1 Abstract

2 **Background**

3 Decreased masticatory performance leads to deterioration of overall health among older adults. However,
4 maintaining and improving masticatory performance by ways other than maintenance of natural teeth and
5 appropriate prosthodontic treatment, remains unclear. If the factors related to the mixing and shearing
6 abilities for the masticatory performance are clarified, it may be possible to maintain and improve the
7 masticatory performance of older adults. We aimed to clarify the association among mixing ability,
8 shearing ability, and masticatory performance-related factors.

9 **Methods**

10 Of the 707 community-dwelling older adults in Kusatsu Town, Japan, 344 who had been treated for any
11 dental defects were enrolled in this study. Masticatory performance was evaluated based on mixing ability
12 and shearing ability. The number of present teeth and artificial teeth, occlusal force, tongue pressure, and
13 oral diadochokinesis /ta/ were measured as masticatory performance-related factors. Their relationship
14 with mixing ability, shearing ability, and masticatory performance-related factors were examined by
15 Spearman's rank correlation coefficient and path analysis.

16 **Results**

17 Among masticatory performance-related factors, the number of present teeth, occlusal force, and tongue
18 pressure were directly associated with both mixing ability and shearing ability. Moreover, mixing ability
19 was also directly associated with shearing ability.

1 **Conclusions**

2 Tongue pressure, which can be improved by training, is a masticatory performance-related factor
3 associated with both mixing and shearing abilities.

4 **Practical implications**

5 Training for tongue pressure after proper prosthetic treatment may provide an effective means of
6 maintaining and improving masticatory performance in older adults.

1 Introduction

2 Recently, the decrease in masticatory performance among older adults has been reported to be one of the
3 risk factors for metabolic syndrome, sarcopenia, and physical frailty.¹⁻³ These conditions are defined
4 according to the 2009 Joint Interim Statement,¹ Asian Working Group for Sarcopenia (AWGS)², and the
5 Cardiovascular Health Study index criteria,^{2,3} respectively. Thus, a decrease in masticatory performance
6 appears to be associated with overall health deterioration. Regular evaluation and efforts to maintain and
7 improve the masticatory performance in older adults may lead to an improvement in overall health.

8 Masticatory performance has been evaluated using a variety of masticatory samples. These samples
9 include peanuts,⁴ silicone,⁵ paraffin wax,⁶ color-changeable chewing gum,⁷ and gummy jelly.⁸ In particular,
10 the color-changeable chewing gum^{7,9-13} and test gummy jelly^{8,11,14-18} are most widely used in both research
11 and clinical practice; of these, the color-changeable chewing gum is used to evaluate the patient's ability to
12 mix food with saliva, while the test gummy jelly is used to evaluate the patient's ability to shear food. Thus,
13 in masticatory performance, these items are used to evaluate different abilities such as mixing ability and
14 shearing ability.¹¹

15 Previous studies have reported that factors (masticatory performance-related factors) such as
16 number of natural teeth,¹⁶ occlusal force,^{16,17,19} tongue pressure,^{17,18,20} and oral diadochokinesis
17 (ODK)^{17,18,20} are associated with masticatory performance among older adults. However, studies that
18 investigate factors related to the mixing ability and shearing ability, which are a part of masticatory
19 performance, are limited. Therefore, effective factors for maintaining and improving mixing ability and

1 shearing ability are not yet clear. By clarifying these factors, it should be possible to maintain and improve
2 masticatory performance among older adults. We hypothesized that a decrease in masticatory
3 performance-related factors would be associated with a decrease in mixing ability and shearing ability. In
4 this study, we aimed to clarify associations among mixing ability, shearing ability, and masticatory
5 performance-related factors.

6 2 Materials and methods

7 2.1 Participants

8 This study included 707 older adults over 65 years living in Kusatsu town, Gunma Prefecture, who
9 participated in a comprehensive geriatric health examination. Participants were informed in writing and
10 verbally about the purpose and content of the health screening, and their consent to participate was
11 obtained in writing. Health screening was conducted at the General Health and Welfare Center for five
12 days in early July 2017. Of the participants, 99 (14.0%) older adults with deficits in masticatory
13 performance examination data were excluded. Additionally, 264 (37.3%) patients who had not been treated
14 for dental defects were excluded from the analysis in line with reports from previous studies^{17,18} to exclude
15 the effect of dental defects on masticatory performance.²¹ As a result, 344 (48.7%) older adults (127 male
16 adults and 217 female adults; mean age 76.3 ± 6.5 years) who had a complete dentition or all dental defects
17 treated prosthodontically were included. Those who usually wore removable dentures were screened while
18 wearing these dentures. This study was approved by the Ethics Committee of the Tokyo Metropolitan
19 Institute of Gerontology (Approval No. 3 in 2008 and No. 23 in 2017).

