A STUDY ON

" PREDICTION OF OUTCOME IN PATIENTS WITH PRIMARY INTRA CRANIAL HEMORRHAGE USING FUNC SCORE"

Dissertation Submitted to

THE TAMIL NADU DR.M.G.R.MEDICAL UNIVERSITY

CHENNAI

In partial fulfillment of the regulations for the award of the degree of

M.D. BRANCH – I (GENERAL MEDICINE)

DEPARTMENT OF GENERAL MEDICINE

GOVERNMENT STANLEY MEDICAL COLLEGE, CHENNAI.

THE TAMIL NADU DR. M.G.R.MEDICALUNIVERSITY

TAMILNADU, INDIA

MAY 2020

CERTIFICATE

This is to certify that this dissertation entitled **" PREDICTION OF OUTCOME IN PATIENTS WITH PRIMARY INTRA CRANIAL HEMORRHAGE USING FUNC SCORE"** submitted by Dr.M. RAJMOHAN to the faculty of General Medicine, The Tamil Nadu Dr. M.G.R Medical University, Chennai, Tamilnadu, in partial fulfillment of the requirement for the award of M.D DEGREE BRANCH-I (GENERAL MEDICINE) is a bonafide research work carried out by him under my direct supervision and guidance.

GUIDE

Prof. Dr. A. SAMUEL DINESH, M.D.,
Chief, Medical Unit-5,
Department of Medicine,
Stanley Medical College and Hospital,
Chennai - 1.

HOD

Prof. Dr. C. HARIHARAN M.D.,
Head of the Department,
Department of Medicine,
Stanley Medical College and Hospital,
Chennai- 1.

PROF. DR.R.SHANTHIMALAR, M.D., D.A.,
DEAN
Government Stanley Medical College and Hospital,
Chennai-1.

DECLARATION

I, Dr. M. RAJMOHAN , solemnly declare that the dissertation titled **" PREDICTION OF OUTCOME IN PATIENTS WITH PRIMARY INTRA CRANIAL HEMORRHAGE USING FUNC SCORE"** is a bonafide work done by me at Government Stanley Hospital, Chennai during May 2018 to April 2019 under the guidance and supervision of Prof.Dr.A.SAMUEL DINESH, Professor of Medicine, Government Stanley Hospital, Chennai. I also declare that this bonafide work or a part of this work was not submitted by me or any other forward degree or diploma to any other university, board either in India or abroad. This dissertation is submitted to the Tamilnadu Dr. M.G.R Medical University, towards the partial fulfillment of requirement for the award of M.D. Degree (Branch – I) in General Medicine.

Place: Chennai Signature of the candidate

Date: **(Dr.M.RAJMOHAN)**

CERTIFICATE - II

This is to certify that this dissertation work titled titled **“ PREDICTION OF OUTCOME IN PATIENTS WITH PRIMARY INTRA CRANIAL HEMORRHAGE USING FUNC SCORE”** of the candidate Dr.M.RAJMOHAN with Registration Number 201711065 for the award of M.D., DEGREE in the branch of BRANCH-I (GENERAL MEDICINE). I personally verified the urkund.com website for the purpose of plagiarism check. I found that the uploaded thesis file contains from introduction to conclusion pages and result shows 4 percentage of plagiarism in the dissertation.

Guide & Supervisor sign with Seal

SPECIAL ACKNOWLEDGEMENT

I gratefully acknowledge and thank

PROF. DR.R. SHANTHI MALAR M.D., D.A.,

DEAN

GOVERNMENT STANLEY MEDICAL COLLEGE AND HOSPITAL, CHENNAI.

For granting me permission to utilize the resources of this

Institution for my study

ACKNOWLEDGEMENT

I am extremely thankful to our beloved Superintendent **Prof.Dr.DHANASEKAR, M.D.,** Government Stanley HospitalChennai-1, for having granted permission to do this dissertation in Government Stanley Hospital, Chennai.

I am very grateful to our Professor and Head of the Department of Medicine **Prof Dr.C.HARIHARAN, M.D.**, for acceptance to do this dissertation.

I am extremely grateful to my unit chief **Dr.A.SAMUEL DINESH, M.D.,** who taught me the basic aspects and clinical skills in internal medicine which is an essential pre requisite for pursuing any dissertation work. The guidance and encouragement they provided need a special mention.

I recall with gratitude the other unit chiefs and Associate Professors of Department of Medicine, Prof **. Dr.G.RAJAN, M.D., Prof. Dr. C.SRIDHAR M.D., Prof.Dr.S.GEETA, M.D., Prof.Dr.T.B.UMADEVI M.D**., **Prof. Dr.A.RAVI M.D., Prof.Dr.I.ROHINI M.D., Prof. Dr. R.THILAKAVATHY M.D., Prof.Dr.P.MALARVIZHI M.D., Prof. Dr. KALPANA RAMANATHAN M.D.,** for their valuable guidance.

I am extremely thankful to our Registrar **Dr.N.RAVICHANDRAN M.D.,** and our unit **Asst. Professors Dr.R.VIJAY ANAND M.D., Dr. K.LAKSHMI M.D.,** for their valuable suggestions, guidance and support.

I thank **Prof.Dr.S. ARUNAN, M.D.,** Professor and Head of the Department of Neurology, Government Stanley Hospital for guiding me in treating the patients which were very crucial for the study.

I thank **Prof. Dr. M.P. SARAVANAN, M.D.,** Professor and Head of the Department of Biochemistry for providing me with facilities for accurate measurement of the biochemical parameters involved in the thesis work which were very crucial for the study.

I also thank **Prof .Dr. C.AMARNATH M.D.,(RD)** , Professor and Head of the Department, Department of Radiology, for allowing me to utilize the CT facility of their department to image the brain of my patients, and also in helping to interpret them.

I also thank all our patients and their attenders, without whom the study would not be possible.

I extend my love and gratitude to my family and friends for their immense help for this study.

I owe my thanks to almighty for successful completion of this study.

Date: Signature of the Candidate

Place: **(Dr.M. RAJMOHAN)**

T2DM	: Type2 Diabetes Mellitus

TABLE OF CONTENTS

INTRODUCTION

Intracranial hemorrhage refers to bleeding within the intracranial vault, that includes the brain parenchyma and surrounding meningeal spaces. This study mainly focuses on the primary intra cerebral hemorrhage (ICH) which is non-traumatic.

Intra cerebral hemorrhage (ICH) the most disturbing and least treatable form of stroke, also in addition, it causes severe disability among survivors.[1–4] Because ICH is considered to be fatal in majority of circumstances, withdrawal of care of such patients commonly occurs early even in the hospital course, in their home that cause a situation that can take away a "fighting chance" to those patients whose prognosis may not be as grave as initially judged.[5,6,18] Providing proper care to such patients not only help in the survival of those patients but also it results in good independent outcome for those who survive the episode.

Accurate prediction regarding the outcome of the patients presenting with ICH is very important for confronting the members of the family. Since most patients with ICH require advanced treatment and care, many times a need of transfer to higher centre may be required. In such instances an accurate prediction regarding the outcome may help the family members in decision making and proper care.[19,20]

Basically, it is identification of patients expected to recover functional independence, rather than just survive, which can address the most persistent concern of families, medical teams in regard to direction of care.[7]

AIMS AND OBJECTIVES

Aim of the study:

The aim of this study is to determine the **Prediction of Outcome in Patients with Primary Intra cranial hemorrhage using FUNC score** in Stanley Government Medical College Hospital.

Primary objective:

1. To calculate the FUNC score in patients admitted with spontaneous intra cerebral hemorrhage confirmed by CT brain.
2. To follow up these patients for a period of 90 days.
3. To compare the outcome of patients with low FUNC score to those with high FUNC score after 90 days
4. Factors determining the outcome are assessed.
5. Functional independence of the surviving patients compared according to their FUNC score.
6. The importance of a score that can predict the outcome of a patient with primary ICH can help the patient in terms of proper care and support apart from treatment.

Study background :

- Intra cerebral hemorrhage (ICH) is the most serious and disturbing stroke subtype.
- Widely used tools that are used for prediction of mortality and outcome are limited such that they don't take into account of effects of care withdrawal and not planned to predict functional outcome and recovery. [2 2-29]
- An acute clinical score to foresee functional independence would help in predicting the outcome.
- Primary (nontraumatic) intracerebral hemorrhage (ICH) accounts for an approximately 10–15 % of strokes.
- Its importance originates from its frequency and its associated high mortality.
- The ICH score and volume is a clinical grading scale that allows risk stratification on patients with ICH.

The use of a scale such as the FUNC score could predict the Outcome in Patients With Primary Intra cranial hemorrhage .

Justification of Study:

- More than 60% of individuals die or are left with severe disability following intra cerebral hemorrhage.
- The accurate prediction of outcome is therefore essential to help families of affected individuals decide on goals of care, as they consider whether their loved one would choose to survive
- FUNC score is based on GCS score, ICH volume, ICH location, Age, Pre ICH Cognitive impairment.
- The score ranged from 0 to 11 with a score of 11 indicating strong likelihood of functional independence.
- Patients revealed no chance of attaining functional independence at 90 days if their score was <4
- Inspite of the effective advances in treatment, the outcome of the patient with Intra cerebral hemorrhage remains poor. The myth that patients presenting with ICH always have a grave prognosis still persists. The care for such patients eventually gets reduced.
- Hence a score or scale that can accurately predict the outcome of such patients maybe helpful for proper care and can result in good functional independence of such patients.

REVIEW OF LITERATURE

HISTORICAL PERSPECTIVE

Stroke is a prehistoric disease. Imhotep, Father of Egyptian medicine, labelled stroke around 3000 BC. In 1600 Thomas Willis termed Circle of Willis and used the term "Apoplexy". Modern era of stroke started when Miller Fisher termed stroke and its features.

In the past few years there was a great change in management of stroke. In 1996, Introduction of IV rt-PA as established effective treatment was a trend setter in the field of medicine. In the field of interventional neurology the use of endovascular therapies is another milestone in treatment of stroke in modern time. A development in neuroimaging and diagnostic services is of supreme importance in the growth of field of neuromedicine.

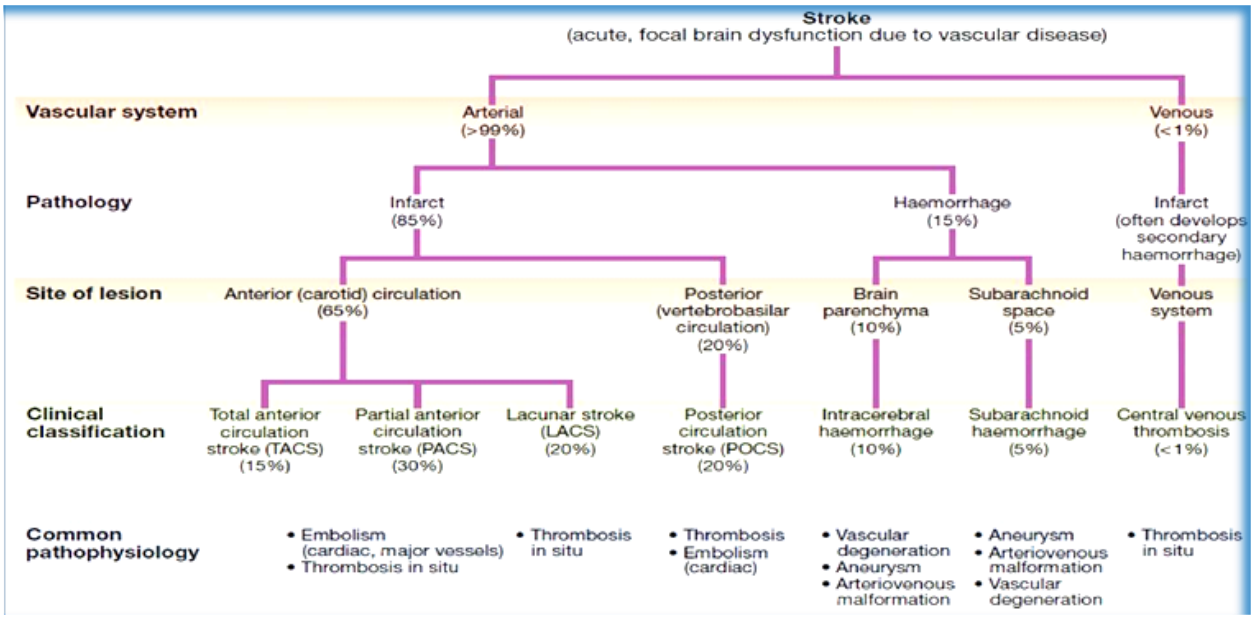
Inspite of the effective advances in treatment, the outcome of the patient with Intra cerebral hemorrhage remains poor. The myth that patients presenting with ICH always have a grave prognosis still persists.

TIME IS BRAIN

The average number of neurons present in human cerebrum is 22 billion. When there is an ischemia, in less than a minute about, 14 billion synapses, 1.9 million neurons and 12 km length of myelinated fibers are lost[3]. With passing of each hour the ischemic brain eons 3.6 years than normal. Prompt intervention is very vital for maintaining the neuronal cell mass by defending them from the ischemic insult.

STROKE classification:

Stroke maybe arterial or venous. Arterial maybe ischemic or hemorrhagic.



Ischemia

Ischemia is divided into 3 mechanisms: thrombosis, embolism, and diminished systemic perfusion.

Thrombosis :

Thrombosis is stated as obstruction to blood flow which can be due to a localized occlusive disease in the blood vessels. The most common pathology is atherosclerosis, here the fibrous and muscular tissues multiply within the sub intima, and fat forms plaques that can encroach the lumen.

Embolism :

In embolism, the thrombus formed elsewhere in the blood vessels gets blocked in an artery and obstructs its blood flow. Embolic luminal blockage, in disparity to thrombosis, is usually not caused by a local process which is originating in the obstructed artery.

The embolized substance mostly arise proximally, from the heart, or from aorta, vertebral arteries ,carotid, or systemic veins.

Decreased Systemic Perfusion :

In decreased systemic perfusion, reduced blood flow to brain tissue is due to low systemic perfusion pressure. The most common causes are cardiac failure (mostly due to MI or rhythm disturbances) and systemic hypotension (which is due to blood loss or hypovolemia).

Poor perfusion is most prominent in border zone ,also known as watershed regions at the junction of the major vascular territories[31-33]

HEMORRHAGE

Hemorrhage can be subdivided into four subtypes: subarachnoid, intracerebral, subdural, and epidural

Subarachnoid Hemorrhage :

In subarachnoid hemorrhage,the blood leaks from the vessel into the brain surface and is disseminated through the cerebrospinal fluid path into the places around the brain, most often comes from aneurysms or AV malformations.

Intracerebral Hemorrhage :

The intracerebral or parenchymal hemorrhage means the bleeding into the brain parenchyma. The most common cause is hypertension, where the leakage of blood is from small intracerebral arterioles which is damaged by the raised blood pressure[18-22]

Subdural and Epidural Hemorrhages :

These are mostly caused by head trauma. Subdural hemorrhages originate from the injured veins which are located between the arachnoid membranes and the duramater.

