## Abstract

This study proposes a method for detection of uncut crop edges using multiple sensors to provide accurate data for the autonomous guidance systems of head-feeding combine harvesters widely used in the paddy fields of Japan for harvesting rice. The proposed method utilizes navigation sensors, such as a real-time kinematic global positioning system (RTK-GPS), GPS compass, and laser range finder (LRF), to generate a three-dimensional map of the terrain to be harvested at a processing speed of 35 ms and obtain the crop height. Furthermore, it can simultaneously detect the uncut crop edges by RANdom SAmple Consensus (RANSAC). The average of the lateral offset value and crop height of the uncut crop edge detected by the proposed method were 0.154 m and 0.537 m, respectively.

[Keywords] Head-feeding combine harvester, Uncut crop edge detection, RTK-GPS, GPS compass, Laser range finder

## I Introduction

1 Crop harvesting in a field environment requires a high  
2 level of concentration because the operator has to  
3 simultaneously control the travel speed and direction of  
4 the harvesting machine while adjusting the height of the  
5 header after considering numerous parameters including  
6 crop height, biomass density, and other terrain conditions.  
7 However, it is challenging for the operator to maintain  
8 his or her health and physical condition because of the  
9 long hours operating the harvester under unfavorable  
10 environmental conditions such as the dust particles  
11 suspended in midair and noise and vibrations generated  
12 from the machine while harvesting. To overcome this  
13 challenge, autonomous guidance systems that perform  
14 the required tasks without human control are being  
15 developed to automatically steer the unmanned  
16 harvesters along the edges of uncut crops.

17 In contrast to a system that helps the operator control  
18 the harvesting during operation by guiding the harvesting  
19 machine along the prearranged target path, the  
20 autonomous guidance system performs unmanned  
21 harvesting and can be used to replace all field operations  
22 performed by the operator (Kise *et al.*, 2005). The  
23 autonomous guidance system does not rely on the  
24 experience and proficiency of the operator and is able to  
25

26 enhance work stability and productivity because the  
27 system allows the harvesting machine to automatically  
28 travel fast and accurately along the target path while  
29 harvesting as it detects the surrounding environment. The  
30 autonomous guidance system utilizes the following  
31 functions for unmanned travel and harvesting. First, by  
32 using the navigation sensors mounted on the harvesting  
33 machine, the current position of the harvester is  
34 estimated in real-time and uncut crop edges are detected  
35 by sensing the surrounding environment. Next the target  
36 path is determined together with the travel direction and  
37 speed of the harvesting machine, which allows the  
38 harvesting machine to travel and perform tasks without  
39 damaging the crops. Finally, the harvest machine is  
40 automatically steered, precisely running on the planned  
41 target path. To fulfill these functions, the autonomous  
42 guidance system requires on-board navigation sensors  
43 and methodologies satisfying the sensor characteristics to  
44 provide guidance information that can be used for path  
45 planning and accurate steering.

46 In recent years, numerous sensor methodologies that  
47 utilize various navigation sensors have been proposed  
48 and developed for an autonomous guidance system of  
49 harvesting machines, for example, global positioning  
50 systems (GPSs), machine vision, laser range finders

1 (LRFs), contact, and azimuth. The researchers at the  
 2 National Agricultural Research Center (Japan) and  
 3 Mitsubishi Farm Machinery Co., Ltd., developed an  
 4 automatic traveling control system that can follow crop  
 5 rows and turn at the end of rows by detecting the uncut  
 6 crops with a contact sensor and gyroscope mounted on  
 7 head-feeding combine harvesters (Sato *et al.*, 1996). A  
 8 team of researchers from the Carnegie-Mellon University  
 9 and National Aeronautic and Space Administration  
 10 (NASA) used a color camera mounted on a hay  
 11 windrower to develop an automated guidance system  
 12 that can travel and perform harvesting tasks along the  
 13 uncut crop edges detected in real-time, which was  
 14 successfully tested for harvesting in a field of alfalfa  
 15 (Ollis and Stentz, 1997). Scientists at Cemagref (France)  
 16 proposed an automatic guidance method that used laser  
 17 sensors mounted on both windrow and combine  
 18 harvesters (Chateau *et al.*, 2000). Benson *et al.* (2003)  
 19 used a monochrome camera mounted on a head directly  
 20 above the uncut crop edge to develop and demonstrate a  
 21 machine-vision-based guidance system for small-grain  
 22 harvesters that can automatically steer by detecting uncut  
 23 crop edges. Rovira-Más *et al.* (2007) proposed a method  
 24 for detecting uncut crop edges that used stereoscopic  
 25 vision for an autonomous guidance system for corn  
 26 harvesters. The researchers at Kyoto University  
 27 developed an autonomous guidance system that plans the  
 28 target path and automatically steers using a real-time  
 29 kinematic global positioning system (RTK-GPS) and  
 30 GPS compass mounted on a head-feeding combine  
 31 harvester along with the field information obtained prior  
 32 to the harvest (Iida *et al.*, 2012). The harvesting  
 33 performance of the system was successfully tested in a  
 34 paddy field.

