29 Abstract

30

Background: Stillbirth rates in Afghanistan have declined little in the past decade with no data
available on key risk factors. Healthcare utilisation and maternal complications are important factors
influencing pregnancy outcomes but rarely captured for stillbirth in national surveys from low- and
middle-income countries. The 2010 Afghanistan Mortality Survey (AMS) is one of few surveys with
this information.

36

37 Methods: We used data from the 2010 AMS that included a full pregnancy history and verbal autopsy. Our sample included the most recent live birth or stillbirth of 13,834 women aged 12-49 38 39 years in the three years preceding the survey. Multivariable Poisson regression was used to identify 40 socio-demographic, maternal, and healthcare utilisation risk factors for stillbirth. 41 Results: The risk of stillbirth was increased among women in the Central highlands (aRR:3.01, 42 95%CI:1.35, 6.70) and of Nuristani ethnicity (aRR:9.15, 95%CI: 2.95, 28.74). Women that didn't 43 44 receive antenatal care had three times increased risk of stillbirth (aRR:3.03, 95% CI:1.73, 5.30), while 45 high-quality antenatal care was important for reducing the risk of intrapartum stillbirth. Bleeding,

46 infection, headache, and reduced fetal movements were antenatal complications strongly associated
47 with stillbirth. Reduced fetal movements in the delivery period increased stillbirth risk by almost

48 seven (aRR:6.82, 95%CI:4.20,11.10). Facility births had a higher risk of stillbirths overall (aRR:1.55,

49 95%CI:1.12, 2.16), but not for intrapartum stillbirths.

50

51 Conclusions: Targeted interventions are needed to improve access and utilisation of services for
52 high-risk groups. Early detection of complications through improved quality of antenatal and obstetric
53 care is imperative. We demonstrate the potential of household surveys to provide country-specific

54 evidence on stillbirth risk factors for LMICs where data is lacking.

- 56 Key words: stillbirth, fetal death, perinatal death, Afghanistan, low- and middle-income country, risk
- 57 factor, household surveys, Demographic and Health Survey

84 Background

85

86 A major challenge for stillbirth prevention in low- and middle-income countries (LMIC), where the largest burden lies, is the lack of adequate data to identify and quantify major risk factors at 87 88 the national level (1). Existing studies have been predominantly with women who have had contact 89 with the formal health care system (2), and while prospective, population-based studies such as those 90 from demographic surveillance sites in LMICs are increasing (3, 4), there are no national-level data 91 for many countries (1). This lack of data on country-specific risk factors makes it challenging to direct 92 attention to stillbirth at a national level and for countries to prioritise programmatic and policy areas 93 for action to reduce stillbirths. 94 95 In 2009, Afghanistan was among the top ten nations accounting for almost two-thirds of the 96 global stillbirth burden, and by 2016 little improvement was observed (5, 6). The annual reduction in 97 stillbirths between 2000 and 2015 in Afghanistan was only 1.9% (6). The stillbirth rate remains high 98 at 27 per 1000 births – six times that of high-income settings, yet there are no published studies to 99 understand stillbirths in this context. Stillbirths have not been a public health priority in Afghanistan 100 partly because of the absence of evidence on the major factors contributing to these deaths. The UN's 101 2016 Global Strategy for Women's, Children's and Adolescent Health now includes reduction in the 102 stillbirth rate as a core indicator, and the 2014 Every Newborn Action Plan set the first-ever targets to reduce stillbirths to 12 per 1000 births by 2030 which was endorsed by 190 countries, including 103 104 Afghanistan (7). It is therefore, both timely and crucial to investigate stillbirths in this high-burden country. 105 106

107 The 2010 Afghanistan Mortality Survey (AMS) was a modified, special Demographic and 108 Health Survey (DHS) and one of a few nationally-representative surveys conducted in a LMIC in the 109 last ten years that collected health service utilisation data for stillbirths and also included a verbal 110 autopsy (8). The country's unique and diverse socio-cultural, linguistic, and geographic characteristics 111 in addition to the current complex humanitarian situation, makes the need for context-specific data

112	imperative (Box 1). The objective of this study was to identify key maternal, obstetric and health-care
113	utilisation factors associated with stillbirth in Afghanistan, and to demonstrate the potential of a
114	modified DHS survey to provide country-specific evidence on risk factors for stillbirth if applied in
115	other LMICs.

