LITERATURE REVIEW

OPEN

Percutaneous Transforaminal Endoscopic Discectomy Versus Open Microdiscectomy for Lumbar Disc Herniation

A Systematic Review and Meta-analysis

Pravesh S. Gadhradj, MD,^a Biswadji S. Harhangi, MD, PhD,^c Jantijn Amelink, BSc,^a
Job van Susante, MD, PhD,^d Steven Kamper, PhD,^{e,f} Maurits van Tulder, PhD,^{b,g}
Wilco C. Peul, MD, PhD,^a Carmen Vleggeert-Lankamp, MD, PhD,^a and Sidney M. Rubinstein, PhD^{b,g}

Study Design. Systematic review and meta-analysis.

Objective. To give a systematic overview of effectiveness of percutaneous transforaminal endoscopic discectomy (PTED) compared with open microdiscectomy (OM) in the treatment of lumbar disk herniation (LDH).

Summary of Background Data. The current standard procedure for the treatment of sciatica caused by LDH, is OM. PTED is an alternative surgical technique which is thought to be less invasive. It is unclear if PTED has comparable outcomes compared with OM.

Methods. Multiple online databases were systematically searched up to April 2020 for randomized controlled trials and prospective studies comparing PTED with OM for LDH. Primary

538 www.spinejournal.com

outcomes were leg pain and functional status. Pooled effect estimates were calculated for the primary outcomes only and presented as standard mean differences (SMD) with their 95% confidence intervals (CI) at short (1-day postoperative), intermediate (3–6 months), and long-term (12 months).

Results. We identified 2276 citations, of which eventually 14 studies were included. There was substantial heterogeneity in effects on leg pain at short term. There is moderate quality evidence suggesting no difference in leg pain at intermediate (SMD 0.05, 95% CI –0.10–0.21) and long-term follow-up (SMD 0.11, 95% CI –0.30–0.53). Only one study measured functional status at short-term and reported no differences. There is moderate quality evidence suggesting no difference in functional status at intermediate (SMD –0.09, 95% CI –0.24–0.07) and long-term (SMD –0.11, 95% CI –0.45–0.24).

Conclusion. There is moderate quality evidence suggesting no difference in leg pain or functional status at intermediate and long-term follow-up between PTED and OM in the treatment of LDH. High quality, robust studies reporting on clinical outcomes and cost-effectiveness on the long term are lacking.

Key words: endoscopic discectomy, lumbar disc herniation, sciatica, systematic review and meta-analysis.

Level of Evidence: 2

Spine 2021;46:538–549

Sciatica is a frequently used term to describe radiating leg pain. It is mostly caused by lumbar disc herniation (LDH).^{1,2} Even though the natural course of sciatica is favorable and most cases respond to conservative treatment, surgery is deemed necessary in some cases.³ The current standard procedure to decompress the nerve root by removing disc fragments, is open microdiscectomy (OM).⁴

In attempts to reduce the surgical invasiveness, techniques which use endoscopes to remove disc fragments were developed. The expectation was that by causing less tissue damage during surgery, patients would have less postoperative back pain, recover sooner from surgery, and have shorter duration of hospitalization.⁵ Development of methods facilitating insertion of surgical endoscopes into the safe

entry zone in the neuroforamen formed (also known as Kambin triangle), enabled the development of percutaneous transforaminal endoscopic discectomy (PTED).^{6,7} During PTED no paraspinal muscles are detached from their origin and bony anatomy is affected limited. Previous studies which have examined PTED demonstrated favorable clinical outcomes, with the result that percutaneous full-endoscopic discectomy has made its way into small scale clinical practice.^{4,8,9}

A previous review published in 2009 which compared the effects of PTED with OM concluded that the quality of the evidence regarding effectiveness of PTED is low¹⁰ and PTED could not be recommended for the treatment of LDH. Since then large observational studies as well as randomized controlled trials (RCTs) have examined the effects of endoscopic discectomy techniques *versus* OM, which have been summarized in recent reviews, including meta-analyses.^{11–16} Despite similar aims, these meta-analyses differ in methodology. As a result, the uncertainty regarding the effectiveness of PTED compared with OM remains.

In 2014, a systematic review was published by our research group, comparing minimally invasive surgery with OM.¹⁷ Due to the low number and high risk of bias of the included studies as well as small sample sizes, no pooled effect estimates were calculated for the effects of PTED *versus* OM.¹⁸ Preliminary analysis of studies published since then, suggested that there were sufficient studies to warrant an update of our previous review, focusing on the effects of PTED *versus* OM in the treatment of LDH.

METHODS

This review follows the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines.^{18–20} This study was registered in the international prospective register of systematic reviews (Prospero CRD 42020177053).

Inclusion Criteria for Studies

Studies were considered to be eligible according to the following inclusion criteria: (1) prospective studies, including RCTs and quasi-randomized studies (*e.g.*, randomization which could include allocation by alternating the date of birth); (2) compared PTED with OM in the treatment of sciatica caused by a primary LDH; (3) measured one of the clinical outcomes (*i.e.*, visual analogue scale [VAS] for leg pain, back pain, functional status, improvement, work status), surgical outcomes (*i.e.*, blood loss, length of stay, complications, reoperations); radiological or biochemical outcomes; or costs (*i.e.*, costs of interventions, health care utilization, total costs); (4) were published in English, German, or Dutch. Retrospective studies were excluded because the level of evidence provided by these studies is low compared with prospective observational and randomized studies.

Intervention

PTED is defined as a lateral, full-endoscopic approach in which the disc fragments are removed through the neuroforamen. PTED is usually performed under local anesthesia.²¹

Control Group

OM is defined as removing the disc fragments from an open transflaval approach by laminotomy.²² OM is usually performed under general anesthesia.

