1 **Abstract**

2 Plants produce a diverse array of secondary metabolites as chemical barriers against
3 herbivores. Many phytophagous insects are highly adapted to these allelochemicals and
4 use such unique substances as the specific host-finding cues, defensive substances of
5 their own, and even as sex pheromones or their precursors by selectively sensing,
6 incorporating and/or processing these phytochemicals. Insects also serve as pollinators
7 often effectively guided by specific floral fragrances. This review demonstrates the
8 ecological significance of such plant secondary metabolites in the highly diverse
9 interactions between insects and plants.

10

11 **Key words:** insect-plant interaction; host-finding cue, defensive substance; pheromone;
12 synomone

13

14 Insects are the most diverse group of animals on the earth, representing more than
15 half of all known living organisms. While most of insects rely on plants' primary
16 metabolites (e.g. carbohydrates, lipids and proteins), plants have evolved a high
17 diversity of secondary metabolites (e.g. alkaloids, terpenoids, phenolics) to cope with
18 heavy herbivory. Insects are continuously challenged with counter mechanisms to
19 detoxify or circumvent plants' defense systems. On the other hand, insects and plants
20 have coevolved mutualistic relationships through pollination. In such a complex
21 ecological network, insects have developed highly sensitive and specific chemical
22 sensors and biochemical processes to detect allelochemicals - to find host plants and
23 nectar sources, to avoid noxious plants and to escape from predators, in addition to their
24 intraspecific recognition via pheromonal communications.

25 This review focuses on the chemistry and ecological significance of plant
26 secondary metabolites involved in insect life histories and emphasizing particularly the
27 following 5 subjects that are often closely linked to each other – partly summarizing my
28 45 years of research in insect chemical ecology.

- 1 I. Plant metabolites as host-finding cues
- 2 II. Plant metabolites as chemical barriers
- 3 III. Plant allelochemicals for defense
- 4 IV. Plant metabolites for sexual communication
- 5 V. Floral volatiles in mutualistic associations

6

7 **I. Plant metabolites as host-finding cues**

8 Most phytophagous insects feed on a limited number of plant species that often
9 belong to a single plant family. The choice of host plants is determined both at the
10 egg-laying and larval-feeding stages.¹⁾ Insects' host recognition involves multiple
11 sensory modalities, including visual, olfactory, gustatory and tactile cues. My attention
12 has been focused on the phytochemical factors controlling egg-laying and larval feeding
13 behavior in swallowtail butterflies and sap-sucking behavior in aphids. These insects
14 respond to specific chemical ingredients in the host plants.

15

16 *1. Oviposition stimulants of swallowtail butterflies*

17 "How can a citrus swallowtail butterfly sharply distinguish her host plants such as
18 citrus and zanthoxylum-pepper trees, from many other neighboring plants?" was a
19 question in my mind since childhood. The selection of an oviposition site by an adult
20 female is crucial to the survival of her offspring, because the larvae are destined to eat
21 only selected plant species. Thus, the mother butterflies must lay their eggs with great
22 precision on the host plants. Females of swallowtails detect specific chemicals in the
23 host plants by vigorously drumming upon the leaf surface with their forelegs.
24 Toothbrush-like chemosensilla were found on the foretarsi of the female butterflies.²⁾
25 When a piece of filter paper impregnated with a host plant extract was brought in
26 contact with the tarsal sensilla, she immediately deposited one or more eggs on the
27 substrate.

28 The complex chemical profiles of oviposition stimulant systems have been

1 revealed step by step in several papilionid species mainly by Keiichi Honda (Hiroshima
2 Univ.), Paul Feeny's group (Cornell Univ.) and our group (Nishida, Kyoto Univ.), and
3 providing a fairly systematic model for understanding the chemical basis and
4 evolutionary process of host selection in phytophagous insects.

5 Rutaceae-feeders: Oviposition stimulants of a citrus swallowtail butterfly, *Papilio*
6 *xuthus* in *Citrus unshiu* leaves were found to consist of multiple components, which
7 included flavonoids (hesperidin **(1)**, narirutin **(2)**, rutin **(3)**, vicenin-2 **(4)**), a nucleoside
8 (adenosine **(5)**), alkaloids ((-)-synephrine **(6)**, 5-hydroxy-*N*-methyltryptamine **(7)**,
9 bufotenine **(8)**), a cyclitol ((+)-*chiro*-inositol **(9)**) and an amino acid derivative
10 ((-)-stachydrine **(10)**) (Fig. 1).³⁻⁵⁾ None of the individual components elicited
11 oviposition responses alone. The specific activity was provoked only when these
12 compounds were applied as a mixture, indicating the importance of a synergistic effect
13 of multiple components in host recognition. Honda⁶⁾ elucidated the oviposition
14 stimulants of another citrus-feeding swallowtail, *P. protenor*, which also shares the same
15 host, *C. unshiu*. Among the 7 stimulant components, 3 components **(1, 6 and 10)** were
16 shared by *P. xuthus* and *P. protenor*.⁷⁾ More than 70 swallowtail species in the tribe
17 Papilionini are known to feed on the citrus family (Rutaceae). The oviposition
18 stimulants of *P. macilentus* and *P. bianor*, which share a common rutaceous host, *Orixa*
19 *japonica*, were characterized as cnidioside A **(11)** (*P. macilentus*, unpublished result)
20 and a mixture of a hydroxylated γ -lactone **(12)** and a hydroxycinnamoyl ester **(13)** (*P.*
21 *bianor*), respectively, demonstrating the distinct difference in the host finding cues
22 between these two sympatric species.^{8,9)}

23 Apiaceae-feeders: Females of an Apiaceae-feeding common yellow swallowtail, *P.*
24 *machaon hippocrates*, "mistakenly" lay eggs on plants belonging to Rutaceae family,
25 such as *Poncirus trifoliata* and *Zanthoxylum piperitum*, common hosts of *P. xuthus* and
26 *P. protenor*. The same reaction can be induced by stimulating a *P. machaon* females
27 with extracts of these plants, although the response is much weaker than that induced by
28 an extract from a carrot leaf, one of its major host, suggesting some common

