1. HAPPISBURGH

This internal report from the faculty of Archaeology of the University of Leiden provides an overview of excavations done at the coastal area referred to as Happisburgh I at the east Anglian coast. Here several excavations have produced archaeological and biological material relevant to early hominin occupation on the British coastal area.

1.1 Background

Happisburgh is a part of Norfolk, eastern England, that used to be a salty marsh. It was drained in the 11th century AD but still most parts are only a few feet above sea level with some large areas below sea level. The defenses against the waves along stretches of the coast have been abandoned, partly because they are considered too expensive. The coastline is rapidly eroding (see Figure 1 which also shows the locations of some of the archaeological excavations at Happisburgh). In some areas meters of cliff-face per year are removed. A local disaster but an opportunity for researchers as the erosion exposes materials that have been buried for hundreds of thousands of years. This includes archaeological material from some of the earliest Britons, making this location one of the most interesting sites in the area (Parfitt *et al.* 2010, Roberts and Grün 2010). Continued erosion including removal of the modern beach sands during the winter storms, have recently revealed the oldest known hominin footprints outside Africa (Ashton et al. 2014).

Figure 1 - The danger of a shifting shoreline taken by the winds and the waves. The red arrow indicates a crumbled road and disappearing houses. From here southwards the coast line is heavily eroded away. Figure from GoogleEarth, accessed 8 May 2012.

Collection of archaeological material from the coastal area has a long history. Due to natural erosion of the cliffs incidental finds have been retrieved for over a century. On the beach along large stretches of the coastline sometimes a complex sedimentation layer with a large organic component is exposed, the Cromer Forest-bed Formation (CR-bF) (Field and Paglar 2010). Collected by amateur archaeologists and generally stored at the Norwich museum the finds include cut-marked bones, a hand-axe and other flint tools from the organic mud at the foreshore. Inspired by these finds several formal excavations were undertaken at Happisburgh, thus creating sites named Happisburgh 1, Happisburgh 3, etc. (see Figure 1) (Ashton *et al.* 2008, Field 2012, Parfitt *et al.* 2010). Work is expected to continue at these locations for years to come. In chronological order past excavations here include (a more detailed overview up to 2011 is given in Knul (2012):

 2000 – onwards: along the beach, archaeologists and amateurs collected and sieved organic mud and other elements of the CF-bF at low tide or when exposed;

- 2000 onwards: Materials from Happisburgh 5 (HAP 5), located off the beach at an unknown position, often wash ashore during strong wave action in the form of large iron rich accretions. They are collected and examined, often revealing well preserved organic contents, including bones bearing cut-marks;
- 2002: Happisburgh 1 (HAP 1), by the Royal Holloway University of London and the British Geological Survey: studying the relationship between the organic mud and the glacial sediments on top;
- 2004: Happisburgh 3 (HAP 3), by the British Museum, Ancient Human Occupation of Britain (AHOB) project and Norfolk Museums Service: retrieving archaeological, faunal and macro plant remains from the organic mud by excavating a 2x3m trench producing seven tons of sediment bearing 30 artefacts;
- 2004: HAP 1, excavating the organic mud (top level fluvial deposits) where a hand-axe was found. Several flint flakes were retrieved next to organic materials;
- 2004-2010: HAP 3 and Happisburgh 2 (HAP 2)¹, retrieval of archaeological and paleoenvironmental material from several trenches and exposed soils;
- 2009-2012 Happisburgh 1, by the University of Leiden: collecting archaeological and paleoenvironmental material. The eroding and retreating coastline allows tracking the sedimentation channel that marks HAP 1 (see Figure 2).

See Figure 4 for an overview of all excavated pits from all seasons (which is also the frontal image of this internal report).

¹ HAP 2 is located 500m north-west of the old slipway, HAP 3 is located 300 m north-west from the slipway.

