Abstract

Recent years have seen an increasing number of genetically engineered pig models of human diseases including cancer. We previously generated pigs with a modified *TP53* allele that carries a Cre-removable transcriptional stop signal in intron 1, and an oncogenic mutation *TP53*^{R167H} (orthologous to human *TP53*^{R175H}) in exon 5. Pigs with the unrecombined mutant allele (*flTP53*^{R167H}) develop mainly osteosarcoma but also nephroblastomas and lymphomas. This observation suggested that *TP53* gene dysfunction is itself the key initiator of bone tumorigenesis, but raises the question which aspects of the *TP53* regulation lead to the development of such a narrow tumour spectrum. Molecular analysis of p53 revealed the presence of two internal *TP53* promoters (P1 and P2) equivalent to those found in human. Consequently, both pig and human express *TP53* isoforms. Data presented here strongly suggest that P2-driven expression of the mutant R167H-Δ152p53 isoform (equivalent to the human R175H-Δ160p53 isoform) and its circular counterpart *circTP53* determine the tumour spectrum and play a critical role in the malignant transformation in *flTP53*^{R167H} pigs. The detection of Δ152p53 isoform mRNA in serum is indicative of tumorigenesis. Furthermore, we showed a tissue-specific p53-dependent deregulation of the p63 and p73 isoforms in these tumours. This study highlights important species-specific differences in the transcriptional regulation of *TP53*. Considering the similarities of *TP53* regulation between pig and human, these observations provide useful pointers for further investigation into isoform function including the novel *circTP53* in both the pig model and human patients.

Introduction

In human, osteosarcomas (OS) is the major form of primary bone cancer [1]. It predominantly affects young people and is highly malignant, requiring aggressive surgical resection and cytotoxic chemotherapy [2]. The 5-year survival rate has remained unchanged over the past 20 years, at ~60% for patients with primary osteosarcoma and ~20% for patients with metastatic disease [3]. Most OS are sporadic and of unknown cause, but increased incidence is associated with Li–Fraumeni syndrome caused by germ line mutation of *TP53* [4, 5].

The role of *TP53* mutations in numerous cancers has been extensively documented [6]. Yet, potentially important aspects of *TP53* gene function still remain unclear, including the role of various p53 isoforms. Human *TP53* is known to express at least 9 different mRNA transcripts [7] and at least 12 protein isoforms [8], with transcription initiated by two promoters: P1 at the 5' end and P2 in intron 4; alternative splicing across introns 2 and 9; and alternative translation initiated at internal

start codons 40, 133 and 160. The internal promoter P2 originates the $\Delta 133p53$ and $\Delta 160p53$ isoforms in humans. While the function of $\Delta 160p53$ is less studied, the $\Delta 133p53$ is involved in the regulation of replicative cellular senescence [9], angiogenesis, cytokine secretion/immune response and tumour progression in some cancer types [10].

Pigs have become an important animal model for human cancers research, translational studies and preclinical trials [11, 12]. We have generated genetically engineered (GE) pigs with mutations in key tumour suppressor genes and proto-oncogenes [13] to facilitate preclinical studies [14]. As part of this programme we generated pigs modelled on GE mice carrying a Cre-inducible oncogenic mutant *Trp53*^{R172H} allele, in which a floxed transcriptional stop cassette is inserted into *Trp53* intron 1 to block transcription of the mutated allele [15]. The latent allele can be experimentally activated by Cre recombinase to express mutant p53^{R172H} and model spontaneous somatic *Trp53* mutation in chosen organs. These mice have been used successfully to model a series of cancers, e.g., pancreatic, breast and lung [16–19]. Similarly, our pig line carries an engineered endogenous *TP53* gene with a floxed transcriptional stop signal in intron 1 and a point mutation resulting in an arginine to histidine substitution at codon 167 in exon 5 (*TP53*^{R167H}, orthologous to mouse *Trp53*^{R172H} and human *TP53*^{R175H}) [20]. As this pig line was being established it became apparent that animals with the latent non-induced allele (designated here as *fTP53*^{R167H}) in both heterozygous and homozygous form developed OS [21] and less frequently kidney tumours and lymphomas.

This phenotype contrasts sharply with that reported for mice carrying the apparently equivalent non-induced *Trp53*^{R172H} allele, which mostly develop lymphoma [22]. None of the murine *Trp53* mutant strains so far generated show a preponderance of OS in the tumour spectrum [22, 23]. These include Cre-inducible point mutations [23], partial deletions of the *Trp53* coding region [15] and transgenic lines that overexpress mutant *Trp53*^{R270H} and *Trp53*^{R172H} from exogenous promoters [24]. To increase the incidence of OS, several mouse strains expressing osteoblast- and mesenchymal-specific Cre coupled with conditional *p53* and *Rb1* mutant alleles were generated [25].

These findings indicate a species-specific difference in *p53* gene regulation. Differences in the *p53* isoforms and internal promoters have been described for humans, primates, zebrafish, drosophila and mouse [8]. Here we show that unlike the mouse, the porcine *TP53* locus contains internal P1 and P2 promoters equivalent to those found in human, resulting in expression of $\Delta 152p53\alpha$ isoform and its circular counterpart *circTP53*. Both are involved in the development of OS and others tumours in the *fTP53*^{R167H} pigs and the detection of $\Delta 152p53\alpha$ isoform in serum is indicative of tumorigenesis. A tissue-specific *p53*-dependent deregulation of *p63* and *p73* isoforms could be observed in these tumours.

Results

Cancer spectrum in *fTP53*^{R167H} pigs

Since our publication describing the generation of *fTP53*^{R167H} pigs [20], a total of 29 *fTP53*^{R167H/+} heterozygous and 10 *fTP53*^{R167H/R167H} homozygous pigs were examined by necropsy. All had reached sexual maturity. Animals were sacrificed as soon as they showed symptoms effecting their wellbeing or in case of the heterozygous animals latest at the age of 36 months. By this time 18 of the 29 heterozygous animals had developed tumours, all of which were classified histologically as osteoblastic OS. Spontaneous OS is very rare in wild-type pigs [21, 26]. All homozygous pigs had OS by the age of 16 months or earlier and five of these (aged 7–14 months) also had nephroblastoma (kidney) and diffuse large B-cell lymphomas (spleen). In each case the anatomical location and histological analyses of the tumours resembled those of the human juvenile cancer.

Identification of a $\Delta 152p53\alpha$ isoform in pigs

The observation that the tumour repertoire was restricted to a few tissue types (100% OS, 22% nephroblastoma and 17% B-cell lymphomas) leads to the question which aspects of *TP53* expression or absence thereof support the formation of mainly OS rather than other tumour entities? To answer this question, we first establish if expression of the floxed *fTP53*^{R167H} allele was silenced in all organs.

