

# Scientific, Technical and Economic Committee for Fisheries (STECF) 

# Report of the SGMED-09-02 Working Group on the Mediterranean Part I 

## 8-12 JUNE 2009, Villasimius, Sardinia, ITALY

Edited by Massimiliano Cardinale, Hans-Joachim Rätz \& Anna Cheilari

The mission of the Institute for the Protection and Security of the Citizen (IPSC) is to provide research results and to support EU policy-makers in their effort towards global security and towards protection of European citizens from accidents, deliberate attacks, fraud and illegal actions against EU policies

European Commission
Joint Research Centre
Institute for the Protection and Security of the Citizen

## TABLE OF CONTENTS

TABLE OF CONTENTS ..... 1

1. BACKGROUND ..... 36
2. TERMS OF REFERENCE ..... 36
3. STECF OBSERVATIONS ..... 39
4. STECF COMMENTS AND CONCLUSIONS ..... 40
SGMED-09-02 WORKING GROUP REPORT THE MEDITERRANEAN PART I ..... 43
5. EXECUTIVE SUMMARY AND RECOMMENDATIONS ..... 44
6. INTRODUCTION ..... 46
2.1. Terms of Reference for SGMED-09-02 ..... 46
2.2. Participants ..... 48
7. SUMMARY OF DATA PROVIDED FOR THE MEDITERRANEAN THROUGH THE DCF CALL ..... 49
8. DATA PROVISION POLICY ..... 51
9. WORKING DOCUMENTS ..... 51
5.1. Working document 1: Recent changes of small pelagics fish abundance as detected in the eastern part of GSA 17 by acoustic surveys ..... 51
5.2. Working document 2: The use of acoustics in identifying small pelagics' juvenile habitat in the Mediterranean ..... 51
5.3. Working document 3: Rapido trawl survey for Solea solea and other shared benthic species in the GSA 17 ..... 52
5.4. Working document 4: Spawning grounds of the European anchovy Engraulis encrasicolus in the Strait of Sicily (GSA 16) and relationships with hydrographic surface circulation ..... 52
5.5. Working document 5: Data on hake nurseries in the Gulf of Lions (GSA 7) ..... 52
5.6. Working document 6: Estimation of natural mortality and redefinition of current divisions of GSA for stock assessment ..... 53
5.7. Working document 7: Nursey localization of some key demersal species in the GSA 10,18 and 19 . ..... 53
5.8. Working document 8: Nursey localization of demersal species in the italian GSAs54
10. SGMED 09-02 RESPONSES TO SPECIAL QUESTIONS OF TOR C, D, G, IAND K55
6.1. c) Review and propose biological reference points related to high yields and low risk of fishery collapse in long term of each of the stocks assessed. ..... 55
6.1.1. European hake (Merluccius merluccius) in GSA 6 ..... 55
6.1.2. Deep water rose shrimp (Parapenaeus longirostris) in GSA 6 ..... 56
6.1.3. Appropriateness of exploitation rate $\mathrm{E} \leq 0.4$ for anchovy (Engraulis encrasicolus) and sardine (Sardina pilchardus) in the Mediterranean Sea ..... 56
6.1.4. Biomass reference points for Anchovy (Engraulis encrasicolus) in GSA 17 ..... 57
6.1.5. Biomass reference points for Sardine (Sardina pilchardus) in GSA 17 ..... 57
6.2. d) update and assess historic and recent trends (capacity, technological creeping, nominal fishing effort) in the major fisheries by GSAs or, if the case, by bigger areas merging adjacent GSAs exploiting the stocks assessed. The trends should be interpreted in light of management regulations applicable to them 58
6.3. g) Review of proposed methodologies to standardize the MEDITS and GRUND surveys time series to account for unbalanced sampling designs and appropriate data distributions. Specific work has been initiated in this regard.
6.4. i) Based on the "Survey of existing bio-economic models" under Studies and Pilot Projects for carrying out the Common Fisheries Policy No FISH/2007/07 and data made available by MS, develop specific case studies for Mediterranean fisheries (e.g. anchovy, sardine and Nephrops), and advise on possible short-term and long-term economic consequences of the selected harvesting strategies. Evaluate the possibility to use existing bioeconomic models for comparing the proposed harvesting strategies with long-term economic profitability (MEY) of the main fisheries exploiting the assessed stocks (to be continued in SGMED-09-03).
6.5. k) Protection of Juveniles and Spawning Aggregations
6.5.1. Provide relevant information on spatial and temporal distribution of seasonal or persistent juveniles' aggregations and provide scientific elements indicating that possible protection of these areas may allow to control and reduce the overall fishing mortality on the stock and further improve the exploitation pattern with a view to increase the yield.82
6.5.2. Provide relevant information on fishing gear selectivity (mesh size/shape, twine thickness, hanging ratio, hook size, hook shape, etc.) with a view to further improve the exploitation pattern, reduce the fishing mortality on juveniles and increase the yield.
6.5.3. Provide relevant information on spatial and temporal distribution of seasonal or persistent aggregations of spawners and provide scientific elements indicating that possible protection of these areas may reduce the risk of stock collapse and maintain the reproductive capacity of the exploited stocks. 106

## 7. STOCK SUMMARY SHEETS

### 7.1. Hake in GSA 06 115

7.2. Hake in GSA 09 118
7.3. Hake in GSA $10 \quad 121$
7.4. Hake in GSA $11 \quad 124$
$\begin{array}{lll}\text { 7.5. Red mullet in GSA } 09 & 126\end{array}$
7.6. Red mullet in GSA $25 \quad 128$
7.7. Pink shrimp in GSA 06 131
7.8. Pink shrimp in GSA 09 133
7.9. Anchovy in GSA $16 \quad 135$
7.10. Anchovy in GSA 17 ..... 138
7.11. Anchovy in GSA 22 ..... 140
7.12. $\quad$ Sardine in GSA 16 ..... 143
7.13. $\quad$ Sardine in GSA 17 ..... 146
7.14. $\quad$ Sardine in GSA 22 ..... 148
7.15. Sole in GSA 17 ..... 151
7.16. Blue and red shrimp in GSA 06 ..... 154
7.17. Giant red shrimp in GSAs 15 and 16 ..... 156
7.18. Norway lobster in GSA 09 ..... 159
8. STOCK ASSESSMENTS REVIEWED OR CONDUCTED ..... 162
8.1. Introductory notes ..... 162
8.2. Stock assessment of hake in GSA 01 ..... 163
8.2.1. $\quad$ Stock identification and biological features ..... 163
8.2.1.1. Stock Identification ..... 163
8.2.1.2. Growth ..... 163
8.2.1.3. Maturity ..... 163
8.2.2. Fisheries ..... 163
8.2.2.1. General description of fisheries ..... 163
8.2.2.2. Management regulations applicable in 2008 and 2009 ..... 164
8.2.2.3. Catches ..... 164
8.2.2.3.1. Landings ..... 164
8.2.2.3.2. Discards ..... 165
8.2.2.3.3. Fishing effort ..... 165
8.2.3. Scientific surveys ..... 165
8.2.3.1. Medits ..... 165
8.2.3.1.1. Methods ..... 165
8.2.3.1.2. Geographical distribution patterns ..... 166
8.2.3.1.3. Trends in abundance and biomass ..... 167
8.2.3.1.4. Trends in abundance by length or age ..... 167
8.2.3.1.5. Trends in growth ..... 169
8.2.3.1.6. Trends in maturity ..... 169
8.2.4. Assessment of historic stock parameters ..... 170
8.2.5. Long term prediction ..... 170
8.2.5.1. Justification ..... 170
8.2.5.2. Input parameters ..... 170
8.2.5.3. Results ..... 170
8.2.6. Scientific advice ..... 170
8.2.6.1. Short term considerations ..... 170
8.2.6.1.1. State of the spawning stock size ..... 170
8.2.6.1.2. State of recruitment ..... 170
8.2.6.1.3. State of exploitation ..... 170
8.3. Stock assessment of hake in GSA 05 ..... 171
8.3.1. Stock identification and biological features ..... 171
8.3.1.1. Stock Identification ..... 171
8.3.1.2. Growth ..... 171
8.3.1.3. Maturity ..... 171
8.3.2. Fisheries ..... 171
8.3.2.1. General description of fisheries ..... 171
8.3.2.2. Management regulations applicable in 2008 and 2009 ..... 171
8.3.2.3. Catches ..... 171
8.3.2.3.1. Landings ..... 171
8.3.2.3.2. Discards ..... 171
8.3.2.3.3. Fishing effort ..... 172
8.3.3. Scientific surveys ..... 172
8.3.3.1. Medits ..... 172
8.3.3.1.1. Methods ..... 172
8.3.3.1.2. Geographical distribution patterns ..... 173
8.3.3.1.3. Trends in abundance and biomass ..... 173
8.3.3.1.4. Trends in abundance by length or age ..... 173
8.3.3.1.5. Trends in growth ..... 175
8.3.3.1.6. Trends in maturity ..... 175
8.3.4. Assessment of historic stock parameters ..... 175
8.3.5. Long term prediction ..... 175
8.3.5.1. Justification ..... 175
8.3.5.2. Input parameters ..... 175
8.3.5.3. Results ..... 176
8.3.6. Scientific advice ..... 176
8.3.6.1. Short term considerations ..... 176
8.3.6.1.1. State of the spawning stock size ..... 176
8.3.6.1.2. State of recruitment ..... 176
8.3.6.1.3. State of exploitation ..... 176
8.4. Stock assessment of hake in GSA 06 ..... 177
8.4.1. Stock identification and biological features ..... 177
8.4.1.1. Stock Identification ..... 177
8.4.1.2. Growth ..... 177
8.4.1.3. Maturity ..... 177
8.4.2. Fisheries ..... 177
8.4.2.1. General description of fisheries ..... 177
8.4.2.2. Management regulations applicable in 2008 and 2009 ..... 177
8.4.2.3. Catches ..... 177
8.4.2.3.1. Landings ..... 177
8.4.2.3.2. Discards ..... 178
8.4.2.3.3. Fishing effort ..... 178
8.4.3. Scientific surveys ..... 178
8.4.3.1. MEDITS ..... 178
8.4.3.1.1. Methods ..... 178
8.4.3.1.2. Geographical distribution patterns ..... 179
8.4.3.1.3. Trends in abundance and biomass ..... 179
8.4.3.1.4. Trends in abundance by length or age ..... 180
8.4.3.1.5. Trends in growth ..... 182
8.4.3.1.6. Trends in maturity ..... 182
8.4.4. Assessment of historic stock parameters ..... 183
8.4.4.1.1. Method 1: XSA ..... 183
8.4.4.1.2. Justification ..... 183
8.4.4.1.3. Input parameters ..... 183
8.4.4.1.4. Results including sensitivity analyses ..... 184
8.4.5. Long term prediction ..... 186
8.4.5.1. Justification ..... 186
8.4.5.2. Input parameters ..... 186
8.4.5.3. Results ..... 186
8.4.6. Scientific advice ..... 186
8.4.6.1. Short term considerations ..... 186
8.4.6.1.1. State of the spawning stock size ..... 186
8.4.6.1.2. State of recruitment ..... 187
8.4.6.1.3. State of exploitation ..... 187
8.5. Stock assessment of hake in GSA 07 ..... 188
8.5.1. Stock identification and biological features ..... 188
8.5.1.1. Stock Identification ..... 188
8.5.1.2. Growth ..... 188
8.5.1.3. Maturity ..... 188
8.5.2. Fisheries ..... 188
8.5.2.1. General description of fisheries ..... 188
8.5.2.2. Management regulations applicable in 2008 and 2009 ..... 188
8.5.2.3. Catches ..... 188
8.5.2.3.1. Landings ..... 188
8.5.2.3.2. Discards ..... 189
8.5.2.3.3. Fishing effort ..... 189
8.5.3. Scientific surveys ..... 189
8.5.3.1. Medits ..... 189
8.5.3.1.1. Methods ..... 189
8.5.3.1.2. Geographical distribution patterns ..... 190
8.5.3.1.3. Trends in abundance and biomass ..... 190
8.5.3.1.4. Trends in abundance by length or age ..... 191
8.5.3.1.5. Trends in growth ..... 193
8.5.3.1.6. Trends in maturity ..... 193
8.5.4. Assessment of historic stock parameters ..... 194
8.5.5. Long term prediction ..... 194
8.5.5.1. Justification ..... 194
8.5.5.2. Input parameters ..... 194
8.5.5.3. Results ..... 194
8.5.6. Scientific advice ..... 194
8.5.6.1. Short term considerations ..... 194
8.5.6.1.1. State of the spawning stock size ..... 194
8.5.6.1.2. State of recruitment ..... 194
8.5.6.1.3. State of exploitation ..... 194
8.6. Stock assessment of hake in GSA 08 ..... 195
8.6.1. Stock identification and biological features ..... 195
8.6.1.1. Stock Identification ..... 195
8.6.1.2. Growth ..... 195
8.6.1.3. Maturity ..... 195
8.6.2. Fisheries ..... 195
8.6.2.1. General description of fisheries ..... 195
8.6.2.2. Management regulations applicable in 2008 and 2009 ..... 195
8.6.2.3. Catches ..... 195
8.6.2.3.1. Landings ..... 195
8.6.2.3.2. Discards ..... 195
8.6.2.3.3. Fishing effort ..... 195
8.6.3. Scientific surveys ..... 195
8.6.3.1. Medits ..... 195
8.6.3.1.1. Methods ..... 196
8.6.3.1.2. Geographical distribution patterns ..... 196
8.6.3.1.3. Trends in abundance and biomass ..... 197
8.6.3.1.4. Trends in abundance by length or age ..... 197
8.6.3.1.5. Trends in growth ..... 199
8.6.3.1.6. Trends in maturity ..... 199
8.6.4. Assessment of historic stock parameters ..... 200
8.6.5. Long term prediction ..... 200
8.6.5.1. Justification ..... 200
8.6.5.2. Input parameters ..... 200
8.6.5.3. Results ..... 200
8.6.6. Scientific advice ..... 200
8.6.6.1. Short term considerations ..... 200
8.6.6.1.1. State of the spawning stock size ..... 200
8.6.6.1.2. State of recruitment ..... 200
8.6.6.1.3. State of exploitation ..... 200
8.7. Stock assessment of hake in GSA 09 ..... 201
8.7.1. Stock identification and biological features ..... 201
8.7.1.1. Stock Identification ..... 201
8.7.1.2. Growth ..... 202
8.7.1.3. Maturity ..... 203
8.7.2. Fisheries ..... 203
8.7.2.1. General description of fisheries ..... 203
8.7.2.2. Management regulations applicable in 2009 ..... 204
8.7.2.3. Catches ..... 204
8.7.2.3.1. Landings ..... 204
8.7.2.3.2. Discards ..... 206
8.7.2.3.3. Fishing effort ..... 206
8.7.3. Scientific surveys ..... 207
8.7.3.1. MEDITS ..... 207
8.7.3.1.1. Methods ..... 207
8.7.3.1.2. Geographical distribution patterns ..... 208
8.7.3.1.3. Trends in abundance and biomass ..... 209
8.7.3.1.4. Trends in abundance by length or age ..... 210
8.7.3.1.5. Trends in growth ..... 212
8.7.3.1.6. Trends in maturity ..... 212
8.7.4. Assessment of historic stock parameters ..... 213
8.7.4.1. Method 1: Trends in LPUE ..... 213
8.7.4.1.1. Justification ..... 213
8.7.4.1.2. Input parameters ..... 213
8.7.4.1.3. Results ..... 213
8.7.4.2. Method 2: SURBA ..... 214
8.7.4.2.1. Justification ..... 214
8.7.4.2.2. Input parameters ..... 214
8.7.4.2.3. Results ..... 217
8.7.4.3. Method 3: LCA on DCR data ..... 220
8.7.4.3.1. Justification ..... 220
8.7.4.3.2. Input parameters ..... 220
8.7.4.3.3. Results ..... 222
8.7.5. Long term prediction ..... 222
8.7.5.1. Justification ..... 222
8.7.5.2. Input parameters ..... 222
8.7.5.3. Results ..... 222
8.7.6. Scientific advice ..... 224
8.7.6.1. Short term considerations ..... 224
8.7.6.1.1. State of the spawning stock size ..... 224
8.7.6.1.2. State of recruitment ..... 224
8.7.6.1.3. State of exploitation ..... 224
8.8. Stock assessment of hake in GSA 10 ..... 225
8.8.1. Stock identification and biological features ..... 225
8.8.1.1. Stock Identification ..... 225
8.8.1.2. Growth ..... 225
8.8.1.3. Maturity ..... 226
8.8.2. Fisheries ..... 226
8.8.2.1. General description of fisheries ..... 226
8.8.2.2. Management regulations applicable in 2009 ..... 226
8.8.2.3. Catches ..... 227
8.8.2.3.1. Landings ..... 227
8.8.2.3.2. Discards ..... 227
8.8.2.3.3. Fishing effort ..... 227
8.8.3. Scientific surveys ..... 228
8.8.3.1. Medits ..... 228
8.8.3.1.1. Methods ..... 229
8.8.3.1.2. Geographical distribution patterns ..... 230
8.8.3.2. GRUND ..... 230
8.8.3.2.1. Methods ..... 230
8.8.3.2.2. Geographical distribution patterns ..... 230
8.8.3.2.3. Trends in abundance and biomass ..... 230
8.8.3.2.4. Trends in abundance by length or age ..... 232
8.8.3.2.5. Trends in growth ..... 235
8.8.3.2.6. Trends in maturity ..... 235
8.8.4. Assessment of historic stock parameters ..... 236
8.8.4.1. Method 1: Surba ..... 236
8.8.4.1.1. Justification ..... 236
8.8.4.1.2. Input parameters ..... 236
8.8.4.1.3. Results ..... 236
8.8.4.2. Method 2: Aladym ..... 238
8.8.4.2.1. Justification ..... 238
8.8.4.2.2. Input parameters ..... 238
8.8.4.2.3. Results ..... 239
8.8.5. Long term prediction ..... 240
8.8.5.1. Justification ..... 240
8.8.5.2. Input parameters ..... 240
8.8.5.3. Results ..... 240
8.8.6. Scientific advice ..... 240
8.8.6.1. Short term considerations ..... 240
8.8.6.1.1. State of the spawning stock size ..... 240
8.8.6.1.2. State of recruitment ..... 241
8.8.6.1.3. State of exploitation ..... 241
8.9. Stock assessment of hake in GSA 11 ..... 242
8.9.1. Stock identification and biological features ..... 242
8.9.1.1. Stock Identification ..... 242
8.9.1.2. Growth ..... 242
8.9.1.3. Maturity ..... 243
8.9.2. Fisheries ..... 243
8.9.2.1. General description of fisheries ..... 243
8.9.2.2. Management regulations applicable in 2008 and 2009 ..... 244
8.9.2.3. Catches ..... 244
8.9.2.3.1. Landings ..... 244
8.9.2.3.2. Discards ..... 245
8.9.2.3.3. Fishing effort ..... 245
8.9.3. Scientific surveys ..... 246
8.9.3.1. MEDITS ..... 246
8.9.3.1.1. Methods ..... 246
8.9.3.1.2. Geographical distribution patterns ..... 247
8.9.3.1.3. Trends in abundance and biomass ..... 247
8.9.3.1.4. Trends in abundance by length or age ..... 248
8.9.3.1.5. Trends in growth ..... 250
8.9.3.1.6. Trends in maturity ..... 250
8.9.4. Assessment of historic stock parameters ..... 251
8.9.4.1. Method 1: SURBA ..... 251
8.9.4.1.1. Justification ..... 251
8.9.4.1.2. Input parameters ..... 251
8.9.4.1.3. Results ..... 251
8.9.5. Long term prediction ..... 254
8.9.5.1. Justification ..... 254
8.9.5.2. Input parameters ..... 254
8.9.5.3. Results ..... 254
8.9.6. Scientific advice ..... 254
8.9.6.1. Short term considerations ..... 254
8.9.6.1.1. State of the spawning stock size ..... 254
8.9.6.1.2. State of recruitment ..... 255
8.9.6.1.3. State of exploitation ..... 255
8.10. Stock assessment of hake in GSAs 15 and 16 ..... 256
8.10.1. Stock identification and biological features ..... 256
8.10.1.1. $\quad$ Stock Identification ..... 256
8.10.1.2. Growth ..... 257
8.10.1.3. Maturity ..... 257
8.10.2. Fisheries ..... 258
8.10.2.1. General description of fisheries ..... 258
8.10.2.2. Management regulations applicable in 2008 and 2009 ..... 258
8.10.2.3. Catches ..... 259
8.10.2.3.1. Landings ..... 259
8.10.2.3.2. Discards ..... 261
8.10.2.3.3. Fishing effort ..... 261
8.10.3. Scientific surveys ..... 263
8.10.3.1. Medits ..... 263
8.10.3.1.1. Methods ..... 263
8.10.3.1.2. Geographical distribution patterns ..... 264
8.10.3.1.3. Trends in abundance and biomass ..... 265
8.10.3.1.4. Trends in abundance by length or age ..... 265
8.10.3.1.5. Trends in growth ..... 268
8.10.3.1.6. Trends in maturity ..... 268
8.10.4. Assessment of historic stock parameters ..... 269
8.10.5. Long term prediction ..... 269
8.10.5.1. Justification ..... 269
8.10.5.2. Input parameters ..... 269
8.10.5.3. Results ..... 269
8.10.6. Scientific advice ..... 269
8.10.6.1. Short term considerations ..... 269
8.10.6.1.1. State of the spawning stock size ..... 269
8.10.6.1.2. State of recruitment ..... 269
8.10.6.1.3. State of exploitation ..... 269
8.11. Stock assessment of hake in GSA 17 ..... 270

## COMMITTEE FOR FISHERIES (STECF)

STECF COMMENTS ON THE REPORT OF THE SGMED-09-02<br>WORKING GROUP ON THE MEDITERRANEAN PART I<br>Villasimius, Sardinia, Italy, 8-12 ${ }^{\text {th }}$ June 2009

# STECF UNDERTOOK THE REVIEW DURING THE PLENARY MEETING 

## HELD IN BRUSSEL 9-13 NOVEMBER 2009

## 1. Background

The European Community is expected to establish long-term management plans (LTMP) for relevant Mediterranean demersal and small pelagic fisheries, based on the precautionary approach and adaptive management in taking measures designed to protect and conserve living aquatic resources, to provide for their sustainable exploitation and to minimise the impact of fishing activities on marine ecosystems.

STECF can play an important role in focusing greater contributions for European scientists towards stocks and fisheries assessment, in identifying a common scientific framework regarding specific analyses to advise on Community plans, to be then channeled into or completed by the GFCM working groups.
STECF was requested at its 2007 November plenary session to set up an operational work programme for 2008, beginning in the 1st quarter of 2008 , with a view to update the status of the main demersal stocks and evaluate the exploitation levels with respect to their biological and economic production potentials and the sustainability of the stock by using both trawl surveys and commercial catch/landing data as collected through the Community Data Collection regulation $\mathrm{N}^{\circ} 1543 / 2000$ as well as other scientific information collected at national level.

The work of STECF's subgroup on Mediterranean continued in 2009 with a dedicated workshop in Murcia, Spain, 2-6 March 2009, the SGMED-09-01 meeting on advice reviews for 2009 for sprat and turbot in the Black Sea in Ranco, Italy, 23-27 March 2009, and the present report of SGMED-09-02 part I on the historic assessments and management advice regarding historic status of Mediterranean stocks. During the forthcoming meeting SGMED-09-03 will be dealing mainly with short and medium term forecasts of stock size and landings of Mediterranean stocks under different management options.

## 2. Terms of reference

Terms of reference for the STECF/SGMED-09-02 meeting (8-12/6/2009) were defined as follows:
a) Update and assess the status and trends of the stocks by all relevant GSAs, or, if the case, by bigger areas merging adjacent GSAs, in the Mediterranean Sea, taking into account the recommendations of the SGMED workshop in March and the following STECF comments. Advise on the status of the exploited stocks of the species listed below, with respect to high yields harvesting strategies and to maintain their reproductive capacity and ensure a low risk.

- $\quad$ Sardine (Sardina pilchardus)
- Anchovy (Engraulis encrasicolus)
- European hake (Merluccius merluccius)
- Red mullet (Mullus barbatus)
- Deep-water rose shrimp (Parapenaeus longirostris)
- Other species out of the list given to STECF and recalled both under point i) of the ToRs for SGMED 0903 and in tables 1 and 2 of the data call
b) Assess the status and trends of the stocks by all relevant GSAs, or, if the case, by bigger areas merging adjacent GSAs, in the Mediterranean Sea. Advise on the status of the following exploited stocks of the species listed below, with respect to high yields harvesting strategies and to maintain their reproductive capacity and ensure a low risk.
- $\quad$ Red shrimp (Aristeus antennatus)
- Giant red shrimp (Aristaeomorpha foliacea)
- Norway lobster (Nephrops norvegicus)
- Other species out of the list given to STECF and recalled both under point i) of the ToRs for SGMED 0903 and in tables 1 and 2 of the data call
c) Review and propose biological reference points related to high yields and low risk of fishery collapse in long term of each of the stocks assessed.

## SPECIFIC QUESTIONS UNDER POINT C)

- advice whether 300 tonnes for deep water rose shrimp and 2200 tonnes for hake may be considered as adequate minimum biological acceptable level (MBAL=Blim) in GSA 6 or in any other more appropriate spatial aggregation of adjacent GSAs; otherwise advice on which values could be used to this end.
- advice whether 1200 tonnes for deep water rose shrimp and 4000 tonnes for hake, which correspond to the long-term average over the last 8 and 16 years respectively, may be considered as precautionary biomass reference point ( $=\mathrm{Bpa}$ ) in GSA 6 or in any other more appropriate GSA spatial aggregation of adjacent GSAs; otherwise advice on which values could be used to this end.
- advice whether $\mathrm{F} \leq 0.2$ per year on appropriate age groups can be considered as an adequate Fpa both for hake and deep water rose shrimp in GSA 6 or in any other more appropriate GSA spatial aggregation of adjacent GSAs.
- advice whether the exploitation rate $\mathrm{E} \leq 0.4$ per year on appropriate age groups is an adequate precautionary reference point both for anchovy and sardine stocks in all GSAs; otherwise advice on likely value to be used to this end.
- advice whether 50000 tonnes may be considered as adequate minimum biological acceptable levels (MBAL= Blim) both for anchovy and sardine stocks in GSA 17; otherwise advice on which values could be used to this end.
- advice whether 300000 tonnes for sardine and 80000 tonnes for anchovy may be considered as precautionary biomass reference point (=Bpa) in GSA 17; otherwise advice on which values could be used to this end.
d) Update and assess historic and recent trends (capacity, technological creep, nominal fishing effort) in the major fisheries by GSAs or, if the case, by bigger areas merging adjacent GSAs exploiting the stocks assessed. The trends should be interpreted in light of management regulations applicable to them.
e) Review the applicability and fully document all applied methodologies for the assessments and determination of the proposed biological reference points.
f) Fully document the data used and their origin for the assessments and determination of the proposed biological reference points.
g) To review proposed methodologies to standardize the MEDITS and GRUND surveys time series to account for unbalanced sampling designs and appropriate data distributions. Specific work has been initiated in this regard.
h) Investigate the requirements for reorganising the MEDITS database that result from the recommendations of STECF for combining some GSAs for some species.
i) Based on the "Survey of existing bio-economic models" under Studies and Pilot Projects for carrying out the Common Fisheries Policy No FISH/2007/07 and data made available by MS, develop specific case studies for Mediterranean fisheries (e.g. anchovy, sardine and Nephrops), and advise on possible short-term and long-term economic consequences of the selected harvesting strategies. Evaluate the possibility to use existing bioeconomic models for comparing the proposed harvesting strategies with long-term economic profitability (MEY) of the main fisheries exploiting the assessed stocks (to be continued in SGMED-09-03).
j) With a view to enhance the number of stocks jointly assessed on the spot at the forthcoming GFCMSAC working groups, either within one or by merging more than one adjacent GFCM-GSAs, identify for each selected assessment methodology the data needs, data format and start datasets preparatory work.
k) - PROTECTION OF JUVENILES AND SPAWNING AGGREGATIONS:

1) Provide relevant information on spatial and temporal distribution of seasonal or persistent juveniles aggregations and provide scientific elements indicating that possible protection of these areas may allow to control and reduce the overall fishing mortality on the stock and further improve the exploitation pattern with a view to increase the yield.
2) Provide relevant information on fishing gear selectivity (mesh size/shape, twine thickness, hanging ratio, hook size, hook shape, etc.) with a view to further improve the exploitation pattern, reduce the fishing mortality on juveniles and increase the yield.
3) Provide relevant information on spatial and temporal distribution of seasonal or persistent aggregations of spawners and provide scientific elements indicating that possible protection of these areas may reduce the risk of stock collapse and maintain the reproductive capacity of the exploited stocks.

## TABLES 1 and 2 of the Data Call

SGMED is requested to provide for each species listed below the following information needed for the different variables of the data calls:

- length type, length class interval and length range
- age class interval and age range

TABLE 1: Additional species as included in the data collection regulations and for which Member States are invited to provide relevant data before 24 November 2009.

| Species common name | Species scientific name | $\begin{gathered} \text { FAO } \\ \text { CODE } \end{gathered}$ |
| :---: | :---: | :---: |
| 1. Bogue | Boops boops | BOG |
| 2. Common dolphinfish | Coryphaena hippurus | DOL |
| 3. Sea bass | Dicentrarchus labrax | BSS |
| 4. Grey gurnard | Eutrigla gurnardus | GUG |
| 5. Black-bellied angler | Lophius budegassa | ANK |
| 6. Anglerfish | Lophius piscatorius | MON |
| 7. Blue whiting | Micromesistius poutassou | WHB |
| 8. Grey mullets (Mugilidae) | Mugilidae | MUL |
| 9. Striped red mullet | Mullus surmuletus | MUR |
| 10. Common Pandora | Pagellus erythrinus | PAC |
| 11. Caramote prawn | Penaeus kerathurus | TGS |
| 12. Mackerel | Scomber spp. | MAZ |
| 13. Common sole | Solea solea (=Solea vulgaris) | SOL |
| 14. Gilthead seabream | Sparus aurata | SBG |
| 15. Picarel | Spicara smaris | SPC |
| 16. Spottail mantis squillids | Squilla mantis | MTS |
| 17. Mediterranean horse mackerel | Trachurus mediterraneus | HMM |
| 18. Horse mackerel | Trachurus trachurus | HOM |
| 19. Tub gurnard | Trigla lucerna (=Chelidonichthys lucerna) | GUU |

TABLE 2: Additional species not included in the data collection regulations and for which interested Member States are invited to provide relevant data before 24 November 2009.

| Species common name | Species scientific name | FAO CODE |
| :---: | :--- | :--- |
| 1. Sargo breams | Diplodus spp. | SRG |
| 2. Axillary seabream | Pagellus acarne | SBA |
| 3. Blackspot seabream | Pagellus bogaraveo | SBR |
| 4. Greater forkbeard | Phycis blennoides | GFB |
| 5. Poor cod | Trisopterus minutus | POD |

## 3. STECF ObSERVATIONS

STECF concludes that overall the SGMED framework has so far represented an excellent forum to support stock assessment and advice within the region and built the foundations upon which assessment work can be successfully undertaken. The meetings in 2008 and 2009 also allowed the standardization of procedures for data collection and analysis within the region. In order to ensure that
this is continued, the Working Group suggests that inter-sessional workshops or training courses be pursued to expand the number of scientists fully able to undertake assessments within the Mediterranean region.
STECF notes that the working group SGMED 09-02 was able exhaustively address all TORs. The SGMED 09-02 report deals mainly with the assessment of historic and recent trends in stock parameters (stock size, recruitment and exploitation) and relevant scientific advice. Where applicable, long-term forecasts are provided in order to allow assessments of the stock against proposed management reference points F0.1, Fmax and FMSY. In this context F0.1 was considered as the most reliable proxy of FMSY. For most of the stocks assessed, current exploitation rates are estimated larger or much larger than any level of fishing mortality that is associated with high long-term sustainable targets. STECF endorses such conclusion. STECF notes that deterministic short and medium term forecast of landings and stock size and related management advice will be delivered through the forthcoming SGMED 09-03 meeting in December 2009.
STECF supports SGMED 09-02 reiteration that recovery plans should be developed and established with urgency in order to achieve advised effort reductions and those recovery plans should be enforced until the stocks are proved to be exploited consistently with the sustainable targets. The development of recovery plans needs to consider catches of other species in a mixed fishery context and should be socio-economically evaluated.

STECF endorses the SGMED recommendations regarding its future working procedures. The stocks to be assessed within each working group should be clearly identified by the TORs prior to the meeting, rather than being faced with an open list of potential assessments and with experts facing ad hoc decisions on which stock to assess. Also, the data call should cover the needs to fulfill the TORs rather than having to undertake additional analyses at the meeting. In this context, SGMED considers a reasonable approach would be to attempt no more than 25 stock assessments over the 2 -weekly working group meetings scheduled for future years. SGMED considers that a system, whereby each stock is assessed every 2 or 3 years, could represent an achievable working arrangement. This will also allow SGMED to conduct a more careful examination of the quality of input data and dedicate more time to a discussion of the observed trends and provision of advice.
Furthermore, SGMED-09-02 recommends the stock assessments should be continued in 2010 within two meetings. SGMED considers that a maximum of $10-15$ selected stocks should be assessed in each meeting, which should also include predictions of catch and biomass under different management scenarios in the short-term for the assessed stocks.

## 4. STECF COMMENTS AND CONCLUSIONS

ToR a-b: STECF notes that during the meeting, data compilations and assessments of 59 demersal and small pelagic species/GSA combinations were conducted (ToR a-b). The species were anchovy, sardine, European hake, red mullet, deepwater pink shrimp, blue and red shrimp, giant red shrimp, Norway lobster and sole. The assessed stocks covered geographical sub-areas (GSA) from western part of the Mediterranean to Cyprus in the east. Those assessments were supported by a DCR data call as defined during a previous meeting of SGMED (SGMED 09-01; Murcia, 2-6 March 2009) and followed procedures agreed at SGMED 09-01. The layout of the assessments was designed to allow scientists and managers to review in a consistent way the data underlying the assessments outputs and the specific issues encountered during the assessment, and review the assumptions made and the management advice. The report includes summary sheets for stocks of anchovy (3), sardine (3), European hake (4), red mullet (2), pink shrimp (2), blue and red shrimp (1), giant red shrimp (1), Norway lobster (1) and sole (1) for which SGMED-09-02 concluded on definitive assessments and provided advice. STECF endorses the assessments and results obtained by SGMED 09-02.
STECF notes that a total of 13 stocks (out of 18 for which an advice was given) were considered overfished in accordance to the proposed reference points. No particular regional patterns of stock developments and exploitation emerged, while the only stocks that are exploited sustainably are the stocks of sardine, anchovy and pink shrimp. The assessment confirmed the results of the analyses conducted in the previous 2008 meetings of SGMED,
showing a general state of overfishing for most of the stocks, especially for hake and red shrimps, with an exception for some of the pelagic stocks.
ToR c: After a general discussion on candidate reference points applied in fisheries management of Mediterranean fish and shellfish stocks, SGMED recommends that high priority should be given to exploitation indicators (fishing mortality) and the appropriate levels to achieve high sustainable longterm yield. Considering data availability and the recent political agreements (UN, 2002) and EU communications (Council Conclusions 2007), SGMED recommends the application of $\mathrm{F}_{\mathrm{MSY}}$ (maximum sustainable yield), with $\mathrm{F}_{0.1}$ derived from Yield per Recruit analysis as the appropriate proxy in cases where data are lacking or there is uncertainty (Kell and Fromentin, 2007). In contrast, state indicators of stock size in terms of biomass are rather difficult to interpret, as decreases in biomass below reference levels such as $\mathrm{B}_{\mathrm{lim}}$ (biomass of all adult specimens at the level of impaired recruitment) and $\mathrm{B}_{\mathrm{pa}}$ (precautionary reference of the biomass of all adult specimens including uncertainty) can be due to many ecological effects in addition to fishery impacts. In addition, the shortness of the assessment time series for most of the Mediterranean stocks and the lack of appropriate historical data, impede the establishment of biomass reference points. In the light of the fact that the actual stock size cannot be directly controlled through fisheries management, SGMED recommends stock biomass reference points be given lower priority in the management of Mediterranean fisheries (finfish and shellfish) than exploitation indicators. SGMED further recommends that levels of fishing mortality $\mathrm{F}_{\text {MSY }}$ or its proxy $\mathrm{F}_{0.1}$ should rather be interpreted and applied as management targets than any category boundaries, accounting also for uncertainty. Therefore, SGMED considers that emphasis should been given to exploitation rates rather than level of biomass. STECF agrees with SGMED 09-02.

STECF endorses the SGMED recommendations regarding fisheries management reference points for European hake in GSA 6. STECF recommends that $\mathrm{F}=0.16\left(\mathrm{~F}_{0.1}\right)$ be adopted as the reference point for fishery management. SGMED is not in the position to estimate or propose adequate limit ( $\mathrm{B}_{\mathrm{lim}}$ ) or precautionary ( $\mathrm{B}_{\mathrm{p} 2}$ ) biomass reference points given the data available due to the shortage of the time series and the limited stock dynamics it covers. The time series indicates that the stock has always been below the proposed $\mathrm{B}_{\mathrm{lim}}=2,200 \mathrm{t}$ and $\mathrm{B}_{\mathrm{pa}}=4,000 \mathrm{t}$. SGMED notes that the recent stock size is estimated at a much lower level and thus recommends as an interim measure, the proposed biomass reference points of $B_{l i m}$ and $B_{\mathrm{pa}}$ be adopted as biomass reference points. Those values may be revised in future when more information becomes available.
STECF endorses the SGMED recommendations regarding fisheries management reference points for pink shrimp in GSA 6. SGMED is not in the position to estimate and propose appropriate management targets of fishing mortality or biomass reference points due to the shortage of the time series and the extreme stock dynamics it covers. SGMED notes that the proposed $\mathrm{F} \leq 0.2$ is much lower than the current exploitation of $\mathrm{F}=0.5$ for ages 2-5. In the light of the management advice of SGMED to reduce F in order to allow the stock to rebuild, SGMED recommends that as an interim measure $\mathrm{F} \leq$ 0.2 be adopted as the reference point for fishery management. This value might be revised in the future when more information becomes available. After a continuous decline in spawning stock biomass, the 2008 SSB is estimated to amount to 111 t , the lowest level observed since 2002. STECF notes that this level is much lower than the proposed management references of $\mathrm{B}_{\mathrm{lim}}=300 \mathrm{t}$ and $\mathrm{B}_{\mathrm{pa}}=1,200 \mathrm{t}$, respectively. Given the management advice of SGMED to allow the stock to recover, STECF recommends the proposed state reference points of $B_{l i m}$ and $B_{p a}$ be adopted as biomass reference points. Those values might be revised in the future when more information becomes available.

STECF endorses the SGMED recommendations regarding the appropriateness of the exploitation rate $\mathrm{E} \leq 0.4$ for anchovy and sardine stocks in the Mediterranean Sea as a sustainable fisheries management reference point consistent with high long-term yield. SGMED concludes that the shortterm responses of the assessed anchovy and sardine stocks to recent exploitation rates indicate that an exploitation rate in the order of $\mathrm{E} \leq 0.4$ might be consistent with the management goal of high longterm yields, taking into account the dynamic of the stocks. SGMED underlines that limited area and temporal coverage of the available stock assessments impede any quantification of risk related to this statement. As such, the expressed indication regarding Mediterranean small pelagic stocks is in agreement with empirical findings of Patterson (1992), who has proposed this exploitation level.

SGMED recommends the application of the proposed exploitation rate $\mathrm{E} \leq 0.4$ as management threshold for stocks of anchovy and sardine in the Mediterranean Sea. This value might be revised in the future when more information becomes available.

STECF endorses the SGMED recommendations regarding the biomass reference points for anchovy in GSA 17. SGMED bases its recommendations regarding the proposed biomass reference points of $B_{\text {lim }}=50,000 t$ and $B_{p a}=80,000 t$ on a revised stock assessment accounting for natural mortality rates as advised during the SGMED workshop in Murcia, 2-6 March 2009. The visual inspection of the scatter plot of recruitment versus spawning stock biomass clearly indicates that recruitment is impaired at stock sizes below 50,000 t. Thus, SGMED recommends that $\mathrm{B}_{\mathrm{lim}}=50,000 \mathrm{t}$ be adopted for the stock of anchovy in GSA 17. According to FAO recommendations (Cadima, 2003), $\mathrm{B}_{\mathrm{pa}}$ should be in the range of $1.39 * \mathrm{~B}_{\mathrm{lim}}-1.64 * \mathrm{~B}_{\mathrm{lim}}$, accounting for uncertainty in the estimations of fishing mortality. Such factors would determine $\mathrm{B}_{\mathrm{pa}}$ being in the range of $70,000 \mathrm{t}-82,000 \mathrm{t}$. Thus, SGMED recommends that $\mathrm{B}_{\mathrm{pa}}=80,000 \mathrm{t}$ be adopted for the stock of anchovy in GSA 17.

STECF endorses the SGMED recommendations regarding the biomass reference points for sardine in GSA 17. SGMED bases its recommendations regarding the proposed biomass reference points of $B_{\lim }=50,000 \mathrm{t}$ and $\mathrm{B}_{\mathrm{pa}}=300,000 \mathrm{t}$ on a revised stock assessment accounting for natural mortality rates as advised during the SGMED workshop in Murcia, 2-6 March 2009. The visual inspection of the scatter plot of recruitment versus spawning stock biomass clearly indicates that recruitment is impaired at stock sizes below 180,000 t. Thus, SGMED recommends adopting $\mathrm{B}_{\mathrm{lim}}=180,000$ t for the stock of sardine in GSA 17. According to FAO recommendations (Cadima, 2003), $\mathrm{B}_{\mathrm{pa}}$ should be in the range of $1.39 * \mathrm{~B}_{\mathrm{lim}}-1.64 * \mathrm{~B}_{\mathrm{lim}}$, accounting for uncertainty in the estimations of fishing mortality. Such factors would determine $\mathrm{B}_{\mathrm{pa}}$ being in the range of $250,000 \mathrm{t}-295,000 \mathrm{t}$. Thus, SGMED recommends $\mathrm{B}_{\mathrm{pa}}=270,000 \mathrm{t}$ for the stock of sardine in GSA 17.

TOR d: STECF notes that SGMED 09-02 compiled a data set of fishing effort trends in accordance to the DCR data call issued in 2009. The fleet specific effort trends are also listed in the respective stock specific assessment sections of the SGMED report. No general conclusions were drawn from these data.

ToR e and f: STECF acknowledges that SGMED 09-02 compiled and listed relevant data and methods used for stock assessments and associated biological reference points for management. However, STECF requests that such documentation is continued and further improved in future meetings of SGMED.

ToR g and h: STECF notes that SGMED has provided specific advice on how to undertake standardization of MEDITS and GRUND surveys and that a more structured approach is needed. STECF supports the SGMED recommendation noting that this particular issue would best be solved by convening an ad-hoc working group to develop and test species-specific R script to be applied to standardize MEDITS and GRUND time series for use as quantitative fishery-independent information in stock assessments.

ToR i: STECF endorses the recommendation by SGMED 09-02 that the bio-economic models MEFISTO and/or BIRDMOD should be used in future studies to simulate the effects of the management measures of Mediterranean fisheries and evaluate the models' outcomes. Such work is planned for the forthcoming meeting SGMED 09-03.

ToR k: STECF acknowledges that SGMED 09-02 compiled an extensive amount of information and analyses regarding the definition of the areas of aggregation and persistence of juveniles and, partially, also of spawners in several GSAs and stocks. STECF endorses the use of the index of persistence as estimated for example in Colloca et al. (2009) as a robust method to define such areas and verify their persistency. If this task is to be continued, STECF advises to address it by mean of a specific data call and a dedicated working group under the STECF framework.

## SGMED-09-02 WORKING GROUP REPORT THE MEDITERRANEAN PART I

Villasimius, Sardinia, Italy, 8-12 June 2009

This report does not necessarily reflect the view of the European Commission and in no way anticipates the Commission's future policy in this area

## 1. EXECUTIVE SUMMARY AND RECOMMENDATIONS

With the aim of establishing the scientific evidence required to support development of long-term management plans for selected fisheries in the Mediterranean, consistent with the objectives of the Common Fisheries Policy, and to strengthen the Community's scientific input to the work of GFCM, the Commission made a number of requests to STECF. The Terms of Reference (TORs) for SGMED-$09-02$ were extensive and are listed in section 2.1.

Due to time and human resources constraints, the working group was able to answer exhaustively to all TORs, except TORs e, $\mathrm{f}, \mathrm{h}$ and j . SGMED 09-02 report deals mainly with the assessment of historic and recent trends in stock parameters (stock size, recruitment and exploitation) and relevant scientific advice. Deterministic short and medium term forecast for stock size and exploitation, including predicted landings and stock advice, will be delivered through the forthcoming SGMED 09-03 meeting in December 2009. Where applicable, long term forecasts are provided in order to allow assessments of the stock against established management reference points $\mathrm{F}_{0.1}, \mathrm{~F}_{\text {max }}$ and $\mathrm{F}_{\text {msy }}$.

During the meeting, data compilations and assessments of 59 demersal and small pelagic species/GSA combinations were conducted (ToR a-b). The species were anchovy, sardine, European hake, red mullet, deepwater pink shrimp, red shrimp, giant red shrim, Norway lobster and sole. The assessed GSA covered stocks from western part of the Mediterranean to Cyprus in the east. Those assessments were supported by a DCR data call as defined during a previous meeting of SGMED (SGMED 09-01; Murcia, 2-6 March 2009) and followed procedures agreed at SGMED 09-01. The layout of the assessments was designed to allow scientists and managers to revise in a consistent way the data underlying the assessments outputs and the specific issues encountered during the assessment, and review the assumptions made and the management advice. The report includes summary sheets for stocks of anchovy (3), sardine (3), European hake (4), red mullet (2), deepwater shrimp (2), red shrimp (1), giant red shrimp (1), Norway lobster (1) and sole (1) for which SGMED-09-02 concluded on definitive assessments and gave advice.

A total of 13 stocks (out of 18 for which an advice was given) were considered overfished in accordance to the proposed reference points. No particular regional patterns of stock developments and exploitation emerged, while the only stocks that are exploited sustainably are some of the sardine and anchovy stocks.

The assessment confirmed the results of the analyses already conducted in the previous SGMED 08-03 and 04 , showing a general condition of overfishing for most of the stocks, especially for hake and red shrimps, with exception of some of the pelagic stocks. The stock status was evaluated against F reference points and in this context $\mathrm{F}_{0.1}$ was considered as the most reliable proxy of $\mathrm{F}_{\text {msy }}$. For most of the stocks assessed, current exploitation rates are larger or much larger than any level of fishing mortality that is associated with high long term sustainable targets.

Concerning TOR c , reference points in terms of both exploitation rates and biomass were given for all the stocks concerned. SGMED recommends the application of $\mathrm{F}_{0.1}$ derived from Yield per Recruit analysis as the appropriate proxy of $\mathrm{F}_{\text {msy }}$ (maximum sustainable yield) in case of data lack or uncertainty (Kell and Fromentin, 2007). On the other hand, state indicators of stock size in terms of biomass are rather difficult to interpret, as changes in biomass in relation to reference levels such as $\mathrm{B}_{\mathrm{lim}}$ and $\mathrm{B}_{\mathrm{pa}}$. Also, the shortness of the time series for most of the Mediterranean stocks, the fact that landings are regarded as uncertain and also the lack of historical data, impede the establishment of such biomass reference points. Therefore, SGMED consider that emphasis should been given on exploitation rates rather than level of biomass. SGMED also recommends that any exploitation targets should be applied within an adaptive management framework of multiannual plans. In the specific case ot TORc, SGMED did not apply any analytical approach to comment on appropriate fisheries management reference points regarding biomass indicators as $\mathrm{B}_{\mathrm{lim}}$ or $\mathrm{B}_{\mathrm{pa}}$ but bases its comments on visual inspection of relationships between recruitment and spawning stock size.

For TOR d, SGMED concludes that there is no evidence of a general decline in fishing capacity of the Mediterranean fleets although this might be also the result of changes in the classification system (i.e., from polyvalent to a specific gear type).

Concerning TOR h, specific advice has been given on how to conduct standardization of MEDITS and GRUND surveys but SGMED considers that a more structured approach is needed. Thus, SGMED recommends that this particular issue would be solved with an ad-hoc working group to develop and test species specific R script that should be used to standardise MEDITS and GRUND time series of the different GSAs to be used in stock assessment as quantitative fishery independent information.

For TOR i, the bio-economic models MEFISTO and BIRDMOD were used to evaluate possible shortterm and long-term biological and economic consequences of specific management options for Mediterranean fisheries. SGMED recommends that the bio-economic models MEFISTO and/or BIRDMOD, using ad-hoc biological and economic data of selected case studies, should be used in future studies to simulate the effects of the management measures of Mediterranean fisheries and evaluate the models outcomes.

Concerning TOR k, SGMED recognise that an extensive amount of information and analysis is now available to define and quantify the areas of aggregation and persistence of juveniles and, partially, also spawners for several GSAs and stocks. SGMED consider that index of persistence as estimated for example in Colloca et al. (2009) can be used as a robust method to define such areas and verify that they are constant during time. This work should be addressed by a specific working group under the STECF framework.

SGMED reiterates that recovery plans should be developed and established with urgency in order to achieve advised effort reductions and those recovery plans should be enforced until the stocks are proved to be exploited consistently with the sustainability targets. The development of recovery plans needs to consider catches of other species in a mixed fishery context and should be socioeconomically evaluated.

SGMED also recommends that stocks to be assessed within each working group should be clearly identified by the TORs prior to the meeting, rather than allowing an open list with experts chosing which stock to deal just at the meeting. Also, the data call should cover the needs to fullfill the TORs rather than allows for any kind of analyses at the meeting. In this context, SGMED considers reasonable that no more than 25 stock are assessed within 2 weeks of the two working groups scheduled for future years. SGMED considers that a rotation system, with each stock assessed every 2 or 3 years (similar to the ICES benchmark system), could represent a reasonable compromise. This will also allow SGMED to conduct a more carefull examination of the quality of input data and dedicate more time to the discussion of the observed trends and advice within the group.

Futhermore, SGMED-09-02 recommends the stock assessments should be continued in 2010 within two meetings. SGEMD considers that a maximum of $10-15$ selected stocks should be assessed in each meeting, that should also include predictions of catch and biomass under different management scenarios in the short term for the assessed stocks.

Overall the SGMED framework has so far represented an excellent forum to support stock assessment and advice within the region and built the foundations upon which assessment work can be successfully undertaken. The meeting also allowed the standardisation of procedures for data collection and analysis within the region. In order to ensure that this is continued, the Working Group suggests that inter-sessional workshops or training courses be pursued to expand the number of scientists fully able to undertake assessments within the Mediterranean region.

## 2. INTRODUCTION

The European Community is expected to establish long-term management plans (LTMP) for relevant Mediterranean demersal and small pelagic fisheries, based on the precautionary approach and adaptive management in taking measures designed to protect and conserve living aquatic resources, to provide for their sustainable exploitation and to minimise the impact of fishing activities on marine ecosystems.

STECF can play an important role in focusing greater contributions for European scientists towards stocks and fisheries assessment, in identifying a common scientific framework regarding specific analyses to advise on Community plans, to be then channeled into or completed by the GFCM working groups.

STECF was requested at its November plenary session to set up an operational work programme for 2008, beginning in the $1^{\text {st }}$ quarter of 2008, with a view to update the status of the main demersal stocks and evaluate the exploitation levels with respect to their biological and economic production potentials and the sustainability of the stock by using both trawl surveys and commercial catch/landing data as collected through the Community Data Collection regulation $N^{\circ} 1543 / 2000$ as well as other scientific information collected at national level.

To address the requests, the STECF Subgroup on the Mediterranean (SGMED-09-02) for demersal and pelagic stocks met in Villasimius, Sardinia, Italy, from 8-12 ${ }^{\text {th }}$ June 2009. The meeting was opened at 15:00 on the $8^{\text {th }}$, and closed at 17:00 on the $12^{\text {th }}$. The meeting built upon the work performed during SGMED meetings conducted during 2008 and 2009 to pursue the Commission's requests.

In accordance with the ToR given in the following chapter, the present report is structured in 3 main parts. The first part consists of the stock specific (species and area) summary sheets of the various assessments concluded by SGMED 09-02, the second part covers SGMED 09-02 responses to the specific questions, and the third part documents the various assessments in detail with the raw data (where available), methods applied and results.

### 2.1. Terms of Reference for SGMED-09-02

The overall terms of reference for the SGMED meetings are listed in Appendix 1. The specific terms of reference for SGMED-09-02 were:

## STECF SGMED-09-02 Subgroup for Mediterranean is requested to:

a) Update and assess the status and trends of the stocks by all relevant GSAs, or, if the case, by bigger areas merging adjacent GSAs, in the Mediterranean Sea, taking into account the recommendations of the SGMED workshop in March and the following STECF comments. Advise on the status of the exploited stocks of the species listed below, with respect to high yields harvesting strategies and to maintain their reproductive capacity and ensure a low risk.

- $\quad$ Sardine (Sardina pilchardus)
- Anchovy (Engraulis encrasicolus)
- European hake (Merluccius merluccius)
- Red mullet (Mullus barbatus)
- Deep-water rose shrimp (Parapenaeus longirostris)
- Other species out of the list given to STECF and recalled both under point i) of the ToRs for SGMED 0903 and in tables 1 and 2 of the data call
b) Assess the status and trends of the stocks by all relevant GSAs, or, if the case, by bigger areas merging adjacent GSAs, in the Mediterranean Sea. Advise on the status of the following exploited stocks of the species listed below, with respect to high yields harvesting strategies and to maintain their reproductive capacity and ensure a low risk.
- $\quad$ Red shrimp (Aristeus antennatus)
- Giant red shrimp (Aristaeomorpha foliacea)
- Norway lobster (Nephrops norvegicus)
- Other species out of the list given to STECF and recalled both under point i) of the ToRs for SGMED 0903 and in tables 1 and 2 of the data call
c) Review and propose biological reference points related to high yields and low risk of fishery collapse in long term of each of the stocks assessed.

## SPECIFIC QUESTIONS UNDER POINT C)

- advice whether 300 tonnes for deep water rose shrimp and 2200 tonnes for hake may be considered as adequate minimum biological acceptable level (MBAL=Blim) in GSA 6 or in any other more appropriate spatial aggregation of adjacent GSAs; otherwise advice on which values could be used to this end.
- advice whether 1200 tonnes for deep water rose shrimp and 4000 tonnes for hake, which correspond to the long-term average over the last 8 and 16 years respetively, may be considered as precautionary biomass reference point ( $=\mathrm{Bpa}$ ) in GSA 6 or in any other more appropriate GSA spatial aggregation of adjacent GSAs; otherwise advice on which values could be used to this end.
- advice whether $\mathrm{F} \leq 0.2$ per year on appropriate age groups can be considered as an adequate Fpa both for hake and deep water rose shrimp in GSA 6 or in any other more appropriate GSA spatial aggregation of adjacent GSAs.
- advice whether the exploitation rate $\mathrm{E} \leq 0.4$ per year on appropriate age groups is an adequate precautionary reference point both for anchovy and sardine stocks in all GSAs; otherwise advice on likely value to be used to this end.
- advice whether 50000 tonnes may be considered as adequate minimum biological acceptable levels (MBAL= Blim) both for anchovy and sardine stocks in GSA 17; otherwise advice on which values could be used to this end.
- advice whether 300000 tonnes for sardine and 80000 tonnes for anchovy may be considered as precautionary biomass reference point (=Bpa) in GSA 17; otherwise advice on which values could be used to this end.
d) Update and assess historic and recent trends (capacity, technological creep, nominal fishing effort) in the major fisheries by GSAs or, if the case, by bigger areas merging adjacent GSAs exploiting the stocks assessed. The trends should be interpreted in light of management regulations applicable to them.
e) Review the applicability and fully document all applied methodologies for the assessments and determination of the proposed biological reference points.
f) Fully document the data used and their origin for the assessments and determination of the proposed biological reference points.
g) To review proposed methodologies to standardize the MEDITS and GRUND surveys time series to account for unbalanced sampling designs and appropriate data distributions. Specific work has been initiated in this regard.
h) Investigate the requirements for reorganising the MEDITS database that result from the recommendations of STECF for combining some GSAs for some species.
i) Based on the "Survey of existing bio-economic models" under Studies and Pilot Projects for carrying out the Common Fisheries Policy No FISH/2007/07 and data made available by MS, develop specific case studies for Mediterranean fisheries (e.g. anchovy, sardine and Nephrops), and advise on possible short-term and long-term economic consequences of the selected harvesting strategies. Evaluate the possibility to use existing bioeconomic models for comparing the proposed harvesting strategies with long-term economic profitability (MEY) of the main fisheries exploiting the assessed stocks (to be continued in SGMED-09-03).
j) With a view to enhance the number of stocks jointly assessed on the spot at the forthcoming GFCMSAC working groups, either within one or by merging more than one adjacent GFCM-GSAs, identify for each selected assessment methodology the data needs, data format and start datasets preparatory work.
k) - PROTECTION OF JUVENILES AND SPAWNING AGGREGATIONS:

1) Provide relevant information on spatial and temporal distribution of seasonal or persistent juveniles aggregations and provide scientific elements indicating that possible protection of these areas may allow to control and reduce the overall fishing mortality on the stock and further improve the exploitation pattern with a view to increase the yield.
2) Provide relevant information on fishing gear selectivity (mesh size/shape, twine thickness, hanging ratio, hook size, hook shape, etc.) with a view to further improve the exploitation pattern, reduce the fishing mortality on juveniles and increase the yield.
3) Provide relevant information on spatial and temporal distribution of seasonal or persistent aggregations of spawners and provide scientific elements indicating that possible protection of these areas may reduce the risk of stock collapse and maintain the reproductive capacity of the exploited stocks.

### 2.2. Participants

The full list of participants at SGMED-09-02 is presented in Appendix 2.

## 3. Summary of data provided for the Mediterranean through the DCF call

A summary of the data provided to the SGMED-09-02 meeting by country is presented in Table 3.1.
Details of the total landing, discards and effort data by species, GSA, fishing technique and years successfully obtained through the DCF call is presented in Appendix 3.

In 2009, SGMED-09-02 experienced significant difficulties in the timing of the DCF data call and the data deliveries by Member States, although the recommended data call was prepared by the workshop SGMED 09-01 and reviewed by STECF during its spring plenary session in April 2009. In addition, many national data deliveries hardly met minimum standards requested in the data call regarding deadlines, inconsistent codification and units of data. This caused extra work and intersessional cooperation on all levels from data receipt, quality checking, data access and evaluation. SGMED recommends appropriate time be allowed for such processing of data. In addition and in accordance with the provivions of the DCF to allow appropriate data preparation by Member States, SGMED recommends future data calls be issued at least 2 months in advance of assessment meetings.

Table 3.1. Overview of data provided by country from the first DCR call for SGMED-09-02 (all stocks).

## 4. DATA PROVISION POLICY

Working Group members were reminded that data collected under the DCF call and supplied to SGMED-0902 for all GSAs could not be used outside the meeting. Requests will be made to relevant country contacts to allow the data to be stored by the EU to enable future assessments under the auspices of SGMED or related groups to be performed without the need to produce further DCF calls.

## 5. WORKING DOCUMENTS

### 5.1. Working document 1: Recent changes of small pelagics fish abundance as detected in the eastern part of GSA 17 by acoustic surveys

by Vjekoslav Ticina

The presentation described recent changes (2003-2008) in small pelagic fish abundance in the eastern part of GSA 17 (Adriatic Sea), as detected by acoustic surveys (PELMON). Directly measured acoustic indices of fish abundance ( $\mathrm{S}_{\mathrm{A}}$ or NASC, $\mathrm{m}^{2} / \mathrm{nm}^{2}$ ) were averaged over the survey area (i.e. Croatian territorial waters and protected ecological-fishery zone), and the values compared over 6-year period. With aim to detect changes in fish abundance in the given period, linear trend analyses were performed for anchovy, sardine and both species together. Correlation coefficients for all respective trend lines were calculated and tested for significance. Due to large annual changes in abundance of anchovy and sardine, in all cases (anchovy, sardine, anchovy plus sardine) it was found that no significant correlation exists ( $\mathrm{p}>0.05$ ) between trend lines and abundance data. Despite a positive trend in abundance calculated for both species together, due to nonsignificant correlation, as well as lack of acoustic data from western part of GSA 17 (MEDIAS area) during SGMED-09-02 meeting, the group was not able to make a conclusion about positive nor negative recent changes in small pelagic fish abundance in the GSA 17. Also, as it was mentioned in previous SGMED meetings, the situation detected in eastern part of GSA 17 can be different from situation in its western part.

### 5.2. Working document 2: The use of acoustics in identifying small pelagics' juvenile habitat in the Mediterranean

by Giannoulaki Marianna et al.
Acoustic and satellite environmental data as well as bathymetry data were used to model the presence of sardine juveniles, Sardina pilchardus, during early summer as well as anchovy juveniles, Engraulis encrasicolus, during autumn and winter, in the Mediterranean Sea. Acoustic data recorded with a 38 kHz split beam echosounder from the Aegean Sea (Eastern Mediterranean), the Adriatic Sea and the Gulf of Lions (Western Mediterranean) has been analyzed for this purpose. Satellite data were used as proxies to infer spatial variations of environmental factors and assess possible ecological relationships. Generalized Additive Models (GAMs) were used for modelling and subsequently applied in a predictive mode to identify those regions in the study areas and the entire Mediterranean basin that could support juveniles' presence. Model results were evaluated with the estimation of Receiver Operating Characteristic (ROC)-plots. Mapping the estimated environmental conditions indicated areas that generally agree with the known distribution grounds of anchovy and sardine juveniles. Such habitat maps that are based on speciesenvironment relations could indicate suitable areas that can consistently support juveniles' presence and might be useful to fisheries management and conservation.

### 5.3. Working document 3: Rapido trawl survey for Solea solea and other shared benthic species in the GSA 17

by Giuseppe Scarcella
The common sole Solea solea (Linnaeus, 1758) is one of the most important valuable species in the FAO GFCM area, which provides for $13 \%$ of the word overall catches of this species. Around $22 \%$ of the GFCM area landings comes from the Adriatic Sea, especially the northern and central basins (GSA 17) representing an important spawning and aggregation area for sole. Taking into consideration the importance of sole in GSA 17 and the lack of scientific data for sustainable managing the stock, the SoleMon project was initiated in 2005. The aims of the project are to provide a stock assessment of $S$. solea through surveys at sea, carried out by the rapido trawl, and analysis of landings of the fleets catching the common sole either as target species (rapido trawl and set nets) or as a portion of a multi-species catch (otter trawl). The spatial distribution of the entire population, recruits and spawning females of $S$. solea is also studied. Moreover the survey at sea provides information on trends and spatial distribution of other benthic shared resources (e.g. Sepia officinalis, Pecten jacobaeus, Melicerthus kerathurus, Squilla mantis, Chelidonichthys lucerna). The project involves CNR - ISMAR Ancona (Italy), ISPRA Chioggia (Italy), IOF Split (Croatia) and FRIS Ljubliana (Slovenia) and has been financed by MIPAF in 2005-2006 and ADRIAMED in 2007-2008. Considering the results presented at the GFCM meetings since 2005, it can be concluded that the rapido trawl survey is a very efficient tool for providing useful data for the stock assessment, spatial distribution of sole and other benthic species and management advice. It is suggested that the survey is considered to be cofounded within the Data Collection Framework.

### 5.4. Working document 4: Spawning grounds of the European anchovy Engraulis encrasicolus in the Strait of Sicily (GSA 16) and relationships with hydrographic surface circulation

## by B. Patti et al.

Some aspects of the effects of the hydrographic circulation on the reproductive strategy of the European anchovy (Engraulis encrasicolus, L. 1758) population off the southern coast of Sicily were investigated, using information from satellite SST data and anchovy egg horizontal distributions. Ichthyoplanktonic data used in this study were collected during summer oceanographic surveys carried out from 1997 to 2006. The general circulation pattern is locally controlled by the motion of the Modified Atlantic Water, the Atlantic Ionian Stream (AIS). During summer the water mass advected by the AIS to the south of Sicily is fresher and also warmer than the surrounding waters north of it at the same depth. This characteristic permits to use temperature as a tracer to depict the AIS trajectory. The year to year variability of AIS path, inferred from SST data, while establishing different environmental conditions along the southern coast of Sicily, appeared to be able to affect the spawning strategy of anchovy, which has preference for warm waters. Namely, the analysis of available information permitted to identify correlation patterns between standardized SST and the location of major spawning grounds, with some important exceptions suggesting that, occasionally, environmental factors other than temperature may control spawning behaviour.

### 5.5. Working document 5: Data on hake nurseries in the Gulf of Lions (GSA 7)

by H. Farrugio et al.
During the European project Données sur la distribution des principales espèces commerciales du golfe du Lion (et plus particulièrement des groupes 0 et 1), distribution maps of the juveniles of hake and other 12 species exploited in the gulf of Lions have been estimated. The data used came from three trawl surveys conducted by IFREMER in 1988on the continental shelf between 10 and 250 m depth, sampling in the main fish markets and on board professional fishing boats. Indices of abundance in number of fish per hectar and by depth stratum were calculated using the Pennington \& Gryslein (1978) method and the results have been mapped for the three periods of observations, February, June and November. This work shows that the highest abundance ( $62 \%$ ) of the 0 -group was observed in June, while they were less abundant in November
(36\%) and almost absent in February. The 0 -group hake was mainly caught on the external border of the continental shelf, in the vicinity of the top of the slope canyons. For the present SGMED working group the available data on juvenile hakes ( 0 group) coming from the MEDITS surveys in the gulf of Lions for the period 1998 to 2008 have been preliminary analysed by a group of IEO/IFREMER French and Spanish scientists. For each of the 11 years, standardized indices of abundance of age 0 individuals have been calculated. The SURFER software was used to create contour maps showing their distribution. An attempt was made to apply the kriging methodology, but unfortunately, except for the data of the year 1998, it was not possible to obtain a suitable variograms. Hence, the contour maps were finally created by applying the inverse distance to a power method. A great variability was observed in the abundance of the age 0 group, however the geographic pattern of recruitment appears to be fairly constant throughout the time series analysed. This pattern is even clearer by combining the data coming from the whole series of MEDITS surveys. The map obtained in this way shows that in June, the hake recruits are mainly concentrated in the eastern part of the Gulf of Lions, along the external border of the continental shelf, in the vicinity of the top of the slope canyons where a Fishery Restricted Area has been established in 2009 by the GFCM in order to protect the large spawners living there.

### 5.6. Working document 6: Estimation of natural mortality and redefinition of current divisions of GSA for stock assessment

## By Alvero Abella

In the ToRs of the Murcia meeting, it was posed the problem of the choice of methods allowing the estimation of natural mortality rates. It was stressed the need of considering as a preferred choice those that assume declining vectors of M at age or at size. The assumption of a constant value is likely to provide, in the case of the Mediterranean fisheries, a wrong perception of the stocks status with consequences on management. It was recommended, when available data make it feasible, to use two approaches that allow defining a decreasing M at size vector, namely the Gislason et al (2005) model, based on growth parameters and the Abella et al (1997) model, based on considerations on biomass and production (see details in the final SGMED 09-01 report). The group also suggested that other approaches could be used in the case scientists were not confident with the estimates of parameters needed for the use of the above mentioned approaches. In this case, the different choice must be justified. During the SGMED meeting there was also addressed the problem of the definition of the current divisions of GSAs for stock assessment. Most of the GSAs definitions approved by GFCM were more based on political considerations than biological knowledge. It was presented a paper as a base of discussion that analysed the trends in abundance observed in each GSA for a selected number of species and checking on consistence of these trends among neighbouring GSAs. Results of the analysis were considered useful for helping on decisions related to the convenience of merging neighbouring GSAs. The merging of neighbouring GSAs might be taken under consideration as an attempt of improving the reliability of stock assessments and may imply the definition of different units of management. It was stressed that the need to merge GSAs may be species-specific and may depend on the spatial scale of some biological phenomena as migrations, spawning and nursery areas, oceanography as well as on spatial dynamics of fleets. Proposals of mergings are included in the final report of the Murcia meeting.

### 5.7. Working document 7: Nursey localization of some key demersal species in the GSA 10 , 18 and 19.

## by M.T. Spedicato

Nursery area of relevant demersal species (hake, deep water rose shrimp) were localised in the centralsouthern Tyrrhenian Sea (GSA 10), in the south Adriatic (GSA 18) and in the western Ionian Sea (GSA 19) in the framework of a research project conducted at national level. Juveniles were identified analysing the length frequency distribution of trawl survey data and cut-off size used to split the LFD of each species into juvenile and adult components. Geo-referenced abundance indices were used to assess the spatial distribution of juveniles, applying geostatistical methods and kriging techniques. Structural analysis was conducted and the more common variogram model fitted to the data was the exponential and spherical ones with ranges generally describing a structure at small spatial scale. Localization of the nurseries was obtained by Indicator

Kriging that allows interpreting the localization in terms of probability, after defining cut-off thresholds based on the ranking of the cumulative abundance and the number of hauls. Maps of the modelled nurseries were then analysed throughout the time to estimate the persistence of the localization. The applied techniques was based on the averaging of the probability contours when these were higher than 0.6 . In the southern Tyrrhenian sea nursery of hake and deep water rose shrimp were localised off Ischia Island, in the Napoli and Salerno Gulf and offshore Cape Bonifati (Calabria coasts), whilst persistent nuclei for the same species were located along the Gargano promontory and off Capo Santa Maria di Leuca in the GSA 18 and 19 , respectively.

### 5.8. Working document 8: Nursey localization of demersal species in the italian GSAs

by M. Murenu

A national project conducted by SIBM was devoted to analyze the recruitment of the demersal species economically most relevant (Eledone cirrhosa, Merluccius merluccius, Mullus barbatus, Nephrops norvegicus, Parapenaeus longirostris, Phycis blennoides) in all the italian GSAs. In few GSAs other important species were considered (Aristaeomorpha foliacea, Illex coindetii, Loligo vulgaris, Pagellus erythrinus). A geostatistical approach is used to define the main nursery areas of demersal resources and define their persistence by means of direct estimation of fish densities. Data collected during trawl surveys carried out in the 7 Italian GSAs in the late-spring and autumn from 1994 to 2006 were analysed to locate aggregation of 0 group individuals (recruits) and check their stability by means of geo-spatial methods and common criteria. Juveniles were identified analysing the length frequency distribution of trawl survey data and cut-off size used to split the LFD of each species into juvenile and adult components. Juveniles georeferenced abundance indices were afterwards used to assess their spatial distribution, applying geostatistical methods and kriging techniques. Localization of the nurseries was obtained by Indicator Kriging that allows interpreting the localization in terms of probability, after defining cut-off thresholds based on the ranking of the cumulative abundance and the number of hauls. As a case study of the project results for the European Hake are reported in Murenu et al. (submitted paper). Although a certain degree of variability in extension and shape of areas with high concentrations of hake recruits was observed over the years in each GSA, the results of persistence analysis showed a considerable stability in their location. Most of the nursery areas are located inside the territorial waters with the notable exception of those of the GSAs 16,17 , and 18 . In these GSAs the percentage of the recruitment area which falls in international waters ranges from $86 \%$ in the GSA 17 to $100 \%$ in the GSA 18 .

## 6. SGMED 09-02 RESPONSES TO SPECIAL QUESTIONS OF TOR C, D, G, I AND K

## 6.1. c) Review and propose biological reference points related to high yields and low risk of fishery collapse in long term of each of the stocks assessed.

SGMED considers the establishment of management reference points crucial to achieve high sustainable long term yield of Mediterranean fish and shellfish stocks in the short and medium term. Within its mandate, STECF can endorse management reference points as proposed by its subgroup SGMED. After a general discussion on candidate reference points applied in fisheries management of Mediterranean fish and shellfish stocks, SGMED recommends that high priority should be given to exploitation indicators (fishing mortality) and its appropriate levels to achieve high sustainable long term yield. Considering data availability and the recent political agreements (UN, 2002) and EU communications (Council Conclusions 2007), SGMED recommends the application of $\mathrm{F}_{\mathrm{msy}}$ (maximum sustainable yield), with $\mathrm{F}_{0.1}$ derived from Yield per Recruit analysis as the appropriate proxy in case of data lack or uncertainty (Kell and Fromentin, 2007). Contrarily, state indicators of stock size in terms of biomass are rather difficult to interpret, as decreases in biomass below reference levels such as $\mathrm{B}_{\text {lim }}$ (biomass of all adult specimens at the level of impaired recruitment) and $\mathrm{B}_{\mathrm{pa}}$ (precautionary reference of the biomass of all adult specimens including uncertainty) can be due to many ecological effects in addition to the fishery impact. Also, the shortness of the assessment time series for most of the Mediterranean stocks and the lack of historical data, impede the establishment of biomass reference points. In the light of the fact that the actual stock size cannot be directly controlled through fisheries management, SGMED recommends stock biomass reference points be given less priority in fisheries management of Mediterranean fish and shellfish stocks than exploitation indicators. SGMED further recommends that levels of fishing mortality $\mathrm{F}_{\mathrm{msy}}$ or its proxy $\mathrm{F}_{0.1}$ should rather be interpreted and applied as management targets than any category boundaries, accounting also for uncertainty. Given the limited but best data and stock assessment results available, SGMED recommends such targets being applied within an adaptive management framework of multiannual plans.

SGMED did not apply any analytical approach to comment on appropriate fisheries management reference points regarding state indicators $\mathrm{B}_{\text {lim }}$ or $\mathrm{B}_{\mathrm{pa}}$ but bases its comments on visual inspection of relationships between recruitment and spawning stock size. Proposed fisheries management reference points regarding exploitation indicators are commented in relation to estimated $\mathrm{F}_{\mathrm{ms}}, \mathrm{F}_{0.1}$ values and evaluations of the stock response to different levels of exploitation.

### 6.1.1.European hake (Merluccius merluccius) in GSA 6

SGMED recommends that the proposed $\mathrm{F} \leq 0.2$ reference point can be interpreted as a management target. SGMED bases its recommendation of a revised stock assessment accounting for the fast growth hypothesis. Such revised stock assessment is presented in this report in section 8.4. SGMED notes that $\mathrm{F}_{\max }=0.23$ and $\mathrm{F}_{0.1}$ $=0.17$ (ages 2-4) are within the range of the proposed value. Thus, SGMED recommends the establishment of $\mathrm{F} \leq 0.2$ as a management target. SGMED notes that the age range 2-4 does not cover ages 0 and 1 , which contributed to most of the landings. SGMED recommends that the reference ages of the mean fishing mortality and the reference points be revised to 1-4 in order to include the youngest age groups.

SGMED is not in the position to estimate or propose adequate limit $\left(\mathrm{B}_{\mathrm{lim}}\right)$ or precautionary ( $\mathrm{B}_{\mathrm{pa}}$ ) biomass reference points given the data available. Major scientific concerns arise from the shortage of the time series and the limited stock dynamics it covers. The time series hardly covers the proposed $\mathrm{B}_{\mathrm{lim}}=2,200 \mathrm{t}$ and $\mathrm{B}_{\mathrm{pa}}=4,000$ t. SGMED notes that the recent stock size is estimated at a much lower level and thus recommends the proposed biomass reference points of $\mathrm{B}_{\mathrm{lim}}$ and $\mathrm{B}_{\mathrm{pa}}$ be established as biomass reference points. Those values might be revised in the future when more information becomes available.

SGMED is not in the position to estimate and propose appropriate management targets of fishing mortality or biomass reference points. Major scientific concerns arise from the shortage of the time series and the extreme stock dynamics it covers. SGMED notes that the proposed $\mathrm{F} \leq 0.2$ is much lower than the current exploitation of $\mathrm{F}=0.5$ for ages 2-5. In the light of the management advice of SGMED to reduce F in order to allow the stock to rebuild, SGMED recommends that $\mathrm{F} \leq 0.2$ be established as a management target and a proxy for $\mathrm{F}_{\text {msy }}$. This value might be revised in the future when more information becomes available.

After a continuous decline stock biomass in 2008 is estimated to amount to 111 t , the lowest level observed since 2002. STECF notes that this level is much lower than the proposed management references of $\mathrm{B}_{\mathrm{lim}}=300 \mathrm{t}$ and $\mathrm{B}_{\mathrm{pa}}=1,200 \mathrm{t}$, respectively. Given the management advice of SGMED to allow the stock to recover, SGMED recommends the proposed state reference points of $\mathrm{B}_{\mathrm{lim}}$ and $\mathrm{B}_{\mathrm{pa}}$ be established as biomass reference points. Those values might be revised in the future when more information becomes available.

### 6.1.3.Appropriateness of exploitation rate $E \leq 0.4$ for anchovy (Engraulis encrasicolus) and sardine (Sardina pilchardus) in the Mediterranean Sea

SGMED notes that stock productivity may differ between stocks in various regions of the Mediterranean Sea. Furthermore, stock productivity may also change over time. Neither the spatial nor the temporal coverage of stock assessments of anchovy and sardine in the Mediterranean Sea can provide a definitive answer regarding the appropriateness of an $\mathrm{E} \leq 0.4$. However, SGMED summarized the stocks of anchovy and sardine assessed and compared the stock trends with the current and historical exploitation rates.

The following table (Tab. 6.1.3.1) lists recruitment and the stock size in comparison with the estimated exploitation rates of the 5 stocks of each species anchovy and sardine assessed. Only the stocks of anchovy and sardine in GSA 17 have historical time series of stock size and exploitation extending to periods before 2000. 5 out of 6 stocks exploited at $\mathrm{E} \geq 0.5$ are in a reduced or low status of SSB or recruitment, with Sardine in GSA 22 being the only exception where both recruitment and SSB are either high or recovering, respectively. All the remaining 4 stocks with $\mathrm{E}<0.5$ display a medium, recovering, recovered or even high stock size. Only sardine in GSA 01 displays a poor recruitment at $\mathrm{E}<0.5$. However, the conclusions drawn from a comparison of long term stock responses to E > 0.4 in GSA 17 of anchovy and sardine stock are conflicting. Both stocks have undergone continuously declining trends with an exploitation rate in excess of 0.4 for anchovy and an exploitation rate of less than 0.4 for sardine.

SGMED concludes that the short term responses of the assessed anchovy and sardine stocks to recent exploitation rates indicate that an exploitation rate in the order of $\mathrm{E} \leq 0.4$ might be consistent with the management goal of high long term yields, taking into account the dynamic of the stocks. SGMED underlines that limited area and temporal coverage of the available stock assessments impede any quantification of risk related to this statement. As such, the expressed indication regarding Mediterranean small pelagic stocks is in agreement with empirical findings of Patterson (1992), who has proposed this exploitation level. SGMED recommends the application of the proposed exploitation rate $\mathrm{E} \leq 0.4$ as management target for stocks of anchovy and sardine in the Mediterranean Sea. This value might be revised in the future when more information becomes available.

Tab. 6.1.3.1. Recent and historic status of the stock parameters spawning stock biomass (SSB) and recruitment $(\mathrm{R})$ in comparison with assessed exploitation rates E .

| Stock | recent E | recent R | recent SSB | historic E | historic SSB |
| :--- | :---: | :---: | :---: | :---: | :---: |
| Anchovy GSA 01 | 0.74 | low | low |  |  |
| Anchovy GSA 06 | 0.78 | low | low |  |  |
| Anchovy GSA 16 | 0.64 | unknown | low |  |  |
| Anchovy GSA 17 | 0.45 | recovered | recovered | E $>0.4$ | declining |
| Anchovy GSA 22 | 0.30 | high | high |  |  |
| Sardine GSA 01 | 0.48 | reduced | med |  |  |
| Sardine GSA 06 | 0.71 | reduced | reduced |  |  |
| Sardine GSA 16 | 0.22 | unknown | recovering |  |  |
| Sardine GSA 17 | 0.50 | low | low | E<0.4 | declining |
| Sardine GSA 22 | 0.50 | high | recovering |  |  |

### 6.1.4.Biomass reference points for Anchovy (Engraulis encrasicolus) in GSA 17

SGMED bases its recommendations regarding the proposed biomass reference points of $\mathrm{B}_{\mathrm{lim}}=50,000 \mathrm{t}$ and $\mathrm{B}_{\mathrm{pa}}=80,000 \mathrm{t}$ on a revised stock assessment accounting for natural mortality rates as advised during the SGMED workshop in Murcia, 2-6 March 2009. Such revised stock assessment is presented in this report in section 8.42.

The visual inspection of the scatter plot of recruitment versus spawning stock biomass clearly indicates that recruitment is impaired at stock sizes below 50,000 t. Thus, SGMED recommends establishing $\mathrm{B}_{\mathrm{lim}}=50,000 \mathrm{t}$ for the stock of anchovy in GSA 17.

According to FAO recommendations (Cadima, 2003), $\mathrm{B}_{\mathrm{pa}}$ should be in the range of $1.39 * \mathrm{~B}_{\mathrm{lim}}-1.64 * \mathrm{~B}_{\mathrm{lim}}$, accounting for uncertainty in the estimations of fishing mortality. Such factors would determine $B_{p a}$ being in the range of $70,000 t-82,000$ t. Thus, SGMED recommends establishing $\mathrm{B}_{\mathrm{pa}}=80,000 \mathrm{t}$ for the stock of anchovy in GSA 17.

### 6.1.5.Biomass reference points for Sardine (Sardina pilchardus) in GSA 17

SGMED bases its recommendations regarding the proposed biomass reference points of $\mathrm{B}_{\mathrm{lim}}=50,000 \mathrm{t}$ and $\mathrm{B}_{\mathrm{pa}}=300,000 \mathrm{t}$ on a revised stock assessment accounting for natural mortality rates as advised during the SGMED workshop in Murcia, 2-6 March 2009. Such revised stock assessment is presented in this report in section 8.45 .

The visual inspection of the scatter plot of recruitment versus spawning stock biomass clearly indicates that recruitment is impaired at stock sizes below 180,000 t. Thus, SGMED recommends establishing $\mathrm{B}_{\mathrm{lim}}=180,000 \mathrm{t}$ for the stock of sardine in GSA 17.

According to FAO recommendations (Cadima, 2003), $\mathrm{B}_{\mathrm{pa}}$ should be in the range of $1.39 * \mathrm{~B}_{\mathrm{lim}}-1.64 * \mathrm{~B}_{\mathrm{lim}}$, accounting for uncertainty in the estimations of fishing mortality. Such factors would determine $\mathrm{B}_{\mathrm{pa}}$ being in the range of $250,000 \mathrm{t}-295,000$ t. Thus, SGMED recommends establishing $\mathrm{B}_{\mathrm{pa}}=270,000 \mathrm{t}$ for the stock of sardine in GSA 17.
6.2. d) update and assess historic and recent trends (capacity, technological creeping, nominal fishing effort) in the major fisheries by GSAs or, if the case, by bigger areas merging adjacent GSAs exploiting the stocks assessed. The trends should be interpreted in light of management regulations applicable to them

Fleet specific trends in fishing effort are given under the stock specific assessments in section 8 by area.

## Cyprus

Data are available for the period 2005-2007 by fleet segment and for the period 2005-2008 for the effort, and possibly concerns GSA 25 . The complete set of information (number of vessels, kw, GT, age, days, kw/day and GT/day) is available by gear. Previous data were not available at the meeting.

Demersal trawlers
There is a decreasing trend either in number of vessels or capacity (GT and kw) or effort (days, $\mathrm{kw}^{*}$ day and GT*day) in the segment 12-24 m. No other segments are present.

Fig. 6.2.1 Trends in Cyprian fleet specific effort.

## Purse seiners

According to the data, only one purse seiner was active in 2005 (GT 51; kw 270). This vessel become inactive in 2006 and was possibly dismissed in 2007.

## France

Fleet characteristics (number of vessels, GT and kw) and effort data (fishing days, kw*day and GT*day) are available for the period 2003-2008 by gear and for GSA 7. The number of vessels and data concerning the purse-seine sector were not provided by MS. Previous data and data from GSA 8 were not available at the meeting.

## Bottom trawlers (OTB - GSA 7)

There is a clear decreasing trend for all the fleet parameters and also for the number of fishing days and the kw*day, while GT*day shows a slight decreasing trend. Data are concerning mostly the fleet segment 12-24 m.

Fig. 6.2.2 Trends in French fleet specific effort.

Pelagic trawlers (OTM - GSA 7)
As concerns the fleet data, all the trends show a remarkable increase. On the opposite, there is a clear decreasing trend for the number of fishing days and the $\mathrm{kw}^{*}$ day, while GT*day shows only a slight decreasing trend. Data are concerning mostly the fleet segment 12-24 m.

Fig. 6.2.3 Trends in French fleet specific effort.

## Greece

No fleet or capacity data have been submitted by Greece at the meeting. Data used in SGMED-08-03 are here included. They concerns only fleets exploiting the European hake in GSA 20, 22 and 23, by all gear and fleet segments, with the historical trends.

Fleets exploiting the European hake in GSA 20: The available capacity indicators (number of vessels and GT) show declining trends over the period 1991-2007.

| GSA-20: Trawlers | GSA-20: Hooks |  |  |  | GSA-20: Static nets |  |  |  | GSA-20: Polyvalent artisanal |  |  |  | GSA-20: Boat Seine |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

Fig. 6.2.4 Trends in Greek fleet specific effort.

Fleets exploiting the European hake in GSA 22: The available capacity indicators (number of vessels and GT) show declining trends over the period 1991-2007, with the exception of the GT for trawlers.

Fig. 6.2.5 Trends in Greek fleet specific effort.

Fleets exploiting the European hake in GSA 23: The available capacity indicators (number of vessels and GT) show declining trends over the period 1991-2007, except for the set nets, which show an increasing trend.

Fig. 6.2.6 Trends in Greek fleet specific effort.

## Italy

Data are available for the period 2002-2007 by fleet segment and by GSA. The complete set of information (number of vessels, kw, GT, age, days, kw*days and GT*days) is available by gear. Trends are possibly affected by the gear classification adopted, which moved several polyvalent vessels to trawlers or to other segments. Previous historical data were not available at the meeting. Due to the number of variables, data on fishing effort are not showed in graphs in this synthesis.

Demersal trawlers (number of vessels by length segment and GSA):
GSA 9 -There is a slight increasing trend in the segment $0-12 \mathrm{~m}$ and an increasing trend in the segment 1224 m .
GSA 10 - There is an increasing trend in the segment $12-24 \mathrm{~m}$.
GSA 11 - There is an increasing trend in the segment $12-24 \mathrm{~m}$ and a decreasing trend for the segment $24-40$ m.

TYPEINUMBER

## Malta

Capacity data (days, $\mathrm{kw}^{*}$ days and GT*days) from 2005 to 2008 , by segment, have been provided for the meeting. The data are related to GSA 15.

## Bottom trawlers (OTB)

The data related to the bottom trawlers (OTB) are concerning two segments ( $18-24 \mathrm{~m}$ and $24-40 \mathrm{~m}$ ), but disaggregated data on the number of vessels are available only for 2008. All data show increasing trends over the period considered.

Fig. 6.2.23 Trends in Maltesean fleet specific effort.

## Other bottom trawlers (TBB)

The capacity table provided by Malta includes this new category only in 2008, with two segments ( $0-12 \mathrm{~m}$ and 12-24 m). There are no data on the related fleet.

Purse-seiners (LA)
Capacity data on purse seiners (Lampara) targeting small pelagics are available for the period 2006-2008, but no information on the fleet is available. Data are showing a decreasing trend over the short period taken into account.

Fig. 6.2.24 Trends in Maltesean fleet specific effort.
Other surrounding nets (PS) for small pelagics.
The capacity table provided by Malta includes this new category only in 2008, with two segments ( $0-12 \mathrm{~m}$ and 12-24 m). There are no data on the related fleet.

## Slovenia

Fleet data (number of vessels, GT and kw by segment) have been provided for the period 2006-2007, while data on fishing days have been provided for the period 2006-2008 but only for purse-seiners by segment. It is supposed that data are related to GSA 17.

## Bottom trawlers (DTS)

Data on bottom trawlers are available by segment, but they are here presented in total by year. All trends are increasing in the two years available and this is due to the higher number $(+2)$ of larger trawlers $(12-24 \mathrm{~m})$.

Fig. 6.2.25 Trends in Slovenian fleet specific effort.

Data on purse seiners are partly confusing, due to the lack of fleet data for 2008 and to the use of different codes for the effort data. As a matter of fact, fleet data are referred to PTS for all segments in 2006 and 2007, while effort data are referred to PS for the segments $0-12 \mathrm{~m}$ and 12-24 m and to PTM for the segment 24-40 m for the period 2006-2008. Effort data for 2008 cannot be correlated to any reference fleet data. In this situation, it is difficult to define and understand trends: the fleet decreased in 2007 ( -1 vessel in the segment $0-12 \mathrm{~m}$ ), but data on 2008 are not available; kw and GT are stable in 2006 and 2007, but data on 2008 are again not available, while the total number of fishing days is slightly decreasing over the period 2006-2008.

Fig. 6.2.26 Trends in Slovenian fleet specific effort.

## Spain

No data have been provided by Spain for the meeting. Fleet data have been provided by the experts during the meeting, for the fleets in GSA 1 and 6 . No data are available for GSA 2 and 5 , or for capacity or effort in all the GSAs.

## Bottom trawlers (GSA 1 and GSA 6)

The few data available for GSA 1 (2005-2007) show a slightly increasing trend of the fleet. The historical trend of the fleet in GSA 6 (1998-2007) shows a clear decreasing trend.

Fig. 6.2.27 Trends in Spanish fleet specific effort.

The historical trends of the fleets in GSA 1 and GSA 6 (1998-2007, with a hole in 1999) shows a clear decreasing trend during the period analysed.

Fig. 6.2.28 Trends in Spanish fleet specific effort.
SGMED conclusions and recommendations:

The following Table 6.2 .1 summarises the data presented in the document by GSA and MS concerned, for the major fisheries analysed. For bottom trawlers, trends are equally positive and negative, with data missing in several GSAs. For purse seiners, trends are again equally positive and negative, with a majority of GSAs were data are not available.

SGMED concludes that there is no evidence of a general decline in fishing capacity of the Mediterranean fleets. However, this might be also the result of changes in the classification system (i.e: from polyvalent to a specific gear type).

Table 6.2.1 Overview on effort trends observed over recent years as plotted in the figures above, by country and GSA.

| Cyprus | 25 | 2005-2007 | MS | - | - | - | - |  |  |  |  | - | - | - | - |
| legenda: MS Member State; E Experts; - negative trend; + positive trend; = stability; $\mathbf{n d}$-no data available; $\mathbf{n a}$-non applicable; a -data available but not plotted. |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |

From the above reported data, it is also evident that it is essential to improve the data collection system for the fleet information. Several MS did not provide the relevant data on fleets, capacity and effort (required under the economic section), while updated information is often missing. Data provided are often incomplete and sometimes are inconsistent. It should be essential to revise the available data series trying to provide coherence between the previous DCR data and the new DCF data otherwise it will be impossible to define trends of the basic fleet parameters. Reported data on fleets are not always usable and their utility for stock assessments and management purposes appears questionable, even if it is reasonable to assume that reliable data are available at national level in all MS.

## 6.3. g) Review of proposed methodologies to standardize the MEDITS and GRUND surveys time series to account for unbalanced sampling designs and appropriate data distributions. Specific work has been initiated in this regard.

Main General Points

Issues and importance of CPUE data
CPUE data can be generated from commercial data as catch/fishing day/boat/area, or from survey as catch/swept area/area/strata. CPUE's are the easiest data to collect and analyze, however the analysis of this data can generate various types of errors. The factors that can make CPUE's non representative of stock biomass are: unaccounted changes in catchability over time, changes in fish spatial distribution and availability (a), changes in fishing behavioural responses that would affect a and cause hyperdepletion or hyperstability of the CPUE time series (Hilborn and Walters, 1992). These are all sources of errors and biases that can be generated by modeling CPUEs under varying catchability (q) and a. The bias can propagate as errors in the estimation of stock biomass indices and thus in the stock assessment.

Generalized Linear Models (GLM) (MacCullagh and Nelder 1999), Generalized Additive Models (GAM) (Hastie and Tibshirani, 1990) and Generalized Mixed Models (GLMM) (Venables and Dichmont, 2004) are powerful tool for standardizing CPUEs and to build robust stock indices. In addition if year is treated as a factor, the time effect will be the best estimate of the abundance trend (Hilborn and Walters, 1992, Stefánsson, 1996). However, if there are effects, such as gear modification or others, that affect the catchability but are unquantifiable in the model, the GLM/GAM/GLMM models will ascribe those effects to change in abundance rather than gear (Hilborn and Walters, 1992). Therefore, the use of CPUE data must be conducted very carefully, considering the temporal and spatial development of fishing or survey spatial/temporal stratification.

## Need and advantages of standardization

The risk associated with building stock assessments on "raw" catch rates from either survey or commercial data have been known for many years and various methods to standardise catch and effort data have been developed. Fishery data are well known to be highly variable and noisy, thus a wide range of methodologies are applied to improve experimental design and data analysis. Although this group of methods were revealed successful in respect to the need to provide unbiased indices of abundance, one of their major difficulties is related to the high occurrence of low values or zeros. This kind of data represented a real challenge for scientists and statisticians mining some of the main assumptions on which Gaussian models rely. These data are generally referred as zero-inflated distributed and an array of different approaches has been developed in the last years for working with them. The problem of zero inflated data is particularly true for species with very rare occurrence such as some elasmobranchs or in the case the indices of abundance are estimated by year classes (i.e. that it is usually the case for indices used for tuning of VPA type of models) which greatly reduces the numbers of non- zero tows (Stefánsson, 1996).
The GLM/GAM/GLMM models has the advantage over the stratified analysis that the underlying spatial pattern of the fish density can be modeled explicitly, an aspect ignored by the stratified analysis. Also, data from all years of the survey can be analyzed at once and data from incomplete surveys can be included.

Survey data standardization (MEDITS, GRUND)
Distribution and link function
GLM/GAM/GLMM models extend the framework of classical (normal-based) linear models to allow the error distribution to be any member of the exponential dispersion family. According to the type of data different distributions and relative link functions need to be chosen.

- If the interest is to model the density (numbers of individuals), e.g. discrete data, a Poisson, Binomial, Negative binomial distribution among the others can be used. More specifically depending on the number of zero's in the data some distributions are more appropriate than others.
- If abundance data (kg), e.g. continuous data, is modelled a Gaussian, LogNormal, Gamma, Negative binomial and quasi-poisson distributions among the others can be used.

The link function, which relates the linear predictor to the mean, needs to be chosen depending on the error distribution and the type of data.

## Swept area

The swept area estimation is an essential parameter that needs to be as accurate as possible as it used to scale fish abundance or density. The swept area enters into the regression model as the part of the modelled CPUE index and either as an offset parameter or as a predictor depending on whether the estimate is very accurate or not. Setting swept area as a model offset in a GLM/GAM/GLMM models are equivalent to setting it's regression coefficient equal to 1 (MacCullagh and Nelder, 1999) and this is commonly used in survey standardization (Helser et al., 2004; Gutiérrez et al., 2008).

## Zero inflation

There are different methods to deal with zero inflated data. Within GLM's the simplest way to deal with zeros is the transformation of the CPUE (by addition of 1 or a small number to the zero catch), however this approach has been widely criticized as it can yield biased estimates. Alternatively the use of the negative binomial error structure to model the predicted catch also avoids the need to adjust the observed catch values (Campbell, 2004). For situations with even more inflated data, the Delta method can be used (Lo et al., 1992; Stefánsson,, 1996). This is based on the product of fitted values from two GLM/GAM/GLMM models. The index combines year effects from a binomial GLM/GAM/GLMM models that estimates the probability, p, of a positive observation, and a second GLM/GAM/GLMM models that estimates the mean, $\mu$, conditioned on a positive observation. The final Delta GLM/GAM/GLMM models abundance index is the product of the year effects from the two models, $p \mu$.

Thus, within GLM/GAM/GLMM models to address zero inflation the following method can be adopted:

1. presence/absence $(1,0)$ are firstly modeled as a binary process using the binomial distribution. Model predictions Pij (where i and j are geographical coordinates) indicate the probability of finding a certain species at a particular location
2. fish density ( $\mathrm{nkm}-2$ ) is modeled using a negative binomial distribution (or any other appropriate distribution for the data) to obtain the model predictions Dij.
3. Final overall predictions Yij are obtained by multiplying the results of the previous two model fit: Yij = Pij * Dij

## Environmental data

Environmental variables as explanatory covariates can be used to separate the variation in the catch rates per tow into that due to inter-annual variation in population size and that due to differences in the environmental variables (Brynjarsdottir and Stefansson, 2004)

Spatial and Temporal data correlation
A common problem with fisheries data is autocorrelation at a temporal and spatial level. Regression models such as GLM's and GAM's assume data independence and therefore when dealing with CPUE data this assumption is violated if not dealt with explicitly. As a consequence data exhibiting the autocorrelation of time series and spatial processes are excluded although there are some ways to relax such assumptions as using quasi-likelihood estimation (MacCullagh and Nelder, 1999). To deal with spatial correlation in GLM's the use of Spatial-GLM's resolves the spatial bias and yields unbiased indices (Nishida and Chen, 2004). To account for the spatial correlation effect in GAMs and get a more accurate estimate of the significance of the terms, the p-values were computed using a wild bootstrap approach (Davison and Hinkley, 1997). Specifically, for a given fitted model: (1) the residuals were extracted, (2) rescaled, to have the same variance as the estimated scale parameter of the model, (3) their signs randomly inverted before being (4) used as a response variable in a model (having the same set of covariates as the original model). Steps 3-4 are repeated usually 1000 times.

Working procedure for MEDITS standardization in R

1. Select species of interest
2. Merge MEDITS TA with either TB or TC files for all years available
3. Code season, mean depth, environmental variables, etc.
4. Transform latitude and longitude in UTM system
5. Calculate swept area
6. Subset for biomass or abundance as response
7. If abundance is selected divide in age classes or not
8. Assess the degree of zero inflation to decide which method to use
9. Chose modelling framework (GLM, GAM, GLMM) and initial error distribution and link function
10. Example of a GLM model script for hake in R:

GLM(individuals MERLMER/swep area~year+season+lat+lon+ depth+offset=(swept),
family="Gaussian"(link=log), na.action=na.remove)
11. Compare different models checking term significance, AIC, GCV and others and residuals fits using ANOVA tests and other diagnostics
12. Plot fits over years to visualize temporal trends and add confidence intervals

## GRUND

In Italian waters the GRUND is an important source of survey information that ranges over the period 1985 to present. This survey in most GSA's charters commercial vessels with un-standardized nets and there have been frequent gear/vessels changes over time within the same GSAs. An exception is the GSA 15 and 16 where the same net and boat have been used consistently until summer 2008. The standardization of the GRUND survey indices is extremely important to build unbiased indices of abundance/density. The critical point is the fact that fishing power and catchability have changed at each gear change thus introducing a potential bias. That is that likely fishing equipment has undergone technological creeping over the 25 years and the fishing power has increased. This could potentially mask stock declines unless it is accounted for. Standardizing for increased fishing power is difficult unless an inter-calibration is performed. One intercalibration experiment has been carried out in 1999 (Lembo 1999) between the vessels of all the Italian GSA's. In this context some correcting coefficients had been estimated and could be revised using a methodological approach. The inter-calibration is however a one point in time that is valid only for the boats that participated at the time. Prior and posterior gear change within GSA has no inter-calibration coefficient. One possibility is jointly fitting a GLM/GLMM/GAM to GRUND and MEDITS data from 1994 onward, in the same areas. Such model would estimate survey effect and estimate the changes in catchability at each gear change in the GRUND survey using as a reference the MEDITS which is assumed to have remained constant over time.

MEDITS intercalibration
In the MEDITS survey the same net is used on vessels ranging from small trawlers to oceanographic vessels. While still untested, this has likely an effect on catchability and survey data. As SGMED is exploring the possibility of doing assessments on merged GSA's, understanding how the MEDITS net performs on different types of vessels is very important. Within data standardization effort, the performance of different vessels should be investigated. If mayor differences between GSA's emerge, the MEDITS steering committee should address it.

## Commercial CPUE Standardization

Standardizing commercial CPUE's entails the same steps as for survey data with some further complications and risks of bias than with survey CPUEs. The main problems are the estimation of fishing time/effort, fishing area, fishing strategy and change in fishing power and technological creep over time. Fishing time/effort needs to be known with accuracy as it is used to build the CPUE and can be used as an offset parameter. In some areas there are only daily fishing trips and others multiple day trips. Fishing area should be available for standardization of the CPUE as if there are unaccounted shifts of fishing pattern or of the stock distribution the CPUEs tend to be biased. For this reason the interaction between year and geographical information should be modelled. In a multi-species fishery as in the Mediterranean, identifying the fishing strategy is important for the standardization. PCA approaches are used routinely (Sbrana et al., 2003; Maynou et al., 2004) to identify the different metiers and quantify the amount of effort directed towards a
single specie (or group of species). Target fishery can lead to overestimated CPUE's if fishermen are able to find fish aggregations, like for the North Sea cod, while non-target fisheries tend to be less biased (Maynou et al., 2003). In the standardization process once year, month and geographical information are used as predictors a choice needs to be made regarding the use of fleet technical characteristics as covariates. In some cases only vessel ID is used as a covariate (Bataille and Quinn, 2004) or others vessel technical details can be used such as HP/Kw, GRT/GT and vessel Length. Depending on how much variance is explained by either set of predictors or the correlation between them, one can use either or combine all the predictors in the CPUE standardization.

SGMED conclusions and recommendations
The current SURBA assessments models made using MEDITS time series or VPA tuned with MEDITS time series are run on un-standardized data of abundance biomass or year class strength. SGMED consider that this particular aspect would require an ad-hoc working group to develop and test species specific R script that would be used by the different GSA to standardise MEDITS time series used into stock assessment. In addition the performance and estimates of SURBA assessments and VPA should be compared when the models that are run with standardized or un-standardized data. Thus, SGMED recommends that such ad-hoc working group should convene next year and deal specifically with this task.
6.4. i) Based on the "Survey of existing bio-economic models" under Studies and Pilot Projects for carrying out the Common Fisheries Policy No FISH/2007/07 and data made available by MS, develop specific case studies for Mediterranean fisheries (e.g. anchovy, sardine and Nephrops), and advise on possible short-term and long-term economic consequences of the selected harvesting strategies. Evaluate the possibility to use existing bioeconomic models for comparing the proposed harvesting strategies with long-term economic profitability (MEY) of the main fisheries exploiting the assessed stocks (to be continued in SGMED-09-03).

The final report "Survey of existing bioeconomic models" by Prellezo et al. (2009) contains a review of the technical characteristics of bioeconomic models developed in Europe. According to the technical characteristics of the models reviewed, this working group is asked to select the model(s) most likely to be applicable to Mediterranean fisheries, using stock assessments (made during STECF/SGMED meetings, which will provide the biological information) and the economic data provided by the fisheries Data Collection Regulation (DCR). The models reviewed by Prellezo et al. (2009) were:

EIAA, TEMAS, MOSES, BEMMFISH ${ }^{1}$, BIRDMOD (with Aladym), MEFISTO, AHF-EFIMAS ${ }^{2}$, EMMFID, SRRMCF, COBAS, ECOCORP, ECONMULT and FLR-EFIMAS ${ }^{2}$.

We followed the same assessment criteria employed by Prellezo et al. (2009):

- Model orientation: If the model is output or input driven (i.e., quota based fishery or effort based management).
- If it is a simulation (what if) or an optimization model (what's best).
- Characteristics of the economic and biological modules and the links between them.
- Data requirements: Biological and economic modules initializations. We have paid particular attention to the model requirements of stocks assessments and also analyzed data requirements in relation to whether the DCR provides sufficient information for each model.
- The output format and in particular the bioeconomic indicators that each model produces.

In the context of Mediterranean fisheries and to answer to the ToR of the STECF/SGMED-09-02, we selected those simulation models that are input driven, and based on age-structured populations. This reduces the number of applicable models to: BIRDMOD (with Aladym) and MEFISTO. The toolbox FLR can be used to develop adhoc bioeconomic fisheries models, and has been used in the context of the EFIMAS

[^0]project in 3 Mediterranean case studies, but there is no sufficient expertise within the working group to apply FLR modelling tools to produce advice to STECF at present, although it would certainly be interesting to explore FLR in the near future.

BIRDMOD with Aladym ${ }^{3}$ :
BIRDMOD is a bio-economic multi-species and multi-gear simulation model. The main objective of the model is to measure the effects of different management policies from a biological, economic and social point of view. These are mainly based on fishing effort restrictions, but also technical and economic measures, such as variations in gear selectivity and introduction of taxes and subsidies. It is an analytical model composed by four modules and structured into three different dimensions. The managerial, biological, economic and that of state variation are the modules considered. The dimensions taken into account are the temporal dimension, technical dimension related to the fleet and the structural dimension related to the species. The model simulates the sector evolution over the number of years specified by users. The final output is represented by the historical series simulated for the variables included in the logical-conceptual pattern of the model. Some references and applications: Accadia and Spagnolo (2006), Lembo et al. (2009).

Biological sub-model:
Aladym uses classical age-length models with (trawl) survey derived population parameters and indices (i.e. recruitment) as primary information. It can predict catches although does not use fishery-dependent information. It can be used as a single-stock, single-fleet (trawl) simulation model. It accounts for sex differences in biological growth parameters and works at monthly time steps. It allows including stochasticity in some biological parameters. Basic biological parameters needed are: von Bertalanffy Growth Function parameters, a-b parameters of the length-weight relationship, Selection parameters of the fleet, maturity ogives, $\mathrm{S} / \mathrm{R}$ parameters or vectors of offspring, sex-ratio, total and natural mortality, the latter as a point value or a vector. Also initial "guesstimates" for recruitment are necessary to start the model. Aladym can assist in building up different scenarios.

## Economic sub-model:

The BIRDMOD economic sub-model is structured by fleet segment. This produces simulations by constant time intervals equal to a year. The main elements of the economic box are prices and costs functions. Two potential functional forms can be used to simulate price dynamics. Prices by fleet segment and species can be assumed as constant or a function of landings. Landings can be identified either with the production of the single fleet segment or the aggregate production of the reference market. The costs considered for each fishing system are broken down as follows: variable costs, fixed costs, labour costs, and interests and amortizations. On the basis of the structure of the economic account adopted, variable costs are subdivided into three components: cost of fuel and lubricant, commercial, and others variable costs. The first and the third are considered as a function of the total fishing days, whilst the commercial costs are estimated as a function of the aggregate landings. The fixed costs, subdivided into maintenance and other fixed costs, are estimated as a function of the gross tonnage. Finally, labour cost is calculated as a quota of the difference between revenues and variable costs.

Output: The final output is composed of the historical series simulated for the biological and economic variables included in the logical-conceptual pattern of the model, and several population indicators. This is reported in the following table:

3 Note that the Aladym version reviewed here is the latest: Lembo et al. (2009), Aquatic Living Resources, $\operatorname{vol}(22)$.

| BIRDMOD model output |  |  |  |
| :--- | :--- | :--- | :--- |

| Net Profit | Biomass in number <br> Biomass in weight <br> Landings <br> Landings per unit of GRT <br> CPUE | Biomass in number <br> Biomass in weight <br> Total tonnage | Landings <br> Revenues <br> Total effort |
| SSB |  |  |  |

## MEFISTO

It is a fully integrated bio-economic simulation model, allowing simulating alternative management scenarios (technical measures, such as effort or selectivity changes, or economic measures such as subsidies or changing in fuel price). It is a multi-stock and multi-fleet model, incorporating technical interactions. It uses a linear or non-linear relationship between main (or target) species and secondary (or commercial bycatch) species. It uses a very detailed economic model at the vessel level (but can be easily adapted to work at fleet level, given that the economic data provided by DCR are aggregated at fleet level).

Some references and applications are: Lleonart et al. (2003), Maynou et al. (2006), Merino et al. (2007), Silvestri and Maynou (2009).

Biological sub-model:
MEFISTO uses classical age-structured models. It can simulate any number of main species and fleets and works at a yearly step. It can include stochasticity in the $\mathrm{S} / \mathrm{R}$ function. Basic biological parameters needed: von Bertalanffy Growth Function parameters, a-b parameters of the length-weight relationship, Selection ogives, maturity ogives, $\mathrm{S} / \mathrm{R}$ parameters (optionally, by default: constant recruitment). Abundance and fishing mortality of each cohort of each main stock must be provided and can be derived from annual assessments, such as those performed by this working group.

## Economic submodel:

The economic submodel is hierarchically organized around the basic unit of vessel. A collection of vessels practicing the same fishery ( $\sim$ métier) are aggregated in a fleet object. Each vessel may have different technical characteristics, different costs, etc. but common parameters are entered at the fleet level (e.g., number of fishing days at sea, fuel price, etc.) The model allows computing the net profits over each simulation cycle (year) for each vessel. Depending on the net profits each vessel will allocate its effort or catchability level at the following iteration, depending on some pre-programmed behavioral rules.

Output: the standard set of indicators are: mean biomass, mean spawning stock biomass, number of recruits, stock averaged fishing mortality, catches by stock or fleet, effort, catchability, capital, number of boats, profits, total revenues and total costs. The value of each model's state variable can also be examined.

## Comparing MEFISTO and BIRDMOD

The biological simulation box in MEFISTO and BIRDMOD are very similar in the sense that they follow standard age-structured biological models. But the steps followed to obtain the biological parameterization are fundamentally different: MEFISTO directly incorporates biological data from standard VPA-type assessment, while BIRDMOD is based on the Aladym biological simulation model. The Aladym model makes use of fishery-independent data, while MEFISTO uses only fishery-dependent data. In this sense, BIRDMOD and MEFISTO can be applied in a complementary and non-exclusive manner. One of the main differences between BIRDMOD and MEFISTO comes from the dimensions used to analyze the fleet. BIRDMOD (and the FLR-EFIMAS models for Mediterranean fisheries) perform simulations at level of fleet
segment, while MEFISTO can produce projections for each vessel in the fleet. Fleet behaviour is then simulated following two different approaches. The Fisherman module in MEFISTO simulates the entry-exit and investment decisions for each vessel based on the profit generated in the past by the vessel. The State variation box in BIRDMOD (and FLR-EFIMAS models) simulates changes in the number of vessels and average days at sea by fleet segment based on the total profits realized by the fleet segment in the past.

Operational aspects: BIRDMOD (with Aladym) and FLR are based on the command-based R computer language. They can be run on any operating system. MEFISTO is a standalone, menu-driven, freeware program for Windows. Some participants in this working group have ample experience in running these programs.

Applicability to case studies
The two selected bioeconomic models -or any other that can be specifically built using e.g. the FLR toolboxcan be applied to case studies fulfilling the following conditions:

- A case study is defined by a group of fleets (or fleet segments) catching a pool of target species in a given GSA.
- Assessment data should exist for at least the main 3-4 target species making a strong proportion of the catches of the group of fleets analyzed
- Complete economic data should exist for the group of fleets selected.

As Mediterranean fisheries are generally multi-species and multi-fleet, biological and economic consequences of management strategies should be evaluated taking into account a pool of species and a set of fleet segments. The bio-economic models MEFISTO and BIRDMOD, developed for Mediterranean fisheries, are able to simulate the effects of management policies on a set of target species and fleet segments. The combination of species and fleet segments in a specific area identifies a case study. Therefore, a prior identification of case studies is needed to define data requirement and produce simulations. A minimum data series of 2-3 years of assessment and economic data is required to meaningfully estimate the biological or economic parameters of the bio-economic models considered. Working in less than ideal cases may be feasible, but the results obtained need to be taken with extreme care when producing advice.

Data required by MEFISTO against data that should be available for a particular stock, provided by assessment groups (biological) and DCR (economic)

Economic parameters to be estimated to simulate management scenarios by BIRDMOD

| Parameters | Estimation |
| :--- | :--- |
| Price flexibility coefficient by species, fleet segment <br> and area | To be estimated on time series data |
| Flexibility coefficient of the average days in <br> comparison with the profits by fleet segment and <br> area | To be estimated on time series data |
| Flexibility coefficient of the overall GRT in <br> comparison with the profits by fleet segment and <br> area | To be estimated on time series data |
| Costs parameters | To be estimated on time series data |

Both bio-economic models can be run by using the data collected under DCR. The aim of MEFISTO and BIRDMOD is to simulate the implementation of specific management options for a case study and evaluate the biological and economic outcomes in the short and long run. Management options should be defined in terms of input or technical restrictions. In particular, input restrictions are related to reductions in nominal fishing effort (reduction of days at sea or number of vessels) for a specific fleet segment. The following steps are needed for using a bio-economic model in the next SGMED meeting:

1. Definition of case studies based on:
a. Identification of the fishery (e.g., "demersal fishery in GSA x" or "pelagic fishery in GSA y");
b. Identification of the fleet segments involved in that fishery (e.g., "bottom trawlers 12-24m", "purse seine $24-40 \mathrm{~m} "$ );
c. Identification of the most relevant target species for each fleet segment involved in terms of revenues (e.g., "European hake", "Striped mullet", "Sardine");
2. For each case study, definition of a set of management measures to be simulated (e.g., "reduction of $20 \%$ in days at sea for bottom trawlers $12-24 \mathrm{~m}$ ');
3. Collection of the relevant biological and economic data (as reported above) to be used in the bioeconomic model (at least 2-3 years data) for each case study defined.

## SGMED conclusions and recommendations

In order to test the bio-economic models MEFISTO and BIRDMOD in evaluating possible short-term and long-term biological and economic consequences of specific management options for Mediterranean fisheries, the following is recommended:
Define a set of Mediterranean case studies by identifying the fishery (e.g., "demersal fishery in GSA x" or "pelagic fishery in GSA y"), the fleet segments involved in that fishery (e.g., "bottom trawlers 12-24m", "purse seine $24-40 \mathrm{~m}$ "), and the most relevant target species in terms of revenues for each fleet segment involved (e.g., "European hake", "Striped mullet", "Sardine"). For each case study, define a set of management measures to be simulated (e.g., "reduction of $20 \%$ in days at sea for bottom trawlers 12-24m"). By using the bio-economic models MEFISTO and/or BIRDMOD with the biological and economic data to be provided for the SGMED-09-03 meeting, simulate the effects of the management measures defined and evaluate the models outcomes.

## 6.5. k) Protection of Juveniles and Spawning Aggregations

6.5.1.Provide relevant information on spatial and temporal distribution of seasonal or persistent juveniles' aggregations and provide scientific elements indicating that possible protection of these areas may allow to control and reduce the overall fishing mortality on the stock and further improve the exploitation pattern with a view to increase the yield.

## BACKGROUND

The implementation of management measures aimed at reducing the effects of fishing on juveniles and their habitats requires the spatial identification of nurseries. Usually, any area where juveniles occur in relatively high densities has been considered as a nursery (Dahlgren et al. 2006) but without providing a clear definition. Some recent attempts to establish a definition of nurseries within a general conservation framework have been developed mainly for coastal species. Beck et al. (2001) defined a nursery as a habitat that, compared to other habitats on a per-unit-area basis, gives a greater contribution to the adult population of a given species; Dahlgren et al. (2006) introduced the concept of Effective Juvenile Habitats, referring to habitats that make a greater than average overall contribution to the adult population. Many authors agree that the most effective way of assessing the importance of a specific habitat in terms of juvenile production is to directly measure the movement of individuals from juvenile habitats to the adult population (Beck et al. 2001, Gillanders et al. 2003).
A possible alternative approach to the use of connectivity measures to identify and evaluate nursery role is to use the spatial abundance of juvenile fish and the persistence over time of density hot-spots. This approach is based on the assumption that the average contribution to the adult population can be expected to be higher for nurseries with higher juvenile density and higher spatio-temporal stability (Colloca et al., 2009). In fact, maintenance of a population depends on successful recruitment of young fish to nursery areas and from nursery areas back to the parent population (Hinckley et al. 2001). The location of nursery areas is therefore an integral component of the adaptation of marine fish life cycles to their environments.

In this context, the stability of a density hot-spot of fish juveniles in a given area can be assumed to be indirect evidence of the importance of that area to the recruitment success of the population. Furthermore, the temporal persistence of the characteristics of an area is a fundamental prerequisite for its inclusion in a conservation network, as commonly considered in terrestrial ecosystems (Early et al. 2008). The same approach defined for juveniles can be used also for the identification of spawning grounds using survey data of spatial distribution of mature specimens.

The identification of nurseries and spawning grounds would need to be completed with an evaluation of the potential effect of protection of these areas on the stock. A first evaluation can be obtained considering the proportion of fish included into the identified nurseries or spawning areas.

## METHODS

The approach suggested for identification of nursery and spawning aggregation requires the use of temporal series of maps of density or biomass hot-spot that can be obtained with different geostatistical approaches applied to survey data. The estimation of the temporal persistence of each hot spot can be obtained measuring the relative persistence of the cell $i$ as an annual nursery (Fiorentino et al. 2003). Let $\delta_{i k j}=1$ if the grid cell $i$ is included in a nursery in year $j$ and in survey $k$, and $\delta_{i k j}=0$ otherwise. A persistence index Ii can be computed as follows:
$I i=\frac{1}{n} \sum_{\mathrm{k}=1}^{\mathrm{n}} \mathrm{d}_{\mathrm{ij}}$
where $n$ is the number of surveys considered. Ii ranges between 0 (cell $i$ never included in an annual nursery area) and 1 (cell $i$ always included in an annual nursery area) for each cell in the study area. Alternatively, and when geostatistical techniques as indicator kriging are applied, an average of the probability can be used contouring the areas where the level is higher than $60 \%$, especially where the geometry and/or the sample allocation make for example the ordinary kriging estimates poor (smoothing effects).

Different conservation scenarios can be evaluated using different levels of $I$, the area occupied by nurseries and the proportion of hake recruits included in the nurseries can be calculated. For instance in the case of hake in the GSA 9 highly persistent nurseries ( $I i>80 \%$ ) covered $5.3 \%$ of the study area and included on average $39.2 \%$ of recruits (proportion calculated over the entire study period). Nurseries occurring in at least 60 to $80 \%$ of surveys included $12.4 \%$ of the whole area and $65.6 \%$ of recruits (Colloca et al., 2009).
This can be used to maximize the amount of protected fish (juveniles or spawners) and, at the same time, minimize the area closed to fisheries and therefore the impact on the fleet. A cumulative relative abundance of juveniles can be plotted against proportion of area covered by nurseries according to different persistence level (Fig. 6.5.1.1).

Fig. 6.5.1.1. Proportion of juvenile hake within GSA 9 nursery areas in relation to proportion of area covered by nursery areas according to different level of temporal persistence.

## EXAMPLE OF CONSEQUENCES OF REDUCTION OF FISHING PRESURE ON NURSERY GROUNDS

In order to enhance the value of the fishery and to increase the reproductive output, limitations related to effort and a legal minimum size limit was gradually enforced since 1995 for a group of species (EC regulation 1626/94), with an improvement of control since the year 2000. Available data proceeding from trawl surveys and commercial catch allowed the monitoring of the evolution of the European hake before and during the process of enforcement of the legal size (Abella et al, 2005). Reconstructed size structure of the catch and at sea and time series of abundance and catch rates of the commercial fleet were analyzed. The mentioned legal restrictions conditioned the behavior of the fishing fleets targeting demersal resources, and related to hake, they produced a drastic reduction of the fishing pressure on the nursery grounds.

Fig. 6.5.1.2 Distribution of fishing effort showing a reduction of fishing pressure on nursery areas (shaded zones)

Fig. 6.5.1.3. Trends in numbers at sea and biomass in the Southern Ligurian from trawl surveys. Standardized numbers at sea in the different years from trawl surveys shows a clear increase in numbers in the more recent years

## STATUS OF KNOWLEDGE

## Western Mediterranean

A European project: Impact of fishery and environment on hake recruitment in Northwestern Mediterranean. EU Contract FAIR CT-97-3522 (1998-2000) (Lleonart, coord. 2001) was devoted to analyze the hake recruitment. A number of specific results were published for Gulf of Lions, Catalonia and North Tyrrhenian Sea.

During the European project, Données sur la distribution des principales espèces commerciales du golfe du Lion (et plus particulièrement des groupes 0 et 1, in Campillo, 1999) distribution maps of the juveniles of hake and other 12 species exploited in the gulf of Lions were estimated. The data used came from three IFREMER trawl surveys on the continental shelf between 10 and 250 m depth, together with sampling in the main fish markets and on board professional fishing boats. Indices of abundance in number of fish per ha and by depth stratum were calculated using the Pennington \& Grosslein (1978) method to assess the stratified random trawl surveys and the results have been hand mapped for the 3 periods of observations.: February, June and November 1988.

Results shows that the highest abundance (62\%) of the juvenile hake ( 0 group) was observed in June while recruits were less abundant in November ( $36 \%$ ) and near zero in February. Juvenile hakes were mainly caught on the external border of the continental shelf, in the vicinity of the top of the slope canyons.

For the present SGMED working group the available data on juvenile hakes coming from the MEDITS surveys in the gulf of Lions for the period 1998 to 2008 have been preliminary analysed by a group of IEO/IFREMER French and Spanish scientists. For each of the 11 years standardized indices of abundance have been calculated. Except for the data of the year 1988, it was not possible to obtain a suitable variogram to apply the kriging method, so the maps have been established by using the SURFER software.

By combining the data coming from the whole series a map has been established which shows that in June, during the MEDITS surveys, the hake recruits are mainly concentrated in the eastern part of the gulf of Lions
on the external border of the continental shelf, in the vicinity of the top of the slope canyons where a Fishery Restricted Area have been adopted in 2009 by the GFCM in order to protect the spawners in this area.

Hake O group Gulf of Lions

## Spanish waters

The provision of information for the geographical distribution of demersal species (nursery and feeding areas) in the Mediterranean Sea is a strong recommendation of the GFCM. Mapping with trawl survey results (MEDITS_ES 2001-2005) requires the use of spatial analysis. The data used was the density (number by haul) and biomass ( kg by haul), length and geographical position. Nursery areas of different species have been identified and their spatial dimension estimated. The importance of closing these areas for juvenile protection has also been highlighted, but there has been less understanding of the need to protect spawning stocks in areas where juvenile fisheries are predominant (Fiorentino et al., 2006).

Fig. 6.5.1.5.

## Catalonia

Maynou et al. (2003) studied the patterns of seasonal variability in hake recruitment by means of quarterly surveys conducted over the shelf and the upper slope of the Catalan coast ( $50-350 \mathrm{~m}$ depth), with the aims of establishing the areas where hake recruitment is important throughout the year, and determining the environmental factors of the sea-floor characterizing the habitat of hake recruits. In addition to sampling juvenile hake, we sampled its trophic resource (mainly suprabenthos and zooplankton) with a Macer-GIROQ sledge sampler, to determine the characteristics of the sediment: temperature, redox potential, organic matter contents, carbonate contents and grain size. Hake juveniles were found between 60 and 160 m depth in autumn and winter, while in spring and summer their depth range extended down to 300 m depth. A multiple analysis of variance (MANOVA) model with interactions was used to partition the variability in hake recruits density. Season and depth stratum were the main factors accounting for the variability in hake recruitment. Well-defined nursery areas were apparent between 68 and 168 m depth, but the density in welldefined nursery areas was not different from the density in occasional nursery areas. Some sediment variables (redox potential and organic matter contents) were statistically different in nursery areas and in occasional nursery areas, indicating that juvenile hake recruit on bottoms where food resources are enhanced. The vagile macrofauna (mainly mysids and euphausiids), which constitute the main trophic resource of juvenile hake, did not overlap spatially with the main nursery areas, as they were found in higher concentrations over the 200 m depth isobath. This suggests that juvenile hake and their main food resource are spatially uncoupled, at least during daytime, when both sets of samples were obtained. Establishing nursery areas for heavily exploited stocks such as hake in the Catalan sea are a valuable tool for fisheries management.

Fig. 6.5.1.6.

## Sicily channel

Fiorentino et al. (2003). Aspects of the recruitment of hake (Merluccius merluccius L., 1758) and greater fork beard (Phycis blennoides Brunnich, 1768) in the Strait of Sicily (Central Mediterranean) are presented. Data were collected from 1994 to 1999 during the international bottom trawl survey program MEDITS. In view of the available literature on juvenile growth of these two species in the Mediterranean area, a lengthbased criterion was adopted to separate fish belonging to the 0 group (recruits). Recruit density indices ( $\mathrm{n} / \mathrm{km} 2$ ) by haul were calculated based upon the likely variability of recruit growth among years and used to study abundance variability and spatial pattern of recruitment and to identify the main nursery areas. Although there was inter-annual variability, two stable areas for M. merluccius were identified on the eastern side of the Adventure Bank and the Malta Bank at depths ranging between 100 and 200 m . The main nursery areas for $P$. blennoides were deeper (from 200 to 400 m ) and two stable nursery areas were identified on the western and eastern side of the Adventure Bank; other nurseries were found in the easternmost part of the Strait in 1998 and 1999. Recruitments of the two species were significantly correlated, with the strongest recruitment occurring in 1998 and 1999 for each species.

Fig. 6.5.1.7. Mean pattern of highest concentration of YOY's in the Strait of Sicily in Spring (MEDITS surveys at the top) and Autumn (GRUND surveys at the bottom).

Fiorentino et al. (2006) present the results of a spatial analysis by life stage of hake (Merluccius merluccius, L., 1758) in the Strait of Sicily (Central Mediterranean. The general spatial pattern in the whole region of investigation showed that hake occurs at any life stage in two distinct geographical areas, the Adventure and Malta Banks, well separated by a wide area where hake abundance is very scanty. Specifically, two areas where young of the year are highly and almost exclusively concentrated (nurseries) were identified on the eastern sides of both the Adventure Bank and Malta Bank respectively, at depths ranging mainly between 100 and 200 m . The position of concentration areas of juveniles suggests their spreading from nurseries towards the shallower bottoms on both the Adventure and Malta Banks. As regards, mature females the highest abundances were found in two areas, sited up stream and west of the nurseries on both Banks. Overall, it appears that while young of the year and females occupy discrete grounds, differing both for bathymetry and bottom type, juvenile concentration areas are large and show partial overlap with those of the other life stages.

Fig. 6.5.1.8.

## Malta

Trawl survey data gathered around the Maltese Islands during the MEDITS project in 2003-2008 were analysed for Merluccius merluccius, Mullus barbatus, Mullus surmuletus, Parapenaeus longirostris, Nephrops norvegicus and Aristaemorpha foliacea (Knittweis \& Dimech, 2009). Abundance and biomass indices were calculated, and maps of the distribution of immature individuals plotted in order to reveal the location of nursery sites. Data for M. merluccius, M. barbatus, M. surmuletus and N. norvegicus was analysed for the years 2003-2008, data for P. longirostris and A. foliacea was analysed for 2003-2007. Nursery areas were defined as those areas where individuals which had not reached maturity were concentrated. Data sets normalized in order to identify zones of high concentration regardless of interannual variability in abundance indices. This was done by scaling data between the observed maximum and minimum values (after Garofalo et al. 2004). Distribution maps based on pooled data of all abundance indices for all years combined were produced, using inverse distance weighting interpolation, a method which uses a distance weighted average of data points to calculate grid cell values.

