23 **Abstract**

24 The relevance of  $H_2O_2$  as biomarker for different neurodegenerative diseases and  
25 cancer has been one of the most significant incentives for the development of new  
26 (bio)sensors that allow a more sensitive, selective, fast, and stable quantification of  
27  $H_2O_2$ . In this regard, the association of carbon nanotubes with hemoproteins,  
28 nanoparticles, and other nanostructures and different electrochemical transducers,  
29 has offered new avenues for the construction of innovative  $H_2O_2$  bioanalytical  
30 platforms. This short review highlights the most relevant contributions in the field of  
31 electrochemical (bio)sensors for  $H_2O_2$  based on carbon nanotubes published in the  
32 period 2016-2018.

48 **Introduction**

49 Hydrogen peroxide is a compound of great importance in different fields. It is  
50 a product of several metabolic routes [1,2] and high levels may produce diseases  
51 connected with oxidative stress like cancer, cardiovascular disorders and  
52 Alzheimer disease [3-7]. The concentrations go from nM to  $\mu\text{M}$  depending on the  
53 fluid and cell-type [2]. Due to their oxidative properties,  $\text{H}_2\text{O}_2$  has been also used  
54 for the synthesis of organic compounds, pulp and paper bleaching, sterilization,  
55 clinical and pharmaceutical applications [8,9].

56 Several sensing methodologies have been proposed for the quantification of  
57  $\text{H}_2\text{O}_2$  [10-13], new analytical platforms that allow the fast, highly sensitive and  
58 selective quantification are highly required. Electrochemical sensors have  
59 demonstrated to be very useful for the quantification of different analytes [14-20]  
60 and  $\text{H}_2\text{O}_2$  hydrogen peroxide in particular [17-20]. There are two types of  $\text{H}_2\text{O}_2$   
61 electrochemical sensors, the enzymatic ones, based on the use of biocatalysts  
62 (heme-proteins) [17,18] and the non-enzymatic ones, based on the use of different  
63 catalytic (nano)materials [19,20]. The enzymatic biosensors demonstrated to be a  
64 very interesting alternative for the quantification of  $\text{H}_2\text{O}_2$ ; however, they have some  
65 drawbacks associated with the cost and instability of the enzymes. Consequently,  
66 the development of non-enzymatic strategies for the quantification of hydrogen  
67 peroxide is currently a very hot topic.

68 In this short review, we discuss the most relevant electrochemical sensing  
69 strategies for  $\text{H}_2\text{O}_2$  based on the use of carbon nanotubes (CNTs) developed in the  
70 period 2016-2018 (Figure 1). CNTs are allotropes of carbon that consist of a

71 graphene sheet rolled into a tube [21,22] either defining a cylinder (single-walled  
72 carbon nanotubes, SWCNTs) or concentric and closed tubules (multi-walled  
73 carbon nanotubes, MWCNTs) [23]. Due to their unique properties of CNTs [24-28],  
74 the incorporation of CNTs in these (bio)sensors presents several advantages:  
75 facilitates the charge transfer and/or increases the surface area, and/or enables  
76 the anchoring of different (bio)molecules and/or improves the conductivity of the  
77 resulting platform. The working potential to quantify  $H_2O_2$  in a sensitive and  
78 selective way is a key point. However, the reduction of  $H_2O_2$  requires, in general,  
79 negative potentials to obtain a sensitive response, making necessary a rigorous  
80 desoxygenation of the buffer, standard solutions and samples to avoid the  
81 interference of oxygen reduction. On the other hand, for the oxidation of  $H_2O_2$  is  
82 necessary to work at very positive potentials and under these conditions, the  
83 interference of easily oxidizable compounds usually present in biological fluids or in  
84 foods samples is a critical problem. In these cases, the presence of nanostructures  
85 is very important to decrease the overvoltages. Table 1 summarizes the most  
86 relevant analytical parameters and experimental conditions for the different  $H_2O_2$   
87 electrochemical (bio)sensors discussed in the review.

