13	Abstract
14	Niemann-Pick type C1 (NPC1) receptor is an endosomal membrane protein that

regulates intracellular cholesterol trafficking, which is crucial in the Ebola virus 15 16 (EBOV) cycle. The severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) enters the cell by binding of the viral spike (S) protein to 17 18 the ACE2 receptor. This requires S-protein processing either by the 19 surface transmembrane serine protease TMPRSS2 for plasma membrane fusion 20 or cathepsin L for endosomal entry. Additional host factors are required for viral 21 fusion at endosomes. Here, we report a novel interaction of the SARS-CoV-2 22 nucleoprotein (N) with the cholesterol transporter NPC1. Moreover, small 23 molecules interfering with NPC1 that inhibit EBOV entry, also inhibited human 24 coronavirus. Our findings suggest an important role for NPC1 in SARS-CoV-2 25 infection, a common strategy shared with EBOV, and a potential therapeutic 26 target to fight against COVID-19.

27

28 Keywords: SARS-CoV-2, N protein, NPC1, target, antivirals.

30 Introduction

31

To date, the COVID-19 pandemic has caused over one million of deaths and affected over 73-millions of people around the world (*1*). COVID-19 is caused by the emerging and pathogenic severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) first reported in the city of Wuhan (China) as a rare pneumonia (*2*, *3*) that rapidly spread worldwide. A better understanding of the biology of SARS-CoV-2 is vital in order to develop effective therapeutics.

- 38 A key step of the biology of SARS-CoV-2 is the cell entry mechanism. Viral entry 39 involves the activation of its trimeric spike glycoprotein by TMPRSS2 protease 40 upon interaction with the angiotensin-converting enzyme 2 (ACE2) receptor at 41 the plasma membrane to mediate fusion (4-8). Also, the virus can enter via 42 endosomes under cathepsin L processing, similar to SARS-CoV-1 (7, 9). In fact, 43 the inhibition of both alternative entries is necessary for full inhibition of SARS-44 CoV-2 entry (10, 11). Other cellular proteases facilitate SARS-CoV-2 cell tropism, 45 like furin, possibly at a post-binding step (12, 13).
- 46 Considering that SARS-CoV-2 may enter the cell by endocytosis, it would be 47 partially acid pH dependent and should exit endosomes by fusion to start 48 replication (*13*). SARS-CoV-2 replication occurs in the cytoplasm at double 49 membrane vesicles of possible origin in the endoplasmic reticulum, which provide 50 support to the viral RNA replication and transcription complex (*14-16*).
- 51 SARS-CoV-2 endosomal pH-dependent masking through endosomal cleavage 52 was recently described (8). Similarly, endosomal processing of the Ebola virus 53 (EBOV) glycoprotein trimer enhances infectivity and evidence a conformational 54 masking of the receptor binding site of this protein (17, 18). A similar process has 55 been described for the human immunodeficiency virus (HIV) envelope trimer (19). Therefore, the similarities found between these viruses were the start point of this 56 57 work. EBOV enters the cell using the endocytic pathway, and its entry is mediated by the viral glycoprotein (GP), which decorates the viral surface organized in 58 59 trimeric spikes (20). The GP is then processed by endosomal cathepsins to 60 remove its heavily glycosylated C-terminal residues and the glycan cap. This 61 removal produces the cleaved form of the N-terminal receptor binding subunit 62 GP1 (GPcL) that is required to mediate fusion at the endosomal membrane. Two 63 simultaneous publications described first that the endosomal receptor called

NPC1 is an intracellular host receptor for EBOV (*21, 22*). Since then, the
relevance of NPC1 on viral infections have been shown for different viruses
including HIV (*23*), Hepatitis C (HCV) (*24, 25*), Chikungunya virus (CHIKV) (*26*)
and several Flaviviruses such as Dengue (DENV) (*27, 28*) and ZIKA virus (*29*)
among others (*26, 30*).

Given SARS-CoV-2 can be internalized via clathrin- and non-clathrin-mediated endocytosis; some researchers hypothesized a role for NPC1 in SARS-CoV-2 infection that remains to be determined (*31-34*). Due to the increasing relevance of this molecule, we designed our study to investigate the potential binding of

- 74 SARS-CoV-2 proteins to NPC1, according to the existing evidence of SARS-
- 75 CoV-2 endosomal passage (35).