1 2.2 Masticatory performance

2 The mixing ability was evaluated using a color-changeable chewing gum (Masticatory Performance
3 Evaluating Gum XYLITOL, Lotte Co., Ltd., Tokyo, Japan).^{7,10} Participants chewed the gum freely, in 60
4 chewing cycles. After chewing, the gum was transferred to a transparent plastic bag and compressed to a
5 thickness of 1.5 mm. Subsequently, a* representing redness was measured randomly at three points using a
6 color-difference meter (CR-20 Color Reader, KONICA MINOLTA, Tokyo, Japan), and the mean was
7 defined as the mixing ability.^{9,13} Mixing ability was assessed by four dentists who were pre-trained in the
8 evaluation criteria.

9 Shearing ability was also assessed using test gummy jelly (Test gummy jelly for evaluating
10 masticatory performance, UHA Mikakuto Co., Ltd., Osaka, Japan).⁸ The gummy jelly was chewed freely
11 in 30 chewing cycles and collected on gauze. The chewed gummy jelly was visually compared with the
12 score chart by Yashui et al. and shearing ability was evaluated in 10 stages.¹⁴ The shearing ability was
13 assessed by two dentists pre-trained in the evaluation criteria.

14 2.3 Masticatory performance-related factors

15 The number of present teeth and artificial teeth, presence of removable dentures, occlusal force, tongue
16 pressure, and ODK /ta/ were measured as masticatory performance-related factors. Occlusal force was
17 evaluated using pressure-sensitive sheets (Dental Prescale 50 H R type; Fuji Film Co., Tokyo, Japan).²²
18 The pressure sensitive sheet was interposed between the maxillary and mandibular dental arches and
19 clenched with maximum occlusal force for 3 seconds in the intercuspal position according to the

1 evaluator's instructions. Tongue pressure was evaluated using a tongue pressure measurement device (JMS
2 tongue pressure device; JMS Co., Ltd., Hiroshima, Japan).²³ The balloon of the tongue pressure probe was
3 positioned on the anterior palate and compressed onto the palate with the tongue for approximately 7
4 seconds. Maximal tongue pressures were recorded three times at 30-second intervals, and the mean was
5 recorded as tongue pressure. ODK was evaluated using an oral function measurement device
6 (KENKOU-KUN Handy; Takei Scientific Instruments Co., Ltd., Niigata, Japan).²⁴ ODK was evaluated
7 using the articulatory velocity of /ta/.¹⁷ /ta/ was repeated as fast as possible for 5 seconds, and the number
8 of syllables produced per second was calculated. Masticatory performance-related factors were evaluated
9 by six dentists who had been trained in advance and who standardized evaluation criteria.

10 2.4 Other recorded variables

11 In order to understand the characteristics of the participants, handgrip strength and gait speed,²⁵ skeletal
12 muscle mass index (SMI)²⁶ (a muscle mass assessment), body mass index (BMI), Japan Science and
13 Technology Agency Index of Competence (JST-IC)²⁷ (to assess competence), Geriatric Depression Scale
14 (GDS)-short version²⁸ (to assess depression), and the Mini-Mental State Examination (MMSE)²⁹ (to assess
15 cognitive status), among other survey items, were evaluated. In addition, sarcopenia was adjudged from
16 the values of handgrip strength (male: <26.0 kg, female: <18.0 kg), gait speed (\leq 0.8 m/s), and SMI (male:
17 <7.0 kg/m², female: <5.7 kg/m²) according to the criteria of the AWGS³⁰ to evaluate the physical functions
18 of the participants. The results were evaluated by 12 nurses and clinical psychologists who had been
19 trained in advance and who used standardized evaluation criteria.

1 2.5 Chewing syndrome

2 “Chewing syndrome,” proposed by Nasu,³¹ is defined as a condition involving difficulty in bolus formation
3 related to chewing caused by malfunctioning of one or more organs, from the lip through the oral cavity
4 proper to the upper part of the epiglottis.

