#### Abstract

Ring-fused benzimidazolequinones are well-known anti-tumour agents, but dimeric ring-fused adducts are new. The alicyclic [1,2-a] ring-fused dimethoxybenzimidazole-benzimidazolequinone (DMBBQ) intermediate allows late-stage functionalization of bis-p-benzimidazolequinones. DMBBQs are chlorinated and brominated at the $p$-dimethoxybenzene site using nontoxic sodium halide and Oxone in HFIP/water. X-ray crystallography is used to rationalize site preference in terms of the discontinuity in conjugation in the DMBBQ system. Quinone formation occurs by increasing in situ halogen generation and water. Conversely, radical trifluoromethylation occurs at the quinone of the DMBBQ.

Dimethoxybenzimidazole-benzimidazolequinone (DMBBQ) 4a was obtained in high yield ( $86 \%$ ) when using less CAN, and in contrast to bis-p-quinone 3, DMBBQ 4a was insensitive to light. Radical trifluoromethylation of $\mathbf{4 a}$ using Langlois' reagent $\left(\mathrm{NaSO}_{2} \mathrm{CF}_{3}\right)$ occurred at the quinone to give $\mathbf{4 b}$ in $54 \%$ yield. ${ }^{8}$

Elemental chlorine and bromine are corrosive, toxic, and ordinarily inconvenient for synthesis. The useful halogen is however generated in situ from the oxidation of a benign and inexpensive alkali metal halide. ${ }^{9}$ Oxone $\left(2 \mathrm{KHSO}_{5} \cdot \mathrm{KHSO}_{4} \cdot \mathrm{~K}_{2} \mathrm{SO}_{4}\right)$ is a stable, safe and cheap external oxidant. ${ }^{10}$ The active ingredient of Oxone is potassium peroxymonosulfate $\left(\mathrm{KHSO}_{5}\right)$ and when accompanied by stoichiometric equivalents of halide ( $\mathrm{NaX)}$ can generate molecular halogen ( $\mathrm{X}_{2}$ ) for electrophilic chlorination and bromination (Scheme 1d). The halide with Oxone gives oxidative transformations with an accompanying halogenation of naphthols and phenols, ${ }^{11}$ and with and without halogenation for indoles. ${ }^{12,13}$ Other metal-free oxidations, such as N -bromosuccinimde (NBS) with a small amount of $\mathrm{H}_{2} \mathrm{SO}_{4}{ }^{14,15}$ and $\mathrm{PhI}\left(\mathrm{OCOCF}_{3}\right)_{2}$ (PIFA), ${ }^{8,16,17}$ are reported to induce conversion of $p$-dimethoxybenzenes to $p$-quinones without halogenation. The disadvantage of using NBS and PIFA is the generation of organic waste products. Moreover, the combination of $\mathrm{H}_{2} \mathrm{O}_{2}$ with HX gives chlorinated and brominated alicyclic [1,2-a] ringfused benzimidazolequinones from $p$-dimethoxybenzene precursors. ${ }^{18}$ The accompanying aromatic halogenation is considered advantageous, since it offers further functionalization opportunities. However, unlike monomeric benzimidazoles, milder room-temperature conditions are required for $\mathrm{Cl}_{2}$ and $\mathrm{Br}_{2}$ generation when using DMBBQs as the substrates (see below), which

This work

Scheme 1 Development of DMBBQs as precursors to difunctionalized bis-benzimidazolequinones.
led us to use $\mathrm{NaX} /$ Oxone. The use of Oxone is unprecedented in oxidative demethylations to give $p$-quinones. Herein, we disclose selective chlorination and bromination of novel CAN-derived alicyclic ring-fused DMBBQs at the aromatic site, despite possible activation at the quinone (Scheme 1e). Electrophilic aromatic halogenation of DMBBQs 5a-5d (Scheme 1f) is accompanied by one-pot quinone formation.

## Results and discussion

Five to seven-membered alicyclic ring-fused dimethoxybenzimidazoles $\mathbf{6 a - 6 c}$ are readily available, ${ }^{17}$ and used to prepare new DMBBQs $\mathbf{5 a - 5} \mathbf{c}$. DMBBQ 5b was prepared in $\mathbf{7 3} \%$ yield by

Scheme 2 Synthesis of alicyclic ring-fused DMBBQs.
optimizing the conditions for CAN-oxidation of $\mathbf{6 b}$ in MeCN/ $\mathrm{H}_{2} \mathrm{O}$ (Scheme 2). ${ }^{5-8}$ The latter solvent system also gave pyrido [1,2-a]benzimidazolequinone 7 in $15 \%$ yield. Replacing the MeCN with hexafluoroisopropanol (HFIP) improved the yield of the required DMBBQ 5b to $87 \%$ with no monomeric benzimidazolequinone 7 detected. Similar high yields ( 88 and 84\%) using HFIP $/ \mathrm{H}_{2} \mathrm{O}$ were obtained for the formation of pyrroloand azepino ring-fused DMBBQs $5 \mathbf{a}$ and $5 \mathbf{c}$ from $\mathbf{6 a}$ and $\mathbf{6 c}$, respectively. The formation of 7 requires the intervention of a water molecule at the CAN generated radical cation to prevent dimerization. ${ }^{6,18}$ The persistence of radical cation intermediates in HFIP, ${ }^{19}$ and their shielding from water due to the formation of heterogeneous environments, ${ }^{20}$ may account for the exclusive CAN-mediated dimerization.

DMBBQs 5a-5c were insufficiently crystalline for X-ray crystallography. However, the premise for the regioselective halogenation was supported by the preparation of bis(chloro-methyl)-substituted DMBBQ 8 ( $76 \%$ yield), in an analogous fashion to 1 (see above), ${ }^{7,8}$ but using less CAN ( 2.0 equiv.). The crystal structure of dimethylchloride 8 showed that the aromatic and quinone rings adopt an out-of-plane conformation with respect to each other (Scheme 3 and Fig. S1 $\dagger$ ). The torsion angle $(\theta)$ of $67.6^{\circ}$ describes the angle between the planes of the benzimidazole and benzimidazolequinone, which prevents effective orbital overlap over both rings, ruling out resonance activation of the 6 -quinone position. Cyclic voltammetry and TD-DFT on DMBBQ 4a, provides further support for the site-selectivity for the electrophilic substitution with localized HOMO and LUMO at the respective dimethoxybenzimidazole and benzimidazolequinone motifs. ${ }^{8}$

${ }^{a}$ Conditions: DMBBQ 5a ( 0.20 mmol ), MeCN or HFIP $(2 \mathrm{~mL}), \mathrm{H}_{2} \mathrm{O}$ $(0.1 \mathrm{~mL}) .{ }^{b}$ Used as Oxone. ${ }^{c}$ Isolated yields. Values in parentheses recovered 5a. ${ }^{d} \mathrm{H}_{2} \mathrm{O}_{2}(4 \mathrm{mmol}), \mathrm{HCl}(0.20 \mathrm{mmol})$, MeCN $(2 \mathrm{~mL})$, reflux, $1 \mathrm{~h} .{ }^{e}$ Intractable mixture. ${ }^{f} 16 \mathrm{~h} .{ }^{g}$ HFIP ( 2 mL ), $\mathrm{H}_{2} \mathrm{O}(0.2 \mathrm{~mL}), 9 \mathrm{~h}$.

Chlorination of pyrrolo-fused dimer $5 \mathbf{5 a}$ was initially attempted using $\mathrm{H}_{2} \mathrm{O}_{2}$ with HCl under conditions which mediated the regioselective chlorination of anilines (Table 1). ${ }^{17}$ Reaction monitoring by TLC indicated the complete consumption of $\mathbf{5 a}$ after 1 h of reflux, but a low yield of $7^{\prime}$-chloride 9a ( $21 \%$ ) was attributed to the formation of intractable baseline decomposition products. The requirement for milder conditions, led us to investigate the room temperature Oxone $/ \mathrm{NaCl}$ reaction.