77 Materials and Methods

78

79 Cell culture and viruses

80 Human embryonic kidney cells 293T/17 (HEK 293T: ATCC-CRL-11268) were 81 cultured in Dulbecco modified Eagle medium (DMEM) at 37 °C and 5% CO₂ atmosphere, supplemented with 100 IU/ml penicillin, 100 µg/ml streptomycin, 1X 82 83 GlutaMAX (Thermo Fisher) and 10% heat-inactivated fetal bovine serum (FBS). Huh-7 Lunet C3 cells, a gift from T. Pietschman (Twincore, Germany), were 84 85 cultured at 37 °C in Dulbecco's modified Eagle's medium (DMEM) supplemented 86 with 100 IU/ml penicillin, 100 µg/ml streptomycin, 10mM HEPES, 1X NEAA and 87 10% of heat-inactivated fetal bovine serum (FBS).

For virus infections, we used common cold coronavirus 229E, which expresses the green fluorescent protein (GFP) gene (229E-GFP) (*36*). This recombinant virus was kindly given by V. Thiel, at the University of Bern, in Switzerland. The infection experiments were conducted at 33°C and 5% CO₂.

92

Design and construction of plasmid that express the SARS-CoV-2 N tag toEGFP.

95 The methodology used in this part of the study was previously used in Garcia-96 Dorival et al., 2016 (*37*). To generate the SARS-CoV-2 N with N-terminal EGFP 97 tag (EGFP-N), a codon optimized cDNA sequence for the ORF of SARS-CoV-2 98 N (NCBI reference sequence number: NC_045512) was cloned into the pEGFP-99 C1 (by GeneArt-Thermo Fisher Scientific). Once cloned, the sequence of the 910 plasmid EGFP-N was confirmed by sequencing (Gene Art–Thermo Fisher 911 Scientific).

102

103 Expression of tagged-N protein and EGFP in HEK 293T cells.

To transfect HEK 293T cells, four 60mm dishes were seeded with 2.5 x10⁶ cells 104 105 each 24 hours prior to transfection in DMEM complete medium described above. Then, a transfection of EGFP or EGFP-N was done using Lipofectamine 2000 106 107 (Thermo Fisher Scientific), following the instructions of the manufacturer. Twenty-108 four hours post transfection the cells were harvested. lysed and 109 immunoprecipitated using a GFP-Trap kit (Chromotek).

111 Immunoprecipitations (IP)

112 EGFP-N and EGFP immunoprecipitations (IP) were done using a GFP-Trap®_A 113 (Chromotek). To do the IPs, the cell pellet was resuspended in 200µl of lysis 114 buffer (10mM Tris/Cl pH 7.5; 150mM NaCl; 0.5mM EDTA; 0.5%NP40) and then 115 incubated for 30 minutes on ice. The lysate was then clarified by centrifugation at 116 14000 x g and diluted five-fold with dilution buffer (10mM Tris/Cl pH 7.5: 150mM 117 NaCl; 0.5mM EDTA). The GFP-Trap agarose beads were equilibrated with ice-118 cold dilution buffer and then incubated with diluted cell lysate overnight at 4°C on 119 a rotator, followed by centrifugation at 2700 x g for 2 minutes. The bead pellet 120 was wash two times with wash buffer (10mM Tris/Cl pH 7.5; 150mM NaCl; 0.5mM 121 EDTA). After removal of wash buffer, the beads were resuspended in 100µl of 122 Sample Buffer, Laemmli 2X Concentrate (Sigma Aldrich) and boiled at 95° for ten 123 minutes to elute the bound proteins. Buffers used for Immunoprecipitations were 124 all supplemented with Halt[™] Protease Inhibitor Cocktail EDTA-Free (Thermo 125 Fisher Scientific).