Results revealed that recruits of the species M. merluccius, M. barbatus, M. surmuletus and P. longirostris were concentrated to the east/north-east of the Maltese Islands, in the vicinity of the Malta Bank. The distribution of immature individuals of $N$. norvegicus and $A$. foliacea was found to be patchier, with sites distributed throughout the deeper waters lying to the west / northwest of the Maltese Islands (see figures below).

## A. Merluccius merluccius

Fig. 6.5.1.9. Density and biomass indices, immature M. merluccius.

## B. Mullus barbatus

Fig. 6.5.1.10. Density and biomass indices, immature M. barbatus.

## C. Mullus surmuletus

Fig. 6.5.1.11. Density and biomass indices, immature M. surmuletus.

## D. Parapenaeus longirostris

Fig. 6.5.1.12. Density and biomass indices immature $P$. longirostris.

## E. Nephrops norvegicus

Fig. 6.5.1.13. Density and biomass indices, immature $N$. norvegicus.

## F. Aristaemorpha foliacea

Fig. 6.5.1.14. Density and biomass indices, immature $A$. foliacea.

The presence of M. merluccius, M. barbatus, M. surmuletus and $P$. longirostris recruits in the vicinity of the Malta Bank may be explained by local oceanographic features. In particular the presence of a cyclonic current between Adventure Bank and Malta Bank, and a permanent thermal front on the eastern edge of Malta Bank (MEDSUDMED, 2007, 2008) have in previous studies been suggested to explain the distribution of juvenile M. merluccius (Fiorentino et al. 2003; Abella et al. 2008; MEDSUDMED 2007), M. barbatus (GAROFALO et al. 2004; MEDSUDMED 2007) and P. longirostris (MEDSUDMED 2007). The fact that a number of sites with high densities of immature individuals were found close to the border of GSA 15 indicates that the vulnerable habitats of the demersal species studied overlap with adjacent GSAs. Indeed, it has previously been suggested that Maltese fishing stocks are at least partly sustained by young individuals transported by currents from adjacent GSAs, and that stocks are shared with neighbouring jurisdictions (Garofalo et al. 2004; MEDSUDMED 2007, 2008). It follows that a spatial analysis of nursery sites throughout the entire Central Mediterranean, ideally in combination with regional scale oceanographic data, is necessary to fully understand the observed patterns. Notwithstanding the underlying causes, and the precise nature of stock boundaries in the study area, the area to the northeast of Malta in the vicinity of Malta Bank has been suggested a priority site for potential future fisheries closures based on these results.

## Tyrrhenian - Ligurian Sea

Abella et al. (2009) explores the relationships between the spatial patterns of the distribution of the young hakes of the year (YOY) and the oceanographical features in two areas of the Central Mediterranean (the

Ligurian Sea and the Strait of Sicily), characterized by the occurrence of straits and channels. Comparative and correlative approaches were used to investigate coupling between biological and physical patterns. Density indices of the YOY were derived from annual trawl surveys from 1994 to 2004 in spring and autumn. Mean patterns of the YOY distributions were compared with the mesoscale oceanographical features reported in literature. No evident trends in recruitment strength were found in both areas. Interannual variability in YOY abundance in the Ligurian Sea was higher than in the Strait of Sicily. The location of nursery grounds in the study areas coincides with zones of relatively higher production, where upwelling and other enrichment processes regularly occur. The presence of predictable eddies and the frontal systems play a major role in the localization of nursery areas in the Strait of Sicily, maintaining their stable position throughout the years. The strongest transport of southern waters from the Tyrrhenian to the Ligurian Sea, due to the East Corsica Current, which is negatively correlated to winter North Atlantic Oscillation, is associated with the highest abundance of hake recruits in the nurseries of the Northern Ligurian Sea.

the besent
Fig. 6.5.1.15. Mean pattern of highest concentration of YOY's in the Ligurian Sea in Spring (MEDITS surveys at the top) and Autumn (GRUND surveys at the bottom).

Colloca et al. (2009) proposed a 3-step methodological approach to identify and classify fish nurseries for fisheries management purposes. We applied our approach to juvenile European hake Merluccius merluccius in the central Mediterranean Sea. Time series of trawl-survey fish-density data were used to map juvenile hake distribution with Bayesian kriging, while geostatistical aggregation curves were used to find density hot-spots. Persistence measures were adopted to identify nurseries on the basis of their spatio-temporal persistence. We found that areas with a high density of juvenile hake showed a high temporal persistence on both a seasonal and annual basis, with the most persistent nursery areas covering about $5 \%$ of the study areas while including about $39 \%$ of hake recruitment (averaged over 10 years). We believe the persistence of these areas is indirect evidence of their importance to the productivity of the population, with many potentially
important implications for fisheries management. The approach that we developed to identify hake nurseries can be applied to different species and life stages to improve knowledge of the role of habitat for populations and communities.

Nursery areas of deep sea pink shrimp have been identified in the GSA 9 using the same approach used for hake (Nursery project, MIPAAF). Recruits (CL<20 mm) are patchily distributed around the shelf-break with denser and persistent nurseries in the southern part of the GSA (Tyrrhenian Sea). These nurseries overlapped largely with hake nurseries.

Fig. 6.5.1.16. Temporal persistence of the estimated nurseries of Merluccius merluccius in the period 1994 to 2005 based on GRUND and MEDITS surveys

Fig. 6.5.1.17. Temporal persistence of the estimated nurseries of Parapenaeus longirostris in the period 1994 to 2005 based on GRUND and MEDITS surveys

## Aegean Sea

Karlou-Riga \& Varkitzi (2002) analysed nursery areas in the Aegean Sea. Samplings were carried out with chartered trawler and beach seiner monthly in the Saronikos Gulf (September 1998 to August 1999) and bimonthly in the Cyclades islands (September 1999 to August 2000) in order to identify sites of juvenile concentrations. Juveniles of hake in the Saronikos Gulf were observed throughout the year, whereas these juveniles favorite mainly the outer part of the Gulf. The number of sites when juveniles occurs increases progressively form January to June, and decrease afterwards. In the Cyclades islands juveniles of hake are disperse. Although they do not show any dependence on depth, they prefer areas rich in nutrients. Juveniles of striped mullet (Mullus surmuletus) are also caught by beach seiner in the Cyclades islands from May to August. Due to the occurrence of juveniles in the catch of beach seiners mainly during spring, the fishing season for this gear has recently decreased.

Juveniles of picarel (Spicara smaris) and bogue (Boops boops) caught by beach seiner were not observed in the Saronikos Gulf during the open fishing season (October-May) except for bogue caught during October. On the contrary juveniles of these species, caught by beach seiner as well, were observed in the Cyclades islands during late spring and spring respectively. The time difference between the two areas when juveniles occur is due to different time of spawning the last related with the seawater temperature. In the Saronikos Gulf juveniles of Mediterranean horse mackerel (Trachurus mediterraneus) caught by beach seiner and of horse mackerel (Trachurus trachurus) caught by trawler were observed during October and May (open fishing season) respectively. Trawler in the Cyclades islands did not catch juveniles of small pelagics. Due to the occurrence of juveniles in the catch of beach seiners mainly during spring, the fishing season for this gear has recently decreased.

## Sole nursery area in northern and central Adriatic Sea

The spatial distribution of Solea solea was evaluated throughout yearly rapido trawl surveys (2005-2008) carried out in fall in the central and northern Adriatic Sea. Age class 0+ aggregated inshore, mostly in the area close to the Po river mouth and along the Italian coast. Age class 1+ gradually migrated off-shore and adults concentrated in the deepest waters located at South West from Istria peninsula. The age classes were estimated on the base of a slicing carried out by LFDA 5.0 utilizing growth parameters of sole estimated through the length frequency distributions obtained from surveys. Linf ( 39.60 cm ) was computed by the Powell-Wetherall method (Powell, 1979; Wetherall, 1986) and used to estimate $K(0.44)$ and $t 0(-0.46)$.

Fig. 6.5.1.19. Nursery of hake with the persistence along time.

## South Adriatic and western Ionian Sea

The spatial pattern of the nursery areas of red mullet (Mullus barbatus), hake (Merluccius merluccius) (Linnaeus, 1758) and deep-water rose shrimp (Parapenaeus longirostris) (Lucas, 1846) was studied in the South Adriatic and North Ionian Seas (Eastern-Central Mediterranean) applying geostatistical techniques and data from time series trawl surveys conducted in the area. The analysed variables were: R (number of recruits $/ \mathrm{km}^{2}$ ) and $\mathrm{n} /$ tot (fraction of recruits on the total sampled population). The structural analysis showed a spatial pattern of both variables characterized by continuity on a small scale. Predictions of nursery area localization with probability of finding recruits at different threshold values were obtained through median indicator kriging. For the red mullet the nurseries were mainly identified in the South Adriatic Sea off the Gargano peninsula and between Molfetta and Monopoli within 50 m in depth. The main concentration of hake juveniles were found to be between $100-200 \mathrm{~m}$ in depth along the Gargano peninsula and between Otranto and Santa Maria di Leuca, where a nursery of deep-water rose shrimp was also detected. An overlapping depth, between 100 and 200 m , was identified for hake and deep-water rose shrimp nurseries.

Fig. 6.5.1.20. Nursery of hake in the GSA 18 and 19 located with a threshold of $4000 \mathrm{ind} / \mathrm{km}^{2}$

## Sardinia

With the aim to identify the main nursery areas for the Sardinian grounds geo-referenced abundance indices of autumn (GRUND) and spring (MEDIT) scientific bottom trawl survey were analysed. Standardized $\left(\mathrm{km}^{2}\right)$ LFD were processed by means of the Bhattacharya method in order to identify the first modal component which be referred to the recruits ( $0^{+}$group). Once the cohorts features were identified, the cut-off to isolate recruits was calculated and recruits by haul were estimated as all individuals whose TL is less than the average length +1 standard deviation. Juveniles indices were then used to model the spatial distribution applying geostatistical methods and kriging techniques.
Before building the geostatistical model the exploratory data analysis was carried out. The Indicator Kriging was applied to locate the sites where number of recruits exceeded, at a given probability, a conditioned threshold value ( $75^{\text {th }}$ percentile of the cumulative abundance). The temporal persistence of high density patches of recruits was then evaluated by means of an index of spatial persistence.
As shown in the figures below, results revealed that recruits of the species E. cirrhosa, M. merluccius, M. barbatus and P. blennoides were stably concentrated to the west of the Sardinian Islands. P. blennoides showed high and persistent concentrations in deep waters (more than 200m) of the south-west Sardinian shores. In the southern portion of the Island, in the coastal Carloforte waters and in the Gulf of Cagliari was found the presence of nursery areas stable in time for the species M. barbatus. The distribution of immature individuals of $M$. merluccius showed high and persistent concentrations in the shelf break.

## SMALL PELAGICS NURSERY HABITATS FROM ACOUSTIC SURVEYS

## BACKGROUND

An alternative approach has been applied to map the Essential Fish Habitat (as "those waters and substrate necessary for spawning, breeding, feeding, or growth to maturity defined in the Magnuson- Stevens Fishery Conservation and Management Act in 1996) of small pelagic fish based on spatial analysis and GIS techniques (Valavanis et al., 2008). Within this framework the potential Fish Habitat of anchovy (Engraulis encrasicolus) and sardine (Sardina pilchardus) has been modeled (Bellido et al., 2008; Giannoulaki et al., 2008) using data from acoustic surveys and satellite environmental data. The nursery habitat of sardine has been also addressed based on data from northern Aegean Sea (Tsagarakis et al., 2008). Similarly, the potential spawning habitat of anchovy (Engraulis encrasicolus) and round sardinella (Sardinella aurita) has been modeled based on data from ichthyoplankton surveys in northern Aegean Sea (Schismenou et al., 2008). This approach is based on modeling the presence of a certain species (i.e. presence of adults, juveniles, or eggs) with environmental satellite data as well as bathymetry data that are used as proxies to infer spatial variations of environmental factors in order to identify those areas that could be suitable to support the presence of the species (Planque et al., 2007) and subsequently obtain probability maps that correspond to suitable environmental conditions.

Similarly, to the previous approach the stability of high probability areas that could support the presence of small pelagic fish juveniles in a given area can be assumed to be indirect evidence of the importance of that area to the recruitment success of the population. The same approach defined for juveniles can be used also for the identification of spawning grounds using survey data of the spatial distribution of eggs.

## METHODS

The suggested approach for the identification of nursery areas requires the use of presence/absence acoustic data referring to small pelagic fish juveniles as well as environmental satellite data and bathymetry data in order to estimate a habitat distribution model (Guisan \& Zimmerman 2000; Planque et al 2007). The principle of this approach is based on the examination of the influence of oceanographic key parameters on the distribution and biology of the juveniles of small pelagic fish. Within this framework an ongoing European project titled "SARDONE Improving assessment and management of small pelagics in the Mediterranean" aims at the development of a series of tools which will enable a better understanding, stock assessment and fishery management of small pelagic fish resources (anchovy and sardine) of the Mediterranean. Within the scope of the project is to detect nursery areas, develop echo-surveys for the estimation of the recruitment strength and to fill the gap in knowledge on the ecology of late larvae and juveniles. Three major small pelagic stocks and fisheries i.e. the NW Mediterranean, the Adriatic and the Aegean have been chosen for this purpose.

Specifically, within the framework of the SARDONE project the relationships between the spatial patterns of the presence/absence of sardine juveniles in June (Aegean Sea) and in July (Gulf of Lions) have been modeled along with satellite environmental data as well as bathymetry data. Furthermore, the spatial patterns of the presence/absence of anchovy juveniles in September have been modeled in a similar way. Acoustic data recorded with a 38 kHz split beam echosounder from the northern Aegean Sea (2004-2006), the Adriatic Sea (2004-2008) and the Gulf of Lions (2003-2006) have been analyzed for this purpose. Sardine and anchovy juveniles' echoes discrimination was based on the characteristic echogram shape of the schools and the catch composition of pelagic trawling held in the surveyed area (MacLennan \& Simmonds, 1992). Satellite data included mean monthly values of sea surface temperature, sea surface chlorophyll concentration, Photosynthetically Active Radiation, sea surface salinity distribution and sea level anomaly (Giannoulaki et al., 2008). Statistical modelling was applied using Generalized Additive Models (GAMs, Hastie \& Tibshirani 1990, Wood 2006) following the same methodology as described in Giannoulaki et al., 2008; Schismenou et al., 2008).

For this purpose three different GAM models (each one representing different area and sampling period) were estimated, using pooled data from all years for the specific area and period, in order to ensure potentiality and calibration of the model over a wider range of environmental conditions (Planque et al., 2007). The probability of the occurrence of suitable environmental conditions for sardine/anchovy juveniles’
presence was estimated and mapped. The model performance was evaluated with the AUC criterion (Elith et al, 2008). Similarly to the approach used in demersal species, we believe that the persistence of these areas is indirect evidence of their importance to the productivity of the population, with many potentially important implications for fisheries management. The approach that we developed to identify sardine and anchovy nurseries can be applied to different species and life stages to improve knowledge of the role of habitat for populations and communities.

## STATUS OF KNOWLEDGE

Preliminary results of the SARDONE project concerning the detection of anchovy and sardine juveniles in the Mediterranean have been recently presented in the ICES WGFAST that was held in Ancona during May 2009 and are shown below.

## Gulf of Lions

Within the SARDONE presence/ absence data of sardine (Sardina pilchardus) juveniles from acoustic surveys (2003-2006) held in the Gulf of Lions (GSA 7) during July have been used. The methodology used is the one already described and the final GAM model selected included bathymetry, sea surface temperature, sea level anomaly as well as chlorophyll concentration explaining almost $50 \%$ of the total deviance. The probability of the occurrence of suitable environmental conditions for sardine juveniles' presence was estimated and mapped. The model was evaluated with the AUC criterion (Elith et al, 2008) and indicated good model performance (AUC $>0.75$ ).

Fig. 6.5.1.25. Map of areas representing sardine juveniles potential habitat in the Gulf of Lions during July based on the GAM model. Gray scale indicates the probability of suitable areas for nursery grounds.

The indicated nursery areas consist shallow waters (<70m bottom depth), warmer waters in respect to the available temperature values, associated with high productivity values. These results should be considered as preliminary since SARDONE is an ongoing project. In addition, the probability threshold that defines an area as "nursery hot-spot" of sardine juveniles as well as the temporal persistency of this nursery area should be examined, in order to consider it as indirect evidence of the importance of that area to the recruitment success of the sardine population and use these maps for management and conservation purposes.

## Adriatic Sea

Within the SARDONE presence/ absence data of anchovy (Engraulis encrasicolus) juveniles from acoustic surveys (2004-2008) held in the western part of the Adriatic Sea (GSA 17) during September have been used. The methodology used is the one already described and the final GAM model selected included bathymetry, sea surface temperature, sea level anomaly as well as chlorophyll concentration explaining $40 \%$ of the overall deviance. The probability of the occurrence of suitable environmental conditions for anchovy juveniles' presence was estimated and mapped. The model was evaluated with the AUC criterion (Elith et al, 2008) and indicated good model performance (AUC $>0.75$ ).

The indicated nursery areas consist shallow waters ( $<65 \mathrm{~m}$ bottom depth) associated with waters of lower temperatures compared to the available ones. These results should be considered as preliminary since SARDONE is an ongoing project. Within the framework of the specific project work concerning the anchovy juveniles habitat during the winter period remains to be done. In addition, the probability threshold that defines an area as "nursery hot-spot" of anchovy juveniles as well as the temporal persistency of this nursery area should be examined, in order to consider it as indirect evidence of the importance of that area to the recruitment success of the anchovy population and use these maps for management and conservation purposes.

Fig. 6.5.1.26. Map of areas representing sardine juveniles potential habitat in the Adriatic Sea during September based on the GAM model. Gray scale is the probability of suitable areas for nursery grounds.

## Aegean Sea

Within the SARDONE presence/ absence data of sardine (Sardina pilchardus) juveniles from acoustic surveys (2004-2006) held in northern Aegean Sea (GSA 22) during June have been used. The methodology used is the one already described and the final GAM model selected included bathymetry, photosynthetic active radiation, sea level anomaly as well as chlorophyll concentration explaining $55.5 \%$ of the total
deviance. The probability of the occurrence of suitable environmental conditions for sardine juveniles' presence was estimated and mapped. The model was evaluated with the AUC criterion (Elith et al, 2008) and indicated good model performance (AUC $>0.75$ ).

Fig. 6.5.1.27. Map of areas representing sardine juveniles potential habitat in Greek waters during June based on the GAM model from the northern Aegean Sea. Gray scale is the probability of suitable areas for nursery grounds.

The indicated nursery areas consist shallow areas ( $<70 \mathrm{~m}$ bottom depth) associated with waters of high productivity. These results should be considered as preliminary since SARDONE is an ongoing project. In addition, the probability threshold that defines an area as a "nursery hot-spot" of sardine juveniles as well as the temporal persistency of this nursery area should be examined.

Tsagarakis et al. 2008 explores the relationships between the spatial patterns of the distribution of sardine juveniles in northern Aegean Sea (GSA 22) using data from experimental pelagic hauls that were held within acoustic surveys in the northern Aegean Sea (June 2003-2006). The presence of sardine juveniles was modelled using multivariate techniques and satellite environmental data as well as bathymetry data. Regions characterized by those environmental conditions that are likely to support increased presence of juvenile sardine were mapped.

Fig. 6.5.1.28. Geographic distribution of regions classified as "juvenile" areas within the Greek Seas, for June 2004-2006 based on Tsagarakis et al. 2008.

Again, comparison of the maps obtained with the two different approaches and the temporal persistency of the areas that are characterised as nurseries should be examined, in order to assume it as indirect evidence of the importance of that area to the recruitment success of the sardine population and use these maps for management and conservation purposes.
6.5.2.Provide relevant information on fishing gear selectivity (mesh size/shape, twine thickness, hanging ratio, hook size, hook shape, etc.) with a view to further improve the exploitation pattern, reduce the fishing mortality on juveniles and increase the yield.

No information or analysis was provided during the SGMED.
6.5.3.Provide relevant information on spatial and temporal distribution of seasonal or persistent aggregations of spawners and provide scientific elements indicating that possible protection of these areas may reduce the risk of stock collapse and maintain the reproductive capacity of the exploited stocks.

## Gulf of Lions slope

Part of the fishing fleets of northern Catalonia (Spain, NW Mediterranean) and Sète (France) exploit the fishing resources of the Gulf of Lions. This is a relatively well known fishery, with its main target species being hake (Merluccius merluccius), which is exploited using trawlnets (both countries), longlines (Spain) and gillnets (France). Since the first Franco-Spanish joint assessment of hake (Aldebert et al., 1993), longer data series and more sophisticated procedures (i.e. from LCA at the beginning to XSA the last assessment) have been carried out. In the SCSA sessions up to four $(2001,2003,2005,2006)$ and point to heavy growth overexploitation and likely recruitment overexploitation. Despite the heavy fishing pressure on all classes and the evidences of overfishing (both growth and recruitment), historical series of catches appear to be rather stable. The remaining spawning fraction of the hake stock appears to be limited to the most inaccessible areas on the continental slope of the Gulf of Lions, where it is only lightly exploited. Its preservation from full commercial exploitation is considered vital for avoiding the intensification of recruitment overexploitation and the associated collapse of the fishery. The character of lightly exploited refuges was confirmed by a series of experimental trawl cruises carried out in 2007 (Massutí et al. 2008).

As consequence a Fishery Restricted Area (FRA) proposal was submitted to the SCMEE of GFCM, which was endorsed by SCMEE (GFCM, 2008a) and SAC (GFCM, 2008b) and approved by the Commission (GFCM, 2009) with some modifications (Recommendation GFCM/33/2009/1: On the establishment of a fisheries restricted area in the Gulf of Lions to protect spawning aggregations and deep sea sensitive habitats).

The current proposal reveals key findings of a study carried out in the Gulf of Lions, in which results indicate that the continental slope of the Eastern Gulf of Lions acts as a refuge for large spawners of several commercially important species, including Merluccius merluccius, Aristeus antennatus, Nephrops norvegicus, Lophius piscatorius, Micromesistius poutassou, Lepidopus caudatus, Trachurus trachurus and other species

Based on this finding, and with fishing activities expected to shift to areas further out on the continental shelf in future years due to the dismal state of stocks closer the shore, the current proposal suggests that a fisheries restricted area be established on the continental slope of the Eastern Gulf of Lions in order to protect one of the last refuges for large spawning adults of hake and other important fish species. The suggested management measure would be to prohibit any kind of demersal fishing, towed or not, including trawl gears, bottom and midwater longlines, bottom nets (gillnets, trammel nets) and traps in the proposed zone. This measure is expected to result in major socio-economic benefits, since preserving the area would preserve the source of recruits supporting the current demersal fishery in the Gulf of Lions and even further south, in Northern Catalonia.

## Spawning Sites in Central Mediterranean - Malta, GSA 15

Trawl survey data gathered around the Maltese Islands during the MEDITS project in 2003-2008 were analysed for Merluccius merluccius, Mullus barbatus, Mullus surmuletus, Parapenaeus longirostris, Nephrops norvegicus and Aristaemorpha foliacea (Knittweis \& Dimech 2009). Abundance and biomass indices were calculated, and maps of the distribution of mature individuals plotted using MapInfo in order to reveal the location of spawning sites. Data for for M. merluccius, M. barbatus, M. surmuletus and N. norvegicus was analysed for the years 2003-2008, data for P. longirostris and A. foliacea was analysed for 2003-2007. Data sets were normalized in order to identify zones of high concentration regardless of interannual variabilities in abundance indices. This was done by scaling data between the observed maximum and minimum values (after Garofalo et al. 2004). Distribution maps based on pooled data of all abundance indices for all years combined were produced, using inverse distance weighting interpolation, a method which uses a distance weighted average of data points to calculate grid cell values.

Results revealed that spawners of the species M. merluccius, M. barbatus, M. surmuletus and P. longirostris were concentrated to the east / north-east of the Maltese Islands, in the vicinity of the Malta Bank. The distribution of mature individuals of $N$. norvegicus and $A$. foliacea was found to be patchier, with sites distributed throughout the deeper waters lying to the west / northwest of the Maltese Islands (see Figures 112 below).

## Small pelagics spawning grounds in Aegean Sea (GSA 22)

Schismenou et al. (2008) explored the relationships between the spatial patterns of the distribution of eggs and larvae of anchovy and round sardinella in Aegean Sea (GSA 22) and attempted to map the potential spawning habitat of anchovy and round sardinella in Aegean Sea. The term "potential spawning habitat," (PSH) has been recently defined by Planque et al. (2007). It is used to describe the areas where the environmental conditions are suitable for spawning, i.e., the broad geographical area that could support the spawning activity of a species, defined by environmental conditions and the preferred ranges for spawning.

To estimate the PSH for anchovy and round sardinella, the presence/absence egg data from DEPM (Daily Egg Production Method) surveys in the northern Aegean Sea (June 2003-2006, Somarakis et al., 2007) was modeled with satellite environmental data using Generalized Additive Models (GAMs). The probability of the occurrence of suitable environmental conditions for spawning was estimated and mapped. The model performance was evaluated with the AUC criterion (Elith et al, 2008).

Fig. 6.5.3.14. Map of areas representing anchovy potential spawning habitat in Greek waters based on the GAM model from the northern Aegean Sea. Gray color:[25\%; black color:[50\% probability of suitable areas for spawning.

More specifically, in the Greek Seas the main spawning areas for anchovy were shown in the northern Aegean Sea, which is in agreement with the observed distribution patterns of eggs and data from previous surveys (Somarakis et al., 2004; Somarakis, 2005; Somarakis et al., 2006). The North Aegean Sea is largely influenced by the Black Sea Water and river runoffs exhibiting characteristics that are favorable for anchovy spawning (Somarakis et al., 2002a; Somarakis \& Nikolioudakis, 2007). Other smaller spawning grounds were also predicted by the model in the central Ionian and Aegean Seas, which match well survey results of July 1998 and June 1999 in this area (Somarakis et al., 2002b; Somarakis et al., 2006). The temporal persistency of these areas should be examined, in order to assume it as indirect evidence of the importance of that area to the spawning success of anchovy population and use these maps for management and conservation purposes.

## SGMED conclusions and recommendations

SGMED recognise that an extensive amount of information and analysis is now available to define and quantify the areas of aggregation and persistence of juveniles and, partially, also spawners for several GSAs and stock. SGMED consider that index of persistence as estimated for example in Colloca et al. (2009) can be used as a robust method to define such areas and verify that they are constant during time. For example, the index of persistence has been already calculated for GSA 9 and 11. SGMED recommends that the estimation of the index of persistence should be performed also for the other areas and species where spatial
information about the yearly distribution of juveniles and adults are available. This work could be addressed by a specific working group under the STECF framework.

## 7. STOCK SUMMARY SHEETS

SGMED 09-02 provides summary sheets (short versions of the important information from the assessment sections of this report) only in cases where exploitation rates are estimated analytically and respective fisheries management advice could be formulated.

Unlike the 2008 report of SGMED 08-04, the summary sheets provided in this report of SGMED 09-02 deal with assessment of historic and recent trends in stock parameters (stock size, recruitment and exploitation) and relevant scientific advice only. Deterministic short and medium term for such parameters including landings and relevant scientific advice will we delivered through the forthcoming SGMED 09-03 meeting in the fourth quarter of 2009. However, long term forecasts are provided in order to allow stock status reviews with regard to the estimated management reference points $F_{0.1}, F_{\max }$ and $F_{m s y}$.

Where assessments and respective summary sheets could not be updated due to lack of data or expertise present at the meeting, a short reference to last year's report of SGMED 08-04 is provided.

### 7.1. Hake in GSA 06

| Species common name: | European hake |
| :--- | :--- |
| Species scientific name: | Merluccius merluccius |
| Geographical Sub-area(s) GSA(s): | GSA 06 |

## Most recent state of the stock

- State of the adult abundance and biomass:

Since 2006, SSB has increased from historical lows and varies slightly above average since then. SSB is estimated to about $1,500 \mathrm{t}$ in 2008. SGMED 09-02 notes that this level of SSB is significantly below the proposed $\mathrm{B}_{\mathrm{lim}}=2,200 \mathrm{t}$ and $\mathrm{Ba}_{\mathrm{pa}}=4,000 \mathrm{t}$.

- State of the juvenile (recruits):

Recruitment has been low in recent years and has decreased to the lowest level observed in 2008.

- State of exploitation:

SGMED 09-02 recommends $\mathrm{F} \leq 0.2$ as target management reference point (basis $\mathrm{F}_{0.1}$ ).
Fishing mortality has fluctuated without a trend at 1.6 ( $\mathrm{F}_{\text {bar }} 0-2$ ), or 1.5 for $\mathrm{F}_{\text {bar }}$ for ages 2 to 4 . Comparing such estimates with $\mathrm{F}_{0.1}=0.16$ and $\mathrm{F}_{\max }=0.23$, it can be concluded that the resource is heavily over-exploited, with future catches Being highly dependent on incoming recruitment.

The continued low abundance of adult fish in the surveyed population and landings indicate a very high exploitation pattern far in excess of those achieving high yields and low risk of fisheries collapse.

- Source of data and methods:

MEDITS surveys and official landings and biological data as collected within the DCR framework were used for the assessment.

The state of exploitation was assessed for the period 1995-2008 by means of a VPA Separable, tuned with standardised CPUE from abundance indices from trawl survey (MEDITS). Analysis was carried out applying the Extended Survivor Analysis (XSA) method (Lowestoft suite; Darby and Flatman, 1994) over the period 1995-2008. In addition, a yield-per-recruit (Y/R) analysis (VIT program; Lleonart and Salat, 1992) was applied on the mean pseudo-cohorts 1995-2008 for the GFCM geographical sub-area Northern Spain (GSA06). Both methods were performed from size composition of trawl catches (obtained from on board and on port monthly sampling) and official landings, transforming length data to age data by slicing (L2AGE program).

Growth parameters used were those from Garcia-Rodriguez (2002) over otolith readings and length distributions analysis ( $\mathrm{L}_{\text {inf }}=106.7$; $\mathrm{K} 0.20 ; \mathrm{t}_{0}=0.0028$ ), and length-weight relationship and maturity ogive from García Rodriguez and Esteban (1995). The size composition of commercial landings were obtained by monthly length samplings carried out in one of the sampling ports used for the present assessment (Santa Pola) during the 1995-2008 period. Landings and effort data were obtained combining different sources, such as Official Landings provided by Autonomous Community, and from the Information and Sampling Network of the Spanish Oceanographic Institute (IEO). In this assessment, a new set of parameters (fast growth hypothesis) were considered and a natural mortality vector (PROBIOM, Caddy and Abella, 1999) was applied. SGMED-09-02 notes that the set of growth parameters used in the assessment were different to those used the year before, and the recommendation made last year regarding the use of parameters representing "fast growth hypothesis" has been followed.

## Outlook and management advice

SGMED recommends the relevant fleets' effort to be reduced until fishing mortality is below or at the proposed level $\mathrm{F}_{0.1}$, in order to avoid future loss in stock productivity and landings. This should be achieved
by means of a multi-annual management plan taking into account mixed-fisheries effects. Catches consistent with the effort reductions should be estimated.

Short and medium term scenarios:
Will be conducted and delivered by SGMED 09-03 (14-18 December 2009).

## Fisheries

Exploitation is based on very young age classes, mainly 0 and 1 year old individuals, with immature fish dominating the landings.
During last years, the annual landings of this species were around 3,500 tons in the whole GSA. From official data, the total trawl fleet of the whole geographical sub-area 06 (Northern Spain) is made up by 647 boats: on average, 47 TRB, 58 GT and 297 HP. Some of these units (smaller vessels) operate almost exclusively on the continental shelf (targeted at red mullet, octopus, hake and sea breams), others (bigger vessels) operate almost exclusively on the continental slope (targeting decapod crustaceans) and the rest can operate indistinctly on the continental shelf and slope fishing grounds, depending on the season, the weather conditions and also economic factors (e.g. landings price). The percentages of these trawl fleet segments have been estimated around 30, 40 and $30 \%$ of the boats, respectively.

## Comments on assessment

During the STECF 09-06, an assessment on Hake from GSA 06 was performed. Official data were not sent on time, but the expert provided a copy of some of the data. Files dealing with official landings and effort were not available. Consequently data on landings and effort for 2008, were derived from the series.

### 7.2. Hake in GSA 09

| Species common name: | European hake |
| :--- | :--- |
| Species scientific name: | Merluccius merluccius (L., 1758) |
| Geographical Sub-area(s) GSA(s): | GSA 09 |

## Most recent state of the stock

- State of the adult abundance and biomass:

SSB is likely to amout to $5-10 \%$ of the SSB at Fmsy. STECF SGMED-09-02 underlines that this conclusion could be influenced by the observed exploitation patterns in the surveys and fisheries, which almost exclusively represent the juvenile part of the stock.

- State of the juveniles (recruits):

In recent years recruitment has varied without a clear trend.

- State of exploitation:

SGMED 09-02 recommends $\mathrm{F}=0.2$ as target management reference point (basis $\mathrm{F}_{0.1}$ ).
The stock appears to be heavily overexploited and F needs a consistent reduction from the current F of 1.21.7 (SURBA and VIT estimates) towards the candidate reference points for long term sustainability based on F between 0.2-0.4 ( $\mathrm{F}_{0.1}-\mathrm{F}_{\text {max }}$ ). However, considering the high productivity in terms of incoming year classes, this stock has the potential to recover quickly if F is reduced towards $\mathrm{F}_{0.1}$.
The continued lack of older fish in the surveyed population indicates exploitation rates far beyond those considered consistent with high yields and low risk. This fact, on the other hand, may reduce the risk of fisheries collapse.

- Source of data and methods:

Data coming from MEDITS (1994-2008) and GRUND (1994-2004) trawl surveys were used to estimate relative SSB and F with Surba. Data coming from DCR (size distribution of landings for trawl and gillnet data on trawl discards for 2006) for the period 2006-2008 were used to run LCA analyses.

The following parameters were used both for SURBA and VIT analyses:

| Growth parameters (Von Bertalanffy) |
| :--- |
| $\mathrm{L}_{\infty}=104(\mathrm{~cm}$, total length $) ; \mathrm{k}=0.2 ; \mathrm{t}_{0}=-0.03$ |
| $\mathrm{~L}^{*} \mathrm{~W}: \mathrm{a}=0.006657 ; \mathrm{b}=3.028$ |
| M vector $\mathrm{Age}_{1}=1.3, \mathrm{Age}_{2}=0.6, \mathrm{Age}_{3}=0.46, \mathrm{Age}_{4}=0.41, \mathrm{Age}_{5}=0.3($ ProBiom $)$ |
| $\mathrm{q}($ age $1+)=0.8, \mathrm{q}($ age $2+)=1.0, \mathrm{q}($ age $3+)=0.7, \mathrm{q}(\mathrm{age} 4+4+=0.7, \mathrm{q}($ age $5+)=0.7$ |
| Length at maturity $\left(\mathrm{L}_{50}\right)=30 \mathrm{~cm}$ total length (sex combined $)$ |

## Outlook and management advice

SGMED recommends the relevant fleets' effort to be reduced until fishing mortality is below or at the proposed level $\mathrm{F}_{0.1}$, in order to avoid future loss in stock productivity and landings. This should be achieved by means of a multi-annual management plan taking into account mixed-fisheries effects. Catches consistent with the effort reductions should be estimated.

Short and medium term scenarios:
Will be conducted and delivered by SGMED 09-03 (14-18 December 2009).

## Fisheries

Hake is the demersal species providing the highest landings and incomes in the GSA 09 . About $90 \%$ of landings of hake are due to bottom trawl vessels; the remaining fraction is caught by artisanal vessels using set nets, in particular gillnets. Hake trawl fishery exploits a highly diversified species assemblage: horned octopus (Eledone cirrhosa), poor cod (Trisopterus minutus capelanus), squids (Illex coindetii), are among the most important species in the by catch. The trawl fleet of GSA 09 at the end of 2007 accounted for 360 vessels. The main trawl fleets of GSA 09 are present in the following continental harbours: Viareggio, Livorno, Porto Santo Stefano (Tuscany), Fiumicino, Terracina, Gaeta (Latium). The fishing capacity of the GSA 09 has shown in these last 20 years a progressive decrease; from 1996 to 2006 the number of bottom trawlers of GSA9 decreased of about $30 \%$. Consequently also fishing effort decreased, even though in a lesser extent, in this period. In the last five years the total landings of hake of GSA 09 fluctuated between 1,000 to about 2,300 tons. In 2008 the landing was 1,329 tons.

Due to large concentration of hake juveniles in GSA 09, trawl landings are traditionally dominated by small sized specimens; they are basically composed by age groups $0+$ and $1+$. Gillnet fishery lands mostly age 2 and age 3 fish. High quantities of small size hake are routinely discarded, especially in summer and on fishing grounds located near the main nursery areas of the species. About 450 tons of hake discards were estimated in 2006 for the trawl fishery in GSA 09. Due to the introduction of the EU Regulations on MLS, a progressive increase of the size at which $50 \%$ of the specimens caught was discarded has been observed in the last ten years.

## Limit and target management reference points or levels

## Comments on assessment

GRUND data prior to 1994 should be standardised and used within this assessment.

### 7.3. Hake in GSA 10

| Species common name: | European hake |
| :--- | :--- |
| Species scientific name: | Merluccius merluccius (L., 1758) |
| Geographical Sub-area(s) GSA(s): | GSA 10 |

## Most recent state of the stock

- State of the adult abundance and biomass:

Survey indices indicate a variable pattern of abundance ( $\mathrm{n} / \mathrm{h}$ ) and biomass ( $\mathrm{kg} / \mathrm{h}$ ) without a clear trend. However, recent values are among the highest observed since 1994. The hindcasting approach using Aladym model shows that the SSB was continuously decreasing. A similar pattern shows also the spawning potential ratio that was in the range 6 and $4 \%$ from 1994 and 2008. SGMED-09-02 is unable to interpret such different trends and thus unable to advice on the state of the spawning stock size, in particular due to a lack of a estimated management reference points.

- State of the juvenile (recruits):

Recent recruitment since 2006 appears to be above average.

- State of exploitation:

SGMED 09-02 proposes $\mathrm{F} \leq 0.24$ as target management reference point (basis $\mathrm{F}_{0.1}$ ).
Given the results of the present analysis, the stock appears overexploited. Considering the level of F estimated in 2008 by Aladym, i.e. 0.55, the stock appears overfished and a reduction of $55 \%$ would be necessary to reach $\mathrm{F}_{0.1}(0.244)$.

- Source of data and methods:

The data used in the analyses were from trawl surveys (time series of MEDITS and GRUND surveys from 1994 to 2008 and from 1994 to 2006 respectively) and from the effort and landings. The analyses on the population were conducted using SURBA and ALADYM models in a complementary way. The following growth parameters were used to split the LFD for the SURBA analyses and to parameterize Aladym model as well as Yield software: $\mathrm{L}_{\infty}=97.9 \mathrm{~cm}, \mathrm{~K}=0.135, \mathrm{t}_{0}=-0.4$; males: $\mathrm{L}_{\infty}=50.8 \mathrm{~cm}, \mathrm{~K}=0.25, \mathrm{t}_{0}=-0.4$; lengthweight relationship: $a=0.00355, b=3.2$. Size at first maturity was varying around 32 cm (maturity range 2 cm ). Estimates of total mortality and recruitment from SURBA were used to feed Aladym model, reestimating the total and fishing mortality.

## Outlook and management advice

SGMED recommends the relevant fleets' effort to be reduced until fishing mortality is below or at the proposed level $\mathrm{F}_{0.1}$, in order to avoid future loss in stock productivity and landings. This should be achieved by means of a multi-annual management plan taking into account mixed-fisheries effects. Catches consistent with the effort reductions should be estimated.

Short and medium term scenarios:
Will be conducted and delivered by SGMED 09-03 (14-18 December 2009).

## Fisheries

Available landing data are from DCR regulations and range from 1012 tons of 2002 to $1,544 \mathrm{t}$ in 2006, being the lowest value of 393 tons registered in 2006. Landings were rising from 2002 to 2006 and then were decreasing tol,122 tons in 2008. The whole fishing effort (kw-days) of fishing segments (2002-2004) or métier (2005-2007) related with hake capture in the GSA 10 shows a decreasing from 2002 till now, with trawlers almost stable and slightly decreasing in the last 3 years and small scale fishery decreasing from 2002 to 2007 .

### 7.4. Hake in GSA 11

| Species common name: | European hake |
| :--- | :--- |
| Species scientific name: | Merluccius merluccius (L., 1758) |
| Geographical Sub-area(s) GSA(s): | GSA 11 |

## Most recent state of the stock

- State of the adult abundance and biomass:

SGMED-09-02 could not estimate the absolute levels of stock abundance. Survey abundance ( $\mathrm{n} / \mathrm{km}^{2}$ ) and biomass $\left(\mathrm{kg} / \mathrm{km}^{2}\right)$ indices do not indicate a significant trend. The stock SSB is more variable over the last decade. No biomass reference points have been proposed for this stock. As a result, SGMED is unable to evaluate the status of the stock with respect to biomass.

- State of the juvenile (recruits):

SGMED-09-02 could not estimate the absolute levels of recruitment. Relative indices estimated by SURBA indicated very high fluctuations of recruitment in the period 1994-2008, without a clear temporal pattern.

- State of exploitation:

SGEMD 09-02 recommends $\mathrm{F} \leq 0.17$ as target management reference point (basis $\mathrm{F}_{0.1}$ ).
The reference points ( $\mathrm{F}_{0.1}$ and $\mathrm{F}_{\max }$ ) estimated for this species using the Yield software were 0.17 and 0.25 , respectively. SGMED notes that the current $\mathrm{F}\left(\mathrm{F}_{1-3}=1.0-2.3\right)$ is far in excess of the proposed target reference point $\mathrm{F}_{0.1}$ and also exeeds $\mathrm{F}_{\text {max }}$. Assuming similar selection patters of the survey and the commercial fishery, SGMED concludes that the stock is heavily overfished.

- Source of data and methods:

The SURBA software program was used to analyse the MEDITS time series and to estimate relative SSB and F. Data coming from DCR (size distribution of landings for trawl) for the period 2006-2007 were used to run stock analyses.

The following parameters were used both for SURBA and VIT analyses:

| VBGF | $\mathrm{L}_{\infty}=97.15 \mathrm{~cm}, \mathrm{~K}=0.165, \mathrm{t}_{0}=-0.03$ |
| :--- | :--- |
| $\mathrm{~L}^{*}$ W relationship | $\mathrm{a}=0.004, \mathrm{~b}=3.156$ |
| M vector | $\mathrm{Age}_{1}=1.11, \quad \mathrm{Age}_{2}=0.51, \quad \mathrm{Age}_{3}=0.40, \quad \mathrm{Age}_{4}=0.35$, <br> $\mathrm{Age}_{5}=0.33$ |
| Catchability (q) | $\mathrm{q}_{1}=0.9, \mathrm{q}_{2-3}=1.0, \mathrm{q}_{4}=0.75, \mathrm{q}_{5}=0.55$ |
| Length at maturity (L50) | 36 cm (sex combined) |

## Outlook and management advice

SGMED recommends the relevant fleets' effort to be reduced until fishing mortality is below or at the proposed level $\mathrm{F}_{0.1}$, in order to avoid future loss in stock productivity and landings. This should be achieved by means of a multi-annual management plan taking into account mixed-fisheries effects. Catches consistent with the effort reductions should be estimated.

Short and medium term scenarios:
Will be conducted and delivered by SGMED 09-03 (14-18 December 2009).

## Fisheries

Hake is exploited in all trawlable areas around Sardinia and is one of the most important target species showing the highest landings.

According to the scientist's knowledge of the GSA 11 landings of hake comes almost entirely from bottom trawl vessels whereas catches from trammel nets or longlines are negligible. Small hakes are commonly caught from shallow waters about 50 m to 300 m depth, whereas adults reach the maximum depths exploited ( 800 m ). Both small and adults catches coming from a mixed fishery, then in the GSA there is not a specific Hake fishery. The most important by catch species are horned octopus (Eledone cirrhosa), squids (Illex coindetii), poor cod (Trisopterus minutus capelanus) at depths less than 350 m and (Chlorophtalmus agassizii), greater forkbeard (Phycis blennoides) and deep-water pink shrimp at greater depth (Parapenaeus longirostris).

At the end of 2006 the trawl fleet of GSA11 accounted for 157 vessels $(11.7 \%$ of the overall Sardinian fishery fleet). The main trawl fleets of GSA11 are present in the following harbors: Cagliari, Alghero, Porto Torres, La Caletta, Sant'antioco, Oristano, Alghero and Arbatax. The fishing capacity of the GSA trawl fleet has shown in these last 15 years remarkable changes. From 1994 to 2004 a general increase in the number of vessels and by the replacement of the old, low tonnage wooden boats by larger steel boats. In the latest years the effort shows a peak in 2005. In the last five years the total landings of hake of GSA 11 fluctuated between 592 to about 768 tons, with a consistent drop ( $-25 \%$ of the mean) in the last year.

## Comments on the assessment

GRUND data should be standardised and used in the assessment.

### 7.5. Red mullet in GSA 09

| Species common name: | Red mullet |
| :--- | :--- |
| Species scientific name: | Mullus barbatus |
| Geographical Sub-area(s) GSA(s): | GSA 09 |

## Most recent state of the stock

- State of the adult abundance and biomass:

The index of stock abundance from GRUND survey shows high variability throughout the time series, but no trend is observed. The index of abundance from MEDITS survey, that approximates a spawning stock biomass index (mostly represented by mature fish), suggests an increasing trend from 1994 to 2008. High inter-annual variation is observed from 2002 to 2008. The current spawning stock biomass roughly estimated through simulations with LCA outputs and yield-per-recruit analysis is assumed to be lower than $20 \%$ of the pristine one. Such surviving rate of spawners, is considered very low for ensuring the stock self-renewal.

- State of the juvenile (recruits):

Recruitment shows a slight increasing trend, especially in the most recent years.

- State of exploitation:

SGMED 09-02 proposes $\mathrm{F} \leq 0.58$ as target management reference point (basis $\mathrm{F}_{\text {MSY }}$ ).
Quite consistent estimates of the current fishing mortality were obtained with 3 alternative approaches (F2008 $=0.85$ with ASPIC, F2006-2008 $=0.97$ with LCA) all of them higher than the values recently estimated for the limit reference points $\mathrm{F}_{\mathrm{MSY}}=0.58$ and its proxy $\mathrm{F}_{0.1}=0.49$ as well as with a previous biomass dynamics model based on trawl surveys time series of Z and biomass index, that provided a $\mathrm{F}_{\text {MSY }}$ rate of 0.59 (SGMED-08-03). The stock is considered overexploited. The size of first capture is too low (growth overfishing) and an increase in yield can be expected in the case a reduction of fishing effort do occur and/or more selective gears are used. It is advisable to avoid the illegal fishing within the 3 miles zone from the base line as well as the landing of undersized individuals in order to decrease fishing pressure on juveniles.

- Source of data and methods:

Data used derive from trawl surveys on size composition and abundance indices and on landings by size/age and direct fishing effort from commercial catch assessement surveys. LCA with data from 2008 was used for the estimation of the $F$ vector, using catches from trawlers and small scale fisheries. Yield per recruit analysis was used for the definition of $\mathrm{F}_{\max }$ and $\mathrm{F}_{0.1}$. A dynamic Biomass Production model (ASPIC) using both a time series from 1994 and 2008 of catch and effort of commercial vessels proceeding from two of the main ports (Viareggio and Porto Santo Stefano) and an abundance index derived from trawl surveys for the same time interval allowed to estimate $F_{\mathrm{MSY}}, q$ for each fishery, $B_{\mathrm{MSY}}, f_{\mathrm{MSY}}$, and a value of $F$ for each year along the time series. SURBA was also used for deriving $F$ estimates by year and other features.

The parameters used: $\operatorname{Linf}=29, \mathrm{~K}=0.6$, to $=-0.1 \quad \mathrm{~L} / \mathrm{W}$ relationship $\mathrm{a}=0.00053 \quad \mathrm{~b}=3.12$; An M vector (age1 $=1.30$, age2 0.79 , age 30.62 , age $4=0.54$ ) and a weighted mean value of M of 0.8

## Outlook and management advice

SGMED recommends the relevant fleets' effort to be reduced until fishing mortality is below or at the proposed $\mathrm{F}_{\text {MSY }}$ level, in order to avoid future loss in stock productivity and landings. This should be achieved by means of a multi-annual management plan taking into account mixed-fisheries effects. Catches consistent with the effort reductions should be estimated.

Short and medium term scenarios:
Will be conducted and delivered by SGMED 09-03 (14-18 December 2009).

## Fisheries

The species is caught as a part of a species mix that constitutes the target of the trawlers operating near shore. The main species caught in GSA 09 are Squilla mantis, Sepia officinalis, Trigla lucerna, Merluccius merluccius, Mullus barbatus, Gobius niger. The species is mainly caught in late summer-beginnings of autumn, when juveniles are highly concentrated near shore. Age of first capture is of about 7 cm . Catch is mainly composed by age 0 individuals while the older age classes are poorly represented in the catch. Catch rates increased along the analysed period and considering that no dramatic changes occurred on effort allocation nor on other aspects of fishing behaviour in the analysed years, this increase has to be attributed to an enhancement in biomass. Even if catch within the coastal 3 miles stripe is forbidden, illegal fishing do occur considering the high value that small-sized individuals have in the area.

Total catches GSA9 of Mullus barbatus

| YEAR | Bottom trawls | Longlines | MISCELANEOUS | Nets | Seines |

### 7.6. Red mullet in GSA 25

| Species common name: | Red mullet |
| :--- | :--- |
| Species scientific name: | Mullus barbatus |
| Geographical Sub-area(s) GSA(s): | GSA 25 |

## Most recent state of the stock

- State of the adult abundance and biomass:

In the absence of proposed or agreed precautionary refernce points SGMED 09-02 is unable to fully evaluate the status of the spawning stock size. In the current stock assessment no trend in the spawning stock biomass is evident.

- State of the juvenile (recruits):

SGMED-09-02 is unable to provide any scientific advice of the state of the recruitment as no trend in recruitment is evident.

- State of exploitation:

SGMED recommends $\mathrm{F}_{0.1}$ of ages $1-3=0.22$ as an approximation of $\mathrm{F}_{\mathrm{msy}}(\mathrm{F} \leq 0.22)$ and thus as the target management reference of sustainable exploitation.

The estimated reference points of $\mathrm{F}_{0.1}(0.22)$ and $\mathrm{F}_{\max }(0.34)$, in relation with the estimated value of $\mathrm{F}_{\text {bar }}(1-3)$ ( $=0.84$ ), sugggest an overexploitation state of the stock.

- Source of data and methods:

The present assessment was performed by means of VPA analysis, using a mean pseudo-cohort from catch-at-age data for the period of 2005-2008. A Yield per Recruit (Y/R) Analysis was also performed for the estimation of $\mathrm{F}_{\max }$ and $\mathrm{F}_{0.1}$. The VIT software (Lleonart and Salat, 1992) was used for both analyses. Catch-at-age data derived from landings for each fishing gear exploiting the stock (bottom otter trawl and trammel net), and discards data from bottom otter trawl.
An M vector was used as estimated by PROBIOM. The biological data used were collected within the framework of the Cyprus National Data Collection Programme and submitted under the 2009 Spring Official EC Data Call.
All data required under the 2009 Spring Official EC Data Call were available during the meeting.

## Outlook and management advice

SGMED 09-02 recommends a reduction in fishing effort of the relevant fleets until sustainable levels of fishing effort are achieved ( $\mathrm{F} \leq 0.22$ ). This shoud be done by means of a multi-annual management plan taking into account mixed fisheries implications. Catches consistent with the effort reductions should be estimated.

Short and medium term scenarios:
Will be conducted and delivered by SGMED 09-03 (14-18 December 2009).

## Fisheries

Red mullet in GSA 25 is exploited with other demersal species by the bottom otter trawlers and the artisanal fleet using trammel nets. The main species caught with M. barbatus are: Spicara spp. (mostly S. smaris), Boops boops, M. surmuletus, Pagellus erythrinus and cephalopods (Octopus vulgaris, Loligo vulgaris and Sepia officinalis). The artisanal (inshore) fishery catches also relatively large quantities of Diplodus spp, Sparisoma cretense and Siganus spp. The average percentage of M. barbatus in the overall landings of the bottom trawl and artisanal fishery, for the period 2005-2008, was $7 \%$ and $2 \%$ respectively.

Figure 7.6.1 provides the official landings of $M$. barbatus in GSA 25 by fishing gear, for the years 19852008. The figure presents a declining trend in the landings from both gears, mostly from the trammel nets. For the same period, the overall LPUE by fishing fleet (all gears combined for the artisanal fishery) is provided in Figure 7.6.2. LPUE of both fleets show a declining trend until 2006; since then, LPUE for the artisanal seems to be stable, while for the bottom trawl fishery LPUE in 2007 reached the highest value of the time period. It is noted that since 2006 the number of licensed bottom trawlers operating in GSA 25 has been reduced by $50 \%$ (from 8 to 4 ).

Fig. 7.6.1 Landings of M. barbatus in GSA 25 by fishing fleet for the period 1985-2008.

Fig. 7.6.2 Overall LPUE in GSA 25 by fishing fleet for the period 1985-2008.

## Precautionary and target management reference points or levels

### 7.7. Pink shrimp in GSA 06

| Species common name: | Deepwater pink shrimp |
| :--- | :--- |
| Species scientific name: | Parapenaeus longirostris |
| Geographical Sub-area(s) GSA(s): | GSA 06 |

## Most recent state of the stock

- State of the adult abundance and biomass:

Since 2002, SSB, with an average for the whole period of 342 t , declined rapidly and continuously to the lowest value observed in 2008 ( 111 t ) which represents only $8 \%$ of that observed in 2002. SGMED notes that the MEDITS survey abundance index shows a very high peak in abundance in the 1999-2001 period, which represents the start of the assessment period. Prior to 1999, abundance levels were comparable to those seen in the 2002-2008 period. SGMED notes that the level of 111 t is much lower than the proposed management references of $\mathrm{B}_{\mathrm{lim}}=300 \mathrm{t}$ and $\mathrm{B}_{\mathrm{pa}}=1,200 \mathrm{t}$, respectively. The stock is therefore considered not having its full reproductive capacity.

## - State of the juvenile (recruits):

Recruits (aged 0 individuals) were estimated to have declined from 2002 to 2005 in the same pattern as SSB and continued to be very low in 2006-2007. However, in 2008, recruitment increased significantly and appears to be at the level of the 2003 value. Such increased recruitment has the potential to contribute to a recovery of the spawning stock in short time.

## - State of exploitation:

SGMED recommends that $\mathrm{F} \leq 0.2$ be established as a management target and a proxy for $\mathrm{F}_{\text {msy }}$.
Fishing mortality over ages $2-5$ displays a high variation with an average value of $\mathrm{F}=0.5$. SGMED 09-02 considers the stock being subject to overfishing.

- Source of data and methods:

The state of exploitation was assessed for the period 2002-2008 by means of a VPA Separable, tuned with standardised CPUE from abundance indices from trawl survey (MEDITS). Analysis was carried out applying the Extended Survivor Analysis (XSA) method (Lowestoft suite; Darby and Flatman, 1994) over the period 2002-2008. In addition, a yield-per-recruit (Y/R) analysis (VIT program; Lleonart and Salat, 1992) was applied on the mean pseudo-cohorts 2002-2008 for the GFCM geographical sub-area Northern Spain (GSA06). Both methods were performed from size composition of trawl catches (obtained from on board and on port monthly sampling) and official landings, transforming length data to age data by slicing (L2AGE program).

The parameters of the size-weight relationship used in this assessment (García Rodriguez et al., 2009) are similar to those calculated by other authors, (Ribeiro-Cascalho \& Arrobas, 1987; Sobrino, 1998; Tosunoglu et al., 2007). The estimates made for the VBGF parameters (García Rodriguez et al., 2009) show that, although the $\mathrm{L}_{\infty}$ values were similar, the values for the growth rate $(\mathrm{K})$ calculated in this study are lower than those presented by other authors both for the Mediterranean (Ardizzone et al., 1990; D'Ongia et al., 1998) and for the Atlantic (Ribeiro-Cascalho, 1988; Sobrino, 1998), The size composition of commercial landings were obtained by monthly length samplings carried out both in one of the ports (Santa Pola) as well as on board samplings, during the 2002-2008 period. Landings and effort data were obtained combining different sources, such as Official Landings provided by Autonomous Community, and from the Information and Sampling Network of the Spanish Oceanographic Institute (IEO).

## Outlook and management advice

SGMED recommends the relevant fleets' effort to be reduced until fishing mortality is below or at the proposed $\mathrm{F}_{\mathrm{MSY}}$ level, in order to avoid future loss in stock productivity and landings. This should be achieved by means of a multi-annual management plan taking into account mixed-fisheries effects. Catches consistent with the effort reductions should be estimated.

Short and medium term scenarios:
Will be conducted and delivered by SGMED 09-03 (14-18 December 2009).

## Fisheries

Deep-water pink shrimp (Parapenaeus longirostris) is one of the most important crustacean species for the trawl fisheries developed along the GFCM geographical sub-area Northern Spain (GSA 06). This resource is an important component of commercial landings in some ports of the Mediterranean Northern Spain and occasionally target species of the trawl fleet, composed by around 600 vessels, and especially by 260 vessels which operate on the upper slope. During the last years, a sharp increase in landings was observed, starting in 1998 and reaching the maximum value in 2000, followed by a decreasing trend during the period 2001-2008. In 2008 the annual landings of this species amounts 33 tons in the whole area, which it has been the lowest value of the historical series.

Fishing effort has reduced from 50,000 days in 2000 to 13,000 in 2006, with a slight increase in 2007 and 2008 to 18,000 . SGMED notes that the fishing effort below only includes vessels that have landed pink shrimp in the given years.

| Year | $\mathbf{2 0 0 2}$ | $\mathbf{2 0 0 3}$ | $\mathbf{2 0 0 4}$ | $\mathbf{2 0 0 5}$ | $\mathbf{2 0 0 6}$ | $\mathbf{2 0 0 7}$ | $\mathbf{2 0 0 8}$ |

## Comments on assessment

SGMED-09-02 suggested the use of seasonal VPA models for assessment of short lived crustaceans. During the STECF 09-02, an assessment on deepwater pink shrimp from GSA 06 was performed. Official data were not sent on time, but the expert provided a copy of some of the data. Files dealing with official landings and effort were not available. Consequently data on landings and effort for 2008, were derived from the series.

### 7.8. Pink shrimp in GSA 09

| Species common name: | Deepwater pink shrimp |
| :--- | :--- |
| Species scientific name: | Parapenaeus longirostris |
| Geographical Sub-area(s) GSA(s): | GSA 09 |

## Most recent state of the stock

- State of the adult abundance and biomass:

A new assessment was performed assuming a different natural mortality vector calculated using the ProdBiom routine. SGMED was unable to estimate the absolute stock size. Since 1998, SSB shows a high variation without a clear trend. As no precautionary level for the stock of deep-sea pink shrimp in GSA 09 is proposed or agreed, SGMED cannot evaluate the stock status in relation the precautionary approach.

- State of the juveniles (recruits):

Recent recruitment in 2004-2006 is indicated to be above average.

- State of exploitation:

SGMED proposed $\mathrm{F} \leq 0.7$ as target management reference point (basis $\mathrm{F}_{0.1}$ ).
SGMED's advice relies on the VIT analysis and considers the stock being harvested sustainably, as $\mathrm{F}_{1-3}$ was estimated to range among $0.5-0.6$ for the period 2006-2008.

- Source of data and methods:

Time series of survey data were used (MEDITS: 1994-2008; GRUND: 1994-2007) to investigate trends in abundance and F with SURBA. Length cohort analysis was used on 2006 and 2007 DCR data. The following parameters were used both for SURBA and VIT analyses:

| $\bullet \quad$ Growth |
| :--- |
| $\mathrm{L} \infty=43.5 \mathrm{~mm}$ carapace length |
| $\mathrm{K}=0.6$ |
| to $=0$ |
| $\bullet \quad$ Length-Weight relationhips |
| $\mathrm{a}=0.00686$ |
| $\mathrm{~b}=2.24$ |
| $\quad$ Natural mortality |
| Mvector $=1.0$ (age 1), 0.78 (age 2), 0.69 (age 3), 0.65 (age 4) |
| $\bullet \quad$ Length-at-maturity (L50) |
| L50 $=24 \mathrm{~mm}$ |
| Lc100 $=20 \mathrm{~mm}$ |

## Outlook and management advice

Given the current uncertainty in F estimates, SGMED recommends the relevant fleet effort to not be increased, in order to avoid future low stock productivity and landings. Any management measure should consider the mixed nature of the fisheries exploiting the stock.

Short and medium term scenarios:
Will be conducted and delivered by SGMED 09-03 (14-18 December 2009).

## Fisheries

The species is exploited by trawl fleet mostly on muddy bottoms from 150 to 500 m depth. Annual trawl landings increased from 160 tons in 2002 to 450 tons in 2006, decreasing to 220 tons in 2007 and 254 tons in 2008.

Annual landings ( t ) by fishing technique in GSA 09.

| SPECIES | COUNTRY | FT_LV4 | 2002 | 2003 | 2004 | 2005 | 2006 | 2007 | 2008 |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| DPS | ITA | DTS | 133 | 308 | 367 | 430 | 462 | 215 | 253 |

| SUM | ITA |  | 161 | 323 | 376 | 431 | 462 | 217 | 254 |

A total of 9 tons of discards, composed by individuals smaller than 20 mm carapace length, was estimated in 2006 (approx. $2 \%$ of total landings). Trawl landings showed a marked difference in the length composition between 2006 and 2007. Proportion of juveniles ( $0+$ ) increased in 2007 landing. The total trawl fleet of GSA 09 at the end of 2006 accounted for 361 vessels. Deep sea pink shrimp is mostly exploited in the southern part of the GSA9 (fleets of Porto Santo Stefano Porto Ercole, Fiumicino, Terracina and Gaeta. The fishing capacity of the GSA 09 has shown in the last 20 years a progressive decrease. From 1996 to 2006 the number of bottom trawlers of GSA 09 decreased of about $30 \%$. Also fishing effort decreased, even though in a lesser extent, in this period.

Trends in annual fishing effort by fishing technique deployed in GSA 09, 2002-2007.

### 7.9. Anchovy in GSA 16

| Species common name: | Anchovy |
| :--- | :--- |
| Species scientific name: | Engraulis encrasicolus |
| Geographical Sub-area(s) GSA(s): | GSA 16 - South of Sicily |

## Most recent state of the stock

- State of the adult abundance and biomass:

Biomass estimates of total population obtained by hydro-acoustic surveys for anchovy in GSA 16 show a decreasing trend over the last years. The 2008 estimate is the lowest value of the series and represents approximately just one-tenth of the maximum recorded value. However, in the absence of proposed or agreed references, SGMED-09-02 is unable to fully evaluate the state of the stock and provide any scientific advice in relation to them.

- State of the juvenile (recruits):

No recruitment data were provided by this assessment.

- State of exploitation:

SGMED 09-02 recommends the exploitation rate $\mathrm{E} \leq 0.4$ as target management reference point.
The high and increasing yearly exploitation rates, as estimated by the ratio between total landings and biomass, indicates high fishing mortality levels. If this estimate of exploitation rate can be considered as equivalent to $\mathrm{F} / \mathrm{Z}$ estimate obtained from the fitting of standard stock assessment models, the current exploitation ( 0.64 ) is higher than the suggested reference point. The fishing mortality level corresponding to $\mathrm{F} / \mathrm{Z}=0.64$ is $\mathrm{F}=1.17$, if $\mathrm{M}=0.66$ is estimated with Pauly (1980) empirical equation. Thus, the stock is considered to be overexploited.

- Source of data and methods:

Census data for catch and effort data were obtained from census information (on deck interviews) in Sciacca port, the most important base port for the landings of small pelagic fish species along the southern Sicilian coast (GSA16), accounting for about $2 / 3$ of total landings in GSA 16. Acoustic data were used for fish biomass evaluations. Natural mortality was set at 0.66 , estimate obtained with Pauly (1980) empirical equations. An attempt to fit a surplus production (logistic) model to the available data series (catch-effort and acoustic biomass estimates) was also done by means of ASPIC (Prager, 1994), but results were not mentioned in this document as the basic assumption about the proportionality between CPUE and biomass was not fulfilled.

## Outlook and management advice

Given the very low biomass for three consecutive years (2006, 2007 and 2008) and the current high exploitation rates, fishing mortality should be reduced towards $F / Z=0.4$ in order to promote stock recovery and avoid future loss in stock productivity and landings.

Taking into account that fishing effort was relatively stable in last decade, whereas CPUE trend was even increasing, results would suggest that also environmental factors are important to explain the variability on yearly recruitment success. However, the stock biomass did not recover from the 2006 "collapse" in biomass ( $-69 \%$ from July 2005 to June 2006), and even further decreased ( $-53 \%$ ) in 2008. This fact, along with the quite high and increasing level of exploitation rates experienced over the last years, also suggests questioning about the sustainability of current levels of fishing effort. In addition, possible negative effects on the stock could result from pressure of other fishing gears on larval stages.

A warning on the fishing of larval stages (locally named bianchetto) is also relevant for anchovy population if derogation of the fishing ban, normally operated for GSA 16 in wintertime, is postponed after the start of
the anchovy spawning season, even though more data and investigation are needed in order to estimate the possible impact of this fishing activity on the exploited populations

Short and medium term scenarios:
Will be conducted and delivered by SGMED 09-03 (14-18 December 2009).

## Fisheries

In Sciacca port, the most important base port for the landings of small pelagic fish species along the southern Sicilian coast (GSA16), accounting for about $2 / 3$ of total landings in GSA 16, two operational units (OU) are presently active, purse seiners and pelagic pair trawlers. The fleet in GSA16 is composed by about 50 units ( 17 purse seiners and 30 pelagic pair trawlers were counted up in a census carried out in December 2006). In both OUs, anchovy represents the main target species due to the higher market price.

Average anchovy landings over the last decade (1997-2008) were about 1,600 metric tons, with large interannual fluctuations. Total effort was slightly increasing over the same period.

Fig. 7.9.1 Anchovy landings over the last decade (1998-2008) by fleet segment

### 7.10. Anchovy in GSA 17

| Species common name: | Anchovy |
| :--- | :--- |
| Species scientific name: | Engraulis encrasicolus |
| Geographical Sub-area(s) GSA(s): | GSA 17 |

## Most recent state of the stock

SGMED 09-02 has modified the assessment carried out last year in accordance with its recommendations regarding natural mortality to be applied (Murcia workshop of SGMED 09-01, 2-6 March 2009). No update with 2008 catch data was conducted.

- State of the adult abundance and biomass:

SGMED 09-02 recommends $\mathrm{Bpa}=80,000 \mathrm{t}$ and $\mathrm{Blim}=50,000 \mathrm{t}$ be defined as precautionary management reference points.
After a drastic decline the stock reached its minimum in the late 1980s and recovered thereafter to about $130,000 \mathrm{t}$ in 2007. The stock is considered to having its full reproductive capacity.

- State of the juvenile (recruits):

SGMED 09-02 estimates recent recruitment to be at an average level.

- State of exploitation:

SGMED recommends the application of the proposed exploitation rate $\mathrm{E} \leq 0.4$ as management target for stocks of anchovy and sardine in the Mediterranean Sea. This value might be revised in the future when more information becomes available.
SGMED 09-02 estimated the most recent exploitation rates in 2005-2007 as at or slightly below the proposed sustainable level. As such, the stock is considered sustainably harvested.

- Source of data and methods:

The assessment of this stock was carried out by means of Virtual Population Analysis (VPA), using catch data collected for Italy, Slovenia and Croatia, from 1975 to 2007. Split-year data were used assuming the first of June as the birth date of anchovy. The annual natural mortality rates were derived from Probiom software, according to the first SGMED meeting of 2009 (Tab. 1). The values of von Bertalanffy parameters Linf $=16.15, \mathrm{k}=0.40, \mathrm{t} 0=-2.04$ and length-weight parameters $\mathrm{a}=0.0025, \mathrm{~b}=3.37$ were used into the calculations of the M at age vectors and were derived from DCR (biological sampling of landing data, GSA 17, year 2007).

## Outlook and management advice

SGMED 09-02 recommends to maintain the effort constant and to determine consistent catches. Technical interactions regarding the fisheries targeting the sardine stock in GSA 17 need to be taken into account when managing the anchovy fisheries.

- Short, medium and long term scenarios:

Projections of stock status were not performed.

## Fisheries

Mid-water trawlers and purse seiners. In 2007, the Italian fleet was composed of about 130 ( 65 pairs) pelagic trawlers (volante) mainly operating from Trieste to Ancona (average GRT 43, average engine power 290 kW ) and about 45 purse seiners attracting fish with light (lampara), operating in the Gulf of Trieste ( 24 small lampara, average GRT 9, average engine power 110 kW ) and in the Central Adriatic (21 big lampara,
average GRT 97, average engine power 390 kW ). In 2007, the Slovenian fleet was composed of 1 pelagic trawler pair and 7 purse seiners; no updated data are available for the Croatian fleet.

The main fraction of the total catch has been usually taken by the Italian fleet but, in recent years, the fraction relative to the fleets of the eastern part of the GSA 17 has increased.

## Limit and target management reference points or levels

## Comments on the assessment

SGMED notes that there was no information presented during the meeting regarding the fry fishery within GSA 17. The catches of fry fishery are believed to be negligible in this GSA by CNR-ISMAR-SPM Fish Population Dynamics Unit. Fry fishery may be more important in GSA 18 and an ongoing EU funded project (SARDONE) will allow to evaluate if this fishery has an impact also on the stock in GSA 17.

Inclusion of all catch data for anchovy in GSA 17 should be ensured.
Explore the possibility to include acoustic survey data carried out in the eastern part of GSA 17 as a tuning fleet within the assessment.

### 7.11. Anchovy in GSA 22

| Species common name: | Anchovy |
| :--- | :--- |
| Species scientific name: | Engraulis encrasicolus |
| Geographical Sub-area(s) GSA(s): | GSA 22 |

## Most recent state of the stock

- State of the adult abundance and biomass:

Given the short length of the time series, SGMED is unable to precisely estimate the absolute levels of stock abundance and biomass. Survey indices and VPA analyses indicate that average total biomass and SSB increased since 2005 to 2008. Biomass limit reference points have not been estimated for this stock, and hence advice relative to these cannot be provided by SGMED in respect to those.

- State of the juvenile (recruits):

ICA model estimates suggest an increase in recruitment since 2004, with a pronounced increase in 2008. However the model predicts a decrease in the population abundance at age 0 for 2009 to the 2006 abundance level.

- State of exploitation:

SGMED recommends the application of the proposed exploitation rate $\mathrm{E} \leq 0.4$ as management target for stocks of anchovy and sardine in the Mediterranean Sea. This value might be revised in the future when more information becomes available.

Based on ICA results, the mean $E=F / Z$ ( $F$ averaged over ages 1 to 3 ) has fluctuated around 0.36 and since 2004 has been below the empirical level of sustainability suggested as target exploitation level for this stock.Thus, the stock is considered to be exploited sustainably.

- Source of data and methods:

This assessment is based on fishery independent surveys information as well as on Integrated Catch at Age (ICA) analysis model. Specifically, acoustic surveys estimations were used for Total Biomass estimates and DEPM surveys for the estimation of SSB. ICA assessment method uses separable virtual population analysis (VPA) with weighted tuning indices. The application of ICA was based on commercial catch data (20002008) and as tuning indices were used the biomass estimates from acoustic surveys and the Daily Egg Production Method (DEPM) estimates over the period 2003-2008 but with a gap for 2007. Anchovy data were comprised of annual anchovy landings, annual anchovy catch at age data (2000-2008), mean weights at age, maturity at age at age and the results of acoustic and DEPM surveys. Since, acoustics and DEPM are being applied at the same time and with the same research vessel acoustic estimates were used as an index for the numbers at age of the population and DEPM estimates as stock spawning biomass estimates. Different natural mortality were applied per age group but constant for all years based on ProBiom (Abella et al., 1997) as recommended in the report of the SG-ECA/RST/MED 09-01. This method of the estimation of the natural mortality is consistent with the methodology used in GSAs 5,6 and 17 for small pelagics.

Natural mortality values applied for anchovy stock in GSA 22.

| Age0 | Age1 | Age2 | Age3 | Age4 |
| :--- | :--- | :--- | :--- | :--- |
| 1.5 | 1 | 0.74 | 0.66 | 0.62 |

Reference age for the fishery was age group 2 , as fully exploited and fully recruited. The age groups 0,4 and 5 were underweighted in the analysis based on their percentage in the catch. Age 1 was also underweighted in the acoustic surveys (0.5). Catchability for the DEPM index is assumed as absolute indicator of biomass and linear catchability relationship is assumed for the acoustic surveys.

## Outlook and management advice

Taking the empirical level as a reference point for sustainable exploitation, the stock is considered to be exploited sustainably. Increased fishing is not expected to result in increased landings in the long term. SGMED 09-02 recommends not to increase the effort and to determine consistent catches. Technical interactions regarding the fisheries targeting the sardine stock in GSA 22 need to be taken into account when managing the anchovy fisheries.

For precautionary reasons the possibility of changing the closed period should be examined. Since the purse seine fishery is a multispecies fishery targeting both anchovy and sardine, a shift of the closed period (present: mid December to end of February) towards the recruitment period of anchovy (e.g. October to December) / or the recruitment period of sardine (e.g. February to April) could be suggested. This approach has the potential to improve the selectivity of the fishery, and thus provide higher potential catch in the long term.

- Short, medium and long term scenarios:

Projections of stock status were not performed.

## Fisheries

In GSA 22 (Greek part) anchovy is almost exclusively exploited by the purse seine fleet. Pelagic trawls are banned and benthic trawls are allowed to fish small pelagics in percentages less than $5 \%$ of their total catch. Regarding the regulations enforced they concern a closed period from the mid December till the end of February and technical measures such as minimum distance from shore, gear and mesh size, engine, GT. There is a minimum landing size at 9 cm .

Anchovy landings showed an increasing trend towards 2008 Anchovy reported landings have showed an increasing trend since 2002, comprising 24,480 tons in 2008. Information regarding the age and length distribution of sardine landings prior to 2003 is based on the Hellenic Centre of Marine Research data collection system.

Data of the fishing effort (Days at Sea) and the landings per vessel class indicate that small vessels ( $12-24 \mathrm{~m}$ ) (Tables below) are mainly responsible for anchovy catches ( $>70 \%$ of anchovy catches).

Table of anchovy landings (in t) in GSA 22 per vessel size for 2003 to 2006 and 2008 concerning the purse seine fleet in Greek waters. Since there was no Data Collection Program in Greece in 2007, data concerning this year are estimations of the Hellenic Centre for Marine Research based on data from other research projects that were held in GSA 22.

| Year | PS 12-24 m | PS 24-40 m |
| :---: | :---: | :---: |
| 2003 | 12507 | 1495 |
| 2004 | 12222 | 3877 |
| 2005 | 11073 | 5274 |
| 2006 | 16121 | 6190 |
| 2007 | 14875 | 6625 |
| 2008 | 18188 | 6293 |

Discards values are less than $1 \%$, reaching approximately $0.06 \%$ data for GSA 22 .

## Limit and target management reference points or levels

No reference points concerning biomass can be suggested at this point due to the small time series of data available. $\mathrm{E}_{\text {msy }}$ should be set as the fishing mortality that assures exploitation rate below the empirical level of $\mathrm{E}<0.4$ (Patterson 1992).

Discards were also included within this assessment representing however only $0.06 \%$ of total landings.

### 7.12. Sardine in GSA 16

| Species common name: | Sardine |
| :--- | :--- |
| Species scientific name: | Sardina pilchardus |
| Geographical Sub-area(s) GSA(s): | GSA 16 - South of Sicily |

## Most recent state of the stock

- State of the adult abundance and biomass:

Biomass estimates of the total population obtained by hydro-acoustic surveys for sardine in GSA 16 show that the recent stock level is well below the average value over the last decade. However, in the absence of proposed or agreed references, SGMED-09-02 is unable to fully evaluate the state of the stock and provide any scientific advice in relation to them.

- State of the juvenile (recruits):

Data not available.

- State of exploitation:

SGMED recommends the application of the proposed exploitation rate $\mathrm{E} \leq 0.4$ as management target for stocks of anchovy and sardine in the Mediterranean Sea. This value might be revised in the future when more information becomes available.

Annual exploitation rates, as estimated by the ratio between total landings and biomass, indicates relatively low fishing mortality during the last decade. If this estimate of exploitation rate can be considered as equivalent to $\mathrm{F} / \mathrm{Z}$ estimate obtained from the fitting of standard stock assessment models, the current exploitation rate ( 0.22 ) and even all the previous available estimates are lower than the reference point suggested by Patterson (1992) and confirmed by SGMED 09-02 in this report (section 6.1.3). The fishing mortality level corresponding to $\mathrm{F} / \mathrm{Z}=0.22$ is $\mathrm{F}=0.14$, if $\mathrm{M}=0.51$, estimated with Pauly (1980) empirical equation, is assumed.

Using the exploitation rate as a target reference point, the stock of sardine in GSA 16 is considered as being sustainably exploited.

- Source of data and methods:

Census data for catch and effort data were obtained from census information (on deck interviews) in Sciacca port, the most important base port for the landings of small pelagic fish species along the southern Sicilian coast (GSA16), accounting for about $2 / 3$ of total landings in GSA 16. Acoustic data were used for fish biomass evaluations. Natural mortality was set at 0.51 , estimate obtained with Pauly (1980) empirical equations. An attempt to fit a surplus production (logistic) model to the available data series (Catch-effort and acoustic biomass estimates) was also done by means of ASPIC software ver. 5.33 (Prager, 1994), but results were not mentioned in this document, mainly due to their quite high variability depending on the adopted parameter starting guesses in the estimation procedure.

## Outlook and management advice

Given that biomass was quite low for three consecutive years (2006, 2007 and 2008) and that the exploitation rate of sardine was occasionally moderate over the last decade, SGMED recommends the relevant fleet effort should not be allowed to increase in order to avoid future loss in stock productivity and landings. However, as the small pelagic fishery is generally multispecies, any enforcement about fishing effort for anchovy stock (see management advice for anchovy in GSA 16) would also have effects on sardine. In addition, due to the low level of the anchovy stock, measures should be taken to prevent a shift of effort from anchovy to sardine.

Taking into account that fishing effort was relatively stable in the last decade, results would suggest that also environmental factors are important to explain the variability on yearly recruitment success. However, the stock did not recover from the 2006 "collapse" in biomass ( $-52 \%$ from July 2005 to June 2006), and this fact, along with the moderate exploitation rates experienced over the last decade and the decreasing trend in landings, also suggests questioning about the sustainability of current levels of fishing effort. In addition, possible negative effects on these populations could results from pressure of other fishing gears on larval stages.

A warning on the fishing of larval stages (locally named bianchetto) is relevant, taking into account that in the past years derogation of the fishing ban was normally operated in wintertime, i.e. during the sardine spawning season, even though more data and investigation are needed in order to estimate the possible impact of this fishing activity on the exploited populations.

- Short, medium and long term scenarios

Projections of stock status were not performed.

## Fisheries

In Sciacca port, the most important base port for the landings of small pelagic fish species along the southern Sicilian coast (GSA 16), accounting for about $2 / 3$ of total landings in GSA 16 , two operational units (OU) are presently active, purse seiners and pelagic pair trawlers. The fleet in GSA 16 is composed by about 50 units (17 purse seiners and 30 pelagic pair trawlers were counted up in a census carried out in December 2006). In both OUs, anchovy represents the main target species due to the higher market price.

Average sardine landings over the last decade (1997-2008) were about 1,500 metric tons, with a general decreasing trend. Total effort was slightly increasing over the same period.

Fig. 7.12.1 Sardine landings over the last decade (1998-2008) by fleet segment

Fig. 7.12.2 Trend in fishing effort by major gear types, 1998-2008.

### 7.13. Sardine in GSA 17

| Species common name: | Sardine |
| :--- | :--- |
| Species scientific name: | Sardina pilchardus |
| Geographical Sub-area(s) GSA(s): | GSA 17 |

## Most recent state of the stock

SGMED 09-02 has modified the assessment carried out last year in accordance with its recommendations regarding natural mortality to be applied (Murcia workshop of SGMED 09-01, 2-6 March 2009). No update assessment with 2008 catch data was conducted.

- State of the adult abundance and biomass:

SGMED 09-02 recommends $\mathrm{B}_{\mathrm{pa}}=270,000 \mathrm{t}$ and $\mathrm{B}_{\mathrm{lim}}=180,000 \mathrm{t}$ be defined as precautionary management reference points.

The average stock biomass estimated by VPA was 440,000 tonnes in 1975-2007 and 90,000 tonnes in 20052007. Spawning stock biomass showed the lowest levels just in recent years.

SGMED 09-02 considers the stock status of sardine in GSA 17 being far below its reproductive capacity.
In September 2004 there was a point estimate of abundance in the eastern part of GSA17: 213,332 tons. SGMED did not have the opportunity to verify this point estimate.

- State of the juvenile (recruits):

Since the mid 1995, recruitment remained significantly below the average recruitment.

- State of exploitation:

SGMED recommends the application of the proposed exploitation rate $\mathrm{E} \leq 0.4$ as management target for stocks of anchovy and sardine in the Mediterranean Sea. This value might be revised in the future when more information becomes available.

SGMED 09-02 considers the stock of sardine to be over-exploited, as the estimated E almost continuously exceeds 0.4 since 1998.

- Source of data and methods:

The assessment of this stock was carried out by means of Virtual Population Analysis (VPA), using catch data collected for Italy, Slovenia and Croatia, from 1975 to 2007. Natural mortality was estimated by the Probiom model. The Laurec-Shepherd tuning of VPA was performed using an abundance index series derived from echo-surveys carried out in the western part of the GSA 17.

In 2009, VPA was also carried out using vectors of natural mortality rate at age, i.e. not constant over age as in the stock assessment of 2008. They were derived from Probiom software and Gislason's method, according to the first SGMED meeting of 2009. The values of von Bertalanffy parameters Linf $=18.783, \mathrm{k}=$ $0.379, \mathrm{t} 0=-2.302$ and length-weight parameters $\mathrm{a}=0.0095, \mathrm{~b}=2.94$ were used into the calculations of the $M$ at age vectors and were derived from DCR (biological sampling of landing data, GSA 17, year 2007).

## Outlook and management advice

SGMED 09-02 recommends recovering the stock biomass in order to increase stock productivity. Fishing mortality should be reduced until fishing mortality is below $\mathrm{F} / \mathrm{Z}=0.4$ in order to allow future recruitment contributing to stock recovery. In order to decrease the fishing mortality, SGMED 09-02 advises to reduce fishing effort by means of a multiannual management plan and consistent catches should be determined. The management of the sardine fisheries in GSA 17 needs to account for multi-species effects, mainly the interaction with anchovy.

- Short, medium and long term scenarios:

Projections of stock status were not performed.

## Fisheries

In 2007, the Italian fleet was composed of about 130 ( 65 pairs) pelagic trawlers (volante) mainly operating from Trieste to Ancona (average GRT 43, average engine power 290 kW ) and about 45 purse seiners attracting fish with light (lampara), operating in the Gulf of Trieste ( 24 small lampara, average GRT 9, average engine power 110 kW ) and in the Central Adriatic ( 21 big lampara, average GRT 97, average engine power 390 kW ). In 2007, the Slovenian fleet was composed of 1 pelagic trawler pair and 7 purse seiners; no updated data are available for the Croatian fleet.

The fractions of the total catch due to the fleets of the Italy and Slovenia-Croatia were quite similar, but the latter one accounted increased in recent years.

## Limit and target management reference points or levels

## Comments on the assessment

Inclusion of all catch data for sardine in GSA17 should be ensured.

Explore the possibility to include acoustic survey data carried out in the eastern part of GSA17 as a tuning fleet in the assessment.

SGMED notes that there was no information presented during the meeting regarding the fry fishery within GSA 17. The catches of fry fishery are believed to be negligible in this GSA by CNR-ISMAR-SPM Fish Population Dynamics Unit. Fry fishery may be more important in GSA 18 and an ongoing EU funded project (SARDONE) will allow to evaluate if this fishery has an impact also on the stock in GSA 17.

The natural mortality rate was taken as fixed over ages and years. Trials with a vector of natural mortality rates at age could be done in the future. Abundance data from echo-surveys carried out also in the eastern part of the GSA 17 could be useful.

### 7.14. Sardine in GSA 22

| Species common name: | Sardine |
| :--- | :--- |
| Species scientific name: | Sardina pilchardus |
| Geographical Sub-area(s) GSA(s): | GSA 22 |

## Most recent state of the stock

- State of the adult abundance and biomass:

The results of the short time series of data do not allow concluding on reference points of $\mathrm{B}_{\mathrm{lim}}$ or $\mathrm{B}_{\mathrm{pa}}$. In the absence of proposed or agreed references, SGMED-09-02 is unable to fully evaluate the state of the stock and provide scientific advice.
Results of the Integrated Catch at Age analysis indicated an increasing trend in total biomass and SSB showing a slight recovery of SSB to $20,000 \mathrm{t}$ in 2008 from the low 2003-2004 estimates of $7,000 \mathrm{t}$.

- State of the juvenile (recruits):

ICA model estimates showed above average recruitment since 2007, with a very high peak in 2008.

## - State of exploitation:

SGMED recommends the application of the proposed exploitation rate $\mathrm{E} \leq 0.4$ as management target for stocks of anchovy and sardine in the Mediterranean Sea. This value might be revised in the future when more information becomes available.
Based on ICA results, the mean fishing mortality (averaged over ages 1 to 3 ) showed a clear decreasing trend, and has remained below 0.75 since 2004. The mean F/Z has declined from 2003 but remains above the suggested level of sustainability ( $\mathrm{E} \leq 0.4$ ) for this stock. Taking the empirical level as a reference point for sustainable exploitation, the stock is considered to be overexploited.

- Source of data and methods:

This assessment is based on fishery independent surveys information as well as on Integrated Catch at Age (ICA) analysis model. Acoustic surveys estimations were used for Total Biomass estimates. ICA assessment method uses separable virtual population analysis (VPA) with weighted tuning indices. The application of ICA was based on commercial catch data (2000-2008) and as tuning indices were used the biomass estimates from acoustic surveys estimates over the period 2003-2008 with a gap in 2007, as no acoustic survey data were available for this year. Sardine data were comprised of annual sardine landings, annual sardine catch at age data (2000-2008), mean weights at age, maturity at age at age and the results of acoustic surveys. Different natural mortality were applied per age group but constant for all years based on ProdBiom (Abella et al., 1997) as recommended in the report of the SG-ECA/RST/MED 09-01. This method of the estimation of the natural mortality is consistent with the methodology used in GSAs 5,6 and 17 for small pelagics.

Natural mortality values applied for sardine stock in GSA 22.

| Age0 | Age1 | Age2 | Age3 | Age4 |
| :--- | :--- | :--- | :--- | :--- |
| 1.5 | 0.95 | 0.69 | 0.61 | 0.57 |

Reference age for the fishery was age group 2, as fully exploited and fully recruited. The age groups 0,4 and 5 were underweighted in the analysis based on their percentage in the catch. Age 1 was also underweighted in the acoustic surveys ( 0.5 ). Linear catchability relationship assumed for the acoustic surveys. Discards were also included within this assessment representing however only $0.3 \%$ of total landings.
$\mathrm{Y} / \mathrm{R}$ analyses were performed but were not considered reliable due to its flat-topped shape.

## Outlook and management advice

Given the current high exploitation rates, SGMED recommends that fishing mortality should be reduced towards $\mathrm{F} / \mathrm{Z}=0.4$ in order to promote stock recovery and avoid future loss in stock productivity and landings.

In order to decrease the fishing mortality, SGMED 09-02 advises to reduce fishing effort by means of a multiannual management plan and consistent catches should be determined. The management of the sardine fisheries in GSA 22 needs to account for multi-species effects, mainly the interaction with anchovy.

For precautionary reasons the possibility of changing the closed period should be examined. Since the purse seine fishery is a multispecies fishery targeting both anchovy and sardine, a shift of the closed period (present: mid December to end of February) towards the recruitment period of anchovy (e.g. October to December) / or the recruitment period of sardine (e.g. February to April) could be suggested. This approach has the potential to improve the selectivity of the fishery, and thus provide higher potential catch in the long term.

- Short, medium and long term scenarios:

Not performed.

## Fisheries

In GSA 22 (Greek part) sardine is almost exclusively exploited by the purse seine fleet. Pelagic trawls are banned and benthic trawls are allowed to fish small pelagics in percentages less than $5 \%$ of their total catch. Regarding the regulations enforced they concern a closed period from the mid December till the end of February and technical measures such as minimum distance from shore, gear and mesh size, engine, GT. There is a minimum landing size at 11 cm .

Sardine landings showed high variability indicating a decreasing trend since 2005 to 2008 , comprising approximately 9700 tons in 2008. Information regarding the age and length distribution of sardine landings prior to 2003 is based on the Hellenic Centre of Marine Research data collection system.

Data of the fishing effort (Days at Sea) and the landings per vessel class indicate that small vessels (12-24 m) (Tables below) are mainly responsible for sardine catches (> $88 \%$ of the total catches). The purse seine fishery is considered a mixed fishery, where sardine, anchovy and other species are caught.

Table of sardine landings (in t) in GSA 22 per vessel size for 2003 to 2006 and 2008 concerning the purse seine fleet in Greek waters derived from data provided to DCR call. Since there was no Data Collection Program in Greece in 2007, data concerning this year are estimations of the Hellenic Centre for Marine Research based on data from other research projects that were held in GSA 22. Discards were also included within this assessment representing however only $0.3 \%$ of total landings.

| Year | PS 12-24 m | PS 24-40 m |
| :---: | :---: | :---: |
| 2003 | 7158 | 634 |
| 2004 | 7267 | 902 |
| 2005 | 12159 | 1468 |
| 2006 | 11618 | 1166 |
| 2007 | 6603 | 1948 |
| 2008 | 7704 | 1447 |

Discards values are less than 1\%, reaching approximately $0.3 \%$ data for GSA 22.

Table of fishing effort in GSA 22 per vessel size for 2003 to 2008 concerning the purse seine fleet in Greek waters. GRT=Gross tonnage, $\mathrm{KW}=$ engine horsepower.

## Limit and target management reference points or levels

No reference points concerning biomass can be suggested at this point. $\mathrm{F}_{\max }$ and $\mathrm{F}_{0.1}$ are overestimated so precautionary the $\mathrm{F}_{\mathrm{pa}}$ is suggestd to be set as the fishing mortality that assures exploitation rate below the empirical level for stock decline ( $\mathrm{E}<0.4$, Patterson 1992) for small pelagic.

### 7.15. Sole in GSA 17

| Species common name: | Sole |
| :--- | :--- |
| Species scientific name: | Solea solea |
| Geographical Sub-area GSA: | GSA 17 |

## Most recent state of the stock

- State of the adult abundance and biomass:

SGMED $09-02$ is unable to fully evaluate the stock status due to a lack of precautionary management reference points.
After the minimum value observed in 2005 the SSB was constant in 2006 and 2007 and increased in 2008.

- State of the juvenile (recruits):

Recruitment varied without any trend in the years 2005-2008, reaching a minimum in 2006. The value estimated in 2008 was similar to that of 2007.

- State of exploitation:

SGMED 09-02 recommends $\mathrm{F} \leq 0.26$ as a target management reference point for sustainable exploitation related to high long term yield (basis $\mathrm{F}_{0.1}$ ).

Exploitation decreased from 2005 to 2006, was constant in 2006-2007 and increased in 2008. The most recent estimate of fishing mortality $\left(\mathrm{F}_{0.4}\right)$ is $\mathrm{F}=1.35$. With $\mathrm{F}_{0.1}=0.26$ and $\mathrm{F}_{\max }=0.46$, the stock is considered being subject to overexploitation.

- Source of data and methods:

This assessment is based on VPA (XSA) methods. VPA Lowestoft software suite (Darby and Flatman 1994) was used and XSA was the assessment method. A separable VPA (Pope and Sheperd, 1982) was also run as exploratory analysis for this stock. In addition, a yield-per-recruit (Y/R) analysis was carried out (Yield program; Branch et al., 2000).

Data used for XSA:

- Landings at age from 2005-2008 from all fishing harbours of GSA 17.
- Biological sampling 2005-2006 for Maturity at age and Length-Weight relationships.
- M vector, estimated using PROBIOM.
- Tuning data from rapido trawl surveys and commercial fleet of Rimini for years 2005 to 2008.

Data derived from a regional project (SoleMon) founded by MIPAF and ADRIAMED. Catch data were obtained from on board observations and auction documents of the principal markets of the Italian coast. Length data were transformed to age data by slicing (LFDA 5.0) using the parameters estimated by lengthfrequency distributions from surveys ( $\mathrm{L}_{\mathrm{inf}}: 39.6 \mathrm{~cm} ; \mathrm{k}: 0.44 \mathrm{y}^{-1} ; \mathrm{t}_{0}:-0.46 \mathrm{y}$ ). Discard of $S$. solea is negligible (also damaged specimens are sold at a lower price), information on the level of mis-reporting for this stock has been provided in the framework of the SoleMon project. Italian rapido trawlers exploit this resource providing more than $80 \%$ of landings. Sole is also a target species of the Italian and Croatian set netters, while it represents an accessory species for otter trawlers.

The stock was also assessed by SURBA methods. Both XSA and SURBA methods gave the same perception of the state of the stock.

## Outlook and management advice

SGMED recommends the relevant fleets' effort to be reduced until fishing mortality is below or at the proposed level $\mathrm{F}_{0.1}$, in order to avoid future loss in stock productivity and landings. This should be achieved
by means of a multi-annual management plan taking into account mixed-fisheries effects. Catches consistent with the effort reductions should be estimated.

A reduction of fishing pressure, especially by rapido trawling, would be recommended, also taking into account that the exploitation is mainly orientated towards juveniles and the success of recruitment is strictly related to environmental conditions. Hence, in the case of both increasing fishing effort and yearly bad recruitment there could be a high risk of stock depletion. A two-months closure for rapido trawling inside 11 km offshore along the Italian coast, after the biological fishing ban (August), would be advisable to reduce the portion of juvenilespecimens in the catches.

For the same reason, specific studies on rapido trawl selectivity are necessary. In fact, it is not sure that the adoption of a larger mesh size would correspond to a decrease of juvenile catches, considering that the mesh opening currently used by the Italian rapido trawlers is larger ( 48 mm or more) than the legal one. The same uncertanty regards the adoption of square mesh. SSB increased over the 4 years, maybe because in late fall winter the main spawning area is only partially exploited by the Croatian set netters and Italian fleets. The safeguard of such area (identified by the rapido trawl survey) to prevent a possible future exploitation might be crucial for the sustainability of the Adriatic sole stock. Finally, a set of specific management rules for rapido trawl fishery would be advisable (e.g.: size and number of gears, mesh size, towing speed).

Short and medium term scenarios:
Will be conducted and delivered by SGMED 09-03 (14-18 December 2009).

## Fisheries

The Italian fleets exploit this resource with rapido trawl and set nets (gill nets and trammel nets), while only trammel net is used in the countries of the eastern coast. Sole is an accessory species for otter trawling. More than $90 \%$ of catches come from the Italian side. Landings fluctuated between 1,000 and $2,300 t$ in the period 1996-2006 (data source: FAO-FishStat and IREPA-SISTAN time series). The fishing effort applied by the Italian rapido trawlers gradually increased from 1996 to 2005, and slightly decreased in the last years.

## Brief description of trends:

Exploitation is based on young age classes, mainly 1 and 2 year old individuals, with immature fraction dominating the landings. In the last years, the annual landings of this species were around 2184 tons in the overall GSA. From SoleMon project data, the overall Italian fleet exploiting sole in the GSA 17 is made up by around 1,300 vessels. Otter and rapido trawlers carry out their activity all year round, with the only exception of the fishing ban (end of July - beginning of September), while set netters show a seasonal activity (spring-fall). The fishing grounds exploited by rapido trawlers extend from 5.5 km from the shoreline to $50-60 \mathrm{~m}$ depth, while otter trawlers carry out their activity in the overall area, except for the Croatian waters. Set netters operate in the shallower waters usually close to the fishing harbours.

### 7.16. Blue and red shrimp in GSA 06

| Species common name: | Red shrimp |
| :--- | :--- |
| Species scientific name: | Aristeus antennatus |
| Geographical Sub-area(s) GSA(s): | GSA 06 |

## Most recent state of the stock

- State of the adult abundance and biomass:

SGMED-09-02 cannot fully evaluate the state of the spawning stock relative to precautionary reference points, as these have not been proposed or defined.
Since 2002, SSB, with an average for the whole period of 637 mt , declined rapidly from 2002 to 2004 reaching the lowest value ( 384 t) observed in 2002-2008 which represents a $25 \%$ of that observed in 2002. Thereafter, SSB is estimated to increase until 2008 almost to the level seen in the beginning of the assessed time period.

- State of the juvenile (recruits):

Recruits (aged 0 individuals) were estimated to increase significantly from 2003 to 2007 and remain high in 2008.

- State of exploitation:

The lack of a target management reference point for exploitation causes SGMED-09-02 being unable to fully evaluate the state of exploitation. Mean fishing mortality from 2002 to 2008 varied without a clear trend between 0.8 and 1.3. The highest value is observed in 2008.

- Source of data and methods:

The state of exploitation was assessed for the period 2002-2008 by means of a VPA Separable, tuned with standardised CPUE from abundance indices from trawl survey (MEDITS). Analysis was carried out applying the Extended Survivor Analysis (XSA) method (Lowestoft suite; Darby and Flatman, 1994) over the period 2002-2008. In addition, a yield-per-recruit (Y/R) analysis (VIT program; Lleonart and Salat, 1992) was applied on the mean pseudo-cohorts 2002-2008 for the GFCM geographical sub-area Northern Spain (GSA06). Both methods were performed from size composition of trawl catches (obtained from on board and on port monthly sampling) and official landings, transforming length data to age data by slicing (L2AGE program). The parameters of the size-weight relationship used in this assessment (García Rodriguez et al., 2003) are similar to those calculated by other authors ( $a=0.0024 ; b=2.464$ ) (Ribeiro-Cascalho \& Arrobas, 1987). The estimates made for the VBGF parameters (García Rodriguez et al., 2003) show also similar values ( $\mathrm{L} \infty=77 ; \mathrm{K}=0.38 ; \mathrm{t} 0=-0.065$ ).

The size composition of commercial landings were obtained by monthly length samplings carried out both in one of the ports (Santa Pola) as well as on board samplings, during the 2002-2008 period. Landings and effort data were obtained combining different sources, such as Official Landings provided by Autonomous Community, and from the Information and Sampling Network of the Spanish Oceanographic Institute (IEO).

## Outlook and management advice

SGMED has no basis to provide specific managment advice. Management of the fisheries of blue and red shrimp need to consider the mixed fisheries interactions.

- Short and medium term scenarios:

Will be conducted and delivered by SGMED 09-03 (14-18 December 2009).

## Fisheries

Red shrimp (Aristeus antennatus) is one of the most important crustacean species for the trawl fisheries developed along the GFCM geographical sub-area Northern Spain (GSA 06). This resource is an important component of commercial landings in some ports of the Mediterranean Northern Spain, and is a target species of a specific trawl fleet. Updated information on landings and effort has been done on annual basis (2002-2008). Throughout the time series landings fluctuated between 300 and 650 tonnes, with an average of c.a. 500 tonnes. The red shrimp has a wide bathymetric distribution, between 80 and 3300 m depth (Sardà et al., 2005), and some areas may constitute a reservoir for the resource since they are located a long way from ports and in deeper zones up to 1000 m . Females predominate in the landings nearly $80 \%$ of the total. Discards of the red shrimp are null. The number of harbours with red shrimp fleets is 14 for the whole area. Exploitation is based on very young age classes, mainly 1 and 0 year old individuals, indicating a dependence on recruitments.

Fishing effort has reduced from 20,000 days in 2002 to 9,000 in 2006, with a increase thereafter, reaching the 23,000 in 2008. SGMED notes that the fishing effort below only includes vessels that have landed pink shrimp in the given years.

| Year | $\mathbf{2 0 0 2}$ | $\mathbf{2 0 0 3}$ | $\mathbf{2 0 0 4}$ | $\mathbf{2 0 0 5}$ | $\mathbf{2 0 0 6}$ | $\mathbf{2 0 0 7}$ | $\mathbf{2 0 0 8}$ |

## Comments on assessment

During the SGMED-09-02, an assessment on red shrimp from GSA 06 was performed. Official data were not received on time, but the expert provided a copy of some of the data. Files dealing with official landings and effort were not available. Consequently data on landings and effort for 2008 were derived from the series.

A yield per Recruit analysis should be undertaken during the upcoming meeting of SGMED 09-03 (14-18 December 2009).

### 7.17. Giant red shrimp in GSAs 15 and 16

| Species common name: | Giant red shrimp |
| :--- | :--- |
| Species scientific name: | Aristaeomorpha foliacea |
| Geographical Sub-area(s) GSA(s): | GSAs 15 and 16 |

## Most recent state of the stock

- State of the adult abundance and biomass:

SGMED-09-02 cannot fully evaluate the state of the SSB due to the lack of precautionary management references.
SGMED-09-02 estimated the absolute levels of stock abundance in 2006, 2007 and 2008 using the VIT approach on length structure of Sicilian trawlers which catch about $98 \%$ of the total yield in the area. Mean total biomass ranges between $1,721 \mathrm{t}$ (2008) and $1,883 \mathrm{t}$ (2006), the SSB representing about $75 \%$ of the total stock biomass.
Survey indices (MEDITS) combining GSAs indicate the stock to vary without an evident trend in the last year (2002-2008), although SSB reached its highest level in 2008 compared with the last 6 years. Considering only the GSA 16, where the time series is longer (1994-2008), SSB remained at a low level since 2001.

- State of the juvenile (recruits):

Absolute estimate of recruitment ( $18-22 \mathrm{~mm}$ CL) from VIT ranged between 63 (2008) and 95 (2007) millions of recruits. A low variability in recruitment indices derived from SURBA was observed when combining GSA data from 2002 to 2007, with the exception of sudden fall in recruit density observed in 2006 both in GSAs 15 and 16. The stability of recruitment indices in the last years is also confirmed by the analysis of the longer series from GSA 16.

- State of exploitation:

SGMED-09-02 proposes $\mathrm{F} \leq 0.35$ (average if both applied methods) as target management reference point of exploitation consistent with high long term yield (basis $\mathrm{F}_{0.1}$ ).
The giant red shrimp in the Northern sector of the Strait of Sicily is considered overfished since the current fishing mortality is significantly higher than both $\mathrm{F}_{0.1}$ and $\mathrm{F}_{\text {max }}$.

- Source of data and methods:

Data derived both from indirect (fisheries monitoring) and direct (scientific surveys) sources. Stock status was assessed by using Y and SSB per recruit analysis with package VIT and Yield on females, which reach larger size and represents more than $60 \%$ of the landing in weight. Current F was assessed with steady state VPA with VIT by length and by age on LFD of 2006, 2007 and 2008 landings. Further estimations of F, SSB and recruitment indices derived from The SURBA software program was used to analyse the MEDITS time series. Biological parameters used were: $\mathrm{K}=0.61$; Linf $=68.9 \mathrm{~cm}$; $\mathrm{t}_{0}=-0.2$. M -at-age vector (PROBIOM sheet $): 0.62 ; 0.30 ; 0.23 ; 0.19 ; 0.17 ; 0.16$. q vector $=$ estimate: $q($ Age 0$)=0.4 ; q($ Age $1+)=1.0 ; q($ Age $2+)=1.0$; $\mathrm{q}\left(\right.$ Age3 + ); $\mathrm{tq}($ Age4+ $)=1.0 . \mathrm{F}_{\text {max }}$ and $\mathrm{F}_{0.1}$ was estimated by VIT, with vector M by size (PROBIOM sheet) and Yield package (2000 runs) with scalar $\mathrm{M}=0.42$.

## Outlook and management advice

SGMED recommends the relevant fleets' effort to be reduced until fishing mortality is below or at the proposed $\mathrm{F}_{0.1}$ level, in order to avoid future loss in stock productivity and landings. This should be achieved by means of a multi-annual management plan taking into account mixed-fisheries effects. Catches consistent with the effort reductions should be estimated.

SGMED-09-02 noted that the Italian government is adopting a management plan, in which a reduction of fishing mortality of $25 \%$ is planned within 2013. SGMED-08-04 was informed that medium term management plan for 2008-2013 has been agreed for Italian trawlers catching hake in GSA 15 and 16.

The effect of 5 different management scenarios considered by the Italian Management Fishery Plans were

- a fleet reduction of $25 \%$ of the current capacity obtained in two steps. The first (12.5\%) from 2008 to 2010, and the second (12.5\%) from 2011 to 2013;
- trawling ban of 45 days per year between January and March (targeted to deep water pink shrimp fishery which is the main commercial species in the GSA 15 and 16);
- changing the mesh opening in the cod-end from the 40 mm to 50 mm (diamond) from 2010 ;
- the above three measures combined; and
- maintaining the status quo.

Although designed mainly for deep water pink shrimps, the adoption of the management measures of the IFMP is expected to improve also the stock status of giant red shrimp in the area.

Short and medium term scenarios:
Will be conducted and delivered by SGMED 09-03 (14-18 December 2009).

## Fisheries

Brief description of trends:
The giant red shrimps is a relevant target species of the Sicilian and Maltese trawlers and is caught on the slope ground during all year round, but landing peaks are observed in summer. Yield of the Italian trawlers in 2006 was about 1883 t decreasing to 1721 t in 2008. The Maltese trawlers landed 25 t in 2006 and 34 t in 2007. A.foliacea is fished exclusively by otter trawl, mainly in the central -eastern side of the Strait of Sicily, whereas in the western side it is substitute by the red shrimp, Aristeus antennatus Due to reduction of catch rate since 2004 some distant trawlers based in Mazara del Vallo, which is the main fleet in the area, move to the eastern Mediterranean (Aegean and Levant Sea) to fish red shrimps.

Landings (t) by year and major gear types, 2005-2008 as reported through DCR

| Species | Area | Country | Fleet | 2005 | 2006 | 2007 | 2008 |

### 7.18. Norway lobster in GSA 09

| Species common name: | Norway lobster |
| :--- | :--- |
| Species scientific name: | Nephrops norvegicus (L., 1758) |
| Geographical Sub-area(s) GSA(s): | GSA 09 |

## Most recent state of the stock

- State of the adult abundance and biomass:

SGMED-09-02 cannot fully evaluate the state of the SSB due to a lack of precautionary management reference points.
Relative spawning stock biomass (SSB) indices derived from MEDITS (1994-2008) and GRUND (19942006) showed a fluctuating trend in the spawning stock biomass (SSB). An increase in SSB occurred in recent years (2005-08, MEDITS survey).

- State of the juveniles (recruits):

Recruitment (age groups 1+ and 2+) showed a significant increasing trend since 1994.

- State of exploitation:

The reference points ( $\mathrm{F}_{0.1}$ and $\mathrm{F}_{\max }$ ) estimated for this species using the Yield software were 0.21 and 0.36 (median values), respectively. Recent values of $\mathrm{F}_{3-7}$ obtained on commercial data with LCA (VIT) were: 0.32 (2006), 0.30 (2007), 0.36 (2008). Similar $\mathrm{F}_{3-7}$ values were obtained from MEDITS data using Surba ( 0.36 in 2006 and 0.33 in 2007) which indicates that the stock is currently fully exploited or lightly overexploited.

SGMED-09-02 proposes the $\mathrm{F} \leq 0.21$ as target management reference point for sustainable exploitation consistent with high long term yield (basis $\mathrm{F}_{0.1}$ ).
Recent values of $\mathrm{F}_{3-7}$ obtained on commercial data with LCA (VIT) and using SURBA indicate that the stock is currently overexploited.

- Source of data and methods:

Data coming from MEDITS (1994-2008) and GRUND (1994-2006) trawl surveys were used to estimate relative SSB and F with Surba. DCR data (size distribution of trawl landings 2006-2008) were used to estimate F at age, absolute abundance at age with VIT (LCA analysis).

The following parameters were used both for SURBA and VIT analyses:

```
Growth parameters (Von Bertalanffy)
\(\mathrm{L} \infty=74\) (mm, carapace length); \(\mathrm{k}=0.17 ; \mathrm{t}_{0}=0\)
    \(\mathrm{L}^{*} \mathrm{~W}: \mathrm{a}=0.0005 ; \mathrm{b}=3.04\)
    \(\mathrm{M}=0.4\) constant from 3-7 age classes (from ProdBiom)
    \(\mathrm{q}=1\)
    Length at maturity \(\left(\mathrm{L}_{50}\right)=29 \mathrm{~mm}\) total length (sex combined)
```

## Outlook and management advice

SGMED recommends the relevant fleets' effort to be reduced until fishing mortality is below or at the proposed $\mathrm{F}_{0.1}$ level, in order to avoid future loss in stock productivity and landings. This should be achieved by means of a multi-annual management plan taking into account mixed-fisheries effects. Catches consistent with the effort reductions should be estimated.

Short and medium term scenarios:
Will be conducted and delivered by SGMED 09-03 (14-18 December 2009).

## Fisheries

Norway lobster is one of the most important commercial species in the GSA as total annual landing value. All the landing is due to bottom trawl vessels exploiting slope muddy bottoms mainly between 300 and 500 $m$ depth.
Catch of vessels targeting Norway lobster is composed of a mix of both commercial (hake, deep-sea pink shrimp, horned octopus (Eledone cirrhosa), squids (Todaropsis eblanae)), and non-commercial species.
The trawl fleet of GSA 09 at the end of 2007 accounted for 360 trawlers. To date about 80-100 trawlers are involved in this fishery.
In the last five years the total landings of Norway lobster of GSA 09 fluctuated between 248 (2005) to 228 tons (2008).

Landings ( t ) by year and major gear types, 2002-2007 as reported through DCR.

| YEAR | 2005 | 2006 | 2007 | 2008 |

Table of limit and target management reference points or levels agreed by fisheries managers

| $\mathrm{F}_{0.1}$ (age range $)=$ |  |
| :--- | :--- |
| $\mathrm{F}_{\text {max }}($ age range $)=$ |  |
| $\mathrm{F}_{\text {msy }}($ age range $)=$ |  |
| $\mathrm{F}_{\text {pa }} \mathrm{F}_{\text {lim }}$ (age range $)=$ |  |
| $\mathrm{B}_{\text {mys }}($ spawning stock $)=$ |  |
| $\mathrm{B}_{\mathrm{pa}}\left(\mathrm{B}_{\text {lim }}\right.$, spawning stock $)=$ |  |

## Comments on assessment

GRUND data prior to 1994 should be standardised and used within this assessment. MEDITS survey data does not allow the calculation of length-at-maturity because the survey period (late spring-early summer) does not cover the spawning season (autumn-winter). Recent increase in SSB and recruitment seems poorly correlated with fishing mortality. This may suggest that other factors can be affecting the stock dynamics during recent years.

## 8. STOCK ASSESSMENTS REVIEWED OR CONDUCTED

### 8.1. Introductory notes

SGMED-09-02 presents the following stock assessment approaches in an agreed and consistent format in order to allow scientists and fisheries managers a quick review of all information provided, the methods used and the assessment results.

Constrained by data availability and the fact, that the framework of SGMED has just been created in 2008, not all the assessments presented are considered final. SGMED will continue to improve and update the assessments in the future, especially where data or scientific advice with respect to target and limit references of stock size and exploitaiton is lacking.

The assessments are largely based on data obtained through the DCR and an official call issued in 2009 for fisheries and scientific survey data, also covering data collected during national programmes or projects cofunded by the EU-Commission. SGMED was often unable to verify the origin or quality of the data used in the assessment but will continue its effort to validate the data through expert knowledge and transparent presentation of the data.

In some assessments, SGMED applied a number of different approaches in order to verify the assessment results. The assessment tools applied are CPUE analyses from surveys, hydro-acoustic surveys, daily egg productions, virtual population analyses (XSA or ICA) calibrated with survey or commercial data on stock abundance, pseudo-cohort analyses (VIT) and various dynamic production models under equilibrium (YpR) or non-equilibrium conditions (ALADYM, ASPIC).

Unlike the 2008 report of SGMED 08-04, this SGMED 09-02 report deals with assessment of historic and recent trends in stock parameters (stock size, recruitment and exploitation) and relevant scientific advice only. Deterministic short and medium term for such parameters including stock size, landings and relevant scientific advice will we delivered through the forthcoming SGMED 09-03 meeting in the fourth quarter of 2009.

### 8.2. Stock assessment of hake in GSA 01

### 8.2.1.Stock identification and biological features

### 8.2.1.1. Stock Identification

The delimitation of the hake stock in GSA01 is considered unknown. Likely connections with hake in GSA06 may exist, because of the continuity of shelf. Large exchanges with the south Alborán Sea (GSA03) are believed insignificant.

### 8.2.1.2. Growth

Two growth parameter sets were considered: fast and slow. Also different values were used for males and females. They are shown in Table 8.2.1.2.1.

Tab. 8.2.1.2.1. Two sets of growth parameters (v. Bertalanffy) by sex for hake in GSA 01.

|  | Fast growth Females | Fast growth Males | Slow growth Females | Slow growt Males | Units |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Linf | 100.7 | 72.8 | 100.7 | 72.8 | cm |
| K | 0.248 | 0.298 | 0.124 | 0.149 | year ${ }^{-1}$ |
| t0 | -0.35 | -0.383 | -0.35 | -0.383 | year |
| a | 0.0069 | 0.0069 | 0.0069 | 0.0069 | gr |
| b | 3.03 | 3.03 | 3.03 | 3.03 |  |
| M | 0.18 | 0.22 | 0.18 | 0.22 | year $^{-1}$ |

8.2.1.3. Maturity

Fig. 8.2.1.3.1 shows the maturity at length ogive for female hake in GSAs 01,05 and 06 . The more recent years indicate significant reduction in size at maturation.

Fig. 8.2.1.3.1 Maturity ogives for female hake in GSAs 01,05 and 06.

### 8.2.2.Fisheries

8.2.2.1. General description of fisheries

Hake is one of the most important target species for the trawl fisheries in GSA 01. It is exploited in all trawlable areas from Gibraltar straight to Cape of Gata, including the deep-bottom fishing grounds about GSA 02. Commonly small hakes are caught in shallow waters about 50 m to 300 m depth, whereas adults reach the maximum depths exploited ( 800 m ), associated with the red shrimp (Aristeus antennatus) fishery.

Fishing grounds M. Merluccius in GSA 1 (Source: I.E.O.)
Fig. 8.2.2.1.1 Fishing grounds of hake in GSA 01. Countries: only Spain
8.2.2.2. Management regulations applicable in 2008 and 2009

No information was documented.

### 8.2.2.3. Catches

### 8.2.2.3.1. Landings

Tab. 8.2.2.3.1.1 shows the trend in reported landings taken by trawlers (Spain only). The data were reported to SGMED-09-02 through the Data collection regulation and are listed in Table A3.1 of Appendix 3.

Tab. 8.2.2.3.1.1 Annual hake landings ( t ) by Spanish trawlers.

| SPECIES | AREA | COUNTRY | FT_LVL4 | 2002 | 2003 | 2004 | 2005 | 2006 | 2007 | 2008 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| HKE | 1 | ESP | OTB | 353 | 201 | 374 | 208 | 212 | 220 | 242 |

Annual lengths of landings were reported to SGMED-09-02 only for 2005-2008 and are shown in Fig. 8.2.2.3.1.2.

Fig. 8.2.2.3.1.2 Annual size composition of hake landings (thousands) by Spanish trawlers, 2005-2008.

### 8.2.2.3.2. Discards

SGMED-09-02 received discard data only for 2005 and 2008. A total of 6 tons discarded in 2005 and 16 tons for $2008(2.9 \%$ and $6.6 \%$ of the landings, respectively). The data were compiled and reported through the Data collection regulation and are listed in Table A3.9 of Appendix 3.

Fig. 8.2.2.3.2.1 Annual size composition of hake landings and discards (thousands) by Spanish trawlers, in 2008.

### 8.2.2.3.3. Fishing effort

No effort data were reported to SGMED-09-02 through the DCF data call for Spain.

### 8.2.3.Scientific surveys

### 8.2.3.1. Medits

### 8.2.3.1.1. Methods

Based on the DCR data call, abundance and biomass indices were calculated. In GSA 01 the following number of hauls were reported per depth stratum (s. Tab. 8.2.3.1.1.1)

Tab. 8.2.3.1.1.1. Number of hauls per year and depth stratum in GSA 01, 1994-2008.

| STRATUM | 1994 | 1995 | 1996 | 1997 | 1998 | 1999 | 2000 | 2001 | 2002 | 2003 | 2004 | 2005 | 2006 | 2007 | 2008 |
| :--- | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| GSA01_010-050 | 3 | 1 | 2 | 2 | 2 | 2 | 2 | 3 | 3 | 3 | 3 | 2 | 3 | 3 | 4 |
| GSA01_050-100 | 6 | 4 | 5 | 6 | 5 | 7 | 6 | 5 | 6 | 10 | 7 | 7 | 6 | 6 | 6 |
| GSA01_100-200 | 3 | 3 | 3 | 5 | 5 | 5 | 5 | 5 | 8 | 6 | 5 | 6 | 5 | 6 | 6 |
| GSA01_200-500 | 7 | 9 | 11 | 10 | 8 | 11 | 12 | 10 | 11 | 11 | 13 | 11 | 12 | 11 | 11 |
| GSA01_500-800 | 6 | 10 | 13 | 10 | 13 | 12 | 10 | 13 | 15 | 14 | 13 | 11 | 15 | 10 | 9 |

Data were assigned to strata based upon the shooting position and average depth (between shooting and hauling depth). Few obvious data errors were corrected. Catches by haul were standardized to 60 minutes hauling duration. Hauls noted as valid were used only, including stations with no catches of hake, red mullet or pink shrimp (zero catches are included).

The abundance and biomass indices by GSA were calculated through stratified means (Cochran, 1953; Saville, 1977). This implies weighting of the average values of the individual standardized catches and the variation of each stratum by the respective stratum areas in each GSA:
$\mathrm{Yst}=\Sigma\left(\mathrm{Yi}^{*} \mathrm{Ai}\right) / \mathrm{A}$
$\mathrm{V}(\mathrm{Yst})=\Sigma\left(\mathrm{Ai}^{2} * \mathrm{si}^{2} / \mathrm{ni}\right) / \mathrm{A}^{2}$
Where:
A=total survey area
$\mathrm{Ai}=$ area of the i -th stratum
$\mathrm{si}=$ standard deviation of the i-th stratum
ni=number of valid hauls of the i-th stratum
$\mathrm{n}=$ number of hauls in the GSA
$\mathrm{Yi}=$ mean of the i-th stratum
Yst=stratified mean abundance
$\mathrm{V}(\mathrm{Yst})=$ variance of the stratified mean
The variation of the stratified mean is then expressed as the $95 \%$ confidence interval: Confidence interval $=$ Yst $\pm \mathrm{t}$ (student distribution) $* \mathrm{~V}(\mathrm{Yst}) / \mathrm{n}$

It was noted that while this is a standard approach, the calculation may be biased due to the assumptions over zero catch stations, and hence assumptions over the distribution of data. A normal distribution is often assumed, whereas data may be better described by a delta-distribution, quasi-poisson. Indeed, data may be better modelled using the idea of conditionality and the negative binomial (e.g. O'Brien et al. (2004)).

Length distributions represented an aggregation (sum) of all standardized length frequencies (subsamples raised to standardized haul abundance per hour) over the stations of each stratum. Aggregated length frequencies were then raised to stratum abundance * 100 (because of low numbers in most strata) and finally aggregated (sum) over the strata to the GSA. Given the sheer number of plots generated, these distributions are not presented in this report.

### 8.2.3.1.2. Geographical distribution patterns

No analyses were conducted during SGMED-09-02.

### 8.2.3.1.3. Trends in abundance and biomass

Fishery independent information regarding the state of the hake in GSA 01 was derived from the international survey Medits. Figure 7.2.3.1.3.1 displays the estimated trend in hake abundance and biomass for the GSA 01.
It can be seen in the following figures, that the Medits indices for hake in GSA 01 do not follow the general increasing trend but appear to having recently increased from a very low to an average level estimated since 1994 (Fig. 8.2.3.1.3.1). The analyses of Medits indices are considered preliminary.

Fig. 8.2.3.1.3.1. Abundance and biomass indices of hake in GSA 01.
8.2.3.1.4. Trends in abundance by length or age

The following Fig. 8.2.3.1.4.1 and 2 display the stratified abundance indices of GSA 01 in 1994-2001 and 2002-2008. These size compositions are considered preliminary.

Fig. 8.2.3.1.4.1 Stratified abundance indices by size, 1994-2001.

| GSA01 2006 |  |
| :---: | :---: |
| $\begin{array}{r} 500 \\ 450 \\ 400 \\ 350 \\ 300 \\ 250 \\ 200 \\ 150 \\ 100 \\ 50 \\ 0 \end{array}$ |  |
|  | GSA01 2007 |

Fig. 8.2.3.1.4.2 Stratified abundance indices by size, 2002-2008.

### 8.2.3.1.5. Trends in growth

No analyses were conducted.
8.2.3.1.6. Trends in maturity

No analyses were conducted

### 8.2.4.Assessment of historic stock parameters

SGMED 09-02 did not undertake any analytical assessment of hake in GSA 01. Last year's assessment using SURBA and VIT can be found in the report of SGMED-08-04 working group (Cardinale et al., 2008).
8.2.5.Long term prediction

### 8.2.5.1. Justification

No forecast analyses were conducted.

### 8.2.5.2. Input parameters

No forecast analyses were conducted.
8.2.5.3. Results

No forecast analyses were conducted.

### 8.2.6.Scientific advice

8.2.6.1. Short term considerations

### 8.2.6.1.1. State of the spawning stock size

SGMED-09-02 is unable to provide any scientific advice of the state of the spawning stock in relation to proposed precautionary level given the preliminary state of the data and analyses.

### 8.2.6.1.2. State of recruitment

SGMED-09-02 is unable to provide any scientific advice of the state of the recruitment given the preliminary state of the data and analyses.

### 8.2.6.1.3. State of exploitation

SGMED cannot estimate recent or historic exploitation rates. No proposed or agreed reference points were available to SGMED to identify stock status.

### 8.3. Stock assessment of hake in GSA 05

### 8.3.1.Stock identification and biological features

### 8.3.1.1. Stock Identification

No information was documented during SGMED-09-02.

### 8.3.1.2. Growth

No information was documented during SGMED-09-02.

### 8.3.1.3. Maturity

No information was documented during SGMED-09-02.

### 8.3.2.Fisheries

### 8.3.2.1. General description of fisheries

STECF in 2007 (stock review part II) noted that the trawl fishery off Mallorca is developed by around 40 vessels, corresponding to about $72 \%$ of the total trawl fleet of the Balearic Islands (GFCM GSA 05). The total annual landings are approximately 1,400 tonnes, representing around $90 \%$ of the total catch of GSA 05 . The European hake (Merluccius merluccius) is a target species for this fishery, mainly exploited on the deep shelf and upper slope, with annual landings oscillating between 50 and 190 t during the last decades.

### 8.3.2.2. Management regulations applicable in 2008 and 2009

No information was documented during SGMED-09-02.

### 8.3.2.3. Catches

### 8.3.2.3.1. Landings

Tab 8.3.2.3.1.1 shows the trend in reported landings taken by trawlers (Spain only). The data were reported to SGMED-09-02 through the Data Collection Regulation and are listed in Table A3.1 of Appendix 3. Since 2002 the annual landings varied between 40 and 100 t .

Tab. 8.3.2.3.1.1 Annual hake landings (t) by Spanish trawlers.

| SPECIES | AREA | COUNTRY | FT_LVL4 | 2002 | 2003 | 2004 | 2005 | 2006 | 2007 | 2008 |
| :--- | :--- | :--- | :--- | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| HKE | 5 | ESP | OTB | 91 | 44 | 57 | 86 | 102 | 72 | 68 |

### 8.3.2.3.2. Discards

Reported discards through the DCF data call to SGMED-09-02 varied among 5 and 10 t annually during 2002 to 2008. The data are listed in Table A3.9 of Appendix 3.

### 8.3.2.3.3. Fishing effort

No effort data were reported to SGMED-09-02 through the DCF data call for Spain.

### 8.3.3.Scientific surveys

### 8.3.3.1. Medits

### 8.3.3.1.1. Methods

Based on the DCF data call, abundance and biomass indices were recalculated. In GSA 05 the following number of hauls were reported per depth stratum (s. Tab. 8.3.3.1.1.1)

Tab. 8.3.3.1.1.1. Number of hauls per year and depth stratum in GSA 05, 1994-2008.

| STRATUM | 1994 | 1995 | 1996 | 1997 | 1998 | 1999 | 2000 | 2001 | 2002 | 2003 | 2004 | 2005 | 2006 | 2007 | 2008 |  |
| :--- | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| GSA05_050-100 |  |  |  |  |  |  |  |  |  |  |  |  |  |  | 8 | 7 |
| GSA05_100-200 |  | 1 |  |  |  |  | 1 |  | 1 |  |  |  | 1 |  | 1 | 5 |

Data were assigned to strata based upon the shooting position and average depth (between shooting and hauling depth). Few obvious data errors were corrected. Catches by haul were standardized to 60 minutes hauling duration. Hauls noted as valid were used only, including stations with no catches of hake, red mullet or pink shrimp (zero catches are included).

The abundance and biomass indices by GSA were calculated through stratified means (Cochran, 1953; Saville, 1977). This implies weighting of the average values of the individual standardized catches and the variation of each stratum by the respective stratum areas in each GSA:
$\mathrm{Yst}=\Sigma\left(\mathrm{Yi}^{*} \mathrm{Ai}\right) / \mathrm{A}$
$\mathrm{V}(\mathrm{Yst})=\Sigma\left(\mathrm{Ai}^{2} * \mathrm{si}^{2} / \mathrm{ni}\right) / \mathrm{A}^{2}$
Where:
$\mathrm{A}=$ total survey area
$\mathrm{Ai}=$ area of the i -th stratum
si=standard deviation of the i-th stratum
ni=number of valid hauls of the i-th stratum
$\mathrm{n}=$ number of hauls in the GSA
$\mathrm{Yi}=$ mean of the i -th stratum
Yst=stratified mean abundance
$\mathrm{V}(\mathrm{Yst})=$ variance of the stratified mean
The variation of the stratified mean is then expressed as the $95 \%$ confidence interval: Confidence interval $=$ Yst $\pm \mathrm{t}$ (student distribution) $* \mathrm{~V}(\mathrm{Yst}) / \mathrm{n}$

It was noted that while this is a standard approach, the calculation may be biased due to the assumptions over zero catch stations, and hence assumptions over the distribution of data. A normal distribution is often assumed, whereas data may be better described by a delta-distribution, quasi-poisson. Indeed, data may be better modelled using the idea of conditionality and the negative binomial (e.g. O'Brien et al. (2004)).