Addition of an aqueous solution of NaCl (1 equiv.) and Oxone ( $\mathrm{KHSO}_{5}, 1.2$ equiv.) to $\mathbf{5 a}$ in MeCN gave chloride 9 a in $39 \%$ yield, with column chromatography providing $52 \%$ recovery of 5 a (Table 1). Polyfluorinated alcohols improve yields for $\mathrm{NaCl} /$ Oxone-mediated aliphatic and aromatic chlorinations, ${ }^{21}$ and are known to accelerate aromatic chlorination in systems that generate in situ $\mathrm{Cl}_{2} .{ }^{22}$ The reaction solvent was thus changed from MeCN to HFIP, with a greater consumption of

Scheme 4 Halogenation and quinone formation. Conditions: Method $A$ is the same as Table 1, entry 4. Method B is the same as Table 1 , entry 6. Isolated yields. ${ }^{a}$ X-ray crystal structure (Fig. $\mathrm{S} 2 \dagger$ ) with thermal ellipsoids set at $50 \%$ probability, except for the hydrogen atoms at a fixed radius of $0.2 \AA$. The torsional angle highlighted is $79.2^{\circ}$. ${ }^{b}$ Inseparable with 5 b or 5 c.
substrate 5a observed, and $\mathbf{9 a}$ isolated in an improved yield of $51 \%$. The highest yield of $9 \mathrm{a}(79 \%)$ after 5 h was obtained using a greater amount of NaCl ( 2 equiv.) with chlorination also accompanied by oxidation to give the bis-p-quinone $\mathbf{1 0 a}$ in $12 \%$ yield. $\mathrm{Cl}_{2}$ and water are responsible for conversion of the $p$-dimethoxybenzimidazole to benzimidazolequinone. ${ }^{18}$ Thus, optimized conditions for one-pot chlorination and quinone formation were achieved by increasing the amount of $\mathrm{KHSO}_{5}$ (4 equiv.) and NaCl (4 equiv.), so increasing the likelihood of NaCl reaction with HOCl , over HOCl reaction with the substrate $5 \mathbf{a}$ (Scheme 1d). These conditions favoured $\mathrm{Cl}_{2}$ formation and gave bis-benzimidazolequinone 10a in $71 \%$ yield, with an increase in water from 5 to $10 \%$ relative to HFIP giving exclusively $\mathbf{1 0 a}$ in $89 \%$ yield after 9 h .

The conditions which favored selective chlorination over quinone formation (entry 4, Table 1) were applied to pyrido and azepino-ring fused DMBBQs $\mathbf{5 b}$ and $\mathbf{5 c}$ to respectively give 9b $(75 \%)$ and $9 \mathbf{c}(72 \%)$ (Method A, Scheme 4). In these cases, column chromatography removed co-eluting mixtures of substrates $\mathbf{5 b}$ and $\mathbf{5 c}$ with respective bis-p-quinones $\mathbf{1 0 b}$ and $\mathbf{1 0}$. The optimized conditions for quinone formation (entry 6, Table 1) were applied to $\mathbf{5 b}$ and $\mathbf{5 c}$ to respectively give $\mathbf{1 0 b}$ and 10c in isolated yields of 88 and $74 \%$, with only the latter giving some dimethoxybenzene intermediate, 9c in $12 \%$ yield (Method B, Scheme 4).

NaBr replaced NaCl to facilitate regioselective bromination of $\mathbf{5 a - 5 c}$ (using entry 4, Table 1 conditions). There was a marginal decrease in the tendency for bromination compared to chlorination. Complete consumption of 5 a occurred with the difference in $R_{\mathrm{f}}$ values allowing separation of 7 '-bromoDMBBQ 11a from bis-p-quinone 12a by column chromatography in respective yields of $76 \%$ and $10 \%$ (Method A, Scheme 4). X-ray crystallographic structure determination for 11a supported the site for bromination (Scheme 4 and Fig. S2†).