126

127 **Co-Immunoprecipitation (Co-IP)**

Similar to what was described in Garcia-Dorival et al, 2016 (37), Co-IP for NPC1 128 129 was performed using 50µl of the Immobilized Recombinant Protein G Resin 130 (Generon) and specific antibodies against NPC1 (Abcam, ab108921). The cell 131 pellets were incubated for 30 minutes on ice with 200µl lysis buffer. The lysate 132 was then clarified by centrifugation and diluted five-fold with dilution buffer prior 133 to adding 2µg of the primary antibody and then incubated at 4°C on a rotator for 134 two hours. The protein G resin (Generon) were equilibrated with ice-cold dilution 135 buffer and then incubated at 4°C on a rotator with diluted cell lysate containing 136 the antibody overnight at 4°C on a rotator, followed by centrifugation at 2500 x q137 for 2 minutes to remove non-bounds fractions. The wash and elution steps were performed as describe previously in GFP co-immunoprecipitation. 138

139

140 Western blot analysis

To do confirm the expression of GFP and GFP-N proteins, an SDS-PAGE and a
western blot (WB) was done. For the SDS-PAGE, a Mini-PROTEAN TGX Gels
were used (Bio-Rad 4561096), then, the gels were transferred to PVDF

144 membranes using the Trans-Blot Turbo Transfect Pack (Bio-Rad 1704159) and 145 the Trans-Blot Turbo system (Bio-Rad). Following this, the transferred 146 membranes were then blocked in 10% skimmed milk powder dissolved in TBS-147 0.1% Tween (TBS-T) (50mM Tris-HCI (pH8.3), 150mM NaCI and 0.5% (v/v) 148 Tween-20) buffer for one hour at room temperature. Primary antibody was diluted 149 1:1000 in blocking buffer and then incubated at 4°C overnight. After three 150 washes, blots were incubated with appropriate HRP secondary antibody diluted 151 in blocking buffer at a 1:5000 for 1 hour at room temperature. Blots then were 152 developed using enhanced chemiluminescence reagent (Bio-Rad) and detected with ChemiDoc[™] XRS Gel Imaging System using Image Lab[™] software (Bio-153 154 Rad).

155

156 **Production of SARS-CoV-2 N protein in the baculovirus system**

157 The sequence of the N protein published in the NCBI database was selected 158 (GenBank accession number: 43740575 / NCBI reference sequence number: 159 NC 045512). The codon usage of the N encoding gene was optimized for its expression in insect cells (OptimumGene[™]-Codon Optimization algorithm) and 160 161 the coding sequence for this protein was synthesized by the company GenScript. 162 The donor plasmid pFastBac1 containing an expression cassette expressing the 163 recombinant protein under the control of the polyhedrin promoter was obtained. 164 The Bacmid for the generation of the baculovirus was prepared in E. Coli 165 DH10Bac bacterial cells containing the mini-Tn-7-replicon. Bacmids were 166 transfected in the regulatory Sf9 cells and a viral clone selection was made by 167 two rounds of plaque cloning to obtain the working virus stock. The baculovirus 168 genome region was sequenced to determine the integrity of the N gene in the 169 recombinant baculovirus named rBacN.

170

171 SARS-CoV-2 N protein production in pupae

The production of SARS-CoV-2 N protein in insect pupae (*Tricoplusia ni; T. ni*) was performed as previously described (*38*). Briefly, pupae were allocated in the inoculation robot that dispensed a maximum of 5 µl with the baculovirus titers protein in 5 days pupae incubation time in constant temperature and humidity chambers. After that period, pupae were collected and stored frozen, before downstream processing. *T.ni* pupae containing the recombinant protein were

178 homogenized in extraction buffer. Then, subsequent steps of clarification, 179 diafiltration and His-tag purification were carried, out in order to obtain purified 180 SARS-CoV-2 N protein. Protein concentration, yield and level of purity were 181 determined by SDS-PAGE analysis using 4-20 % or 12 % Mini-Protean TGX 182 precast gels from Bio-Rad. Gels were stained with QC Colloidal stain (3 ng 183 sensitivity) in the case of concentration and yield evaluation and with SYPRO 184 Ruby (1 ng sensitivity) in the case of level purity analysis, both from Bio-Rad. 185 Recombinant SARS-CoV-2 N protein produced in pupae was measured by band 186 densitometry with the ChemiDoc[™] XRS Gel Imaging System using Image Lab[™] 187 software (Bio-Rad). A BSA standard curve was used for quantification.

