New infrared emitting d-f (ruthenium(II)–neodymium(III)) heterobimetallic complexes with alkoxy(silyl) functional groups have been prepared. Visible excitation evidenced energy transfer processes from the ruthenium(II) donor to neodymium(III) acceptors leading to infrared emission. Energy transfer rates (k_{EnT}) and efficiency of energy transfer (η_{EnT}) are, respectively, $0.61 \times 10^7 \text{ s}^{-1}$ and 44% for $\text{RuL}^1\text{-NdL}^3$ complex. Larger values of k_{EnT} ($3.04 \times 10^7 \text{ s}^{-1}$) and η_{EnT} (84%) were detected for $\text{RuL}^2\text{-NdL}^4$ complex. $\text{RuL}^1\text{-NdL}^3$ and $\text{RuL}^2\text{-NdL}^4$ complexes were fully characterized by elementary analysis (EA), mass spectrometry (MS), Fourier transform infrared spectroscopy (FTIR) and Fourier transform Raman spectroscopy (FT-Raman). Total correlation spectroscopy (TOCSY1D), $^1\text{H}\{^{13}\text{C}\}$ heteronuclear single quantum correlation (HSQC) and $^1\text{H}\{^{13}\text{C}\}$ heteronuclear multiple bond correlation (HMBC) nuclear magnetic resonance (NMR) analyses were also carried out to characterize NdL^3 and $\text{RuL}^1\text{-NdL}^3$ complexes. The presence of trialkoxysilyl-substituted ligands would allow further grafting onto any silica or silicated surface aiming at applications as new luminescent near infrared (NIR)-emitting biosensors or biomarkers.

Keywords: ruthenium(II), neodymium(III), silylated heterobimetallic complexes, d-f energy transfer, grafting trialkoxysilyl group, visible and NIR luminescent complexes

Introduction

The design and assembly of heterobimetallic complexes based on d-block metalloligands with near-infrared (NIR) emitting lanthanides (Ln) have attracted interest in the recent years due to potential applications in non-invasive bio-analysis and bio-imaging.¹⁻⁶ Given the inherent low molar absorption coefficients of lanthanide(III) ions ($\epsilon < 10 \text{ mol L}^{-1} \text{ cm}^{-1}$), d-block chromophores serve as effective light-harvesting groups to sensitize Ln-emissive centres.¹ Beyond that, most of lanthanide complexes require excitation in the ultraviolet (UV) region, which is

harmful for the biological systems. The aromatic residues of proteins and deoxyribonucleic acid (DNA) absorb in competition with the chromophores. In addition, the UV excitation cause damages in these biological systems.¹ One of the strategies to overcome these limitations consists on using d-block chromophores as antenna groups to sensitize luminescence from lanthanide(III) ions with low energy f-f excited states.

Typically, ruthenium(II) complexes displaying polypyridine bridging ligands are used to sensitize NIR emitting lanthanide ions through the strong absorption of the visible light by ³MLCT (MLCT = metal-to-ligand charge transfer) excited state.¹ These d-block chromophores, with relatively low ³MLCT states, act as good energy donors

*e-mail: rafaelmsabio@gmail.com

to f-f levels of praseodymium(III), neodymium(III), erbium(III) and ytterbium(III). In particular, $[\text{Ru}(\text{bpy})_3]^{2+}$ (bpy = 2,2'-bipyridine) possesses a broad and strong absorption in the visible and a low triplet state (energy of triplet state = 17400 cm^{-1}) that can allow lanthanide(III) to be efficiently excited.¹ Authors⁷ reported the use of distinct lengthy bridging ligands (saturated or unsaturated) between energy donor (d-block) and acceptor fragments (f-block) and concluded that the role of ligands is vital in determining the ruthenium(II) \rightarrow lanthanide(III) energy transfer (EnT), and the energy level of triplet state was related with the bridging processes.⁷

Pyridine derivate ligands can also serve as bridging ligands to prepare ruthenium(II)–lanthanide(III) heterobimetallic d-f complexes. Specifically, 2,2'-bipyrimidine (bpmd) is widely used to synthesize planar heterobimetallic complexes since it can easily coordinate two metal centers through four nitrogen sites leading to a relatively short metal-metal distance. As a result, an efficient channel is available for energy and electron transfer from d-block chromophores in the visible region to NIR emitting lanthanide(III) centres.⁷⁻¹⁴

