23

1 INTRODUCTION

2

3 In order to maintain harmonious and coordinated cellular society, epithelial tissues are
4 equipped with several homeostatic mechanisms to actively eliminate harmful or
5 suboptimal cells from epithelial layers. Among them, apical cell extrusion plays a
6 vital role in eradication of transformed or apoptotic epithelial cells, especially in
7 vertebrates. For instance, when oncogenic transformation such as Ras, Src, or ErbB2
8 occurs in single cells within epithelia at the initial stage of carcinogenesis, newly
9 emerging transformed cells are often extruded into the apical lumen of an epithelial
10 monolayer; the process of apical extrusion has been observed in cultured cells and
11 zebrafish and mouse *in vivo* model systems [1-6]. When transformed cells alone are
12 present, they stay in a monolayer, suggesting that the presence of surrounding normal
13 cells induces apical extrusion of the transformed cells. In addition to transformed
14 cells, apoptotic cells are also apically eliminated from epithelial monolayers [7].
15 Several lines of evidence suggest that cell-cell communication between the extruded
16 and surrounding cells triggers the process of apical extrusion, however, the underlying
17 molecular mechanisms are still largely unknown.

18 Calcium signaling plays a versatile role in cell-cell communication [8, 9]. In this
19 study, we demonstrate that calcium wave occurs from the extruding cell and
20 propagates across the surrounding cells, which triggers and facilitates the process of
21 cell extrusion.

23

1 **RESULTS**

2

3 **Calcium Wave Triggers and Facilitates Apical Extrusion of RasV12-**

4 **Transformed Cells**

5 To examine whether and how calcium signaling is involved in the intercellular
6 communication between normal and transformed epithelial cells, we have established
7 Madin-Darby canine kidney (MDCK) epithelial cells stably expressing GCaMP6S, a
8 GFP-based intracellular calcium sensor (Figure S1A) [10, 11]. When Myc-RasV12
9 and mCherry were transiently co-expressed in a mosaic manner within a monolayer of
10 MDCK-GCaMP6S cells, RasV12-expressing cells were apically extruded as observed
11 within that of parental MDCK cells (Figure S1B) [1]. Time-lapse analyses revealed
12 that before the apical extrusion started, the calcium level of RasV12 cells was acutely
13 elevated, which then induced an explosive calcium propagation through the
14 surrounding normal cells (Figures 1A, 1C, S1C, S1D, Videos S1). In most cases, this
15 intercellular calcium propagation, hereafter called calcium wave, occurred once
16 around RasV12 cells during the time-lapse observation (Figure S1F). The calcium
17 wave was spread across 3-16 cell-length with a speed of 5-8 $\mu\text{m/s}$ (Figures 1A, S1D,
18 S1E, and S1G). The GCaMP6S fluorescence intensity was comparable between
19 proximal and distal cells (Figures S1D and S1E), suggesting that the calcium wave is
20 not mediated just by simple diffusion of calcium ion from RasV12 cells. This
21 phenomenon occurred in about half of the RasV12 cells during the time-lapse
22 observation (Figure 1E). In contrast, when mCherry alone was expressed, the calcium
23 wave did not occur (Figures 1B, 1D, 1E, and Video S2). The calcium wave was not
24 also observed when RasV12 cells alone were cultured (Video S3). Prior to calcium
25 wave, no obvious morphological changes were observed in either RasV12 cells or the

1 surrounding cells (data not shown). When calcium wave occurred, RasV12 cells were
2 apically extruded more frequently (Figure 1F). The xy-image analysis of apically
3 extruding RasV12 cells demonstrated that just after calcium wave, the area of RasV12
4 cells started to decrease (Figures 1G, 1H, S1H, and S1I). Collectively, these data
5 imply that calcium wave triggers and facilitates apical extrusion of RasV12-
6 transformed cells.

7

8 **IP₃ Receptor, Gap Junction, and Mechanosensitive Calcium Channel TRPC1** 9 **Are Involved in Calcium Wave**

10 Intracellular calcium level can be regulated mainly by three channels: plasma
11 membrane calcium channel, ER calcium channel, and gap junction. Then, we
12 analyzed the effect of various channel inhibitors on calcium wave. Addition of
13 GsMTx (mechanosensitive calcium channel inhibitor), Xestospongins C (Xesto) (IP₃
14 receptor inhibitor), or 18 α -Glycyrrhetic acid (α GA) (gap junction inhibitor)
15 diminished the occurrence of calcium wave (Figures 2A, S2A, and S2B).
16 Furthermore, GsMTx, Xesto, or α GA significantly suppressed apical extrusion of
17 RasV12 cells (Figures 2B and 2C). In contrast, Amlodipine (Am) (L-type calcium
18 channel inhibitor) or Dantrolene (Dan) (ryanodine receptor inhibitor) did not affect
19 calcium wave or apical extrusion (Figures 2A and 2C). Knockdown of IP₃ receptor or
20 gap junction protein connexin 43 suppressed the occurrence of calcium wave (Figures
21 2D-2F and S2B-S2E). These results indicate that mechanosensitive calcium channel,
22 IP₃ receptor, and gap junction regulate these processes. A previous study has shown
23 that during the extrusion of apoptotic cells, actomyosin rings form around the
24 apoptotic cells, thereby producing contractile forces and driving the extrusion process
25 [7]. We found that myosin-II accumulated around RasV12 cells at the final step of

1 apical extrusion (Figures S2F and S2G). Addition of Xesto substantially diminished
2 the myosin ring formation (Figure S2H). Furthermore, the ROCK inhibitor Y27632
3 did not suppress calcium wave, but diminished apical extrusion of RasV12 cells
4 (Figures S2B, S2I, and S2J). These results suggest that calcium wave acts upstream of
5 myosin accumulation. GsMTx suppresses mechanosensitive calcium channels such as
6 transient receptor potential (TRP) C1 and C6 channels. We then established MDCK-
7 GCaMP6S cells stably expressing TRPC1-shRNA or TRPC6-shRNA (Figures S3A
8 and S3B). When RasV12 expression was transiently induced in TRPC1-knockdown
9 epithelia, either calcium wave or apical extrusion was substantially suppressed, but
10 not when induced in TRPC6-knockdown epithelia (Figures 2G, 2H, and S2B). In
11 addition, comparable effect of TRPC1-knockdown was also observed in another
12 experimental condition where MDCK cells stably expressing RasV12 cells were
13 surrounded by TRPC1-knockdown cells (Figures S3C-S3E); TRPC1-knockdown in
14 the surrounding cells did not obviously affect the initial calcium pulse in RasV12
15 cells, but suppressed the following calcium wave propagation in the surrounding cells
16 (Figure S3F and S3G). Knockdown of another mechanosensitive calcium channel
17 Piezo1 did not affect calcium wave or apical extrusion (Figures S3H-S3K). These
18 results indicate that TRPC1 plays a crucial role in the calcium propagation across the
19 surrounding cells, which facilitates apical extrusion. Both IP₃R and TRPC1 are
20 involved in store-operated calcium entry (SOCE), which is mediated by stromal
21 interaction molecule (STIM) 1 that bridges the ER and plasma membranes [12-14].
22 The STIM1 inhibitor SKF96365 suppressed both calcium wave and apical extrusion
23 (Figures 2I, 2J, and S3L), suggesting the involvement of SOCE in these processes.
24