188

189 ELISA assays

190 High-binding 96-well ELISA plates (Nunc) were coated with 0.5 µg/well of purified 191 SARS-CoV-2 N protein in carbonate/bicarbonate buffer 0.05 M pH 9.6 and 192 allowed to bind over night at 4°C. Then, endogenous human NPC1 and HSP90 193 were purified using immobilized Recombinant Protein G Resin (Generon) and 4 194 µg of specific antibodies against NPC1 (Abcam, ab108921) or HSP90 (Enzo Life 195 Sciences, ADI-SPA-835) respectively. All steps were performed as described in 196 Co-IP assays. Serial dilutions of these endogenous NPC1 and HSP90 were 197 added to the plate and capture was allowed to proceed for 1 hour at 37°C. After 198 that, plates were washed with PBST (PBS 0.1%Tween20) and the binding of 199 NPC1 to SARS-CoV-2 N protein was detected with a rabbit anti-NPC1 antibody 200 (1:2000), revealed with an anti-rabbit-horseradish peroxidase (HRP) (1:2000) 201 using a colorimetric substrate (OPD) and finally, quantified by absorbance at 492 202 nm in the EnSight multimode plate reader of PerkinElmer. Effect of the 203 compounds on the binding was performed pre-incubating 50 µM and 100µM of 204 each compound with NPC1 1h a 37°C before adding it to the plate.

205

206 **Compounds studied**

All the compounds tested in this work have a purity ≥95% by HPLC. SC compounds were synthesized at Centro de Investigaciones Biológicas (CIB-CSIC) following described procedures. All these molecules were included in the MBC chemical library and some of them were previously characterized as potential inhibitors of the protein-protein interaction between NPC1 and EBOV-

212 GP (39. 40). The compounds tested in this study are shown in Figure 2 and were 213 resuspended in DMSO at 50 mM. Sulfides SC198 and SC073, and carbazole 214 SC816, were used at working concentrations of 5, 50 and 50 μ M; benzothiazepines SC397, SC593, SC567, at working concentrations of 75 µM 215 216 and SC338 at 100 µM respectively. The first three compounds were shown 217 previously to be active against EBOV while the others were inactive (40). 218 Compounds MBX2254 and MBX2270 were used as gold standards as they have 219 been reported to inhibit EBOV-GP/NPC1 interaction with high selectivity (41). 220 These compounds were purchased from MolPort and used at concentrations of 221 75 µM and 25 µM, respectively. Class II cationic amphiphilic compound U18666A 222 is a drug that blocks cholesterol flux out of lysosomes and also inhibits Ebola 223 virus infections. It was acquired from Sigma-Aldrich and used at 10µM (42). 224 Imipramine, a hydrophobic amine and FDA-approved antidepressant drug was 225 acquired from Sigma-Aldrich and used at 25 μ M (26, 43).

226

227 Cytotoxicity assays

Huh-7 cells were seeded in 96-well plates and incubated with DMEM containing
each compound at concentrations ranging from 0 to 100 µM. After 24 hours, cell
viability was measured by Cell Titer 96 AQueous Non-Radioactive Cell
Proliferation Assay (Promega) following the manufacturer's instructions.
Absorbance was measured at 490 nm using an ELISA plate reader.

Cell viability was reported as the percentage of absorbance in treated cells
relative to DMSO- treated cells (Figure S3). The 50% cytotoxic concentration
(CC₅₀) was calculated and non-toxic working concentrations (over 80% cell
viability) used to test the activities of these compounds on CoV infection.

The values of the half maximal inhibitory concentration (IC_{50}) inhibition of the infection presented on Figure 3 table correspond to the mean of 3 independent experiments. The IC_{50} s values and dose-response curves were estimated using GraphPad Prism v6.0 with a 99% confidence interval.

241

242 Flow cytometry analysis

Detection of CoV infected cells was performed by flow cytometry. Huh-7 cells were pre-treated with compounds at the indicated concentrations in growth medium for 1 h at 33 °C, followed by infection with 229E-GFP at a multiplicity of

infection (MOI) of 1 pfu/cell for 24 h. Cells were washed twice with growth medium 246 after 90 min of adsorption at 33°C, and incubated with DMEM 10% 24 h. Cells 247 248 were then harvested with PBS-EDTA 5mM, and diluted in PBS. Detection of 249 229E-GFP infected cells was performed by analyzing GFP expression. In order 250 to determine the percentage of infected cells per condition, 8,000 cells/time point 251 were scored using FACS Canto II flow cytometer (BD Sciences) and analyzed 252 using the FlowJo software. Untreated control infected cultures yielded 75-90% 253 of infected cells from the total cells examined. Infected cell percentages obtained 254 after drug treatments were normalized to DMSO values.

