# Solid-state and solution-phase conformations of pseudoproline-containing dipeptides 

#### Abstract

The conformations of 14 threonine-derived pseudoproline-containing dipeptides (including four d -allo-Thr derivatives) have been investigated by NMR. In solution, the major conformer observed for all dipeptides is that in which the amide bond between the pseudoproline and the preceding amino acid is cis. For dipeptides in which the N -terminus is protected, the ratio of cis- to trans-conformers does not depend significantly on the side chain of the N -terminal amino acid, or the stereochemistry of the Thr residue. However, for dipeptides bearing a free N-terminus, there are significant differences in the ratios of cis- to trans-conformers depending on the side chain present. Three dipeptides were crystallized and their X-ray structures determined. In two cases, (benzyloxycarbonyl (Cbz)-Val-Thr( $\Psi$ Me,Mepro)-OMe and Cbz-Val$\operatorname{Thr}(\Psi \mathrm{Me}, \mathrm{Mepro})-\mathrm{OH})$, the dipeptides adopt a trans-conformation in the solid state, in contrast to the structures observed in solution. In the third case, ( 9 -fluorenylmethoxycarbonyl (Fmoc)-Val-d-allo$\operatorname{Thr}(\Psi \mathrm{Me}, \mathrm{Mepro})-\mathrm{OH})$, a cis-amide geometry is observed. These structural differences are attributed to crystal-packing interactions.

#### Abstract

The conformations of 14 threonine-derived pseudoproline-containing dipeptides (including four D-allo-Thr derivatives) have been investigated by NMR. In solution, the major conformer observed for all dipeptides is that in which the amide bond between the pseudoproline and the preceding amino acid is cis. For dipeptides in which the $N$-terminus is protected, the ratio of cis- to trans-conformers does not depend significantly on the side chain of the $N$-terminal amino acid, or the stereochemistry of the Thr residue. However, for dipeptides bearing a free $N$-terminus, there are significant differences in the ratios of cis- to trans-conformers depending on the side chain present. Three dipeptides were crystallized and their X-ray structures determined. In two cases, (benzyloxycarbonyl ( Cbz )-Val- $\operatorname{Thr}\left(\Psi^{\mathrm{Me}, \mathrm{Me}}\right.$ pro)-OMe and Cbz-Val-Thr( $\Psi^{\mathrm{Me}, \mathrm{Me}}$ pro)OH ), the dipeptides adopt a trans-conformation in the solid state, in contrast to the structures observed in solution. In the third case, ( 9 -fluorenylmethoxycarbonyl (Fmoc)-Val-D-allo-Thr( $\Psi^{\mathrm{Me}, \mathrm{Me}} \mathrm{pro}$ )-OH), a cis-amide geometry is observed. These structural differences are attributed to crystal-packing interactions.

## Introduction

Pseudoprolines ( $\Psi^{\mathrm{R}, \mathrm{R}^{\prime}}$ pro) are oxazolidine or thiazolidine derivatives of serine, threonine, and cysteine residues that form on cyclocondensation of the amino acid with an aldehyde or ketone (Fig. 1). Their five-membered ring structure is reminiscent of a proline residue. These modified amino acid residues were introduced by Mutter and coworkers as temporary protecting groups for peptide synthesis and were found to exert a pronounced effect on the peptide backbone conformation. ${ }^{[1,2]}$ The oxazolidine derivatives are now extensively used as tools to impart better solubility to a growing peptide chain in solid-phase

Fig. 1. Synthesis of an $\operatorname{Xaa}-\operatorname{Thr}\left(\Psi^{\mathrm{Me}, \mathrm{Me}}\right.$ pro $)$ dipeptide and the two conformers accessible by rotation about the Xaa-Thr amide bond.
synthesis because they prevent aggregation of growing peptide chains ${ }^{[3,4]}$ and have been found to significantly increase the yields of difficult peptide sequences ${ }^{[5-9]}$ by improving solvation and peptide coupling kinetics. This is attributed to a conformational preference for cis-amide bond formation. The ability of $\Psi^{\mathrm{R}, \mathrm{R}^{\prime}}$ pro residues to induce cis-amide bonds is well established by experimental ${ }^{[4,10,11]}$ and theoretical ${ }^{[12]}$ studies. In particular, disubstitution at the $2-\mathrm{C}$ position (e.g. $\Psi^{\mathrm{Me}, \mathrm{Me}}$ pro) strongly favours the cis-conformer and can be used to tailor peptide backbone conformation for specific applications. We have recently exploited this conformational ability to improve the head-to-tail cyclization yields of short peptide sequences by incorporation of $\Psi^{\mathrm{Me}, \mathrm{Me}}$ pro residues in the linear precursors. ${ }^{[13,14]}$ We have found that, in some cases, cyclization yields vary substantially depending on the side chain of the amino acids preceding the $\Psi^{\mathrm{Me}, \mathrm{Me}}$ pro residues, suggesting that these may influence the cis-trans isomerization of the amide bond. ${ }^{[15]}$ This prompted us to investigate the ratios of cis- and trans-conformers of several model dipeptides with and without $N$ - and $C$-termini protecting groups present, to examine the influence of both side chain and protecting groups on the pseudoproline conformation. Previous studies on the conformations of similar dipeptides have focussed on examining the effects of changing the nature of the $\Psi^{R, R^{\prime}}$ pro derivative (whether it is derived from Ser, Thr, and Cys and changing the $2-\mathrm{C}$ substituents R and $\left.\mathrm{R}^{\prime}\right),{ }^{[10]}$ but the influence of protecting groups and side chain bulk has not been investigated and is of significance in applying the results obtained from model studies to the conformations of longer peptides. We report here the results of an investigation of the solution-phase cis:trans ratios of several Xaa- $\operatorname{Thr}\left(\Psi^{\mathrm{Me}, \mathrm{Me}}\right.$ pro) derivatives, varying both the Xaa substituents and the protecting groups (or lack thereof) at both $N$ - and $C$-termini and including several novel

D-allo- $\operatorname{Thr}\left(\Psi^{\mathrm{Me}, \mathrm{Me}}\right.$ pro $)$ derivatives, and their comparison with solid-state structures for three of the compounds as determined by X-ray crystallography.

## Results and Discussion

In order to investigate the cis-trans isomerization of the peptide bond in differently protected $\Psi^{\mathrm{Me}, \mathrm{Me}}$ pro-containing dipeptides, we prepared several derivatives $\mathbf{1} \mathbf{- 1 4}$ (Fig. 2) with either full protection (both $N$ - and $C$-termini), $N$-terminus protection or

Fig. 2. Structures of the $\operatorname{Xaa}-\operatorname{Thr}\left(\Psi^{\mathrm{Me}, \mathrm{Me}}\right.$ pro $)$ dipeptides.