Search Strategy

An experienced librarian conducted a systematic search using a combination of terms related to endoscopic techniques, percutaneous techniques, and LDH. As this study updates our previously published review, the previous search terms were optimized and this search only included studies published after January 2013, the search date used by Kamper *et al.*¹⁷ The updated search is available in supplementary Table 1, <http://links.lww.com/BRS/B683>. On the April 20, 2020 MEDLINE, PubMed, Embase, Emtree, Web of Science, and the Cochrane library were systematically searched for eligible articles. In addition, additional eligible articles were searched for by reference checking the included studies. All available records were screened by two reviewers independently based on title and/or abstract. In case of disagreements, a third independent reviewer was consulted. Following this step, two authors independently screened the full-text of the manuscripts based on the inclusion criteria. Disagreements were resolved through consensus with the involvement of a third reviewer.

Data Collection and Analysis

Two authors independently extracted all data in a prespecified spreadsheet. Discrepancies in extraction were resolved by consensus. This spreadsheet included (1) study characteristics; (2) clinical outcomes; (3) surgical outcomes; (4) biochemical outcomes, namely c-reactive protein (CRP) and creatine kinase (CK) which are indicators of inflammation and muscle injury, respectively; (5) radiological outcomes (6) costs; and (7) timing of the outcomes.

Assessment of Risk of Bias

Risk of bias analysis was performed for only RCTs using the criteria recommended by the Cochrane Collaboration.²³ These criteria cover selection bias, performance bias, attrition bias, detection bias, and selective outcome reporting bias. Two authors independently scored these criteria as: low risk of bias, high risk of bias, or unclear. Disagreements were resolved by consensus and if necessary, by evaluation of a third author.

Bias Across Studies

Conflict of interest was determined for all included studies based upon the information provided by the authors in their publication. Publication bias was assessed using a funnel plot and based upon symmetry.

Data Analyses

Measures of Treatment Effect

Only data from RCTs were considered for the meta-analysis, as the observational studies may be of limited value due to the risk of selection bias. Primary continuous outcomes (leg pain and

functional status) were expressed as a standardized mean difference (SMD), including 95% confidence intervals (CI). A negative effect size indicates that PTED is more beneficial than OM, meaning subjects have less pain or better functional status. The primary outcomes were defined as short-term (1 day), intermediate (3–6 months), and long-term (12–16 months) and data were analyzed according to the closest time interval. When multiple outcomes were available from a single study, the value was used which was thought to be best correlated to that time interval. A random-effects model was used for all analyses based upon the DerSimonian and Laird approach.²⁴ RevMan 5.3 (The Nordic Cochrane Center, The Cochrane Collaboration, Denmark) was used to perform the meta-analysis. Data from prospective studies and data of the secondary outcomes were described.

Statistical Heterogeneity

Statistical heterogeneity was examined by inspecting the Forest plot and formally tested by the Q -test (chi-square) and I^2 . There was insufficient data to explore cases of considerable heterogeneity.

Data Synthesis and Quality of the Evidence

We evaluated the overall quality of the evidence for the primary outcomes, back pain, and the following complications: durotomies, (transient) neurological deficits, and wound infections. The GRADE-method was applied, which ranges from high to very low quality and is based upon the following five domains: limitations of design, inconsistency of results, indirectness, imprecision, and other factors (*e.g.*, publication bias).²⁵

RESULTS

Search Results

The initial search retrieved 2276 studies. Of these, 2255 were excluded based on title and/or abstract checking, while an additional 10 studies were excluded based on assessing the full-text articles (see supplementary Table 2, <http://links.lww.com/BRS/B683>). With the addition of the three studies identified by Kamper *et al*,¹⁷ 14 studies were included for this systematic review and meta-analysis comprising a total of 1465 patients^{26–39} (Figure 1). Of the 14 studies, nine were (quasi)-randomized studies and the remaining were observational studies (Table 1).

Risk of Bias Analysis

The results of the risk of bias analysis are shown in Figure 2. Three studies reported a random sequence generation, of which two had an adequate allocation concealment.^{27,31} All studies had a high risk of performance bias due to the fundamental differences of PTED and OM. As all studies measured patient-reported outcome measures, all had a high risk of detection bias.

Bias Across Studies

Eight out of nine RCTs reported on the conflict of interest.^{26–33} Of these studies, only one had authors that would

receive benefits from a commercial party.³³ The remaining studies declared no conflict of interest.^{26–32} Publication bias was not formally assessed given too few data.

Primary Outcomes

Leg Pain

Twelve studies reported VAS scores, of which seven were RCTs (Table 2). Four of these RCTs did not specifically describe that the VAS-score referred to leg pain.^{26,28,30,33} Only two provided data which could be used for meta-analysis.^{28,30} Short-term leg pain did not differ between groups (SMD -1.28 , 95% CI -3.65 – 1.08 ; two studies, $N = 556$) but there was high heterogeneity ($I^2 = 99\%$) (Figure 3). At intermediate and long-term, there was moderate quality evidence of no difference in leg pain between groups (SMD 0.05 , 95% CI -0.10 – 0.21 ; three studies, $N = 621$ and SMD 0.11 , 95% CI -0.30 – 0.53 , two studies, $N = 152$, respectively) (see Table 3). Omitting the RCT that did not specifically mention VAS for leg pain did not affect the results.^{28,30} Of the studies that were not included in the meta-analysis, Akçakaya *et al*²⁶ showed that patients who underwent PTED had less leg pain at short-term and Tacconi *et al*²⁷ showed no difference in leg pain at intermediate-term. In the study of Hermantin *et al*³³ the average pain score was 1.9 in the OM-group versus 1.2 in the PTED group on a scale of 0 to 10. At 2 years of follow-up, Gibson *et al*³¹ showed that patients who underwent PTED had less leg pain than patients who underwent OM (35 vs. 19, $N = 123$).