255

256 Statistical analysis

The experimental data was analyzed by one-way ANOVA by Graph Pad Prism 6 software. For multiple comparisons, Bonferroni's correction was applied. Values were expressed in graph bars as mean \pm SD of at least three independent experiments unless otherwise noted. A *p* value <0.05 was considered as statistically significant.

263 Results

264

265 Interaction of SARS-CoV-2 N protein with NPC1

266 To investigate the interaction of SARS-CoV-2 Nucleoprotein (N) with NPC1, N 267 protein was expressed as an EGFP-fusion protein in HEK 293T cells. Then, 268 proteins were extracted from lysed cells and assayed for immunoprecipitation (IP) 269 using a high affinity EGFP immunoprecipitation kit (GFP-Trap). Finally, protein expression/interaction was confirmed by fluorescence and western blot analysis 270 271 (Figure 1A and 1C). This pipeline (Figure 1B) has been used to detect protein interacting partners for other RNA virus such as EBOV (37, 44). HEK 293T cells 272 273 were selected due to their high efficiency of transfection, being the cell line of 274 choice for protein-protein interaction studies of several viruses including SARS-275 CoV-2 (45).

276 Protein expression of EGFP-N and EGFP alone was confirmed using western 277 blot analysis and fluorescence (Figure 1A and 1C). The efficiency of transfection 278 for both plasmids was approximately 80% (Figure 1A). EGFP-N and EGFP were 279 then immunoprecipitated using an EGFP-Trap. After immunoprecipitation, both input (cell lysate) and bound (or elution) samples were analysed by western blot. 280 281 Proteins corresponding to the molecular weight of EGFP-N (70 kDa) and the 282 EGFP empty (27 kDa) were detected using an anti-EGFP antibody (Figure 1C). 283 NPC1, as an endogenous protein, was also detected in both input samples 284 (EGFP-N and EGFP); but only in the bound fraction of EGFP-N sample (Figure 285 1C). This experiment was repeated three times to ensure reproducibility 286 (Supplementary figure S1A).

To further validate a specific interaction between EGFP-N and NPC1, two cellular proteins were selected as negative controls. In this case, HSP90 chaperone and endosomal protein EEA1 were used as controls given the abundance of these proteins in cells (Figure 1C).

291

292 Validation of SARS-CoV-2 N interaction with NPC1

293 Co-immunoprecipitations against NPC1 (or reverse pull down) were performed 294 to confirm and further validate the interaction between SARS-CoV-2 N and 295 NPC1. SARS-CoV-2 N was overexpressed in HEK 293T cells and then cellular 296 extracts were analysed by co-immunoprecipitation using protein G-beads and

specific monoclonal antibodies against NPC1 (Figure 1B). Bound samples
obtained from the co-immunoprecipitations were then analysed by western blot,
which confirmed the presence of SARS-CoV-2 N (Figure 1D). As a result of this
interaction, we hypothesized that NPC1 might have an important function in virus
biology.

302

Figure 1. Immunoprecipitation analysis of SARS-CoV 2 N protein with endogenous NPC1.

304 A. Expression of SARS-CoV-2 Nucleoprotein. Immunofluorescence of HEK 293T cells transiently 305 expressing EGFP at the upper panel and EGFP-N protein at the lower panel showing different distribution 306 as expected. GFP, Topro3 and Merge are indicated in upper panels in different colours. The scale bar 307 indicates 25 µm. B. Schematic representation of the methodology used in this study for immunoprecipitation. 308 C, D. Detection of SARS-CoV-2 N fussed to GFP, GFP control and cellular proteins analysed in the 309 immunoprecipitation assay by western blot. C. Endogenous NPC1, EEA1, HSP90; and transfected EGFP-310 N and EGFP control were detected at the expected molecular weights. D. Endogenous NPC1, HSP90 and 311 transfected EGFP-N and EGFP control were detected at the expected molecular weights from samples 312 collected from the co-immunoprecipitations (reverse pulldown). Molecular weighs: NPC1~175kD, 313 EEA1~110kD, HSP90~75kD, EGFP-N~70kD, EGFP~27kD.