147 Methods

148

149 Data sources

150 Data for this analysis are from the 2010 Afghanistan Mortality Survey (9). This was the 151 country's first nationally representative household survey and is currently the only national, 152 population-based survey that has collected data on women's health service utilisation for stillbirth. 153 The survey adopted a two-stage sampling design based on the 2011 Population and Housing Census 154 preparatory frame from the Central Statistics Organisation. The design produced a sample representative at the country level for rural and urban areas, and for the North, Central and South 155 156 geographical domains that are regroupings of eight geographical regions (Figure 1). The rural areas of 157 Kandahar, Helmand, and Zabul provinces in the South were not surveyed for security reasons. Overall, the survey covered 87% of the population; the 13% not surveyed belonged mostly to the 158 159 South zone (9).

160

161 [Insert Figure 1]

162

163 We used data from three questionnaires in the AMS survey; the household, women's, and verbal autopsy (VA) questionnaire, based on the DHS model questionnaires developed by the DHS 164 program and adapted for Afghanistan. The women's questionnaire collected information from ever-165 married women aged 12-49 years including background characteristics and a complete pregnancy 166 history which captured all pregnancies and their outcomes in a woman's lifetime. Among women that 167 gave birth in the preceding five years, the women's questionnaires captured maternal health care 168 utilisation including antenatal, delivery and post-natal care for the mother's last live birth or stillbirth. 169 The VA questionnaire was completed for each death that occurred in the preceding three years. 170 171

In total, 22,351 households were interviewed, which included 47,848 women aged 12-49
years, yielding a response of 98%. We limited our analysis to all women's births within the last three
years, giving a base of 17,215 births. We merged data from the VA with the women's and household

175	data so that selected variables not available in the pregnancy histories for stillbirths could be included
176	(fetal sex, multiple pregnancy, and timing of the stillbirth). We further restricted our sample to
177	mothers' most recent birth, giving a sample of 13,844 women/births (13,528 live births, 316
178	stillbirths) then corrected any misclassification between miscarriages, stillbirths or early neonatal
179	deaths using the VA data. This gave a final sample of 13834 births (13,523 live births, 311 stillbirths).
180	Details on this procedure is available in the Appendix.
181	
182	Study variables
183	
184	Dependent variable: pregnancy outcome
185	Our main outcome variable was pregnancy outcome for the mothers' most recent pregnancy
186	and was coded as stillbirth or live birth (see Appendix for detail). We used the definition of stillbirth
187	to be a late fetal death at \geq 28 weeks' gestation as recommended by WHO for international
188	comparisons. The 2010 AMS recorded gestational age in months so we used seven months or more as
189	our cut off. We defined intrapartum stillbirths as those stillbirths where the mother reported no signs
190	of skin maceration based on the VA data.
191	
192	Independent variables and analytical framework
193	We included individual, household, and community-level explanatory variables based on
194	those identified in the literature as having an important effect on stillbirth, and availability in the 2010
195	AMS dataset (1, 10) (see Appendix). To guide the analysis, we developed an analytical framework by
196	adapting existing frameworks (11, 12). This framework mapped explanatory variables according to
197	proximity to the outcome as distal, intermediate and proximal determinants (Figure A2) and
198	represented three defined time periods - pre-conception, pregnancy, and childbirth.
199	
200	
201	
202	

204 Statistical analysis

205

All analyses were performed using STATA/SE version 14.2. For the binary outcome, stillbirth, we used Poisson regression models with a log link function to estimate relative risks. All models were weighted using sample weights to account for the complex survey design and adjusted standard errors were used to obtain Wald test p-values and 95% confidence intervals.

210

We fitted univariable models and built three multivariable regression models to examine the 211 association between stillbirth and the explanatory variables. We applied a sequential approach (13) 212 based on the three stages of pregnancy (Figure A2): model 1 included variables from the pre-213 214 conception period (community level, socio-economic, environmental & maternal factors); model 2 included factors related to the pregnancy period (antenatal care and pregnancy complications), having 215 216 adjusted for the variables from stage 1; and model 3 included factors related to the delivery period (complications during the delivery period and delivery care), having adjusted for the variables from 217 the first two stages. In the first model, no p-value criterion was used for including variables, but for 218 subsequent models (model 2 and model 3) only variables with p≤0.20 from the previous model were 219 220 included into the next stage. Wealth, maternal age and education, fetal sex, and multiple gestation 221 were considered important factors and were retained in the models regardless of their p-values. All 222 other variables were removed one at time, starting with the highest p-value, until only those that had 223 p≤0.05 remained. Multi-collinearity was checked using variance inflation factors. Area under the curve (AUC) and calibration plots were used to assess model performance. We used the same model 224 225 building approach for identifying independent risk factors for intrapartum stillbirth.