Functional Outcomes

Functional outcomes were measured with the ODI in nine studies.^{27,29–31} Two studies reported on short term function and did not find a difference between PTED and OM.^{26,30} At intermediate term there was evidence of moderate quality of no difference between PTED and OM (SMD -0.09 , 95% CI -0.24 – 0.07 ; three studies, $N = 621$); the same was found at long term (SMD -0.11 , 95% CI -0.45 – 0.24 ; two studies, $N = 152$).

Secondary Outcomes

Back Pain

Two RCTs reported VAS scores for back pain.^{27,31} Gibson *et al*³¹ reported no differences between PTED or OM in back pain at intermediate (30 vs. 31, $N = 121$) and long term (31 vs. 31, $N = 114$). Tacconi *et al*²⁷ reported lower postoperative back pain at short term in favor of PTED (20 vs. 40; $N = 50$, see Table 2). Overall, there is low quality evidence suggesting no difference in back pain between techniques at intermediate and long term (see Table 3).

Patient Satisfaction

Seven studies reported on patient satisfaction following surgery; five of which were RCTs.^{30–35,38} Gibson *et al*³¹ used the Odom's criteria to assess patient satisfaction and found a higher rate of satisfaction in the PTED group 2 years after surgery, but no difference at 3 and 12 months.