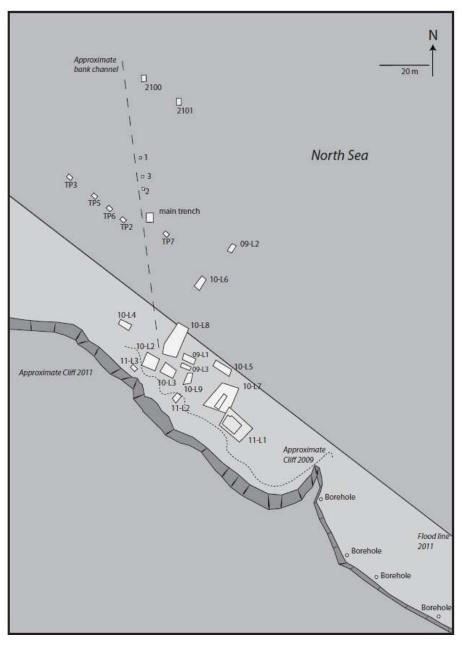

Figure 2 - Excavation overview of Happisburgh 1 up to 2011 inclusive (Knul 2012, Figure 8), adapted from the MapInfo GIS dataset. GIS data courtecy of E. Dullaart.

The main components of the stratigraphy at HAP 1 have been analyzed extensively and occur at and underneath the modern beach along the coast stretching from Weybourne down to Pakefield (Ashton and Lewis in press, Field 2012, Hosfield 2011, Preece and Parfitt in press). Table 1 presents a summary of these stratigraphical layers at HAP 1.

Table 1 - Stratigraphic layers at Happisburgh 1 (for more detail, see Knul (2012)).

1.	Modern beach sand, from 0 up to 1.5 meters thick in some places.
2.	<i>Happisburgh Formation, containing the Happisburgh Till</i> , a diamiction containing erratic clasts, the lowest part of this formation extending underneath the beach sands. The cliffs

	along the beach are glaciogenic deposits containing this formation.		
3.	Cromer Forest-bed Formation (CR-bF), including the organic mud which contains well preserved wood and other remains (sometimes 80 centimeters thick). Due to acidic conditions the calcareous fossils including most skeletal material have disappeared. This formation is deposited in Pleistocene interglacial conditions and forms a complex sequence of fresh-water, estuarine, and marine sediments.		
4.	Grey sandy silts with clay lenses. A fluvial deposit in which numerous artefacts were found.		
5.	<i>Wroxham Formation</i> with Early Pleistocene marine sands (formerly known as the Weybourne Crag) and reaching a bedrock of Chalk at around 27 meter deep.		
glacio layer (At certain locations elements from some layers have penetrated other layers, mainly due to glaciogenic forces of the Anglian ice sheets. For instance clay lenses penetrating the organic mud layer (Field 2012, 3, see Figure 1 therein), or parts of the Happisburgh Till pushed into the organic mud (2011 excavation results at HAP 1).		

Stratigraphic layers 3 and 4 in HAP 1 are complex fluvial deposits in marine sands and are attributed to the pre-diversion Thames, the Bytham and the Ancaster rivers (Ashton *et al.* 2008, Hosfield 2011, Westaway 2011). Controversies around dating of the stratigraphy have led to two contrasting age models (Preece and Parfitt in press). One model, the 'New Glacial Stratigraphy' dates the Anglian Till according to glacial formation processes and suggests that the Happisburgh Till can be dated to MIS 16, implying an early date for the underlying CR-bF beds (Lee *et al.* 2004, 2008, Hamblin *et al.* 2005, Rose 2009).

A biological oriented approach, apptly named the 'Biostratigraphic Age Model', suggests a more recent date of MIS 12 for the Till (Preece *et al.* 2009, Westaway 2011). This fits the biological evidence. The presence of *Arvicola terrestris cantiana* in the underlying CR-bF (Ashton *et al.* 2008) suggests a recent MIS 13 (or 15) origin, similar to Waverley Wood where this species is also found (Shotton *et al.* 1993). Also the beetle signature suggests MIS 13, based on similarities with the collection found at High Lodge (Lee *et al.* 2004). Handaxe technology in these parts of Europe has so far been dated to MIS 13 or later, also suggesting a recent origin of the CR-bF from which in-situ hand-axes have been retrieved (Ashton *et al.* 2008, Preece and Parfitt in press). OSL dating and aminostratigraphy seem to support this age model as well (Preece *et al.* 2009, Preece and Parfitt in press).

