Abstract: Topochemical reactions between CaCrO₃ and polyvinylidene difluoride yield the new fluorinated phase CaCrO_{2.5}F_{0.5}, which was characterized by powder synchrotron X-ray diffraction, X-ray photoemission spectroscopy, and magnetic susceptibility measurements. The reaction proceeds via reduced oxide intermediates, CaCrO_{2.67} and CaCrO_{2.5}, in which CrO₆ octahedral and CrO₄ tetrahedral layers are stacked in a different manner along the *c* axis of CaCrO₃. These two intermediate phases can be selectively synthesized by the carbothermal reduction with g-C₃N₄. Both CaCrO₃ and CaCrO_{2.5}F_{0.5} adopt the same orthorhombic space group, *Pbnm*; however, the fluorinated phase has decreased Cr-O-Cr bond angles as compared to the parent compound in both the *ab* plane and along the *c*-direction, which indicates an increased orthorhombic distortion due to the fluorination. While the oxygen vacancies are ordered in both intermediate phases, CaCrO_{2.67} and CaCrO_{2.5}F_{0.5} undergo antiferromagnetic phase transitions involving spin canting, where the fluorination causes the transition temperature to increase from 90 K to 110 K, as a result of the competition between the increased octahedral tilting and the enhancement of superexchange interactions involving Cr³⁺ ions in the CaCrO_{2.5}F_{0.5} structure.

Introduction:

Recently, the development of topochemical techniques have allowed for the facile synthesis of phases with new anion lattices or metal coordination geometries in oxides, the synthesis of which has been central in solid state chemistry, as it expands our knowledge of structure property relationships.¹ A number of oxygen deficient or oxyfluoride phases have been obtained by treating oxides normally obtained easily by solid state reactions with either a reducing or fluorinating agent.^{2, 3} Topochemical reduction using an alkali/alkaline hydride yields novel oxyhydrides and oxygen-vacancy ordered compounds. For example, LaSr₃NiRuO₄H₄ with metal hydride sheets and *A*FeO₂ (*A* = Ca, Sr, Ba) with square-planar oxides ⁴ are obtained from the corresponding oxide phases.⁵⁻⁷ Low-temperature fluorination reactions using fluorine gas, fluoropolymer or a binary metal fluoride also allow for unique anion-lattice modification via the substitution of fluorine for oxygen and/or fluorine insertion, ⁸ as exemplified by the synthesis of superconducting Sr₂CuO₂F_{2+□} from Sr₂CuO₃. ⁹

Applying these topochemical methods to materials obtained from high-pressure synthesis, a 'hard-soft' synthetic approach, is under explored and can lead to the exploration of metal coordination environments that aren't readily accessible at ambient pressures. For example, it is well known the tetravalent chromium cation strongly favors tetrahedral coordination over octahedral coordination and the ionic radius is too small to be incorporated into perovskite structures, although these observations are not without exceptions. Previously, alkaline chromium oxide perovskites such as ACrO₃ (A = Ca, Sr) have been stabilized under high pressures, $^{11, 12}$ and Arevalo-Lopez and Attfield et al. have discovered new oxygen-vacancy ordered phases CaCrO_{3-x} (x = 0.33, 0.4, 0.5) $^{13, 14}$ and SrCrO_{3-y} (y = 0.2, 0.25), 15 which were synthesized

by reduction of ACrO₃ (A =Ca, Sr) with hydrogen gas. CaCrO_{2.5} was found to adopt the brownmillerite structure. These oxygen deficient layers depend on the A site cations: vacancies in CaCrO_{3-x} are formed in the (001) plane of the cubic perovskite structure, but vacancies in SrCrO_{3-y} are formed in the (111) plane (Figure 1).

