# Relative Intrinsic Distance and Hyperbolic Imbedding 

Shoshichi Kobayashi＊

December 1， 1992

Let $Y$ be a complex space and $X$ a complex subspace with compact closure $\bar{X}$ ．Let $d_{X}$ and $d_{Y}$ denote the intrinsic pseudo－distances of $X$ and $Y$ ，respectively，（see［3］）．We say that $X$ is hyperbolically imbedded in $Y$ if，for every pair of distinct points $p, q$ in the closure $\bar{X} \subset Y$ ，there exist neighborhoods $U_{p}$ and $U_{q}$ of $p$ and $q$ in $Y$ such that $d_{X}\left(U_{p} \cap X, U_{q} \cap X\right)>0$ ． （In applications，$X$ is usually a relatively compact open domain in $Y$ ．）It is clear that a hyperbolically imbedded complex space $X$ is hyperbolic．The condition of hyperbolic imbedding says that the distance $d_{X}\left(p_{n}, q_{n}\right)$ remains positive when two sequences $\left\{p_{n}\right\}$ and $\left\{q_{n}\right\}$ in $X$ approach two distinct points $p$ and $q$ of the boundary $\partial X=\bar{X}-X$ ．The concept of hyperbolic imbedding was first introduced in Kobayashi［3］to obtain a generalization of the big Picard theorem．The term＂hyperbolic imbedding＂was first used by Kiernan［2］．

We shall now introduce a pseudo－distance $d_{X, Y}$ on $\bar{X}$ so that $X$ is hy－ perbolically imbedded in $Y$ if and only if $d_{X, Y}$ is a distance．

Let $\mathcal{F}_{X, Y}$ be the family of holomorphic maps $f: D \rightarrow Y$ such that $f^{-1}(X)$ is either empty or a singleton．Thus，$f \in \mathcal{F}_{X, Y}$ maps all of $D$ ，with the exception of possibly one point，into $X$ ．The exceptional point is of course mapped into $\bar{X}$ ．

We define a pseudo－distance $d_{X, Y}$ on $\bar{X}$ in the same way as $d_{Y}$ ，but using only chains of holomorphic disks belonging to $\mathcal{F}_{X, Y}$ ：

$$
\begin{equation*}
d_{X, Y}(p, q)=\inf _{\alpha} l(\alpha), \quad p, q \in \bar{X}, \tag{1}
\end{equation*}
$$

[^0]where the infimum is taken over all chains $\alpha$ of holomorphic disks from $p$ to $q$ which belong to $\mathcal{F}_{X, Y}$. If $p$ or $q$ is in the boundary of $X$, such a chain may not exist. In such a case, $d_{X, Y}(p, q)$ is defined to be $\infty$. For example, if $X$ is a convex bounded domain in $\mathbf{C}^{n}$, any holomorphic disk passing through a boundary point of $X$ goes outside the closure $\bar{X}$, so that $d_{X, \mathrm{C}^{n}}(p, q)=\infty$ if $p$ is a boundary point of $X$. On the other hand, if $X$ is Zariski-open in $Y$, any pair of points $p, q$ in $\bar{X}=Y$ can be joined by a chain of holomorphic disks beloning to $\mathcal{F}_{X, Y}$, so that $d_{X, Y}(p, q)<\infty$.

Since

$$
\operatorname{Hol}(D, X) \subset \mathcal{F}_{X, Y} \subset \operatorname{Hol}(D, Y)
$$

we have

$$
\begin{equation*}
d_{Y} \leq d_{X, Y} \leq d_{X} \tag{2}
\end{equation*}
$$

where the second inequality holds on $X$ while the first is valid on $\bar{X}$.
For the punctured disk $D^{*}=D-\{0\}$, we have

$$
\begin{equation*}
d_{D \cdot, D}=d_{D} \tag{3}
\end{equation*}
$$

The inequality $d_{D \cdot, D} \geq d_{D}$ is a special case of (2). Using the identity map $\operatorname{id}_{D} \in \mathcal{F}_{D \cdot, D}$ as a holomorphic disk joining two points of $D$ yeilds the opposite inequality.

Let $X^{\prime} \subset Y^{\prime}$ be another pair of complex spaces with $\bar{X}^{\prime}$ compact. If $f: Y \rightarrow Y^{\prime}$ is a holomorphic map such that $f(X) \subset X^{\prime}$, then

$$
\begin{equation*}
d_{X^{\prime}, Y^{\prime}}(f(p), f(q)) \leq d_{X, Y}(p, q) \quad p, q \in \bar{X} \tag{4}
\end{equation*}
$$

We can also define the infinitesimal form $F_{X, Y}$ of $d_{X, Y}$ in the same way as the infinitesimal form $F_{Y}$ of $d_{Y}$, again using $\mathcal{F}_{X, Y}$ instead of $\operatorname{Hol}(D, Y)$. Theorem. A complex space $X$ is hyperbolically imbedded in $Y$ if and only if $d_{X, Y}(p, q)>0$ for all pairs $p, q \in \bar{X}, p \neq q$.

Proof. From $d_{X, Y} \leq d_{X}$ it follows that if $d_{X, Y}$ is a distance, then $X$ is hyperbolically imbedded in $Y$.

Let $E$ be any length function on $Y$. In order to prove the converse, it suffices to show that there is a positive constant $c$ such that $c E \leq F_{X, Y}$ on $\bar{X}$. Suppose that there is no such constant. Then there exist a sequence of tangent vectors $v_{n}$ of $\bar{X}$, a sequence of holomorphic maps $f_{n} \in \mathcal{F}_{X, Y}$ and a sequence of tangent vectors $e_{n}$ of $D$ with Poincaré length $\left\|e_{n}\right\| \searrow 0$ such that $f_{n}\left(e_{n}\right)=v_{n}$. Since $D$ is homogeneous, we may assume that $e_{n}$ is a vector at the origin of $D$.

