First Report of *Phytophthium vexans* causing decline syndrome of *Actinidia deliciosa* 'Hayward' in Italy

Journal:	<i>Plant Disease</i>
Manuscript ID	Draft
Manuscript Type:	Plant Disease Note
Date Submitted by the Author:	n/a
Complete List of Authors:	<p>Prencipe, Simona; University of Torino, Dept. Agricultural, Forestry and Food Sciences (DISAFA) Savian, Francesco; University of Udine, Dept. Agricultural, Food, Environmental and Animal Sciences (DI4A) Nari, Luca; AGRION, Fondazione per la ricerca l'innovazione e lo sviluppo tecnologico dell'agricoltura piemontese Ermacora, Paolo; University of Udine, Agricultural and Environmental Sciences Spadaro, Davide; University of Torino, DISAFA - Dept. Agricultural, Forestry and Food Sciences; University of Torino, AGROINNOVA MARTINI, Marta; University of Udine, Agriculture and Environmental Sciences</p>
Keywords:	Oomycetes < Causal Agent, tree fruits < Fruit < Crop Type, Etiology < Subject Areas, kiwifruit, flooding, Koch's postulates

35
36 Italy is the second worldwide producer of kiwifruit (*Actinidia deliciosa* C.F. Liang & A.R. Ferguson)
37 with a production of approximately 571,020 tons/year and 26,650 ha of cultivated area. A new disease
38 characterized by decline and root rot has been reported in Italy since 2012 and currently affects 12%
39 (3,160 ha) of Italian kiwifruit production area (Sorrenti et al. 2019). During 2016 and 2018, 18
40 orchards were monitored in Piedmont (NW Italy), and 100% sampled trees showed typical symptoms
41 of the disease with diffuse root rot, reduction of plant vigor, leaf curling, and sudden decline.
42
43 Experimental trials were set up in Friuli Venezia Giulia (NE Italy), to reproduce the disease in
44 controlled environment applying waterlogging conditions to kiwifruit plants grown on soil (sterilized
45 and unsterilized) collected from diseased orchards. Rotting and decline appeared in 90% of the plants
46 when flooding conditions on unsterilized soil were used, whereas decline was not observed on plants
47 grown on flooded sterilized soil (Savian et al. submitted for publication).

1
2
3 Isolations were carried out by cutting pieces of symptomatic roots. Tissue fragments were surface-
4
5 disinfected with 1% sodium hypochlorite for 30 s and rinsed in sterile water. Five fragments of each
6
7 root were cut and plated onto corn meal agar (CMA) supplemented with pimaricin, ampicillin,
8
9 rifampicin and pentachloronitrobenzene. Representative isolates were transferred onto V8 agar and
10
11 morphological observations were performed according to de Cock et al. (2015). After 3 days, colonies
12
13 showed typical mycelia of a *Pythium* species. Older cultures showed subglobose non-papillate
14
15 sporangia (11.25 to 18.47 μm), bell-shaped antheridia, smooth oogonia and spherical zoospores
16
17 typical of *Phytopythium vexans* (de Bary A.) (de Cock et al. 2015). Species identification was
18
19 confirmed by sequencing rDNA internal transcribed spacer (ITS) using primers ITS1/ITS4 (White et
20
21 al. 1990), the large subunit (LSU) rDNA using primers NL1/NL4 (Baten et al. 2014) and cytochrome
22
23 oxidase I (COI) regions using FM85mod/OomCOILevup primers (Robideau et al. 2011). Two
24
25 sequences per region were deposited in GenBank (Accession N° MN510425, MN510426,
26
27 MN510427, MN510428, MN510423 and MN510424) and were BLAST-searched in GenBank,
28
29 obtaining 99 to 100% homology with strains of *P. vexans* (Accession N° AY598713, HQ665090 and
30
31 GU133476).
32
33
34
35
36

37 Pathogenicity was tested on 1-year-old *Actinidia deliciosa* 'Hayward' potted plants and the different
38
39 isolates of *P. vexans*, grown on wheat and hemp for 7 days, were inoculated into the soil at a rate of
40
41 6 g/liter. Plants were kept in a greenhouse at $32\pm 3^\circ\text{C}$. To mimic waterlogging conditions that were
42
43 found necessary for symptom induction, three rounds of flooding and drainage were applied
44
45 according to the protocol devised by Savian et al. (submitted for publication). Similar symptoms to
46
47 those observed in the field occurred after 14 to 24 days in all the plants, depending on the isolate,
48
49 while controls remained symptomless. To fulfil Koch's postulates, re-isolations were performed from
50
51 symptomatic plants and the pathogen was molecularly identified as *P. vexans*. *P. vexans* was first
52
53 described on kiwifruit by Polat et al. (2017) in Turkey. To the best of our knowledge, this is the first
54
55 report of *P. vexans* causing kiwifruit decline syndrome in Italy. The identification of the causal agent
56
57
58
59
60

1
2
3 will permit to establish appropriate disease management strategies to face this emerging disease on
4
5 kiwifruit.
