In this article, we consider a compound Poisson insurance risk model with a random discount factor. This model is also known as the compound filtered Poisson model. By using some stochastic analysis techniques, a convergence result for the discounted surplus process, an expression for the ruin probability, and the upper bounds for the ruin probability are obtained.

1. INTRODUCTION

Recently, the interplay between actuarial science and finance has attracted much attention. One important question is, “What happens if we consider the investment risk in the insurance risk model?” There are many recent articles in actuarial science literature which tackle this problem. Sundt and Teugels [13] considered a compound Poisson model with a constant interest rate. Renewal-type equations satisfied by the ruin probability, asymptotic expression, and the upper bounds for the ruin probability were obtained. Yang and Zhang [15] extended the work in Sundt and Teugels [13] and considered the joint distribution of the surplus immediately before and after ruin. Yang [14] considered a discrete model with a constant interest rate. By using

martingale inequalities, both exponential and nonexponential bounds were obtained. Paulsen [10] and Norberg [9] used diffusion models with stochastic interest incomes. Paulsen and Gjessing [11] provided some results for a model with stochastic investment incomes. Asmussen [2] summarized some recent works on ruin probability with investment income.

Delbaen and Haezendonck [5] considered the risk theory problems in an economic environment by discounting the value of the surplus from the current (or future) time to the initial time. The present article is in the spirit of Delbaen and Haezendonck [5], but whereas they used a deterministic discount factor, we will use a random discount factor. This is somewhat the same as when we consider the compound Poisson model with a stochastic interest rate. We call the model a filtered compound Poisson model.

This article is organized as follows. Section 2 provides the model and assumptions, Section 3 obtains a convergence result for the discounted surplus process, Section 4 gives an expression for the ruin probability, Section 5 discusses the constant interest force and exponential claim case, Section 6 obtains some upper bounds for the ruin probability, and the last section deals with the case of negative security loading.

2. THE MODEL

The classical risk model can be described as follows:

$$U(t) = u + ct - \sum_{i=1}^{N(t)} X_i, \quad (2.1)$$

where $U(t)$ denotes the surplus at time t , u denotes the initial surplus, c denotes the premium rate in a unit time, X_i denotes the amount of the i th claim, and $N(t)$ denotes the number of claims occurring in the time interval $(0, t]$. It is assumed that $\{N(t); t > 0\}$ is a homogeneous Poisson process with an intensity of λ . It is also assumed that the claim amounts are independent of the claim number process and are positive and mutually independent and identically distributed (i.i.d.) with common distribution function F , where F satisfies $F(0) = 0$. Moreover, we assume that F has a mean p_1 and

$$p_2 = \int_0^{+\infty} x^2 dF(x) < +\infty.$$

We assume that

$$ct = (1 + \theta)\lambda p_1 t = (1 + \theta)E\left(\sum_{i=1}^{N(t)} X_i\right), \quad (2.2)$$

where θ is called security loading. We assume that $\theta > 0$ in the first part (up to Section 6) of this article, and we discuss the case where $\theta \leq 0$ in Section 7.

In the literature, there are many articles dealing with the ruin problems for the classical risk model. However, in the real world, investment income plays a very important role. In this article, we consider the insurance risk model where the interest rate is random. Let T_i denote the i th claim time and let W_t denote the discount factor. The discounted value of total claim amounts occurring in the time interval $(0, t]$ can then be described as

$$S(t) = \sum_{i=1}^{N(t)} X_i W_{T_i}.$$

$S = \{S_t\}$ is called a filtered Poisson process. Using the properties of the filtered Poisson process (see Deng and Liang [6] or Snyder [12]), we have

$$E\left(\sum_{i=1}^{N(t)} X_i W_{T_i} \mid \sigma(W_s : 0 \leq s < t)\right) = \lambda p_1 \int_0^t W_s ds \tag{2.3}$$

$$\text{Var}\left(\sum_{i=1}^{N(t)} X_i W_{T_i} \mid \sigma(W_s : 0 \leq s < t)\right) = \lambda E(X_i^2) \int_0^t W_s^2 ds, \tag{2.4}$$

where $\sigma(W_s : 0 \leq s < t)$ denotes the σ -field generated by $\{W_s : 0 \leq s < t\}$.

Assuming that the interest rate is random (equivalently, the discount factor W_t is random), similar to (2.1), the surplus process of an insurance company can then be described by the following model:

$$U_t^{(W)} = u + (1 + \theta)\lambda p_1 \int_0^t W_s ds - \sum_{i=1}^{N(t)} X_i W_{T_i}, \tag{2.5}$$

where $U_t^{(W)}$ denotes the discounted value of the surplus (discounted from time t to time 0) and all the other notations remain the same as earlier. We call model (2.5) the compound filtered Poisson model.