In constructing $\left\{f_{n}\right\}$, instead of using the fixed disk $D$ and varying vectors $e_{n}$, we can use varying disks $D_{R_{n}}$ and a fixed tangent vector $e$ at the origin with $R_{n} \nearrow \infty$. (We take $e$ to be the vector $d / d z$ at the origin of $D$, which has the Euclidean length 1 . Let $\left|e_{n}\right|$ be the Euclidean length of $e_{n}$, and $R_{n}=1 /\left|e_{n}\right|$. Instead of $f_{n}(z)$ we use $f_{n}\left(\left|e_{n}\right| z\right)$.) Let $\mathcal{F}_{X, Y}^{R_{n}}$ be the family of holomorphic maps $f: D_{R_{n}} \rightarrow Y$ such that $f^{-1}(X)$ is either empty or a singleton. Having replaced $D, e_{n}$ by $D_{R_{n}}, e$, we may assume that $f_{n} \in \mathcal{F}_{X, Y}^{R_{n}}$ and $f_{n}(e)=v_{n}$. We want to show that a suitable subsequence of $\left\{f_{n}\right\}$ converges to a nonconstant holomorphic map $f: \mathbf{C} \rightarrow \bar{X}$.

By applying Brody's lemma [1] to each $f_{n}$ and a constant $0<c<\frac{1}{4}$ we obtain holomorphic maps $g_{n} \in \operatorname{Hol}\left(D_{R_{n}}, Y\right)$ such that
(a) $g_{n}^{*} E^{2} \leq c R_{n}^{2} d s_{R_{n}}^{2}$ on $D_{r_{n}}$ and the equality holds at the origin 0 ;
(b) Image $\left(g_{n}\right) \subset \operatorname{Image}\left(f_{n}\right)$.

Since $g_{n}$ is of the form $g=f_{n} \circ \mu_{r_{n}} \circ h_{n}$, where $h_{n}$ is an automorphism of $D_{R_{n}}$ and $\mu_{r_{n}},\left(0<\mu_{r_{n}}<1\right.$, is the multiplication by $r_{n}$, each $g_{n}$ is also in $\mathcal{F}_{X, Y}$.

Now, as in the proof of Brody's theorem [1] we shall construct a nonconstant holomorphic map $h: \mathrm{C} \rightarrow Y$ to which a suitable subsequence of $\left\{g_{n}\right\}$ converges. In fact, since

$$
g_{n}^{*} E^{2} \leq c R_{n}^{2} d s_{R_{n}}^{2} \leq c R_{m}^{2} d s_{R_{m}}^{2} \quad \text { for } \quad n \geq m,
$$

the family $\mathcal{F}_{m}=\left\{g_{n} \mid D_{R_{m}}, n \geq m\right\}$ is equicontinuous for each fixed $m$. Since the family $\mathcal{F}_{1}=\left\{g_{n} \mid D_{R_{1}}\right\}$ is equicontinuous, the Arzela-Ascoli theorem implies that we can extract a subsequence which converges to a map $h_{1} \in$ $\operatorname{Hol}\left(D_{R_{1}}, Y\right)$. (We note that this is where we use the compactness of $\bar{X}$.) Applying the same theorem to the corresponding sequence in $\mathcal{F}_{2}$, we extract a subsequence which converges to a map $h_{2} \in \operatorname{Hol}\left(D_{R_{2}}, Y\right)$. In this way we obtain maps $h_{k} \in \operatorname{Hol}\left(D_{R_{k}}, Y\right), k=1,2, \cdots$ such that each $h_{k}$ is an extension of $h_{k-1}$. Hence, we have a map $h \in \operatorname{Hol}(\mathbf{C}, Y)$ which extends all $h_{k}$.

Since $g_{n}^{*} E^{2}$ at the origin 0 is equal to $\left(c R_{n}^{2} d s_{R_{n}}^{2}\right)_{z=0}=4 c d z d \bar{z}$, it follows that

$$
\left(h^{*} E^{2}\right)_{z=0}=\lim _{n \rightarrow \infty}\left(g_{n}^{*} E^{2}\right)_{z=0}=4 c d z d \bar{z} \neq 0,
$$

which shows that $h$ is nonconstant.
Since $g_{n}^{*} E^{2} \leq c R_{n}^{2} d s_{R_{n}}^{2}$, in the limit we have

$$
h^{*} E^{2} \leq 4 c d z d \bar{z} .
$$

By suitably normalizing $h$ we obtain

$$
h^{*} E^{2} \leq d z d \bar{z} \quad \text { with the equality holding at } \quad z=0 .
$$

We may assume that $\left\{g_{n}\right\}$ itself converges to $h$. Since $h$ is the limit of of $\left\{g_{n}\right\}$, clearly $h(\mathbf{C}) \subset \bar{X}$. Let $p, q$ be two points of $h(\mathbf{C})$, say $p=h(a)$ and $q=h(b)$. Taking a subsequence and suitable points $a, b$ we may assume that $g_{n}(a), g_{n}(b) \in X$. Then $\lim g_{n}(0)=p$ and $\lim g_{n}(a)=q$ and

$$
d_{X}\left(g_{n}(a), g_{n}(b)\right) \leq d_{D_{R_{n}}}(a, b) \rightarrow 0 \quad \text { as } \quad n \rightarrow \infty,
$$

contradicting the assumption that $X$ is hyperbolically imbedded in $Y$. Q.E.D.
This relative distance $d_{X, Y}$ simplifies the proof of the big Picard theorem as formulated in [3].