Length distributions represented an aggregation (sum) of all standardized length frequencies (subsamples raised to standardized haul abundance per hour) over the stations of each stratum. Aggregated length frequencies were then raised to stratum abundance * 100 (because of low numbers in most strata) and finally aggregated (sum) over the strata to the GSA. Given the sheer number of plots generated, these distributions are not presented in this report.

### 8.3.3.1.2. Geographical distribution patterns

No analyses were conducted during SGMED-09-02.

### 8.3.3.1.3. Trends in abundance and biomass

Fishery independent information regarding the state of the hake in GSA 05 was derived from the international survey Medits. Figure 8.3.3.1.3.1 displays the estimated trend in hake abundance and biomass in GSA 05.

The few hauls may indicate a general increasing trend in both abundance and biomass since 1994. The analyses of Medits indices are considered preliminary.

Fig. 8.3.3.1.3.1 Abundance and biomass indices of hake in GSA 05 .

### 8.3.3.1.4. Trends in abundance by length or age

The following Fig. 8.3.3.1.4.1 and 2 display the stratified abundance indices of GSA 05 in 1995-2004 and 2005-2008. These size compositions are considered preliminary.

Fig. 8.3.3.1.4.1 Stratified abundance indices by size, 1995-2004.

Fig. 8.3.3.1.4.2 Stratified abundance indices by size, 2005-2008.

### 8.3.3.1.5. Trends in growth

No analyses were conducted during SGMED-09-02.

### 8.3.3.1.6. Trends in maturity

No analyses were conducted during SGMED-09-02.

### 8.3.4.Assessment of historic stock parameters

SGMED-09-02 did not undertake any analytical assessment. It was noted that hake in GSA 05 was assessed in 2007 and presented to SCSA/SAC/GFCM. This assessment can be viewed at:
http://www.gfcm.org/ for GSA05 open Doc05-HKE0508Gui.xls

### 8.3.5.Long term prediction

### 8.3.5.1. Justification

No forecast analyses were conducted.

### 8.3.5.2. Input parameters

No forecast analyses were conducted.

### 8.3.5.3. Results

Given the preliminary state of the data and analyses SGMED-09-02 is not in the position to provide a long term prediction of catch and stock biomass for hake in GSA 05.

### 8.3.6.Scientific advice

### 8.3.6.1. Short term considerations

### 8.3.6.1.1. State of the spawning stock size

SGMED-09-02 is unable to provide any scientific advice of the state of the spawning stock in relation to proposed precautionary level given the preliminary state of the data and analyses.

SGMED-09-02 noted that the hake 'population' of GSA 05 is unlikely to be independent from that of the adjacent GSA 06. SGMED therefore recommends exploring the alternative of merging data from GSA 05 and GSA 06 and perfoming a single assessment for both GSAs together.

### 8.3.6.1.2. State of recruitment

SGMED-09-02 is unable to provide any scientific advice of the state of the recruitment given the preliminary state of the data and analyses.

### 8.3.6.1.3. State of exploitation

SGMED-09-02 is unable to provide any scientific advice of the state of the exploitation in relation to proposed precautionary and target levels given the preliminary state of the data and analyses.

### 8.4. Stock assessment of hake in GSA 06

### 8.4.1.Stock identification and biological features

### 8.4.1.1. Stock Identification

No information was documented.

### 8.4.1.2. Growth

SGMED-09-02 notes that the set of growth parameters used in the assessment were different to those used the year before, and the recommendation made last year on the use of a set more agreed with the "fast growth hypothesis" has been followed. Growth parameters used were those from Garcia-Rodriguez (2002) over otolith readings and length distributions analysis ( $\operatorname{Linf}=106.7 ; \mathrm{K}=0.20$; $\mathrm{t} 0=0.0028$ ), and length-weight relationship ( $a=0.0048 ; b=$ 3.12) from García Rodriguez \& Esteban (1995).

### 8.4.1.3. Maturity

Maturity ogive was taken from García Rodriguez and Esteban (1995), with size at first maturity (50 \%) at 33 cm Tl.

| Age class | 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 |
| :--- | :--- | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| Maturity ratio | 0 | 0.312 | 1 | 1 | 1 | 1 | 1 | 1 |

### 8.4.2.Fisheries

### 8.4.2.1. General description of fisheries

STECF in 2007 (stock review part II) noted that hake (Merluccius merluccius) is one of the most important target species for the trawl fisheries carried out by around 647 vessels in the Northern Spain (GSA 06) with an average of 47 TRB, 58 GT and 297 HP. Some of these units (smaller vessels) operate almost exclusively on the continental shelf (targeted at red mullet, octopus, hake and sea breams), others (bigger vessels) operate almost exclusively on the continental slope (targeted at decapod crustaceans) and the rest can operate indistinctly on the continental shelf and slope fishing grounds, depending on the season, the weather conditions and also economic factors (e.g. landings price). The percentage of these trawl fleet segments has been estimated around 30,40 and $30 \%$ of the boats, respectively. In the last years, the annual landings of this species, which are mainly composed by juveniles living on the continental shelf, the annual landings of this species were around 3800 tons in the whole GSA.
8.4.2.2. Management regulations applicable in 2008 and 2009

No information was documented.

### 8.4.2.3. Catches

### 8.4.2.3.1. Landings

Fig. 8.4.2.3.1.1 shows the trend in reported landings taken by trawlers (Spain only). The data were reported to SGMED-09-02 through the Data Collection Regulation and are listed in Table A3.1 of Appendix 3. The annual landings show an a stable trend, with some oscillations.

Fig. 8.4.2.3.1.1 Annual hake landings ( t ) by Spanish trawlers.
Tab. 8.4.2.3.1.1 lists the trend in reported landings by fishing technique. The data were reported to SGMED-09-02 through the Data Collection Regulation and are listed in Table A3.1 of Appendix 3. Since 2002 the annual landings fluctuated around an average of 3500 t . The landings were only taken by demersal otter trawls.

Tab. 8.4.2.3.1.1 Annual landings ( t ) by fishing technique in GSA 06.

| SPECIES | AREA | COUNTRY | FT_LVL4 | 2002 | 2003 | 2004 | 2005 | 2006 | 2007 | 2008 |
| :--- | :--- | :--- | :--- | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| HKE | 6 | ESP | OTB | 3195 | 3411 | 3441 | 3363 | 3864 | 3701 | 3494 |

### 8.4.2.3.2. Discards

Reported discards through the DCR data call to SGMED-09-02 amount 80 t in 2005. The data are listed in Table A3.9 of Appendix 3.

### 8.4.2.3.3. Fishing effort

SGMED-09-02 did not receive fishing effort data for GSA 06. STECF (stock review part II in 2007) noted that the trawl fishery off northern Spain (GSA 06) is carried out by around 647 vessels.

### 8.4.3.Scientific surveys

### 8.4.3.1. MEDITS

### 8.4.3.1.1. Methods

Based on the DCR data call, abundance and biomass indices were recalculated. In GSA 06 the following number of hauls were reported per depth stratum (s. Tab. 8.4.3.1.1.1).

Tab. 8.4.3.1.1.1. Number of hauls per year and depth stratum in GSA 06, 1994-2008.

| STRATUM | 1994 | 1995 | 1996 | 1997 | 1998 | 1999 | 2000 | 2001 | 2002 | 2003 | 2004 | 2005 | 2006 | 2007 | 2008 |
| :--- | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| GSA06_010-050 | 7 | 8 | 7 | 8 | 7 | 8 | 9 | 8 | 11 | 9 | 9 | 11 | 12 | 6 | 8 |
| GSA06_050-100 | 21 | 28 | 27 | 26 | 28 | 30 | 30 | 31 | 36 | 39 | 31 | 32 | 34 | 40 | 43 |
| GSA06_100-200 | 11 | 19 | 17 | 15 | 13 | 17 | 19 | 20 | 20 | 21 | 17 | 18 | 19 | 24 | 30 |
| GSA06_200-500 | 10 | 13 | 10 | 12 | 7 | 13 | 12 | 16 | 17 | 18 | 16 | 15 | 18 | 18 | 19 |
| GSA06_500-800 | 7 | 8 | 9 | 7 | 4 | 9 | 6 | 8 | 7 | 11 | 11 | 8 | 10 | 15 | 14 |

Data were assigned to strata based upon the shooting position and average depth (between shooting and hauling depth). Few obvious data errors were corrected. Catches by haul were standardized to 60 minutes hauling duration. Hauls noted as valid were used only, including stations with no catches of hake, red mullet or pink shrimp (zero catches are included).

The abundance and biomass indices by GSA were calculated through stratified means (Cochran, 1953; Saville, 1977). This implies weighting of the average values of the individual standardized catches and the variation of each stratum by the respective stratum areas in each GSA:
$\mathrm{Yst}=\Sigma\left(\mathrm{Yi}^{*} \mathrm{Ai}\right) / \mathrm{A}$
$\mathrm{V}(\mathrm{Yst})=\Sigma\left(\mathrm{Ai}^{2} * \mathrm{si}^{2} / \mathrm{ni}\right) / \mathrm{A}^{2}$
Where:
$\mathrm{A}=$ total survey area
Ai=area of the i-th stratum
si=standard deviation of the i-th stratum
ni=number of valid hauls of the i-th stratum
n=number of hauls in the GSA
$\mathrm{Yi}=$ mean of the i -th stratum
Yst=stratified mean abundance
$\mathrm{V}(\mathrm{Yst})=$ variance of the stratified mean
The variation of the stratified mean is then expressed as the $95 \%$ confidence interval: Confidence interval $=$ Yst $\pm \mathrm{t}$ (student distribution) $* \mathrm{~V}(\mathrm{Yst}) / \mathrm{n}$

It was noted that while this is a standard approach, the calculation may be biased due to the assumptions over zero catch stations, and hence assumptions over the distribution of data. A normal distribution is often assumed, whereas data may be better described by a delta-distribution, quasi-poisson. Indeed, data may be better modelled using the idea of conditionality and the negative binomial (e.g. O'Brien et al. (2004)).

Length distributions represented an aggregation (sum) of all standardized length frequencies (subsamples raised to standardized haul abundance per hour) over the stations of each stratum. Aggregated length frequencies were then raised to stratum abundance * 100 (because of low numbers in most strata) and finally aggregated (sum) over the strata to the GSA. Given the sheer number of plots generated, these distributions are not presented in this report.

### 8.4.3.1.2. Geographical distribution patterns

No specific analyses were conducted.

### 8.4.3.1.3. Trends in abundance and biomass

Fishery independent information regarding the state of the hake in GSA 06 was derived from the international survey Medits. Figure 8.4.3.1.3.1 displays the estimated trend in hake abundance and biomass in GSA 06.

The hauls indicate a general increasing trend in both abundance and biomass since 1996, except for the most recent years 2007 and 2008, when the indices suddenly decreased to the lowest level observed.

Fig. 8.4.3.1.3.1 Abundance and biomass indices of hake in GSA 06.

### 8.4.3.1.4. Trends in abundance by length or age

The following Fig. 8.4.3.1.4.1 and 2 display the stratified abundance indices of GSA 06 in 1994-2001 and 2002-2008.

Fig. 8.4.3.1.4.1 Stratified abundance indices by size, 1994-2001.

Fig. 8.4.3.1.4.2 Stratified abundance indices by size, 2002-2008.

### 8.4.3.1.5. Trends in growth

No analyses were conducted.

### 8.4.3.1.6. Trends in maturity

No analyses were conducted.

### 8.4.4.Assessment of historic stock parameters

During the SGMED-09-02, an assessment on hake from GSA 06 was performed. There was no official effort data available.
8.4.4.1.1. Method 1: XSA

### 8.4.4.1.2. Justification

An XSA was performed calibrated with fishery independent survey abundance indices.

### 8.4.4.1.3. Input parameters

The following Table 8.4.4.1.3.1 lists the input parameters to the XSA, i.e. catch at age, weight at age, matutity at age, natural mortality at age and the tuning series at age (MEDITS).

Table 8.4.1.1.3.1 The input parameters to the XSA, i.e. catch at age, weight at age, matutity at age, natural mortality at age and the tuning series at age (MEDITS).

Fig. 8.4.4.1.4.1 Trends in spawning stock SSB and recruits at age 0 .

Fig. 8.4.4.1.4.2 Trends in landings and mean fishing mortality over ages 0-2.

Fishing mortality has fluctuated without trend in the average of 1.6 (Fbar 0-2), or 1.5 for Fbar from 2 to 4 age classes. Those values are high, but consistent with "fast growth hypothesis and a mean $\mathrm{M}=0.43$. The exploitation is concentrated on very low age classes, mainly 0 and 1 .

### 8.4.5.Long term prediction

### 8.4.5.1. Justification

No forecast analyses were conducted.

### 8.4.5.2. Input parameters

No forecast analyses were conducted.

### 8.4.5.3. Results

Given the preliminary state of the data and analyses SGMED-09-02 is not in the position to provide a long term prediction of catch and stock biomass for hake in GSA 06.

### 8.4.6.Scientific advice

### 8.4.6.1. Short term considerations

### 8.4.6.1.1. State of the spawning stock size

Since 2006, SSB has increased from historical lows and varies slighty above average since then.

### 8.4.6.1.2. State of recruitment

Recruitment has been low in recent years and has decreased to the lowest level observed in 2008.

### 8.4.6.1.3. State of exploitation

Fishing mortality has fluctuated without a trend at 1.6 (Fbar 0-2), or 1.5 for Fbar for ages 2 to 4 . Comparing such estimates with $\mathrm{F}_{0.1}=0.16$ and $\mathrm{F}_{\max }=0.23$, it can be concluded that the resource is heavily overexploited, with a high dependence on incoming recruitment.

The continued low abundance of adult fish in the surveyed population and landings indicate a very high exploitation pattern far in excess of those achieving high yields and low risk of fisheries collapse.

### 8.5. Stock assessment of hake in GSA 07

### 8.5.1.Stock identification and biological features

### 8.5.1.1. Stock Identification

No information was documented during SGMED-09-02.

### 8.5.1.2. Growth

No information was documented during SGMED-09-02.

8.5.1.3. Maturity

No information was documented during SGMED-09-02.

### 8.5.2.Fisheries

### 8.5.2.1. General description of fisheries

STECF in 2007 (stock review part II) noted that hake (Merluccius merluccius) is one of the most important demersal target species of commercial fisheries in the Gulf of Lions (GFCM GSA 7). In this area, hake is exploited by French trawl, French gillnet, Spanish trawl and Spanish long-line. Around 250 boats are involved in the fishery. According to the official statistics the total annual landings decreased from 2,751 t in 2003 to $1,341 \mathrm{t}$ in 2004 (this was mainly due to the decrease of the French trawlers landings (from 2,024 t to $1,023 \mathrm{t}$ ) and of the Spanish trawlers landings (from 207 t to 101 t ).

### 8.5.2.2. Management regulations applicable in 2008 and 2009

No information was documented during SGMED-09-02.

### 8.5.2.3. Catches

### 8.5.2.3.1. Landings

SGMED-09-02 received French landings data for GSA 07 which are listed in Tab. 8.5.2.3.1.1. Otter trawls dominate the landings which in 2008 have increase to previous levels, after a major decrease in 2004 by about half. The data are listed in Table A3.1 of Appendix 3.

No Spanish data for GSA 07 were provided.
Table 8.5.2.3.1.1 French landings (t) by year and major gear types, 2002-2008 as reported through DCF.

| SPECIES | AREA | COUNTRY | FT_LVL4 | 2002 | 2003 | 2004 | 2005 | 2006 | 2007 | 2008 |
| :--- | ---: | :--- | :--- | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| HKE | 7 | FRA | GNS | 177 | 248 | 99 | 255 | 299 | 168 | 111 |
| HKE | 7 | FRA | LLS | 5 |  |  |  |  |  |  |
| HKE | 7 | FRA | OTB | 2163 | 2029 | 1018 | 995 | 1011 | 1277 | 1898 |

### 8.5.2.3.2. Discards

Reported discards through the DCF data call to SGMED-09-02 are listed in Table A3.9 of Appendix 3.However, some values regarding French discards data for bottom trawl appear unreasonable.

### 8.5.2.3.3. Fishing effort

STECF (stock review part II in 2007) noted that about 250 boats from France and Spain are engaged in the fishery. The trends in fishing effort by year and major gear type is listed in Tab. 8.5.2.3.3.1 only in terms of kW *days.

No Spanish effort data for GSA 07 were provided.
Tab. 8.5.2.3.3.1 Trend in fishing effort (kW*days) for France by major gear types, 2003-2008. No values were reported for 2002.

### 8.5.3.Scientific surveys

### 8.5.3.1. Medits

### 8.5.3.1.1. Methods

Based on the DCR data call, abundance and biomass indices were recalculated. In GSA 07 the following number of hauls was reported per depth stratum (s. Tab. 8.5.3.1.1.1).

Tab. 8.5.3.1.1.1. Number of hauls per year and depth stratum in GSA 07, 1994-2008.

| STRATUM | 1994 | 1995 | 1996 | 1997 | 1998 | 1999 | 2000 | 2001 | 2002 | 2003 | 2004 | 2005 | 2006 | 2007 | 2008 |
| :--- | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| GSA07_010-050 | 12 | 12 | 12 | 15 | 12 | 12 | 12 | 12 | 12 | 13 | 12 | 12 | 12 | 15 | 12 |
| GSA07_050-100 | 32 | 32 | 32 | 38 | 39 | 33 | 33 | 33 | 32 | 38 | 31 | 31 | 33 | 31 | 25 |
| GSA07_100-200 | 10 | 9 | 9 | 9 | 9 | 9 | 10 | 9 | 9 | 10 | 13 | 11 | 10 | 10 | 7 |
| GSA07_200-500 | 6 | 6 | 5 | 6 | 5 | 5 | 6 | 6 | 5 | 5 | 5 | 5 | 5 | 5 | 4 |
| GSA07_500-800 | 8 | 7 | 5 | 5 | 4 | 5 | 6 | 5 | 4 | 5 | 6 | 5 | 6 | 5 | 5 |

Data were assigned to strata based upon the shooting position and average depth (between shooting and hauling depth). Few obvious data errors were corrected. Catches by haul were standardized to 60 minutes
hauling duration. Hauls noted as valid were used only, including stations with no catches of hake, red mullet or pink shrimp (zero catches are included).

The abundance and biomass indices by GSA were calculated through stratified means (Cochran, 1953; Saville, 1977). This implies weighting of the average values of the individual standardized catches and the variation of each stratum by the respective stratum areas in each GSA:

$$
\mathrm{Yst}=\Sigma\left(\mathrm{Yi}^{*} \mathrm{Ai}\right) / \mathrm{A}
$$

$$
\mathrm{V}(\mathrm{Yst})=\Sigma\left(\mathrm{Ai}^{2} * \mathrm{si}^{2} / \mathrm{ni}\right) / \mathrm{A}^{2}
$$

Where:
A=total survey area
$\mathrm{Ai}=$ area of the i -th stratum
si=standard deviation of the i-th stratum
ni=number of valid hauls of the i-th stratum
$\mathrm{n}=$ number of hauls in the GSA
$\mathrm{Yi}=$ mean of the i-th stratum
Yst=stratified mean abundance
$\mathrm{V}(\mathrm{Yst})=$ variance of the stratified mean
The variation of the stratified mean is then expressed as the $95 \%$ confidence interval: Confidence interval $=$ Yst $\pm \mathrm{t}$ (student distribution) $* \mathrm{~V}(\mathrm{Yst}) / \mathrm{n}$

It was noted that while this is a standard approach, the calculation may be biased due to the assumptions over zero catch stations, and hence assumptions over the distribution of data. A normal distribution is often assumed, whereas data may be better described by a delta-distribution, quasi-poisson. Indeed, data may be better modelled using the idea of conditionality and the negative binomial (e.g. O'Brien et al. (2004)).

Length distributions represented an aggregation (sum) of all standardized length frequencies (subsamples raised to standardized haul abundance per hour) over the stations of each stratum. Aggregated length frequencies were then raised to stratum abundance * 100 (because of low numbers in most strata) and finally aggregated (sum) over the strata to the GSA. Given the sheer number of plots generated, these distributions are not presented in this report.

### 8.5.3.1.2. Geographical distribution patterns

No analyses were conducted during SGMED-09-02.

### 8.5.3.1.3. Trends in abundance and biomass

Fishery independent information regarding the state of the hake in GSA 07 was derived from the international survey Medits. Figure 8.5.3.1.3.1 displays the estimated trend in hake abundance and biomass in GSA 07.

The estimated abundance and biomass indices do not reveal any significant trends since 1994. However, the recent abundance indices since 2005 appear low. In 2008 the highest values have been observed. The analyses of Medits indices are considered preliminary.

Fig. 8.5.3.1.3.1 Abundance and biomass indices of hake in GSA 07.

### 8.5.3.1.4. Trends in abundance by length or age

The following Fig. 8.5.3.1.4.1 and 2 display the stratified abundance indices of GSA 07 in 1994-2001 and 2002-2008. These size compositions are considered preliminary.

Fig. 8.5.3.1.4.1 Stratified abundance indices by size, 1994-2001.

Fig. 8.5.3.1.4.2 Stratified abundance indices by size, 2002-2008.

### 8.5.3.1.5. Trends in growth

No analyses were conducted during SGMED-09-02.
8.5.3.1.6. Trends in maturity

No analyses were conducted during SGMED-09-02.

### 8.5.4.Assessment of historic stock parameters

SGMED-09-02 did not undertake any analytical assessment.
8.5.5.Long term prediction

### 8.5.5.1. Justification

No forecast analyses were conducted.

### 8.5.5.2. Input parameters

No forecast analyses were conducted.

### 8.5.5.3. Results

Given the preliminary state of the data and analyses SGMED-09-02 is not in the position to provide a long term prediction of catch and stock biomass for hake in GSA 07.

### 8.5.6.Scientific advice

### 8.5.6.1. Short term considerations

### 8.5.6.1.1. State of the spawning stock size

SGMED-09-02 is unable to provide any scientific advice of the state of the spawning stock in relation to proposed precautionary level given the preliminary state of the data and analyses.

### 8.5.6.1.2. State of recruitment

SGMED-09-02 is unable to provide any scientific advice of the state of the recruitment given the preliminary state of the data and analyses.

### 8.5.6.1.3. State of exploitation

SGMED-09-02 is unable to provide any scientific advice of the state of the exploitation in relation to proposed precautionary and target levels given the preliminary state of the data and analyses.

### 8.6. Stock assessment of hake in GSA 08

### 8.6.1.Stock identification and biological features

8.6.1.1. Stock Identification

No information was documented during SGMED-09-02.

### 8.6.1.2. Growth

No information was documented during SGMED-09-02.
8.6.1.3. Maturity

No information was documented during SGMED-09-02.

### 8.6.2.Fisheries

8.6.2.1. General description of fisheries

No information was documented during SGMED-09-02.
8.6.2.2. Management regulations applicable in 2008 and 2009

No information was documented during SGMED-09-02.

### 8.6.2.3. Catches

### 8.6.2.3.1. Landings

No information was documented during SGMED-09-02.

### 8.6.2.3.2. Discards

No information was documented during SGMED-09-02.

### 8.6.2.3.3. Fishing effort

No information was documented during SGMED-09-02.
8.6.3.Scientific surveys
8.6.3.1. Medits

### 8.6.3.1.1. Methods

Based on the DCF data call, abundance and biomass indices were recalculated. SGMED-09-02 notes that the reported Medits data in GSA 08 only cover the eastern coast of Corsica. In GSA 08 the following number of hauls was reported per depth stratum (s. Tab. 8.6.3.1.1.1).

Tab. 8.6.3.1.1.1. Number of hauls per year and depth stratum in GSA 08, 1994-2008.

| STRATUM | 1994 | 1995 | 1996 | 1997 | 1998 | 1999 | 2000 | 2001 | 2002 | 2003 | 2004 | 2005 | 2006 | 2007 | 2008 |
| :--- | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| GSA08_010-050 | 4 |  |  |  |  |  |  |  |  |  |  |  |  |  |  |
| GSA08_050-100 | 6 | 5 | 8 | 4 | 8 | 7 | 5 | 5 |  | 6 | 6 | 8 | 8 | 5 | 7 |
| GSA08_100-200 | 3 | 5 | 6 | 2 | 5 | 5 | 5 | 5 | 1 | 5 | 5 | 5 | 5 | 4 | 5 |
| GSA08_200-500 | 10 | 11 | 12 | 8 | 12 | 10 | 11 | 10 |  | 10 | 11 | 11 | 11 | 10 | 12 |
| GSA08_500-800 | 6 | 5 | 4 | 4 | 5 | 6 | 5 | 5 |  | 4 | 5 | 5 | 5 | 5 | 5 |

Data were assigned to strata based upon the shooting position and average depth (between shooting and hauling depth). Few obvious data errors were corrected. Catches by haul were standardized to 60 minutes hauling duration. Hauls noted as valid were used only, including stations with no catches of hake, red mullet or pink shrimp (zero catches are included).

The abundance and biomass indices by GSA were calculated through stratified means (Cochran, 1953; Saville, 1977). This implies weighting of the average values of the individual standardized catches and the variation of each stratum by the respective stratum areas in each GSA:
$\mathrm{Yst}=\Sigma\left(\mathrm{Yi}^{*} \mathrm{Ai}\right) / \mathrm{A}$
$\mathrm{V}(\mathrm{Yst})=\Sigma\left(\mathrm{Ai}^{2} * \mathrm{si}^{2} / \mathrm{ni}\right) / \mathrm{A}^{2}$
Where:
$\mathrm{A}=$ total survey area
$\mathrm{Ai}=$ area of the i-th stratum
si=standard deviation of the i-th stratum
ni=number of valid hauls of the i-th stratum
n=number of hauls in the GSA
Yi=mean of the i-th stratum
Yst=stratified mean abundance
$\mathrm{V}(\mathrm{Yst})=$ variance of the stratified mean
The variation of the stratified mean is then expressed as the $95 \%$ confidence interval: Confidence interval $=$ Yst $\pm \mathrm{t}$ (student distribution) $* \mathrm{~V}(\mathrm{Yst}) / \mathrm{n}$

It was noted that while this is a standard approach, the calculation may be biased due to the assumptions over zero catch stations, and hence assumptions over the distribution of data. A normal distribution is often assumed, whereas data may be better described by a delta-distribution, quasi-poisson. Indeed, data may be better modelled using the idea of conditionality and the negative binomial (e.g. O'Brien et al. (2004)).

Length distributions represented an aggregation (sum) of all standardized length frequencies (subsamples raised to standardized haul abundance per hour) over the stations of each stratum. Aggregated length frequencies were then raised to stratum abundance * 100 (because of low numbers in most strata) and finally aggregated (sum) over the strata to the GSA. Given the sheer number of plots generated, these distributions are not presented in this report.

### 8.6.3.1.2. Geographical distribution patterns

No analyses were conducted during SGMED-09-02.

### 8.6.3.1.3. Trends in abundance and biomass

Fishery independent information regarding the state of the hake in GSA 08 was derived from the international survey Medits. SGMED-9-02 notes that the reported Medits data in GSA 08 only cover the eastern coast of Corsica. Figure 8.6.3.1.3.1 displays the estimated trend in hake abundance and biomass in GSA 08.

The estimated abundance and biomass indices do not reveal any significant trends since 1994. However, the recent abundance and biomass indices since 2006 appear high but are subject to high variation (uncertainty). The analyses of Medits indices are considered preliminary.

Fig. 8.6.3.1.3.1 Abundance and biomass indices of hake in GSA 08.

### 8.6.3.1.4. Trends in abundance by length or age

The following Fig. 8.6.3.1.4.1 and 2 display the stratified abundance indices of GSA 08 in 1994-2001 and 2002-2008. These size compositions are considered preliminary.

Fig. 8.6.3.1.4.1 Stratified abundance indices by size, 1994-2001.

Total length (cm)

Fig. 8.6.3.1.4.2 Stratified abundance indices by size, 2002-2008.

### 8.6.3.1.5. Trends in growth

No analyses were conducted during SGMED-09-02.

### 8.6.3.1.6. Trends in maturity

No analyses were conducted during SGMED-09-02.
8.6.4.Assessment of historic stock parameters

SGMED-09-02 did not undertake any analytical assessment.
8.6.5.Long term prediction

### 8.6.5.1. Justification

No forecast analyses were conducted.

### 8.6.5.2. Input parameters

No forecast analyses were conducted.

### 8.6.5.3. Results

Given the preliminary state of the data and analyses SGMED-09-02 is not in the position to provide a long term prediction of catch and stock biomass for hake in GSA 08.

### 8.6.6.Scientific advice

### 8.6.6.1. Short term considerations

### 8.6.6.1.1. $\quad$ State of the spawning stock size

SGMED-09-02 is unable to provide any scientific advice of the state of the spawning stock in relation to proposed precautionary level given the preliminary state of the data and analyses.

### 8.6.6.1.2. $\quad$ State of recruitment

SGMED-09-02 is unable to provide any scientific advice of the state of the recruitment given the preliminary state of the data and analyses.

### 8.6.6.1.3. State of exploitation

SGMED-09-02 is unable to provide any scientific advice of the state of the exploitation in relation to proposed precautionary and target levels given the preliminary state of the data and analyses.

### 8.7. Stock assessment of hake in GSA 09

### 8.7.1.Stock identification and biological features

### 8.7.1.1. Stock Identification

Due to a lack of information about the structure of hake population in the western Mediterranean, this stock was assumed to be confined within the GSA 09 boundaries.

Hake is distributed in the whole area between 10 and 800 m depth (Biagi et al., 2002; Colloca et al., 2003). Recruits peak in abundance between 150 and 250 m depth over the continental shelf-break and appear to move slightly deeper when they reach $10-\mathrm{cm}$ total length. Crinoid (Leptometra phalangium) bottoms over the shelf-break are the main settlement habitat for hake in the area (Colloca et al., 2004, 2006; Reale et al., 2005). Migration from nurseries takes place when juveniles attained a critical size between 13 and 15.5 cm TL (Bartolino et al., 2008a). Maturing hakes ( $15-35 \mathrm{~cm} \mathrm{TL}$ ) persist on the continental shelf with a preference for water of 70-100 m depth, while larger hakes can be found in a larger depth range from the shelf to the upper slope. Juveniles show a patchy distribution with some main density hot spots (i.e. nurseries areas) showing a high spatio-temporal persistence (Abella et al., 2005; Colloca et al., 2006, Jona Lasinio et al., 2007; Colloca et al., 2008) (Fig. 8.7.1.1.1) in areas with frontal terms and other oceanographic structures that can enhance larval retention (Abella et al., 2008).

Fig 8.7.1.1.1 Temporal persistence of hake nurseries calculated from MEDITS and GRUND time-series density maps (1994-2005) of juveniles.

Although hakes are demersal fish feeding typically upon fast-moving pelagic preys while ambushed in the water column (Alheit and Pitcher, 1995). There is evidence that hakes feed in mid-water or at the surface during night-time, undertaking daily vertical migrations (Orsi-Relini et al., 1989, Carpentieri et al., 2008) which are more intense for juveniles. In GSA 09 many different studies are available on hake diet. Results from stomach data collected in the 1996-2001 period can be found in Sartor et al. (2003a) and Carpentieri et al. (2005). Hake diet shifts from euphausids and mysiids, consumed by smaller hake ( $<16 \mathrm{~cm} \mathrm{TL}$ ), to fishes consumed by larger hake.

Before the transition to the complete ichthyophagous phase (TL> 36 cm ) hake shows more generalized feeding habits where decapods, benthic (Gobiidae, Callionymus spp.,) and necktonic fish (S. pilchardus, E. encrasicolus) dominated the diet, whereas cephalopods had a lower incidence (Fig. 8.7.1.1.2).

Fig. 8.7.1.1.2 A) Hake diet composition in GSA 09 by size class (from Carpentieri et al., 2005). B) Relationships between recruitment and cannibalism rate (proportion by weight, $\% \mathrm{~W}$, of hake in hake stomachs).

Estimation of cannibalism rate has been provided for the southern part of the GSA (Latium, EU Because project). Cannibalism increased with size and can be considered significant for hakes between 30 and 40 cm TL (up to $20 \%$ by weight in diet) and seems to relate closely to hake recruitment density and level of spatial overlapping.

Consumption rate has been estimated for juveniles and piscivorous hakes. Daily consumption of juveniles, calculated in proportion of body weight (\%BW), varied between 5 (July) and $5.9 \%$ BW (Carpentieri et al., 2008). The estimated relative daily consumption for hake between 14 and 40 cm , estimated using a bioenergetic approach (EU Because project) TL was between 2.9 and $2.3 \mathrm{BW} \%$.

### 8.7.1.2. Growth

Juvenile growth rate was estimated to be about 1.5 cm month $^{-1}$ using daily growth increments on otoliths (Belcari et al., 2006). According to this growth rate, hake reaches an average length of about 18 cm TL at the end of the first year. According to these observations, the growth of hake in the GSA 09 seems to follow the pattern estimated in the NW Mediterranean (Garcia-Rodriguez and Esteban, 2002) adopting the hypothesis that two rings are laid down on otoliths each year. This new interpretation of otolith ring patterns returns a growth rate $\left(\mathrm{L}_{\infty}=103.9, \mathrm{~K} /\right.$ year $\left.=0.212, \mathrm{t}_{0}=0.031\right)$ almost double than that assumed in the past.

As showed in the Fig. 8.7.1.2.1, cohorts obtained through age slicing of LFDS MEDITS data according to fast growth parameters, can be consistently followed during time, while a less reliable pattern was obtained using parametersconform to the slow growth hypothesis.

Fig. 8.7.1.2.1 Trends in abundance of age classes obtained using age slicing according to two different sets of growth parameters on MEDITS data.

### 8.7.1.3. Maturity

The catchability of hake spawners to the Mediterranean trawl nets is rather limited. Either the distribution of adults which are more abundant on deeper or untrawable grounds, or the ability of larger fish to avoid capture have been claimed as causes of the observed extremely reduced catch of adult hake by trawlers in the Mediterranean (Abella et al., 1997). Also during trawl surveys (MEDITS and GRUND) the catch rate of mature specimens was very low, reducing the possibility of use trawl survey data to explore patterns in gonad development as well as the relationships between growth rate and maturation processes.

Large size hake are targets of a specifically targeted gillnet fishery carried out by several vessels working in the southern part (northern and central Tyrrhenian Sea) of the GSA 09 (Sartor et al., 2001a).

Reproductive biology and fecundity of hake have been studied in northern Tyrrhenian Sea (Biagi et al., 1995; Nannini et al., 2001; Recasens et al., 2008) by monthly samplings of adults caught by trawling and gillnets.

Females in advanced maturity stages, spawning and partial post-spawning are present all year round, but reproductive activity is concentrated from January to May, with two peaks of spawning in February and May. The presence of hake spawners seems to be more concentrated in the southern part of GSA 09.

Female length at first maturity was estimated at 35 cm TL in northern Tyrrhenian Sea (Recasens et al., 2008). This value is consistent with the observations obtained from trawl surveys over the Latium (Colloca, pers. comm.) reporting first maturity from 31 to 37 cm TL for females and from 21 to 25 cm TL for males.

Batch fecundity was about 200 eggs per gonad-free female gram, with asynchronous oocyte development (Recasens et al., 2008).

### 8.7.2.Fisheries

### 8.7.2.1. General description of fisheries

Hake is among the most important component of bottom trawlers targeting a species complex and is the demersal species providing the highest landings and incomes for the GSA 09. The analysis of available
information suggests that about $90 \%$ of landings of hake are obtained by bottom trawl vessels; the remaining fraction is provided by artisanal vessels using set nets, in particular gillnets.

The trawl fleet of GSA 09 at the end of 2006 accounted for 361 vessels (Tab. 8.7.2.1.1).
The main trawl fleets of GSA 09 are present in the following continental harbours: Viareggio, Livorno, Porto Santo Stefano (Tuscany), Fiumicino, Terracina, Gaeta (Latium).

Tab. 8.7.2.1.1 Technical characteristics of the trawl fleet of GSA 09.

| N. of boats | 361 |
| :--- | :--- |
| GT | 13.191 |
| kW | 75.514 |
| Mean GT | 36.5 |
| Mean kW | 209.2 |

As concerns fishing activity, the majority of bottom trawlers of GSA 09 operate daily fishing trips with only some vessels staying out for two-three days and especially in summer.

Hake fishing grounds comprise all the soft bottoms of continental shelves and the upper part of continental slope. Fishing pressure shows some geographical differences inside the GSA 09 according to the consistency of the fleets and the characteristics of the bottoms.

The artisanal fleets, according to the last official data (end of 2006), accounted for 1,309 vessels that operate in several harbours along the continental and insular coasts. Of these, about 50 vessels, mainly located in some harbors of the GSA 09 (e.g. Marina di Campo, Ponza, Porto Santo Stefano), utilize gillnets and target medium and large-sized hakes (larger than 25 cm TL ) especially from winter to summer.

### 8.7.2.2. Management regulations applicable in 2009

- Fishing closure for trawling: 45 days in late summer (not every year have been enforced )
- Minimum landing sizes: EC regulation 1967/2006: 20 cm TL for hake.
- Cod end mesh size of trawl nets: 40 mm (stretched, diamond meshes) till 30/05/2010. From 1/6/2010 the existing nets will be replaced with a cod end with 40 mm (stretched) square meshes or a cod end with 50 mm (stretched) diamond meshes.
- Towed gears are not allowed within three nautical miles from the coast or at depths less than 50 m when this depth is reached at a distance less than 3 miles from the coast.
- Two small No Take Zones ("Zone di Tutela Biologica", ZTB) are present inside the GSA 09; one off the Giglio Island ( $50 \mathrm{~km}^{2}$, northern Tyrrhenian Sea) another off Gaeta, ( $125 \mathrm{~km}^{2}$, central Tyrrhenian Sea). Bottom fishing was not allowed in the two ZTB. A recent regulation of the Italian Ministry of Agricultural, Food and Forestry Policies established that fishing activities can be carried out in these two areas from July $1^{\text {st }}$ to December $31^{\text {st }}$.

### 8.7.2.3. Catches

### 8.7.2.3.1. Landings

In the last seven years the total landings of hake of GSA 09 fluctuated between 1,000 to about 2,300 tons (Fig. 8.7.2.3.1.1).

Fig. 8.7.2.3.1.1 Landings of hake (all gears) in the GSA 09, from 2002 to 2008 (DCR official data).
Due to huge concentration of hake juveniles in GSA 09, trawl landings were traditionally dominated by small sized specimens; they are basically composed by $0+$ and $1+$ age class individuals. Gillnet fishery lands mostly $2+$ and $3+$ fishes, as shown, as an example, by the two following histograms (Fig. 8.7.2.3.1.2).

Fig. 8.7.2.3.1.2 Size structure of the landings of hake provided in 2006 by otter trawling and by set nets in the GSA 09 (DCR official data).

The following Table 8.7.2.3.1.1 lists the landings data of Hake in GSA 09 coming from the Data Collection Regulation, by major gear types.

According to the STECF-SGMED-09-02 scientist's knowledge, DCR landing data for GSA 09 give an overstimation of the amount derived from the set nets. This aspect underlines both the need of some improvements of the data collection, paying particular attention to the sampling design and the importance of a routinely check made by experts of the official data.

Table 8.7.2.3.1.1 Landings (t) by year and major gear types, 2002-2008 as reported through DCF. Figures for 2002 and 2003 are obviously wrong. Data are listed in Table A3.1 in Appendix 3.

| AREA | COUNTRY | FT_LVL4 | 2002 | 2003 | 2004 | 2005 | 2006 | 2007 | 2008 |
| ---: | :--- | :--- | ---: | ---: | ---: | ---: | ---: | ---: | ---: |

|  |  | 905 | 2080 | 1195 | 1919 | 2330 | 1753 |  |  |

### 8.7.2.3.2. Discards

Several EU and national projects carried out in GSA 09 highlighted the problem of discard of hake by trawl fisheries. High quantities of small sized hakes are routinely discarded, especially in summer and on the fishing grounds located near the main nursery areas of the species (Fig. 8.7.2.3.2.1).

Due to the introduction of the EU Regulations on MLS a progressive increase of the size at which $50 \%$ of the specimens caught was discarded has been observed in these last years: from about 11 cm TL in 1995 (Sartor et al., 2001b), to about 17 cm TL in 2006 (De Ranieri, 2007). In the last years this size is even increasing (Sartor, pers. obs.) This phenomenon might be also explained with the reduction of the fishing pressure on the nursery areas of this species.

Fig. 8.7.2.3.2.1 Size structure of the hake discarded by the trawl fleets operating in the GSA 09 in 2006 (DCR official data).

Reported discards through the DCR data call to SGMED-09-02 amount 467 t in 2006 for trawlers. The data are listed in Table A3.9 of Appendix 3.

### 8.7.2.3.3. Fishing effort

The fishing capacity of the GSA 09 has shown in these last 20 years a progressive decrease; from 1996 to 2006 the number of bottom trawlers of GSA 09 decreased of about $30 \%$.

The total fishing days carried out by all the GSA 09 trawlers varied from about 65,000 in 2004 to about 63,000 in 2006 (Fig. 8.7.2.3.3.1), a little decrease of the mean number of fishing days/year per vessel was observed in this period, from 187 to 177.

Fig. 8.7.2.3.3.1 Effort trends (days and $\mathrm{kW}^{*}$ days) by major fleets, 2004-2007. The data are listed below and in Tables A3.10 and A3.12 of Appendix 3.

Tab. 8.7.2.3.3.1 Effort trends ( kW *days) by major fleets as reported through DCF, 2002-2007 (no data available in 2008), s. Tab. A3.10-12 of Appendix 3.

| SPECIES | AREA | COUNTRY | FT_LVL4 | 2002 | 2003 | 2004 | 2005 | 2006 | 2007 | 2008 |

### 8.7.3.Scientific surveys

### 8.7.3.1. MEDITS

### 8.7.3.1.1. Methods

Based on the DCF data call, abundance and biomass indices were recalculated. In GSA 09 the following number of hauls were reported per depth stratum ( s . Tab. 8.7.3.1.1.1).

Tab. 8.7.3.1.1.1. Number of hauls per year and depth stratum in GSA 09, 1994-2008.

| STRATUM | 1994 | 1995 | 1996 | 1997 | 1998 | 1999 | 2000 | 2001 | 2002 | 2003 | 2004 | 2005 | 2006 | 2007 | 2008 |
| :--- | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| GSA09_010-050 | 19 | 18 | 18 | 18 | 19 | 18 | 18 | 18 | 13 | 13 | 13 | 14 | 13 | 13 | 13 |
| GSA09_050-100 | 19 | 20 | 18 | 19 | 18 | 19 | 20 | 20 | 15 | 15 | 15 | 14 | 16 | 16 | 13 |
| GSA09_100-200 | 35 | 35 | 36 | 35 | 35 | 35 | 34 | 34 | 26 | 27 | 26 | 27 | 25 | 26 | 28 |
| GSA09_200-500 | 32 | 33 | 33 | 36 | 32 | 36 | 37 | 35 | 27 | 27 | 27 | 28 | 29 | 33 | 30 |
| GSA09_500-800 | 31 | 30 | 32 | 28 | 30 | 28 | 27 | 29 | 24 | 22 | 21 | 20 | 20 | 17 | 18 |

Data were assigned to strata based upon the shooting position and average depth (between shooting and hauling depth). Few obvious data errors were corrected. Catches by haul were standardized to 60 minutes hauling duration. Hauls noted as valid were used only, including stations with no catches of hake, red mullet or pink shrimp (zero catches are included).

The abundance and biomass indices by GSA were calculated through stratified means (Cochran, 1953; Saville, 1977). This implies weighting of the average values of the individual standardized catches and the variation of each stratum by the respective stratum areas in each GSA:
$\mathrm{Yst}=\Sigma\left(\mathrm{Yi}^{*} \mathrm{Ai}\right) / \mathrm{A}$
$\mathrm{V}(\mathrm{Yst})=\Sigma\left(\mathrm{Ai}^{2} * \mathrm{si}^{2} / \mathrm{ni}\right) / \mathrm{A}^{2}$
Where:
A=total survey area
$\mathrm{Ai}=$ area of the i -th stratum
si=standard deviation of the i-th stratum
ni=number of valid hauls of the i-th stratum
n=number of hauls in the GSA
$\mathrm{Yi}=$ mean of the i-th stratum
Yst=stratified mean abundance
$\mathrm{V}(\mathrm{Yst})=$ variance of the stratified mean
The variation of the stratified mean is then expressed as the $95 \%$ confidence interval: Confidence interval $=$ Yst $\pm \mathrm{t}$ (student distribution) $* \mathrm{~V}(\mathrm{Yst}) / \mathrm{n}$

It was noted that while this is a standard approach, the calculation may be biased due to the assumptions over zero catch stations, and hence assumptions over the distribution of data. A normal distribution is often assumed, whereas data may be better described by a delta-distribution, quasi-poisson. Indeed, data may be better modelled using the idea of conditionality and the negative binomial (e.g. O'Brien et al. (2004)).

Length distributions represented an aggregation (sum) of all standardized length frequencies (subsamples raised to standardized haul abundance per hour) over the stations of each stratum. Aggregated length frequencies were then raised to stratum abundance * 100 (because of low numbers in most strata) and finally aggregated (sum) over the strata to the GSA. Given the sheer number of plots generated, these distributions are not presented in this report.

### 8.7.3.1.2. Geographical distribution patterns

According to recent studies (Orsi Relini et al., 2002), the density of hake recruits concentrations in nursery areas in GSA 09 is by far higher than that of the other GSAs of the western Mediterranean and, probably, also of the other Mediterranean GSAs (Fig. 8.7.3.1.2.1).

Fig. 8.7.3.1.2.1 MEDITS density indices of the hake recruits ( $<12 \mathrm{~cm}$ TL) obtained in different Mediterranean GSAs (from Orsi-Relini et al., 2002, modified).

Generalized additive models were developed to investigate hake recruitment dynamics in the Tyrrhenian Sea in relation to spawner abundance and selected key oceanographic variables. Thermal anomalies in summer, characterized by high peaks in water temperature, revealed a negative effect on the abundance of recruits in autumn, probably due to a reduction in hake egg and larval survival rate. Recruitment was reduced when
elevated sea-surface temperatures were coupled with lower levels of water circulation. Enhanced spring primary production, related to late winter low temperatures could affect water mass productivity in the following months, thus influencing spring recruitment. In the central Tyrrhenian a dome-shaped relationship between wind mixing in early spring and recruitment could be interpreted as an "optimal environmental window" in which intermediate water mixing level played a positive role in phytoplankton displacement, larval feeding rate and appropriate larval drift (Bartolino et al., 2008b) (Fig. 8.7.3.1.2.2).

Fig. 8.7.3.1.2.2 Effects of: (a) sstm.w, (b) sstmax8 and (c) wmix4 on hake recruitment in the central Tyrrhenian (from Bartolino et al., 2007).

The temporal trend in spatial distribution of hake $>26 \mathrm{~cm}$ TL showed a clear reduction of distribution area, particularly in the Tyrrhenian part of the GSA (GRUND data, Fig. 8.7.3.1.2.3).

Fig. 8.7.3.1.2.3 Distribution of hakes larger than 26 cm TL in 1985-87, 1996-98, 2000-01, 2002-03.

### 8.7.3.1.3. $\quad$ Trends in abundance and biomass

The national GRUND trawl survey (Relini, 1998) has been performed out along the Italian coasts in addition to MEDITS. It has been carried out since 1985, with some years lacking (1988, 1989 and 1999, 2007). Sampling is random stratified, except in the period 1990-93 where a different sampling design, based on
transects, was applied. Locations of stations were selected randomly within each stratum in the period 198587, while starting from 1996, the same stations were sampled the following years. Therefore from 1994 in Italy two trawl surveys are regularly carried out each year: MEDITS, in spring, and GRUND, in autumn. The two surveys provide integrate pictures on different seasons, allowing to monitor the most important biological events (recruitment, spawning) for the majority of the demersal species.

Figure 8.7.3.1.3.1 shows the density and biomass indices of hake obtained from 1994 to 2008; no evident trends are present.

Fig. 8.7.3.1.3.1 Density and biomass indices of hake according to the GRUND and MEDITS surveys.

Figure 8.7.3.1.3.2 displays the re-estimated trend in hake abundance and biomass in GSA $09(\mathrm{~kg} / \mathrm{h})$ based on the MEDITS DCR data call. Both MEDITS trends presented are similar without any long term trend.

Fig. 8.7.3.1.3.2 Abundance and biomass indices of hake in GSA 09.

### 8.7.3.1.4. $\quad$ Trends in abundance by length or age

The following Fig. 8.7.3.1.4.1 and 2 display the stratified abundance indices of GSA 09 in 1994-2001 and 2002-2008.

| GSA09 1998 |  |
| :---: | :---: |

Fig. 8.7.3.1.4.1 Stratified abundance indices by size, 1994-2001.

Fig. 8.7.3.1.4.2 Stratified abundance indices by size, 2002-2008.

### 8.7.3.1.5. Trends in growth

No analyses were conducted.

### 8.7.3.1.6. Trends in maturity

No analyses were conducted.

### 8.7.4.Assessment of historic stock parameters

Due to its importance as demersal resource, hake has been object of several assessments in the GSA 09 (Reale et al., 1995; Fiorentino et al., 1996; Ardizzone et al., 1998; Abella et al., 1999; 2007; Colloca et al., 2000). These results are published and regularly updated in the GFCM SAC sheets. The assessments, often performed with different approaches in different periods or in different subareas of the GSA 09, showed substantially convergent results.

The hake in the GSA 09 seems to be in a "chronic" overexploitation, as shown by the results of the analytical models (reference points as $\mathrm{F}_{\text {max }}, \mathrm{F}_{0.1}$ and $\mathrm{SSB}_{\text {curr }} / \mathrm{SSB}_{0}$ ). Also the production models based on total mortality provided total mortality estimates greater than the mortality corresponding to the maximum biological production (ZMBP).

A growth overfishing situation was detected, with excessive fishing mortality on $0+$ and $1+$ age classes. The values of the $\mathrm{SSB}_{\text {curr }} / \mathrm{SSB}_{0}$ ratio are always lower than 0.1.

As concern the STECF-SGMED-09-02, two new assessments were produced. The main results are presented below.

### 8.7.4.1. Method 1: Trends in LPUE

As concerns the Landings per Unit of Effort, quite long time series are available for some important fleets operating in this GSA 09.

### 8.7.4.1.1. Justification

Trends in LPUE may provide insight into trends in stock size. SGMED-09-02 recommends that technological creep should be considered when trends in LPUE are interpreted.

### 8.7.4.1.2. Input parameters

These data come from independent monitoring activities performed by the research institutes working in the GSA.

### 8.7.4.1.3. Results

As an example, the LPUE evolution in the period 1991-2008 is reported in Fig. 8.7.4.1.3.1. LPUE showed a continuous decreasing trend till 2004 while LPUE remained substantially stable in the last four years. The decrease in LPUE is mainly due to a change in fishing pattern experienced by the local fleets: the progressive disappearance of the smallest specimens from the landings is the effect of the introduction of the EU Regulations ( $1626 / 94$ and 1967/06) concerning MLS ( 20 cm TL for hake). Also a progressive reduction of fishing pressure on the nursery areas is occurring in the last years, especially on the northern fishing grounds of GSA 09 .

Fig. 8.7.4.1.3.1 Hake LPUE of the Porto Santo Stefano trawl fleet (1991-2008); above: LPUE by size class; below: total LPUE

### 8.7.4.2. Method 2: SURBA

### 8.7.4.2.1. Justification

The relatively long time series of data available from the GRUND and MEDITS surveys provided the most useful data sets for analysis. The survey-based stock assessment approach SURBA (Needle, 2003) was used both on MEDITS (1994-2007) and GRUND (1994-2004) data of the hake of GSA 09.

### 8.7.4.2.2. Input parameters

The following set of parameters was adopted:

| Growth parameters (Von Bertalanffy) |
| :--- |
| $\mathrm{L} \infty=104$ (mm, length) |
| $\mathrm{K}=0.2$ |
| $\mathrm{t}_{0}=-0.03$ |
| $\mathrm{~L}^{*} \mathrm{~W}$ |
| $\mathrm{a}=0.006657$ |
| $\mathrm{~b}=3.028$ |
| Natural mortality |

| M vector $\mathrm{Age}_{1}=1.3, \mathrm{Age}_{2}=0.6, \mathrm{Age}_{3}=0.46, \mathrm{Age}_{4}=0.41, \mathrm{Age}_{5}=0.3$ |
| :--- |
| Catchability $(\mathrm{q})$ |
| $\mathrm{q}($ age $0+)=0.8, \mathrm{q}($ age $1+)=1.0, \mathrm{q}($ age $2+)=0.7, \mathrm{q}($ age3 +$)=0.7, \mathrm{q}($ age $4+)=0.7$ |
| Length at maturity $($ L50 $)$ |
| L50 $=30 \mathrm{~cm}$ |
| Length of first capture $(\mathrm{Lc})$ |
| $\mathrm{Lc}=12 \mathrm{~cm}$ |

Tab. 8.7.4.2.2.1 Input parameters used for the SURBA model.

### 8.7.4.2.3. Results

The two surveys gave a similar picture for $\mathrm{F}_{1-3}$ which shows a clear increasing trend (MEDITS, $\mathrm{p}<0.01$ ) from 0.8 (1994) to 1.6 (2008). Relative SSB decreased significantly (MEDITS, p<0.01). Recruitment fluctuated from year to year without a clear temporal pattern during MEDITS. The largest year classes were observed in 1998 and 2008. GRUND showed a more constant pattern in recruitment with the lowest value in 2003 and a high peak in 2004 (Fig. 8.7.4.2.3.1).

Fig. 8.7.4.2.3.1 MEDITS and GRUND surveys. Estimated trend in F, relative SSB and recruitment using SURBA. 50th percentile of bootstrapped runs (solid line) and $5 \%$ and $95 \%$ percentiles of bootsrapped runs (dashed lines).

Model diagnostics are shown in the following Fig. 8.7.4.2.3.2 and Fig. 8.7.4.2.3.3.

Fig. 8.7.4.2.3.2. Model diagnostic for Surba model in the GSA 09. A) Comparison between observed (points) and fitted (lines) of MEDITS survey abundance indices, for each year. B) Log survey abundance indices by cohort. Each line represents the log index abundance of a particular cohort throughout its life.

Fig. 8.7.4.2.3.3. Model diagnostic for Surba model in the GSA 09. A) Comparison between observed (points) and fitted (lines) of GRUND survey abundance indices, for each year. B) Log survey abundance indices by cohort. Each line represents the log index abundance of a particular cohort throughout its life.

### 8.7.4.3. Method 3: LCA on DCR data

### 8.7.4.3.1. Justification

Assessment was performed using an LCA (VIT software, Lleonart and Salat, 1997) on an annual pseudocohort (year 2006 and 2008).

### 8.7.4.3.2. Input parameters

Data coming from DCR contained, for GSA 09 , information on hake landings and the respective size/age structure for the period 2005-2008; discard size structure was also available but only for 2006. Such data were available for the two main fishing gears exploiting hake in GSA 09: trawling and set nets (gillnets). Anyway, the short data series did not allow the use of VPA models.

LCA was performed using VIT software on data of the years 2006 and 2008. For 2006, landing data were "corrected" including the available information on discard. Fig. 8.7.4.3.2.1 shows the size frequency distributions of the landings and discards, by gear.

Fig. 8.7.4.3.2.1. Length frequency distributions of the M. merluccius landings and discards in 2006 in the GSA 09.

Tab. 8.7.4.3.2.1 shows the input data concerning 2006. The used parameters were the same of the SURBA analysis, including the same M-vector and the same maturity ogive.

According to the STECF-SGMED-09-02 scientist's knowledge, DCR landing data for GSA 09 have been adjusted concerning to the contribution of artisanal fishery to the total catch. DCR data gave a proportion of about $60 \%$ for trawling and about $40 \%$ for set nets. An overestimation of the set nets was detected, so the percentage contribution of set nets was reduced to a more realistic value of $10 \%$, taking into account the expert's knowledge of the GSA 09 fisheries. This aspect underlines both the need of some improvements of the data collection, paying particular attention to the sampling design and the importance of a routinely check made by experts of the official data.

### 8.7.4.3.3. Results

The general results of LCA highlight an exploitation focused on young age classes, mainly $0+$ and $1+$, reflecting a growth overfishing state.
As concerns 2006 data a mean value of $\mathrm{F}(1-3)$ of 1.24 was estimated, while for the 2008 data a value of 1.53 was obtained.
Fig. 8.7.4.3.3.1 shows, as an example, the results of 2006.

Fig. 8.7.4.3.3.1. LCA outputs: catch in numbers, catch in weight, numbers-at-age and fishing mortality at age of M. merluccius in the GSA 09 (2006 data).

### 8.7.5.Long term prediction

### 8.7.5.1. Justification

Equilibrium YPR reference points for the stock estimated through the Yield software (Hoggarth et al., 2006) were assessed.

Further YPR analyses were conducted based on the VIT (pseudocohort) results.

### 8.7.5.2. Input parameters

Equilibrium YPR reference points for the stock were estimated through the Yield software (Hoggarth et al., 2006) assuming recruitment fluctuating randomly around a constant value and $20 \%$ uncertainty in input parameters.
The second YPR analyses used the results of VIT (pseudocohort) as inputs.
The used parameters were the same of the SURBA and LCA analyses given above.
8.7.5.3. Results

Yield software quantified uncertainty by repeatedly selecting a set of biological and fishery parameters by sampling from the probability distributions for uncertain parameters set by the user, and then calculating the quantities of interest. In this sampling, it is assumed that each of the uncertain parameters are independently distributed, even though for some biological parameters, this assumption is almost certainly incorrect (Hoggarth et al., 2006). $\mathrm{F}_{\text {max }}$ and $\mathrm{F}_{\text {ref }}$, this latter corresponding to F at $\mathrm{SSB} /$ initial $\mathrm{SSB}=0.30$, were assumed as limiting reference points. $\mathrm{F}_{0.1}$ was assumed as target reference point. The probability distributions of the three RPs showed a considerable variations (Fig. 8.7.5.3.1). The following mean values were obtained: $\mathrm{F}_{\text {max }}$ $=0.35 ; \mathrm{F}_{0.1}=0.22$ and $\mathrm{F}_{\text {ref }}=0.28$. The maximum predicted values were respectively $0.59\left(\mathrm{~F}_{\max }\right), 0.36\left(\mathrm{~F}_{01}\right)$ and $0.41\left(\mathrm{~F}_{\text {ref }}\right)$. RPs suggest an overfishing situation for the stock considering current F about six times higher than the limit and target RPs F.

Fig. 8.7.5.3.1 Probability distribution of hake RPs in the GSA9 obtained using the Yield software (age groups 1-5).

Fig. 8.7.5.3.2. shows the YPR analysis performed with VIT software with DCR data of 2006. A similar picture was obtained with 2008 data. With the forecasting routine of VIT, due to the fact of the use of a M vector declining with age, a higher value of $\mathrm{F}_{\max }$ and $\mathrm{F}_{0.1}$ can be obtained and a better exploitation status of the stock is derived, even though still high regarding the mentioned F reference values.

Fig. 8.7.5.3.2 Y/R curves from VIT analyses. F values (age groups 1-5) are also shown.

### 8.7.6.Scientific advice

8.7.6.1. Short term considerations

### 8.7.6.1.1. State of the spawning stock size

From the above reported analyses, SSB is likely to amout to $5-10 \%$ of the SSB at $\mathrm{F}_{\text {mys. }}$. STECF SGMED-0902 underlines that this conclusion could be influenced by the observed exploitation patterns in the surveys and fisheries, which almost exclusively represent the juvenile part of the stock.

### 8.7.6.1.2. State of recruitment

In recent years recruitment has varied without a clear trend.

### 8.7.6.1.3. State of exploitation

The stock appears to be heavily overexploited and F needs a consistent reduction from the current F of 1.21.7 (SURBA and VIT estimates) towards the candidate reference points for long term sustainability based on F around $\mathrm{F}_{0.1}(0.2)$. However, considering the high productivity in terms of incoming year classes, this stock has the potential to recover quickly if F is reduced towards $\mathrm{F}_{\text {msy }}$.
The continued lack of older fish in the surveyed population indicates exploitation rates far beyond those considered consistent with high yields and low risk. This fact, on the other hand, may reduce the risk of fisheries collapse.
An improvement of the estimates of catchability of adults is needed to better estimate the stock dynamics and to assess the likely impact of fishing activity on this stock

### 8.8. Stock assessment of hake in GSA 10

### 8.8.1.Stock identification and biological features

### 8.8.1.1. Stock Identification

The stock of European hake was assumed in the boundaries of the whole GSA 10, lacking specific information on stock identification. M. merluccius is with red mullet and deep-water rose shrimp a key species of fishing assemblages in the central-southern Tyrrhenian Sea (GSA 10). It is generally also ranked among species with higher abundance indices in the trawl surveys (e.g. Spedicato et al. 2003). It is a long lived fish mainly exploited by trawlers, especially on the continental shelves of the Gulfs (e.g. Gaeta, Salerno, Palermo) but also by artisanal fishers using fixed gears (gillnets, bottom long-line).

Trawl-survey data have evidenced highest biomass indices on the continental shelf of the GSA (100-200 m; Spedicato et al., 2003), where juveniles (less than 12 cm total length) are mainly concentrated. During autumn trawl surveys, one of the main recruitment pulses of this species is observed. Two main recruitment events (in spring and autumn; Spedicato et al. 2003) are reported in GSA 10 as for other Mediterranean areas (Orsi Relini et al., 2002). European hake is considered fully recruited to the bottom at 10 cm TL (from Samed, Anonymous, 2002). The length structures from trawl surveys are generally dominated by juveniles, while large size individuals are rare, this might be also due to the different vulnerability of older fish (Abella and Serena, 1998) beside the effect of high exploitation rates. The few large European hake caught during trawl surveys are generally females and inhabit deeper waters. The overall sex ratio ( $\sim 0.41-0.47$ ) estimated from trawl survey data is slightly skewed towards males.

### 8.8.1.2. Growth

Estimates of growth parameters were achieved during the Samed project (Anonymous, 2002). The approach was based on the analysis of length frequency distributions and the following von Bertalanffy parameters were estimated by sex: females $L_{\infty}=74.2 \mathrm{~cm} ; \mathrm{K}=0.178 ; \mathrm{t}_{0}=-0.20$; males: $\mathrm{L}_{\infty}=46.3 \mathrm{~cm} ; \mathrm{K}=0.285 ; \mathrm{t}_{0}=-0.20$.
In the DCR framework the growth has been studied ageing fish by otolith readings using the whole sagitta and thin sections for older individuals. Length frequency distributions were also analyzed using techniques as Batthacharya for separation of modal components. The observed maximum length of European hake was 83 cm for females and 45.5 cm for males both registered during the biological samplings (bottom long-lines). The following estimates of von Bertalanffy growth parameters for each sex were obtained from average length at age using an iterative non-liner procedure that minimises the sum of the square differences between observed and expected values (excel): females: $\mathrm{L}_{\infty}=97.9 \mathrm{~cm}, \mathrm{~K}=0.135, \mathrm{t}_{0}=-0.4$; males: $\mathrm{L}_{\infty}=50.8 \mathrm{~cm}, \mathrm{~K}=0.25$, $\mathrm{t}_{0}=-0.4$. Parameters of the length-weight relationship estimated were $\mathrm{a}=0.00350, \mathrm{~b}=3.2$ for females and $a=0.0086, b=3.215$ for males, for length expressed in cm .

Fig. 8.8.1.2.1. V. Bertalanffy growth functions for female and male of hake in the GSA 10.

### 8.8.1.3. Maturity

A proxy of size at first maturity as estimated in the Samed project (Anonymous, 2002) using the average length at stage 2 (females with gonads at developing stage) indicates an average length of about 30 cm . According to the data obtained in the DCR, the proportion of mature females (fish belonging to the maturity stage 2 onwards) by length class is reported in the table below together with the estimated maturity ogive which indicates a $\mathrm{L}_{\mathrm{m} 50 \%}$ of about $33 \mathrm{~cm}( \pm 0.8 \mathrm{~cm})$.

| TL <br> $(\mathrm{cm})$ | Proportion <br> of mature | TL <br> $(\mathrm{cm})$ | Proportion <br> of mature |
| :---: | :---: | :---: | :---: |
| 15 | 0.000 | 33 | 0.476 |
| 17 | 0.032 | 35 | 0.364 |
| 19 | 0.041 | 37 | 0.714 |
| 21 | 0.092 | 39 | 0.714 |
| 23 | 0.217 | 41 | 0.909 |
| 25 | 0.367 | 43 | 0.375 |
| 27 | 0.565 | 45 | 0.800 |
| 29 | 0.300 | 47 | 0.909 |
| 31 | 0.211 | 49 | 1.000 |

Fig. 8.8.1.3.1 Maturity ogive and proportions of mature female of hake in the GSA 10 (MR indicates the difference $\mathrm{Lm}_{75 \%}-\mathrm{Lm}_{25 \%}$ ).

### 8.8.2.Fisheries

### 8.8.2.1. General description of fisheries

European hake is mostly targeted by trawlers, but also by small scale fisheries using nets and bottom longlines. Fishing grounds are located along the coasts of the whole GSA offshore 50 m depth or 3 miles from the coast. Catches from trawlers are from a depth range between $50-60$ and 500 m and hake occurs with other important commercial species as Illex coindetii, M. barbatus, P. longirostris, Eledone spp., Todaropsis eblanae, Lophius spp., Pagellus spp., P. blennoides, N. norvegicus.

### 8.8.2.2. Management regulations applicable in 2009

Management regulations are based on technical measures closed number of fishing licenses for the fleet and area limitation (distance from the coast and depth). In order to limit the over-capacity of fishing fleet, the Italian fishing licenses have been fixed since the late eighties. After 2000, in agreement with the European Common Policy of Fisheries, a gradual decreasing of the fleet capacity is implemented. Along northern Sicily coasts two main Gulfs (Patti and Castellammare) have been closed to the trawl fishery up 200 m depth, since 1990. Two closed areas were also established in 2004 along the mainland, in front of Sorrento peninsula (Napoli Gulf) and Amantea (Calabrian coasts), although these protected area mainly cover the distribution of coastal species. Other measures on which the management regulations are based regard technical measures (mesh size) and minimum landing sizes (EC 1967/06). In the GSA 10 the fishing ban has not been mandatory along the time, and from one year to the other it was adopted on a voluntary basis by fishers.

### 8.8.2.3. Catches

### 8.8.2.3.1. Landings

Available landing data are from DCR regulations. SGMED-09-02 received Italian landings data for GSA 10 by major fishing gears which are listed in Tab. 8.8.2.3.1.1. The fishing segments DTS, LLS, PGP, PMP and PTS indicate respectively trawler, long-lines, small scale fishery (nets), polyvalent, and pair trawl. Since 2002, landings of hake increased from $1,013 \mathrm{t}$ to $1,544 \mathrm{t}$ in 2006 and decreased to $1,122 \mathrm{t}$ in 2008 (Fig. 8.8.2.3.1.1). The data are listed in Table A3.1 of Appendix 3. Most part of the landings of hake is from trawlers and nets.

Tab. 8.8.2.3.1.1. Annual landings (t) by major gear type, 2002-2008.

| Sum of Weight (tons) | FISHING_TECH |  |  |  |  |  |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| YEAR | SPECIES | DTS | PTS | PGP | PMP | Tol |
| 2002 | HKE | 515.30 | 26.50 | 224.80 | 245.60 | 1012.30 |
| 2003 | HKE | 425.10 | 21.30 | 328.50 | 321.70 | 1096.70 |

| Sum of Weight (tons) |  | FT_LVL4 |  |  |  |  |  |  |
| :--- | :--- | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| YEAR |  | OTB | GNS |  | GTR | LLS | SB-SV | Total |
| 2004 | HKE | 487.20 | 382.90 | 202.20 | 266.40 |  | 1338.60 |  |
| 2005 | HKE | 623.80 | 293.80 | 297.40 | 269.70 |  | 1484.70 |  |

| 2008 | HKE | 500.60 | 319.30 | 67.60 | 233.90 | 1.40 | 1122.80 |  |

Fig. 8.8.2.3.1.1 Landings (t) by year and major gear types, 2002-2008 as reported through DCR in the GSA 10.

### 8.8.2.3.2. Discards

The discards of hake in the GSA 10 are assessed to be low. About 5 and 6 tons of discards in 2005 and 2006 were reported to SGMED-09-02 (Tab. A3.9 of Appendix 3).

### 8.8.2.3.3. Fishing effort

The trends in fishing effort by year and major gear type is listed in Tab. 8.8.2.3.3.1 and shown in Fig. 8.8.2.3.3.1 in terms of $\mathrm{kW}^{*}$ days. The fishing segments DTS, HOK, PGP, PMP and PTS indicate respectively trawlers, long-lines, small scale fishery (nets), polyvalent, and pair trawl. The fishing effort in $\mathrm{kW} *$ days of
the trawlers seems almost stable, whilst that of the fishing segments and métiers forming the aggregation of the small scale fishery is decreasing. As a result the whole pattern is decreasing.

Tab. 8.8.2.3.3.1 Trend in fishing effort ( $\mathrm{kW}^{*}$ days) for GSA 10 by major gear types, 2002-2007. No data are available for 2008.

| Sum od EF |  |  |  | Total |

Fig. 8.8.2.3.3.1 Trend in fishing effort ( $\mathrm{kW}^{*}$ days) for GSA 10 by major gear types, 2002-2007.

### 8.8.3.Scientific surveys

### 8.8.3.1. Medits

### 8.8.3.1.1. Methods

According to the MEDITS protocol (Bertrand et al., 2002), trawl surveys were yearly (May-July) carried out, applying a random stratified sampling by depth ( 5 strata with depth limits at: $50,100,200,500$ and 800 m ; each haul position randomly selected in small sub-areas and maintained fixed throughout the time). Haul allocation was proportional to the stratum area. The same gear (GOC 73, by P.Y. Dremière, IFREMERSète), with a 20 mm stretched mesh size in the cod-end, was employed throughout the years. Detailed data on the gear characteristics, operational parameters and performance are reported in Dremière and Fiorentini (1996). Considering the small mesh size a complete retention was assumed. All the abundance data (number of fish per surface unit) were standardised to square kilometre, using the swept area method.

Based on the DCR data call, abundance and biomass indices were recalculated. In GSA 10 the following number of hauls was reported per depth stratum (s. Tab. 8.8.3.1.1.1).

Tab. 8.8.3.1.1.1. Number of hauls per year and depth stratum in GSA 10, 1994-2008.

| STRATUM | 1994 | 1995 | 1996 | 1997 | 1998 | 1999 | 2000 | 2001 | 2002 | 2003 | 2004 | 2005 | 2006 | 2007 | 2008 |
| :--- | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |

| GSA10_500-800 | 31 | 30 | 31 | 31 | 31 | 30 | 31 | 29 | 26 | 27 | 26 | 26 | 26 | 26 | 26 |

Data were assigned to strata based upon the shooting position and average depth (between shooting and hauling depth). Few obvious data errors were corrected. Catches by haul were standardized to 60 minutes hauling duration. Hauls noted as valid were used only, including stations with no catches of hake, red mullet or pink shrimp (zero catches are included).

The abundance and biomass indices by GSA were calculated through stratified means (Cochran, 1953; Saville, 1977). This implies weighting of the average values of the individual standardized catches and the variation of each stratum by the respective stratum areas in each GSA:
$\mathrm{Yst}=\Sigma\left(\mathrm{Yi}^{*} \mathrm{Ai}\right) / \mathrm{A}$
$\mathrm{V}(\mathrm{Yst})=\Sigma\left(\mathrm{Ai}^{2} * \mathrm{si}^{2} / \mathrm{ni}\right) / \mathrm{A}^{2}$
Where:
$\mathrm{A}=$ total survey area
Ai=area of the i-th stratum
si=standard deviation of the i-th stratum
ni=number of valid hauls of the $i$-th stratum
n=number of hauls in the GSA
$\mathrm{Yi}=$ mean of the i -th stratum
Yst=stratified mean abundance
$\mathrm{V}(\mathrm{Yst})=$ variance of the stratified mean
The variation of the stratified mean is then expressed as the $95 \%$ confidence interval: Confidence interval $=$ Yst $\pm \mathrm{t}$ (student distribution) $* \mathrm{~V}(\mathrm{Yst}) / \mathrm{n}$

It was noted that while this is a standard approach, the calculation may be biased due to the assumptions over zero catch stations, and hence assumptions over the distribution of data. A normal distribution is often assumed, whereas data may be better described by a delta-distribution, quasi-poisson. Indeed, data may be better modelled using the idea of conditionality and the negative binomial (e.g. O'Brien et al. 2004).

Length distributions represented an aggregation (sum) of all standardized length frequencies (subsamples raised to standardized haul abundance per hour) over the stations of each stratum. Aggregated length frequencies were then raised to stratum abundance * 100 (because of low numbers in most strata) and finally aggregated (sum) over the strata to the GSA. Given the sheer number of plots generated, these distributions are not presented in this report.

### 8.8.3.1.2. Geographical distribution patterns

The geographical distribution pattern of European hake has been studied in the area using trawl-survey data and the geostatistical methods. In these studies both the total abundance indices (Lembo et al., 1998a) and the abundance indices of recruits were analysed (Lembo et al., 1998b, 2000). The higher concentration of recruits in the GSA 10 were localised in the northern side (Gulfs of Napoli and Gaeta).
On average, considering the analyzed distributions (years 1994-2005), the recruits are individual smaller than $12.3 \mathrm{~cm}( \pm 1.41)$. These individual are belonging to the age 0 group.
More recent analyses performed in project at national scale confirmed the presence of important zone for recruits in the northernmost part of the GSA, although sites with a high probability of locating a nursery appeared also along the coasts of southern part of the mainland and North Sicily. From Grund data (autumn survey) the higher abundance of recruits were instead localised in the central part of the GSA, along the mainland coasts. Persistence of the nursery areas along the time was estimated from the indicator kriging. Further details and maps are given in the section of this report dedicated to the nursery.

### 8.8.3.2. GRUND

### 8.8.3.2.1. Methods

Since 2003 Grund surveys (Relini, 2000) was conducted using the same vessel and gear in the whole GSA. Sampling scheme, stratification and protocols were similar as in Medits. All the abundance data (number of fish and weight per surface unit) were standardised to square kilometre, using the swept area method.

### 8.8.3.2.2. Geographical distribution patterns

Mapping of the hake recruits obtained applying the indicator krigging technique with contouring that represents probability (in percentage) is reported in the Nursery section of this report.

### 8.8.3.2.3. Trends in abundance and biomass

Fishery independent information regarding the state of the hake in GSA 10 was derived from the international survey MEDITS. Figure 8.8.3.2.3.1 displays the estimated trend of hake abundance and biomass in GSA 10. Indices from Medits trawl-surveys show an increasing pattern in the last years, although variability is high (Fig. 8.8.3.2.3.1).

Fig. 8.8.3.2.3.1 Trends in survey abundance and biomass (mean and standard deviation) derived from Medits.

The re-estimated abundance and biomass indices (Figure 8.8.3.2.3.2) also reveal increasing trends since 2002. However, the recent high abundance and biomass indices are subject to high uncertainty.

Fig. 8.8.3.2.3.2 Abundance and biomass indices of hake in GSA 10.

Trends derived from the GRUND surveys are shown in Fig. 8.8.3.2.3.3. Abundance indices were significantly increasing ( $\mathrm{p}<0.05$ on ln-transformed data), as well as recruitment indices (Fig. 8.8.3.2.3.3) while biomass indices were almost stationary.

Fig. 8.8.3.2.3.3. Abundance and biomass indices of hake in GSA 10 derived from Grund surveys. Recruitment indices $\left(\mathrm{N} / \mathrm{km}^{2}\right)$ with standard deviation are also reported.

### 8.8.3.2.4. Trends in abundance by length or age

No trend in the mean length was observed in Medits survey (Fig. 8.8.3.2.4.1), nor at the third quantile lengths, as obtained from the length structures of Grund time series from 1994 to 2006 (Fig. 8.8.3.2.4.2).

Fig. 8.8.3.2.4.1 Mean length, variance and quantiles derived from the Medits length compositions in 19952007.

Fig. 8.8.3.2.4.2 III Quantile derived from the GRUND length structures in 1994-2006.

### 8.8.3.2.5. Trends in growth

No analyses were conducted.

No analyses were conducted.

### 8.8.4.Assessment of historic stock parameters

8.8.4.1. Method 1: Surba

### 8.8.4.1.1. Justification

Surba software was applied to both MEDITS and GRUND abundance estimates as described above.

### 8.8.4.1.2. Input parameters

The following growth parameters were used to split the LFD for the Surba analyses and to parameterize the Aladym model as well as Yield software: $\mathrm{L}_{\infty}=97.9 \mathrm{~cm}, \mathrm{~K}=0.135, \mathrm{t}_{0}=-0.4$; males: $\mathrm{L}_{\infty}=50.8 \mathrm{~cm}, \mathrm{~K}=0.25, \mathrm{t}_{0}=-$ 0.4 ; length-weight relationship: $a=0.00355, b=3.22$ for sex combined. Size at first maturity was put varying around 32 cm (maturity range 2 cm ), according to the maturity ogive derived in the area. Estimates of total mortality and recruitment from Surba were used to feed Aladym model, which routines re-estimated the total and fishing mortality using the whole information on the population parameters and exploitation pattern. The recruitment estimated by Surba was raised to the GSA area accounting for the q parameter adopted in the model parameterization for the first age group.

### 8.8.4.1.3. Results

Estimates of total mortality for sex combined from Surba were as follows:

| Year | $\begin{aligned} & \text { Original } \\ & \text { SSB } \quad \text { Z } \end{aligned}$ |  | SSB | Smoothed Z |
| :---: | :---: | :---: | :---: | :---: |
| 1994 | 1.208 | 1.536 | 1.153 | 1.508 |
| 1995 | 0.965 | 1.634 | 1.046 | 1.558 |
| 1996 | 1.202 | 1.81 | 1.035 | 1.623 |
| 1997 | 0.707 | 1.497 | 0.936 | 1.417 |
| 1998 | 0.888 | 1.096 | 0.954 | 1.432 |
| 1999 | 1.38 | 1.976 | 1.27 | 1.556 |
| 2000 | 1.21 | 1.731 | 1.174 | 1.737 |
| 2001 | 0.872 | 1.844 | 0.894 | 1.705 |
| 2002 | 0.544 | 1.078 | 0.682 | 1.402 |
| 2003 | 0.933 | 2.223 | 0.716 | 1.46 |
| 2004 | 0.725 | 1.327 | 0.926 | 1.579 |
| 2005 | 1.122 | 1.68 | 0.983 | 1.499 |
| 2006 | 0.968 | 2.253 | 1.065 | 1.675 |
| 2007 | 0.75 | 1.017 | 1.16 | 1.688 |
| 2008 | 1.526 NA |  | 1.004 | NA |

An average of the last two years was used for 2008.
The following vector of natural mortality estimated by Prodbiom method was applied in both models.

| Age | 0 | 1 | 2 | 3 | 4 | $5+$ |
| :--- | ---: | ---: | ---: | ---: | ---: | ---: |
| M | 0.85 | 0.46 | 0.37 | 0.33 | 0.31 | 0.29 |

The following q parameters were used to set Surba

| q | 0.9 | 1 | 1 | 0.75 | 0.5 | 0.5 |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- |

Surba rel.SSB

Fig. 8.8.4.1.3.1 Relative estimates of SSB from Surba, 1994-2008.

The abundance indices from trawl surveys showed an increasing pattern as well as those estimated using Surba, as showed in the figure below.

Fig. 8.8.4.1.3.2 Relative estimates of recruits from Surba, 1994-2008.

Other relevant results are showed in the following Fig. 8.8.4.1.3.3.

Fig. 8.8.4.1.3.3. Trends in various stock parameters as estimated by SURBA.

8.8.4.2. Method 2: Aladym

### 8.8.4.2.1. Justification

Aladym software was applied to both MEDITS and GRUND abundance estimates as described above.

### 8.8.4.2.2. Input parameters

The following growth parameters were used to split the LFD for the Surba analyses and to parameterize the Aladym model as well as Yield software: $\mathrm{L}_{\infty}=97.9 \mathrm{~cm}, \mathrm{~K}=0.135, \mathrm{t}_{0}=-0.4$; males: $\mathrm{L}_{\infty}=50.8 \mathrm{~cm}, \mathrm{~K}=0.25, \mathrm{t}_{0}=-$ 0.4 ; length-weight relationship: $a=0.00355, b=3.22$ for sex combined. Size at first maturity was put varying around 32 cm (maturity range 2 cm ), according to the maturity ogive derived in the area. Estimates of total
mortality and recruitment from Surba were used to feed Aladym model, which routines re-estimated the total and fishing mortality using the whole information on the population parameters and exploitation pattern. The recruitment estimated by Surba was raised to the GSA area accounting for the q parameter adopted in the model parameterization for the first age group.

In Aladym spawning was considered to occur along the year with peaks in winter and late spring that means peaks of recruitment occurring in spring and autumn months. The ratio between the month and the average year landing was used to tune the fishing mortality coefficient in Aladym. This was done for 2004-2006 and assumed similar in the previous and successive years. Selectivity of the fleet was simulated using an ogive ( $\mathrm{Lc}=12 \mathrm{~cm}$; selection range 3 cm ) coupled with a deselection ogive with $50 \%$ deselection size at 38 cm and a deselection range of 7 cm (Abella et al., 1997).

### 8.8.4.2.3. Results

Outcomes from Aladym converged with the Z estimates of Surba and yield simulated using Aladym well approximated the observed ones.
M. merluccius (2004-2007)

Fig. 8.8.4.2.3.1 Trend in landings and landings simulated by Aladym.

The state of the stock in relation to reference points was estimated using the software YIELD in an equilibrium condition using a point estimate of natural mortality of 0.35 .

Fig. 8.8.4.2.3.2 Trend in SSB in tons from Aladym simulations, 1994-2008.

Estimates of total mortality from SURBA and Aladym were converging, also a similar pattern was observed for the fishing mortality with difference in levels due to the age range considered.

Fig. 8.8.4.2.3.3. Comparison of Z and F estimates as derived from SURBA and Aladym.

### 8.8.5.Long term prediction

### 8.8.5.1. Justification

A yield per recruit analyses was conducted using the Yield software.

### 8.8.5.2. Input parameters

Like used in the Surba and Aladym assessments described above.

### 8.8.5.3. Results

Table 8.8.5.3.1 lists the reference points estimated from the yield per recruit analysis.

Table 8.8.5.3.1. Fisheries management reference values derived from yield per recruit analysis.

| Equilibrium <br> "Yield results" | F | $\mathrm{Y} / \mathrm{R}$ | $\mathrm{B} / \mathrm{R}$ | $\mathrm{SSB} / \mathrm{R}$ |
| :---: | :---: | :---: | :---: | :---: |
| $\mathrm{F}(0.1)$ | 0.244 | 0.615 | 2.643 | 1.619 |
| $\mathrm{~F}($ Max $)$ | 0.419 | 0.659 | 0.824 | 1.691 |
| F (Current) | 0.548 | 0.645 | 0.5 | 1.27 |

### 8.8.6.Scientific advice

### 8.8.6.1. Short term considerations

### 8.8.6.1.1. State of the spawning stock size

Survey indices indicate a variable pattern of abundance ( $\mathrm{n} / \mathrm{h}$ ) and biomass ( $\mathrm{kg} / \mathrm{h}$ ) without a clear trend. However, recent values are among the highest observed since 1994.
The hindcasting approach using Aladym model shows that the SSB was continously decreasing. A similar pattern shows also the spawning potential ratio that was in the range 6 and $4 \%$ from 1994 and 2008.

SGMED-09-02 is unable to interprete such different trends and thus unable to advice on the state of the spawning stock size, in particular due to a lack of a estimated management reference points.

No biomass reference points have been proposed for this stock. As a result, SGMED is unable to evaluate the status of the stock with respect to biomass.

### 8.8.6.1.2. State of recruitment

Recent recruitment since 2006 appears to be above average.

### 8.8.6.1.3. State of exploitation

Given the results of the present analysis, the stock appears overexploited. Considering the level of F estimated in 2008 by Aladym, i.e. 0.55, the stock appears overfished and a reduction of $55 \%$ would be necessary to reach $\mathrm{F}_{0.1}(0.244)$.

### 8.9. Stock assessment of hake in GSA 11

### 8.9.1.Stock identification and biological features

### 8.9.1.1. Stock Identification

This stock is assumed to be confined within the GSA boundaries, where it is distributed between 30 and 650 m of depth, with a peak in abundance (due to high number of recruits) over the continental shelf-break (between 150 and 250 m depth). The stock is mainly exploited by the local fishing fleet, although seasonally and occasionally some other Italian fleet use to fish in some areas. Spawning is taking place almost all year around, with a peak during winter -spring.

Juveniles showed a patchy distribution with some main density hot spots (nurseries) showing a high spatiotemporal persistence (Murenu et al., 2007) in western areas.

Fig. 8.9.1.1.1 Temporal persistence of hake nurseries calculated from data survey time-series density maps (1994-2006) of juveniles.

### 8.9.1.2. Growth

Data coming from LFDA hake showed a slow growth pattern both in male and female (Samed, 2002). A slower growth pattern for the GSA 11 hake population comes from otolith readings (DCR, 2008). New Von Bertalanffy Growth Function parameters have been calculated and used within this assessment. This is much in line with recent evidences that suggest a fast growing pattern hypothesis for hake either in the Western Mediterranean (Garcia-Rodriguez and Esteban, 2002; Jadaud et al., 2006; Piñeiro et al., 2007) or in the Bay of Biscay (De Pontual et al., 2003).

### 8.9.1.3. Maturity

Due to the well-known limited trawl nets catchability of hake spawners, the catch rate of mature specimens during the MEDITS survey was very low thus influencing the analysis to identify the pattern in gonad development as well as the growth rate and maturation processes relationship. The logistic model detect female length at first maturity at 36 cm . Although spawning off Sardinian coast (GSA 11) occurs nearly all over the year (Jan. to Sept.) the maturity peak is usually observed in winter (Feb.-May).

### 8.9.2.Fisheries

### 8.9.2.1. General description of fisheries

STECF in 2007 (stock review part II) noted that hake is one of the most important commercial species in the Sardinian seas. In this area, the biology and population dynamics have been studied intensively in the past fifteen years.
Although hake is not a target of a specific fishery, such as deep red shrimp, it is the third species in terms of biomass landed in GSA 11 (Murenu M., pers. com.). In the GSA 11 hake is caught exclusively by a mixed bottom trawl fishery at depth between 50 and 600 m . No gillnet or longline fleets target on this species. Although different nets are used in shallow, mid and deep water ("terra" mainly targeting Mullus spp., "mezzo fondo" targeting fish and "fondale" net targeting deep shrimp) the main trawl used is an "Italian trawl net" type with a low vertical opening ( $\max$ up to 1.5 m ). The dimensions change in relation to the trawlers engine power.
Important by catch species are horned octopus, squids, poor cod, shortnose greeneye, greater forkbeard and deep-water pink shrimp.

Detailed maps of the trawlers fishing-grounds are reported in Murenu et al. (2006). Most of the GSA effort is concentrated within a relative short radius around the major fishing ports (Cagliari, Alghero, Porto Torres, La Caletta, Sant'antioco, Oristano, Alghero). However some big trawlers seasonally move in different fishing grounds far from the usual ports.

From 1994 to 2004, in GSA 11, the trawl fleet remarkably changed. The change mostly consisted of a general increase in the number of vessels and by the replacement of the old, low tonnage wooden boats by larger steel boats. For the entire GSA an increase of $85 \%$ for boats $>70$ Tons class occurred. A decrease of $20 \%$ for the smaller boats ( $<30$ GRT) was also observed.

As in other areas of the Mediterranean, the stock management is based on control of fishing capacity (licenses), fishing effort (fishing activity), technical measures (mesh size and area closures), and minimum landing sizes (EC 1967/06).
Two small closed areas were also established along the mainland (west and east coast respectively), although these are defined to mainly protect Norwegian lobster. Since 1991, a fishing closure for 45 trawling days has been enforced (month and year are reported on the following figure) almost every year. Red points means no closing measure adopted).

Towed gears are not allowed within three nautical miles from the coast or at depths less than 50 m when this depth is reached at a distance less than 3 miles from the coast.

### 8.9.2.3. Catches

### 8.9.2.3.1. Landings

SGMED-09-02 received Italian landings data for GSA 11 by major fishing gears which are listed in Tab. 8.9.2.3.1.1. Since 2002, landings increased from 360 t to 930 t in 2005 and decreased to 340 t in 2008 (Fig. 8.9.2.3.1.1). Landings are dominated by demersal trawl fisheries (DTS, OTB and partially PMP). The data are listed in Table A3.1 of Appendix 3.

Tab. 8.9.2.3.1.1 Landings (t) by year and major gear types, 2002-2008 as reported through DCR.

| FT_LVL4 | 2002 | 2003 | 2004 | 2005 | 2006 | 2007 | 2006 |
| :--- | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| DTS | 167 | 592 |  |  |  |  |  |

| total landings | 361 | 697 | 711 | 928 | 824 | 550 | 340 |
| (all gears) |  |  |  |  |  |  |  |

Fig. 8.9.2.3.1.1 Landings (t) by year and major gear types, 2002-2007 as reported through DCR.

### 8.9.2.3.2. Discards

Discards reported to SGMED-09-02 sum 15 t and 63 t in 2005 (long-lines) and 2006 (trawlers) respectively. The data are listed in Table A 3.9 of Appendix 3.

### 8.9.2.3.3. Fishing effort

The trends in fishing effort by year and major gear type is listed in Tab. 8.9.2.3.3.1 and shown in Fig. 8.9.2.3.3.1 in terms of kW *days.

Taking into account that landing of hake are mostly from trawler and trawl net are one of the gears for the polyvalent segments, the trend of fishing effort by trawler would be read as stable, i.e. matching the same pattern of the total fishing effort.

Tab. 8.9.2.3.3.1 Trend in fishing effort ( $k W^{*}$ days) for Italy by major gear types, 2002-2007. No values were reported for 2008.

### 8.9.3.Scientific surveys

### 8.9.3.1. MEDITS

### 8.9.3.1.1. Methods

Since 1994 the Medits trawl surveys have been yearly carried out between May and July (except in 2007). According to the MEDITS protocol (Relini, 2000; Bertand et al., 2002) a stratified random sampling design with allocation of hauls proportional to depth strata extension (depth strata: $10-50 \mathrm{~m}, 51-100 \mathrm{~m}, 101-200 \mathrm{~m}$, $201-500 \mathrm{~m}, 501-800 \mathrm{~m}$ ) was adopted. A specific gear (GOC 73, with a 20 mm stretched mesh size in the cod-end) was always used following the instruction stated and reported in Dremière and Fiorentini (1996).

Based on the DCR data call, abundance and biomass indices were recalculated. In GSA 11 the following number of hauls was reported per depth stratum (s. Tab. 8.9.3.1.1.1).

Tab. 8.9.3.1.1.1. Number of hauls per year and depth stratum in GSA 11, 1994-2008.

| STRATUM | 1994 | 1995 | 1996 | 1997 | 1998 | 1999 | 2000 | 2001 | 2002 | 2003 | 2004 | 2005 | 2006 | 2007 | 2008 |
| :--- | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| GSA11_010-050 | 17 | 19 | 21 | 21 | 21 | 21 | 19 | 18 | 20 | 18 | 17 | 17 | 19 | 19 | 17 |
| GSA11_050-100 | 27 | 21 | 22 | 22 | 20 | 22 | 22 | 24 | 19 | 19 | 18 | 21 | 18 | 20 | 19 |
| GSA11_100-200 | 22 | 23 | 30 | 31 | 31 | 30 | 31 | 30 | 24 | 24 | 24 | 24 | 24 | 24 | 22 |
| GSA11_200-500 | 35 | 29 | 29 | 26 | 25 | 27 | 24 | 25 | 20 | 24 | 21 | 20 | 20 | 20 | 21 |
| GSA11_500-800 | 23 | 16 | 21 | 25 | 25 | 24 | 27 | 26 | 16 | 14 | 15 | 14 | 16 | 17 | 16 |

Data were assigned to strata based upon the shooting position and average depth (between shooting and hauling depth). Few obvious data errors were corrected. Catches by haul were standardized to 60 minutes hauling duration. Hauls noted as valid were used only, including stations with no catches of hake, red mullet or pink shrimp (zero catches are included).
The abundance and biomass indices by GSA were calculated through stratified means (Cochran, 1953; Saville, 1977). This implies weighting of the average values of the individual standardized catches and the variation of each stratum by the respective stratum areas in each GSA:
$\mathrm{Yst}=\Sigma\left(\mathrm{Yi}^{*} \mathrm{Ai}\right) / \mathrm{A}$

$$
\mathrm{V}(\mathrm{Yst})=\Sigma\left(\mathrm{Ai}^{2} * \mathrm{si}^{2} / \mathrm{ni}\right) / \mathrm{A}^{2}
$$

Where:
$\mathrm{A}=$ total survey area
$\mathrm{Ai}=$ area of the i -th stratum
$s i=s t a n d a r d$ deviation of the i-th stratum
ni=number of valid hauls of the i-th stratum
$\mathrm{n}=$ number of hauls in the GSA
$\mathrm{Yi}=$ mean of the i-th stratum
Yst=stratified mean abundance
$\mathrm{V}(\mathrm{Yst})=$ variance of the stratified mean
The variation of the stratified mean is then expressed as the $95 \%$ confidence interval: Confidence interval $=$ Yst $\pm \mathrm{t}$ (student distribution) $* \mathrm{~V}(\mathrm{Yst}) / \mathrm{n}$

It was noted that while this is a standard approach, the calculation may be biased due to the assumptions over zero catch stations, and hence assumptions over the distribution of data. A normal distribution is often assumed, whereas data may be better described by a delta-distribution, quasi-poisson. Indeed, data may be better modelled using the idea of conditionality and the negative binomial (e.g. O'Brien et al. (2004)).

Length distributions represented an aggregation (sum) of all standardized length frequencies (subsamples raised to standardized haul abundance per hour) over the stations of each stratum. Aggregated length frequencies were then raised to stratum abundance * 100 (because of low numbers in most strata) and finally aggregated (sum) over the strata to the GSA. Given the sheer number of plots generated, these distributions are not presented in this report.

### 8.9.3.1.2. Geographical distribution patterns

The spatial structure of European hake has been described by modelling the spatial correlation structure of the abundance indices through geostatistical techniques (i.e. kriging). In different studies either total abundance index or abundances of recruits and adults were analysed (Murenu et al., 2007).
On average, considering the analyzed distributions (years 1994-2005), the recruits are individual smaller than $12.3 \mathrm{~cm}( \pm 1.41)$. These individual are belonging to the age 0 group. Persistence of the nursery areas along the years was studied by applying indicator kriging technique (Journel 1983, Goovaerts, 1997) to abundance estimations of recruits (Murenu et al., 2008). Main results and maps are reported in the "nursery section" of this report.

### 8.9.3.1.3. Trends in abundance and biomass

Fishery independent information regarding the state of the hake in GSA 11 was derived from the international survey MEDITS. Figure 8.9.3.1.3.1 displays the estimated trend in hake abundance and biomass in GSA 11.

The estimated abundance and biomass indices since 2000 show high variation without any trend.

Fig. 8.9.3.1.3.1 Abundance and biomass indices of hake in GSA 11.

### 8.9.3.1.4. Trends in abundance by length or age

The following Fig. 8.9.3.1.4.1 and 2 display the stratified abundance indices of GSA 11 in 1994-2001 and 2002-2008 respectively.

Fig. 8.9.3.1.4.1 Stratified abundance indices by size, 1994-2001.

Fig. 8.9.3.1.4.2 Stratified abundance indices by size, 2002-2008.

### 8.9.3.1.5. Trends in growth

No analyses were conducted.

### 8.9.3.1.6. Trends in maturity

No analyses were conducted.

### 8.9.4.Assessment of historic stock parameters

### 8.9.4.1. Method 1: SURBA

### 8.9.4.1.1. Justification

The SURBA analyses was applied to the MEDITS survey estimates.

### 8.9.4.1.2. Input parameters

Data from trawl surveys (time series of Medits from 1994 to 2008) and effort and landings data from DCR have been used for the analysis. The SURBA software package (Needle, 2003) lets to take advantage of the trawl surveys data time series available from the Medits research program. Using the software the evolution of fishing mortality rates of hake in the GSA 11 was reconstruct starting from the analysis of the length frequency distribution (LFD).
The LFDs were converted in numbers by age group using the subroutine "age slicing" as implemented in the software package LFDA (Kirkwood et al., 2001). Moreover the VBGF parameters used to split the LFD are: $\mathrm{L}_{\infty}=97.15 \mathrm{~cm}, \mathrm{~K}=0.165, \mathrm{t}_{0}=0.03$.
According to the Prodbiom approach by Caddy and Abella (1999), a vectorial natural mortality at age was computed for the stock analysis (Tab. 8.9.4.1.2.1).
Guess estimates of catchability by age are given in Tab. 8.9.4.1.2.1.
Tab. 8.9.4.1.2.1 Input parameters used in the SURBA analysis (sex combined) in the (GSA11).

| VBGF | $\mathrm{L}_{\infty}=97.15 \mathrm{~cm}, \mathrm{~K}=0.165, \mathrm{t}_{0}=-0.03$ |
| :--- | :--- |
| M vector | $\mathrm{Age}_{1}=1.11, \mathrm{Age}_{2}=0.51, \mathrm{Age}_{3}=0.40, \mathrm{Age}_{4}=0.35, \mathrm{Age}_{5}=0.33$ |
| Catchability $(\mathrm{q})$ | $\mathrm{q}_{1}=0.9, \mathrm{q}_{2-3}=1.0, \mathrm{q}_{4}=0.75, \mathrm{q}_{5}=0.55$ |
| Length at maturity $\left(\mathrm{L}_{50}\right)$ | $36 \mathrm{~cm}($ sex combined $)$ |

### 8.9.4.1.3. Results

Estimates of total mortality for sex combined from Surba were as follows:

Fig. 8.9.4.1.3.1 Total mortalities estimated by SURBA using trawl surveys age composition (MEDITS).

Trends in estimated fishing mortalities are plotted in Fig. 8.9.4.1.3.2.

Fig. 8.9.4.1.3.2 Fishing mortalities estimated by SURBA using trawl surveys age composition (MEDITS).

Fig. 8.9.4.1.3.3 SSB trend estimated by SURBA using trawl surveys age composition (MEDITS).

Relative indices estimated by SURBA indicated very high fluctuations of recruitment in the period 19942008, without a clear temporal pattern.

Fig. 8.9.4.1.3.4 Recruitment trend estimated by SURBA using trawl surveys age composition (MEDITS).

Fig. 8.9.4.1.3.5 Estimates of stock parameters derived from SURBA.

Fig. 8.9.4.1.3.6 Estimates of total and fishing mortality from SURBA.
Estimates of total and fishing mortality from SURBA showed a similar oscillatory pattern, increasing in the last years.

### 8.9.5.Long term prediction

### 8.9.5.1. Justification

State of the stock in relation to reference points was estimated using Yield software (Hoggarth et al., 2006).

### 8.9.5.2. Input parameters

See chapter 8.9.4.1.2.

### 8.9.5.3. Results

$\mathrm{F}_{0.1}$ was assumed as target reference point. $\mathrm{F}_{\text {max }}$ and $\mathrm{F}_{\text {ref }}$ were considered as limit reference points. $\mathrm{F}_{\text {ref }}$ match to F where the ratio SSB /initial SSB is equal to 0.30 . The following mean values were obtained: $\mathrm{F}_{\max }=0.25$; $\mathrm{F}_{0.1}=0.17$ and $\mathrm{F}_{\mathrm{ref}}=0.21$.

### 8.9.6.Scientific advice

### 8.9.6.1. Short term considerations

### 8.9.6.1.1. State of the spawning stock size

SGMED-09-02 could not estimate the absolute levels of stock abundance. Survey abundance ( $\mathrm{n} / \mathrm{km}^{2}$ ) and biomass $\left(\mathrm{kg} / \mathrm{km}^{2}\right)$ indices do not indicate a significant trend. The stock SSB is more variable over the last decade.

No biomass reference points have been proposed for this stock. As a result, SGMED is unable to evaluate the status of the stock with respect to biomass.

### 8.9.6.1.2. State of recruitment

SGMED-09-02 could not estimate the absolute levels of recruitment. Relative indices estimated by SURBA indicated very high fluctuations of recruitment in the period 1994-2008, without a clear temporal pattern.

### 8.9.6.1.3. State of exploitation

Trends in the average fishing mortality over ages 1 to 3 derived from MEDITS surveys ranged from 1 to 2.3, with the highest value observed in the last year. SGMED notes that the current F is far in excess of the proposed target reference point $\mathrm{F}_{0.1}$. Assuming similar selection patters of the survey and the commercial fishery, SGMED concludes that the stock is heavily overfished.

### 8.10. Stock assessment of hake in GSAs 15 and 16

### 8.10.1. Stock identification and biological features

### 8.10.1.1.Stock Identification

The stock structure of hake in the Strait of Sicily is not well known. Levi et al. (1994) compared the growth of $M$. merluccius in Mediterranean and found quite a similar pattern in individuals from the Northern side of the Strait of Sicily (GSAs 15 and 16) and those caught in the Gulf of Gabes (GSA 14). Lo Brutto et al. (1998) have also found no evident of genetic subdivisions or significant differences in allelic frequencies, between samples near Sicily and those from the mid-line. More recently Levi et al. (2004) applied electrophoretic, morphometric and growth analyses to test the hypothesis of the existence of a unique stock of hake in the Sicily channel, which includes part of the North African continental shelf off the Tunisian coast and the shelf off the southern Sicilian coast. Although the level of genetic variation detected at five selected sampling sites was very low, morphometric analyses and otolith readings revealed some significant differences at phenotypic level, mainly in females. On the basis of the spatial distribution of spawning and nursery areas compared with the current patterns in the Strait of Sicily, Camilleri et al., (in press) believed the existence of genetic exchange between hake sub-populations inhabiting GSAs 15 and 16. In consequence it was decided to perform a common assessment for hake in GSA 15 and 16.

Despite very small specimens of 3.5 cm TL (Sinacori G., pers. com.) were caught during fine mesh trawl surveys, hake is considered fully recruited to grounds at 10 cm TL (SAMED, 2002). Differently to other areas of the Mediterranean, where two main recruitment pulses are known (Orsi Relini et al., 2002), the analysis of the length frequency distribution through year suggest that in GSA 15 and 16 recruits reach grounds all year round (SAMED, 2002).

Fig. 8.10.1.1.1 Areas showing stable presence of recruits of M. merluccius between 1994 and 1999 in GSA 15 and 16, excluding the Maltese Fisheries Management Zone (FMZ). The index of persistence ranges between 0 and 1 , where 1 indicates stable nursery and 0 absence of nursery (modified from Fiorentino et al., 2003b).

In the northern sector of the Strait of Sicily (GSA 15 and 16), although some inter-annual variability in the nurseries distribution was evident, two stable areas for hake were identified, which are related with the
presence of meso-scale oceanographical processes. These nurseries were located on the eastern side of the Adventure and Malta banks, between 100 and 200 m depth (Fig. 8.10.1.1.1).

On the basis of trawl surveys carried out in the northern side of the Strait (GSA $15 \& 16$ ) sex ratio is around 0.5 between 12 and 24 cm TL, while females prevail on males mainly at larger sizes ( $\mathrm{SR} \geq 0.90$ after 36 cm TL) (SAMED, 2002). In GSA 16 sex ratio shows a significant decrease ( $\mathrm{r}_{\mathrm{s}}=-0.673$ ) with time, showing a reduction of females in the population since 1994 (Fiorentino et al., 2005).

A study by Andaloro et al., (1985) in the Strait of Sicily found that hake's diet varied according to size. Smallest fish of 4.5-12 cm TL feed mainly on Euphausiacea. Decapods are the main preys of hake between 13 and 24 cm TL, while fish is the preferred food of individuals larger than 25 cm TL. Similar feeding behaviour that varied with size has also been observed for other areas in the Mediterranean (see Colloca, 1999).

### 8.10.1.2.Growth

Considering the northern sector of the Strait of Sicily (GSA 15 and 16) the observed maximum length is 88 cm TL in females (Fiorentino et al., 2003a) and 53 cm TL in males (Sinacori G., pers. com.). According to Fiorentino et al. (2003a), the maximum estimated age in years in the exploited standing stock, resulted to be 15 years. This was established by thin section otolith lectures of largest females collected in trawl surveys for over 15 years. On the basis of comparison of results produced by different methods to estimate natural mortality (Chen \& Watanabe; Beverton \& Holt Invariants, Alagaraya), $\mathrm{M}=0.34$ in females and $\mathrm{M}=0.43$ in males were proposed as reference values for stock assessment purposes (SAMED, 2002).

With the exception of Andaloro et al. (1985), hake showed similar growth patterns in populations inhabiting the Strait of Sicily and the adjacent seas. Excluding the values given by Andaloro et al. (1985), the mean growth rates per month during the first two years range between 0.92 and 1.1 cm in females and 0.86 and 1.0 cm in males. These rates are compatible with those reported for juvenile hake in the Mediterranean by Fiorentino et al. (2000). The growth parameters were reported in Table 7.10.1.2.1.

Tab. 8.10.1.2.1 Von Bertalanffy growth function ( $\mathrm{cm} ; \mathrm{y}$ ) and length-weight relationship ( $\mathrm{cm} ; \mathrm{g}$ ) parameters in GSA 16.

|  | Sex | Linf | K | $\mathrm{t}_{0}$ | a | b |

| CNR_IAMC; <br> 2007 | Females | 81.54 | 0.15 | -0.08 | 0.0043 | 3.1525 |
|  | Males | 53.58 | 0.22 | -0.13 | 0.0049 | 3.1028 |

### 8.10.1.3.Maturity

Although spawning off Tunisia (GSA 12) occurs all over the year, Bouhlel (1973) reported three maturity peaks, in summer, winter and spring depending to the size of females. The largest females (LT> 40 cm ) spawn mainly in spring, while the smallest $(29<T L<39 \mathrm{~cm})$ have two main spawning peaks one in summer and another one in winter. Bouaziz et al. (1998), studied samples from Bou-Ismail (GSA 4), reported that the spawning season runs throughout the whole year, even if a peak in summer is evident. According to Levi (1991), in GSA 15 and 16 mature specimens were collected both in autumn (November) and winter (February). Information on the northern sector of the Strait of Sicily (GSA 16) show that outer shelf on the western side of Adventure Bank might be a relevant spawning area (Fiorentino et al., 2006). According to literature spawning should occur in the outer shelf-upper slope. Aggregation of mature adults was reported between 100 and 200 m in the Gulf of Tunis (Bouhlel, 1973).
The parameters of maturity ogive were: L50\% of 35.6 cm TL and 0.29 the corresponding slope in females, L50\% of 24.6 cm TL and 0.23 the corresponding slope in males (CNR_IAMC, 2007).

### 8.10.2.1.General description of fisheries

Although hake is not a target of a specific fishery, such as deep water pink shrimp and striped mullet, it is the third species in terms of biomass which is landed in GSA 16 (Fiorentino et al., 2005). Hake is caught by trawling in a wide depth range ( $50-500 \mathrm{~m}$ ) together with other important species such as Nephrops norvegicus, Parapenaeus longirostris, Eledone spp., Illex coindetii, Todaropsis eblanae, Lophius spp., Mullus spp., Pagellus spp., Zeus faber, Raja spp. among others. In the northern sector of the Strait of Sicily (GSA 15 and 16) although hake is fished by long lines and gill-net (Gangitano et al., 2007) more than 95\% of the catches are obtained by bottom trawling.

A rough delimitation of the most important commercial macro-areas for a large part of the Strait of Sicily is reported in Andaloro (1996). Main fishing-grounds, species caught, fishing periods and other relevant information of the Mazara distant trawl fleet fishing for hake in the Strait of Sicily are reported in Fiorentino et al. (2007). Very detailed maps of the trawling grounds for Maltese Fisheries Management Zone (FMZ), including a wide part of GSA 15 are available (Camilleri et al., in press). Most of the Maltese effort of bottom longlining and trammel netting is concentrated within a short radius around the major fishing ports with large areas being slightly exploited (Camilleri et al., in press).

The Italian and Maltese trawlers operating in the Strait of Sicily use the same typology of trawl net called "Italian trawl net". Although some differences in material between the net used in shallow waters ("banco" net, mainly targeted to shelf fish and cephalopods) and that employed in deeper ones ("fondale" net, mainly targeted to deep water crustaceans) exist, the Italian trawl net is characterized by a low vertical opening (up to 1.5 m ) with dimensions changing with engine power (Fiorentino et al., 2003a).
8.10.2.2. Management regulations applicable in 2008 and 2009

At present there are no formal management objectives for hake fisheries in the Strait of Sicily. As in other areas of the Mediterranean, the stock management is based on control of fishing capacity (licenses), fishing effort (fishing activity), technical measures (mesh size and area closures), and minimum landing sizes (EC 1967/06).

In order to limit the over-capacity of fishing fleet, the Italian fishing licenses have been fixed since the late eighties. After 2000, in agreement with the European Common Policy of Fisheries, a gradual decreasing of the fleet capacity is occurring. Furthermore from 1987 to 2005 a $30-45$ days stopping of fishing activities was enforced each year, although in different ways, in order to reduce fishing effort. However this measure is considered less effective in order to protect hake juveniles. In Malta the trawling fleet has been stable since the early 2000 with 16 trawlers having a license to fish. Unfortunately in 2008 due to a reduction in capacity of other fleets 8 new trawl licenses will be issued that will increase the trawl capacity for Malta by $50 \%$.

The new regulation EC 1967 of 21 December 2006 fixed a minimum mesh size of 40 mm for bottom trawling of EU fishing vessels (Italian and Maltese trawlers). The mesh has to be modified in square 40 mm or diamond 50 mm after July 2008, however derogations are possible up to 2010.

A further and more effective improvement in the exploitation pattern of hake might be obtained through an integrative technical measure having a similar effect to the increasing of mesh size, i.e. the protection of hake nurseries. Differently from red mullet, whose nurseries are in the already protected bottoms within three nautical miles from the coast, the location of hake nurseries are on discrete off-shore areas on the outer shelf (100-200 m) and in international waters making the possibility of protecting the nursery areas a difficult task especially with respect to enforcement (see Fig. 8.10.1.1.1).

It must be outlined the existence in the Strait of Sicily of the Maltese FMZ which extends up to 25 nautical miles from baselines around the Maltese islands, where fisheries are specifically managed on the basis of capacity control (EC 813/04; EC 1967/06).

The access of Community vessels to the waters and resources in the FMZ is regulated as follows:
(a) fishing within the management zone is limited to fishing vessels smaller than 12 metres overall length using other than towed gears and;
(b) the total fishing effort of those vessels, expressed in terms of the overall fishing capacity, does not exceed the average level observed in 2000-2001 that corresponds to 1950 vessels with an overall engine power and tonnage of 83000 kW and 4035 GT respectively.

Trawlers not exceeding an overall length of 24 metres are authorised to fish in certain areas within the management zone. The overall fishing capacity of the trawlers allowed to operate in the management zone must not exceed the ceiling of 4800 kW and the fishing capacity of any trawler authorised to operate at a depth of less than 200 metres must not exceed 185 kW . Trawlers fishing in the management zone hold a special fishing permit in accordance with Article 7 of Regulation (EC) No 1627/94 and are included in a list containing their external marking and vessel's Community fleet register number (CFR) to be provided to the Commission annually by the Member States concerned.

### 8.10.2.3.Catches

### 8.10.2.3.1. Landings

The most recent Italian and Maltese data were collected within the framework of the DCR. Available information is considered feasible by the experts attending the working group. Andreoli et al. (1995) estimated yield of hake landed by trawling with 1-2 day trip of commercial fisheries of southern coasts of Sicily (GSA 15 and 16) in the middle eighties. Between April 1985 and March 1986 landing was about 1440 tons; the next year it amounted to 1,238 tons.

Tab. 8.10.2.3.1.1 Landings ( t ) of hake by fishing technique by the Sicilian (ITA) and Maltese (MLT) fleets (DTS = demersal trawl; HOK = gears using hooks; PGP = polyvalent passive gears; PMP = combining mobile and passive gears; PTS = pelagic trawl). Landings data provided for the years 2002 and 2003, must have a mistake in the units used.

Considering that overall yield of trawling was about 9,666 tons in 2006 and 8,052 tons in 2007, hake landings representing about $14-15 \%$ of total yield in the area. On the basis of 2008 data, about $98 \%$ of Sicilian landings are due to trawling (Table 8.10.2.3.1.1). Furthermore, hake yield corresponded to less than $10 \%$ of the whole demersal landing of Sicilian fisheries in the Strait of Sicily. To note that landings of hake
in the Sicilian ports do not derive solely from GSA 16 but from GSA 15 and 16 with some catches also from other GSAs in the Strait of Sicily.

The Maltese hake yield decreased from 10 t in 1985 to about 1 t in 1992; the following years it fluctuated around 5 t . This reduction could be partially explained by the reduction in the amount of trawlers during the 1980s and a change in target species of the remaining trawlers, which fished mainly for red shrimps from the mid nineties onwards.

Total annual landings are shown in Fig. 8.10.2.3.1.1 IREPA source. The data as reported through the DCF data call are listed in Table A3.1 of Appendix 3.

Fig. 8.10.2.3.1.1 The Italian hake yield in GSA 15 and 16 (IREPA source).

Fig. 8.10.2.3.1.2 The Maltese hake yield (GSA 15; all gears combined).
As the length compositions of landing concerns, information is available only for the Sicilian vessels. Data were considered representative since the $3^{\text {rd }}$ quarter of 2005 , when a sampling scheme allowing a realistic raising of the sampled catches to the total ones was adopted (SIBM, 2005).

Fig. 8.10.2.3.1.3 Yearly length structure of hake landings by sex in absolute numbers of Sicilian trawlers in 2006 (GSA 15 and 16).

Fig. 8.10.2.3.1.4 Yearly length structure of hake landings by sex in absolute numbers of Sicilian trawlers in 2007 (GSA 15 and 16).

### 8.10.2.3.2. Discards

In the late nineties Sicilian trawlers fishing off-shore ( $15-25$ days of trip) had higher discard rates of hake ( $86 \%$ in number and $31 \%$ in weight) than the inshore trawlers (1-2 days trips) ( $32 \%$ in number and $9 \%$ in weight) (Anon., 2000). For distant fisheries the first modal group ( $10-12 \mathrm{~cm}$ ) in the catches was totally discarded. This is due to the intensive use of the working time and the space in the cold cellar for high prised crustaceans. Conversely trawlers operating in coastal waters tend to reduce the discarded fraction to the smallest specimens of the first age group present in the catches.

More recent data, collected within the framework of DCR, showed that discarded fraction of undersized hakes by Sicilian trawlers seems to decrease ( $13 \%$ in number and $3 \%$ in weight in 2006), amounting to about 48 tons in 2008. The mean size of the discarded hakes varies according to the season. During 2006 the length at $50 \%$ discard of the Sicilian trawlers ranged between 12.9 (summer and autumn) and 15.0 (spring) cm TL, being 13.5 cm TL the yearly value (Gancitano V., pers. comm.).

Annual discards are listed in Table A3.9 of Appendix 3.

### 8.10.2.3.3. Fishing effort

The trend in fishing effort by year and major gear type is listed in Tab. 8.10.2.3.3.1. The data are listed in Tables A3.10-A3.12 of Appendix 3.

Tab. 8.10.2.3.3.1 Trend in annual effort (days at sea, GT*days, $\mathrm{kW}^{*}$ days) by country and gears in GSAs 15 and 16, 2002-2008.

### 8.10.3.Scientific surveys

### 8.10.3.1.Medits

### 8.10.3.1.1. Methods

Based on the DCR data call, abundance and biomass indices were recalculated. In GSAs 15 and 16 the following number of hauls was reported per depth stratum (s. Tab. 8.10.3.1.1.1).

Tab. 8.10.3.1.1.1. Number of hauls per year and depth stratum in GSAs 15 and 16, 1994-2008.

| STRATUM | 1994 | 1995 | 1996 | 1997 | 1998 | 1999 | 2000 | 2001 | 2002 | 2003 | 2004 | 2005 | 2006 | 2007 | 2008 |

Data were assigned to strata based upon the shooting position and average depth (between shooting and hauling depth). Few obvious data errors were corrected. Catches by haul were standardized to 60 minutes hauling duration. Hauls noted as valid were used only, including stations with no catches of hake, red mullet or pink shrimp (zero catches are included).

The abundance and biomass indices by GSA were calculated through stratified means (Cochran, 1953; Saville, 1977). This implies weighting of the average values of the individual standardized catches and the variation of each stratum by the respective stratum areas in each GSA:
$\mathrm{Yst}=\Sigma\left(\mathrm{Yi}^{*}{ }^{*} \mathrm{Ai}\right) / \mathrm{A}$
$\mathrm{V}(\mathrm{Yst})=\Sigma\left(\mathrm{Ai}^{2} * \mathrm{si}^{2} / \mathrm{ni}\right) / \mathrm{A}^{2}$
Where:
$\mathrm{A}=$ total survey area
Ai=area of the i-th stratum
si=standard deviation of the i-th stratum
ni=number of valid hauls of the $i$-th stratum
$\mathrm{n}=$ number of hauls in the GSA
$\mathrm{Yi}=$ mean of the i -th stratum
Yst=stratified mean abundance
$\mathrm{V}(\mathrm{Yst})=$ variance of the stratified mean
The variation of the stratified mean is then expressed as the $95 \%$ confidence interval: Confidence interval $=$ Yst $\pm \mathrm{t}$ (student distribution) $* \mathrm{~V}(\mathrm{Yst}) / \mathrm{n}$

It was noted that while this is a standard approach, the calculation may be biased due to the assumptions over zero catch stations, and hence assumptions over the distribution of data. A normal distribution is often assumed, whereas data may be better described by a delta-distribution, quasi-poisson. Indeed, data may be better modelled using the idea of conditionality and the negative binomial (e.g. O'Brien et al. (2004)).

Length distributions represented an aggregation (sum) of all standardized length frequencies (subsamples raised to standardized haul abundance per hour) over the stations of each stratum. Aggregated length frequencies were then raised to stratum abundance * 100 (because of low numbers in most strata) and finally aggregated (sum) over the strata to the GSA. Given the sheer number of plots generated, these distributions are not presented in this report.

### 8.10.3.1.2. Geographical distribution patterns

No analyses were conducted during SGMED-09-02.

### 8.10.3.1.3. Trends in abundance and biomass

The trend in abundance and biomass as re-estimated by SGMED-09-02 are shown in Figures 8.10.3.1.3.4 and 8.10.3.1.3.5 for GSAs 15 and 16. While the trend in GSA 15 is quite short, recent abundance and biomass indices (2005-2008) in GSA 16 appear at the highest level observed since 1994. Such analyses of Medits indices are considered preliminary.

Fig. 8.10.3.1.3.4 Abundance and biomass indices of hake in GSA 15.

Fig. 8.10.3.1.3.5 Abundance and biomass indices of hake in GSA 16.

### 8.10.3.1.4. Trends in abundance by length or age

The following Fig. 8.10.3.1.4.1 displays the stratified abundance indices of GSA 15 in 2002-2008. These size compositions are considered preliminary.

The Figures 8.10.3.1.4.2 and 7.10.3.1.4.3 display the stratified abundance indices of GSA 16 in 1994-2001 and 2002-2008. These size compositions are considered preliminary.

Fig. 8.10.3.1.4.1 Stratified abundance indices by size in GSA 15, 2002-2008.

Fig. 8.10.3.1.4.2 Stratified abundance indices by size in GSA 16, 1994-2001.

Fig. 8.10.3.1.4.3 Stratified abundance indices by size in GSA 16, 2002-2008.

### 8.10.3.1.5. Trends in growth

No analyses were conducted during SGMED-09-02.

### 8.10.3.1.6. Trends in maturity

No analyses were conducted during SGMED--09-02.

SGMED 09-02 did not undertake any analytical assessment of hake in GSAs 15 and 16. Last year's assessments using Trends in LPUE, SURBA and VIT can be found in the report of SGMED-08-04 working group (Cardinale et al., 2008).
8.10.5. Long term prediction
8.10.5.1.Justification

No forecast analyses were conducted.

### 8.10.5.2.Input parameters

No forecast analyses were conducted.

### 8.10.5.3.Results

Given the state of the data and analyses SGMED-09-02 is not in the position to provide a long term prediction of catch and stock biomass for hake in GSAs 15 and 16.
8.10.6. Scientific advice

### 8.10.6.1.Short term considerations

### 8.10.6.1.1. State of the spawning stock size

The last updated information regarding the state of spawning stock for hake in GSAs 15 and 16 can be found in the last year's report of SGMED-08-04 working group (Cardinale et al., 2008).

### 8.10.6.1.2. State of recruitment

SGMED-09-02 is unable to provide any scientific advice of the state of the recruitment given the preliminary state of the data and analyses.

### 8.10.6.1.3. State of exploitation

The last updated information regarding the state of exploitation for hake in GSAs 15 and 16 can be found in the last year's report of SGMED-08-04 working group (Cardinale et al., 2008).

### 8.11. Stock assessment of hake in GSA 17

### 8.11.1.Stock identification and biological features

### 8.11.1.1.Stock Identification

The distribution of hake (Merluccius merluccius) in GSA 17, in spring-summer, is shown in the maps below, imported from Sabatella and Piccinetti (2004). The picture on the left provides details on the depth, increasing with darker colour ( $0-50,50-100,100-200,200-800,>800 \mathrm{~m}$ ). The picture on the right displays the hake densities at sea from MEDITS trawl survey in the second half of the 1990s, expressed as number of individuals per square kilometre. In the GSA 17, higher densities are observed in the southern part and at depths between 100 and 200 m .

In the subsequent three maps, again imported from Sabatella and Piccinetti (2004), densities at sea are plotted taking into account different length ranges (increasing in the maps from left to right). In particular, individuals with length lower than 12 cm are concentrated in the southern part of the GSA 17. The individuals with length between 12 and 20 cm display the same pattern but are more diffuse; the same holds true for the individuals with length higher than 20 cm , but they are more abundant on the eastern side of Adriatic.

Spawning of hake occurs throughout the year with two peaks in winter and summer. Earliest spawning occurs in winter in deeper waters, up to 200 m , in the Pomo/Jabuka Pit (where the greatest depths in GSA 17 are observed). In the summer period, spawning occurs in shallower waters. Nursery areas are located close just to the Pomo/Jabuka Pit (Vrgoc et al., 2004).

### 8.11.1.2.Growth

No information was documented during SGMED-09-02.

### 8.11.1.3.Maturity

A reasonable value of length at the first sexual maturity for hake, in the GSA 17, is between 23 and 33 cm for females and between 20 and 28 cm for males, as reported by Zupanovic and Jardas (1986) (mentioned in Vrgoc et al., 2004).

The summary of the values of length at the first sexual maturity estimated for the Adriatic Sea was imported from Vrgoc et al. (2004), as follows.

| Author | Sex | $\mathbf{L}_{\text {m }}$ (cm) |
| :--- | :---: | :---: |
| Zei, 1949 | M | $22-30$ |
| Županović, 1968; | M | $20-28$ |
|  | F | $26-33$ |
|  | M | $20-28$ |
| Ungaro et al., 1993 | F | $23-33$ |
| Cetinić et al., 1999 | $\mathrm{M}+\mathrm{F}$ | $25-30$ |

In conclusion, a meaningful percentage of caught hake has a length below the values of sexual maturity. This is a further reason for caution in managing this stock.

### 8.11.2.Fisheries

### 8.11.2.1.General description of fisheries

The fisheries for hake are one of the most important in the GSA 17. Fishing grounds mostly correspond to the distribution of the stock (SEC (2002) 1374).
8.11.2.2.Management regulations applicable in 2008 and 2009

According to Regulation (EC) 1967/2006 the minimum legal length for fishery is, for hake, equal to 20 cm .
8.11.2.3.Catches

### 8.11.2.3.1. Landings

On the basis of data collected for Italy through DCR from 2002 to 2008 (Tab. 8.11.2.3.1.1), landings are due, mainly, to bottom otter trawlers, which account for over $90 \%$ of the total. The data are listed in Table A3.1 of Appendix 3.

Tab. 8.11.2.3.1.1. Hake landings in GSA 17 by fishing technique, 2002-2008. Landings data provided for the years 2002 and 2003, probably have a mistake in the units used.

| HKE | 17 | ITA | TBB |  |  | 88 | 142 | 237 | 212 | 105 |

Moreover, according to the FAO statistics (ftp://ftp.fao.org/fi/stat/windows/fishplus/gfcm.zip), in the northern and central Adriatic Sea, the annual landings of hake (see the figure below) in the 1980s and 1990s were estimated at around $2,000-4,000 \mathrm{t}$, with some peaks over 5,000 tonnes. A decreasing trend occurred from 1993 to 2000.

Fig. 8.11.2.3.1.1 FAO landing statistics 1970-2003.

### 8.11.2.3.2. Discards

No discards were reported to SGMED-09-02 through the DCR data call.

### 8.11.2.3.3. Fishing effort

Table 8.11.2.3.3.1 reveals an overall decreasing trend in effort of the major bottom otter trawl fleet.

Tab. 8.11.2.3.3.1. Trend in annual effort (days at sea, GT*days, $\mathrm{kW} *$ days) by country and gears in GSA 17 , 2002-2008.

### 8.11.3.Scientific surveys

### 8.11.3.1.Medits

### 8.11.3.1.1. Methods

Based on the DCR data call, abundance and biomass indices were recalculated. In GSA 17 the following number of hauls was reported per depth stratum (s. Tab. 8.11.3.1.1.1).

Tab. 8.11.3.1.1.1. Number of hauls per year and depth stratum in GSA 17, 1994-2008.

| STRATUM | 1994 | 1995 | 1996 | 1997 | 1998 | 1999 | 2000 | 2001 | 2002 | 2003 | 2004 | 2005 | 2006 | 2007 | 2008 |
| :--- | :--- | :--- | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |

| GSA17_050-100 |  |  |  |  |  |  |  |  | 54 | 36 | 37 | 62 | 38 | 38 | 37 |
| GSA17_100-200 |  |  |  |  |  |  |  |  | 50 | 27 | 23 | 43 | 22 | 24 | 23 |
| GSA17_200-500 |  |  |  |  |  |  |  |  | 9 | 7 | 5 | 7 | 5 | 5 | 5 |
| GSA17_500-800 |  |  |  |  |  |  |  |  | 1 | 1 |  |  |  |  |  |

Data were assigned to strata based upon the shooting position and average depth (between shooting and hauling depth). Few obvious data errors were corrected. Catches by haul were standardized to 60 minutes hauling duration. Hauls noted as valid were used only, including stations with no catches of hake, red mullet or pink shrimp (zero catches are included).

The abundance and biomass indices by GSA were calculated through stratified means (Cochran, 1953; Saville, 1977). This implies weighting of the average values of the individual standardized catches and the variation of each stratum by the respective stratum areas in each GSA:
$\mathrm{Yst}=\Sigma\left(\mathrm{Yi}^{*}{ }^{*} \mathrm{Ai}\right) / \mathrm{A}$
$\mathrm{V}(\mathrm{Yst})=\Sigma\left(\mathrm{Ai}^{2} * \mathrm{si}^{2} / \mathrm{ni}\right) / \mathrm{A}^{2}$

Where:
$A=$ total survey area
$\mathrm{Ai}=$ area of the i -th stratum
si=standard deviation of the i-th stratum
ni=number of valid hauls of the i-th stratum
n=number of hauls in the GSA
$\mathrm{Yi}=$ mean of the i-th stratum
Yst=stratified mean abundance
$\mathrm{V}(\mathrm{Yst})=$ variance of the stratified mean
The variation of the stratified mean is then expressed as the $95 \%$ confidence interval: Confidence interval $=$ Yst $\pm \mathrm{t}$ (student distribution) $* \mathrm{~V}(\mathrm{Yst}) / \mathrm{n}$

It was noted that while this is a standard approach, the calculation may be biased due to the assumptions over zero catch stations, and hence assumptions over the distribution of data. A normal distribution is often assumed, whereas data may be better described by a delta-distribution, quasi-poisson. Indeed, data may be better modelled using the idea of conditionality and the negative binomial (e.g. O'Brien et al. (2004)).

Length distributions represented an aggregation (sum) of all standardized length frequencies (subsamples raised to standardized haul abundance per hour) over the stations of each stratum. Aggregated length
frequencies were then raised to stratum abundance $* 100$ (because of low numbers in most strata) and finally aggregated (sum) over the strata to the GSA. Given the sheer number of plots generated, these distributions are not presented in this report.

### 8.11.3.1.2. Geographical distribution patterns

See section 8.11.1.1.

### 8.11.3.1.3. Trends in abundance and biomass

Fishery independent information regarding the state of the hake in GSA 17 was derived from the international survey Medits. Figure 8.11.3.1.3.1 displays the estimated trend in hake abundance and biomass in GSA 17.

The analyses of Medits indices are considered preliminary.

Fig. 8.11.3.1.3.1 Abundance and biomass indices of hake in GSA 17.

### 8.11.3.1.4. Trends in abundance by length or age

The following Fig. 8.11.3.1.4.1 displays the stratified abundance indices of GSA 17 in 2002-2008. These size compositions are considered preliminary.

GSA172003

Total length (cm)
GSA17 2004
$\left.\begin{array}{r}1500 \\ 1250 \\ 1000 \\ 750 \\ 500\end{array}\right] \quad \quad \mid \|_{\|}$

### 8.11.3.1.6. Trends in maturity

No analyses were conducted during SGMED-09-02.
8.11.4.Assessment of historic stock parameters

SGMED 09-02 did not undertake any analytical assessment of hake in GSA 17. Last year's preliminary assessment using Length Cohort Analysis (LCA) can be found in the report of SGMED-08-04 working group (Cardinale et al., 2008).

### 8.11.5.Long term prediction

### 8.11.5.1.Justification

No forecast analyses were conducted.

### 8.11.5.2.Input parameters

No forecast analyses were conducted.

### 8.11.5.3.Results

Given the preliminary state of the data and analyses SGMED-09-02 is not in the position to provide a long term prediction of catch and stock biomass for hake in GSA 17.
8.11.6.Scientific advice

### 8.11.6.1.Short term considerations

### 8.11.6.1.1. State of the spawning stock size

The average stock biomass estimated by LCA in 2006-2007 was around 4,000 tonnes. Without any biomass reference proposed or agreed, SGMED-09-02 is unable to fully evalute the state of the stock size.

### 8.11.6.1.2. State of recruitment

SGMED-09-02 is unable to provide any scientific advice of the state of the recruitment given the preliminary state of the data and analyses.

### 8.11.6.1.3. State of exploitation

Without any biomass reference proposed or agreed, SGMED-09-02 is unable to fully evaluate the state of the exploitation.

### 8.12. Stock assessment of hake in GSA 18

8.12.1.Stock identification and biological features

### 8.12.1.1.Stock Identification

No information was documented during SGMED-09-02.

### 8.12.1.2.Growth

No information was documented during SGMED-09-02.

### 8.12.1.3.Maturity

No information was documented during SGMED-09-02.

### 8.12.2.Fisheries

### 8.12.2.1.General description of fisheries

STECF (stock review part II in 2007) noted that Merluccius merluccius is one of the most important species in the Geographical Sub Area 18 representing more than $20 \%$ of landings from trawlers. Trawling represents the most important fishery activity in the southern Adriatic Sea and a yearly catch of around 30,000 tonnes could be estimated for the last decades. Demersal species catches are landed on the western side (Italian coast) and the eastern side (Albanian coast), with an approximate percentage of $97 \%$ and $3 \%$, respectively. Trawling is the most important fishery activity on the whole area (about 900 boats, $60 \%$ of total number of fishing vessels; $85 \%$ of gross tonnage). The Mediterranean hake is also caught by off-shore bottom longlines, but these gears are utilised by a low number of boats (less than $5 \%$ of the whole South-western Adriatic fleet).
8.12.2.2. Management regulations applicable in 2008 and 2009

No information was documented during SGMED-09-02.

### 8.12.2.3.Catches

### 8.12.2.3.1. Landings

SGMED-09-02 received the following information about hake landings in GSA 18 through the official DCR data call (Tab. 8.12.2.3.1.1). The landings are listed in Tab. A3.1 of Appendix 3. Landings by demersal trawlers dominate by far.

Tab. 8.12.2.3.1.1 Hake landings in GSA 18 by fishing technique, 2002-2008. Landings data provided for the years 2002 and 2003, probably have a mistake in the units used.

### 8.12.3.1.Medits

### 8.12.3.1.1. Methods

Based on the DCR data call, abundance and biomass indices were recalculated. In GSA 18 the following number of hauls was reported per depth stratum (s. Tab. 8.12.3.1.1.1).

Tab. 8.12.3.1.1.1. Number of hauls per year and depth stratum in GSA 18, 1994-2008.

| STRATUM | 1994 | 1995 | 1996 | 1997 | 1998 | 1999 | 2000 | 2001 | 2002 | 2003 | 2004 | 2005 | 2006 | 2007 | 2008 |
| :--- | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| GSA18_010-050 | 14 | 15 | 15 | 14 | 14 | 14 | 14 | 15 | 13 | 13 | 12 | 9 | 10 | 11 | 10 |
| GSA18_050-100 | 14 | 14 | 14 | 15 | 15 | 15 | 15 | 14 | 21 | 21 | 23 | 16 | 15 | 15 | 14 |
| GSA18_100-200 | 24 | 23 | 23 | 23 | 23 | 23 | 23 | 23 | 34 | 31 | 32 | 25 | 25 | 23 | 22 |
| GSA18_200-500 | 10 | 10 | 10 | 10 | 10 | 10 | 10 | 10 | 15 | 15 | 16 | 10 | 10 | 9 | 8 |
| GSA18_500-800 | 10 | 10 | 10 | 10 | 10 | 10 | 10 | 10 | 14 | 14 | 14 | 7 | 7 | 7 | 5 |

Data were assigned to strata based upon the shooting position and average depth (between shooting and hauling depth). Few obvious data errors were corrected. Catches by haul were standardized to 60 minutes hauling duration. Hauls noted as valid were used only, including stations with no catches of hake, red mullet or pink shrimp (zero catches are included).

The abundance and biomass indices by GSA were calculated through stratified means (Cochran, 1953; Saville, 1977). This implies weighting of the average values of the individual standardized catches and the variation of each stratum by the respective stratum areas in each GSA:
$\mathrm{Yst}=\Sigma\left(\mathrm{Yi}^{*} \mathrm{Ai}\right) / \mathrm{A}$
$\mathrm{V}(\mathrm{Yst})=\Sigma\left(\mathrm{Ai}^{2} * \mathrm{si}^{2} / \mathrm{ni}\right) / \mathrm{A}^{2}$
Where:
$\mathrm{A}=$ total survey area
$\mathrm{Ai}=$ area of the i -th stratum
$s i=$ standard deviation of the i-th stratum
ni=number of valid hauls of the i-th stratum
$\mathrm{n}=$ number of hauls in the GSA
Yi=mean of the i-th stratum
Yst=stratified mean abundance
$\mathrm{V}(\mathrm{Yst})=$ variance of the stratified mean
The variation of the stratified mean is then expressed as the $95 \%$ confidence interval: Confidence interval $=$ Yst $\pm \mathrm{t}$ (student distribution) $* \mathrm{~V}(\mathrm{Yst}) / \mathrm{n}$

It was noted that while this is a standard approach, the calculation may be biased due to the assumptions over zero catch stations, and hence assumptions over the distribution of data. A normal distribution is often assumed, whereas data may be better described by a delta-distribution, quasi-poisson. Indeed, data may be better modelled using the idea of conditionality and the negative binomial (e.g. O'Brien et al. (2004)).

Length distributions represented an aggregation (sum) of all standardized length frequencies (subsamples raised to standardized haul abundance per hour) over the stations of each stratum. Aggregated length frequencies were then raised to stratum abundance * 100 (because of low numbers in most strata) and finally
aggregated (sum) over the strata to the GSA. Given the sheer number of plots generated, these distributions are not presented in this report.

### 8.12.3.1.2. Geographical distribution patterns

No analyses were conducted during SGMED-09-02.

### 8.12.3.1.3. Trends in abundance and biomass

Fishery independent information regarding the state of the hake in GSA 18 was derived from the international survey Medits. Figure 8.12.3.1.3.1 displays the estimated trend in hake abundance and biomass in GSA 08.

The estimated abundance and biomass indices do not reveal any significant trends since 1995 until 2003, increased to the highest values in 2005 and dropped sharply to the lowest level of the time series in 2007. The analyses of Medits indices are considered preliminary.

Fig. 8.12.3.1.3.1 Abundance and biomass indices of hake in GSA 18.

### 8.12.3.1.4. Trends in abundance by length or age

The following Fig. 8.12.3.1.4.1 and 2 display the stratified abundance indices of GSA 18 in 1996-2003 and 2004-2008. These size compositions are considered preliminary.

Fig. 8.12.3.1.4.1 Stratified abundance indices by size, 1996-2003.

Fig. 8.12.3.1.4.2 Stratified abundance indices by size, 2004-2008.

### 8.12.3.1.5. Trends in growth

No analyses were conducted during SGMED-09-02.

### 8.12.3.1.6. Trends in maturity

No analyses were conducted during SGMED-09-02.
8.12.4.Assessment of historic stock parameters

SGMED-09-02 did not undertake any analytical assessment.
8.12.5.Long term prediction

### 8.12.5.1.Justification

No forecast analyses were conducted.

### 8.12.5.2.Input parameters

No forecast analyses were conducted.

### 8.12.5.3.Results

Given the preliminary state of the data and analyses SGMED-09-02 in not in the position to provide a long term prediction of catch and stock biomass for hake in GSA 18.

### 8.12.6.Scientific advice

### 8.12.6.1.Short term considerations

### 8.12.6.1.1. State of the spawning stock size

SGMED-09-02 is unable to provide any scientific advice of the state of the spawning stock in relation to proposed precautionary level given the preliminary state of the data and analyses.

### 8.12.6.1.2. State of recruitment

SGMED-09-02 is unable to provide any scientific advice of the state of the recruitment given the preliminary state of the data and analyses.

### 8.12.6.1.3. State of exploitation

SGMED-09-02 is unable to provide any scientific advice of the state of the exploitation in relation to proposed precautionary and target levels given the preliminary state of the data and analyses.

### 8.13. Stock assessment of hake in GSA 19

### 8.13.1.Stock identification and biological features

### 8.13.1.1.Stock Identification

No information was documented during SGMED-09-02.

### 8.13.1.2.Growth

Three sets of data on growth parameters were submitted, for females (F) and males (M) separately, estimated by otolith reading. Since the assessment was done for males and females combined, the growth parameters used were those proposed by García-Rodríguez and Esteban (2002), estimated by otolith reading and length frequency analysis, which correspond to the "fast growth" hypothesis, in line with the recommendations of SGMED in previous meetings. These growth parameters were used in the assessment of hake in GSA 19. Three sets of data on the paramenters of the length-weight relationship were submitted, for females and males separately, and one set for both sexes combined, which were those used in the assessment.

|  |  | a | b |
| :---: | :---: | ---: | ---: |
| $2003-2005$ | F | 0,0036 | 3,100 |
| 2008 | F | 0,0047 | 3,134 |
| $2002-2005$ | F | 0,0036 | 3,100 |
| $2003-2005$ | M | 0,004 | 3,100 |
| 2008 | M | 0,0045 | 3,150 |
| $2002-2005$ | M | 0,004 | 3,100 |
| 2008 | C | 0,0048 | 3,129 |

Fig. 8.13.1.2.1 V. Bertalanffy growth functions and parameters by sex.

### 8.13.1.3.Maturity

## Merluccius merluccius- Size-at-first maturity

Fig. 8.13.1.3.1 Maturity ogives by sex.

Three sets of data on the percentage of mature individuals by size and sex, two for females and one for males, were submitted to SGMED-09-02. According to these sets, size-at-first-maturity ( $50 \%$ of individual mature, $\mathrm{L}_{50}$ ) would be around 18 cm TL for males and 34 cm TL for females. The observed $\mathrm{L}_{50}$ for females is similar to that determined in other Mediterranean areas.

### 8.13.2.Fisheries

### 8.13.2.1.General description of fisheries

STECF (stock review part II in 2007) noted that Merluccius merluccius is one of the most important species in the GSA 19, considering both the amount of catch and the commercial value. It is fished with different strategies and gears (bottom trawling and long-line). In the year 2004 the landings in the Ionian area were detected around 850 tonnes (IREPA data). The main fisheries operating in GSA 19 are from Gallipoli, Taranto, Schiavonea and Crotone. The fishing pressure varies between fisheries and fishing grounds. No new documentation on the hake fishery in GSA19 was submitted to SGMED-09-02.
8.13.2.2.Management regulations applicable in 2008 and 2009

No information was documented.

### 8.13.2.3.Catches

### 8.13.2.3.1. Landings

Since 2002 until 2006, landings as provided to SGMED-09-02 through the DCR data call, varied between 1,300 and 1,600 t. In 2007 and 2008, landings dropped significantly regarding the period 2002-2006 (Tab. 8.13.2.3.1.1). The data are listed in Tab. A3.1 of Appendix 3. Demersal otter trawls (OTB) appear the major fishing gear at present. Current landings are similar to those in 2002 and 2003, although the current OTB fishing effort is much higher than in 2002 and 2003. Landings by nets were much higher during 2002-2003, when the fishing effort of this fishing technique was much higher than at present (see Tab. 8.13.2.3.3.1).

Tab. 8.13.2.3.1.1 Hake landings in GSA 19 by fishing technique, 2002-2008.

| landings | 2002 | 2003 | 2004 | 2005 | 2006 | 2007 | 2008 |
| ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| OTB | 688 | 668 | 852 | 1077 | 1330 | 572 | 635 |
| NETS | 653 | 845 | 308 | 123 | 218 | 257 | 206 |
| LONGLINE |  |  | 139 | 72 | 81 | 54 | 39 |
| PURSE SEINE | 15 | 1 |  |  |  |  |  |
|  | 1356 | 1514 | 1299 | 1272 | 1629 | 883 | 879 |

Fig. 8.13.2.3.1.1 Size frequency distributions, by fishing technique, 2006-2008.

By far, highest landings in number correspond to bottom otter trawl, most of them made up of immature individuals. The smallest landed recorded size class is 16 cm TL. Gillnets fish immature and mature individuals, while long lining landings correspond to mature individuals (Data submitted to SGMED-09-02).

### 8.13.2.3.2. Discards

Discards reported to SGMED-09-02 amount to 10 t in 2006, estimated for demersal otter trawls only. Discards as obtained through the DCR data call are listed in Table A3.9 of Appendix 3. No data on discards were reported for 2008. No data on the hake discards size distribution were available to SGMED-09-02.
Hake discard was less than $10 \%$ in weght so, according to the national protocol, the length distributions were not presented in the data.

### 8.13.2.3.3. Fishing effort

Tab. 8.13.2.3.3.1 lists the fishing effort reported to SGMED-09-02 through the DCR data call. The overview is given in Tab. A3.10-3.12 of Appendix 3 to this report. The dominant demersal otter trawl fleet increased in effort since 2002.

Tab. 8.13.2.3.3.1 Fishing effort in different units by fishing technique deployed in GSA 19, 2002-2007. No data are available for 2008.

### 8.13.3.1.MEDITS

### 8.13.3.1.1. Methods

Based on the DCR data call, abundance and biomass indices were recalculated. In GSA 19 the following number of hauls was reported per depth stratum (s. Tab. 8.13.3.1.1.1).

Tab. 8.13.3.1.1.1. Number of hauls per year and depth stratum in GSA 19, 1994-2008.

| STRATUM | 1994 | 1995 | 1996 | 1997 | 1998 | 1999 | 2000 | 2001 | 2002 | 2003 | 2004 | 2005 | 2006 | 2007 | 2008 |
| :--- | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| GSA19_010-050 | 9 | 9 | 9 | 9 | 9 | 9 | 9 | 9 | 9 | 9 | 9 | 9 | 9 | 8 | 9 |
| GSA19_050-100 | 7 | 8 | 8 | 8 | 8 | 8 | 8 | 8 | 8 | 8 | 8 | 8 | 8 | 9 | 8 |
| GSA19_100-200 | 10 | 10 | 10 | 10 | 10 | 10 | 10 | 10 | 10 | 10 | 10 | 10 | 10 | 10 | 11 |
| GSA19_200-500 | 16 | 15 | 15 | 15 | 15 | 15 | 15 | 15 | 21 | 21 | 14 | 15 | 14 | 14 | 14 |
| GSA19_500-800 | 31 | 32 | 32 | 32 | 32 | 32 | 32 | 32 | 29 | 29 | 29 | 28 | 29 | 29 | 29 |

Data were assigned to strata based upon the shooting position and average depth (between shooting and hauling depth). Few obvious data errors were corrected. Catches by haul were standardized to 60 minutes hauling duration. Hauls noted as valid were used only, including stations with no catches of hake, red mullet or pink shrimp (zero catches are included).

The abundance and biomass indices by GSA were calculated through stratified means (Cochran, 1953; Saville, 1977). This implies weighting of the average values of the individual standardized catches and the variation of each stratum by the respective stratum areas in each GSA:
$\mathrm{Yst}=\Sigma\left(\mathrm{Yi}^{*}{ }^{*} \mathrm{Ai}\right) / \mathrm{A}$
$\mathrm{V}(\mathrm{Yst})=\Sigma\left(\mathrm{Ai}^{2} * \mathrm{si}^{2} / \mathrm{ni}\right) / \mathrm{A}^{2}$
Where:
A=total survey area
$\mathrm{Ai}=$ area of the i-th stratum
$s i=s t a n d a r d$ deviation of the i-th stratum
ni=number of valid hauls of the i-th stratum
$\mathrm{n}=$ number of hauls in the GSA
$\mathrm{Yi}=$ mean of the i-th stratum
Yst=stratified mean abundance
$\mathrm{V}(\mathrm{Yst})=$ variance of the stratified mean

The variation of the stratified mean is then expressed as the $95 \%$ confidence interval: Confidence interval $=$ Yst $\pm \mathrm{t}$ (student distribution) $* \mathrm{~V}(\mathrm{Yst}) / \mathrm{n}$

It was noted that while this is a standard approach, the calculation may be biased due to the assumptions over zero catch stations, and hence assumptions over the distribution of data. A normal distribution is often assumed, whereas data may be better described by a delta-distribution, quasi-poisson. Indeed, data may be better modelled using the idea of conditionality and the negative binomial (e.g. O'Brien et al. (2004)).

Length distributions represented an aggregation (sum) of all standardized length frequencies (subsamples raised to standardized haul abundance per hour) over the stations of each stratum. Aggregated length frequencies were then raised to stratum abundance $* 100$ (because of low numbers in most strata) and finally
aggregated (sum) over the strata to the GSA. Given the sheer number of plots generated, these distributions are not presented in this report.

### 8.13.3.1.2. Geographical distribution patterns

No analyses were conducted during SGMED-09-02.

### 8.13.3.1.3. Trends in abundance and biomass

Fishery independent information regarding the state of the hake in GSA 19 was derived from the international survey MEDITS. Figure 8.13.3.1.3.1 displays the estimated trend in hake abundance and biomass in GSA 19.

The time series of estimated abundance and biomass indices reveals a significant increase in stock size since 2004.

Fig. 8.13.3.1.3.1 Abundance and biomass indices of hake in GSA 19.

### 8.13.3.1.4. Trends in abundance by length or age

The following Fig. 8.13.3.1.4.1 and 2 display the stratified abundance indices of GSA 19 in 1994-2001 and 2002-2008, respectively. These size compositions are considered preliminary.

Fig. 8.13.3.1.4.1 Stratified abundance indices by size, 1994-2001.

Total length (cm)

Fig. 8.13.3.1.4.2 Stratified abundance indices by size, 2002-2008.

### 8.13.3.1.5. Trends in growth

No analyses were conducted.

### 8.13.3.1.6. Trends in maturity

No analyses were conducted.

### 8.13.4.Assessment of historic stock parameters

### 8.13.4.1.Method 1: VIT

### 8.13.4.1.1. Justification

VPA analysis was performed using VIT program (Lleonart and Salat, 1992) using as input data the mean pseudo-cohort for the period 2006-2008 to provide a general overview of the current state of exploitation of hake in GSA 19.

### 8.13.4.1.2. Input Data

Size distribution data were available only for 2006-2008. VIT was performed using as input size distribution by fishing technique the corresponding "mean" pseudo- cohort for the period 2006-2008, estimated from the annual length distribution of landings. In any case, according to the landings and effort data in Tab. 8.13.2.3.1.1 and Tab. 8.13.2.3.3.1, the hake fishery does not appear to be in equilibrium.

Fig. 8.13.4.1.2.1 Size compositions of landings by gears.

The size distribution of the total landings is very similar to that of bottom trawl and consists mostly of $<30 \mathrm{~cm}$ TL individuals. The size distribution of gillnets and longline landings are also presented separately, to show the different size-ranges exploited by each gear. Since the smallest landed size is 16 cm TL, and also considering the size distribution obtained by OTB, this species should be discarded although data on discards were not available.
About the observed landed sizes by fishing technique, gillnets (assumed to be both trammel net and gillnet) and longline landings overlap over a wide size range. The mode of the nets landings (around $24-28 \mathrm{~cm} \mathrm{TL}$ ) and that of long line (around 40 cm TL ) are smaller than those reported for gillnets and longline in other Mediterranean areas.
Some inconsistencies were observed between the annual size distributions by gear and the landings expressed in weight.

Growth parameters were taken from García-Rodríguez and Esteban (2002); length-weight relationship parameters and maturity ogive for females were submitted to SGMED 09-02; and M Vector by age was estimated using PROBIOM (Caddy and Abella, 1999). $\mathrm{M}_{\text {mean }}$ as estimated from PROBIOM is 0.43 . Weight at length and maturity at length were transformed into ages during the analysis.

### 8.13.4.1.3. Results including sensitivity analyses

This is the first assessment of hake in GSA19. All results refer to the landed range of lengths/ages. Results show that, although longline and nets target big-sized hakes, exploitation is concentrated on recruits, age classes 0 and 1. Accordingly, the exploitation rate is very high and Y/R for nets and long line are very low. Also, F must be even higher than that shown in results, since no data on discards were used as input for the
analysis but discard is know to occur. In fact, bottom trawl landings in 2007 and 2008 were much lower than in the previous years, while trawl fishing effort did not decrease.

Taking into account the input data used in the assessment (2006-2008 mean pseudo- cohort, no discards data, which means F values are underestimated) and that the data on fishing effort and landing do not correspond to a situation of equilibrium, these results are to be considered only as preliminary, and no management advice can be provided.

All results refer to the current state of exploitation.

### 8.13.5.Long term prediction

### 8.13.5.1.Justification

Yield per recruit analysis was performed, although, from data on landings and fishing effort during 20062008 and in the previous years, equilibrium conditions cannot be assumed. Thus, this analysis is presented only to provide a general overview of the exploitation of hake in GSA 19, and cannot be taken as a proposal for advice.

### 8.13.5.2.Input parameters

Input data are the exploitation pattern resulting for VPA (VIT) and its population parameters.

### 8.13.5.3.Results

Overall results of the yield per recruit analysis are given below.
Table 8.13.5.3.1. YpR results: column factor ( x axis in the figure below), indicates the level of fishing effort regarding the current effort which would correspond to $\mathrm{F}_{(0,1)}$, to the maximum Y/R for each gear, and for the three gears combined, as well as the current situation (Factor=1) and the situation in case the effort level was twice the current effort (Factor=2).

Fig. 8.13.5.3.1. GSA 19. Merluccius merluccius. Yield per recruit results (current effort= 1; red: total; green: bottom trawl; yellow: nets; blue: longline).

Yield per recruit results suggest a clear situation of overexploitation, for the three different fishing techniques targeting hake in GSA19. $\mathrm{F}_{\text {max }}(\mathrm{F}$ corresponding to the highest $\mathrm{Y} / \mathrm{R})$ is in all cases well below the current effort.

Given the preliminary state of the data and analyses SGMED-09-02 is not in the position to provide a long term prediction of catch and stock biomass for hake in GSA 19.

### 8.13.6.1.Short term considerations

### 8.13.6.1.1. State of the spawning stock size

Survey results indicate a recent increase in stock abundance. However, due to the data deficiencies in the assessment and the lack of estimated limit or target management reference points, SGMED-09-02 is unable to fully review the status of the spawing stock.

### 8.13.6.1.2. State of recruitment

Survey results indicate a recent increase in stock abundance. Recent recruitment appears above average.

### 8.13.6.1.3. State of exploitation

Due to the data deficiencies in the assessment and the lack of estimated limit or target management reference points, SGMED-09-02 is unable to fully review the status of the exploitation. However, the persistent lack of older fish in the surveyed population and catches indicate high exploitation rates far in access of any sustainable level.

### 8.14. Stock assessment of hake in GSA 20

### 8.14.1.Stock identification and biological features

### 8.14.1.1.Stock Identification

Hake is one of the most important fish stocks in GSA 20 for bottom trawlers, nets (mainly gill nets) and longlines. The stock is distributed in depth between $50-600 \mathrm{~m}$, with a peak in abundance in depths between 200 and 300 m . The stock is exploited almost exclusively by the Greek fishing fleet. Spawning takes place all year around, with a peak during winter - spring.

### 8.14.1.2.Growth

No information was documented during SGMED-09-02.

### 8.14.1.3.Maturity

No information was documented during SGMED-09-02.

### 8.14.2.Fisheries

### 8.14.2.1.General description of fisheries

Hake mainly lives on muddy substrates in depths between $50-600 \mathrm{~m}$. The main landing port in the area is the port of Patra. Other important landing ports are in Igoumenitsa, Kerkyra, Preveza, Killini and Kalamata.

The bottom trawl fishery in Greece is a mixed fishery, operating 24 hr per day. Bottom trawl fishing targeting hake, is taking place mainly during the day in muddy bottoms in depths $80-400 \mathrm{~m}$ (approximately). The mesh size of the cod end of bottom trawls is 40 mm . Apart from hake, important target species are shrimps, anglerfish, blue whiting, megrims, picarel and red mullet.

The gill nets are setting in the morning and are hauling the next day in depth from 80-300 m . The mesh size used is about 48 to 64 mm . The fishery is carried out mainly during summer when bottom trawl fishery is closed. Long line fishery for hake is taking place in deeper waters down to 500 m mainly during summer. Fishing is taking place during the day. The size of the hook is No 6-8. Gillnet and especially longline fisheries have a relatively greater species and size selectivity. The main by catch species in the gill net fishery is horse mackerel.

Due to the selectivity of each gear the length composition differs significantly. The catch from bottom trawls consists mainly of small individuals (hake with lengths between 6 and 18 cm are $\sim 75 \%$ of the catch by number). The catch of gill nets comprises mainly of specimens with lengths between 20 and 40 cm , while longliners catch relatively large fish.
8.14.2.2.Management regulations applicable in 2008 and 2009

RD 917/1966 is the principal law regulating the operation of trawlers. Although this law is still in effect, it has been superseded by EC Regulation 1626/1994, and its replacement Regulation 1967/2006. The main restrictions established by Greek and European legislation are:
(1) establishment of a total exclusion zone one and a half mile from the coastline of the mainland and the islands,
(2) a total fishing ban from the 1 st of June till the end of September,
(3) establishment of a total exclusion zone which is: either a zone three miles from the coastal line or a zone shallower than 50 m ,
(4) minimum cod-end mesh size is 40 mm (EC regulation 1967/2006); from 1 July 2008, the net shall be replaced by a square-meshed net of 40 mm at the cod-end or, at the duly justified request of the shipowner, by a diamond meshed net of 50 mm .

Additional restrictions exist for bottom trawling in specific areas: in Amvrakikos Gulf and some parts of the Korinthiakos Gulf and the Ionian Sea, trawling is prohibited all year around, while in Patraikos Gulf trawling is prohibited from the 1st of March till the end of November.

The operation of the bottom set nets is subject to the following main restrictions:
(1) the maximum total length of the trammel net is 6000 m .
(2) the minimum mesh size opening is 16 mm .
(3) monofilament or twine diameter of the net should not exceed 0.5 mm .
(4) the maximum drop of a combined trammel and gill net should not exceed 10 m and the length of combined nets should not exceed $2,500 \mathrm{~m}$.

### 8.14.2.3.Catches

### 8.14.2.3.1. Landings

Estimation of landings was based on random sampling in 66 sampling stations (ports) in GSA 20. Sampling was conducted on a monthly basis at each sampling station, where a sufficient number of vessels from each fleet segment and gear type was randomly selected and landings by species recorded. Based on these data, average landings per fishing day, by species and for each fishing gear were estimated. Based on total effort estimations, sampled data were raised to the whole fleet to estimate total landings by species, fleet segment, fishing gear, and GSA.

Tab. 8.14.2.3.1.1 shows the trend in reported landings taken by major gear types. The data were reported to SGMED-09-02 through the Data Collection Regulation and are listed in Table A3.1 of Appendix 3.

Tab. 8.14.2.3.1.1 Greek landings (t) by year and major gear types, 2002-2008 as reported through DCF.

### 8.14.2.3.2. Discards

No discards data were reported to SGMED-09-02 through the DCF data call for Greece.

### 8.14.2.3.3. Fishing effort

Estimation of effort was based on interviews conducted with random sampling in 30 sampling stations (ports) in GSA 20. Sampling was conducted on a monthly basis at each sampling station, where a sufficient number of vessels from each fleet segment and gear type were randomly selected and effort was recorded. In addition, all fishing vessels present in the sampling stations were categorized as full-time, part-time, occasionally fishing, or inactive and the proportion of the year when they were active was estimated. Based on this information, sampled data were raised to the whole fleet to estimate total effort per fleet segment, fishing gear, and GSA. Should be noted that the estimated effort do not refer to the effective effort targeting to hake but to the entire effort of each fleet segment. This is very important for the long lines and gill nets because the effort targeting hake is much smaller than the effort of the fleets.

Tab. 8.14.2.3.3.2 lists the fishing effort reported to SGMED-09-02 through the DCR data call. The overview is given in Tab. A3.10-3.12 of Appendix 3 to this report.

Tab. 8.14.2.3.3.2 Fishing effort in different units by fishing technique deployed in GSA 20, 2003-2008.

### 8.14.3.Scientific surveys

### 8.14.3.1.Medits

### 8.14.3.1.1. Methods

Tables TA, TB, TC were provided according to the MEDITS protocol. The MEDITS survey was carried out in GSA 20 every summer from 1994 to 20068, except in 2002 because of administrative problems. For similar reasons, no MEDITS survey was conducted in Greece in 2007. During 1994 and 1995 the survey in GSA 20 was carried out in a small number of stations ( 12 and 15). The number of stations kept increasing and in 1998 was more than doubled ( 32 stations). The survey vessel changed in 1998. Due to these changes in the survey design, caution is needed when investigating the trends of relevant indicators in the MEDITS time series. More details on methodology and trends on selected indicators may be found in MEDITS (2007).

Based on the DCR data call, abundance and biomass indices were recalculated. In GSA 20 the following number of hauls was reported per depth stratum (s. Tab. 8.14.3.1.1.1).

Tab. 8.14.3.1.1.1. Number of hauls per year and depth stratum in GSA 20, 1994-2008.

| STRATUM | 1994 | 1995 | 1996 | 1997 | 1998 | 1999 | 2000 | 2001 | 2002 | 2003 | 2004 | 2005 | 2006 | 2007 | 2008 |
| :--- | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |

| GSA20_050-100 | 3 | 4 | 8 | 7 | 11 | 10 | 11 | 10 |  | 10 | 10 | 10 | 9 |  | 10 |
| GSA20_100-200 | 2 | 3 | 4 | 2 | 5 | 6 | 5 | 6 |  | 6 | 6 | 5 | 6 | 6 |  |
| GSA20_200-500 | 2 | 3 | 4 | 4 | 7 | 7 | 7 | 8 |  | 8 | 9 | 8 | 8 | 7 |  |
| GSA20_500-800 | 3 | 3 | 4 | 3 | 5 | 5 | 5 | 5 |  | 5 | 4 | 5 | 4 | 6 |  |

Data were assigned to strata based upon the shooting position and average depth (between shooting and hauling depth). Few obvious data errors were corrected. Catches by haul were standardized to 60 minutes hauling duration. Hauls noted as valid were used only, including stations with no catches of hake, red mullet or pink shrimp (zero catches are included).

The abundance and biomass indices by GSA were calculated through stratified means (Cochran, 1953; Saville, 1977). This implies weighting of the average values of the individual standardized catches and the variation of each stratum by the respective stratum areas in each GSA:
$\mathrm{Yst}=\Sigma\left(\mathrm{Yi}^{*} \mathrm{Ai}\right) / \mathrm{A}$
$\mathrm{V}(\mathrm{Yst})=\Sigma\left(\mathrm{Ai}^{2} * \mathrm{si}^{2} / \mathrm{ni}\right) / \mathrm{A}^{2}$
Where:
$\mathrm{A}=$ total survey area
$\mathrm{Ai}=$ area of the i-th stratum
si=standard deviation of the i-th stratum
ni=number of valid hauls of the i-th stratum
n=number of hauls in the GSA
$\mathrm{Yi}=$ mean of the i -th stratum
Yst=stratified mean abundance
$\mathrm{V}(\mathrm{Yst})=$ variance of the stratified mean
The variation of the stratified mean is then expressed as the $95 \%$ confidence interval: Confidence interval $=$ Yst $\pm \mathrm{t}$ (student distribution) $* \mathrm{~V}(\mathrm{Yst}) / \mathrm{n}$

It was noted that while this is a standard approach, the calculation may be biased due to the assumptions over zero catch stations, and hence assumptions over the distribution of data. A normal distribution is often assumed, whereas data may be better described by a delta-distribution, quasi-poisson. Indeed, data may be better modelled using the idea of conditionality and the negative binomial (e.g. O'Brien et al. (2004)).

Length distributions represented an aggregation (sum) of all standardized length frequencies (subsamples raised to standardized haul abundance per hour) over the stations of each stratum. Aggregated length frequencies were then raised to stratum abundance * 100 (because of low numbers in most strata) and finally aggregated (sum) over the strata to the GSA. Given the sheer number of plots generated, these distributions are not presented in this report.

### 8.14.3.1.2. Geographical distribution patterns

No analyses were conducted during SGMED-09-02.

### 8.14.3.1.3. Trends in abundance and biomass

Fishery independent information regarding the state of the hake in GSA 20 was derived from the international survey Medits. Figure 8.14.3.1.3.1 displays the estimated trend in hake abundance and biomass in GSA 20.

The estimated abundance and biomass indices reveal a significantly increased level of stock size since 2003. However, the recent abundance and biomass indices are subject to high variation (uncertainty). The analyses of Medits indices are considered preliminary.

Fig. 8.14.3.1.3.1 Abundance and biomass indices of hake in GSA 20.

### 8.14.3.1.4. Trends in abundance by length or age

The following Fig. 8.14.3.1.4.1 and 2 display the stratified abundance indices of GSA 20 in 1994-2001 and 2003-2008. These size compositions are considered preliminary.

Fig. 8.14.3.1.4.1 Stratified abundance indices by size, 1994-2001.

Fig. 8.14.3.1.4.2 Stratified abundance indices by size, 2003-2008.

### 8.14.3.1.5. Trends in growth

No analyses were conducted during SGMED-09-02.

### 8.14.3.1.6. Trends in maturity

No analyses were conducted during SGMED-09-02.

### 8.14.4.Assessment of historic stock parameters

SGMED 09-02 did not undertake any analytical assessment of hake in GSA 20. Last year's preliminary assessment using SURBA can be found in the report of SGMED-08-04 working group (Cardinale et al., 2008).

### 8.14.5.1.Justification

No forecast analyses were conducted.

### 8.14.5.2.Input parameters

No forecast analyses were conducted.

### 8.14.5.3.Results

No forecast analyses were conducted.
8.14.6.Scientific advice

### 8.14.6.1.Short term considerations

### 8.14.6.1.1. State of the spawning stock size

SGMED-09-02 is unable to provide any scientific advice of the state of the recruitment given the preliminary state of the data and analyses.

### 8.14.6.1.2. State of recruitment

SGMED-09-02 is unable to provide any scientific advice of the state of the recruitment given the preliminary state of the data and analyses.

### 8.14.6.1.3. State of exploitation

SGMED-09-02 is unable to provide any scientific advice of the state of the recruitment given the preliminary state of the data and analyses.

### 8.15. Stock assessment of hake in GSAs 22 and 23 combined

### 8.15.1.Stock identification and biological features

### 8.15.1.1.Stock Identification

Hake is one of the most important fish stocks in GSAs 22-23 for bottom trawlers, nets (mainly gillnets) and longlines. The stock is distributed in depth between $50-600 \mathrm{~m}$, with a peak in abundance in depths between 200 and 300 m . The stock is exploited by the Greek fishing fleet in the National Greek waters and by the Greek and Turkish fleet in the international waters. Spawning is taking place all year around, with a peak during winter - spring.

### 8.15.1.2.Growth

No information was documented during SGMED-09-02.

### 8.15.1.3.Maturity

No information was documented during SGMED-09-02.

### 8.15.2.Fisheries

8.15.2.1.General description of fisheries

Hake mainly lives on muddy substrates in depths between $50-600 \mathrm{~m}$. The main landing ports in the GSAs 22-23 are the port of Pireus, Thessaloniki, Kavala, Alexandroupolis, Volos, Chalkida and Chios.

The bottom trawl fishery in Greece is a mixed fishery, operating 24 hr per day. Bottom trawl fishing targeting hake, is taking place mainly during the day in muddy bottoms in depths $80-400 \mathrm{~m}$ (approximately). Especially for the offshore fisheries in the international waters, the duration of the trip could be up to 3 days. The mesh size of the cod end of bottom trawls is 40 mm . Important bycatch species are shrimps, anglerfish, blue whiting, Norway lobster, megrims, picarel and red mullet.

The gill nets are setting in the morning and are hauling the next day in depth from $80-300 \mathrm{~m}$. The mesh size used is about 48 to 64 mm . The fishery is carried out mainly during summer when bottom trawl fishery is closed. Long line fishery for hake is taking place in deeper waters down to 500 m mainly during summer. Fishing is taking place during the day. The size of the hook is No 6-8. Gillnet and especially longline fisheries have a relatively greater species and size selectivity. The main by catch species in the gill net fishery is horse mackerel.

Due to the selectivity of each gear the length composition differs significantly. The catch from bottom trawls consists mainly of small individuals (hake with lengths between 6 and 18 cm are $\sim 75 \%$ of the catch). The catch of gillnets comprises mainly of specimens with lengths between 20 and 40 cm , while longliners catch relatively larger fish.
8.15.2.2.Management regulations applicable in 2008 and 2009

The most important measures for managing bottom trawl or net fisheries in Greece have been described in the section 8.14.2.2.

### 8.15.2.3.1. Landings

Estimation of landings was based on random sampling in 127 sampling stations (ports) in GSA 22-23. Sampling was conducted on a monthly basis at each sampling station, where a sufficient number of vessels from each fleet segment and gear type was randomly selected and landings by species recorded. Based on these data, average landings per fishing day, by species and for each fishing gear were estimated. Based on total effort estimations, sampled data were raised to the whole fleet to estimate total landings by species, fleet segment, fishing gear, and GSA

Tab. 8.15.2.3.1.1 shows the trend in reported landings taken by major gear types. The data were reported to SGMED-09-02 through the Data Collection Regulation and are listed in Table A3.1 of Appendix 3.

Tab. 8.15.2.3.1.1 Greek landings (t) by year and major gear types, 2002-2008 as reported through DCF.

| SPECIES | AREA | COUNTRY | FT_LVL4 | 2002 | 2003 | 2004 | 2005 | 2006 | 2007 | 2008 |

### 8.15.2.3.2. Discards

No discards data were reported to SGMED-09-02 through the DCF data call for Greece.

### 8.15.2.3.3. Fishing effort

Estimation of effort was based on interviews conducted with random sampling in 127 sampling stations (ports) in GSA 22-23. Sampling was conducted on a monthly basis at each sampling station, where a sufficient number of vessels from each fleet segment and gear type were randomly selected and effort was recorded. In addition, all fishing vessels present in the sampling stations were categorized as full-time, parttime, occasionally fishing, or inactive, and the proportion of the year they were active was estimated. Based on this information, sampled data were raised to the whole fleet to estimate total effort per fleet segment, fishing gear, and GSA. Should be noted that the estimated effort do not refer to the effective effort targeting to hake but to the entire effort of each fleet segment. This is very important for the long lines and gill nets because the effort targeting hake is much smaller than the effort of the fleets.

Tab. 8.15.2.3.3.1 lists the fishing effort reported to SGMED-09-02 through the DCR data call. The overview is given in Tab. A3.10-3.12 of Appendix 3 to this report.

Tab. 8.15.2.3.3.1 Fishing effort in different units by fishing technique deployed in GSAs 22 and 23, 20032008.

### 8.15.3.Scientific surveys

### 8.15.3.1.Medits

### 8.15.3.1.1. Methods

Tables TA, TB, TC were provided according to the MEDITS protocol. The MEDITS survey was carried out in GSAs 22-23 every summer from 1994 to 2006, except in 2002 because of administrative problems. For similar reasons, no MEDITS survey was conducted in Greece in 2007. In GSA 22 and 23, the number of stations was 98 in 1994 and gradually increased to 146 in 1996 and onwards. During the first two years $(1994,1995)$ the survey was conducted by two scientific teams from two institutes but with the same vessel. From 1996 three scientific teams were involved. During 1996 and 1997 two commercial vessels were used, and three vessels from 1998. Due to these changes in the survey design, caution is needed when investigating the trends of relevant indicators in the MEDITS time series. More details on methodology and trends on selected indicators may be found in MEDITS (2007).

Based on the DCR data call, abundance and biomass indices were recalculated. In GSAs 22 and 23 the following number of hauls was reported per depth stratum (s. Tab. 8.15.3.1.1.1).

Tab. 8.15.3.1.1.1. Number of hauls per year and depth stratum in GSAs 22 and 23, 1994-2008.

| STRATUM | 1994 | 1995 | 1996 | 1997 | 1998 | 1999 | 2000 | 2001 | 2002 | 2003 | 2004 | 2005 | 2006 | 2007 | 2008 |
| :--- | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| GSA22+23_010-050 | 10 | 10 | 11 | 10 | 13 | 12 | 13 | 13 |  | 13 | 13 | 14 | 14 |  | 13 |
| GSA22+23_050-100 | 19 | 21 | 22 | 28 | 24 | 26 | 21 | 25 |  | 25 | 23 | 24 | 24 |  | 27 |
| GSA22+23_100-200 | 19 | 26 | 38 | 36 | 36 | 33 | 38 | 35 |  | 36 | 43 | 41 | 41 | 40 |  |
| GSA22+23_200-500 | 32 | 35 | 45 | 50 | 51 | 54 | 50 | 48 |  | 51 | 53 | 52 | 52 |  | 52 |
| GSA22+23_500-800 | 18 | 13 | 19 | 22 | 22 | 21 | 20 | 17 |  | 17 | 17 | 17 | 17 |  | 17 |

Data were assigned to strata based upon the shooting position and average depth (between shooting and hauling depth). Few obvious data errors were corrected. Catches by haul were standardized to 60 minutes
hauling duration. Hauls noted as valid were used only, including stations with no catches of hake, red mullet or pink shrimp (zero catches are included).

The abundance and biomass indices by GSA were calculated through stratified means (Cochran, 1953; Saville, 1977). This implies weighting of the average values of the individual standardized catches and the variation of each stratum by the respective stratum areas in each GSA:

$$
\mathrm{Yst}=\Sigma\left(\mathrm{Yi}^{*} \mathrm{Ai}\right) / \mathrm{A}
$$

$$
\mathrm{V}(\mathrm{Yst})=\Sigma\left(\mathrm{Ai}^{2} * \mathrm{si}^{2} / \mathrm{ni}\right) / \mathrm{A}^{2}
$$

Where:
A=total survey area
$\mathrm{Ai}=$ area of the i -th stratum
si=standard deviation of the i-th stratum
ni=number of valid hauls of the i-th stratum
$\mathrm{n}=$ number of hauls in the GSA
$\mathrm{Yi}=$ mean of the i-th stratum
Yst=stratified mean abundance
$\mathrm{V}(\mathrm{Yst})=$ variance of the stratified mean
The variation of the stratified mean is then expressed as the $95 \%$ confidence interval: Confidence interval $=$ Yst $\pm \mathrm{t}$ (student distribution) $* \mathrm{~V}(\mathrm{Yst}) / \mathrm{n}$

It was noted that while this is a standard approach, the calculation may be biased due to the assumptions over zero catch stations, and hence assumptions over the distribution of data. A normal distribution is often assumed, whereas data may be better described by a delta-distribution, quasi-poisson. Indeed, data may be better modelled using the idea of conditionality and the negative binomial (e.g. O'Brien et al. (2004)).

Length distributions represented an aggregation (sum) of all standardized length frequencies (subsamples raised to standardized haul abundance per hour) over the stations of each stratum. Aggregated length frequencies were then raised to stratum abundance * 100 (because of low numbers in most strata) and finally aggregated (sum) over the strata to the GSA. Given the sheer number of plots generated, these distributions are not presented in this report.

### 8.15.3.1.2. Geographical distribution patterns

No analyses were conducted during SGMED-09-02.

### 8.15.3.1.3. Trends in abundance and biomass

Fishery independent information regarding the state of the hake in GSAs 22 and 23 was derived from the international survey Medits. Fig. 8.15.3.1.3.1 displays the estimated trend in hake abundance and biomass in GSAs 22 and 23.

The estimated abundance and biomass indices do not reveal any significant trends since 1994. However, the recent abundance and biomass indices in 2006 appear high but are subject to high variation (uncertainty). The analyses of Medits indices are considered preliminary.

Fig. 8.15.3.1.3.1 Abundance and biomass indices of hake in GSAs 22 and 23.

### 8.15.3.1.4. Trends in abundance by length or age

The following Fig. 8.15.3.1.4.1 and 2 display the stratified abundance indices of GSAs 22 and 23 combined in 1994-2001 and 2003-2008. These size compositions are considered preliminary.

Fig. 8.15.3.1.4.1 Stratified abundance indices by size, 1994-2001.

Fig. 8.15.3.1.4.2 Stratified abundance indices by size, 2003-2008.

### 8.15.3.1.5. Trends in growth

No analyses were conducted during SGMED-09-02.

### 8.15.3.1.6. Trends in maturity

No analyses were conducted during SGMED-09-02.

### 8.15.4.Assessment of historic stock parameters

SGMED 09-02 did not undertake any analytical assessment of hake in GSAs 22 and 23. Last year's preliminary assessment using SURBA can be found in the report of SGMED-08-04 working group (Cardinale et al., 2008).

No forecast analyses were conducted.

### 8.15.5.2.Input parameters

No forecast analyses were conducted.

### 8.15.5.3.Results

Given the preliminary state of the data and analyses SGMED-09-02 is not in the position to provide a long term prediction of catch and stock biomass for hake in GSAs 22 and 23.

### 8.15.6.Scientific advice

SGMED-09-02 considers all analyses presented to assess the status of hake in GSAs 22 and 23 as preliminary and not suitable to provide sound scientific advice.

### 8.15.6.1.Short term considerations

### 8.15.6.1.1. State of the spawning stock size

SGMED-09-02 is unable to provide any scientific advice of the state of the spawning stock in relation to proposed precautionary level given the preliminary state of the data and analyses.

### 8.15.6.1.2. State of recruitment

SGMED-09-02 is unable to provide any scientific advice of the state of the recruitment given the preliminary state of the data and analyses.

### 8.15.6.1.3. State of exploitation

SGMED-09-02 is unable to provide any scientific advice of the state of the exploitation in relation to proposed precautionary and target levels given the preliminary state of the data and analyses.

### 8.16. Stock assessment of red mullet in GSA 01

8.16.1.Stock identification and biological features
8.16.1.1.Stock Identification

No information was documented during SGMED-09-02.

### 8.16.1.2.Growth

No information was documented during SGMED-09-02.

### 8.16.1.3.Maturity

No information was documented during SGMED-09-02.

### 8.16.2.Fisheries

### 8.16.2.1.General description of fisheries

STECF (second stock review in 2007) notes that this species mainly appears in the mixed catches of bottom trawlers operating in sandy areas, being also caught with set gears, in particular trammel-nets and gillnets. Catch data are incomplete. Red mullets (Mullus barbatus and Mullus surmuletus) are one of the most important target species for the trawl fisheries. In the GSA 01 there are 142 trawlers that land over 150 t by year.
8.16.2.2. Management regulations applicable in 2008 and 2009

No information was documented during SGMED-09-02.

### 8.16.2.3.Catches

### 8.16.2.3.1. Landings

Landings data were reported to SGMED-09-02 through the Data collection regulation and are listed in Table A3.2 of Appendix 3. Only landings by otter trawlers are considered, which increased from 68 t in 2002 to 113 t in 2008.

Table 8.16.2.3.1.1 Annual landings ( t ) by fishing technique as reported to SGMED-09-02 through the DCR data call.

| SPECIES | AREA | COUNTRY | FT_LVL4 | 2002 | 2003 | 2004 | 2005 | 2006 | 2007 | 2008 |

Data were assigned to strata based upon the shooting position and average depth (between shooting and hauling depth). Few obvious data errors were corrected. Catches by haul were standardized to 60 minutes hauling duration. Hauls noted as valid were used only, including stations with no catches of hake, red mullet or pink shrimp (zero catches are included).

The abundance and biomass indices by GSA were calculated through stratified means (Cochran, 1953; Saville, 1977). This implies weighting of the average values of the individual standardized catches and the variation of each stratum by the respective stratum areas in each GSA:
$\mathrm{Yst}=\Sigma\left(\mathrm{Yi}^{*} \mathrm{Ai}\right) / \mathrm{A}$
$\mathrm{V}(\mathrm{Yst})=\Sigma\left(\mathrm{Ai}^{2} * \mathrm{si}^{2} / \mathrm{ni}\right) / \mathrm{A}^{2}$
Where:
A=total survey area
$\mathrm{Ai}=$ area of the i -th stratum
si=standard deviation of the i-th stratum
ni=number of valid hauls of the $i$-th stratum
n=number of hauls in the GSA
$\mathrm{Yi}=$ mean of the i -th stratum
Yst=stratified mean abundance
$\mathrm{V}(\mathrm{Yst})=$ variance of the stratified mean
The variation of the stratified mean is then expressed as the $95 \%$ confidence interval: Confidence interval $=$ Yst $\pm \mathrm{t}$ (student distribution) $* \mathrm{~V}(\mathrm{Yst}) / \mathrm{n}$

It was noted that while this is a standard approach, the calculation may be biased due to the assumptions over zero catch stations, and hence assumptions over the distribution of data. A normal distribution is often assumed, whereas data may be better described by a delta-distribution, quasi-poisson. Indeed, data may be better modelled using the idea of conditionality and the negative binomial (e.g. O'Brien et al. (2004)).

Length distributions represented an aggregation (sum) of all standardized length frequencies (subsamples raised to standardized haul abundance per hour) over the stations of each stratum. Aggregated length frequencies were then raised to stratum abundance * 100 (because of low numbers in most strata) and finally aggregated (sum) over the strata to the GSA. Given the sheer number of plots generated, these distributions are not presented in this report.

### 8.16.3.1.2. Geographical distribution patterns

No analyses were conducted during SGMED-09-02.

### 8.16.3.1.3. Trends in abundance and biomass

Fishery independent information regarding the state of the red mullet in GSA 01 was derived from the international survey Medits. Figure 8.16.3.1.3.1 displays the estimated trend in red mullet abundance and biomass in GSA 01.

The estimated abundance and biomass indices do not reveal any significant trends since 1994. However, the recent abundance and biomass indices since 2006 appear high but are subject to high variation (uncertainty). The analyses of Medits indices are considered preliminary.

Fig. 8.16.3.1.3.1 Abundance and biomass indices of red mullet in GSA 01.

### 8.16.3.1.4. Trends in abundance by length or age

The following Fig. 8.6.3.1.4.1 and 2 display the stratified abundance indices of GSA 01 in 1994-2001 and 2002-2008. These size compositions are considered preliminary.

Fig. 8.16.3.1.4.1 Stratified abundance indices by size, 1994-2001.

Fig. 8.16.3.1.4.2 Stratified abundance indices by size, 2002-2008.

### 8.16.3.1.5. Trends in growth

No analyses were conducted during SGMED-09-02.

### 8.16.3.1.6. Trends in maturity

No analyses were conducted during SGMED-09-02.

SGMED 09-02 did not undertake any analytical assessment of red mullet in GSA 01. Last year's assessment using VIT can be found in the report of SGMED-08-04 working group (Cardinale et al., 2008).

### 8.16.5.Long term prediction

### 8.16.5.1.Justification

No forecast analyses were conducted.
8.16.5.2.Input parameters

No forecast analyses were conducted.

### 8.16.5.3.Results

No forecast analyses were conducted.
8.16.6.Scientific advice

### 8.16.6.1.Short term considerations

### 8.16.6.1.1. State of the spawning stock size

SGMED-09-02 is unable to provide any scientific advice of the state of the spawning stock in relation to proposed precautionary level given the preliminary state of the data and analyses.

### 8.16.6.1.2. State of recruitment

SGMED-09-02 is unable to provide any scientific advice of the state of the recruitment given the preliminary state of the data and analyses.

### 8.16.6.1.3. State of exploitation

SGMED-09-02 is unable to provide any scientific advice of the state of the exploitation in relation to proposed precautionary and target levels given the preliminary state of the data and analyses.

### 8.17. Stock assessment of red mullet in GSA 06

### 8.17.1.Stock identification and biological features

### 8.17.1.1.Stock Identification

No information was documented during SGMED-09-02.

### 8.17.1.2.Growth

No information was documented during SGMED-09-02.

### 8.17.1.3.Maturity

No information was documented during SGMED-09-02.

### 8.17.2.Fisheries

### 8.17.2.1.General description of fisheries

STECF in 2007 (stock review part II) noted that Red mullet (Mullus barbatus) is one of the target species of the trawl fishery in the GFCM geographical sub-area 06 (Northern Spain). The trawl fleet operating in this area is composed by 647 boats averaging 47 TRB, 58 GT and 297 HP. Some of these units (smaller vessels) operate almost exclusively on the continental shelf, targeting red mullet, octopus, hake and different species of sea breams. According to official data, landings increased considerably between 1973 and 1982 and from this year until now a decreasing trend has been observed. In the period 1998-2004 landings of this species averaged 1315 t per year.
8.17.2.2.Management regulations applicable in 2008 and 2009

No information was documented during SGMED-09-02.

### 8.17.2.3.Catches

### 8.17.2.3.1. Landings

Tab. 8.17.2.3.1.1 lists the trend in reported landings taken by trawlers (Spain only). The data were reported to SGMED-09-02 through the Data Collection Regulation and are listed in Table A3.2 of Appendix 3. Since 2002 the annual landings varied between 960 and 1,230 t.

Tab. 8.17.2.3.1.1 Annual landings ( t ) by fishing technique (otter trawlers only) in GSA 06.

### 8.17.2.3.2. Discards

No information was documented during SGMED-09-02.

### 8.17.2.3.3. Fishing effort

Fishing effort data are listed in Appendix 3, Tables 3.10-3.12.

### 8.17.3.Scientific surveys

### 8.17.3.1.Medits

### 8.17.3.1.1. Methods

Based on the DCR data call, abundance and biomass indices were recalculated. In GSA 06 the following number of hauls was reported per depth stratum (s. Tab. 8.17.3.1.1.1).

Tab. 8.17.3.1.1.1. Number of hauls per year and depth stratum in GSA 06, 1994-2008.

| STRATUM | 1994 | 1995 | 1996 | 1997 | 1998 | 1999 | 2000 | 2001 | 2002 | 2003 | 2004 | 2005 | 2006 | 2007 | 2008 |
| :--- | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |

| GSA06_050-100 | 21 | 28 | 27 | 26 | 28 | 30 | 30 | 31 | 36 | 39 | 31 | 32 | 34 | 40 | 43 |
| GSA06_100-200 | 11 | 19 | 17 | 15 | 13 | 17 | 19 | 20 | 20 | 21 | 17 | 18 | 19 | 24 | 30 |
| GSA06_200-500 | 10 | 13 | 10 | 12 | 7 | 13 | 12 | 16 | 17 | 18 | 16 | 15 | 18 | 18 | 19 |
| GSA06_500-800 | 7 | 8 | 9 | 7 | 4 | 9 | 6 | 8 | 7 | 11 | 11 | 8 | 10 | 15 | 14 |

Data were assigned to strata based upon the shooting position and average depth (between shooting and hauling depth). Few obvious data errors were corrected. Catches by haul were standardized to 60 minutes hauling duration. Hauls noted as valid were used only, including stations with no catches of hake, red mullet or pink shrimp (zero catches are included).

The abundance and biomass indices by GSA were calculated through stratified means (Cochran, 1953; Saville, 1977). This implies weighting of the average values of the individual standardized catches and the variation of each stratum by the respective stratum areas in each GSA:
$\mathrm{Yst}=\Sigma\left(\mathrm{Yi}^{*}{ }^{*} \mathrm{Ai}\right) / \mathrm{A}$
$\mathrm{V}(\mathrm{Yst})=\Sigma\left(\mathrm{Ai}^{2} * \mathrm{si}^{2} / \mathrm{ni}\right) / \mathrm{A}^{2}$
Where:
A=total survey area
$\mathrm{Ai}=$ area of the i -th stratum
si=standard deviation of the i-th stratum
ni=number of valid hauls of the i-th stratum
$\mathrm{n}=$ number of hauls in the GSA
$\mathrm{Yi}=$ mean of the i-th stratum
Yst=stratified mean abundance
$\mathrm{V}(\mathrm{Yst})=$ variance of the stratified mean
The variation of the stratified mean is then expressed as the $95 \%$ confidence interval: Confidence interval $=$ Yst $\pm \mathrm{t}$ (student distribution) $* \mathrm{~V}(\mathrm{Yst}) / \mathrm{n}$

It was noted that while this is a standard approach, the calculation may be biased due to the assumptions over zero catch stations, and hence assumptions over the distribution of data. A normal distribution is often assumed, whereas data may be better described by a delta-distribution, quasi-poisson. Indeed, data may be better modelled using the idea of conditionality and the negative binomial (e.g. O'Brien et al. (2004)).

Length distributions represented an aggregation (sum) of all standardized length frequencies (subsamples raised to standardized haul abundance per hour) over the stations of each stratum. Aggregated length frequencies were then raised to stratum abundance * 100 (because of low numbers in most strata) and finally aggregated (sum) over the strata to the GSA. Given the sheer number of plots generated, these distributions are not presented in this report.

### 8.17.3.1.2. Geographical distribution patterns

No analyses were conducted during SGMED-09-02.

### 8.17.3.1.3. Trends in abundance and biomass

Fishery independent information regarding the state of the red mullet in GSA 06 was derived from the international survey Medits. Figure 8.17.3.1.3.1 displays the estimated trend in red mullet abundance and biomass in GSA 06.

The estimated abundance and biomass indices do not reveal any significant trends since 1994. However, the recent abundance and biomass indices in 2007 appear high but are subject to high variation (uncertainty). The analyses of Medits indices are considered preliminary.

Fig. 8.17.3.1.3.1 Abundance and biomass indices of red mullet in GSA 06.

### 8.17.3.1.4. Trends in abundance by length or age

The following Fig. 8.17.3.1.4.1 and 2 display the stratified abundance indices of GSA 06 in 1994-2001 and 2002-2008. These size compositions are considered preliminary.

Fig. 8.17.3.1.4.2 Stratified abundance indices by size, 2002-2008.

### 8.17.3.1.5. Trends in growth

No analyses were conducted during SGMED-09-02.
8.17.3.1.6. Trends in maturity

No analyses were conducted during SGMED-09-02.

### 8.17.4.Assessment of historic stock parameters

SGMED-09-02 did not undertake any analytical assessment. SGMED noted that red mullet in GSA 06 was assessed in 2008 and presented to SCSA/SAC/GFCM. This assessment can be viewed at:
http://www.gfcm.org/ for GSA06 open Doc04-MUT0608Gui.xls
8.17.5.Long term prediction

### 8.17.5.1.Justification

No forecast analyses were conducted.

### 8.17.5.2.Input parameters

No forecast analyses were conducted.

### 8.17.5.3.Results

Given the preliminary state of the data and analyses SGMED-09-02 is not in the position to provide a long term prediction of catch and stock biomass for red mullet in GSA 06.

### 8.17.6.Scientific advice

### 8.17.6.1.Short term considerations

### 8.17.6.1.1. State of the spawning stock size

SGMED-09-02 is unable to provide any scientific advice of the state of the spawning stock given the preliminary state of the data and analyses.

### 8.17.6.1.2. State of recruitment

SGMED-09-02 is unable to provide any scientific advice of the state of the recruitment given the preliminary state of the data and analyses.

### 8.17.6.1.3. State of exploitation

SGMED-09-02 is unable to provide any scientific advice of the state of the exploitation in relation to proposed precautionary and target levels given the preliminary state of the data and analyses.

### 8.18. Stock assessment of red mullet in GSA 07

8.18.1.Stock identification and biological features
8.18.1.1.Stock Identification

No information was documented during SGMED-09-02.

### 8.18.1.2.Growth

No information was documented during SGMED-09-02.

### 8.18.1.3.Maturity

No information was documented during SGMED-09-02.

### 8.18.2.Fisheries

8.18.2.1.General description of fisheries

No information was documented during SGMED-09-02.
8.18.2.2. Management regulations applicable in 2008 and 2009

No information was documented during SGMED-09-02.

### 8.18.2.3.Catches

### 8.18.2.3.1. Landings

Tab. 8.18.2.3.1.1 lists the trend in reported landings taken by trawlers (France only). The data were reported to SGMED-09-02 through the Data Collection Regulation and are listed in Table A3.2 of Appendix 3.

Tab. 8.18.2.3.1.1 Annual landings (t) by fishing technique (otter trawlers only) in GSA 07.

| SPECIES | AREA | COUNTRY | FT_LVL4 | 2002 | 2003 | 2004 | 2005 | 2006 | 2007 | 2008 |

| MUT | 7 | FRA | OTB |  |  |  |  | 183 | 172 | 111 |

### 8.18.2.3.2. Discards

Reported discards through the DCF data call to SGMED-09-02 are listed in Table A3.9 of Appendix 3.However, some values regarding French discards data appear unreasonable.

### 8.18.2.3.3. Fishing effort

Tab. 8.18.2.3.2.1 lists the trends in fishing effort by fishing technique deployed in GSA 07, 2003 to 2008 (Tab. A3.10-3.12 in Appendix 3). The data were reported to SGMED-09-02 trough the DCR data call.

Tab. 8.18.2.3.2.1 Trends in fishing effort by fishing technique deployed in GSA 07, 2003 to 2008. No values were reported for 2002.

8.18.3.Scientific surveys

### 8.18.3.1.Medits

### 8.18.3.1.1. Methods

Based on the DCR data call, abundance and biomass indices were recalculated. In GSA 07 the following number of hauls was reported per depth stratum (s. Tab. 8.18.3.1.1.1).

Tab. 8.18.3.1.1.1. Number of hauls per year and depth stratum in GSA 07, 1994-2008.

| STRATUM | 1994 | 1995 | 1996 | 1997 | 1998 | 1999 | 2000 | 2001 | 2002 | 2003 | 2004 | 2005 | 2006 | 2007 | 2008 |
| :--- | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| GSA07_010-050 | 12 | 12 | 12 | 15 | 12 | 12 | 12 | 12 | 12 | 13 | 12 | 12 | 12 | 15 | 12 |
| GSA07_050-100 | 32 | 32 | 32 | 38 | 39 | 33 | 33 | 33 | 32 | 38 | 31 | 31 | 33 | 31 | 25 |
| GSA07_100-200 | 10 | 9 | 9 | 9 | 9 | 9 | 10 | 9 | 9 | 10 | 13 | 11 | 10 | 10 | 7 |
| GSA07_200-500 | 6 | 6 | 5 | 6 | 5 | 5 | 6 | 6 | 5 | 5 | 5 | 5 | 5 | 5 | 4 |
| GSA07_500-800 | 8 | 7 | 5 | 5 | 4 | 5 | 6 | 5 | 4 | 5 | 6 | 5 | 6 | 5 | 5 |

Data were assigned to strata based upon the shooting position and average depth (between shooting and hauling depth). Few obvious data errors were corrected. Catches by haul were standardized to 60 minutes hauling duration. Hauls noted as valid were used only, including stations with no catches of hake, red mullet or pink shrimp (zero catches are included).

The abundance and biomass indices by GSA were calculated through stratified means (Cochran, 1953; Saville, 1977). This implies weighting of the average values of the individual standardized catches and the variation of each stratum by the respective stratum areas in each GSA:
$\mathrm{Yst}=\Sigma\left(\mathrm{Yi}^{*} \mathrm{Ai}\right) / \mathrm{A}$
$\mathrm{V}(\mathrm{Yst})=\Sigma\left(\mathrm{Ai}^{2} * \mathrm{si}^{2} / \mathrm{ni}\right) / \mathrm{A}^{2}$
Where:
A=total survey area
$\mathrm{Ai}=$ area of the i-th stratum
si=standard deviation of the i-th stratum
ni=number of valid hauls of the i-th stratum
$\mathrm{n}=$ number of hauls in the GSA
$\mathrm{Yi}=$ mean of the i-th stratum
Yst=stratified mean abundance
$\mathrm{V}(\mathrm{Yst})=$ variance of the stratified mean
The variation of the stratified mean is then expressed as the $95 \%$ confidence interval: Confidence interval $=$ Yst $\pm \mathrm{t}$ (student distribution) $* \mathrm{~V}(\mathrm{Yst}) / \mathrm{n}$

It was noted that while this is a standard approach, the calculation may be biased due to the assumptions over zero catch stations, and hence assumptions over the distribution of data. A normal distribution is often assumed, whereas data may be better described by a delta-distribution, quasi-poisson. Indeed, data may be better modelled using the idea of conditionality and the negative binomial (e.g. O'Brien et al. (2004)).

Length distributions represented an aggregation (sum) of all standardized length frequencies (subsamples raised to standardized haul abundance per hour) over the stations of each stratum. Aggregated length frequencies were then raised to stratum abundance * 100 (because of low numbers in most strata) and finally aggregated (sum) over the strata to the GSA. Given the sheer number of plots generated, these distributions are not presented in this report.

### 8.18.3.1.2. Geographical distribution patterns

No analyses were conducted during SGMED-09-02.

### 8.18.3.1.3. Trends in abundance and biomass

Fishery independent information regarding the state of the red mullet in GSA 07 was derived from the international survey Medits. Figure 8.18.3.1.3.1 displays the estimated trend in red mullet abundance and biomass in GSA 07.

The estimated abundance and biomass indices do not reveal any significant trends since 1994. However, the recent abundance and biomass indices in 2007 appear high but are subject to high variation (uncertainty). The analyses of Medits indices are considered preliminary.

Fig. 8.18.3.1.3.1 Abundance and biomass indices of red mullet in GSA 07.

### 8.18.3.1.4. Trends in abundance by length or age

The following Fig. 8.18.3.1.4.1 and 2 display the stratified abundance indices of GSA 07 in 1994-2001 and 2002-2008. These size compositions are considered preliminary.

Fig. 8.18.3.1.4.1 Stratified abundance indices by size, 1994-2001.

Fig. 8.18.3.1.4.2 Stratified abundance indices by size, 2002-2008.

### 8.18.3.1.5. Trends in growth

No analyses were conducted during SGMED-09-02.

### 8.18.3.1.6. Trends in maturity

No analyses were conducted during SGMED-09-02.
8.18.4.Assessment of historic stock parameters

SGMED-09-02 did not undertake any analytical assessment.

### 8.18.5.Long term prediction

### 8.18.5.1.Justification

No forecast analyses were conducted.

### 8.18.5.2.Input parameters

No forecast analyses were conducted.

### 8.18.5.3.Results

Given the preliminary state of the data and analyses SGMED-09-02 is not in the position to provide a long term prediction of catch and stock biomass for red mullet in GSA 07.
8.18.6.Scientific advice

### 8.18.6.1.Short term considerations

### 8.18.6.1.1. State of the spawning stock size

SGMED-09-02 is unable to provide any scientific advice of the state of the spawning stock in relation to proposed precautionary level given the preliminary state of the data and analyses.

### 8.18.6.1.2. State of recruitment

SGMED-09-02 is unable to provide any scientific advice of the state of the recruitment given the preliminary state of the data and analyses.

### 8.18.6.1.3. State of exploitation

SGMED-09-02 is unable to provide any scientific advice of the state of the exploitation in relation to proposed precautionary and target levels given the preliminary state of the data and analyses.

### 8.19. Stock assessment of red mullet in GSA 08

8.19.1.Stock identification and biological features
8.19.1.1.Stock Identification

No information was documented during SGMED-09-02.
8.19.1.2.Growth

No information was documented during SGMED-09-02.
8.19.1.3.Maturity

No information was documented during SGMED-09-02.

### 8.19.2.Fisheries

8.19.2.1.General description of fisheries

No information was documented during SGMED-09-02.
8.19.2.2. Management regulations applicable in 2008 and 2009

No information was documented during SGMED-09-02.

### 8.19.2.3.Catches

### 8.19.2.3.1. Landings

No information was documented during SGMED-09-02.

### 8.19.2.3.2. Discards

No information was documented during SGMED-09-02.

### 8.19.2.3.3. Fishing effort

No information was documented during SGMED-09-02.
8.19.3.Scientific surveys
8.19.3.1.Medits

### 8.19.3.1.1. Methods

Based on the DCR data call, abundance and biomass indices were recalculated. SGMED-09-02 notes that the reported Medits data in GSA 08 only cover the eastern coast of Corsica. In GSA 08 the following number of hauls was reported per depth stratum (s. Tab. 8.19.3.1.1.1).

Tab. 8.19.3.1.1.1. Number of hauls per year and depth stratum in GSA 08, 1994-2008.

Data were assigned to strata based upon the shooting position and average depth (between shooting and hauling depth). Few obvious data errors were corrected. Catches by haul were standardized to 60 minutes hauling duration. Hauls noted as valid were used only, including stations with no catches of hake, red mullet or pink shrimp (zero catches are included).

The abundance and biomass indices by GSA were calculated through stratified means (Cochran, 1953; Saville, 1977). This implies weighting of the average values of the individual standardized catches and the variation of each stratum by the respective stratum areas in each GSA:
$\mathrm{Yst}=\Sigma\left(\mathrm{Yi}^{*} \mathrm{Ai}\right) / \mathrm{A}$

$$
\mathrm{V}(\mathrm{Yst})=\Sigma\left(\mathrm{Ai}^{2} * \mathrm{si}^{2} / \mathrm{ni}\right) / \mathrm{A}^{2}
$$

Where:
A=total survey area
$\mathrm{Ai}=$ area of the i-th stratum
si=standard deviation of the i-th stratum
ni=number of valid hauls of the i-th stratum
n=number of hauls in the GSA
$\mathrm{Yi}=$ mean of the i-th stratum
Yst=stratified mean abundance
$\mathrm{V}(\mathrm{Yst})=$ variance of the stratified mean
The variation of the stratified mean is then expressed as the $95 \%$ confidence interval: Confidence interval $=$ Yst $\pm \mathrm{t}$ (student distribution) $* \mathrm{~V}(\mathrm{Yst}) / \mathrm{n}$

It was noted that while this is a standard approach, the calculation may be biased due to the assumptions over zero catch stations, and hence assumptions over the distribution of data. A normal distribution is often assumed, whereas data may be better described by a delta-distribution, quasi-poisson. Indeed, data may be better modelled using the idea of conditionality and the negative binomial (e.g. O'Brien et al. (2004)).

Length distributions represented an aggregation (sum) of all standardized length frequencies (subsamples raised to standardized haul abundance per hour) over the stations of each stratum. Aggregated length frequencies were then raised to stratum abundance $* 100$ (because of low numbers in most strata) and finally aggregated (sum) over the strata to the GSA. Given the sheer number of plots generated, these distributions are not presented in this report.

### 8.19.3.1.2. Geographical distribution patterns

No analyses were conducted during SGMED-09-02.

### 8.19.3.1.3. Trends in abundance and biomass

Fishery independent information regarding the state of the red mullet in GSA 08 was derived from the international survey Medits. SGMED-09-02 notes that the reported Medits data in GSA 08 only cover the eastern coast of Corsica. Figure 8.19.3.1.3.1 displays the estimated trend in red mullet abundance and biomass in GSA 08.

The estimated abundance and biomass indices do not reveal any significant trends since 1994. However, the recent abundance and biomass indices in 2007 appear very low. The analyses of Medits indices are considered preliminary.

Fig. 8.19.3.1.3.1 Abundance and biomass indices of red mullet in GSA 08.

### 8.19.3.1.4. Trends in abundance by length or age

The following Fig. 8.19.3.1.4.1 and 2 display the stratified abundance indices of GSA 08 in 1994-2001 and 2002-2008. These size compositions are considered preliminary.

Fig. 8.19.3.1.4.1 Stratified abundance indices by size, 1994-2001.

Fig. 8.19.3.1.4.2 Stratified abundance indices by size, 2002-2008.

### 8.19.3.1.5. Trends in growth

No analyses were conducted during SGMED-09-02.
8.19.3.1.6. Trends in maturity

No analyses were conducted during SGMED-09-02.
8.19.4.Assessment of historic stock parameters

SGMED-09-02 did not undertake any analytical assessment.
8.19.5.Long term prediction

### 8.19.5.1.Justification

No forecast analyses were conducted.

### 8.19.5.2.Input parameters

No forecast analyses were conducted.

### 8.19.5.3.Results

Given the preliminary state of the data and analyses SGMED-09-02 is not in the position to provide a long term prediction of catch and stock biomass for red mullet in GSA 08.
8.19.6. Scientific advice

### 8.19.6.1.Short term considerations

### 8.19.6.1.1. State of the spawning stock size

SGMED-09-02 is unable to provide any scientific advice of the state of the spawning stock in relation to proposed precautionary level given the preliminary state of the data and analyses.

### 8.19.6.1.2. State of recruitment

SGMED-09-02 is unable to provide any scientific advice of the state of the recruitment given the preliminary state of the data and analyses.

### 8.19.6.1.3. State of exploitation

SGMED-09-02 is unable to provide any scientific advice of the state of the exploitation in relation to proposed precautionary and target levels given the preliminary state of the data and analyses.

### 8.20. Stock assessment of red mullet in GSA 09

### 8.20.1.Stock identification and biological features

### 8.20.1.1.Stock Identification

Red mullet is distributed along the shelf of all the Mediterranean countries. Even though the species can be found at depths over 200 m , it is mainly concentrated in the depth range $0-100 \mathrm{~m}$. All the year classes and nursery and spawning areas are well distributed along the narrow Mediterranean shelves. There is not any available definition of unit stocks neither based on genetics, bio-chemistry, fishery-based nor on any alternative method based on somatic features. Under a management point of view, in the frame of GFCM, it has been decided, when the lack of any evidence does not allow suggesting an alternative hypothesis, that inside each one of the GSAs boundaries inhabits a single, homogeneous red mullet stock that behaves as a single well-mixed and self-perpetuating population. The GSA boundaries are however arbitrary and certaintly do not take under consideration neither the existence of any local biological feature nor of any difference in the spatial allocation in fishing pressure within it. The hypothesis of a single stock of red mullet in GSA 09, which includes waters belonging to 2 seas (Ligurian and Tyrrhenian) separated by the Elba Island and fleets that does not show any spatial overlapping is almost unlikely. The inability to account for spatial structure reduces flexibility and can lead to uncertainty in the definition of the status of the stocks, due to the possibility of local depletions and to a worse utilization of the potential productivity of the resources.

### 8.20.1.2.Growth

The species is fast growing, and reaches half of its total size when is one year old. Some light differences in growth speed has been observed within different zones within the GSA 09. In zones where the species is less exploited, individuals more densely concentrated or available food is lower, the mean size of 6 months old individuals is from 1 to 1.5 cm lower than in other areas of the same GSA were the species is more highly exploited and hence less abundant. In any case, the parameters reported as follows may be considered suitable for the description of an average growth performance valid for the whole GSA 09.

Table 8.20.1.2.1 Common growth parameters and natural mortality rates considered representative for $M$. barbatus in the GSA 09 utilized in the successive analyses.

| $L_{\infty}$ |  | 29 |
| :---: | :---: | :---: |
| K |  | 0.6 |
| to |  | -0.1 |
| L/W | a | 0.00 |
|  | b | 3.12 |
| An M vector was used for LCA with age 0 0.30 , age $1=0.79$, age $2=0.62$, ase 3 or older $=0.54$ and a weighted mean value of Mof 0.8 for YR. computations |  |  |

### 8.20.1.3.Maturity

The species reaches massively the sexual maturity at one year old. Observations of proportion of mature individuals by size and analysis with the standard procedure have produced the following sizes at age maturity by sex.

The classical approach for the definition of Lm , as expected, produces a light underestimation of this size. In fact, the bulk of the females spawn at a size of about 14 cm .

In GSA 09 there have been performed studies on fecundity. The following relationship of fecundity at size (in cm ) was defined in the area: $\mathrm{Fec}=0.7599 * \mathrm{TL} \wedge 3.336$

### 8.20.2. Fisheries

### 8.20.2.1.General description of fisheries

STECF in 2007 (stock review part II) notes that Mullus barbatus is among the most commercially valuable species in the area and is an important component of a species assemblage that is the target of the bottom trawling fleets operating near shore. It becomes a first order target of part of the fleet in some particular periods when the juveniles of the species are densely concentrated near the coast. The species in GSA 09 is mainly caught with three different variants of the Italian bottom trawl net ("tartana", "volantina" and wide vertical opening or "francese"). The small mesh size of the cod end in all cases defines a very precocious size/age of first capture.
$L_{c} \quad 7.4 \mathrm{~cm}$ TL (males + females) $\quad$ De Ranieri et al. , 2000

Set nets catch modest quantitatives of relatively large individuals, in general over 12 cm TL . The exerted fishing pressure on this species on different zones of GSA 09 is quite variable because conditioned by the structural composition of the fractions of the fleets that operate close to their respective ports, by the bottom characteristics potentially exploitable close to the ports and also by differences in the fisheries' target among fleets and zones. Mullus barbatus catch rates are higher during the post-recruitment period (from September to November). About 200 of the 350 trawlers and a small number of artisanal vessels exploit the species in the GSA 09. Annual landings, mostly proceeding from trawling, ranged from 500 to 1100 tons in the last years. Discards of undersized individuals is in general limited (about $10 \%$ in weight in 2006), mainly due to the fact that immediately after recruitment, small sized individuals, even though potentially vulnerable to the gear, are mostly concentrated inside the 3 miles where trawling practices are forbidden.

Fig. 8.20.2.1 Landings per unit of effort by year in two of the more important ports of GSA 09.

Fishing closure for trawling: 45 days in late summer have been enforced certain years for some fleets in GSA 09. In 2008 it was compulsory for all the trawlers in the area and is expected this measure will be repeated in 2009.

Minimum landing sizes: EC regulation 1967/2006 defined 12 cm TL as minimum legal landed size for red mullet.
Cod end mesh size of trawl nets: the 40 mm (stretched, diamond meshes) will continue to be utilized up to $30 / 05 / 2010$. Since $1 / 6 / 2010$, such cod end will be replaced by a 40 mm square meshes or alternatively by a net with a cod end of 50 mm (stretched) diamond meshes. It is not expected a noticeable increase in the size of entering to the fishery with the introduced changes because this size is only patially defined by the gear but also by the spatial distribution of juveniles.
Towed gears are not allowed within three nautical miles from the coast or at depths less than 50 m when this depth is reached at a distance less than 3 miles from the coast.

### 8.20.2.3.Catches

### 8.20.2.3.1. Landings

Landings data were reported through the Data collection regulation and are listed in Table A3.2 of Appendix 3. Since 2002 annual landings varied between 620 and 1,100 (Tab. 8.20.2.3.1.1). Demersal bottom trawlers dominate the landings by far. Landings size show a very high seasonal variability, with peaks at the end of summer (September) determined by the increase in availability/vulnerability after the massive recruitment on the coastal area.

Fig. 8.20.2.3.1.1 Monthly catches with regular seasonal fluctuations in red mullet landings in two of the main ports of GSA 09 .

Tab. 8.20.2.3.1.1 Annual landings (t) by fishing technique as reported to SGMED-09-02 through the DCR data call.

| YEAR | Bottom trawls | Nets | Total catch (Tons) |
| :---: | :---: | :---: | :---: |

### 8.20.2.3.2. Discards

158 t of discards in 2006 were reported to SGMED-09-02 and are listed in Tab. A3.9 of Appendix 3.

### 8.20.2.3.3. Fishing effort

Tab. 8.20.2.3.3.1 lists the effort by fishing technique deployed in GSA 09 as reported to SGMED-09-02 through the DCR data call and listed in Tab. A3.10-3.12 of Appendix 3. A minor decrease is observed for the main gear demersal otter trawl. It is however difficult to extract from these figures the real number of vessels that target red mullet.
In the last 15 years, a general decrease in the size of the fishing fleets operating in the GSA 09 targeting demersal species was observed. The number of vessels targeting the species in question and the changes (reduction) in number along the time interval 1990-2007 is only known for some ports of the GSA. The reduction of number of vessels has been particularly important in Porto Santo Stefano fleet (about $50 \%$ of reduction) in the South and in Viareggio (about 30\%) in the North. It is likely that this general reduction in numbers of vessels also apply for the fraction of the fleet that exert its fishing effort on M. barbatus over all the GSA 09 fleets.

Fig. 8.20.2.3.3.1 Number of vessels and fishing activity in the port of Viareggio (1990-2008)

Fig. 8.20.2.3.3.2 Number of vessels in the port of Santo Stefano (1990-2002).

Tab. 8.20.2.3.3.1 Effort trends by fishing technique in GSA 09. Data regards the whole fleets by fishing typology without any distinction regarding targets, season nor operations depth interval).

### 8.20.3.1.Medits

### 8.20.3.1.1. Methods

Based on the DCR data call, abundance and biomass indices were recalculated. In GSA 09 the following number of hauls was reported per depth stratum ( s . Tab. 8.20.3.1.1.1).

Tab. 8.20.3.1.1.1. Number of hauls per year and depth stratum in GSA 09, 1994-2008.

| STRATUM | 1994 | 1995 | 1996 | 1997 | 1998 | 1999 | 2000 | 2001 | 2002 | 2003 | 2004 | 2005 | 2006 | 2007 | 2008 |

| GSA09_500-800 | 31 | 30 | 32 | 28 | 30 | 28 | 27 | 29 | 24 | 22 | 21 | 20 | 20 | 17 | 18 |

Data were assigned to strata based upon the shooting position and average depth (between shooting and hauling depth). Few obvious data errors were corrected. Catches by haul were standardized to 60 minutes hauling duration. Hauls noted as valid were used only, including stations with no catches of hake, red mullet or pink shrimp (zero catches are included).

The abundance and biomass indices by GSA were calculated through stratified means (Cochran, 1953; Saville, 1977). This implies weighting of the average values of the individual standardized catches and the variation of each stratum by the respective stratum areas in each GSA:
$\mathrm{Yst}=\Sigma\left(\mathrm{Yi}^{*} \mathrm{Ai}\right) / \mathrm{A}$
$\mathrm{V}(\mathrm{Yst})=\Sigma\left(\mathrm{Ai}^{2} * \mathrm{si}^{2} / \mathrm{ni}\right) / \mathrm{A}^{2}$
Where:
A=total survey area
$\mathrm{Ai}=$ area of the i -th stratum
si=standard deviation of the i-th stratum
ni=number of valid hauls of the i-th stratum
$\mathrm{n}=$ number of hauls in the GSA
$\mathrm{Yi}=$ mean of the i-th stratum
Yst=stratified mean abundance
$\mathrm{V}(\mathrm{Yst})=$ variance of the stratified mean
The variation of the stratified mean is then expressed as the $95 \%$ confidence interval: Confidence interval $=$ Yst $\pm \mathrm{t}$ (student distribution) $* \mathrm{~V}(\mathrm{Yst}) / \mathrm{n}$

It was noted that while this is a standard approach, the calculation may be biased due to the assumptions over zero catch stations, and hence assumptions over the distribution of data. A normal distribution is often assumed, whereas data may be better described by a delta-distribution, quasi-poisson. Indeed, data may be better modelled using the idea of conditionality and the negative binomial (e.g. O'Brien et al. (2004)).

Length distributions represented an aggregation (sum) of all standardized length frequencies (subsamples raised to standardized haul abundance per hour) over the stations of each stratum. Aggregated length frequencies were then raised to stratum abundance * 100 (because of low numbers in most strata) and finally aggregated (sum) over the strata to the GSA. Given the sheer number of plots generated, these distributions are not presented in this report.

### 8.20.3.1.2. Geographical distribution patterns

The species is distributed all along the continental shelf of the GSA 09 , with major abundance in the depth range $0-100 \mathrm{~m}$. The species is highly concentarted along the coastal stripe $0-30 \mathrm{~m}$ when in late summerbeginnings of autumn juveniles massively settle to the bottom. The major nursery areas are allocated in the northern portion of the GSA, Northwards the Elba Island (yellow areas in Fig. 8.20.3.1.2.1).

Fig. 8.20.3.1.2.1 Distribution of juveniles of red mullet in autumn 2004 (GRUND survey) in $\mathrm{kg} / \mathrm{km}^{2}$.
Also mature individuals are more abundant in the Northern part of the GSA 09.

Fig. 8.20.3.1.2.2 Distribution of mature adults of red mullet in spring 2004 (MEDITS survey) in numbers/km ${ }^{2}$.

The nursery concentrations show a marked spatial stability. Fig. 8.20.3.1.2.3 shows the areas where a major stability along time has been observed (in dark brown)

Fig. 8.20.3.1.2.3 Analysis of stability along time of red mullet nursery areas in GSA 09.

### 8.20.3.1.3. Trends in abundance and biomass

Fishery independent information regarding the state of the red mullet in GSA 09 was derived from the international surveys Medits and Grund. Fig. 8.20.3.1.3.1 and 2 display the estimated trends in abundance and biomass.

The estimated abundance and biomass indices do not reveal any significant trend since 1994. However, since 2002 estimated abundance indices displayed a pronounced interannual variability and were subject to high uncertainty (high confidence intervals).

Fig. 8.20.3.1.3.1 GRUND and MEDITS survey abundance and biomass estimates.

Fig. 8.20.3.1.3.2 Abundance and biomass indices of red mullet in GSA 09 derived from MEDITS.

### 8.20.3.1.4. Trends in abundance by length or age

The following Fig. 8.20.3.1.4.1 and 2 display the stratified abundance indices of GSA 09 in 1994-2001 and 2002-2008.

Fig. 8.20.3.1.4.1 Stratified abundance indices by size, 1994-2001.

Fig. 8.20.3.1.4.2 Stratified abundance indices by size, 2002-2008.

### 8.20.3.1.5. Trends in growth

No analyses were conducted.

### 8.20.3.1.6. Trends in maturity

No analyses were conducted.
8.20.4.Assessment of historic stock parameters

### 8.20.4.1.Method 1: Length cohort analysis LCA

### 8.20.4.1.1. Justification

A LCA was performed aimed at the estimation of a vector of $F$ at size, using data on total annual catches by size, including discard. Considering the short time series available, it was not possible to perform VPA. An average size distribution of the catch for the years 2006-2008 was used in order to approch an equilibrium status.

### 8.20.4.1.2. Input parameters

Catch of red mullet proceeds from two fisheries (bottom trawlers targeting a coastal demersal assemblage and artisanal fisheries using trammel nets. The catch of trammel nets is quite modest ( $<2 \%$ in numbers). A reasonable hypothesis of a declining rate of M with age derived from ProdBiom was used in the computations (mean values for age $0=1.30$, age $1=0.79$, age $2=0.62$, age $3=>0.54$ ).

### 8.20.4.1.3. Results

The analysis suggests a weighted mean $F$ of about 0.97 between 8 cm and 20 cm which are the sizes with major contribution to the catch. The values of $F$ for the bigger sizes may be handled with care due to the limited number of individuals included in the analysis. Very big sized individuals live at deeper waters and are seldom caught.
The simulations suggest that the current spawning stock biomass in the area is reduced to about $18 \%$ of the pristine SSB.

### 8.20.4.2.Method 2: Stock Production Model

### 8.20.4.2.1. Justification

The analysis was performed using the ASPIC. 5 software (A Stock-Production model Incorporating Covariates) (Prager, 1994, 2005) assuming a Schaefer (1954) model. This program implements a nonequilibrium, continuous-time, observation-error estimator for the dynamic production model (Schnute, 1977; Prager, 1994). The model was used to estimate $r$ (the intrinsic rate of population growth), $M S Y$, the ratios of both current biomass or $F$ to the biomass or F at which $M S Y$ can be attained, and $q$ (the catchability coefficient, the proportion of total stock removed by one unit of fishing effort).

### 8.20.4.2.2. Input parameters

Input data consist of 2 sets of time series of total landings (in kg ) and fishing effort expressed as $\mathrm{kg} / \mathrm{hour}$ and $\mathrm{kg} / \mathrm{day}$ for two of the main ports of the GSA 09 (Viareggio and Porto Santo Stefano) which are considered representative for the area and a time series of an index of abundance $\left(\mathrm{kg} / \mathrm{km}^{2}\right)$ for the whole GSA 09 derived from MEDITS surveys. This is a new extension incorporated in ASPIC new versions.

INFORMATION FOR REPAST (Prager, Porch, Shertzer, \& Caddy. 2003. NAJFM 23: 349-361)

| Unitless limit reference point in F (Fmsy/F.): | 0.6727 |
| :--- | :--- |
| CV of above (from bootstrap distribution): | 0.1406 |

Fig. 8.20.4.2.3.1 Precision of estimated value of F for 2008 with bootstrapping with ASPIC. Bars display the range of the bootstrapped estimates; the percent confidence intervals can be derived from the inverse cumulative frequency.

The results of the Biomass Dynamic Model suggest that the species in the GSA 09 is overexploited (current $\mathrm{F}_{\text {curr }} / \mathrm{F}_{\mathrm{MSY}}=1.4$ on average). Data of abundance index of Porto Santo Stefano have shown a lower correlation with surveys data, probably due to the fact that in this port, the fleet has a lightly different and variable spatial/temporal behaviour (they operate at a higher mean depth) because the species is not a priority commercial species. A value of $F_{\text {MSY }}$ of 0.58 was estimated while for the more recent year the model estimated a value of $F$ of about 0.86 . It is important to highlight, as shown in Fig. 8.20.4.2.3.1, that the level of biomass shows a general increasing trend while $F$ decreases along the analysed period.

Fig. 8.20.4.2.3.2 Historic trend in estimated fishing mortality as F/FMSY ratio (upper panel) and biomass as B/BMSY ratio (lower panel).

### 8.20.5.Long term prediction

### 8.20.5.1.Justification

A traditional Beverton \& Holt Y/R analysis was performed with the "Yield" software. The software does not allow using a vector of $M$ and hence, in alternative, a weighted average value was used in input. The aproach also assumes an asymptotic behavior of catchability over the size of first capture. All the analysis were performed as a per-recruit basis, assuming recruitment constant with only a random fluctuation.

### 8.20.5.2.Input parameters

The used growth and L/W parameters are those included in Table 8.20.1.2.1. The characteristics of the software constrained the use of a weighted mean value of $M=0.8$ instead of a $M$-at-size vector.

### 8.20.5.3.Results

A value of $F \max =0.63$ was estimated and of $F_{0.1}=0.42$ while the $F$ rate at which the Spawning Biomass is expected to be reduced to $30 \%$ of the pristine Biomass $\left(F 30 \% \mathrm{SSB}_{0}\right)$ was estimated as 0.24 . Relative per recruit estimated values of $Y, S S B$, Fished $B$ and Total $B$ are shown in Fig 8.20.5.3.1.

Fig. 8.20.5.3.1. Results of the Y/R analysis.

Fig. 8.20.5.3.2. Yield-per-Recruit isoplets. The red circle represents the current combination of $F$ and $t c$.

### 8.20.6.Scientific advice

8.20.6.1.Short term considerations

### 8.20.6.1.1. State of the spawning stock size

The index of stock abundance from GRUND survey shows high variability throughout the time series, but no trend is observed.
The index of abundance from MEDITS survey, that approximates a spawning stock biomass index (mostly represented by mature fish), suggests an increasing trend from 1994 to 2008. High interannual variation is observed from 2002 to 2008.

The current spawning stock biomass roughly estimated through simulations with LCA outputs and yield-perrecruit analysis is assumed to be lower than $20 \%$ of the pristine one. Such surviving rate of spawners, is considered very low for ensuring the stock self-renewal (Clark, 1991; Mace \& Sissenwine, 1993).

### 8.20.6.1.2. State of recruitment

Recruitment shows a slight increasing trend, especially in the most recent years.

### 8.20.6.1.3. State of exploitation

The stock can be considered overexploited. Quite consistent estimates of the current fishing mortality were obtained with 3 alternative approaches ( $\mathrm{F} 2008=0.85$ with ASPIC, F2006-2008 $=0.97$ with LCA) all of them decisely higher than the values recently estimated for the limit reference points $\mathrm{F}_{\mathrm{MSY}}=0.58$ and its proxy $\mathrm{F}_{0.1}$ $=0.49$ as well as with a previous biomass dynamics model based on trawl surveys time series of Z and biomass index, that provided a $\mathrm{F}_{\text {MSY }}$ rate of 0.59 (SGMED-08-03). The size of first capture is too low (growth overfishing) and an increase in yield can be expected in the case a reduction of fishing effort do occur and/or more selective gears are used. It is advisable to avoid the illegal fishing within the 3 miles zone from the base line as well as the landing of undersized individuals in order to decrease fishing pressure on juveniles.

### 8.21. Stock assessment of red mullet in GSA 10

### 8.21.1.Stock identification and biological features

### 8.21.1.1.Stock Identification

Red mullet stock was assumed in the boundaries of the whole GSA 10, lacking specific information on stock identification. M. barbatus is with European hake and deep-water rose shrimp a key species of fishing assemblages in the central-southern Tyrrhenian Sea (GSA 10). The species is almost exclusively distributed on the continental shelf and is a rather small-sized, fast-growing and characterized by a relatively short lifespan. It spawns in late spring-early summer with a peak in June-July. In late summer, recently settled juveniles are highly concentrated near shore and this concentration is still present up to October. Aggregation of juveniles and subsequent movements towards more offshore grounds have been reported and indicated as a source of increased vulnerability of this population component to the harvest strategy (Voliani et al., 1998). During late summer-early autumn (September-October), the species is intensely caught and often represent an important fraction of the landings of the coastal bottom trawlers. About three-four months after settlement, red mullet has spread up to depths of about 100 m .

### 8.21.1.2.Growth

The growth of red mullet has been studied in the GSA using two different approaches that also allowed validation of the aging: 1) whole otolith readings and 2) the analysis of length-frequency distributions using techniques as Batthacharya for separation of modal components. The estimates of von Bertalanffy growth parameters for sex combined obtained using DCR data sets were the following: $\mathrm{L}_{\infty}=26 \mathrm{~cm} \mathrm{k}=0.412 \mathrm{t}_{0}=-0.4$. Parameters of the length-weight relationship estimated from the DCR data sets and related to the sex combined were $a=0.0087 ; b=3.08$ for length expressed in cm .

### 8.21.1.3.Maturity

Estimates of size at first maturity of females were conducted using Medits trawl survey data and the method developed within the Fisboat project (Rochet and Trenkel, 2005; Fisboat web-site: $\underline{\mathrm{http}} / / / \mathrm{www} . \mathrm{ffremer.fr/drvecohal/fisboat//)} .\mathrm{In} \mathrm{the} \mathrm{following} \mathrm{table} \mathrm{the} \mathrm{size} \mathrm{at} \mathrm{first} \mathrm{maturity} \mathrm{(in} \mathrm{~cm}$ ) of females and the associated errors are reported.

| Year | $\mathrm{L}_{50}$.maturity | SdL $_{50}$.maturity |
| ---: | ---: | ---: |
| 1994 | 13.7 | 0.0544 |
| 1995 | 13.2 | 0.09 |
| 1996 | 13.3 | 0.0964 |
| 1997 | 13.4 | 0.0808 |
| 1998 | 12.9 | 0.0258 |
| 1999 | 13.7 | 0.0309 |
| 2000 | 13.2 | 0.0386 |
| 2001 | 13.1 | 0.041 |

Size at first maturity of females was ranging from about 13 to 14 cm , which is when fish are aged 1 year. This range of length at first maturity was used in the assessment.

### 8.21.2.1.General description of fisheries

Red mullet is mostly targeted by trawlers, but also by small scale fisheries using trammel nets. Fishing grounds are located along the coasts of the whole GSA offshore 50 m depth or 3 miles from the coast.
8.21.2.2.Management regulations applicable in 2008 and 2009

Management regulations are based on technical measures and do not differ from those applied in the previous years: closed number of fishing licenses for the fleet and area limitation (fishing forbidden within 50 m depth or 3 miles from the shore, depending on the zone). Along northern Sicily coasts two main Gulfs (Patti and Castellammare) have been closed to the trawl fishery up 200 m depth, since 1990 . Effects of protection have been also evaluated (Fiorentino et al., in press). Two closed areas were also established since 2004 along the mainland, in front of Sorrento peninsula (Napoli Gulf) and Amantea (Calabrian coasts), the latter including one of the areas where red mullet is more concentrated. In the GSA 10 the fishing ban has not been mandatory along the time, and from one year to the other it was adopted on a voluntary basis by fishers.

### 8.21.2.3.Catches

### 8.21.2.3.1. Landings

Available landing data are from DCR regulations and range from 839 tons of 2002 to 501 tons in 2007, being the lowest value of 393 tons registered in 2006. Most part of the landings of red mullet come from trawlers and shows a pattern similar to the total landing of red mullet, except for the last two years. In 2006 the landings of trawlers were increasing compared to 2005, while in 2007 they were decreasing. Opposite directions were observed from all the fishing segments (Fig. 8.21.2.3.1.1). This is more evident if the respective contributions of DTS and PGP segments along the years are considered.

Tab. 8.21.2.3.1.1 lists the annual landings by major fishing techniques. Data are listed in Tab. A3.2 of Appendix 3.

Fig. 8.21.2.3.1.1 Annual landings of red mullet in tons (DTS and total)

Tab. 8.21.2.3.1.1 Annual landings (t) by fishing technique, 2002-2008. . Landings data provided for the years 2002 and 2003, probably have a mistake in the units used.

| MUT | 10 | ITA | SB-SV |  |  |  | 2 |  |  |  |  |  |

The length distribution of landings is reported in Fig. 8.21.2.3.1.2 for 2006 and 2007 and for the DTS and Nets segments. Both number of individuals and weight are reported. The number of individuals was raised to the total landings of the fleet segment using the proportion of the number of individuals by size class observed in the sample. The total weight corresponding to each length class was calculated using the obtained number of individuals and the average weight, from the length-weight relationship, at each central value of the length class.

The LFDs of the two years present a different pattern between the two fishing segments as showed in the Fig. 8.21.2.3.1.2. The contribution in term of number of individuals is more relevant for the nets segments in 2007, although the contribution in weight of trawlers (DTS) is more conspicuous. Analogously also the distribution by age and fleet segment shows a different pattern in the two years (Fig. 8.21.2.3.1.3).

Fig. 8.21.2.3.1.2 Landings by length in thousands and tons in 2006 and 2007 for DTS and nets segments.

Fig. 8.21.2.3.1.3 Landings by age in thousands and tons in 2006 and 2007 for DTS and Nets segments.

### 8.21.2.3.2. Discards

The proportion of the discards of red mullet in the GSA 10 was generally low and concentrated in the third and fourth quarter, when recruitment is occurring. In 2006 the estimation of discard proportion compared to the total landings in the GSA was $3 \%$. Despite this value was lower than the prescription of reg UE $1639 / 2001(10 \%$ in weight or $20 \%$ in number) the composition in length and age was estimated, that highlighted the prevailing of the age 0 group; the average length was 8.7 cm (Fig. 8.21 .2 .3 .2 .1 ).

Fig. 8.21.2.3.2.1 Size and age composition of discards.
Only 3 t of discards in 2006 were reported to SGMED-09-02 (Tab. A3.9 of Appendix 3).

### 8.21.2.3.3. Fishing effort

In the area, the total fishing effort of the trawlers (OTB or DTS) and small scale fishery (PGP or Nets), the two main fishing segments targeting red mullet, is shown in Fig.8.21.2.3.3.1. The whole fishing effort ( $\mathrm{kw}^{*}$ days) of trawlers in the GSA shows an increasing trend from 2002 to 2005, and a decrease in 2006, while the effort of the small scale fishery (PGP) shows a slight decrease until 2005 and an increase in 2006.

Fig.8.21.2.3.3.1 Trend in trawl and small scale fishery fishing effort (in kwdays) along 2002-2006.

Tab. 8.21.2.3.3.1 lists the effort by fishing technique deployed in GSA 10 as reported to SGMED-09-02 through the DCR data call and listed in Tab. A3.10-3.12 of Appendix 3.

Tab. 8.21.2.3.3.1 Effort trends by fishing technique in GSA 10.

### 8.21.3.1.Medits

### 8.21.3.1.1. Methods

According to the MEDITS protocol (Bertrand et al., 2002), trawl surveys were yearly (May-July) carried out, applying a random stratified sampling by depth ( 5 strata with depth limits at: $50,100,200,500$ and 800 m ; each haul position randomly selected in small sub-areas and maintained fixed throughout the time). Haul allocation was proportional to the stratum area. The same gear (GOC 73, by P.Y. Dremière, IFREMERSète), with a 20 mm stretched mesh size in the cod-end, was employed throughout the years. Detailed data on the gear characteristics, operational parameters and performance are reported in Dremière and Fiorentini (1996). Considering the small mesh size a complete retention was assumed. All the abundance data (number of fish per surface unit) were standardised to square kilometre, using the swept area method.

Based on the DCR data call, abundance and biomass indices were recalculated. In GSA 10 the following number of hauls was reported per depth stratum (s. Tab. 8.21.3.1.1.1).

Tab. 8.21.3.1.1.1. Number of hauls per year and depth stratum in GSA 10, 1994-2008.

| GSA10_500-800 | 31 | 30 | 31 | 31 | 31 | 30 | 31 | 29 | 26 | 27 | 26 | 26 | 26 | 26 | 26 |

Data were assigned to strata based upon the shooting position and average depth (between shooting and hauling depth). Few obvious data errors were corrected. Catches by haul were standardized to 60 minutes hauling duration. Hauls noted as valid were used only, including stations with no catches of hake, red mullet or pink shrimp (zero catches are included).

The abundance and biomass indices by GSA were calculated through stratified means (Cochran, 1953; Saville, 1977). This implies weighting of the average values of the individual standardized catches and the variation of each stratum by the respective stratum areas in each GSA:
$\mathrm{Yst}=\Sigma\left(\mathrm{Yi}^{*} \mathrm{Ai}\right) / \mathrm{A}$
$\mathrm{V}(\mathrm{Yst})=\Sigma\left(\mathrm{Ai}^{2} * \mathrm{si}^{2} / \mathrm{ni}\right) / \mathrm{A}^{2}$
Where:
A=total survey area
$\mathrm{Ai}=$ area of the i -th stratum
$s i=$ standard deviation of the i-th stratum
ni=number of valid hauls of the i-th stratum
$\mathrm{n}=$ number of hauls in the GSA
$\mathrm{Yi}=$ mean of the i-th stratum
Yst=stratified mean abundance
$\mathrm{V}(\mathrm{Yst})=$ variance of the stratified mean

The variation of the stratified mean is then expressed as the $95 \%$ confidence interval: Confidence interval $=$ Yst $\pm \mathrm{t}$ (student distribution) * V(Yst) / n

It was noted that while this is a standard approach, the calculation may be biased due to the assumptions over zero catch stations, and hence assumptions over the distribution of data. A normal distribution is often assumed, whereas data may be better described by a delta-distribution, quasi-poisson. Indeed, data may be better modelled using the idea of conditionality and the negative binomial (e.g. O'Brien et al. (2004)).

Length distributions represented an aggregation (sum) of all standardized length frequencies (subsamples raised to standardized haul abundance per hour) over the stations of each stratum. Aggregated length frequencies were then raised to stratum abundance * 100 (because of low numbers in most strata) and finally aggregated (sum) over the strata to the GSA. Given the sheer number of plots generated, these distributions are not presented in this report.

GRUND survey was conducted in the area using a commercial gear and different vessels until 2003, when a unique sampler (combination of vessel and gear) was adopted in the whole GSA. Sampling scheme, stratification and protocols were as in Medits.

### 8.21.3.1.2. Geographical distribution patterns

Map of the bubble plot of the survey indices indicates a higher abundance of the population in the southernmost part of the area, along the mainland and the north Sicily coasts. The approach based on spatial indicators (Woillez et al., 2007) to characterise the spatial dynamics of red mullet life stages has been applied to the GSA 10 (Spedicato et al., 2007), with the objectives of identifying areas where red mullet recruits are more concentrated, establishing relationships with the adult distribution and detecting the ability of spatial indicators to capture the stability of the spatial occupation of preferential sites across the years. The spatial indices mainly studied were the centre of gravity (CG), the inertia (I) and the global index of collocation (GIC). Gravity centres (xcg-longitude; ycg-latitude; graph below) by age groups across years and life-stages highlighted a less changing spatial location of the younger age (A1) compared to the older ones (A2 and A3) that were more dispersed. The approach of the spatial indicators enabled the location of the geographical zone (along the Calabrian coast, southwards in the study area) where recruits (age 0 fish) of red mullet are mainly distributed and to verify that these locations are rather stable across years. Furthermore a first absolute estimate of juvenile abundance was performed.

Fig. 8.21.3.1.2.1 Scaled survey catches of red mullet in GSA 10 and centre of gravity (CG) of recruits and adults.

### 8.21.3.1.3. Trends in abundance and biomass

Indices from Medits trawl-survey show a decreasing pattern from 1999 onwards (significant for the biomass index). In the year 2007, an increase of both indices was observed (Fig. 8.21.3.1.3.1).

Fig. 8.21.3.1.3.1 Trends in survey abundance and biomass derived from Medits.

Fishery independent information regarding the state of the red mullet in GSA 10 was derived from the international survey Medits. Figure 8.21.3.1.3.2 displays the estimated trend in red mullet abundance and biomass in GSA 10.

The re-estimated abundance and biomass indices do reveal identical trends to those shown above. However, the recent abundance and biomass indices in 2007 appear high but are subject to high variation (uncertainty). The analyses of Medits indices are considered preliminary.

Fig. 8.21.3.1.3.2 Abundance and biomass indices of red mullet in GSA 10 derived from Medits.

### 8.21.3.1.4. Trends in abundance by length or age

No trend in the mean length was observed in Medits survey.

Fig. 8.21.3.1.4.1 Mean length, variance and quantiles derived from the Medits length compositions in 19952007.

The following Fig. 8.21.3.1.4.2 and 3 display the stratified abundance indices of GSA 10 in 1994-2001 and 2002-2008. These size compositions are considered preliminary.

Fig. 8.21.3.1.4.2 Stratified abundance indices by size, 1994-2001.

Fig. 8.21.3.1.4.3 Stratified abundance indices by size, 2002-2008.

### 8.21.3.2.GRUND

### 8.21.3.2.1. Methods

Since 2003 Grund surveys (Relini, 2000) was conducted using the same sampler (vessel and gear) in the whole GSA. Sampling scheme, stratification and protocols were similar as in Medits. All the abundance data (number of fish and weight per surface unit) were standardised to square kilometre, using the swept area method.

### 8.21.3.2.2. Geographical distribution patterns

Map of abundance of recruits $\left(\mathrm{N} / \mathrm{km}^{2}\right)$ as estimated using Grund data and the ordinary kriging shows that the sub-zones where the recruits are mainly concentrated along the nearshore grounds of the southernmost part of the GSA, except a nucleus located in the northernmost side (Fig. 7.21.3.1.2.2). The higher values were around 25000 recruits $/ \mathrm{km}^{2}$.

Figure 8.21.3.1.2.2 shows a map of abundance of recruits $\left(\mathrm{N} / \mathrm{km}^{2}\right)$ as estimated using Grund data and the ordinary kriging. The recruits were estimated each year using the length frequency distribution and separating the first mode applying the Bhattacharya method. On average, considering the analyzed distributions (years 1994-2005), the recruits are individual smaller than $11.5 \mathrm{~cm}( \pm 1.08)$. These individual are mostly belonging to the age 0 group.

Fig. 8.21.3.1.2.2 Map of abundance of recruits $\left(\mathrm{N} / \mathrm{km}^{2}\right)$ as estimated using Grund data and the ordinary kriging.

### 8.21.3.2.3. Trends in abundance and biomass

Similar trends are derived from the GRUND survey and shown in Fig. 8.21.3.2.3.1. Biomass and abundance indices were both significantly decreasing ( $\mathrm{p}<0.05$ on ln-transformed data), while the recruitment indices were highly variable but without any significant trend. Low levels were however observed in the periods 1994-1996 and 2003-2006. The analyses of Grund indices are considered preliminary.

Fig. 8.21.3.1.3.3. Abundance and biomass indices of red mullet in GSA 10 derived from Grund survey. Ln transformed values and linear regression results are also presented and the recruitment indices $\left(\mathrm{N} / \mathrm{km}^{2}\right)$ with standard deviation are reported.

### 8.21.3.2.4. Trends in abundance by length or age

Fig. 8.21.3.1.4.4 III Quantile derived from the GRUND length compositions in 1994-2006.

### 8.21.3.2.5. Trends in growth

The occurrence of growth change along time was not fully explored during SGMED-09-02.

### 8.21.3.2.6. Trends in maturity

No analyses were conducted during SGMED-09-02.

### 8.21.4.Assessment of historic stock parameters

SGMED 09-02 did not undertake any analytical assessment of red mullet in GSA 10. Last year's assessment using Aladym model and VIT can be found in the report of SGMED-08-04 working group (Cardinale et al., 2008).

### 8.21.5.Long term prediction

### 8.21.5.1.Justification

Yield per recruit analysis has been conducted.

### 8.21.5.2.Input parameters

### 8.21.5.3.Results

Figures 8.21.5.3.1 and 8.21.5.3.2 show the per recruit predictions. Changes of the stock indicators: Biomass, Spawning Stock Biomass and Yield per recruit at increasing levels of fishing mortality, as derived by multiplying the current value ( F status quo) by the F factor, are presented.

Fig. 8.21.5.3.2.1 Biomass, Spawning Stock Biomass and Yield per recruit at increasing levels of fishing mortality, as derived multiplying the current value ( F status quo) by the F factor according to the VIT package (2006 analysis).

Fig. 8.21.5.3.2 Biomass, Spawning Stock Biomass and Yield per recruit at increasing levels of fishing mortality, as derived multiplying the current value ( F status quo) by the F factor according to the VIT package (2007 analysis).

Assuming no variation of the exploitation pattern, the main results of Y/R analysis are reported in the Table 8.21.5.3.1 for 2006 and 2007.

Tab. 8.21.5.3.1 Estimation of yield (Y), biomass (B) and spawning stock biomass (SSB) per recruit (R) varying current fishing mortality ( F ) by a multiplier F factor.

| 2006 | Factor | F | $\mathrm{Y} / \mathrm{R}$ | $\mathrm{B} / \mathrm{R}$ | SSB |
| :---: | :---: | :---: | :---: | :---: | :---: |
| $\mathrm{F}(0.1)$ | 0.53 | 0.37 | 7.761 | 17.873 | 10.911 |
| F (Max) | 0.94 |  | 8.304 | 12.162 | 5.944 |
| F (Current) | 1.01 |  | 8.295 | 11.514 | 5.414 |
| F (Double) | 2 |  | 7.503 | 6.524 | 1.779 |
| 2007 | Factor |  | $\mathrm{Y} / \mathrm{R}$ | $\mathrm{B} / \mathrm{R}$ | SSB |
| $\mathrm{F}(0.1)$ | 0.91 | 0.59 | 11.709 | 21.51 | 18.001 |
| F(Max) | 1.75 |  | 12.671 | 13.082 | 9.666 |
| F (Current) | 1.01 |  | 11.971 | 20.078 | 16.58 |
| F (Double) | 2 |  | 12.635 | 11.752 | 8.364 |

Considering the level of F in 2006, (i.e. 0.7), a reduction of $47 \%$ would be necessary to reach F0.1 (0.37) (Table 8.21.7.3.1). In 2007 the situation seems different. Despite the fact that the value of status quo $\mathrm{F}(0.65)$ is close to that of 2006, the exploitation pattern was different and thus a reduction of about $10 \%$ would be needed to reach F0.1 (0.59).

### 8.21.6.Scientific advice

### 8.21.6.1.Short term considerations

### 8.21.6.1.1. State of the spawning stock size

SGMED-09-02 cannot provide any scientific advice of the state of the spawning stock in relation to proposed target level, given the preliminary state of the data and analyses, and the non availability of agreed reference points. However, the results of Aladym model suggested that the continuation of the level of pressure exerted in the recent past will contribute to the reduction of the spawning stock, bringing it around the lower level of the past.

### 8.21.6.1.2. State of recruitment

The recruitment observed from Grund survey data is in the recent years show low levels of abundance.

### 8.21.6.1.3. State of exploitation

Given the results of the present analysis, the stock appears to be subject to overfishing. The overfishing might be lower if the estimates related to the fishing mortality in 2007 will be confirmed in the successive years. Other signals, from survey indices and Aladym model predictions, showed that the condition of the stock could be at risk of being harvested unsustainably if the mortality levels observed in the past years (except 2007) will occur in the future.

### 8.22. Stock assessment of red mullet in GSA 11

### 8.22.1.Stock identification and biological features

### 8.22.1.1.Stock Identification

This stock was assumed to be confined within the GSA 11 boundaries, but no scientific evidence is available to confirm this hypothesis. Under a management point of view, in the frame of GFCM, it has been decided, when the lack of any evidence does not allow suggesting an alternative hypothesis that inside each one of the GSAs boundaries inhabits a single, homogeneous red mullet stock that behaves as a single well-mixed and self-perpetuating population.

In the GSA 11 red mullet is distributed between 0 and 300 m of depth, even though is generally found on shelf bottoms (within 200 m of depths) where the bulk of abundance and biomass is up to 100 m . Even though the species can be found at depths over 200 m , it is mainly concentrated in the depth range $0-100 \mathrm{~m}$. The stock is mainly exploited by the local fishing fleet only, both with trawl and net gears.

Juveniles showed a patchy distribution with some main density hot spots (nurseries) showing a high spatiotemporal persistence in western and southern areas.

### 8.22.1.2.Growth

Tab. 8.22.1.2.1. Growth parameters and natural mortality rates for $M$. barbatus in the GSA 11 used in the analyses.

| $\mathrm{L}_{m}$ | 29.1 |
| :--- | :--- |
| K | 0.41 |
| $\mathrm{t} . \mathrm{a}$ | -0.39 |
| $\mathrm{~L} / W$ | a |
| $\mathrm{L} / W \mathrm{~b}$ | 0.001 |

### 8.22.1.3.Maturity

The species reaches massively the sexual maturity at one year old. Observations of proportion of mature individuals by size and analysis with the standard procedure show the bulk of the females spawn at a size of about 10 cm .

Fig. 8.22.1.3.1 Maturity ogive for females M. barbatus in the GSA 11.
Data on spawning (DCR 2006 and 2007) confirm that is taking place on spring (April-June), with a peak during late spring (May).

### 8.22.2.Fisheries

8.22.2.1.General description of fisheries

STECF in 2007 (stock review part II) noted that red mullet Mullus barbatus is among the most commercially important species in the area and forms part of an assemblage that is the target of the bottom trawling and small scale fleets, which operate near the shore. During the peak of post-recruitment (September-October), small trawlers target this species on shallower waters near the cost.

From 1994 to 2004, in GSA 11, the trawling-fleet has remarkably changed. The change has mostly consisted of a general increase of the number of vessels and by the replacement of the old, low tonnage wooden boats by larger steel boats. For the entire GSA a decrease of $20 \%$ for the smaller boats ( $<30$ GRT), which principally exploit this species, was also observed.
8.22.2.2.Management regulations applicable in 2008 and 2009

As in other areas of the Mediterranean, the stock management is based on control of fishing capacity (licenses), fishing effort (fishing activity), technical measures (mesh size and area closures), and minimum landing sizes (EC 1967/06).
Two small closed areas were also established along the mainland (west and east coast respectively), although these are finalised to protected lobsters mainly.
Since 1991, a fishing ban for trawling for 45 days have been enforced almost every year in different periods for the small scale fishery (March, TSL<=15) and for the big vessels, hence trawlers (September, TSL<15). In Fig. 8.22.2.2.1, differences in the closure regime are showed; red points means that no fishing ban measure has been adopted for the year.

Fig. 8.22.2.2.1 Closed seasons since 1990.

Furthermore, in 2006 the closure was differentiated in time also considering the different coasts (west and east). Towed gears are not allowed within three nautical miles from the coast or at depths less than 50 m when this depth is reached at a distance less than 3 miles from the coast.

### 8.22.2.3.Catches

### 8.22.2.3.1. Landings

Tab. 8.22.2.3.1.1 lists the trend in reported landings by fishing technique. The data were reported to SGMED-09-02 through the Data Collection Regulation and are listed in Table A3.2 of Appendix 3. Since 2002 the annual landings varied between 115 and 354 t . The landings were mainly from demersal otter trawls (on overage catches from nets are no more than $5 \%$ of the total).

Tab. 8.22.2.3.1.1 Annual landings (t) by fishing technique in GSA 11, 2002-2008 as reported through DCR.

| FT LVL4 | $\frac{20022003}{30 \quad 253}$ |  | 20114 | 2015 |  | 201720108 |  |

### 8.22.2.3.2. Discards

7 t of discards in 2006 were reported to SGMED-09-02 through the DCR data call and are listed in Tab. A3.9 of Appendix 3.

### 8.22.2.3.3. Fishing effort

The trends in fishing effort by fishing technique reported to SGMED-09-02 are listed in Tab. 8.22.2.3.3.1 and in Tab. A3.10-3.12 of Appendix 3. The effort of the major trawler fleet has doubled during 2003-2004 and stayed at the high level thereafter.

Tab. 8.22.2.3.3.1 Trends in annual fishing effort ( $\mathrm{kW}^{*}$ days) by fishing technique deployed in GSA 11, 20022007. No effort data were reported for 2008.

### 8.22.3.Scientific surveys

### 8.22.3.1.MEDITS

### 8.22.3.1.1. Methods

Based on the DCR data call, abundance and biomass indices were recalculated. In GSA 08 the following number of hauls was reported per depth stratum (s. Tab. 8.22.3.1.1.1).

Tab. 8.22.3.1.1.1. Number of hauls per year and depth stratum in GSA 11, 1994-2008.

| STRATUM | 1994 | 1995 | 1996 | 1997 | 1998 | 1999 | 2000 | 2001 | 2002 | 2003 | 2004 | 2005 | 2006 | 2007 | 2008 |
| :--- | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| GSA11_010-050 | 17 | 19 | 21 | 21 | 21 | 21 | 19 | 18 | 20 | 18 | 17 | 17 | 19 | 19 | 17 |
| GSA11_050-100 | 27 | 21 | 22 | 22 | 20 | 22 | 22 | 24 | 19 | 19 | 18 | 21 | 18 | 20 | 19 |
| GSA11_100-200 | 22 | 23 | 30 | 31 | 31 | 30 | 31 | 30 | 24 | 24 | 24 | 24 | 24 | 24 | 22 |
| GSA11_200-500 | 35 | 29 | 29 | 26 | 25 | 27 | 24 | 25 | 20 | 24 | 21 | 20 | 20 | 20 | 21 |
| GSA11_500-800 | 23 | 16 | 21 | 25 | 25 | 24 | 27 | 26 | 16 | 14 | 15 | 14 | 16 | 17 | 16 |

Data were assigned to strata based upon the shooting position and average depth (between shooting and hauling depth). Few obvious data errors were corrected. Catches by haul were standardized to 60 minutes hauling duration. Only hauls noted as valid were used, including stations with no catches of hake, red mullet or pink shrimp (zero catches are included).

The abundance and biomass indices by GSA were calculated through stratified means (Cochran, 1953; Saville, 1977). This implies weighting of the average values of the individual standardized catches and the variation of each stratum by the respective stratum areas in each GSA:
$\mathrm{Yst}=\Sigma\left(\mathrm{Yi}^{*}{ }^{*} \mathrm{Ai}\right) / \mathrm{A}$
$\mathrm{V}(\mathrm{Yst})=\Sigma\left(\mathrm{Ai}^{2} * \mathrm{si}^{2} / \mathrm{ni}\right) / \mathrm{A}^{2}$

```
Where:
    A=total survey area
    Ai=area of the i-th stratum
    si=standard deviation of the i-th stratum
    ni=number of valid hauls of the i-th stratum
    n=number of hauls in the GSA
    Yi=mean of the i-th stratum
    Yst=stratified mean abundance
    V(Yst)=variance of the stratified mean
```

The variation of the stratified mean is then expressed as the $95 \%$ confidence interval: Confidence interval $=$ Yst $\pm \mathrm{t}$ (student distribution) $* \mathrm{~V}(\mathrm{Yst}) / \mathrm{n}$

It was noted that while this is a standard approach, the calculation may be biased due to the assumptions over zero catch stations, and hence assumptions over the distribution of data. A normal distribution is often assumed, whereas data may be better described by a delta-distribution, quasi-poisson. Indeed, data may be better modelled using the idea of conditionality and the negative binomial (e.g. O'Brien et al. (2004)).

Length distributions represented an aggregation (sum) of all standardized length frequencies (subsamples raised to standardized haul abundance per hour) over the stations of each stratum. Aggregated length frequencies were then raised to stratum abundance * 100 (because of low numbers in most strata) and finally aggregated (sum) over the strata to the GSA. Given the sheer number of plots generated, these distributions are not presented in this report.

### 8.22.3.1.2. Geographical distribution patterns

The spatial structure of red mullet have been achieved by modelling the spatial correlation structure of the abundance indices through geostatistical techniques (i.e. krigging), showing clear areas of persistence in the south (Gulf of Cagliari) and western coasts (Carloforte and coast between Bosa Marina and Capo Mannu). Detailed results and maps are reported in the "nursery section" of this report.

### 8.22.3.1.3. Trends in abundance and biomass

Fishery independent information regarding the state of the red mullet in GSA 11 was derived from the international survey Medits. Fig. 8.22.3.1.3.1 and 2 displays the estimated trend in red mullet abundance and biomass in GSA 11.

The estimated abundance and biomass indices do not reveal any significant trends since 1994. However, the recent abundance and biomass indices since 2005 appear high but are subject to high variation.

Fig. 8.22.3.1.3.1 Abundance and biomass indices of red mullet in GSA 11.

Fig. 8.22.3.1.3.2 Abundance and biomass indices of red mullet in GSA 11.

### 8.22.3.1.4. Trends in abundance by length or age

The following Fig. 8.22.3.1.4.1 and 2 display the stratified abundance indices of GSA 11 in 1994-2001 and 2002-2008.

Fig. 8.22.3.1.4.1 Stratified abundance indices by size, 1994-2001.

Fig. 8.22.3.1.4.2 Stratified abundance indices by size, 2002-2008.

### 8.22.3.1.5. Trends in growth

No analyses were conducted.
8.22.3.1.6. Trends in maturity

No analyses were conducted.

### 8.22.4.Assessment of historic stock parameters

### 8.22.4.1.Method 1: VIT

### 8.22.4.1.1. Justification

An approach under steady state (pseudocohort) assumption was applied due to the availability of length frequency distributions of landing (2006-2007 only, DCR). Cohort (VPA equation) and Y/R analyses as been carried out with VIT software on trawl fishery only.

### 8.22.4.1.2. Input parameters

No discard data were included and a plus group has been used.
According to the Prodbiom approach by Caddy and Abella (1999), a vectorial natural mortality at age was computed for the stock analysis (Tab. 8.22.4.1.2.1). Terminal F was fixed to 0.6 .

Tab. 8.22.4.1.2.1 Input parameters used of the analysis (sex combined) in the GSA11.

| VB GF | $\mathrm{L}_{\mathrm{Q}}=29.1 \mathrm{~cm}, \mathrm{~K}=0.41, \mathrm{t}_{0}=-0.39$ |
| :--- | :--- |
| M wector | $\mathrm{Age}_{0}=1.3, \mathrm{Ag}_{\mathrm{l}}=0.45, \mathrm{Age}_{2}=0.27, \mathrm{Age}_{3}=0.24, \mathrm{Ag}_{\mathrm{g}}=0.21$ |
| Length at maturity (L50) | 13 cmin(sex combined) |

### 8.22.4.1.3. Results

Fishing mortality rates (F), total fishing mortality and total mortality rate Z by length estimated by LCA using VIT (age groups 0-3).

Fig. 8.22.4.1.3.1 Fishing $(\mathrm{F})$ and total mortality $(\mathrm{Z})$ rates by size in GSA 11.

### 8.22.5.1.Justification

A YpR analysis was conducted applying the VIT software.

### 8.22.5.2.Input parameters

VIT inputs and resulting exploitation pattern was used.

### 8.22.5.3.Results

Assuming no variation of the exploitation pattern, the main result of $\mathrm{Y} / \mathrm{R}$ analysis is reported in the table below.