35 These earlier researchers proposed sensor  
 36 methodologies that can successfully detect uncut crop  
 37 edges from the sensory data by using the inherent  
 38 characteristics of sensors and applying them to the  
 39 autonomous guidance systems. However, the sensor  
 40 methodologies proposed by these researchers have  
 41 limitations, depending on sensor characteristics. In the  
 42 studies that utilized machine vision and LRFs mounted  
 43 on harvesters for the detection of uncut crop edges (Ollis  
 44 and Stentz, 1997; Chateau *et al.*, 2000; Benson *et al.*,  
 45 2003; Rovira-Más *et al.*, 2007), the positions of the  
 46 detected uncut crop edges were identified in relation to  
 47 the mounted sensors. However, because the absolute  
 48 position of the harvester could not be obtained from the  
 49 mounted sensors, the locations of the detected uncut crop  
 50 edges in the field were not identifiable. On the contrary,

51 in a study that configured the autonomous guidance  
 52 system by mounting on the harvester RTK-GPS detectors  
 53 that could acquire absolute positions (Iida *et al.*, 2012),  
 54 the location of the harvester could be identified in the  
 55 field. However, because information about the upcoming  
 56 harvesting environment could not be acquired, the actual  
 57 harvesting was only limited to following pre-specified  
 58 paths.

59 To overcome the above constraints, this paper  
 60 proposes a method that uses multiple sensors to detect  
 61 uncut crop edges to provide data for autonomous  
 62 guidance systems of head-feeding combine harvesters  
 63 that are widely used in Japan for the harvesting of rice  
 64 and wheat crops. At a rapid processing speed of 35 ms,  
 65 the proposed method uses navigation sensors, such as an  
 66 RTK-GPS, a GPS compass, and an LRF, mounted on a  
 67 head-feeding combine harvester to provide the current  
 68 position of the machinery and a three-dimensional (3D)  
 69 map of the terrain to be harvested, which are needed for  
 70 planning of the target path. Moreover, the uncut crop  
 71 areas can be separated from the ground areas, and the  
 72 edge and height of the uncut crops can be determined  
 73 from the generated 3D map data.

74

## 75 II Materials and Methods

### 76 1. Experimental setup

#### 77 (1) Navigation sensors

78 The navigation sensors used for this study were an  
 79 RTK-GPS (Topcon Co., Ltd., Legacy-E+), a GPS  
 80 compass (Hemisphere Co., Ltd., V110), an LRF (SICK  
 81 AG, LMS111) and machine vision (Sensor Technology  
 82 Co., Ltd., STC-TC33USB). As shown in Fig. 1, the  
 83 navigation sensors (an RTK-GPS antenna and GPS  
 84 compass) were mounted on the roof, the LRF was  
 85 mounted on the upper front, and machine vision was  
 86 installed in the ceiling inside the operation room of the  
 87 head-feeding combine harvester (Mitsubishi Agricultural  
 88 Machinery Co., Ltd., VY50CLAM). The sensors serve  
 89 the following functions.

90

1 Fig. 1 Navigation sensors mounted on the head-feeding  
2 combine harvester (modified from Iida *et al.*, 2012).

3  
4 An RTK-GPS was used to obtain the absolute and  
5 accurate position of the head-feeding combine harvester.  
6 To compensate for the signal errors generated by the  
7 sensors, a virtual reference station (VRS) system was  
8 used. A personal digital assistance device  
9 (HewlettPackard Co., Ltd., iPAQ hx2190b) and mobile  
10 phone (Docomo Co., Ltd., FOMA P2403), both installed  
11 with global navigation satellite system software, were  
12 used as reference stations. Using the VRS RTK method,  
13 a positioning accuracy of up to  $\pm 3$ cm was achieved.