Epidural hemorrhages are due to tearing of the meningeal arteries, more commonly the middle meningeal artery. Blood collects quickly over minutes to hours in between dura mater and the skull.

STROKE DUE TO ICH

Stroke attributable to intracerebral haemorrhage is around 20-30% of the various causes[1],The importance is due to the high frequency and 30 day mortality and its predilection to affect middle aged hypertensives and elderly on anti-thrombotic therapy.Alleles of apolipoprotein E have an important role in lobar hemorrhages.

BLOOD SUPPLY OF THE BRAIN:

The blood supply of the brain is predominantly from the branches of the internal carotid and vertebral arteries[2]. The two vertebral arteries at the base of the pons unite to form the basilar artery which terminates into the right and left posterior cerebral arteries. The internal carotid artery divides into the smaller anterior cerebral and larger middle cerebral arteries. Around the interpeduncular fossa, in the subarachnoid cistern lies the circle of Willis which is formed by the anterior cerebral and anterior communicating arteries anteriorly, posterior communicating arteries laterally and the posterior cerebral arteries branching off the basilar artery. Aneurysmal rupture induced bleeds may occur in this region.

Branches of the cranial part of vertebral artery:

Anterior spinal artery

Posterior spinal artery

Posterior inferior cerebellar artery

Meningeal branches

Medullary arteries

Branches of the Basilar artery:

Pontine branches

Labyrinthine artery

Superior cerebellar artery

Posterior cerebral artery: This artery further divides to form anterior temporal,posterior temporal branch, parieto-occipital branch and calcarine branch.

Branches of the Internal carotid artery:

Ophthalmic artery

Anterior cerebral artery

Middle cerebral artery

Posterior communicating artery

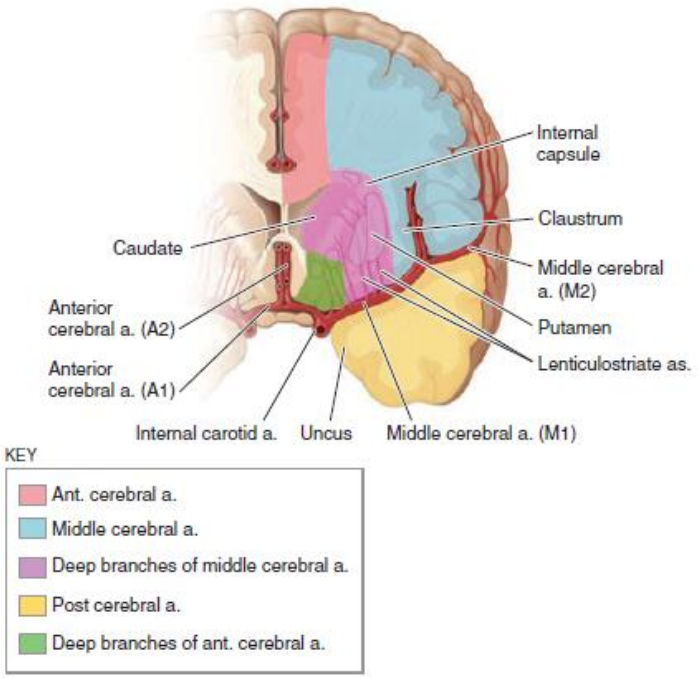
Anterior choroidal artery

ARTERIAL SUPPLY OF THE CEREBRUM:

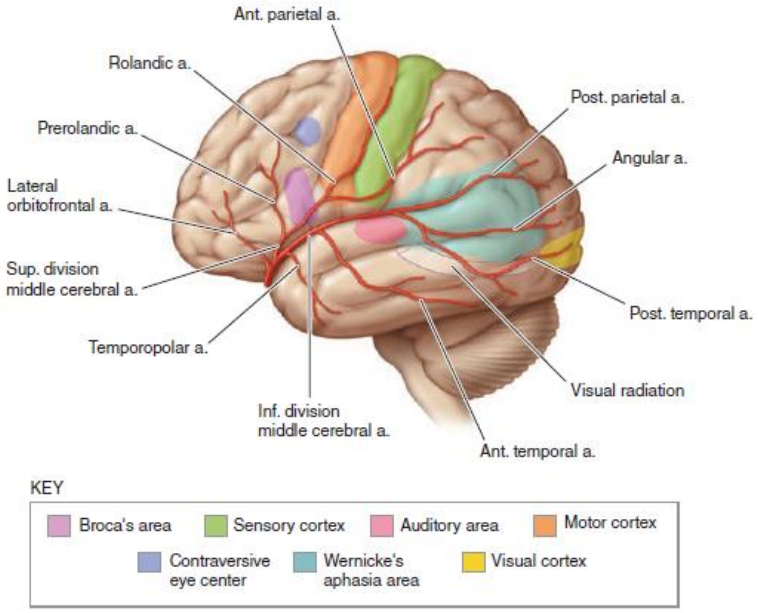
The anterior, middle and posterior cerebral arteries predominantly supply the various cerebral hemispheres. Arterial supply of the supero-lateral surface is by the middle

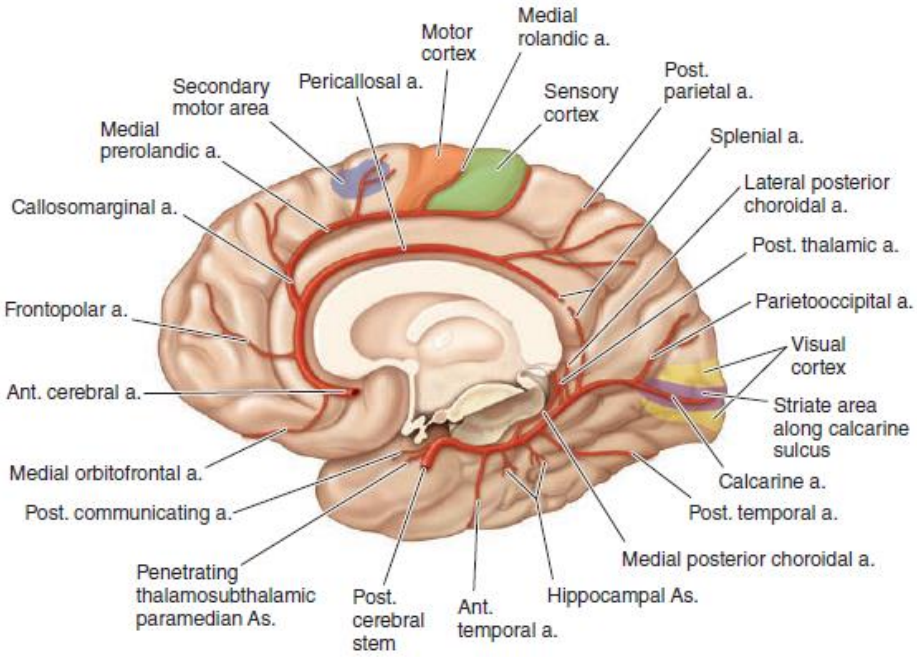
cerebral artery. This covers most of the vital areas including the primary motor and sensory areas, Broca's and Wernicke's speech areas in the dominant hemispheres and the frontal eye field. A portion along the superomedial border upto the parieto-occipital sulcus is supplied by the anterior cerebral artery. Likewise a potion along the lower aspect of the temporal lobe and occipital lobe is supplied by the posterior cerebral artery. The medial supply of the brain is supplied by the anterior cerebral artery predominantly with the middle and posterior cerebral arteries supplying the temporal and occipital lobes respectively. The inferior surface of the brain is supplied by the posterior cerebral artery mainly with contributions from the middle and anterior cerebral arteries. The internal capsule and corpus striatum are supplied by the central branches of the middle and anterior cerebral arteries. The thalamus and midbrain are supplied by the posterior cerebral, basilar arteries alongside the posterior communicating supplying the thalamus and superior cerebellar supplying the midbrain. Pontine supply is from the basilar,superior cerebellar and anterior inferior cerebellar arteries. The cerebellum derives its blood supply from the superior, anterior inferior and posterior inferior cerebellar arteries.

BRANCHES OF INTERNAL CAROTID ARTERY:



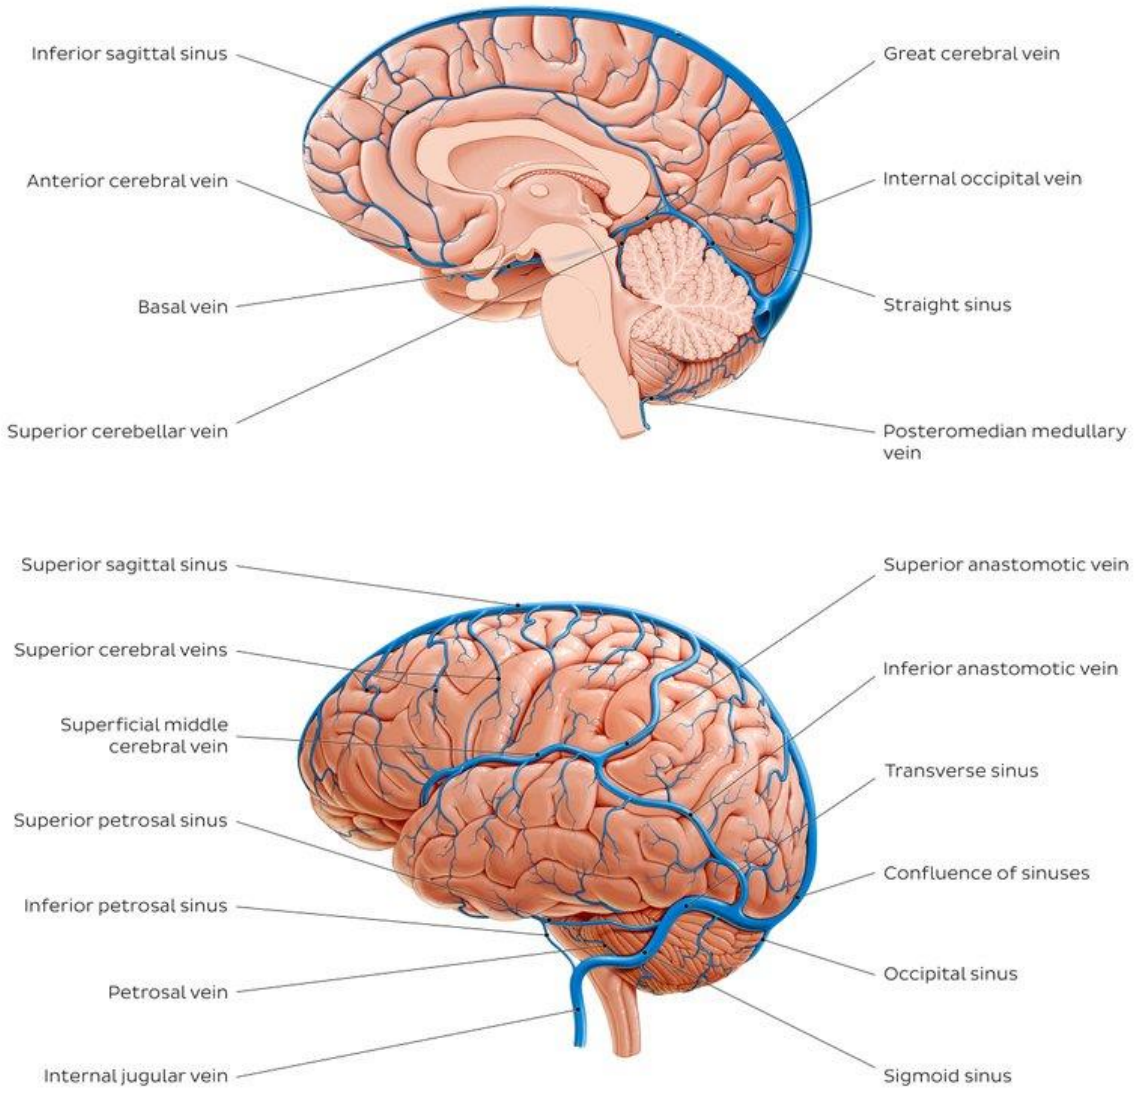
BLOOD SUPPLY OF LATERAL AND MEDIAL ASPECT OF BRAIN:





VENOUS DRAINAGE OF THE BRAIN:

Superior cerebral veins drain the upper portion of the superolateral surface into the superior saggital sinus. Inferior cerebral veins drain the lower potio of the superolateral surface into the superficial middle cerebral vein. The medial surface of the brain is drained by superior,inferior cerebral veins and the anterior cerebral vein. The inferior surface of the brain is drained by the inferior cerebral veins.



CAUSES OF ICH:

Hypertension

Vascular malformations

Vasculitis

Tumoral bleed

Bleeding diathesis

Cerebral amyloid angiopathy

Sympathomimetic agents

Head injury

Haemorrhagic infarction

Hypertension:

Presence of a high frequency of hypertensive population suffering from ICH, high admission blood pressure and echocardiographic evidence of hypertension signifies the importance of hypertension as a causative factor in ICH. Smoking, sedentary lifestyle, dyslipidemia, excess alcohol consumption constitute modifiable risk factors. Lipohyalinosis of the arteries due to chronic hypertension and microaneurysms cause bleeding.

Vascular Malformations:

Intracranial aneurysms, AV malformations, cavernous angiomas at the subcortical white matter. These can be diagnoses by CT or MRI imaging. Cavernous angiomas can be recognised by the presence of a central nidus of irregular bright signal with popcorn pattern and a hypointense ring of hemosiderin on T2-images.Those located in the

posterior fossa present with a progressive course with recurrent small hemorrhages. Recurrence risk is greatest among women and is highest in the first two years.

Intracranial tumors:

Glioblastoma multiforme, metastasis from vaious organs may bleed within resulting in ICH.The unique features include its distinct location from hypertensive bleeds, imaging revealing presence of hyperdense region surrounding a low density area; bleeds at multiple sites, presence of papilloedema, presence of severe cerebral oedema with mass effect.Craniotomy with biopsy of suspected lesion can be done however it carries grave prognosis.

ICH secondary to bleeding diathesis, anticoagulants and fibrinolytic therapy:

Young patients presenting with ICH should be evaluated for the presence of bleeding disorders such as haemophilia. Immune thrombocytopenia, acute leukemia especially acute promyelocytic form and acute lymphocytic leukemia may present as ICH.

9-14% of ICH is due to anticoagulant related causes and is more common in the elderly with history of hypertension, prior cerebral infarction and INR prolongation. Hence maintenance of INR between 2 to 3 may help in reducing the risk of ICH. This type of ICH presents with a slowly progressive course with a large volume bleed and occasionally with other bleeding manifestations. Use of fibrinolytic therapy such as streptokinase or tissue plasminogen activators for thrombolysis may also lead to ICH, a higher incidence being found in those with hyperglycemia, cerebral amyloid

angiopathy,use of dual anti-platelets and higher baseline blood pressure post thrombolysis. Presence of cerebral microbleeds also increases the risk.

