

The promise of omega-3 against sudden unexpected death in epilepsy: until further notice, it remains innocent, until proven guilty

Promessa do ômega-3 contra a morte súbita em epilepsia: até segunda ordem, continua inocente, até que se prove o contrário

ABSTRACT

The present paper highlighted the importance of the recommended levels of fish consumption or omega-3 supplementation in order to minimize the frequency of seizures in people with uncontrolled epilepsy and, especially, to reduce the occurrence of sudden unexpected death in epilepsy (SUDEP).

Key words: omega-3, SUDEP, seizures, epilepsy.

RESUMO

O presente trabalho destacou a importância dos níveis recomendados de consumo de peixe ou suplementação de ômega-3 com o intuito de minimizar a frequência de crises epiléticas em pessoas com epilepsia refratária e, especialmente, de reduzir a ocorrência de morte súbita inesperada em epilepsia (SUDEP).

Palavras-Chave: ômega-3, SUDEP, convulsões, epilepsia.

Epilepsy is a common and very heterogeneous chronic neurological condition^{1,2}. Often, it is still seen as a benign condition in which individuals only have seizures. Unfortunately, the story is not as simple as it seems. Observational data over the years have shown that epilepsy is a malignant condition that has a high rate of premature death compared with the general population³⁻⁵. Thus, sudden unexpected death in epilepsy (SUDEP) is the most important fatal complication of epilepsy⁶. In fact, it is responsible for 7.5 to 17% of all deaths in people with epilepsy and has an incidence among adults between 1:500 and 1:1,000 patient-years⁷.

Recent research suggests that multiple risk factors may contribute for SUDEP, such as refractoriness of the epileptic

condition, increased frequency of convulsive seizure, anti-epileptic medication (polytherapy with antiepileptic drugs), longer duration of epilepsy, young age at onset, male sex, symptomatic cause, and lamotrigine therapy (in people with idiopathic generalized epilepsy)^{5,6,8-10}. The cause or causes of SUDEP is/are still unknown, however experimental and clinical research suggest that the main mechanism involved is autonomic dysregulation, i.e., respiratory and cardiovascular abnormalities during and after seizures^{6,9-11}.

In this context, relevant putative mechanisms involved are cardiac arrhythmia, due to myocardial ischemia; electrolyte disturbances; arrhythmogenic drugs; or transmission of the epileptic activity via the autonomic nervous system to

the heart^{9,11-13}. Actually, it is clear that SUDEP is mainly (but not exclusively) a problem for people with chronic uncontrolled epilepsy¹⁰, but our understanding of the best way to prevent is still incomplete. As SUDEP is probably a seizure-related event, the successful seizure control is the best preventive measure¹⁹. Furthermore, others strategies have been suggested, which could be useful in reducing its risk^{10,14,15}, although strict evidence for their effectiveness is still lacking. Following this line of reasoning, the ultimate goal of research in SUDEP is to develop new methods for its prevention and actions other than medical and surgical therapies that could be very useful. Nutritional aspects, i.e., omega-3 fatty acids (omega-3 FAs), could have a prominent place in this scenario, since promising research and evolving clinical experience support the idea that the omega-3 FAs have anti-seizure properties, as well as a possible effect in the prevention of cardiovascular abnormalities and a reduction of SUDEP occurrence¹⁴⁻¹⁶. Thus, a number of considerations could be put forward to explain these findings.

Firstly, we must bear in mind that polyunsaturated FAs are present at high levels in the brain¹⁷. The four polyunsaturated FAs are designated eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA), which are omega-3 FAs; and dihomo-gammalinolenic (DGLA) and arachidonic acids (AA), which are n-6 FAs (omega-6), comprising over 10% (w/w) of the brain dry weight^{17,18}. Fish and fish oil long-chain omega-3 FAs may interfere with certain nervous system diseases¹⁹. Furthermore, a diet rich in fish may be a good way to improve the development of the brain and, undeniably, omega-3 FAs are important for the treatment and prevention of cardiovascular and neurological diseases, including epilepsy^{16,19}.

Concerning epilepsy, Spierer et al. suggested, in 1994, that omega-3 FAs may be used as a prophylactic to prevent febrile seizures in susceptible children²⁰. The authors postulated that since the most important substance mediating the febrile response is interleukin-1 (IL-1), febrile convulsions could be prevented by reducing the concentration of secreted IL-1 and supplementing the diet with omega-3 FAs²⁰. In the same year, Yehuda et al. demonstrated anticonvulsant properties in a mixture of non-esterified alpha-linolenic and linoleic acids with a ratio of 1:4 (SR-3) in four rat models of epileptic seizures²¹. In brief, these authors found that treatment with SR-3 (about 40 mg/kg intra-peritoneal) in a three-week prior to challenge was effective in each experimental model and caused up to a 22-fold increase in latency to major motor seizures, up to 84% reduction in the number of rats with seizures, and up to 97% reduction in the duration of seizures²¹.

Four years later, using the cortical stimulation seizure model in rats, Voskuyil et al.²² demonstrated a long-term modest anticonvulsant effect as a result of the administration of omega-3 FAs. Moreover, pharmacology studies show that omega-3 FAs applied extra-cellularly raise the stimulatory thresholds of CA1 neurons in hippocampal slices²³. In a

clinical study, it was reported on an open trial in which five patients took omega-3 FAs supplements²⁴. In that study, a special spread, containing 65% omega-3 FAs, was added to the daily diet of five patients with epilepsy²⁴. The patients consumed 5 g of this spread at every breakfast for 6 months, and all of them showed a marked reduction in both frequency and strength of epileptic seizures, suggesting that a dietary supplement containing omega-3 FAs may be beneficial for the suppression of some cases of epileptic seizures²⁴.