14 A GPS compass was used to obtain the heading  
15 information of the head-feeding combine harvester and  
16 consisted of various components, such as dual GPS  
17 antennas, a differential GPS beacon module, a  
18 single-axis gyro, and a tilt sensor. Although the GPS  
19 heading information was typically used as a primary  
20 information source, backup heading information  
21 obtained from the gyro and tilt sensors could also be  
22 used in instances where the main source could not be  
23 accessed because of signal blockings. The heading  
24 information accuracy of the GPS compass was within  
25  $0.50^\circ$  RMS.

26 An LRF was used to obtain the profile information of  
27 the terrain to be harvested by the head-feeding combine  
28 harvester. The LRF performed two-dimensional (2D)  
29 scanning and its technical specifications are shown in  
30 Table 1. For this experiment, the field of view ( $90^\circ$ ),  
31 angular resolution ( $0.25^\circ$ ), and rotation frequency (25 Hz)  
32 were set as intrinsic parameters of the LRF.

33 Table 1 Technical specification of the LRF.

Model	LMS111
Maximum field of view ( $^\circ$ )	270
Angular resolution ( $^\circ$ )	0.25, 0.50
Maximum scanning range (m)	20
Rotation frequency (Hz)	25, 50
Data interface type	Ethernet, RS-232, CAN

34  
35 Although machine vision was not used for the  
36 detection of uncut crop edges, it was used for visual  
37 recording and storing of the traveling and harvesting  
38 tasks of the head-feeding combine harvester. The  
39 machine vision used in this study used CCD image  
40 sensors and supports a USB 2.0 interface. The sensor  
41 also acquired color images with a 640 pixels (horizontal)  
42 by 480 pixels (vertical) resolution, at a speed of 10 FPS.  
43 The lens (Pentax Ricoh Imaging Co., Ltd.,  
44 FL-CC815B-VG) installed on the machine vision system

45 had a field of view of  $56.5^\circ$ . For this study, the acquired  
46 color images were saved in the audio video interactive  
47 format.

## 49 (2) Control system

50 Two electronic control units (ECU), named ECU-KU1  
51 and ECU-KU2, were developed to integrate the control  
52 of the components of the head-feeding combine  
53 harvester and the navigation sensors mounted on the  
54 harvester, and the pre-existing control system for the  
55 head-feeding combine harvester was remodeled (Iida *et al.*,  
56 2012). As shown in Fig. 2, ECU-KU1 communicates  
57 with the components of the head-feeding combine  
58 harvester, and ECU-KU2 with the navigation sensors  
59 (RTK-GPS and GPS compass). ECU-KU1 and  
60 ECU-KU2 communicate with one another via the control  
61 area network bus. The personal computer (PC) used for  
62 integrated system control communicates with ECU-KU1  
63 via the RS-232C ports, while the LRF communicates  
64 with the PC via Ethernet, and the machine vision via  
65 USB port.

66 Fig. 2 Control system architecture of head-feeding  
67 combine harvester.  
68  
69

## 70 (3) Integrated sensor control platform

71 The study implemented a guidance method using  
72 multiple sensors by introducing the integrated sensor  
73 control platform (ISCP), currently developed by our  
74 project team for head-feeding combine harvesters. ISCP  
75 supports various navigation sensors, such as machine  
76 vision, LRFs, and GPSs that are mainly used for the  
77 autonomous guidance systems of head-feeding combine  
78 harvesters, and they can also display real-time sensor  
79 data with a graphical user interface. In addition, the  
80 open-source platform can be freely modified and  
81 re-distributed without license restrictions (<https://github.com/FiroKyoto/IntegratedSensorControlPlatform.git>).  
82

1 In this study, ISCP was used to obtain data about the  
2 components and navigation sensors of the head-feeding  
3 combine harvester from ECU-KU1, ECU-KU2, the  
4 machine vision, and LRF at a frequency of 10 Hz.

## 6 2. 3D terrain mapping

7 Because rice is planted evenly in 0.3 m inter-row ( $d_r$ )  
8 and 0.2 m intra-row ( $d_c$ ) intervals in the paddy fields of  
9 Japan, as shown in Fig. 3, each row is parallel to its  
10 neighbors. Because the head-feeding combine harvester  
11 performs its harvesting task while traveling along the  
12 uncut crop edge, the precise detection of the crop edge is  
13 pivotal to the performance enhancement of the  
14 autonomous guidance system. The 2D profile data from  
15 the LRF, the heading angle data from the GPS compass,  
16 and the absolute position data from the RTK-GPS, all  
17 obtained from the sensors mounted on the head-feeding  
18 combine harvester, were used to generate a 3D map of  
19 the to be harvested terrain and to obtain location of the  
20 uncut crop edge and crop height.