226

227

228

231 Results

We included 13,834 births, of which 311 were stillbirths and 13,523 were live births (23 232 233 stillbirths per 1000 total births) (Table A2). Most women resided in rural areas (80.9%), were married (99.5%), and had no formal education (89.4%). First-time mothers comprised 16% of the sample, 234 however, fertility was high with over 40% of women having at least five children prior to the index 235 pregnancy. Approximately 5% had experienced a previous pregnancy loss. Over one-third (36.0%) of 236 237 women had not received ANC for their last birth, while 16% had the recommended four or more visits. Quality of ANC was generally low, with most women receiving less than five of the nine 238 239 recommended services. Only one-third of births took place at a health facility with a skilled birth 240 attendant, and less than 2% of births were caesarean. Almost two-thirds (60.6%) of stillbirths 241 occurred during the intrapartum period; although the timing was unknown for nearly 20%. The most 242 frequent maternal conditions during pregnancy were headaches, possible hypertension or infection, and bleeding. Common complications in the delivery period were headaches, blurry vision, possible 243 hypertension or infection, excessive bleeding, prolonged labour/malpresentation. About 1% of women 244 in the pregnancy and delivery periods reported reduced fetal movements (Table A2). 245

246

Disparities in stillbirth rates across the eight geographical regions were high, ranging from 13
per 1000 births in the Northern regions to over 40 per 1000 births in the Central Highlands (Table 1).
In the univariate analysis, region of residence, ethnicity and maternal age were strongly associated
with stillbirth, but wealth quintile and education were not. First and higher order pregnancies,
multiple gestation, previous pregnancy loss, and not receiving ANC, were all associated with stillbirth
(Table 1).

253

```
254 [Insert Table 1]
```

255

Table 2 shows the multivariable results of factors associated with stillbirth. Factors associated with stillbirth in the pre-pregnancy period (model 1) were region of residence, ethnicity, previous

258 pregnancy loss, and nulliparity. In particular, women in the Central highlands and South-Eastern regions had twice the risk of stillbirth and women of Nuristani ethnicity were ten times more likely to 259 260 experience stillbirth. Once pregnant, taking into account utilisation of ANC and pregnancy 261 complications, region of residence was no longer associated with stillbirth, but ethnicity remained, 262 with Nuristani women having over nine times increased risk of stillbirth (model 2). Not receiving any 263 ANC during pregnancy increased the likelihood of stillbirth by almost three times, while women that 264 experienced possible infection, bleeding, and headache during their pregnancy had approximately 265 twice the risk of stillbirth, while women with reduced fetal movement were almost four times more 266 likely to have a stillbirth. Factors independently associated with stillbirth in the delivery period (model 3) were, again, region of residence, ethnicity, previous pregnancy loss, first and multiple 267 268 pregnancies, not receiving ANC, and giving birth in a health facility. The same pregnancy 269 complications were predictive of stillbirth, except that the effect of reduced or no fetal movement as a 270 pregnancy complication was reduced. This is likely due to the inclusion of reduced or no fetal 271 movement as a delivery complication in the final model, which was now the factor with the highest relative risk, increasing risk of stillbirth by nearly seven times. Across all models Nuristani women 272 consistently had a higher risk of stillbirth being over 12 times that of the Tajik population. There was 273 274 no difference in stillbirth across wealth quintiles or levels of maternal education or age after accounting for all other factors. Models were well calibrated (Figures A5) and discrimination 275 improved from model 1 to model 3 (see AUC in Table 2). 276

277

278 [Insert Table 2]

279

The sub-group analysis on intrapartum stillbirth showed that being of Nuristani or Pashai ethnicity, nulliparous women, multiple pregnancies, receiving no or low-quality ANC, or experiencing possible infection or headache during pregnancy increased the risk of stillbirth. Reduced or no fetal movement during the delivery period was also a strong predictor, whereas reduced or no fetal movement as a pregnancy complication and giving birth in health facility were no longer associated with intrapartum stillbirth once other factors were taken into account (Table 3, Figure A6).