In this article, we make the following assumptions:

1. $\{W_t\}$, $\{X_i\}$, and $\{N(t)\}$ are mutually independent.
2. $W_0 = 1$, and $W_t > 0$ for all $t > 0$, a.e.

The first assumption is a common one in actuarial science. Although, recently, there have been some works on the dependent risk in the actuarial literature, we do not consider this issue here. The second assumption states that the interest rate cannot be positive infinity. Our model here is very general. In practice, we usually assume that the interest rate is nonnegative at any time. This corresponds to $W_t > 0$ and W_t is nonincreasing for all $t > 0$.

3. CONVERGENCE OF $U_t^{(W)}$

In this section, we will prove a convergence result. This convergence result will then be used in later sections to prove some useful results in the insurance risk theory. In this section, we assume that the discount factor W_t satisfies the following assumption:

$$E\left(\int_0^{+\infty} W_s ds\right) = \frac{1}{\gamma_1} < +\infty. \tag{3.1}$$

Under the above assumption, we have the following result.

THEOREM 1: *Under assumption (3.1), there exists an integrable random variable $U_\infty^{(W)}$ such that*

$$\lim_{t \rightarrow +\infty} U_t^{(W)} \stackrel{\text{a.e.}}{=} U_\infty^{(W)} \tag{3.2}$$

and

$$E(U_\infty^{(W)}) = \frac{\theta \lambda p_1}{\gamma_1} + u, \tag{3.3}$$

where a.e. means almost everywhere with respect to probability measure P . Moreover, the characteristic function of $U_\infty^{(W)}$ is given by

$$E(e^{ixU_\infty^{(W)}}) = E\left[\exp\left\{ix\left(u + \lambda p_1 \theta \int_0^{+\infty} W_s ds\right) - \frac{1}{2} x^2 \lambda p_2 \int_0^{+\infty} W_s^2 ds + \lambda \int_0^{+\infty} \int_0^{xW_t} (xW_t - s) E[X^2(1 - e^{-isX})] ds dt\right\}\right].$$

PROOF: Let

$$M_t = \lambda p_1 t - \sum_{i=1}^{N(t)} X_i. \tag{3.4}$$

Then, M_t is a martingale with a mean of zero, and M_t is independent of the discount factor W_t . Using this notation, the discounted surplus can be rewritten as

$$U_t^{(W)} = u + \theta \lambda p_1 \int_0^t W_s ds + H_t, \tag{3.5}$$

where $H_t = \int_0^t W_s dM_s$ is also a martingale with a mean of zero.

First, we will prove the convergence of $\int_0^t W_s ds$. Since W_s is nonnegative for all $s \geq 0$, the monotone convergence theorem implies

$$\int_0^t W_s ds \uparrow \int_0^{+\infty} W_s ds$$

because

$$E\left[\int_0^{+\infty} W_s ds\right] = \frac{1}{\gamma_1}.$$

The random variable $\int_0^\infty W_s ds$ is $P -$ a.s. finite, which proves the convergence of $\int_0^t W_s ds$. Next, we will prove the convergence of H_t . Note that $\{H_t\}$ is an L_2 -bounded martingale; the result follows from a standard result. Therefore, there exists a finite random variable H_∞ such that

$$\lim_{t \rightarrow \infty} H_t \stackrel{\text{a.e.}}{=} H_\infty \quad \text{and} \quad EH_\infty = EH_0 = 0.$$

From the above results, we see that there exists a finite random variable $U_\infty^{(W)}$ such that

$$\lim_{t \rightarrow +\infty} U_t^{(W)} \stackrel{\text{a.e.}}{=} U_\infty^{(W)} \quad \text{and} \quad E(U_\infty^{(W)}) = \frac{\theta \lambda p_1}{\gamma_1} + u.$$

The characteristic function of $U_\infty^{(W)}$ is obtained by straightforward calculation. ■

Remark 1: It is well known that for the classical compound Poisson model, if $\theta > 0$, the surplus process will move toward $+\infty$ with a probability 1 as the time $t \rightarrow \infty$. This means that in the classical compound Poisson model, if we let the surplus process continue even when the ruin occurs, the surplus process will eventually become very large (tend to infinity with probability 1 as time tends to infinity). See Dassios and Embrechts [4], for further detailed discussions on this issue. Theorem 1 tells us that if we include the interest effect in the model, this is not the case.

4. AN EXPRESSION OF RUIN PROBABILITY

Ruin probability has been one of the most important research topics for almost a century, ever since the pioneering work of Lundberg [7,8]. Elegant mathematics has been developed on this topic.

In this section, we will use the result of Theorem 1 to give an expression for the ruin probability. Let $T^{(u)} = \inf\{t; U_t^{(W)} < 0\}$ and $\psi(u)$ denote the ruin probability of model (2.5). Then,

$$\psi(u) = P\{T^{(u)} < \infty | U^{(W)}(0) = u\}. \tag{4.1}$$

Let $U_t = (1 + \theta)\lambda p_1 t - \sum_{i=1}^{N(t)} X_i$; then,

$$U_t^{(W)} = u + \int_0^t W_s dU_s.$$

Let

$$V_t^{(W)} = W_t^{-1} \int_t^{+\infty} W_s dU_s;$$

then,

$$U_\infty^{(W)} = U_t^{(W)} + W_t V_t^{(W)}. \quad (4.2)$$

Notice that U_t has stationary and independent increments and that it is independent of W_t . If we assume

$$-\ln(W_t) \text{ has stationary and independent increments,} \quad (*)$$

then we can obtain that

$$V_t^{(W)} = \int_0^{+\infty} \widetilde{W}_s d\widetilde{U}_s \stackrel{d}{=} U_\infty^{(W)} - u, \quad (4.3)$$

where

$$\widetilde{W}_s = \frac{W_{t+s}}{W_t} \stackrel{d}{=} W_s, \quad \widetilde{U}_s = U_{t+s} - U_t \stackrel{d}{=} U_s.$$

Remark 2: Because we do not require that W_t be nonincreasing in this article, any Levy processes will satisfy assumption (*).

LEMMA 1: *The process $\{U_t^{(W)}\}$, condition on $\sigma(W_s: 0 \leq s < t)$, has an independent increment, and under assumption (*),*

$$[(U_{t+s}^{(W)} - U_s^{(W)}) | \sigma(W_v: 0 \leq v < s)] \stackrel{d}{=} (U_t^{(W)} - u) W_s, \quad (4.4)$$

where $\stackrel{d}{=}$ means that both the left-hand side and the right-hand side of (4.4) have the same distribution.

PROOF: For $t > s > 0$,

$$\begin{aligned} U_t^{(W)} - U_s^{(W)} &= (1 + \theta)\lambda p_1 \int_s^t W_v dv - \sum_{i=N(s)+1}^{N(t)} X_i W_{T_i} \\ &= (1 + \theta)\lambda p_1 \int_s^t W_s \frac{W_v}{W_s} dv - \sum_{i=N(s)+1}^{N(t)} X_i W_s \frac{W_{T_i}}{W_s} \\ &= W_s \left[\int_s^t \frac{W_v}{W_s} d \left((1 + \theta)\lambda p_1 v - \sum_{i=N(s)+1}^{N(v)} X_i \right) \right]. \end{aligned}$$

Notice that $\{W_t\}$ is independent of $\{N(t): t \geq 0\}$ and $\{X_i: i = 1, 2, \dots\}$, so $(1 + \theta)\lambda p_1 v - \sum_{i=N(s)+1}^{N(v)} X_i$ has independent increments and is independent of W_s . Therefore, this lemma holds. \blacksquare

From the above results, we have the following theorem.

THEOREM 2: *Under assumption (*), let $F_\infty(x)$ be the distribution function of $U_\infty^{(W)} - u$. Then,*

$$\psi(u) = \frac{F_\infty(-u)}{E(F_\infty(-W_{T^{(u)}}^{-1} U_{T^{(u)}}^{(W)} | T^{(u)} < \infty))}. \quad (4.5)$$

PROOF:

$$\begin{aligned} F_\infty(-u) &= P(U_\infty^{(W)} < 0) = P(U_\infty^{(W)} < 0, T^{(u)} < \infty) \\ &= P\{U_{T^{(u)}}^{(W)} + W_{T^{(u)}} V_{T^{(u)}}^{(W)} < 0; T^{(u)} < \infty\} \\ &= P\{W_{T^{(u)}}^{-1} U_{T^{(u)}}^{(W)} + V_{T^{(u)}}^{(W)} < 0, T^{(u)} < \infty\} \\ &= P\{V_{T^{(u)}}^{(W)} < -W_{T^{(u)}}^{-1} U_{T^{(u)}}^{(W)}, T^{(u)} < \infty\} \\ &= \int_0^\infty P\{V_{T^{(u)}}^{(W)} < -W_{T^{(u)}}^{-1} U_{T^{(u)}}^{(W)} | T^{(u)} = t\} P^{T^{(u)}} dt \\ &= \int_0^\infty P\{U_\infty^{(W)} - u < -W_t^{-1} U_t^{(W)}\} P^{T^{(u)}} dt \\ &= \int_0^\infty F_\infty(-W_t^{-1} U_t^{(W)}) P^{T^{(u)}} dt = E[F_\infty(-W_{T^{(u)}}^{-1} U_{T^{(u)}}^{(W)}) I_{\{T^{(u)} < \infty\}}] \\ &= E[F_\infty(-W_{T^{(u)}}^{-1} U_{T^{(u)}}^{(W)}) | T^{(u)} < \infty] P(T^{(u)} < \infty) \\ &= E[F_\infty(-W_{T^{(u)}}^{-1} U_{T^{(u)}}^{(W)}) | T^{(u)} < \infty] \psi(u). \end{aligned}$$