88

### 89 **$H_2O_2$ electrochemical sensors based on the association of CNTs and** 90 **hemoproteins**

91 Eguílaz et al. [29\*\*] reported the non-covalent functionalization of MWCNTs  
92 with cytochrome c (Cyt c) and the highly sensitive and selective  $H_2O_2$  biosensing  
93 using a glassy carbon electrode (GCE) modified with MWCNTs-Cyt c. The close  
94 interaction of MWCNTs with Cyt c and the efficient biocatalytic activity of the

95 heme protein that supports the MWCNTs, made possible the efficient amperometric  
96 response for  $\text{H}_2\text{O}_2$  at  $-0.100\text{V}$  from the direct electron transfer (DET) of Cyt c. A  
97 linear range from  $1.0 \times 10^{-6}$  to  $1.6 \times 10^{-4}\text{M}$ , a sensitivity of  $(43 \pm 1) \text{mAM}^{-1}\text{cm}^{-2}$ , a limit of  
98 detection (LOD) of  $1.5 \times 10^{-7}\text{M}$ , and very good repeatability, reproducibility and long-  
99 term stability were reported for this biosensor. It was successfully used to quantify  
100  $\text{H}_2\text{O}_2$  in mouthwash and enriched low-fat milk samples. Aghamiri et al. [30]  
101 discussed the advantages of the immobilization of Cyt c at GCE modified with a  
102 porous and conductive thin-film of electropolymerized polyaniline(PANI)/MWCNTs.  
103 The immobilization of the enzyme in the net of the polymer-CNTs facilitated the  
104 DET of the iron center and the quantification of  $\text{H}_2\text{O}_2$  was successfully performed  
105 at submicromolar levels from amperometric measurements at  $-0.400\text{V}$ . It is  
106 important to mention that, as in the case of other pseudoperoxidases, the absence  
107 of the sixth axial heme-ligand in cytochrome c is essential to bind  $\text{H}_2\text{O}_2$  and  
108 catalyze its reduction [31].

109 Alim et al. [32] proposed a very sensitive third-generation  $\text{H}_2\text{O}_2$  biosensor  
110 based on the immobilization of multiporous  $\text{SnO}_2$  nanofiber ( $\text{SnO}_2\text{NFs}$ ), MWCNTs,  
111 and hemoglobin (Hb) at GCE by using chitosan (CS). The proposed architecture  
112 allowed the DET of the protein metallic center and, consequently, the  
113 amperometric detection of  $\text{H}_2\text{O}_2$  at  $-0.400\text{V}$  at nanomolar levels. Another  
114 interesting sensing strategy for the nanomolar detection of  $\text{H}_2\text{O}_2$  was based on a  
115 3D bis-aniline-crosslinked network of 4-aminothiophenol-modified horseradish  
116 peroxidase (HRP) and aniline-modified SWCNTs at a 4-aminothiophenol self-  
117 assembled monolayer (SAM)-modified gold electrode [33]. An original approach  
118 was described by Draminska and Bilewickz [34] who proposed a bienzymatic

119 biosensor based on the use of a nanocomposite integrated by MWCNTs, catalase  
120 and laccase or bilirubin oxidase cross-linked with glutaraldehyde (GAD). Catalase  
121 transforms the  $H_2O_2$  into oxygen and water and the multi-copper enzymes catalyze  
122 the reduction of the enzymatically generated oxygen to water. The sensor was  
123 successfully used to quantify  $H_2O_2$  in different pharmaceutical formulations. The  
124 strategy is interesting although the analytical performance is not as competitive as  
125 the previous ones.