1 **Calcium Wave Precedes Apical Extrusion of RasV12-Transformed Cells in**
2 **Zebrafish Embryos as Well**

3 To demonstrate the prevalence of this phenomenon, we examined the involvement of
4 calcium wave in apical extrusion of transformed cells in zebrafish embryos. In the
5 outermost epithelial monolayer of embryos in late somitogenesis stages, the newly
6 emerging mKO2-RasV12-expressing cells were apically extruded (Figures 3A and
7 3B). We found that prior to apical extrusion, the calcium wave was often propagated
8 from RasV12 cells towards the surrounding epithelial cells (Figures 3C, 3D, S4A,
9 S4B, and Videos S4). In about half of the cases, calcium wave occurred once during
10 the time-lapse observation (Figure S4C) and was spread across 2-7 cell-length (Figure
11 S4D). Upon calcium wave, the area of RasV12 cells abruptly decreased, accompanied
12 by the morphological change into a round shape and the progression of apical
13 extrusion (Figures 3C and 3E), compatible with the phenotypes observed in MDCK
14 cells. When calcium wave occurred, apical extrusion of RasV12 cells was more
15 frequently observed (Figure 3F). In contrast, expression of mKO2 alone did not
16 induce calcium wave (Figure 3D and Video S5). Furthermore, addition of 2-
17 aminoethoxydiphenylborane (2APB), the inhibitor for mechanosensitive calcium
18 channel and IP₃ receptor, significantly suppressed calcium wave and apical extrusion
19 of RasV12 cells (Figures 3A and 3B, and data not shown). Collectively, these data
20 demonstrate that calcium wave is involved in apical elimination of transformed cells
21 in zebrafish embryos as well.

22

23 **Calcium Wave Induces the Polarized Movement of the Surrounding Cells**
24 **toward the Extruding Transformed Cells during Apical Extrusion**

1 Next, we explored the functional significance of calcium wave. While transformed
2 cells are apically extruding, the surrounding cells fill the vacant space, but the
3 underlying molecular mechanism of this process remains enigmatic. We then
4 analyzed the movement of vertices of the surrounding cells that reside inside or
5 outside of calcium wave; the displacement and direction of movement of cell vertices
6 were quantified during apical extrusion (Figures 4A-4C). The vertices inside calcium
7 wave moved further than those outside calcium wave (Figures 4D, 4E, and S5A). In
8 addition, the vertices inside calcium wave moved preferentially toward the extruding
9 transformed cell, whereas those outside calcium wave did not show the polarized
10 movement (Figures 4F and S5B). The polarized movement of the surrounding cells
11 continued until the completion of apical extrusion (Figures S5C and S5D).
12 Furthermore, around the apically extruded cells without calcium wave, the polarized
13 movement was less prominently observed (Figures S5E and S5F). Moreover, TRPC1-
14 knockdown significantly diminished increased and polarized movement of vertices
15 (Figures 4G-4I, S5A, and S5B). The displacement and direction of movement of cell
16 vertices inside calcium wave showed correlation, which was diminished by TRPC1-
17 knockdown (Figure S5G). These data suggest that calcium wave regulates the
18 orchestrated movement of the surrounding cells during apical extrusion.

19

20 **Calcium Wave Facilitates Apical Extrusion by Inducing Actin Rearrangement in** 21 **the Surrounding Cells**

22 Calcium signaling can influence actin cytoskeletons [15, 16]; therefore we examined
23 the localization of F-actin during apical extrusion. We then observed that F-actin was
24 often accumulated in the cytosol and perinuclear region in cells that surrounded
25 apically extruding transformed cells, but not in those surrounding not-extruded

1 transformed cells (Figures 5A, 5B, and S6A). The F-actin accumulation in the cytosol
2 and perinuclear region was observed in more than half of the cells that calcium wave
3 had reached (Figure S6B). GsMTx treatment or TRPC1-knockdown significantly
4 suppressed this actin phenotype (Figures 5C-5F). The actin phenotype was also
5 diminished by the pan PKC inhibitor BIM-1 or the Ca²⁺-dependent conventional PKC
6 inhibitor Go6976, or the IP₃ receptor inhibitor Xesto (Figures 5G-5K). These data
7 suggest that calcium signaling acts upstream of the actin rearrangement during apical
8 extrusion. Previous studies have shown that increased intracellular calcium can induce
9 perinuclear actin accumulation via inverted formin 2 (INF2) [15, 16]. Indeed, INF2-
10 knockout profoundly diminished the actin phenotype around the apically extruding
11 cells (Figures 6A-6D, and S6C). In addition, INF2-knockout significantly suppressed
12 frequency of apical extrusion (Figure 6E). Even when apical extrusion of transformed
13 cells occurred within INF2-knockout epithelia, the process of apical extrusion was
14 prolonged (Figure 6F). Moreover, the polarized movement, but not the displacement,
15 of the surrounding cells was significantly inhibited by INF2-knockout (Figures 6G
16 and S6D). Collectively, these results imply that calcium wave facilitates apical
17 extrusion, at least partly, by inducing actin rearrangement in the surrounding cells.

18

19 **Calcium Wave Also Plays a Positive Role in Apical Extrusion of Apoptotic Cells**

20 Previous studies have demonstrated that cells undergoing apoptosis are apically
21 extruded from the epithelial layer [7, 17]. Thus, we examined whether calcium wave
22 is also involved in apoptosis-mediated cell extrusion. Expression of the pro-apoptotic
23 factor caspase-8 induced apoptosis within the MDCK epithelia (Figure 7A). At 15-70
24 min after caspase-8 expression, apoptotic cells were apically extruded from the
25 epithelial layer. We observed that after induction of caspase-8 expression,

1 intracellular calcium was often elevated in a caspase-8-expressing cell, which was
2 followed by explosive calcium wave across the surrounding cells (Figure 7B and
3 Video S6). The calcium wave was observed in about 80% of caspase-8-expressing
4 cells (Figure 7D). In contrast, calcium wave did not occur when mCherry alone was
5 expressed (Figures 7C and 7D). Most of caspase-8-expressing cells eventually
6 underwent apical extrusion irrespective of calcium wave, but upon calcium wave the
7 extrusion time was substantially shortened after caspase-8 induction compared with
8 when calcium wave did not occur (Figure 7E), suggesting that calcium wave
9 facilitates the process of apoptosis-mediated cell extrusion, though not absolutely
10 required for the occurrence of extrusion. Addition of GsMTx, Xesto, or α GA
11 suppressed the frequency of calcium wave and prolonged the extrusion time after
12 caspase-8 expression (Figures 7G and 7H), implying that common molecular
13 machineries are, at least partly, involved in extrusion of both transformed and
14 apoptotic cells. The vertex analyses showed that the vertices of cells inside calcium
15 wave moved further and more preferentially toward apoptotic cells during apical
16 extrusion (Figures 7I and 7J). Furthermore, the cytosolic and perinuclear
17 accumulation of F-actin was frequently observed in the cells surrounding extruding
18 apoptotic cells (Figures 7K and 7L). Moreover, calcium wave was also observed
19 around laser-ablated dying cells in zebrafish embryos (Figure S7A and Video S7),
20 which induced comparable effects on the movement of the surrounding cells (Figures
21 S7B-S7D). Collectively, these results indicate that calcium wave also plays a positive
22 role in apical extrusion of apoptotic cells.