Here, we have used the notation $V_t^{(W)} \stackrel{d}{=} U_\infty^{(W)} - u$. From this, the result is proved. ■

We say that a distribution function $F(x)$ is a new worse than used (NWU) distribution if $F(x)$ is a distribution function (d.f.) of a nonnegative random variable and $\bar{F}(x) = 1 - F(x)$ satisfies that $\bar{F}(x)\bar{F}(y) \leq \bar{F}(x+y)$ for $x \geq 0$ and $y \geq 0$. We say that a distribution function $F(x)$ is a new better than used (NBU) distribution if $F(x)$ is a d.f. of a nonnegative random variable and satisfies that $\bar{F}(x)\bar{F}(y) \geq \bar{F}(x+y)$ for $x \geq 0$ and $y \geq 0$.

PROPOSITION 1: *Under assumptions (3.1) and (*), we have the following:*

1. *If X_i 's distribution function is NWU, then, in this case, we have that*

$$\psi(u) \leq \frac{F_\infty(-u)}{E(F_\infty(X_i))}. \quad (4.6)$$

2. If X_i 's distribution function is NBU, then, in this case, we have

$$\psi(u) \geq \frac{F_\infty(-u)}{E(F_\infty(X_i))}. \tag{4.7}$$

3. If X_i 's distribution function is exponential, then, in this case, we have

$$\psi(u) = \frac{F_\infty(-u)}{E(F_\infty(X_i))}. \tag{4.8}$$

PROOF: We only give the proof for part 1 because part 2 can be proved by the same method, and part 3 can be obtained from parts 1 and 2 because the exponential distribution is both NWU and NBU.

$$\begin{aligned} &P\{U_\infty^{(W)} - u < -W_{T^{(u)}}^{-1} U_{T^{(u)}}^{(W)} | T^{(u)} < \infty\} \\ &= P\{U_\infty^{(W)} - u < -W_{T^{(u)-}}^{-1} U_{T^{(u)-}}^{(W)} + X_i | X_i > W_{T^{(u)-}}^{-1} U_{T^{(u)-}}^{(W)}\} \\ &= P\{X_i > U_\infty^{(W)} - u + W_{T^{(u)-}}^{-1} U_{T^{(u)-}}^{(W)} | X_i > W_{T^{(u)-}}^{-1} U_{T^{(u)-}}^{(W)}\}, \end{aligned}$$

where $T^{(u)-}$ means the time just before ruin.

When $U_\infty^{(W)} - u > 0$, we can get from the distribution of X_i is NBU, that the above probability is less than $P\{X_i > U_\infty^{(W)} - u\}$ —that is, the value $E(F_\infty(X_i))$. When $U_\infty^{(W)} - u < 0$, the above probability is 1 and the value $P\{X_i > U_\infty^{(W)} - u\}$ also equals one.

After all, when the distribution of X_i is NBU, we have

$$P\{U_\infty^{(W)} - u < -W_{T^{(u)}}^{-1} U_{T^{(u)}}^{(W)} | T^{(u)} < \infty\} \leq E(F_\infty(X_i)),$$

so we can get part 1. ■

Remark 3:

1. When $F_\infty(0) > 0$, we have

$$F_\infty(-u) \leq \psi(u) \leq \frac{F_\infty(-u)}{F_\infty(0)}. \tag{4.9}$$

2. From the expression

$$F_\infty(-u) = P\{U_\infty^{(W)} - u \leq -u\} = P\{U_\infty^{(W)} \leq 0\},$$

we can say that $F_\infty(-u)$ is just the probability of ruin for good (i.e., the probability of the surplus tends to negative infinity).

3. It is interesting that the ruin probability can be determined by the limit distribution of the discounted surplus process. Theorem 2 indicates the relationship between the ruin probability and the limit distribution of the discounted surplus process.

5. CONSTANT DISCOUNT RATE AND EXPONENTIAL CLAIM SIZE

We consider a special case in which the discount rate is a constant δ and the claim size is an exponentially distributed random variable. This case was treated in Sundt and Teugels [13]. We will obtain this result as a special case of our results in the previous sections. In this section, we will assume that $W_t = e^{-\delta t}$ and X_i is exponentially distributed with a mean of p_1 . We will first give Lemma 2.

