.2$  cm $\cdot$ s $^{-1}$ ·mmHg $^{-1}$ ,  $P = 0.18$ ) was similar between groups.

**CONCLUSION:** These results indicate the large interindividual variability in heat-stress induced reductions in orthostatic tolerance is not related to the degree to which cerebral perfusion is reduced in this thermal condition.

---

1581 Board #362 MAY 30 9:30 AM - 11:00 AM

**Reduced Cardiac Baroreceptor Responsiveness is Associated with Reductions in Orthostatic Tolerance in Hyperthermic Individuals**

Joshua F. Lee, Michelle L. Harrison, Skyler Brown, R. Matthew Brothers. *University of Texas at Austin, Austin, TX.* (No relationships reported)

Orthostatic tolerance is reduced in hyperthermic humans; however, there is a large degree of variability in this response with tolerance being reduced more in some individuals than others. The factors underlying the variability in orthostatic tolerance during hyperthermic conditions remain largely unknown.

**PURPOSE:** To test the hypothesis that individuals with the largest difference in orthostatic tolerance during heat stress relative to normothermia would have a reduced heart rate response to spontaneous reductions in systolic blood pressure (lower cardiac baroreflex sensitivity) during heat stress compared to individuals with the least difference in tolerance between the thermal conditions.

**METHODS:** On 2 different days, one during normothermia and another during heat stress, 15 individuals were exposed to a simulated hemorrhage via lower body negative pressure (LBNP) to pre-syncope. Tolerance to LBNP was quantified using a cumulative stress index (CSI). The difference in CSI between thermal conditions was calculated for each subject. The 6 individuals with the largest CSI difference (LargeDif) and the 6 with the least CSI difference (SmallDif) between conditions were grouped together. The effect of heat stress on spontaneous cardiac baroreflex sensitivity during reductions in systolic blood pressure (prior to LBNP) was assessed using the sequence technique. Cardiac baroreflex sensitivity was assessed during reductions in systolic blood pressure since this is the relevant analysis for orthostatic tolerance.

**RESULTS:** The difference in CSI between thermal conditions was greater in the LargeDif relative to the SmallDif group ( $1243 \pm 135$  mmHg  $\times$  min vs.  $605 \pm 311$  mmHg  $\times$  min;  $P < 0.01$ ) despite a similar rise in core temperature (LargeDif:  $1.47 \pm 0.15$  °C vs. SmallDif:  $1.50 \pm 0.13$  °C;  $P = 0.70$ ). The increase in heart rate during spontaneous reductions in systolic blood pressure (i.e. cardiac baroreflex sensitivity) was lower in the LargeDif group relative to the SmallDif group during hyperthermia (LargeDif:  $-0.50 \pm 0.47$  beats  $\cdot$  min $^{-1}$   $\cdot$  mmHg $^{-1}$  vs. SmallDif:  $-1.81 \pm 1.13$  beats  $\cdot$  min $^{-1}$   $\cdot$  mmHg $^{-1}$ ,  $P = 0.03$ ).

**CONCLUSION:** These data support the hypothesis that individuals with lower spontaneous cardiac baroreflex sensitivity during heat stress are less able to tolerate orthostatic challenges in this thermal condition.

1582 Board #363 MAY 30 9:30 AM - 11:00 AM

**Thermoregulatory Adaptations Following Sprint Interval Training**

Charles P. Katicka<sup>1</sup>, Andrew T. Del Pozzi<sup>1</sup>, Elisha Williams<sup>1</sup>, Svetlana Nepocaty<sup>2</sup>, Greg A. Ryan<sup>1</sup>, Jonathan E. Wingo<sup>1</sup>. <sup>1</sup>*University of Alabama, Tuscaloosa, AL.* <sup>2</sup>*Elon University, Elon, NC.* (No relationships reported)

Traditional endurance training (TET) typically involves weeks of long duration (60-90 min) exercise performed at a moderate to vigorous intensity. Recently, attention has focused on sprint interval training (SIT), a paradigm characterized by multiple bouts of short-duration, high-intensity exercise. Similar fitness benefits from TET and SIT have been demonstrated, but whether SIT, like TET, promotes heat acclimation, remains unclear.

**PURPOSE:** Was to test the hypothesis that SIT performed over 6 sessions results in measureable thermoregulatory and cardiovascular adaptations consistent with heat acclimation.

**METHODS:** Seven active men [mean  $\pm$  SD, 12.9  $\pm$  4.6% body fat, 22  $\pm$  3 yrs, 3.1  $\pm$  0.3 L/min peak oxygen uptake ( $VO_{2peak}$ )] performed 6 SIT sessions over 12 days with 48-72 h between

sessions. Each session consisted of 4-6 30-s Wingate Anaerobic Tests separated by ~4 min. Four individuals performed SIT in ~40 °C while 3 performed SIT in ~25 °C. Before and after the 2-week SIT protocol, participants cycled for 30 min at 65% VO<sub>2peak</sub> in 25 °C to assess the effects of SIT on heat acclimation.

**RESULTS:** Group outcomes were not different, so data were combined for simplification. There were no differences from pre- to post-training for any of the main outcome variables tested (onset of sweating, sweat sensitivity, heart rate at end of exercise, and rectal temperature change from pre- to post-exercise; all P > 0.05).

**CONCLUSIONS:** These results indicate that 2 weeks of SIT performed under the conditions specified does not result in heat acclimation.

**1583** Board #364 MAY 30 9:30 AM - 11:00 AM

**Variability in Simulated Hemorrhagic Challenge Tolerance is not Explained by Differences in Body Temperature**

Matthew S. Gano<sup>1</sup>, Kimberly Hubing<sup>2</sup>, James Pearson<sup>2</sup>, Rebekah A.I. Lucas<sup>3</sup>, Robert Matthew Brothers<sup>4</sup>, Craig G. Crandall, FACSM<sup>3</sup>. <sup>1</sup>University of Arkansas, Fayetteville, AR. <sup>2</sup>Texas Health Presbyterian Hospital, Dallas, TX. <sup>3</sup>Texas Health Presbyterian Hospital, Dallas, TX. <sup>4</sup>University of Texas Austin, Austin, TX.  
(No relationships reported)

**PURPOSE:** To examine if body temperature variations in normothermic and heat stressed conditions explain the variability in tolerance to simulated hemorrhage within each thermal condition.

**METHODS:** Data were retrospectively examined in individuals who underwent a simulated hemorrhagic challenge to pre-syncope (onset of syncopal symptoms) via lower body negative pressure (LBNP). The correlation between mean body temperature (T<sub>body</sub>, calculated from core and skin temperatures) and LBNP tolerance time while normothermic (n=45) and passively heat stressed (n=90) was examined. Second, LBNP time while normothermic and heat stressed in the 15 lowest T<sub>body</sub> was compared to the 15 highest T<sub>body</sub> within each thermal condition. Third, for subjects tested in both thermal conditions (n=33), the correlation between the increase in T<sub>body</sub> and the decrease in LBNP time was examined, as was LBNP times of the 10 smallest T<sub>body</sub> increases relative to the 10 largest T<sub>body</sub> increases.

**RESULTS:** LBNP time while normothermic (1237 ± 240 sec) and heat stressed (635 ± 275 sec) was not correlated to T<sub>body</sub> within each condition (normothermic range = 36.21-37.24°C, r=-0.15, p=0.33; heat stress range = 37.69-39.46°C, r=-0.12, p=0.28). Normothermic LBNP times of those with the lowest (36.35 ± 0.07°C) and highest (36.87 ± 0.15°C) T<sub>body</sub> were not different (1241 ± 256 and 1233 ± 294 sec, respectively; p=0.94). Similarly, heat stressed LBNP times of those with the lowest (37.86 ± 0.09°C) and highest (38.82 ± 0.20°C) T<sub>body</sub> were not different (690 ± 266 and 559 ± 282 sec; p=0.20). For subjects tested in both thermal conditions, decreases in heat stressed LBNP time (606 ± 218 sec) were not correlated to the magnitude of T<sub>body</sub> elevation (1.64 ± 0.23°C; r=0.04; p=0.83); moreover LBNP time of those with the smallest T<sub>body</sub> increase (664 ± 231 sec, 1.38 ± 0.14°C) was not different than those with the largest T<sub>body</sub> increase (611 ± 212 sec, 1.91 ± 0.07°C; p=0.60).

**CONCLUSIONS:** Between subject variations in T<sub>body</sub> while normothermic and heat stressed do not explain the within-condition variability in tolerance to a simulated hemorrhagic challenge. Although heat stress compromises blood pressure control, differences (1.1-2.0°C) in the magnitude of body temperature increase during a heat stress do not explain the variability in tolerance.

**Caffeine's Effect on Hydration and Body Temperature During Exercise in ≥26.6°C Environments: A Systematic Review**

Kelly D. Pagnotta<sup>1</sup>, Douglas J. Casa, FACSM<sup>1</sup>, Kerri E. Gavin<sup>2</sup>, Lindsay M. McDowell<sup>3</sup>. <sup>1</sup>Korey Stringer Institute, University of Connecticut, Storrs, CT. <sup>2</sup>Villanova University, Philadelphia, PA. <sup>3</sup>The Pomfret School, Pomfret, CT.  
(No relationships reported)

Caffeine (CAF) has become the most widely used behaviorally active substances in the world today and has recently been removed from the list of banned substance by the International Olympic Committee. Previous studies related to CAF and performance indicate that CAF prior to exercising clearly enhances endurance performance. Recent studies have been completed to assess how CAF effects heat tolerance in warm or hot environments, but few, if any, have systematically consolidated the findings.

**PURPOSE:** To analyze how CAF directly effects hydration and core temperature (T<sub>c</sub>) while exercising in a warm or hot environment.

**METHODS:** Two independent searches were completed in various databases for CAF, T<sub>c</sub> and exercise and CAF hydration status and exercise, using a variety of search terms. Inclusion criteria included original research with human subjects, controlled, counter balanced hydration strategies, valid measurements of hydration status and T<sub>c</sub>, CAF dosages of 3-9 mg.kg body mass administered less than 3 hours prior to exercise, exercise lasting greater than 30 minutes, environmental conditions greater than or equal to 26.6°C. Quality control was obtained by a PEDro score of greater than or equal to 7 and 2 independent reviews of each article. Studies were excluded if they included time to exhaustion as the exercise component, the effects of CAF could not be isolated, or they had no control group (CON). The initial search revealed 342 studies and 49 were further analyzed. 41 studies were excluded for not meeting the inclusionary criteria, leaving a total of 8 studies for inclusion. Studies with multiple trials examining various doses of caffeine were counted as separate studies, resulting in a total of 12 possible data sources.

**RESULTS:** Studies included in the analysis of change in T<sub>c</sub>. (n=10) mean difference (CAF-CON =0.08°C ). Independent of the mode used to assess, CAF had no effect on hydration status (CAF-CON) (%body mass Δ [n=7] = 0.033%, Uosmo [n=4] = 48.5, Usg [n=3]= 0.003).

**CONCLUSIONS:** Because CAF can have an ergogenic effect on performance, and, as our results suggest, little physiological effect on heat tolerance and hydration status, it seems to not have detrimental thermoregulatory effects when athletes who are exercising in the heat and utilizing doses between 3-9 mg.kg body mass.

**Biomechanical Simulation Of The Passive Mechanical Coupling In The Hand And Wrist**

Benjamin I. Binder-Macleod, Jules P.A. Dewald, Wendy M. Murray. Northwestern University, Evanston, IL.  
(No relationships reported)

The muscles that control the hand cross multiple joints, particularly the extrinsic finger muscles which cross the wrist and extend to the fingers. This complex musculoskeletal anatomy creates passive mechanical linkages between joints, coupling the movement of multiple joints. In healthy individuals the passive coupling between the wrist and hand facilitates opening and closing of the fingers. Impairments, due to stroke, OA, or other injuries, may disrupt this coupling and cause a loss of hand control.

**PURPOSE:** To use a multi-joint biomechanical model of the upper limb to evaluate how the musculoskeletal structures couple the motion of the index finger and wrist.

**METHODS:** A biomechanical model of the upper extremity was utilized to calculate the rest posture of the MCP joint at different wrist postures via static equilibrium analysis. Rest postures were calculated to be the MCP joint angle at which the sum of the total passive torques (ligaments, joint capsule, and intrinsic and extrinsic finger muscles) and the torque produced by the mass of the phalanges of the finger equal 0 Nm. Work done passively to resist motion of the MCP joint from the rest position by the musculoskeletal structures was calculated. A sensitivity analysis of the effects the muscle properties have on the rest posture and work was conducted at 0° wrist posture by varying the extrinsic flexor muscles' optimal fiber lengths (L<sub>fo</sub>) and tendon slack lengths (L<sub>ts</sub>).

**RESULTS:** The rest posture of the first MCP joint at wrist flexion angles of -60°, 0°, and 60° were 75°, 51°, and -20° respectively. At wrist angles -60° and 0° the extrinsic finger flexors contributed the largest percentage of work (91% and 59%) to resist MCP motion, and at 60° the extrinsic finger extensors primarily (74%) resisted MCP motion. The sensitive analysis of L<sub>fo</sub> and L<sub>ts</sub> to 99%, 95% and 90% of nominal length showed changes in rest postures (L<sub>fo</sub>: 51°, 51°, & -63°; L<sub>ts</sub>: 51°, 80°, & 90°) and increases in the passive resistive work (L<sub>fo</sub>: 125%, 268%, & 579% ; L<sub>ts</sub> 187%, 1000% & 3779%).

**CONCLUSIONS:** When passive properties of the musculoskeletal structures of the hand are incorporated into a multiarticular biomechanical model of the upper limb, simulations of the mechanical coupling of the hand and wrist can be analyzed, along with how alterations to muscle properties, due to disorders, may affect this coupling.

**1586** Board #367 **MAY 30** **9:30 AM - 11:00 AM**  
**The Influence of Patient's Body Size on Dental Hygienist Shoulder Kinematics**

Tal Amasay<sup>1</sup>, Andrew Karduna<sup>2</sup>. <sup>1</sup>Barry University, Miami Shores, FL. <sup>2</sup>University of Oregon, Eugene, OR.  
(No relationships reported)

Dental Hygienists have been identified, as an occupational group that is at risk for musculoskeletal disorders of the upper extremities, and that the prevalence of these disorders increases with years of occupational exposure. Additionally, in the United States, the prevalence of overweight and obese people has increased sharply for both adults and children. This increase may introduce more exposure of dental hygienists to obese patients which may result in an increased prevalence of shoulder musculoskeletal disorders.

**PURPOSE:** The aim of this study was to evaluate the influence of patient girth on dental hygienists shoulder kinematics and exposure during teeth instrumentation in a simulated occupational environment.

**METHODS:** Sixteen female dental hygienists, mean age of 49.6 years (28 - 64 years) and current work experience ranging from 1.5 - 32 years participated in the study. Three dimensional kinematics of the scapula and humerus were collected at a sampling rate of 120 Hz using the Polhemus Liberty magnetic tracking system. During data collection, the participants instrumented three different teeth on two different manikin representing the 50<sup>th</sup> and 99<sup>th</sup> percentiles of body size. To quantify differences in humeral and scapular kinematics and humeral exposure parameters, two independent variables with two levels were chosen, Hand Dominance and Body Type size. Separate two-way ANOVAs with repeated measures were conducted.

**RESULTS:** Significant higher mean humeral elevation angles were observed while instrumenting the big manikin for the dominant (33 vs. 45 deg) and non-dominant (31 vs. 36 deg) hands. Significant higher mean scapular upward rotation angles were observed while instrumenting the big manikin for the dominant (2 vs. 6 deg) and non-dominant (-1 vs. 2 deg) hands. Furthermore, dental hygienist spent significantly more time above 30 deg (dominant 42% vs. 68%, non dominant 47% vs. 60%) and 60 deg (dominant 13% vs. 28%, non dominant 4% vs. 11%) of humeral elevation while instrumenting the big manikin.

**CONCLUSION:** This study provided evidence that dental hygienists alter their shoulder kinematics while instrumenting big girth patients. Consequently, patients of greater girth may increase dental hygienists' risk of developing shoulder musculoskeletal disorders.

**1587** Board #368 **MAY 30** **9:30 AM - 11:00 AM**  
**Kinematics Of The Shoulder Complex During Ergonomic Hand Drive Wheelchair Propulsion: Shoulder Impingement Implications**

Mark D. Tillman, FACSM, Zukowski A. Lisa, Patty W. Hovis, Otzel M. Dana, Roper A. Jaimie, Orit Shechtman. *Univ. of Florida, Gainesville, FL*  
(No relationships reported)

The shoulder is the most mobile joint in the body and vitally important to the manual wheelchair user for propulsion and transfers. Shoulder impingement (SI) syndrome is the most frequently reported upper extremity pathology for wheelers. SI pain is exacerbated by various combinations of four particular movements of the shoulder complex: scapular protraction and arm flexion (FLX), abduction (ABD) and internal rotation (IR). Alternative drive mechanisms may provide relief.

**PURPOSE:** To test an ergonomic hand drive mechanism (EHDM) for a conventional manual wheelchair (CMW) that may lead to improved wheeling mechanics as related to SI.

**METHODS:** Thirteen adult full-time wheelchair users (43.0±15.0 yrs, 74.5±16.8 kg, 173.1±13.2 cm) completed five trials in a CMW and five trials in the same chair equipped with an EHDM. All participants were medically and functionally stable and at least six months post injury. Digital video data were captured by 11 cameras as each participant wheeled at their preferred pace across a flat, smooth 8m long surface. Angular kinematics of the shoulder (flexion/extension, abduction/adduction, internal and external rotation) and one measure of scapular motion (protraction/retraction) were computed for right and left sides. At least one push cycle was analyzed per trial with average values calculated for all five trials. Paired sample t-tests were used to compare maximum values between the two conditions ( $\alpha=0.05$ ).

**RESULTS:** The following changes were noted with EHDM use compared to CMW: FLX increased ( $p<.001$ ), ABD decreased ( $p=.002$ ), IR decreased ( $p<.001$ ), and scapular protraction decreased ( $p=.025$ ).

**CONCLUSION:** The kinematic alterations while using the EHDM may have clinical implications regarding SI. ABD was reduced by 14.6%, IR was reduced by 48.2%, and scapular protraction decreased by 57.5%. Alternatively, FLX increased over three fold to 31.5°, but presumably not to a level of impingement. EHDM use may lessen SI risk by reducing three of the four injurious movements. The influence of these movements in combination was not considered and should be addressed in future research.

**1588** Board #369 **MAY 30** **9:30 AM - 11:00 AM**  
**Quantitative Examination of Pelvic and Scapular Stabilizing Muscle Activation during Shoulder Rehabilitation**

Michael Sola, Gretchen D. Oliver, Sean Huddleston. *University of Arkansas, Fayetteville, AR*. (Sponsor: Heidi Kluess, FACSM)  
(No relationships reported)

The kinetic chain approach to shoulder rehabilitation has become the standard. Incorporating proximal stability for distal mobility requires a stable base of not only the hips and pelvis but also the scapula. Thus shoulder rehabilitation should encompass the musculature about the shoulder as well as stabilizing musculature of the pelvis and hips.

**PURPOSE:** To quantify muscle activation of the gluteus maximus and upper trapezius muscle groups during shoulder rehabilitation exercises.

**METHODS:** Bipolar surface electrodes were applied to the 30 participants' (23.5 ± 1.34yr; 174.4 ± 11.0 cm; 76.6 ± 16.9 kg) dominate upper trapezius and gluteus maximus muscle groups. sEMG data were collected and expressed as percent of maximum voluntary isometric contraction (% MVIC). Data were interpreted as minimal activation 0-20% MVIC, moderate activation 20-35% MVIC, moderately strong activation 35-50% MVIC, and significantly high activation >50% MVIC. Participants performed shoulder dump, dynamic physioball (DPB), standing dynamic abduction, and standing dynamic flexion exercises.

**RESULTS:** Moderate activation was seen in the shoulder dump and standing dynamic abduction exercise for the gluteus maximus. Standing dynamic abduction and DPB showed high upper trapezius activation, while standing dynamic flexion and the shoulder dump showed moderately strong activation (Figure 1).

**CONCLUSION:** The exercises performed allowed for moderate to moderately strong activation in both upper and lower extremity musculature. When trying to incorporate total kinetic chain during shoulder rehabilitation, it is important that the shoulder exercises are focused not only on the shoulder but also on the stabilizing base of the lower extremity.

**1589** Board #370 **MAY 30** **9:30 AM - 11:00 AM**  
**Wheelchair Propulsion Using an Ergonomic Hand Drive Mechanism Reduces Wrist Jerk Throughout Range of Motion**

Lisa A. Zukowski, Jaimie A. Roper, Dana Otzel, Patty Hovis, Orit Shechtman, Mark D. Tillman, FACSM. *University of Florida, Gainesville, FL*  
(No relationships reported)

Forty-nine to 63% of conventional manual wheelchair (CMW) users suffer from carpal tunnel syndrome (CTS), which is likely induced by a combination of potentially large forces transmitted through the wrist and an extreme wrist range of motion (ROM). The ergonomic hand drive mechanism (EHDM) tested in this study utilizes a more neutral wrist orientation. Further, because the EHDM uses continuous contact between the lever and hand, more constant force application and therefore reduced jerk ( $\Delta a/\Delta t$ ) should result.

**PURPOSE:** To evaluate wrist jerk in relation to angular orientation while using the EHDM.

**METHODS:** Thirteen adult full-time CMW users who were medically and functionally stable and at least six months post injury were recruited (43.0±15.0 yrs, 74.5±16.8 kg, 173.1±13.2 cm). Motion data were captured by 11 cameras as participants propelled across a length of 8m completing 5 trials in a CMW and 5 trials in the same CMW fitted with the EHDM. Angular

kinematics of the wrist (flexion/extension, radial/ulnar deviation) were computed and third derivatives (jerk) were calculated. At least one push phase was analyzed per trial and all trials were combined to calculate an average push per participant that was divided into ten consecutive time intervals. Maximum jerk values (MJV) from each interval were compared between conditions using paired samples t-tests ( $\alpha=0.05$ ). Wrist orientation at statistically different MJV were then compared between conditions using the Wilcoxon signed-rank test ( $\alpha=0.05$ ).

**RESULTS:** Use of the EHDM resulted in reduced MJV within both planes of motion throughout the majority (60%) of the intervals ( $p<0.05$ ). Wrist orientation however did not vary ( $p>0.05$ ) at significantly different MJV except for a reduction in radial deviation with use of the EHDM ( $p<0.033$ ).

**CONCLUSION:** EHDM use reduces jerk throughout the push phase of propulsion. These results evince more constant force application with EHDM use and infer a reduction in wrist joint reaction forces, which may lessen both the symptoms as well as the likelihood of developing CTS.

**1590** Board #371 MAY 30 9:30 AM - 11:00 AM

**Reliability of Motion Capture Shoulder Kinematics in Wheelchair Propulsion Utilizing an Ergonomic Hand Drive**

Patty W. Hovis, Lisa A. Zukowski, Jaimie A. Roper, Otzel M. Dana, Kaitlin Murphy, Orit Shechtman, Mark D. Tillman, FACSM. *Univ. of Florida, Gainesville, FL*  
(No relationships reported)

Obtaining motion capture data from wheelchair users during propulsion requires multiple reliable trials. Data reliability (repeatability/consistency) implies precision of both measurements and the detection of differences between trials. Researchers commonly collect 5 trials; however, loss of trial data can occur due to intrinsic or extrinsic error leaving fewer trials for analysis. Reliability of results may be affected when only 3 to 4 successful trials are obtained. Thus, it is important to determine the minimum number of trials necessary to achieve data reliability.

**PURPOSE:** To determine the reliability of analyzing 3, 4, and 5 trials with a conventional manual wheelchair (CMW) and the same CMW with an attached ergonomic hand drive (EHD).

**METHODS:** Ten full-time wheelchair users ( $39.6 \pm 9.8$  yrs,  $172.0 \pm 13.3$  cm,  $72.5 \pm 15.0$  kg), at least six months post injury, completed 5 trials in a CMW and 5 trials in the same chair equipped with an EHD. Digital video data were captured as each participant wheeled at their preferred pace across a flat, smooth 8m long surface. Shoulder angular kinematics (max flexion [FL], max extension [EXT], and range of motion [ROM]) for the right side were computed for all 5 propulsion trials. Intra class correlation coefficients (ICC) were calculated and compared between the conditions.

**RESULTS:** The ICC for FL, EXT, and ROM for 3 trials (0.89, 0.88, 0.79 respectively), 4 trials (0.87, 0.89, 0.79 respectively), and 5 trials (0.89, 0.90, 0.84 respectively) varied. The ICC for FL angles obtained from 3, 4 and 5 trials with the EHD were greater than CMW trials ( $>0.90$  vs.  $0.80-0.84$ , respectively). The ICC for EXT angles were greater for CMW trials than EHD trials ( $>0.90$  vs.  $0.77-0.81$ , respectively). The ICC for ROM were greater for EHD than CMW trials ( $0.80-0.84$  vs.  $0.76-0.80$ , respectively).

**CONCLUSION:** High ICC values for the EHD FL and CMW EXT indicate high reliability for 3, 4, and 5 trials. However, higher variability was found between trials with ROM, EHD EXT, and CMW FL. Therefore, a minimum of 5 trials is recommended for manual wheeling motion capture with additional trials being performed based on participant capabilities.

This work supported in part by NIH/NCRRTS award to the University of Florida ULI RR029890. The hand drive mechanism used in this study is the intellectual property of Shands Healthcare.

**1591** Board #372 MAY 30 9:30 AM - 11:00 AM

**Changes in Shoulder Range of Motion and Humeral Torsion in High School Baseball Players**

Sakiko Oyama, Elizabeth E. Hibberd, Joseph B. Myers. *University of North Carolina at Chapel Hill, Chapel Hill, NC*  
(No relationships reported)

Baseball participation involves repetitive throwing and/or pitching, and has been theorized to lead to musculoskeletal adaptations at the shoulder that are associated with injuries. However, no study has evaluated changes in both shoulder range of motion (ROM) and humeral retrotorsion (HT) in high school baseball players over a year.

**PURPOSE:** To describe changes in shoulder ROM and HT over a year in high school baseball players ( $16.1 \pm 0.8$  years, range=14-17 years) using a longitudinal study design.

**METHODS:** In spring of 2010, shoulder internal/external rotation ROM (digital inclinometer) and HT (ultrasonographic method) was measured in 339 participants. Measurements were repeated on the 108 returners in spring of 2011. Dominant-limb shoulder internal/external rotation ROM, total rotation ROM, and HT were compared pre-post the follow-up period using paired t-tests.

**RESULTS:** Shoulder internal rotation (mean difference=  $-4.0 \pm 9.5^\circ$ ,  $p<.001$ ), external rotation (mean difference=  $-5.1 \pm 14.3^\circ$ ,  $p<.001$ ), and total rotation (mean difference=  $-9.4 \pm 18.7^\circ$ ,  $p<.001$ ) ROM decreased over a year. HT (mean difference=  $1.2^\circ \pm 5.7^\circ$ ,  $p=.04$ ) increased slightly, yet the change was clinically insignificant.

**CONCLUSIONS:** Alterations in shoulder ROM without concomitant changes in HT indicates that the changes in shoulder ROM in high school baseball players are mainly attributed to changes in soft tissue property rather than osseous adaptation. This may be due to the fact that participants were approaching the end of skeletal maturity. Decreased internal rotation and total rotation ROM have been linked to upper extremity injuries in overhead athletes. Therefore, observations from this study supports the benefit of implementing stretching programs in high school baseball players to help maintain shoulder ROM and possibly prevent upper extremity injuries. Supported by NIH-NIAMS R03AR055262.

**1592** Board #373 MAY 30 9:30 AM - 11:00 AM

**Comparison Of Sleeper’S, Cross Body And Manual Stretching For Posterior Shoulder Tightness: Randomized Controlled Trial**

Hande Guney, Gul Baltaci, Nihan O. Pekyavas, Gul Oznur Karabicak, Buket Teker, Pinar Balci, Ece Nohutlu Gunaydin. *Hacettepe University Faculty of Health Sciences Physiotherapy and Rehabilitation, Ankara, Turkey*  
(No relationships reported)

**BACKGROUND:** Glenohumeral internal rotation deficit (GIRD) and posterior shoulder tightness (PST) have been link to each other and associated with the shoulder pain. Lately, many researchers have focused on efficiency of different stretching methods on PST and GIRD.

**PURPOSE:** To determine if the acute effects of manual stretching method is superior to cross-body stretching and sleeper stretch to resolve the PST and GIRD.

**METHODS:** Fifty-six asymptomatic female (mean age:  $24.95 \pm 3.03$  years) who have more than  $20^\circ$  of GIRD, randomly assigned to 1 of 3 intervention groups. The manual stretching group ( $n=20$ ), the cross-body stretch group ( $n=18$ ), the sleeper stretch group ( $n=18$ ) (Table 1). Shoulder internal rotation ROM, with the arm abducted  $90^\circ$  was measured before and after 1-week intervention period. Subjects were asked to perform twice daily for 5 repetitions, holding each stretch for 30 seconds. One-way analysis of variance (ANOVA) was used for determination of equivalence among groups and evaluation of subject characteristics.

**RESULTS:** The increase in internal rotation ROM for the subjects in the manual stretching group (mean  $\pm$  SD:  $19.0^\circ \pm 4.6^\circ$ ) were significantly greater than the cross-body stretch group ( $11.0^\circ \pm 2.6^\circ$ ,  $p=0.001$ ) and sleeper stretch group ( $9.3^\circ \pm 2.8^\circ$ ,  $p=0.001$ ). The improvements in the sleeper stretch group were not different from the cross-body stretch ( $p=0.385$ )

**CONCLUSION:** Based on our results, the manual stretching appears to be more effective when comparing to both cross-body stretch and sleeper stretch group to gain internal rotation ROM. While the improvement in internal rotation from the cross-body stretch was greater than the sleeper stretch, this difference could not be statistically significant.

**1593 Board #1 MAY 30 2:00 PM - 3:30 PM****Quercetin Supplementation Reduces Chemotherapy-induced Fatigue In Mice: Possible Role Of MCP-1**Sara E. Mahoney<sup>1</sup>, E. Angela Murphy<sup>2</sup>, Jamie L. McClellan<sup>2</sup>, Benjamin Gordon<sup>2</sup>, M. Marjory Pena<sup>2</sup>, J. Mark Davis, FACSM<sup>2</sup>. <sup>1</sup>Texas A&M University, Kingsville, Kingsville, TX. <sup>2</sup>University of South Carolina, Columbia, SC.*(No relationships reported)*

Chemotherapy induces a range of severe side effects in cancer patients including nausea, vomiting, and fatigue. Although chemotherapy-induced fatigue is reported in up to 99% of cancer patients, little has been done to elucidate the mechanisms and possible treatments; however we have preliminary evidence that MCP-1 induced inflammation may play a role in the development of fatigue and that the dietary flavonoid quercetin can blunt this effect.

**PURPOSE:** To determine the efficacy of quercetin in reducing MCP-1 and subsequent fatigue after the administration of 5-fluorouracil (5-FU) chemotherapy.

**METHODS:** First, the effect of quercetin on voluntary wheel cage running was assessed using C57BL/6 mice assigned to one of four groups; normal diet-placebo (ND-PLA), normal diet-5-FU (ND-60), quercetin-placebo (Q-PLA), and quercetin-5-FU (Q-60). Mice were given a daily injection of either 60 mg/kg of 5-FU or phosphate buffered saline for five days and their activity was monitored 24 hours per day until 14 days post the initial injection. A second group of mice was used to assess blood following 5-FU. Mice were sacrificed at 5 or 14 d post initial injection.

**RESULTS:** Voluntary wheel running was reduced in both ND-60 and Q-60 as compared to the placebo groups ( $p < 0.05$ ), however, this response was blunted in Q-60 ( $p < 0.05$ ). Quercetin also blocked the 5-FU induced increase in plasma MCP-1 ( $146.5 \pm 22.08$  ng/mL for ND-14d vs.  $59.7 \pm 7.04$  for Q-14d,  $p < 0.001$ ). Both ND-60 and Q-60 had reduced hematocrit and hemoglobin at 5 and 14 days, but the reduction was less severe at 14 days in Q-60 ( $18.11 \pm 1.77$  % Hct for ND-60 vs.  $29.87 \pm 1.12$  for Q-60, and  $6.21 \pm 0.61$  g/dL Hb for ND-14d vs.  $9.68 \pm 0.26$  for Q-14d,  $p < 0.001$ ).

**CONCLUSION:** These results suggest a beneficial role of quercetin not only in reducing MCP-1 and presumably inflammation, but in blunting the severity of common side effects of chemotherapy such as anemia and fatigue.

---

**1594 Board #2 MAY 30 2:00 PM - 3:30 PM****The Effect of a Breast Cancer Diagnosis on Physical Activity Attitude and Barriers**Stacy E. Cutrono<sup>1</sup>, Mark Stoutenberg<sup>2</sup>, Arlette Perry, FACSM<sup>1</sup>. <sup>1</sup>University of Miami, Coral Gables, FL. <sup>2</sup>University of Miami, Miller School of Medicine, Miami, FL.*(No relationships reported)*

Breast cancer (BCa) survivorship issues have become more prevalent as improvements in diagnostic measures and treatment have increased. A cancer diagnosis may serve as a teachable moment for the adoption of a healthy lifestyle. Evidence suggests that engagement in regular physical activity has numerous benefits for BCa survivors; yet physical activity levels still remain low.

**PURPOSE:** To assess the change in self-reported attitude toward physical activity and barriers to exercise pre- and post-diagnosis among BCa survivors.

**METHODS:** A web-based survey was developed and distributed to BCa survivors through community-based cancer organizations in South Florida. Respondents were asked to complete the survey pertaining to their physical activity attitudes and behaviors prior to diagnosis, their current physical activity levels, the importance of physical activity in their lives, and limitations to engaging in regular physical activity.

**RESULTS:** A total of forty-three BCa survivors completed the survey. The majority of respondents were between the ages of 50-69 years (61.0%), Caucasian (70.7%), employed (61.0%), and within three years since treatment completion (51.2%). Prior to diagnosis, 58.6% of respondents ranked the importance of physical activity as important or very important compared to 92.5% post-diagnosis. There was a significant improvement in the proportion of survivors who changed their self-reported importance of physical activity from pre- to post-diagnosis ( $p < 0.001$ ). The majority of respondents reported being at least somewhat active pre- and post-diagnosis. The most commonly reported type of activity was aerobic training. Time was the greatest limitation to engaging in regular physical activity both pre- and post-diagnosis.

**CONCLUSIONS:** As indicated by the survey, the majority of BCa survivors in this sample were engaging in regular physical activity pre- and post-diagnosis. There was an increase in the self-reported importance of physical activity post-diagnosis among the BCa survivors, possibly indicating a greater importance of lifestyle factors. Time was reported as the most common activity barrier and future efforts may focus on cognitive and social behavioral training focusing on ways to overcome this and other similar barriers.

---

**1595 Board #3 MAY 30 2:00 PM - 3:30 PM****Relationships Between Physical Activity, Social Participation, And Health-related Quality Of Life In Colorectal Cancer Survivors**

Keith M. Thraen-Borowski, Amy Trentham-Dietz, Dorothy Farrar Edwards, Kelli F. Koltyn, Lisa H. Colbert, FACSM. University of Wisconsin-Madison, Madison, WI.

*(No relationships reported)*

**PURPOSE:** To examine the relationships between physical activity (PA), social participation (SP) and health-related quality of life (HQOL) in older, long-term colorectal cancer survivors (CRCS).

**METHODS:** Surveys were mailed to 1,768 male and female CRCS, aged  $\geq 65$  years and at least 5 years post cancer diagnosis, as identified by the WI state cancer registry. Surveys provided information on PA, SP, HQOL, health history and relevant covariates. Analysis of covariance was used to evaluate the cross-sectional relationship between PA and SP with each of the SF-36 subscales, as well as both summary scores (physical component summary score (PCS) and mental health component summary score (MCS)).

**RESULTS:** The final analytic sample consisted of 871 cases, the mean age was  $81.5 \pm 5.8$  yrs (mean $\pm$ SD) and mean time since diagnosis was  $8.2 \pm 1.7$  yrs. After adjustment for relevant covariates, PA, when classified as meeting or not meeting the current recommendation of 150 min/wk of moderate-vigorous activity, was associated with a 5-point higher PCS score ( $p < 0.001$ ), as well as higher physical function, role-physical, pain, general health, vitality, and social function subscale scores, but not MCS scores ( $p = 0.30$ ). SP, classified as "some" vs. "none," was not associated with higher PCS scores ( $p = 0.13$ ), but was associated with a 3-point higher MCS score ( $p = 0.003$ ), as well as higher physical function, role-physical, general health, social function, role-emotional, and mental health subscale scores. Subjects reporting greater amounts of moderate-vigorous intensity PA had significantly higher scores on PCS ( $p < 0.001$ ) than those reporting lower amounts. Participation in greater amounts of light intensity was not significantly associated with higher PCS or MCS scores after adjustment for moderate-vigorous PA ( $p = 0.21$ ;  $p = 0.43$ , respectively). Individuals participating in greater weekly hours of SP had higher PCS and MCS scores ( $p = 0.01$ ;  $p < 0.001$ , respectively) than those participating less.

**CONCLUSIONS:** Results suggest that both PA and SP are associated with greater HQOL in older, long-term colorectal cancer survivors. While PA is related to the physical health of these survivors, SP is related to both physical and mental health.

1596 Board #4 MAY 30 2:00 PM - 3:30 PM

**Cancer-Related Fatigue Interferes with Walking and Recreational Activities among 287 Older Cancer Patients Receiving Chemotherapy**

Lisa Sprod, Supriya G. Mohile, Luke J. Peppone, Michelle C. Janelins, Gary R. Morrow, Karen M. Mustian. *University of Rochester, Rochester, NY.*  
(No relationships reported)

Cancer-related fatigue (CRF) is hypothesized to impair quality of life by interfering with patients' abilities to perform activities of daily living (ADL).

**PURPOSE:** The purpose of this study is to describe the interference of CRF with ADL in older cancer patients.

**METHODS:** 287 patients (all >65 yrs; M=72 yrs; N=171 female) with mixed cancer diagnoses were assessed on CRF and its interference with ADL 7 days after their first 2 chemotherapy infusions as part of a large nationwide clinical trial conducted by the URCC CCOP Research Base. CRF and interference with ADL were assessed using questions from the Multidimensional Assessment of Fatigue instrument (10-point Likert Scale; 1=Not at all to 10=A great deal). Results are presented as means and standard errors (M+SE).

**RESULTS:** Nearly half (145 of 287) of patients reported CRF at cycle 1 (5.67+0.16) and cycle 2 (5.20+0.17). During cycle 1, 59% of patients reported that CRF interfered with socializing (5.39+0.18), participating in recreational or leisure activities (5.34+0.28), household chores (5.32+0.18), and running errands (5.16+0.20). CRF interfered with walking in 56% (.04+0.20), cooking in 51% (5.17+0.20), bathing in 46% (6.11+0.25), dressing in 45% (6.04+0.26), working in 33% (6.51+1.02) and engaging in sexual activity in 28% (5.35+0.32) of patients. During cycle 2, CRF interfered with household chores in 54% (4.94+0.18), running errands in 53% (5.07+0.20), socializing in 52% (5.11+0.20), walking in 49% (4.73+0.20), participating in recreational or leisure activities in 47% (5.05+0.22), cooking in 44% (4.91+0.21), dressing in 43% (5.91+0.28), bathing in 42% (5.76+0.27), working in 26% (4.94+0.27), and engaging in sexual activity in 27% (4.54+0.28) of patients. CRF was significantly correlated with interference for all ADL at cycles 1 and 2 (all  $p < 0.01$ ).

**CONCLUSION:** CRF interferes with older cancer patients' abilities to perform ADL, such as walking, dressing, bathing, performing household chores, working, running errands, participating in recreational activities and leisure activities, socializing, and engaging in sexual activity while receiving chemotherapy.

1597 Board #5 MAY 30 2:00 PM - 3:30 PM

**Physical Activity Patterns in Breast Cancer Patients and Survivors - Results from a German Patient Cohort Study**

Karen Steindorf, Christina Huy, Martina E. Schmidt, Alina Vrieling, Jenny Chang-Claude. *German Cancer Research Center (DKFZ), Heidelberg, Germany.*  
(No relationships reported)

Breast cancer is the most frequent type of cancer in women with rising numbers of patients and survivors. The benefits of physical activity (PA) for breast cancer patients are well known, including both physical and psychological effects. Thus, PA is increasingly discussed as concomitant therapy after breast cancer diagnosis and can add to the alleviation of therapy- and disease-related symptoms. However, little is known about PA behaviour in breast cancer patients during the course of the disease.

**PURPOSE:** To describe PA patterns including sports and active transportation in the course of breast cancer and to identify factors associated with these activities.

**METHODS:** The cohort study included 1,067 postmenopausal breast cancer patients from Southwest Germany. We collected quantitative information about walking and bicycling for transportation as well as sports before diagnosis, during therapy and one year after surgery and calculated MET-hours per week (MET=metabolic equivalent). Associations between these activities and clinical, behavioral and social characteristics were analyzed using logistic regression.

**RESULTS:** Median PA decreased significantly during therapy compared to PA before diagnosis from 36 to 14 MET<sup>2</sup>h/week and proportions decreased for walking (89.7% vs. 75.1%), bicycling (56.5% vs. 19.3%) and sports (64.6% vs. 14.8%, all  $p < 0.001$ ). The most frequent PA pattern during therapy was walking without any bicycling and sports (48.7%), followed by a pattern with none of the investigated activities (21.7%). Chemo-/radiotherapy was negatively associated with sports (OR: 0.35 [0.17-0.73]), but positively associated with walking during therapy (OR: 2.08 [1.04-4.15]). Participation in rehabilitation increased the likelihood for bicycling (OR: 1.48 [1.06-2.09]) and sports one year after surgery (OR: 1.88 [1.38-2.58]).

**CONCLUSION:** The results highlight the need for interventions to increase PA after breast cancer diagnosis, in particular for moderate to vigorous activities. Increasing participation in rehabilitation might help to increase the proportion of patients who bicycle and engage in sports.

---

1598 Board #6 MAY 30 2:00 PM - 3:30 PM

**Move On: Feasibility Of A Walking Intervention In Colon Cancer Survivors**

Kathleen Y. Wolin, FACS, Casey Fagin, Matthew Mutch. *Washington University School of Medicine St Louis, St Louis, MO.*  
(No relationships reported)

In observational studies of colon cancer survivors, physical activity has been associated with prolonged survival and lower rates of recurrence. Exercise interventions in cancer survivors are often supervised and require regular travel by participants. There is little data on the feasibility of interventions with stepped contact.

**PURPOSE:** To evaluate the feasibility of recruiting colon cancer survivors and effectively delivering an intervention to increase walking delivered through an existing evidence based physical activity intervention paradigm.

**METHODS:** Colon cancer survivors >age 18 with resected new primary stage II or III colon cancer who were at least one month post-adjuvant therapy were recruited to a 12 week phased walking intervention. Participants met with a coach weekly for 4 weeks and walked on their own outside of meetings. In the second phase, lasting 8 weeks, survivors received brief weekly phone calls. Intervention messaging and content was based on an existing evidence-based walking intervention for diabetics. Participants self-reported physical activity and wore accelerometers at baseline and follow-up. The Freedson equation was used to calculate estimated energy expenditure.

**RESULTS:** Surgeons referred 95 potentially eligible patients to the study. 23 were found ineligible, 62 declined and 11 enrolled. Between completion of the baseline assessment and their first intervention visit, three participants dropped-out of the study. Two of whom developed health problems that precluded their participation. Mean estimated energy expenditure at baseline was 1040 and at follow-up was 1552 kcal. 7 participants recorded valid step count data on their accelerometer. Mean step counts increased from 4365 at baseline to 6114 at follow-up. There were no statistically significant changes.

**CONCLUSIONS:** A stepped contact walking intervention can feasibly recruit colon cancer survivors after active treatment and engage them in significant behavior change.

1599 Board #7 MAY 30 2:00 PM - 3:30 PM

**Exercise Effects on Cancer-Related Symptoms in Breast Cancer Survivors**

Lynette L. Craft<sup>1</sup>, Erik H. Vanlterson<sup>1</sup>, Maura P. Waldron<sup>1</sup>, Mark D. Huffman<sup>1</sup>, Seema A. Khan<sup>1</sup>, Kerry S. Courneya<sup>2</sup>. <sup>1</sup>*Feinberg School of Medicine, Northwestern University, Chicago, IL.* <sup>2</sup>*University of Alberta, Edmonton, AB, Canada.*  
(No relationships reported)

**PURPOSE:** There are over two million breast cancer survivors in the United States. Cancer-related symptoms such as depression, fatigue, and pain can last for years, negatively affecting the survivor's quality of life. Exercise programs provide relief for some cancer-related symptoms. However, researchers have not examined the ability of exercise to "overlap" symptoms and provide simultaneous relief for the commonly occurring symptom cluster of depression, fatigue, and pain in breast cancer survivors.

**METHODS:** Women with early stage breast cancer, who were 6 months-5 years post treatment, non-exercising, and self-reporting moderate symptoms for at least two symptoms of the cluster were enrolled in a pilot randomized controlled trial (RCT). Women were randomized to a standard exercise intervention, an intermittent exercise intervention, or a usual care control group. The exercise interventions consisted of 4-weeks of supervised exercise, followed by 8-weeks of unsupervised, home-based exercise. Assessments were conducted at Baseline, 4, 8, and 12-weeks post entry and included questionnaires, measurements of height, weight, cardiovascular fitness, and cancer-related symptoms.

**RESULTS:** Currently, 25 women have enrolled and most are Caucasian (63%) with Stage II disease (54%). At baseline, women were 52±9 years old, were overweight (Body Mass Index:  $M = 31.5$ ,  $SD = 7.5$ ), and had low fitness ( $VO_{2peak}$ :  $M = 24.6$ ,  $SD = 4.5$ ). They also endorsed relatively high levels of depression (Center for Epidemiologic Studies Depression Scale:  $M = 23.4$ ,  $SD = 8.9$ ), fatigue (Functional Assessment of Cancer Therapy-Fatigue:  $M = 24.3$ ,  $SD = 6.8$ ), and pain (Brief Pain Inventory:  $M = 3.0$ ,  $SD = 2.2$ ). At the completion of the supervised exercise (4 week follow-up), effect sizes [ES] for depression were large in the exercise groups [Standard Exercise Intervention:  $ES = 1.7$ , Intermittent Exercise Intervention:  $ES = 1.4$ ] and medium for the control group [ $ES = 0.5$ ]. Similarly large ES were found among the exercise groups for fatigue, but not for pain.

**CONCLUSION:** Initial data from this pilot RCT suggest that exercise is effective in alleviating cancer-related depression and fatigue among breast cancer survivors experiencing a symptom cluster. However, results are less clear for the effect of exercise on cancer-related pain among these survivors.

**Age-Based Predictions Of HRpeak Overestimate Achieved HRpeak In Cancer Survivors**

G. Stephen Morris, FACSM, Webb A. Smith, Melissa M. Hudson, James G. Gurney, Leslie L. Robison, Kiri K. Ness. *St. Jude Children's Research Hospital, Memphis, TN.*

*(No relationships reported)*

**PURPOSE:** Current guidelines for cancer survivors define exercise training intensity relative to age predicted peak heart rate (HRpeak). Because chemotherapy and radiation are cardiotoxic, we hypothesized that HRpeak predicted by published, age-based equations would not accurately reflect achieved HRpeak in cancer survivors. To test this hypothesis, achieved HRpeaks were compared to HRpeaks estimated by the prediction equations of Inbar (1994); Tanaka (2001), Gellish (2007) and 220-age.

**METHODS:** Adult survivors of childhood cancer enrolled in the St. Jude Children's Research Hospital Lifetime Cohort Study (SJLIFE) completed a cardiopulmonary stress test (CPT). Heart rate (HR), oxygen consumption and respiratory exchange ratio (RER) were measured continuously during a modified Bruce treadmill protocol. Participants who achieved a RER  $\geq$  1.10 during CPT (n = 93) were considered to have achieved maximal exercise exertion. Their achieved HRpeak was compared to the HRpeak predicted by each equation using a Bland-Altman analysis with an acceptable agreement between actual and predicted HR peak defined as a mean bias of  $\pm$  2 SD.

**RESULTS:** Table 1 presents the mean differences between the HRpeak predicted by each equation and the achieved HRpeak ( $\sum$  (HRpeak - achieved HRpeak)/93) and the 95% confidence intervals. In all cases, predicted HRpeak exceeded achieved HRpeak. The Bland-Altman analysis indicates that the 95% limit of agreement between the observed HRpeak exceeded the acceptable level of bias ( $\pm$  2 SD) for all tested prediction equations.

**CONCLUSIONS:** Because the tested equations overestimated achievable HRpeak, their use would underestimate exercise intensity defined relative to estimates of HRpeak.

TABLE 1. Mean difference between predicted HRpeak and achieved HRpeak.

| Method                    | Mean HR difference (BPM) | 95% CI    |
|---------------------------|--------------------------|-----------|
| Tanaka (208-0.7*age)      | 29.4 + 6.2               | 17.0-41.8 |
| Inbar (205.8-0.685 * age) | 27.6 + 6.2               | 15.2-40.0 |
| Gellish (207-0.7*age)     | 28.4 + 6.1               | 16.2-40.6 |
| Age Prediction (220-age)  | 32.9 + 6.2               | 20.5-45.3 |

**Fundamental Measurements Of Body Composition And Heart Rate To Advise Women On Healthy Lifestyle Choices.**

David H. Jones<sup>1</sup>, Melisa Nestore<sup>2</sup>, Sara Henophy<sup>2</sup>, Helen Hu<sup>2</sup>, Jean Boucher, FACSM<sup>3</sup>, Alain S. Comtois<sup>3</sup>, John Keyserlingk<sup>4</sup>. <sup>1</sup>Concordia University, Montreal, QC, Canada. <sup>2</sup>Ville Marie Fitness Wellness Center, Montreal, QC, Canada. <sup>3</sup>Université du Québec à Montréal, Montreal, QC, Canada. <sup>4</sup>Ville Marie Breast and Oncology Center, Montreal, QC, Canada. (Sponsor: Jean Boucher, FACSM)

*(No relationships reported)*

The Ville Marie Breast Centre has established a prevention and early detection program for women at risk of developing breast cancer. A component of this program is to encourage the women to work towards and continue to maintain their ideal body composition. This includes reducing the total amount of body fat and in particular, the total amount of visceral fat which accumulates on the body. Previous work has shown that as a woman's BMI increases, her risk for developing breast cancer also increases. Women that have been diagnosed and had treatment for breast cancer also have a greater risk of recurrence, as their BMI increases. Previous work at the centre has shown that women who have undergone adjuvant therapy tend to have a significantly higher BMI than women who have not undergone treatment for breast cancer.

**PURPOSE:** The goal behind this study was to determine body composition and basic cardiovascular measurements of the women who utilize the wellness services at the Ville Marie women's health centre.

**METHODS:** As part of the standard medical evaluation, a team of kinesiologists performed base line measurements on 4096 patient at The Ville Marie Breast Center. Measurements were obtained on 3400 non oncology female patients and 696 oncology female patients. The data obtained included age, height, weight, BMI, resting heart rate and blood pressure. Additional data was also obtained on lean muscle mass, body fat and waist-to- hip ratio on just over 1000 of the women.

**RESULTS:** The mean age of the oncology patients was 60.1 years (SD  $\pm$  9.2). The mean age of all subjects was 56.3 years (28- 88 years). The mean blood diastole pressure 75 mmHg (SD  $\pm$  9.8) and mean systole pressure was 127 mmHg (SD  $\pm$  17.4). The mean resting heart rate was 73 beats/ min (SD  $\pm$  11.95). The mean height and weight was 161 cm (SD 7.7) and 67 kg (SD  $\pm$  13.5) respectively. The mean Body mass index, BMI was 25.95(SD  $\pm$  5.37).

**CONCLUSION:** The information obtained from these measurements is utilized by the medical team to help direct the women on healthy lifestyle choices which include diet and exercise, as part of the prevention program. The physicians and medical team are able to incorporate the morphological measurements and heart rate and blood pressure values into the patients chart to determine the patient's level of risk.

**Test-retest-reliability Of Metabolic And Cardiovascular Load During Isokinetic Strength Testing.**

Josefine Weber<sup>1</sup>, Juliane Müller<sup>1</sup>, Christoph Otto<sup>1</sup>, Friederike Scharhag-Rosenberger<sup>2</sup>, Anja Carlssohn<sup>1</sup>, Frank Mayer<sup>1</sup>. <sup>1</sup>Outpatient Clinic University of Potsdam, Potsdam, Germany. <sup>2</sup>University of Applied Science for Prevention and Health Management, Saarbrücken, Germany.

*(No relationships reported)*

Isokinetic strength tests are evident to quantify strength deficits in healthy subjects or patients in physio- or sports therapy. However, the metabolic and cardiovascular load as well as the reliability of these measures during isokinetic strength testing is unknown.

**PURPOSE:** The aim of this study was to analyze the reproducibility of metabolic and cardiovascular measures during isokinetic strength testing of the lower limb.

**METHODS:** 15 healthy subjects (7 f/8 m; 28  $\pm$  5 yrs; 1.75  $\pm$  0.08 m; 72  $\pm$  9 kg; maximum oxygen uptake VO<sub>2max</sub> = 49  $\pm$  10 ml/min/kg) were included. Metabolic (VO<sub>2</sub> [ml/min/kg]) and cardiovascular variables (heart-rate [beats/min]) were measured at the end of an isokinetic test for local muscular endurance (LME; 60sec., leg-extension concentric, 0.3 m/s alternate; Legpress). Reproducibility was evaluated in a test-retest study-design over a period of 14 days (M1, M2). Intraclass correlation coefficient (ICC), Bland and Altman analysis (Bias  $\pm$  LoA) and Test-Retest-Variability (TRV) were calculated. VO<sub>2</sub> and heart-rate was analyzed descriptively (mean  $\pm$  SD).

**RESULTS:** The mean value of pretest for VO<sub>2</sub> was 37.4  $\pm$  3.57 ml/min/kg and for retest 35.4  $\pm$  3.43 ml/min/kg. Heart-rate was 172  $\pm$  10 beats/min in M1 and 170  $\pm$  9 beats/min in M2. ICC was

calculated .86 ( $p < .001$ ) for  $\text{VO}_2$  and .72 ( $p < .008$ ) for heart-rate. Bias for  $\text{VO}_2$  was  $-1.2 \text{ ml/min/kg}$  ( $\pm 5.23 \text{ ml/min/kg}$ ) and for heart-rate  $-0.5 \text{ beats/min}$  ( $\pm 14.3 \text{ beats/min}$ ). TRV was  $6.0 \pm 4.55\%$  for  $\text{VO}_2$  and  $3.29 \pm 2.51\%$  for heart rate.

**CONCLUSIONS:** It can be concluded that a one-minute strength test of the lower extremity elicits reasonable metabolic and cardiovascular reactions in healthy subjects. Both  $\text{VO}_2$  and heart-rate can be measured reliably during isokinetic strength tests for local muscular endurance.

**1603** Board #11 MAY 30 3:30 PM - 5:00 PM

**Effects of a Single Resistance Training on Cardiovascular Health Indicators**

Huan-Chieh Chen, Shui-Yu Liu, Yi-Ting Su, Sandy S. Hsieh, FACSM. *National Taiwan Normal University, Taipei, Taiwan.*

(No relationships reported)

**PURPOSE:** To investigate the effects of a single resistance training on cardiovascular health indicators.

**METHODS:** Twenty four (24) males who have engaged in resistance exercise up to 6 months or more were recruited in this study. Subjects were divided into three groups with a circular-randomly order according to their maximum leg press strength: 1) high intensity with low repetition group (HL; 90%1RM $\times$ 4) (age:  $22.0 \pm 2.7$  yr, height:  $179.0 \pm 5.8$  cm, weight:  $73.6 \pm 8.3$  kg, BMI:  $22.9 \pm 1.9$ , maximum strength:  $282.0 \pm 97.2$  kg); 2) middle intensity with middle repetition group (MM; 75%1RM $\times$ 10) (age:  $23.3 \pm 2.5$  yr, height:  $175.4 \pm 6.4$  cm, weight:  $69.7 \pm 9.2$  kg, BMI:  $22.6 \pm 2.2$ , maximum strength:  $267.1 \pm 109.0$  kg); and 3) low intensity with high repetition group (LH; 60%1RM $\times$ 15) (age:  $22.6 \pm 2.5$  yr, height:  $174.0 \pm 2.6$  cm, weight:  $69.3 \pm 6.4$  kg, BMI:  $22.9 \pm 1.9$ , maximum strength:  $252.2 \pm 93.1$  kg). The single resistance training protocol included 2 sets (40%1RM) of warm up and 4 sets of the main exercise (leg press) with 2 minutes rest between sets. Blood samples were collected at rest, after warm up and immediately after each main exercise set (1<sup>st</sup>, 2<sup>nd</sup>, 3<sup>rd</sup>, and 4<sup>th</sup>). The values of C-reactive protein (CRP), triglycerides (TG), and high density lipoprotein (HDL) were analyzed with a mixed design two-way ANOVA.

**RESULTS:** There were no significant differences among groups for CRP and HDL. However, for TG, the 2<sup>nd</sup>, 3<sup>rd</sup> and 4<sup>th</sup> values of LH exercise were significantly higher ( $p < .05$ ) than that of HL exercise ( $137.5 \pm 68.7$  vs.  $77.0 \pm 18.4$ ,  $135.9 \pm 64.6$  vs.  $75.8 \pm 18.8$ ,  $134.1 \pm 59.5$  vs.  $76.8 \pm 21.5$  mg/dL). The consistent trend for within group comparison is that the HDL levels were significantly higher ( $p < .05$ ) for all 3 groups after the 4<sup>th</sup> set as compared to the baseline (HL:  $56.3 \pm 7.3$  vs.  $53.4 \pm 8.4$  mg/dL; MM:  $55.9 \pm 11.9$  vs.  $52.0 \pm 10.2$  mg/dL; LH:  $56.9 \pm 14.7$  vs.  $51.2 \pm 13.1$  mg/dL).

**CONCLUSION:** A single resistance training for those who have been accustomed with regular resistance exercise have acute benefits on cardiovascular health indicators. The rise in blood HDL values has a protective effect on cardiovascular system. Also, different intensities and repetitions of a single resistance training only affect TG in the LH group, but not the values of HDL and CRP.

**Influence of Temperature on Vascular Adaptation to Muscle Endurance Exercise**

Leland Nielsen<sup>1</sup>, K. K. McCully, FACSM<sup>2</sup>. <sup>1</sup>Lander University, Greenwood, SC. <sup>2</sup>University of Georgia, Athens, GA.

(No relationships reported)

**PURPOSE:** The aim of this study was to determine whether temperature is a factor that influences the magnitude of vascular adaptation to training.

**METHODS:** Using a pretest-posttest design, twenty-two healthy, able-bodied subjects performed endurance-type training of the forearm with one arm in a warm condition and one arm in a cool condition. Subjects trained 4 times per week for 5 weeks. Both arms were submerged in water for 5 minutes with one arm exposed to warm water ( $42\text{-}44^\circ\text{C}$ ) and the other exposed to cool water ( $18\text{-}20^\circ\text{C}$ ). Once the 5-minute bathing period was completed, the corresponding arm was wrapped with either a heating pad or a cold pack. Once wrapped, the 20-minute training session began consisting of full range wrist curls using free-weight dumbbells. The subject was instructed to perform 10 repetitions in one arm over the period of 15 seconds then repeat with the opposite arm. Following this pattern, the subject performed exercise with one arm at a time over the 20-minute session with each arm performing 20 repetitions per minute (400 repetitions per session). The resistance was set to equal 15% of their 1-RM for each arm and progressed as tolerated. The outcome variables measured in each arm included arterial range in the radial artery, peak blood flow, lean tissue mass of the forearm assessed via dual energy x-ray absorptometry (DXA), and forearm strength assessed by a test of one-repetition maximum (1RM).

**RESULTS:** 1-RM strength significantly increased in both the warm ( $13.3 \pm 11.9\%$ , mean  $\pm$  SD) and cool ( $14.8 \pm 12.2\%$ ) conditioned arms ( $p < 0.0001$ ), although no temperature effect was observed ( $p = 0.44$ ). Despite a significant increase in forearm lean tissue mass ( $598 \pm 218.1$  vs.  $609 \pm 219.4$  grams), no difference was seen between temperature conditions ( $p = 0.39$ ). Arterial range in the radial artery did not change from pre to post in either arm ( $p = 0.68$ ). Peak blood flow in the radial artery did not change in either arm with training ( $p = 0.09$ ).

**CONCLUSION:** Increasing muscle temperature did not enhance arterial range or muscular adaptations following endurance training in able-bodied subjects. While people with SCI often have cool limb temperatures, our study suggests that temperature is not an important factor in determining muscle adaptations with training.

**1605** Board #13 MAY 30 3:30 PM - 5:00 PM

**Handgrip Exercise Training Following Transradial Catheterization Ameliorates Arterial Dysfunction**

Nigel T. Cable<sup>1</sup>, Ellen Dawson<sup>1</sup>, Amr Alkarmi<sup>2</sup>, D. Jay Wright<sup>2</sup>, Daniel J. Green<sup>1</sup>. <sup>1</sup>Liverpool John Moores University, Liverpool, United Kingdom. <sup>2</sup>Liverpool Heart and Chest Hospital, Liverpool, United Kingdom. (Sponsor: Keith George, FACSM)

(No relationships reported)

**PURPOSE:** The aim of the present study was to assess radial artery vasodilator function prior to transradial catheterization and again following randomisation to 6 weeks of rehabilitative localized handgrip training or a similar inactive control period.

**METHODS:** Twenty-five subjects undergoing transradial catheterization were recruited and assessed before (Pre) and 6 weeks following (Post) catheterization. Subjects were randomized to either 6 weeks of handgrip exercise training (Exercise,  $n=14$ ) or a similar non-exercise group (Control,  $n=11$ ). Radial artery flow-mediated dilatation (FMD; endothelium- and NO-dependent) and dilation in response to a sublingual dose of glyceryl trinitrate (GTN; endothelium-independent and NO-mediated) were assessed using high-resolution ultrasonography. In a subgroup of subjects ( $n=12$ , 8 Exercise, 4 Control), radial artery blood flow responses to graded upstream brachial artery infusion of acetylcholine (ACh; an endothelial-dependent nitric oxide-dependent vasodilator) and sodium nitroprusside (SNP; an endothelial-independent, nitric oxide-dependent vasodilator) were assessed. Procedures were undertaken 4 weeks prior to, and 6 weeks following catheterization and blood flow assessed as above.

**RESULTS:** FMD was significantly impaired following catheterisation in the Control group ( $7.9 \pm 1.4$  to  $4.5 \pm 0.6\%$ ), but was maintained in the Exercise group ( $6.0 \pm 0.9$  to  $6.6 \pm 0.9\%$ ; pre versus post) ( $P < 0.05$ ). There were no significant differences between the groups or across time for either the ACh or the SNP protocols ( $P > 0.05$ ). Post-hoc t-tests in the Exercise group showed a significant increase from baseline blood flows with all SNP infusions ( $P < 0.05$ ).

**CONCLUSIONS:** Six weeks of localized handgrip exercise training preserved radial artery endothelium-dependent vasodilator function following transradial catheterization. We suggest that exercise training should be considered to enhance radial artery function, prevent possible clinical consequences of catheterization and preserve the viability of the artery for subsequent catheterization or use as a bypass graft.

**1606** Board #14 MAY 30 3:30 PM - 5:00 PM

**QT Interval Shortening in Long Term Androgenic Anabolic Steroid Users**

Nicholas Sculthorpe<sup>1</sup>, Fergal Grace<sup>2</sup>, Lee Taylor<sup>1</sup>, Bruce Davies, FACSM<sup>3</sup>. <sup>1</sup>University of Bedfordshire, Bedford, United Kingdom. <sup>2</sup>University of Western Scotland, Hamilton, United Kingdom. <sup>3</sup>University of Glamorgan, Pontypridd, United Kingdom.

(No relationships reported)

Androgenic anabolic steroid (AAS) abuse is associated with a growing number of cardiac consequences and has been implicated in cardiac electrophysiological changes. However conflicting reports have been published regarding the effect of AAS on rate corrected QT interval (QTc) at rest.

**PURPOSE:** this study aimed to further investigate the effect of AAS on QTc in a cohort of long-term AAS users in whom the effects may be more pronounced.

**METHODS:** A cross sectional independent groups design was used with AAS using resistance athletes ((AS) n=15) compared with a group of non-AAS using, resistance trained, age matched controls ((C) n=15). AS had a significant history of AAS use (18±2 yrs) and both AS and C had >19 year history of resistance training. Participants underwent a resting 12 lead ECG, from which QT interval was calculated and corrected to QTc using the Bazett formula. The main outcome measure was determined as evidence for differences in mean corrected QTc between groups. As previous research had reported both increases and decreases in response to AAS use, a 2-tailed analyses was performed. A secondary outcome was to calculate QTc interval that best differentiated between C and AAS users.

**RESULTS:** QTc was shorter in AS than in C (382.0 ± 21.01 ms versus 409 ± 18.77 ms for AS and C respectively p<0.001). Chi squared analyses revealed a greater incidence of QTc< 380ms in AS versus C p<0.01, specificity 93% sensitivity 60%.

**CONCLUSION:** The results support previous findings that AAS use causes a reduction in QTc which may be due to the effect of AAS on cardiac ion channels. Additionally the specificity and sensitivity of QTc in differentiating between AS and C in our sample is lower than that reported previously. This may be due to a number of factors e.g. increasing age countering the QTc shortening effects of long term AAS abuse.

**1607** Board #15 MAY 30 3:30 PM - 5:00 PM

**The Post Exercise Blood Pressure Response of Two Popular Kettlebell Routines**

John D. Martin, Daryl L. Parker, Roberto Quintana. *I.E Faria Exercise Physiology Research Laboratory, CSU-Sacramento, Sacramento, CA.*

(No relationships reported)

Hypertension (HTN) is a primary risk factor for cardiovascular disease (CVD). Exercise provides a highly beneficial post exercise hypotensive response (PEH) for healthy and hypertensive adults. Currently, ACSM recommends exercise that uses "large muscle groups, can be maintained continuously, and is rhythmical and aerobic in nature" to obtain the benefits of PEH (Pescatello, 2004). Kettlebell exercise meets these recommendations. A kettlebell is a cannonball shaped weight with a handle that is lifted using ballistic, Olympic lifting style, full-body movements.

**PURPOSE:** To determine if kettlebell exercise produces a PEH response that is statistically and clinically significant in a pre-hypertensive and hypertensive resistance trained male population.

**METHODS:** Eight resistance trained pre-hypertensive and hypertensive males (SBP = 133 ± 7 mmHg; DBP = 82 ± 6 mmHg; 29 ± 6 yrs) performed a randomized cross-over designed study which included 3 sets of a 6 exercise circuit (CIR), 12 minutes of continuous two-handed swings (THS), and a resting control (CON). Resting blood pressure (BP) and heart rate (HR) measurements were recorded before each trial. Participants recovered for 20 minutes after exercise before post-exercise BP and HR were recorded. Measurements occurred every 30 minutes for 120 minutes. Statistical significance was determined by two-way ANOVA with repeated measures and Tukey post-hoc analysis. Post-exercise BP responses were classified as clinical significance based on SBP <130 mmHg or DBP < 80 mm Hg.

**RESULTS:** Both CIR and THS averaged statistically significant decreases in SBP post-exercise compared to pre-exercise values (-7.2 ± 1.2 and -7.1 ± 1.5 mmHg respectively, p<0.05). All post-exercise SBP measurements were clinically significant for CIR and for THS at minute 0, 60, 90, & 120. A clinically significant decrease in DBP post-exercise compared to rest occurred at minute 30 and 60 for CIR. Heart rate was significantly elevated above CON during minute 0 for CIR and THS (23 ± 4.7 and 21 ± 4.7 bpm respectively, p<0.001).

**CONCLUSIONS:** The results indicate that kettlebell exercise is effective at producing an acute decrease in post-exercise BP in pre-hypertensive or hypertensive resistance trained males. The magnitude of the decrease in post-exercise blood pressure is clinically significant.

---

**1608** Board #16 MAY 30 3:30 PM - 5:00 PM

**Cardiorespiratory Responses and Excess Postexercise Oxygen Consumption from Kettlebell Exercise**

Christy L. Hutchison, Brandon G. Grubbs, Allen Jeter, Marcus Lawrence, Robert R. Kraemer, Robert R. Kraemer, FACSM. *Southeastern Louisiana University, Hammond, LA.* (Sponsor: Robert R. Kraemer, FACSM)

(No relationships reported)

Kettlebell exercises appear to produce considerable cardiovascular stress, however, only one peer-review article exists examining effects of acute kettlebell exercise on cardiovascular and metabolic stress without standardized number of repetitions.

**PURPOSE:** To determine the cardiovascular responses and oxygen costs during kettlebell circuit training as well as recovery (excess post-exercise oxygen consumption, EPOC) using a standardized protocol. It was hypothesized that kettlebells would elicit substantial increases in heart rate and blood pressure responses as well as a moderate oxygen cost during kettlebell circuit training and caloric expenditure during and following exercise.

**METHODS:** Five males (24.6±5.59 y) and 5 females (21.6±2.51 y) completed a preliminary session to determine VO<sub>2</sub> max, body composition, and kettlebell loading (based upon ability to complete presses) and to become familiarized with the kettlebell exercises. Subject completed a subsequent kettlebell session at least one week following the preliminary session, and consumed a liquid meal (Ensure™) two hours prior to the onset of exercise. The kettlebell session included 2 circuits of 4 exercises: two-arm swing, one-arm pull, around the world, and overhead press. All movements were timed such that each subject completed a standardized number of movements across the session with 1:1 exercise/rest intervals of 45s and 2 min rest between circuits for a total session time of 17 minutes and 30 seconds.

**RESULTS:** From rest to peak exercise, there was a significant increase in heart rate (69.6±3.43 to 148.3±21.99 b/min), systolic blood pressure (117.7±2.62 to 141.4±16.96 mmHg), mean arterial pressure (90.15±1.48 to 114.25±14.52 mmHg), and VO<sub>2</sub> (0.22±0.01 to 1.29±0.63 L/min). Rating of perceived exertion (RPE, 15 pt. scale) increased significantly during exercise to peak at 9.8±1.68. Total caloric expenditure during exercise was 93.65±35 kcal. EPOC was 3.74±2.16 L. Total caloric expenditure for exercise and recovery was 112.36±43.1 kcal.

**CONCLUSIONS:** Using the loadig protocol from the present study, data suggest that kettlebell exercise produces significant cardiovascular stress with a low to moderate metabolic cost.

---

**1609** Board #17 MAY 30 3:30 PM - 5:00 PM

**Impact of Cold Exposure With Concurrent Isometric Handgrip Exercise on Wave Reflection and Heart Rate Variability**

Marcos A. Sanchez-Gonzalez, Alexei Wong, Andrew P. Koutnik, Katherine J. Ramirez, Song Y. Park, Arturo Figueroa. *The Florida State University, Tallahassee, FL.* (Sponsor: Bo Fernhall, FACSM)

(No relationships reported)

The incidence of adverse cardiovascular events such as myocardial infarction and arrhythmias peaks during winter. Cold may exacerbate adverse cardiovascular events in susceptible individuals performing physical activity.

**PURPOSE:** To examine the effect of cold and concurrent isometric handgrip exercise (IHG) on aortic mean pressure (aMAP), wave reflection, and cardiac autonomic function. We hypothesized that cold with IHG would evoke a greater increase in aMAP, augmentation index (AIx), and decrease heart rate variability (HRV) than IHG in room temperature.

**METHODS:** Twenty healthy men (23 ± 3 y) were randomized to assume the supine position for 30 min in an environmental chamber at cold (4°C) or temperate (24°C, temp) trials. Radial waveforms and HRV were obtained by applanation tonometry and HR monitor respectively. After resting measurements (RES), subjects performed a 3 min IHG (30% MVC) followed by a 3 min recovery period (REC).

**RESULTS:** At RES, aMAP and AIx were higher (P<.01) in the cold vs. the temp trial while normalized low frequency (nLF) and high frequency (nHF) were not different between trials. During IHG, AIx, aMAP, and nLF were increased (P<.01), while nHF was decreased (P<.01) in both trials; but aAIx was higher in the cold vs. temp. During REC, aMAP and aAIx remained elevated (P<.05) in the cold vs. temp. The nLF was lower (~.08 ms) and nHF was higher (~.10 ms, vagal rebound) than RES in the temp trial compared to a full REC of nLF and nHF in the cold.

**CONCLUSIONS:** cold evokes an additional increase in aortic wave reflection during and after acute exercise. Cold may attenuate cardiac vagal reactivation after acute exercise. Research is warranted to evaluate the effects of cold and exercise in populations at cardiovascular risk.

| ab vs COLD<br>cd vs RES | COLD      |            |           | TEMP      |            |             |
|-------------------------|-----------|------------|-----------|-----------|------------|-------------|

**The Effect of Bikram Yoga on Vascular Function**

Stacy D. Hunter. *Pure Action, Inc., Austin, TX.*  
*(No relationships reported)*

Stacy D. Hunter, Mandeep Dhindsa, Emily Cunningham, Takashi Tarumi, Mohammed Alkatan, Nantinee Nualnim, and Hirofumi Tanaka, FACSM. The University of Texas at Austin. Austin, TX

Bikram yoga is a trademarked form of hatha yoga in which a series of 26 yoga postures are performed in a heated, humidified environment over a 90-minute period. The 90-minute session consists of pranayama (breathing), and standing, balancing, strengthening, and stretching asanas (postures) all performed in a sauna-like environment. Although this highly controlled style of Bikram yoga provides an optimal choice for interventional research studies, few studies have attempted to elucidate the health benefits associated with Bikram yoga.

**PURPOSE:** To determine the effects of Bikram yoga on key vascular functions and metabolic risk factors.

**METHODS:** 25 obese (42±12 yrs) and 27 lean (34±12 yrs) sedentary adults were studied before and after an 8-week Bikram yoga intervention. Subjects attended 3 90-minute Bikram yoga classes per week (24 sessions). During each class, a series of 26 postures were performed to scripted instruction in a room heated to 105° F with 60% relative humidity.

**RESULTS:** Body mass, body fat (via DEXA), systolic blood pressure, and total cholesterol were greater (p<0.05) in obese than in lean subjects. After the intervention period, there were no changes in body mass, body fat, or blood pressure, but trunk flexibility (via sit-and-reach test) increased in both groups (p<0.05). Serum concentrations of glucose, insulin, lipids, and lipoprotein did not change. Quality of life as assessed by SF-36 questionnaire improved after 8 weeks (p<0.05). No changes in measures of central arterial stiffness (aortic pulse wave velocity and carotid artery compliance) were observed after the yoga intervention. An index of endothelium-dependent vasodilation (brachial artery flow-mediated dilation) and glucose area under the curve (in oral glucose tolerance test) tended to decrease (p=0.08 and 0.07, respectively) in obese but not in lean adults.

**CONCLUSIONS:** Even though Bikram yoga was efficacious in improving quality of life and flexibility, it does not appear to improve arterial stiffness, endothelial function, or glucose tolerance in either lean or obese subjects.

**1611 Board #19 MAY 30 3:30 PM - 5:00 PM**  
**Cardiac Autonomic Control During Alternate Nostril Breathing at a Slow Breathing Rate**

Shreya Ghiya<sup>1</sup>, Matt Lee<sup>2</sup>. <sup>1</sup>SF State University, Plainview, NY. <sup>2</sup>SF State University, San Francisco, NY. (Sponsor: Marialice Kern, FACSM)  
*(No relationships reported)*

Alternate nostril breathing (ANB) has been shown to enhance autonomic control of the heart by increasing vagal modulation, but there is little information on autonomic control during ANB at slow breathing rates.

**PURPOSE:** To examine cardiac autonomic modulation during ANB at a slow rate and to compare the effects of ANB to that of paced breathing (PB) at the same respiratory rate.

**METHODS:** Twenty healthy individuals (22.3 ± 2.9 yr) with no prior experience with ANB engaged in 30 min of both ANB and PB at a breathing rate of 5 breaths/min which were preceded by 5 minutes of normal breathing (PRE). Mean arterial pressure (MAP) and an electrocardiogram (EKG) were collected during all conditions and the EKG was evaluated for mean RR interval and heart rate variability (HRV) indices. HRV was reported as spectral power in the total (TP), low- (LF), and high-frequency (HF) ranges and were natural log (ln) transformed. Analysis of covariance (ANCOVA) using sex as a covariate was used to examine differences in the variables between conditions.

**RESULTS:** ANCOVA revealed differences in all HRV indices between the conditions (Table 1). Post-hoc analysis found that lnTP, lnLF/lnHF, and normalized LF (LFNU) were greater during PB and ANB compared to PRE. Conversely, normalized HF (HFNU) was lower during PB and ANB compared to PRE. There were no differences in MAP or mean RR interval between conditions.

**CONCLUSION:** Both ANB and PB at 5 breaths/min resulted in decreased parasympathetic and/or increased sympathetic control of the heart.

Table 1. Data are mean ± SEM.

|              | PRE          | PB           | ANB           | P-value |
|--------------|--------------|--------------|---------------|---------|
| lnTP (ms2)   | 8.51 ± 0.12  | 9.32 ± 0.15* | 9.10 ± 0.13*  | 0.026   |
| lnLF (ms2)   | 7.51 ± 0.13  | 9.10 ± 0.16* | 8.78 ± 0.16*† | <0.001  |

**Influence of Alternate Nostril and Paced Breathing on Cardiac Autonomic Balance**

Dante Andres, Shreya Ghiya, Matthew Lee, FACSM, M. Dot Fullwood. *San Francisco State University, San Francisco, CA.* (Sponsor: Marialice Kern, FACSM)  
*(No relationships reported)*

Alternate nostril breathing (ANB) has been shown to alter autonomic control of the heart, but it is unclear if these changes are due to ANB itself or due solely to the change in breathing rate.

**PURPOSE:** To examine cardiac autonomic modulation during ANB and to compare the effects of ANB on autonomic balance to that of paced breathing (PB) at the same respiratory rate.

**METHODS:** Ten healthy individuals (23.4 ± 1.9 yr) with no prior experience with ANB engaged in 10 min of both ANB and PB at a breathing rate of 12 breaths/min which were preceded by 5 minutes of normal breathing (PRE). An electrocardiogram (EKG) was collected during all conditions and the EKG was evaluated for mean RR interval and heart rate variability (HRV)

indices. HRV was reported as spectral power in the low- (LF; 0.04-0.15 Hz), and high-frequency (HF; 0.15-0.40 Hz) ranges and were natural log (ln) transformed. Analysis of variance (ANOVA) was used to examine differences in the variables between conditions.

**RESULTS:** Data are presented in Table 1. ANOVA revealed that lnLF, lnLF/lnHF, and normalized LF (LFNU) were lower during ANB and PB compared to PRE. Additionally, normalized HF (HFNU) was greater during ANB and PB compared to PRE. Lastly, lnLF and mean RR interval were lowest during PB.

**CONCLUSION:** Both ANB and PB at 12 breaths/min resulted in increased vagal modulation of the heart compared to normal breathing. These data suggests that PB has a similar effect on cardiac autonomic balance as ANB when breathing rate is the same.

Table 1. Data are mean ± SEM.

|              | PRE        | ANB         | PB          | P-value |
|--------------|------------|-------------|-------------|---------|
| lnLF (ms2)   | 7.58±0.48  | 6.49±0.27*† | 6.04±0.26*  | 0.016   |
| lnHF (ms2)   | 6.70 ±0.46 | 7.10±0.33   | 6.77±0.37   | 0.400   |
| lnLF/lnHF    | 1.12±0.07  | 0.92±0.03*  | 0.91±0.05*  | 0.006   |
| LFNU (%)     | 63.0±7.3   | 36.7±5.4*   | 35.1±7.2*   | 0.004   |
| HFNU (%)     | 37.0±7.3   | 63.3±5.4*   | 65.0±7.2*   | 0.004   |
| Mean RR (ms) | 872.6±75.3 | 835.3±55.6† | 761.3±49.6* | 0.043   |

**Influence of Alternate Nostril Breathing on Heart Rate Variability in Non-Practitioners of Yogic Breathing**

Clarence M. Lee, Shreya Ghiya. *San Francisco State University, San Francisco, CA.* (Sponsor: Marialice Kern, FACSM)

(No relationships reported)

Although chronic alternate nostril breathing (ANB) has been shown to increase vagal modulation, there is no information on the immediate effects of ANB on autonomic control compared to paced breathing (PB) at the same rate.

**PURPOSE:** To examine cardiac autonomic modulation, as assessed by heart rate variability (HRV), following ANB in comparison to that following PB.

**METHODS:** Twenty individuals (age: 22.3 ± 2.9 yr) with no prior experience with ANB engaged in 30 min of both ANB and PB in a randomly assigned order. ANB and PB were preceded and followed by 5 min of normal breathing (PRE, Post-ANB, and Post-PB, respectively). An electrocardiogram was recorded during all conditions for HRV analysis, along with mean arterial pressure (MAP). HRV was reported as spectral power in the total (TP), low- (LF), and high-frequency (HF) ranges and were natural log (ln) transformed. Analysis of covariance (ANCOVA) using sex as a covariate was used to examine differences in variables between conditions and a significance level of 0.05 was used for all tests.

**RESULTS:** Data are presented in Table 1. The ANCOVA revealed lnTP, lnLF and lnHF were greater during both Post-ANB and Post-PB compared to PRE. The ANCOVA also revealed that there were differences in the mean RR interval between conditions (p < 0.05), although post-hoc tests were not significant. lnLF/lnHF and MAP did not significantly differ between conditions.

**CONCLUSION:** These data suggest that there was an increase in cardiac autonomic modulation following ANB and PB without a shift in autonomic balance. To our knowledge, this is the first study to investigate the autonomic effects of ANB in this population and to compare the effects of ANB and PB at the same breathing rate.

Table 1. Data are mean ± SEM.

|              | PRE         | Post-ANB     | Post-PB      |
|--------------|-------------|--------------|--------------|
| Mean RR (ms) | 821.1±22.2  | 843.3±28.3   | 852.9±38.4   |
| lnTP (ms2)   | 8.51 ± 0.14 | 9.51 ± 0.20* | 9.75 ± 0.22* |
| lnLF (ms2)   | 7.57 ± 0.18 | 8.46 ± 0.14* | 8.69 ± 0.22* |
| lnHF (ms2)   | 6.62 ± 0.21 | 7.96 ± 0.28* | 8.38 ± 0.30* |
| lnLF/lnHF    | 1.15 ± 0.03 | 1.07 ± 0.03  | 1.05 ± 0.03  |

**The Effect Of Mild Exercise On Circulatory Responses During Simulated Aircraft Cabin Hypoxia And Dehydration**

Steve P. Hunter<sup>1</sup>, Gary Kitchen<sup>1</sup>, David P. Summers<sup>2</sup>. <sup>1</sup>*London South Bank University, London, United Kingdom.* <sup>2</sup>*Kings College London, London, United Kingdom.*

(No relationships reported)

**INTRODUCTION:** The incidence of a deep vein thrombosis or pulmonary embolism is increased with flight time over 6 hours (Lapostolle et al 2001). Immobilization PiO2 and lower ambient humidity encountered in the aircraft cabin are associated with hypohydration, hypovolaemia, increased blood viscosity, and reduced venous blood flow in the legs. (Greenleaf et al 2004). Schiffer et al (2005) stated mild exercise performed for 3 mins every 15 mins did not protect against DVT.

**PURPOSE:** To evaluate the effect of intermittent mild dorsi-plantar flexion exercise on circulatory responses during protracted sitting in a simulated aircraft cabin environment

**METHODS:** Six healthy male subjects participated in this study (age:21.2±2.2y); Trials were allocated by systematic rotation. Prior to each trial subjects were hypohydrated until they lost 0.3-0.5kg of body mass. Each trial required the subjects to breath 15% inspired oxygen whilst sitting and for 40 minutes. Blood velocity was measured at the femoral artery for a 1- minute period every 5 minutes. In the exercise trial 1-minute of ankle plantar flexion was carried out every 10 minutes.

**RESULTS:** Normalised peak femoral artery blood velocity (BV) was significantly higher immediately post ankle plantar flexion in the exercise trial (1.09±0.06 vs 0.83±0.13 p=0.04). This tendency was maintained across the 4 exercise bouts but had disappeared 5 minutes post exercise. Evidence of a cumulative effect of exercise on blood velocity was not seen. Heart rate (HR, bpm) was significantly elevated following exercise compared to rest trial (84.3±8.2 vs 74.3± 7.4bpm. p=0.002) and this difference was maintained 5 minutes post exercise (75.6±9.5 vs 71.9±8.0 bpm. p=0.043). Systolic blood pressure showed no significant differences immediately following exercise (137.9±14.5 vs 117.6±13.5 p=0.07).

**CONCLUSION:** Intermittent plantar flexion exercise elevated HR, SBP and peak BV significantly immediately post exercise. Elevation in HR but not in BV 5-minutes post exercise was seen. BV measured at the femoral artery may not be sensitive enough to determine peripheral short-term BV responses. Future studies should include measures of microcirculation and tissue swelling to determine the potential protective circulatory benefits of this form of exercise, or use more intense/frequent exercise.

**Impact of Air Travel and Marathon Running on Markers of Thrombotic and Vascular Risk in Endurance Athletes**

Beth A. Parker<sup>1</sup>, Amanda L. Augeri<sup>1</sup>, Jeffrey A. Capizzi<sup>1</sup>, Kevin D. Ballard<sup>2</sup>, Brian R. Kupchak<sup>2</sup>, Peter Kriz<sup>3</sup>, Christopher Troyanos<sup>4</sup>, Pierre A. D'Hemecourt, FACSM<sup>4</sup>, Paul D. Thompson, FACSM<sup>1</sup>. <sup>1</sup>Hartford Hospital, Hartford, CT. <sup>2</sup>University of Connecticut, Storrs, CT. <sup>3</sup>Center for Sports Medicine, East Providence, RI. <sup>4</sup>Children's Hospital, Boston, MA.

(No relationships reported)

**PURPOSE:** D-dimer and p-selectin are markers of venous thrombotic risk and elevated p-selectin has been associated with increased cardiovascular events. We examined the effects of exercise and air travel on markers of vascular risk in marathon runners.

**METHODS:** Forty-one adults participating in the 114th Boston Marathon (April 19, 2010) were divided into travel (n=23) and non-travel "control" (n=18) groups based on whether they lived > 4 hr plane flight or < 2 hr car trip from Boston. Subjects provided venous blood samples the day before (PRE), immediately after (FINISH), and after returning home the day after the marathon (POST). Blood was analyzed for soluble D-dimer and p-selectin.

**RESULTS:** D-dimer increased more PRE to FINISH (142±83 to 387±196 ng/mL) in travel than in control subjects (85±26 to 233±95 ng/mL; p=0.02 for comparison). Moreover, 6 travel vs. 0 control subjects had d-dimer values >500 ng/mL, the clinical threshold for excluding venous thrombosis (p = 0.03 for Fisher's exact test). P-selectin increased with exercise (p < 0.01) regardless of travel (p = 0.09), but age was related to p-selectin (p = 0.01) such that older subjects exhibited higher p-selectin values PRE (r<sup>2</sup> = 0.14; p = 0.02), and FINISH (r<sup>2</sup> = 0.16, p=0.01).

**CONCLUSIONS:** These results demonstrate that the combination of exercise and travel increases venous and arterial thrombotic risk. Moreover, resting and post-exercise p-selectin levels are higher with age. These results may explain reports of venous thrombosis with air travel after athletic events as well as reports of cardiac events in older individuals running marathons.

1616 Board #24 MAY 30 3:30 PM - 5:00 PM

**One Week of Swimming Training Influences Resting Heart Rate Variability in Young Swimmers**

José Morgado, Francisco Alves, Cristina Paula Monteiro, Maria José Laires. *Faculty of Human Kinetics, Lisbon, Portugal.*

(No relationships reported)

Researches have been insufficient to generate a sustained relationship between Heart Rate Variability (HRV) changes, an indirect measure of autonomic control, and the training process.

**PURPOSE:** to investigate the effect of 1-wk of swim training on young swimmers HRV parameters at rest.

**METHODS:** 12 swimmers (7 female: 13±.3 yrs, 47±6.1 kg; 5 male: 14±.6 yrs, 48± 6.4 kg) swam an incremental maximal step test (2x200 m front crawl) and undertook HRV recordings at the 1st (M1) and 6th (M3) days of a training week and at the 3rd day (M2) for HRV also. A 5-min R-R interval (RR) data was collected, in supine position under controlled breathing, using Polar RS800™ and processed by HRV Analysis software. Time and frequency domain analysis gave: heart rate, std. deviation (dv.) of normal RR intervals (SDRR), square root of the mean of the sum of the squares of differences between adjacent NN interval (RMSSD), number of interval differences of successive NN intervals greater than 50 ms (NN50), percent of NN50 (pNN50), std. dv. of the instantaneous beat-to-beat variability of data (SD1), and std. dv. of the continuous long-term variability (SD2). Very low (VLF; .003 - .04 Hz), low (LF; .04 - .15 Hz), and high (HF; .15 - .4 Hz) frequency bands, were analyzed in absolute (ms<sup>2</sup>), percentage (%) and normalized units (nu) power. LF/HF ratio was calculated. T test and Wilcoxon tests were used (p<.05).

**RESULTS:** In females, RR rose from M1 to M3 (.8±.1 / .9±.1) and from M2 (.8±.1) to M3. pNN50 augmented from M2 to M3 (22±16 / 38±17). HF% increased from M1 to M2 (33±13 / 25±12) and HFnu from M1 to M3 (42±15 / 59±11). LFnu (59±15 / 41±11) and LF/HF ratio (1.7±.1 / .7±.3) declined from M1 to M3. The lower time performed on the 2nd 200 m rep from M1 to M3 (171±18 / 167±16 s) came with elevated swimming speed (1.18±.1 / 1.2±.1 m.s<sup>-1</sup>) and percent of 200 m race swimming speed (94±2 / 96±3 %). In males, pNN50 declined from M2 to M3 (33±13 / 30±11).

**CONCLUSION:** Training seems to be the main determinant of increases on HRV time domain indexes. Frequency domain variations, suggesting an increased parasympathetic and suppressed sympathetic modulations, occurred only in females. The predominance of vagal influence may be associated with the higher performance observed after 1-wk of swim training. Further studies are needed to determine how can these disturbances be useful in training methodology.

---

1617 Board #25 MAY 30 3:30 PM - 5:00 PM

**The Link Between Physical Activity, Heart Rate Variability and Bone Mineral Content in Women**

Christa Janse van Rensburg, Paola S. Wood, Catharina C. Grant. *University of Pretoria, Pretoria, South Africa.*

(No relationships reported)

Studies have demonstrated that cardiovascular disease (CVD) and mortality are associated with reduced bone mineral content (BMC) and bone fractures. Heart rate variability (HRV) has been considered a strong predictor of increased cardiac mortality. However, little is known about the link between HRV and BMC in woman.

**METHODS:** HRV parameters were investigated in the supine and standing positions in 48 healthy females (20,6 years ± 1.25). Several anthropometric measurements were taken, including: height (158,98 cm ± 5,92), body mass (59,6 ± 8,5 kg), and BMI (23,68 kg/m<sup>2</sup> ± 3,1). HRV was analysed using the time domain, frequency domain and Poincaré plot analysis. Dual-energy x-ray absorptiometry (DEXA) was used to obtain the participants body bone mineral content (BMC). Statistical analysis included the determination of the Pearson correlation coefficient for the normal distributed data and Spearman correlation coefficient for non-normal distributed data sets. The strength of the correlations coefficients were defined as weak (0.1 to 0.2), moderate (0.3 to 0.4) and strong (>0.5). A p-value of <0.05 was considered statistically significant.

**RESULTS:** Associations were found between BMC and HRV. A statistically significant moderate positive correlation was found between standing heart rate (HR) and leg BMC (p=0.025) as well as standing HR and total BMC (p=0.033). Significant moderate negative correlations were found between: (a) Mean RR (standing) and BMC of the leg (p=0.019), trunk (p=0.028) and total BMC (p=0.018); (b) HFms<sup>2</sup> (standing) and leg BMC (p=0.021). A weak negative correlation was observed between HFms<sup>2</sup> (standing) and trunk BMC (p=0.045).

**CONCLUSION:** Several associations were found between BMC and the standing HRV measurements. Supine heart rate is regulated primarily by the parasympathetic branch of the ANS, while the response to standing is regulated by the withdrawal of the parasympathetic and increase of the sympathetic tone. These results support the fact that increased BMC and responsiveness to an orthostatic challenge may be found in the more active and fit individuals. However, further studies are necessary to define the relationship between CVD risk factors, bone mineral content and osteoporosis, more specifically and to understand the complex interaction between these risk factors.

1618 Board #26 MAY 30 3:30 PM - 5:00 PM

**Sex Differences in Blood Pressure Variability and Baroreflex Sensitivity Following 8 Weeks of Endurance Training**

Rebecca M. Kappus, Sushant M. Ranadive, Huimin Yan, Abbi D. Lane, Marc D. Cook, Ken Wilund, Jeffrey A. Woods, FACSM, Bo Fernhall, FACSM. *The University of Illinois Urbana-Champaign, Champaign, IL.*

(No relationships reported)

**INTRODUCTION:** Blood pressure variability (BPV) is associated with poor cardiovascular outcome. The low frequency component of the BPV measurement (LF-BPV) is used as an index of sympathetic modulation and baroreceptor sensitivity (BRS) is an indicator of parasympathetic control. Since both parasympathetic and sympathetic modulation is also affected by intense physical exertion, the response to physical exertion may provide further insight.

**PURPOSE:** To determine if there are sex specific responses in BPV and BRS before and after a maximal exercise bout and the effect of an 8 week endurance exercise intervention on these responses.

**METHODS:** Baseline and post training measurements were obtained in 58 previously sedentary subjects (30 females and 28 males). BPV measurements were assessed using finger plethysmography, during paced breathing in a supine position. The 8 week endurance training program consisted of 30-60 min of endurance exercise at 60-90% of HR<sub>max</sub> 3 times per week. Pre-

and post-intervention values were compared between sexes using a repeated measures (2x2) ANOVA. If data were not normally distributed, they were log transformed before statistical analyses.

**RESULTS:** Acute exercise increased LF-BPV significantly both pre and post training ( $p=0.025$  and  $0.039$ , respectively) in women ( $5.31\pm 0.71$  to  $8.23\pm 1.34$  pre training and from  $4.83\pm 0.75$  to  $7.73\pm 0.91$  post training) but not in men. Men had significantly higher baseline values of LF-BPV compared to women ( $p=0.013$  and  $0.020$ , pre and post training, respectively) but LF-BPV did not significantly change with an acute bout of exercise either pre ( $10.16\pm 1.90$  to  $8.02\pm 1.40$ ) or post ( $8.96\pm 1.64$  to  $9.11\pm 1.36$ ) training in men. Exercise training also did not significantly change resting or post exercise levels of LF-BPV. However, exercise training increased ( $p=.038$ ) the reduction in BRS in response to the acute exercise bout in men ( $-9.40\pm 3.30$  to  $-12.86\pm 1.69$ ) but not in women.

**CONCLUSION:** Acute maximal exercise increases sympathetic modulation in females to values closer to those of males, but this effect is not changed with training. With training, men, but not women, increased vagal withdrawal in response to acute exercise. The impact of these sex differences in autonomic control on cardiovascular risk needs further investigation.

**1619 Board #27 MAY 30 3:30 PM - 5:00 PM**

**Effects Of Sprint Interval And Traditional Endurance Training On Heart Rate Recovery In Obese Children**

Ana Carolina C. Araujo, Ana Lúcia S. Pinto, Hamilton Roschel, Danilo L. Prado, Maria Beatriz Perondi, Sandra M. Villares, Bruno Gualano. *University of São Paulo, São Paulo, Brazil.*

(No relationships reported)

Heart-rate recovery after maximal graded exercise test (HRR) has been identified as a strong predictor of cardiovascular mortality in adults. Previous studies have found a positive association between adiposity and reduced HRR, which suggests cardiovascular autonomic dysfunction. However, the differential effects of sprint interval training (ST) and endurance training (ET) on HRR have been overlooked in obese children.

**PURPOSE:** The main aim of this study was to compare the effects of ST and ET on HRR in obese children.

**METHODS:** Thirty obese children aged  $10 \pm 0.8$  years were randomly assigned into either ST or ET group. The training program was comprised of two exercise sessions per week for 12 weeks. The ST group performed 3-6 sets of 1-minute running exercise at the VO<sub>2</sub> peak velocity (vVO<sub>2</sub>) interspersed by 3-minute rest intervals. The ET group performed 30 to 60-minute running sessions at 80% of the VO<sub>2</sub> peak. At baseline and after the intervention, a maximal graded exercise test was performed to determine VO<sub>2</sub> peak. Furthermore, HRR at the first minute ( $\Delta$ HRR1) and second minute ( $\Delta$ HRR2) were assessed following the exercise test.

**RESULTS:** Both groups equally and significantly improved HHR (Table 1). Additionally, VO<sub>2</sub> peak and time-to-exhaustion were improved in both ST (delta changes:  $4.8 \pm 1.7\%$ ,  $1.8 \pm 0.5\%$ , respectively;  $p<0.05$ ) and ET groups (delta changes:  $4.6 \pm 0.9\%$ ,  $1.8 \pm 0.2\%$ , respectively;  $p<0.05$ ).

**CONCLUSIONS:** ET and ST equally improved HHR after exercise in obese children, suggesting that the both types of exercise training are able to improve autonomic function in obese children. Furthermore, classical cardiovascular adaptations to exercise training were improved at a similar extent following ST and ET training programs.

Table 1. Effect of a 12-week sprint (ST) vs endurance training (ET) program on HRR in obese children

|               | ST              |                   | ET              |                   |
|---------------|-----------------|-------------------|-----------------|-------------------|
|               | Pre             | Post              | Pre             | Post              |
| $\Delta$ HRR1 | $33.1 \pm 12.6$ | $45.8 \pm 14.1^*$ | $30.7 \pm 10.3$ | $44.4 \pm 7.3^*$  |
| $\Delta$ HRR2 | $45.1 \pm 13.4$ | $59.3 \pm 8.3^*$  | $46.8 \pm 9.5$  | $59.6 \pm 12.7^*$ |

**Acute Exercise Training Enhances Resting Microvascular Nutritive Exchange; Nitric Oxide and  $\alpha$ -Adrenergic Mediated Mechanisms**

Justin D. La Favor, Raymond M. Kraus, Timothy P. Gavin, FACSM, Robert C. Hickner, FACSM. *East Carolina University, Greenville, NC.*

(No relationships reported)

Acute exercise training has been shown to improve vascular function and nitric oxide (NO) bioavailability.

**PURPOSE:** To determine if muscular nutritive exchange is enhanced by seven days of exercise training, and if changes are mediated by a NO mechanism.

**METHODS:** 16 men and 16 women performed seven consecutive days of exercise on a cycle ergometer for one hour at 70% VO<sub>2</sub>peak. One day prior to and one day following training, a muscle biopsy was taken and six microdialysis probes were inserted into the vastus lateralis and perfused with a control solution (0.9% saline containing 5 mM ethanol) at 2  $\mu$ l/min and the outflowing dialysate was collected under resting, non-stimulated conditions. Perfusion media was changed on five probes to contain the control solution and one of the following: 1) 10 mg/ml L-NMMA (NOS inhibitor), 2) 30 mg/ml sodium nitroprusside (SNP), 3) 30 mg/ml acetylcholine (ACh), 4) 1  $\mu$ M phentolamine (Phen), an  $\alpha$ -adrenoceptor blocker, 5) 1  $\mu$ M norepinephrine (NE), an  $\alpha$ -adrenoceptor agonist. Nutritive exchange was assessed via the ethanol outflow/inflow ratio and converted to units of blood flow. NOS activity was determined from muscle homogenate using a commercial assay kit.

**RESULTS:** Nutritive blood flow increased in response to training [ $10.1 \pm 7.2$  ml/(100g \* min) pre vs.  $13.9 \pm 12.8$  ml/(100g \* min) post,  $p = 0.03$ ]. Treatment nutritive blood flows (ml/100g \* min) pre- and post-training, respectively, were: ACh ( $15.9 \pm 22.6$  pre,  $p = 0.07$  vs control)( $22.0 \pm 25.3$  post,  $p = 0.03$  vs control), SNP ( $30.2 \pm 19.0$ ,  $p < 0.01$ )( $45.9 \pm 39.9$ ,  $p < 0.01$ ), NE ( $7.9 \pm 8.1$ ,  $p = 0.07$ )( $9.4 \pm 12.0$ ,  $p = 0.11$ ), Phen ( $16.7 \pm 13.3$ ,  $p = 0.02$ )( $14.9 \pm 13.5$ ,  $p = 0.68$ ), L-NMMA ( $11.5 \pm 10.3$ ,  $p = 0.99$ )( $11.4 \pm 10.7$ ,  $p = 0.22$ ). Statistics compared treatments to respective controls. NOS activity ( $3786 \pm 1040$  vs.  $4478 \pm 2091$  dpm/ $\mu$ g protein,  $p = 0.100$ ) did not increase with training.

**CONCLUSIONS:** Exercise training increased resting nutritive exchange. Training did not increase total NOS activity or the response to ACh, SNP, or L-NMMA. Thus, it is unlikely that the increased nutritive exchange is due to increased NO production or action. However,  $\alpha$ -receptor blockade blunted vasoconstriction pre-training but not post-training indicating a decrease in  $\alpha$ -adrenergic vasoconstrictor activity. Therefore, enhanced nutritive exchange may be due to a reduced sympathetic tone.

**1621 Board #29 MAY 30 3:30 PM - 5:00 PM**

**The Red Blood Cell NOS System after Blood Donation and Re-infusion in Moderately Trained Subjects**

Lena Willkomm<sup>1</sup>, Eric Polzer<sup>1</sup>, Thierry Konou<sup>1</sup>, Galina Balakirski<sup>1</sup>, Wilhelm Bloch<sup>1</sup>, Julia Franke<sup>2</sup>, Eike Marek<sup>2</sup>, Ina Hawener<sup>2</sup>, Dennis Mank<sup>2</sup>, Timo Hinrichs<sup>2</sup>, Klara Brixius<sup>1</sup>, Petra Platen<sup>2</sup>. <sup>1</sup>German Sport University, Cologne, Germany. <sup>2</sup>Ruhr University, Bochum, Germany.

(No relationships reported)

Transfusing Red Blood Cells (RBC) is the oldest form of blood doping and recent media reports suggest it is still widely used among different groups of athletes. Our research group has demonstrated that the procedure of blood-sampling, storage, and re-infusion in patients with hip-surgery induce an increase in nitric oxide synthase (NOS) activity in the RBC concentrate as well as in the patients' blood after re-infusion. These findings implicate that the RBC NOS system could potentially be used for the detection of autologous blood doping.

**PURPOSE:** The aim of the study was to demonstrate that blood donation and re-infusion causes a shift in NOS activity that can be used as an indicator of autologous blood doping.

**METHODS:** Moderately trained subjects received a medical examination including iron status and basal blood parameters. Subjects then donated 500 mL of blood according to standard blood donation procedure. After 2 weeks, the blood concentrate was re-infused. Blood samples were drawn off the subjects before, during and after the donation and re-infusion process. The withdrawn blood was analysed for routine blood parameters and NOS activation at pSer116 and pSer117. Furthermore, erythropoietin (Epo) levels were measured.

**RESULTS:** Routine blood parameters showed the expected changes over the time course of the study. pSer116 and pSer117 increased slightly after blood donation from basal values of  $10.8 \pm 4.0$  to  $12.0 \pm 4.0$  and from  $15.6 \pm 2.4$  to  $17.0 \pm 2.2$ , respectively, but values did not change significantly with the blood re-infusion. Furthermore, Epo levels rose from  $5.1 \pm 2.7$  mIU/mL to  $14.4 \pm 3.9$  mIU/mL after the blood donation and fell back to initial values ( $6.6 \pm 2.6$  mIU/mL) after the blood-re-infusion.

**CONCLUSIONS:** Blood withdrawal but not blood re-infusion activates the RBC NOS system. Possibly, this induction was caused by the increase in Epo, but other mechanisms seem also to be responsible for this observation. However, RBC NOS is no valuable parameter for the detection of blood doping.

**1622** Board #30 MAY 30 3:30 PM - 5:00 PM

**Forearm Ischemia-reperfusion Injury Reduces FMD but Augments L-FMC Irrespective of Menstrual Cycle Phase**

Mark Rakobowchuk<sup>1</sup>, Emily R. Parsloe<sup>2</sup>, Sarah E. Gibbins<sup>1</sup>, Emma Harris<sup>1</sup>, Karen M. Birch<sup>1</sup>. <sup>1</sup>University of Leeds, Leeds, United Kingdom. <sup>2</sup>University of Cambridge, Cambridge, United Kingdom. (Sponsor: Keith P George, FACSM)  
(No relationships reported)

Twenty minutes of forearm ischemia followed by reperfusion is used as a model to induce endothelial injury. Exercise training does not protect from this effect however the impact of oestrogen availability has not been assessed, nor has the complete vascular response to this stimulus been quantified.

**PURPOSE:** To determine the impact of menstrual cycle phase on recovery from induced endothelial injury.

**METHODS:** 9 women (33 ± 10yr) attended the lab during the follicular, ovulation and mid-luteal phases of the menstrual cycle. After 30 minutes of supine rest, brachial artery vascular function was assessed using ultrasound and 5 minutes forearm ischemia. Subsequently, a 20-minute forearm ischemia-reperfusion period was completed. Following this period vascular function assessments were made 15, 30 and 45 minutes into recovery. FMD and low-flow mediated constriction (L-FMC) were determined at all time points.

**RESULTS:** FMD was reduced following ischemia-reperfusion but recovered at 30 and 45 minutes (PRE: 7.1 ± 1.0%, POST15: 4.5 ± 0.6%, POST30: 5.5 ± 0.7% POST45: 5.9 ± 0.4%, p < 0.01). L-FMC exhibited an inverse pattern when compared to FMD with more constriction apparent after vascular injury (PRE: -1.3 ± 0.4 %, POST15: -3.3 ± 0.6%, POST30: -2.5 ± 0.5% POST45: -1.5 ± 0.12%, p < 0.01). Endothelial sensitivity (sum of absolute values of FMD and L-FMC) was unaltered (PRE: 8.8 ± 0.9% POST15: 7.8 ± 0.5%, POST30: 8.1 ± 0.7% POST45: 7.4 ± 0.5%, p = 0.11). Data were unaffected by menstrual phase.

**CONCLUSIONS:** The forearm ischemia-reperfusion model elicits an alteration of vascular function that may be related as much to enhanced vasoconstriction as it is to impaired vasodilation. This suggests that throughout recovery from injury the haemodynamic and/or circulating vasoactive milieu alter vasodilatory and vasoconstrictive responses. Fluctuations in oestradiol however, have no effect upon these responses.

**1623** Board #31 MAY 30 3:30 PM - 5:00 PM

**The Interval Between Pre-conditioning and Regional Ischemia is Critical to Cardioprotection in Perfused Rat Hearts**

Cathryn E. Krier, Patricia Colloton, Cassandra R. Nelson, Robert H. Fitts, FACSM. Marquette University, Milwaukee, WI.  
(No relationships reported)

Ischemic heart disease leading to cardiac cell death (infarct) is one of the leading contributors to heart failure. Pre-conditioning (PC) the heart with a brief period of global ischemia prior to regional ischemia (RI) has been shown to be cardioprotective.

**PURPOSE:** To determine the optimal time interval between PC and RI that produces maximal cardioprotection and assess gender differences.

**METHODS:** Female (31) and male (35) rats were anesthetized with Nembutal (50mg/kg body wt.) and hearts excised, weighed, and cannulated on a Langendorff apparatus. A balloon inserted into the left ventricle measured ventricular pressures and heart rate (HR). Following 30 min of baseline recordings, hearts were subjected to one of three conditions: 1) 30 min of RI by occluding the left anterior descending coronary artery, regional only (RO); 2) 5 min of global ischemia followed by 5 min of reperfusion, then 30 min of RI (PC5); 3) 5 min of global ischemia followed by 10 min of reperfusion, then 30 min of RI (PC10). Post RI hearts were reperused for 3 hrs before RI was reestablished and the heart perfused with Trypan Blue dye. The left ventricle was cut into 1 mm pieces and the non-stained occluded area stained with triphenyl tetrazolium chloride. Infarct size was determined from the ratio of dye absorbing living cells to the pale dead cells using color detection software.

**RESULTS:** Pre-RI the systolic - diastolic (i.e. delta pressures) for males and females were 144 + 4 mmHg and 144 + 3 mmHg, respectively. PC10 significantly (p<0.01) decreased infarct size in males (PC10: 29 + 2% vs. RO: 46 + 4%) and females (PC10:35 + 6% vs. RO: 55% + 4), however % recovery of delta pressure after 3 hrs of reperfusion was not significantly different between groups in males (RO: 59 +5%, PC5: 48 + 3%, PC10: 49 + 2%, p=0.113) or females between PC10 and RO (40 + 3% vs. 45 + 4%, p=0.376). In contrast, PC5 significantly decreased the functionality of the heart in females (26 + 2% vs. RO: 45 + 4%).

**CONCLUSIONS:** The results indicate that the time between PC and the onset of RI is critical to cardioprotection with 10 min reperfusion providing greater protection than 5 min in both genders. While limiting cell death, PC did not prevent loss of function, and it can decrease function in females if reperfusion time is too short.

**Post Exercise Blood Pressure Response To Exercise With Blood Flow Restriction**

Alexander T. Sougiannis, Juliane P. Wallace, FACSM. Southern Illinois University Carbondale, Carbondale, IL.  
(No relationships reported)

The restriction of muscle blood flow with short term low-intensity exercise has been shown to enhance muscle size and strength. Post exercise hypotension is consistently elicited following 30-60min bouts of moderate intensity (50-60% peak aerobic capacity) exercise. Following an acute bout of exercise, systemic resistance does not completely recover, resulting in post exercise hypotension.

**PURPOSE:** To determine if exercise with blood flow restriction in healthy individuals is as effective as traditional exercise in eliciting post exercise hypotension.

**METHODS:** Ten healthy (age =23±2y; VO<sub>2</sub>max=38.4±10ml\*kg<sup>-1</sup>\*min<sup>-1</sup>; bodyfat =18±5%) college-aged individuals volunteered to participate in this within subject's design. Participants were randomly assigned to one of two exercise trials: one with blood flow restriction and one without. The normal exercise (NE) trial consisted of level walking at 60% of heart rate max for a total of 60 minutes. Exercise with blood flow restriction (EBR) consisted of level walking at 53.6m/min (2.0mph) for 20 minutes (two bouts of 10 min). In order to create blood flow restriction, large blood pressure cuffs were placed around the most proximal portion of both legs. Prior to exercise, the pressure in each cuff was increased in stages of 120mmHg, 140mmHg, and 160mmHg while decreasing to 80mmHg and 100mmHg intervals between the first and second and second and third stages respectively. In both exercise trials, heart rate (HR), systolic blood pressure (SBP) and diastolic blood pressure (DBP) were assessed every 5 minutes. Post exercise HR, SBP, and DBP were assessed every 5 minutes for a total of 60 minutes.

**RESULTS:** SBP was significantly lower post NE at minutes 30(111±4 vs. 115±5 mmHg), 35(109±3 vs. 114±5 mmHg), 40(110±2 vs. 115.4±5 mmHg), and 50(111±4 vs. 113±4 mmHg) compared to EBR. DBP was significantly lower in the first 5 minutes post exercise (76±7 vs. 83±4 mmHg) in the NE vs. the EBR trial. No differences in post exercise heart rate were noted.

**CONCLUSION:** Exercise with blood flow restriction utilizing a lower duration and intensity of exercise does not yield the same post exercise hypotension as traditional moderate intensity exercise.

**Participation in a 10K Running Race Significantly Decreases Post Exercise Blood Pressure**

Mark A. Schafer<sup>1</sup>, James W. Navalta<sup>1</sup>, Scott W. Arnett<sup>1</sup>, Scott Lyons<sup>1</sup>, Gina L. Sobrero<sup>1</sup>, Steven Bean<sup>1</sup>, Shannon Sims<sup>1</sup>, Demetrice Kirkwood<sup>1</sup>, Fredric L. Goss, FACSM<sup>2</sup>. <sup>1</sup>Western Kentucky University, Bowling Green, KY. <sup>2</sup>University of Pittsburgh, Pittsburgh, PA.  
(No relationships reported)

Previous investigations have indicated that following aerobic exercise of various durations and intensities, blood pressure may drop significantly for a period of time (i.e. 1 to 24 hours). These investigations have mainly employed laboratory-based protocols administered at a particular prescribed exercise intensity.

**PURPOSE:** The primary purpose of this investigation was to determine if healthy, trained, normotensive male and female runners (18 to 39 years old) would show evidence of post exercise hypotension (PEH) following a competitive 10K running race.

**METHODS:** Nineteen male (n = 13) and female (n = 6) runners from the Medical Center 10K Classic road race participated in the study. Subjects reported to the Exercise Physiology lab the morning of the race to have their resting blood pressure taken and receive study instructions. Immediately following the 10K race, participants returned to the lab where they remained seated and their blood pressure was taken in 30-minute intervals for 1.5 hours (30 min, 60, min, & 90 min). All post exercise systolic (SBP, mm Hg) and diastolic (DBP, mmHg) blood pressures were then compared to the baseline prerace resting values using a repeated measures ANOVA.

**RESULTS:** The SBP was significantly lower ( $p < 0.05$ ) at all time intervals (30, 60 & 90 min) following the 10K running race compared to the prerace measurements (Pre SBP =  $116 \pm 11.6$  mmHg, Post 30 min SBP =  $101.5 \pm 10.4$  mmHg, Post 60 min SBP =  $90.5 \pm 15$  mmHg, and Post 90 min =  $99.7 \pm 15.1$  mmHg). There was no significant difference in the prerace DBP and any of the post race time intervals (Pre DBP =  $71.7 + 11.0$  mmHg, Post 30 min DBP =  $66.3 + 9.4$  mmHg, Post 60 min DBP =  $66.3 + 9.0$  mmHg, Post 90 min DBP =  $69.7 + 11.3$  mmHg).

**CONCLUSIONS:** The findings of the present investigation indicated that healthy normotensive runners demonstrate PEH as indicated by the drop in SBP for up to 90 minutes following a 10K running race. The PEH noted presently may have health-fitness benefits in healthy, trained normotensive runners. Future studies should track the blood pressure responses following a 10K running race for a longer period of time (3 to 24 hrs) and attempt to determine the potential mechanism(s) that lead to PEH in normotensive competitive runners.

**Exercise Timing Affects the Direction (Positive/Negative) of Relationships Between Blood Pressure and Sleep Architecture**

Dwight Joseph The<sup>1</sup>, Ben W. Cartner<sup>2</sup>, Kimberly Fairbrother<sup>2</sup>, Chelsea D. Curry<sup>2</sup>, Scott R. Collier, FACSM<sup>2</sup>. <sup>1</sup>Montana Tech, Butte, MT. <sup>2</sup>Appalachian State University, Boone, NC.

(No relationships reported)

Previously, our laboratory has shown that exercise at 7pm produced a greater dip in nocturnal blood pressure (BP) and more time in REM sleep than exercise at 1pm, yet exercise at 7pm was similar in benefits to morning exercise. The **PURPOSE** of this study was to determine the differences between exercise at 7am vs. 7pm in an older prehypertensive cohort.

**METHODS:** Thirteen 40-60 year old pre-hypertensive subjects (height =  $67.84 \pm 2.71$  in; weight =  $163.88 \pm 27.46$  lbs;  $VO_{2peak} = 38.31 \pm 7.89$  ml/Kg/min) performed 30 minute bouts of moderate intensity aerobic exercise (65% of  $VO_{2peak}$ ) on three separate, counterbalanced laboratory visits at 7am, 1pm, & 7pm. Ambulatory BP was monitored every 20 minutes for 24 hours after exercise. Sleep architecture was assessed using a Zeo™ ambulatory sleep EEG monitor.

**RESULTS:** Statistically significant ( $^*p \leq 0.05$ ;  $^{**}p \leq 0.01$ ) values for two different non-parametric, bivariate correlations are tabled below. The correlations for exercise at 7pm are in the opposite direction (positive or negative) of those for exercise at 7am and 1pm.

**CONCLUSIONS:** These data confirm REM sleep is only correlated with BP variables (Mean SBP & Mean DBP) for the 7pm exercise bout. Exercising at 7pm seems to produce a beneficial relationship between blood pressure and sleep architecture that is not observed following exercise at 7am/1pm.

|   | Spearman's Rank ( $\rho$ ) | Kendall's Tau ( $\tau$ ) |

**The Effects Of Constant-load Exercise At Percentages Of The Ventilation Thresholds On The Magnitude Of Heart Rate Drift**

Raymond Martinez Jr, Rick T. Bradley, Max M. Polin, Roberto Quintana, Daryl L. Parker. *Irvin Faria Exercise Physiology Research Laboratory CSU Sacramento, Sacramento, CA.*

(No relationships reported)

Traditionally cardiovascular drift (CVdrift), the changes in cardiovascular responses over time, despite no change in exercise intensity, has been examined at intensities set relative to a percentage of  $VO_{2max}$ . Previously little consideration has been given to the HR response relative to ventilation threshold (TH1) and respiratory compensation point (TH2).

**PURPOSE:** The purpose of this study was to investigate the effects of exercising at percentages of TH1 and TH2, on the magnitude of heart rate drift (HRdrift), a component of CVdrift.

**METHODS:** Four male cyclists age  $29 \pm 6$ yr, weight  $82.9 \pm 28.3$ kg, height  $176.1 \pm 8.3$ cm,  $VO_{2max}$   $56.3 \pm 14.7$ ml·kg<sup>-1</sup>·min<sup>-1</sup> volunteered for this study. Visit 1 consisted of a graded exercise test (GXT) to determine TH1 and TH2, and two power detection rides used to determine the workloads that would be used for the constant-load exercise (CLE) rides to fatigue. Visit 2 consisted of a randomized CLE ride to fatigue at a power output that elicited a  $VO_2$  that was either 5% below TH1 (-5%TH) or a  $VO_2$  that was midpoint of TH1 and TH2 (midTH) in a thermal neutral environment. Visit 3 consisted of the remaining CLE ride to fatigue. Heart rate was recorded every minute; expired air, blood pressure, and RPE were recorded for the last 2 minutes of every 10 minutes. A paired t-test was used to analyze the % change in HR and  $VO_2$  from minute 5 to fatigue during both trials ( $p < 0.05$ ).

**RESULTS:** Subjects had a  $21.7 \pm 9.3$  and  $17.8 \pm 4.6$  increase in HR and  $VO_2$  respectively for the -5%TH ride ( $220 \pm 47$ W) and a  $15.2 \pm 6.2$  and  $12.0 \pm 2.3$  increase in HR and  $VO_2$  respectively during the midTH ride ( $244 \pm 51$ W). Time to fatigue was  $93 \pm 18$  minutes and  $56 \pm 11$  minutes for the -5%TH and midTH rides respectively. HRdrift was significantly greater in the -5% TH ( $p < 0.02$ ). The change in  $VO_2$  between trials was not statistically significant ( $p < 0.09$ ). Terminal HR for -5%TH ride and midTH ride ( $177 \pm 8$  bpm and  $182 \pm 13$  bpm) drifted near TH2 HR ( $177 \pm 17$  bpm) determined from the GXT.

**CONCLUSION:** There was a statistically significant difference ( $p < 0.02$ ) in the magnitude of HRdrift for both trials. The terminal HR drifting to TH2 for both trials in each subject suggests that TH2 HR may represent an upper limit during CLE for cardiovascular parameters. The ventilation thresholds should be considered when designing protocols in future CVdrift studies.

**1628** Board #36 MAY 30 3:30 PM - 5:00 PM

**Relationships between Blood Pressures at Resting State and Anaerobic Threshold Point**

Shigeru Obara<sup>1</sup>, Takuro Matsuda<sup>2</sup>, Hiroaki Tanaka<sup>2</sup>. <sup>1</sup>The University of Tokushima, Tokushima, Japan. <sup>2</sup>Fukuoka University, Fukuoka, Japan.

(No relationships reported)

**PURPOSE:** It is a well-known fact that mild intensity exercise is safe and effective exercise for persons with lifestyle-related diseases. The mild intensity indicates the anaerobic threshold (AT) point in exercise. The AT point has been determined as a lactate threshold (LT), a double product breaking point (DPBP) or a ventilation threshold (VT). Recently, the heart sounds breaking point (HSBP), which was determined from change in amplitude of the first heart sound (AHS1) during graded exercise, is used as an AT point. The purpose of this study is to examine the relationship between systolic pressures (SBP) at rest and at AT point determined by HSBP, and also between both diastolic pressures (DBP). These results may be useful for the exercise prescription.

**METHODS:** Thirty subjects aged 19 - 79 years with a BMI of  $21.8 \pm 2.3$  kg/m<sup>2</sup>, underwent a graded cycle ergometer test. The work rate started at 20 watts and then increased by 10 watts every 90sec until 15-point of RPE was reached. The heart sound was collected in a personal computer via an A/D converter throughout the exercise test. For determining the HSBP of each subject, AHS1 of each stage was plotted on a graph versus workload. The point of the abrupt increase in AHS1 was determined from visual inspection. Blood pressure was determined from

recordings of cuff pressure, vessel sounds, and height of mercury for the last 30 sec of each stage during exercise. SBP was determined at the point of the first appearance of vessel sounds, while DBP at disappearance of the sounds at rest, and at Swan's fourth point during exercise.

**RESULTS:** The relationship between resting and AT point SBPs was significant, and also the relationship between both DBPs was significant. At AT point, four subjects whose resting SBP was over 130mmHg showed over 200mmHg of SBP. The subjects whose resting DBPs were over 90mmHg showed a tendency towards elevation of DBP at AT point exercise, it was over 100mmHg in middle and high aged persons. The DBPs of young and a few middle aged subjects showed a tendency of a small decrease from resting value at AT point exercise.

**CONCLUSIONS:** The AT point exercise was thought as a safe and effective intensity for making healthier body condition. However, this result indicates that a person having high SBP and/or DBP had better choose around 80% of an AT point intensity during cycle exercise.

(No relationships reported)

**PURPOSE:** Aim of the present study was to evaluate the cardiovascular changes in a professional soccer team along one agonistic season, from the pre-championship training phase ( $T_0$ ), during the championship ( $T_1$ ) and in the detraining phase ( $T_2$ ).

**METHODS:** Obtained the informed consent, we included 24 healthy professional soccer players (age  $22 \pm 5$ ; weight  $70 \pm 7$  Kg). Anthropometric data, blood pressure and heart rate have been evaluated early morning, when all players have not eaten since 10 hours. Cardiac Echo-Doppler (GE Vivid 7) and the anterior descending artery flow (LAD) values were performed. All measurements have been repeated three times ( $T_0$ ,  $T_1$  and  $T_2$ ). In 2-tailed tests, a value of  $P < 0.05$  was considered statistically significant and calculated with a standard statistical package (SPSS for Windows version 12.0).

**RESULTS:** Obviously we observed a little but significant reduction of the blood pressure and heart rate in  $T_2$ . The echocardiographic measurements showed a statistically significant increase of the indexed left ventricular mass just in  $T_1$  (interventricular septum  $T_0 = 0.93 \pm 0.11$  cm;  $T_1 = 1.09 \pm 0.09$  cm;  $P < 0.0001$ ), without important differences in volumes ( $T_0 = 5.40 \pm 0.30$  cm;  $T_1 = 5.25 \pm 0.30$  cm;  $P < 0.053$ ). This increase was associate to a reduction of the ejection fraction ( $T_0 = 73.63 \pm 5.26\%$ ;  $T_1 = 69.74 \pm 6.05\%$ ;  $P < 0.002$ ) and an increase of the shortening fraction ( $T_0 = 34.8 \pm 4.04\%$ ;  $T_1 = 35.2 \pm 5.44\%$ ;  $P < 0.005$ ), without significant changes of the stroke volume. These findings may be due to a reduction of the longitudinal shortening velocity of the myocardial fibers ( $S'$   $T_0 = 0.12 \pm 0.02$  cm/sec;  $T_1 = 0.10 \pm 0.01$  cm/sec). In  $T_2$  we noted an increase of the shortening velocity of the myocardial fibers ( $0.13 \pm 0.02$  cm/sec;  $P = 0.002$ ) for an adequate functional adaptation. Moreover in the anaerobic training phase we observed a reduction of the LAD flow ( $T_0 = 0.19 \pm 0.05$  m/sec;  $T_1 = 0.17 \pm 0.03$  m/sec) with a successive significant increase in  $T_2$  ( $P < 0.0001$ ).