A series of RT-PCR primers hybridising to different porcine *TP53* exons (Fig. 1a) were used to screen RNA samples from various organs ($n = 11$) of *fTP53*^{R167H/R167H} homozygous pigs ($n = 3$). No mRNA expression was detected using RT-PCR primers specific for exon 1 to exon 2 (1F/1R), or exon 2 to 4 (2F/2R) in all tissues analysed including bone and OS samples (Fig. 1b), confirming that the LSL efficiently blocked transcription. However, RT-PCR using primers between exons 5 and 11 (5F/9R, see Fig. 1a) revealed a tissue-specific expression (Fig. 1c), where the strongest RT-PCR signal was obtained for bone, lymph node and kidney tissues. This indicated the presence of a promoter element in intron 4 similar to human. No expression of the short *TP53* mRNA was detected in heart and aorta. To determine the start and termination of the porcine *TP53* isoform 5' and 3' rapid amplification of cDNA end (RACE) analysis was performed (Fig. 1d, e). This placed the start of the isoform 11 base pairs upstream of exon 5 with a possible ATG at amino acid position 152 ($\Delta 152p53$ isoform), which translates in frame and terminates at the same stop codon as the full length *p53* and corresponds to *TP53 α* isoform (Supplementary Fig. 1). The identified $\Delta 152p53\alpha$ mRNA has a length of 1295 bp; the nucleotide sequence was verified by sequencing.

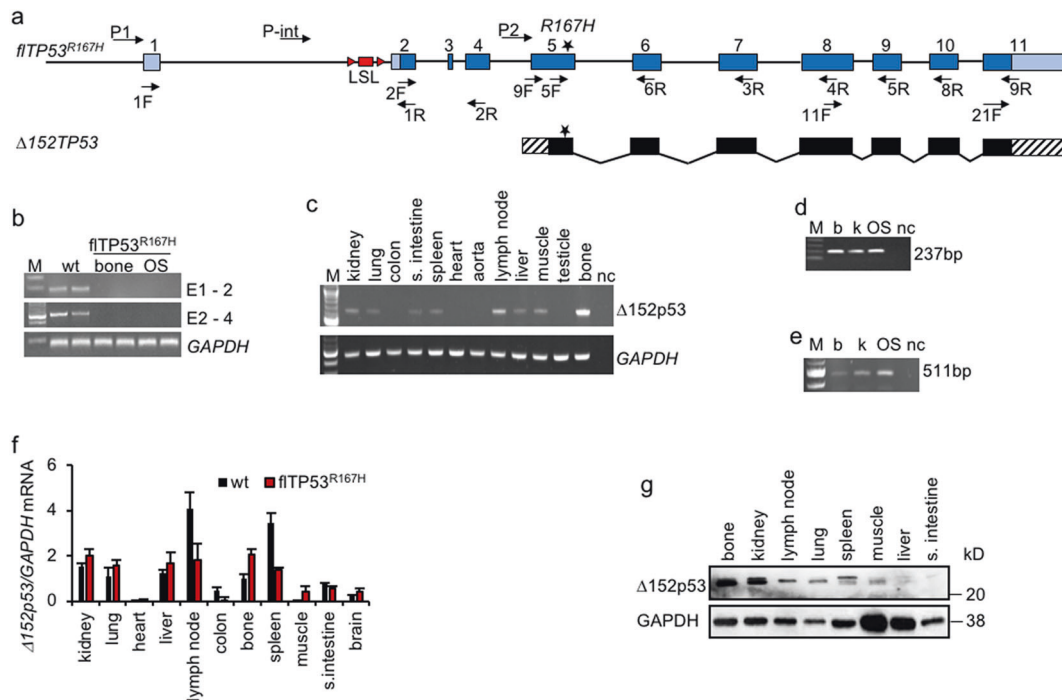

Fig. 1 Identification of $\Delta 152p53\alpha$ isoform in pigs. **a** Schematic representation of the *TP53* gene and the $\Delta 152p53\alpha$ mRNA. **b** Expression analysis across exon 1 to 2 (186 bp), exon 2 to 4 (591 bp) of bone samples from wild-type pigs and healthy bone and OS samples from *fTP53^{R167H/R167H}* pigs showing lack of expression for mutant *TP53*. **c** Expression analysis across exon 5 to 11 (492 bp) for 11 different organ samples from *fTP53^{R167H/R167H}* pigs. **d** 5' RACE using a reverse primer hybridising to exon 6 of *TP53* and resulting in a 237 bp fragment and **e** 3' RACE using forward primer hybridising to

exon 11 of *TP53* resulting in a 511 bp fragment. Healthy bone (**b**), kidney (**k**) and osteosarcoma (OS) samples from *fTP53^{R167H/R167H}* pigs. M marker, nc negative control. **f** Quantitative RT-PCR analysis using primers hybridising to extended exon 5 and exon 6 and detecting the $\Delta 152p53$ isoform mRNA expression in different tissues of *fTP53^{R167H/R167H}* ($n = 6$) and wild-type ($n = 3$) pigs. *GAPDH* was used as a reference gene to calculate the relative expression levels. **g** Detection of $\Delta 152p53$ isoform by western blot analysis using SAPU antibody in different tissues from *fTP53^{R167H/R167H}* pigs.

Expression of $\Delta 152p53\alpha$ isoform is highest in organs susceptible to cancer development

By using primers (9F/6R) specific for the $\Delta 152p53\alpha$ isoform its expression was quantified by qPCR in different healthy tissues ($n = 11$) from *fTP53^{R167H}* homozygous ($n = 10$) and wild-type ($n = 3$) pigs. The highest $\Delta 152p53\alpha$ mRNA expression in *fTP53^{R167H}* homozygous pigs was observed in lymph nodes, spleen, kidney and bone (Fig. 1f), all organs prone to tumour development in mutant pigs. Except for lymph node, colon and small intestine the $\Delta 152p53\alpha$ mRNA expression was generally lower in wild-type samples, than in *fTP53^{R167H}* homozygous samples.

The porcine $\Delta 152p53\alpha$ isoform encodes a 30kDa protein

The methionine codon 152 in pigs corresponds to codon 160 in human p53, which is located within a highly conserved Kozak sequence [27]. An in silico analysis predicted that the 1295 bp mRNA encodes a 224 amino acid N-terminal-truncated $\Delta 152p53\alpha$ isoform using the same reading frame as full length p53. The predicted porcine isoform shares 88%

amino acid sequence homology with the human $\Delta 160p53\alpha$ isoform, which uses the $\Delta 133/160p53$ alternative transcriptional initiation site in exon 5 [27] and contains part of the highly conserved p53 DNA binding region [8]. To determine whether the porcine *TP53* alternative transcript can produce $\Delta 152p53\alpha$ protein, western blot analysis of different healthy tissue samples from *fTP53^{R167H/R167H}* homozygous pigs was performed using the polyclonal sheep SAPU antibody recognising all human p53 isoforms. Two bands (doublet) of ~30 kDa were detected (Fig. 1g). As with the mRNA highest protein expression was observed in bone, kidney, lymph node and spleen. The size of the western blot bands was comparable to the human $\Delta 160p53$ isoforms [27], and most likely represent splice variant or post-translational modifications of R167H- $\Delta 152p53$ proteins.

Identification of internal promoters in the porcine *TP53*

Results above clearly indicated the presence of at least one internal promoter. To determine the location of all possible internal promoters, nucleotide sequence alignment was carried out between the porcine (NC_010454, GenBank Sscrofa 11.1)

and human (NC_000017, Genbank GRCh38.p12) *TP53* gene. Apart of exons, three genomic regions with high homology (>70% similarity) were detected (−1877 to +11 bp, +2125 to +3200 bp and +9985 to +10,470 bp; relative to the major transcription start site). These porcine *TP53* regions correspond to the locations of the P1 (5′ end), Pint (intron 1) and P2 (intron 4) promoters in human *TP53*. As for the human sequence, the porcine intron 4 sequence (P2) contains binding sites for the transcription factors NFIC, Hltf and SPI1. In contrast, the sequence of mouse *Trp53* intron 4 showed less than 50% homology to human *TP53*, and lacks binding sites for these transcription factors (Supplementary Fig. 2). Interestingly, the NFIC transcription factor regulates osteoblast differentiation [28], and can promote or suppress the development of various cancers [29] via epigenetic changes [30]. The SPI1 transcription factor regulates alternative transcription of target genes, and both Hltf and SPI1 are frequently mutated in paediatric cancers [31, 32].