LEMMA 2: *The discounted value of all of the claim amounts occurring in the time interval $(0, t]$, $S(t) = \sum_{i=1}^{N(t)} X_i e^{-\delta T_i}$, converges to a random variable $S(+\infty)$. Furthermore, $S(+\infty)$ has a gamma distribution with parameters $(\lambda/\delta, p_1^{-1})$.*

PROOF: According to the properties of the filtered Poisson process, we can derive the characteristic function of $S(t)$ by (see Snyder [12])

$$E(e^{i\tau S(t)}) = \exp\left[\lambda \int_0^t E(e^{i\tau X_i \exp(-\delta s)} - 1) ds\right] = \exp\left(\lambda \int_0^t \frac{i\tau e^{-\delta s}}{p_1^{-1} - i\tau e^{-\delta s}} ds\right).$$

Let $t \rightarrow +\infty$; then,

$$\begin{aligned} \lambda \int_0^{+\infty} \frac{i\tau e^{-\delta s}}{p_1^{-1} - i\tau e^{-\delta s}} ds &= \frac{\lambda}{\delta} \int_0^\tau \frac{i dy}{p_1^{-1} - iy} \\ &= \frac{\lambda}{\delta} [\ln(p_1^{-1}) - \ln(p_1^{-1} - i\tau)] = \frac{\lambda}{\delta} \ln\left(\frac{p_1^{-1}}{p_1^{-1} - i\tau}\right). \end{aligned}$$

The characteristic function of $S(+\infty)$ is then

$$E(e^{i\tau S(+\infty)}) = \left(\frac{p_1^{-1}}{p_1^{-1} - i\tau}\right)^{\lambda/\delta}.$$

This is the characteristic function of a gamma-distributed random variable with parameters $(\lambda/\delta, p_1^{-1})$. Therefore, the lemma holds. ■

As explained in Remark 4, part 2 that follows, the following theorem gives the same result as that in Sundt and Teugels [13].

THEOREM 3: *Under the assumptions in this section, the ruin probability $\psi(u)$ of model (2.5) has the following expression:*

$$\psi(u) = \frac{1 - F_{\Gamma(\lambda\delta^{-1}, p_1^{-1})}\left(u + \frac{(1 + \theta)\lambda}{\delta p_1^{-1}}\right)}{1 - E\left\{F_{\Gamma(\lambda\delta^{-1}, p_1^{-1})}\left(\frac{(1 + \theta)\lambda}{\delta p_1^{-1}} - X_i\right)\right\}}, \tag{5.1}$$

where $F_{\Gamma(\lambda\delta^{-1}, p_1^{-1})}(\cdot)$ denotes the distribution function of the Γ random variable with the parameters $(\lambda\delta^{-1}, p_1^{-1})$.

PROOF: Under the assumptions in this section, model (2.5) becomes

$$U_t^{(W)} = u + \frac{1 + \theta}{\delta} \lambda p_1 (1 - \exp(-\delta t)) - \sum_{i=1}^{N(t)} X_i e^{-\delta T_i}.$$

From Lemma 2, we know that

$$\sum_{i=1}^{N(t)} X_i e^{-\delta T_i} \xrightarrow[t \rightarrow \infty]{\text{a.e.}} S(+\infty),$$

where $S(+\infty)$ is gamma-distributed with the parameters $(\lambda/\delta, p_1^{-1})$, (i.e., $u + [(1 + \theta)/\delta] p_1 \lambda - U_t^{(W)}$ converges to a Γ random variable with the parameters $(\lambda/\delta, p_1^{-1})$). Then, using Theorem 2, the result is proved. ■

Remark 4:

1. Notice that

$$\begin{aligned} & 1 - E \left\{ F_{\Gamma} \left(\frac{\lambda}{\delta}, \frac{1}{p_1} \right) \left(\frac{1 + \theta}{\delta} \lambda p_1 - X_i \right) \right\} \\ &= 1 - \int_0^{[(1+\theta)/\delta] \lambda p_1} \frac{1}{p_1} e^{-y/p_1} \\ & \quad \times \int_0^{[(1+\theta)/\delta] \lambda p_1 - y} \frac{\left(\frac{1}{p_1} \right)^{\lambda/\delta}}{\Gamma \left(\frac{\lambda}{\delta} \right)} e^{-(x/p_1)} x^{(\lambda/\delta)-1} dx dy \\ &= \int_{[(1+\theta)/\delta] \lambda p_1}^{\infty} \frac{\left(\frac{1}{p_1} \right)^{\lambda/\delta}}{\Gamma \left(\frac{\lambda}{\delta} \right)} e^{-(x/p_1)} x^{(\lambda/\delta)-1} dx + e^{-[(1+\theta)/\delta]} \\ & \quad \times \frac{\delta}{\lambda} \left(\frac{(1 + \theta) \lambda p_1}{\delta} \right)^{\lambda/\delta} \frac{\left(\frac{1}{p_1} \right)^{\lambda/\delta}}{\Gamma \left(\frac{\lambda}{\delta} \right)} \end{aligned}$$

Therefore, the result in Theorem 3 is the same as that in Sundt and Teugels [13].