23

24

1 **DISCUSSION**

2 In this study, we demonstrate that calcium wave promotes apical extrusion of
3 transformed cells in both mammalian cultured cells and zebrafish embryos. In both
4 experimental conditions, the calcium level is first elevated in transformed cells, and
5 then calcium wave propagates across the surrounding cells. Calcium wave also plays
6 a positive role in extrusion of apoptotic cells, and comparable molecular mechanisms
7 are involved in both extrusion processes. However, apoptotic cells less depend on
8 calcium wave for extrusion, and much more intense actomyosin rings are formed
9 around apoptotic cells, compared with those around transformed cells (data not
10 shown). This suggests the presence of additional, distinct mechanism(s) for apoptosis-
11 mediated extrusion.

12 Addition of the IP₃ receptor inhibitor Xestospongin C or knockdown of IP₃
13 receptor suppresses both the initial calcium elevation in RasV12-transformed cells
14 and the following calcium propagation across the surrounding cells. When RasV12
15 cells (with intact IP₃ receptor) are surrounded by IP₃ receptor-knockdown cells,
16 calcium propagation is still suppressed, indicating that IP₃ receptor in both Ras cells
17 and the surrounding cells is required for calcium wave. Furthermore, addition of the
18 gap junction inhibitor α GA or knockdown of connexin 43 does not affect the initial
19 calcium elevation in RasV12 cells, but blocks calcium propagation, demonstrating an
20 essential role of gap junction in the latter process.

21 Either GsMTx treatment or TRPC1-knockdown suppresses both elevation of
22 calcium in RasV12 cells and the following calcium propagation. Together with the
23 data that the STIM1 inhibitor suppresses calcium wave, store-operated calcium entry
24 (SOCE) plays a role in calcium propagation. In SOCE, Ca²⁺ is first released from the
25 ER in response to activation of IP₃ receptor, which causes the conformational change

1 of ER-residing STIM1 and its recruitment into the plasma membrane that brings ER
2 closer to plasma membrane. STIM1 then activates TRPC1 channel, resulting in the
3 further elevation of the intracellular Ca^{2+} level [12-14]. In these processes, IP_3 is the
4 key upstream regulator. As shown in Figures S1D and S1E, the calcium propagation
5 is not caused just by simple diffusion of calcium ion, suggesting that other second
6 messenger(s) may be also propagated through gap junction. It is thus plausible that
7 during calcium wave, IP_3 is propagated through gap junction as proposed in another
8 type of intercellular calcium wave [18, 19]. In addition, regarding the functional mode
9 of TRPC1, TRPC1 might be activated not only by SOCE, but also by membrane
10 stretching. Upon apical extrusion, non-cell-autonomous activation of myosin-II occurs
11 in RasV12-transformed cells [1]. Similarly, actomyosin contraction is induced in
12 apoptotic cells at the initial step of cell extrusion [7, 17, 20]. Then, contractile forces
13 generated in extruding cells promote membrane stretching of the neighboring cells
14 [21]. Thus, activity of TRPC1 may be also provoked by the stretching of the
15 surrounding cells. These possibilities need to be further examined in future studies.

16 Intercellular calcium wave has been observed under various conditions [9]. In
17 particular, the wound scratch within a cell monolayer induces calcium propagation
18 from the wound, which resembles the cell extrusion-mediated calcium wave in certain
19 aspects. For example, both processes involve the coordinated cell movement after
20 calcium wave. In addition, IP_3 receptor and gap junction are involved in the
21 propagation of calcium [19, 22, 23], though the involvement of gap junction in
22 wound-mediated calcium wave remains controversial [22, 24, 25]. However, there are
23 some differences between these two processes. First, the velocity of extrusion-
24 mediated calcium wave is 5-8 $\mu\text{m/s}$, whereas that of wound-mediated calcium wave is
25 10-30 $\mu\text{m/s}$ [24, 26]. Second, soluble factors from the wounded cells play a role in

1 wound-mediated calcium wave [22, 24, 27]. Third, upon wound-mediated calcium
2 wave, perinuclear accumulation of actin filaments abruptly occurs, a process called
3 calcium-mediated actin reset (CaAR) [15]. But, the mode of perinuclear F-actin
4 accumulation seems different between wound healing and apical extrusion. In
5 particular, during wound healing CaAR appears quite temporarily for just 2 min,
6 whereas during apical extrusion perinuclear accumulation of F-actin can stay for
7 much longer duration after calcium wave. Thus, the two types of calcium wave are
8 governed by overlapping, but distinct molecular mechanisms.

9 Calcium signaling-mediated actin rearrangement promotes polarized movement
10 of the surrounding cells during apical extrusion. However, the cytosolic and
11 perinuclear F-actin do not show obvious planar-polarized localization. Thus, at
12 present it is still unknown how the flow of calcium wave from extruding cells is
13 converted into the polarized movement of the surrounding cells. Upon calcium wave,
14 certain molecules or structures might be aligned or polarized toward the extruding
15 cell; the functional roles of calcium wave remain to be further elucidated.

16 In summary, we demonstrate that calcium wave promotes apical extrusion of
17 transformed and apoptotic cells in mammalian cultured cells and zebrafish embryos.
18 Hence, calcium wave is an evolutionarily conserved, general regulatory mechanism of
19 cell extrusion.

7 extrusion (B and C). Doxycycline-inducible MDCK-pTRE3G Myc-RasV12 cells
8 stained with CMTPX (red) were co-cultured with MDCK-GCaMP6S cells at a ratio of
9 1:50 in the presence of doxycycline and the indicated inhibitor for 24 h. The

10 following inhibitors suppress the respective calcium channels: Am (Amlodipine), L-
11 type calcium channel; GsMTx, mechanosensitive calcium channel; Dan (Dantrolene),
12 ryanodine receptor; Xesto (Xestospongine C), IP₃ receptor; α GA (18 α -Glycyrrhetic
13 acid), GAP junction. (A) n=30, 51, 33, 32, 29, and 33 cells from three independent
14 experiments. $^{\dagger}P < 0.05$, $^{\ddagger}P < 0.01$, $^{\text{+++}}P < 0.001$ (chi-square test). (B) Fluorescence
15 images of xz sections of Myc-RasV12 cells surrounded by normal cells. Scale bars,
16 20 μm . (C) Data are mean \pm SD from three independent experiments. $n \geq 50$ cells for
17 each experimental condition. $*P < 0.05$, $***P < 0.001$ (two-tailed Student's *t*-tests).