287 [Insert Table 3]

289	We examined health care access disaggregated by ethnicity and region of residence to
290	understand the disparities in stillbirth observed in access between different ethnic groups and
291	geographic regions (Table A3, Figures A3-A4) and found that Nuristani women had the largest
292	proportion of women that did not receive any ANC (89%) and the lowest levels of skilled birth
293	attendance (2.5%) for their last pregnancy. The highest proportion of women receiving low quality
294	ANC were residents of the Capital and Northern region (Figure A3). The South-Eastern, Western and
295	Central highlands regions had the most women who did not receive any ANC. Skilled birth
296	attendance was highest in the capital and lowest in the Central highlands, North-Eastern and Western
297	regions (Figure A4).

315 Comment

316

317 *Principal findings*

318 Our analysis of the 2010 Afghanistan Mortality Survey has highlighted several socio-319 demographic, health service utilisation, and maternal conditions that increase stillbirth in Afghan 320 women, some of which are modifiable and can inform and prioritise programmatic focus for future 321 stillbirth prevention in the country. Determinants of stillbirth in Afghanistan included residing in the Central highlands, being of Nuristan ethnicity, not receiving ANC, and experiencing bleeding, 322 323 possible infection or headache during pregnancy. Reduced or no fetal movements during the delivery 324 period and giving birth in a health facility were also strongly associated with stillbirth. Factors 325 associated with intrapartum stillbirths differed slightly and included being of Nuristan or Pashai 326 ethnicity, utilisation and quality of ANC, possible infection or headache during pregnancy, and reduced fetal movements in the delivery period. Women with first or multiple pregnancies, and 327 previous pregnancy loss also had increased risk of intrapartum stillbirth. These findings offer an 328 329 evidence-base to integrate efforts into health service delivery programmes focused on maternal, 330 perinatal and newborn survival, as well as future national health policies where until now, no such information was available. We also demonstrate how DHS surveys can be adapted to generate more 331 332 data to understand the underlying factors driving stillbirths in other LMIC settings. DHSs

333

The overall stillbirth rate of 23 per 1000 total births is lower than adjusted rates reported for 334 Afghanistan in 2009 (29.3 per 1000) and in 2015 (26.7 per 1000) from the Lancet series which 335 accounted for under-reporting (1). Intrapartum stillbirths constituted almost two-thirds of stillbirths in 336 our study and is consistent with findings from other LMICs (3). Within-country variations in stillbirth 337 risk have been observed in many countries, as have ethnic differences (14, 15). Nuristani people are a 338 minority group that reside predominantly in the Eastern part of Afghanistan (Nuristan province) and 339 340 the low levels of healthcare utilisation may explain the extremely high rates of stillbirth. The 2015 341 Afghanistan DHS also found only 1% of births in Nuristan province were in a health facility, and this

342 province had the lowest levels of ANC utilisation across the country (11%). Exacerbating the 343 situation is that the East is a high-intensity conflict zone and one of the poorest regions in the country. 344 For intrapartum stillbirths, both Nuristani and Pashai women had higher risk of stillbirth. Pashai 345 women also reside in the East, where high levels of conflict could have compromised access and 346 quality of health services. The 2010 AMS did not report mortality rates according to province or 347 ethnicity; however, the 2015 DHS reported provincial level mortality rates which showed that 348 Nuristan province had the highest infant and under-five child mortality rates nation-wide (123 and 349 170 per 1000 live births respectively, compared to 45 and 55 per 1000 live births nationally) (16). The 350 high stillbirth rates in this group appears to reflect the pattern in regional disparities in other mortality 351 rates.

