COMMUNICATION

Synthesis and coordination behavior of Cu^I bis(phosphaethenyl)pyridine complexes

Yumiko Nakajima,*^{a,b} Yu Shiraishi,^b Takahiro Tsuchimoto^b and Fumiyuki Ozawa*^{a,b}

Received (in XXX, XXX) Xth XXXXXXXX 20XX, Accepted Xth XXXXXXXX 20XX 5 DOI: 10.1039/b000000x

 Cu^{I} complexes bearing BPEP as a PNP-pincer type phosphaalkene ligand undergo effective bonding interactions with SbF₆⁻ and PF₆⁻ as non-coordinating anions to give [Cu(SbF₆)(BPEP)] and [Cu₂(BPEP)₂(μ -PF₆)]⁺, respectively

- ¹⁰ [BPEP = 2,6-bis(1-phenyl-2-phosphaethenyl)pyridine]. NMR and theoretical studies indicate a reduced anionic charge of the μ -PF₆ ligand, which is induced by the strong π -accepting ability of BPEP.
- Phosphaalkenes with P=C bond(s) are low-coordinate ¹⁵ phosphorus compounds that possess extremely low-lying π^* orbitals around the phosphorus atom, and thus exhibit strong π -acceptor properties towards transition metals.^{1,2} We have demonstrated with bidentate diphosphinidenecyclobutene ligands (DPCB-Y) that this property is useful for catalysis,
- ²⁰ leading to highly efficient organic transformations.³ More recently, we have developed 2,6-bis[1-phenyl-2-(2,4,6-tri-*tert*-butylphenyl)-2-phosphaethenyl]pyridine (BPEP) as a tridentate PNP-pincer type phosphaalkene ligand, which successfully stabilizes a coordinatively unsaturated 15-25 electron complex with a high-spin Fe¹ center.⁴
- This paper reports the synthesis and structures of BPEP complexes of copper. Although PNP-pincer type ligands are ongoing research topics in coordination chemistry,⁵ their copper complexes have been extremely limited.⁶⁻⁸ In this ³⁰ study, we found that BPEP forms a Cu^I complex of a highly
- electron-deficient nature, causing effective bonding interactions with "non-coordinating" anions such as SbF_6^- and PF_6^- . The BPEP ligand was introduced to CuBr in toluene at
- 90 °C (Scheme 1). The resulting [CuBr(BPEP)] (1) was 35 characterized by NMR spectroscopy and elemental analysis. While it has been shown that [CuBr(pnp)] [pnp = 2,6-bis(di*tert*-butylphosphinomethyl)pyridine] as a phosphine analogue adopts a three-coordinate structure without Cu–N bonding,⁶
- complex 1 has the four-coordinate structure with a distorted ⁴⁰ tetrahedral configuration as confirmed by X-ray diffraction analysis (see ESI). A similar structure has been found for the complex with a PNP-pincer type phosphinine ligand, and attributed to lower σ -donating ability of low-coordinate phosphorus ligands than phosphine ligands.⁷
- ⁴⁵ Complex **1** reacted with silver salts of non-coordinating anions (AgX; $X = SbF_6$ and PF_6) to afford complexes of the formula "CuX(BPEP)" [X = SbF₆ (**2a**), PF₆ (**2b**)]. Since both

Scheme 1 Mes* = 2,4,6-tri-*tert*-butylphenyl.

- ⁵⁰ complexes exhibited the same ³¹P NMR chemical shift (δ 213.3) in CD₂Cl₂, they should exist in ionic form in a polar solvent without direct interaction between [Cu(BPEP)]⁺ and X⁻.
- Complex **2a** readily coordinated with MeCN, CO, and ⁵⁵ [']BuNC in CD₂Cl₂ to form $[Cu(L)(BPEP)]^+SbF_6^-[L = MeCN$ **(3)**, CO**(4)**, [']BuNC**(5)**], respectively. The v(CO) band of**3** appeared at 2132 cm⁻¹ in the IR spectrum; the value is close tothat of free CO (2143 cm⁻¹). Complex**5**exhibited the v(NC)band at 2198 cm⁻¹. This value is higher than that of the $⁶⁰ phosphine analogue <math>[Cu('BuNC)(pnp)]^+SbF_6^-$ (2177 cm⁻¹).⁶ These data illustrate the highly electron-deficient nature of the copper center.

CODEC CONTROL CONTRO

cationic $[Cu(BPEP)]^+$ moiety to form a neutral complex in nonpolar C₆D₆. To examine this point, single crystals of **2a** ⁷⁵ were grown from a toluene solution (87%), and examined by X-ray diffraction analysis.