Fig. 3. Portion of the $300 \mathrm{MHz}{ }^{1} \mathrm{H}$ NMR spectrum of 4 illustrating the peaks observed for the carbamate NH of the cis- and trans-conformers (cis:trans $=85: 15$ ).
uncapped $N$ - and $C$-termini. We positioned Val, Phe, and Gly in the Xaa position to examine the effect the Xaa side chain had on the cis:trans ratio of the $\mathrm{Xaa}-\mathrm{Thr}\left(\Psi^{\mathrm{Me}, \mathrm{Me}}\right.$ pro) amide bond. We included four D-allo-threonine derivatives (5, 6, 9, and 12) because, while the influence of inverting the relative stereochemistry at the $\alpha$-position of the residue preceding a $\operatorname{Thr}\left(\Psi^{\mathrm{Me}, \mathrm{Me}}\right.$ pro $)$ has been reported, ${ }^{[4]}$ the effect of changing the relative stereochemistry between the $\alpha$ - and $\beta$-positions on $\operatorname{Thr}\left(\Psi^{\mathrm{Me}, \mathrm{Me}}\right.$ pro) formation and conformation has not been previously investigated.

Our standard conditions for the synthesis of Xaa$\operatorname{Thr}\left(\Psi^{\mathrm{Me}, \mathrm{Me}}\right.$ pro $)$ derivatives involve treatment of the Thrcontaining dipeptides with 2 -methoxypropene at $0^{\circ} \mathrm{C}$ in the presence of an acid catalyst. ${ }^{[13,14]}$ Compounds $\mathbf{1 - 4}$ were readily synthesized from the corresponding fully protected dipeptides according to this general method. In the case of the D-allo-Thr derivatives 5 and $\mathbf{6}$, this method gave only low yields of the corresponding pseudoprolines, but these were substantially improved using more forcing conditions (2,2-dimethoxypropane, pyridinium $p$-toluenesulfonate (PPTS), toluene, $80^{\circ} \mathrm{C}$ ). Hydrolysis of the methyl esters of $\mathbf{1 , 2}$, and $\mathbf{5}$, and hydrogenolysis of the benzyl ester of $\mathbf{6}$ were performed under standard conditions ${ }^{[13,14]}$ to yield the carboxylic acids 7-9 and 12, respectively. Hydrogenolysis of the benzyloxycarbonyl (Cbz)-groups of 7 and $\mathbf{8}$ was performed under standard conditions ${ }^{[13]}$ to give 13 and 14 , respectively, Compounds $\mathbf{1 0}$ and $\mathbf{1 1}$ were prepared according to the method of Mutter et al. ${ }^{3]}$

We determined the cis:trans ratios of the amide bonds in dipeptides 1-14 using NMR spectroscopic techniques. In the fully protected dipeptides $\mathbf{1 - 4}$, a major and minor set of resonances were clearly observed in both the ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ NMR spectra, indicating the presence of two conformers in slow exchange (Fig. 3). In all cases, the major conformer was determined to be that with a cis-amide bond by the presence of typical nuclear Overhauser effect (NOE) cross peaks observed by 2D NMR rotating frame Overhauser effect spectroscopy (ROESY) and nuclear Overhauser effect correlation spectroscopy (NOESY) experiments (i.e. $\alpha \mathrm{H}_{\mathrm{i}-1}-\alpha \mathrm{H}_{\mathrm{i}}$ and $\alpha \mathrm{H}_{\mathrm{i}-1}-\beta \mathrm{H}_{\mathrm{i}}$ crosspeaks) that reflect the spatial proximity of the $\alpha \mathrm{H}_{\mathrm{i}-1}$ and $\alpha \mathrm{H}_{\mathrm{i}}$ protons in the cis-form. ${ }^{[16]}$ The cis:trans ratios are given in Table 1. NMR spectra of a representative dipeptide $\mathbf{1}$ were obtained in a variety of

Table 1. Ratios of cis:trans conformers as determined by ${ }^{1} \mathrm{H}$ NMR

solvents $\left(\mathrm{CD}_{3} \mathrm{CN}, \mathrm{CDCl}_{3},\left[\mathrm{D}_{8}\right]\right.$ toluene, $\left.\left[\mathrm{D}_{6}\right] \mathrm{DMSO}, \mathrm{CD}_{3} \mathrm{OD}\right)$ and at varying temperatures ( $300-370 \mathrm{~K}$ in $\left[\mathrm{D}_{8}\right]$ toluene $)$ but the ratio of cis:trans conformers did not change significantly under these conditions. Substitution of the $N$-terminal Val with Phe (2) did not affect the ratio of cis:trans conformers, but a slightly lower proportion of cis-amide conformer (75:25) was observed for the Gly-containing dipeptide 3. This is consistent with the proposal that steric interactions between the methyl groups of the $\Psi^{\mathrm{Me}, \mathrm{Me}} \mathrm{Pro}$ and the side chain (or peptide backbone in the case of Gly) of the preceding amino acid are predominantly responsible for the favoured cis-conformation of these peptides. ${ }^{[3]}$ Dipeptide 4, with alternative $N$ - and $C$-terminal protecting groups (9-fluorenylmethoxycarbonyl (Fmoc)- and trichloroethyl ester, respectively) had an identical cis:trans ratio to the Cbz-, methyl ester protected analogue 2.

For the D-allo-Thr derivatives 5 and $\mathbf{6}$, a major set of resonances was observed in the ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ NMR spectra, with a second set of resonances from a second conformer present but difficult to distinguish owing to their low intensity and signal overlap. The observed major conformers were identified as those having a cis-amide bond by the presence of $\alpha \mathrm{H}_{\mathrm{i}-1}-\alpha \mathrm{H}_{\mathrm{i}}$ NOE crosspeaks observed by 2D NMR ROESY and NOESY experiments (Fig. 4). Despite the differences in stereochemistry with the previously discussed systems, an analysis of CPK models indicates that in $\mathbf{5}$ and $\mathbf{6}$, the $\alpha \mathrm{H}_{\mathrm{i}-1}$ and $\alpha \mathrm{H}_{\mathrm{i}}$ protons in the cis-conformer are in close proximity, whereas those in the transconformer are much further away from each other, so an NOE interaction is likely to be observed only for the conformer with a cis-amide bond. This proximity in the cis-conformer is evident in the X-ray structure of the carboxylic acid derivative 12 (see below).