To confirm promoter function five luciferase reporter constructs were generated containing the P1 promoter (−2000 bp to TSS), the putative P2 promoter (intron 4) and three different fragments covering the first intron (Pint_1, Pint_2, Pint_3), see Fig. 2a. Luciferase expression driven by the SV40 promoter was used as positive control.

Luciferase activity was measured after transfection of various porcine primary cells: wild-type bone marrow mesenchymal stem cells (bmMSC) and kidney fibroblasts; *fTTP53^{R167H/R167H}* OS cells and healthy osteoblasts; and human HEK293 cells. In comparison to the positive control two of the putative promoter fragments led to moderate (P1, 40–70% and Pint_1, 30–45%) and one to low (P2, 10–25%) luciferase activity (Fig. 2a). These three promoter fragments shared the greatest homology with the corresponding human *TP53* sequence. The in silico and experimental data provide evidence for the presence of internal promoters within intron 1 (Pint) and intron 4 (P2) of the porcine *TP53*, similar to those in human *TP53*.

Expression from the P1 and Pint promoters is blocked by lox-stop-lox cassette in *fTTP53^{R167H}* homozygous pigs. Additional deletion of the P2 promoter fragment should result in a complete inactivation of porcine *TP53*. Using the Crispr-Cas9 system and two guide RNAs a DNA fragment from 9665 to 10,374 bp of pig *TP53* (NC_010454) was excised in OS cells from *fTTP53^{R167H}* homozygous pigs (Supplementary Fig. 3a). RT-PCR analysis showed no *TP53* expression in the edited porcine OS cells (Supplementary Fig. 3b), confirming that the P2 promoter is responsible for the $\Delta 152p53\alpha$ expression.

The R167H- $\Delta 152p53\alpha$ isoform is overexpressed in tumours

To assess the RNA and protein expression of $\Delta 152p53\alpha$ isoform in cancer, we analysed tumours collected from *fTTP53^{R167H}* pigs. Quantitative PCR and western blot revealed

more than three-fold ($P < 0.001$) higher expression of R167H- $\Delta 152p53\alpha$ isoform in OS compared to matched healthy bones (Fig. 2b–d). The level of $\Delta 152p53\alpha$ mRNA expression increased ($P = 1.17 \times 10^{-5}$) with OS tumour size (Fig. 2e).

The expression level of the $\Delta 152p53\alpha$ mRNA in healthy bones correlated with the onset of cancer clinical symptoms in homozygous *fTTP53^{R167H}* pigs (Fig. 2f). The higher R167H- $\Delta 152p53\alpha$ was expressed the earlier tumours became evident. In wild-type pigs the level of $\Delta 152p53\alpha$ expression remained unchanged with age (Fig. 2f).