**CONCLUSION:** This first longitudinal study, regarding professional soccer players, demonstrates that the cardiac adaptation improves significantly only during the aerobic/anaerobic training phase. Our results may be contribute to modify the workout of the professional athletes.

**Morphologic And Functional Cardiac Modifications In Adolescent Soccer Players**

Girolamo Matteo Milicia<sup>1</sup>, Laura Stefani<sup>2</sup>, Valentina Di Tante<sup>2</sup>, Giorgio Galanti<sup>2</sup>. <sup>1</sup>*Sport Medicine, Florence, Italy.* <sup>2</sup>*Sports Medicine, Florence, Italy.*

(No relationships reported)

**PURPOSE:** Almost all the study on athlete's heart have been carried out on adult players, while few data are now available on the cardiac adaptations to regular sport activity in adolescents. The study aims to describe the morphological and functional modification in a group of professional adolescent soccer players matched with a group of non-professional one in order to evaluate any possible differences and also relationship with the anthropometric parameters

**METHODS:** 40 professional male soccer players (PSP) and 47 non professional NPSP, were evaluated since the age of 12 up to 17 years. Once a year every athlete underwent to a 2 D echocardiography with the evaluation of the main morphological and functional left ventricle parameters including the wall thickness and systo-diastolic chamber sizes.

**RESULTS:** A significant increase of the absolute values of all the echocardiographic parameters examined ( $p < 0.05$ ) in adolescent PSP compared to NPSP has been found, especially for LVM. LVM values did not show any relationship to BSA measurements in both groups.

**CONCLUSION:** the data are indicative for an early cardiac remodeling especially in highly trained athletes. However there are no evident correlations between LVM and BSA values. Intensive training does not seem to have any influence on BSA growth while a positive factor on LVM has been verified.

**1631** Board #39 MAY 30 3:30 PM - 5:00 PM

**Effect Of Acute Active Video Game On Pulse Wave Velocity In Young Health Adults**

Ki Won Lee, Eun Sun Yoon, Soo Hyun Park, Yong Hee Lee, Sun Joo Lee, Jae Yoon Lim, Jin Hee Park, Sae Young Jae. *University of Seoul, Seoul, Korea, Republic of.*

(No relationships reported)

Active video games are now highly popular and play a role in promoting physical activity. Although aerobic exercise improves arterial function, there is little information on the effects of active video game on arterial stiffness.

**PURPOSE:** The purpose of this study was to examine the acute effect of active video game on pulse wave velocity in young healthy subjects.

**METHODS:** Twenty-three healthy young subjects (age  $21 \pm 3$  years and body mass index  $22.6 \pm 1.9$  kg/m<sup>2</sup>) were randomly assigned to acute bout of active video game ( $n = 11$ , 50-minute, Nintendo Wii sports (boxing, tennis) and a walking exercise ( $n = 12$ , 30-minute, 60-70% of heart rate reserve) as a control exercise. Carotid-femoral pulse wave velocity as an index of aortic stiffness was measured using applanation tonometry (SphygmoCor, AtCor Medical, Australia). All variables were measured at baseline and 40 minutes after each exercise.

**RESULTS:** Walking exercise significantly decreased systolic blood pressure ( $116.2 \pm 10.7$  to  $106.8 \pm 9.6$  mmHg,  $p = 0.001$ ), but there was no significant changes following the active video game ( $111.1 \pm 12.4$  to  $110.1 \pm 10.6$ ,  $p = 0.612$ ). Carotid-femoral pulse wave velocity was decreased after walking exercise ( $6.28 \pm 0.61$  to  $6.03 \pm 0.57$  m/s) and increased after active video game ( $5.96 \pm 0.75$  to  $6.03 \pm 0.56$  m/s), but these changes were not statistically significant ( $p = 0.181$ ).

**CONCLUSIONS:** These findings suggest that an active video game does not decrease pulse wave velocity in young healthy adults. Further studies are needed to clarify the effects of long term active video game on arterial stiffness.

**Active Video Game Does Not Attenuate A High Fat Meal Induced Vascular Dysfunction In Young Healthy Adults**

Eun-Sun Yoon, Soo-Hyun Park, Yong Hee Lee, Sae Young Jae. *University of Seoul, Seoul, Korea, Republic of.*

(No relationships reported)

**PURPOSE:** A high fat meal transiently decreases vascular function, while acute aerobic exercise improves vascular function. Active video games are now highly popular and play a role in promoting physical activity. Although studies suggest that acute aerobic exercise attenuates high fat meal induced vascular dysfunction, but it is not clear whether an active video game could attenuate vascular dysfunction after a high fat meal. We tested the hypothesis that an active video game would partially prevent the unfavorable effect of vascular function by high fat meal in young adults.

**METHODS:** Using a randomized cross over design, sixteen healthy young subjects (male 9, female 7; age  $24 \pm 4$  yrs, BMI  $22.4 \pm 2.1$  kg/m<sup>2</sup>) were assigned to both an active video game (60 minutes, Nintendo Wii sports (boxing, tennis) and a seated rest after a high fat meal. Endothelial function was measured by brachial artery flow mediated dilation and arterial stiffness was measured by carotid-femoral pulse wave velocity. These variables were measured at baseline, 3 and 5 hours after a high fat meal.

**RESULTS:** Blood triglyceride levels were similarly increased in two treatment conditions after a high fat meal and did not significantly different between two groups (active video game : 74.06±43.36, 160.63±106.20, 126.81±91.41mg/dl; control : 70.06±38.67, 168.38±85.89, 128.75±87.26mg/dl, p=0.878). Brachial artery flow mediated dilation was decreased in the group with seated rest(9.32±2.86 to 8.13±3.56%), but increased in the group with active video game(8.74±3.13% to 9.21±3.40%) at 3hr after a high fat meal. However, there was no significantly different between two groups(p=0.189). Carotid-femoral pulse wave velocity was similarly decreased in two treatment conditions after a high fat meal and did not significantly different between two groups (active video game group : 6.39±1.12, 6.08±0.94, 6.38±1.07m/s; control group : 6.34±0.85, 6.19±0.89, 6.28±1.01m/s, p=0.483).

**CONCLUSIONS:** These findings show that a high fat meal caused a temporary decrease in endothelial function, but these decreases were not significantly attenuated in the group with active video game compare to the group with seated rest. Therefore, active video game may not have a cardioprotective effect in young healthy adults exposed to acute high fat meal.

**Cardiovascular Fitness is Associated with Venous Compliance in Healthy Subjects**

Ingeborg M. Leinan<sup>1</sup>, Øystein Grønnevik<sup>1</sup>, Asbjørn Støylen<sup>2</sup>, Ulrik Wisløff<sup>1</sup>, Trine Karlsen<sup>1</sup>. <sup>1</sup>Norwegian University of Science and Technology, Trondheim, Norway.

<sup>2</sup>Norwegian University of Science and Technology and St. Olavs University Hospital, Trondheim, Norway.

(No relationships reported)

Reduced venous outflow (VOF) is negatively associated with 6 minutes walk test performance in heart failure patients when compared to healthy age matched subjects, indicating that exercise intolerance may be linked to an insufficiency in venous circulation.

**PURPOSE:** Compare the relationship between venous compliance (VC) and cardiovascular fitness measured as maximal oxygen uptake ( $VO_{2max}$ ) in healthy subjects.

**METHODS:** Twenty-eight healthy subjects 20-70 years of age ( $46.4 \pm 16.2$  years,  $72.8 \pm 13.7$  kg,  $174 \pm 8.4$  cm, men n= 16, women n= 12) were recruited to a cross sectional study.  $VO_{2max}$  was measured during an individual ramp treadmill protocol. Resting venous and arterial flow and diameters were measured with ultrasound during a 10-minute occlusion protocol aiming to alter arterial and venous in- and outflow in the brachial vein and artery. Occlusion of VOF was achieved by occluding the upper arm to 7mmHg below diastolic blood pressure, and alternation in arterial inflow by occluding the wrist at 240mmHg. Vascular measures were normalized for dimensional scaling due to difference in subjects body composition. Measured diameters were scaled with fat free mass (FFM)<sup>-0.33</sup>, and measured VOF with FFM<sup>-0.67</sup>. Compliance (cross-sectional area/venous pressure) was expressed as the difference between resting and maximal occlusion compliance. Total blood, plasma volume and red cell mass were measured after the vascular examination with the improved CO-rebreathing method.

**RESULTS:** Mean  $VO_{2max}$  was  $3.38 \pm 0.8$  L · min<sup>-1</sup>, delta VC  $16.57 \pm 7.6$  mm<sup>2</sup> · mmHg<sup>-1</sup> · kg FFM<sup>-0.33</sup> and blood volume  $5.95 \pm 1.3$  L.  $VO_{2max}$  (L · min<sup>-1</sup>) was positively correlated with delta VC (mm<sup>2</sup> · mmHg<sup>-1</sup> · kg FFM<sup>-0.33</sup>) ( $r = 0.542$  and  $p = 0.004$ ) and VOF (cm · s<sup>-1</sup> FFM<sup>-0.67</sup>) ( $r = 0.554$  and  $p = 0.006$ ). Additionally a significant correlation was found between delta VC (mm<sup>2</sup> · mmHg<sup>-1</sup> · kg FFM<sup>-0.33</sup>) and total plasma ( $r = 0.598$  and  $p = 0.002$ ) and total blood volume ( $r = 0.638$  and  $p = 0.001$ ).

**CONCLUSION:**  $VO_{2max}$  is positively correlated with delta VC in the investigated population of healthy subjects. Additionally there is a positive correlation between  $VO_{2max}$  and VOF and total plasma volume. As  $VO_{2max}$  and arterial flow mediated dilatation previously have been positively correlated, the present result may indicate that exercise intolerance may also be linked to venous circulation.

---

**Effects Of The Combined Treatment Of Aerobic Exercise Training And Curcumin Intake On Arterial Function**

Nobuhiko Akazawa<sup>1</sup>, Youngju Choi<sup>1</sup>, Asako Miyaki<sup>1</sup>, Jun Sugawara<sup>2</sup>, Ryuichi Ajisaka<sup>1</sup>, Seiji Maeda<sup>1</sup>. <sup>1</sup>University of Tsukuba, Tsukuba, Japan. <sup>2</sup>National Institute of Advanced Industrial Science and Technology (AIST), Tsukuba, Japan.

(No relationships reported)

Reduction in arterial function with aging increases risk of cardiovascular disease. Lifestyle modifications, in particular aerobic exercise and dietary modifications, result in the favorable outcome in the vascular aging. Curcumin, a major component of turmeric, has an anti-inflammatory effect, therefore it is plausible to hypothesize that curcumin improves arterial function.

**PURPOSE:** The purpose of this study was to test the effects of curcumin ingestion alone and in combination with aerobic exercise training on arterial function in postmenopausal women.

**METHODS:** A total of 38 postmenopausal women were assigned randomly to four group: placebo (PLA), curcumin (CUR), exercise + placebo (EX+PLA), and exercise + curcumin (EX+CUR). Curcumin or placebo was ingested orally for 8 weeks. The exercise groups underwent 8 weeks moderate aerobic exercise training. PLA and CUR groups did not change their physical activity level. Before and after each intervention, carotid arterial compliance and flow-mediated dilation (FMD) were measured.

**RESULTS:** There were no differences in baseline carotid arterial compliance, FMD, and most other key dependent variables among the groups. Aerobic capacity in the EX+PLA and EX+CUR groups increased significantly after each intervention. Carotid arterial compliance increased significantly in CUR ( $0.087 \pm 0.005$  vs.  $0.097 \pm 0.006$  mm<sup>2</sup>/mmHg,  $P < 0.05$ ), EX+PLA ( $0.081 \pm 0.004$  vs.  $0.092 \pm 0.006$  mm<sup>2</sup>/mmHg,  $P < 0.05$ ), and EX+CUR ( $0.089 \pm 0.005$  vs.  $0.103 \pm 0.006$  mm<sup>2</sup>/mmHg,  $P < 0.05$ ) after each intervention. The change in carotid arterial compliance in EX+CUR was the greatest among the groups. FMD also increased significantly in CUR ( $2.7 \pm 0.5$  vs.  $4.4 \pm 0.7$  %,  $P < 0.05$ ), EX+PLA ( $2.7 \pm 0.6$  vs.  $4.6 \pm 0.7$  %,  $P < 0.05$ ), and EX+CUR ( $3.3 \pm 0.6$  vs.  $4.5 \pm 0.8$  %,  $P < 0.05$ ) after each intervention. There was no significant difference in the magnitude of increases in FMD among the groups.

**CONCLUSIONS:** The present study demonstrated that curcumin ingestion improved arterial function and that the combined aerobic exercise training and curcumin ingestion was more efficacious in increasing central arterial compliance than either treatment alone in postmenopausal women.

**Sex Differences in Cardiovascular Function at Rest and During Submaximal Exercise in Healthy Humans**

Courtney M. Wheatley<sup>1</sup>, Eric M. Snyder<sup>1</sup>, Bruce D. Johnson<sup>2</sup>, Thomas P. Olson<sup>2</sup>. <sup>1</sup>University of Arizona, Tucson, AZ. <sup>2</sup>Mayo Clinic and Foundation, Rochester, MN.

(No relationships reported)

**BACKGROUND:** Differences in cardiovascular function between sexes has been documented at rest and maximal exercise; however, these differences during submaximal steady-state exercise are less clear. This study investigated the cardiovascular response to submaximal steady-state exercise between sexes.

**METHODS:** We recruited 31 male and 33 female (age=30±1 vs. 28±1yrs, ht=1.8±1.3 vs. 1.7±1.3m, wt=82±1.8 vs. 64±1.8kg, BSA=2.0±0.0 vs. 1.7±0.0m<sup>2</sup>, respectively,  $p < 0.001$  for ht, wt, and BSA). Study visit 1 included a maximal exercise test. Study visit 2 included 9 minutes of low and 9 minutes of moderate intensity submaximal exercise (40 and 75% of peak watts). Measurements included: intra-arterial blood pressure (SBP and DBP), cardiac index ( $Q_i$ ), heart rate (HR), oxygen consumption ( $VO_2$ ) and arterial catecholamines (epinephrine=EPI and norepinephrine=NE), and blood gases. Mean arterial pressure (MAP), stroke volume index ( $SV_i$ ), and systemic vascular resistance index ( $SVR_i$ ), arterial oxygen content ( $CaO_2$ ) and systemic oxygen transport (SOT) were calculated. We indexed  $Q$ ,  $SV$ , and  $SVR$  for BSA.

**RESULTS:** At rest,  $Q_i$ ,  $SV_i$ , SBP, MAP, NE,  $CaO_2$ , and SOT were lower in females compared to males ( $p < 0.05$  for all). In females at low intensity, these differences were retained, additionally EPI and DBP were lower ( $p < 0.05$  for all) despite a higher HR ( $p < 0.05$ ). At moderate intensity,  $VO_2$ ,  $Q_i$ ,  $SV_i$ , SBP, MAP, EPI, NE,  $CaO_2$ , and SOT were lower and  $SVR_i$  was higher in females ( $p < 0.05$  for all). The slope of the relationship between HR and  $Q_i$  was greater in females compared to males from rest to moderate exercise ( $14.7 \pm 1$  vs.  $21.4 \pm 1$ ,  $p < 0.001$ ).

**CONCLUSION:** This study demonstrates differences in the cardiovascular response to submaximal steady-state exercise between sexes. Men had higher  $Q$  and  $SV$  at both low and moderate intensities. Females demonstrated a higher HR at low intensity with an increased slope of HR throughout exercise. These data demonstrate differential regulation of cardiac output, with a greater reliance on HR in females, during steady-state submaximal exercise.

**Sex Affects the Ventricular-Vascular Coupling Ratio Following 8 Weeks of Endurance Training**

Abbi D. Lane<sup>1</sup>, Huimin Yan<sup>1</sup>, Sushant M. Ranadive<sup>1</sup>, Rebecca M. Kappus<sup>1</sup>, Peng Sun<sup>1</sup>, Kenneth Wilund<sup>1</sup>, Jeffrey Woods, FACSM<sup>1</sup>, Bo Fernhall, FACSM<sup>2</sup>.

<sup>1</sup>University of Illinois, Urbana, IL. <sup>2</sup>University of Illinois-Chicago, Chicago, IL.

(No relationships reported)

**BACKGROUND:** The ventricular-vascular coupling ratio (VVC) is determined by the ratio of arterial elastance (Ea) to ventricular elastance (Elv). Previous work has shown that endurance exercise training can attenuate Ea, and, thus, reduce the coupling ratio. The role of sex in the VVC response to endurance training has not yet been elucidated.

**PURPOSE:** To determine the role of sex in changes in VVC after an 8-week endurance exercise intervention.

**METHODS:** Baseline and post training measurements were obtained in 53 previously sedentary subjects (25 women and 28 men), including: brachial blood pressures and end-systolic pressure (BP and ESP) using a standard cuff and applanation tonometry, and ultrasound images of the heart. Simpson's rule was used to calculate heart volumes. Elastances were determined from the formula  $Ea=ESP/SV$  and  $Elv=ESP/ESV$ . These values were then indexed to body surface area (EaI and ElvI). A VO<sub>2</sub> peak test was also performed. Subjects completed an 8-week endurance training program which consisted of 30-60 min of endurance exercise at 60-90% of max HR 3 times per week. Pre- and post-intervention values were compared between sexes using a repeated measures (2x2) ANOVA.

**RESULTS:** Subjects mean age at baseline was 24.7±4 yr, average BSA was 1.73±0.07 and mean VO<sub>2</sub> peak was 34.8±9.8 ml/kg/min. Compared to men, women had higher EaI (women=0.86 before and 0.87 mmHg/ml/m<sup>2</sup> after training; men=0.60 and 0.62 mmHg/ml/m<sup>2</sup>, p<0.05) and higher Ea/ElvI before and after training, p<0.05. Women decreased Ea/ElvI (from 0.41 to 0.37 mmHg/ml/m<sup>2</sup>, p<0.05). EaI was not altered by training in either group, but training increased ElvI (from 1.25 to 1.43 mmHg/ml/m<sup>2</sup>) in women only (p<0.05).

**CONCLUSION:** Women and men exhibit different VVC responses to endurance exercise training. EaI was not altered by training in either sex, while women augmented ElvI following training. As a result, women decreased Ea/ElvI suggesting training induced improvement in ventricular performance and energetics in women but not in men.

**Acute Arterial Compliance Responses to Whole-Body Vibration and Resistance Exercise in Postmenopausal Women**

Carmen Chrisman, Vanessa Sherk, Christopher A. Fahs, Kaelin Young, Harshvardhan Singh, Jessica Smith, Michael Bembem, FACSM, Debra Bembem, FACSM. University of Oklahoma, Norman, OK.

(No relationships reported)

No studies to date have investigated the acute arterial compliance responses to resistance and whole-body vibration exercise in postmenopausal women.

**PURPOSE:** To investigate the acute arterial compliance responses to high-intensity resistance exercise with and without whole-body vibration exercise in postmenopausal women.

**METHODS:** Seven women (58 ± 2 years) participated in this randomized crossover study. 1-RM testing on the leg press, seated row, hip extension, shoulder press, hip abduction, and hip adduction exercise machines. The exercise and control protocols, random in order and separated by 2-week washout periods, were comprised of whole-body vibration + resistance exercise (WBV), resistance exercise only (RES), or no exercise (CON). For the whole-body vibration, subjects stood barefoot on a teeterboard whole-body vibration plate for 5, 1-minute intervals at 20 Hz and 1.25 mm (amplitude), followed by the resistance exercise. For the resistance exercise, subjects completed 3 sets of 10 repetitions 80% 1RM. Arterial compliance measurements were obtained by radial applanation tonometry before (Pre) and immediately after (Post) each protocol.

**RESULTS:** There were significant (p < 0.05) time effects for heart rate (HR) and augmentation index (AI); and significant (p < 0.01) protocol × time interactions for HR, ejection duration (ED) and the Buckberg sub-endocardial viability ratio (SEVR). HR increased pre to post exercise for WBV (Pre - 67.4 bpm ± 2.6 vs. Post - 73.9 ± 4.1 bpm) and RES (Pre - 67.0 ± 3.7 bpm vs. 78.6 ± 6.1 bpm). AI significantly (p < 0.05) decreased post exercise for each condition (WBV Pre 35.4 ± 2.7% vs. Post 32.3 ± 3.7%; RES Pre 35.1 ± 4.1% vs. Post 30.1 ± 3.9%; CON Pre 38.9 ± 2.8% vs. Post 37.4 ± 2.0%). ED significantly (p < 0.05) increased and SEVR significantly (p < 0.05) decreased post exercise for WBV and RES, however, there were no differences in Post ED or SEVR between WBV and RES protocols.

**CONCLUSIONS:** Arterial compliance responses, as measured by the augmentation index, were not altered by the addition of whole-body vibration to acute resistance exercise. Our findings suggest that whole-body vibration exercise may be added to resistance exercise without inducing greater cardiovascular stress.

**von Willebrand Factor and Blood Flow Response to Whole Body Vibration in Diabetic Peripheral Neuropathy**

Michael M. Lockard, Nathan J. Kessler, Junggi J. Hong, Rachel A. Siebuhr. Willamette University, Salem, OR. (Sponsor: Peter Harmer, FACSM)

(No relationships reported)

Elevated plasma levels of von Willebrand factor antigen (vWF:Ag), indicative of endothelial damage, have been associated with diabetes mellitus and impaired vascular health. Whole body vibration (WBV) is an emerging treatment modality for diabetics with potential to enhance endothelial maintenance and peripheral blood flow; however, the chronic effects of WBV are unknown.

**PURPOSE:** To identify the chronic effects of four weeks of WBV treatment on vascular endothelium in diabetics with peripheral neuropathy, and to determine whether these WBV-induced changes are correlated with changes in peripheral blood flow.

**METHODS:** Subjects were 11 diagnosed diabetics with peripheral neuropathy (6 male, 5 female), mean age 58.5±11.4 years, and BMI 32.4±5.5 kg/m<sup>2</sup>. Subjects underwent three WBV sessions per week for four weeks. Each session included four three-minute treatments at a frequency of 25 Hz. Blood samples were analyzed in duplicate for vWF:Ag via ELISA test. Toe-brachial index, the rate of systolic pressure at the brachial artery compared to the great toe, was used to assess peripheral blood flow. Final testing was performed at least 24 hours after the most recent vibration treatment to reduce the potential acute effect of vibration therapy.

**RESULTS:** Plasma vWF:Ag decreased significantly with WBV from 117.8±35.7% to 96.3±25.1% (p=0.032). No gender difference in plasma vWF:Ag was observed. The change in plasma vWF:Ag was significantly correlated with the WBV-induced change in TBI (r=-0.635, p=0.036).

**CONCLUSION:** These data suggest that regular treatment with WBV decreases chronic endothelial damage associated with diabetic peripheral neuropathy, and that this change is associated with improved peripheral blood flow.

**Mechanoreceptors in Skeletal Muscles Lead to Augmented Pressor Response in Obese Children**

Hosung Nho, Hyun-Min Choi, Joon-Sung Park, Kwang-Il Kim, Hyun-Tae Seo, Kyung-Ae Kim, Jong-Kyung Kim, Hye-Lim Yoo. Kyung Hee University, Yong In, Korea, Republic of.

(No relationships reported)

**Mechanoreceptors in Skeletal Muscles Lead to Augmented Pressor Response in Obese Children** Hosung Nho, Hyun-Min Choi, Joon-Sung Park, Kwang-Il Kim, Hyun-Tae Seo, Kyung-Ae Kim, Jong-Kyung Kim, Hae-Lim Yoo Graduate School of Physical Education, Kyung Hee University, Yongin, Republic of Korea

Previous studies strongly indicate that the muscle metaboreflex evokes altered cardiovascular responses to exercise in obese children. However, the effect of the mechanoreflex, another component of exercise pressor reflex (EPR), on the hemodynamic responses is not well understood.

**PURPOSE:** To investigate the effects of the mechanoreflex on the cardiovascular responses in obese children.

**METHODS:** Thirty subjects (8 obese and 13 lean groups, body mass index:  $28.4 \pm 1.0$  vs.  $18.8 \pm 2.3$  kg/m<sup>2</sup>, respectively) participated. The testing protocol involved 5 min of baseline and 1 min brief passive dorsiflexion of the foot.

**RESULTS:** Mean arterial blood pressure (MAP) increased with the mechanoreflex activation in both groups, however, the peak MAP was significantly higher in obese groups. Inasmuch as cardiac output (CO) tended to be lower, the increase in MAP in lean groups was mainly due to lower levels of total vascular conductances (TVC) (see Table). On the other hand, the higher MAP in obese groups was due to both increase in CO and decrease in TVC. There was no difference between two groups during cold pressor test.

| Event | $\Delta$ HR (bpm) | $\Delta$ SV (ml)   | $\Delta$ CO (L/min) | $\Delta$ MAP (mmHg) | $\Delta$ TVC (ml/min/mmHg) |
|-------|-------------------|--------------------|---------------------|---------------------|----------------------------|
| Lean  | $-4 \pm 2^*$      | $-0.6 \pm 0.8$     | $-0.2 \pm 0.1^*$    | $8 \pm 1^*$         | $-4.5 \pm 0.7^*$           |
| Obese | $0 \pm 3$         | $4.8 \pm 1.3^{\#}$ | $0.4 \pm 0.1^{\#}$  | $15 \pm 3^{\#}$     | $-4.2 \pm 1.2^*$           |

\*A significant effect of the mechanoreflex, # vs. Lean.

**CONCLUSIONS:** This augmented pressor response was associated with an augmented increase in both CO and peripheral vasoconstriction in obese children. These results may imply that mechanic stimuli induced by muscle contraction contribute to the overactive EPR observed in obese groups.

(No relationships reported)

**BACKGROUND:** Peripheral adaptations to whole body aerobic exercise may not be optimized in individuals with central cardiovascular or pulmonary limitations due to their reduced exercise capacity. Single-leg cycling reduces the active muscle mass and may allow them to exercise at greater peripheral intensity without increasing central demand. However, single-leg cycling is hard to coordinate due to the need to recruit hip flexor muscles during the second half of the crank cycle (180 to 360). Incorporating a counterweight on the non-used crank arm may minimize this difficulty imparted during this exercise.

**PURPOSE:** Determine the cardiovascular responses to double-leg cycling and single leg cycling with and without the use of a counter weight.

**METHODS:** Six healthy volunteers participated in three cycling trials consisting of double-leg cycling, single-leg cycling without the use of a counterweight and single-leg cycling with the use of 9 kg counterweight attached to the crank on the opposite side of the active leg. Each trial consisted of 5 minutes at three workloads: 40, 80 and 120 watts. Pedaling rate was kept constant at 80 rpm. During each workload VO<sub>2</sub>, RER, HR and RPE were obtained. VO<sub>2</sub> and RER were used to calculate cycling efficiency.

**RESULTS:** Statistical analysis revealed a significant main effect of intensity and condition on VO<sub>2</sub>, HR, RER and efficiency. Paired T-test analysis indicated, on average, across all three workloads the use of a counterweight reduced VO<sub>2</sub> ( $23.7 \pm 6.8$  to  $18.1 \pm 5.3$  ml/kg/min), RER ( $0.96 \pm 0.04$  to  $0.91 \pm 0.02$ ), HR ( $143 \pm 18$  to  $120 \pm 19$  bpm) and RPE ( $14.8 \pm 2.2$  to  $12.2 \pm 2.2$ ) and increased efficiency ( $13.3 \pm 0.03$  to  $17.8 \pm 0.04$  %) compared to the non-counterweight condition. VO<sub>2</sub>, HR and efficiency were not, however, different between the single-leg counterweight and double leg cycling conditions while RPE and RER were higher with the counterweight ( $12.2 \pm 2.2$  and  $0.91 \pm 0.02$ ) compared to the double leg condition ( $10.7 \pm 1.6$  and  $0.84 \pm 0.04$ ).

**CONCLUSION:** Based on these data, counterweighted single leg cycling provides an exercise modality that allows for greater exercise intensity at the peripheral level, without increasing central cardiovascular and pulmonary demand and therefore may be beneficial to those with cardiovascular or pulmonary limitations.

### Determinants of Exercise Cardiac Output in Paralympic Athletes with Locomotor Impairments

Marco Bernardi<sup>1</sup>, Silvia Carucci<sup>2</sup>, Alessandro D'Alessio<sup>3</sup>, Emanuele Guerra<sup>4</sup>, Angelo Rodio<sup>5</sup>, Yaghesh Bhambhani<sup>6</sup>. <sup>1</sup>School of Specialization in Sports Medicine - Sapienza University of Rome; <sup>2</sup>Italian Paralympic Committee, Rome, Italy. <sup>3</sup>School of Specialization in Sports Medicine - Sapienza University of Rome, Italy, Rome, Italy. <sup>4</sup>Sapienza University of Rome, Rome, Italy. <sup>5</sup>Italian Paralympic Committee, Rome, Italy. <sup>6</sup>University of Cassino, Cassino, Italy. <sup>7</sup>Faculty of Rehabilitation Medicine, University of Alberta, Edmonton, AB, Canada.

(No relationships reported)

Stroke volume (SV) during arm cranking exercise (ACE) is significantly lower in individuals with paraplegia (PA), compared to other wheelchair confined subjects and to able bodied individuals, for a reduced cardiac preload due to venous pooling in the lower body. At our best knowledge, no such data exist on top level PA athletes (PA-A).

**PURPOSE:** The purposes of this study was to: (1) assess the cardiac output determinants (SV and heart rate -HR) in Paralympic PA-A (N = 16) and those with lower limb amputation (AMP-A, N=10) and poliomyelitis (PM-A, N =6), (2) compare their relationships between aerobic fitness (peak oxygen uptake - VO<sub>2</sub>peak) and maximal SV, and (3) examine the inter-relationships between oxygen pulse (O<sub>2</sub> pulse) and both SV and (a - v)O<sub>2</sub>diff in these athletes.

**METHODS:** Each athlete completed a continuous maximal ACE test up to volitional fatigue to assess VO<sub>2</sub>peak. In a different session subsequent cardiac output determinations from carbon dioxide re-breathing at 30%, 50% and 70% of VO<sub>2</sub>peak were carried out.

**RESULTS:** PA-A showed maximal ACE SV values ( $107 \pm 28.0$  ml) significantly lower than in AMP-A/PM-A ( $137 \pm 20.5$  ml) with a concomitant higher HR ( $136 \pm 16.4$  vs  $116 \pm 11.2$  beats •min<sup>-1</sup>). Maximal SV was significantly correlated with VO<sub>2</sub>peak in both PA-A (R<sub>2</sub> = 0.809) and AMP-A/PM-A (R<sub>2</sub> = 0.577) groups, with the following overall equation:

$$VO_{2peak} (ml \cdot min^{-1}) = 0,0165 SV + 0,3423 (R^2 = 0,6502).$$

Significant correlations were observed between O<sub>2</sub> pulse and SV in both PA-A (R<sub>2</sub> = 0.83) and AMP-A/PM-A (R<sub>2</sub> = 0.62) but not between O<sub>2</sub> pulse and (a - v)O<sub>2</sub>diff. O<sub>2</sub> pulse was a valid predictor of SV as there were no outliers in both groups of athletes (Bland-Altman analysis).

**CONCLUSIONS:** This study shows that maximal SV, lower in PA-A than in AMP-A/PM-A, is a significant determinant of VO<sub>2</sub>peak in Paralympic athletes with locomotor impairments. O<sub>2</sub> pulse at the submaximal level of VO<sub>2</sub> peak in which maximal SV is reached ( $62 \pm 10.1\%$  in PA-A and  $57 \pm 13.9\%$  in AMP-A/PM-A) can be used to characterize differences in aerobic fitness between Paralympic athletes and predict exercise SV when direct measurement is not possible.

### Left Ventricle speckle tracking in Young Elite Athletes

Alessio De Luca<sup>1</sup>, Laura Stefani<sup>1</sup>, Gianni Pedrizzetti<sup>2</sup>, Stefano Pedri<sup>1</sup>, Giorgio Galanti<sup>1</sup>. <sup>1</sup>Sports Medicine, Florence, Italy. <sup>2</sup>Civil Engineering Department, Trieste, Italy.

(No relationships reported)

**PURPOSE:** Regular training, induces in adult myocardial adaptation, so-called "athletes heart". The assessment of myocardial function is currently possible by deformation parameters. Aim of study is to verify the role of rotation and twist parameters for better characterize the heart performance in trained elite young athletes from different kind of sports.

**METHODS:** 50 young athletes (16 cyclists, 17 soccer players, 17 basket players) regularly trained at least three times a week for at least 9 months a year and 10 young controls (mean age  $18.5 \pm 0.5$  years) were evaluated either by 2D echocardiography or by a Speckle Tracking (ST) multi-layer approach to calculate Left Ventricle (LV) endocardial and epicardial rotation, twist, circumferential strain (CS) and longitudinal strain (LS). Data were compared by ANOVA test.

**RESULTS:** All the found values were within the normal range (fig. 1). Left Ventricle Diastolic Diameter (LVDD,  $51.7 \pm 2.6$  mm, p=.001), Cardiac Mass index (CMi,  $114.5 \pm 18.5$  g/m<sup>2</sup>, p<.01), epi-CS, epi-LS, epicardial apex rotation and the Endo/Epi twist were significantly higher only in cyclists. In all the groups, a physiological difference of the Endo/Epi basal circumferential strain and twist values have been found. A weak but not significant relationship between the Endo and twist values and LVDD ( $r^2=0.44$  p=.005) and CMi was also reported in cyclists.

**CONCLUSIONS:** Progressive increase of apical LV twist may represent an important component of myocardial remodelling. This aspect is particularly evident in the young cyclists group where the CMi and the LVDD are higher. ST multilayer approach completes the LV performance evaluation in young trained athletes showing values similar to adults.

1643 Board #51 MAY 30 3:30 PM - 5:00 PM

### The Influence of Cold Water Immersion on Limb and Cutaneous Blood Flows Following Exercise

Christopher Mawhinney<sup>1</sup>, Helen Jones<sup>1</sup>, David A. Low<sup>2</sup>, Chang Hwa-Joo<sup>1</sup>, Keith P. George<sup>1</sup>, Daniel J. Green<sup>3</sup>, Warren Gregson<sup>1</sup>. <sup>1</sup>Liverpool John Moores University, Liverpool, United Kingdom. <sup>2</sup>Imperial College London, London, United Kingdom. <sup>3</sup>The University of Western Australia, Perth, Australia.  
(No relationships reported)

Cold-water immersion is a commonly employed treatment to facilitate recovery from exercise-induced muscle damage. Benefits may partly arise from reduction in limb blood flow, however no study has comprehensively investigated the influence of different degrees of cooling on femoral blood flow responses following exercise.

**PURPOSE:** To determine the influence of cold (8°C) and cool (22°C) water immersion on lower limb and cutaneous blood flow following exercise.

**METHODS:** Twelve males (25±1.36yrs) completed a continuous cycle exercise protocol at 70% peak power output until a core temperature of 38°C was attained. In a randomized order, subjects were then placed in a semi-reclined position and hoisted into either 8°C or 22°C water to the iliac crest for 10 min or rested (Control). Rectal and thigh skin temperature, deep and superficial muscle temperature ( $T_m$ ), thigh and calf skin blood flow (laser Doppler flowmetry) and superficial femoral artery blood flow (duplex ultrasound) were measured prior to and after 30 min immersion. Vascular conductance was calculated for cutaneous and femoral flow and mean arterial pressure. Data were analyzed using repeated measures ANOVA. Cutaneous data is presented as % of pre-immersion.

**RESULTS:** Compared with Control, femoral artery conductance was reduced to a similar extent in both immersion conditions (Cold, 1.58±0.13; Cool, 1.76±0.20; Control, 2.38±0.22 ml·min<sup>-1</sup>·mmHg,  $p < 0.01$ ). When compared to control, thigh (-72.07±3.43%; Cool, -61.05±5.73%; Control, -21.85±8.04%,  $p < 0.01$ ) and calf skin conductance (Cold, -65.41±7.09%; Cool, -53.62±4.50%; Control, -28.48±7.39%,  $p < 0.01$ ) was similar between immersion conditions. The greatest reduction in  $T_m$  occurred at a depth of 1cm and was dependent on the condition (Cold, 31.10±0.48°C; Cool, 33.96±0.38°C; Control, 36.22±0.31°C,  $p < 0.01$ ). Deep  $T_m$  (3cm) decreased over the recovery period, with the magnitude of  $T_m$  decrease dependent on the condition (Cold, 35.52±0.2°C; Cool, 36.00±0.15°C; Control, 36.91±0.09°C,  $p < 0.01$ ).

**CONCLUSION:** A core temperature load of similar magnitude induces similar reductions in femoral and skin blood flows, irrespective of the lower body being immersed in cold or cool water. Cold-water may be more effective in the treatment of exercise-induced muscle damage by virtue of a greater reduction in  $T_m$ .

### Effects of Dietary Fish Oil on Exercising Muscle Blood Flow in Chronic Heart Failure Rats

Clark T. Holdsworth<sup>1</sup>, Steven W. Copp<sup>1</sup>, Daniel M. Hirai<sup>1</sup>, Scott K. Ferguson<sup>1</sup>, K Sue Hageman<sup>1</sup>, Charles L. Stebbins<sup>2</sup>, David C. Poole, FACS<sup>1</sup>, Timothy I. Musch, FACS<sup>1</sup>. <sup>1</sup>Kansas State University, Manhattan, KS. <sup>2</sup>University of California, Davis, Davis, CA.  
(No relationships reported)

Impaired vasomotor control in chronic heart failure (CHF) limits the delivery of O<sub>2</sub> to skeletal muscle during exercise. Previous results demonstrate significant increases in skeletal muscle blood flow (Q) during exercise with omega-3 polyunsaturated fatty acid (PUFA) supplementation via fish oil (FO) versus safflower oil (SO) in healthy rats (Stebbins CL et al., Int J Sport Nutr Exerc Metab 20:475-86, 2010). Whether PUFA supplementation with FO will improve vasomotor control in CHF and skeletal muscle Q during exercise remains to be determined.

**PURPOSE:** This investigation tested the hypothesis that PUFA supplementation with FO would augment the skeletal muscle Q response to exercise in rats with CHF when compared to SO.

**METHODS:** CHF was induced in male Sprague-Dawley rats (568 ± 24 g) by myocardial infarction produced by left coronary ligation. Rats were then randomized to dietary FO (20% docosahexaenoic acid and 30% eicosapentaenoic acid, n = 8) or SO (5% safflower, n = 6) supplementation for 6 weeks. After 6 weeks of dietary intervention, rats remained on their respective diets until final experiments were conducted. Following acute instrumentation and recovery (> 1 hour), mean arterial pressure (MAP), skeletal muscle Q to the total hindlimb and individual muscles (via radiolabeled microspheres), and blood lactate concentration were determined during submaximal treadmill exercise (20 m · min<sup>-1</sup>, 5% incline).

**RESULTS:** Left ventricular end-diastolic pressure (LVEDP) measured in the SO and FO groups during instrumentation were similar and demonstrated moderate CHF (LVEDP; SO: 11 ± 1; FO: 10 ± 2 mmHg,  $p > 0.05$ ). During submaximal exercise, MAP (SO: 132 ± 3; FO: 138 ± 4 mmHg), total hindlimb skeletal muscle Q (SO: 113 ± 15; FO: 92 ± 7 ml · min<sup>-1</sup> · 100 g<sup>-1</sup>) and blood lactate (SO: 4.0 ± 0.8; FO: 5.1 ± 0.6 mmol · l<sup>-1</sup>) were similar ( $p > 0.05$ ) between groups. In addition, all 28 individual hindlimb muscle Q's were similar ( $p > 0.05$ ) between SO and FO groups.

**CONCLUSION:** These data suggest that PUFA supplementation with FO in rats with moderate CHF does not increase the skeletal muscle Q response to submaximal whole body exercise.

### The Changes Of Muscle Blood Flow And Oxy-hemoglobin Saturation After Different Exercise Intensity In Water

Nai-Wen Kan<sup>1</sup>, Kuei-Yu Chien<sup>1</sup>, Mei-Chieh Hsu<sup>1</sup>, Yung-Hua Lin<sup>2</sup>, Yea-Lih Lin<sup>1</sup>. <sup>1</sup>National Taiwan Sport University, Taoyuan, Taiwan. <sup>2</sup>National Taipei University, New Taipei, Taiwan.  
(No relationships reported)

Water aerobics can improve circulation and muscle blood flow (MBF) which may improve oxygen availability and utilization by tissue to have cardiovascular protective effect.

**PURPOSE:** This study was to understand the changes of MBF and muscle oxygen saturation (SmO<sub>2</sub>) with different exercise intensity in three styles of water exercise moment.

**METHODS:** We recruited 12 menopausal women (age: 57-65 years old) respectively completed, water running, rocking, and scissor, three trails of water exercise moments by random and crossover trial. Each moment was carried out three stages of six-minutes testing including low (50±5%), medium (65±5%), and high (80±5%) intensity determined by heart rate reserve (HRR). The MBF and SmO<sub>2</sub> were detected over both of 4x8 cm<sup>2</sup> biceps brachii and quadriceps femoris muscles area at same time by two optical probes of near-infrared spectroscopy (NIRS).

**RESULTS:** There was no significant difference in change rates of MBF after completing each intensity level of three water exercise moments. We found significant changes of SmO<sub>2</sub> (oxy-hemoglobin / total hemoglobin) in upper arm after three stages of exercise and period of recover but the phenomenon did not be revealed in frontal thigh. The change rate of SmO<sub>2</sub> between upper and lower limbs existed positive correlation ( $p < .05$ ):  $r = 0.75$  (after low intensity running),  $r = 0.86$  (after medium intensity running),  $r = 0.83$  (after low intensity scissor), and negative correlation ( $p < .05$ ):  $r = -7.2$  (after low intensity rocking), and  $r = -7.2$  (after high intensity rocking).

**CONCLUSIONS:** In water rocking trails, upper arms may have relative exerted than lower limbs for reaching target HRR, so they appear negative correlation of SmO<sub>2</sub> changes unlike water running and scissor steps. Different exercise trials in water for menopausal women may induce the change of oxygen re-distribution between upper and lower limbs during recover time.

### Endurance Exercise Training and Curcumin Supplementation Inverses Lead-Induced Cardiotoxicity

Mahdi Hossein Zadeh<sup>1</sup>, Valiollah Dabidi Roshan<sup>2</sup>, Javad Ashrafi<sup>2</sup>, Jonathan Myers, FACSM<sup>3</sup>, <sup>1</sup>Aalborg University, Center for Sensory-Motor Interaction (SMI), Aalborg, Denmark. <sup>2</sup>College of Physical Education and Sport Sciences, University of Mazandaran, Babolsar, Iran, Babolsar, Iran, Islamic Republic of. <sup>3</sup>Cardiology Division, VA Palo Alto Health Care System, Stanford University, Palo Alto, CA, USA, Palo Alto, CA.  
(No relationships reported)

**BACKGROUND:** According to the American Heart Association, air pollution can develop cardiovascular disease. Lead is an environmental pollutant that can induce to long-lasting health problems including cardiovascular toxicity. Apelin is a novel endogenous peptide, and heat shock protein (HSP72) is detected in a variety of tissues and organs; both apelin and HSP72 play important protective role in the cardiovascular system.

**PURPOSE:** To investigate the cardioprotective effects of aerobic exercise training and/or curcumin supplementation, an antioxidant, alone or combined on left ventricular apelin, HSP72, total antioxidant capacity (TAC), and malondialdehyde (MDA) in rats chronically exposed to lead.

**METHODS:** Forty male Wistar rats were randomly divided to 5 groups: (1) lead acetate; (2) curcumin; (3) treadmill running; (4) treadmill + curcumin; and (5) sham-treated. The rats in groups 1 to 4 received lead acetate (20 mg/kg). Groups 3 and 4 underwent treadmill running, 15 to 22 m/min for 25 to 64 minutes, 5 times a week for 8 weeks, while groups 2 and 4 received curcumin solution (30 mg/kg) intraperitoneally. The sham group received curcumin solvent (ethyl oleat), only.

**RESULTS:** Lead administration resulted in a significant decrease in apelin (38%, P < 0.001), and TAC levels (27%, P < 0.001), and significantly increased HSP72 (15%, P < 0.01) and MDA (71%, P < 0.01) in the left ventricle in comparison to the sham group. However, both treadmill running and curcumin supplementation resulted in a significant increase in heart mass (12%, P < 0.01), as well as apelin (89%, P < 0.001), and TAC (27%, P < 0.001) levels, and significantly decreased HSP72 (57%, P < 0.01) and MDA levels (84%, P < 0.01) in comparison to the lead only group.

**CONCLUSIONS:** These results suggest a cardioprotective effect of concomitant antioxidants and regular endurance training in ameliorating lead-induced cardiotoxicity.

### Three Decades Of Participation In Cardiac Rehab

Allison Poremba, BS, Kirk Hendrickson. *Beaumont Health System, Royal Oak, MI. (Sponsor: Barry A. Franklin, FACSM)*  
(No relationships reported)

**HISTORY:** An 84-year-old male has a history of coronary disease, including 2 four-vessel coronary artery bypass graft (CABG) surgeries; 1980 and 2003, and an angioplasty in 2003 to an occluded graft. In 2010, he underwent a cardiac catheterization as a follow-up to an abnormal graded exercise stress test (GXT).

**PHYSICAL EXAMINATION:** The patient was asymptomatic after initial CABG (1980) and began a progressive walking program. Prior to surgery he had anginal symptoms.

**DIFFERENTIAL DIAGNOSIS:** Myocardial ischemia

**TEST AND RESULTS:** Status post initial CABG (04/1980): Exercise capacity = 7.4 metabolic equivalents (METs); unremarkable exercise ECG; body mass index (BMI) = 25.5 kg/m<sup>2</sup>.

Status post secondary CABG (03/2003): Exercise capacity = 6.0 METs; unremarkable exercise ECG; BMI = 26.5 kg/m<sup>2</sup>. Lipid values (10/2003): Total cholesterol (TC), HDL-C, LDL-C, triglycerides (TG) and glucose (G) were 144, 33, 76, 174, and 99 mg/dL, respectively; HbA1c = 5.9.

Percutaneous Coronary Intervention (09/2003): Stent placed in saphenous vein graft supplying obtuse marginal branch.

Recent GXT (02/2010): Exercise capacity = 6.2 METs; horizontal/downsloping ST depression; BMI = 25.0 kg/m<sup>2</sup>. Lipid values (02/2010): TC, LDL-C, TG, and G were 110, 55, 34, 104 and 104 mg/dL, respectively; HbA1c = 5.7.

Cardiac catheterization (04/2010): Left heart catheterization revealed native left anterior descending coronary artery occlusion; medical management was recommended.

Lower extremity arterial Doppler (06/2011): > 75% stenosis in right and left femoral arteries, signifying peripheral vascular disease (PVD).

**FINAL WORKING DIAGNOSIS:** Coronary artery disease/PVD

**TREATMENT AND OUTCOMES:** He began cardiac rehabilitation in 1980 and has been a participant for the past 31.5 years. His current lifestyle includes regular aerobic exercise and a heart healthy diet. He exercises 3 days/week for ~ 60 minutes/session using stationary cycle ergometry, arm-leg ergometry, and walking. He is physically active at home and regularly performs domestic chores and yard work. He denies cardiac complaints but was limited by leg fatigue on his most recent GXT; PVD was diagnosed in 2011. Most notably, the patient's BMI and functional capacity have remained largely unchanged over the past 3 decades, and he has experienced no acute cardiac events.

### The Associations Of Plasma Fibrinogen With Self-reported Leisure-time Physical Activity And Sitting Time In Australian Adults

Bethany J. Howard<sup>1</sup>, Alicia A. Thorp<sup>1</sup>, Balkau Beverley<sup>2</sup>, Neville Owen<sup>1</sup>, David W. Dunstan<sup>1</sup>, <sup>1</sup>Baker IDI Heart & Diabetes Institute, Melbourne, Australia. <sup>2</sup>INSERM CESP U<sup>1018</sup>, Villejuif, France. (Sponsor: Charles Matthews, FACSM)  
(No relationships reported)

Plasma fibrinogen, an inflammatory marker is positively associated with all-cause and cardiovascular mortality. Leisure-time physical activity (LTPA) has been shown to be inversely associated with fibrinogen, indicating a protective role. Recent studies have shown that sedentary behaviour (sitting), independent of LTPA is associated with an increased risk of all-cause and cardiovascular mortality, however, the association of plasma fibrinogen with daily sitting time has not been studied.

**PURPOSE:** To examine the associations of daily LTPA and sitting time with plasma fibrinogen in Australian adults.

**METHODS:** Plasma fibrinogen was measured in 2,346 men and 3,052 women aged  $\geq 30$  years (mean age 54 years) without cardiovascular disease from the 2004-2005 Australian Diabetes, Obesity and Lifestyle (AusDiab) study. Multivariate linear regression analyses examined associations of self-reported daily LTPA (hr/day) and sitting time (hr/day) with plasma fibrinogen (as a continuous measure), adjusting for potential confounding variables, including age, smoking, education and energy intake.

**RESULTS:** Each 1 hour increment per day in LTPA was associated with a 0.06g.l-1 (95% CI: -0.09, -0.03],  $P \leq 0.001$ ) and a 0.07g.l-1 (95% CI: -0.14, -0.01],  $P < 0.05$ ) reduction in plasma fibrinogen for men and women respectively. For daily sitting time, each 1 hour increment per day was associated with a 0.02g.l-1 increase in plasma fibrinogen in men (95% CI: 0.01, 0.03],  $P \leq 0.001$ ) and in women (95% CI: 0.002, 0.04],  $P < 0.05$ ). These associations remained significant for men and women following further adjustment for sitting time and LTPA in the respective models, but remained significant in men only with further adjustment for BMI.

**CONCLUSIONS:** This is the first study to describe a deleterious association between daily sitting time and plasma fibrinogen, independent of LTPA. While the findings from this study will need to be examined in prospective settings, the results suggest that in addition to the promotion of regular physical activity during leisure time, preventative efforts could be directed at reducing sitting time to attenuate the deleterious effects known to be associated with fibrinogen.

**Cardiorespiratory Fitness And The Risk Of Cardiovascular Disease Mortality In Men With Hypercholesterolemia**

Xuemei Sui<sup>1</sup>, Duck-chul Lee<sup>1</sup>, Enrique G. Artero<sup>1</sup>, Timothy S. Church, FACSM<sup>2</sup>, Gregory A. Hand, FACSM<sup>1</sup>, Steven N. Blair, FACSM<sup>1</sup>. <sup>1</sup>University of South Carolina, Columbia, SC. <sup>2</sup>Pennington Biomedical Research Center, Baton Rouge, LA.  
(No relationships reported)

**PURPOSE:** Elevated blood cholesterol is associated with increased risk of cardiovascular disease (CVD). Whether higher cardiorespiratory fitness (CRF) confers protection against CVD in individuals with manifest hypercholesterolemia is poorly understood. This longitudinal study sought to examine the association between CRF and risk of death from CVD in men with hypercholesterolemia in the Aerobics Center Longitudinal Study.

**METHODS:** Participants were 8,920 men (mean  $\pm$  SD age 45.9  $\pm$  8.7 years, range from 20 to 82) with no history of CVD and cancer, and received a preventive examination at the Cooper Clinic in Dallas, TX during 1974 - 2001. At baseline, all men had hypercholesterolemia on the basis of measured fasting blood cholesterol  $\geq$  6.20 mmol/L. CRF was quantified as maximal treadmill exercise test duration and was grouped for analysis as low (lowest 20% of exercise duration), moderate (middle 40%), and high (upper 40%) Using Cox regression analyses, we computed hazard ratios and 95% confidence intervals.

**RESULTS:** During an average of 17 years of follow-up, 329 CVD deaths occurred. Age-adjusted CVD mortality rates per 10,000 person-yrs according to low, moderate, and high CRF groups were 34.9, 19.4, and 16.8 (trend  $P < 0.0001$ ). After further control for baseline year of examination, body mass index, smoking, alcohol intake, physical activity, hypertension, diabetes, fasting blood cholesterol, and family history of CVD, hazard ratios (95% confidence interval) for CVD deaths across moderate and high categories of CRF (with low fit as referent = 1.00) were: 0.65 (0.49-0.86), 0.54 (0.38-0.78). There was an inverse association between CRF and CVD death within both normal weight men (trend  $P < 0.0001$ ) and overweight/obese men (trend  $P = 0.01$ ). After stratifying data by baseline physical activity level, an inverse association between CRF and CVD death was observed in sedentary men (trend  $P = 0.0004$ ); and a borderline significance was found in active men (trend  $P = 0.08$ ).

**CONCLUSIONS:** Among men with hypercholesterolemia, higher CRF is associated with lower risk of dying from CVD, independent of other clinical risk factors. Our findings underscore the importance of promoting CRF in the primary prevention of CVD in patients with hypercholesterolemia. Supported by NIH grant DK088195.

**Feasibility Of Aerobic Interval Training In Cardiac Rehabilitation**

Inger-Lise Aamot<sup>1</sup>, Siv Hege Forbord<sup>2</sup>, Vibeke Løckra<sup>2</sup>, Kjersti Gustad<sup>3</sup>, Andreas Stensen<sup>3</sup>, Astrid T. Berg<sup>2</sup>, Håvard Dalen<sup>1</sup>, Trine Karlsen<sup>1</sup>, Asbjørn Støylen<sup>1</sup>. <sup>1</sup>NTNU, Trondheim, Norway. <sup>2</sup>St.Olav's Hospital, Trondheim, Norway. <sup>3</sup>Levanger Hospital, Levanger, Norway.  
(No relationships reported)

There is growing evidence that high-intensity aerobic interval training (AIT) is more efficient than continuous moderate exercise training in improving aerobic capacity, both in healthy and in cardiac patients. It is therefore important to provide efficient exercise training in the health care system. However, how easily AIT is performed in a clinical outpatient setting is not clear, in regard to both achieving exercise intensity and exercise adherence.

**PURPOSE:** The aim of the study was to assess feasibility of AIT in cardiac rehabilitation (CR) in two Norwegian hospitals.

**METHODS:** 90 patients (80 men/10 women, mean age 57 $\pm$ 8) referred to CR, diagnosed Myocardial Infarction (MI, n=61), Acute Coronary Syndrome treated with PCI (n=7) or Coronary Artery Bypass graft (CABG, n=22), were invited to participate. Cardiopulmonary exercise test was performed before and after intervention to determine exercise tolerance, peak oxygen consumption (VO<sub>2</sub>peak) and peak heart rate (HRpeak). The intervention consisted of 12 weeks of AIT, twice a week with 4x4 intervals with 3 minutes of active break between. Target heart rate (THR) was set to 85-95% of HRpeak, and all patients exercised with a heart rate (HR) monitor. HR monitor data were downloaded regularly to assess exercise intensity and to give feedback to the participants. Main outcome measure was VO<sub>2</sub>peak, secondary outcome was exercise adherence. Paired Students T-test was used to analyse change within group.

**RESULTS:** There were 7 drop-outs (6 men) during the intervention period, due to orthopaedic problems (3), withdraw (3), and gastro intestinal problems (1). 83 patients completed the training programme (92%), and 80 of them logged 17 training sessions or more (median 24, range 7-24). THR was achieved by all except one. No adverse events were noticed during the training period. VO<sub>2</sub>peak changed from 34 $\pm$ 6.3 to 37.5 $\pm$ 6.7 ml/kg/min ( $p=0.001$ ), weight from 88.1 $\pm$ 14.1 to 87.3 $\pm$ 13.7 kg ( $p=0.005$ ), resting HR from 59 $\pm$ 9 to 57 $\pm$ 8 beats/min ( $p=0.011$ ), systolic blood pressure from 139 $\pm$ 20 to 135 $\pm$ 14 mmHg ( $p=0.056$ ), and diastolic blood pressure from 85 $\pm$ 11 to 83 $\pm$ 8 mmHg ( $p=0.047$ ).

**CONCLUSIONS:** AIT increased VO<sub>2</sub>peak significantly, was conducted without adverse events at THR, with an excellent exercise adherence and low drop-out rate. AIT should be considered as an option in cardiac rehabilitation.

**Women Doing Tai Chi During Phase III Cardiac Rehabilitation Have Better Physical Functioning Than Men**

Ruth E. Taylor-Piliae. University of Arizona, Tucson, AZ.  
(No relationships reported)

Exercise is well-recognized and effective for secondary prevention in patients with coronary heart disease (CHD). Traditional cardiac rehabilitation (TCR) efforts are targeted towards optimal physical functioning following a CHD event. Tai Chi exercise appeals to women as an adjunct physical activity for cardiac rehabilitation. **PURPOSE:** Examine gender differences in physical functioning.

**METHODS:** Secondary analysis using data from a cross-sectional study examining the effects of Classic Wu style Tai Chi compared to TCR, among phase III cardiac rehabilitation adults  $\geq$  45 years. Physical functioning tests included a 2-minute step-in-place test to assess aerobic endurance, single leg stance and functional reach tests to assess balance, arm curl and chair stand tests to assess strength, and back scratch and chair-sit-and-reach tests to assess flexibility.

**RESULTS:** Subjects (n=51) were 70 $\pm$ 8 years (range=49-86 years), and attended cardiac rehabilitation for 45 $\pm$ 37 months. Coronary artery bypass surgery (65%) was the most commonly self-reported cardiac event, followed by angioplasty/stent (57%), and a myocardial infarction (51%). Compared to men, women attended Tai Chi more than TCR (33% vs. 73%,  $X^2=6.84$ ,  $p<0.01$ ). Women scored  $\geq$  50th percentile on all physical functioning measures, while the men scored  $\geq$  50th percentile only on the balance and strength measures; compared to norms (Table).

**CONCLUSIONS:** Tai Chi appeals to women following a CHD event. Tai Chi offers additional options for women to improve physical functioning, whether as an adjunct to a TCR program, as part of a maintenance program for persons with CHD, or as an exercise alternative at any point along this continuum.

---

Table: Physical Functioning Compared to Norms

|   | Women, n=15 |                          | Men, n=36   |                          |
|---|-------------|--------------------------|-------------|--------------------------|
|   | mean ± SD   | 50th % score, age=71 yrs | mean ± SD   | 50th % score, age=69 yrs |
| Aerobic Endurance, steps in 2-min.        | 89.7 ± 17.2 | 84                       | 87.5 ± 19.9 | 101                      |
| Balance                                   |             |                          |             |                          |
| Functional Reach, inches                  | 16.7 ± 4.0  | 10.5                     | 17.1 ± 3.3  | 15                       |
| Single Leg Stance, Right (number of sec.) | 27.1 ± 23.7 | 17.2                     | 37.1 ± 23.5 | 27                       |
| Single Leg Stance, Left (number of sec.)  | 30.0 ± 22.5 | 17.2                     | 27.9 ± 23.8 | 27                       |
| Strength                                  |             |                          |             |                          |
| Upper body, arms curls in 30 sec.         | 15.2 ± 3.2  | 15                       | 17.8 ± 5.1  | 18                       |
| Lower Body, chair stands in 30 sec.       | 13.7 ± 3.3  | 13                       | 12.1 ± 3.1  | 15                       |
| Flexibility                               |             |                          |             |                          |

**1652 Board #60 May 30 2:00 PM - 3:30 PM****Change In Total Volume Of Physical Activity And Its Relationship With Change In Arterial Stiffness**

Marquis Hawkins<sup>1</sup>, Kelley Pettee Gabriel<sup>2</sup>, Jennifer Cooper<sup>1</sup>, Kristi Storti<sup>1</sup>, Kim Sutton-Tyrrell<sup>1</sup>, Andrea Kriska, FACSM<sup>1</sup>. <sup>1</sup>University of Pittsburgh, Pittsburgh, PA. <sup>2</sup>The University of Texas Health Science Center at Houston, Austin, TX.

(No relationships reported)

Arterial stiffness (AS) is a subclinical measure of cardiovascular disease that predict future cardiovascular events. Physical activity (PA) has been shown to reduce AS; however, the specific mechanisms are unknown.

**PURPOSE:** To determine the impact of PA on arterial stiffness in overweight, sedentary adults (20-45yrs) participating in a lifestyle intervention.

**METHODS:** The Slow Adverse Vascular Effects of excess weight (SAVE) trial is a study evaluating the relationships between weight loss, dietary sodium, and vascular health. Subjects were randomly assigned to a regular or reduced sodium diet, with all receiving one-year nutrition and PA intervention. Data was collected at baseline and 12 months follow-up. PA Intensity was assessed with the ActiGraph accelerometer. AS was assessed by brachial-ankle PWV (baPWV) using an automated device. Mixed models examined the associations between changes over 12 months in time spent in light intensity PA (LPA), moderate to vigorous PA (MVPA), sustained bouts of MVPA (>8 minutes), sedentary activity, total accelerometer counts (counts/day) on change in baPWV. Models were adjusted for time since baseline visit, age, sex, race, and smoking status, homeostatis model of assessment of insulin resistance (HOMA score), body mass index (BMI) and accelerometer wear time.

**RESULTS:** MVPA significantly increased from baseline to 12 months while time spent in LPA significantly decreased. BMI decreased from baseline to 12 months. Mean baPWV was similar at each time point. Change in baPWV was inversely related to change in total counts per day in the fully adjusted models (p=0.02). BaPWV and MVPA bouts were inversely related (p=0.07) when adjusting for age, race, gender, smoking status, and accelerometer wear time but was further attenuated when BMI was added to the model (p=0.12). Change in sedentary time was positively related to change in arterial stiffness in women (p=0.02) but not men.

**CONCLUSIONS:** Total accelerometer counts appeared to be more important for reducing arterial stiffness than time spent in any intensity of activity.

**1653 Board #61 May 30 2:00 PM - 3:30 PM****High Intensity Exercise Better For Improving Cardiovascular Function And Ventilatory Efficiency In Coronary Disease Patients**

Gustavo G. Cardozo<sup>1</sup>, Ricardo B. Oliveira<sup>2</sup>, Vivian C. Barreto<sup>2</sup>, Luisa R. Meirelles<sup>3</sup>, Paulo de Tarso V. Farinatti<sup>4</sup>. <sup>1</sup>Total Care (RJ)- Grupo Amil, Rio de Janeiro, Brazil. <sup>2</sup>Universidade do Estado do Rio de Janeiro, Rio de Janeiro, Brazil. <sup>3</sup>Total Care (RJ) - Grupo Amil, Rio de Janeiro, Brazil. <sup>4</sup>Universidade Salgado de Oliveira, Niterói, Brazil.

(No relationships reported)

High intensity interval training (HIT) has been shown to be more effective than moderate intensity continuous training (MIT) for improving maximal oxygen uptake (VO<sub>2</sub>peak) in patients with coronary heart disease (PCHD), suggesting greater cardioprotective benefits. Whether HIT is more effective for improving newly emerged cardiopulmonary exercise testing variables (CPXv), such as VE/VCO<sub>2</sub> slope, OUES and peak oxygen pulse is not known.

**PURPOSE:** Our objective was to compare the effects of HIT and MIT on CPXv associated with cardiorespiratory function and prognosis in PCHD.

**METHODS:** Fifty-eight PCHD (aged 61±1.7 yrs; 71% men) with optimized treatment underwent maximal CPX as part of their clinical evaluation. PCHD were assigned to either MIT (n=18), consisting of 30 minutes of continuous aerobic exercise at 70 to 75% of maximal measured heart rate (HRmax) or HIT (n=19), consisting of a total of 30 minutes, divided in two minutes intervals at 60% and 90% of HRmax. Both protocols were performed 3 times per week for an average of 4.2±2.5 months. A control group (CG) was set (n=21) and did not perform any exercise routine during the experimental period. PCHD that changed their clinical status (medications and diseases) were excluded from the study. Groups were all similar in baseline.

**RESULTS:** Except for the VE/VCO<sub>2</sub> slope, the HIT group exhibited better improvements in all CPXv when compared to MIT (Table 1). No differences were found in CG for all CPXv.

**CONCLUSIONS:** HIT was more effective for improving CPX clinical valuable variables other than VO<sub>2</sub>peak when compared to MIT. These findings have important implications for exercise prescription in rehabilitation programs.

**Physical Improvements after Yoga for People with Chronic Stroke**

Arlene A. Schmid<sup>1</sup>, Kristine K. Miller<sup>1</sup>, Marieke Van Puymbroeck<sup>2</sup>, Tracy A. Dierks<sup>3</sup>, Peter Altenburger<sup>3</sup>, Nancy Schalk<sup>4</sup>, Linda S. Williams<sup>1</sup>, Erin DeBaun<sup>1</sup>, Teresa Damush<sup>1</sup>. <sup>1</sup>Indiana University/Roudebush VAMC, Indianapolis, IN. <sup>2</sup>Indiana University, Bloomington, IN. <sup>3</sup>Indiana University, Indianapolis, IN. <sup>4</sup>Heartland Yoga, Indianapolis, IN. (Sponsor: NiCole Keith, FACSM)  
(No relationships reported)

**PURPOSE:** Assess the impact of therapeutic-yoga on physical performance measures in people with chronic stroke.

**METHODS:** Forty-seven individuals with stroke were recruited and randomized 3:1 to yoga or waitlist control. The yoga group completed one hour yoga sessions twice a week for 8 weeks. Yoga was taught by a certified yoga therapist and included modified physical postures, yoga breathing, bilateral movements, and concluded with relaxation while seated, standing, and supine. Assessments before and after the 8 weeks included: flexibility via passive range of motion (PROM) for the hamstrings (HS) and active range of motion (AROM) for hip flexion, cervical rotation, and cervical lateral flexion; strength with the chair to stand and arm curl and hip flexion manual muscle test; and endurance with a 6 minute walk. We compared groups with a t-test/Mann Whitney. We used paired t-tests/Wilcoxon non-parametric tests to compare baseline and 8-week data.

**RESULTS:** The average age of participants completing the study was 64, 76% were male, and 63% were white. There were no differences in demographics or outcomes between the yoga and control groups. There were no improvements in the waitlist control group. In the yoga group (n=29), improvements were found in flexibility with PROM and AROM, arm curl, and endurance, see Table. The chair to stand test and hip flexion AROM did not change (p>.05).

| Variable                        | Baseline   | 8 weeks    | p value |
|---------------------------------|------------|------------|---------|
| Left hamstring PROM             | -22.20±9.8 | -12.10±4.3 | <.001   |
| Right hamstring PROM            | -19.25±5.5 | -12.20±4.4 | <.001   |
| Left cervical Rotation          | 54.45±8.3  | 65.85±8.2  | <.001   |
| Right cervical rotation         | 57.65±8.9  | 65.55±8.0  | .002    |
| Left cervical lateral flexion   | 19.4±10    | 27.05±9.6  | .001    |
| Right cervical lateral flexion  | 15.4±8.8   | 23.8±8.3   | <.001   |
| Arm curl strength               | 13.76±4.1  | 15.4       | .003    |
| 6-minute walk, walking capacity | 869±380    | 949±370    | .002    |

**CONCLUSIONS:** These findings suggest therapeutic-yoga improved flexibility, arm strength, and endurance for individuals post-stroke. Therapeutic-yoga requires repetitive, slow and sustained muscle activation which may contribute to these findings. Further testing, however, is warranted as these findings are preliminary.

1655 Board #63 May 30 2:00 PM - 3:30 PM

**The Antihypertensive Effects of Aerobic Exercise Training: A Meta-Analysis**

Hayley V. MacDonald, TaShauna U. Goldsby, Blair T. Johnson, Tania B. Huedo-Medina, Linda S. Pescatello, FACSM. University of Connecticut, Storrs, CT.  
(No relationships reported)

Meta-analyses report aerobic exercise (AE) training reduces blood pressure (BP) 3-5 mmHg but have yet to demonstrate how this effect might vary according to patient characteristics, Frequency, Intensity, Time and Type (FITT) of the AE intervention, and other factors.

**PURPOSE:** To investigate the effectiveness of AE training as antihypertensive therapy while exploring factors likely to moderate the BP response to AE training.

**METHODS:** A systematic search was conducted to locate relevant randomized controlled trials. Studies were included if they had adults (≥19 yr); a non-exercise, non-diet control, or comparison group or session; and reported pre and post-BP for AE and control groups and the FITT of the AE intervention. Studies were excluded if they involved any dietary or medication intervention, and/or special population with diseases unrelated to cardiovascular disease. Analyses followed random-effects assumptions.

**RESULTS:** 32 studies were included yielding 45 interventions with 1906 participants (exercise n= 998, control n= 908). Participants were white (93%), middle-aged (49.6±12.7yr) women (48%) and men (52%) who were overweight [body mass index (BMI) 27.4± 2.4kg•m<sup>-2</sup>] and had pre-hypertension [systolic BP (SBP) 125.4±22.9/diastolic BP (DBP) 78.0±14.8mm Hg] with 12.8% taking antihypertensive medication (n= 244). AE interventions were performed at moderate to vigorous intensity (6.3±1.7 MET) for 37.6 ±12.4 min•session<sup>-1</sup>, 3.5±1.1 d•wk<sup>-1</sup> for 22.7±23 wk. SBP (d+=-0.22; 95%CI:-0.36,-0.08; -1.2±5.8 mmHg) and DBP (d+=-0.22; 95%CI:-0.36,-0.08; -1.8±3.3 mmHg) decreased following AE training compared to control. SBP was reduced to greater levels in individuals who were older (β=-0.37, p<=.01) and had a higher BMI (kg•m<sup>-2</sup>) (β=-0.35, p<.05). DBP was reduced to greater levels as baseline BP increased (β=-0.36, p<.05) and among those taking antihypertensive medications (β=-0.76, p<.05).

**CONCLUSIONS:** Our results confirm AE training reduces BP, but our overall result of 1-2 mmHg is 30-80% less than past meta-analyses, likely due to our use of relatively rigorous effect size calculation methods. More importantly, our results demonstrate that the antihypertensive effects of AE are more pronounced in those were older, had higher BP, greater BMI, or taking antihypertensive medications.

1656 Board #64 May 30 2:00 PM - 3:30 PM

**The Effect of Supervised vs. Unsupervised Summer Break on Cardiac Autonomic Modulation in Adolescents.**

Marco Meucci<sup>1</sup>, Hannah Crawford<sup>2</sup>, Chelsea Curry<sup>2</sup>, Hannah Wheeler<sup>2</sup>, Carol Cook<sup>2</sup>, Kris Hartley<sup>2</sup>, Scott R. Collier, FACSM<sup>2</sup>. <sup>1</sup>University of Rome, Rome, Italy. <sup>2</sup>Appalachian State University, Boone, NC.  
(No relationships reported)

Active adolescents report higher levels of HRV when compared to age-matched sedentary adolescents counterparts. Yet, few children take part in physical training as most adolescents participate in play-based physical activity. However, the effect of a short-term, play-based physical activity program on cardiac autonomic modulation in adolescents has not been established.

**PURPOSE:** Therefore, the purpose of this study was to investigate the effects of 4 (4w) and 8 weeks (8w) of supervised play-based physical activity vs. an 8-week unsupervised summer break (C) on HRV in adolescents.

**METHODS:** 22 adolescents (8 to 12 years-old) were divided into three groups blinded to the investigators: The 4 (n=6) and 8 (n=6) week activity groups performed supervised, play-based physical activity 6 hours/day, 5 times/wk vs. a control group (n=10) which has been instructed to maintain regular summer break habits. HRV was assessed via heads-up tilt (supine at 0 degrees and heads-up tilt at 80 degrees) both pre and post intervention. HRV data was collected via 3-lead EKG (BioPac, Systems, inc.) while simultaneous beat-to-beat blood pressure was collected using finger plethysmography (Finometer) in 10-min epochs.

**RESULTS:** TP increased at rest and with tilt following 8 weeks of activity (resting pre 7479.759 ± 2326.283 to post 12007 ± 3392.293 and tilt pre 2183.125 ± 850.642 to post 2938.125 ± 1121.615). nLF show significant decreases at rest for 8 weeks of activity (pre 0.488 ± 0.065 to post 0.470 ± 0.062) and increases for 8 weeks control (pre 0.052 ± 0.075 to post 0.644 ± 0.072). nHF increased after 8 weeks training (pre 0.489 ± 0.062 to post 0.51 ± 0.062) and decreased following the control period (pre 0.394 ± 0.072 to post 0.336 ± 0.71). LF/HF ratio was better preserved in the 8 week activity group (pre 115.2 ± 60.347 to post 115.262 ± 78.235) vs the control group (pre 263.550 ± 69.682 to post 199.250 ± 90.338).

**CONCLUSIONS:** 8 weeks of play-based physical activity can increase HRV enhancing sympathovagal balance in adolescents.

Supported by a grant from the BeActive/Appalachian Partnership. (PI - Scott Collier, PhD, FACSM)

**The Influence Of Aerobic Exercise Training On Blood Pressure Among Non-Hispanic Blacks: A Meta-analysis**

TaShauna U. Goldsby, Hayley V. MacDonald, Blair T. Johnson, Tania B. Huedo-Medina, Linda S. Pescatello, FACSM. *University of Connecticut, Storrs Mansfield, CT.*

(No relationships reported)

**PURPOSE:** Nearly 41% of non-Hispanic blacks in the United States have hypertension (HTN), a higher prevalence than any other ethnic group. Because aerobic exercise lowers blood pressure (BP) 5-7 mmHg, it is recommended as a lifestyle treatment to prevent, treat, and control HTN. Currently, there is no convincing evidence to evaluate these recommendations among non-Hispanic blacks. Therefore, we reviewed studies evaluating the efficacy of aerobic exercise training to reduce BP among non-Hispanic blacks.

**METHODS:** A systematic search was conducted to locate relevant studies in electronic databases. Studies included enrolled 100% non-Hispanic black adults 19y+; had a non-exercise, non-diet control or comparison group; reported pre- and post-intervention BP measurement; and specified the frequency, intensity, time and type (FITT) of the aerobic exercise intervention. Studies were excluded if they involved any special population with chronic diseases unrelated to cardiovascular disease and/or were prospective or cross-sectional studies. Analyses followed random-effects assumptions.

**RESULTS:** 9 trials met the inclusion criteria including 10 interventions (exercise n=133, control n= 98) involving 231 participants (83% women, 17% men) 32.6±3.5y with normal BP to pre-HTN (122.3±11.3/76.3±8.2mmHg) and a body mass index (BMI) of 29.4±7.5kg/m<sup>2</sup>. Exercise interventions were performed at moderate intensity (5.9±2.1 METs) for 43.8±10.8min•session<sup>-1</sup>, 3.6±1.1 d•wk<sup>-1</sup> for 13.5±7.1 wk. Modalities were primarily walking, jogging, or treadmill (k=7), cycling (k=2), and rowing (k=1). Systolic BP (d=-0.62, 95% CI: -1.10, -0.14; I<sup>2</sup> = 68.5; -5.4 mm Hg) and diastolic BP (d=-0.69; 95% CI: -1.09, -0.28, I<sup>2</sup> = 42.6; -5.2 mm Hg) exhibited moderate to large reductions.

**CONCLUSIONS:** Our findings indicate that aerobic exercise training is efficacious for lowering BP among non-Hispanic blacks yielding BP reductions of equal to or greater magnitude than those reported in other racial/ethnic groups. The current paucity of data limit model testing of moderators; thus, it remains unknown what patient characteristics and FITT features of exercise interventions are associated with the greatest BP benefits among non-Hispanic blacks.

1658 Board #66 May 30 2:00 PM - 3:30 PM

**The Relation Between The Blood Pressure Response To Exercise During Training And Detraining Periods**

Emily A. Moker<sup>1</sup>, Lori A. Bateman<sup>2</sup>, William E. Kraus, FACSM<sup>2</sup>, Linda S. Pescatello, FACSM<sup>1</sup>. <sup>1</sup>University of Connecticut, Storrs, CT. <sup>2</sup>Duke University, Durham, NC.

(No relationships reported)

Exercise training lowers blood pressure (BP) 5-7 mmHg, but the relation between the BP response to exercise training and detraining is unclear.

**PURPOSE:** To examine the BP response after 6m of training followed by 2wk of detraining among a subsample from the Studies of a Targeted Risk Reduction Intervention through Defined Exercise study.

**METHODS:** Subjects were 38 men and 37 women 50.2±10.6y with a body mass index of 30.5±3.2kg-m<sup>-2</sup> and resting BP of 120.0±13.7/79.1±9.2mmHg. Subjects completed 1 of 3 types of exercise training: aerobic (AE) vigorous intensity (n=34); resistance training (RT) (n=28); or AE vigorous and RT (n=13). Simple linear and multivariable regression tested the response of BP to exercise and detraining. Chi square tested the frequency of subjects that increased/decreased BP after training and detraining.

**RESULTS:** Among the total sample, BP was not different after training and detraining, regardless of modality (p>.05). However, subjects who responded to the BP lowering effects of exercise training reduced BP 10.0±6.7/9.1±4.9 mmHg; whereas those that did not respond increased BP 9.6±7.6/6.2±5.3 mmHg (p<.001). The SBP/DBP response to training and detraining was negatively correlated (r=-0.474/-0.540, p<.01). Interestingly, 65.5% of participants that reduced SBP after training (n=19), increased SBP after detraining; and 73.7% of the participants that increased SBP after training (n=28), decreased SBP after detraining (p<.05). Similarly, 80.6% of the participants that reduced DBP after training (n=28), increased DBP after detraining, and 81.3% of the participants that increased DBP after training (n=26), decreased DBP after detraining (p<.001). The SBP response to detraining (r=-0.521, p<.001), resting SBP (r=-0.444, p<.001), and the metabolic syndrome (r=0.288, p<.01) accounted for 44.8% of variability in the SBP response to training (p<.001). The DBP response to detraining (r=-0.553, p<.001), resting DBP (r=-0.450, p<.001), and the metabolic syndrome (r=0.463, p<.001) accounted for 60.1% variability in the DBP response to training (p<.001).

**CONCLUSIONS:** Future work is needed to elucidate mechanisms that explain why some people lower BP with exercise training, while others lower BP with detraining. Grant: 1R01HL57354; 2003-2008; NCT00275145

1659 Board #67 May 30 2:00 PM - 3:30 PM

**Effectiveness Of A Home-based Exercise Program On Fitness And Blood Pressure Of Hypertensive Patients**

Paulo T.V. Farinatti<sup>1</sup>, Ricardo B. Oliveira<sup>1</sup>, Leonardo G.O. Luz<sup>2</sup>, Felipe Sanjuliani<sup>1</sup>, Walace D. Monteiro<sup>1</sup>. <sup>1</sup>Rio de Janeiro State University, Rio de Janeiro, Brazil. <sup>2</sup>Universidade Federal de Alagoas, Arapiraca, Brazil.

(No relationships reported)

The benefits of exercise in reducing blood pressure (BP) have been mostly described in studies conducted in university-based programs that are difficult to generalize to more representative populations.

**PURPOSE:** This study aimed to investigate the influence of a long-term home-based exercise program on BP, biochemical variables and functional capacity of hypertensive patients

**METHODS:** In this controlled clinical trial, 29 patients with hypertension underwent 16 months of exercise composed by 30 minutes of light to moderate intensity walking, followed by stretching exercises. Longitudinal changes in BP, aerobic capacity, flexibility, lipid profile and glucose were assessed every two months.

**RESULTS:** Mean compliance in the experimental group was 83±7% of the planned exercise sessions. Differently from experimental group, no differences were found in control group comparisons after 16 months, except for weight and skin sum fold (higher 3.6±0.2 kg and 3.0±1.2 cm, respectively). In the experimental group, when compared to baseline, differences in weight and body fat were only found after 6 months of exercise, remaining relatively stable thereafter (78.9±9.9 kg vs. 73.5±7.9 kg and 33.5±4.6% vs. 28.8±3.1%, respectively). Aerobic capacity, expressed by the ratio between heart rate and workload, and flexibility, were improved after 16 months of exercise (p<0.05 for all comparisons). The most striking differences in systolic BP were found in the first 6 months of exercise (141.1±19.8 mmHg vs. 134.7 mmHg, p<0.05 - baseline vs. 6th month, respectively). Even though significant differences were remained after 16 months of exercise, no further reductions were observed after the first 6 months of exercise. Except for glucose and LDL cholesterol, the exercise program led to significant but modest benefits in all other biochemical variables.

**CONCLUSIONS:** The home-based exercise program was revealed as an effective strategy for improving in functional capacity, biochemical variables and most importantly, blood pressure control of stage I and II hypertensive patients. Paulo T.V. Farinatti, CNPq Research Grant Recipient

**Effects Of Circuit Class Training As A Replacement For Usual Physiotherapy In Patients After Stroke**

Ingrid van de Port<sup>1</sup>, Lotte Wevers<sup>1</sup>, Eline Lindeman<sup>1</sup>, Gert Kwakkel<sup>2</sup>. <sup>1</sup>Rehabilitation Centre De Hoogstraat, Utrecht, Netherlands. <sup>2</sup>Research Institute MOVE VU, Amsterdam, Netherlands.

(No relationships reported)

Most patients who suffer a stroke experience reduced walking competency and health-related quality of life (HRQoL). A key factor in effective stroke rehabilitation is intensive, task-specific training. Task-oriented circuit class training (CCT) is a physiotherapy intervention used to improve gait and gait related activities in patients with stroke.

**PURPOSE:** To study the effects of CCT as a replacement for usual physiotherapy (usual PT) for stroke patients in a single-blinded, randomized controlled trial.

**METHODS:** Patients discharged from inpatient rehabilitation to an outpatient rehabilitation clinic were included and randomly allocated to CCT, 2 sessions per week for 90 minutes during 12 weeks, or to usual PT in one of nine rehabilitation centres. The primary outcome was the mobility domain of the Stroke Impact Scale (SIS, version 3-0). Secondary outcomes were standing

balance, self-reported abilities, mobility, instrumental activities of daily living, fatigue, anxiety and depression. All outcomes were assessed in a repeated measurement design for 24 weeks. Between-group differences were analyzed using random coefficient analysis, according to intention-to-treat analysis.

**RESULTS** 126 patients were included in the CCT group and 124 in the usual PT group. One patient dropped out from the CCT and seven from the usual PT group. CCT was a safe intervention and no serious adverse events were reported. Significant differences were found for gait speed ( $\beta = 0.091$  (0.023),  $p < 0.001$ ), and walking distance ( $\beta = 20.002$  (7.442),  $p = 0.004$ ) in favour of the CCT group, but no significant between-group differences were found for the SIS-mobility domain ( $\beta = 0.049$  (0.682);  $p = 0.47$ ) at 12 weeks. No significant between group differences were found for the secondary outcomes, except for the Nottingham Extended ADL Leisure and the memory and thinking domain of the Stroke Impact Scale at 12 weeks. With exception of gait speed ( $\beta = -0.035$  (0.017),  $p < 0.05$ ), no significant between-group differences were found at follow-up.

**CONCLUSION** Task-oriented CCT is a safe replacement for usual PT in patients who are discharged from an inpatient rehabilitation setting to the community and need further training of gait- and gait-related activities in an outpatient clinical setting.

1661 Board #69 May 30 2:00 PM - 3:30 PM

**Stroke Outpatients with Different Physical Fitness Level Need Individualized Exercise Prescription?**

Long Pio Chio<sup>1</sup>, Pei Jhen Lee<sup>2</sup>, Hsuei Chen Lee<sup>2</sup>, Ku Chou Chang<sup>3</sup>, Jin Jong Chen<sup>2</sup>. <sup>1</sup>Institution of Physical Therapy and Assistive Technology, National Yang-Ming University, Taiwan, Taipei, Taiwan. <sup>2</sup>National Yang-Ming University, Taiwan, Taipei, Taiwan. <sup>3</sup>Chang-Gung Memorial Hospital, Kaohsiung, Taiwan.

(No relationships reported)

**PURPOSE:** Previous studies showed that moderate intensity physical activity could promote physical fitness in stroke patients. However, there is a diversity of the mild stroke, the exercise recommendation may not fit all patients. This study aimed to investigate the effects of exercise on physical fitness for mild stroke outpatients with different fitness level.

**METHODS:** This was a quasi-experimental study. The participants were distributed into exercise and control group. Each group was categorized into three subgroups: low(Lf), moderate(Mf) and high(Hf) fitness group based on the quartile of baseline 6-minute walk test (6MWT) performance. Exercise group received 3 sessions of supervised exercise class (1 session/month) and 12-week home-based exercise program. Each exercise educational class contained the warm up, cardiopulmonary fitness training, strengthening and balance training for 40 minutes. Control group received only one exercise consultation session during the first visit. Outcome measures include the body composition, muscle strength, (6MWT), gait speed, flexibility, and Berg balance scale(BBS). Measurement was conducted at baseline and the 12<sup>th</sup> week.

**RESULTS:** Eighty five mild stroke patients were recruited: 42 in exercise group and 43 in control group. There were 71 males and 14 females; with mean age 62.8±9.5yrs. After 12 weeks, the exercise group demonstrated greater improvements than the control group on most physical fitness measure. The exercise program seemed to have more positive effects in Mf group than the LF and HF groups, including waist circumference (↓1.89 vs. ↑0.38cm,  $p = 0.01$ ), 6MWT (↑97.8 vs. ↓30.6m,  $p = 0.001$ ), 10 meter walk time (↓1.84 vs. ↓0.04sec,  $p < 0.001$ ), upper limb muscle strength index (lb/kg, ↑0.41 vs. ↓0.12,  $p < 0.001$ ), lower limb muscle strength index (lb/kg, ↑0.73 vs. ↓0.22,  $p = 0.001$ ) and BBS (↑1.64 vs. ↓0.14,  $p = 0.04$ ).

**CONCLUSIONS:** Supervised exercise class combined with home exercise program potentially improved physical fitness for mild stroke outpatient, especially in Mf group. The result may attribute to that (1) Lf group may have more disabilities that affect them to participate in the exercise; (2) the exercise intensity is not enough for the Hf group. More studies are recommended to find out the individualized prescription for patients with different fitness.

1662 Board #70 May 30 2:00 PM - 3:30 PM

**Improvements in Lipoprotein Subfractions and Oxidized Low-Density Lipoprotein Following Lifestyle Intervention in Obese Latino Adolescents**

Justin R. Ryder<sup>1</sup>, Sonia Vega-Lopez<sup>1</sup>, Rocio Ortega<sup>1</sup>, Darwin Tsinajinnie<sup>2</sup>, Dawn Coletta<sup>2</sup>, Gabriel Shaibi<sup>1</sup>. <sup>1</sup>Arizona State University, Phoenix, AZ. <sup>2</sup>Mayo/ASU, Tempe, AZ.

(No relationships reported)

**PURPOSE:** The distribution of cholesterol among different low-density lipoprotein (LDL) and high-density lipoprotein (HDL) subfractions, in conjunction with oxidized LDL concentrations are novel biomarkers of cardiovascular disease risk. These measures may be more responsive to lifestyle changes than traditional cholesterol measures and may give light to early alterations in the atherogenesis process. Whether these measures can be improved through diet and exercise in high-risk populations of youth has not been established. Therefore, the purpose of this study was to examine the impact of a lifestyle intervention on the distribution of cholesterol among LDL and HDL subfractions as well as oxidized LDL in a sample of high-risk Latino adolescents.

**METHODS:** Fifteen (7 male; 8 female) obese (BMI percentile = 96.4 ± 4.5) Latino adolescents (15.0 ± 1.0 years) completed a 12-week lifestyle intervention that included weekly nutrition education classes and 180 minutes of moderate to vigorous exercise per week (3 X 60 minute sessions). Fasting blood samples were collected at baseline and 12-week follow-up. The distribution of cholesterol in HDL and LDL subfractions was measured via polyacrylamide gel electrophoresis and oxidized LDL was quantified via competitive enzyme-linked immunosorbent assay. Paired sample t-tests were used to determine difference ( $p < 0.05$ ) between baseline and 12-week post-intervention.

**RESULTS:** The intervention resulted in an increase in mean LDL-particle size (269.3 ± 0.9 to 271.6 ± 0.7Å,  $p = 0.0003$ ), a 65.6% decrease in the amount of total cholesterol in the more atherogenic small LDL particles (1.6 ± 0.5 to 0.6 ± 0.3%,  $p = 0.007$ ), a 19.6% increase in the amount of HDL cholesterol in the more antiatherogenic large HDL particles (22.4 ± 2.9 to 26.8 ± 2.7%,  $p = 0.007$ ) and a 21.8% decrease in oxidized LDL (58.7 ± 10.3 to 45.9 ± 17.5U/L,  $p = 0.001$ ). The improvements in lipoprotein subfractions and oxidized LDL were observed in the absence of significant weight loss (90.7 ± 6.8 to 89.9 ± 7.2kg).

**CONCLUSIONS:** These findings suggest that lifestyle interventions may improve the cardiovascular health of high-risk youth by shifting the lipoprotein profile towards a less atherogenic phenotype. These measures should be considered as potential targets for determining the success of prevention programs in the future.

1663 Board #71 May 30 2:00 PM - 3:30 PM

**Effects Of High-intensity Task-oriented Training On Energy-cost Of Walking And Walking Capacity In Subacute Stroke.**

Jacqueline Outermaans<sup>1</sup>, Ingrid van de Port<sup>2</sup>, Harriet Wittink<sup>1</sup>. <sup>1</sup>Hogeschool Utrecht University of Applied Sciences, Utrecht, Netherlands. <sup>2</sup>Centre of Excellence for Rehabilitation Medicine Utrecht, Utrecht, Netherlands.

(No relationships reported)

Patients with stroke have reduced aerobic capacity, but also use more energy during walking. While decreased aerobic capacity can limit a person's ability to perform activities, higher energy-cost of the activities a person performs, caused by decreased motor control, may also limit the ability to function for a prolonged period of time. Physical therapy is therefore often aimed at improving aerobic capacity and optimizing gait economy. Previous studies suggest that a task-oriented training paradigm is beneficial to improve walking ability.

**PURPOSE:** To investigate the effects of high-intensity task-oriented training on the energy-cost of walking and walking capacity in patients with subacute stroke compared to a low-intensity physical therapy program.

**METHODS:** Forty-four patients with stroke were included in this randomized controlled trial at 2 to 8 weeks post stroke. The high-intensity training incorporated a high aerobic workload during 4 weeks. Energy-cost of walking was calculated using the Physiological Cost Index (PCI) in heartbeats/meter. Heart rate was measured with a Polar Heart Monitor during the 6 Minute Walk Test (6MWT). Walking capacity was assessed using the distance covered during the 6MWT. Between group differences were analyzed using the Students T-test.

**RESULTS:** Differences between groups on baseline were not significant. Energy-cost of walking decreased by 0.01 beats/meter in the high-intensity group but increased by 0.03 beats/meter in the low-intensity group. Analysis showed a non-significant difference in favor of the high-intensity task-oriented training for the PCI ( $p = 0.43$ ). Significant differences in favor of the high-intensity group were found for the distance covered during the 6MWT ( $p = 0.02$ ). The high-intensity group showed an increase on post intervention assessment of 59 m. (mean 460 m. to 519 m.), whereas the low-intensity group only showed an increase of 21 m. (mean 401 m. to 422 m.).

**CONCLUSIONS:** The effectiveness of a high-intensity task-oriented training program exceeds a low-intensity physical therapy-program in terms of walking capacity in patients with subacute stroke. There is a trend for a positive effect on energy-cost of walking. In a future larger sample study more responsive measures to evaluate energy-cost of walking should be used in a longer intervention.

**Effects of Circuit Training Workout or Walking Exercise on Diabetic-Hypertensive Elderly Subjects**

Waléria Christiane R. Fett, Rosilene Andrade S R RAS Rodrigues, Fabrício A. Voltarelli, Conceição de Maria M. Carvalho, Giulia Schauffert, Adilson R. Filho, Carlos A. Fett. *Federal University of Mato Grosso, Cuiabá-MT, Brazil.*  
(No relationships reported)

**PURPOSE:** The arterial blood pressure (ABP) and glycaemia can be controlled by the combination of regular physical exercise (PE) and drugs. There are different types of PE, for instance, continuous and intermittent exercises. It is known that the prescription of circuit training workout intermittent exercise (CTW) for the elderly is not common. Thus, the aim of the present study was to verify the acute (before and after a single session of PE) and chronic (after 12 weeks of training) effects of CTW or walking exercise training (WET) on capillary glucose (CG), arterial blood pressure, and physical fitness of elderly women.

**METHODS:** Twenty-three diabetic-hypertensive subjects, who were medicated with beta-blockers or angiotensin-converting enzyme inhibitor, were subjected to WET (n = 9) and to CWT (n = 14) three times a week, intensity of 40 to 60% of maximum heart rate, and 11 to 13 scores related to Borg scale. The CG concentration was determined by a portable glucometer (ONE TOUCH®). In order to measure the ABP, we used a sphygmomanometer and an arm stethoscope. The comparison between the pre and post intervention was made by paired Student's t test ( $P \leq 0.05$ ).

**RESULTS:** After acute bout of CWT and WET, the CG concentration (mg/dL) was reduced from  $103 \pm 12$  to  $91 \pm 12$  and from  $98 \pm 11$  to  $91 \pm 10$ , respectively. In relation to chronic exercise, it was also observed reductions in CG concentrations, being: CWT: from  $92 \pm 12$  to  $84 \pm 10$ ; and WET: from  $97 \pm 10$  to  $86 \pm 6$  ( $P \leq 0.05$ ). The systolic blood pressure (SBP; mmHg) increased after acute CWT (from  $127 \pm 12$  to  $121 \pm 11$  ( $p \leq 0.05$ ), and decreased after WET (from  $143 \pm 11$  to  $133 \pm 17$ ); whereas, in the last case, no statistical difference was observed.

**CONCLUSIONS:** The both types of exercise (CWT and WET [both acute and chronic]) contributed to reduced capillary glucose as well as improved glucose metabolism, once, probably, increased the glucose uptake from skeletal muscle cells. In addition, both CWT and WET subjects had positive adherence to the program; this occurrence is suggested to be an important part of the elderly diabetic-hypertensive treatment.

1665 Board #73 May 30 2:00 PM - 3:30 PM

**Effect Of STEPTM And Home Monitoring In Rural Primary Care On Blood-pressure Metabolic Syndrome**

Kristin Sabourin<sup>1</sup>, Melanie I. Stuckey<sup>1</sup>, Sheree Shapiro<sup>1</sup>, Claudio Munoz<sup>2</sup>, Robert J. Petrella<sup>3</sup>. <sup>1</sup>University of Western Ontario, London, ON, Canada. <sup>2</sup>Gateway Rural Health Research Institute, Seaforth, ON, Canada. <sup>3</sup>Lawson Health Research Institute, London, ON, Canada.  
(No relationships reported)

Adults with metabolic syndrome (MetS) are at a high risk for developing type II diabetes and cardiovascular disease (CVD). As well, rural populations have lower access to lifestyle modifications (recreational centres) to manage this condition. MetS is a clustering of risk factors that increase the risk of CVD. The first line of therapy for MS is lifestyle intervention that includes aerobic activity. Aerobic activity is known to have a blood pressure (BP) lowering affect in those with MetS, and subsequently targets another prominent CVD risk factor (hypertension).

**PURPOSE:** To evaluate the effect of a 6 month exercise intervention at the primary care level in conjunction with home BP monitoring technology to decrease risk factors of CVD and type II diabetes in adults with MetS.

**METHODS:** Adults with MetS (n=64; mean age=56.4 years; 71.6% female) were recruited from rural southwestern Ontario and reported to the rural family health clinic for three visits (baseline, V0; 3 months, V1; 6 months, V2). At each visit, resting BP was measured, waist circumference (WC) was measured, a predictive fitness (VO<sub>2</sub>max) test was offered and exercise was prescribed using the Step Test Exercise Prescription (STEPTM). Home-monitoring technology included a BlackberryTM and a BP monitor.

**RESULTS:** Clinic systolic BP (SBP; mmHg) showed a decrease from V0 ( $141.9 \pm 19.4$ ) to V2 ( $133.1 \pm 13.3$ ;  $p < 0.001$ ) and home SBP followed the same pattern decreasing from  $129.4 \pm 16.3$  at V0 to  $124.4 \pm 12.9$  at V2 ( $p = 0.001$ ). Clinic diastolic BP (DBP; mmHg) showed significant decreases from V0 ( $86.8 \pm 10.9$ ) to V1 ( $83.8 \pm 10.5$ ;  $p < 0.01$ ) and continued to decrease into V2 ( $81.5 \pm 9.7$ ;  $p < 0.05$ ). Home DBP showed the same pattern as clinic DBP, decreasing from  $83.4 \pm 10.3$  at V0 to  $81.5 \pm 9.2$  at V1 ( $p < 0.05$ ) and continuing to decrease to  $79.8 \pm 9.1$  at V2 ( $p < 0.01$ ). VO<sub>2</sub>max (ml/kg/min) increased from V0 to V1 ( $30.9 \pm 7.3$  to  $32.3 \pm 7.3$ ;  $p = 0.01$ ) and remained elevated into V2. WC (cm) showed a decrease from V0 ( $105.1 \pm 13.0$ ) to V1 ( $102.9 \pm 12.4$ ;  $p < 0.01$ ) and continued to decrease into V2 ( $100.7 \pm 12.0$ ;  $p < 0.001$ ).

**CONCLUSIONS:** A lifestyle intervention in primary care using STEPTM with home BP monitoring technology decreased both SBP and D BP at home and in the clinic as well as increased fitness and decreased WC in adults from rural communities with MetS. Supported by CIHR Grant #CCT-83029

1666 Board #74 May 30 2:00 PM - 3:30 PM

**Nationwide Prevalence of Ideal Cardiovascular Health and Relationship with Cardiovascular Disease and All-Cause Mortality**

Samuel S. Lee, Chong-Do Lee, FACSM. *Arizona State University, Phoenix, AZ.*  
(No relationships reported)

The American Heart Association recently defined 7 ideal health metrics setting a goal to improve the cardiovascular health of Americans by 20% by 2020. However, the prevalence of ideal cardiovascular health for U.S. adults and its relationship with cardiovascular disease (CVD) and all-cause mortality remain less explored.

**PURPOSE:** We estimated the nationwide prevalence of ideal cardiovascular health (i.e., ideal levels of all 7 factors) and the combined effects of 7 ideal health metrics and CVD and all-cause mortality in U.S. men and women.

**METHODS:** We followed 15,801 men and women, ages 20-89 years, who completed a health and medical evaluation from the Third National Health and Nutrition Examination Survey. We classified all participants as ideal, intermediate, and poor categories of health behaviors (not smoking, BMI, physical activity, healthy diet) and health factors (total cholesterol, blood pressures, glucose), respectively. They were further categorized as having 0 to 7 combined ideal health metrics.

**RESULTS:** Approximately 0.8% had ideal cardiovascular health, and 11.8% had intermediate and 87.4% had poor cardiovascular health. During an average of 13.7 years of follow-up, there were a total of 1,343 CVD deaths and 3,251 all-cause deaths. After adjustment for age, sex, race, alcohol intake, education, poverty-income ratio, and family history of CVD, there was a strong inverse association between the number of ideal health metrics and CVD and all-cause mortality ( $P$  for trend  $< 0.001$ ). The hazard ratios (95% CI) of CVD events across 0, 1, 2, 3, 4, 5, 6, 7 combined ideal health metrics were: 1.00 (reference), 0.79 (0.67, 0.92), 0.69 (0.59, 0.81), 0.63 (0.53, 0.75), 0.45 (0.36, 0.57), 0.36 (0.25, 0.53), 0.32 (0.16, 0.62), and 0.0 (no events). Approximately 64% (95% CI, 48%-75%) of total CVD deaths might have been avoided if men and women had maintained intermediate or ideal cardiovascular health. Men and women with poor cardiovascular health compared with intermediate or ideal cardiovascular health had a shorter life expectancy by 9.1 years (95% CI, 5.7-12.2 years).

**CONCLUSIONS:** The prevalence of ideal cardiovascular health is extremely low in U.S. men and women. We need to increase healthy low-risk populations at the population and individual levels using the primordial prevention, which is a key to CVD prevention.

1667 Board #75 May 30 2:00 PM - 3:30 PM

**Maintaining Healthy Lifestyles and Risk of Cardiovascular Disease and All-Cause Mortality in Men**

Chong-Do Lee, FACSM<sup>1</sup>, Xuemei Sui<sup>2</sup>, Samuel S. Lee<sup>1</sup>, Steven P. Hooker, FACSM<sup>1</sup>, Steven N. Blair, FACSM<sup>2</sup>. <sup>1</sup>Arizona State University, Phoenix, AZ. <sup>2</sup>University of South Carolina, Columbia, SC.  
(No relationships reported)

The long-term effect of maintaining healthy lifestyles on cardiovascular disease and all-cause mortality in U.S. population has not been thoroughly explored.

**PURPOSE:** We examined the effects of maintaining healthy lifestyle factors (i.e., not smoking, moderate or high fitness, and normal waist girth) over 16 years on cardiovascular disease (CVD) and all-cause mortality in U.S. men.

**METHODS:** We identified a total of 5,330 men, ages 20-78 years, who had completed two preventive medical examinations between 1970 and 2001 (mean interval between examinations, 4.9

years) in the Aerobics Center Longitudinal Study. We followed these participants from the second examination to the date of death or through December 31, 2003. A low-risk profile was defined as not smoking, moderate or high fitness, and normal waist girth; and they were further categorized as having 0, 1, 2, or 3 combined low-risk factors in both examinations. A healthy lifestyle group was defined as those participants who had maintained 3 combined low-risk factors at both examinations, whereas an unhealthy lifestyle group was defined as those participants who had maintained "0, 1, or 2" combined low-risk factors in both examinations.

**RESULTS:** During an average of 11.4 years of follow-up, there were a total of 62 CVD deaths and 216 all-cause deaths. After adjustment for age, examination year, and baseline multiple risk factors (i.e., alcohol intake, high density lipoprotein cholesterol and total cholesterol levels, diabetes mellitus, systolic blood pressure, history of hypertension, family history of CVD, and interval between examinations in years), men who maintained a healthy lifestyle had a 52% lower risk of CVD (95% CI, 11%-74%) and a 38% lower risk of all-cause mortality (95% CI, 16%-55%) compared with men with an unhealthy lifestyle. Men with a healthy lifestyle had an 8.2-year (95% CI: 4.1-10.6) longer life expectancy as compared with men with an unhealthy lifestyle. Approximately 40% (95% CI, 13%-58%) of CVD deaths might have been avoided if the men had maintained a healthy lifestyle over 16 years.

**CONCLUSIONS:** Maintaining a healthy lifestyle for long-term is associated with lower risk of CVD and all-cause mortality in men. Comprehensive nationwide primordial prevention efforts are needed to support the attainment of healthy lifestyles for lifetime.

**1668** Board #76 May 30 2:00 PM - 3:30 PM

**Exercise Capacity, Left Ventricular Hypertrophy and Mortality**

Peter Kokkinos, FACSM, Charles Faselis, Eric Nylen, Raya Kheirbek, Helen Sheriff, John Peter Kokkinos, Lauren Korshak. *Veterans Affairs Medical Center, Washington, DC.*

(No relationships reported)

Left ventricular hypertrophy (LVH) is an independent risk factor for mortality. Exercise capacity is inversely associated with lower mortality risk and lower left ventricular mass (LVM). The association between exercise capacity and LVM has not been adequately studied.

**PURPOSE:** Assess the association between LVH, exercise capacity and mortality risk.

**METHODS:** Exercise capacity and echocardiographic evaluations were performed in 1,467 men (age: 61±12) at the V.A. Medical Center, Washington, DC. We established three fitness categories based on the

MET level achieved. Low-Fit: Peak MET level within the 25<sup>th</sup> percentile (n=311); Moderate-Fit: MET levels between the 26<sup>th</sup> and 75<sup>th</sup> percentile (n=770); and High-Fit: MET levels > 80<sup>th</sup> percentile (n=386). LVM was calculated by a standardized formula (Penn) and was indexed to body size.

**RESULTS:** For every 1-MET increase in exercise capacity the risk of LVH was lowered by 15% (HR=0.85; CI: 0.78-0.91). After adjusting for age and BP, mortality risk was 49% (HR=0.51; CI: 0.36-0.73) and

67% (HR=0.33; CI: 0.18-0.61) lower for Moderate and High-fit individuals with LVH compared to Low-fit. To further explore the fitness-mortality association, we assessed the mortality risk individuals with low fitness and no LVH and compared them to moderate and high-fit individuals with LVH. Mortality rate for High-fit individuals with LVH was 38% lower when compared to those without LVH, but unfit (Table).

**CONCLUSIONS:** An inverse and graded association was noted between exercise capacity and mortality risk in those with and without LVH. Mortality risk was significantly reduced in those with LVH but fit when

compared to those without LVH, but Unfit. Thus, it is better to be fit and have LVH than unfit and no LVH.

Mortality Risk According to Fitness and LVH

|          | Low-Fit/No LVH      | High-Fit/No LVH    | Low-Fit/LVH         | High-Fit/LVH |
|----------|---------------------|--------------------|---------------------|--------------|
| Referent | 0.42<br>(0.31-0.57) | 1.16<br>(0.85-1.6) | 0.62<br>(0.45-0.86) |              |

**1669** Board #77 May 30 2:00 PM - 3:30 PM

**Effect Of An Office Worksite-based Yoga Program On Heart Rate Variability: A Randomized Controlled Trial**

Birinder Cheema<sup>1</sup>, Angeliqe Houridis<sup>1</sup>, Lisa Busch<sup>1</sup>, Verena Raschke-Cheema<sup>1</sup>, Geoff Melville<sup>1</sup>, Paul Marshall<sup>1</sup>, Dennis Chang<sup>1</sup>, Bianca Machliss<sup>2</sup>, Chris Lonsdale<sup>1</sup>, Julia Bowman<sup>1</sup>, Ben Colagiuri<sup>3</sup>. <sup>1</sup>University of Western Sydney, Campbelltown, NSW, Australia. <sup>2</sup>Yoga Synergy Pty, Bondi Junction, Australia. <sup>3</sup>University of New South Wales, Kensington, NSW, Australia.

(No relationships reported)

Chronic work-related stress is an independent risk factor for cardiometabolic diseases and associated mortality, particularly when compounded by a sedentary work environment.

**PURPOSE:** To determine if an office worksite-based yoga program could improve physiological stress, evaluated via heart rate variability (HRV), and physical and psychological health outcomes.

**METHODS:** Thirty-seven healthy adults employed in university-based office positions were randomized upon the completion of baseline testing to an experimental or control group. The experimental group completed a 10-week yoga program, prescribed three sessions per week during lunch hour (50 min per session). An experienced instructor led the sessions, which involved asanas (postures), vinyasa (exercises), pranayama (breathing exercise) and meditation. The primary outcome was the high frequency (HF) power component of HRV. Secondary outcomes included additional HRV parameters (i.e. low frequency (LF) and total power, and LF:HF), musculoskeletal fitness (i.e. push-up, side-bridge, and sit & reach tests) and psychological indices (i.e. state and trait anxiety, quality of life and job satisfaction).

**RESULTS:** Thirty-four participants, 17 per group, completed the study and were included in per protocol analyses. Measures of HRV all failed to change in the experimental group versus the control group, except that the experimental group significantly increased LF:HF versus control (p=0.04), contrary to our hypothesis. Flexibility, evaluated via sit & reach test increased in the experimental group versus the control group (p<0.001). No other adaptations were noted. Post hoc analysis comparing participants who completed ≥70% of yoga sessions (n=11) to control (n=17) yielded the same findings, except that the high adherers also reduced state anxiety (p=0.04) and tended to reduce HF power (p=0.07) and increase push ups (p=0.11).

**CONCLUSIONS:** A 10-week yoga intervention delivered at the office worksite during lunch hour did not improve HF power or other HRV parameters. However, improvements in flexibility, state anxiety and musculoskeletal fitness were noted with high adherence. Future investigations should involve more frequent and longer durations of yoga training, and cohorts who suffer from high work-related stress.

**1670** Board #78 May 30 2:00 PM - 3:30 PM

**The Effects of Intermittent Hypoxic Exposure on Heart Rate Variability in a Sedentary Population.**

Catherine A. Lizamore<sup>1</sup>, Yasotha Kathiravel<sup>2</sup>, John M. Elliott<sup>3</sup>, John Hellemans<sup>2</sup>, Michael J. Hamlin<sup>1</sup>. <sup>1</sup>Lincoln University, Lincoln, New Zealand. <sup>2</sup>Active Health, Christchurch, New Zealand. <sup>3</sup>University of Otago, Christchurch, Christchurch, New Zealand.

(No relationships reported)

Heart rate variability (HRV) is a reliable, non-invasive means of predicting future cardiovascular health. Increased HRV is associated with increased physical fitness, while lower HRV is indicative of future cardiovascular disease. Recent research has suggested that intermittent hypoxic exposure (IHE) may enhance exercise tolerance in unhealthy adults, however, little is known about the effects of IHE on HRV in a middle aged, sedentary population.

**PURPOSE:** To examine the effects of 4 weeks of IHE on HRV in a middle aged, sedentary population.

**METHODS:** Sixteen participants (5 male, 11 female, aged 56.3±5.1 years, BMI 28.9±6.2, mean±SD) were exposed to 16 IHE sessions [IHE: 5 min normobaric hypoxia (FIO<sub>2</sub> = 0.16 at week 1, decreasing to FIO<sub>2</sub> = 0.10 at week 4); 5 min ambient air, repeated for 1 hour, n=8] and [Control (C): 5 min placebo (FIO<sub>2</sub> = 0.21); 5 min ambient air, repeated for 1 hour; n=8]. Arterial blood pressure (BP), HRV and oxygen consumption (VO<sub>2</sub>) were monitored during lying (last 5 min of a 10 min period), standing, sub-maximal exercise (75% of age predicted HR<sub>max</sub>) and recovery (last 3 min of a 5 min period) pre- and post- intervention.

**RESULTS:** Relative to the control group the IHE group decreased lying HR by 9.1 ± 8.3% (mean ± 90% confidence limits) [IHE: 59.2 ± 6.1 to 56.8 ± 6.2 beats/min; and C: 64.6 ± 11.0 to 66.2 ± 9.2 mean ± SD beats/min for the pre and post groups respectively]. Standing HR decreased by 6.8 ± 8.6% in the IHE compared to the control group (IHE: 70.8 ± 5.7 to 68.8 ± 4.9 beats/min, C: 74.7 ± 15.2 to 75.2 ± 12.6 beats/min). HRV (rMSSD) increased in the IHE group relative to the C group during lying (76.8 ± 67.0%; IHE: 32.51 ± 15.12 to 35.95 ± 12.07 rMSSD; C: 21.04 ± 8.75 to 20.35 ± 9.54 rMSSD) and exercise (23.2 ± 27.7%; IHE: 4.13 ± 1.86 to 5.08 ± 2.96; C: 4.64 ± 3.84 to 4.06 ± 2.58; rMSSD; mean ± SD beats/min for the pre and post groups). There were no changes between groups in resting BP or VO<sub>2</sub>, standing or recovery HRV.

**CONCLUSIONS:** These findings suggest 16 IHE sessions in a sedentary population may improve resting HRV and HR, but has little effect on resting BP or submaximal VO<sub>2</sub>. As HRV is generally associated with improved health, this may prove beneficial for patients unable to engage in more traditional physical activity. More research with a larger population is needed to test these findings.

1671 Board #79 May 30 2:00 PM - 3:30 PM

### Cardiovascular Health Benefits Of Moderate-To-Vigorous And Vigorous Physical Activity In Healthy Adolescents

Thomas Radtke<sup>1</sup>, Susi Kriemler<sup>2</sup>, Kerstin Khattab<sup>1</sup>, Hugo Saner<sup>1</sup>, Matthias Wilhelm<sup>1</sup>. <sup>1</sup>University Hospital and University of Bern, Inselspital, Bern, Switzerland.

<sup>2</sup>Institute of Social and Preventive Medicine, University of Basel, Basel, Switzerland.

(No relationships reported)

**PURPOSE:** Physical activity (PA) is inversely associated with clustering of cardiovascular disease (CVD) risk factors in children and adolescents. We examined the impact of PA on surrogate markers of cardiovascular health in healthy adolescents.

**METHODS:** In a prospective, cross-sectional study, 52 adolescents (28 females, mean age 14.5 ± 0.7 years, BMI 20.1 ± 2.5 kg/m<sup>2</sup>) were investigated. Microvascular function was assessed by peripheral arterial tonometry to determine the reactive hyperemic index (RHI). Autonomic tone was assessed by time-domain analysis of heart rate variability and vagal activity was measured using the root mean square of successive normal-to-normal intervals (RMSSD). Cardiopulmonary exercise testing was performed to determine peak oxygen uptake (VO<sub>2peak</sub>) and maximum power output. PA was assessed by accelerometry for 8 consecutive days. We applied two different models and dichotomized the cohort into two activity groups (low vs. high) based on the daily time spent in moderate-to-vigorous PA (MVPA, 3000-5200 counts.min<sup>-1</sup>, model 1) and vigorous PA (VPA, >5200 counts.min<sup>-1</sup>, model 2). Data were adjusted for age, sex, skinfold, and pubertal status.

**RESULTS:** In a multivariate regression analysis MVPA was an independent predictor for RMSSD (beta=0.416, P=0.022), and VPA was independently associated with maximum power output (beta 0.310, P=0.009). In model 1, the high MVPA group exhibited a higher vagal tone (RMSSD 49.9±12.9 vs. 38.4±12.4 ms, P=0.006) and a lower systolic blood pressure (106.7±9.8 vs. 113.2±7.0 mmHg, P=0.031). In comparison, in model 2, the high VPA group had higher maximum power output values (3.8±0.6 vs. 3.5±0.6 watt kg<sup>-1</sup>, P=0.010). In both models, no significant differences were observed for RHI, VO<sub>2peak</sub> and body composition.

**CONCLUSIONS:** In healthy normalweight adolescents, PA intensity reveals different beneficial effects on cardiovascular health-related parameters. In particular, MVPA had favourable effects on vagal tone and systolic blood pressure, whereas VPA contributes to an improvement in exercise capacity.

### Effects Of Exercise On Postural Balance And Mobility In Rural And Urban-dwelling Elderly Adults

Justus D. Ortega, Sarah A. Landis. *Humboldt State University, Arcata, CA.*

(No relationships reported)

The increased risk of falling among the elderly is closely associated with reduced postural stability and impaired walking performance. Strength and balance exercise has been shown to improve balance, mobility, and reduce fall risk in urban-dwelling elderly adults. However, it remains unclear whether such exercise programs are as effective among elderly adults living in rural communities.

**PURPOSE:** To determine the effect of a combined strength and balance exercise program and unstructured exercise on postural balance and mobility in rural-dwelling (RD) and urban-dwelling (UD) elderly adults.

**METHODS:** A cross-sectional analysis of postural balance and physical performance measures from 106 elderly adults (mean age 778.2 yrs) including 43 RD (23 structured exercisers, 9 unstructured exercisers, and 11 sedentary) and 47 UD (30 structured exercisers, 9 unstructured exercisers, and 8 sedentary) adults was performed. Postural balance was assessed using single limb balance and modified CTSIB tests. Mobility was assessed using Timed "Up and Go" (TUG), 20 meter walking performance (WP), and chair stand (CS) tests. We determined the effects of exercise and dwelling location on balance and mobility using a 2 X 3 MANOVA.

**RESULTS:** For RD and UD elderly adults, structured exercisers performed 64.7% (p=0.009), 28.8% (p=0.005), and 63.8% (p=0.005) better on the TUG, WP, and CS, respectively, compared to the sedentary group. Although there was no main effect of living location on balance and mobility measures (p=0.073), living location and exercise groups had an interactive effect on balance and mobility (p=0.048). For RD elderly, mobility test scores for the sedentary group (WP 6.5 s, TUG 12.7 s, CS 15.1 s) were similar to both exercise groups (WP 5.5 s, TUG 10.8 s, CS 11.0 s). However, UD sedentary elderly adults exhibited greater times for all mobility measures compared to their exercising counterparts (WP 8.20 vs. 5.07 s, TUG 15.6 vs. 9.41 s, CS 19.6 vs. 10.80 s; respectively).

**CONCLUSIONS:** Among both RD and UD elderly, exercise performed in an organized strength and balance class or independently improves mobility. Moreover, RD sedentary elderly exhibit greater mobility as compared to their UD counterparts, possibly due to a higher demand from activities of daily living associated with a rural environment.

1673 Board #81 May 30 2:00 PM - 3:30 PM

### Effects Of A 15 Week Exercise Intervention On Postural Control Components In Community Dwelling Older Adults

Forest L. Melton, Pooja Mehta, Christopher Ray. *The University of Texas at Arlington, Arlington, TX.*

(No relationships reported)

1 in 3 older adults will experience a fall each year. Falls are the leading cause of accidental death in adults over 65 years, and are the leading cause of nonfatal injuries and hospital admissions for trauma. Falls often lead to adverse changes in confidence and lifestyle that trigger a cyclical decline in health and postural control. Postural control can be broken down into its component systems: visual, somatosensory, and vestibular. Decreased fitness is known to negatively affect postural control.

**PURPOSE:** To analyze the impact of a traditional group fitness program (fitness) and a Wii exercise program (fitness + cognition + visual) on individual's component postural control systems.

**METHODS:** 89 community dwelling seniors were randomized into 1 of 3 groups (Control, Wii-Fit, Traditional Group-Fit). Interventions were delivered 3 times per week, for 15 weeks. Neurocom SOT was used to assess postural control before and after the intervention.

**RESULTS:** The Wii-Fit group showed significant improvement in their vestibular and visual components after 15 weeks of exercise. There was a significant difference between pre vestibular scores (0.70 ± 0.17) and post vestibular scores (= 0.75 ± 0.16), p=0.006. The visual scores showed a significant difference between pre (0.80 ± 0.16) and post (0.87 ± 0.07), p=0.011 as well. There was no significant improvement in somatosensory scores. The traditional exercise group did improve significantly in pre (0.84 ± 0.08) and post (0.87 ± 0.06) scores for vision, p=.002. However, they did not improve significantly in vestibular or somatosensory components. The control group did not show any significant improvements in any components.

**CONCLUSIONS:** Results indicated that both intervention programs were successful at improving postural control. It appears the most amendable component to postural control is the visual system, as both groups showed significant improvement. Additionally, interventions that include virtual environments have a greater impact on the vestibular system than traditional exercise programs. This may be due to the added head movement, eye tracking, and cognitive stimulation inherent in gaming. This further elucidates how different exercise programs targeting older adults affect specific components of postural control.

1674 Board #82 May 30 2:00 PM - 3:30 PM

**Effect of Tai Chi on Physical Function during Dietary Weight Loss in Obese, Older Women**

Marisa C. Benson, Lynn A. Katkowski, Steven Magnanti, Furong Xu, Ingrid E. Lofgren, Matthew J. Delmonico. *University of Rhode Island, Kingston, RI.*  
(No relationships reported)

**BACKGROUND:** The increased prevalence of obesity-related disability and loss of physical function is a major public health problem, especially in older women. Research has shown that obesity and declines in physical functioning are preventable and treatable via regular physical activity. Tai Chi, a low-impact martial art, is an alternative exercise modality that shows promise as an intervention strategy to improve physical function. Nonetheless, the addition of Tai Chi exercise to dietary weight loss has not been examined in obese older women.

**PURPOSE:** The purpose of this study was to study the effects of Tai Chi during dietary weight loss on measures of physical function.

**METHODS:** A 16 week intervention was performed in 27 obese (BMI =  $34.6 \pm 4.1$  kg/m<sup>2</sup>) women randomized to either a Tai Chi during weight loss (TCWL, (n = 14, age =  $60.4 \pm 5.9$  yrs) or weight loss only group (WL, n = 13, age =  $62.7 \pm 6.0$  yrs). Both groups completed one weekly 45 minute dietary session based on a modified Dietary Approaches to Stop Hypertension diet, while the TCWL group completed three, 45 minute session of a modified Yang style Tai Chi per week. Body mass was measured using a balance beam scale and height via a stadiometer. Outcome measures included 400 meter walk, short physical performance battery (SPPB), timed up and go (TUG), seated sit and reach, grip and leg strength. Between-group comparisons for changes were done using analysis of covariance (ANCOVA) adjusted for baseline values.

**RESULTS:** There was a decrease in body mass in the TCWL ( $-2.2 \pm 0.9$  kg, p = 0.033) and WL ( $-3.7 \pm 0.9$  kg, p < 0.001) groups, but there were no between-group differences. The TCWL group had significant improvements in flexibility whereas the WL group did not ( $5.4 \pm 8.9$  cm, p = 0.041 vs.  $2.5 \pm 6.6$  cm, p = 0.198;  $2.72 \pm 3.13$  cm, p = 0.393) and leg strength ( $39.6 \pm 67.2$  N, p = 0.046 vs.  $10.5 \pm 42.5$  N, p = 0.390;  $36.8 \pm 18.8$  N, p = 0.062). The WL group worsened in their TUG time ( $1.03 \pm 1.0$  sec, p = 0.003) but the TCWL group did not ( $0.48 \pm 0.93$  sec, p = 0.075;  $-0.57 \pm 0.30$  sec, p = 0.069). There were no significant differences between groups in 400 meter walk time, SPPB, and grip strength changes.

**CONCLUSIONS:** Tai chi did not have a significant additive effect on most global measures of physical function but may increase leg strength during dietary weight loss in obese older women.

**Can Yoga Improve Balance Performance in Older adults?**

Man-Ying Wang<sup>1</sup>, Shin-Yuan Yu<sup>1</sup>, Michelle Haines<sup>1</sup>, Rami Hashish<sup>1</sup>, Sachithra Samarawickrame<sup>1</sup>, Gail Greendale<sup>2</sup>, George Salem, FACSM<sup>1</sup>. <sup>1</sup>*University of Southern California, Los Angeles, CA.* <sup>2</sup>*University of California at Los Angeles, Los Angeles, CA.*  
(No relationships reported)

Falling is a significant contributing factor to morbidity and mortality in older adults. Improving the ability to modulate postural sway and control center of mass (COM) during static and dynamic tasks may reduce fall risk.

**PURPOSE:** To study the effects of a 32-week Hatha Yoga intervention on static and dynamic balance performance in healthy older adults.

**METHODS:** Twenty older adults (70.6  $\pm$  3.8 yrs) participated in a yoga program, twice per week, for 32 weeks. Static sway was assessed under double-legged stance conditions with eyes open and eyes closed and dynamic balance was evaluated during normal walking. Reflective markers were placed on the subject's bony landmarks (head, trunk, pelvis, upper extremities, and lower extremities) and recorded by an 11-camera motion capture system. Tri-planar COM positions were estimated using a 15-segment, rigid mathematical model based on motion capture data and body mass. Coordinates of the center of pressure (COP) were obtained via force platforms. Outcome variables for static sway measurement were average displacement and normalized area of sway of COP. Outcome variables of dynamic balance included displacement, velocity, and acceleration of COM in X, Y, and Z axes and maximum COM-COP separations in the horizontal plane. Paired t-tests and covariate analyses were used to detect significant differences in these variables following the 32-week Yoga intervention.

**RESULTS:** There were no statistically significant differences in static sway measures after the intervention. Conversely, COM acceleration and COM-COP separation in the anteroposterior direction were significantly smaller than those at the baseline ( $-16.8\%$ , p < .01;  $-17.6\%$ , p < .001; respectively), even after adjusting for the walking speed. Moreover, the average COM-COP separation decreased significantly by 15.9% following the Yoga intervention (p < .001).

**CONCLUSIONS:** Improvements in dynamic balance but not static sway were found after the 32-week Yoga intervention designed specifically for older adults. Significantly reduced COM acceleration and maximum COM-COP separation in the direction of propulsion may decrease the risk of forward falling.