Cerebral Amyloid Angiopathy:

Deposition of β-amyloid in the cerebral vessel wall especially of those in the leptomeninges and cortex occurs in cerebral amyloid angiopathy.It predominantly affects elderly patients with a lobar location of bleedIt may anifest as focal neurological deficits and seizures weeks prior to onset of ICH.Histology reveals presence of Congo red positive, birefringent amyloid material in the intima media.

Vasculitides:

Polyarteritis nodosa may present as ICH which is characterized by mononuclear inflammation of small and medium sized vessels.There are signs of systemic involvement such as fever,malaise,renal failure,hypertension and elevation of erythrocyte sedimentation rate.

Sympathomimetic agents:

The use of sympathomimetic agents is associated with transient hypertension and areas of spasm and dilatation in the vessels resulting in ICH. Cocaine is most commonly implicated.

Hemorrhagic infarction:

Occurs from embolic stroke with maximal symptoms at onset with a spotted appearance on computed tomography with a cortical distribution around arterial branches.

CLINICAL FEATURES:

Altered level of consciousness

Headache

TABLE 66.3 Clinical Features of Anatomic Forms of Intracerebral Hemorrhage

Type of intracerebral hemorrhage	Hemiplegia	Hemisensory syndrome	Aphasia	Homonymous Visual Defects	Gaze palsy		Brainstem Signs
					Horizontal	*Vertical*	
Putaminal	Generally dense	Frequent	Globab>motor>conduction	In large hematomas	Contralateral	No	No (only present with herniation)
Caudate	Absent or mild, transient	Absent	No	No	Generally absent	No	No
Thalamic	Generally dense	Frequent, prominent	Occasional, thalamic variety	In large hematomas	Contralateral, occasionally ipsilateral	Yes, upward	Skew deviation, Horner syndrome, Parinaud syndrome
Lobar	Prominent in frontoparietal location	Prominent in frontoparietal location	In dominant temporoparietal location	In occipital hematomas	Contralateral in frontal hematomas	No	No (only present with herniation)
Cerebellar	Absent	Absent	No	No	Ipsilateral	No	Ipsilateral fifth through seventh nerve palsy, Horner syndrome
Pontine	Variable, usually bilateral	Variable, usually bilateral	No	No	Bilateral	No	Pinpoint reactive pupils, ocular "bobbing," decerebrate rigidity, respiratory rhythm abnormalities
Mesencephalic	Variable, usually present	Rare	No	No	No	Occasional, upward	Unilateral or bilateral third nerve palsy
Medullary	Generally absent	Occasional	No	No	No	No	Nystagmus, ataxia, hiccups, facial hypesthesia, dysarthria, dysphagia, twelfth nerve palsy, Horner syndrome
Intraventricular	Generally absent	Rare	No	No	Occasional	Occasional	Rare (decerebrate rigidity)

Vomiting

Focal neurological deficits that progresses over hours

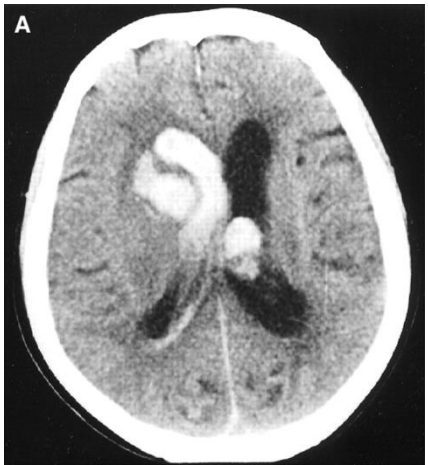
Specific features pertaining to the site of bleed is as follows:

Putaminal bleed:

Constitutes the most common form of ICH. Presentation varies from hemiparesis to decerebrate rigidity.

Caudate bleed:

Occurs from rupture of penetrating arteries of anterior and middle cerebral arteries. Presents with signs of meningeal irritation, focal neurological deficits such as hemiparesis, Horner's syndrome, horizontal gaze palsy, language and memory disturbances. Intraventricular extension with hydrocephalous



occurs however the overall outcome is good.

Thalamic haemorrhage:

Constitutes 10-15% of the ICH with an abrupt onset and slow progression.Intraventricular clot may cause aqueductal obstruction leading to a hydrocephalous that may be reversed with a ventriculostomy procedure.

Lobar haemorrhage:

Second most common form frequently a result of non-hypertensive causes of bleed like arteriovenous malformations, sympathomimetic agents and amyloid angiopathy. Features pertaining to the lobe involved occur such as hemiparesis involving predominantly the upper limbs in frontal lobe, aphasia in dominant temporal hemisphere, hemianopia with sensorimotor deficit in parietal lobe lesions and homonymous hemianopia in occipital lesions.

Cerebellar haemorrhage:

Presents as vertigo, vomiting, inability to walk with a triad of ataxia, horizontal gaze palsy, facial palsy at the side of haemorrhage.

Pontine haemorrhage:

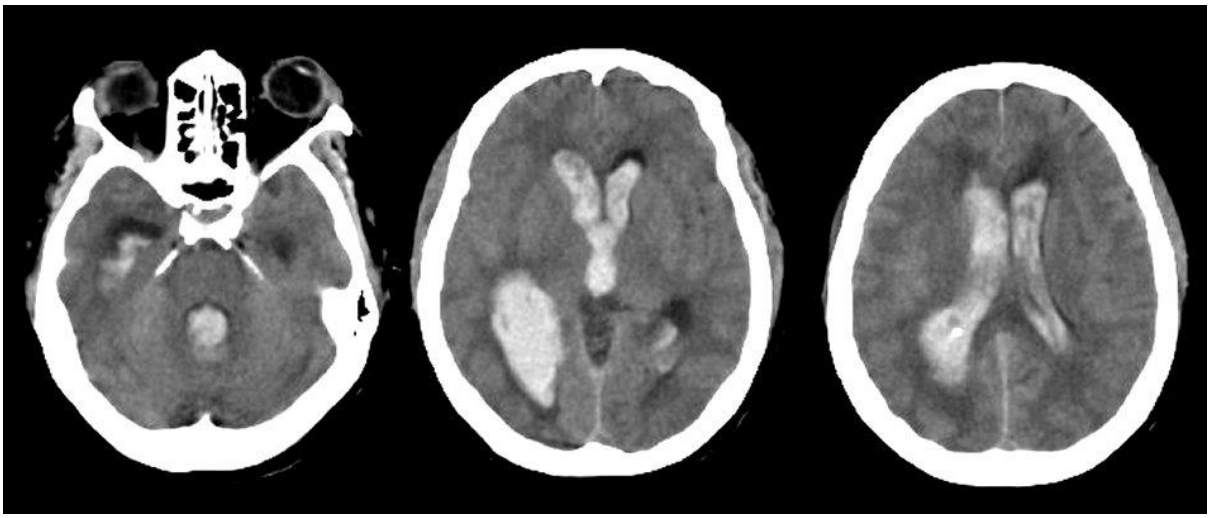
Bilateral involvement of the tegmentum results in quadriplegia, coma, ocular bobbing, horizontal gaze palsy, pin-point pupil and respiratory abnormalities. One and a half syndrome, fifth and sixth cranial nerve palsies and internuclear ophthalmoplegia may occur.

Medullary haemorrhage:

A rare variant that usually affects one half of the medulla resulting in ipsilateral hypoglossal nerve palsy and contralateral hemiparesis thereby differentiating it from Wallenberg syndrome.

Intraventricular haemorrhage:

Commonly occurs in thalamic and caudate haemorrhages. The vasculature of the subependymal layer is thought to be the site of origin of the bleed. Focal neurological deficits are very rare in presentation. Patients who are comatose with brainstem involvement succumb to the illness.



IMAGING:

CT and MRI imaging with angiography form essential components in the diagnosis and prognostification.

Presence of spot sign-contrast extravasation may signify hematoma expansion which occurs in almost 77% of the patients.

TREATMENT:

Rapid evaluation of the patients is to be done with immediate endotracheal intubation for those with a Glasgow Coma Scale score below 8 with the administration of thiopental or lignocaine to prevent increases in intracranial pressure

secondary to tracheal stimulation or intubation. Routine evaluation with specific investigations such as use of toxin screening, blood glucose levels, coagulation profile.

If the patient has been previously on heparin anticoagulation protamine sulphate has to be administered while those on warfarin should be given Vitamin K, fresh frozen plasma or prothrombin complex concentrate.[17] If the ICH was secondary to thrombolytic therapy cryoprecipitate or fresh frozen plasma should be transfused.

Initial treatment is aimed at controlling the blood pressure and seizures as hypertension may further worsen the cerebral oedema. The goal should be aimed at around 160/90mmHg; labetalol being the anti-hypertensive of choice. Nicardipine is an alternative.

Raised intracranial pressure may be managed with hyperventilation, osmotic diuretics and steroids. Intravenous mannitol may be given for reducing the cerebral oedema. If the intracranial pressure is not controlled with the above measure, need for surgical intervention should be considered.

Studies comparing the surgical and non-surgical methods of treatment did not find any significant alteration in the mortality rates.[16] Lobar haemorrhage with progressive deterioration in consciousness, ICH due to AV malformation, aneurysm or cavernous angioma are indications for surgery. Cerebellar haemorrhage is another indication for surgery. Radiologically, a hematoma

diameter of greater than or equal to 3cm, obliteration of the quadrigeminal cistern or presence of hydrocephalous are indications for surgery.

Surgical options include hematoma evacuation, ventricular drainage for hydrocephalous.

Newer treatment modalities include the use of Recombinant activated factor VIIa and is under research along with alternative agents such as tranexamic acid

Sample size: 134 cases

Formula

$n = Z^2pq/d^2$

Where Z =1.96(statistical constantfor 95% CI)

p (prevalence) =62% (incidence of deaths due to ICH volume >60ml in patiens with primary ICH)

q (100-p) = 38%

d = 15% relative precision (i.e 15% of 62)which is 9

Therefore using the formula

n = 1.96 x 1.96 x 62 x 38/81

n = 111

Adding 10% non response rate (i.e 10% of 111 which is 11)

Minimum sample size n = 122

Therefore Sample size n = 134.

Study duration: March 2018 to March 2019 (12 Months)

Inclusion criteria:

- Patients with age ≥12 years
- Patients with spontaneous ICH of nontraumatic origin detected on CT/magnetic resonance imaging or angiographic study
- Who have presented with history of acute severe headache, altered sensorium, slurring of speech, acute hemiparesis, and accelerated hypertension—suggestive of acute cerebrovascular stroke

Exclusion criteria:

- Patients <12 years of age
- Patients with history of trauma
- Patient with ischemic stroke and venous thrombosis
- Patients with sub arachnoid hemorrhage
- Patients with epidural hematoma
- Patientswith sub dural hematoma
- Patients with berry aneurysm

METHODOLOGY

During the study period, patients admitted with Intra cranial haemorrhage were performed imaging study. The most basic and useful imaging study was the computed tomography of the brain. Preliminary basic details like name, age, sex, residence were noted. A detailed history was elicited from the patients regarding trauma, road traffic accidents or other modes of injury. All traumatic cases were excluded even when they presented with elevated blood pressures.

In non-traumatic patients, the history of mode of onset, time and place of onset were elicited. Most of the Presenting complaints were like weakness of limbs, difficulty in speaking, altered sensorium, loss of consciousness, seizures, projectile vomiting and all other associated co morbidities were noted.

Since most of the patients presenting as epidural and subdural hemorrhage are due to trauma, they were excluded. Aneurysms and AV malformations being the primary cause of SAH, they may prsent even with modest elevation of blood pressure. Hence EDH, SDH, SAH are all excluded and patients with non traumatic primary ICH(intra cerebral hemorrhage) alone were included in the study group.

Detailed past history of hypertension, diabetes, cognitive impairment, coronary artery disease, prior use of anti-platelet drugs were noted. Recent surgeries or any factors leading to the event are noted. Prior medications and other native

medical history were noted. Previous episodes of ICH if any were noted. If so, such patients were excluded.

A family history of hypertension is noted since hypertension is strongly associated with ICH. Any family history of similar episodes were noted. A chance of aneurysm is suspected in patients having with family history of ICH.

Personal history of alcohol intake, smoking, IV drug abuse were elicited in detail. Alcohol being an individual risk factor, also can lead to seizures causing head injury. It may also lead to cognitive impairment, can lead to repeated falls and trivial injury. All these were asked from the presenting patient's attenders in view of reliability.

EXAMINATION:

Patient's vitals including pulse rate, blood pressure, temperature, CBG, saturation were noted and monitored in the zero delay ward. All the patients presenting with ICH had elevated blood pressure levels, indicating uncontrolled blood pressure as the major risk factor for primary ICH.

Patient's level of consciousness, co-operation, orientation, speech, memory, articulation, mood were examined. Furthermore, patient's behaviour, appearance, judgement, power of abstraction, intellect, attention and concentration were checked. MMSE was calculated.

The most important aspect of examination in patients with ICH is GCS calculation as it readily tells about the general condition of the patient and it marks as one of the important components of FUNC score

GCS CALCULATION

(I)EYE OPENING: RESPONSE	SCORE
Opens spontaneously	4
Opens to verbal command	3
Opens to pain	2
Does not open	1
(ii)VERBAL RESPONSE:	
Oriented	5
Confused	4
Inappropriate words	3
Incoherent sounds	2
No response	1
(iii) MOTOR RESPONSE:	
Obeys commands	6
Localising pain	5
Withdrawal from pain	4
Decorticate posture	3
Decerebrate posture	2
No response	1
TOTAL SCORE	15

As mentioned earlier, GCS calculation is essential in all patients with ICH. Minimum score of 3 and maximum score of 15 was obtained.

The duration of presentation is noted as timely intervention is the most important aspect in management of stroke irrespective of aetiology. Patients who are referred from primary care health centres to our hospital took longer time for presentation due to various reasons.

INVESTIGATIONS:

CT scan of brain was taken immediately. Along with that additional imaging studies like Doppler study of carotid arteries, angiogram- CT angiogram, MRI brain with MRA and MRV – plain and contrast were taken. The purpose angiogram was to rule out any AV malformations, aneurysms like berry aneurysm. Patients with aneurysmal bleed causing SAH were excluded.

Apart from imaging studies routine blood investigations like complete blood count, renal function tests, and liver function tests were taken. Renal function tests were essential for contrast studies. Liver function tests were important for drug modification in treatment.

The 2 components of FUNC score ICH volume and ICH location is calculated from the CT brain. Besides providing the conclusive diagnosis, CT also show basic features of the hematoma, such as: hematoma location, extension to the ventricular system, presence of surrounding edema, development of mass effect and midline shift.

CALCULATION OF ICH VOLUME:

Estimation of the hematoma volume can be quickly performed in the ED with the help of validated ABC/2 technique[8] (Figure 1).

Steps to follow using this method are:

• The CT slice with the biggest area of hemorrhage is carefully chosen.

• A is the biggest hemorrhage diameter on the selected cut (in centimeters [cm]).

• B is the biggest diameter perpendicular to A on the same cut.

• C is the approximate number of cuts in which the hemorrhage is noted multiplied by the slice thickness (frequently 0.5cm slices).

• A, B, and C are multiplied and the product is divided by 2.