Fig. 1 ORTEP drawing of 2a with 50% probability ellipsoids. Hydrogen atoms, disordered *tert*-butyl groups and disordered F6 atom were omitted for clarity. Selected bond distances (Å) and angles (deg): Cu–N 2.107(3), 5 Cu–P1 2.2526(11), Cu–P2 2.2612(11), Cu–F1 2.190(3), Sb–F1 1.916(3), Sb–F2 1.843(4), Sb–F3 1.859(5), Sb–F4 1.846(4), Sb–F5 1.850(5), N–Cu–F1 146.05(15), P1–Cu–P2 156.25(5), Cu–F1–Sb 143.9(2).

Figure 1 shows the structure of **2a**. The copper center has a distorted tetrahedral configuration with the N–Cu–F1 angle of 10 146.04(15)° and the P1–Cu–P2 angle of 156.25(5)°. The Cu–

- F1–Sb bond angle is $143.9(2)^{\circ}$, and the Sb atom adopts a typical octahedral configuration. The Cu–N and Cu–P lengths are in the range of PNP-pincer complexes (2.06–2.16 and 2.22–2.32 Å, respectively).^{6–8}
- ¹⁵ The most striking feature of **2a** is the significantly short Cu–F1 bond [2.190(3) Å], which is comparable to that of Cu¹ fluorides (~2.1 Å).¹⁰ Reflecting the occurrence of an effective bonding interaction between the Cu and F1 atoms, the Sb–F1 bond is elongated by 0.057–0.073 Å, compared with the other
- ²⁰ Sb-F bonds. To the best of our knowledge, this is the first example of a Cu^I complex with a coordinated SbF₆⁻ anion. Next, we attempted to crystallize PF₆ complex **2b** from a
- toluene solution. However, the crystalline product obtained was not 2b, but a cationic PF₆-bridged dimer of Cu(BPEP)
- ²⁵ units, having a PF₆⁻ counter anion (6). Figure 2 shows the X-ray structure of the cationic portion, which adopts C_i symmetry with the P3 atom at the point of symmetry. Two Cu(BPEP) units are connected by a μ-PF₆ group in a zigzag conformation. The length of the Cu–F1 bond is 2.241(2) Å, ³⁰ which is somewhat longer than that of **2a**, but still in the range
- of an effective bonding interaction between the Cu and F atoms.¹¹ Moreover, the P3–F1 bond [1.637(2) Å] is clearly longer than the other P–F bonds [1.586(2) and 1.588(2) Å].
- NMR spectroscopy revealed that the dimeric structure of **6** $_{35}$ was preserved in CD₂Cl₂, even in the presence of excess MeCN or CO. Furthermore, dynamic behavior on the NMR time-scale was observed within the molecule (Scheme 2).

$$(\mathsf{BPEP})\mathsf{Cu} \xrightarrow{\mathsf{F}}_{\mathsf{F}} \xrightarrow{\mathsf{F}}_{\mathsf{F}} \xrightarrow{\mathsf{F}}_{\mathsf{Cu}(\mathsf{BPEP})} \xrightarrow{\mathsf{F}}_{(\mathsf{BPEP})\mathsf{Cu}} \xrightarrow{\mathsf{F}}_{\mathsf{F}} \xrightarrow{\mathsf{F}}_{\mathsf{F}} \xrightarrow{\mathsf{F}}_{\mathsf{F}} \xrightarrow{\mathsf{Cu}(\mathsf{BPEP})} \operatorname{color indication:} \mathbf{F} = F1, \mathbf{F} = F2, \mathbf{F} = F3$$

Scheme 2

Figure 3(a) shows the ¹⁹F NMR spectrum measured at room temperature, showing two sets of doublets at δ -73.7 (¹J_{PF} = 711 Hz) and -77.8 (¹J_{PF} = 978 Hz). Since the chemical shift and ¹J_{PF} constant for the former signal were identical to those ⁴⁵ of Bu₄NPF₆, this signal is assigned to PF₆⁻ as the counter anion. Accordingly, the latter arises from the μ -PF₆ group. A

Fig. 2 ORTEP drawing of 6 with 50% probability ellipsoids. Hydrogen atoms and counter anion (PF₆[−]) are omitted for clarity. Selected bond ⁵⁰ distances (Å) and angles (deg): Cu–N 2.097(3), Cu–P1 2.2613(10), Cu–P2 2.2638(9), Cu–F1 2.241(2), P3–F1 1.637(2), P3–F2 1.586(2), P3–F3 1.588(2), N–Cu–F1 144.32(9), P1–Cu–P2 157.34(4), N–Cu–F1 144.32(9), Cu–F1–P3 128.95(13).