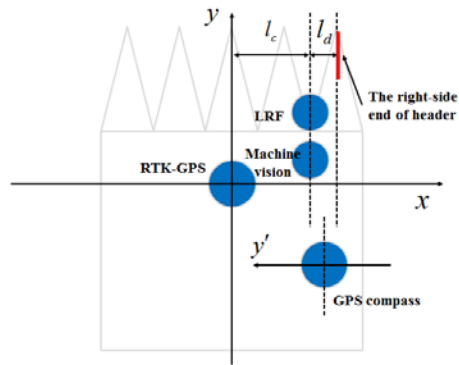

21 Fig. 3 Rows of rice plants in a paddy field.

22  
23  
24 Fig. 4 depicts the extrinsic parameters of the  
25 navigation sensors mounted on the head-feeding  
26 combine harvester. Parameters  $\theta_{LRF}$  and  $h_{LRF}$  are  
27 defined as the tilt angle and height of the installed LRF  
28 from the ground, which are  $50.5^\circ$  and 2.5 m,  
29 respectively. The longitudinal distance ( $l_a$ ) and  
30 transverse distance ( $l_c$ ) of the LRF from the origin of the  
31  $xy$  plane of the 3D Euclidean space ( $W = \{(x, y, z)\} \in$   
32  $E^3$ ), configured with the center of the RTK-GPS as the  
33 base point, are 0.45 m and 0.59 m, respectively.  
34 Moreover, the longitudinal distance ( $l_b$ ) and transverse  
35 distance ( $l_d$ ) of the divider of the right-side end of the  
36 header from the center of the LRF are 0.6 m and 0.07 m,  
37 respectively. The GPS compass is installed in parallel to  
38 the  $xy$  plane of  $W$  space and calculates the angle  
39 between the GPS compass in the clockwise direction,  
40 which is aligned to the magnetic north direction of the

41 Earth, and the  $y'$  axis. Therefore, the heading angle ( $\varphi$ )  
42 of the head-feeding combine harvester can be obtained  
43 by adding  $+90^\circ$  to the angle obtained above. The center  
44 of the lens installed as part of the machine vision is  
45 located 2.3 m perpendicular to the ground surface ( $h_{MV}$ )  
46 at a tilt angle ( $\theta_{MV}$ ) of  $38.5^\circ$ . Moreover, because the  
47 machine vision is positioned on the  $yz$  plane, together  
48 with the LRF, both centers of the machine vision lens  
49 and LRF are positioned on the  $yz$  plane.

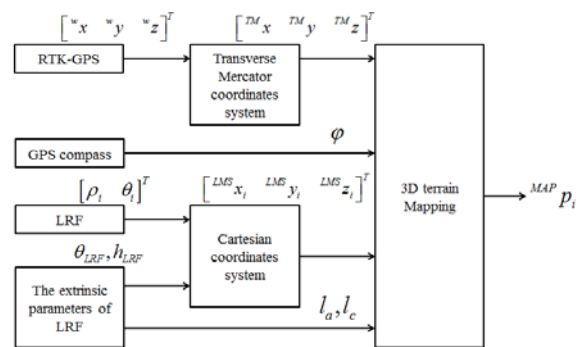

50  
51 (a)  $yz$  plane.

52  
53 (b)  $xy$  plane.

54 Fig. 4 Extrinsic parameters of the navigation sensors.

55  
56 During the process of transformation and integration, a  
57 3D terrain map is generated from the data acquired by  
58 the navigation sensors mounted on the head-feeding  
59 combine harvester, and it has the mathematical  
60 relationship, as shown in Fig. 5.

61  
62 Fig. 5 Mathematical relationship between sensors.