18 (D) Effect of IP₃ receptor (IP₃R)-shRNA expression on the IP₃R mRNA level in
19 MDCK-GCaMP6S cells. Data are mean \pm SD from three independent experiments.
20 $*P < 0.05$, $**P < 0.01$ (two-tailed Student's *t*-tests).

21 (E and F) Effect of IP₃R-knockdown on calcium wave. IP₃R was knocked down in
22 both RasV12 and the surrounding cells in (E) or only in the surrounding cells in (F).

23 (E) Expression of Myc-RasV12 was transiently induced in MDCK-GCaMP6S or
24 MDCK-GCaMP6S IP₃R-shRNA1 cells. n=30 and 52 cells from three independent
25 experiments. $^{\dagger}P < 0.05$ (chi-square test). (F) MDCK-pTRE3G Myc-RasV12 cells

1 were surrounded by MDCK-GCaMP6S or MDCK-GCaMP6S IP₃R-shRNA1 cells.

2 n=30 and 60 cells from three independent experiments. [†]*P* < 0.05 (chi-square test).

3 The comparable effect of IP₃R-knockdown on calcium wave was also observed using

4 IP₃R-shRNA2 cells. Note that the expression level of IP₃R is not influenced by the

5 RasV12 expression (data not shown).

6 (G and H) Effect of the transient receptor potential C1 (TRPC1)- or C6 (TRPC6)-

7 knockdown on calcium wave (G) or apical extrusion (H). (G) n=30, 31, 32, 31, and 32

8 cells from three independent experiments. ^{††}*P* < 0.01 (chi-square test). (H) Data are

9 mean ± SD from three independent experiments. n ≥ 50 cells for each experimental

10 condition. ^{**}*P* < 0.01, ^{***}*P* < 0.001 (two-tailed Student's *t*-test). In the following

11 experiments, for TRPC1-knockdown cells, MDCK-GCaMP6S TRPC1-shRNA1 cells

12 were used if not indicated.

13 (I and J) Effect of the STIM1 inhibitor SKF96365 (SKF) on calcium wave (I) or

14 apical extrusion (J). (I) n=30 and 29 cells from three independent experiments. [†]*P* <

15 0.05 (chi-square test). (J) Data are mean ± SD from three independent experiments.

16 n ≥ 50 cells for each experimental condition. ^{***}*P* < 0.001 (two-tailed Student's *t*-test).

17 See also Figure S2 and S3.

18

19 **Figure 3. Calcium Wave Occurs Prior to Apical Extrusion in Zebrafish Embryos**
20 **as Well**

21 (A) Immunofluorescence images of zebrafish embryos in the absence or presence of

22 2-aminoethoxydiphenylborane (2APB), the inhibitor for mechanosensitive calcium

23 channel and IP₃ receptor.

1 (B) Quantification of apical extrusion. Data are mean \pm SD from three independent
2 experiments. $n \geq 50$ cells for each experimental condition. $*P < 0.05$ (two-tailed
3 Student's *t*-tests).

4 (C) Time-lapse images of calcium wave from an extruding mKO2-RasV12-
5 expressing cell in the enveloping layer of zebrafish embryos. Images were captured
6 every 10.8 s.

7 (D) Frequency of calcium wave around mKO2-expressing cells. $n=30$ and 86 cells
8 from 15 independent experiments. $^{\dagger}P < 0.05$ (chi-square test).

9 (E) Reduction of area of an extruding mKO2-RasV12 cell after calcium waves. The
10 comparable area change of RasV12 cells after calcium wave has been observed in a
11 well-reproducible manner.

12 (F) Correlation between calcium wave and apical extrusion. $n=58$ and 28 cells from
13 10 independent experiments. $^{\dagger\dagger\dagger}P < 0.001$ (chi-square test).

14 (A and C) Scale bars, 50 μm .

15 See also Figure S4, Videos S4 and S5.

16

17 **Figure 4. Calcium Wave Induces the Polarized Movement of the Surrounding**
18 **Cells toward the Extruding Transformed Cells**

19 (A-D) Analyses of vertices of the surrounding cells that reside inside or outside of
20 calcium wave during apical extrusion of Myc-RasV12-expressing cells. (A)
21 Representative images of an extruding Myc-RasV12 cell stained with a blue
22 fluorescence dye CMAC (left), calcium wave (center), and the far-red silicon
23 rhodamine (SiR)-actin fluorescence probe (right). MDCK-pTRE3G Myc-RasV12
24 cells were co-cultured with MDCK-GCaMP6S cells with the SiR-actin probe. After
25 incubation with doxycycline for 10 h, we performed time-lapse observation for 16 h.

1 Images are extracted from a representative time-lapse analysis. (B) Reduction of area
2 of an extruding Myc-RasV12 cell after calcium wave. Time 0 denotes the occurrence
3 of calcium wave. 'Start' represents the start of apical extrusion when the area
4 reduction starts, whereas 'End' indicates the completion of apical extrusion when the
5 area becomes zero. (C) Schematic diagram for the displacement and direction of
6 movement of cell vertices during apical extrusion. The yellow arrow denotes the
7 vertex movement from Start to End. Arrow angle (θ) is formed between the End and
8 Start vertices, and the centroid of the extruding RasV12 cell. Arrow length and angle
9 indicate the displacement and direction of the vertex movement, respectively. (D)
10 Representative images of SiR-actin (Start). The white line indicates the border of
11 calcium wave. The red dot (Border-In vertex) or blue dot (Border-Out vertex) is one-
12 row inside or outside vertex from the border of calcium wave, respectively.
13 (E) Quantification of the displacement of the vertex movement. The displacement of
14 each vertex movement is depicted as a dot. Data are mean \pm SD. n=88 and 87 from
15 three independent experiments. * P <0.05 (unpaired t -tests).
16 (F) Quantification of the direction of the vertex movement. Arrow angle (θ) was
17 classified into 4 categories (0-45, 45-90, 90-135, 135-180), and the ratio of each
18 category was quantified. Data are mean \pm SD from three independent experiments.
19 n=88 and 87 from three independent experiments. ** P <0.01 (unpaired t -tests).
20 (G) Representative images of SiR-actin (Start). Images are extracted from a
21 representative time-lapse analysis. MDCK-pTRE3G Myc-RasV12 cells stained with
22 CMAC were co-cultured with MDCK-GCaMP6S or MDCK-GCaMP6S TRPC1-
23 knockdown cells with the far-red silicon rhodamine (SiR)-actin fluorescence probe.
24 After incubation with doxycycline for 10 h, we performed time-lapse observation for
25 16 h with doxycycline. Most of the analyzed Border-Inside vertices (red dots) reside

1 at 3-6 cells away from RasV12 cells; thus, comparable areas are selected for the
2 analysis of TRPC1-knockdown (KD) cell vertices (green dots).
3 (H) Quantification of the displacement of the vertex movement. The displacement of
4 each vertex movement is depicted as a dot. Data are mean \pm SD. n=234, 397, and 233
5 from three independent experiments. * P <0.05, ** P <0.01 (unpaired t -tests).
6 (I) Quantification of the direction of the vertex movement. Data are mean \pm SD from
7 three independent experiments. n= 205, 220, and 362 from three independent
8 experiments. * P <0.05 (unpaired t -tests).
9 (A, D, and G) Scale bars, 50 μ m.
10 See also Figure S5.