Exact dating of the underlying grey sandy silts is also not straightforward. The surprising retrieval of part of a seed of *Actinidia faveolata*, a lone Tertiary relic, from this layer could suggest an Early Pleistocene age, opposed to the early Middle Pleistocene date for the CR-bF (Field 2012). Another possibility is that both fluvial layers are of the same age, with the *Actinidia* seed an outlier being

either reworked from earlier sediments or an odd survivor indicating a late range and date extension into north-west Europe for this species. A sedimentation hiatus caused by erosion might be present, especially if the lower fluvial deposits could be correlated with Dutch Early Pleistocene sediments (Field 2012). West (1980) has described a similar layer overlain by a thin gravel bed, which has not been observed in all excavated pits.

Both the organic muds as well as the grey sandy silts are fluvial deposits (see Figure 3). Research at HAP 3, around one km north-west of HAP 1, suggests an origin of mainly pre-diversion Thames and with some contribution by the Bytham river, due to the presence of for instance Rhaxella chert that is not present in the Thames (Parfitt *et al.* 2010). The approximate location of the river channel associated with the deposits in the 2004 excavation in relation to the 2009-2011 excavations is indicated in Figure 2. The location and height of former river terraces more inland from these rivers are used in geologically dating the sites (Hosfield 2011). However, the exact former positions of these rivers, the contribution of each of these rivers to the sediments as reflected in the ratio of flint, quartz, and chert and the followed interpretations within the dating method are not uncontested (Westaway 2011).

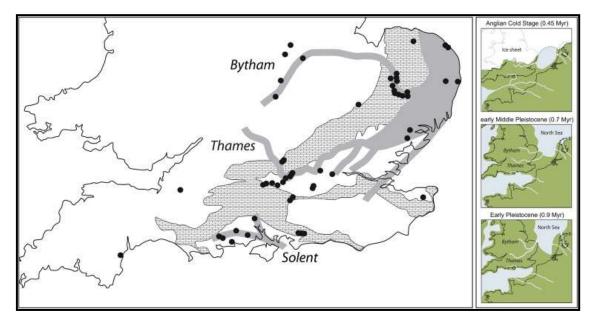

Figure 3 - Overview of Lower Paleolithic sites from before the Anglian glaciation with suggested river beds of the Thames and Bytham pre-Anglian river systems and shaded the chalk layer from which most flint derives. On the side a changing English Channel for the three different relevant time periods. Figure taken from (Preece and Parfitt in press, Figure 3).

The archaeological excavations and the collecting efforts throughout the years have resulted in a diverse collection of paleoenvironmental material from the CR-bF layers. These include vertebrate faunal remains, beetles, pollen, and plant macro fossils. The information obtained from the coleopteran species suggests a slightly colder environment than today with marshy, wet conditions

(Coope 2006). The vertebrates from HAP 1 suggest interglacial conditions in a rather open, moist environment with some trees and fresh water flowing nearby (Ashton *et al.* 2008). The few preserved bones bear cut-marks, breakage to obtain marrow, and carnivore gnawing marks. Wood charcoal is preserved in most samples but anthropogenic origin is unclear (Ashton *et al.* 2008).

The palynological information for both CR-bF and the grey sandy silts at HAP 1 similarly suggests presence of a coniferous forest with diverse fresh water vegetation, including species indicating slow moving water and marshes (Field 2012). Plant macro fossils from the CR-bF layer suggest a brackish element, whereas pollen results indicate fresh water with damp open ground at the margins of the river channel. There is heath land in the area. Recent analysis also points to a deepening through time of the channel, with a higher concentration of edge oriented and marshy plants like *Eleocharis palustris, Cyperus fuscus, Potentilla palustris* and *Lythrum portula* in the lower layers. With little proof for marine influence the CR-bF could have become a cut-off channel with decreasing fluvial characteristics².