1 components involved as oviposition stimulants between Apiacea and Rutaceae.²⁾ The
2 oviposition stimulants of another Apiaceae-feeder, *P. polyxenes*, was identified as a
3 blend of a malonylated flavone glycoside (**14**), tyramine (**15**) and chlorogenic acid
4 (**16**).^{10,11)} The synergistic effects of combinations of flavonoids, hydroxycinnamates and
5 phenethylamine derivatives appeared to be a common feature of oviposition stimulant
6 system among these two closely related butterfly species, even though the host plant
7 taxa (Apiaceae and Rutaceae) are remote to each other. Such an underlying
8 phytochemical similarity might have provided a route to colonization on novel hosts
9 among the papilionid butterflies.^{12,13)}

10 Aristolochiaceae-feeders: Most of the swallowtail butterflies in the tribe Troidini
11 and Zerynthiini feed exclusively on the Aristolochiaceae. The oviposition stimulants
12 of the troidine species *Atrophaneura alcinous* were isolated from the aerial parts of a
13 pipevine, *Aristolochia debilis*, and identified as a mixture of aristolochic acids (AAs)
14 (AA-I, **17**) and sequoyitol (**18**).¹⁴⁾ AAs bear a nitro group on the phenanthrene ring,
15 unique alkaloidal metabolites contained exclusively in the Aristolochiaceae, and thus
16 would serve as an excellent cue. However, AAs exhibited very low activity alone.
17 This represents an importance of synergism between **17** and **18**. In addition,
18 3-hydroxy-4-methoxycinnamoylmalic acid (**19**), closely related to hydroxycinnamoyl
19 esters (**13** and **16**) utilized as a chemical cue by several Rutaceae-feeders, was involved
20 as an additional factor in *A. alcinous* (unpublished results). Further, pinitol (**20**), a
21 hybrid compound between **9** and **18** was characterized as an oviposition stimulant for
22 another troidine, *Battus philenor* together with **17**.¹⁵⁾ One of the oviposition stimulants
23 of a primitive zerynthiine swallowtail, *Luehdorfia japonica*, was isolated from the
24 leaves of *Heterotropa aspera* and identified as a new flavonol triglycoside (**21**).¹⁶⁾ The
25 tribe Zerynthiini, to which *L. japonica* belongs, is considered to represent remnants of
26 the stock from which the rest of the Papilionidae evolved.¹⁷⁾ Utilization of flavonoids as
27 the oviposition stimulant components by both the most advanced genus, *Papilio*, and
28 one of the most primitive genera, *Luehdorfia*, suggests the underlying conservative

1 nature in host recognition within the family Papilionidae. Flavonoids seem certainly to
2 provide a phytochemical diversity and specificity together with other stimulant
3 ingredients as the host finding cues for these phytophagous insects.

4

5 2. Larval phagostimulants of swallowtail butterflies

6 The cabbage white butterflies, *Pieris rapae* and *P. brassicae* (Pieridae), recognize
7 host crucifers by glucosinolates both during oviposition and larval feeding.¹⁸⁻²⁰⁾
8 Likewise, larvae of an Aristolochiaceae-feeding swallowtail, *A. alcinous*, were found to
9 be stimulated by the host specific secondary metabolites **17** together with unknown
10 cofactors.^{14,21)} These facts suggested a congruent sensory mechanism between the tarsal
11 chemoreceptors of adults and the gustatory chemoreceptors of larvae towards
12 host-specific plant allelochemicals. However, the nature of such chemosensory
13 processes at both larval and adult stages is not well understood.

14 Larval feeding stimulants for a Rutaceae-feeding swallowtail, *P. xuthus*, were
15 examined in *Citrus unshiu* leaves in comparison with the oviposition stimulants
16 described above, using thin paper strips as a substrate. Stimulation of feeding on the
17 extracts was found to require a mixture of chemicals including sugars (D-glucose,
18 D-fructose, and D-sucrose), stachydrine, a cyclic peptide (citrusin I (**22**)), a
19 polymethoxyflavone (isosinensetin (**23**)) and lipids (i.e. four 1-monoacylglycerols and a
20 glycolipid (**24**)) (Fig. 1).²²⁾ The larvae readily consumed the test strips treated with
21 a mixture of all the 11 compounds, while very few larvae consumed the strip when each
22 compound were tested alone, indicating that host recognition by *P. xuthus* larvae is
23 mediated by a specific combination of both primary and secondary metabolites. This
24 result is in contrast to the 10 oviposition stimulant components of *P. xuthus* contained in
25 the same host species (*C. unshiu*) in which only one compound, stachydrine (**10**), was
26 an ingredient in common. While the larval feeding-stimulant mixture is dominated by
27 nutrients and other compounds of general significance for primary metabolism, the
28 component oviposition stimulants are exclusively secondary substances that have fairly

1 restricted distributions in plants. Since the initial host choice for the larvae is made by
2 the ovipositing female, unique secondary metabolites may be less important cues for
3 larval feeding than are compounds useful for indicating food and microhabitat quality
4 once settled on the host plant. Likewise, our recent study revealed that the larvae of a
5 primitive Aristolochiaceae-feeding swallowtail butterfly, *Sericinus montela* (tribe
6 Zerynthiini), were stimulated to feed by a mixture of secondary substances specific to
7 the host *A. debilis* (**17** and **18**) plus a series of ubiquitous sugars (glucose, fructose,
8 sucrose) and a lipid (**24**). The complex blend of these primary compounds was
9 identical to the key larval feeding stimulants of *P. xuthus* (unpublished results). This
10 result further substantiates the common nature of both primary and secondary plant
11 metabolites serving as gustatory cues to which oligophagous lepidopteran larvae are
12 tuned.

13 Initially, the complexities of host recognition and feeding stimulation were
14 demonstrated in some lepidopteran larvae: some volatile essential oil components were
15 found to act as olfactory cues in determining the choice of host plants prior to contact
16 with the leaves by larvae of the Apiaceae-feeding swallowtail species, *P. polyxenes*.²³⁾ In
17 the silkworm moth, *Bombyx mori* (Bombycidae), larval feeding behavior is controlled
18 by three distinct factors: attractants (e.g. citral, linalool, 3-hexenol), biting factors (e.g.,
19 isoquercitrin, β -sitosterol), and swallowing factor (cellulose) in addition to cofactors
20 (e.g. sucrose, *myo*-inositol, inorganic phosphate)²⁴⁾; a recent study has revealed an
21 olfactory receptor protein responsible for a key mulberry leaf volatile, jasmone.²⁵⁾
22 Elucidation of olfactory and gustatory chemical cues and their chemosensory
23 mechanisms of host recognition both at egg-laying and larval feeding will contribute to
24 a greater understanding of the evolution of host selection in Lepidoptera.