1 First, the data in the polar coordinates system acquired  
 2 from the LRF and extrinsic parameters ( $\theta_{LRF}, h_{LRF}$ ) of  
 3 the LRF are substituted in Eq. (1), and then converted  
 4 into data in the Cartesian coordinates system, which can  
 5 be expressed in  $W$  space. Next, the absolute position  
 6 data acquired from the RTK-GPS is converted to data in  
 7 the transverse mercator coordinates system, which  
 8 assumes the absolute position of the RTK-GPS mounted  
 9 on the harvester at the beginning of the harvesting task as  
 10 the center of origin. Lastly, the sensory data converted by  
 11 the above process, heading angle ( $\varphi$ ) of the harvester,  
 12 and extrinsic parameters ( $l_a, l_c$ ) of the LRF are  
 13 substituted in Eq. (2) and then converted into data in the  
 14 Cartesian coordinates system, which can be expressed in  
 15  $W$  space. The converted data is consecutively saved in a  
 16 dynamic array until the head-feeding combine harvester  
 17 reaches the end of the row.

$$LMS p_i = \begin{bmatrix} LMS x_i \\ LMS y_i \\ LMS z_i \end{bmatrix} = \begin{bmatrix} \rho_i \cos \theta_i \\ \rho_i \sin \theta_i \sin \theta_{LRF} \\ h_{LRF} - \rho_i \sin \theta_i \cos \theta_{LRF} \end{bmatrix} \quad (1)$$

where

$\theta_i$  is the measurement angle acquired from the LRF,  
 $\rho_i$  is the reflection distance acquired from the LRF,  
 and  $\theta_{LRF}$  and  $h_{LRF}$  are the tilt angle and the height  
 of the LRF from the ground, respectively.

$$MAP p_i = \begin{bmatrix} MAP x_i \\ MAP y_i \\ MAP z_i \end{bmatrix} = \begin{bmatrix} TM x_i \\ TM y_i \\ TM z_i \end{bmatrix} + \begin{bmatrix} \cos \varphi & \sin \varphi & 0 \\ -\sin \varphi & \cos \varphi & 0 \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} l_c + LMS x_i \\ l_a + LMS y_i \\ LMS z_i \end{bmatrix} \quad (2)$$

where

$TM_x, TM_y, TM_z$  are values acquired from the  
 RTK-GPS converted into values in the transverse  
 mercator coordinates system,  $\varphi$  is the heading angle  
 of the head-feeding combine harvester, and  $l_a$  and  
 $l_c$  are the longitudinal and transverse distances from  
 the RTK-GPS to the LRF.

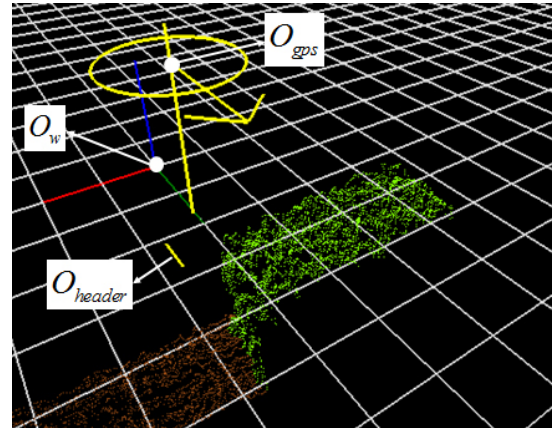

18 The LRF data transformed into Cartesian coordinate  
 19 system data was used for the discrimination of the 3D  
 20 points generated into the uncut crop and ground areas.  
 21 Because the head-feeding combine harvester performed  
 22 harvesting while traveling counter clockwise in this  
 23 study, the uncut crop area was located on the left side  
 24 and the ground area on the right side of the border points  
 25 obtained from the LRF data. Fig. 6 explains the  
 26 distribution of the LRF data expressed on the  $xz$  plane  
 27 of space  $W$ . Leveraging such characteristics, segment  
 28  $l_{hn}$  connects at point  $p_h$  where  $z$  of the LRF dataset  
 29 ( $LMS p_i$ ) becomes maximum, with the end points ( $p_n$ )  
 30 calculated, as well as point ( $p_k$ ), where the length ( $d_k$ ) of

31 the perpendicular to the data set and the segment  
 32 becomes maximum, by using Eq. (3) (Kimberling, 1998).  
 33 Because the resulting  $p_k$  denotes the outermost  
 34 boundary point of the uncut crop area, as shown in Fig. 6,  
 35 the uncut crop area and ground area can be discriminated  
 36 based on  $p_k$ .