352

Geographic disparities underlie maternal and child mortality, morbidity, and healthcare seeking 353 354 in Afghanistan (17). The high rates of stillbirth among women in the Central highlands are likely due to lack of access and availability of health services, as these areas are characterised by mountainous 355 terrain often isolated by snow. This region experiences scarcities in medical supplies due to poor 356 transport infrastructure and security concerns, and a shortage of medical doctors willing to work there. 357 358 Women from the South-Eastern region had higher risk of stillbirth in the initial multivariable model until adjustment with antenatal and delivery care variables, indicating the importance of health service 359 360 utilisation in this area. High levels of conflict would likely limit access and availability of services in this area. 361

362

The diverse geographical terrain with concentrated ethnic groups in specific regions, combined with insecurity will require tailored approaches to reach these hard-to-reach, high-risk women. Tappis et. al. in their study examining coverage of intrapartum care in selected areas of Afghanistan also identified the importance of context-specific service delivery models to ensure women in high conflict areas can access services (18). A major barrier to ensuring facility deliveries in some parts of the country was the inability to travel at night along major roads because of insecurity. Delivering health services to remote and mountainous areas is challenging especially in the context of insecurity, but

strategies which strengthen the role of local community health workers and task shifting can be
effective. A revised primary health care service delivery model, currently under development by the
Ministry of Public Health may provide an opportunity to integrate alternative approaches to facilitate
reductions in stillbirth.

374

375 Mothers who did not receive ANC were three times more likely to experience stillbirth and 376 while quality did not appear to make a difference for all stillbirths, it did matter for intrapartum 377 stillbirths. This suggests having any ANC is important for preventing stillbirths, but that quality and 378 content of care may be critical for identifying and managing maternal conditions early that could lead 379 to childbirth complications and intrapartum stillbirth. Overall, ANC utilisation was very low, and we 380 measured quality according to whether the mother received any of the nine checks, not necessarily, 381 the adequacy of the service or the initiation of treatment. Our measurement method may partly 382 explain the absence of an overall effect of quality of ANC for stillbirths. These downstream factors are important to consider when assessing the effectiveness of ANC on stillbirth (19). Further 383 investigation is needed to examine the quality of care provided and adherence to recommended advice 384 among women. Our analysis showed that areas that achieved higher coverage of ANC (i.e. the Capital 385 386 and Northern regions) actually had a higher proportion of women receiving lower quality of ANC. Ensuring adequate and high-quality ANC is one of the simplest and most cost-effective recommended 387 interventions to reduce stillbirths (20). Efforts to strengthen ANC are in progress where the Afghan 388 government is administering a maternal and child health handbook that contains information on safe 389 pregnancy, childbirth, and childcare to each pregnant woman and documents details of visits. It will 390 391 be important to record the services received, pregnancy progress, and results from any screening tests in this handbook. 392

393

We identified several pregnancy conditions that were associated with stillbirth and are preventable. Signs of infection and antepartum bleeding were important determinants in our study and are well-established risks. Effective interventions exist for treating malaria and syphilis to reduce stillbirth (21), and while malaria is endemic in some of the semi-arid Eastern and northern provinces

398 in Afghanistan, syphilis and HIV prevalence in Afghanistan is generally very low and limited to high risk groups such as injecting drug users and sex workers (22, 23). Further research is needed to 399 400 identify common infections contributing to stillbirth in this setting. Hirose et al.(24) identified that 401 care-seeking delays in Afghanistan were higher among women experiencing severe infections 402 compared to other complications with more concerning symptoms, so it would be important to ensure 403 early detection and management of both bleeding and infections by educating women and family 404 members on the urgency of care-seeking for symptoms. Headaches during pregnancy were also a 405 strong risk factor of both stillbirth and intrapartum stillbirth and likely a sign of pre-eclampsia or 406 pregnancy-induced hypertension, which are known risk factors for stillbirth. Ensuring that ANC 407 includes blood pressure checks and appropriate management will be critical for reducing 408 complications that lead to stillbirth. Reduced fetal movements have rarely been examined in low-409 income countries but is a known risk factor for stillbirth (25). Of all delivery complications, reduced 410 fetal movements was one of the strongest determinants for both stillbirth and intrapartum stillbirth in our study. It would be important to ensure women understand the need to act upon any perceived 411 reduction or change in fetal movements, and that during the intrapartum period movements are 412 closely monitored. 413

414

Variations exist on the effect of delivery location on stillbirth with some studies showing an 415 416 increase in risk (26) while others indicate a protective effect (3). We found facility births had increased odds of stillbirth overall, but for intrapartum stillbirth place of birth had no effect. Referral 417 bias, delays in care-seeking, or quality of care may account for these findings. The absence of an 418 419 association with intrapartum stillbirths is likely related to the quality of care or care-seeking delays. A study examining delays in care-seeking in Afghanistan showed substantial departure and decision 420 making delays among pregnant women with life-threatening conditions (27). Concerns regarding 421 quality of intrapartum care in maternity hospitals in Afghanistan have also been documented (28). 422 Ballard et al. (29) in their Ethiopian study also found that women with an intrapartum emergency 423 were twice as likely to give birth in a health facility and that facility births did not reduce stillbirth 424 425 risk, suggesting the three delays was at play here (30).