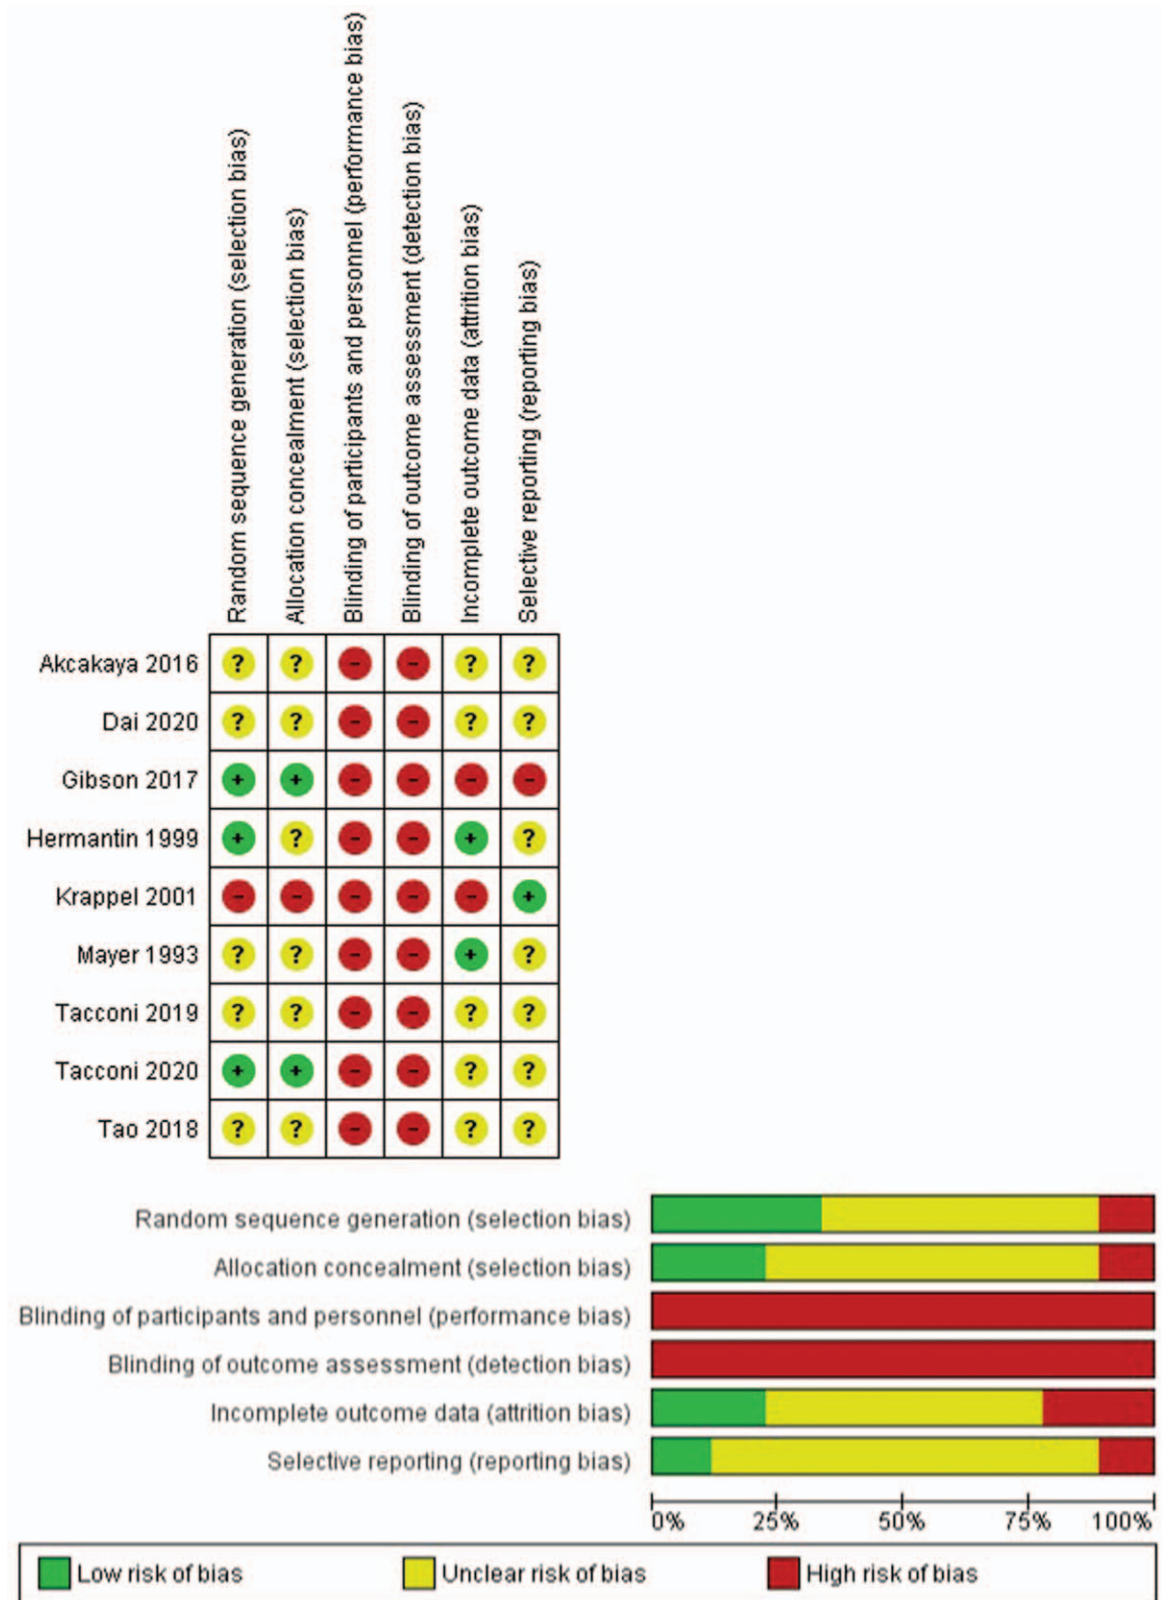

Figure 1. Flow-chart of the study selection process.

Hermantin *et al* used an unclear instrument to measure patient satisfaction while the other RCTs used the modified McNab score. Two of these reported no differences in patient satisfaction using the McNab score.^{30,32}

Surgical Outcomes: Blood Loss, Stay in Hospital, Complications, Reoperation for Recurrent LDH, Return to Work Blood loss was reported in seven studies and all showed results in favor of PTED (Table 2).^{28-30,35,37-39} Of the

TABLE 1. Overview of the Included Studies

Study	Study Period	Study Location	Study Type	Sample Size (PTED/OM)	Average age	Inclusion Criteria	Outcomes
Mayer <i>et al</i> , 1993	1987	Germany	RCT	40 (20/20)	41	Radiculopathy caused by small non-contained LDH, confirmed on imaging, failed cons. Rx	Surgical outcomes, patient satisfaction, RTW, clinical scoring system modified from Suezawa and Schreiber.
Hermantin <i>et al</i> , 1999	-	USA	RCT	60 (30/30)	40	Radiculopathy, positive tension signs, imaging confirming single small intracanalicular LDH at L2-S1, failed cons. Rx, absence of central or lateral stenosis, absence of litigation claim due to LDH.	Surgical outcomes, pain, improvement, RTW, patient satisfaction, narcotic usage.
Krappel <i>et al</i> , 2001	1996–1997	Germany	RCT	40 (20/20)	40	Persistent radiculopathy of 4 to 6 weeks, failed cons. Rx, MRI confirmed LDH at L4–5 or L5–S1, no motor or only limited sensory neurological deficit.	Surgical outcomes, patient satisfaction, RTW, complications, radiological outcomes, costs.
Akcakaya <i>et al</i> , 2016	-	Turkey	RCT	30 (15/15)	44	Indication for LDH surgery	Surgical outcomes, sciatica VAS, functional outcomes, serology.
Gibson <i>et al</i> , 2017	-	UK	RCT	140 (70/70)	41	Age 25–70, single level LDH, failure of cons.Rx.	Surgical outcomes, leg pain, back pain, QoL, patient satisfaction.