Removal of the $C$-terminal protecting groups resulted in some changes in the cis:trans ratios. For the Cbz-protected dipeptides 7-9, a slightly lower amount of the cis-conformer was observed than for the analogous methyl esters. More notably, for

Fig. 4. 400 MHz nuclear Overhauser effect (NOE) correlation spectrum of 6 indicating the NOE interaction between the Val $\alpha-\mathrm{H}(3.83 \mathrm{ppm})$ and the D -allo- $\mathrm{Thr}\left(\Psi^{\mathrm{Me}, \mathrm{Me}} \mathrm{pro}\right) \alpha-\mathrm{H}(4.95 \mathrm{ppm})$. Small baseline peaks are attributable to the trans-conformer.
the dipeptides bearing Fmoc protecting groups, ester hydrolysis resulted in significant increases in the amount of cis-conformer present, with only a single (cis) conformer observed by ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ NMR for $\mathbf{1 0}, 11$ and the D-allo-Thr derivative $\mathbf{1 2}$.

In two cases, the effect of deprotection of the $N$-terminus on dipeptide conformation was also investigated. Fully deprotected dipeptides $\mathbf{1 3}$ and $\mathbf{1 4}$ had significantly different ratios of cis:trans conformers in comparison with the fully protected analogues 1 and 2. In contrast to the results observed for the fully protected analogues and $N$-protected peptides where the side chain of the Xaa amino acid had little effect on the ratio of amide bond conformers, for the fully deprotected dipeptides, the cis:trans ratio depends significantly on the side chain of the $N$-terminal amino acid, with the Val derivative $\mathbf{1 3}$ having a significantly lower proportion of the cis-conformer than the Phe derivative 14. This difference cannot easily be explained by steric interactions, although the increased proportion of cis-conformer in 14, which has an aromatic side chain, reflects a similar propensity for Xaa-Pro dipeptides that has been attributed to stabilization of the cis-confomer as a result of $\mathrm{CH}-\pi$ interactions between the aromatic side chain and the protons at the $\alpha$-position of the proline ring. ${ }^{[17]}$ A similar interaction between the protons of the $\operatorname{Thr}\left(\Psi^{\mathrm{Me}, \mathrm{Me}}\right.$ pro) methyl groups and the aromatic side chain of the Phe residue would provide a similar stabilization and may explain the observed differences between 13 and $\mathbf{1 4}$, although we did not observe any evidence for such an interaction.

In all $14 \mathrm{Xaa}-\mathrm{Thr}\left(\Psi^{\mathrm{Me}, \mathrm{Me}}\right.$ pro) dipeptides that we examined by NMR spectroscopy, the cis-conformer was predominant, with cis:trans ratios varying from $65: 35$ to $>95:<5$. For dipeptides bearing $N$-protecting groups, this ratio did not significantly depend on the side chain of the Xaa residue or the stereochemistry of the Thr residue. However, it was affected by the presence of protecting groups at the $N$ - and $C$-termini, suggesting that studies of longer peptides are required to provide a better understanding of the influence of the side chain on the conformation of $\operatorname{Thr}\left(\Psi^{\mathrm{Me}, \mathrm{Me}}\right.$ pro) peptides.

## Solid-State Studies

Although several solution-phase studies of ( $\Psi^{\mathrm{R}, \mathrm{R}^{\prime}}$ pro)containing peptides have been performed, little is known about the conformations of these peptides in the solid state. To the best of our knowledge, only one X-ray structure of a ( $\Psi^{\mathrm{Me}, \mathrm{Me}}$ pro)containing dipeptide has been reported previously, indicating that Fmoc-Ala-Cys( $\Psi^{\mathrm{Me}, \mathrm{Me}}$ pro)-OH retains the cis-amide conformation in the solid state, although the amide bond is slightly twisted $\left(\omega_{i}=-9.7^{\circ}\right) .{ }^{[18]}$ To obtain further information about the conformations of our $\operatorname{Xaa}-\operatorname{Thr}\left(\Psi^{\mathrm{Me}, \mathrm{Me}}\right.$ pro) dipeptides, we investigated the solid-state structures of three compounds.

Colourless prismatic crystals of $\mathbf{1}$ suitable for X-ray crystallography were grown by slow diffusion of diethyl ether into a methanolic solution (see Accessory Publication for ORTEP plot). The X-ray analysis indicates that in the solid state, the amide bond preceding the $\operatorname{Thr}\left(\Psi^{\mathrm{Me}, \mathrm{Me}}\right.$ pro $)$ adopts a trans-conformation (Fig. 5). This is in contrast to the NMR experiments, which indicate that in the solution-phase, the cis-conformer predominates (cis:trans $85: 15$ ) independently of solvent or temperature. In the solid state, the amide bond ( $\mathrm{N}(1)-$ $\mathrm{C}(9)$ ) is $1.3517(13) \AA$ in length, which is similar to the length of the bond between the Val nitrogen atom and the Cbz protecting group $(\mathrm{N}(2)-\mathrm{C}(14)=1.3474(14) \AA)$. The amide bond is slightly twisted ( $\left.\omega_{i}=171.36(11)^{\circ}\right)$, indicating the steric hindrance that
would result between the $\operatorname{Thr}\left(\Psi^{\mathrm{Me}, \mathrm{Me}}\right.$ pro $)$ methyl substituents and the Val side chain if it were planar.

An analysis of the crystal packing shows a strong carbamate ( $\mathrm{N}(2)$ ) to $\operatorname{Thr}\left(\Psi^{\mathrm{Me}, \mathrm{Me}}\right.$ pro) oxygen ( $\mathrm{O}(1)$ ) hydrogen bond (see Table 2) as the most significant motif present within the lattice. This interaction results in the formation of infinite one-dimensional polymeric chains of molecules that propagate down the crystallographic $b$-axis. A section of one of these chains is shown in Fig. 5. Given the energy difference between the cis- and trans-conformers of $\Psi^{\mathrm{Me}, \mathrm{Me}}$ pro dipeptides is $\sim 62-75 \mathrm{~kJ} \mathrm{~mol}^{-1},{ }^{[10]}$ the stabilization introduced in the solid state by this hydrogenbonding interaction may explain the differences observed between the solution-phase and solid-state conformations of this dipeptide.

Fig. 5. A schematic representation of the one-dimensional polymeric chain formed in $\mathbf{1}$. Dashed lines indicate hydrogen-bonding interactions.