Despite the examples of ruthenium(II)–lanthanide(III) heterobimetallic complexes being reported in the last few years, their use as luminophors for biosensors or biomarkers is yet scarce. The most likely reasons are their low water solubility and relatively weak luminescence.¹⁵ As an alternative to explore the potentialities of such heterobimetallic complexes in biological applications, these complexes need to be functionalized to be covalently anchored on silica nano and microparticles. We have demonstrated the preparation of bipyridine and diketone derivative ligands such as bpy-Si (4-methyl-4'-[methylamino-3(propyltriethoxysilyl)]-2,2'-dipyridine)¹⁶ and TTA-Si (4,4,4-trifluoro-2-(3-(trimethoxysilyl)-propyl)-1-(2-thienyl)-1,3-butanedione)¹⁷ appropriately substituted by a trialkoxysilyl groups. Sequentially, silylated ruthenium(II) and lanthanides(III) complexes have been isolated and grafted at the surface¹⁶⁻²¹ or embedded^{17,18,21,22} in nanosized silica. These previous results stimulated us to design d-f heterobimetallic complexes by introducing silylated appropriated ligands, bpy-Si or TTA-Si, involving NIR emitting lanthanides as neodymium(III) and bipyrimidine as bridging d-f ligand.

In this way, two routes were employed to obtain two types of dyads based on the chemistry of bipyridine ruthenium(II) and diketone neodymium(III) derived complexes according to the position of the silylated functional group. For the sake of brevity we will use a labelling Scheme 1 whereby the complexes are referred to as: $\text{RuL}^2\text{-NdL}^4$ dinuclear complexes, bearing the alkoxysilyl group on

bipyridine ruthenium moiety (*i*), and $\text{RuL}^1\text{-NdL}^3$ bearing the alkoxysilyl groups on the TTA lanthanide complex (*ii*). In both cases bipyrimidine is the bridging ligand on ruthenium center. Successful structural characterization of the silylated d-f heterobimetallic complexes is described and discussed in this work. Furthermore, photophysical properties of these heterobimetallic complexes are examined with respect to the efficiency of energy transfer processes from ruthenium(II) moieties to the luminescent NIR-emitting neodymium(III) ions.

Experimental

Materials

The silylating ligands, 4-methyl-4'-[methylamino-3(propyltriethoxysilyl)]-2,2'-dipyridine (bpy-Si), and 4,4,4-trifluoro-2-(3-(trimethoxysilyl)-propyl)-1-(2-thienyl)-1,3-butanedione (TTA-Si), were synthesized as previously described by Menu and co-workers.^{16,17} [*cis*- $\text{RuCl}_2(\text{bpy})_2$], (bpy = 2,2'-bipyridine), $[\text{RuCl}_2(\text{bpy})(\text{bpy-Si})]$ and $[\text{Nd}(\text{TTA})_3]\cdot 2\text{H}_2\text{O}$ were synthesized as previously described.^{16,17} Thenoyltrifluoro-acetone (TTA), neodymium chloride anhydrous, ytterbium chloride anhydrous were purchased from Aldrich (Toulouse, France). 2,2'-Bipyrimidine were purchased from Acros (Toulouse, France). These reagents were used as received. Acetone, dichloromethane, diethylether, ethanol and pentane were purified by distillation in an inert atmosphere, degassed and dried using cryogenic and drying procedures, respectively. All manipulations concerning the preparation of ligands and complexes were performed in an inert atmosphere using the Schlenk tube technique.