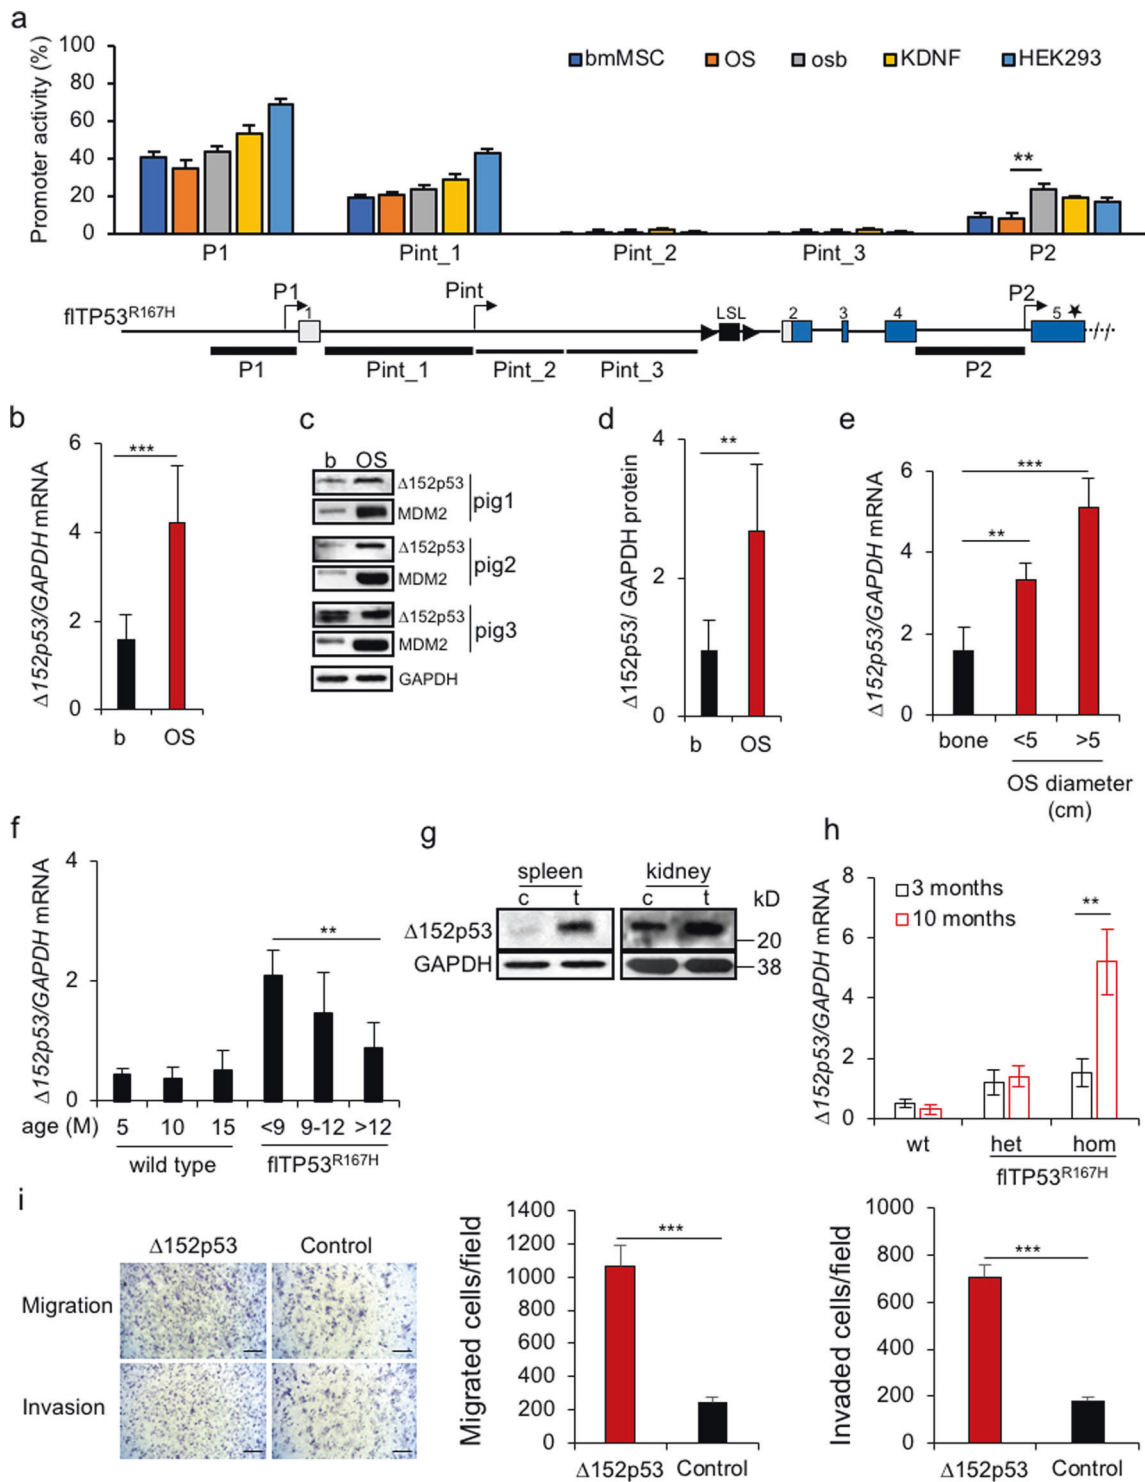

The above results hinted that overexpression of the mutant R167H- $\Delta 152p53\alpha$ isoform was essential for tumorigenesis. To assess if this also applied to other tumour types samples from the nephroblastomas and B-cell lymphomas were analysed. As for the OS, an overexpression of $\Delta 152p53\alpha$ isoform was observed in kidney and spleen tumours (Fig. 2g). Finally, we also tested if the orthologous $\Delta 133/160p53$ mRNA was expressed in human OS samples. These too were positive (Supplementary Fig. 4).

Overexpression of the $\Delta 152p53\alpha$ isoform seemed essential for tumour growth. To confirm this, and to assess if the effect was due to the expression of the wild-type or mutant isoform, a proliferation assay was performed. Pig OS cells transfected with an expression vector carrying the wild-type $\Delta 152p53\alpha$ or mutant R167H $\Delta 152p53\alpha$ cDNA sequence under the control of the CAG promoter showed significantly increased proliferation compared to those transfected with control GFP vector (Supplementary Fig. 5). The highest proliferative increase was obtained for the mutant isoform. Next, we tested if expression of the mutant R167H $\Delta 152p53\alpha$ isoform also increases cell migration and invasion. Compared to the control a significant difference was observed (Fig. 2i).

The MDM2 oncoprotein is a key regulator of p53 expression, which is stabilised by mutant p53 [33]. To determine if the mutant $\Delta 152p53\alpha$ protein isoform retains this function, western blot analysis was carried out and showed an increased MDM2 protein expression in OS tumour samples (Fig. 2c). Taken together, these data indicate that the mutant $\Delta 152p53\alpha$ isoform plays a critical role in the malignant transformation of bones, kidney or spleen in *fTTP53^{R167H}* pigs.

Blood exosomal $\Delta 152p53\alpha$ expression is indicative of tumorigenesis

In order to investigate whether the increased expression of R167H- $\Delta 152p53\alpha$ mRNA during malignancy can be detected in serum samples and used as a biomarker, exosomes were isolated from *fTTP53^{R167H}* heterozygous ($n = 6$), homozygous ($n = 6$) and wild-type ($n = 3$) pigs aged 3 and 10 months. At the age of 3 months all animals were disease free while at the age of 10 months the *fTTP53^{R167H}* homozygous pigs showed first signs of cancer, confirmed later by necropsy. QPCR showed a six-fold higher level ($P < 0.01$)

of R167H-Δ152p53α mRNA in exosomes from 10-month old *flTP53^{R167H}* homozygous pigs than from the same pigs at the age of 3 months (Fig. 2h). The exosomal Δ152p53 mRNA expression in *flTP53^{R167H}* heterozygous and wild-type pigs was low and unchanged over the same time period (Fig. 2h). These data suggest that detection of Δ152p53α isoform mRNA in serum is indicative of tumorigenesis.

The DNA methylation in the P2 promoter is negatively correlated with the mutant Δ152p53α expression in OS cells and tumours

The P2 promoter showed an increased activity in tumours. It has been reported that intragenic *TP53* methylation differs between normal and transformed human colorectal cancer

◀ Fig. 2 Identification of porcine *TP53* promoters and expression of $\Delta 152p53\alpha$ isoform in osteosarcomas. **a** Dual-luciferase assay: luciferase was expressed from the SV40 promoter and used to normalise the Renilla expression under the control of the putative promoter fragments. Their location relative to the gene structure is depicted. Values represent mean \pm standard deviation, six transfections per construct. Promoterless luciferase vector was used as a negative control. bmMSC bone marrow mesenchymal stem cells, osb porcine *fTTP53^{R167H/R167H}* osteoblasts, OS porcine *fTTP53^{R167H/R167H}* osteosarcoma cells, KDNF porcine kidney fibroblasts, HEK293 human embryonic kidney cell line. **b** Quantitative PCR results of $\Delta 152p53\alpha$ mRNA expression in OS ($n = 48$) and matched healthy bone samples. **c** Representative western blots showing $\Delta 152p53\alpha$ protein and MDM2 expression in OS and healthy matched bone samples of homozygous *fTTP53^{R167H}* pigs. **d** Quantitative measurements of proteins in OS ($n = 10$) and healthy matched bone samples from homozygous *fTTP53^{R167H}* pigs. **e** The $\Delta 152p53\alpha$ mRNA expression in small (< 5 cm, $n = 29$) vs. large (> 5 cm, $n = 19$) tumours. **f** Age-dependent $\Delta 152p53\alpha$ mRNA expression in healthy bones of homozygous *fTTP53^{R167H}* ($n = 10$) and wild-type ($n = 3$) pigs. **g** Western blots showing $\Delta 152p53\alpha$ isoform expression kidney and spleen tumours and healthy matched tissues of *fTTP53^{R167H/R167H}* pigs. **h** QPCR analysis of $\Delta 152p53\alpha$ mRNA expression in blood exosomes from *fTTP53^{R167H}* heterozygous ($n = 6$), homozygous ($n = 6$) and wild-type ($n = 3$) pigs aged 3 and 10 months. **i** Migration and invasion Transwell assays for pig OS cells transfected with mutant R167H $\Delta 152p53\alpha$ isoform or a GFP control vector. cell lines [34]. To evaluate if epigenetic changes correlate with altered expression levels a comparison of the DNA methylation in healthy osteoblasts and OS cells derived from *fTTP53^{R167H/R167H}* pigs was carried out. CpG regions in the P1 promoter, intron 1 (fragments Pint_1, Pint_2, Pint_3), P2 promoter and exon 5 were identified. DNA methylation at four or more CpG sites was analysed for each region. Overall, CpG methylation was higher in the gene body than in the P1 promoter (Fig. 3a), which is consistent with *TP53* methylation pattern in human [35]. The highest DNA methylation ($> 80\%$) was observed in Pint_2 and Pint_3 fragments that showed no promoter activity. The genomic regions of P1, Pint_1 and P2 promoters showed 18%, 28%, and 64% DNA methylation in healthy osteoblasts, respectively. The DNA methylation at five CpG sites in Pint_1, P2 and exon 5 was significantly lower in OS than in healthy osteoblasts cells (Fig. 3a). The level of DNA methylation in osteoblasts and OS cells inversely correlated with promoter activity (Fig. 3b).

