Moloney murine leukemia virus reverse transcriptase (MMLV RT) contains fingers, palm, 1 $\mathbf{2}$ thumb, and connection subdomains as well as an RNase H domain. The DNA polymerase 3 active site resides in the palm subdomain, and the RNase H active site is located in the RNase H domain. The RNase H domain contains a positively charged α -helix called the 4 C helix (H⁵⁹⁴GEIYRRR⁶⁰¹), that is thought to be involved in substrate recognition. In this $\mathbf{5}$ study, we expressed three versions of the RNase H domain in Escherichia coli, the wild-6 $\overline{7}$ type domain (WT) (residues Ile498-Leu671) and two variants that lack the regions 8 containing the C helix (Ile593–Leu603 and Gly595–Thr605, which we called Δ C1 and 9 Δ C2, respectively) with a strep-tag at the N-terminus and a deca-histidine tag at the Cterminus. These peptides were purified from the cells by anion-exchange, Ni²⁺ affinity, 10 11 and Strep-Tactin affinity column chromatography, and then the tags were removed by proteolysis. In an RNase H assay using a 25-bp RNA-DNA heteroduplex, WT, ΔC1, and 1213 Δ C2 produced RNA fragments ranging from 7 to 16 nucleotides (nt) whereas the fulllength MMLV RT (Thr24-Leu671) produced 14-20-nt RNA fragments, suggesting that 14elimination of the fingers, palm, thumb, and connection subdomains affects the binding 15of the RNase H domain to the RNA-DNA heteroduplex. The activity levels of WT, $\Delta C1$, 16 17and $\Delta C2$ were estimated to be 1%, 0.01%, and 0.01% of full-length MMLV RT activity, 18 indicating that the C helix is important, but not critical, for the activity of the isolated RNase H domain. 19

 template-primer; thermostabilization

1 Introduction

 $\mathbf{2}$

Retroviral reverse transcriptase (RT) possesses RNA- and DNA-dependent DNA polymerase as well as RNase H activities. Moloney murine leukemia virus (MMLV) RT is a 75-kDa monomer, comprised of the fingers (Thr24–Asp124 and Phe156–Ser195), palm (Ile125–Phe155 and Pro196–Glu275), thumb (Gly276–Leu338), and connection (Pro339–Asp468) subdomains and an RNase H domain (Arg469–Leu671). The active site of the DNA polymerase activity is located in the palm subdomain while the RNase H activity is in the RNase H domain [1, 2].

Due to its high catalytic activity and fidelity, MMLV RT is extensively used in cDNA synthesis [3]. Thermostability of DNA polymerase activity of MMLV RT increases by inactivating the RNase H activity by the mutation of the catalytically important residue, Asp524 [4-6]. The same strategy was successful to improve the thermostabilities of RTs from human immunodeficiency virus type-1 (HIV-1) [7] and avian myeloblastosis virus (AMV) [5, 8].

The whole structure of MMLV RT has not been determined yet. From the crystal of 16 full-length MMLV RT (Thr24-Leu671), the structures of the fingers, palm, thumb, and 1718 connection subdomains (Thr24-Asn479) have been determined, but that of the RNase H domain has not [1, 9]. On the other hand, from the crystal of the isolated RNase H domain, 1920its whole structure has been determined [10]. In that study, the RNase H domain variant lacking the polypeptide Ile593-Leu603 was successfully crystallized, while the wild-type 2122RNase H domain was not [10]. The deleted polypeptide region, Ile593-Leu603, contains a positively charged α -helix called the C helix (H⁵⁹⁴GEIYRRR⁶⁰¹). In xenotropic murine 23leukemia virus-related virus (XMRV) RT, which has 95% amino-acid sequence homology 24

with MMLV RT, like MMLV RT, the structure of the isolated RNase H domain has been 1 $\mathbf{2}$ determined whereas the whole structure has not [11-13]. Under these backgrounds, Das 3 et al. [1] and Cote et al. [2] have proposed the structural model of MMLV RT that the RNase H domain is positioned far from the fingers/palm/thumb domain. However, 4 $\mathbf{5}$ Pandey et al. have proposed another model that the polypeptide region Pro480-Arg506 of the RNase H domain, the structure of which has not been determined from the crystal 6 of the full-length molecule or the RNase H domain, interacts with the fingers/palm/thumb 7subdomain, supporting the floor of the DNA polymerase active-site cleft. In MMLV RT, 8 9 it is difficult to clarify the interaction between the DNA polymerase and RNase H active 10 sites due to the lack of the crystal structure of the whole MMLV RT molecule.