Tab. 8.22.5.3.1 Estimation of yield (Y), biomass (B) and spawning stock biomass (SSB) per recruit (R) varying current fishing mortality $(\mathrm{F})$ by a multiplier F factor.

|  | Factor 4 | $\mathrm{Y} / \mathrm{R}$ | $\mathrm{B} / \mathrm{R}$ | $\mathrm{SSB} / \mathrm{R}$ |
| :---: | ---: | ---: | ---: | ---: |
| $\mathrm{F}($ Current $)$ | 1 | 2.954 | 3.227 | 2.236 |
| $\mathrm{~F}(0.1)$ | 0.6 | 2.8 | 5.3 | 4.0 |
| F (Max) | 0.91 | 2.961 | 3.568 | 2.521 |
| F (Doubile) | 2 | 2.645 | 1.7 | 1.015 |

### 8.22.6.Scientific advice

### 8.22.6.1.Short term considerations

### 8.22.6.1.1. State of the spawning stock size

Survey indices did not reveal any significant trend. SGMED-09-02 is unable to provide any scientific advice of the state of the spawning stock in relation to precautionary or target levels given the preliminary state of the data and analyses.

### 8.22.6.1.2. State of recruitment

According to the data provided, the first length caught ( 11 cm, ) corresponds to 0.87 years (i.e. $0+$ ). However it is likely that smaller individuals are abundant in catches as in other Mediterranean regions, although not reported in the official data.
Index of abundance of juveniles obtained from MEDITS surveys shows a high variability.

### 8.22.6.1.3. State of exploitation

SGMED-09-02cannot fully evaluate the state of the stock. The landings appear incompletely reported as the very limited fraction of the passive gears segments (hooks, lines and nets) seems to be unrealistic, given that
the fishing effort of the small scale fishery (DCR data) is almost as high as the effort of the trawlers. Furthermore, the length range of red mullet size in the landings is expected to be wider than those reported in the official data (i.e. 11-24 cm). Because of obvious data deficiencies with unknown effects on the estimates of exploitation rates and the reference points derived from the YpR analysis, SGMED-09-02 is unable to provide any scientific advice.

### 8.23. Stock assessment of red mullet in GSA 16

### 8.23.1.Stock identification and biological features

### 8.23.1.1.Stock Identification

### 8.23.3.1.Medits

### 8.23.3.1.1. Methods

Based on the DCR data call, abundance and biomass indices were recalculated. In GSA 16 the following number of hauls was reported per depth stratum ( s . Tab. 8.23.3.1.1.1).

Tab. 8.23.3.1.1.1. Number of hauls per year and depth stratum in GSA 16, 1994-2008.

| STRATUM | 1994 | 1995 | 1996 | 1997 | 1998 | 1999 | 2000 | 2001 | 2002 | 2003 | 2004 | 2005 | 2006 | 2007 | 2008 |
| :--- | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| GSA16_010-050 | 4 | 4 | 4 | 4 | 4 | 4 | 4 | 4 | 7 | 7 | 7 | 10 | 10 | 11 | 11 |
| GSA16_050-100 | 9 | 8 | 8 | 8 | 8 | 8 | 7 | 8 | 11 | 12 | 12 | 20 | 22 | 23 | 23 |
| GSA16_100-200 | 4 | 4 | 4 | 4 | 5 | 5 | 6 | 5 | 11 | 10 | 11 | 20 | 19 | 21 | 21 |
| GSA16_200-500 | 10 | 11 | 11 | 12 | 11 | 11 | 11 | 11 | 19 | 18 | 27 | 37 | 31 | 27 | 27 |
| GSA16_500-800 | 10 | 14 | 14 | 13 | 14 | 14 | 14 | 14 | 20 | 20 | 21 | 33 | 33 | 38 | 38 |

Data were assigned to strata based upon the shooting position and average depth (between shooting and hauling depth). Few obvious data errors were corrected. Catches by haul were standardized to 60 minutes hauling duration. Hauls noted as valid were used only, including stations with no catches of hake, red mullet or pink shrimp (zero catches are included).

The abundance and biomass indices by GSA were calculated through stratified means (Cochran, 1953; Saville, 1977). This implies weighting of the average values of the individual standardized catches and the variation of each stratum by the respective stratum areas in each GSA:
$\mathrm{Yst}=\Sigma\left(\mathrm{Yi}^{*}{ }^{*} \mathrm{Ai}\right) / \mathrm{A}$
$\mathrm{V}(\mathrm{Yst})=\Sigma\left(\mathrm{Ai}^{2} * \mathrm{si}^{2} / \mathrm{ni}\right) / \mathrm{A}^{2}$
Where:
$\mathrm{A}=$ total survey area
$\mathrm{Ai}=$ area of the i -th stratum
si=standard deviation of the i-th stratum
ni=number of valid hauls of the i-th stratum
$\mathrm{n}=$ number of hauls in the GSA
$\mathrm{Yi}=$ mean of the i-th stratum
Yst=stratified mean abundance
$\mathrm{V}(\mathrm{Yst})=$ variance of the stratified mean
The variation of the stratified mean is then expressed as the $95 \%$ confidence interval: Confidence interval $=$ Yst $\pm \mathrm{t}$ (student distribution) $* \mathrm{~V}(\mathrm{Yst}) / \mathrm{n}$

It was noted that while this is a standard approach, the calculation may be biased due to the assumptions over zero catch stations, and hence assumptions over the distribution of data. A normal distribution is often assumed, whereas data may be better described by a delta-distribution, quasi-poisson. Indeed, data may be better modelled using the idea of conditionality and the negative binomial (e.g. O'Brien et al. (2004)).

Length distributions represented an aggregation (sum) of all standardized length frequencies (subsamples raised to standardized haul abundance per hour) over the stations of each stratum. Aggregated length frequencies were then raised to stratum abundance * 100 (because of low numbers in most strata) and finally aggregated (sum) over the strata to the GSA. Given the sheer number of plots generated, these distributions are not presented in this report.

### 8.23.3.1.2. Geographical distribution patterns

No analyses were conducted during SGMED-09-02.

### 8.23.3.1.3. Trends in abundance and biomass

Fishery independent information regarding the state of the red mullet in GSA 16 was derived from the international survey Medits. Figure 8.23.3.1.3.1 displays the estimated trend in red mullet abundance and biomass in GSA 16.

The estimated abundance and biomass indices reveal a significant increasing trend since 1999. However, the highest abundance in 2003 coincides with the high landings recorded. The analyses of Medits indices are considered preliminary.

Fig. 8.23.3.1.3.1 Abundance and biomass indices of red mullet in GSA 16.

### 8.23.3.1.4. Trends in abundance by length or age

The following Fig. 8.23.3.1.4.1 and 2 display the stratified abundance indices by size of GSA 16 in 19942001 and 2002-2008. These size compositions are considered preliminary.

Fig. 8.23.3.1.4.1 Stratified abundance indices by size, 1994-2001.

Fig. 8.23.3.1.4.2 Stratified abundance indices by size, 2002-2008.

### 8.23.3.1.5. Trends in growth

No analyses were conducted during SGMED-09-02.

### 8.23.3.1.6. Trends in maturity

No analyses were conducted during SGMED-09-02.
8.23.4.Assessment of historic stock parameters

SGMED-09-02 did not undertake any analytical assessment.

### 8.23.5. Long term prediction

### 8.23.5.1.Justification

No forecast analyses were conducted.

### 8.23.5.2.Input parameters

No forecast analyses were conducted.

### 8.23.5.3.Results

Given the preliminary state of the data and analyses SGMED-09-02 is not in the position to provide a long term prediction of catch and stock biomass for red mullet in GSA 16.

### 8.23.6.Scientific advice

### 8.23.6.1.Short term considerations

### 8.23.6.1.1. State of the spawning stock size

SGMED-09-02 is unable to provide any scientific advice of the state of the spawning stock in relation to proposed precautionary level given the preliminary state of the data and analyses.

### 8.23.6.1.2. State of recruitment

SGMED-09-02 is unable to provide any scientific advice of the state of the recruitment given the preliminary state of the data and analyses.

### 8.23.6.1.3. State of exploitation

SGMED-09-02 is unable to provide any scientific advice of the state of the exploitation in relation to proposed precautionary and target levels given the preliminary state of the data and analyses.

### 8.24. Stock assessment of red mullet in GSA 17

### 8.24.1.Stock identification and biological features

### 8.24.1.1.Stock Identification

Red mullet is found across the whole GSA 17. However, patterns of abundance are observed over seasons and space. Along the eastern side of Adriatic, abundance seems to be relatively constant over the year. Along the western side, in late summer and autumn, large concentrations of individuals are observed in the shallow waters along the coast, whereas, in the subsequent months, a migration towards deeper waters occurs (Arneri and Jukic, 1986; SEC (2002) 1374; see also below).

The distribution of red mullet (Mullus barbatus) in the GSA 17, in spring-summer, is shown in the maps below (Fig. 8.24.1.1.1), imported from Sabatella and Piccinetti (2004). The picture on the left shows the depth contours, increasing with darker colour ( $0-50,50-100,100-200$, > 200 m ). The picture on the right displays mullet densities at sea from the MEDITS trawl survey in the second half of the 1990s, expressed as number of individuals per square kilometer.

Fig. 8.24.1.1.1 Topography and geographical distribution patterns of red mullet in GSA 17.
Spawning of red mullet occurs in late spring and summer (Vrgoc et al., 2004). In particular, the life cycle is characterized by the occurrence of juveniles in shallow coastal waters in late summer and autumn, and subsequent occurrence of adult individuals offshore in deeper waters during winter and spring months ((SEC (2002) 1374).

### 8.24.1.2.Growth

No information was documented during SGMED-09-02.

### 8.24.1.3.Maturity

The summary of the values of length at the first sexual maturity estimated for the Adriatic Sea was imported from Vrgoc et al. (2004) and listed in Table 8.24.1.3.1.

Tab. 8.24.1.3.1 Length and age at maturity and literature references.

| Author | Sex | $\mathrm{L}_{\mathrm{m}}$ (cm) | Age (yr) |

|  | $\mathrm{M}+\mathrm{F}$ | $11-14$ |  |

### 8.24.2.Fisheries

### 8.24.2.1.General description of fisheries

The fishery for red mullet is one of the most important in the GSA 17. Fishing grounds correspond to the distribution of the stock particularly within 100 m depth. The allocation of fishing effort depends on the features of the life cycle as described above (SEC (2002) 1374).
8.24.2.2. Management regulations applicable in 2008 and 2009

No information was documented during SGMED-09-02.

### 8.24.2.3.Catches

### 8.24.2.3.1. Landings

Landings data were reported to SGMED-09-02 through the Data collection regulation and are listed in Table A3.2 of Appendix 3. Annual landings decreased from 3,884 tin 2004 to 3.236 t in 2008 (Tab. 8.24.2.3.1.1). Demersal otter trawlers dominate the landings by far.

Tab. 8.24.2.3.1.1 Annual landings (t) by fishing technique as reported to SGMED-09-02 through the DCR data call. Data provided for the years 2002 and 2003, probably have a mistake in the units used.

According to FAO statistics (ftp://ftp.fao.org/fi/stat/windows/fishplus/gfcm.zip), in the northern and central Adriatic Sea, the annual landings of Mullus spp. (Fig. 8.24.2.3.1.1) were estimated to be over 2,000 tonnes in many years of the 1980s and 1990s. An increasing trend occurred over the 1990s.

Fig. 8.24.2.3.1.1 Annual landings of red mullet in the northern and central Adriatic Sea according to FAO.

### 8.24.2.3.2. Discards

No discards data were reported to SGMED-09-02 for red mullet in GSA 17.

### 8.24.2.3.3. Fishing effort

Tab. 8.24.2.3.3.1 lists the effort by fishing technique deployed in GSA 17 as reported to SGMED-09-02 through the DCR data call and listed in Tab. A3.10-3.12 of Appendix 3. The main gear demersal otter trawl reveals a significant decreasing trend in effort deployed.

Tab. 8.24.2.3.3.1 Effort trends by fishing technique in GSA 17.

### 8.24.3.Scientific surveys

### 8.24.3.1.Medits

### 8.24.3.1.1. Methods

Based on the DCR data call, abundance and biomass indices were recalculated. In GSA 17 the following number of hauls was reported per depth stratum (s. Tab. 8.24.3.1.1.1).

Tab. 8.24.3.1.1.1. Number of hauls per year and depth stratum in GSA 17, 1994-2008.

| STRATUM | 1994 | 1995 | 1996 | 1997 | 1998 | 1999 | 2000 | 2001 | 2002 | 2003 | 2004 | 2005 | 2006 | 2007 | 2008 |
| :--- | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |

| GSA17_500-800 |  |  |  |  |  |  |  |  | 1 | 1 |  |  |  |  |  |

Data were assigned to strata based upon the shooting position and average depth (between shooting and hauling depth). Few obvious data errors were corrected. Catches by haul were standardized to 60 minutes hauling duration. Hauls noted as valid were used only, including stations with no catches of hake, red mullet or pink shrimp (zero catches are included).

The abundance and biomass indices by GSA were calculated through stratified means (Cochran, 1953; Saville, 1977). This implies weighting of the average values of the individual standardized catches and the variation of each stratum by the respective stratum areas in each GSA:
$\mathrm{Yst}=\Sigma\left(\mathrm{Yi}^{*} \mathrm{Ai}\right) / \mathrm{A}$
$\mathrm{V}(\mathrm{Yst})=\Sigma\left(\mathrm{Ai}^{2} * \mathrm{si}^{2} / \mathrm{ni}\right) / \mathrm{A}^{2}$
Where:
A=total survey area
$\mathrm{Ai}=$ area of the i -th stratum
$s i=s t a n d a r d$ deviation of the i-th stratum
ni=number of valid hauls of the i-th stratum
$\mathrm{n}=$ number of hauls in the GSA
$\mathrm{Yi}=$ mean of the i-th stratum
Yst=stratified mean abundance
$\mathrm{V}(\mathrm{Yst})=$ variance of the stratified mean
The variation of the stratified mean is then expressed as the $95 \%$ confidence interval: Confidence interval $=$ Yst $\pm \mathrm{t}$ (student distribution) $* \mathrm{~V}(\mathrm{Yst}) / \mathrm{n}$

It was noted that while this is a standard approach, the calculation may be biased due to the assumptions over zero catch stations, and hence assumptions over the distribution of data. A normal distribution is often assumed, whereas data may be better described by a delta-distribution, quasi-poisson. Indeed, data may be better modelled using the idea of conditionality and the negative binomial (e.g. O'Brien et al. (2004)).

Length distributions represented an aggregation (sum) of all standardized length frequencies (subsamples raised to standardized haul abundance per hour) over the stations of each stratum. Aggregated length frequencies were then raised to stratum abundance * 100 (because of low numbers in most strata) and finally
aggregated (sum) over the strata to the GSA. Given the sheer number of plots generated, these distributions are not presented in this report.

### 8.24.3.1.2. Geographical distribution patterns

No analyses were conducted during SGMED-09-02.

### 8.24.3.1.3. Trends in abundance and biomass

Fishery independent information regarding the state of the red mullet in GSA 17 was derived from the international survey Medits. Figure 8.24.3.1.3.1 displays the estimated trend in red mullet abundance and biomass in GSA 17.

The analyses of Medits indices are considered preliminary.

Fig. 8.24.3.1.3.1 Abundance and biomass indices of red mullet in GSA 17.

### 8.24.3.1.4. Trends in abundance by length or age

The following Fig. 8.24.3.1.4.1 displays the stratified abundance indices of GSA 17 in 1999-2008. These size compositions are considered preliminary.

Fig. 8.24.3.1.4.1 Stratified abundance indices by size, 1999-2008.

### 8.24.3.1.5. Trends in growth

No analyses were conducted during SGMED-09-02.

### 8.24.3.1.6. Trends in maturity

No analyses were conducted during SGMED-09-02.

### 8.24.4.Assessment of historic stock parameters

SGMED 09-02 did not undertake any analytical assessment of red mullet in GSA 17. Last year's assessment using LCA can be found in the report of SGMED-08-04 working group (Cardinale et al., 2008).
8.24.5.Long term prediction

### 8.24.5.1.Justification

No forecast analyses were conducted.

### 8.24.5.2.Input parameters

No forecast analyses were conducted.

### 8.24.5.3.Results

SGMED-09-02 is not in the position to provide a long term prediction of catch and stock biomass for hake in GSA 17.
8.24.6.Scientific advice

### 8.24.6.1.Short term considerations

### 8.24.6.1.1. State of the spawning stock size

The average stock biomass estimated by LCA in 2006-2007 was around 4,000 tonnes. In the absence of any proposed or agreed target referendes, SGMED-09-02 cannot fully evaluate the state of the stock.

### 8.24.6.1.2. State of recruitment

SGMED-09-02 is unable to provide any scientific advice of the state of the recruitment given the preliminary state of the data and analyses.

The average F not weighted on abundance was estimated to amount to 1.08 , while the weighted average F amounted to 0.62 . According to Rochet and Trenkel (2003), it would be safe to avoid F/Z higher than 0.50 . Also, the seasonality of the fishing mortality of red mullet (from September to November) has to be taken into account. Thus, there is some risk of overexploitation for red mullet in GSA 17. However, in the absence of any proposed or agreed target referenses, SGMED-09-02 cannot fully evaluate the state of the exploitation.

### 8.25. Stock assessment of red mullet in GSA 18

### 8.25.1.Stock identification and biological features

### 8.25.1.1.Stock Identification

The stock of red mullet is defined within the boundaries of the whole GSA 18. Genetic studies conducted in the Adriatic (Garoia et al., 2004) evidenced that samples were characterised by high genetic diversity, but the spatial genetic heterogeneity was not related to a geographic cline. However, the randomness of genetic differences among samples indicated that the Adriatic red mullet stock probably belongs to a single population unit. Nevertheless, individuals may group into local, genetically differentiated sub-populations. The observed genetic fragmentation in the Adriatic stock might be due to reproductive success, survival rates or fishing pressure.

In addition to the genetic considerations, indications agreed upon by SGMED/ECA/RST-09-01 and based on correlation matrices of trawl-survey data in adjacent areas suggested a more geographically localised pattern for the distribution of red mullet.

In the Adriatic Sea Red mullet spawns in late spring and summer and according to Haidar (1970) the most intensive spawning occurs at depths of 60 to 70 m . After spawning, post larvae move towards shallower water $(30-40 \mathrm{~m})$ and then towards sandy coastal areas to become demersal at 4 cm TL. Later, they start their dispersion in deeper waters towards sandy, muddy and gravel grounds (Relini et al., 1999). Regarding the sex ratio males are generally prevailing up to $14-15 \mathrm{~cm}$, while females are more frequent over $15-16 \mathrm{~cm} \mathrm{TL}$. The relative index of the population abundance is observed to decrease with depth. According to Haidar (1970) the main fish predators of juvenile and adult red mullet are Lophius piscatorius, Raja clavata, Zeus faber and Merluccius merluccius.

### 8.25.1.2.Growth

Literature data on the growth of red mullet in the Adriatic Sea are very variable (AdriaMed website). Asymptotic length for sex combined varies from 19.7 to 31.5 cm (range for females and males respectively: $26.2-34.5 \mathrm{~cm} ; 17.8-27 \mathrm{~cm}$ ), while the curvature parameter ranges for females and males respectively $0.122-$ 0.23 and $0.184-0.282$. According to Jardas (1996), red mullet grows up to about 30 cm (about 0.5 kg ), although the usual total length in catches is from 10 to 20 cm . On average, females have greater body length than males and grow faster, which can be already noticed in the first year of their life (Haidar, 1970). Therefore, almost all largest specimens are females.

According to Scaccini (1947) the life cycle is 8 years with a faster growth rate in the firsts three years for both sexes, after a slower pattern is evidenced ( $\mathrm{y} 1=12.6-12.7 \mathrm{~cm}$ for males and females respectively, $\mathrm{y} 2=17.5-20.3$; $\mathrm{y} 3=20.4-23.9$; $\mathrm{y} 8=25.5-29.3 \mathrm{~cm}$ ). The estimated VBGF for sex combined from Scaccini (1947) were: $\mathrm{L}_{\infty}=27.5 \mathrm{~cm} ; \mathrm{K}=0.5 ; \mathrm{t}_{0}=-0.25$. The growth parameters estimated by sex in the central-northern Adriatic area during the SAMED project (AAVV, 2002), using the analysis of length frequency distributions of MEDITS data, were: females: $\mathrm{L}_{\infty}=27 \mathrm{~cm} ; \mathrm{K}=0.396 ; \mathrm{t}_{0}=-0.78$; males: $\mathrm{L}_{\infty}=23 \mathrm{~cm} ; \mathrm{K}=0.43 ; \mathrm{t}_{0}=-0.80$.

Estimates of growth parameters were achieved using otolith data collected within the DCR framework. The following von Bertalanffy parameters were estimated for sex combined: $\mathrm{L}_{\infty}=26.3 \mathrm{~cm} ; \mathrm{K}=0.45 ; \mathrm{t}_{0}=-0.3$. Parameters of the length-weight relationship reported in literature for sex combined are $\mathrm{a}=0.008-0.0125$, b=3.09-2.97 (Marano et al., 1994; 1998; Marano, 1996).

The parameters estimated within the $D C R$ for sex combined were: $a=0.0122, b=2.94$; for females: $a=0.017$, $b=2.85$; and for males $a=0.0169, b=2.85$.

### 8.25.1.3.Maturity

According to Haidar (1970) females always have an annual reproduction cycle and reach sexual maturity in the first year of life at lengths around 12 cm . According to other literature data the size at first maturity for females is in the range $10-14 \mathrm{~cm}$ (AdriaMed website).

According to the data obtained in the DCR, the proportion of mature females (specimens belonging to the maturity stage 2 onwards) by length class is reported in the table below together with the maturity ogive estimated by a maximum likelihood procedure which indicates a $L_{m 50 \%}$ of about $12.3 \mathrm{~cm}( \pm 0.072 \mathrm{~cm})$ and a maturity range $\left(\mathrm{MR}=\mathrm{L}_{\mathrm{m} 75 \%}-\mathrm{L}_{\mathrm{m} 25 \%}\right)$ of $1.14 \pm 0.089 \mathrm{~cm}$.

Tab. 8.25.1.3.1 and Fig. 8.25.1.3.1 Female maturity ogive (MR indicates the difference Lm75\%-Lm25\%).

| CL $(\mathrm{cm})$ | Proportion of mature females |
| :--- | :--- |
| 9 | 0 |
| 10 | 0.032 |
| 11 | 0.141 |
| 12 | 0.642 |
| 13 | 0.906 |
| 14 | 0.976 |
| 15 | 0.996 |
| 16 | 0.995 |
| 17 | 1 |
| 18 | 1 |
| 19 | 1 |
| 20 | 1 |

The sex ratio from DCR evidenced the prevalence of males in the size class from 9 to 15 cm and from 16 cm onwards the proportion of females was dominant.

Fig. 8.25.1.3.2 Sex ratio at length for red mullet in GSA 18.

### 8.25.2.Fisheries

8.25.2.1.General description of fisheries

Red mullet is targeted by of trawlers but also small scale fisheries using gillnets and trammel nets. Fishing grounds are located along the coasts of the whole GSA. In the period from 1989 to 1994, the CPUE in the southern Adriatic was from 0.33 to $2.45 \mathrm{~kg} / \mathrm{h}$ (EC XIV/298/96-EN, 1996). Red mullet co-occurs with other important commercial species as Pagellus sp., Eledone sp., Octopus sp., M. merluccius.

Management regulations are based on technical measures, like the number of fishing licenses and area limitation (distance from the coast and depth). In order to limit the over-capacity of the fleet, the Italian fishing licenses have been fixed since the late 1980 s. After 2000, in agreement with the European Common Fisheries Policy, a gradual decreasing of the fleet capacity is implemented. Two closed areas were also established in 2004 along the mainland, in front of Bari and in the vicinity of Tremiti MPA on the northernmost part of the GSA. Other measures are mesh size, minimum landing sizes and the minimum distance (or depth) from the coastline (EC Reg. 1967/06). In the GSA 18 the fishing ban has been almost always mandatory since 1988 for a period of 30-45 days, generally during late July-early September.

### 8.25.2.3.Catches

### 8.25.2.3.1. Landings

Available landing data are from DCR regulations. SGMED-09-02 received Italian landings data for GSA 18 by major fishing gears which are listed in Tab. 8.25.2.3.1.1. The fishing segments (FT_LVL4) DTS and OTB identify the trawlers (OTB from 2004 onwards), while PGP and PMP indicate respectively small scale fishery (nets) and polyvalents. Also miscellanea (MIS) and pelagic trawlers (PTM) are reported although their contribution to the landings is negligible. Trawlers account for the major of the landing. Since 2002 to 2005 landings of red mullet were continuously decreasing. In 2006 and 2007 the quantities were slightly rising. In 2008 a reduction is observed (Fig. 8.25.2.3.1.1).

Tab. 8.25.2.3.1.1. Annual landings ( t ) of red mullet in GSA 18, by major gear type, 2002-2008.

| Sum of weight (tons) | FT LV L4 |  |  |  |  |  |  |  |  |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |

### 8.25.2.3.2. Discards

No information was documented.

### 8.25.2.3.3. Fishing effort

Available fishing effort data are from DCR regulations. The trends in fishing effort by year and major gear type is listed in Tab. 8.25.2.3.3.1 and shown in Fig. 8.25.2.3.3.1 in terms of $\mathrm{kW}^{*}$ days. The fishing segment (FT_LVL4) DTS and OTB, that identify trawlers, and PGP, PMP, GNS, GTR that mainly identify small scale fishery using fixed gears (gillnet and trammel net mainly) were considered for the fishing effort trend because the red mullet is exploited by these fleet segments. The fishing effort in $\mathrm{kW}^{*}$ days was declining from 2002 to 2004, whilst since 2004 to 2006 it is slightly rising, decreasing again in 2007. In Fig. 8.25.2.3.3.1 also the ratio between trawlers fishing effort and total fishing effort as in Tab. 8.25.2.3.3.1 is reported. This indicator is increasing from 2002 to 2004, while after it remained almost stable.

Tab. 8.25.2.3.3.1. Trend in fishing effort ( $\mathrm{kW}^{*}$ days) in the GSA $18,2002-2007$.

### 8.25.3.Scientific surveys

8.25.3.1.Medits

### 8.25.3.1.1. Methods

Trawl surveys were carried out applying a random stratified sampling by depth ( 5 strata with depth limits at: $50,100,200,500$ and 800 m ; each haul position randomly selected in small sub-areas and maintained fixed throughout the time). Haul allocation was proportional to the stratum area (Bertrand et al., 2002). The same gear (GOC 73, by P.Y. Dremière, IFREMER-Sète), with a 20 mm stretched mesh size in the cod-end, was employed throughout the years. Detailed data on the gear characteristics, operational parameters and performance are reported in Dremière and Fiorentini (1996). Considering the small mesh size a complete retention was assumed.

Based on the DCR data call, abundance and biomass indices were calculated. In GSA 18 the following numbers of hauls were reported per depth stratum (Tab. 8.25.3.1.1.1).

Tab. 8.25.3.1.1.1. Number of hauls per year and depth stratum in GSA 18, 1994-2008.

| STRATUM | 1994 | 1995 | 1996 | 1997 | 1998 | 1999 | 2000 | 2001 | 2002 | 2003 | 2004 | 2005 | 2006 | 2007 | 2008 |
| :--- | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |

| GSA18_200-500 | 10 | 10 | 10 | 10 | 10 | 10 | 10 | 10 | 15 | 15 | 16 | 10 | 10 | 9 | 8 |
| GSA18_500-800 | 10 | 10 | 10 | 10 | 10 | 10 | 10 | 10 | 14 | 14 | 14 | 7 | 7 | 7 | 5 |

Data were assigned to strata based upon the shooting position and average depth (between shooting and hauling depth). Few obvious data errors were corrected. Catches by haul were standardized to 60 minutes hauling duration. Only hauls considered valid were used, including stations with no catches of red mullet (zero catches are included).

The abundance and biomass indices were calculated through stratified means (Cochran, 1953; Saville, 1977). This implies weighting of the average values of the individual standardized catches and the variation of each stratum by the respective stratum areas in each GSA:
$\mathrm{Yst}=\Sigma\left(\mathrm{Yi}^{*}{ }^{*} \mathrm{Ai}\right) / \mathrm{A}$
$\mathrm{V}(\mathrm{Yst})=\Sigma\left(\mathrm{Ai}^{2} * \mathrm{si}^{2} / \mathrm{ni}\right) / \mathrm{A}^{2}$
Where:
A=total survey area
$\mathrm{Ai}=$ area of the i -th stratum
si=standard deviation of the i-th stratum
ni=number of valid hauls of the i-th stratum
$\mathrm{n}=$ number of hauls in the GSA
$\mathrm{Yi}=$ mean of the i-th stratum
Yst=stratified mean abundance
$\mathrm{V}(\mathrm{Yst})=$ variance of the stratified mean
The variation of the stratified mean is then expressed as the $95 \%$ confidence interval:
Confidence interval $=\mathrm{Yst} \pm \mathrm{t}($ student distribution $) * \mathrm{~V}(\mathrm{Yst}) / \mathrm{n}$
It was noted that while this is a standard approach, the calculation may be biased due to the assumptions over zero catch stations, and hence assumptions over the distribution of data. A normal distribution is often assumed, whereas data may be better described by a delta-distribution, quasi-poisson. Indeed, data may be better modelled using the idea of conditionality and the negative binomial (e.g. O'Brien et al. (2004)).

Length distributions represented an aggregation (sum) of all standardized length frequencies (subsamples raised to standardized haul abundance per hour) over the stations of each stratum. Aggregated length frequencies were then raised to stratum abundance * 100 (because of low numbers in most strata) and finally aggregated (sum) over the strata to the GSA.

### 8.25.3.1.2. Geographical distribution patterns

The geographical distribution pattern of red mullet in the GSA 18 has been studied using trawl-survey data and geostatistical methods. In these studies the abundance indices of recruits were analysed. Results highlighted a patchy distribution of red mullet juveniles mostly concentrated along the coast of the South Adriatic Sea within 50 m of depth. The areas showing the highest probability and persistency were detected from 1997 to 2002 using cut-offs of 5000 and $10000 \mathrm{~N} / \mathrm{km} 2$. In particular, the nursery areas distributed along the Gargano peninsula and along the coasts off the area between Molfetta and Brindisi were observed with a probability up to 0.8 , within 50 m of depth. Mapping of the red mullet nursery obtained applying the median indicator kriging technique are reported below.

Fig. 8.25.3.1.3 Geographical distribution patterns.

### 8.25.3.1.3. Trends in abundance and biomass

Fishery independent information regarding the state of the red mullet in the GSA 18 was derived from the international survey Medits. Figure 8.25.3.1.3.1 displays the estimated trend of red mullet abundance and biomass in GSA 18. Abundance and biomass indices show high interannual variations without a clear trend. However, estimated biomass indices appear at an increased level since 1999.

Fig. 8.25.3.1.3.1 Abundance and biomass indices of red mullet in GSA 18.

### 8.25.3.1.4. Trends in abundance by length or age

The following Fig. 8.25.3.1.4.1 and 2 display the stratified abundance indices of GSA 18 in 1994-2001 and 2002-2008.

Fig. 8.25.3.1.4.1 Stratified abundance indices by size, 1994-2001.

Fig. 8.25.3.1.4.2 Stratified abundance indices by size, 2002-2008.

### 8.25.3.1.5. Trends in growth

No analyses were conducted during SGMED-09-02.
8.25.3.1.6. Trends in maturity

No analyses were conducted during SGMED-09-02.

### 8.25.4.Assessment of historic stock parameters

SGMED-09-02 did not undertake any analytical assessment.

### 8.25.5.Long term prediction

### 8.25.5.1.Justification

No forecast analyses were conducted.

### 8.25.5.2.Input parameters

No forecast analyses were conducted.

### 8.25.5.3.Results

Given the preliminary state of the data and analyses SGMED-09-02 is not in the position to provide a long term prediction of catch and stock biomass for red mullet in GSA 18.

### 8.25.6.Scientific advice

### 8.25.6.1.Short term considerations

### 8.25.6.1.1. State of the spawning stock size

SGMED-09-02 is unable to provide any scientific advice of the state of the spawning stock in relation to proposed precautionary level given the preliminary state of the data and analyses.

### 8.25.6.1.2. State of recruitment

SGMED-09-02 is unable to provide any scientific advice of the state of the recruitment given the preliminary state of the data and analyses.

### 8.25.6.1.3. State of exploitation

SGMED-09-02 is unable to provide any scientific advice of the state of the exploitation in relation to proposed precautionary and target levels given the preliminary state of the data and analyses.

### 8.26. Stock assessment of red mullet in GSA 19

### 8.26.1.Stock identification and biological features

### 8.26.1.1.Stock Identification

No information was documented.

### 8.26.1.2.Growth

The data provided during the meeting refer to von Bertalanffy parameters estimates, and are presented in the following table. The growth parameters agreed for red mullet in other areas are comprised between 25 and 27 cm for L (inf) and 0.3 and 0.5 for K (with negative correlation between both). Considering also other growth parameter estimates and that the maximum length is 24 cm , the following growth parameters have been adopted for assessment: 26, 0.3 and -1.0 . With similar criteria the length-weight relationship are 0.007 and 3.17.

Table 8.26.1.2.1 Growth parameters and methods applied.

| COUNTRY | GSA | YEAR_PERIOD | SPECIES | SEX | L_INF | K | TO | A | B | METHOD_USED |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| ITA | 19 | $2003-2005$ | MUT | F | 27.5 | 0.35 | -0.9 | 0.0068 | 3.1 | otoliths reading |
| ITA | 19 | 2008 | MUT | F |  |  |  | 0.005 | 3.2 |  |
| ITA | 19 | $2002-2005$ | MUT | F | 24.5 | 0.27 | -1.9 | 0.0072 | 3.2 | otoliths reading |
| ITA | 19 | $2003-2005$ | MUT | M | 20.3 | 0.6 | -0.6 | 0.0102 | 3.1 | otoliths reading |
| ITA | 19 | 2008 | MUT | M |  |  |  | 0.006 | 3.2 |  |
| ITA | 19 | $2002-2005$ | MUT | M | 22.4 | 0.28 | -2 | 0.009 | 3.1 | otoliths reading |
| ITA | 19 | $2003-2005$ | MUT | C |  |  |  | 0.0063 | 3.21 |  |
| ITA | 19 | 2008 | MUT | C |  |  |  | 0.0055 | 3.2 |  |

### 8.26.1.3.Maturity

Data available during SGMED-09-02 allow to estimate the maturity ogives, for males and females separately for 2008 and compare them with females in the period 2002-2005. It appears that the length at first maturity (L50\%) for females has increased from 10.5 to 11.75 cm .

Fig. 8.26.1.3.1 Maturity ogives by sex and years.
Individuals larger than 19 cm are all females, implying sexual dimorphism regarding growth, with the asymptotic length of females larger than males (probably associated with differential natural mortality).

Fig. 8.26.1.3.2 Female maturity ogive.

### 8.26.2.Fisheries

STECF in 2007 (stock review part II) noted that red mullet Mullus barbatus is among the species with high commercial value. The highest trawl fishing pressure occurs along the Calabrian coast while the presence of rocky bottoms on the shelf along the Apulian coast prevents the fishing by trawling in this sector. The landings in the 2004 in the whole GSA 19 were detected around 321 t coming mainly from bottom trawling and small-scale boats.
8.26.2.2.Management regulations applicable in 2008 and 2009

No information was documented.

### 8.26.2.3.Catches

### 8.26.2.3.1. Landings

Tab. 8.26.2.3.1.1 lists the trend in reported landings by fishing technique. The data were reported to SGMED-09-02 through the Data Collection Regulation and are listed in Table A3.2 of Appendix 3. Since 2003 the annual landings decreased from $2,450 \mathrm{t}$ to only 540 t in 2008 . Many geras contributed to the reported landings.

Data on landings are available for 2002 and 2003 according to the file provided by the secretariat during the meeting. However in the report SGME-08-04 part IV there are data from 2002 to 2007. FAO FishStat data on mullets are available from 1970 to 2005.

There are some inconsistencies between the data reported to FAO (Italy, Ionian Sea, MUX -both species mixed) and data reported to STECF for red mullet in GSA 16 and 19. In 2002 and 2003 STECF data are estimated to be twice what reported by FAO while this pattern is reversed in 2004 and 2005.

Fig. 8.26.2.3.1.1 Landings in GSAs 16 and 19 combined.

Tab. 8.26.2.3.1.1. Annual landings (t) by fishing technique in GSA 19.

| Species | AREA | COUNTRY | FT_LVL4 | 2002 | 2003 | 2004 | 2005 | 2006 | 2007 | 2008 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

| Sum |  |  |  | 2267 | 2449 | 951 | 1102 | 872 | 533 | 447 |

To proceed to the analysis we consider PTS and DTS as trawl and PGP and PMP as nets.

Fig. 8.26.2.3.1.2 Length composition of the landings by gear.

### 8.26.2.3.2. Discards

7 t of discards in 2005 were reported to SGMED-09-02 through the DCR data call and are listed in Tab. A3.9 of Appendix 3.

### 8.26.2.3.3. Fishing effort

The trends in fishing effort by fishing technique reported to SGMED-09-02 are listed in Table 8.26.2.3.3.1.

Tab. 8.26.2.3.3.1 Trends in annual fishing effort by fishing technique deployed in GSA 19, 2002-2007. No data provided for 2008.

### 8.26.3.1.MEDITS

### 8.26.3.1.1. Methods

Based on the DCR data call, abundance and biomass indices were recalculated. In GSA 19 the following number of hauls were reported per depth stratum (s. Tab. 8.26.3.1.1.1).

Tab. 8.26.3.1.1.1. Number of hauls per year and depth stratum in GSA 19, 2002-2008.

| STRATUM | 1994 | 1995 | 1996 | 1997 | 1998 | 1999 | 2000 | 2001 | 2002 | 2003 | 2004 | 2005 | 2006 | 2007 | 2008 |
| :--- | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| GSA19_010-050 | 9 | 9 | 9 | 9 | 9 | 9 | 9 | 9 | 9 | 9 | 9 | 9 | 9 | 8 | 9 |
| GSA19_050-100 | 7 | 8 | 8 | 8 | 8 | 8 | 8 | 8 | 8 | 8 | 8 | 8 | 8 | 9 | 8 |
| GSA19_100-200 | 10 | 10 | 10 | 10 | 10 | 10 | 10 | 10 | 10 | 10 | 10 | 10 | 10 | 10 | 11 |
| GSA19_200-500 | 16 | 15 | 15 | 15 | 15 | 15 | 15 | 15 | 21 | 21 | 14 | 15 | 14 | 14 | 14 |
| GSA19_500-800 | 31 | 32 | 32 | 32 | 32 | 32 | 32 | 32 | 29 | 29 | 29 | 28 | 29 | 29 | 29 |

Data were assigned to strata based upon the shooting position and average depth (between shooting and hauling depth). Few obvious data errors were corrected. Catches by haul were standardized to 60 minutes hauling duration. Hauls noted as valid were used only, including stations with no catches of hake, red mullet or pink shrimp (zero catches are included).

The abundance and biomass indices by GSA were calculated through stratified means (Cochran, 1953; Saville, 1977). This implies weighting of the average values of the individual standardized catches and the variation of each stratum by the respective stratum areas in each GSA:
$\mathrm{Yst}=\Sigma\left(\mathrm{Yi}^{*}{ }^{*} \mathrm{Ai}\right) / \mathrm{A}$
$\mathrm{V}(\mathrm{Yst})=\Sigma\left(\mathrm{Ai}^{2} * \mathrm{si}^{2} / \mathrm{ni}\right) / \mathrm{A}^{2}$
Where:
A=total survey area
$\mathrm{Ai}=$ area of the i-th stratum
$s i=s t a n d a r d$ deviation of the i-th stratum
ni=number of valid hauls of the i-th stratum
$\mathrm{n}=$ number of hauls in the GSA
$\mathrm{Yi}=$ mean of the i-th stratum
Yst=stratified mean abundance
$\mathrm{V}(\mathrm{Yst})=$ variance of the stratified mean

The variation of the stratified mean is then expressed as the $95 \%$ confidence interval: Confidence interval $=$ Yst $\pm \mathrm{t}$ (student distribution) $* \mathrm{~V}(\mathrm{Yst}) / \mathrm{n}$

It was noted that while this is a standard approach, the calculation may be biased due to the assumptions over zero catch stations, and hence assumptions over the distribution of data. A normal distribution is often assumed, whereas data may be better described by a delta-distribution, quasi-poisson. Indeed, data may be better modelled using the idea of conditionality and the negative binomial (e.g. O'Brien et al. (2004)).

Length distributions represented an aggregation (sum) of all standardized length frequencies (subsamples raised to standardized haul abundance per hour) over the stations of each stratum. Aggregated length frequencies were then raised to stratum abundance * 100 (because of low numbers in most strata) and finally
aggregated (sum) over the strata to the GSA. Given the sheer number of plots generated, these distributions are not presented in this report.

### 8.26.3.1.2. Geographical distribution patterns

No analyses were conducted during SGMED-09-02.

### 8.26.3.1.3. Trends in abundance and biomass

Fishery independent information regarding the state of the red mullet in GSA 19 was derived from the international survey Medits. Figure 8.26.3.1.3.1 displays the estimated trend in red mullet abundance and biomass in GSA 19.

The estimated abundance and biomass indices do not reveal any significant trends during 1994-2006. However, the recent abundance and biomass indices in 2007 and 2008 represent the highest values observed in the time series but are subject to high variation.

Fig. 8.26.3.1.3.1 Abundance and biomass indices of red mullet in GSA 19.

### 8.26.3.1.4. Trends in abundance by length or age

The following Fig. 8.26.3.1.4.1 and 2 display the stratified abundance indices of GSA 19 in 1994-2001 and 2002-2008, respectively.

Fig. 8.26.3.1.4.1 Stratified abundance indices by size, 1994-2001.

Fig. 8.26.3.1.4.2 Stratified abundance indices by size, 2002-2008.

### 8.26.3.1.5. Trends in growth

No analyses were conducted.

### 8.26.3.1.6. Trends in maturity

No analyses were conducted．

8．26．4．Assessment of historic stock parameters

## 8．26．4．1．Method 1：LCA VIT

## 8．26．4．1．1．Justification

SGMED－09－02 undertook an analytical assessment of this stock by means of Length Cohort Analysis（LCA）， using Italian mean length frequency data from 2006 to 2008．Software VIT was used．

## 8．26．4．1．2．Input Data

Eight VIT runs were performed，using 4 terminal F （i．e． $0.05,0.01,0.005$ and 0.001 ）and two different M vectors of decreasing values following a negative exponential function．The mean M were 0.31 and 0.68 ．

## 8．26．4．1．3．Results

In Table 8．26．4．1．3．1 a summary of the main indicators from different analyses are presented．

Tab．8．26．4．1．3．1 VIT resulting parameters．

＊the estimator of Virgin Biomass by VIT is not very reliable
The estimated mortality rates by length are presented in Fig．8．26．4．1．3．1（being gear 1 trawl and gear 2 nets）．

Fig. 8.26.4.1.3.1 Estimated mortalities at length with increasing length.

### 8.26.5. Long term prediction

### 8.26.5.1.Justification

A YpR analysis was conducted using the VIT software.

### 8.26.5.2.Input parameters

VIT data inputs are described above and VIT estimates of exploitation patterns were used.

### 8.26.5.3.Results

Considering the two extreme cases 1) M low and Ft 0.05 , and 2) M high and Ft 0.001 the $\mathrm{Y} / \mathrm{R}$ analysis shows even in the most pessimistic case (1) a low growth overexploitation. This is due to the "good" selectivity of the gears, especially trawl (no catch of individuals smaller than 11 cm ) which is not reliable.

Fig. 8.26.5.3.1 Resulting YpR curves for 2 extreme input scenarios.

Given the catch data deficiencies SGMED-09-02 is not in the position to provide a long term prediction of catch and stock biomass for red mullet in GSA 19.

### 8.26.6.Scientific advice

### 8.26.6.1.Short term considerations

### 8.26.6.1.1. State of the spawning stock size

Survey indices show significant abundance increases in 2007 and 2008. SGMED-09-02 is unable to fully evalute the stock status due to a lack of estimated target and precautionary levels of SSB.

### 8.26.6.1.2. State of recruitment

SGMED 09-02 notes that the recruitment in 2007 was exceptionally high resulting in stock size increases in 2007 and 2008.

### 8.26.6.1.3. State of exploitation

SGMED-09-02 is unable to fully evalute the stock status due to a lack of estimated target and precautionary levels of SSB. Significant landings data deficiency makes the results of analytical assessment approaches unreliable.

### 8.27. Stock assessment of red mullet in GSA 20

### 8.27.1.Stock identification and biological features

### 8.27.1.1.Stock Identification

Red mullet is one of the most common and most valuable fish species in Greek Seas. The species is fished by bottom trawl and nets (mainly gill nets) in shallow-mid waters along the Greek coast. The stock is distributed mainly on muddy bottoms along the coast. Its depth distribution is limited in depths less than 200 m . However, is not abundant in water deeper than 150 m . Spawning takes place during spring-early summer. The juveniles of the species are concentrated in shallow waters ( $10-50 \mathrm{~m}$ ). Nursery grounds in GSA 20 have been defined along the Western Coast of Peloponnese and Epirus. The stock in GSA 20 is exploited exclusively by the Greek fleet.

### 8.27.1.2.Growth

No information was documented during SGMED-09-02.

### 8.27.1.3.Maturity

No information was documented during SGMED-09-02.

### 8.27.2.Fisheries

### 8.27.2.1.General description of fisheries

The main fishing gears targeting red mullet in GSA 20 are bottom trawls and gill nets. In some cases, trammel nets are used as well. According to the European and Greek Legislation, bottom trawls operate in waters deeper than 50 m or in a distance 3 miles from the coasts. Thus the gear is targeting the species in waters from the limit (as defined by the legislation) down to 150 m (or deeper but the abundance is not high so red mullet is not the target or one of the target species). Illegal fishing by bottom trawls was very common in the past (in waters less than 50 m or in a distance less than 3 miles) and could be considered as harmful for the species. Large quantities of 0 age specimens, with length $5-9 \mathrm{~cm}$, were caught during autumn. Nowadays, with the use of VMS the situation has been improved significantly but the problem still exists.

There is no depth limit or restriction related to distance from shore for the nets in Greece. However, nets from October to May usually fish at depths $<50 \mathrm{~m}$ or in a distance $<3$ miles from the coasts. During summer, when bottom trawl fishery is closed, nets may be used in deeper waters. The mesh size is usually $36-44 \mathrm{~mm}$ but there are cases where smaller mesh size ( 32 or 34 mm ) is used. Mesh sizes $>36 \mathrm{~mm}$ have no important impact on the juveniles. The optimum selection lengths were at $13.5 \mathrm{~cm}, 15 \mathrm{~cm}, 16.5 \mathrm{~cm}$ and 17 cm for the $34 \mathrm{~mm}, 38 \mathrm{~mm}, 42 \mathrm{~mm}$ and 44 mm nets respectively (Petrakis, 1998, SELMED Selectivity of fixed nets in Mediterranean EEC contract: 95/C/76/15). There is a clear seasonal pattern of the red mullet net metier, which varies between different areas depending on the abundance of the species and on the availability of other more profitable resources.
8.27.2.2.Management regulations applicable in 2008 and 2009

No specific regulation to manage the species is enforced.
The MLS is 11 cm (according to EE 1967/2006 regulation). The most important measures for managing bottom trawl or net fisheries in Greece have been described in the section 8.14.2.2.

### 8.27.2.3.Catches

### 8.27.2.3.1. Landings

Landings of red mullet in GSA 20 for the years 2003-2008 are presented in Tab. 8.27.2.3.1.1.
Tab. 8.27.2.3.1.1 Annual landings ( t ) by fishing technique as reported to SGMED-09-02 through the DCR data call, 2003-2008.

| SPECIES | AREA | COUNTRY FT_LVL4 | 2002 | 2003 | 2004 | 2005 | 2006 | 2007 | 2008 |  |

8.27.3.Scientific surveys
8.27.3.1.Medits
8.27.3.1.1. Methods

Based on the DCR data call, abundance and biomass indices were calculated. In GSA 20 the following number of hauls was reported per depth stratum (s. Tab. 8.27.3.1.1.1).

Tab. 8.27.3.1.1.1. Number of hauls per year and depth stratum in GSA 20, 1994-2008.

| STRATUM | 1994 | 1995 | 1996 | 1997 | 1998 | 1999 | 2000 | 2001 | 2002 | 2003 | 2004 | 2005 | 2006 | 2007 | 2008 |
| :--- | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| GSA20_010-050 | 2 | 2 | 2 | 2 | 4 | 4 | 3 | 3 |  | 3 | 3 | 3 | 3 |  | 3 |
| GSA20_050-100 | 3 | 4 | 8 | 7 | 11 | 10 | 11 | 10 |  | 10 | 10 | 10 | 9 |  | 10 |
| GSA20_100-200 | 2 | 3 | 4 | 2 | 5 | 6 | 5 | 6 |  | 6 | 6 | 5 | 6 | 6 |  |
| GSA20_200-500 | 2 | 3 | 4 | 4 | 7 | 7 | 7 | 8 |  | 8 | 9 | 8 | 8 | 7 |  |
| GSA20_500-800 | 3 | 3 | 4 | 3 | 5 | 5 | 5 | 5 |  | 5 | 4 | 5 | 4 | 6 |  |

Data were assigned to strata based upon the shooting position and average depth (between shooting and hauling depth). Few obvious data errors were corrected. Catches by haul were standardized to 60 minutes hauling duration. Hauls noted as valid were used only, including stations with no catches of hake, red mullet or pink shrimp (zero catches are included).

The abundance and biomass indices by GSA were calculated through stratified means (Cochran, 1953; Saville, 1977). This implies weighting of the average values of the individual standardized catches and the variation of each stratum by the respective stratum areas in each GSA:
$\mathrm{Yst}=\Sigma\left(\mathrm{Yi}^{*} \mathrm{Ai}\right) / \mathrm{A}$
$\mathrm{V}(\mathrm{Yst})=\Sigma\left(\mathrm{Ai}^{2} * \mathrm{si}^{2} / \mathrm{ni}\right) / \mathrm{A}^{2}$
Where:
$\mathrm{A}=$ total survey area
$\mathrm{Ai}=$ area of the i -th stratum
si=standard deviation of the i-th stratum
ni=number of valid hauls of the i-th stratum
$\mathrm{n}=$ number of hauls in the GSA
Yi=mean of the $i$-th stratum
Yst=stratified mean abundance
$\mathrm{V}(\mathrm{Yst})=$ variance of the stratified mean
The variation of the stratified mean is then expressed as the $95 \%$ confidence interval: Confidence interval $=$ Yst $\pm \mathrm{t}$ (student distribution) $* \mathrm{~V}(\mathrm{Yst}) / \mathrm{n}$

It was noted that while this is a standard approach, the calculation may be biased due to the assumptions over zero catch stations, and hence assumptions over the distribution of data. A normal distribution is often assumed, whereas data may be better described by a delta-distribution, quasi-poisson. Indeed, data may be better modelled using the idea of conditionality and the negative binomial (e.g. O'Brien et al. (2004)).

Length distributions represented an aggregation (sum) of all standardized length frequencies (subsamples raised to standardized haul abundance per hour) over the stations of each stratum. Aggregated length frequencies were then raised to stratum abundance * 100 (because of low numbers in most strata) and finally aggregated (sum) over the strata to the GSA. Given the sheer number of plots generated, these distributions are not presented in this report.

### 8.27.3.1.2. Geographical distribution patterns

No analyses were conducted during SGMED-09-02.

### 8.27.3.1.3. Trends in abundance and biomass

Fishery independent information regarding the state of the red mullet in GSA 20 was derived from the international survey Medits. Figure 8.27.3.1.3.1 displays the estimated trend in red mullet abundance and biomass in GSA 20.

The estimated abundance and biomass indices do not reveal any significant trends since 1997 when the indices increased from a lower level. The analyses of Medits indices are considered preliminary.

Fig. 8.27.3.1.3.1 Abundance and biomass indices of red mullet in GSA 20.

### 8.27.3.1.4. Trends in abundance by length or age

The following Fig. 8.27.3.1.4.1 and 2 display the stratified abundance indices of GSA 20 in 1994-2001 and 2003-2008. These size compositions are considered preliminary.

Fig. 8.27.3.1.4.1 Stratified abundance indices by size, 1994-2001.

Fig. 8.27.3.1.4.2 Stratified abundance indices by size, 2003-2008.

### 8.27.3.1.5. Trends in growth

No analyses were conducted during SGMED-09-02.

### 8.27.3.1.6. Trends in maturity

No analyses were conducted during SGMED-09-02.

### 8.27.4.Assessment of historic stock parameters

SGMED 09-02 did not undertake any analytical assessment of red mullet in GSA 20. Last year's preliminary assessment using SURBA can be found in the report of SGMED-08-04 working group (Cardinale et al., 2008).

### 8.27.5.1.Justification

No forecast analyses were conducted.

### 8.27.5.2.Input parameters

No forecast analyses were conducted.

### 8.27.5.3.Results

Given the preliminary state of the data and analyses SGMED-09-02 is not in the position to provide a long term prediction of catch and stock biomass for red mullet in GSA 20.

### 8.27.6.Scientific advice

### 8.27.6.1.Short term considerations

### 8.27.6.1.1. State of the spawning stock size

SGMED-09-02 is unable to provide any scientific advice of the state of the spawning stock in relation to proposed precautionary level given the preliminary state of the data and analyses.

### 8.27.6.1.2. State of recruitment

SGMED-09-02 is unable to provide any scientific advice of the state of the recruitment given the preliminary state of the data and analyses.

### 8.27.6.1.3. State of exploitation

SGMED-09-02 is unable to provide any scientific advice of the state of the exploitation in relation to proposed precautionary and target levels given the preliminary state of the data and analyses.

### 8.28. Stock assessment of red mullet in GSAs 22 and 23 combined

### 8.28.1.Stock identification and biological features

### 8.28.1.1.Stock Identification

Red mullet is one of the most common and most valuable fish species in Greek Seas. The species is fished by bottom trawl and nets (mainly gill nets) in shallow-mid waters along the Greek coast. The stock is distributed mainly on muddy bottoms along the coast. Its depth distribution is limited in depths less than 200 m . However, is not abundant in water deeper than 150 m . Spawning occurs during spring-early summer. The juveniles of the species are concentrated in shallow waters ( $10-50 \mathrm{~m}$ ). Part of the stock in GSA 22 (in the coasts of eastern Aegean) is exploited by the Turkish fleet.

### 8.28.1.2.Growth

No information was documented during SGMED-09-02.

### 8.28.1.3.Maturity

No information was documented during SGMED-09-02.

### 8.28.2.Fisheries

### 8.28.2.1.General description of fisheries

The main fishing gears targeting red mullet in GSA 22-23 are bottom trawls and gill nets. In some cases, trammel nets are used as well. According to the European and Greek Legislation, bottom trawls operate in waters deeper than 50 m or in a distance $>3$ miles from the coasts. Thus the gear is targeting the species in waters from the limit (as defined by the legislation) down to 150 m (or deeper but the abundance is not high so red mullet is not the target or one of the target species). Illegal fishing by bottom trawls was very common in the past (in waters $<50 \mathrm{~m}$ or in a distance less than 3 miles) and could be considered as harmful for the species. Nowadays, with the use of VMS the situation has been improved significantly but the problem still exists.

There is not depth limit or distance from the coasts restriction for the nets in Greece. However, the nets from October to May are mainly used in waters $<50 \mathrm{~m}$ or in a distance $<3$ miles from the coasts. During summer, when bottom trawl fishery is closed, nets could be used in deeper waters. The mesh size is usually $36-44 \mathrm{~mm}$ but there are cases where smaller mesh size ( 32 or 34 mm ) is used. Mesh sizes larger than 36 mm have no important impact on the juveniles. The optimum selection lengths were at $13.5 \mathrm{~cm}, 15 \mathrm{~cm}, 16.5 \mathrm{~cm}$ and 17 cm for the $34 \mathrm{~mm}, 38 \mathrm{~mm}, 42 \mathrm{~mm}$ and 44 mm nets respectively (Petrakis, 1998, SELMED Selectivity of fixed nets in Mediterranean EEC contract: 95/C/76/15). There is a seasonal pattern of the red mullet net metier, which varies between different areas depending on the behaviour of the species and on the availability of other more profitable resources.
8.28.2.2.Management regulations applicable in 2008 and 2009

The MLS is 11 cm (according to EE 1967/2006 regulation). The most important measures for managing bottom trawl or net fisheries in Greece have been described in the section 8.14.2.2.

### 8.28.2.3.Catches

### 8.28.2.3.1. Landings

Landings of red mullet in GSA 22-23 for the years 2003-2008 are presented in Tab. 8.28.2.3.1.1.
Tab. 8.28.2.3.1.1 Annual landings (t) by fishing technique as reported to SGMED-09-02 through the DCR data call, 2003-2008.

| SPECIES | AREA | COUNTRY | FT_LVL4 | 2002 | 2003 | 2004 | 2005 | 2006 | 2007 | 2008 |

[^1]
### 8.28.3.1.Medits

### 8.28.3.1.1. Methods

Based on the DCR data call, abundance and biomass indices were calculated. In GSAs 22 and 23 the following number of hauls were reported per depth stratum (s. Tab. 8.28.3.1.1.1).

Tab. 8.28.3.1.1.1. Number of hauls per year and depth stratum in GSAs 22 and 23, 1994-2008.

| STRATUM | 1994 | 1995 | 1996 | 1997 | 1998 | 1999 | 2000 | 2001 | 2002 | 2003 | 2004 | 2005 | 2006 | 2007 | 2008 |
| :--- | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| GSA22+23_010-050 | 10 | 10 | 11 | 10 | 13 | 12 | 13 | 13 |  | 13 | 13 | 14 | 14 | 13 |  |
| GSA22+23_050-100 | 19 | 21 | 22 | 28 | 24 | 26 | 21 | 25 |  | 25 | 23 | 24 | 24 |  | 27 |
| GSA22+23_100-200 | 19 | 26 | 38 | 36 | 36 | 33 | 38 | 35 |  | 36 | 43 | 41 | 41 | 40 |  |
| GSA22+23_200-500 | 32 | 35 | 45 | 50 | 51 | 54 | 50 | 48 |  | 51 | 53 | 52 | 52 | 52 |  |
| GSA22+23_500-800 | 18 | 13 | 19 | 22 | 22 | 21 | 20 | 17 |  | 17 | 17 | 17 | 17 | 17 |  |

Data were assigned to strata based upon the shooting position and average depth (between shooting and hauling depth). Few obvious data errors were corrected. Catches by haul were standardized to 60 minutes hauling duration. Hauls noted as valid were used only, including stations with no catches of hake, red mullet or pink shrimp (zero catches are included).

The abundance and biomass indices by GSA were calculated through stratified means (Cochran, 1953; Saville, 1977). This implies weighting of the average values of the individual standardized catches and the variation of each stratum by the respective stratum areas in each GSA:

```
\(\mathrm{Yst}=\Sigma\left(\mathrm{Yi}^{*}{ }^{*} \mathrm{Ai}\right) / \mathrm{A}\)
\(\mathrm{V}(\mathrm{Yst})=\Sigma\left(\mathrm{Ai}^{2} * \mathrm{si}^{2} / \mathrm{ni}\right) / \mathrm{A}^{2}\)
```

Where:
A=total survey area
$\mathrm{Ai}=$ area of the i-th stratum
si=standard deviation of the i-th stratum
ni=number of valid hauls of the i-th stratum
n=number of hauls in the GSA
$\mathrm{Yi}=$ mean of the i-th stratum
Yst=stratified mean abundance
$\mathrm{V}(\mathrm{Yst})=$ variance of the stratified mean
The variation of the stratified mean is then expressed as the $95 \%$ confidence interval: Confidence interval $=$ Yst $\pm \mathrm{t}$ (student distribution) $* \mathrm{~V}(\mathrm{Yst}) / \mathrm{n}$

It was noted that while this is a standard approach, the calculation may be biased due to the assumptions over zero catch stations, and hence assumptions over the distribution of data. A normal distribution is often assumed, whereas data may be better described by a delta-distribution, quasi-poisson. Indeed, data may be better modelled using the idea of conditionality and the negative binomial (e.g. O'Brien et al. (2004)).

Length distributions represented an aggregation (sum) of all standardized length frequencies (subsamples raised to standardized haul abundance per hour) over the stations of each stratum. Aggregated length frequencies were then raised to stratum abundance * 100 (because of low numbers in most strata) and finally aggregated (sum) over the strata to the GSA. Given the sheer number of plots generated, these distributions are not presented in this report.

### 8.28.3.1.2. Geographical distribution patterns

No analyses were conducted during SGMED-09-02.

### 8.28.3.1.3. Trends in abundance and biomass

Fishery independent information regarding the state of the red mullet in GSAs 22 and 23 was derived from the international survey Medits. Figure 8.28.3.1.3.1 displays the estimated trend in red mullet abundance and biomass in GSAs 22 and 23.

After a significant increase in abundance until 1999 and in biomass until 2001, the estimated indices decreased again to a low level in 2005-2006. The analyses of Medits indices are considered preliminary.

Fig. 8.28.3.1.3.1 Abundance and biomass indices of red mullet in GSAs 22 and 23.

### 8.28.3.1.4. Trends in abundance by length or age

The following Fig. 8.28.3.1.4.1 and 2 display the stratified abundance indices of GSAs 22 and 23 in 19942001 and 2002-2008. These size compositions are considered preliminary.

Fig. 8.28.3.1.4.1 Stratified abundance indices by size, 1994-2001.

Fig. 8.28.3.1.4.2 Stratified abundance indices by size, 2003-2008.

### 8.28.3.1.5. Trends in growth

No analyses were conducted during SGMED-09-02.

### 8.28.3.1.6. Trends in maturity

No analyses were conducted during SGMED-09-02.

### 8.28.4.Assessment of historic stock parameters

SGMED 09-02 did not undertake any analytical assessment of red mullet in GSAs 22 and 23. Last year's preliminary assessment using SURBA can be found in the report of SGMED-08-04 working group (Cardinale et al., 2008).

### 8.28.5.1.Justification

No forecast analyses were conducted.

### 8.28.5.2.Input parameters

No forecast analyses were conducted.

### 8.28.5.3.Results

Given the preliminary state of the data and analyses SGMED-09-02 is not in the position to provide a long term prediction of catch and stock biomass for red mullet in GSAs 22 and 23.

### 8.28.6.Scientific advice

### 8.28.6.1.Short term considerations

### 8.28.6.1.1. State of the spawning stock size

SGMED-09-02 is unable to provide any scientific advice of the state of the spawning stock in relation to proposed precautionary level given the preliminary state of the data and analyses.

### 8.28.6.1.2. State of recruitment

SGMED-09-02 is unable to provide any scientific advice of the state of the recruitment given the preliminary state of the data and analyses.

### 8.28.6.1.3. State of exploitation

SGMED-09-02 is unable to provide any scientific advice of the state of the exploitation in relation to proposed precautionary and target levels given the preliminary state of the data and analyses.

### 8.29. Stock assessment of red mullet in GSA 25

### 8.29.1.Stock identification and biological features

### 8.29.1.1.Stock Identification

Red mullet is a common demersal fish in the Mediterranean Sea, found in depths ranging from 10-200 meters, and mostly distributed in depths less than 100 m . It inhabits sandy and muddy bottoms. The species in GSA 25 is considered as a single stock, though this has not been evidenced by studies on population structure.

### 8.29.1.2.Growth

The von Bertalanffy growth parameters of red mullet in GSA 25 were estimated using otolith readings; the estimates for sex combined data, for the years 2006-2008, are the following: $\mathrm{L}_{\text {inf }}=26.61, \mathrm{~K}=0.183$ and $\mathrm{t}_{0}=-2.488$.

Parameters of the length-weight relationship, related to sex combined data for the years 2006-2008, are: $\mathrm{a}=0.00797, \mathrm{~b}=3.12$ (for length expressed in cm ).

The data used for the growth parameters were collected under the Cyprus National Data Collection Programme, within the Data Collection Regulation framework, and were provided through the 2009 Spring Official EC Data Call.

### 8.29.1.3.Maturity

The maturity ogive of the stock (sex combined), as provided through the 2009 Spring Official EC Data Call, is presented in Table 8.29.1.3.1. Data used were collected under the Cyprus National Programme during 2006-2008.

Tab. 8.29.1.3.1: Maturity ogive of $M$. barbatus

| TL (cm) | Proportion of <br> mature |
| ---: | ---: |
| 7 | 0.00 |
| 8 | 0.33 |
| 9 | 0.60 |
| 10 | 0.87 |
| 11 | 0.88 |
| 12 | 0.88 |
| 13 | 0.94 |
| 14 | 0.95 |
| 15 | 0.98 |
| 16 | 0.99 |
| 17 | 1.00 |

### 8.29.2. Fisheries

### 8.29.2.1.General description of fisheries

Red mullet in GSA 25 is exploited with other demersal species by the bottom otter trawlers and the artisanal fleet using set nets (basically trammel nets). The main species caught with M. barbatus are: Spicara spp.
(mostly S. smaris), Boops boops, M. surmuletus, Pagellus erythrinus and cephalopods (Octopus vulgaris, Loligo vulgaris and Sepia officinalis). The artisanal (inshore) fishery catches also relatively large quantities of Diplodus spp, Sparisoma cretense and Siganus spp. The average percentage of M. barbatus in the overall landings of the bottom trawl and artisanal fishery, for the period 2005-2008, was $7 \%$ and $2 \%$ respectively.

The average composition of the landings of the artisanal and the bottom trawl fishery during the period 20022006 is provided in Figure 8.29.2.1.1.

Fig. 8.29.2.1.1. Composition of landings of the artisanal and trawl fishery in Cyprus for the period 20022006.

Discards from the bottom otter trawl were evaluated for the first time in 2006, through a pilot study carried out as part of the 2006 Cyprus National Fisheries Data Collection Programme. The study suggested that discard quantities of $M$. barbatus are less than $1 \%$ in terms of biomass and $2 \%$ in terms of numbers.

Discards from the artisanal fishery are considered negligible.
8.29.2.2. Management regulations applicable in 2008 and 2009

The National and Community legislation provide for a number of management measures for the regulation of the Cyprus fisheries, including:

- Restrictive access to the fisheries (limited number of licenses for each fleet segment).
- Effort control: Restrictions on the use of fishing gears (quantities, soaking time, depth and distance off shore) and regulation of fishing capacity (scrapping, assignment for other uses than fishing, engine restrictions, ceiling of the fleet vessel register).
- Market restriction measures: minimum landing sizes for several species. For red mullet the minimum landing size applied is 11 cm (as set in Regulation (EC) 1967/2006).
- Technical conservation measures: minimum mesh sizes.
- Seasonal and area closures.

For the bottom otter trawl fishery in terrirorial waters (GSA 25) the following management measures were applicable in the last two years (2007-2008):

- Maximum number of licenses restricted to 4.
- Closed trawling period from the beginning of June until the $7^{\text {th }}$ of November (in force since the mid '80s).
- Minimum mesh size of the trawl net at 40 mm (diamond shape). It is noted that from November 2009 the trawl net will be replaced by a square meshed net of 40 mm at the cod-end or by a diamond meshed net of 50 mm , in accordance with the provisions of the new Mediterranean Regulation (EC) No 1967/2006.
- Prohibition of bottom trawling at depths less than 50 meters and at distances less than 0.7 nautical miles off the coast. From November 2008 there is a prohibition of bottom trawling at distances between 0.7 and 1.5 nautical miles in certain areas within the terrirtorial waters, with the intention to fully implement this measure in all territorial waters.

For the artisanal fishery the following management measures were applicable in the last two years:

- Assignment of licensed fishermen in 3 categories, based on their fishing activity and certain criteria.
- Restriction of the maximum number of licenses
- Implementation of the provisions of the Mediterranean Regulation on restrictions on the use of fishing gears. Implementation of additional restrictions on fishing effort (use of fishing gears and number of fishing days) depending on the fishing license category.

### 8.29.2.3.Catches

### 8.29.2.3.1. Landings

Figure 8.29.2.3.1.1. provides the official landings of $M$. barbatus in GSA 25 by fishing gear, for the years 1985-2008. The figure presents a declining trend in the landings from both gears, mostly from the trammel nets. For the same period, the overall LPUE by fishing fleet (all gears combined for the artisanal fishery) is provided in same Figure. LPUE of both fleets show a declining trend until 2006; since then, LPUE for the artisanal fleet seems to be stable, while for the bottom trawl fishery LPUE in 2007 reached the highest value of the time period. It is noted that since 2006 the number of licensed bottom trawlers operating in GSA 25 has been reduced by $50 \%$ (from 8 to 4 ).

Fig. 8.29.2.3.1.1: Landings and LPUE of M. barbatus in GSA 25 by fishing gear for the period 1985-2008.

Data on landings and fishing effort are collected by the Department of Fisheries and Marine Research by the following sources:

- Logbooks (for vessels larger than 12 m )
- Landing declarations/inshore reports (from a $15 \%$ sample of licensed vessels less than 12 m )
- Sampling of vessels at landing sites (for vessels less than 12m)

Landings data provided through the 2009 Spring Official EC Data Call refer to the years 2005-2008. The length distribution of the landings for this period for each fishing gear, as officially submitted, is provided in Figure 8.29.2.3.1.2.

Fig. 8.29.2.3.1.2: Landings length distribution of $M$. barbatus in GSA 25 per fishing gear for the years 20052008.

### 8.29.2.3.2. Discards

The estimation of discards of the species involves on-board sampling of bottom otter trawlers; data are collected under the Cyprus National Data Collection Programme since 2006. Discards from the artisanal fishery is considered negligible.

The discard estimates of M. barbatus in terms of weight for 2006 and 2008 were less than 200kg (as provided through the 2009 Spring Official EC Data Call), accounting for about $1 \%$ of the total catch of the species. Under the official call, data were also sent on discards length distribution for the year 2008 (provided in figure 8.29.2.3.2.1).

Fig. 8.29.2.3.2.1: Discards length distribution of M. barbatus in GSA 25 for the year 2008.

### 8.29.2.3.3. Fishing effort

Fishing effort data in GSA 25 were provided according to the 2009 Spring Official EC Data Call. Table 8.29.2.3.3.1 lists the reported effort by fishing technique deployed in GSA 25.

Tab. 8.29.2.3.3.1 Effort by métier in GSA 25, 2005-2008.

| TYPE | AREA | COUHTRY | FT LR4 | $\begin{aligned} & \text { ME SSEL } \\ & \text { LEHGTH } \end{aligned}$ | 2005 | 2006 | 2007 | 200. |

### 8.29.3. Scientific surveys

### 8.29.3.1.Medits

### 8.29.3.1.1. Methods

Based on the DCR data call, abundance and biomass indices were recalculated. In GSA 25 the following numbers of hauls were reported per depth stratum (s. Tab. 8.29.3.1.1.1).

Tab. 8.29.3.1.1.1. Number of hauls per year and depth stratum in GSA 25, 2005-2008.

| STRATUM | 2005 | 2006 | 2007 | 2008 |
| :--- | ---: | ---: | ---: | ---: |
| GSA25_010-050 | 5 | 5 | 5 | 6 |
| GSA25_050-100 | 6 | 6 | 6 | 9 |
| GSA25_100-200 | 5 | 5 | 5 | 5 |
| GSA25_200-500 | 3 | 3 | 3 | 3 |
| GSA25_500-800 | 4 | 4 | 4 | 4 |

Data were assigned to strata based upon the shooting position and average depth (between shooting and hauling depth). Few obvious data errors were corrected. Catches by haul were standardized to 60 minutes hauling duration. Hauls noted as valid were used only, including stations with no catches of hake, red mullet or pink shrimp (zero catches are included).

The abundance and biomass indices by GSA were calculated through stratified means (Cochran, 1953; Saville, 1977). This implies weighting of the average values of the individual standardized catches and the variation of each stratum by the respective stratum areas in each GSA:
$\mathrm{Yst}=\Sigma\left(\mathrm{Yi}^{*} \mathrm{Ai}\right) / \mathrm{A}$
$\mathrm{V}(\mathrm{Yst})=\Sigma\left(\mathrm{Ai}^{2} * \mathrm{si}^{2} / \mathrm{ni}\right) / \mathrm{A}^{2}$

Where:
A=total survey area
$\mathrm{Ai}=$ area of the i -th stratum
si=standard deviation of the i-th stratum
ni=number of valid hauls of the i-th stratum
$\mathrm{n}=$ number of hauls in the GSA
$\mathrm{Yi}=$ mean of the i-th stratum
Yst=stratified mean abundance
$\mathrm{V}(\mathrm{Yst})=$ variance of the stratified mean
The variation of the stratified mean is then expressed as the $95 \%$ confidence interval: Confidence interval $=$ Yst $\pm \mathrm{t}$ (student distribution) $* \mathrm{~V}(\mathrm{Yst}) / \mathrm{n}$

It was noted that while this is a standard approach, the calculation may be biased due to the assumptions over zero catch stations, and hence assumptions over the distribution of data. A normal distribution is often assumed, whereas data may be better described by a delta-distribution, quasi-poisson. Indeed, data may be better modelled using the idea of conditionality and the negative binomial (e.g. O'Brien et al. (2004)).

Length distributions represented an aggregation (sum) of all standardized length frequencies (subsamples raised to standardized haul abundance per hour) over the stations of each stratum. Aggregated length frequencies were then raised to stratum abundance * 100 (because of low numbers in most strata) and finally aggregated (sum) over the strata to the GSA. Given the sheer number of plots generated, these distributions are not presented in this report.

### 8.29.3.1.2. Geographical distribution patterns

Figure 8.29.3.1.2.1. provides the distribution of sampling hauls of the Medits survey in GSA 25. No analyses on geographical distribution patterns were conducted during SGMED-09-02.

Fig. 8.29.3.1.2.1. Distribution of sampling hauls of the Medits survey in GSA 25.

### 8.29.3.1.3. Trends in abundance and biomass

Fishery independent information regarding the state of the red mullet in GSA 25 was derived from the international survey Medits. SGMED-09-02 notes that the MEDITS survey covers only the southern and north-western slopes off Cyprus.

Figure 8.29.3.1.3.1 displays the estimated trend in red mullet abundance and biomass in GSA 25. The estimated abundance and biomass indices do not reveal any significant trends since 2005 and are subject to high variability (uncertainty). This trend seems to be in agreement with the trend in the landings during the same period (see Figures 8.29.2.3.1.1 and 8.29.4.1.2.2).

Fig. 8.29.3.1.3.1 Abundance and biomass indices of red mullet in GSA 25.

### 8.29.3.1.4. Trends in abundance by length or age

The following Fig. 8.29.3.1.4.1 displays the stratified abundance indices of GSA 25 in 2005-2008. These size compositions are considered preliminary.

| GSA25 2007 |  |  |  |  |  |  |  |  |  |  |  |  |  |

Fig. 8.29.3.1.4.1 Stratified abundance indices by size, 2005-2008.

### 8.29.3.1.5. Trends in growth

No analyses were conducted during SGMED-09-02.

### 8.29.3.1.6. Trends in maturity

No analyses were conducted during SGMED-09-02.

### 8.29.4.Assessment of historic stock parameters

### 8.29.4.1.Method 1: VIT

### 8.29.4.1.1. Justification

Due to the short time data series provided under the DCR Data Call (2005-2008), and the almost equal exploitation of the stock by two fishing gears, the VIT software (Lleonart and Salat, 1992) was considered as the most appropriate software for assessing the stock in GSA 25.

The assessment was performed by means of VPA analysis (running the classic catch equation - Gulland 1965), using a mean pseudo-cohort from catch-at-age data for the period 2005-2008.

### 8.29.4.1.2. Input parameters

The biological parameters used were the ones collected within the framework of the Cyprus National Data Collection Programme and submitted under the 2009 Spring Official EC Data Call:

- VBGF growth parameters: $\mathrm{L}_{\mathrm{inf}}=26.61, \mathrm{~K}=0.183$ and $\mathrm{t}_{0}=-2.488$.
- Length-weight relationship: $\mathrm{a}=0.00797, \mathrm{~b}=3.12$ (for length expressed in cm )
- Maturity ogive by age class (transformed from submitted maturity at length class, as shown in table 8.29.4.1.2.1)

Tab. 8.29.4.1.2.1 Maturity at Age for M. barbatus in GSA 25 for the period 2006-2008.

| Age | 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| Prop. Miatures | 0.465 | 0.9 | 0.94 | 1 | 1 | 1 | 1 | 1 |

An M vector was used, as estimated by PRODBIOM spreadsheet (Abella et al., 1997) (see Table 8.29.4.1.2.2.).

Tab. 8.29.4.1.2.2 M vector used for the assessment of $M$. barbatus in GSA 25 (estimated by PRODBIOM).

| PERIOD | Age | 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $2005-2008$ | M | 0.26 | 0.12 | 0.1 | 0.09 | 0.08 | 0.08 | 0.08 | 0.08 |

During SGMED 09-01 a range of $\mathrm{L}_{\text {inf }}$ between 27 to 31 cm TL was recommended to be adopted for the estimation of M of the species; since the value of $\mathrm{L}_{\mathrm{inf}}$ is very close to this range, it was considered realistic. Because of the highly negative value of the parameter $t_{0}$, the following two sets of VBGF parameters were also used for estimating the M vector, for comparing the resulting values:

- $\mathrm{L}_{\mathrm{inf}}=34.5, \quad \mathrm{~K}=0.34$ and $\mathrm{t}_{0}=-0.143$, proposed by SGMED 08-04 as "Fast" growth parameters
- $\mathrm{L}_{\text {inf }}=26.01, \mathrm{~K}=0.41$ and $\mathrm{t}_{0}=-0.4$, proposed by SGMED 08-04 as "Slow" growth parameters.

Figure 8.29.4.1.2.1. provides the estimated M vectors that resulted from the Cyprus and the other two VBGF parameters. As indicated by the figure, the estimated M from the Cyprus parameters is lower than the ones
estimated using the other two sets. The M values used in the final assessment are shown in Table 8.29.4.1.2.2.

Fig. 8.29.4.1.2.1: M vectors of $M$. barbatus in GSA 25 as estimated by PRODBIOM, using different growth parameters.

Terminal fishing mortality ( $\mathrm{F}_{\text {term }}$ ) was set to 0.3 . For the estimation of this parameter the length frequency data from the Medits survey (2005-2008) were used for plotting length-converted catch curves of the oldest ages, using the LFDA software (Kirkwood et al., 2001).

Catch-at-age data derived from landings for each fishing gear exploiting the stock (bottom otter trawl-OTB and trammel net-GTR), and discards data from bottom otter trawl. The input catch-at-age data are shown in Table 8.29.4.1.2.3.

The mean catch and the relevant percentage by fishing gear was used in terms of weight (g) (see table 8.29.4.1.2.4). The mean catch per gear was calculated using the landings and discards data, submitted under the 2009 Spring Official EC Data Call. Discards data were available only for bottom otter trawl for the years 2006 and 2008; as the discard values for these two years were similar, their average value was used for the years 2005 and 2007. Figure 8.29.4.1.2.2 provides the annual catches (in tons) by fishing gear for the period 2005-2008.

Tab. 8.29.4.1.2.3 Average age structure of M. barbatus catches for the period 2005-2008.

| Age classOTB Catch <br> (\%) | GTR Catch <br> (\%) |  |
| :---: | ---: | ---: |
| 0 | 3.06 | 0.17 |

|  | Catch (tuns) |
| :--- | :--- |
| Bottom Otter Trawi (OTB) | $19.41(49 \%)$ |
| Trammel net (GTR) | $20.21(51 \%)$ |
| Total | 39.63 |

Fig. 8.29.4.1.2.2. Annual catches (t) by fishing gear for the period 2005-2008.

### 8.29.4.1.3. Results

Table 8.29.4.1.3.1 shows the summary results from the pseudocohort analysis on catch-at-age data, using the VBGF parameters provided by Cyprus under the Official Call. As indicated by the table the two gears show a similar exploitation patter and contribute almost equally to the landings (for the period 2005-2008). Mean age and mean length in the catch are higher ( 2.2 yr and 15.1 cm ) than in the current stock ( 1.3 yr and 13 cm ); figure 8.29.4.1.3.1 also shows that age class 2 is the most exploited age in the population. The estimated value of $\mathrm{F}_{\text {mean }}$ was 0.566 , while $\mathrm{F}_{\text {bar (1-3) }}$ was estimated at the value of 0.84 . The mean biomass at sea was estimated at 71.72 tonnes, which is about double the mean catch for the relevant period.

Fig. 8.29.4.1.3.1 Fishing mortality over age for M. barbatus in GSA 25 from pseudocohort analysis.

### 8.29.5.1.Justification

Y/R analysis was conducted assuming equilibrium conditions, using VIT software.

### 8.29.5.2.Input parameters

For the analysis the results of VIT (pseudocohort) were used as inputs.

### 8.29.5.3.Results

Table 8.29.5.3.1 and Figure 8.29.5.3.1 present the results from Y/R analysis.

Tab. 8.29.5.3.1 Y/R results on $M$. barbatus in GSA 25 from VIT software.

| Factor $\varphi$ | $\mathrm{B} / \mathrm{R}$ | SSE/R | Y/R | Y/R Bottom trawl | Y/R Trammel net |
| ---: | ---: | ---: | ---: | ---: | ---: |
| F current |  |  |  |  |  |
| $(1)$ | 48.388 | 39.237 | 26.74 | 13.102 | 13.637 |
| $\mathrm{~F}_{\mathrm{Q} .1}(0.38)$ | 115.7 | 105.687 | 27.017 | 12.811 | 14.205 |
| $\mathrm{~F}_{\text {mar }}(0.6)$ | 78.922 | 69.255 | 28.4 | 13.596 | 14.803 |
| Virgin <br> Biomass <br> (tons) | 445.1930957 |  |  |  |  |

Accepting that $\mathrm{F}_{\text {current }}$ is equal to $\mathrm{F}_{\text {mean }}(=0.566$, as estimated by the pseudocohort analysis) then the values of $\mathrm{F}_{0.1}$ and $\mathrm{F}_{\text {max }}$ equal with 0.22 and 0.34 respectively. Furthermore, the results suggest that the current stock biomass ( $=71.72$ tons, as estimated by the pseudocohort analysis) is $16 \%$ of the virgin stock biomass.

Fig. 8.29.5.1.1 Y/R analysis results.
A sensitivity analysis was carried out for investigating the sensitivity of $\mathrm{Y} / \mathrm{R}$ results to changes in the input parameters (using the VIT software). Initially an automatic analysis was performed for each parameter with a factor increasing from 0.1 to 0.3 . A sensitivity analysis followed on a combination of the VBGF parameters, as the results seem to be sensitive on these parameters. The results from the sensitivity analysis are provided in Table 8.29.5.1.2.

Tab. 8.29.5.1.2 Results from sensitivity analysis by VIT software on M. barbatus in GSA 25.

### 8.29.6.Scientific advice

### 8.29.6.1.Short term considerations

### 8.29.6.1.1. State of the spawning stock size

In the absence of proposed or agreed precautionary refernce points SGMED 09-02 is unable to fully evaluate the status of the spawning stock size. In the current stock assessment no trend in the spawning stock biomass is evident.

### 8.29.6.1.2. State of recruitment

SGMED-09-02 is unable to provide any scientific advice of the state of the recruitment as no trend in recruitment is evident.

### 8.29.6.1.3. State of exploitation

The estimated reference points of $\mathrm{F}_{0.1}(0.22)$ and $\mathrm{F}_{\text {max }}(0.34)$, in relation with the estimated value of $\mathrm{F}_{\text {bar (1-3) }}$ ( $=0.84$ ), sugggest an overexploitation state of the stock. SGMED 09-02 recommends a reduction in fishing effort of the relevant fleets until sustainable levels of fishing effort are achieved. This shoud be done by means of a multi-annual management plan taking into account mixed fisheries implications.

Given the assessment results, SGMED recommends $F_{0.1}$ of ages $1-3=0.22$ be accepted as an approximation of $\mathrm{F}_{\text {msy }}$ and thus as the target management reference of sustainable exploitation.

### 8.30. Stock assessment of pink shrimp in GSA 01

### 8.30.1.Stock identification and biological features

### 8.30.1.1.Stock Identification

No information was documented during SGMED-09-02.

### 8.30.1.2.Growth

Two sets of parameters were submitted to the meeting, obtained within the frame of the DCR call. These were for males and females combined, and GSA 01, GSA 05 and GSA 06 also combined. Growth parameters were estimated through length frequency analysis: "Slow" for the period 2005-2008 and "Fast" for the period 2002-2004.

Tab. 8.30.1.2.1 v. Bertalanffy growth parameters for the two options considered, fast and slow growth (data source: DCR).

|  | Linf $(\mathrm{cm})$ | K | T0 | Source |
| :--- | ---: | ---: | ---: | :--- |
| Fast | 4.2 | 0.62 | -0.08 | Length freq. analysis |
| Slow | 4.5 | 0.34 | -0.06 | Length freq. analysis |

| 0.8148 | 2.61 | slow growth set |

Fig. 8.30.1.3.1 Maturity ogive for males and females combined in GSA 01. Maturity stage determined macroscopically during the reproduction period (data source: DCR).

### 8.30.2.Fisheries

### 8.30.2.1.General description of fisheries

The bottom trawl fishery in GSA 01 is multispecies, targeting fish, cephalopods and crustaceans. Main target species are Merluccius merluccius, Pagellus acarne, Octopus vulgaris and Parapenaeus longirostris. Crustaceans get the highest values in the market representing $24 \%$ in the total catch, although Nephrops norvegicus and Parapenaeus longirostris contribute $6 \%$ to the total catch in weight. Fishing grounds are characterized by a narrow continental shelf, between 3 and 11 nautical miles wide (SEC(2004)772).

The species is found mainly at depths of between 140 and 400 m , i.e. on the continental shelf and in the upper slope on muddy or sandy muddy bottoms (Sbrana et al. 2006).
8.30.2.2.Management regulations applicable in 2008 and 2009

Unknown, assumed to be the same regulations in force within the Spanish Mediterranean ( 5 fishing days a week; to be practiced at $>50$ depth; 12 hours at sea per day). In the last years a two-month closure has been implemented in the first half of the year.

### 8.30.2.3.Catches

### 8.30.2.3.1. Landings

Tab. 8.30.2.3.1.1 lists the trend in reported landings by fishing technique. The data were reported to SGMED-09-02 through the Data Collection Regulation and are listed in Table A3.3 of Appendix 3. Since 2002 the annual landings decreased from 173 t to only 37 t in 2006 and remained low in 2007. In 2008112 t of landings were reported. The landings were only taken by demersal otter trawls.

Tab. 8.30.2.3.1.1 Annual landings (t) by fishing technique in GSA 01.

| SPECIES | AREA | COUNTRY | FT_LVL4 | 2002 | 2003 | 2004 | 2005 | 2006 | 2007 | 2008 |
| :--- | :--- | :--- | :--- | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| DPS | 1 ESP | OTB | 173 | 123 | 117 | 81 | 37 | 58 | 112 |  |

### 8.30.2.3.2. Discards

Reported discards through the DCF data call to SGMED-09-02 are listed in Table A3.9 of Appendix 3.

### 8.30.2.3.3. Fishing effort

No effort data were reported to SGMED-09-02 through the DCF data call for Spain.
8.30.3.Scientific surveys

### 8.30.3.1.Medits

### 8.30.3.1.1. Methods

Based on the DCR data call, abundance and biomass indices were calculated. In GSA 01 the following number of hauls was reported per depth stratum (s. Tab. 8.30.3.1.1.1).

Tab. 8.30.3.1.1.1. Number of hauls per year and depth stratum in GSA 01, 1994-2008.

| STRATUM | 1994 | 1995 | 1996 | 1997 | 1998 | 1999 | 2000 | 2001 | 2002 | 2003 | 2004 | 2005 | 2006 | 2007 | 2008 |
| :--- | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| GSA01_010-050 | 3 | 1 | 2 | 2 | 2 | 2 | 2 | 3 | 3 | 3 | 3 | 2 | 3 | 3 | 4 |
| GSA01_050-100 | 6 | 4 | 5 | 6 | 5 | 7 | 6 | 5 | 6 | 10 | 7 | 7 | 6 | 6 | 6 |
| GSA01_100-200 | 3 | 3 | 3 | 5 | 5 | 5 | 5 | 5 | 8 | 6 | 5 | 6 | 5 | 6 | 6 |
| GSA01_200-500 | 7 | 9 | 11 | 10 | 8 | 11 | 12 | 10 | 11 | 11 | 13 | 11 | 12 | 11 | 11 |
| GSA01_500-800 | 6 | 10 | 13 | 10 | 13 | 12 | 10 | 13 | 15 | 14 | 13 | 11 | 15 | 10 | 9 |

Data were assigned to strata based upon the shooting position and average depth (between shooting and hauling depth). Few obvious data errors were corrected. Catches by haul were standardized to 60 minutes hauling duration. Hauls noted as valid were used only, including stations with no catches of hake, red mullet or pink shrimp (zero catches are included).

The abundance and biomass indices by GSA were calculated through stratified means (Cochran, 1953; Saville, 1977). This implies weighting of the average values of the individual standardized catches and the variation of each stratum by the respective stratum areas in each GSA:
$\mathrm{Yst}=\Sigma\left(\mathrm{Yi}^{*}{ }^{*} \mathrm{Ai}\right) / \mathrm{A}$
$\mathrm{V}(\mathrm{Yst})=\Sigma\left(\mathrm{Ai}^{2} * \mathrm{si}^{2} / \mathrm{ni}\right) / \mathrm{A}^{2}$
Where:
$\mathrm{A}=$ total survey area
$\mathrm{Ai}=$ area of the i -th stratum
si=standard deviation of the i-th stratum
ni=number of valid hauls of the i-th stratum
n=number of hauls in the GSA
$\mathrm{Yi}=$ mean of the i-th stratum
Yst=stratified mean abundance

The variation of the stratified mean is then expressed as the $95 \%$ confidence interval: Confidence interval $=$ Yst $\pm \mathrm{t}$ (student distribution) $* \mathrm{~V}(\mathrm{Yst}) / \mathrm{n}$

It was noted that while this is a standard approach, the calculation may be biased due to the assumptions over zero catch stations, and hence assumptions over the distribution of data. A normal distribution is often assumed, whereas data may be better described by a delta-distribution, quasi-poisson. Indeed, data may be better modelled using the idea of conditionality and the negative binomial (e.g. O'Brien et al. (2004)).

Length distributions represented an aggregation (sum) of all standardized length frequencies (subsamples raised to standardized haul abundance per hour) over the stations of each stratum. Aggregated length frequencies were then raised to stratum abundance * 100 (because of low numbers in most strata) and finally aggregated (sum) over the strata to the GSA. Given the sheer number of plots generated, these distributions are not presented in this report.

### 8.30.3.1.2. Geographical distribution patterns

No analyses were conducted during SGMED-09-02.

### 8.30.3.1.3. Trends in abundance and biomass

Fishery independent information regarding the state of the pink shrimp in GSA 01 was derived from the international survey Medits. Figure 8.30.3.1.3.1 displays the estimated trend in pink shrimp abundance and biomass in GSA 01.

The estimated abundance and biomass indices peaked in 1998 and decreased significantly until 2003. Since then, the indices varied at a low level. The analyses of Medits indices are considered preliminary.

Fig. 8.30.3.1.3.1 Abundance and biomass indices of pink shrimp in GSA 01.

### 8.30.3.1.4. Trends in abundance by length or age

The following Fig. 8.30.3.1.4.1 and 2 display the stratified abundance indices of GSA 01 in 1995-2002 and 2003-2008. These size compositions are considered preliminary.

Fig. 8.30.3.1.4.1 Stratified abundance indices by size, 1995-2002.

Fig. 8.30.3.1.4.2 Stratified abundance indices by size, 2003-2008.

### 8.30.3.1.5. Trends in growth

No analyses were conducted during SGMED-09-02.

### 8.30.3.1.6. Trends in maturity

No analyses were conducted during SGMED-09-02.

### 8.30.4.Assessment of historic stock parameters

SGMED 09-02 did not undertake any analytical assessment of din GSA 01. Last year's assessment using SURBA and VIT can be found in the report of SGMED-08-04 working group (Cardinale et al., 2008).

No analyses were conducted during SGMED-09-02.

### 8.30.5.1.Justification

Yield per recruit analyses were conducted assuming equilibrium conditions.

### 8.30.5.2.Input parameters

Based on the exploitation pattern resulting from the VPA (VIT) and its population parameters, yield per recruit analyses were formulated.
8.30.5.3.Results

Fig. 8.30.5.3.1 Yield per recruit for fast (left) and slow growing scenarios (right) for the pink shrimp stock in GSA 01 (current effort).

Assuming equilibrium conditions, Fmax ( F corresponding to the highest $\mathrm{Y} / \mathrm{R}$ ) seems to be in the region near the current $\mathrm{F}(\mathrm{F}=1)$ in the fast growth scenario, or below it, in the slow growth scenario. Results suggest the stock would be in a situation near full exploitation in the fast growth scenario, where an increase in F would not result in an increase in $\mathrm{Y} / \mathrm{R}$, or underexploited in the case of slow growth scenario, where increasing F would lead to higher Y/R.

Because of the differences in growth, and under constant M , higher mean biomass and spawning stock biomass are needed in the case of slow growth scenario than in the fast growth, to sustain a given amount of landings. Also, current Fmean would be higher in the fast growth scenario.

SURBA results show decreasing F in the last years, when landings are at their lowest, and abundance and biomass indices from MEDITS are also low.

### 8.30.6.Scientific advice

### 8.30.6.1.Short term considerations

8.30.6.1.1. State of the spawning stock size

In the absence of proposed or agreed references SGMED-09-02 is unable to fully evaluate the state of the stock and provide any scientific advice in relation to them.

### 8.30.6.1.2. State of recruitment

SGMED-09-02 is unable to provide any scientific advice of the state of the recruitment given the preliminary state of the data and analyses.

### 8.30.6.1.3. State of exploitation

In the absence of proposed or agreed references SGMED-09-02 is unable to fully evaluate the state of the stock and provide any scientific advice in relation to them.

### 8.31. Stock assessment of pink shrimp in GSA 06

### 8.31.1.Stock identification and biological features

### 8.31.1.1.Stock Identification

No information was documented during SGMED-09-02.

### 8.31.1.2.Growth

SGMED-09-02 notes that the set of growth parameters used in the assessment were different to those used the year before, and a set more agreed with the "slow growth hypothesis" has been followed. Growth parameters used were those from Garcia-Rodriguez et al. (2009) over length distributions analysis (Linf= 45.0; $\mathrm{K}=0.39$; t0= 0.1019 ), and length-weight relationship ( $a=0.0019 ; b=2.611$ ).

### 8.31.1.3.Maturity

Maturity ogive was taken from García Rodriguez et al. (2009), with size at first maturity ( $50 \%$ ) at 25.65 mm Cl .

Tab. 8.31.1.3.1 Maturity ogive for deep-water pink shrimp in GSA 06.

| Age class | 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 |
| :--- | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| Maturity ratio | 0 | 0.1343973 | 0.5044019 | 0.7877772 | 0.9015605 | 0.9738161 | 1 | 1 |

### 8.31.2.Fisheries

### 8.31.2.1.General description of fisheries

Deep-water pink shrimp (Parapenaeus longirostris) is one of the most important crustacean species for the trawl fisheries developed along the GFCM geographical sub-area Northern Spain (GSA 06). This resource is an important component of commercial landings in some ports of the Mediterranean Northern Spain and occasionally target species of the trawl fleet, composed by around 600 vessels, and especially by 260 vessels which operate on the upper slope.
8.31.2.2.Management regulations applicable in 2008 and 2009

No information was documented during SGMED-09-02.
8.31.2.3.Catches

### 8.31.2.3.1. Landings

During the last years, a sharp increase in landings was observed, starting in 1998 and reaching the maximum value in 2000, followed by a decreasing trend during the period 2001-2008. In 2008 the annual landings of this species amounts 33 tons in the whole area, which represents the lowest value of the historical series.

Fig. 8.31.2.3.1.1 Landings as used by GFCM SAC in 2007.

Tab. 8.31.2.3.1.1 lists the trend in reported landings by fishing technique. The data were reported to SGMED-09-02 through the Data Collection Regulation and are listed in Table A3.3 of Appendix 3. Since 2002 the annual landings decreased from 380 t to only 33 t in 2008. The landings were only taken by demersal otter trawls.

Tab. 8.31.2.3.1.1 Annual landings ( t ) of deep-water pink shrimp by fishing technique in GSA 06 .

| ESP | AREA | COUNTRY | FT_LVL4 | 2000 | 2003 | 2004 | 2005 | 2006 | 2007 | 2008 |
| :--- | ---: | :--- | :--- | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| DPS | 6 | ESP | OTB | 380 | 190 | 117 | 63 | 49 | 41 | 33 |

### 8.31.2.3.2. Discards

No information was documented during SGMED-09-02.

### 8.31.2.3.3. Fishing effort

Fishing effort has reduced from 50,000 days in 2000 to 13,000 in 2006, with a slight increase in 2007 and 2008 to 18,000 . SGMED-09-02 notes that the fishing effort below only includes vessels that have landed pink shrimp in the given years. No official data have been reported to SGMED 09-02.

### 8.31.3.Scientific surveys

### 8.31.3.1.MEDITS

### 8.31.3.1.1. Methods

Based on the DCR data call, abundance and biomass indices were recalculated. In GSA 06 the following number of hauls were reported per depth stratum (s. Tab. 7.31.3.1.1.1).

Tab. 8.31.3.1.1.1. Number of hauls per year and depth stratum in GSA 06, 1994-2008.

| STRATUM | 1994 | 1995 | 1996 | 1997 | 1998 | 1999 | 2000 | 2001 | 2002 | 2003 | 2004 | 2005 | 2006 | 2007 | 2008 |
| :--- | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| GSA06_010-050 | 7 | 8 | 7 | 8 | 7 | 8 | 9 | 8 | 11 | 9 | 9 | 11 | 12 | 6 | 8 |
| GSA06_050-100 | 21 | 28 | 27 | 26 | 28 | 30 | 30 | 31 | 36 | 39 | 31 | 32 | 34 | 40 | 43 |
| GSA06_100-200 | 11 | 19 | 17 | 15 | 13 | 17 | 19 | 20 | 20 | 21 | 17 | 18 | 19 | 24 | 30 |
| GSA06_200-500 | 10 | 13 | 10 | 12 | 7 | 13 | 12 | 16 | 17 | 18 | 16 | 15 | 18 | 18 | 19 |
| GSA06_500-800 | 7 | 8 | 9 | 7 | 4 | 9 | 6 | 8 | 7 | 11 | 11 | 8 | 10 | 15 | 14 |

Data were assigned to strata based upon the shooting position and average depth (between shooting and hauling depth). Few obvious data errors were corrected. Catches by haul were standardized to 60 minutes hauling duration. Hauls noted as valid were used only, including stations with no catches of hake, red mullet or pink shrimp (zero catches are included).

The abundance and biomass indices by GSA were calculated through stratified means (Cochran, 1953; Saville, 1977). This implies weighting of the average values of the individual standardized catches and the variation of each stratum by the respective stratum areas in each GSA:
$\mathrm{Yst}=\Sigma\left(\mathrm{Yi}^{*}{ }^{*} \mathrm{Ai}\right) / \mathrm{A}$
$\mathrm{V}(\mathrm{Yst})=\Sigma\left(\mathrm{Ai}^{2} * \mathrm{si}^{2} / \mathrm{ni}\right) / \mathrm{A}^{2}$
Where:
A=total survey area
$\mathrm{Ai}=$ area of the i -th stratum
si=standard deviation of the i-th stratum
ni=number of valid hauls of the i-th stratum
n=number of hauls in the GSA
$\mathrm{Yi}=$ mean of the i-th stratum
Yst=stratified mean abundance
$\mathrm{V}(\mathrm{Yst})=$ variance of the stratified mean
The variation of the stratified mean is then expressed as the $95 \%$ confidence interval: Confidence interval $=$ Yst $\pm \mathrm{t}$ (student distribution) $* \mathrm{~V}(\mathrm{Yst}) / \mathrm{n}$

It was noted that while this is a standard approach, the calculation may be biased due to the assumptions over zero catch stations, and hence assumptions over the distribution of data. A normal distribution is often assumed, whereas data may be better described by a delta-distribution, quasi-poisson. Indeed, data may be better modelled using the idea of conditionality and the negative binomial (e.g. O'Brien et al. (2004)).

Length distributions represented an aggregation (sum) of all standardized length frequencies (subsamples raised to standardized haul abundance per hour) over the stations of each stratum. Aggregated length frequencies were then raised to stratum abundance * 100 (because of low numbers in most strata) and finally aggregated (sum) over the strata to the GSA. Given the sheer number of plots generated, these distributions are not presented in this report.

### 8.31.3.1.2. Geographical distribution patterns

No analyses were conducted during SGMED-09-02.

### 8.31.3.1.3. Trends in abundance and biomass

Fishery independent information regarding the state of the pink shrimp in GSA 06 was derived from the international survey Medits. Figure 8.31.3.1.3.1 displays the estimated trend in pink shrimp abundance and biomass in GSA 06.

The estimated abundance and biomass indices were high in 2000 and 2001 but varied at a low level since then. The analyses of Medits indices are considered preliminary.

Fig. 8.31.3.1.3.1 Abundance and biomass indices of pink shrimp in GSA 06.

### 8.31.3.1.4. Trends in abundance by length or age

The following Fig. 8.31.3.1.4.1 and 2 display the stratified abundance indices of GSA 06 in 1994-2001 and 2002-2008.

Fig. 8.31.3.1.4.1 Stratified abundance indices by size, 1994-2001.

Fig. 8.31.3.1.4.2 Stratified abundance indices by size, 2002-2008.

### 8.31.3.1.5. Trends in growth

No analyses were conducted during SGMED-09-02.

### 8.31.3.1.6. Trends in maturity

No analyses were conducted during SGMED-09-02.
8.31.4.Assessment of historic stock parameters

### 8.31.4.1.Method 1: XSA

### 8.31.4.1.1. Justification

During the SGMED-09-02, an assessment on pink shrimp from GSA 06 was performed applying XSA. Files dealing with official landings and effort were not available.

### 8.31.4.1.2. Input parameters

The following Table 8.31.4.1.2.1 lists the various input parameters at age.

Tab. 8.31.4.1.2.1 XSA input parameters.

| Pink shrimp GSA 06 |  |  | Catch at age |  |  |  |  |

No forecast analyses were conducted.

### 8.31.5.3.Results

Given the preliminary state of the data and analyses SGMED-09-02 is not in the position to provide a long term prediction of catch and stock biomass for pink shrimp in GSA 06.

### 8.31.6.Scientific advice

### 8.31.6.1.Short term considerations

### 8.31.6.1.1. State of the spawning stock size

Since 2002, SSB, with an average for the whole period of 342 tons, declined rapidly and continuously to the lowest value observed in 2008 ( 111 mt ) which represents only $8 \%$ of that observed in 2002. SGMED notes that the MEDITS survey abundance index shows a very high peak in abundance in the 1999-2001 period, which represents the start of the assessment period. Prior to 1999 , abundance levels were comparable to those seen in the 2002-2008 period. SGMED cannot evaluate the state of the spawning stock relative to reference points, as these have not been proposed or defined. Given the rapid decline by $90 \%$ from 2001 values, SGMED considers the stock status to be far below any sustainable levels.

### 8.31.6.1.2. State of recruitment

Recruits (aged 0 individuals) were estimated to have declined from 2002 to 2005 in the same pattern as SSB and continued to be very low in 2006-2007. However, in 2008, recruitment increased significantly and appears to be at the level of the 2003 value. Such increased recruitment has the potential to contribute to a recovery of the spawning stock in short time.

### 8.31.6.1.3. State of exploitation

Fishing mortality over ages 2-5 displays a high variation with an average value of 0.5 . SGMED 09-02 is unable to fully evaluate the exploitation status as no limit or target reference points have been estimated.

F and effort should be kept at a low level to allow any strong future recruitments to rebuild the stock. SGMED recommends a recovery plan to be established for this stock that takes into account the mixed species nature of the fishery.

### 8.32. Stock assessment of pink shrimp in GSA 09

### 8.32.1.Stock identification and biological features

### 8.32.1.1.Stock Identification

Stock delimitations are considered unknown.
The species shows a wide bathymetric distribution in the GSA 09 , being present from 50 to 650 m depth with greatest abundance between 150 and 400 m depth over muddy or sandy-muddy bottoms (Ardizzone and Corsi, 1997; Biagi et al., 2002).

The highest abundances have been found in the Tyrrhenian part of the GSA (south Tuscany and Latium).
Recruits ( $\mathrm{CL} \leq 15 \mathrm{~mm}$ ) occur all year round with a main peak from July to October (De Ranieri et al., 1997). The main nurseries revealed a high spatio-temporal persistency (Fig. 8.32.1.1.1) between 60 and 220 m depth. The core of nursery areas overlap with crinoid beds (Leptometra phalangium) areas over the shelfbreak (Colloca et al., 2004, 2006; Reale et al., 2005). This is a peculiar habitat in the GSA 09 which is also an essential fish habitat for other commercially important species as the European hake, Merluccius merluccius. A positive size-depth distribution was found with an increased abundance of larger females with depth (Ardizzone et al., 1990).

Fig. 8.32.1.1.1 Temporal persistence of $P$. longirostris nurseries in the GSA 09 .

The growth of $P$. longirostris has been studied in the southern part of the GSA 09 (central Tyrrhenian Sea) using modal progression analysis (Ardizzone et al., 1990). The following sets of Von Bertalanffy growth parameters were estimated: Females: $\mathrm{L} \infty=43.5, \mathrm{~K}=0.74$, $\mathrm{t}_{0}=-0.13$; Males: $\mathrm{L} \infty=33.1, \mathrm{~K}=0.93, \mathrm{t}_{0}=-0.05$. The life cycle is of 3-4 years. Females grow faster than males attaining larger size-at-age.
P. longirostris diet is composed of a great variety of organisms; the prey items consisted mostly of external skeletons of bottom organisms, always crushed and often in an advanced state of deterioration. Crustaceans dominated the diet both qualitatively and quantitatively; they were characterized by a high abundance of peracarids, mainly represented by mysids (Lophogaster typicus) and amphipods (Lysianassidae). Molluscs (juvenile bivalves and gastropods); cephalopods (Sepiolids), small echinoderms, annelids, small fishes, foraminiferans, (Globigerinidae) and organic detritus are other important food item in the diet of the species (Mori et al., 2000b).

### 8.32.1.3.Maturity

In the northern Tyrrhenian Sea, the reproduction area of $P$. longirostris is located from 150 to 350 m ; mature females are present all year round, even though the species shows two peaks in reproductive activity, one in spring and another at the beginning of autumn (Mori et al., 2000a). In the central Tyrrhenian Sea, the southern part of GSA 09, a main winter spawning was hypothesized (Ardizzone et al., 1990). The size at onset of sexual maturity estimated for different years in northern Tyrrhenian Sea is about 24 mm CL (Mori et al., 2000a).

The number of oocytes in the ovary was related to the size of the females and ranged from 23,000 oocytes at 26 mm CL to 204,000 at 43 mm CL. An exponential relationship was observed between fecundity and carapace length: Fecundity $=0.0569$ CL4.0177 $(\mathrm{r}=0.829)($ Mori et al. $(2000 \mathrm{a})$.

### 8.32.2.Fisheries

### 8.32.2.1.General description of fisheries

In the GSA 09 the deep water pink shrimp is one of the most important target species of the fishery carried out on the shelf break and upper part of continental slope. The species is exclusively exploited with otter bottom trawling.

The fishing grounds are located in the southern part of the GSA 09, to the south of Elba Island (northern and central Tyrrhenian Seas); they are mainly exploited by several trawlers of Porto Santo Stefano, Porto Ercole, Fiumicino, Terracina and Gaeta. P. longirostris belongs to a fishing assemblage distributed from 150 to 350 m depth, where the main target species are hake, Merluccius merluccius, horned octopus, Eledone cirrhosa and Norway lobster, Nephrops norvegicus, at greater depths (Biagi et al., 2002; Colloca et al., 2003; Sartor et al., 2003; Sbrana et al., 2006).

The majority of bottom trawlers of GSA 09 operate daily fishing trips with some vessels (especially those of Porto Santo Stefano) staying out for two-three days and mainly in the summer. The mean number of fishing days/year per vessel carried out by the GSA 09 trawlers varied from 187 in 2004 to 177 in 2006. Due to the distance of the fishing grounds to the main harbours, fishing activity targeting $P$. longirostris shows some seasonal variations, with maxima from mid spring to mid autumn.

## P. longirostris LPUE trend-

Fig. 8.32.2.1.1 P. longirostris LPUE of P. S. Stefano and Viareggio trawlers since 1991 (bottom).
The size structure of the landings, according to the DCR data, shows that the most exploited sizes ranged from 24 to 35 mm CL (Fig. 8.32.2.1.2); the presence of specimens under the MLS $(20 \mathrm{~mm} C L)$ is negligible. According to the growth pattern of the species, fishing exploits mainly $1^{+}-3^{+}$age classes.

Fig. 8.32.2.1.2 Length frequency distribution of $P$. longirostris landed in the GSA 09 in 2006 and 2007.
8.32.2.2.Management regulations applicable in 2008 and 2009

The minimum legal landing size is 20 mm Carapace Length (EC regulation 1967/2006). The other management regulations are the same described for hake in the GSA 09.

### 8.32.2.3.Catches

### 8.32.2.3.1. Landings

Total landings of deep water rose shrimps fluctuated from 161 tons in 2002 to 254 tons in 2008, showing a peak in 2006 corresponding to 462 tons (Fig. 8.32.2.3.1.1; Tab. 8.32.2.3.1.1). The landings were mainly taken by demersal otter trawlers. The fluctuating trend is a proper characteristic of the landings of this species, as shown by the LPUE produced by the fleets of Porto Santo Stefano and Viareggio in the period 2001-2005 (Sartor et al., 2005) (Fig. 8.32.2.1.1). The values of the two fleets showed the same temporal pattern with maxima in 1992, 1999 and 2004.

Fig. 8.32.2.3.1.1 Total landings in GSA 09.

Tab. 8.32.2.3.1.1 Annual landings (t) by fishing technique in GSA 09.

### 8.32.2.3.2. Discards

Discards of P. longirostris are scarce; according to Sbrana et al. (2006) they ranged from 0.35 to $1.24 \%$ of the total catch of the species. Discards occurred mainly on the fishing grounds located at depths of less than 200 m , where juvenile specimens are more abundant.

About 9 t of discards were reported to SGMED-09-02 for 2006 (Tab. A3.9 of Appendix 3).

### 8.32.2.3.3. Fishing effort

The trends in fishing effort by fishing technique reported to SGMED-09-02 are listed in Tab. 8.32.2.3.3.1 and in Tab. A3.10-12 of Appendix 3. After 2006, the effort of the major demersal trawler fleet decreased slightly.

Tab. 8.32.2.3.3.1 Trends in annual fishing effort by fishing technique deployed in GSA 09, 2002-2008.

### 8.32.3.1.MEDITS

### 8.32.3.1.1. Methods

From 1994 two trawl surveys are regularly carried out each year: MEDITS, in spring, and GRUND, in autumn. The two surveys gave a similar temporal increasing trend in density and biomass of deep water pink shrimp, even though large fluctuations are present from year to year (Fig. 8.32.3.1.1.1). A similar increasing trend in abundance has been observed also in other Italian geographic subareas and could be related to the warming trend in water temperature. $P$. longirostris is a thermophile species that could benefit by the ongoing climatic change in the Mediterranean region. The relationship between environmental variability and deep-sea pink shrimp population dynamic has not been investigated yet.

Fig. 8.32.3.1.1.1 P. longirostris: GRUND and MEDITS trends in density and biomass from 1994 to 2008 in GSA 09.

Based on the DCR data call, abundance and biomass indices were recalculated. In GSA 09 the following number of hauls was reported per depth stratum (s. Tab. 8.32.3.1.1.1).

Tab. 8.32.3.1.1.1. Number of hauls per year and depth stratum in GSA 09, 1994-2008.

| STRATUM | 1994 | 1995 | 1996 | 1997 | 1998 | 1999 | 2000 | 2001 | 2002 | 2003 | 2004 | 2005 | 2006 | 2007 | 2008 |

| GSA09_200-500 | 32 | 33 | 33 | 36 | 32 | 36 | 37 | 35 | 27 | 27 | 27 | 28 | 29 | 33 | 30 |
| GSA09_500-800 | 31 | 30 | 32 | 28 | 30 | 28 | 27 | 29 | 24 | 22 | 21 | 20 | 20 | 17 | 18 |

Data were assigned to strata based upon the shooting position and average depth (between shooting and hauling depth). Few obvious data errors were corrected. Catches by haul were standardized to 60 minutes hauling duration. Hauls noted as valid were used only, including stations with no catches of hake, red mullet or pink shrimp (zero catches are included).

The abundance and biomass indices by GSA were calculated through stratified means (Cochran, 1953; Saville, 1977). This implies weighting of the average values of the individual standardized catches and the variation of each stratum by the respective stratum areas in each GSA:
$\mathrm{Yst}=\Sigma\left(\mathrm{Yi}^{*}{ }^{*} \mathrm{Ai}\right) / \mathrm{A}$
$\mathrm{V}(\mathrm{Yst})=\Sigma\left(\mathrm{Ai}^{2} * \mathrm{si}^{2} / \mathrm{ni}\right) / \mathrm{A}^{2}$
Where:
$\mathrm{A}=$ total survey area
$\mathrm{Ai}=$ area of the i -th stratum
si=standard deviation of the i-th stratum
ni=number of valid hauls of the i-th stratum
$\mathrm{n}=$ number of hauls in the GSA
$\mathrm{Yi}=$ mean of the i-th stratum
Yst=stratified mean abundance
$\mathrm{V}(\mathrm{Yst})=$ variance of the stratified mean
The variation of the stratified mean is then expressed as the $95 \%$ confidence interval: Confidence interval $=$ Yst $\pm \mathrm{t}$ (student distribution) $* \mathrm{~V}(\mathrm{Yst}) / \mathrm{n}$

It was noted that while this is a standard approach, the calculation may be biased due to the assumptions over zero catch stations, and hence assumptions over the distribution of data. A normal distribution is often assumed, whereas data may be better described by a delta-distribution, quasi-poisson. Indeed, data may be better modelled using the idea of conditionality and the negative binomial (e.g. O'Brien et al. (2004)).

Length distributions represented an aggregation (sum) of all standardized length frequencies (subsamples raised to standardized haul abundance per hour) over the stations of each stratum. Aggregated length frequencies were then raised to stratum abundance * 100 (because of low numbers in most strata) and finally aggregated (sum) over the strata to the GSA. Given the sheer number of plots generated, these distributions are not presented in this report.

### 8.32.3.1.2. Geographical distribution patterns

No analyses were conducted.

### 8.32.3.1.3. Trends in abundance and biomass

Fishery independent information regarding the state of the pink shrimp in GSA 09 was derived from the international survey MEDITS. Figure 8.32.3.1.3.1 displays the estimated trend in pink shrimp abundance and biomass in GSA 09.

The estimated abundance and biomass indices do not reveal a clear trend.

Fig. 8.32.3.1.3.1 Abundance and biomass indices of pink shrimp in GSA 09.

### 8.32.3.1.4. Trends in abundance by length or age

The following Fig. 8.32.3.1.4.1 and 2 display the stratified abundance indices of GSA 09 in 1994-2001 and 2002-2008. These size compositions are considered preliminary.

Fig. 8.32.3.1.4.1 Stratified abundance indices by size, 1994-2001.

Fig. 8.32.3.1.4.2 Stratified abundance indices by size, 2002-2008.

### 8.32.3.1.5. Trends in growth

No analyses were conducted during SGMED-09-02.

### 8.32.3.1.6. Trends in maturity

No analyses were conducted during SGMED-09-02.
8.32.4.Assessment of historic stock parameters

### 8.32.4.1.Method 1: SURBA

### 8.32.4.1.1. Justification

The MEDITS survey provided the longer standardized time-series data on abundance and population structure of $P$. longirostris in the GSA 09.

### 8.32.4.1.2. Input parameters

The survey-based stock assessment model SURBA (Needle, 2003) was used to reconstruct trend in population structure and fishing mortality.

The following set of input data and parameters were used (Tab. 8.32.4.1.2.1 and 2).

Tab. 8.32.4.1.2.1 Input data used in the SURBA model.

Standardized time series of MEDITS length-frequency-distributions were sliced into different age-groups using the same growth parameters for the whole time series (Fig. 8.32.4.1.2.1). The resulting age structures showed a very high internal consistency, thus showing the reliability of the growth parameters used (Fig. 8.32.4.1.2.1).

Fig. 8.32.4.1.2.1 Length frequency distributions of P. longirostris for 2000 to 2005 (left). Relationship between the estimated shrimp abundance at age 1 (time t ) and age 2 (time $\mathrm{t}+1$ ) (right).

A preliminary attempt to use Surba was made excluding $0+(\mathrm{CL}<20 \mathrm{~mm})$ specimens from the dataset due to their low catchability with the MEDITS trawl net. A fixed $M$ mortality value ( $M=1.0$ ) obtained from literature was used.

### 8.32.4.1.3. Results

Average mortality ( $\mathrm{F}_{1-3}$ ) estimated from MEDITS ranged between 0.78 and 1.8 ( 1.16 in 2007). GRUND returned higher $\mathrm{F}_{1-3}$ values with some outliers in 2002-03. Relative indices derived from MEDITS survey for the period 1994-2008 indicated an increasing trend of the spawning stock biomass with three peaks in 1999, 2006 and 2008. In 2008 the SSB was the highest observed since 1994. GRUND data showed a very similar temporal trend in SSB (Fig. 8.32.4.1.3.1). Young of the year ( $0+$ ) are poorly sampled by the MEDITS survey. GRUND survey showed a clear increase of 0+ specimens since 1994 (Fig. 8.32.4.1.3.1).

Fig. 8.32.4.1.3.1 Estimated trend in $\mathrm{F}_{1-3}$, relative SSB and recruitment index at age $1+$ of $P$. longirostris in the GSA 09 , dotted lines are $2.5 \%$ and $97.5 \%$ confidence intervals.

## Model diagnostics

The Surba model for $P$. longirostris fits very well on survey data as showed in Fig. 8.32.4.1.3.2.

Fig. 8.32.4.1.3.2. Model diagnostic for Surba model of in the GSA 9. A) Comparison between observed (points) and fitted (lines) MEDITS survey abundance indices, for each year. B) Log survey abundance indices by cohort. Each line represents the log index abundance of a particular cohort throughout its life.

### 8.32.4.2.Method 2: LCA

### 8.32.4.2.1. Justification

The pseudo-cohort analysis VIT was applied.
8.32.4.2.2. Input parameters

Data coming from DCR provided at SGMED-09-02 contained information on deep water pink shrimp landings and the respective size structure for 2006-2007 (Fig. 8.32.4.3.2.1). VIT software was used to run an LCA analysis for each year separately, using data in Tab. 8.32.4.2.2.1 and biological parameters listed in Tab. 8.32.4.1.2.2. The same M-vector used for SURBA (ProdBiom estimation) was used (age 1: 1; age 2: 0.78 ; age 3: 0.69 ; age 4: 0.65 ; age 5. 0.5).

Fig. 8.32.4.3.2.1. Length frequency distributions of the $P$. longirostris catch in 2006 and 2007 in the GSA 09.

### 8.32.4.2.3. Results

Deep water pink shrimp landings in 2006 and 2008 were concentrated on adults of age classes 2-4. High landings were observed in 2006. Fishing mortality peaked for specimens of age classes 2 and 3 (Fig. 8.32.4.3.3.1). $\mathrm{F}_{1-3}$ (obtained averaging the estimated F values of age classes 2,3 and 4 ) was $0.53,0.61$ and 0.58 in 2006, 2007 and 2008, respectively.

Fig. 8.32.4.3.3.1 Lca outputs: catch numbers, numbers-at-age and fishing mortality at age of $P$. longirostris in the GSA 09.

### 8.32.5.Long term prediction

### 8.32.5.1.Justification

The Yield software (Hoggarth et al., 2006) was used to estimate $F_{01}$ as target equilibrium YPR reference point for the stock assuming a $20 \%$ uncertainty in parameters estimations.

### 8.32.5.2.Input parameters

The following parameters were used to estimate F0.1 through Yield software.
Tab. 8.32.5.2.1 Input to long term forecast.

| $\mathrm{L} \infty=43.5 \mathrm{~mm}$ carapace length |
| :--- |
| $\mathrm{K}=0.6$ |
| $\mathrm{t}_{0}=0$ |
| $\mathrm{a}=0.00686$ |
| $\mathrm{~b}=2.24$ |
| $\mathrm{M}=1.2 \mathrm{CV}=0.1$ |
| $\mathrm{~L}_{50}=24 \mathrm{~mm}, \mathrm{CV}=0.05$ |
| $\mathrm{Lc} 100=20 \mathrm{~mm}, \mathrm{CV}=0.05$ |
| Spawning season: March-August |
| Fishing season: January-December |

### 8.32.5.3.Results

Fig. 8.32.5.3.1 shows the probability distribution of $\mathrm{F}_{0.1}$ ( 1,000 simulations). Uncertainty in model parameters produced considerable variations in $\mathrm{F}_{0.1}$ which ranged between 0.5 and 1.1 (mean $=0.7$ ) with an increased probability for values between 0.7 and 0.8.

Fig. 8.32.5.3.1 Probability distribution of F0.1 obtained using the Yield software.

According to these $\mathrm{F}_{0.1}$ estimates, Fcurr was in most of the year above the average and maximum estimated $\mathrm{F}_{0.1}$ values.
8.32.6. Scientific advice
8.32.6.1.Short term considerations

### 8.32.6.1.1. State of the spawning stock size

SSB showed an increasing trend during the last 13 years.

### 8.32.6.1.2. State of recruitment

Relative indices for age $1+$ indicated a general increasing trend since 1994 with two main recruitment peaks in 1999 and 2005. In 2007 recruitment estimated by GRUND survey (age 0) was $61 \%$ of the short term average (2004-06). In 2008 recruitment at age 1 (MEDITS) was $170 \%$ of the short term average (2005-07).

### 8.32.6.1.3. State of exploitation

According to the F estimates obtained using trawl surveys indices (GRUND and MEDITS) with SURBA, Fcurr was in most of the years (especially in the last five years) above the average and maximum estimated $\mathrm{F}_{0.1}$ values. In this case, the stock would not appear to be able to sustain the current level of fishing effort in the GSA 09. In the period considered (1994-2007) it seemed to be in an overexploited status.

A different picture comes from the F estimates through LCA on the last three years of landing data. $\mathrm{F}_{1-3}$ was between 0.5 and 0.6 for the period 2006-2008, little below the estimated reference value of $\mathrm{F}_{0.1}=0.7$. SGMED's advice relies on the LCA and considers the stock being harvested sustainably. It is important to consider that this stock could be strongly driven by environmental and ecological factors (e.g. water temperature, predatory release effect) that can make difficult to evaluate the effect of fishing on the stock.

### 8.33. Stock assessment of pink shrimp in GSA 10

### 8.33.1.Stock identification and biological features

### 8.33.1.1.Stock Identification

The stock of pink shrimp was assumed in the boundaries of the whole GSA10, lacking specific information on stock identification. The pink shrimp is epibenthic and inhabits the muddy or sandy- muddy bottoms of the continental shelf. A gradient of increasing size with depth has been observed in GSA 10 as in other areas, being the smallest specimens found more frequently in the upper part of the continental shelf ( $100-200 \mathrm{~m}$ ), while the largest ones are mainly distributed along the slope at depths greater than 200 m (Spedicato et al., 1996). Aggregations with higher abundance were localised between 100 and 200 m depth, with some intrusions in the deeper levels. Two most important patches were located in the Gulf of Naples and along the Calabrian coasts in correspondence with Cape Bonifati, while a third one in the Gulf of Salerno (Lembo et al., 1999). These are also the areas where the main nurseries are localised (Lembo et al., 2000).

In the Central-Southern Tyrrhenian Sea the occurrence of mature females was observed in spring (May), summer (July-August) and autumn (October), with a higher relative frequency in spring-summer seasons (Spedicato et al., 1996). Thus, a continuous recruitment pattern is shown which, however, exhibits a main pulse in the autumn season. At 16 mm carapace length the pink shrimp is considered recruited to the grounds (AA.VV., 2002)

The overall sex ratio is about 0.5 . The structure of the sizes of $P$. longirostris is characterised by differences in growth between the sexes, the larger individuals being females. The pink shrimp is a short-living crustacean with a life span of about 4 years (Carbonara et al., 1998).

The deep-water rose shrimp with hake and red mullet is a key species for fisheries in the central-southern Tyrrhenian Sea. In the last decade it is also generally ranked among the species with higher abundance indices (number of individuals) in the trawl surveys (e.g. Spedicato et al. 2003) as observed in other Mediterranean areas (Abellò et al., 2002).

The pink shrimp is caught on the same fishing grounds as European hake and the production of this shrimp is steadily growing in the last decade in the southern basin and it has reached about $10 \%$ of the demersal landings in 2006.

### 8.33.1.2.Growth

No information was documented during SGMED-09-02.
Past estimates of the growth pattern of the pink shrimp females were obtained using different methods based on the LFD analysis (modal progression analysis-MPA, Elefan, Multifan) applied to Grund data from 1990 to 1995. Parameters of VBGF were: $\mathrm{L}_{\infty}=45.9 ; \mathrm{K}=0.673 \mathrm{t}_{0}=-0.251$ (Carbonara et al., 1998). VBGF parameters were also re-estimated during the Samed project (AA.VV., 2002) using the Medits time series from 1994 to 1999, that gave the following values: females: $\mathrm{CL}_{\infty}=45.0 \mathrm{~mm}, \mathrm{~K}=0.7, \mathrm{t}_{0}=-0.15$; males: $\mathrm{CL}_{\infty}=40.0 \mathrm{~mm} ; \mathrm{K}=0.78 ; \mathrm{t}_{0}=-$ 0.2 . Maximum carapace lengths (CL) observed for females and males were respectively 42.3 mm and 39 mm . The growth parameters from DCR are as follows: females $\mathrm{CL}_{\infty}=46 \mathrm{~mm}, \mathrm{~K}=0.575, \mathrm{t}_{0}=-0.2$; males $\mathrm{CL}_{\infty}=40 \mathrm{~mm}, \mathrm{~K}=0.68, \mathrm{t}_{0}=-0.25$. They also describe a fast growing pattern albeit slightly lower than that previously observed. The length weight relationships by sex and for sex combined are as follows: females: $\mathrm{a}=0.8777-1.0103, \mathrm{~b}=2.496-2.422$; males $\mathrm{a}=0.9189-1.0242 ; \mathrm{b}=2.42-2.204$ sex combined $\mathrm{a}=0.88125-0.9756 ; \mathrm{b}=$ 2.483-2.447.

### 8.33.1.3.Maturity

The maturity ogive Fig. 8.33.1.3.1 was obtained from a maximum likelihood procedure applied grouping as "mature" individuals belonging to the maturity stage $2 \mathrm{~b}-2 \mathrm{e}$ (according to the Medits maturity scale). The fitting of the curve was fairly good, although the estimates of the size at first maturity $\mathrm{L}_{\mathrm{m} 50 \%}(1.92 \mathrm{~cm} \pm 0.006$ $\mathrm{cm})$ and of the maturity range $(0.31 \mathrm{~cm} \pm 0.009 \mathrm{~cm})$ seem to be underestimated when compared with literature values (average of the smallest females = 24 mm CL ; in Syndem, 1999).