Characterization methods

Fourier transform infrared (FTIR) spectra were obtained in the spectral range from 4000 to 650 cm^{-1} (4 cm^{-1} of resolution) with a Bruker Vector 22 (KBr dispersion). The Raman spectra from all complexes were collected on a RFS 100 FT-Raman Bruker spectrometer equipped with a Ge detector using liquid nitrogen as the coolant and a Nd:YAG laser emitting at 1064 nm . The laser light, with a power varying from 30 to 150 mW , was introduced and focused on the sample, and the scattered radiation was collected at 180° . For each spectrum, an average of 1024 scans was performed at a resolution of 4 cm^{-1} over a range from 3500 to 50 cm^{-1} . The OPUS 6.0 (Bruker Optik, Ettlingen, Germany) software was used for Raman data acquisition. For the lanthanide and heterobimetallic complexes, nuclear magnetic resonance (NMR) spectra were obtained using a

Scheme 1. Synthesis of the heterobimetallic complexes, RuL¹--NdL³ (i) and RuL²--NdL⁴ (ii). Numbering of the hydrogen and carbon atoms are identified as red and blue labels.

Bruker Advance 600 MHz spectrometer at room temperature in deuterated solvents. Total correlation spectroscopy (TOCSY1D) spectra were recorded by selective irradiation of different aromatic hydrogen atoms of the complex with a selective pulse. The spectra were recorded after magnetization transfer at 120 ms of mixing time. ¹H{¹³C} heteronuclear single quantum correlation (HSQC) NMR experiments were recorded using the spectral widths of 12 000 and 24 000 Hz for the ¹H and ¹³C dimensions, respectively. The number of collected complex points was 1024 for the ¹H dimension with a recycle delay of 1.5 s. The number of transients was from 24 to 48 depending of the sample and 128 time increments were recorded in the ¹³C dimension. The ¹J_{H-C} used was 145 Hz. Prior to Fourier transformation, the data matrices were zero filled to 1024 points in the ¹³C dimension. ¹H{¹³C} heteronuclear

multiple bond correlation (HMBC) NMR experiments were carried out using the spectral widths of 12000 and 24000 Hz for the ¹H and ¹³C dimensions, respectively. The number of collected complex points was 1024 for the ¹H dimension with a recycle delay of 2.0 s. The number of transients was from 16 to 32 depending of the sample and 128 time increments were recorded in the ¹³C dimension. The ³J_{H-C} used was 8 Hz. Prior to Fourier transformation, the data matrices were zero filled to 1024 points in the ¹³C dimension. Data processing was performed using standard Bruker Topspin-NMR software. The central solvent line was used as an internal chemical shift reference point. Mass spectra (MS) were recorded using Q TOF 1er (Waters) spectrometer: source electrospray (ESI) or DSQ Thermo Fisher Scientific spectrometer equipped with chemical ionization source (NH₃). UV-Vis spectra were recorded

using a Varian spectrophotometer model Cary 5000 in the region of 800 to 200 nm (resolution of 1 nm) using Cary WinUV software. Elemental analyses of C, H, N and S were performed on a Carlo Erba instrument (EA 1110). Luminescence spectra were measured at room temperature using a Jobin-Yvon Model Fluorolog FL3-22 spectrometer equipped with a H10330-75 Hamamatsu detector, TE: cooled NIR-photomultiplier module and a 450 W Xe excitation lamp. Excitation and emission spectra were recorded under CW excitation and were corrected with respect to the Xe lamp intensity and spectrometer response. Fluorescence intensity decays were obtained using the time-correlated single-photon counting technique. The excitation source was a mode-locked Ti:sapphire laser (Tsunami 3950 pumped by Millennia X Spectra Physics) producing 5 ps FWHM pulses ranging from 0.5 to 8.0 MHz repetition rate, regulated by the 3980 Spectra Physics pulse picker. The laser was tuned to give output at 892 nm and a second harmonic generator BBO crystal (GWN-23PL Spectra Physics) gave the 448 nm excitation pulses that were directed to an Edinburgh FL900 spectrometer adjusted in L-format configuration. The emission wavelength of 620 and 670 nm were selected by a monochromator and emitted photons were detected by a cooled Hamamatsu R3809U microchannel plate photomultiplier. The whole instrument response function was typically 100 ps. Energy transfer rate constant (k_{EnT}) and efficiency of energy transfer (η_{EnT}) were obtained using ruthenium ³MLCT decay values from ruthenium precursors and the respective heterobimetallic complexes.

Synthesis

[Nd(TTA-Si)₃] (NdL³)

This complex was obtained by the procedure adapted from Duarte *et al.*¹⁷ 6 mmol (2.30 g) of the TTA-Si and 2 mmol (0.50 g) of neodymium chloride anhydrous were added to 20 mL of anhydrous ethanol. The reaction mixture was kept under nitrogen atmosphere and stirred for 18 h. The solvent was evaporated and the powder was then washed with pentane and diethylether, and dried under vacuum. The Nd(TTA-Si)₃ complex (NdC₄₂H₅₄F₉O₁₅S₃Si₃, MW 1294.54) was obtained as a greenish powder (1.9 g, yield: 77%). Elemental analysis found: C 38.45, H 3.5; calcd. for NdC₄₁H₅₂O₁₅F₉S₃Si₃ (one methoxy group hydrolyzed): C 38.45, H 4.1%; UV (EtOH) λ / nm 267 and 340; IR (KBr) ν / cm⁻¹ 3108w (ν CH), 2960m and 2923m (ν_{as} CH₂, CH₃), 2855w (ν_{s} CH₂, CH₃), 1609vs-br (ν CO), 1539s and 1510m (ν CCO), 1410s and 1356s (ν CCS_{thenoyl}), 1304vs-br (ν CF₃), 1060s-br (ν SiOCH₃), 788s (δ CH_{thenoyl}), 721m (δ CF₃); ¹H NMR (600 MHz, CDCl₃) δ 0.83 (2H, CH₂, 11-H), 1.90 (2H, CH₂, 10-H), 3.57 (2H,

CH₂, 9-H and 9H, CH₃, 12-H), 7.19 (1H, dd, $J_{\text{H-H}}$ 4.5 and 3.4 Hz, CH, 2-H), 7.75 (1H, d, $J_{\text{H-H}}$ 4.9 Hz, CH, 1-H), 7.79 (1H, d, $J_{\text{H-H}}$ 3.4 Hz, CH, 3-H); MS (ESI) m/z , found for [(M - OCH₃ + OH) - TTA-Si]: 895.9.

[Nd(TTA)₃(H₂O)₂] (NdL⁴)

This complex was obtained by the procedure described by Duarte *et al.*¹⁷ 3 mmol (0.666 g) of TTA were added to 30 mL of ethanol. Then 450 μ L of NH₄OH were added. 1 mmol (0.279 g) of neodymium chloride were dissolved in 30 mL of water and added to the previous solution. The reaction mixture was kept under stirring for 3 h. The obtained powder was recovered and dissolved in acetone; then it was re-crystallized by precipitation on cold water and dried under vacuum. The [Nd(TTA)₃H₂O₂] complex (NdC₂₄H₁₆O₈F₉S₃, MW 843.80) was obtained as a yellow powder (0.59 g, yield: 70%). Elemental analysis found: C 34.1, H 1.5; calcd. for NdC₂₄H₁₆O₈F₉S₃: C 34.1, H 1.9%; UV (EtOH) λ / nm 268 and 340; IR (KBr) ν / cm⁻¹ 3330m-br (ν OH), 3115 (ν CH), 1606vs (ν CO), 1542s and 1514s (ν CCO), 1411s and 1358s (ν CCS_{thenoyl}), 1300vs-br (ν CF₃), 789w (δ CH_{thenoyl}), 716w (δ CF₃); MS (desorption chemical ionization, DCI, NH₃) m/z , found for [M + H⁺ - 2H₂O]: 807.8; [M + H⁺ - H₂O]: 825.8.

[Ru(bpy)₂(bpmd)]Cl₂ (RuL¹)

1.88 mmol (0.307 g) of 2,2'-bipyrimidine and 1.71 mmol (0.830 g) of [*cis*-RuCl₂(bpy)₂], were added to 40 mL of anhydrous and degassed ethanol. The reaction mixture was kept under nitrogen atmosphere and refluxing at 78 °C for 72 h. The solvent was evaporated, and the powder was then washed with pentane and diethyl ether, and dried under vacuum. The [Ru(bpy)₂(bpmd)]Cl₂ complex (RuC₂₈H₂₂N₈Cl₂, MW 642.50) was obtained as a brown powder (1.1 g, yield: 85%). Elemental analysis found: C 49.7, H 3.4, N 16.8; calcd. for RuC₂₈H₂₂N₈Cl₂.H₂O: C 52.3, H 3.45, N 17.4%; UV (EtOH) λ / nm 245, 286 and 424; IR (KBr) ν / cm⁻¹ 3064w (ν CH), 1630m-br and 1601s (ν CN), 1572s, 1463s, 1443s 1420m and 1400vs (ν CC), 772vs (δ CH_{ar}); MS (ESI) m/z , found for [M²⁺/2]: 286.1.