Under the same conditions, the pyrido- and azepino[1,2-a]fused dimers $\mathbf{5 b}$ and $5 \mathbf{c}$ gave selectively brominated DMBBQs $\mathbf{1 1 b}$ and 11c in respective yields of $68 \%$ and $71 \%$. In a similar manner to the chlorinations, ring-expanded DMBBQs $5 \mathbf{b}$ and $5 \mathbf{c}$ were less reactive towards bromination than the pyrrolofused DMBBQ 5a with unreacted material separated by column chromatography as inseparable mixtures with respective bis- $p$ quinones 12b and 12c. One-pot bromination and quinone formation (entry 6, Table 1 conditions) gave mostly the brominated dimeric quinones 12a-12c (69-75\% yield), however column chromatography separated some dimethoxybenzimidazole intermediates 11a-11c (13-22\% yield). The lower yields (with Method B) of brominated quinones 12a-12c are presumably due to the inferior oxidizing ability of $\mathrm{Br}_{2}$ relative to $\mathrm{Cl}_{2} .{ }^{23}$ The presence of a red-brown vapour in the $\mathrm{NaBr} / \mathrm{Oxone}$ mediated oxidative brominations is evidence for the in situ formation of $\mathrm{Br}_{2}$ (Fig. S3 $\dagger$ ).

Functionalization at both available alicyclic ring-fused DMBBQ CH-positions was established. Trifluoromethylation at the quinone of $\mathbf{5 b}$ gave substrate $\mathbf{5 d}$ in a similar moderate yield ( $51 \%$, Scheme 5) to that reported for DMBBQ 4b. ${ }^{8}$ Using

${ }^{a}$ Recovered 5d (18\%) + 14 (trace); ${ }^{\text {b }}$ Isolated yield of 13 in parentheses

Scheme 5 Radical and electrophilic functionalization.
the Langlois' reagent, intractable baseline products were observed and Baran et al. have attributed peroxide reaction with sulfinate as a significant wastage reaction. ${ }^{24}$ The ${ }^{\circ} \mathrm{CF}_{3}$ radical is considered weakly nucleophilic, ${ }^{25}$ and reported CHalkylations occur at the 'electron-poor' quinone. ${ }^{26,27}$ Chlorination with quinone formation to give the fully functionalized bis- $p$-quinone 14 can be carried out in one or two steps with $\mathbf{5 d}$ depending on the desire to isolate more of the intermediate chloride 13. Using the optimized conditions for chlorination only (Table 1, entry 4 conditions) gave 13 in $73 \%$ yield, with the regioselectivity confirmed by the X-ray crystal structure (Scheme 5 and Fig. $\mathrm{S} 4 \dagger$ ). The torsional angle is almost identical to that of $\mathbf{8}$, indicating the substituents of $\mathbf{1 3}$ have no influence on the adopted solid-state geometry. Oxidation of isolated DMBBQ 13 using NaCl and Oxone gave bis-p-quinone 14 in $85 \%$ yield. Increasing the amount of NaCl and Oxone to favour one pot oxidative chlorination (Table 1, entry 6 conditions), gave bis-p-quinone $\mathbf{1 4}$ from 5d in 68\% yield, with some intermediate DMBBQ 13 (19\%) separated by column chromatography. The smaller yields for chlorides 13 and $\mathbf{1 4}$ reflect the deactivation of the trifluoromethylated DMBBQs $\mathbf{5 d}$ and $\mathbf{1 3}$ towards the electrophilic oxidizing mixture.
$\mathrm{NaX} /$ Oxone system is clearly an efficient system for ringfused DMBBQs, allowing one-pot halogenation and quinone formation. The reality is transformations developed for our specific heterocyclic system (ring-fused DMBBQs) are not readily transferable to other similar systems. According to the literature, ${ }^{28}$ halogenation using NaX/Oxone would not be siteselective where there are other available heterocyclic CH-positions, e.g. the non-functionalised imidazole-2-position.

Nevertheless, future work will aim to take advantage of the difference in reactivity between the two DMBBQ-CHs to increase scope to other site-selective functionalizations.

## Conclusions

New alicyclic $[1,2-a]$ ring-fused DMBBQs undergo one-pot electrophilic aromatic substitution and oxidative demethylation to give halogenated bis-p-quinones using the harmless and inexpensive $\mathrm{NaX} /$ Oxone system. The tuneable system gives mainly the site-selective chlorination and bromination intermediate at lower halogen concentrations. The torsion angle in DMBBQs supports the chemoselectivity by lack of MeO-activation at the quinone-CH. HFIP enhances the oxidative aromatic halogenation and for the first time is used in CAN-mediated oxidative aromatic couplings, which formed DMBBQs. Overall, this article details the synthesis in good to excellent yields of new ringfused bis-benzimidazolequinone heterocyclic systems, and provides reliable late-stage methods for incorporating two different substituents into bis-p-quinones.