427	We could not include mode of delivery in our multivariable analysis, but caesarean births
428	showed a high positive association with stillbirth in the univariate results. A study of over 50,000
429	births in Kabul hospitals identified high rates of stillbirth in caesareans done for obstructed labour,
430	malpresentation and uterine rupture, which are preventable with timely intervention (31). We did not
431	have data on indication for caesarean but an assessment of 78 first line referral facilities in
432	Afghanistan found 88% of caesarean births were emergencies (32), so it is likely most were
433	unplanned. The ideal caesarean rate to observe reductions in intrapartum stillbirth is between 5-10%
434	(33), but here we found it was under 2% and more recent national data reports a rate of only 3% (16),
435	therefore, improving access to caesarean would be important to prevent stillbirths in Afghanistan.
436	
437	Male babies have an increased risk of stillbirth (34); however, we only found a slightly
438	increased risk among intrapartum stillbirths but not in the analysis of the full sample of stillbirths.
439	This may have been affected by the skewed sex ratio among stillbirths in our sample which had
440	almost 20% more male babies to female. This is higher than the usual 10% elevated risk of stillbirth
441	in male babies (34). The 2010 AMS (9) and 2015 Afghanistan DHS (16) both identified under-
442	reporting of neonatal and under-five child female deaths, as have other household surveys from
443	Afghanistan (35). This might suggest that under-reporting could also be a problem with female
444	stillborn deaths and partly contributing to the overall under-estimate of the true stillbirth burden.
445	Under-reporting of stillbirths can occur due to social, cultural or other factors including stigma or
446	blame towards the mother or other consequences that might preclude disclosure (36). Further
447	investigation into these issues is needed for Afghanistan.

Strengths of the study

A key strength of this study is the use of a large nation-wide population sample to identify
risk factors for stillbirth. In addition, this survey collected a comprehensive range of sociodemographic, maternal and fetal characteristics, maternal complications and health care utilisation
factors for stillbirths which are not usually available in similar household surveys in LMICs.

455 *Limitations of the data*

456 There are several limitations to this study that should be considered. Although the 2010 AMS was a national survey, there was an underrepresentation of the South because of highly insecure areas 457 458 that were not surveyed. Concerns about the accuracy of maternal and child mortality measures from 459 this survey have been noted (37) and highlight the challenges with collecting reliable data in conflict 460 zones. While we acknowledge this limitation, this is currently the only data source in the country with 461 information to enable understanding of key determinants of stillbirth. Although an updated DHS survey was subsequently conducted, it did not capture health service utilisation, maternal or fetal 462 463 factors for stillbirth, which precludes the kind of analysis reported in this paper.

464

Collecting information on pregnancy histories is challenging in low-income settings, and 465 466 stillbirths are known to be under-estimated by about 30% when collected through household surveys (5). The overall stillbirth rate of 22.5 per 1000 births in our study is low given the high levels of 467 neonatal and maternal mortality in the country. It is possible these estimates have been affected by 468 under-reporting and the data quality concerns raised with the 2010 AMS survey. The exclusion of 469 470 some rural areas of the South zone of Afghanistan during sampling because of security reasons also meant that the survey covered only 66% of the South (94% of urban and 63% of rural areas were 471 sampled) and so many stillbirths from rural areas would not have been included. The lower stillbirth 472 rates observed in the Southern region (17.8 per 1000 births) is likely to have been affected by under-473 sampling of rural areas of the south. Medical terminations are illegal in Afghanistan, so women may 474 report these as stillbirths or omit them entirely which might affect the total number of pregnancies and 475 stillbirths reported. Misclassification of stillbirths and early neonatal deaths is an issue with household 476 surveys, but we have minimised this by using data from the VA. The reliability of using skin 477 appearance to determine the timing of stillbirth may lead to an overestimate of intrapartum stillbirth 478 (38). Due to the small number of antepartum stillbirths we were not able to model antepartum 479 480 stillbirth risk factors separately to compare with the intrapartum stillbirth risk factors. Several known 481 risk factors were not captured, and we could not adjust for them (i.e. consanguinity, maternal

nutrition, distance to health facility, and care-seeking delays). Exposures related to the armed conflict
including chemicals and radiation, are known to increase the risk of stillbirth (39), but we had no
measurement of these exposures. Finally, it is possible there was under-reporting of the self-reported
maternal complications due to recall bias.