11

12 **Figure 5. F-Actin Is Accumulated in the Cytosol and Perinuclear Region in Cells**
13 **that Surround Apically Extruding RasV12-Transformed Cells**

14 (A) Fluorescence images of F-actin (red) with Alexa-Fluor-568-conjugated phalloidin
15 in the mixed culture of MDCK and MDCK-pTRE3G Myc-RasV12 cells in the
16 absence or presence of doxycycline (DOX). Myc-RasV12 cells stained with CMFDA
17 (green) were surrounded by normal MDCK cells. The status of Myc-RasV12 cells is
18 not-extruded (left and center) or extruding (right).
19 (B) Quantification of the actin phenotype. The actin phenotype indicates the condition
20 where F-actin accumulates at both cytosol and perinuclear region. Cells directly
21 contacting Myc-RasV12 cells are examined. Data are mean \pm SD from three
22 independent experiments. n= 364, 293, and 377 from three independent experiments.
23 ** P <0.01 (two-tailed Student's t -tests).
24 (C-K) Effect of the mechanosensitive calcium channel inhibitor GsMTx (C and D),
25 TRPC1-knockdownon (E and F), the PKC inhibitor BIM-1 or Go6976 (G-I), or the

1 IP₃ receptor inhibitor Xesto (Xestospongin C) (J and K) on the actin phenotype.
2 MDCK-pTRE3G Myc-RasV12 cells stained with CMAC (blue) (C-F) or CMFDA
3 (green) (G-K) were surrounded by MDCK-GCaMP6S cells.
4 (D, F, H, I, and K) Quantification of the actin phenotype. Data are mean ± SD from
5 three independent experiments. (D) n= 248 and 197 from three independent
6 experiments. ** $P < 0.01$ (two-tailed Student's *t*-tests). (F) n= 341 and 507 from three
7 independent experiments. *** $P < 0.001$ (two-tailed Student's *t*-tests). (H) n= 362 and
8 325 from three independent experiments. * $P < 0.05$ (two-tailed Student's *t*-tests). (I) n=
9 312 and 65 from three independent experiments. ** $P < 0.01$ (two-tailed Student's *t*-
10 tests). (K) n= 226 and 157 from three independent experiments. * $P < 0.05$ (two-tailed
11 Student's *t*-tests).

12 (A, C, E, G, and J) Scale bars, 10 μm.

13 See also Figure S6.

14

15 **Figure 6. Effect of Knockout of Inverted Formin 2 (INF2) in the Surrounding**
16 **Cells on the Actin Phenotype**

17 (A and B) Establishment of MDCK-INF2-knockout cells. (A) MDCK-INF2-knockout
18 mutant No.1 and No.2 are homologous recombination of the *INF2* gene. (B)
19 Expression of INF2 was examined by western blotting with the indicated antibodies.
20 Lane 1: MDCK; Lane 2: MDCK-INF2-knockout mutant No.1 (homo); Lane 3:
21 MDCK-INF2-knockout mutant (hetero); Lane 4: MDCK-INF2-knockout mutant No.2
22 (homo). In the following experiments, for INF2-knockout cells, MDCK-GCaMP6S
23 INF2-knockout mutant No.1 cells were used if not indicated.

1 (C) Effect of knockout of inverted formin 2 (INF2) in the surrounding cells on the
2 actin phenotype. MDCK-pTRE3G Myc-RasV12 cells stained with CMFDA (green)
3 were surrounded by MDCK or MDCK-INF2-knockout cells. Scale bars, 10 μ m.

4 (D) Quantification of the actin phenotype. Cells directly contacting extruding Myc-
5 RasV12 cells were examined. Data are mean \pm SD from three independent
6 experiments. n= 337 and 282 from three independent experiments. *** P <0.001 (two-
7 tailed Student's t -tests).

8 (E) Effect of knockout of INF2 in the surrounding cells on apical extrusion of Myc-
9 RasV12 cells. Data are mean \pm SD from three independent experiments. $n \geq 50$ cells
10 for each experimental condition. ** P <0.01, *** P <0.001 (two-tailed Student's t -tests).

11 (F) Effect of knockout of INF2 in the surrounding cells on area reduction of extruding
12 Myc-RasV12 cells. Area reduction was examined for Myc-RasV12 cells that were
13 surrounded by MDCK-GCaMP6S (red line: n=7) or MDCK-GCaMP6S INF2-
14 knockout cells (blue line: n=4). Time 0 denotes the point where the area reduction
15 starts.

16 (G) Quantification of the direction of the vertex movement. Data are mean \pm SD from
17 three independent experiments. n= 220, 193, and 176 from three independent
18 experiments. * P <0.05, ** P <0.01 (unpaired t -tests).

19 See also Figure S6.

20

21 **Figure 7. Calcium Wave Facilitates the Process of Apoptosis-Induced Cell**

22 **Extrusion**

23 (A) Fluorescence images of xz sections of an mCherry- or mCherry-caspase-8-
24 expressing cell.

1 (B and C) Time-lapse analyses of calcium imaging of caspase-8-expressing cells
2 surrounded by normal epithelial cells. mCherry-caspase-8 (B) or mCherry (C) was
3 transiently expressed in a monolayer of MDCK-GCaMP6S cells. The GFP intensity
4 of GCaMP6S is quantified in an mCherry-expressing cell (red line) or surrounding
5 cells (green line). For surrounding cells, the average GFP intensity of cells directly
6 contacting the mCherry-expressing cell is calculated. Values are expressed as a ratio
7 relative to that at time 0.

8 (D) Frequency of calcium wave around caspase-8 cells. $n=57$ and 49 cells from three
9 independent experiments. $^{\dagger\dagger\dagger}P < 0.001$ (chi-square test).

10 (E) Quantification of extruding time of apoptotic cells. Data are mean \pm SD from
11 three independent experiments. $n=11$ and 26 from three independent experiments.
12 $^{***}P < 0.001$ (unpaired t -tests).

13 (F) Reduction of area of an apically extruding caspase-8 cell after calcium wave.
14 Time 0 denotes the occurrence of calcium wave.

15 (G and H) Effect of various calcium channel inhibitors on calcium wave (G) or
16 extrusion time of apoptotic cells (H). The following inhibitors are used: Z-VAD-
17 FMK, pan-caspase inhibitor; GsMTx, mechanosensitive calcium channel inhibitor;
18 Xestospongine C (Xesto), IP_3 receptor inhibitor; α GA (18 α -Glycyrrhetic acid), GAP
19 junction inhibitor. (G) $n=33, 58, 74, 61,$ and 141 cells from three independent
20 experiments. $^{\dagger\dagger}P < 0.01, ^{\dagger\dagger\dagger}P < 0.001$ (chi-square test). (H) Data are mean \pm SD.
21 $n=37, 63, 46,$ and 73 cells from three independent experiments. $^{**}P < 0.01$ (unpaired t -
22 tests).