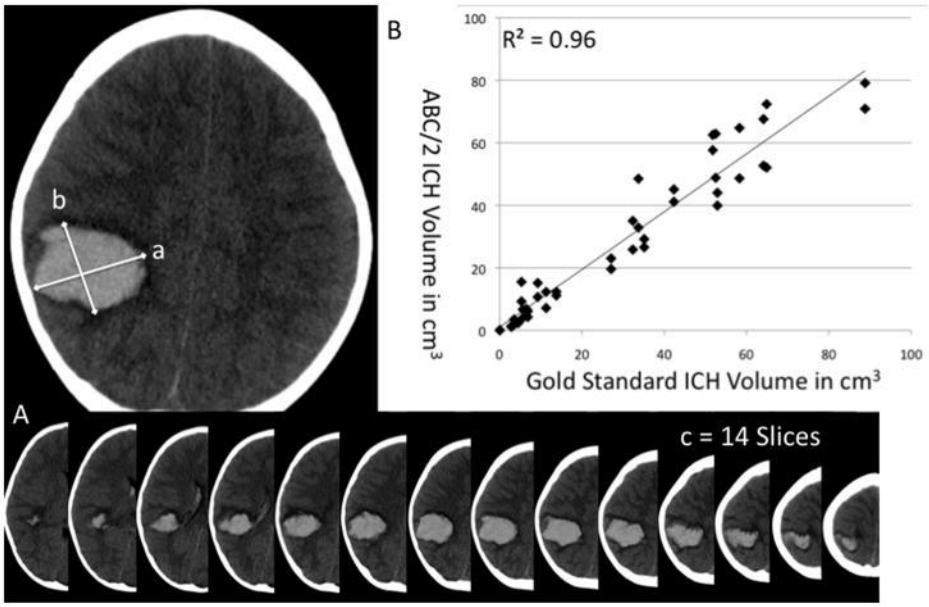


Figure-1: calculation of ICH volume

ICH is considered to be small if the volume is <30 cm^3. Moderate volume of ICH is between 30-60 cm^3. Those having ICH volume >60cm^3 are considered to be large ICH.

After calculating ICH volume, it is essential to see the ICH location as location is also a component of FUNC score and is considered to be the most important component of FUNC score apart from GCS. The location may be superficial/lobar, deep or infra tentorial.

ICH was said to be lobar in location if the source of the hemorrhage appeared to be in cerebral hemispheres superficial to deep gray matter structures. Hemorrhages originating in the thalamus and basal ganglia are said to be "deep" in location.[9,10] ICH is considered to be infra tentorial if the hemorrhage is below the tentorium cerebelli. The infra tentorial region mainly consists of the cerebellum and its peduncles.

Apart from volume and location, midline shift and intra ventricular extension of the bleed are noted. Since the midline shift and intra ventricular extension are life threatening, patient with these complications are intervened surgically depending on patient's condition.

After obtaining all these parameters FUNC score is calculated for all the patients.

DETERMINANTS OF FUNC SCORE:

COMPONENT	**FUNC SCORE POINT**
ICH VOLUME(cm3):	
<30	4
30-60	2
>60	0
AGE	
<70	2
70-79	1
>79	0
ICH LOCATION	
Lobar	2
Deep	1
Infratentorial	0
GCS SCORE	
>=9	2
=<8	0
PRE ICH COGNITIVE IMPAIRMENT	
NO	1
YES	0
TOTAL FUNC SCORE	11

The prediction of outcome is entirely dependent on FUNC score. Score of >8 is considered good and the patient is expected to be alive after 90 days. A score of <4 is considered poor and the patient is expected to be dead after 90 days. All the patients are followed up for a period of 90 days and the outcome is compared.

FUNC score was once again calculated along with GCS score. 90^{th} day measurement of FUNC and GCS is to determine whether the patient is functionally independent or not. A FUNC score of more than 7 along with GCS of more than 8 is considered to be functionally independent.

In these 90 days patient were evaluated for any re-bleed, seizures and time taken for ambulation with support. Earlier the time taken for ambulation denotes that the person improved well and indirectly tells the patient is functionally independent.

90^{th} day cognitive impairment and bed sores was examined. Bed sores was considered significant as it not only tells about the status of the patient whether he is bed ridden or not, but also the care given for the patient. Improper care results in deep bed sores requiring wound debridement.

Informed consent:

Consent form will be written in both English and Tamil and also orally explained in their own language and consent will be obtained from the participants, confidentiality will be maintained.

Statistical analysis:

Data will be entered in excel sheet and the analysis will be done using SPSS version 17. For numerical data mean and standard deviation will be used, for continuous variable chi square will be used and to find out the association of the two variables. Students't' test will be used. Results will be analyzed using students''t' test the probability (p –value) will be calculated.

***Conflict of interest if any -** Nil

STATISTICAL ANALYSIS

Frequency Table

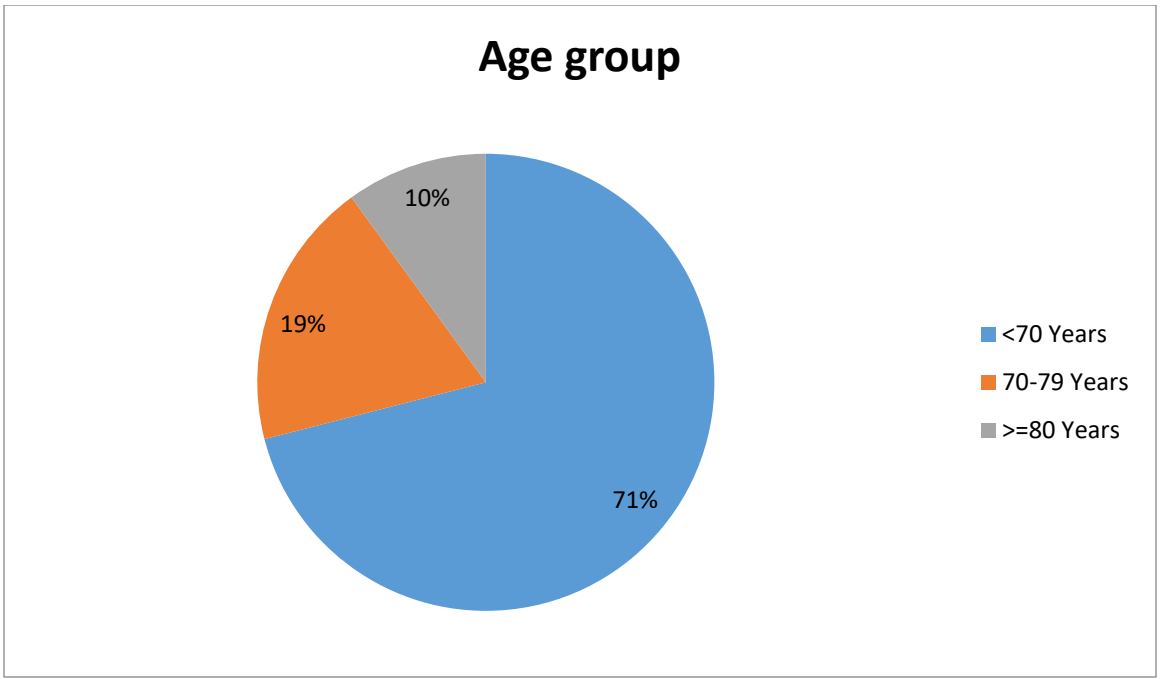
AGE GROUP	FREQUENCY	PERCENT
<70 Years	95	70.9
70-79 Years	26	19.4
>=80 Years	13	9.7
Total	134	100.0

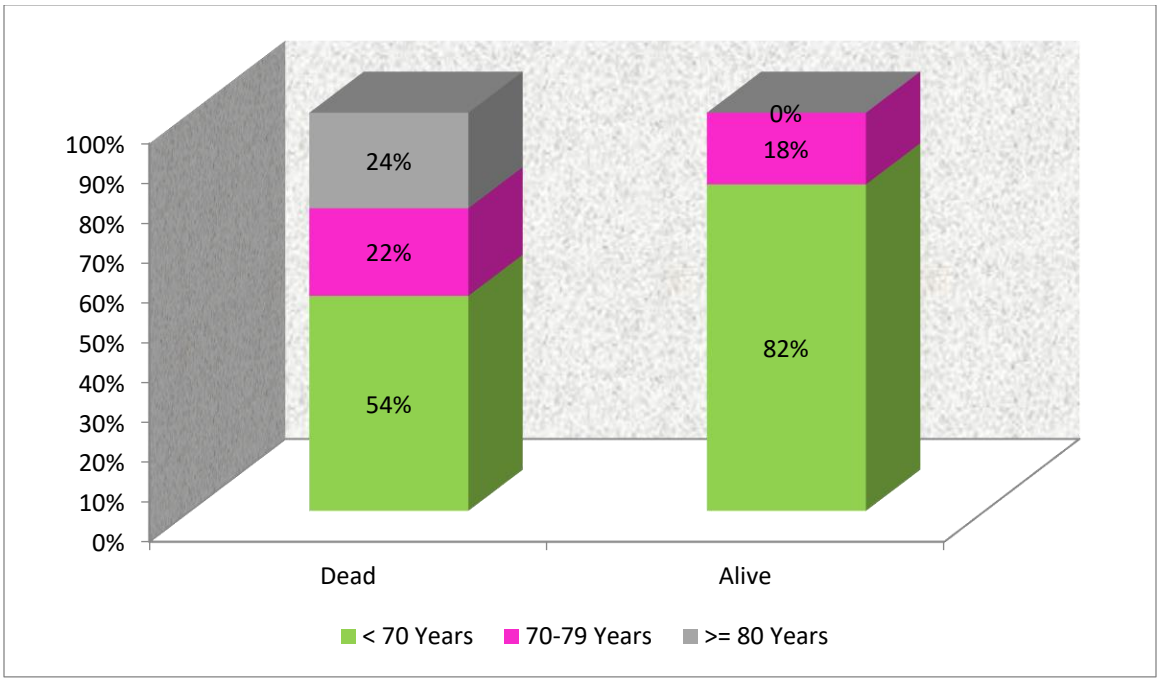
Crosstab

			90th_DAY_OUTCOME		Total
			Dead	Alive	
age_group	<70 Years	Count	30	65	95
		%	54.5%	82.3%	70.9%
	70-79 Years	Count	12	14	26
		%	21.8%	17.7%	19.4%
	>=80 Years	Count	13	0	13
		%	23.6%	0.0%	9.7%
Total		Count	55	79	134
		%	100.0%	100.0%	100.0%

Pearson Chi-Square=22.471**p<0.001

- Among the total population 71% were of less than 70 yrs
- 19% were between 70 to 79 yrs
- 10% were above 80 yrs of age





- All the patients >80 yrs of age presenting with ICH did not survive at the end of 90 days
- 82% of the people <70 yrs of age survived at the end of 90 days.
- Age has a significant impact on the outcome of patients presenting with ICH.

SEX DISTRIBUTION

Frequency table:

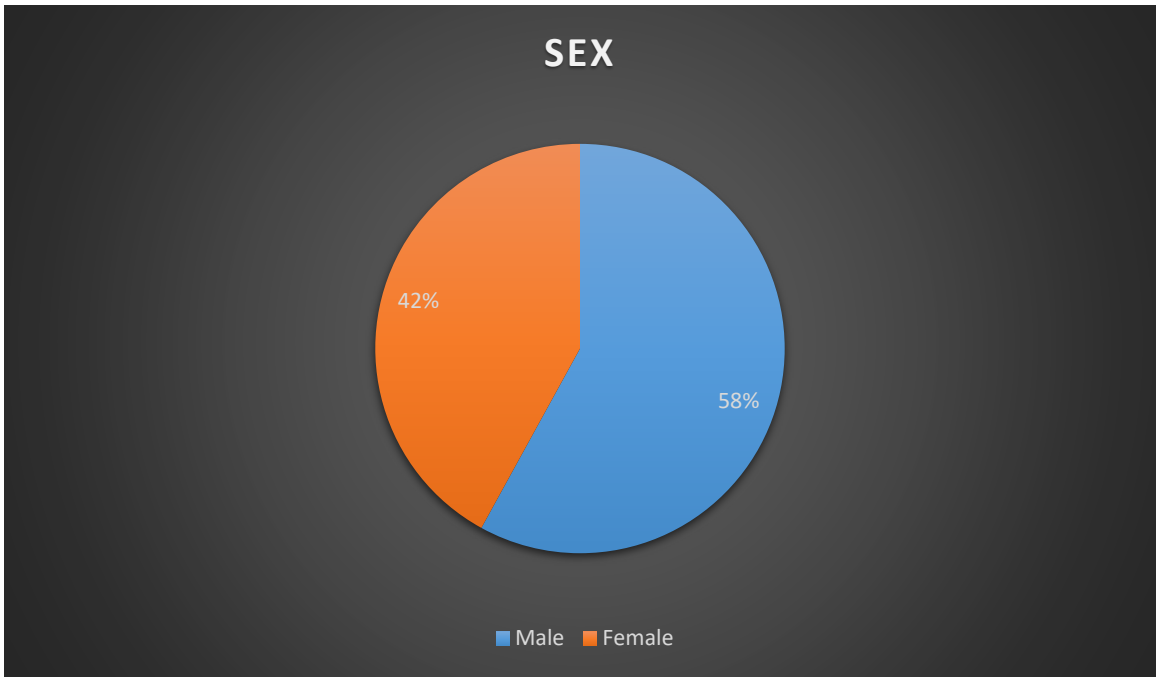
SEX	Frequency	Percent
Male	78	58.2
Female	56	41.8
Total	134	100.0

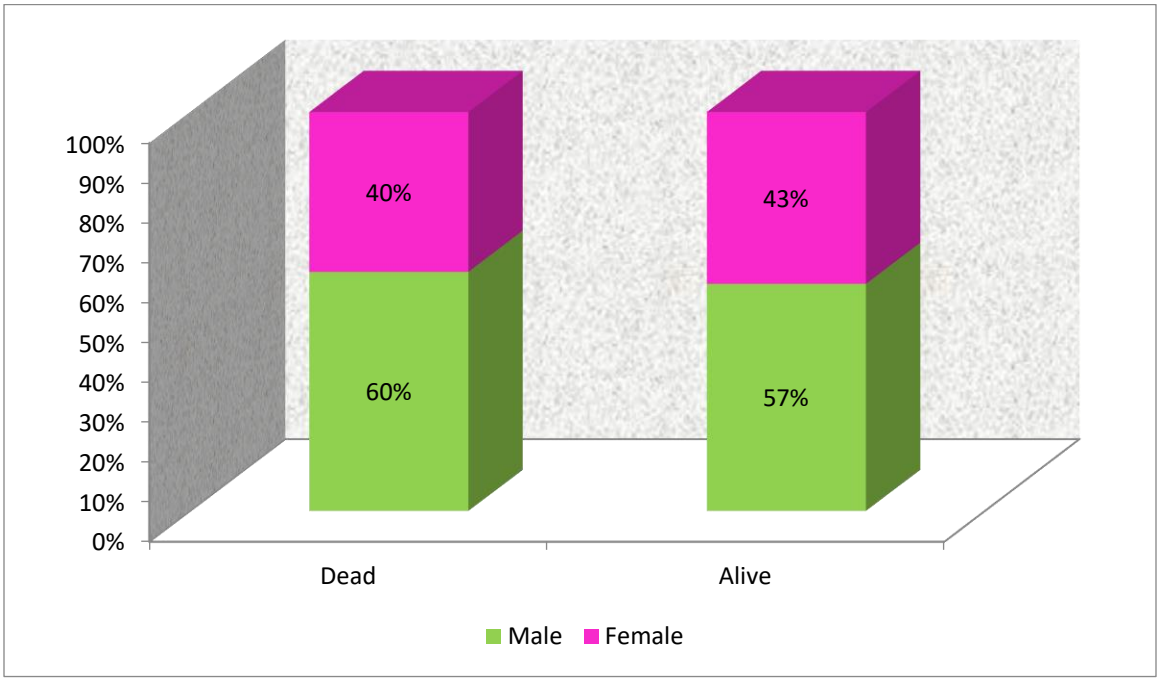
Crosstab

			90th_DAY_OUTCOME		Total
			Dead	Alive	
SEX	Male	Count	33	45	78
		%	60.0%	57.0%	58.2%
	Female	Count	22	34	56
		%	40.0%	43.0%	41.8%
Total		Count	55	79	134
		%	100.0%	100.0%	100.0%