## Experimental

## Materials

All chemicals obtained from commercial sources used as received. 5,8-Dimethoxy-2,3-dihydro-1H-pyrrolo[1,2- $a$ ]benzimidazole (6a), 6,9-dimethoxy-1,2,3,4-tetrahydropyrido[1,2-a]benzimidazole (6b), and 1,4-dimethoxy-7,8,9,10-tetrahydro-6H-azepino[1,2-a]benzimidazole ( $\mathbf{6 c}$ ) were prepared in $89 \%$, $72 \%$ and $91 \%$ yield respectively, according to our reported oxidative ring-closure of the appropriate 3,6-dimethoxy-2-(cycloamino) aniline. ${ }^{17} \quad 1,2,3,4$-Tetrahydropyrido $[1,2-a]$ benzimidazole-6,9dione (7) has melting point, chromatographic and spectroscopic data consistent with that previously reported. ${ }^{29}$ 2-(Chloromethyl)-4,7-dimethoxy-1-methyl-1 $H$-benzimidazole was prepared in $85 \%$ yield by $N$-methylation and chlorination of (4,7-dimethoxy-1 H -benzimidazol-2-yl)methanol. ${ }^{8}$ Thin layer chromatography (TLC) was performed on TLC silica gel $60 \mathrm{~F}_{254}$ plates. Flash column chromatography was carried out on silica gel (Apollo Scientific 60/40-63 $\mu \mathrm{m}$ ) and dry column vacuum chromatography used Apollo Scientific silica gel (ZEOprep 60 and $15-35 \mu \mathrm{~m}$ particle size). ${ }^{30}$

## Measurements

All melting points were measured on a Stuart Scientific melting point apparatus SMP1. IR spectra were recorded using a PerkinElmer Spec 1 with ATR attached.

All NMR spectra were recorded using a Bruker Avance III 400 MHz spectrometer equipped with a 5 mm BBFO+, broadband autotune probe and controlled with TopSpin 3.5.7 acquisition software and IconNMR 5.0.7 automation software Copyright © 2017 Bruker BioSpin GmbH. The exception was $2,2^{\prime}$-bis(chloromethyl)-4', $7^{\prime}$-dimethoxy-1, $1^{\prime}$-dimethyl-1H, $1^{\prime} H$ - $\left[5,5^{\prime}-\right.$ bibenzimidazole]-4,7-dione (8) recorded on a JEOL ECX

400 MHz NMR spectrometer equipped with a DEC AXP 300 computer workstation. The chemical shifts are in ppm relative to TMS. ${ }^{13} \mathrm{C}$ NMR spectra at 100 MHz are with complete proton decoupling. NMR assignments are supported by DEPT-135. ${ }^{19} \mathrm{~F}$ NMR spectra were obtained at 376 MHz using automatic digital lock correction in the absence of an internal standard.

HRMS spectra were obtained at the National Mass Spectrometry Facility at Swansea University using a Waters Xevo G2-S or Thermo Scientific LTQ Orbitrap XL 1 mass spectrometer with an Atmospheric Solids Analysis Probe (ASAP), except for DMBBQ 8 obtained at NUI Galway using ESI time-of-flight mass spectrometer (TOFMS) in positive mode using a Waters LCT Mass Spectrometer. The precision of all accurate mass measurements was better than 5 ppm .

A single crystal of 8 was grown by slow evaporation from $10 \% \mathrm{MeOH} / \mathrm{CH}_{2} \mathrm{Cl}_{2}$ at room temperature (Fig. $\mathrm{S} 1 \dagger$ ). Single crystal data for 8 was collected at 299 K using an Oxford Diffraction Xcalibur (equipped with a Mo K $\alpha$ X-ray source and a Sapphire detector) using the CrysAlis ${ }^{\text {Pro }}$ software at NUI Galway.