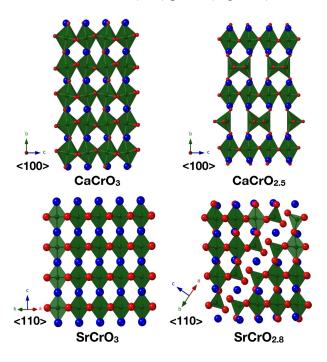

Figure 1. Structures of ACrO $_3$ (A = Ca, Sr) and their reduced products obtained by reductive reactions carried out with g-C $_3$ N $_4$. CaCrO $_2$. $_5$ adopts the brownmillerite structure. Chromium octahedra are shown in green, oxygen atoms in red, and A atoms in blue.

Very recently, our research group reported the topochemical fluorination of SrCrO₃ with polyvinylidene difluoride (PVDF), which involved the formation of SrCrO_{2.8} as an intermediate oxide. The layers of tetrahedrally coordinated Cr⁴⁺ in SrCrO_{2.8} create a pathway for the subsequent fluorine insertion, and the resulting oxyfluoride phase was the cubic SrCrO_{2.8}F_{0.2} with fluoride ions randomly distributed in the structure. Furthermore, SrCrO_{2.8} could be isolated for the first time by topochemical reduction with g-C₃N₄. It should be noted that the degree of fluorination in SrCrO₃ seems to be restricted by the amount of the oxygen deficiencies in the intermediate phase. Thus, to gain deeper understanding of the fluorination mechanism for SrCrO₃,

it is useful to perform chemical substitution in the parent materials and explore the different types of oxygen deficient phases obtained by reduction.

In this study, we report the fluorination and reduction of CaCrO₃ with PVDF and g-C₃N₄, which revealed stepwise fluorination processes similar to that for SrCrO₃ but different pathways for oxygen removal and fluorine insertion as well as higher degree of fluorination.

Experimental

Synthesis. CaCrO₃ powder was obtained using a multi-anvil high-pressure method previously reported by Weiher *et al.*¹¹ CaCO₃ was heated over night at 1000 °C in air to obtain CaO, which was combined stoichiometrically with CrO₂ (Aldrich) in an Ar filled glovebox and loaded into a Pt capsule. The Pt capsule was loaded into a high-pressure cell and heated at 900 °C under a pressure of 5 GPa for 1 h before quenching to room temperature by turning off the heat before releasing the pressure. The black polycrystalline product, CaCrO₃, contained a CaCr₂O₄ impurity (13 wt.%) and was fluorinated using PVDF (Aldrich) in molar ratios of 0.1 to 0.5 (PVDF/CaCrO₃). PVDF and CaCrO₃ were mixed, pelletized, and sealed in a glass tube under vacuum before heating at temperatures of 350, 370, and 400 °C. CaCrO₃ was also reduced using g-C₃N₄ (synthesized in house) in ratios of 0.25 (C₃N₄/CaCrO₃) following a similar procedure.

Structure. The structures of the resulting powders were analyzed by Rietveld refinement using synchrotron X-ray powder diffraction (SXRD) data collected at room temperature using one-dimensional X-ray detectors installed on BL15XU, NIMS beamline at SPring-8 in Japan. The synchrotron radiation X-rays were monochromatized to the wavelength of 0.65298 Å. The samples were loaded in glass capillaries and inner diameter of 0.1mm, and the diffraction data were

recorded in 0.003° increments over the range of $4 \le 2\theta \le 60^{\circ}$. Structure refinements were performed using the Rietveld method with the program RIETAN-FP.¹⁷ X-ray Photoemission spectroscopy (XPS) measurements were performed by using Mg $K\alpha$ X-ray source (JEOL JPS-9010MC). The Fermi level was calibrated using the C1s signal.