126 Another innovative and competitive alternative involving a catalytic center  
127 that mimics the active site of hemoproteins was presented by Wu et al. [35\*\*]. They  
128 reported the non-covalent immobilization of hemin, an iron(III)protoporphyrin IX,  
129 at MWCNTs using tetraoctylammonium bromide (TOAB) to provide the cations  
130 necessary to bind to the carboxyl groups of hemin and MWCNTS, reducing, in this  
131 way, the electrostatic repulsion of hemin and MWCNTs carboxylic groups, and  
132 preventing the aggregation of the nanomaterials. The resulting platform allowed the  
133 quantification of  $H_2O_2$  between 0.82 and 278.6 $\mu$ M, with a LOD of 0.26 $\mu$ M and a  
134 stability up to 11 days.

135 In general, the enzymatic biosensors allow a sensitive quantification of  
136  $H_2O_2$ , and the overall performance is highly dependent on the efficiency of the  
137 hemoprotein immobilization, being the robustness and the intimate contact with the  
138 carbon nanostructures, key aspects to ensure a competitive analytical device. The  
139 presence of CNTs at the electrode surfaces allows a more efficient DET and the  
140 incorporation of higher amounts of enzyme, largely improving the analytical  
141 performance of the resulting biosensors compared to their counterparts of graphite,  
142 as it have been already demonstrated by Gorton et al. [36, 37].

143

144 **H<sub>2</sub>O<sub>2</sub> electrochemical sensors based on the association of metallic**  
145 **nanoparticles and CNTs**

146 In the last years, the association of metallic nanoparticles (NPs) with CNTs  
147 have demonstrated to be an advantageous alternative for developing highly  
148 sensitive and selective H<sub>2</sub>O<sub>2</sub> sensing [19, 20, 38-45].

149 Joshi et al. [39] addressed the need for a highly sensitive H<sub>2</sub>O<sub>2</sub> microsensor  
150 able to be used in scanning electrochemical microscopy to simultaneously perform  
151 the approach curves and detect low levels of H<sub>2</sub>O<sub>2</sub> in complex matrixes like  
152 bacterial biofilms. The sensor was obtained by electrodeposition of PtNPs at  
153 oxidized-MWCNTs and mixing with the 1-butyl-4-methylpyridinium  
154 hexafluorophosphate ionic liquid (IL) (Figure 2). The LOD was 250nM and the  
155 sensor allowed to obtain a 3D distribution of the H<sub>2</sub>O<sub>2</sub> produced by a bacterial  
156 biofilm.

157 Hamidi and Haghghi [40] reported the modification of GCEs with a  
158 nanocomposite of PdNPs and MWCNTs dispersed in dimethylformamide (DMF).  
159 The catalytic activity of PdNPs largely improved the response of the sensor and  
160 allowed the fast and reproducible quantification of H<sub>2</sub>O<sub>2</sub> either at 0.350V or at  
161 -0.250V, with LODs of 1.2 and 14μM, respectively. Zhang et al. [41\*] presented an  
162 interesting flexible nanohybrid microelectrode based on the use of carbon fiber  
163 (CF), an excellent flexible substrate due to its small size and elasticity modulus,  
164 modified with highly ordered nitrogen doped CNTs arrays (N-CNTAs) decorated  
165 with AuNPs. The synergistic catalytic activity of N-CNTAs and AuNPs allowed to  
166 obtain a fast, stable and reproducible analytical signal at -0.300V, with LOD at

167 nanomolar levels, and successful application for sensing the  $\text{H}_2\text{O}_2$  secreted from  
168 MCF-7 and MDA-MB-231 cells without the influence of bending-induced  
169 mechanical stress. Taking advantage of the inkjet printing potential,  
170 Shamkhalichenar and Choi [42\*] introduced disposable and fast  $\text{H}_2\text{O}_2$  sensors  
171 obtained by inkjet printing of a MWCNTs-based ink on paper followed by the  
172 incorporation of AgNPs to catalyze the reduction of  $\text{H}_2\text{O}_2$ .

173 The association of two or more catalytic centers demonstrated to be very  
174 useful to improve the analytical characteristics of electrochemical sensors. Ko et al.  
175 [43] demonstrated an interesting synergism by incorporating Au and Ag NPs in  
176 addition to SWCNTs. The sensing was performed at  $-0.150\text{V}$  in nitrogen-saturated  
177 solutions, with a LOD of  $0.3\mu\text{M}$  and a very wide linear range, demonstrating the  
178 advantages of the presence of CoNPs in addition to PdNPs.