In the first randomized, placebo-controlled parallel trial of omega-3 FAs supplementation in 57 patients with refractory epilepsy, seizure frequency was reduced over the first 6 weeks of treatment in the supplemented group, however this effect was not sustained over the 12-week total trial²⁵. The authors believe that the loss of effect following the initial six weeks is a result of omega-3 FAs preparations, doses, treatment duration, and sample sizes²⁵. Specifically, the researchers used in their study a total daily dose of approximately 1.7 g omega-3 FAs (approximately 1 g EPA and 0.7 g DHA), but believe that higher doses and different omega-3 FAs ratios should be tested²⁵.

Recently, our research was the first to demonstrate that a chronic treatment with omega-3 FAs promoted neuroprotection and positive plastic changes in the hippocampal formation of rats with epilepsy^{26,27}. In addition, Taha et al. assessed the dose-dependent anticonvulsant effects of a fatty acid mixture with linoleic and alpha-linolenic acids in a 4:1 ratio (the SR-3 compound), and demonstrated that linoleic and alpha-linolenic polyunsaturated FAs in a 4:1 ratio raises omega-3 FAs composition of unesterified FAs in the brain and increases resistance to pentylenetetrazol-induced seizures²⁸. In 2009, we have described the effectiveness of daily intake of a moderate amount of omega-3 FAs in a case of canine epilepsy²⁹. Briefly, a two-year-old female Great Dane with history of idiopathic epilepsy initiated the pharmacological treatment under the supervision of a veterinary neurologist aimed at seizure control²⁹.

A trial therapy with phenobarbital (2.5 mg/kg, twice a day orally) failed to adequately control the seizures: after eight weeks of treatment, there remained two seizure episodes per month²⁹. Typically, potassium bromide is used to supplement phenobarbital in refractory cases. However, in this case, it was decided to supplement the dog's diet with moderate amounts of omega-3 FAs (oral, 2 g/day). The frequency of the epileptic seizures markedly decreased after 50 days of combination therapy with phenobarbital and omega-3 FAs. During the subsequent 18-month period, seizure frequency fell to one per three months, a reduction of about 85%²⁹. In 2012, Yuen et al. evaluated a non-randomized open assessment of EPA supplementation, omega-3 FAs, in ten people with refractory focal seizures³⁰. The authors showed that six people had fewer seizures during the supplementation period compared with baseline, and one other person had markedly

reduced seizure severity, suggesting that although the small number of participants and open nature of the study, interpretation of the results is difficult, but a possible weak effect of EPA on seizures cannot be discounted³⁰.

From these results, we are totally in agreement with the proposal of Taha et al., therefore future clinical trials involving the omega-3 FAs should involve higher doses and longer periods of administration in order to definitively assess their possible anti-seizure effects¹⁶. We also must consider that the data presented so far confirm that omega-3 FAs reduce the frequency of epileptic seizures, promote neuroprotection and establish the safety of omega-3 FAs supplementation in people and animal models of refractory epilepsy^{14,15,26,27,29,31}.

Concerning SUDEP, there is now great interest in omega-3 FAs supplementation for its prevention. As we know, the association between fish consumption and low rates of cardiovascular disease was studied nearly 40 years ago in the seafood diets consumed by Greenland Eskimos, Alaskan Natives, and Japanese people residing in fishing villages³². Actually, several studies have shown that omega-3 FAs have protective effects in preventing coronary heart disease, reducing arrhythmias and thrombosis, lowering plasma triglyceride levels, and reducing blood clotting tendency³³. Furthermore, substantial evidence from epidemiological and case-control studies indicate that omega-3 FAs reduce the risk of cardiovascular mortality, with a potent effect on sudden cardiac death^{34,35}. Thus, considering that omega-3 FAs *per se* are able to minimize cardiac arrhythmias and sudden cardiac deaths^{34,35}, Yuen and Sander³⁶ proposed the interesting hypothesis that omega-3 FAs supplementation in people with refractory epilepsy may not only reduce seizures but also cardiac arrhythmias and hence SUDEP. Four years later,

our research group reinforced this hypothesis³⁷ from two experiments conducted in our laboratory. Firstly, we evaluated the heart rate, *in vivo* (ECG) and isolated *ex vivo* preparation (Langendorf preparation) of rats with epilepsy³⁸. Our results showed significant differences in the mean heart rate *in vivo* between the groups. In contrast, we did not find differences in the isolated *ex vivo* situation, suggesting a central nervous system modulation of the heart, which could explain SUDEP. Secondly, Scorza et al. (unpublished data) performed a similar set of experiments (heart rate *in vivo* and isolated *ex vivo* preparation) of rats with epilepsy before and after chronic omega-3 FAs supplementation. Their results showed differences in the mean heart rate *in vivo*, but surprisingly, none in heart rate could be observed in the isolated *ex vivo* condition.

On the whole, omega-3 FAs consumption improves vascular and cardiac hemodynamics, triglycerides, autonomic control, inflammation, thrombosis, and arrhythmia and reduces risk of cardiac death³⁵. In this context, Brazilian and international guidelines have converged on consistent recommendations for the general population to consume at least 250 mg/day of long-chain omega-3 FAs or at least two servings/week of oily fish³⁵.

Finally, it is very important to emphasize that supplementation with omega-3 FAs for individuals with epilepsy is not a substitute for anticonvulsant medications. Thus, neurologists should recommend fish consumption for their patients, and government and public health agencies should implement strategies to improve attainment of the recommended levels of fish consumption or omega-3 FAs supplementation in order to minimize the frequency of seizures in people with uncontrolled epilepsy and mainly to reduce the occurrence of SUDEP in these individuals.