Colourless plate-like crystals of 7, the free-acid analogue of $\mathbf{1}$, were isolated by slow diffusion of diethyl ether into a methanol solution and subjected to a crystallographic study (see Accessory Publication for ORTEP plot). The X-ray analysis revealed that 7 adopts a conformation $\left(\omega_{i}=174.27(17)^{\circ}\right)$ in the solid state that is almost identical to that of $\mathbf{1}$ (Fig. 6), again in contrast to the solution-phase conformation of this molecule. In fact, both $\mathbf{1}$ and 7 crystallize in the same chiral space group (orthorhombic $P 2_{1} 2_{1} 2_{1}$ ) with similar unit cells. In both structures, the $a$ and $b$ axis lengths are comparable, while the $c$ axis lengths differ by only $2.1 \AA$. Given their chemical similarity, their structural similarity is not surprising, but suggests the possibility of use of species such as these in crystal engineering studies. Such a possibility is further demonstrated by the analysis of the crystal packing.

Fig. 6. A schematic representation of the one-dimensional polymeric chain formed in 7 through carbamate-oxygen hydrogen bonds. Dashed lines indicate hydrogen-bonding interactions.

[^0]Much like 1, molecules of 7 pack along the crystallographic $b$-axis to form a one-dimensional polymeric chain through carbamate $(\mathrm{N}(2))$ to pseudoproline oxygen $(\mathrm{O}(1))$ hydrogen-bonding interactions (see Table 2). A portion of this chain is shown in Fig. 6.

The presence of the free carboxylic acid group in 7 (compared with 1) adds an additional site for hydrogen bonding. Although this site does bind to the corresponding carboxylic site in adjacent molecules, unexpectedly, it does not bind in the classic carboxylic acid dimer and instead forms a polymeric chain (see Fig. 7), which propagates along the crystallographic $a$-axis at $\sim 90^{\circ}$ to the amide-oxygen hydrogen-bonding chain. Overall, these two sets of hydrogen-bonding interactions combine to form infinite two-dimensional sheet-like arrays that stack parallel to the crystallographic $a b$-plane.

The D-allo-Thr derivative $\mathbf{1 2}$ also crystallizes in the orthorhombic $P 2_{1} 2_{1} 2_{1}$ space group. Colourless plate-like crystals were grown by the slow evaporation of a chloroform solution and there are two chloroform solvent molecules present in the lattice for each peptide molecule. In contrast to the previous two structures, in this case the amide bond has the expected cis geometry $\left(\omega_{i}=-1.7(5)^{\circ}\right)$. The structure is given in Fig. 8 and illustrates the short distance between the two $\alpha$-protons $(\mathrm{H}(2)$ and $H(9)$ ) observed in the NOESY spectrum of this molecule.

Once again, the dominant crystal-packing effects are hydrogen-bonding interactions. However, in contrast to 1 and 7, these do not involve the $\operatorname{Thr}\left(\Psi^{\mathrm{Me}, \mathrm{Me}}\right.$ pro) oxygen. Interestingly, again despite the presence of a carboxylic acid, the dimeric carboxylic acid motif is not present. Instead the carboxylic acid binds to the carbamate $(\mathrm{N}(2))$ nitrogen and amide $(\mathrm{O}(4))$ oxygen of the Val residue (Table 2), forming an infinite one-dimensional polymer (Fig. 9) along the $a$-axis. There is also a weak methyl$\pi$ interaction within the lattice. There are several non-classical hydrogen-bonding interactions present in the lattice, with the
chloroform solvent molecules acting as H -bond donors and oxygen atoms as acceptors (Fig. 10). In particular, the presence of an H -bond between chloroform and the $\operatorname{Thr}\left(\Psi^{\mathrm{Me}, \mathrm{Me}}\right.$ pro) oxygen $(\mathrm{O}(3))$ is notable, as this prevents the formation of the carbamate to $\operatorname{Thr}\left(\Psi^{\mathrm{Me}, \mathrm{Me}}\right.$ pro) oxygen H -bonds that are the predominant crystal packing interactions in $\mathbf{1}$ and $\mathbf{7}$. This may explain the conformational differences observed for $\mathbf{1 2}$ (cis-amide) in comparison with $\mathbf{1}$ and $\mathbf{7}$ (trans-amide) in the solid state. It is notable that no solvent is present in the crystal lattices of $\mathbf{1}$ and $\mathbf{7}$, despite their crystallization from methanol, a solvent that is more likely to form H -bonds than chloroform.

## Conclusions

In solution, the predominant conformer for $\mathrm{Xaa}-\mathrm{Thr}\left(\Psi^{\mathrm{Me}, \mathrm{Me}}\right.$ pro $)$ dipeptides is that in which the amide bond between the Xaa and $\operatorname{Thr}\left(\Psi^{\mathrm{Me}, \mathrm{Me}}\right.$ pro $)$ residues adopts a cis geometry. For dipeptides bearing both $N$ - and $C$-terminal protecting groups, the ratio of cis:trans conformers does not depend strongly on solvent, temperature or the size of the Xaa side chain. It is notable that the relative stereochemistry of the $\operatorname{Thr}\left(\Psi^{\mathrm{Me}, \mathrm{Me}}\right.$ pro) residue does not have a significant impact on the cis:trans amide bond ratio, with D -allo-Thr-containing peptides having similar (or enhanced) conformational preferences for the cis-isomer to the L-Thr derivatives in solution. It has previously been shown that the relative stereochemistry between the Xaa and ( $\Psi^{\mathrm{Me} e \mathrm{Me}}$ pro) $\alpha$-carbons does not have a significant influence on the amide bond conformation. ${ }^{[4]}$ Minor differences in the cis:trans ratios are observed for N -protected dipeptides with a free carboxylic acid, depending on whether the $N$-protecting group is Cbz or Fmoc, with Fmoc-protected dipeptides having a higher proportion ( $>95 \%$ ) of cis-conformer. However, for dipeptides with free $N$ - and $C$-termini, the cis:trans ratio is strongly influenced by the Xaa side chain, with $\mathbf{1 4}$, which has an aromatic side

Fig. 7. A schematic representation of the one-dimensional polymeric chain formed via carboxylic acid-carboxylic acid hydrogen bonds in 7. Dashed lines indicate hydrogen-bonding interactions.

Fig. 8. An ORTEP representation of $\mathbf{1 2}$ shown with $50 \%$ probability ellipsoids. Chloroform solvent molecules omitted for clarity.