2. The result in Theorem 3 was obtained in Sundt and Teugels [13] by solving the associated renewal equation. We have obtained the result here by using the limit distribution of the surplus process. Therefore, we have, in fact, provided more information than in Sundt and Teugels [13]; that is, we have also proved that the limit distribution of the discounted surplus process is a gamma distribution.

6. UPPER BOUNDS FOR RUIN PROBABILITY

In this section, we will derive the upper bounds for ruin probability. The main results are given in the following two theorems. The techniques used in the proof are similar to those in Yang [14].

THEOREM 4: *Suppose that $G(\cdot)$ is a nonnegative measurable function, $U_t^{(W)}$ is the discounted surplus of the insurance company at time t , and $G(U_t^{(W)})$ is a supermartingale with respect to σ -field $\mathcal{F}_t \supset \sigma(U_s^{(W)} | 0 \leq s < t)$. Then,*

$$\psi(u) \leq \frac{G(u)}{E(G(U_{T^{(u)}}^{(W)}) | T^{(u)} < \infty)}. \tag{6.1}$$

If $\lim_{t \rightarrow \infty} E(G(U_t^{(W)}) | T^{(u)} > t) = 0$ and $G(U_t^{(W)})$ is an \mathcal{F}_t martingale, then

$$\psi(u) = \frac{G(u)}{E(G(U_{T^{(u)}}^{(W)}) | T^{(u)} < \infty)}, \tag{6.2}$$

where $T^{(u)}$ is the same as earlier.

PROOF: $T^{(u)}$ is an \mathcal{F}_t stopping time. For $\forall t > 0$, $T^{(u)} \wedge t$ is a bound \mathcal{F}_t stopping time. Using Doob's bounded stopping time theorem, we have

$$\begin{aligned} G(u) &= E(G(U_0^{(W)})) \geq E(G(U_{T^{(u)} \wedge t}^{(W)})) \\ &= E(G(U_{T^{(u)}}^{(W)}) | T^{(u)} < t) \cdot P\{T^{(u)} < t\} + E(G(U_{T^{(u)}}^{(W)}) | T^{(u)} \geq t) \cdot P\{T^{(u)} \geq t\}. \end{aligned}$$

Let $t \rightarrow +\infty$; by the positive of $G(\cdot)$, we have

$$G(u) \geq E(G(U_{T^{(u)}}^{(W)}) | T^{(u)} < \infty) \psi(u).$$

Therefore, (6.1) holds.

Moreover, if $\lim_{t \rightarrow +\infty} E(G(U_{T^{(u)}}^{(W)}) | T^{(u)} > t) = 0$ and $G(U_t^{(W)})$ is an \mathcal{F}_t martingale, then (6.2) also holds. ■

THEOREM 5: *If, for all $t \geq 0$, $0 < W_t < 1$ a.e., assume that there exists $R > 0$ such that*

$$E(e^{RX_i} - 1) = R(1 + \theta)E(X_i) = R(1 + \theta)p_1.$$

Then,

$$\psi(u) \leq \frac{\exp(-Ru)}{E(\exp(-RU_{T^{(u)}}^{(W)}) | T^{(u)} < \infty)} \leq e^{-Ru}. \tag{6.3}$$

PROOF: For all $x \in (0, 1]$, $y > 0$,

$$\sum_{n=1}^{\infty} \frac{(xy)^n}{n!} \leq \sum_{n=1}^{\infty} \frac{x(y)^n}{n!}$$

holds; that is,

$$e^{xy} - 1 \leq x(e^y - 1).$$

Let $h(r) = E(e^{rX_i} - 1)$. Because for all $t > 0$, $0 < W_t < 1$ a.e, we then have

$$h(RW_s) \leq W_s h(R).$$

Let

$$N_t = \exp \left\{ R \sum_{i=1}^{N(t)} X_i W_{T_i} - R(1 + \theta)p_1 \lambda \int_0^t W_s ds - Ru \right\}$$

and

$$\mathcal{F}'_t = \sigma(N_s : s \leq t) \vee \sigma(W_\tau : \tau > 0).$$

Using a similar argument as that in Deng and Liang [6, pp. 329–332] (also see Snyder [12]) and after some calculations, we obtain

$$E \left[\exp \left\{ R \sum_{i=N(s)+1}^{N(t)} X_i W_{T_i} \right\} \middle| \sigma(W_\tau : \tau \geq 0) \right] = \exp \left(\lambda \int_s^t h(RW_\tau) d\tau \right),$$

so

$$\begin{aligned} E(N_t | \mathcal{F}'_s) &= N_s E \left[\exp \left(R \sum_{i=N(s)+1}^{N(t)} X_i W_{T_i} - R(1 + \theta)p_1 \lambda \int_s^t W_\tau d\tau \right) \middle| \mathcal{F}'_s \right] \\ &= N_s \exp \left(\lambda \int_s^t h(RW_\tau) d\tau - R(1 + \theta)p_1 \lambda \int_s^t W_\tau d\tau \right) \\ &\leq N_s \exp \left(\lambda \int_s^t W_\tau h(R) d\tau - R(1 + \theta)p_1 \lambda \int_s^t W_\tau d\tau \right) \\ &= N_s. \end{aligned} \tag{6.4}$$