11 The expression and purification of the isolated RNase H domains of MMLV RT in 12Esherichia coli were previolusly reported [1, 14-16]. They were expressed without tags [14, 16] or S-transferase fusion protein [1, 15]. In this study, we describe expression, 13purification, and characterization of three versions of the RNase H domain of MMLV RT, 14the wild-type domain and the two C helix-deficient variants. They were expressed with 15N-terminal strep-tag and C-terminal deca-histidine tag in E. coli, purified from the cells, 1617and then the tags were removed by proteolysis. The enzyme preparations thus obtained were characterized and compared with full-length MMLV RT. 18

19

20 Materials and methods

21

22 Materials

23

24

[γ -³²P]dATP (111 TBq/mmol) was purchased from PerkinElmer (Waltham, MI).

Oligonucleotides were from Fasmak (Atsugi, Japan). The RT concentration was
 determined by the method of Bradford [17] using Protein Assay CBB Solution (Nacalai
 Tesque, Kyoto, Japan) with bovine serum albumin (Nacalai Tesque) as standard.

4

5 Plasmids

6

 $\overline{7}$ We previously constructed the expression plasmid for C-teminally (His)₆-tagged MMLV RT (pET-MRT) by inserting the C-teminally (His)₆-tagged MMLV RT gene into 8 9 the *NdeI* and *Eco*RI sites of pET-22b(+) plasmid (Merck Bioscience, Tokyo, Japan). The expression plasmids for the wild-type RNase H domain (Ile498-Leu671) (WT), its 10 variant lacking Ile593-Leu603 (Δ C1), and its variant lacking Gly595–Thr605 (Δ C2), 11 each with C-teminal (His)₆ tag (pET22b-RNaseH-WT, pET22b-RNaseH- Δ C1, and 12pET22b-RNaseH- Δ C2, respectively) were constructed as follows. Site-directed 13mutagenesis was carried out using the following nucleotide 5'-14primers 15CAACACAACTGCCATATGATCCTGGCCGAA-3' (497Nde) and 5'-16 TTCGGCCAGGATCATATGGCAGTTGTGTGTG-3' (497Nde_cp) to change the nucleotide sequence CTTGAT encoding ⁴⁹⁶Leu⁴⁹⁷Asp into a *Nde*I recognition sequence 1718 CATATG. The resuting plasmid, pET-MRT(Nde), was digested with NdeI and self-ligated to produce the expression plasmid for WT, pET22b-RNaseH-WT. The 391-bp fragment 1920(F1) was amplified from pET22b-RNaseH-WT using the following nucleotide primers 5'-TAATACGACTCACTATAGGG-3' 21(Pro) and 5'-GCCTTCTGATGTGAGATGGGCAGTAGCAAA-3' (DelI593-L603rev-4), and the 247-22bp fragment (F2) was amplified using the following nucleotide primers 5'-23 $\mathbf{24}$ TTTGCTACTGCCCATCTCACATCAGAAGGC-3' (DelI593-L603for-4) 5'and

 $\mathbf{5}$

HISB). The 608-bp fragment was amplified using the nucleotide primers Pro and MRT- $\mathbf{2}$ 3 HISB from the mixture of F1 and F2, digested with the restriction enzymes XbaI and EcoRI, and inserted in pET-22b(+) digested with XbaI and EcoRI to produce the 4 expression plasmid for $\Delta C1$, pET22b-RNaseH- $\Delta C1$. The expression plasmid for $\Delta C2$, $\mathbf{5}$ pET22b-RNaseH- Δ C1 was constructed by the same method but using the nucleotide 6 primers 5'-CTCTTTGCCTTCTGATGTGAGATGGGCAGT-3' (DelG595-T605rev-4) 75'-ACTGCCCATATCCATTCAGAAGGCAAAGAG-3' 8 and (DelG595-T605for-4) 9 instead of DelI593-L603rev-4 and DelI593-L603for-4, respectively.