23 (I) Quantification of the displacement of the vertex movement. The displacement of
24 each vertex movement is depicted as a dot. Data are mean \pm SD. $n=46$ and 28 from
25 three independent experiments. $^{**}P < 0.01$ (unpaired t -tests).

1 (J) Quantification of the direction of the vertex movement. Data are mean \pm SD from
2 three independent experiments. n= 101 and 62 from three independent experiments.
3 **** P <0.01** (unpaired t -tests).

4 (K) Fluorescence images of the actin phenotype (red) around extruding iRFP/caspase-
5 8-expressing cells. iRFP alone or iRFP and caspase-8 were transiently expressed in a
6 monolayer of MDCK cells.

7 (L) Quantification of the actin phenotype. Cells directly contacting iRFP-expressing
8 cells were examined. Data are mean \pm SD from three independent experiments. n=
9 112 and 135 cells from three independent experiments. **** P <0.01** (Student t -tests).

10 Scale bars, 20 μ m (A), 50 μ m (B and C), and 10 μ m (K).

3 **LEAD CONTACT AND MATERIALS AVAILABILITY**

4 Further information and requests for resources and reagents should be directed to and
5 will be fulfilled by the Lead Contact, Yasuyuki Fujita (yasu@igm.hokudai.ac.jp).

6 This study did not generate new unique reagents. There are no restrictions on any data
7 or materials presented in this paper.

8

9 **EXPERIMENTAL MODEL AND SUBJECT DETAILS**

10

11 **Animals**

12 Wild-type and the Tg[krt4:GAL4] line were used in this study. The Tg[krt4:GAL4]
13 line was kindly provided by K. Kawakami and H. Wada [30]. All zebrafish
14 experiments were performed with the approval of the Animal Studies Committees in
15 the Nara Institute of Science and Technology, Gunma University, and/or Kyushu
16 University.

17

18 **Cell Lines**

19 MDCK cell lines were used in this study. The parental MDCK cell was a gift from W.
20 Birchmeier. Mycoplasma contamination was regularly tested for all cell lines in use
21 using a commercially available kit (MycoAlert, Lonza). MDCK and MDCK-pTRE3G
22 Myc-RasV12 cells were cultured as previously described [5]. To establish MDCK-
23 GCAMP6S or MDCK-pTRE3G Myc-RasV12 GCAMP6S cells, MDCK or MDCK-
24 pTRE3G Myc-RasV12 cells were transfected with PB-EF1-MCS-IRES-Neo-
25 GCaMP6S by nucleofection (Nucleofector™ 2b Kit L, Lonza), followed by selection

1 in medium containing 800 $\mu\text{g ml}^{-1}$ of G418 (Geneticin, Gibco). MDCK-GCaMP6S
2 cells stably expressing IP₃R-shRNA, connexin 43-shRNA, TRPC1-shRNA, TRPC6-
3 shRNA, or Piezo1-shRNA in a tetracycline-inducible manner were established as
4 follows; IP₃R-shRNA oligonucleotides (IP₃R-shRNA1: 5'-
5 CCGGGCAGATCTTCAAGTTGTTACTCGAGTAACAACCTGAAGATCTGCTTT
6 TTG-3' and 5'-
7 AATTCAAAAAGCAGATCTTCAAGTTGTTACTCGAGTAACAACCTGAAGAT

 14 AATTCAAAAATACAAATTTGGGCTAGAGATACTCGAGTATCTCTAGCCCA
 15 AATTTGTA-3' or Piezo1-shRNA2: 5'-
 16 CCGGCACCGTCAAAGGCTACTATGACTCGAGTCATAGTAGCCTTTGACGG
 17 TGTTTTT-3' and 5'-
 18 AATTCAAAAACACCGTCAAAGGCTACTATGACTCGAGTCATAGTAGCCTT
 19 TGACGGTG-3') were cloned into the AgeI/EcoRI site of pLKO-TetOn-puro
 20 (Addgene). MDCK-GCaMP6S cells were transfected with pLKO-TetOn IP₃R-
 21 shRNA, connexin 43-shRNA, TRPC1-shRNA, TRPC6-shRNA, or Piezo1-shRNA,
 22 followed by selection in medium containing 500 ng ml⁻¹ of puromycin (Sigma-
 23 Aldrich). For MDCK-pTRE3G Myc-RasV12 cells, 1 µg ml⁻¹ of doxycycline (Sigma-
 24 Aldrich) was used to induce RasV12 expression. For MDCK-GCaMP6S-pLKO-
 25 TetOn IP₃R-shRNA, connexin 43-shRNA, TRPC1-shRNA, TRPC6-shRNA, or

1 Piezo1-shRNA cells, 2 $\mu\text{g ml}^{-1}$ of tetracycline (Sigma-Aldrich) was used to induce
2 expression of the respective shRNA. MDCK-GCaMP6S-pLKO-TetOn IP₃R-shRNA,
3 connexin 43-shRNA, TRPC1-shRNA, TRPC6-shRNA, or Piezo1-shRNA cells were
4 incubated with tetracycline for 48 h to induce sufficient knockdown prior to co-
5 incubation with MDCK-pTRE3G Myc-RasV12 cells. To establish MDCK cells stably
6 expressing MLC-GFP, MDCK cells were transfected with pEGFP-N1-MLC using
7 Lipofectamine™ 2000 (Life Technologies) according to the manufacturer's
8 instructions, followed by selection in medium containing 800 $\mu\text{g ml}^{-1}$ of G418.

9

10 **METHODS DETAILS**

11

12 **Antibodies, plasmids, and materials**

13 The following antibodies were used in this study: mouse anti- β -actin (MAB1501R
14 clone C4) antibody from Millipore, rabbit anti-INF2 antibody (20466-1-AP) from
15 Proteintech, and rabbit anti-cleaved caspase-3 (Asp175) antibody from Cell Signaling.
16 Alexa-Fluor-568- and -647-conjugated phalloidin (Life Technologies) were used at
17 1.0 U ml^{-1} . Hoechst 33342 (Life Technologies) was used at a dilution of 1:5,000 for
18 fluorescence and scratch assay. pGP-CMV-GCaMP6S and iRFP-C1 were obtained
19 from Addgene. To construct pcDNA4-TO-mCherry-caspase-8, the cDNA of caspase-
20 8 was excised from pcDNA3-HA-caspase-8 (gift from H. Nakano) and inserted into
21 the HindIII/NotI site of pcDNA4-TO-mCherry [2]. To generate PB-EF1-MCS-IRES-
22 Neo-GCaMP6S, the cDNA of GCaMP6S was excised from pGP-CMV-GCaMP6S
23 and cloned into the BamHI/EcoRI site of pPB-TRE3G-MCS-CEH-rtTA3-IP [5].
24 pEGFPN1-MLC (myosin-II light chain) was a gift from H. Hosoya [28]. The
25 inhibitors Amlodipine besylate (25 μM), α -Glycyrrhetic acid (50 μM), and Go6976