**Effect of Wheelchair Tai Chi Intervention on Physical Health among Elderly with Disability**

Katherine Dietzel, Kelly FitzGerald, Matthew Hanks, Rebecca Kittiko, Julitta Lam, Sarah Martinez, Kara Strauss, Xiang Ke, Yong Tai Wang, FACSM. *Georgia State University, Atlanta, GA.*  
(No relationships reported)

**PURPOSE:** The purpose of the study was to examine the effect of Wheelchair Tai Chi Modified 10-Form (WTC10) intervention on select physical health variables among the elderly with disability.

**METHODS:** Thirty elderly with disability (using wheelchair or walker) from 3 assisted living facilities were recruited from Metro Atlanta area. Twelve joined WTC10 intervention group ( $85.70 \pm 7.67$  years) and 18 joined the control group ( $89.91 \pm 7.71$  years) at their will after signing the informed consent forms. Only the WTC10 group received a 12 week Tai Chi intervention, twice a week and an hour each time. A pretest and a posttest were performed for both groups at the beginning and at the end of the intervention. Seven in the WTC10 group and 14 in the control group completed the study. The selected physical health measurements included rest heart rate (HR), systolic (SBP) and diastolic blood pressure (DBP), function reach (FR), and Pain Self Efficacy Questionnaire (PSEQ). A Mixed-Model ANOVA and Bonferroni pos hoc test (p < .05) were employed to examine the differences between the pre-test and post-[Unsupported Character - Codename &shy;]test within each group and between the two groups.

**RESULTS:** No statistically significant differences were found from the Mixed-Model ANOVA and Bonferroni analyses among the comparisons of the aforementioned five variables between two groups. However, the WTC10 group had improvements among the five aforementioned variables with the rest HR decreased 4.25 beats/min, and SBP and DBP decreased 18.75 and 19.25 units, respectively, after the WTC10 intervention. Whereas, the control group had increased rest HR 3.90 beats/min, and increased SBP 14.60 units. Therefore, there were interactions among the heart rate and blood pressure (WTC10 Group: pretest HR  $71.5 \pm 5.19$  vs posttest  $67.25 \pm 8.38$  beats/min, and pretest SBP/SBP  $137 \pm 38/97 \pm 25$  vs posttest  $118 \pm 14/78 \pm 8$ ; and Control Group: pretest HR pretest  $70.80 \pm 10.05$  vs posttest  $74.70 \pm 11.85$  beats/min, and pretest SBP/DBP  $112 \pm 7/71 \pm 8$  vs posttest  $126 \pm 27/69 \pm 15$ ).

**CONCLUSIONS:** A 12 week WTC10 intervention may have positive effect on the rest heart rate and blood pressure among the elderly with disability, and the WTC10 is a feasible exercise for the elderly with disability.

1677 Board #85 May 30 2:00 PM - 3:30 PM

**Age-related Site-specific Thigh Muscle Loss Is Associated With Amount Of Vigorous Physical Activity**

Takashi Abe<sup>1</sup>, Madoka Ogawa<sup>2</sup>, Naotoshi Mitsukawa<sup>3</sup>, Mark Loftin, FACSM<sup>4</sup>. <sup>1</sup>*University of Oklahoma, Norman, OK.* <sup>2</sup>*University of Tokyo, Kashiwa, Japan.* <sup>3</sup>*Toyo Gakuen University, Nagareyama, Japan.* <sup>4</sup>*University of Mississippi, Oxford, MS.*  
(No relationships reported)

We recently demonstrated that age is associated with site-specific loss of skeletal muscle mass in men and women. Interestingly, in the anterior and posterior regions of the thigh, age-related muscle loss was observed in the quadriceps but not in the posterior region. The cause of age-related site-specific muscle loss is unknown.

**PURPOSE:** To investigate the relationship between age-related site-specific loss of thigh muscle and accelerometer-determined daily physical activity.

**METHODS:** Fifty-one middle-aged and old women aged 52-83 years (means [SD], age 66.0 [7.1] yrs, height 1.53 [0.05] m, weight 52.4 [5.4] kg, and body mass index 22.4 [2.5] kg/m<sup>2</sup>) volunteered. Muscle thickness (MTH) was measured by B-mode ultrasound at five sites on the anterior (quadriceps [QF] 30%, 50%, and 70% of thigh length) and posterior (hamstring [HM] 50% and 70% of thigh length) aspects of the thigh. MTH was expressed in terms relative to thigh length (MTH/L). Habitual daily activities during consecutive 30 days were recorded using an accelerometer, and the exercise intensity was classified 10 graded levels from sedentary (level 0) to light (levels 1-3), moderate (levels 4-6) and vigorous (levels 7-9) exercise. Total duration time (minute) for each level of exercise intensity was calculated. Physical-activity-related energy expenditure (EE) was estimated.

**RESULTS:** The daily step count and physical-activity-related EE averaged 7826 (SD 3183) steps per day and 177 (SD 85) kcal, respectively. Age was inversely correlated with the QF-50% MTH/L ( $r=-0.286$ ,  $P=0.042$ ), but not the HM-50% MTH/L ( $r=0.102$ ,  $P=0.474$ ). Age was also inversely correlated with the ratio of QF/HM 50% MTH ( $r=-0.330$ ,  $P=0.018$ ), thus the site-specific muscle loss of the thigh was observed in the present sample. There were no significant correlations between the QF/HM 50% MTH ratio and daily step counts ( $r=0.205$ ,  $P=0.150$ ), duration time of light ( $r=0.204$ ,  $P=0.150$ ) as well as moderate ( $r=0.145$ ,  $P=0.308$ ) intensity exercise, and physical-activity-related EE ( $r=0.223$ ,  $P=0.116$ ). However, the QF/HM 50% MTH ratio was significantly correlated to duration time of vigorous intensity exercise ( $r=0.287$ ,  $P=0.041$ ).

**CONCLUSIONS:** Age-related site-specific loss of thigh muscle is associated with amount of vigorous physical activity in middle-aged and old women.

1678 Board #86 May 30 2:00 PM - 3:30 PM

**Prevention Of Falls By Outdoor-walking In The Elderly At Risk ("Power") - A Pilot Study**

Heidi Keller, Stefan Bösner, Antje Wöhner, Christian Wöhner, Norbert Donner-Banzhoff. *Philipps University, Marburg, Germany.*

(No relationships reported)

**BACKGROUND:** A broad range of factors contribute to falls in older people with the frequency of falls rising with age. It has been shown that morbidity and mortality associated with falls can be reduced by physical activity. We aimed to test the feasibility and acceptability of a program of regular assisted outdoor walking for nursing home residents including a possible impact on the prevention of falls.

**METHODS:** We included five nursing homes; three of these were assigned for the intervention and two for the control group. Inclusion criteria were age above 65 years and increased risk of falls. The intervention group ( $n=32$ ) benefited from regular assisted outdoor walking, the control group ( $n=20$ ) did not practice physical activities. We evaluated participants at the start of the study (T0) and after 6 months (T1) for history of falls, physical and cognitive impairment. In addition we performed qualitative interviews with nursing home managers.

**RESULTS:** The program was evaluated positively by the participating nursing homes. Half of the participants reported an improvement in their general condition, general mood and walking ability. There was a slight intervention effect on depressive symptoms, but no differences between intervention and control group in the proportion of falls, in regard to risk of falls and functional status (daily activities).

**CONCLUSIONS:** This study shows the feasibility of implementing a simple program of outdoor walking for elderly people in nursing homes. A sufficiently powered randomized controlled trial is necessary to show a possible effect on the number of falls and additional secondary outcomes.

1679 Board #87 May 30 2:00 PM - 3:30 PM

**Development Of A Visual Anticipatory Training And Balance Evaluation System For Elderly**

Po-Jung Chen, FACSM, Shun-Hwa Wei, Wen-Hsu Sung, FACSM. *National Yang-Ming University, Taipei, Taiwan.*

(No relationships reported)

Balance dysfunction in older persons often causes them suffering fall accidents. High insurance cost was found in medical care for elderly fall every year. Anticipatory balance training is a useful method that is gradually adopted in rehabilitation clinic; especially for aging person. Therefore, developing a system based on anticipatory balance theory may provide a useful selection for balance rehabilitation.

**PURPOSE:** The purpose was to develop a system that can be used to assess and train balance function for elderly.

**METHODS:** The system consisted of a customized forceplate which could detect subject's center of force (COF) in real time. System software contained two modules: assessment module and rehabilitation module. The two modules can simultaneously execute and communicate with TCP/IP technique. Assessment module could measure real-time COF changes, and rehabilitation module could provide video-game based rehabilitation program on balance training. To achieve anticipatory balance training, a PC game that fitted training requirement in visual alert and body balance control was included. The real-time COF data, game scores (GS) and game finished time (GFT) were collected for performance analysis.

**RESULTS:** Two subjects (66 y/o female and 26 y/o female) were recruited to use the system. The results showed that elderly had larger COF distance and velocity than that of adults (the following %diff = (elderly-adult)/adult: total COF distance = 75.0%, total COF distance in anterior posterior (AP) direction= 79.1%, total COF distance in lateral medial (LM) direction =65.7%, COF average velocity= 67.2%, COF average velocity in AP direction= 58.8%, COF average velocity in LM direction =108.7%). It means young adult had more effective moving pattern than elderly when they were asked to do the same tasks. Although the elderly subject did more shifting of COF to do the tasks, the performance in the game was still lower than adult (GFT in seconds: adult= 49.47, elderly= 41.97; GS: adult= 11, elderly= 6).

**CONCLUSIONS:** The results found elderly had less effective moving pattern in COF-shifting tasks and lower performance in rehabilitation game playing. The preliminary study showed the system can distinguish the different performance between adult and elderly, and it may be used as a new selection for balance rehabilitation.

**Effects Of Taichi Training On Health Status In Normoweight, Overweight And Obese Postmenopausal Women**

Sebastien Barbat-Artigas, Marie-Eve Ringuet, Sophie Dupontgand, Antony Karelis, Mylène Aubertin-Leheudre. *Université du Québec à Montréal, Montréal, QC, Canada. (Sponsor: Jean P Boucher, FACSM)*

(No relationships reported)

In older people, obesity is a public health issue. Physical activity appears to be one of the most efficient interventions used for weight loss. However, depending on the type of activity, the drop out and/or the injury rate can be relatively high. In addition, 65% of older people are sedentary. On the other hand, emergent practices such as Taichi have been shown to have increasing success among older people. It has been shown that Taichi had beneficial effects on health status in community-living older adults. However, its specific effects in obese postmenopausal women are still unknown.

**PURPOSE:** The aim of the present study was to investigate the effectiveness of 12 weeks of Taichi on health status in obese postmenopausal women compared with normoweight and overweight postmenopausal women.

**METHODS:** Sixty-two postmenopausal women were recruited. Women were divided in 3 groups according to their fat mass percentage (40%). Body composition, blood pressure, muscle strength, functional capacities, physical activity level, energetic balance and general health perception were measured before and after the intervention.

**RESULTS:** We observed that body weight ( $p=0.029$ ), BMI ( $p=0.028$ ), systolic ( $p=0.010$ ) and diastolic ( $p=0.007$ ) blood pressure as well as fat mass percentage ( $p=0.011$ ) significantly decreased in obese postmenopausal women while general health perception ( $p=0.033$ ) and chair stand test score ( $p=0.020$ ) significantly increased. In overweight women, systolic ( $p<0.001$ ) and diastolic ( $p=0.033$ ) blood pressure significantly decreased while chair stand ( $p=0.027$ ) and balance ( $p=0.009$ ) tests scores significantly increased. In normoweight women, waist circumference ( $p=0.018$ ), systolic ( $p=0.015$ ) and diastolic ( $p=0.037$ ) blood pressure significantly decreased while chair stand test score ( $p=0.001$ ) significantly increased. The effectiveness of the intervention was identical in the 3 groups.

**CONCLUSIONS:** Our results showed that Taichi may be effective in enhancing body composition, functional capacity and in lowering blood pressure, independently of the obesity status. This activity may thus be considered as an effective alternative for weight loss programs in obese postmenopausal women. Further larger studies are needed to confirm our results.

Torezan<sup>1</sup>, Marcio M. Tritapepe<sup>1</sup>, Vittorio Bianchi, FACSM<sup>3</sup>, Roberto C. Burini<sup>1</sup>. <sup>1</sup>UNESP - Univ Estadual Paulista, Medical School, Botucatu, Brazil. <sup>2</sup>USP - PRONUT, São Paulo, Brazil. <sup>3</sup>SH Health Service, Rimini, Italy.  
(No relationships reported)

Soccer is a worldwide sport professionally and recreationally practiced and has its benefits and risks. In relation to cardiovascular risks (CVR) the intensity of exercise might be the trigger for adverse outcomes.

**PURPOSE:** To evaluate the CVR of recreational soccer game for senior players.

**METHODS:** 27 voluntary male subjects were selected by their game skill fullness and assembled in two age groups, under (n=10; 47 + 2 yrs old; G1) and over (n=17; 57 + 5 yrs old; G2) 50 yrs old. They all were successfully submitted to a maximal treadmill test (Balke protocol), preceded and proceeded by a blood sampling for analysis of metabolic markers of exertion: acidosis (pH, HCO<sub>3</sub><sup>-</sup>, pCO<sub>2</sub>), hemoconcentration (Ht and Hb) and muscle damage (CK and AST). They also were assessed during 20x20 minutes soccer games of 6x6 and 5x5 players in a 814m<sup>2</sup> turf field. The game measurements included resting blood pressure (BP) and heart rate (HR) before and immediately after the game. During the game were registered maximum, average, and minimum HR, distance, maximum and minimum speed (GPS monitor - Garmin® Forerunner 305). The two groups (G1 and G2) were set up in teams either inside the group (6x6 or 5x5) or mixed up with 3 G2 plus 3 G1 for 6x6 games (67.8 m<sup>2</sup>/player) or 3 G2 plus 2 G1 for 5x5 games (81.4 m<sup>2</sup>/player). The statistical comparisons inter or intra groups were undertaken by Student's t test or ANOVA, for p<0.05.

**RESULTS:** Both groups were similar in anthropometry, resting values of BP, HR and responded similarly to the maximum treadmill test by reducing blood levels of pH, HCO<sub>3</sub><sup>-</sup>, and pCO<sub>2</sub> and increasing values of Ht, Hb, AST and CK. However, the younger group presented slightly higher VO<sub>2</sub>max (11.9%) than the older (p=0.07). The game performance differed groups only by younger covering larger distance (16.1%) with higher average speed (21.1%) and presenting higher average HR (10.7%) than the older. However these differences disappeared during the aged-mixed teams. In both age groups, the maximum HR registered during the game surpassed the expected values from the treadmill test, although in both cases the HR remained under the maximum values predicted by age.

**CONCLUSIONS:** Besides being intense and emotional, the recreational soccer is yet a suitable physical activity for senior cardiorespiratory fitness. Supported by CNPq, CAPES and FUNDAP.

**1682** Board #90 May 30 2:00 PM - 3:30 PM

**Ageing And Strength Reduction; Inactivity Or Ageing?**

Eivind Wang, Lubomir Kafonek, Jan Helgerud, Klaus Jungbluth, Jan Hoff. *Norwegian University of Science and Technology, Trondheim, Norway.*  
(No relationships reported)

**PURPOSE:** Muscular strength shows an average decrease with age. The reduced strength is related to the ageing process, but might to a larger degree be a result of inactivity. The hypothesis for this study is that strength training responses in young and old subjects is not different.

**METHODS:** 12 old (60 ± 6 yr) and 13 young (22 ± 2 yr) subjects trained maximal strength training 4 sets of 4 repetitions at ~90% of one repetition maximum (1RM) 3 times a week for 8 weeks in a hack squat and a knee extension apparatus. None of the subjects performed strength training on a regularly basis before participating in the study.

**RESULTS:** At pretest the old group showed significantly (p<0.05) lower 1RM in hack squat (190 ± 35 kg vs. 207 ± 37 kg including bodyweight) and knee extension (84 ± 13 kg vs. 105 ± 15 kg) compared to the young group. Following training 1RM improved significantly (p<0.05) in both squat: 33 ± 15% (old); 30 ± 14% (young) and knee extension: 28 ± 12% (old); 31 ± 10% (young), but with no differences between the groups. Also dynamic rate of force development (RFD) displayed no differences between groups. Knee extension static RFD and electromyogram root mean square (EMGRMS)/maximal M-wave (Mmax) measured in vastus lateralis, vastus medialis and rectus femoris displayed no significant differences within or between groups except for a vastus lateralis increase of 21 ± 26% within the old group.

**CONCLUSIONS:** Old and young subjects showed similar training responses when employing maximal strength training. Young subjects showed a higher initial strength baseline compared to old. EMGRMS/Mmax could not detect the strength responses following the training intervention. The old subjects seem to have a large potential for strength improvements similar to the young subjects, indicating that the major part of strength reduction with age might be an activity component rather than an aging component.

**1684** Board #92 May 30 2:00 PM - 3:30 PM

**Physical Activity and Brachial Arterial Flow-Mediated Vasodilatation in 20-69-y-old Women**

Hong Juan Li<sup>1</sup>, Chun Yan Zhang<sup>1</sup>, Le Qin Chen<sup>2</sup>. <sup>1</sup>Beijing Sport University, Beijing, China. <sup>2</sup>Shanxi Normal University, Linfen, China.  
(No relationships reported)

Endothelial dysfunction plays an important role in the development of cardiovascular disease as a concomitant disorder of atherosclerosis. Physical activity was a protecting factor of cardiovascular health. However, the Age-related change of endothelial function and relationship of physical activity and endothelial function in women are unclear.

**PURPOSE:** the purpose of present study is to explore the age-related change of brachial arterial flow-mediated vasodilatation (FMD) in women, and association of physical activity level and FMD.

**METHODS:** 405 healthy women aged 20-69 were recruited from Haidian District, Beijing, China. Physical activity history was investigated by questionnaires. High-resolution Doppler Ultrasonography Equipment with a 7.5-MHz transducer (UNEX) was used to record the resting brachial arterial parameters and flow-mediated vasodilatation (FMD) after reactive hyperemia. Written informed consent was signed by each participant for the measurement.

**RESULTS:** the resting brachial arterial diameter and flow-mediated maximal dilation diameter were increased in the women over 40-y old, comparing to the 20-39-y group (resting diameter and deflation diameter were 3.26±0.36mm vs 3.52±0.51mm and 3.62±0.37mm vs 3.90±0.55mm, respectively. P=0.000), and the time for reaching maximal flow velocity was reduced (24.55±16.02s vs 20.64±16.24s, respectively. P=0.018). FMD was significantly decreased in 60-69-y group, comparing to younger age-group (9.24±2.64 vs 11.39±2.19, P<0.05). Maximal blood flow velocity is lower in group with moderate or higher physical activity, comparing to group with lack or lower physical activity (7.35 ± 5.21 vs 8.49 ± 5.40 m / s, P <0.05).

**CONCLUSIONS:** changes in brachial arterial diameter in resting and maximum diastolic diameter might be related to endothelial function. Resting brachial artery diameter and maximal dilation diameter over 40-yrs was increased might be a predictor of endothelial dysfunction. FMD in women over 60 declined significantly, which might be related to increased cardiovascular risk. Moderate physical activity or exercise might have a protective effect on endothelial function. Supported by the National Science and Technology Infrastructure Program of China 2006BAK33B02.

**Combined Physical Exercise Program Has a Beneficial Effect on Exercise Capacity and MMSE**

Yi-Sub Kwak<sup>1</sup>, Jin Han<sup>2</sup>. <sup>1</sup>Dong-Eui University, Busan, Korea, Republic of. <sup>2</sup>Inje University, Busan, Korea, Republic of.  
(No relationships reported)

Dementia population in worldwide is considerable in the aged people. Exercise regulates the brain function, but the mechanism by which it does so is unknown.

**PURPOSE:** The effect of regular exercise on cognitive function and exercise capacity in senile dementia patient was investigated.

**METHODS:** Thirty female patients with senile dementia who participated in the study were divided into two groups: the exercise group (EG, n=15) and the control group (CG, n=15). The exercise group completed regular exercise program, and their cognitive function (MMSE: mini-mental state examination), activities of daily living (ADL) and exercise capacity (cardiopulmonary function, muscle strength, muscle endurance, flexibility, balance, agility) levels were evaluated at baseline, 6 months and after 12 months. Subjects exercised 30-60 minute a day, 2-3 times per week for 12 months.

**RESULTS:** MMSE and ADL score were significantly enhanced in exercise group with senile dementia, compared to these of control group ( $p < 0.05$ ). Exercise capacities in exercise group also increased as period dependent manner.

**CONCLUSIONS:** These results suggested that senile dementia may improve by participating in a regular exercise program.

**Growth Mixture Modeling of Screening Time Among US Children**

Youngdeok Kim, Peter D. Hart, Rose M. Carter, Joshua T. Haley, Minsoo Kang, FACSM. *Middle Tennessee State University, Murfreesboro, TN.*

*(No relationships reported)*

**PURPOSE:** The screening time, such as TV viewing and computer/video game, are the growing risk factors of obesity among the children, which may consequently be linked to chronic diseases in later years. Given that the childhood is an important period in which one's habitual behaviors are being confirmed, more information is needed in order to reduce the screening time during this period. The purpose of this study was to explore the longitudinal trajectory of screening time for better understanding of individual variations in the development of screening time.

**METHODS:** Data from the Youth Media Campaign Longitudinal Survey (YMCLS) which was conducted from 2002 to 2006 among US children aged 9-13 were analyzed in this study. A remaining sample of 1,623 children in 2006 after completion of follow-up surveys for each of four consecutive year were used. The screening time was obtained by a self-reported measure asking time spent in watching TV, playing video or computer games at a day before interview with the exception of time spent doing homework on computer. Latent growth modeling (LGM) was applied to investigate the latent trajectory of screening time and growth mixture modeling (GMM) was further applied for taking into account population heterogeneity of growth parameters (i.e., intercept and slopes) across unknown subpopulations using latent trajectories classes. Demographic variables used in GMM for predicting latent trajectories classes and growth parameters were gender, baseline age, parental education level, and family income.

**RESULTS:** The LGM with a quadratic function showed better model fit indices with the parameter estimates of 98.65 for minutes of screening time at baseline, 10.93 minutes for growth rate, and -1.64 minutes for acceleration rate. Following GMM revealed three latent trajectories classes with heterogeneous growth parameters [i.e., normal incliners (87.6%), decliners (6.3%), and drastically incliners (6.1%)].

**CONCLUSIONS:** The findings indicated that the growth trajectories of screening time among US children varied across different subpopulations. Disparities in screening time among these subpopulations should be take into consideration when targeting the population in promoting healthy behaviors.

**The effect of Arch Rehabilitation Exercise Program on Plantar Pressure and Growth index in Children with Obesity Autistic**

Jae Soon Chung<sup>1</sup>, Soung Yob Rhi, FACSM<sup>2</sup>. <sup>1</sup>*Chungju National Univ., Chungju, Korea, Republic of.* <sup>2</sup>*Seoul National Univ., Seoul, Korea, Republic of.*

*(No relationships reported)*

**The purpose of this study** was to the effect arch rehabilitation exercise program on plantar pressure and growth index in children with obesity autistic. Following written, informed consent, 10 obesity autism (mean age = 9.11 $\pm$ 1.45 years; mean wt = 46.92 $\pm$ 9.53 kg; mean ht = 127.27 $\pm$ 10.71 cm; mean BMI = 28.97 $\pm$ 2.41) and 10 normal obesity children (mean age = 9.62 $\pm$ 1.50 years; mean wt = 50.28 $\pm$ 9.39 kg; mean ht = 133.46 $\pm$ 11.55 cm; mean BMI = 28.23 $\pm$ 3.84) completed a battery of test to determine growth index (height, weight and BMI) and plantar pressure.

**RESULTS** from the intermittent arch rehabilitation exercise program have shown that growth index was improved [ height increased significantly before exercise in between obesity autism group and normal obesity children group ( $p < .05$ ), before and after exercise in autism group ( $p < .01$ ) and normal children group ( $p < .01$ ), BMI decreased significantly after exercise in between obesity autism and normal obesity children ( $p < .05$ ). ] and plantar pressure measurement was improved [ average pressure left increased significantly before and after exercise in obesity autism group ( $p < .01$ ), average pressure right increased significantly before and after exercise in obesity autism group ( $p < .01$ ), rear foot pressure left increased significantly before and after exercise in obesity autism ( $p < .05$ ), rear foot pressure right increased significantly before and after exercise in obesity autism ( $p < .05$ ). ].

**CONCLUSIONS:** The lower plantar pressure found in obesity autism children suggests that foot pressure characteristic of obesity autism children may be caused by obesity. It is postulated that these foot pressure changes, which may affect the functional capacity and stabilization of rear foot pressure might be normalized if moderate weight bearing and arch rehabilitation exercise program continues throughout childhood and into adulthood.

**Long-term Effects Of Exercise And Activity Prescription In Children With CMT: An Exercise-Is-Medicine™ Case Study**

Robert D. Chetlin, Corrie Mancinelli, Steven Wheeler, Laurie Gutmann. *West Virginia University, Morgantown, WV. (Sponsor: Robert R. Kraemer, FACSM)*

*(No relationships reported)*

Charcot-Marie-Tooth disease (CMT), the most commonly inherited peripheral neuropathy (1-in-2,500 persons), affects motor & sensory nerves and is characterized by progressive extremity weakness & atrophy, foot & gait abnormalities, chronic pain/fatigue, and balance deficits. ~30 CMT types/subtypes are known; CMT1a is most common (~70% of all cases). There is no treatment to slow or prevent the disease process.

**PURPOSE:** To evaluate the effects of a 1-year, home-based exercise & activity Rx, combining resistance and endurance training, in a CMT1a pediatric patient.

**METHODS:** A 16 year-old girl, genetically diagnosed with CMT1a, participated in the study. Subject followed a home-based training program, with resistance (using "Therabands") and aerobic (using "Dance-Dance-Revolution") exercise, each performed 3 days/week for 1 year. Outcomes included isometric strength, body composition, MVO<sub>2</sub>, blood lipids, and postural stability, taken at baseline, 6 months, and 1 year. Percent changes were calculated over the study duration.

**RESULTS:** Clinical improvements were seen in max upper & lower body strength, lean mass, bone mineral density, body fat %, MVO<sub>2</sub>, exercise tolerance, triglycerides, LDLs, total cholesterol, and sensory responses associated with balance and postural stability.

| Variable                       | Baseline | 6 months | 1 year | % Change |
|--------------------------------|----------|----------|--------|----------|
| Ht (cm)                        | 158.7    | 160.0    | 160.0  | 0.8      |
| Wt (kg)                        | 51.7     | 52.6     | 54.4   | 5.2      |
| BMD (g/cm <sup>2</sup> )       | 0.99     | 1.00     | 1.02   | 3.0      |
| Lean Mass (kg)                 | 30.1     | 30.9     | 31.1   | 3.3      |
| Fat Mass (kg)                  | 18.8     | 19.0     | 19.3   | 2.6      |
| Total Mass (kg)                | 50.5     | 51.4     | 53.2   | 5.3      |
| Body Fat %                     | 37.2     | 37.1     | 36.6   | -1.6     |
| Total UE Strength (kg)         | 67.2     | 75.2     | 79.0   | 17.6     |
| Total LE Strength (kg)         | 91.5     | 91.6     | 100    | 9.3      |
| Total Exercise Time (min)      | 8:02     | 10:00    | 11:56  | 48.5     |
| Time to MVO <sub>2</sub> (min) | 6:37     | 8:08     | 9:56   | 50.1     |
| Max Work (W)                   | 91.0     | 111.0    | 133.0  | 46.1     |
| MVO <sub>2</sub> (ml/kg/min)   | 27.2     | 24.4     | 31.1   | 14.3     |
| Fasting Glucose (mg/dl)        | 83.0     | 87.0     | 90.0   | 8.4      |
| Triglycerides (mg/dl)          | 145.0    | 111.0    | 69.0   | -52.4    |
| LDLs (mg/dl)                   | 163.0    | 140.0    | 127.0  | -22.1    |
| HDLs (mg/dl)                   | 54.0     | 47.0     | 51.0   | -5.5     |
| Total Cholesterol (mg/dl)      | 246.0    | 209.0    | 192.0  | -21.9    |

**CONCLUSIONS:** This case study demonstrated that an Exercise-Is-Medicine™ rubric (1-year combined resistance & endurance training), clinically improved strength, body composition, MVO<sub>2</sub>, exercise tolerance, balance, postural stability, and heart disease risk in a 16 year-old girl with CMT1a. This is also the first clinical or scientific exercise study, to our knowledge, which resulted in beneficial changes in afferent function in a CMT patient.

**Using a Technology-Based Prenatal Physical Activity Program: A Pilot Study**

Bridget Melton<sup>1</sup>, Helen Bland<sup>1</sup>, Elaine Marshall<sup>1</sup>, Michael Schmidt<sup>2</sup>, Kent W. Guion<sup>3</sup>, Jacquelyn Nagle<sup>4</sup>. <sup>1</sup>Georgia Southern University, Statesboro, GA. <sup>2</sup>University of Georgia, Athens, GA. <sup>3</sup>Georgia Health Sciences University, Augusta, GA. <sup>4</sup>University of Pittsburgh, Pittsburgh, PA. (Sponsor: Jim Morrow, FACSM)  
(No relationships reported)

Recent studies have linked excessive gestational weight gain to childhood obesity. Health educators now use pregnancy as a critical point of intervention to impact health outcomes for mother and child. However, little is known about the feasibility of using technology enhanced intervention modalities to impact women's health behaviors.

**PURPOSE:** To examine the feasibility of a technology enhanced physical activity (PA) program to control excessive gestational weight gain in pregnant women. A 6-week online PA course was administered while the participants were in their second trimester. The learning module included: Benefits of Exercise During Pregnancy; Safety Concern for Pregnancy; Nutrition During Pregnancy; Improving Birth Outcomes; Childhood Obesity; and After the Baby Is Here. Each module included an online presentation, discussion, ask the expert blog, a knowledge test (self-quiz) and weekly PA logs.

**METHODS:** The study was a pilot non-randomized controlled trial with pregnant women that followed women from their first trimester (intervention group, online education [n=16]; control group, usual care [n=6]). PA patterns were assessed via accelerometer data at 1st, 2nd and 3rd trimester; content knowledge, self-efficacy and benefits and exercise precaution were assessed pre and post intervention. Course satisfaction was assessed by a participant focus group (N = 11). Repeated measure ANOVA analyses determined significant differences between pre- and post- test.

**RESULTS:** There was a significant increase in the intervention group pre and post content knowledge (p<0.05), however no significant changes were detected in the self-efficacy or benefits/safety of prenatal exercise (p>0.05). There was a trend toward an increased in PA patterns, normal birth weights, and normal gestational weight gain. Although gestational weight gain and birth weight were measured, the sample size did not allow for significance to be detected. The results from the focus group showed good feasibility and acceptability for delivery of online content material, web link, social networking and self-monitoring.

**CONCLUSIONS:** This pilot online PA intervention mode demonstrated feasibility in application and promoted increases in knowledge for the participants.

**1690** Board #98 May 30 2:00 PM - 3:30 PM

**Physical Activity Patterns in Postpartum Latinas: Madres para la Salud**

Colleen Keller<sup>1</sup>, Barbara E. Ainsworth, FACSM<sup>1</sup>, Michael Belyea<sup>1</sup>, Allison Nagel-Williams<sup>1</sup>, Stephen Herrmann<sup>2</sup>, Sonia Vega-Lopez<sup>1</sup>, Paska Permana<sup>3</sup>, Kathie Records<sup>1</sup>, Dean V. Coonrod<sup>4</sup>. <sup>1</sup>Arizona State University, Phoenix, AZ. <sup>2</sup>University of Kansas, Kansas City, KS. <sup>3</sup>Phoenix VA Health Care System, Phoenix, AZ. <sup>4</sup>Maricopa Integrated Health System, Phoenix, AZ.  
(No relationships reported)

**INTRODUCTION:** The post-partum period is a critical time for loss of pregnancy-associated weight gain. Among young Latinas, overweight and obesity rates are high and leisure-time moderate- and vigorous intensity physical activity (PA) is low.

**PURPOSE:** To describe the volume and types of PA performed by postpartum Latinas prior to initiating Madres para la Salud, a social-support mediated walking intervention to promote post-partum weight loss.

**METHODS:** 139 women (age = 28.3 ± 5.6 years and BMI = 29.7 ± 3.5 kg.m<sup>2</sup>) completed the Stanford Brief Activity Survey (SBAS) and concurrently wore an ActiGraph GT3X accelerometer (AG) and an Omron HJ-720ITC pedometer, and kept a PA record (PAR) to identify the type and duration of activities performed. The SBAS rates occupational and leisure-time PA to compute a 5-point PA rating from inactive to very hard PA. The AG Freedson and Matthews cut-points were used to compute PA intensities. AG min.d-1 and steps.d-1 were averaged over 7 days. The PARs were coded using the 2011 Compendium of PA with MET intensity cut-points as sedentary (1.0-1.5), light (1.6-2.9), moderate (3.0-5.9), and vigorous (≥ 6.0).

**RESULTS:** Only 33 women in the sample were employed. Most demonstrated inactive-to-low PA [SBAS categories: inactive (51%), light (37%), moderate (11%)]. AG wear time was: 849.7 ± 140.6 min.d-1 (14.1 hr.d-1). AG durations in min.d-1 were: sedentary (512.0 ± 169.9), light (242.4 ± 51.4), moderate lifestyle (78.3 ± 39.9), moderate walking (16.6 ± 14.4), and vigorous (0.34 ± 1.5). Pedometer steps.d-1 were low (total = 4,973 ± 2,202 steps; aerobic = 412 ± 774). PAR showed most min.d-1 in sedentary (158.2 ± 75.4) and light-intensity PA (412.4 ± 131.0), with less moderate (157.8 ± 106.1) or vigorous (9.8 ± 32.4) intensity PA.

**CONCLUSIONS:** Post-partum Latinas enrolled in our study showed low levels of moderate- and vigorous intensity PA on all measures. An intervention designed to increase walking to 150 min.wk-1 and/or 30 min.d-1 is warranted. Supported by NIH R010356-01A2

1691 Board #99 May 30 2:00 PM - 3:30 PM

**Physical Activity And Cardiovascular Risk In Individuals With A Low Ankle Brachial Index**

Marquis Hawkins<sup>1</sup>, Kelley Pettee Gabriel<sup>2</sup>, Molly Conroy<sup>1</sup>, Jennifer Cooper<sup>1</sup>, Kim Sutton-Tyrrell<sup>1</sup>. <sup>1</sup>University of Pittsburgh, Pittsburgh, PA. <sup>2</sup>The University of Texas Health Science Center at Houston, Austin, TX. (Sponsor: Andrea Kriska, FACSM)  
(No relationships reported)

Individuals with a low ankle brachial index (ABI) are often inactive and both characteristics are associated with an increased risk for cardiovascular (CVD) events. Given that individuals with a low ABI may have difficulty performing activities of higher intensity due to symptoms incurred during exercise, examining the role of lower intensity physical activity (PA) on CVD risk in these individuals is important.

**PURPOSE:** To examine the relationship between intensity of physical activity and cardiovascular risk in a nationally representative sample of United States adults with a normal and below normal ABI.

**METHODS:** In 2003-04, the National Health and Nutrition Examination Survey included an accelerometer PA module and collected ABI data. Sedentary activity, light intensity PA (LPA), and moderate-to-vigorous intensity PA (MVPA), were defined with the following cutpoints values: 0-100, 100-1952, &gt;1952, respectively. Individuals were classified as having a normal (1-1.4) or below normal (0.4-0.99) ABI. The Framingham risk score was used to determine 10 year risk of developing CVD. Multivariable regression models were used to determine the relationship between average time spent per day in various PA intensities and CVD risk in both ABI groups.

**RESULTS:** Individuals with a normal ABI spent significantly more time engaging in MVPA (p=0.001) and less time in sedentary pursuits (p=0.018) when compared to those with low ABI. Time spent engaging in LPA was similar between the groups. MVPA, but not LPA, was inversely related to the 10-year risk of developing CVD in both normal and low ABI groups (p<0.001 and p=0.001, respectively).

**Discussion:** While on average, individuals with a low ABI did not accumulate much time in MVPA, CVD risk does appear to decrease linearly with increasing levels of activity of this intensity. Encouraging individuals with a low ABI to gradually increase their participation in MVPA may reduce future risk of cardiovascular events.

1692 Board #100 May 30 2:00 PM - 3:30 PM

**Aerobic Exercise Training Induces Muscle Hypertrophy in Both Young and Old Men**

Adam R. Konopka, Matthew P. Harber, Miranda K. Udem, Leonard A. Kaminsky, FACSM, Todd A. Trappe, Scott W. Trappe, FACSM. *Human Performance Laboratory, Ball State University, Muncie, IN.*  
(No relationships reported)

We have previously reported that aerobic exercise training induces substantial (12±2%) muscle hypertrophy in older women (70±2 yr). However, it is unclear if this is an age and/or gender dependent response.

**PURPOSE:** Examine the influence of progressive aerobic exercise training on aerobic capacity, whole muscle size, and knee extensor muscle function in young and old men.

**METHODS:** Seven young (Y; 20±1 yr) and six old (O; 74±3 yr) men performed 12-weeks of exercise training on a cycle ergometer. Training workload was based on relative intensity (% heart rate reserve) and progressively increased throughout the training program. Aerobic capacity, quadriceps muscle volume (via magnetic resonance imaging), and knee extensor muscle function (peak isometric torque and power) were assessed before and after the training intervention.

**RESULTS:** The training program improved (P<0.05) aerobic capacity in both Y (14±4%) and O (17±3%), however the absolute increase was greater (P<0.05) in Y (0.5±0.1 L·min<sup>-1</sup>) compared to O (0.2±0.1 L·min<sup>-1</sup>). Quadriceps muscle volume was higher (P<0.05) after training in both Y (54±13 cm<sup>3</sup>; 5±1%) and O (49±11 cm<sup>3</sup>; 6±1%). Peak work output during the graded cycle exercise test was ~20% higher (P<0.05) in both Y and O after training while knee extensor isometric torque, peak power, and peak angular velocity were not influenced.

**CONCLUSIONS:** The potential for muscle hypertrophy in response to aerobic exercise training is preserved with aging in both men and women. These data further support the use of aerobic exercise as a successful countermeasure to the age-related loss of muscle mass and aerobic capacity.

1693 Board #101 May 30 2:00 PM - 3:30 PM

**Correlates of Exercise Capacity in Elderly Individuals with and without Coronary Artery Disease**

Sandra Mandic<sup>1</sup>, Rob Walker<sup>1</sup>, Emily Stevens<sup>1</sup>, Casey Brown<sup>1</sup>, Diana Giraldo Ocampo<sup>1</sup>, Edwin R. Nye<sup>1</sup>, Dianne Body<sup>2</sup>, Leanne Barclay<sup>1</sup>, Michael J A Williams<sup>1</sup>.  
<sup>1</sup>University of Otago, Dunedin, New Zealand. <sup>2</sup>Dunedin Public Hospital, Dunedin, New Zealand. (Sponsor: Jonathan Myers, FACSM)  
(No relationships reported)

Exercise capacity declines with aging and in the presence of coronary artery disease (CAD). However, mechanisms underlying reduced exercise capacity in elderly individuals with stable CAD compared to age-matched healthy individuals remain unclear.

**PURPOSE:** To compare correlates of peak oxygen consumption (VO<sub>2</sub>peak) in age- and gender-matched elderly individuals with stable CAD and without CAD (no-CAD).

**METHODS:** Seventy-six elderly individuals (age: 72±5 years (range: 61 to 82), 37% women) with CAD (n=38) and no-CAD (n=38) completed: 1) symptom-limited graded exercise test with expired gas analysis and bioimpedance assessment of cardiovascular response to exercise; 2) physical function testing (Short Physical Performance Battery); 3) bioimpedance assessment of body composition; 4) lower-extremity muscle strength (30-second chair stand test); and 5) 12-month physical activity recall.

**RESULTS:** The CAD group had significantly lower VO<sub>2</sub>peak (19.6±4.8 vs. 22.2±4.9 ml/kg/min; p=0.027), maximal heart rate (122±17 vs. 139±19 bpm; p<0.001), maximal cardiac output (12.5±2.2 vs. 14.4±3.1 L/min; p<0.002) and increased percentage of body fat (32.8 vs. 27.5%; p=0.026) compared to the no-CAD group. In both groups, VO<sub>2</sub>peak was positively related to maximal cardiac output (no-CAD: r=0.44; CAD: r=0.38), maximal heart rate (no-CAD: r=0.32; CAD: r=0.56), percentage of muscle mass (no-CAD: r=0.62; CAD: r=0.73) and last year physical activity (no-CAD: r=0.65; CAD: r=0.41) (all comparisons p<0.05) but not age (no-CAD: r=0.13, p=0.438; CAD: r=-0.01, p=0.959). In addition, in the CAD group VO<sub>2</sub>peak was positively related to muscle strength (r=0.54, p=0.001) and physical function (r=0.43, p=0.007) and negatively related to percentage of body fat (r=-0.73, p<0.001).

**CONCLUSIONS:** In addition to impaired cardiovascular function, reduced muscle strength and increased body fat contribute to reduced VO<sub>2</sub>peak in elderly individuals with stable CAD. Long-term cardiac rehabilitation programs should focus on improving these outcomes.

### Vt2 Is A Valid Parameter To Determinate Anaerobic Threshold For People With Spinal Cord Injury

Roberto Aguado-Jimenez<sup>1</sup>, Beatriz Crespo<sup>2</sup>, Laura Mordillo<sup>2</sup>, Angel Gil<sup>2</sup>, Juan Reyes-Aguilar<sup>3</sup>, Antonio Oliviero<sup>3</sup>. <sup>1</sup>Public University of Navarra, Tudela (Navarra), Spain. <sup>2</sup>Fundacion Hospital Nacional De Paraplejicos, Toledo, Spain. <sup>3</sup>Fundacion Hospital Nacional De Paraplejicos, Toledo, Spain.  
(No relationships reported)

Anaerobic threshold determination has usually been employed in the training process. Anaerobic threshold can be calculated using ventilatory parameters (VT2, Beaver 1986) or acidity parameters in blood (Lactate, Coyle 1984). The purpose of this study was to determine if the anaerobic threshold, for people with spinal cord injury, can be calculated using ventilatory or blood lactate methods. Methods. Data were obtained from the project "Central fatigue in athletes: role of the cerebral cortex in relation to the effort in healthy and injured spinal cord". 18 subjects were recruited (Age: 34 ± 0.7 years; weight: 67.3 ± 4.5 kg; IMC: 22.8 ± 0.7; Aerobic Training: 3-6 h/week). Subjects were divided in 2 groups. SCI (people with spinal cord injury and accustomed to the wheelchair) and CON (control or healthy people and not accustomed to the wheelchair). They performed an incremental aerobic test to exhaustion on treadmill using an standard wheelchair. First velocity was 4 km•h<sup>-1</sup>, increasing 1 km•h<sup>-1</sup> every 3 minutes, with 1 minute recoveries after each stage. The test was maximal and finished considering ACSM criteria. During the test, VE, VO<sub>2</sub> y VCO<sub>2</sub> were analyzed. Anaerobic threshold was calculated at the time in which VE/VCO<sub>2</sub> increased nonlinearly (Beaver 1986). Blood lactate was analyzed to determine the anaerobic threshold (Coyle 1984). Results. In both groups, Anaerobic threshold velocity value was statistically higher (P<0.05) when it was obtained from ventilatory parameters (VT2). However, the difference did not exceed 0.4 km•h<sup>-1</sup>. When the anaerobic threshold velocity was compared between groups, it was observed that an habituation of exercise over the wheelchair, was reflected in a higher anaerobic threshold velocity. It was observed in the results from VT2 (SCI: 7.6 ± 1.9 km•h<sup>-1</sup> y CON: 5.0 ± 0.6 km•h<sup>-1</sup>, P<0.05.) or Blood Lactate (SCI: 8.0 ± 2.0 km•h<sup>-1</sup> y CON: 5.4 ± 1.6 km•h<sup>-1</sup>, P<0.05). Discussion. Results show that despite ventilatory differences in SCI, the methods based on ventilatory parameters (VT2), are valid in these populations. Los resultados ponen de manifiesto, que a pesar de las diferencias ventilatorias que pudieramos observar en PLM, las mediciones de umbral anaeróbico a partir de métodos ventilatorios son válidos para estas poblaciones, showing the same results as those found with lactate methods.

---

1695 Board #103 MAY 30 3:30 PM - 5:00 PM

### Investigate The Needed Walking Ability Of Patients With Stroke For Training With Non-motorized Treadmill

Ya Ling Chang<sup>1</sup>, Hsing Yu Chen<sup>1</sup>, Wen Hsu Sung<sup>1</sup>, Tien Yow Chuang<sup>2</sup>. <sup>1</sup>National Yang-Ming University, Taipei, Taiwan. <sup>2</sup>Taipei Veterans General Hospital, Taipei, Taiwan.  
(No relationships reported)

**BACKGROUND:** Damage of walking ability on patients with stroke usually limited their activities of daily living. Non-motorized treadmill (NMT) can provide active walking training, but the tilted walking belt and high walking resistance of this device may keep patients with lower walking ability from training with it. So the needed ability for walking on NMT has to be determined.

**PURPOSE:** The purpose of the study is to investigate the needed walking ability of patients with stroke for training with NMT.

**METHOD:** Ten patients with stroke who could walk on the ground were recruited in the study. They were divided into group A (could not walk on NMT, n=4) and group B (can walk on NMT, n=6). All subjects were the first hemorrhagic or ischemic stroke (aged 30-81 y/o), and evaluated with functional walking tests and questionnaires. Functional walking tests included time up and go test (TUG), straight walking test (normal and fast speed). Questionnaires included the walking ability questionnaire, activities specific balance confidence scale (ABC) and Frenchay activities index (FAI). Measured data was analyzed by Kruskal-Wallis H test and Mann-Whitney U test. The level of .05 was set for statistical significance.

**RESULT:** The data including age, sex, body height, body weight and affected side has no significant difference between two groups. There are significant differences (p <0.05) found on straight walking test in normal speed (group A: 0.58 ± 0.23 m/sec; group B: 0.90 ± 0.28 m/sec) and straight walking test in fast speed (group A: 0.63 ± 0.27 m/sec; group B: 1.06 ± 0.32 m/sec). All the other tests found no significant difference, including TUG (group A: 23.55±13.53 sec; group B: 15.39±6.64 sec), walking ability questionnaire (group A: 53±10.80; group B: 58.17±12.32), ABC scale (group A: 67.34±23.74; group B: 60±17.91), and FAI (group A: 12.55±8.66; group B: 10.83±4.62).

**CONCLUSION:** The results showed that the needed walking ability of patients with stroke for walking on NMT was related with the performance of straight walking test. Although other tests found no significant difference, all scores of group B were better than scores of group A. The preliminary results may be a simple index for the minimum requirement for active walking training with NMT. Supported by TVGH Grant (IRB No: 201008022OB).

1696 Board #104 MAY 30 3:30 PM - 5:00 PM

### Exercise Responses between Outdoor and Virtual Reality Indoor Arm+FES-leg Cycling in Individuals with Spinal Cord Injury

Nazirah Hasnan<sup>1</sup>, Che Fornusek<sup>2</sup>, Ruby Husain<sup>3</sup>, Glen M. Davis, FACSM<sup>2</sup>. <sup>1</sup>University of Sydney & University of Malaya, Sydney, Australia. <sup>2</sup>University of Sydney, Sydney, Australia. <sup>3</sup>University of Malaya, University of Malaya, Malaysia.  
(No relationships reported)

Functional electrical stimulation (FES) leg cycling has the potential to improve cardiorespiratory fitness after spinal cord injury (SCI). Combined arm and leg ('hybrid') exercise develops a higher oxygen uptake and greater cardiovascular demand compared to FES-leg cycling alone. Recent technologies have enabled outdoor hybrid cycling as well as virtual reality (VR) indoor hybrid exercise. VR-enhanced exercise enables the individual to interact within a virtual environment mimicking outdoor exercise, and provides a sense of participation and exercise motivation.

**PURPOSE:** This study compared submaximal exercise responses during outdoor hybrid cycling versus VR-enhanced indoor hybrid cycling.

**METHODS:** Eight individuals with chronic thoracic-lesion SCI were recruited. They performed voluntary arm and FES-assisted leg cycling on a commercially available hybrid recumbent tricycle. The experiments were conducted outdoors and indoors incorporating VR technology whereby the same outdoor environment was simulated on a large flat screen monitor. Four separate trials (2 outdoor, 2 VR) were conducted at least two days apart. Electrical stimulation was applied bilaterally to the quadriceps, hamstrings and glutei muscle groups and individuals modulated stimulation intensity according to preference and comfort. They were instructed to cycle to their best ability and safely. Oxygen consumption, heart rate and energy expenditures were measured over a 30-min outdoor and VR-simulated indoor test course.

**RESULTS:** During outdoor cycling, mean VO<sub>2</sub> was 15.95 ± 1.20 ml•kg<sup>-1</sup>•min<sup>-1</sup> compared to 16.60 ± 0.87 ml•kg<sup>-1</sup>•min<sup>-1</sup> for indoor VR exercise. Energy expenditures were 25.7 ± 1.4 kJ•min<sup>-1</sup> for outdoor cycling versus 26.8 ± 1.0 kJ•min<sup>-1</sup> indoors. The outdoor cycling heart rate was 128 ± 3 b•min<sup>-1</sup> compared to 125 ± 3 b•min<sup>-1</sup> during VR exercise. T-tests revealed that there is no significance difference (p>0.05) between indoor and outdoor test responses. There was also no significance differences in the highest VO<sub>2</sub> or heart rates observed over the 30-min test courses.

**CONCLUSION:** This study concluded that VR-enhanced hybrid cycling produces no different physiological responses than outdoor arm+leg cycling. Virtual reality technology may provide new opportunities for exercise rehabilitation in the SCI population.

**Lower Extremity Functional Electrical Stimulation Isometric Contractions Augment Arm Cycling Peak Oxygen Uptake In Spinal Cord Injured Individuals**

Berit Brurok. *Norwegian University of Science and technology, Trondheim, Norway.*  
(No relationships reported)

Functional electrical stimulation (FES) cycling augment arm cycling (ACE) peak oxygen uptake ( $VO_{2peak}$ ) in spinal cord injured (SCI) individuals, but high resource demands limits its access. Thus equally effective but less resource demanding training modalities are needed.

**PURPOSE:** To determine if FES lower extremity isometric muscle contractions augments ACE  $VO_{2peak}$  in individuals with SCI.

**METHODS:** Cross sectional single-subject design. Fifteen individuals with C<sub>4</sub> to T<sub>12</sub> SCI, and ASIA Impairment scale A, mean age of 40.2 (13.6) years were recruited and divided into two groups; injury above (SCI-high n=8) or below (SCI-low n=7) the T<sub>6</sub> level.  $VO_{2peak}$  was measured during and compared between; 1) ACE combined with FES isometric contractions (FES iso hybrid), 2) ACE combined with FES cycling (FES hybrid cycling), and 3) ACE alone.

**RESULTS:** In the SCI-high group, FES iso hybrid and FES hybrid cycling increased  $VO_{2peak}$  compared to ACE alone from 17.6 ( $\pm 5.0$ ) to 23.6 ( $\pm 3.6$ ) mL $\cdot$ kg<sup>-1</sup> $\cdot$ min<sup>-1</sup> and from 17.6 ( $\pm 5.0$ ) to 24.4 ( $\pm 4.1$ ) (P = 0.001) respectively.  $VO_{2peak}$  and related parameters were not different between the two FES hybrid modalities. In the SCI-low group, there was no difference in  $VO_{2peak}$  and related parameters between the three test modalities.

**CONCLUSIONS:** FES lower extremity isometric contractions and FES cycling augmented arm cycling  $VO_{2peak}$  in individuals with SCI high level injuries in the present study. However a portable FES apparatus may serve as a less resource demanding alternative to stationary FES cycling. These findings may have important implications for training compliance and exercise prescription for SCI

**1698** Board #106 MAY 30 3:30 PM - 5:00 PM  
**Failure To Reproduce VO<sub>2</sub>max In Patients With Chronic Fatigue Syndrome As An Objective Indicator Of Disease**

Betsy A. Keller, FACSM, J. Luke Pryor, Sarah Simunovich, Kelsey Corrigan. *Ithaca College, Ithaca, NY.*  
(B.A. Keller: Contracted Research - Including Principle Investigator; NIH Grant A1090553-01, PI - Maureen Hanson.)

**PURPOSE:** To assess the reproducibility of  $VO_{2max}$  in subjects diagnosed with chronic fatigue syndrome (CFS) compared to healthy controls. Prior research demonstrates that  $VO_{2max}$  in healthy subjects is highly reproducible over days and even months ( $r > .95$ ), with a SEM of < 6-7% . :

**METHODS:** Subjects were 10 females and 2 males (41.3 $\pm$ 1.11 yrs) diagnosed with CFS by a physician experienced in the diagnosis of CFS, and 3 male and 4 female healthy controls (23.3 $\pm$ 1.11 yrs) . Each subject completed two maximum exercise tests on a cycle ergometer separated by 24 hrs to assess the reproducibility of  $VO_{2max}$  and associated measures.  $VO_{2max}$ , max heart rate (HRmax), anaerobic threshold (AT), max workload (Wmax), workload at AT (ATwork), and respiratory exchange ratio (RER) were measured. :

**RESULTS:** For CFS subjects, significant decreases from test 1 to test 2 were 13.5% for  $VO_{2max}$  (21.5 to 18.6 mL $\cdot$ kg<sup>-1</sup> $\cdot$ min<sup>-1</sup>; p<0.01), 8 bpm for HRmax (p<0.01), 18.8% for AT (12.0 to 9.7 mL $\cdot$ kg<sup>-1</sup> $\cdot$ min<sup>-1</sup>; p<0.05), 9.4% for Wmax (121 to 109 W, p<0.05), and 17.3% for ATwork (58.3 to 48.2 W; p<0.05). However, max RER did not change (1.11 to 1.12; p=0.23) indicating that CFS subject effort was consistently high for both tests. As expected for healthy controls, there were no significant differences in  $VO_{2max}$  (mean diff=1.5%; 47.5 to 48.2 mL $\cdot$ kg<sup>-1</sup> $\cdot$ min<sup>-1</sup>), HRmax (181.6 to 183.1 bpm), AT (26.4 to 25.9 mL $\cdot$ kg<sup>-1</sup> $\cdot$ min<sup>-1</sup>), Wmax (264 to 271 W), ATwork (150 to 143 W), and max RER (1.17 for both tests). :

**CONCLUSION:** Healthy controls were able to reproduce  $VO_{2max}$  as expected. In contrast, CFS subjects were unable to reproduce  $VO_{2max}$  and/or AT, despite evidence of maximum effort during both tests. A maximum graded exercise test-retest protocol with ventilatory gas exchange could provide CFS patients with an objective indicator of underlying physiologic dysfunction.:

**1699** Board #107 MAY 30 3:30 PM - 5:00 PM  
**Forced And Voluntary Exercise Improve Vo<sub>2</sub>max In Parkinson's Patients**

Amanda L. Penko, Gordon Blackburn, Michael Crawford, Jay L. Alberts. *Cleveland Clinic, Cleveland, OH.*  
(No relationships reported)

High cadence exercise, or forced exercise, has been shown to be beneficial in symptom reduction in Parkinson's disease (PD) patients. With the increase in knowledge of the benefits of forced exercise to PD, it is important to examine the cardiovascular responses to forced and voluntary exercise interventions.

**PURPOSE:** To examine changes in  $VO_{2max}$  in PD patients who have completed an eight-week exercise intervention, either forced or voluntary.

**METHODS:** 60 males and females (58.62  $\pm$  8.47 yrs) with a clinical diagnosis of idiopathic PD completed two maximal progressive cycling exercise tests separated by eight weeks. Heart rate (HR) and  $VO_2$  was monitored throughout the test.

**RESULTS:** Both modes of exercise resulted in a significant (p=.003) improvement in  $VO_{2max}$ , however greater improvements were observed in the voluntary group. Neither group exhibited any change in peak exercise heart rate pre- to post-intervention (p=.705).

**CONCLUSION:**  $VO_2$  was significantly different pre-exercise to post exercise as determined during a progressive exercise test to maximal exertion for both the forced exercise group and the voluntary exercise group. These data support the efficacy of aerobic exercise for increasing aerobic capacity in PD patients.

This project supported by R01NS065198-01 and Lincy Foundation.

**1700** Board #108 MAY 30 3:30 PM - 5:00 PM  
**Cardiopulmonary Exercise Testing and Reduced Work Efficiency in Chronic Fatigue Syndrome**

Chris Snell, Staci Stevens, Todd Davenport, J. Mark VanNess. *University of the Pacific, Stockton, CA.*  
(No relationships reported)

**PURPOSE:** Reduced functional capacity and post-exertional fatigue following physical activity are hallmark symptoms of Chronic Fatigue Syndrome (CFS). That these symptoms are often delayed may explain the equivocal results for clinical cardiopulmonary exercise testing among individuals with CFS. Test reproducibility in healthy subjects is well documented. This may not be the case with CFS due to delayed recovery symptoms. The objectives for this study were to compare results from repeated exercise tests as indicators of post-exertional fatigue and reduced work efficiency in CFS.

**METHODS:** Gas exchange data, workloads and related physiological parameters were compared between 51 individuals with CFS and 10 control subjects, all females, for two maximal exercise tests separated by 24 hours.

**RESULTS:** Multivariate analysis showed no significant differences between controls and CFS for test 1. However, for test 2 the individuals with CFS achieved significantly lower values for oxygen consumption and workload at peak exercise and at the ventilatory/anaerobic threshold. Follow-up classification analysis differentiated between groups with an overall accuracy of 86.9%.

**CONCLUSIONS:** The lack of any significant differences between groups for the first exercise test would appear to support a deconditioning hypothesis for CFS symptoms. However, results from the second test indicate the presence of a CFS related post-exertional fatigue. It might be concluded that a single exercise test is insufficient to reliably demonstrate functional impairment in individuals with CFS. A second test may be necessary to document the atypical recovery response and protracted fatigue possibly unique to CFS which can severely limit productivity in the home and workplace.

---

1701 Board #109 MAY 30 3:30 PM - 5:00 PM

**Economy of Pedaling in Individuals With Down Syndrome**

Myriam Guerra<sup>1</sup>, Eduardo Garrido<sup>2</sup>, M<sup>a</sup> Carmen Martin-Borras<sup>1</sup>, Maria Gine-Garriga<sup>1</sup>, Guillermo Oviedo<sup>1</sup>, Bo Fernhall, FACSM<sup>3</sup>. <sup>1</sup>FPCEE Blanquerna (URL), Barcelona, Spain. <sup>2</sup>Hospital General de Catalunya, Sant Cugat del Valles, Spain. <sup>3</sup>University of Illinois at Chicago, Chicago, IL.  
(No relationships reported)

**INTRODUCTION:** Individuals with Down Syndrome (DS) have low aerobic capacity. Because of motor disabilities, cycling is difficult for them. Little is known about VO<sub>2</sub> economy when they perform tests over cycle ergometry.

**PURPOSE:** We investigated the relation between VO<sub>2</sub>peak and peak power during a maximal exercise test in persons with DS when cycling.

**METHODS:** 10 individuals with DS (age=20±2 years; BMI=24.5±4.1) and 7 without DS (age=20±2 years; BMI=23.3±2.7), all of them males, participated in this study. They completed a maximal cycle ergometer exercise test consisting of a 3-min warm up followed by an increase in load of 16 watts every minute until exhaustion. Metabolic data were continuously collected. Aerobic economy (peak VO<sub>2</sub> / peak power) was calculated in both groups and compared to predicted values.

**RESULTS:** Individuals with DS exhibited lower (p<.05) VO<sub>2</sub>peak (1.56±0.38 vs 3.22±0.46 L/min; 26.5±7.0 vs 44.1±4.7 ml/kg/min) and lower peak power (102.6±32.1 vs. 231.1±36.1W; 2.5±0.6 vs 3.2±0.3 W/kg). When comparing the actual economy (15.9±3.1 L/min/W) to the predicted value (10.3 L/min/W) it was significantly higher (p<.05) in DS group, meanwhile there were no significant differences in the control group (14.00±0.9 vs 10.3 L/min/W). When the actual economy between DS and control groups were compared (15.9±3.1 vs 14.0±0.9 L/min/W), there was no significant difference, even though the DS group had a higher mean.

**CONCLUSIONS:** Individual with DS exhibit poorer cycling economy than expected based on current formulas. However, there was no significant difference between persons with DS and controls, although this may have been influenced by a lack of statistical power. Thus, individuals with DS have low aerobic capacity and low exercise economy, which may partially explain their reduced ability to exercise. (Supported by MEC, reference DEP2005-00202-C04-01)

1702 Board #110 MAY 30 3:30 PM - 5:00 PM

**Prediction Of METs From The Heart Rate Index In Persons With Down Syndrome**

Stamatis Agiovlasitis<sup>1</sup>, Bo Fernhall, FACSM<sup>2</sup>. <sup>1</sup>Mississippi State University, Mississippi State, MS. <sup>2</sup>University of Illinois at Chicago, Chicago, IL.  
(No relationships reported)

Persons with Down syndrome (DS) have problems with autonomic control of heart rate that may alter their relationship between metabolic equivalent units (METs) and the heart rate index (HR<sub>index</sub>). HR<sub>index</sub> may be a practical indirect method for estimating METs and assessing physical activity intensity in persons with DS.

**PURPOSE:** To examine whether the relationship between METs and HR<sub>index</sub> differs between persons with and without DS and whether predictability of METs differs between groups.

**METHODS:** Oxygen uptake and heart rate were measured in 18 persons with DS (25 ± 7 yrs; 10 women) and 18 persons without DS (26 ± 5 yrs; 10 women) at rest and during six over-ground walking trials, each lasting 6 minutes, at the preferred speed and at 0.5, 0.75, 1.0, 1.25, and 1.5 m/s. Each participant's METs and HR<sub>index</sub> at each speed were calculated by dividing oxygen uptake and heart rate during walking by resting oxygen uptake and resting heart rate, respectively. The relationship between METs and HR<sub>index</sub> in the two groups was analyzed using multi-level regression with random intercepts and slopes. Independent variables included HR<sub>index</sub>, group (DS vs. Non-DS), the group by HR<sub>index</sub> interaction, and body mass index (BMI). Prediction accuracy in each group was assessed with the mean absolute error and Bland-Altman plots.

**RESULTS:** The relationship between METs and HR<sub>index</sub> differed between persons with and without DS. HR<sub>index</sub> and group significantly predicted METs (p ≤ 0.025; R<sup>2</sup> = 0.66). Neither the group by HR<sub>index</sub> interaction nor BMI contributed significantly to the model. The prediction equation was METs = -4.736 + (6.375×HR<sub>index</sub>) - (0.433×Group [1=DS; 0=Non-DS]). The HR<sub>index</sub> cut-off for moderate-intensity activity was 1.15 and 1.21 for persons with and without DS, respectively. Mean absolute prediction error did not differ between groups (p > 0.05; DS: 22.8 ± 16.5%; Non-DS: 19.9 ± 13.0%). Bland-Altman plots showed somewhat greater variability in the difference between actual and predicted METs for persons with DS.

**CONCLUSION:** Persons with DS have altered METs to HR<sub>index</sub> relationship and lower cut-offs for moderate-intensity physical activity as estimated by the HR<sub>index</sub> than persons without DS. Predictability of METs from HR<sub>index</sub> is similar between persons with and without DS.

**Pre-Participation Screening For College Athletes: The Role of Resting ECG**

Brian Hughes, Steve Burns, David Glover, Missy Briet, Casandra Davis, Heather D'Errico, Andrew Gai, Lindsey McFarland, Halie Thomas, William Miller.  
University of Central Missouri, Warrensburg, MO.  
(No relationships reported)

An unexpected death in athletes who most would consider to be in good health is particularly disconcerting and often visible to the public. Effective pre-participation screening is controversial and the addition of resting ECG has been suggested to be of limited value.

**PURPOSE:** The purpose of the current study was to determine the efficacy of adding a resting ECG as part of the pre-participation screening of Division 2 athletes.

**METHODS:** Resting ECG's were conducted on 326 male and female athletes to determine cardiac anomalies. ECG's were interpreted by a sports medicine physician experienced in the athlete ECG. All ECG's were also evaluated for mean QRS axis and rate corrected long QT syndrome (QTc).

**RESULTS:** Based on resting ECG's, 3 athletes were referred to the local hospital for further cardiac studies (echocardiogram and stress ECG) however all were cleared for activity due to negative results. Mean QRS axis Of the 326 ECG's was 85.5° with 15 athletes documenting right axis deviation @ 120-130 degrees and 1 athlete with left axis deviation @ -30°. Mean QTc was 414.4 ms with 19 athletes demonstrating QTc > 440ms.

**CONCLUSION:** Based on the data analyzed, resting ECG's for pre participation screening have little value in elucidating cardiovascular risk but may have great value as a baseline for future reference.

---

1704 Board #112 MAY 30 3:30 PM - 5:00 PM

**Menstrual Irregularity Incidence and Body Composition in Korean Female University Athletes**

Namju Lee<sup>1</sup>, Jongkyu Kim<sup>1</sup>, Misook Lee<sup>1</sup>, Tae-sam Kim<sup>1</sup>, Sun-kyung Ki<sup>1</sup>, Hyun-chul Cho<sup>2</sup>. <sup>1</sup>Sports Science Institute, Korea National Sport University, Seoul, Korea, Republic of. <sup>2</sup>Yong-in University, GyeonGi-Do, Korea, Republic of.  
(No relationships reported)

**PURPOSE:** To investigate menstrual irregularity incidence in relation to training volume, bone mineral density, and body composition in Korean female university athletes based upon sports type.

**METHODS:** 108 female University athletes and 22 controls participated in this study. Menstrual history questionnaire was used and dual energy x-ray absorptiometry (DXA) total body scans were conducted.

**RESULTS:** Menstrual irregularity incidence was 57% in total, 27% in controls, and 63% in athletes ( $\chi^2(1)=9.494, p=0.002$ ). Menstrual irregularity incidence was 100% in Kendo, 100% in Judo, 91.7% in basketball, 67.7% in Taekwondo, and 33.3% in fencing athletes, which was higher than other sports type athletes ( $\chi^2(7)=61.798, p<0.0001$ ). Otherwise, menstrual irregularity incidence was 0% in gymnastics, 8.3% in field hockey, and 16.7% in badminton athletes, which was lower than controls. As total bone mineral density (TBMD) was increased, menstrual irregularity incidence was decreased in controls ( $\chi^2(2)=8.225, p=0.016$ ) and was increased in athletes ( $\chi^2(2)=4.025, p=0.13$ ). As percent body fat (%BF) was increased, menstrual irregularity incidence was increased in controls ( $\chi^2(2)=7.435, p=0.024$ ) and was decreased in athletes ( $\chi^2(2)=25.954, p<0.0001$ ). As muscle mass was increased, menstrual irregularity incidence was increased in athletes ( $\chi^2(2)=8.249, p=0.016$ ). As weekly training hours increased, menstrual irregularity incidence in athletes was significantly increased.

**CONCLUSIONS:** Regular over training might cause menstrual irregularity incidence in athletes even though they had higher BMD, and not lower %BF. It would be more needed to find out what body composition factors mainly affect health concerns of female athletes and what levels of each body composition factor they need to maintain.

**1705** Board #113 MAY 30 3:30 PM - 5:00 PM

#### **Insulin Sensitivity Characteristics of College Athletes with Smoking Habit**

Sheng-Ju Chuang<sup>1</sup>, Szu-Hsien Yu<sup>1</sup>, Feng-Chih Hsu<sup>2</sup>, Mallikarjuna Korivi<sup>1</sup>. <sup>1</sup>Taipei Physical Education College, Taipei, Taiwan. <sup>2</sup>Physical Education Section, National Taoyuan Agricultural & Industrial Vocational High School, Taoyuan, Taiwan, Physical Education Section, Taiwan. (Sponsor: Chia-Hua Kuo, FACSM)  
(No relationships reported)

**PURPOSE:** Chronic inflammation and improper liver function play an important role in insulin sensitivity. The purpose of this study was to investigate the smoking habit on insulin sensitivity among young college athletes.

**METHODS:** In this study, total 552 nonsmokers and 98 current smokers (8.4±0.7 cigarette per day) athletes were recruited. Indices of glucose metabolism [glucose, insulin, glycated hemoglobin (HbA1c)], inflammation (white blood cells, WBC) and liver damage [(alanine aminotransferase (ALT), aspartate aminotransferase (AST)] were measured.

**RESULTS:** We found that gender-, alcohol consumption- and age-adjusted insulin, HOMA-IR (homeostasis model assessment of insulin resistance), HOMA-β (homeostasis model assessment β-cell func[Unsupported Character - Codename &shy;]tion) and white blood cell number in smokers were higher than nonsmokers. We also found that smoking habit is positively associated with serum insulin, HOMA-IR, HOMA-β, HbA1c and white blood cell numbers and negatively associated with QUICKI before and after adjusting the gender, alcohol consumption and age. Smoking was also negatively related to adjust AST. WBC is positively correlated to HOMA-IR and HOMA-β.

**CONCLUSIONS:** In conclusion, we suggested that smoking behavior can influence insulin sensitivity of athletes; the possible reason might be due to high systemic inflammation.

#### **The Use Of Instrument Assisted Soft Tissue Mobilization To Change Perception Of Functional Ability In College-aged Students.**

John Vardiman, Matt Andre, Patrick Moodie, Justin Maresh, Zach Graham, Mike Lane, David Carr, Yayah Alayafi, Philip Gallagher. University of Kansas, Lawrence, KS.  
(No relationships reported)

Many manual therapy techniques and therapeutic modalities are utilized to return patients to functional activities or activities of daily living.

Assessing the change in a patients perception of their functional ability after receiving Instrument Assisted Soft Tissue Mobilization (IASTM) treatment has yet to be determined.

**PURPOSE:** The purpose of this project was to assess the efficacy of the Instrument Assisted Soft Tissue Mobilization (IASTM) technique at changing a patients functional ability as well as their perception of functional ability of the functional squat test.

**METHODS:** Twenty-seven college-aged students (21.29±1.89 years, 64.81±15.52 kg, 170.05±9.89cm) participated in this study. Thirteen subjects (8 female, 5 male) were randomly selected to receive the IASTM treatment (TG) and 14 subjects (11 female, 3 male) were selected for the control group (CG). All subjects completed the Perception of Functional Ability Questionnaire (PFAQ) and then performed a baseline functional squat test in a 3-D Marker-less Motion Capture System (Dynamic Athletics, Overland Park, KS). The TG received a bilateral IASTM treatment to the posterior lower leg and the CG rested in a prone position for 10 minutes and did not receive the treatment. After the IASTM or 10 minute rest period all subjects performed a follow-up functional squat test in the motion capture system and completed a follow-up PFAQ. All data was analyzed using a 2x2 repeated measures ANOVA (p<.05).

**RESULTS:** There was no significant difference in data from the PFAQ between the TG and CG. There was significantly more stability in body weight distribution found in the TG following the IASTM treatment compared to the CG. There was also significantly more posterior heel shift in the TG following IASTM compared to the CG.

**CONCLUSION:** Though not statistically significant, all components of perception of functional ability improved following IASTM with the healthy, college-aged subjects. IASTM treatment did significantly increase critical components of the functional squat test. These data indicate that IASTM is an effective modality for increasing functional ability with the functional squat test.

**1707** Board #115 MAY 30 3:30 PM - 5:00 PM

#### **Skin Cancer Knowledge, Attitudes, And Behaviors In Collegiate Athletes**

Courtney Hobbs<sup>1</sup>, Martha Bass<sup>2</sup>, Jeffrey S. Hallam<sup>2</sup>, Allison Ford-Wade<sup>2</sup>. <sup>1</sup>Texas A&M Commerce, Commerce, TX. <sup>2</sup>The University of Mississippi, University, MS.  
(Sponsor: Mark Loftin, FACSM)  
(No relationships reported)

Skin cancer, specifically melanoma, is the deadliest and most preventable type of cancer in the world. Athletes have an increased risk for developing serious malignant growths due to unavoidable sun exposure during practice and competition times, and the lack of recommended sunscreen use.

**PURPOSE:** The purpose of this study was to assess skin cancer knowledge, attitudes, and behaviors among collegiate athletes. Behaviors that expose the athletes to UV rays, such as tanning bed use and sunlight exposure during peak hours, were of question. Strategies that athletes take to avoid overexposure to UV radiation when their practice/game times are scheduled outdoors during peak exposure hours were also examined.

**METHODS:** Three-hundred-forty-three athletes, from various intercollegiate sports at a mid-sized southern university, completed a modified version of the Melanoma Risk Behavior Survey.

**RESULTS:** The total mean score for knowledge was 8.88 ± 4.39, with a total possible score of zero - 24. A majority of the athletes were unable to identify basal cell carcinoma as the most common form of skin cancer. The mean score for attitude was 41.91 ± 6.22, with a total possible score of 11-55. A majority of the athletes felt a good tan was worth the increased risk of skin cancer. The mean score for behavior was 3.00 ± 2.70, with the total possible score of zero - 12. Less than 15% of the athletes attempted to avoid the sun during peak UV hours or wear protective clothing. Less than 25% regularly applied sunscreen before practice or during non-practice sun exposure.

**CONCLUSION:** Our results show that college athletes lack knowledge regarding skin cancer and sun protection, and engage in high-risk behaviors such as indoor tanning. There is a need to educate the collegiate athletic population about low-risk sun protection behaviors and skin cancer in general. Athletic directors, athletic trainers, coaches, and other individuals involved in the health and safety of college athletes need to include sun safety procedures in their discussions with the athletes during meetings and practice sessions.

**1708** Board #116 MAY 30 3:30 PM - 5:00 PM

#### **Holistic Lifespan Health Outcomes Among Intercollegiate Student-Athletes: Data from the Trojan Lifetime Champions Study**

Shawn C. Sorenson, Russ Romano, Robin Scholefield, E. Todd Schroeder, FACSM, George J. Salem, FACSM. University of Southern California, Los Angeles, CA.  
(No relationships reported)

**PURPOSE:** Despite prominent attention, lifespan health data for elite athletes remain sparse. This investigation provides descriptive epidemiology on holistic lifetime health among Division I intercollegiate athletes.

**METHODS:** 488 university students and alumni, including varsity student-athletes (SA) and non-athletes (NA), completed anonymous questionnaires documenting lifetime physical, mental, & emotional health, health-related quality-of-life (HRQL), and exercise behaviors & attitudes. Age-stratified, cross-sectional analyses were used to evaluate relative risk (unadjusted odds ratios

with 95% confidence intervals) for professional treatment of joint, cardiopulmonary, and psychosocial health concerns, in SA compared to NA.

**RESULTS:** Older alumni SA (ages 43+) had nearly 8x the risk of treatment for joint concerns, compared to age-matched NA; odds ratio = 7.9 (1.5 - 4.3). Current and younger alumni SA had similar risk vs. NA. Collapsed across groups, older alumni were 9x as likely as current students to be treated for cardiopulmonary concerns, but risk was similar for SA and NA. Treatment for psychosocial concerns was similar, irrespective of age and athletic participation.

**CONCLUSIONS:** These data suggest that intercollegiate athletic participation increases risk for treatment of joint concerns later in life. Despite high levels of exercise as young adults, SA demonstrated no protective cardiopulmonary health effects, and no differences in psychosocial health. This may offer valuable guidance for interventions seeking to optimize lifespan outcomes in this population. Additional studies are necessary to evaluate exercise and HRQL outcomes, and generalize these results to larger & more diverse populations.

---

**1709** Board #117 MAY 30 3:30 PM - 5:00 PM

**Differences on the Upper Quarter Y Balance Test Between High School and College Baseball Players**

Grant E. Garrigues<sup>1</sup>, Paul P. Gorman<sup>2</sup>, Phillip J. Plisky<sup>3</sup>, Kyle B. Kiesel<sup>3</sup>, Heather Myers<sup>1</sup>, Douglass Black<sup>1</sup>, Robin M. Queen<sup>1</sup>, Robert J. Butler<sup>1</sup>. <sup>1</sup>Duke University, Durham, NC. <sup>2</sup>ProRehab, Evansville, IN. <sup>3</sup>University of Evansville, Evansville, IN.  
(No relationships reported)

Athlete injury screening tests have received significant attention recently with the aim of reducing sport related injuries. Few tests have been developed to screen for upper extremity injury risk. The Upper Quarter Y Balance Test (YBT-UQ) was developed to provide a more fundamental upper extremity assessment. The YBT-UQ requires stance hand stability combined with reach hand mobility and coordination while maintaining a three point plank position.

**PURPOSE:** To examine how competition level affects performance on the YBT-UQ in baseball athletes.

**METHODS:** 37 male high school (HS) baseball players and 26 male college (COL) players were screened on the YBT-UQ prior to the spring season. Athletes with pain were excluded from the study. YBT-UQ performance was collected bilaterally in the medial, inferolateral, and superolateral directions. The maximum score for each direction was normalized to upper extremity length (C7 spinous process to tip of the middle finger) and used for analysis. The average of the normalized scores was used to develop a composite score. The bilateral normalized scores (%AL) were averaged and compared between groups. Reach symmetry was determined as the difference (cm) between the left and right side for each direction prior to normalization. Specific differences between the HS and COL players were statistically analyzed using independent samples t-tests ( $p < 0.05$ ).

**RESULTS:** HS baseball players had a significantly shorter average arm length ( $90.9 \pm 4.4$  cm) when compared to the COL players ( $93.9 \pm 3.9$  cm). No significant differences existed for the medial (HS:  $96.2 \pm 5.3$  %AL, COL:  $95.3 \pm 7.1$  %AL), inferolateral (HS:  $86.4 \pm 6.9$  %AL, COL:  $88.2 \pm 7.4$  %AL), superolateral (HS:  $69.3 \pm 9.6$  %AL, COL:  $69.2 \pm 7.1$  %AL) or composite (HS:  $84.0 \pm 5.7$  %AL, COL:  $84.2 \pm 5.9$  %AL) scores. Similarly no significant differences were observed for bilateral symmetry in the medial (HS:  $4.2 \pm 4.2$  cm, COL:  $4.9 \pm 4.1$  cm), inferolateral (HS:  $5.1 \pm 4.4$  cm, COL:  $4.3 \pm 3.6$  cm) or superolateral (HS:  $4.5 \pm 3.8$  cm, COL:  $5.5 \pm 6.0$  cm) directions.

**CONCLUSIONS:** Performance on the YBT-UQ does not appear to be dependent on the competition level in baseball players. Future studies should examine how athletes in other overhead sports perform on the test as well as examining if performance on the test is associated with an elevated injury risk.

---

**1710** Board #118 MAY 30 3:30 PM - 5:00 PM

**Gender Differences on the Upper Quarter Y Balance Test in Collegiate Swimmers**

Michael P. Reiman. Duke University, Durham, NC. (Sponsor: Mitchell J. Rauh, FACSM)  
(No relationships reported)

Recently the Upper Quarter Y Balance Test (YBT-UQ) was developed to examine injury risk and provide a more fundamental assessment of upper extremity ability that minimizes the role of strength and power. Currently there is no reported research on YBT-UQ performance.

**PURPOSE:** To examine how gender affects performance on the YBT-UQ in athletes participating in swimming.

**MATERIALS/METHODS:** Twenty-four male and twenty-six female Division I college swimmers were recruited for the study prior to the pre-season. All athletes who reported pain or current injury at the time of testing or were currently under the sports medicine team's care for an injury were excluded from the study. YBT-UQ performance was collected for the left and right limb in the medial, inferior-lateral, and superior-lateral directions. The maximum score for each direction was utilized for analysis. The scores were normalized to upper extremity length (C7 spinous process to tip of the middle finger). The average of the normalized reach scores was used to develop a composite score. For analytical purposes, left and right side normalized scores (%AL) were averaged. To examine reach symmetry between genders, the difference (cm) between the left and right side was calculated for each direction prior to normalization. Statistical analysis was conducted using an independent samples t-tests ( $p < 0.05$ ).

**RESULTS:** Statistically significant differences were observed for the medial ( $p < 0.01$ , F:  $89.7.2 \pm 7.4$  %AL, M:  $97.4 \pm 7.3$  %AL) and composite ( $p < 0.04$ , F:  $80.6 \pm 7.3$  %AL, M:  $85.1 \pm 8.1$  %AL) scores. No statistically significant differences were observed for reach symmetry in the medial (F:  $3.8 \pm 3.3$  cm, M:  $3.2 \pm 1.9$  cm), inferior-lateral (F:  $5.5 \pm 5.4$  cm, M:  $3.2 \pm 2.8$  cm) or superior-lateral (F:  $5.1 \pm 4.2$  cm, M:  $5.6 \pm 4.5$  cm) directions.

**CONCLUSIONS:** Performance on several YBT-UQ indices appears to be lower for females than male collegiate swimmers. Future research should be conducted to assess if performance on the test has any validity as an assessment of injury risk.

**1711** Board #119 MAY 30 3:30 PM - 5:00 PM

**Alcohol, Cigarette, Marijuana and Anabolic Steroid Consumption Among University Athletes in Bogota, Colombia**

Natalia Cano<sup>1</sup>, Laura Cárdenas<sup>1</sup>, Carolina Donado<sup>1</sup>, Olga Lucia Sarmiento<sup>1</sup>, John Duperly<sup>2</sup>. <sup>1</sup>Universidad de los Andes, Bogota, Colombia. <sup>2</sup>Fundacion Santa Fe de Bogota, Universidad de los Andes, Bogota, Colombia. (Sponsor: Michael Pratt, FACSM)  
(No relationships reported)

**PURPOSE:** University athletes (UA) are considered to have adequate academic performance, teamwork and health benefits from exercise, but there is evidence that UA in the US consume more alcohol (OH) and other illicit drugs than socially expected for athletes. In Colombia there are no studies on this topic, as well as no clear evidence concerning the use of anabolic steroids. We aimed to estimate the prevalence of OH, cigarettes (CC), marijuana (MJ) and anabolic steroids (AS) consumption amongst UA that competed in the Colombian University Association (ASCUN) tournament during 2011.

**METHODS:** In this cross sectional study, 801 males and females UA were randomly selected for a survey in an anonymous and voluntary way, as they participated in different competitions organized by ASCUN in the fall semester of 2011. The sample size was representative of all UA in Bogotá, Colombia. A translated and adapted version of the National Collegiate Athletic Association (NCAA) survey was used. The survey evaluated the patterns of OH, CC, MJ, and AS consumption. The life time prevalence of consumption of these substances was calculated by gender, sport (team vs. individual sports) and team captaincy.

**RESULTS:** Overall, of those surveyed 56.0% were male. The consumption of OH (85.0%) was the most prevalent, followed by CC (39.0%) and MJ (14.3%). The highest prevalence of consumption was among indoor soccer, volleyball and soccer players, for OH (14.9%, 13.5% and 11.4% respectively), CC (6.4%, 6.7% and 5.9% respectively), and MJ (2% for the three sports). In general for each substance the consumption was higher in males participating in a team sport (35.2% OH, 38.1% CC and 43.0% MJ). We didn't find a significant difference between team captains and other athletes, for OH (58.8% vs. 53.3%;  $p = 0.22$ ) or for consumption of other substances. The prevalence of AS use was 0.9% (85.7% males; 14.3% females), mostly among soccer athletes.

**CONCLUSIONS:** This study, the first on this topic in Latin America, shows a worrisome prevalence of OH, CC and MJ consumption among UA. Consumption was highest in men's team sports. This data should be taken into account for future interventions to reduce this burden in Colombia.

**Influence of Gender on Knowledge, Attitude, Perceived Social Pressures, and Perceived Behavioral Control Concerning Concussion among High School Athletes**

Johna K. Register-Mihalik<sup>1</sup>, Laura A. Linnan<sup>1</sup>, Tamara C. Valovich McLeod<sup>2</sup>, Stephen W. Marshall<sup>1</sup>, Frederick O. Mueller, FACSM<sup>1</sup>, Kevin M. Guskiewicz, FACSM<sup>1</sup>. <sup>1</sup>The University of North Carolina at Chapel Hill, Chapel Hill, NC. <sup>2</sup>A.T. Still University, Mesa, AZ.  
(No relationships reported)

Few studies have examined gender differences in health behavior concepts such as knowledge, attitude, perceived social pressures, and perceived behavioral control concerning concussion reporting among high school athletes.

**PURPOSE:** To examine the association between gender and knowledge, attitude, perceived social pressures, and perceived behavioral control concerning concussion.

**METHODS:** A pre-validated, cross-sectional survey was completed at home and returned via mail by a convenience sample of 162 high school athletes (98 males, 64 females; age=15.7±1.4 years). The main outcome measures were attitude total score (total of the 14 attitude Likert score answers), knowledge total score (number of questions correct out of 35), subjective norm average score (average of five separate question concerning social pressures, and norms), and perceived behavioral control average score (average of three questions concerning perceived control over concussion reporting). Higher scores indicate more favorable outcomes. Four separate regression models were used to examine the association between gender and these outcomes. Mean differences were examined as male scores minus female scores.

**RESULTS:** Gender was significantly associated with attitude (MD=-4.18; 95% CI:-7.99,-0.38; p=0.030), perceived social pressures (MD=-0.49, 95% CI:-0.91,-0.08; p=0.018), and perceived behavior control (MD=-0.43; 95% CI:-0.83,-0.03; p=0.018) with females having higher scores for each outcome. No association was observed between gender and knowledge scores (MD=0.77; 95% CI:-0.15,1.69; =0.10).

**CONCLUSIONS:** Although knowledge regarding concussion is similar between males and females, females may have a better attitude toward concussion reporting, a more favorable perception that important social referents (parents, teammates, and coaches) feel positively about concussion reporting, and more perceived control over concussion reporting. Clinicians should be mindful of these differences when educating males and females about concussion in an effort to improve attitudes and beliefs concerning concussion and concussion reporting in high school athletes. These findings may help direct the educational efforts mandated by recent statutes and legislation.

Funded by an NFL Charities Medical Research Grant

(No relationships reported)

**INTRODUCTION :** The APOE e4 allele is significantly associated with poor outcome after severe TBI in non-athletic subjects. Previous prospective cohort studies (PCS) on athletes have studied the association of APOE e4 with acute concussion (conc) have been limited by small sample size. In addition, no other genetic polymorphisms (GPs) were included in prior studies. We report on the largest PCS involving college football and men’s/women’s soccer players in the literature and include the APOE G-219T promoter and two Tau gene exon 6 GPs in our analysis.

**PURPOSE:** To evaluate the association between sport related concussion and baseline neuropsychological (NP) test scores with several genetic polymorphisms (GPs) [GPs are APOE, APOE G-219T promoter (APOEProm), Tau exon 6 Ser53Pro (TauSer) and Tau Hist47Tyr (TauHis)] in college athletes.

**METHODS:** A multi-center PCS of 1186 college athletes from 15 institutions completed a conc/medical history (hx) questionnaire, genetic sampling (buccal swab, saliva, and blood), and baseline web-based NP testing (Headminder™). The overall population was 87% male, 59% white and mainly played football (67%) and soccer (24.4%).

**RESULTS:** Chi Square showed no significant association between experiencing an acute conc and the GPs. The Tau Ser TT genotype was associated with a trend towards reduced prospective concs (p<0.094). T tests showed that baseline NP test results such as Simple Reaction Time (SRT), Complex RT (CRT), CRT Errors, and Processing Speed (PS) had no significant association with any genotype from the GPs. The APOE e4 allele was associated with a significantly lower SRT Errors score (p=0.0131) and the TauSer TT genotype was associated with a significantly prolonged SRT (p=.017). The APOEProm TT genotype trended towards having a significant association with PS (TT having slower PS than GG/GT genotypes). The APOEProm TT/GT genotypes trended towards significantly prolonged CRT scores (p=0.088).

**CONCLUSION:** This large PCS of college athletes showed no significant association between APOE, APOEProm, Tau exon 6 Ser53Pro and Hist47Tyr and experiencing an acute conc. Future plans are to study the association between various GPs and post conc neurocognitive recovery.

**Acknowledgements:** NOCSAE and the AMSSM Foundation provided funding for this study.

**Balance Testing of Concussion Patients Using Dual-Task Interference**

Verle D. Valentine, Jason C. Dorman, Thayne A. Munce, Hannah K. Nelson, Ashley L. Miller, Paul A. Thompson, Michael F. Bergeron, FACSM. Sanford USD Medical Center, Sioux Falls, SD.  
(No relationships reported)

As proper medical care for sports concussions is increasingly emphasized, balance testing (BT) is emerging as a relatively new and promising method of concussion evaluation that warrants further investigation.

**PURPOSE:** To examine the diagnostic value of a novel BT protocol using dual-task interference from a cognitive challenge and compare longitudinal data from this and other concomitantly-used clinical concussion assessment tools.

**METHODS:** Clinically relevant data were collected from 68 concussed individuals (14-24 y) through standard symptom score evaluations, a computer-based neurocognitive test (ImPACT™), and the dual-task BT protocol. Additionally, 26 healthy, age- and sex-matched individuals performed identical BT on two separate occasions to provide normative data. Postural stability (AMTI force platform) was assessed during four BT conditions: eyes open (O), eyes open + cognitive task (OC), eyes closed (C), and eyes closed + cognitive task (CC). The cognitive task required subjects to recite the months of the year backwards.

**RESULTS:** Normative BT values for each condition were determined from the control data. An abnormal test was defined as 2.0 SD or more above the normative mean. Using these criteria, five distinct categories of concussion patients were identified: no balance deficits (ND), balance deficits only when vision was removed by closing the eyes (VD), balance deficits only during cognitive task (CD), balance deficits during both the VD and CD conditions (VCD), and non-specific balance deficits (BD). ANOVA analysis revealed higher symptom score reports by the BD vs. ND group in total symptom score ( $p = 0.014$ ), total physical symptoms ( $p = 0.005$ ), total cognitive symptoms ( $p = 0.018$ ), severity of complaint of balance problems ( $p < 0.001$ ), and severity of complaint of difficulty with attention and concentration ( $p = 0.003$ ).

**CONCLUSION:** Non-specific BT deficits in concussed patients are associated with greater reporting of symptoms. Dual-task interference BT with a cognitive challenge is a potentially valuable method of evaluation; yet, its clinical relevance is just now being established. Validation of this novel methodology may help to further establish BT as an effective tool in concussion treatment and research.

**1716** Board #124 MAY 30 3:30 PM - 5:00 PM

**Incidence And Neurocognitive Effects Of Concussion In Youth (8-12 Yrs) American Football: A Prospective Study**

Anthony P. Kontos, R. J. Elbin, Scott Burkhart, Michael W. Collins. *University of Pittsburgh-School of Medicine, Pittsburgh, PA.* (Sponsor: Janet Buckworth, FACSM)

*(No relationships reported)*

As many as 5.5 million youth play American football each year, and recent reports indicate a two-fold increase in emergency department visits for sport-related concussions in youth (8-13 yrs) sport participants (Bakhos et al., 2008). Surprisingly, research on sport-related concussion in American football has been limited to high school, collegiate, and professional populations. There has been no research to date on concussion and its effects in youth American football.

**PURPOSE:** The purpose of the current study was to examine the incidence and neurocognitive effects of concussion in youth (8-12 yrs) American football using a newly developed, youth-specific computerized neurocognitive test.

**METHODS:** The study employed a prospective repeated measures design involving 453 youth football players aged 8-12 yrs. Participants completed the Pediatric Immediate Post-concussion Assessment and Cognitive Test (Pediatric ImPACT) and concussion symptom inventory at pre- and postseason. Concussed athletes also completed Pediatric ImPACT and reported symptoms at 1-3 days, 5-7 days, and 10-14 days post-injury. Additional injury information was obtained from parents using the Acute Concussion Evaluation (ACE). Player exposure and incidence rates for practices and games were recorded throughout the season. A series of correlations, reliable change estimates (RCE), and ANOVAs were conducted to analyze the data.

**RESULTS:** A total of 20 (4.4%) athletes incurred a concussion during the season. All concussions occurred during tackling and were the result of helmet to ground or helmet to helmet impacts. Clinical decreases (i.e., RCE) in neurocognitive performance were evident at 1-3 days and 5-7 days post-concussion, but returned to baseline levels by 10-14 days post-concussion. Pre- to post-season test-retest correlations for the Pediatric ImPACT individual test modules were moderate and ranged from .20 to .52.

**CONCLUSIONS:** The results suggest that youth American football has a relatively low rate of concussion compared to high school and college levels. The results also suggested that the Pediatric ImPACT test was effective in measuring neurocognitive deficits in youth following concussion. Most deficits resolved by 10-14 days. This research was supported by a grant from the National Football League Charities.

**1717** Board #125 MAY 30 3:30 PM - 5:00 PM

**New Concussion Symptom Factors: Age and Sex Differences among High School and College Athletes**

R.J. Elbin<sup>1</sup>, Anthony P. Kontos<sup>1</sup>, Phil Schatz<sup>2</sup>, Tracey Covassin<sup>3</sup>, Jamie Pardini<sup>1</sup>, Michael W. Collins<sup>1</sup>. <sup>1</sup>*University of Pittsburgh, Pittsburgh, PA.* <sup>2</sup>*St. Joseph's University, Philadelphia, PA.* <sup>3</sup>*Michigan State University, East Lansing, MI.* (Sponsor: Janet Buckworth, FACSM)

*(No relationships reported)*

**PURPOSE:** The primary purpose of the current study was to examine using exploratory factor analyses (EFA) the factor structure of the 22-item Post-concussion Symptom Scale (PCSS) in independent samples of baseline and post-concussion high school and collegiate athletes. A secondary purpose of the study was to examine sex and age differences in the symptom factor scores.

**METHODS:** Baseline participants included 30,455 athletes (27,008 high school, 3,447 collegiate; 14,295 female, 16,160 male). Post-concussion participants included 1,438 athletes (944 high school, 494 collegiate; 477 females, 961 males) within 1-7 days of a concussion. Participants completed the PCSS. Two EFAs for baseline and post-concussion samples were conducted. A series of 2 (age) x 2 (sex) ANOVAs with Bonferroni correction for multiple comparisons were conducted for the baseline and post-concussion factors.

**RESULTS:** The baseline EFA supported a four factor solution (49.1% variance): 1) Cognitive-Migraine, 2) Sleep, 3) Vestibular-Headache, and 4) Emotional. The post-concussion EFA supported a four factor solution (58.3% variance): 1) Cognitive-Migraine, 2) Emotional, 3) Somatic, and 4) Sleep. High school athletes reported higher baseline Migraine (1.28:1.16) and Vestibular factors (.83:.61), but lower Sleep factor scores (1.86:1.99). Females reported higher Migraine (1.43:1.12), Sleep (2.13: 1.65), Vestibular (.95:.67), and Emotional factors scores (1.57:.85). High school athletes reported lower post-concussion Sleep factor scores (1.41:2.03). Females reported higher post-concussion Emotional factor scores (1.56:.90).

**CONCLUSIONS:** The results supported a four factor structure for both the baseline and post-concussion samples. However, several differences between baseline and post-concussion factor and age and sex differences were apparent and should be considered by clinicians and researchers.

**1718** Board #126 MAY 30 3:30 PM - 5:00 PM

**Dual-task Assessment Of Concussion: Switch-task Stability Reliability Estimation**

Phillip D. Tomporowski, FACSM, Stephanie L. Cooper, Michelle S. Okumura, Michael S. Ferrara. *University of Georgia, Athens, GA.*

*(No relationships reported)*

The incidence of sport-related concussion is high, with 1.6 to 3.0 million sport-related concussions reported annually. Standardized, computer-based neurocognitive test batteries have been used in the assessment and management of sport-related concussion; however these tests are limited to cognitive functioning only. The dual-task methodology combines a physical and a mental task and closely replicates practice and game conditions, which can yield valuable information for return to play decisions.

**PURPOSE:** To examine the stability reliability of a dual-task test that combines stair stepping with an auditory detection task.

**METHODS:** 59 young adults (Mean age = 20.32 years; 40 female) performed a 5-min modified Harvard step test and an auditory switch test during two sessions separated by 7 days. The switch task measures the time required for an individual to inhibit an ongoing mental task and to initiate a different mental task, processes that are characteristic of executive function. Switch-task trials involved letter (vowel/consonant) or number (even/odd) discriminations to stimuli presented on headphones and recorded via two keys on a hand-held computer mouse. The stability reliability was assessed for switch-task tests consisting of 30, 40 and 60 items.

**RESULTS:** Intraclass correlations (ICC) estimated the stability of response time for switch and non-switch trials. The ICCs for the 30-item test were 0.60 (switch) and 0.61 (non-switch). The 40-item test yielded ICCs of 0.89 (switch) and 0.72 (non-switch). The 60-item test yielded ICCs of 0.85 (switch) and 0.75 (non-switch).

**CONCLUSION:** The auditory dual-task methodology shows acceptable reliability for both the 40 and 60 item tests. As part of a comprehensive concussion management plan, the dual task methodology may prove to be especially useful for making return-to-play decisions as it closely mimics physical activity and on-field performance by combining controlled motor movements and complex mental task performance.

---

**1719** Board #127 MAY 30 3:30 PM - 5:00 PM  
**Baseline Concussion Scores are Influenced by Measured Levels of Effort**

Julianne D. Schmidt, Katrina J. Trinidad, Kevin M. Guskiewicz, FACSM. *The University of North Carolina at Chapel Hill, Chapel Hill, NC.*  
(No relationships reported)

Athletes are inherently less motivated when completing preseason concussion baseline testing than during post-concussion evaluations. When comparing back to baseline values during post-concussion evaluations, improved effort may mask deficits.

**PURPOSE:** To determine if baseline neurocognitive and postural control performance differ between athletes who demonstrate poor effort (PE) and those who demonstrate satisfactory effort (SE).

**METHODS:** 165 incoming student-athletes completed baseline testing including a computerized neurocognitive test (CNS Vital Signs), a postural control exam (SOT; Sensory Organization Test), and a measure of test-taking effort (DCT; Rey Dot Counting Test). PE was defined as a DCT combination score  $\geq 15$  and SE was defined as a DCT combination score  $< 15$ . We first identified 27 athletes (16%) that demonstrated PE at baseline. Each athlete in the PE group was matched based on gender, concussion history, learning disability diagnosis, and ADHD diagnosis to a single control who demonstrated SE at baseline (PE: n=27, SE: n=27). Separate one-way ANOVA models were used to compare the SE and PE groups on 8 CNS Vital Signs standard scores (composite memory, psychomotor speed, reaction time, complex attention, cognitive flexibility, processing speed, executive functioning, and reasoning) and a postural control score (SOT composite score) with an a priori alpha level of 0.05.

**RESULTS:** The PE group performed significantly worse than the SE group on composite memory (PE:89.6 $\pm$ 17.4 vs. SE:99.8 $\pm$ 14.6,  $F_{1,50}=5.3$ ,  $p=0.03$ ), psychomotor speed (PE:100.2 $\pm$ 11.3 vs. SE:106.1 $\pm$ 9.4,  $F_{1,52}=4.4$ ,  $p=0.04$ ), reaction time (PE:93.5 $\pm$ 18.6 vs. SE:102.2 $\pm$ 9.6,  $F_{1,52}=4.6$ ,  $p=0.04$ ), cognitive flexibility (PE:81.9 $\pm$ 26.9 vs. SE:95.4 $\pm$ 21.8,  $F_{1,52}=4.1$ ,  $p=0.05$ ), and processing speed (PE:88.6 $\pm$ 22.7 vs. SE:101.5 $\pm$ 14.5,  $F_{1,50}=6.2$ ,  $p=0.03$ ). No other significant differences were observed.

**CONCLUSION:** Athletes who demonstrated PE at baseline performed significantly worse on several neurocognitive domains. This supports the notion that baseline neurocognitive scores are only as good as the effort that an athlete extends. Sports medicine professionals administering baseline testing may consider incorporating this brief measure of effort at baseline and post-concussion to determine an appropriate evaluation plan.

---

**1720** Board #128 MAY 30 3:30 PM - 5:00 PM  
**Normal Cognitive Function Following Self-reported "Dings" In A Cohort Of Collegiate Rugby Players.**

Tamerah N. Hunt, Donald LeMay. *The Ohio State University, Columbus, OH.* (Sponsor: Thomas Best, FACSM)  
(No relationships reported)

Previous concussion guidelines have suggested that adult athletes with mild concussions (dings) may be returned to play if asymptomatic for 15 minutes. The incidence of "dings" in rugby can be high and consequences of reporting may lead to stoppage of play. Athletes that continue to play while suffering from the physiological effects of concussion may increase their risk for further and potentially catastrophic injury.

**PURPOSE:** This study examined if self-reported "dings" result in decreases in cognitive function as measured by ImPACT.

**METHODS:** This study was a prospective cohort design. Collegiate rugby football athletes were observed on-field throughout their fall competitive season. Fourteen collegiate rugby players (age 21.5 + 1.34 years) participated in the study. All athletes completed ImPACT to establish a baseline prior to the competitive season. After the completion of their competitive season, all participants were re-tested utilizing ImPACT. Athletes were grouped by self-reported dings that continued to participate and those without dings "normals". Post-season ImPACT composite scores served as dependent variables.

**RESULTS:** Four athletes sustained a ding during the season (28.5%). No significant differences were observed on ImPACT composite scores between those with self-reported dings and "normals". Means + SD (CI) for Impulse control in "normals" 4.6 + 4.9 (CI 1.0-8.2) and dings 9.5 + 1.7 (CI 6.7-12.3) ( $F(1, 12) = 3.5$ ,  $p > .05$ ,  $\eta^2 = 0.23$ ). Verbal memory in "normals": 90.0 + 8.8 (87.7- 96.3) and dings 79.0 + 12.8 (58.6 -99.4) ( $F(1, 12) = 3.5$ ,  $p > .05$ ,  $\eta^2 = 0.27$ ); Visual motor in "normals" 41.9 + 6.2 (CI 37.4-46.4) and dings 45.7 + 7.9 (CI 32.9-58.3) ( $F(1, 12) = 0.89$ ,  $p > .05$ ,  $\eta^2 = 0.07$ ). The correlation between time in contact and self-reported dings (0.324) was not significant.

**CONCLUSIONS:** These findings suggest that deficits were not observed following one competitive season of rugby regardless of self-reported dings. A higher mean and confidence interval for impulse control existed which may indicate a long-term effect on impulse control following dings. These findings support the need for additional research to examine long-term effects of deficits following multiple low threshold impacts in rugby players.

---

**1721** Board #129 MAY 30 3:30 PM - 5:00 PM  
**A Qualitative Exploration Of Concussion-related Medical Care Seeking Behavior Among Male Collegiate Ice Hockey Players**

Emily Kroshus<sup>1</sup>, Eric Kroshus<sup>2</sup>. <sup>1</sup>Harvard School of Public Health, Boston, MA. <sup>2</sup>Harvard University, Cambridge, MA.  
(No relationships reported)

**OBJECTIVE:** The objective of this study was to explore the subjective and contextualized experience of concussion recovery among male collegiate ice hockey players who sustained a concussion while participating in their sport, with particular attention paid to how their own subjectivity influenced their medical care seeking behaviors.

**METHODS:** A phenomenological qualitative approach was used, guided by the paradigm of social constructivism. Eleven semi-structured individual qualitative interviews were conducted with male collegiate ice hockey players who sustained concussions during their collegiate ice hockey career. Transcripts were coded in two cycles and were reviewed by an independent coder, achieving a minimum inter-coder agreement of 85%.

**RESULTS:** Three key themes emerged from the data: initial on ice self-assessment, player initiated medical care, and honesty of symptom reporting once care had been initiated. Initial on ice self-assessment often included a discounting of initial symptom severity, attributed one of three factors: a lack of knowledge about concussion symptoms, a comparison of symptoms to previous hits that were not diagnosed as concussions, and to a "tough it out" mentality characteristic of ice hockey players. After some duration of time, from minutes to days, these players recognized that symptoms were not going away and chose to initiate medical care by presenting themselves to either the team trainer or team physician. Despite the often self-initiated nature of this medical care, once initiated it became for many of the athletes a push to return to the ice as quickly as possible. Many of the athletes recognized the subjective nature of symptom reporting and the strong influence that their self-report had on their return to play. Some chose to distort their self-report to speed up the return to play process.

**CONCLUSIONS:** The assessment and treatment of concussions among male collegiate ice hockey players may be complicated by the patient's subjective role in both medical care seeking and symptom reporting once care has been initiated.

---

**1722** Board #130 MAY 30 3:30 PM - 5:00 PM  
**Effect of Sport Related Concussion on Clinically Measured Reaction Time**

James T. Eckner, Jeffrey S. Kutcher, Steven P. Broglio, James K. Richardson. *University of Michigan, Ann Arbor, MI.*  
(No relationships reported)

Reaction time is a sensitive marker of concussion (mild traumatic brain injury). Until recently its measurement required specialized computer software which limited its availability to the clinician. To address this, we developed a simple, inexpensive clinical measure of reaction time (RTclin) that has been shown to be valid and reliable in athletes over multiple time periods. Preliminary results suggest that RTclin is sensitive to the known prolongation of reaction time following sport related concussion. However, these results were uncontrolled and included only 9 concussed athletes.

**PURPOSE:** To determine the effect of sport related concussion on RTclin in high school and collegiate athletes in a larger controlled study.

**METHODS:** Baseline RTclin was measured during pre-participation physical examinations in high school and collegiate athletes. RTclin is the average time over 8 trials required to catch a

suspended vertical shaft by hand closure after its release at random intervals by the examiner. Twenty-five athletes who subsequently sustained a concussion during the athletic season and 25 matched control athletes repeated RTclin testing within 48 hours of injury. Control athletes were members of the same team as the concussed athlete who presented to the training room for a non-concussive injury. A 2-way ANOVA with repeated measures was used to compare preseason and after-injury RTclin values in concussed versus control athletes.

**RESULTS:** Concussed and control athletes demonstrated similar baseline RTclin values during the preseason ( $202 \pm 23$  ms and  $203 \pm 17$  ms, respectively.  $P = 0.839$ ). After-injury RTclin values were significantly longer in the 25 concussed athletes as compared to their own baseline values ( $222 \pm 29$  ms;  $p = .001$ ), while there was a trend toward shorter RTclin values in the 25 control athletes ( $193 \pm 16$  ms,  $p = .054$ ).

**CONCLUSIONS:** RTclin is prolonged within 48 hours of injury in concussed athletes, both with respect to their own baseline RTclin results as well as to repeat RTclin results in uninjured control athletes. This study supports the application of RTclin as part of a multifaceted sport concussion assessment battery, particularly in venues where high technology concussion testing cannot be utilized due to cost or access.

**1723** Board #131 MAY 30 3:30 PM - 5:00 PM

**Knowledge Transfer and Exchange About Sport-related Concussion: A Survey of Family Physicians in Alberta, Canada**

Constance M. Lebrun, FACSM<sup>1</sup>, Martin Mrazik<sup>2</sup>, Abhaya Prasad<sup>2</sup>, Verle D. Valentine<sup>3</sup>. <sup>1</sup>Glen Sather Sports Medicine Clinic, University of Alberta, Edmonton, AB, Canada. <sup>2</sup>University of Alberta, Edmonton, AB, Canada. <sup>3</sup>Sanford USD Medical Center, Sioux Falls, SD.

(No relationships reported)

Ever-increasing involvement of individuals in athletic endeavors has resulted in sport-related concussion receiving major attention over the last decade. Concussion is frequently seen in recreational and competitive sports, and is a major public health concern worldwide. There have been considerable changes to the diagnosis, classification and management of concussion in recent years, causing confusion due to a lag in knowledge translation to the end users.

**PURPOSE:** This study sought to identify current knowledge, practice patterns, and optimal forums for fostering knowledge translation among family physicians in Alberta, Canada.

**METHODS:** Family physicians were mailed letters of recruitment through the Alberta Family Practice Research Network (AFPRN), and asked to reply with their willingness to participate in the on-line survey. Seventy-eight of 3154 family physicians responded (2.5% response rate).

**RESULTS:** While 96% of these physicians reported diagnosing and treating concussions in their work settings, only 54% consistently utilized current concussion guidelines. Sport-related activities constituted the majority (71%) of concussions seen. Physicians relied primarily on clinical examination (32%), and player self-report of symptoms (32%) to make return-to-play decisions. Only 2% reported using any form of neurocognitive testing, and (surprisingly) 5% were still using concussion grading scales. Physical rest was recommended as treatment by 96%, but only 71% also suggested cognitive rest. Seventy-one percent (71%) of physicians had taken continuing medical education (CME) credits to learn more about concussion. Physicians rated CME courses (14%), conferences (12%), training in medical school or residency (18%), consultation with colleagues (15%) or specialists (10%), and websites (14%) as their best sources of information regarding concussion. However, they rated CME courses and on-line courses with CME credits (total 46%) as their most preferred method to gain further knowledge.

**CONCLUSION:** Significant gaps still exist in knowledge transfer to family physicians about up-to-date practices for clinical diagnosis and treatment of sport-related concussion. More educational efforts and training opportunities are needed to optimize physician management of this common condition.

**1724** Board #132 MAY 30 3:30 PM - 5:00 PM

**No Evidence of Neuropsychological Performance Deficits in a Group of Male Collegiate Soccer Players from Purposeful Heading**

Thomas W. Kaminski, FACSM, Jenifer Halterman, Charles B. Swanik, Joseph J. Glutting. University of Delaware, Newark, DE.

(No relationships reported)

Purposeful heading is an inherent and strategic part of soccer, and has the potential to result in concussion if performed incorrectly. Some have questioned whether or not each episode of heading results in minor insults to the brain and if there are cumulative effects resulting in impaired neurocognitive functioning.

**PURPOSE:** This study examined the relationship between heading exposure, playing position, and neuropsychological test scores.

**METHODS:** The database consisted of collegiate male soccer athletes who completed yearly pre and post-participation ImPACT neuropsychological tests; however only 16 players had data from three consecutive playing seasons. The number and type of header were tracked for each player at both practices and games. Bivariate correlation coefficients were calculated between the three predictors: total practice (toheadpx), game (toheadg) and combined headers (tohead). The criteria included the six ImPACT composite scores. Additionally, differences between playing positions (midfield/offense vs. defenders) were examined using independent samples *t*-tests.

**RESULTS:** The total headers ranged from 160 to 422. Correlations table:

| Criteria     | Predictors |         |        |
|--------------|------------|---------|--------|
|              | Toheadpx   | Toheadg | Tohead |
| verbmam      | .083       | .301    | .267   |
| vismam       | .280       | -.023   | .083   |
| vismotpspeed | -.291      | .093    | -.032  |
| rxntime      | .030       | -.176   | -.128  |
| impulsecont  | -.189      | -.224   | -.245  |
| totalsxscore | .168       | .122    | -.036  |

None of the correlation coefficients were statistically significant; nor were there significant differences between any of the ImPACT scores and the position groups.

**CONCLUSIONS:** Despite many anecdotal reports suggesting links between purposeful heading and deficits in brain function, this study indicates that no relationship exists between the number of headers and neuropsychological test performance in male collegiate soccer players. Despite some player positions accumulating more total headers, there were no differences in ImPACT scores between groups.

**1725** Board #133 MAY 30 3:30 PM - 5:00 PM

**Sport Concussion Knowledge, Clinical Practices, and Needs for Continuing Education: A Survey of Family Physicians**

B. Joel Tjarks<sup>1</sup>, Verle D. Valentine<sup>2</sup>, Constance M. Lebrun, FACSM<sup>3</sup>, Jason C. Dorman<sup>2</sup>, Martin Mrazik<sup>3</sup>, Abhaya S. Prasad<sup>3</sup>, Thayne A. Munce<sup>2</sup>, Michael F. Bergeron, FACSM<sup>2</sup>. <sup>1</sup>University of South Dakota, Vermillion, SD. <sup>2</sup>Sanford USD Medical Center, Sioux Falls, SD. <sup>3</sup>University of Alberta, Edmonton, AB, Canada.

(No relationships reported)

Concussions are the most common form of head injury in recreational and competitive sports and have recently been identified as a major public health concern worldwide. With greater clinical and scientific appreciation of effects and recovery time, new research and discoveries, newly adopted legislation and revised management guidelines, sport-related concussion has received considerable attention recently from the media and healthcare organizations. Concomitantly, it is challenging for healthcare professionals to remain informed of the latest evidence-based concussion information.

**PURPOSE:** To identify current knowledge and practice patterns of family physicians in North Dakota and South Dakota regarding their clinical management of patients with sport-related concussion; and to examine their preferred delivery methods of knowledge transfer and exchange on this subject.

**METHODS:** A brief, internet-based survey (21 questions) was distributed to family physicians in North Dakota and South Dakota from a database provided by the American Academy of Family Physicians. One hundred nine (109) out of five hundred forty-five (545) family physicians completed the survey (20% response rate).

**RESULTS:** Only nine physicians (9.4%) said they are currently using the most up-to-date guidelines established at the 3rd International Conference on Concussion in Sport held in Zurich in

2008. Physical rest is recommended by 75% of physicians, while only 65% recommend cognitive rest. Outdated grading scales are still being used by physicians for their initial assessments (27%) and return-to-play decisions (12%). There were assorted answers regarding these physicians' current sources for learning about concussions, but the most preferable method (66.7%) was through a Continuing Medical Education (CME) course (online or otherwise). The majority of respondents (84%) indicated that they would like to receive additional education on concussions.

**CONCLUSIONS:** Myriad family physicians are managing sport-related concussions using clinical diagnoses and management practices that are inconsistent with current information and guidelines. Accordingly, a more deliberate and effective effort to re-educate and maintain knowledge in family physicians is critical to enhance patient care in this population.

1726 Board #134 MAY 30 3:30 PM - 5:00 PM

**Concussion History and Exertional Heat Illness-Related Symptomatology Among Division-I Collegiate Athletes**

Michael L. Alosco<sup>1</sup>, Krysten Knecht<sup>1</sup>, Ellen Glickman, FACSM<sup>1</sup>, Michael F. Bergeron, FACSM<sup>2</sup>, John Gunstad<sup>1</sup>. <sup>1</sup>Kent State University, Kent, OH. <sup>2</sup>University of South Dakota, Sioux Falls, SD.

(No relationships reported)

Sports-related concussions are prevalent and increasingly recognized to be associated with a variety of adverse short- and long-term clinical outcomes. Recent findings indicate that traumatic brain injury is associated with disruption of the autonomic nervous system (ANS). However, while exertional heat illness (EHI) is also a familiar problem in many sports, the effect of concussion history on EHI risk has not been elucidated.

**PURPOSE:** This study examined the association between concussion and EHI symptomatology histories among a sample of NCAA division-I athletes.

**METHODS:** Analyses were conducted on 100 baseline assessments of NCAA division-I football, soccer, and field hockey athletes (58 males, 42 females; 19.8±1.4 years). All athletes completed baseline ImpACT™ testing and a brief questionnaire assessing history of EHI-related symptomatology.

**RESULTS:** Concussion history was common in the sample, with 28% reporting a history of at least one concussion. Chi-square statistics revealed a greater frequency of EHI symptoms in athletes with a history of concussion compared to those without such history, including getting tired faster than normal ( $\chi^2(1, N = 100) = 5.08, p = .02$ ), very fast heart rate ( $\chi^2(1, N = 100) = 6.86, p = .01$ ), muscle cramps ( $\chi^2(1, N = 100) = 5.90, p = .02$ ), and feeling light headed ( $\chi^2(1, N = 100) = 4.58, p = .03$ ). When restricting the sample to only football players, similar findings emerged, specifically for muscle cramps ( $\chi^2(1, N = 59) = 6.14, p = .01$ ), feeling like they might black out ( $\chi^2(1, N = 59) = 6.65, p = .05$ ), and fast heart rate ( $\chi^2(1, N = 59) = 4.59, p = .03$ ).

**CONCLUSIONS:** Athletes with a history of concussion may be at greater risk for EHI than those without such history and thus might warrant more deliberate EHI prevention measures and closer monitoring. Prospective studies of ANS function following concussion and concomitant effects on exertional heat strain will clarify potential changes in EHI risk.

**The Relation Between Bone Mineral Density And Cardiovascular Factors Among Iranian Female Athletes With Amenorrhea/oligomenorrhea**

Haleh Dadgostar<sup>1</sup>, Ghazaleh Soleimani, female<sup>2</sup>, Sara Lotfian, female<sup>3</sup>, Mazyar Moradi lakeh, male<sup>4</sup>, Elham Dadgostar, female<sup>5</sup>, Shafieh Movaseghi, female<sup>6</sup>, Talia Alenabi, female<sup>7</sup>. <sup>1</sup>Sports Medicine Research Center. Tehran University of Medical Sciences, Tehran, Iran, Islamic Republic of. <sup>2</sup>Rasoule akram hospital. Tehran University of medical sciences, Tehran, Iran, Islamic Republic of. <sup>3</sup>Sports Medicine Research Center. Tehran University of Medical Sciences, Tehran, Iran, Islamic Republic of. <sup>4</sup>Tehran University of medical sciences, Tehran, Iran, Islamic Republic of. <sup>5</sup>Sports Medicine Federation, Tehran, Iran, Islamic Republic of. <sup>6</sup>Eman Khomeini hospital. Tehran University of medical sciences, Tehran, Iran, Islamic Republic of. <sup>7</sup>Sports medicine Federation, Tehran, Iran, Islamic Republic of.

(No relationships reported)

**PURPOSE:** Oligo/amenorrhea, as a part of the Female Athletic Triad has adverse effects on the athlete's bone mineral density and cardiovascular system. Hypoestrogenism, due to suppression of PHO axis as a result of energy imbalance, is the possible cause of the Triad. This study was designed to clarify the effects of hormone therapy on bone mineral density and cardiovascular factors.

**METHODS:** The study is a 9-month clinical trial in the first part of which 22 female athletes with a history of at least 2 years of oligo/amenorrhea, bone mineral densitometry (BMD) and some of the cardiovascular factors were measured. In the second part of the study 18 athletes were randomized in two groups of OCP (n=10) and control (n=8). After 9 months densitometry and cardiovascular lab study were repeated.

**RESULTS:** In the first assessment, Mean of all cardiovascular factors was in the normal range except for HDL, however, most of the athletes had abnormalities in their lipid profile. Inverse relationship between the increase in the BMD of spine and total cholesterol, Apo A, and VLDL and also positive correlation between BMD of spine and HbA1C were significant. In the second part, VLDL and Apo B reduced significantly in the OCP group. Increase of Apo A was observed in control group. Changes in the ratio of Apo B to Apo A was significant in both groups.

**CONCLUSIONS:** There may be a common factor affecting both skeletal and cardiovascular systems, as with the increase of the BMD of spine, there is a decrease in the amount of serum total cholesterol, Apo A, and VLDL. Results of this study imply that although estrogen administration may not increase bone density, it could have positive effects cardiovascular system, especially lipid profile. In order to evaluate the long-term effect of estrogen administration in athletes suffering from menstrual irregularities, studies with larger sample size and longer duration is required.

1728 Board #136 MAY 30 3:30 PM - 5:00 PM

**Need For A Tool: Handling Professional Soccer Players Biochemical Data**

Giulio Tempesti<sup>1</sup>, Alice Bartolini<sup>1</sup>, Niccolò Gori<sup>1</sup>, Giovanni Romagnoli<sup>2</sup>, Paola Pezzati<sup>3</sup>, Laura Stefani<sup>1</sup>, Giorgio Galanti<sup>1</sup>. <sup>1</sup>Sports Medicine, Florence, Italy. <sup>2</sup>Engineering Informatic Faculty, Florence, Italy. <sup>3</sup>General Laboratory Diagnostic Department, Florence, Italy.

(No relationships reported)

**PURPOSE:** According to Italian regulation, professional athletes undergo to a periodical biochemical parameters evaluation addressed to maintain health. A software toolkit analyzes biochemical parameters focused on monitoring of Least Significant Change (LSC) for hematological variables. **Method:** Since January 2008 to July 2011, 81 professional soccer players blood samples were collected. According to quality standard reference Clinical Laboratory, a dedicated software ("Victory") allows the user retrieving LSC in the team's athletes. LSC =  $2.77(CV_i^2 + CV_a^2)^{1/2}$  equation, including every athlete's data, derived from soccer seasonal training period. The software identifies hematological values exceeded the LSC values.

**RESULTS:** Standard hematological mean team values (2009/2010), examined considering ethnicity, age and role, were within the normal range (Hb  $15.2 \pm 0.6g/dL$ , min 13.9, max 16.6; HcT  $43.0 \pm 1.9\%$ , min 41.0, max 49.0; MCV  $87.3 \pm 3.0fL$ , min 82.0, max 93.5; reticulocytes  $0.0433 \pm 0.0128 \times 10^{12}/L$ , min 0.0186, max 0.0732). In parallel the LSC for Hb (5.80%), HT (8.20%) and MCV (2.41%) and reticulocytes count (17.96%) resulted to be normal, with the exclusion of soccer players data that exceed LSC value in consequence of the training period at the same work load. In the 6.2% of the all samples investigated for each athlete, the hematological variation was over the LSC.

**CONCLUSION:** The software retrieves epidemiological information based on the physiological changes of the hematological parameters occurring during the seasonal competitions. It can therefore be propose to clarify several clinical questions related to regular training or to risk factors particularly if in presence of different work load or recurrent injuries.

1729 Board #137 MAY 30 3:30 PM - 5:00 PM

**A Long Term Sport Activity and Myocardial Performance In Breast Cancer Women**

Laura Stefani, Gabriele Innocenti, Valentina Di Tante, Ilaria Corsani, Gabriele Mascherini, Irene Scacciati, Alessio De Luca, Giorgio Galanti. *Sports Medicine, Florence, Italy.*  
(No relationships reported)

**PURPOSE:** The beneficial effects of the exercise as prescription in cancer is well known, however few information are now available on the cardiovascular performance when competitive sport is regularly practiced. The study was aimed to evaluate in a group of breast cancer women (BCW), the effects of dragon boat sport on the myocardial performance during a 4 years follow up study.

**METHODS:** Since 2006 to 2010, one year after breast cancer treatment, a group of 30 regularly trained (Dragon-Boat) women, without metastasis, has been followed at Sports Medicine Center in Florence -Italy. They were yearly submitted to a maximal cardio-pulmonary test and to a 2D echocardiographic exam evaluating morphological and functional cardiac parameters in addition to Heart Rate (HR) and Blood Pressure (BP) values, measured at rest and at the end of the effort. All data were compared (T-Student Test) to a group of competitive healthy women (HW).

**RESULTS:** At the end of the 4 follow-up years all the echo parameters were within the normal range in both groups. (Fig1) Despite CMI and BMI were significantly higher in HW than in BCW, the EF resulted to be similar. After 4 years of training in BC group the HR at rest was lower ( $78.12 \pm 13$ ) than at the beginning ( $80.7 \pm 11.7$ ) of the study. Systolic and Diastolic BP were comparable to the healthy athletes normal values.

**CONCLUSIONS:** The results obtained are suggestive for a beneficial effect of sports activity in breast cancer with an excellent exercise tolerance. A long term competitive sport activity does not seem to have any negative impact on the myocardial performance in them.

---

1730 Board #138 MAY 30 3:30 PM - 5:00 PM

**Cardiovascular Performance And Prevalence Of Menstrual Disorders**

Silvia Lorini<sup>1</sup>, Laura Stefani<sup>1</sup>, Loira Toncelli<sup>1</sup>, Maria Concetta Robertina Vono<sup>1</sup>, Metella Dei<sup>2</sup>, Giorgio Galanti<sup>1</sup>. <sup>1</sup>*Sports Medicine, Florence, Italy.* <sup>2</sup>*Child and Women Health Department, Florence, Italy.*  
(No relationships reported)

**PURPOSE:** The incidence of amenorrhea is much greater observed among the athletes than in sedentary, however the implication of this feature with the cardiovascular performance remain less clear. The study is aimed to investigate this aspect in a larger group of athletes from sports at different static and dynamic component.

**METHODS:** Two groups of athletes 1Group (1G of 50 subjects) aged  $16 \pm 2$ , from swimming and dance at high dynamic and low static load and 2Group (2G of 50 subjects) from volleyball and gymnastic artistic at moderate/high dynamic and static load, were submitted to a questionnaire to evaluate the prevalence of menstrual disorders and also to an echocardiographic exam to verify the associated morphological and functional pattern.