10 The expression plasmids for WT, $\Delta C1$, and $\Delta C2$, each with an N-terminal strep tag 11 and a C-teminal (His)₁₀ tag (pET52b-RNaseH-WT, pET52b-RNaseH- Δ C1, and pET52b-12RNaseH- Δ C2, respectively) were constructed as follows. The 550-bp fragment was amplified with 5'-13the following nucleotide primers 5'-14TTTTGGTACCTTGATGTCCTGGCCGAAGCC-3' (497Kpn) and 15TTTTGAGCTCGAGGAGGGTAGAGGTGTC-3' (671Sac) from pET22b-RNaseH-WT, and the 517-bp fragments were amplified from 497Kpn and 671Sac from pET22b-1617RNaseH- Δ C1 or pET22b-RNaseH- Δ C2. These three fragments were digested with the restriction enzymes KpnI and SacI, and inserted in pET-52b(+) (Merck Bioscience) to 18 produce pET52b-RNaseH-WT, pET52b-RNaseH- Δ C1, and pET52b-RNaseH- Δ C2, 19respectively. 20

21

22 Expression and purification of recombinant RNase H domain

23

24 E. coli strain BL21(DE3) [F-, ompT, $hsdS_B(r_B-m_B-)$ gal dcm (DE3)] was transformed

1 with either pET52b-RNaseH-WT, pET52b-RNaseH- Δ C1, or pET52b-RNaseH- Δ C2. The $\mathbf{2}$ overnight culture of the transformants (20 ml) was added to 2,000 ml of LB broth and in 3 a 2-liter flask and incubated at 37° C under vigorous aeration by air-pump. When OD_{660} reached 0.6-0.8, 0.5 mL of 0.5 M IPTG was added and growth was continued at 30°C for 4 4 h. After centrifugation at $10,000 \times g$ for 10 min, the cells were harvested, suspended $\mathbf{5}$ with 20 ml of 0.02 M potassium phosphate (pH 7.2), 2.0 mM dithiothreitol (DTT), 10% 6 7glycerol (buffer A) containing 1 mM phenylmethylsulfonyl fluoride (PMSF) and 8 disrupted by sonication. After centrifugation at $20,000 \times g$ for 40 min, the supernatant 9 was collected and applied to a column [25 mm (inner diameter) × 120 mm] packed with 10 Toyopearl DEAE-650M gel (Tosoh, Tokyo, Japan), previoulsy equilibrated with buffer A. The bound RNase H domain was eluted with buffer A containing 100 mM NaCl and 11 12applied to a HisTrap column, previously equilibrated with 50 mM Tris-HCl (pH 8.3), 200 mM KCl, 2.0 mM DTT, 10% glycerol (buffer B). The bound RNase H domain was eluted 13with buffer B containing 250 mM imidazole and applied to a Strep-Tactin Superflow 14column (IBA, Göttingen, Germany), previously equilibrated with 100 mM Tris-HCl (pH 1516 8.0), 150 mM NaCl, 1 mM EDTA (buffer C). The bound RNase H domain was eluted with buffer C containing 2.5 mM desthiobiotin, 50% glycerol. Two mg of the obtained 1718 RNase H domain was subjected to the digestion by 10 units of HRV 3C protease (Accelagen, San Diego, CA) to cleave the strept tag and 50 units of thrombin (GE 1920Healthcare) to cleave the (His)₁₀ tag in 12.5 ml of 40 mM Tris-HCl (pH 7.5), 120 mM 21NaCl, 10% glycerol at 4°C for 36 h (buffer D). Then, the solution was three-fold diluted 22by adding 25 ml of water and further incubated at 4°C for 36 h. The digest was applied 23to a HisTrap column, previously equilibrated with buffer B. The RNase H domain without tags had weak binding ability to a HisTrap column, and it was collected from a HisTrap 24