37 Fig. 6 LRF data distribution expressed on  $xz$  plane.

$$d_k = \frac{|(x_n - x_h)(z_h - z_k) - (x_h - x_k)(z_n - z_h)|}{\sqrt{(x_n - x_h)^2 + (z_n - z_h)^2}} \quad (3)$$

41 Fig. 7 3D terrain map using OpenGL.

42 Fig. 7 shows the 3D terrain map obtained when  
 43 applying the proposed method. The 3D terrain map is  
 44 expressed by using Open Graphics Library (OpenGL)  
 45 application programming interface (API). OpenGL is an  
 46 API that performs the rendering of 3D objects, such as  
 47 lines, rectangles, and other primitive graphic elements,  
 48 and projects the results onto a 2D screen (Shreiner, 2009).  
 49 Every time  $MAP p_i$  data is added onto the dynamic array,  
 50 which is used for storing  $MAP p_i$ , the  $glVertex3f$  function,  
 51 which is provided for the conversion of the data into 3D  
 52 point expression in OpenGL, is used to express in  
 53 real-time the data value of  $MAP p_i$  in the 3D point format  
 54 in space  $W$  of OpenGL.  $O_w$  signifies the coordinate  
 55 system of space  $W$ , which is configured using the

1 absolute position obtained from the RTK-GPS at the start  
 2 of harvesting as the origin.  $O_{gps}$  and  $O_{header}$  refer to  
 3 the center of the RTK-GPS and right-side end of the  
 4 header, respectively. Additionally, the 3D points of the  
 5 uncut crops and ground are expressed in green and  
 6 brown, respectively.

### 8 3. Uncut crop edge detection

9 For the detection of the uncut crop edge from the 3D  
 10 terrain map generated in real-time, the study utilized  
 11 RANdom SAMple Consensus (RANSAC). The  
 12 RANSAC algorithm predicts the model parameters from  
 13 the original data that has severe measurement noise  
 14 (Fischler and Bolles, 1981). RANSAC randomly  
 15 performs samplings of the minimum data required for  
 16 determining the model parameters from the total original  
 17 data and calculates the values repeatedly to find the  
 18 optimal values.

19 The original data applied to the RANSAC algorithm is  
 20 the previously calculated set of the outermost boundary  
 21 points ( $p_k$ ) of the uncut crop area, configured in a  
 22 dynamic array. The dynamic array is initialized at the  
 23 start of harvest and consecutively adds  $p_k$  until the  
 24 head-feeding harvester reaches the end of the row. In this  
 25 case,  $z$  values from  $p_k$  are not used because the uncut  
 26 crop edge exists on the  $xy$  plane of space  $W$ .  
 27 Furthermore,  $p_k$  is determined as an inlier where the  
 28 perpendicular distance value of  $p_k$  to the direct line of  
 29 the model is smaller than the threshold value and an  
 30 outlier if bigger. In this study, the threshold value was set  
 31 as 0.1. The number of repeats ( $\bar{N}$ ) of the RANSAC  
 32 algorithm can be calculated from Eq. (4). In this study,  
 33  $\bar{N}$  was determined by setting the number of sample data  
 34 ( $\bar{m}$ ) as 5, the probability ( $\bar{p}$ ), where at least one sample  
 35 set included valid data, such as 0.99, and the probability  
 36 ( $\bar{\mu}$ ) of the data validity as 0.5. The RANSAC algorithm is  
 37 then given as follows:

38

---

#### RANSAC algorithm

---

- 1 Initial: A set of  $N$  points in dynamic array
- 2 **repeat**
- 3     Choose a sample of  $m$  points uniformly at random
- 4     Fit a straight line model through the  $m$  points
- 5     Compute the perpendicular distance of other points  
to the straight line model
- 6     Construct the inlier set
- 7     If there are enough inliers, re-compute the straight  
line model parameters, store the straight line, and  
remove the inliers from the set

8 **until** Maximum  $\bar{N}$  iterations reached

9 **return** Best-fit straight line model

---

39

$$\bar{N} = \frac{\log(1 - \bar{p})}{\log(1 - \bar{\mu}^{\bar{m}})} \quad (4)$$

40

41 Fig. 8 shows the results of determining the uncut crop  
 42 edge from the 3D terrain map by using the RANSAC  
 43 algorithm. The uncut crop edge was determined and  
 44 updated by the RANSAC algorithm every time  
 45 additional data was received from the navigation sensors  
 46 until the head-feeding combine harvester reached the end  
 47 of the row. As can be observed in Fig. 8, the uncut crop  
 48 edge is expressed as a red line on the 3D terrain map,  
 49 which can be accurately determined by RANSAC.