**RESULTS:** the menstrual disorders result to be generally low (13%) with an exclusive presence in the 2G. All the echo parameter are within the normal range in both without any significant variation with the exclusion of the Cardiac Mass Index (CMI) value that results to be significantly lower in the 2G respect of the 1G (Fig1). Otherwise the nutrition parameters show a significant increase of the Fat Free Mass (FFM) in the 1G vs the 2G. An inverse behavior (Fig2) has been observed for the Fatty Mass (FM)

**CONCLUSIONS:** The results support the hypothesis that the prevalence of the irregular menstrual cycle are independent from the nutritional parameters in sports at high-moderate dynamic component. An opposite trend is evident for the CMI that seems to be associated to a superior and more equilibrate body composition.

Lindsey E. Eberman<sup>1</sup>, Leamoh Kahanov<sup>1</sup>, Nicholas Long<sup>1</sup>, Heather Adams<sup>1</sup>, Michelle L. Landis<sup>1</sup>, Janis Ingebretsen<sup>2</sup>. <sup>1</sup>*Indiana State University, Terre Haute, IN.* <sup>2</sup>*Union Hospital, Terre Haute, IN.*  
(No relationships reported)

Research suggests that endurance athletes experience lower than normal hematology levels during season, thought to be the result of overtraining. Serum ferritin has been identified as a biochemical indicator of iron deficiency and may also be a result of overtraining.

**PURPOSE:** We sought to observe serum ferritin, hemoglobin, and hematocrit levels of collegiate runners.

**METHODS:** As part of the pre-participation physical exam in an NCAA Division I Institution in the mid-western US, male ( $n=23$ ; age= $20 \pm 1$ ; height= $69.7 \pm 2.5$ in; weight= $147.4 \pm 16.3$ lb; in-season mileage= $60.2 \pm 19.6$ wk; off-season mileage= $75.4 \pm 13.0$ wk) and female ( $n=19$ ; age= $20 \pm 1$ ; height= $64.2 \pm 2.7$ in; weight= $126.0 \pm 14.5$ lb; in-season mileage= $40.1 \pm 7.9$ wk; off-season mileage= $39.3 \pm 5.9$ wk) cross country and track athletes underwent blood-draw and physical history examinations. Following the examinations, we acquired access to the anonymous data for further analysis. We collected age, height, weight, gender, ferritin, hematocrit, and hemoglobin levels from all participating athletes.

**RESULTS:** Overall, the collegiate runners demonstrated within normal limits ferritin (males= $63.4 \pm 29.38$ ng/mL, normal range= $30-400$ ng/mL; females= $44.1 \pm 50.8$ ng/mL, normal range= $13-150$ ng/mL), hematocrit (males= $41.7 \pm 2.2\%$ , low range= $<45\%$ ; females= $38.9 \pm 2.2\%$ , low range= $<40\%$ ), and hemoglobin levels (males= $14.6 \pm 0.8$ g/dL, normal range= $13.8-18.0$ g/dL; females= $13.7 \pm 0.7$ g/dL, normal range= $12.1-15.1$ g/dL). However, when determining athletes with low levels, we found differences in at-risk athletes based on the criteria. We identified lower than normal ferritin levels in 2 males and 1 female. We identified 22 males and 12 females with insufficient levels of hematocrit. Hemoglobin was lower than normal in 6 males.

**CONCLUSIONS:** The collected hematology levels may be an indication of over-training; however, such levels are expected of the body's response to stress and return to normal levels during periods of rest/off-season. The research suggests that observing ferritin levels alone may not be sufficient to determine iron deficiency. Hematocrit level is a more sensitive indicator of iron deficiency when triangulated with ferritin and training regime.

1732 Board #140 MAY 30 3:30 PM - 5:00 PM

**Diet Versus Diet Plus Exercise On Weight And Depression In The Severely Obese**

Amy D. Rickman, Bret H. Goodpaster, John M. Jakicic, FACSM, The RENEW Study Research Group. *University of Pittsburgh, Pittsburgh, PA.*  
(No relationships reported)

Severe obesity (BMI  $\geq 35$  kg/m<sup>2</sup>) is associated with increased risk for depression compared to those at a lower BMI. Depressive symptomatology has been shown to improve with both weight loss and exercise. However, it is unclear if weight loss induced by dietary restriction compared to dietary restriction plus exercise have differential effects on depressive symptoms in individuals with severe obesity.

**PURPOSE:** To examine the effect of diet with delayed exercise (D) versus diet plus exercise (DE) on depressive symptoms and weight in individuals classified with Class II (BMI: 35.0-39.9 kg/m<sup>2</sup>) or III (BMI:  $\geq 40$  kg/m<sup>2</sup>) obesity.

**METHODS:** 118 obese individuals (age= $46.2 \pm 6.3$  years; BMI= $43.5 \pm 5.4$  kg/m<sup>2</sup>) were randomized to a D or DE intervention. Both D and DE received a reduced calorie diet (1200-2000 kcal/wk) through a behavioral modification program. DE was also prescribed exercise that progressively increased to 300 min/wk by month 6. Weight and the Beck Depression Inventory (BDI) were measured at baseline and 6 months.

**RESULTS:** Weight loss was significantly different between D ( $8.1 \pm 5.9$  kg) and DE ( $11.0 \pm 7.3$  kg) ( $p < 0.05$ ). Both D and DE significantly decreased BDI score with no difference between groups. Subjects were grouped as having lower (BDI  $\leq 13$ , N=89) and higher baseline BDI scores ( $>13$ , N=29). There was no significant difference in weight loss or improvement in BDI score between D and DE for those a lower baseline BDI. However, weight loss was significantly different in D ( $6.5 \pm 6.3$  kg) vs. DE ( $12.3 \pm 8.6$  kg) for those with a higher baseline BDI, but no difference for improvement in BDI.

---

**CONCLUSIONS:** Results suggest severely obese adults lose significantly more weight with DE compared to D; however, both result in similar improvements in depressive symptoms. DE and D were equally effective for weight loss in individuals with less depressive symptoms. Of importance is that for those with more severe depressive symptoms, DE was more effective for weight loss than D, suggesting the clinical implication of prescribing DE for weight loss in these individuals. Strategies to maximize adherence to both diet and exercise are recommended.

**1733** Board #141 MAY 30 3:30 PM - 5:00 PM

**Web-Based Questionnaire to Identify Low Energy Availability in Endurance Trained Women: A Cluster Analysis.**

Maria Bentley<sup>1</sup>, Nick Garrett<sup>1</sup>, Mary Jane De Souza, FACSM<sup>2</sup>, Andrew Kilding<sup>1</sup>. <sup>1</sup>AUT University, Auckland, New Zealand. <sup>2</sup>The Pennsylvania State University, University Park, PA.

(No relationships reported)

**PURPOSE:** Low energy availability (EA) in endurance-trained women may develop by intentional or unintentional means in the presence of diverse eating attitudes and behaviours. This study investigated the ability of an on-line web-based survey to identify the clustering and prevalence of at-risk factors for low EA in endurance-trained.

**METHODS:** Women registered for endurance running events in New Zealand completed an anonymous web-based questionnaire comprising questions pertaining to eating attitudes and behaviours, medical, menstrual and injury history. Descriptive information (e.g. self reported age, height, body weight and training load) was also sought.

**RESULTS:** Sufficient data was completed by 698 respondents (29.6±7.1y). Cluster analysis encompassing at-risk factors for low EA identified three distinct subgroups. One cluster classified 57.6% of the sample 'not-at-risk' for low EA as defined by normal Eating Disorders Inventory drive for thinness (DFT, 1.5±2.0), Three Factor Eating dietary restraint (TFE-R, 5.0±3.0) and Eating Disorder Examination restraint (EDE-R, 0.6±0.8) scores. Elevated DFT (7.0±3.9) and TFE-R scores (13.3±2.5) classified 29.8% of respondents in a second cluster 'at-risk' for low EA. High DFT (18.1±2.7), TFE-R (15.3±3.0) and EDE-R (3.3±1.2) scores classified 13.3% of respondents in a third cluster 'at-high-risk' for low EA. The frequency of answering yes to "do you think you may have an eating disorder?" and weight loss attempts for sport and social reasons was also high (36.4%, 31.8% and 46.6% respectively) in this cluster. A high number of respondents (38.8%, 45.7% and 69.3% in clusters 1, 2 and 3 respectively) did not attempt to increase energy intake when exercise energy expenditure was increased.

**CONCLUSION:** A web-based questionnaire identified diverse subgroups of eating attitudes and behaviours and a high prevalence of at-risk factors for low EA in a large sample of endurance-trained women. Online tools that consider the complexity of eating attitudes and behaviours and other currently established at-risk factors (e.g. BMI, menstrual irregularity) may be useful for wide-spread screening for low EA in endurance-trained women.

**1734** Board #142 MAY 30 3:30 PM - 5:00 PM

**Supplement, Prescribed And OTC Medication Use Among Participants In A High-altitude Ultra-endurance Mountain Bike Race**

Morteza Khodaei, Matthew Leiszler, John C. Hill, FACSM. University of Colorado Denver, Denver, CO.

(No relationships reported)

The Leadville100 Mountain Bike Race is an ultra-endurance high altitude race in Colorado. The course ranges in altitude from 2804m to 3840m.

**PURPOSE:** To determine the frequency of supplement, prescribed and OTC medication use during the race and whether their usage is associated with successfully finishing this ultra-endurance race.

**METHODS:** All participants were asked to complete an electronic medical questionnaire and also an electronic survey. Information regarding cyclists' age, gender, and race time is also available to the public on-line.

**RESULTS:** Out of 1604 competitors who started the race, 1140 (71.1%) completed the medical questionnaire and the survey online. Average age was 41.9 (range 18-78) years. Most participants (87.2%) were male. The majority (n=1168, 72.8%) finished the race under the cut-off time of 12 hours. Only 106 (9.3%) of responders reported having an ongoing medical condition and 190 (16.7%) were taking prescribed medications. Respiratory/allergy medications were the most commonly used medications (28.4%), followed by thyroid (24.2%), and cardiac (22.6%) medications. Regular use of supplement and OTC medication was not very common (n=176, 15.4%) among respondents. Vitamins were the most commonly used supplements/OTC medications (38.6%), followed by NSAIDs (28.4%), respiratory/allergy (15.9%), and other sports supplements (15.3%). More than a quarter (n=317; 27.8%) of the respondents was planning to take supplements/medications during the race. Interestingly, 240 cyclists (21.1% of respondents) were planning to take NSAIDs during the race. Only 7 cyclists (0.6%) planned to take Acetazolamide for preventing altitude sickness. Participants who reported having ongoing medical conditions, taking prescribed medications, or OTC medications were less likely to complete the race ( $p < 0.005$ ,  $p < 0.005$ , and  $p < 0.001$  respectively). Interestingly, cyclists who planned to take supplements/medications during the race were also less likely to complete the race ( $p < 0.001$ ).

**CONCLUSION:** In this high altitude event, significant numbers of participants still plan to take NSAID's despite discouragement by race medical team. Cyclists who reported having ongoing medical conditions or the ones who took prescribed/OTC medications were less likely to successfully complete the race.

**1735** Board #143 MAY 30 3:30 PM - 5:00 PM

**Age and Gender Differences Pertaining to Modes of Locomotion in Triathlons**

Jada L. Stevenson<sup>1</sup>, Huaxin Song<sup>2</sup>, Jamie A. Cooper<sup>1</sup>. <sup>1</sup>Texas Tech University, Lubbock, TX. <sup>2</sup>Texas Tech University Medical Science Center, Lubbock, TX.

(No relationships reported)

The magnitude of change in gender differences across age groups in triathlon performance for the Ironman distance has been established. However, the influence of age on gender differences at shorter distance triathlons is yet to be determined.

**PURPOSE:** The purpose of this study was to compare gender differences across age groups for the different modes of locomotion among varying triathlon distances (Sprint, Olympic, and Ironman 70.3) in amateur triathletes from the 2008-2010 World Championship triathlons.

**METHODS:** Data for the top ten male and female amateur triathletes for the age groups between 18-64 yrs was collected from the 2008, 2009, and 2010 World Championships for the Sprint distance triathlon, Olympic distance triathlon, and the Ironman 70.3 or "half Ironman" triathlon. Gender differences across age groups were compared using time performances for different methods of locomotion (swimming, cycling, and running), overall race time, and estimated power output.

**RESULTS:** Total time difference between genders were largest in the age groups 18-24 and 50-64 for Sprint distance, 18-24 and 60-64 for Olympic distance, and 18-24 and 55-64 for Ironman 70.3 distance. In comparing the modes of locomotion, mean gender difference in performance time was smallest for cycling in the Sprint distance (12.4±0.71%,  $p < 0.05$ ) and in the Ironman 70.3 distance (10.5±0.9%,  $p < 0.05$ ), whereas running showed the smallest gender difference in the Olympic distance (7.5±0.64%,  $p < 0.05$ ). Mean gender differences in estimated power output were significantly greater for swimming versus cycling and running in the Sprint distance (44.6±3.14%, 36.4±2.21%, 33.1±0.70%,  $p < 0.05$ ), Olympic distance (39.8±2.43%, 33.6±0.97%, 26.9±0.51%,  $p < 0.05$ ), and Ironman 70.3 distance (40.4±3.04%, 32.8±1.96%, 33.1±0.88%,  $p < 0.05$ ), respectively.

**CONCLUSION:** The magnitude of change for total performance time between genders was greatest in the youngest age groups and older age groups for Sprint, Olympic and Ironman 70.3 distances. Gender differences varied among the modes of locomotion for the three distances of triathlons; however, for short to mid distance triathlons both performance time and estimated power output seem to indicate that the largest gender differences exist for swimming.

**Influence Of Self-reporting Ongoing Medical Conditions On Successfully Completing A High-altitude Ultra-marathon Race**

John Spittler, Morteza Khodaei, John Hill, FACSM. University of Colorado, Denver, CO.

(No relationships reported)

The Leadville 100 is a high altitude ultra-marathon in Colorado. The course ranges in altitude from 2804m to 3840m.

**PURPOSE:** To determine whether having an ongoing medical condition has any influence on successfully finishing this ultra-marathon and to determine the frequency of NSAID use during the race.

**METHODS:** All participants completed either electronic or paper surveys before the race. Information regarding runners' age, gender, and race time is also available to the public online.

**RESULTS:** Out of 625 competitors who started the race, 616 (98.6%) completed the medical questionnaire and the survey. Average age was 40.9 (range 17-85) years. Most participants (84%) were male. More than half (n = 346, 55.4%) finished the race under the cut-off time of 30 hours. Only 53 (8.6%) runners reported having an ongoing medical condition and 46 (7.4%) were taking prescribed medications. Less than one third of the runners (28.2%) reported wearing OTC or custom-fit orthotics. Interestingly, 169 runners (27.61%) were planning to take NSAIDs during the race. There was no statistical correlation (p > 0.05) between successfully finishing the race and whether or not the runners reported having ongoing medical conditions, taking prescribed/OTC medications, and wearing orthotics.

**CONCLUSION:** It seems that having an ongoing medical condition, taking prescribed/OTC medications, or wearing orthotics have no significant influence on successfully completing this high-altitude ultra-marathon. Significant numbers of participants still planned to take NSAIDs despite discouragement by race medical team.

**1737 Board #145 MAY 30 3:30 PM - 5:00 PM**  
**Changes In Serum Sodium Before And After A 10 Kilometer Race**

Mark Troxler, FACSM. *USA Track & Field, Allen, TX.*

(No relationships reported)

**PURPOSE:** To demonstrate that a clinically significant change in serum sodium occurs before and after a 10 Kilometer race.

**METHODS:** A randomized controlled trial with each subject acting as their own control. 35 randomized volunteer participants of a 10K run. Two hours before the race each study athlete was taken for a post-urine/bowel void weight measurement and 5cc of blood was drawn. After the race each athlete reported how many 8oz cups of water they drank and 5cc of additional blood was drawn as well as each athlete was weighed. The change in the serum sodium was the primary outcome and the body weight change and fluid consumption was the secondary outcomes. Change in serum sodium versus change in body weight and fluid consumption was analyzed.

**RESULTS:** 55 run participants volunteered for the study. After randomization 35 randomized volunteer participants of the 10K run entered the study. 24 were male and 11 were female. Of the 35 runners, zero had a serum sodium level above 145mmol/L, three had a serum sodium level below 135mmol/L, and thirty two had a serum sodium of 135-143mmol/L. Of the hyponatremic (sodium <135mmol/L) participants two runners (Premenopausal Females) were low before the race and one runner (Postmenopausal Female) was low after the race. Only three runners, all men, drink a greater total amount of water than the female post-race hyponatremic runner. Only 6 runners, all men, drink more water before the race than the two pre-race hyponatremic female runners. Ten runners had a reduction in serum sodium during the race.

**CONCLUSIONS:** Premenopausal women should limit their fluid intake before the race regardless of the distance. Postmenopausal women should limit their fluid intake during the 10K race.

| Serum Sodium Level of 35 10K Runners |                       |
|--------------------------------------|-----------------------|
| Number of Runners                    | Serum Sodium (mmol/L) |
| 0                                    | >145 mmol/L           |
| 3                                    | <135 mmol/L           |
| 32                                   | 135-144 mmol/L        |

**B-30 Free Communication/Poster - Exercise Training Effects on Muscle**

MAY 30, 2012 1:00 PM - 6:00 PM

ROOM: Exhibit Hall

---

**1738 Board #146 MAY 30 2:00 PM - 3:30 PM**  
**Resistance Training Induces Similar Hypertrophy in the Arm and Thigh Musculature of Young Women.**

William J. Booth<sup>1</sup>, Adam N. Upshaw<sup>1</sup>, Sarah B. Wilkinson<sup>2</sup>, Peter W. R. Lemon, FACSM<sup>1</sup>, Charles L. Rice, FACSM<sup>1</sup>, Greg D. Marsh<sup>1</sup>. <sup>1</sup>The University of Western Ontario, London, ON, Canada. <sup>2</sup>University of Guelph-Humber, Toronto, ON, Canada.

(No relationships reported)

Muscle strength is strongly related to muscle cross-sectional area (CSA). Resistance training can increase muscle CSA and this hypertrophy can be optimized by combining resistance training with post exercise dietary supplementation. Previous research has shown that following resistance training young men hypertrophy to a greater extent in the arm (~16.0%) than in the thigh (~8.5%). This differential hypertrophy has been less well studied in women.

**PURPOSE:** To compare hypertrophy of the thigh to the arm in young women following a 10 week resistance training program with post-workout supplementation.

**METHODS:** Forty untrained females (23±4y) engaged in supervised resistance training three times per week targeting both the upper and lower body for 10 weeks. Participants performed 1-RM testing at pre-, week 3, week 6 and week 9 to ensure that the resistance remained between 80-85% of their 1-RM. All participants refrained from any food intake for at least 1 h prior to their workouts. Immediately after each session, participants ingested a protein, carbohydrate drink containing at least 21g of protein. All participants were assessed with 3T magnetic resonance (MR) imaging on their non-dominant side prior to the 10 week program and again at least 5 days (no more than 8 days) after their final session. The largest CSA (averaged over 5 slices) pre-training was analysed using computer software and compared to the same CSA post-training.

**RESULTS:** Post-training both arm and thigh musculature CSA significantly increased (1.6cm<sup>2</sup> and 6.8cm<sup>2</sup>, respectively) (p<0.05). However, the increase in the thigh (7.3%) was not significantly different than the increase in the arm (8.0%).

**CONCLUSIONS:** Although CSA significantly increased in both the thigh and arm musculature, the change for these women was not significantly different between upper and lower limbs. Further, the % increase in arm CSA was similar to that previously reported in men while the thigh hypertrophy was less than that found in men. Differences between male and female hypertrophy may be explained by fibre type differences, hormonal influences, or body mass distribution differences.

---

**1739 Board #147 MAY 30 2:00 PM - 3:30 PM**  
**The Effects of Low Intensity Resistance Training and Detraining on Isokinetic Strength in Postmenopausal Women**

Meng-yu Chen<sup>1</sup>, Chiao-Hsin Chen<sup>2</sup>, Linda Lin<sup>1</sup>. <sup>1</sup>National Cheng Kung University, Tainan, Taiwan. <sup>2</sup>Chi-Mei Medical Center, Tainan, Taiwan.

(No relationships reported)

**PURPOSE:** To examine the effects in isokinetic strength and body composition's factors after one year of low intensity resistance training, and 24 weeks of detraining in postmenopausal women.

**METHODS:** There were 15 healthy volunteers matched for strength were assigned to a control (n=7, age: 55.26±3.09 years, BMI: 23.89±5.02 kg/m<sup>2</sup>) or exercise group (n=8, age: 55.63±5.03 years, BMI: 21.3±3.41 kg/m<sup>2</sup>). The exercise group exercised one year by using the elastic bands or body weight for resistance. The training program consisted of 2 sessions per week of a supervised progressive high repetition and low resistance training. The measurement was performed by Biodex System to collect data of muscle strength of upper and lower limb. Body composition was estimated by dual energy X-ray absorptiometry (DEXA). The body fat and lean body mass were assessed at baseline, after training and detraining. Pearson product-moment correlation and Mann-Whitney U test were used for data analysis.

**RESULTS:** The exercise group demonstrated significant improvements in peak torque divided by weight of biceps (2.01%) after one year training. And the fat percentage of legs were significantly greater in exercise group (-7.5 %) than the control groups (+2.0 %) (p<.05). The muscular isokinetic strength was positively correlated with lean body mass in the upper limb

( $p < .05$ ). In addition, the peak torque of biceps (3.9%), and fat mass of the leg (-5.17%) in the exercise group were still greater than the baseline after 24 weeks of detraining. However, there was no significant difference in lean mass, and no significant changes were observed in muscle strength of lower limb.

**CONCLUSIONS:** The results of the present study provide evidence that low intensity resistance training program has beneficial effects on body composition and muscular isokinetic strength. The low intensity resistance training still could maintain the gains in strength and body composition for more prolonged periods after training ceased in postmenopausal women.

---

**1740** Board #148 MAY 30 2:00 PM - 3:30 PM

**The Effects of Short-Term Training on Isometric and Concentric Torque Production of the Forearm Flexors**

Daniel A. Traylor, Terry J. Housh, FACSM, Glen O. Johnson, Richard J. Schmidt, Clayton L. Camic, Jorge M. Zuniga, Haley C. Bergstrom, Robert W. Lewis.

University of Nebraska-Lincoln, Lincoln, NE. (Sponsor: Terry Housh, FACSM)

(No relationships reported)

**PURPOSE:** The purpose of the present study was to examine the effects of 3 days of concentric isokinetic training of the forearm flexors on peak torque (PT) at maximal isometric voluntary contraction (MVIC), 60, 180, and 300°·s<sup>-1</sup>.

**METHODS:** Ten adult male (mean age  $\pm$  SD = 21.8  $\pm$  1.2 years; body weight = 87.8  $\pm$  18.4 kg; height = 182.0  $\pm$  9.5 cm) subjects completed two pretests (pretest 1 and 2) that included maximal unilateral isometric and concentric isokinetic forearm flexion (non-dominant arm) muscle actions at MVIC, 60, 180, and 300°·s<sup>-1</sup>. These pretests served as the within subjects control phase of the study. During the training phase, the subjects performed five sets of ten maximal isokinetic concentric forearm flexion (non-dominant arm) repetitions at 60°·s<sup>-1</sup>. The final visit involved the same testing procedures as pretests 1 and 2 and served as the posttest.

**RESULTS:** The results indicated that there was no significant ( $p > 0.05$ ) time  $\times$  velocity interaction, but significant main effects for time and velocity. The follow-up t-tests for the marginal means for time (collapsed across velocity) indicated that there was no significant difference between pretest 1 and pretest 2, but the posttest was greater than both pretest 1 and pretest 2 ( $p < 0.05$ ). Thus, the short-term training resulted in increases in PT at all velocities. The follow-up t-tests for the marginal means for velocity (collapsed across time) indicated that PT decreased significantly with velocity.

**CONCLUSIONS:** Thus, unlike a previous short-term training study that found no increases in PT for the forearm flexors after 2 days of isokinetic training, these findings indicated that 3 days of concentric isokinetic training for the forearm flexors was sufficient to elicit increases in PT. These findings provide specific information for use by allied health professionals, such as physical therapists and athletic trainers, who are responsible for developing resistance training programs to prepare injured athletes to return to practice and competition. In addition, the results of the present study may be useful for physical and occupational therapists in prescribing rehabilitation programs to help patients return to work.

**1741** Board #149 MAY 30 2:00 PM - 3:30 PM

**Skeletal Muscle Architectural Adaptations to Endurance Run Training**

Kevin Murach, Leslie Fey, Seth Wineland, Katelyn Guerriere, Nick Luden. James Madison University, Harrisonburg, VA.

(No relationships reported)

Skeletal muscle architectural plasticity resulting from resistance and power training is well-documented, yet adaptations to endurance run training have not been examined. Existing cross-sectional data indicates that thickness and pennation angle are greater and fascicle length shorter in running-specific musculature of competitive runners versus sprinters, suggesting the potential for run training adaptations.

**PURPOSE:** To determine whether a 15-week marathon training program alters skeletal muscle architectural parameters (thickness [ $T$ ], pennation angle [ $\theta$ ], and fascicle length [ $FL$ ]) in the vastus lateralis (VL) and lateral gastrocnemius (LG) of 10 recreationally active but untrained college-aged subjects.

**METHODS:** Before and after training, VL and LG architecture was imaged using B-mode ultrasonography in addition to maximal voluntary contraction (MVC) and treadmill cardiovascular testing.  $T$  and  $\theta$  was measured offline using NIH imaging software and  $FL$  was formulated using a prediction equation. Dependent t-tests were used to compare pre-post values for each parameter.

**RESULTS:** LG  $T$  and  $\theta$  increased (3.8  $\pm$  6.7% and 19.3  $\pm$  2.2%, respectively [ $p < 0.05$ ]) and LG  $FL$  decreased (14.5  $\pm$  44.6%,  $p < 0.07$ ) while only VL  $T$  increased (and 6.6  $\pm$  11.1%,  $p < 0.05$ ). Fractional oxygen utilization at 11.1  $\pm$  0.5 km/hr improved (70.3  $\pm$  2.4% vs 65.9  $\pm$  2.1%,  $p < 0.05$ ) while other cardiovascular parameters and MVC were unchanged.

**CONCLUSION:** 15 weeks of endurance run training modifies LG architecture and fractional oxygen utilization. These muscle-specific architectural adaptations reflect single muscle fiber observations from the same training program in that the LG seems to be more sensitive to run training than the VL. Further, LG alterations substantiate previous cross-sectional data gathered in distance runners (higher pennation angle and shorter fascicles), implying that the distance runners' architectural profile can at least partially be attributed to training. The functional implications of these adaptations warrant further investigation.

---

**1742** Board #150 MAY 30 2:00 PM - 3:30 PM

**The Effect of Preparation Period Training on Aerobic Power and Muscle Oxygenation in Rowers**

Kazuki Esaki<sup>1</sup>, Koutarou Yamakawa<sup>1</sup>, Toshiyuki Kurihara<sup>2</sup>, Takafumi Hamaoka, FACSM<sup>2</sup>. <sup>1</sup>Shiga University, Shiga, Japan. <sup>2</sup>Ritsumeikan University, Shiga, Japan.

(Sponsor: Takafumi Hamaoka, FACSM)

(No relationships reported)

The aim of preparation period training is to increase the aerobic power and muscle strength in rowing. However, the effect of training on muscle oxygenation during preparation period is unclear.

**PURPOSE:** The purpose of this study was to examine whether the preparation period training improved the aerobic power and the thigh muscle reoxygenation recovery during and following a rowing exercise.

**METHODS:** Fourteen male collegiate rowers participated (age: 20  $\pm$  1 yrs, height: 178.4  $\pm$  7.9 cm, weight: 75.8  $\pm$  7.9 kg) in this study. Subjects were tested before and after a 3-month preparation period training. We evaluated the performance time and the peak pulmonary oxygen uptake (VO<sub>2peak</sub>) during a 2000 m rowing ergometer test and the half-recovery time of muscle reoxygenation (1/2reoxy time) using near-infrared spectroscopy in the vastus lateralis (VL) and rectus femoris (RF) during the recovery phase following the 2000 m rowing ergometer test.

**RESULTS:** The 2000 m performance time and VO<sub>2peak</sub> were significantly improved (415  $\pm$  9  $\rightarrow$  411  $\pm$  11 sec and 62.1  $\pm$  5.6  $\rightarrow$  63.7  $\pm$  6.1 ml/kg/min, respectively,  $p < 0.05$ ). The 1/2reoxy time of the VL was not significantly different between pre- and post-training. On the other hand, 1/2reoxy time of the RF was significantly increased post-training. The value of change in 1/2reoxy time of the VL was significantly correlated with both the 2000 m performance time ( $r = 0.545$ ,  $p < 0.05$ ) and VO<sub>2peak</sub> ( $r = -0.573$ ,  $p < 0.05$ ). The value of change in 1/2reoxy time of the RF was not correlated with the performance time or VO<sub>2peak</sub>.

**CONCLUSION:** The result suggested that the improvement of performance in the preparation period rowing training was correlated not only with VO<sub>2peak</sub>, but also with the muscle oxidative capacity.

**Effect of Different Frequency Of Endurance And Strength Training on Muscle Functional Deterioration During Immobilization**

Masako Fujioka<sup>1</sup>, Takafumi Hamaoka, FACSM<sup>1</sup>, Takuya Osada<sup>2</sup>, Norio Murase<sup>2</sup>, Ryotaro Kime<sup>2</sup>, Yuko Kurosawa<sup>1</sup>, Shiro Ichimura<sup>3</sup>, Toshiyuki Homma<sup>4</sup>, Kazuki Esaki<sup>5</sup>, Fumiko Nakamura<sup>6</sup>, Toshihito Katsumura<sup>2</sup>. <sup>1</sup>*Ritsumeikan University, Shiga, Japan.* <sup>2</sup>*Tokyo Medical University, Tokyo, Japan.* <sup>3</sup>*Tokyo University of Science, Tokyo, Japan.* <sup>4</sup>*Japan Institute of Sports Sciences, Tokyo, Japan.* <sup>5</sup>*Shiga University, Shiga, Japan.* <sup>6</sup>*Kokugakuin University, Tokyo, Japan.* (Sponsor: Hamaoka Takafumi, FACSM)

(No relationships reported)

In our previous research, muscle functions declined after a 3-week forearm immobilization (3W-IMM) (Kitahara et al., 2003), and endurance and strength handgrip exercise training twice weekly during 3W-IMM prevented the decrease in muscle oxidative capacity and strength (Matsumura et al., 2008). However, the effect of lower amount of exercise training on muscle functions has never been examined.

**PURPOSE:** To investigate the effects of different training volume (once weekly and twice weekly) on muscle functions, particularly, on muscle energy metabolism during exercise pre- and post-3W-IMM.

**METHODS:** Twenty healthy male subjects participated in this study and the non-dominant arm was immobilized for 3 weeks with a cast. The subjects were assigned to an immobilization-only group (IMM-group), endurance [30% of maximum voluntary contraction (MVC), 1 contraction every second until exhaustion] and strength (70% MVC, 10 repetitions) grip exercise training once weekly (EST1-group, n=6) or twice weekly (EST2-group, n=7) during the 3W-IMM period. The MVC and the endurance performance evaluated as maximal workload achieved during handgrip exercise test (30% MVC, 1 Hz, until exhaustion) were examined both pre- and post-3W-IMM. Muscle phosphocreatine (PCr) and muscle pH were evaluated using <sup>31</sup>-phosphorus magnetic resonance spectroscopy.

**RESULTS:** The difference in maximal workload during endurance test between pre- and post-3W-IMM decreased more markedly in IMM-group than in EST2-group (p=0.074). Muscle PCr and muscle pH were not significantly different between three groups during endurance exercise test and between pre- and post-3W-IMM. The difference in MVC between pre- and post-3W-IMM was significantly greater in IMM-group than both in EST1-group and EST2-group (p<0.05).

**CONCLUSIONS:** The endurance and strength training, not only twice weekly but also once weekly, was effective for preventing the decrease in muscle strength during 3W-IMM. The training twice weekly was effective, but not for the training once weekly, to maintain endurance performance. Muscle PCr and muscle pH kinetics during endurance test were unchanged with 3W-IMM.

**Improvements with Electrical Stimulation Resistance Training in Men and Women with Complete Spinal Cord Injury**

Jared T. Brizendine, Terence E. Ryan, Melissa L. Erickson, Kevin K. McCully, FACSM. *University of Georgia, Athens, GA.*

(No relationships reported)

Eighty percent of the individuals with spinal cord injury (SCI) in the United States are male consequently little research exists concerning females with SCI. Electrically induced resistance training has been shown to improve muscle mass and muscle strength in males with spinal cord injury. The current hypothesis is that resistance training will result in less changes and slower gains.

**PURPOSE:** To compare training improvements with electrical resistance training in males and females with SCI.

**METHODS:** Ten male and three female subjects with complete spinal cord injury gave informed consent prior to inclusion in this study. A training session consisted of four sets of leg extensions on each leg with up to 10 repetitions per set. Two sessions were performed per week for four months. Stimulation current was recorded and maintained constant after the first week, weight was increased after two successful sessions. Performance adaptations were measured as change in weight pre and post training, change in repetitions pre and post training, and time to 16 pounds lifted.

**RESULTS:** Two out of ten males and two out of three females reached the goal weight of 20 pounds by conclusion of training. Seven men who reached 10 pounds did so in 49, 55, 65, 80, 103, 111, and 124 days. The two women who reached ten pounds reached so in 34 and 63 days. One male and one female were much weaker than the other participants prior start of training. The man went from no lifts to completing at least one lift at the end of training and the woman went from six lifts to forty lifts at the end of training. The average gains in quadriceps muscle mass were similar between males and females as measured with MRI.

**CONCLUSIONS:** There was no evidence that females with SCI improve less rapidly than males with SCI in response to electrical induced training. More females need to be tested to confirm this finding, though females are certainly not limited in their response to training. Supported by NIH R01 HD039676.

**Peak Power Training Reduces SDH Activity In Type Iib Fibers Of Rat Medial Gastrocnemius Muscle**

Regula Furrer, Arnold de Haan, Bauke J. van Dijk, Nathalie Bravenboer, Paul Lips, Richard T. Jaspers. *Research Institute MOVE, VU University and VU Medical Center, Amsterdam, Netherlands.*

(No relationships reported)

Muscle fibers are limited in increasing size and oxidative capacity simultaneously. The combination of resistance training to increase muscle size and peak power and endurance training to increase oxidative capacity can cause conflicting situations at the molecular level. Since several sports require both, high peak power and oxidative capacity, strategies may have been adopted to deal with this problem. Using specific recruitment of different muscle fibers during resistance and endurance training may allow increasing both. The rat medial gastrocnemius muscle (GM) is composed of a high and a low oxidative compartment which are recruited task specifically (the latter only being recruited during high intensity activities).

**PURPOSE:** To investigate whether task specific recruitment of the rat GM allows the muscle to increase in size and oxidative capacity simultaneously in response to combined peak power and endurance training.

**METHODS:** 39 rats were assigned to peak power training (PT, n = 10), resembling resistance exercise, endurance training (ET, n = 10), both peak power and endurance training (PET, n = 10), or controls (n = 9). Trainings were progressive and performed on a treadmill 5 days per week for 6 weeks (PET performed both training sessions each day with 8 hours rest in between). After 6 weeks, fiber cross-sectional area (CSA<sub>f</sub>) and succinate dehydrogenase (SDH) activity (representing mitochondrial activity) were assessed for all fiber types in both compartments. SDH mRNA levels in both compartments were quantified by RT-PCR.

**RESULTS:** None of the training modalities induced a change in CSA<sub>f</sub> in either compartment. In the high oxidative compartment, SDH activity was not significantly different between the groups, although SDH mRNA levels were increased after ET (p < 0.05). In the low oxidative compartment, for PT and PET groups, SDH activity of type Iib fibers was ~30% lower than in the ET and control groups (p < 0.05), whereas SDH mRNA levels remained constant.

**CONCLUSIONS:** Peak power training induced a substantial decrease in SDH activity in the type Iib fibers of the low oxidative compartment without a decrease in SDH mRNA levels, indicating that peak power training reduced the rate of translation of mitochondrial proteins and/or enhanced mitochondrial degradation.

1746 Board #154 MAY 30 2:00 PM - 3:30 PM

**TNF- $\alpha$  Induced Loss Of Force In The Diaphragm Of Mice Is Prevented By Exercise Training**

Norman Mangner<sup>1</sup>, Axel Linke<sup>1</sup>, Andreas Oberbach<sup>2</sup>, Stephan Gielen<sup>1</sup>, Marcus Sandri<sup>1</sup>, Robert Höllriegel<sup>1</sup>, Yasuharu Matsumoto<sup>3</sup>, Gerhard Schuler<sup>1</sup>, Volker Adams<sup>1</sup>.  
<sup>1</sup>University of Leipzig - Heart Center, Leipzig, Germany. <sup>2</sup>University of Leipzig, Leipzig, Germany. <sup>3</sup>Tohoku University Graduate School of Medicine, Sendai, Japan.  
(No relationships reported)

**PURPOSE:** Inflammatory cytokines are known to impair respiratory muscle function, e.g. in congestive heart failure. Further, TNF- $\alpha$  produces reactive oxygen species (ROS) and leads to irreparable damage of muscle proteins. Exercise training (E) is characterized by a distinct antioxidative capacity. Therefore, we tested the hypothesis if exercise training is capable to prevent the TNF- $\alpha$  induced loss of force in the diaphragm of mice.

**METHODS:** C57Bl6 were assigned to 4 weeks of treadmill E or sedentary behaviour (S). After 4 weeks mice were randomly injected intraperitoneally with TNF- $\alpha$  or saline. Force was determined in diaphragm bundles using an electrostimulation protocol. Expression and activity of glutathione peroxidase (GPX) and of the NAD(P)H oxidase and protein carbonylation were measured using standard methods.

**RESULTS:** TNF- $\alpha$  reduced force at 125 Hz in sedentary animals. E prevented this force reduction (S NaCl: 11.6 $\pm$ 1.0, S TNF: 6.8 $\pm$ 0.9, E NaCl: 11.2 $\pm$ 0.8, E TNF: 10.8 $\pm$ 1.2 N/cm<sup>2</sup>, p<0.01). TNF- $\alpha$  led to an increased activity of NAD(P)H oxidase in both sedentary and exercised animals (S NaCl: 1.0 $\pm$ 0.1, S TNF: 1.8 $\pm$ 0.2, E NaCl: 1.1 $\pm$ 0.2, E TNF: 1.5 $\pm$ 0.3 mU/mg, p=0.01). Carbonylated proteins as a marker of oxidative stress were only elevated under the influence of TNF- $\alpha$  in sedentary animals, whereas E prevented the TNF- $\alpha$  induced increase in carbonylated proteins. TNF- $\alpha$  induced loss in muscle force correlated with the total amount of carbonylated proteins (r=-0.62, p<0.05). TNF- $\alpha$  led to an increased carbonylation of alpha-actin (by ~400%) and creatine kinase (by ~500%), whereas E again prevented the TNF- $\alpha$  induced increase

The mRNA expression and activity of GPX were enhanced by E (mRNA: S NaCl: 42.5 $\pm$ 17.5, S TNF: 63.4 $\pm$ 15.4, E NaCl: 179 $\pm$ 39.2, E TNF: 190 $\pm$ 55.6 arb. units, p<0.01; activity: S NaCl: 19.8 $\pm$ 0.7, S TNF: 23.3 $\pm$ 2.0, E NaCl: 33.1 $\pm$ 2.39, E TNF: 33.6 $\pm$ 1.2 mU/mg, p=0.01).

**CONCLUSION:** TNF- $\alpha$  administration leads to reduced force development in the diaphragm of mice. This effect is attenuated by preconditional exercise training. This may be, at least in part, a result of reduced carbonylation of alpha-actin and creatine kinase due to an increased expression in radical scavenger enzymes resulting in a reduced ROS concentration.

---

1747 Board #155 MAY 30 2:00 PM - 3:30 PM

**The Effect of Exercise Training on Muscle Energy Status in IL-6 Induced Cachexia**

Melissa Puppa, Aditi Narsale, Kandy Velazquez, Shu Sato, James White, James Carson, FACSM. University of South Carolina, Columbia, SC.  
(No relationships reported)

Cachexia is a condition involved with the loss of bodyweight, muscle mass, and adipose tissue mass. The ApcMin/+ mouse develops an IL-6 dependent cachexia which can be accelerated with IL-6 overexpression.

**PURPOSE:** The purpose of this study was to determine the effect of moderate intensity treadmill exercise training on skeletal muscle energy status in cachectic mice.

**METHODS:** Mice were randomly assigned to exercise training (Ex) or cage control (CC) groups. Starting at 6wks of age, exercised mice ran on a treadmill at a moderate intensity (18 m/min, 1h, 6 days/wk, 5% grade) until 14wks of age. At 12wks of age, the mice were electroporated with either a vector (V) or IL-6 over-expression plasmid (IL-6) in the right quadriceps muscle and at 14wks of age were sacrificed

**RESULTS:** Cachexia induced a 12% decrease in quadriceps weight and moderate aerobic exercise training attenuated muscle mass loss. Cachexia induced a 3 fold increase in the activation of the energy sensor AMPK, p<0.05, and exercise training attenuated this induction; however, the combination of exercise and cachexia still stimulated a 2 fold increase in AMPK activation compared to control animals, p<0.05. Neither exercise nor cachexia had an effect on total AMPK levels. Activation of a downstream target of AMPK, ACC, was also increased with cachexia and exercise was able to attenuate this increase.

**CONCLUSIONS:** Our data demonstrated that the decrease in skeletal muscle mass with cachexia is associated with an altered energy state of the muscle. Exercise needs to be explored further as potential a therapy to alleviate muscle energy imbalance with cachexia. Funded by ROICA121249-01

**Myogenin, MyoD and IGF-I Regulate Muscle Mass But Not Fiber-Type Conversion During Resistance Training In Rats**

Andreo Fernando Aguiar<sup>1</sup>, Ivan José Vechetti-Júnior<sup>2</sup>, Rodrigo Wagner Alves de Souza<sup>2</sup>, Eduardo Paulino Castan<sup>2</sup>, Rachel Colauto Milanezi Aguiar<sup>2</sup>, Robson Francisco Carvalho<sup>2</sup>, Cosme Franklim Buzzachera<sup>3</sup>, Maéli Dal-Pai-Silva<sup>2</sup>. <sup>1</sup>North University of Parana, Londrina, Brazil. <sup>2</sup>Univ Estadual Paulista (UNESP), Botucatu, Brazil. <sup>3</sup>North University of Parana, Londrina, Brazil. (Sponsor: Carlo Baldari, FACSM)  
(No relationships reported)

**PURPOSE:** To determine whether skeletal muscle hypertrophy and fiber-type conversion induced by long-term resistance training (RT) are associated with increased myogenin, MyoD and IGF-I mRNA expression.

**METHODS:** Male *Wistar* rats (80 days old, 250-300 g) were randomly divided into two groups (n=8 per group): 8-week control (C8) and 8-week trained (T8). T8 group was submitted to progressive RT program (four sets of 10-12 repetitions at 65-75% of the 1RM, 3 day/week) for 8 weeks. At the end of the experiment, the animals were euthanized by decapitation and the plantaris muscle was collected for morphometrical (muscle fiber area), histochemical (fiber-type frequency by myofibrillar ATPase histochemistry) and molecular (myogenin, MyoD and IGF-I mRNA expression by RT-qPCR) analysis. Fiber-type frequency data were analyzed using the Goodman Test for contrasts between intermultinomial and intramultinomial populations. Muscle fiber area, and myogenin, MyoD and IGF-I mRNA expression data were analyzed by an unpaired *t* test. Differences were considered significant at p < 0.05.

**RESULTS:** RT promoted an increase in muscle fibers area (T8 vs. C8: 29.0% increase, p < 0.05) that was accompanied by the increases in myogenin (T8 vs. C8: 44.8% increase, p < 0.05), MyoD (T8 vs. C8: 22.9% increase, p < 0.05) and IGF-I (T8 vs. C8: 30.1% increase, p < 0.05) mRNA expression. Additionally, there was a significant positive correlation between the muscle fiber area and mRNA expression for myogenin (r=0.87), MyoD (r=0.85) and IGF-I (r=0.88), as analyzed by individual data points of the trained group. On the other hand, the increase in myogenin, MyoD and IGF-I mRNA expression was not associated with changes in the fiber-type frequency.

**CONCLUSIONS:** These results indicate a possible interaction between myogenin, MyoD and IGF-I in the control of muscle hypertrophy during long-term RT and suggest that these factors are involved more in the regulation of muscle mass than in fiber-type conversion.

---

1749 Board #157 MAY 30 2:00 PM - 3:30 PM

**Prior Exercise Training Prevents Statin-Associated Skeletal Muscle Dysfunction in Mice**

Kimberly Huey, Michelle Godar, Carissa Chamney, Rachel Bump. Drake University, Des Moines, IA. (Sponsor: Roland R Roy, FACSM)  
(No relationships reported)

The most common side effect of statin treatment, skeletal muscle myopathy, is more likely in exercisers. We previously reported that 2 weeks of running wheel exercise prior to statin treatment protected against muscle dysfunction, rather than exacerbated it, as seen with novel exercise. However, the minimal amount of prior exercise necessary to protect against statin-associated muscle dysfunction remains unclear.

**PURPOSE:** We investigated the interaction of statin treatment with novel vs. 3 days of prior exercise on muscle function and heat shock protein (Hsp) expression and hypothesized that exacerbation of statin-induced myopathy by exercise is specific to untrained muscle, while some prior training is protective against dysfunction. Within the Hsp family, Hsp25 and  $\alpha$ B-crystallin are both up-regulated with exercise training and are associated with maintenance of muscle integrity after damaging contractions.

**METHODS:** Mice received daily atorvastatin (15 mg/kg) or placebo for 2 wks, with/without voluntary wheel running (RW) (Novel & Sedentary groups) and the accustomed group completed 3 days of RW prior to beginning placebo or statin treatment (n= 6-7/group). In vivo plantarflexor isometric force and fatigability were measured with a dual mode lever system and Hsp25 and  $\alpha$ B-crystallin muscle protein levels were quantified with Western blot.

**RESULTS:** Statin treatment significantly reduced RW activity on days 1-3 in novel compared to accustomed groups. Statin treatment reduced force in sedentary and novel-exercise groups compared to placebo (21 and 35%, respectively,  $p < 0.05$ ), while accustomedization prevented statin-associated force loss. Fatigability was not different among groups. Hsp25 and  $\alpha$ B-crystallin levels were increased 2- to 9-fold with novel and accustomed RW compared to sedentary, independent of statin treatment ( $p < 0.05$ ).

**CONCLUSIONS:** These results suggest that as little as 3 days of exercise prior to statin treatment can protect against statin-associated losses in muscle force production observed under sedentary or novel exercise conditions and exercise-induced Hsp up-regulation may contribute to this protective effect.

1750 Board #158 MAY 30 2:00 PM - 3:30 PM

**Skeletal Myofiber-expressed Veg Is Required For Adaptation To Exercise Training**

Hamid Delavar, Leonardo Nogueira, Kechun Tang, Michael C. Hogan, Peter D. Wagner, Ellen C. Breen. *University of California, San Diego, La Jolla, CA.*

(No relationships reported)

Increased muscle capillarization is a normal adaptation to exercise training. We hypothesized that VEGF expression in mature skeletal myofibers is necessary for this angiogenic response and contributes to an improvement in locomotor muscle function and exercise capacity.

**PURPOSE:** To determine whether a reduction in myofiber-expressed VEGF limits the adaptive response to exercise training.

**METHODS:** Using a tamoxifen-inducible skeletal myofiber-specific VEGF gene deletion mouse model (HSA-Cre-ER<sup>T2</sup> X VEGF<sup>LoxP</sup>), VEGF levels are reduced by >80% in skeletal muscle of adult myofiber VEGF gene-deleted mice (myoVEGF<sup>-/-</sup>) compared to control littermates (WT). Exercise capacity was evaluated by measuring maximal treadmill speed and endurance running time before tamoxifen-induced gene deletion, 3 weeks after tamoxifen treatment, and after an additional 8 weeks of progressive exercise training (1 hr/d, 5 d/wk). The capillary/fiber ratio was measured in the soleus, plantaris and gastrocnemius after training. Maximal tension in the EDL and soleus was measured *in vitro*.

**RESULTS:** Exercise endurance was impaired in myoVEGF<sup>-/-</sup> mice 3 weeks after VEGF deletion (WT, 97 min  $\pm$  26, myoVEGF<sup>-/-</sup>, 54 min  $\pm$  34,  $p < 0.05$ ), but maximal speed was unaffected (WT, 62 cm/s  $\pm$  4.5, myoVEGF<sup>-/-</sup>, 59 cm/s  $\pm$  6). Post-training, exercise endurance (WT, 161  $\pm$  16 min, myoVEGF<sup>-/-</sup> 57 minutes  $\pm$  29,  $p < 0.001$ ) and maximal speed (WT, 72 cm/s  $\pm$  3.4, myoVEGF<sup>-/-</sup>, 54 cm/s  $\pm$  12,  $p < 0.001$ ) were improved only in the WT mice. Capillary/fiber ratio post-training was less in myoVEGF<sup>-/-</sup> (Gastroc. WT, 1.75  $\pm$  0.20, myoVEGF<sup>-/-</sup>, 1.03  $\pm$  0.11. Soleus, WT 1.85  $\pm$  0.21, myoVEGF<sup>-/-</sup>, 1.65  $\pm$  0.18. Plantaris, WT, 1.66  $\pm$  0.35, myoVEGF<sup>-/-</sup>, 1.39  $\pm$  0.21). Post-training maximal tetanic tension (N/cm<sup>2</sup>) produced by the EDL and soleus was not different between groups.

**CONCLUSION:** Mice deficient in skeletal myofiber VEGF were unable to improve exercise capacity in response to training. This is accompanied by a lower skeletal muscle capillary/fiber ratio in locomotor skeletal muscle. These data suggest myofiber VEGF is required to regulate the adaptive response to exercise training.

1751 Board #159 MAY 30 2:00 PM - 3:30 PM

**Diabetic Patients With Different Training Status Show Different Levels Of Muscle Weakness And Electrophysiological Impairment.**

Jonida Haxhi<sup>1</sup>, Stefano Balducci<sup>2</sup>, Ilenia Bazzucchi<sup>1</sup>, Alessandro Scotto di Palumbo<sup>1</sup>, Flaminia Carlucci<sup>1</sup>, Giuseppe Pugliese<sup>2</sup>, Massimo Sacchetti<sup>1</sup>. <sup>1</sup>University of Rome "Foro Italico", Rome, Italy. <sup>2</sup>Second Medical School, "La Sapienza" University, Rome, Italy. (Sponsor: Carl Foster, FACSM)

(No relationships reported)

**PURPOSE:** Diabetes is associated to muscle weakness and disability. We investigated neuromuscular function, in the upper and lower limb, in 31 T2D patients and 12 Controls.

**METHODS:** Subjects comprised 4 groups: sedentary diabetic patients with lower (1st quartile-D1) and higher (4th quartile-D2) motor nerve conduction velocity (MNCV), trained diabetic patients (TD) and non-diabetic sedentary control subjects (C). Isokinetic and Maximal isometric strength (MVC) for a wide angular-velocity range (0°/s to 240°/s) were assessed for the knee extensors (KE) and elbow flexors (EF). Muscle fiber conduction velocity (MFCV) was estimated from sEMG recordings of the vastus lateralis (VL) and biceps brachii (BB) activity.

**RESULTS:** EF and KE MVC were similar between groups. Sedentary diabetics showed significantly decreased dynamic strength of KE at all velocities, when compared to Controls and TD (% decrease M $\pm$ SD, 15°/s to 240°/s,  $p < .05$ : D1 = 58.6% $\pm$ 3.0; D2 = 61% $\pm$ 3.3 vs. C = 43.9% $\pm$ 4.0; TD = 58.0% $\pm$ 2.6), with C and TD being similar to each other, especially at low angular velocities. D2 showed higher KE strength than D1, but differences reached statistical significance only at 90°/s. Strength in the elbow flexors was affected at higher contraction speeds, with the untrained diabetics showing significantly lower strength at 180°/s (Nm M $\pm$ SD: D1=34.1 $\pm$ 3.0; D2=28.8 $\pm$ 2.4 vs. C=42.1 $\pm$ 2.8;  $p < .05$ ) and 240°/s (Nm M $\pm$ SD: D1=28.0 $\pm$ 2.7; D2=24.1 $\pm$ 1.9 vs. C=36.4 $\pm$ 2.4). No strength differences resulted between D1 and D2 for the arm. There were significant within-group differences in the ratio between leg torque and arm torque for the D1 (-35%), D2 (-31%) and TD (-31%), but not for the control group. Groups showed differences in isometric MFCV for the VL, but not for the BB. MFCV was significantly lower in D1 (-24%,  $p = .01$ ) and D2 (-23%,  $p = .02$ ) compared to the control group. TD was not different from C, in terms of MFCV.

**CONCLUSIONS:** Muscle weakness in diabetes is dependent on contraction velocity, especially in the lower limbs, whereas MNCV has only a marginal effect. The different neuromuscular impairment is confirmed by differences in MFCV. Training status is associated with better neuromuscular function. Finally, MFCV could represent a sensitive marker for monitoring neuromuscular function impairment and training-induced reconditioning.

1752 Board #160 MAY 30 2:00 PM - 3:30 PM

**Exercise Training-induced Improvement Of Impaired Muscle Glucose Metabolism Is Associated With Muscular Sex Steroid Hormone Level In Zucker Fatty Diabetic Rats**

Koji Sato<sup>1</sup>, Kumiko Minato<sup>2</sup>, Satoshi Fujita<sup>1</sup>, Hideki Yamauchi<sup>3</sup>, Noboru Mesaki<sup>4</sup>, Motoyuki Iemitsu<sup>1</sup>. <sup>1</sup>Ritsumeikan University, Kusatsu, Shiga, Japan. <sup>2</sup>Wayo Women's University, Ichikawa, Chiba, Japan. <sup>3</sup>The Jikei University School of Medicine, Tokyo, Japan. <sup>4</sup>Teikyo Heisei University, Ichihara, Chiba, Japan. (Sponsor: Takafumi Hamaoka, FACSM)

(No relationships reported)

Effect of exercise training in type 2 diabetes patients to improve hyperglycemia via enhancement of muscle glucose metabolism signaling is well known. We have recently reported that sex steroid hormones can be synthesized locally in the skeletal muscle which improves fasting blood glucose level in obese rats.

**PURPOSE:** To determine whether exercise training-induced secretion of muscular sex steroid hormone may improve insulin resistance in Zucker obese fatty rats.

**METHODS:** Thirty Zucker fatty diabetic rats (6-week old) were randomly assigned to either control, exercise training or exercise training with continuous infusion of 5 $\alpha$ -reductase inhibitor groups. Exercise training was conducted by voluntary wheel running for 6 weeks, with average running distance of 2,752 m per day.

**RESULTS:** The results indicate that 6 weeks of exercise training significantly attenuated serum insulin and fasting glucose levels compared with the control group. Muscle concentrations of DHEA and DHT, and protein expression levels of 5 $\alpha$ -reductase were all significantly higher in the exercise-training group. Moreover, exercise training upregulated GLUT4 translocation with concomitant increases in protein kinase B and protein kinase C- $\zeta/\lambda$  phosphorylations. Furthermore, significant correlations were observed between fasting glucose levels and muscular DHEA ( $r = -0.87$ ,  $P < 0.001$ ) and DHT levels ( $r = -0.80$ ,  $P < 0.001$ ). Interestingly, exercise training-induced improvements in serum insulin and fasting glucose levels concomitant with GLUT4-regulated signaling were all suppressed with 5 $\alpha$ -reductase inhibitor.

**CONCLUSIONS:** These results indicated that exercise-induced improvements in muscle glucose metabolism signaling and fasting glucose level may be attributed to the increased muscular levels of sex steroid hormones.

**Effect Of Aerobic Training On Three-dimensional Capillary Architecture In Soleus Muscle**

Shinichiro Murakami<sup>1</sup>, Naoto Fujita<sup>2</sup>, Takashi Morifuji<sup>2</sup>, Hiroyo Kondo<sup>3</sup>, Hidemi Fujino Fujino<sup>2</sup>. <sup>1</sup>Himeji Dokkyo University, Himeji, Japan. <sup>2</sup>Kobe University Graduate School of Health Sciences, Kobe, Japan. <sup>3</sup>Nagoya Women's University, Nagoya, Japan.  
(No relationships reported)

Aerobic exercise has been known an effective therapy against the muscle endurance fitness.

**PURPOSE:** To clarify the effect of aerobic training on three-dimensional (3-D) capillary architecture in slow muscle has been investigated in the present study.

**METHODS:** Twelve male Wistar rats (9 weeks old) were used and divided into exercise training (EX) and control (Con) groups. The rats in EX group were performed aerobic exercise training on a treadmill (speed = 15 m/min, duration = 60 min) for 3 weeks. The contrast medium-injected capillary in the soleus muscle was visualized using a confocal laser microscope. The succinate dehydrogenase (SDH) activity and vascular endothelial growth factor (VEGF) expression were measured.

**RESULTS:** The SDH activity and VEGF expression in EX were significantly higher than those in Con ( $p < 0.05$ ). The number of capillaries and the number of the anastomoses in the EX were increased than those of Con ( $p < 0.05$ ). The capillary diameter in the soleus of EX rat was thicker than that of Con rat ( $p < 0.05$ ). In addition, the mean capillary volume in EX was significantly higher than that in Con ( $p < 0.05$ ). Whereas the anastomoses diameter was not different in the soleus muscle between EX and Con rat.

**CONCLUSIONS:** These data show that aerobic training builds 3-D capillary architecture in soleus muscle. These results of the present study indicate endurance training creates a powerful stimulus for structural remodeling of the vasculature.

This study was supported by Grants-in-Aid for Scientific Research from the Japanese Ministry of Education, Culture, Sports, Science and Technology no. 23650340, 23650324, 23700600, 23700932 and 22300189.

**PURPOSE:** Physical activity can enhance bone structure and estimated strength at the proximal femur in children and adolescents, but whether these benefits are maintained into early adulthood remains controversial. The purpose of this study was to investigate whether males and females, described as active (ACT), moderately active (MOD) and inactivate (INACT) during adolescence, display differences in estimated bone structure and strength at the proximal femur in early adulthood.

**METHODS:** One hundred and four participants (55 males, 49 females) from the Pediatric Bone Mineral Accrual Study (PBMA) were tertiled into adolescent physical activity groupings (ACT, MOD, INACT) using the Physical Activity Questionnaire for Adolescents (PAQ-A). Cross sectional area (CSA) and section modulus (Z) at the narrow neck (NN) and femoral shaft (S) sites of the proximal femur were assessed using hip structural analysis (HSA) in adulthood. Group differences were assessed using an analysis of covariance (ANCOVA), controlling for adult height (Ht), total body lean tissue (LTM) and fat mass (FM) and adult physical activity levels (PA).

**RESULTS:** Once controlling for Ht, LTM, FM, and adult PA, the ACT females had significantly greater adult NN CSA ( $2.5 \pm 0.1$  vs.  $2.2 \pm 0.1$  cm<sup>2</sup>,  $p = 0.01$ ) and NN Z ( $1.11 \pm 0.04$  vs.  $0.96 \pm 0.03$  cm<sup>3</sup>,  $p = 0.004$ ) than INACT females. Additionally, ACT females had significantly greater adult NN Z than the MOD group ( $1.11 \pm 0.04$  vs.  $1.00 \pm 0.03$  cm<sup>3</sup>,  $p = 0.02$ ). In males, the ACT ( $2.19 \pm 0.06$  cm<sup>3</sup>) and MOD ( $2.20 \pm 0.06$  cm<sup>3</sup>) groups had significantly greater adult S Z than their INACT peers ( $1.95 \pm 0.07$  cm<sup>3</sup>,  $p > 0.001$ ).

**CONCLUSIONS:** There may be sex and site specific effects of adolescent physical active on bone structure and strength at the proximal femur. Despite these differences, being highly physically active during adolescence may provide site specific benefits to proximal femur structure and estimated strength in adulthood.

**Augmented TLR4-CD14 Expression in Response to Lengthening Muscle Actions Are Blunted by Eccentric Training**

Rodrigo Fernandez-Gonzalo<sup>1</sup>, José A. de Paz<sup>2</sup>, Paula Rodriguez-Miguelez<sup>2</sup>, María J. Cuevas<sup>2</sup>, Per A. Tesch<sup>1</sup>, Javier Gonzalez-Gallego<sup>2</sup>. <sup>1</sup>Karolinska Institutet, Stockholm, Sweden. <sup>2</sup>University of León, León, Spain.  
(No relationships reported)

Chronic eccentric training reduces strength and power losses and inflammatory response to an eccentric exercise challenge. While the mechanisms involved are not fully understood, the toll-like receptor 4 (TLR4) signaling pathway has been proposed to control inflammation and may also be responsible for the decreased inflammation noted after chronic eccentric training.

**PURPOSE:** This study aimed at investigating TLR4 and associated molecule cluster differentiation14 (CD14) responses to an acute bout of eccentric exercise in healthy subjects, and to assess whether the repeated bout effect and chronic training modified the responses.

**METHODS:** Twenty recreationally active women ( $22 \pm 2$  yrs) were randomly assigned to either a control (CG,  $n = 8$ ) or a training group (TG,  $n = 12$ ). Both groups performed two exercise bouts consisting of 120 eccentric actions at 60% of maximal voluntary isometric strength (MVIC) using a squat machine, 9-wks apart. Between these two exercise bouts, TG was subjected to a 6-wk eccentric training program (3 sessions/wk). CG maintained their habitual activities. Lower limb MVIC and power were measured before and 24 hrs after each bout. Quadriceps muscle soreness was assessed before and over 4 consecutive days following each bout. CD14 and TLR4 protein concentration and the inflammatory marker tumor necrosis factor  $\alpha$  (TNF $\alpha$ ), were measured in peripheral blood mononuclear cells, before, immediately after and 2 hrs after each eccentric bout.

**RESULTS:** After the first bout, MVIC (-19%) and power (-14%) were reduced, and soreness increased in both TG and CG ( $P < 0.05$ ). CD14 (26%), TLR4 (32%) and TNF $\alpha$  (30%) protein concentration increased ( $P < 0.05$ ) in both groups. TG showed increased ( $P < 0.05$ ) MVIC (2200 N to 2600 N) and power (1024 to 1180 W) after 6-wk training. There were no changes in CG. Following the second bout, strength and power losses showed greater attenuation in TG compared with CG ( $P < 0.05$ ). CD14, TLR4 and TNF $\alpha$  decreased ( $P < 0.05$ ) after the second bout compared with the first one in TG, but not in CG.

**CONCLUSION:** The inflammation associated with an acute bout of lengthening exercise is reduced by eccentric training through down-regulation of the TLR4 signaling pathway. These results support the use of eccentric training as a therapeutic exercise aid.

1756 Board #164 MAY 30 2:00 PM - 3:30 PM

**Functional Adaptations to Voluntary Wheel Running in Young and Elderly Mice**

Lisa Ferguson-Stegall, Ted G. Graber, LaDora V. Thompson. University of Minnesota, Minneapolis, MN. (Sponsor: Donald R. Dengel, FACSM)  
(No relationships reported)

Sarcopenia and frailty are major causes of disability in the elderly. Resistance training (RT) studies have demonstrated that significant muscle specific functional adaptations can occur in the elderly, although the hypertrophic response is blunted compared to that of the young. It has also been demonstrated that the old require a greater training volume to maintain muscle adaptations following a period of RT compared to the young. In contrast to RT, the amount of endurance exercise necessary to elicit muscle-specific and functional improvements in the old are not well understood.

**PURPOSE:** We compared the effects of 4 wk of voluntary wheel running (VWR) or no exercise (control) on measures of physiological function in young (6-8 mo,  $n = 10$ ) and elderly (28-30 mo,  $n = 13$ ) C57BL/6 male mice.

**METHODS:** 5 young (XY) and 4 elderly (XO) mice were housed individually in cages outfitted with running wheels for 4 wk. Control animals (CY,  $n = 5$ , and CO,  $n = 9$ ) were housed without a wheel for 4 wk. An inverted cling test for grip time and Rota-Rod test were performed prior to the 4-wk intervention and at the end. Animals were sacrificed and the soleus (SOL) and extensor digitorum longus (EDL) muscles harvested for physiological contractility.

**RESULTS:** Daily VWR was significantly higher in the young (XY) than the old (XO) mice ( $5.04 \pm 0.64$  vs  $2.72 \pm 0.27$  km,  $P < 0.05$ ). Change from baseline in grip time was significantly higher in CY and XY than CO and XO ( $97.4 \pm 37.3$  and  $96.6 \pm 36.6$  vs  $-12.1 \pm 11.2$  and  $19.0 \pm 26.2$  s, respectively,  $P < 0.05$ ). Change from baseline in Rota-Rod time increased in the young

VWR group (XY) compared to the other 3 groups (XY,  $53.5 \pm 8.6$  vs XO,  $15.2 \pm 7.3$  s; CY,  $-32.0 \pm 16.0$ ; CO,  $-7.8 \pm 9.0$  s, respectively,  $P < 0.05$ ). No differences were found between groups for SOL or EDL muscle contractility (maximal power, specific peak tension, and specific peak twitch). EDL mass was significantly higher in XO compared to CO ( $0.01545$  vs  $0.01122$  g,  $P < 0.05$ ). **CONCLUSION:** While 5 km/d is associated with improved physiological performance in the young as determined by Rota-Rod testing, the mechanism for this improvement is not linked to changes in muscle strength. The lower amount of VWR performed by the old mice is not associated with improvements in physiological performance or muscle contractility, although the exercise may stimulate some muscle hypertrophy in the old.

**1757** Board #165 **MAY 30** **2:00 PM - 3:30 PM**  
**Body Composition Changes Over A One Year Period**

Simon Smith<sup>1</sup>, Blake Hamill<sup>1</sup>, Tyler Karnes<sup>1</sup>, Taniqua Ward<sup>1</sup>, Dalton Delaney<sup>1</sup>, Kelsey Hubble<sup>1</sup>, Zac Geary<sup>1</sup>, Pam Farris<sup>1</sup>, Justin Steffy<sup>1</sup>, Kayla Garver<sup>1</sup>, Melissa Powers<sup>1</sup>, Michelle Gray<sup>2</sup>. <sup>1</sup>University of Central Oklahoma, Edmond, OK. <sup>2</sup>University of Arkansas, Fayetteville, AR.  
(No relationships reported)

The amounts of lean tissue mass (LTM), fat mass (FM), and bone mineral density (BMD) all play a key role in the health and functioning of older adults. In order to combat age-related changes, it is often advised that individuals participate in resistance training. Understanding the body composition changes in senior adults during one year of resistance training programs at different intensities and velocities could provide the needed knowledge about optimal training protocol for this population.

**PURPOSE:** The purpose of this study was to examine the changes of body composition in older adults over one year of resistance training at either high intensity/low velocity (LV) or low intensity/high velocity (HV).

**METHODS:** Seventeen adults over the age of 75 were randomly assigned to the LV group which performed resistance training at 80% of their one-repetition maximum (IRM) and the HV group which lifted at 50% of their IRM as quickly as possible. All participants started in the LV group for 24 weeks then seven randomly chosen participants transitioned to the HV group. An iDXA was used to measure total body LTM, FM, and BMD at baseline, 24 weeks, and after one year of training. Repeated measures ANOVA were used to analyze interaction and main effects for each outcome ( $\alpha = .001$ ).

**RESULTS:** No significant interaction or main effects were observed for FM, LTM, and BMD. Due to non-significance, univariate effect sizes (d) were calculated for each group. The HV group exhibited a small decrease in LTM ( $d = 0.102$ ), while LTM was maintained in the LV group ( $d = -0.007$ ).

**CONCLUSION:** Although no significant differences were found in LTM, FM, or BMD over the one year, meaningful changes are illustrated by the effect sizes. These results suggest that senior adults who participated in high intensity resistance training can maintain their lean tissue while those who train at a lower intensity are less likely to successfully mitigate the negative age related changes despite moving the weight at a greater velocity. To our knowledge, this is the first study to examine the impact of velocity on body composition over this length of time. This research is important for helping health professionals to understand proper resistance training interventions when attempting to address age related body composition changes.

**1758** Board #166 **MAY 30** **3:30 PM - 5:00 PM**  
**The Training Effects of an Active Video Game on Reaction Time and Power**

Hsuan Su, Yuh-Jen Lin, I-Hua Chu. Kaohsiung Medical University, Kaohsiung, Taiwan.  
(No relationships reported)

An active video game combines with exercise training, thus has a potential to improve health-related fitness, as well as train skill-related fitness in the general population. Reaction time and power are skill-related fitness components that can help individuals maintain their quality of life and deal with unexpected life events. Whether an active video game can be used as a training tool to improve one's reaction time and power is unknown.

**PURPOSE:** The purpose of this pilot study was to examine the training effects of an active video game on reaction time and power in a group of healthy college students.

**METHODS:** Fourteen subjects (mean age  $21.6 \pm 9$  yr, 4 males and 10 females) were recruited from university campus. Subjects were excluded from the study if they answered "YES" to one or more questions in the Physical Activity Readiness Questionnaire (PAR-Q). All eligible subjects completed measures of reaction time and power (Side Step) at study entry and every two weeks during the 4-week training program. When playing the active video game, subjects would encounter different obstacles and must immediately respond to the game with vertical jumping, left and right side stepping, and squatting. The training program was 3 times per week, 20 minutes per session, for 4 weeks. Two separate Repeated Measures Analysis of Variance (ANOVA) and post hoc comparisons were conducted to compare changes in reaction time and power over the 4 weeks.

**RESULTS:** For reaction time, the results showed no significant change after 4 weeks of training ( $277.9 \pm 93$  vs.  $230.0 \pm 53$  ms,  $p = 0.147$ ). For power, the results showed significant improvements in subjects' power after the training program ( $22.7 \pm 9$  vs.  $27.0 \pm 9$  times,  $p < 0.001$ ). In addition, the subjects' power began to improve in as early as 2 weeks ( $22.7 \pm 9$  vs.  $25.3 \pm 9$  times,  $p = 0.001$ ) and continue to improve from 2 to 4 weeks ( $25.3 \pm 9$  vs.  $27.0 \pm 9$  times,  $p = 0.017$ ).

**CONCLUSIONS:** The results of this pilot study indicate that a 4-week active video game training program appears to be effective in improving power in healthy college students. On the other hand, it may require a longer training duration to show any improvements in reaction time in this population. It is suggested that an active video game can be used as a training tool for improving power in young healthy adults.

**1759** Board #167 **MAY 30** **3:30 PM - 5:00 PM**  
**The Training Effects of an Active Video Game on Balance**

Yuh-Jen Lin, Hsuan Su, I-Hua Chu. Kaohsiung Medical University, Kaohsiung, Taiwan.  
(No relationships reported)

An active video game combined with exercise training may have a potential to improve skill-related fitness in the general population. Both static and dynamic balance play important roles in reducing risk of falls and enhancing exercise performance. Whether an active video game can be used as a training tool to improve one's static and dynamic balance is unknown.

**PURPOSE:** The purpose of this pilot study was to examine the training effects of an active video game on static and dynamic balance in healthy college students.

**METHODS:** Fourteen subjects (mean age  $21.6 \pm 9$  yr, 4 males) were recruited from university campus. Subjects were excluded from the study if they answered "YES" to one or more questions in the Physical Activity Readiness Questionnaire (PAR-Q). All eligible subjects completed measures of static balance (Close-Eyes Single Limb Balance) and dynamic balance (Star Excursion Balance Test, SEBT) at study entry and every two weeks during the 4-week training program. The SEBT tests subjects' dynamic balance in 8 directions: anterior (A), anteromedial (AM), medial (M), posteromedial (PM), posterior (P), posterolateral (PL), lateral (L), and anterolateral (AL). When playing the video game, subjects would encounter different obstacles and must immediately respond to the game with vertical jumping, side stepping, and squatting. The training program was 3 times per week, 20 minutes per session, for 4 weeks. Two Repeated Measures Analysis of Variance and post hoc comparisons were conducted to compare changes in static and dynamic balance over the 4 weeks.

**RESULTS:** The results showed significant improvement in static balance after the 4-week training program ( $35.2 \pm 32$  vs.  $63.7 \pm 42$  s,  $p = 0.015$ ). For dynamic balance, there was no significant improvement in three directions, including A, AL, and AM. Dynamic balance in all other directions have improved significantly for both legs after training (L,  $0.80 \pm 0.2$  vs.  $0.96 \pm 0.1$ ,  $p < 0.001$ ; PL,  $1.04 \pm 0.1$  vs.  $1.12 \pm 0.1$ ,  $p = 0.003$ ; P,  $1.06 \pm 0.1$  vs.  $1.14 \pm 0.1$ ,  $p = 0.002$ ; PM,  $1.08 \pm 0.1$  vs.  $1.14 \pm 0.1$ ,  $p = 0.012$ ; M,  $1.05 \pm 0.1$  vs.  $1.10 \pm 0.1$ ,  $p = 0.007$ ) (data for right leg).

**CONCLUSIONS:** The results of this pilot study suggested that an active video game might be used as a training tool for improving static and dynamic balance in young healthy adults.

1760 Board #168 MAY 30 3:30 PM - 5:00 PM

**The X-box Exergaming System Requires More Physical Activity Than The Wii Or Playstation Platforms**

Ellis B. Jensen<sup>1</sup>, Enrique A. Becwar<sup>2</sup>. <sup>1</sup>Utah Valley University, Orem, UT. <sup>2</sup>Viterbo University, La Crosse, WI. (Sponsor: Tim Gavin, FACSM)  
(No relationships reported)

Exergaming couples exercise with gaming and may increase physical activity, fitness, and health in its players. While all exergaming systems require physical activity, differences in motion detection capability between the gaming platforms may cause some systems to less accurately measure activity in players.

**PURPOSE:** To determine whether the superior motion tracking of the Xbox Kinect (Xbox) system requires players to expend more energy than players of the Wii Fit (Wii) and PlayStation Move (PS3) platforms.

**METHODS:** Subjects played each of the three exergaming systems at high intensity (High) and tried to earn the highest possible score. They also played with the lowest effort possible (Low) that still allowed them to reach the same high score as during the High trial. Energy expenditure was estimated during game play by SenseWear activity monitors and by the exergaming systems.

**RESULTS:** As measured by the SenseWear device, the Wii and PS3 allowed less vigorous activity in the Low trial than in the High trial. However, the Wii and PS3 gaming systems did not recognize decreased activity in the Low compared to the High trial. The Xbox tracked player movement very well and required players in the Low trial to expend relatively the same amount of calories as players in the High group.

| Platform | Trial | System (cal) | $\delta$ =High-Low (cal) | p-value | SenseWear (cal) | $\delta$ =High-Low (cal) | p-value |
|----------|-------|--------------|--------------------------|---------|-----------------|--------------------------|---------|
| Wii      | High  | 74           | 19                       | .114    | 90              | 44                       | .049*   |
|          | Low   | 55           |                          |         | 46              |                          |         |
| PS3      | High  | 107          | 6                        | .57     | 118             | 52                       | .023*   |
|          | Low   | 101          |                          |         | 66              |                          |         |
| Xbox     | High  | 59           | 5                        | .602    | 72              | 3                        | .766    |
|          | Low   | 54           |                          |         | 69              |                          |         |

**CONCLUSION:** Both the Wii and PS3 platforms allowed players to perform well in games while exerting very little effort in the Low trial. The Xbox exergaming platform only rewards high physical activity levels with high gaming scores. This study suggests that the Xbox platform is a better option than the Wii and the PS3 systems for players trying to increase their physical activity through exergaming.

**Influence of Wii Fit Plus Exercises on Lower Extremity Strength and Balance in Middle-Aged Adults**

Renee M. DeSalvo, Brandon S. Pollock, Nicholas T. Potenzini, Ronald Otterstetter, Judi A. Juvancic-Heltzel, Carrie Fister. *The University of Akron, Akron, OH.*  
(Sponsor: Gary H. Kamimori, FACSM)  
(No relationships reported)

**BACKGROUND:** Regular exercise can decrease the risk of falls, fractures, low back pain, and joint injuries by improving balance and strength. The WiiFit Plus incorporates programs such as yoga, strength training, aerobics, and balance games which are intended to improve balance, strength, flexibility, fitness, and general well-being.

**PURPOSE:** The purpose of this study was to examine the effect of WiiFit Plus exercises on lower leg muscular strength and balance in middle-aged adults.

**METHODS:** Three (3) healthy males (age  $53.3 \pm 2.3$  yrs) and 22 healthy females (age  $51.4 \pm 6.2$  yrs) were randomized into a control group ( $n=12$ ) and experimental group ( $n=13$ ) based on Godin Leisure Time Exercise Questionnaire results. Baseline strength (quadriceps, hamstrings, peroneals and tibialis anterior) using a computerized dynamometer and balance (overall stability index, anterior/posterior index and medial/lateral index) were assessed. The experimental group attended 40 minute WiiFit Plus exercise sessions on 2 non-consecutive days for eight weeks. Workload was modified on a biweekly basis based on heart rate and rate of perceived exertion (RPE). The control group continued normal activities of daily living. After eight weeks, post-intervention strength and balance measurements were assessed for both groups.

**RESULTS:** The experimental group demonstrated greater ( $p=0.02$ ) gains in quadriceps strength at  $90^\circ$  ( $8.28 \pm 15.8$  ft-lbs) than the control group ( $-11.57 \pm 22.0$  ft-lbs). No significant gains were observed ( $p \geq 0.08$ ) in all other dependent variables for lower extremity strength and balance.

**CONCLUSION:** Based on the results achieved, positive trends comparing the mean differences of the experimental population to the control group indicate that the Wii Fit Plus may be an effective supplement to exercise and a useful tool in preventing and/or improving functional deficiencies in the knee or ankle.

1762 Board #170 MAY 30 3:30 PM - 5:00 PM

**The Effects of Using a Gaming System to Improve Balance Parameters in Phase III Cardiac Rehabilitation Patients**

Peter Ellison<sup>1</sup>, Kent D. Johnson, FACSM<sup>1</sup>, Denny Pon<sup>2</sup>, Mary Beth Riley<sup>2</sup>. <sup>1</sup>Lipscomb University, Nashville, TN. <sup>2</sup>Saint Thomas Hospital, Nashville, TN.  
(No relationships reported)

Falls are a primary concern in geriatric populations and can result in critical injuries or even death. Fall prevention programs and balance exercises should be included in any exercise program developed specifically for individuals whose balance is compromised due to age or compromised health.

**PURPOSE:** The purpose of this project was to test the effectiveness of the Nintendo® Wii Fit Plus gaming system for improving balance in Phase III Cardiac Rehabilitation patients.

**METHODS:** Twenty-three Phase III Cardiac Rehabilitation patients from a local Cardiac Rehabilitation Program volunteered for the study. Subjects were initially pre-tested for balance equilibrium using The Berg Balance Scale and for lower body strength using the 30-second sit-stand test from the Senior Fitness Test. Following initial testing, subjects were required to participate in a total of 20 balance class sessions (three days per week) over a 12-week period. After the 12-week training period, subjects were retested for balance equilibrium (Berg Balance Scale) and lower body strength (30-second sit-stand test).

**RESULTS:** Results from The Berg Balance Scale test demonstrated a significantly improved balance score ( $42 \pm 4.06$  to  $50 \pm 3.65$ ;  $p < 0.05$ ) in these Phase III Cardiac Rehabilitation subjects. There were no significant changes ( $p > 0.05$ ) in the lower body strength scores (pre-test to post-test).

**CONCLUSION:** These data demonstrate the potential for using the Nintendo® Wii Fit Plus as an effective program to improve balance equilibrium in Phase III Cardiac Rehabilitation patients.

1763 Board #171 MAY 30 3:30 PM - 5:00 PM

**Heart Rate, Oxygen Consumption, and Ventilation due to Different Physically Active Video Game Systems**

Krista Scheer<sup>1</sup>, Sarah Siebrandt<sup>1</sup>, Gregory A. Brown, FACSM<sup>1</sup>, Brandon S. Shaw<sup>2</sup>, Ina Shaw<sup>3</sup>. <sup>1</sup>University of Nebraska Kearney, Kearney, NE. <sup>2</sup>Tshwane University of Technology, Johannesburg, South Africa. <sup>3</sup>Monash South Africa, Johannesburg, South Africa.  
(No relationships reported)

Several years ago, the Nintendo Wii ushered in the era of “physically active” home video game systems. Since then, the Sony Move and XBOX Kinect have been introduced as alternate “physically active” home video game systems. All of these gaming systems involve movement of the player to control on-screen game play, rather than simply pushing buttons.

**PURPOSE:** The purpose of this study was to compare heart rate, oxygen consumption, and ventilation while playing three similar hand to hand combat style games when playing Nintendo Wii Boxing, XBOX Kinect Boxing, and Sony Move Gladiatorial Combat.

**METHODS:** Twelve college aged participants (19.7 ± 1.0 y, 175.2 ± 6.8 cm, 76.0 ± 20.7 kg, 25.9 ± 9.9 % Body Fat) were assessed for resting heart rate, oxygen consumption, and ventilation. The participants then engaged in a maximal exercise test evaluating heart rate, oxygen consumption, and ventilation. On another day, in a randomly assigned manner, the participants played Nintendo Wii Boxing, XBOX Kinect Boxing, and Sony Move Gladiatorial Combat against either a computer or human opponent for 8 minutes in each condition.

Table 1. Heart rate, oxygen consumption, and ventilation (Data are means ± sd).

| VE(L/min)                      | 19.5 ± 7.0                           | 19.5 ± 5.4                        | 20.4 ± 9.9                                 | 21.0 ± 4.7                              | 20.0 ± 7.9   | 19.5 ± 6.1  |

**CONCLUSIONS.** Playing Nintendo Wii Boxing, XBOX Kinect Boxing, and Sony Move Gladiatorial Combat all increase heart rate, oxygen consumption, and ventilation above resting levels. However, the magnitude of increase in heart rate, oxygen consumption, and ventilation is not influenced by gaming system, or playing against another person. Overall, playing a “physically active” home video game system meets only the minimal threshold for moderate intensity physical activity.

1764 Board #172 MAY 30 3:30 PM - 5:00 PM

**Is Exergaming Appropriate For At-Home Physical Therapy?**

Enrique A. Becwar<sup>1</sup>, Ellis B. Jensen<sup>2</sup>. <sup>1</sup>Viterbo University, La Crosse, WI. <sup>2</sup>Utah Valley University, Orem, UT. (Sponsor: Tim Gavin, FACSM)  
(No relationships reported)

**INTRODUCTION:** Today’s sedentary American lifestyle has led to decreased health and greater rates of obesity in recent years. Some physical therapy clinics have begun to use exergaming (video games that include an exercise component) to help patients complete at-home exercises prescribed to improve patient recovery. Key to this function is the exergaming system’s ability to accurately track specific body motion.

**PURPOSE:** To assess the ability of the Wii Fit (Wii), PlayStation Move (PS3), and Xbox Kinect (Xbox) to track body motion.

**METHODS:** Volunteer subjects played the Wii, PS3, and Xbox systems at two intensities: high intensity (Full) and low intensity (Relaxed). During Full trials, subjects tried to obtain the highest score possible. During Relaxed trials, subjects used as little energy as possible while earning the same scores they had during Full trials. Total energy expenditure was estimated using SenseWear activity bands and the exergaming systems. Paired t-tests identified systems that were not able to detect motion differences in subjects during Full and Relaxed trials.

**RESULTS:** The PS3 and the Wii were both unable to detect motion differences in subjects exercising at high or low intensity. The Xbox differentiated high from low-intensity movements and required subjects to expend similar energy during Full and Relaxed trials.

|      | Level | Activity band<br>(cal) | Difference<br>(cal) | P-Value Full<br>vs. Relaxed | Exergame<br>(cal) | Difference<br>(cal) | P-value Full vs.<br>Relaxed |
|------|-------|------------------------|---------------------|-----------------------------|-------------------|---------------------|-----------------------------|
| Wii  | High  | 90                     | 44                  | 0.049                       | 74                | 19                  | 0.114                       |
|      | Low   | 46                     |                     |                             | 55                |                     |                             |
| PS3  | High  | 118                    | 52                  | 0.023                       | 107               | 6                   | 0.57                        |
|      | Low   | 66                     |                     |                             | 101               |                     |                             |
| Xbox | High  | 72                     | 3                   | 0.766                       | 59                | 5                   | 0.602                       |
|      | Low   | 69                     |                     |                             | 54                |                     |                             |

**CONCLUSION:** The Wii and PS3 are unable to differentiate between vigorous and relaxed body movement while the Xbox was able to differentiate body movements and hold the user to higher movement standards. This ability may allow the Xbox to play a role in at-home physical therapy.

1765 Board #173 MAY 30 3:30 PM - 5:00 PM

**Assessment of the Aerobic and Muscular Demands of Playstation Move’s Table Tennis and Gladiator Games.**

Randi Lite, Dana Griffin, Natalie Moy. Simmons College, Boston, MA.  
(No relationships reported)

**PURPOSE:** to determine central demand (HR, METS) and local demand (EMG) while playing Playstation Move’s Table Tennis and Gladiator Games. Muscle activity while gaming is compared with muscle activity while performing a muscle endurance test specific for each of the four muscles assessed.

**METHODS:** Eight healthy, college-aged volunteers had EMG recordings of the dominant side of rectus femoris, rectus abdominus, lattisimus dorsi, and pectoralis major made during a 1-minute curlup test, a 1 minute pushup test, a 1 minute modified pullup test, and the Forestry Step Test. The subjects completed a 20-minute tutorial, then played each game for 3 minutes in randomized order with 2-3 minutes rest between games. EMG activity, heart rate, RPE, and VO<sub>2</sub> were recorded. RMS values for each muscle were calculated, both while playing the games and while performing the muscle endurance tests.

**RESULTS:** Gladiator produced a HR of  $67.0 \pm 7.65\%$  of predicted HRmax and an intensity of  $2.87 \pm 1.21$  METs. The mean RPE was  $10.2 \pm 3.0$ . There was no significant difference in RMS for any muscle compared with its corresponding 1-minute muscle endurance test. Table Tennis produced a HR of  $57.3 \pm 7.83\%$  of predicted HRmax and an intensity of  $2.13 \pm 0.39$  METs. The mean RPE was  $7.5 \pm 1.6$ . The RMS for the rectus femoris during table tennis was significantly less than the RMS during the Step Test. Gladiator had a significantly greater RPE ( $p=.02$ ) and HR ( $p=.01$ ) compared with Table Tennis.

| Muscle           | Muscle Endurance Test RMS | Gladiator RMS  | Table Tennis RMS |
|------------------|---------------------------|----------------|------------------|
| Pectoralis major | $0.47 \pm .18$            | $0.65 \pm .56$ | $0.41 \pm .32$   |
| Rectus abdominis | $0.42 \pm .56$            | $0.94 \pm .87$ | $0.78 \pm .86$   |
| Latissimus dorsi | $0.38 \pm .23$            | $.61 \pm .51$  | $0.40 \pm .37$   |
| Rectus femoris   | $2.07 \pm .79$            | $1.13 \pm .70$ | $0.81 \pm .57^*$ |

\* $p=.02$

**CONCLUSION:** ACSM Guidelines suggest 30 minutes of moderate activity (3-6 METS) for 5-7 days/week. Both games were below the 3 MET level. The RMS for four muscles were not different from standard muscle endurance activities, suggesting that the games may develop muscle endurance at least on the dominant side.

#### Anaerobic Power Output in College Division 2 Athletes

Steve Burns, Brian Hughes, Andrew Gai, Aryn Lessmeier, Curtis Sartin, Trevor Swaine, Halie Thomas, Casandra Davis. *University of Central Missouri, Warrensburg, MO.*

(No relationships reported)

The Wingate anaerobic test is considered to be an accurate measure of anaerobic capacity of an individual.

**PURPOSE:** The purpose of this study was to begin development of updated norms of division 2 college athletes for peak power (PP) mean power (MP), and fatigue index (FI) on the Wingate anaerobic test using advanced technology (RacerMate® Velotron).

**METHODS:** A total of 337 athletes participated in their respective preseason weeks. After signing IRB approved informed consent, subject's height and weight was measured (Inbody520, Biospace Inc, CA). Subjects were guided through the Wingate procedures, after a 5 minute warm-up including 2-3, 10 sec sprints. Wingate 30 second test consisted of a 5 second sprint before the calculated resistance was applied ( $.075 \text{ kg} \cdot \text{kg}^{-1}$ ). Peak Power (PP) and Mean Power (MP) in both watts and watts/kg were recorded in addition to fatigue index.

**RESULTS:** The data indicate that football athletes have the highest PP ( $1604.9 \pm 289.0\text{W}$ ), MP ( $787.7 \pm 95.6\text{W}$ ) and FI ( $41.6 \pm 9.9\text{W} \cdot \text{sec}^{-1}$ ). Men's track and cross country produced the highest MP relative to body weight ( $8.4 \pm 7.0\text{W} \cdot \text{kg}^{-1}$ ) and women's track and cross country produced the lowest FI ( $10.7 \pm 2.8\text{W} \cdot \text{sec}^{-1}$ ) (See table below).

**CONCLUSION:** Based on the current data, these results provide norms for comparison of peak anaerobic power and mean anaerobic power in division 2 college athletes. Additionally Football players exhibit higher power output than other sports represented.

| Anaerobic Power      |    |         |        |           |        |           |            |
|----------------------|----|---------|--------|-----------|--------|-----------|------------|
| Sport                | N  | Wt (kg) | PP (W) | PP (W/kg) | MP (W) | MP (W/kg) | FI (W/sec) |
| Volleyball           | 27 | 72.6    | 776.6  | 10.7      | 503.1  | 7.0       | 14.7       |
| Baseball             | 42 | 87.7    | 1158.9 | 13.3      | 682.6  | 7.8       | 23.9       |
| Women's Basketball   | 12 | 72.8    | 816.6  | 11.0      | 545.5  | 7.3       | 14.8       |
| Men's Basketball     | 16 | 89.6    | 1133.9 | 12.6      | 719.7  | 8.0       | 23.0       |
| Softball             | 17 | 72.7    | 634.9  | 9.5       | 400.4  | 6.0       | 12.5       |
| Wrestling            | 53 | 83.1    | 981.7  | 12.2      | 617.2  | 7.7       | 19.2       |
| Women's Track and CC | 11 | 58.7    | 637.2  | 10.9      | 412.5  | 7.0       | 10.7       |
| Men's Track and CC   | 17 | 71.1    | 896.2  | 12.7      | 597.3  | 8.4       | 15.8       |
| Golf                 | 15 | 77.7    | 981.0  | 11.8      | 612.6  | 8.3       | 20.5       |
| Soccer               | 38 | 61.7    | 670.9  | 11.0      | 422.6  | 7.0       | 12.6       |
| Football             | 75 | 102.6   | 1604.9 | 15.8      | 787.7  | 8.0       | 41.6       |
| Bowling              | 14 | 75.8    | 962.0  | 12.4      | 575.0  | 7.7       | 20.1       |

### 1767 Board #175 MAY 30 3:30 PM - 5:00 PM

#### Assessment Of Leg Power Using Stairs With A Low Step Height In Elderly

Yutaka Yoshitake<sup>1</sup>, Yoshiki Kawano<sup>2</sup>, Akiyo Higashionna<sup>1</sup>, Goichiro Yoshida<sup>1</sup>, Xiang Fan<sup>1</sup>, Takafumi Hamaoka, FACSM<sup>3</sup>. <sup>1</sup>National Institute of Fitness and Sports in Kanoya, Kanoya, Japan. <sup>2</sup>Laboratory of Physical Science Inc, Fukuoka, Japan. <sup>3</sup>Ritsumeikan University, Kusatsu, Japan.

(No relationships reported)

A stair-climbing power test using ordinary stairs is an inexpensive test that is simple to perform. This test can also be completed in less than 1 minute. However, there has so far been no report on the usefulness of using stairs with a lower step height to assess the leg muscle power in elderly people as a field test.

**PURPOSE:** To determine the usefulness of the low height step stair-climbing power (LSSCP) test by comparing the results obtained from the LSSCP test with those from a knee extension torque (KET), leg extensor power (LEP), Time Up & Go (TUG) test and 10 m maximal walking speed (MWS) in elderly people.

**METHODS:** The subjects of this study consisted of healthy elderly men (N=65, aged 71.1+/-5.6 yrs) and women (N=146 aged 70.3+/-5.9 yrs). The LSSCP was measured using stairs with a lower height step (9 cm step height, 10-stair flights, 72 cm total height). The time spent in stair climbing was measured by a contact mat connected to an electronic timer. The circuit automatically opens at take off and closes when the subjects touch the mat. The subjects were instructed to ascend the stairs as fast as they could. The stair-climbing power was then calculated with the body mass, the time spent in stair climbing, the vertical height travelled, and the gravitational acceleration. The bilateral LEP was measured using an isotonic leg power measuring system in a sitting position. The KET was measured on each side of the knee using a specially designed dynamometer. The test-test reliability of LSSCP was determined in the participants by using an intraclass correlation coefficient (ICC) model.

**RESULTS:** The LSSCP was 201.2±/30.6 watts (mean +/- SD) for men and 179.7±/24.4 watts for women. The LSSCP significantly correlated with KET (p<0.001), LEP (p<0.05), MWS (p<0.05) and TUGT (p<0.05) in elderly men and women, respectively. The ICC value of LSSCP was 0.73 for men and 0.84 for women, thus indicating a good reliability. A significantly negative correlation was found between LSSCP and age in both genders (p<0.05).

**CONCLUSION:** From a practical viewpoint for use as a field test, the LSSCP test was found to be useful for assessing the functional leg power levels in community-dwelling elderly people.

**1768** Board #176 MAY 30 3:30 PM - 5:00 PM

**Leg Power in Elite Male Fencers: A Comparative Study among the Three Competitive Disciplines**

Gustavo D. Aquilino, Aldo F. Longo, Néstor A. Lentini. *Exercise Physiology Laboratory, National Sport High Performance Center (CeNARD), Buenos Aires, Argentina.*

(No relationships reported)

The motor response of a fencer is required to be fast and explosive. Leg power plays a key role in the competitive fencing disciplines.

**PURPOSE:** To compare leg power performance of elite male fencers by competitive discipline.

**METHODS:** Data of 18 fencers who took part in the Argentine national team were considered in the study (Age = 24.38 ± 5.26 yr, Weight = 74.82 ± 8.16 kg, Height = 1.81 ± 0.06 m; mean ± SD). Three groups of 6 subjects each were defined according to the competitive disciplines of the sport: Épée, Foil and Sabre. Leg Power was indirectly measured through the assessment of height jumped following three well-known protocols: Abalakov Jump, Counter Movement Jump and Squat Jump. A contact platform was used to assess height jumped. Lewis formula was employed for calculation of Average Power (AP). Based on data gathered over several years, the best performance of each subject was selected for the analyses. ANCOVAs were conducted on AP for Abalakov, Counter Movement and Squat Jumps; Weapon was the independent factor in the analyses and Weight was introduced as a covariable. Linear associations among the three vertical jumps were evaluated on the whole sample by means of Pearson correlation tests; height jumped was used for these analyses.

**RESULTS:** Sample means of height jumped in cm for Épée, Foil and Sabre were, respectively, 51.77, 51.52 and 53.42 in Abalakov Jump; 44.83, 45.43 and 46.95 in Counter Movement Jump; and 38.97, 39.80 and 41.02 in Squat Jump. ANCOVAs on AP were not statistically significant (p>0.05) for Weapon for any of the tests: Abalakov Jump (1159.7, 1168.0 and 1182.1 W; F = 0.14), Counter Movement Jump (1080.6, 1096.1 and 1109.8 W; F = 0.41) and Squat Jump (1011.2, 1024.8 and 1037.1 W; F = 0.24). As predictable, there were found high correlations among vertical jumps ( $r_{A,C} = 0.92$ ,  $r_{A,S} = 0.83$ ,  $r_{C,S} = 0.91$ ; p<0.05).

**CONCLUSIONS:** The results obtained showed negligible differences in AP among the three disciplines of the sport. It would be desirable to obtain further statistical evidence from a larger sample size.

**1769** Board #177 MAY 30 3:30 PM - 5:00 PM

**Effects of Self Myofascial Release & Static Stretching on Anaerobic Power Output**

Jeffrey M. Janot, Brittany Malin, Ryan Cook, Jacob Hagenbucher, Andrew Draeger, Melissa Jordan, Gary Van Guilder. *University of Wisconsin-Eau Claire, Eau Claire, WI.* (Sponsor: Mark Blegen, FACSM)

(No relationships reported)

The application of pre-exercise self-myofascial release (MFR) techniques to enhance exercise performance is an understudied topic. In contrast, the effects of pre-exercise static stretching (SS) are well-known, especially in regards to changes in anaerobic performance variables such as sprinting speed and vertical jump. Less is known specific to the effects of SS on cycling performance.

**PURPOSE:** The aim of this study was to determine the effects of SS and MFR on anaerobic power output.

**METHODS:** Cycling (30-sec Wingate) tests were used to assess power output in 9 male and 14 female subjects. Peak power output (PPO) and percent power drop (PPD) were examined among subjects to determine the differences between interventions.

**RESULTS:** In female subjects, PPO was significantly reduced following SS, in comparison to control (Control: 536.29 ± 69.11 W; SS: 508.30 ± 67.10 W). PPD was significantly decreased in the SS and MFR treatments compared to the control (Control: 44.95 ± 5.29%; SS: 40.45 ± 6.69%; MFR: 41.53 ± 5.97%). In male subjects, PPO was significantly increased following SS, in comparison to control (Control 850.62 ± 165.41 W; SS: 881.14 ± 169.33 W). PPD was significantly increased in MFR compared to the control group (Control: 44.69 ± 7.75%; MFR: 48.91 ± 8.27%).

**CONCLUSIONS:** The effects of MFR on anaerobic power output appear to be gender specific with evidence of a positive effect on performance in women. Given that there is very little scientific inquiry with respect to the influence of MFR on maximal anaerobic power performance, it can only be speculated on the possible mechanisms for the gender disparity.

**1770** Board #178 MAY 30 3:30 PM - 5:00 PM

**Effects Of Temperature And Prior Sprint Efforts On Maximum Cycling Power And Optimal Pedaling Rate**

Kyle W. Wehmanen, Camden S. Marshall, James C. Martin, FACSM, Steven J. Elmer. *University of Utah, Salt Lake City, UT.*

(No relationships reported)

Warm up protocols are commonly used prior to exercise, particularly before maximal power performance. Specifically, these protocols may serve to increase muscle temperature and to provide potentiation of muscle force production. However, warm-ups must balance increasing muscle temperature and inducing muscle fatigue.

**PURPOSE:** To determine the effects of passive warm-up, active warm-up, passive cooling, and prior maximal cycling on maximum cycling power ( $P_{max}$ ) and optimal pedaling rate ( $RPM_{opt}$ ).

**METHODS:** Twelve participants (mass 69 ± 13 kg, height 173 ± 7 cm, age 25 ± 5 yrs) performed two maximal cycling trials on an inertial load ergometer before and after three different experimental treatments: passive warm-up, active warm-up, and passive cooling. For the passive warm-up and cooling treatments, participants were immersed up to iliac crest for 30 min in 40° C and 18° C water, respectively. For the active warm-up, participants rested at room temperature for 25 min, then performed a 5 min cycling warm-up at 100-120 rpm.

**RESULTS:**  $P_{max}$  increased by 6 ± 5% (906 ± 214 vs. 961 ± 216 W, p < 0.001) and 8 ± 4% (908 ± 230 vs. 983 ± 249 W, p < 0.001) following the passive and active warm-ups, respectively, and decreased by 23 ± 6% (955 ± 238 vs. 738 ± 187 W, p < 0.001) following passive cooling. Compared to baseline, passive and active warm-up increased  $RPM_{opt}$  (114 ± 13 vs. 122 ± 15 rpm and 114 ± 9 vs. 127 ± 11 rpm, respectively, p < 0.05), whereas passive cooling decreased  $RPM_{opt}$  (116 ± 7 vs. 101 ± 11 rpm, p < 0.01). Following passive and active warm-ups, there was no additional increase in  $P_{max}$  between the first and second maximal cycling trials.

**CONCLUSION:** These results indicate that passive and active warm-ups increased  $P_{max}$  by similar magnitudes whereas passive cooling substantially compromised  $P_{max}$ . Temperature also influenced  $RPM_{opt}$ , likely reflecting effects on muscle shortening velocity. Although  $P_{max}$  increased following passive and active warm-ups, there was no further increase following the first maximal trial, suggesting that no additional potentiation occurred. Finally, these results may have implications for athletes who warm-up before performing short duration maximal effort tasks. That is, passive warm-up may provide an alternative strategy for increasing temperature while minimizing fatigue.

**1771** Board #179 MAY 30 3:30 PM - 5:00 PM

**Comparison of Peak Power for Cycling on Ergometer and Trainer**

Edward M. Heath, FACSM, Andrew I. Miller, Eadric Bressel, Gerald A. Smith, FACSM. *Utah State University, Logan, UT.*

(No relationships reported)

The ability of a cyclist to produce peak power may be related to the apparatus that is used for testing. Laboratory research has an advantage of tighter control compared to field studies; however, ecological validity is important for application to the target population and environment. A stationary cycle ergometer is often the default instrumentation for lab data collections, but results may not generalize well because a cycle ergometer may differ substantially from a cyclist's own bicycle. A stationary trainer equipped with the cyclist's own bicycle compared to an ergometer can be used to address this concern.

**PURPOSE:** To compare peak power during cycling on an ergometer and a stationary trainer.

**METHODS:** Highlytrained cyclists ( $n = 5$ , age =  $37.6 \pm 4.5$  yr,  $VO_2$  peak =  $63.3 \pm 5.3$  ml/kg-1/min-1) performed a peak power test, in randomized order, on an modified Monark ergometer and CycleOps Supermagneto trainer. After adequate warm-up, subjects ramped up by self-selecting gear and cadence on the trainer until self-determined peak power was achieved. On the ergometer, subjects increased to peak cadence just prior to application of a resistance equal to  $6.7 \pm 1.0\%$  of body weight. For the ergometer, cadence was determined by video analysis (Vicon motion analysis system).

**RESULTS:** Peak power was significantly ( $p = .026$ ) greater on the trainer ( $925.0 \pm 162.5$  W) compared to the ergometer ( $840.0 \pm 154.7$  W).

**CONCLUSION:** Subjects were able to produce 10% higher power on the trainer compared to the ergometer. The increased ability to produce power on the trainer is likely due to subjects being more familiar and better fitted to their own bicycles.

**Revisiting The Relationship Between Power And Time To Fatigue**

Ming-Chang Tsai, Scott Thomas. *University of Toronto, Toronto, ON, Canada.*

(No relationships reported)

A well-established model, Critical Power, has been extensively used in numerous endurance sports to characterize an individual's work performance; anaerobic work capacity and critical power. A linear relationship between the work and time to fatigue, given by  $Work = AWC + CP \cdot t$ , was initially proposed by Monod and Scherrer in 1965 in small muscle groups and was extended to whole-body exercise by Moritani et al. in 1981. This linear relationship was determined from plotting the limit work expressed in the product of force and limit time against the limit time. Since limit time is indirectly plotted against each other, the relationship will inevitably be linear.

**PURPOSE:** To revisit the relationship between power and time to fatigue in rowing exercise using a mathematically equivalent critical power model,  $Power = AWC/t^n + CP$ .

**METHODS:** Ergometer testing results (power outputs for 1 minute, 1000m, 2000m, and 6000m) were obtained from 55 male ( $19.48$  yrs  $\pm 3.34$ ) and 35 female ( $20.63$  yrs  $\pm 3.16$ ) athletes. Power output for 1 minute, 1000m, and 6000m were used to determine the relationship (exponent  $n$  in the above equation) between power and time to fatigue. This relationship is then used to construct a critical power model for each individual athlete. Together with the theoretical 2000m power output curve, a predicted 2000m power output can be calculated through numerical methods. Power output comparisons were made using two-sample independent t-tests for the traditional model relationship and the new model relationship.

**RESULTS:** The exponent  $n$  of the critical power model was determined to be  $0.3998$  ( $p < 0.001$ ). The predicted 2000m power outputs from the traditional relationship ( $n=1$ ) showed a significant difference from the actual 2000m power outputs ( $t=2.14$   $p=0.0337$ ), while the 2000m power outputs from the new relationship ( $n=0.5$ ) showed no significant difference from the actual 2000m power output result ( $t=1.03$   $p=0.3045$ ).

**CONCLUSION:** The new relationship ( $n=0.5$ ) between power and time to fatigue appears to predict the actual 2000m power output better than the traditional relationship ( $n=1$ ) between power and time to fatigue.

**Effects of Football Equipment on Power in High School Players**

Stefan L. Bergeron, Brian J. Campbell, Torie M. Guidry, Cole M. Thompson. *University of Louisiana at Lafayette, Lafayette, LA.*

(No relationships reported)

Traditional speed testing of football players has normally been done in the absence of game equipment. Research in the area of football equipment's impact on strength and conditioning assessments is limited. Determining power from 40-yard dash times in the use and absence of football equipment can give coaches valuable insight on athletes' potential. Changes to functional power (FP) in the presence of game equipment have yet to be investigated in the 40-yard dash.

**PURPOSE:** To assess changes in FP during the 40-yard dash with football equipment (EQ) and with no football equipment (NEQ).

**METHODS:** Sixty-four high school football players (weight:  $78.28 \pm 15.45$  kg) were timed in the 40-yard dash on a natural grass field using an automatic timing system with a high speed video camera (30 frames/sec), starter pistol, receiver, and timing software. Players performed two trials with nylon shorts and a t-shirt, then two trials with standard issued football game equipment. The fastest times of the two trials for each condition were used for analysis. A paired samples t-Test was utilized to assess the significance between 40-yard dash EQ and NEQ at an alpha level of 0.05.

**RESULTS:** There was a significant increase in power with EQ condition ( $t = 11.040$ ,  $p < .001$ ).

**CONCLUSION:** Literature suggested that speed decreased with the addition of football equipment, but measuring and understanding power increase can be beneficial to coaches and trainers. Certain players may be capable of handling increased overall lean muscle mass while still having quality on-field performance. Poor FP with equipment can be identified in order for coaches to implement a specific conditioning program.

**1774** Board #182 MAY 30 3:30 PM - 5:00 PM

**Football Equipment Effects on 20-yard Agility Power in High School Football Players**

Brittany S. Richard, Lauren E. Miller, Brian J. Campbell, Katie C. Morgan, Stefan L. Bergeron, Cole M. Thompson, Torie M. Guidry. *University of Louisiana at Lafayette, Lafayette, LA.*

(No relationships reported)

Traditional sports performance test does not incorporate (game like) conditions when determining the speed or agility of an athlete. Agility power testing with equipment (APE) gives more evidence on how the players will perform in game like situations than testing without equipment (APW). This also gives coaches valuable insight on the players potential and further allows them to implement effective conditioning programs specific to the individual.

**PURPOSE:** To assess the effects of football equipment on agility power in High School Football players. **Method:** 64 high school football players (weight:  $78.28 \pm 15.45$  kg) were timed in the 20 yard agility run on a natural grass field. Each player was tested in two trials of both APE and APW conditions. Agility time was administered by experienced, hand held timers with the best trial being used for analysis. Power scores were then calculated and compared using a paired samples t-test.

**RESULTS:** A significant difference was noted between APE and APW ( $t = 5.679$ ,  $p < .001$ ).

**DISCUSSION:** The results suggest that players significantly increase their agility power with equipment. Coaches can use this information to target players with higher power output in presence of added equipment. This implies that players with higher power output may transition more lean muscle mass to the football field. Participants who demonstrate less power than average should be targeted for improvement through specific strength and conditioning.

**Cross Training Program Induces Specific Changes on Anthropometric Profile and Leg Power in Women Dancer**

Claudia E. Carrasco-Legleu, Rosalinda Rivas-Castilla, Ofelia Urita, Ma Concepcion Soto-Valenzuela, Lidia G. De Leon. *Universidad Autonoma de Chihuahua, Chihuahua, Chih., Mexico.*

(No relationships reported)

Cross training is a fitness method which incorporates various activities in a work session; it reduces the risk of overload injury, increases the quality of movement and improves technique. Scientific literature about the results of morphological evaluation of physical performance or administration of dancers training programs is currently limited, therefore, knowledge of the morphology of the dancers will provide training tools to develop the basic and specialized skills in dance activity.

**PURPOSE:** To evaluate the effect of a specific fitness program based on "cross training" technique on anthropometric and physical performance profile of a semi-professional dancers group.

**METHOD:** The participants were nine women dancers 20 to 24 years of age. The evaluation of anthropometric profile, the proportional sum of six skinfolds (PS6S), the feeding and physical

performance (aerobic capacity, muscular strength, leg power and others), was performed before and after to apply the cross training program (12 weeks). Descriptive statistics, Student t test and ANOVA were used and statistical significance was set at  $p < 0.05$ .

**RESULTS:** Only five dancers,  $22.4 \pm 1.4$  years old,  $51.3 \pm 7.0$  kg of weight and  $161.1 \pm 2.0$  cm of height, with  $8.0 \pm 2.8$  years of experience in the discipline completed the program. Iliac crest skinfold decreased from  $14.5 \pm 6.3$  to  $11.4 \pm 4.8$  mm,  $p=0.011$ , abdominal ( $19.3 \pm 7.3$  to  $15.8 \pm 6.5$  mm,  $p=0.014$ ), front thigh from  $24.9 \pm 6.9$  to  $17.9 \pm 3.6$  mm ( $p=0.013$ ), medial calf ( $13.6 \pm 6.6$  to  $10.9 \pm 4.7$  mm,  $p=0.045$ ). The forearm circumference increased ( $p=0.009$ ), while the hip ( $p=0.003$ ), ankle ( $p=0.034$ ) and PS6S ( $101.3 \pm 32.0$  to  $78.8 \pm 25.6$  mm) decreased significantly. Energy intake, aerobic capacity and muscular endurance remained unchanged. The results indicated an increased potency (jump Grand Jete) of  $124.7 \pm 11.2$  to  $152.4 \pm 11.5$  cm ( $p = 0.028$ ).

**CONCLUSIONS:** Cross training program showed effectiveness to improve some of the skills required in the performance of contemporary dance, however it will be interesting to search an increase in aerobic capacity, a basic characteristic for physical training as well as to adapt the diet in this group.

**1776 Board #184 MAY 30 3:30 PM - 5:00 PM**

**Attenuated Wingate Test Power Outcomes from "All-Out" Pre-Test Pedaling Cadence Compared to Moderate Cadence**

William R. Lunn, Maria Zenoni, Ian Crandall, Ashley Dress, Christopher Fountain, Jason Pereira, Michelle Berglund. *Southern Connecticut State University, New Haven, CT.*

(No relationships reported)

Published research employing the Wingate Anaerobic Test for muscular power (WAnT) describes instructing the participant to either pedal as fast as possible or maintain a constant, moderate cadence in the seconds before test start. It is unclear whether non-standardized, pre-test pedal cadences can influence power data.

**PURPOSE:** The aim was to determine the effect of different pre-test pedaling cadences on power outcomes obtained during the WAnT.

**METHODS:** Vigorously-exercising adult males ( $n = 14$ ,  $24.9 \pm 1.2$  y,  $80.1 \pm 2.7$  kg, BMI =  $24.4 \pm 0.6$ , body fat =  $11.0 \pm 1.0\%$ ) and females ( $n = 14$ ,  $20.4 \pm 0.6$  y,  $61.4 \pm 2.6$  kg, BMI =  $22.2 \pm 0.5$ , body fat =  $21.4 \pm 1.3\%$ ) participated in a randomized study during which they performed the 30-s WAnT on a cycle ergometer on two occasions. Each WAnT was separated by at least 48 h for adequate recovery. Flywheel load was standard at  $0.075$  kg/kg body weight. In one trial, the participant was instructed to pedal as fast as possible with an unloaded flywheel during the 5 s before resistance was applied and the test began (FAST). In the second trial, the participant was instructed to maintain a moderate cadence of 80 rpm during the 5 s before resistance was applied (MOD). All other components of the WAnT were identical in both trials. Peak power (PP), mean power (MP), minimum power (MinP), time at peak power (PTime), and power drop (Pdrop) were recorded. Body composition was determined by 3-site skinfolding. Comparisons were made using a 2x2 factorial ANOVA (gender x cadence).

**RESULTS:** Regardless of gender, the FAST protocol resulted in 22.2% lower PP ( $612.6 \pm 33.0$  W vs.  $788.3 \pm 43.5$  W), 13.3% lower MP ( $448.4 \pm 22.2$  W vs.  $517.2 \pm 26.4$  W), 11.7% lower MinP ( $280.9 \pm 14.8$  W vs.  $318.3 \pm 17.2$  W), and 9.0% lower Pdrop ( $53.5 \pm 1.3\%$  vs.  $58.8 \pm 1.5\%$ ) than in MOD ( $p < 0.01$ ; means  $\pm$  SE). No difference was observed in PTime. Similar outcomes were observed within gender.

**CONCLUSION:** Commonly-used protocols which instruct the WAnT participant to pedal either as fast as possible or at a moderate cadence with an unloaded flywheel before resistance is applied result in a divergence of anaerobic muscular power indices. Expanding the WAnT protocol to include standardizing the pre-test pedal cadence may be important to exercise testing professionals who are comparing the data to norms or generating norms for specific populations.

**No Difference in Power Output For Seated Versus Standing Position During Wingate Anaerobic Power Test**

Jeffrey A. Potteiger, FACSM<sup>1</sup>, Jacob Hamm<sup>2</sup>, Mark Walsh<sup>2</sup>, Dean Smith<sup>2</sup>. <sup>1</sup>Grand Valley State University, Grand Rapids, MI. <sup>2</sup>Miami University, Oxford, OH.

(No relationships reported)

**PURPOSE:** To determine if differences in power output exist between the seated versus standing position during the Wingate Anaerobic Power Test (WAPT).

**METHODS:** 14 males (body mass  $79.6 \pm 7.1$  kg) from a College Club level ice hockey team participated in the study. All testing occurred at the same time of day following a 4 h fast. On day one, body fat percent and fat free mass (FFM) were determined using air displacement plethysmography and subjects were given two practice Wingate Anaerobic Power tests (one each in the seated and standing position). On two different days, the subjects performed two 30 s maximal effort WAPT, with each test separated by 7 days. All data were collected using a Monark computerized bicycle ergometer. Following a standard 5 min warm-up, each subject was given a 3 minute rest. The resistance for testing was 7.5% of body mass. Subjects were ramped up during the test with load application and data collection beginning when subjects reached 120 rpm. Differences in power output between the seated and standing position were determined using a paired t-test, with significance set at  $p \leq 0.05$ .

**RESULTS:** The data (means $\pm$ SD) for the primary dependent variables are shown in the table below.

|          | Peak Power (W)   | Peak Power (W/kg) | Peak Power (W/kg/FFM) | Average Power (W) | Average Power (W/kg) | Average Power (W/kg/FFM) |
|----------|------------------|-------------------|-----------------------|-------------------|----------------------|--------------------------|
| Seated   | 959.1 $\pm$ 96.7 | 12.1 $\pm$ 1.4    | 13.5 $\pm$ 1.4        | 618.6 $\pm$ 48.3  | 7.8 $\pm$ 0.5        | 8.7 $\pm$ 0.5            |
| Standing | 971.5 $\pm$ 90.0 | 12.2 $\pm$ 1.5    | 13.7 $\pm$ 1.4        | 629.3 $\pm$ 45.8  | 7.9 $\pm$ 0.7        | 8.9 $\pm$ 0.7            |

There were no significant differences between the two positions for any of the primary dependent variables.

**CONCLUSION:** During Wingate Anaerobic Power testing subjects should be allowed to select the most comfortable position for testing, as both seated and standing produced similar peak and average power measures.

**1778 Board #186 MAY 30 3:30 PM - 5:00 PM**

**Associations of Upper Body Power Tests and Upper and Lower Body Power in ROTC Cadets**

Anita M. Gust, Katie Jorissen, Nicklaus Rendinius, John Schuna, Jr., Sarah Hilgers, Bryan Christensen, Gary Liguori. *North Dakota State University, Fargo, ND.*

(Sponsor: Donna J. Terbizan, FACSM)

(No relationships reported)

Upper and lower body power are important physical attributes for a successful soldier, yet are not part of the current U.S. Army physical fitness assessment.

**PURPOSE:** This study assessed the relationship between upper and lower body power in U.S. Army ROTC cadets in an attempt to identify useful power measures for future Army testing. Upper body power was measured by a seated medicine ball throw (MB) and a push up test (PU), and lower body power was measured by a counter-movement vertical jump (VJ).

**METHODS:** A total of 79 cadets (20 females and 59 males) performed all three tests in a single session. The seated MB test consisted of three separate throws of a 4kg medicine ball, measuring for greatest distance. The PU test consisted of three separate, quick and forceful PUs performed on an AMTI Accupower force plate (W/kg). The VJ consisted of three separate double leg counter-movement vertical jumps on the AMTI force plate (W/kg). Participants were asked to perform each test with maximal volitional effort and acceleration. Each attempt was recorded with the best score on each test retained for use in further analysis. Pearson product-moment correlations were calculated to assess the relationship between the MB, PU, and VJ. All analyses were conducted using PASW statistics version 18, with alpha set  $< .05$ .

**RESULTS:** For males, a significant moderate correlation was found between the MB and VJ ( $r=.44$ ,  $p = .001$ ). For females, significant moderate correlations were found between the MB and VJ ( $r=.45$ ,  $p = .047$ ) and between the MB and PU ( $r=.51$ ,  $p=.022$ ).

**CONCLUSIONS:** Although both the MB and PU tests were intended to measure upper body power and thought to be related, our study found mixed results based on gender. There was a significant relationship between the two upper body tests in the females, but not in the males. A significant relationship between upper and lower body power was found in both males and females with the MB and VJ. Limitations of this study include a small sample of women, and not having a gold standard of an upper body power measure to determine which upper body test

was most valid. Including a power measure in future fitness assessment is suggested; however, further investigation is needed to determine which power tests are most reliable and valid for assessing power in ROTC cadets.

---

**1779** Board #187 MAY 30 3:30 PM - 5:00 PM  
**Validity Of Adapted Running Anaerobic Sprint Test (arast) For Assessing Anaerobic Power And Predicting Short-distance Performances In Wheelchair Patients.**  
Jorge Franchella, FACSM<sup>1</sup>, Juan Ignacio Sagastibelza<sup>2</sup>, Germán Laurora<sup>2</sup>, Hernán Castro<sup>2</sup>. <sup>1</sup>UBA, Buenos Aires, Argentina. <sup>2</sup>UBA, BUENOS AIRES, Argentina.  
(No relationships reported)

The **PURPOSE** of this study was to investigate, based on a well known test (RAST), the validity of an adapted running anaerobic sprint test (ARAST), specially designed for wheelchair patients, predicting short-distance performance.

**METHODS:** Fifteen members of three different basketball wheelchair teams were recruited for this research. It was divided in two stages. The first stage investigated the distance to be traveled six times to be tested with ARAST. It was performed by using the time people usually last to reach each stage. The RAST test was applied in 20 volunteers. Time to cover 35 meters maximal running performance was measured. Then it was determined the distance 20 patients using their wheelchair, were able to cover in this time. We found the proper distance was between 15 and 20 meters. So we tested both distances in 15 basketball wheelchair patients. The results of 15 meters six times test did not showed negative trend between the last and the first travel. When we tested in 20 meters we found a significant difference  $p < 0.5$  between the last and the first, similar to those seen with original RAST test.

**RESULTS:** in the 20 meters test we founded. Maximum speed: average 3.58 m/sec. Standard deviation: 0.37. Time to cover distance: average 6.05 sec. Standard deviation: 0.66. Losing speed in percentage average: 11.44% Standard deviation: 7.43. We also determined peak power and mean power taking in account power = mass\* distance<sup>2</sup>/ time<sup>3</sup>.

**CONCLUSION:** The advantage of using ARAST for measuring anaerobic power wheelchair patients is that it allows the execution of more specific movements, It is easily applied and low cost, and due to its simplicity can be incorporated into routine training. Future direction could be to test larger number of disable athletes, and also in different Sports. We concluded that this procedure is valid, and can be used to measure running anaerobic power and predict short-distance performances in wheelchair patients.

---

**1780** Board #188 MAY 30 3:30 PM - 5:00 PM  
**Peak Power Output During A 15m Wheelchair Overground Sprint Can Be A Measure Of Anaerobic Capacity**  
Jan W. van der Scheer<sup>1</sup>, Sonja de Groot<sup>1</sup>, Tom A. Gakes<sup>2</sup>, Marlies Bouma<sup>2</sup>, Dirk-Jan H.E.J. Veeger<sup>2</sup>, Lucas H.V. van der Woude<sup>1</sup>. <sup>1</sup>University Medical Center Groningen, Groningen, Netherlands. <sup>2</sup>VU University Amsterdam, Amsterdam, Netherlands. (Sponsor: Thomas W.J. Janssen, FACSM)  
(No relationships reported)

Wheelchair-specific anaerobic capacity can be assessed with a 30s Wingate-like sprint test in a handrim-propelled wheelchair ergometer (WC ergometer). Performance on this test has been found sensitive to change in high and low-intensity training programs. However, the ergometer test cannot easily be employed in a sports or rehabilitation setting. An alternative test might be a 15m overground sprint in a handrim-propelled wheelchair (15m WC sprint) equipped with torque sensors.

**PURPOSE:** To test the hypothesis that 1) peak power output and 2) time of a 15m WC overground sprint are valid alternatives for outcome measures of a 30s Wingate-like sprint test in a WC ergometer.

**METHODS:** Able-bodied men and women (age: 18-30y, length: 163-195 cm, weight: 50-94 kg) performed a 30s Wingate-like sprint test in a WC ergometer (start velocity = 0 m·s<sup>-1</sup>). Torque around the right wheel axle was measured, enabling determination of 1) peak power output, 2) mean power over the full 30s-test, and 3) mean power over a 5s-interval after the first start-up strokes. Resistance was individualized to ensure a velocity < 2 m·s<sup>-1</sup>. On another day, subjects performed a 15m WC overground sprint. As in the ergometer sprint, unilateral peak power output was determined from torque around the right wheel axle (measured with a commercially available torque sensor-equipped wheel). In addition, similar to current use of 15m WC sprint tests in rehabilitation settings, performance time was manually recorded. Descriptive statistics and correlation coefficients (Pearson's *r*) were used to test the hypothesis.

**RESULTS:** Unilateral peak power in the 15m WC sprint was 228 (±72) W, and 250 (±85) W in the WC ergometer test. Ergometer-30s power was 44 (±17) W, and ergometer-5s power was 54 (±21) W. Time over 15m was 7.2 (±1.0) seconds. Unilateral peak power in the 15m overground test was strongly correlated to ergometer peak power ( $r = 0.765$ ), 30s-power ( $r = 0.836$ ), and 5s-power ( $r = 0.716$ ) at  $P \leq 0.001$ . Pearson's *r* between 15m time and ergometer peak, 30s-, and 5s-power ranged between -0.479 and -0.612 ( $P < 0.05$ ).

**CONCLUSION:** Peak power output in a 15m WC overground sprint seems to be a valid alternative for mean power output measured in a 30s Wingate-like sprint test in a WC ergometer. Performance time on the 15m sprint seems less suitable for this purpose.

---

**Physiological Different In Taiwan Youth Basketball Player In Different Levels**  
Yen Ting Lin. Asia University, Taichung, Taiwan.  
(No relationships reported)

**PURPOSE:** The purpose of this study was to investigate the physical and physiological different in Taiwan youth basketball player (college age) between different level (elite level: amateur team and college level: first division basketball player).

**METHODS:** 42 players (elites level: n=21, 23.4yr and college level: n= 21, 22.6yr) were involved in this study. The explosive power of the lower limbs was measured by counter movement jump and squat jump. The speed was measured by 20 m sprint. The 505 test was used to measure agility. The anaerobic power of the lower limbs was measured with a 5x6-second repeat-effort test. The maximal oxygen consumption was estimated by a 20-meter multistage shuttle run test. The data were analyzed by independent T-test and significant was accepted at  $p = .05$ .