486

487 Interpretation

488 We provide for the first-time the major risk factors associated with stillbirth in Afghanistan, 489 where there was previously a complete absence of evidence to inform future interventions and 490 prevention efforts. Evidence-based interventions to prevent stillbirth exist (20) and their 491 implementation should be a priority for Afghanistan. We outline some recommendations in Box 2. 492 This study also demonstrates it is feasible to rapidly produce a comprehensive analysis of stillbirth 493 determinants for other LMICs if appropriate DHS data was available. To achieve this outcome would 494 require some modification to the standard DHS questionnaire format to include a full pregnancy history as opposed to a live birth history (8), as well as the inclusion of stillbirth in collection of 495 information on women's health care utilisation and maternal complications during pregnancy and 496 childbirth. The 2010 AMS provides a model from which future household surveys can be adapted to 497 498 collect better data for stillbirth.

499

500 *Conclusions*

Countries affected by conflict and instability account for the largest burden of stillbirths (40), 501 but strategies to improve reproductive outcomes in these areas have not received sufficient global 502 attention and is urgently needed. Development assistance and international focus on Afghanistan has 503 declined recently as the security situation has worsened, and gains in maternal and child health are at 504 risk of deteriorating. To accelerate reductions in stillbirth, concerted efforts and commitment by the 505 government and international donors are needed to invest in prioritising implementation of 506 interventions to reduce stillbirth. Evaluating different approaches to overcome challenges in the 507 508 access and utilisation of care during pregnancy and childbirth to ensure services can reach the most

509	hard-to-reach women where the majority of stillbirths occur, will be imperative for future stillbirth
510	reduction in Afghanistan.

710 Tables and Boxes

712 Box 1: Afghanistan country context and health situation713

Afghanistan is a culturally rich nation located in south-central Asia sharing borders with six different countries, the longest being with Pakistan. The country's 34 provinces comprise a diverse range of ethnicities, languages, and geographic terrains. It is mostly a mountainous landscape with the Hindu Kush mountain range dividing the country from the northeast to the southwest into three distinct regions – the mountainous central highlands, the south-west plateaus characterised by deserts, and the smaller and most fertile northern plains. The current population is estimated to be approximately 30 million. The country is one of the least developed nations in the world, ranked 169 out of 188 nations on the human development index in 2015. About one third (37%) of the population lives below the poverty line and this has remained unchanged since 2007-08. Afghanistan has a very young population structure with 48% aged under 15 years, and average life expectancy of only 60 years. Fertility rates are high with an average of 5.3 children in 2015 – a slight increase from 2010 rate of 5.1 (9, 16). Adult literacy rates remain low at 31%, particularly among females (males 45%; females 17%).

Afghanistan has faced over four decades of ongoing conflict, unstable governance and population displacement which continues. In 2016, the conflict led to the displacement of over half a million people, more than half of whom were children, and an unexpected influx of over one million Afghan refugees and returnees from Pakistan. It is estimated that over nine million people have limited or no access to essential health services, straining an already weak and recovering health system. The impact of the conflict on access to health services and health education for women and their families is therefore, particularly challenging.

Since its release from Taliban rule in 2002, immense efforts have been made by the Afghan government and international community to repair and strengthen the health system. Although rates of maternal and child deaths continue to be some of the highest in the world, there have been some encouraging improvements; maternal mortality has declined from 1600 deaths per 100,000 in 2002 to 327 per 100,000 in in 2010, however, a 2013 analysis suggests these rates may be inaccurate and could be around 885 per 100 000 live births. Recent estimates for under five child mortality suggest around 70 deaths per 1000 live births and a neonatal mortality rate of 40 per 1000 live births. In 2015, 18% of women received the recommended four or more ANC visits and 50% reported attendance of a skilled birth provider at their most recent birth, an increase from 34% in 2010 (9). Despite these improvements, there remains inadequate access to, and utilisation of, ANC and quality obstetric care services (28), with stark inequities in access between urban and rural areas and across regions (17). Health system challenges exist around sufficient numbers of female health care providers and the costs of health services and treatment. There are also additional contextual challenges and social and cultural norms surrounding women's low levels of autonomy and education that directly impact on care-seeking delays and child health outcomes (27).