Pearson Chi-Square=0.123 p=0.726

- Of the total 134 population 58% were male and 42% were female indicating a male predominance in the people presenting with ICH
- This can also be attributed to the overall male population more than female population





- The outcome or FUNC score is independent of sex
- **<u>Sex doesnot have a significant impact on the outcome of patients presenting with ICH</u>**

ROLE OF HYPERTENSION

Frequency table:

SHT	Frequency	Percent
No	83	61.9
Yes	51	38.1
Total	134	100.0

Crosstab

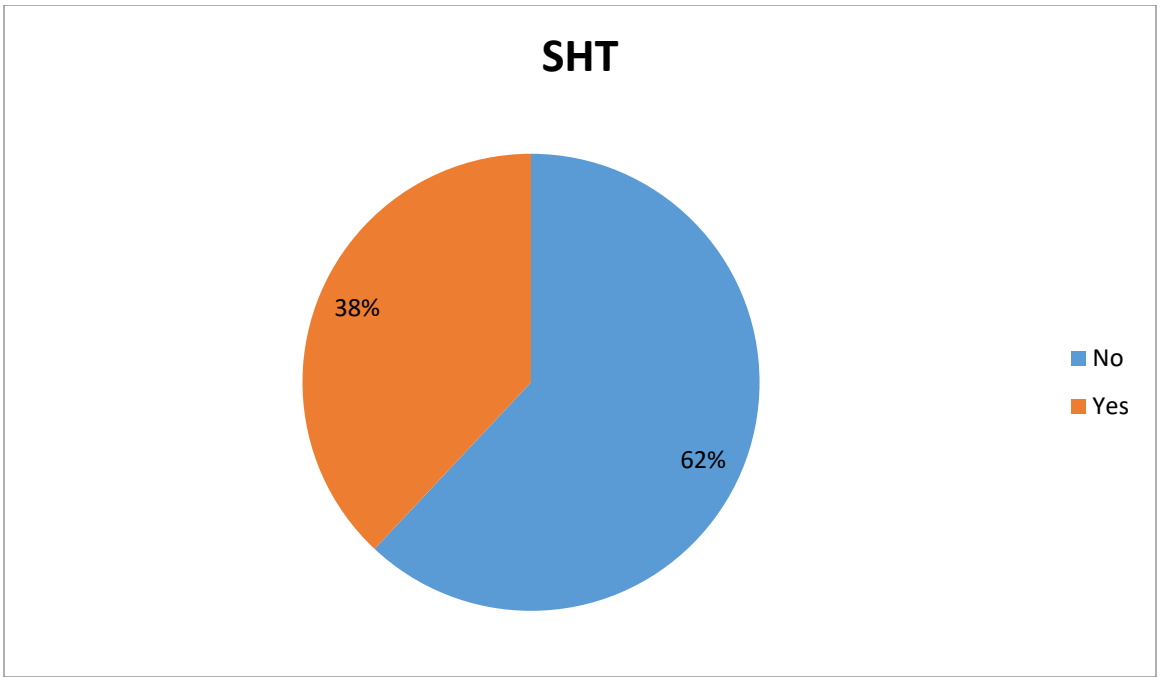
			90th_DAY_OUTCOME		Total
			Dead	Alive	
SHT	No	Count	28	55	83
		%	50.9%	69.6%	61.9%
	Yes	Count	27	24	51
		%	49.1%	30.4%	38.1%
Total		Count	55	79	134
		%	100.0%	100.0%	100.0%

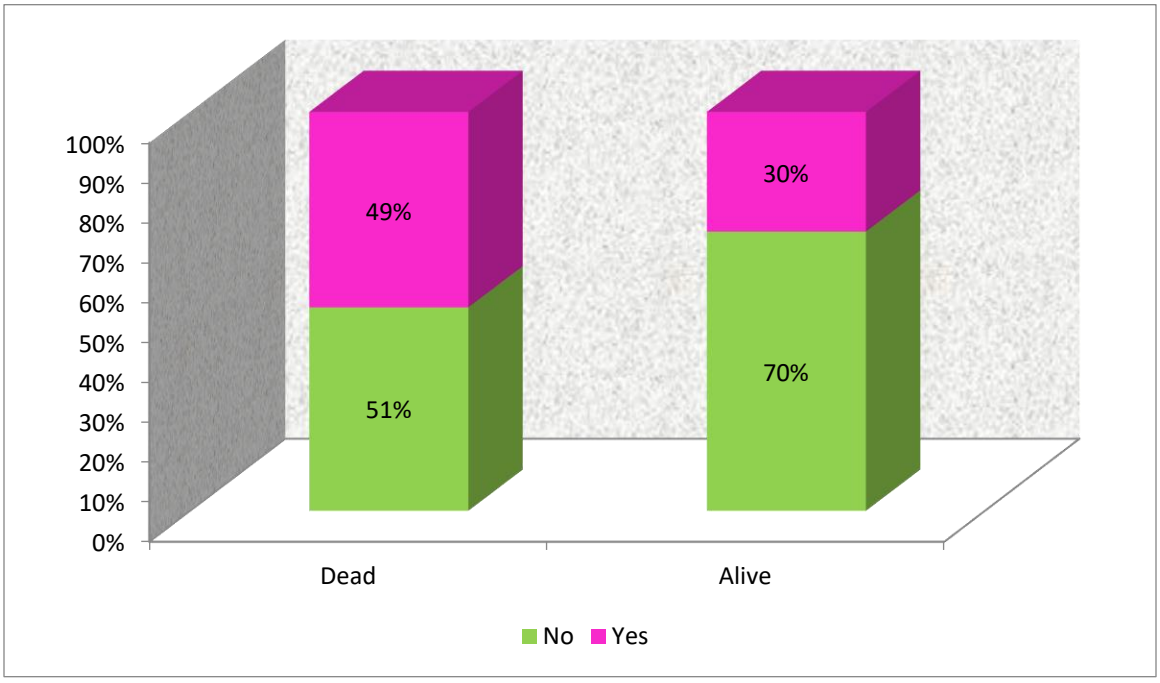
Pearson Chi-Square=4.816* p=0.028

All the patients (100%) admitted for ICH had high blood pressure of whom 28 patients (20%) have systolic BP >200mmHg.

Only 50 patients (38%) of the total subjects were known hypertensive.

If the remaining patients were screened for hypertension in their early life and started on anti hypertensive drugs, they would have prevented the event.





This data suggest the importance of screening for hypertension and an early intervention would have prevented them from this devastating event.

DIABETES MELLITUS

Frequency table:

T2DM	Frequency	Percent
No	101	75.4
Yes	33	24.6
Total	134	100.0

Crosstab

			90th_DAY_OUTCOME		Total

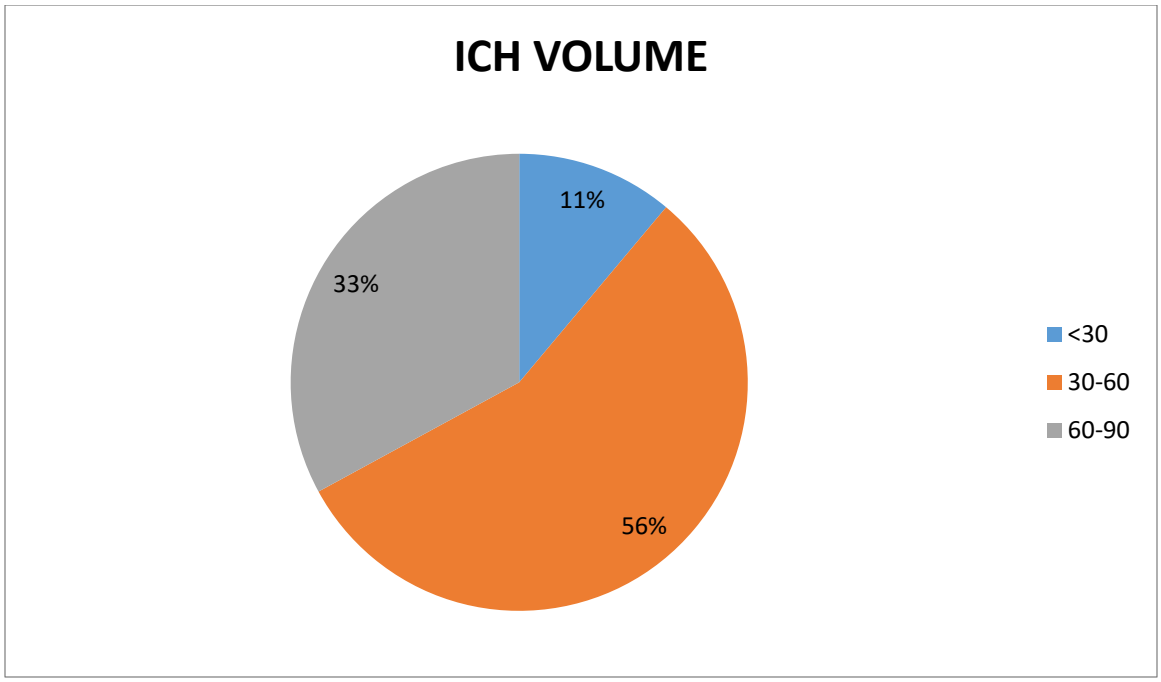
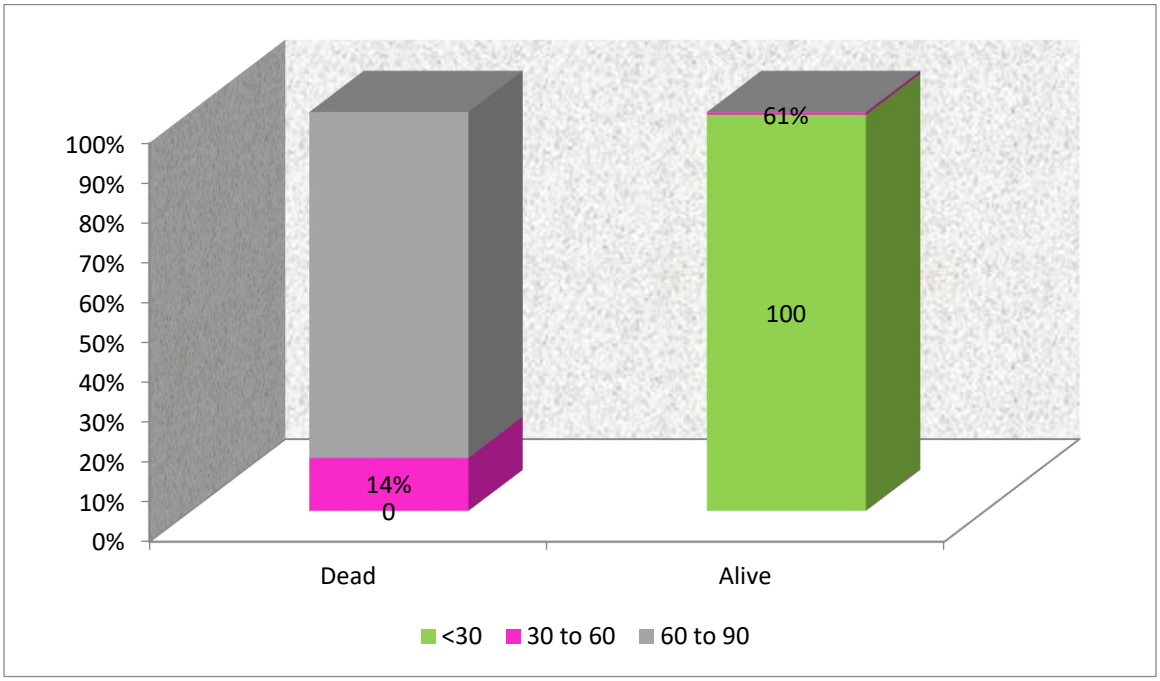
		%	18.6%	81.4%	56%
	60-90	Count	40	4	44
		%	90.9%	10.1%	33%
Total		Count	55	79	134
		%	100.0%	100.0%	100.0%

- Pearson Chi-Square=70.184** p<0.001
- Among the 134 population, 15 patients had ICH volume of <30ml and all of them survived at the end of 90 days
- Of the 44 patients presenting with ICH volume >60ml, 40(90%)expired





- ICH volume has a significant impact on the outcome of patients presenting with ICH; smaller the volume, better the outcome.