**RESULTS:** The physiological significant different in basketball player between levels were found in (1) The explosive power of the lower limbs (elite level: CMJ power: 5739.12± 659.06 W, SJ power: 4585.64± 497.32 W; college level: CMJ power: 5241.33± 675.88W, SJ power: 4182.76± 602.15W), (2) agility ability (left foot: elite level: 2.36±0.12 sec; college level: 2.47±0.14 sec, right foot: elite level: 2.35±0.13 sec, college level: 2.47±0.14), and (3) anaerobic power of the lower limbs (elite level: total work: 267.25±43.56 J/kg, power decrement: 10.43± 4.8%; college level: total work: 233.15± 42.63 J/kg, power decrement: 17.35± 0.15%).

**CONCLUSIONS:** The physiological different between level were found in the explosive power and anaerobic power of lower limbs and the agility ability. As the result, the elite level demonstrated better explosive power, anaerobic power, lower power decrement, and better agility ability.

Key words: Leg explosive Power, Intermittent anaerobic power, Speed, Agility, cardiovascular endurance.

---

**1782** Board #190 MAY 30 3:30 PM - 5:00 PM  
**Bilateral Strength Assymetry During The Vertical Jump In Professional Soccer Goalkeepers**  
Frantisek Zahalka, Tomas Maly, Lucia Mala, Jaroslav Teplan. Charles University, FPES, Prague, Czech Republic.  
(No relationships reported)

Explosive strength of lower limbs is an important predisposition for specific locomotion of soccer goalkeepers. Powerful legs enable them to leap up and over their teammates and opponents to collect balls kicked into the goal area. For soccer goalkeepers, functional strength is more important than absolute strength.

**PURPOSE:** The aim of the study is to assess the level of explosive strength and asymmetry of biomechanical parameters during the bilateral jump (counter movement jump with free arms - CMJ<sub>FA</sub>) in professional goalkeepers.

**METHODS:** The monitored group was composed of elite soccer goalkeepers (n = 25, age = 26.5±9.1 years, body height = 186.1±7.8 cm, body weight = 86.7±14.8 kg). Strength indicators during CMJ<sub>FA</sub> were observed by means of force platform Kistler B8611A. For statistical processing, methods from descriptive statistics were used; a bilateral difference between parameters was assessed by dependent *t*-test and relation between the height of the jump and monitored parameters was determined by Pearson's correlation coefficient.

**RESULTS:** The jump height of players was 45.26±3.36 cm. Total bilateral force produced at take-off was 2260.6±353.8 N. Take-off force produced by the dominant leg (DL) was

significantly higher when compared to the non-dominant leg (ND) ( $F_{DL} = 1174.6 \pm 167.5$  N vs.  $F_{NL} = 1086.0 \pm 202.8$  N,  $t_{2d} = 3.86$ ,  $p < 0.01$ ). The mean difference in generated force was  $101.0 \pm 103.5$  N, which indicates high heterogeneity in the symmetry of jump implementation in the monitored group of professional players. The smallest difference was 4 N (0.4%) and the greatest 373 N (34.7%). The jump height did not correlate significantly with the size of the bilateral difference in force generated during the jump ( $r = -0.11$ ,  $p < 0.01$ ).

**CONCLUSIONS:** Results showed a lower jump height in our players compared to the values of elite players stated in literature. A significant difference between strength generated in DL and NL, as well as differences on the basis of inter-individual comparison, are the evidence of strength asymmetries in the jump implementation. However, jump height is not dependent on the symmetric implementation of both legs in terms of maximum strength production.

**Estimated Times to Exhaustion And Power Outputs At Four Fatigue Thresholds**

Haley C. Bergstrom<sup>1</sup>, Terry J. Housh, FACSM<sup>1</sup>, Jorge M. Zuniga<sup>2</sup>, Clayton L. Camic<sup>3</sup>, Daniel A. Traylor<sup>1</sup>, Glen O. Johnson, FACSM<sup>1</sup>, Richard J. Schmidt<sup>1</sup>.

<sup>1</sup>University of Nebraska-Lincoln, Lincoln, NE. <sup>2</sup>Western New Mexico University, Silver City, NM. <sup>3</sup>University of Wisconsin-Platteville, Platteville, WI.

(No relationships reported)

**PURPOSE:** The purposes of this study were to compare the power outputs and estimated times to exhaustion ( $T_{lim}$ ) at the gas exchange threshold (GET), physical working capacity at the rating of perceived exertion threshold ( $PWC_{RPE}$ ), critical power (CP), and respiratory compensation point (RCP).

**METHODS:** Three male and five female subjects (mean  $\pm$  SD: age  $22.4 \pm 2.8$  yr) performed an incremental test to exhaustion on an electronically braked cycle ergometer to determine (dot above)  $VO_2$  peak, GET, and RCP. The two-parameter, linear,  $W_{lim}$  versus time  $T_{lim}$  model was used to estimate CP from four rides to exhaustion at four separate power outputs. Ratings of perceived exertion (RPE) were recorded during the rides to exhaustion. The  $PWC_{RPE}$  was determined from the slope coefficients for the RPE versus time relationships calculated for three rides to exhaustion and plotted as a function of the corresponding power outputs to estimate the  $PWC_{RPE}$ . The estimated  $T_{lim}$  values for each subject at GET, CP,  $PWC_{RPE}$ , and RCP were determined from power curve analyses ( $T_{lim} = ax^b$ ).

**RESULTS:** The results indicated that GET (154 42 W) was significantly ( $p < 0.05$ ) less than RCP (181 54 W). There were no significant differences, however, among the CP (167 46 W),  $PWC_{RPE}$  (176 55 W) or RCP. The estimated  $T_{lim}$  for the GET (26.1 9.8 min) was significantly ( $p < 0.05$ ) greater than  $PWC_{RPE}$  (14.6 5.6 min) and RCP (11.2 3.1 min). The CP (16.0 1.6 min), however, was not significantly different from GET.

**CONCLUSION:** The results indicated that the  $PWC_{RPE}$  occurred at a mean power output that was 12.5% greater than the GET and, therefore, it is likely that the  $PWC_{RPE}$  occurred within the heavy exercise intensity domain. Furthermore, the RCP was 8% greater than CP and, therefore, these thresholds may be associated with different mechanisms of fatigue.

**1784 Board #192 MAY 30 3:30 PM - 5:00 PM**

**Ground Reaction Force Analysis of the Anterior and Crossover Single Leg Hop Tests**

Michael Nelson, Brent Sloss, Bryan L. Riemann. *Armstrong Atlantic State University, Savannah, GA.* (Sponsor: T. Jeff Chandler, FACSM)

(No relationships reported)

In contrast to the landing phase, less research has examined the propulsion phase of the single leg anterior (AHT) and cross over (COHT) hop tests. Additionally, there appears to be a void regarding objective support for using 15cm for the COHT.

**PURPOSE:** To compare propulsive vertical, anterior, and lateral ground reaction forces (GRF) between AHT and COHT.

**METHODS:** Thirty-eight healthy, Division I male basketball, football, baseball, and soccer athletes ( $88.3 \pm 12.3$  kg;  $183.9 \pm 6.0$  cm;  $20.6 \pm 1.4$  years) completed AHT and COHT in a counterbalanced order using their dominant limb. One week prior to data collection, participants completed a practice session of the two tests until performance (hop distance) plateaued. GRF data was collected during the propulsive phase of four trials for each test variation. The propulsive phase was defined as the interval between the end of counter-movement and ground off. Vertical, anterior and lateral peak force and impulse were computed. The composite impulse was computed as the sum of the vertical, anterior and lateral impulses. Acceptable trials were defined as being within  $\pm 5\%$  of the distances established during practice session. Paired t-tests were conducted to statistically compare respective dependent variables between the variations.

**RESULTS:** There was no significant difference in the distance hopped ( $P = .550$ ) or in the composite impulse ( $P = .348$ ) between the variations. In contrast to the lateral impulse being significantly greater for the COHT ( $P < .001$ ), there was no significant difference for either the vertical impulse ( $P = .890$ ) or the anterior impulse ( $P = .176$ ). Both the vertical ( $P < .001$ ) and anterior ( $P < .001$ ) peak forces were significantly greater for the AHT, whereas the lateral peak force ( $P = .045$ ) was significantly greater for the COHT.

**CONCLUSION:** Despite peak force and impulse differences, the total propulsive effort was equal between the two variations as evidenced by the hop distances and composite impulses. These data support the traditional use of 15cm crossover distance to stimulate greater lateral force production demands. Future research is recommended to consider different crossover distances as well as the impacts on ankle, knee and hip contributions.

**Critical Power and Body Composition during Preparation for a Bodybuilding Competition: A Case Study**

David H. Fukuda<sup>1</sup>, Lindy M. Rossow<sup>1</sup>, Jeremy P. Loenneke<sup>1</sup>, Christopher A. Fahs<sup>1</sup>, Kristina L. Kendall<sup>1</sup>, Abbie E. Smith<sup>2</sup>, Jordan R. Moon<sup>3</sup>, Jeffrey R. Stout<sup>1</sup>, Michael G. Bemben, FACSM<sup>1</sup>. <sup>1</sup>University of Oklahoma, Norman, OK. <sup>2</sup>University of North Carolina, Chapel Hill, NC. <sup>3</sup>United States Sports Academy, Daphne, AL.

(No relationships reported)

Critical power from an all-out cycling test reflects changes to physical training and may provide insight to the under-researched sport of natural bodybuilding.

**PURPOSE:** The purpose of this study was to examine the critical power and body composition adaptations during six months of preparation for a natural bodybuilding competition.

**METHODS:** The subject was a 27 year old bodybuilder (height=186 cm; weight=88.9-102.9 kg) who performed four days of resistance training and two to three days of aerobic training of varying intensity per week. At baseline (M0) and alternating months during the six months of contest preparation (M2, M4, and M6), critical power (CP) and anaerobic working capacity ( $W'$ ) were calculated from a three-minute all-out cycling test, and muscle mass (MM) and body fat percentage (Fat%) were determined from bioelectrical impedance spectroscopy. Change scores between each time point were compared to minimal difference values (MD=standard error of the measurement  $\times 1.96 \times \sqrt{2}$ ) from previous reliability measurements for CP (MD=26 watts;  $n=10$ ),  $W'$  (MD=3.8 kJ;  $n=10$ ), MM (MD=0.3 kg;  $n=11$ ), and Fat% (MD=2.5%;  $n=11$ ).

**RESULTS:** The change in CP exceeded MD between each time point with an increase between M0 and M2 (43 watts), and decreases from M2 to M4 (37 watts) and M4 to M6 (30 watts). The change in  $W'$  exceeded MD between each time point with decreases ranging from 4.2 to 5.9 kJ. Fat% and MM decreased throughout the event preparation and changes were greater than MD for each time point, ranging from 3 to 6% and 0.4 to 1.8 kg, respectively.

**Table 1**

| Time | Weight (kg) | CP (watts) | $W'$ (kJ) | MM (kg) | Fat% |
|------|-------------|------------|-----------|---------|------|
| M0   | 102.9       | 223        | 25.0      | 40.3    | 16.8 |
| M2   | 96.5        | 266        | 19.1      | 38.5    | 13.0 |
| M4   | 90.8        | 229        | 14.9      | 38.1    | 6.6  |
| M6   | 88.9        | 199        | 9.6       | 37.5    | 3.8  |

**CONCLUSION:** Preparatory training for a natural bodybuilding competition was associated with varying reductions in CP,  $W'$ , Fat%, and MM.

**1786 Board #194 MAY 30 2:00 PM - 3:30 PM****Asymmetrical Loading Affects Intersegmental Dynamics During The Swing Phase Of Walking**

Jeremy D. Smith<sup>1</sup>, Todd D. Royer<sup>2</sup>, Philip E. Martin, FACS<sup>3</sup>. <sup>1</sup>University of Northern Colorado, Greeley, CO. <sup>2</sup>University of Delaware, Newark, DE. <sup>3</sup>Iowa State University, Ames, IA.  
(No relationships reported)

Much of the research related to lower extremity inertia manipulations has focused on temporal, kinematic and traditional inverse dynamics assessments during locomotion. Intersegmental dynamics is an analytical technique that provides further insights into mechanisms underlying linked-segment motion.

**PURPOSE:** To determine how intersegmental dynamics during the swing phase of walking are altered during asymmetrical lower extremity loading.

**METHODS:** Seven male and five female young healthy adults (Age = 26 ± 6 yrs; Mass = 72.5 ± 10.6 kg; Height = 173.1 ± 6.2 cm), free of any notable gait or structural asymmetries, participated in the study. Participants walked overground at a speed of 1.57 m·s<sup>-1</sup> with 0, 0.5, 1.0, and 2.0 kg attached to one foot. A three segment lower extremity inverse dynamics model was used to determine net, interaction, gravitational, and muscle moments at the ankle, knee, and hip of each leg during each trial. Nine (3 moments x 3 joints) paired Hotellings T<sup>2</sup> tests (SAS 8.02, Cary, NC) were used to test whether asymmetrical lower extremity loading had an effect on the relative contributions of interaction, gravitational, and muscle moments to the absolute angular impulse at each joint.

**RESULTS:** Moment magnitudes at joints of the loaded leg increased systematically with increasing load, whereas unloaded leg moments were unaffected by loading. With increasing load, relative contributions of interaction moments about the knee and hip and gravitational moment about the ankle increased (i.e., 21%, 8%, and 44% increases, respectively for unloaded vs. 2.0 kg; all statistical comparisons had  $F > 65.0$ ,  $p < 0.001$ ), whereas the relative contributions of muscle moments about all three joints declined (i.e., -4%, -13%, and -8% decreases for the ankle, knee, and hip, respectively for unloaded vs. 2.0 kg; all statistical comparisons had  $F > 5.5$ ,  $p < 0.019$ ).

**CONCLUSION:** These results suggest that altered inertia properties of the limb not only affected the amount of muscular effort required to swing the leg, but also increased the influence of the interaction and gravitational moments on leg swing during walking.

---

**1787 Board #195 MAY 30 2:00 PM - 3:30 PM****Effect Of Stride Frequency On Metabolic Costs And RPE During Walking In Water**

Kenji Masumoto<sup>1</sup>, Yoshiko Nishizaki<sup>2</sup>, Ayako Hamada<sup>2</sup>. <sup>1</sup>Fukuoka Prefectural University, Tagawa, Japan. <sup>2</sup>Kyushu University, Kasuga, Japan.  
(No relationships reported)

Walking in water has been included in exercise and rehabilitation programs, however, no previous research has investigated the effect of stride frequency (SF) on metabolic costs and the rating of perceived exertion (RPE) during walking in water. Such information is important if gait mechanics in water is to be better understood.

**PURPOSE:** To investigate the effect of SF on metabolic costs and RPE during walking in water.

**METHODS:** Eleven male subjects (means ± SD: age = 23.8 ± 4.2 years, height = 175.7 ± 7.3 cm, body mass = 68.6 ± 7.0 kg) walked on a treadmill on dry land and on an underwater treadmill at their preferred stride frequency (PSF) and walked at an SF which was lower and higher than the PSF (i.e., PSF ± 5, 10, and 15 strides·min<sup>-1</sup>). Walking speed was kept constant at each subject's preferred walking speed in water and on dry land. Oxygen consumption (VO<sub>2</sub>), respiratory exchange ratio, heart rate, minute ventilation, RPE, PSF and preferred walking speeds were measured.

**RESULTS:** Metabolic costs and RPE were significantly higher when walking at low or high SF conditions than when walking at the PSF condition both in water and on dry land (e.g., 73% and 58% increases in VO<sub>2</sub> and RPE during walking in water at PSF+15 versus PSF conditions, respectively; both  $p < 0.001$ ). Additionally, the high SF condition produced significantly higher metabolic costs and RPE than the equivalent low SF condition during walking in water (e.g., 31% increase in VO<sub>2</sub> between PSF+15 versus PSF-15 conditions;  $p < 0.001$ ). Furthermore, metabolic costs (e.g., 12.3 ± 2.4 and 15.3 ± 2.2 ml·kg<sup>-1</sup>·min<sup>-1</sup> in VO<sub>2</sub> for water and dry land conditions, respectively;  $p < 0.05$ ), RPE (i.e., 7.2 ± 1.2 and 8.5 ± 1.4 for water and dry land conditions, respectively;  $p < 0.05$ ), PSF (i.e., 33.1 ± 2.6 and 60.0 ± 3.9 strides·min<sup>-1</sup> for water and dry land conditions, respectively;  $p < 0.001$ ), and the preferred walking speed (1.5 ± 0.3 and 4.7 ± 0.6 km·h<sup>-1</sup> for water and dry land conditions, respectively;  $p < 0.001$ ) were significantly lower in water than on dry land when walking at the PSF.

**CONCLUSION:** These observations suggest that a change in SF may influence metabolic costs and RPE during walking in water.

**1788 Board #196 MAY 30 2:00 PM - 3:30 PM****Influence Of Physical Activity History On Ground Reaction Force During Walking**

Henry Wang, Jeff Frame, Clark Dickin. Ball State University, Muncie, IN.  
(No relationships reported)

Military recruits are commonly afflicted by lower-extremity overuse injuries such as tibial stress fracture (TSF). In particular, recruits with low levels of fitness are at a higher risk. Thus, it is advisable to precondition recruits before basic training. Running and basketball are common exercises to improve physical condition. However, patterns of ground impact loading are different between running and playing basketball. Multi-directional loading in basketball may lead to bone adaptation and reduce the risk of TSF. As loaded walking, a major task in basic training exposes recruits to high ground impact forces leading to increased risk of injury, it is important to examine if and how physical activity history (PAH) of running or basketball influences ground impact forces during loaded walking.

**PURPOSE:** To determine differences in vertical ground reaction force (VGRF) and loading rate (VLR) during loaded walking between runners and basketball players.

**METHODS:** Forty recreational runners (n=20, 21±2 yr.) and basketball players (n=20, 21±2 yr.) participated in this study. Participants completed four walking tasks in the following order: walking with 0kg (W00), 15kg (W15), 25kg (W25), and 35kg (W35) loads. Each task was performed for 5 min on a force instrumented treadmill (AMTI) at 1.67 m/s. Peak VGRF and VLR at weight acceptance were normalized to body weight (BW). Two-way repeated measures ANOVAs were performed.  $\alpha = 0.05$ .

**RESULTS:** No statistical differences in VGRF and VLR were found between the two groups ( $P > 0.05$ ). Increasing load carried had a significant effect on VGRF and VLR ( $P < 0.001$ ). As load carried increased, linear increases of VGRF (1.29±0.06, 1.57±0.11, 1.77±0.22, and 1.99±0.19 BW for W00, W15, W25, and W35, respectively) and VLR (17.92±3.72, 22.51±5.02, 27.01±8.33, and 31.56±7.18 BW/s for W00, W15, W25, and W35, respectively) were observed ( $P < 0.001$ ).

**CONCLUSION:** The significant increases of mechanical loading and loading rate are proportional to the increment of load carried. Despite differences in activity loading patterns between runners and basketball players, there were no differences in mechanical loading. Future studies should examine aspects of how PAH influences mechanical responses of tibia during loaded walking to improve the understanding of TSF. US ARMY#W81XWH-08-1-0587

**1789 Board #197 MAY 30 2:00 PM - 3:30 PM****Metabolic Demands Of Split Belt Treadmill Walking**

Jaimie A. Roper, Ryan T. Roemmich, Lisa A. Zukowski, Mark D. Tillman, FACS<sup>M</sup>, Chris J. Hass, FACS<sup>M</sup>. University of Florida, Gainesville, FL.  
(No relationships reported)

Split belt treadmill walking (SBTW) is a novel intervention shown to improve gait asymmetry and locomotor function in neurologic populations. SBTW is thought to provide an advantage

over traditional treadmill walking (TW) due to its increased reliance on motor learning. To better understand the mechanisms underlying these improvements, it is important to determine whether or not the metabolic costs associated with SBTW are different than TW.

**PURPOSE:** Evaluate effects of SBTW on  $\text{VO}_2$ , heart rate (HR), and rating of perceived exertion (RPE, 16 point).

**METHODS:** Ten participants (age=22.2±1.6 yr; height=168.4±6.2 cm; weight=65.1±7.7 kg) were recruited. Participants were asked to select their fastest comfortable walking speed (fast speed, FS) on the treadmill. Fifty percent of the FS was used as the slow speed (SS). Participants walked for five minutes at both the FS and SS, and five minutes with the belt under the nondominant limb set to the FS and the dominant limb set to the SS (SBTW).  $\text{VO}_2$ , HR, and RPE obtained during the last 30 seconds of each condition were compared by treadmill condition (SS, FS, SBTW) using a one-way repeated measures ANOVA ( $\alpha=0.05$ ).

**RESULTS:** Gait speed and metabolic measures are reported in Table 1.  $\text{VO}_2$  and HR were significantly lower for SS compared to FS and SBTW ( $P=.001$ ,  $.002$ ;  $P<.001$ , respectively). RPE scores were significantly lower for SS compared to FS and SBTW ( $P=.003$ ,  $P=.001$ ).

**CONCLUSION:** SBTW and FS walking exhibit equivalent energy expenditures and RPE scores but differ from SS walking. These findings may indicate that improvements in gait mechanics measured by previous studies are likely due to asymmetric walking patterns used with SBTW rather than exercise intensity.

| Condition | Speed (m/s) | RPE    | $\text{VO}_2$ (ml/min/Kg) | HR       |
|-----------|-------------|--------|---------------------------|----------|
| SS        | 0.78 (.11)  | 7 (1)  | 7.67 (1.2)                | 98 (16)  |
| FS        | 1.56 (.22)  | 10 (2) | 13.54 (3.7)               | 121 (20) |
| SBTW      | 1.17 (.16)  | 9 (1)  | 11.23 (2.4)               | 115 (24) |

**1790 Board #198 MAY 30 2:00 PM - 3:30 PM**

**Does Backward Walking Enhance Gait or Balance Performance in Older Adults?**

Janet S. Dufek, FACSM<sup>1</sup>, Jennifer M. Aldridge<sup>2</sup>, John A. Mercer, FACSM<sup>1</sup>, Philana-Lee Gouws<sup>1</sup>. <sup>1</sup>University of Nevada, Las Vegas, Las Vegas, NV. <sup>2</sup>Brooke Army Medical Center, Fort Sam Houston, TX.

(No relationships reported)

With advancing age, falls are a major cause of morbidity and mortality.

**PURPOSE:** To investigate the effects of a backward walking intervention on selected gait and balance characteristics in older adults.

**METHODS:** Ten healthy young adults (G1; 21.9±2.1 yrs; 175±10.5 cm; 70.3±11.5 kg) and 10 healthy, non-faller older adults (G2; 69.8±7.7 yrs; 168±11.8 cm; 70.7±15.2 kg) performed self-selected speed forward and backward walking over a 10 m calibrated space during which time three-dimensional lower extremity kinematic parameters were measured with a 12-camera motion capture system (120Hz). Prior to the first walking trial, following the fifth trial and after the last (10<sup>th</sup>) walking trial, a series of static balance measures were completed. The balance tests consisted of four quiet stance conditions: 1) firm surface, eyes open, 2) firm surface, eyes closed, 3) soft surface, eyes open, and 4) soft surface, eyes closed. The intervention consisted of 10-15 min of backward walking, three days/wk, for four wks. Post-intervention testing (week four) replicated the pretest procedures while mid-intervention (week 2) testing evaluated balance only. Kinematic gait descriptors (stride length, cadence, walking velocity, range of motion) during forward walking were evaluated with correlated t-tests for G2. Balance scores and anterior-posterior sway range were assessed with a 2 (group) x 3 (time) mixed model ANOVA ( $\alpha=0.05$ ).

**RESULTS:** G2 exhibited significantly faster self-selected forward walking velocity post-intervention (1.10±0.17 vs 1.22±0.12 m/s;  $p=0.048$ ). Balance scores were significantly different between groups (G1: 90.4±2.0, G2: 85.5±5.13;  $p=0.005$ ) and across time (G1-Pre: 89.85±1.79, Mid: 90.8±2.0, Post: 90.4±2.3; G2-Pre: 83.4±5.9, Mid: 87.3±3.7, Post: 85.9±5.8;  $p=.012$ ) for the most challenging balance test. Anterior-posterior sway range (cm) was also significantly different between groups (0.97±0.10 vs 1.42±0.13  $p=0.014$ ) and across time (Pre: 1.04±0.15 vs 1.60±0.66; Mid: 0.91±0.20 vs 1.27±0.38; Post: 0.96±0.23 vs 1.37±0.58 for G1 vs G2 respectively;  $p=0.028$ ).

**CONCLUSION:** Older adults demonstrated improved balance and increased walking velocity after 2-4 weeks of backward walking. Consideration should be given to including backward walking as part of a regular exercise program for older adults.

**1791 Board #199 MAY 30 2:00 PM - 3:30 PM**

**Strength Asymmetry Increases Gait Asymmetry and Variability in Older Women**

Dain P. LaRoche<sup>1</sup>, Summer B. Cook<sup>1</sup>, Harold Greeley<sup>2</sup>, Krzysztof Mackala<sup>3</sup>, Timothy J. Quinn, FACSM<sup>1</sup>. <sup>1</sup>University of New Hampshire, Durham, NH. <sup>2</sup>Response Applications, LLC, Hanover, NH. <sup>3</sup>University School of Physical Education, Wroclaw, Poland.

(No relationships reported)

Poor lower-extremity strength and increased gait variability are strongly associated with fall risk in older adults but the relationship between these performance measures has not been well studied.

**PURPOSE:** To determine how bilateral knee extensor strength asymmetry influences gait asymmetry and variability in older women.

**METHODS:** Maximal torque of the knee extensors was measured via dynamometry in 24 older women (65 - 80 yr). Subjects were separated into symmetrical (SG, n = 13) and asymmetrical strength groups (AG, n = 11) based on a knee extensor strength asymmetry cutoff of 20%. Subjects walked at a standard speed of 0.8 m s<sup>-1</sup> and at a self-selected, maximal walking speed on an instrumented treadmill while spatial, temporal, and kinetic gait variables were measured. Gait and strength asymmetry were calculated as (Weak leg value - Strong leg value)/ Strong leg value x 100% and gait variability was computed as the coefficient of variation across ten sequential strides.

**RESULTS:** No difference in strength existed between SG and AG for the strong leg (1.55 ± 0.29 vs. 1.50 ± 0.38 Nm kg<sup>-1</sup>,  $P = 0.352$ ) but differences existed for the weak leg (1.36 ± 0.22 vs. 1.09 ± 0.29 Nm kg<sup>-1</sup>,  $P = 0.008$ ) resulting in greater strength asymmetry in AG (11.7 ± 5.4% vs. 27.4 ± 5.5%,  $P < 0.001$ ). Significant main effects for speed existed for the variability of weight acceptance force, push off force, foot strike location, and stride width such that the average variability of these measures increased from 5.0% at the standard speed to 7.3% at maximal speed ( $P < 0.01$ ). A group x speed interaction ( $P = 0.02$ ) occurred for weight acceptance force variability as the increase from standard to maximal speed was greater in AG (2.5 ± 0.6% to 5.0 ± 2.4%) than in SG (2.7 ± 1.3% to 3.7 ± 1.2%). A group x speed interaction ( $P = 0.017$ ) occurred for weight acceptance force asymmetry such that AG had greater increases in asymmetry at the maximal speed (2.2 ± 1.3% to 6.4 ± 5.3%) than SG (2.1 ± 1.7% to 2.5 ± 2.3%).

**CONCLUSION:** Spatial and kinetic gait variability and asymmetry are increased when older women walk near their maximal capacities and this increase is greatest in those with knee extensor strength asymmetry greater than 20%. The maintenance of strength symmetry may be an important tool in reducing gait variability and fall risk in older adults.

**1792 Board #200 MAY 30 2:00 PM - 3:30 PM**

**Women's Leg Stiffness Increases More than Men's During Fast Forced Cadence Load Carriage**

Shane G. Sauer, Joseph F. Seay, Peter N. Frykman. United States Army Research Institute of Environmental Medicine, Natick, MA.

(No relationships reported)

Forced cadence marching is a common activity in Army Basic Combat Training (BCT) and occurs over a wide range of prescribed cadences (106 - 120 steps/min) at speeds up to 1.7 m/s. During BCT, women suffer proportionally more lower extremity overuse injuries than men. It is possible that women adapt to training activities, like marching in step while carrying a load, differently than men. Increases in leg stiffness ( $K_{Leg}$ ) can be linked to increases in lower extremity overuse injuries. Differences of changes in  $K_{Leg}$  between marching cadences may be linked with higher rates of lower extremity overuse injuries in female BCT recruits.

**PURPOSE:** To evaluate relative changes to  $K_{Leg}$  between men and women while marching at different cadences and speeds.

**METHODS:** Ten volunteers (6M, 4F) with no military experience walked on a force sensing treadmill for 1 hour at 1.3 m/s and 1.7 m/s on separate days. They carried a 20kg load and marched at various cadences, including 106 and 120 steps/min for 10 min each. On each day, kinematic and kinetic data were recorded for 20s after the 5<sup>th</sup> min of both the 106 and 120 cadences.  $K_{Leg}$  was calculated as a ratio of the peak vertical ground reaction force to a kinematically determined change in leg length. A 2-way ANOVA evaluated differences between gender and cadence at each of the two speeds.

**RESULTS:** Men ( $253.0 \pm 172.4$  kN/m) had a significantly greater  $K_{Leg}$  than women ( $106.1 \pm 26.3$  kN/m) at the slower speed of 1.3 m/s, and  $K_{Leg}$  for both increased similarly with cadence. However, as cadence increased at the faster speed of 1.7 m/s the women experienced an increase in  $K_{Leg}$  ( $\Delta 41.9$  kN) ( $p = 0.026$ ) that was 3.5 times greater than the increase in men ( $\Delta 12.0$  kN).

**CONCLUSION:** As expected,  $K_{Leg}$  increased with rising cadence at each speed in both genders. However, a 3.5-fold greater relative increase was observed in women as compared to men. This may indicate that forced cadence load carriage at fast speeds and cadences is a contributing factor to the higher incidence of lower extremity injuries seen in female BCT recruits.

**1793** Board #201 MAY 30 2:00 PM - 3:30 PM

**The Effect Of Balance Exercise Therapy On Gait Parameters In Individuals With Chronic Stroke**

Tracy A. Dierks<sup>1</sup>, Peter A. Altenburger<sup>1</sup>, Kristine K. Miller<sup>2</sup>, Arlene A. Schmid<sup>2</sup>. <sup>1</sup>Indiana University, Indianapolis, IN. <sup>2</sup>Roudebush VA Medical Center, Indianapolis, IN. (Sponsor: Stuart J. Warden, FACSM)

(No relationships reported)

Balance and gait deficits frequently impact those with chronic stroke. While therapy often aims at improving balance and walking speed for independent community ambulation, improvements remain ambiguous, and little is known regarding the sustainability of such a gait speed once achieved.

**PURPOSE:** Investigate the effect of a balance exercise therapy program on balance and gait speed parameters in those with chronic stroke.

**METHODS:** This is an ongoing study with 29 subjects with chronic stroke to date. Subjects completed an 8-week group exercise program (1-hour twice a week) that incorporated components of yoga. Pre-intervention, balance was assessed with the Berg Balance Scale (BBS). Subjects completed a 10-meter walk, with a gaitmat positioned in the middle, and were instructed to walk at the fastest pace possible that felt safe. Lastly, subjects performed a 6-minute walk at their preferred pace while traversing a 30-meter walkway with the gaitmat positioned in the middle, allowing for multiple passes to measure change in gait parameters over the 6-minutes.

**RESULTS:** Post-program, subjects showed improved balance and faster gait speeds with longer steps/strides and less time in double support (Table 1). No changes were noted for base of support and unilateral stance variables. Over the 6-minute walk, both maximum and end gait velocities increased post-program, but subjects continued to show an inability to sustain a consistent speed compared to the end.

**CONCLUSION:** The intervention was successful at improving balance, which likely led to improved gait parameters and a faster functional gait speed. Further development and testing of a yoga based balance exercise program to address both bilateral and unilateral activities is warranted.

**1794** Board #202 MAY 30 2:00 PM - 3:30 PM

**Knee Joint Angular Adaptations Due To Asymmetric Load Carrying While Walking On A Treadmill**

Junsig Wang, Ryan T. Roemmich, Mark D. Tillman, FACSM. University of Florida, Gainesville, FL

(No relationships reported)

Bags (backpacks and single sling/messenger bags) have become a daily necessity for individuals of all ages. In particular, messenger bags seem to be increasing in popularity for young people. However, carrying single strap bags induces asymmetrical loading and could be harmful to the human body due to altered postures while walking.

**PURPOSE:** To evaluate gait kinematics and coordinative patterns for lower extremity joints during asymmetrical load carrying.

**METHODS:** Six university students ( $22.6 \pm 3.72$  yrs,  $172.6 \pm 7.5$  cm,  $69.2 \pm 8.2$  kg) walked on a treadmill under three different load conditions: (1) no bag, (2) carrying a messenger bag on one shoulder hanging vertically down to the hip, and (3) carrying a messenger bag on one shoulder draped across the trunk to opposite hip. All participants walked at their preferred pace for one minute in each condition. Kinematic data were acquired using a Vicon motion analysis system with 7 digital cameras (120Hz). Changes in hip, knee, and ankle joint angles across the gait cycle were assessed in frontal and sagittal planes via Cross Correlation Coefficients (CCC). Each gait cycle was divided into swing and stance phases.

**RESULTS:** CCC of knee, ankle, and hip joints in frontal and sagittal planes were high ( $0.954 \pm 0.061$ ) during the swing phase of the gait and slightly lower during stance ( $0.897 \pm 0.164$ ). Within the stance phase, the CCC values for hip and knee joint angles in the frontal plane appear to be altered. More specifically, CCC for the knee joint decreased 25% while carrying a single strap bag (2) compared to no bag (1) and decreased 7.8% under load condition (3) compared to no bag (1). Also, CCC for the hip joints in the frontal plane decreased 8% and 10% under load conditions (2) and (3) respectively compared to (1).

**CONCLUSIONS:** During the stance phase of walking on a treadmill while carrying an asymmetric load, the hip and knee joints follow different movement patterns when comparing right and left. Thus, the bilateral joint movements are less symmetrical. There was no effect on the ankle joints during the gait cycle. The frontal plane differences observed at the hip and knee may be indicative of an adaptive strategy (e.g. lateral bending) that could result in changes in joint forces and moments.

**1795** Board #203 MAY 30 2:00 PM - 3:30 PM

**Detecting Gait Kinematic Patterns associated with Knee Osteoarthritis using a Support Vector Machine Algorithm**

Kelsey H. Collins, Reginaldo K. Fukuchi, Blayne A. Hettinga, Reed Ferber. University of Calgary, Calgary, AB, Canada. (Sponsor: Louis Osternig, FACSM)

(No relationships reported)

Knee osteoarthritis (KOA) is a degenerative disease known to alter gait kinematics as compared with healthy individuals. It is necessary to understand which factors best describe the kinematic differences between healthy and KOA individuals to gain insight into KOA aetiology. To our knowledge, this research is the first to use a Support Vector Machine (SVM) and feature selection algorithm to objectively rank the most important kinematic variables when discriminating between KOA and control subjects.

**PURPOSE:** Determine which combination of variables best differentiate healthy and KOA subjects by using a SVM along with a feature selection algorithm and assess the ability to predict KOA subjects.

**METHODS:** 38 KOA subjects (27 F, 11 M age  $54 \pm 8$  yrs;  $169 \pm 11$  cm;  $73 \pm 12$  kg) and 30 healthy controls (21 F, 9 M age  $53 \pm 12$  yrs;  $168 \pm 10$  cm;  $69 \pm 13$  kg) were included. Kinematic data were collected using an 8-camera 3D motion capture system. Sixteen discrete kinematic gait variables were chosen to train the SVM algorithm. A 10-fold cross-validation was implemented to assess the SVM recognition rate

**RESULTS:** The overall classification accuracy rate achieved 66.2% when all input variables were considered. This rate improved to 75% when the first 5 selected variables, determined by the feature selection algorithm, were considered. The combination of variables that achieved the best recognition rate were: knee flexion at heel strike (KOA  $-6.1^\circ \pm 4.9^\circ$ , CON  $-3.6^\circ \pm 5.0^\circ$ ), peak knee adduction (KOA  $3.9^\circ \pm 5.6^\circ$ , CON  $1.8^\circ \pm 3.4^\circ$ ), knee abduction excursion (KOA  $3.7^\circ \pm 1.7^\circ$ , CON  $4.1^\circ \pm 1.4^\circ$ ), peak pelvic drop (KOA  $0.3^\circ \pm 3.6^\circ$ , CON  $-0.4^\circ \pm 3.9^\circ$ ), and peak knee abduction (KOA  $-0.5^\circ \pm 4.8^\circ$ , CON  $-2.7^\circ \pm 3.4^\circ$ ).

**CONCLUSIONS:** The SVM was able to classify KOA subjects accurately when using 5 selected variables combined. We expect that the classification accuracy would increase in future studies with more kinematic variables. This methodology identified important variables to consider in future KOA research.

**A Pilot Study: Acute Effects of Doxorubicin on Hind-limb Gait Kinematics in Rats**

John M. Yager, Jeremy D. Smith, Abigail L. Carpenter, Noah M. Gibson, David S. Hydock. *University of Northern Colorado, Greeley, CO.*  
(No relationships reported)

Doxorubicin (DOX) is an effective chemotherapy drug, but it also has detrimental effects on healthy tissues, such as skeletal muscle. For example, *in vivo* DOX treatment in the rat has been shown to decrease hind-limb muscle force production. DOX-induced lower extremity muscle dysfunction and is likely to alter the ability of the muscle to accelerate the limb during the recovery phase of locomotion, but this effect has yet to be determined.

**PURPOSE:** To determine the effects of DOX treatment on rat hind-limb gait mechanics, with specific focus on the acceleration of the limb and spatiotemporal characteristics of gait.

**METHODS:** Fifteen adult male Sprague-Dawley rats were randomly assigned and injected with saline, 10 mg/kg DOX, 12.5 mg/kg DOX, or 15 mg/kg DOX delivered as a bolus *i.p.* injection. Retro-reflective markers were positioned on the left hind-limb at the knee, ankle and foot. Sagittal plane video were collected while rats walked on a treadmill at 27 cm/sec prior to injection and 72 hours post-injection (or as many days as possible). Videos were digitized, and individual stride cycles were identified based on foot contact events. Custom written software was used to filter marker position data (cut-off = 5 Hz), compute ankle angles, and compute accelerations. Two MANOVAS with Helmert contrasts were used to determine effects of DOX on kinematic and spatiotemporal measures.

**RESULTS:** Spatiotemporal measures were not significantly altered by DOX injections ( $\Lambda^*=0.59$ ,  $F_{3,10}=2.31$ ,  $p=0.14$ ). However, DOX injections did affect limb accelerations ( $\Lambda^*=0.08$ ,  $F_{3,10}=6.96$ ,  $p=0.02$ ). Follow-up Helmert contrasts revealed decreased accelerations in ankle vertical motion (-13%,  $p=0.002$ ,  $ES=1.07$ ), foot horizontal motion (-5%,  $p=0.04$ ,  $ES=0.27$ ), and foot vertical motion (-14%,  $p=0.001$ ,  $ES=0.97$ ) for all dose groups compared to the saline group. However, dose magnitude had no effect beyond the baseline comparison ( $p > 0.25$  for all contrasts).

**CONCLUSION:** Regardless of cumulative DOX dosage, reductions in limb accelerations occurred during swing when compared to a saline treated group. These reduced limb accelerations were consistent with reductions in isolated muscle force production previously reported suggesting muscle dysfunction due to DOX treatments may transfer to activities of daily living.

**Effects of Walking Speed on Net Muscle Moments and Contact Forces at the Knee**

Derek J. Haight, Michelle M. Reynolds, Wayne J. Board, Trevor Connor, Melissa Nolte, Raymond C. Browning, FACSM. *Colorado State University, Fort Collins, CO.*  
(No relationships reported)

Lower extremity net muscle moments (NMM) are used as a proxy measure of joint loading, particularly at the knee. However, there is little information regarding the relationship between knee NMM and joint contact forces (JCF) across a range of walking speeds.

**PURPOSE:** To quantify the magnitudes and changes in NMM and JCF during slow and fast walking.

**METHODS:** We collected kinematic and kinetic data as ten subjects (mass = 63.5 (11.0) kg, mean (SD)) walked on a dual-belt force measuring treadmill at 0.75 m/s 1.50 m/s. An OpenSim three-dimensional musculoskeletal model with 23 degrees of freedom and 92 muscles was scaled to each subject. We used OpenSim to calculate NMMs and muscle forces via inverse dynamics and static optimization, respectively, for 5 gait cycles for each subject. We determined JCFs from the vector sum of the joint reaction force and individual muscle forces crossing the knee joint, reported in the tibial reference frame.

**RESULTS:** The peak extensor NMM at the knee increased ~140% from 0.30 (0.23) Nm/kg to 0.7 (0.21) Nm/kg and the peak flexor NMM increased ~50% from 0.38 (0.14) Nm/kg to 0.58 (0.07) Nm/kg as walking speed was increased from 0.75 m/s to 1.50 m/s, ( $p<.01$ , Figure 1a). Peak axial JCF increased ~15% from 3.65 (0.44) BW to 4.18 (0.54) BW at 0.75 m/s and 1.50 m/s respectively, ( $p<.01$ , Figure 1b).

**CONCLUSIONS:** While NMMs increased considerably with gait speed, the increase in axial knee joint force was modest, suggesting that slower walking speeds may not substantially reduce joint loading. These results also suggest that NMM may not be a good proxy measure of joint loading and that musculoskeletal models should be used to quantify joint loads.

1798 Board #206 MAY 30 2:00 PM - 3:30 PM

**Biomechanical Characteristics of Stairway Walking between Able-bodies and Those Wearing Lower Limb Prosthetics**

Yugang Li, Haozhe Ma. *Wuhan Institute of Physical Education, Wuhan, China.* (Sponsor: Yong Tai Wang, FACSM)  
(No relationships reported)

**PURPOSE:** This study was to compare the biomechanical characteristics of stairway walking between the able-bodies and those wearing lower limb prosthetics while negotiating the different stairway slopes.

**METHODS:** Six male able-bodies and six males who wearing lower limb prosthetics (one side) participated in this study. The participants were able to perform stairway walking using the rail with the stairways slopes of 15° and 30°. A three-dimensional motion analysis system was used to record the kinematics and the hand and foot pressure sensors were used to record the hand and foot reaction forces when the participants walked up stairs with the stairway slopes of 15° and 30°. Three trials of walking on each stairway slope were recorded and the trials were averaged. The selected biomechanical variables included the knee flexion angle, speed of the center of mass (COM), peak hand and foot reaction forces. The independent t-test was employed to determine the differences between the able-body group (ABG) and the lower limb prosthetic group (LLPG).

**RESULTS:** For the 15° stairway walking, the knee flexion angles were 73.5°±2.1 for the ABG and 77.7°±4.9 for the LLPG; and the speeds of COM were 0.9±0.05 m/s for the ABG and 0.75±0.17 m/s for the LLPG, respectively. For the 30° stairway walking, the knee flexion angles were 82.5°±3.7 for the ABG and 86.4°±5.3 for the LLPG; and the speeds of COM were 0.81±0.09 m/s for the ABG and 0.66 m/s±0.11 for the LLPG, respectively. For the 15° stairway walking, the hand peak reaction force (46.2%±0.9) of the body weight) in the LLPG is significantly greater ( $p < .05$ ) than that (22.9%±1.7) in the ABG. However, the foot reaction forces were 131%±2.5 for the LLPG and 136%±2.0 for the ABG ( $p > .05$ ). For the 30° stairway walking, the hand and foot reactions forces showed the patterns similar to the 15° stairway walking condition, but no significant difference was observed. During the knee extension phase, the ABG showed the area of center of pressure (COP) around the five toes and front foot, and the LLPG showed the area of the COP around the front and middle foot.

**CONCLUSIONS:** The lower limb prosthetics has a good substitute function for stairway walking. However, attention should be paid to the training of standing/swing phases of the prosthetic leg, and the stairway slopes may affect the stairway walking speed and stability.

1799 Board #207 MAY 30 2:00 PM - 3:30 PM

**Do Old Adults Modulate Walking Velocity Differently Than Young Adults?**

Paul DeVita, FACSM<sup>1</sup>, Alexis Sidiropoulos<sup>1</sup>, Patrick Rider<sup>1</sup>, Aubrey Taylor<sup>1</sup>, Tibor Hortobagyi, FACSM<sup>2</sup>. <sup>1</sup>East Carolina University, Greenville, NC. <sup>2</sup>University of Groningen, Groningen, Netherlands.  
(No relationships reported)

Young and old adults walk with stereotypical yet distinctly different lower extremity joint power patterns. Old vs. young adults use greater power at the proximal hip and lower power at the more distal knee and ankle when walking at the same velocity. We now ask, does this distal to proximal mechanical plasticity with age also govern the modulation of walking velocity in old vs. young adults? Hypothesis was: old adults have a stronger relationship between hip power and weaker relationships between knee and ankle powers with walking velocity compared to young adults.

**PURPOSE:** Identify the relationships among hip, knee and ankle joint powers and walking velocity in young and old adults.

**METHODS:** Walking velocities and lower limb joint powers were assessed for 20 trials of various velocities in each of 22 young (20 yrs) and 22 old (74 yrs) subjects. Velocities ranged from 0.62 to 2.71 m/s. Joint powers were regressed onto velocity for the both samples and for individual subjects within each sample (over trials).

**RESULTS:** All group maximum powers were moderately related to walking velocity. Group relationships with velocity were also similar at all joints ranging from  $R^2=0.445$  to  $0.608$ . Individual subjects had stronger relationships than group results; nearly all individual  $R^2$  values were higher than analogous group values. Hip power in old adults had the highest explained variance in both ages and all joints.

**CONCLUSIONS:** Individual subject analyses revealed a preference for velocity modulation through hip power adjustments in old but not young adults. Ankle and knee power-velocity relationships did not decrease in strength with age.

Regression analyses between walking velocity and maximum joint

**Multiscale Entropy Analysis of Gait Control in Health Subjects**

Kuo-Wei Tseng, Hung-Wen Cheng, Hui-mei Lin, Yu-Hua Tseng, *Taipei Physical Education College, Taipei City, Taiwan.*

(No relationships reported)

Traditional approaches to measuring the complexity of biological signals fail to account for the multiple time scales inherent in such time series. The multiscale entropy (MSE) method is notable to studying a wide variety of other physiologic and physical time series data.

**PURPOSE:** To analysis the multiscale entropy of stride interval time series for normal gait group and two unstable gait groups of eyes-closed and dizziness in health subjects.

**METHODS:** We apply the MSE method to the gait cycle interval time derived from acceleration. The accelerometer recordings strides interval time series of 15 health subjects (age:  $21.26 \pm 0.85$  yrs) who walked for 2000 strides at normal gait pattern (N), eyes-closed gait (E) and dizziness gait (D). The subjects performed normal gait with normal spontaneous walking, eyes-closed gait with closed eyes, and dizziness gait with 20 standing spins in each 200 strides.

**RESULTS:** The stride interval in D and E group are shorter than N group ( $520.33 \pm 86.72$ ,  $557.31 \pm 64.53$  vs.  $574.07 \pm 63.60$  ms,  $p < 0.05$ ). In all cases, D and E groups are assigned higher entropy values than N group at larger scales, such as scale factor 18 ( $0.96 \pm 0.08$ ,  $0.92 \pm 0.12$  vs.  $0.62 \pm 0.23$ ,  $p < 0.05$ ), scale factor 19 ( $1.11 \pm 0.07$ ,  $0.94 \pm 0.12$  vs.  $0.61 \pm 0.19$ ,  $p < 0.05$ ) and scale factor 20 ( $0.94 \pm 0.13$ ,  $0.88 \pm 0.09$  vs.  $0.61 \pm 0.13$ ,  $p < 0.05$ ). The results indicate that time series of D and E groups are more complex than N group. (Fig.1)

**CONCLUSION:** The motor control of human locomotor system during unstable walking is more complex than normal walking. The results obtained increasing complex is one of the strategies when the ambulation be disturbed.

**1801** Board #209 MAY 30 2:00 PM - 3:30 PM

**Sex Differences in the Stride Frequency of Walking while Carrying a Toddler Manikin**

Marcella J. Myers<sup>1</sup>, Alice A. Fasnacht<sup>1</sup>, Cara M. Wall-Scheffler<sup>2</sup>, <sup>1</sup>St. Catherine University, St. Paul, MN. <sup>2</sup>Seattle Pacific University, Seattle, WA. (Sponsor: Mark Blegen, FACSM)

(No relationships reported)

Despite the frequency and necessity of infant/toddler-carrying by parents and other caregivers, very little research has focused on the energetic and behavioral consequences of this activity in adults. In particular, sex differences in carrying behavior and biomechanics has been virtually ignored.

**PURPOSE:** Our specific goal was to determine whether women and men carrying a toddler-sized manikin on their hip or their shoulders choose different stride frequencies at a given speed when asked to walk around the perimeter of a gym at moderate to brisk walking speeds.

**METHODS:** To determine how child-carrying affects the free walking gait choices of adults as a function of sex and task, we calculated the walking speed of 6 females and 6 males as they walked around the perimeter of a gym while performing 6 tasks in a randomized order. Tasks consisted of all combinations of 3 loading conditions - carrying a 10kg toddler-proportioned manikin on the shoulders or hip, or a comparable mass around the waist - and 2 walking speed directives ("walk-all-day" or "brisk" walks). Stride frequency and walking speed were determined from videotape using a stopwatch. Speed was calculated from the time required to walk between two markers 3.7 meters apart, stride frequency was determined over 4 consecutive strides.

**RESULTS:** When speed directive was accounted for, females walked faster than males ( $p=0.001$ ), and this effect was only enhanced by including body mass in the regression model (i.e. body mass differences could not explain the sex difference in walking speed). At a given walking speed, females used higher stride frequencies than males ( $p < 0.001$ ) and stride frequency increased as the load position changed from belt, to shoulder, to hip ( $p=0.006$ ). Adding body mass to the model removed the sex effect.

**CONCLUSIONS:** Although the carrying task was a larger burden for the females due to their smaller body mass, females consistently chose faster walking speeds than males for a given speed directive, and higher stride frequencies for a given walking speed. Sex differences appeared to be the result of differences in body mass and the relative size of the toddler load. Supported by 3M Faculty/Student Collaborative Grant #212607 and the Endowed Professor in the Sciences at St. Catherine University, St. Paul, Minnesota.

**1802** Board #210 MAY 30 2:00 PM - 3:30 PM

**Effectiveness of a Novel Therapeutic Technique on Improving Gait Characteristics among Children with Cerebral Palsy**

Jeffrey R. McClellan, Janet S. Dufek, FACSM, Robbin Hickman, *University of Nevada, Las Vegas, Las Vegas, NV.*

(No relationships reported)

Large amplitude, high-intensity movement therapy has led to gait improvements in individuals with Parkinson's Disease. Children with Cerebral Palsy (CP) typically demonstrate gait characteristics such as scissoring of the legs during gait and toe walking, with greater unilateral dysfunction being common.

**PURPOSE:** Test the concept of adapting large amplitude, whole body movements, similar to those used in Lee Silverman Voice Training BIG® in order to improve gait characteristics among children with CP.

**METHODS:** After receiving institutionally approved informed consent from a parent and child assent, five children diagnosed with CP ( $7.0 \pm 1.0$  yrs;  $125.7 \pm 7.3$  cm;  $26.0 \pm 5.1$  kg) walked twice across an instrumented electronic walkway (CIR Systems, Inc.; 120hz) at a preferred speed, before and after a 15 minute intervention session focused on large amplitude, whole body movements. Foot pressure data were extracted and analyzed by right and left footfalls, for the heel, midfoot, and forefoot area of the foot. Two dependent variables, pressure-time ( $P^*t$ ) detailing the percent of total pressure distributed across time, and Area (A) detailing the percent of total foot area, in a given foot segment during stance were used to analyze the data. Data were compared pre-post intervention using a single-subject Model Statistic procedure ( $\alpha = 0.01$ ).

**RESULTS:** Results trended towards improvement, but were generally non-significant. S3 improved gait by walking with a more standard heel-toe gait pattern and significantly increased  $P^*t$  ( $0 \pm 0\%$  vs.  $3.4 \pm 2.3\%$ ) and A ( $0 \pm 0\%$  vs.  $13.6 \pm 7.1\%$ ) in the right foot heel segment. S5 improved gait by decreasing pressure from the right heel for  $P^*t$  ( $44.6 \pm 7.3\%$  vs.  $32.7 \pm 8.4\%$ ) and transitioning more to the midfoot as shown by an increase in A ( $27.6 \pm 1.7\%$  vs.  $30.2 \pm 2.0\%$ ) for this segment. Results for other subjects showed no significant results (S1) or displayed mixed results (S2, S4).

**CONCLUSION:** While results remain inconclusive the general effectiveness of large amplitude exercise appears to be strengthened. Future testing and comparison of children with CP to typically developing children is recommended, while continued exploration regarding the effectiveness of clinical doses of large-amplitude movement interventions for this population should be determined.

**1803 Board #211 MAY 30 3:30 PM - 5:00 PM****Exercise Training Response In Patients With Heart Failure Is Modulated By Adrb1 And Gnas Polymorphisms**

Alberto J. Alves<sup>1</sup>, Fernando Ribeiro<sup>1</sup>, Ehud Goldhammer<sup>2</sup>, Yelena Rivlin<sup>2</sup>, Uri Rosenschein<sup>2</sup>, João Luís Viana<sup>3</sup>, José Alberto Duarte<sup>1</sup>, Michael Sagiv<sup>4</sup>, José Oliveira<sup>1</sup>.  
<sup>1</sup>University of Porto, Faculty of Sport, Porto, Portugal. <sup>2</sup>Bnai-Zion Haifa Medical Center, Haifa, Israel. <sup>3</sup>Loughborough University, School of Sport, Exercise and Health Sciences, Loughborough, United Kingdom. <sup>4</sup>The Zinman College of Physical Education and Sport Sciences at the Wingate Institute, Netanya, Israel.  
(No relationships reported)

Beta1-adrenergic receptors (ADRB1) and Gs proteins (GNAS) play important roles in the regulation of cardiac function.

**PURPOSE:** the aim of the present study was to investigate whether ADRB1 Arg389Gly (rs1801253), GNAS -1211 G/A (rs6123837) and GNAS 2291 C/T (rs6026584) functional polymorphisms have an impact on diastolic function and exercise tolerance measured before and after exercise training in patients with heart failure.

**METHODS:** A total of 61 patients with heart failure completed a 6-month exercise-training program. Mitral inflow velocities (deceleration time of early mitral flow and E/A ratio) and exercise tolerance (METs) were assessed before and after exercise training. Polymorphisms were detected through restriction fragment length polymorphism analysis.

**RESULTS:** There were no associations between polymorphisms and E/A ratio measured before and after exercise training. In contrast, deceleration time at baseline was elevated in GNAS -1211GG and -1211AG genotype carriers compared to -1211A allele homozygotes (238.6 ± 40.3 vs. 239.9 ± 40.6 vs. 196.3 ± 51.0 ms, P<0.05). Exercise training attenuated deceleration time in -1211GG (from 238.6 ± 40.3 to 224.3 ± 21.8 ms, P<0.05) and -1211AG genotypes (from 239.9 ± 40.6 to 224.6 ± 22.2 ms, P<0.05) but not in -1211A allele homozygotes (from 196.3 ± 51.0 to 201.4 ± 30.4 ms, n.s.). There were no associations between polymorphisms and exercise tolerance measured before exercise training. On the other hand, ADRB1 389Gly homozygotes had a greater training-induced increase in exercise tolerance than 389Arg homozygotes (0.88 ± 0.80 vs. 0.33 ± 0.50 METs, P=0.04). However, these differences were no longer significant after being controlled for treatment with Metoprolol and Atenolol.

**CONCLUSIONS:** Our data show that the functional GNAS -1211 G/A polymorphism influences diastolic function measured before and after exercise training in heart failure patients. Furthermore, our data suggest that there is an association between the ADRB1 Arg389Gly polymorphism and the exercise training response in heart failure patients. However, this association seems to be attenuated by treatment with Metoprolol and Atenolol.

**1804 Board #212 MAY 30 3:30 PM - 5:00 PM****High LDL In A Young, Healthy, Canadian Population: A Valuable Target For Gene-stratified Interventions**

Angie Karlos, Elizabeth Gnatiuk, Dustin Hittel. *University of Calgary, Calgary, AB, Canada.*  
(No relationships reported)

Cardiovascular disease (CVD) is the leading cause of death and disability in the world. Historically, observations that siblings and children of those with CVD were more likely to develop the disease led to the conclusion that CVD is heritable. A recently published GWAS identified 95 loci associated with total cholesterol (TC), LDL, HDL and TG levels in over 100 000 individuals of European descent. Despite identifying a large number of SNP's associated with lipid traits, effect sizes were significantly lower than previously reported heritabilities. This has led to the hypothesis that a portion of this missing heritability is due to gene-age interactions. It is expected that studying a young, healthy sample will produce larger effect sizes due to the presence of fewer confounding variables.

**PURPOSE:** To determine the prevalence of abnormal LDL, TC, HDL and TC:HDL ratio levels in a young, healthy, Canadian university population to inform subsequent gene-stratified interventions.

**METHODS:** Subjects were recruited at the University of Calgary (UCalgary) using posters around campus, classroom information sessions and recruitment booths in high traffic areas. Inclusion criteria included being between 18 and 35 years-old, post-pubertal status and ability to provide informed consent. Dependent variables include, HDL, and TC measured via fasting blood draw, and LDL, calculated using the Friedewald method. The National Cholesterol Education Program, III Adult Education Panel criteria was used to identify abnormal cholesterol values.

**RESULTS:** Subjects from UCalgary have a mean age of 22.97 ± 4.04 years for females and 23.56 ± 3.89 years for males. Mean values for body fat, BMI, LDL, HDL and TC were within normal ranges. However, 25.8% of females and 28.3% of males had high LDL. Although very few subjects had below threshold levels of HDL, 22.6% of females and 40% of males had TC:HDL ratios >3.0.

**CONCLUSION:** A higher than expected proportion of subjects had above cutoff values of LDL and TC:HDL cholesterol ratios. Cholesterol is currently the primary focus for gene-stratified nutrition based interventions.

---

**1805 Board #213 MAY 30 3:30 PM - 5:00 PM****Candidate Gene Associations with the Blood Pressure Response to Aerobic Exercise Training: A Meta-Analysis**

Michael L. Bruneau, Jr., Tania B. Huedo-Medina, Blair T. Johnson, Kara A. Larson, Linda S. Pescatello, FACSM. *University of Connecticut, Storrs, CT.*  
(No relationships reported)

**PURPOSE:** Aerobic exercise (AE) lowers blood pressure (BP) 5-7 mmHg among those with hypertension, but there is considerable inter-individual variability in the BP response to AE. Genetic predispositions account for 40-65% of this variability; however, identifying genetic variants that associate with the BP response to AE is a challenge. We performed a meta-analysis to integrate the small number of studies that examined the influence of candidate genes on the BP response to AE training.

**METHODS:** Studies retrieved included an AE training intervention; human Caucasians; and BP before and after AE by genotype. Effect sizes were the standardized mean difference of post- vs. pre-exercise BP disaggregated for genotype adjusted for baseline BP differences. Analyses followed fixed-effects assumptions.

**RESULTS:** 11 studies qualified (N=3,218). AE interventions were performed at 63.1±16.5% (Mean±SD) maximum oxygen consumption 2.8±1.1 d/wk for 40 min/session for 15.8±10.6 wk. Participants were mostly men (N= 1,805, 56%) 48.8±13.0 yr with a body mass index of 27.3±3.2 kg/m<sup>2</sup> and BP of 136.0±15.7 / 82.6±10.7 mmHg. The effect of genotype on the BP response to AE was small, non-significant, and very heterogeneous for systolic BP (SBP) (d+ = 0.044 [95% CI = - 0.034 to 0.122], 1.67 mmHg, I<sup>2</sup>=81.51); and diastolic BP (DBP) (d+ = 0.016 [95% CI = - 0.062 to 0.0984], 0.55 mmHg, I<sup>2</sup>=71.35). To explain the large heterogeneity, we categorized genotype by BP regulatory pathway. The genotype effect for SBP was moderate for polymorphisms involved with energy metabolism [d+ = -0.422 (95% CI = - 0.127 to - 0.758, -1.60 mmHg)] and weak for those in the sympathetic nervous system [SNS, d+ = - 0.280 (95% CI = - 0.125 to -0.436, - 0.46 mmHg)]. The genotype effect for DBP was weak for polymorphisms in the renin-angiotensin system [RAS, d+ = - 0.119 (95% CI = - 0.227 to - 0.010, - 0.05 mmHg)] and SNS [d+ = - 0.237 (95% CI = -0.083 to - 0.391, - 0.016 mmHg)].

**CONCLUSIONS:** The overall effect of genetic predispositions on the BP response to AE training is small due to the large heterogeneity among trials. When polymorphisms are grouped by BP regulatory pathway, polymorphisms involved with energy metabolism and those in the SNS and RAS emerge as genetic variants more likely to be associated with the BP response to AE training that should be explored in future work.

**Cardiorespiratory Fitness Affects Polymorphism In FABP2 Ala54Thr-caused Increase In Arterial Stiffness And Blood Pressure**

Shumpei Fujie<sup>1</sup>, Motoyuki Iemitsu<sup>1</sup>, Haruka Murakami<sup>2</sup>, Kiyoshi Sanada<sup>1</sup>, Hiroshi Kawano<sup>3</sup>, Yuko Gando<sup>3</sup>, Ryoko Kawakami<sup>2</sup>, Motohiko Miyachi<sup>2</sup>. <sup>1</sup>*Ritsumeikan University, Kusatsu, Japan.* <sup>2</sup>*National Institute of Health and Nutrition, Tokyo, Japan.* <sup>3</sup>*Waseda University, Tokorozawa, Japan.* (Sponsor: Izumi Tabata, FACSM)  
(No relationships reported)

Fatty acid binding protein 2 (FABP2) Ala54Thr polymorphism is a candidate gene associated with the risk of cardiovascular disease. Recently, the ThrThr genotype of FABP2 polymorphism causes the decrease in systolic blood pressure compared with AlaAla and AlaThr genotypes. Habitual exercise brings higher cardiorespiratory fitness and results in the improvement of cardiovascular disease risk. However, the effect of cardiorespiratory fitness level and FABP2 Ala54Thr polymorphism on the risk of cardiovascular disease remains unclear.

**PURPOSE:** In the present study, a cross-sectional investigation of 843 Japanese men and women (18-70 years old) was performed to clarify the effects of cardiorespiratory fitness on the relationship between risk of cardiovascular disease and FABP2 Ala54Thr gene polymorphism.

**METHODS:** Carotid beta-stiffness, measured by ultrasound and tonometry, and brachial blood pressure, measured by oscillometry, were assessed as risks of arteriosclerosis and arteriosclerosis. We measured peak oxygen uptake (VO<sub>2</sub>peak) during an incremental cycle ergometer exercise test, and then the study subjects were divided into high-cardiorespiratory fitness (High-Fit) and low-cardiorespiratory fitness (Low-Fit) groups based on the median value of VO<sub>2</sub>peak in each sex and decade. FABP2 Ala54Thr polymorphism was determined by real-time PCR with Taqman probe.

**RESULTS:** There were no significant effect of FABP2 Ala54Thr polymorphism on carotid beta-stiffness and blood pressure. Carotid beta-stiffness, systolic blood pressure, and diastolic blood pressure in the Low-Fit subjects increased in AlaAla genotype individuals compared with AlaThr and ThrThr genotype of FABP2 Ala54Thr, however, had no effect on FABP2 polymorphisms in High-Fit subjects. Additionally, serum triglyceride and plasma glucose levels were lower and serum HDL cholesterol levels were higher in High-Fit subjects compared with in Low-Fit subjects, but there were no significant effect of FABP2 polymorphism.

**CONCLUSION:** These results suggest that the higher cardiorespiratory fitness may be associated with attenuated central arterial stiffness and blood pressure related to FABP2 Ala54Thr polymorphism, regardless of increase in conventional metabolic risk factors, such as hyperglycemia and dyslipidemia.

1807 Board #215 MAY 30 3:30 PM - 5:00 PM

**A Systematic A Priori Search for Candidate Genes Associated with the Exercise Blood Pressure Response**

Garrett I. Ash<sup>1</sup>, Amanda L. Augeri<sup>2</sup>, John D. Eicher<sup>3</sup>, Michael L. Bruneau, Jr.<sup>1</sup>, Linda S. Pescatello, FACSM<sup>1</sup>. <sup>1</sup>*University of Connecticut, Storrs, CT.* <sup>2</sup>*Hartford Hospital, Hartford, CT.* <sup>3</sup>*Yale University School of Medicine, New Haven, CT.*  
(No relationships reported)

Identifying genetic variants associated with the blood pressure (BP) response to exercise is hindered by lack of standard criteria for candidate gene selection, underpowered samples, and lack of conclusive whole genome studies.

**PURPOSE:** To develop a prioritized panel of candidate genetic variants that may have increased likelihood of associating with the BP response to exercise to be used in conjunction with genome wide association studies (GWAS).

**METHODS:** We searched for candidate genetic variants meeting preestablished criteria using PubMed and published systematic reviews. These preestablished criteria were: 1) associated with BP, exercise, and/or the response to antihypertensive medications in major BP regulatory pathways; 2) from GWAS of BP meeting preestablished statistical criteria for genome-wide significance; 3) associated with energy metabolism and/or body composition as obesity is a risk factor for hypertension; 4) associated with other established and emerging cardiovascular disease (CVD) risk factors that have been implicated in the etiology of hypertension; and 5) from GWAS of BP meeting nominal statistical significance after correction for multiple testing.

**RESULTS:** Meeting the inclusion criteria were: 1) 167 variants from 56 candidate genes within major BP regulatory pathways including the renal and renin angiotensin systems (114 variants, 32 genes), sympathetic nervous system (39 variants, 20 genes), and nitric oxide synthase pathway (14 variants, 4 genes); 2) 60 variants from GWAS meeting pre-established statistical criteria; 3) 68 variants on 25 candidate genes associated with energy metabolism and/or body composition; 4) 102 variants on 27 candidate genes associated with other CVD risk factors including lipids and lipoproteins (57 variants, 9 genes) and inflammatory, thrombotic, or haemostatic factors (45 variants, 18 genes); and 5) 129 variants from GWAS meeting nominal statistical significance after correction for multiple testing.

**CONCLUSIONS:** This prioritized panel of 526 genetic variants provides function and mapping information that can serve as a reference for future work investigating the genetic basis of the BP response to exercise.

1808 Board #216 MAY 30 3:30 PM - 5:00 PM

**Insulin Secretion-related SNPs Are Associated With Prevalent And Incident Diabetes In The Sos Bariatric Surgery Cases**

Tuomo Rankinen, FACSM<sup>1</sup>, Markku Peltonen<sup>2</sup>, Mark A. Sarzynski<sup>1</sup>, Lars Sjöström<sup>2</sup>, Claude Bouchard, FACSM<sup>1</sup>, Lena M. S. Carlsson<sup>2</sup>. <sup>1</sup>*Pennington Biomedical Research Center, Baton Rouge, LA.* <sup>2</sup>*Gothenburg University, Gothenburg, Sweden.*  
(No relationships reported)

Obesity is a major risk factor for type 2 diabetes mellitus (T2DM) and weight loss is an effective way to prevent the onset of T2DM or even reverse the disease process. Positive family history is a strong predictor of T2DM morbidity and recent genome-wide association studies (GWAS) have identified dozens of DNA sequence variants associated with T2DM.

**PURPOSE:** The purpose of our study was to investigate associations between GWAS-derived T2DM risk SNPs and 1) prevalent T2DM in obese subjects, and 2) incidence of T2DM in obese subjects treated with bariatric surgery.

**METHODS:** A total of 17 SNPs shown to be associated with T2DM in several GWAS reports were genotyped in 1835 obese (average BMI 42.5 kg/m<sup>2</sup> [SD 4.5]) subjects who underwent bariatric surgery in the Swedish Obese Subjects study. Ten of the SNPs have been reported to be related to insulin secretion (CAMK1D, CDKAL1, HHEX, HNF1B, IFGBP2, KCNJ11, SLC30A8, TCF7L2, THADA, WFS1) and three to insulin sensitivity (ADAMTS9, FTO, PPARG) while four (CDKN2A, JAZF1, NOTCH2, TSPAN8) do not yet have a clear functional assignment.

**RESULTS:** At baseline, 320 subjects had T2DM, while 1515 were T2DM-free. Among the latter, during a mean follow-up of 9.9 years, average maximum weight loss was 34.9 kg (28.7%) and 105 subjects developed T2DM. At baseline (pre-surgery), three of the 17 SNPs were associated with prevalent T2DM: TCF7L2 (OR 1.37 [95% CI 1.13-1.67], p=0.001), HNF1B (1.30 [1.02-1.90], p=0.003), and SLC30A8 (1.28 [1.06-1.56], p=0.011). Only one SNP (SLC30A8: 1.39 [1.02 - 1.90], p=0.04) was associated with T2DM incidence. A summary score capturing the number of risk alleles in 10 insulin secretion-related SNPs was associated with both T2DM prevalence (1.12 [1.05-1.09], p<0.0001) and incidence (1.08 [1.00 - 1.17], p=0.04), while a score reflecting insulin sensitivity-related markers was not associated with T2DM prevalence or incidence (P>0.7 for both).

**CONCLUSION:** Our results suggest that in obese individuals, insulin secretion-related SNPs are associated with prevalent T2DM as well as with T2DM incidence after bariatric surgery, while SNPs related to insulin sensitivity do not show similar associations.

---

1809 Board #217 MAY 30 3:30 PM - 5:00 PM

**The Effect Of Salbutamol On Cycling Performance Partitioned By The ADRB2 C79G SNP Genotype**

Sarah Koch, Martin J. MacLinnis, James L. Rupert, Benjamin C. Sporer, Michael S. Koehle. *University of British Columbia, Vancouver, BC, Canada.*  
(No relationships reported)

The C79G single nucleotide polymorphism (SNP) of the adrenergic  $\beta_2$ -receptor gene (*ADRB2*) is associated with the regulation of cardiorespiratory responses to the inhalation of salbutamol, including the regulation of bronchodilation, heart rate and ventilation. The GG genotype at the C79G SNP (rs 1042714, Glu<sup>27</sup>Gln) was associated with decreased airway response to inhaled  $\beta_2$ -agonists compared to the CC genotype in asthmatics.

**PURPOSE:** To determine the effect of genetic variation at the *ADRB2* C79G SNP on lung function and athletic performance in cyclists with and without exercise-induced bronchoconstriction (EIB) after the inhalation of salbutamol (SAL).

**METHODS:** The C79G SNP genotype (CC:  $n=14$ ; CG:  $n=19$ ; GG:  $n=7$ ; unidentified:  $n=2$ ) was determined in competitive 19 - 40 year old male cyclists with EIB (EIB+,  $n=10$ ) and without EIB (EIB-,  $n=32$ ). Athletes performed two 10-km time trials (TTs) on a cycle ergometer 60-min after the inhalation of either 400  $\mu\text{g}$  SAL or placebo. Forced expiratory volume in 1 second (FEV<sub>1</sub>) was assessed immediately before and 30-min after inhalation of SAL. Performance was measured by mean power output relative to body weight.

**RESULTS:** There was no association between the C79G SNP and EIB prevalence ( $p \geq 0.05$ ). The significant increase in FEV<sub>1</sub> after the inhalation of SAL ( $p \leq 0.001$ ) was independent of the genotypes at the C79G SNP: GG ( $M$  (SD) = 4.70 (2.51) %), CG (7.88 (8.23) %); and CC (5.94 (2.31) %); ( $p \geq 0.05$ ). The C79G SNP did not affect average power output after the inhalation of SAL: GG (4.1 (0.4)  $\text{W}\cdot\text{kg}^{-1}$ ), CG (3.9 (0.3)  $\text{W}\cdot\text{kg}^{-1}$ ) and CC (4.0 (0.2)  $\text{W}\cdot\text{kg}^{-1}$ );  $p \geq 0.05$ . Nevertheless, the C79G SNP was associated with the change in ventilation during the TT after SAL inhalation: Athletes with the CC genotype presented with an increased minute ventilation (1.82 (0.35)  $\text{L}\cdot\text{kg}^{-1}\text{min}^{-1}$ ) compared to placebo (1.64 (0.38)  $\text{L}\cdot\text{kg}^{-1}\text{min}^{-1}$ ;  $p = 0.03$ ), but athletes with the GG genotype maintained ventilation after the inhalation of SAL (1.82 (0.27)  $\text{L}\cdot\text{kg}^{-1}\text{min}^{-1}$ ), compared to placebo (1.83 (0.32)  $\text{L}\cdot\text{kg}^{-1}\text{min}^{-1}$ ).

**CONCLUSIONS:** In competitive male cyclists, FEV<sub>1</sub> is improved after the inhalation of 400  $\mu\text{g}$  SAL. Despite this improvement in lung function, mean power output during a 10-km TT was not altered regardless of the athletes' susceptibility to EIB and genetic variation at the *ADRB2* C79G SNP.

**1810 Board #218 MAY 30 3:30 PM - 5:00 PM**

**The Association Between An Indel Polymorphism In The Alp Gene And Athletic Performance**

Guilherme G. Artioli<sup>1</sup>, Nan Yang<sup>2</sup>, Peter J. Houweling<sup>2</sup>, Monkol Lek<sup>2</sup>, Fiona Zheng<sup>2</sup>, Antonio H. Lancha Jr<sup>1</sup>, Kathryn N. North<sup>2</sup>. <sup>1</sup>Laboratory of Applied Nutrition, Sao Paulo University, Sao Paulo, Brazil. <sup>2</sup>Institute for Neuroscience and Muscle Research, The Children's Hospital at Westmead, Sydney, Australia.

(No relationships reported)

the presence of alpha-actinin-3 in type-II fibres is known to affect skeletal muscle function and metabolism. The R-allele of the gene ACTN3 (polymorphism R577X) is associated with sprint/power performance, whilst the X-allele (alpha-actinin-3 absent) is associated with endurance performance. ALP is a muscle protein that interacts with alpha-actinins, possibly affecting its expression/function. The human ALP gene displays a large Indel polymorphism (~2.6 kb) whose function remains poorly understood. Here, we explored the possibility of this polymorphism being associated with athletic performance.

**PURPOSE:** to compare the frequency of the polymorphic allele (I-allele) of the gene ALP between two distinct cohorts (athletes vs. non-athletes).

**METHODS:** DNA from 307 Australian athletes and 160 Australian Caucasian controls were submitted to a PCR reaction designed to amplify a fragment of the ALP gene with (I-allele) and without the ~2.6 kb insertion (D-allele). Allele's frequencies were compared by means of the  $\chi^2$  test.

**RESULTS:** although no differences were found between athletes and controls, the I-allele was slightly more frequent in power/sprint athletes as compared to endurance and controls. The frequency of the I-allele was twice as high in specific sports (i.e., T&F and cycling) and three times lower in rowing when compared to the control group (Table 1).

**CONCLUSIONS:** the frequency of the I-allele may help to explain the success in specific sports, especially T&F, cycling and rowing.

| Allele frequencies among athletes and controls. |          |          |                |
|---|----------|----------|----------------|
|   | D-allele | I-allele | chi-square (p) |
| Controls (n=160)                                | 92%      | 8%       | -              |
| Power/sprint athletes (n=112)                   | 87%      | 13%      | 2.85 (0.06)    |
| Endurance athletes (n=195)                      | 91%      | 9%       | 0.14 (0.99)    |
| Specific sports T&F (n=65)                      | 83%      | 17%      | 6.06 (0.008)   |
| Cycling (n=84)                                  | 86%      | 14%      | 4.01 (0.027)   |
| Rowing (n=83)                                   | 97%      | 3%       | 4.48 (0.02)    |
| Swimming (n=59)                                 | 93%      | 6.8%     | 0.34 (0.58)    |

**Genome-wide Association Study On Physical Performance Among Children: Panic Study**

Antti Huuskonen, Tuomo Tompuri, Virpi Lindi, Mustafa Atalay, Timo Lakka. University of Eastern Finland, Kuopio, Finland.

(No relationships reported)

Low physical performance increases the risk of many chronic diseases and mortality. In past decades physical performance among children has decreased mainly due to sedentary lifestyle. However, genetic factors associated with physical performance in children are unclear. Genome-wide association studies (GWAS) provide an efficient strategy to investigate the associations of large numbers of common gene variants with many health-related phenotypes in large human data sets.

**PURPOSE:** To identify new gene variants associated with physical performance in children.

**METHODS:** We studied the associations of 194 729 single nucleotide polymorphisms (SNPs), analyzed by MetaboChip array, with maximal work load in Watts divided by lean body mass in kilograms ( $W_{\text{max}}/\text{LBM}$ , in  $\text{W}/\text{kg}$ ), assessed by bicycle ergometer exercise test, in a representative population sample of 512 Caucasian girls and boys 6-8 years of age. The genome-wide associations with  $W_{\text{max}}/\text{LBM}$  were analyzed with unadjusted dominant linear regression models. Altogether 17 SNPs with genome-wide significance ( $p < 9.99 \times 10^{-5}$ ) were further analyzed with multiple linear regression models adjusted for gender and age.

**RESULTS:** After adjustment for gender and age, 2 SNPs were associated with  $W_{\text{max}}/\text{LBM}$ . Rs212593 near *CBLN4* explained 1.2% of variance in  $W_{\text{max}}/\text{LBM}$  ( $p=0.008$  for linear regression model), and carriers of minor T allele had a 0.7  $\text{W}/\text{kg}$  higher  $W_{\text{max}}/\text{LBM}$  than major C allele homozygotes ( $p=0.006$  for difference between 2 genotype groups). There were no minor T allele homozygotes in the cohort. Rs11596811 near *PRKCQ* explained 0.6% of variance in  $W_{\text{max}}/\text{LBM}$  ( $p=0.042$  for linear regression model), and homozygotes for minor A allele had a 0.3  $\text{W}/\text{kg}$  lower  $W_{\text{max}}/\text{LBM}$  than heterozygotes and a 0.5  $\text{W}/\text{kg}$  lower  $W_{\text{max}}/\text{LBM}$  than major C allele homozygotes ( $p=0.162$  for difference across 3 genotypes).

**CONCLUSIONS:** These preliminary data suggest that SNPs near *CBLN4* and *PRKCQ* genes are associated with physical performance among children. These findings should be replicated in other populations.

1812 Board #220 MAY 30 3:30 PM - 5:00 PM

**Genetic And Environmental Influences On Longitudinal Changes In Physical Activity From Adolescence To Young Adulthood**

Sari Aaltonen<sup>1</sup>, Alfredo Ortega-Alonso<sup>2</sup>, Jaakko Kaprio<sup>3</sup>, Urho M. Kujala<sup>1</sup>. <sup>1</sup>University of Jyväskylä, Jyväskylä, Finland. <sup>2</sup>University of Helsinki, Helsinki, Finland. <sup>3</sup>University of Helsinki and National Institute for Health and Welfare, Helsinki, Finland.

(No relationships reported)

Leisure time physical activity (LTPA) habits are the results of a complex interplay of both genetic and environmental influences. Large epidemiological cross-sectional studies have evidenced that the heritability of physical activity behavior ranges between 30% and 70%. However, at present little is known about the factors mediating change in physical activity behavior across the critical periods of life.

**PURPOSE:** The aim of this study was to estimate genetic and environmental influences on the longitudinal evolution of LTPA habits from adolescence to young adulthood.

**METHODS:** The research is part of the FinnTwin16 Cohort study and the sample consisted of 4 915 monozygotic and dizygotic twins, born between the years 1975 and 1979. The LTPA volume was assessed as frequency of physical activity and participants were categorized in three groups: inactive, moderately active and active. Data was gathered at four time points; mean ages 16.1, 17.1, 18.6 and 24.4. Genetic and environmental influences on change in LTPA were estimated using linear growth modeling with a multiple threshold approach and sex-limitation effects. Analyses were developed in R-CRAN software utilizing the OpenMX package.

**RESULTS:** For both boys and girls the heritability of LTPA remained moderate (25%–40%) during the 8-year follow-up. The main results suggested important sex-differences in the estimates for additive genetic (A), common environmental (C), and specific environmental (E) influences on this behavior. The overall level of LTPA during the follow-up was moderately accounted for by A in boys (A=36.6%, C=56.2%, E=7.2%), while the corresponding percentage was lower in girls (A=17.3%, C=77.3%, E=5.4%). More noticeably, longitudinal changes in LTPA were largely accounted for by C in boys (A=1.0%, C=96.5%, E=2.4%) and by A in girls (A=62.5%, C=17.5%, E=20.0%).

**CONCLUSIONS:** The study evidenced relevant sex-differences in genetic and environmental influences in the evolution of LTPA habits from adolescence to young adulthood. Environmental factors showed critical to explain longitudinal changes in LTPA in boys, while girls' variations were mostly accounted for by additive genetic influences. These outcomes emphasize the need of specific actions to each sex in order to promote physical activity habits during this period of life.

1813 Board #221 MAY 30 3:30 PM - 5:00 PM

**Effects Of Cag Repeat Polymorphism In The Androgen Receptor Gene On Fitness In Children.**

Lorena Rodríguez-García, Jesús G. Ponce-González, Amelia Guadalupe-Grau, Jose Losa-Reyna, Francisco Germán Rodríguez-González, Cecilia Dorado, Bonifacio Nicolás Díaz-Chico, José A. L Calbet. UNIVERSIDAD DE LAS PALMAS DE GRAN CANARIA, LAS PALMAS, Spain.

(No relationships reported)

Androgen receptor (AR) CAG<sub>n</sub> (polyglutamine) repeat polymorphism determines part of the androgenic effect and may influence body composition and physical performance.

**PURPOSE:** To determine if androgen receptor polymorphism (CAG<sub>n</sub>) may influence body composition and the physical fitness in children.

**METHODS:** The association between body fat mass and physical fitness with the AR CAG<sub>n</sub> polymorphism was studied in 250 physically active children, 145 boys and 105 girls (mean±SD: 11.7±2.6 and 10.2±3.4 years old, respectively). The vertical jumping height (and power), running speed, and VO<sub>2</sub>max was determined in all subjects. CAG repeat number was determined by PCR and fragment analysis, and confirmed by DNA sequencing of selected samples. Boys were grouped as CAG short (CAG<sub>S</sub>) if harboring repeat lengths ≤21, the rest as CAG long (CAG<sub>L</sub>). The corresponding cut-off CAG number for girls was 22.

**RESULTS:** The boys harboring CAG<sub>S</sub> achieved better running performance in the 300 m running test than their CAG<sub>L</sub> counterparts (71.0±12.3 vs 74.2±13.0, respectively; P=0.018). This difference remained statistically significant after accounting for height and age covariates. No statistically significant differences between CAG<sub>S</sub> and CAG<sub>L</sub> groups were found either in boys or in girls for the rest of the physical fitness variables.

**CONCLUSION:** Androgen receptor (AR) CAG<sub>n</sub> (polyglutamine) repeat polymorphism has if any little influence on children physical fitness. However, a short CAG repeat number may favor performance in the 300 m running speed test in boys.

**Androgen Receptor Gene Polymorphisms Fat Mass Accumulation, And Maximal Fat Oxidation Capacity. A Longitudinal Study**

Jesús G. Ponce-González<sup>1</sup>, Amelia Guadalupe-Grau<sup>1</sup>, Francisco G. Rodríguez-González<sup>1</sup>, Cecilia Dorado<sup>1</sup>, Rafael S. de Torres-Peralta<sup>1</sup>, David Morales-Alamo<sup>1</sup>, Lorena Rodríguez-García<sup>2</sup>, Bonifacio N. Díaz-Chico<sup>1</sup>, José A. L Calbet<sup>1</sup>. <sup>1</sup>University of Las Palmas De Gran Canaria, Las Palmas De Gran Canaria, Spain.

<sup>2</sup>University of Las Palmas De Gran Canaria, Las Palmas De Gran Canaria, Spain.

(No relationships reported)

Androgens play an important role in the regulation of lipolysis and fat tissue mass. The cellular sensitivity to androgens varies depending on polymorphic variations of androgen receptors (AR).

**PURPOSE:** The aim of this longitudinal study was to evaluate if extreme CAG and GGN repeat polymorphisms of the AR may influence body fat mass, its regional distribution, fat accumulation, basal metabolic rate, and basal and maximal fat oxidation (MFO), maximal oxygen uptake (VO<sub>2</sub>max), as well as the serum concentration of hormones implicated in the regulation of fat mass like leptin, testosterone and osteocalcin.

**METHODS:** CAG and GGN repeats length were measured in 319 young and physically active men (mean ± SD: 28.3 ± 7.6 years old). From these we selected the subjects with short (CAG<sub>S</sub>; ≤ 19) and long (CAG<sub>L</sub>; ≥ 24) CAG repeats, and the subjects with short (GGN<sub>S</sub>; ≤ 22) and long (GGN<sub>L</sub>; ≥ 25) GGN repeats, using the median CAG and GGN value as a cut off value.

**RESULTS:** CAG repeat polymorphism was not associated to fat mass. CAG<sub>S</sub> and CAG<sub>L</sub> subjects had similar basal metabolic rate and maximal fat oxidation capacity and accumulated comparable amounts of fat tissue over 6.4 ± 1.0 years of follow up. Men with GGN<sub>S</sub> ≤ 22 had greater whole body and trunk fat mass than men with GGN<sub>L</sub> ≥ 25. This concurs with a trend for a greater maximal fat oxidation capacity in the GGN<sub>L</sub> group (P=0.06), who accumulated less fat mass, particularly in the trunk region seven years later. In the whole group of subjects the VO<sub>2</sub>max (per kg of lower extremity lean mass) explained 53% of the variance in MFO, whilst age explained an additional 5%.

**CONCLUSION:** The CAG repeat polymorphism has little, if any, influence in fat mass deposition in young adults whilst a long GGN polymorphic variant may protect from fat mass accumulation.

This study was supported by Ministerio de Educación y Ciencia (DEP2006-56076-C06-04/ACTI) and FEDER, Gobierno de Canarias (PI2005/177), Proyecto Interreg IIB BIOPOLIS, Fundación del Instituto Canario de Investigación del Cáncer (FICIC), Cabildo de Gran Canaria, Cabildo de Tenerife and La Caja de Canarias, and Proyecto Estructurante "Integración de los grupos de investigación en Ciencias de la Salud", ULPGC, Gobierno de Canarias.

(No relationships reported)

The  $\alpha$ -actinin-3 (ACTN3) and angiotensin-converting enzyme (ACE) genes have been the subject of considerable investigation in terms of associating with sporting performance with conflicting results reported in ethnically diverse groups.

**PURPOSE:** To investigate whether ACTN3 R577X and ACE I/D polymorphisms are associated with elite Japanese track and field athlete status.

**METHODS:** 257 elite Japanese track and field athletes (93 sprint/power athletes: SPA [sprinters, jumpers and throwers]; 164 middle-power/endurance athletes: MEA [middle- and long-distance runners]) and 649 Japanese population controls (CON) were genotyped for ACTN3 R577X and ACE I/D polymorphisms using TaqMan Genotyping Assay, and allele and genotype frequencies were compared between groups using a Chi-square test. All athletes were national or international level, and the group included medalists at the Olympic games.

**RESULTS:** For ACTN3 R577X polymorphism, the frequency of the R allele was significantly higher in SPA than in CON (0.55 vs. 0.47,  $P=0.032$ ); there was no significant difference between MEA and CON (0.49 vs. 0.47,  $P=0.438$ ) and between EMA and SPA (0.55 vs. 0.49,  $P=0.191$ ). When the three genetic models were tested, SPA showed a higher frequency of RR+RX genotype than CON (80/93 [86.0%] vs. 478/649 [73.7%],  $P=0.010$  under the R dominant model). There was also a significant difference between SPA and CON when using the additive genetic model ( $P=0.025$ ). Further subgroup analysis dividing the SPA into sprinters ( $n=61$ ) and field athletes ( $n=32$ ) revealed a higher RR+RX genotype frequency in sprinters than in CON (56/61 [91.8%] vs. 478/649 [73.7%],  $P=0.002$  under the R dominant model) and than in EMA (56/61 [91.8%] vs. 125/164 [76.3%],  $P=0.009$  under the R dominant model). No association was found for ACE I/D polymorphism in elite Japanese track and field athletes.

**CONCLUSIONS:** The ACTN3 R577X polymorphism-and not the ACE I/D polymorphism-was associated with elite Japanese track and field athlete status and only in sprint/power performance (not endurance).

1816 Board #224 MAY 30 3:30 PM - 5:00 PM

**Genome-Wide Association Study In Elite Japanese Track And Field Athletes**

Noriyuki Fuku<sup>1</sup>, Eri Mikami<sup>2</sup>, Takashi Kawahara<sup>3</sup>, Hideyuki Takahashi<sup>3</sup>, Nao Ohiwa<sup>3</sup>, Hiroaki Tanaka<sup>4</sup>, Yannis P. Pitsiladis, FACSM<sup>5</sup>, Masashi Tanaka<sup>1</sup>. <sup>1</sup>Tokyo Metropolitan Institute of Gerontology, Tokyo, Japan. <sup>2</sup>Waseda University, Saitama, Japan. <sup>3</sup>Japan Institute of Sports Sciences, Tokyo, Japan. <sup>4</sup>Fukuoka University, Tokyo, Japan. <sup>5</sup>University of Glasgow, Glasgow, United Kingdom.

(No relationships reported)

Although an ever increasing number of genes, both the nuclear and mitochondrial genomes, have been suggested to effect performance and health-related fitness, there is very little replication of this evidence linking the putative performance genes with sporting performance.

**PURPOSE:** To identify genetic polymorphisms that associate with elite Japanese sprint/power or endurance athlete status by use of the genome-wide association study (GWAS) approach.

**METHODS:** A GWAS was performed in 48 elite sprint/power athletes and 48 elite endurance athletes (representing Japan in Olympic Games, World and Asian Championships and including several medalists) by use of Illumina HumanOmniExpress BeadChip Arrays. Frequencies of each polymorphism between sprint/power and endurance athletes were compared using Chi-square tests by use of JMP Genomics version 4.

**RESULTS:** Among 730,525 genetic polymorphisms analyzed by GWAS, 5 allele frequencies differed significantly ( $p$  value  $< 1.0 \times 10^{-5}$ ) between sprint/power and endurance athletes. These polymorphisms are located in gene loci, which are related to cell differentiation, cell proliferation, cell adhesion and blood coagulation.

**CONCLUSION:** Despite the relatively small sample size in terms of GWAS, 5 genetic polymorphisms were associated with elite athlete status. Further studies are necessary to replicate these findings.

1817 Board #225 MAY 30 3:30 PM - 5:00 PM

**Predictive power of a Genetic Predisposition Score For Knee Strength Responses to Training in Seniors**

Martine A.I. Thomis, Sabine Verschuere, Christophe Delecluse. *Faculty of Kinesiology and Rehabilitation Sciences, Leuven, Belgium.*

(No relationships reported)

Genetic profiling efforts have been applied to predict elite athlete status, however, prediction of training responses in older individuals are lacking. **PURPOSE:** To test the predictive value of a genetic predisposition score (GPS) for the response in isometric knee extension strength in older subjects after an 11 month intervention program.

**METHODS:** 22 variants in 12 genes (CNTF/R, GR, IL6, IL15RA, VDR, ACTN3, IGF2, PPP3R1, GDF8, COL1A1, MYLK), previously associated with muscle mass/strength phenotypes were analyzed in an 'increasing allele' approach. Subjects were randomized over three intervention programs: a supervised aerobic/strength/balance training (FIT, 5 x/2 weeks), a whole body vibration training (WBV, 5 x/2 weeks) or a home-based life time intervention program (LIFE). Regression analysis tested the significance for GPS, with age, gender, height, weight, exercise type and baseline strength as covariates. Genotyping data ( $>20$  variants), baseline and post-training isometric knee extension force (Biodex) were available in 68 male and 74 female seniors (66.5 $\pm$ 4.3 yr).

**RESULTS:** Baseline knee strength was equal in all groups. Responses to training were higher in the FIT and WBV group compared to LIFE ( $P=0.01$ ), whereas all groups showed large individual variability. The GPS did significantly contribute to response variability in knee strength ( $r^2=8.0\%$ ,  $P=0.02$  in multiple regression model). Each additional increasing allele increased the response in knee strength by 0.9%, while age, LIFE and baseline strength were negative predictors.

**CONCLUSIONS:** A 22 variant GPS could only partially explain knee strength responses after training in seniors, with about 1% increase in strength response per additional increasing allele.

1818 Board #226 MAY 30 3:30 PM - 5:00 PM

**Trhr Single Nucleotide Polymorphisms And Sarcopenia**

Ricardo J. Oliveira<sup>1</sup>, Claudia C. Lunardi<sup>1</sup>, Ana Bárbara M. Siqueira<sup>2</sup>, Tailce K.M. Leite<sup>3</sup>, Rinaldo W. Pereira<sup>3</sup>, Ricardo Moreno Lima<sup>1</sup>. <sup>1</sup>Universidade de Brasilia, Brasilia, Brazil. <sup>2</sup>Universidade Católica de Brasilia, Brasilia, Brazil. <sup>3</sup>Universidade Católica de Brasilia, Brasilia, Brazil.

(No relationships reported)

Sarcopenia is described as a substantial loss of skeletal muscle mass and is related to important changes in body composition and related functions. Its etiology is not fully known, however, there is controversy in the literature regarding the contribution of genetic variability in fat-free mass.

**PURPOSE:** This study aims to examine the association of single nucleotide polymorphisms TRHR (Thyrotropin-releasing Hormone Receptor) and sarcopenia.

**METHODS:** Blood samples and total fat-free mass (TFFM) were collected of 241 elderly in the Federal District - Brazil. Were selected for this study the SNPs rs16892496 (alleles G and T) and rs7832552 (alleles A and G). Were classified as sarcopenia the elderly women who had values of relative TFFM (TFFM/ body weight) below 5.45 kg/m<sup>2</sup>.

**RESULTS:** The sample showed the following average values for age, body mass, height, years of menopause, fat-free mass: 66.65  $\pm$  5.5 years, 65.81  $\pm$  11.9 kg, 1.53  $\pm$  0.1 cm, 17.96  $\pm$  7.5 years, 37.95  $\pm$  4.9 kg, respectively. The prevalence of sarcopenia was 17.4%. There was no significant association ( $p > 0.05$ ) between the SNPs and the values of TFFM relative and sarcopenia.

**CONCLUSIONS:** Although current studies have found significant association between the TRHR's polymorphisms and phenotype of sarcopenia, this study found no association. Thus, we can conclude that in our sample, the SNPs rs16892496 and rs7832552 were not associated with sarcopenia.

**Total Weightings Genotype Score predicting Explosive Leg Strength among Elite Italian Soccer Players.**

Myosotis Massidda, Carla M. Calò. *University of Cagliari, Cagliari, Italy.*  
(No relationships reported)

Some authors have quantified an “optimal” polygenic profile by means of an algorithm resulting from the best accumulation of the polymorphisms candidate to explain individual variations in sport performance.

**PURPOSE:** Constructing a new model aimed to quantify the weightings attributable to genotypes in explaining the individual variations of explosive leg strength among elite soccer players.

**METHODS:** Using the model originally developed by Williams and Folland (2008) we determined the “Total Genotype Score” (TGS, from the accumulated combination of ACE, ACTN-3, BDKRB2, VDR-ApaI, VDR-BsmI genes, associated with muscle performance) in a groups of 84 top-level soccer players and 102 sedentary healthy males (controls). Successively, we determined the “Total Weighting Genotype Score” (TWGS) computed on the basis of the proportion of the variance of muscle strength significantly predicted by the accumulated combined genotypes. Forward stepwise multiple regression models were used to explore the predictive role of each genotypic variables for muscle phenotypes, measured by means of Squat Jump (SJ) and Counter Movement Jump (CMJ). Finally, correlation between TWGS and explosive leg strength was tested by means of linear regression analysis.

**RESULTS:** There were no significant differences ( $F=0.076$ ,  $p=0.782$ ) in the TGS between athletes and controls. The soccer players with higher TGS score have performed a significantly better performance in SJ ( $R^2=.0902$ ,  $F=6.550$ ,  $p=0.012$ ). The number of polymorphisms which significantly enter in the regression equation were only three (ACTN-3, ACE and BDKRB2) for both tests. Among all polymorphisms, the ACTN-3 was the most important. Finally, the soccer players with higher TWGS have performed a better performance in both SJ ( $R^2=.1546$ ,  $F=12.075$ ,  $p<0.001$ ) and CMJ ( $R^2=.1012$ ,  $F=7.438$ ,  $p<0.001$ ) tests.

**CONCLUSIONS:** Our results showed that giving the respective weighting to each predictor genotypes and by means of the new TWGS model, it could identified a polygenic profile that allows, at least partly, to predict the levels of explosive muscle strength in professional soccer players. Nevertheless, other genetic variants that we did not include in our model could also contribute to better explain the individual variations for attaining a high level of explosive strength in soccer.

**1820** Board #228 **MAY 30 3:30 PM - 5:00 PM**  
**Ghrelin Precursor Gene Variants and Fluid Intake in 10-km Runners**

Miguel A. Rivera<sup>1</sup>, Juan L. Martinez-Barreda<sup>2</sup>, Thomas D. Fahey<sup>3</sup>. <sup>1</sup>*University of Puerto Rico, San Juan, Puerto Rico.* <sup>2</sup>*Hospital Civil de Culiacan, Culiacan, Mexico.* <sup>3</sup>*California State University, Chico, CA.*  
(No relationships reported)

**PURPOSE:** We examined the association between three single-nucleotide polymorphisms (SNPs) within the ghrelin precursor gene (GHRL) and fluid intake in 10-km runners.

**METHODS:** The subjects ( $n=91$ ) were apparently healthy biologically unrelated Hispanic male recreational long distance runners (Age =  $26 \pm 3$  yr; Ht =  $170 \pm 11$  cm; Wt =  $61.5$  kg; mean  $\pm$  SD). Data were collected before and after an international 10-km road race. For each subject a “race number labeled” 500 mL water bottle was available at the 3<sup>rd</sup>, 5<sup>th</sup>, 7<sup>th</sup> and 9<sup>th</sup> km. Fluid intake was calculated by measuring the weight of bottles before and after fluid ingestion. Three SNPs were genotyped: rs35684 (A/G: a transition substitution in exon 1), rs2075356 (C/T: intron), and rs26311 (A/G: near the 3' untranslated region) of GHRL were genotyped.

**RESULTS:** All SNPs were in Hardy-Weinberg equilibrium ( $X^2$ ,  $P \geq 0.05$ ). Carriers of the rs26311 A allele had a significantly greater fluid intake ( $1.4 \pm 1.8$  L) than non-carriers ( $0.5 \pm 1.1$  L) ( $P < 0.05$ ).

**CONCLUSIONS:** The present study provide some support to the hypothesis of association between a genetic variation in the ghrelin precursor gene (GHRL) and fluid intake in long distance runners.

**Actn3 R577x Polymorphism Influences Muscular Power In Japanese Athletes**

Naoki Kikuchi<sup>1</sup>, Dai Ueda<sup>2</sup>, Koichi Nakazato<sup>3</sup>, Soek-ki Min<sup>3</sup>, Inkwon Hwang<sup>3</sup>, Shoji Igawa<sup>3</sup>. <sup>1</sup>*Graduate School of Health and Sport Science, Nippon Sport Science University, Tokyo, Japan.* <sup>2</sup>*Bunkyo University, Kanagawa, Japan.* <sup>3</sup>*Nippon Sport Science University, Tokyo, Japan.*  
(No relationships reported)

$\alpha$ -actinin-3 (ACTN3) is one of the most studied “performance genes” and have been reported about the relationship with muscle composition, muscular strength and elite performance.

**PURPOSE:** To investigate whether ACTN3 R577X polymorphism would be relevant to muscular power in Japanese collegiate athletes.

**METHODS:** 105 male athletes and 243 controls (94 male and 149 female) were recruited in this study. Athletes performed 30s Wingate Anaerobic Test (WnAT) with a load equal to 7.5% of body weight. Genotyping was executed by using TaqMan approach for the ACTN3 (rs1815739) polymorphism.

**RESULTS:** ACTN3 polymorphism of athletes and controls was in Hardy-Weinberg Equilibrium. The distribution of ACTN3 XX genotype was significantly lower in athletes than controls (16% vs. 29%;  $P < 0.001$  under the R allele dominant model). There was no significant difference in 30s WnAT mean power among each genotype. However, WnAT peak power was significantly higher in RR or R allele dominant model groups than XX group.

**CONCLUSIONS:** The above data suggested that the ACTN3 RR and R allele would influence peak power of Wingate Anaerobic Test in Japanese collegiate athletes.

Hoffman<sup>9</sup>, Linda S. Pescatello, FACSM<sup>1</sup>. <sup>1</sup>*University of Connecticut, Storrs, CT.* <sup>2</sup>*University of Central Florida, Orlando, FL.* <sup>3</sup>*University of Massachusetts, Amherst, MA.* <sup>4</sup>*University of Michigan, Ann Arbor, MI.* <sup>5</sup>*Dublin City University, Dublin, Ireland.* <sup>6</sup>*University of New England, Biddeford, ME.* <sup>7</sup>*Florida Atlantic University, Boca Raton, FL.* <sup>8</sup>*Children's National Medical Center, Washington, DC.* <sup>9</sup>*Hartford Hospital, Hartford, CT.*  
(No relationships reported)

Ghrelin (GHRL) acts on the central nervous system to regulate energy homeostasis. Ghrelin (GHRL) single nucleotide polymorphisms (SNPs) associate with obesity, the metabolic syndrome, and habitual physical activity (PA).

**PURPOSE:** We sought to replicate whether GHRL 408G>T (Leu72Met; rs696217), 346G>A (Arg51Gln; rs34911341), and 3412A>T (Gln90Leu; rs4684677) SNPs associate with PA among healthy, Caucasian adults.

**METHODS:** Subjects [ $n=476$ ,  $23.5 \pm 0.3$ yr, body mass index (BMI):  $24.7 \pm 0.2$ kg·m<sup>-2</sup>] were genotyped for GHRL 408G>T, 346G>A, and 3412A>T. They completed the Paffenbarger PA Questionnaire. PA phenotypes were total kcal/wk, and kcal/wk in vigorous, moderate and light intensity PA, and sports and recreation. Multivariable ANCOVA tested associations among genotypes and PA by gender adjusted for age and BMI.

**RESULTS:** Subjects carrying the GHRL 408 T allele reported expending more kcal/wk than non-carriers ( $3551.1 \pm 292.8$  vs  $2708.1 \pm 129.0$ ) ( $p=0.009$ ). Subjects carrying the T allele reported more kcal/wk in moderate intensity PA ( $836.5 \pm 121.4$  vs  $488.4 \pm 53.5$ ) ( $p=0.009$ ) and sports and recreation ( $2176.6 \pm 256.5$  vs  $1526.5 \pm 113.0$ ) ( $p=0.021$ ) than non-carriers. Men with the T allele reported more kcal/wk than non-carriers ( $4292.4 \pm 495.9$  vs  $2682.4 \pm 215.3$ ) ( $p=0.003$ ). Men with the T allele reported more kcal/wk in moderate intensity PA ( $875.9 \pm 135.1$  vs  $377.3 \pm 58.7$ ) ( $p=0.001$ ) and sports and recreation ( $2629.1 \pm 418.0$  vs  $1480.3 \pm 181.3$ ) ( $p=0.012$ ) than non-carriers. GHRL 408G>T explained approximately 3.8% of total kcal/wk and 5.5% of moderate PA in men ( $p < 0.05$ ). GHRL 408G>T did not associate with PA in women ( $p \geq 0.05$ ). GHRL 346G>A and 3412A>T did not associate with PA ( $p \geq 0.05$ ).

**CONCLUSION:** GHRL 408G>T, but not GHRL 346G>A or 3412A>T, modulated habitual PA in men. GHRL 408G>T encodes an amino acid that may affect splicing of prepro-GHRL

## B-35 Free Communication/Poster - Nitrates

MAY 30, 2012 1:00 PM - 6:00 PM  
ROOM: Exhibit Hall

---

### 1823 Board #231 MAY 30 2:00 PM - 3:30 PM

#### Did Popeye® Know Something About Nitrates?

Simone Porcelli<sup>1</sup>, Lorenzo Pugliese<sup>2</sup>, Enrico Rejc<sup>2</sup>, Gaspare Pavei<sup>2</sup>, Matteo Bonato<sup>2</sup>, Antonio La Torre<sup>2</sup>, Mauro Marzorati<sup>1</sup>, Claudio Marconi<sup>1</sup>. <sup>1</sup>National Council of Research, Segrate (MI), Italy. <sup>2</sup>University of Milan, Milan, Italy. <sup>3</sup>University of Udine, Udine, Italy.  
(No relationships reported)

In 1930s, Popeye became so popular for his incredible strength due to ingestion of a can of spinach that immediately increased muscular strength and power. Recent studies suggest a physiological relevance of nitrates (abundant in green leafy vegetables, such as spinach) in skeletal muscle fibers. Nitrate seem to reduce O<sub>2</sub> cost of exercise and enhance mechanical efficiency.

**PURPOSE:** No studies have investigated if nitrates supplementation enhances muscle strength and anaerobic performance as well.

**METHODS:** Seven healthy male subjects (age 25.2 years) participated in a randomized double-blind cross-over study and were tested before (PRE) and after 6 days of 0.5 l/day spinach juice (5.5 mol/day nitrate) (SPINACH) or placebo (PLACEBO). The following tests were carried out: a) maximal voluntary isometric contraction (MVC) of knee extensors; b) fatiguing, intermittent sub-maximal (75% MVC) isometric knee extension; c) Wingate 30s test (W<sub>30s</sub>); d) Repeated Sprint Ability test (RSA) comprising one set of 5 x 6-s maximal sprints with 24 s of passive recovery between repetitions. During the isometric exercises, EMG of vastus lateralis and biceps femoris was recorded. Blood lactate (La) was obtained at rest and after exercise on a mechanically braked cycle ergometer.

**RESULTS:** Relative to PRE, in PLACEBO there were not significant differences for the investigated variables. In contrast, SPINACH vs. PLACEBO: a) Maximal voluntary torque of knee extensors was not significantly different (187 ± 13 vs. 189 ± 13 Nm, p<0.05); total muscle work, estimated as the sum of impulses generated during the fatiguing sub-maximal contractions, was significantly higher (361 ± 69 vs. 254 ± 57 Nm\*s\*kg<sup>-1</sup>, p<0.05). b) During W<sub>30s</sub> mean power was significantly higher (541 ± 22 vs. 506 ± 19 W, p<0.05) and fatigue index was significantly lower (40.4 ± 1.8 vs. 45.9 ± 2.9 %, p<0.05). La<sub>peak</sub> was not significantly different. As for RSA, peak power was significantly higher during the 3<sup>rd</sup>, 4<sup>th</sup> and 5<sup>th</sup> repetition.

**CONCLUSIONS:** A moderate dietary dose of nitrates significantly enhanced variables of anaerobic performance in humans. These effects could be due both to a reduction of ATP cost and to an increase of ATP oxidative production. Although Popeye didn't know anything about nitrate, we can hypothesize that nitrates could be the "force" of Popeye's spinach.

---

### 1824 Board #232 MAY 30 2:00 PM - 3:30 PM

#### Acute Dietary Nitrate Supplementation Does Not Improve 50-mile Time Trial Performance in Highly Trained Cyclists

Daryl P. Wilkerson, Giles Hayward, Bailey J. Stephen, Vanhatalo Anni, Blackwell R. Jamie, Jones M. Andrew, FACSM. *Exeter University, Exeter, United Kingdom.*  
(No relationships reported)

Dietary nitrate supplementation has been shown to improve 4 and 16.1 km time trial (TT) performance by ~2.7% in sub-elite cyclists. However, it is not known if these ergogenic effects persist in longer endurance events or if dietary nitrate supplementation can enhance performance to the same extent in highly trained individuals.

**PURPOSE:** To determine the effect of acute dietary nitrate supplementation on 50-mile TT performance in trained cyclists.

**METHODS:** After familiarization, 8 trained male cyclists performed 50-mile TTs under two experimental conditions: i) 2.5 h after consuming 0.5 L of beetroot juice (BR; containing ~6.2 mmol of nitrate) and ii) 2.5 h after consuming 0.5 L of nitrate-depleted BR (placebo; containing ~0.005 mmol of nitrate). The two conditions were administered using a counter-balanced, single-blind, crossover design. A minimum of 7 days separated visits to allow recovery and washout.

**RESULTS:** BR significantly elevated plasma [nitrite] (BR: 500 ± 59 vs. placebo: 411 ± 22 nM; P<0.05) and resulted in a group mean reduction in completion time for the 50-mile TT of 0.8% (BR: 136.7 ± 5.6 vs. placebo: 137.9 ± 6.4 min) which was not statistically significant (P>0.05). There was a significant correlation between the increased post-beverage plasma [nitrite] with BR and the reduction in TT completion times (r = -0.84, P<0.05). Power output (PO) was not different between the conditions at any point (P>0.05) but oxygen uptake (V<sub>O2</sub>) tended to be lower in BR (P=0.06), resulting in a significantly greater PO:V<sub>O2</sub> ratio (BR: 67.4 ± 5.5 vs. placebo: 65.3 ± 4.8 W·L<sup>-1</sup>·min<sup>-1</sup>; P<0.05).

**CONCLUSION:** Acute dietary nitrate supplementation with nitrate-rich beetroot juice did not significantly improve 50-mile TT performance in trained cyclists despite the significantly greater PO:V<sub>O2</sub>. It appears that rather than attain a higher PO for a given O<sub>2</sub>, the cyclists maintained a similar PO but at a lower V<sub>O2</sub>. It is noteworthy that although the reduction in 50-mile TT completion time of 0.8% did not attain statistical significance, an improvement in performance of this magnitude would likely be practically meaningful to an athlete.

---

### 1825 Board #233 MAY 30 2:00 PM - 3:30 PM

#### The Impact of a 6-Week Resistance Training Program with Exercise Performance Supplementation on Cardiovascular Risk in Trained Men

D David Thomas<sup>1</sup>, Jeong-Su Kim<sup>1</sup>, W Kyle Mandler<sup>1</sup>, Amber W. Kinsey<sup>1</sup>, Timothy P. Scheett<sup>2</sup>, Lynn B. Panton, FACSM<sup>1</sup>, Michael J. Ormsbee<sup>1</sup>. <sup>1</sup>Florida State University, Tallahassee, FL. <sup>2</sup>The College of Charleston, Charleston, SC.  
(No relationships reported)

**PURPOSE:** The potential cardiovascular or metabolic health risks or benefits associated with consumption of performance enhancing supplements containing multiple ingredients over the course of a periodized resistance training (RT) regimen are unknown. The purpose of this study was to investigate the combined effect of resistance training (RT) and commercial pre- and post-exercise performance supplements, NO-Shotgun® (SHOT) and NO-Synthesize® (SYN), respectively, on cardiovascular (CV) risk in resistance-trained men.

**METHODS:** Twenty-four resistance-trained men completed 6 weeks (3d/wk) of whole-body periodized RT. The participants were randomly assigned to 2 groups. Group 1 (n=13; Performance Supplement; PS) consumed one serving of SHOT before and 1 serving of SYN immediately after each RT session; SYN was also consumed on all non-RT days. Group 2 (n=11; Placebo; PL) consumed an isocaloric maltodextrin placebo in an identical manner as utilized by PS. Pre and post-RT measures included: resting heart rate (HR), blood pressures (BP), fasting blood lipids, total body fat, android fat, gynoid fat and plasma nitrate concentrations. Statistical analysis was conducted using a 2 x 2 (group x time) repeated measures ANOVA. Significance is set at p<0.05.

**RESULTS:** There were no group x time interactions for HR, BP, blood lipids or plasma nitrate concentrations. However, there were significant decreases in body fat (PS: -1.2±1.2%; PL: -0.9±1.1%), android fat (PS: -1.8±2.1%; PL: -1.6±2.0%), and gynoid fat (PS: -1.3±1.6%; PL: -1.0±1.4%) for both groups. There were also no significant group, time, or group x time effects for plasma nitrate concentrations.

**CONCLUSIONS:** Six weeks of SHOT and SYN supplementation during RT does not alter CV health parameters in healthy, resistance-trained men. This study was supported by a supplement donation from Vital Pharmaceuticals, Inc.

1826 Board #234 MAY 30 2:00 PM - 3:30 PM

**Dietary Nitrate Supplementation Reduces The Oxygen Cost Of Exercise In Healthy Older Adults**

James Kelly, Anni Vanhatalo, Jonathan Fulford, Olivia French, James R. Blackwell, Andrew M. Jones, FACSM. *University of Exeter, Exeter, United Kingdom.*  
(No relationships reported)

Dietary nitrate (NO<sub>3</sub><sup>-</sup>) supplementation, which might enhance nitric oxide bioavailability, has recently been shown to reduce resting blood pressure and the oxygen cost of exercise in healthy young adults.

**PURPOSE:** We investigated whether the beneficial effects of nitrate supplementation reported previously in young adults are also evident in healthy older adults.

**METHODS:** Twelve (6 males) healthy, older (60-70 yrs) adults volunteered to participate in this ethically-approved study which employed a double-blind, randomized, crossover design. The subjects supplemented their diet for 3 days with either nitrate-rich concentrated beetroot juice (BR; 2 x 70 ml·d<sup>-1</sup>, each containing ~0.3 g NO<sub>3</sub><sup>-</sup>) or a nitrate-depleted beetroot juice placebo (PL; 2 x 70 ml·d<sup>-1</sup>, containing ~0.74 mg NO<sub>3</sub><sup>-</sup>). Before and after the intervention periods, resting blood pressure was measured and venous blood samples were drawn for the determination of plasma nitrite concentration. The subjects also completed two 6-min bouts of moderate-intensity treadmill walking for the assessment of exercise economy by respiratory gas exchange. Differences between conditions were assessed by paired samples t-tests and statistical significance was accepted at *P*<0.05.

**RESULTS:** Dietary nitrate supplementation significantly increased plasma nitrite concentration (BR: 1037 ± 627 vs. PL: 286 ± 188 nM; *P*<0.01), while both systolic blood pressure (BR: 115 ± 9 vs. 120 ± 6 mmHg; *P*<0.05) and mean arterial pressure (BR: 85 ± 5 vs. PL: 88 ± 4 mmHg; *P*<0.05) were reduced. There was a reduction in the V<sub>O<sub>2</sub></sub> amplitude (BR: 373 ± 182 vs. PL: 437 ± 219 ml·min<sup>-1</sup>, *P*<0.05) and steady-state V<sub>O<sub>2</sub></sub> (BR: 901 ± 233 vs. PL: 955 ± 270 ml·min<sup>-1</sup>, *P*<0.05) during moderate-intensity treadmill walking.

**CONCLUSIONS:** In accordance with previous studies in young healthy adults, dietary nitrate supplementation elevated plasma nitrite concentrations and reduced both resting blood pressure and the oxygen cost of moderate-intensity treadmill exercise in healthy older adults. These results may have important implications for the enhancement of cardiovascular health, functional capacity and quality of life in senescence.

---

1827 Board #235 MAY 30 2:00 PM - 3:30 PM

**Effects Of Performance Supplements On Body Composition And Strength In Trained Men During 6 Weeks Of Resistance Training.**

Michael J. Ormsbee, W. Kyle Mandler, D. David Thomas, Amber W. Kinsey, Colin J. Riley, Lynn B. Pantan, FACSM, Jeong-Su Kim. *Florida State University, Tallahassee, FL*  
(No relationships reported)

**PURPOSE:** Resistance training (RT) enhances muscle protein synthesis and increases muscle strength and hypertrophy. Performance supplements have been shown to augment the physiological improvements associated with RT. The purpose of this study was to investigate the impact of pre- and post-workout performance supplements on body composition, muscle strength, and power.

**METHODS:** Twenty-four (24.6 ± 4.9 yrs; 180.4 ± 5.5 cm; 80.7 ± 8.8 kg), resistance trained men completed 6 wks of periodized RT (3x/wk). They were assigned to one of two groups based upon maximal voluntary contraction of the quadriceps (Biodex) to lean mass (LM) ratio. Group 1 (n=13; Performance Supplement; PS) consumed NO-Shotgun® before each workout and NO-Synthesize® (Vital Pharmaceuticals, Inc., Davie, FL) immediately after each workout as well as on non-RT days, while Group 2 (n= 11; Placebo; PLA) consumed a flavor-matched isocaloric placebo. Body composition (DXA) and circumferences, 1-repetition maximal strength (1RM) of the upper (chest press; CP) and lower body (leg press; LP), and anaerobic power (Wingate test) were assessed. A 2 x 2 (group x time) ANOVA with repeated measures was used. Tukey LSD post hoc tests were used to examine pairwise difference. Significance was set at (*p*<0.05).

**RESULTS:** The PS group increased LM by 4.7% with no change for PLA. LP 1RM increased in the PS group with training by 19.56% and the PLA group increased by 25.94%. BP 1RM increased in the PS group by 8.4% and the PLA group increased by 6.9%. There were no significant differences between groups for 1RM in either BP or LP. Circumferences increased for the arm in both groups (PS 2.2%, PLA 2.6%), but only the PS group increased thigh measures by 2.5%. The PS group significantly increased relative anaerobic power by 9.38%, while PLA remained unchanged.

**CONCLUSIONS:** Pre- and post-exercise consumption of NO-Shotgun® and NO-Synthesize® during 6 wk-periodized RT facilitated RT-induced improvements in LM and anaerobic power in trained males. These supplements do not appear to alter 1RM muscle strength or reduce body fat mass. This project was supported by supplement donation by Vital Pharmaceuticals.

1828 Board #236 MAY 30 2:00 PM - 3:30 PM

**Effects Of The Phosphodiesterase-5 Inhibitor Tadalafil On Parameters Of Aerobic Fitness In Healthy Men**

Cosme Franklim Buzzachera, Gian Pietro Emerenziani, Emanuele Franciosi, Maria Chiara Gallotta, Luigi Di Luigi, Laura Guidetti, Carlo Baldari, FACSM. *University of Rome Foro Italico, Rome, Italy.*  
(No relationships reported)

The stimulation of nitric oxide (NO)-3'5' cyclic guanosine monophosphate (cGMP) signaling pathway results in vasorelaxation and increased muscle blood flow during rest and exercise. Tadalafil, a phosphodiesterase-5 inhibitor used for therapeutic and nontherapeutic purposes, reduces cGMP hydrolysis inducing vasodilation and increases exercise capacity in healthy men in hypoxia.

**PURPOSE:** To examine whether 48 h exposure to Tadalafil influences aerobic fitness parameters during graded exercise test (GXT) in healthy men in normoxia.

**METHODS:** Twelve subjects were randomly assigned to receive either a two consecutive days administration of placebo or Tadalafil (e.g. 20 mg with 36 hours of interval) in a double-blind crossover design, with a 14-days wash-out period between conditions. About 12 hours after the second administration of either placebo or Tadalafil, the subjects performed GXT on a cycle ergometer. Gas exchange measures and heart rate (HR) were recorded throughout GXT and blood lactate concentrations (La) were measured every 3-min stage of the test. Lactate threshold (LT), maximal oxygen uptake (V<sub>O<sub>2</sub></sub>max), maximal power output (MPO), time to fatigue (TTF), time to achieve V<sub>O<sub>2</sub></sub>max, and time at V<sub>O<sub>2</sub></sub>max were assessed. Differences in aerobic fitness parameters between Tadalafil and placebo conditions were compared by paired t-tests (*P*<0.05).

**RESULTS:** Compared to placebo, the Tadalafil condition did not influence LT (3.75 ± 0.41 vs. 3.88 ± 0.44 mmol/L) and V<sub>O<sub>2</sub></sub>max (3.46 ± 0.33 vs. 3.31 ± 0.28 L/min, respectively for placebo and Tadalafil conditions). Similarly, MPO (285.2 ± 27.0 vs. 275.0 ± 25.0 Watts) and TTF (1306.2 ± 101.8 vs. 1340.0 ± 146.5 s, respectively for placebo and Tadalafil conditions) did not differ between the two conditions. However, time to achieve V<sub>O<sub>2</sub></sub>max was significantly faster in Tadalafil (1228.7 ± 91.4 s) compared with placebo (1288.7 ± 132.2 s), whereas the time at V<sub>O<sub>2</sub></sub>max was longer in Tadalafil (77.5 ± 32.5 s) than in placebo condition (51.2 ± 26.7 s) (*P*<0.05).

**CONCLUSION:** In healthy men, the 48 hours exposure to Tadalafil did not substantially influence parameters of aerobic fitness during exercise in normoxia. However, Tadalafil significantly affected temporal responses during GXT by shortening the time to achieve V<sub>O<sub>2</sub></sub> max and delaying the exhaustion at V<sub>O<sub>2</sub></sub>max.

1829 Board #237 MAY 30 2:00 PM - 3:30 PM

**Dietary Nitrate Supplementation Improves Rowing Performance In Highly Trained Rowers**

Andrea J. Braakhuis<sup>1</sup>, Hannah Bond<sup>2</sup>, Lillian Morton<sup>2</sup>. <sup>1</sup>United States Olympic Committee, Chula Vista, CA. <sup>2</sup>Waikato Institute of Technology, Hamilton, New Zealand.  
(No relationships reported)

Increased plasma nitrate concentrations from dietary sources of nitrate have proven to benefit exercise performance. Beetroot contains relatively high levels of sodium nitrate which increases nitric oxide production.

**PURPOSE:** This study investigated whether dietary nitrate supplementation, in the form of a beetroot beverage, improved rowing performance during ergometer repetitions.

**METHODS:** In a randomised crossover design, fourteen elite male rowers consumed either beetroot containing ~5.5mmol.day<sup>-1</sup> NO<sub>3</sub> (BR) or placebo (PL) isocaloric drinks daily, for six days. Following supplementation, rowers completed six maximal 500m ergometer repetitions and times were recorded. A seven day washout period separated the two trials. Blood pressure, oxygen

saturation, maximum heart rate, urine (specific gravity, pH and nitrites) and lactates were collected for analysis at baseline (one-month testing prior to experiment), once, 30-min pre and then immediately, 1- and 2-min post-performance testing.

**RESULTS:** Changes in the mean with 95% confidence limits were calculated. There was a likely benefit to average repetition time in the BR condition, compared to PL (0.4%, 95% confidence limits,  $\pm 1.0\%$ ). In particular, repetitions 4 - 6 showed an almost certain benefit in rowing time on BR (1.7%, 95% CL,  $\pm 1.0\%$ ). The underlying mechanisms for the observed results remain unknown as differences observed in rowers' physiological measures between the two conditions were generally unclear.

**CONCLUSIONS:** Nitrate supplementation in the form of beetroot juice resulted in improved maximal rowing ergometer repetitions, particularly in the later stages of exercise.

#### Effects of Branched-chain Amino Acids Supplementation on Glucose Homeostasis and Lipid Profile in Humans

Claudia R. da Luz<sup>1</sup>, Humberto Nicastro<sup>1</sup>, Daniela FS Chaves<sup>1</sup>, Nelo E. Zanchi<sup>1</sup>, Daniel Simoes<sup>1</sup>, Katherine MA Veras<sup>1</sup>, Luis AR Costa<sup>1</sup>, François Blachier<sup>2</sup>, Antonio H. Lancha, Jr.<sup>1</sup> <sup>1</sup>University of São Paulo, São Paulo, Brazil. <sup>2</sup>INRA/AgroParisTech, Paris, France.

(No relationships reported)

Branched-chain amino acids (BCAA), particularly leucine, play an important role on glucose homeostasis through insulin secretagogue action. Some studies have also demonstrated that BCAA may modulate the immune response on inflammatory conditions. However, it is unknown if BCAA may affect the glucose homeostasis kinetics at rest and if the inflammatory response can modulate such response.

**PURPOSE:** To evaluate the effects of BCAA and leucine supplementation on glucose homeostasis, lipid profile, and the possible interaction with inflammatory response in healthy humans.