Single crystals of $7^{\prime}$-bromo- $5^{\prime}, 8^{\prime}$-dimethoxy- $2,2^{\prime}, 3,3^{\prime}$ 'tetrahy-dro- $1 H, 1^{\prime} H$-[6, $6^{\prime}$-bipyrrolo[1,2-a]benzimidazole]-5,8-dione (11a) and $8^{\prime}$-chloro- $6^{\prime}, 9^{\prime}$-dimethoxy-8-(trifluoromethyl)-1, $1^{\prime}, 2,2^{\prime}, 3,3^{\prime}, 4,4^{\prime}-$ octahydro[7, $7^{\prime}$-bipyrido[1,2-a]benzimidazole]-6,9-dione (13) were grown at room temperature by slow evaporation from 1,2-dichloroethane and vapour diffusion of hexane into 1,2-dichloroethane, respectively (Fig. S2 and $\mathrm{S} 4 \dagger$ ). X-ray diffraction data on single crystals of compounds 11a and 13 were collected using an Agilent Oxford Diffraction SuperNova (equipped with a microfocus $\mathrm{Cu} \mathrm{K} \alpha$ X-ray source, a Cryojet5®, and an Atlas CCD detector) using the CrysAlis ${ }^{\text {Pro }}$ software at University College London.

The crystal structures of 8, 11a, and $\mathbf{1 3}$ were solved using SHELXT $^{31}$ and refined using SHELXL, ${ }^{32}$ both of which were operated from within either the Oscail ${ }^{33}$ or the OLEX2 ${ }^{34}$ software packages. For compound 11a, a split atom model for the disorder of the methoxy group containing atom $\mathrm{O}(3)$ was used to model the disorder, which refined to $72.5 \%$ for the methyl group of $\mathrm{C}(13 \mathrm{~A})$ compared to $27.5 \%$ for the methyl group of C(13B).

Crystallographic data for compounds 8, 11a and 13 were deposited with the Cambridge Data Centre with deposition numbers CCDC 1948449, 2022191, and 2022190, $\dagger$ respectively.

## Synthesis of alicyclic ring-fused DMBBQs (5a-5c)

CAN ( $8.793 \mathrm{~g}, 16.04 \mathrm{mmol}$ ) in $\mathrm{H}_{2} \mathrm{O}(80 \mathrm{~mL})$ was added over 30 min to ring-fused benzimidazoles $\mathbf{6 a - 6 c}(8.00 \mathrm{mmol})$ in HFIP $(20 \mathrm{~mL})$ at $0^{\circ} \mathrm{C}$. The solution was stirred for 30 min and evaporated to dryness. $\mathrm{H}_{2} \mathrm{O}(200 \mathrm{~mL})$ was added, and the mixture extracted with $\mathrm{CH}_{2} \mathrm{Cl}_{2}(4 \times 150 \mathrm{~mL})$. The organic extracts were dried $\left(\mathrm{MgSO}_{4}\right)$, evaporated, and purified by flash column chromatography using gradient elution of $\mathrm{CH}_{2} \mathrm{Cl}_{2} /$ MeOH .