The same analysis was carried out for OS tissue samples. Compared to healthy bone the same five CpG sites as mentioned above showed significantly reduced DNA methylation in OS. The level of DNA methylation was as follows: in Pint_1—CpG3 (41% vs. 22%, healthy bone vs. OS, $P < 0.01$), in the P2 promoter—CpG2 (99% vs. 62%, $P < 0.0001$) and CpG3 (96% vs. 65%, $P < 0.0001$) site, and CpG5 (94% vs. 63%, $P < 0.01$) and CpG6 (67% vs. 52%, $P < 0.01$) site within the Kozak sequence (Fig. 3c and Supplementary Fig. 6e). CpGs in this region have been

shown to be differentially methylated for the $\Delta 133/160$ isoforms in human [34]. The regression analysis revealed that the decreased methylation at CpG2 and CpG3 sites in the P2 promoter is correlated with higher R167H- $\Delta 152p53\alpha$ mRNA expression in OS ($P = 2.9 \times 10^{-7}$; Fig. 3d).

***TP53* circular RNA enhances proliferation of OS cells**

There is increasing evidence that circular RNAs (circRNAs) play a role in human cancer [36, 37], but so far no data have been reported showing expression of a circRNA for *TP53* (*circTP53*). To identify *circTP53* in *fTTP53^{R167H/R167H}*, several pairs of divergent primers were designed for RT-PCR analysis resulting in the detection of four different *circTP53* in *fTTP53^{R167H/R167H}* tissues (*circTP53-1* to *-4*, Fig. 4a), of which *circTP53-3* was highly expressed in bone. All were expressed from the P2 promoter and encoded within the $\Delta 152p53\alpha$ isoform, which was confirmed by Sanger sequencing and RNase R digestion (Fig. 4b). RT-PCR analysis revealed a tissue-specific expression of *circTP53* variants, with their highest expression in bone, kidney and colon (Fig. 4c). No expression of *circTP53* was found in heart and aorta, which is consistent with the lack of $\Delta 152p53\alpha$ expression in these organs. Compared to healthy bones, the *circTP53* expression was significantly increased ($P < 0.001$) in OS (Fig. 4d, e).

To test, whether the newly detected *circTP53* has any effect on cell proliferation, an overexpression vector, consisting of exon 5 to exon 9 (*circTP53-3*) and the R167H mutation under the control of CMV promoter, was generated. As shown in Fig. 4f, the proliferation of pig OS cells overexpressing the *circTP53* was significantly increased ($P < 0.001$) compared to cells transfected with a control GFP vector.

Altered expression of p63 and p73 in tumours from *fTTP53^{R167H}* pigs

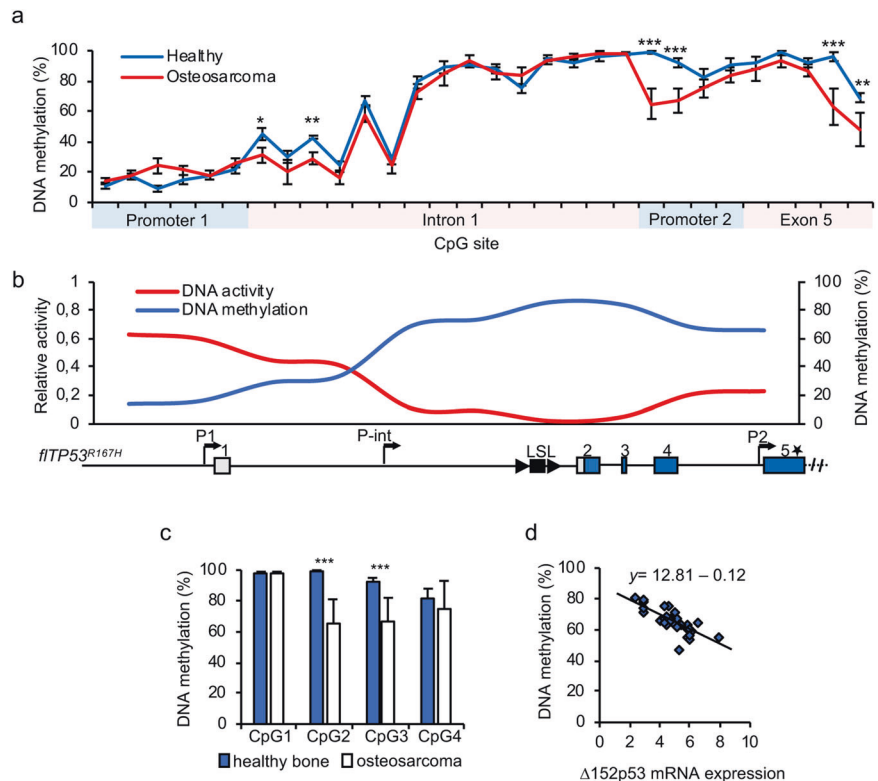

The p53 family includes two other members: p63 and p73, all three genes are structurally similar, and have been implicated in cell regulation and cancer [38, 39]. This raised the question whether the *TP53* mutation also influenced the expression of p63 and p73 in *fTTP53^{R167H}* pigs.

p63

p63 has two major isoforms, TAp63 and Δ Np63, which have different roles in tumorigenesis. While Δ Np63 isoform promotes, the TAp63 suppresses tumour growth in mice [40]. Different tissues ($n = 11$) from *fTTP53^{R167H}* homozygous ($n = 10$) and wild-type ($n = 3$) pigs were analysed by qPCR with primers located in exon 3 and

Fig. 3 DNA methylation level of porcine TP53 promoters.

a DNA methylation analysis of CpGs located in putative promoter regions in *TP53* in osteoblasts and OS cells of *fTP53^{R167H/R167H}* pigs. **b** The correlation plot for promoter activity and DNA methylation. The values on the plot are aligned to the *TP53* gene structure. **c** Pyrosequencing analysis of four CpG sites in P2 promoter (P2 fragment) in OS ($n = 48$) and matched healthy bone ($n = 29$) of *fTP53^{R167H}* pigs. Values shown represent mean \pm SD. $**P < 0.01$, $***P < 0.001$. **d** Regression analysis between CpG methylation at site 2 in P2 promoter and $\Delta 152p53\alpha$ mRNA expression in OS ($y = 12.81 - 0.12x$, $P = 2.9 \times 10^{-7}$).

exon 4. The expression of the detected *TP63* mRNA variant was significantly lower in heart, lung, bones and higher in lymph node, colon, spleen in *fTP53^{R167H}* homozygous compared to wild-type pig tissues (Fig. 5a). Western blot analysis revealed tissue-specific expression of two TAp63 isoforms, TAp63 α and TAp63 δ and no expression of Δ Np63 (Fig. 5b). While the TAp63 α isoform was highly expressed in wild-type kidney, the TAp63 δ showed an overexpression in wild-type bones, and kidney and spleen tumours (Fig. 5c), and variable expression in OS (Fig. 5d) from *fTP53^{R167H}* pigs, indicating that the *TP53* mutation has a tissue- and tumour-specific effect on the TAp63 δ isoform expression.