5 2.6 Statistical analysis

6 First, Spearman’s correlation analyses were performed to evaluate the correlations among mixing ability,
7 shearing ability, and masticatory performance-related factors. Next, we referred to the “chewing
8 syndrome,”³¹ proposed by Nasu, to hypothesize pathways leading to decreased mixing ability and shearing
9 ability (Figure 1). Finally, path analysis was performed with reference to the results of the Spearman’s
10 correlation analysis to estimate the relationship among a set of observed variables. The variables at the
11 base of the arrow are considered to affect the variables at the tip of the arrow. The Bentler–Bonett normed
12 fit index (NFI), the comparative fit index (CFI), and the root mean square error of approximation
13 (RMSEA) were used as fit indices of the path diagram. All analyses were performed using SPSS version
14 22 (IBM Corp., Armonk, NY, USA). SPSS AMOS Version 20 (IBM) was used for path analysis. The
15 significance level was set at $\alpha = 0.05$.

16 3 Results

17 3.1 Participant characteristics

18 The number of present teeth and artificial teeth were found to be 12.1 ± 11.0 and 15.2 ± 11.3 , respectively
19 (Table 1). There were 262 (76.2%) removable denture users, and Eichner index was the largest in class C

1 with 179 (52.0%). Mixing ability score was 17.0 ± 6.0 and that of shearing ability was 3.4 ± 2.5 .
2 During the course of sarcopenia evaluation according to the criteria of the AWGS³⁰, 95 (27.6%) of the
3 participants were found to have low handgrip strength, 10 (2.9%) had low gait speed, and 0 had low SMI.
4 None of the three elements of the diagnostic criteria for sarcopenia were met.

5 3.2 Spearman's correlation analysis

6 Spearman's correlation analysis showed that the correlation coefficients between mixing ability and
7 shearing ability were significantly and positively correlated at $r = 0.516$. Both mixing and shearing abilities
8 were significantly correlated with the number of natural and artificial teeth, removable denture use,
9 occlusal force, and tongue pressure among the masticatory performance-related factors (Table 2). ODK /ta/
10 showed a significant correlation only with shearing ability. The correlation coefficient between the number
11 of present teeth and the number of artificial teeth was -0.973 among the participants, while that between
12 the number of present teeth and removable denture use was -0.697 .

13 3.3 Path analysis

14 Path analysis with reference to the Spearman's correlation analysis is shown in Figure 2. From multiple
15 hypothesis models, the best fit was adopted. Among masticatory performance-related factors, the number
16 of present teeth, occlusal force, and tongue pressure were directly associated with mixing ability and
17 shearing ability. Moreover, it was shown that the mixing ability was directly associated with shearing
18 ability. The fit of the path diagram was 0.978 for NFI, 0.992 for CFI, and 0.039 for RMSEA.

1 4 Discussion

2 A decrease in masticatory performance among older adults is associated with the risk of deterioration in
3 overall health.¹⁻³ Our results suggest that maintaining and improving masticatory performance may
4 improve overall health. Prevention of tooth loss and prosthetic replacement of missing teeth are the main
5 factors to accomplish this goal.³¹ However, recently in Japan, there has been a decreasing trend in the
6 number of missing teeth in older adults who are not treating tooth-related defects.³² To maintain and
7 improve the masticatory performance of aging adults whose dental defects have been treated, it is
8 necessary to evaluate its association with mixing ability, shearing ability, and other masticatory
9 performance-related factors. Appropriate countermeasures should also be continued, including those
10 related to masticatory performance factors from the early stages of decline. Therefore, in this study, the
11 masticatory performance decline pathway was estimated using path analysis to highlight the association
12 among mixing ability, shearing ability, and other masticatory performance-related factors in community
13 dwelling older adults.

14 The evaluation of participants' physical function with the diagnostic criteria of sarcopenia³⁰ revealed
15 no applicable participants, indicating that the physical functions of the participants in this study were
16 maintained. MMSE and GDS short-version scores also showed that most participants did not show a
17 severe decrease in cognitive function or severe depressive tendencies.

18 The model of the path analysis is referred to as the “chewing syndrome” and was proposed by
19 Nasu.³¹ Path analysis showed that a decrease in the number of present teeth leads directly to a decrease in

1 occlusal force and indirectly to a decrease in occlusal force via the use of removable dentures, and may
2 lead directly to a decrease in mixing ability and shearing ability.