Besides organic materials also artefacts were recovered from the different stratigraphical layers. These include a hand-axe found by Mike Chambers (Ashton *et al.* 2008) and some 53 other flint pieces collected from the beach and the cliffs throughout the years, 101 flints retrieved during the 2004 excavation and 118 flint pieces collected in the 2009 and 2010 excavation campaigns by Leiden University (Knul 2011). Included are cores, flakes, chunks and modified pieces. Generally these artefacts are in fresh, not rolled condition from a possible primary archaeological context and created using a similar, unprepared core technology applying hard-hammer percussion³. Dating this technology is difficult. Not all material has a local origin, but generally it is a dark grey, fine grained flint with shiny black patination. Due to the used excavation techniques (see Figure 8) spatial clustering or activity zones cannot be distinguished.

1.2 Excavations

Excavation data is digitally collected in the following years:

- 2004
- 2009
- 2010

² Personal communication with F.J. Feijen, 7 May 2012.

³ Personal communication Jonathan Croese, 31 May 2012, suggesting a transient use of the implements with little visible use-wear. There is no obvious technological difference between HAP 1 and HAP 3 flint material.

- 2011
- 2012

All data has been processed in MapInfo, using separate tables for each type of object (see Appendix). Data is presented in the next chapters, one chapter for each year of excavation. Where useful, tables are exported from MapInfo to Excel using the Export Wizard. Column titles are kept.

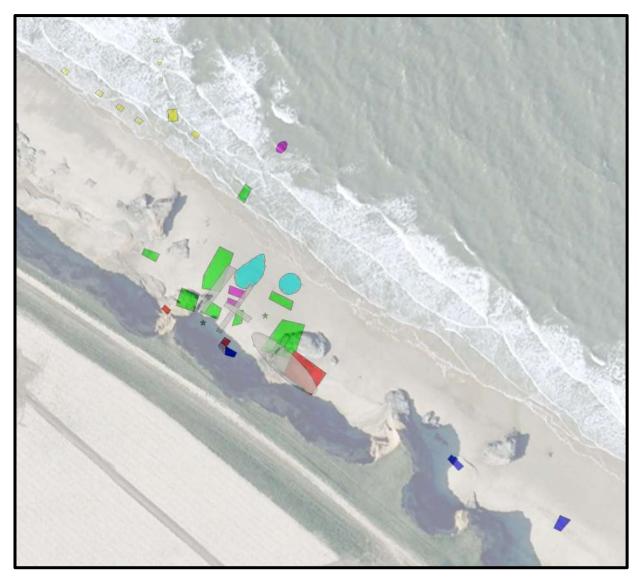

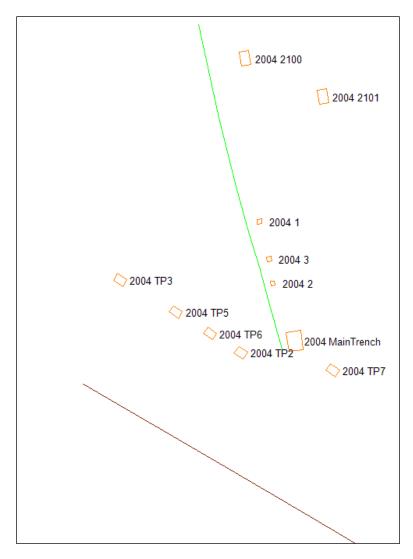

Figure 4 - Excavated pits at Happisburgh I: 2004 (yellow), 2009 (purple), 2010 (green), 2011 (red) and 2012 (dark blue and translucent grey).

Cross-sections and detailed descriptions of stratigraphy are available for the excavations of 2009 and 2010 in (Knul 2012, Appendix 1 Field Reports Happisburgh Site 1 2009-2010). Some cross section measurements were made for 2011 and 2012 field seasons by Robin Nieuwenkamp (email 20 June 2014), but these have not been digitized yet.

2. EXCAVATION 2004

Main objective of the first excavation in this area is to confirm the presence of hominins at this locality.

Data for 2004 was initially manipulated using AutoCAD in British location, and only later converted to MapInfo. With this conversion the measuring points themselves were lost, the drawn figures were preserved. For instance, for a trench the four corner points are not individually stored, only the square figure.