Ich LOCATION

Frequency table

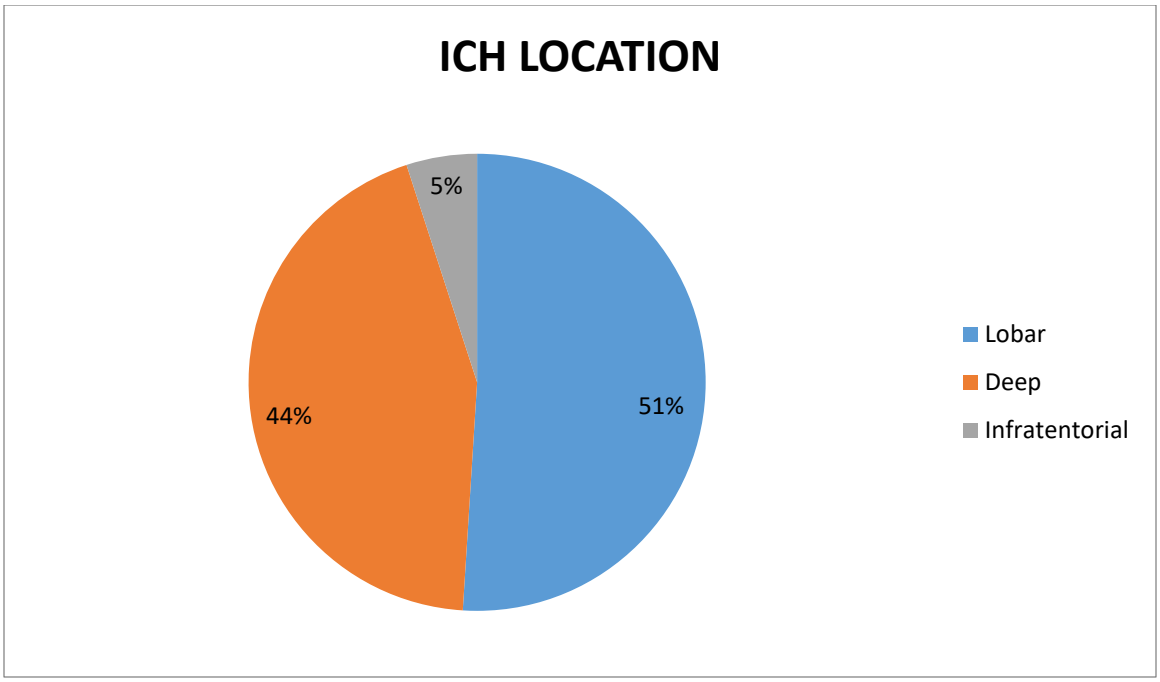
ICH_LOCATION	Frequency	Percent
Lobar	68	50.7
Deep	59	44.0
Infratentorial	7	5.2
Total	134	100.0

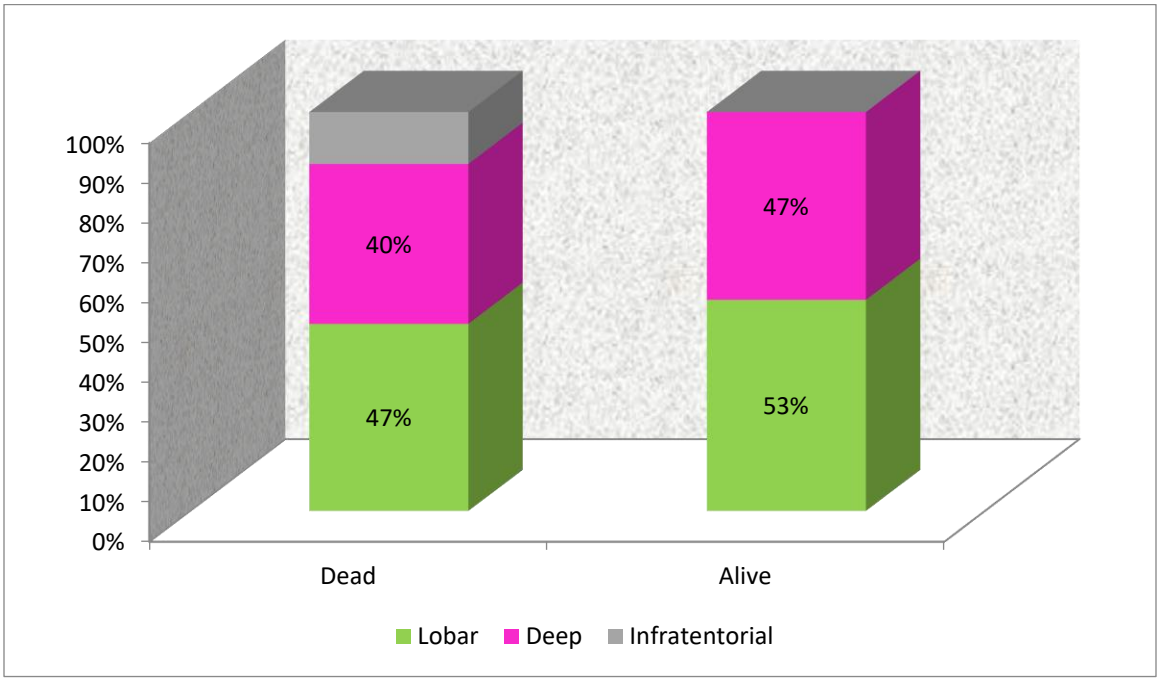
Crosstab

			90th_DAY_OUTCOME		Total
			Dead	Alive	
ICH_LOCATION	Lobar	Count	26	42	68
		%	47.3%	53.2%	50.7%
	Deep	Count	22	37	59
		%	40.0%	46.8%	44.0%
	Infratentorial	Count	7	0	7
		%	12.7%	0.0%	5.2%
Total		Count	55	79	134
		%	100.0%	100.0%	100.0%

Pearson Chi-Square=10.620** p=0.005

- 50% of the study group presented as lobar bleed, of them 61% survived after 90 days, 61% of deep bleed also survived.
- Whereas all the 7(100%) who had infratentorial bleed expired after 90 days
- This data suggest that infratentorial bleed has 100% mortality rate.





- ICH location has a significant impact on the outcome of patients presenting with ICH; lobar and deep bleeds have better prognosis than infratentorial bleed.

GCS

GCS_score	Frequency	Percent
<=8	52	38.8
>=9	82	61.2
Total	134	100.0

Crosstab

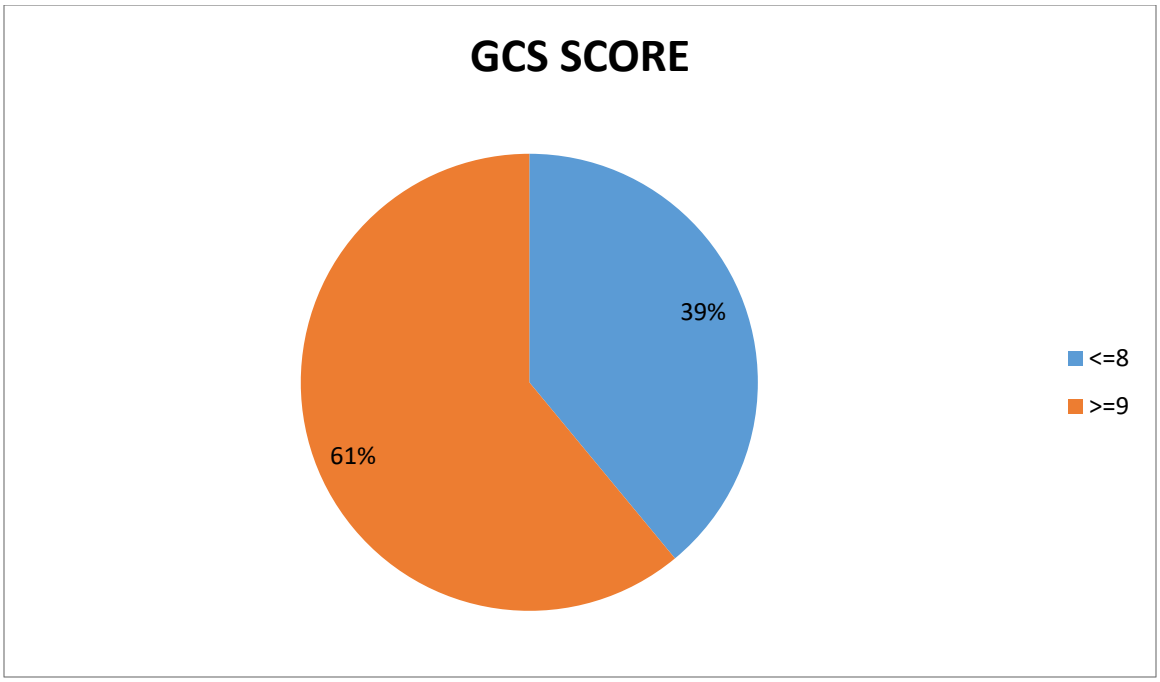
			90th_DAY_OUTCOME		Total
			Dead	Alive	
gcs_score	<=8	Count	45	7	52
		%	81.8%	8.9%	38.8%
	>=9	Count	10	72	82
		%	18.2%	91.1%	61.2%
Total		Count	55	79	134
		%	100.0%	100.0%	100.0%

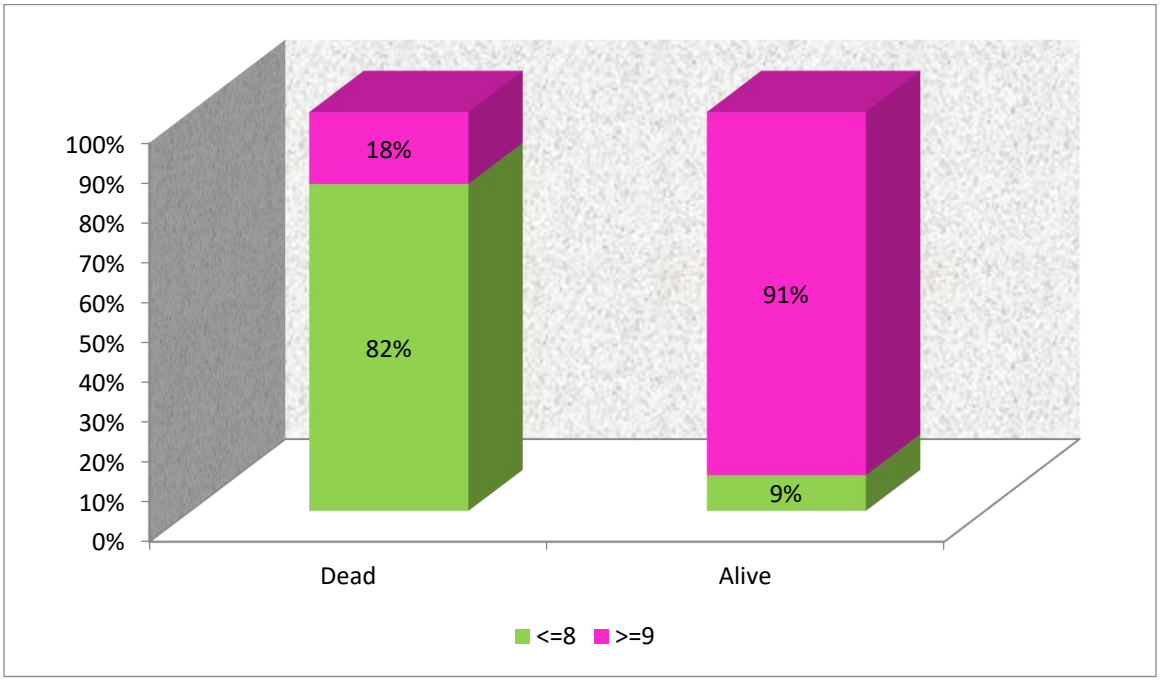
Pearson Chi-Square=72.680** p<0.001

- Of the total study group around 39% had GCS less than 8, of them 86% expired after 90 days

- Among the 82 people (61% of the study group)presenting with GCS >=9, 87% were alive after 90 days; signifying the importance of GCS score.

- GCS at the time of presentation makes an important predictor in the outcome and is the most important component of the FUNC score





- <u>GCS score has a significant impact on the outcome of patients presenting with ICH; GCS>=9 have better prognosis and GCS<=8 has poor prognosis.</u>

PRE ICH COGNITIVE IMPAIRMENT

Frequency table

PRE_ICH_COGNITIVE_IMPAIRMENT	Frequency	Percent

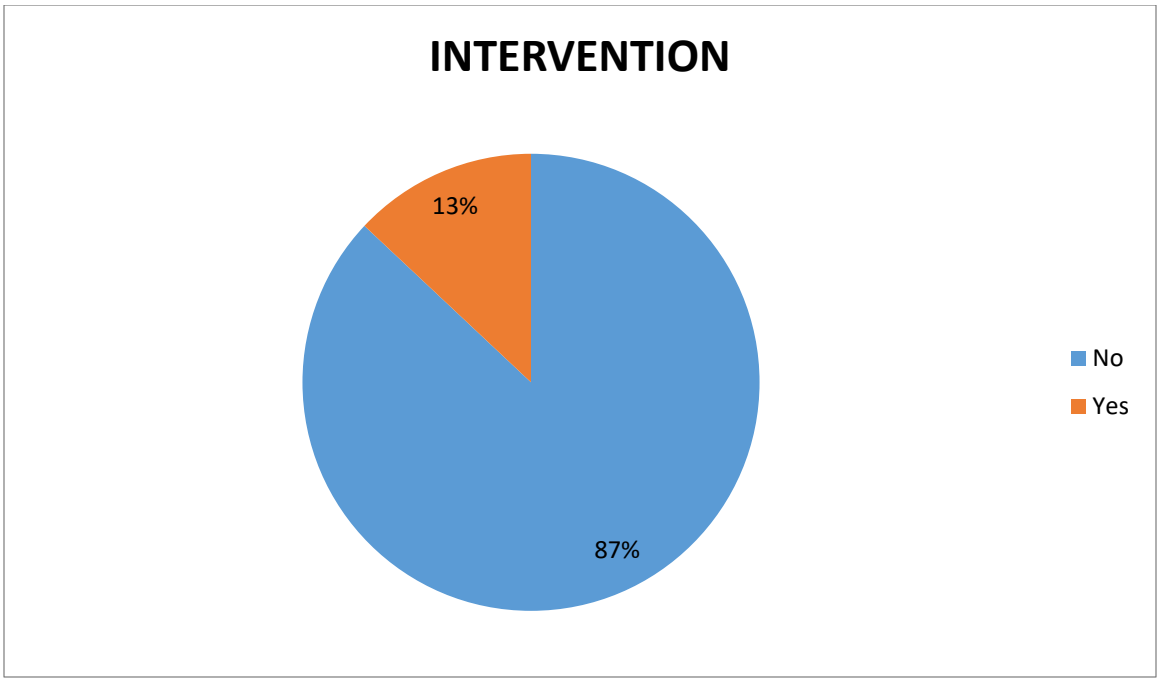
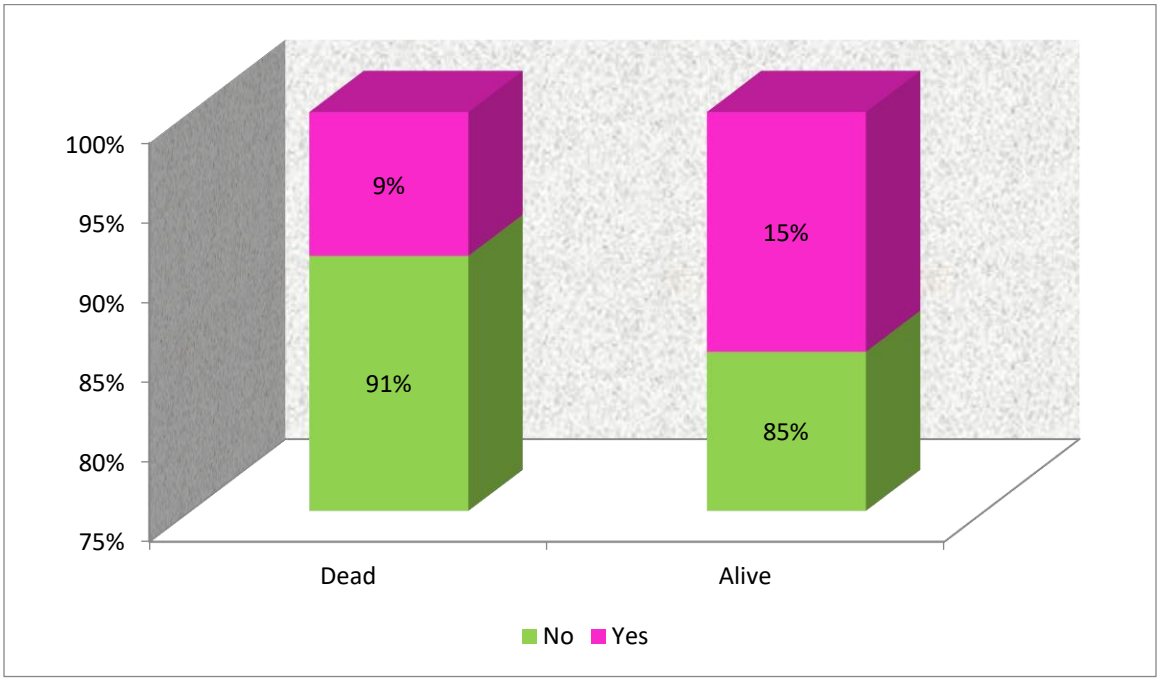
		%	9.1%	15.2%	12.7%
Total		Count	55	79	134
		%	100.0%	100.0%	100.0%

Pearson Chi-Square=1.089 p=0.297

- Among the 134 subjects 17 underwent surgery as a part of theirtreatment, among those 17 subjects 5patients(30%) expired at the end of 90 days

- Among the 117subjects who don't had intervension, 67(57%) were alive at the end of 90 days
- Inspite of intervension, there happens only a little change in the outcome of the patients.



