1 **Abstract**

2 Fistulas between the aorta and the digestive tract are rare complications. There are some reports of
3 aorto-esophageal fistulas that are rare but fatal complications after esophagectomies or esophageal stent
4 implantations. An aortoenteric fistula (AEF) occasionally occurs after an aortic intervention or
5 vascular procedures; however it is quite rare after gastrointestinal surgeries. This paper demonstrates a
6 case of an AEF after laparoscopic total gastrectomy for an advanced gastric cancer. This is the first
7 case report describing an AEF after the so-called overlap method of esophagojejunal anastomosis.
8 This report describes a case of 77-year-old Japanese woman who underwent laparoscopic total
9 gastrectomy and esophagojejunal anastomosis with Roux-en-Y reconstruction for advanced gastric
10 cancer. The patient exhibited bacterial peritonitis five days after the operation, due to a partial necrosis
11 and perforation of the small intestine. The patient was treated successfully with laparoscopic partial
12 resection of the small intestine. However, the patient died of massive hematemesis caused by the AEF
13 30 days after the primary surgery.

14

15 Key word; Aortoenteric fistula, laparoscopic total gastrectomy, overlap anastomosis

16

1 **Introduction**

2 Fistulas between the aorta and a digestive tract are quite rare complications after
3 gastrointestinal surgeries. There are some reports of aortoesophageal fistulas after esophagectomy as
4 fatal complications. Previous studies reported anastomotic leakage or peptic ulceration of the gastric
5 tube as a cause of fistula formation [1-4]. However, an aortoenteric fistula (AEF) after total
6 gastrectomy is a quite rare complication. Recent technical advancements in endoscopic surgery have
7 increased the number of laparoscopic gastrectomies for gastric cancer. Several types of anastomotic
8 techniques have been developed; experienced surgeons have even made advancements that allow
9 completely laparoscopic total gastrectomies [5-7]. This paper describes a case of an AEF at the site of
10 esophagojejunal anastomosis after laparoscopic total gastrectomy. This is the first case report
11 describing an AEF after applying the so-called overlap method of esophagojejunal anastomosis [6, 7].
12
13

14 **Case presentation**

15 The patient was a 77-year-old Japanese female referred with a diagnosis of advanced gastric
16 cancer. The patient had been receiving medication for type II diabetes and hypertension. Preoperative
17 examinations included computed tomography, endoscopy, and an upper gastrointestinal series.
18 Endoscopy showed that the tumor had invaded the esophagus about 15mm above the esophagogastric
19 junction. Computed tomography demonstrated lymph node metastasis around the cardia and the
20 esophageal hiatus. The patient was diagnosed with T3N2M0 Stage IIIB, according to the TNM
21 classification of Union for International Cancer Control (UICC) edition 6.

22 The patient received neoadjuvant chemotherapy using a combination of S-1 and cisplatin. S-1 (80
23 mg/day) was orally administered for three weeks, and cisplatin (60 mg/m²) was given intravenously on day
24 8. This regimen was repeated every five weeks for a total of two cycles. Two courses of chemotherapy did
25 not significantly change the size of the primary lesion or the metastatic lymph nodes. There were no new
26 lesions or progression, thus the disease was judged to be stable disease (SD) according to the response
27 evaluation criteria in solid tumors (RECIST, version 1.1). Because her tumor was still diagnosed as
28 resectable, total gastrectomy was planned. The patient participated in a clinical trial of a phase II study of
29 laparoscopic gastrectomy for clinical stage II or higher gastric cancer (UMIN00002085), and successfully
30 underwent a laparoscopic total gastrectomy with D2 lymph node dissection and a radical lymph node
31 resection in the lower mediastinum; this included lymph nodes No. 20, 110 as per the UICC edition 6
32 classification. During the operation, SonoSurg™ (Olympus Medical, Tokyo, Japan) was used.

33 Following the removal of the specimen, laparoscopic Roux-en Y reconstruction was done. The
34 lower esophagus was resected to obtain a safety margin, and esophagojejunostomy was created in the lower
35 mediastinum using linear staplers, using the overlap method. A side-to-side anastomosis was created
36 between the left dorsal side of the esophagus and the jejunal limb, and the entry hole was closed using an
37 interrupted hand-sewn technique [5, 7].

38 The tumor was histopathologically diagnosed as a poorly differentiated adenocarcinoma of
39 the stomach. Lymph node metastases were found in 10 among 28 removed nodes, and the pathological

1 stage was pT3N2M0, Stage IIIB (**Fig 1 A&B**). The proximal and distal margins were negative, thus
2 R0 resection was achieved.

3 On postoperative day 4, the patient exhibited severe abdominal pain. A computed
4 tomography (CT) scan was taken after administration of gastrographin, and it did not reveal any sign
5 of anastomotic leakage. (**Fig. 2A&B**) However, a significant amount of gram positive and negative
6 cocci were detected from the drainage fluid, indicating a bacterial peritonitis. During the emergency
7 operation, a segmental necrotic change of the ileum with small perforation was found, which was
8 located at 45cm on the oral side from the ileocecum, and we thought that this caused peritonitis. The
9 affected ileum was resected, and the abdominal cavity was washed with large amounts of saline.
10 Neither the abscess nor any evidence of leakage was observed in the upper abdomen, and ischemic
11 ulcer associated with thromboembolic occlusion of a mesenteric artery was determined pathologically.
12 Following the operation, the patient was treated with endotoxin absorption therapy, continuous
13 hemodiafiltration, appropriate intravenous antibiotics, and total parenteral nutrition in the intensive
14 care unit. The patient gradually recovered and restarted a soft diet 17 days after the emergency
15 operation. We measured the concentration of amylase in the drainage fluid multiple times, although
16 the level had been less than 107 IU/L during the clinical course.