2.1 Excavated pits

The following pits were recorded:

2004 TP7
2004 MainTrench
2004 2
2004 3
2004 1
2004 2100
2004 2101
2004 TP2
2004 TP6
2004 TP5
2004 TP3

2.2 Measured features: edge channel and cliff position

Furthermore the edge channel and the cliff position were recorded. Both of these are interpretations, from which the measured points are lost. The values of these objects is limited as no further information is available on how these were constructed/drawn.

3. EXCAVATION 2009

In 2009 three excavation pits were dug, mainly to excavate artefacts to increase the sample size and to understand the stratigraphy of the site and to retrieve paleoecological data. Furthermore two wells were identified and the coastline was mapped. Only geographical X and Y coordinates are available for all these elements. See Figure 6. No height is recorded and individual measuring points were not stored.

Figure 6 - 2009 mapped features and pits superimposed upon a Google Earth view of the area.

3.1 Excavated pits

The following pits were recorded, for each pit an autocad_elevation of 3.620543 is given:

2009 L1	
2009 L2	
2009 L3	

3.2 Measured features: two wells and coastline

Two wells (unnamed) were identified on the beach, and mapped.

The coastline was mapped.

GPS coordinates for station points and excavation features are available in Knul (2012).

4. EXCAVATION 2010

In the 2010 excavation season ten pits were dug, researching the stratigraphy of the site and the relationships between the different layers. Geography of the channel was mapped (see Knul (2012, Chapter 4), more artefacts excavated and paleobotanical and palaeomagnetic samples were taken (Knul 2012, see also detailed excavation report in the supplementary information). From the ten pits, two pits (1 and 10) were recorded with center point only. L1, L2 and L10 would locate previous pits and expand these. The position of two boreholes was recorded, five measuring points and three location leveller points were mapped and the location of the cliff was stored. See Figure 7.

Figure 7 - Stored elements in the 2010 season.

4.1 Excavated pits

The following pits were recorded with elevation information for each object preserved through the AutoCAD conversion process, see Table 2. For pits L1 and L10 only the center point is stored, without elevation information. In pit L7 a subsection has been excavated deeper, this is referred to as 2010 L7_2.

Name	Elevation	Remarks
2010 L7	1.55200000000000	
2010 L7_2	1.55200000000000	
2010 L9	1.37200000000000	
2010 L2	1.33200000000000	
2010 L3	1.33200000000000	
2010 L8	0.69600000000000	
2010 L5	0.59200000000000	
2010 L6	3.6205430000001	This elevation is expected to be lower than the others?
2010 L4	1.40200000000000	

Table 2 - 2010 excavated pits L2 through L9 with elevation information.

4.2 Measured features: leveller and measuring points, boreholes, cliff position

Five measuring points and three location leveller points were mapped, all unnamed. No further information is available for these points but geographical X and Y coordinates. Two boreholes were recorded: BH 1 2010 and BH 2 2010. The position of the cliff has been measured, but is only indicated by a single linear feature (see Figure 7).

GPS coordinates for station points and excavation features are available in Knul (2012).

5. EXCAVATION 2011

The main aims of this season are similar to the 2010 excavation (Knul 2012, see also detailed excavation report in the supplementary information). In the 2011 season three pits were excavated, of which one was deepened for further research. Many features were mapped, including the cliff base and top and five boreholes. An exact height was for the first time transferred to the site from the locality of the lighthouse, where an elevation of 20.1615 meter is recorded (email E. Dullaart 3-7-2012).

Figure 8 - Mechanical digger used to expose and excavate the deposits in the 2011 excavation by Leiden University (Photo courtesy of H. Kamermans).

5.1 Excavated pits

Three pits were excavated in 2011, see Figure 9. Z-coordinates are not stored with the HAP2011_Pitts objects, but were saved with the individual data points from which the pits were drawn.

Figure 9 - 2011 Excavated pits and mapped cliff base and top.

The following pits have been excavated:

2011 L1	
2011 L1_2	Deepened section of 2011 L1
2011 L2	
2011 L3	

5.2 Measured features: coastline, boreholes, sightlines, HAP3

All features have been stored in data points. These are shown in Figure 10. For each point a PointID (the label), coordinates Xcoord, Ycoord, Zccord, a Code field and a Remark column are stored.