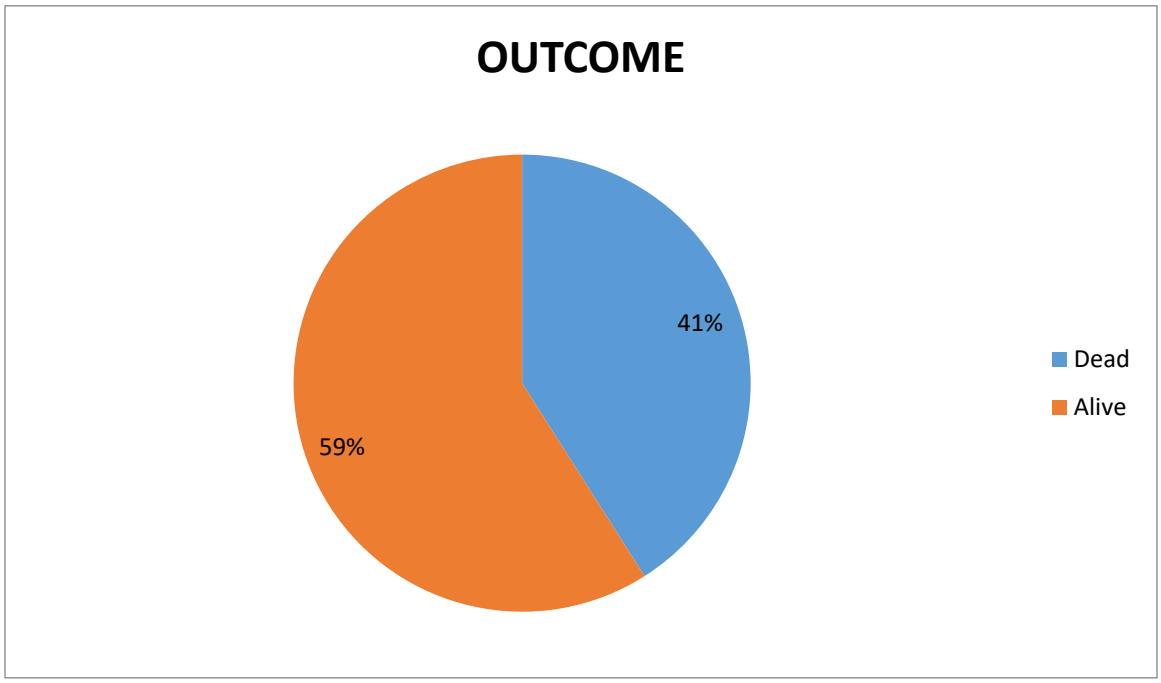


- Surgical intervension doesn't have any major effect on the outcome of patients compared to those who were managed conservatively.

OUTCOME

Frequency table:

	Frequency	Percent
Dead	55	41.0
Alive	79	59.0
Total	134	100.0

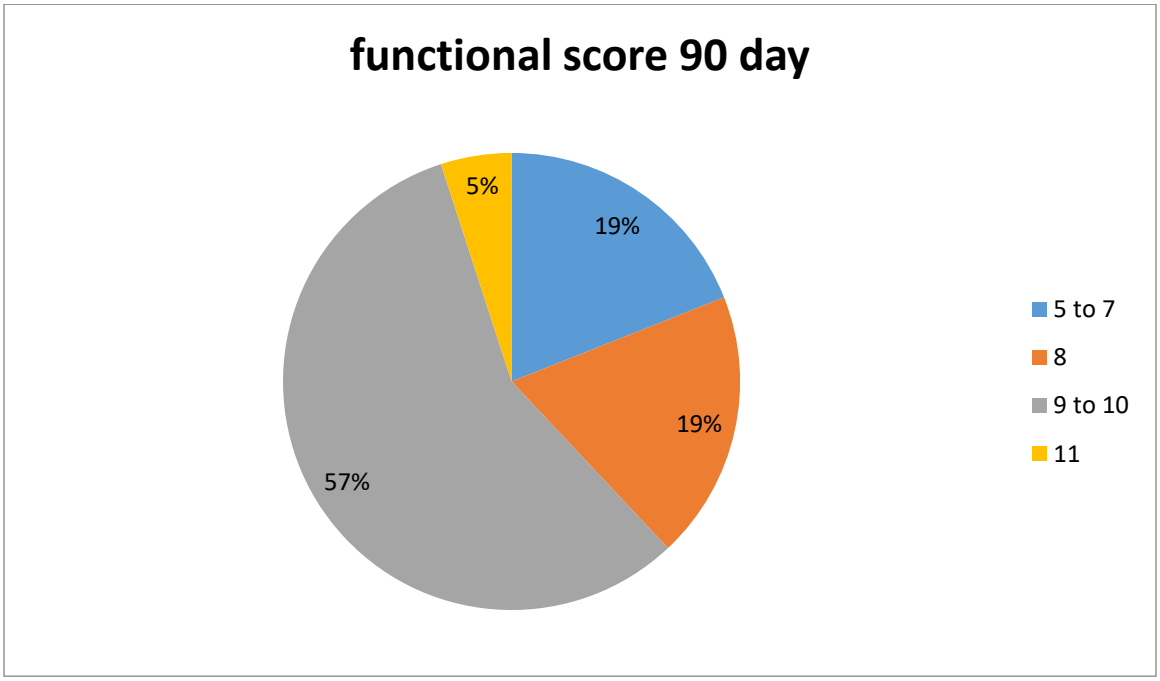


Among the total 134 subjects 79 were alive at the end of 90 days and 55 expired at the end of 90 days. The outcome is independent on the mode of management. Func score at the time of admission is compared to those with dead and those with alive.

90TH DAY FUNC SCORE

Frequency table:

func_score_90_day	Frequency	Percent
5-7	15	19.0
8	15	19.0
9-10	45	57.0
11	4	5.1
Total	79	100.0



At the end of 90 deays FUNC score was allotted for the alive patients. 57% had a score of 9 to 10 and 19% had a score of 8. Overall 81%(score >8) had a good independent outcome.

90TH DAY GCS

GCS_90DAY

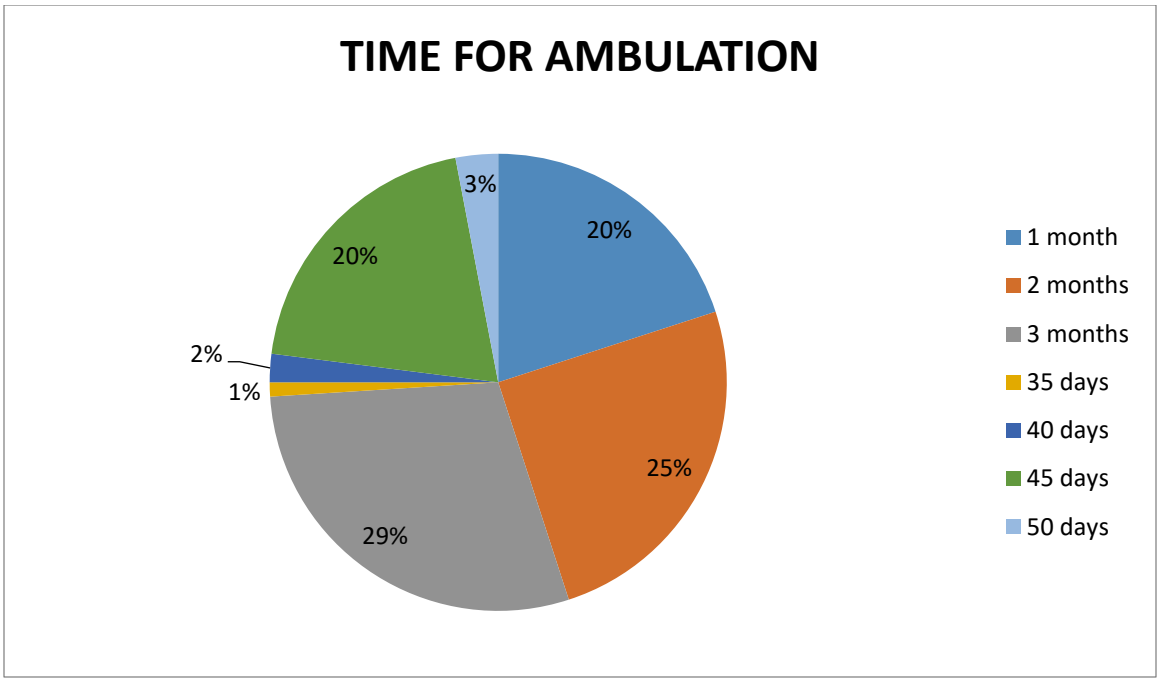
	Frequency	Percent	Valid Percent	Cumulative Percent
Valid	134	100.0	100.0	100.0

90th_DAY_GCS	Frequency	Percent
10	9	11.4
11	9	11.4
12	9	11.4
13	11	13.9
14	16	20.3
15	13	16.5
7	1	1.3
9	11	13.9
Total	79	100.0

- Among the 79 persons who were alive at the end of 90 days, only one had a GCS<=7. 11 people had GCS 9. Remaining 67 had GCS>=10 and had an independent outcome.

TIME FOR AMBULATION

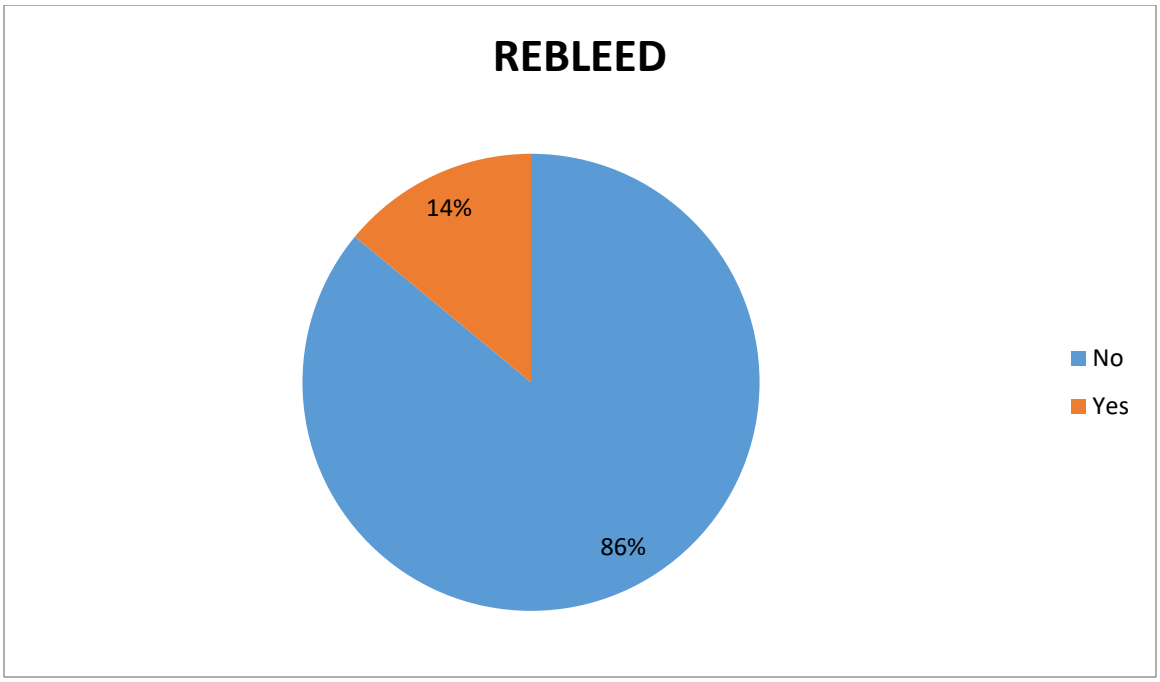
TIME_FOR_AMBULATION	Frequency	Percent
1 month	16	20.3
2 months	20	25.3
3 months	23	29.1
35 days	1	1.3
40 days	1	1.3
45 days	16	20.3
50 days	2	2.5
Total	79	100.0



- 29% of the alive population took 3 months for ambulation with support.
- Ambulation depends on lotof factors and is found to vary from person to person and is independent of the FUNC score or GCS score or ICH volume.
- Younger patients were found to be early ambulant when compared to older people.