Fig. 9. A schematic representation of the one-dimensional polymeric chain formed in 12. Dashed lines indicate hydrogen-bonding interactions. Val side chains and $\operatorname{Thr}\left(\Psi^{\mathrm{Me}, \mathrm{Me}}\right.$ pro $)$ methyl groups have been removed for clarity.
chain, having a significantly higher proportion of cis-conformer than 13, which bears an isopropyl side chain. This suggests that an analysis of the conformation of longer ( $\Psi^{\mathrm{Me}, \mathrm{Me}}$ pro)containing peptides must be performed on the fully deprotected

Fig. 10. A schematic representation of 12 illustrating the H -bonding interactions observed with $\mathrm{CHCl}_{3}$ solvent molecules.
systems to avoid any influence of the protecting groups on conformation.

In the solid state, $\mathbf{1}$ and $\mathbf{7}$ adopt a trans-amide bond conformation, although in both cases the amide bond is slightly twisted. This directly contrasts with their solution structures and can be attributed to crystal-packing effects, with X-ray structures of both $\mathbf{1}$ and $\mathbf{7}$ showing a predominant carbamate ( N ) to $\operatorname{Thr}\left(\Psi^{\mathrm{Me}, \mathrm{Me}}\right.$ pro) oxygen hydrogen-bonding interaction in the crystal lattice. The stabilization provided in the solid state by this hydrogen-bonding interaction and other crystal lattice effects is clearly greater than the $62-75 \mathrm{~kJ} \mathrm{~mol}^{-1}$ stabilization of the cis-conformer relative to the trans-conformer in solution. ${ }^{[10]}$ In contrast, $\mathbf{1 2}$ adopts a cis-amide bond in both solution and the solid state. In this case, the co-crystallized chloroform solvent molecules act as hydrogen bond donors to the D -allo$\operatorname{Thr}\left(\Psi^{\mathrm{Me}, \mathrm{Me}}\right.$ pro) oxygen hydrogen-bond acceptor, preventing the formation of the stabilizing carbamate-pseudoproline oxygen hydrogen bonds observed for 1 and 7. An investigation
of the solution and solid-state structures of longer $\Psi^{\mathrm{Me}, \mathrm{Me}}$ procontaining peptides and the relationship between peptide conformation and head-to-tail cyclization yields is ongoing in our laboratories

## Experimental

Synthesis
Preparative column chromatography was carried out using Ajax Finechem silica gel $\left(\mathrm{SiO}_{2}, 0.040-0.063 \mathrm{~mm}\right)$ with the indicated solvents. Melting points were determined using a Gallenkamp melting point apparatus and are reported in degrees Celsius (uncorrected). NMR spectra were recorded on a 200,300 , or 400 MHz spectrometer. The solvent ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ signals, $\delta_{\mathrm{H}} 7.26$ for residual $\mathrm{CHCl}_{3}$ and $\delta_{\mathrm{C}} 77.0$ for $\mathrm{CDCl}_{3} ; \delta_{\mathrm{H}} 3.31$ and $\delta_{\mathrm{C}} 49.0$ for $\left[\mathrm{D}_{4}\right] \mathrm{MeOH} ; \delta_{\mathrm{H}} 2.50$ and $\delta_{\mathrm{C}} 39.5$ for $\left[\mathrm{D}_{6}\right] \mathrm{DMSO} ; \delta_{\mathrm{H}} 1.94$ and $\delta_{\mathrm{C}} 1.3$ for $\mathrm{CD}_{3} \mathrm{CN}$ were used as internal references. Signal assignments are based on a combination of 1D (including ${ }^{1} \mathrm{H}$ selective homonuclear decoupling and ${ }^{13} \mathrm{C}$ Distortionless Enhancement by Polarisation Transfer (DEPT)) and 2D spectral data (including $\mathrm{H}, \mathrm{H}$-correlation spectroscopy, heteronuclear multiple bond correlation, heteronuclear single-quantum correlation, and gradient-NOESY (gr-NOESY)). Optical rotations were measured on a dual-wavelength polarimeter in a $0.25-\mathrm{dm}$ cell at $22^{\circ} \mathrm{C}$ using the indicated spectroscopic grade solvents. Elemental analyses were performed by Campbell Microanalytical Laboratories. Compounds $\mathbf{1 - 4}$, and 7-8 were synthesized from the appropriately protected dipeptides according to previously reported methods. ${ }^{[13-15]}$ Compounds $\mathbf{1 0}$ and $\mathbf{1 1}$ were prepared according to the method of Mutter and coworkers. ${ }^{[3]}$ Compounds 13 and 14 were prepared on removal of the Cbz protecting groups from 7 and $\mathbf{8}$, respectively, by hydrogenolysis under previously reported conditions ${ }^{[13]}$ and used without purification for ${ }^{1} \mathrm{H}$ NMR studies.