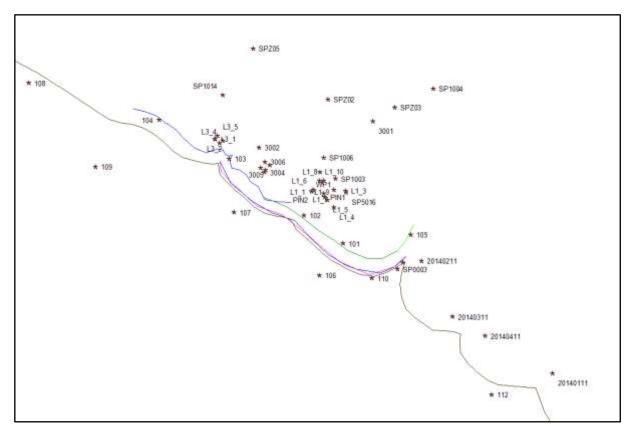

Figure 10 - Data points mapped in 2011.

The following features have been mapped:

- The coastline has been mapped in great detail, see Figure 12.
- Four boreholes are stored: 20140211, 20140311, 20140411, and 20140111.
- Points PIN1, PIN2 and 2003 are sight lines.
- Several data points were taken at the location of Happisburgh 3, see Figure 11 and compare Figure 1. Height for these points has been transferred through SP1015 (not visible in Figure 10) and SP1014.

Note: the coordinates for the following data points are incorrect: Lighthouse, ATTL, WEYB, and GORS. In the blue line forming the cliff base some inconsistencies are visible at the end to the right. In the table for HAP2011 the column Zccord should be named Zccord.

Figure 11 - Data points mapped in 2011 at the location of Happisburgh 3, shown on Google Earth.

Figure 12 - 2011 Measured points along the coastline, mapping cliff bottom and top.

6. EXCAVATION 2012

Figure 13 - 2012 Excavating near promontory (Photo courtecy of F. Scherjon).

The 2012 GIS measured data can be distinguished into two major categories:

- Excavation pits
- Measured surface data: features, finds and structures

In the 2012 season two different types of excavation pits were dug: excavation pits to retrieve archaeology and trenches to locate past excavation features. The measured data can be subdivided into three broad categories: boreholes, surface features and mapping of the current coastline. Identification of the measuring points also fits into the measured surface data major category.

6.1 Excavated pits and trenches

Figure 14 - Location of the 2012 Pits and Trenches in the excavation area superimposed upon a detailed GoogleEarth view of the area.

Figure 15 - Excavation area in relation to Happisburgh town.

Several pits and trenches have been renamed for consistency reasons:

Old name	New name
2012 L2 (duplicate)	2012 L1
2012 L1	2012 L1_2
2012 L4	2012 L4 (unchanged)
2012 L4_1	2012 L4_2
2012 L5 (duplicate)	2012 L6
2012 L6	2012 L6_2

6.1.1 Pits

Pits to excavate new archaeology:

- 2012 L1
- 2012 L1_2
- 2012 L4 but excavation materials are not sieved and not completely analysed on finds

6.1.2 Trenches

Several trenches were dug to locate previous excavation traces, see Figure 16 with identification of past features.

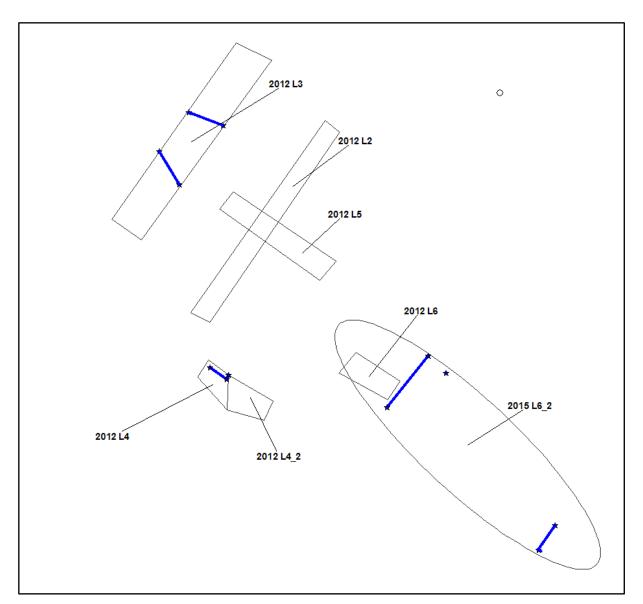

Figure 16 - Excavation trenches, with features from previous excavations in Blue.