8-Chloro-8'-(trifluoromethyl)-1,1',2,2',3,3',4,4'-octahydro[7,7'-bipyrido[1,2-a]benzimidazole]-6,6',9,9'-tetrone (14). (Method A: trace); (Method B: $69 \mathrm{mg}, 68 \%$ ); orange crystals; $R_{\mathrm{f}} 0.49$ (19:1 $\mathrm{CH}_{2} \mathrm{Cl}_{2} / \mathrm{MeOH}$ ); mp (decomp. $>239^{\circ} \mathrm{C}$ ); $\nu_{\text {max }}\left(\right.$ neat, $\left.\mathrm{cm}^{-1}\right) 1669$ $(\mathrm{C}=\mathrm{O}) ;{ }^{1} \mathrm{H}$ NMR ( $400 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta: 4.39(\mathrm{t}, J=5.9 \mathrm{~Hz}, 4 \mathrm{H})$, $3.05(\mathrm{t}, J=6.2 \mathrm{~Hz}, 4 \mathrm{H}), 2.15-2.06(\mathrm{~m}, 4 \mathrm{H}), 2.06-1.96(\mathrm{~m}, 4 \mathrm{H}) ;{ }^{13} \mathrm{C}$ $\left\{{ }^{1} \mathrm{H}\right\}$ NMR $\left(100 \mathrm{MHz}, \mathrm{CDCl}_{3}\right) \delta: 175.7,175.5,172.1,168.6$ (all $\mathrm{C}=\mathrm{O}$ ), 153.7, 153.4, 141.6, 140.7, 140.5, 139.8, 137.1 (all C), $132.0\left(\mathrm{q},{ }^{2} J_{\mathrm{C}-\mathrm{F}}=28.3 \mathrm{~Hz}, 8^{\prime}-\mathrm{C}\right), 130.2,129.5$ (both C), 121.0 (q, $\left.{ }^{1} J_{\mathrm{C}-\mathrm{F}}=277.0 \mathrm{~Hz}, \mathrm{CF}_{3}\right), 45.9,45.8,25.00,24.99($ all CH 2$), 22.1(2 \times$ $\mathrm{CH}_{2}$ ), 19.51, 19.48 (both $\mathrm{CH}_{2}$ ); ${ }^{19} \mathrm{~F}$ NMR ( $376 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta$ : -59.03; HRMS (ASAP) $m / z:[\mathrm{M}+\mathrm{H}]^{+}$calcd for $\mathrm{C}_{23} \mathrm{H}_{17} \mathrm{~N}_{4} \mathrm{O}_{4} \mathrm{~F}_{3}{ }^{35} \mathrm{Cl} 505.0891$; found $505.0889 ; \mathrm{m} / \mathrm{z} 508$ (12\%), 507 $\left(\mathrm{C}_{23} \mathrm{H}_{17} \mathrm{~N}_{4} \mathrm{O}_{4} \mathrm{~F}_{3}{ }^{37} \mathrm{Cl}, 34\right), 506(25), 505\left(\mathrm{C}_{23} \mathrm{H}_{17} \mathrm{~N}_{4} \mathrm{O}_{4} \mathrm{~F}_{3}{ }^{35} \mathrm{Cl}, 100\right)$.

## Oxidation of DMBBQ 13

Oxone ( $74 \mathrm{mg}, 0.12 \mathrm{mmol}$, containing $\mathrm{KHSO}_{5}, 0.24 \mathrm{mmol}$ ) and $\mathrm{NaCl}(14 \mathrm{mg}, 0.24 \mathrm{mmol})$ in $\mathrm{H}_{2} \mathrm{O}(0.12 \mathrm{~mL})$ were added over the course of 5 min to a stirred solution of DMBBQ 13 ( 64 mg , $0.12 \mathrm{mmol})$ in HFIP $(1.2 \mathrm{~mL})$ at room temperature, and stirred for $4 \mathrm{~h} . \mathrm{H}_{2} \mathrm{O}(3 \mathrm{~mL})$ was added, and the mixture extracted with $\mathrm{CH}_{2} \mathrm{Cl}_{2}(3 \times 3 \mathrm{~mL})$. The organic extracts were dried $\left(\mathrm{MgSO}_{4}\right)$, evaporated to dryness, and purified by flash column chromatography using gradient elution of $\mathrm{CH}_{2} \mathrm{Cl}_{2} / \mathrm{MeOH}$ to give bis-pquinone 14 ( $51 \mathrm{mg}, 85 \%$ ); orange crystals; spectral data and melting point were consistent with the above.

## Author contributions

D. Conboy - investigation, methodology and writing; P. Kielty - investigation and visualization; J. C. Bear - investigation (X-ray); J. K. Cockcroft - investigation (X-ray); P. Farràs - supervision; P. McArdle - investigation (X-ray); R. J. Singer resources; D. A. Smith - supervision; F. Aldabbagh - conceptualization, funding acquisition, main supervision and writing.

## Conflicts of interest

There are no conflicts to declare.

## Note after first publication

This article replaces the version published on 05 March 2021, in which part of Scheme 1 was missing.

## Acknowledgements

We thank Kingston University for a PhD Scholarship for Darren Conboy and the Irish Research Council for an Enterprise Partnership Postgraduate Scholarship for Patrick Kielty.