Fig. 3 (a) ¹⁹F and (b) ³¹P{¹H} NMR spectra of **6** in CD₂Cl₂ at 20 °C.

remarkable feature of the spectrum is the significantly weak intensity of the latter signal at δ -77.8. The ¹*J*_{PF} value (978 Hz) is clearly larger than that of the PF₆⁻ anion (711 Hz), and comparable to that of neutral PF₅ (938 Hz).¹²

⁶⁰ The ³¹P{¹H} NMR spectrum shown in Fig. 3(b) consists of two sets of signals at δ –17.3 (¹J_{PF} = 978 Hz) and –143.0 (¹J_{PF} = 711 Hz), arising from μ -PF₆ and PF₆⁻, respectively. The former signal appears as a triplet, while the latter shows septet coupling as expected for PF₆⁻; namely, the P–F couplings for ⁶⁵ four out of the six fluorine atoms are missing from the signal of the μ -PF₆ group. This phenomenon is rationalized by assuming effective interactions of the four fluorine atoms with copper centers having a quadrupole moment (I = 3/2) via the rapid motion illustrated in Scheme 2. This behavior was not ⁷⁰ frozen at –80 °C.

To gain further insight into the bonding interaction between copper and the μ -PF₆ group, DFT calculations were carried out. Initially, we attempted geometry optimization for a model compound of the cationic part of **6**, [(bpep)Cu-(μ -PF₆)-Cu-⁷⁵ (bpep)]⁺ (**6**'), in which the 2,4,6-tri-*tert*-butylphenyl (Mes*) and phenyl groups on the BPEP ligands were replaced by hydrogen atoms. However, although the dimeric structure of **6** was reproduced, distances between the Cu and F atoms were unreasonably shortened (Cu-F1 = 2.16 Å; Cu-F2 = 2.48 Å).

This is probably due to the absence of the bulky Mes* groups. Therefore, the geometry of the Cu-(μ -PF₆)-Cu core was fixed to the X-ray structure, and the remaining portion was optimized assuming C_2 symmetry around the F3–Cu–F3* axis.

- ⁵ Figure 4 shows the optimized geometry of **6'** under the above structural constraints. The Mayer's bond orders (*B*) for Cu–F and P–F bonds are also presented. There is evidence for a bonding interaction between Cu and F1 (B = 0.32) and a weakening of the P3–F1 bond (B = 0.66). It is also observed ¹⁰ that the F2 atom interacts with the Cu atom with a bond order
- a that the F2 atom interacts with the Cu atom with a bond order of 0.13, despite the long distance between those atoms (3.054 Å). Bonding interactions of F atoms with Cu centers are also observed in several molecular orbitals (see ESI).
- Table 1 compares the charge distributions in $[(bpep)Cu-(\mu-15 \text{ PF}_6)-Cu(bpep)]^+$ (6') and $[Cu(bpep)]^+$ (2'), which were evaluated by natural population analysis. The μ -PF₆ group of 6' is charged to -0.84, meaning that the negative charge of the PF₆⁻ anion (-1.00) is reduced by bridging coordination with two molecules of 2'. Since the copper center of 6' is more
- ²⁰ positively charged than that of **2'**, it is concluded that the negative charge of the PF_6^- anion is distributed to the bpep ligand upon the formation of **6'**, very probably via π -backbonding between copper and bpep.

Complexes 2a and 2b undergo ionic dissociation in CD₂Cl₂

- ²⁵ as a polar solvent (*vide supra*). It was found that the complexes cleave the Si–N bond of Me₃SiN₃ to afford $[Cu_2(BPEP)_2(\mu-N_3)]^+X^-$ [X = SbF₆ (**7a**), PF₆ (**7b**)] in 96 and 36% yields, respectively, along with Me₃SiF (Scheme 3). The reactions probably proceed via cooperative activation of
- ³⁰ Me₃SiN₃ by the electrophilic copper center and nucleophilic fluoride ion. Since it is known that it is very difficult to dissociate a fluoride ion from SbF_6^- and PF_6^- as non-coordinating anions,¹³ the high reactivity of **2a** and **2b** should be attributed to the high electrophilicity of [Cu(BPEP)]⁺.
- In summary, we have reported novel Cu^I complexes bearing a phosphaalkene-based PNP-pincer ligand (BPEP). Thanks to the strong π -accepting ability of the P=C bonds, the $[Cu(BPEP)]^+$ species possesses a highly electron-deficient copper center, exhibiting strong affinity towards SbF₆⁻ and
- ⁴⁰ PF₆⁻ as non-coordinating anions. Thus, SbF₆⁻ is coordinated with [Cu(BPEP)]⁺ to form [Cu(SbF₆)(BPEP)] (**2a**) as a neutral species. On the other hand, PF₆⁻ formed [Cu₂(BPEP)₂(μ-PF₆)]⁺PF₆⁻ (**6**). The dinuclear structure of **6** is stable in solution even in the presence of excess MeCN or CO. This is ⁴⁵ due to the occurrence of effective bonding interactions
- between the Cu and F atoms.