p73

In humans, p73 has two different promoters, which regulate several isoforms: full length TAp73 and N-terminal truncated Δ Np73, which can be distinguished by their transactivation functions [41, 42]. It has been suggested that TAp73 has a tumour suppressor function similar to that of p53, whereas Δ Np73 isoforms would promote cell growth by regulating activities of p53 family members [43]. QPCR analysis revealed a high *TP73* mRNA expression in kidney, lung, liver, colon, spleen, bone, lymph node and no expression in muscle and brain of wild-type animals (Fig. 6a). It was significantly lower in colon and small

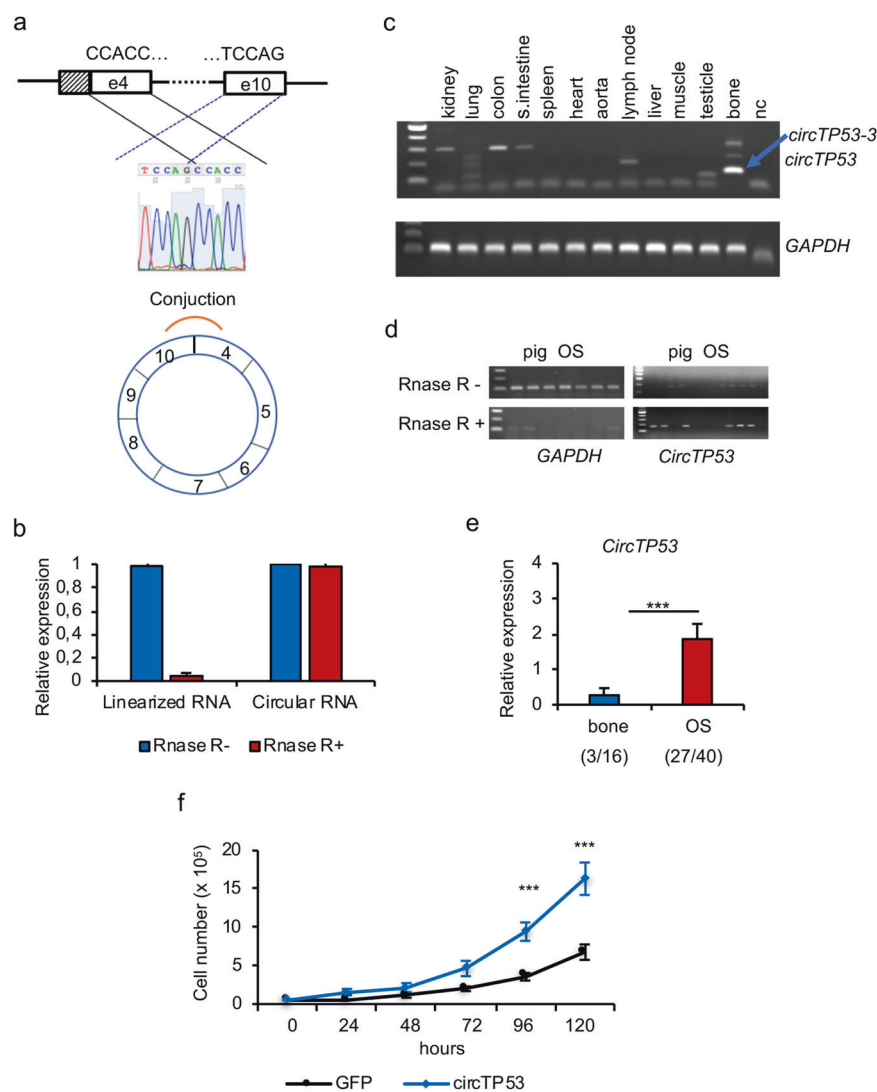

intestine but higher in lung, bone, spleen of *fTP53^{R167H}* homozygous pigs compared to wild-type (Fig. 6a). Western blot detected the TAp73 α isoform in kidney and liver and the TAp73 δ isoforms in spleen, liver, lung of *fTP53^{R167H}* homozygous and wild-type pigs (Fig. 6b). Compared to wild-type, an overexpression of TAp73 δ isoform was observed in healthy bones (Fig. 6b) and tumours (Fig. 6c, d) from *fTP53^{R167H}* homozygous pigs.

We next determined if the p73 isoforms expression is correlated with DNA methylation in the two promoter regions. A hypermethylation of the Δ Np73 promoter and a hypomethylation of the TAp73 promoter was observed. The DNA methylation at all five CpG sites of TAp73 promoter differed significantly, in particular at CpG1 (21% vs. 9%, $P < 0.001$) between OS and matched healthy bone samples (Fig. 6f), which suggests that the CpG sites may be involved in the regulation of the TAp73 isoform expression.

To further investigate the function of p73 in tumorigenesis, a porcine *TP73* full length cDNA expression vector, containing both the TAp73 and Δ Np73 translation start codons, was transfected into porcine OS and human OS (SAOS2) cells. The *TP73*-transfected cells showed an overexpression of the TAp73 δ , no expression of Δ Np73 isoform (Fig. 6e) and significantly ($P < 0.01$) increased growth rate compared to the GFP transfected control cells. These data indicated that the TAp73 δ isoform is

Fig. 4 Identification of *circTP53* in *flTP53^{R167H}* pigs. **a**

Schematic presentation of *circTP53* identification and confirmation by sanger sequencing. **b** Q-RT-PCR results showing the effect of RNAase R digestion. **c** RT-PCR analysis of *circTP53* in different tissues in *flTP53^{R167H/R167H}* pigs. **d** RT-PCR amplification showing the effect of RNase R digestion on *circTP53* and *GAPDH* amplification. **e** Relative expression of *circTP53* in healthy bones and OS. In parenthesis the number of *circTP53* positive to analysed samples is shown. **f** Proliferation assay in pig *flTP53^{R167H/R167H}* OS cells transfected with *circTP53* overexpression vector, consisting of exon 5 to exon 9 (*circTP53-3*) under the control of CMV promoter.

predominantly translated from the *TP73* cDNA and has an effect on the proliferation of these cells.

In summary, these analyses showed for the first time the expression of p63 and p73 isoforms in porcine tissues and the upregulation of the two isoforms (TAp63 and TAp73) presumed to have tumour suppressor function in porcine tumours. However, overexpression of TAp73 δ did not lead to a reduction but to an increase in cell proliferation, which may confirm that different C-terminal variants may lack growth suppressing function.

Discussion

It is becoming evident that p53 isoforms, including those derived from the internal P2 promoter, have implications in human cancers [8]. Further elucidation of their roles, interactions, regulation and patterns of expression could

open novel approaches for the prognosis and treatment of cancer. But the study of p53 isoforms and its involvement in tumorigenesis had been hampered by the fact that the main experimental mammal, the mouse, lacks internal P2 promoter activity [8]. This motivated the generation of mice that ubiquitously express a $\Delta 133$ p53-like protein ($\Delta 122$ p53) through deletion of exon 3 and 4 [44, 45]. Homozygous $\Delta 122$ p53 mice show an enhanced proinflammatory phenotype and are prone to develop B-cell tumours [46] with low incidence of OS (17%) [45]. Although this mouse model does not replicate the situation in human, it strongly supports the notion that p53 isoforms play a role in cancer.