Therefore, N_t is an \mathcal{F}'_t supermartingale. From Theorem 4, we have

$$\psi(u) \leq \frac{\exp(-Ru)}{E(\exp(-RU_{T^{(u)}}^{(W)}) | T^{(u)} < \infty)},$$

where $R > 0$ and $U_{T^{(u)}}^{(W)} < 0$. Note that $E[\exp(-RU_{T^{(u)}}^{(W)}) | T^{(u)} < \infty] > 1$. Therefore, the result of the theorem holds. ■

7. UPPER BOUNDS FOR RUIN PROBABILITY IN THE CASE OF NEGATIVE LOADING

It is well known that, in the classical model, if the loading is negative, the ruin becomes certain. We will show below that this is not the case in the model with stochastic interest rate. We first introduce the following sets:

$$D = \{r > 0 : E[\exp\{rX_1\}] < +\infty\}, \quad (7.1)$$

$$D_t = \left\{ r > 0 : \int_0^t [E\{\exp(rW_s X_1)\} - 1] ds < +\infty \right\} \quad \text{for } 0 < t \leq +\infty. \quad (7.2)$$

From the definition, we can easily see that D is an interval of the form $(0, \bar{r})$ or $(0, \bar{r}]$. It is not difficult to see that for $0 < t < \infty$, we have $D_t = D$ if $D = (0, \bar{r}]$, and if $D = (0, \bar{r})$ with $\bar{r} < \infty$, then $D_t = (0, \bar{r})$ or $(0, \bar{r}]$. Furthermore, if $0 < t$ and $u < \infty$, then $D_t = D_u$.

It is not difficult to prove that the assumption $E[\int_0^{+\infty} W_s ds] = 1/\gamma_1$ implies that $D_\infty = D_t$.

The following theorem provides us with an upper bound for ruin probability in the case of negative safety loading.

THEOREM 6: *Assume that the safety loading $\theta \leq 0$ and $0 < t < \infty$. Then, we have the following results:*

$$P(T \leq t) \leq \inf_{r \geq 0} \exp \left\{ \lambda \int_0^t E[\exp\{rW_s X_1\} - 1 - (1 + \theta)rW_s X_1] ds - ru \right\}, \quad (7.3)$$

$$P(T < \infty) \leq \inf_{r \geq 0} \exp \left\{ \lambda \int_0^\infty E[\exp\{rW_s X_1\} - 1 - (1 + \theta)rW_s X_1] ds - ru \right\}. \quad (7.4)$$

PROOF: For $r \in D_t$, let $h(r) = E[\exp(rX_1)] - 1$ and define

$$\begin{aligned} M_t &= \exp \left\{ r \sum_{i=1}^{N(t)} W_{T_i} X_i - \lambda \int_0^t h(rW_s) ds \right\} \\ &= \exp \left\{ r \sum_{i=1}^{N(t)} W_{T_i} X_i + \lambda t - \lambda \int_0^t E[\exp\{rW_s X_1\}] ds \right\}. \end{aligned} \quad (7.5)$$

With the same arguments as in the proof of Theorem 5, it is not difficult to check that M_t is a martingale with respect to \mathcal{F}_t , where

$$\mathcal{F}_t = \sigma\{M_s : s \leq t\} \vee \sigma\{W_\tau : \tau \geq 0\}.$$

Applying Doob's bounded stopping time theorem to the martingale $\{M_t : t \in R_+\}$ for the stopping time $T \wedge t$, $0 < t < \infty$, we have

$$\begin{aligned} 1 &= E[M_0] = E[M_{T \wedge t}] \geq E[M_T I_{\{T \leq t\}}] \\ &= E \left[\exp \left\{ r \sum_{i=1}^{N(T)} W_{T_i} X_i + \lambda T - \lambda \int_0^T E[\exp\{rW_s X_1\}] ds \right\} I_{\{T \leq t\}} \right] \\ &\geq E \left[\exp \left\{ ru - \lambda \int_0^T E[\exp\{rW_s X_1\} - 1 - (1 + \theta)rW_s X_1] ds \right\} I_{\{T \leq t\}} \right] \\ &\geq \exp \left\{ ru - \sup_{0 \leq s \leq t} \lambda \int_0^s E[\exp\{rW_v X_1\} - 1 - (1 + \theta)rW_v X_1] dv \right\} P(T \leq t), \end{aligned}$$

where $I_{\{A\}}$ denotes the indicator function of set A , and we have used the fact that, at the ruin time T , $\sum_{i=1}^{N(t)} W_{T_i} X_i > u + (1 + \theta)\lambda p_1 \int_0^T W_s ds$.