Tao <i>et al</i> , 2018	2011–2016*	China	RCT	462 (231/231)	45	LDH >1 year, VAS pain >6, confirmed by imaging, failed cons.Rx for 4 to 8 weeks.	Surgical outcomes, pain, functional outcomes, patient satisfaction, serology.
Tacconi <i>et al</i> , 2019	2014–2018	Italy	RCT	38 (18/20)	45	Age >18 years, clinical diagnosis of extraforaminal LDH, confirmed on MRI, symptoms lasting >6 weeks, failed cons. Rx, at least 14 months clinical follow-up.	Surgical outcomes, leg pain, functional outcomes.
Tacconi <i>et al</i> , 2020	2017–2019	Italy	RCT	50 (25/25) [†]	44	Confirmed single-level LDH, protrusion preferentially localized at disk level, invalidating radicular pain lasting >6 weeks and adequate imaging studies.	Surgical outcomes, back pain, leg pain, radiological outcomes.
Dai <i>et al</i> , 2020	2017–2018	China	RCT	94 (47/47)	43	LDH	Surgical outcomes, pain, QoL, serology.
Pan <i>et al</i> , 2016	2009–2012	China	Pros.	106 (48/58)	41	LDH confirmed by imaging.	Surgical outcomes, leg pain, back pain, functional outcomes, patient satisfaction, serology, radiological outcomes.
Wang <i>et al</i> , 2017	2015–2016	China	Pros.	110 (60/50)	54	Single segment LDH, confirmed by imaging and conforming diagnostic criteria, failed cons.Rx after three months, no contraindication for surgery.	Surgical outcomes, pain, functional outcomes, serology.
Choi <i>et al</i> , 2018	-	Korea	Pros.	40 (20/20)	43	Sciatica and back pain >6 weeks, failed cons.Rx, clinical LDH confirmed by imaging.	Surgical outcomes, leg pain, back pain, functional outcomes, serology, radiological outcomes.
Chang <i>et al</i> , 2018	2015–2016	China	Pros.	110 (60/50)	45	Meeting diagnostic criteria of LDH, single segment LDH confirmed by imaging, failed cons. Rx, no surgical contraindications.	Surgical outcomes, pain, functional outcomes, serology.
Xu <i>et al</i> , 2020	2017–2018	China	Pros.	145 (58/87)	37	LDH meeting diagnostic criteria, failed cons.Rx, without spondylolisthesis and spinal stenosis	Surgical outcomes, patient satisfaction functional outcomes, serology, pain.