3 Previous studies have shown that a decrease in the number of present teeth is associated with a
4 decrease in occlusal force and masticatory performance even if the defects were replaced by removable
5 prostheses.^{15,20} Our results also support this claim. Another pathway showed an association between age
6 and tongue pressure. Tongue pressure was shown to decrease with age, similar to findings from previous
7 studies.³³ Occlusal force was shown to be associated with the number of present teeth and sex, and these
8 results are also supported by previous studies.³⁴ Although both tongue pressure and occlusal force are
9 masticatory performance-related factors representing muscular strength, the reason for the differences in
10 their associated factors were due to tongue pressure being minimally affected by the number of present
11 teeth. The results of Spearman's correlation analysis showed a correlation between shearing ability and
12 ODK /ta/, whereas path analysis did not show any association between both mixing ability and shearing
13 ability with ODK /ta/. Several previous studies have reported an association between masticatory
14 performance and ODK /ta/ among older adults.^{17,18} In contrast, in a study of young people, both mixing
15 ability and shearing ability have not been found to be associated with ODK /ta/.¹¹ The relationship among
16 masticatory performance, tongue dexterity, and motor speed should be further investigated.

17 This study showed that a decrease in the number of present teeth, occlusal force, and tongue
18 pressure among masticatory performance-related factors may lead to a decrease in mixing ability and
19 shearing ability. Among masticatory performance-related factors, occlusal force, which is considered to

1 represent muscle strength, is affected by sex and number of present teeth, while tongue pressure is
2 considered to be affected by aging. In order to maintain and improve masticatory performance, we should
3 identify declining muscle strength in its early stages by assessing tongue pressure.

4 Mastication proceeds in the order of shearing food and mixing it with saliva. Based on clinical
5 experience indicating that the influence of tooth loss is more pronounced on shearing ability than mixing
6 ability, we hypothesized that a decrease in shearing ability contributes to a decrease in mixing ability.
7 However, the path diagram showed results that were contrary to our hypothesis, suggesting the possibility
8 that a decrease in mixing ability may lead to a decrease in shearing ability instead. Previous studies have
9 reported that tongue muscle force and speed of tongue movement are associated with masticatory
10 performance.^{17,18} Our results suggest that a decrease in tongue-centered coordinated movement, which
11 mixes food with saliva, can result in a decrease in the movement of transporting food to the occlusal
12 surface, leading to a decrease in shearing ability.

13 It is clear that masticatory performance is affected by tooth loss²¹. In this study, those who had
14 untreated missing teeth other than the third molar were excluded in order to evaluate masticatory
15 performance in patients who had received prosthodontic treatment for all their missing teeth.^{17,18} In other
16 words, all missing teeth of the participants had been replaced with dental prostheses. Therefore, our results
17 are not applicable to those who have untreated tooth loss. This study showed that tongue pressure was
18 associated with both mixing ability and shearing ability in participants with appropriate prosthodontic
19 treatment.

1 Previous studies have reported that tongue pressure improves with training.³⁵ These results suggest
2 that training to improve tongue pressure contributes to the maintenance and improvement of masticatory
3 performance, and we believe these are clinically meaningful results.

4 In this study, the selected masticatory performance-related factor associated with removable
5 dentures was not the number of artificial teeth but the presence or absence of removable dentures, to avoid
6 multicollinearity of the number of present teeth and number of artificial teeth.

7 There are some limitations in this study. We did not evaluate the occlusion and fit of dentures, so the
8 effect of removable denture quality on masticatory performance could not be assessed. However,
9 considering the fit of the path diagram, we consider that the association between masticatory performance
10 and removable dentures can be adequately evaluated among older adults whose tooth-related defects have
11 been treated. Since the study was conducted at a single clinical site, evaluation of the masticatory
12 performance factors of older adults was limited to a small population. In addition, the mean number of
13 present teeth of the participants (mean age of 76.3) was 12.1, which was less than the mean number of
14 present teeth (18.0) in Japan for those aged 75-79 years.³⁶ This selection bias limits the generalization of
15 our findings, and it cannot be claimed that the results represent the mean population of older Japanese
16 adults. However, clarification of the factors affecting masticatory performance is one of the important
17 findings of this study, and this may lead to better maintenance or improvements in masticatory
18 performance of older adults.

19 Salivary flow has been reported to be associated with masticatory performance,¹⁶ however, it was

1 not evaluated this study. In a previous study in which color-changeable chewing gum was used, it was
2 reported that chewing-stimulated salivary flow affected the results.¹² The evaluation of the mixing ability
3 by using color-changeable chewing gum used in this study may have indirectly evaluated the effect of
4 salivary flow as well; however, it is necessary to critically evaluate this in future research.