## Cbz-L-Val-D-allo-Thr ( $\Psi^{\text {Me,Me }}$ pro)-OMe 5

Dimethoxypropane $(1.00 \mathrm{~mL}, 8.14 \mathrm{mmol})$ and pyridinium- $p$ toluene sulfonate $(124 \mathrm{mg}, 0.540 \mathrm{mmol})$ were added to a solution of Cbz-L-Val-D-allo-Thr-OMe $(0.533 \mathrm{mg}, 1.46 \mathrm{mmol})$ dissolved in toluene $(25 \mathrm{~mL})$ and the mixture stirred at $80^{\circ} \mathrm{C}$ for 16 h . The solution was cooled to ambient temperature and dichloromethane $(100 \mathrm{~mL})$ was added. The solution was then washed with saturated aqueous $\mathrm{NaHCO}_{3}(100 \mathrm{~mL})$ and the aqueous layer re-extracted with dichloromethane $(2 \times 30 \mathrm{~mL})$. The combined organic layers were then washed with brine $(2 \times 100 \mathrm{~mL})$, dried $\left(\mathrm{Na}_{2} \mathrm{SO}_{4}\right)$, and the solvent removed under reduced pressure. The crude product was purified by flash chromatography ( $4: 1 \mathrm{v} / \mathrm{v}$ dichloromethane $/ \mathrm{EtOAc}$ ). Concentration of the appropriate fractions $\left(R_{\mathrm{F}} 0.74\right)$ yielded title peptide 5 ( $474 \mathrm{mg}, 80 \%$ ) as a yellow oil. $[\alpha]_{\mathrm{D}}+8.40^{\circ}\left(c 1.0\right.$ in $\left.\mathrm{CHCl}_{3}\right)$. $\delta_{\mathrm{H}}\left(200 \mathrm{MHz}, \mathrm{CDCl}_{3}\right) 7.33(5 \mathrm{H}, \mathrm{m}, \mathrm{ArH}), 5.09(1 \mathrm{H}, \mathrm{d}, J 9.1$, $\operatorname{Val}(\mathrm{NH})), 5.01\left(2 \mathrm{H}, \mathrm{s}, \mathrm{Cbz}\left(\mathrm{CH}_{2}\right)\right), 4.98(1 \mathrm{H}, \mathrm{d}, J 6.1, \operatorname{Thr} \Psi(\alpha-$ $\mathrm{CH})$ ), $4.40(1 \mathrm{H}, \mathrm{m}, \operatorname{Thr} \Psi(\beta-\mathrm{CH})), 3.85(1 \mathrm{H}, \mathrm{m}, \operatorname{Val}(\alpha-\mathrm{CH})), 3.78$ $(3 \mathrm{H}, \mathrm{s}, \mathrm{Me}), 1.91-1.74(1 \mathrm{H}, \mathrm{m}, \operatorname{Val}(\beta-\mathrm{CH}))$, $1.68(3 \mathrm{H}, \mathrm{s}, \mathrm{Me})$, $1.57(3 \mathrm{H}, \mathrm{s}, \mathrm{Me}), 1.28\left(3 \mathrm{H}, \mathrm{d}, J 6.3, \operatorname{Thr}\left(\gamma-\mathrm{CH}_{3}\right)\right), 0.93(3 \mathrm{H}, \mathrm{d}, J$ 6.7, $\left.\operatorname{Val}\left(\gamma-\mathrm{CH}_{3}\right)\right), 0.85\left(3 \mathrm{H}, \mathrm{d}, J 6.7, \operatorname{Val}\left(\gamma-\mathrm{CH}_{3}\right)\right) . \delta_{\mathrm{C}}(75 \mathrm{MHz}$, $\mathrm{CDCl}_{3}$ ) 170.2, 169.9, 156.6, 136.4, 128.5, 128.2, 127.9, 96.4, $72.5,70.0,63.6,57.0,52.0,27.9,24.9,23.6,19.7,18.0,15.2$. $m / z$ (electrospray ionization (ESI)) $429[\mathrm{M}+\mathrm{Na}]^{+}(100 \%)$, 356 (40), 349 (30); m/z (high resolution mass spectroscopy (HRMS) ESI, $\mathrm{MNa}^{+}$) Calc. for $\mathrm{C}_{21} \mathrm{H}_{30} \mathrm{~N}_{2} \mathrm{O}_{6} \cdot \mathrm{Na} 429.1996$; found 429.1990.

## Cbz-L-Val-D-allo-Thr ( $\Psi^{\text {Me,Me }}$ pro)-OH 9

$\mathrm{NaOH}(400 \mathrm{mg}, 0.100 \mathrm{~mol})$ was dissolved in distilled water $(2 \mathrm{~mL})$ and added to a solution of $5(650 \mathrm{mg}, 1.60 \mathrm{mmol})$ in THF ( 3 mL ) and methanol ( 3 mL ). The reaction mixture was stirred for 24 h before the solution was partitioned between 1 M $\mathrm{HCl}(50 \mathrm{~mL})$ and dichloromethane $(50 \mathrm{~mL})$. The aqueous phase was extracted with dichloromethane $(2 \times 20 \mathrm{~mL})$ and the combined organic phases were washed with brine $(2 \times 100 \mathrm{~mL})$, then dried $\left(\mathrm{Na}_{2} \mathrm{SO}_{4}\right)$. Removal of the solvent under reduced pressure gave the title compound $9(0.390 \mathrm{~g}$, quantitative) as a yellow foam. $\delta_{\mathrm{H}}\left(200 \mathrm{MHz}, \mathrm{CDCl}_{3}\right) 7.33(5 \mathrm{H}, \mathrm{s}, \mathrm{ArH}), 5.47(1 \mathrm{H}, \mathrm{d}$, $J$ 9.3, $\operatorname{Val}(\mathrm{NH})), 5.10\left(2 \mathrm{H}, \mathrm{s}, \mathrm{Cbz}\left(\mathrm{CH}_{2}\right)\right), 5.02(1 \mathrm{H}, \mathrm{d}, J 6.1$, $\operatorname{Thr} \Psi(\alpha-\mathrm{CH})), 4.47-4.41(1 \mathrm{H}, \operatorname{Thr} \Psi(\beta-\mathrm{CH})), 3.94-3.65(1 \mathrm{H}, \mathrm{m}$, $\operatorname{Val}(\alpha-\mathrm{CH})), 2.0-1.96(1 \mathrm{H}, \mathrm{m}, \operatorname{Val}(\beta-\mathrm{CH})), 1.84(3 \mathrm{H}, \mathrm{s}, \mathrm{Me})$ $1.59(3 \mathrm{H}, \mathrm{s}, \mathrm{Me}), 1.37\left(3 \mathrm{H}, \mathrm{d}, J 6.1, \operatorname{Thr}\left(\gamma-\mathrm{CH}_{3}\right)\right), 0.93(3 \mathrm{H}, \mathrm{d}, J$ 6.7, $\left.\operatorname{Val}\left(\gamma-\mathrm{CH}_{3}\right)\right), 0.87\left(3 \mathrm{H}, \mathrm{d}, J 6.7, \operatorname{Val}\left(\gamma-\mathrm{CH}_{3}\right)\right) . \delta_{\mathrm{C}}(75 \mathrm{MHz}$, $\mathrm{CDCl}_{3}$ ) 173.1, 170.4, 156.9, 136.3, 128.6, 128.2, 127.8, 96.7, $72.6,67.1,63.6,59.6,29.5,24.9,23.6,19.6,18.2,15.3 . m / z(\mathrm{ESI})$ $415.1[\mathrm{M}+\mathrm{Na}]^{+}(100 \%), 393$ (10), 357 (5), 353 (10), 341 (5), 335 (15); $m / z$ (HRMS ESI, $\mathrm{MNa}^{+}$) Calc. for $\mathrm{C}_{20} \mathrm{H}_{28} \mathrm{~N}_{2} \mathrm{O}_{6} \cdot \mathrm{Na}$ 415.1857; found 415.1857.