50

51 Fig. 8 Uncut crop edge detection by RANSAC.

52

### 53 4. Experimental method

54 To evaluate the performance of the proposed method,  
 55 data from the navigation sensors were obtained during  
 56 the harvest operations of a head-feeding combine  
 57 harvester controlled by an operator in a rice paddy field  
 58 in Nantan City, Kyoto Prefecture, Japan. The  
 59 head-feeding combine harvester harvested rice along  
 60 target paths at an average travel speed of 0.6 m/s.  
 61 Because the head-feeding combine harvester performed  
 62 its operations while traveling counter clockwise, as  
 63 shown in Fig. 9, the sensor data obtained were  
 64 categorized into four datasets according to the movement  
 65 directions.

66

67 In this study, the proposed method was used to  
 68 evaluate the performance of the determination of the  
 69 uncut crop edge from each section. First, target paths that  
 70 functioned as the baseline for each determination zone  
 71 were set. Then, the lateral offset was calculated between  
 72 the determined uncut crop edges and baseline target  
 paths. As shown in Fig. 9, the target path for each zone is

1 a single straight line, which is derived by connecting the  
 2 3D points on the right-side end of the headers expressed  
 3 on the 3D terrain map at the beginning and end-of-row  
 4 time points of the harvesting task. Because the straight  
 5 line is expressed on the  $xy$  plane,  $z$  values are not used  
 6 from the 3D points obtained above. To derive the target  
 7 path from each harvest zone, an experienced operator  
 8 accurately operated the combine in a paddy field filled  
 9 with rice plants planted at regular intervals. The combine  
 10 traveled at a speed of 0.6 m/s, lower than the normal  
 11 harvest travel speed of 1.0 m/s, and followed the uncut  
 12 crop row to perform the harvesting task.

13 Fig. 9 Traveling path of the head-feeding combine  
 14 harvester (image from Google Maps).

 16

### 17 III Results and Discussion

18 Fig. 10 shows the result of a 3D terrain map generated  
 19 with the navigation sensor data obtained using the  
 20 proposed method. The movie clip of the results can be  
 21 accessed via the following address (<http://youtu.be/juy-YuOfvgkk>). The proposed method, at an average  
 22 processing speed of 35 ms, acquires data from the  
 23 mounted sensors, generates a 3D terrain map by using  
 24 the sensory data, and simultaneously determines the  
 25 uncut crop edge and average crop height from the 3D  
 26 terrain map.  
 27

28 The average crop height obtained for each harvest  
 29 section under the proposed method and lateral offset  
 30 values of the target path to the determined uncut crop  
 31 edge are summarized in Table 2. Fig. 11 shows the target  
 32 paths set for each section as well as the result of the  
 33 uncut crop edge determined by RANSAC. The target  
 34 path and the uncut crop edge are expressed as blue and  
 35 red lines, respectively, while the set of boundary points  
 36 applied by RANSAC are shown in gray. In Fig. 11, the  
 37  $x$ -axis refers to the distance traveled by the head-feeding

38 combine harvester while performing the harvesting task,  
 39 starting from the absolute position acquired from the  
 40 RTK-GPS mounted on the head-feeding combine  
 41 harvester at the start of the harvest as the center of origin.  
 42 The  $y$ -axis signifies the perpendicular distance from the  
 43 determined values (the set of boundary points and uncut  
 44 crop edge) to the assumed target path, obtained by using  
 45 the proposed method. Regarding the signs of  $y$ -axis  
 46 values, they will be negative ( $-$ ) when the determined  
 47 values are located on the left side of the target path in the  
 48 traveling direction of the head-feeding combine harvester  
 49 on the 3D terrain map, and positive ( $+$ ) when located on  
 50 the right side of the target path. The lateral offset for  
 51 each zone, shown in Table 2, indicates the average of  
 52  $y$ -axis values of the uncut crop edge, as shown in Fig. 11.  
 53 Moreover, the “average crop height” for each zone refers  
 54 to the average of the  $z$  values of the 3D points  
 55 (expressed in green in Fig. 10) that are distinguished as  
 56 uncut crop area of the generated 3D terrain map.