The study presented here shows that the porcine *TP53*—unlike the mouse—has two internal promoters, P1 in intron 1 and P2 in intron 4. In humans the expression from the P2 promoter results in two isoforms, $\Delta 160$ p53 and $\Delta 133$ p53. The porcine $\Delta 152$ p53 protein isoform is

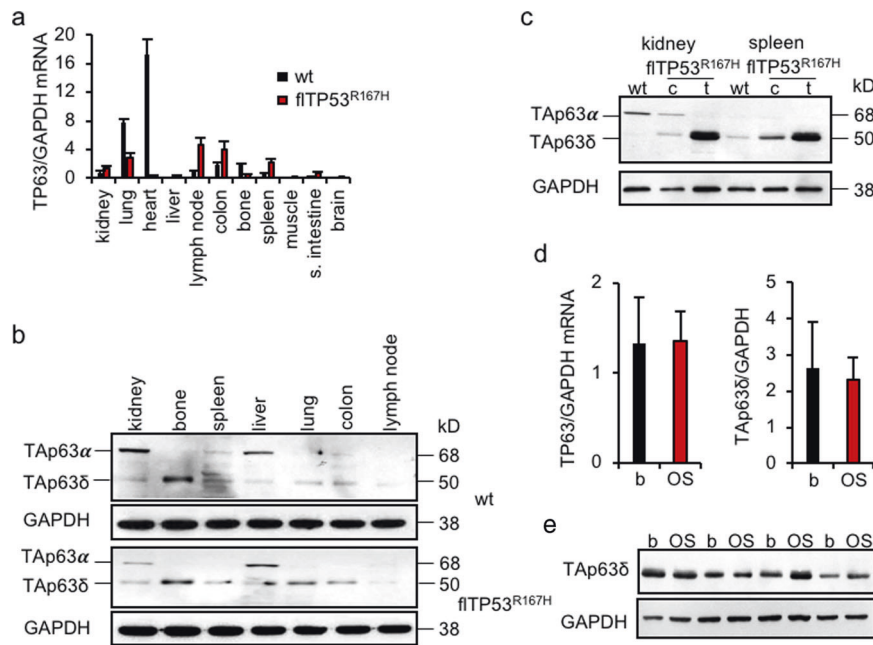

Fig. 5 Expression of p63 in *flTP53^{R167H}* pigs. **a** Quantitative RT-PCR analysis of different tissues ($n = 11$) from *flTP53^{R167H/R167H}* ($n = 6$) and wild-type ($n = 3$) pigs. **b** Representative western blots showing p63 protein expression in different tissues of *flTP53^{R167H/R167H}* and wild-type pigs. **c** Western blots showing p63 isoforms expression in healthy and tumour tissues of kidney and spleen of *flTP53^{R167H/R167H}* and wild-type

pigs. **d** Quantitative PCR results of p63 mRNA expression in OS ($n = 48$) and matched healthy bone samples. **e** Representative western blots showing p63 protein expression in OS and healthy matched bone samples of homozygous *flTP53^{R167H}* pigs. Quantitative measurements of protein in OS ($n = 10$) and matched healthy bone samples of homozygous *flTP53^{R167H}* pigs.

equivalent to human $\Delta 160p53$. The pig lacks the transcription initiation site, which in humans enables translation of the $\Delta 133p53$ protein isoform. Three N-terminal variants have been observed in humans ($p53\alpha, \beta, \gamma$). The porcine mRNA isolated by RT-PCR represents the $\Delta 152p53\alpha$ mRNA. However, western blot analysis indicated that N-terminal variants are present in the pig.

To our best knowledge this is the first report showing an association between P2 promoter activity and epigenetic modifications in normal and tumour tissue. This is an important finding as epigenetic modulation has been suggested as a means of restoring wild-type p53 function, or inactivating mutant p53 activity in human cancer [47].

Comparison with human data shows that the porcine $\Delta 152p53\alpha$ mRNA is expressed in a similar tissue-specific manner, including high expression, e.g., in bone and lack of expression in heart tissue [7]. Our study strongly suggests that the predominance of OS followed by nephroblastomas and B-cell lymphomas in pigs carrying the *flTP53^{R167H}* allele is related to the higher level of $\Delta 152p53\alpha$ expression in these organs. This is further supported by the finding that pigs with early onset of OS have also higher expression of the $\Delta 152p53\alpha$ isoform in healthy bone tissue.

Expression of $\Delta 152p53\alpha$ isoform increases during tumorigenesis, which is consistent with the expression of p53

isoforms in human cancers [48]. The overexpression of $\Delta 133/\Delta 160p53$ variants and their potential oncogenic function have been reported in lung, colon, breast and ovarian cancers and in melanoma [49–52]. In the pig, an overexpression of the wild-type and mutant $R167H\Delta 152p53\alpha$ isoform enhanced cell proliferation, finding consistent with data for mutant $\Delta 160p53$ isoform in human cancer cells [53]. It was more pronounced for mutant isoform, which would imply that the tissue-specific expression of the mutant $\Delta 152p53\alpha$ isoform drives tumorigenesis in our pig model and is an indicative blood biomarker.

TP53^{R167H} Yucatan minipig model generated by Sieren et al. [54] develops a similar tumour spectrum, but the role of the $\Delta 152p53$ in this model is unknown. It is questionable if the P2 promoter is functional in this model due to the insertion of a selectable marker gene in intron 4.

It has been suggested that one of the key mechanisms for p53 gain of function mutations is its interaction with p63/p73 [55, 56], and that the ratio of TA/ $\Delta Np63/p73$ isoforms determines their effect on tumorigenesis [57, 58]. We observed an upregulation of the TAp63 δ and TAp73 δ isoforms in all studied tumours, and proved that experimental overexpression of the TAp73 δ isoform increased proliferation of human and porcine OS cells. Further research is required to prove a direct interaction between the specific isoforms.