Results and Discussion

Synthesis. For both post-synthetic fluorination and reductive reactions, a temperature of 400 °C produced better results, although the reactions can be carried out at 350 and 370 °C but the reactions did not reach completion at these temperatures. The reactions of CaCrO₃ with PVDF at different ratios show a stepwise fluorination of CaCrO₃, where CaCrO₃ is first reduced to CaCrO_{2.67} and CaCrO_{2.5}, before the fluorinated phase forms (see Figure 2). At ratios of 0.1 and 0.2 (PVDF/CaCrO₃) CaCrO_{2.67} and CaCrO_{2.5} are formed, and these phases disappear as the fluorinated phase, CaCrO_{3-x}F_x, begins to form at a ratio of 0.3 (PVDF/CaCrO₃). These behaviors suggest that fluorine is inserted into the tetrahedral layers of CaCrO_{2.5}. The fluorinated phase obtained at 0.5 (PVDF/CaCrO₃) can be assigned to an orthorhombic cell with a = 5.34098(9) Å, b = 5.40324(9) Å, and c = 7.53180(10) Å. Low-temperature reduction using g-C₃N₄ was also examined on CaCrO₃, which resulted in the successful isolation of CaCrO_{2.5} and CaCrO_{2.67} under controlled reaction temperatures, although a few uncharacterized peaks, which disappear at higher temperatures, were detected in CaCrO_{2.67} as indicated in the right panel of Fig. 2. We notice that both the fluorination and reduction of CaCrO₃ causes peak broadening, which is probably due to a reduced crystallinity through the topochemical reactions.

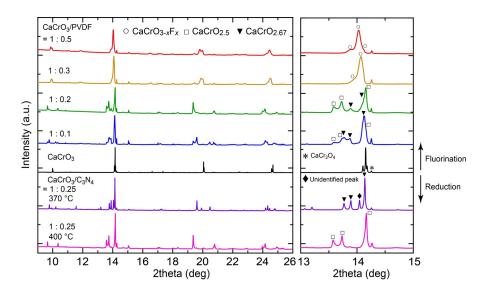

Figure 2. SXRD patterns of the products obtained by reactions of CaCrO₃ with PVDF or g-C₃N₄. CaCrO₃ is fluorinated via two oxygen deficient phases, i.e. CaCrO_{2.67} and CaCrO_{2.5}. These reduced phases can be isolated by controlling the reaction temperature with g-C₃N₄.

Structure. Figure 3 shows the result of Rietveld refinement against the PXRD data collected from the product obtained by the reaction of CaCrO₃ with PVDF at 400 °C. Even after the fluorination reaction, the structure retained the orthorhombic space group *Pbnm*, but the lattice constants increased by 0.98, 1.60, and 0.60% along a, b, and c directions, respectively. The variation in volume ($\Delta V/V$) is 3.2%, which is larger than the volume change between SrCrO₃ and SrCrO_{2.8}F_{0.2} (2.5%) but smaller than that between SrFeO₃ and SrFeO₂F (8.2%).^{15, 16} No additional peaks associated with O/F anion ordering were detected. For structural refinement of the oxyfluoride phase, the crystal structure of CaCrO₃ was used as a starting model. No attempt was made to distinguish oxide and fluoride ions because of their similar X-ray scattering factors. CaCr₂O₄ and CaF₂ were also added to the refinement as secondary phases. The refinement readily converged well to $R_{wp} = 2.01\%$ and $R_B = 3.73\%$. No anion-site deficiencies were found within the error margin, indicating that the oxygen vacant sites in CaCrO_{2.5}F_{0.5}, implying higher degree of

fluorination than that for SrCrO₃.¹⁶ Rietveld refinements were performed on PXRD data collected on the parent structure, CaCrO₃, and the reduced structure, CaCrO_{2.5}, and are shown in Figures S1 and S2, although there are no new results considering both structures have previously been thoroughly characterized.^{14,11,18} The refined atomic coordinates for CaCrO_{2.5}F_{0.5}, CaCrO₃, and CaCrO_{2.5} are shown in Tables S1-3.

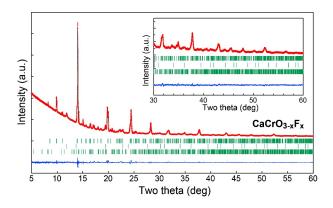

Figure 3. Rietveld refinement against the PXRD data collected from the fluorinated product at room temperature. The observed (red crosses), calculated (black solid line), and difference (blue solid line) plots are shown. The vertical lines represent the fluorinated phase (81%), CaF_2 (12%), and $CaCr_2O_4$ (7%) from top to bottom. The inset shows an enlarged plot in a high 2θ region.