Fig. 8.33.1.3.1 Maturity ogive of pink shrimp in the GSA10 (MR indicates the difference $\mathrm{Lm}_{75 \%}-\mathrm{Lm}_{25 \%}$ ).
The sex ratio from DCR evidenced the prevalence of males between 1.2 and 2.0 cm , while from 2.4 cm onwards the proportion of females was dominant.

Fig. 8.33.1.3.2 Maturity ogive of pink shrimp in the GSA10 (MR indicates the difference $\mathrm{Lm}_{75 \%}$ - $\mathrm{Lm}_{25 \%}$ ).

### 8.33.2. Fisheries

### 8.33.2.1.General description of fisheries

The pink shrimp is only targeted by trawlers and fishing grounds are located offshore 50 m depth, on the continental shelf and slope of the whole GSA. The pink shrimp occurs mainly with M. merluccius, M. barbatus, Eledone cirrhosa, Illex coindetii and Todaropsis eblanae, N. norvegicus, P. blennoides, depending on depth and area.
8.33.2.2.Management regulations applicable in 2008 and 2009

Management regulations are based on technical measures, like the number of fishing licenses and area limitation (distance from the coast and depth). In order to limit the over-capacity of fishing fleet, the Italian fishing licenses have been fixed since the late 1980s. After 2000, in agreement with the European Common

Policy of Fisheries, a gradual decreasing of the fleet capacity is implemented. Along the northern Sicily coasts two main Gulfs (Patti and Castellammare) have been closed to the trawl fishery up 200 m depth, since 1990. Two closed areas were also established in 2004 along the mainland, in front of Sorrento peninsula (Napoli Gulf) and Amantea (Calabrian coasts), although these protected area mainly cover the distribution of coastal species. Other measures on which the management regulations are based regard technical measures (mesh size) and minimum landing sizes (EC reg. 1967/06). In the GSA 10, the fishing ban has not been mandatory and it has been adopted on a voluntary basis by the fleet.

### 8.33.2.3.Catches

### 8.33.2.3.1. Landings

Available landing data are from DCR regulations. SGMED-09-02 received Italian landings data for GSA 10 by fishing gears which are listed in Tab. 8.33.2.3.2.1. The fishing segments DTS, PGP, PMP and PTS indicate respectively trawlers, small scale fishery (nets) polyvalent and pair trawl. After 2004, landings of the blue and red shrimp decreased in 2008 to the level of 2003 (about 20 t ) (Fig. 8.33.2.3.1.1). Most part of the landings is from trawlers.

Tab. 8.33.2.3.1.1. Annual landings (t) by gear type in GSA 10, 2002-2008.

| 2004 |  |  | 552 |  |  |  | 552 |
| 2005 | 6 | 1.06 | 769 |  |  |  | 776 |
| 2006 |  |  | 1089 |  |  |  | 1089 |
| 2007 |  |  | 534 |  |  |  | 534 |
| 2008 | 0.13 |  | 400 |  |  |  | 4010 |

If the value of 2002 is excluded, that seems anomalous, the catches of the species are rising from 2003 to 2006 when the 1089 tons were recorded and then are decreasing to 400 tons in 2008 that is a value very close to that of 2003 ( 487 tons).

Landings of $P$. Jongirostris

Fig. 8.33.2.3.1.1 Total landings (t) 2003-2008, as reported by DCR in the GSA 10 .

### 8.33.2.3.2. Discards

1 t of discards in 2006 was reported to SGMED-09-02 through the DCR data call and is listed in Tab. A.3.9 of Appendix 3.

### 8.33.2.3.3. Fishing effort

The trends in fishing effort by year and gear type is listed in Tab. 8.33.2.3.3.1 and shown in Fig. 8.33.2.3.2.1 in terms of kW *days. The fishing segments DTS, HOK, PGP, PMP and PTS indicate respectively trawlers, long-lines, small scale fishery (nets), polyvalent, and pair trawls. The fishing effort in $\mathrm{kW}^{*}$ days of the trawlers, that is the fishing segment targeting the giant red shrimp, was rising in 2004 and 2005 and then decreasing in 2006 and 2007.

Tab. 8.33.2.3.3.1 Trends in annual fishing effort by fishing technique deployed in GSA 10, 2002-2007.

### 8.33.3.Scientific surveys

### 8.33.3.1.Medits

### 8.33.3.1.1. Methods

According to the MEDITS protocol (Bertrand et al., 2002), trawl surveys were carried out yearly (May-July), applying a random stratified sampling by depth ( 5 strata with depth limits at: 50, 100, 200, 500 and 800 m ; each haul position randomly selected in small sub-areas and maintained fixed throughout the time). Haul allocation was proportional to the stratum area. The same gear (GOC 73, by P.Y. Dremière, IFREMERSète), with a 20 mm stretched mesh size in the cod-end, was employed throughout the years. Detailed data on the gear characteristics, operational parameters and performance are reported in Dremière and Fiorentini (1996). Considering the small mesh size a complete retention was assumed. All the abundance data (number of fish and weight per surface unit) were standardised to square kilometre, using the swept area method.

Based on the DCR data call, abundance and biomass indices were recalculated.
In GSA 10 the following number of hauls was reported per depth stratum (Tab. 8.33.3.1.1.1).
Tab. 8.33.3.1.1.1. Number of hauls per year and depth stratum in GSA 10, 1994-2008.

| STRATUM | 1994 | 1995 | 1996 | 1997 | 1998 | 1999 | 2000 | 2001 | 2002 | 2003 | 2004 | 2005 | 2006 | 2007 | 2008 |

| GSA10_200-500 | 26 | 27 | 26 | 26 | 27 | 26 | 26 | 28 | 22 | 22 | 22 | 22 | 22 | 22 | 22 |
| GSA10_500-800 | 31 | 30 | 31 | 31 | 31 | 30 | 31 | 29 | 26 | 26 | 26 | 26 | 26 | 26 | 26 |

Data were assigned to strata based upon the shooting position and average depth (between shooting and hauling depth). Few obvious data errors were corrected. Catches by haul were standardized to 60 minutes hauling duration. Hauls noted as valid were used only, including stations with no catches of hake, red mullet or pink shrimp (zero catches are included).

The abundance and biomass indices by GSA were calculated through stratified means (Cochran, 1953; Saville, 1977). This implies weighting of the average values of the individual standardized catches and the variation of each stratum by the respective stratum areas in each GSA:
$\mathrm{Yst}=\Sigma\left(\mathrm{Yi}^{*}{ }^{*} \mathrm{Ai}\right) / \mathrm{A}$
$\mathrm{V}(\mathrm{Yst})=\Sigma\left(\mathrm{Ai}^{2} * \mathrm{si}^{2} / \mathrm{ni}\right) / \mathrm{A}^{2}$
Where:
$\mathrm{A}=$ total survey area
$\mathrm{Ai}=$ area of the i -th stratum
si=standard deviation of the i-th stratum
ni=number of valid hauls of the i-th stratum
n=number of hauls in the GSA
$\mathrm{Yi}=$ mean of the i-th stratum
Yst=stratified mean abundance
$\mathrm{V}(\mathrm{Yst})=$ variance of the stratified mean
The variation of the stratified mean is then expressed as the $95 \%$ confidence interval: Confidence interval $=$ Yst $\pm \mathrm{t}$ (student distribution) $* \mathrm{~V}(\mathrm{Yst}) / \mathrm{n}$

It was noted that while this is a standard approach, the calculation may be biased due to the assumptions over zero catch stations, and hence assumptions over the distribution of data. A normal distribution is often assumed, whereas data may be better described by a delta-distribution, quasi-poisson. Indeed, data may be better modelled using the idea of conditionality and the negative binomial (e.g. O'Brien et al. (2004)).

Length distributions represented an aggregation (sum) of all standardized length frequencies (subsamples raised to standardized haul abundance per hour) over the stations of each stratum. Aggregated length frequencies were then raised to stratum abundance * 100 (because of low numbers in most strata) and finally aggregated (sum) over the strata to the GSA. Given the sheer number of plots generated, these distributions are not presented in this report.

### 8.33.3.1.2. Geographical distribution patterns

No analyses were conducted during SGMED-09-02.

### 8.33.3.1.3. Trends in abundance and biomass

Fishery independent information regarding the state of the pink shrimp in GSA 10 was derived from the international survey Medits. Figure 8.33.3.1.3.1 displays the estimated trend in pink shrimp abundance and biomass in GSA 10.

The estimated abundance and biomass indices peaked in 1999 and 2005-2006. However, the recent abundance and biomass indices in 2007 and 2008 appear low, which appears consistent with the low landings in these years.

Fig. 8.33.3.1.3.1 Abundance and biomass indices of pink shrimp in GSA 10.

### 8.33.3.1.4. Trends in abundance by length or age

The following Fig. 8.33.3.1.4.1 and 2 display the stratified abundance indices of GSA 10 in 1994-2001 and 2002-2008. These size compositions are considered preliminary.

Fig. 8.33.3.1.4.1 Stratified abundance indices by size, 1994-2001.

Fig. 8.33.3.1.4.2 Stratified abundance indices by size, 2002-2008.
8.33.3.2.GRUND

### 8.33.3.2.1. Methods

GRUND survey trends were estimated and are shown in the following sections.

### 8.33.3.2.2. Geographical distribution patterns

No analyses were conducted during SGMED-09-02.

### 8.33.3.2.3. Trends in abundance and biomass

Trends derived from the GRUND surveys are shown in Fig. 8.33.3.2.1.1 Abundance and biomass indices show an increasing trend up to 2005 and a decreasing in 2006, as well as recruitment indices. In 1999 the survey was not performed.

Fig. 8.33.3.2.1.1 Abundance and biomass indices of the pink shrimp in GSA 10 (bars indicate standard deviations). Recruitment indices $\left(\mathrm{N} / \mathrm{km}^{2}\right)$ computed in the total depth range with standard deviation is also reported.

### 8.33.3.2.4. Trends in abundance by length or age

Fig. 8.33.3.2.1.1 Mean length, variance and quantiles derived from the Medits length compositions in 19952008.

Third quartil length $P$. Iongirostris

Fig. 8.33.3.2.1.2 III Quantile derived from the GRUND length structures in 1994-2006.

For most years the LFDs are rather similar throughout the Medits surveys, with a prevalence of individuals between 10 and 20 mm CL. The distribution of 1994 and 2006 are different due to a lower occurrence of juveniles, while the distribution of 2003 is different because of the higher number of recruits (Fig. 8.33.3.2.1.3).

Fig. 8.33.3.2.1.3 Cumulative frequencies of the Medits LFDs (in percentage).

### 8.33.3.2.5. Trends in growth

No analyses were conducted during SGMED-09-02.

### 8.33.3.2.6. Trends in maturity

No analyses were conducted during SGMED-09-02.

### 8.33.4.Assessment of historic stock parameters

SGMED-09-02 did not undertake any analytical assessment.

### 8.33.5.Scientific advice

### 8.33.5.1.Short term considerations

### 8.33.5.1.1. State of the spawning stock size

In the absence of proposed precautionary reference levels SGMED-09-02 is unable to fully evaluate the state of the spawning stock and provide scientific advice. Survey indices of total stock size appear highly variable and most recent indices are at an average level as observed during 1994-2007.

### 8.33.5.1.2. State of recruitment

SGMED-09-02 is unable to provide any scientific advice of the state of the recruitment given the preliminary state of the data and analyses.

### 8.33.5.1.3. State of exploitation

SGMED-09-02 is unable to provide any scientific advice of the state of the exploitation in relation to proposed precautionary and target levels given the preliminary state of the data and analyses.

### 8.34. Stock assessment of pink shrimp in GSA 11

### 8.34.1.Stock identification and biological features

### 8.34.1.1.Stock Identification

No information was documented during SGMED-09-02.

### 8.34.1.2.Growth

No information was documented during SGMED-09-02.

### 8.34.1.3.Maturity

No information was documented during SGMED-09-02.

### 8.34.2.Fisheries

8.34.2.1.General description of fisheries

No information was documented during SGMED-09-02.
8.34.2.2. Management regulations applicable in 2008 and 2009

No information was documented during SGMED-09-02.

### 8.34.2.3.Catches

### 8.34.2.3.1. Landings

Tab. 8.34.2.3.1.1 lists the trend in reported landings by fishing technique. The data were reported to SGMED-09-02 through the Data Collection Regulation and are listed in Table A3.3 of Appendix 3. Since 2002 the annual landings varied, reaching 552 t in 2005 and decreasing to 46 t in 2008. The landings were mainly taken by demersal otter trawls.

Tab. 8.33.2.3.1.1 Annual landings ( t ) by fishing technique in GSA 11. Landings data provided for the years 2002 and 2003, probably have a mistake in the units used.

### 8.34.3.1.Medits

### 8.34.3.1.1. Methods

Based on the DCR data call, abundance and biomass indices were recalculated. In GSA 11 the following number of hauls was reported per depth stratum (s. Tab. 8.34.3.1.1.1).

Tab. 8.34.3.1.1.1. Number of hauls per year and depth stratum in GSA 11, 1994-2008.

| STRATUM | 1994 | 1995 | 1996 | 1997 | 1998 | 1999 | 2000 | 2001 | 2002 | 2003 | 2004 | 2005 | 2006 | 2007 | 2008 |
| :--- | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| GSA11_010-050 | 17 | 19 | 21 | 21 | 21 | 21 | 19 | 18 | 20 | 18 | 17 | 17 | 19 | 19 | 17 |
| GSA11_050-100 | 27 | 21 | 22 | 22 | 20 | 22 | 22 | 24 | 19 | 19 | 18 | 21 | 18 | 20 | 19 |
| GSA11_100-200 | 22 | 23 | 30 | 31 | 31 | 30 | 31 | 30 | 24 | 24 | 24 | 24 | 24 | 24 | 22 |
| GSA11_200-500 | 35 | 29 | 29 | 26 | 25 | 27 | 24 | 25 | 20 | 24 | 21 | 20 | 20 | 20 | 21 |
| GSA11_500-800 | 23 | 16 | 21 | 25 | 25 | 24 | 27 | 26 | 16 | 14 | 15 | 14 | 16 | 17 | 16 |

Data were assigned to strata based upon the shooting position and average depth (between shooting and hauling depth). Few obvious data errors were corrected. Catches by haul were standardized to 60 minutes hauling duration. Hauls noted as valid were used only, including stations with no catches of hake, red mullet or pink shrimp (zero catches are included).

The abundance and biomass indices by GSA were calculated through stratified means (Cochran, 1953; Saville, 1977). This implies weighting of the average values of the individual standardized catches and the variation of each stratum by the respective stratum areas in each GSA:

Yst $=\Sigma\left(\mathrm{Yi}^{*} \mathrm{Ai}\right) / \mathrm{A}$
$\mathrm{V}(\mathrm{Yst})=\Sigma\left(\mathrm{Ai}^{2} * \mathrm{si}^{2} / \mathrm{ni}\right) / \mathrm{A}^{2}$
Where:
$\mathrm{A}=$ total survey area
$\mathrm{Ai}=$ area of the i -th stratum
si=standard deviation of the i-th stratum
ni=number of valid hauls of the $i$-th stratum
$\mathrm{n}=$ number of hauls in the GSA
Yi=mean of the i-th stratum
Yst=stratified mean abundance
$\mathrm{V}(\mathrm{Yst})=$ variance of the stratified mean
The variation of the stratified mean is then expressed as the $95 \%$ confidence interval: Confidence interval $=$ Yst $\pm \mathrm{t}$ (student distribution) * $\mathrm{V}(\mathrm{Yst}) / \mathrm{n}$

It was noted that while this is a standard approach, the calculation may be biased due to the assumptions over zero catch stations, and hence assumptions over the distribution of data. A normal distribution is often assumed, whereas data may be better described by a delta-distribution, quasi-poisson. Indeed, data may be better modelled using the idea of conditionality and the negative binomial (e.g. O'Brien et al. (2004)).

Length distributions represented an aggregation (sum) of all standardized length frequencies (subsamples raised to standardized haul abundance per hour) over the stations of each stratum. Aggregated length frequencies were then raised to stratum abundance * 100 (because of low numbers in most strata) and finally
aggregated (sum) over the strata to the GSA. Given the sheer number of plots generated, these distributions are not presented in this report.

### 8.34.3.1.2. Geographical distribution patterns

No analyses were conducted during SGMED-09-02.

### 8.34.3.1.3. Trends in abundance and biomass

Fishery independent information regarding the state of the pink shrimp in GSA 11 was derived from the international survey Medits. Figure 8.34.3.1.3.1 displays the estimated trend in pink shrimp abundance and biomass in GSA 11.

The estimated abundance and biomass indices peaked in 1998-1999 and 2003. However, the recent abundance and biomass indices since 2005 appear low. The analyses of Medits indices are considered preliminary.

Fig. 8.34.3.1.3.1 Abundance and biomass indices of pink shrimp in GSA 11.

### 8.34.3.1.4. Trends in abundance by length or age

The following Fig. 8.34.3.1.4.1 and 2 display the stratified abundance indices of GSA 11 in 1994-2001 and 2002-2008. These size compositions are considered preliminary.

Fig. 8.34.3.1.4.1 Stratified abundance indices by size, 1994-2001.

Fig. 8.34.3.1.4.2 Stratified abundance indices by size, 2002-2008.

### 8.34.3.1.5. Trends in growth

No analyses were conducted during SGMED-09-02.
8.34.3.1.6. Trends in maturity

No analyses were conducted during SGMED-09-02.
8.34.4.Assessment of historic stock parameters

SGMED-09-02 did not undertake any analytical assessment.

### 8.34.5.Long term prediction

### 8.34.5.1.Justification

No forecast analyses were conducted.

### 8.34.5.2.Input parameters

No forecast analyses were conducted.

### 8.34.5.3.Results

Given the preliminary state of the data and analyses SGMED-09-02 is not in the position to provide a long term prediction of catch and stock biomass for pink shrimp in GSA 11.

### 8.34.6.Scientific advice

### 8.34.6.1.Short term considerations

### 8.34.6.1.1. State of the spawning stock size

In the absence of proposed or agreed reference SGMED-09-02 is unable to fully evaluate the stock and provide any scientific advice of the state of the spawning stock in relation to them.

### 8.34.6.1.2. State of recruitment

SGMED-09-02 is unable to provide any scientific advice of the state of the recruitment given the preliminary state of the data and analyses.

### 8.34.6.1.3. State of exploitation

In the absence of proposed or agreed reference SGMED-09-02 is unable to fully evaluate the stock and provide any scientific advice of the state of the spawning stock in relation to them.

### 8.35. Stock assessment of pink shrimp in GSAs 15 and 16

### 8.35.1.Stock identification and biological features

### 8.35.1.1.Stock Identification

Stock structure of the species in the Strait of Sicily is not well known. Levi et al. (1995) have hypothesed a flux from east to west of eggs, larvae and juveniles of $P$. longirostris due to the intermediate water current. More recently the existence of at least two sub-populations in the northern side of the area (GSA 15 and 16) were advanced by Camilleri et al. (in press). This idea is based on the occurrence of local spawning and nursery areas that are connected by the Atlantic Ionian Stream flow ( $0-150 \mathrm{~m}$ depth), which are considered the current in which the development of larval and juveniles phases occurs. These local sub-populations, one on the Adventure Bank and one on the Malta Bank, are separated by a wide area where the species abundance is scanty.

The maximum observed lengths in GSAs 15 and 16 recorded during trawl surveys over 14 years were 46 and 41 mm CL for females and males respectively (Sinacori G., pers. com.). Although very small specimens were caught in trawl surveys samples from a minimum size of 5 mm CL (Sinacori G., pers. com.), the size class at fully recruitment to the bottom in the GSAs 15 and 16 were 17 and 18 mm for females and males, respectively (SAMED, 2002).

A rough geographical mapping of nurseries in GSA 15 and 16 was reported in Fiorentino et al. (2004). The annual variability in nurseries' position was low. One important nursery was located off Capo Rossetto, in the western-central part of the area, another in the Eastern side of the Malta Bank, close to 200 m depth.

On the basis of trawl surveys carried out in the northern side of the Strait in GSA 16 sex ratio remained stable and close to 0.5 (Fiorentino et al., 2005). Sex ratio in weight from commercial landings (2006-2007) as $\mathrm{F} /(\mathrm{M}+\mathrm{F})$ was 0.66 .

Tursi et al. (1999) reported that $P$. longirostris feed on a wide variety of preys. During the hunting phase it eats small fish, cephalopods and crustaceans while during the digging phase it searches for preys in mud, such as polichets, bivalves, echinoderms and mostly foraminifers.

### 8.35.1.2.Growth

According to Ardizzone et al. (1990), the life cycle of $P$. longirostris lasts two years with the possibility of some larger animals entering a third year, and it is characterized by high rates of growth and mortality.

On the basis of comparison of results produced by different methods to estimate natural mortality (Chen \& Watanabe; Beverton \& Holt Invariants, Alagaraya), values of 1.04 and 1.15 for females and males, respectively, were proposed as reference values for stock assessment purposes in GSA 15 and 16 (SAMED, 2002). These last estimates of natural mortalities are compatible with longevities ranging between 4 and 4.5 years. The growth parameters were reported in Table 8.35.1.2.1.

Tab. 8.35.1.2.1 Von Bertalanffy growth function (cm; y) and length-weight relationship (cm; g) parameters in GSA 16.

| Source | Sex | Linf | K | $\mathrm{t}_{0}$ | a | b |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: |
| Samed, 2002 | Females | 43.0 | 0.68 | -0.2 | 0.0035 | 2.4457 |
|  | Males | 38.0 | 0.75 | -0.2 | 0.0038 | 2.4090 |

8.35.1.3.Maturity

According to Levi et al. (1995) mature females are found in the GSAs 15 and 16 all round the year, although a wide maturity peak extended from November to February and another in April. The lowest percentage of mature females appeared in June-July, but continuous spawning seems to occur. Ben Mariem et al. (2001) reported that $P$. longirostris off the Tunisian coasts (GSA 12) reproduces all year along, with a peak in JuneJuly and a minimum in winter.

The most recent parameters of maturity ogive were: $\mathrm{L} 50 \%$ of 22.1 mm CL and the corresponding slope 0.45 in females, $L 50 \%$ of 14.3 mm CL and the corresponding slope 1.5 in males (CNR_IAMC, 2007).

### 8.35.2.Fisheries

### 8.35.2.1.General description of fisheries

The deep water pink shrimp is main target species of the Sicilian trawlers and is caught both on shelf and upper slope during all year round, but landing peaks are observed from March to July.

The Sicilian trawlers between 12 and 24 m LOA, are based in seven harbours along the southern coasts of Sicily. They operate mainly on a short-distance trawl fishery with trips from 1 to 2 days at sea, fishing on outer shelf and upper slope.

Fig. 8.35.2.1.1 The three main fishing areas for P. longirostris in the Strait of Sicily. Each fishing areas is divided into several fishing grounds (from Levi et al., 1995).

The distant trawlers of Mazara del Vallo represents the main commercial fleet of trawlers of the area and one of the most important of the Mediterranean. Differently from the other Sicilian fleets, the large trawlers of Mazara fleet ( $\mathrm{LOA}>24 \mathrm{~m}$ ) are employed on long fishing trips ( $3-4$ weeks) in offshore waters, both national and international, of the Strait of Sicily. The main fishing grounds of Mazara distant trawlers in the Strait of Sicily are shown in Fig. 8.35.2.1.1. After the recent increase of the fuel costs a critical phase for the deep water pink shrimp fishery started, affecting mainly the distant fleet, which needs about 1 ton of fuel per day during the fishing trip. $\$
P. longirostris is fished exclusively by otter trawl, together with other species (Nephrops norvegicus, Merluccius merluccius, Eledone sp., Illex coindetii, Todaropsis eblanae, Lophius sp., Mullus sp., Pagellus sp., Zeus faber and Raja sp.) (Anon., 2000).
8.35.2.2.Management regulations applicable in 2008 and 2009

At present there are no formal management objectives for deep water pink shrimp fisheries in the Strait of Sicily. As in other areas of the Mediterranean, the stock management is based on control of fishing capacity (licenses), fishing effort (fishing activity), technical measures (mesh size and area closures), and minimum landing sizes of 20 mm CL (EC 1967/06).

In order to limit the over-capacity of fishing fleet, the Italian fishing licenses have been fixed since the late eighties. After 2000, in agreement with the European Common Policy of Fisheries, a gradual decreasing of the fleet capacity is occurring. Furthermore from 1987 to 2005 a $30-45$ days stopping of fishing activities was enforced each year, although in different ways, in order to reduce fishing effort. However this measure is considered less effective in order to protect hake juveniles. In Malta the trawling fleet has been stable since the early 2000 with 16 trawlers having a license to fish. Unfortunately in 2008 due to a reduction in capacity of other fleets 8 new trawl licenses will be issued that will increase the trawl capacity for Malta by $50 \%$.

The new regulation EC 1967 of 21 December 2006 fixed a minimum mesh size of 40 mm for bottom trawling of EU fishing vessels (Italian and Maltese trawlers). The mesh has to be modified in square 40 mm or diamond 50 mm after July 2008, however derogations are possible up to 2010.

A further and more effective improvement in the exploitation pattern of deep water pink shrimp might be obtained through an integrative technical measure having a similar effect to the increasing of mesh size, i.e. the protection of hake nurseries. Differently from red mullet, whose nurseries are in the already protected bottoms within three nautical miles from the coast, the location of deep water pink shrimp nurseries are on discrete off-shore areas on the outer shelf (100-200 m) and in international waters making the possibility of protecting the nursery areas a difficult task especially with respect to enforcement.

It must be outlined the existence in the Strait of Sicily of the Maltese FMZ (GSA 15) which extends up to 25 nautical miles from baselines around the Maltese islands, where fisheries are specifically managed on the basis of capacity control (EC 813/04; EC 1967/06).

The access of Community vessels to the waters and resources in the FMZ is regulated as follows:
(a) fishing within the management zone is limited to fishing vessels smaller than 12 metres overall length using other than towed gears and;
(b) the total fishing effort of those vessels, expressed in terms of the overall fishing capacity, does not exceed the average level observed in 2000-2001 that corresponds to 1950 vessels with an overall engine power and tonnage of 83000 kW and 4035 GT respectively.

Trawlers not exceeding an overall length of 24 metres are authorised to fish in certain areas within the management zone. The overall fishing capacity of the trawlers allowed to operate in the management zone must not exceed the ceiling of 4800 kW and the fishing capacity of any trawler authorised to operate at a depth of less than 200 metres must not exceed 185 kW . Trawlers fishing in the management zone hold a special fishing permit in accordance with Article 7 of Regulation (EC) No 1627/94 and are included in a list containing their external marking and vessel's Community fleet register number (CFR) to be provided to the Commission annually by the Member States concerned.

### 8.35.2.3.Catches

### 8.35.2.3.1. Landings

The estimation of yearly overall yield of Sicilian trawlers with 1-2 day trips in middle eighties ranged between 1290 and 1640 tons (Andreoli et al., 1995). The estimation of yearly overall yield of the Mazara distant fleet in late eighties-early nineties ranged between 2360 and 5180 tons (Levi et al., 1995).

Tab. 8.35.2.3.1.1 Annual landings ( t ) by fishing technique in GSAs 15 and 16. Landings data provided for the years 2002 and 2003, probably have a mistake in the units used.

| SPECIES | AREA | COUNTRY | FT_LVL4 | 2002 | 2003 | 2004 | 2005 | 2006 | 2007 | 2008 |
| :--- | :--- | :--- | :--- | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| DPS | 15 | MLT | OTB |  |  |  | 1 | 15 | 8 | 22 |
| DPS | 16 | ITA | DTS | 7462540 | 7387992 |  |  |  |  |  |
| DPS | 16 | ITA | GTR |  |  |  |  |  | 15 |  |
| DPS | 16 | ITA | OTB |  |  | 6665 | 8584 | 8441 | 5966 | 5941 |
| DPS | 16 | ITA | PGP | 682 | 22714 |  |  |  |  |  |
| DPS | 16 | ITA | PMP | 100569 |  |  |  |  |  |  |
| DPS | 16 | ITA | PTS | 19571 | 54912 |  |  |  |  |  |

Considering that overall yield of trawling was about 9,666 tons in 2006 and 8,052 tons in 2007, deep water pink shrimp landings representing about $74-87 \%$ of total yield in the area. It should be noted that landings of deep water pink shrimp in the Sicilian ports do not derive solely from GSA 16 but from GSA 15 and 16 with some catches also from other GSAs in the Strait of Sicily.

The Maltese shrimp yield ranged from 1 t in 2005 to 22 t in 2008.
Since 2002 onwards the yield of all the Sicilian boats fishing in the Strait of Sicily (inshore and distant fisheries) ranged from 8600 tons in 2006 and 5990 tons in 2007 (from IREPA data).

Fig. 8.35.2.3.1.1 Yield of Italian trawlers based in GSA 16 in the Strait of Sicily.

Detailed information on yield in 2006 and 2007 by trawler size is given in Table 8.35.2.3.1.2. The smaller trawlers (LOA 12-24 m) operating in more inshore water are more numerous (about $67 \%$ in number) and produce between $53 \%$ (2006) and $65 \%$ (2007) of the deep water pink shrimp yield of Sicilian trawlers in the Strait of Sicily.

Tab. 8.35.2.3.1.2 Yield by sex of Italian trawlers in the Strait of Sicily (number of boats: LOA $12-24 \mathrm{~m}=$ 350 in 2006 and 315 in 2007; LOA >24 m = 172 in 2006 and 151 in 2007) (IREPA source).

| 2006 | LOA 12_24 m |  | LOA $>24 \mathrm{~m}$ |  | total |
| :---: | :---: | ---: | :---: | :---: | :---: |
|  | Yield | 4535 | Yield | 3920 | 8455 |
|  | Females | 3018 | Females | 2755 | 5773 |
|  | Males | 1517 | Males | 1165 | 2682 |
| 2007 | Yield | 3880 | Yield | 2108 | 5989 |
|  | Females | 2140 | Females | 1255 | 3395 |
|  | Males | 1741 | Males | 853 | 2594 |

As the length compositions of landing concerns, information is available only for the Sicilian trawlers. Data were considered representative since the 3rd quarter of 2005, when a sampling scheme allowing a realistic raising of the sampled catches to the total ones was adopted (SIBM, 2005). Since there are differences in biological parameters by sex stock assessment based on length structure of landing was done only by females, since they represent about the $66 \%$ of landing and reach the largest size.

Fig. 8.35.2.3.1.2 Absolute catches in number of Italian trawlers in the Strait of Sicily, 2006-2007. Catches of the two operational units (LOA12-24 and LOA>24) are distinguished.

### 8.35.2.3.2. Discards

According to Levi et al. (1995) the length at $50 \%$ capture of 32 mm mesh size trawling estimated by catch curve on commercial landing was 16.1 mm CL (Selection Factor=0.5). More recently experiments of selectivity for the same mesh size gave a $\mathrm{L} 50 \%=13.0 \pm 0.1$ (mm) (Selection Range $=5.2$ and $\mathrm{SF}=0.42$ ) (Ragonese \& Bianchini, 2006). The modal size of the catch and discarded fraction of P. longirostris of Sicilian trawlers is very variable according to the season and the deep range of fisheries. The amount of discards are also variable, being higher in autumn-winter and between 150 and 300 m (Anon., 2000).

Tab. 8.35.2.3.2.1 Yearly modal length (LC in mm ) of discarded fraction and landings of $P$. longirostris in typical inshore (Porto Palo- South eastern Sicily) and distant (Mazara del Vallo - South western Sicily) Sicilian trawling fisheries (from Anon., 2000).

|  | Modal length (mm) |  |
| :--- | :---: | :---: |
|  | discards | landings |
| Inshore fisheries | 12 | 16 and 19 |
| Distant fisheries | 19 | $25-26$ |

Recent studies on the discarded fraction of trawlers in GSA 16 during 2006 gave a length at $50 \%$ discard ranging between 14.6 and 17.0 mm CL (Gancitano V., pers. comm.)

### 8.35.2.3.3. Fishing effort

No information on specific effort of trawling on deep water pink shrimp is available. The trends in overall fishing effort by year and major gear type is listed in Tab. 8.35.2.3.3.1 and shown in Fig. 8.35.2.3.3.1 in terms of kW * days for the otter trawls.

Fig. 8.35.2.3.3.1 Trend in annual effort ( $\mathrm{kW}^{*}$ days) of the Italian otter trawlers operating in the Strait of Sicily, 2002-2007.

Tab. 8.35.2.3.3.1 Trend in annual effort (days at sea, GT*days, $\mathrm{kW}^{*}$ days) by country and gears in GSA 15 and 16, 2002-2008.

### 8.35.3.Scientific surveys

### 8.35.3.1.Medits

### 8.35.3.1.1. Methods

Based on the DCR data call, abundance and biomass indices were recalculated. In GSAs 15 and 16 the following number of hauls was reported per depth stratum (s. Tab. 8.35.3.1.1.1).

Tab. 8.35.3.1.1.1. Number of hauls per year and depth stratum in GSAs 15 and 16, 1994-2008.

Data were assigned to strata based upon the shooting position and average depth (between shooting and hauling depth). Few obvious data errors were corrected. Catches by haul were standardized to 60 minutes hauling duration. Hauls noted as valid were used only, including stations with no catches of hake, red mullet or pink shrimp (zero catches are included).

The abundance and biomass indices by GSA were calculated through stratified means (Cochran, 1953; Saville, 1977). This implies weighting of the average values of the individual standardized catches and the variation of each stratum by the respective stratum areas in each GSA:
$\mathrm{Yst}=\Sigma\left(\mathrm{Yi}^{*}{ }^{*} \mathrm{Ai}\right) / \mathrm{A}$
$\mathrm{V}(\mathrm{Yst})=\Sigma\left(\mathrm{Ai}^{2} * \mathrm{si}^{2} / \mathrm{ni}\right) / \mathrm{A}^{2}$
Where:
A=total survey area
$\mathrm{Ai}=$ area of the i -th stratum
si=standard deviation of the i-th stratum
ni=number of valid hauls of the i-th stratum
n=number of hauls in the GSA
$\mathrm{Yi}=$ mean of the i-th stratum
Yst=stratified mean abundance
$\mathrm{V}(\mathrm{Yst})=$ variance of the stratified mean
The variation of the stratified mean is then expressed as the $95 \%$ confidence interval: Confidence interval $=$ Yst $\pm \mathrm{t}$ (student distribution) $* \mathrm{~V}(\mathrm{Yst}) / \mathrm{n}$

It was noted that while this is a standard approach, the calculation may be biased due to the assumptions over zero catch stations, and hence assumptions over the distribution of data. A normal distribution is often assumed, whereas data may be better described by a delta-distribution, quasi-poisson. Indeed, data may be better modelled using the idea of conditionality and the negative binomial (e.g. O'Brien et al. (2004)).

Length distributions represented an aggregation (sum) of all standardized length frequencies (subsamples raised to standardized haul abundance per hour) over the stations of each stratum. Aggregated length frequencies were then raised to stratum abundance * 100 (because of low numbers in most strata) and finally aggregated (sum) over the strata to the GSA. Given the sheer number of plots generated, these distributions are not presented in this report.

### 8.35.3.1.2. Geographical distribution patterns

No analyses were conducted during SGMED-09-02.

### 8.35.3.1.3. Trends in abundance and biomass

Fishery independent information regarding the state of the hake in GSAs 15 and 16 was derived from the international surveys Medits. Figures 8.35.3.1.3.1 and 2 display the estimated trend in deep water pink shrimps density and biomass in GSAs 15 and 16.

Fig. 8.35.1.3.1 Density indices (DI as N per $\mathrm{km}^{2}$ ) obtained during the MEDITS and GRUND survey in GSAs 15 and 16.

Fig. 8.35.1.3.2 Biomass indices (BI as kg per $\mathrm{km}^{2}$ ) obtained during the MEDITS and GRUND survey in GSAs 15 and 16.

In the last years the biomass indices for both GSAs 15 and 16 show a similar pattern with an increasing trend since 2002 till 2005-2006 and decrease in 2006-2007.

Density indices (DI) of recruits (individuals less than 18 mm CL ) derived from MEDITS trawl surveys were used to estimate recruitment strength in GSAs 15 and 16 assuming that recruitment occurs within 50 and 200 $m$ depth ( $16500 \mathrm{~km}^{2}$ ). The mean value ( $\pm$ sd) of DI and absolute number of recruits from 1994 to 2004 was $1601 \pm 969$ individuals per $\mathrm{km}^{2}$ and $26.376 \pm 15.959$ millions of individuals (Fiorentino et al., in press).

Fig 8.35.1.3.3 Percentage variation of annual values from mean recruitment of $P$. longirostris in the GSAs 15 and 16 .

The trend in abundance and biomass as re-estimated by SGMED-09-02 are shown in Figures 8.35.3.1.3.4 and 8.35.3.1.3.5 for GSAs 15 and 16. Such analyses of Medits indices are considered preliminary.

Fig. 8.35.3.1.3.4 Abundance and biomass indices of deep water pink shrimp in GSA 15.

Fig. 8.35.3.1.3.5 Abundance and biomass indices of deep water pink shrimp in GSA 16.

### 8.35.3.1.4. Trends in abundance by length or age

The following Fig. 8.35.3.1.4.1 displays the stratified abundance indices of GSA 15 in 2002-2008. These size compositions are considered preliminary.

The Figures 8.35.3.1.4.2 and 8.35.3.1.4.3 display the stratified abundance indices of GSA 16 in 1994-2001 and 2002-2008. These size compositions are considered preliminary.

Fig. 8.35.3.1.4.2 Stratified abundance indices by size, 2002-2008.

### 8.35.3.1.5. Trends in growth

No analyses were conducted during SGMED-09-02.
8.35.3.1.6. Trends in maturity

No analyses were conducted during SGMED-09-02.
8.35.4.Assessment of historic stock parameters

SGMED 09-02 did not undertake any analytical assessment of deep water pink shrimp in GSAs 15 and 16. Last year's assessments using Trends in LPUE and VIT can be found in the report of SGMED-08-04 working group (Cardinale et al., 2008).

### 8.35.5.Long term prediction

### 8.35.5.1.1. Justification

No forecast analyses were conducted.

### 8.35.5.1.2. Input parameters

No forecast analyses were conducted.

### 8.35.5.1.3. Results

Given the state of the data and analyses SGMED-09-02 is not in the position to provide a long term prediction of catch and stock biomass for pink shrimp in GSAs 15 and 16.

### 8.35.6.Scientific advice

### 8.35.6.1.Short term considerations

### 8.35.6.1.1. State of the spawning stock size

In the absence of proposed or agreed references SGMED-09-02 is unable to fully evaluate the state of the stock. The last updated information regarding the state of spawning stock for pink shrimp in GSAs 15 and 16 can be found in the last year's report of SGMED-08-04 working group (Cardinale et al., 2008).

### 8.35.6.1.2. State of recruitment

No information available to SGMED-09-02.

### 8.35.6.1.3. State of exploitation

The last updated information regarding the state of exploitation for pink shrimp in GSAs 15 and 16 can be found in the last year's report of SGMED-08-04 working group (Cardinale et al., 2008).

### 8.36. Stock assessment of pink shrimp in GSA 18

### 8.36.1.Stock identification and biological features

### 8.36.1.1.Stock Identification

The stock of pink shrimp was assumed in the boundaries of the whole GSA18, lacking specific information on stock identification and given the preliminary indications agreed upon by SGMED 01.09. The deep-water rose shrimp inhabits only muddy sediments, at depths over 130 m (Karlovac, 1949) and in the southern Adriatic it is distributed mostly between 30 and 600 m depth although it is more abundant between 200 and 400 m depth (Pastorelli et al., 1996). Within the southern Adriatic, the eastern part is characterised by the higher occurrence and abundance of the species, given the charateristics of the water masses (warmer and saltier) and the lower fishing pressure (Abellò et al., 2002; Mannini et al., 2004) and particularly of the juvenile component of the population (Ungaro et al., 2006). Spawning time is considered extended almost all the year round, as for other Mediterranean areas (Relini, 1999) and sex ratio as estimated from trawl-survey data is approximately 0.45 . The abundance of this shrimp is steadily growing in the last decade (Ungaro et al., 2006) that is one of the target species of the central and southern Adriatic multispecies trawl catches. In some fisheries the pink shrimp can represent a percentage between 5 and $10 \%$ of the total catches (Medits 2007).

### 8.36.1.2.Growth

P. longirostris can grow up to 16 cm (males) and 19 cm (females) in total length. However, males are usually 8 to 14 cm long and females from 12 to 16 cm long. Larger specimens are caught mainly in deeper waters. During the expedition "Hvar", the largest specimen caught was a 17 cm long female (Karlovac, 1949). The growth rate differs between the sexes. Size distribution and growth parameters indicate a life cycle of 3-4 years (Froglia, 1982).

Estimates of growth parameters were achieved made in thewith data collected within the DCR framework using the analysis of length frequency distributions. The following von Bertalanffy parameters were estimated by sex: females $\mathrm{CL}_{\infty}=44.0 \mathrm{~mm} ; \mathrm{K}=0.628$; $\mathrm{t} 0=-0.20$; males: $\mathrm{CL}_{\infty}=39 \mathrm{~mm} ; \mathrm{K}=0.69 ; \mathrm{t} 0=-0.20$.
Parameters of the length-weight relationship reported in literature for carapace length expressed in mm and sex combined (Marano et al., 1998) are $a=0.0034, \mathrm{~b}=2.4364$. The parameters estimated within the DCRhere for sex combined and carapace length expressed in cm were: $\mathrm{a}=1.0692, \mathrm{~b}=2.23$.

### 8.36.1.3.Maturity

In the Mediterranean Sea, both sexes of $P$. longirostris reach maturity in the first year of life (Froglia, 1982). After being spawned, the planctonic larval phases (nauplius, zoea and mysis) develop; the postlarva, similar to adults, reaches the sandy-muddy bottoms on the continental shelf and begins the bentho-pelagic cycle (Heldt, 1938). According to the data obtained in the DCR, the proportion of mature females (specimens belonging to the maturity stage 2 onwards) by length class is reported in the table below together with the maturity ogive estimated by a maximum likelihood procedure which indicates a $\mathrm{L}_{\mathrm{m} 50 \%}$ of about 1.83 cm $( \pm 0.01 \mathrm{~cm})$ and a maturity range (MR) equal to $0.24 \mathrm{~cm},\left(\mathrm{~L}_{\mathrm{m} 75 \%}-\mathrm{L}_{\mathrm{m} 25 \%} \pm 0.013 \mathrm{~cm}\right)$.

Fig. 8.36.1.3.1 Maturity ogive and proportions of mature female of pink shrimp in the GSA 18 (MR indicates the difference $\mathrm{L}_{\mathrm{m} 75 \%}-\mathrm{L}_{\mathrm{m} 25 \%}$ ).

The sex ratio evidenced the prevalence of males in the size class from 1.6 to 1.8 cm and from 2.3 to 2.5 cm , while from 2.7 cm onwards the proportion of females was dominant.

Fig. 8.36.1.3.2 Sex ratio at length of pink shrimp in the GSA 18.

### 8.36.2.Fisheries

### 8.36.2.1.General description of fisheries

Pink shrimp is only targeted by trawlers and fishing grounds are located along the coasts of the whole GSA. Catches from trawlers are from a depth range between 50-60 and 500 m and pink shrimp may co-occurs with other important commercial species as M. merluccius, Illex coindetii, Eledone cirrhosa, Lophius spp., Lepidorhombus boscii, N. norvegicus.
8.36.2.2.Management regulations applicable in 2008 and 2009

Management regulations are based on technical measures, like the number of fishing licenses and area limitation (distance from the coast and depth). In order to limit the over-capacity of the fleet, the Italian fishing licenses have been fixed since the late 1980s. After 2000, in agreement with the European Common Policy of Fisheries, a gradual decreasing of the fleet capacity is implemented. Two closed areas were also established in 2004 along the mainland, in front of Bari and in the vicinity of Tremiti MPA on the northernmost part of the GSA. Other management regulations are mesh size, minimum landing sizes and the minimum distance (or depth) from the coastline (EC reg. 1967/06). In the GSA 18 the fishing ban has been almost always mandatory since 1988 for a period of 30-45 days, generally during late July-early September.

### 8.36.2.3.Catches

### 8.36.2.3.1. Landings

Available landing data are from DCR regulations. SGMED-09-02 received Italian landings data for GSA 18 by major fishing gears which are listed in Tab. 8.36.2.3.1.1. The fishing segments DTS and OTB identify the trawlers, while PGP and PMP indicate respectively small scale fishery (nets) and polyvalents, however trawlers account for the major landing quantity. Since 2002 to 2004 landings of pink shrimp were rising from $1,147 \mathrm{t}$ to $1,857 \mathrm{t}$ whereas in 2007 and 2008, a strong reduction is observed (Fig. 8.36.2.3.1.1).

Tab. 8.36.2.3.1.1. Annual landings (t) by major gear type, 2002-2008.

| Surn of landinge (tons) | FT LVL4 |  |  |  |  |
| :--- | :--- | :--- | :--- | :--- | :--- |
| YEAR | DTS | OTB | PGP | PMP | T otal |

| 2008 |  | 766 |  |  | 766 |

Fig. 8.36.2.3.1.1 Landings (t) by year (2002-2008) as reported through DCR in the GSA 18.

### 8.36.2.3.2. Discards

No information was documented during SGMED 09-02.

### 8.36.2.3.3. Fishing effort

The trends in fishing effort by year and major gear type is listed in Tab. 8.36.2.3.3.1 and shown in Fig. 8.36.2.3.3.1 in terms of $\mathrm{kW}^{*}$ days. The fishing segment DTS and OTB, that identify trawlers, were considered for the fishing effort trend because the pink shrimp is exploited only by this fleet segment. The fishing effort in $\mathrm{kW}^{*}$ days was declining from 2002 to 2004 , whilst since 2004 to 2006 it is rising but a reduction to the levels of 2004 is observed in 2007.

Tab. 8.36.2.3.3.1 Trend in fishing effort ( $\mathrm{kW}^{*}$ days) of trawlers (DTS-OTB) in the GSA 18, 2002-2007.

|  | FT LVL4 | Kw* days |  |  |

### 8.36.3.Scientific surveys

### 8.36.3.1.Medits

### 8.36.3.1.1. Methods

Trawl surveys were carried out applying a random stratified sampling by depth ( 5 strata with depth limits at: $50,100,200,500$ and 800 m ; each haul position randomly selected in small sub-areas and maintained fixed throughout the time). Haul allocation was proportional to the stratum area (Bertrand et al., 2002). The same gear (GOC 73, by P.Y. Dremière, IFREMER-Sète), with a 20 mm stretched mesh size in the cod-end, was employed throughout the years. Detailed data on the gear characteristics, operational parameters and performance are reported in Dremière and Fiorentini (1996). Considering the small mesh size a complete retention was assumed.

Based on the DCR data call, abundance and biomass indices were calculated. In GSA 18 the following number of hauls was reported per depth stratum (Tab. 8.36.3.1.1.1).

Tab. 8.36.3.1.1.1. Number of hauls per year and depth stratum in GSA 18, 1994-2008.

Data were assigned to strata based upon the shooting position and average depth (between shooting and hauling depth). Few obvious data errors were corrected. Catches by haul were standardized to 60 minutes hauling duration. Hauls noted as valid were used only, including stations with no catches of hake, red mullet or pink shrimp (zero catches are included).

The abundance and biomass indices by GSA were calculated through stratified means (Cochran, 1953; Saville, 1977). This implies weighting of the average values of the individual standardized catches and the variation of each stratum by the respective stratum areas in each GSA:

Yst $=\Sigma\left(\mathrm{Yi}^{*} \mathrm{Ai}\right) / \mathrm{A}$
$\mathrm{V}(\mathrm{Yst})=\Sigma\left(\mathrm{Ai}^{2} * \mathrm{si}^{2} / \mathrm{ni}\right) / \mathrm{A}^{2}$
Where:
A=total survey area
$\mathrm{Ai}=$ area of the i -th stratum
si=standard deviation of the i-th stratum
ni=number of valid hauls of the i-th stratum
n=number of hauls in the GSA
Yi=mean of the i-th stratum
Yst=stratified mean abundance
$\mathrm{V}(\mathrm{Yst})=$ variance of the stratified mean
The variation of the stratified mean is then expressed as the $95 \%$ confidence interval: Confidence interval $=$ Yst $\pm \mathrm{t}$ (student distribution) $* \mathrm{~V}(\mathrm{Yst}) / \mathrm{n}$

It was noted that while this is a standard approach, the calculation may be biased due to the assumptions over zero catch stations, and hence assumptions over the distribution of data. A normal distribution is often assumed, whereas data may be better described by a delta-distribution, quasi-poisson. Indeed, data may be better modelled using the idea of conditionality and the negative binomial (e.g. O'Brien et al. (2004)).

Length distributions represented an aggregation (sum) of all standardized length frequencies (subsamples raised to standardized haul abundance per hour) over the stations of each stratum. Aggregated length frequencies were then raised to stratum abundance * 100 (because of low numbers in most strata) and finally aggregated (sum) over the strata to the GSA. Given the sheer number of plots generated, these distributions are not presented in this report.

### 8.36.3.1.2. Geographical distribution patterns

The geographical distribution pattern of pink shrimp in the GSA 18 has been studied using trawl-survey data and geostatistical methods. In these studies the abundance indices of recruits were analysed. Results highlighted that areas localised in the Gulf of Manfredonia and between Monopoli and Brindisi coasts within 200 m depth are mainly characterised by higher concentration of pink shrimp recruits reaching 2000 individuals $/ \mathrm{km}^{2}$ in 2000-2001. A peak of 5000 individuals $/ \mathrm{km}^{2}$ was observed in the southernmost location (border between GSA 18 and 19) off Capo S. Maria di Leuca.

Maps of the pink shrimp nursery obtained applying the indicator kriging techniques are reported below.

Fig. 8.36.3.1.2.1 Geographical distribution patters as derived from MEDITS.

### 8.36.3.1.3. Trends in abundance and biomass

Fishery independent information regarding the state of the pink shrimp in GSA 18 was derived from the international survey Medits. Figure 8.39.3.1.3.1 displays the estimated trend of pink shrimp abundance and biomass in GSA 18. Considering only the period from 2001 to 2008, indices show an increasing pattern up to 2005 and a sharp decline afterwards.

Fig. 8.36.3.1.3.1 Abundance and biomass indices of pink shrimp in GSA 18.
The Medits 2007 report highlighted some changes in the abundance of demersal resources from 1996 to 2006. They mostly refer to the general increase of the species characterised by short life span such as cephalopods and crustaceans (i.e. Parapenaeus longirostris) and the decrease of some gadiforms fish such as Micromesistius poutassou and Trisopterus minutus. The report stated that changes could be influenced by both the fishery pressure on large- sized and long-lived species (Jukic-Peladic et al. 2001) and the effects of the environmental conditions (i.e. increase of bottom temperature).

### 8.36.3.1.4. Trends in abundance by length or age

The following Fig. 8.36.3.1.4.1 and 2 display the stratified abundance indices of GSA 18 in 1996-2003 and 2004-2008.

Fig. 8.36.3.1.4.1 Stratified abundance indices by size, 1996-2003.

Fig. 8.36.3.1.4.2 Stratified abundance indices by size, 2004-2008.

### 8.36.3.1.5. Trends in growth

No analyses were conducted during SGMED-09-02.

### 8.36.3.1.6. Trends in maturity

No analyses were conducted during SGMED-09-02.

### 8.36.4.Assessment of historic stock parameters

SGMED 09-02 did not undertake any analytical assessment.

### 8.36.5.1.Justification

No forecast analyses were conducted.
8.36.6. Scientific advice

### 8.36.6.1.Short term considerations

### 8.36.6.1.1. State of the spawning stock size

SGMED-09-02 is unable to provide any scientific advice of the state of the spawning stock in relation to proposed precautionary level given the preliminary state of the data and analyses. Survey results indicate the recent stock size being low.

### 8.36.6.1.2. State of recruitment

SGMED-09-02 is unable to provide any scientific advice of the state of recruitment in relation to proposed precautionary level given the preliminary state of the data and analyses.

### 8.36.6.1.3. State of exploitation

In the absence of proposed or agreed references, SGMED 09-02 is unable to fully evaluate the state of the stock and provide scientific advice.

### 8.37. Stock assessment of pink shrimp in GSA 19

### 8.37.1.Stock identification and biological features

### 8.37.1.1.Stock Identification

No information was documented during SGMED-09-02.

### 8.37.1.2.Growth

No information was documented during SGMED-09-02.

### 8.37.1.3.Maturity

No information was documented during SGMED-09-02.

### 8.37.2.Fisheries

### 8.37.2.1.General description of fisheries

No information was documented during SGMED-09-02.
8.37.2.2. Management regulations applicable in 2008 and 2009

No information was documented during SGMED-09-02.

### 8.37.2.3.Catches

### 8.37.2.3.1. Landings

Tab. 8.37.2.3.1.1 lists the trend in reported landings by fishing technique. The data were reported to SGMED-09-02 through the Data Collection Regulation and are listed in Table A3.3 of Appendix 3. The landings in 2007 represent the record low. The landings were mainly taken by demersal otter trawls.

Tab. 8.37.2.3.1.1 Annual landings ( t ) by fishing technique in GSA 19. Landings data provided for the years 2002 and 2003, probably have a mistake in the units used.

### 8.37.3.1.Medits

### 8.37.3.1.1. Methods

Based on the DCR data call, abundance and biomass indices were recalculated. In GSA 19 the following number of hauls was reported per depth stratum (s. Tab. 8.37.3.1.1.1).

Tab. 8.37.3.1.1.1. Number of hauls per year and depth stratum in GSA 19, 1994-2008.

| STRATUM | 1994 | 1995 | 1996 | 1997 | 1998 | 1999 | 2000 | 2001 | 2002 | 2003 | 2004 | 2005 | 2006 | 2007 | 2008 |
| :--- | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| GSA19_010-050 | 9 | 9 | 9 | 9 | 9 | 9 | 9 | 9 | 9 | 9 | 9 | 9 | 9 | 8 | 9 |
| GSA19_050-100 | 7 | 8 | 8 | 8 | 8 | 8 | 8 | 8 | 8 | 8 | 8 | 8 | 8 | 9 | 8 |
| GSA19_100-200 | 10 | 10 | 10 | 10 | 10 | 10 | 10 | 10 | 10 | 10 | 10 | 10 | 10 | 10 | 11 |
| GSA19_200-500 | 16 | 15 | 15 | 15 | 15 | 15 | 15 | 15 | 21 | 21 | 14 | 15 | 14 | 14 | 14 |
| GSA19_500-800 | 31 | 32 | 32 | 32 | 32 | 32 | 32 | 32 | 29 | 29 | 29 | 28 | 29 | 29 | 29 |

Data were assigned to strata based upon the shooting position and average depth (between shooting and hauling depth). Few obvious data errors were corrected. Catches by haul were standardized to 60 minutes hauling duration. Hauls noted as valid were used only, including stations with no catches of hake, red mullet or pink shrimp (zero catches are included).

The abundance and biomass indices by GSA were calculated through stratified means (Cochran, 1953; Saville, 1977). This implies weighting of the average values of the individual standardized catches and the variation of each stratum by the respective stratum areas in each GSA:
$\mathrm{Yst}=\Sigma\left(\mathrm{Yi}^{*} \mathrm{Ai}\right) / \mathrm{A}$
$\mathrm{V}(\mathrm{Yst})=\Sigma\left(\mathrm{Ai}^{2} * \mathrm{si}^{2} / \mathrm{ni}\right) / \mathrm{A}^{2}$
Where:
$\mathrm{A}=$ total survey area
$\mathrm{Ai}=$ area of the i -th stratum
si=standard deviation of the i-th stratum
ni=number of valid hauls of the i-th stratum
$\mathrm{n}=$ number of hauls in the GSA
$\mathrm{Yi}=$ mean of the i-th stratum
Yst=stratified mean abundance
$\mathrm{V}(\mathrm{Yst})=$ variance of the stratified mean
The variation of the stratified mean is then expressed as the $95 \%$ confidence interval: Confidence interval $=$ Yst $\pm \mathrm{t}$ (student distribution) $* \mathrm{~V}(\mathrm{Yst}) / \mathrm{n}$

It was noted that while this is a standard approach, the calculation may be biased due to the assumptions over zero catch stations, and hence assumptions over the distribution of data. A normal distribution is often assumed, whereas data may be better described by a delta-distribution, quasi-poisson. Indeed, data may be better modelled using the idea of conditionality and the negative binomial (e.g. O'Brien et al. (2004)).

Length distributions represented an aggregation (sum) of all standardized length frequencies (subsamples raised to standardized haul abundance per hour) over the stations of each stratum. Aggregated length frequencies were then raised to stratum abundance * 100 (because of low numbers in most strata) and finally aggregated (sum) over the strata to the GSA. Given the sheer number of plots generated, these distributions are not presented in this report.

### 8.37.3.1.2. Geographical distribution patterns

No analyses were conducted during SGMED-09-02.

### 8.37.3.1.3. Trends in abundance and biomass

Fishery independent information regarding the state of the pink shrimp in GSA 19 was derived from the international survey Medits. Figure 8.37.3.1.3.1 displays the estimated trend in pink shrimp abundance and biomass in GSA 19.

The estimated abundance and biomass varied without a clear trend. The recent abundance and biomass indices in 2007 appear very low, which appears consistent with the low landings in 2007. The analyses of Medits indices are considered preliminary.

Fig. 8.37.3.1.3.1 Abundance and biomass indices of pink shrimp in GSA 19.

### 8.37.3.1.4. Trends in abundance by length or age

The following Fig. 8.37.3.1.4.1 and 2 display the stratified abundance indices of GSA 19 in 1994-2008. These size compositions are considered preliminary.

Fig. 8.37.3.1.4.1 Stratified abundance indices by size, 1994-2001.

Fig. 8.37.3.1.4.2 Stratified abundance indices by size, 2002-2008.

### 8.37.3.1.5. Trends in growth

No analyses were conducted during SGMED-09-02.

No analyses were conducted during SGMED-09-02.

### 8.37.4.Assessment of historic stock parameters

SGMED-09-02 did not undertake any analytical assessment.

### 8.37.5.Long term prediction

### 8.37.5.1.Justification

No forecast analyses were conducted.

### 8.37.5.2.Input parameters

No forecast analyses were conducted.

### 8.37.5.3.Results

Given the preliminary state of the data and analyses SGMED-09-02 is not in the position to provide a long term prediction of catch and stock biomass for pink shrimp in GSA 19.

### 8.37.6.Scientific advice

### 8.37.6.1.Short term considerations

### 8.37.6.1.1. State of the spawning stock size

In the absence of proposed or agreed references, SGMED-09-02 is unable to fully evaluate the state of the stock and provide scientific advice.

### 8.37.6.1.2. State of recruitment

SGMED-09-02 is unable to provide any scientific advice of the state of the recruitment given the preliminary state of the data and analyses.

### 8.37.6.1.3. State of exploitation

SGMED-09-02 is unable to provide any scientific advice of the state of the exploitation in relation to proposed precautionary and target levels given the preliminary state of the data and analyses.

### 8.38. Stock assessment of pink shrimp in GSAs 22 and 23 combined

### 8.38.1.Stock identification and biological features

### 8.38.1.1.Stock Identification

No information was documented during SGMED-09-02.

### 8.38.1.2.Growth

### 8.38.2.3.Catches

### 8.38.2.3.1. Landings

Tab. 8.38.2.3.1.1 lists the trend in reported landings by fishing technique. The data were reported to SGMED-09-02 through the Data Collection Regulation and are listed in Table A3.3 of Appendix 3. Since 2003 the annual landings increased significantly from $1,074 \mathrm{t}$ in 2003 and 3,899 tin 2008. The landings were mainly taken by demersal otter trawls.

Tab. 8.38.2.3.1.1 Annual landings ( t ) by fishing technique in GSAs 22 and 23.

### 8.38.2.3.2. Discards

No discards data were reported to SGMED-09-02 through the DCF data call for Greece.

### 8.38.2.3.3. Fishing effort

The trends in fishing effort by fishing technique reported to SGMED-09-02 are listed in Tab. 8.38.2.3.3.1 and in Tab. A3.10-3.12 of Appendix 3.

Tab. 8.38.2.3.3.1 Trends in annual fishing effort by fishing technique deployed in GSAs 22 and 23, 20032008.

### 8.38.3.Scientific surveys

### 8.38.3.1.Medits

### 8.38.3.1.1. Methods

Based on the DCR data call, abundance and biomass indices were calculated. In GSAs 22 and 23 the following number of hauls was reported per depth stratum (s. Tab. 8.38.3.1.1.1).

Tab. 8.38.3.1.1.1. Number of hauls per year and depth stratum in GSAs 22 and 23, 1994-2008.

| STRATUM | 1994 | 1995 | 1996 | 1997 | 1998 | 1999 | 2000 | 2001 | 2002 | 2003 | 2004 | 2005 | 2006 | 2007 | 2008 |
| :--- | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| GSA22+23_010-050 | 10 | 10 | 11 | 10 | 13 | 12 | 13 | 13 |  | 13 | 13 | 14 | 14 |  | 13 |
| GSA22+23_050-100 | 19 | 21 | 22 | 28 | 24 | 26 | 21 | 25 |  | 25 | 23 | 24 | 24 |  | 27 |
| GSA22+23_100-200 | 19 | 26 | 38 | 36 | 36 | 33 | 38 | 35 |  | 36 | 43 | 41 | 41 | 40 |  |
| GSA22+23_200-500 | 32 | 35 | 45 | 50 | 51 | 54 | 50 | 48 |  | 51 | 53 | 52 | 52 | 52 |  |
| GSA22+23_500-800 | 18 | 13 | 19 | 22 | 22 | 21 | 20 | 17 |  | 17 | 17 | 17 | 17 | 17 |  |

Data were assigned to strata based upon the shooting position and average depth (between shooting and hauling depth). Few obvious data errors were corrected. Catches by haul were standardized to 60 minutes hauling duration. Hauls noted as valid were used only, including stations with no catches of hake, red mullet or pink shrimp (zero catches are included).

The abundance and biomass indices by GSA were calculated through stratified means (Cochran, 1953; Saville, 1977). This implies weighting of the average values of the individual standardized catches and the variation of each stratum by the respective stratum areas in each GSA:

```
\(\mathrm{Yst}=\Sigma\left(\mathrm{Yi}^{*} \mathrm{Ai}\right) / \mathrm{A}\)
\(\mathrm{V}(\mathrm{Yst})=\Sigma\left(\mathrm{Ai}^{2} * \mathrm{si}^{2} / \mathrm{ni}\right) / \mathrm{A}^{2}\)
Where:
    A=total survey area
    \(\mathrm{Ai}=\) area of the i -th stratum
    si=standard deviation of the i-th stratum
    ni=number of valid hauls of the i-th stratum
    \(\mathrm{n}=\) number of hauls in the GSA
    Yi=mean of the i-th stratum
    Yst=stratified mean abundance
    \(\mathrm{V}(\mathrm{Yst})=\) variance of the stratified mean
```

The variation of the stratified mean is then expressed as the $95 \%$ confidence interval: Confidence interval $=$ Yst $\pm \mathrm{t}$ (student distribution) $* \mathrm{~V}(\mathrm{Yst}) / \mathrm{n}$

It was noted that while this is a standard approach, the calculation may be biased due to the assumptions over zero catch stations, and hence assumptions over the distribution of data. A normal distribution is often assumed, whereas data may be better described by a delta-distribution, quasi-poisson. Indeed, data may be better modelled using the idea of conditionality and the negative binomial (e.g. O'Brien et al. (2004)).

Length distributions represented an aggregation (sum) of all standardized length frequencies (subsamples raised to standardized haul abundance per hour) over the stations of each stratum. Aggregated length frequencies were then raised to stratum abundance * 100 (because of low numbers in most strata) and finally aggregated (sum) over the strata to the GSA. Given the sheer number of plots generated, these distributions are not presented in this report.

### 8.38.3.1.2. Geographical distribution patterns

No analyses were conducted during SGMED-09-02.

### 8.38.3.1.3. Trends in abundance and biomass

Fishery independent information regarding the state of the pink shrimp in GSAs 22 and 23 was derived from the international survey Medits. Fig. 8.38.3.1.3.1 displays the estimated trend in pink shrimp abundance and biomass in GSAs 22 and 23.

The estimated abundance and biomass indices increased from a very low level in 1994 to the highest value of the time series in 2006. The analyses of Medits indices are considered preliminary.

Fig. 8.38.3.1.3.1 Abundance and biomass indices of pink shrimp in GSAs 22 and 23.

### 8.38.3.1.4. Trends in abundance by length or age

The following Fig. 8.38.3.1.4.1 and 2 display the stratified abundance indices of GSAs 22 and 23 in 19942001 and 2003-2008. These size compositions are considered preliminary.

Fig. 8.38.3.1.4.1 Stratified abundance indices by size, 1994-2001.

Fig. 8.38.3.1.4.2 Stratified abundance indices by size, 2003-2008.

### 8.38.3.1.5. Trends in growth

No analyses were conducted during SGMED-09-02.

### 8.38.3.1.6. Trends in maturity

No analyses were conducted during SGMED-09-02.

### 8.38.4.Assessment of historic stock parameters

SGMED-09-02 did not undertake any analytical assessment.

### 8.38.5.1.Justification

No forecast analyses were conducted.

### 8.38.5.2.Input parameters

No forecast analyses were conducted.

### 8.38.5.3.Results

Given the preliminary state of the data and analyses SGMED-09-02 in not in the position to provide a long term prediction of catch and stock biomass for pink shrimp in GSAs 22 and 23.
8.38.6. Scientific advice

### 8.38.6.1.Short term considerations

### 8.38.6.1.1. State of the spawning stock size

In the absence of proposed or agreed references, SGMED-09-02 is unable to fully evaluate the state of the stock and provide scientific advice.

### 8.38.6.1.2. State of recruitment

SGMED-09-02 is unable to provide any scientific advice of the state of the recruitment given the preliminary state of the data and analyses.

### 8.38.6.1.3. State of exploitation

In the absence of proposed or agreed references, SGMED-09-02 is unable to fully evaluate the state of the stock and provide scientific advice.

### 8.39. Stock assessment of anchovy in GSA 01

### 8.39.1.Stock identification and biological features

### 8.39.1.1.Stock Identification

Little or no specific work has been focus on the biological stock delimitation of anchovy in the Western Mediterranean, but exchanges between the Northern Alboran Sea (GSA 01) with both the Northern Spain (GSA 06) and South Alboran Sea (GSA 03) are believed non-existent. During the STECF-SGMED-08-02 the experts recommend continuing with the assessments on GFCM-GSA basis. The attached figure shows the GFCM Geographical Sub-Area GSA 01 (Northern Alboran Sea).

Fig. 8.39.1.1.1 Stock distribution area.

### 8.39.1.2.Growth

Growth parameters were estimated throughout the DCR biological sampling on a triennial basis. The method used was the Von Bertalanffy equation fit to the age (otoliths reading) and growth data using non-linear estimation with minimum least squares (Gauss-Newton algorithm) and bootstrapped precision estimates.

Tab. 8.39.1.2.1 Growth parameters.

| PERIOD | L $\infty$ | K | t0 | A | B |
| :--- | :--- | :--- | :--- | :--- | :--- |
| $2002-2004$ | 19.0 | 0.3395 | -1.8815 | 0.0029 | 3.3171 |
| $2005-2008$ | 19.0 | 0.3419 | -2.3210 | 0.0040 | 3.1945 |

### 8.39.1.3.Maturity

Maturity at age was estimated throughout the DCR biological sampling from years 2003-2007. These values were considered constant through the years of the assessed time series (2002-2007).

Tab. 8.39.1.3.1 Maturity ogive.

| Age | 0 | 1 | 2 | 3 |
| :--- | :--- | :--- | :--- | :--- |
| Prop Matures | 0.50 | 0.89 | 1.0 | 1.0 |

### 8.39.2. Fisheries

### 8.39.2.1.General description of fisheries

The current fleet in GSA 01 the Northern Alborán Sea is composed by 136 units, characterised by small vessels. $22 \%$ of them are smaller than 12 m and $78 \%$ between 12 and 24 m . The purse seine fleet has been continuously decreasing in the last two decades, from more than 230 vessels in 1980 to 136 in 2007.
Sardine (Sardina pilchardus) and anchovy (Engraulis encrasicolus) are the main target species of the purse seine fleet in Northern Alboran GSA 01, but other species with lower economical mackerel (Trachurus spp.), mackerel (Scomber spp.) and gilt sardine (Sardinella aurita).
8.39.2.2.Management regulations applicable in 2008 and 2009

- Fishing license
- Minimum landing size 11 cm .
- Time at sea 12 hours per day and 5 days a week (no fishing allowed on weekend)
- Several technical measures regulations (gear and mesh size, engine, GRT, etc.)
- Temporary fishing closures (March and April).

### 8.39.2.3.Catches

### 8.39.2.3.1. Landings

The annual landings of anchovy in the Northern Alborán Sea show a strong annual fluctuation for the last six years ranged between 3268 and 112 tons. Landings decreased in 2008, reaching up 112 t that are the lowest of the time series. The data were reported to SGMED-09-02 through the Data Collection Regulation and are listed in Table A3.4 of Appendix 3.

Tab. 8.39.2.3.1.1 Annual landings ( t ) by fishing technique (Spanish purse seiners) in GSA 01.

| SPECIES | AREA | COUNTRY | FT_LVL4 | 2002 | 2003 | 2004 | 2005 | 2006 | 2007 | 2008 |
| :--- | ---: | :--- | :--- | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| ANE | 1 ESP | PS | 3268 | 245 | 746 | 518 | 637 | 245 | 112 |  |

### 8.39.2.3.2. Discards

Anchovy discards in GSA 01 are negligible.

### 8.39.2.3.3. Fishing effort

No effort data were reported to SGMED-09-02 through the DCF data call for Spain.

### 8.39.3.1.1. Methods

Estimation of abundance index with Acoustic Survey (Biomass in metric tons and abundance in number of individuals by species and sector).

The ECOMED survey provided data from 1990 onwards, although the abundance time series used for XSA tuning goes from 2003 to 2006 because of acoustic data are being re-evaluated. As a result of a gradual increase in the abundance of other species (usually considered as accessory species in the pelagic system) it has been necessary to revaluate the previous data in ECOMED surveys using different values of the parameter target strength (TS).

The sampling coverage was completed only for two analysed years in GSA 01 (2004 and 2005), the survey did not cover the whole area only sampling the two most representative bays in 2003 and 2006, no data for 2007 was available as weather conditions and lack of available time did not allow to sample the area.

Surveys are carried out on board the R/V Cornide de Saavedra during late autumn (November-December). A multifrequency echosounder is utilised (SIMRAD-ER60) sampling at frequencies of $38 \mathrm{kHz}, 70 \mathrm{kHz}, 120$ kHz and 200 kHz . The ESDU is 1 nm . The pulse duration is 1 msg . The software used echogram identification is SonarData Ecoview.

The sampling grid is comprised by parallel tracks, perpendicular to the coast. Acoustic sampling is performed during daytime. Experimental fishing with pelagic trawl for schools identification was done at night in the previously tracked positions.

### 8.39.3.1.2. Geographical distribution patterns

Anchovy in North Alborán Sea (GSA 01) is concentrated in Málaga Bay. This Bay is the most important recruitment and fishery area and this represent $85 \%$ of total landings.

### 8.39.3.1.3. Trends in abundance and biomass

Both XSA and acoustics methods have the same perception of the state of the stock. During the period from 1996-2006, the catches of anchovy stock in the Alborán Sea showed marked fluctuations. A successful recruitment, estimated by echo-acoustic tracking, was observed during 2001 ( 13,000 tons) producing a strong increment of landings in 2002. The catch dropped in 2003, continuing at low level to 2006 ( 600 tons). This decline is consistent with both XSA and acoustics methods.

Fig. 8.39.3.1.3.1 Trends in biomass estimates and landings.
8.39.3.1.4. Trends in abundance by length or age

Fig. 8.39.3.1.4.1 Age compositon of the stock.

### 8.39.3.1.5. Trends in growth

No analyses were conducted during SGMED-09-02.

### 8.39.3.1.6. Trends in maturity

No analyses were conducted during SGMED-09-02.
8.39.4.Assessment of historic stock parameters

SGMED-09-02 did not undertake any analytical assessment of anhovy in GSA 01. Last year's assessment using VPA Extended Survivors Analysis (XSA) can be found in the report of SGMED-08-04 working group (Cardinale et al., 2008).

### 8.39.5. Long term prediction

### 8.39.5.1.Justification

No forecast analyses were conducted.

### 8.39.5.2.Input parameters

No forecast analyses were conducted.

### 8.39.5.3.Results

Given the preliminary state of the data and analyses SGMED-09-02 is not in the position to provide a long term prediction of catch and stock biomass for anchovy in GSA 01.
8.39.6. Scientific advice

It should be noted that small pelagic fishery in GSA 01 is multispecies and effort on anchovy and sardine should be considered together.

Some work was done in SGMED-08-04 and some preliminary reference points were estimated based on yield-per-recruit analysis $\left(\mathrm{F}_{0.1} \& \mathrm{~F}_{\max }\right)$. However the use of yield-per-recruit targets for long-term management of pelagic fisheries has been specifically discouraged (Patterson, 1992) and no reference points can be proposed at this time. Further research is aimed to produce effective Reference Points in this small pelagic fishery as well as Harvest Control Rules.

### 8.39.6.1.Short term considerations

### 8.39.6.1.1. State of the spawning stock size

No reference points were proposed for biomass levels, and hence SGMED-09-02 cannot comment on the state of the stock with this respect.

### 8.39.6.1.2. State of recruitment

SGMED-09-02 is unable to provide any scientific advice of the state of the recruitment given the preliminary state of the data and analyses.

### 8.39.6.1.3. State of exploitation

No reference points were proposed for fishing mortality levels, and hence SGMED-09-02 cannot comment on the state of the stock with this respect.

### 8.40. Stock assessment of anchovy in GSA 06

### 8.40.1.Stock identification and biological features

### 8.40.1.1.Stock Identification

The small pelagic stock assessments in the Mediterranean are accomplished by Geografical Sub-Areas (GSAs) as defined in the GFCM. Little or no specific work has been focus on the biological stock identification of small pelagic species in the Mediterranean and more study is needed.

The attached figure shows the GFCM Geographical Sub- Area GSA 06, comprising all landings ports. Sampled ports are highlighted in blue.

Fig. 8.40.1.1.1 Stock distribuition area.

### 8.40.1.2.Growth

Growth parameters were estimated throughout the DCR biological sampling on a triennial basis. The growth parameters come from the anchovy off GSA 01 and were applied to anchovy off GSA 06 . The used method was the Von Bertalanffy equation fit to the age (otolith readings) and growth data using non-linear estimation with minimum least squares (Gauss-Newton algorithm) and Bootstrapped precision estimates.

Table 8.40.1.2.1 Growth paramters.

| PERIOD | L $\infty$ | K | t0 | A | B |
| :--- | :--- | :--- | :--- | :--- | :--- |
| $2002-2004$ | 19.0 | 0.3395 | -1.8815 | 0.0029 | 3.3171 |
| $2005-2008$ | 19.0 | 0.3419 | -2.3210 | 0.0040 | 3.1945 |

### 8.40.1.3.Maturity

Maturity at age was estimated throughout the DCR biological sampling from years 2004-2007. These values were considered constant through the years of the assessed time series (1994-2007).

Tab. 8.40.1.3.1 Maturity ogive.

| Age | 0 | 1 | 2 | 3 |
| :--- | :--- | :--- | :--- | :--- |
| Prop. Matures | 0.50 | 0.89 | 1.00 | 1.00 |

### 8.40.2.Fisheries

### 8.40.2.1.General description of fisheries

The purse seine fleet operate in GSA 06 Northern Spain is composed by 132 units: $4 \%$ are smaller than 12 m in length, $87 \%$ between 12 and 24 m and $9 \%$ bigger than 24 m . The fleet continuously decreased in the last decade, from more than 222 vessels in 1995 to 132 in 2007. This strong reduction $(59 \%$ ) is possibly linked to a decreasing in anchovy catches.

Anchovy (Engraulis encrasicolus) and sardine (Sardina pilchardus) are the main target species of the purse seine fleet in Northern Spain GSA 06, but other species with lower economical importance are also captured, sometimes representing a high percentage of the capture: horse mackerel (Trachurus spp.), mackerel (Scomber spp.) and gilt sardine (Sardinella aurita).

This report is exclusively focused on fishery of anchovy.
8.40.2.2. Management regulations applicable in 2008 and 2009

- Fishing license.
- Minimum landing size 11 cm .
- No fishing allowed on weekend. Time at sea 12 hours per day and 5 days a week: fully observed
- Several technical measures regulations (gear and mesh size, engine, GRT, etc.)
- Temporary fishing closures (From $1^{\text {st }}$ December to $31^{\text {st }}$ January).

### 8.40.2.3.Catches

### 8.40.2.3.1. Landings

The annual landings of anchovy (Engraulis encrasicolus) in the Northern Spain for the last seven years ranged between 14,338 and $2,570 \mathrm{t}$. This species is the most valuable one in pelagic fisheries off GSA 06.

Landings in 2008 were $2,888 \mathrm{t}$. The time series shows a very sharp decrease from the beginning of the times series in 2002. The lowest values of the assessed time series were reported in 2007.

Tab. 8.40.2.3.1.1 Annual landings (t) by fishing technique (purse seiners) in GSA 06.

| SPECIES | AREA | COUNTRY | FT_LVL4 | 2002 | 2003 | 2004 | 2005 | 2006 | 2007 | 2008 |
| :--- | :--- | :--- | :--- | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| ANE |  | 6 ESP | PS | 14338 | 8538 | 8097 | 6216 | 3096 | 2570 | 2888 |

### 8.40.2.3.2. Discards

Discards are negliglible. Only 17 t in 2004 were reported to SGMED-09-02 through the Data Collection Regulation and are listed in Table A3.9 of Appendix 3.

### 8.40.2.3.3. Fishing effort

No effort data were reported to SGMED-09-02 through the DCF data call for Spain.

### 8.40.3.Scientific surveys

### 8.40.3.1.ECOMED acoustic survey

### 8.40.3.1.1. Methods

The ECOMED survey provided data from 1990 onwards, although the abundance time series used for XSA tuning goes from 2003 onwards. The sampling coverage is completed for all analysed years in GSA 06.

Surveys are carried out on board the R/V Cornide de Saavedra during late autumn (November-December). A multifrequency echosounder is utilised (SIMRAD-ER60) sampling at frequencies of $38 \mathrm{kHz}, 70 \mathrm{kHz}, 120$ kHz and 200 kHz . The ESDU is 1 nm . The pulse duration is 1 msg . The software used echogram identification is SonarData Ecoview.

The sampling grid is comprised by parallel tracks, perpendicular to the coast. Acoustic sampling is performed during daytime. Experimental fishing with pelagic trawl for schools identification was done at night in the previously tracked positions.

### 8.40.3.1.2. Geographical distribution patterns

The studied area is usually split in two regions, the Tramontana Region (from Cape Creus to Cape La Nao) and Levantine Region (from Cape La Nao to Cape Palos). This allows the use of the complete historic time series of ECOMED, which is carried out along the Tramontana Region from 1990. The time period (November - December) where the survey is conducted corresponds to the recruitment season of the anchovy and spawning season of sardine. Hence the acoustic provides an estimation of the recruitment of the anchovy. They are two recruitment areas: one located between Barcelona and the south of the Ebro River Delta (the most important) and other in Rosas Bay.

### 8.40.3.1.3. Trends in abundance and biomass

Anchovy biomass in year 2007 was the lowest for the past 8 years, 4,906 tons, $40 \%$ lower than in year 2006. There is not defined trend in calculated biomass since 1996, but it appears that the stock shows a dramatic decline trend since 2001. The recruitment has been low, the population consists almost exclusively of the recruits and has practically disappeared between southern Rosas Bay and Tarragona (North Ebro River Delta).

Fig. 8.40.3.1.3.1 Trends in estimated biomass and landings.
Up to date, the areas of greatest density for this species have been the two areas of recruitment: Rosas Bay and the mouth of the Ebro river. In 2007 the highest density was located in the Gulf of Valencia, where $67 \%$ of the total biomass was concentrated. This represents a change from the usual strategy of this species (see figure below).

Fig. 8.40.3.1.3.2 Abundance in the survey area, 2003-2007.

- Trends in the pelagic community

Total small pelagics biomass, for all the 9 considered species, was $57,542 \mathrm{t}$ in 2007. This accounted for a half from that estimated in 2006 ( $116,896 \mathrm{t}$ ). The distribution area of small pelagics has been reduced by $50 \%$, especially in the key areas of recruitment of anchovy where the platform is wider: Rosas and Ebro River Delta. In these areas, acoustic integration was minimal out of the 80 m deep range.

It is important to note that for the last six years there was a gradual increase in the estimated biomass of other small pelagic species (mainly the three species of horse mackerel and bogue and in 2006 the Scomber scombrus) which are predators either eggs or anchovy larves as well as resources competitors. As regards 2007, the biomass of sardine and anchovy represented $44 \%$ of the total estimated biomass, in contrast to $63 \%$ and $83 \%$ in 2004 and 2003, respectively. The biomass of horse mackerel and bogue is still rising. In year 2007 accounted for $49 \%$ of the total biomass.

Other surveys: Some other surveys exist covering this area. The French survey PELMED2008 made an acoustic tracking of the area as far as the Gulf of Valencia. Some DEPM survey targeted to anchovy were also carried in 1993, 1994 and 2007. The document of the DEPM 2007 survey can be found in www.gfcm.org. The coverage of this survey was quite extensive, covering GSA 07 and GSA 06, although it was noted that Gulf of Alicante was not sampled. WG highlighted that DEPM results are not fitted to the management units GSA 06 and encourages re-estimating the SSB by considering those management units. This will allow making use of this survey for tuning the assessment model.

### 8.40.3.1.4. Trends in abundance by length or age

No analyses were conducted during SGMED-09-02.

### 8.40.3.1.5. Trends in growth

No analyses were conducted during SGMED-09-02.

### 8.40.3.1.6. Trends in maturity

No analyses were conducted during SGMED-09-02.

### 8.40.4.Assessment of historic stock parameters

SGMED-09-02 did not undertake any analytical assessment of anhovy in GSA 06. Last year's assessment using Extended Survivors Analysis (XSA) can be found in the report of SGMED-08-04 working group (Cardinale et al., 2008).
8.40.5. Long term prediction

> 8.40.5.1.Justification

No forecast analyses were conducted.

### 8.40.5.2.Input parameters

No forecast analyses were conducted.
8.40.5.3.Results

Given the preliminary state of the data and analyses SGMED-09-02 is not in the position to provide a long term prediction of catch and stock biomass for anchovy in GSA 06.

It should be noted that small pelagic fishery in GSA 06 is multispecies and effort on anchovy and sardine should be considered together.

### 8.40.6.1.Short term considerations

### 8.40.6.1.1. State of the spawning stock size

No reference points were proposed for biomass levels, and hence SGMED cannot comment on the state of the stock with this respect.

### 8.40.6.1.2. State of recruitment

SGMED-09-02 is unable to provide any scientific advice of the state of the recruitment given the preliminary state of the data and analyses.

### 8.40.6.1.3. State of exploitation

In the absence of proposed or agreed references, SGMED-09-02 is unable to fully evaluate the state of the stock and provide scientific advice.

### 8.41. Stock assessment of anchovy in GSA 16

### 8.41.1. Stock identification and biological features

### 8.41.1.1.Stock Identification

This assessment of the anchovy stock in GSA 16 is mainly based on information collected over the last decade relating fishery grounds off the southern Sicilian coast (GSA 16, South of Sicily), and specifically using biomass estimates obtained by hydro-acoustic surveys and catch/effort data from local small pelagic fisheries. The main distribution area of the anchovy stock in GSA 16 is the narrow continental shelf area between Mazara del Vallo and the southernmost tip of Sicily, Cape Passero (Patti et al., 2004). Daily Egg Production Method (DEPM) surveys were also carried out starting from 1998, giving also information on spawning areas distribution.

### 8.41.1.2.Growth

Growth parameters were not used for this assessment.

> 8.41.1.3.Maturity

Maturity data were not used for this assessment.

### 8.41.2. Fisheries

### 8.41.2.1.General description of fisheries

In Sciacca port, the most important base port for the landings of small pelagic fish species along the southern Sicilian coast (GSA 16), accounting for about $2 / 3$ of total landings in GSA 16 , two operational units (OU) are presently active, purse seiners and pelagic pair trawlers. The fleet in GSA 16 is composed by about 50 units ( 17 purse seiners and 30 pelagic pair trawlers were counted up in a census carried out in December 2006). In both OUs, anchovy represents the main target species due to the higher market price.
8.41.2.2.Management regulations applicable in 2008 and 2009

Fisheries policy is strongly conditioned by EU regulations through the Common Fisheries Policy (CFP), based on the following principles: protection of resources; adjustment of (structure) facilities to the available resources; market organization; and definition of relationships with other countries.

The main technical measures regulating fishing concern minimum landing size ( 9 cm for anchovy, 11 cm for sardine), mesh regulations ( 20 mm for pelagic pair trawlers, 14 mm for purse seiners) and restrictions on the use of fishing gear. Towed fishing gears are not allowed in the coastal area in less than 50 m depth, or within a distance of 3 nautical miles from the coastline. A seasonal closure for trawling, generally during summerautumn, has been established since 1993. In GSA 16, two operational units fishing for small pelagic are based in Sciacca port: purse seiners (lampara vessels, locally known as "Ciancioli") and midwaters pair trawlers ("Volanti a coppia"). Midwaters trawlers are based in Sciacca port only, and receive a special permission from Sicilian Authorities on an annual basis. Another fleet fishing on small pelagic fish species is based in some northern Sicilian ports and targets on juvenile stages (mainly sardines). Also this fishery is allowed for a limited period (usually one or two months during the winter season) by a special Regional law renewed year by year.

### 8.41.2.3.Catches

### 8.41.2.3.1. Landings

Landings were obtained within the framework of the census data collection carried out by IAMC-CNR (Mazara del Vallo) in Sciacca port since 1998. Information collected in the framework of CA.SFO. study project (Patti et al., 2007) showed that landings in Sciacca port account for about $2 / 3$ of the total landings in GSA 16. Average anchovy landings in Sciacca port over the last decade (1997-2008) were about 1,600 metric tons, with large inter-annual fluctuations.

It is worth noting that, though trend in biomass is clearly decreasing over the last years (Fig. 8.41.2.3.1.1), landings levels over the same period were relatively high, indicating an increased vulnerability of the resource.

Fig. 8.41.2.3.1.1. Landings data regarding the purse seine and pelagic pair trawl fleets in Sciacca port (GSA 16), 1998-2008.

### 8.41.2.3.2. Discards

No discards data for anchovy were used for this assessment. However, discards are estimated to be less than $5 \%$ of total catch for both the pelagic pair trawl and the purse seine fisheries (Kallianiotis and Mazzola, 2002)

### 8.41.2.3.3. Fishing effort

Fishing effort data refer to census data collected in Sciacca port, the most important base port for the landings of small pelagic fish species along the southern Sicilian coast (GSA 16), accounting for about $2 / 3$ of total landings in GSA 16.

Fig. 8.41.2.3.3.1. Effort data regarding the purse seine and pelagic pair trawl fleets in Sciacca port (GSA 16), 1998-2008.

### 8.41.3. Scientific surveys

### 8.41.3.1.Acoustics

### 8.41.3.1.1. Methods

## Acoustic surveys methodology

Steps for biomass estimation

- Collection of acoustic and biological data during surveys at sea;
- Extraction of NASC Fish (Fishes Nautical Area Scattering Coeffcient $\left[\mathrm{m}^{2} / \mathrm{n} . \mathrm{mi}^{2}\right]$ ) by means of Echoview (Sonar Data) post-processing software;
- Link of NASC values to control catches;
- Calculation of Fish density $(\rho)$ from NASC Fish values and biological data;
- Production of $\rho$ distribution maps for different fish species and size classes;
- Integration of density areas for biomass estimation.

## Collection of acoustic and biological data

Since 1998 the IAMC-CNR has been collecting acoustic data for evaluating abundance and distribution pattern of small pelagic fish species (mainly anchovy and sardine) in the Strait of Sicily (GSA 16). The scientific echosounder Kongsberg Simrad EK500 was used for acquiring acoustic data until summer 2005; for the echosurvey in the period 2006-2009 the EK60 echosounder was used. In both cases the echosounder was equipped with three split beam transducers pulsing at 38,120 and 200 kHz . During the period 19982008 acoustic data were collected continuously during day and night time; since the 2009 echosurvey acoustic data are collected during day time, according to the MEDIAS protocol.

Before or after acoustic data collection a standard procedure for calibrating the three transducers was carried out by adopting the standard sphere method (Johannesson and Mitson, 1983).

Biological data were collected by a pelagic trawl net with the following characteristics: total length 78 m , horizontal mouth opening 13-15 m, vertical mouth opening 6-8 m , mesh size in the cod-end 10 mm . The net was equipped with two doors with weight 340 kg . During each trawl the monitoring system SIMRAD ITI equipped with trawl-eye and temp-depth sensors was adopted.

## Extraction of NASC Fish by means of Echoview (Sonar Data) post-processing software

The evaluation of the NASC Fish (Fishes Nautical Area Scattering Coeffcient $\left[\mathrm{m}^{2} / \mathrm{n} . \mathrm{mi}^{2}\right]$ ) and the total NASC for each nautical mile of the survey track was performed by means of the SonarData Echoview software v3.50, taking into account the day and night collection periods.

## Link of NASC values to control catches

For the echo trace classification the nearest haul method was applied, taking into account only representative fishing stations along transects.

## Calculation of Fish density ( $\rho$ ) from NASC Fish values and biological data

For each trawl haul the frequency distribution of the $j$-th species $\left(v_{j}\right)$ and for the $k$-th lenght class $\left(f_{j k}\right)$ are estimated as

$$
v_{j}=\frac{n_{j}}{N} \quad \text { and } \quad f_{j k}=\frac{n_{j k}}{n_{j}}
$$

where $n_{j}$ is the total number of specimens of the $j$-th species, $n_{j k}$ is the total number of specimens of the $k$-th lenght class in the $j$-th species, and $N$ is the total number of specimens in the sample.

For each nautical mile the densities for each size class and for each fish species are estimated as

$$
\begin{aligned}
& \rho_{j k}=\frac{N A S C_{F I S H} * n_{j k}}{\sum_{j=1}^{n} \sum_{k=1}^{m} n_{j k} * \sigma_{j k}} \\
& \rho_{j k}=\frac{N A S C_{F I S H} * W_{j k} * 10^{-6}}{\sum_{j=1}^{n} \sum_{k=1}^{m} n_{j k} * \sigma_{j k}} \quad\left(\mathrm{t} / \mathrm{n} . \mathrm{mi}^{2}\right)
\end{aligned}
$$

where $W_{j k}$ is the total weight of the $k$-th lenght class in the $j$-th species, and $\sigma_{j k}$ is the scattering cross section of the $k$-th lenght class in the $j$-th species. $\sigma_{j k}$ is given by

$$
\sigma_{s p j k}=4 \pi * 10^{\frac{T S_{j k}}{10}}
$$

where the target strenght (TS) is

$$
T S_{j k}=a_{j} \log _{10}\left(L_{k}\right)+b_{j}
$$

$L_{k}$ is the length of the $k$-th lenght class while the $a_{j}$ and $b_{j}$ coefficient are linked to the fish species.
For anchovy, sardine and trachurus we adopted respectively the following relationships:

$$
\begin{array}{ll}
T S=20 \log L_{k} 76.1 & {[d B]} \\
T S=20 \log L_{k} 70.51 & {[d B]} \\
T S=20 \log L_{k} 72 & {[d B]}
\end{array}
$$

## Integration of density areas for biomass estimation

The abundance of each species was estimated by integrating the density surfaces for each species.

### 8.41.3.1.2. Geographical distribution patterns

No analyses were conducted during SGMED-09-02.

### 8.41.3.1.3. Trends in abundance and biomass

Fishery independent information regarding the state of the anchovy stock in GSA 16 was derived from the acoustics. Figure 8.41.3.1.3.1 displays the estimated trend in anchovy Total Biomass (estimated by acoustics) for GSA 16.

A decreasing trend was observed in biomass during the last years (Fig. 8.41.3.1.3.1).

Fig. 8.41.3.1.3.1. Estimated anchovy biomass indices for GSA 16, years 1998-2008.

### 8.41.3.1.4. Trends in abundance by length or age

Length or age class data were not used for this assessment.

### 8.41.3.1.5. Trends in growth

Growth data were not used for this assessment.

### 8.41.3.1.6. Trends in maturity

Maturity data were not used for this assessement.

### 8.41.4. Assessment of historic stock parameters

Not applicable. No stock assessment model was run for this assessment.

### 8.41.5. Long term prediction

Not applicable. No forecast analyses were conducted.

### 8.41.6. $\quad$ Scientific advice

8.41.6.1.Short term considerations

### 8.41.6.1.1. State of the spawning stock size

Biomass estimates of total population obtained by hydro-acoustic surveys for anchovy in GSA 16 show a decreasing trend over the last years. The 2008 estimate is the lowest value of the series and represents approximately just one-tenth of the maximum recorded value. However, in the absence of proposed or agreed references, SGMED-09-02 is unable to fully evaluate the state of the stock and provide any scientific advice in relation to them.

### 8.41.6.1.2. State of recruitment

No recruitment data were provided by this assessment.

### 8.41.6.1.3. State of exploitation

The high and increasing yearly exploitation rates, as estimated by the ratio between total landings and biomass, indicates high fishing mortality levels. If this estimate of exploitation rate can be considered as equivalent to $\mathrm{F} / \mathrm{Z}$ estimate obtained from the fitting of standard stock assessment models, the current exploitation (0.64) is higher than the reference point suggested by Patterson (1992). The fishing mortality level corresponding to $\mathrm{F} / \mathrm{Z}=0.64$ is $\mathrm{F}=1.17$, if $\mathrm{M}=0.66$, estimated with Pauly's (1980) empirical equation, is assumed.

Using the exploitation rate as a reference point, this stock should be considered as being overexploited.
Given that biomass was very low for three consecutive years (2006, 2007 and 2008), fishing effort should be reduced by means of a multi-annual management plan until there is evidence for stock recovery. Consistent catch reductions along with effort reductions should be determined. The mixed fisheries effects, mainly the interaction with sardine, need to be taken into account when managing the Anchovy fishery.

General considerations for the management of the Anchovy fishery:
Taking into account that fishing effort was relatively stable in last decade, whereas CPUE trend was even increasing, results would suggest the importance of environmental factors variability on yearly recruitment success and/or a possible increase in the vulnerability of the resource.

However, the stock biomass did not recover from the 2006 "collapse" in biomass ( $-69 \%$ from July 2005 to June 2006), and also further decreased ( $-53 \%$ ) in 2008. This fact, along with the quite high and increasing level of exploitation rates experienced over the last years, also suggests questioning about the sustainability of current levels of fishing effort.

A warning on the fishing of larval stages (locally named bianchetto) is also relevant for anchovy population if derogation of the fishing ban, normally operated for GSA 16 in wintertime, is postponed after the start of the anchovy spawning season, even though more data and investigation are needed in order to estimate the possible impact of this fishing activity on the exploited populations.

### 8.42. Stock assessment of anchovy in GSA 17

### 8.42.1.Stock identification and biological features

### 8.42.1.1.Stock Identification

The southern boundary of the GSA 17 is represented from the Gargano Promontory, as shown in the map below. However, the stock distribution area of anchovy in the Adriatic Sea extends into GSA 18. The spawning season of the Adriatic anchovy is in spring-summer. The spawning areas are mainly located in the western part of the GSA 17. On the basis of the database of CNR-ISMAR-SPM Fish Population Dynamics Unit, the maximum age recorded was 6 years while the maximum length was 19 cm .

Fig. 8.42.1.1.1 Stock distribution map.

### 8.42.1.2.Growth

An example of age-length key expressed in number of individuals, obtained through DCR by CNR-ISMARSPM Fish Population Dynamics Unit, for the commercial catches of (Italian) mid-water trawlers in 2007, was reported in the table below.

Tab 8.42.1.2.1 GSA 17 anchovy: age-length key (year 2007, mid-water trawlers).

| L (cm) | Age 0 | Age 1 | AgE 2 | AgE 3 | Age 4 | AgP 5 | Total |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 75 | 5 |  |  |  |  |  | 5 |
| 80 | 11 |  |  |  |  |  | 11 |
| 85 | 15 | 1 |  |  |  |  | 16 |
| 90 | 21 | 2 |  |  |  |  | 23 |
| 95 | 2 | 11 |  |  |  |  | 30 |
| 10.0 | 27 | 22 | 10 |  |  |  | 59 |
| 10.5 | 32 | 41 | 10 |  |  |  | 86 |
| 11.0 | 2 | 72 | 14 |  |  |  | 115 |
| 11.5 | 31 | 93 | 31 | 1 |  |  | 156 |
| 12.0 | 18 | 74 | 74 | 8 |  |  | 174 |
| 12.5 | 4 | 33 | 104 | 14 |  |  | 155 |
| 13.0 |  | 29 | 129 | 18 |  |  | 176 |
| 13.5 |  | 8 | 105 | 34 | 3 |  | 150 |
| 14.0 |  |  | 47 | 42 | 6 |  | 95 |
| 14.5 |  |  | 31 | 36 | 4 | 1 | 72 |
| 15.0 |  |  | 11 | 23 | 2 |  | 3 |
| 15.5 |  |  | 2 | 16 | 3 |  | 21 |
| 16.0 |  |  |  | 5 |  |  | 5 |
| 16.5 |  |  |  | 3 | 1 |  | 4 |
| Total | 215 | 36 | 56 | 200 | 19 | 1 | 139 |

The corresponding age-length key obtained for the commercial catches of purse-seiners was reported in the table below. Different length ranges as a function of the gear were observed: the smallest size individuals can be better represented in the catch of mid-water trawlers.

Tab 8.42.1.2.2 GSA 17 anchovy: age-length key (year 2007, purse seiners).

| L (cm) | AgE 0 | Age 1 | Age 2 | $A_{\text {ge }} 3$ | Age 4 | Total |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 95 | 1 |  |  |  |  | 1 |
| 10.0 |  | 1 |  |  |  | 1 |

| 12.5 |  |  | 2 |  |  | 2 |
| 13.0 |  |  | 3 | 3 |  | 6 |
| 13.5 |  |  | 1 | 4 | 1 | 6 |
| 14.0 |  |  |  | 2 | 2 | 4 |
| 14.5 |  |  | 2 | 2 | 3 | 7 |
| 15.0 |  |  | 2 | 2 | 4 | 8 |
| 15.5 |  |  |  | 5 |  | 5 |
| 16.0 |  |  |  | 2 |  | 2 |
| 16.5 |  |  | 1 | 2 |  | 3 |
| 17.0 |  |  |  | 2 |  | 2 |
| Total | 4 | 6 | 15 | 24 | 10 | 9 |

### 8.42.1.3.Maturity

According to Rampa et al. (2005), the first sexual maturity of Adriatic anchovy is around 8 cm .

### 8.42.2.Fisheries

8.42.2.1.General description of fisheries

In the GSA 17, anchovy is fished by mid-water trawlers and purse seiners attracting fish with light. Additional information was reported below in the paragraph "Catches".

In Italy, the legal minimum length for anchovy is 9 cm (R.(CE) 1967/2006). The same value has been adopted in Croatia (G. Sinovčić, Institute of Oceanography and Fisheries of Split, personal communication).

### 8.42.2.3.Catches

### 8.42.2.3.1. Landings

On the basis of the database of CNR-ISMAR-SPM Fish Population Dynamics Unit, the amount of the total catch of anchovy relative to Italy, Slovenia and Croatia was plotted over years in the figure below. The average total catch was 28000 t in 1976-2007 and 43000 t in 2005-2007. The lowest values of the series corresponding to the calendar year 1987 - were associated to a crisis of the Italian fishery of Adriatic anchovy. The main fraction of the total catch is usually taken by the Italian fleet but, in recent years, the fraction relative to the fleets of the eastern part of the GSA 17 has increased.

Fig. 8.42.2.3.1.1 GSA 17 anchovy: total catch over years.

The average length frequency distribution and the average age frequency distribution of the total catch were shown in the two figures below. The average for length was calculated including only the years from 1988 onwards as, after this date, length was measured using 0.5 cm classes, whereas 1 cm classes were used from 1975 to 1987. A comment relative to the different length range fished by mid-water trawlers and purse seiners was reported above, in the paragraph "Growth".

Fig. 8.42.2.3.1.2 GSA 17 anchovy: average length frequency distribution of the total catch.

Fig. 8.42.2.3.1.3 GSA 17 anchovy: average age frequency distribution of the total catch.

### 8.42.2.3.2. Discards

This feature was investigated by CNR-ISMAR-SPM Fish Population Dynamics Unit, through an EU funded project at the end of 1990s (Santojanni et al., 2005) and DCR in 2005.

Discards of anchovy in the GSA 17, at least for the Italian fleet, can be considered as negligible because anchovy, usually, is strongly required by the market (more than sardine). For example, on the basis of the DCR investigation, the amount of anchovy discarded at sea by the Italian fleet was 65 t and 206 t in the third and fourth quarter of 2005, respectively. These quantities were very low in comparison with the corresponding landings: from 2000 to 2007, the annual amount of anchovy landed by the Italian fleet was always higher than 20000 t and, in 2005-2007, it was over 30000 t . In conclusion, the estimates of discards obtained for only one half of 2005 was considered negligible and fluctuating during the year and thus those were not included in the estimation of total catches.

### 8.42.2.3.3. Fishing effort

No information was presented on fishing effort

### 8.42.3.Scientific surveys

As mentioned below in the paragraph "Method", the results of the acoustic surveys carried out by CNR-ISMAR-SPM Marine Acoustics Unit from the mid-line to the western coast of the GSA 17, from 1976 to 2007, were used for VPA tuning.

### 8.42.4.Assessment of historic stock parameters

### 8.42.4.1.Method: VPA

### 8.42.4.1.1. Justification

The assessment of this stock was carried out by means of Virtual Population Analysis (VPA), using catch data collected for Italy, Slovenia and Croatia, from 1975 to 2007 (Cingolani et al., 1996; Santojanni et al., 2003, 2005, 2006a,b,c; 2008; Barange et al., in press; Santojanni, in press).

The Laurec-Shepherd tuning of VPA was performed using an abundance index series derived from echosurveys carried out in the western part of the GSA 17. The software developed by Darby and Flatman (1994) was used for the VPA runs. The results of the assessment were also discussed during the last SCSA-SACGFCM meeting (Santojanni et al., 2008). Split-year data were used assuming the first of June as the birth date of Adriatic anchovy: e.g. split-year 1976 was composed of the months from June to December of calendar 1975 and months from January to May of calendar 1976.

Given the long time series available, VPA was thought to be a suitable method. Additional trials with Integrated Catch Analysis (ICA) were also done during the last SCSA-SAC-GFCM meeting (Izmir, 22-26 September 2008), but the results were not mentioned in this document; anyway, they were quite consistent with those derived from Laurec-Shepherd tuned VPA, as shown also in the report of SGMED-08-04 working group (Cardinale et al., 2008).

### 8.42.4.1.2. Input parameters

A time series of annual total catch at age in numbers of individuals is the main data input of VPA. It was shown (expressed using proportions) in the figure below. The age class $4+$ is a plus group: it includes the class 4 (years) along with those classes higher than 6 , i.e. 5 and 6 in the present case.

Fig. 8.42.4.1.2.1 GSA 17 anchovy: relative catch at age over years.
The annual natural mortality rates $\mathrm{M}=0.6$ and $\mathrm{M}=0.8$ ( year $^{-1}$ ) were employed for VPA calculations. However, more emphasis was given to the results obtained with $\mathrm{M}=0.6$.

The two values were selected taking into account the literature and the maximum life-span observed in the commercial catches from 1976 onwards, i.e. 4 and even 5 and 6 years.

About the inverse relationship between longevity and mortality, as reported by Barange (2001), Pacific sardine (Sardinops sagax) is usually assumed to have a relatively low annual natural mortality rate, $\mathrm{M}=0.4$, and a lifespan of about 10 years, whereas for northern anchovy (Engraulis mordax) $\mathrm{M}=0.8$ is associated to a lifespan of about 4 years.

Moreover, useful information was gained from the relationship between total mortality $\mathrm{Z}(=\mathrm{F}+\mathrm{M})$ and maximum life span tmax (year), $\mathrm{Ln} Z=1.44-0.982 \mathrm{Ln}$ tmax, found by Hoenig (1983; see also Hewitt and Hoenig, 2005). It was "based largely on data from unexploited stocks", thus with Z being very close to M. On the basis of this equation, for example (table below), $\operatorname{tmax}=6$ is associated to $\mathrm{Z}=0.73$.

Tab. 8.42.4.1.2.1 Relationship between total mortality rate Z and maximum life-span tmax (see text).

| tmax (year) | Z (year ${ }^{\mathbf{- 1}}$ ) |
| :---: | :---: |
| 1 | 4.22 |

### 8.42.4.1.3. Results

The stock biomass estimated by means of VPA using both $\mathrm{M}=0.6$ and $\mathrm{M}=0.8$ was plotted over years in the figure below, along with the total catch. The average stock biomass estimated by the VPA with $\mathrm{M}=0.6$ was $120,000 \mathrm{t}$ in 1976-2007 and $210,000 \mathrm{t}$ in 2005-2007; higher values were obtained with $\mathrm{M}=0.8$. The corresponding average ratio between total catch and stock biomass (with $\mathrm{M}=0.6$ ) was 0.23 in 1976-2007 and 0.20 in 2005-2007. The collapse in the second half of 1980s after a peak in the second half of 1970s was evident as well as recent fluctuations.

Fig. 8.42.4.1.3.1 GSA 17 anchovy: total catch and stock biomass estimated by VPA over years.

The stock biomass estimated by means of VPA using both $\mathrm{M}=0.6$ and $\mathrm{M}=0.8$ was compared over years with the stock biomass estimated by means of the echo-surveys carried out in the western part of the GSA 17. On the whole, there was agreement between the trends obtained with the two different methods: initial peak, decline, collapse and recovery. However, the recovery was more pronounced in the echo-survey data and, in the most recent years, the two series were clearly out of phase.

Fig. 8.42.4.1.3.2 GSA 17 anchovy: stock biomass estimated by VPA and echo-surveys over years.
The relationship between spawning stock biomass and number of recruits (age class 0 ) obtained from the VPA with $\mathrm{M}=0.6$ was plotted in the figure below. The current spawning stock biomass was over the values recorded immediately before the collapse in 1987.

Fig. 8.42.4.1.3.3 GSA 17 anchovy: stock-recruitment relationship (VPA with $\mathrm{M}=0.6$ ).

The fishing mortality rate F derived from the VPA with $\mathrm{M}=0.6$ was plotted over ages and years in the figure below (left and right picture, respectively). In the former case, the average for the complete time series was calculated. In the latter case, two averages were calculated both weighting and without weighting the F at age values on the corresponding numbers of fish at sea.
Some average values over years were the following:

- unweighted F0-3 in 1976-2007: 0.32;
- unweighted F0-3 in 2005-2007: 0.24;
- weighted F0-4 in 1976-2007: 0.22;
- weighted F0-4 in 2005-2007: 0.19.

Fig. 8.42.4.1.3.4 GSA 17 anchovy: fishing mortality rate $F$ over ages and years.
The annual exploitation rate $\mathrm{E}=\mathrm{F} /(\mathrm{F}+\mathrm{M})$ or $\mathrm{F} / \mathrm{Z}$ was also calculated, both using the weighted and unweighted Fs mentioned above.

The values obtained were compared with the threshold $\mathrm{F} / \mathrm{Z}=0.4$ (biological reference point), above which the stock collapse should be relatively likely, as pointed out by Patterson (1992) for small pelagics. Here, more emphasis was given to the F/Z calculated using unweighted Fs, as the author performed his statistical analysis on a data set mainly formed by unweighted Fs.

The values of $\mathrm{F} / \mathrm{Z}$ were plotted over years in the figure below. Some average values over time were the following:

- F/Z in 1976-2007 with unweighted F0-3 : 0.34;
- F/Z in 2005-2007 with unweighted F0-3: 0.28;
- F/Z in 1976-2007 with weighted F0-4 : 0.26;
- F/Z in 2005-2007 with weighted F0-4 : 0.24.

All these values are lower than 0.4 . Values higher than 0.4 and even than 0.5 - which is the highest and more dangerous limit pointed by Patterson (1992) - were observed before the collapse. Likely, both fishery and some environmental factors contributed to this event (Santojanni et al., 2006a; Santojanni, in press).

Fig. 8.42.4.1.3.5 GSA 17 anchovy: exploitation rate F/Z over years.

In 2009, VPA was also carried out using vectors of natural mortality rate at age, i.e. not constant over age as in the stock assessment of 2008. They were derived from Probiom software and Gislason's method, according to the first SGMED meeting of 2009 (Tab. 8.42.4.1.3.1). The values of von Bertalanffy parameters Linf $=16.15, \mathrm{k}=0.40, \mathrm{t} 0=-2.04$ and length-weight parameters $\mathrm{a}=0.0025, \mathrm{~b}=3.37$ were used for the calculations of the M at age vectors and were derived from DCR (biological sampling of landing data, GSA 17, year 2007).

Some limits of the use of these M at age vectors are worth noting: with Probiom, values for oldest age classes seem to be quite low and thus not very realistic (e.g. 0.34 for age class 2); Gislason's should be preferably used for demersals rather than small pelagics. The new results obtained were compared with those based on the use of constant $\mathrm{M}=0.6$.

Substantial differences were not observed between constant $\mathrm{M}=0.6$ and Gislason's while Probiom provided lower estimates of stock biomass and higher values of the exploitation rate (Fig. 8.42.4.1.3.6 and Fig. 8.42.4.1.3.7). Stock recruitment relationships were also compared (Fig. 8.42.4.1.3.8 and Fig. 8.42.4.1.3.9).

Tab. 8.42.4.1.3.1 Values of natural mortality at age used.

| Age | Constant | Probiom | Gislason |
| :---: | :---: | :---: | :---: |
| 0 | 0.60 | 0.74 | 0.90 |
| 1 | 0.60 | 0.50 | 0.67 |
| 2 | 0.60 | 0.34 | 0.56 |
| 3 | 0.60 | 0.29 | 0.52 |
| $4+$ | 0.60 | 0.29 | 0.50 |

Fig. 8.42.4.1.3.6 Stock biomass estimated by VPA with constant $M$ at age ( 0.6 as in the stock assessment performed in 2008) and M at age vectors obtained by means of Probiom software and Gislason's method.

Fig. 8.42.4.1.3.7 Exploitation rate estimated by VPA with constant $M$ at age ( 0.6 as in the stock assessment performed in 2008) and M at age vectors obtained by means of Probiom software and Gislason's method.

Fig. 8.42.4.1.3.8 Stock-recruitment relationship with constant M at age ( 0.6 as in the stock assessment performed in 2008). The split-years from 1977 to 2007 displayed are relative to the recruitment.

Fig. 8.42.4.1.3.9 Stock-recruitment relationship with M at age vectors, obtained by Probiom and Gislason's methods. The split-years 1985, 1986 and 1987 displayed are relative to the recruitment.

### 8.42.5. Long term prediction

### 8.42.5.1.Justification

No forecast analyses were conducted.

### 8.42.5.2.Input parameters

No forecast analyses were conducted.

Given the preliminary state of the data and analyses SGMED 09-02 is not in the position to provide a long term prediction of catch and stock biomass for anchovy in GSA 17.

### 8.42.6. $\quad$ Scientific advice

### 8.42.6.1.Short term considerations

Consistent with it's own recommendations developed during the workshop 2-6 March 2009 held in Murcia(Spain), SGMED 09-02 considers the re-assessment based on the M-vector derived by the Probiom method as the most realistic one. SGMED 09-02 notes that this assessment consistently results in the lowest stock size and highest fishing mortality over the historic period 1976-2007.

### 8.42.6.1.1. State of the spawning stock size

The visual inspection of the scatter plot of recruitment versus spawning stock biomass clearly indicates that recruitment is impaired at stock sizes below $50,000 \mathrm{t}$. Thus, SGMED recommends establishing $\mathrm{B}_{\mathrm{lim}}=50,000 \mathrm{t}$ for the stock of anchovy in GSA 17. According to FAO recommendations (Cadima, 2003), $\mathrm{B}_{\mathrm{pa}}$ should be in the range of $1.39 * \mathrm{~B}_{\text {lim }}-1.64 * \mathrm{~B}_{\text {lim }}$, accounting for uncertainty in the estimations of fishing mortality. Such factors would determine $\mathrm{B}_{\mathrm{pa}}$ being in the range of $70,000-82,000 \mathrm{t}$. Thus, SGMED recommends establishing $\mathrm{B}_{\mathrm{pa}}=80,000 \mathrm{t}$ for the stock of anchovy in GSA 17.

Based on these reference points, SGMED-09-02 considers the stock of anchovy in GSA 17 by 2007 (about $120,000 \mathrm{t}$ ) as fully recovered from its low abundance estimated in the late 1980s.

### 8.42.6.1.2. State of recruitment

SGMED-09-02 estimates recent recruitment to be at an average level.

### 8.42.6.1.3. State of exploitation

SGMED concludes that the short term responses of the assessed anchovy stock to recent exploitation rates indicate that an exploitation rate in the order of $\mathrm{E} \leq 0.4$ might be consistent with the management goal of high long term yields, taking into account the dynamic of the stocks. SGMED underlines that limited area and temporal coverage of the available stock assessments impede any quantification of risk related to this statement. As such, the expressed indication regarding Mediterranean small pelagic stocks is in agreement with empirical findings of Patterson (1992), who has proposed this exploitation level. SGMED recommends the application of the proposed exploitation rate $\mathrm{E} \leq 0.4$ as management target for stocks of anchovy and sardine in the Mediterranean Sea. This value might be revised in the future when more information becomes available.

SGMED-09-02 estimated the most recent exploitation rates in 2005-2007 as at or slightly below the proposed sustainable level. As such, the stock is considered sustainably harvested. SGMED-09-02 recommends to maintain the effort constant and to determine consistent catches.

### 8.43. Stock assessment of anchovy in GSA 22

### 8.43.1. Stock identification and biological features

### 8.43.1.1.Stock Identification

This assessment of the anchovy stock in GSA 22 has been based on information derived from the Greek part of the Aegean Sea (GSA 22). The main distribution area of the anchovy stock in Aegean Sea is located in the continental shelf of the northern Aegean Sea (Giannoulaki et al., 2004; 2008a; Somarakis et al., 2007). Anchovy juveniles spatial distribution is strongly related to semi closed gulfs, shallow waters (less than 50 m depth) with high productivity, often related to areas of rivers outflows (Tsagarakis et al., 2007; 2008; SARDONE project interim report).

### 8.43.1.2.Growth

Fast growth parameter was considered and parameters are shown in Table 8.43.1.2.1. No sex discrimination was applied. Natural mortality M was estimated based on ProBiom (Abella et al., 1997) as recommended in the report of the SG-ECA/RST/MED 09-01.

Tab. 8.43.1.2.1. Growth parameters (v. Bertalanffy) for anchovy in GSA 22.

| Fast growth |  |  |
| :---: | :---: | :---: |
|  | Unsexed | Units |
| Linf | 191 | cm |
| K | 0.385 | year ${ }^{1}$ |
| t0 | -1.559 | year |
| a | 0.00004 | gr |
| b | 3.1157 |  |
| M age 0 | 1.5 | year ${ }^{\text {a }}$ |
| M age 1 | 1 | year |
| Mage 2 | 0.72 | year |
| Mage 3 | 0.66 | year |
| Mage 4 | 0.62 | year |

### 8.43.1.3.Maturity

The following maturity at age ogive was used for assessments in GSA 22 estimated from biological sampling and the DEPM surveys (Somarakis et al., 2004; 2007). Length at first maturity is estimated approximately at 105 mm (Somarakis, 1993; Somarakis et al., 2004; 2007) in Aegean Sea. The anchovy spawning period in GSA 22 extends from May to August with a peak in June-July. The major spawning grounds of anchovy in the Aegean Sea are located in areas characterized by wide continental shelf and enrichment processes associated with the outflow from large rivers or the Black Sea Water (BSW) in the northern Aegean Sea. Consequently, the highest egg densities have been typically observed over the northern Aegean Sea continental shelf.

Tab. 8.43.1.3.1 Maturity ogives at age for female anchovy in GSA 22.

| Yeall | Age 0 | Age 1 | Age 2 | Age 3 | Age 4 |
| :--- | :--- | :--- | :--- | :--- | :--- |
| 2003 | 0 | 0.62 | 0.99 | 1 | 1 |
| 2004 | 0 | 0.67 | 0.99 | 1 | 1 |
| 2005 | 0 | 0.46 | 0.98 | 1 | 1 |
| 2006 | 0 | 0.40 | 0.98 | 1 | 1 |
| 2007 | 0 | 0.40 | 0.98 | 1 | 1 |
| 2008 | 0 | 0.40 | 0.98 | 1 | 1 |

### 8.43.2. Fisheries

8.43.2.1.General description of fisheries

Anchovy (Engraulis encrasicolus) is one of the most important target species for the purse seine fishery in GSA 22. Anchovy is being exploited only by the purse seine fishery. Pelagic trawls are banned and benthic trawls are allowed to fish small pelagics in percentages less than 5\% of their total catch. Commonly anchovy is caught from shallow waters about 30 m to 100 m depth.
8.43.2.2. Management regulations applicable in 2008 and 2009

Regarding the management regulations enforced they concern a closed period from the mid December till the end of February and technical measures such as minimum distance from shore ( 300 m ), minimum bottom depth ( 30 m ), gear and mesh size, engine, GRT restrictions etc. There is also a minimum landing size at 9 cm .

### 8.43.2.3.Catches

### 8.43.2.3.1. Landings

The trend in reported landings (from Greek purse seiners fleet) is shown in Figs. 8.43.2.3.1.1 and 8.43.2.3.1.2. Landings were obtained within the framework of the Hellenic Centre for Marine Research data collection system that covers the entire GSA 22. The data from 2003 to 2008 were reported to SGMED-0902 through the Data Collection Regulation and are listed in Table A3.4 of Appendix 3. An increasing trend in anchovy landings has been observed (Fig. 8.43.2.3.1.1). Data of the landings per vessel class indicate that small vessels (12-24 m) (Fig. 8.43.2.3.1.2) are mainly responsible for anchovy catches ( $>70 \%$ of anchovy catches).

Annual lengths of landings were reported to SGMED-09-02 for 2003-2008 and are shown in Fig. 8.43.2.3.1.3. No data on the age distribution of landings was reported to the SGMED-09-02, through the DCR. Fig. 8.43.2.3.1.4 shows the landings at age in GSA 22 as reported to SGMED-08-04 for 2003-2006. Data for 2007 and 2008 are based on data obtained within the framework of the Hellenic Centre for Marine Research data collection system that covers the entire GSA 22.

Fig. 8.43.2.3.1.1 Anchovy landings ( t ) in GSA 22 for 2000-2008.

Fig. 8.43.2.3.1.2 Anchovy landings (t) in GSA 22 per fleet size (Greek waters).

Fig. 8.43.2.3.1.3 Length frequency distribution of anchovy landings (t) in GSA 22 for 2003-2008.

Fig. 8.43.2.3.1.4 Anchovy landings per age group (number of individuals in thousands) in GSA 22 for 20032008.

### 8.43.2.3.2. Discards

No discards data for anchovy were reported to the SGMED-09-02 and no data were reported through the Data collection regulation for 2003-2008. According to data obtained within the framework of the Hellenic Centre for Marine Research data collection system that covers the entire GSA 22, discards are estimated to less than $1 \%$, consisting $0.06 \%$ of the purse seine fishery total catch. Although considered negligible they were taken into account for the assessment as a percentage to reported landings. The fishery is multispecies and fishermen tend to avoid schools of undersized anchovies due to sorting difficulties (blocking of the mesh) and low price, practically by using nets of bigger mesh size, targeting mostly mackerels or horse mackerels.

### 8.43.2.3.3. Fishing effort

Based on the fishing effort data reported through the Data collection regulation and data obtained within the framework of the Hellenic Centre for Marine Research data collection system covering the entire GSA 22, the following table was made:

Tab. 8.43.2.3.3.1 Effort data for the purse seine fleet in GSA 22 ( $G T=$ Gross tonnage, $\mathrm{KW}=$ engine power).

| Year | PS 12-24 m | PS 24-40 m | PS 12-24 m | PS 24-40 m | PS $12-24 \mathrm{~m}$ | PS 24-40 m |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  |  | Days at Sea x | Days at Sea x | Days at Sea x | Days at Sea x |

### 8.43.3. Scientific surveys

### 8.43.3.1.Acoustics and DEPM

### 8.43.3.1.1. Methods

## Acoustics

Based on data reported to SGMED-09-02 total biomass, abundance, length and age composition for GSA 22 were estimated by acoustics from 2003 to 2008. No age distribution data were reported through the DCR for 2008. No acoustic survey took place in 2007.

## Acoustic surveys methodology

Acoustic echoes were registered continuously along 70 pre-defined transects in the study area in June 2003, 2004, 2005, 2006 and 2008 with a Biosonics Split Beam 38 kHz DT-X echosounder. The acoustic methodology followed is described in Somarakis et al. (2007) (GFCM 2007 related WD). Hydroacoustic data analysis was performed using the Sonardata Echoview software v3.30. Echo trace classification was applied based on a) echogram visual scrutinisation and direct allocation of school marks that characterise anchovy as well as b) allocation on account of representative fishing stations that were held along transects (MacLennan and Simmonds, 1992).

In order to estimate anchovy biomass, the length-weight relationship is required as well as species length frequency distribution per area. Therefore, 22, 23, 27, 37 and 30 pelagic trawls were made along transects in 2003, 2004, 2005, 2006 and 2008 respectively, in the positions of high fish concentrations. A random sample of 200 specimens was obtained from each haul for further laboratory analysis. Subsequently, the lengthweight relationship was estimated from the total number of hauls according to the equation:

$$
\mathrm{W}=\mathrm{a} \mathrm{~L}^{\mathrm{b}}
$$

where W is the total weight; L is the total length and a and b are constants that are estimated by regression analysis.

The mean length frequency was estimated in two sub-areas: (a) Eastern area (Thracian Sea and Strymonikos Gulf) and (b) Western area (Thermaikos and Evoikos Gulfs). In the two sub-areas, the mean frequency of each length class was estimated as follows:

$$
\mathrm{f}_{\mathrm{j}}=\frac{\sum_{\mathrm{k}=1}^{\mathrm{M}}\left(\frac{\mathrm{n}_{\mathrm{jk}}}{\mathrm{t}_{\mathrm{k}}}\right)}{\sum_{\mathrm{k}=1}^{\mathrm{M}}\left(\frac{\mathrm{~N}_{\mathrm{k}}}{\mathrm{t}_{\mathrm{k}}}\right)}
$$

where $f_{j}$ is the mean frequency of anchovy of length class $j ; n_{j k}$ is the number of specimens of length class $j$ in haul k ; $\mathrm{N}_{\mathrm{k}}$ is the total number of anchovies in haul k ; $\mathrm{t}_{\mathrm{k}}$ is the duration of haul k and M is the number of hauls in the area. The above equation is appropriate even if the catches are small and the length distributions are poorly defined. It takes accounts of the haul duration, since it is supposed that on average, longer hauls will produce more fish (MacLennan and Simmonds, 1992).

The density of targets (F) from the observed echo integrals were estimated according to the equation $\mathrm{F}=$ $(\mathrm{K} /\langle\sigma\rangle) \mathrm{E}$, were K is the calibration factor, $\langle\sigma\rangle$ is the mean cross-section and E is the echo integral after partitioning (MacLennan and Simmonds, 1992). The target strength (TS) - total length relationship used for anchovy was: $\mathrm{TS}=20 \operatorname{logL}-71.2$, where L is fish total length (ICES, 2006). The $\langle\sigma\rangle$ was calculated for the mean total fish length of each area according to the equations $\langle\sigma\rangle=4 \pi \sum_{\mathrm{l}} \mathrm{f}_{\mathrm{i}} 10^{\mathrm{TS} / 10}$, where $\mathrm{f}_{\mathrm{I}}$ is the corresponding length frequency as deduced from the fishing samples (MacLennan and Simmonds, 1992).

The abundance Q was estimated separately for the eastern and the western part of the study area. The abundance Q in each elementary statistical sampling area was calculated from the average density within each sub-area according to the equation:

$$
\mathrm{Q}=\mathrm{A}_{\mathrm{k}} \sum_{\mathrm{i}} \mathrm{~F}_{\mathrm{i}} / \mathrm{N}_{\mathrm{k}}
$$

where $F_{i}$ is the i sample; $A_{k}$ is the area of each elementary statistical sampling area and $N_{k}$ is the number of transects in $\mathrm{A}_{\mathrm{k}}$. The variance V was estimated as

$$
\mathrm{V}=\sum_{\mathrm{i}}\left(\mathrm{AF}_{\mathrm{I}}-\mathrm{Q}\right)^{2} /\left[\mathrm{N}_{\mathrm{r}}\left(\mathrm{~N}_{\mathrm{r}-1}-1\right)\right]
$$

The data were $\log$ transformed and the means and variances of F estimated according to the following equations:
$\mathrm{F}=\exp (\mathrm{m}) \mathbf{G}_{\mathrm{N}}\left[0.5 \mathrm{~S} /(\mathrm{n}-1) ; \mathrm{V}=\mathrm{F}^{2}-\exp (2 \mathrm{~m}) \mathbf{G}_{\mathrm{N}}\left[\mathrm{S}(\mathrm{n}-2) /(\mathrm{n}-1)^{2}\right]\right.$;
where $m=$ average $(\operatorname{lnF}) ; S=$ variance $(\operatorname{lnF})$ and $n=$ independent observations of $F$.
The total abundance $Q_{t}$ and its variance were obtained by summing the results for each region $Q_{1}=Q_{1}+Q_{2}+\ldots$ , and $\mathrm{V}_{\mathrm{t}}=\mathrm{V}_{1}+\mathrm{V}_{2}+\ldots$. Standard error of $\mathrm{Q}_{\mathrm{t}}$ is the square root of V (MacLennan and Simmonds, 1992).

## Daily Egg Production surveys (DEPM) methodology

The methodology of the DEPM is described in detail in Somarakis et al. (2007) GFCM WD. The spawning stock biomass was estimated according to the model described by Parker (1980) and subsequently modified by Stauffer \& Picquelle (1980):

$$
B=(\mathrm{k} \cdot P \cdot \mathrm{~A} \cdot W) /(R \cdot F \cdot S)
$$

where, $B=$ spawning stock biomass in metric tons, $\mathrm{k}=$ conversion factor from grams to metric tons, $P=$ daily egg production (number of eggs per sampling unit, $\mathrm{m}^{2}$ ), $\mathrm{A}=$ total survey area (in sampling units, $\mathrm{m}^{2}$ ), $W=$ average weight of mature females (grams), $R=\operatorname{sex}$ ratio (fraction of mature females by weight), $F=$ batch fecundity (mean number of eggs per mature females per spawning), $S=$ fraction of mature females spawning per day (spawning frequency).