## Fmoc-Val-D-allo-Thr( $\Psi^{\text {Me,Me }}$ pro)-OBn 6

Dimethoxypropane $(472 \mu \mathrm{~L}, 3.85 \mathrm{mmol})$ and pyridinium- $p$ toluene sulfonate $(60.0 \mathrm{mg}, 0.231 \mathrm{mmol})$ were added to a solution of Fmoc-Val-D-allo-Thr-OBn ( $408 \mathrm{mg}, 0.769 \mathrm{mmol}$ ) dissolved in toluene $(10 \mathrm{~mL})$ and the mixture was heated at reflux for 16 h . The solution was cooled to ambient temperature before diluting with EtOAc $(100 \mathrm{~mL})$. The solution was then washed with saturated aqueous $\mathrm{NaHCO}_{3}(100 \mathrm{~mL})$, then the aqueous layer was re-extracted with EtOAc $(2 \times 50 \mathrm{~mL})$. The combined organic layers were then washed with brine $(2 \times 100 \mathrm{~mL})$, dried $\left(\mathrm{Na}_{2} \mathrm{SO}_{4}\right)$, and the solvent removed under reduced pressure. The crude product was purified by flash chromatography $(2: 1 \mathrm{v} / \mathrm{v}$ hexane/EtOAc) to give the title compound 6 as a yellow oil ( $329 \mathrm{mg}, 75 \%$ ) . $[\alpha]_{\mathrm{D}}+29^{\circ}$ (c 0.92 in $\mathrm{CHCl}_{3}$ ). $\delta_{\mathrm{H}}(400 \mathrm{MHz}$, $\left.\mathrm{CDCl}_{3}\right) 7.76(2 \mathrm{H}, \mathrm{d}, J 7.6, \mathrm{ArH}), 7.57,(2 \mathrm{H}, \mathrm{d}, J 7.6, \mathrm{ArH}), 7.42-$ $7.28(9 \mathrm{H}, \mathrm{m}, \mathrm{ArH}), 5.25(1 \mathrm{H}, \mathrm{d}, J 9.4, \operatorname{Val}(\mathrm{NH})), 5.26(1 \mathrm{H}, \mathrm{d}, J$ 12.3, $\left.\mathrm{Cbz}\left(\mathrm{CH}_{2}\right)\right), 5.16\left(1 \mathrm{H}, \mathrm{d}, J 12.3, \mathrm{Cbz}\left(\mathrm{CH}_{2}\right)\right), 4.95(1 \mathrm{H}, \mathrm{d}, J$ 6.0, $\operatorname{Thr} \Psi(\alpha-\mathrm{CH})$ ), $4.37(3 \mathrm{H}, \mathrm{m}), 4.22(1 \mathrm{H}, \mathrm{t}, J 6.8, \operatorname{Fmoc}(\mathrm{CH}))$, $3.83(\mathrm{~m}, 1 \mathrm{H}, \operatorname{Val}(\alpha-\mathrm{CH})), 1.86(1 \mathrm{H}, \mathrm{m}, \operatorname{Val}(\beta-\mathrm{CH})), 1.74(3 \mathrm{H}, \mathrm{s}$, $\mathrm{Me}), 1.59(3 \mathrm{H}, \mathrm{s}, \mathrm{Me}), 1.22\left(3 \mathrm{H}, \mathrm{d}, J 6.7, \operatorname{Thr}\left(\gamma-\mathrm{CH}_{3}\right)\right), 0.83(3 \mathrm{H}$, d, $\left.J 6.7, \operatorname{Val}\left(\gamma-\mathrm{CH}_{3}\right)\right), 0.71\left(3 \mathrm{H}, J 6.7, \operatorname{Val}\left(\gamma-\mathrm{CH}_{3}\right)\right) . \delta_{\mathrm{C}}(100 \mathrm{MHz}$, $\mathrm{CDCl}_{3}$ ) 169.4, 169.3, 156.4, 143.7, 143.1, 134.9, 128.9, 128.7, $127.7,125.1,125.0,96.3,72.7,67.3,67.0,63.4,59.0,47.1,30.5$, $24.9,23.6,19.4,17.7,15.2 \mathrm{~m} / \mathrm{z}(\mathrm{ESI}) 570[\mathrm{M}+\mathrm{Na}]^{+}(100 \%)$, 571 (35); $m / z$ (HRMS ESI, $\mathrm{MNa}^{+}$) Calc. for $\mathrm{C}_{34} \mathrm{H}_{38} \mathrm{~N}_{2} \mathrm{O}_{6} \cdot \mathrm{Na}$ 593.2622; found 593.2614.