25

26 3. Probing stimulants in aphids

27 Aphids (Aphididae) are mostly sap feeders that gregariously suck plant nutrients
28 from the phloem of still developing buds and leaves. Although many agricultural pest

1 species are polyphagous, infesting a wide range of crops and often alternating seasonally
2 between hosts, many other species are oligophagous within a limited number of host
3 species belonging to a single family. Van Emden (1972)²⁶⁾ declared that “aphids are
4 phytochemists”, i.e. their life histories are greatly influenced by plant chemistry. The
5 host ranges of the Aphididae are far more diverse than those of butterflies and include
6 ferns, gymnosperms and angiosperms, yet aphids exhibit some similarities in host
7 selectivity to each other among some oligophagous species. Thus, my studies on aphids
8 were conducted in parallel to those on butterflies to clarify the chemical bases of host
9 specificity among several aphid species.

10 The process of finding food sources in aphids involves the following sequential
11 steps: (1) orientation to a plant, (2) external examination, (3) probing through the plant
12 tissues, (4) tapping the phloem, (5) ingestion.²⁷⁾ Specific chemical cues seem to be
13 associated within each step during the assessment of suitable hosts.

14 My research group has elucidated chemical factors that regulate step (3) to (5) in
15 an oligophagous bean aphid, *Megoura crassicauda*, which feeds selectively on plants in
16 the genus *Vicia* (Fabaceae) and is known as a pest of broad bean, *V. faba*. Two specific
17 probing stimulants were isolated from one of its favorite hosts, narrowleaf vetch, *V.*
18 *angustifolia*, and were characterized as acylated flavonol diglycosides (**25** and its
19 glucosidic isomer).²⁸⁾ These compounds strongly induced formation of a proteinous
20 stylet sheath on a parafilm membrane when applied as a solution in distilled water,
21 suggesting that they act as a factor in navigating the stylet towards the phloem in step
22 (3). In contrast, their corresponding deacyl analogs, present abundantly in the host
23 tissues, were suggested to serve as a negative stimulus to allow the aphid to refrain from
24 sucking during tissue penetration before tapping the phloem, although the distribution
25 of these analogs in the plant tissues remains unknown. Chemical factors in the host
26 plant extract involved in the feeding steps (4) and (5), were represented by sucrose and
27 amino acids, because the aphids positively imbibed an artificial diet composed of
28 primary nutrients mimicking a phloem sap in addition to the probing stimulants and

1 produced a large quantity of honeydews.²⁹⁾ Thus, the feeding behavior of *M.*
2 *crassicauda* was shown to be controlled by multiple chemical stimuli composed of
3 primary and secondary plant metabolites mediating the process of the settlement on its
4 hosts.

5 A dihydrochalcone, phlorizin, is known as a host-specific chemical cues for an
6 apple aphid *Aphis pomi*.³⁰⁾ We have also identified the probing stimulants of a cowpea
7 aphid, *Aphis craccivora* (host broad bean, *Vicia faba*), rose aphid, *Sitobion ibarae* (host
8 Japanese rose, *Rosa multiflora*) and an elder aphid, *Acyrtosiphon magnoliae* (winter
9 host elder, *Sambucus racemota*) to be flavonol glycosides present in the corresponding
10 hosts (unpublished results). These results provide additional examples of utilization of
11 flavonoids as kairomonal cues by aphids.

12

13 **II. Plant metabolites as chemical barriers**

14 Besides insecticidal and other noxious plant allelochemicals, there is a diverse
15 array of secondary metabolites to disrupt processes such as insect host-finding behavior
16 and endocrinological systems. This section illustrates the ecological and physiological
17 roles of some of these phytochemicals as potential chemical modulators of
18 phytophagous insects' activities.

19

20 *1. Oviposition and feeding deterrents in butterflies*

21 Although the citrus swallowtail, *P. xuthus*, feeds on various rutaceous species,
22 both the female butterflies and larvae avoid a rutaceous plant, *Orixa japonica*, due to
23 potent deterrent chemicals in the plant. The most abundant flavonoid triglycoside (**26**)
24 was characterized as one of the major oviposition deterrents from the leaves (Fig. 2).³¹⁾
25 This compound is a xylosyl derivative of rutin (**3**), a positive ovipositional stimulant for
26 the butterfly (Fig. 1), and thus may possibly disrupt the oviposition stimulant activity
27 due to its structural resemblance, competing for the same chemoreceptor neurons on the
28 foretarsi. Further, two hydroxybenzoic acid derivatives were characterized as potent

1 deterrents of both oviposition and larval feeding in *P. xuthus*: a glycosylated
2 hydroxybenzoic acid (**27**) and disyringoyl glucaric acid (**28**).³²⁾ Simultaneous
3 occurrence of these compounds in *O. japonica* appears to provide an effective chemical
4 barrier against *P. xuthus*. This suggests a congruent chemosensory mechanism of
5 allomonal chemicals acting on both female tarsal chemoreceptors and larval maxillary
6 taste receptors, which can be contrasted to the case of oviposition stimulants/larval
7 feeding stimulants in *P. xuthus* as discussed above (**I-1** and **I-2**).

8

9 *2. Probing deterrent in aphids*

10 As mentioned in **I-3**, the bean aphid, *M. crassicauda*, feeds selectively on plants
11 of the genus *Vicia*. However, it never infests the tiny vetch, *V. hirsuta*, even though the
12 plant often forms a mixed community with *V. angustifolia*, one of the most favorite
13 hosts of the aphid. A specific probing deterrent was isolated from *V. hirsuta* by
14 monitoring the inhibitory effect, and its structure was elucidated as a hemiterpene
15 glucoside (**29**).³³⁾ Because the stylet insertion process is a crucial step for the aphid's
16 settlement on a plant, the deterrent glucoside seems to act as an effective chemical
17 barrier for *V. hirsuta*.