314

315 **Functional assays**

- For an orthogonal characterization of the interaction, we used NPC1 inhibitor
- 317 drugs to inhibit human coronavirus (HCoV) infection. To do this, Huh-7 cells were
- 318 treated with the inhibitor compounds for an hour at different concentrations and
- then, infected with HCoV 229E-GFP recombinant virus at a MOI of 1 pfu/ml. Cells
- 320 were then analysed at 16 hpi.

321 322 323

324

Figure 2. Chemical structure of small molecules used in this study.

Inhibitors MBX2254 and MBX2270 (Figure 2) were selected as they target NPC1 with high selectivity and both have been described to inhibit HIV-pseudotyped-EBOV-GP binding to NPC1 (*41*). MBX2254 and MBX2270 were used at 75 and 25 μ M, respectively. We also used imipramine, a Food and Drug Administration (FDA)-approved drug, that inhibits EBOV and other viruses due to its ability to induce a phenotype similar to NPC1 deficiency (*46*).

331 Finally, we assayed a set of compounds initially selected by virtual screening of 332 the MBC chemical library in the EBOV-GP/NPC1 interaction (40). These 333 compounds were previously found to inhibit infection with EBOV pseudotyped 334 retrovirus and some of them - sulfides and carbazoles - were able to disturb the 335 NPC1-GP interaction in an ELISA assay. Compounds were classified in three chemical classes, sulfides SC198 and SC073, and carbazole SC816 used at 5, 336 337 50 and 50 µM respectively; and benzothiazepines SC397, SC593, SC567 (Figure 2), that were used at 75 µM, or 100 µM of SC338. Noteworthy, sulfides and 338 carbazoles were found to potentially act through inhibition of NPC1-GP 339 340 interaction, while benzothiazepines do not affect this interaction (40). Based on

these previous results, the three classes were included in this study for comparative purposes. As a reference, we used U18666A compound (10 μ M), known to inhibit cholesterol transport function of NPC1 and the infectious entry of several viruses including EBOV and ASFV (*23, 26, 42*).

345 We detected that MBX2270 derivative potently inhibited HCoV infection (50% 346 inhibitory concentration IC_{50} = 3.26 µM, selectivity index 28.36; Figure 3). In general, our results yielded significant inhibition >99% of HCoV infection with the 347 348 U18666A compound and imipramine treatment and with sulfides from the library 349 compounds (Figure 3A). Others yielded over 80% of infectivity inhibition (except 350 for SC397 and SC338; Figure 3B). IC₅₀ was <1 μ M in several sulfide compounds 351 (SC073 IC₅₀= 0.53 µM, Index 151.47), U18666A (IC₅₀ 0.1 µM, Index 362.34) and 352 imipramine (FDA085; IC_{50} = 0.75 μ M, Index 72.3). Full information of 353 dose/response curves for these chemicals are included in Supplementary Fig. 354 S4.

355

Figure 3. Activity of small-molecule inhibitors of NPC1 and related compounds against HCoV. A. Infectivity percentages of HCoV 229E-GFP in Huh-7 cells at 24 hpi. Y axis depicts GFP fluorescence intensity in controls and cells pretreated 1 h before infection with selected compounds at the concentrations above described (**p < 0.001; ***p < 0.0001). B. IC₅₀ values (μ M) were determined for these compounds. For determination of CC₅₀ values, cells were treated with compound alone, and values (μ M) were determined from linear portions of the dose-response curves shown in Supplementary Figure S4. SI, selectivity index (CC₅₀/IC₅₀).

363

In addition to these functional experiments, we also tested the ability of these compounds to disrupt the NPC1/SARS-CoV-2 N protein interaction in an ELISA assay, as described in Materials and Methods. First, we tested increasing concentrations of NPC1 and control protein HSP90 in plates coated with SARS-

368 CoV-2 N protein. We detected a positive reaction with increasing concentrations 369 of NPC1, while negative control HSP90 remained unaltered (Figure 4A). Then, 370 we analysed the inhibition of NPC1/SARS-CoV-2 N binding with a sample of the 371 compounds previously described in this study. We obtained a significant inhibition 372 of this specific binding in those samples tested with one inhibitor compound from 373 each class 100 μ M SC073 and 50 or 100 μ M of MBX2270 (Figure 4B).