179 Heli et al. [45] proposed the use of a carbon paste modified with hexagonal  
180 Co-Al-layered double hydroxide nanoshales (CoAILDH) and MWCNTs synthesized  
181 by reflux heating. The resulting sensor was successfully used to quantify  $\text{H}_2\text{O}_2$   
182 either at  $0.230\text{V}$  or at  $-0.350\text{V}$  with LODs of  $5$  and  $10\mu\text{M}$ , respectively.

183 The comparative analysis of the different strategies clearly indicates that the  
184 selection of the metallic center/s, the strategy to incorporate them to the transducer  
185 surface and the efficiency of the interaction with the carbon nanostructures are the  
186 most critical aspect for the development of  $\text{H}_2\text{O}_2$  electrochemical sensors based on  
187 the use of metallic nanoparticles and CNTs.

188

189  **$\text{H}_2\text{O}_2$  electrochemical sensors based on CNTs associated with other**  
190 **nanostructures**

191 Bai et al. [46] presented an innovative work based on GCEs modified with a  
192 nanocomposite of carbon dots (CDs) and oxidized-MWCNTs. The good electrical  
193 conductivity and huge surface area of MWCNTs, their electron acceptor  
194 characteristics and the excellent donor capacity of CDs made possible the  
195 construction of an electrode with high electrocatalytic activity and notable  
196 synergism. MWCNTs:CDs ratio was very important for the analytical performance  
197 of the sensor, being 10:1 the selected one. A fast and stable response, with a  
198 linear range between  $3.5 \times 10^{-6}$  and  $3.0 \times 10^{-4}$  M, a LOD of  $0.25 \mu\text{M}$  and a successful  
199 application for the quantification of the  $\text{H}_2\text{O}_2$  released from HeLa cells and the  $\text{H}_2\text{O}_2$   
200 present in enriched human serum samples was also reported.

201 The use of  $\text{MnO}_2$  as catalytic center for building  $\text{H}_2\text{O}_2$  sensors has received  
202 great attention [47-50]. Begum et al. [47] reported the analytical performance of  
203 GCEs modified with a  $\delta\text{-MnO}_2/\text{MWCNTs}$  nanocomposite obtained by one-step  
204 hydrothermal process in alkaline medium, where  $\text{MnO}_2$  worked as electrocatalyst  
205 and MWCNTs was the responsible for the improvement of the platform  
206 conductivity. The resulting electrode made possible the fast, selective and  
207 reproducible detection of  $\text{H}_2\text{O}_2$  at  $-0.300\text{V}$  in Ar saturated- $0.1\text{ M}$  PBS solution with a  
208 detection limit of  $1\mu\text{M}$ . Recoveries between 98 and 102% were reported in tomato  
209 sauce and tap water samples.

210 An innovative platform was obtained by the modification of GCE with a  
211 rGONR/ $\text{MnO}_2$  nanocomposite obtained by one-step hydrothermal co-reduction of  
212  $\text{KMnO}_4$  and GONR (generated from the unzipping of MWCNTs) using citric acid  
213 [50\*]. The resulting sensor showed an excellent analytical response at  $0.800\text{V}$  in

214 PBS pH 7.4 due to the important synergistic catalytic activity of  $\text{MnO}_2/\text{rGONRs}$  for  
215 the oxidation of  $\text{H}_2\text{O}_2$  and the high surface area and excellent conductivity of  
216 rGONR (Figure 3). The sensor allowed the detection of nanomolar levels of  $\text{H}_2\text{O}_2$   
217 and its quantification in a fetal bovine serum.