**METHODS:** In a double-blind, randomized, and crossover design 08 healthy male adults (24.4  $\pm$  1.2 years; 79.1  $\pm$  3.5 kg; 179.5  $\pm$  2.5 cm; BMI 24.55  $\pm$  1.0 kg·m<sup>-2</sup>) ingested either BCAA (2.4 g of leucine, 1.6 g of isoleucine, and 1.6 g of valine), leucine (LEU; 2.4 g of leucine + 3.2 g of alanine) or isonitrogenous supplement (PLA; 5.6 g of alanine). Experimental sessions were conducted on different days (7 d apart). After an overnight fast, participants ingested a single dose of the supplement and blood samples were collected before, and after 15, 30, 60, 90, and 120 min to determine serum glucose and insulin concentrations, lipid profile, and interleukin (IL)-6 concentration. Data were analyzed using repeated measures ANOVA ( $p < 0.05$ ) one-way or two-way as appropriated and are presented as mean  $\pm$  SEM changes.

**RESULTS:** Serum glucose curve and AUC did not differ between treatments ( $p > 0.05$ ). BCAA and LEU increased serum insulin 60' after ingestion when compared to PLA (BCAA 75.1  $\pm$  23.8 mU·L<sup>-1</sup>; LEU 76.2  $\pm$  12.3 mU·L<sup>-1</sup>; PLA 25.3  $\pm$  3.6 mU·L<sup>-1</sup>;  $p < 0.05$ ). However, there was no difference on serum insulin AUC ( $p > 0.05$ ). There was no difference on serum lipid profile curve and AUC in all time points between treatments ( $p > 0.05$ ). LEU decreased serum IL-6 concentration 60' after ingestion when compared to BCAA and PLA (LEU -1.7  $\pm$  0.3 pg·mL<sup>-1</sup>; BCAA 1.1  $\pm$  1.5 pg·mL<sup>-1</sup>; PLA 2.3  $\pm$  0.4 pg·mL<sup>-1</sup>;  $p < 0.05$ ).

**CONCLUSION:** BCAA and leucine supplementation had no effects on serum glucose and lipid profile kinetics but increased serum insulin concentration 60' after ingestion. This effect may be related to insulin secretagogue role of BCAA and/or to the possible role of leucine on IL-6 secretion.

### 1831 Board #239 MAY 30 3:30 PM - 5:00 PM

#### Effect of an Amino Acid Beverage on Exercise Recovery and Subsequent Anaerobic Exercise Performance

Bei Wang, Zhenping Ding, Wanyi Wang, Jungyun Hwang, Yi-Hung Liao, John L. Ivy, FACSM. University of Texas at Austin, Austin, TX.

(No relationships reported)

An amino acid mixture, composed of 5 amino acids, has been reported to lower glucose response to an oral glucose challenge in healthy overweight adults. Glucose uptake by skeletal muscle may be the major mechanism responsible for the hypoglycemic effect of the mixture.

**PURPOSE:** To investigate the effect of two different doses of an amino acid mixture on exercise recovery and subsequent anaerobic exercise performance in healthy active individuals.

**METHODS:** After a 2 h intense cycling bout, ten subjects (27.5 $\pm$ 2.0 yrs) received a CHO/HAA (1.2g/kg bw CHO, 13g amino acid mixture), CHO/LAA (1.2g/kg bw CHO, 6g amino acid mixture), or CHO (1.2g/kg bw CHO) supplement immediately and 2 h post exercise. Muscle biopsies were performed immediately and 4 h post exercise. After the second biopsy, a Wingate Anaerobic Test (WAnT) was performed.

**RESULTS:** The CHO/HAA and CHO/LAA treatments significantly decreased glucose response compared with CHO, which was supported by the finding that the glucose AUC for the CHO/HAA and CHO/LAA treatments was significantly lower than that for the CHO treatment (CHO/HAA 1259.9 $\pm$ 27.7, CHO/LAA 1251.5 $\pm$ 47.7, CHO 1376.8 $\pm$ 52.9 mmol/L·4h,  $p < 0.05$ ). However, glycogen storage rate was significantly lower in the CHO/HAA compared with CHO, while it did not differ significantly between the CHO/LAA and CHO treatments (CHO/HAA 15.4 $\pm$ 2.0, CHO/LAA 18.1 $\pm$ 2.0, CHO 21.5 $\pm$ 1.4  $\mu$ mol/g wet wt·4h<sup>-1</sup>). Phosphorylation of AS160 and glycogen synthase did not differ across treatments. Likewise, there were no differences in blood lactate, creatine kinase, or myoglobin responses or WAnT performance across treatments.

**CONCLUSION:** An amino acid mixture lowers the glucose response to a carbohydrate supplement after strenuous exercise. However, it was not effective in facilitating subsequent muscle glycogen storage or anaerobic performance.

### 1832 Board #240 MAY 30 3:30 PM - 5:00 PM

#### Acute and Long-term Branched Chain Amino Acid Changes With Gastric Bypass Surgery

Monica J. Hubal<sup>1</sup>, Lynn Yieh<sup>2</sup>, John Pender<sup>3</sup>, William Chapman<sup>3</sup>, Walter Pories<sup>3</sup>, G. Lynis Dohm<sup>3</sup>. <sup>1</sup>Children's National Medical Center, Washington, DC. <sup>2</sup>Johnson and Johnson, San Diego, CA. <sup>3</sup>East Carolina University, Greenville, NC. (Sponsor: Eric S. Rawson, FACSM)

(No relationships reported)

Gastric bypass surgery (RYGB) often initiates a weight-loss independent resolution of Type 2 diabetes, though the underlying mechanism(s) driving this effect are unknown. One possible mechanism involves amino acid metabolism changes with surgery that can affect glucose homeostasis. Studies have reported branched chain amino acid (BCAA) correlations to obesity and changes in BCAAs during the months following RYGB, but fasting glucose levels often drop more acutely (within days following surgery), necessitating earlier inquiry.

**PURPOSE:** To define acute and chronic changes in amino acids and clinical correlates in diabetic versus non-diabetic obese women following RYGB. Baseline differences between these groups and lean controls were also defined.

**METHODS:** Fasting plasma samples were obtained from the following groups of Caucasian females: Lean controls (N=7; L; baseline only), obese diabetics (D; N=9) and obese non-diabetic (Ob; N=8) subjects at baseline, 7d and 3mo after RYGB. Metabolite profiling was completed on a combination of mass spectroscopy platforms (Metanomics Health GmbH). Other clinical values obtained included anthropomorphic measures and insulin/glucose-related values from IVGTT. Statistical tests included RM ANCOVA and Pearson correlations with alpha set at  $< 0.05$ .

**RESULTS:** RYGB caused similar reductions in BMI over time between groups, with greater reduction in fasting plasma glucose (FPG; 2 fold;  $p = 0.04$ ) in the D group. Baseline differences were found for all BCAAs (Leu, Ile and Val), such that D>Ob>L, but no BCAA differences were seen between groups following surgery. Val levels in the D group dropped 20% acutely, while Leu and Ile did not significantly change. Acute elevations were seen in Leu (20%) and Ile (17%) in Ob, with no change in Val. All BCAAs dropped at 3 mo post-surgery in both groups (-35 to -46% for D, -23 to -57% for Ob), to lean control levels. While BCAA levels at baseline and across all time points correlated well with BMI (r=0.6), FPG (r=0.7) and HOMA (r=0.6), changes in BCAAs at either time point did not significantly correlate to changes in clinical values.

**CONCLUSIONS:** While BCAAs decrease to lean control levels over 3 months following RYGB, these changes do not occur as rapidly as improvements in glucose homeostasis.

**ACKNOWLEDGEMENT:** Study sponsored by Johnson & Johnson.

**The Effects of Endurance Training and Different Methionine-contained Diets on Insulin/IGF-1 System in Skeletal Muscle**

Young-Yu Liang<sup>1</sup>, Hsin-wen Chang<sup>1</sup>, Liang-Tong Kuo<sup>1</sup>, Sandy S. Hsieh<sup>2</sup>, Ming-Shin Chang<sup>1</sup>, Tsang-Hai Huang<sup>1</sup>. <sup>1</sup>National Cheng Kung University, Tainan, Taiwan, Tainan, Taiwan. <sup>2</sup>National Taiwan Normal University, Taipei, Taiwan, Taipei, Taiwan.

(No relationships reported)

**PURPOSE:** To investigate the effects of different methionine (M)-contained diets combined with endurance exercise (E) training on insulin/IGF-1 system in skeletal muscles.

**METHODS:** Male Sprague Dawley rats (7 weeks old, n=72) were randomly assigned to six groups, which were the 0.86%M, 0.52%M, 0.17%M, 0.86%M+E, 0.52%M+E, and 0.17%M+E groups (n=12 for each group). After 8-week diets and exercise training interventions, animals were sacrificed, and skeletal muscle and blood samples were collected and stored for further analysis. Two-way ANOVA (M×E) was used for statistical analysis ( $\alpha=0.05$ ).

**RESULTS:** Serum TBARS, insulin, insulin-like growth factor-binding protein-3(IGFBP-3), IGF-1/IGFBP-3 ratio reached the significant level both in the main effects of diet and exercise. The results of *post hoc* comparisons were: 1) TBARS( $\mu$ M) (E: 20.2±2.0 < non-E: 33.9±2.0; 0.86%M: 32.0±2.4 > 0.17%M: 21.6±2.4); 2) insulin( $\mu$ g/l) (E: 0.27±0.02 < non-E: 0.34±0.02; 0.52%M: 0.38±0.02 > 0.86%M: 0.31±0.02 > 0.17%M: 0.23±0.02); 3) IGFBP-3(ng/ml) (E: 132.1±18.5 < non-E: 204.8±19.1; 0.52%M: 209.7 ± 22.3 > 0.17%M: 122.4±18.5); 4) IGF-1/IGFBP-3 ratio (E: 1.73±0.32 < non-E: 2.75±0.33, 0.86%M: 3.0±0.4 & 0.52%M : 2.55±0.38 > 0.17% 1.09±0.4). Significant interaction was shown in serum IGF-1(ng/ml)(*post hoc* comparison: 0.86%M : 539.1±53.6 > 0.86%M+E: 330.1±51.2; 0.52%M: 673.3±90.5 > 0.52%M+E: 219.9±33.7; 0.17%M: 320.3±52.9 > 0.17%M+E: 38.6±15.6; 0.86%M: 539.1±53.5 & 0.52%M : 673.3±90.5 > 0.17%M: 212.4±39.3 ; 0.86%M+E: 347.1±50.1 > 0.52%M+E: 219.9±33.7 > 0.17%M+E: 38.6±15.1). Skeletal muscle markers, IGF-1 receptor (IGF-1R), insulin receptor (IR) all reached the significant level in the main effect of exercise. The results of *post hoc* comparison were 1) IGF-1R (E: 0.01±0.05% < non-E: 1.15±0.04%); 2) IR: (E: 0.91±0.04%, non-E 1.18±0.04%).

**CONCLUSIONS:** Compared to 0.86%M and 0.52%M diets, 0.17%M diet showed better effects on the longevity index. The endurance exercise mainly improved the sensitivity of insulin/IGF-1 system.

**1834** Board #242 **MAY 30** **3:30 PM - 5:00 PM**

**The Importance Of Leucine In Stimulating Protein Signaling After Resistance Exercise In Young Females**

Marcus Borgenvik, William Apró, Marjan Pontén, Björn Ekblom, Eva Blomstrand. Åstrand Laboratory, Swedish School of Sport & Health Sciences, Stockholm, Sweden.

(No relationships reported)

Essential amino acids (EAA) and resistance exercise are well-documented in their capacity to stimulate human muscle protein. Out of the EAA, leucine has been proposed to have a unique role in promoting protein synthesis through activation of the mammalian target of rapamycin (mTOR) pathway.

**PURPOSE:** To evaluate the role of leucine with regard to mTOR signaling and mRNA expression of possible regulators of mTOR in young females following resistance exercise.

**METHODS:** Eight healthy females performed two sessions of leg press exercise and were randomly supplied a mixture of EAA with or without leucine (EAA-Leu). Blood samples were taken repeatedly throughout the experiment and muscle biopsy samples were collected before, 1h, and 3h after resistance exercise and analyzed for phosphorylation status of proteins in the mTOR pathway and mRNA expression of mTOR-associated genes. In addition, levels of free amino acids were determined plasma and muscle samples.

**RESULTS:** The phosphorylation of mTOR at Ser<sup>2448</sup> was elevated ~2-fold above baseline at 1h and 3h post exercise with both supplements (P<0.05). During EAA supplementation the phosphorylation of p70<sup>S6K</sup> at Thr<sup>389</sup> was 30-fold higher than at baseline and 5-fold higher than EAA-Leu (P<0.05) 1h post exercise. The mRNA expression of Rheb increased ~ 1.7 fold and that of Redd1 decreased ~ 60 % 3h post exercise (P<0.05), with no differences between supplements. The plasma levels of isoleucine, valine, methionine, tryptophan and tyrosine were all 16 to 58 % lower after EAA than EAA-Leu following 2 and 3h of recovery (P<0.05). At 3h after exercise muscle levels of these amino acids were 28 to 59 % lower when leucine was present in the drink (P<0.05). In addition, in the EAA trial muscle levels of leucine increased 64 and 32 % while in the EAA-Leu trial a 44 and 39 % reduction was observed 1 and 3h post exercise, respectively.

**CONCLUSION:** The significantly higher response with regard to p70<sup>S6K</sup> phosphorylation in the presence of leucine emphasizes its importance in the activation of enzymes in the mTOR pathway. In addition, the larger reduction of essential amino acids in plasma and muscle provide further support for a specific role of leucine in stimulating protein synthesis. Supported by Swedish National Center for Research in Sports

**Role of Dietary Leucine on Amino Acid Transporter mRNA Expression Following Resistance Exercise**

Tyler A. Churchward-Venne<sup>1</sup>, Andrew Philp<sup>2</sup>, George R. Marcotte<sup>1</sup>, Cameron J. Mitchell<sup>1</sup>, Daniel W.D. West<sup>1</sup>, Leigh Breen<sup>1</sup>, Steven K. Baker<sup>1</sup>, Keith Baar, FACSM<sup>2</sup>, Stuart M. Phillips, FACSM<sup>1</sup>. <sup>1</sup>McMaster University, Hamilton, ON, Canada. <sup>2</sup>University of California, Davis, CA.

(No relationships reported)

Skeletal muscle amino acid transporters (AAT) may play a key role in the regulation of muscle protein metabolism via their ability to transport amino acids (AA) across the sarcolemma and relay signals to downstream protein targets. The mRNA expression of some AAT is increased after essential amino acid (EAA) intake and resistance exercise (RE); however, the combined effect of AA and RE on AAT mRNA expression and whether greater leucine intake alters the response is unknown.

**PURPOSE:** To examine the effect of AA/whey protein intake (with high and low leucine content) after RE on the mRNA expression of select AAT in human skeletal muscle.

**METHODS:** 24 adult men (22±1 y) completed unilateral knee-extensor RE before consuming one of the following: WHEY (25 g whey protein); LEU (6.25 g whey protein supplemented with leucine to be iso-leucine with WHEY); and EAA-LEU (6.25 g whey protein supplemented with EAA except leucine to be iso-EAA with WHEY for each EAA except for leucine). Muscle biopsies were obtained before RE and 1, 3, and 5h after from both rested-fed (FED) and exercise-fed legs (EX-FED). qRT-PCR was used to determine changes in mRNA expression of LAT-1, CD-98, and PAT-1 AAT and members of the general AA control pathway GCN-2 and ATF-4.

**RESULTS:** mRNA expression of CD-98 and LAT-1 (fold-change from basal) increased in FED and EX-FED, however the response at 5h was greater in EX-FED (CD-98 FED = 2.17 vs. EX-FED = 3.52 (P=0.003); LAT-1 FED = 3.58 vs. EX-FED = 5.18 (P=0.025)). PAT-1 increased in FED and EX-FED, however EX-FED was greater in WHEY vs. EAA-LEU (WHEY = 3.26 vs. EAA-LEU = 1.89 (P=0.031)). ATF-4 showed time dependent changes in all treatments while the FED response of GCN-2 was greater in LEU vs. WHEY and EAA-LEU at 5h (LEU = 2.07 vs. WHEY = 1.44 vs. EAA-LEU = 1.02 (P=0.004)).

**CONCLUSION:** RE prior to whey protein/AA intake increases the mRNA expression of select AAT above feeding alone at 5h post RE. WHEY induced greater changes in PAT-1 vs. EAA-LEU suggesting unique benefits of whey protein that extend beyond total leucine content. EAA-LEU resulted in robust increases in select AAT comparable to LEU despite containing ~75% less leucine, suggesting that a high leucine content is not critical in increasing AAT expression after AA intake. The functional physiological significance of these changes remains to be elucidated. Supported by NSERC.

**1836** Board #244 **MAY 30** **3:30 PM - 5:00 PM**

**Effect Of  $\beta$ -alanine And Sodium Bicarbonate Supplementation On High Intensity Performance**

Anu Koivisto<sup>1</sup>, Ida Svendsen<sup>1</sup>, Erlend J. Hem<sup>1</sup>, Truls Råstad<sup>2</sup>. <sup>1</sup>Olympiatoppen, The Norwegian Olympic and Paralympic Committee and Confederation of Sports, Oslo, Norway. <sup>2</sup>Norwegian School of Sport Sciences, Oslo, Norway.

(No relationships reported)

Supplementation with  $\beta$ -alanine can increase the level of intracellular buffer carnosine in skeletal muscle. Studies have shown that increased carnosine concentration can limit metabolic

acidosis and enhance high-intensity exercise performance. Supplementation with sodium bicarbonate can increase buffer capacity in blood and enhance maximal exercise capacity in sports lasting 1-5 minutes.

**PURPOSE:** To determine the effect of  $\beta$ -alanine and sodium bicarbonate supplementation, separately and in combination, on high-intensity cycling capacity.

**METHODS:** Fourteen physically active students were block randomised to either a placebo or  $\beta$ -alanine group (4g/day for 5 weeks) based on  $\text{VO}_{2\text{max}}$ . Before and after the 5-week loading phase with either  $\beta$ -alanine or placebo, two 5-minute cycling tests (test 1, test 2, with a 20-minute break between tests) were conducted. Performance was measured as average power in 5 minutes ( $W_{5\text{min}}$ ). The repeated performance tests were conducted twice, before and after the loading phase, with either sodium bicarbonate (0.3g/kg body weight) or placebo (maltodextrin) in a randomised cross-over design.

**RESULTS:** Bicarbonate supplementation alone did not have any effect on  $W_{5\text{min}}$ . As a result of 5-week loading phase there was a significant increase in  $W_{5\text{min}}$  in  $\beta$ -alanine ( $9 \pm 7 \text{ W}$  (3-4%),  $p=0.03$ ) but not in placebo group.  $W_{5\text{min}}$  decrease between the repeated performance tests (test 1 and 2) was smaller when subjects received bicarbonate supplementation vs placebo ( $-5 \pm 10 \text{ W}$ , vs.  $-16 \pm 19 \text{ W}$   $p = 0.04$ ) after the  $\beta$ -alanine loading phase.

**CONCLUSIONS:** Supplementation with  $\beta$ -alanine enhanced performance in a 5-minute cycling capacity test. Supplementation with sodium bicarbonate alone did not have any performance enhancing effect, but when combined with  $\beta$ -alanine, the reduction in cycling capacity in the repeated performance test (after 20min) was reduced.

**1837** Board #245 **MAY 30** **3:30 PM - 5:00 PM**

**Effects Of Beta-alanine Supplementation Combined Or Not With Sodium Bicarbonate On Anaerobic Performance**

Gabriel C. Tobias, Guilherme G. Artioli, Fabiana B. Benatti, Antonio H. Lancha, Jr. *University of São Paulo, São Paulo, Brazil.*

(No relationships reported)

Evidences indicate that muscle acidosis is one major cause of fatigue during short-term, high-intensity exercises. It is well known that anaerobic performance is improved by artificially increasing intra or extracellular buffering capacity. However, the additional ergogenic effects of increasing both intra and extracellular buffering capacity are yet to be determined.

**PURPOSE:** to investigate the effects of isolated or combined Beta-Alanine (BA) and Sodium Bicarbonate (SB) supplementation on Anaerobic Performance of upper Limbs.

**METHODS:** This was a randomized, double-blinded, placebo-controlled trial. Subjects were divided into 4 groups (BA + Placebo; Placebo + SB; Placebo+Placebo; and BA + SB). Thirty athletes (age=25 $\pm$ 5 yrs; weight=78.8 $\pm$ 9.9 kg; training experience= 6 $\pm$ 4 yrs; training volume=6.8 $\pm$ 2 h/wk) were assessed for intermittent anaerobic performance, through the use of 4 bouts of the Wingate Anaerobic Test for upper body, interspersed by 3 min recovery period. All athletes undertook the same experimental procedures twice (i.e., PRE and POST the supplementation period).

**RESULTS:** We observed a significant main effect of time ( $F=38.81$ ;  $p<0.0001$ ) and a significant group\*time interaction ( $F=6.7$ ;  $p<0.001$ ). BA, SB and BA+SB elicited significant improvement in performance (between subjects;  $p<0.05$ ), whereas performance did not change in placebo group whatsoever. Moreover, the athletes from BA+SB group presented the highest improvement in performance as compared to BA or SB alone.

|         | PRE                 | POST                 |
|---------|---------------------|----------------------|
| BA      | 477824 $\pm$ 41994  | 513169 $\pm$ 53935a  |
| SB      | 512340 $\pm$ 81878  | 548953 $\pm$ 84608b  |
| BA + SB | 470424 $\pm$ 49407  | 549338 $\pm$ 79530c  |
| Placebo | 548524 $\pm$ 113000 | 549988 $\pm$ 99842ns |

<sup>a</sup> $p=0.009$ ; <sup>b</sup> $p=0.005$ ; <sup>c</sup> $p<0.0001$ ; <sup>ns</sup>nonsignificant

**CONCLUSION:** BA or SB alone improves intermittent anaerobic performance in a very similar fashion, and BA+SB combined showed additive ergogenic effects.

---

**Effects Of  $\beta$ -alanine Supplementation On Exercise Performance: A Meta-analysis**

Ruth M. Hobson<sup>1</sup>, Bryan Saunders<sup>1</sup>, Graham Ball<sup>1</sup>, Roger Harris<sup>2</sup>, Craig Sale<sup>1</sup>. <sup>1</sup>*Nottingham Trent University, Nottingham, United Kingdom.* <sup>2</sup>*Juniper Ltd, Newmarket, United Kingdom.*

(No relationships reported)

$\beta$ -alanine is a substrate of carnosine (which contributes to  $\text{H}^+$  buffering during high-intensity exercise) and is a popular ergogenic aid to sports performance.

**PURPOSE:** There have been several recent qualitative reviews published on the topic; here we present a preliminary quantitative review of the literature through meta-analysis.

**METHODS:** A comprehensive literature search identified all studies suitable for inclusion; strict exclusion criteria, generally relating to inappropriate methodological design, were applied. Exercise tests were analysed as a complete group for the overall effect of  $\beta$ -alanine supplementation (BA) compared to a placebo (PLA). Due to the mechanisms by which  $\beta$ -alanine is proposed to have an ergogenic effect, the data were then sub-divided into type of exercise test (capacity, performance); duration of exercise test (<60 s, 60-240 s, >240 s); and the daily and total dose of  $\beta$ -alanine administered. Mann-Whitney U-tests and Spearman's correlation coefficients were used to analyse the data.

**RESULTS:** Fifteen published manuscripts were included in the analysis, which reported the results from 57 exercise tests, using 18 supplementation regimes and a total of 360 participants (174 BA, 186 PLA). BA improved the outcome of exercise tests to a greater extent than PLA (median effect size (IQR): BA 0.366 (0.138-0.665), PLA 0.108 (-0.019-0.465);  $P=0.002$ ). Some of this effect might be explained by the improvement in exercise capacity tests with BA (0.591 (0.341-1.071)) compared to PLA (0.156 (0.040-0.566);  $P=0.013$ ); no improvement was seen for performance tests ( $P=0.204$ ). In line with the purported mechanisms for an ergogenic effect of  $\beta$ -alanine, exercise tests lasting 60-240 s were improved in BA (0.665 (0.481-1.110)) compared to PLA (0.121 (0.087-0.221);  $P=0.001$ ), as were exercise tests of >240 s (BA 0.368 (0.133-0.797); PLA 0.095 (-0.059-0.607);  $P=0.046$ ). In contrast, there was no benefit of BA on exercise tests lasting <60 s ( $P=0.312$ ). There was also no relationship between the dose of  $\beta$ -alanine administered and the difference between the effect size of the BA and PLA groups in the exercise tests ( $P=0.337$ ).

**CONCLUSION:** Overall,  $\beta$ -alanine supplementation results in a 2.85% (-0.37-10.49%) improvement in the outcome of an exercise test, when a total of 179g of  $\beta$ -alanine is supplemented.

**Effects Of Bcaa Administration On Fatigue, Muscle Damage And Energy Metabolism Substances After Endurance Exercise**

Woosuk Jung<sup>1</sup>, Donghee Kim<sup>1</sup>, Hayan Lee<sup>1</sup>, Doohong Kuk<sup>1</sup>, Michael G. Bembem, FACSM<sup>2</sup>, Daeyeol Kim<sup>2</sup>, Meehyun Yang<sup>3</sup>, Seokhwan Kim<sup>4</sup>, Jieun Jang<sup>5</sup>. <sup>1</sup>*Chonnam National University, Gwangju, Korea, Republic of.* <sup>2</sup>*University of Oklahoma, Oklahoma, OK.* <sup>3</sup>*University of Gwangju Women's, Gwangju, Korea, Republic of.* <sup>4</sup>*Seoyeong University, Gwangju, Korea, Republic of.* <sup>5</sup>*Dongshin University, Naju, Korea, Republic of.* (Sponsor: Michael G. Bembem, FACSM)

(No relationships reported)

**PURPOSE:** examine the effects of branched-chain amino acids (BCAA) administration on fatigue substances (serotonin, ammonia and lactate), muscle damage substances (CK and LDH) and energy metabolism substances (FFA and glucose) after endurance exercise.

**METHODS:** Subjects ( $n = 20$ , college-aged males) were randomly divided into an experimental ( $n=10$ , EXP) and a placebo ( $n=10$ , CON) group. Subjects both EXP and CON performed a bout of cycle training (70%  $\text{VO}_{2\text{max}}$  intensity) to exhaustion. Subject in the EXP were administered BCAA (78ml/kg[[Unsupported Character - &#8228;]]w) prior to the bout of cycle exercise. Fatigue substances, muscle damage substances and energy metabolism substances were measured before administration, 10 min before exercise, 30 min into exercise, post exercise, and recovery 30 min. Data were analyzed by two-way repeated measure ANOVA, with statistical significance was set at  $p<0.05$ .

**RESULTS:** There were no significant differences between groups for any of the outcome variables. During experimental period, serotonin was decreased in the EXP but not the CON. The post exercise, ammonia in the EXP was significantly increased ( $p<0.011$ ) but decreased at the recovery 30min. At the 30 min into exercise, lactate was significantly increased in both EXP and

CON ( $p < .001$ ). CK in the EXP was decreased during experimental period. LDH in both EXP and CON was increased at the 30 min into exercise. FFA in the EXP was significantly increased at the post exercise and recovery 30 min ( $p < .001$ ). Glucose was significantly decreased during experimental period in both EXP and CON ( $p < .001$ ).

**CONCLUSIONS:** These results indicate that supplementary BCAA decreased serum concentrations of the intramuscular enzymes as CK and LDH following exhaustive exercise. This observation suggests that BCAA supplementation may reduce the muscle damage associated with endurance exercise.

**Beta-alanine Supplementation Increases Muscle Carnosine Content And Physical Capacity In Elderly Subjects**

Serena del Favero<sup>1</sup>, Hamilton Roschel<sup>1</sup>, Marina Y. Solis<sup>1</sup>, Ana P. Hayashi<sup>1</sup>, Guilherme G. Artioli<sup>1</sup>, Maria Concepción Otaduy<sup>2</sup>, Fabiana B. Benatti<sup>1</sup>, Roger C. Harris<sup>3</sup>, John A. Wise<sup>4</sup>, Cláudia C. Leite<sup>2</sup>, Rosa M. Pereira<sup>5</sup>, Ana L. de Sá-Pinto<sup>5</sup>, Antonio Herbert Lancha-Junior<sup>1</sup>, Bruno Gualano<sup>1</sup>. <sup>1</sup>School of Physical Education and Sport – University of Sao Paulo, Sao Paulo, Brazil. <sup>2</sup>School of Medicine – Division of Radiology - University of Sao Paulo, Sao Paulo, Brazil. <sup>3</sup>Junipa Ltd, Newmarket, Suffolk, United Kingdom. <sup>4</sup>Natural Alternatives International Inc., San Marcos, CA. <sup>5</sup>School of Medicine – Division of Rheumatology - University of Sao Paulo, Sao Paulo, Brazil.

(S. del Favero: Royalty; Natural Alternatives International Inc., San Marcos, USA. Consulting Fee; Natural Alternatives International Inc., San Marcos, USA. Ownership Interest; Natural Alternatives International Inc., San Marcos, USA.)

Ageing is associated with a significant reduction in skeletal muscle carnosine resulting in a decline in the buffering capacity of the muscle. As a result elderly subjects will experience a decrease in their capacity to undertake anaerobic exercise. It has been shown that supplementation with beta-alanine has the potential to increase muscle carnosine content by 60 to 80% in healthy young adults, and this is accompanied by an improvement in the ability to perform high-intensity exercise. Improving the buffering capacity of muscle could be important for muscle function and daily-life activities in the elderly.

**PURPOSE:** To investigate the effects of beta-alanine supplementation on exercise performance capacity and on the muscle carnosine content in elderly subjects.

**METHODS:** Eighteen elderly subjects ( $65 \pm 4$  yrs) were randomly assigned to receive either beta-alanine (BA,  $n=12$ ) or placebo (PL,  $n=6$ ) for 12 weeks. The BA group received 3.2g of beta-alanine per day (2x800mg, given 2 times per day). The PL group received the exact same amount of placebo. At baseline (PRE) and after 12 weeks (POST-12) of supplementation we assessed the muscle carnosine content and anaerobic exercise capacity. Food intake was monitored throughout the study.

**RESULTS:** A significant increase in the muscle carnosine content of the gastrocnemius muscle was found in the BA group (+85.4%) when compared with the PL group (+7.2%) ( $p=0.004$ ; ES: 1.21). The time-to-exhaustion in the TLIM test was significantly improved ( $p=0.05$ ; ES: 1.71) in the BA group (+36.5%) versus the PL group (+8.6%). Similarly, time-to-exhaustion in the incremental test was also significantly increased ( $p=0.04$ ; ES: 1.03) following beta-alanine supplementation (+12.2%) when compared with placebo (+0.1%). We also observed significant positive correlations between the relative change in the muscle carnosine content and the relative change in the time-to-exhaustion in the TLIM test ( $r=0.62$ ;  $p=0.01$ ) and in the incremental test ( $r=0.48$ ;  $p=0.02$ ). Dietary intake was unchanged.

**CONCLUSION:** beta-alanine supplementation is effective in increasing the muscle carnosine content in healthy elderly subjects, with subsequent improvement in their exercise capacity.

**L-Alanyl-L-Glutamine Ingestion Maintains Performance during a Competitive Basketball Game**

Jay R. Hoffman, FACSM, David R. Williams, Nadia S. Emerson, Mattan W. Hoffman, Adam J. Wells, Daniele M. McVeigh, William P. McCormack, Gerald T. Mangine, Adam M. Gonzalez, Maren S. Fragala. University of Central Florida, Orlando, FL.

(No relationships reported)

**PURPOSE:** Examine the efficacy of L-alanyl-L-glutamine (AG) ingestion on basketball performance, including jump power, reaction time, shooting accuracy and fatigue during a basketball game.

**METHODS:** Ten women ( $21.2 \pm 1.6$  years; height:  $177.8 \pm 8.7$  cm; body mass:  $73.5 \pm 8.0$  kg), all scholarship NCAA Division I basketball players, volunteered for this study. Subjects participated in four trials, each consisting of a 40-min basketball game with controlled time-outs for rehydration. During the first trial (DHY) subjects were not allowed to rehydrate, and the total weight lost during the contest was used to determine fluid replenishment during the subsequent three experimental trials. During one trial subjects consumed only water (W), while during the other two trials subjects consumed the AG supplement marketed as Sustamine™ mixed in water using either a low dose (1 g per 500 ml) (AG1) or high dose (2 g per 500 ml) (AG2) concentration.

**RESULTS:** During DHY subjects lost  $1.72 \pm 0.42$  kg (2.3% loss of their body mass). No differences in fluid intake ( $1.55 \pm 0.43$  L) were seen between rehydration trials. A 12.5% ( $p=0.016$ ) difference in basketball shooting performance was noted between DHY and AG1 and an 11.1% ( $p=0.029$ ) difference was seen between AG1 and W. Visual reaction time was significantly greater following AG1 ( $p=0.014$ ) compared to DHY. Differences ( $p=0.045$ ) in fatigue, as determined by player loads, were seen only between AG2 and DHY. No significant differences were seen in the pre to post game differences in either peak or mean vertical jump power during any trial.

**CONCLUSIONS:** In conclusion, rehydration with AG appears to maintain basketball skill performance and visual reaction time to a greater extent than water only.

**The Impact Of Glycine Propionyl-L-Carnitine Supplementation On Power Production In Recreationally Active Women**

Melanie C. Chun, Paul C. Miller, Patrick L. Jacobs, FACSM. Elon University, Elon, NC.

(No relationships reported)

Many people use dietary supplements to enhance the effects of exercise. This has led to the development of a \$14 billion supplement industry (Sarubin, 2000). One such supplement, glycine propionyl-L-carnitine (GPLC), is marketed to non-athlete exercisers for the purpose of increasing work output while delaying fatigue. Such a supplement may assist individuals in establishing an effective exercise routine that meets health recommendations. GPLC has been shown to increase anaerobic power in resistance-trained men (Jacobs et al, 2009). Recognizing that women may respond differently to exercise and nutritional supplementation, a study focusing on women participants is warranted.

**PURPOSE:** To study the effects of GPLC supplementation on anaerobic power production in recreationally active women.

**METHODS:** A double-blind, repeated measures design was used in this investigation. Participants ( $n=8$ ) completed four sessions. The first session served to familiarize the participants to the anaerobic power test. Subsequently, 3 testing sessions were performed separated by 1 week. Sessions were counterbalanced by supplement; 3.0 g GPLC, 1.5 g GPLC, or control (200 mg brown rice powder). Ninety minutes following supplement ingestion, participants completed a 5 minute warm-up and then a 5-stage anaerobic power test on a cycle ergometer. The ergometer was loaded with 5% of the individual's body weight. Each stage lasted 10 seconds and was separated by 1 min of active recovery. Active recovery was done by pedaling an unloaded cycle ergometer at 50 RPM. Peak power (PP) and mean power (MP) were measured and recorded.

**RESULTS:** A RM-GLM revealed a significant time effect for both PP ( $p=.001$ ) and MP ( $p=.001$ ). There was not a significant condition effect for either PP or MP ( $p>.05$ ). A non-significant time\*condition interaction was seen for both PP ( $p=.076$ ) and MP ( $p=.063$ ). Higher initial power was seen for those consuming 3.0 g GPLC ( $313.0 \pm 16.0$  W) than either 1.5 g GPLC ( $304.6 \pm 11.5$  W) or control ( $306.0 \pm 15.1$  W).

**CONCLUSIONS:** Consuming 3.0 g GPLC prior to exercise may result in an increase in power production among recreationally active women. This may enable individuals to exercise at intensities sufficient to derive health benefit.

1843 Board #251 MAY 30 3:30 PM - 5:00 PM

**Effect of an L-Arginine/L-Citrulline Supplement on Muscle Oxygen Saturation and Maximal Exercise Performance**

Greg Ehlers, Stephanie Boehm, Jennifer Brown, Rebecca Gaden, Sara Keller, Megan Mueller, Sarah Schmerber, David Uffenbeck, Reid Nelson. *Concordia University Wisconsin, Mequon, WI.*  
(No relationships reported)

L-Arginine (LA) is a semi-essential amino acid that is commonly used as a supplement to enhance blood flow and improve performance in resistance and aerobic exercise. LA exerts its primary effect by conversion to nitric oxide (NO), increasing vasodilation potential in the vasculature of the body. The addition of L-citrulline (LC) to LA has been shown to enhance the potential ergogenic effects of LA.

**PURPOSE:** To examine the effects of an acute dose of LA/LC supplementation on skeletal muscle oxygen saturation (StO<sub>2</sub>) and maximal cycle exercise performance.

**METHODS:** Twelve healthy, college-aged participants (9 M, 3 F; 20.69 ± 0.95 yr) completed two maximal cycle ergometer exercise tests after ingesting either LA/LC (LA 5000mg, LC 1500mg) in 0.5 L water or placebo approximately 90 minutes prior to testing. Order of drink mixture was determined by randomized, blinded counter balance design. Respiratory gases were collected for the determination of maximal oxygen consumption (VO<sub>2</sub>max) and ventilatory threshold (VT). Heart rate (HR), blood pressure (BP) and rating of perceived exertion (RPE) were measured throughout exercise. Near infrared spectroscopy (NIR) was used to assess StO<sub>2</sub> in the vastus lateralis muscle by analyzing the StO<sub>2</sub> slope measured from the first significant reduction during exercise to the point of the VT.

**RESULTS:** No significant difference was found between supplement and placebo for time to exhaustion (13.50 ± 0.56 vs 13.64 ± 0.57 min; *P* = 0.279), maximal workload (315.8 ± 18.3 vs 317.6 ± 18.2 watts; *P* = 0.653), VO<sub>2</sub>max (47.97 ± 3.07 vs 47.69 ± 2.68 ml·kg<sup>-1</sup>·min<sup>-1</sup>; *P* = 0.731), StO<sub>2</sub> slope (-0.0418 ± 0.0033 vs -0.0384 ± 0.0043; *P* = 0.448), and time to VT (10.55 ± 0.492 vs 10.55 ± 0.494 min; *P* = 0.999), respectively. All participants showed consistency in maximal effort based on an RER of greater than 1.10 for all tests for both supplement and placebo trials.

**CONCLUSION:** The results of this study suggest that acute LA/LC supplementation does not significantly affect maximal exercise test results or the onset of the VT. In addition, skeletal muscle oxygen utilization from the beginning of exercise up to the VT was not affected by the LA/LC supplement when compared to placebo.

1844 Board #252 MAY 30 3:30 PM - 5:00 PM

**L-arginine Combined With Resistance Exercise On Growth Hormone, Growth Hormone Secretagogues, And Insulin-like Growth Factor-1**

Scott C. Forbes, Vicki Harber, Gordon Bell. *University of Alberta, Edmonton, AB, Canada.* (Sponsor: Dr. Darren Delorey, FACSM)  
(No relationships reported)

Acute resistance exercise and L-arginine independently have both been shown to elevate plasma growth hormone (GH) concentrations; however, their combined effect in strength trained participants is controversial.

**PURPOSE:** To investigate the combined effects of resistance exercise and L-arginine supplementation on plasma L-arginine, GH, GH secretagogues, and IGF-1 in strength trained males.

**METHODS:** Fourteen strength trained males (age: 25±4 yrs; weight: 81.4±9.0 kg; height: 179.4±6.9 cm; body fat: 11.5±3.8 %; training experience: 6.3±3.4 yrs; one repetition maximum (1RM) bench press relative to body mass ratio: 1.3±0.2) participated in a crossover study (separated by ~7 days) in which they were randomized to L-arginine supplementation (0.075 g·kg<sup>-1</sup> body mass) or a placebo. Subjects reported to the laboratory at 08:00 in a fasted state, consumed the supplement 60 min prior to performing a resistance training session (3 sets of 8 exercises, 10 repetitions at ~75% 1RM). Blood samples were collected at rest, before exercise, and 0, 15, 30, 60 minutes after exercise.

**RESULTS:** The L-arginine condition significantly increased plasma L-arginine concentrations (from 236 to 518 μmol·L<sup>-1</sup>) while no change was detected in the placebo condition. There were no differences between conditions for GH, GH-releasing hormone, GH-inhibiting hormone, ghrelin, or IGF-1 at any time point. However, integrated area under the curve for GH was significantly blunted in the L-arginine condition (L-arginine = 288.4±368.7 vs. placebo = 487.9±482.0 min·ng·ml<sup>-1</sup>, *p*<0.05).

**CONCLUSION:** Acute L-arginine supplementation when combined with resistance exercise blunted the GH response; however, this response was not due to changes in GH-releasing hormone, GH-inhibiting hormone, ghrelin, or IGF-1.

1845 Board #253 MAY 30 3:30 PM - 5:00 PM

**Effects Of β-hydroxy-β-methylbutyrate (hmb) Supplementation On Exercise Performance, Body Composition And Hematological Response In Male Athletes**

Minayuki Shirato<sup>1</sup>, Hirokazu Osanai<sup>2</sup>, Kazuhiro Suzukawa<sup>2</sup>, Hidenori Otani<sup>3</sup>, Naoto Kimura<sup>2</sup>. <sup>1</sup>Mejiro University College, Tokyo, Japan. <sup>2</sup>Nippon Sport Science University, Tokyo, Japan. <sup>3</sup>Himeji Dokkyo University, Hyogo, Japan.  
(No relationships reported)

**PURPOSE:** Studies have shown that β-hydroxy-β-methylbutyrate (HMB) supplementation is able to increase muscle strength and lean-body mass and to prevent muscle damage with resistance training in untrained individuals. However, there have been less studies to examine the effects of HMB supplementation on these responses in trained individuals. The purpose of this study was therefore to examine the effects of HMB supplementation on exercise performance, body composition and hematological response over 4 weeks of resistance training in athletes.

**METHODS:** Fourteen male athletes were divided into two groups: HMB supplementation group (HMB, 3.0 g/day; *n* = 7) and placebo group (maltodextrin; *n* = 7). Resistance training consisted of 2 different exercises (bench press and leg press) at 75-80% of 1-repetition maximum (1-RM), performed 2-3 days/week for 4 weeks. 1-RM muscle strength, anaerobic power (Wingate test) and body composition were assessed before and after 4 weeks of resistance training. Blood samples were obtained before and at 2 and 4 weeks after starting HMB supplementation.

**RESULTS:** No significant differences were observed between the groups in 1-RM muscle strength, body composition, and hepatic enzyme activity. Anaerobic power at 5 sec during the Wingate test was significantly greater in the HMB group than in the placebo group (880±61 W vs. 804±40 W, *p*<0.05). The rate of increase in 1-RM leg press tended to be higher in the HMB group than in the placebo group (15±12% vs. 7±5%, *p*=0.15). High-density lipoprotein was significantly lower in the HMB group than in the placebo group after 4 weeks (46±5 mg/dl vs. 58±5 mg/dl, *p*<0.01). There were decreasing tendencies of creatine phosphokinase (*p*=0.11) and lactate dehydrogenase (*p*=0.07) in the HMB group compared with the placebo group.

**CONCLUSION:** These results suggest that HMB supplementation for 4 weeks is unable to increase muscle strength and lean body mass in athletes. However, it tends to reduce training-induced muscle damage by increasing cholesterol metabolism, and to maintain anaerobic performance.

1846 Board #254 MAY 30 3:30 PM - 5:00 PM

**The Effect Of N-acetylcysteine Supplementation On Recovery Of Strength Following Eccentric Muscle Injury**

Ryan C. Luke<sup>1</sup>, Dan A. Benardot, FACSM<sup>2</sup>, Jeffrey L. Rupp, FACSM<sup>2</sup>, Christopher P. Ingalls, FACSM<sup>2</sup>, Benjamin T. Corona<sup>3</sup>, Michael S. Green<sup>4</sup>, J. Andrew Doyle, FACSM<sup>2</sup>. <sup>1</sup>California State University, Monterey Bay, Seaside, CA. <sup>2</sup>Georgia State University, Atlanta, GA. <sup>3</sup>US Army Institute of Surgical Research, San Antonio, TX. <sup>4</sup>Troy University, Troy, AL.  
(No relationships reported)

N-acetylcysteine (NAC) supplementation has demonstrated pro- and anti-inflammatory effects in human subjects following exercise-induced muscle injury. However, there is limited data examining the effects of NAC on recovery of maximal isometric torque (MIT) following injurious exercise.

**PURPOSE:** The purpose of this study was to examine the effect of NAC supplementation on recovery of MIT following eccentric contraction-induced muscle injury.

**METHODS:** Non-resistance-trained female subjects (*n* = 21, age = 20.7 ± .1 yr, weight = 68.1 ± 10 kg, height = 1.7 ± .07 m) performed one bout of eccentric exercise involving the non-dominant forearm flexor muscles. Subjects were given a placebo (P) (*n* = 10) or NAC supplement (10 mg·kg<sup>-1</sup> bw·d<sup>-1</sup>; *n* = 11) for 7d prior to and 10d following the eccentric exercise bout. Maximal isometric torque, muscle soreness (SORE), range of motion (ROM), and arm circumference (CIRC) were measured at pre-exercise (PRE), immediately post-exercise (POST), and at 1d, 3d, 7d and 10d post-exercise. In addition, serum interleukin-6 (IL-6), serum creatine kinase (CK), and serum glutathione were measured. Subjects completed a food frequency questionnaire (FFQ) to determine the antioxidant content of their diet.

**RESULTS:** There was no difference in MIT values between the P and NAC group POST ( $26.93 \pm 6.4$  vs.  $24.95 \pm 9.4$  Nm) or at 1d ( $27.83 \pm 5.7$  vs.  $26.9 \pm 8.5$  Nm), 3d ( $38.35 \pm 6.7$  vs.  $34.69 \pm 10.2$  Nm), 7d ( $46.9 \pm 8.8$  vs.  $42.5 \pm 11.8$  Nm), or 10d ( $57.83 \pm 11.7$  vs.  $52.92 \pm 14.3$  Nm) post-exercise. In addition, there was no difference in SORE ( $p = .752$ ), CIRC ( $p = .535$ ), ROM ( $p = .539$ ), serum CK ( $p = .449$ ), serum glutathione ( $p = .967$ ), or serum IL-6 ( $p = .360$ ) at any time point. FFQ scores demonstrated that dietary antioxidant intake was not significantly different between groups ( $p = .054$ ).

**CONCLUSION:** A bout of eccentric forearm flexor resulted in a significant decrease in MIT values (>50% PRE MIT at POST) in both groups. Supplementation with NAC had no effect on recovery of MIT, SORE, CIRC, ROM, serum CK, serum IL-6, or serum glutathione at any time point following the exercise bout when compared to a P group. These results suggest that oral ingestion of NAC, at a dosage of  $10 \text{ mg}\cdot\text{kg}^{-1}\text{ bw}\cdot\text{d}^{-1}$ , has no effect on recovery of MIT following eccentric muscle injury. Supported by doctoral dissertation grant from Gatorade Sports Science Institute.

**Muscle Protein Metabolism In Neonatal Alloxan-administered Rats: Effects Of Resistance Training**

Carla Ribeiro, Lucieli Teresa Cambri, Fabricio de Azevedo Voltarelli, Rodrigo Augusto Dalia, Michel Barbosa de Araujo, Jose Diego Botezelli, Leandro Pereira de Moura, Maria Alice Rostom de Mello. *Sao Paulo State University, Rio Claro, Brazil.*

(No relationships reported)

Currently, it has been observed that type 2 diabetes mellitus (T2DM) changes the serum levels of several amino acids that may contribute to disturbances in insulin secretion and action. However resistance training has the potential for increasing muscle strength and lean muscle mass which could enhance functional status on muscle protein metabolism in the T2DM.

**PURPOSE:** Thus, this study aimed to examine the effects of resistance training on muscle protein metabolism in neonatal alloxan-administered rats.

**METHODS:** Alloxan was injected in newborn rats at 6 days of age ( $250 \text{ mg/kg bw}$ ). At 28 days of age, the animals were divided into sedentary alloxan (SA), sedentary control (SC), resistance trained alloxan (TA), resistance trained control (TC) groups. The resistance training protocol (T) consisted of four series of 10 jumps in the water in individual cylinder tanks (25cm diameter x 50 cm depth), one min interval between them, with an overload of 50% of b. w during 12weeks, 5days a week. At 120 days the animals were subjected to glucose tolerance test (GTT), analyzed by the total area under the serum glucose curve (AUC mg/dLx120min). After 48hs of the last test, all animals were killed for analysis of protein synthesis (pmol/mg.h) and degradation (pmol/mg.h) in the soleus muscle; DNA concentrations (mg/100mg) and DNA/protein ratio in the gastrocnemius muscle. Data were analyzed by 2- way ANOVA ( $p < 0.05$ ), followed by Newman-Keuls post hoc.

**RESULTS:** The AUC was higher in the SA and TA when compared to corresponding controls SC and TC (SA=14140  $\pm$  672 > SC=13064  $\pm$  683 TA=15234  $\pm$  657 > TC=14085  $\pm$  392). No differences in protein synthesis (SC=12.77  $\pm$  5.76 SA= 11.06  $\pm$  2.21 TC=15.32  $\pm$  2.73 TA=16.48  $\pm$  3.03) and protein degradation (SC=287.93  $\pm$  37.38 SA=350.56  $\pm$  90.71 TC= 281.26  $\pm$  127.88 TA= 305.11  $\pm$  124.13) in the soleus muscle among the groups were observed. The DNA concentrations were higher in the SC group than the TC group (SC=0.058  $\pm$  0.010 SA=0.053  $\pm$  0.013 TC= 0.037  $\pm$  0.013 TA= 0.043  $\pm$  0.016), whereas the DNA/protein ratio was higher in the resistance training groups (SC=108.02  $\pm$  27.80 SA=110.35  $\pm$  20.37 TC= 161.04  $\pm$  26.59 TA= 161.20  $\pm$  42.13).

**CONCLUSIONS:** It was concluded that resistance training sessions were effective in altering muscle growth by hypertrophy in alloxan-administered animals.

**Routine Practice of Yoga Effects Whole Body Protein Utilization in Middle-Aged Women**

Megan Colletto, Jose Rodriguez, Jeffrey DelFavero, Nancy Rodriguez, FACSM. *University of Connecticut, Storrs, CT.*

(No relationships reported)

Whole body protein turnover (WBPTO) reflects the balance between protein flux (Q), protein breakdown (PB) and protein synthesis (PS). The influence of routine yoga practice on WBPTO in middle-aged men and women has not been characterized.

**PURPOSE:** To determine differences in WBPTO between middle-aged (50-70 y) men and women who practice yoga and healthy sedentary controls.

**METHODS:** WBPTO, protein (g/d) and energy intake (cal/d) were determined in healthy middle-aged yoga practitioners (YOGA) and sedentary controls (CON). The 15N glycine method was used to measure WBPTO. Following the evening meal, subjects provided a spot urine sample for background enrichment of 15N glycine and then consumed the 2 mg/kg 15N glycine dose. Urine was collected overnight for 7-10 h and urinary 15N ammonia enrichment determined by IRMS at a commercial laboratory (Metabolic Solutions, Nashua, NH). Protein and energy intakes were estimated from 7 d diet records. Subjects estimated portion sizes with a food scale and visual guide. Records were verified by research assistants and analyzed using Nutritionist Pro software version 4.7.0 (Stafford, TX).

**RESULTS:** Data are presented as mean  $\pm$  SE. Age, weight and BMI were similar for YOGA ( $n=8$ ,  $58.2 \pm 1.5$  y,  $67.0 \pm 4.2$  kg, BMI =  $24.7 \pm 0.6$ ) and CON ( $n=11$ ,  $55.4 \pm 1.5$  y,  $73.7 \pm 4.8$  kg, BMI =  $26.3 \pm 0.8$ ). Components of WBPTO did not differ between YOGA and CON ( $p = 0.09$ ; Q:  $0.74 \pm 0.10$  vs.  $0.94 \pm 0.098$ ,  $p = 0.26$ ; PB:  $3.43 \pm 0.60$  vs.  $4.05 \pm 0.66$ ,  $p = 0.12$ ; PS:  $3.97 \pm 0.58$  vs.  $5 \pm 0.58$ ). For women only, Q and PS were lower for YOGA versus CON ( $p < 0.05$ ; Q:  $0.60 \pm 0.06$  vs.  $0.75 \pm 0.04$ ,  $p < 0.05$ ; PS:  $3.22 \pm 0.40$  vs.  $4.47 \pm 0.52$ ) while PB did not differ ( $p = 0.26$ ;  $3.43 \pm 0.60$  vs.  $4.05 \pm 0.66$ ). No group or gender specific differences were found for protein ( $81 \pm 6$  vs.  $91 \pm 8$ ) and calorie ( $1811 \pm 120$  vs.  $2077 \pm 626$ ) intake.

**CONCLUSIONS:** Findings suggest that protein turnover may be down regulated in middle-aged women who routinely practice yoga. Given the increased popularity of yoga, further research is warranted to characterize the protein related metabolic response of this alternative mode of exercise in middle-aged men and women as a potential strategy for maintenance of muscle mass with aging.

**Post-exercise Carbohydrate Plus Whey Protein Hydrolysates Supplementation Stimulates Muscle Protein Synthesis In Rats**

Atsushi Kanda<sup>1</sup>, Kyosuke Nakayama<sup>1</sup>, Tomoyuki Fukasawa<sup>1</sup>, Jinichiro Koga<sup>1</sup>, Kentaro Kawanaka<sup>2</sup>, Mitsuru Higuchi, FACSM<sup>3</sup>. *Meiji Co., Ltd., Saitama, Japan.*  
<sup>2</sup>Niigata University of Health and Welfare, Niigata, Japan. <sup>3</sup>Waseda University, Saitama, Japan.

(No relationships reported)

**PURPOSE:** Recent studies have shown that co-ingestion of carbohydrate and protein is more effective than ingestion of carbohydrate alone for stimulating muscle protein synthesis after exercise. However, it remains to be demonstrated which form of whey protein (intact protein, protein hydrolysates, or amino acids) is the most effective stimulator of protein synthesis and translation initiation in skeletal muscle. The aim of this study was to compare the effects of different forms of dietary whey protein on protein synthesis and translation initiation in skeletal muscle in the post-exercise phase.

**METHODS:** Male Sprague-Dawley rats, pre-trained for 3 days, swam for 2 hours. Immediately after the exercise, one of the following four isocaloric solutions was administered: carbohydrate (CHO); carbohydrate plus protein (intact whey protein [WPC], whey protein hydrolysates [WPH], or whey amino acid mixture [WAA]) ( $n = 8$ ). A bolus dose ( $45 \text{ mg/kg BW}$ ,  $22.5 \text{ mg/mL}$ ) of phenylalanine labeled with deuterium was injected via the tail vein 45 min after administration for the measurement of the protein fractional synthesis rate (FSR). One hour after administration, the triceps muscle was excised and quickly frozen. Subsequently, plasma insulin level, and protein synthesis and phosphorylated Akt/PKB in the triceps muscle were analyzed.

**RESULTS:** WPH caused significant increases ( $p < 0.05$ ) in FSR ( $6.93 \pm 0.10$  %/day), compared with WPC ( $6.01 \pm 0.23$  %/day), WAA ( $5.83 \pm 0.30$  %/day), or CHO ( $4.56 \pm 0.22$  %/day). Post-exercise ingestion of WPH or WPC caused significant increases ( $p < 0.05$ ) in plasma insulin (WPH,  $0.86 \pm 0.12$  ng/mL; WPC,  $0.83 \pm 0.07$  ng/mL) levels compared with CHO ( $0.44 \pm 0.06$  ng/mL). In contrast, there were no significant differences in the plasma insulin increase after WAA ingestion ( $0.63 \pm 0.12$  ng/mL) and CHO ingestion. Furthermore, the level of Akt/PKB phosphorylation was significantly higher ( $p < 0.05$ ) after WPH ingestion (164%) than after CHO ingestion, but not significantly different after WPC (140%), WAA (127%), and CHO ingestion.

**CONCLUSIONS:** It is concluded that post-exercise supplementation with WPH increases skeletal muscle protein synthesis better than post-exercise supplementation with WPC or WAA by activating key enzymes such as Akt/PKB.

1850 Board #258 MAY 30 3:30 PM - 5:00 PM

**Muscle Protein Balance with the Ingestion of a Protein Blend Following Resistance Exercise**

Paul T. Reidy<sup>1</sup>, Dillon K. Walker<sup>1</sup>, Jared M. Dickinson<sup>1</sup>, David M. Gundermann<sup>1</sup>, Micah J. Drummond<sup>1</sup>, Kyle L. Timmerman<sup>1</sup>, Christopher S. Fry<sup>1</sup>, Mark B. Cope<sup>2</sup>, Ratna Mukherjee<sup>2</sup>, Elena Volpi<sup>1</sup>, Blake B. Rasmussen<sup>1</sup>. <sup>1</sup>UTMB, Galveston, TX. <sup>2</sup>Solae, LLC, St. Louis, MO. (Sponsor: Elizabeth Protas, FACSM)  
(No relationships reported)

The ingestion of amino acids or protein following resistance exercise are necessary to produce a greater overall muscle protein net balance compared to exercise alone. Proteins such as whey are digested at a fast rate whereas soy and casein are digested at an intermediate and slow rate, respectively.

**PURPOSE:** To determine if the ingestion of a protein blend of soy, whey and casein would extend post-exercise muscle protein synthesis and reduce muscle protein breakdown resulting in an overall greater net protein balance as compared to whey.

**METHODS:** Twenty young adults participated in a double-blind, randomized clinical trial and ingested ~20g of a protein blend or ~20g of whey (N=10 per group) 1h after a bout of high-intensity leg resistance exercise. We utilized stable isotopic methods in conjunction with femoral catheterization to measure leg muscle protein synthesis and breakdown with the 2- and 3-pool mathematical models. Muscle biopsies (*vastus lateralis*) and blood samples were collected at baseline following an overnight fast and from 1-5h following exercise. As we are currently blinded to this ongoing trial, we report differences between the two beverages as Protein A and Protein B (data will be unblinded for presentation at the ACSM meeting).

**RESULTS:** With post-ex averages we found similar blood flow ( $3.4\pm 0.3$ ,  $3.6\pm 0.8$  ml/100g muscle/min) and amino acid delivery ( $219\pm 28$ ,  $195\pm 41$  nmol/100g muscle/min) to the muscle for Protein A and B, respectively ( $p>0.05$ ). Also, net phenylalanine balance across the leg increased from baseline to a similar extent ( $7.4\pm 1.8$ ,  $11.6\pm 3.3$  nmol/100g muscle/min) in both A and B, respectively ( $p>0.05$ ). Protein breakdown across the leg was reduced post-exercise with no differences between Protein A and B.

**CONCLUSION:** We conclude, from these preliminary data, that the ingestion of a protein blend affects the overall muscle protein anabolic response following resistance exercise to a similar extent compared to whey protein.

**Effect Of Protein Intake On Muscle Strength And Muscle Mass According To Physical Activity Level**

Marie-Eve Filion, Sebastien Barbat-Artigas, Marie-Eve Ringuet, Antony D. Karelis, Mylène Aubertin-Leheudre. *Université du Québec à Montréal, Montréal, QC, Canada.* (Sponsor: Jean P Boucher, FACSM)  
(No relationships reported)

**INTRODUCTION:** Several studies reported that muscle mass and strength play a key role in the maintenance of functional capacities with aging. Protein intake and physical activity appear to be important for maintaining muscle mass and strength. However, there is no clear recommendation concerning the needs in protein for elderly. Indeed, Vellas et al. have proposed 1.2 gr/kgBW/d for elderly instead of the Recommended Daily Allowance (RDA) of 0.8 gr/kgBW/d.

**PURPOSE:** The purpose of this study was to investigate the relationship between protein intake and muscle mass or muscle strength according to physical activity level among postmenopausal women.

**METHOD:** Seventy-two sedentary postmenopausal women aged between 50 and 75 years with a body mass index (BMI) between 20 to 35 kg/m<sup>2</sup> were recruited. Body composition (BIA), muscle strength (grip strength), physical activity level (Podometer), resting metabolic rate (RMR: Moxus) and dietary intake (Candat) were evaluated. Women were divided in 2 groups according to their protein intake (Prot+: > 1.2 g/kgBW/d; Prot-: < 1.2 g/kgBW/d).

**RESULTS:** No significant difference was observed for age, RMR and physical activity level between groups. Prot- group have significantly higher body weight, BMI and fat mass percentage. No differences for skeletal muscle mass and muscle mass index were noted between the 2 groups. However, Prot+ presents significantly higher handgrip (kg/BW;  $p<0.001$ ) and knee extensor strength (kg/BW;  $p<0.001$ ). Total calorie intake ( $p=0.002$ ), essential amino acid ( $p<0.001$ ) and non-essential amino acid intake ( $p<0.001$ ) were also higher in Prot+. Finally, Prot+ presented a significantly higher excessive energetic balance compared with Prot- ( $p=0.023$ ).

**CONCLUSION:** In conclusion, our results showed that high protein intake is associated with high muscle strength, independently of the physical activity level. Furthermore, a high protein intake seems to be associated with lower BMI and fat mass percentage, in spite of an excessive energetic balance. Thus, a protein intake of 1.2 gr/kgBW/d should probably be considered as a recommended daily allowance in elderly individuals. Future studies need to investigate the effect of a high protein intake combined with exercise interventions on muscle mass and muscle strength as well as their impact on functional capacities.

**Effectiveness Of Protein, Leucine And  $\beta$ -hydroxy- $\beta$ -methylbutyrate On Signaling Proteins Involved In Protein Synthesis And Degradation**

Wanyi Wang, Yi-Hung Liao, Ming Hsieh, Joowon Lee, Zhenping Ding, John L. Ivy, FACSM. *University of Texas at Austin, Austin, TX.* (Sponsor: John L. Ivy, FACSM)  
(No relationships reported)

Whey protein, which is high in leucine content, has been used extensively to stimulate protein synthesis. Leucine alone can stimulate protein synthesis by activating mTOR and its downstream proteins, whereas its metabolite  $\beta$ -hydroxy- $\beta$ -methylbutyrate (HMB) is able to attenuate protein degradation when provided chronically. However, the mechanisms of HMB's actions remain unclear.

**PURPOSE:** To investigate the effects of HMB on signaling pathways regulating protein synthesis and degradation. **METHOD:** Female rats were orally administered by vehicle, whey protein (187.5mg/kg), HMB (400mg/kg) or leucine (1.4g/kg). Blood was collected before, 45 min and 90 min after supplement administration. Gastrocnemius muscle was excised 90 min after supplement administration and fast-twitch red (RG) and white (WG) portions separated.

**RESULTS:** Blood glucose area under curve (AUC) for leucine was lower than all other treatments (vehicle  $-40.0\pm 167.5$ , protein  $-3.8\pm 176.9$ , HMB  $90.0\pm 164.0$  leucine  $-953.0\pm 113.3$  mg/dl  $\cdot 90$ min,  $p<0.05$ ). Insulin AUC for HMB was lower than vehicle, but it was higher for leucine (vehicle  $9.9\pm 7.2$ , protein  $-14.1\pm 6.6$ , HMB  $-28.5\pm 11.6$ , leucine  $16.5\pm 6.6$  ng/ml  $\cdot 90$ min,  $p<0.05$ ). Western blot analysis revealed that HMB increased Akt phosphorylation in RG (vehicle  $0.18\pm 0.03$ , protein  $0.17\pm 0.03$ , HMB  $0.28\pm 0.05$  leucine  $0.20\pm 0.03$  arbitrary units,  $p<0.05$ ). Both HMB and leucine increased phosphorylation of mTOR in RG (vehicle  $0.40\pm 0.08$ , protein  $0.39\pm 0.04$ , HMB  $0.65\pm 0.06$ , leucine  $1.06\pm 0.10$  arbitrary units,  $p<0.05$ ) and WG (vehicle  $0.34\pm 0.06$ , protein  $0.36\pm 0.02$ , HMB  $0.46\pm 0.03$ , leucine  $0.59\pm 0.06$  arbitrary units,  $p<0.05$ ), but the effect of leucine was stronger. Leucine also increased the phosphorylation of p70s6k and 4E-BP1 in both RG and WG, whereas HMB did not. Conversely, phosphorylation of FOXO3A was stimulated only by HMB (vehicle  $0.53\pm 0.09$ , Protein  $0.59\pm 0.09$ , HMB  $1.61\pm 0.24$  Leucine  $0.81\pm 0.08$  arbitrary units,  $p<0.05$ ).

**CONCLUSION:** Leucine appears to be an effective activator of signaling proteins involved in protein synthesis, whereas HMB appears to be involved in inhibiting protein related to protein degradation. These results suggest that supplementing with a combination of leucine and HMB could possibly increase protein synthesis and limit protein degradation thereby increasing protein accretion.

1853 Board #261 MAY 30 3:30 PM - 5:00 PM

**Whey Protein Supplementation Results in Greater Gains in Lean Body Mass Compared to Soy Protein during a Progressive 9-month Resistance Training Program**

Brittanie M. Volk, Erin E. Quann, Kevin D. Ballard, Brian R. Kupchak, Ana L. Gomez, William J. Kraemer, FACSM, Jeff S. Volek. *University of Connecticut, Storrs, CT.*  
(No relationships reported)

**PURPOSE:** Whey and soy are two quality protein sources used by athletes. Few studies have directly compared their ability to promote gains in lean body mass. We compared the effect of

daily supplementation with whey protein (WP) or soy protein (SP) on lean body mass responses to a 9-month progressive resistance training program

**METHODS:** Non-resistance trained men and women were randomized into a WP (n=19) or SP (n=22) group. The supplement provided ~22 g carbohydrate plus 21 g of either whey protein concentrate or soy isolate. All subjects participated in a supervised, whole-body non-linear periodized resistance training program for 9 months (3x/wk). Body composition was assessed every 3 months via dual x-ray energy absorptiometry (DXA).

**RESULTS:** Average daily protein intake, including the supplement, was 1.4 g/kg body weight. Despite consuming similar calories and protein during the intervention, gains in lean body mass were significantly greater in the WP (3.3 ± 1.5 kg) than the SP (1.8 ± 1.6 kg) group. There were no significant differences in body mass and fat mass responses between groups.

**CONCLUSION:** Whey protein supplementation was more effective than soy protein in promoting gains in lean body mass in response to chronic resistance training.

### **Effects Of Chocolate Milk And A Whey Protein Drink On Muscle Damage And Performance**

Jamie R. Fornal, Catherine G.R. Jackson, FACSM, Timothy R. Anderson, Felicia A. Greer. *California State University, Fresno, Fresno, CA.*

*(No relationships reported)*

**PURPOSE:** To compare muscle recovery effects of fat-free chocolate milk (CHOCM) and a chocolate whey protein drink mixture (CWPM) on performance and measures of muscle damage.

**METHODS:** Eight male recreational athletes (age 24 ± 4y; body mass 80.1 ± 12.5 kg; height 17.87 ± 0.66 m) completed three testing sessions after muscle damage, measured by elevated serum creatine kinase (CK) levels, was induced by a sprint protocol. On day one of each testing session, a standardized warm-up was followed by 15 X 30 meter sprints with a 10 meter deceleration zone leading to a complete stop with 60 second rest periods. CK and performance assessments [peak quadriceps isometric force (MVC), vertical jump (VJ), pro agility (PA), muscle soreness (MS), and Mental and Physical State and Trait Energy and Fatigue Scales (MPSTEFs)] were measured immediately after and at 48 and 96 hours post. Testing session 1 established baseline measures with no supplementation. In testing sessions 2 and 3, subjects received 2 cups of either CHOCM or CWPM post-exercise. Treatment beverages were isocaloric and given in a randomly counterbalanced double-blind protocol.

**RESULTS:** One-way ANOVA with repeated measures revealed no significant differences in sprint performances across tests, indicating no training effect over time (p>0.05). Individual univariate ANOVAs were used to analyze all other dependent variables. CK levels were clinically elevated (mean=517.13 U/L) above normal range (44-196 U/L) immediately following all sprint protocols indicating exercise-induced muscle damage. CK levels were highest 48 hours post (mean=603.92 U/L) and lowest 96 hours post (mean=444.61 U/L) exercise. When CK levels at 48 and 96 hours were compared, CHOCM (mean=400.94 U/L) levels were significantly lower (p<0.05) than CWPM (mean=448.93 U/L). There were no differences between CHOCM and CWPM for MVC, VJ, PA, MS, or MPSTEFs assessments (p>0.05).

**CONCLUSION:** These findings indicate that CHOCM attenuates elevated CK following exercise-induced muscle damage faster at 48 and 96 hours than CWPM. Although there were no significant differences found for performance variables, cellular level muscle recovery was enhanced. CHOCM may therefore lessen exercise-induced muscle damage if used chronically as a post-exercise drink.

### **Whey Protein Supplementation Exhibits Limited Additional Benefit in Older Men Undergoing Resistance Training**

Alan Hayes, Graeme J. Smith. *Victoria University, Melbourne, Australia.*

*(No relationships reported)*

The loss of muscle mass that occurs with age can be at least partially reversed by resistance training (RT). While whey protein isolate (WPI) supplementation has proven effective in augmenting the effects of RT in younger individuals, any benefit in older individuals is less established, as is any effect of WPI on the redox status of the cell in older individuals.

**PURPOSE:** To assess the effect of WPI supplementation in addition to 12 weeks RT on body composition, strength, and cellular redox status in older males.

**METHODS:** Male participants (aged >55 years, n=16) gave written, informed consent to be randomized, double-blinded, to undertake progressive overload RT (3 days/week for 12 weeks) either with (1.5 g/kg/day) or without WPI supplementation. Body composition, muscle strength and protein content, and redox status were measured before and after training. All procedures were approved by the Victoria University Human Research Ethics Committee.

**RESULTS:** No differences existed between the groups at baseline, with the exception that the group to be supplemented had a higher energy intake (2132 ± 239 vs 1728 ± 333 kcal/day, p<0.05) due to higher carbohydrate intake. As expected, 12 weeks RT significantly improved 1-repetition maximum muscle strength (129 ± 27 vs 186 ± 43 kg and 61 ± 25 vs 76 ± 22 kg in the leg press and bench press, respectively, p<0.001). Isometric and isokinetic knee extension and isokinetic knee flexion strength was similarly increased. In addition, highly significant (p<0.001) improvements in body composition (increased lean mass, decreased fat mass) were also observed. However, WPI supplementation demonstrated no incremental benefit in the above measures compared to RT alone. Total muscle protein content was not altered by RT, although there was a significant difference (p<0.05) in the change in the WPI group (+13.4 mg/g) compared to the change in the non-supplemented group (-10.9 mg/g). Plasma and tissue thiols and disulfides were unaffected by RT, nor were they changed by WPI supplementation.

**CONCLUSION:** WPI supplementation offered no incremental benefit over RT in novice older male participants in terms of body composition or muscle strength. Neither a 12-week RT program on its own, nor in combination with WPI dietary supplementation, altered the plasma or tissue redox states.

### **The Influence of Bovine Colostrum Combined with a Recovery Beverage During an 8-Week Resistance Training Program**

Fabrizio Gargiulo, Justin D. Roberts, Lindsay S. Kass, Michael G. Roberts. *University of Hertfordshire, Hatfield, United Kingdom.*

*(No relationships reported)*

Current research interest exists concerning the use of bovine colostrum (BC) supplementation to enhance strength and performance gains during high intensity training programmes. Furthermore, there is minimal information regarding the use of BC in combination with additional recovery formulas to enhance ergogenic benefits.

**PURPOSE:** To determine if combined supplementation of BC and a carbohydrate-protein recovery beverage (REC) enhances maximal strength performance and recovery during an 8-week resistance training programme.

**METHODS:** In a randomised, double blind, placebo controlled, repeated measures design, 24 healthy males volunteered for participation (Age: 26.8±7.4 years; Weight: 84.8±10.8 kg; Height: 179.9±4.8cm). Subjects were administered daily either 20g BC or a calorie matched placebo in the morning; additionally subjects consumed either a REC beverage or calorie matched placebo post-resistance training after each training session (3d.week-1) during the 8-week programme. Laboratory based measurements for 1-repetition maximum strength (1RM), body composition, plasma creatine kinase (CK), subjective muscle soreness (SMS) and muscular fatigue were assessed every 2 weeks.

**RESULTS:** 1RM squat strength performance improved by 35.6% in the placebo group over the 8 week programme, however, data for the BC/REC group was significantly greater in comparison (40.3%; p=0.006). 1RM bench press performance increased significantly amongst all groups across the 8 week programme (p=0.001), although no significant differences were found between groups (p=0.824). Total body composition, for both fat free mass and percentage body fat, was not

significantly altered across the 8-week programme. Additionally, CK (mean results for BC/REC; baseline - 75.5±24.8, week 8 -

82.3±54.7u.L-1) SMS and sub-maximal performance to fatigue was not found to be significantly influenced by the BC/REC supplementation intervention after 8-weeks.

**CONCLUSION:** Overall, recovery was not influenced by the supplementation intervention. It is however possible that elevated levels of insulin-like growth factors found in BC, could have influenced increases in muscle protein synthesis via mTOR pathways, resulting in increased strength performance but did not affect recovery from resistance exercise.

### Differences In Electromyography Activity Of Five Lower Limb Muscles During One-legged And Two-legged Squats

John K. Petrella, FACSM, Thomas G. Broussard, Jeremy R. Towns, Robert W. Hensarling, Alan P. Jung, FACSM. *Sanford University, Birmingham, AL*

(No relationships reported)

**PURPOSE:** Neuromuscular activation of the gluteal muscle group while executing the single-leg squat has been well studied. The electrical activity of other major muscle groups of the lower leg during single-leg squats is not as well known. The purpose of this study was to examine the electrical activity of the quadriceps, hamstrings, adductors, gastrocnemius, and tibialis anterior during a single-leg and double-leg squat.

**METHODS:** Eleven male intercollegiate athletes participated in the study. Electromyography (EMG) of the quadriceps, hamstrings, adductors, gastrocnemius, and tibialis anterior were recorded during 5 repetitions of dual-legged squats and single-leg squats. Participants performed the squat in time with a metronome such that each complete squat occurred in 2 seconds resulting in total of 10 seconds of activity for each trial. For the dual-leg movement, participants were instructed to squat until the thigh was parallel to the ground and then return to a standing position. Subjects then recovered for 3-5 minutes and performed five single-legged squats. These squats were completed while standing on a 17inch high bench with the dominant leg only. Participants were instructed to lower themselves until their non-dominant leg touched the floor, then return to a standing position using only the dominant leg. This movement was repeated 5 times at a cadence of 2 seconds per single-leg squat. All EMG activity was recorded, transformed, and reported as root mean square (RMS) activity.

**RESULTS:** Mean RMS EMG activity for the hamstring (.024 mV, 121% increase,  $p<0.01$ ) and gastrocnemius (.022 mV, 108% increase,  $p<0.01$ ) was significantly higher during the single leg squat compared to the dual-leg squat. There was also a trend for greater quadriceps activation (.013 mV, 29%,  $p=0.07$ ) with the single-leg movement. No differences were detected in adductor activity (.009 mV, 25%,  $p=0.42$ ) or tibialis anterior activity (.008 mV, 6%,  $p=0.48$ ).

**CONCLUSION:** These results suggest that single-leg squats result in greater lower limb activation for the same number of repetitions. These findings may be useful for developing rehabilitation or training techniques that focus on lower limb activation.

1858 Board #266 MAY 30 2:00 PM - 3:30 PM

### Comparison Of Unilateral Versus Bilateral Resistance Training On Absolute And Relative Strength

Kevin McCurdy<sup>1</sup>, George Langford<sup>2</sup>, Michael Doscher<sup>2</sup>, John Walker, FACSM<sup>1</sup>. <sup>1</sup>Texas State University, San Marcos, TX. <sup>2</sup>Valdosta State University, Valdosta, GA.

(No relationships reported)

**PURPOSE:** The purpose of this study was to determine whether a bilateral versus unilateral strength training program improved absolute and relative 1RM bilateral and unilateral squat performances in young adult males and females.

**METHODS:** Subjects were young adults ranging in age from 18-26. Subjects' 1RM bilateral and unilateral (each leg) squat were measured both prior to and following an 8 week resistance training program. Subjects were randomly assigned to either a bilateral or unilateral, lower-body training program utilizing the back and front squat and Romanian deadlift. The resistance training consisted of a linear periodization program with intensity increasing weekly from 60-95% while decreasing the volume.

**RESULTS:** A trial-by-gender interaction was also observed for both left- and right-leg squat, both absolute and relative to lean body mass. For left-leg squat ( $p=.002$ ), males improved from 174.7 to 220.3 lbs, while females only improved from 95.8 to 113.3 lbs. For left-leg squat strength/lbm ( $p=.01$ ), males improved from 2.55 to 3.34 lbs/lbm, while females only improved from 2.02 to 2.35 lbs/lbm. For right-leg squat ( $p=.002$ ), males improved from 174.6 to 220.4 lbs, while females only improved from 95.0 to 111.7 lbs. For right-leg squat/lbm ( $p=.01$ ), males improved from 2.55 to 3.34 lbs/lbm, while females only improved from 2.00 to 2.30 lbs/lbm. For bilateral squat, no gender difference in improvement was observed ( $p=.89$ ). Males improved from 296.8 to 331.8 lbs, while females demonstrated similar improvement, from 142.3 to 175.8 lbs. For bilateral squat/lbm, a trial-by-group interaction was observed ( $p=.004$ ). The bilateral-training group improved from 3.81 to 4.76 lbs/lbm, while the unilateral-training group only improved from 3.82 to 4.23 lbs/lbm.

**CONCLUSIONS:** These data suggest that bilateral resistance training is more effective for improving bilateral 1RM squat relative to lean body mass than unilateral resistance training; however, for unilateral 1RM squat performance, males show greater improvement than females, and bilateral training is equally effective compared to unilateral training.

1859 Board #267 MAY 30 2:00 PM - 3:30 PM

### Progression Of Core Muscle Activation During The Performance Of Exercises With Different Types Of Stability

Julio Martin, Sebastien Borreani, Juan Carlos Colado, Joaquin Calatayud, Fernando Martin, Joao Alves. *University of Valencia, Valencia, Spain.*

(No relationships reported)

Nowadays there is a lack of knowledge about the correct progression and application of the exercises during the core training, especially if it is necessary to choose between different devices.

**PURPOSE:** To compare core muscular activity during nine exercises performed in stable and unstable conditions using Thera-Band® devices. **METHODS:** 18 physically fit and healthy male subjects took part in a randomized, within-subject design assessment. The maximum isometric voluntary contraction (MIVC) was evaluated for the purpose of normalization. Lumbar erector spinae (LES), thoracic erector spinae (TES), lumbar multifidus (LM), thoracic multifidus (TM) and gluteus maximus (GM) muscular activities were recorded, and then the average root mean square values of all of them were calculated for each condition. Surface electromyography activity was analyzed during the central 16 seconds of 20 of the 9 isometric standing postures (140° and 60° of knee and hip flexion respectively), with the arms flexed parallel to the floor and always above the Thera-Band Exercise Station. Three positions: (a) bipodal, (b) unipodal and (c) unipodal with Thera-Band elastic tubings were performed in three conditions: (a) stable, (b) Thera-Band Soft Stability and (c) Thera-Band Rocker Board.

All values were expressed as the mean of the 5 muscles regarding %MIVC, they were compared using a mixed-model MANOVA with a post-hoc analysis of Bonferroni. Significance level was set at  $p\leq 0.05$ .

**RESULTS:**

Table 1. Average muscular activation comparisons between conditions (n=18).

| Device/conditions                           | Mean    | SEM  |
|---|---------|------|
| Stable/bipodal                              | 12.48   | 0.79 |
| Soft Stability/bipodal                      | 13.08   | 0.76 |
| Rocker Board/bipodal                        | 14.02   | 0.87 |
| Stable/unipodal                             | 14.28‡  | 0.95 |
| Soft Stability/unipodal                     | 15.08‡  | 0.89 |
| Rocker Board/unipodal                       | 15.15‡  | 0.93 |
| Stable/unipodal with elastic tubing         | 21.82*  | 1.30 |
| Soft Stability/unipodal with elastic tubing | 22.78*  | 1.40 |
| Rocker Board/unipodal with elastic tubing   | 23.38*† | 1.43 |

Data is expressed as a mean (SEM) in percentage of the MIVC.  
 \* indicates significant differences (p<0.05) related to bipodal and unipodal conditions without elastic tubings.  
 † indicates significant differences (p<0.05) related to stable condition.  
 ‡ indicates significant differences (p<0.05) related to bipodal condition.

**CONCLUSION:** In the evaluated exercises, the use of elastic tubings always provokes in a statistically significant way a higher level of muscular activation in the CORE independently of the unstable device used and/or of the modification of the support.

**1860 Board #268 MAY 30 2:00 PM - 3:30 PM**  
**Electromyographic Activation Of 3 Back Muscles During Pronated, Supinated, And Behind The Neck Pull-ups**

Vincent C. Marsh, Kelly Kirby, Cameron Allmandinger, Anthony Caterisano, FACSM. *Furman University, Greenville, SC.*  
 (No relationships reported)

Hand placement during upper back exercises is often varied to target or enhance recruitment of specific muscles and or muscle groups. However, little research has been published regarding the validity of these practices and claims.

**PURPOSE:** To analyze and compare the activation of three back muscles while performing three sets of pull-ups in different variations.

**METHODS:** Eleven resistance-trained, college males performed randomized trials of three different varieties of pull-ups for five repetitions each: supinated (SP), pronated (PP), and behind the neck pull-ups (BP). Electromyography (EMG) was used through the use of silver silver chloride surface electrodes positioned on the upper trapezius (TR), upper latissimus dorsi (UL), and lower latissimus dorsi (LL). EMG data were filtered, then quantified by integration, and expressed as a percentage of the total electrical activity of the three muscles.

**RESULTS:** A mixed design analysis of variance (ANOVA) and Tukey post hoc tests indicated no significant difference between total muscle activation and pull-up orientation (p = 0.992), the muscle activation consistently remained LL (45% MVC), UL (39%), and TR (16%MVC) throughout the trials.

**CONCLUSION:** While the results suggested that the latissimus dorsi provided a greater relative contribution than the trapezius throughout the three variations of pull-ups (p< 0.05), there were no significant changes to that ratio when hand placement was altered (p=.396).

**1861 Board #269 MAY 30 2:00 PM - 3:30 PM**  
**Lumbopelvic Muscular Activation During Push-ups Performed Under Different Unstable Surfaces**

Martin Fernando, Sebastien Borreani, Joao Alves, Juan Carlos Colado, David Gramage, Julio Martin. *University of Valencia, Valencia, Spain.*  
 (No relationships reported)

Suspension devices for physical conditioning have increased the work possibilities of the professionals that use devices that generate instability. Suspension training devices seem to have the same possibilities as the rest of the unstable devices during the performance of global exercises, as for example the push-ups. However, there is no agreement in the current studies.

**PURPOSE:** To compare lumbopelvic muscular activation during push-ups performed in five different unstable conditions.

**METHODS:** 30 physically fit and healthy subjects took part in a counterbalanced, within-subject design assessment. Muscular activation was evaluated in muscles Multifidus Lumbar (MFL), Erector Espinae Thoracic (EED), External Oblicue (OE), and Rectus Femoris (RF), during execution of 5 push-ups in different stability conditions: TRX Suspension Training (TRX), Fitness Dome (FD), Thera-Band® Stability Disc (SD), Thera-Band® Wobble board (WBR) and floor (CE). Surface electromyography was recorded and then the peak root mean square values were calculated for each condition and execution. The maximum isometric voluntary contraction (MIVC) was evaluated for the purpose of normalization. All values, expressed as the %MIVC, were compared using a mixed-model MANOVA with a post-hoc analysis of Bonferroni. Significance level was set at p<0.05.

**RESULTS:** Table 1. Peak muscular activation between conditions (n= 30).

|     | OE              | MFL           | EED          | RF            |
|-----|-----------------|---------------|--------------|---------------|
| CE  | 154.16(26.59)   | 8.01(1.64)    | 79.11(26.61) | 23.17(2.36)   |
| WBR | 144.24(20.90)   | 9.78(2.73)    | 80.86(28.94) | 21.49(1.89)   |
| SD  | 212.18(36.98)†  | 8.70(1.88)    | 64.09(20.86) | 27.96(3.16)†  |
| FD  | 192.69(40.78)   | 8.64(2.28)    | 65.71(22.81) | 25.75(2.68)   |
| TRX | 331.56(40.60)†‡ | 16.76(3.37)†‡ | 58.09(11.64) | 38.80(3.41)†‡ |

\*Data is expressed as mean (standard error) regarding the % of maximum voluntary isometric contraction.  
 TRX= TRX Suspension Training; FD=Fitness Dome; SD= Stability Disc; WBR= Wobble board;  
 CE= floor.  
 OE= External Oblicue; MFL= Multifidus Lumbar; EED= Erector Espinae Thoracic; RF= Rectus Femoris.  
 † indicates significant differences (p<0.05) related to WBR.  
 ‡ indicates significant differences (p<0.05) related to CE, SD, FD.

**CONCLUSION:** Push-ups performed with TRX provoke more lumbopelvic muscular activation than employing other unstable devices and/or stable condition. There were no differences between the other conditions (unstable and stable) except in the OE and RF where the muscular activation was higher with the SD versus the WBR.

1862 Board #270 MAY 30 2:00 PM - 3:30 PM

**Effects of Stance Width on Hip Displacement during Parallel Squat in Women**

Leeanna Woodworth, Kyra Marshall, George J. Davies, Bryan L. Riemann, *Armstrong Atlantic State University, Savannah, GA.* (Sponsor: T. Jeff Chandler, FACSM)  
(No relationships reported)

While sagittal plane kinematics and kinetics have been compared between squats of varying stance widths, limited research has considered the frontal and transverse planes.

**PURPOSE:** To examine effects of stance width on frontal and transverse plane hip kinematics, total body center of mass (COM) vertical displacement and to examine the relationships between hip kinematics and hip abductor (AB)/external rotator (ER) isometric muscle strength (IsoM).

**METHODS:** 18 healthy, physically active young women (21.6±2.6 yrs) performed 8 repetitions of squats using both neutral stance (NS) and wide stance (WS) using a load equal to each subject's 8 repetition maximum. Neutral stance was 1.5x anterior superior iliac spine (ASIS) distance and wide stance was 2.5x ASIS distance. Dominant limb frontal and transverse plane hip kinematic data was collected using an extended range electromagnetic motion analysis system (Motion Monitor, IST, Inc). Starting, peak and start to peak displacement abduction/adduction and internal/external rotation angles were computed. Dependent t-tests ( $\alpha=.05$ ) were used to compare dependent variables between NS and WS. Hip AB and ER IsoM strength was evaluated using hand held dynamometry. Pearson correlational analyses were conducted between peak/displacement angles and AB/ER IsoM strength.

**RESULTS:** COM vertical displacement was significantly ( $P<.001$ ) greater for NS. During WS, both starting ( $P<.001$ ) and peak ( $P<.001$ ) AB angles were significantly greater, however, no difference for angular displacement ( $P=.332$ ). Additionally, during WS, the hip started with significantly greater ER ( $P=.047$ ). The peak internal rotation angle ( $P<.001$ ) and displacement ( $P<.001$ ) were also significantly greater for WS. No significant correlations ( $r=.016$  to  $.183$ ) were noted between peak and displacement angles and IsoM strength.

**CONCLUSION:** Despite greater squat depth based on the COM displacement for NS, the hip joint experienced increased abduction/internal rotation during WS squats. Thus, NS squats should be considered when less abduction and internal rotation is warranted. As evidenced by no significant relationships, IsoM strength of hip AB and ER do not appear to be a contributing factor to frontal and transverse plane hip movement during squats.

1863 Board #271 MAY 30 2:00 PM - 3:30 PM

**Isometric Rapid Torque Characteristics As Predictors Of Playing Status In Division I Collegiate Football Players**

Brennan J. Thompson<sup>1</sup>, Eric D. Ryan<sup>2</sup>, Eric J. Sobolewski<sup>2</sup>, Doug B. Smith<sup>1</sup>, Eric C. Conchola<sup>1</sup>, Kaz Akehi<sup>1</sup>, Tyler Buckminster<sup>1</sup>, Joel T. Cramer, FACSM<sup>1</sup>.

<sup>1</sup>Oklahoma State University, Stillwater, OK. <sup>2</sup>University of North Carolina - Chapel Hill, Chapel Hill, NC.

(No relationships reported)

**INTRODUCTION:** Rapid torque characteristics are an important measure of muscle performance and may provide a sensitive measure for talent identification in collegiate football players.

**PURPOSE:** To examine the effectiveness of maximal isometric strength and rapid torque characteristics to discriminate among football playing ability in elite Division I collegiate football players.

**METHODS:** Sixteen starters (age=20.81±1.28 yr) and 15 non-starters (20.40±1.68) volunteered to participate in the study. Participants performed two isometric maximal voluntary contractions (MVCs) with the leg flexor and extensor muscle groups with one minute of recovery between each contraction and three minutes of recovery between muscle groups. Peak torque (PT; Nm) was calculated as the highest 0.5 s epoch of the torque - time curve. Rate of torque development (RTD; N·sec<sup>-1</sup>) and contractile impulse (IM; N·m·s) were determined from the time intervals of 0-30, 0-50, 0-100, and 100-200ms of the torque - time curve. Peak rate of torque development (PRTD), time to PRTD (TTPRTD) and absolute torque (TORQUE at 30,50,100 and 200ms) were also calculated. 2-way mixed factorial ANOVAs were used to analyze all torque - time variables. Follow up analyses included independent samples t-tests and paired samples t-tests with Bonferroni-corrected post-hoc comparisons.

**RESULTS:** For the leg flexors, RTD30, IM30, IM50 and TORQUE30 were greater ( $P=0.02-0.03$ ) and TTPRTD was shorter ( $P=0.02$ ) for the starters when compared to the non-starters. There were no significant differences between starters and non-starters for maximal isometric PT, RTDpeak, and later rapid torque characteristics (>100 ms from onset of contraction) of the leg flexors and all isometric torque and torque - time variables for the leg extensors ( $P=0.06-0.33$ ). In addition, the leg extensors were greater ( $P<0.001$ ) for all torque and rapid torque variables and less for TTPRTD when compared to the leg flexors for all players.

**CONCLUSIONS:** These findings showed that early rapid torque - time variables of the leg flexor muscle group may effectively discriminate among playing ability in Division I collegiate football players. Strength coaches may consider designing strength programs aimed at maximizing early rapid muscle contraction characteristics, specifically for the leg flexors.

**Neuromuscular and Metabolic Responses to Power Training: Effects of Different Rest Intervals**

Saulo Martorelli<sup>1</sup>, André Martorelli<sup>1</sup>, Rafael Cunha<sup>1</sup>, Maria Cláudia Pereira<sup>1</sup>, Diego Jesus<sup>1</sup>, Valdinar Rocha Júnior<sup>2</sup>, Lee E. Brown, FACSM<sup>3</sup>, Martim Bottaro<sup>1</sup>. <sup>1</sup>University of Brasília, Brasília, Brazil. <sup>2</sup>National Academy of Police (Federal Police), Brasília, Brazil. <sup>3</sup>California State University, Fullerton, Fullerton, CA.

(No relationships reported)

The between-set rest interval (RI) is an important factor in the resistance training prescription. The American College of Sports Medicine (ACSM) recommends at least 2-3 min of RI for individuals who perform power training for core exercises. However, according to the ACSM (2009) this recommendation is based on poor scientific evidence (evidence category D).

**PURPOSE:** To compare the effects of three different RI on mean power output (PW), blood lactate concentration (BLa), and electromyography (EMG) in trained men.

**METHODS:** Fourteen healthy men (22.43 ± 3.01 years) performed six sets of six repetitions of squat exercise at 60% of 1RM on a Smith machine. Each volunteer performed three different RI protocols (1, 2 and 3 min) on three different days in counterbalanced order, separated by at least 72 h. PW was measured every set using a velocity transducer. BLa concentration and vastus medialis (VM) EMG (maximum isometric voluntary contractions) were measured before and after the 6 sets of each RI.

**RESULTS:** No significant differences were observed between RI protocols on PW. However, the 1min RI protocol showed a significant ( $p \leq 0.05$ ) reduction (9.90%; 488.05 ± 112.48 to 439.75 ± 91.60 W) in PW from 1<sup>st</sup> to 6<sup>th</sup> set. In contrast, no significant reduction was observed between the 1<sup>st</sup> and 6<sup>th</sup> sets for 2 min (0.04%; 477.83 ± 123.44 to 477.62 ± 97.60 W) or 3 min (4.32%; 488.69 ± 118.67 to 467.59 ± 98.82 W) RI protocols. BLa was significant greater ( $p \leq 0.05$ ) after 1 min (5.67 ± 1.71 mmol/L) when compared to 2 min (4.59 ± 1.51 mmol/L) and 3 min (4.00 ± 2.47 mmol/L). Only the 3 min RI presented a significant reduction in root mean square (RMS) values of the VM EMG (27.10 ± 4.06 to 21.64 ± 3.31).

**CONCLUSION:** Our data suggest that 1 min RI showed greater decline in muscular performance and greater levels of fatigue metabolic by products. Also, after 3 min, muscle activation was less at the end of the training session. In summary, if an individual wants to maintain power output with less fatigue and greater muscle activation during power training, 2 min RI should be used. These results concur with ACSM (2009) recommendations that a RI of at least 2 min should be used when young individuals are training muscle power using multi-joint exercise.

1865 Board #273 MAY 30 2:00 PM - 3:30 PM

**The Effect of Remote Voluntary Muscle Contractions on Strength and Power Performance**

Daniel Haughney, Nabil Boutagy, Robert M. Otto, FACSM, John W. Wygand, *Adelphi University, Garden City, NY.*

(No relationships reported)

In an effort to maximize muscular performance from a specific muscle group, the simultaneous recruitment of ancillary muscle groups has been proposed. This theory of remote voluntary contractions (RVC) suggests that concurrent activation of remote muscle groups, in addition to the prime movers, may stimulate enhanced sympathetic drive in proximity to the control center of the brain and potentially improve performance. Several studies (Hiroshi, et al., Ebben et al. and Ebben) have demonstrated improvements in time to peak force and rate of force development when using jaw clenching to activate RVC.

**PURPOSE:** This study was designed to examine the effects of RVC by jaw clenching with a mouthpiece (MP) and with the jaw in a relaxed state without a mouthpiece (R-noMP) on acute muscular performance.

**METHODS:** Thirteen subjects (10 males and 3 females, age  $22.9 \pm 1.9$  yrs, ht  $174.2 \pm 9.1$  cm, body mass  $77.3 \pm 14.6$  kg) volunteered to perform a grip dynamometer test with a Jamar Grip Dynamometer (Gr), a Vertical Jump Test (VJ), a 6 repetition maximum (RM) chest press (CP) and a 6 RM leg extension (LE) on Nautilus equipment. Subjects performed familiarization trials and the MP and R-noMP trials were conducted in a random design. A paired-samples t-test ( $p < 0.05$ ) was applied to these data.

**RESULTS:** Statistical analysis revealed no significant difference between MP vs R-noMP for grip strength (35.6 vs 35.5 kg), vertical jump (40.6 vs 40.9 cm), 6 RM chest press (47.5 vs 47.4 kg) and 6RM leg extension (44.4 vs 44.1 kg), respectively.

**CONCLUSION:** The use of RVC by jaw clenching failed to amplify the outcome measures of four acute muscular strength and power measures. Therefore the use of RVC to enhance acute anaerobic performance is not supported.

### Upper Extremity And Core Muscle Activation During An Aquatic Resistance Exercise Performed At Different Depths

Sebastien Borreani, Juan Carlos Colado, Josep Furio, Fernando Martin, Juan Benavent, Joaquin Madera. *University of Valencia, Valencia, Spain.*

(No relationships reported)

It is positive to train the strength of the limb and core to improve the physical performance. The aquatic medium has been shown as an efficient tool, however nowadays there is a lack of knowledge about the influence of the level of immersion on muscle activation.

**PURPOSE:** To compare upper extremity and core muscle activation during a shoulder extension performed at maximal velocity at different depths (xiphoid vs clavicle). **METHODS:** 24 physically fit and healthy subjects took part in a counterbalanced, within-subject design assessment. Maximum isometric voluntary contraction (MIVC) was evaluated for the normalization. Agonist: latissimus dorsi (LD); and core: rectus abdominis (RA) and lumbar erector spinae (LES) muscular activities were recorded, and then the peak root mean square values of all of them were calculated for each condition. Surface electromyography was isolated and the activity was analyzed during the shoulder extension of 3 repetitions performed with an aquatic device that increases drag force moved at maximal velocity. All values, expressed as the %MIVC, were compared using a mixed-model MANOVA with a post-hoc analysis of Bonferroni. Significance level was set at  $p \leq 0.05$ .

#### RESULTS:

|                | LD           | RA            | LES         |
|----------------|--------------|---------------|-------------|
| Xiphoid depth  | 73.0 (10.3)* | 114.9 (30.3)* | 36.0 (12.1) |
| Clavicle depth | 61.9 (9.9)*  | 92.8 (27.3)*  | 41.5 (11.6) |

Data is expressed as a mean (SEM).  
\* indicates significant differences between conditions ( $p \leq 0.05$ )  
LD= Latissimus Dorsi, RA=Rectus abdominis, LES=Lumbar Erector Spinae

**CONCLUSION:** Xiphoid depth condition generates significantly a higher LD and RA activation than clavicle depth. This shows that a lower level of immersion provokes a higher muscular activation because the body stability is increased during the performance of the movement. However, this fact is not relevant for the LES due to the direction of the movement of the upper extremity. These results are similar to previous studies in dry land. Consequently, monitoring the level of immersion is very important during the aquatic resistance exercises.

### Effects of Squat Flywheel Training on Strength, Muscle Structure and Performance.

Giuseppe Coratella<sup>1</sup>, Gianluca Giorgi<sup>1</sup>, Impellizzeri Franco<sup>2</sup>, Federico Schena<sup>1</sup>. <sup>1</sup>University of Verona, Verona, Italy. <sup>2</sup>Schultess Klinik, Zurich, Switzerland.

(No relationships reported)

**PURPOSE:** Inertial flywheel device (YoYo Technology) is well known to induce strength adaptations and increase muscle mass after short term training. (Norrbrand 2011, Tesch 2004). Changes in muscle architectural parameters appropriate to improve peak torque has been described (Seynnes, 2007). However these adaptations were not directly related to specific performances like jump, velocity and change direction ability. Aim of the study is to evaluate quadriceps strength and architecture, lower limb fat free mass, and performance parameters after short term YoYo squat training.

**METHODS:** 31 healthy young males has been randomly assigned at training (TR) or control (CON) group. TR underwent 16 training sessions in 9 weeks each consisting in 60 maximal reps at YoYo squat. Maximal Voluntary Contraction (MVC), Fat Free Mass (FFM), Fascicle length and thickness, Squat Jump (SJ) and Countermovement Jump (CMJ) Height and time on 30m dash and 20m shuttle have been measured pre and post training. Analysis of covariate has been done after log transformation.

**RESULTS:** Compare to CON, TR showed higher MVC isometric (avg 25%, CI 95 13% to 38%), concentric (10%, 2% to 19%), eccentric (9%, 2% to 17%) extension (for each parameters,  $p < 0.01$ ). In TR, FFM (4%, 1% to 7%), fascicle length (8%, 1% to 16%), fascicle thickness (6%, 1% to 15%) increased compare to CON ( $p < 0.01$ ). SJ (9%, 2% to 16%), CMJ (8%, 1% to 14%), 20m shuttle (-4%, -7% to -1%) significantly improve ( $p < 0.05$ ) in TR compare to CON. 30m dash did not improve significantly compare to CON (-1%, -4% to 2%,  $p = 0.445$ ), indicating that 20m shuttle performance is specially due by an augmented control of decreasing and increasing speed.

**CONCLUSION:** Augmented strength and changed muscle structure are in agreement with previous study. Longer fascicle is correlated with higher velocity of sarcomere contraction (Blazevich 2006). Outcomes show positive transfers in sport performance tasks, like jumping or braking and change sprinting direction. Flywheel device can be successfully used to improve performance in sport in which jumping or speed are key factors.

### Effect of Exercise with Blood Flow Restriction Depends on Total Work Regardless of Mechanical Intensity

Shingo Takada<sup>1</sup>, Koichi Okita<sup>2</sup>, Masashi Omokawa<sup>2</sup>, Tadashi Suga<sup>1</sup>, Noriteru Morita<sup>3</sup>, Masahiro Horiuchi<sup>4</sup>, Tomoyasu Kadoguchi<sup>1</sup>, Takashi Sato<sup>2</sup>, Masashige Takahashi<sup>1</sup>, Arata Fukushima<sup>1</sup>, Tsuneaki Homma<sup>1</sup>, Yoshihiro Masaki<sup>1</sup>, Shintaro Kinugawa<sup>1</sup>, Hiroyuki Tsutsui<sup>1</sup>. <sup>1</sup>Hokkaido University Graduate School of Medicine, Sapporo, Japan. <sup>2</sup>Hokusho University, Ebetsu, Japan. <sup>3</sup>Hokkaido University of Education, Iwamizawa, Japan. <sup>4</sup>Northern Regions Lifelong Sports Research Center (SPOR), Ebetsu, Japan.

(No relationships reported)

**BACKGROUND:** Resistance exercise with blood flow restriction (BFR) is a new training method providing significant training effects despite the use of low-intensity mechanical loads. We previously demonstrated that BFR remarkably enhances muscular metabolic stress in resistance exercise (*J Appl Physiol* 2009) and that the metabolic stress was effectively enhanced by increasing mechanical intensity but not BFR pressure (*J Appl Physiol* 2010). However, because of blocking the metabolic recovery by BFR, it is possible that even with low intensity, metabolic stress might gradually increase with respect to increased repetitions and reach sufficient level.

**PURPOSE:** Therefore, we compared muscular metabolic stress during multiple intensity resistance exercise with BFR adjusted by totally the same work volume (load  $\times$  repetitions).

**METHODS:** Twenty-six young subjects (male/female, 13/13,  $21 \pm 1$  yrs, means  $\pm$  SE) were recruited and performed unilateral plantar-flexion at 30 repetitions/min in a whole body magnetic resonance system. The exercise protocols were as follows: (A) exercise with 10% of one repetition maximum (1-RM) for 6 min, (B) 15% 1-RM for 4 min, (C) 20% 1-RM for 3 min, (D) 30%

1-RM for 2 min, and (E) 40% 1-RM for 1.5 min. All protocols were same in total work volume (load × repetitions=1800). Muscular metabolic stress in the calf muscle, defined as phosphocreatine and intramuscular pH decrease were evaluated by using 31P-magnetic resonance spectroscopy.

**RESULTS:** Phosphocreatine depletion (A: 15.6±0.7, B: 14.8±0.8, C: 15.2±0.6, D: 14.3±0.6, E: 10.9±0.5 mM, ns) and intramuscular pH decrease (A: 6.82±0.02, B: 6.84±0.01, C: 6.83±0.02, D: 6.83±0.02, E: 6.77±0.02, ns) at the end of each exercise protocol were statistically similar.

**CONCLUSIONS:** If the total exercise volume calculated as a product of mechanical load multiplied by repetitions were equal, metabolic stress in exercising muscle might achieve the similar level at the end of exercise with BFR and could provide similar training effects.

Supported by JSPS KAKENHI (23500784) and Hokusho University Northern Regions Lifelong Sports Research Center (SPOR).

### Optimizing Resistance During Multiple-set Weight Training to Increase Training Volume in Women

Young Sub Kwon<sup>1</sup>, Suzanne M. Schneider<sup>2</sup>. <sup>1</sup>Washburn University, Topeka, KS. <sup>2</sup>University of New Mexico, Albuquerque, NM.

(No relationships reported)

We previously reported that a greater training volume is attained using descending resistance (DR) method than using a constant resistance (CR) method in men.

**PURPOSE:** When a resistance-trained person performs multiple sets with short or incomplete rest periods between sets, the resistance must be reduced to maintain the same number of reps until fatigue or, the number of reps will be reduced if the same resistance is used. There is no benchmark method for optimizing resistance to maximize training volume in women when training with multiple sets with short rest periods. In this study we hypothesized that a greater training volume (sets × reps × resistance) would be produced using a training protocol where resistance is decreased with each training set (DR) based on the subject's fatigue ratio (using an individualized regression equation) vs. during a training protocol where subjects use a constant resistance (CR), and the number of repetitions declines with each set in women.

**METHODS:** Ten female subjects (mean±SD, age = 26±6 yr, height = 164±7 cm, body mass = 59±7 kg, weight training experience = 6±2 yr) completed 4 sets of 65% 1RM leg press, 75% 1RM bench press and 85% 1RM seated row exercise to failure, with 30 second (for 65%), 90 second (for 75%) and 180 second (for 85%) rest intervals. Data were analyzed using paired sample t-tests.

**RESULTS:** There was a greater training volume ( $p < 0.01$ ) when subjects exercised with decreased load sets compared to training with same load sets at all three exercises (table 1).

**CONCLUSIONS:** In women as previously shown in men, a greater training volume is also attained using this DR method based on subject's fatigue ratio than when using a CR training method suggesting this may be a more effective training method.

Table 1. Training volumes (kg, sets × reps × resistance) completed during 4 set exercises.

| Training Method | 65% Leg Press | 75% Bench Press | 85% Seated Row |
|-----------------|---------------|-----------------|----------------|
| CR              | 11908 ± 1452  | 1330 ± 365      | 400 ± 79       |
| DR              | 13754 ± 1403  | 1621 ± 376      | 472 ± 50       |
| Significant     | < 0.01        | < 0.01          | < 0.01         |

### The Influence of Body Weight and Strength Fitness Status on Markers of Cardiometabolic Health

Mary M. Lee, Christopher S. Oh, Michael Katirae, Christian K. Roberts, FACSM. UCLA, Los Angeles, CA.

(No relationships reported)

**PURPOSE:** We have previously demonstrated that overweight untrained (OU), overweight trained (OT) and lean trained (LT) young men with differing muscle strength levels exhibit differences in body composition and indices of vascular health, independent of body weight. We examined the influence of body weight vs. training status on blood markers of cardiometabolic health including blood lipids, steroid hormones, inflammation and adipokines in this cohort.

**METHODS:** 90 young adult males were categorized into 3 groups: OU (n=30, BMI 30.8±2.1 kg/m<sup>2</sup>), OT (n=30, BMI 29.2±2.2, ≥4 d/wk resistance training (RT)) and LT (n=30, BMI 23.7±1.4, ≥4 d/wk RT). Subjects were assessed for serum glucose, lipids (including total-cholesterol, LDL, HDL, TG, oxLDL), hormones (testosterone, SHBG, free androgen index (FAI), cortisol), inflammation (CRP, TNF-α, IL-8, MCP-1), and adipokines (amylin, leptin, adiponectin).

**RESULTS:** BMI and body weight were similar in OT and OU and both higher than LT (all  $P < 0.0001$ ). Fasting glucose was lowest in LT and significantly different from OU and OT (all  $P < 0.007$ ). LT and OT exhibited higher HDL, lower TG, and lower oxLDL than OU (all  $P < 0.001$ ). LDL was significantly lower in LT vs. OU and OT showed a trend of lower LDL ( $P = 0.08$ ) vs. OU. Similarly, both trained groups had elevated SHBG (OT: 30.0±13.5, LT: 35.0±10.8 nmol/L) and lower FAI (OT: 71.2±29.0, LT: 64.2±20.0) compared to OU (15.6±5.6 nmol/L; 116.0±45.6) (all  $P < 0.0001$ ). Testosterone was highest in LT (622.8±194.9 ng/dL) and significantly different from OU (476.6±112.6,  $P < 0.002$ ) while values for OT (544.1±160.6) were nominally higher than OU ( $P < 0.09$ ). CRP (OT: 1.3±2.8, LT: 1.3±3.7 mg/L) was lower in the trained groups compared to OU (2.5±3.5, all  $P < 0.02$ ), while IL-8 was lower in LT (65.1±82.4 pg/mL) but not OT (49.3±46.3) compared to OU (67.7±173.7,  $P = 0.02$ ). Additionally, amylin (23.3±13.4 pM) and leptin (766.5±731.9 pM) were significantly higher in OU compared to OT (13.4±8.6; 311.0±406.1) and LT (9.7±3.4; 90.3±91.0, all  $P < 0.004$ ), while adiponectin was significantly lower in OU (3.2±1.4 ng/mL) compared to OT (5.7±3.4) and LT (6.0±3.3, all  $P < 0.003$ ).

**CONCLUSION:** These results provide further evidence that fitness, in this study as assessed by muscular strength, is a better predictor of metabolic health compared with body weight *per se* in young men.

**1871** Board #279 **MAY 30** **2:00 PM - 3:30 PM**

### Acute Effects Of Lower Body Aerobic Exercise On Lower And Upper Body Resistance Exercise Workouts

Jeremy G. Tan, Jared W. Coburn, FACSM, Daniel A. Judelson, FACSM, Lee E. Brown, FACSM, Bryan Barsaga, Joseph R. Morales, Andrea M. Du Bois, Garrett C. Nelson, Vanessa L. Cazas, Leah Truong. California State University Fullerton, Fullerton, CA.

(No relationships reported)

**PURPOSE:** It's been suggested that performance of an acute lower body aerobic exercise bout negatively affects a subsequent lower body resistance exercise workout. The effects of lower body aerobic activity on an upper body resistance exercise workouts is unknown. Therefore, the purpose of this study was to compare lower and upper body resistance exercise workout responses following acute bouts of lower body aerobic exercise on an elliptical machine.

**METHODS:** Twelve men (mean ± SD age = 24.1 ± 2.3 y, height = 180.8 ± 6.9 cm, body mass = 91.9 ± 16.4 kg) volunteered for this study and completed four trials in random order. Two trials consisted of thirty minutes on the elliptical machine at 70% of age-predicted maximum heart rate prior to either a back squat (ES) or bench press (EB) workout, consisting of three sets to failure performed at 75% 1RM. The other two trials consisted of only the back squat (SO) or bench press (BO) resistance workouts.

**RESULTS:** The results indicated that an acute bout of aerobic exercise on an elliptical machine significantly reduced the number of repetitions completed for the back squat (ES = 24.8 ± 5.0 repetitions; SO = 28.5 ± 5.1 repetitions), but not bench press (EB = 25.6 ± 5.2 repetitions, BO = 26.0 ± 6.3 repetitions) exercise.

**CONCLUSIONS:** The performance of an acute bout of lower body aerobic exercise reduces the number of repetitions completed during a subsequent lower body, but not upper body, resistance training workout. These results suggest that in order to optimize the quality of a resistance training workout, the workout should not be preceded by an aerobic exercise bout using the same muscle groups.

1872 Board #280 MAY 30 2:00 PM - 3:30 PM

**The Effects of Load on Lower-Body Joint Power Output during Jump Squats**

Gavin L. Moir, Jared M. Gollie, Chad A. Witmer, Shala E. Davis, FACSM. *East Stroudsburg University of Pennsylvania, East Stroudsburg, PA.*  
(No relationships reported)

Previous researchers have investigated the loads that maximize power output of the system ( $PO_{system}$ ) during jump squats (JS). However, it is unclear how different loads affect the power output at the lower-body joints ( $PO_{joint}$ ) during JS.

**PURPOSE:** The purpose of this study was to investigate the effects of different loads on  $PO_{system}$  and lower-body  $PO_{joint}$  during JS.

**METHODS:** Twelve men ( $21.2 \pm 2.7$  yr;  $1.83 \pm 0.06$  m;  $97.7 \pm 12.5$  kg; back squat 1RM:  $181.8 \pm 40.4$  kg) performed JS under seven different loading conditions: 0, 12, 27, 42, 56, 71, 85% of maximal dynamic strength (MDS). The order of the loads was counterbalanced and the loads were achieved by having the subjects jump with a plastic bar (0% MDS) or a loaded barbell held on the shoulders. JS were performed on two force platforms synchronized with a 3D motion analysis system, both sampling at 200 Hz. Instantaneous  $PO_{system}$  was calculated as the product of the vertical component of the ground reaction force and the vertical velocity of the bar during its ascent. Instantaneous  $PO_{joint}$  was calculated as the product of the joint moment and joint angular velocity during bar ascent for the hip, knee and ankle joints in the sagittal plane. Both  $PO_{system}$  and  $PO_{joint}$  were averaged during bar ascent to provide average power output. The data were analyzed using a one-way ANOVA with repeated measures.

**RESULTS:**  $PO_{system}$  was maximized at 0% MDS ( $p < 0.001$ ) with polynomial contrasts showing a significant linear trend ( $p < 0.001$ ) caused by  $PO_{system}$  decreasing as the load increased. Similar findings were found for the knee and ankle power output, with  $PO_{joint}$  being maximized at 0% MDS ( $p < 0.001$ ) and decreasing with increasing load producing a significant linear trend ( $p < 0.001$ ).  $PO_{joint}$  at the hip was maximized at 42% MDS ( $p = 0.016$ ), producing a significant quadratic trend ( $p = 0.030$ ).

**CONCLUSIONS:**  $PO_{system}$  during JS reflects the  $PO_{joint}$  at both the knee and ankle joints, being maximized with loads equivalent to 0% MDS and decreasing with increasing load. However,  $PO_{joint}$  at the hip does not correspond to  $PO_{system}$  during loaded JS. Practitioners may need to vary the loads used during phases of resistance training that focus on power output to ensure that  $PO_{joint}$  is maximized at the lower-body joints.

**Effects Of Resistance Training With Maximal Voluntary Co-contraction On Neuromuscular Function**

Sumiaki Maeo, Yasuhide Yoshitake, Yohei Takai, Tetsuo Fukunaga, Hiroaki Kanehisa. *National Institute of Fitness and Sports in Kanoya, Kanoya, Japan.*  
(No relationships reported)

Simultaneous contractions of antagonistic muscles (co-contraction) produce resistive force which acts against each other. We hypothesized that a training mode with maximal voluntary co-contraction would be a novel form for improving the strength capability of the muscles within antagonistic pairs without any apparatuses or external loads.

**PURPOSE:** The present study aimed to examine neuromuscular adaptations following maximal voluntary co-contraction training.

**METHODS:** Sixteen healthy young men (training group: TG,  $n = 9$ ; control group: CG,  $n = 7$ ) participated in this study. TG performed a 12-wk training program (3 days / week) for elbow flexors (EF) and extensors (EE), which consisted of a 4-s maximal co-contraction of EF and EE at 90 degrees of the elbow joint, followed by a 4-s muscle relaxation (10 repetitions / set, 5 sets / day). The torque during isometric maximal voluntary contraction (MVC) of each of EF and EE, the electromyogram (EMG) activities of EF and EE during MVC and maximal co-contraction, and the muscle thickness of the EF and EE (by ultrasound) were determined before (Pre), at the ends of 4 weeks (4-wk), and at the end of 12 weeks (12-wk) of the intervention.

**RESULTS:** The EMG activities of EF and EE during maximal co-contraction, expressed relative to those during the MVC of the corresponding muscle group, were 43% and 60%, respectively, and were unchanged through the intervention period. CG did not show any significant changes in all measured variables. For TG, MVC torque was significantly increased in both EF (+12.5% at 4-wk,  $P < 0.01$ , +15.4% at 12-wk,  $P < 0.01$ ) and EE (+27.4% at 4-wk,  $P < 0.01$ , +46.0% at 12-wk,  $P < 0.001$ ) as compared to Pre. Muscle thickness for TG was also significantly increased in both EF (+1.2 mm,  $P < 0.001$ ) and EE (+1.2 mm,  $P < 0.001$ ) at 12-wk compared to Pre. In addition, TG showed significant gains in agonist EMG activities during MVC in both EF (+31.1% at 4-wk,  $P < 0.05$ , +44.0% at 12-wk,  $P < 0.01$ ) and EE (+27.3% at 4-wk,  $P < 0.01$ , +39.8% at 12-wk,  $P < 0.01$ ), without change in antagonist involuntary coactivation level in each of the two muscle groups.

**CONCLUSION:** Maximal voluntary co-contraction can be a resistance modality which increases the strength capability of both of the antagonistic muscles, without any increases in involuntary coactivation level during MVC. No funding was granted for this study.

1874 Board #282 MAY 30 2:00 PM - 3:30 PM

**Blood Flow Restriction Enhances Oxidant Stress and Anti-oxidant Capacity during Aerobic Exercise in Healthy Subjects**

Toshiaki Nakajima<sup>1</sup>, Miwa Kurano<sup>1</sup>, Haruhito Takano<sup>1</sup>, Tomohiro Yasuda<sup>1</sup>, Nami Takano<sup>1</sup>, Haruko Iida<sup>1</sup>, Taira Fukuda<sup>1</sup>, Kazuya Fukumura<sup>1</sup>, Yoshiaki Sato<sup>2</sup>, Toshihiro Morita<sup>1</sup>, Tatsuya Yamasoba<sup>1</sup>. <sup>1</sup>University of Tokyo, Tokyo, Japan. <sup>2</sup>Kaatsu International University, Rajagiriya, Sri Lanka.  
(No relationships reported)

**PURPOSE:** Moderate intensity-exercise induces transient oxidant stress, and stimulates redox-sensitive signals, and then increases antioxidant defense system. However, extremely heavy exercise induces excessive oxidant stress, resulting in tissue injury. Aerobic interval training (AIT) and low-load resistance exercise with blood flow restriction (BFR), named as Kaatsu training, are promising methods for promoting aerobic power and increasing muscle mass, respectively. In addition, low-intensity aerobic exercise (AE) such as walking under BFR, enhance muscle strength and muscle size. We examined the effect of BFR on markers of oxidant stress during aerobic exercises in healthy subjects, and compared it with AIT.

**METHODS:** Six male healthy subjects ( $25 \pm 3$  years old) performed three types of ergometer exercise. 1) AIT (work load at 60% of  $VO_{2peak}$  10 min, and 4 sets at 80% 4 min and 60% 3 min), 2) Moderate continuous training (MCT, work load at 40% of  $VO_{2peak}$  40 min), 3) AE-BFR (work load at 40% of  $VO_{2peak}$  20 min) under BFR of 220-250 mmHg. Plasma level of derivatives of reactive oxidative metabolites (DROM), an index of oxidative stress, and BAP, an index of anti-oxidant capacity, were measured before, immediately, and after exercise.

**RESULTS:** The mean maximal HR reached to 156/min (AIT), 100 (MCT) and 110 (AE-KAATSU). The mean Borg scale reached to 16 (AIT and AE-KAATSU) and 11 (MCT). Both AIT and AE-KAATSU significantly increased dROMs (AIT;  $273.8 \pm 22.4$  CARR units (pre) to  $299.3 \pm 18.2$  (peak exercise,  $P < 0.05$ ); AE-KAATSU ( $276.3 \pm 14.3$  (pre) to  $300.5 \pm 6.9$  (peak exercise,  $P < 0.05$ ), while MCT did not change dROMs significantly. Both AIT and AE-KAATSU also significantly increased BAP (AIT;  $1900 \pm 123$  ( $\mu$ M/l) (pre) to  $2175 \pm 100$  (peak exercise,  $P < 0.05$ ); AE-KAATSU;  $1870 \pm 65.8$  (pre) to  $2153.8 \pm 142.0$  (peak exercise,  $P < 0.05$ )). However, MCT did not change it significantly.

**CONCLUSIONS:** The present study shows that BFR enhances oxidant stress and anti-oxidant capacity during low-intensity aerobic exercise as AIT. The transient nature of oxidant stress may contribute to stimulate antioxidant defense system, and subsequently promote the health. But, to avoid the excessive oxidant stress, the use of low level of BFR may be safe at the start of training, especially in older subjects and patients with high-oxidant stress.

1875 Board #283 MAY 30 2:00 PM - 3:30 PM

**Characterization Of The Electromyographic Activity Of Ten Muscles Participants In Four Different Pullover Exercises.**

Pedro de Medeiros<sup>1</sup>, Orlando Fernandes<sup>2</sup>, João Vaz<sup>1</sup>, Pedro Pezarat-Correia<sup>1</sup>. <sup>1</sup>Faculty of Human Kinetics, Lisbon, Portugal. <sup>2</sup>University of Évora, Évora, Portugal.  
(No relationships reported)

**PURPOSE:** Pullover exercises are common in athletes' training routines. There is a great uncertainty about the pattern of muscle activity when performing different types of exercise. The purpose of this study was to quantify and compare the activity of ten muscles in four pullover exercises (PEX).

**METHODS:** 15 healthy men with at least two years of experience in resistance training, executed in a random order, 6 repetitions with 60% of 1RM, for 4 different PEX: lying down on a step with a bar and grip 100% biacromial (bial), lying on a step with a bar and grip 150% bial, lying on a fitball and grip 100% bial and lying on a step with a cable, grip 100% bial. Surface EMG was recorded from the anterior deltoid (AD), clavicular (PC) and sternal (PE) portions of the pectoralis major, serratus anterior (SA), rectus abdominis (RA), internal oblique and transverse abdominal (IO/T), posterior deltoid (PD), infraspinatus (IF), long head of triceps brachii (TB) and latissimus dorsi (LD). EMG normalization was performed for each muscle using the EMG of

the maximum voluntary isometric contraction MVC. (MVIC). The data normality was tested through the Shapiro-Wilk test. The normalized mean values of EMG, during the each exercise, were compared between muscles on each exercise and between exercises, using Anova for repeated measures. The significance level was set at  $p < 0.05$ .

**RESULTS:** EMG activity was very similar among the 3 bar exercises. For those exercises, AD(33-36% MVC), SA(36-39% MVC) and RA(35-42% MVC) muscles registered significant less activation than the other muscles. Most requested muscles were IF(51-53% MVC) and PD(49-51% MVC). For the cable exercise, PC(47% MVC) and PD(49% MVC) were the muscles that registered less activation. The most requested muscles were IF(60% MVC) and TB(63% MVC). When comparing muscles between bar and cable exercises, AD(33-36% vs 57% MVC), PE(43-47% vs 52% MVC), SA(36-39% vs 57% MVC), RA(35-42% vs 53% MVC), PO/T(45-47% vs 57% MVC), IF(51-53% vs 60% MVC), TB(46-47% vs 63% MVC) and LD(44-46% vs 55% MVC) muscles registered significant superior activation in the cable exercise. For PC(46-49% vs 47% MVC) and PD(49-51% vs 49% MVC) muscles, there were no significant differences. **Conclusion:** Pullover with cable stimulates higher muscle activation, compared to other types of pullover, for 60% MVIC of 1RM.

1876 Board #284 MAY 30 2:00 PM - 3:30 PM

**Varying Muscle-Specific Exercise Between Consecutive Training Sessions does not Diminish the Repeated Bout Effect**

Edward Jo<sup>1</sup>, Michael C. Zourdos<sup>1</sup>, Jacob M. Wilson<sup>2</sup>, Ken Kazunori Nosaka<sup>3</sup>, Sang-Rok Lee<sup>1</sup>, Marshall Naimo<sup>1</sup>, Paul C. Henning<sup>4</sup>, Young-Min Park<sup>5</sup>, Andy V. Khamoui<sup>1</sup>, Bong-Sup Park<sup>1</sup>, Lynn B. Panton, FACSM<sup>1</sup>, Jeong-Su Kim<sup>1</sup>. <sup>1</sup>The Florida State University, Tallahassee, FL <sup>2</sup>The University of Tampa, Tampa, FL. <sup>3</sup>Edith Cowan University, Joondalup, Australia. <sup>4</sup>U.S. Army Research Institute of Environmental Medicine, Military Performance Division, Natick, MA. <sup>5</sup>Syracuse University, Syracuse, NY.

(No relationships reported)

Repeated high-intensity contractions produce significant myofiber damage leading to a period of decreased force production, soreness, and edema. However, the repeated bout effect (RBE) indicates that if the same exercise is repeated within six months, the magnitude of muscle damage is attenuated compared to that ensuing the initial exercise bout. Myofiber damage has been previously considered a key stimulus for muscle hypertrophy. However, it has been recently shown that muscle growth may manifest independent of myofiber damage. Thus, invoking the RBE may be advantageous to minimize undue fatigue during muscle hypertrophy training. However, it remains undetermined if varying muscle-specific exercise selection between consecutive training bouts diminishes the RBE.

**PURPOSE:** To determine if muscle-specific exercise variation between successive training sessions alters the magnitude of the RBE.

**METHODS:** Twenty healthy, untrained males (age=21 ± 2 yrs) were assigned to one of two groups: 1) two sessions of dumbbell incline curls (DIC, n=10) or 2) one session of dumbbell incline curls and one session of dumbbell preacher curls (DIC/DPC, n=10). The two training sessions for each group were separated by seven days. Both groups performed 5 sets of 6 repetitions of each exercise at ~50% of maximal isometric elbow flexor strength in both training sessions. Muscle damage indices, which included range of motion (ROM), muscle soreness, maximal voluntary isometric contraction (MVIC), and serum creatine kinase (CK) and lactate dehydrogenase (LDH), were measured at pre, and immediate post (IP), 24, 48, 72, and 96 hours after each training session.