*The abstract of Tao *et al* describes June 2012 to May 2016, while the methods section June 2011 to May 2014 as enrollment period.

[†]Tacconi *et al* 2019 performed OM through Wilkes approach.

cons.Rx indicates conservative therapy; LDH, lumbar disc herniation; QoL, quality of life; RTW, return to work; VAS, visual analogue scale. Surgical outcomes: duration of surgery, length of hospital stay, reoperations, complications and/or blood loss.

Serological outcomes: CRP, CK, TNF- α , IL-4, IL-6, CD3+ T-cells, CD4+ T-cells, CD8+ T-cells, malondialdehyde, myeloperoxidase, superoxide dismutase, total antioxidant capacity.

Patient satisfaction: modified McNab-score, Odom's criteria.

Functional outcomes: Oswestry disability index.

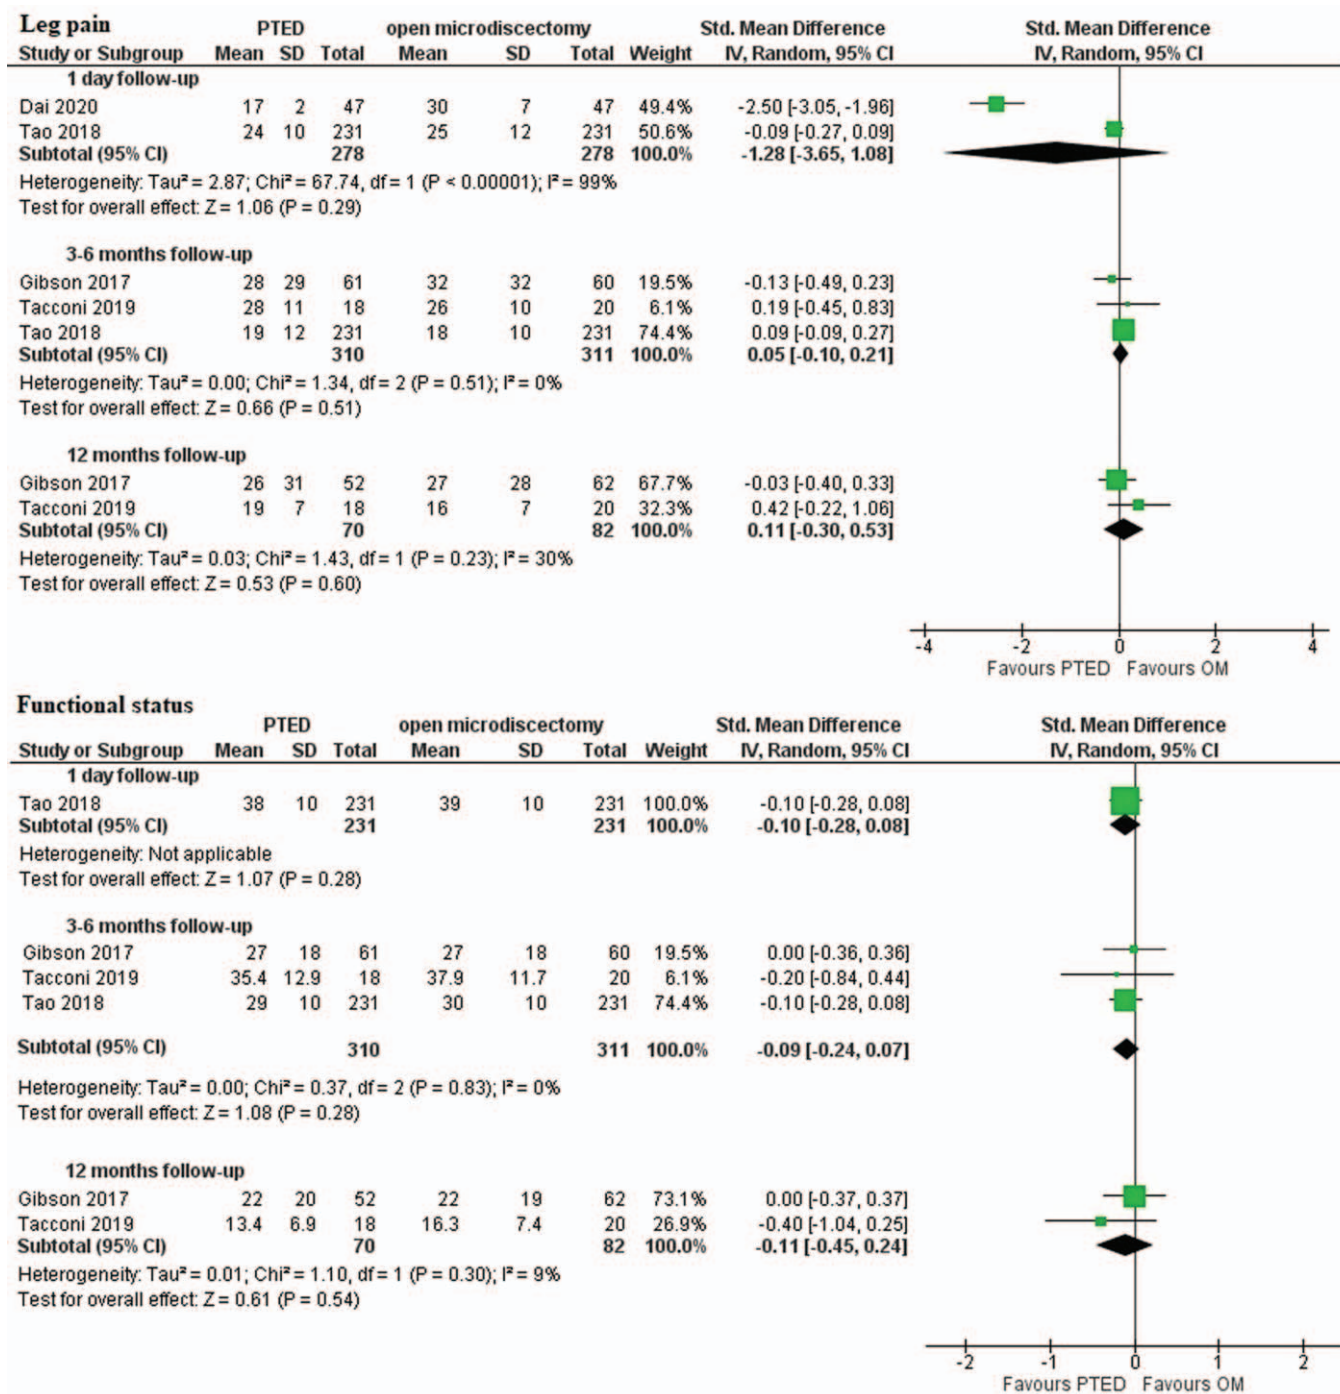

Figure 2. Risk of bias assessment for all included RCTs.

studies that measured postoperative length of hospital stay all but one RCT found shorter hospitalization duration in the PTED group.^{26,28,30,31,35,36,38}

Complications among patients who underwent PTED and OM were reported in 12 studies (Table 4).²⁷⁻³⁸ Overall, there was very low quality of evidence that complication rates (of dural tears, neurological deficits, and wound infections) between PTED and OM were comparable.

Six RCTs reported reoperation rates for recurrent disc herniation.^{27,29,31-34} Reoperation rates were low (2%–10%) and none of the studies showed significant differences between groups. Return to work was reported in four studies.³¹⁻³⁴ Hermantin *et al* reported that patients who underwent PTED returned earlier to work than patients who underwent OM (27 vs. 49 days). Mayer *et al*³⁴ reported that 95% of the patients in the PTED group returned to work after 12 months compared with 72% in the OM group.

TABLE 2. Outcomes of RCTs and of Observational Studies

Study (PTED/OM)	Leg Pain	Functional Outcome	Back Pain	Patient Satisfaction	Serology	Radiology	Blood Loss	Length of Hospital Stay	Reoperation for LDH	Return to Work	Costs

*One additional procedure in PTED group due to lumbar spinal stenosis.

[‡]Favors PTED on two different MRI reconstructions, but found no difference on two other MRI reconstructions.

[‡]Favors PTED in reduction of the Cobb angle but no differences in intervertebral space height were found.

For clinical outcomes of RCTs values measured at the latest moment of follow-up are shown with their standard deviations, when reported. + indicates the outcome is in favor of PTED, - , the outcome is in favor of OM; +/-, there is no difference between PTED and OM. Favors means a statistically significant difference was shown in individual studies. In case if differences were not tested, no symbol is shown. Scores for leg pain, back pain and functional status are reported from 0 to 100 with 0 indicating no pain or disability. NR, not reported

Krappel et al³² and Gibson et al³¹ found no differences in return to work rates.

Biochemical Outcomes

Five studies reported on CRP and were all in favor of PTED at one or more postoperative time points (ranging from 1 hour to 7 days after surgery).^{30,36-39} Four studies reported on the CK values^{26,30,36,38}; all studies showed significantly higher CK rates in the OM group at one or more time points.

Radiological Outcomes

Four studies reported radiological outcomes of PTED versus OM.^{27,33,36,38} One study compared scarring measured on postoperative MRIs and found less scarring in the

PTED group, but no correlation to clinical outcomes.³³ Another study assessed lumbar stability by measuring the Cobb angle and the height of the intervertebral space as measured on x-rays and found a significant reduction in the Cobb angle in the PTED group postoperatively.³⁸ No differences were found in the postoperative Cobb angle in the OM group or in the measured intervertebral space height in either group. Choi et al³⁶ measured the cross-sectional area of high-intensity lesions in the paraspinal muscles on MRIs postoperatively, which were larger in patients that underwent OM compared with PTED. Finally, in a randomized study that analyzed paraspinal muscle signal intensity changes on postoperative MRI, higher mean volume of paravertebral muscle alterations