We investigated the change in oxidation state of the chromium ions due to the fluorination of CaCrO₃ by XPS measurements. Figure 4 shows the Cr 2p spectra collected from CaCrO₃ and its fluorinated phase. The Cr $2p^{3/2}$ spectrum of CaCrO₃ is decomposed into three components which could be assigned as Cr^{3+} , Cr^{4+} , and Cr^{6+} with binding energies of 576.38, 578.96, and 582.35 eV, respectively.¹⁹ The trivalent and tetravalent chromium should be derived from CaCr₂O₄ and CaCrO₃, respectively. The atomic ratio of Cr^{3+} to Cr^{4+} estimated from the spectral area is 0.15:0.80, which agrees well with that obtained from the Rietveld analysis (0.17:0.83). The Cr^{6+} species, which were not detected by the SXRD pattern, should be attributed to surface defects. For the oxyfluoride phase, the Cr $2p^{3/2}$ spectrum can be decomposed into Cr^{3+} and Cr^{4+} species in an

atomic ratio of 0.40:0.60. The increase in the Cr^{3+} component is consistent with O-to-F substitution in CaCrO₃. However, the atomic ratio of Cr^{3+} to Cr^{4+} determined by XPS (0.40:0.60) deviates from that estimated from the PXRD analysis (0.50:0.50) assuming the oxyfluoride phase as $CaCrO_{2.5}F_{0.5}$. This discrepancy is likely due to the low signal-to-noise ratio caused by residual C-F species from the fluorinating agent, as seen from the wide-scan spectra in Figure S3.

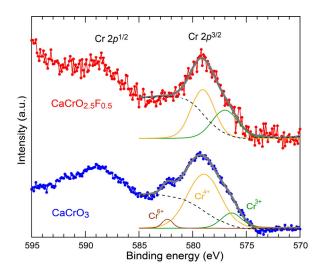

Figure 4. Cr 2p core level photoelectron spectra collected from CaCrO₃ and its fluorinated phase at 300 K. The bold grey and dashed black lines represent the fitting curves and the Shirley background, respectively. The green, orange, and brown solid lines correspond to Cr^{3+} , Cr^{4+} and Cr^{6+} components.

The structure of CaCrO₃ is well studied and adopts the ABO_3 perovskite structure with an orthorhombic distortion due to the small size of the Ca²⁺ ion, ^{18, 20} as compared to the cubic SrCrO₃, and crystallizes in the *Pbnm* space group with lattice parameters a = 5.28912(1) Å, b = 5.31796(1) Å, and c = 7.48677(1) Å. The oxygen vacancies are ordered in CaCrO_{2.5} and CaCrO_{2.67}, creating layers of Cr octahedra and tetrahedra (Figure 5). In CaCrO_{2.67}, the tetrahedral layer occurs every third layer, while in CaCrO_{2.5}, which adopts the brownmillerite structure, it occurs every other layer. The relationship of the octahedral layers to the tetrahedral layers can be understood as the removal of every other infinite chain of oxygen atoms as illustrated in Figure 5. This reduces the coordination of Cr from 6 to 4, and as a result the Cr-O-Cr bond which is nearly linear in the

octahedral layers contracts to form the approximately 109° bond angle found in tetrahedral coordination environments.

Rietveld refinement against the SXRD data of CaCrO_{2.5}F_{0.5} revealed all of the anion sites in the ABO_3 structure were fully occupied upon fluorination and CaCrO_{2.5}F_{0.5} adopted the same space group of the parent compound. The structure symmetry allows anions to occupy two unique sites, namely the sites on the ab plane (X1) and along the c axis (X2). Thus, the existence of a selective fluorine distribution over the anion sites cannot be ruled out. To examine the possible anion ordering of O/F ions, bond-valence-sum (BVS) calculations were carried out on the assumption of three types of fluorine distribution, namely, on X1, X2, or both sites. The BVS values for all atoms are summarized in Table S4. Unfortunately, we could not conclude any types of anion ordering: the BVS values for X1 and X2 sites as well as Ca and Cr sites were consistent with the assumed fluorine distribution patterns.