[Ru(bpy)(bpy-Si)(bpmd)]Cl₂ (RuL²)

1.38 mmol (0.225 g) of 2,2'-bipyrimidine and 1.38 mmol (1.01 g) of [RuCl₂(bpy)(bpy-Si)] were added to 40 mL of anhydrous and degassed ethanol. The reaction mixture was kept under nitrogen atmosphere and refluxing at 78 °C for 72 h. The solvent was evaporated, and the powder was washed with diethyl ether, and dried under vacuum. The [Ru(bpy)(bpy-Si)(bpmd)]Cl₂ complex (RuC₃₉H₄₇N₉O₃SiCl₂, MW 889.91) was obtained as a black powder (0.98 g, yield: 80%). Elemental analysis found:

C 50.0, H 4.9, N 13.65; calcd. for $\text{RuC}_{39}\text{H}_{47}\text{N}_9\text{O}_3\text{SiCl}_2$: C 52.6, H 5.3, N 14.1%; UV (EtOH) λ / nm 250, 287 and 443; IR (KBr) ν / cm^{-1} 3064w (νCH), 2967w and 2923w ($\nu_{\text{as}}\text{CH}_2, \text{CH}_3$), 2867w ($\nu_s\text{CH}_2, \text{CH}_3$), 1637sh and 1618s (νCN), 1553s, 1464m, 1444m, 1421m and 1400vs (νCC), 1072s-br (νSiOC), 771s ($\delta\text{CH}_{\text{ar}}$); MS (ESI) m/z , found for $[\text{M}^{2+}/2]$: 409.4.

$[\text{Ru}(\text{bpy})_2(\text{bpmd})\text{Nd}(\text{TTA-Si})_3]\text{Cl}_2$ ($\text{RuL}^1\text{-NdL}^3$)

0.33 mmol (0.208 g) of the $[\text{Ru}(\text{bpy})_2(\text{bpmd})]\text{Cl}_2$ (RuL^1) was added to 10 mL of anhydrous and degassed ethanol and then 0.33 mmol (0.420 g) of $\text{Nd}(\text{TTA-Si})_3$ (NdL^3) diluted in 10 mL of anhydrous and degassed dichloromethane were added to the first solution. The reaction mixture was kept under nitrogen atmosphere for 12 h at room temperature. The solvent was half evaporated and filtered. The obtained powder was washed with pentane and diethyl ether, and dried under vacuum. The $[\text{Ru}(\text{bpy})_2(\text{bpmd})\text{Nd}(\text{TTA-Si})_3]\text{Cl}_2$ complex ($\text{C}_{70}\text{H}_{76}\text{N}_8\text{O}_{15}\text{F}_9\text{S}_3\text{Si}_3\text{RuNdCl}_2$, MW: 1937.05) was obtained as a dark brown powder (0.35 g, yield: 55%). Elemental analysis found: C 41.4, H 2.95, N 5.8, S 5.1; calcd. for $\text{C}_{70}\text{H}_{76}\text{N}_8\text{O}_{15}\text{F}_9\text{S}_3\text{Si}_3\text{RuNdCl}_2$: C 43.4, H 3.95, N 5.8, S 5.0%; UV (EtOH) λ / nm 257, 270, 285, 339 and 423; IR (KBr) ν / cm^{-1} 3070w (νCH), 2972w ($\nu_{\text{as}}\text{CH}_2, \text{CH}_3$), 1631sh and 1605vs (νCN), 1535s and 1508m (νCCO), 1576w, 1463m and 1446m (νCC), 1411s-br and 1354m ($\nu\text{CCS}_{\text{thenoyl}}$), 1302vs (νCF_3), 1060w (νSiOCH_3), 785w ($\delta\text{CH}_{\text{thenoyl}}$), 767w ($\delta\text{CH}_{\text{ar}}$), 728w (δCF_3); ^1H NMR (600 MHz, CDCl_3) δ 0.85 (br s, CH_2 , 11-H), 1.91 (br s, CH_2 , 10-H), 3.59 (br s, CH_2 , 9-H and br s, CH_3 , 12-H), 7.15 (br s, CH, IV'-H), 7.18 (dd, $J_{\text{H-H}}$ 6.2 Hz, V-H), 7.29 (dd, $J_{\text{H-H}}$ 6.4 Hz, CH, 5-H), 7.38 (d, $J_{\text{H-H}}$ 4.9 Hz, VI-H), 7.53 (br s, CH, 2-H), 7.55 (br s, CH, 6-H), 7.65 (br s, CH, V'-H), 7.70 (dd, $J_{\text{H-H}}$ 6.2 Hz, CH, IV-H), 7.80 (dd, $J_{\text{H-H}}$ 7.7 Hz, CH, 4-H), 7.97 (d, $J_{\text{H-H}}$ 3.8 Hz, CH, 1-H), 8.15 (d, $J_{\text{H-H}}$ 5.9 Hz, CH, III-H), 8.19 (d, $J_{\text{H-H}}$ 7.4 Hz, CH, 3-H), 8.72 (br s, CH, III'-H), 9.08 (br s, CH, 3-H); MS (ESI) m/z , found for $[\text{Ru}(\text{bpy})_2(\text{bpmd})]^{2+}/2$: 286.1; $[\text{M} - \text{TTA-Si}]$: 1551.0.