17 However, the patient had a sudden hematemesis on postoperative day 30. An aortoenteric
18 fistula (AEF) was suspected in addition to the massive amount of hematemesis. The patient was
19 immediately transferred to an angiography room for a radiological intervention. However, the patient
20 died from hemorrhagic shock before the procedure was initiated. The autopsy revealed AEF at the site
21 of esophagojejunostomy (**Fig 3**). Neither a hemorrhage nor abscess was observed in the abdominal
22 cavity. Rapid exsanguination from the fistula was determined to have been the cause of death.

25 **Discussion**

26 Fistulas between the aorta and a digestive tract are quite rare complications after
27 gastrointestinal surgeries. AEFs occur after aortic interventions or vascular procedures, most
28 commonly after an open abdominal aortic aneurysm repair because of mechanical erosion or infection
29 of the suture line and the prosthetic graft into the overlying duodenum [8]. The other causes of AEFs
30 are gallstones, periaortic malignancies or metastases, peptic ulcers, complicated diverticulitis,
31 appendicitis, and radiation therapy [9-13]. There are some recent reports of large-scale randomized
32 control studies of gastric surgery [10, 14-16]. Major complications after total gastrectomy include
33 anastomotic leakage, pancreatic fistulas, abdominal abscesses, intestinal obstructions, and pneumonia
34 [17-19]. However, there are no reports of AEF following either open or laparoscopic total
35 gastrectomies [5-7].

36 This rare but devastating complication requires prompt surgical or interventional
37 management. There are a few cases of successful treatment of aortoesophageal fistulas [20, 21].
38 Treatment generally requires closing of the aortic stump and repair of the fistula or endovascular
39 intervention [20, 22, 23]. As a result, the difficulty in predicting this complication remains a critical

1 problem [8, 24].

2 The role of NAC in the treatment of gastric cancer has been under discussion. [25] NAC can
3 increase the rate of achievement of R0 resection or pathological complete response (pCR). However,
4 Yeong et al. reported that NAC increased the incidence of surgical complications, although there were
5 no deaths directly related to surgical site failures. [26] Schuhmacher et al. also reported that the total
6 number of postoperative complications was higher in the neoadjuvant cohort than the surgery-alone
7 cohort. [27] However, there were no fatal complications documented during surgery. On the other
8 hand, Ge et al. reported the rate of complications in the neoadjuvant cohort was not obviously higher
9 than in the surgery-alone cohort. [28] According to these reports, it seems to be difficult to deny the
10 possibility that NAC may have affected the incidence of AEF in our case. However, there are no
11 reports that describe the incidence of AEF not only after NAC but also after surgeries in gastric cancer
12 patients.

13 The current case was similar to esophageal fistulas between the aorta and the gastric tube. Le
14 Roux reported 8 cases of fistulas between the gastric tube and aorta from 418 patients after
15 esophagectomy [29]; the fistula was located at the anastomosis in 7 cases and it was at the closure line
16 of the gastric tube in one case. He suggested that the two most common etiological factors of AEFs
17 were anastomotic leakage, and the exposure of aortic sheath by extensive lymph node dissection. In
18 the current case, a radical lymph node resection in the lower mediastinum was performed because of
19 evident lymph node metastasis. This resulted in the exposure of the descending aorta. A review of CT
20 after the first operation revealed that the staple line of the anastomosis was in direct contact with the
21 descending aorta (**Fig 2A&B**).

22 There may be some reasons for the fistula in our case, for example, anastomotic leakage,
23 pancreatic fistula, infection, sustained contact between the staples and the aorta, chemotherapy,
24 energized devices such as ultrasonically activated scalpels and so on. Among them, we thought the
25 persistent contact of the staple line could have caused erosion of the aortic wall and lead to the
26 formation of the aortoenteric fistula, because there was no sign of anastomotic leakage, pancreatic
27 fistula or concomitant abscess formation during the clinical course or autopsy (**Fig 3 &4**). Therefore,
28 we would like to emphasize the importance of being mindful of the direction of the closure line of the
29 anastomosis or adverse covering the staple line by adding sero-muscular sutures to avoid direct contact
30 with other organs. This anastomotic technique is new, and we don't have enough experience to discuss
31 the pros and cons of this technique. More data is necessary for further clinical practice.

32 In conclusion, though we couldn't obtain the clear reason for the cause of the fistula from the
33 autopsy, we hypothesized that it could have been the result of persistent contact of and subsequent
34 abrasion by the staple line upon the aortic sheath. We would like to declare the importance of
35 immediate intervention or surgery if AEF is suspected.

Figure 1

(A) The resected stomach. The tumor occupied the lesser curvature of the gastric corpus. However, no tumor cell was detected at the proximal end (*) and the distal end (**).
(B) The tumor was histopathologically diagnosed to be a poorly differentiated adenocarcinoma (por1) of the stomach. Lymph node metastasis was detected among ten of the twenty-eight resected lymph nodes. The pathological stage was pT3 (SE) N2 M0 Stage IIIB.

Figure 2

Contrast enhanced CT taken 4 days after the first operation demonstrated a small amount of fluid collection at the subphrenic lesion and atelectasis. Arrows indicate the site of the anastomosis and staples, which are close to the descending aorta. (A) Axial plane. (B) Coronal plane.

Figure 3

An autopsy revealed the fistula at the site of the anastomosis (A) and communicated to the descending aorta (B). Arrows indicate the site of fistula. The broken line indicates the anastomosis between the esophagus (*) and the jejunum (**).

Figure 4

The fistula located at the top of a triangular anastomosis, where the staple line might have been exposed to the descending aorta.