1 (10 μM) were from Sigma-Aldrich. GsMTx (10 μM) was from PEPTIDE
2 INSTITUTE, Inc. Xestospongins C (20 μM) and Ionomycin (2 μM) were from
3 FUJIFILM WAKO Pure Chemical Corporation. Dantrolene (10 μM) and SKF96365
4 (50 μM) were from Santa Cruz Biochemistry. 2-aminoethoxydiphenylborane (2APB)
5 (6.25 μM) was from Sigma-Aldrich. Thapsigargin (10 μM) was from Cayman
6 CHEMICAL. Y27632 (20 μM), Bisindolylmaleimide (BIM)-I (10 μM), and Z-VAD-
7 FMK (100 μM) were from Calbiochem. The Lucifer Yellow Probe (25 μM) for
8 scratch assay was obtained from Molecular probes. Type I collagen (Cellmatrix®
9 Type I-A) was obtained from Nitta Gelatin and was neutralized on ice to a final
10 concentration of 2 mg ml⁻¹ according to the manufacturer's instructions. The
11 CellTracker dyes CMTPX (red), CMFDA (green), and CMAC (blue) (Life
12 Technologies) were used according to the manufacturer's instructions. The SiR-actin
13 Kit (far-red silicon rhodamine (SiR)-actin fluorescence probe) was obtained from
14 SPIROCHROME for live imaging of F-actin and was used according to the
15 manufacturer's instructions.

16

17 **Cell culture**

18 For the induction of caspase-8, MDCK or MDCK-GCaMP6S cells were transfected
19 with pcDNA4-TO-mCherry-caspase-8 or co-transfected with pcDNA3-HA-caspase-8
20 and iRFP-C1 using Lipofectamine™ 2000. For analyses of calcium wave, apical
21 extrusion, and actin phenotype, cells were incubated with the indicated inhibitor for
22 24 h. For scratch assay, cells were pre-incubated in medium containing Lucifer yellow
23 and Hoechst for 15 min. At 10 min after scratching, they were observed by the
24 Olympus FV1000 system.

25

1 **CRISPER/Cas9-based generation of INF2-knockout cells**

2 Guide sequences of INF2 single-guide RNA (sgRNA) targeting *Canis INF2* were
3 designed on exon 1, as described previously [5]. INF2 sgRNA sequence (5'-
4 CCCTCTGTGGTCAACTACTCGG-3') was introduced into the pCDH-EF1-Hygro-
5 sgRNA vector. First, MDCK cells were infected with lentivirus carrying pCW-Cas9
6 and cultured in medium containing 500 ng ml⁻¹ of puromycin. Tetracycline-inducible
7 MDCK-Cas9 cells were pre-incubated with 2 µg ml⁻¹ of tetracycline and transfected
8 with pCDH-EF1-INF2 sgRNA by nucleofection, followed by selection in medium
9 containing 200 µg ml⁻¹ of hygromycin. Indels on the INF2 exon in each monoclonal
10 were analysed by direct sequencing using following primers (5'-
11 GGAAAGGACGAAACACCGCCCTCTGTGGTCAACTACTGTTTTAGAGCTAG
12 AAATAGC-3' and 5'-
13 GCTATTTCTAGCTCTAAAACAGTAGTTGACCACAGAGGGCGGTGTTTCGTC
14 CTTTCC-3'). To generate INF2-deleted cells carrying GCaMP6S, PB-EF1-MCS-
15 IRES-Neo-GCaMP6S was introduced into the INF2-deleted cells by nucleofection,
16 followed by selection in medium containing 800 µg ml⁻¹ of G418.

17

18 **Immunofluorescence and western blotting**

19 For immunofluorescence, MDCK-pTRE3G Myc-RasV12 cells were mixed with
20 MDCK, MDCK-GCaMP6S, MDCK-INF2-knockout, MDCK-GCaMP6S-pLKO-
21 TetOn TRPC1-shRNA, TRPC6-shRNA, or Piezo1-shRNA cells at a ratio of 1:50 and
22 plated onto collagen-coated coverslips as previously described [1]. The mixture of
23 cells was incubated for 8–12 h, followed by doxycycline treatment for 16 h, except for
24 analyses of apical extrusions that were examined after 24 h of doxycycline addition.
25 Cells were fixed with 4% paraformaldehyde (PFA) in PBS and permeabilized as

1 previously described [2]. Primary antibodies were used at 1:100, and all secondary
2 antibodies were used at 1:200. Immunofluorescence images were analyzed with the
3 Olympus FV1000 or FV1200 system and Olympus FV10-ASW software. Images
4 were quantified with the Metamorph software (Molecular Devices). For quantification
5 of apical extrusion of RasV12-transformed cells, 2-8 RasV12-transformed cells that
6 were surrounded by normal epithelial cells were analyzed. More than 50 cells of
7 RasV12-transformed cells were analyzed for each condition. The ratio of apically
8 extruded RasV12-transformed cells was quantified. The frequency of actin phenotype
9 is calculated by the ratio of cells that exhibited the actin phenotype among cells
10 adjacent to extruding Myc-RasV12 cells. Western blotting was carried out as
11 previously described [29]. Primary antibodies were used at 1:1000. Western blotting
12 data were analyzed using ImageQuant™ LAS4010 (GE Healthcare).

13

14 **Quantitative real-time PCR**

15 MDCK-GCaMP6S-pLKO-TetOn IP₃R-shRNA, connexin 43-shRNA, TRPC1-
16 shRNA, TRPC6-shRNA, or Piezo1-shRNA cells were cultured on 6-well plates
17 (Corning). After incubation with tetracycline for 48 h, total RNA was extracted using
18 Trizol (Thermo Fisher Scientific) and a RNeasy Mini Kit (QIAGEN) and reverse-
19 transcribed using a QuantiTect Reverse Transcription Kit (QIAGEN). GeneAce
20 SYBR qPCR Mix (NIPPON GENE) was used to perform qPCR using the StepOne
21 system (Thermo Fisher Scientific). For data analysis, relative quantification analysis
22 was performed using the comparative CT ($2^{-\Delta\Delta CT}$) method. For each sample, the
23 mRNA level of IP₃R, connexin 43, TRPC1, TRPC6, or Piezo1 was normalized to the
24 β -actin mRNA. The primer sequences were as follows. IP₃R: 5'-
25 TTGTCAGTCTGGTGCGAAAG-3' and 5'-AGAGCCACACCTCCTCTTCA-3';

1 connexin 43: 5'-GGACATGCACTTGAAGCAGA-3' and 5'-
2 ATGAGGGCAGGGTTCTCTTT-3'; TRPC1: 5'-CATGAGGCAGAAGATGCAAA-
3 3' and 5'-TGCAAATGCAGTCTTTCAGG-3'; TRPC6: 5'-
4 GCCAATGAGCATCTGGAAAT-3' and 5'-GCTGGTTGCTAACCTCTTGC-3';
5 Piezo1: 5'-CTTCCTGCTGGCACTCCTAC-3' and 5'-
6 CAGTGACCATGTGGTTGAGG -3'; β -actin: 5'-GGCACCCAGCACAATGAAG-
7 3' and 5'-ACAGTGAGGCCAGGATGGAG-3'.