**RESULTS:** Following the first session, ROM decreased and muscle soreness increased significantly up to 72 hours, while MVIC significantly declined by 15% IP. Serum CK was significantly elevated by 28% 48 hours post while LDH increased IP. There were no significant differences in these responses between groups. After the second session, both groups demonstrated similar damage responses (RBE) with MVIC declining only 7.5% IP.

**CONCLUSION:** Variation of muscle-specific exercise between consecutive training sessions does not alter the magnitude of the RBE. Further research is necessary to determine chronic adaptations to training implementing varied or repeated exercise selection.

1877 Board #285 MAY 30 2:00 PM - 3:30 PM

**Influence Of Rest Intervals On Knee Extension Flexibility And Mechanical Properties**

Sandro R. Freitas, João R. Vaz, Tiago Neto, Paula M. Bruno, Maria J. Valamatos, Pedro Mil-Homens. *Human Kinetics Faculty, Lisbon - Portugal, Cruz Quebrada - Dafundo, Portugal.*

(No relationships reported)

**PURPOSE:** It is common in stretching and flexibility training the use of a certain number of repetitions to induce flexibility gains. However, there are different recommendations for number of repetitions and it has never been tested the influence of rest intervals in the range of motion and acute mechanical adaptations. The aim of the present study was to understand the acute effect of rest intervals in flexibility and mechanical behavior of passive knee extension (PKE).

**METHODS:** A PKE protocol (velocity of 2°/s, and 90 seconds in the static phase) was applied in asymptomatic adults (n=22; 21.8±2.9 years, 73.9±8.9 kg 1.75±0.07 meters) in two randomized experimental conditions: a maximum number of repetitions (rep) with no rest intervals (NRI) and five repetitions with 15 seconds rest interval (RI). Knee passive range of motion (ROM) and torque (PT), semitendinosus and vastus lateralis electromyographic surface activity (EMG), and stretching perceptual intensity (SPI) at maximum knee range of motion (using a Visual Analog Scale) were assessed during the protocols. Subjects were instructed to produce maximum range of motion without feeling pain or discomfort in all repetitions. Data was processed in MatLab® routines and statistically analyzed with a p-value set at 0.05.

**RESULTS:** No differences were found between the first repetition of the RI and NRI protocols in knee 'PT-ROM' in different angles, as well as in SPI at maximum ROM. In all repetitions EMG stayed lower than 3% of MVC. In NRI condition, subjects ranged in the number of maximum REP from 2 to 5 (2, n=4; 3, n=9; 4, n=8; 5, n=1). Subjects obtained a higher end ROM in NRI compared to RI condition, having a superior relative ROM increase in the NRI second rep compared to the RI fifth rep (112.8% vs. 110.4%). Viscoelastic stress relaxation amplitude tended to be lower over the repetitions and was statistically different between the first and last rep in NRI condition, but in RI condition was only different between the first and second rep. All previous results were statistically significant ( $p < 0.05$ ).

**CONCLUSION:** Rest intervals between repetitions influences considerably range of motion and joint mechanical parameters. The use of rest intervals should be questioned in flexibility programs when the goal is to increase flexibility by manipulating intensity.

1878 Board #286 MAY 30 2:00 PM - 3:30 PM

**Power Output of the Clean Complex**

Charles J. Fountaine<sup>1</sup>, Jake Steffen<sup>2</sup>. <sup>1</sup>University of Minnesota Duluth, Duluth, MN. <sup>2</sup>South Dakota State University, Brookings, SD. (Sponsor: John R. Keener, FACSM)

(No relationships reported)

It has been well established that in-season training is crucial for the maintenance of power and strength throughout a college football season. Strength and conditioning coaches typically prescribe variations of Olympic weightlifting exercises, such as the clean complex, to develop and maintain power. However, due to the physical toll of collisions in practice and games, the selection of in-season resistance training exercises that maintain explosiveness while minimizing additional orthopedic stress can be very challenging.

**PURPOSE:** To determine differences in power output of the clean complex.

**METHODS:** A total of 8 NCAA Division I collegiate football players were recruited for this study. A Tendo Weightlifting Analyzer unit was used to measure the average power generated during the power clean (PC), hang clean (HC), clean pull (CP) and hang clean pull (HCP) exercises. Load assignments for all varieties of the clean complex were based on each participant's 1-repetition maximum (1RM) PC. After completing a 5-minute dynamic warm-up, participants performed a warm-up set at 50% of 1RM on the PC. The barbell was then loaded to 75% of 1RM, the Tendo unit was attached to the barbell, and the PC was performed for 3 repetitions with the average power in watts (W) for each repetition recorded for data analysis. After a 3-minute rest period, the above procedure was performed for the HC, CP, and HCP. For the CP and HCP, 3 repetitions at 85% of 1RM were performed to adjust for the lack of the catch phase.

**RESULTS:** Repeated measures ANOVA indicated no significant difference in power output between PC, HP, CP and HCP (1814, 1766, 1831, 1831 W, respectively;  $F = .402$ ,  $p = .753$ ).

**CONCLUSIONS:** No one exercise of the clean complex variations resulted in significantly greater power output. As such, exercises that produce less orthopedic stress on wrists, elbows, and shoulders such as the CP or HCP, may be beneficial to an athlete during in-season workouts.

**The Acute Effect of Isometric Maximal Voluntary Contractions on Sprint and Jump Performance**

Tim R. Burnham, Nick Collins, Leo D'Acquisto, Kevin Adkisson. *Central Washington University, Ellensburg, WA.* (Sponsor: Scott O. Roberts, FACSM)  
(No relationships reported)

Post-activation potentiation (PAP) is a phenomenon in which contractile performance improves following a conditioning stimulus. Maximal voluntary contractions (MVC) can be used as a conditioning stimulus to elicit PAP, which may increase speed of contraction. This phenomenon may result in increased power performance.

**PURPOSE:** To examine the effect of a maximal effort isometric dead-lift exercise on vertical jump and 40 yard dash performance.

**METHODS:** Ten male collegiate varsity track athletes participated as subjects. A randomized crossover design was used where each subject served as his own control. The treatment consisted of a standardized warm-up followed by three, 3 second MVC of static dead lifts separated by one minute of rest. The control condition performed the warm-up but not the MVC's. The dependent measures were two vertical jump height trials separated by 30 seconds and two 40 yard dash times separated by 1 minute.

**RESULTS:** The control group 40 yard dash time decreased .41% from attempt 1 to attempt 2 (5.152 +0.197 to 5.131 +0.173 seconds) while the treatment group decreased run time by .73% (5.189 +0.197 to 5.151 +0.179 seconds). The main effect for this result approached significance ( $p = .052$ ) however the interaction between groups was not significantly different ( $p = .54$ ) suggesting that the result was not due to the treatment. The control group vertical jump height increased 1.98% from attempt 1 to attempt 2 (64.07 +5.17 to 65.34 +5.17 cm) while the treatment group decreased jump height by .29% (64.96+5.12 to 64.77+5.13). The main effect for this result approached significance ( $p = .10$ ). The interaction between the groups was significant ( $p = .02$ ) suggesting that there was a significant increase in jump height for the control group compared to the treatment group.

**CONCLUSIONS:** The main trend identified in this data is an increase in performance for second attempts compared to first attempts for all 40 yard dash times and for the control condition in the vertical jump height. It may be that the first attempt for vertical jump and 40 yard dash time in the control condition acted as a conditioning stimulus to improve performance. The MVC's treatment may have had a dampening effect on both run and jump performance, therefore isometric exercise should not be used prior to performance in this population.

**Metabolic & Psychological Adaptations In Jamaican Athletes**

Tanielle Beckford<sup>1</sup>, Kerith Golden<sup>1</sup>, Melanie Poudevigne, FACSM<sup>2</sup>, Rachael Irving<sup>1</sup>. <sup>1</sup>*University of West Indies, Kingston, Jamaica.* <sup>2</sup>*Clayton State University, Morrow, GA.*  
(No relationships reported)

The systematic culture of Jamaica's approach to athletics has led to the "Jamaican sprinting phenomenon". Hence an exploration of the physiological systems and psychological skill sets in young Jamaican athletes will provide insight into the "trainability" of these variables and a foundation for future research.

**PURPOSE:** To differentiate diverse sprint performance by the investigation of psychological skills and serum levels of lactate, creatine kinase (CK) and lactate dehydrogenase (LDH) among young Jamaican sprinters.

**METHODS:** Subjects were divided into two groups based on results of previous athletic achievement: elite (EG; n=7) and sub-elite (SEG; n=9) sprinters. Blood lactate levels at baseline and following a 350m sprint (3, 8 and 15 minutes) were measured using a portable lactate meter (~ 0.7  $\mu$ l) under passive recovery mode. Subjects provided blood at baseline and 30 minutes post 350m run via venipuncture in a seated position for CK and LDH determination. The Athletic Coping Skills Inventory-28 (ACSI-28) and the Mental Toughness Questionnaire-48 (MTQ-48) were completed at 35 minutes post exercise.

**RESULTS:** Mean age was 17( $\pm$  1.20) and 16.8( $\pm$  1.60) years for the EG and SEG respectively. Mean sprint velocity and anaerobic capacity were positively correlated for both the EG ( $r=0.8$ ,  $p<0.05$ ). Recovery indicators as measured by the change in lactate levels between 8 and 15 minutes showed a greater recovery of 2.5mmol/L  $\pm$  6.6 (11.6%) for the EG with the versus - 1.8 mmol/L  $\pm$  4.3, (-22.9%) for SEG. No statistically significant correlation was found between sprint velocity and post exercise CK and LDH serum levels for either group.

Levene's independent t-test showed no statistically significant difference between groups for scores of coping and mental toughness. Regression analysis showed that personal coping resource (57%) and subscales Coping with Adversity (34%), Concentration (47%), Freedom from worry (45.8%) were statistically significant predictors of mental toughness. Mean mental toughness was higher in the EG (5.86  $\pm$  1.95) versus (5.33  $\pm$  2.55) SEG; mean coping showed a similar trend (52.86  $\pm$  8.67 vs. 49.56  $\pm$  13.21).

**CONCLUSIONS:** Findings of this study indicate that at the youth level metabolic profiling and psychological skills may distinguish Jamaican elite from average athletes.

**On-hill Delayed Video Enhances Skill Development in Alpine Skiers during a Single Week of Summer Camp Training**

David W. Bacharach, FACSM. *St Cloud State University, St. Cloud, MN.*  
(No relationships reported)

**INTRODUCTION:** Using a delayed video system in alpine ski race

training over 10 weeks has shown to have a moderate correlation ( $r=.84$ ) to skill acquisition in skiers age 9-15 years (Bacharach & Berg, 2011). What remains unknown is whether a similar portable system can enhance skill acquisition of junior alpine skiers during a single week of summer camp training and if age might influence such a system's effectiveness.

**PURPOSE:** 1.) Collect data during one week of ski training addressing the impact of a delayed video feedback system on ski skill improvements by junior alpine ski racers.

**METHODS:** Racers (N=30, 17 females, 13 males, ages 9-18) trained in groups of six, each with an assigned coach at Red Lodge International Summer Race Camp in June 2011. Video was provided five of the six training days. Skiers viewed their performance on the monitor ad libitum. On the last day, athletes were given a survey that asked them to put a mark along a 100 mm line with anchor phrases "Not useful" and "Extremely useful" indicating how useful the on-hill video system was for their training. The midpoint of the line was marked as zero to allow the data to range from -50 to +50. A similar 100 mm line using anchors "Got worse" and "Got better" with a zero mark in the middle was given to the coaches to rate each athlete s/he coached during the week as to the level of improvement each skier made. Simple regressions and correlations were performed on the data as a whole and split by age groups (9-12 yrs and 13-18 yrs).

**RESULTS:** The overall regression equation ( $y=.86x + 0.15$ ,  $r=.85$ ) yielded a significant correlation as did each of the age group regression models (9-12 yrs:  $y=.76x + 2.4$ ,  $r=.89$ ; 13-18 yrs:  $y=.93-1.6$ ,  $r=.84$ ). Athletes who felt video helped improve their ski skills more so, were also rated higher in skill improvement by their coach.

**CONCLUSIONS:** Young alpine skiers appear to improve their skills when they are given the chance to receive on-hill delayed video feedback of their performance. Age did not appear to impact this relationship suggesting young alpine ski racers can enhance their skill development more in one week of training when a delayed video system is available to them.

Acknowledgements: Thank you to Red Lodge International Summer Ski and Snowboard Camp, Roger Bay and his coaches and all the athletes.

**Maintaining Ball Serving Performance Against Psychological Stress from Tennis Court Spectator**

Chia-Hua Kuo, FACSM<sup>1</sup>, Kuo-Long Ho<sup>1</sup>, Szu-Hsien Yu<sup>1</sup>, Shu-Man Chen<sup>2</sup>. <sup>1</sup>Taipei Physical Education College, Taipei, Taiwan. <sup>2</sup>Shih Hsin University, Taipei, Taiwan.

(No relationships reported)

**PURPOSE:** This study compared ball serving performance for ordinary and national-level tennis players under surveillance by famous tennis star.

**METHODS:** Subjects were informed that their ball serving performance test will be watching by a well-known tennis star (world rank: 30, 2007, silver medal in Australia Open) or a normal court spectator (baseline) 1 h later. Heart rate variability was then recorded quietly after 5-min rest to reflect autonomic nervous activity under the anticipatory stress. Subjects reported their profile of mood states (POMS) followed by blood sample collection for cortisol analysis before the performance test. Performance score was the sum of the product of velocity (km per hr) and accuracy (targeted area, 2; inside, 1; outside, 0) after 10 ball servings.

**RESULTS:** Overall mood disturbance was increased when court spectator was famous tennis star compared to normal spectator. Interestingly, the fatigue subscale and cortisol were elevated significantly only in elite tennis players. However, ball serving performance in the elite tennis players was unaffected under surveillance by famous tennis star. In contrast, performance score was substantially elevated for ordinary tennis players without cortisol change. In addition, vagal power (ln HF of HRV) was reduced when famous tennis player is watching.

**CONCLUSIONS:** Our result demonstrated that surveillance by famous tennis star can elicit psychological stress for athletes. Intriguingly, such stress has no effect for elite players but appears to be stimulatory in ball serving performance for the ordinary tennis players. The result of the study found that ordinary and elite athletes can respond differently in coping against stress from court spectator.

1883 Board #291 MAY 30 2:00 PM - 3:30 PM

**Self-Efficacy Effect on Anaerobic Performance and Perceived Exertion during a Wingate Bike Test**

Todd Sherman<sup>1</sup>, Jasmin Hutchinson<sup>2</sup>. <sup>1</sup>University of Tennessee @ Martin, Martin, TN. <sup>2</sup>Springfield College, Springfield, MA.

(No relationships reported)

**PURPOSE:** This study examined the effect of self-efficacy (SE) on perceived effort (RPE) and performance using a maximal effort anaerobic task.

**METHODS:** A repeated measures experimental design was employed, with male and female collegiate athletes ( $N = 36$ ) randomly assigned to one of three groups; (a) high-efficacy (HE); (b) low-efficacy (LE), or (c) control group. Efficacy expectations were manipulated via false performance feedback. A manipulation check confirmed that this method successfully impacted SE in the intended direction ( $p < .01$ ). Before and after the SE intervention, participants completed a 30-second Wingate bike test to fatigue. During the task participants provided differentiated ratings of perceived exertion at 15s intervals. Effort tolerance was determined by the length of time the participant could maintain the task. Differences in peak power (PKPWR), mean power (MPWR), maximum heart rate (MHR), and RPE were analyzed using a RM MANOVA.

**RESULTS:** Results revealed that the HE participants found the task less strenuous and more enjoyable than the LE or control group following the manipulation. Furthermore HE resulted in significantly greater tolerance of the task than either the LE or control conditions. Compared to the control group PKPWR increased significantly ( $p < .05$ ) in both intervention groups.

**CONCLUSIONS:** Changes in SE, regardless of direction, appear to positively influence anaerobic performance. However, this positive impact appears to affect only the initial burst of anaerobic exercise, since no significant results were found for MPWR or MHR. We further conclude that athletes tend to perform better with any feedback at all, whether positive or negative, than no feedback. The maximal nature of this task was such that the manipulation did not affect RPE, as might be expected (c.f. Tenenbaum, 2001). Such findings may have important implications for the role played by self-efficacy in enhancing physical activity participation.

1884 Board #292 MAY 30 2:00 PM - 3:30 PM

**Contextual Interference Effects On The Acquisition Of Strength And Skill Of The Bench Press**

Marshall Naimo<sup>1</sup>, David W. Eccles<sup>1</sup>, Jacob M. Wilson<sup>2</sup>, Michael C. Zourdos<sup>1</sup>, Jeong-Su Kim<sup>1</sup>, Lynn B. Panton, FACSM<sup>1</sup>. <sup>1</sup>The Florida State University, Tallahassee, FL. <sup>2</sup>University of Tampa, Tampa, FL.

(No relationships reported)

It is well known that resistance exercise training (RET) causes increases in muscular strength through neural and morphological adaptations. Previous studies of contextual interference (CI) have shown that practicing several motor skills randomly [high CI (HCI)] facilitates learning in comparison to practicing the same tasks in a blocked order [low CI (LCI)]. This effect has not been investigated in regards to RET. If HCI can enhance the learning of complex RET tasks, HCI could lead to increased strength and decreased risk of injury.

**PURPOSE:** To test if HCI is superior to LCI for the acquisition of (a) movement skill and (b) strength of the bench press (BP).

**METHODS:** Twenty four healthy, college-aged males ( $n=15$ ) and females ( $n=9$ ) were randomly assigned to a control (C), LCI, or HCI group. LCI and HCI were shown proper BP form and performed this exercise for 4wks, 3 times/wk for 4 sets, separated by 90 s, 10-12 reps at 50-55% of one repetition maximum (1RM). Both groups also completed 4 dart-throw sets (4 throws per set). HCI undertook one dart-throw set following each BP set. LCI simply stood between BP sets and carried out all 4 dart-throw sets after completing their 4 sets of BP. C only did testing. 1RM tests were filmed; using the film, BP movement technique (BPMT) was scored using a 13-point movement checklist by a CSCS expert blinded to the groups. Measurements were taken at pre, 1 wk, 2 wks, post, and at a retention test 9 days after post. Alpha was set at 0.05.

**RESULTS:** LCI had a significantly greater increase in %1RM than C at post (LCI: 23.5±2.9; HCI: 14.8±2.9; C: 10.2±2.9%). At retention, LCI and HCI had a greater increase in %1RM than C (LCI: 21.1±2.6; HCI: 17.9±2.6; C: 11.1±2.6%), but LCI and HCI were not different from each other. The %1RM increase from wks 1 and 2 to retention was significant for the HCI group only. In LCI and HCI, BPMT scores were significantly higher than C at 1 (LCI: 12±1; HCI: 11±2; C: 9±2) and 2 wks (LCI: 12±2; HCI: 12±1; C: 8±3). HCI had significantly greater BPMT scores than C at post (13±1 vs. 9±3) and retention (12±1 vs. 9±3); there were no differences between LCI and C at post or retention.

**CONCLUSION:** HCI led to better retention of the BP movement after training compared to the other conditions. Thus, HCI may augment strength and movement skill on the BP since proper technique is an important component of strength-based tasks.

1885 Board #293 MAY 30 2:00 PM - 3:30 PM

**The Effect Of Stretching And Motor Imagery On Anaerobic Performance In Trained Cyclists**

Hannah Claeys<sup>1</sup>, Rebecca Zakrajsek<sup>2</sup>, Maria Martinson<sup>3</sup>, Kaci Smith<sup>3</sup>, Sara Hochgesang<sup>3</sup>, Andrea Brewer<sup>3</sup>, Michelle Ritchey<sup>3</sup>, Adam Edwards<sup>3</sup>, Tom Nesser<sup>3</sup>, Matt Gage<sup>3</sup>, J. Derek Kingsley<sup>3</sup>. <sup>1</sup>Ball State University, Muncie, IN. <sup>2</sup>University of Tennessee, Knoxville, TN. <sup>3</sup>Indiana State University, Terre Haute, IN. (Sponsor: Lynn Panton, FACSM)

(No relationships reported)

Stretching has been suggested to decrease force and power production while motor imagery (MI) may improve it. MI is the visualization of simple or complex motor activities in the absence of physical movement. However, the effects of static stretching (SS) compared to MI on anaerobic performance in trained cyclists are currently unknown.

**PURPOSE:** To examine the effects of SS compared to MI and quiet rest (QR; sitting and reading the student newspaper) on anaerobic performance in trained cyclists.

**METHODS:** Thirteen trained cyclists (9 males; 4 females; aged: 21±2 yrs) were assessed for height (1.76±0.07m), weight (73.4±13kg), % body fat (10.8±6.2%) and maximal oxygen consumption (VO<sub>2</sub>max: 42.0±5.6 ml/kg/min). Participants performed 3 randomized sessions, separated by at least 72 hours, consisting of cycling for 30 minutes at 65% of VO<sub>2</sub>max before undergoing 15 minutes of SS, MI or QR, followed by an anaerobic performance test. SS consisted of 3 sets of 30-second stretches for the knee flexors/extensors, hip flexors/extensors and the piriformis. Imagery was based on the physical, environmental, task, learning, emotion, and perspective (PETTLEP) and was conducted by a trained technician. The physical nature of the imagery included wearing the same clothing and positioning themselves on the bike as when they are performing. The environmental component included performing imagery in the physical

environment that the task was actually performed. Both relative and absolute powers, as well as peak rpm, were quantified using the 30-second Wingate anaerobic threshold test. Significance was set a priori at  $p \leq 0.05$ .

**RESULTS:** No significant interactions existed among SS, MI and QR for relative peak power, absolute peak power or peak rpm.

**CONCLUSION:** In disagreement with current literature, the present study suggests that neither SS nor MI affect anaerobic performance in trained cyclists. This may be explained by the influence of several variables such as the length of the exercise bout, the duration of the stretching and the participants' experience with imagery and/or quality of imagery.

**1886** Board #294 **MAY 30** **2:00 PM - 3:30 PM**

**Irritable Bowel Syndrome Disrupts Mental and Physical Function in Female Endurance Athletes**

Emily Crohare<sup>1</sup>, Samantha Rhodes<sup>1</sup>, Trevor Gillum<sup>2</sup>, Matthew Kuennen<sup>1</sup>. <sup>1</sup>West Texas A&M University, Canyon, TX. <sup>2</sup>California Baptist University, Riverside, CA.  
(No relationships reported)

Gastrointestinal distress is a common complaint among female endurance athletes. Irritable bowel syndrome (IBS), characterized by recurrent abdominal pain, inflammation and disturbed bowel function, is a common diagnosis. IBS also causes severe anxiety, depression and fatigue; the combination of these physical and psychological symptoms severely hinders athletic performance. While quercetin's analgesic and anti-inflammatory properties have been extensively studied in healthy male athletes, the efficacy of this supplement in diseased female athletes is unknown.

**PURPOSE:** To determine whether quercetin improves the mental and physical health of female endurance athletes with IBS.

**METHODS:** 6 female endurance athletes (age:  $21.2 \pm 0.5$  yrs; weight:  $54.8 \pm 2.2$  kg; bodyfat:  $18.1 \pm 1.6$ %;  $VO_{2max}$ :  $49.9 \pm 1.7$  ml/kg/min) consumed 1g/d quercetin for 21 consecutive days. 3 had been previously diagnosed with IBS (Rome III criteria); the other 3 served as controls. Subjects completed questionnaires (Medical Hospital Anxiety & Depression Scale, Fatigue Impact Scale, IBS-Symptom Severity Scale, IBS Quality of Life) and exercise (45 minutes at 70% of  $VO_{2max}$ ) on the 1<sup>st</sup> and 21<sup>st</sup> days of supplementation to assess changes in mental and physical health. Saliva, collected before, immediately after and 1hr after exercise was assayed for cortisol using ELISA.

**RESULTS:** IBS-associated fatigue, anxiety, depression, symptom severity and quality of life was worse in athletes with IBS than those without ( $p < .05$ ); these issues did not improve with quercetin supplementation ( $p > .05$ ). Athletes with IBS exhibited an increase in salivary cortisol from pre to post-exercise on the 1<sup>st</sup> ( $13.5 \pm 4$ %;  $p < .05$ ) and 21<sup>st</sup> ( $38.3 \pm 4$ %;  $p < .05$ ) days of supplementation; each day cortisol values returned to baseline by 1hr after exercise. Surprisingly, control subjects did not exhibit an increase in salivary cortisol with exercise on either the 1<sup>st</sup> or 21<sup>st</sup> days of supplementation ( $p > .05$ ). **DISCUSSION:** Our results suggest female endurance athletes with IBS suffer from greater fatigue, anxiety, depression, and gastrointestinal distress than their non-afflicted counterparts. This likely has a significant impact on athletic performance and warrants further investigation. Preliminary data do not support a role of quercetin in diminishing the stress response.

**Educational Achievement And Career Transition Among Chinese Elite Athletes After Retirement**

Fan Zhang<sup>1</sup>, Flavia Andrade<sup>2</sup>, Weimo Zhu, FACSM<sup>2</sup>. <sup>1</sup>Qsinghua University, Beijing 100084, China. <sup>2</sup>University of Illinois at Urbana-Champaign, Champaign, IL.  
(No relationships reported)

**PURPOSE:** This study investigated the factors associated with attending college and career transition among the Chinese elite athletes who have retired.

**METHODS:** The sample focused on retired elite athletes who had registered in the Beijing Sports Administration. These athletes (N=212, mean age=24.7, 55% female) had formally played professional sports on the national or provincial teams. Data were collected in 2010. Former athletes received the questionnaires through their former coaches. Descriptive statistics and logistic regressions were used to explore whether educational achievement and career transitions differed across sports. We also explored whether these associations varied by gender and social background.

**RESULTS:** In multivariate analyses, higher age of retirement was associated with a higher likelihood of getting a job versus going to college (OR=1.31, 95% CI 1.13-1.52). Other variables such as sex, parental background and type of sport in which they competed as athletes were not statistically significant. However, only 26% were satisfied with their jobs after the retirement. When athletes were asked about who have played a role in their decision to go to college, 56% highlighted the role of their parents as important (or very important). Most categorized the help of their friends/trainers (64%) as neutral. Their own self-efforts were also mostly seen as neutral in the decision to attend college (59%).

**CONCLUSIONS:** The retirement transition of Chinese elite athletes is affected by their retirement age. Those retiring at older ages were less likely to attend college which may reduce their career options in the future. Most retired athletes seem dissatisfied with their jobs. Further implications are discussed.

---

**1888** Board #296 **MAY 30** **2:00 PM - 3:30 PM**

**Motivation In Soccer - A Comparison Between Professionals, Semi-professionals And Amateurs Soccer Players**

Hugo M. Sarmiento<sup>1</sup>, Adilson Marques<sup>2</sup>, Joao F. Martins<sup>2</sup>, Luis M. Catita<sup>1</sup>, António M. Fonseca<sup>1</sup>. <sup>1</sup>University of Porto, Porto, Portugal. <sup>2</sup>Technical University of Lisbon, Lisboa, Portugal.  
(No relationships reported)

In spite of the existence of a significant quantity of studies that examine motivation in context to physical and leisure activities, very few coincide in contexts of a natural competitiveness, especially in what concerns adult competition.

**PURPOSE:** To compare the achievement goal, self-determination and beliefs about the nature and determinants of sport competence according to the competitive level: Professionals (PF), Semi-Professionals (SP) and Amateurs (AM).

**METHODS:** 105 professional soccer players (I and II Professional Leagues), 156 semi-professionals (II and III National Leagues) and 78 amateurs (Regional Leagues), completed the following tools: Task and Ego Orientation in Sports Questionnaire; Self-Regulation Questionnaire; Questionnaire relative to Beliefs about the Nature and Determinants of Sports Competency. ANOVA was used to analyse the differences between the three groups, post hoc comparisons were done using the Tukey test ( $p < 0.05$ ).

**RESULTS:** The analysis of results shows that the three groups were predominantly task oriented and significant differences were not found between them. The professionals, when compared with the amateurs, reported significant higher levels in respect to the introjected regulation (PF,  $3.53 \pm 0.82$ ; AM,  $3.19 \pm 0.76$ ;  $p = 0.015$ ), identified regulation (PF,  $4.38 \pm 0.66$ ; AM,  $4.10 \pm 0.69$ ;  $p = 0.012$ ) and for the beliefs that the sports competence was a result to learning (PF,  $4.47 \pm 0.57$ ; AM,  $4.25 \pm 0.71$ ;  $p = 0.030$ ) and subject to improvement (PF,  $4.14 \pm 0.68$ ; AM,  $3.89 \pm 0.85$ ;  $p = 0.47$ ). The amateurs showed significant higher levels of amotivation (PF,  $1.42 \pm 0.60$ ; AM,  $1.69 \pm 0.93$ ;  $p = 0.003$ ) and believe more than the professionals that sport competence is stable (PF,  $2.39 \pm 0.63$ ; AM,  $2.66 \pm 0.80$ ;  $p = 0.021$ ). On the other hand, the semi-professionals, when compared with the amateurs, also tended to report significant higher levels of introjected regulation (SP,  $3.52 \pm 0.85$ ; AM,  $3.19 \pm 0.76$ ;  $p = 0.015$ ) and to believe that sport competence for playing football results from learning (SP,  $4.56 \pm 0.42$ ; AM,  $4.25 \pm 0.71$ ;  $p = 0.000$ ) and is subject to improvement (SP,  $4.25 \pm 0.61$ ; AM,  $3.89 \pm 0.85$ ;  $p = 0.001$ ).

**CONCLUSION:** The differences found concerning the several motivation determinants in function of the competitive level, underline the existence of a relation between the competitive level and motivation.

---

1889 Board #297 MAY 30 2:00 PM - 3:30 PM

**Contextual Analysis Of Soccer Clubs**

Artur J. Santos, Carlos E. Gonçalves. *Faculty of Sport Sciences and Physical Education - University of Coimbra, Coimbra, Portugal.* (Sponsor: Carl Foster, FACSM)  
(No relationships reported)

From an ecological approach it's believed that the context can influence the individual development. Sport clubs are important, since they provide conditions for individual involvement. To induce or promote sport involvement is needed to better understand sport organizations and how they're organized, their culture and relationship with the local environment.

**PURPOSE:** The aim of this study is to identify the soccer clubs model of organization, their culture, goals and answers to the demands of the surrounding environment.

**METHOD:** Three Portuguese soccer clubs from different contexts were analyzed. One professional club (PC) and two amateur (AC) of regional level, one of a rural area (RAC), other of an urban area (UAC). The criteria to select the clubs were: a) belong to the same district, b) experience in collaboration with research studies. Field observations and guide tour to club infrastructures were registered. And semi-structured interviews were recorded, followed by text transcription and respectively speech analysis.

**RESULTS:** Comparative to the AC's the PC is more complex, formalized, specialized and is more orientated to performance goals. The volunteers in the PC that work with the youth athletes receive compensation (e.g., monetary, merchandising, tickets).

The AC's present a simple structure, lack of formal training and bureaucracy, suggesting high centralization. The goals declared are related to promotion of sport practice. Volunteers' involvement is based on friendship and relationships. The protocols established with local authorities seem to be an important factor that helps UAC to have better capacity to obtain income than the RAC.

**CONCLUSIONS:** The PC is more prepared and capable to provide better conditions for soccer skills development, but the orientation to performance goals could promote anti-social and anti-ethical attitudes and values in the athletes. The AC's are more dependent from the local authorities, but their function could be improve if they develop good partnerships with local authorities. These can see in the clubs an opportunity to promote social capital, provide informal education and promote active citizenship. It's possible that these organizational differences promote different values and skills of youth athletes.

1890 Board #298 MAY 30 2:00 PM - 3:30 PM

**Cognitive Function of Retired Professional Football Athletes**

Gregory W. Stewart, FACSM, Roberta A. Bell, Jenifer J. Sudkamp. *Tulane Institute of Sports Medicine, New Orleans, LA.*  
(No relationships reported)

**BACKGROUND:** Exposure to repeated head injuries can alter the expected cognitive recovery course, increasing the risk of long-term neuropsychological problems over the lifespan. Due to age associated memory decline and the prevalence of multiple concussions in professional football players, clinicians are often concerned about the cognitive status of retired professional football athletes.

**PURPOSE:** To examine the cognitive function of retired professional football players during a health screening event

**METHODS:** Twenty-three retired professional football players (ranging in age from 32 to 70 years, with a mean age of 54 years) participated in a health screening event and reported multiple "bell ringers" during their athletic careers. All participants were independent with mobility and ambulation. The Montreal Cognitive Assessment (MoCA) and a self-report Likert scale of memory function were administered to 21 of the 23 participants. MoCA total scores, MoCA Memory subtest scores and self-reported total memory scores were calculated. Age comparisons of those fifty years of age or older versus those under 50 years will be made using regression analysis.

**RESULTS:** Thirteen (62%) participants scored below 26 on the MoCA (mean score= 23.62), 18 participants (86%) scored below 3.73 on the memory subtest (mean memory score=1.76) and 13 (62%) participants reported functional impairment in daily living activities associated with memory deficits.

**CONCLUSION:** Cognitive screenings should be routine for annual health examinations of retired professional football players. Future research is needed to examine additional factors contributing to cognitive decline among these individuals, including medical conditions and psychosocial factors.

---

1891 Board #299 MAY 30 2:00 PM - 3:30 PM

**The Mental Health Of Apprentice Horse Racing Jockeys: Is There A Need For Risk Assessment?**

Justine Stynes. *Australian Catholic University, Sydney, Australia.* (Sponsor: Mike Climstein, FACSM)  
(No relationships reported)

The life of the apprentice horse racing jockey is grueling. There is no 'off' season. The 4-year apprenticeship involves early morning track work (3 to 4 hours a day, 5 to 6 days a week), daily stable work (e.g., feeding and grooming horses), weekly trial meetings, and at least one race meeting a week (up to 8 rides per meeting). Injuries can be debilitating and life threatening. Jockeys constantly battle with meeting weight for competition. Evidence in other sports suggests that meeting weight can be psychologically debilitating, impacting the performance, longevity and well-being of the athlete. Despite the physical and psychological demands of the sport, there is limited research on the mental health of the apprentice jockey.

**PURPOSE:** To determine whether apprentice jockeys experience distress. To identify potential risk and protective factors for mental health in apprentice jockeys.

**METHODS:** Male (n=13) and female (n=1) apprentice jockeys with a mean age of 20.00 (SD=3.01) and mean weight of 49.89 kg (SD=7.91) were assessed using structured questionnaires and open ended questions. Distress was assessed using the Depression, Anxiety and Stress Scale and the Athlete Burnout Questionnaire. The potential risk and protective factors for mental health assessed were: resiliency (Resiliency Scales for Children and Adolescents), coping strategies (Adolescent Coping Scale), social support, and stressors.

**RESULTS:** The jockeys reported levels of depression (range=0-36, M=11.14, SD=10.69), anxiety (range=0-34; M =7.43, SD=8.28) and stress (range=0-40, M=12.74, SD=10.45) in the normal to severe range. Levels of burnout were reported in the low to high range for reduced accomplishment (M=2.52, SD= 0.74), emotional and physical exhaustion (M =2.43, SD=1.03), and sport devaluation (M=1.94, SD=0.81). Potential risk factors identified included: lack of social support, poor coping strategies (e.g., ignore the stressor, wishful thinking) and various sport related stressors (e.g., weight restrictions, getting rides). Potential protective factors identified included: social support (e.g., emotional) and constructive coping strategies (e.g., problem solve).

**CONCLUSION:** There is evidence of distress and burnout in apprentice jockeys. A risk assessment of mental health in apprentice jockeys is recommended.

1892 Board #300 MAY 30 2:00 PM - 3:30 PM

**Personality Variables And Barefoot Running**

Janet Buckworth, FACSM, Nicholas Hanson, Heather Preston. *The Ohio State University, Columbus, OH.*  
(No relationships reported)

Interest in barefoot running has grown in recent years, although many runners have not attempted or implemented barefoot running into their training. It is hypothesized that personality characteristics may be a factor in this decision.

**PURPOSE:** To determine if there are differences in personality between barefoot and shod runners.

**METHODS:** An online survey was administered to both male and female runners who had completed a footrace of at least 13.1 miles in the last two years [Project ULTRA (Understanding Long-distance Training and Runners' Affect)]. The runners were asked, "Have you ever run barefoot?" and were classified as either barefoot (BF) or shod (SH) runners by their response. The Big Five Inventory was used to assess five main dimensions of personality traits: Extraversion, Agreeableness, Openness, Conscientiousness and Neuroticism. This is a 44-item inventory that utilizes a 5 point Likert-style scale for each question. The subjects were asked to answer from 1 "disagree strongly" to 5 "agree strongly" regarding statements about their personality. Independent samples t-tests were used to compare the means of the two groups on the five personality dimensions.

**RESULTS:** Runners from 46 of the 50 states were represented in the sample. The mean age of the respondents was 39.86 yrs (range 18-80, SD 10.99 yrs). Of the 601 runners who completed the survey, 217 reported they had run barefoot. The barefoot runners scored significantly higher on the personality trait Agreeableness (BF mean 3.90 ± 0.57 SD vs SH mean 3.86 ± 0.66 SD, p<.01) and lower on Extraversion (BF mean 3.18 ± 0.85 SD vs SH mean 3.26 ± 0.85 SD, p<.01). There were no significant differences on Openness, Conscientiousness or Neuroticism. Additionally, 45% of shod runners were women (n=174) while only 30% of barefoot runners were women (n=65).

**CONCLUSION:** Our results show that runners who have at least attempted barefoot running tend to be more introverted (low-key, deliberate, quiet) and agreeable (sympathetic, cooperative, kind, affectionate). Very little is known about the participation of women in barefoot running, or personality factors that may distinguish them from shod female runners or male runners; therefore, further research is warranted on the extent of barefoot running and psychological factors in men and women.

---

**1893** Board #301 MAY 30 2:00 PM - 3:30 PM

**Mood State And Pre-performance Anxiety In Cirque Du Soleil Artists: Similar Yet Different From Competitive Athletes**

John S. Raglin, FACSM<sup>1</sup>, Janet Powell<sup>2</sup>, Ian Shier, FACSM<sup>3</sup>. <sup>1</sup>Indiana University, Bloomington, IN. <sup>2</sup>Cirque du Soleil, Las Vegas, NV. <sup>3</sup>Centre for Clinical Epidemiology and Community Studies, Lady Davis Institute for Medical Research, Jewish General Hospital, McGill University, Montreal, QC, Canada.  
(No relationships reported)

**PURPOSE:** To contrast mood state profiles and pre-performance anxiety trends between circus artists and competitive sport athletes.

**METHODS:** In a pilot study on injury prediction, 33 (17F, 16M) modern circus artists performing acts related to sport or music completed the Profile of Mood States (POMS) and State-Trait Anxiety Inventory (STAI) (Spielberger et al., 1993) under baseline and recalled best performance using methods based on Hanin's Individual Zones of Optimal Functioning (IZOF) model. POMS results were compared to published values for athletes (Raglin et al., 1991; Terry, 2000) with independent t-tests and the distribution of IZOF values contrasted with compiled athlete values (Raglin & Hanin, 2000) via Z-score transformations.

**RESULTS:** Mean POMS subscale values were: Tension; 14.7 (6.7), Depression; 8.0 (9.3), Anger; 8.9 (8.0), Vigor; 20.1 (5.4), Fatigue; 9.0 (5.8) and Confusion; 12.3 (4.4). Circus artists' scores for Anger, Vigor, Fatigue were similar to athletes ( $p > .05$ ), whereas Tension and Confusion were similar to non-athletes ( $p > 0.05$ , i.e. higher than athletes  $p < .05$ ). Baseline anxiety values did not differ from published norms for State: 37.2 (12.5) or Trait: 38.8 (10.8) anxiety. The mean score for optimal pre-performance anxiety was 31.9 (10.1). Compared to athletes, a greater proportion of circus artists (57.6% vs 21.6%) reported their optimal performance occurring at a lower anxiety range (T-score  $< 35$ ), but the proportions of artists with optimal performances at moderate (T-score 35-45) and high (T-score  $> 45$ ) anxiety levels were less than athletes (moderate: 27.3% vs. 44.2%; high: 15.1% vs 34.2%).

**CONCLUSIONS:** The mood state profiles of modern circus artists in this pilot study were similar to typical athlete profiles except for higher yet normal values for POMS tension and confusion, consistent with the tenets of Morgan's (1980) mental health model of sport performance. As predicted by the IZOF model, we found considerable variation on self-reported optimal pre-performance anxiety level ( $R = 20-55$ ). Finally, a greater proportion of circus artists appear to perform optimally at a lower level of anxiety compared to athletes, perhaps because of differences in performance context (e.g., competitive vs. non-competitive) or scheduling (occasional competition vs. 10-12 shows weekly).

**1894** Board #302 MAY 30 2:00 PM - 3:30 PM

**Motivations to Participate in Sport at the 2010 Pan Pacific Masters Games**

Kent J. Adams, FACSM<sup>1</sup>, Joe Walsh<sup>2</sup>, Stephen Burke<sup>2</sup>, Ian T. Heazlewood<sup>3</sup>, Jyrki Kettunen<sup>4</sup>, Mark DeBeliso<sup>5</sup>, Mike Climstein, FACSM<sup>6</sup>. <sup>1</sup>California State University Monterey Bay, Seaside, CA. <sup>2</sup>Australian Catholic University, Sydney, Australia. <sup>3</sup>Charles Darwin University, NT, Australia. <sup>4</sup>Arcada University of Applied Sciences, Helsinki, Finland. <sup>5</sup>Southern Utah University, Cedar City, UT. <sup>6</sup>Bond University, Gold Coast, Australia.  
(No relationships reported)

The Pan Pacific Masters Games are based on a philosophy that promotes and encourages mature athletes to compete in sport throughout life. Participating athletes have either pursued a sport for an extended period of time or have initiated sport involvement in later life. Pan Pacific Game's philosophy advocates competition, participation, and socialization in an environment rich in camaraderie. Due to health and functional implications, it is important to understand why this unique cohort of masters athletes participate in sport.

**PURPOSE:** To investigate athletes' motivations for participation in their sport at the 2010 Pan Pacific Masters Games held in Gold Coast, Australia.

**METHODS:** As part of an online survey, over 10,000 participants from 34 sports were asked to rate on a scale of 1 thru 7 the importance of 56 different reasons as to why they participate in their sport (1 = item is not a reason, 7 = item is a very important reason).

**RESULTS:** A total of 1,824 participants responded (response rate = 18%) with a mean age of 49.1 yrs (range 25 to 83 yrs). Competitors from 14 countries completed the survey. On a scale of 1-7 the top three reasons to participate were (mean (SD)): to socialize with other participants = 5.91 (1.41); to become more physically fit = 5.25 (1.76); and to improve my health = 5.25 (1.82). ANOVA revealed a significant difference ( $p = 0.000$ ) in reasons to participate. Post hoc analysis showed that socializing with other participants was a stronger reason for participation ( $p = 0.000$ ) than either improving health or developing fitness, and that no difference existed between the motivators of health and fitness. Participation with family and friends (5.22 (1.89)) and competition (5.20 (1.66)) were the 4<sup>th</sup> and 5<sup>th</sup> most important reasons to participate in the Games. All other reasons to participate scored less than 5 on average. The least important motivators to compete were to have time alone with the world (2.14 (1.6)) and to solve problems (2.21 (1.6)).

**CONCLUSIONS:** Socialization with other participants was the most important personal motivation for sport participation in the 2010 Pan Pacific Masters games. Health and fitness were less important motivators than socializing to these masters level athletes, but still stronger than competition.

**1895** Board #303 MAY 30 2:00 PM - 3:30 PM

**Characteristics of Elite Table Tennis Athletes' Brains Activity in Spin-Serve Judging Process**

Anmin Li, Male, Yuhui Zhang, female. Shanghai University of Sport, Shanghai, China.  
(No relationships reported)

**PURPOSE:** This study compared the brain activity of Chinese Olympic table tennis athletes and Chinese National League table tennis athletes when they executed a spin-serve judging tasks. The reactions of the cerebral areas involved with perception and response times were measured during the tasks. The purpose of the study was to examine differences in cognitive processing activities in the central nervous systems of athletes with different table tennis skill levels during the judging the spin of table tennis serves.

**METHODS:** Six female athletes from the Chinese Olympic table tennis team and 12 female athletes from the Shanghai University of Sports with National League table tennis participated in the study. All the participants were instructed to watch a video in which four kinds of serve spins. The participants' task was to identify the type of serve spin and to react by pressing one of four buttons to indicate which type of serve was. The participants' event-related potentials, response times, and accuracy were recorded at the same time.

**RESULTS:** The latency to the greatest activation in the occipital region of Olympic group was 200 ms shorter than that of the National League group. The ending of parietal cortex activation of the Olympic group was 270 ms earlier than the National League group. Positive waves were observed in the frontal lobes of the Olympic group, while negative ones appeared in the National League group 550-760 ms after the stimuli. The Olympic group had longer P3 latency and lower amplitude in occipital and parietal areas compared with the National League group. Further, P3 amplitudes in the left and right occipitals were significantly larger than that of the Olympic group.

**CONCLUSIONS:** (1) The transformation from occipital activation to parietal activation occurred more quickly in the Olympic group relative to the National League group. This faster transfer between the regions provided more time for making correct decisions.

(2) The Olympic group showed hemispheric asymmetry in the processing of visual stimuli by utilizing primarily the right occipital resources, whereas the National League group showed bilateral occipital activation.

(3) The Olympic Group showed a resource-saving mode with fewer occipital and parietal resources, allowing them to perform cognitive tasks more efficiently.

---

1896 Board #304 MAY 30 2:00 PM - 3:30 PM

**Effects of Transcranial Direct Current Stimulation on Performance, Autonomic Nervous System, and Rating of Perceived Exertion during Incremental Exercise**

Alexandre Hideki Okano<sup>1</sup>, Rafael Ayres Montenegro<sup>2</sup>, Edilson Serpeloni Cyrino<sup>3</sup>, Paulo De Tarso Veras Farinatti<sup>2</sup>, Eduardo Bodnariuc Fontes<sup>4</sup>. <sup>1</sup>Federal University of Rio Grande Do Norte, Natal/RN, Brazil. <sup>2</sup>State University of Rio De Janeiro, Rio De Janeiro/RJ, Brazil. <sup>3</sup>State University of Londrina, Londrina, Brazil. <sup>4</sup>State University of Campinas, Campinas/SP, Brazil.  
(No relationships reported)

Alexandre H. Okano, Rafael Ayres Montenegro, Edilson Serpeloni Cyrino, Paulo de Tarso Veras Farinatti, Eduardo Bodnariuc Fontes. Federal University of Rio Grande do Norte, State University of Campinas.

**PURPOSE:** We investigated the effects of transcranial direct current stimulation (tDCS) on heart rate variability, rating of perceived exertion (RPE) and time to exhaustion (TE) during in a maximal incremental exercise test to exhaustion in trained cyclists.

**METHODS:** Ten male national-level road cyclists volunteered to participate in this study (32.9±8.5 years; 171.5±5.8 cm; 72.8±9.5 kg; 24.8±3.2 kg/m<sup>2</sup>; 10.2±10.7 training years). The cyclists performed two maximal incremental exercise test: (a) anodal tDCS; (2) or sham for 20 minutes. Heart rate (HR), R-R interval (HRV), and RPE were recorded continuously through all stages of the experiment. From the data collected during the incremental test, the peak power output (PPO), HRV determined every minute and estimated HRV threshold (HRV<sub>TH</sub>) were determined. The testers and the cyclists were blinded to the test condition.

**RESULTS:** HRV<sub>TH</sub>, PPO and TE were all significantly higher for anodal tDCS than the SHAM condition (HRV<sub>TH</sub> anodal: 147.5 ± 53.3W vs sham: 125.0 ± 35.4, p=0.04; PPO anodal: 313.2 ± 29.9W vs sham: 301.0 ± 19.8, p=0.043; TE anodal: 751.4 ± 71.5s vs. sham: 723.7 ± 45.0s, p=0.05). RPE are significantly more slowly during the first six stages of the test in subjects received anodal tDCS.

**CONCLUSION:** We conclude that tDCS decreased RPE and improved performance and cardiac autonomic control.

Supported by FAPESP, CNPq, and CAPES.

1897 Board #305 MAY 30 2:00 PM - 3:30 PM

**The Stress and Depression Questionnaire as a Screening Tool for Depression and Suicide Risk in Collegiate Athletes.**

Katherine Rutherford, William Dexter, FACSM. *Maine Medical Center, Portland, ME.*  
(No relationships reported)

**BACKGROUND:** Collegiate and high school athletes, despite lower depression rates, are at equal risk for suicide behaviors and greater risk for self harm from suicide attempts compared with non-athletes. Athletes are thought to be less likely to seek psychiatric care than non-athletes due to social stigma. A tool that removes this barrier may increase athletes' utilization of psychiatric services.

The Stress and Depression Questionnaire (SDQ) is an anonymous online questionnaire, used at 50 universities in the U.S., which identifies and offers services to college students at highest risk for suicide. The current national average rate of response to email invitations to answer the SDQ is 8%. The SDQ's anonymity may reduce social stigma, encouraging utilization of this increasingly available tool by collegiate athletes.

**PURPOSE:** To determine whether collegiate athletes respond to the SDQ at the same rate as collegiate non-athletes.

**METHODS:** A retrospective review was performed of SDQs at the University of Southern Maine (USM) from September 22, 2010 to May 15, 2011. A question prompting self identification as varsity athlete (yes/no answer) was added to the USM SDQ at the beginning of this time period. 2850 members of the general student population were invited by email to answer the SDQ over this time period. Focused invitation to all 454 athletes was issued by the same email process in the spring semester. Self-identification as athlete or non-athlete on SDQ response and the total number of each population invited to answer the SDQ were used to calculate response rates of the two populations. These rates were compared using a chi-square test.

**RESULTS:** 98 students responded to the SDQ online survey in the study period. Six self-identified as athletes and 91 as non-athletes; there was one non-response. The athletes had a significantly lower response rate (6/494, 1.3%) compared with non-athletes (91/2850, 3.2%) (chi-square test = 4.179, p= 0.04) Both groups at USM had significantly lower response rates than the national average response rate of 8%.

**CONCLUSION:** At USM, athletes responded to the SDQ at a significantly lower rate than non-athletes. Both populations were well below the national average, suggesting that there may be something unique to USM's student population causing overall decreased utilization of this tool.

---

1898 Board #306 MAY 30 2:00 PM - 3:30 PM

**Pilot Normative Data for Verbal Fluency and Perseverative Errors among High School Athletes**

Jenifer W. Sudkamp, Roberta A. Bell, Gregory W. Stewart, FACSM. *Tulane Institute of Sports Medicine, New Orleans, LA.*  
(No relationships reported)

**BACKGROUND:** Sport related concussion is serious and often challenging to diagnose and manage. Sideline health care providers are the first responders to concussion in athletics, but currently have limited access to brief, portable, and reliable cognitive screenings of acute concussion in the absence of loss of consciousness.

Evidence suggests that phonemic and semantic verbal fluency and frequency of perseveration errors during verbal fluency tasks are sensitive to brain injury. Despite their potential as portable measures of cognitive dysfunction, systematic study of the relationships of perseveration errors and verbal fluency to pre- and post-concussion cognitive status has been slighted.

**PURPOSE:** To establish normative data for verbal fluency and perseveration errors in high school athletes

**METHODS:** 42 athletes completed pre-participation phonemic and semantic verbal fluency tasks. Age ranged from 14 to 18 years, while education varied from eight to 11 years. Perseverative frequency, words generated in one minute for the letter "m" (phonemic fluency), and animal names generated in one minute (semantic fluency) were documented.

**RESULTS:** Means and standard deviations for the two fluency tasks and perseveration errors will be calculated for each of four levels of education (zero to eight, nine, ten, and eleven years). The effects of education level on verbal fluency (phonemic and semantic) and perseveration frequency will be determined by regression analyses. Finally, a correlational analysis of animals named and words with the initial "m" will be completed.

**CONCLUSIONS:** Results of this study will provide pilot norms for two verbal fluency tests and perseveration frequency in high school athletes. Further research with a larger sample is warranted to establish more valid norms. These norms will increase the potential for sideline health care providers to accurately and quickly assess post-concussion cognitive function.

---

1899 Board #307 MAY 30 2:00 PM - 3:30 PM

**The Influence of a Collegiate Soccer Season on Perceived Stress and Recovery Scores**

Stephen J. Rossi, Jim McMillan, Thomas Buckley. *Georgia Southern Univ, Statesboro, GA.*  
(No relationships reported)

The pre-season for collegiate men's soccer is short and requires athletes to participate in a heavy training load to get ready for the upcoming season. It is important that these athletes are able to recover mentally and physically during training to prevent injuries and mental fatigue during the upcoming competitive season.

**PURPOSE:** The intent of the present study was to examine the influence of a competitive collegiate men's soccer season on perceived stress and recovery (RESTQ-Sport).

**METHODS:** Nine male NCAA Division I soccer players filled out a RESTQ-Sport questionnaire before the start of the pre-season (T1), three times during the season (T2, T3, T4), and post-season (T5). Participants were given the same instructions at each time point on how to properly answer the questionnaire. Repeated Measures ANOVA was run on all general and sport specific stress and recovery scale means and significance was set at p<0.05.

**RESULTS:** Repeated measures ANOVA revealed a significant time effect for the general stress scale ( $p = 0.015$ ) and a simple contrast using T1 ( $0.94 \pm 0.39$ ) as a baseline revealed significant difference at T2 ( $1.92 \pm 1.20$ ;  $p = 0.017$ ), T3 ( $1.56 \pm 0.61$ ;  $p = 0.009$ ), T4 ( $1.31 \pm 0.54$ ;  $p = 0.038$ ), and T5 ( $1.67$  vs.  $0.86$ ;  $p = 0.010$ ). Social stress showed a significant time effect ( $p = 0.02$ ) and a simple contrast using T1 ( $1.34 \pm 0.65$ ) as a baseline revealed significant difference at T2 ( $2.44 \pm 0.92$ ;  $p = 0.003$ ), T3 ( $2.10 \pm 0.98$ ;  $p = 0.042$ ), and T5 ( $2.10 \pm 0.73$ ;  $p = 0.011$ ). Fatigue showed a significant time effect ( $p = 0.001$ ) and a simple contrast using T1 ( $1.34 \pm 0.65$ ) as a baseline revealed significant difference at T3 ( $3.11 \pm 1.12$ ;  $p = 0.011$ ) and T5 ( $2.40 \pm 0.94$ ;  $p = 0.008$ ).

**CONCLUSION:** These data indicate general stress, social stress, and fatigue were negatively influenced by a collegiate soccer season. Higher scores on the three general stress scales have been associated with complaints of being stressed, depressed, having conflicts with others, and feeling over fatigued, and having problems sleeping. The RESTQ-Sport may provide useful information about an athlete's recovery status and readiness to train and compete. This information could be beneficial when designing an athletes' training program.

---

**1900** Board #308 MAY 30 2:00 PM - 3:30 PM

**Athletic Perseverance: Assessing Perseverance Attributes Of Athletes And Non-athletes**

Matthew C. Wagner<sup>1</sup>, Judy L. Sandlin<sup>2</sup>, Rosanne S. Keathley<sup>1</sup>. <sup>1</sup>Sam Houston State University, Huntsville, TX. <sup>2</sup>Texas A&M University, College Station, TX.  
(No relationships reported)

**PURPOSE:** The purpose of this study was to gather baseline data on athletic perseverance of college students and student-athletes.

**METHODS:** Participants ( $n = 75$ ) were selected university students and a matched sample of Division 1 student-athletes. Each was given the 30-item Mental Toughness Scale (Goldberg, 2006). The instrument contains five subscales - Reboundability, Ability to Handle Pressure, Concentration, Confidence, and Motivation - these are summed to yield an overall Athletic Perseverance Score. The maximum score for each subscale is 6 thereby producing an over all maximum score of 30.

**RESULTS:** A one-way MANOVA was utilized to determine if significant differences were observed between the athletes and non-athletes on the five subscales. Significant differences were found between athletes and non-athletes, Wilks lambda = .69,  $F(5, 68) = 6.09$ ,  $p = .000$ . Analyses of variances were conducted as follow-up tests to the MANOVA. The ANOVA for Pressure,  $F(1, 72) = 13.21$ ,  $p = .001$ , Concentration,  $F(1, 72) = 17.12$ ,  $p = .000$ , Confidence,  $F(1, 72) = 11.49$ ,  $p = .001$ , and Motivation,  $F(1, 72) = 10.57$ ,  $p = .002$  were each significant. For each significant subscale, the athletes scored higher when compared to students.

**CONCLUSIONS:** Athletes demonstrated higher levels of athletic perseverance than non-athletes. Further research could investigate the effectiveness of different aspects of mental training for both student-athletes and students.

---

**1901** Board #309 MAY 30 2:00 PM - 3:30 PM

**Psychological Determinates of Injury: Expanding the Mechanical Model**

Diane L. Elliot, FACSM, Esther L. Moe, Linn Goldberg, FACSM, Chondra M. Lockwood. Oregon Health & Science University, Portland, OR.  
(No relationships reported)

Adolescent female athletes are at increased risk for sport injuries, especially knee trauma. To date, the focus of understanding knee injuries' pathophysiology and prevention has been on anatomy and neuromuscular control. Identifying other determinants of injury might allow for a more comprehensive prevention paradigm.

**PURPOSE:** Define an injury model for female high school athletes that uses psychological dimensions as predictors of sport trauma.

**METHODS:** A 45-minute anonymous survey using validated indices of psychological traits/states was administered to female athletes from a range of sports and a spectrum of high schools. Reliable constructs were assessed as predictors in both an 'any injury' and 'knee injury' model.

**RESULTS:** Data were collected from 490 female (soccer, volleyball, cross country) athletes from 9 high schools. Any injury (prevalence 41% total) was related to aggression (OR=1.44 [1.05-1.97]), hypercompetitive attitude (OR 1.30 [1.06-1.60]), and home stress (OR 1.38 [1.14-1.66]), each  $p < .05$ . Knee injury (prevalence 10.6%) related to win-at-all-costs (OR 1.31 [1.07-1.60]) and perfectionism (OR 1.28 [1.08-1.51]), both  $p < .05$ .

**CONCLUSION:** Expanding existing injury prevention models to include psychological determinants might better prevent injury and provide young female athletes with mental resilience that would benefit them on and off the playing field.

---

**1902** Board #310 MAY 30 2:00 PM - 3:30 PM

**Independent And Interactive Effects Of Mother, Father, And Coach Autonomy Support On Athletes' Self-determined Motivation**

Anthony J. Amorose<sup>1</sup>, Lindley McDavid<sup>2</sup>, Allison Riley<sup>3</sup>, Aidyn Iachini<sup>4</sup>. <sup>1</sup>Illinois State University, Normal, IL. <sup>2</sup>Purdue University, West Lafayette, IN. <sup>3</sup>Ohio State University, Columbus, OH. <sup>4</sup>University of South Carolina, Columbia, SC. (Sponsor: Kristen M. Lagally, FACSM)  
(No relationships reported)

Given the numerous achievement-related benefits associated with athletes' adoption of a more self-determined motivational orientation toward sport, understanding the processes that impact the development of athletes' motivation is critical for those working to promote youth sport participation. While many factors may affect athletes' motivation, the degree of autonomy support provided by parents and coaches are assumed to be particularly important according to self-determination theory. Studies have shown that coach autonomy support is predictive of athletes' motivation; however, limited research exists on the effect of parents' autonomy support, particularly in relationship to how each of these social influences may impact motivation separately. Scholars also have shown the value of considering how multiple social influences combine to influence athletes' motivational outcomes, yet this has not been tested when considering parent and coach autonomy support.

**PURPOSE:** The purpose of this study was to examine the independent and interactive influences of athletes' perceptions of autonomy support from their mothers, fathers, and coaches on athletes' self-determined motivation.

**METHODS:** Athletes ( $N=335$ ; M age=15.75 years; 62.4% female; 84.2% Caucasian) from a variety of school-sponsored sport teams completed survey measures near the end of their competitive season assessing their level of self-determined motivation and their perception of autonomy support provided by their coach, mother, and father.

**RESULTS:** Hierarchical regression analysis results showed that autonomy support from all three social agents significantly and positively predicted the athletes' self-determined motivation ( $R^2 = .32$ ). The addition of the two-way and three-way interactions between coach, mother, and father autonomy support significantly added to the overall prediction (total  $R^2 = .35$ ). The pattern of results showed that relatively high levels of perceived autonomy support from any two of the social agents was associated with higher levels of self-determined motivation.

**CONCLUSIONS:** The findings of this study demonstrate how the combination of perceived autonomy support from these three influential social agents (i.e. coaches, mothers, fathers) can add to the understanding of athletes' sport motivation.

---

**1903** Board #311 MAY 30 2:00 PM - 3:30 PM

**The Effect Of Growth And Maturation On Mental Skills Of Junior Elite African Soccer Players**

Linda Van den Berg<sup>1</sup>, Julius Jooste<sup>2</sup>. <sup>1</sup>Tshwane University of Technology, Eldoraigne, South Africa. <sup>2</sup>Tshwane University of Technology, Pretoria, South Africa.  
(No relationships reported)

**Abstract:** Physical characteristics associated with superior performance in soccer favor males who are advanced in their biological maturity status. Players who are successful at senior level, can mostly be identified by their psychological approach to their sport. Research indicates that early developers are usually chosen at a young age above late developers due to their advantage in size and power. Despite this, the impact of biological growth and maturation on the psychological development of young athletes has received relatively little attention.

**PURPOSE:** The study investigated if a difference exist in mental skills of junior elite African players of different maturity levels.

**METHODS:** A total of 155 male soccer players with an average age of 16.3 years, representing 11 countries in Africa formed part of this study. A Biological maturation questionnaire was compiled to ascertain biological maturation, and accordingly classified the group into early (ED,  $n = 29$ ), average (AD,  $n = 77$ ) and late developers (LD,  $n = 46$ ). Sport psychological skills (Coping with adversity, Peaking under pressure, goal-setting and mental preparation, concentration, freedom from worry) as determined by the Athletic coping Skills inventory-28 and

(imagery ability, mental preparation, goal setting, self-confidence, anxiety and worry management, concentration ability, relaxation ability, and motivation) as determined by the Bull's Mental Skills Questionnaire (MSQ) were measured. The results for each group were expressed as percentage values.

**RESULTS:** Descriptive results indicated that for most of the sub components, the LD showed better results than the ED and the AD. Despite this tendency, statistically significant differences could only be found for Imagery ability ( $p=0.00$ ), relaxation ( $p=0.36$ ), Coping with adversity ( $p=0.01$ ) and goal setting and mental preparation (0.007), with LD showing better results than the ED.

**CONCLUSION:** According to this study late developers showed a bigger advantage regarding mental skills abilities above ED and this might have contributed to them being selected for national teams. This study delivered insightful results, which proves the important role that mental skills should play in the talent identification process in specifically young soccer players.

**1904** Board #312 MAY 30 2:00 PM - 3:30 PM

**Comparison of Exercise and Eating in Collegiate Athletes vs. Non-Athletes Active in High School Sports**

Laura Blair, Melinda W. Valliant, Kathy Knight, Yunhee Chang, John C. Garner. *The University of Mississippi, University, MS.* (Sponsor: Mark Loftin, FACSM)

(No relationships reported)

Numerous studies have been conducted on eating disorders (ED) in collegiate athletes. Many studies conclude that collegiate athletes are more at risk of developing an ED compared to non-athletes, while some report the opposite.

**PURPOSE:** To determine if collegiate athletes are more likely to exhibit ED characteristics compared to those who only participated in high school sports. **Method:** Each participant completed The Eating Attitude Test-26 (EAT), The Eating Disorder Inventory subscales Body Dissatisfaction (EDIBD), Drive for Thinness (EDIDFT), and Bulimia (EDIBUL) and The Body Shape Questionnaire-34 (BSQ).

Group differences were examined for males ( $N=101$ ), females ( $N=189$ ), collegiate athletes ( $N=107$ ), non-athletes who played sports in high school (high school athletes) ( $N=183$ ), and those who did not play sports in high school (non-athletes) ( $N=31$ ).

**RESULTS:** Two-tailed independent T tests for equality of means were computed to examine group differences. In comparison to males, females scored significantly higher on the EAT ( $t=3.186$ ,  $p=.002$ ), the EDIDFT ( $t=-4.897$ ,  $p=.000$ ), EDIBD ( $t=-4.075$ ,  $p=.000$ ), and BSQ ( $t=-6.618$ ,  $p=.000$ ). No significant differences were found regarding EDIBUL. Combined collegiate athletes and high school athletes ( $N=259$ ), showed no significant differences in comparison to non-athletes in EAT, EDIDFT, and EDIBUL. However, non-athletes scored significantly higher on the EDIBD ( $t=-2.629$ ,  $p=.013$ ) and BSQ ( $t=-2.617$ ,  $p=.013$ ) compared to collegiate athletes and high-school athletes. Compared to collegiate athletes, high school athletes scored significantly higher on the EAT ( $t=3.570$ ,  $p=.000$ ) EDIDFT ( $t=-2.983$ ,  $p=.003$ ), EDIBD ( $t=-4.750$ ,  $p=.000$ ), and BSQ ( $t=4.308$ ,  $p=.000$ ). No significant differences were found between these two groups regarding EDIBUL.

**DISCUSSION:** Compared to collegiate athletes, high school athletes scored significantly higher on the EAT, EDIDFT, EDIBD, and BSQ, indicating they are at a greater risk of an ED. The mixed results found when combining collegiate athletes and high school athletes in comparison to non-athletes suggest that more research is needed to determine if one group is at a greater risk than the other. Overall, this study suggests high school only athletes are more at risk of developing an eating disorder compared to collegiate athletes.

**Self Reported Alcohol Consumption and its Effect on Fatigue and Hydration**

David D. Dziedzicki, Lindsey E. Eberman, Leamor Kahanov, Heather Mata. *Indiana State University, Terre Haute, IN.*

(No relationships reported)

Research suggests that collegiate students athletes are at an increased risk for binge drinking behaviors. Alcohol has numerous negative physiological effects. For collegiate athletes these effects may lead to decreased performance.

**PURPOSE:** The purpose was to identify the relationship between self reported alcohol consumption and fatigue and hydration existed.

**METHODS:** We used a correlational design to determine the relationship between the dependent measures. We acquired IRB approval to evaluate 5 Division I athletic teams from one educational institution (ages of 18-26; football=15, baseball=25, softball=11, soccer=25, volleyball=15; men=40, women=51). We measured hydration status using a clinical refractometer, self reported alcohol consumption using the alcohol use disorders identification test (AUDIT) questionnaire, and fatigue using the visual analog scale for fatigue (VAS-F). During the initial team meeting we acquired informed consent and measured baseline fatigue. Athletic Training Services performed baseline hydration status testing during pre-participation physicals (PPEs). Each team participated separately on an "off day" post competition and again 3 days following. During the follow-up data collection sessions, we assessed hydration status, VAS-F, and AUDIT.

**RESULTS:** We identified no significant or strong relationships between our dependent variables (Spearman's rho correlation range=0.003-0.079,  $p$  range=0.192-0.973). We identified significant differences in hydration status over time ( $F_{2,269}=5.226$ ,  $p=0.006$ ,  $\eta^2=0.037$ ) between baseline hydration status (1.017±0.001) and follow-up day 1 (1.021±0.001) as well as follow-up day 3 (1.020±0.001). We also identified a significant difference between sports on the AUDIT score ( $F_{4,86}=4.279$ ,  $p=0.003$   $\eta^2=0.166$ ) with significant differences between this highest risk athletes from softball (9.73±1.22) and the lower risk athletes in soccer (4.36±0.81) and baseball (4.36±0.81).

**CONCLUSIONS:** Although we were unable to identify strong correlations between dependent measures, our results may indicate alcohol consumption has an impact on hydration status and ultimately performance. Although other factors may have influenced hydration, we did identify significant dehydration following alcohol consumption.

**The Relations Between sEMG and Knee Angles Of 24 Style Tai Chi (TC)**

Dong Zhu<sup>1</sup>, Li Li, FACSM<sup>2</sup>, Hongguang Hua<sup>1</sup>, Shan Luo<sup>1</sup>, Song Wang<sup>1</sup>, Guohai Cheng<sup>1</sup>. <sup>1</sup>Shanghai University of Sport, Shanghai, China. <sup>2</sup>Louisiana State University, Baton Rouge, LA.

(No relationships reported)

Many studies indicate that the TC practice has the positive effect on participants' health. However, a few studies have negative reports for Taichi practitioners' knee health after TC practice. These reports focus on incorrect skills might cause practitioners' knee pain. One of incorrect skills is excessive knee internal rotation when TC practitioner shifts their center of gravity.

**PURPOSE:** To investigate the relationship between knee angles and surface electromyography (sEMG) among TC practitioners' lower extremity muscles.

**METHODS:** Sixteen female subjects participated in 24 styles TC practices (age: 21.3±1.9 yrs, height: 162.6±4.2 cm, mass: 53.6±4.4 kg). Subjects were divided into two groups, advanced (AL) and beginner (BL) levels, respectively. Surface electromyography (sEMG) was collected from vastus medialis (VM), rectus femoris, vastus lateralis (VL), and tibialis anterior at 1500Hz. Electric goniometer (2D) was attached to subjects' right knee. sEMG signals were rectified and smoothed using the root square mean with a 50ms smoothing window. Independent-Samples T test was used for statistical analysis.

**RESULTS:** Mean knee joint flexion-extension range of motions (ROM) were 48.7±7.2 and 48.6±8.6 deg, for AL and BL, respectively. Mean knee joint internal-external rotation ROMs were 2.8±8.8 and 0.4±8.6 deg, for AL and BL, respectively. Meanwhile, the peak knee joint flexion angle for AL group was 99.9±24.6 deg, 22 degrees higher than that in the BL group. The peak knee joint internal rotation angle was 23.7±14.2 deg for AL, and 14.6±14.2 deg for BL. There was significant correlation ( $r=-0.39$ ,  $P<0.01$ ) between mean sEMG values of VL and knee internal-external rotation ROM with AL group. In comparison, there was significant correlation ( $r=0.42$ ,  $P<0.001$ ) between mean sEMG values between VM and knee internal-external rotation ROM with BL group.

**CONCLUSIONS:** The knee joint ROM and peak angles were different between groups. Moreover, knee joint internal-external rotation was correlated with VL activity among the AL group whereas with VM among the BL group. Further investigation should focus on the differential effect of knee rotation on different muscle groups among different TC practice levels.

**The Evaluation Of Active Drag: A New Proposal**

Bruno Mezêncio<sup>1</sup>, João G O Claudino<sup>1</sup>, Pollyana P. Takao<sup>1</sup>, Rafael Soncin<sup>2</sup>, Jacielle C. Ferreira<sup>2</sup>, Leszek A. Szmuchrowski<sup>2</sup>, Rudolf Huebner<sup>2</sup>, Alberto C. Amadio<sup>1</sup>, Júlio C. Serrão<sup>1</sup>. <sup>1</sup>USP, São Paulo, Brazil. <sup>2</sup>UFMG, Belo Horizonte, Brazil.

(No relationships reported)

The active drag has a strong influence on swimmers performance, but it is a controversial issue because of complexity of the flow around the swimmer. Used methods for estimating this variable need greater specificity or accuracy.

**PURPOSE:** Measure the mean drag active of swimmers through the difference between the net force in dynamometry testing with (WD) and no displacement (ND).

**METHODS:** In a ND test the active drag is approximately zero due to drag-speed relationship. Thus, the strength difference between ND and WD tests is the drag active experienced by the swimmer on test speed with displacement. Twelve tests were conducted to measure the propulsive force ND and WD, the minimum time of rest between attempts was five minutes. A unidirectional load cell, with sampling rate of 1000Hz, measured net force in both situations. The sequence of tests was randomized and balanced. The study included eight swimmers with performance equivalent to 81.9 ± 6.4% of the world record of 50 meters freestyle and height of 1.74 ± 0.06 m. The stroke rate and kick count, per cycle, was used to evaluate the technical differences between the tests. A camcorder with 1000 fps was used to recorder the underwater motion of swimmer. The measurement errors were calculated by the method of propagation of uncertainties considering the individual variability and characteristics of the measuring equipment.

**RESULTS:** There was no significant difference between the technique evaluated from the stroke rate (ND = 1.083 ± 0.069 and WD = 1.088 ± 0.075 s, p> 0.05), and kick count (ND = 6 ± 0 and WD = 6 ± 0, p> 0.05) of the different tests. The mean drag active was evaluated 153.74 ± 9.75 N with associated error estimated at 12.44%.

**CONCLUSION:** The estimated active drag values are within the range of values previously reported for swimmers of similar performance (42 to 167 N). However, the associated error of estimate was lower than was showed in other methods (30%). Thus, the proposed method is a practicable alternative to assess the active drag of swimmers.

**1908** Board #316 **MAY 30** **3:30 PM - 5:00 PM**

**Kinematic Comparison Of Different Step Lengths In A Swimming Incremental Protocol**

Ricardo J. Fernandes<sup>1</sup>, João Ribeiro<sup>1</sup>, Ana Sousa<sup>1</sup>, Marisa Sousa<sup>1</sup>, Arturo Abraldes<sup>2</sup>, Carmen Ferragut<sup>3</sup>, Pedro Figueiredo<sup>1</sup>, J. Paulo Vilas-Boas<sup>1</sup>. <sup>1</sup>CIFIZD and LABIOMEPE, University of Porto, Porto, Portugal. <sup>2</sup>Faculty of Sport Sciences, University of Murcia, Murcia, Spain. <sup>3</sup>Faculty of Physical Activity and Sport, University of Alcalá de Henares, Madrid, Spain. (Sponsor: Carlo Baldari, FACSM)

(No relationships reported)

Swimming incremental protocols are frequently used for swimming aerobic performance assessment. Nevertheless, different step lengths might impose differences in swimming technique.

**PURPOSE:** To determine and compare the stroke rate (SR) and length (SL), arm coordination (IdC) and propelling efficiency (np) during an intermittent incremental protocol with different step lengths.

**METHODS:** Eight long distance swimmers (25.6±8.8yrs, 69.9±5.5kg, 1.78±0.49m) performed 7x200, 300 and 400m (0.05m/s increments; 30s rest between steps and 24h between protocols) in front crawl until exhaustion; the velocity of each step was common to the three protocols. Two arm stroke cycles of the last 50m lap of each step were digitized (APASystem). SL was assessed using the right hip point, and SR was measured as the ratio of velocity to SL. np was considered as: (velocity\*0.9/2π\*SR\*shoulder to hand distance)\*2/π. IdC was determined by the lag time between propulsive inter-arm phases. Comparison between protocols was done using Friedman test (p≤.05).

**RESULTS:** In Table 1 it is possible to observe a SR increase and a SL decrease throughout the protocols, with a tendency to lower SL values in the last steps of the 400m protocol. The IdC values expressed a catch-up coordination mode, similar in all step lengths, increasing at higher velocities. The np decreased throughout the steps of each protocol, without significant differences between protocols.

**The Effect of a Dynamic and Static Start on Snatch Pull Technique and Performance**

Erich J. Petushek<sup>1</sup>, Karen Roemer<sup>1</sup>, Brett Hamlin<sup>1</sup>, William P. Ebben<sup>2</sup>, Breanne R. Carlson<sup>3</sup>, Casey Mallo<sup>3</sup>, Andy Tysz<sup>3</sup>, Randall L. Jensen, FACSM<sup>3</sup>. <sup>1</sup>Michigan Technological University, Houghton, MI. <sup>2</sup>University of Wisconsin-Parkside, Kenosha, WI. <sup>3</sup>Northern Michigan University, Marquette, MI.

(No relationships reported)

The start and "first pull" phase of the snatch lift is important for weightlifting success, however, two styles are often displayed. The variations are a "static" and "dynamic" movement of the hips just prior to barbell liftoff. The differences in these technique variations have yet to be assessed in elite weightlifting athletes.

**PURPOSE:** To assess the differences between a static and dynamic start on snatch pull technique and performance at various loads.

**METHODS:** Eight male and three female weightlifters (Mean  $\pm$  SD; Age = 20.18  $\pm$  1.40 yrs; Mass = 77.89  $\pm$  17.12 kg; Ht = 169.55  $\pm$  11.37 cm; Snatch 1RM = 99.09  $\pm$  32.35 kg) competing at the national or international level performed two snatch pulls at 90, 100 and 110% of their 1RM in the snatch using a static and dynamic starting technique, which were counterbalanced. Performance was assessed by maximum vertical ground reaction force (VGRFmax), barbell displacement (Ymax), and velocity (Vmax) while technique was assessed by maximum horizontal barbell displacement (Hmax) and mean angle of the resultant GRF vector during the first pull (GRFang). A two-way repeated measures ANCOVA was used to compare differences between a static and dynamic starting technique across loads while controlling for the athlete's preferential starting technique.

**RESULTS:** Five athletes preferred the static whereas six preferred the dynamic technique. Significant main effects for load condition were displayed for VGRFmax (110>100, 110>90), Ymax, and Vmax (Both: 90>100>110%) regardless of starting technique ( $p < 0.01$ ). No significant main effect or interaction for starting technique were displayed for any of the performance: VGRFmax (dynamic = 2801.89  $\pm$  691.02 N, static = 2784.69  $\pm$  689.85 N), Ymax (dynamic = 1.15  $\pm$  0.09 m, static = 1.14  $\pm$  0.09 m), and Vmax (dynamic = 1.72  $\pm$  0.18 m/s, static = 1.72  $\pm$  0.19 m/s); or technique: Hmax (dynamic = 0.074  $\pm$  0.029 m, static = 0.073  $\pm$  0.021 m) and GRFang (dynamic = 89.35  $\pm$  0.58°, static = 89.23  $\pm$  0.51°) variables ( $p > 0.05$ ).

**CONCLUSIONS:** Snatch pull performance and technique at various high intensities remains unaffected by a dynamic or static starting technique. Thus, coaches may teach either starting technique based on individual athlete needs.

**Simulation Of Micro-fracture In Skiers**

Harcharan S. Ranu. *King Saud University, Riyadh, Saudi Arabia.* (Sponsor: WF Straub, FACSM)

(No relationships reported)

**PURPOSE:** To simulate and quantify the micro-fracture in skiers.

**METHODS:** Paramed Datalogger® was used to measure insole plantar pressures to simulate micro-fractures in ski jumping during take-off. For heel and big toe maximum pressures measured were 221 $\pm$ 99.45 N.cm<sup>-2</sup> and 558 $\pm$ 234.36 N.cm<sup>-2</sup> respectively. These data were used in model to simulate the micro-fractures in skiers. Number of cycles to cause failure of bone due to repetitive take-offs were obtained using the following equations: The crack growth model is taken as  $a \propto a_i (1)$  Where  $a_i$  is initial plan size and  $a$  is crack growth increment associated with  $i$ th applied load and the process continues until a terminal flaw size is obtained. The fatigue crack propagation rate (FCPR) is defined as the length (or area) propagated during one stress/strain cycle,  $da/dN$ . FCPR model provides a functional relationship between the crack growth rate  $da/dN$  and the stress intensity factor range  $\Delta K$ , i.e.,  $da/dN = C(\Delta K)^m (2)$  Where  $a$  is the crack length,  $N$  is the number of cycles and  $C$  and  $m$  are material constants that characterize the crack propagation rate. From Equation # 2 obtains number of cycles of repetitive jumps to cause failure ( $N_f$ ) of bone follows: where,  $a_i$  and  $a_f$  are initial and final crack length respectively. Using  $a_i = 10.0 \times 10^{-8}$  m,  $\Delta K = 1.0 \times 10^{-6}$  m,  $m = 1.25$ , and  $\Delta K = 1.12$ , integrated numerically with an increment of  $10 \times 10^{-6}$  m to the final value of the crack length ( $a_f$ )  $10 \times 10^{-6}$  m. Rate of change of crack length with the number of cycles ( $da/dN$ ) was obtained.

**RESULTS:** Typical behavior of crack growth rate characteristics for a plantar pressure of 792 N.cm<sup>-2</sup> and  $m$  being 1.25, reveals that 6 take-offs were sufficient to initiate micro-fracture of big toe bone in skiers. Similarly for a plantar pressure of 321 N.cm<sup>-2</sup> and  $m$  being 1.25, reveals that 15 take-offs were sufficient to initiate micro-fracture in heel bone of skiers. The results of this study also indicate that the number of take-offs for micro-fracture of skier bone decreases as the value of  $m$  increases.

**CONCLUSIONS:** These data predicted development of an in vivo micro-fracture in skiers even before it occurred and micro-fracture was sensitive to number of take-offs. Model was of significance in bone remodeling, fracture fixation of bone, prosthetic and shoe design, etc. It showed that shoes, and other supports can reduce the propagation of bone crack or injury prevention.

**Cycling on Rollers: Motion Characteristics for Dynamic Stability**

Gerald A. Smith, FACSM, Andrew Miller, Eadric Bressel, Edward Heath, FACSM. *Utah State University, Logan, UT.*

(No relationships reported)

During off-season, cyclists maintain or improve fitness and technique by training on rollers or stationary trainers. Because of the balance required on a narrow riding surface, rollers are often recommended as a means of training cycling technique.

**PURPOSE:** Compare bike and rider motion characteristics on a stationary trainer with those on rollers at similar power outputs.

**METHODS:** Experienced cyclists ( $n = 5$ ) rode at similar power outputs on a CycleOps Supermagneto trainer and CycleOps aluminum rollers with magnetic resistance. Power was measured with an instrumented rear wheel (Powertap SL+) and targeted to demand 70% of peak oxygen uptake. A Vicon motion analysis system was used to record bike and rider 3D positions at 100 Hz. Bike lean, yaw, steering, and pedaling angles were calculated along with rider relative motion during 60 seconds of stable riding.

**RESULTS:** Similar power outputs were obtained for both conditions (275  $\pm$  42 W). Considerable fluctuation of crank angular velocity was evident during a pedaling cycle with peak rotation rate near mid-downstroke and minima with pedals near top or bottom of the rotation. Some riders exhibited shifts of timing for peak angular velocity from trainer to rollers. While bike motion on the stationary trainer was minimal as expected, medio-lateral motion on the rollers was about 22 mm (SD about midpoint). Lean angles (SD of 0.8°) were coordinated with pedaling and displayed lean to the left during right downstroke and to the right during left downstroke. Similar coordination with pedaling was observed for yaw and steering angles (SDs of 0.6 and 0.8°, respectively) during riding on rollers. Relative motion of trunk to bike exhibited unique individual patterns that were very repeatable but for some riders were different for the two conditions.

**CONCLUSIONS:** Subtle differences of rider motion and pedaling characteristics were observed for cycling on rollers compared to a fixed position trainer. Due to balance requirements, bike motion with each pedaling cycle on rollers involved a complex angular interplay which is likely a closer approximation to overground riding than is a stationary trainer.

**Strength Ratios of Hip Musculature in Male and Female Collegiate Soccer Players**

Meghan M. Miller<sup>1</sup>, Jay Hertel, FACSM<sup>2</sup>, Bonnie Van Lunen<sup>3</sup>, Nelson Cortes<sup>4</sup>, Matthew Schroeder<sup>1</sup>, Dustin Grooms<sup>1</sup>, James Onate<sup>1</sup>. <sup>1</sup>The Ohio State University, Columbus, OH. <sup>2</sup>University of Virginia, Charlottesville, VA. <sup>3</sup>Old Dominion University, Norfolk, VA. <sup>4</sup>George Mason University, Washington, DC.

(No relationships reported)

Weak hip musculature has been identified as a factor in lower extremity injury which affects women at a rate 2-6 times greater than men. Gender differences in muscular strength ratio (agonist:antagonist) may exist; in turn, affecting injury disproportionality.

**PURPOSE:** The purpose of this study was to determine if strength ratio differences existed between male and female collegiate soccer players.

**METHODS:** Peak isometric hip strength was measured for 144 male (179.6  $\pm$  6.7 cm, 76.6  $\pm$  7.8 kg, 19.5  $\pm$  1.3 years) and 157 female (167.4  $\pm$  6.0 cm, 62.7  $\pm$  7.1 kg, 19.3  $\pm$  1.1 years) collegiate soccer players using a portable load cell (BTE Technologies, Hanover, MD). Frontal and sagittal plane motions were measured in the standing position, transverse plane rotations were measured in the seated position. Peak strength values were arranged into three strength ratios: Hip flexion:extension (FLX:EXT), hip abduction:adduction (ABD:ADD), hip external:internal rotation (ER:IR). Ratio values were obtained by dividing peak strength of the agonist muscle by peak strength of the antagonist. A 2 (gender) x 3 (strength ratio) MANOVA was conducted, with an alpha level of 0.05, in order to determine the existence of gender differences in strength ratios.

**RESULTS:** No significant differences were seen between genders for any of the three strength ratios (FLX:EXT  $p = .139$ , ABD:ADD  $p = .890$ , ER:IR  $p = .424$ ). Average (mean  $\pm$  sd) strength ratios were: FLX:EXT - 110.4%  $\pm$  36.9% for males and 116.6%  $\pm$  36.0% for females, ABD:ADD - 82.1%  $\pm$  35.1% for males and 81.6%  $\pm$  24.0% for females, ER:IR - 111.4%  $\pm$  31.2% for males and 108.7%  $\pm$  28.6% for females.

**CONCLUSIONS:** There is no difference in hip strength ratios between male and female collegiate soccer players. These findings warrant further research of strength measures and the possible impact they may have on predicting injury.

1913 Board #321 MAY 30 3:30 PM - 5:00 PM

**Ground Reaction Forces and Osteogenic Index of the Sport of Cyclocross**

Brian Tolly, Alison Brooks, Elizabeth Chumanov. *University of Wisconsin, Madison, WI.*  
(No relationships reported)

Increasing weight-bearing activity has been suggested to improve bone health and minimize fracture risk. Cyclocross, in contrast to conventional cycling, demands bouts of weight-bearing activity as cyclists dismount and remount their bicycles to jump over barriers and run pitched terrain.

**PURPOSE:** To measure peak and mean vertical ground reaction forces (vGRF) during cyclocross-specific activities and calculate their osteogenic index (OI).

**METHODS:** Twenty-five healthy cyclocross athletes (18 M, 7 F) participated: 35.5(8.3) yrs old, 73.3(10.2) kg, 3.8(2.5) yrs of competition. vGRF was measured with pressure sensitive insoles (Novel Inc.) during seated cycling and four activities: barrier flat, barrier uphill, uphill run-up, downhill run-up. Peak vGRF and mean vGRF (%BW) across loading cycles were determined for each activity. OI of each activity was computed using:  $OI = \text{peak vGRF (\%BW)} \times \ln(\text{loading cycles} + 1)$ . vGRF and OI comparisons were made using repeated measure ANOVA. Relationship between cycling speed and vGRF was assessed with Pearson correlation coefficient.

**RESULTS:** Number of loading cycles per activity was 11.9(2.3) for barrier flat, 17.0(3.0) barrier uphill, 14.2(2.5) uphill run-up, 23.8(5.1) downhill run-up. All activities had significantly ( $p < 0.05$ ) higher peak vGRF, mean vGRF and OI than seated cycling. The barrier flat condition had the significantly ( $p < 0.05$ ) highest peak vGRF (2.9 (0.4) %BW) and mean vGRF (2.3 (0.3) %BW). Downhill run-up had the significantly ( $p < 0.05$ ) highest OI of 6.5(1.1). During barrier flat and barrier uphill conditions the peak vGRF occurred during a jumping or landing maneuver, while the peak vGRF during uphill run-up and downhill run-up occurred on the initial foot strike following cycle dismount. Mean vGRF was positively correlated with maximum cycling speed for all activities except uphill run-up.

**CONCLUSIONS:** Peak vGRF generated during the barrier flat activity measured in this study is similar in magnitude to previously reported GRFs during running and soccer. vGRFs during all four activities were significantly higher than seated cycling. OI of the barrier flat condition alone is higher than seated cycling for an equivalent number of loading cycles. Cyclocross-specific activities may be more beneficial to bone health than seated road cycling.

1914 Board #322 MAY 30 3:30 PM - 5:00 PM

**Analysis of Upper Limbs Dynamometry in Two Variants of Backstroke Start Technique**

Karla de Jesus<sup>1</sup>, Kelly de Jesus<sup>1</sup>, Pedro A. Figueiredo<sup>1</sup>, Pedro Gonçalves<sup>1</sup>, Suzana M. Pereira<sup>2</sup>, João Paulo Vilas-Boas<sup>1</sup>, Ricardo J. Fernandes<sup>1</sup>. <sup>1</sup>*Faculty of Sport, Porto University, Porto, Portugal.* <sup>2</sup>*State University of Santa Catarina, Porto, Portugal.* (Sponsor: Carlo Baldari, FACSM)  
(No relationships reported)

The measurement of lower limbs force has been assessed in studies including individual swimming start techniques for ventral and dorsal events. Concerning the contribution of the upper limbs for the total impulse, the number of studies is rather scarce, and none of which has yet dealt with the technical adjustments allowed by the new international rules for backstroke start.

**PURPOSE:** To compare upper limbs horizontal impulse during backstroke start variants performed with the feet parallel and entirely submerged and with the feet parallel and entirely above the water surface.

**METHODS:** Five high level swimmers (age:  $21.40 \pm 3.36$  years, weight:  $74.54 \pm 8.28$  kg of body mass, height:  $1.78 \pm 0.05$  m, training experience:  $13.60 \pm 6.06$  years) performed two sets of four maximal repetitions of each backstroke start variant over a distance of 15 m. An iron handgrip instrumented with a load cell (Globus, Italy), recording at 100Hz, was fixed to the starting block and was connected to a Globus Ergometer data acquisition system (Globus, Italy). The handgrip system was adapted to comply with the swimming rules: 0.30 to 0.60 m above the water surface both horizontally and vertically. Data obtained from the load cell were low-pass digital filtered (20Hz Butterworth). Data were normalized for body weight. The backstroke start variants were divided into three phases: initial starting position, trunk lifting and release of the hands. The reference instants determined to assess the three phases were characterized in each individual force-time curve. Descriptive statistics, Student's t-test for paired samples ( $p < 0.05$ ) and effect size ( $d$ ) were calculated.

**RESULTS:** Similar values were observed for the horizontal impulse between backstroke start variant performed with the feet parallel and immersed and the feet parallel and emerged at initial starting position phase ( $0.055 \pm 0.023$  s vs  $0.056 \pm 0.026$  s,  $d = -0.02$ ,  $p > 0.05$ ), at trunk lifting phase ( $0.026 \pm 0.007$  s vs  $0.029 \pm 0.011$  s,  $d = -0.26$ ,  $p > 0.05$ ) and, at release of the hands phase ( $0.101 \pm 0.022$  s vs  $0.097 \pm 0.022$  s,  $d = 0.13$ ,  $p > 0.05$ ).

**CONCLUSION:** Despite the task constrain provided for the new rules for backstroke start, high level swimmers were able to apply similarly horizontal impulse throughout hands-off phases in both starting variants.

1915 Board #323 MAY 30 3:30 PM - 5:00 PM

**Trunk Rotation During the Delivery Phase of Shot Put in Elite Male Trans-femoral Amputee Athletes**

Peter C. Raffalt<sup>1</sup>, Kathy J. Simpson<sup>2</sup>, Benjamin L. Patrilli<sup>3</sup>, Lee Nolan<sup>4</sup>. <sup>1</sup>*University of Copenhagen, Copenhagen, Denmark.* <sup>2</sup>*University of Georgia, Athens, GA.* <sup>3</sup>*Harvard Medical School, Boston, MA.* <sup>4</sup>*Karolinska Institutet and GIH, Stockholm, Sweden.*  
(No relationships reported)

The rotational movement of the body is considered to be important for high power production during the delivery phase of the shot put in nonamputee athletes. Trans-femoral amputee athletes (TF) are more likely to adapt their throwing technique due to their loss of musculature and motions about the knee and hip joints.

**PURPOSE:** To investigate how elite male TF use rotation of the body during the shot put and its relationship to throwing distance.

**METHODS:** A 3D-kinematic analysis was made of the shot put technique in seven athletes competing in the final of the mens F42 shot put competition at the 2008 Paralympic Games. The athletes (mean  $\pm$  SD:  $35.0 \pm 2.9$  yrs) were all right handed. They were left leg amputated and using a trans-femoral prosthesis with a locked or absent knee component. All TF throw performances were recorded using two digital cameras (100 Hz) and the best official result by each athlete was used for analysis. The athlete, shot and throwing circle were manually digitized, reconstructed and filtered. The delivery phase was defined as the time from left leg touch-down to release of the shot. The hip flexion-extension angle defined as the angle between the line from mid way between shoulder joints to mid way between hip joints and the right thigh, and trunk rotation defined as the difference in angle between the shoulder joints and the hip joints in the transverse plane were calculated. Pearson correlation coefficients were calculated between the measured parameters and the official result.

**RESULTS:** The hip angle at the start of the delivery phase was significantly and inversely correlated to the hip angle at release ( $R = -0.891$ ,  $p = 0.007$ ). Hip angle velocity at the start of delivery ranged between 54 and 489 °/s and was significantly correlated with put distance ( $R = 0.817$ ,  $p = 0.025$ ). The trunk rotation velocity was significantly correlated with the resultant release velocity ( $R = 0.774$ ,  $p = 0.041$ ).

**CONCLUSION:** The fast hip extension during the delivery phase of elite male TF caused a trunk rotation with high angular velocity, which resulted in a high release velocity of the shot. During this trunk rotation, upper body muscles are delivered thereby possibly increasing rate of force development during the following contraction. The TF adapted their technique due to the prosthesis and depended highly on a fast trunk rotation.

1916 Board #324 MAY 30 3:30 PM - 5:00 PM

**Muscle Activation and Co-contraction Patterns in Healthy Older Adults Performing Hatha Yoga**

Shin-Yuan Yu<sup>1</sup>, Man-Ying Wang<sup>1</sup>, Gail Greendale<sup>2</sup>, George Salem, FACSM<sup>1</sup>. <sup>1</sup>*University of Southern California, Los Angeles, CA.* <sup>2</sup>*University of California, Los Angeles, Los Angeles, CA.*  
(No relationships reported)

Knee osteoarthritis (OA), a disorder that is affected by joint loading forces, is associated with a reduction in quality of life and independence in older adults. Yoga requires motor coordination and joint stability and is commonly suggested as a strengthening exercise for seniors. Since joint loading at the knee may be altered during exercise and magnified by co-contraction, we examined the muscular activation and co-contraction patterns of senior participants during Yoga performance.

**PURPOSE:** To examine muscle activation and co-contraction patterns of the knee joint in Chair (CH), Tree (TR), Warrior I (W1), and Warrior II (W2) Yoga poses performed by healthy older adults.

**METHODS:** 20 healthy older adults (70.6 ± 3.8 yrs) participated in a 16-week Yoga program. After intervention, the participants were instrumented for biomechanical analysis and performed the Yoga poses with guidance from an instructor. Surface electromyographic (EMG) signals of the hamstrings (HAM) and vastus lateralis (VL) were collected at 1560 Hz for a 3-s interval during the pose. The EMG raw data were full-wave rectified and smoothed with a 75-ms constant window. The processed EMG signals were further integrated over the collected interval (iEMG) to quantify muscle activation. The average co-contraction value (CV) was calculated as  $iEMG_{HAM} / iEMG_{VL}$  times the summation of  $iEMG_{HAM}$  and  $iEMG_{VL}$ . It reflects the level of muscle co-contraction and takes the overall activation level into account. Repeated measures ANOVA and Tukey's HSD of post hoc tests were used to examine the difference in muscle activation and CV across the poses.

**RESULTS:** Both HAM and VL muscle activation during TR were significantly less than during CH, W1, and W2 ( $p < .05$ ). There was no significant difference between poses among CH, W1 and W2. CV during W1 and W2 was significantly greater than during CH and TR ( $p < .05$ ). No significant difference was observed between W1 and W2; or between CH and TR.

**CONCLUSION:** Comparing the target poses, TR placed less demands on both knee flexors and extensors. High muscle co-contraction values at the knee in W1 and W2 indicate higher joint loading when performing these poses. These findings suggest that senior practitioners with knee OA should reduce or avoid Warrior I and II poses to prevent exacerbation of their OA.

### Gender Differences In Heave And Pitch Phase Relationships In Maximal Undulatory Underwater Swimming (UUS).

Chris Connaboy<sup>1</sup>, Simon Coleman<sup>2</sup>, Ross H. Sanders<sup>2</sup>. <sup>1</sup>Edinburgh Napier University, Edinburgh, United Kingdom. <sup>2</sup>University of Edinburgh, Edinburgh, United Kingdom.

(No relationships reported)

The phase relationship between the heaving and pitching motions of the end-effector in UUS is critical to the production of an effective propulsive force and simultaneous minimisation of active drag, as it determines the formation and the timing of the shedding of the vortices from the leading edge of the end-effector (Anderson et al., 1998, *Jnl Fluid Mech*, 360, 41-72). A phase angle difference of approx. 75° has been shown to represent the optimal phase difference between heaving and pitching motions in oscillating foils with high propulsive efficiency (Anderson et al., 1998).

**PURPOSE:** Examine gender differences in the relationship between the mean absolute relative phase of the heaving and pitch (MARP HnP) movements of the end-effectors with the production of maximal UUS velocity in skilled swimmers.

**METHODS:** 17 (Male=8; Female=9) national age-group swimmers (Age 16.9±1.3yrs, Ht 171.2±9.4cm, Wt 63.2±11.4kg) were recorded using a single underwater video camera swimming 3 trials of maximal UUS to collect 6 cycles of data. 2D kinematics were analysed from the digitised motions of the wrist, shoulder, hip, knee ankle and 5th metatarsal phalangeal joint (MPJ) centres. Continuous Relative Phase (CRP) was determined from the phase angles of vertical heave motions and pitch angle of the end-effector. The MARP was calculated from the CRP using circular statistics. The relationships between the cycle frequency (Hz) of the end-effector (5th MPJ), cycle length (CL-distance travelled by the hip marker per cycle) and the average velocity of the hip marker per cycle (VEL) to the MARP HnP were determined using Pearson's correlation coefficient.

**RESULTS:** No sig. differences in Hz, CL, or VEL by gender. MARP HnP (female 117.4±4.5; male=118.9±4.4;  $p=0.088$ ) also showed no difference by gender. Correlation coefficients showed moderately large relationship between MARP HnP and Hz (female  $r=-0.553$ ,  $p=0.003$ ; Male  $r=0.597$ ,  $p=0.002$ ). Female swimmers showed a large correlation with CL ( $r=0.704$ ,  $p=0.001$ ) compared to males ( $r=0.182$ ,  $p=0.395$ ). All correlations between MARP HnP and VEL were small and not sig.

**CONCLUSION:** MARP HnP was considerably different to the suggested 75° optimal phase relationship. The differences in the correlation coefficients suggest males and females adopt different coordination patterns to achieve maximal UUS.

1918 Board #326 MAY 30 3:30 PM - 5:00 PM

### 100-m Freestyle Race Analysis of the 5th World Down Syndrome Swimming Championship

Ana Querido<sup>1</sup>, Dália Araújo<sup>1</sup>, Susana Soares<sup>1</sup>, J. Paulo Vilas-Boas<sup>1</sup>, Rui Corredeira<sup>1</sup>, Daniel Daly<sup>2</sup>, Ricardo J. Fernandes<sup>1</sup>. <sup>1</sup>University of Porto, Faculty of Sports, Porto, Portugal. <sup>2</sup>University of Leuven, Faculty of Kinesiology and Rehabilitation Sciences, Porto, Belgium. (Sponsor: Carlo Baldari, FACSM)

(No relationships reported)

Down syndrome (DS) is a common genetic cause of intellectual disability but there is a lack of knowledge on factors leading to sport success in these persons.

**PURPOSE:** To analyze 100-m freestyle race from the 5<sup>th</sup> World DS Swimming Championships.

**METHODS:** The event was videotaped with two side view cameras, and 34 swimmers (17 men and 17 women) from the preliminary heats were analyzed for start, turn and swim times and stroke length (SL) and rate (SR). Mean and SD were obtained, Student t-tests and repeated measures ANOVA were computed to compare gender groups. Correlation analysis was performed between race components, stroking variables and end results ( $p \leq 0.05$ ).

**RESULTS:** There were significant differences between male and female swimmers in start time (6.07±0.47 & 7.37±.99s), swim time (34.45±2.90 & 44.18±4.49s), turn time (32.36±2.64 & 37.94±3.85s), finish time (9.08±1.32 & 10.25±1.33s), final time (81.97±6.44 & 99.74±9.63s), speed (1.18±0.09 & 0.92±.09m/s), and SL (1.65±.16 & 1.38±.17m); no differences between genders were observed for SR (43.16±4.87 & 40.78±5.45st/min). Differences within laps can be observed on Figure. The higher  $r$  values were obtained for swim time and final time (men: .97 & women: .91) and final time and turn time (men: .94 & women: .95). Inverse correlations were observed between stroke rate and stroke length (men: -.67 & women: -.76).

**CONCLUSIONS:** Male DS swimmers are significantly faster than female counterparts in the 100-m freestyle event. For a similar number of strokes per min, men are able to attain higher stroke lengths than woman. For this specific event, swim and turn times are most determinant for the final time and SL is determinant for swimming speed and not SR.

### Spatio-temporal Coordination in High Intensity Swimming

Pedro Figueiredo<sup>1</sup>, Ludovic Seifert<sup>2</sup>, João Paulo Vilas-Boas<sup>1</sup>, Ricardo J. Fernandes<sup>1</sup>. <sup>1</sup>CIFIZD, Faculty of Sport, University of Porto, Porto, Portugal. <sup>2</sup>CETAPS, Faculty of Sports Sciences, University of Rouen, Rouen, France. (Sponsor: Carlo Baldari, FACSM)

(No relationships reported)

Rhythmic inter-limb behavior in humans is characterized by intrinsic coordination modes: in-phase, the simultaneous contraction of homologous muscles (e.g. flexing or extending the arms simultaneously), and anti-phase, the simultaneous activation of non-homologous muscle groups (e.g. flexing one arm and extending the other one). The inter-limb coordination emerges due to changes in the constraints imposed on action. In swimming, temporal changes have been used to characterize coordination changes. However, its use could be completed with spatial data to enable spatio-temporal analysis.

**PURPOSE:** To assess the spatio-temporal coupling in front crawl upper limbs performed at high intensity swimming.

**METHODS:** Ten front crawl male competitive swimmers (21.6±2.4 yrs, 1.85±0.7 m, and 76.4±6.1 kg) swam 200 m front crawl at race pace. The swimming test was recorded by two above water and four underwater cameras operating at 50 Hz. The 21 body landmarks digitized (APASystem) underwent a three-dimensional direct linear transformation to yield the three-dimensional anatomical points position of one complete stroke cycle per each 50 m lap. The mean swimming velocity was calculated as the horizontal displacement of the whole body center of mass over its total duration. The spatio-temporal relationship between the upper limbs was quantified by the continuous relative phase. A one-way repeated measures ANOVA (Bonferroni post-hoc) and effect size (f) were used to analyze changes between the four moments over the 200 m ( $p < 0.05$ ).

**RESULTS:** Swimming velocity decreased significantly from the first (1.57±0.08 m.s<sup>-1</sup>) to the last 50 m lap (1.35±0.08 m.s<sup>-1</sup>) (F(3,27)=24.58, p<0.001, f=1.26). The mean continuous relative phase angles were 188.1±7.5, 186.8±8.5, 190.1±7.1, and 190.7±4.8°, respectively for the first, second, third and fourth 50 m lap, remaining constant throughout the effort (F(3,27)=1.88, p<0.16, f=0.15).

**CONCLUSION:** Front crawl swimming inter-limb relationship is strongly preserved in an anti-phase coordination mode despite the changes in velocity due to fatigue development.

Supported by SFRH/BD/38462/2007 and PTDC/DES/101224/2008 (FCOMP-01-0124-FEDER-009577) FCT grants.

**A Simple Instruction Increases Relative Contribution of Hip Extension Action during Concentric Cycling**

Ernest G. Rimer, Camden S. Marshall, Kyle W. Wehmanen, Jedidiah R. Farley, James C. Martin, FACSM. *University of Utah, Salt Lake City, UT.*

(No relationships reported)

Previous authors have suggested that cycling performance can be improved by increasing relative contribution of the large, hip extension musculature. Hip extension torque functions to extend both the torso and the thigh.

**PURPOSE:** Determine the effect of torso extension on the relative contribution of hip extension during cycling.

**METHODS:** Four, recreational cyclists (75.7 ± 7.9 kg, 175 ± 5 cm) performed two submaximal cycling trials at approximately 250 watts and 80 rpm. During each trial, the participants were instructed to pedal with either their self selected technique, or to maintain the same torso position while reducing pressure on the handlebars by extending the torso. Pedal forces and limb kinematics were recorded. Joint moments were calculated using a sagittal plane, inverse dynamics model. Work produced during hip extension was determined from hip moment and hip angle data and was normalized to work delivered to the pedals. Normalized hip extension work from the self selected pedaling technique and the torso extension trials were compared with a paired Students t test.

**RESULTS:** During the self selected and torso extension trials, hip extension contributed to 33 ± 8% and 48 ± 8% of total work, respectively (p < .01).

**CONCLUSION:** In cycling, the contribution of hip extension action to total work increased with a simple instruction to reduce handlebar pressure. Previous authors have suggested that experienced cyclists attempt to recruit greater involvement from the large hip extensor muscles, posing that such action may reduce localized metabolic stress. The current investigation demonstrated that a simple instruction caused a transfer of work so that the large muscles responsible for hip extension action made a greater contribution toward a given, submaximal workload. More research is needed to determine if these findings can contribute to a reduction in metabolic stress during a given workload, or to an enhancement in cycling performance. Additionally, understanding how to change the relative contribution of joint actions at the hip, knee, and ankle may have implications in rehabilitation settings, in which clinicians may want to specifically target hip extensors.

**1921** Board #329 MAY 30 3:30 PM - 5:00 PM

**Insight To Muscle Activity During The Lacrosse Shot.**

Ciro J. Agnelli<sup>1</sup>, Jeffrey McClellan<sup>1</sup>, Jason Tarno<sup>1</sup>, Jason Nielson<sup>2</sup>, John A. Mercer, FACSM<sup>1</sup>. <sup>1</sup>UNLV, Las Vegas, NV. <sup>2</sup>Children's Bone and Spine Surgery, Las Vegas, NV.

(No relationships reported)

An advanced lacrosse player typically has the ability to shoot both left- and right-handed. When shooting right-handed, the right arm is the top arm and the left the bottom arm. When shooting left-handed, the arms are switched. There is a lack of research on muscle activity of the top and bottom arms during shooting.

**PURPOSE:** The purpose of this study was to compare upper extremity muscle activity patterns during shooting right- and left-handed.

**METHODS:** Experienced high school male players (n=8; 1.7±0.1 m; 69.6±9.4 kg; 16.3±0.9 y) had the dominant instrumented with electromyography (EMG) leads to measure muscle activity of the flexor carpi radialis (FCR), extensor carpi radialis (ECR), biceps brachii (BB), triceps brachii (TB), anterior deltoid (AD), and latissimus dorsi (LD). The top arm elbow flexion/extension was recorded using an electrogoniometer. Subjects were instructed to shoot with maximal velocity using approach steps. Each subject shot 5 times right-handed and 5 times left-handed. When shooting right-handed, muscle activity was recorded on the top arm. When shooting left-handed, muscle activity was recorded on the bottom arm. All data were collected at 1000 Hz and EMG data band passed filtered (20-50 Hz). Ball release was approximated by identifying maximal elbow extension velocity. EMG data were extracted 0.5 s before (1st phase) and after (2nd phase) this point and average EMG was calculated for each 0.5 s data set for each shooting side. A 2 (top, bottom arm) x 2 (1st phase, 2nd phase) repeated measures ANOVA was used to compare EMG for each muscle.

**RESULTS:** FCR, ECR, and BB were not different between sides or phases (p>.05). AD was 57% more active as a top vs. bottom arm (p<.05). TB and LD were both influenced by the interaction of arm and phase (p<.05) with TB being 144% more active during the 2nd phase for top vs. bottom arm. LD was 73% more active during the 1st phase on the bottom vs. top arm.

**CONCLUSIONS:** There was substantial variability in muscle activity patterns between subjects suggesting level of skill and/or experience likely influences muscle patterns. The main observation was that the LD was more active on the contralateral vs. ipsilateral side in the preparatory movements. For the other muscles, coordination of muscle activity is likely more important than magnitude of activity.

**1922** Board #330 MAY 30 3:30 PM - 5:00 PM

**The Effect On Swimmer's Hydrodynamic Drag Wearing Two Swimsuits**

Daniel A. Marinho<sup>1</sup>, Vishveshwar R. Mantha<sup>2</sup>, Rui J. Ramos<sup>1</sup>, Tiago M. Barbosa<sup>3</sup>, J. Paulo Vilas-Boas<sup>4</sup>, Abel I. Rouboa<sup>2</sup>, António J. Silva<sup>2</sup>. <sup>1</sup>University of Beira Interior / CIDESD, Covilhã, Portugal. <sup>2</sup>University of Trás-os-Montes and Alto Douro / CIDESD, Vila Real, Portugal. <sup>3</sup>Polytechnic Institute of Bragança / CIDESD, Bragança, Portugal. <sup>4</sup>Porto Laboratory of Biomechanics / FADEUP, Porto, Portugal. (Sponsor: Carlo Baldari, FACSM)

(No relationships reported)

The popularization of polyurethane swimsuits has got a large media and sports attention around the pools in the past couple of seasons. However, little scientific evidence was reported in main literature about such relationship in this type of high-tech swimsuits.

**PURPOSE:** To analyze the effect of wearing a swimsuit on swimmer passive drag.

**METHODS:** A computational fluid dynamics analysis was carried-out to determine the hydrodynamic drag of a female swimmer's model: (i) wearing a textile swimsuit (ii) wearing a last generation high-tech swimsuit and; (iii) with no swimsuit, wearing light underwear. The three-dimensional surface geometry of a female swimmer's model with different swimsuit/underwear was acquired through standard commercial laser scanner. Passive drag force and drag coefficient were computed with the swimmer in a prone position at a depth of 0.75 m for a steady flow velocity of 2.0 m/s.

**RESULTS:** Higher hydrodynamic drag values were determined when the swimmer was with no swimsuit in comparison when the swimmer was wearing textile or a high-tech swimsuit. The high-tech swimsuit was the one with lower hydrodynamic drag values, although very similar to textile swimsuit (table 1).

Table 1. Drag coefficient and drag force values to each swimsuit condition.

| Swimsuit condition | Drag coefficient | Drag force (N) |
|--------------------|------------------|----------------|
| Textile suit       | 0.325            | 76.23          |
| High-tech suit     | 0.323            | 75.82          |
| Underwear          | 0.453            | 105.84         |

**CONCLUSIONS:** One can state that wearing a swimsuit may positively influence swimmer's hydrodynamics, especially reducing the pressure drag component. Moreover, minor differences were obtained between a standard and a high-tech swimsuit.

The Portuguese Government supported this work by a grant of the Science and Technology Foundation (PTDC/DES/098532/2008; FCOMP-01-0124-FEDER-009569).

**1923** Board #331 MAY 30 3:30 PM - 5:00 PM

**Changes in Speed Skating Technique are Related to Changes in Skating Velocity**

Dionne A. Noordhof<sup>1</sup>, Carl Foster, FACSM<sup>2</sup>, Marco J. M. Hoozemans<sup>1</sup>, Jos J. de Koning, FACSM<sup>1</sup>. <sup>1</sup>VU University, Amsterdam, Netherlands. <sup>2</sup>University of Wisconsin-La Crosse, La Crosse, WI.

(No relationships reported)

**BACKGROUND:** Efficiency is an important parameter in endurance sports. In speed skating the push-off angle, or effectiveness ( $e$ ), is most likely related to efficiency. As the skating posture favors lactate accumulation resulting in muscle fatigue, we hypothesized that skating efficiency decreases during a race.

**PURPOSE:** To evaluate the change in  $e$  and skating velocity ( $v$ ) during a 5000 m speed skating race and to determine whether  $\Delta e$  is associated with  $\Delta v$ .

**METHODS:** Video recordings were made during a 5000 m ISU World Cup race ( $n = 34$  males). Two JVC mini DV cameras were placed outside the track, in line with the straight part of the lap. Ones every 400 m lap pixel coordinates of the middle of the push-off leg at the height of the hip and the tip of the skate blade were determined just before opening the hinge of the klapskate.  $e$  was determined, as the angle between the push-off leg and the horizontal. The average  $v$  was determined over the same part of the track. To increase precision,  $e$  and  $v$  were averaged over 3 successive laps, and differences were determined between these averages. The association between  $\Delta e$  and  $\Delta v$ , accounting for the effect of part of the race, was determined with Generalized Estimating Equations (GEE).

**RESULTS:** Fig. 1 shows that  $e$  increased and  $v$  decreased during the race.

The interaction between  $\Delta$ lap and  $\Delta e$ , which would indicate a different association between  $\Delta e$  and  $\Delta v$  for each of the  $\Delta$ laps, was not significant. Therefore,  $\Delta$ lap was only included as a confounder in the regression (not significant), which resulted in a significant association between  $\Delta e$  and  $\Delta v$  ( $\beta = -0.066$ ,  $p < 0.001$ ).

**CONCLUSION:** During a 5000 m speed skating race  $e$  increased and  $v$  decreased. Besides that,  $\Delta e$  is significantly associated with  $\Delta v$ , independent of part of the race.

**Hip And Knee Joint Mechanics During Cutting Maneuver With And Without A Lacrosse Stick**

Manabu Sanomura, Masanori Sakaguchi, Yasuaki Saho, Toru Fukubayashi. Waseda university, Saitama, Japan.

(No relationships reported)

Most non-contact anterior cruciate ligament (ACL) injuries occur during jumping and cutting maneuvers. Women's lacrosse is associated with a higher incidence rate of ACL injuries than other women's sports. Lacrosse-specific movements such as jumping and cutting maneuvers with a lacrosse stick cause compensatory lower limb motions such as excessive knee abduction and hip adduction.

**PURPOSE:** To compare the hip and knee joint kinematics and kinetics during a cutting maneuver with and without a lacrosse stick.

**METHODS:** Nine female collegiate lacrosse players (mean age,  $20.0 \pm 1.3$  years; height,  $159.6 \pm 5.8$  cm; weight,  $55.1 \pm 6.3$  kg; lacrosse experience,  $24 \pm 3.4$  months) participated in this study. Thirty-six reflective markers were placed on the upper limb, trunk, pelvis, and right lower limb. An eight-camera motion analysis system (Motion Analysis Corp.) and a force plate (Kistler Corp.) were used to record the three-dimensional marker positions and ground reaction forces sampled at 240 Hz and 2400 Hz, respectively, during the cutting maneuver. The subjects were instructed to run a distance of 4-5 m and then land with their right foot on a force plate, followed by a change in direction to the left to cut an angle of  $45^\circ$ . Each trial was performed while holding a lacrosse stick in the right hand (with their right and left hands on the top and bottom of the shaft, respectively; RH), left hand (with their left and right hands on the top and bottom of the shaft, respectively; LH), and not holding a lacrosse stick (NH). The peak values of knee abduction angle, hip adduction angle, knee abduction moment, and hip adduction moment during the stance phase of the cutting maneuver were analyzed.

**RESULTS:** The peak hip adduction angle in the RH trial was significantly greater than that in the NH trial ( $5.7 \pm 5.8^\circ$  vs.  $1.1 \pm 7.9^\circ$ ,  $p = 0.041$ ), and the peak hip adduction moment in the RH trial was significantly higher than that in the NH trial ( $2.02 \pm 0.63$  vs.  $1.76 \pm 0.56$  Nm/(kg\*h),  $p = 0.025$ ). The peak knee abduction angle and the peak knee abduction moment were not significant differences between the RH, LH and NH trials.

**CONCLUSION:** The results of this study suggested that the cutting maneuvers with a lacrosse stick have significant effect on hip joint mechanics which has been implicated as a risk factor for non-contact ACL injury compared to those without a lacrosse stick.

**Rotational Velocities, Pelvic: Torso Separation, and Spiked Ball Velocity in Female Collegiate Volleyball Athletes**

Charlie A. Hicks-Little, Patricia A. Eisenman, FACSM, Michael Waller, Justin Brown, Bader J. Alsarraf. University of Utah, Salt Lake City, UT.

(No relationships reported)

High velocity provides a competitive advantage in volleyball. High ball velocity in other rotational skills, like the baseball pitch and golf swing, is achieved by initiating pelvic rotation before torso rotation (Pelvic Torso Separation Angle) in combination with high rotational velocities of the pelvis and torso. Little is known about the contribution of pelvic and torso rotational velocities and the amount of separation of the pelvic and torso rotation on ball velocity during the spike.

**PURPOSE:** The primary aim of the current study was to examine the influence of peak pelvic rotational velocity (PPRV), peak upper torso rotational velocity (PUTRV), and peak pelvic torso separation angle (PPTSA) on spiked ball velocity (SBV) during both down-the-line (DL) and diagonally across-court (DAC) spikes.

**METHODS:** Three-dimension motion capture analysis was used to examine the kinematics of the volleyball spike and SBV. Fourteen collegiate female players ( $20.9 \pm 2.8$  yrs) were fitted with 21 reflective markers; each performed 10 DL spikes and 10 DAC spikes. Differences in SBV, PUTRV, PPRV, and PPTSA between DL and DAC spikes were determined by using a two-way factor mixed repeated measures factorial ANOVA. Correlations were used to examine relationships between the kinematic variables and SBV.

**RESULTS:** Statistically significant differences between the DL and DAC spikes were observed for SBV ( $17.54 \pm 2.35$  m/s vs.  $15.97 \pm 2.36$  m/s,  $p = 0.039$ ) and for PPTSA ( $-9.16 \pm 5.32^\circ$  vs.  $-12.65 \pm 5.36^\circ$ ;  $p = .043$ ). Moderate positive correlation coefficients were observed between DAC SBV and PPRV during the forward swing phase ( $r = 0.47$ ), PUTRV during the forward swing phase ( $r = 0.66$ ), and PPTSA at the top of the back swing phase ( $r = 0.56$ ). A multiple regression analysis predicting SBV from the rotational variables for DAC spikes resulted in a statistically significant multiple  $R^2$  value ( $R^2 = 0.58$ ). The most important predictor of SBV was PPTSA. Additionally, a low to moderate positive correlation ( $r = 0.31$ ) was observed between SBV and PPTSA at the top of the back swing phase for the DL spikes. A multiple regression analysis for DL spike was not statistically significant.

**CONCLUSION:** PPTSA is an important contributor to DAC SBV. Further research is warranted to determine if PPTSA can be altered, thus improving SBV.

**Intra-limb Coordination In Karate Roundhouse Kick**

Federico Quinzi, Valentina Camomilla, Paola Sbriccoli. Rome Foro Italico, Rome, Italy. (Sponsor: Carl Foster, FACSM)

(No relationships reported)

**INTRODUCTION:** Intra-limb coordination in sport activities has been the focus of many studies, where it has been quantified using Continue Relative Phase (CRP). In martial arts no previous study investigated lower limb coordination during kicking actions.

**PURPOSE:** The aim of this study is to investigate differences in CRP in elite athletes performing the roundhouse kick, directed respectively to the opponent's face (HRK) and waist (LRK).

**METHODS:** After signing written informed consent, 6 elite karateka volunteered to participate in this study. All subjects performed 3 trials of each kick (HRK; LRK). Pelvis and lower limb kinematics were acquired with a stereophotogrammetric system (Vicon System), using the CAST protocol. Intra-limb coordination was computed for the Hip and Knee joints of the kicking leg

on the sagittal plane starting from the ready stance to knee full extension (considered as the end of the kick). For both joints, the Phase Plots (PP) was generated by plotting the normalized angular displacement vs. the normalized angular velocity (Li et al. 1999). Subsequently, for each joint the angle between the positive horizontal axis and each point of the PP was computed (Phase Angle-PA). The Continue Relative Phase (CRP) was computed by subtracting the PA of the Distal segment from that of the Proximal one. A CRP value of 0 rad means in-phase movement whereas  $\pm 3.14$  rad means anti-phase movement. In order to test for differences between the CRP of HRK and LRK, a repeated measures ANOVA was performed on the CRP mean absolute value (Stergiou et al. 2000) computed on 10% intervals and on CRP mean peak.

**RESULTS:** The CRP differentiated the kicks only from 51 to 80% of the kick corresponding to Hip and Knee flexion phase: being higher in the HRK from 51 to 70% (51-60%: HRK 0.47 $\pm$ 0.07 rad; LRK 0.20 $\pm$ 0.04 rad; 61-70%: HRK 1.13 $\pm$ 0.07 rad; LRK 0.55 $\pm$ 0.08 rad;  $p < .002$ ) and then in the LRK from 71 to 80% (LRK 1.21 $\pm$ 0.14 rad; HRK 0.58 $\pm$ 0.10 rad  $p < .002$ ).

**CONCLUSION:** Kicking height influences the timing but not the magnitude of Hip and Knee flexion-extension CRP mean peak in Karate elite athletes. This difference in timing might be attributed to differences in the occurrence of angular velocity peak between the two joints during the flexion phase.

**1927** Board #335 **MAY 30 3:30 PM - 5:00 PM**  
**Gender Differences in Plantar Loading During Unanticipated Cutting on FieldTurf**

Conor Irwin, Robert J. Butler, Claude T. Moorman, III, William E. Garrett, Jr, FACSM, Robin M. Queen. *Duke University, Durham, NC.*  
(No relationships reported)

Fifth metatarsal stress fractures are more common in men and have a high incidence of delayed union, non-union, and re-fracture. Cleat plate design has been altered to avoid loading beneath the fifth metatarsal, however, gender differences in loading patterns were not considered in the design process.

**PURPOSE:** To determine if total foot, lateral midfoot (LMF) and lateral forefoot (LFF) loading (as defined by maximum force [MF], contact area [CA], and force-time integral [FTI]) were significantly different between men and women when performing an unanticipated cut on FieldTurf.

**METHODS:** Plantar loading in 32 (16 men, 16 women) healthy, collegiate, recreational athletes was evaluated using the Pedar-X in-shoe system collecting at 100Hz (Novel, St. Paul, MN, USA). Exclusions included any lower extremity injuries in the past 6 months, foot or ankle surgery in the past 3 years, and previous metatarsal stress fractures. Subjects completed 12 unanticipated cutting trials in a firm ground soccer cleat on FieldTurf. Subjects were asked to run straight forward until a light came on to have them cut to the left or right at which time they cut 45 degrees in the indicated direction. The plant foot was used for analysis. A series of independent t-tests were used to examine differences between genders during unanticipated cutting ( $\alpha=0.05$ ).

**RESULTS:** Men were significantly taller and heavier than the women ( $P < 0.001$ ). CA was greater for the women in the LMF (8.3%,  $P=0.046$ ) and the LFF (9.9%,  $P < 0.001$ ). The FTI was greater beneath the total foot for the men when compared to the women (23.9%,  $P < 0.001$ ), with no significant differences in the LMF and LFF. MF was greater for the women than the men in the LMF (21.7%,  $P=0.001$ ) and the LFF (17.2%,  $P=0.001$ ).

**CONCLUSIONS:** During unanticipated cutting, women loaded the lateral column of the foot more than men, which is contrary to the current literature. Future work will need to examine the differences between genders to determine the need for gender specific footwear design as well as to determine if different cleat plate configurations are able to optimize foot loading patterns while completing an unanticipated cutting task.

**Biomechanical Measures of the Knee Predict Anterior Cruciate Ligament Injury Risk in Female Basketball Athletes**

Heng-Ju Lee, Tung-Hsi Tseng, Yu-Ming Lee. *National Taiwan Normal University, Taipei, Taiwan.*  
(No relationships reported)

Basketball is a sport that involved many pivoting and cutting maneuvers. Female basketball players suffer ACL injuries at a 4- to 6-fold greater rate than do male basketball players. Most ACL injuries in female athletes occur during a noncontact episode, typically during deceleration, lateral pivoting, or landing tasks that are often associated with high external knee joint loads and high anterior knee shear forces.