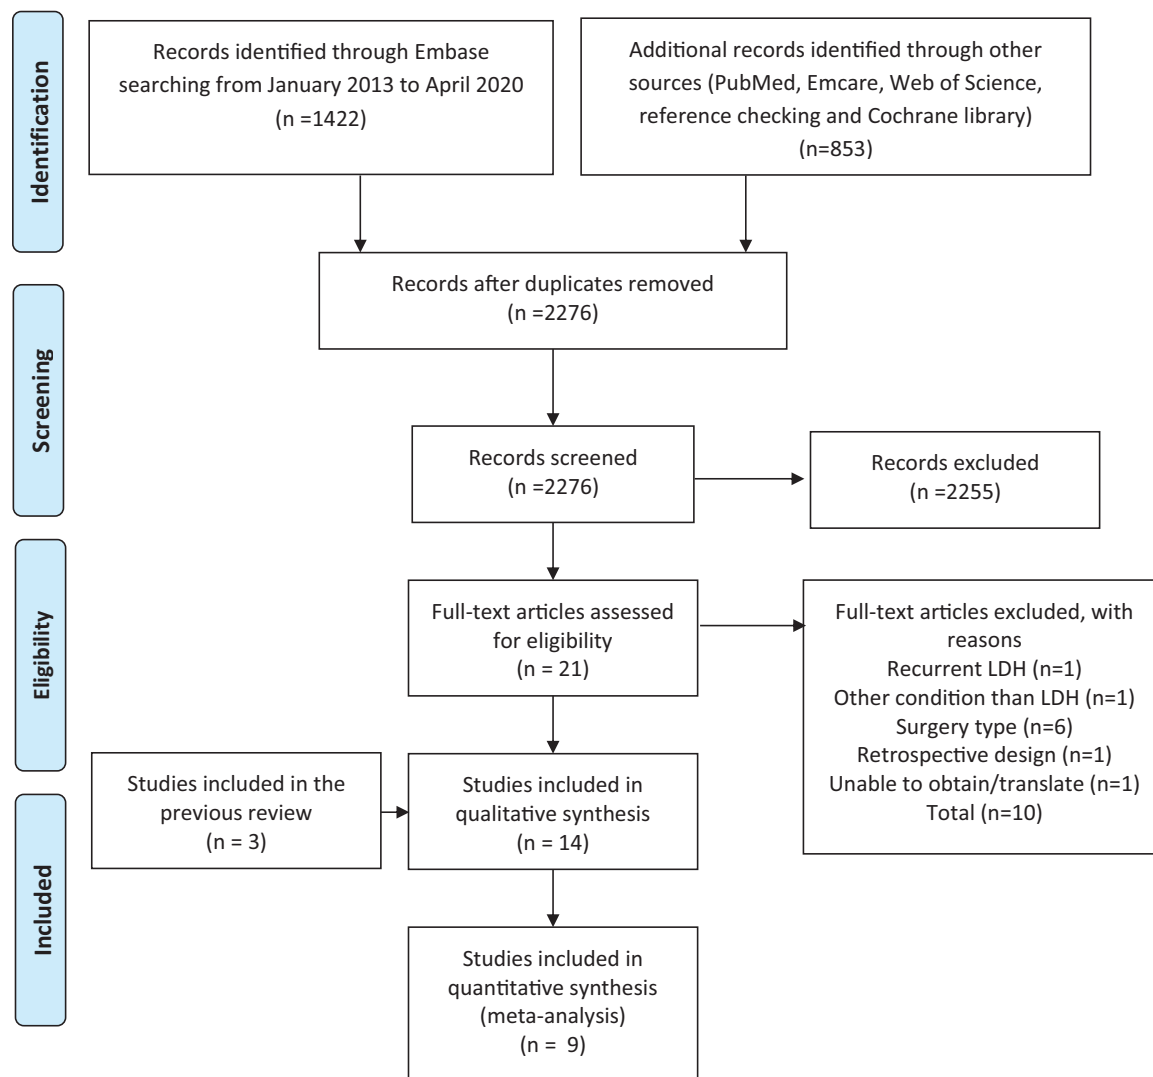

Figure 3. Pooled results of PTED *versus* OM on the primary outcomes. OM indicates open microdiscectomy; PTED, percutaneous transforaminal endoscopic discectomy.

were found in the OM group on two specific MRI reconstructions.²⁷

Costs and Cost-Effectiveness

Two studies reported on some of the costs of the interventions. Krappel *et al* calculated the costs by computing the costs of the operating room, hospitalization, endoscopes, and sterilization of the equipment. Total costs of PTED were higher than for OM (U.S.\$ 7707 *vs.* U.S.\$ 1417, respectively).^{32,40} Of the total costs of PTED, 66.2% were attributable to the costs of the endoscope. Pan *et al*³⁸ only reported the costs of hospitalization which were lower in the PTED group (U.S.\$ 1279 for PTED *vs.* U.S.\$ 1622 for OM).⁴⁰ None of the identified studies performed economic evaluations.

DISCUSSION

The update of our systematic review which examined the effect of PTED *versus* OM for the treatment of LDH

suggests that there is moderate quality evidence of no difference in leg pain and functional status at the intermediate and long-term follow-up. Data on short-term leg pain showed substantial heterogeneity, and only one study provided data on short-term functional status. These data on leg pain and functional status didn't show any differences between PTED and OM. Our review could not affirm a lower rate of back pain which could be expected from full-endoscopic spine surgery. Back pain was only assessed by one RCT and there was low quality evidence of no difference in back pain between patients who underwent PTED *versus* OM. Overall, complications were more frequently reported in patients who underwent OM, although the incidence of complications after lumbar discectomy is low.

Comparison With Other Studies

In recent years, other reviews with different methodology have been published.^{11,13,41,42} The current review differs in that we only compared full endoscopic transforaminal

TABLE 3. GRADE Evidence Summary of Findings for the Effect of PTED Versus Open Microdiscectomy

	Quality Assessment							No. of Patients		Effect (95% CI)	Quality of Evidence
	No. of Studies	Design	Limitations	Inconsistency	Indirectness	Imprecision	Other	PTED	OM		
Leg pain (intermediate term)	4	RCT	Serious limitations*	No serious inconsistency	No serious indirectness	No serious imprecision	No serious considerations	335	336	SMD 0.05 (-0.10 to 0.21)	Moderate
Leg pain (long term)	3	RCT	No serious limitations	No serious inconsistency	No serious indirectness	Serious imprecision [§]	No serious considerations	100	112	SMD 0.11 (-0.30 to 0.53)	Moderate
Functional outcome (intermediate term)	3	RCT	Serious limitations*	No serious inconsistency	No serious indirectness	No serious imprecision	No serious considerations	309	311	SMD -0.09 (-0.24 to 0.07)	Moderate
Functional outcome (long term)	2	RCT	No serious limitations	No serious inconsistency	No serious indirectness	Serious imprecision [§]	No serious considerations	70	82	SMD -0.11 (-0.45 to 0.24)	Moderate
Back pain (intermediate term)	1	RCT	No serious limitations	Serious inconsistency [†]	No serious indirectness	Serious imprecision [§]	No serious considerations	61	60	SMD -0.04 (-0.39 to 0.32)	Low
Back pain (long term)	1	RCT	No serious limitations	Serious inconsistency [†]	No serious indirectness	Serious imprecision [§]	No serious considerations	52	62	SMD 0 (-0.37 to 0.37)	Low
Complications	12	RCT Prosp.	Serious limitations*	No serious inconsistency	No serious indirectness	Serious imprecision [§]	Serious considerations [¶]	647	678	Not calculated	Very low