18

19 *3. Insect growth regulators*

20 Plants even manufacture exact insect hormone molecules such as
21 20-hydroecdysone and juvenile hormone (JH) III (**30**) in massive quantities.^{34,35)}
22 During my collaborative investigations of hormonal substances with Professor William
23 S. Bowers at Cornell University, two novel compounds, juvocimenes I and II (**31**), with
24 an extraordinarily high JH activity were isolated from an essential oil of sweet basil,
25 *Ocimum basilicum* (Labiatae).³⁶⁾ Juvocimenes possess a fused structure between
26 (*E*)- β -ocimene (monoterpene) and (*E*)-anethole (phenylpropanoid).³⁷⁾ Juvocimene II
27 showed about 3000 times as much activity as that of JH I in the milkweed bug,

1 *Oncopeltus fasciatus* in a topical application. Similarly, a compound with a significant
2 JH activity was isolated from the plant, *Macropiper excelsum* (Piperaceae), and was
3 determined as 1-(3,4-methylenedioxyphenyl)-(E)-3-decene (**32**) (named juvadecene).³⁸⁾

4 It is of great interest if plants have developed specific biosynthetic pathways in
5 response to intensive herbivory by modifying existing molecular units to make a novel
6 arsenal as mentioned above: oviposition deterrent flavonoid triglycosides (**26**) with rutin
7 (**3**) + xylose; juvocimenes (**31**) with monoterpene + phenylpropanoid; juvadecene (**32**)
8 by extension of side chain of a phenylpropanoid commonly present in Piperaceae.

10 **III. Sequestration of plant allelochemicals for defense**

11 A number of phytophagous insects seem to have been selected to sequester plant
12 allelochemicals in their body tissues and/or integuments.^{39,40)} Thus, such insects can
13 obtain a potent defense mechanism without manufacturing noxious chemicals of their
14 own. Sequestered phytochemicals include highly toxic alkaloids, terpenoids and
15 phenolics, which normally function in plants to repel or poison herbivores. This
16 section presents examples of a variety of sequestrates and their defensive modes of
17 action against potential predators.

19 *1. Recycling of larval host chemicals for defense*

20 Pipevine swallowtails - aristolochic acids: A number of aposematic swallowtail
21 species belonging to both tribe Troidini and Zerynthiini feed on the Aristolochiaceae
22 and sequester a series of toxic AAs from their host plants for defense.⁴⁰⁻⁴²⁾ Larvae of *A.*
23 *alcinous* selectively incorporate AAs from their host plant, *Aristolochia debilis*, into
24 their body tissues. A large titer was found in eversible defensive glands (osmeteria) as a
25 concentrated solution in glycerol.²¹⁾ AAs act as a feeding deterrent for bird predators.
26 AAs are present in pupal and adult tissues as well as in eggshells and yolk, which
27 suggests there is an effective protection of every life stages from potential enemies by

1 depending solely upon the host pipevine. Since AAs act as host-finding cues both by the
2 adult female butterflies (**I-1**) and larvae and (**I-2**), an assessment of the host-plant
3 quality both at the oviposition and larval feeding stages could guarantee subsequent
4 protection.¹⁴⁾ Ecological adaptation of *A. alcinous* thus seems to be strongly associated
5 with sensory mechanisms specifically developed for perception of AAs.

6 Danaine butterflies - pyrrolizidine alkaloids: Most danaine butterflies acquire
7 pyrrolizidine alkaloids (PAs) during their adult stage by foraging for non-host plants
8 rich in PAs. However, a giant danaine butterfly, *Idea leuconoe* (Nymphalidae), in
9 Okinawa feeds on *Parsonsia laevigata* (Apocynaceae) and sequesters a series of
10 pyrrolizidine alkaloids including new macrocyclic alkaloids, ideamines B (**33**) and C as
11 *N*-oxide forms, directly from its host plant (Fig. 3).^{43,44)} The alkaloids are considered to
12 function as defensive substances against predators, and are used as pheromone
13 precursor by males during courtship (see section **IV**). Most other danaine species
14 acquire PAs not from the hosts but as adults by foraging from PA-containing plants (see
15 **III-2**). It has been suggested the host *Parsonsia* is one of the ancestral food plants of the
16 Danainae, and the insects retained the ability to acquire PAs through pharmacophagy
17 even after they shifted to other plants.⁴⁵⁾ This primitive butterfly may provide a clue for
18 understanding the evolution of pharmacophagous behavior in the subfamily Danainae.

19 Apollo butterflies - cyanoglucoside: It was initially found that a number of
20 day-flying *Abaxas* moth species (e.g. *A. miranda*, *A. latifasciata*, *A. glossulariata* etc.,
21 Geometridae) feeding on leaves of *Euonymus* spp. (Celastraceae) during the larval stage
22 store a large quantity of a bitter-tasting cyanoglucoside, sarmentosin (**34**), in the adult
23 body tissues from the larval hosts.^{41,46)} Sarmentosin itself is not cyanogenic, but its
24 epoxide spontaneously liberates HCN (Nahrstedt, 1982)⁴⁷⁾. During discussion with Dr.
25 Miriam Rothschild, a possible involvement of sarmentosin with Apollo butterflies
26 (*Parnassius* spp., Papilionidae) was suggested, because they feed on *Sedum*, which was
27 reported to contain sarmentosin. As predicted, sarmentosin was detected in a substantial
28 quantity in adults of *P. apollo* in Europe and in *P. phoebus* in the Rocky Mountains in

1 the USA.^{42,48)} Thus, the secret of their aposematic life style both as larvae and adults can
2 be explained by sermentosin, although any potential predators and the actual defensive
3 roles of the compound remain to be clarified.