723 Box 2: Recommendations for the prevention and reduction of stillbirth in Afghanistan

Health systems strengthening and health service delivery

- Improved coverage and monitoring of content of ANC for the early identification and management of high-risk pregnancies and early referral.
- The high number of intrapartum stillbirths indicates a need for improved quality and timely management of childbirth complications. Ensuring birth attendants at all levels of the health system are adequately trained and have the skills and resources available to manage complications will be essential.
- Increasing the availability and access to timely caesarean sections for high-risk pregnancies and minimising delays at the facility level.
- The highest burden of stillbirth in the country falls in the Central highlands and among minority ethnolinguistic groups which will require specialised attention and targeted strategies.

Community-based education and mobilisation

- Improve community awareness and education on key danger signs during pregnancy and childbirth that need immediate action.
- Sensitisation of community specifically about stillbirths and their prevention will also be important but will require additional strategies to overcome barriers and delays in care-seeking.

Further research

- Identification of the leading infections that may be contributing to stillbirth in Afghanistan require further research and understanding.
- Improved understanding of bottlenecks and barriers at the health facility level in regard to the prevention of stillbirth.
- Assessment of the quality of antenatal and intrapartum care provided at the various levels of health facilities.
- Development of strategies to strengthen referral linkages and facilitate referral and reduce careseeking delays at the community level.

Commitment to stillbirth targets in national health strategies and policies & continued data collection on stillbirth

- Afghanistan's current National Health Policy for 2015-2020 and Reproductive, Maternal, Newborn Child and Adolescent Health (RMNCAH) Strategy for 2017-2021 do not include targets for stillbirth reduction. National commitment in future policies and strategies to the recommended targets agreed upon as part of the 2014 Every Newborn Action Plan and endorsed at the World Health Assembly will direct national attention, prioritisation and funding towards reducing stillbirths.
- Future national population-based surveys should include a full pregnancy history similar to the 2010 Afghanistan Mortality Survey to ensure ongoing data availability on the key risk factors for stillbirths. This survey data will assist with tracking progress towards meeting the global target of 12 stillbirths per 1000 births by 2030 and identifying key areas of need for interventions.

Abbreviation: ANC- antenatal care; RR- risk ratio

Footnotes

^a N= 13 834 unless otherwise indicated

^b Any education refers to any primary, secondary or higher level of education

^c These variables were not included in the multivariable analyses. ANC variables not included due to multi-collinearity with quality of ANC. Delivery assistant was not included due to collinearity with place of delivery. Mode of delivery not included as these are procedures might

have occurred after the outcome. Severe bleeding during labour was not included as it was unknown if this was pre or post-partum haemorrhage and may have occurred after the outcome.

^d Includes first pregnancies

^eSkilled/trained provider refers to doctor, nurse or midwife

^f Unskilled/untrained provider refers to traditional birth attendant (TBA), Community health worker (CHW), relative or friend

^gReference category are those that did not receive the intervention

^h ANC quality score calculated by number of components received out of a total of 9 components (1- weight taken, 2- blood pressure

taken, 3- blood sample taken, 4- urine sample taken, 5- informed signs of pregnancy complications, 6- informed where to seek care for

complications, 7- received 2+ tetanus injections, 8- received iron/folic acid, and 9- received anti-helminths)

Probable hypertension was based on mother's report of convulsions/fits/shaking/eclampsia/pre-eclampsia and/or swelling/oedema

730 731 732 733 734 735 736 737 738 739 740 741 742 743 744 745 746 747 748 749 ^j Probable infection was based on mother's report of high fever and/or foul-smelling vaginal discharge Missing values (unweighted observations): ¹ n=11; ² n=24 ³ n=9, ⁴ n=23, ⁵ n=16, ⁶n=49, ⁷ n=122, ⁸ n=118, ⁹ n=22, ¹⁰ n=58, ¹¹ n=48 ¹² n=65, ¹³ n=69, ¹⁴ n=20, ¹⁵ n=133, ¹⁶ n=49, ¹⁷ n=10, ¹⁸ n=133, ¹⁹ n=78, ²⁰ n=29, ²¹ n=230