REBLEED

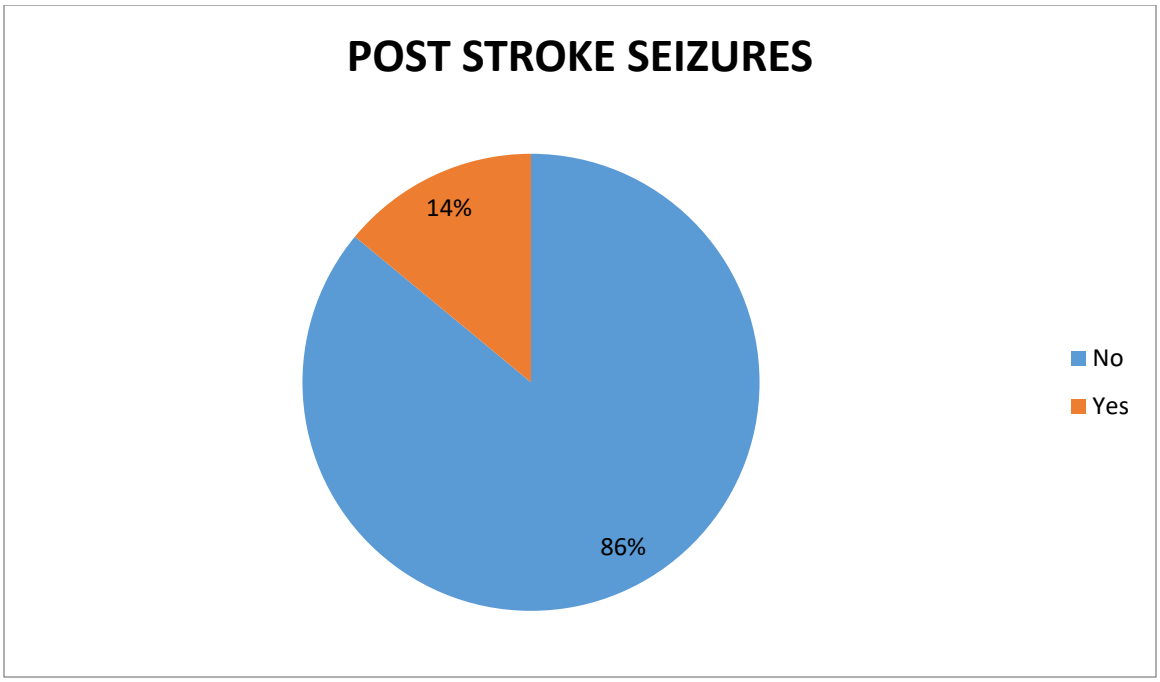
REBLEED	Frequency	Percent
No	68	86.1
Yes	11	13.9
Total	79	100.0



- Among the 79 alive patients, 11 persons had rebleed and found to have poor compliance with treatment such as antihypertensives. All were functionally dependent.
- Strict adherent to drugs would have prevented them from recurrence.

POST STROKE SEIZURES

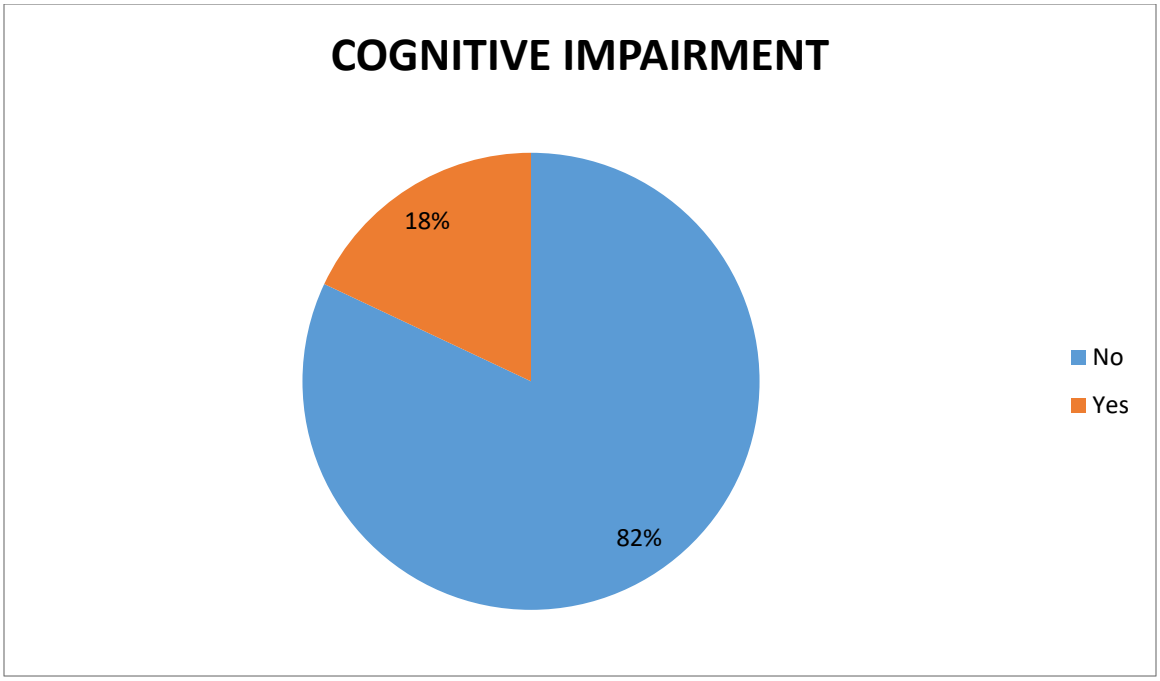
POST_STROKE_SEIZURES	Frequency	Percent
No	68	86.1
Yes	11	13.9
Total	79	100.0



- Among the 79 alive patients, 11 persons had seizures and among them 10 were those with re-bleeding. Only 1 among the non re-bleeders had seizures within the 90 day period.There is a chance of seizures in all the alive patients and were started on anti-epileptic prophylaxis

COGNITIVE IMPAIRMENT

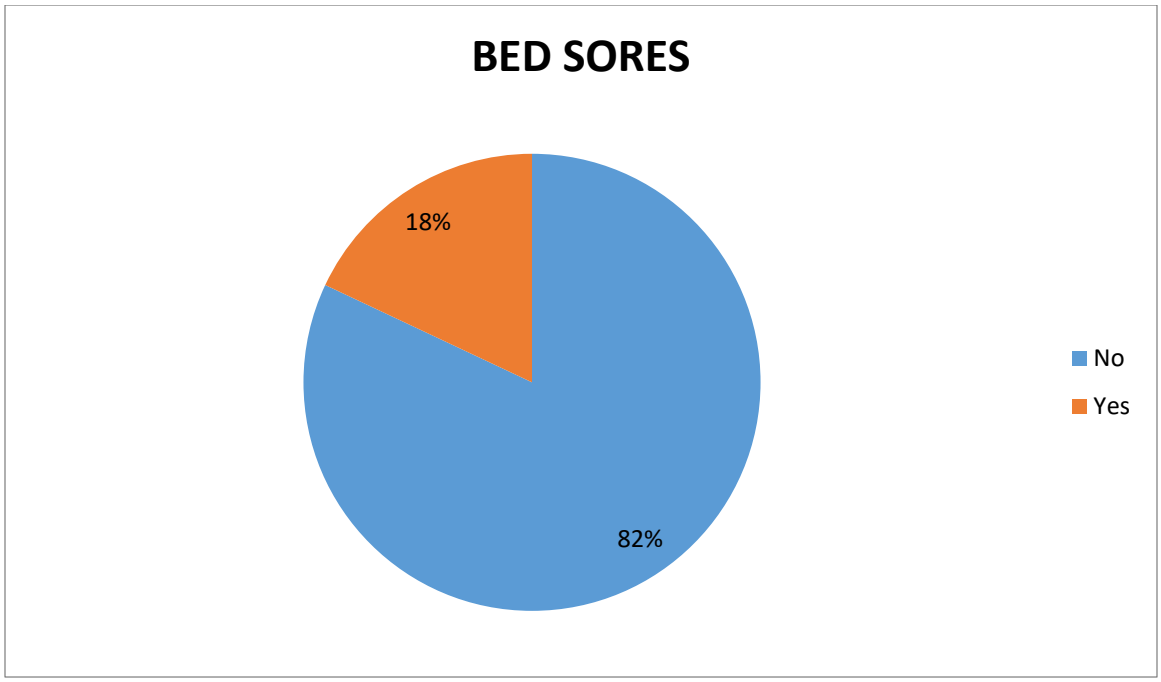
COGNITIVE_IMPAIRMENT	Frequency	Percent
No	65	82.3
Yes	14	17.7
Total	79	100.0



- Among the 79 alive patients, 14 persons had cognitive impairment and among them 9 were those with GCS 8. Only 5 among the GCS>=9 had cognitive impairment within the 90 day period.

BED SORES

BED_SORES	Frequency	Percent
No	65	82.3
Yes	14	17.7
Total	79	100.0



- Among the 79 alive patients, 14 persons had bed sores and among them 9 were those with GCS 8. Only 5 among the GCS>=9 had bed sores within the 90 day period.

RESULTS

Of the total 134 cases in the study, whom were selected as per inclusion and exclusion criteria, 79 patients survived (59 %) and 55 patients (41 %) expired during the hospital stay period or within 90 day period of follow up.

There were 78 males (58.2%) and 56 females (41.8%). Among the expired, majority were males (60%), which did not bear any significance of gender with prognosis (p=0.726)

The mean age of patients in both the survivor and expired group was 52 years. In the age group <=70 years, there were 95 patients; 26 patients in age group 70-79 years and 13 patients in age group >=80 years.

Among the total expired patients , 54.5 % belonged to the age group of 70<=years, 21.8% belong to 70-79 years, 23.6% belong to >80 years of age. There is 100% mortality in the age group of >80 years and 85.7% mortality in age group of 70-79 years which shows significance of age in prognosis (p< 0.001).

In the analysis of FUNC scoring, among the expired patients 31 patients(56.4%) belonged to score <=4 ; 24 patients (43.6%) belonged to score 5-7; and all the patients presenting with FUNC score of >=8 were alive at the end of 90 days which shows high significance of FUNC scoring(p<0.001) in predicting the outcome.

On assessing the volume of ICH 15 patients (11%) were in <30 mm^3, 75 patients (56%) were having 30-60mm^3, 44 patients (33%) were having volume of 60-90mm^3. Of the expired patients 91% were having ICH volume of 60-90 mm^3. All the patients having ICH volume of <30mm^3 were alive shoeing the significance of ICH volume($p<0.001$)

In analysis of ICH location, among patients who expired 26 patients (47.3%%) were having lobar bleed, 22 patients(40%) werehaving deep bleed, 7 patients (12.7%) were having infra tentorial bleed. 100% of people with infratentorial bleed expired and 50.7% of the lobar bleed were alive showing significance($p=0.oo5$)

Of the total study group around 39% had GCS less than 8, of them 86% expired after 90 days. Among the 82 people (61% of the study group) presenting with GCS >=9, 87% were alive after 90 days; signifying the importance of GCS score($p<0.001$)

Among the study group >50% of the people presented only after 2 hrs 23% of the study population presented very lately of 4-6 hrs, 33.6% presented after 2 -4 hrs, 40.3% presented within1-2 hrs. 0f the 58 people presenting within 2 hrs only 4 expired at the end of 90days signifying the importance of duration of presentation.

Among the total population 22 people had pre ICH cognitive impairment, all of them expired at the end of 90 days Of the 112 without cognitive impairment, 70% were alive at the end of 90days signifying the importance of pre ICH cognitive impairment.

Among the 134 subjects 17 underwent surgery as a part of theirtreatment, among those 17 subjects 5patients(30%) expired at the end of 90 days. Among the 117subjects who don't had intervension, 67(57%) were alive at the end of 90 days. Inspite of intervension, there happens only a little change in the outcome of the patients.

DISCUSSION

Flaherty ML, Woo D, Haverbusch M, et al. states that At one year, mortality ranges from 51% to 65% depending on the location of the hemorrhage.[11] which slightly correlates with this study that the mortality at 90 days is 41% and may rise at the end of one year.

Brott T, Broderick J, Kothari R, et al. states that Hematoma expansion, highly associated with clinical deterioration and poor outcomes, is evident in nearly 40% of cases within the first 3 hours after onset of symptoms is also well-documented with CT scanning.[12,13] correlates with this study that longer the duration of presentation poorer the outcome.

Broderick J, Brott T, Duldner JE, et al. states that The volume of the ICH and the clinical grade on the Glasgow Coma Scale on admission are the most powerful predictors of 30-day mortality.[14,30] which correlates with this study that GCS and ICH volume are the two most important factors contributing to the FUNC score in prediction of outcome after 90 days.

Broderick J, Connolly S, Feldmann E, et al. states that Hemispheric lesions >30 cc have a high mortality rate and Patients with GCS <9 and hematoma >60 cc have a 90% mortality rate.[15]

Mendelow AD, Gregson BA, Fernandes HM, et al. proposed in the STITCH trial that Surgery doesn't appear to be useful in most cases and is possibly harmful in persons presenting in coma[16] which is similar to this study that surgical intervention doesn't modify the outcome of the patient in sucha way that only a very few patients had benefit on the performance of surgery.

Woo D, Haverbusch M, Sekar P, et al. states that proper control of hypertension can result in reduction of re-bleed[29] which is similar to this study result that patient who did not take proper anti-hypertensive medication tend to had re-bleed.

CONCLUSION

This study concludes that FUNC score can be used as a reliable tool in predicting the outcome of patients presenting with primary intracerebral hemorrhage. By using this scale withdrawal of care for patients with predicted good outcome can be prevented and can lead to a reduction in mortality and help them in early mobilisation.

Even though a number of factors are involved in predicting the outcome of patients with ICH, GCS of the patient and volume of ICH remains the two most important factors in predicting the outcome.

Other factors that are reliable in predicting the outcome are age, duration of presentation, pre ICH cognitive impairment, location of ICH.

Early screening for hypertension, proper intake of anti-hypertensive medication, adequate control of blood pressure will prevent such catastrophe and can also reduce the episodes of rebleeding in patients presenting with ICH.

INSTITUTIONAL ETHICS COMMITTEE

TITLE OF THE WORK	:	PREDICTION OF OUTCOME IN PATIENTS WITH PRIMARY INTRA CRANIAL HEMORRHAGE USING FUNC SCORE
PRINCIPAL INVESTIGATOR	:	DR. M. RAJMOHAN
DESIGNATION	:	PG IN MD GENEGAL MEDICINE,
DEPARTMENT	:	DEPARTMENT OF GENEGAL MEDICINE, GOVT. STANLEY MEDICAL COLLEGE.

The request for an approval from the Institutional Ethical Committee (IEC) was considered on the IEC meeting held on 11..05.2018 at the Council Hall, Stanley Medical College, Chennai-1 at 10am.

The members of the Committee, the secretary and the Chairman are pleased to approve the proposed work mentioned above, submitted by the principal investigator.

The Principal investigator and their team are directed to adhere to the guidelines given below:

1. You should inform the IEC in case of changes in study procedure, site investigator investigation or guide or any other changes.
2. You should not deviate from the area of the work for which you applied for ethical clearance.
3. You should inform the IEC immediately, in case of any adverse events or serious adverse reaction.
4. You should abide to the rules and regulation of the institution(s).
5. You should complete the work within the specified period and if any extension of time is required, you should apply for permission again and do the work.
6. You should submit the summary of the work to the ethical committee on completion of the work.

MEMBER SECRETARY,
IEC, SMC, CHENNAI

INFORMED CONSENT

"PREDICTION OF OUTCOME IN PATIENTS WITH PRIMARY INTRA CRANIAL HEMORRHAGE USING FUNC SCORE"

Place of study: Govt. Stanley medical college, Chennai

I ……. have been informed about the details of the study in my own language.

I have completely understood the details of the study.

I am aware of the possible risks and benefits, while taking part in the study.

I agree to collect samples of blood/saliva/urine/tissue if study needs.

I understand that I can withdraw from the study at any point of time and even then, I can receive the medical treatment as usual.

I understand that I will not get any money for taking part in the study.

I will not object if the results of this study are getting published in any medical journal, provided my personal identity is not revealed.

I know what I am supposed to do by taking part in this study and I assure that I would extend my full cooperation for this study.