4 Ericaceae-feeding moth - grayanoid diterpenes: Grayanotoxins (GTs, grayanoids)
5 are highly oxygenated diterpenes with 5 and 7 membered rings, unique in ericaceous
6 plants. These compounds exhibit potent neurotoxicity in mammals by binding to
7 specific sodium ion channels in cell membranes, and thus herbivorous animals avoid the
8 plant.⁴⁹⁾ However, larvae of the leopard moth, *Arichanna gaschkevitchii* (Geometridae),
9 selectively eat with impunity the young leaves of an ericaceous plant, *Pieris japonica*,
10 even though it contains high concentrations of GTs. Several GTs, including two new
11 analogs, arichannatoxins I (**35**) and II, were identified from the body tissues of adult
12 moths in a concentration as high as 300 µg/moth, which was sufficient to deter
13 predatory house lizards.^{41,50)} The adult moth exhibits an aposematic color pattern with
14 orange-yellow hind-wings and it flies during the day like a butterfly. A related species
15 with a similar wing pattern, *A. melanaria*, oligophagous on several ericaceous plants
16 often lacking GTs, sequesters much lower amounts of GTs when fed on *P. japonica*
17 (less than 60 µg/moth). This represents a case of Müllerian mimicry in the same genus,
18 sharing the same host, with different loads of the defense substances.⁴⁰⁾

19 Rubiaceae-feeding aphid - Iridoid glucoside: A ruby-red colored aphid,
20 *Acyrtosiphon nipponicus* (Aphididae), monophagously feeds on *Paederia scandens*
21 (Rubiaceae). The aphid is seldom attacked by the ladybird beetle, *Harmonia axyridis*
22 (Coccinellidae). A potent deterrent against the beetle was isolated from the aphid and
23 identified as paederoside (**36**), an iridoid glycoside containing a sulfur atom in the
24 molecule, unique in the aphid's host, *P. scandens*.⁵¹⁾ The aphids secrete a mixture of **36**
25 and lipids from the cornicles (aphids' defensive glands), and quickly smear the fluid
26 onto a predator's mouthpart. Once an adult of *H. axyridis* bites into the aphid, it
27 immediately releases the aphid, regurgitates, and quickly flees from the aphid colony.
28 This exemplifies a typical case of usurpation of plant's defensive substance by a

1 phytophagous insect effectively to repel its major predator in a tritrophic interaction.
2 The effect of the aposematic red color of the aphid against the ladybirds is not known.
3 Kamo et al.⁵²⁾ recently reported that the black-colored cowpea aphid, *Aphis craccivora*,
4 that infests the black locust, *Robinia pseudoacacia* (Fabaceae), showed toxicity to *H.*
5 *axyridis* due to cyanamide (NH₂-CN), whereas the same aphid that infests the common
6 vetch, *V. angustifolia* (free from the toxin), is suitable prey for *H. axyridis* larvae,
7 further exemplifying this multitrophic adaptation mechanism in aphid-host plant
8 interactions (cf. I-3).

9

10 2. Pharmacophagy - sequestration of non-host plant chemicals

11 "Plants are not only a 'grocery store' for feeding, but can also be a 'pharmacy'",
12 this observation by Boppré (1984)⁵³⁾ being the basis for his metaphorical term,
13 "pharmacophagy". If an animal acquires plant substances not for primary metabolism
14 but for specific purpose other than nutrition or host recognition, it is defined as
15 pharmacophagous. Adults of many danaine butterflies and some arctiid moths gather
16 PAs pharmacophagously from specific plants rich in the alkaloids instead of acquiring
17 them from their larval hosts (cf. *Idea leuconoe*, III-1)⁴²⁾. Several other
18 pharmacophagous associations have been found in Diptera, Hymenoptera and
19 Coleoptera, as described below⁵⁴⁾.

20 Turnip sawfly - *neo*-clerodane diterpenoids: Adults of the turnip sawfly, *Athalia*
21 *rosae ruficornis* (Tenthredinidae), visit a plant, *Clerodendron trichotomum*
22 (Verbenaceae), and feed voraciously on glandular trichomes on the leaf surface. A
23 series of bitter-tasting *neo*-clerodane diterpenoids (e.g. clerodendrins A, B, D (**37**) were
24 characterized as the potent phagostimulants for the sawfly (Fig. 3).^{54,55)} The insect
25 subsequently sequesters some of the analogs and likely becomes extremely bitter to
26 predators on its body surface. The major sequestrate **37** deterred feeding by sparrows
27 and tree lizards.^{54,56)}

28 Leaf beetle - cucurbitacin triterpenes: Polyphagous leaf beetles, *Diabrotica*

1 *speciosa* and *Cerotoma arcuata* (Chrysomelidae) are destructive pests of various crops
2 in Brazil. They are strongly arrested by root components from the cucurbit plant,
3 *Ceratosanthes hilariana* (a non-host for larvae). Although the major phagostimulants
4 were identified as cucurbitacins B and D, the adults selectively accumulated a relatively
5 more stable minor component, 23,24-dihydrocucurbitacin D (**38**), gaining bitterness
6 effective against a bird predator.^{54,57)} Similarly, four Asian Cucurbitaceae-feeding
7 specialists in the genus *Aulacophora* were found to sequester the same compound
8 directly from the larval/adult host cucurbits.⁵⁸⁾ The strong affinity to cucurbitacins,
9 selective sequestration of the analogs and consequent protection from predators
10 suggested an ecological adaptation mechanism developed in common among these two
11 geographically isolated subtribes in the Luperini - both of the New and Old Worlds.⁵⁸⁾

12 Oriental fruit fly - methyl eugenol: The oriental fruit fly, *Bactrocera dorsalis*
13 (Tephritidae) is a serious agricultural pest, infesting most succulent fruit species in the
14 tropics and subtropics. Methyl eugenol (ME, **44**) is known as an extremely potent
15 attractant for *B. dorsalis* males (Fig. 4), and the compound was successfully used as a
16 mass-trapping agent in eradication programs such as in Okinawa.⁵⁹⁾ The males attracted
17 to the chemical source voraciously feed on the intact chemical and sequester its
18 metabolites, 2-allyl-4,5-dimethoxyphenol (**45**) and (*E*)-coniferyl alcohol (**46**),
19 selectively in the rectal glands known to be a sex pheromone reservoir.⁶⁰⁾ The total
20 amount of the metabolites accumulated in the rectal glands was often as high as
21 100 µg/male, sufficient to deter feeding by predators, such as sparrows, lizards and
22 spiders.^{54,61)} Because **44** is distributed widely in plants, males can acquire the compound
23 pharmacophagously by foraging during adulthood.⁶²⁾ Many host fruits of *B. dorsalis*
24 contain **44** as a minor component. However, the larvae fed on an artificial diet
25 containing **44** did not carry over the compounds to the adults.⁶³⁾ Pheromonal roles of
26 ME-metabolites are discussed in Section **IV**, and synomonal associations are discussed
27 in Section **V**.