57 Table 3 shows the average perpendicular distances of  
 58 the determined uncut crop edge from the set of boundary  
 59 points used for RANSAC and the inlier ratio of the set of  
 60 boundary points for each harvest section. The inlier ratio,  
 61 shown in Table 3, refers to the ratio of the number of  
 62 elements out of the set of boundary points stored in the  
 63 dynamic array that have perpendicular distances to the  
 64 uncut crop edges within the inlier range. When the  
 65 perpendicular distance is smaller than the threshold value,  
 66 the boundary point is regarded as an inlier, and regarded  
 67 as an outlier if bigger. In this study, the threshold value  
 68 is set at 0.1 for the proposed uncut crop edge detection  
 69 method. As the value for the inlier ratio increase, the  
 70 number of elements out of the set of boundary points,  
 71 determined by RANSAC with the uncut crop edge as the  
 72 basis, is dispersed in high densities. As shown in Fig. 11,  
 73 the uncut crop edge determined for each section is  
 74 located on the right side of the target path, as viewed  
 75 from the perspective of the traveling direction of the  
 76 head-feeding combine harvester, and the average lateral  
 77 offset to the target path is 0.154 m.  
 78

79 Table 2 Results using the proposed method.

Dataset	Movement Direction	Average Crop Height [m]	Lateral Offset [m]
A	South	0.514	0.294
B	East	0.503	0.139
C	North	0.549	0.067
D	West	0.580	0.119
Average		0.537	0.154

1 Table 3 Average perpendicular distance and  
2 inlier ratio of the set of boundary points.

Dataset	Average Perpendicular Distance [m]	Inlier Ratio [%]
A	0.070	74.4
B	0.052	90.2
C	0.072	78.2
D	0.059	83.6
Average	0.063	81.6

20 by RANSAC.

21

22 The main reason for the lateral offset between the  
23 determined uncut crop edge and target path when  
24 applying the proposed method can be explained from Fig.  
25 12. The paddy field image in Fig. 12 was acquired from  
26 the machine vision, which was mounted on the  
27 head-feeding combine harvester that was performing the  
28 harvest task in Section A. When performing the task in  
29 Section A, the harvester was operated accurately,  
30 following the target path (blue line), as perceived by an  
31 experienced operator. Therefore, the right-side end of the  
32 header can be considered to be located on the straight  
33 line of the target path, as shown in Fig. 12. Moreover, the  
34 red line shown in Fig. 12 signifies the row of crops  
35 already harvested that is located on the right-side of the  
36 target path. Because an inter-row interval of rice plants in  
37 a Japanese paddy field is 0.3 m, the lateral offset of the  
38 red line to the target path is 0.3 m. The lateral offset  
39 value between the determined uncut crop edge and target  
40 path in Section A is 0.294 m, which is almost identical to  
41 the lateral offset value (0.3 m) between the red line and  
42 the target path shown in Fig. 12. As described, the lateral  
43 offset is caused by the lodging of the uncut crops, which  
44 obscures the region between the target path and red line,

1 thereby making it difficult for the LRF to scan the region  
 2 from the location where it is mounted ( ${}^{LRF}O_a$ ). To  
 3 resolve the above issue, the mounting location of the  
 4 LRF needs to be moved to the right-side ( ${}^{LRF}O_b$ ) on the  
 5 right-side end of the header.

#### 11 IV Summary and Conclusions

12 This study proposed a method to detect uncut crop  
 13 edges using multiple sensors to provide accurate data for  
 14 the autonomous guidance systems of head-feeding  
 15 combine harvesters that are widely used in the paddy  
 16 fields of Japan for harvesting rice. The proposed method  
 17 was able to generate 3D maps of the terrain to be  
 18 harvested at a processing speed of 35 ms by using  
 19 navigation sensors, such as an RTK-GPS, a GPS  
 20 compass, and an LRF. At the same time, the location of  
 21 the uncut crop edge and crop height were obtained. The  
 22 average of the lateral offset value and crop height of the  
 23 uncut crop edge, determined by the proposed method,  
 24 were 0.154 m and 0.537 m, respectively.

25 While the proposed method was robust in determining  
 26 the uncut crop edge in general, its performance displayed  
 27 a tendency to decline when the target path was obscured  
 28 by the lodging of rice plants. Therefore, to enhance the  
 29 performance of the proposed method, the mounting  
 30 position of the LRF needs to be modified to allow for a  
 31 more accurate scanning of the target path, together with  
 32 the addition of an algorithm that can adjust for the error  
 33 in results.