### 8.43.3.1.2. Geographical distribution patterns

No analyses were conducted during SGMED-09-02.

### 8.43.3.1.3. Trends in abundance and biomass

Fishery independent information regarding the state of the anchovy stock in GSA 22 was derived from the acoustics and the DEPM surveys. Figure 8.43.3.1.3.1 displays the estimated trend in anchovy Total Biomass (estimated by acoustics) and Spawning Stock Biomass (estimated by DEPM) for GSA 22. Figure 8.43.3.1.3.2 shows the estimated trend in anchovy abundance (estimated by acoustics).

Fig. 8.43.3.1.3.1 Estimated anchovy biomass indices for GSA 22, 2003-2006 and 2008.

Fig. 8.43.3.1.3.2 Estimated abundance indices for GSA 22, 2003-2006 and 2008.
An increasing trend was observed in both biomass and abundance indices (Fig. 8.43.3.1.3.1, Fig. 8.43.3.1.3.2).
8.43.3.1.4. Trends in abundance by length or age

Figure 8.43.3.1.4.1 shows the length frequency composition of the anchovy stock as derived from the acoustic surveys in GSA 22.

Fig. 8.43.3.1.4.1 Estimated changes in size compositions for GSA 22 for 2003-2006 and 2008.
The following Fig. 8.43.3.1.4.2 and Fig. 8.43.3.1.4.3 show the abundance indices by size and age of GSA 22 for 2003-2006 and 2008 based on acoustic surveys.

Fig. 8.43.3.1.4.2. Abundance indices by size for 2003-2006 and 2008.

Fig. 8.43.3.1.4.3. Abundance indices by age for 2003-2006 and 2008.

### 8.43.3.1.5. Trends in growth

No analyses were conducted during SGMED-09-02. Growth equation was supplied through DCR and it was estimated based on aggregated data collected in GSA 22 for the period 2003 to 2008.

### 8.43.3.1.6. Trends in maturity

No analyses were conducted during SGMED-09-02. Maturity ogive based on the results of the DEPM surveys was used (Table 8.43.3.1.6.1).

Tab. 8.43.3.1.6.1. Maturity ogive for anchovy in GSA 22 based on the results of DEPM surveys.

| Age |  | 2003 | 2004 | 2005 | 2006 | 20108 |

|  | 4 | 1 | 1 | 1 | 1 | 1 |

### 8.43.4 Assessment of historic stock parameters

8.43.4.1.Method: ICA

### 8.43.4.1.1. Justification

Integrated Catch at Age (ICA) analysis for stock assessment (Patterson and Melvin, 1998) was applied. Integrated Catch at age analysis uses separable virtual population analysis (VPA) (Pope \& Shepherd, 1985)
with weighted tuning indices. It was applied regarding the Aegean anchovy stock during the SGMED-09-02 as an update of the one adapted in the SGMED-08-04 report (Cardinale et al., 2008). This assessment of the anchovy stock in GSA22 is based on a short time series of available, so results should be considered with caution. In addition Y/R analysis was applied during the SGMED-09-02.

### 8.43.4.1.2. Input parameters

ICA was based on commercial catch data (2000-2008). Biomass estimates from acoustic surveys over the period 2003-2006 and 2008 and Daily Egg Production Method (DEPM) estimates were used as tuning indices. Anchovy data concerned annual anchovy landings, annual anchovy catch at age data (2000-2008), mean weights at age, maturity at age and the results of acoustic and DEPM surveys (2003-2006 and 2008) presented in Tables 8.43.4.1.2.1 to 8.43.4.1.2.7. Age-Length-Key was applied on a six month basis to convert length distribution into age distribution. In addition discards were taken into account. Specifically, according to data obtained within the framework of the Hellenic Centre for Marine Research data collection system that covers the entire GSA 22, discards are estimated to less than $1 \%$, consisting $0.06 \%$ of the purse seine fishery total catch. Although considered negligible they were taken into account for the assessment as a percentage to reported landings.

Since, acoustics and DEPM are being applied at the same time and with the same research vessel in Aegean Sea, acoustic estimates were used as an index for the numbers at age of the population and DEPM estimates as stock spawning biomass estimates. Reference age for the fishery was age group 2, as fully exploited and fully recruited. Eight years separability was selected.The age groups 0,4 and 5 were underweighted in the analysis based on their percentage in the catch. Age 1 was also underweighted in the acoustic surveys ( 0.5 ). Catchability for the DEPM index is assumed as absolute indicator of Biomass, linear catchability relationship is assumed for the acoustic surveys. Different natural mortality values were applied per age group but constant for all years based on ProBiom (Abella et al., 1997) as recommended in the report of the SGECA/RST/MED 09-01. This method for estimating natural mortality is consistent with the methodology used in GSAs 05,06 and 17 for small pelagics. Average values of maturity ogive and weight at age in the stock were used for 2007.

### 8.43.4.1.3. Results including sensitivity analyses

The graphical diagnostics of the model shown in Figs. 8.43.4.1.3.1 to 8.43.4.1.3.5, generally showed good model fit besides year 2002 and age 4, probably because they are poorly sampled. This further justifies the down weighting of age 4 in the model. Residual plots for recent years showed no strong deviations from separability. SSQ plot (Fig. 8.43.4.1.3.6) indicated moderate consistency between the model and the indices (minima fairly close to each other on x-axis, Needle (2000)).

Fig. 8.43.4.1.3.5 The catch at age residuals plots for catch of anchovy ICA model for GSA 22 (2001-2008).

Fig. 8.43.4.1.3.6 Sum of Squares (SSQ) surface plot of the Anchovy ICA Model.

ICA model results for anchovy stock in GSA 22 are shown in Fig. 8.43.4.1.3.7, indicating an increasing trend for recruitment since 2004 with a pronounced increase for 2008. However this is probably an overestimation of the last year as the model predicts a decrease at the level of 2006 for 2009. An increase in biomass has also been observed since 2005. Average fishing mortality for ages 1 to 3 (which are target ages for the fishery) shows a decrease since 2004. The landings to total biomass ratio also decreases, approximating on average less than $10 \%$ based on model results in 2008. Similarly, the landings to SSB ratio also decreases, approximating on average $40 \%$ based on model results in 2008.

Fig. 8.43.4.1.3.7 Anchovy ICA Model results: Recruitment, SSB, Total biomass, exploitation rate (F/Z), F mean for ages 1-3, landings to biomass ratio.

Retrospective analysis was applied in the ICA model for the Aegean anchovy 2000-2008 with one year backward analysis. Applying the analysis with more than one year backward was not possible due to the short time series available. Results are presented in Fig. 8.43.4.1.3.8, showing no particular retrospective bias and consistency in the beginning of the time series.

Fig. 8.43.4.1.3.8 The results of retrospective analysis in the Aegean Sea anchovy ICA model 2000-2008, concerning F mean 1-3, SSB and recruitment.

### 8.43.5. Long term prediction

### 8.43.5.1.Justification

Yield per recruit analysis was conducted in the SGMED-09-02 assuming equilibrium conditions.

### 8.43.5.2.Input parameters

Yield per recruit analyses was conducted based on the exploitation pattern resulting from the ICA model and population parameters, Minimum and maximum age for the analysis were considered to be age group 0 and 4, respectively. Stock weight at age, catch weight at age and maturity ogive were estimated as mean values on a long term basis (2000-2008). Different natural mortality values were applied per age group but constant for all years based on ProBiom (Abella et al., 1997) as recommended in the report of the SG-

ECA/RST/MED 09-01. Fishing mortalities were estimated in a short term basis (2004-2008). Reference F was considered to be mean $F$ for ages 1 to 3. Input parameters are shown in Table 8.43.5.2.1.

Tab. 8.43.5.2.1. Input parameters for $\mathrm{Y} / \mathrm{R}$ analysis.

| age group | stock <br> weight | catch <br> weight | maturity | F | M |
| :--- | :--- | :--- | :--- | :--- | :--- |
| 0 | 0,003 | 0,008 | 0 | 0,0011 | 1,50 |
| 1 | 0,005 | 0,014 | 0.51 | 0,1561 | 1,00 |
| 2 | 0,016 | 0,016 | 0.98 | 0,0291 | 0,74 |
| 3 | 0,021 | 0,017 | 1 | 0,4169 | 0,66 |
| 4 | 0,025 | 0,028 | 1 | 0,3744 | 0,62 |

8.43.5.3.Results

Y/R analyses were performed (Fig. 8.43.5.3.1) but were not considered reliable due to its flat-topped shape. Therefore, $\mathrm{F}_{0.1}(1.44)$ cannot be used as a reference point for this stock.

Fig. 8.43.5.3.1. Yield per recruit for the anchovy stock in GSA 22.

### 8.43.6. $\quad$ Scientific advice

### 8.43.6.1.Short term considerations

### 8.43.6.1.1. State of the spawning stock size

Estimates of fishery independent surveys for anchovy in GSA 22 indicated a slight increase from lower levels in 2005 to the most recent estimates in 2006 and 2008 concerning both Total Biomass $(62,604 \mathrm{t}$ in 2006 and $60,600 \mathrm{t}$ estimated by acoustics) and SSB (48,700 tin 2006 and 37,400 in 2008 t estimated by DEPM). Similarly, results of the Integrated Catch at Age analysis indicated an increasing trend in total biomass and in SSB showing an increase in 2008 from the lower level observed in 2005. The state of the spawning biomass in relation to precautionary limits cannot be evaluated since there are no reference points
derived form the short series of data available. However the level of anchovy SSB in 2008 is well above the lowest SSB level (in 2005) observed.

It should be considered that this assessment is based on a short time series of data and not suitable to suggest reference points of $\mathrm{B}_{\mathrm{lim}}$. Moreover, anchovy is a short lived species characterized by high fluctuations in abundance and recruitment strongly depends on environmental conditions.

### 8.43.6.1.2. State of recruitment

ICA model estimates had shown an increase in the number of recruits towards 2008. However the model predicts a decrease in 2009, similar to the 2006 level.

### 8.43.6.1.3. State of exploitation

Based on ICA results, the mean F (for ages 1 to 3) showed a decrease since 2003 with mean for 2000-2008 equal to 0.33 and, since 2004, is being well below the exploitation reference points ( $\mathrm{E}<0.4$, Patterson (1992)) suggested by SGMED as an appropriate target reference for small pelagics.

Furthermore, due to the high values of natural mortality used, Y/R analysis indicated no significant reduction in SSB at high values of F . Therefore the use of $\mathrm{F}_{\max }$ and $\mathrm{F}_{0.1}$ as a reference point was not considered appropriate. Precautionary the use of $\mathrm{F}_{(\mathrm{E} 0.4)}$ that assures exploitation rate below the empirical level for stock decline ( $\mathrm{E}<0.4$, Patterson (1992)) for small pelagics was suggested by the SGMED-09-02 as exploitation reference point for this stock.

Based on this assessment results the stock is considered to be harvested sustainably, operating below but close to an optimal yield level, with no expected room for further increase in catch and effort. SGMED recommends that fishing effort should not increase beyond the current levels and consistent catches should be determined. This should allow maintaining the current levels of fishing mortality. However this has to be confirmed in following years and the anchovy stock should be monitored on an annual basis. Mixed fisheries implications, i.e. the interaction with sardine, need to be considered when managing this fishery.

For precautionary reasons the possibility of changing the closed period should be examined. Since the fishery is considered a multispecies targeting both anchovy and sardine, a shift of the closed period (present: mid December to end of February) towards the recruitment period of anchovy (e.g. October to December) / or the recruitment period of sardine (e.g. February to April) could be suggested allowing more individuals of anchovy and/or sardine to enter the fishery at an older age.

### 8.44. Stock assessment of sardine in GSA 16

### 8.44.1. Stock identification and biological features

### 8.44.1.1.Stock Identification

This assessment of the sardine stock in GSA 16 is mainly based on information collected over the last decade relating fishery grounds off the southern Sicilian coast (GSA 16, South of Sicily), and specifically on biomass estimates obtained by hydroacoustic surveys and catch-effort data from local small pelagic fisheries. The main distribution area of the sardine stock in GSA 16 is the narrow continental shelf area between Mazara del Vallo and the southernmost tip of Sicily, Cape Passero (Patti et al., 2004).

### 8.44.1.2.Growth

Growth parameters were not used for this assessement.

### 8.44.1.3.Maturity

Maturity data were not used for this assessement.

### 8.44.2. Fisheries

### 8.44.2.1.General description of fisheries

In Sciacca port, the most important base port for the landings of small pelagic fish species along the southern Sicilian coast (GSA16), accounting for about $2 / 3$ of total landings in GSA 16, two operational units (OU) are presently active, purse seiners and pelagic pair trawlers. The fleet in GSA 16 is composed by about 50 units (17 purse seiners and 30 pelagic pair trawlers were counted up in a census carried out in December 2006). In both OUs, anchovy represents the main target species due to the higher market price.
8.44.2.2. Management regulations applicable in 2008 and 2009

Fisheries policy is strongly conditioned by EU regulations through the Common Fisheries Policy (CFP), based on the following principles: protection of resources; adjustment of (structure) facilities to the available resources; market organization and definition of relationships with other countries.

The main technical measures regulating fishing concern minimum landing size ( 9 cm for anchovy, 11 cm for sardine), mesh regulations ( 20 mm for pelagic pair trawlers, 14 mm for purse seiners) and restrictions on the use of fishing gear. Towed fishing gears are not allowed in the coastal area in less than 50 m depth, or within a distance of 3 nautical miles from the coastline. A seasonal closure for trawling, generally during summerautumn, has been established since 1993. In GSA 16, the two operational units fishing for small pelagic are present, mainly based in Sciacca port: purse seiners (lampara vessels, locally known as "Ciancioli") and midwaters pair trawlers ("Volanti a coppia"). Midwaters trawlers are based in Sciacca port only, and receive a special permission from Sicilian Authorities on an annual basis. Another fleet fishing on small pelagic fish species is based in some northern Sicilian ports and targets on juvenile stages (mainly sardines). Also this fishery is allowed for a limited period (usually one or two months during the winter season) by a special Regional law renewed year by year.

### 8.44.2.3.Catches

### 8.44.2.3.1. Landings

Landings were obtained within the framework of the census data collection carried out by IAMC-CNR (Mazara del Vallo) in Sciacca port since 1998. Information collected in the framework of CA.SFO. study project (Patti et al., 2007) showed that landings in Sciacca port account for about $2 / 3$ of the total landings in GSA 16. Average sardine landings over the last decade (1997-2008) were about 1,500 metric tons, with a general decreasing trend.

It is worth noting that, though trend in biomass is clearly decreasing over the last years (Fig. 8.44.3.1.3.1.), landings levels over the same period were relatively high, indicating an increased vulnerability of the resource (Fig. 8.44.2.3.1.1).

Fig. 8.44.2.3.1.1. Landings data regarding the purse seine and pelagic pair trawl fleets in Sciacca port (GSA 16), 1998-2008.

### 8.44.2.3.2. Discards

No discards data for sardine were used for this assessment. However, discards are estimated to be less than $5 \%$ of total catch for both the pelagic pair trawl and the purse seine fisheries (Kallianiotis and Mazzola, 2002)

### 8.44.2.3.3. Fishing effort

Fishing effort data refer to census data collected in Sciacca port, the most important base port for the landings of small pelagic fish species along the southern Sicilian coast (GSA 16), accounting for about $2 / 3$ of total landings in GSA 16.

Fig. 8.44.2.3.3.1. Effort data regarding the purse seine and pelagic pair trawl fleets in Sciacca port (GSA 16), 1998-2008.

### 8.44.3. Scientific surveys

### 8.44.3.1.Acoustics

### 8.44.3.1.1. Methods

## Acoustic surveys methodology

Steps for biomass estimation

- Collection of acoustic and biological data during surveys at sea;
- Extraction of NASC Fish (Fishes Nautical Area Scattering Coeffcient $\left[\mathrm{m}^{2} / \mathrm{n} . \mathrm{mi}^{2}\right]$ ) by means of Echoview (Sonar Data) post-processing software;
- Link of NASC values to control catches;
- Calculation of Fish density $(\rho)$ from NASC Fish values and biological data;
- Production of $\rho$ distribution maps for different fish species and size classes;
- Integration of density areas for biomass estimation.

## Collection of acoustic and biological data

Since 1998 the IAMC-CNR has been collecting acoustic data for evaluating abundance and distribution pattern of small pelagic fish species (mainly anchovy and sardine) in the Strait of Sicily (GSA 16). The scientific echosounder Kongsberg Simrad EK500 was used for acquiring acoustic data until summer 2005; for the echosurvey in the period 2006-2009 the EK60 echosounder was used. In both cases the echosounder was equipped with three split beam transducers pulsing at 38,120 and 200 kHz . During the period 19982008 acoustic data were collected continuously during day and night time; since the 2009 echosurvey acoustic data are collected during day time, according to the MEDIAS protocol.

Before or after acoustic data collection a standard procedure for calibrating the three transducers was carried out by adopting the standard sphere method (Johannesson and Mitson, 1983).

Biological data were collected by a pelagic trawl net with the following characteristics: total length 78 m , horizontal mouth opening 13-15 m, vertical mouth opening 6-8 m , mesh size in the cod-end 10 mm . The net was equipped with two doors with weight 340 kg . During each trawl the monitoring system SIMRAD ITI equipped with trawl-eye and temp-depth sensors was adopted.

## Extraction of NASC $C_{\text {Fish }}$ by means of Echoview (Sonar Data) post-processing software

The evaluation of the NASC Fish (Fishes Nautical Area Scattering Coeffcient $\left[\mathrm{m}^{2} / \mathrm{n} . \mathrm{mi}^{2}\right]$ ) and the total NASC for each nautical mile of the survey track was performed by means of the SonarData Echoview software v3.50, taking into account the day and night collection periods.

## Link of NASC values to control catches

For the echo trace classification the nearest haul method was applied, taking into account only representative fishing stations along transects.

## Calculation of Fish density ( $\rho$ ) from $N A S C_{\text {Fish }}$ values and biological data

For each trawl haul the frequency distribution of the $j$-th species $\left(v_{j}\right)$ and for the $k$-th lenght class $\left(f_{j k}\right)$ are estimated as

$$
v_{j}=\frac{n_{j}}{N} \quad \text { and } \quad f_{j k}=\frac{n_{j k}}{n_{j}}
$$

where $n_{j}$ is the total number of specimens of the $j$-th species, $n_{j k}$ is the total number of specimens of the $k$-th lenght class in the $j$-th species, and $N$ is the total number of specimens in the sample.

For each nautical mile the densities for each size class and for each fish species are estimated as

$$
\begin{aligned}
& \rho_{j k}=\frac{N A S C_{F I S H} * n_{j k}}{\sum_{j=1}^{n} \sum_{k=1}^{m} n_{j k} * \sigma_{j k}} \\
& \rho_{j k}=\frac{N A S C_{F I S H} * W_{j k} * 10^{-6}}{\sum_{j=1}^{n} \sum_{k=1}^{m} n_{j k} * \sigma_{j k}} \quad\left(\mathrm{t} / \mathrm{n} . \mathrm{mi}^{2}\right. \text { ) }
\end{aligned}
$$

where $W_{j k}$ is the total weight of the $k$-th lenght class in the $j$-th species, and $\sigma_{j k}$ is the scattering cross section of the $k$-th lenght class in the $j$-th species. $\sigma_{j k}$ is given by

$$
\sigma_{s p j k}=4 \pi * 10^{\frac{T S_{j k}}{10}}
$$

where the target strenght (TS) is

$$
T S_{j k}=a_{j} \log _{10}\left(L_{k}\right)+b_{j}
$$

$L_{k}$ is the length of the $k$-th lenght class while the $a_{j}$ and $b_{j}$ coefficient are linked to the fish species.
For anchovy, sardine and trachurus we adopted respectively the following relationships:

$$
\begin{array}{ll}
T S=20 \log L_{k} 76.1 & {[d B]} \\
T S=20 \log L_{k} 70.51 & {[d B]} \\
T S=20 \log L_{k} 72 & {[d B]}
\end{array}
$$

The abundance of each species was estimated by integrating the density surfaces for each species.

### 8.44.3.1.2. Geographical distribution patterns

No analyses were conducted during SGMED-09-02.

### 8.44.3.1.3. Trends in abundance and biomass

Fishery independent information regarding the state of the sardine stock in GSA 16 was derived from the acoustics. Figure 8.44.3.1.3.1 displays the estimated trend in sardine Total Biomass (estimated by acoustics) for GSA 16.

Values of the last three years are relatively low, well below the general average value over the last decade (about 17,000 t) (Fig. 8.44.3.1.3.1).

Fig. 8.44.3.1.3.1. Estimated sardine biomass indices for GSA 16, years 1998-2008.

### 8.44.3.1.4. Trends in abundance by length or age

Length or age class data were not used for this assessment.

### 8.44.3.1.5. Trends in growth

Growth data were not used for this assessment.
8.44.3.1.6. Trends in maturity

Maturity data were not used for this assessement.

### 8.44.4. Assessment of historic stock parameters

Not applicable. No stock assessment model was run for this assessment.

### 8.44.5. Long term prediction

Not applicable. No forecast analyses were conducted.

### 8.44.6. $\quad$ Scientific advice

### 8.44.6.1.Short term considerations

### 8.44.6.1.1. State of the spawning stock size

Biomass estimates of the total population obtained by hydro-acoustic surveys for sardine in GSA 16 show that the recent stock level is well below the average value over the last decade. However, in the absence of proposed or agreed references, SGMED-09-02 is unable to fully evaluate the state of the stock and provide any scientific advice in relation to them.

### 8.44.6.1.2. State of recruitment

No recruitment data were used for this assessment.

### 8.44.6.1.3. State of exploitation

Annual exploitation rates, as estimated by the ratio between total landings and biomass, indicates relatively low fishing mortality during the last decade. If this estimate of exploitation rate can be considered as equivalent to $\mathrm{F} / \mathrm{Z}$ estimate obtained from the fitting of standard stock assessment models, the current exploitation rate ( 0.22 ) and even all the previous available estimates are lower than the reference point suggested by Patterson (1992) and confirmed by SGMED 09-02 in this report (section 6.1.3). The fishing mortality level corresponding to $\mathrm{F} / \mathrm{Z}=0.22$ is $\mathrm{F}=0.14$, if $\mathrm{M}=0.51$, estimated with Pauly (1980) empirical equation, is assumed.

Using the exploitation rate as a target reference point, the stock of sardine in GSA 16 is considered as being sustainably exploited.

Given that biomass was quite low for three consecutive years $(2006,2007$ and 2008) and that the exploitation rate of sardine is moderate, fishing effort should not be increased beyond the current levels and consistent catches should be determined. However, as the small pelagic fishery is generally multispecies, any management of fishing effort targeting the anchovy stock (see above recommendations) would also have effects on sardine. In addition, due to the low level of the anchovy stock measures should be taken to prevent a shift of effort from anchovy to sardine.

## General considerations

Taking into account that fishing effort was relatively stable in last decade, results would suggest the importance of environmental factors variability on yearly recruitment success. However, the stock did not recover from the 2006 "collapse" in biomass ( $-52 \%$ from July 2005 to June 2006), and this fact, along with a
moderate exploitation rate and the decreasing trend in landings, also suggests questioning about the sustainability of current levels of fishing effort. In addition, possible negative effects on these populations could results from pressure of other fishing gears on larval stages.

A warning on the fishing of larval stages (locally named bianchetto) is relevant, taking into account that in the past years derogation of the fishing ban was normally operated in wintertime, i.e. during the sardine spawning season, even though more data and investigation are needed in order to estimate the possible impact of this fishing activity on the exploited populations.

### 8.45. Stock assessment of sardine in GSA 17

### 8.45.1. Stock identification and biological features

### 8.45.1.1.Stock Identification

The southern boundary of the GSA 17 is represented from the Gargano Promontory, as shown in the map below. However, the stock distribution area of sardine in the Adriatic Sea extends into GSA 18. The spawning season of the Adriatic sardine is in autumn-winter. The spawning areas are mainly located in the eastern part of the GSA 17. On the basis of the database of CNR-ISMAR-SPM Fish Population Dynamics Unit, the maximum age recorded was 12 years while the maximum length was 22.0 cm .

Fig. 8.45.1.1.1 Boundaries of the GSA 17.

### 8.45.1.2.Growth

An example of age-length key expressed in number of individuals, obtained through DCR by CNR-ISMARSPM Fish Population Dynamics Unit, for the commercial catches of (Italian) mid-water trawlers in 2007, was reported in the table below.

Tab. 8.45.1.2.1 GSA 17 sardine: age-length key (year 2007, mid-water trawlers).

| L (cmin | Age 0 | Age 1 | Age? | Age 3 | Age 4 | Age 5 | Age 6 | Age 7 | Age 8 | Age 9 | Total |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 11.5 | 8 |  |  |  |  |  |  |  |  |  | 8 |
| 12.0 | 19 |  |  |  |  |  |  |  |  |  | 19 |
| 12.5 | 22 | 9 | 1 |  |  |  |  |  |  |  | 32 |
| 13.0 | 25 | 12 |  |  |  |  |  |  |  |  | 37 |
| 13.5 | 40 | 19 | 3 |  |  |  |  |  |  |  | 62 |
| 14.0 | 33 | 23 | 5 |  |  |  |  |  |  |  | 66 |
| 14.5 | 13 | 53 | 7 | 1 |  |  |  |  |  |  | 74 |
| 15.0 | 3 | 10 | 52 | 8 |  |  |  |  |  |  | 73 |
| 15.5 | 1 | 3 | 57 | 14 | 1 |  |  |  |  |  | 76 |
| 16.0 |  |  | 34 | 28 | 8 |  |  |  |  |  | 70 |
| 16.5 |  |  | 14 | 40 | 10 | 2 |  |  |  |  | 6 |
| 17.0 |  |  | 2 | 6 | 14 | 7 |  |  |  |  | 29 |
| 17.5 |  |  |  | 2 | 12 | 9 | 1 |  |  |  | 24 |
| 18.0 |  |  |  |  |  | 1 | 3 | 2 |  |  | 6 |
| 18.5 |  |  |  |  | 1 | 1 | 1 | 3 | 1 | 1 | 8 |
| 19.0 |  |  |  |  |  |  |  | 1 |  | 1 | 2 |
| 19.5 |  |  |  |  | 1 |  |  |  |  |  | 1 |
| Total | 164 | 134 | 175 | 99 | 47 | 30 | 5 | 6 | 1 | 2 | 653 |

The corresponding age-length key obtained for the commercial catches of purse-seiners was reported below. Different length ranges as a function of the gear were observed: the smallest size individuals can be better represented in the catch of mid-water trawlers. However, such a difference is more typical for anchovy than sardine.

Tab. 8.45.1.2.2 GSA 17 sardine: age-length key (year 2007, mid-water trawlers).

| L (cmi) | Age 1 | Age 2 | $A_{\text {g }} 3$ | Age 4 | Age 5 | Age 6 | Age 7 | Age 8 | Total |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 14.0 | 3 |  |  |  |  |  |  |  | 3 |
| 14.5 | 3 |  |  |  |  |  |  |  | 3 |
| 150 | 1 | 5 |  |  |  |  |  |  | 6 |
| 15.5 |  | 4 | 1 |  |  |  |  |  | 5 |
| 16.0 |  | 1 | 5 |  |  |  |  |  | E |
| 16.5 |  |  | 1 | 2 | 1 |  |  |  | 4 |
| 17.0 |  |  | 2 |  | 1 |  |  |  | 3 |
| 17.5 |  |  |  | 2 | 2 |  |  |  | 4 |
| 18.0 |  |  |  | 1 |  | 1 | 1 | 1 | 4 |
| 18.5 |  |  |  |  | 1 | 1 | 1 |  | 3 |
| 19.0 |  |  |  |  | 1 | 1 | 1 |  | 3 |
| 19.5 |  |  |  |  |  | 1 | 1 | 1 | 3 |
| Total | 7 | 10 | 9 | 5 | 6 | 4 | 4 | 2 | 47 |

8.45.1.3.Maturity

According to Sinovčić et al. (2003), the first sexual maturity of sardine in Krka River estuary, in the eastern Adriatic Sea, is around 8 cm . Also, Sinovčić (1984) mentioned a study from literature reporting 14 cm .

### 8.45.2. Fisheries

### 8.45.2.1.General description of fisheries

In the GSA 17, sardine is fished by mid-water trawlers and purse seiners attracting fish with light. Additional information was reported below in the paragraph "Catches".
8.45.2.2. Management regulations applicable in 2008 and 2009

In Italy, the legal minimum length for sardine is 11 cm (R.(CE) 1967/2006). The value 10 cm has been adopted in Croatia (G. Sinovčić, Institute of Oceanography and Fisheries of Split, personal communication).

### 8.45.2.3.Catches

### 8.45.2.3.1. Landings

On the basis of the database of CNR-ISMAR-SPM Fish Population Dynamics Unit, the amount of the total catch of sardine relative to Italy, Slovenia and Croatia was plotted over years in Fig. 8.45.2.3.1.1. The average total catch was 44,000 tonnes in 1975-2007 and 17,000 tonnes in 2005-2007. A decrease was observed after the peak in the middle of 1980s, particularly in the Italian catches. The fractions of the total catch due to the fleets of the Italy and Slovenia-Croatia were quite similar, but the latter one accounted for higher fractions in recent years.

Fig. 8.45.2.3.1.1 GSA 17 sardine: total catch over years.
The average length frequency distribution and the average age frequency distribution of the total catch were shown in Fig. 8.45.2.3.1.2 and Fig. 8.45.2.3.1.3. The average for length was calculated including only the years from 1988 onwards as, since 1988 length was measured using 0.5 cm classes, whereas 1 cm classes were used before. A comment relative to the different length range fished by mid-water trawlers and purse seiners was reported above, in the paragraph "Growth".

Fig. 8.45.2.3.1.2 GSA 17 sardine: average length frequency distribution of the total catch.

Fig. 8.45.2.3.1.3 GSA 17 sardine: average age frequency distribution of the total catch.

### 8.45.2.3.2. Discards

This feature was investigated by CNR-ISMAR-SPM Fish Population Dynamics Unit, through an EU funded project at the end of 1990s (Santojanni et al., 2005) and DCR in 2005.

Discards of sardine in the GSA 17, at least for the Italian fleet, were not considered as negligible in 19871999 and landings were corrected by adding amounts of smallest size sardine ranging from 1,000 to 4,000 tonnes; in fact, for the Italian fleet, this species is required at a lower degree than anchovy.

On the basis of the DCR investigation, the amount of sardine discarded at sea by the Italian fleet was 126 tonnes and 11 tonnes in the third and fourth quarter of 2005, respectively. These quantities were low in comparison with the corresponding landings: from 2000 to 2007, the annual amount of sardine landed by the Italian fleet ranged from 2,000 to 11,000 tonnes. Moreover, it is possible that, due the lower availability of sardine at sea, the proportion of the discarded catch in recent years was lower than in 1987-1999. In conclusion, the estimates of discards obtained for only one half of 2005 was considered negligible and fluctuating during the year and thus those were not included in the estimation of total catches.

### 8.45.2.3.3. Fishing effort

On the basis of the database of CNR-ISMAR-SPM Fish Population Dynamics Unit, in the calendar year 2007, the Italian fleet was composed of about 130 ( 65 pairs) pelagic trawlers (volante), mainly operating from Trieste (extreme north harbour) to Ancona (average GRT 43, average engine power 290 kW ) and about 45 purse seiners attracting fish with light (lampara), operating in the Gulf of Trieste ( 24 small lampara, average GRT 9, average engine power 110 kW ) and south of Ancona ( 21 big lampara, average GRT 97, average engine power 390 kW ). In 2007, the Slovenian fleet was composed of 1 pelagic trawler pair and 7 purse seiners; no updated data are available for the Croatian fleet.

### 8.45.3. Scientific surveys

As mentioned below in the paragraph "Method", the results of the acoustic surveys carried out by CNR-ISMAR-SPM Marine Acoustics Unit from the mid-line to the western coast of the GSA 17, from 1976 to 2007, were used for VPA tuning.

### 8.45.3.1.1. Trends in growth

No analyses were conducted during SGMED-09-02.

### 8.45.3.1.2. Trends in maturity

No analyses were conducted during SGMED-09-02.

### 8.45.4 Assessment of historic stock parameters

8.45.4.1.Method 1: VPA

### 8.45.4.1.1. Justification

Given the long time series available, VPA was thought to be a suitable method.

### 8.45.4.1.2. Input parameters

A time series of annual total catch at age in numbers of individuals is the main data input of VPA. It is shown (expressed using proportions) in Fig. 8.45.4.1.2.1. The age class $6+$ is a plusgroup: it includes the class 6 (years) along with those classes higher than 6 , thus up to 12 in the present case.

Fig. 8.45.4.1.2.1 GSA 17 sardine: total catch at age over years.
The annual natural mortality rates $\mathrm{M}=0.5$ (year ${ }^{-1}$ ) was employed for VPA calculations.
This value was selected taking into account the literature and the maximum life-span observed in the commercial catches from 1975 onwards, i.e. higher even than 8 years.

About the inverse relationship between longevity and mortality, as reported by Barange (2001), Pacific sardine (Sardinops sagax) is usually assumed to have a relatively low annual natural mortality rate, M $=0.4$, and a lifespan of about 10 years, whereas for northern anchovy (Engraulis mordax) M $=0.8$ is associated to a lifespan of about 4 years.

Moreover, useful information was gained from the relationship between total mortality $\mathrm{Z}(=\mathrm{F}+\mathrm{M})$ and maximum life span tmax (year), Ln Z = 1.44-0.982 Ln tmax , found by Hoenig (1983; see also Hewitt and Hoenig, 2005). It was "based largely on data from unexploited stocks", thus with Z being very close to M . On the basis of this equation, for example (Tab. 8.45.4.1.2.1), $\operatorname{tmax}=8$ is associated to $\mathrm{Z}=0.55$.

Tab. 8.45.4.1.2.1 Relationship between total mortality rate Z and maximum life-span tmax (see text).

| tmax (year) | $\mathrm{Z}\left(\right.$ year ${ }^{\mathbf{1}}$ ) |
| :---: | :---: |
| 1 | 4.22 |
| 2 | 2.14 |
| 3 | 1.43 |
| 4 | 1.08 |
| 5 | 0.87 |
| 6 | 0.73 |
| 7 | 0.62 |
| 8 | 0.55 |
| 9 | 0.49 |
| 10 | 0.44 |
| 11 | 0.40 |
| 12 | 0.37 |
| 13 | 0.34 |
| 14 | 0.32 |
| 15 | 0.30 |
| 16 | 0.28 |
| 17 | 0.26 |
| 18 | 0.25 |
| 19 | 0.23 |
| 20 | 0.22 |

### 8.45.4.1.3. Results

The stock biomass estimated by means of VPA was plotted over years in Fig. 8.45.4.1.3.1, along with the total catch.

The average stock biomass estimated by VPA was 440,000 tonnes in 1975-2007 and 90,000 tonnes in 20052007. The corresponding average ratio between total catch and stock biomass was 0.10 in 1975-2007 and 0.19 in 2005-2007.

A strong decline of stock biomass occurred after the peak in the first half of 1980s; this decline was continuous till the end of 1990s: then, biomass was quite stable around values slightly lower than 100,000 tonnes, which corresponded to the lowest abundance of the series.

In the same picture, the stock biomass estimated by means of the echo-surveys carried out in the western part of the GSA 17 was reported: also this series showed (most of) the lowest values after the end of 1990s.

Fig. 8.45.4.1.3.1 GSA 17 sardine: total catch and stock biomass estimated by VPA (entire GSA 17) and echo-surveys (western part of GSA 17) over years.

The relationship between spawning stock biomass and number of recruits (age class 0 ) obtained from VPA was plotted in Fig. 8.45.4.1.3.2. The values of current spawning stock biomass were the lowest of the series as well as the recruitment level.

Fig. 8.45.4.1.3.2 GSA 17 sardine: stock-recruitment relationship.
The fishing mortality rate F derived from VPA was plotted over ages and years in Fig. 8.45.4.1.3.3 (left and right picture, respectively). In the former case, the average for the complete time series was calculated. In the latter case, two averages were calculated both weighting and without weighting the F at age values on the corresponding numbers of fish at sea.

Some average values over years were the following:

- unweighted F0-5 in 1975-2007 : 0.27;
- unweighted F0-5 in 2005-2007 : 0.48;
- weighted F0-6 in 1975-2007: 0.12;
- weighted F0-6 in 2005-2007: 0.17.

Fig. 8.45.4.1.3.3 GSA 17 sardine: fishing mortality rate F over ages and years.
The annual exploitation rate $\mathrm{E}=\mathrm{F} /(\mathrm{F}+\mathrm{M})$ or $\mathrm{F} / \mathrm{Z}$ was also calculated, both using the weighted and unweighted Fs mentioned above.

The values obtained were compared with the threshold $\mathrm{F} / \mathrm{Z}=0.4$ (biological reference point), above which the stock collapse should be relatively likely, as pointed out by Patterson (1992) for small pelagics. Here,
more emphasis was given to the $\mathrm{F} / \mathrm{Z}$ calculated using unweighted Fs, as the same author performed his statistical analysis on a data set mainly formed by unweighted Fs.

The values of $\mathrm{F} / \mathrm{Z}$ were plotted over years in the figure below. Some average values over time were the following:

- F/Z in 1975-2007 with unweighted F0-5: 0.32;
- F/Z in 2005-2007 with unweighted F0-5: 0.48;
- F/Z in 1975-2007 with weighted F0-6: 0.19;
- F/Z in 2005-2007 with weighted F0-6: 0.25.

Hence, in 2005-2007, the value of F/Z based on F0-5 unweighted was estimated to be higher than 0.4 and close to 0.5 ( 0.48 ), which is the highest and more dangerous limit pointed by Patterson (1992). When the unweighted F1-3 was used instead of F0-5, F/Z in 2005-2007 was still higher than 0.4 (0.42).

Fig. 8.45.4.1.3.4 GSA 17 sardine: exploitation rate $F / Z$ over years.
In 2009, VPA was also carried out using vectors of natural mortality rate at age, i.e. not constant over age as in the stock assessment of 2008. They were derived from Probiom software and Gislason's method, according to the first SGMED meeting of 2009 (Tab. 8.45.4.1.3.1). The values of von Bertalanffy parameters $\operatorname{Linf}=18.783, \mathrm{k}=0.379, \mathrm{t} 0=-2.302$ and length-weight parameters $\mathrm{a}=0.0095, \mathrm{~b}=2.94$ were used for the calculations of the $M$ at age vectors and were derived from DCR (biological sampling of landing data, GSA 17, year 2007).

Some limits of the use of these $M$ at age vectors are worth noting: with Probiom, values for oldest age classes seem to be quite low and thus not very realistic (e.g. 0.25 for age classes $4-6+$ ); Gislason's should be preferably used for demersal species rather small pelagics.

The new results obtained were compared with those based on the use of constant $\mathrm{M}=0.5$.

Substantial differences in stock biomass estimated by VPA between the three series were observed at the higher levels of biomass observed in the past (Fig. 8.45.4.1.3.5). These differences were less relevant for recent years (Fig. 8.45.4.1.3.5 and Tab. 8.45.4.1.3.2). On the whole, the results obtained with constant M and Gislason's vector were more similar. This was also true for the exploitation rate, particularly in recent years (Fig. 8.45.4.1.3.6). Stock recruitment relationships were also compared (Fig. 8.45.4.1.3.7 and Fig. 8.45.4.1.3.8). Finally, ratios between recruits and spawners were also shown over years (Fig. 8.45.4.1.3.9).

Tab. 8.45.4.1.3.1 - Values of natural mortality at age used.

| Age | Constant | Probiom | Gislason |
| :---: | :---: | :---: | :---: |
| 0 | 0.50 | 0.71 | 0.75 |
| 1 | 0.50 | 0.47 | 0.68 |
| 2 | 0.50 | 0.32 | 0.58 |
| 3 | 0.50 | 0.28 | 0.53 |
| 4 | 0.50 | 0.25 | 0.49 |
| 5 | 0.50 | 0.25 | 0.47 |
| $6+$ | 0.50 | 0.25 | 0.43 |

Fig. 8.45.4.1.3.5 Stock biomass estimated by VPA with constant M at age ( 0.5 as in the stock assessment performed in 2008) and $M$ at age vectors obtained by means of Probiom software and Gislason's method.

Tab. 8.45.4.1.3.2 Average values of estimated stock biomass (tonnes) using different values of M at age.

| Period | Constant | Frobiom | Gislasoni |
| :---: | :---: | :---: | :---: |
| $1999-2007$ | 84000 | 67000 | 103000 |
| $2005-2007$ | 91000 | 71000 | 113000 |

Fig. 8.45.4.1.3.6 Exploitation rate estimated by VPA with constant M at age ( 0.5 as in the stock assessment performed in 2008) and M at age vectors obtained by means of Probiom software and Gislason's method.

Fig. 8.45.4.1.3.7 Stock-recruitment relationship from VPA with constant M at age ( 0.5 as in the stock assessment performed in 2008). The years from 1976 to 2007 displayed are relative to the recruitment.

Fig. 8.45.4.1.3.8 Stock-recruitment relationships from VPA with M at age vectors, obtained by Probiom and Gislason's methods. The years from 1976 to 2007 displayed are relative to the recruitment.

Fig. 8.45.4.1.3.9 Stock biomass (TSB) and spawning biomass (SSB) are compared with ratios between recruits and spawning biomass over years, on the basis of VPA with constant M at age ( 0.5 as in the stock assessment performed in 2008).

### 8.45.5. Long term prediction

### 8.45.5.1.Justification

No forecast analyses were conducted.

### 8.45.5.2.Input parameters

No forecast analyses were conducted.

### 8.45.5.3.Results

Given the preliminary state of the data and analyses SGMED-09-02 is not in the position to provide a long term prediction of catch and stock biomass for sardine in GSA 17.
8.45.6. Scientific advice
8.45.6.1.Short term considerations

### 8.45.6.1.1. State of the spawning stock size

SGMED 09-02 bases its recommendations regarding the proposed biomass reference points of $\mathrm{B}_{\mathrm{lim}}=50,000 \mathrm{t}$ and $\mathrm{B}_{\mathrm{pa}}=300,000 \mathrm{t}$ on a revised stock assessment taking into consideration natural mortality rates as recommended by the Murcia SGMED workshop 2-6 March 2009 (Probiom model results). The visual inspection of the scatter plot of recruitment versus spawning stock biomass clearly indicates that recruitment is impaired at stock sizes below $180,000 \mathrm{t}$. Thus, SGMED recommends establishing $\mathrm{B}_{\mathrm{lim}}=180,000 \mathrm{t}$ for the stock of sardine in GSA 17.

According to FAO recommendations (Cadima, 2003), $\mathrm{B}_{\mathrm{pa}}$ should be in the range of $1.39 * \mathrm{~B}_{\mathrm{lim}}-1.64 * \mathrm{~B}_{\mathrm{lim}}$, accounting for uncertainty in the estimations of fishing mortality. Such factors would determine $B_{p a}$ being in the range of $250,000 \mathrm{t}-295,000 \mathrm{t}$. Thus, SGMED-09-02 recommends establishing $\mathrm{B}_{\mathrm{pa}}=270,000 \mathrm{t}$ for the stock of sardine in GSA 17.

Since 2000, SGMED 09-02 estimates of SSB remained significant below $\mathrm{B}_{\mathrm{lim}}$. In 2007, SSB was estimated to amount to less than $100,000 \mathrm{t}$. SGMED 09-02 therefore recommends recovering the stock biomass in order to increase stock productivity.

### 8.45.6.1.2. State of recruitment

Since the mid 1995, recruitment remained significantly below the average recruitment.

### 8.45.6.1.3. State of exploitation

SGMED-09-02 concludes that the short term responses of the assessed sardine stock to recent exploitation rates indicate that an exploitation rate in the order of $\mathrm{E} \leq 0.4$ might be consistent with the management goal of high long term yields, taking into account the dynamic of the stocks of small pelagics. SGMED-09-02 underlines that limited area and temporal coverage of the available stock assessments impede any quantification of risk related to this statement. As such, the expressed indication regarding Mediterranean small pelagic stocks is in agreement with empirical findings of Patterson (1992), who has proposed this exploitation level. SGMED-09-02 recommends the application of the proposed exploitation rate $\mathrm{E} \leq 0.4$ as management target for stocks of anchovy and sardine in the Mediterranean Sea.

SGMED 09-02 considers the stock of sardine to be over-exploited, as the estimated $\mathrm{E}>0.4$. Fishing mortality should be reduced in order to allow future recruitment contributing to stock recovery. In order to decrease the fishing mortality, SGMED 09-02 advises to reduce fishing effort by means of a multiannual management plan and consistent catches should be determined. The management of the sardine fisheries in GSA 17 needs to account for multi-species effects, mainly the interaction with anchovy.

### 8.46. Stock assessment of sardine in GSA 22

### 8.46.1. Stock identification and biological features

### 8.46.1.1.Stock Identification

This assessment of the sardine stock in GSA 22 has been based on information derived from the Greek part of the Aegean Sea (GSA 22). In Aegean Sea, the main distribution area of the sardine stock of GSA 22 is located in the continental shelf of the northern Aegean Sea (Giannoulaki et al., 2004; 2007; Machias et al., 2007; Tsagarakis et al., 2008). Sardine juveniles spatial distribution is strongly related to semi closed gulfs, shallow waters (less than 30 m depth) with high productivity, influenced by the presence of rivers outflows (Tsagarakis et al., 2007; SARDONE project interim report).

### 8.46.1.2.Growth

Fast growth parameter was considered and parameters are shown in Table 8.46.1.2.1. No sex discrimination was applied.

Tab. 8.46.1.2.1. Growth parameters (v. Bertalanffy) for sardine in GSA 22.

|  | Fast growth <br> Unsexed | Units |
| :--- | :---: | :--- |
| Linf | 195 | Cmi |
| K | 0.39 | year $^{-1}$ |
| t.0 | -0.48 | year |
| a | 0.00003 | gr |
| b | 3.2144 |  |
| Mage0 | 1.5 | year $^{-1}$ |
| Mage1 | 0.96 | year $^{-1}$ |
| Mage2 | 0.69 | Year $^{-1}$ |
| Mage3 | 0.61 | Year $^{-1}$ |
| Mage4 | 0.57 | year $^{-1}$ |

### 8.46.1.3.Maturity

The following maturity at age ogive was used for sardine assessments in GSA 22 as estimated from biological sampling based on length at first maturity estimated approximately at 115 mm (Machias et al., 2001 ; 2007) in Aegean Sea. The sardine spawning period in GSA 22 extends from November to April with a peak in December-January.

Tab. 8.46.1.3.1 Maturity ogives at age for female sardine in GSA 22.

| Year | Age 0 | Age 1 | Age 2 | Age 3 | Age 4 |
| :---: | :--- | :--- | :--- | :--- | :--- |
| 2003 | 0 | 0.5 | 1 | 1 | 1 |
| 2004 | 0 | 0.5 | 1 | 1 | 1 |
| 2005 | 0 | 0.5 | 1 | 1 | 1 |
| 2006 | 0 | 0.5 | 1 | 1 | 1 |
| 2007 | 0 | 0.5 | 1 | 1 | 1 |
| 2008 | 0 | 0.5 | 1 | 1 | 1 |

8.46.2. Fisheries

Sardine (Sardina pilchardus) is one of the most important target species for the purse seine fishery in GSA 22. Sardine is being exploited only by the purse seine fishery. Pelagic trawls are banned and benthic trawls are allowed to fish small pelagics in percentages less than $5 \%$ of their total catch. Commonly sardine is caught from shallow waters about 30 m to 100 m depth.
8.46.2.2. Management regulations applicable in 2008 and 2009

Regarding the management regulations enforced they concern a closed period from the mid December till the end of February and technical measures such as minimum distance from shore ( 300 m ), minimum bottom depth ( 30 m ), gear and mesh size, engine, GRT restrictions etc. There is also a minimum landing size at 11 cm .

### 8.46.2.3.Catches

Landings were obtained within the framework of the Hellenic Centre for Marine Research data collection system that covers the entire GSA 22. The data from 2003 to 2008 were reported to SGMED-09-02 through the Data Collection Regulation and are listed in Table A3.4 of Appendix 3.

### 8.46.2.3.1. Landings

The trend in reported landings (from Greek purse seiners fleet) is shown in Figs. 8.46.2.3.1.1 and 8.46.2.3.1.2. The data from 2003 to 2006 and 2008 were reported to SGMED-09-02 through the Data Collection Regulation and are listed in Table A3.5 of Appendix 3. The rest of the data are obtained within the framework of the Hellenic Centre for Marine Research data collection system that covers the entire GSA 22. A decreasing trend in sardine landings has been observed in the long term (2000-2008). Landings per vessel class indicate that small vessels (12-24 m) (Fig. 8.46.2.3.1.2) are mainly responsible for sardine catches ( $>88 \%$ of the total catches).

Annual lengths of landings were reported to SGMED-09-02 for 2003-2006 and 2008 and are shown in Fig. 8.46.2.3.1.3. Fig. 8.46.2.3.1.4 shows the landings at age in GSA 22 as reported to SGMED-08-04 for 20032006. Data for 2007 and 2008 are based on unreported data obtained within the framework of the Hellenic Centre for Marine Research data collection system that covers the entire GSA 22.

Fig. 8.46.2.3.1.1 Sardine landings (t) in GSA 22 for 2000-2008.

Fig. 8.46.2.3.1.2 Sardine landings (t) in GSA 22 per fleet size (purse seine fleet in Greek waters) for 20032008.

Fig. 8.46.2.3.1.3 Length frequency composition of sardine landings for 2003-2008.

Fig. 8.46.2.3.1.4 Sardine landings per age group (number of individuals in thousands) for GSA 22 for 20032008.

### 8.46.2.3.2. Discards

No discards data for sardine were reported to the SGMED-09-02 and no data were reported through the Data collection regulation for 2003-2008. According to data obtained within the framework of the Hellenic Centre for Marine Research data collection system that covers the entire GSA 22, discards are estimated to less than $1 \%$, consisting $0.3 \%$ of the purse seine fishery total catch. Although considered negligible they were taken into account for the assessment as a percentage to reported landings. The fishery is multispecies and fishermen tend to avoid schools of undersized sardines due to sorting difficulties (blocking of the mesh) and low price, practically by using nets of bigger mesh size, targeting mostly mackerels or horse mackerels.

### 8.46.2.3.3. Fishing effort

Based on the fishing effort data reported through the Data collection regulation and data obtained within the framework of the Hellenic Centre for Marine Research data collection system covering the entire GSA 22, the following table was made:

Tab. 8.46.2.3.3.1 Effort data for the purse seine fleet in GSA 22 (GT=Gross tonnage, $\mathrm{KW}=$ engine power).

| Year | PS 12-24 m | PS 24-40 m | PS 12-24 m | PS 24-40 m | PS 12-24 m | PS 24-40 m |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |

### 8.46.3.1.Acoustics

### 8.46.3.1.1. Methods

## Acoustics

Based on data reported to SGMED-09-02 total biomass, abundance, length and age composition for GSA 22 were estimated by acoustics from 2003 to 2008. No age distribution data were reported through the DCR for 2008. No acoustic survey took place in 2007.

## Acoustic surveys methodology

Acoustic echoes were registered continuously along 70 pre-defined transects in northern Aegean Sea in June 2003, 2004, 2005, 2006 and 2008 with a Biosonics Split Beam 38 kHz DT-X echosounder. The acoustic methodology followed is described in Machias et al., 2007 (see GFCM 2007 related WD). Hydroacoustic data analysis was performed using the Sonardata Echoview software v3.30. Echo trace classification was applied based on a) echogram visual scrutinisation and direct allocation of school marks that characterise sardine as well as b) allocation on account of representative fishing stations that were held along transects (MacLennan and Simmonds, 1992).

In order to estimate sardine biomass, the length-weight- relationship is required as well as species length frequency distribution per area. Therefore, 22, 23, 27, 37 and 30 pelagic trawls were made along transects in 2003, 2004, 2005, 2006 an 2008 respectively, in the positions of high fish concentrations. A random sample of 200 specimens was obtained from each haul for further laboratory analysis. Subsequently, the length-weight- relationship was estimated from the total number of hauls according to the equation:

$$
\mathrm{W}=\mathrm{a} \mathrm{~L}^{\mathrm{b}}
$$

where W is the total weight; L is the total length and a and b are constants that are estimated by regression analysis.

The mean length frequency was estimated in two sub-areas: (a) Eastern area (Thracian Sea and Strymonikos Gulf) and (b) Western area (Thermaikos and Evoikos Gulfs). In the two sub-areas, the mean frequency of each length class was estimated as follows:

$$
\mathrm{f}_{\mathrm{j}}=\frac{\sum_{\mathrm{k}=1}^{\mathrm{M}}\left(\frac{\mathrm{n}_{\mathrm{jk}}}{\mathrm{t}_{\mathrm{k}}}\right)}{\sum_{\mathrm{k}=1}^{\mathrm{M}}\left(\frac{\mathrm{~N}_{\mathrm{k}}}{\mathrm{t}_{\mathrm{k}}}\right)}
$$

where $f_{j}$ is the mean frequency of sardine of length class $j ; n_{j k}$ is the number of specimens of length class $j$ in haul $k$; $N_{k}$ is the total number of sardines in haul $k$; $t_{k}$ is the duration of haul $k$ and $M$ is the number of hauls in the area. The above equation is appropriate even if the catches are small and the length distributions are poorly defined. It takes accounts of the haul duration, since it is supposed that on average, longer hauls will produce more fish (MacLennan and Simmonds 1992).

The density of targets ( F ) from the observed echo integrals were estimated according to the equation $\mathrm{F}=$ $(\mathrm{K} /\langle\sigma\rangle) \mathrm{E}$, were K is the calibration factor, $\langle\sigma\rangle$ is the mean cross-section and E is the echo integral after partitioning (MacLennan and Simmonds ,1992). The target strength (TS) - total length relationship used for sardine was: TS $=20 \operatorname{logL}-72.6$, where L is fish total length (ICES 2006). The $\langle\sigma\rangle$ was calculated for the mean total fish length of each area according to the equations $\langle\sigma\rangle=4 \pi \sum_{\mathrm{l}} \mathrm{f}_{\mathrm{i}} 10^{\mathrm{TS} / 10}$, where $\mathrm{f}_{\mathrm{I}}$ is the corresponding length frequency as deduced from the fishing samples (MacLennan and Simmonds, 1992).

The abundance Q was estimated separately for the eastern and the western part of the study area. The abundance Q in each elementary statistical sampling area was calculated from the average density within each sub-area according to the equation:

$$
\mathrm{Q}=\mathrm{A}_{\mathrm{k}} \sum_{\mathrm{i}} \mathrm{~F}_{\mathrm{i}} / \mathrm{N}_{\mathrm{k}}
$$

where $F_{i}$ is the $i$ sample; $A_{k}$ is the area of each elementary statistical sampling area and $N_{k}$ is the number of transects in $\mathrm{A}_{\mathrm{k}}$. The variance V was estimated as

$$
\mathrm{V}=\sum_{\mathrm{i}}\left(\mathrm{AF}_{\mathrm{I}}-\mathrm{Q}\right)^{2} /\left[\mathrm{N}_{\mathrm{r}}\left(\mathrm{~N}_{\mathrm{r}-1}-1\right)\right]
$$

The data were $\log$ transformed and the means and variances of F estimated according to the following equations:

$$
\mathrm{F}=\exp (\mathrm{m}) \mathbf{G}_{\mathbf{N}}\left[0.5 \mathrm{~S} /(\mathrm{n}-1) ; \mathrm{V}=\mathrm{F}^{2}-\exp (2 \mathrm{~m}) \mathbf{G}_{\mathbf{N}}\left[\mathrm{S}(\mathrm{n}-2) /(\mathrm{n}-1)^{2}\right] ;\right.
$$

where $m=$ average $(\operatorname{lnF}) ; S=$ variance $(\operatorname{lnF})$ and $n=$ independent observations of $F$.
The total abundance $Q_{t}$ and its variance were obtained by summing the results for each region $Q_{1}=Q_{1}+Q_{2}+\ldots$ , and $\mathrm{V}_{\mathrm{t}}=\mathrm{V}_{1}+\mathrm{V}_{2}+\ldots$. Standard error of $\mathrm{Q}_{\mathrm{t}}$ is the square root of V (MacLennan and Simmonds 1992).

### 8.46.3.1.2. Geographical distribution patterns

No analyses were conducted during SGMED-09-02.

### 8.46.3.1.3. Trends in abundance and biomass

Fishery independent information regarding the state of the sardine stock in GSA 22 was derived from the acoustics surveys. Figure 8.46 .3 .1 .3 .1 shows the estimated trend in sardine Total Biomass (estimated by acoustics) for GSA 22. Figure 8.46.3.1.3.2 shows the estimated trend in sardine abundance (estimated by acoustics).

Fig. 8.46.3.1.3.1 Estimated sardine biomass indices for GSA 22, 2003-2006 and 2008.

Fig. 8.46.3.1.3.2 Estimated sardine abundance indices from acoustic surveys for GSA 22, 2003-2006 and 2008.

An increasing trend was observed in both biomass and abundance indices since 2005 based on acoustic surveys estimates (Fig. 8.46.3.1.3.1, Fig. 8.46.3.1.3.2).

### 8.46.3.1.4. Trends in abundance by length or age

Figure 8.46.3.1.4.1 displays the length frequency composition of the sardine stock as derived from the acoustic survey for GSA 22.

Fig. 8.46.3.1.4.1 Estimated changes in size compositions for GSA 22 for 2003-2006 and 2008.
Fig. 8.46.3.1.4.2 and Fig. 8.46.3.1.4.3 show the abundance indices by size and age of GSA 22 in 2003-2006 and 2008 as derived from acoustic surveys.

Fig. 8.46.3.1.4.2. Abundance indices by size for sardine in GSA 22 based on acoustic surveys for 2003-2006 and 2008.

Fig. 8.46.3.1.4.3. Abundance indices by age for sardine in GSA 22 based on acoustic surveys for 2003-2006 and 2008.

### 8.46.3.1.5. Trends in growth

No analyses were conducted during SGMED-09-02. Growth equation was supplied through DCR and it was estimated based on aggregated data collected in GSA22 for the period 2003 to 2008.

### 8.46.3.1.6. Trends in maturity

No analyses were conducted during SGMED-09-02. Maturity ogive based on biological sampling and length at first maturity estimates were used (Tab. 8.46.3.1.6.1).

Tab. 8.46.3.1.6.1. Maturity ogive for sardine in GSA 22.

| Age | 200.3 | 2004 | 200.5 | 2006 | 2007 | 2008 |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| 2 | 1 | 1 | 1 | 1 | 1 | 1 |
| 3 | 1 | 1 | 1 | 1 | 1 | 1 |
| 4 | 1 | 1 | 1 | 1 | 1 | 1 |

### 8.46.4. Assessment of historic stock parameters

8.46.4.1.Method: ICA

### 8.46.4.1.1. Justification

Integrated Catch at Age (ICA) analysis for stock assessment (Patterson and Melvin 1996; Patterson, 1998) was applied. Integrated Catch at age analysis uses separable virtual population analysis (VPA) (Pope \& Shepherd, 1985) with weighted tuning indices. It was applied regarding the Aegean sardine stock during the SGMED-09-02 as an update of the one adapted in the SGMED-08-04 report (Cardinale et al., 2008). In addition Y/R analysis was applied during the SGMED-09-02.

### 8.46.4.1.2. Input parameters

ICA was based on commercial catch data (2000-2008) and biomass estimates from acoustic surveys over the period 2003-2006 and 2008 were used as tuning indices. Sardine data concerned annual sardine landings, annual sardine catch at age data (2000-2008), mean weights at age, maturity at age and the results of acoustic surveys presented in Table 8.46.4.1.2.1 to 8.46.4.1.2.6. Reference age for the fishery was age group 2, as fully exploited and fully recruited. Six years separability was selected. The age groups 0,4 and 5 were underweighted in the analysis based on their percentage in the catch. Age 1 was also underweighted in the acoustic surveys (0.5). Linear catchability relationship was assumed for the acoustic surveys. Different natural mortality values were applied per age group but constant for all years based on ProBiom (Abella et al., 1997) as recommended in the report of the SG-ECA/RST/MED 09-01. This method for estimating natural mortality is consistent with the methodology used in GSAs 05,06 and 17 for small pelagics. Estimated $M$ was considered realistic, representative of the actual situation in the area taking into account the abundance of predators in the area and the strong dependence of the juveniles of small pelagics from environmental conditions. Average values of maturity ogive and weight at age in the stock were use for 2007.

### 8.46.4.1.3. Results including sensitivity analyses

The graphical diagnostics of the model shown in Figs. 8.46.4.1.3.1 to 8.46.4.1.3.4 generally showed good model fit besides the acoustic surveys index at age 3 in years 2006 and 2008. Residual plots for recent years showed no strong deviations from separability. SSQ plot (Fig. 8.46.4.1.3.5) possibly indicated some degree of inconsistency between the model and the indices (minima not fairly close to each other on $x$-axis, Needle (2000)).

Fig. 8.46.4.1.3.1 Residual plots for age 1 indices of sardine ICA model for GSA 22 (2003-2008).

Fig. 8.46.4.1.3.2 Residual plots for age 2 indices of sardine ICA model for GSA 22 (2003-2008)

Fig. 8.46.4.1.3.3 Residual plots for age 3 indices of sardine ICA model for GSA 22 (2003-2008)

Fig. 8.46.4.1.3.4 The catch at age residuals Residual plots for catch of sardine ICA model for GSA 22 (20032008)

Fig. 8.46.4.1.3.5 Sum of Squares (SSQ) surface plot of the Anchovy ICA Model.

ICA model results for sardine stock in GSA 22 are shown in Fig. 8.46.4.1.3.6, indicating an increasing trend for recruitment in 2008 . However this is probably an overestimation of the last year as the model predicts a
decrease at the level of 2006 for 2009. An increase in biomass has also been observed since 2004. F mean (ages 1to 3) shows a decrease since 2006. The landings to Total Biomass ratio decreases, approximating on average $2 \%$ in 2008 based on model results. Similarly, the landings to SSB ratio decreases approximating on average $40 \%$ based on model results

Fig. 8.46.4.1.3.6 Sardine ICA Model results: Recruitment, SSB, Total biomass, exploitation rate (F/Z), Fmean for ages 1-3, landings to biomass ratio.

Retrospective analysis was applied in the ICA model for the Aegean sardine 2000-2008 with one year backward analysis. Applying the analysis with more than one year backward was not possible due to the short time series available. Results are presented in Fig. 8.46.4.1.3.7., showing no particular retrospective bias.

Fig. 8.46.4.1.3.7. The results of retrospective analysis in the Aegean Sea sardine ICA model 2000-2008, concerning F mean 1-3, SSB and recruitment.

### 8.46.5. Long term prediction

### 8.46.5.1.Justification

Yield per recruit analysis was conducted in the SGMED-09-02 assuming equilibrium conditions.

### 8.46.5.2.Input parameters

Yield per recruit analyses was conducted based based on the exploitation pattern resulting from the ICA model and population parameters, Minimum and maximum age for the analysis were considered to be age group 0 and 4, respectively. Stock weight at age, catch weight at age and maturity ogive were estimated as mean values on a long term basis (2000-2008). Natural mortality was considered different per age group based on ProBiom estimations. Fishing mortalities were estimated in a short term basis (2004-2008). Reference $F$ was considered to be mean $F$ for ages 1 to 3. Input parameters are shown in Table 8.46.5.2.1.

Tab. 8.46.5.2.1. Input parameters for $Y / R$ analysis.

| age group | stock <br> weight | catch <br> weight | maturity | F | M |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 0 | 0.004 | 0.007 | 0 | 0.0003 | 1.50 |
| 1 | 0.015 | 0.020 | 0.5 | 0.1804 | 0.96 |
| 2 | 0.020 | 0.022 | 1 | 1.7100 | 0.69 |
| 3 | 0.024 | 0.024 | 1 | 1.3951 | 0.61 |
| 4 | 0.038 | 0.050 | 1 | 0.7055 | 0.57 |

### 8.46.5.3.Results

Y/R analyses were performed (Fig. 8.46.5.3.1) but were not considered reliable due to its flat-topped shape. Therefore, $\mathrm{F}_{0.1}(1.20)$ cannot be used as a reference point for this stock.

Fig. 8.46.5.3.1. Yield per recruit for the sardine stock in GSA 22.

### 8.46.6. $\quad$ Scientific advice

### 8.46.6.1.Short term considerations

### 8.46.6.1.1. State of the spawning stock size

The results of the short time series of data do not allow to conclude on reference points of $B_{\text {lim }}$ or $B_{p a}$. In the absence of proposed or agreed references, SGMED-09-02 is unable to fully evaluate the state of the stock and provide scientific advice.

Recent estimates of fishery independent surveys for sardine in GSA 22 indicated an increase of total biomass estimates when compared to the earlier years 2003-2005 (42,850 tin 2006 and $39,000 \mathrm{t}$ in 2008 estimated by acoustics). Similarly, results of the Integrated Catch at Age analysis indicated an increasing trend in total biomass and SSB showing a slight recovery of SSB to 20,000 t in 2008 from the low 2003-2004 estimates of 7,000 t.

### 8.46.6.1.2. State of recruitment

ICA model estimates showed above average recruitment since 2007, with a very high peak in 2008.

### 8.46.6.1.3. State of exploitation

Based on ICA results, the mean fishing mortality (averaged over ages 1 to 3 ) is highly variable but showed a clear decreasing trend since 2006, amounting approximating 0.64 in 2008.

The mean $\mathrm{F} / \mathrm{Z}$ has declined from 2003 reaching the value of 0.41 which approximates the exploitation reference points ( $\mathrm{E}<0.4$, Patterson 1992) suggested by SGMED for small pelagics. Taking into account the uncertainty in the estimate, SGMED-09-02 considers the stock as being harvested sustainably. The exploitation rate should be kept at this level through constant effort and consistent catches should be determined. The management of the sardine fishery requires mixed fisheries implications to be considered, mainly with anchovy.

### 8.47. Stock assessment of sole in GSA 17

### 8.47.1. Stock identification and biological features

### 8.47.1.1. Stock Identification

Tagging experiments carried out on common sole in the northern Adriatic Sea, using the traditional mark-and-recapture procedure, showed that all individuals were re-captured within the sub-basin (Pagotto et al., 1979). Local currents, eddies and marked differences of oceanographic features of this sub-basin with respect to those of southern Adriatic and Ionian Sea (Artegiani et al., 1997) may prevent a high rate of exchange of adult spawners and the mixing of planktonic larval stages from nursery areas of adjacent basins (Magoulas et al., 1996). Guarnieri et al. (2002), taking into account differences of sole specimens from five different central Mediterranean areas in the control region sequence marker, suggested that two nearpanmictic populations of common sole could exist in the Adriatic Sea. The former population would inhabit the entire GSA 17 (northern Adriatic Sea). The second unit seems to be spread along the Albanian coasts (eastern part of the GSA 18). The hydrogeographical features of this semi-enclosed basin might support the overall pattern of differentiation of the Adriatic common soles.

The northern Adriatic Sea has a high geographical homogeneity, with a wide continental shelf and eutrophic shallow-waters. The southern Adriatic in contrast is characterized by narrow continental shelves and a marked, steep continental slope ( 1200 m deep; Adriamed, 2000). This deep canyon could represent a significant geographical barrier for S. solea.

On these bases, different actions for fishery management should be proposed for the Adriatic common sole stocks in GSA 17 and GSA 18. In the former area the stock is shared among Italy, Slovenia and Croatia, while in the latter one seems to be shared only between Montenegro and Albania.
S. solea is a demersal and sedentary species, living on sandy and muddy bottoms (Tortonese, 1975, Fisher et al., 1987, Jardas, 1996). Although Jardas (1996) stated that the species is distributed from coastal waters to 250 m depth, it was exclusively caught up to 100 m during the expedition MEDITS (1996-1998) (Vrgoč, 2000).

Common sole usually feeds very often on small quantities of prey (Sà et al., 2003). This suggests a high evacuation rate between the stomach and the intestine, and lack of digestion in the stomach (Lagardere, 1987). The fish feeds night and day and for the remaining time usually lives embedded in the seabed. In the Adriatic Sea food items mostly include invertebrates and small fish (Tortonese, 1975; Fisher et al., 1987; Jardas, 1996). Within the framework of SoleMon project, a study of gut content using carbon- and nitrogen stable isotopes along the sole food web was carried out, indicating that S. solea diet depends on both the geographical position and the size of soles, which change their feeding habit with the increase of the age. This could be related to the fact that the sole selects its preys basing on both their energetic value and the energy spent to catch them. The choice of sole would be also related to prey abundance, as postulated by the "optimal foraging theory" (MacArthur and Pianka, 1966) and observed in other flatfish (Hinz et al., 2005). Stergiou and Karpouzi (2002) found that in the Mediterranean Sea the sole increases its trophic level with the increasing of the size, reaching values around 3.4. The mean trophic level estimated from the SoleMon project data through the stable isotope analysis was slightly higher (3.9), but similar to the value obtained in a study carried out in the Rodano mouth (Darnaude, 2005).

### 8.47.1.2. Growth

In the Adriatic sea, growth analyses on this species have been made using otoliths, scales and tagging experiments. A great variability in the growth rate was noted: some specimens had grown 2 cm in one month, while others, of the same age group, needed a whole year (Piccinetti and Giovanardi, 1984; Tab. 8.47.1.2.1.). Von Bertalanffy growth equation parameters have been calculated using various methods. Within the framework of SoleMon project, growth parameters of sole were estimated through the lengthfrequency distributions obtained from surveys (Fig. 8.47.1.2.1; Tab. 8.47.1.2.2).

Tab. 8.47.1.2.1. Growth rates of S. solea from different studies (TL, cm; age, yr).

Fig. 8.47.1.2.1. Von Bertalanffy growth functions for sole in the GSA 17, based on SoleMon length frequency distributions.

### 8.47.1.3. Maturity

In the Mediterranean Sea, the reproduction of common sole occurs from December to May (Bini, 1968-70; Tortonese, 1975; Fisher et al., 1987). Within the framework of SoleMon project, it has been observed that in the central and northern Adriatic Sea the reproduction takes place from November to March. Data on the spatial distribution of spawners provided by the project show a higher concentration of reproducers outside the western coast of Istria (Fabi et al., 2009).

Length at first maturity is 25 cm (Fisher et al., 1987; Jardas, 1996; Vallisneri et al., 2000); this value has been estimated at 25.8 using data from SoleMon project. Females having a weight of 300 g have about 150,000 eggs, while those weighting 400 g have about 250,000 eggs (Piccinetti and Giovanardi, 1984); eggs are pelagic. The male-female ratio is approximately 1:1 (Piccinetti and Giovanardi, 1984; Fabi et al., 2009).

Hatching occurs after eight days and the larva measures 3 to 4 mm TL (Tortonese, 1975). Eye migration starts at 7 mm TL and ends at $10-11 \mathrm{~mm}$ TL. Benthic life begins after seven or eight weeks ( 15 mm ) in coastal and brackish waters (Bini, 1968-70; Fabi et al., 2009).

### 8.47.2. Fisheries

### 8.47.2.1. General description of fisheries

The common sole is a very important commercial species in the central and northern Adriatic Sea (Ghirardelli, 1959; Piccinetti, 1967; Jardas, 1996; Vallisneri et al., 2000; Fabi et al., 2009). Italian rapido trawlers exploit this resource providing more than $80 \%$ of landings. Sole is also a target species of the Italian and Croatian set netters, while it represents an accessory species for otter trawlers.

From censuses carried out at the landing sites, the Italian rapido trawl fleet operating in GSA 17 was made of 155 vessels in 2005 and 124 vessels in 2006 ranging from 9 to 30 m in vessel length, GRT ranged from 4 to 100 and the engine power from 60 to 1000 HP . Each vessel can tow from 2 to 4 rapido trawls depending on its dimensions. The rapido trawl is a gear used specifically for catching flatfish and other benthic species (e.g. cuttlefish, mantis shrimp, etc.). It resembles a toothed beam-trawl and is made of an iron frame provided with 3-5 skids and a toothed bar on its lower side. These gears are usually towed at a greater speed (up to $10-13 \mathrm{~km} \mathrm{~h}^{-1}$ ) in comparison to the otter trawl nets; this is the reason of the name "rapido", the Italian word for "fast". The mesh opening of the codend used by the Italian rapido trawlers is larger ( 48 mm stretched or more) than the legal one. The main Italian rapido trawl fleets of GSA 17 are sited in the following harbours: Ancona, Rimini and Chioggia.

The Italian artisanal fleet in GSA 17, according to SoleMon project data (end of 2006), accounted for 469 vessels widespread in many harbours along the coast. They use gill net or trammel net especially from spring to fall and target small and medium sized sole (usually smaller than 25 cm TL ).
8.47.2.2. Management regulations applicable in 2008 and 2009

- Fishing closure for trawling: 30 days in summer.
- Minimum landing sizes: EC regulation 1967/2006: 20 cm TL for sole.
- Cod end mesh size of trawl nets: 40 mm (stretched, diamond meshes) till 30/05/2010. From 01/06/2010 the existing nets will be replaced with a cod end with 40 mm (stretched) square meshes or a cod end with 50 mm (stretched) diamond meshes.
- Towed gears are not allowed within three nautical miles from the coast or at depths less than 50 m when this depth is reached at a distance less than 3 miles from the coast.

### 8.47.2.3. Catches

### 8.47.2.3.1. Landings

In the last four years the total landings of sole of GSA 17 fluctuated between 1,673 to about 2,184 tons and even though the time series is short, the general shape suggests a stable trend (Fig. 8.47.2.3.1.1).

Fig. 8.47.2.3.1.1 Landings of sole (all gears) in the GSA 17, from 2005 to 2008.

Rapido trawl landings were traditionally dominated by small sized specimens; they are basically composed by 1 and 2 year old individuals. Set net fishery lands mostly the same portion of the population, while the otter trawl fishery, exploiting wider fishing grounds, shows a different size distribution of the landings (Fig. 8.47.2.3.1.2).

Fig. 8.47.2.3.1.2 Size structure of the landings of common sole provided in 2005-2006 by rapido trawl, otter trawl and set nets in the GSA 17 (SoleMon project data).

### 8.47.2.3.2. Discards

Several projects carried out in a portion of GSA 17 highlighted that the discard of sole both by rapido trawl and set net fisheries is negligible (Fabi et al., 2002a; 2002b) as the damaged specimens are also commercialized, even though at a lower price.

### 8.47.2.3.3. Fishing effort

Exploitation is based on young age classes, mainly 1 and 2 year old individuals, with immature fraction dominating the landings. From SoleMon project data, the overall Italian fleet exploiting sole in the GSA 17 is made up by around 1,300 vessels (rapido trawlers, set netters, otter trawlers; Tab. 8.47.2.3.3.1)

Tab. 8.47.2.3.3.1 Number of vessels $x$ days exploiting sole in GSA 17 (SoleMon project data).

| Year | $\mathbf{2 0 0 5}$ | $\mathbf{2 0 0 6}$ | $\mathbf{2 0 0 7}$ | $\mathbf{2 0 0 8}$ |
| :--- | ---: | ---: | ---: | ---: |
| Effort (vessels x days) | 152,182 | 122,669 | 108,830 | 116,860 |

The trends of the fishing effort of Ancona and Rimini rapido trawl fleets have been analyzed over the years 1996-2009 and 2005-2008 respectively. The fishing effort of Ancona fleet increased from 1996 to 2003 and declined in the subsequent years. A similar decreasing pattern also occurred for the Rimini fleet in the last four years (Fig. 8.47.2.3.3.1).

Fig. 8.47.2.3.3.1 Trends of effort (days* vessel) by Ancona and Rimini rapido trawl fleets

### 8.47.3. Scientific surveys

8.47.3.1. SoleMon

### 8.47.3.1.1. Methods

Six rapido trawl fishing surveys were carried out in GSA 17 from 2005 to 2008: two systematic "presurveys" (spring and fall 2005) and four random surveys (spring and fall 2006, fall 2007-2008) stratified on the basis of depth ( $0-30 \mathrm{~m}, 30-50 \mathrm{~m}, 50-100 \mathrm{~m}$ ). Hauls were carried out by day using 2-4 rapido trawls simultaneously (stretched codend mesh size $=40.2 \pm 0.83$ ). The following number of hauls was reported per depth stratum (Tab. 8.47.3.1.1.1).

Tab. 8.47.3.1.1.1 Number of hauls per year and depth stratum in GSA 17, 2005-2008.

| Depth strata | Spring 2005 | Fall 2005 | Spring 2006 | Fall 2006 | Fall 2007 | Fall 2008 |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: |
| $0-30$ | 30 | 30 | 20 | 35 | 32 | 39 |
| $30-50$ | 14 | 12 | 10 | 20 | 19 | 17 |
| $50-100$ | 24 | 15 | 8 | 8 | 11 | 11 |
| HR islands | 0 | 5 | 4 | 4 | 0 | 0 |
| TOTAL | 68 | 62 | 42 | 67 | 62 | 67 |

Abundance and biomass indices from rapido trawl surveys were computed using ATrIS software (Gramolini et al., 2005) which also allowed drawing GIS maps of the spatial distribution of the stock, spawing females and juveniles. Underestimation of small specimens in catches due to gear selectivity was corrected using the selective parameters given by Ferretti and Froglia (1975).

The abundance and biomass indices by GSA 17 were calculated through stratified means (Cochran, 1953; Saville, 1977). This implies weighting of the average values of the individual standardized catches and the variation of each stratum by the respective stratum area in the GSA 17:

Yst $=\Sigma\left(\mathrm{Yi}^{*} \mathrm{Ai}\right) / \mathrm{A}$

$$
\mathrm{V}(\mathrm{Yst})=\Sigma\left(\mathrm{Ai}^{2} * \mathrm{si}^{2} / \mathrm{ni}\right) / \mathrm{A}^{2}
$$

Where:
A=total survey area
$\mathrm{Ai}=$ area of the i-th stratum
si=standard deviation of the i-th stratum
ni=number of valid hauls of the i-th stratum
$\mathrm{n}=$ number of hauls in the GSA
$\mathrm{Yi}=$ mean of the i-th stratum
Yst=stratified mean abundance
$\mathrm{V}(\mathrm{Yst})=$ variance of the stratified mean
The variation of the stratified mean is then expressed as the $95 \%$ confidence interval: Confidence interval $=$ Yst $\pm \mathrm{t}$ (student distribution) $* \mathrm{~V}(\mathrm{Yst}) / \mathrm{n}$

It was noted that while this is a standard approach, the calculation may be biased due to the assumptions over zero catch stations, and hence assumptions over the distribution of data. A normal distribution is often assumed, whereas data may be better described by a delta-distribution, quasi-poisson. Indeed, data may be better modelled using the idea of conditionality and the negative binomial (e.g. O'Brien et al., 2004).

Length distributions represented an aggregation (sum) of all standardized length frequencies over the stations of each stratum. Aggregated length frequencies were then raised to stratum abundance and finally aggregated (sum) over the strata to the GSA. Given the sheer number of plots generated, these distributions are not presented in this report.

### 8.47.3.1.2. Geographical distribution patterns

According to data collected during SoleMon surveys (Fabi et al., 2009), age class 0+ aggregates inshore along the Italian coast, mostly in the area close to the Po river mouth (Fig. 8.47.3.1.2.1). Age class 1+ gradually migrates off-shore and adults concentrate in the deepest waters located at South West from Istria peninsula (Fig. 8.47.3.1.2.1).

Fig. 8.47.3.1.2.1 Example of abundance indices (ind. $\cdot \mathrm{km}^{-2}$ ) for sole from SoleMon survey carried out in GSA 17 (fall 2007) interpolated using Kriging (Fabi et al., 2009).

### 8.47.3.1.3. Trends in abundance and biomass

The SoleMon trawl surveys provided data either on sole total abundance and biomass as well as on important biological events (recruitment, spawning).

Fig. 8.47.3.1.3.1 shows the abundance and biomass indices of sole obtained from 2005 to 2008; slightly increasing trends occurred till fall 2007, followed by a decrease in fall 2008.

Fig. 8.47.3.1.3.1 Abundance and biomass indices of sole obtained from SoleMon surveys.
The recruitment showed a fluctuating trend with the lowest values in 2006 and 2008 (Fig. 8.47.3.1.3.2). The number and biomass of spawners remained practically constant from 2005 to 2008 (Fig. 8.47.3.1.3.3).

Fig. 8.47.3.1.3.2 Abundance and biomass indices of recruits of sole obtained from SoleMon surveys.

Fig. 8.47.3.1.3.3 Abundance and biomass indices of spawners of sole obtained from SoleMon surveys.

### 8.47.3.1.4. Trends in abundance by length or age

Fig. 8.47.3.1.4.1 displays the stratified abundance indices obtained in the GSA 17 in the years 2005-2008.

Fig. 8.47.3.1.4.1 Stratified abundance indices by size, 2005-2008.

### 8.47.3.1.5. Trends in growth

No analyses were conducted during SGMED-09-02.

### 8.47.3.1.6. Trends in maturity

No analyses were conducted during SGMED-09-02.

### 8.47.4. Assessment of historic stock parameters

Sole has been object of assessments in the GSA 17 and results are published and regularly updated in the GFCM SAC sheets. The assessments, often performed with different approaches, showed substantially convergent results.

From the last GFCM SAC meeting (Fabi et al., 2008), the sole stock in the GSA 17 seems to be overexploited, as shown by the results of the analytical models (reference points as $\mathrm{F}_{\mathrm{max}}, \mathrm{F}_{0.1}$ ). A growth overfishing situation was detected, with excessive fishing mortality on $1+$ and $2+$ age classes.

As concern the STECF-SGMED-09-02, two new assessments were produced. The main results are presented below.

### 8.47.4.1. Method 1: XSA

### 8.47.4.1.1. Justification

Despite of the short data series, the assessment is based on non-equilibrium method. VPA Lowestoft software suite (Darby and Flatman, 1994) was used and XSA was the assessment method. A separable VPA (Pope and Sheperd, 1982) was also run as exploratory analysis for this stock.

### 8.47.4.1.2. Input parameters

Landings time series 2005-2008 from all fishing ports from GSA17.
Length distributions 2005-2008 (SoleMon project).
Biological sampling 2005-2006 for Maturity at age and Weight-Length relationships (SoleMon project).
Tuning data from SoleMon surveys carried out in fall for the years 2005-2008.
These data come from independent monitoring activities performed by the research institutes working in the GSA 17 (Tab. 8.47.4.1.2.1).

Tab. 8.47.4.1.2.1 Input parameters.

### 8.47.4.1.3. Results

A separable VPA was run as exploratory analysis. Log catchability residual plots were produced (Fig. 8.47.4.1.3.1) and no major conflict between ages seems to appear.

Fig. 8.47.4.1.3.1 Residuals of log catchabilities.

Then a XSA assessment was made. The main settings for the XSA are the following:

- $\mathrm{F}_{\text {bar }} 0-4$.
- Age 1 for q stock-size independent and age 1 for q independent of age.
- F shrink age $=0.500$ and S.E. for fleet terminal estimates $\geq 0.300$

XSA Diagnostics in the form of residuals by survey data are shown in the Fig. 8.47.4.1.3.2.

Fig. 8.47.4.1.3.2 Residuals by fleet.

The inclusion of tuning data from rapido trawl commercial fleet of Rimini did not provide additional information or different results. Therefore, the definitive assessment only included tuning data from SoleMon survey.

Fig. 8.47.4.1.3.3 presents the main results from the XSA: fishing mortality, relative F at age, total biomass, spawning stock biomass (SSB) and recruitment.

Fig. 8.47.4.1.3.3 Final assessment results.
State of exploitation: Exploitation decreased from 2005 to 2006, was constant in 2006-2007 and increased in 2008. The most recent estimate of fishing mortality $\left(\mathrm{F}_{0-4}\right)$ is 1.35 , the highest values of relative F are for ages 1 and 2.
State of the juveniles (recruits): Recruitment varied without any trend in the years 2005-2008, reaching a minimum in 2006.
State of the total biomass and adult biomass: The total biomass regularly decreased from 2005 to 2007 and increased in 2008 reaching the maximum value. The SSB reached the minimum value in 2005, was constant in 2006 and 2007 and increased in 2008.

### 8.47.4.2. Method 2: SURBA

### 8.47.4.2.1. Justification

The availability of a time series of data from SoleMon surveys allows the use of the SURBA assessment tool. Using the software, the evolution of fishing mortality rates of sole in the GSA 17 was reconstruct starting from the analysis of the length frequency distribution (LFD).

### 8.47.4.2.2. Input parameters

The main input parameters to run the SURBA-survey based stock analysis are abundances, natural mortality rates and catchability. The parameters used in this analysis were the same used in the XSA analysis.

### 8.47.4.2.3. Results

The results and the diagnostic of the analyses are summarized in Fig. 8.47.4.2.3.1 and 8.47.4.2.3.2 respectively. The results of the model are in general accordance with the previous method providing the same perception of the state of the stock. Comparison between observed $v s$ fitted data obtained with SURBA (Fig. 8.47.4.2.3.2A) shows an adequate fitting of the model in sole data in GSA 17.

Fig. 8.47.4.2.3.1 Trends in stock parameters (SoleMon survey) in GSA 17 from SURBA.
(A)

(B)

Fig. 8.47.4.2.3.2. Model diagnostic (SoleMon survey) in GSA 17 from SURBA. Comparison between observed (points) and fitted (lines) of SoleMon survey abundance indices, for each year (A); bubble plot of log-index residuals by age (B).

### 8.47.5. Long term prediction

### 8.47.5.1. Justification

Availability of biological parameter and length at first capture allows to quantify by simulation the likely changes in Y, B and SSB per recruit in function of fishing mortality ( F ) with the Yield package.

### 8.47.5.2. Input parameters

Growth, length-weight relationship, natural mortality and maturity ogive were the same used in the previous paragraphs. Length at first capture was 16 cm TL (about 0.7 year old).

A guess estimate of uncertainty in terms of coefficient of variation $(\mathrm{CV}=0.2)$ was added to each parameter.

Beverton and Holt stock-recruit relationship commonly employed for North Sea flatfish (Kell et al., 2005; Pilling et al., 2008) was used with steepness of 0.9 and virgin SSB of $13,000 \mathrm{t}$. The value of steepness represents a hypotheses on the high resilience of the stocks at low spawning-stock size. The value of virgin SSB was estimated from previous analyses carried out by VIT package. The recruitment variability among years was estimated as $\mathrm{CV}=0.3$ from recruit indices obtained in trawl surveys.

### 8.47.5.3. Results

Estimation of Y and SSB per recruit are shown in Fig 8.47.5.3.1.

Fig. 8.47.5.3.1 Yield and spawning stock biomass per recruit and corresponding uncertainty of sole in the GSA 17 according to the Yield Package.

Searching for biological reference points (BRP) through 1000 simulation produced the median values reported in Tab. 8.47.5.3.1. $\mathrm{Y} / \mathrm{R}_{\max }, \mathrm{F}_{\max }$ and $\mathrm{Y} / \mathrm{R}_{\text {ref }}, \mathrm{F}_{\text {ref }}$, the two latter corresponding to $\mathrm{Y} / \mathrm{R}$ and F at SSB/initial $S S B=0.30$, were assumed as limiting reference points. Whereas $Y / R_{0.1}$ and $F_{0.1}$, should be considered as target reference points.

RPs suggest an overfishing situation for the stock considering F current ( 1.35 from XSA) is much higher than the limit and target RPs F.

The effect of several bad recruitment years in a row has been evaluated using the transient analysis of SSB. A fishing mortality rate of 0.24 will result in a probability of 0.1 of the SSB falling below 0.2 of its unexploited level at least once in 20 years.

Tab. 8.47.5.3.1 Yield (kg) per recruit and fishing mortality based BRP of sole for GSA 17 according to the Yield package.

| Yield based RP | value | F based RP | value |
| :---: | :---: | :---: | :---: |
| $Y / R_{\mathrm{msx}}$ | 0.054 | $\mathrm{~F}_{\mathrm{mm}}$ | 0.46 |
| $\mathrm{Y} / \mathrm{R}_{\mathrm{Trf}}$ | 0.051 | $\mathrm{~F}_{\mathrm{Tef}}$ | 0.32 |
| $\mathrm{Y} / \mathrm{R}_{0.1}$ | 0.048 | $\mathrm{~F}_{0.1}$ | 0.26 |

### 8.47.6. Scientific advice

### 8.47.6.1.Short term considerations

### 8.47.6.1.1. State of the spawning stock size

According to the XSA and SURBA analyses the SSB was practically constant in the period considered but, taking into account the high values of relative F for the oldest ages, the stock is considered overexploited.

### 8.47.6.1.2. State of recruitment

According to the XSA and SURBA analyses the recruitment of sole in GSA 17 fluctuated since 2005, despite of the fact that the SSB remained practically constant during this period.

### 8.47.6.1.3. State of exploitation

Based on the XSA estimates, in 2008 the fishing mortality appears much higher than reference points calculated by the Yield package and, hence, it can be concluded that the resource is overexploited. Fishing effort should be reduced by means of a multi-annual management plan. Annual catches consistent with such effort reductions should be determined.

SGMED 09-02 recommends $\mathrm{F}_{0.1}=0.26$ as a target management reference point for sustainable exploitation related to high long term yield.

Further fisheries management recommendations:
A reduction of fishing pressure, especially by rapido trawling, would be recommended, also taking into account that the exploitation is mainly orientated towards juveniles and the success of recruitment seems to be strictly related to environmental conditions (Domenichetti et al., 2009). Hence, in the case of both increasing fishing effort and yearly bad recruitment, there could be a high risk of stock depletion.

A two-months closure for rapido trawling inside 11 km off-shore along the Italian coast, after the biological fishing ban (August), would be advisable to reduce the portion of juvenile specimens in the catches. For the same reason, specific studies on rapido trawl selectivity are necessary. In fact, it is not sure that the adoption of a larger mesh size would correspond to a decrease of juvenile catches, considering that the mesh opening
currently used by the Italian rapido trawlers is larger ( 48 mm or more) than the legal one. The same uncertainty regards the adoption of a square mesh.

SSB was practically constant over the 4 years, maybe because, as observed during the SoleMon project, in late fall - winter the main spawning area is only partially exploited by the Croatian set netters and Italian fleets (Figure 8.47.6.1.3.1). The safeguard of such area (identified by the rapido trawl survey) to prevent a possible future exploitation might be crucial for the sustainability of the Adriatic sole stock.

Fig. 8.47.6.1.3.1 Spatial distribution of spawning females in fall (left) and fishing grounds of the Italian rapido trawl fleets (right; in yellow Chioggia rapido trawl fleet; in red Rimini rapido trawl fleet; in light blue Ancona rapido trawl fleet).

### 8.48. Stock assessment of blue and red shrimp in GSA 06

### 8.48.1. Stock identification and biological features

### 8.48.1.1.Stock Identification

No information was documented during SGMED-09-02.

### 8.48.1.2.Growth

Growth parameters used were those from Garcia-Rodriguez (2003) over length distributions analysis (Linf = $77.0 ; \mathrm{K}=0.38 ; \mathrm{t} 0=-0.065$ ), and length-weight relationship ( $a=0.0024 ; \mathrm{b}=2.467$ ).

### 8.48.1.3.Maturity

Maturity ogive was taken from García Rodriguez (2003), with size at first maturity ( $50 \%$ ) at 23.5 mm Cl .

| Age class | 0 | 1 | 2 | 3 | 4 | 5 |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: |
| Maturity ratio | 0.07863309 | 0.7669088 | 0.9980806 |  | 1 |  |

### 8.48.2. Fisheries

### 8.48.2.1.General description of fisheries

Blue and red shrimp (Aristeus antennatus) is one of the most important crustacean species for the trawl fisheries developed along the GFCM geographical sub-area Northern Spain (GSA 06). This resource is an important component of commercial landings in some ports of the Mediterranean Northern Spain, and is a target species of a specific trawl fleet. The red shrimp has a wide bathymetric distribution, between 80 and 3300 m depth (Sardà et al., 2005), and some areas may constitute a reservoir for the resource since they are located a long way from ports and in deeper zones up to 1000 m . Females predominate in the landings nearly $80 \%$ of the total. Discards of the red shrimp are null. The number of harbours with red shrimp fleets is 14 for the whole area. Exploitation is based on very young age classes, mainly 1 and 0 year old individuals, indicating a dependence on recruitments.
8.48.2.2. Management regulations applicable in 2008 and 2009

No information was documented during SGMED-09-02.

### 8.48.2.3.Catches

### 8.48.2.3.1. Landings

Updated information on landings and effort has been collected on annual basis (2002-2008). Throughout the time series landings fluctuated between 300 and 650 tonnes, with an average of c.a. 500 tonnes, with a recovering trend in 2007 and 2008.

LANDINGS

Fig. 8.48.2.3.1.1 Annual blue and red shrimp landings (t) by Spanish trawlers.

Tab. 8.48.2.3.1.1 lists the trend in reported landings by fishing technique. The data were reported to SGMED-09-02 through the Data Collection Regulation and are listed in Table A3.6 of Appendix 3. Since 2002 the annual landings decreased from 645 t to 316 t in 2005 , recovering the initial values in 2008 . The landings were only taken by demersal otter trawls.

Tab. 8.48.2.3.1.1 Annual landings ( t ) by fishing technique in GSA 06.

| SPECIES | AREA |  | COUNTRY | FT_LVL4 | 2002 | 2003 | 2004 | 2005 | 2006 | 2007 | 2008 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| ARA |  | 6 | ESP | OTB | 645 | 647 | 347 | 316 | 320 | 470 | 638 |

### 8.48.2.3.2. Discards

No information was documented during SGMED-09-02.

### 8.48.2.3.3. Fishing effort

Fishing effort has reduced from 20,000 days in 2002 to 9,000 in 2006, with an increase thereafter, reaching the 23,000 in 2008. SGMED notes that the fishing effort below only includes vessels that have landed blue and red shrimp in the given years.

No official data have been reported to SGMED 09-02.

### 8.48.3. Scientific surveys

### 8.48.3.1.Medits

### 8.48.3.1.1. Methods

Based on the DCR data call, abundance and biomass indices were recalculated. In GSA 06 the following number of hauls were reported per depth stratum (s. Tab. 8.48.3.1.1.1).

Tab. 8.48.3.1.1.1. Number of hauls per year and depth stratum in GSA 06, 1994-2008.

| STRATUM | 1994 | 1995 | 1996 | 1997 | 1998 | 1999 | 2000 | 2001 | 2002 | 2003 | 2004 | 2005 | 2006 | 2007 | 2008 |
| :--- | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| GSA06_010-050 | 7 | 8 | 7 | 8 | 7 | 8 | 9 | 8 | 11 | 9 | 9 | 11 | 12 | 6 | 8 |
| GSA06_050-100 | 21 | 28 | 27 | 26 | 28 | 30 | 30 | 31 | 36 | 39 | 31 | 32 | 34 | 40 | 43 |
| GSA06_100-200 | 11 | 19 | 17 | 15 | 13 | 17 | 19 | 20 | 20 | 21 | 17 | 18 | 19 | 24 | 30 |
| GSA06_200-500 | 10 | 13 | 10 | 12 | 7 | 13 | 12 | 16 | 17 | 18 | 16 | 15 | 18 | 18 | 19 |
| GSA06_500-800 | 7 | 8 | 9 | 7 | 4 | 9 | 6 | 8 | 7 | 11 | 11 | 8 | 10 | 15 | 14 |

Data were assigned to strata based upon the shooting position and average depth (between shooting and hauling depth). Few obvious data errors were corrected. Catches by haul were standardized to 60 minutes hauling duration. Hauls noted as valid were used only, including stations with no catches of hake, red mullet or red shrimp (zero catches are included).

The abundance and biomass indices by GSA were calculated through stratified means (Cochran, 1953; Saville, 1977). This implies weighting of the average values of the individual standardized catches and the variation of each stratum by the respective stratum areas in each GSA:

Yst $=\Sigma\left(\mathrm{Yi}^{*} \mathrm{Ai}\right) / \mathrm{A}$
$\mathrm{V}(\mathrm{Yst})=\Sigma\left(\mathrm{Ai}^{2} * \mathrm{si}^{2} / \mathrm{ni}\right) / \mathrm{A}^{2}$
Where:
A=total survey area
$\mathrm{Ai}=$ area of the i -th stratum
si=standard deviation of the $i$-th stratum
ni=number of valid hauls of the i-th stratum
$\mathrm{n}=$ number of hauls in the GSA
$\mathrm{Yi}=$ mean of the i -th stratum
Yst=stratified mean abundance
$\mathrm{V}(\mathrm{Yst})=$ variance of the stratified mean
The variation of the stratified mean is then expressed as the $95 \%$ confidence interval: Confidence interval $=$ Yst $\pm \mathrm{t}$ (student distribution) * V(Yst) / n

It was noted that while this is a standard approach, the calculation may be biased due to the assumptions over zero catch stations, and hence assumptions over the distribution of data. A normal distribution is often assumed, whereas data may be better described by a delta-distribution, quasi-poisson. Indeed, data may be better modelled using the idea of conditionality and the negative binomial (e.g. O'Brien et al. (2004)).

Length distributions represented an aggregation (sum) of all standardized length frequencies (subsamples raised to standardized haul abundance per hour) over the stations of each stratum. Aggregated length
frequencies were then raised to stratum abundance * 100 (because of low numbers in most strata) and finally aggregated (sum) over the strata to the GSA. Given the sheer number of plots generated, these distributions are not presented in this report.

### 8.48.3.1.2. Geographical distribution patterns

No analyses were conducted during SGMED-09-02.

### 8.48.3.1.3. Trends in abundance and biomass

Fishery independent information regarding the state of the red shrimp in GSA 06 was derived from the international survey Medits. Figure 8.48.3.1.3.1 displays the estimated trend in blue and red shrimp abundance and biomass in GSA 06.

The estimated abundance and biomass indices were high in 2000, 2001 and 2002 but varied at a low level since then. The last year (2008) shows a big increase in values.

Fig. 8.48.3.1.3.1 Abundance and biomass indices of red shrimp in GSA 06.

### 8.48.3.1.4. Trends in abundance by length or age

The following Fig. 8.48.3.1.4.1 and 2 display the stratified abundance indices of GSA 06 in 1994-2008.

| GSA06 1998 |  |
| :---: | :---: |

Fig. 8.48.3.1.4.2 Stratified abundance indices by size, 2002-2008.

### 8.48.3.1.5. Trends in growth

No analyses were conducted during SGMED-09-02.
8.48.3.1.6. Trends in maturity

No analyses were conducted during SGMED-09-02.
8.48.4. $\quad$ Assessment of historic stock parameters
8.48.4.1.Method 1: XSA

### 8.48.4.1.1. Justification

During the SGMED-09-02, an assessment on red shrimp from GSA 06 was performed. Files dealing with official landings and effort were not available. Consequently data on landings and effort for 2008, were derived, by regression, from the series.

### 8.48.4.1.2. Input data

### 8.48.5. Long term prediction

### 8.48.5.1.Justification

No forecast analyses were conducted.

### 8.48.5.2.Input parameters

No forecast analyses were conducted.

### 8.48.5.3.Results

Given the preliminary state of the data and analyses SGMED-09-02 is not in the position to provide a long term prediction of catch and stock biomass for red shrimp in GSA 06.
8.48.6. $\quad$ Scientific advice
8.48.6.1.Short term considerations

### 8.48.6.1.1. State of the spawning stock size

Since 2002, SSB, with an average for the whole period of 637 mt , declined rapidly from 2002 to 2004 reaching the lowest value ( 384 t ) observed in 2002-2008 which represents a $25 \%$ of that observed in 2002. Thereafter, SSB is estimated to increase until 2008 almost to the level seen in the beginning of the assessed time period.

SGMED-09-02 notes that the MEDITS survey abundance index shows oscillations along the period, generally decreasing from 1996 to 2007 and largely increasing in 2008. The large variation in the CPUE might be related to the fact that MEDITS survey is principally able to track recruitment or that the SSB is such low that the stock (and relative stock indices) is highly dependent to the incoming year classes. However, this would require further data and analysis.

SGMED-09-02 cannot evaluate the state of the spawning stock relative to reference points, as these have not been proposed or defined.

### 8.48.6.1.2. State of recruitment

Recruits (aged 0 individuals) were estimated to increase significantly from 2003 to 2007 and remain high in 2008.

### 8.48.6.1.3. State of exploitation

Mean fishing mortality from 2002 to 2008 varied without a clear trend between 0.8 and 1.3. The highest value is observed in 2008.

The lack of a target management reference point for exploitation causes SGMED-09-02 being unable to fully evaluate the state of exploitation.

### 8.49. Stock assessment of blue and red shrimp in GSA 10

### 8.49.1. Stock identification and biological features

### 8.49.1.1.Stock Identification

Recent studies based on microsatellite DNA analysis have evidenced genetic differences between the centralsouthern Tyrrhenian Sea (Sardinia and north Sicily) populations and north Tyrrhenian-Ligurian Sea and Algeria populations (AAVV, 2008, EU Project, Ref. Fish/2004/03-32). Given the preliminary state of these outcomes and lacking other specific analyses the stock of blue and red shrimp Aristeus antennatus was assumed in the boundaries of the whole GSA 10. This species and the giant red shrimp Aristaeomorpha foliacea are deep-water decapods characterised by seasonal variability and annual fluctuations of abundance (Spedicato et al., 1995), as reported for other geographical areas (e.g. Relini and Orsi Relini, 1987). The blue and red shrimp is mainly distributed beyond 500 m depth.

The depth factor appears to influence the sex ratio, which is generally dominated by the females (sex ratio $\sim 0.8-0.9$ ) at $500-700 \mathrm{~m}$ depth, as sexes are partially segregated into different bathymetric ranges (e.g. Sardà et al., 2004). The spawning period extends from April to October-November with a peak in July-August (Spedicato et al., 1995). Males are mature all year round. The smallest mature female observed in the area was 18 mm carapace length.

Considering the length of the spawning season, the recruitment has an almost continuous pattern, although there are no clear and well separated peaks of recruit abundance in the LFDs, because this fraction of the population is not fully available. Indeed, from Medits and Grund surveys, individuals less than 20 mm are in general about $2 \%$ and, according to the current literature knowledge on the growth pattern, they should already been older than 1 year ( 16 mm average length at 1 year; e.g. Orsi Relini and Relini, 1998).

In general, the length frequency distributions of the blue and red shrimp have a pattern with overlapping modes and poorly separable components. For the females a life span of $6-10$ years was estimated. The structure of the sizes of A. antennatus is characterised by marked differences in growth between the sexes. The larger individuals are females.

According to the benthic bionomic classification of Pérès and Picard (1964) P. longirostris, N. norvegicus and red-shrimps typify the populations of slope and bathyal bottoms in the GSA 10. Depending on the depth and zone, this fauna is accompanied by characteristic bentic species as Funiculina quadrangularis, Geryon longipes, Polycheles typhlops, Isidella elongata, Griphus vitreus.

In the central-southern Tyrrhenian Sea the blue and red shrimp represents a specific target of deep-waters trawling fishery given its high economic value (Spedicato et al., 1995).

### 8.49.1.2. Growth

In the central-southern Tyrrhenian the maximum carapace length (CL) observed in females and males was 65 mm and 39.7 mm (Spedicato et al., 1995). After estimates of VBGF obtained in the past, growth has been also recently re-assessed in the DCR framework and in the Red Shrimps project (AAVV, 2008) through the analysis of the LFDs. Given the difficulty to separate LFDs into normal components, the LFDs have been analysed according to the procedure first adopted in the Samed project (Anonymous 2002). Thus, an $\mathrm{L}_{\text {max }}$ (predicted maximum length; procedure implemented in FiSAT) value to be used as guess estimate of $\mathrm{L}_{\infty}$ was computed. This value was then tuned with that obtained from the Powell and Wetherall approach, which gives also estimates of the $\mathrm{Z} / \mathrm{K}$ ratio. According to the hypothesis of a slow growth pattern (Orsi Relini and Relini, 1998) age 1 at a mean size of 16 mm was assumed and a first estimate of K derived from the ratio: average length at age $1 / \mathrm{L} \infty$. Thus also a first value of Z was obtained. These parameters were finally calibrated trough the Length Converted Catch Curve (LCCC) and the set giving the better determination
coefficient was adopted: females $C L_{\infty}=66 \mathrm{~mm}, \mathrm{~K}=0.243, \mathrm{t}_{0}=-0.2$. Parameters of the length-weight relationship were $\mathrm{a}=0.8512, \mathrm{~b}=2.4$ for females and $\mathrm{a}=0.9747, \mathrm{~b}=2.187$ for males, for length expressed in cm .

### 8.49.1.3. Maturity

The maturity ogive was estimated from a maximum likelihood procedure considering as mature the individuals with maturity stage 2 and onwards. The value of $\mathrm{CL}_{\mathrm{m} 50 \%}$ was $2.44 \mathrm{~cm}( \pm 0.049 \mathrm{~cm})$. However the fitting obtained was poor and seems to overestimates the length at first maturity.

Fig. 8.49.1.3.1 Maturity ogive of blue and red shrimp in the GSA 10 (MR indicates the difference $\mathrm{Lm}_{75 \%}{ }^{-}$ $\mathrm{Lm}_{25 \%}$ ).

The sex ratio from DCR evidenced the prevalence of males in the first two size classes (1.8-2.0 cm) while from 2.4 cm onwards the proportion of females was dominant (Fig. 8.49.1.3.2).

Fig. 8.49.1.3.2 Sex ratio over length.

### 8.49.2. Fisheries

8.49.2.1. General description of fisheries

The blue and red shrimp is only targeted by trawlers on fishing grounds located offshore 200 m depth, mainly southward Salerno Gulf. Catches from trawlers are from a depth range between 400 and 700 m depth
and the blue and red shrimp occurs with A. foliacea, P. longirostris and N. norvegicus, P. blennoides, M. merluccius, depending on operative depth and area.
8.49.2.2. Management regulations applicable in 2008 and 2009

Management regulations are based on technical measures, like the number of fishing licenses and area limitation (distance from the coast and depth). In order to limit the over-capacity of the fishing fleet, the Italian fishing licenses have been fixed since the late 1980s. After 2000, in agreement with the European Common Policy of Fisheries, a gradual decreasing of the fleet capacity is implemented. Along northern Sicily coasts two main Gulfs (Patti and Castellammare) have been closed to the trawl fishery up 200 m depth, since 1990. Two closed areas were also established in 2004 along the mainland, in front of Sorrento peninsula (Napoli Gulf) and Amantea (Calabrian coasts) although these protected area mainly cover the distribution of coastal species. Other measures on which the management regulations are based are technical measures (mesh size) and minimum landing sizes (EC reg. 1967/06). In the GSA 10 the fishing ban has not been mandatory and it has been adopted on a voluntary basis by the fleet.

### 8.49.2.3.Catches

### 8.49.2.3.1. Landings

Available landing data are from DCR regulations. SGMED-09-02 received Italian landings data for GSA 10 by major fishing gears which are listed in Tab. 8.49.2.3.1.1. The fishing segments DTS and OTB, GNS, and PMP indicate respectively trawlers and small scale fishery (gillnet and polyvalent). After 2004, landings of the blue and red shrimp decreased in 2008 to the level of 2003 (about 20 t ) (Fig. 8.49.2.3.1.1). Most part of the landings is from trawlers.

Tab. 8.49.2.3.1.1. Annual landings (t) by gear type, 2003-2008.

| Sum <br> of LW | FT_LVL4 |  |  |  |  |
| :--- | :--- | :--- | :--- | :--- | :--- |

Landings of A. antennatus

Fig. 8.49.2.3.1.1Total landings (t) 2003-2008 as reported by DCR in the GSA10.

### 8.49.2.3.2. Fishing effort

The trends in fishing effort by year and major gear type is listed in Tab. 8.49.2.3.2.1 and shown in Fig. 8.49.2.3.2.1 in terms of $\mathrm{kW}^{*}$ days. The fishing segments DTS, HOK, PGP, PMP and PTS indicate respectively trawlers, long-lines, small scale fishery (nets), polyvalent and pair trawls. The fishing effort in kW *days of the trawlers, that is the fishing segment targeting the giant red shrimp, was rising in 2004 and 2005 and then decreasing in 2006 and 2007.

### 8.49.3. Scientific surveys

8.49.3.1.Medits

### 8.49.3.1.1. Methods

According to the MEDITS protocol (Bertrand et al., 2002), trawl surveys were carried out yearly (May-July), applying a random stratified sampling by depth (5 strata with depth limits at: 50, 100, 200, 500 and 800 m ; each haul position randomly selected in small sub-areas and maintained fixed throughout the time). Haul
allocation was proportional to the stratum area. The same gear (GOC 73, by P.Y. Dremière, IFREMERSète), with a 20 mm stretched mesh size in the cod-end, was employed throughout the years. Detailed data on the gear characteristics, operational parameters and performance are reported in Dremière and Fiorentini (1996). Considering the small mesh size a complete retention was assumed.

Based on the DCR data call, abundance and biomass indices were calculated. In GSA 10 the following number of hauls were reported per depth stratum (Tab. 8.49.3.1.1.1).

Tab. 8.49.3.1.1.1 Number of hauls per year and depth stratum in GSA 10, 1994-2008.

| STRATUM | 1994 | 1995 | 1996 | 1997 | 1998 | 1999 | 2000 | 2001 | 2002 | 2003 | 2004 | 2005 | 2006 | 2007 | 2008 |
| :--- | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |

| GSA10_050-100 | 12 | 12 | 12 | 12 | 12 | 12 | 12 | 12 | 10 | 10 | 10 | 10 | 10 | 10 | 10 |
| GSA10_100-200 | 20 | 20 | 20 | 20 | 20 | 20 | 20 | 20 | 17 | 17 | 17 | 17 | 17 | 17 | 17 |
| GSA10_200-500 | 26 | 27 | 26 | 26 | 27 | 26 | 26 | 28 | 22 | 22 | 22 | 22 | 22 | 22 | 22 |
| GSA10_500-800 | 31 | 30 | 31 | 31 | 31 | 30 | 31 | 29 | 26 | 27 | 26 | 26 | 26 | 26 | 26 |

Data were assigned to strata based upon the shooting position and average depth (between shooting and hauling depth). Few obvious data errors were corrected. Catches by haul were standardized to 60 minutes hauling duration. Only hauls considered as valid were used in the analysis including stations with no catches (zero catches are included).

The abundance and biomass indices by GSA were calculated through stratified means (Cochran, 1953; Saville, 1977). This implies weighting of the average values of the individual standardized catches and the variation of each stratum by the respective stratum areas in each GSA:
$\mathrm{Yst}=\Sigma\left(\mathrm{Yi}^{*} \mathrm{Ai}\right) / \mathrm{A}$
$\mathrm{V}(\mathrm{Yst})=\Sigma\left(\mathrm{Ai}^{2} * \mathrm{si}^{2} / \mathrm{ni}\right) / \mathrm{A}^{2}$
Where:
A=total survey area
$\mathrm{Ai}=$ area of the i-th stratum
si=standard deviation of the i-th stratum
ni=number of valid hauls of the i-th stratum
n=number of hauls in the GSA
$\mathrm{Yi}=$ mean of the i -th stratum
Yst=stratified mean abundance
$\mathrm{V}(\mathrm{Yst})=$ variance of the stratified mean
The variation of the stratified mean is then expressed as the $95 \%$ confidence interval: Confidence interval $=$ Yst $\pm \mathrm{t}$ (student distribution) $* \mathrm{~V}(\mathrm{Yst}) / \mathrm{n}$

It was noted that while this is a standard approach, the calculation may be biased due to the assumptions over zero catch stations, and hence assumptions over the distribution of data. A normal distribution is often assumed, whereas data may be better described by a delta-distribution, quasi-poisson. Indeed, data may be better modelled using the idea of conditionality and the negative binomial (e.g. O'Brien et al. (2004)).

Length distributions represented an aggregation (sum) of all standardized length frequencies (subsamples raised to standardized haul abundance per hour) over the stations of each stratum. Aggregated length frequencies were then raised to stratum abundance * 100 (because of low numbers in most strata) and finally aggregated (sum) over the strata to the GSA.

### 8.49.3.1.2. Geographical distribution patterns

No analyses were conducted during SGMED-09-02.

### 8.49.3.1.3. Trends in abundance and biomass

Fishery independent information regarding the state of the red shrimp in GSA 10 was derived from the international survey Medits. Figure 8.49.3.1.3.1 displays the estimated trend in blue and red shrimp abundance and biomass in GSA 10 .

The estimated abundance and biomass indices varied without a clear trend during 1994-2008.

Fig. 8.49.3.1.3.1 Abundance and biomass indices of red shrimp in GSA 10.

### 8.49.3.1.4. Trends in abundance by length or age

The following Fig. 8.49.3.1.4.1 and 2 display the stratified abundance indices of GSA 10 in 1994-2008.

Fig. 8.49.3.1.4.2 Stratified abundance indices by size, 2002-2008.

### 8.49.3.1.5. Trends in growth

No analyses were conducted during SGMED-09-02.
8.49.3.1.6. Trends in maturity

No analyses were conducted during SGMED-09-02.

### 8.49.3.2.GRUND

### 8.49.3.2.1. Methods

Since 2003 Grund surveys (Relini, 2000) was conducted using the same sampler (vessel and gear) in the whole GSA. Sampling scheme, stratification and protocols were similar as in Medits. All the abundance and biomass data were standardised to the square kilometre, using the swept area method.

### 8.49.3.2.2. Geographical distribution patterns

No analyses were conducted during SGMED-09-02.

### 8.49.3.2.3. Trends in abundance and biomass

Trends derived from the GRUND surveys are shown in Fig. 8.49.3.2.3.1. Abundance and biomass indices show some fluctuations with peaks in different years from Medits (Fig. 8.49.3.1.3.1). Higher values were recorded in 1996 and 2005.

Fig. 8.49.3.2.3.1. Abundance and biomass indices of blue and red shrimp in GSA 10 (bars indicate standard deviations) derived from Grund surveys.

### 8.49.3.2.4. Trends in abundance by length or age

No annual figures of length compositions were constructed.
A positive trend in the mean length was observed in Medits survey (Fig. 8.49.3.2.4.1), while no trend at the third quantile lengths was observed in the length structures of Grund time series from 1994 to 2006 (Fig. 8.49.3.2.4.2).

Fig. 8.49.3.2.4.1 Mean length, variance and quantiles derived from the Medits length compositions in 19952008.

Third quartile carapace length (mm) A. antennatus

Fig. 8.49.3.2.4.2 III Quantile derived from the GRUND length structures in 1994-2006.

### 8.49.3.2.5. Trends in growth

No analyses were conducted during SGMED-09-02.

### 8.49.3.2.6. Trends in maturity

No analyses were conducted during SGMED-09-02.

### 8.49.4. Assessment of historic stock parameters

No analytical assessment was performed.

### 8.49.5. Long term prediction

### 8.49.5.1.Justification

No forecast analyses were conducted.
8.49.5.2. Input parameters

No forecast analyses were conducted.
8.49.5.3. Results

Given the preliminary state of the data and analyses SGMED-09-02 is not in the position to provide a short term prediction of catch and stock biomass for blue and red shrimp in GSA 10.

### 8.49.6. $\quad$ Scientific advice

8.49.6.1. Short term considerations

### 8.49.6.1.1. State of the spawning stock size

SGMED-09-02 is unable to provide any scientific advice of the state of the spawning stock in relation to proposed precautionary level given the preliminary state of the data and analyses.

### 8.49.6.1.2. State of recruitment

SGMED-09-02 is unable to provide any scientific advice of the state of recruitment in relation to proposed precautionary level given the preliminary state of the data and analyses.

### 8.49.6.1.3. State of exploitation

SGMED-09-02 is unable to provide any scientific advice of the state of exploitation in relation to proposed precautionary level given the preliminary state of the data and analyses.

### 8.50. Stock assessment of blue and red shrimp in GSA 11

### 8.50.1.Stock identification and biological features

### 8.50.1.1.Stock Identification

No information was documented during SGMED-09-02.

### 8.50.1.2.Growth

No information was documented during SGMED-09-02.

### 8.50.1.3.Maturity

No information was documented during SGMED-09-02.

### 8.50.2.Fisheries

8.50.2.1.General description of fisheries

No information was documented during SGMED-09-02.
8.50.2.2.Management regulations applicable in 2008 and 2009

No information was documented during SGMED-09-02.

### 8.50.2.3.Catches

### 8.50.2.3.1. Landings

Tab. 8.50.2.3.1.1 lists the trend in reported landings by fishing technique. The data were reported to SGMED-09-02 through the Data Collection Regulation and are listed in Table A3.8 of Appendix 3. The landings were mainly taken by demersal otter trawls.

Tab. 8.50.2.3.1.1 Annual landings (t) by fishing technique in GSA 11. Landings data provided for the year 2003 probably have a mistake in the units used.

| SPECIES | AREA | COUNTRY | FT_LVL4 | 2002 | 2003 | 2004 | 2005 | 2006 | 2007 | 2008 |

8.50.3.Scientific surveys

### 8.50.3.1.Medits

### 8.50.3.1.1. Methods

Based on the DCR data call, abundance and biomass indices were recalculated. In GSA 11 the following number of hauls was reported per depth stratum (s. Tab. 8.50.3.1.1.1).

Tab. 8.50.3.1.1.1. Number of hauls per year and depth stratum in GSA 11, 1994-2008.

| STRATUM | 1994 | 1995 | 1996 | 1997 | 1998 | 1999 | 2000 | 2001 | 2002 | 2003 | 2004 | 2005 | 2006 | 2007 | 2008 |
| :--- | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| GSA11_010-050 | 17 | 19 | 21 | 21 | 21 | 21 | 19 | 18 | 20 | 18 | 17 | 17 | 19 | 19 | 17 |
| GSA11_050-100 | 27 | 21 | 22 | 22 | 20 | 22 | 22 | 24 | 19 | 19 | 18 | 21 | 18 | 20 | 19 |
| GSA11_100-200 | 22 | 23 | 30 | 31 | 31 | 30 | 31 | 30 | 24 | 24 | 24 | 24 | 24 | 24 | 22 |
| GSA11_200-500 | 35 | 29 | 29 | 26 | 25 | 27 | 24 | 25 | 20 | 24 | 21 | 20 | 20 | 20 | 21 |
| GSA11_500-800 | 23 | 16 | 21 | 25 | 25 | 24 | 27 | 26 | 16 | 14 | 15 | 14 | 16 | 17 | 16 |

Data were assigned to strata based upon the shooting position and average depth (between shooting and hauling depth). Few obvious data errors were corrected. Catches by haul were standardized to 60 minutes hauling duration. Hauls noted as valid were used only, including stations with no catches of hake, red mullet or pink shrimp (zero catches are included).

The abundance and biomass indices by GSA were calculated through stratified means (Cochran, 1953; Saville, 1977). This implies weighting of the average values of the individual standardized catches and the variation of each stratum by the respective stratum areas in each GSA:
$\mathrm{Yst}=\Sigma\left(\mathrm{Yi}^{*} \mathrm{Ai}\right) / \mathrm{A}$
$\mathrm{V}(\mathrm{Yst})=\Sigma\left(\mathrm{Ai}^{2} * \mathrm{si}^{2} / \mathrm{ni}\right) / \mathrm{A}^{2}$
Where:
$\mathrm{A}=$ total survey area
$\mathrm{Ai}=$ area of the i -th stratum
si=standard deviation of the i-th stratum
ni=number of valid hauls of the i-th stratum
n=number of hauls in the GSA
Yi=mean of the i-th stratum
Yst=stratified mean abundance
$\mathrm{V}(\mathrm{Yst})=$ variance of the stratified mean
The variation of the stratified mean is then expressed as the $95 \%$ confidence interval: Confidence interval $=$ Yst $\pm \mathrm{t}$ (student distribution) $* \mathrm{~V}(\mathrm{Yst}) / \mathrm{n}$

It was noted that while this is a standard approach, the calculation may be biased due to the assumptions over zero catch stations, and hence assumptions over the distribution of data. A normal distribution is often assumed, whereas data may be better described by a delta-distribution, quasi-poisson. Indeed, data may be better modelled using the idea of conditionality and the negative binomial (e.g. O'Brien et al. (2004)).

Length distributions represented an aggregation (sum) of all standardized length frequencies (subsamples raised to standardized haul abundance per hour) over the stations of each stratum. Aggregated length frequencies were then raised to stratum abundance * 100 (because of low numbers in most strata) and finally aggregated (sum) over the strata to the GSA. Given the sheer number of plots generated, these distributions are not presented in this report.

### 8.50.3.1.2. Geographical distribution patterns

No analyses were conducted during SGMED-09-02.

### 8.50.3.1.3. Trends in abundance and biomass

Fishery independent information regarding the state of the blue and red shrimp in GSA 11 was derived from the international survey Medits. Figure 8.50.3.1.3.1 displays the estimated trend in blue and red shrimp abundance and biomass in GSA 11. The analyses of Medits indices are considered preliminary.

Fig. 8.50.3.1.3.1 Abundance and biomass indices of blue and red shrimp in GSA 11.

### 8.50.3.1.4. Trends in abundance by length or age

The following Fig. 8.50.3.1.4.1 and 2 display the stratified abundance indices of GSA 11 in 1994-2008. These size compositions are considered preliminary.

Fig. 8.50.3.1.4.1 Stratified abundance indices by size, 1994-2001.

Fig. 8.50.3.1.4.2 Stratified abundance indices by size, 2002-2008.

### 8.50.3.1.5. Trends in growth

No analyses were conducted during SGMED-09-02.

No analyses were conducted during SGMED-09-02.
8.50.4.Assessment of historic stock parameters

SGMED-09-02 did not undertake any analytical assessment.
8.50.5.Long term prediction
8.50.5.1.Justification

No forecast analyses were conducted.

### 8.50.5.2.Input parameters

No forecast analyses were conducted.

### 8.50.5.3.Results

Given the preliminary state of the data and analyses SGMED-09-02 is not in the position to provide a long term prediction of catch and stock biomass for blue and red shrimp in GSA 11.

### 8.50.6.Scientific advice

### 8.50.6.1.Short term considerations

### 8.50.6.1.1. State of the spawning stock size

SGMED-09-02 is unable to provide any scientific advice of the state of the spawning stock given the preliminary state of the data and analyses.

### 8.50.6.1.2. State of recruitment

SGMED-09-02 is unable to provide any scientific advice of the state of the recruitment given the preliminary state of the data and analyses.

### 8.50.6.1.3. State of exploitation

SGMED-09-02 is unable to provide any scientific advice of the state of the exploitation in relation to proposed precautionary and target levels given the preliminary state of the data and analyses.

### 8.51. Stock assessment of blue and red shrimp in GSA 16

### 8.51.1.Stock identification and biological features

### 8.51.1.1.Stock Identification

No information was documented during SGMED-09-02.

### 8.51.1.2.Growth

No information was documented during SGMED-09-02.

### 8.51.1.3.Maturity

No information was documented during SGMED-09-02.

### 8.51.2.Fisheries

8.51.2.1.General description of fisheries

No information was documented during SGMED-09-02.
8.51.2.2.Management regulations applicable in 2008 and 2009

No information was documented during SGMED-09-02.

### 8.51.2.3.Catches

### 8.51.2.3.1. Landings

Tab. 8.51.2.3.1.1 lists the trend in reported landings by fishing technique. The data were reported to SGMED-09-02 through the Data Collection Regulation and are listed in Table A3.8 of Appendix 3. The landings were taken by demersal otter trawls.

Tab. 8.51.2.3.1.1 Annual landings ( t ) by fishing technique in GSA 16.

Data were assigned to strata based upon the shooting position and average depth (between shooting and hauling depth). Few obvious data errors were corrected. Catches by haul were standardized to 60 minutes hauling duration. Hauls noted as valid were used only, including stations with no catches of hake, red mullet or pink shrimp (zero catches are included).

The abundance and biomass indices by GSA were calculated through stratified means (Cochran, 1953; Saville, 1977). This implies weighting of the average values of the individual standardized catches and the variation of each stratum by the respective stratum areas in each GSA:
$\mathrm{Yst}=\Sigma\left(\mathrm{Yi}^{*}{ }^{*} \mathrm{Ai}\right) / \mathrm{A}$
$\mathrm{V}(\mathrm{Yst})=\Sigma\left(\mathrm{Ai}^{2} * \mathrm{si}^{2} / \mathrm{ni}\right) / \mathrm{A}^{2}$
Where:
A=total survey area
$\mathrm{Ai}=$ area of the i -th stratum
si=standard deviation of the i-th stratum
ni=number of valid hauls of the i-th stratum
$\mathrm{n}=$ number of hauls in the GSA
$\mathrm{Yi}=$ mean of the i-th stratum
Yst=stratified mean abundance
$\mathrm{V}(\mathrm{Yst})=$ variance of the stratified mean
The variation of the stratified mean is then expressed as the $95 \%$ confidence interval: Confidence interval $=$ Yst $\pm \mathrm{t}$ (student distribution) $* \mathrm{~V}(\mathrm{Yst}) / \mathrm{n}$

It was noted that while this is a standard approach, the calculation may be biased due to the assumptions over zero catch stations, and hence assumptions over the distribution of data. A normal distribution is often assumed, whereas data may be better described by a delta-distribution, quasi-poisson. Indeed, data may be better modelled using the idea of conditionality and the negative binomial (e.g. O'Brien et al. (2004)).

Length distributions represented an aggregation (sum) of all standardized length frequencies (subsamples raised to standardized haul abundance per hour) over the stations of each stratum. Aggregated length frequencies were then raised to stratum abundance * 100 (because of low numbers in most strata) and finally aggregated (sum) over the strata to the GSA. Given the sheer number of plots generated, these distributions are not presented in this report.

### 8.51.3.1.2. Geographical distribution patterns

No analyses were conducted during SGMED-09-02.

### 8.51.3.1.3. Trends in abundance and biomass

Fishery independent information regarding the state of the blue and red shrimp in GSA 16 was derived from the international survey Medits. Figure 8.51.3.1.3.1 displays the estimated trend in blue and red shrimp abundance and biomass in GSA 16. The analyses of Medits indices are considered preliminary.

Fig. 8.51.3.1.3.1 Abundance and biomass indices of blue and red shrimp in GSA 16.

### 8.51.3.1.4. Trends in abundance by length or age

The following Fig. 8.51.3.1.4.1 and 2 display the stratified abundance indices of GSA 16 in 1994-2008. These size compositions are considered preliminary.

### 8.51.3.1.5. Trends in growth

No analyses were conducted during SGMED-09-02.
8.51.3.1.6. Trends in maturity

No analyses were conducted during SGMED-09-02.

### 8.51.4.Assessment of historic stock parameters

SGMED-09-02 did not undertake any analytical assessment.

### 8.51.5.Long term prediction

### 8.51.5.1.Justification

No forecast analyses were conducted.

### 8.51.5.2.Input parameters

No forecast analyses were conducted.

### 8.51.5.3.Results

Given the preliminary state of the data and analyses SGMED-09-02 is not in the position to provide a long term prediction of catch and stock biomass for blue and red shrimp in GSA 16.