28

1 **IV. Plant metabolites for sexual communication**

2 Insects produce a diverse assemblage of sex pheromones to attract the opposite
3 sex of the same species. These compounds are strictly species-specific with unique
4 chemical structures and/or combinations of multiple components manufactured by
5 specific biosynthetic pathways. However, in some instances, insects employ specific
6 plant secondary metabolites to attract and excite the partners during courtship.

7

8 *1. Plant-derived sex pheromones*

9 Giant danaine butterfly - pyrrolizidine alkaloids: Males of the danaine butterfly,
10 *Idea leuconoe*, display 'hairpencils', a pair of brush-like glandular organs, to cause the
11 female to become quiescent during courtship. The hairpencil volatiles are composed of
12 a complex mixture, including danaidone (**40**) and viridifloric β -lactone (**41**) (Fig.
13 4).^{64,65} Virgin females were visually attracted to and olfactorily arrested by an
14 artificial butterfly model scented with a blend of the two PA fragments **40** and **41**.
15 These two compounds appeared to be fragments of a pyrrolizidine alkaloid such as
16 lycopsamine **39** originated from the host, *P. laevigata*, and sequestered in the body
17 tissues as *N*-oxide forms for defense (see Section **III-1**). The female seems to verify a
18 male's ability to provide protection via the quality of pheromone volatiles emitted from
19 hairpencils. This strong allelochemical linkage by this primitive butterfly suggests that a
20 secondary colonization of danaine species to PA-free plants such as Asclepiadaceae
21 might have taken place with retention of the PA-mediated allomonal and pheromonal
22 systems via pharmacophagous acquisition of the precursors from non-host PA plants.⁴²⁾

23 Oriental fruit moth - herbal essence: Males of the oriental fruit moth, *Grapholita*
24 *molesta*, emit a herbal scent, such as methyl epijasmonate (**42**) and ethyl (*E*)-cinnamate
25 (**43**), from hairpencils to attract conspecific females after himself attracted to the
26 female's vicinity by the female pheromone (e.g. (*Z*)-8-dodecenyl acetate).⁶⁶⁾ Ester **42**,
27 known as the key ingredients in high-grade perfumes originally extracted from jasmine
28 flowers, is a plant hormone that regulates various physiological processes. These herbal

1 essences are presumably derived from their larval host fruits, although the origin of
2 these compounds remains to be clarified.⁶⁷⁾

3 Oriental fruit fly - phenylpropanoids: The strong attractiveness of *B. dorsalis*
4 males to phenylpropanoid **44** (ME) is a unique characteristic to obtain a defensive
5 measure as discussed above (see Section **III**). Males fed with **44** significantly had their
6 performance during courtship enhanced, and they competed for virgin females
7 significantly better than ME-deprived males.⁶⁸⁻⁷⁰⁾ The pharmacophagously acquired
8 ME-metabolites **45** and **46** were shown to arrest females, inducing their acceptance
9 posture as illustrated in Fig. 4. Males of several other closely related *Bactrocera*
10 species (*B. carambolae*, *B. zonata*, *B. correcta*) fed on ME selectively converted it into
11 other unique subsets of ME-metabolites, including (Z)-coniferyl alcohol and
12 (Z)-3,4-dimethoxycinnamyl alcohol, and stored these in the rectal gland.^{71,72)} A series of
13 sesquiterpene hydrocarbons such as β -caryophyllene (**47**) was identified from the rectal
14 gland of wild *B. correcta* males.⁷³⁾ These pharmacophagously acquired rectal
15 sequestrates (both phenylpropanoids and sesquiterpenes) were suggested to function
16 possibly as a unique sex pheromone to attract conspecific females of this highly
17 diverged species radiating from central Southeast Asia. Compound **47** was found to be a
18 more attractive male lure than **44** in *B. correcta*, and **47** thus serves as a highly selective
19 monitoring agent not attractive to other sympatric pest species in Thailand (unpublished
20 results).

21 In these instances, the male pheromone systems are suggested to have advanced
22 within the context of sexual selection – the female’s preference for the specific
23 components linked to fitness-related defensive compounds. These plant-originated male
24 pheromones may have evolved possibly through a sensory exploitation process to
25 appeal to the female’s chemoreceptors, and as a consequence females recognize males
26 that are coincidentally highly endowed with a defensive armament (Nishida, 2002).⁴²⁾
27 These male-initiated pheromone systems can be contrasted to the case of the turnip
28 sawfly, *A. rosae ruficornis* (see Section **III-2**), wherein females pharmacophagously

1 acquire clerodendrins (e.g. **37**) from *C. trichotomum* and males select females loaded
2 with the bitter-tasting diterpenoids.⁷⁴⁾ Sexual selection in these cases appeared to be
3 tightly linked with defensive fitness properties arising from natural selection via plant
4 secondary metabolites.

5

6 *2. Plant signals for rendezvous cues*

7 Observation of patrolling males of the citrus swallowtail butterflies, *P. xuthus* and
8 *P. protenor*, searching for females along the edge of citrus bushes suggests an
9 involvement of some chemical cues from the hosts (personal observations). However, a
10 possible role of the host odor in this precopulatory step has rarely been investigated.⁷⁵⁾

11 Mediterranean fruit fly - α -copaene: A sesquiterpene hydrocarbon, α -copaene (**48**),
12 initially found in *Angelica* oil as a potent attractant for males of the Mediterranean fruit
13 flies, *Ceratitis capitata* (Tephritidae), is also found as a minor leaf volatiles of various
14 plant species, including its major hosts such as orange, guava, and mango.⁷⁶⁾ Despite the
15 specific attraction of male flies, they never ingest the chemical during exposure to **48**,
16 unlike the case of *B. dorsalis* males in which they incorporate **44** as a pheromone
17 precursor. In a laboratory test, lek-like behavior of *C. capitata* has been induced by
18 either citrus leaves containing **48** or artificially by using a plastic leaf model thinly
19 coated with **48**.⁷⁷⁾ Mating occurred exclusively on the artificial leaves treated with **48**,
20 suggesting the compound potentially serves as a chemical cue to facilitate orientation of
21 flies to the rendezvous site. This represents an “external use” of plant volatiles for
22 courtship other than (or in addition to) their own sex/aggregation pheromones.