Hence, if $r \geq 0$,

$$P(T \leq t) \leq \sup_{0 \leq s \leq t} \exp \left\{ \lambda \int_0^s E[\exp\{rW_v X_1\} - 1 - (1 + \theta)rW_v X_1] dv - ru \right\}.$$

Therefore,

$$P(T \leq t) \leq \inf_{r \geq 0} \sup_{0 \leq s \leq t} \exp \left\{ \lambda \int_0^s E[\exp\{rW_v X_1\} - 1 - (1 + \theta)rW_v X_1] dv - ru \right\}. \tag{7.6}$$

From the inequality $e^x - 1 \geq x$, $\theta \leq 0$, and that W_s and X_1 are positive random variables, we have that

$$E[\exp\{rW_s X_1\} - 1 - (1 + \theta)rW_s X_1] \geq 0. \tag{7.7}$$

Hence, (7.6) can be rewritten as

$$P(T \leq t) \leq \inf_{r \geq 0} \exp \left\{ \lambda \int_0^t E[\exp\{rW_s X_1\} - 1 - (1 + \theta)rW_s X_1] ds - ru \right\}. \tag{7.8}$$

From this, the theorem follows. ■

Notice that the upper bounds in theorem 6 only make sense if the right-hand sides of (7.6) and (7.7) are smaller than one. We will address this problem now.

For $0 < t \leq \infty$, let

$$g_t(r) = \lambda \int_0^t E[\exp\{rW_s X_1\} - 1 - (1 + \theta)rW_s X_1] ds - ru, \tag{7.9}$$

$$\Phi_t(r) = \exp\{g_t(r)\}. \tag{7.10}$$

PROPOSITION 2: *Suppose that $0 < t \leq \infty$ and the safety loading $\theta \leq 0$. $\Phi_t(r)$ is then a convex mapping on R_+ and is finite on D_t .*

PROOF: Similar to Lemma 4.5 of Delbaen and Haezendonck [5], we can prove the following:

If

$$\frac{d^-}{dr} \Phi_t(r) \neq \frac{d^+}{dr} \Phi_t(r),$$

then

$$\frac{d^-}{dr} \Phi_t(r) < \frac{d^+}{dr} \Phi_t(r).$$

If

$$\frac{d^-}{dr} \Phi_t(r) = \frac{d^+}{dr} \Phi_t(r),$$

then

$$\frac{d^2}{dr^2} \Phi_t(r) > 0.$$

From this, it follows that $\Phi_t(r)$ is a convex mapping on R_+ . It is obvious that $\Phi_t(r)$ is finite on D_t .

The above analysis indicates that $\inf_{r \geq 0} \Phi_t(r) < 1$ if the right derivative of $\Phi_t(r)$ at $r = 0$ is strictly negative. However,

$$\begin{aligned} \frac{d^+}{dr} \Phi_t(0) &= \left(\lambda \int_0^t E[W_s X_1 [\exp(rW_s X_1) - (1 + \theta)]] ds - u \right) \exp\{g_t(r)\}|_{r=0} \\ &= -\lambda\theta \int_0^t E(W_s X_1) ds - u = -\lambda\theta p_1 \int_0^t E(W_s) ds - u, \end{aligned}$$

where the last equality holds because X_1 and W_s are independent. This leads to the following proposition.

PROPOSITION 3: *If $0 < t < \infty$ and*

$$0 \geq \theta > -\frac{u}{\lambda p_1 \int_0^t E(W_s) ds}, \tag{7.11}$$

there exists a real number $r_t > 0$ such that

$$P(T < t) \leq \Phi_t(r_t) = \inf_{r \geq 0} \Phi_t(r) < 1. \tag{7.12}$$

Furthermore, if

$$0 \geq \theta > -\frac{u}{\lambda p_1 \int_0^\infty E(W_s) ds}, \tag{7.13}$$

there exists a real number $r_\infty > 0$, such that

$$P(T < \infty) \leq \Phi_\infty(r_\infty) = \inf_{r \geq 0} \Phi_\infty(r) < 1. \tag{7.14}$$

We conclude this section by giving two special cases. First, we consider the classical compound Poisson model ($W_s = 1$). In this case, if the risk loading θ is negative, the ultimate ruin probability will be one. The upper bound for the ruin probability at a finite time, say before time t , is nontrivial if

$$t < -\frac{u}{\lambda p_1 \theta} \quad \text{and} \quad \theta \leq 0.$$

The second case is the situation with a constant interest force. In this case, $W_s = e^{-\delta s}$. A detailed discussion on this case can be found in Boogaert and Crijins [3].

Acknowledgments

The authors would like to thank Professor Elias Shiu for pointing out an error and some problems with the model in the earlier version of this article. This work was supported by grants from Research Grants Council of HKSAR (project no. HKU 7139/01H).