### 8.51.6.Scientific advice

### 8.51.6.1.Short term considerations

### 8.51.6.1.1. State of the spawning stock size

SGMED-09-02 is unable to provide any scientific advice of the state of the spawning stock given the preliminary state of the data and analyses.

### 8.51.6.1.2. State of recruitment

SGMED-09-02 is unable to provide any scientific advice of the state of the recruitment given the preliminary state of the data and analyses.

### 8.51.6.1.3. State of exploitation

SGMED-09-02 is unable to provide any scientific advice of the state of the exploitation in relation to proposed precautionary and target levels given the preliminary state of the data and analyses.

### 8.52. Stock assessment of giant red shrimp in GSA 10

### 8.52.1. Stock identification and biological features

### 8.52.1.1.Stock Identification

The stock of giant red shrimp, Aristaeomorpha foliacea was assumed in the boundaries of the whole GSA10, lacking specific information on stock identification. This species and the blue-red shrimp, Aristeus antennatus, are deep-water decapods characterised by seasonal variability and annual fluctuations of abundance (Spedicato et al., 1994), as reported for different geographical areas (e.g. Relini and Orsi Relini, 1987). The giant red shrimp A. foliacea is distributed beyond 350 m depth, but mainly in water deeper than 500 m . Generally mean length estimated using trawl survey data varies remarkably with depth, for the whole population and the two sexes, increasing at deeper waters.

In the recent years A. foliacea is ranked among the more abundant species (in number and weight) in the trawl survey catches. Higher biomass indices occur particularly southwards the Gulf of Naples (Spedicato et al., 1994).

This species has a discrete recruitment pattern and during spring trawl surveys (Medits) a recruitment pulse is observed. Since the reproduction takes place in the late spring-summer, recruits could be attributed to the spawning events of the previous year (Spedicato et al., 1999). A. foliacea is considered fully recruited to grounds at about 24 mm CL (from Samed, AAVV, 2002). Recently a study at Mediterranean scale, using Medits data from 1994 to 2004, has evidenced that the higher abundance indices of recruits were observed in the central-southern Tyrrhenian Sea (AAVV, 2008).

In general the length frequency distributions of the giant red shrimp have a polymodal pattern, with 4-5 components for females (the modes of adults are less defined) and 2-3 components for the males. For the females a life span of $6-8$ years was estimated. The structure of the sizes of $A$. foliacea is characterised by marked differences in growth between the sexes. The larger individuals are females and inhabit deeper waters.

Sex ratio values of about 0.5 shows that males and females are not segregated into different bathymetric ranges (Spedicato et al., 1994). The reproduction period extends from May to September, with a peak in the summer (July-August) (Spedicato et al., 1999). Mature males have been observed all year round.

According to the benthic bionomic classification of Pérès and Picard (1964) P. longirostris, N. norvegicus and red-shrimps typify the populations of slope and bathyal bottoms in the GSA 10. Depending on the depth and zone, this fauna is accompanied by characteristic benthic species as Funiculina quadrangularis, Geryon longipes, Polycheles typhlops, Isidella elongata, Griphus vitreus.

In the central-southern Tyrrhenian Sea the giant red shrimp represents a specific target of the deep-waters trawling fishery given its high economic value (Spedicato et al., 1994).

### 8.52.1.2. Growth

Estimates of the growth pattern of the giant red shrimp in the GSA 10 were previously obtained using Grund length frequency distributions from 1991 to 1995 and methods as Elefan and Batthacharya for the analysis of LFDs. Parameters of females were as follows: $\mathrm{CL}_{\infty}=73.24 \mathrm{~mm} ; \mathrm{K}=0.483 ; \mathrm{t}_{0}=-0.435$ (Spedicato et al., 1998). In the Samed project (AAVV, 2002) and using the Medits data from 1994 to 1999 a new set of parameters was estimated for the Tyrrhenian Sea down the Strait of Messina (females: $L_{\infty}=73 \mathrm{~mm} ; \mathrm{K}=0.44 ; \mathrm{t}_{0}=-0.05$; males: $L_{\infty}=48 \mathrm{~mm} ; \mathrm{K}=0.59 ; \mathrm{t}_{0}=-0.2$ ). The observed maximum carapace length of females and males were 72 and 46 mm respectively.

Growth has been also studied in the DCR framework and in the Red Shrimps project (AAVV, 2008) through the analysis of the LFDs and the separation of modal components. These estimates have been done using both Medits and Grund average length at estimated age, where age was set according to the date of each survey with a birthday on $1^{\text {st }}$ July. Table 8.52.1.2.1 reports estimated ages, mean carapace lengths with relative standard deviations for females.

The following estimates of von Bertalanffy growth parameters for each sex were obtained from average length at age using an iterative non-liner procedure that minimises the sum of the square differences between observed and expected values and fixing the asymptotic length on the basis of the observed maximum values: females $\mathrm{CL}_{\infty}=72.5 \mathrm{~mm}, \mathrm{~K}=0.438, \mathrm{t}_{0}=-0.1$; males: $\mathrm{CL}_{\infty}=44 \mathrm{~cm}, \mathrm{~K}=0.5, \mathrm{t}_{0}=-0.1$. These estimates are more accurate, although very close to those previously obtained.

Parameters of the length-weight relationship were $a=0.54, b=2.71$ for females and $a=0.48, b=2.81$ for males, for length expressed in cm .

Tab. 8.52.1.2.1 Estimated age, mean length of modal components of the LFD of Medits and Grund survey and relative standard deviations.

GSA 10 - Aristaeomorpha foliacea - females

Fig. 8.52.1.2.1 V. Bertalanffy growth functions and parameters for female of giant red shrimp in the GSA 10 . Used data are those reported in the Tab. 8.52.1.2.1.

### 8.52.1.3.Maturity

The maturity ogive Fig. 8.52.1.3.1 was obtained from a maximum likelihood procedure applied grouping as mature individuals belonging to the maturity stage 2 b (according to the Medits maturity scale) and onwards. The fitting of the curve was fairly good, however the estimates of the size at first maturity $\mathrm{L}_{\mathrm{m} 50 \%}$ ( 3.5 cm $\pm 0.023 \mathrm{~cm}$ ) and the maturity range ( $0.36 \mathrm{~cm} \pm 0.020 \mathrm{~cm}$ ) seem underestimated if compared with literature values (average of the smallest females in the GSA is 34 mm CL; 39.6 mm carapace length according to Ragonese \& Bianchini, 1995).

Fig. 8.52.1.3.1 Maturity ogive and proportions of mature female of giant red shrimp in the GSA 10 (MR indicates the difference $\mathrm{Lm}_{75 \%}-\mathrm{Lm}_{25 \%}$ ).

The sex ratio from DCR evidenced the prevalence of males in the size class from 3.4 to 3.8 cm while from 4 cm onwards the proportion of females was dominant.

Fig. 8.52.1.3.2 Sex ratio over length.

### 8.52.2. Fisheries

8.52.2.1.General description of fisheries

The Giant red shrimp is only targeted by trawlers on fishing grounds located offshore deeper than 200 m , mainly southward Salerno Gulf. Catches from trawlers are from a depth range between 400 and 700 m depth and giant red shrimp occurs with A. antennaus, P. longirostris and N. norvegicus, P. blennoides, M. merluccius, depending on depth and area.
8.52.2.2.Management regulations applicable in 2008 and 2009

Management regulations are based on technical measures, like the number of fishing licenses and area limitation (distance from the coast and depth). In order to limit the over-capacity of the fleet, the Italian fishing licenses have been fixed since the late 1980s. After 2000, in agreement with the European Common Policy of Fisheries, a gradual decreasing of the fleet capacity is implemented. Along northern Sicily coasts two main Gulfs (Patti and Castellammare) have been closed to the trawl fishery up 200 m depth, since 1990. Two closed areas were also established in 2004 along the mainland, in front of Sorrento peninsula (Napoli Gulf) and Amantea (Calabrian coasts) although these protected areas mainly cover the distribution of coastal species. Other measures on which the management regulations are based are technical measures (mesh size) and minimum landing sizes (EC reg. 1967/06). In the GSA 10 the fishing ban has not been mandatory and it was adopted on a voluntary basis by the fleet.

### 8.52.2.3. Catches

### 8.52.2.3.1. Landings

Available landing data are from DCR regulations. SGMED-09-02 received Italian landings data for GSA 10 by major fishing gears which are listed in Tab. 8.52.2.3.1.1. The fishing segments DTS and OTB, PGP PMP and GNS indicate respectively trawlers, small scale fishery (nets), polyvalent and pair trawl. Since 2003, landings of the giant red shrimp increased from 148 t to 505 t in 2005 and decreased to 120 t in 2008 (Fig. $8.52 .2 .3 .1 .1)$. Most part of the landings is from trawlers.

Tab. 8.52.2.3.1.1. Annual landings (t) by gear type, 2003-2008.

| YEAR | Sum of LW DTS | $\begin{aligned} & \text { FT_LVL4 } \\ & \text { GNS } \end{aligned}$ | ОТВ | PGP | PMP | Total |

Landings of A. foliacea

Fig. 8.52.2.3.1.1 Total landings (t) 2003-2008 as reported through DCR in the GSA10.

### 8.52.2.3.2. Fishing effort

The trends in fishing effort by year and major gear type is listed in Tab. 8.52.2.3.2.1 and shown in Fig. 8.52.2.3.2.1 in terms of kW *days. The fishing segments DTS, HOK, PGP, PMP and PTS indicate respectively trawlers, long-lines, small scale fishery (nets), polyvalent and pair trawls. The fishing effort in kW *days of the trawlers, that is the fishing segment targeting the giant red shrimp, was rising in 2004 and 2005 and decreasing in 2006 and 2007.

### 8.52.3. Scientific surveys

8.52.3.1.Medits
8.52.3.1.1. Methods

According to the MEDITS protocol (Bertrand et al., 2002), trawl surveys were carried out yearly (May-July), applying a random stratified sampling by depth ( 5 strata with depth limits at: $50,100,200,500$ and 800 m ; each haul position randomly selected in small sub-areas and maintained fixed throughout the time). Haul allocation was proportional to the stratum area. The same gear (GOC 73, by P.Y. Dremière, IFREMERSète), with a 20 mm stretched mesh size in the cod-end, was employed throughout the years. Detailed data on the gear characteristics, operational parameters and performance are reported in Dremière and Fiorentini (1996). Considering the small mesh size a complete retention was assumed. All the abundance data (number of fish and weight per surface unit) were standardised to square kilometre, using the swept area method.

Based on the DCR data call, abundance and biomass indices were recalculated. In GSA 10 the following number of hauls was reported per depth stratum (s. Tab. 8.52.3.1.1.1).

Tab. 8.52.3.1.1.1. Number of hauls per year and depth stratum in GSA 10, 1994-2008.

| GSA10_500-800 | 31 | 30 | 31 | 31 | 31 | 30 | 31 | 29 | 26 | 27 | 26 | 26 | 26 | 26 | 26 |

Data were assigned to strata based upon the shooting position and average depth (between shooting and hauling depth). Few obvious data errors were corrected. Catches by haul were standardized to 60 minutes hauling duration. Hauls considered as valid were used in the analysis, including stations with no catches (zero catches are included).

The abundance and biomass indices by GSA were calculated through stratified means (Cochran, 1953; Saville, 1977). This implies weighting of the average values of the individual standardized catches and the variation of each stratum by the respective stratum areas in each GSA:
$\mathrm{Yst}=\Sigma\left(\mathrm{Yi}^{*} \mathrm{Ai}\right) / \mathrm{A}$

$$
\mathrm{V}(\mathrm{Yst})=\Sigma\left(\mathrm{Ai}^{2} * \mathrm{si}^{2} / \mathrm{ni}\right) / \mathrm{A}^{2}
$$

Where:
$\mathrm{A}=$ total survey area
$\mathrm{Ai}=$ area of the i -th stratum
si=standard deviation of the i-th stratum
ni=number of valid hauls of the i-th stratum
$\mathrm{n}=$ number of hauls in the GSA
$\mathrm{Yi}=$ mean of the i-th stratum
Yst=stratified mean abundance
$\mathrm{V}(\mathrm{Yst})=$ variance of the stratified mean
The variation of the stratified mean is then expressed as the $95 \%$ confidence interval: Confidence interval $=$ Yst $\pm \mathrm{t}$ (student distribution) $* \mathrm{~V}(\mathrm{Yst}) / \mathrm{n}$

It was noted that while this is a standard approach, the calculation may be biased due to the assumptions over zero catch stations, and hence assumptions over the distribution of data. A normal distribution is often assumed, whereas data may be better described by a delta-distribution, quasi-poisson. Indeed, data may be better modelled using the idea of conditionality and the negative binomial (e.g. O'Brien et al. (2004)).

Length distributions represented an aggregation (sum) of all standardized length frequencies (subsamples raised to standardized haul abundance per hour) over the stations of each stratum. Aggregated length
frequencies were then raised to stratum abundance * 100 (because of low numbers in most strata) and finally aggregated (sum) over the strata to the GSA.

### 8.52.3.1.2. Geographical distribution patterns

A comparative analysis of MEDITS and GRUND distribution patterns is presented in the following section 8.52.3.2.2 under the GRUND survey results.

### 8.52.3.1.3. Trends in abundance and biomass

Fishery independent information regarding the state of the giant red shrimp in GSA 10 was derived from the international survey Medits. Figure 8.52.3.1.3.1 displays the estimated trend of A. foliacea abundance and biomass standardized to the surface unit in GSA 10. Indices from Medits trawl-surveys show a fluctuating pattern with two peaks in 1997 and 2005, but without any trend (Fig. 8.52.3.1.3.1).

Dersity Afoliacea GSA10 ( $200-800 \mathrm{~m}$ ) - Medit

Biomass A.fliacea GSA10 (200-800m) - Medits

Fig. 8.52.3.1.3.1 Trends in survey abundance and biomass indices standardized to the surface unit and derived from Medits.

Medits indices were re-estimated based on the data obtained from the international data call. Such reestimated indices from Medits trawl-surveys show a fluctuating pattern with two peaks in 1997 and 2005, but without any trend (Fig. 8.52.3.1.3.2). The indices vary without a clear trend.

Fig. 8.52.3.1.3.2 Abundance and biomass indices of giant red shrimp in GSA 10.

### 8.52.3.1.4. Trends in abundance by length or age

The following Fig. 8.52.3.1.4.1 and 2 display the stratified abundance indices of GSA 10 in 1994-2008.

Fig. 8.52.3.1.4.1 Stratified abundance indices by size, 1994-2001.

Fig. 8.52.3.1.4.2 Stratified abundance indices by size, 2002-2008.

### 8.52.3.2.GRUND

### 8.52.3.2.1. Methods

Since 2003 Grund surveys (Relini, 2000) was conducted using the same sampler (vessel and gear) in the whole GSA. Sampling scheme, stratification and protocols were similar as in Medits. All the abundance and biomass data were standardised to the square kilometre, using the swept area method.

The geographical distribution pattern of the giant red shrimp has been studied in the area using trawl-survey data, length frequency distribution analyses via modal component separation techniques and geostatistical methods. The abundance of the whole population, as derived from both Medits and Grund surveys, was higher in the southern part of the GSA, along the Calabrian coast (Fig. 8.52.3.2.2.1) as well as the abundance of recruits (Fig. 8.52.3.2.2.2). The probability of find a nursery area was the highest in the same zone with a high temporal continuity.

Fig. 8.52.3.2.2.1 Maps of the abundance of the giant red shrimp from Medits and Grund surveys.

Fig. 8.52.3.2.2.2 Maps of the abundance of the giant red shrimp recruits (left) and of the probability of nursery localization (right) from Medits survey of 1997 and 2003 respectively. The contour of persistence areas is also evidenced in the map of abundance.

### 8.52.3.2.1. Trends in abundance and biomass

Trends derived from the GRUND surveys are shown in Fig. 8.52.3.2.1.1. Abundance and biomass indices show some peaks and fluctuations, but without any trend, as well as recruitment indices (Fig. 8.52.3.2.1.1). Higher values are recorded in 2003 and 2005. Although less varying, the pattern is similar to that observed in the Medits series.

Fig. 8.52.3.2.1.1. Abundance and biomass indices of giant red shrimp in GSA 10 (bars indicate standard deviations) derived from Grund surveys. Recruitment indices ( $\mathrm{N} / \mathrm{km}^{2}$ ) computed in the stratum 200-800 m depth with standard deviation is also reported.

### 8.52.3.2.2. Trends in abundance by length or age

No trend in the mean length was observed in Medits survey (Fig. 8.52.3.2.2.1), nor at the third quantile lengths, as obtained from the length structures of Grund time series from 1994 to 2006 (Fig. 8.52.3.2.2.2).

Fig. 8.52.3.2.2.1 Mean length, variance and quantiles derived from the Medits length compositions in 19952008.

Fig. 8.52.3.2.2.2 III Quantile derived from the GRUND length structures in 1994-2006.

The LFDs are rather varying throughout the Medits surveys, mainly for the recruitment strength that determines a dominance of the juvenile component in the LFDs of 1995, 1997, 2003 and 2005, while in the other years recruits are on average $30-50 \%$ of the total distribution (Fig. 8.52.3.2.2.3).

Fig. 8.52.3.2.2.3 Cumulative frequencies of the Medits LFDs (in percentage) and box plots.

### 8.52.3.2.3. Trends in growth

No analyses were conducted during SGMED-09-02.

### 8.52.3.2.4. Trends in maturity

No analyses were conducted during SGMED-09-02.

### 8.52.4. Assessment of historic stock parameters

No analytical assessment of historic stock parameters was conducted.

### 8.52.5. Long term prediction

### 8.52.5.1. Justification

No forecast analyses were conducted.

### 8.52.5.2. Input parameters

No forecast analyses were conducted.
8.52.5.3. Results

Given the preliminary state of the data and analyses SGMED-09-02 is not in the position to provide a short term prediction of catch and stock biomass for giant red shrimp in GSA 10.

### 8.52.6. Scientific advice

8.52.6.1.Short term considerations
8.52.6.1.1. State of the spawning stock size

SGMED-09-02 is unable to provide any scientific advice of the state of the spawning stock in relation to proposed precautionary level given the preliminary state of the data and analyses.

### 8.52.6.1.2. State of recruitment

SGMED-09-02 is unable to provide any scientific advice of the state of recruitment in relation to proposed precautionary level given the preliminary state of the data and analyses.

### 8.52.6.1.3. State of exploitation

SGMED-09-02 is unable to provide any scientific advice of the state of exploitation in relation to proposed precautionary level given the preliminary state of the data and analyses.

### 8.53. Stock assessment of giant red shrimp in GSA 11

### 8.53.1.Stock identification and biological features

### 8.53.1.1.Stock Identification

No information was documented during SGMED-09-02.

### 8.53.1.2.Growth

No information was documented during SGMED-09-02.

### 8.53.1.3.Maturity

No information was documented during SGMED-09-02.

### 8.53.2.Fisheries

8.53.2.1.General description of fisheries

No information was documented during SGMED-09-02.
8.53.2.2.Management regulations applicable in 2008 and 2009

No information was documented during SGMED-09-02.

### 8.53.2.3.Catches

### 8.53.2.3.1. Landings

Tab. 8.53.2.3.1.1 lists the trend in reported landings by fishing technique. The data were reported to SGMED-09-02 through the Data Collection Regulation and are listed in Table A3.8 of Appendix 3. The landings were mainly taken by demersal otter trawls.

Tab. 8.53.2.3.1.1 Annual landings (t) by fishing technique in GSA 11. Landings data provided for the year 2003 probably have a mistake in the units used.

### 8.53.2.3.2. Discards

According to information available to the SGMED-09-02 no catches of Aristaeomorpha foliacea were discarded by the Italian fleet.

### 8.53.2.3.3. Fishing effort

The trends in fishing effort by fishing technique reported to SGMED-09-02 are listed in Tab. 8.53.2.3.3.1 and in Tab. A3.10-3.12 of Appendix 3.

Tab. 8.53.2.3.3.1 Trends in annual fishing effort by fishing technique deployed in GSA 11, 2002-2007.

### 8.53.3.1.Medits

### 8.53.3.1.1. Methods

Based on the DCR data call, abundance and biomass indices were recalculated. In GSA 11 the following number of hauls was reported per depth stratum (s. Tab. 8.53.3.1.1.1).

Tab. 8.53.3.1.1.1. Number of hauls per year and depth stratum in GSA 11, 1994-2008.

| STRATUM | 1994 | 1995 | 1996 | 1997 | 1998 | 1999 | 2000 | 2001 | 2002 | 2003 | 2004 | 2005 | 2006 | 2007 | 2008 |
| :--- | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| GSA11_010-050 | 17 | 19 | 21 | 21 | 21 | 21 | 19 | 18 | 20 | 18 | 17 | 17 | 19 | 19 | 17 |
| GSA11_050-100 | 27 | 21 | 22 | 22 | 20 | 22 | 22 | 24 | 19 | 19 | 18 | 21 | 18 | 20 | 19 |
| GSA11_100-200 | 22 | 23 | 30 | 31 | 31 | 30 | 31 | 30 | 24 | 24 | 24 | 24 | 24 | 24 | 22 |
| GSA11_200-500 | 35 | 29 | 29 | 26 | 25 | 27 | 24 | 25 | 20 | 24 | 21 | 20 | 20 | 20 | 21 |
| GSA11_500-800 | 23 | 16 | 21 | 25 | 25 | 24 | 27 | 26 | 16 | 14 | 15 | 14 | 16 | 17 | 16 |

Data were assigned to strata based upon the shooting position and average depth (between shooting and hauling depth). Few obvious data errors were corrected. Catches by haul were standardized to 60 minutes hauling duration. Hauls noted as valid were used only, including stations with no catches of hake, red mullet or pink shrimp (zero catches are included).

The abundance and biomass indices by GSA were calculated through stratified means (Cochran, 1953; Saville, 1977). This implies weighting of the average values of the individual standardized catches and the variation of each stratum by the respective stratum areas in each GSA:

Yst $=\Sigma\left(\mathrm{Yi}^{*} \mathrm{Ai}\right) / \mathrm{A}$
$\mathrm{V}(\mathrm{Yst})=\Sigma\left(\mathrm{Ai}^{2} * \mathrm{si}^{2} / \mathrm{ni}\right) / \mathrm{A}^{2}$
Where:
$\mathrm{A}=$ total survey area
$\mathrm{Ai}=$ area of the i -th stratum
si=standard deviation of the i-th stratum
ni=number of valid hauls of the $i$-th stratum
$\mathrm{n}=$ number of hauls in the GSA
$\mathrm{Yi}=$ mean of the i -th stratum
Yst=stratified mean abundance
$\mathrm{V}(\mathrm{Yst})=$ variance of the stratified mean
The variation of the stratified mean is then expressed as the $95 \%$ confidence interval: Confidence interval $=$ Yst $\pm \mathrm{t}$ (student distribution) * $\mathrm{V}(\mathrm{Yst}) / \mathrm{n}$

It was noted that while this is a standard approach, the calculation may be biased due to the assumptions over zero catch stations, and hence assumptions over the distribution of data. A normal distribution is often assumed, whereas data may be better described by a delta-distribution, quasi-poisson. Indeed, data may be better modelled using the idea of conditionality and the negative binomial (e.g. O'Brien et al. (2004)).

Length distributions represented an aggregation (sum) of all standardized length frequencies (subsamples raised to standardized haul abundance per hour) over the stations of each stratum. Aggregated length frequencies were then raised to stratum abundance * 100 (because of low numbers in most strata) and finally
aggregated (sum) over the strata to the GSA. Given the sheer number of plots generated, these distributions are not presented in this report.

### 8.53.3.1.2. Geographical distribution patterns

No analyses were conducted during SGMED-09-02.

### 8.53.3.1.3. Trends in abundance and biomass

Fishery independent information regarding the state of the giant red shrimp in GSA 11 was derived from the international survey Medits. Figure 8.53.3.1.3.1 displays the estimated trend in giant red shrimp abundance and biomass in GSA 11. The analyses of Medits indices are considered preliminary.

Fig. 8.53.3.1.3.1 Abundance and biomass indices of giant red shrimp in GSA 11.

### 8.53.3.1.4. Trends in abundance by length or age

The following Fig. 8.53.3.1.4.1 and 2 display the stratified abundance indices of GSA 11 in 1994-2008. These size compositions are considered preliminary.

Fig. 8.53.3.1.4.1 Stratified abundance indices by size, 1994-2001.

$\square$

Fig. 8.53.3.1.4.2 Stratified abundance indices by size, 2002-2008.

### 8.53.3.1.5. Trends in growth

No analyses were conducted during SGMED-09-02.

### 8.53.3.1.6. Trends in maturity

No analyses were conducted during SGMED-09-02.
8.53.4.Assessment of historic stock parameters

SGMED-09-02 did not undertake any analytical assessment.

### 8.53.5.Long term prediction

### 8.53.5.1.Justification

No forecast analyses were conducted.

### 8.53.5.2.Input parameters

No forecast analyses were conducted.

### 8.53.5.3.Results

Given the preliminary state of the data and analyses SGMED-09-02 is not in the position to provide a long term prediction of catch and stock biomass for giant red shrimp in GSA 11.

### 8.53.6.Scientific advice

### 8.53.6.1.Short term considerations

### 8.53.6.1.1. State of the spawning stock size

SGMED-09-02 is unable to provide any scientific advice of the state of the spawning stock given the preliminary state of the data and analyses.

### 8.53.6.1.2. State of recruitment

SGMED-09-02 is unable to provide any scientific advice of the state of the recruitment given the preliminary state of the data and analyses.

### 8.53.6.1.3. State of exploitation

SGMED-09-02 is unable to provide any scientific advice of the state of the exploitation in relation to proposed precautionary and target levels given the preliminary state of the data and analyses.

### 8.54. Stock assessment of giant red shrimp in GSAs 15 and 16

### 8.54.1. Stock identification and biological features

### 8.54.1.1.Stock Identification

No information is available to the SGMED-09-02 on stock unity in the area and thus the stock was assumed to be confined within the boundaries of the GSA 15 and 16 also according recommendations made by SGMED-09-01.

### 8.54.1.2. Growth and natural mortality

Considering the northern sector of the Strait of Sicily (GSA 15 and 16) the observed maximum length was 70 mm . After age slicing with the parameters estimated by CNR-IAMC (2009; Tab. 8.54.1.2.1), the maximum estimated age in years in the exploited part of the stock resulted to be 6 years. The growth parameters estimated in the past for the Strait of Sicily are reported in Tab. 8.54.1.2.1 for comparative purposes.

During SGMED-09-02 new parameters were estimated in order to allow a better performance of the VIT approach. These new parameters, had a higher $\mathrm{L}_{\mathrm{inf}}$ and lower k than the parameters given by the data call, but were nevertheless characterised by a very similar growth performance (see $\Phi^{\prime}$ column in Tab. 8.54.1.2.1), as obtained by the Powel-Wetherall method (linf) and the ELEFAN "K scan" routine (K). The data used for this application were the length frequency distributions collected in trawl surveys from 1994 to 2008. Parameters were then estimated by the package FISAT II (Gayanilo et al., 2005).

Tab. 8.54.1.2.1 Von Bertalanffy growth function, growth performance index and length-weight relationship parameters in the Strait of Sicily (GSA 15 and 16) ( $\mathrm{L}_{\text {inf }}$ as CL in mm).

### 8.54.1.3.Maturity

Although spawning in A. foliacea occurs from spring till autumn in the Strait of Sicily, maturity peaks in summer (Ragonese and Bianchini, 1995). According to Ragonese et al. (2004) the length at $50 \%$ of maturity is 42 mm CL in females and $30-33 \mathrm{~mm}$ CL in males. The most recent assessment of maturity ogive was given by CNR_IAMC (2009), with $\mathrm{L}_{50 \%}=37.17$ (es $=0.108$ ) mm CL and slope $\mathrm{g}=0.541$ (es $=0.028$ ) in females and $\mathrm{L}_{50 \%}=27.41(\mathrm{es}=0.0 .037) \mathrm{mm}$ CL and slope $\mathrm{g}=0.988(\mathrm{es}=0.031)$ in males.

### 8.54.2.1.General description of fisheries

The giant red shrimps is a relevant target species of the Sicilian and Maltese trawlers and is caught on the slope ground during all year round, although landing peaks are observed in summer. A.foliacea is fished mainly in the central - eastern side of the Strait of Sicily, whereas in the western side it is substituted by the blue and red shrimp, Aristeus antennatus. A rough delimitation of the most important fishing grounds of red shrimps in the Strait of Sicily is reported in Ragonese (1989) (Fig. 8.54.2.1.1). However, due to reduction of catch rates since 2004, some trawlers based in Mazara del Vallo, which is the main fleet in the area, recently moved to the eastern Mediterranean (Aegean and Levant Sea) to fish red shrimps (Garofalo et al., 2007).

Fig 8.54.2.1.1 Main fishing grounds of red shrimps in the Strait of Sicily according to Ragonese (1989).

In Maltese waters, trawlers targeting the giant red shrimp A. foliacea within the 25 nm fisheries management zone trawl either to the north / north-west of the Island of Gozo, or to the west / south-west of Malta, at depths of about 600 m . Detailed maps of the trawling grounds for Maltese Fisheries Management Zone (FMZ), including a wide part of GSA 15 will soon be available in Camilleri et al. (in press).

In terms of fishing gear, the Italian and Maltese trawlers operating in the Strait of Sicily use the same typology of trawl net called "Italian trawl net", which is a type of otter trawl. Although some differences in
material between the net used in shallow waters ("banco" net, mainly targeting shelf fish and cephalopods) and that employed in deeper ones ("fondale" net, mainly targeting deep water crustaceans) exist, the Italian trawl net is characterized by a low vertical opening (up to 1.5 m ) with dimensions changing with engine power (Fiorentino et al., 2003). Using this gear, giant red shrimps are frequently caught together with Norway lobster (Nephrops norvegicus), large sized deep water pink shrimp (Parapenaeus longirostris), the more rare blue and red shrimp (Aristeus antennatus) as well as large hake (Merluccius merluccius).

### 8.54.2.2. Management regulations applicable in 2008 and 2009

At present there are no formal management objectives for giant red shrimp fisheries in the Strait of Sicily. As in other areas of the Mediterranean, the stock management is based on control of fishing capacity (licenses), fishing effort (fishing activity) and technical measures (mesh size and area/season closures). In addition, a compulsive fishing ban for 30 days was adopted by Sicilian Government (August - September). No minimum landing sizes have been established for this species (EC 1967/06).

In Maltese waters there are no closed seasons, however in order to limit the over-capacity of fishing fleet, Maltese fishing licenses have been fixed at a total of 16 trawlers since 2000 . Eight new licences were however issued in 2008, a move made possible under EU law by the reduction of the capacities of other Maltese fishing fleets. Moreover, the Maltese Islands are surrounded by a 25 nautical miles (nm) fisheries management zone, where fishing effort and capacity are being managed by limiting vessel sizes, as well as total vessel engine powers (EC 813/04; EC 1967/06). Trawling is allowed within this designated conservation area, however only by vessels not exceeding an overall length of 24 m . Such vessels fishing in the management zone hold a special fishing permit in accordance with Article 7 of Regulation (EC) No 1627/94, and are included in a list containing their external marking and vessel's Community fleet register number (CFR) to be provided to the Commission annually by the Member State. Moreover, the overall capacity of the trawlers allowed to fish in the 25 nm zone can not exceed $4,800 \mathrm{~kW}$, and the total fishing effort of all vessels is not allowed to exceed an overall engine power and tonnage of $83,000 \mathrm{~kW}$ and 4,035 GT respectively. The fishing capacity of any single vessel with a license to operate at less than 200 m depth can not exceed 185 kW . In addition, the use of all trawl nets within 1.5 nm of the coast is prohibited according to EC regulation 1967/2006, although a transitional derogation is at present in place until 2010.

In terms of technical measures, the EC regulation 1967/2006 fixed a minimum mesh size of 40 mm for bottom trawling of EU fishing vessels (Italian and Maltese trawlers). Mesh size had to be modified to square 40 mm or diamond 50 mm in July 2008, however derogations are possible up to 2010.

In addition to these management measures, the protection of spawning grounds has been suggested to be one of the most effective management approaches to enhance recruitment whilst maintaining the reproductive potential of the populations. Similarly, reducing fishing effort on juveniles is vital if stocks are to be harvested at maximum sustainable yield, in particular when juveniles are vulnerable to unselective fishing gears. The location of nursery and spawning areas of A. foliacea was recently identified using MEDITS trawl survey data from GSA 15 (2003-2007). The distribution of mature and immature individuals of $N$. norvegicus and A. foliacea was however found to be patchy, with sites distributed throughout the waters lying to the west / northwest of the Maltese Islands (Fig 8.54.2.2.1 and Fig 8.54.2.2.2). This makes difficult the designation of a single protected area for protecting the vulnerable life cycle stages of this species.

Fig. 8.54.2.2.1: Map of GSA 15, showing distribution of normalised density indices for immature $A$. foliacea.

Fig. 8.54.2.2.1: Map of GSA 15, showing distribution of normalised density indices for mature A. foliacea.

Yield of the Italian trawlers in 2006 was about $1,883 \mathrm{t}$ decreasing to $1,721 \mathrm{t}$ in 2008. The Maltese trawlers landed 25 t in 2006 and 34 t in 2007.

Tab. 8.54.2.3.1.1 Landings (t) by year and major gear types, 2005-2008 as reported through DCR, OTB = bottom otter trawls.

| Species | Area | Country | Fleet | 2005 | 2006 | 2007 | 2008 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| ARS | 15 | Malta | OTB | 17 | 26 | 34 | 27 |
| ARS | 16 | Italy | OTB | 1270 | 1424 | 1540 | 1260 |
| ARS | 158 \& 16 | Italy | OTB | 1287 | 1450 | 1574 | 1287 |

The most recent Italian and Maltese data were collected within the framework of the DCR. Available information is considered feasible by the experts attending the working group.

In GSA 15 about 704 tonnes of fish were landed in 2007. The most landed species in terms of weight were Thunnus thynnus (34\%), Coryphaena hippurus (25\%), Xiphias gladius (19\%). These species together constitute about $78 \%$ of the total landed catch in 2007. A. foliacea was the most landed crustacean by total weight, making up $1.3 \%$ of catches. The following table summarises the percentage distribution of landings estimtated through sales vouchers.

Tab. 8.54.2.3.1.2 Landed catch for GSA 15 in 2007 estimated through sales vouchers (from Malta Technical Report 2007).

|  | \% <br> impurtance <br> uf tutal catch |
| :--- | ---: |
| Species | 34.2 |
| Thupnus thynnus | 25.2 |
| Coryphaena hippuris | 19.3 |
| Siphas gladius | 1.8 |
| Squalus blainvillei | 1.5 |
| Boops boops | 1.4 |
| Scorpaena scrofa | 1.3 |
| Aristaeomorpha foliacea | 1.3 |
| Epinephelus spp. | 14.0 |
| Others | $\mathbf{1 0 1 \%}$ |
| Grand Tutal |  |

Regarding length compositions of landings, information is only available for Sicilian vessels (Fig. 8.54.2.3.1.1). Data were considered representative since the $3^{\text {rd }}$ quarter of 2005 , when a sampling scheme allowing a realistic raising of the sampled catches to the total ones was adopted (SIBM, 2005).

Fig. 8.54.2.3.1.1 Yearly length structure of giant red shrimp landings (females) in absolute numbers of Sicilian trawlers (GSA 16).

### 8.54.2.3.2. Discards

According to information available to the SGMED-09-02 no catches of red shrimp were discarded by Italian trawlers. An assessment of the discards made by the Maltese fishing industry was carried out in 2005. Results showed that there is no discard practice amongst boats smaller than 10 m and that for larger boats the discard rate is negligible (average $4.7 \%$ ). More detailed information on volume and species composition of the discards of vessels larger than 10 m by gear type and fleet segment is at present being compiled under the new Data Collection Framework. The bottom otter trawl fleet is being monitored monthly since January 2009, however preliminary analyses are still not available.

### 8.54.2.3.3. Fishing effort

The trends in fishing effort by year and major gear type is listed in Tab. 8.54.2.3.3.1 and shown in Fig. 8.54.2.3.3.1 in terms of GT*days for the otter trawls.

Fig. 8.54.2.3.3.1 Fishing effort in terms of GT*days of trawlers targeted to demersal species in GSAs 15 and 16.

8.54.3. Scientific surveys

### 8.54.3.1.Medits

### 8.54.3.1.1. Methods

In GSA 15 and 16 the following number of hauls was reported per depth stratum (s. Tab. 8.54.3.1.1.1).

Tab. 8.54.3.1.1.1 Number of hauls per year and depth stratum in GSAs 15 and 16, 1994-2008.

| GSA | Stratum | 94 | 95 | 96 | 97 | 98 | 99 | 00 | 01 | 02 | 03 | 04 | 05 | 06 | 07 | 08 |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| 15 | a |  |  |  |  |  |  |  |  | 1 | 1 | 2 | 1 | 1 | 0 | 0 |
| 15 | b |  |  |  |  |  |  |  |  | 5 | 5 | 4 | 5 | 2 | 12 | 6 |
| 15 | c |  |  |  |  |  |  |  |  | 13 | 13 | 13 | 13 | 13 | 12 | 13 |
| 15 | d |  |  |  |  |  |  |  |  | 10 | 10 | 10 | 9 | 10 | 4 | 9 |
| 15 | e |  |  |  |  |  |  |  |  | 16 | 16 | 15 | 17 | 16 | 17 | 17 |
| 16 | a | 4 | 4 | 4 | 4 | 4 | 4 | 4 | 4 | 7 | 7 | 7 | 10 | 10 | 11 | 11 |
| 16 | b | 8 | 8 | 8 | 8 | 8 | 8 | 7 | 8 | 11 | 12 | 12 | 20 | 22 | 23 | 23 |
| 16 | c | 4 | 4 | 4 | 4 | 5 | 5 | 6 | 5 | 10 | 8 | 9 | 18 | 19 | 21 | 21 |
| 16 | d | 10 | 11 | 11 | 12 | 11 | 11 | 11 | 11 | 19 | 18 | 19 | 28 | 31 | 27 | 27 |
| 16 | e | 10 | 14 | 14 | 13 | 14 | 14 | 14 | 14 | 19 | 20 | 19 | 32 | 33 | 38 | 38 |

Data were assigned to strata based upon the shooting position and average depth (between shooting and hauling depth). Few obvious data errors were corrected. Catches by haul were standardized to 60 minutes hauling duration. Hauls noted as valid were used only, including stations with no catches of hake, red mullet or pink shrimp (zero catches are included).

The abundance and biomass indices by GSA were calculated through stratified means (Cochran, 1953; Saville, 1977). This implies weighting of the average values of the individual standardized catches and the variation of each stratum by the respective stratum areas in each GSA:
$\mathrm{Yst}=\Sigma\left(\mathrm{Yi}^{*} \mathrm{Ai}\right) / \mathrm{A}$
$\mathrm{V}(\mathrm{Yst})=\Sigma\left(\mathrm{Ai}^{2} * \mathrm{si}^{2} / \mathrm{ni}\right) / \mathrm{A}^{2}$
Where:
A=total survey area
$\mathrm{Ai}=$ area of the i -th stratum
si=standard deviation of the i-th stratum
ni=number of valid hauls of the $i$-th stratum
$\mathrm{n}=$ number of hauls in the GSA
$\mathrm{Yi}=$ mean of the i -th stratum
Yst=stratified mean abundance
$\mathrm{V}(\mathrm{Yst})=$ variance of the stratified mean
The variation of the stratified mean is then expressed as the $95 \%$ confidence interval: Confidence interval $=$ Yst $\pm \mathrm{t}$ (student distribution) $* \mathrm{~V}(\mathrm{Yst}) / \mathrm{n}$

It was noted that while this is a standard approach, the calculation may be biased due to the assumptions over zero catch stations, and hence assumptions over the distribution of data. A normal distribution is often assumed, whereas data may be better described by a delta-distribution, quasi-poisson. Indeed, data may be better modelled using the idea of conditionality and the negative binomial (e.g. O'Brien et al. (2004)).

Length distributions represented an aggregation (sum) of all standardized length frequencies (subsamples raised to standardized haul abundance per hour) over the stations of each stratum. Aggregated length frequencies were then raised to stratum abundance * 100 (because of low numbers in most strata) and finally aggregated (sum) over the strata to the GSA. Given the sheer number of plots generated, these distributions are not presented in this report.

### 8.54.3.1.2. Geographical distribution patterns

No analyses were conducted during SGMED-09-02. However some information on aggregates of female spawners have been reported by Ragonese and Bianchini (1995).These are shown in Fig. 8.54.3.1.2.1 below.

Fig. 8.54.3.1.2.1 Spawning areas of female according to Ragonese and Bianchini (1995).

### 8.54.3.1.3. Trends in abundance and biomass

Fishery independent information regarding the state of the giant red shrimp in GSAs 15 and 16 was derived from the international surveys MEDITS. Fig. 8.54.3.1.3.1 and Fig. 8.54.3.1.3.2 indicate the stock to vary without an evident trend in the last year (2002-2008), although the abundance of giant red females in both GSAs reached its highest level in 2008 compared with the last 3 years.

Fig. 8.54.3.1.3.1 DI in $\mathrm{N} / \mathrm{km}^{2}$ (MEDITS survey data) in GSAs 15 and 16 for female A. foliacea. Only slope grounds were considered (201-800 m).

Fig 8.54.3.1.3.2. BI in $\mathrm{kg} / \mathrm{km}^{2}$ (MEDITS survey data) in GSAs 15 and 16 for female A. foliacea. Only slope ground was considered (201-800 m).

The trend in abundance and biomass as re-estimated by SGMED-09-02 are shown in Figures 8.54.3.1.3.3 and 8.54.3.1.3.4 for GSAs 15 and 16. Such analyses of Medits indices are considered preliminary.

Fig. 8.35.3.1.3.4 Abundance and biomass indices of giant red shrimp in GSA 15.

Fig. 8.35.3.1.3.5 Abundance and biomass indices of giant red shrimp in GSA 16.

### 8.54.3.1.4. Trends in abundance by length or age

Fig. 8.54.3.1.4.1 displays the stratified abundance indices (strata d and e) of giant red shrimp in GSAs 15 and 16 in 2002-2008.

Fig. 8.54.3.1.4.1 Stratified abundance indices by size class in GSAs 15 and 16, 2002-2008.

Figure 8.54.3.1.4.2 displays the stratified abundance indices of giant red shrimp in GSA 16 in 1994-2001.

Fig. 8.54.3.1.4.2 Stratified abundance indices by size class in GSA 16, 1994-2001.

### 8.54.3.1.5. Trends in growth

No analyses were conducted during SGMED-09-02.

### 8.54.3.1.6. Trends in maturity

No analyses were conducted during SGMED-09-02.

### 8.54.4. Assessment of historic stock parameters

> 8.54.4.1.Method 1: SURBA

### 8.54.4.1.1. Justification

The availability of length frequency distribution (LFD) time series (2002-2008 for GSA 15 and 1994-2008 for GSA 16) from trawl survey data allowed the reconstruction of the evolution of main stock parameters (recruitment and spawning stock biomass indices, as well as fishing mortality rates) of giant red shrimps in the GSA 15 and 16 by using the SURBA software package. Since females reach the largest size and they are more sensitive to fishery pressure, analyses were carried out only on the female fraction, which represented about $70 \%$ of the commercial catches (Gancitano et al., 2008).

Firstly the LFD by sex from the MEDITS trawl surveys was corrected by including the data for the individuals with unidentified sex. This was based on the sex ratio per size class. The corrected LFDs by sex for each GSA were then converted in numbers by age group using the subroutine "age slicing" as implemented in the software package LFDA (Kirkwood et al., 2001). Secondly we estimated the mean weight and maturity at age using VBGF and natural mortality at age (PROBIOM excel sheet as implemented by Abella in SGMED-09-01) for the SURBA software to run the analysis. Then the numbers at age were used to estimate time series of fishing mortality rates, as well as recruitment and SSB indices. This was done due to the difficulties in obtaining feasible information from commercial fisheries data, especially from GSA 15 where length frequencies distributions from landings do not exist. For GSA 16 data from commercial fisheries were only available since 2002, when the DCR regulation (EC 1639/01; EC 1581/04) was implemented, although data were considered reliable since 2005.

### 8.54.4.1.2. Input parameters

The input parameters are reported in Tab. 8.54.4.1.2.1.
Tab. 8.54.4.1.2.1 Biological parameters used for SURBA analyses for giant red shrimp (females) in the Strait of Sicily (GSAs 15 and 16).

| Growth |  |  | maturity |  | weight |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Linf | K | t 0 | Lm | g | a | b |
| 68.9 | 0.61 | -0.2 | 37.17 | 0.541 | 0.0016 | 2.5884 |

A declining value of M with age instead of a constant value was used based on the outcome of discussions held at SGMED-09-01, where the experts concluded such an approach is necessary considering the early age of first capture and the massive catch of juveniles characterised by higher M rates in most of the Mediterranean fisheries: Natural mortality rates by age were thus calculated according to the ProBiom model developed by Abella, Caddy and Serena (1997), based on Caddy (1991).

The value by age used in the analysis are given in Tab. 8.54.4.1.2.2. The age slicing in GSA 15 produced only 4 age groups (up age $3+$ ).

Tab. 8.54.4.1.2.2. Values by age used for SURBA analyses for giant red shrimp (females) in GSAs 15 and 16.

| Age | 0 | 1 | 2 | 3 | 4 | $5+$ |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| Natural mortality at age | 0.62 | 0.30 | 0.23 | 0.19 | 0.17 | 0.16 |
| Maturità at age | 0.00 | 1.0 | 1.0 | 1.0 | 1.0 | 1.0 |
| Weight at age | 10.44 | 34.95 | 56.48 | 70.97 | 79.72 | 85.5 |
| Catchability coefficient | 0.4 | 1.0 | 1.0 | 1.0 | 1.0 | 1.0 |

### 8.54.4.1.3. Results

State of adult / juvenile abundance:

Figures 8.54.4.1.3.1 and 8.54.4.1.3.2 combining GSAs indicate the stock to vary without an evident trend in the last year (2002-2008), although SSB reached its highest level in 2008 compared with the last 6 years.

Fig. 8.54.4.1.3.1 SSB in $\mathrm{kg} / \mathrm{km}^{2}$ (MEDITS survey) in GSAs 15 and 16 from SURBA. Only slope grounds were considered (201-800 m).

Considering only the GSA 16 where the time series is longer (1994-2008), SSB shows stably low level since 2001.

Fig. 8.54.4.1.3.2 SSB in $\mathrm{kg} / \mathrm{km}^{2}$ (MEDITS survey), as median of SURBA bootstrapped values, in GSAs 15 and 16. Only slope grounds were considered (201-800 m).

Survey indices in 2008 indicate the recruitment level to have recovered to average levels following a sharp drop in 2006.

Fig. 8.54.4.1.3.3 Recruits $\mathrm{n} / \mathrm{km}^{2}$ (MEDITS survey) in GSAs 15 and 16 from SURBA analysis.

Fig. 8.54.4.1.3.4. Recruits $\mathrm{n} / \mathrm{km}^{2}$ (MEDITS survey), as median of SURBA bootstrapped values, in GSAs 15 and 16 . Only slope ground was considered (201-800 m).

The stability of recruitment indices in the last years is also confirmed by the analysis of the longer series from GSA 16.

The values of F (age 1-3) in GSA 16 from 2000 to 2004 remains very stable around 0.83 ( $\mathrm{SD}=0.06$ ). Time series from GSA 15 is still no long enough to evaluate any trend.

Fig. 8.54.4.1.3.5. Development of fishing mortality in GSAs 15 and 16.

### 8.54.4.2.Method 3: VIT

### 8.54.4.2.1. Justification

According to the SGMED-08-03, an approach assuming a steady state (pseudocohort) was used, keeping separate the available years (2006, 2007 and 2008). Cohort (VPA equation) and Y/R analysis as implemented in the package VIT4win were used (Lleonart and Salat, 2000). Data were derived from the DCR data call.

### 8.54.4.2.2. Input parameters

The parameters used in the analysis are reported in Tab. 8.54.4.2.2.1. No discard data were included as those were considered negligible. Analysis were carried out on the landings of the Italian trawlers which contribute to more than $97 \%$ of the total yield in the GSAs 15 and 16 (Tab. 8.54.2.3.1.1). Since females reach larger size than males and amount to more than $75 \%$ of landing in weight (Gancitano et al., 2008), females parameters were used to asses stock exploitation.

Natural mortality and maturity by size are shown in Fig. 8.54.4.2.2.1.

Fig. 8.54.4.2.2.1 Natural mortality (M) and maturity by length (CL) in females of giant red shrimp in the Strait of Sicily.

Tab. 8.54.4.2.2.1 Absolute number by length class (CL in mm) of females landed by year in the Strait of Sicily.

| CL (mm) | $\mathbf{2 0 1 6}$ | $\mathbf{2 0 1 7}$ | $\mathbf{2 0 0 8}$ |
| :---: | :---: | :---: | :---: |
| 18 | 0 | 1147734 | 0 |
| 20 | 0 | 2127086 | 100309 |
| 22 | 237775 | 1890516 | 100309 |

### 8.54.4.2.3. Results

Fishing mortality rates (F) by size of female giant red shrimps caught by trawlers in GSAs 15 and 16 are shown in Fig. 8.54.4.2.3.1.

Fig. 8.54.4.2.3.1 Fishing mortality by size size of female giant red shrimps caught by trawlers in GSA 15 and 16.

The reconstructed yields obtained by the VIT package are virtually equal to the observed ones. Absolute recruitment estimation and other major results of the VIT analysis, including current mortality rates, are listed in Tab. 8.54.4.2.3.1.

Tab. 8.54.4.2.3.1. The main results of VIT analysis.

| Year | 2006 | 2007 | 2008 | Median |
| :---: | :---: | :---: | :---: | :---: |
| Recostructed yield (t) | 1424 | 1540 | 1260 | 1424 |
| Biomass at sea (t) | 1883 | 1825 | 1721 | 1825 |
| SSB at sea (t) | 1418 | 1307 | 1304 | 1307 |
| Recruitment (ml) | 73.8 | 95.3 | 62.8 | 73.8 |
| Mean Z over all sizes | 0.989 | 0.985 | 0.943 | 0.985 |
| Mean F over all sizes | 0.733 | 0.806 | 0.774 | 0.774 |
| Mean F (1-3 age <br> groups) | 0.879 | 1.010 | 0.849 | 0.879 |

### 8.54.5. Long term prediction

### 8.54.5.1.1. Justification

The VIT approach to Biomass and Yield per recruit analysis has been applied in order to analyse the stock production with increasing exploitation under equilibrium conditions.

Fig. 8.54.5.1.1.1. Yield per recruit varying current fishing mortality $(\mathrm{Fc})$ by a multiplicative factor according to the VIT package. Analyses deal with pseudo-cohorts 2006, 2007 and 2008.

Assuming no variation in the exploitation pattern, the main result of $\mathrm{Y} / \mathrm{R}$ analysis in terms of current F and optimal ones are reported in Tab. 8.54.5.1.1.1.

Tab. 8.54.5.1.1.1 Estimation of current F , as $\mathrm{F}_{\text {mean }}$, and optimal ones, as $\mathrm{F}_{\text {max }}$ and $\mathrm{F}_{0.1}$, by pseudo cohorts according to VIT package. Median values are reported in bold.

| Fishing mortalities | 2006 | 2007 | 2008 |
| :---: | :---: | :---: | :---: |
| Fcurrent | $\mathbf{0 . 7 7 4}$ | 0.806 | 0.733 |
| Fmax | 0.913 | 0.451 | $\mathbf{0 . 4 7 6}$ |
| F0.1 | 0.542 | 0.282 | $\mathbf{0 . 2 9 3}$ |

Comparing current F with BRP according to the obtained by VIT steady state VPA, a overfishing was clearly detected.
8.54.5.2. Method 2: Y, B and SSB per recruit according to the Yield package

### 8.54.5.2.1. Justification

Availability of biological parameter and length at first capture information allows the simulated quantification of likely changes in Y, B and SSB per recruit as a function of fishing mortality ( F ) with the

Yield package (Branch et al., 2001). The package was also used to calculate a probability estimation of BRP ( $\mathrm{F}_{\max }$ and $\mathrm{F}_{0.1}$ ).

### 8.54.5.2.2. Input parameters

All parameters were converted from Carapace Length (CL) in mm to Total Length (TL) by using the relation given by Gancitano (Pers. Com.): TL $(\mathrm{mm})=2.678$ CL $(\mathrm{mm})+28.564$

The new parameters were subsequently converted in terms of cm and g . A guess estimate of uncertainty in terms of coefficient of variation was added to each parameter (Tab. 8.54.5.2.2.1). The natural mortality rate was assumed constant at $\mathrm{M}=0.40$ (Ragonese et al., 2004). Stock-recruitment relationship was not used, and instead recruitment was assumed to be constant with a random variability among years of $\mathrm{CV}=0.4$.

Tab. 8.54.5.2.2.1. Parameters used for stock assessment through Yield approach. Lengths are in cm and weights in gr. Only the female fraction of the fished stock was assessed.

| $\mathbf{L} \omega$ | $21.6(0.1)$ | $\mathbf{T m}$ | $1(0.1)$ |
| :---: | :---: | :---: | :---: |
| $\mathbf{K}$ | $0.61(0.1)$ | $\mathbf{T c}$ | $1(0.1)$ |
| $\mathbf{t 0}$ | $-0.2(0.1)$ | $\mathbf{M}$ | $0.40(0.1)$ |
| $\mathbf{A}$ | 0.0034 | Recruitment | Constant with <br> CV=0.4 |
| $\mathbf{B}$ | 3.3562 |  |  |

### 8.54.5.2.3. Results

Estimation of Y and SSB per recruit according to the Yield package are shown in Fig 8.54.5.2.3.1.

Fig. 8.54.5.2.3.1 Median of yield and spawning stock biomass per recruit and corresponding uncertainty of female giant red shrimp in the GSAs 15 and 16 according to the Yield Package.

Searching for biological reference points (BRP) through 2000 simulation produced the probability distribution of $\mathrm{F}_{\max }$ and $\mathrm{F}_{0.1}$ shown in Fig. 8.54.5.2.3.2.

The median value of $\mathrm{F}_{\max }=0.75$ should be considered as Limit Reference Points (LRP) whereas the median value of $\mathrm{F}_{0.1}=0.4$ should be considered as Target reference points (TRP).

Fig. 8.54.5.2.3.2 Probability distribution of $\mathrm{F}_{\max }$ and $\mathrm{F}_{0.1}$ according to Yield package.

### 8.54.6. $\quad$ Scientific advice

8.54.6.1. Short term considerations

### 8.54.6.1.1. State of the spawning stock size

SGMED-09-02 estimated the absolute levels of stock abundance in 2006, 2007 and 2008 using the VIT approach on length structure of Sicilian trawlers which catch about $98 \%$ of the total yield in the area. Mean total biomass ranges between $1,721 \mathrm{t}$ (2008) and $1,883 \mathrm{t}$ (2006), being SSB about $75 \%$ of the total stock biomass.

Survey indices (MEDITS) combining GSAs indicate the stock to vary without an evident trend in the last year (2002-2008), although SSB reached its highest level in 2008 compared with the last 6 years. Considering only the GSA 16, where the time series is longer (1994-2008), SSB shows stably low level since 2001.

SGMED-09-02 cannot fully evaluate the state of the SSB due to the lack of precautionary management references.

### 8.54.6.1.2. State of recruitment

Absolute estimate of recruitment (18-22 mm CL) from VIT ranged between 63 (2008) and 95 (2007) millions of recruits. A low variability in recruitment indices derived from SURBA was observed when
combining GSA data from 2002 to 2007, with the exception of sudden fall in recruit density observed in 2006 both in GSAs 15 and 16. The stability of recruitment indices in the last years is also confirmed by the analysis of the longer series from GSA 16.

### 8.54.6.1.3. State of exploitation

8.54.6.2. Medium term considerations

SGMED-09-02 proposes $\mathrm{F}_{0.1}=0.35$ (average if both applied methods) as target management reference point of exploitation consistent with high long term yield.

The giant red shrimp in the Northern sector of the Strait of Sicily is considered overfished since the current fishing mortality is significantly higher than both $\mathrm{F}_{\max }$ and $\mathrm{F}_{0.1}$.

SGMED-09-02 recommends fishing mortality to be reduced by about $50 \%$ in order to avoid significant long term loss in potential yield. This should be realized by a multi-annual management plan reducing the fishing effort accordingly. It is advised to estimate the landings in accordance with the effort reductions.

SGMED-09-02 noted that the Italian government is adopting a management plan, in which a reduction of fishing mortality of $25 \%$ is planned within 2013. SGMED-09-02 supports the adoption of a management plan to continuously reduce current F through consistent effort reductions and catch estimations.

### 8.55. Stock assessment of giant red shrimp in GSA 19

### 8.55.1.Stock identification and biological features

8.55.1.1.Stock Identification

No information was documented during SGMED-09-02.

### 8.55.1.2.Growth

No information was documented during SGMED-09-02.

### 8.55.3.Scientific surveys

### 8.55.3.1.Medits

### 8.55.3.1.1. Methods

Based on the DCR data call, abundance and biomass indices were recalculated. In GSA 19 the following number of hauls was reported per depth stratum (s. Tab. 8.55.3.1.1.1).

Tab. 8.55.3.1.1.1. Number of hauls per year and depth stratum in GSA 19, 1994-2008.

| STRATUM | 1994 | 1995 | 1996 | 1997 | 1998 | 1999 | 2000 | 2001 | 2002 | 2003 | 2004 | 2005 | 2006 | 2007 | 2008 |
| :--- | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| GSA19_010-050 | 9 | 9 | 9 | 9 | 9 | 9 | 9 | 9 | 9 | 9 | 9 | 9 | 9 | 8 | 9 |
| GSA19_050-100 | 7 | 8 | 8 | 8 | 8 | 8 | 8 | 8 | 8 | 8 | 8 | 8 | 8 | 9 | 8 |
| GSA19_100-200 | 10 | 10 | 10 | 10 | 10 | 10 | 10 | 10 | 10 | 10 | 10 | 10 | 10 | 10 | 11 |
| GSA19_200-500 | 16 | 15 | 15 | 15 | 15 | 15 | 15 | 15 | 21 | 21 | 14 | 15 | 14 | 14 | 14 |
| GSA19_500-800 | 31 | 32 | 32 | 32 | 32 | 32 | 32 | 32 | 29 | 29 | 29 | 28 | 29 | 29 | 29 |

Data were assigned to strata based upon the shooting position and average depth (between shooting and hauling depth). Few obvious data errors were corrected. Catches by haul were standardized to 60 minutes hauling duration. Hauls noted as valid were used only, including stations with no catches of hake, red mullet or pink shrimp (zero catches are included).

The abundance and biomass indices by GSA were calculated through stratified means (Cochran, 1953; Saville, 1977). This implies weighting of the average values of the individual standardized catches and the variation of each stratum by the respective stratum areas in each GSA:
$\mathrm{Yst}=\Sigma\left(\mathrm{Yi}^{*} \mathrm{Ai}\right) / \mathrm{A}$
$\mathrm{V}(\mathrm{Yst})=\Sigma\left(\mathrm{Ai}^{2} * \mathrm{si}^{2} / \mathrm{ni}\right) / \mathrm{A}^{2}$
Where:
$\mathrm{A}=$ total survey area
$\mathrm{Ai}=$ area of the i -th stratum
si=standard deviation of the i-th stratum
ni=number of valid hauls of the i-th stratum
n=number of hauls in the GSA
Yi=mean of the $i$-th stratum
Yst=stratified mean abundance
$\mathrm{V}(\mathrm{Yst})=$ variance of the stratified mean
The variation of the stratified mean is then expressed as the $95 \%$ confidence interval: Confidence interval $=$ Yst $\pm \mathrm{t}$ (student distribution) $* \mathrm{~V}(\mathrm{Yst}) / \mathrm{n}$

It was noted that while this is a standard approach, the calculation may be biased due to the assumptions over zero catch stations, and hence assumptions over the distribution of data. A normal distribution is often assumed, whereas data may be better described by a delta-distribution, quasi-poisson. Indeed, data may be better modelled using the idea of conditionality and the negative binomial (e.g. O'Brien et al. (2004)).

Length distributions represented an aggregation (sum) of all standardized length frequencies (subsamples raised to standardized haul abundance per hour) over the stations of each stratum. Aggregated length
frequencies were then raised to stratum abundance * 100 (because of low numbers in most strata) and finally aggregated (sum) over the strata to the GSA. Given the sheer number of plots generated, these distributions are not presented in this report.

### 8.55.3.1.2. Geographical distribution patterns

No analyses were conducted during SGMED-09-02.

### 8.55.3.1.3. Trends in abundance and biomass

Fishery independent information regarding the state of the giant red shrimp in GSA 19 was derived from the international survey Medits. Figure 8.55.3.1.3.1 displays the estimated trend in giant red shrimp abundance and biomass in GSA 19. The analyses of Medits indices are considered preliminary.

Fig. 8.55.3.1.3.1 Abundance and biomass indices of giant red shrimp in GSA 19.

### 8.55.3.1.4. Trends in abundance by length or age

The following Fig. 8.55.3.1.4.1 and 2 display the stratified abundance indices of GSA 19 in 1994-2008. These size compositions are considered preliminary.

Fig. 8.55.3.1.4.1 Stratified abundance indices by size, 1994-2001.

Fig. 8.55.3.1.4.2 Stratified abundance indices by size, 2002-2008.

### 8.55.3.1.5. Trends in growth

No analyses were conducted during SGMED-09-02.

### 8.55.3.1.6. Trends in maturity

No analyses were conducted during SGMED-09-02.
8.55.4.Assessment of historic stock parameters

SGMED-09-02 did not undertake any analytical assessment.

### 8.55.5.Long term prediction

### 8.55.5.1.Justification

No forecast analyses were conducted.

### 8.55.5.2.Input parameters

No forecast analyses were conducted.

### 8.55.5.3.Results

Given the preliminary state of the data and analyses SGMED-09-02 is not in the position to provide a long term prediction of catch and stock biomass for giant red shrimp in GSA 19.

### 8.55.6.Scientific advice

### 8.55.6.1.Short term considerations

### 8.55.6.1.1. State of the spawning stock size

SGMED-09-02 is unable to provide any scientific advice of the state of the spawning stock given the preliminary state of the data and analyses.

### 8.55.6.1.2. State of recruitment

SGMED-09-02 is unable to provide any scientific advice of the state of the recruitment given the preliminary state of the data and analyses.

### 8.55.6.1.3. State of exploitation

SGMED-09-02 is unable to provide any scientific advice of the state of the exploitation in relation to proposed precautionary and target levels given the preliminary state of the data and analyses.

### 8.56. Stock assessment of Norway lobster in GSA 09

### 8.56.1. Stock identification and biological features

### 8.56.1.1. Stock identification

Due to a lack of information about the structure of Norway lobster (Nephrops norwegicus) population in the western Mediterranean, this stock was assumed to be confined within the GSA 09 boundaries. Adults tend to be territorial, with limited migration. However, transferal of larvae between areas may occur.
$N$. norvegicus is a mud-burrowing species that prefers sediments with mud mixed with silt and clay in variable proportions. The emergence from burrows of individuals may vary depending on biological features or environmental factors (moult or reproduction cycles, light intensity, etc).

The species lives on muddy substrates at depths between 150 and 800 m , but in the area is more commonly found between 250 and 800 m depth (Biagi et al., 2002; Colloca et al., 2003).

Recruits peak in abundance between 400 and 500 m depth over the upper slope and appear to move slightly deeper when they reach 30 mm carapace length (Fig. 8.56.1.1.1).

Fig. 8.56.1.1.1 Size-depth distribution of Norway lobster in the GSA 09 in 1996 and 1997 (GRUND survey).

### 8.56.1.2. Growth

The species shows a noticeable sexual dimorphism, with males that reach bigger sizes than females. Maximum observed size in the GSA 09 was 72 mm CL for males and 57 mm CL for females.
Growth parameters defined in the area were:
$\mathrm{L}_{\infty}=72.1$ (males) 56 (females)
$\mathrm{K}=0.169$ (males) $\quad 0.214$ (females)
Length-weight relationship for both sexes: $a=0.00040, b=3.126$

### 8.56.1.3. Maturity

Males reach maturity at 40 mm CL and females at 30.3 mm CL. Sex ratio is about $1: 1$ until 26 mm CL; in favour of females from 26 to 35 mm CL ; in favour of males from 38 mm CL (De Ranieri et al., 1996). Reproduction peak is between spring and summer, and females with external eggs are observed in autumnwinter.

### 8.56.2. Fisheries

### 8.56.2.1. General description of fisheries

Norway lobster is one of the most important components of bottom trawlers catch in the GSA 09, as total annual value of the landings.

The trawlers fleet of GSA 09 at the end of 2006 accounted for 361 vessels (Tab. 8.56.2.1.1). From those vessels, only a fraction targets Nephrops norvegicus.

The main trawl fleets of GSA 09 are present in the following continental harbours: Viareggio, Livorno, Porto Santo Stefano (Tuscany), Fiumicino, Terracina, Gaeta (Latium).

Tab. 8.56.2.1.1 Technical characteristics of the trawl fleet of GSA 09 (year 2007, DCR official data).

| N. of boats | 361 |
| :--- | :--- |
| GT | 13.191 |
| kW | 75.514 |
| Mean GT | 36.5 |
| Mean kW | 209.2 |

As concerns fishing activity, the majority of bottom trawlers of GSA 09 operates daily fishing trips with only some vessels able to stay out of the port for two-three days and especially in summer.

Norway lobster fishing grounds include soft bottoms of upper slope, generally between 350 and 600 m depth. Fishing pressure shows some geographical differences inside the GSA 09 according to the consistency of the fleets, the availability of the resources and the morphology of the continental shelf and upper slope. The species by-catch is mainly represented by Micromesistius poutassou, Phycis blennoides, Lepidorhombus bosci, Galeus melastomus, Parapenaeus longirostris, Eledone cirrhosa, Todaropsis eblanei, Trachurus spp.

### 8.56.2.2. Management regulations applicable in 2009

- Fishing closure for trawling: 45 days in late summer (not every year have been enforced).
- Minimum landing sizes: EC regulation 1967/2006: 20 mm CL for Norway lobster.
- Cod end mesh size of trawl nets: 40 mm (stretched, diamond meshes) till 30/05/2010. From $01 / 06 / 2010$ the existing nets will be replaced with a cod end with 40 mm (stretched) square meshes or a cod end with 50 mm (stretched) diamond meshes.
- Towed gears are not allowed within three nautical miles from the coast or at depths less than 50 m when this depth is reached at a distance less than 3 miles from the coast.

### 8.56.2.3. Catches

### 8.56.2.3.1. Landings

Landings of Norway lobster in GSA 09 are almost exclusively provided by trawling. In the last three years the total landings of $N$. norvegicus of GSA 09 varied between 228 and 260 tons (Fig. 8.56.2.3.1.1).

Tab. 8.56.2.3.1.1 Landings (t) of Norway lobster in GSA 09 by gear type.

| Species | Year | DTS | PGP | PTS | Total |
| :---: | :---: | :---: | :---: | :---: | :---: |
| NEP | 2006.0 | 247.4 | 0.7 |  | 248.1 |
| NEP | 2007.0 | 260.3 | 0.2 |  | 260.5 |
| NEP | 2008.0 | 227.7 | 0.1 |  | 227.8 |

Fig. 8.56.2.3.1.1 Landings of Norway lobster (trawl nets) in the GSA 09, from 2006 to 2008 (DCR official data).

Landings are mostly composed by specimens from 25 to 50 mm CL (Fig. 8.56.2.3.1.2). Due to the sexual dimorphism of the species, the majority of the specimens greater than 40 mm CL are males.

Fig. 8.56.2.3.1.2 Size structure of the landings of $N$. norvegicus in 2006-2008 caught by otter trawling in the GSA 09 (DCR official data).

Several EU and national projects carried out in GSA 09 highlighted that discard of Norway lobster in GSA 09 is negligible. At the same time, the presence of specimens under the MLS $(20 \mathrm{~mm} \mathrm{CL})$ in the landings is very scarce. The same picture was obtained during the monitoring of discard performed in the 2006 DCR.

### 8.56.2.3.3. Fishing effort

The fishing capacity of the GSA 09 has shown in these last 10 years a progressive decrease; from 1996 to 2006 the number of bottom trawlers of GSA 09 decreased of about $30 \%$.

The total fishing days carried out by all the GSA 09 trawlers varied from about 65,000 in 2004 to about 63,000 in 2006 (Fig. 8.56.2.3.3.1), a little decrease of the mean number of fishing days/year per vessel was observed in this period, from 187 to 177. Anyway, there is no information on the specific effort directed to $N$. norvegicus in GSA 09.

Fig. 8.56.2.3.3.1 Effort trends (days and kW *days) in 2004-2007 by major fleets for GSA 09 . The data are listed in Tables A3.10 and A3.12 of Appendix 3.

### 8.56.3. Scientific surveys

### 8.56.3.1. MEDITS

### 8.56.3.1.1. Methods

Based on the DCR data call, abundance and biomass indices were recalculated. In GSA 09 the following number of hauls was reported per depth stratum (s. Tab. 8.56.3.1.1.1).

Tab. 8.56.3.1.1.1. MEDITS survey. Number of hauls per year and depth stratum in GSA 09, 1994-2008.

| STRATUM | 1994 | 1995 | 1996 | 1997 | 1998 | 1999 | 2000 | 2001 | 2002 | 2003 | 2004 | 2005 | 2006 | 2007 | 2008 |
| :--- | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| GSA_09_010-50 M | 21 | 20 | 20 | 20 | 21 | 20 | 20 | 19 | 15 | 14 | 15 | 16 | 15 | 16 | 16 |
| GSA_09_050-100 M | 21 | 21 | 20 | 20 | 20 | 21 | 22 | 23 | 17 | 18 | 17 | 16 | 18 | 18 | 18 |
| GSA_09_100-200 M | 38 | 40 | 40 | 40 | 39 | 39 | 38 | 38 | 30 | 30 | 30 | 31 | 30 | 29 | 29 |
| GSA_09_200-500 M | 40 | 40 | 42 | 42 | 41 | 41 | 42 | 41 | 32 | 33 | 36 | 35 | 35 | 36 | 35 |
| GSA_09_500-800 M | 33 | 32 | 31 | 31 | 32 | 32 | 31 | 32 | 26 | 25 | 22 | 22 | 22 | 21 | 22 |
| TOTAL |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |
| T153 | 153 | 153 | 153 | 153 | 153 | 153 | 153 | 120 | 120 | 120 | 120 | 120 | 120 | 120 |  |

Data were assigned to strata based upon the shooting position and average depth (between shooting and hauling depth). Few obvious data errors were corrected. Catches by haul were standardized to 60 minutes hauling duration. Hauls noted as valid were used only, including stations with no catches of hake, red mullet or pink shrimp (zero catches are included).

The abundance and biomass indices by GSA were calculated through stratified means (Cochran, 1953; Saville, 1977). This implies weighting of the average values of the individual standardized catches and the variation of each stratum by the respective stratum areas in each GSA:

$$
\begin{aligned}
& \mathrm{Yst}=\Sigma\left(\mathrm{Yi}^{*} \mathrm{Ai}\right) / \mathrm{A} \\
& \mathrm{~V}(\mathrm{Yst})=\Sigma\left(\mathrm{Ai}^{2} * \mathrm{si}^{2} / \mathrm{ni}\right) / \mathrm{A}^{2}
\end{aligned}
$$

Where:
A=total survey area
$\mathrm{Ai}=$ area of the i-th stratum
si=standard deviation of the i-th stratum
ni=number of valid hauls of the i-th stratum
$\mathrm{n}=$ number of hauls in the GSA
$\mathrm{Yi}=$ mean of the i-th stratum
Yst=stratified mean abundance
$\mathrm{V}(\mathrm{Yst})=$ variance of the stratified mean
The variation of the stratified mean is then expressed as the $95 \%$ confidence interval: Confidence interval $=$ Yst $\pm \mathrm{t}$ (student distribution) $* \mathrm{~V}(\mathrm{Yst}) / \mathrm{n}$

It was noted that while this is a standard approach, the calculation may be biased due to the assumptions over zero catch stations, and hence assumptions over the distribution of data. A normal distribution is often assumed, whereas data may be better described by a delta-distribution, quasi-poisson. Indeed, data may be better modelled using the idea of conditionality and the negative binomial (e.g. O'Brien et al. (2004)).

Length distributions represented an aggregation (sum) of all standardized length frequencies (subsamples raised to standardized haul abundance per hour) over the stations of each stratum. Aggregated length frequencies were then raised to stratum abundance $* 100$ (because of low numbers in most strata) and finally aggregated (sum) over the strata to the GSA. Given the sheer number of plots generated, these distributions are not presented in this report.

### 8.56.3.1.2. Geographical distribution patterns

Norway lobster is distributed in the whole GSA with the highest abundance in the south Ligurian Sea and northern Tyrrhenian Sea.

### 8.56.3.1.3. Trends in abundance and biomass

Fishery independent information regarding the state of the $N$. norvegicus in GSA 09 was derived from the international survey MEDITS. Figure 8.56.3.1.3.1 displays the re-estimated trend in $N$. norvegicus abundance and biomass in GSA 09 based on the DCR data call. No particular long term trend is present.

Fig. 8.56.3.1.3.1 Abundance and biomass indices of Nephrops norvegicus in GSA 09.

### 8.56.3.1.4. Trends in abundance by length or age

The following Fig. 8.56.3.1.4.1 and 2 display the stratified abundance indices of GSA 09 in 1994-2001 and 2002-2008.

Fig. 8.56.3.1.4.1 Stratified abundance indices by size, 1994-2001.

Fig. 8.56.3.1.4.2 Stratified abundance indices by size, 2002-2008.

### 8.56.3.2. GRUND

### 8.56.3.2.1. Methods

The national GRUND trawl survey (Relini, 1998) is regularly carried out along the Italian coasts in addition to MEDITS. It has been carried out since 1985, with some years lacking (1988, 1989 and 1999). Sampling is random stratified, except in the period 1990-93 where a different sampling design, based on transects, was applied. Locations of stations were selected randomly within each stratum in the period 1985-87, while since

1996, the same stations were sampled every year. Therefore from 1994 two trawl surveys are regularly carried out in Italy each year: MEDITS, in spring, and GRUND, in autumn. The two surveys provide integrate pictures on different seasons, allowing to monitor the most important biological events (recruitment, spawning) for the majority of the demersal species.

### 8.56.3.2.2. Geographical distribution patterns

Norway lobster is distributed in the whole GSA with the highest abundance in the south Ligurian Sea and northern Tyrrhenian Sea.

### 8.56.3.2.3. Trends in abundance and biomass

Fig. 8.56.3.2.3.1 shows the density and biomass indices of Norway lobster obtained from 1994 to 2008. The GRUND data series show a fluctuating trend and quite stable trend till 2006, while in 2008 values considerably lover than those of the previous years were recorded.

Fig. 8.56.3.2.3.1 Density and abundance indices of $N$. norvegicus according to the GRUND (left) and MEDITS (right) surveys.

### 8.56.3.2.4. Trends in abundance by length or age

Not presented to SGMED-09-02.

### 8.56.3.2.5. Trends in growth

No analyses were conducted during SGMED-09-02.

### 8.56.3.2.6. Trends in maturity

No analyses were conducted during SGMED-09-02.

### 8.56.4. Assessment of historic stock parameters

Due to its importance as demersal resource, $N$. norvegicus has been object of several assessments in the GSA 09 (Ardizzone et al., 1998; Abella et al., 1995; 1998; 1999; 2002; 2007; Biagi et al., 1990a; 1990b; 1990c; De Ranieri 1999; Mori et al., 1993; 1998; Sartor et al., 2003, Sbrana et al., 2003). These results are published and have been regularly updated in the GFCM SAC sheets. The assessments performed with different approaches in different periods or in different subareas of the GSA 09 showed divergent results as Nephrops grounds within GSA 09 are not exploited with the same rate. It is likely that the current status (abundance and demographic structure) may depend mainly on the fishing pressure exerted in the different sub areas of the GSA. This fact does not exclude the possibility of drifting of eggs and larvae from one ground to others contributing to recruitments in grounds different from the parental ones.

The Norway lobster in the GSA 09 seems to be fully or in some cases underexploited, as shown by the results of the analytical models (reference points as $\mathrm{F}_{\text {max }}, \mathrm{F}_{0.1}$ and $\mathrm{SSB}_{\text {curr }} / \mathrm{SSB}_{0}$ ). The production models based on Z provided total mortality estimates for the whole GSA 09 greater than the mortality corresponding to the maximum biological production ( $\mathrm{Z}_{\text {MBP }}$ ).

A clear growth overfishing is not observed, considering that the smaller individuals, even though present in the fishing grounds, show a limited vulnerability to the fishing gear, due to the lower frequency of emergence fishing mortality on $0+$ and $1+$ age classes. The values of the $\mathrm{SSB} / \mathrm{SSB}_{0}$ ratio are between 0.33 and 0.45 .

As concern the SGMED-09-02, two new assessments were produced. The main results are presented below.

### 8.56.4.1. Method 1: SURBA

### 8.56.4.1.1. Justification

The relatively long time series of data available from the GRUND and MEDITS surveys provided the most promising data sets for analysis. The survey-based stock assessment approach SURBA (Needle, 2003) was used both on MEDITS (1994-2007) and GRUND (1994-2004) data of the Norway lobster of GSA 09.

### 8.56.4.1.2. Input parameters

The following set of parameters was adopted:
Tab. 8.56.4.1.2.1 Input parameters.

| Growth parameters (Von Bertalanffy) |
| :--- |
| $\mathrm{L} \infty=74 \mathrm{~mm}$, carapace length |
| $\mathrm{K}=0.17$ |
| to $=0$ |
| $\mathrm{~L} * \mathrm{~W}$ |
| $\mathrm{a}=0.0005$ |
| $\mathrm{~b}=3.04$ |
| Natural mortality |
| $\mathrm{M}=0.4$ |
| Catchability (q) |
| $\mathrm{q}=1$ for all the age classes |
| Length at maturity (L50) |
| L50 $=29 \mathrm{~mm}$ |

Tab. 8.56.4.1.2.2 Input parameters used for the SURBA model.

### 8.56.4.1.3. Results

Fishing mortality $\left(\mathrm{F}_{3-6}\right)$ estimated with MEDITS showed large fluctuations in the first three years (19941996) while successively the range was narrower (0.23-0.57) from 1997 to 2007, with values between 0.31 and 0.36 in the last three years (2005-07). $\mathrm{F}_{3-6}$ obtained from GRUND data ranged between 0.16 in 1995 and 0.67 in 2005

Relative spawning stock biomass (SSB) indices derived from MEDITS (1994-2008) and GRUND (19942006) showed a fluctuating trend in the spawning stock biomass (SSB). An increase in SSB occurred in recent years (2005-08, MEDITS survey, Fig. 8.56.4.1.3.1).

Young of the year are poorly captured by the commercial fleet and during surveys. Relative indices for ages $1+$ and $2+$, obtained from MEDITS survey indicated a clear increasing trend (Fig. 8.56.4.1.3.2).

Fig. 8.56.4.1.3.1 MEDITS and GRUND surveys. SURBA estimates of mean $\mathrm{F}_{1-3}$ and relative SSB .

Fig. 8.56.4.1.3.2 MEDITS abundance trend of age groups $1+$ and $2+$ (data pooled).

Model diagnostics are shown in the Fig. 8.56.4.1.3.3.

Fig. 8.56.4.1.3.3. Model diagnostic for Surba model in the GSA 09. a) Comparison between observed (points) and fitted (lines) of MEDITS survey abundance indices, for each year. b) Log survey abundance indices by cohort. Each line represents the log index abundance of a particular cohort throughout its life.

### 8.56.4.2. Method 2: LCA on DCR data

### 8.56.4.2.1. Justification

Assessment was performed using an LCA (VIT software, Lleonart and Salat 1997) on an annual pseudocohort (year 2006).

### 8.56.4.2.2. Input parameters

Data coming from DCR provided at SGMED-09-02 contained, for GSA 09, information on hake landings and the respective size/age structure for 2006-2008. The short data time series did not allow the application of VPA.

LCA was performed using VIT software on data of the years 2006, 2007, 2008. Tab. 8.56.4.2.2.1 shows the input data. The used parameters were the same of the SURBA analysis, including the M -vector and the maturity ogive.

Tab. 8.56.4.2.2.1. Input data for LCA of the Norway lobster in GSA 09.

| Carapace <br> Length (mm) | 2006 | 2007 | 2008 |

### 8.56.4.2.3. Results

The general results of LCA (Fig. 8.56.4.2.3.1) show mean values of F (3-6) ranging from 0.30 to 0.36 , very similar to those estimated with SURBA.

Fig. 8.56.4.2.3.1. LCA outputs: catch numbers, numbers-at-age and fishing mortality at age of $N$. norvegicus in GSA 09.

### 8.56.5. Long term prediction

### 8.56.5.1. Justification

Equilibrium YPR reference points for the stock estimated through the Yield software (Hoggarth et al., 2006) were assessed. Further YPR analyses were conducted based on the VIT (pseudocohort) results.

### 8.56.5.2. Input parameters

Equilibrium YPR reference points for the stock were estimated through the Yield software (Hoggarth et al., 2006) assuming recruitment fluctuating randomly around a constant value and $20 \%$ uncertainty in input parameters.

The second YPR analyses used the results of VIT (pseudocohort) as inputs. The used parameters were the same of the SURBA and LCA analyses previously shown.

### 8.56.5.3. Results

Yield software quantified uncertainty by repeatedly selecting a set of biological and fishery parameters by sampling from the probability distributions for uncertain parameters set by the user, and then calculating the quantities of interest. In this sampling, it is assumed that each of the uncertain parameters are independently
distributed, even though for some biological parameters, this assumption is almost certainly incorrect (Hoggarth et al., 2006). $\mathrm{F}_{\max }$ and $\mathrm{F}_{0.1}$ were assumed respectively as limiting and target reference points. Their probability distributions showed a considerable variation (Fig. 8.56.5.3.1). The following median values were obtained: $\mathrm{F}_{\max }=0.36 ; \mathrm{F}_{0.1}=0.21$. The maximum predicted values were respectively $0.59\left(\mathrm{~F}_{\max }\right)$ and 0.30 ( $\mathrm{F}_{01}$ ).

Considering that the estimated current F was arround 0.3 , RPs suggest that the $N$. norvegicus stock is currently overexploited.

Fig. 8.56.5.3.1 Probability distribution of Norway lobster RPs in the GSA 09 obtained using the Yield software.
8.56.6. $\quad$ Scientific advice

### 8.56.6.1. Short term considerations

### 8.56.6.1.1. State of the spawning stock size

Relative spawning stock biomass (SSB) indices derived from MEDITS (1994-2008) and GRUND (19942006) showed a fluctuating trend in the spawning stock biomass (SSB). An increase in SSB occurred in recent years (2005-08, MEDITS survey).

SGMED-09-02 cannot fully evaluate the state of the SSB due to a lack of precautionary management reference points.

### 8.56.6.1.2. State of recruitment

Recruitment (age groups 1+ and 2+) showed a significant increasing trend since 1994.

### 8.56.6.1.3. State of exploitation

SGMED-09-02 proposed the estimated $\mathrm{F}_{0.1}=0.21$ as target management reference point for sustainable exploitation consistent with high long term yield.

Recent values of $\mathrm{F}_{3-7}$ obtained on commercial data with LCA (VIT) and using SURBA indicate that the stock is currently overexploited. SGMED-09-02 recommends a reduction of fishing effort to be achieved by means of a multiannual management plan towards the target exploitation in order to avoid long term losses in yield. Such management plan should consider the mixed fisheries implications for the Nephrops fisheries. SGMED-09-02 recommends the resulting catches consistent with the effort reductions be determined.

### 8.57. Stock assessment of Norway lobster in GSA 10

### 8.57.1. Stock identification and biological features

### 8.57.1.1.Stock Identification

The stock of Norway lobster was assumed in the boundaries of the whole GSA 10, lacking specific information on stock identification. $N$. norvegicus is a sedentary long-living, slow growing lobster which inhabits burrows constructed in muddy substrates of the upper slope and its presence appears to be related with heterogeneity in the characteristics of the sediment as well as with variations in fishing effort (e.g. Maynou and Sardà, 1997). Abundance of Norway lobster is generally rather scant in the southern Tyrrhenian Sea and the areas with the highest concentration of biomass are found between 200 and 500 m depth. Patchiness in population structure characteristics has been also identified in the GSA 10.

It has been reported that in GSA 10 the mean length of this crustacean is slightly lower than in the Northern Tyrrhenian but higher (38 against 39) than in Sicily Strait (38 against 34). Total mortality has been found negatively correlated with the mean size obtained in different Mediterranean GSAs, although also environmental influences at geographical scale could play an important role (Abellò et al., 2002). Indeed, differences in growth have been highlighted for $N$. norvegicus from different habitats in the same geographical area (Central Adriatic) (Froglia and Gramitto, 1987).

The overall sex ratio is about 0.5 . The Norway lobster is a long-living crustacean with a life span of 16-18 years (AA.VV., 2002) and larger individuals are males.

In the Central-Southern Tyrrhenian Sea the occurrence of mature females was observed in late spring-early summer with a spawning beginning mainly at the end of the summer (September, Carbonara et al., 2006) as reported by other authors for the western Mediterranean basin (Orsi Relini et al., 1998). Thus, a continuous recruitment pattern is shown and at $34-36 \mathrm{~mm}$ carapace length the Norway lobster is considered recruited to the grounds (AA.VV., 2002).

In the central-southern Tyrrhenian Sea commercial catches of Norway lobster are taken on the same fishing grounds as pink shrimp and European hake but are less abundant than other crustaceans (AA.VV. 2000; EU project 97/0066-Medland).

### 8.57.1.2.Growth

Estimates of the growth pattern of Norway lobster in the Tyrrhenian Sea were obtained in the Samed project (Anonymous 2002) according to the following procedure. $\mathrm{L}_{\text {max }}$ (predicted maximum length; procedure implemented in FiSAT) value to be used as guess estimate of $\mathrm{L}_{\infty}$ was computed for each sex. This value was then tuned with that obtained from the Powell and Wetherall approach, which gives also estimates of the $\mathrm{Z} / \mathrm{K}$ ratio. According to literature (Mytilineou et al., 1998) estimate of the phi' indicator was obtained and thus preliminary guess values of K computed. Thus also a first value of Z was obtained. These parameters were finally calibrated through the Length Converted Catch Curve (LCCC) and the set giving the better determination coefficient was adopted: females $\mathrm{CL}_{\infty}=60 \mathrm{~mm} ; \mathrm{K}=0.18 ; \mathrm{t}_{0}=-0.5$; males $\mathrm{CL}_{\infty}=72 \mathrm{~mm} ; \mathrm{K}=0.17$; $\mathrm{t}_{0}=-0.5$.

In the DCR framework parameters were re-estimated following the same procedure and the following values were obtained: females $\mathrm{CL}_{\infty}=58 \mathrm{~mm} ; \mathrm{K}=0.19 ; \mathrm{t}_{0}=-0.2$; males $\mathrm{CL}_{\infty}=75 \mathrm{~mm} ; \mathrm{K}=0.15 ; \mathrm{t}_{0}=-0.5$.

Parameters of the length-weight relationship were $a=0.668, b=3.027$ for females and $a=0.7329, b=2.991$ for males (length in cm ).

> 8.57.1.3.Maturity

Maturity and fecundity of Norway lobster have been studied in the GSA 10 using trawl-survey data (19942004) collected in a ten years period (20 surveys carried out in late spring and early summer) (Carbonara et al., 2006). Results evidenced that maturity process is completed from late-spring summer through autumn and the smallest ovigerous female was 23.5 mm carapace length. Length at first maturity $\left(\mathrm{Lm}_{50}\right)$ was within $30.6-34.8 \mathrm{~mm}$, depending on the year. These differences were probably due to the seasonal variations and diverse availability of the species to the gear. The lower value was similar to findings in other Mediterranean areas ( $29.9 \mathrm{~mm}-32.1 \mathrm{~mm}$ : e.g. Bianchini et al., 1998; AA.VV., 2002), while the upper size was higher and more close to the Alboran figure ( 36 mm ; Orsi Relini et al., 1998).

The proportion of mature females per length class (Tab. 8.57.1.3.1) from DCR data is similar to the estimates previously calculated for the area.

The relationship between carapace length and number of early eggs on the pleopods is fitted by the following non-linear equation: $\mathrm{F}=0.0029 * \mathrm{LC}^{3,7221}\left(\mathrm{R}^{2}=0.79\right)$ comparable with the findings of Froglia and Gramitto (1980).

Fig. 8.57.1.3.1 The maturity ogives and relationship between fecundity and carapace length of females.

Tab. 8.57.1.3.1 Proportion of mature females for length class from DCR.

| CL | Proportion of thature females |
| :---: | :---: |
| 2.6 | 0.017 |
| 2.8 | 0.05 |
| 3 | 0.119 |
| 3.2 | 0.362 |
| 3.4 | 0.557 |
| 3.6 | 0.779 |
| 3.8 | 0.938 |
| 4 | 1 |

The sex ratio from DCR evidenced the prevalence of males in the different size classes.

Fig. 8.57.1.3.2 Sex ratio over length (carapace length).

### 8.57.2. Fisheries

### 8.57.2.1.General description of fisheries

The Norway lobster is only targeted by trawlers on fishing grounds located offshore at 200 m depth, on the slope of the whole GSA. The Norway lobster occurs mainly with M. merluccius, P. longirostris, P. blennoides, depending on depth and area.

### 8.57.2.2.Management regulations applicable in 2008 and 2009

Management regulations are based on technical measures, like the number of fishing licenses and area limitation (distance from the coast and depth). In order to limit the over-capacity of fishing fleet, the Italian fishing licenses have been fixed since the late 1980s. After 2000, in agreement with the European Common Policy of Fisheries, a gradual decreasing of the fleet capacity is implemented. Along the northern Sicily coasts two main Gulfs (Patti and Castellammare) have been closed to the trawl fishery up 200 m depth, since 1990. Two closed areas were also established in 2004 along the mainland, in front of Sorrento peninsula (Napoli Gulf) and Amantea (Calabrian coasts), although these protected area mainly cover the distribution of coastal species. Other measures on which the management regulations are based regard technical measures (mesh size) and minimum landing sizes (EC reg. 1967/06). In the GSA 10, the fishing ban has not been mandatory and it has been adopted on a voluntary basis by the fleet.

### 8.57.2.3. Catches

### 8.57.2.3.1. Landings

Available landing data are from DCR regulations. SGMED-09-02 received Italian landings data for GSA 10 by fishing gears which are listed in Tab. 8.57.2.3.1.1. The fishing segments DTS, PGP, PMP and PTS indicate respectively trawlers, small scale fishery (nets) polyvalent and pair trawls. Landings of the Norway lobster decreased from 2002 to 2004 from about 140 to 60 tons. Then landings were fairly stable until 2007 ( 60 tons) with a peak in 2005 ( 80 tons), while in 2008 a further decrease to 40 tons was observed (Fig. 8.57 .2 .3 .1 .1 ). Most part of the landings is from trawlers.

Tab. 8.57.2.3.1.1. Annual landings (t) by gear type, 2002-2008.

### 8.57.2.3.2. Fishing effort

The trends in fishing effort by year and gear type is listed in Tab. 8.57.2.3.2.1 and shown in Fig. 8.57.2.3.2.1 in terms of kW *days. The fishing segments DTS, HOK, PGP, PMP and PTS indicate respectively trawlers, long-lines, small scale fishery (nets), polyvalent, and pair trawls. The fishing effort in kW *days of the trawlers, that is the fishing segment targeting the giant red shrimp, was rising in 2004 and 2005 and then decreasing in 2006 and 2007.

### 8.57.3. Scientific surveys

### 8.57.3.1.Medits

### 8.57.3.1.1. Methods

According to the MEDITS protocol (Bertrand et al., 2002), trawl surveys were carried out yearly (May-July), applying a random stratified sampling by depth ( 5 strata with depth limits at: $50,100,200,500$ and 800 m ; each haul position randomly selected in small sub-areas and maintained fixed throughout the time). Haul allocation was proportional to the stratum area. The same gear (GOC 73, by P.Y. Dremière, IFREMERSète), with a 20 mm stretched mesh size in the cod-end, was employed throughout the years. Detailed data on the gear characteristics, operational parameters and performance are reported in Dremière and Fiorentini (1996). Considering the small mesh size a complete retention was assumed. All the abundance data (number of fish and weight per surface unit) were standardised to square kilometre, using the swept area method.

Based on the DCR data call, abundance and biomass indices were recalculated. In GSA 10 the following number of hauls was reported per depth stratum (Tab. 8.57.3.1.1.1).

Tab. 8.57.3.1.1.1. Number of hauls per year and depth stratum in GSA 10, 1994-2008.

| STRATUM | 1994 | 1995 | 1996 | 1997 | 1998 | 1999 | 2000 | 2001 | 2002 | 2003 | 2004 | 2005 | 2006 | 2007 | 2008 |
| :--- | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |

| GSA10_500-800 | 31 | 30 | 31 | 31 | 31 | 30 | 31 | 29 | 26 | 27 | 26 | 26 | 26 | 26 | 26 |

Data were assigned to strata based upon the shooting position and average depth (between shooting and hauling depth). Few obvious data errors were corrected. Catches by haul were standardized to 60 minutes hauling duration. Hauls noted as valid were used only, including stations with no catches (zero catches are included).

The abundance and biomass indices by GSA were calculated through stratified means (Cochran, 1953; Saville, 1977). This implies weighting of the average values of the individual standardized catches and the variation of each stratum by the respective stratum areas in each GSA:
$\mathrm{Yst}=\Sigma\left(\mathrm{Yi}^{*} \mathrm{Ai}\right) / \mathrm{A}$

$$
\mathrm{V}(\mathrm{Yst})=\Sigma\left(\mathrm{Ai}^{2} * \mathrm{si}^{2} / \mathrm{ni}\right) / \mathrm{A}^{2}
$$

Where:
A=total survey area
$\mathrm{Ai}=$ area of the i -th stratum
$s i=s t a n d a r d$ deviation of the i-th stratum
ni=number of valid hauls of the i-th stratum
$\mathrm{n}=$ number of hauls in the GSA
$\mathrm{Yi}=$ mean of the i-th stratum
Yst=stratified mean abundance
$\mathrm{V}(\mathrm{Yst})=$ variance of the stratified mean
The variation of the stratified mean is then expressed as the $95 \%$ confidence interval: Confidence interval $=$ Yst $\pm \mathrm{t}$ (student distribution) $* \mathrm{~V}(\mathrm{Yst}) / \mathrm{n}$

It was noted that while this is a standard approach, the calculation may be biased due to the assumptions over zero catch stations, and hence assumptions over the distribution of data. A normal distribution is often assumed, whereas data may be better described by a delta-distribution, quasi-poisson. Indeed, data may be better modelled using the idea of conditionality and the negative binomial (e.g. O'Brien et al. (2004)).

Length distributions represented an aggregation (sum) of all standardized length frequencies (subsamples raised to standardized haul abundance per hour) over the stations of each stratum. Aggregated length frequencies were then raised to stratum abundance * 100 (because of low numbers in most strata) and finally aggregated (sum) over the strata to the GSA.

### 8.57.3.1.2. Geographical distribution patterns

No analyses based on Medits data were presented.
8.57.3.1.3. Trends in abundance and biomass

The re-estimated abundance indices are shown in Figure 8.57.3.1.3.1. No temporal patterns are evident..

Fig. 8.57.3.1.3.1 Trends in survey abundance and biomass indices (Medits) of Norway lobster in GSA 10.
8.57.3.1.4. Trends in abundance by length or age

The following Fig. 8.57.3.1.4.1 and 2 display the stratified abundance indices of GSA 10 in 1994-2001 and 2002-2008.

Fig. 8.57.3.1.4.1 Stratified abundance indices by size, 1994-2001.

Fig. 8.57.3.1.4.2. Stratified abundance indices by size, 2002-2008.

### 8.57.3.2.GRUND

### 8.57.3.2.1. Methods

Since 2003 Grund surveys (Relini, 2000) was conducted using the same sampler (vessel and gear) in the whole GSA. Sampling scheme, stratification and protocols were similar as in Medits. All the abundance and biomass data were standardised to the square kilometre, using the swept area method.

### 8.57.3.2.2. Geographical distribution patterns

The geographical distribution pattern of the Norway lobster has been studied in the area using trawl-survey data (Grund and Medits), length frequency distribution analyses via modal component separation techniques and geostatistical methods. Nurseries were localized with a higher level of probability offshore the Garigliano river in the northernmost part of the GSA and offshore Capo Suvero, on the southern part of the area. These areas were also persistent along the time.

Fig. 8.57.3.2.2.1 Map of nursery area of Norway lobster.
8.57.3.2.3. Trends in abundance and biomass

Trends derived from the GRUND surveys are shown in Fig. 8.57.3.2.3.1. Abundance and biomass indices show an increasing trend up to 2005 and a decreasing in 2006, as well as recruitment indices (Fig. $8.57 .3 .2 .3 .1)$. In 1999 the survey was not performed.

Fig. 8.57.3.2.3.1. Abundance and biomass indices of the Norway lobster in GSA 10 (bars indicate standard deviations) derived from Grund surveys. Recruitment indices ( $\mathrm{N} / \mathrm{km}^{2}$ ) computed in the total depth range with standard deviation is also reported.
8.57.3.2.4. Trends in abundance by length or age

Grund time series of length structures from 1994 to 2006 (Fig. 8.57.3.2.4.1) did not show any trend.

Fig. 8.57.3.2.4.1 III Quantile derived from the GRUND length structures in 1994-2006.

### 8.57.3.2.5. Trends in growth

No analyses were conducted during SGMED-09-02.

### 8.57.3.2.6. Trends in maturity

No analyses were conducted during SGMED-09-02.
8.57.4 Assessment of historic stock parameters

No analytical assessment of historic stock parameters was conducted.
8.57.5. Long term prediction

### 8.57.5.1. Justification

No forecast analyses were conducted.

### 8.57.5.2. Input parameters

No forecast analyses were conducted.

### 8.57.5.3.Results

Given the preliminary state of the data and analyses SGMED-09-02 is not in the position to provide a short term prediction of catch and stock biomass for Norway lobster in GSA 10.

### 8.57.6. Scientific advice

8.57.6.1.Short term considerations
8.57.6.1.1. State of the spawning stock size

SGMED-09-02 is unable to provide any scientific advice of the state of the spawning stock in relation to proposed precautionary level given the preliminary state of the data and analyses.

### 8.57.6.1.2. State of recruitment

SGMED-09-02 is unable to provide any scientific advice of the state of recruitment in relation to proposed precautionary level given the preliminary state of the data and analyses.

### 8.57.6.1.3. State of exploitation

SGMED-09-02 is unable to provide any scientific advice of the state of exploitation in relation to proposed precautionary level given the preliminary state of the data and analyses.

### 8.58. Stock assessment of Norway lobster in GSA 11

### 8.58.1.Stock identification and biological features

### 8.58.1.1.Stock Identification

No information was documented during SGMED-09-02.

### 8.58.1.2.Growth

No information was documented during SGMED-09-02.

### 8.58.1.3.Maturity

No information was documented during SGMED-09-02.

### 8.58.2.Fisheries

### 8.58.2.1.General description of fisheries

No information was documented during SGMED-09-02.
8.58.2.2.Management regulations applicable in 2008 and 2009

No information was documented during SGMED-09-02.

### 8.58.2.3.Catches

### 8.58.2.3.1. Landings

Tab. 8.58.2.3.1.1 lists the trend in reported landings by fishing technique. The data were reported to SGMED-09-02 through the Data Collection Regulation and are listed in Table A3.8 of Appendix 3. The landings were mainly taken by demersal otter trawls.

Tab. 8.58.2.3.1.1 Annual landings (t) by fishing technique in GSA 11. Landings data provided for the years 2002 and 2003, probably have a mistake in the units used.

| SPECIES | AREA | COUNTRY | FT_LVL4 | 2002 | 2003 | 2004 | 2005 | 2006 | 2007 | 2008 |  |

### 8.58.3.Scientific surveys

### 8.58.3.1.Medits

### 8.58.3.1.1. Methods

Based on the DCR data call, abundance and biomass indices were recalculated. In GSA 11 the following number of hauls was reported per depth stratum (s. Tab. 8.58.3.1.1.1).

Tab. 8.58.3.1.1.1. Number of hauls per year and depth stratum in GSA 11, 1994-2008.

| STRATUM | 1994 | 1995 | 1996 | 1997 | 1998 | 1999 | 2000 | 2001 | 2002 | 2003 | 2004 | 2005 | 2006 | 2007 | 2008 |
| :--- | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| GSA11_010-050 | 17 | 19 | 21 | 21 | 21 | 21 | 19 | 18 | 20 | 18 | 17 | 17 | 19 | 19 | 17 |
| GSA11_050-100 | 27 | 21 | 22 | 22 | 20 | 22 | 22 | 24 | 19 | 19 | 18 | 21 | 18 | 20 | 19 |
| GSA11_100-200 | 22 | 23 | 30 | 31 | 31 | 30 | 31 | 30 | 24 | 24 | 24 | 24 | 24 | 24 | 22 |
| GSA11_200-500 | 35 | 29 | 29 | 26 | 25 | 27 | 24 | 25 | 20 | 24 | 21 | 20 | 20 | 20 | 21 |
| GSA11_500-800 | 23 | 16 | 21 | 25 | 25 | 24 | 27 | 26 | 16 | 14 | 15 | 14 | 16 | 17 | 16 |

Data were assigned to strata based upon the shooting position and average depth (between shooting and hauling depth). Few obvious data errors were corrected. Catches by haul were standardized to 60 minutes hauling duration. Hauls noted as valid were used only, including stations with no catches of hake, red mullet or pink shrimp (zero catches are included).

The abundance and biomass indices by GSA were calculated through stratified means (Cochran, 1953; Saville, 1977). This implies weighting of the average values of the individual standardized catches and the variation of each stratum by the respective stratum areas in each GSA:
$\mathrm{Yst}=\Sigma\left(\mathrm{Yi}^{*}{ }^{*} \mathrm{Ai}\right) / \mathrm{A}$
$\mathrm{V}(\mathrm{Yst})=\Sigma\left(\mathrm{Ai}^{2} * \mathrm{si}^{2} / \mathrm{ni}\right) / \mathrm{A}^{2}$
Where:
A=total survey area
$\mathrm{Ai}=$ area of the i -th stratum
si=standard deviation of the i-th stratum
ni=number of valid hauls of the i-th stratum
$\mathrm{n}=$ number of hauls in the GSA
$\mathrm{Yi}=$ mean of the i-th stratum
Yst=stratified mean abundance
$\mathrm{V}(\mathrm{Yst})=$ variance of the stratified mean

The variation of the stratified mean is then expressed as the $95 \%$ confidence interval: Confidence interval $=$ Yst $\pm \mathrm{t}$ (student distribution) $* \mathrm{~V}(\mathrm{Yst}) / \mathrm{n}$

It was noted that while this is a standard approach, the calculation may be biased due to the assumptions over zero catch stations, and hence assumptions over the distribution of data. A normal distribution is often assumed, whereas data may be better described by a delta-distribution, quasi-poisson. Indeed, data may be better modelled using the idea of conditionality and the negative binomial (e.g. O'Brien et al. (2004)).

Length distributions represented an aggregation (sum) of all standardized length frequencies (subsamples raised to standardized haul abundance per hour) over the stations of each stratum. Aggregated length
frequencies were then raised to stratum abundance * 100 (because of low numbers in most strata) and finally aggregated (sum) over the strata to the GSA. Given the sheer number of plots generated, these distributions are not presented in this report.

### 8.58.3.1.2. Geographical distribution patterns

No analyses were conducted during SGMED-09-02.

### 8.58.3.1.3. Trends in abundance and biomass

Fishery independent information regarding the state of the Norway lobster in GSA 11 was derived from the international survey Medits. Figure 8.58.3.1.3.1 displays the estimated trend in Norway lobster abundance and biomass in GSA 11. The analyses of Medits indices are considered preliminary.

Fig. 8.58.3.1.3.1 Abundance and biomass indices of Norway lobster in GSA 11.

### 8.58.3.1.4. Trends in abundance by length or age

The following Fig. 8.58.3.1.4.1 and 2 display the stratified abundance indices of GSA 11 in 1994-2008. These size compositions are considered preliminary.

Fig. 8.58.3.1.4.1 Stratified abundance indices by size, 1994-2001.

Fig. 8.58.3.1.4.2 Stratified abundance indices by size, 2002-2008.

### 8.58.3.1.5. Trends in growth

No analyses were conducted during SGMED-09-02.
8.58.3.1.6. Trends in maturity

No analyses were conducted during SGMED-09-02.
8.58.4.Assessment of historic stock parameters

SGMED-09-02 did not undertake any analytical assessment.

### 8.58.5.Long term prediction

### 8.58.5.1.Justification

No forecast analyses were conducted.

### 8.58.5.2.Input parameters

No forecast analyses were conducted.

### 8.58.5.3.Results

Given the preliminary state of the data and analyses SGMED-09-02 is not in the position to provide a long term prediction of catch and stock biomass for Norway lobster in GSA 11.

### 8.58.6.Scientific advice

### 8.58.6.1.Short term considerations

### 8.58.6.1.1. State of the spawning stock size

SGMED-09-02 is unable to provide any scientific advice of the state of the spawning stock given the preliminary state of the data and analyses.

### 8.58.6.1.2. State of recruitment

SGMED-09-02 is unable to provide any scientific advice of the state of the recruitment given the preliminary state of the data and analyses.

### 8.58.6.1.3. State of exploitation

SGMED-09-02 is unable to provide any scientific advice of the state of the exploitation in relation to proposed precautionary and target levels given the preliminary state of the data and analyses.

### 8.59. Stock assessment of Norway lobster in GSA 16

### 8.59.1.Stock identification and biological features

### 8.59.1.1.Stock Identification

No information was documented during SGMED-09-02.

### 8.59.1.2.Growth

No information was documented during SGMED-09-02.

### 8.59.1.3.Maturity

No information was documented during SGMED-09-02.

### 8.59.2. Fisheries

### 8.59.2.1.General description of fisheries

No information was documented during SGMED-09-02.
8.59.2.2.Management regulations applicable in 2008 and 2009

No information was documented during SGMED-09-02.

### 8.59.2.3.Catches

### 8.59.2.3.1. Landings

Tab. 8.59.2.3.1.1 lists the trend in reported landings by fishing technique. The data were reported to SGMED-09-02 through the Data Collection Regulation and are listed in Table A3.8 of Appendix 3. The landings were mainly taken by demersal otter trawls.

Tab. 8.59.2.3.1.1 Annual landings (t) by fishing technique in GSA 16. Landings data provided for the years 2002 and 2003, probably have a mistake in the units used.

### 8.59.3.1.Medits

### 8.59.3.1.1. Methods

Based on the DCR data call, abundance and biomass indices were recalculated. In GSA 16 the following number of hauls was reported per depth stratum ( s . Tab. 8.59.3.1.1.1).

Tab. 8.59.3.1.1.1. Number of hauls per year and depth stratum in GSA 16, 1994-2008.

| STRATUM | 1994 | 1995 | 1996 | 1997 | 1998 | 1999 | 2000 | 2001 | 2002 | 2003 | 2004 | 2005 | 2006 | 2007 | 2008 |
| :--- | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| GSA16_010-050 | 4 | 4 | 4 | 4 | 4 | 4 | 4 | 4 | 7 | 7 | 7 | 10 | 10 | 11 | 11 |
| GSA16_050-100 | 9 | 8 | 8 | 8 | 8 | 8 | 7 | 8 | 11 | 12 | 12 | 20 | 22 | 23 | 23 |
| GSA16_100-200 | 4 | 4 | 4 | 4 | 5 | 5 | 6 | 5 | 11 | 10 | 11 | 20 | 19 | 21 | 21 |
| GSA16_200-500 | 10 | 11 | 11 | 12 | 11 | 11 | 11 | 11 | 19 | 18 | 27 | 37 | 31 | 27 | 27 |
| GSA16_500-800 | 10 | 14 | 14 | 13 | 14 | 14 | 14 | 14 | 20 | 20 | 21 | 33 | 33 | 38 | 38 |

Data were assigned to strata based upon the shooting position and average depth (between shooting and hauling depth). Few obvious data errors were corrected. Catches by haul were standardized to 60 minutes hauling duration. Hauls noted as valid were used only, including stations with no catches of hake, red mullet or pink shrimp (zero catches are included).

The abundance and biomass indices by GSA were calculated through stratified means (Cochran, 1953; Saville, 1977). This implies weighting of the average values of the individual standardized catches and the variation of each stratum by the respective stratum areas in each GSA:
$\mathrm{Yst}=\Sigma\left(\mathrm{Yi}^{*}{ }^{*} \mathrm{Ai}\right) / \mathrm{A}$
$\mathrm{V}(\mathrm{Yst})=\Sigma\left(\mathrm{Ai}^{2} * \mathrm{si}^{2} / \mathrm{ni}\right) / \mathrm{A}^{2}$
Where:
A=total survey area
$\mathrm{Ai}=$ area of the i -th stratum
si=standard deviation of the i-th stratum
ni=number of valid hauls of the i-th stratum
$\mathrm{n}=$ number of hauls in the GSA
$\mathrm{Yi}=$ mean of the i-th stratum
Yst=stratified mean abundance
$\mathrm{V}(\mathrm{Yst})=$ variance of the stratified mean
The variation of the stratified mean is then expressed as the $95 \%$ confidence interval: Confidence interval $=$ Yst $\pm \mathrm{t}$ (student distribution) $* \mathrm{~V}(\mathrm{Yst}) / \mathrm{n}$

It was noted that while this is a standard approach, the calculation may be biased due to the assumptions over zero catch stations, and hence assumptions over the distribution of data. A normal distribution is often assumed, whereas data may be better described by a delta-distribution, quasi-poisson. Indeed, data may be better modelled using the idea of conditionality and the negative binomial (e.g. O'Brien et al. (2004)).

Length distributions represented an aggregation (sum) of all standardized length frequencies (subsamples raised to standardized haul abundance per hour) over the stations of each stratum. Aggregated length frequencies were then raised to stratum abundance * 100 (because of low numbers in most strata) and finally aggregated (sum) over the strata to the GSA. Given the sheer number of plots generated, these distributions are not presented in this report.

### 8.59.3.1.2. Geographical distribution patterns

No analyses were conducted during SGMED-09-02.

### 8.59.3.1.3. Trends in abundance and biomass

Fishery independent information regarding the state of the Norway lobster in GSA 16 was derived from the international survey Medits. Figure 8.59.3.1.3.1 displays the estimated trend in Norway lobster abundance and biomass in GSA 16. The analyses of Medits indices are considered preliminary.

Fig. 8.59.3.1.3.1 Abundance and biomass indices of Norway lobster in GSA 16.

### 8.59.3.1.4. Trends in abundance by length or age

The following Fig. 8.59.3.1.4.1 and 2 display the stratified abundance indices of GSA 16 in 1994-2008. These size compositions are considered preliminary.

Fig. 8.59.3.1.4.1 Stratified abundance indices by size, 1994-2001.

$\square$

Fig. 8.59.3.1.4.2 Stratified abundance indices by size, 2002-2008.

### 8.59.3.1.5. Trends in growth

No analyses were conducted during SGMED-09-02.
8.59.3.1.6. Trends in maturity

No analyses were conducted during SGMED-09-02.
8.59.4.Assessment of historic stock parameters

SGMED-09-02 did not undertake any analytical assessment.

### 8.59.5.Long term prediction

### 8.59.5.1.Justification

No forecast analyses were conducted.

### 8.59.5.2.Input parameters

No forecast analyses were conducted.

### 8.59.5.3.Results

Given the preliminary state of the data and analyses SGMED-09-02 is not in the position to provide a long term prediction of catch and stock biomass for Norway lobster in GSA 16.

### 8.59.6.Scientific advice

### 8.59.6.1.Short term considerations

### 8.59.6.1.1. State of the spawning stock size

SGMED-09-02 is unable to provide any scientific advice of the state of the spawning stock given the preliminary state of the data and analyses.

### 8.59.6.1.2. State of recruitment

SGMED-09-02 is unable to provide any scientific advice of the state of the recruitment given the preliminary state of the data and analyses.

### 8.59.6.1.3. State of exploitation

SGMED-09-02 is unable to provide any scientific advice of the state of the exploitation in relation to proposed precautionary and target levels given the preliminary state of the data and analyses.

### 8.60. Stock assessment of Norway lobster in GSA 18

### 8.60.1.Stock identification and biological features

### 8.60.1.1.Stock Identification

No information was documented during SGMED-09-02.

### 8.60.1.2.Growth

No information was documented during SGMED-09-02.
8.60.1.3.Maturity

No information was documented during SGMED-09-02.

### 8.60.2.Fisheries

8.60.2.1.General description of fisheries

No information was documented during SGMED-09-02.
8.60.2.2. Management regulations applicable in 2008 and 2009

No information was documented during SGMED-09-02.
8.60.2.3.Catches

### 8.60.2.3.1. Landings

Tab. 8.60.2.3.1.1 lists the trend in reported landings by fishing technique. The data were reported to SGMED-09-02 through the Data Collection Regulation and are listed in Table A3.8 of Appendix 3. The landings were mainly taken by demersal otter trawls.

Tab. 8.60.2.3.1.1 Annual landings ( t ) by fishing technique in GSA 18. Landings data provided for the years 2002 and 2003, probably have a mistake in the units used.

8.60.2.3.2. Discards

According to information available to the SGMED-09-02 no catches of Norway lobster were discarded by the Italian fleet.

### 8.60.2.3.3. Fishing effort

The trends in fishing effort by fishing technique reported to SGMED-09-02 are listed in Tab. 8.60.2.3.3.1 and in Tab. A3.10-3.12 of Appendix 3.

Tab. 8.60.2.3.3.1 Trends in annual fishing effort by fishing technique deployed in GSA 18, 2002-2007.

### 8.60.3.1.Medits

### 8.60.3.1.1. Methods

Based on the DCR data call, abundance and biomass indices were recalculated. In GSA 18 the following number of hauls was reported per depth stratum (s. Tab. 8.60.3.1.1.1).

Tab. 8.60.3.1.1.1. Number of hauls per year and depth stratum in GSA 18, 1994-2008.

| STRATUM | 1994 | 1995 | 1996 | 1997 | 1998 | 1999 | 2000 | 2001 | 2002 | 2003 | 2004 | 2005 | 2006 | 2007 | 2008 |
| :--- | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| GSA18_010-050 | 14 | 15 | 15 | 14 | 14 | 14 | 14 | 15 | 13 | 13 | 12 | 9 | 10 | 11 | 10 |
| GSA18_050-100 | 14 | 14 | 14 | 15 | 15 | 15 | 15 | 14 | 21 | 21 | 23 | 16 | 15 | 15 | 14 |
| GSA18_100-200 | 24 | 23 | 23 | 23 | 23 | 23 | 23 | 23 | 34 | 31 | 32 | 25 | 25 | 23 | 22 |
| GSA18_200-500 | 10 | 10 | 10 | 10 | 10 | 10 | 10 | 10 | 15 | 15 | 16 | 10 | 10 | 9 | 8 |
| GSA18_500-800 | 10 | 10 | 10 | 10 | 10 | 10 | 10 | 10 | 14 | 14 | 14 | 7 | 7 | 7 | 5 |

Data were assigned to strata based upon the shooting position and average depth (between shooting and hauling depth). Few obvious data errors were corrected. Catches by haul were standardized to 60 minutes hauling duration. Hauls noted as valid were used only, including stations with no catches of hake, red mullet or pink shrimp (zero catches are included).

The abundance and biomass indices by GSA were calculated through stratified means (Cochran, 1953; Saville, 1977). This implies weighting of the average values of the individual standardized catches and the variation of each stratum by the respective stratum areas in each GSA:

Yst $=\Sigma\left(\mathrm{Yi}^{*} \mathrm{Ai}\right) / \mathrm{A}$
$\mathrm{V}(\mathrm{Yst})=\Sigma\left(\mathrm{Ai}^{2} * \mathrm{si}^{2} / \mathrm{ni}\right) / \mathrm{A}^{2}$
Where:
$\mathrm{A}=$ total survey area
$\mathrm{Ai}=$ area of the i -th stratum
si=standard deviation of the i-th stratum
ni=number of valid hauls of the i-th stratum
$\mathrm{n}=$ number of hauls in the GSA
Yi=mean of the $i$-th stratum
Yst=stratified mean abundance
$\mathrm{V}(\mathrm{Yst})=$ variance of the stratified mean
The variation of the stratified mean is then expressed as the $95 \%$ confidence interval: Confidence interval $=$ Yst $\pm \mathrm{t}$ (student distribution) * $\mathrm{V}(\mathrm{Yst}) / \mathrm{n}$

It was noted that while this is a standard approach, the calculation may be biased due to the assumptions over zero catch stations, and hence assumptions over the distribution of data. A normal distribution is often assumed, whereas data may be better described by a delta-distribution, quasi-poisson. Indeed, data may be better modelled using the idea of conditionality and the negative binomial (e.g. O'Brien et al. (2004)).

Length distributions represented an aggregation (sum) of all standardized length frequencies (subsamples raised to standardized haul abundance per hour) over the stations of each stratum. Aggregated length frequencies were then raised to stratum abundance * 100 (because of low numbers in most strata) and finally
aggregated (sum) over the strata to the GSA. Given the sheer number of plots generated, these distributions are not presented in this report.

### 8.60.3.1.2. Geographical distribution patterns

No analyses were conducted during SGMED-09-02.

### 8.60.3.1.3. Trends in abundance and biomass

Fishery independent information regarding the state of the Norway lobster in GSA 18 was derived from the international survey Medits. Figure 8.60.3.1.3.1 displays the estimated trend in Norway lobster abundance and biomass in GSA 18. The analyses of Medits indices are considered preliminary.

Fig. 8.60.3.1.3.1 Abundance and biomass indices of Norway lobster in GSA 18.

### 8.60.3.1.4. Trends in abundance by length or age

The following Fig. 8.60.3.1.4.1 and 2 display the stratified abundance indices of GSA 18 in 1996-2008. These size compositions are considered preliminary.

Fig. 8.60.3.1.4.1 Stratified abundance indices by size, 1996-2003.

Fig. 8.60.3.1.4.2 Stratified abundance indices by size, 2004-2008.

### 8.60.3.1.5. Trends in growth

No analyses were conducted during SGMED-09-02.

### 8.60.3.1.6. Trends in maturity

No analyses were conducted during SGMED-09-02.
8.60.4.Assessment of historic stock parameters

SGMED-09-02 did not undertake any analytical assessment.
8.60.5. Long term prediction

### 8.60.5.1.Justification

No forecast analyses were conducted.

> 8.60.5.2.Input parameters

No forecast analyses were conducted.

### 8.60.5.3.Results

Given the preliminary state of the data and analyses SGMED-09-02 is not in the position to provide a long term prediction of catch and stock biomass for Norway lobster in GSA 18.
8.60.6.Scientific advice

### 8.60.6.1.Short term considerations

### 8.60.6.1.1. State of the spawning stock size

SGMED-09-02 is unable to provide any scientific advice of the state of the spawning stock given the preliminary state of the data and analyses.

### 8.60.6.1.2. State of recruitment

SGMED-09-02 is unable to provide any scientific advice of the state of the recruitment given the preliminary state of the data and analyses.

### 8.60.6.1.3. State of exploitation

SGMED-09-02 is unable to provide any scientific advice of the state of the exploitation in relation to proposed precautionary and target levels given the preliminary state of the data and analyses.

## 10. APPENDIX 1. SGMED OVERALL TERMS OF REFERENCE

The European Community is expected to establish long-term management plans (LTMP) for relevant Mediterranean demersal and small pelagic fisheries based on precautionary approach and adaptive management in taking measures designed to protect and conserve living aquatic resources, to provide for their sustainable exploitation and to minimise the impact of fishing activities on marine eco-systems.

The plans shall include conservation reference points such as targets against which measuring the recovery to or the maintenance of stocks within safe biological limits for fisheries exploiting stocks at/or within safe biological limits (e.g. population size and/or long-term yields and/or fishing mortality rate and/or stability of catches). The management plans shall be drawn up on the basis of the precautionary approach to fisheries management and take account of limit reference points as identified by scientists. The quantitative scientific assessment should provide sufficiently precise and accurate biological and economic indicators and reference points to allow also for an adaptive management of fisheries.

Stating clearly how stocks and fisheries will be assessed and how decision will be taken is fundamental for proper and effective implementation of management plans as well as for transparency and consultations with stakeholders.

Demersal and small pelagic stocks and fisheries in the Mediterranean are evaluated both at national and GFCM level; however these evaluations are often not recurring, are spatially restricted to only some GFCM geographical sub-areas (see attached reference map), covering only partially the overall spatial range where Community fishing fleets and stocks are distributed, and address only few stocks out of several that may be exploited in the same fisheries. Limited attention is also given to technical interactions between different fishing gears exploiting the same stocks.

A limited, although fundamental, scientific contribution of EU fishery scientists to the GFCM assessment process is increasingly affecting the capacity of this regional fisheries management organization to identify harvesting strategies and control rules and to adopt precautionary and adaptive fisheries management measures based on scientific advice.

Anyhow, GFCM and most of the riparian countries consider that management measures to control the exploitation rate and fishing effort, complemented by technical measures, are the most adequate approach for multi-species and multiple-gears Mediterranean fisheries.

Nevertheless, provided that scientific advice underlines to do so, also output measures may be conceivable to manage fisheries particularly for both small pelagic and benthic fish stocks.

Coherence and certain level of harmonization between Community and multilateral framework measures are advisable for effective conservation measures and to enhance responsible management supported by all concerned Parties and stakeholders in the Mediterranean.

STECF can play an important role in focusing greater contributions of European scientists towards stocks and fisheries assessment, in identifying a common scientific framework regarding specific analyses to advise on Community plans and to be then channeled into or completed by the GFCM working groups ${ }^{4}$.

STECF was requested at its November plenary session to set up an operational work-programme for 2008, beginning in the $1^{\text {st }}$ quarter of 2008 , with a view to update the status of the main demersal stocks and evaluate the exploitation levels with respect to their biological and economic production potentials and the sustainability of the stock by using both trawl surveys and commercial catch/landing data as collected through the Community Data Collection regulation $\mathrm{N}^{\circ} 1543 / 2000$ as well as other scientific information collected at national level.

[^2]Within this work-programme STECF is also requested to provide its advice on the status of the main small pelagic stocks and to evaluate the exploitation levels with respect to their biological and economic production potentials and the sustainability of the stock by using both echo and/or DEPM surveys and commercial catch/landing data as collected through the Community Data Collection regulation $\mathrm{N}^{\circ}$ $1543 / 2000$ as well as other scientific information collected at national level.

STECF should take into consideration the data that Member States have been collecting on a regular basis both via monitoring fishing activities and carrying out direct surveys ${ }^{5}$. STECF, in replying at the following terms of reference, should also take into consideration chapter 7 of the $26^{\text {th }}$ STECF Plenary session of 5-9 November $2007^{6}$, as well as the report of the STECF working group on balance between fishing capacity and fishing opportunities ${ }^{7}$.
STECF shall contribute to identify and setup an advisory framework regarding low risk adaptive management by identifying and using appropriate risk assessment methods in order to understand where we stand with respect to sustainable exploitation of ecologically and economically important stocks and what additional management actions need to be taken.
On the basis of the STECF advice the Commission will launch official data calls to EU Member States requesting submission of data collected under the Community Data Collection regulation $\mathrm{N}^{\circ}$ 1543/2000.
STECF is requested in particular:

- to advice whether the data availability may allow the development of a precautionary conceptual framework within which develop specific harvesting strategies and decision control rules for an adaptive management of demersal and small pelagic fisheries in the Mediterranean;
- to set up a conceptual, methodological and operational assessment framework which will allow STECF to carry out in a standardized way both stocks assessment analyses and detailed reviews of assessments done by other scientific bodies in the Mediterranean. The selected assessment methods shall allow estimating indicators for measuring the current status of demersal and small pelagic fisheries and stocks, the sustainability of the exploitation and to measure progress towards higher fishing productivity (MSY or other proxy) with respect to precautionary technical/biological reference points relating to MSY or other yieldbased reference points, to low risk of stock collapse and to maintaining the reproductive capacity of the stocks;
- to set up a conceptual, methodological and operational assessment framework which will allow STECF to identify economic indicators and reference points compatible with economic profitability of the main fisheries while ensuring sustainable exploitation of the stocks in the Mediterranean;
- to indicate whether age/length-based VPA or statistical catch-at -age/length methods are adequate modelling tools to estimate precautionary indicators and reference points measuring the current status and future development of multispecies/multigears Mediterranean fisheries. STECF shall also provide a conceptual and operational framework to use, if advisable, these methods for demersal and small pelagic Mediterranean fisheries;
- to identify adequate empirical modelling approaches that are adequate to estimate precautionary indicators and reference points measuring the current status and future development of multispecies/multigears Mediterranean fisheries. STECF shall also provide a conceptual and operational framework to use, if advisable, these methods for demersal and small pelagic Mediterranean fisheries;

[^3]- to identify the decision-making support modelling tools that are adequate for the Mediterranean fisheries and that will produce outputs that support sustainable use of fishery resources recognizing the need for a precautionary framework in the face of uncertainty and that may allow to provide projections of alternative scenarios for short-medium and long term management guidance;
- to provide either a qualitative or quantitative understanding of the level of precision and accuracy attached to the estimation of indicators and reference points through the different modelling tools;
- to identify which decision-making support modelling tools may help in setting up stock-size dependent harvesting strategies and respective decision control rules;
- to provide information on the data and standardised format needed for each of the decision-making support modelling tool which will be used to launch official data calls under the DCR n ${ }^{\circ} 1543 / 2000$. STECF should also indicate criteria to ensure quality cross- checks of the data received upon the calls.

#### Abstract

SGMED-09-02 was held on 8-12 June 2009 in Sardinia (Italy). The report is a compilation of information on existing fisheries and stock data in order to update the status of the main demersal and small pelagic stocks. The report deals with assessment of historic and recent trends in stock parameters (stock size, recruitment and exploitation) and relevant scientific advice. STECF reviewed the report during its Plenary meeting on 9-13 November 2009.

## How to obtain EU publications

Our priced publications are available from EU Bookshop (http://bookshop.europa.eu), where you can place an order with the sales agent of your choice.

The Publications Office has a worldwide network of sales agents. You can obtain their contact details by sending a fax to (352) 29 29-42758.

The mission of the JRC is to provide customer－driven scientific and technical support for the conception，development，implementation and monitoring of EU policies．As a service of the European Commission，the JRC functions as a reference centre of science and technology for the Union．Close to the policy－making process，it serves the common interest of the Member States，while being independent of special interests，whether private or national．

EUROPEAN COMMISSION

[^0]:    1 BEMMFISH is the acronym of a multi-species, multi-fleet bioeconomic simulation model developed by Árnason \& Koholka in the context of the BEMMFISH project, but this model should not be confused with the project.
    2 FLR continues to be developed beyond the project EFIMAS