23 In the white-spotted longicorn beetle, *Anoplophora malasiaca* (Cerambycidae),
24 Yasui et al. (2007)⁷⁸⁾ demonstrated that host plant sesquiterpenes (e.g. **47** in *Citrus*
25 leaves) serve as a cue in their intraspecific communication. The host-shift of
26 *Rhagoletis pomonella* (Tephritidae) from its native host downy hawthorn, *Crataegus*
27 *mollis*, to introduced domesticated apple, *Malus domestica*, has been shown to be
28 initiated by specific blends of their native host fruit volatiles where they rendezvous.⁷⁹⁾

1 Divergence of incipient populations and speciation in phytophagous insects may be
2 driven by such host-related chemical cues, both in habitat-specific mating choice and in
3 host preference by ovipositing females, although this warrants further in-depth
4 investigations.

5

6 **V. Floral volatiles in mutualistic associations**

7 Pollination syndromes between higher plants and insects have resulted in the rich
8 flora and fauna of the earth that we see today. Orchids are among the largest and most
9 diverse group of the flowering plants, having radiated via highly specialized
10 associations with specific pollinators. Mutualistic interactions between a group of
11 orchids and pollinator fruit flies via floral synomones were examined as a collaboration
12 projects with Dr. Keng-Hong Tan in a chemoecological study of pest fruit flies in the
13 genus of *Bactrocera* (Tephritidae), particularly for species of economic importance.

14 Flowers of a fruit fly orchid, *Bulbophyllum cheiri* (Orchidaceae), attract males of
15 several *Bactrocera* fruit fly species by floral methyl eugenol (**44**) in the rain forest of
16 Southeast Asia.⁸⁰⁾ The flower has a specialized hinged see-saw lip structure which
17 temporarily traps the fruit fly between its lip and column, and transfers pollinia to the
18 back of his thorax. The fly is rewarded by the floral attractant to be used as a precursor
19 for defensive substances and sex pheromonal components (**45** and **46**) as described in
20 Sections **III**-2 and **IV**-1, respectively. In this orchid-fruit fly association, both organisms
21 gain direct reproductive benefits – the orchid flower gets pollinated without having to
22 offer nectar, while the fruit fly boosts its pheromone and defense system with the
23 attractant chemical **44**. Thus, the floral volatile is defined as synomone, an interspecific
24 semiochemical that is adaptively advantageous to both the emitting and the receiving
25 organisms. Flowers of another related orchid species, *Bulbophyllum vinaceum*, produce
26 a complex mixture of phenylpropanoids including **45** and **46** (major), in addition to **44**,
27 and attract ME-sensitive fruit flies (Fig. 5). The orchid flower seems to endow the male
28 flies not only with precursor attractant (**44**) but also intact pheromone (**45** and **46**),

1 although the complete pollinator spectrum and actual role of such a multi-component
2 system of attractant volatiles is unclear.⁸¹⁾

3 Another fruit fly orchid, *Bulbophyllum apertum* releases raspberry ketone (RK, **49**)
4 in its fragrance to attract several RK-sensitive *Bactrocera* species such as the melon fly,
5 *B. cucurbitae*.⁸²⁾ The pollination takes place when a fly is compulsively feeding on the
6 see-saw lip and momentarily trapped between the lip and column. The attractant
7 chemical can act either as floral synomone (pollinarium-transported, as in *B.*
8 *albistrigata*) or kairomone (accidental removal of pollinarium leading to total pollen
9 wastage, as in *B. cucurbitae*) depending on the size of the visiting fruit fly species.

10 Flowers of *Bulbophyllum patens* attract male of a variety of *Bactrocera* fruit fly
11 species, which show affinity to either **44** or **49**. The attractant component was
12 identified as zingerone (**50**), a pungent essence of ginger.⁸³⁾ Zingerone conforms to a
13 chemical structure resembling both **44** and **49**, and thus shows a potency to attract
14 both ME-sensitive and RK-sensitive fruit fly species (e.g. *B. dorsalis*, *B. carambolae*,
15 *B. umbrosa*, *B. cucurbitae* and *B. caudata*), thereby securing effective pollinators in
16 the complex and dense vegetation in the rain forests. It was demonstrated that *B.*
17 *cucurbitae* males that have fed on **50** sequester the intact compound in the rectal
18 pheromone glands⁸³⁾ and become more successful in mating than unfed males.⁸⁴⁾
19 Interestingly, males of an Australian fruit fly, *B. jarvisi* (a pest of mango fruit) whose
20 specific attractant was initially unknown, was found to be selectively attracted to **50** in
21 the flowers of *Bulbophyllum baileyi* that the male flies frequently visit.⁸⁵⁾ This
22 exemplifies a possible use of floral synomones as new monitoring agents for several
23 specific pest species in the orchards.⁸⁶⁾

24

25 **VI. Conclusion**

26 Insects effectively recognize host plants that produce specific primary and
27 secondary metabolites via their finely tuned chemoreceptors. In a similar process,
28 insects reject non-hosts or harmful plants. Host adaptation and speciation in insects are

1 tightly connected to such chemosensory mechanisms – interactions between specific
2 ligands and chemoreceptors. One of the gustatory receptors involved in host recognition
3 for the citrus swallowtail butterfly, *P. xuthus*, specific to synephrine (**8**) (Fig. 1) has
4 recently been characterized from female tarsal chemosensilla.⁸⁷⁾ A female-specific
5 chemoreceptive protein was shown to specifically bind to a specific oviposition stimulant,
6 aristolochic acid I (**17**) for the pipevine swallowtail butterfly, *A. alcinous*.⁸⁸⁾ Numerous
7 molecular techniques related to biosynthesis (in plants), biotransformation or
8 detoxification (in insects) have been employed to provide evidence for possible
9 (co)evolutionary processes between insects and plants.⁸⁹⁾ The identification of genes
10 related to these processes certainly opens the door to understanding the evolution of host
11 specificity in herbivorous insects. The use of phytochemical cues by insects, both in host
12 finding and in sexual communication, may facilitate a host shift and drive the process of
13 colonization to a new adaptive zone with an explicit genetic isolation from the old host
14 and community. The phytochemical mediation of sexual communication, including
15 rendezvous cues (**IV-2**) in conjunction with host recognition (**I-1**, **I-2**), may be of great
16 importance particularly at the initial stage of speciation, although such a process has not
17 been well understood.^{75,79)}

18 On another front, phytochemical cues and their derivatives also provide us with
19 innovative tools for pest management. However, in the case of fruit fly attractants such as
20 the synomones mediating orchid-fruit fly interactions, the intensive use of such
21 allelochemicals in agricultural fields may threaten their communications and their
22 populations, in the natural habitat. We need to understand more about chemical
23 ecological networks in natural ecosystems as well as agricultural ecosystems, to seek a
24 better way to live together.