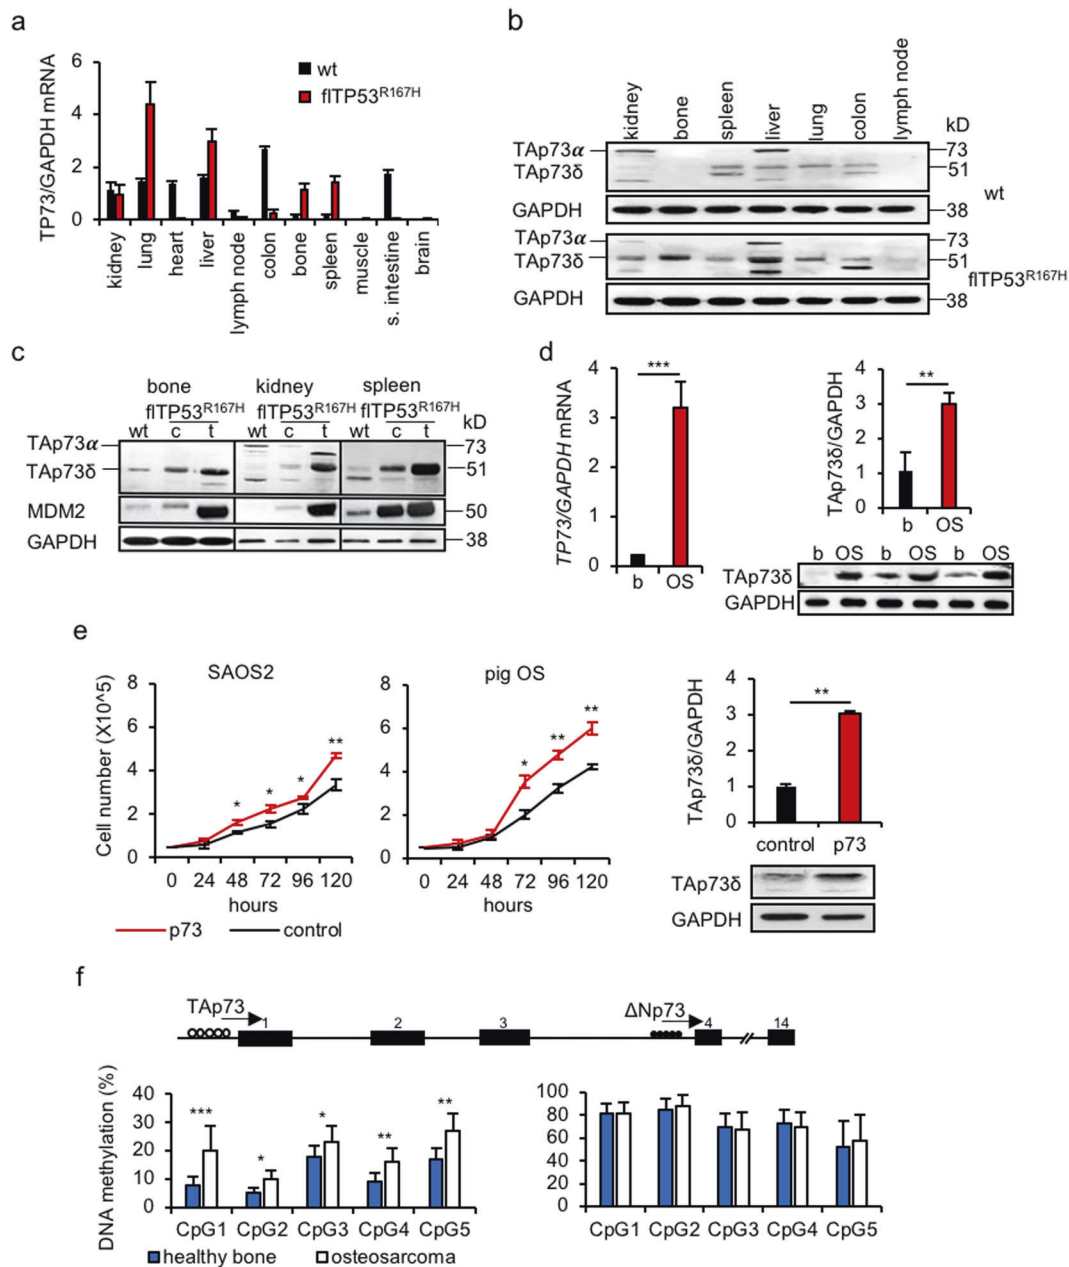

Fig. 6 Expression of p73 in *flTP53^{R167H}* pigs. **a** Quantitative RT-PCR analysis of p73 mRNA expression in different tissues ($n = 11$) of *flTP53^{R167H/R167H}* ($n = 6$) and wild-type ($n = 3$) pigs. **b** Western blots showing the tissue-specific p73 isoforms expression in *flTP53^{R167H/R167H}* and wild-type pigs. **c** Western blots showing p73 isoforms and MDM2 proteins expression in bone, kidney and spleen tumours and healthy matched tissues of *flTP53^{R167H/R167H}* and wild-type pigs. **d** Quantitative PCR (left) and western blot (right) measurements showing p73 expression in OS ($n = 48$) and matched healthy bone samples. Representative western blots (bottom) showing TAp73 δ isoform expression in OS and matched healthy bone samples of homozygous

flTP53^{R167H} pigs. Western blot (right) showing the upregulation of the TAp73 δ isoform in pig OS cells transfected with a full length of *TP73* cDNA vector. The bar plot above shows the quantitative protein measurements ($n = 3$) of western blots. **f** DNA methylation analysis of P1 and P2 promoter regions of *TP73* in OS ($n = 48$) and matched healthy bone samples of *flTP53^{R167H}* pigs. Open and filled circles on the *TP73* gene structure indicate unmethylated and methylated DNA regions.

We present the first description of *circTP53* RNAs expressed from the P2 promoter. As with the parental $\Delta 152p53\alpha$ isoform it is upregulated in tumours such as OS.

Importantly, the functional study demonstrated that high *circTP53* expression increases cellular proliferation of OS cells. Similar mechanisms for gene overexpression and upregulation

of circRNA was described for other genes, e.g., androgen receptor in prostate cancer [59]. The mechanism how *circTP53* affects cell proliferation still needs to be elucidated.

Conclusion

The biology of p53 has been studied extensively for 4 decades and still novel insights are being gained. A cross-species comparison might help to understand the tissue-specific regulation of *TP53*. Our study has highlighted the value of using the pig model. We show that the $\Delta 152$ p53 isoform, its circular counterpart and the p53 family members, TAp63 δ and TAp73 δ , likely play a role in the malignant transformation of bone and other tumours. Considering the similarities of *TP53* regulation between pig and human, the observations presented here provide useful information for further studies on the regulation of p53 in humans.

Material and methods

Animals

Three wild-type, ten (8 males and 2 females) *fTP53^{LSLR167H/R167H}* and 24 (13 males and 11 females) *fTP53^{LSLR167H/+}* pigs aged 7–32 months were produced by normal breeding and raised in our animal husbandry facilities with food and water provided ad libitum.

Necropsy examination and tumour analysis

In total, 51 pigs were euthanised and examined by complete necropsy (without randomisation). Three bone samples from wild-type and 48 OS samples with matched healthy bones from hetero- and homozygous *fTP53^{LSLR167H}* pigs were collected and all samples were included in the analysis. The study was non-blinded.

Porcine primary cells

Porcine bmMSC and kidney fibroblasts were derived in-house and cultured by standard procedures [20]. All cell cultures were routinely tested for mycoplasma.

Primers

All primers used are shown in Supplementary Table S1. For quantitative PCR, 5' and 3'RACE analysis, RNase R digestion, pyrosequencing, functional assays, western blot and sgRNA constructs details see Supplementary text. Unprocessed western blots are shown in Supplementary Fig. 7.

Data availability

All supporting data are included in the Supplementary file.

Acknowledgements The authors thank Johanna Tebbing for technical assistance with molecular biology, Steffen and Viola Loebnitz, Gerhard Kammermeier, Konrad Praller and Andres Sohn for animal husbandry.

Funding This work was supported by the German Research Foundation grant nos. SCHN 971/3-2, SFB 1321 and China Scholarship Council (CSC). Open Access funding enabled and organized by Projekt DEAL.

Author contributions KFlisikowski, AK, DS, J-CB and AS designed the study. GN, IH, TF, BR and AC carried out molecular experiments. KF, GN, KFischer and BK collected samples. BS, BB, EK and KS performed histopathological analysis of tumours. RB provided human OS samples. HP performed statistical analysis. KFlisikowski, TF, AK and AS wrote the manuscript with contributions from other authors. J-CB and DS edited the manuscript. All authors critically reviewed and approved the final manuscript.

Compliance with ethical standards

Conflict of interest The authors declare no competing interests.

Ethical approval All animal experiments were approved by the Government of Upper Bavaria (permit number 55.2-1-54-2532-6-13) and performed according to the German Animal Welfare Act and European Union Normative for Care and Use of Experimental Animals.