374

Figure 4: Inhibition of NPC1 binding to N protein by chemicals in an ELISA assay. A. Binding of increasing concentrations of NPC1 or HSP90 to N protein. HSP90 was used as a negative control. Concentrations analyzed were 5, 2.5, 0.5, 0.1 or 0.05 μ g. B. DMSO or 50/100 μ M chemical compounds were incubated with 5 μ g of purified endogenous NPC1 before being added to ELISA plates previously coated with purified N protein (0.5 μ g/well). Then, the binding of purified NPC1 protein to viral N protein was determined with an anti-NPC1 antibody revealed with an anti-rabbit-HRP. Absorbance was measured at 492 nm after addition of substrate. Percentages of binding were related to DMSO (*p < 0.01).

....

386 **Discussion**

387

388 Current COVID-19 pandemic has affected millions of people all around the globe 389 and has been one of the mayor challenges in this century due to a great loss of 390 lives and significant economic losses (1). This highlights an urgent need for 391 developing efficient therapeutics against SARS-CoV-2 since there is no licensed 392 treatment available.

393

394 There are several pathogenic viruses, that are known to use the endocytic 395 pathway to enter the cell, the most important being EBOV. Two publications 396 described simultaneously that the endosomal protein called NPC1 or Niemann-397 Pick type C1 is a host receptor for EBOV (21, 22). EBOV entry is mediated by 398 the viral glycoprotein (GP) which is organized in trimeric spikes at the viral surface 399 (20). NPC1 binding requires the processing of viral GP. GP cleavage by 400 endosomal cathepsins unmasks the binding site for NPC1 by removing heavily 401 glycosylated C-terminal residues and the glycan cap to produce the cleaved form 402 of the N-terminal receptor binding subunit GP1 (GPcL). Finally, GPcL-NPC1 403 binding within endosomes is required to mediate fusion and viral escape into the 404 host cytoplasm (21, 22) as a second intracellular receptor (47).

Thereby, NPC1 could be used as an important druggable target (*22*) on viral infection. An example of this is compound U18666A, which blocks intracellular cholesterol efflux mediated by NPC1, along with imipramine severely impacts EBOV (*22, 42, 43*) and other viruses like HIV (*23*) and DENV (*27, 28*), CHIK (*26*), ZIKV (*29*) and other Flavivirus. Knockdown or chemical impairment of NPC1 severely reduced cholesterol supply at the Hepatitis C virus replication sites altering the replication membranous web (*25*).

412

413 SARS-CoV-2 infection starts with the interaction between spike glycoprotein (S) 414 with the ACE2 cellular receptor. It requires activation by the TMPRSS2 at the 415 plasma membrane. TMPRSS2 is located at the vicinity of ACE2 in lipid rafts and 416 elicits plasma membrane fusion (*31*) that results severely impaired using 417 chemical inhibitors of this protease (*10, 11*). Apart from TMPRSS2, the lysosomal 418 proteases, specifically cathepsin L, are crucial for SARS-CoV-2 entry via endo-419 lysosomes (*11*). Both, TMPRSS2 and cathepsin L proteases have cumulative

effects along with the cleavage caused by furin at the Golgi (subsequent to Sprotein synthesis during viral packaging) on activating SARS-CoV-2 entry and
penetration in the cytoplasm.

423 SARS-CoV-2 would traffic the endocytic pathway inside the early and late 424 endosomal vesicles to finally fuse with lysosomes, an essential stage for viral 425 uncoating and fusion (31). According to that, viral infection is abrogated by drugs 426 interfering endosome acidification (11). Also, SARS-CoV-2 pseudovirions 427 infection is inhibited using drugs targeting the late endosomal compartments, like 428 cathepsin L, two-pore channel 2 (TPC2), or PIKfyve. Inhibitors against these 429 proteins dramatically reduce infection, indicating that TPC2, cathepsin L, 430 endosomal maturation, and endosomal acidic luminal pH, are crucial host factors for endocytosed SARS-CoV2 entry (11, 35). Thus, late endosomes/lysosomes 431 432 are proposed as relevant organelles to develop therapeutic targets against 433 infection by SARS-CoV-2 (8, 11, 31-34, 48).