25

26 **Acknowledgments**

27 I wish to express my hearty thanks to Professors Emeritus Zenzaburo Kumazawa and late
28 Zenpei Yamashita (Mie University), Professors Emeritus Hiroshi Fukami and late Shoziro

1 Ishii (Kyoto University) for guiding me to this fascinating field of organic chemistry,
2 entomology and chemical ecology. I also thank Professors William S. Bowers, Wendell L.
3 Roelofs, Paul P. Feeny (Cornell University), Professor Keng-Hong Tan (Universiti Sains
4 Malaysia), and late Dr. Miriam Rothschild (UK), for their encouragements and
5 collaboration over a long time. I am grateful to Dr. Thomas C. Baker for useful
6 comments on the manuscript. Sincere thanks are due to many students and colleagues
7 who shared valuable time for studying insect chemical ecology.

Figure Legends

1 Fig. 1. Plant metabolites as host-finding cues in butterflies and aphids.
2 Oviposition stimulants of *Papilio xuthus*: hesperidin (1), narirutin (2), rutin (3),
3 vicenin-2 (4), adenosine (5), 5-hydroxy-*N*ω-methyltryptamine (6), bufotenine (7),
4 (-)-synephrine (8), (+)-*chiro*-inositol (9), (-)-stachydrine (10); *P. macilentus*: cnidioside
5 A (11); *P. bianor*: (-)-2*C*-methyl-D-erythrono-1,4-lactone (12),
6 (-)-4-(*E*)-caffeoyl-L-threonic acid (13); *P. polyxenes*: luteolin
7 7-*O*-(6''-*O*-malonyl)-β-D-glucopyranoside (14), tyramine (15), chlorogenic acid (16);
8 *Atrophaneura alcinous*: aristolochic acid I (17), sequoyitol (18),
9 3-hydroxy-4-methoxycinnamoylmalic acid (19); *Battus philenor*: 17 and pinitol (20);
10 *Luehdorfia japonica*: isorhamnetin
11 3-*O*-glucopyranosyl-(1→6)-galactopyranoside-7-*O*-glucopyranoside (21). Larval
12 feeding stimulant of *P. xuthus*: citrusin I (22), isosinensetin (23),
13 1,2-dilinolenoyl-3-galactopyranosyl-sn-glycerol (24). Probing stimulants in an aphid,
14 *Megoura crassicauda*: quercetin
15 3-*O*-α-L-arabinopyranosyl-(1→6)-(2''-*O*-(*E*)-*p*-coumaroyl)-β-D-galactopyranoside (25).

16
17

18 Fig. 2. Plant metabolites as chemical barrier against insects.

19 Oviposition and feeding deterrents of *P. xuthus*: quercetin
20 3-*O*-(2^G-β-D-xylopyranosylrutinoside) (26),
21 5-[[2-*O*-(β-D-apiofuranosyl)-β-D-glucopyranosyl]oxy]-2-hydroxybenzoic acid (27) and
22 disyringoyl glucaric acid (28). Probing deterrent in aphids, *Megoura crassicauda*:
23 (*E*)-2-methyl-2-butene-1,4-diol 4-*O*-β-D-glucopyranoside (29). Insect growth
24 regulators: juvenile hormone III (30), juvocimene II (31),
25 1-(3,4-methylenedioxyphenyl)-(*E*)-3-decene (juvadecene) (32).

26

27 Fig. 3. Defensive substances sequestered from plants.

28 *Idea leuconoe*: ideamine B (33); *Parnassius apollo* and *Abraxas glossulariata*:

1 sarmentosin (34); *Arichanna gaschkevitchii*: arichannatoxins I (35); *Acyrtosiphon*
2 *nipponicus*: paederoside (36); *Athalia rosae ruficornis*: clerodendrin D (37); *Diabrotica*
3 *speciosa* and *Cerotoma arcuata*: 23,24-dihydrocucurbitacin D (38).

4

5

6 Fig. 4. Plant chemicals for sexual communication.

7 Males of the giant danaine butterfly, *Idea leuconoe*, biotransform defensive

8 pyrrolizidine alkaloid, lycopsamine (39), to danaidone (40) and viridifloric β -lactone

9 (41) and emit from the hairpencil organ as sex pheromone. A female oriental fruit moth,

10 *Grapholita molesta*, is attracted to male sex pheromone composed of methyl

11 epijasmonate (42) and ethyl (*E*)-cinnamate (43). Males of oriental fruit fly, *Bactrocera*

12 *dorsalis*, pharmacophagously acquire methyl eugenol (44) from plants and biotransform

13 to sex pheromone 2-allyl-4,5-dimethoxyphenol (45) and (*E*)-coniferyl alcohol (46),

14 which entice females during courtship. Males of the guava fruit fly, *B. correcta*,

15 sequester β -caryophyllene (47) in the rectal pheromone glands. Mediterranean fruit fly,

16 *Ceratitits capitata*, may use α -copaene (48) as a cue to navigate both sexes to the

17 rendezvous site.

18

19

20 Fig. 5. Floral synomone of fruit fly orchids attracting pollinator *Bactrocera* fruit flies.

21 *Bulbophyllum vinaceum* emits methyl eugenol (ME, 44); *Bulbophyllum apertum*

22 produces raspberry ketone (RK, 49); *Bulbophyllum patens* emits zingerone (ZN, 50)

23 which has a hybrid structure between 44 and 49 and attracts both ME-sensitive (e.g.

24 oriental fruit fly, *B. dorsalis*) and RK-sensitive species (e.g. melon fly, *B. cucurbitae*).