column by eluting with buffer B containing 50 mM imidazole. In this buffer condition,
the RNase H domain with deca-histidine tag was not eluted. The obtained RNase H
domain without tags was applied to a PD-10 column packed with a Sephadex G-25 (GE
Healthcare), previously equilibrated with 20 mM Tris-HCl (pH 7.0), containing 200 mM
NaCl, 2.0 mM DTT, and 10% glycerol. The column was washed and eluted with the same
buffer. Purified RNase H domain was stored at -80°C before use.

7

8 SDS-PAGE

9

10 SDS-PAGE of the RNase H domain was carried out in a 12.5% polyacrylamide gel 11 under reducing conditions. Proteins $(1.2 \mu g)$ were reduced by treatment with 2.5% (v/v) 12of 2-mercaptoethanol at 100°C for 10 min, and then applied onto the gel. A constant 13current of 40 mA was applied for 40 min. After electrophoresis, proteins were stained with Coomassie Brilliant Blue R-250. The molecular mass marker kit consisting of rabbit 14muscle phosphorylase B (97.2 kDa), bovine serum albumin (66.4 kDa), hen egg white 1516 ovalbumin (44.3 kDa), and bovine carbonic anhydrase (29.0 kDa) was purchased from Takara Bio Inc (Otsu, Japan). 17

18

19 *CD spectroscopy*

20

The CD spectra of the RNase H domain was measured with a 2-mm cell using a J-820 spectropolarimeter (Jasco, Tokyo, Japan) under the following condition: spectral range 200-250 nm; 25°C; 100 nm min⁻¹ scan rate; and 10 accumulations.

 $\mathbf{24}$

 $\mathbf{2}$

3 Fluorescence-based RNase H activity assay was carried out according to the method by Parniak et al [18]. Briefly, an RNA/DNA hybrid (named R18/D18) was prepared by 4 mixing the 3'-fluorescein modified 18-nucleotide (nt) RNA 5'-5 GAUCUGAGCCUGGGAGCU-3' (R18) and 5'-dabcyl-modified complementary 18-nt 6 DNA (D18) with a molar ratio of 1.0:1.2 in 50 mM Tris-HCl buffer (pH 8.0) containing 760 mM KCl followed by the incubation at room temperature for 30 min. The RNase H 8 9 reaction was carried out in 50 mM Tris-HCl buffer (pH 8.0) containing 60 mM KCl, 5.0 10 mM MgCl₂, 0.25 µM R18/D18 (the concentration is expressed as that of R18), and 11 indicated concentrations of the RNase H domain or the full-length MMLV RT at 37°C. 12An aliquot (800 µl) was taken from the reaction mixture at a predetermined time and 13added to 0.5 M EDTA (160 µl). The fluorescence spectra of the reaction products were measured with a Shimadzu RF-5300PC fluorescence spectrophotometer (Shimadzu, 14Kyoto, Japan) under the following conditions: excitation wavelength, 490 nm; spectral 15range 500-600 nm; 25°C; 120 nm min⁻¹ scan rate; and 3 accumulations. In each 16 17measurement, the control baseline was obtained with the corresponding buffer in the absence of protein. 18

19

20 Radioisotope-based RNase H assay

21

Radioisotope-based RNase H activity assay was carried out according to the method
by Álvarez *et al* [19]. Briefly, an RNA/DNA hybrid (named R25/D25) was prepared by
mixing 5'-[³²P]-labelled 25-nt RNA 5'-AUGUAUAGCCCUACCAGCAUUCTGG-3'

1	(R25) and unlabelled complementary 25-nt DNA (D25) by the method above described.
2	The RNase H reaction (40 µl) was carried out in 50 mM Tris-HCl (pH 8.0) buffer,
3	containing 50 mM KCl, 0.1 mM MgCl ₂ , 20 nM R25/D25, and indicated concentrations
4	of the RNase H domain or the full-length MMLV RT at 37°C. An aliquot (4 μ l) was taken
5	from the reaction mixture at a predetermined time and added to 4 μ l of sample-loading
6	buffer (10 mM EDTA, 90% (v/v) formamide, 3 mg/ml xylene cyanol FF, 3 mg/ml
7	bromophenol blue, and 50 μ M 31D/21D. (31D/21D was prepared by mixing unlabelled
8	31-nt DNA 5'-TTTTTTTTTAGGATACATATGGTTAAAGTAT-3' (D31) and unlabelled
9	complementary complementary 21-nt DNA 5'-ATACTTTAACCATATGTATCC-3'(D21)
10	by the method above described and used as a carrier DNA.) The RNA fragments of the
11	reaction products were analyzed by denaturing 20% polyacrylamide gel electrophoresis
12	followed by image scanning with a BAS-2500 scanner (Fujifilm, Tokyo, Japan) using the
13	program Multi Gauge version 2.2 (Fujifilm).
14	
15	Results
16	
17	Expression and purification of the RNase H domain
18	
19	We initially attempted to express the wild-type RNase H domain (WT)
20	(Ile498–Leu671) and the two C helix-deficient variants lacking Ile593-Leu603 (Δ C1) and
21	Gly595-Thr605 (Δ C2), with C-terminal (His) ₆ tags at the C-terminus. We constructed
22	three expression plasmids, pET22b-RNaseH-WT, pET22b-RNaseH- Δ C1, and pET2A-A-A-A-A-A-A-A-A-A-A-A-A-A-A-A-A-A-A-
<u></u>	DNaceU AC2 that contain the T7 promotor on ATC initiation and on a 540 or 507 hr

- 23 RNaseH- Δ C2 that contain the T7 promoter, an ATG initiation codon, a 540- or 507-bp
- sequence encoding 180 or 169 amino acids comprising the intact or C helix-deficient

1 RNase H domain (Ile498–Leu671), and a (His)₆ tag, and a stop codon. SDS-PAGE 2 analysis of the soluble fractions of the *E. coli* transformants showed a 20-kDa protein 3 band corresponding to WT or a 19-kDa protein band corresponding to Δ C1 and Δ C2 (data 4 not shown). However, the RNase H domain could not be purified to homogeneity because 5 several contaminating proteins, presumably C-terminal (His)₆-tagged RNase H domain 6 degradation products, could not be completely removed (data not shown).

Next we attempted to express WT, $\Delta C1$, and $\Delta C2$ with both an N-terminal strep tag 78 and a C-terminal (His)10 tag. We constructed three expression plasmids, pET52b-9 RNaseH-WT, pET52b-RNaseH- Δ C1, and pET52b-RNaseH- Δ C2 (Fig. 1), that contain 10 the T7 promoter, an ATG initiation codon, a 711- or 678-bp sequences encoding 237 or 206 amino acids comprising a strep-tag, an HRV 3C protease recognition site, the intact 11 12or C helix-deficient RNase H domain, a thrombin recognition site, and a (His)10 tag, and 13a stop codon. SDS-PAGE analysis of the soluble fractions showed a 25-kDa protein band 14 corresponding to WT in the transformants with pET52b-RNaseH-WT (lane 2 in Fig. 2A) and a 24-kDa protein band corresponding to $\Delta C1$ or $\Delta C2$ in the transformants with 1516pET52b-RNaseH- Δ C1 or pET52b-RNaseH- Δ C2, respectively (data not shown).

To purify WT, $\Delta C1$, and $\Delta C2$, we used an ion-exchange chromatography as the first 17step, the Ni²⁺-sepharose chromatography as the second step, and the Strep-Tactin affinity 18 19 chromatography as the third step. At each step, each fraction was tested for the presence 20of the 25-kDa or 24-kDa protein band by SDS-PAGE, and the active fractions were 21pooled based on coomassie staining. The SDS-PAGE analysis showed that the active 22fractions from the WT purification exhibited 25-kDa protein bands (Fig. 2A), and the purified preparations of WT, Δ C1, and Δ C2 exhibited 25-kDa or 24-kDa protein bands 23 $\mathbf{24}$ (Fig. 2B). In Fig. 2B, the 50 or 55 kDa faint bands were also observed; however their

1 orgins were unknown. Then, the N-terminal strep tag and C-terminal $(His)_{10}$ tag were $\mathbf{2}$ removed by successive proteolysis with HRV 3C protease and thrombin, respectively. 3 After proteolysis, the WT preparation exhibited a single 22-kDa protein band (Fig. 2C), the $\Delta C1$ and $\Delta C2$ preparations exhibited single 21-kDa protein bands (data not shown), 4 $\mathbf{5}$ and the protein bands corresponding to the 50 or 55 kDa faint bands obserbed in Fig. 2B were not observed (Fig. 2C for WT and and data not shown for $\Delta C1$ and $\Delta C2$). From the 6 2 L cultures, 0.5–1.0 mg of purified WT, Δ C1, and Δ C2 were obtained. In 20 mM Tris-7 8 HCl (pH 7.0), 200 mM NaCl, 2.0 mM DTT, and 10% glycerol, WT, Δ Cl, and Δ C2 with 9 tags could be concentrated to 1-2 mg/ml, whereas without tags, these proteins could be 10 concentrated to 10 mg/ml (data not shown), indicating that the removing of the tags 11 increased the solubility.

To examine if the deletion of Ile593-Leu603 or Gly595-Thr605 affects structural 12change of the isolated RNase H domain, we made spectroscopic analyses. UV 1314spectroscopy showed that purified WT, $\Delta C1$, and $\Delta C2$ exhibited spectra with a deep 15trough at approximately 250 nm and a peak at 275 nm (Fig. 3B for WT and data not 16shown for $\Delta C1$ and $\Delta C2$). CD spectroscopy showed that purified WT, $\Delta C1$, and $\Delta C2$ exhibited negative ellipticities at 202-250 nm with peaks at approximately 208 nm and 1718 222 nm (Fig. 3B for WT and data not shown for $\Delta C1$ and $\Delta C2$). No appreciable changes were observed in UV and CD) spectra, suggesting that $\Delta C1$, and $\Delta C2$ did not suffer from 19any global or drastic structural changes by the deletion. 20

21

22 Characterization of the RNase H domain

23

24 To analyze the RNase H activity of the isolated RNase H domains, we performed

1 fluorescence-based RNase H assay. An RNA/DNA hybrid (called R18/D18) consisting of a 3'-fluorescein modified 18-nt RNA (R18) and a 5'-dabcyl-modified 18-nt DNA $\mathbf{2}$ 3 (D18) was used as the substrate (Fig. 4A). R18/D18 is designed to emit strong fluorescence when R18 is cleaved at a site close to the 3' end, and the fluorescein-labeled 4 RNA fragment dissociates from the complementary DNA strand. Figure 4B shows the 5 difference in the fluorescence spectra of R18/D18 before and after the reaction. Based on 6 the previous report, the MgCl₂ concentration was set at 5.0 mM [19]. When R18/D18 was 78 incubated without the full-length RT or the isolated RNase H domain for 30 min, there was no change in the fluorescence spectra. When R18/D18 was incubated with 50 nM 9 10 HIV-1 RT or 1.8 µM WT for 30 min, the fluorescence increased with the peak at 515 nm. When R18/D18 was incubated with Δ C1 or Δ C2 for 30 min, no fluorescence increase was 11 observed. These results suggest that WT has RNase H activity and $\Delta C1$ and $\Delta C2$ do not. 1213To further analyze the RNase H activity of the isolated RNase H domains, we used a radioisotope-based RNase H assay. An RNA/DNA hybrid (R25/D25) consisting of a 5'-1415[³²P]-labelled 25-nt RNA (R25) and an unlabeled complementary DNA (D25) was used 16 as the substrate (Fig. 5A). After the RNase H reaction, the RNA reaction products were 17analyzed by denaturing PAGE. First we examined the effects of MgCl₂ concentration on 18 the RNase H activity of WT and found that reactions containing 0.1-0.2 mM yielded 19 relatively higher amounts of products than those containing other concentrations (0-15)20mM) (data not shown). Thus, 0.1 mM was used in subsequent experiments.

Figure 5B shows the denatured PAGE analysis of the products obtained from the reaction under various conditions. Unreacted R25/D25 showed only a single 25-nt RNA band. When R25/D25 was incubated with 30 nM full-length MMLV RT, 16–20-nt bands were detected at 15 s, and 14–17-nt bands were detected at 10 min. When R25/D25 was

1 incubated with 30 nM WT, only a 25-nt band was detected at both 15 s and 10 min. When $\mathbf{2}$ R25/D25 was incubated with 1.0 or 10 µM WT, only a 25-nt band was detected at 15 s, whereas various bands (mainly 7-16-nt bands) were detected at 10 min. This indicated 3 4 that the cleavage pattern of WT was different from that of the full-length MMLV RT and that the activity of WT was considerably weaker than that of the full-length MMLV RT. 5 6 When R25/D25 was incubated with Δ C1 or Δ C2, various bands (mainly 7–16-nt bands) were only detected at a 10 µM and 10 min. Under all other reaction conditions tested, 7 only the uncleaved 25-nt band was detected. This indicated that although the activities of 8 9 Δ C1 and Δ C2 were weaker than that of WT, the cleavage patterns were the same as that of WT. 10

Figure 5C compares the time courses of the cleavage patterns obtained in the 11 12reactions with 30 nM full-length MMLV RT, 1 μ M WT, and 10 μ M Δ C1 and Δ C2. The results of a densitometry trace of each band were shown in Fig. S1. In full-length MMLV 13RT, 10–20-nt bands were detected, in which the amount of the 17-nt band was the highest 14 at 5-30 min and that of the 14-nt band was the highest at 60 and 120 min. In WT, $\Delta C1$, 1516 and ΔC_2 , 7–20-nt bands were detected, in which the amount of the 7- or 10-nt band was higher than those of other bands. The rates of the decrease in the 25-nt bands in the 17reaction with WT, Δ C1, and Δ C2 were 30%, 3%, and 3% of full-length MMLV RT, 18 respectively. Based on these enzyme concentrations (30 nM for full-length MMLV RT, 1 1920 μ M for WT, and 10 μ M for Δ C1, and Δ C2), the activities of WT, Δ C1, and Δ C2 were roughly estimated to be 1%, 0.01%, and 0.01% of full-length MMLV RT activity, 2122respectively.

1 Discussion

 $\mathbf{2}$

3 We expressed the isolated RNase H domain of MMLV RT with N-terminal strep-tag and C-terminal deca-histidine tag. The use of two tags has an advantage as it allows the 4 removal of degraded products using one of the tags. In our initial attempt to express the 5 6 RNase H domain with only a C-terminal (His)₆-tag, the degraded products could not be 7completely removed, as described in the Results section. In addition, the removing of the 8 tags was important because it increased the solubility. Based on the SDS-PAGE (Fig. 2) 9 and spectroscopic analysis (Fig. 3) results, we considered the purity of the RNase H 10 preparations to be sufficient for use in structural and functional analysis.

11 The DNA in the 25-bp RNA/DNA heteroduplex used in the radioisotope-based RNase H assay lacks the primer 3'-terminus (Fig. 5A). The reaction with full-length 12MMLV RT produced 17-20-nt RNA fragments (Fig. 5B), indicating that the position at 13which the RNA strand of the RNA/DNA hybrid is cleaved is 17-20 bp upstream of the 14 153'-terminus of the primer. This is the same position as previoulsly reported in assays of 16 full-length MMLV RT using RNA/DNA hybrids with primer 3'-termini [20, 21]. This suggests that the DNA polymerase active site binds to the RNA/DNA hybrid in a similar 1718 manner whether it has the primer 3'-terminus or not.

19 Unlike the full-length MMLV RT, WT, Δ C1, and Δ C2 produced RNA fragments 20 mainly ranging from 7 to 16 nt in length (Fig. 5B). We speculate a possible mechanism 21 for the generation of fragments of these lengths as follows: For the full-length MMLV 22 RT, the position at which the RNase H active site binds to the RNA strand of an 23 RNA/DNA hybrid is predetermined, whereas for the isolated RNase H domains, the 24 active site binding position is not; thus the cleavage site by the isolated RNase H domain is different from that by the full-length MMLV RT. This suggests that elimination of the
fingers, palm, thumb, and connection subdomains affects the binding of the RNase H
domain to an RNA/DNA heteroduplex.

In this study, we expressed WT as well as $\Delta C1$ and $\Delta C2$ because the crystal structure 4 of MMLV RT Δ C1 has been determined [1] and the structures of XMRV RT WT and Δ C2 5 have been determined [22, 23]. In the RNase H assay using a fluorescent substrate, WT 6 $\overline{7}$ exhibited activity, whereas $\Delta C1$ and $\Delta C2$ did not (Fig. 4). However, in the RNase H assay using a radioactive substrate, all three exhibited the activity (Fig. 5). Therefore, we 8 9 concluded that the C helix is not critical for the activity of the isolated MMLV RT RNase 10 H domain. However, the RNase H activities of $\Delta C1$ and $\Delta C2$ were only 10% of WT 11 activity (Fig. 5C), suggesting that the C helix is important for activity. Similar results have 12been reported for full-length MMLV RT, and the C helix has been shown to be important 13for both DNA polymerase and RNase H activities [22, 23].

Unlike the MMLV RT RNase H domain, the RNase H domain of HIV-1 RT does not contain the C helix, and the isolated HIV-1 RT RNase H domain lacks activity [24-27]. Interestingly, insertion of a basic loop near at the active site of the isolated RNase H domain generated weak activity in the presence of Mn²⁺ [28]. Recently, Permanasari *et al.* reported that addition of bacterial RNase HI or HII substrate binding domain to the isolated RNase H domain also resulted in weak activity in the presence of Mn²⁺ [29]. These results supports the notion that the C helix is important for RNase H activity.

E. coli RNase HI contains the C helix [30] whereas the RNase H domains of MMLV RT and HIV-1 RT are C helix-deficient. Comparison of the structure of Δ C1 (PDB accession codes SHB5) with that of *E. coli* RNase HI (3AA2) suggests that the C helix of the RNase H domain of MMLV RT is positioned similary to that of *E. coli* RNase HI.

1 Comparison of the structure of Δ C1 with a complex containing the isolated HIV-1 RT 2 RNase H domain and an RNA/DNA heteroduplex (1HYS) suggests that the C helix in the 3 RNase H domain of MMLV RT interacts with the RNA strand of the RNA/DNA 4 heteroduplex. Therefore, the C helix is thought to contribute to substrate recognition, as 5 reported previously by Nowotny *et al.* [31].

6 In conclusion, we expressed the RNase H domain of MMLV RT in E. coli and purified it to homogeneity. Characterization of the recombinant proteins suggested that 78 the C helix is involved in the substrate recognition and that the fingers, palm, thumb, and 9 connection subdomains are involved in positioning of the cleavage sites in the RNA strand 10 of an RNA/DNA heteroduplex. These recombinant RNase H domain proteins might be 11 suitable for use in structural and functional analyses to elucidate the mechanisms of 12thermostabilization of MMLV RT through site-directed mutagenesis. An extensive study is currently underway to prepare crystals of WT, Δ C1, and Δ C2, with and without a 1314mutation of the catalytic Asp (Asp524).