*Quality of evidence is downgraded if >50% of the study population origins of studies with a high or unclear risk of bias for allocation concealment.
[†]Quality of evidence is downgraded if the I² statistic >75% or if only one study reports on the outcome.
[‡]Quality of evidence is downgraded if study results are not generalizable.
[§]Quality of evidence is downgraded if there are <400 patients in the study sample for continuous outcomes or if there are less than 300 events in the study sample for dichotomous outcomes.
[¶]Quality of evidence is downgraded if there are signs of publication bias or conflicts of interest.
^{||}Dural tears, (transient) neurological deficits and wound infections were taken into this analysis.

TABLE 4. Complications Mentioned in All Included Studies

Study	Sample Size (PTED/OM)	Total Complications N (%)	Complications PTED N (%)	Description	Complications OM N (%)	Description
Mayer et al, 1993	40 (20/20)	0	0	-	0*	-
Hermantin et al, 1999	60 (30/30)	1 (1.7%)	0	-	1 (3.3%)	1 (3.3%) incidental durotomy

Overall	1325 (647/678)	138 (10.4%)	30 (4.6%)		108 (15.9%)	

*One patient in the OM group underwent a revision procedure due to scar tissue. This revision procedure was complicated due to the development of spondylodiscitis.

discectomy with OM which is considered to be the standard procedure. Furthermore, our review included four RCTs published after completion of the previous reviews.²⁷⁻³⁰ Nevertheless the results of the present review are in concordance with prior reviews; clinical outcomes such as leg pain, back pain, functional status, and rate of recurrent disc herniation, are comparable or differed minimally between PTED and OM, but PTED is associated with shorter hospitalization duration and blood loss.^{11,13,42}

In our previous review, we identified three RCTs comparing PTED with OM.¹⁷ Of these RCTs, only one evaluated pain and none assessed specifically back pain or functional status as is customary in lumbar spine surgery nowadays.³²⁻³⁴ Furthermore, cautious interpretation of these trials was also warranted because of the unclear or high risk of selection bias. The current search added six RCTs to the results of which two had a low risk of selection bias.^{27,31} Of these two studies only the trial by Gibson *et al*³¹ with moderate sample size (N=140) provided relevant clinical outcomes on short and long term.

Strengths and Limitations

Despite the inclusion of 11 new studies to this update, there remains a paucity of high-quality studies with a low risk of bias reporting on patient-centered outcomes relevant to lumbar disc surgery.¹⁷ For instance, postoperative leg pain was only reported in three and two studies at intermediate and long term respectively, and postoperative back pain was only measured by one study at intermediate and long term. The paucity of studies also led to the inability to formally assess publication bias. Another limitation is inherent to cultural and time differences between the studies. For example, cultural differences may explain the difference in postoperative length of hospital stay following discectomy between studies conducted in European countries in comparison to studies conducted in other countries. An example of timely differences is the trend that the duration of hospitalization for lumbar disc surgery is decreasing over the years.^{9,43} Nevertheless, because these cultural and time differences are applied on both patient categories, we expect the influence of these differences on the outcomes to be limited but they may explain heterogeneity between the studies on these other outcomes. The inability of blinding patients is a limitation which may also warrant cautious interpretation of some outcomes. For instance, some expected short-term benefits such as patient satisfaction, and return-to-work and length-of-hospital stay rates, may be influenced by the patient's own expectation of undergoing endoscopic surgery, also frequently named as minimally invasive surgery.

The findings of the current review warrant further studies of high methodological quality and sufficient sample size to further explore clinical merits of PTED in comparison to OM on core clinical outcomes as leg pain, functional status, and back pain. As we would expect no differences in clinical outcomes or small difference of limited clinical relevance based on the results of this meta-analysis, prospective

economic evaluations are essential, especially since PTED is expected to be more expensive as procedure but to have lower hospitalization costs. Results of a RCT comparing the effectiveness and cost-effectiveness of PTED to OM are expected.⁴⁴

An important concern for the use of PTED for sciatica is the surgical learning curve, which is considered to be relatively long and difficult.⁴⁵⁻⁴⁷ Two studies that focused on the learning curve of full-endoscopic surgery show a steep learning curve of full-endoscopic surgery and suggest that the procedure may be more difficult to master as compared with OM.^{45,46} Despite this learning curve, however, clinical outcomes such as functional status and pain appear to be comparable to those after OM. A recent systematic review attempted to estimate a cutoff number of cases needed to perform to master PTED. A case load of 20 was commonly used, but insufficient evidence was found to support any number of procedures.⁴⁷

CONCLUSION

There is moderate level evidence of no difference in leg pain or functional status at intermediate and long term between PTED and OM in the treatment of LDH. High quality and robust studies reporting on clinical outcomes on the long-term and performing economic evaluations are lacking.

➤ Key Points

- ❑ PTED is an alternative surgical technique to treat lumbar disk herniation. It is unclear if PTED has comparable outcomes compared to open microdiscectomy.
- ❑ Multiple online databases were systematically searched up to April 2020 for randomized controlled trials and prospective studies measuring clinical outcomes.
- ❑ Fourteen studies were included of which nine trials.
- ❑ There is moderate quality evidence suggesting no difference in leg pain or functional status at intermediate and long-term follow-up between PTED and OM in the treatment of LDH.
- ❑ High quality, robust studies reporting on clinical outcomes and cost-effectiveness on the long term are lacking.

Acknowledgments

The authors would like to thank Jan W. Schoones from the Waleus Library, Leiden University Medical Center for performing the systematic search.