8

9 **Time-lapse observation of cultured cells**

10 For live imaging, cells were incubated in Leibovitz's medium (L-15) (Gibco)
11 containing 10% fetal bovine serum (Sigma-Aldrich). For the quantification of calcium
12 wave and area of MDCK-pTRE3G Myc-RasV12 cells, MDCK-GCaMP6S cells were
13 mixed with Myc-RasV12 cells stained with CMTPIX (red) at a ratio of 50:1 and
14 seeded on the collagen-coated 35-mm glass bottom dish (Matsunami). The mixture of
15 cells was incubated for 12-16 h until a monolayer was formed, followed by
16 doxycycline treatment for 12 h. Then, they were observed for 8 h by Olympus epi-
17 fluorescent microscopy (IX-81-ZDC-Meta). For the quantification of the occurrence
18 of calcium wave, 1-4 RasV12-transformed cells that were surrounded by normal
19 epithelial cells were analyzed. The percentage of the occurrence of calcium wave
20 during timelapse-observation was quantified. For analyses of caspase-8-induced
21 apoptosis, timing of mCherry-caspase-8 expression was determined when the
22 mCherry intensity exceeded 1.1 times as the basal level. Apoptotic extrusion was
23 determined by the obvious morphological change using bright field images of time-
24 lapse observation.

1 For analyses of vertex movement of the surrounding cells, MDCK-GCaMP6S
2 cells, MDCK-GCaMP6S TRPC1-knockdown cells, or MDCK-GCaMP6S INF2-
3 knockout cells were mixed with Myc-RasV12 cells stained with CMAC (blue) at a
4 ratio of 50:1 and seeded on the collagen-coated 35-mm glass bottom dishes. After 6 h,
5 they were incubated in medium containing the far-red silicon rhodamine (SiR)-actin
6 fluorescence probes for 24 h until time-lapse observation started. Doxycycline was
7 added 10 h before the start of time-lapse imaging. We then performed time-lapse
8 observation for 16 h. For analyses of the actin phenotype using grid-chamber dishes,
9 MDCK-GCaMP6S cells were mixed with Myc-RasV12 cells stained with CMAC
10 (blue) at a ratio of 50:1 and seeded on the collagen-coated 35-mm glass base dish with
11 grid (Iwaki), followed by time-lapse analysis as described above. Time-lapse images
12 were captured and analyzed by Nikon confocal microscopy (A1 HD25) with the NIS-
13 Elements software (Nikon). Acquired data were analyzed by the Metamorph and
14 ImageJ software.

15

16 **Zebrafish**

17 pCS2-GCaMP7 (gift from J. Nakai), pCS2-Lifeact-GFP (gift from N. Kinoshita), and
18 pmtb-t7-alpha-bungarotoxin were used as templates for mRNA synthesis. mRNAs of
19 GCaMP7, Lifeact-GFP, or bungarotoxin were synthesized using the SP6 mMessage
20 mMachin System (Thermo Fisher Scientific). To observe calcium wave during
21 apical extrusion from the outermost epithelial monolayer in zebrafish embryos,
22 GCaMP7 mRNA (200 pg), pT2 UAS mKO2-T2A-RasV12 DNA (25 pg), and
23 bungarotoxin mRNA (25 pg) were co-injected into the yolk of one-cell-stage embryos
24 obtained by mating of the Tg[krt4:GAL4] line with wild-type zebrafish. When
25 injected embryos were developed until late somitogenesis stages, embryos carrying

1 RasV12-transformed cells mosaically in the outermost epithelial monolayer were
2 selected by confirming mosaic expression of mKO2 fluorescent proteins under the
3 SZX16 stereomicroscope (Olympus). Selected embryos were dechorionated and
4 mounted in holes of a gel made with 1% low-melting point agarose (Nacalai Tesque)
5 on 35-mm glass bottom dishes (Greiner Bio-One). Calcium waves around mKO2-
6 positive transformed cell(s) were observed with a confocal microscope (LSM710,
7 LSM700, or LSM7 Duo, Zeiss) by 9-10 h time-lapse imaging at 9-12-s intervals. In
8 each time point of the time-lapse, Z-stack images of the embryos (5-7 planes at 9-11-
9 μm intervals) were obtained. For control, pT2 UAS mKO2-T2A-stop DNA (25 pg)
10 was co-injected with mRNAs of GCaMP7 and bungarotoxin. pT2 UAS mKO2-T2A-
11 stop was a kind gift from K. Kawakami [31]. To analyze apical extrusion, Lifeact-
12 GFP mRNA (100 pg) and pT2 UAS mKO2-T2A-RasV12 DNA (25 pg) were co-
13 injected into the yolk of one-cell-stage embryos obtained by mating of
14 Tg[krt4:GAL4] with wild-type zebrafish. Injected embryos were developed until bud
15 stage (10 hpf), treated with 6.25 μM 2APB or 0.25% DMSO for 12 h, and then fixed
16 with 4% PFA in PBS. Z-stack images (5-10 planes at 1-2- μm intervals) were obtained
17 with the Olympus FV1000 or FV1200 system and Olympus FV10-ASW software.
18 For laser ablation experiments, Tg[krt4:Lifeact GFP] embryos were injected with
19 GCaMP7 mRNA and developed at around 6 hpf. A single shot of 800-nm laser pulse
20 (100 fs, 200 nJ/pulse) from a Ti: sapphire femtosecond laser amplifier (Spectra-
21 Physics) was focused into the center of epithelial cells in the enveloping layer through
22 a 40 \times /NA0.8 objective lens (Olympus) [32]. Dynamic changes of F-actin and calcium
23 were observed with a confocal microscope (FV300, Olympus) for 5-10 min at 1-s
24 intervals. As reported in a previous study [33], DNA strand breaks were induced by
25 irradiation of femtosecond laser in the nucleus of the cells, leading to apoptosis-like

1 cell death. Indeed, we observed cell blebbing after the laser irradiation. In addition,
2 we have not observed any membrane rupture or cell fragmentation that often occurs
3 during necrotic cell death.

4

5 **QUANTIFICATION AND STATISTICAL ANALYSIS**

6

7 **Statistical analysis**

8 For data analyses, Chi-square test, unpaired *t*-test, two-tailed Student's *t*-test, or two-
9 tailed Pearson *r* correlation was used to determine *p* values. *p* values less than 0.05
10 were considered to be statistically significant.

11

12 **DATA AND CODE AVAILABILITY**

13 This study did not generate any unique datasets or code.

1 **SUPPLEMENTAL VIDEO LEGENDS**