## Fmoc-Val-D-allo-Thr( $\Psi^{\text {Me,Me }}$ pro)-OH 12

Compound $6(200 \mathrm{mg}, 0.350 \mathrm{mmol})$ was dissolved in 10 mL of dry THF and $10 \% \mathrm{Pd} / \mathrm{C}$ catalyst was added. The reaction flask was purged with $\mathrm{H}_{2}$ and evacuated three times and the solution was left stirring under an atmosphere of $\mathrm{H}_{2}$ for 48 h . The solution was then filtered through a pad of Celite and the solvent removed under reduced pressure. The residue was purified by flash chromatography ( $100: 5: 1 \mathrm{CHCl}_{3} / \mathrm{MeOH} / \mathrm{AcOH}$ ) to give the desired peptide as a colourless foam. Recrystallization $\left(\mathrm{CHCl}_{3}\right)$ afforded the title compound $\mathbf{1 2}$ as colourless needles $(138 \mathrm{mg}, 82 \%) . \mathrm{Mp} 95-98^{\circ} \mathrm{C} .[\alpha]_{\mathrm{D}}+19^{\circ}$ (c 0.99 in $\mathrm{CHCl}_{3}$ ) (Found $\mathrm{C} 67.2, \mathrm{H} 6.6, \mathrm{~N} 5.6 . \mathrm{C}_{27} \mathrm{H}_{32} \mathrm{~N}_{2} \mathrm{O}_{6}$ requires $\mathrm{C} 67.5, \mathrm{H}$ $6.7, \mathrm{~N} 5.8 \%$.) $\delta_{\mathrm{H}}(400 \mathrm{MHz}, \mathrm{MeOD}) 7.75(2 \mathrm{H}, \mathrm{d}, J 7.9, \mathrm{ArH})$,
7.58 (2H, d, J 7.9, ArH), 7.4-7.3 (4H, m, ArH), 5.05 (1H, d, J 6.1, $\operatorname{Thr} \Psi(\alpha-\mathrm{CH})), 4.45(1 \mathrm{H}, \mathrm{m}, \operatorname{Thr} \Psi(\beta-\mathrm{CH})), 4.40(2 \mathrm{H}, \mathrm{d}, J$ $\left.6.8, \operatorname{Fmoc}\left(\mathrm{CH}_{2}\right)\right), 4.24(1 \mathrm{H}, \mathrm{t}, J 6.8, \operatorname{Fmoc}(\mathrm{CH})), 3.80(1 \mathrm{H}, \mathrm{m}$, $\operatorname{Val}(\alpha-\mathrm{CH})), 1.87(1 \mathrm{H}, \mathrm{m}, \operatorname{Val}(\beta-\mathrm{CH})), 1.77(3 \mathrm{H}, \mathrm{s}, \mathrm{Me}), 1.61$ ( $3 \mathrm{H}, \mathrm{s}, \mathrm{Me}$ ), 1.38 ( $\left.3 \mathrm{H}, \mathrm{d}, J 6.0, \operatorname{Thr}\left(\gamma-\mathrm{CH}_{3}\right)\right), 0.94(3 \mathrm{H}, \mathrm{d}, 6.6$, $\left.\operatorname{Val}\left(\gamma-\mathrm{CH}_{3}\right)\right), 0.88\left(3 \mathrm{H}, \mathrm{d}, J 6.6, \operatorname{Val}\left(\gamma-\mathrm{CH}_{3}\right)\right) . \delta_{\mathrm{C}}(100 \mathrm{MHz}$, $\mathrm{CDCl}_{3}$ ) 173.3, 170.0, 156.6, 143.6, 141.3, 127.7, 127.1, 125.1, $120.0,96.5,72.4,67.2,63.4,59.4,47.0,31.6,24.8,23.5,19.4$, 18.1, 15.2. $\mathrm{m} / \mathrm{z}$ (ESI) $503[\mathrm{M}+\mathrm{Na}]^{+}$(100\%), 504 (30); $m / z$ (HRMS EI, $\mathrm{MNa}^{+}$) Calc. for $\mathrm{C}_{27} \mathrm{H}_{32} \mathrm{~N}_{2} \mathrm{O}_{6} \cdot \mathrm{Na} 503.2158$; found 503.2161 .

## Crystallography

Data for 1,7 , and 12 were collected with $\omega$ scans to $\sim 56^{\circ}$ $2 \theta$ using a Bruker SMART 1000 diffractometer employing graphite-monochromated $\mathrm{Mo}-\mathrm{K} \alpha$ radiation generated from a sealed tube $(0.71073 \AA)$ at $150(2) \mathrm{K}$. Data integration and reduction were undertaken with SAINT and XPREP. ${ }^{[19]}$ Subsequent computations were carried out using the teXsan, WinGX-32, and XTAL graphical user interfaces. ${ }^{[20-22]}$

Structures were solved by direct methods using SIR97.[23] Multiscan empirical absorption corrections were applied to the dataset using the program $S A D A B S .{ }^{[24]}$ Gaussian ${ }^{[25]}$ adsorption corrections were applied with XPREP. ${ }^{[19]}$ Data were refined and extended with SHELXL-97. ${ }^{[26]}$ In general, non-hydrogen atoms with occupancies greater than 0.5 were refined anisotropically. Carbon-bound hydrogen atoms were included in idealized positions and refined using a riding model. Oxygen- and nitrogenbound hydrogen atoms were first located in the difference Fourier map before refinement. Where these hydrogen atoms could not be located, they were not modelled. Disorder was modelled using standard crystallographic methods including constraints and restraints where necessary. Crystal and structure refinement data, including any specific refinement details are summarized below. Crystallographic information files reported in the present manuscript have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication numbers CCDC 723749-723751. Copies of the data are available free of charge from the CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: $(+44) 1223336033$; email: deposit@ccdc.cam.ac.uk).

## Crystal Data for 12

Formula $\mathrm{C}_{29} \mathrm{H}_{34} \mathrm{Cl}_{6} \mathrm{~N}_{2} \mathrm{O}_{6}, M$ 719.28, orthorhombic, space group $P 2_{1} 2_{1} 2_{1}(\# 19), a$ 13.335(4), $b$ 14.547(4), $c$ 17.684(5) $\AA$, $V 3430.2(16) \AA^{3}, D_{\mathrm{c}} 1.393 \mathrm{~g} \mathrm{~cm}^{-3}, Z 4$, crystal size 0.400 by 0.350 by 0.100 mm , colourless, habit plate, temperature $150(2) \mathrm{K}, \lambda(\mathrm{MoK} \alpha) 0.71073 \AA$, $\mu(\mathrm{MoK} \alpha) 0.543 \mathrm{~mm}^{-1}$, $T(S A D A B S)_{\text {min,max }} 0.860,0.947,2 \theta_{\text {max }} 56.72$, hkl range -17 17, - $1919,-2222, N 34065$, $N_{\text {ind }} 8220\left(R_{\text {merge }} 0.0614\right)$, $N_{\text {obs }}$ $5400(I>2 \sigma(I)), N_{\text {var }} 399$, residuals* $R 1(F) 0.0639$, $w R 2\left(F^{2}\right)$ 0.1454, GoF(all) 1.010, $\Delta \rho_{\text {min,max }}-0.515,0.664 \mathrm{e}^{-} \AA^{-3}$.
${ }^{*} R 1=\Sigma| | F_{\mathrm{o}}\left|-\left|F_{\mathrm{c}}\right| / \Sigma\right| F_{\mathrm{o}} \mid$ for $F_{\mathrm{o}}>2 \sigma\left(F_{\mathrm{o}}\right) ; w R 2=\left[\Sigma w\left(F_{0}^{2}-\right.\right.$ $\left.\left.F_{\mathrm{c}}^{2}\right)^{2} / \Sigma\left(w F_{\mathrm{c}}^{2}\right)^{2}\right]^{1 / 2}$ all reflections $w=1 /\left[\sigma^{2}\left(F_{\mathrm{o}}^{2}\right)+(0.0590 P)^{2}+\right.$ $2.5336 P]$ where $P=\left(F_{\mathrm{o}}^{2}+2 F_{\mathrm{c}}^{2}\right) / 3$.

## Accessory Publication

NOESY NMR spectrum of $\mathbf{1 2}$ and $O R T E P$ plots of $\mathbf{1}$ and $\mathbf{7}$ are available from the Journal's website.

## Acknowledgements

We thank the Australian Research Council for financial support and for the award of a Queen Elizabeth II research fellowship to K.A.J.