Figure 6 shows a comparison between the refined crystal structures of CaCrO₃ and CaCrO_{2.5}F_{0.5}. Hereafter, the full anion disordered model is employed to discuss the structure and properties of the oxyfluoride phase, since no selective fluorine distribution was observed. All the Cr-F/O bond lengths are increased from 1.9002(4), 1.911(1), and 1.912(1) Å to 1.935(1), 1.960(4), and 1.919(4) Å (see Figure 6). These behaviors are consistent with the increased Cr^{3+}/Cr^{4+} via the substitution of fluorine for oxygen. The oxyfluoride structure also contains tightened Cr-O/F-Cr bond angles of 156.6(2) and 153.3(3)° as compared to 157.70(8) and 160.13(13)° in the parent structure. A higher degree of the octahedral tilting in the fluorinated perovskite can be accounted for by considering Goldschmidt's tolerance factor (t), which is expressed as $t = (r_A + r_X)/\sqrt{2}(r_B + r_X)$. The r_A , r_B , and r_X are the Shannon's ionic radii of A-site cation, B-site cation, and X-site anion. The calculated t factor of CaCrO_{2.5}F_{0.5} is 0.979, lower than more ideal value of CaCrO₃ (t = 0.994).

Although no examples of *B*-O-*B* bond angle compression upon fluorinating could be found for chromium oxides, LaSrCoFeO₅F contains tightened (Co/Fe)-(O/F)-(Co/Fe) bond angles as compared to the oxygen-stoichiometric oxide LaSrCoFeO₆, both of which adopt the trigonal space group *R*-3*c*. ²³ La_{0.5}Sr_{0.5}FeO_{2.5}F_{0.5}, which crystalizes in the lower symmetry *Pnma* as compared to the oxide which adopts the *R*-3*c* space group, also exhibits similar changes in local coordination around the metal center where the Fe-O-Fe bond angles contract from 167.0(3) to 163. 39(11) and 159.68(13) and the Fe-O bond distances increase from 1.9567(6) to 1.996(4), 1.9996(6), and 1.986(4), upon fluorination. ²⁴

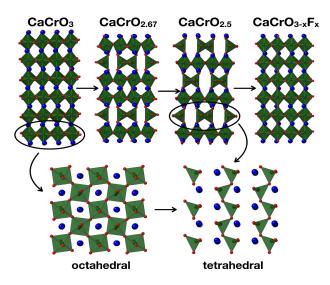

Figure 5. Structures of CaCrO₃, CaCrO_{2.5}, CaCrO_{2.67}, and CaCrO_{3-x}F_x showing the sequences of octahedral and tetrahedral layers as a result of oxygen vacancies where chromium octahedra are shown in green, oxygen atoms in red, and calcium atoms in blue.

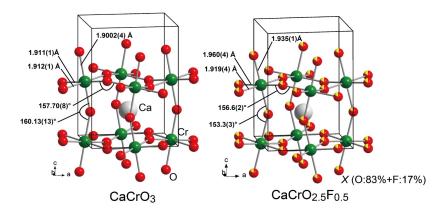

Figure 6: Detailed view of chromium coordination environments in CaCrO₃ and CaCrO_{3-x}F_x where the Cr atoms are shown in green, oxygen atoms in red, and the calcium atoms in white.