Trenches to locate previous excavation pits:

- 2012 L2
- 2012 L3
- 2012 L4
- 2012 L5
- 2012 L6
- 2012 L6_2

6.2 Measured features: cliff position, boreholes, measuring points, exposed layer

• 2012 E1 – English excavation pit (see Figure 14)

- BH 1 2012, BH 2 2012, BH 3 2012, BH 4 2012, BH 5 2012, BH 6 2012: Borehole data
- MP01, MP02, MP03, MP04, MP05, MP06: measuring points (with known coordinates)
- SI501, SI502, SI503, SI504: feature identified on the beach: exposed layer
- MP1019, SPEPOST1: orientation markers on pole
- Cliff position, see Figure 18.

The boreholes are described in detail in the next subparagraph.

6.2.1 Borehole data

Six borehole positions were recorded in the 2012 season. Naming and position details shown in Figure 17 and presentted relative to the cliff base in Figure 18.

Figure 17 - Position of the 2012 boreholes relative to the excavation pits.

Xcoord	Ycoord	Zcoord	Label
638968.66	330511.30	1.563	BH 4 2012
639005.05	330486.89	174	BH 5 2012
638888.56	330518.65	10.799	BH 1 2012
638920.40	330540.03	1.462	BH 2 2012

638990.29	330502.72	1.683	BH 3 2012
638938.21	330517.53	1.679	BH 6 2012

Boreholes Happisburgh I July 2012, height corrected, final results.

1	638888,561	330518,648	11,233	Top of the cliff
2	638920,399	330540,034	1,896	North of promontory
3	638990,293	330502,715	2,117	Furthest south
4	638968,660	330511,300	1,997	
5	639005,048	330486,888	2,174	
6	638938,213	330517,533	2,187	South of promontory

Conversion of height: 102 has measured height of 3.611; real height is 4.045; add 0.434 meter

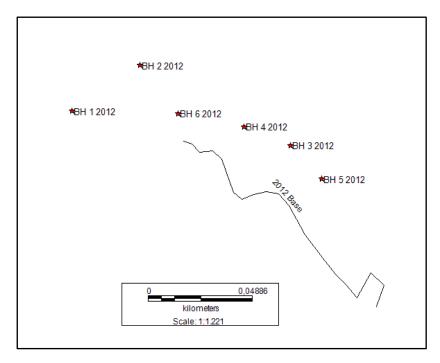

Figure 18 - Current cliff base position

Appendix I – MapInfo data tables

This Appendix lists the data points for season 2011 and 2012 respectively.

HAP2011 data points

The following table presents all available data points for the 2011 excavation season.

Appendix II – Technical procedures and data

How to create Google Earth input files

In the Tool Manager from MapInfo it is possible to activate the Google Earth Connection Utility. This will open a tool menu from which the current view can be exported as kml file, with associated jpg. Within GoogleEarth, layer properties, the Transparency of the MapInfo Saved view can be adjusted. For clarity reasons, pits should have be 4mm thick lines and text should be bold and 10pnts.

Figure 19 - Exported MapInfo view, with transparency set to 60%.

By default this exports a map window screenshot as a registered image in Google Earth. To export vector objects, select the objects you wish to export first. These can be either shapes or points, not both. An alternative method is described in the caption of Figure 20.

Figure 20 - GIS data converted from British National Grid, Ordnance Survey 1936 format into WGS84 lat/lon using ExpertGPS and then projected in Google Earth upon the satellite imagery showing exact positions of the 2004 (yellow), 2009 (purple), 2010 (green) and 2011 (red) excavation trenches.
