18 Sir,

19

The worldwide dissemination of bacteria producing New Delhi metallo-β-lactamase (NDM)is a major public health issue.¹ Since NDM producers are primarily found among individuals
with history of hospitalization or travel to the India subcontinent, many hospitals have
implemented microbiological screening of patients with such an epidemiological history.^{1,2}

24 In mid-2011, the stool sample of a one year-old infant was found to have CRE upon 25 admission screening. The infant was admitted because of cough and intermittent fever in the 26 preceding two weeks. The family had travelled to and stayed in Hunan province, China in the 27 preceding month. Following onset of the symptoms, the infant had been admitted to a 28 hospital in Hunan for 3 days. Patient was given a diagnosis of broncholitis and had been 29 treated with a course of intravenous cefoperazone. At presentation to our hospital, patient had 30 fever of 38 °C. Chest examination was unremarkable. Patient was treated conservatively and 31 the fever resolved without further antibiotic treatment. Patient was discharged 2 days later. In 32 accordance with the screening policy, stool samples were obtained for surveillance culture.

33 In brief, a red-bean size faecal pellet was suspended in saline. A 10 µL aliquot of the 34 suspension was then removed and plated directly onto one ChromID ESBL plate. In addition, 35 a broth enrichment step was performed by inoculating another 10 μ L aliquot of the faecal 36 suspension into nutrient broth with 1 mg/L meropenem, incubated at 37 °C overnight, and 37 then subcultured onto MacConkey plate with 1 mg/L meropenem. All plates were incubated 38 at 37 °C in air for 20 h. All distinct colony types recovered from either the chromogenic or 39 the MacConkey media were investigated for evidence of carbapenemase activity using the combined disc method and boronic acid or EDTA as inhibitor.³ All isolates were identified 40 41 using VITEK 2 and antimicrobial susceptibility was determined by the CLSI disc diffusion method.4 42

43 After the patient's stool samples were found to carry CRE. Stool samples from the 44 infant's parents and other family members were also cultured using the same methodology. A 45 total of four CRE isolates were recovered from the faecal samples of the child and her mother 46 (Table 1). Cultures of the faecal samples from the other household members (father, 47 grandfather, grandmother and aunt) were negative. All four isolates (two Escherichia coli, 48 one *Klebsiella pneumoniae* and one *Enterobacter aerogenes*) exhibited synergy with EDTA 49 in the combined disc testing. No synergy with boronic acid was observed. PCR and 50 sequencing, using previously described methods confirmed presence of NDM-1 in the four CRE isolates.² Additional β-lactamases including other metallo-β-lactamases (IMP, VIM, 51 52 GIM, SPM, SIM), CTX-M and OXA-48-like genes were also sought by PCR and sequencing.⁵ This allowed identification of an additional extended-spectrum β-lactamase 53 54 (ESBL) gene in the K. pneumoniae (CTX-M-65) and the two E. coli (CTX-M-57) isolates. 55 Next, we studied the relationship between the two *E. coli* isolates by PFGE after digestion of 56 their genomic DNAs with XbaI. The two isolates shared the same PFGE banding pattern, 57 indicating that the two isolates were clonally related. Multilocus sequence typing showed that 58 the two E. coli strains and the K. pneumoniae strain belonged to ST744 and ST483, 59 respectively. S1-PFGE demonstrated that the strains had one to three plasmids with sizes of 60 50-90 kb. Hybridization demonstrated that *bla*_{NDM-1} gene was harboured on the 50 kb plasmid in all the strains. In conjugation experiments,² the 50 kb *bla*_{NDM-1} harbouring plasmid could 61 be transferred to J53 E. coli recipient at high frequencies (up to 10^{-1} per donor cell). In the 62 63 transconjugants, there was no co-transfer of resistance to the non-\beta-lactam antibiotics 64 (amikacin, ciprofloxacin, chloramphenicol, fosfomycin, nalidixic acid, sulphonamides, 65 tetracycline and trimethoprim). Transconjugants with the bla_{NDM-1} harbouring plasmid as the only plasmid was investigated by PCR-based replicon typing and *bla*_{CTX-M} PCR. The finding 66

67 showed that the 50 kb plasmid belonged to an untypeable replicon type and was $bla_{\text{CTX-M}}$ 68 negative.

69 Members of this family had no history of travel to the Indian subcontinent. The index 70 patient is the only one with a history of hospitalization. Therefore, the infant has mostly 71 likely acquired the *bla*_{NDM-1} gene during the hospitalization in Hunan province. This indicates that some hospitals in mainland China could be reservoirs of the bla_{NDM-1} gene,⁶ which may 72 73 or may not initially have reached there from the Indian subcontinent. While both the infant 74 and her mother shared the same E. coli strain, it is impossible to tell if there was intra-familial 75 transmission as opposed to the mother and the infant both becoming colonized while in 76 hospital. In China, the burden of CTX-M-producing Enterobacteriaceae is tremendous. 77 Therefore, accumulation of NDM-1 in multiple CTX-M-producing Enterobacteriaceae species is worrying.¹ In conclusion, this report shows the spread of NDM-1 among persons 78 79 with no established links to the Indian subcontinent and demonstrates the usefulness of 80 admission screening for early identification of NDM-1 for patients who have been treated 81 aboard.