Reaction pathway. CaCrO₃ exhibited stepwise fluorination processes as observed in SrCrO₃. 16 However, the important differences between the fluorination mechanisms of CaCrO₃ and SrCrO₃ are as follows, (1) the degree of fluorination for CaCrO₃ is higher than that for SrCrO₃, (2) the formation of two intermediate oxide phases of x = 0.33 and 0.5 are involved, and (3) the plane where oxygen removal and fluorine insertion occurs is (001) for CaCrO₃ but (111) for SrCrO₃. It is apparent that the larger amount of fluorine atoms inserted into CaCrO₃ is attributable not only to its deoxidation capacity but also the reducing power of PVDF. Indeed, the first reduced phase CaCrO_{2.67} is subsequently reduced to CaCrO_{2.5} prior to the fluorination, whereas for the fluorination of SrCrO₃ the first reduced phase SrCrO_{2.8} is not further reduced to SrCrO_{2.75} but directly fluorinated to SrCrO_{2.8}F_{0.2}. The pathway of the oxygen removal and fluorine insertion for CaCrO₃, which is different from those for SrCrO₃, also play an important role in the formation of the highly fluorinated phase CaCrO_{2.5}F_{0.5}. The fluorine insertion mechanism remains an open question. If fluorine atoms simply occupy the oxygen vacant sites, a partial O/F order on the X1 sites is realized. In contrast, fluorine insertion involving migration of apical oxygen, which was observed for layered perovskite compounds, 9, 25 would result in a partial anion order on the X2 sites or the full anion disorder. Mitra et al. investigated the oxygen diffusion pathways in

brownmillerite SrCoO_{2.5} by first-principle calculations, and found that the one-dimensional-ordered oxygen vacant channels in the CoO₄ tetrahedral layers provide the easiest diffusion pathway compared with the directions perpendicular to the vacant channels. ²⁵ Based on this study, it is likely that fluorine also migrates and resides in the CrO₄ tetrahedral layers. Similar to the observed O/F disorder in SrCrO_{2.8}F_{0.2}, the oxygen-deficiency ordered structures do not influence the fluorine sites, perhaps due to the transformation of the Cr coordination from tetrahedron to octahedron which causes the rearrangement of the fluorine atom positions. Similar fluorine migration during fluorination reaction is observed in related perovskite compounds.^{9, 26, 27}

Magnetism. Figure 7 shows the temperature dependence of the magnetic susceptibility χ (= M/H) of CaCrO₃, CaCrO_{2.5}, and CaCrO_{2.5}F_{0.5}, measured under zero-field-cooled (ZFC) and field-cooled (FC) conditions in the temperature range between 5 and 300 K. Anomalies in the magnetic susceptibility of the samples, or the inverse, from the magnetic impurity, CaCr₂O₄, with features at 100 K and 21 K,²⁸ were not observed indicating that CaCr₂O₄ did not significantly impact the susceptibility data. The χ (T) of CaCrO₃ exhibited a sudden increase at T_N = 90 K followed by a divergence between ZFC and FC data. These behaviors can be accounted for by a canted antiferromagnetism.¹⁸ The weak temperature dependence above T_N , which does not obey the Curie-Weiss law, is consistent with the metallic state unambiguously characterized by spectroscopic techniques.^{20, 29} For CaCrO_{2.5}, a small cusp associated with an antiferromagnetic ordering was observed at around 240 K in the ZFC data. The T_N value is close to that determined by the neutron diffraction analysis in Attfield *et al.*.¹⁴ The small anomaly in the susceptibility at T_N is probably due to the decrease in crystallinity during the reductive reaction. In contrast to CaCrO_{2.5}, the χ (T) of CaCrO_{2.5}F_{0.5} is similar to that of CaCrO₃: an antiferromagnetic phase

transition involving spin canting was observed at 110 K. The moderate increase in χ (T) below T_N suggests decreased spin canting angles between Cr ions. It should be noted the high temperature data above T_N cannot be described again by the Curie-Weiss law, although it is somewhat more dependent on temperature than that of CaCrO₃. In fact, the Curie-Weiss fit gave the Curie constant C = 4.17(1) (emu K)/mol, which is unphysically large compared to the value expected from localized magnetic moments of Cr(III) with S = 3/2 and Cr(IV) with S = 1. This behavior suggests that the oxyfluoride has a metallic state like CaCrO₃ or insulating state located near the border between metallic and insulating phases. Unfortunately, even the cold-pressed sample after fluorination was so fragile that electrical measurements could not be performed. In light of the fact that CaCrO₃ resides near the crossover regime from itinerant to localized electron system, ¹⁸ the O-to-F substitution involving a decrease in the Cr-O-Cr tilt angles and lowered pd hybridization via more electronegative fluoride would shift the chromium perovskite to an insulating phase. Similar enhanced Pauli paramagnetic behaviors are observed in early 3d-transition metal insulators such as LaTiO₃ and LaVO₃, ^{30, 31} which are assumed to be near the metal-insulator transition.