218 Shahnavaaz and Hamid [51] proposed the submicromolar detection of  $\text{H}_2\text{O}_2$   
219 at  $-0.65$  V using an electrode modified with MWCNTs- $\text{ZnCr}_2\text{O}_4$ NPs synthesized by  
220 a hydrothermal method and further calcination at  $500$  °C. The resulting sensor  
221 presented a linear range between  $50\mu\text{M}$  and  $0.8\text{mM}$  and was successfully used for  
222 the quantification of  $\text{H}_2\text{O}_2$  in lens cleaning solution.

223 A more elaborated architecture based on the modification of GCEs with a  
224 composite of Pt encapsulated in a sixth-generation poly(amidoamine) dendrimer  
225 with amine terminations (G6- $\text{NH}_2$  PAMAM dendrimer) covalently attached to  
226 carboxylated-CNTs, was reported by Liu et al. [52]. A fast, reproducible and stable  
227 response was obtained at  $-0.150\text{V}$ , with a linear range between  $3$  and  $400\mu\text{M}$ , a  
228 LOD of  $0.8\mu\text{M}$ , and a successful determination of  $\text{H}_2\text{O}_2$  in MCF-7 cells.

229 Currently, metal-organic frameworks (MOF) are under intense investigation  
230 for building electrochemical sensors. Wang et al. [53] proposed the quantification  
231 of  $\text{H}_2\text{O}_2$  in  $0.1\text{M}$  NaOH at  $0.500\text{V}$  using GCEs modified with a dispersion of Ni(II)-  
232 based MOFNPs anchored on CNTs by solvothermal method (Ni(II)-MOF/CNTs),  
233 covered by 2.5% Nafion, where Ni(II) was easily adsorbed at oxidized-CNTs  
234 through the oxygenated groups. A highly reproducible and fast response, with  
235 linear range between  $0.01$  and  $51.6\text{mM}$  was obtained with the sensor.

236 Roushani et al. [54\*\*] reported a sensitive analytical platform for the  
237 quantification of  $\text{H}_2\text{O}_2$  based on a rational selection of the components:  $\text{C}_{60}$ ,

238 MWCNTs, CS, and 1-methyl-3-octylimidazoliumtetrafluoroborate (IL) deposited at  
239 GCE; methylene blue (MB) deposited at the resulting platform; and Cu(II)  
240 preconcentrated through the coordination with MB. This CuNPs/MB/MWCNTs-C<sub>60</sub>-  
241 CS-IL sensor presented advantages such as the large surface area,  $\pi$ - $\pi$   
242 conjugated bonds, good conductivity, and synergism between Cu(II) and MB,  
243 which accelerated the charge transfer and facilitated the reduction of H<sub>2</sub>O<sub>2</sub> at –  
244 0.180V. Reproducible and repeatable signals were obtained between 0.2 and 4 $\mu$ M,  
245 with a LOD of 55nM. The sensor was used to quantify H<sub>2</sub>O<sub>2</sub> in enriched serum  
246 samples with very good recoveries.

247 Layer-by-layer self-assembling of monolayers is another interesting  
248 alternative for the versatile design of different sensing platforms. In this direction,  
249 De Fátima Cardoso Soares et al. [55] proposed a strategy based on ITO modified  
250 by self-assembling of agar-SWCNTs, poly(allylamine hydrochloride)(PAH)-  
251 SWCNTs, and alizarin red S (ARS) as catalyst. The analytical signal was obtained  
252 by amperometry at –0.500V with a LOD of 0.15 $\mu$ M. Zhang et al. [56] reported  
253 another supramolecular strategy based on the self-assembling of 2,9,16,23-tetra[4-  
254 (N-methyl)pyridinyloxy]-phtalocyanine cobalt (II) ([TMPyPcCo]<sup>4+</sup>) and oxidized-  
255 MWCNTs at GCE through electrostatic interaction to obtain an interconnected  
256 assembly (([TMPyPcCo]<sup>4+</sup>/MWCNTs)<sub>n</sub>). The combination of [TMPyPcCo]<sup>4+</sup> and  
257 oxidized-MWCNTs without any inert polymer binders allowed to expose more  
258 active sites for electrocatalysis, aspect very important in the performance of the  
259 sensor at –0.250V. Wang et al. [57] proposed the use of oxygen-doped, nitrogen  
260 rich carbon nanoribbons polymer (ONPCNRs) electrostatically bond to