- A recent study discovered that SARS-CoV-2 non-structural protein 7 (nsp7) strongly interacts with Rab7a, and its depletion causes retention of ACE2 receptor inside late endosomes (*45*). Other reports highlighted the relevance of a variety of proteins involved in cholesterol biosynthesis, including NPC1 infection (*32*). Also, the cholesterol biosynthesis pathway is downregulated during SARS-CoV-2 infection and, according to that, drug treatments that regulate this pathway impact the infection (*49*).
- 441 Here, we described in this study an interaction between SARS-CoV-2 N protein 442 and NPC1. This interaction unveiled a novel host-based target for antivirals and 443 a potential host factor for SARS-CoV-2 infectivity. As in other viruses, this 444 interaction could possibly regulate and modify cholesterol efflux from late 445 endosomes and alter the lipid composition in cellular membranes in its own 446 benefit (50). Besides, we presented data on how several compounds that block 447 NPC1 function severely impact 229E HCoV infection in a functional assay, which 448 suggests an essential role for NPC1 in HCoV infectivity.

Small molecule inhibitors were crucial to determine that NPC1 was essential for
EBOV infection (22). Compounds MBX2254, an aminoacetamide sulfonamide,
and MBX2270, a triazole thioether were reported to inhibit EBOV infection with
high selectivity (41). All those compounds have NPC1 as a target and we found

453 that those chemicals strongly inhibited HCoV 229E infection. Also, compounds 454 found using the NPC1/EBOV-GP interaction for the screening of a library of 455 compounds, namely sulfides, carbazoles and benzothiazepines (shown in Figure 2), were tested for HCoV inhibition. We have shown that compounds that 456 457 inhibited EBOV-GP/NPC1 binding, namely sulfides SC073 and SC198 together 458 with carbazole SC816, and not others, presented a potent inhibition of 229E-CoV 459 infection. These chemicals have been shown to inhibit EBOV binding to NPC1 and the infection of EBOV-GP pseudovirions elsewhere (40). We have shown 460 461 here that those compounds that were able to inhibit EBOV-GP/NPC1 binding 462 were also capable to inhibit SARS-CoV-2 N protein/NPC1 binding in an ELISA 463 assay.

To conclude, according to other authors and recent evidences (*31-34, 49*), we propose NPC1 as a potential therapeutic target for SARS-CoV-2 to combat COVID-19 pandemic. We show for first-time experimental evidences of the binding of SARS-CoV-2 Nucleoprotein (N) to NPC1. This important finding paves the way to direct medical efforts and therapeutics to NPC1 and to continue studies on cholesterol metabolism in SARS-CoV-2 infection.

We are thankful to V. Thiel from the University of Bern, Switzerland for CoV 229E-GFP and T. Pietschman, Twincore, Germany for Huh-7 Lunet C3 cells. BioRender.com was used to created icons in Figures. This research was partially supported through "La Caixa" Banking Foundation (HR18-00469), Instituto de Salud Carlos III (ISCIII-COV20/01007), CSIC (201980E024 and 202020E079), Spanish Ministry of Science and Innovation (RTI2018-097305-R-I00) and the European Commission Horizon 2020 Framework Programme VACDIVA-SFS-12-2019-1-862874.

507 Supplementary Figure Legends

Supplementary Figure S1A: Membranes used to compose the figure 1C. Dashed boxes were taken to 512 create the western blot composition showed in the figure. Membrane 1 triplicates revealed with rabbit anti-513 NPC1 antibody, membrane 2 triplicates revealed with mouse anti-GFP antibody and membrane 2 revealed 514 with the same primary and secondary antibodies double diluted.

518 519 520

Supplementary Figure S1B (cont): Membrane used to compose the figure 1C. Dashed boxes were taken to create the western blot composition showed in the figure. Original membrane.

Membrane was originaly cutted to develope a lower weight protein with a different antibody

521

522 Supplementary Figure S2: Membranes used to compose the figure 1D. Dashed boxes were taken to create 523 the western blot composition showed in the figure. Original membrane 1 developed with Mouse anti-GFP antibody, membrane 2 developed with Rabbit anti-NPC1 antibody and membrane 3 developed with Rat anti-525 HSP90 antibody.

Supplementary Figure S3: Cell viability under chemicals treatment

528 529 Cell viability measured after 24 hours incubation of Huh-7 cells with each compound at concentrations 530 531 ranging from 0-100 µM in DMEM. Absorbance was measured at 490 nm using an ELISA plate reader. Y axis depicts median and standard deviations of the percentages of absorbance in compound treated cells 532 relative to DMSO-treated cells.