5 Since this was a cross-sectional study, it could not determine causal relationships. However, since
6 the goodness of the fit of the path diagram was sufficient, we consider it an adequate representation of the
7 association among the shearing ability, mixing ability, and masticatory performance-related factors. As
8 shown in the path diagram, a decrease in masticatory performance may be due to a decrease in both the
9 number of present teeth, and muscle strength characterized by occlusal force and tongue pressure. Previous
10 studies have only revealed factors associated with masticatory performance.¹⁶⁻²⁰ Although limited by its
11 cross-sectional design, here, we used path analysis to estimate the relationship among certain factors,
12 enabling us to produce results that represent advancements over those of previous studies. The novel aspect
13 of this study was that after excluding the effect of dental defects on masticatory performance, path analysis
14 was used to identify factors that could lead to a decrease in this measure.

15 As a means of maintaining and improving masticatory performance, prevention of loss of teeth and
16 appropriate prosthetic treatment have been the main interventions offered to patients.³¹ This study suggests
17 that training of the tongue after proper prosthetic treatment is another effective means of maintaining or
18 improving masticatory performance. Dentists may want to evaluate tongue pressure using one of the
19 several types of a dedicated device such as JMS tongue pressure device²³ or the Iowa Oral Performance

1 Instrument³⁷ for patients who have undergone prosthetic treatment for dental defects to help prevent a
2 decrease in masticatory performance. When low tongue pressures are identified, the dentist may want to
3 train or refer these patients for training on how to improve their pressures.

4 5 Conclusion

5 Among masticatory performance-related factors, the number of present teeth, occlusal force, and tongue
6 pressure were associated with the mixing ability in community-dwelling older adults. Moreover, shearing
7 ability was also associated with mixing ability. Tongue pressure was found to be associated with both
8 mixing ability and shearing ability in masticatory performance and may be one of the most important
9 factors involved in maintaining or improving masticatory performance among older adults.

1 Figure legends

2 **Figure 1.** Pathways to a decrease in masticatory performance as hypothesized in this study.

3 The pathway leading to a decrease in masticatory performance has been hypothesized in this study. The
4 decreased number of present teeth is considered as the main cause of the decline in masticatory
5 performance. Even in the presence of a full complement of present teeth, muscle strength and dexterity
6 decrease with age. We hypothesized that a decrease in the number of present teeth, muscle strength, and
7 dexterity lead to a decrease in the ability to perform combined movements, such as mixing and shearing,
8 which ultimately lead to a decrease in masticatory performance. Reproduced with permission from Nasu.³¹

9

10 **Figure 2.** Path analysis of factors associated with masticatory performance.

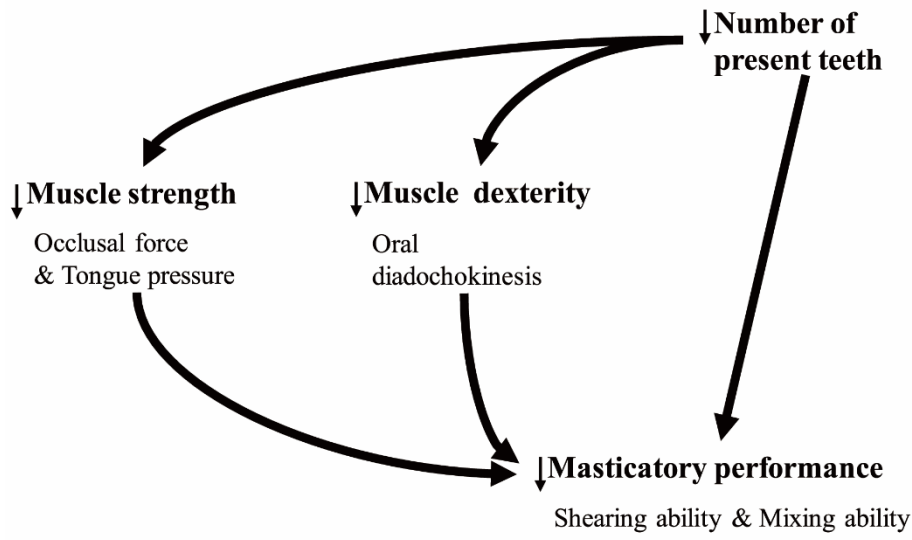

11 Tongue pressure, number of present teeth, and occlusal force were directly associated with mixing ability
12 and shearing ability. Mixing ability was also directly associated with shearing ability.
