Corrigendum

Corrigendum to "Golden carbon of *Sargassum* forests revealed as an opportunity for climate change mitigation" [Sci. Total Environ., 729 (2020) Start page – End page/ 138745]

The authors regret that the printed version of the above article contained errors.

These errors in no way affect the analyses performed in this manuscript, the reported results, or the draw conclusions. The authors would like to apologise for any inconvenience caused.

The requested change does not affect the measures, because all estimation was based on raw values, without conversion to Gg km⁻². The correct and final version follows.

Page 3:

The final value was obtained according to the equation below:

Carbon stock in above – ground biomass (Gg km⁻²): % C X AGB X area (obtained in the Boosted Regression Trees – BRT Model)

Changes to:

Carbon stock in above—ground biomass (Pg C): % C (dry weight) X AGB (dry weight) X area (obtained in the Boosted Regression Trees—BRT Model) * Biomass dry weight corresponds to 10% of wet weight.

Page 4, first paragraph of Results:

"...and a potential standing stock 82.58 Gg km⁻² of floating Sargassum in the Atlantic Ocean. At the global scale, models estimated 305.95 and 139.59 $\cdot 10^4$ km² of floating and benthic Sargassum, respectively (445.54 $\cdot 10^4$ km² in total), and overall biomass of 84.05 Gg km⁻², which corresponds to 13.1 Pg C globally (Fig. 1b)".

Changes to:

"...and a potential standing stock 8.25 Gg km⁻² of floating *Sargassum* in the Atlantic Ocean. At the global scale, models estimated 305.95 and $139.59 \cdot 10^4$ km² of floating and benthic *Sargassum*, respectively (445.54 $\cdot 10^4$ km² in total), and overall biomass of 8.40 Gg km⁻², which corresponds to 13.1 Pg C globally (Fig. 1b)".

Page 4, first paragraph of Discussion:

"These floating Sargassum estimates are increased up to $25.2 \cdot 10^3$ Gg when considering the potential global distribution of the genus (Fig. 1b)". Changes to:

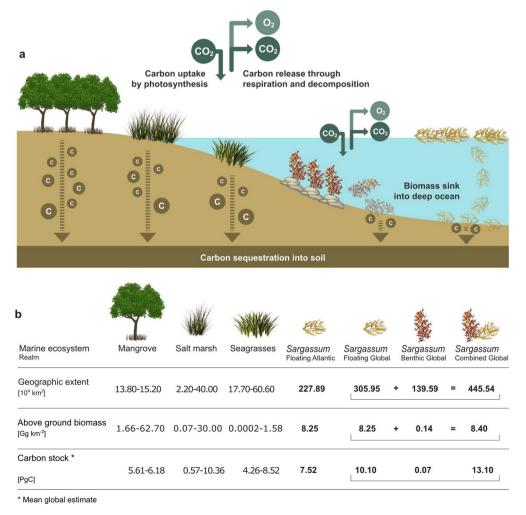

"These floating *Sargassum* estimates are increased up to 25,241 · 10³ Gg when considering the potential global distribution of the genus (Fig. 1b)". Changes in Fig. 1b:

Fig. 1b

Corrections of values in Above ground biomass of 82.58 Gg km⁻², 1.47 Gg km⁻² and 84.05 Gg km⁻². Also, the values of mangrove, salt marsh and seagrasses were converted to Gg km⁻².

Changes to:

8.25 Gg km⁻², 0.14 Gg km⁻² and 8.40 Gg km⁻².Fig. 1(a) Important marine ecosystems (from left to right: mangroves, saltmarshes, seagrasses and *Sargassum* beds). Main scheme represents carbon uptake via photosynthesis (green arrows) and subsequent long-term sequestration into biomass and soil (brown dashed arrows) or respiration (green arrows). The *Sargassum* biomass (floating and benthic) can sequester and transport atmospheric carbon into the deep ocean. (b) Carbon storage potential of important marine ecosystems, including *Sargassum* stock. Geographic extent in km² (10⁴ km²), Mean global estimate of above ground biomass (Gg km⁻²) and Mean global estimate of carbon stock in above ground biomass (PgC). Data obtained from Howard et al. (2017), except for above ground biomass values (Fourqurean et al., 2012; Quintana-Alcantara et al., 2014; Rovai et al., 2016; Castillo et al., 2010). The results obtained in the present study are represented in bold. (For interpretation of the references to color in this figure legend, the reader is referred to the web version of this article.)The images referring to mangrove trees, seagrasses, salt marsh, benthic and floating *Sargassum* were obtained from the websites: http://gratispng.com; belvil2009.blogspot.com and atricolinabiologa.blogspot.com.

We include a reference in the Fig. 1 legend:
