1 **Abstract**

2 Aicardi-Goutières syndrome (AGS) is a rare, genetically determined early-onset progressive
3 encephalopathy. To date, mutations in six genes have been identified as etiologic for AGS. Our Japanese
4 nationwide AGS survey identified six AGS individuals without a molecular diagnosis; we performed
5 whole exome sequencing on three of these individuals. After removal of the common polymorphisms
6 found in SNP databases, we were able to identify *IFIH1* heterozygous missense mutations in all three. In
7 vitro functional analysis revealed that *IFIH1* mutations increased type I interferon production, and the
8 transcription of interferon-stimulated genes were elevated. *IFIH1* encodes MDA5, and mutant MDA5
9 lacked ligand-specific responsiveness, similarly to the dominant *IFIH1* mutation responsible for the SLE
10 mouse model that results in type I interferon overproduction. This study suggests that the *IFIH1*
11 mutations are responsible for the AGS phenotype due to an excessive production of type I interferon.

1 Aicardi-Goutières syndrome (AGS [MIM 225750]) is a rare, genetically determined early-onset
2 progressive encephalopathy¹. Individuals affected with AGS typically suffer from progressive
3 microcephaly associated with severe neurological symptoms, such as hypotonia, dystonia, seizures,
4 spastic quadriplegia, and severe developmental delay². On brain imaging, AGS is characterized by basal
5 ganglia calcification, white matter abnormalities, and cerebral atrophy^{3, 4}. Cerebrospinal fluid (CSF)
6 analyses show chronic lymphocytosis and elevated levels of IFN- α and neopterin³⁻⁵. AGS individuals are
7 often misdiagnosed as having intrauterine infections, such as TORCH syndrome, because of the
8 similarities of these disorders, particularly the intracranial calcifications¹. In AGS, etiological mutations
9 have been reported in the following six genes: *TREX1* (MIM 606609), which encodes a DNA
10 exonuclease; *RNASEH2A* (MIM 606034), *RNASEH2B* (MIM 610326), and *RNASEH2C* (MIM 610330),
11 which together comprise the RNase H2 endonuclease complex; *SAMHD1* (MIM 606754), which encodes
12 a deoxynucleotide triphosphohydrolase; and *ADARI* (MIM 146920), which encodes an adenosine
13 deaminase⁶⁻⁹. Although more than 90% of AGS individuals harbor etiological mutations in one of these
14 six genes, some AGS-affected individuals presenting with the clinical characteristics of AGS still lack a
15 genetic diagnosis, suggesting the existence of additional AGS associated genes¹.

16 We recently conducted a nationwide survey of AGS in Japan and reported 14 AGS individuals¹⁰.
17 We have since recruited three other Japanese AGS individuals, and among these 17 individuals, we have
18 identified 11 individuals with etiologic mutations; namely, *TREX1* mutations in six, *SAMHD1* mutations
19 in three, and *RNASEH2A* and *RNASEH2B* mutations in one each. Of the remaining six individuals
20 without a molecular diagnosis, trio-based whole exome sequencing was performed in three whose parents
21 also agreed to participate in further genome-wide analyses (Figure 1A). Genomic DNA from each
22 individual and their parents was enriched for protein-coding sequences, followed by massively parallel

1 sequencing. The extracted non-synonymous or splice-site variants were filtered to remove those with
2 minor allele frequencies (MAF) >0.01 in dbSNP137. To detect de novo variants, any variants observed in
3 family members, listed in Human Genetic Variation Database (HGVD), or variants with MAF >0.02 in
4 our in-house exome database were removed. To detect autosomal recessive (AR), compound
5 heterozygous (CH), or X-linked (XL) variants, those with MAF >0.05 in our in-house database were
6 removed (Figure S1). All samples were collected with the written informed consents by parents, and the
7 study protocol was approved by the ethical committee of Kyoto University Hospital in accordance with
8 the Declaration of Helsinki.

9 After common polymorphisms were removed, we identified a total of 40, 18, 89, and 22 candidate
10 variants under the de novo, AR, CH, and XL inheritance models, respectively, that were present in at least
11 one of the three individuals (Table S1). Among them, missense mutations were identified in *IFIH1* (MIM
12 606951, RefSeq: NM_022168.2), which encodes MDA5 (NP_071451.2). These missense mutations are
13 c.1354G>A, p.Ala452Thr, in AGS-1; c.1114C>T, p.Leu372Phe, in AGS-2; and c.2336G>A,
14 p.Arg779His, in AGS-3 (Figure 1B). None of the mutations are found in HGVD, including the 1208
15 Japanese samples, or our in-house exome database of 312 Japanese individuals. Multiple-sequence
16 alignment using ClustalW2 revealed that each of the amino acids affected by these mutations are
17 conserved among mammals (Figure 1B). The subsequent amino acid alterations were all suggested to be
18 disease-causing in at least one of the four function-prediction programs used (Table 1). None of the other
19 genes identified in the de novo inheritance model, or any of the genes identified in the other three
20 inheritance models, were mutated in all three individuals. The *IFIH1* mutations identified were validated
21 by Sanger sequencing. The other coding exons of *IFIH1* were also examined by Sanger sequencing, and
22 no other mutations were found.

1 MDA5 is one of the cytosolic pattern recognition receptors that recognizes double-stranded RNA
2 (dsRNA)¹¹. MDA5 consists of N-terminal tandem CARD domains, a central helicase domain, and a
3 C-terminal domain (Figure 1C). When bound to dsRNA, MDA5 forms a closed, C-shaped ring structure
4 around the dsRNA stem, and excludes the tandem CARD as well as creates filamentous oligomer on
5 dsRNA¹². It is hypothesized that the tandem CARD interacts each other, and activates MAVS on the
6 mitochondrial outer membrane. Oligomerization of MAVS induces TBK1 activation, IRF3
7 phosphorylation, and induction of type I interferon transcription, resulting in the activation of a large
8 number of interferon-stimulated genes (ISGs).

9 The neurological findings of the individuals with these *IFIH1* mutations are typical of AGS (Table
10 S2). They were born with appropriate weights for their gestational ages without any signs of intrauterine
11 infection. However, they all demonstrated severe developmental delay in early infancy associated with
12 progressive microcephaly. No arthropathy, hearing loss, or ophthalmological problems were observed. As
13 for extraneural features, all three individuals had at least one of the following autoimmune features:
14 positivity for autoantibodies, hyperimmunoglobulinemia, hypocomplementemia, and thrombocytopenia.
15 Notably, none of the individuals with *IFIH1* mutations had chilblain lesions, although all the five
16 individuals with *TREX1* mutations and two of the three individuals with *SAMHD1* mutations in the
17 Japanese AGS cohort showed chilblain lesions¹⁰. Individuals with *SAMHD1* mutations and *IFIH1*
18 mutations both show autoimmune features; however, chilblain lesions have only been observed in
19 individuals with *SAMHD1* mutations¹⁰.

20 To predict the effects of the identified amino acid substitutions on MDA5, three-dimensional
21 model structures of MDA5 mutants were generated from the crystal structure of human MDA5-dsRNA
22 complex¹² (Protein Data Bank (PDB) code; 4gl2), using PyMOL (Schroedinger) and MOE (Chemical

1 Computing Group) (Figure S2A). The oligomeric model of MDA5 was generated using the electron
2 microscopy imaging data of MDA5 filament lacking CARD domain²² (Electron Microscopic Data Bank
3 (EMDB) code: 5444) (Figure S2B). The three amino acid substitutions in the AGS individuals are all
4 located within the helicase domain (Figures 1C and S2A). Since Ala452 directly contacts the dsRNA
5 ribose O2' atom, the p.Ala452Thr substitution probably affect the binding affinity to dsRNA due to an
6 atomic repulsion between the side chain of Thr452 and the dsRNA O2' atom (Figures S2C and S2D).
7 Leu372 is located adjacent to the ATP binding pocket, and the p.Leu372Phe substitution could increase
8 the side chain volume of the binding pocket, affecting its ATP hydrolysis activity (Figures S2E and S2F).
9 In our oligomeric model, Arg779 is located at the interface between the two monomers, which is
10 consistent with the recent report showing that Lys777, close to Arg779, is in close proximity to the
11 adjacent monomer¹². Furthermore, in our model, Arg779 is in close to Asp572 on the surface of the
12 adjacent monomer. We speculate that losing the positive charge due to the p.Arg779His substitution
13 would possibly affect the electrostatic interaction between the MDA5 monomers (Figures S2G and S2H).

14 To connect the identified *IFIH1* mutations with the AGS phenotype, we examined the type I
15 interferon signature in the individuals by performing reverse transcription quantitative PCR (RT-qPCR)
16 of seven ISGs¹³. Peripheral blood mononuclear cells (PBMCs) from the three AGS individuals showed
17 up-regulation of ISGs transcription (Figure 2), confirming the type I interferon signature in the
18 individuals with *IFIH1* mutations.

19 To elucidate the disease-causing capability of the identified *IFIH1* mutations, three FLAG-tagged
20 *IFIH1* mutant plasmids containing these mutations were constructed using site-directed mutagenesis.
21 These plasmids were transiently expressed on human hepatoma cell line Huh7 and the *IFNB1* promoter
22 activity as well as endogenous expression of *IFIT1* ([MIM 147690]) was measured 48 hours after

1 transfection¹⁴. The three mutant plasmids activated the *IFNBI* promoter in Huh7 cells more strongly than
2 the wild MDA5 and nearby missense variants reported in dbSNP (Figures 3 and S3). The up-regulation of
3 endogenous *IFIT1* was also observed in the transfected cells (Figure S4), suggesting that these AGS
4 mutations enhance the intrinsic activation function of MDA5. Recent genome wide association studies
5 (GWAS) showed association of the *IFIH1* with various autoimmune diseases, such as systemic lupus
6 erythematosus (SLE), type I diabetes, psoriasis, and vitiligo^{15 16 17 18}. We examined *IFNBI* promoter
7 activity induced by the c.2836G>A (p.Ala946Thr) polymorphism (rs1990760) identified in the GWAS.
8 Although the c.2836G>A polymorphism partially activated the promoter activity, the induced activity
9 was lower than those of the AGS-derived mutants. In addition, the dominantly inherited SLE mouse
10 model in the ENU-treated mouse colony is reported to have the *IFIH1* mutation, c.2461G>A
11 (p.Gly821Ser)¹⁴. These observations suggest that *IFIH1* has strong association with various autoimmune
12 diseases, especially SLE, which also has a type I interferon signature¹⁹. Since alteration of *TREX1* has
13 been reported to cause AGS as well as SLE²⁰, it seems quite plausible for *IFIH1* to also be involved in
14 both AGS and SLE. Interestingly, all the individuals identified with *IFIH1* mutations had autoantibodies,
15 suggesting the contribution of *IFIH1* mutations to autoimmune phenotypes.

16 To further delineate the functional consequences of the three *IFH1* mutations, we measured the
17 ligand-specific *Ifnb* mRNA induction by stimulating *Ifh1*^{null} mouse embryonic fibroblasts (MEFs)
18 reconstituted with retrovirus expressing the *IFIH1* mutants by an MDA5-specific ligand,
19 encephalomyocarditis virus (EMCV)²¹. None of the MEF cells expressing the three mutant *IFIH1*
20 responded to the EMCV, which suggested that the MDA5 variants lacked the ligand-specific
21 responsiveness. The response of the three AGS mutants against the MDA5-specific EMCV was similar to

1 that of the p.Gly821Ser variant reported in the dominantly inherited SLE mouse model with type I
2 interferon overproduction¹⁴ (Figures 4 and S5).

3 During the revision of this manuscript, Rice *et al.* identified nine individuals with *IFIH1* mutations,
4 including the c.2336G>A mutation we identified, in a spectrum of neuroimmunological features
5 consistently associated with enhanced type I interferon states including AGS²³. Although we agree that
6 the *IFIH1* mutations cause constitutive type I interferon activation, Rice *et al.* show the mutated MDA5
7 proteins maintain ligand-induced responsiveness, which was not the case in our study. Since we measured
8 the ligand-specific responsiveness of MDA5 in different experimental conditions, further analysis
9 remains to be performed to reveal the biochemical mechanism of interferon overproduction by the
10 mutated MDA5.

11 In conclusion, we identified mutations in *IFIH1* as a cause of AGS. The individuals with the *IFIH1*
12 mutations showed encephalopathy typical of AGS as well as the type I interferon signature with
13 autoimmune phenotypes, but lacked the chilblains. Further analysis remains to elucidate the mechanism
14 how the *IFIH1* mutations identified in AGS cause the type I interferon overproduction.

15

21 gene containing *IFNB1* promoter (p-55C1B Luc), an empty vector (BOS) and expression vectors for

1 FLAG-tagged human wild type *IFIH1*, c.2836G>A polymorphism (p.Ala946Thr) in the GWAS studies,
2 and the identified *IFIH1* mutants. Luciferase activity was measured 48 hours after transfection, and the
3 MDA5 protein accumulation was examined by Western blotting as previously described¹⁴. FLAG
4 indicates the accumulation of FLAG-tagged MDA5. Each experiment was performed in triplicate and
5 data are mean \pm S.E.M. Shown is a representative of two with consistent results. Statistical significance
6 was determined by Student's t-test. * p <0.05, ** p <0.01.

7

8 **Figure 4**

9 *Ifnb* mRNA levels in *Ifih1* deficient MEFs expressing *IFIH1* mutants. The MEFs were infected with
10 retroviruses encoding mouse wild type *Ifih1*, mouse *Ifih1* with NM_027835.3:c.2461G>A (p.Gly821Ser)
11 mutation, or the three AGS mutants of human *IFIH1*. 48hrs after the retroviral infection, these MEFs
12 were infected with indicated multiplicity of infection (MOI) of EMCV for 6 hours, and *Ifnb* mRNA levels
13 were measured by RT-qPCR. The relative abundance of each transcript was normalized to the expression
14 level of 18S ribosomal RNA. Data are shown as mean \pm S.E.M of triplicate samples. Shown is a
15 representative of two independent experiments. Statistical significance was determined by Student's t-test,
16 * p <0.001. The expression of the retrovirally transduced FLAG-tagged constructs was confirmed by
17 Western blotting (Figure S5).

Table 1

Functional predictions of the *IFIH1* variants

Individuals	Nucleotide change	Amino acid change	SIFT	PolyPhen2	Mutation Taster	PROVEAN
AGS-1	c.1354G>A	p.Ala452Thr	Tolerated	Benign	Disease causing	Neutral
AGS-2	c.1114C>T	p.Leu372Phe	Tolerated	Probably damaging	Disease causing	Neutral
AGS-3	c.2336G>A	p.Arg779His	Tolerated	Probably damaging	Disease causing	Deleterious

The potential functional effects of the *IFIH1* variants identified in the AGS individuals were predicted using SIFT, PolyPhen2, Mutation Taster, and PROVEAN.

Figure 4

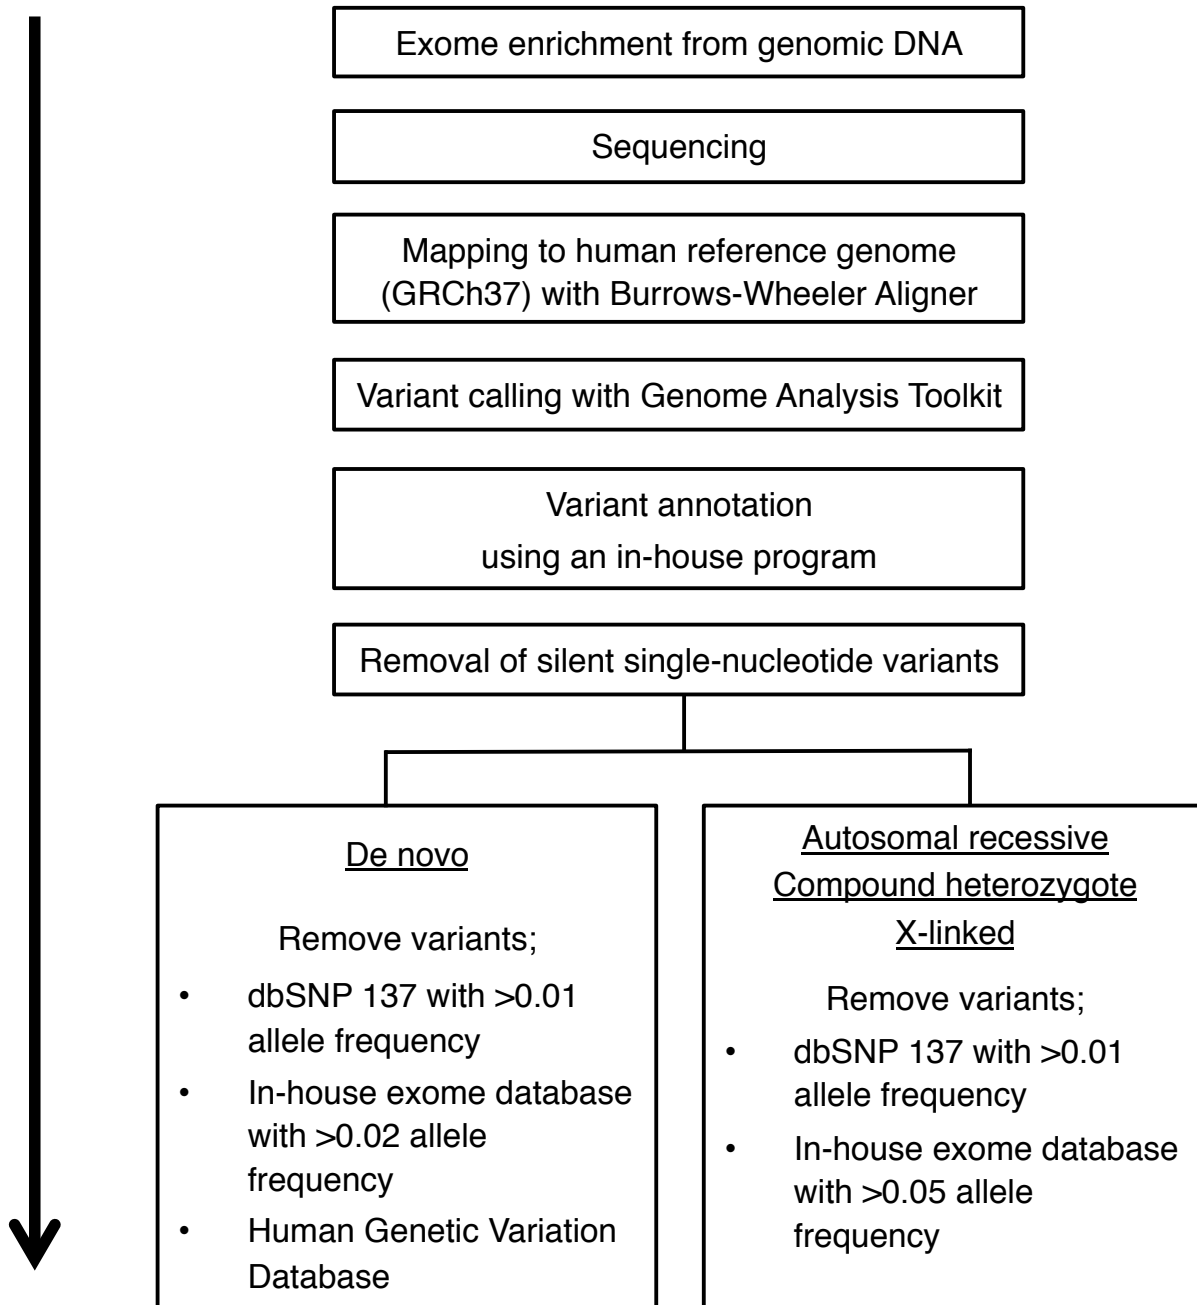

Figure S1. A flow diagram of the trio-based whole exome sequencing process.
GRCh37; Genome Reference Consortium Human build 37.

Figure S2. Predicted effects of MDA5 amino acid substitutions on its protein structure.

(A, B) Mapping of the three mutated amino acids on the crystal structure of MDA5-dsRNA complex (Protein Data Bank (PDB) code; 4gl2). The ATP-binding domain and the other domains of MDA5 are colored green and light-green, while the adjacent MDA5 monomers are colored light blue and orange, respectively. Three residues mutated in the patients, Ala452, Leu372, and Arg779, are shown in space filling models (magenta). (A) Top view of the tertiary structure of the MDA5 protein and dsRNA. (B) Side view of the model of MDA5 monomer oligomerization. The model was constructed by fitting the MDA5 monomers and the 38bps dsRNA structure into the density map from the electron microscopic analysis of the MDA5-dsRNA fibril (EMDB code; 5444).

(C, D, E, F, G, H) Detailed views of the mutated amino acid residues. (C) Ala452 is directly in contact with the O2' atom of the ribose moiety of guanine residue (G7). (D) The p.Ala452Thr substitution is predicted to induce an electric repulsion between the side chain of Thr452 and the O2' atom of RNA. (E) Leu372 is located in the ATP binding pocket. (F) The p.Leu372Phe substitution is predicted to increase the side chain volume of the binding pocket, and would affect the ATP hydrolysis activity of MDA5 by interfering with Asp443, a part of the catalytic residues. (G) Arg779 is located in the interface between MDA5 monomers, and is possibly involved in electrostatic interactions between the monomers. (H) The p.Arg779His substitution is predicted to affect the electrostatic interaction due to loss of the positive charge.

Figure S3. Comparison of the mutant MDA5 reporter activity between the AGS mutants and SNPs. Huh7 cells were transfected with a reporter gene containing *IFNB1* promoter (p-55C1B Luc), along with empty vector, wild-type MDA5, its three AGS mutants, or three MDA5 amino acid variations corresponding to other non-synonymous SNPs; namely, p.Ala452Val (c.1355C>T), p.Ala788Thr (2362G>A), and p.Arg806Cys (c.2416C>T). Luciferase activity was measured 48 hours after transfection. The experiment was performed in triplicate and data are mean \pm S.E.M. The mean of each triplicate was compared between the three AGS mutants and three mutants having other SNPs. Statistical significance was determined by Student's *t*-test. * p <0.005.

Figure S4. Endogenous expression of the *IFIT1* gene in the Huh7 transfection. *IFIT1* expression of the transfected Huh7 cells was measured by RT-qPCR. The relative abundance of each transcript was normalized to the expression level of 18S ribosomal RNA. Each experiment was performed in triplicate and data are mean \pm S.E.M. Statistical significance was determined by Student's *t*-test. * $p < 0.01$.

Figure S5. Retrovirally transduced expression of *IFIH1* constructs in *Ifih1*^{null} MEFs.

Ifih1^{null} MEFs were transfected with empty retrovirus vector, retrovirus encoding FLAG-mouse wild type *Ifih1* (WT) or FLAG-mouse *Ifih1* with p.Gly821Ser mutation, or the FLAG-tagged three AGS mutants of human *IFIH1*. The FLAG-tagged MDA5 and β-Actin accumulation was examined by Western blotting.

Supplemental table 1**Exome sequencing summary**

	AGS-1	AGS-2	AGS-3
Exome enrichment kit	ILLUMINA TruSeq Exome Enrichment Kit	ILLUMINA TruSeq Exome Enrichment Kit	AGILENT SureSelect Human All Exon V5 Kit

Rare variants	AGS-1	AGS-2	AGS-3
Total	34	28	102
De novo	7	4	28
Autosomal recessive	5	2	11
Compound heterozygous	12	10	63
X-linked	10	12	N.D.

Sequence data were mapped against the human reference genome (Genome Reference Consortium Human Build 37) using Burrows-Wheeler Aligner software. Variants were called using the Genome Analysis Toolkit, and were filtered to remove those with variant quality scores less than 50. Gene annotation of each variant was performed using an in-house program. Identified non-synonymous or splice-site variants were filtered to remove those with minor allele frequencies (MAF) >0.01 in dbSNP137. For detecting any rare de novo variants, these variants observed in family members, identified in Human Genetic Variation Database, or those with MAF >0.02 in our in-house exome database were removed. For rare autosomal recessive, compound heterozygous, or X-linked variants, those with MAF >0.05 in our in-house database were removed. N.D.; not determined.

Supplemental table 2 Profiles of the AGS individuals**Clinical findings**

	Age	Sex	GA	BW	Disease onset	Developmental delay	Other neurological manifestations	Chilblain lesions	Extraneural manifestations
AGS-1	5 yr	M	36 wk	2780 g	4 d Omphalitis with thrombocytopenia	Severe	Hypertonia, complex febrile seizure, microcephaly, spastic quadriplegia	No	Idiopathic interstitial pneumonia
AGS-2	6 yr	M	39 wk	3290 g	6 mo Developmental delay	Severe	Regression, dystonia, microcephaly, quadriplegia	No	Atopic dermatitis
AGS-3	2 yr	F	37 wk	2515 g	5 mo Developmental delay	Severe	Complex febrile seizure, dystonia, hypotonia, progressive microcephaly, spastic quadriplegia	No	Recurrent otitis media, sinusitis, periodic fever

Laboratory and radiographic findings

	CSF lymphocytosis	CSF elevated IFN- α	CSF elevated neopterin	Serum elevated autoantibody	Other laboratory features	Cranial calcification	White matter abnormality	Brain atrophy
AGS-1	No (16 mo)	Yes 13.2IU/ml (16 mo)	n.d.	Anti-LKM1	Thrombocytopenia, increased serum transaminases, hypocomplementemia, hypergammaglobulinemia	Yes Bilateral in the basal ganglia and white matter	Yes	Yes
AGS-2	No (3 yr)	No (3 yr)	Yes 285nM (3 yr)	ANA 1:320	None	Yes Bilateral in the basal ganglia and corticomedullary junction	Yes	Yes
AGS-3	No (12 mo)	No <6IU/ml (12 mo)	Yes 71.23nM (12 mo)	ANA 1:320 Anti-dsDNA Anti-Sm PAIgG	Thrombocytopenia, increased serum transaminases, hypocomplementemia, hypergammaglobulinemia	Yes Bilateral spotty in the basal ganglia and subcortical white matter	Yes	Yes

Notes: GA, gestational age; BW, birth weight; M, male; F, female; d, day(s); wk, week(s); mo, month(s); yr, year(s); n.d., not done.

The upper limit of normal CSF neopterin in our institute is 34.6nM at an age of 1-12 months and 25nM at an age of 2-12 years