261 poly(diallyldimethylammonium chloride) (PDDA)-modified SWCNTs. The  
262 nanocomposite showed an improved electrocatalytic activity due to the electron  
263 withdrawing ability of the N-atoms from the ONPCNRs which create net positive  
264 charge on the adjacent carbon atoms in the PDDA/SWCNTs plane. The sensor,  
265 prepared by dropping ONPCNR/SWCNTs-PDDA at GCE, allowed the  
266 submicromolar detection of  $\text{H}_2\text{O}_2$  with stable response for 2 weeks and successful  
267 use for the detection of  $\text{H}_2\text{O}_2$  in enriched ultra-high temperature milk.

268 Mayuri et al. [58] introduced a copper-bipyridyl complex immobilized at  
269 MWCNTs-Nafion modified-GCE as a bioinspired electrocatalytic molecular system  
270 (Figure 4). The 2,2'-bipyridyl-complex was dropped at Nafion/MWCNTs-modified  
271 GCE and the copper center was finally immobilized at the resulting platform by  
272 cycling 40 times in a 2mM  $\text{CuSO}_4$  solution. The flow injection analysis with  
273 amperometric detection at  $-0.200\text{V}$  presented a linear range between  $1\mu\text{M}$  and  
274 1mM and a submicromolar-LOD. The analytical applications of the sensor were  
275 demonstrated by determination of  $\text{H}_2\text{O}_2$  in a cosmetic product.

276 Nasirizadeh et al. [59] proposed the use of a GCE modified with MWCNTs  
277 dispersed in DMF followed by cycling the potential in a solution of reactive blue 19  
278 (RB), a quinone derivative that catalyzes the reduction of  $\text{H}_2\text{O}_2$ , and allowed the  
279 detection of submicromolar concentrations of  $\text{H}_2\text{O}_2$ . The sensor was successfully  
280 used for the quantification of  $\text{H}_2\text{O}_2$  in fruit juices.

281

## 282 **General conclusions and perspectives**

283 This short review addresses the recent trends for  $\text{H}_2\text{O}_2$  electrochemical  
284 (bio)sensing based on the use of CNTs. Special emphasis was given to the

285 discussion of i) the strategies used to build the (bio)sensor, ii) the nature of the  
286 (bio)catalytic center, iii) the origin of the analytical signal, and iv) the most relevant  
287 analytical characteristics of the (bio)sensors.

288 While the use of hemoproteins as biocatalytic centers has allowed to obtain  
289 a highly sensitive H<sub>2</sub>O<sub>2</sub> biosensing, special attention should be given to build  
290 platforms with increased robustness and enhanced biocatalytic activity. H<sub>2</sub>O<sub>2</sub>  
291 sensors based on the use of nanomaterials as catalytic centers has also  
292 demonstrated to be very competitive; however, it is necessary to design new  
293 schemes of synthesis and functionalization of nanomaterials to obtain platforms  
294 that allow a more sensitive and selective quantification of this analyte.

295 Future trends should be focused on i) the rational modification of  
296 peroxidases and peroxidases-like proteins to obtain biocatalysts with increased  
297 robustness and biocatalytic activity, ii) the one-step functionalization of CNTs with  
298 new catalytic nanomaterials and/or catalytic centers that mimics the active sites of  
299 peroxidases or proteins with peroxidase activity, iii) the one-step unzipping of  
300 CNTs and reduction of the resulting GONR to obtain an adequate balance of  
301 mono- and bidimensional carbon nanostructures with different functionalization,  
302 and iv) the development of new inks for screen- or inkjet-printing involving  
303 elements that make possible the preparation of more efficient H<sub>2</sub>O<sub>2</sub> disposable  
304 (bio)sensors.