The impact of fluorination on the magnetism greatly differs between CaCrO₃ and SrCrO₃.¹⁶ In SrCrO₃ showing a Pauli paramagnetic behavior, replacement of 6.7% of oxygen sites with fluorine induces an antiferromagnetic ordered state with $T_N = 230$ K. In contrast, the fluorination of CaCrO₃ increased the magnetic ordering temperature by only 20 K despite the substitution of 16.7% oxygen for fluorine. The difference can be rationalized by considering variations in Cr–(O/F)–Cr bond angles and the oxidation number of Cr ions. In SrCrO_{2.8}F_{0.2} with a cubic structure, the Cr–(O/F)–Cr bond angles are 180°, which maximizes the superexchange interactions between Cr ions. Moreover, the presence of Cr³⁺ ions via the fluorination insertion contributes to the enhancement of magnetic interactions. As a result, the high Néel ordering temperature is obtained. In

CaCrO_{2.5}F_{0.5}, however, Cr–(O/F)–Cr bond angles both along the c axis and on the ab plane become smaller via fluorination, which weakens the nearest neighbor interactions. Thus, the moderate increase in T_N observed in CaCrO_{2.5}F_{0.5} should result from a competition between the increased octahedral tilting and the enhancement of superexchange interactions involving Cr³⁺ ions.

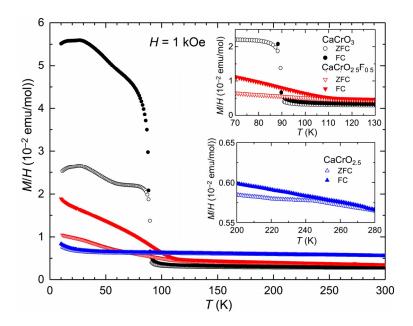

Figure 7. Temperature dependence of the magnetic susceptibility of CaCrO₃, CaCrO_{2.5}, and CaCrO_{2.5}F_{0.5}, measured under zero field cooled and field cooled conditions. The insets highlight anomalies associated with the magnetic phase transitions.

Conclusion

In this study, the new fluorinated phase, CaCrO_{2.5}F_{0.5}, was isolated by reacting CaCrO₃ with PVDF at 400 °C. This reaction proceeds via reduced oxide intermediate phases CaCrO_{2.67} and CaCrO_{2.5}, which can be obtained by reacting CaCrO₃ with g-C₃N₄. The degree of fluorination for CaCrO₃ is higher than that for SrCrO₃, which is attributed to the deoxidation capacity that is more easily maximized by PVDF. The structure of CaCrO_{2.5}F_{0.5} was characterized by synchrotron powder diffraction and adopts the same structure as CaCrO₃ with slightly larger lattice parameters with no

detectable O/F ordering. This structure is supported by the XPS results which reveal Cr³⁺/Cr⁴⁺ ratios close to the expected value of 0.5/0.5 for the proposed CaCrO_{2.5}F_{0.5} structure based on full anion site occupancy. Magnetic measurements reveal that the fluorinated product has an increased spin-canted antimagnetic phase transition temperature as compared to CaCrO₃, which is due to the competition between the increased octahedral tilting and the enhancement of superexchange interactions involving Cr³⁺ ions in the CaCrO_{2.5}F_{0.5} structure.

Supporting Information

The supporting in formation contains plots for the Rietveld refinements and tables atomic positions of CaCrO₃ and CaCrO_{2.5}, a wide scan XPS spectra for CaCrO₃ and CaCrO_{2.5}F_{0.5}, and inverse magnetic susceptibility plots for all three compounds.