**PURPOSE:** To determine ACL injury risk factors between cutting and cross over step maneuvers in female basketball athletes.

**METHODS:** There were 12 healthy female basketball players participated in this study (age: 20.3 $\pm$ 1.8 yrs; height: 174.2 $\pm$ 5.3 cm; weight: 62.5 $\pm$ 5.8 kg). Subjects were instructed to perform a vertical jump, raising both arms to touch the target, which was set at their 50% maximum jump height. Subjects landed with both feet at the same time on separated force plates, then immediately performed cutting or cross over step to the dominant side and kept running for 3 meters. Leg dominance was defined as the leg that would be used to kick a ball. Subjects performed 5 successful trials in each step maneuver with 30 s of rest between trials to minimize the potential effects of fatigue. The motion capture system consisted of 10 digital cameras (200Hz) (Vicon, UK) were used to collect 3D trajectories from 28 reflective markers. The 2 force platforms (Kistler, Germany) collected GRF data at 1000 Hz and were time synchronized with the motion capture data. One-way ANOVA with significance level of 0.05 was used to compare biomechanical measures of the supporting leg between two different step maneuvers.

**RESULTS:** Knee anterior shear force (5.05 $\pm$ 1.88 vs. 3.55 $\pm$ 1.17 N/kg,  $p < 0.05$ ), knee valgus moment (0.66 $\pm$ 0.17 vs. 0.20 $\pm$ 0.10 Nm/kg,  $p < 0.05$ ) and hip flexion moment (0.81 $\pm$ 0.60 vs. 0.51 $\pm$ 0.34 Nm/kg,  $p < 0.05$ ) during cutting were significant greater than cross over step maneuver of the supporting leg.

**CONCLUSION:** Knee anterior shear forces and valgus moments were the primary predictors of ACL injury risk. Physiologic valgus torques on the knee can increase anterior tibial translation and loads on the ACL by several-fold. The current findings indicate that female basketball players might have higher risk of knee injury during cutting step than cross over step maneuver. Supported by NSC grant 100-2628-H-003-013-MY2.

**1929** Board #337 **MAY 30 3:30 PM - 5:00 PM**  
**Footwear Intervene in Typical Badminton Movement**

Yaodong Gu<sup>1</sup>, Jianshe Li<sup>2</sup>, Zhiyong Li<sup>3</sup>. <sup>1</sup>Ningbo University, Ningbo, China. <sup>2</sup>Ningbo University, ningbo, China. <sup>3</sup>Southeast University, Nanjing, China.  
(No relationships reported)

Badminton is very popular physical exercise in all age groups in modern world.

**PURPOSE:** This study aim to investigate the footwear function in badminton sports through biomechanical analysis of typical maneuver. We want to find out whether the professional shoes for badminton existing better advantage or not.

**METHODS:** Twenty subjects participated in this study are badminton players with more than six years training experience. Two different of kinds shoes were selected, one is professional badminton shoes (BS), the other is ordinary training shoes (TS). The badminton ball speed was controlled through the same dropping height, while the subjects were required to hit the ball by lunge step using the same racket. Dynamic foot loading force was measured by force platform (Kistler AG, Winterthur, Switzerland). The testing order of two kinds of shoes was random assigned to the subjects.

**RESULTS:** The contact time of whole lunge step in BS is significantly larger than the TS ( $P < 0.05$ ), as the mean value of movement completion in former condition is 0.68s, and the latter condition is 0.59s. Although the peak reaction force in BS (961N) is smaller than this in TS (978N), no significant different exist ( $P > 0.05$ ). Meanwhile, the peak friction force in BS is significantly larger than this in TS (386N vs. 361N,  $P < 0.05$ ).

**CONCLUSIONS:** From the experimental results finding in this study, it suggested that BS had certain advantages in preventing injury and improving performance through the good ground grip ability. The cause is likely that material and stripe pattern in the sole of BS can better increase friction between outsole and ground.

**Drop Landing Impact Forces in Figure Skaters vs. Non-skaters**

Nathan W. Saunders<sup>1</sup>, Nicholas Hanson<sup>1</sup>, Panagiotis Koutakis<sup>2</sup>, Ajit M. Chaudhari<sup>1</sup>, Steven T. Devor, FACSM<sup>1</sup>. <sup>1</sup>The Ohio State University, Columbus, OH. <sup>2</sup>University of Nebraska Medical Center, Omaha, NE.  
(No relationships reported)

Success of competitive figure skaters (FS) is heavily dependent on the quality of jump landings. Though landing technique is emphasized during training, most FS injuries occur in the lower back and lower extremities. Impact force properties such as time to stabilization (TTS) of ground reaction forces (GRF) and peak relative GRF (GRF<sub>R</sub>) are of interest due to their potential implications on injury risk.

**PURPOSE:** Our specific aim was to determine the ability of TTS and GRF<sub>R</sub> to discriminate between FS and non-skater controls (NS). To achieve our aim, we tested the hypotheses that for a backward single leg landing (SLL) test, compared with NS: 1) FS would have lower TTS; and, 2) greater GRF<sub>R</sub>.

**METHODS:** Twenty-six female FS (14.7±4.5 yr, and 50.4±11.8 kg) with a wide range of competition experience (5.4±3.1 yr) and 18 NS controls (15.4±5.3, and 54.1±14.7 kg) completed three trials of a backward SLL from a 20cm high platform. GRF data along the mediolateral (M-L), anteroposterior (A-P), and vertical axes were collected from a single force plate at 1000 Hz and subsequently low-pass filtered at 10 Hz with a fourth-order and zero-lag Butterworth filter. From that data we were able to calculate TTS and GRF<sub>R</sub>. Between-group differences in TTS (M-L, A-P, and vertical) and GRF<sub>R</sub> (M-L, A-P, and vertical) were determined with two-tailed two-sample t-tests. Significance level was set *a priori* at  $P < 0.05$ .

**RESULTS:** While there were no differences between FS and NS in M-L TTS (2.44±0.54 s, and 2.50±0.50 s, respectively), FS had significantly greater A-P TTS (2.86±0.10 s vs. 2.75±0.11 s) and vertical TTS (2.38±0.07 s vs. 2.22±0.07 s). FS had significantly greater GRF<sub>R</sub> along the M-L (1.97±0.93 vs. 1.12±0.48 N/kg), A-P (10.42±3.34 vs. 2.24±1.63 N/kg), and vertical (37.64±7.60 vs. 30.28±6.62 N/kg) axes.

**CONCLUSIONS:** Hypothesis one was not supported as FS exhibited greater TTS than NS along the A-P and vertical axes. This may have been due to the unfamiliarity of landing barefoot rather than in a skate boot, and/or of landing in a stationary position rather than gliding backwards. Hypothesis two was supported as FS demonstrated greater GRF<sub>R</sub> than NS along all three axes, a result previously documented in gymnasts. Future studies should explore the effectiveness of interventions aimed at decreasing GRF<sub>R</sub> in FS either through technique or equipment modifications.

---

1931 Board #339 MAY 30 3:30 PM - 5:00 PM

**Analyzing Track Sprint Cyclists' Performances Using Position-Specific Maximal Torque- And Power-Cadence Relationships**

David M. Rouffet<sup>1</sup>, Dan Dwyer<sup>2</sup>, Robert Stokes<sup>1</sup>, Ian Fairweather<sup>1</sup>. <sup>1</sup>Victoria University, Footscray, Australia. <sup>2</sup>Victorian Institute of Sport, Melbourne, Australia.  
(No relationships reported)

Performances produced during maximal sprint cycling are generally analyzed in reference to maximal Torque-Cadence (T-C) and Power-Cadence (P-C) relationships. This analysis requires that the performance's conditions that define the interaction between neural, muscular and mechanical processes closely match the testing conditions for which maximal T-C and P-C relationships were measured. Because track sprint cyclists perform in both standing and seated positions, maximal T-C and P-C relationships have to be determined for both positions in order to analyze the performances.

**PURPOSE:** To determine maximal T-C and P-C relationships of sprint track cyclists in seated and standing positions.

**METHODS:** Maximal Torque-Cadence (T-C) and Power-Cadence (P-C) relationships were calculated for eight junior elite track cyclists from the National Talent Identification and Victorian Institute of Sport track squads. T-C and P-C relationships were calculated from four all-out sprints performed in standing and seated positions. Maximal sprints in a standing position were performed on a carbon fiber track bike at the velodrome. Maximal sprints in a seated position were performed on an air-braked stationary ergometer in a laboratory. A calibrated SRM power meter (science version) interfaced to a custom instrumentation package was used for all mechanical measurements. Maximal T-C and P-C relationships were analyzed to calculate the following variables: maximal Torque (T<sub>0</sub>), maximal Power (P<sub>max</sub>) and optimal pedaling cadence (PC<sub>opt</sub>). Paired t-tests were used to compare variables measured during seated and standing efforts. Significance level was set as  $p < 0.05$ . Mean and SD values were reported.

**RESULTS:** All individual T-C and P-C relationships obtained for both body positions were fitted by linear regressions ( $r^2 = 0.95 \pm 0.02$ ) and second order polynomials ( $r^2 = 0.96 \pm 0.01$ ), respectively. Comparisons of the T-C and P-C relationships showed that T<sub>0</sub> was higher (209 ± 2.2N.m vs. 177.0 ± 3.9N.m,  $p < 0.05$ ), PC<sub>opt</sub> was lower (112.5 ± 11.4rpm vs. 120.1 ± 6.7rpm,  $p < 0.05$ ), and P<sub>max</sub> was higher (1261 ± 235W vs. 1076 ± 183W,  $p < 0.05$ ) in standing position.

**CONCLUSIONS:** The analysis of track sprint cyclists' performances can be improved by the determination of position-specific maximal T-C and P-C relationships.

1932 Board #340 MAY 30 3:30 PM - 5:00 PM

**Grip Force And Muscle Activity Are Associated With Kinematics In The Golf Swing**

James Parker, M Charlotte Olsson, Sofia Brorsson. *School of Business and engineering, Halmstad, Sweden.*  
(No relationships reported)

**PURPOSE:** : Golf is a popular sport in the world, today there is little limited

information in the literature that discusses the hand motion and grip force and its relation to the golf swing. A better understanding of how the interaction between grip force, muscle activity and coordination influences the shot length in a golf swing would be beneficial to improve the game for both elite and recreational golfers. Thus, the purpose of this study was to analyze if grip force (finger extension and flexion force) and muscle activity in the forearm were associated to kinematics in the golf swing and to shot length.

**METHODS:** Seven elite golf players (mean age: 22±2 years) were included in the study. Primary outcomes were shot length, finger extension- and flexion force, and muscle activity measured with surface electromyography on the m. extensor digitorum communis (EDC) and the m. flexor carpi radialis (FCR) when performing a golf swing. Maximal voluntary isometric contraction for flexion- and finger extension force was measured on the dominant hand. Each subject was instructed to take five 'normal' swings with their 7-iron and hit into a net 8 meters from the tee area. EMG was synchronized with kinematic data and split the swing up in three phases, backswing, downswing and follow through.

**RESULTS:** Finger extension force was 54±20 N and grip force was 428±108 N in the group. Both extension ( $r_s = 0.81$ ,  $p < 0.01$ ) - and flexion force ( $r_s = 0.78$ ,  $p < 0.01$ ) were positively associated with shot length. Muscle activity in both FCR and EDC were significantly different in the three swing phases ( $p = 0.02$ ), and the muscle activity in all phases were related to shot length ( $p = 0.02$ ).

**CONCLUSIONS:** This study showed that increased grip force and muscle activity in all phases of the swing is positively associated with shot length. These results indicates that both maximal grip force and high muscle activity in the FCR and EDC can be important factors for increasing shot length, and that a highly coordinated pattern between these muscles are useful in order to maximize shot distance.

1933 Board #341 Abstract Withdrawn

1934 Board #342 MAY 30 3:30 PM - 5:00 PM

**Different Pacing Strategies during Time Trials in 18°C and 30°C.**

Bart Roelands<sup>1</sup>, Jos de Koning, FACSM<sup>2</sup>, Floor Hettinga<sup>3</sup>, Romain Meeusen, FACSM<sup>1</sup>. <sup>1</sup>Vrije Universiteit Brussel, Brussels, Belgium. <sup>2</sup>VU-University Amsterdam, Amsterdam, Netherlands. <sup>3</sup>University of Groningen, Groningen, Netherlands.  
(No relationships reported)

Sports performance depends on the rate at which energy can be expended and on the distribution of energy during an event (pacing strategy). Pacing strategy is organized in an anticipatory way to optimize performance and to prevent unreasonable large homeostatic disturbances during exercise. It is not known to what extent a preceding, fatiguing fixed intensity exercise at different ambient temperatures influences pacing strategy during a time trial (TT).

**PURPOSE:** Therefore, the purpose is to examine differences in pacing strategy during a TT in normal and high ambient temperature preceded by 60min of exercise at these temperatures.

**METHODS:** Subjects performed 60min fixed intensity exercise at 55%  $W_{max}$  preceding a TT in 18°C (n=37,  $W_{max}$  344±36W) and 30°C (n=41,  $W_{max}$  341±37W). All subjects were male and endurance-trained. During the TT a predetermined amount of work had to be completed. The TT was started at 75% $W_{max}$ , but subjects were free to change resistance as desired from the onset of exercise. Power output was collected every second and averaged in 5% segments of total TT for statistical analysis.

**RESULTS:** Average TT time in 18°C was 30.7±2.1min, while in 30°C this was 37.8±4.7min (P<0.001). In 18°C there were no differences between the 5% segments and average power output (even paced). In 30°C, subjects decreased power output during the initial 15% of the TT (P=0.008), followed by a slight decrease in power output until it was significantly lower compared to average power at 85% of the TT (P=0.031), when an end spurt commenced. In the heat, final power was significantly higher compared to the average power (P=0.045).

**CONCLUSION:** These data provide evidence for different pacing strategies in different environmental temperatures. After fixed intensity exercise in 18°C, subjects choose an even-paced, strategy until the last 5% of the TT, where there was a non-significant end spurt. In the heat subjects significantly decrease power at the start and an end sprint is obvious in the last 15% of the TT. These data indicate that subjects anticipate to different environmental circumstances and volitionally adapt pacing strategy.

**Acknowledgements;** Bart Roelands is a post-doctoral fellow of the Fund for Scientific Research Flanders (FWO). This study is supported by a VUB research fund (OZR 1236).

### Modeling Relationships between Swimming Attributes for Performance Prediction

Bahadorreza Ofoghi<sup>1</sup>, Danielle Stefano<sup>2</sup>, John Zeleznikow<sup>1</sup>, Clare MacMahon<sup>1</sup>. <sup>1</sup>Victoria University, Melbourne, Australia. <sup>2</sup>Victorian Institute of Sport, Melbourne, Australia.

(No relationships reported)

Swimming is a high profile sport in which an athlete with the fastest overall time wins and even a very small difference in overall times is decisive for medal winning. The inter-relationships between different swimming attributes and the overall time can be used to predict and optimize overall times hence to increase the medal winning chance.

**PURPOSE:** To model pair-wise inter-relationships between swimming attributes and the overall time, predict overall swim times, and train for optimal strategies.

**METHODS:** A linear regression analysis was performed to model the pair-wise inter-relationships between swimming attributes and the overall times in specific subsets of swims from a database of international events, filtered based on sex, age group, stroke, pool size, and distance. The F-statistic was calculated to evaluate regression models.

**RESULTS:** Examples of the results are shown in Table 1. In many cases, as evidenced by the small F-statistics, no significant relationship was found between attributes. We found this was the result of many missing values for those attributes. In some cases, no values were reported for the performance attributes, resulting in a “-” in Table 1. In some other cases, e.g., breath count in M, freestyle, 50m, lcm, open swims, a significant relationship was found thus the model could be used for predicting overall times.

**CONCLUSION:** The linear regression analysis of swimming attributes requires more sophisticated analysis that can handle the large number of missing values. Where enough data exists; however, this model can effectively be used for prediction of overall swim times.

**Table 1.** Examples of the evaluation results of linear regression analysis of swimming performance attributes and overall times

| Swims (sex, stroke, distance, pool size, age group) | F-statistic for some swimming performance attributes |             |            |               |              | #instances |

### Delivery and Pitch Type Alter Ground Reaction Forces in Baseball Pitching

Michael E. Feltner, FACSM, Garrett Kass. *Pepperdine University, Malibu, CA.*

(No relationships reported)

Ground reaction forces (GRFs) exerted on a pitcher in reaction to the push of their legs against the ground create torques about the center-of-mass (CM) and generate the angular momentum necessary to rotate the body, including the segments of the throwing arm. Thus examination of GRFs provides insight into the causal mechanisms responsible for segmental rotation in baseball pitching.

**PURPOSE:** To determine the effects of delivery [wind-up (WU) vs. stretch (ST)] and pitch type [fastball (FB) vs. change-up (CU)] on GRFs in pitching.

**METHODS:** Eight collegiate baseball pitchers (3 right-handed and 5 left-handed) provided voluntary informed consent and threw maximal effort FB and CU pitches from the WU and ST positions from a regulation indoor pitching mound. Five pitches of each type were thrown from each delivery position. Two Kistler (Model 9281B) force plates mounted rigidly to the floor and imbedded in the pitching mound recorded GRFs (1200 Hz) under the push-off and stride foot, respectively. A video camera (60 Hz) was used to estimate the instant of ball release and a radar gun (JUGS Pro-Sports Model; accuracy ± 0.25 m/s) recorded ball speed. Comparisons of the GRF variables were made using two-way repeated measures ANOVA.

**RESULTS:** As expected, FB pitches had a higher ball speed relative to CU pitches (37.3±1.3 vs. 32.9±1.9 m/s, p<0.01); ball speed did not differ by delivery type. No pitch by delivery interactions were present. FB pitches had larger peak magnitude GRFs exerted in the anterior direction (direction of the pitch) on the push-off foot (FB: 0.78±0.13; CU: 0.75±0.14 BW; p<0.05) and exerted in the posterior direction on the stride foot (FB: -1.12±0.13; CU: -1.03±0.12 BW; p<0.01). WU pitches had larger mediolateral GRFs directed toward the throwing arm side exerted on the push-off foot (WU: 0.14±0.03; ST: 0.07±0.04 BW; p<0.01) and larger GRFs directed perpendicular to the surface of the mound (WU: 1.94±0.32; ST: 1.84±0.30 BW; p<0.05) exerted on the stride foot.

**CONCLUSIONS:** FB pitches require greater anteriorly directed forces on the push leg to accelerate the pitcher forward and larger posteriorly directed forces on the stride leg to decrease the forward momentum of the pitcher. WU pitches involve a greater mediolateral range-of-motion of the CM and require larger mediolateral forces exerted on the push-off foot.

### Influence Of Exercise-induced Fatigue On Submaximal And Maximal Joint-specific Power Production

Steven J. Elmer<sup>1</sup>, Camden S. Marshall<sup>1</sup>, Kyle W. Wehmanen<sup>1</sup>, Markus Amann<sup>1</sup>, John McDaniel<sup>2</sup>, David T. Martin<sup>3</sup>, James C. Martin, FACSM<sup>1</sup>. <sup>1</sup>University of Utah, Salt Lake City, UT. <sup>2</sup>Kent State University, Kent, OH. <sup>3</sup>Australian Institute of Sport, Canberra, Australia.

(No relationships reported)

Previous authors have reported reductions in maximum power after high-intensity endurance exercise. Exercise-induced changes in power produced by ankle, knee, and hip joint actions (joint-specific powers), however, have not been reported.

**PURPOSE:** To evaluate joint-specific power production *during* a cycling time trial (TT) and also compare *pre- to post-TT* changes in maximal cycling (MAX<sub>cyc</sub>) joint-specific powers.

**METHODS:** Ten male cyclists performed MAX<sub>cyc</sub> trials (90 rpm) before and after a 10 min TT (288 ± 10W, 90 rpm). Pedal forces and limb kinematics were determined with a force-sensing pedal and an instrumented spatial linkage, respectively. Joint-specific powers were calculated and averaged over complete pedal cycles and over extension and flexion phases.

**RESULTS:** Absolute pedal and joint-specific powers did not change during the TT. Pedal power produced during post-TT MAX<sub>cyc</sub> was reduced by 32 ± 3% (P < 0.001) relative to pre-TT. Relative pre- to post-TT changes in ankle plantar flexion (43±5%) and knee flexion powers (52 ± 5%) were similar but were greater than changes in knee extension (12 ± 4%) and hip extension powers (28 ± 6%) (P < 0.05). Pedal and joint-specific powers produced during post-TT MAX<sub>cyc</sub> were greater than those powers produced during the final 3s of the TT (P < 0.05).

**CONCLUSION:** Exercise-induced changes in MAX<sub>cyc</sub> power manifested with differential power loss at each joint action with ankle plantar flexion and knee flexion exhibiting relatively greater fatigue than knee extension and hip extension. However, changes in MAX<sub>cyc</sub> joint-specific powers were not presaged by changes in TT joint-specific powers. Despite working near maximal effort at the end the TT, participants had considerable neuromuscular reserve as they were able to produce substantially greater power during post-TT MAX<sub>cyc</sub>. We conclude that fatigue induced via high-intensity cycling does not alter submaximal joint-specific power production but has distinct functional consequences for maximal cycling joint-specific powers.

**Kinematic Factors Related to Accuracy for Placekicking in American Football**

Rodney T. Inamura, Michael E. Nave, David Mandeville, Harry Theodorides. *California State University Sacramento, Sacramento, CA.*  
(No relationships reported)

American football placekickers can score a majority of the team's points and often determine the outcome of a game. Despite the importance of the position and the popularity of football, little effort has been made to quantify the biomechanical aspects of placekick accuracy.

**PURPOSE:** To analyze biomechanical factors known to be related to accuracy during made and missed placekicks.

**METHODS:** Five experienced male placekickers were analyzed in three-dimension using two cameras (JVC 240Hz) and motion analysis software (Vicon-Peak Performance Inc. Motus). Each subject performed seven trials, kicking from 40 yards away from the post and dead center. Five variables known to affect kicking accuracy were selected: body lean angle (BL), side arm angle (SA), approach angle (AA), mediolateral plant foot distance from the ball (MLD), and anteroposterior plant foot distance from the ball (APD). All variables were analyzed using dependent t-test ( $\alpha = 0.01$ , SPSS, Chicago, IL).

**RESULTS:** No significant differences were found between made and missed placekicks (Table 1).

**CONCLUSION:** For the variables measured, the findings indicate no significant changes in placekicking mechanics between kicks that were made or missed. The participants in this study performed similar mechanics between kicks and can be considered "well coached" in terms of current coaching perspectives. This indicates the overall complexity of the placekick. The findings necessitate further biomechanics research, particularly with the timing aspects of the placekick.

Table 1. Average body lean angle (BL), side arm angle (SA), approach angle (AA), mediolateral plant foot distance (MLD), and anteroposterior plant foot distance (APD) measurements for made and missed attempts.

|         | BL (deg)     | SA (deg)     | AA (deg)   | MLD (m)         | APD (m)        |
|---------|--------------|--------------|------------|-----------------|----------------|
| Made    | 208<br>(±18) | 102<br>(±10) | 34<br>(±3) | 0.39<br>(±0.05) | 0.18<br>(±.10) |
| Missed  | 207<br>(±21) | 97<br>(±10)  | 34<br>(±3) | 0.36<br>(±.08)  | 0.18<br>(±.09) |
| p level | 0.81         | 0.14         | 0.97       | 0.46            | 0.96           |

**Automatic 3D Motion Capture of Swimming: Marker Resistance**

Per-Ludvik Kjendlie, Bjørn Harald Olstad. *Norwegian School of Sport Science, OSLO, Norway.*  
(No relationships reported)

Motion capture (mo-cap) of swimmers have traditionally been done using manual digitalization of body points. New technology makes automatic 3D mo-cap available for aquatic purposes, and necessitates methodological studies.

**PURPOSE:** The aim of this study was to pioneer a 3D automatic mo-cap system used on human swimmers and to find the increased drag on human swimmers due to mo-cap markers attached to a swimmers body.

**METHODS:** Two subjects performed a total of 80 push offs with an 8 m underwater gliding phase. During each test, the velocity of the swimmers body was recorded using a Qualisys automatic tracking 3D motion capture system. Six underwater motion capture cameras (Oqus Underwater, Qualisys, Sweden) recorded spherical markers attached to the swimmer, using cyan LED light. Using inverse dynamics the drag coefficient was estimated in 40 tests wearing only 3 markers and compared to 40 tests where a total of 24 markers were attached to the swimmer. All markers had a diameter of 19mm.

**RESULTS:** The mean (±sd) passive drag coefficient when gliding with 24 markers was 30.49±1.72 and 26.37±0.96 for the two subjects respectively. Without markers the drag coefficients were 28.49±1.40 and 23.87±0.97 respectively. There was a statistically significant higher drag when wearing markers compared to without (p<0.01), the difference averaging to 7% and 10% for the two subjects respectively, and the effect sizes were large and 1.17 and 2.57 respectively.

**CONCLUSION:** Although spherical markers at a sufficient size are necessary for accurate motion capture under water, these markers create a significant increase in the passive drag of swimmers. This should be taken into account when making kinematical analyses with this system in the aquatic space. The results of this paper are limited to passive drag, and it should be expected that different results appear when active drag is considered.

**B-41 Free Communication/Poster - Strategies to Reduce Heat Stress**

MAY 30, 2012 1:00 PM - 6:00 PM

**1940** Board #348 **MAY 30** **2:00 PM - 3:30 PM**

**Passive Cooling Effects on Microenvironmental and Thermoregulatory Responses in Soft Body Armor in Hot Environments**

Greg A. Ryan<sup>1</sup>, Charles P. Katica<sup>1</sup>, Stacy H. Bishop<sup>1</sup>, Robert L. Herron<sup>1</sup>, Andy M. Bosak<sup>2</sup>, Phillip Bishop<sup>1</sup>. <sup>1</sup>University of Alabama, Tuscaloosa, AL. <sup>2</sup>Georgia Southwestern State University, Americus, GA.  
(No relationships reported)

It has been well established that convective heat loss is reliant on the temperature gradient between the skin and the microenvironment and the volume of air movement over the skin. When either is compromised, excess heat is stored, raising core body temperature (T<sub>rec</sub>). This heat storage is further attenuated when an individual is wearing soft body armor (SBA) which inhibits

convective and evaporative heat loss. In the case of police and military personnel, where SBA use is required, any reduction in heat storage may be able to greatly reduce mortality and morbidity from heat injury. One way to possibly circumvent this excess heat storage is to promote the “chimney effect”, which can be achieved by promoting airflow through bodily movement or by creating venting, and may be beneficial in controlling heat strain.

**PURPOSE:** The purpose of this study was to investigate the effects of adding 1.27 cm standoffs to a Class II Soft Body Armor (SBA) on heat strain and perceived comfort compared to traditionally worn SBA.

**METHODS:** A counterbalanced, repeated measures protocol was performed with seven volunteers (20 ± 2 yr). Prior to each trial, participants were outfitted with a SBA in a traditional vest carrier or one fitted with 1.27 cm standoffs which moved the SBA off the body. Each participant performed cycles of 12 minutes of walking (1.25 L/min) and three min of arm curls (14.3 kg, 0.6 L/min) with a five min rest after every other cycle for a total of 120 min in a hot, humid environment (32°C, 80% RH). During each trial the following variables were recorded every six min: T<sub>rec</sub>; SBA microclimate (temperature and humidity [iButtons]); skin temp (forearm, chest); heart rate; thermal comfort; and perceived exertion. Sweat rate was calculated at the end of each trial. Paired t-tests were used to evaluate: T<sub>rec</sub> (main determinant); microclimate; heart rate; sweat rate; perceived exertion; and comfort.

**RESULTS:** No significant differences (p < 0.05) were noted between the standoff condition and the control in any of the variables tested. The microclimate under the SBA was warmer than the macroclimate during the majority of the tests.

**CONCLUSIONS:** The results indicate that in a controlled environment, the addition of standoffs on Class II SBA did not improve the body’s ability to dissipate heat relative to traditional SBA.

**Passive Vents in CB Uniforms During Low Dressed States Improve Tolerance During High Dress States**

Tom M. McLellan, FACSM<sup>1</sup>, Cathy Boscarino<sup>1</sup>, EJ Scott Duncan<sup>2</sup>. <sup>1</sup>DRDC - Toronto, Toronto, ON, Canada. <sup>2</sup>DRDC - Suffield, Medicine Hat, AB, Canada.  
(No relationships reported)

New lightweight protective assault uniforms (PTAUs) that can be worn as a stand-alone uniform and provide, as required, protection in a chemical and biological (CB) environment are being developed for unique tactical combat situations. The PTAU is designed to lower heat strain and increase tolerance time (TT) when worn in the highest protective dressed state (DS<sub>high</sub>) but also is intended to replace the battle dress uniform (BDU) and worn when the threat is low, during DS<sub>low</sub>.

**PURPOSE:** The purposes of these studies were twofold; first, to examine whether the use of vents in the arms, legs and chest of the PTAU reduced heat strain during DS<sub>low</sub>, and second, to determine whether the use of vents in the PTAU improved TT after the transition to DS<sub>high</sub> compared with the use of the BDU and overgarment (BDU+O).

**METHODS:** In study 1, six males (27 ± 4 y, 77 ± 9 kg, 177 ± 5 cm) performed a familiarization session and 4 trials (2 PTAUs with vents open or closed) at 35°C and 50% relative humidity with low wind (1 m/s) walking at 4.5 km/h for 90 min in DS<sub>low</sub>. For study 2, seven males (27 ± 4 y, 78 ± 8 kg, 177 ± 5 cm) performed 3 trials (2 PTAUs with vents open during DS<sub>low</sub> and BDU+O) which included up to a further 90 min in DS<sub>high</sub>. All trials included wearing a helmet, fragmentation and tactical assault vests, and carrying a rifle.

**RESULTS:** In Study 1, core temperature (T<sub>c</sub>), heart rate and vapor pressures over the thigh and shin were reduced significantly during DS<sub>low</sub> at 90 min when vents were open (37.9 ± 0.2°C, 120 ± 10 b/min, 3.7 ± 0.4 and 3.5 ± 1.0 kPa) vs closed (38.0 ± 0.1°C, 127 ± 5 b/min, 4.3 ± 0.3 and 4.6 ± 0.5 kPa). The vents had no effect on weighted mean skin temperature, ratings of perceived exertion or thermal comfort. In Study 2, there was no difference in physiological strain during DS<sub>low</sub> when the vents were open with the PTAUs compared with BDU. After the transition to DS<sub>high</sub> the rate of increase in T<sub>c</sub> was reduced and TT increased significantly with the PTAUs (1.1 ± 0.2°C/h and 46 ± 24 min) vs BDU+O (1.6 ± 0.2°C/h and 33 ± 16 min).

**CONCLUSION:** It was concluded that the use of vents in the legs of the PTAU reduced heat strain during DS<sub>low</sub> when a fragmentation vest was worn and a rifle was carried. Further, physiological strain during DS<sub>low</sub> with the use of vents in the PTAU was similar to the BDU thereby extending TT and reducing the increase in T<sub>c</sub> after the transition to DS<sub>high</sub> compared with BDU+O.

**1942** Board #350 **MAY 30** **2:00 PM - 3:30 PM**

**Bomb Disposal In The Tropics: An Explosive Cocktail Of Environmental And Metabolic Heat**

Ian B. Stewart, Andrew D. Townshend, Amanda M. Rojek, Andrew P. Hunt. *Queensland University of Technology, Brisbane, Australia.* (Sponsor: Ed Melanson, FACSM)  
(No relationships reported)

Bomb technicians perform their work while encapsulated in explosive ordnance disposal (EOD) suits. Designed primarily for safety, these suits have an unintended consequence of impairing the body’s natural mechanisms for heat dissipation. In tropical environments the potential for heat illness is increased.

**PURPOSE:** To quantify the heat strain encountered during an EOD operational scenario in the tropical north of Australia.

**METHODS:** All active police bomb technicians, located in a tropical region of Australia (n=4, experience 7±2.1 yrs, age 34±4.9 yrs, height 183±4.7 cm, body mass 89±6.6 kg, VO<sub>2max</sub> 43±4.6 mL/kg/min) undertook an operational scenario wearing the Med-Eng EOD 9 suit and helmet (weight ~35 kg). The climatic conditions ranged between 27.1-31.8°C ambient temperature, 66-88% relative humidity, and 30.7-34.3°C wet bulb globe temperature. The scenario involved searching a two story non air-conditioned building for a target; carrying and positioning equipment for taking an x-ray; carrying and positioning equipment to disrupt the target; and finally clearing the site. Core temperature (ingestible pill) and heart rate were continuously monitored, and were used to calculate a physiological strain index (PSI; 1 - no/little strain, 9 - very high strain). Urine specific gravity (USG) assessed hydration status and heat associated symptomatology was reported.

**RESULTS:** The scenario was completed in 120±22 mins (24±0.4% work, 76±0.4% rest/recovery). Maximum core temperature (38.33±0.21°C), heart rate (173±5.4 bpm, 94±3.3 %max), PSI (7.05±0.44) and USG (1.031±0.002) were all significantly elevated. Heat associated symptomatology highlighted that moderate-severe levels of fatigue and thirst were universally experienced, with muscle weakness and heat sensations also experienced by 75% of the bomb technicians. Neurological symptoms of light-headedness, dizziness and confusion were also reported.

**CONCLUSION:** All bomb technicians demonstrated moderate-high levels of heat strain, evidenced by elevated heart rate, core body temperature and PSI. Severe levels of dehydration and noteworthy heat-related symptoms further highlight the risks to health and safety faced by bomb technicians operating in tropical locations.

---

**1943** Board #351 **MAY 30** **2:00 PM - 3:30 PM**

**Effects of Loggers’ Protective Clothing on Thermoregulation**

Aitor Coca, Jeffrey B. Powell, Jung-Hyun Kim, W. Jon Williams, Raymond J. Roberge. *NIOSH/NPPTL, Pittsburgh, PA.*  
(No relationships reported)

Heat stress is common among forestry workers, including loggers.

**PURPOSE:** Evaluate the thermal responses to wearing loggers’ protective clothing (LPC) while performing moderate intensity exercise in the heat.

**METHODS:** Six healthy male participants performed two trials of treadmill exercise in a warm environmental chamber (35°C, 50% relative humidity [RH]) while wearing either sports clothes (CON) or LPC which included a safety vest, chainsaw chaps, gloves, safety helmet, long trousers, long sleeve shirts, wool socks and boots. The study protocol consisted of two stages of 20 min of exercise at a relative workload of 30% and 50% VO<sub>2max</sub>. The participants then performed a chainsaw maneuver (sawing motion against a vertical object) for 1 min followed by a recovery period (15 min rest) in the chamber. Study variables included core temperature (T<sub>co</sub>), mean skin temperature (T<sub>sk</sub>), and heart rate (HR). Data were analyzed by two-way (Trials × Time) repeated measures ANOVA.

**RESULTS:** All 6 subjects (CON) completed 41 min of exercise for CON, but only averaged 38.7 min of exercise (37.7 min treadmill and 1 min chainsaw maneuver) while wearing LPC. T<sub>co</sub> in the LPC was higher than CON. However, it was only statistically higher in the recovery time suggesting that wearing LPC in warm environments hinders the recovery of the users.

| Trial | Variables | Start of Ex | 20min<br>30%VO2max | 20 min<br>50%VO2max | 1min<br>Sawing | 15 min<br>Recovery |
|-------|-----------|-------------|--------------------|---------------------|----------------|--------------------|
| CON   | Tco       | 37.2(0.3)   | 37.4(0.3)          | 37.8(0.2)           | 37.8(0.2)      | 37.6(0.2)*         |
|       | Tsk       | 33.1(0.5)   | 34.9(0.4)*         | 35.4(0.8)*          | 35.5(0.7)*     | 35.1(0.4)*         |
|       | HR        | 93.3(5.9)   | 103.6(11.3)*       | 132.3(4.6)*         | 132.1(10.2)*   | 84.3(8.6)          |
| LPC   | Tco       | 37.2(0.2)   | 37.5(0.2)          | 38.1(0.4)           | 38.2(0.4)      | 38.3(0.3)*         |
|       | Tsk       | 33.5(0.7)   | 35.9(0.2)*         | 36.4(0.4)*          | 36.4(0.4)*     | 36.4(0.3)*         |
|       | HR        | 103.5(13.2) | 120.5(12.8)*       | 168.4(11.4)*        | 162.8(10.5)*   | 100.7(14.6)        |

\*Significant differences between same stages in the different tests (p<0.05)

**CONCLUSION:** Wearing LPC while exercising in the heat at the study specific workloads did impose a significant thermal burden on the wearer evidenced by the elevated HR and Tsk values in the LPC. Tco did not decrease in 15min recovery, showing that LPC imposes a thermal load on the user that may cause heat stress over time if no actions are taken to limit the risk.

**1944 Board #352 MAY 30 2:00 PM - 3:30 PM**

**Physiological and Perceptual Responses to Acute Firefighting Activity in Different Turnout Gear Ensembles**

Paula YS Poh<sup>1</sup>, Eric Goldstein<sup>2</sup>, Gavin P. Horn<sup>2</sup>, Denise L. Smith, FACSM<sup>2</sup>, Steven J. Petruzzello, FACSM<sup>1</sup>. <sup>1</sup>University of Illinois at Urbana-Champaign, Urbana, IL. <sup>2</sup>Illinois Fire Service Institute, Champaign, IL. <sup>3</sup>Skidmore College, Saratoga Springs, NY.

(No relationships reported)

Firefighters (FFs) routinely perform demanding physical work in extreme environmental temperatures. In addition, the weight and encapsulating nature of their protective turnout (TO) gear adds to the thermal and cardiovascular strain. b

**PURPOSE:** To examine the effects of two firefighting TO ensembles (standard vs enhanced) on physiological and perceptual responses to an acute bout of FF activity in the heat.

**METHODS:** 119 male FFs (M±SD: age=29.45 ± 7.94 y; ht=1.77 ± 0.07 m; mass=87.81 ± 15.44 kg; BMI=28.07 ± 4.41) free from known cardiovascular disease were randomly assigned to one of the two TO gear ensembles. The standard TO gear (n=59) consisted of bunker gear with spun Nomex lining, Kevlar fully-encapsulating hood, leather gloves, rubber boots, traditional-style helmet: M wt = 11 kg. The enhanced TO gear (n=60) consisted of bunker gear with Indura FR cotton lining, which circulated exhaled air from the firefighter to the coat's inner lining, Nomex hood, low-profile helmet, leather gloves, lightweight leather boots: M wt = 8.6 kg. FFs underwent 18 min of simulated FF activity (stair climbing, forcible entry, secondary search, hose advance), alternating cycles of 2 min rest with 2 min of activity. Physiological and perceptual measurements were obtained pre- and post-FF activities.

**RESULTS:** No significant differences were observed between TO gear ensembles (P > 0.05). Overall, FF activity resulted in significant (P < 0.05) increases in heart rate (Mpre, 92.9 ± 18.8 b·min<sup>-1</sup>, Mpost, 168.3 ± 14.8 b·min<sup>-1</sup>); core temperature (Mpre, 37.56 ± 0.37°C, Mpost, 38.22 ± 0.69°C); neck temperature (Mpre, 33.40 ± 1.76°C, Mpost, 38.40 ± 1.23°C); thermal sensation (Mpre, 4.3 ± 0.7, Mpost, 5.9 ± 0.9); and respiratory distress (Mpre, 1.1 ± 0.4, Mpost, 2.8 ± 1.1). Conversely, there was a significant (P < 0.05) decrease in feeling scale (Mpre, 3.8 ± 1.2, Mpost, 1.9 ± 1.9).

**CONCLUSIONS:** FF resulted in significant changes in physiological and perceptual measures. TO gear configuration (standard vs enhanced) did not differentially influence the physiological or perceptual strain.

**1945 Board #353 MAY 30 2:00 PM - 3:30 PM**

**Influence of Clothing Layers Under Firefighting Protective Clothing on Physiological/Perceptual Responses to Intermittent Work**

Jeannie M. Haller, Eric M. Hultquist, Wesley K. Lefferts, Denise L. Smith, FACSM, Patricia C. Fehling, FACSM. Skidmore College, Saratoga Springs, NY.

(No relationships reported)

Personal protective clothing protects firefighters from thermal and other occupational hazards; however, it also contributes to the physiological and perceptual strain experienced by the wearer. Although research suggests that the addition of a clothing layer could cause an increase in thermal stress, the influence of additional layers of clothing, such as a station uniform shirt over a t-shirt, has not been well studied.

**PURPOSE:** To examine the effect of clothing layers worn under structural firefighting turnout gear (TOG) on physiological and perceptual responses during alternating work/recovery cycles.

**METHODS:** Ten men (age, 21 ± 1 yr; height, 174 ± 6 cm; weight, 74.3 ± 7.4 kg; VO<sub>2max</sub>, 58.9 ± 6.3 ml·kg<sup>-1</sup>·min<sup>-1</sup>) completed a 110-min intermittent walking protocol (three 20-min exercise bouts/10, 20 and 20 min recovery sessions) in a thermo-neutral (21.0 °C, 58.7% RH) laboratory while wearing a cotton t-shirt (COT) or COT and a station uniform (SU) shirt under firefighting TOG (COT+TOG and COT+SU+TOG, respectively). Some or all TOG was removed during each recovery session. Changes in heart rate (HR), core temperature (T<sub>co</sub>), skin temperature (T<sub>sk</sub>), rating of perceived exertion (RPE), and thermal sensations (TS) were compared across exercise and recovery periods using general linear models with repeated measures ANOVA.

**RESULTS:** During exercise sessions HR, T<sub>co</sub>, T<sub>sk</sub>, and RPE reached similar levels for COT+TOG and COT+SU+TOG. During Recovery 1, 2, and 3, chest T<sub>sk</sub> decreased by 3.96 °C, 6.64 °C, and 6.49 °C, respectively, for COT+TOG compared to 2.24 °C, 3.78 °C and 4.09 °C for COT+SU+TOG (P < 0.05 for each period). Change in TS differed during Exercise 1; however, mean peak TS corresponded to "hot" for both ensembles.

**CONCLUSIONS:** The additional layer of clothing in the COT+SU+TOG ensemble imposed no greater level of physiological or perceptual strain during moderate-intensity work bouts compared with the COT+TOG ensemble. However, some modest benefits were experienced during the recovery sessions for the COT+TOG ensemble as evident by a lower chest T<sub>sk</sub>. These findings could guide departmental decisions about the use of station shirts.

Supported by Department of Homeland Security grant EMW-2009-FP-02044.

**Effects Of A Cooling Vest On Cycling Performance In A Hot And Humid Environment**

Amanda Layton, Tim Burnham, Robert Pritchett, Vince Nethery. Central Washington University, Ellensburg, WA. (Sponsor: Scott O. Roberts, FACSM)

(No relationships reported)

Endurance sporting events often take place in hot and/or humid environments. Exercise in such conditions can significantly raise body temperature and increase physiological demands associated with maintaining homeostasis. It has been well established that exercise induced heat stress will negatively affect performance and lead to premature fatigue in short-term and prolonged exercise. Pre-cooling prior to exercise has been shown to decrease skin and core temperature delay fatigue, and improve anaerobic and aerobic exercise performance. To date, little evidence exists as to the effectiveness of wearing a cooling vest during a performance trial.

**PURPOSE:** To investigate the effects of wearing a cooling vest on cycling performance and thermoregulatory responses during a self-paced 40Km time trial in a hot and humid environment.

**METHODS:** Ten male cyclists (22-55 years) attempted two 40Km laboratory-based time trials consisting of: 1) wearing a light-weight ice vest (1-1.5Kg) for pre-cooling and during the entire trial, and 2) no vest (NV) or other cooling method. Both trials were conducted a hot environment (32.64°C ± 0.66°C, 48.43% ± 3.84% RH).

**RESULTS:** Performance times for 40Km could not be compared for all subjects as 7 of 10 subjects reached critical core temperature (39.5°C) prior to completing the time trials. Four of the 7 subjects rode longer before reaching critical core temperature with the vest (~39 min) compared to NV (~34.75 min), however this difference was not statistically significant (p=0.48). The mean final performance times (Time<sub>Final</sub>) for subjects that were able to finish the 40Km time trial was 1.08 min faster for the vest trials than NV; however, the performance times were not significantly different (p = 0.74). No significant differences were found for core temperature (T<sub>rec</sub>), mean skin temperature (T<sub>sk</sub>), power output (PO), percent max power output (PO<sub>%max</sub>) heart rate (HR), thermal comfort (ThC), thermal sensation (ThS), or rating of perceived exertion (RPE).

**CONCLUSION:** We conclude that wearing a cooling vest during a cycling time trial in a hot and humid environment does not blunt the rise  $T_{rec}$  and  $T_{sk}$ , or HR, and does not influence  $Time_{ec}$ ,  $Time_{final}$ , RPE, ThC or ThS. Therefore, cooling vest use during a time trial does not improve cycling performance.

**The Effect Of Pre-heating And Intermediate Cooling On Firefighting Performance**

Koen Levels<sup>1</sup>, Eric Mol<sup>2</sup>, Carl Foster, FACSM<sup>3</sup>, Jos J. De Koning, FACSM<sup>1</sup>, Hein A.M. Daanen<sup>4</sup>. <sup>1</sup>Research Institute MOVE, VU University Amsterdam, Amsterdam, Netherlands. <sup>2</sup>iXeR.nl; innovation eXperts for emergency Responders, Asten, Netherlands. <sup>3</sup>University of Wisconsin-La Crosse, La Crosse, WI. <sup>4</sup>TNO Behavioural and Societal Sciences, Soesterberg, Netherlands.

(No relationships reported)

During firefighting activities core temperature ( $T_c$ ) can exceed 39.0°C and reduce performance. Therefore it is crucial to prevent or delay the attainment of high  $T_c$ .

**PURPOSE:** To determine the effect of pre-heating and intermediate cooling on speed and quality of firefighting activities.

**METHODS:** Twelve firefighters visited the Fire Training Center based lab three times. In one trial, they were pre-heated (HEAT) prior to a search-and-rescue and fire extinguishing task within a fire drill in a burn building. In the other trials, subjects remained thermoneutral prior to the drill and afterwards they were either cooled by forearm immersion in 10°C water (FC) or remained seated in 20°C ambient temperature (CONTROL). After this 20-min recovery period, they performed a second drill. Core and skin temperature ( $T_{sk}$ ), heart rate (HR), rating of perceived exertion (RPE), speed, and quality of performance (QoP) were measured during the trials. QoP was ranked by two experienced fire instructors and the subjects themselves.

**RESULTS:**  $T_c$  was  $0.54 \pm 0.20^\circ\text{C}$  ( $P < 0.05$ ). After the first drill,  $T_c$  was higher for HEAT ( $38.4 \pm 0.4^\circ\text{C}$ ) than for CONTROL ( $37.9 \pm 0.2^\circ\text{C}$ ;  $P < 0.05$ ). Cooling rate of FC did not differ from CONTROL ( $0.024 \pm 0.014^\circ\text{C min}^{-1}$  and  $0.016 \pm 0.017^\circ\text{C min}^{-1}$ , respectively;  $P > 0.05$ ). No differences in average  $T_c$  and HR were found in the second drill ( $P > 0.05$ ). RPE was higher for HEAT than for CONTROL ( $14.3 \pm 2.1$  and  $12.1 \pm 2.9$ , respectively;  $P = 0.001$ ) whereas no differences were observed between FC and CONTROL ( $12.4 \pm 2.9$  and  $12.8 \pm 3.5$ , respectively;  $P = 0.93$ ). Although no significant difference was observed in time to completion ( $P > 0.05$ ), subjects performed slower in the second half of the first drill in HEAT than in CONTROL and faster in the second half of the second drill in FC than in CONTROL ( $P < 0.05$ ). In HEAT, firefighters rated QoP lower than in CONTROL ( $6.5 \pm 0.7$  vs.  $7.1 \pm 0.3$ , respectively;  $P = 0.02$ ), whereas expert opinion revealed no differences for pre-heating ( $P = 0.39$ ). No differences in QoP were found after forearm cooling ( $P > 0.05$  for self report and expert opinion).

**CONCLUSION:** Pre-heating affected pacing of firefighting exercise and self reported quality of performance. Intermediate forearm cooling was beneficial for pacing but not the quality of firefighting exercise.

**A Comparison Of Two Commercially Available Practical Cooling Interventions On Cycling Capacity In The Heat**

Christopher J. Tyler<sup>1</sup>, Victor Kiril<sup>1</sup>, Saul Cuttelli<sup>2</sup>. <sup>1</sup>Roehampton University, London, United Kingdom. <sup>2</sup>Moulton College, Moulton, United Kingdom.

(No relationships reported)

Exercise performance and capacity are both impaired in hot conditions but cooling interventions can attenuate this impairment. The majority of cooling literature has focussed on cooling prior to exercise (pre-cooling) but cooling during exercise using cooling vests (CV) and modified cooling collars (CC) has recently been shown to also enhance performance in hot conditions. Due to improvements in the technology behind commercially available cooling devices (e.g. reductions in bulk and improvements in cooling magnitude and duration) and an increase in their availability cooling during, rather than before, exercise is receiving greater attention.

**PURPOSE:** To investigate the effect of two unmodified, commercially available cooling devices on cycling capacity in a hot environment.

**METHODS:** Eight non-acclimated, untrained but healthy ( $W_{max}$ :  $240 \pm 25$  W) males completed an incremental cycle test to determine maximum power output ( $W_{max}$ ), a full familiarisation and three experimental cycle tests (either wearing a CV or a CC throughout or with no cooling (NC)). During the familiarisation and main trials the participants cycled to volitional exhaustion at 60%  $W_{max}$  in a hot environment ( $35.0 \pm 0.1^\circ\text{C}$ ;  $50 \pm 1\%$  rh). Exercise capacity, rectal temperature, weighted-mean skin temperature, torso temperature, neck temperature, heart rate, fluid loss and consumption, rating of perceived exertion, thermal sensation and feeling scales were recorded. One-way and two-way repeated-measures analysis of variance tests were conducted to evaluate differences between variables. Significance was set at the  $P < 0.05$  level.

**RESULTS:** Cycling capacity was longer in VC ( $32.2 \pm 9.5$  min) compared to NC ( $27.6 \pm 7.6$  min;  $P = 0.03$ ;  $d = 0.57$ ) and CC ( $30.0 \pm 8.8$  min;  $P = 0.02$ ;  $d = 0.26$ ). There was no difference in cycling capacity in CC compared to NC ( $P = 0.12$ ). Both cooling interventions lowered site-specific skin temperature and site-specific thermal sensation ( $P < 0.01$ ) but had no effect on any of the other physiological or perceptual variables ( $P > 0.05$ ).

**CONCLUSIONS:** Practical torso cooling using a commercially available CV improves the cycling capacity of untrained males in a hot environment without altering non-site-specific physiological or perceptual responses but cooling the neck using an unmodified, commercially available CC does not.

**The Effect of Wearing a Cooling Vest Between Two Heated Exercise Bouts on Core Temperature**

Jessica C. Brown, Lindsay R. Laaman, Nicole E. Pollard, Sarah L. Shultz, Ryanne D. Carmichael, David J. Grannis, Tracey D. Matthews, Vincent J. Paolone, FACSM. Springfield College, Springfield, MA.

(No relationships reported)

**PURPOSE:** The purpose of the investigation was to evaluate the effectiveness of a cooling vest to regulate core temperature following heated self-paced exercise, and the effect on exercise duration of a successive heated exercise bout.

**METHODS:** Six males (age =  $24.5 \pm 1.76$  yrs; body fat =  $12 \pm 2.28\%$ ; estimated  $VO_{2peak}$  =  $41.59 \pm 3.52$  ml/kg min) and six females (age =  $23.83 \pm 1.94$  yrs; body fat =  $21.5 \pm 1.64\%$ ; estimated  $VO_{2peak}$  =  $43.47 \pm 4.36$  ml/kg min) participated in two testing sessions. Each session consisted of two self-paced cycling bouts in a modified heat chamber separated by seated rest. Subjects were required to cycle until core temperature reached  $38.5^\circ\text{C}$  during the first exercise bout. Subjects were then removed from the heat chamber and required to sit until core temperature returned to within  $.3^\circ\text{C}$  of baseline. During the seated rest, subjects wore a cooling vest (experimental session), or a normal t-shirt (control session). During the second exercise bout subjects exercised at the same RPM and wattage as the first bout until core temperature reached  $38.5^\circ\text{C}$  or volitional fatigue. Subjects exercised using the same RPM and wattage for both exercise sessions. Thermoregulatory data was taken every 5 min, except for blood (HCT, Hb) which was taken every 20 min.

**RESULTS:** Time to reach  $38.5^\circ\text{C}$  during the second exercise bout was significantly ( $p < .05$ ) longer following the cooling vest trial ( $43.66 \pm 4.34$  min) than the control trial ( $34.28 \pm 3.97$  min). No significant difference in time to decrease core temperature during seated rest was found between the cooling vest and the control trial ( $p > .05$ ).  $T_{sk}$  was significantly ( $p < .05$ ) greater in female subjects ( $32.92 \pm .17^\circ\text{C}$ ) during seated rest in comparison to male subjects ( $32.13 \pm .17^\circ\text{C}$ ). Core to shell gradient was significantly ( $p < .05$ ) greater in male subjects ( $5.74 \pm .18^\circ\text{C}$ ) during seated rest in comparison to female subjects ( $5.12 \pm .18^\circ\text{C}$ ).

**CONCLUSIONS:** Independent of gender, a cooling vest worn between two heated exercise bouts significantly lengthens time to increase core temperature during the second exercise bout. Gender differences in core to shell gradient may be attributed to the higher body fat percentage in the female subjects.

**Running Performance and Thermoregulation is not Improved when Wearing a Palm Cooling Device**

Cory M. Scheadler, Nathan W. Saunders, Nicholas J. Hanson, Steven T. Devor, FACSM. The Ohio State University, Columbus, OH.

(No relationships reported)

There is evidence that attenuating the rise in core temperature with sophisticated negative pressure and cold application to the palm increases time to exhaustion during endurance exercise. To be athletically applicable during training and competitions more evidence for this effect is necessary with palm cooling devices that are portable.

**PURPOSE:** Our aim was to test the efficacy of a portable palm cooling device at attenuating the rise in core temperature and prolonging time to exhaustion during a run in hot conditions.

**METHODS:** Twelve subjects completed two randomly ordered time to exhaustion (TTE) runs at 75% of their VO<sub>2</sub>max at 30°C and 50% relative humidity. Randomization was based on the use (treatment) or absence (control) of a palm cooling device (PCD), placed in the palm of the hand at the beginning of the TTE. TTE runs started once core temperatures reached 37.5°C during the warm-up. Heart rate (HR), rating of perceived exertion (RPE), feeling, and core temperature (CT) were recorded at 2 minute intervals during the run.

**RESULTS:** The rate of rise of CT was moderate-strongly correlated with TTE in treatment ( $r_2 = 0.91$ ,  $p < 0.05$ ) and control ( $r_2 = 0.68$ ,  $p < 0.05$ ) trials. No significant differences occurred between treatment and control trials for HR, RPE, Feeling and CT. TTE was longer in control than treatment ( $46.7 \pm 31.1$  vs.  $41.3 \pm 26.3$  minutes, respectively,  $p < 0.05$ ), however, when warm-up time was included in analysis, there was no difference between trials for total exercise time ( $52.5 \pm 24.2$  vs.  $54.5 \pm 31.4$  minutes, respectively).

**CONCLUSION:** The use of a PCD during a run in hot conditions did not attenuate the rise in CT. Exercise time in hot conditions did not increase with the use of the PCD and time to exhaustion may have been negatively affected.

### Effects Of Sportswear Design On Thermal Stress And Endurance Running Performance In Hot Condition

Jiao Jiao<sup>1</sup>, Lei Yao<sup>1</sup>, Ya Jun Chen<sup>2</sup>, Stephen H. S. Wong, FACSM<sup>2</sup>, Yue Ping Guo<sup>1</sup>, Frency S. F. Ng<sup>1</sup>, Yi Li<sup>1</sup>. <sup>1</sup>The Hong Kong Polytechnical University, Hong Kong, China. <sup>2</sup>The Chinese University of Hong Kong, Hong Kong, China.  
(No relationships reported)

Clothing designed to minimize total air resistance and facilitate moisture transport would be possible to reduce athlete's thermal stress and improve running performance.

**PURPOSE:** to investigate the effects of clothing design on thermal stress and endurance running performance in hot condition.

**METHODS:** Eight healthy male athletes (mean  $\pm$  SEM: age  $21.8 \pm 0.5$  years, body mass index  $20.7 \pm 0.6$  kg·m<sup>-2</sup>, maximal oxygen consumption- max  $57.0 \pm 2.4$  ml·kg<sup>-1</sup>·min<sup>-1</sup>) participated in a cross-over designed study. Three garments, A, B and C consisted of vest and knee-length short pants and made of Nylon Fabrics, were used in this study. Clothing A had the lower Air Resistance (AR: 0.05 KPa·s·m<sup>-1</sup>) and the higher Overall Moisture Management Capacity (OMMC: 0.70) than Clothing B (AR: 0.08 KPa·s·m<sup>-1</sup>; and OMMC: 0.68). Clothing C was set as the control (AR: 0.67 KPa·s·m<sup>-1</sup>; and OMMC: 0.54). Under hot condition (temperature:  $30 \pm 0.2$  °C, relative humidity:  $50 \pm 5\%$ ), the athletes rested for 30min and then performed 5min warm up. After that, they performed 45min running at their 70% max and 1.5km time trial running. Skin and core temperature were continuously collected throughout the whole study at 1min interval. Mean skin temperature (T<sub>sk</sub>) was calculated by recording the skin temperature at chest, upper arm, thigh and calf respectively by four thermistors, whereas core temperature (T<sub>c</sub>) was recorded by ingested telemetric pill.

**RESULTS:** During 30min resting, T<sub>sk</sub> was higher for A when compared with B (T vs. O:  $33.8 \pm 0.03$  °C vs.  $33.5 \pm 0.03$  °C,  $p < 0.05$ ) and during 45min running, T<sub>sk</sub> was the lowest for A among the three garments (T vs O vs A:  $32.5 \pm 0.06$  °C vs.  $32.8 \pm 0.05$  °C vs.  $32.7 \pm 0.05$  °C,  $p < 0.05$ ). Differences were also found in the change of T<sub>c</sub> ( $\Delta T_c$ ) for A and C during the resting period and during the 10<sup>th</sup> min of running, respectively ( $p < 0.05$ ). During the 1.5km running, faster performance was found when wearing A as compared to the C (T vs. A:  $323.1 \pm 10.4$ s vs.  $349.9 \pm 12.0$ s,  $p < 0.05$ ).

**CONCLUSIONS:** clothing with lower AR and higher OMMC can reduce athletes' thermal stress and enhance endurance performance. Supported by Hong Kong Innovation and Technology Commission and HKRITA, China (ITP/014/08T) and HKSI, China (ITT/001/11TT).

**1952** Board #360 MAY 30 2:00 PM - 3:30 PM

### Precooling Does Not Improve 2000m Rowing Performance Of Females In Hot, Humid Conditions

Paul C. Castle<sup>1</sup>, Natalie Fitch<sup>1</sup>, Lee Taylor<sup>1</sup>, Anthony Webbom, FACSM<sup>2</sup>, Alexis R. Mauger<sup>3</sup>. <sup>1</sup>University of Bedfordshire, Bedfordshire, United Kingdom. <sup>2</sup>University of Brighton, Eastbourne, United Kingdom. <sup>3</sup>University of Kent, Chatham, United Kingdom.  
(No relationships reported)

Performing self paced exercise in hot, humid conditions increases rectal temperature (T<sub>re</sub>) and results in premature fatigue compared to temperate conditions. Precooling lowers skin and core temperature, and can alleviate such performance decline, but has predominantly been studied in males. Females have a greater body surface area to mass ratio than men that provides a thermoregulatory advantage during exercise in hot, humid conditions. The potential ergogenic effect of precooling females remains unknown.

**PURPOSE:** This study investigated the effects of precooling on self-paced 2000 m rowing performance of females in hot, humid conditions. Data are analysed using a two way repeated measures ANOVA.

**METHODS:** Eight physically active females ( $19.9 \pm 1.5$  yrs,  $66.8 \pm 3.1$  kgs,  $30.0 \pm 5.0\%$  body fat) performed three 2000 m rows in a randomised order in temperate (20°C, 40% relative humidity; RH) and hot conditions (35°C, 60% RH). The temperate condition acted as control (CONT) and was preceded by 20 min passive rest. One HOT condition was preceded by 20 mins passive rest and the other was preceded by 20 min precooling via a lower body, cold water, shower (PREC;  $22 \pm 2$ °C). Time to complete the row was measured as performance. Rectal, skin temperature (T<sub>sk</sub>) and power output (PO) were recorded every 100 m of the row.

**RESULTS:** No differences were observed between conditions for performance time (CONT;  $8.89 \pm 0.45$  min; HOT,  $9.01 \pm 0.55$  min; PREC,  $8.87 \pm 0.48$  min). Although PO was 7% higher in PREC compared to HOT, no statistical differences were observed between conditions. Mean T<sub>re</sub> during the row was not different between conditions (CONT,  $37.8 \pm 0.2$ °C; HOT,  $37.7 \pm 0.3$ °C; PREC,  $37.5 \pm 0.2$ °C;  $P = 0.12$ ; Main Effect). However, the effect size between HOT and PREC was large (0.67) and lower T<sub>re</sub> was observed at 1600 m and 1800 m of the row in PREC compared to HOT ( $p < 0.05$ ; interaction). Skin temperature was lower in PREC than HOT for the first 1000 m ( $p < 0.05$ ).

**CONCLUSIONS:** Despite a 7% increase in PO, precooling did not enhance 2000 m rowing performance. The precooling technique used reduced T<sub>sk</sub> but not T<sub>re</sub> which may explain the lack of performance enhancement. More aggressive precooling techniques may be required for females due the higher percentage body fat that protects against the cold stimulus.

---

**1953** Board #361 MAY 30 2:00 PM - 3:30 PM

### The Effect of Shivering on the Precooling Response During Endurance Exercise

Katie J. Bouley, Mary C. Stenson, Tracy D. Matthews, Vincent J. Paolone, FACSM. Springfield College, Springfield, MA.  
(No relationships reported)

Precooling can be utilized prior to endurance competition to lower body temperature in an attempt to delay the increase in core body temperature. The delayed rise of core body temperature may result in a delay of fatigue related to decreased pacing strategies, the CNS, and cardiovascular strain. However, the application of precooling techniques may result in a shivering response causing an increase in metabolic heat production.

**PURPOSE:** The purpose of the investigation was to determine whether shivering impacts on the precooling response during an acute bout of endurance exercise.

**METHODS:** Eight trained males ( $23.8 \pm 3.6$  years) completed three sessions with a minimum of 5 days in between sessions. The sessions included a control (C), precooling (PC), and precooling without shivering (NS) session, where subjects were asked to perform a maximum effort 3200 m run after precooling. Subjects remained seated for 60 min while either shirtless or while wearing an ice-vest in direct contact with the skin. The onset of shivering was determined by increased EMG activity of the sternocleidomastoid and resulted in the removal of the ice-vest until shivering subsided during the NS session. Core body temperature, 400 m run time, heart rate, ratings of perceived exertion (RPE), and thermal sensation were recorded every 400 m during the 3200 m run. Blood lactate was analyzed before and after precooling, and after the 3200 m run.

**RESULTS:** No significant differences ( $p > 0.05$ ) were observed for 3200 m run time between the C, PC, and NS sessions. No significant differences ( $p > 0.05$ ) were observed for blood lactate, core temperature, heart rate, or RPE between the C, PC, and NS sessions. Mean thermal scale values in the NS session were significantly lower than mean thermal scale values in the PC and C sessions ( $4.08 \pm .21$  vs.  $4.53 \pm .12$  and  $4.59 \pm .15$ ,  $p < 0.05$ ). Core body temperature was significantly lower after 60 min of precooling than baseline, at 1600 m, and at 3200 m ( $36.20 \pm .12$ °C vs.  $37.10 \pm .06$ °C,  $38.20 \pm .12$ °C, and  $38.72 \pm .11$ °C,  $p < 0.05$ ) in all sessions.

**CONCLUSION:** Performance of a maximal effort 3200 m run was not affected by precooling for 60 min prior to completion. The shivering response associated with wearing an ice-vest as a precooling technique had no impact on performance variables; however, there was a reduction in thermal sensation scale.

1954 Board #362 MAY 30 2:00 PM - 3:30 PM

**A Meta-analysis Of The Hypothermic Properties Of Exogenous Melatonin In Humans**

Kelly Marrin<sup>1</sup>, Barry Drust<sup>2</sup>, Warren Gregson<sup>2</sup>, Greg Atkinson<sup>2</sup>. <sup>1</sup>Edge Hill University, Ormskirk, United Kingdom. <sup>2</sup>Liverpool John Moores University, Liverpool, United Kingdom.

(No relationships reported)

A number of pre-cooling methods have been developed in order to reduce starting core temperature at rest and thereby attempt to enhance subsequent performance in hot conditions. However, interventions such as cold showers can be impractical and difficult to tolerate (Marino, 2002, Br J Sports Med., 36: 89-94). The extent to which exogenous melatonin changes core body temperature in humans is enigmatic. Individual studies have involved small samples, which leads to imprecision in the population estimate of temperature change. There are also between-study differences in melatonin dose, study population and protocols.

**PURPOSE:** To meta-analyse the effects of exogenous melatonin on core temperature and explore the impact of various moderating variables on this temperature change.

**METHODS:** Following an extensive literature search, 33 studies involving 193 participants and 429 separate melatonin ingestions were meta-analysed. The outcome was the mean difference (95% confidence limits) in core temperature between the melatonin and control conditions in each study, weighted by the reciprocal of each standard error of the differences.

**RESULTS:** Publication bias was assessed using Eggers regression intercept and no significant publication bias was evident ( $P=0.39$ ). The meta-analysed reduction in core temperature was found to be 0.21 (0.18 - 0.24) °C, which was unaffected by gender and time of day of ingestion ( $P>0.05$ ). Low doses (0.1- 4.9 mg) resulted in a mean change in core temperature of 0.17 (0.14 - 0.21) °C compared with values of 0.26 (0.23 - 0.30) °C for high doses (5 - 40 mg). Within the melatonin dose range of 0.003 to 10 mg, a linear, but shallow, dose-response relationship was found with a slope of 0.013 °C.mg<sup>-1</sup> ( $P<0.0001$ ). The mean hypothermic effect was 0.13 (0.05 - 0.20) °C for oral temperature compared with 0.26 (0.20 - 0.32) °C for tympanic and 0.22 (0.19 - 0.25) °C for rectal temperature.

**CONCLUSION:** These data indicate that the hypothermic effect of melatonin is clinically significant and robust across genders and time of day. The hypothermic effect was lowest for oral temperature, probably because this site is more prone to masking influences. The meta-regression revealed a linear dose-response relationship that was, nevertheless, quite shallow in practical terms.

(Sponsor: Fredric L. Goss, FACSM)

(No relationships reported)

**PURPOSE:** The purpose of this study was to verify the self-selected intensity during weight training of elderly women.

**METHODS:** Twenty non-smoking older women (60-70 yrs) underwent to 1) a familiarization period (2-weeks) including the utilization of the weight machines and appropriate form for performing the exercise, as well as the use of the perceptual scales; 2) a maximal load test (one maximal repetition, 1-RM) was performed in the following exercises: Chest press, Leg press at 45°, Lat pulldown, Leg (knee) extension, Lateral Shoulder Raise, Leg (knee) Curl, Biceps curl, and Push Down Triceps; 3) a session of weight training at self-selected intensity. Participants were instructed to self-selected a load for performing 3 sets of 10-15 repetitions. Data were analyzed by mean (standard deviation), and ANOVA with repeated measures ( $p<0.05$ ).

**RESULTS:** Global mean of the 3 sets was: chest press 41.0%1-RM (SP11.9); leg press at 45° 43.0%1-RM (DP: 17.2); lat pulldown 47.2%1-RM (11.1); leg (knee) extension 33.0%1-RM (DP: 8.1); lateral shoulder raise 51.1%1-RM (DP: 12.1); leg (knee) curl 43.5%1-RM (DP: 8.8); biceps curl 48.0%1-RM (DP: 15.5); and push down triceps 51.7%1-RM (DP: 13.3) - there was not significant differences between sets ( $p>0.05$ ).

**CONCLUSIONS:** These results indicated that previously sedentary older women self-selected an exercise intensity during weight training below the ACSM recommendation for improvements on muscle strength and hypertrophy. Nevertheless, it is plausible to suggest the utilization of this strategy because it can promote better muscle conditioning in older women until they achieve a level in which they can perform safely the load recommended for improvements on muscle strength and hypertrophy.

1956 Board #2 MAY 31 8:00 AM - 9:30 AM

**The Impact Of An Instructor-led Ipad-based Program On Physical Activity (Preliminary Validation)**

Megumi Saito, Koji Takenaka, Takashi Shimazaki. Waseda University, Saitama, Japan.

(No relationships reported)

There are high expectations in Europe and the United States on the effects of computer-based intervention programs as a population approach method aimed at increasing the amount of physical activity based on the behavioral change theory. However, very few studies are conducted in Japan to validate the impact of such programs.

**PURPOSE:** To validate an iPad-based behavioral change program for instructors (iBCPI) aimed at changing their health behavior (healthy eating, smoking cessation, and increasing the amount of physical activity) based on the action planning strategy in behavioral change theory. This study was to validate the one of these behaviors such as the amount of physical activity, and to objectively assess by the step count.

**METHODS:** The study was conducted on 48 adults who were recruited by the undergraduate student for 1 month intervention period. Participants (18 men, 30 women; average age of 30.2 years; SD=16.4) were randomly assigned to one of the following three groups: 1) the action planning group (n=16); 2) the goal-setting group (n=16); and 3) the control walking group (n=16). A pedometer, a self-monitoring form were provided to all the participants. In addition to this, 1) the action planning group participants set a goal for step count, and the student engage participants in a discussion with iPad program of an action plan that can help the participant fulfill the goal. 2) the goal-setting group participants were asked set their achievable step count goal, and 3) the control walking group participants were encouraged to devise their own ways of increasing their step count.

**RESULTS:** There was a significant difference in the changes of step count based on the baseline step count between action planning group and control group (+1227±1449 steps vs. -63±1481 steps,  $p<0.05$ ). Actions to be chosen (43%) and executed (68%) to increase the step count the most by action planning group was using stairs when commuting/shopping.

**CONCLUSIONS:** Although preliminary, the iBCPI can be regarded as a promising population approach method. Action planning use of iPad program to define the place, times, frequency gave a positive effect on gradually increasing physical activities in daily life. However, the study period was short, and a longer-term intervention study is desirable.

---

1957 Board #3 MAY 31 8:00 AM - 9:30 AM

**Impact Of A Mentoring Program On Self-esteem, Physical Activity And Perceived Competence In Young Boys**

Brett A. Brawerman, Kendall L. Adkins, Elizabeth K. Bailey. Elon University, Elon, NC. (Sponsor: Stephen P. Bailey, FACSM)

(No relationships reported)

According to a White House proclamation, everyone has a role to play in the fight to end childhood obesity. With increasing levels of sedentary behavior in children, programs aimed at improving activity levels are more important than ever. Coaching Health and Mentoring Positive Students (C.H.A.M.P.S.) is a program for boys in 4<sup>th</sup> and 5<sup>th</sup> grade which uses group education

sessions, physical activity and mentoring relationships with college males to address negative attitudes and unhealthy behavior, particularly lack of physical activity. Given that sports are often the source of physical activity in boys, C.H.A.M.P.S. utilizes sports skills training to improve perceived physical competence, which could result in improved physical activity levels and related positive outcomes.

**PURPOSE:** The purpose of this study was to evaluate whether participation in C.H.A.M.P.S (6 sessions) is related to positive changes in perceived physical competence, physical activity, self esteem and social physique anxiety.

**METHODS:** Prior to and following the conclusion of the program, participants completed: 1) an exercise questionnaire (EQ), 2) the Rosenberg Self-Esteem Scale (SE), 3) The Social Physique Anxiety questionnaire (SR), and 4) a modified version of Harter's Perceived Physical Competence scale (PPCSC). Questionnaire results were analyzed to assess changes from pre to post participation in the program.

**RESULTS:** Significant changes were noted on all measures: EQ (Mean<sub>pre</sub> 8.8 ± 0.45, Mean<sub>post</sub> 10.2 ± 0.52, p < 0.01); SE (Mean<sub>pre</sub> 23.4 ± 0.74, Mean<sub>post</sub> 25.4 ± 1.1, p < 0.05); SR (Mean<sub>pre</sub> 18.4 ± 0.95, Mean<sub>post</sub> 15.8 ± 1.2, p < 0.01); PPCSC (Mean<sub>pre</sub> 40.68 ± 2.07, Mean<sub>post</sub> 46.1 ± 2.09, p < 0.05).

**CONCLUSION:** Given that perceived competence in and enjoyment of physical activity are cited as being essential influences on young people's participation over time, it appears that CHAMPS is an effective vehicle to address the issues which play a role in obesity prevalence in this population.

---

**1958** Board #4 MAY 31 8:00 AM - 9:30 AM

**Effects of Pre-habilitation on Self-Efficacy for Exercise and Outcome Expectations for Exercise Among Patients Before and After Total Knee Arthroplasty**

Kent Brown<sup>1</sup>, Robert Topp<sup>2</sup>, Joseph A. Brosky<sup>1</sup>, David Pariser<sup>1</sup>, Ann Swank, FACS<sup>3</sup>. <sup>1</sup>Bellarmine University, Louisville, KY. <sup>2</sup>Marquette University, Milwaukee, WI. <sup>3</sup>University of Louisville, Louisville, KY.

(No relationships reported)

Osteoarthritis (OA) is a clinical condition affecting over 27 million Americans. There is no known cure for OA other than replacing the diseased joint with a partial or total joint prosthesis, total knee arthroplasty (TKA).

**PURPOSE:** The purpose of this research is to compare pre and post-surgical exercise self-efficacy and outcome expectations for exercise among TKA patients who do and do not receive prehabilitation (exercise intervention before surgery).

**METHODS:** 31 participants (22 female, 9 male) scheduled for a TKA from a single orthopedic practice were randomly assigned to a Control (CON) or a prehabilitation (PRE) group following baseline testing. Outcome variables at baseline testing included the Self-Efficacy for Exercise (SEE) scale and the Outcome Expectations for Exercise (OEE) scale. In addition to baseline (T1), participants completed the outcome data collection protocols just prior to surgery (T2) and at 1 (T3) and 2 (T4) weeks following surgery.

**RESULTS:** Repeated measures ANOVA were conducted examining the effect of group (PRE vs. CON) over the four data collection points (Baseline, T2, T3 & T4). Significant main or interaction effects were explored further by calculating Fischer's least significant difference post hoc comparisons. Conducting a RM-ANOVA with time (T1, T2, T3, T4) [F (1, 18) = .42, p = .53] and group (PRE vs CON) [F (1, 18) = .03, p = .86] and interaction of group and time [F (1, 18) = .69, p = .419] as the sources of variability indicated no significant effect of the time, group or group x time on SEE. The SEE, of the PRE appeared to be consistently maintained over the study, and actually trended upward after their TKA at T3 and T4, but did not significantly increase. Differences in OEE within the sample over the duration of the study indicated a significant time effect [F (1, 18) = 4.57, p = .04]. Post hoc analysis indicated that the CON group significantly declined between T2 and T4; however the PRE group did not significantly change.

**CONCLUSIONS:** These findings indicate self-efficacy for exercise was unaffected by the preoperative exercise intervention (prehabilitation), while the outcome expectations for exercise improved in the PRE group. This improvement in outcome expectations for exercise may contribute to improve compliance with post operative rehabilitation exercises among TKA patients.

---

**1959** Board #5 MAY 31 8:00 AM - 9:30 AM

**Hospital-based Exercise Intervention Program Can Promote Exercise Internal Motivation of Care-giving Housewife**

Jin J. Chen<sup>1</sup>, Wen-Hui Huang<sup>1</sup>, Frank J.H. Lu<sup>2</sup>. <sup>1</sup>National Yang-ming University, Taipei, Taiwan. <sup>2</sup>National Taiwan Sports University, Taipei, Taiwan.

(No relationships reported)

Physical inactivity of care-giving housewives had been noted due to lack of time and motivation to exercise regularly. So, we developed the eight-week hospital-based exercise intervention (HEI) using day-care treatment duration of their children twice per week to provide an accessible exercise time for them. However, motivation, especially internal motivation, was the key determinant for long-term participation of regular physical activity.

**PURPOSE:** to investigate the effects of HEI on exercise motivation promotion.

**METHODS:** Sixty sedentary care-giving housewives were recruited and assigned to two groups: HEI group (n=30) and control group (CG, n=30), voluntarily. HEI program consisted of 16 exercise sessions including 8 walking sessions and 8 Yoga-Pilates sessions. Control group received one exercise consultation session during the first visit only. Chinese-version of Behavior Regulation in Exercise Questionnaire-2 (BREQ-2) was used pre- and post-HEI to evaluate the effects of HEI on motivation promotion.

**RESULTS:** After 8 weeks exercise intervention, total motivation score of HEI group significantly increased from 22.3±19.4 to 32.8±20.2, p=.024, majorly due to significant promotion of identified regulation (17.8±7.7 to 21.1±6.7, p=.015) and intrinsic regulation (29.2±10.3 to 35.1±9.4, p<.000). However, there were no significant changes in external regulation of HEI group and all motivation scores of CG.

**CONCLUSION:** Hospital-based exercise intervention program can promote exercise internal motivation of sedentary care-giving housewives. The small-group hospital-based and caregiver-focused intervention model is an accessible, acceptable and substantial approach.

**1960** Board #6 MAY 31 8:00 AM - 9:30 AM

**Can Public Health Take the HIT? High-Intensity Interval Training and Affect in Obese Women**

Emily S. Decker<sup>1</sup>, Panteleimon Ekkekakis, FACS<sup>2</sup>. <sup>1</sup>University of Kansas, Lawrence, KS. <sup>2</sup>Iowa State University, Ames, IA.

(No relationships reported)

Only 3% of obese women trying to lose weight report being physically active at the minimum recommended level (60 min daily). High-intensity interval training (HIT) is promoted as a way of combining the health and fitness benefits of high-intensity exercise and time efficiency. However, obese women report less positive affective responses compared to their normal-weight and even overweight counterparts, an effect that is accentuated at higher intensities.

**PURPOSE:** To compare the affective responses of obese women during a (shorter) HIT session and a (longer) moderate-intensity (MOD) session.

**METHODS:** Twenty-four obese and inactive women (M = 39 years) first completed a ramp test on a recumbent cycle ergometer to determine their ventilatory threshold (VT). They then completed two counterbalanced conditions: (a) a HIT session (4 iterations of 2 min at 85% of VT and 3 min at 115% of VT, for a total of 20 min) and (b) an isocaloric MOD session consisting of cycling at 90% of VT for 25 min. The Feeling Scale (FS) was administered before, during, and after exercise. The Physical Activity Enjoyment Scale (PACES) was administered post-exercise.

**RESULTS:** Analysis of FS data showed a significant condition by time interaction, F (3.29, 75.68) = 8.48, P < 0.001, as well as a significant condition main effect, F (1, 23) = 14.42, P < 0.05, with the HIT session leading to significantly lower ratings of pleasure overall. Likewise, a paired t-test of the PACES scores indicated that the women reported lower enjoyment after the HIT than the MOD, t = -2.14, P < 0.05.

**CONCLUSION:** Based on findings that affect can predict physical activity, these less positive affective responses could result in reduced adherence. Thus, the long-term sustainability of HIT in this high-risk population seems questionable given minimal time savings and less positive affective experiences.

**1961** Board #7 **MAY 31** **8:00 AM - 9:30 AM**  
**Improving Exercise Adherence Through Online Journaling Following Physical Therapy Treatment for Chronic Low Back Pain**

Claire E. Freson, Sharon M. Henry, Paul R. Buzzell, Mike J. DeSarno. *University of Vermont, Burlington, VT.*  
(No relationships reported)

**BACKGROUND:** Low back pain (LBP) is a musculoskeletal condition that affects up to 80% of all people at some point in their lives. Due to high recurrence rates, this condition often escalates into a chronic, costly problem. We examined if online journaling for a prescribed physical therapy (PT) home exercise program (HEP) increased exercise adherence (EA) and led to decreased pain and improved function for subjects with LBP.

**PURPOSE:** To compare whether online journaling improved 6 month outcomes for pain (Numeric Pain Rating Scale [NPRS]), function (Oswestry Disability Index [ODI]), and EA rates for subjects (age 18-55 years) with LBP.

**METHODS:** Subjects completed the ODI and the NPRS at pre-treatment, and 7 weeks and 6 months post-treatment initiation. Following 6 weekly PT treatments, one group (Web group [WG]; n=20) was discharged with a HEP and online journal to record, daily for 6 months, the number of exercise repetitions done for the prescribed HEP and their pre- and post-exercise pain. The journals were monitored weekly; email reminders were sent to subjects to encourage continued participation. The control group (NoWeb [NW]; n= 20) was discharged from PT with a HEP to continue on their own. Six months after the initiation of PT, the two groups were compared using NPRS and ODI scores with an ANOVA with a significance level set to  $P = .05$ . EA rates were also compared.

**RESULTS:** There were no significant group mean differences in the NPRS or ODI scores ( $P = 0.37$ ,  $P = 0.73$ , respectively) across the three time points. However, there was a significant decrease from pre- to post- treatment in NPRS mean ( $P = 0.0009$ ) and in ODI mean ( $P < 0.0001$ ), but no significant mean differences from post-treatment to 6 months for either measure. Over the 6 months, the WG subjects, on average, completed specific exercises 68% (27 - 97%) of the time. At the 6-month time point, all but one NW subject reported doing specific exercises 25 - 50% of the time or less. The WG subjects demonstrated an average adherence rate for activities of daily living of 3.6 out of 4 while NW subjects reported an average level of 2.6 out of 4.

**CONCLUSIONS:** Although the improvements in pain or disability scores were similar between groups, the WG had better EA rates, suggesting a benefit in the use of online journaling as a method to enhance EA. Supported by a UVM URECA grant.

**1962** Board #8 **MAY 31** **8:00 AM - 9:30 AM**  
**A Study of Messaging for Increasing Physical Activity: Exploring Components of Persuasive Messages**

Takashi Shimazaki, Koji Takenaka, Megumi Saito. *Waseda University, Tokorozawa, Japan.*  
(No relationships reported)

To motivate individuals to adhere to a routine of regular physical activity, guidelines must be translated to a persuasive messages. Most interventions designed to increase physical activity have used a messaging process. The study of messaging includes examination of tailoring, targeting, and framing. Results of previous studies suggest that these approaches should be prepared with regard to acceptability and usability for individuals.

**PURPOSE:** This study explored the constructs of acceptability and usability for persuasive messages.

**METHODS:** Thematic analysis is widely used qualitative analytic method within psychology when notably explored theoretical framework. We examined 177 adults (Age = 19 to 68 years, 83 men and 94 women) by obtaining open-ended responses about acceptable and usable information to motivate physical activity.

**RESULTS:** Thematic analyses revealed six themes of acceptability: constitution of verbal messages, framing, verbal message information, visual message information, desirable delivery channel, and desirable place. Additionally, four themes of usability were identified: information benefiting physical activity, information about how to exercise, information related to physical activity, and tailored information about physical activity. Results of chi-square analysis showed that differences between men and women. Information about anti-ageing ( $\chi^2 = 16.2$ ,  $df = 1$ ,  $p < .01$ ), information about improve stiff shoulder and backache ( $\chi^2 = 4.0$ ,  $df = 1$ ,  $p < .05$ ), and information about ingestion and consumption calorie ( $\chi^2 = 4.6$ ,  $df = 1$ ,  $p < .05$ ) were significantly desired by women in theme of usability. No differences between the sexes were found in theme of acceptability.

**CONCLUSIONS:** These study results are expected to contribute to intervention aimed at increasing individuals' physical activity for improvement of public health.

---

**1963** Board #9 **MAY 31** **8:00 AM - 9:30 AM**  
**Does Stage Of Change Predict Psychological Outcomes In A Physician Delivered Dietary And Physical Activity Intervention?**

Sheree Shapiro, Heather Morton, Robert J. Petrella, FACSM. *Lawson Health Research Institute, London, ON, Canada.*  
(No relationships reported)

**BACKGROUND:** The purpose of the present study was to determine whether a predictive relationship was observed in participants between baseline stage of change (SOC; prior to beginning a stage-matched, physician-delivered physical activity and nutrition counselling program) on decisional balance and self-efficacy for diet and physical activity.

**METHODS:** Participants were eligible for the study if they were between the ages of 30-85 and had elevated blood pressure and blood glucose. Participants (n = 69) attended 5 study visits over the course of 52-weeks. At each visit, they received a Step Test and Exercise Prescription, and were counselled on adopting a Mediterranean diet (MD). In addition, they completed the following questionnaires: 1) Physical Activity Self Efficacy (PASE); 2) MD Self Efficacy (MDSE); 3) Decisional Balance for Physical Activity (DBPA); 4) Decisional Balance for MD (DBMD); and 5) SOC for diet and physical activity. Linear regression was used to determine the relationship between baseline SOC, self-efficacy, and decisional balance.

**RESULTS:** Medium negative correlations were observed between mean baseline SOC (MD = 2.91; PA = 3.09) and cons for DBMD at baseline, 8-and 16-weeks only (mean = 2.19,  $r = -0.35$ ,  $p = 0.13$ ; mean = 2.00,  $r = -0.34$ ,  $p = 0.01$ ; mean = 1.94,  $r = -0.43$ ,  $p = 0.00$  respectively), as well as pros for DBPA at 8-and 16-weeks only (mean = 1.4,  $r = -0.36$ ,  $p = 0.01$ ; mean = 1.45,  $r = -0.36$ ,  $p = 0.02$  respectively). Medium positive correlations were observed between baseline SOC and MDSE at 16-weeks only (mean = 98.26,  $r = 0.35$ ,  $p = 0.02$ ), as well as baseline and 24-weeks for PASE (mean = 52.51,  $r = 0.32$ ,  $p = 0.02$ ; mean = 56.08,  $r = 0.46$ ,  $p = 0.00$  respectively). There were no significant correlations between SOC and either variable at 52-weeks.

**CONCLUSION:** Based on the results, a higher baseline SOC was a moderate predictor of lower perceived cons for diet and physical activity. Interestingly however, a higher baseline SOC for physical activity predicted lower perceived pros of physical activity at 8-and 16-weeks. A higher baseline SOC was also a moderate predictor for higher MDSE and PASE midway through the study. Baseline SOC thus may predict some aspects of success part-way through dietary and physical activity behavioral change interventions.

**1964** Board #10 **MAY 31** **8:00 AM - 9:30 AM**  
**A Comparison Of Exercise Self-efficacy Between Individuals With And Without Asthma**

Greg Farnell, Britton Adams. *University of Central Oklahoma, Edmond, OK.* (Sponsor: Ellen Glickman, FACSM)  
(No relationships reported)

**PURPOSE:** Asthma is a medical condition that is often overlooked as chronic or terminal. Its effects on a person's performance emotionally and physically should be noted and taken into account when a person engages in physical activity. The purpose of this study was to examine the influence of having asthma on exercise self-efficacy where exercise self-efficacy refers to the relationship with exercise behavior and attitudes towards exercise.

**METHODS:** Fifty participants completed the Exercise Self-Regulatory Efficacy scale (Ex-SRES). Fifty participants volunteered to participate in this study and each completed the Ex-SRES. Twenty-one participants (6 male, 19 female) from a general education class at a local university served as a control group and 29 participants (8 male, 17 female) were surveyed at an area asthma clinic. The survey consists of 16 questions that measured the confidence levels of continuing to exercise under specific conditions (e.g. "If the weather was bothering him or her"; "If they had no support from others"). Each question was given a Likert-scale response of "Not at all confident" (0%) to "Highly Confident" (100%). Data was analyzed for between-group differences using a one-way ANOVA.

**RESULTS:** The ANOVA revealed significant difference between groups ( $p < 0.05$ ) for 3 out of the 16 questions. These questions read, "If I feel aches and pains while exercising"; "If I am on vacation or away from home"; and "If I feel stressed".

**CONCLUSIONS:** The findings of this study suggest there is minimal difference in exercise self-efficacy between those individuals with and without asthma.

1965 Board #11 MAY 31 9:00 AM - 10:30 AM

### Maximal Running Velocity Characteristics of 11-14 Years of Age Trained Children

Caner Acikada<sup>1</sup>, Manolya Akin<sup>2</sup>, Nigar Kucukbas<sup>3</sup>, Sultan Harbili<sup>4</sup>, Zambak Sahin BOZER<sup>5</sup>. <sup>1</sup>Indiana University, Bloomington, IN. <sup>2</sup>Mersin University, Mersin, Turkey. <sup>3</sup>Mustafa Kemal University, Hatay, Turkey. <sup>4</sup>Selcuk University, Konya, Turkey. <sup>5</sup>Washington State University, Washington, WA. (Sponsor: Robert Chapman, FACSM)

(No relationships reported)

Earlier sport specialisation of child athlete, raises the question of how the maximal speed is influenced by different sport training.

**PURPOSE:** To determine the influencing factors of different sport training on maximal speed in trained boys and girls.

**METHODS:** 11-14 years of age 53 boys and 41 girls not regularly trained normal healthy children were randomly selected from a nearby school as control group, and 146 boys and 151 girls from track and field athletics, basketball, and volleyball were selected as athletes. Two different tests were conducted in order to determine the maximal (100 %), and sub maximal (97 % and 94 % maximals) velocities and running times over 50 m sprinting, during which the maximal attained 5 m velocity was timed by a photocell placed at each 5 m section. During the second test a video camera was placed to record the 5 m section where the maximal velocity was attained for stride frequency and length. Correlation coefficient of the influencing parameters of stride frequency and length was examined by Pearson Correlation Coefficient Test, and the differences between the attained maximal velocity, according to different training groups, ages and gender were tested by MANOVA.

**RESULTS:** The control group had significantly shorter strides ( $F=57.043$ ,  $p<0.05$ ) and lower stride frequency ( $F=8.363$   $p<0.05$ ) at maximal and sub maximal velocities when compared to athletes. Athletes showed different stride length as a result of anthropometric variables and specific training results. There was no difference in stride frequency between the ages in both sexes ( $F=2.437$   $p>0.05$ ) in all velocities. However, males showed higher stride frequency at all ages ( $F=76.934$ ,  $p<0.05$ ) when compared with female athletes. In general most of the strength parameters showed significant correlation with stride length and frequency both in male ( $r=0.558-0.872$ ;  $r=0.552-0.813$ ;  $p<0.05$ , respectively) and female ( $r=0.551-0.843$ ;  $r=0.557-0.735$ ;  $p<0.05$ , respectively) groups in maximal velocities. There was a higher reading in stride frequency in male athletes ( $F=76.934$ ,  $p<0.05$ ), but no difference in stride length between the sexes ( $F=0.289$ ,  $p>0.05$ ).

**CONCLUSION:** In conclusion at this age and training groups, stride frequency and length are influenced by age, gender, strength, anthropometric variables and specific training.

---

1966 Board #12 MAY 31 9:00 AM - 10:30 AM

### Heart Rate Recovery is related to Vascular Health in Preschoolers

Nicole A. Proudfoot, Maureen J. MacDonald, Leigh Gabel, Brian W. Timmons. *McMaster University, Hamilton, ON, Canada.* (Sponsor: Boguslaw Wilk, FACSM)

(No relationships reported)

Heart rate recovery (HRR) following exercise is an indicator of aerobic fitness and predictive of cardiovascular risk and mortality in adults. The relationship between HRR and vascular health in preschoolers (3- to 5-year-olds) is unknown.

**PURPOSE:** To examine the relationship between HRR and measures of vascular health in preschool-aged children.

**METHODS:** Ninety-six preschoolers ( $4.4 \pm 0.9$  years, 50 girls) participated. Arterial stiffness was assessed in a combination of aortic and peripheral vessels using pulse wave velocity (PWV). ECG and pressure waveforms in the right dorsalis pedis artery were recorded following at least 10 minutes of supine rest. PWV was calculated as the time delay between ventricular depolarization and the arrival of the pulse wave at the dorsalis pedis artery, divided into the measured distance between these sites. Seated blood pressure was measured in the right brachial artery. HRR was determined as the difference in peak heart rate during a maximal exercise test (Bruce protocol) and heart rate 1 minute following exercise. Only children who reached a peak heart rate  $\geq 180$  bpm were included in analyses. Pearson correlations were performed to assess the relationships of HRR with PWV and blood pressure.

**RESULTS:** Participants had an average HRR of  $63 \pm 14$  bpm and PWV of  $3.3 \pm 0.2$  m/s. HRR was inversely related to PWV ( $r=-0.349$ ,  $p=0.002$ ). Systolic and diastolic blood pressure percentiles were also negatively related to HRR ( $r=-0.266$ ,  $p=0.025$  and  $r=-0.275$ ,  $p=0.019$ ; respectively).

**CONCLUSIONS:** Preschoolers with slower HRR have faster PWV (increased arterial stiffness) and higher blood pressure. These findings suggest that young children with higher aerobic fitness levels have more favourable indices of vascular health. Future research is required to determine if vascular health can be improved by increased fitness in preschoolers.

Supported by the Canadian Institutes of Health Research (CIHR).

1967 Board #13 MAY 31 9:00 AM - 10:30 AM

### Reliability of 20 m Sprint Running Test on Adolescent Boys and Girls

Giorgos Paradisis, Panayiotis Pappas, Elias Zacharogiannis, Anastasia Smirniotou, Stavros Tziortzis. *Track and Field Sector, University of Athens, Athens, Greece.*

(No relationships reported)

Sprint running is a complex movement that requires complex motor coordination between upper and lower body segments. Since performance in most individual and team sports depends on the athlete's sprinting ability, the use of reliable and valid testing procedures is beneficial for monitoring the effects of training, especially on adolescent boys and girls.

**PURPOSE:** Hence, the aim of this study was to determine reliability of sprinting ability measured on a large sample of adolescent boys and girls.

**METHODS:** 47 students (age  $14.6 \pm 1.72$  years, height  $168.4 \pm 9.76$  cm, body mass  $62.6 \pm 12.37$  kg) performed three maximal 20 m sprint run tests with standing start interspersed by 48 hours, using a Brower electronic timing system. For each trial of sprinting test mean, standard deviation, and range were calculated. An analysis of variance with repeated measures and correction for sphericity was used for detection of possible systematic bias between trials. Average intertrial correlation coefficients (AVR), intraclass correlation coefficients (ICC) and Cronbach's alpha reliability coefficients ( $\alpha$ ) were used to determine between-subject reliability of tests. Within-subject variation for all tests was determined by calculating coefficient of variation (CV) as outlined by Hopkins (2000).

**RESULTS:** The data of the present study indicated that 20 m sprint running produced very good repeatability between the three days ( $P<0.05$ ). Mean  $\pm$  SD and range of time for 20 m were  $3.64 \pm 0.27$ ,  $3.63 \pm 0.27$ ,  $3.65 \pm 0.27$  m s<sup>-1</sup> and 1.21, 1.38, 1.21 m s<sup>-1</sup> for days 1, 2 and 3 respectively. The AVR was 0.87, the ICC was 0.95, the  $\alpha$  was 0.95 and CV was 1.8%.

**CONCLUSIONS:** It is concluded that sprinting ability is a reliable testing procedure and can be used for monitoring the effects of training, especially on adolescent boys and girls.

Hopkins W. (2000). *Sports Med.* 30(1), 1-15.

### 6 Min Endurance Run And 20m Shuttle Run - Which Field Test Is More Valid To Assess Aerobic Fitness In Children?

Birte von Haaren<sup>1</sup>, Sascha Haertel<sup>2</sup>, Ilka Seidel<sup>3</sup>, Lars Schlenker<sup>2</sup>, Klaus Boes<sup>2</sup>. <sup>1</sup>House of Competence, Karlsruhe, Germany. <sup>2</sup>Institute of Sport and Sports Science, Karlsruhe, Germany. <sup>3</sup>Institute of Applied Training Science, Leipzig, Germany.

(No relationships reported)

Field tests of fitness offer an alternative to expensive and sophisticated laboratory procedures for the assessment of aerobic fitness in children and adolescents. The use of different tests for the assessment complicates the comparison of aerobic fitness between countries. Therefore the validation and standardization has to be a scientific goal.

**PURPOSE:** This study aimed at comparing the validity of two commonly used field tests, the 20m shuttle run and the 6 min endurance run, using the gold standard for aerobic fitness,  $\text{VO}_2\text{max}$ , as criterion reference. A second goal was to identify gender-specific differences.

**METHODS:** 30 children (16 boys) between 9 and 11 years of age ( $10.1 \pm 0.7$ ) performed a 6 min endurance run and a 20m shuttle run.  $\text{VO}_2\text{max}$  was determined via gas analysis during a progressive treadmill test with an initial pace of 6 km/h, a continuous slope of 1 % and a two minutes length of each grade. For data analysis, the total distance (in meters) of the 6 min endurance run and the test duration (in seconds) of the 20m shuttle run were taken into account.

**RESULTS:** The mean overall  $\text{VO}_2\text{max}$ , relative to body weight (ml/min/kg) during the progressive treadmill test was  $49, 8 (\pm 6,4)$ , with boys ( $50,5 \pm 4,4$ ) achieving a slightly higher  $\text{VO}_2\text{max}$  than girls ( $49,2 \pm 8$ ). The boys achieved 67 more meters in the 6 min endurance run compared to the girls (boys:  $1123 \pm 76,8$ ; girls  $1056 \pm 131,4\text{m}$ ). In the 20m shuttle run, the boys kept the pace 47 seconds longer than the girls (boys:  $434 \pm 60,7$ ; girls:  $387 \pm 111,1$ ).

The results of the 6 min endurance run showed higher correlations with  $\text{VO}_2\text{max}$  ( $r=0.69$ ;  $p<.01$ ) compared to the results of the 20m shuttle run ( $r=0.52$ ;  $p<.01$ ). The gender-specific analyses showed significantly lower correlations of the 20m shuttle run and  $\text{VO}_2\text{max}$  for the boys ( $r=0.29$ ;  $p>.05$ ) compared to the girls ( $r=0.58$ ;  $p<.05$ ).

**CONCLUSION:** In this study, the 6 min endurance run proved to be more valid to assess aerobic fitness in 9 to 11-year-old children than the 20m shuttle run.

**1969** Board #15 MAY 31 9:00 AM - 10:30 AM

### Cardiovascular Fitness Improvements From High Intensity Training In Children

Brian K. Sanborn, Pratik Patel, Christian Larson, Bryan S. Heinrich, Nathaniel Fehl, Katie M. Heinrich. *Kansas State University, Manhattan, KS.* (Sponsor: Craig Harms, FACSM)

(No relationships reported)

High intensity exercise improves cardiovascular fitness in children; research has shown significant improvements in cardiovascular fitness for adults who spent <3 hours a week engaging in high intensity exercise. Data show many children do not meet the weekly physical activity recommendations of the ACSM. With high intensity training, cardiovascular fitness and body composition can be improved while spending significantly less time exercising.

**PURPOSE:** The purpose of this study was to determine the effects of a short-duration, high intensity exercise training program lasting four weeks on cardiovascular fitness when compared to active youth of similar age.

**METHODS:** This study used a pre-test posttest quasi-experimental two-group design. Nine children (8 males, 1 female, mean age 10.6y) were in the intervention group (IG) and 6 (6 males, mean age=11.3y) were in the Comparison Group (CG). The IG participated in high intensity exercise and skill training sessions (45 min, 2d/wk for 4wk). In brief, sessions consisted of 5min warm-up, 10min skill/technique work, 10-15min workout, short water break, and 10-15min playing an active game. Both groups completed the Fitnessgram pacer cardiovascular fitness assessment developed by the Cooper Institute. Heart rate was recorded immediately following the Pacer along with heart rate recovery one minute and two minutes following. Difference scores were computed and t-tests were conducted for statistical significance between groups.

**RESULTS:** The number of 20m laps completed during the Pacer decreased for both groups with a mean difference score of -5.44 (sd=5.79) for the IG and -3.67 (sd=8.94) for the CG; this difference was statistically significant,  $t=3.43$ ,  $p=.004$ . Heart rates remained similar and neither group showed significant improvement in their heart rate recovery measured after completion of the PACER test ( $p>.05$ ).

**CONCLUSION:** Both groups failed to show improvements in cardiovascular fitness (as measured by the Pacer test). Failure to improve cardiovascular fitness may be attributed to the overall duration of the intervention and total number of training sessions. Future research should examine if lengthening the intervention or having additional training sessions each week might result in significant improvements in cardiovascular fitness.

### Fitness Gains from a Summer Youth Conditioning Camp

Pratik M. Patel, Brian Sanborn, Christian Larson, Bryan S. Heinrich, Nathaniel Fehl, Katie M. Heinrich. *Kansas State University, Manhattan, KS.* (Sponsor: Craig Harms, FACSM)

(No relationships reported)

High intensity (HI), low volume exercise may improve fitness better than low intensity, high volume training. Children struggling to achieve the recommended 60 minutes of daily exercise could benefit from exercising more intensely for less time.

**PURPOSE:** This study examined the effects of short-duration, HI exercise training on fitness and body composition for youth.

**METHODS:** Two groups of children participated in this quasi-experimental study: 9 in the Intervention Group (IG; mean =10.6 yrs, 8 M, 1 F), and 6 in the Comparison Group (CG; mean =11.3 yrs, 6 M). The IG participated in HI exercise (45 min, 2d/wk, 4wks). Both groups completed pretest and posttest fitness assessments, as well as a Dual-Energy X-ray Absorptiometry scan 4 weeks apart. Difference scores were computed for each fitness test and t-tests were conducted for statistical significance between groups.

**RESULTS:** Significant differences were found between groups for fitness and body composition (all  $p<.05$ ). A higher percentage of IG participants improved over the CG on the Margaria-Kalamen step test (33% vs. 16.7%), while the CG had faster times on a 40m dash (100% vs. 44.4%), agility (50% vs. 44.4%), and the Fitnessgram Pacer test (33.3% vs. 11.1%). Significant differences were found for changes in body composition. More participants in the IG grew taller (77.8% vs. 50.0%), while participants in the CG improved over the IG for total body mass decrease (44.4% vs. 16.7%), fat mass decrease (66.7% vs. 11.1%), lean body mass increase (83.3% vs. 33.3%), and body fat percentage decrease (83.3% vs. 11.1%).

**CONCLUSION:** Four weeks of HI exercise yielded greater increases in power and height. Both groups had participants that showed improvement in each area but the CG showed greater improvement in more areas of fitness (speed, agility, cardiorespiratory endurance) and body composition when compared to the IG. Potential

explanations include the short duration and frequency of the exercise intervention, measurement error and differences in reporting of fitness, body composition, and anthropometric measurement testing, psychological and motivational status of youth during testing sessions, and physical activity and fitness capabilities of youth between both groups.

### Influence Of Resistive Load On Oxygen Uptake During Repeated Sprints In Prepubertal Boys And Men.

Apostolos Theos, Gregory Bogdanis, Anastasios Philippou, Maria Maridaki. *National & Kapodistrian University of Athens, Greece, Athens, Greece.*

(No relationships reported)

Oxygen uptake ( $\text{VO}_2$ ) during repeated sprinting differs significantly between different resistive loads in adults. Furthermore in two consecutive Wingate tests children produce energy more aerobically in comparison to adults.

**PURPOSE:** To examine the influence of two different resistive loads on  $\text{VO}_2$  during repeated sprints and in men and boys.

**METHODS:** Nine men ( $21.7 \pm 0.8$  yrs) and twelve prepubertal boys ( $11.8 \pm 0.2$  yrs) performed a force-velocity test on a friction-loaded cycle ergometer to determine the load corresponding to the optimal pedal rate (Fopt). On two separate occasions, ten 6-s sprints interspersed with 24-s recovery intervals were performed, against a load equal to Fopt or 50%Fopt in random order. Power output was recorded at 200Hz and  $\text{VO}_2$  was continuously monitored. Comparisons between the two conditions of repeated sprints were made using two-way ANOVA with repeated measures. Results are presented as mean  $\pm$  standard error.

**RESULTS:**  $\text{VO}_2$  for all ten sprints in men was higher in the Fopt compared with the 50%Fopt condition ( $37.1 \pm 1.0$  vs.  $34.0 \pm 0.9$  ml/kg/min for the Fopt and 50%Fopt, respectively,  $p<0.01$ ), while  $\text{VO}_2$  in the two conditions was similar in boys ( $35.7 \pm 1.8$  vs.  $34.0 \pm 1.9$  ml/kg/min for the Fopt and 50%Fopt respectively,  $p=0.42$ ). Scaling of  $\text{VO}_2$  per unit of power output (i.e. per Watt; ml/W/min) revealed significant differences between men and boys ( $p<0.001$ ). In particular in both the Fopt and 50%Fopt condition post-hoc analysis indicated that boys had higher values of  $\text{VO}_2$  per Watt compared with men from the second to the sixth sprint (average  $\text{VO}_2$  per Watt for sprints 2-6 for boys vs. men; Fopt:  $3.5 \pm 0.3$  vs.  $4.2 \pm 0.2$  ml/W/min,  $p<0.01$ ; 50%Fopt:  $3.3 \pm 0.2$  vs.  $4.4 \pm 0.2$  ml/W/min,  $p<0.01$ ). From the seventh to the tenth sprint men and boys had similar  $\text{VO}_2$  per Watt.

**CONCLUSION:** The results of the present study suggest that boys may generate power mainly through aerobic pathways during the initial part of a repeated sprint protocol compared with men.

**Association Between Knee Alignment, Body Mass Index And Physical Fitness Among Students**

Andreia Souza, Gerson Ferrari, Joao Pedro Silva Junior, Leonardo Silva, Luis Carlos Oliveira, Victor Matsudo. *Center of Studies of the Physical Fitness Research Laboratory from São Caetano do Sul (CELAFISCS), São Caetano do Sul, Brazil.*  
(No relationships reported)

**PURPOSE:** To assess the association between malalignment of the knees (genu valgum) and variables of physical fitness among schoolchildren.

**METHODS:** Sample is part of the Ilhabela Mixed-Longitudinal Project on Growth, Development and Physical Fitness\*, which is held since 1978 in the state of São Paulo, Brazil. Data were selected from a database of 16,000 schoolchildren measured from 1978 to 2010. We analyzed data collected between the years 2000 to 2009. Sample comprised 1141 schoolchildren of both sexes aged 06 to 18 years, who reached the following criteria: age between 6 and 18 years, and a full assessment of physical fitness, including measurement of genu valgus in at least one of the semester assessments. Postural evaluation (valgus) was determined by the intermalleolar distance, in centimeters. Body Mass Index (BMI) was determined through the growth curves of the World Health Organization. Physical fitness variables (strength of upper and lower limbs and velocity), were taken according to CELAFISCS standardization Statistics: Analysis of prevalence ratio (PR) was performed by unadjusted and adjusted Poisson regression with confidence intervals of 95%. Results:

**CONCLUSION:** There was a positive association between malalignment of the knees and body mass index among schoolchildren. No association was observed among genu valgum and physical fitness.

**Effects of Summer School and Exercise on Physical Fitness and Weight Gain in Hispanic Adolescents**

Jessica S. Zamarripa<sup>1</sup>, Kyung-Shin Park<sup>1</sup>, Noemi Ramirez<sup>1</sup>, David Martinez<sup>2</sup>. <sup>1</sup>Texas A&M International University, Laredo, TX. <sup>2</sup>JB Alexander High School, Laredo, TX.  
(No relationships reported)

Youth overweight and obesity prevalence rates have increased in the last 30 years becoming a significant public health concern particularly among low-income communities and ethnic minorities. Evidence indicates that weight gain and physical fitness declines are a result of physical inactivity and increased food intake during summer break.

**PURPOSE:** The purpose of this study was to determine the effect of a 5 week summer school program, including 12 hours/week of physical activity, on physical fitness and weight gain prevention in Hispanic adolescents.

**METHODS:** 89 high school students participated in this study and 62 (29 males and 33 females) completed three tests, before and after summer school program, and after summer break. For each test, physical characteristics such as height, body weight, BMI, waist and hip circumference, and fitness levels including push-up, sit-up, sit and reach, and Queens' college step test were measured. Variables were analyzed using one way (time) repeated measures analysis of variance (ANOVA) with Tukey post hoc tests.

**RESULTS:** No significant changes were found in height, body weight, BMI, waist and hip circumference, and sit and reach (flexibility) through summer break. Indices of muscular strength such as push-up (P<.01), sit-up (P<.05) and cardiorespiratory fitness (P<.05) were significantly improved through summer school program, but returned to baseline at the end of summer break. Data collected before and after summer school program, and after summer break are as follows: push-up (20.6±1.2→28.9±1.2→24.6±0.8, Mean±SE), Sit-up (26.9±1.3→ 32.4±1.5→ 30.4±1.5) and estimated VO<sub>2max</sub> (46.1±1.2 ml·kg<sup>-1</sup>·min<sup>-1</sup>→49.1±1.2→47.3±1.3).

**CONCLUSIONS:** Data analysis corroborates the initial hypothesis that summer school effectively prevents summer weight gain among Hispanic adolescents. Muscular strength and cardiorespiratory fitness were significantly enhanced during the 5-week summer school program, yet declined through the rest of the summer break. Results indicate that a long summer break may increase summer weight gain among Hispanic youth due to the lack of structure and unrestricted food access, which they would otherwise receive during the school year, thus encouraging physical inactivity and binge eating.

1974 Board #20 MAY 31 9:00 AM - 10:30 AM

**Effects of Obesity and Fitness Levels on Academic performance in Hispanic Male and Female Adolescents**

Joseph Lee<sup>1</sup>, Briana Rodriguez<sup>2</sup>, Blas D. Salinas<sup>2</sup>, Arturo Limon<sup>3</sup>, Kyung-Shin Park<sup>3</sup>. <sup>1</sup>Harmony Science Academy, Laredo, TX. <sup>2</sup>United South High School, Laredo, TX. <sup>3</sup>Texas A&M International University, Laredo, TX.  
(No relationships reported)

Adolescents experience many changes in body structure and psycho-social functioning. Perceived obesity status and lower physical fitness are negatively associated with academic performance and the impact of these variables in academic performance may be different in males and females.

**PURPOSE:** The purpose of this study was to investigate whether levels of obesity and physical fitness have an influence on academic performance in Hispanic male and female adolescents.

**METHODS:** Body mass index (BMI), one-mile run and curl-up scores from 1,401 Hispanic adolescents in grades 9-11 were collected (746 males, 655 females). Students were classified into three groups for BMI score using CDC weight status cut point (normal, overweight, and obese) and three groups for aerobic fitness (one mile run) and muscular strength (curl-up) using FITNESSGRAM standards (ES: exceed standard, MS: meet standard, and US: under standard). Reading and Mathematics scores in Texas Assessment of Knowledge and Skills (TAKS) test were obtained from a South Texas school district. Variables were analyzed using two way (gender×group) analysis of variance (ANOVA) with Tukey post hoc test.

**RESULTS:** Obese male students showed lower scores in both Reading (31.6±1.7, Mean±SE vs. 36.6±0.6 and 36.9±1.1 for normal and overweight, P<0.05) and Math (29.1±1.7 vs. 34.5±0.7 and 34.6±1.2, P<0.05). However, there was no relation between the level of obesity and TAKS scores in female students. US males in curl-up (27.5±1.0) received significantly lower score in Math than NS and ES (32.7±0.9, 37.2±0.8, P<. 0.01) and US females in curl-up showed lower scores in both Reading (34.0±0.9 vs. 41.1±0.8 and 41.7±0.8, P<0.01) and Math (29.1±0.9 vs. 35.5±0.9 and 36.9±1.0, P<0.01). TAKS scores were not affected by levels of aerobic fitness (one-mile run).

**CONCLUSIONS:** Results indicate that academic achievement in Hispanic high school students is associated with level of muscular strength, but not affected by aerobic fitness. Gender difference is visible in the relation between obesity levels and academic achievement in Hispanic adolescents. Academic success in male students is more sensitively affected by level of obesity (body shape) than females.

1975 Board #21 MAY 31 9:00 AM - 10:30 AM

**Factors Relating to VO<sub>2</sub> Peak in Healthy-Weight Versus Obese Young Children**

Elizabeth A. Easley, Linnie Toney, Jody L. Clasey, FACSM. *University of Kentucky, Lexington, KY.*  
(No relationships reported)

Despite concerted efforts to prevent and combat childhood obesity, the high prevalence remains and continues to adversely impact both the present and future health and well-being of these children. Aerobic fitness determined by measures of peak oxygen consumption relative to body weight (VO<sub>2</sub> peak; ml/kg/min) have been demonstrated to be related to both cardiovascular and body composition measures in adults.

**PURPOSE:** To determine the relationships between VO<sub>2</sub> peak and resting measures of heart rate (HR), systolic blood pressure (SBP), diastolic blood pressure (DBP), mean arterial pressure (MAP), rate pressure product (RPP), and percent body fat (%Fat) in healthy-weight (HW) and obese (OB) children; and to examine whether group mean differences exist among these measures in HW versus OB children.

**METHODS:** HW (n=27; 9 girls and 18 boys) and OB (n=16; 6 girls and 10 boys) children ages 7-11 yr old completed a multistage maximal treadmill graded exercise test (GXT). Prior to the GXT, resting HR, SBP, MAP, and RPP were recorded and/or calculated. %Fat was measured using total body DXA scans. Simple regression was used to determine the strength of the relationships; and unpaired t-tests were used to determine the group mean differences between the HW and OB children.

**RESULTS:** In the HW children VO<sub>2</sub> peak (40.6 ± 8.2 ml/kg/min) was significantly (p<0.05) related to HR (86.0 ± 15.0 bpm; r = -0.50) and RPP (8677.7 ± 1742.1; r = -0.44); but not to SBP

(100.9 ± 7.5 mmHg;  $r = 0.03$ ), DBP (64.8 ± 11.1 mmHg;  $r = 0.05$ ), MAP (76.8 ± 8.6 mmHg;  $r = 0.05$ ) or %Fat (17.0 ± 6.0 %;  $r = -0.15$ ). In the OB children  $\text{VO}_2$  peak (27.2 ± 6.3 ml/kg/min) was significantly related to %Fat (42.5 ± 5.6;  $r = -0.52$ ); but not to HR (99.9 ± 13.9 bpm;  $r = -0.31$ ); SBP (109.3 ± 8.2 mmHg;  $r = -0.16$ ), DBP (74.1 ± 6.3 mmHg;  $r = -0.30$ ); MAP (85.8 ± 5.7 mmHg;  $r = -0.29$ ); or RPP (10926.1 ± 1795.0;  $r = -0.31$ ). With the exception of  $\text{VO}_2$  peak, the OB children had significantly greater resting HR, SBP, DBP, MAP, RPP and %Fat measurement compared to the HW children.

**CONCLUSION:** The relationships among  $\text{VO}_2$  peak, body composition, and resting cardiovascular measures and indexes may vary between young children of different levels of adiposity. Supported in part by the University of Kentucky PEP Laboratory Endowment Fund.

**1976** Board #22 MAY 31 9:00 AM - 10:30 AM

**Effects Of Summer Physical Education Program On BMI And Level Of Fitness In Hispanic Adolescents**

Noemi Ramirez<sup>1</sup>, Kyung-Shin Park<sup>1</sup>, Jessica Zamaripa<sup>1</sup>, David Martinez<sup>2</sup>. <sup>1</sup>Texas A&M International University, Laredo, TX. <sup>2</sup>JB Alexander High School, Laredo, TX.  
(No relationships reported)

The dramatic increase in the prevalence of overweight and obese children over the past several decades poses a significant public health concern, especially among low-income communities and ethnic minorities. Some evidence suggests that physical fitness declines during the summer months and that children gain most of their extra weight during this period due to physical inactivity and an increase in food intake.

**PURPOSE:** The purpose of this study is to investigate whether attending a 5-week summer physical education program for Hispanic high school students is beneficial for maintaining body weight and physical fitness through the summer break.

**METHODS:** Total of 132 students participated in measurements at the beginning and end of summer break such as height, body weight, BMI, muscular strength, and cardiorespiratory fitness. Only 62 students (treatment) attended a 5-week summer physical education program, which included 12 hours/week of physical activity. Variables were analyzed using two way (group×time) repeated measures analysis of variance (ANOVA) with Bonferroni's correction.

**RESULTS:** Non-summer school attendants gained body weight (63.6±1.9kg→65.6±1.9,  $P<.01$ , Mean±SE) and BMI (24.4±.7→24.97±.6,  $P<.05$ ) without significant change in height. Estimated cardiorespiratory fitness via step test also significantly decreased (43.4±1.0ml<sup>1</sup>kg<sup>-1</sup>min<sup>-1</sup> →41.7±0.9,  $P<.05$ ). Summer school attendants showed no significant changes in variables during summer break.

**CONCLUSIONS:** Results of study correspond with previous findings that adolescent weight gain during summer break may be due to physical inactivity and easy access to food. It is proposed that school districts incorporate a structured physical activity program throughout the summer break to prevent the prevalence of obesity.

**1977** Board #23 MAY 31 9:00 AM - 10:30 AM

**Metabolomic Signatures following 8 Weeks of Play-Based Activity vs. Controls in Overweight Adolescent Children**

Scott R. Collier, FACSM<sup>1</sup>, Chelsea D. Curry<sup>1</sup>, Marco Meucci<sup>2</sup>, Carol B. Cook<sup>1</sup>, Carlo Baldari<sup>2</sup>, Wei Jia<sup>3</sup>. <sup>1</sup>Appalachian State University, Boone, NC. <sup>2</sup>Università degli Studi di Roma "Foro Italico", Rome, Italy. <sup>3</sup>University of North Carolina at Greensboro, Greensboro, NC.  
(No relationships reported)

Play-based activities can be used to increase participation of overweight and obese children increasing the time spent on movement activities increases. Urinary metabolomic signatures of exercise can elucidate an elemental shift in the metabolome giving investigators the potential mechanistic explanations behind improvements in physiological systems. The purpose of our study was to elucidate the dose-response urinary metabolomic signature shift in overweight adolescents following 4 or 8 weeks of play-based activity vs. a typical summer break control group.

**METHODS:** Twenty-two recreationally active adolescent children participated in the study. Subjects were assigned to each activity group due to the 8 or 4 week camp their parents enrolled them into (8w or 4w, respectively). The control group (C) was randomly chosen from flyers distributed throughout the community. They were not enrolled in any activities and had no plans of changing typical activity levels throughout the summer. Subjects reported to the Vascular Biology and Autonomic Studies Laboratory on two separate visits, at the beginning and end of 4 or 8 weeks of their enrolled group to give urinary samples at which time a graded exercise test was given and descriptive characteristics were recorded. A supervised partial least squares-discriminant analysis (PLS-DA) models were used to analyze the difference between pre- and post-exercise samples.

**RESULTS:** A valid PLS-DA model was obtained between post-exercise subjects in 8w group and C group (3 components,  $R^2X=0.332$ ,  $R^2Y=0.976$ ,  $Q^2=0.091$ ).

**CONCLUSION:** These data indicate that 8 weeks of play-based activity yielded identifiable metabolomic changes with several identifiable elements.

**1978** Board #24 MAY 31 9:00 AM - 10:30 AM

**Reliability Of The Bruininks-Oseretsky Test Of Motor Proficiency In Children And Adolescents With Prader-Willi Syndrome**

Elizabeth White, Lindsay Schroeder, Pamela Wright, Daniela Rubin, Debra J. Rose, Lenny Wiersma. California State University, Fullerton, Fullerton, CA.  
(No relationships reported)

Individuals with Prader-Willi Syndrome (PWS) present with overall motor deficiency, but the specific areas have yet to be identified in youth. To determine specific areas of deficiency, a reliable instrument must be used.

**PURPOSE:** To determine if the Bruininks-Oseretsky Test of Motor Proficiency, Second Edition (BOT-2) is a reliable instrument for assessing motor proficiency in children and adolescents with PWS.

**METHODS:** 10 children with PWS (5 girls/5 boys, mean age 11.1±1.7 yrs) participated in this study. Participants completed the test on two separate morning visits, one week apart. The BOT-2 test evaluates seven items related to motor proficiency: Fine motor precision, fine motor integration, manual dexterity, bilateral coordination, balance, running speed and agility, upper limb coordination, and strength. The test provides subtest item scores and a total composite score (TCS).

**RESULTS:** The Pearson product correlation coefficients between visits ranged from  $r=.712$  to  $r=.965$ , with a total composite test score  $r=.989$  (all significant at  $p<0.021$ ).

**CONCLUSION:** The total composite test score and the majority of subtest item scores showed moderate-to- high test-retest correlation coefficients. In conclusion, based on these pilot data, the BOT appears to be a reliable test to assess motor proficiency in children and adolescents with PWS ages 8 to 15 years old. Supported by USAMRAA W81XWH-09-1-0682

**1979** Board #25 MAY 31 9:00 AM - 10:30 AM

**Accumulation of Physical Activity Training on the Cardiorespiratory and Cognitive Function in Obese Adolescents**

Saejong Park<sup>1</sup>, Dong Sik Chung<sup>1</sup>, Kwang Joon Kim<sup>1</sup>, Yong Seung Kim<sup>1</sup>, Won Il Park<sup>1</sup>, In Deok Kong<sup>2</sup>, Justin Jeon<sup>3</sup>, Jung Hoon Oh<sup>4</sup>, Kwang Hee Lee<sup>5</sup>. <sup>1</sup>Korea Institute of Sport Science, Seoul, Korea, Republic of. <sup>2</sup>Yonsei University Meical School, Wonju, Korea, Republic of. <sup>3</sup>Yonsei University, Seoul, Korea, Republic of. <sup>4</sup>Seoul Metropolitan Office of Education, Seoul, Korea, Republic of. <sup>5</sup>Dogok Middle School, Seoul, Korea, Republic of.  
(No relationships reported)

Adolescent obesity rate was almost doubled last 10 years in Korea. Regular physical activity (PA) improves cardiorespiratory and cognitive function in adolescents. However, it is still unknown the effects of accumulating short bouts of PA ( $\text{PA}_{\text{accum}}$ ) on cardiorespiratory and cognitive function in obese and overweight adolescents.

**PURPOSE:** To examine the effects of a  $\text{PA}_{\text{accum}}$  and a continuous PA ( $\text{PA}_{\text{cont}}$ ) training for 8 weeks on cardiorespiratory and cognitive function in obese adolescents.

**METHODS:** Obese and overweight male adolescents ( $n=32$ ; 12.8±0.8 yrs; body mass index, BMI = 27.3±3.1kg/m<sup>2</sup>) completed the training study. They were assigned to one of the three groups: a control (CON,  $n=8$ ) and two PA groups, the  $\text{PA}_{\text{accum}}$  (two 20-min sessions 4-hour apart;  $n=12$ ); and the  $\text{PA}_{\text{cont}}$  (a 40-min session;  $n=12$ ). The components of two PA programs composed of endurance (70% of peak oxygen uptake,  $\text{VO}_2$ peak) and strength exercise 5 days/week for 8 weeks were identical. All the participants performed maximal graded cycle ergometer test and cognitive function using standardized Korea multi-intelligence test including vocabulary, understanding, figure perception, numeracy, space perception and space inference before and after the training. Two-way ANOVAs with repeated measures were used ( $p<.05$ ).

**RESULTS:** Interactions were found in  $\dot{V}O_{2peak}$  ( $p=.025$ ), vocabulary ( $p=.002$ ), figure perception ( $p=.047$ ), space perception ( $p=.011$ ) and space inference ( $p=.003$ ). After the training,  $\dot{V}O_{2peak}$  was increased all three groups ( $PA_{con}$   $7.8\pm 4.6$  kg/ml/min;  $PA_{accum}$   $9.7\pm 6.3$  kg/ml/min;  $CON$   $2.8\pm 3.1$  kg/ml/min). BMI was not changed after the training. In cognition, after the training vocabulary ( $3.3\pm 4.2$ ), space perception ( $6.5\pm 9.2$ ) and space inference ( $6.5\pm 6.5$ ) was increased in  $PA_{accum}$ , only space perception ( $7.6\pm 7.3$ ) was increased in  $PA_{con}$  while none was changed in the control.