$[\text{Nd}(\text{TTA})_3(\text{bpmd})\text{Ru}(\text{bpy})(\text{bpy-Si})]\text{Cl}_2$ ($\text{RuL}^2\text{-NdL}^4$)

0.28 mmol (0.250 g) of the $[\text{Ru}(\text{bpy})(\text{bpy-Si})(\text{bpmd})]\text{Cl}_2$ (RuL^2) was added to 10 mL of anhydrous and degassed ethanol and then 0.28 mmol (0.240 g) of $[\text{Nd}(\text{TTA})_3(\text{H}_2\text{O})_2]$ (NdL^4) diluted in 10 mL of anhydrous and degassed dichloromethane were added to the ruthenium solution. The reaction mixture was kept under nitrogen atmosphere for 12 h at room temperature. The solvent was half evaporated and filtered. The obtained powder was washed with pentane and diethyl ether, and dried under vacuum. The $[\text{Ru}(\text{bpy})(\text{bpy-Si})(\text{bpmd})\text{Nd}(\text{TTA})_3]\text{Cl}_2$ complex ($\text{C}_{63}\text{H}_{59}\text{N}_9\text{O}_9\text{F}_9\text{S}_3\text{SiRuNdCl}_2$, MW 1697.68) was obtained as a black powder (0.26 g, yield:

55%). Elemental analysis found: C 44.15, H 3.5, N 7.6; calcd. for $\text{C}_{63}\text{H}_{59}\text{N}_9\text{O}_9\text{F}_9\text{S}_3\text{SiRuNdCl}_2$: C 44.6, H 3.7, N 7.4%; UV (EtOH) λ / nm 258, 287, 339 and 437; IR (KBr) ν / cm^{-1} 3069w (νCH), 2978w and 2923w ($\nu_{\text{as}}\text{CH}_2, \text{CH}_3$), 1634sh and 1609vs (νCN), 1555s and 1506m (νCCO), 1575w, 1465m and 1446m (νCC), 1413s, and 1355m ($\nu\text{CCS}_{\text{thenoyl}}$), 1302vs-br (νCF_3), 1076w (νSiOC), 783m ($\text{CH}_{\text{thenoyl}}$), 767w ($\delta\text{CH}_{\text{ar}}$), 717w (δCF_3); MS (ESI) m/z , found for $[\text{M}^+ - \text{Cl}]$: 1662.2.

Results and Discussion

Synthesis and structural characterization of silylated ruthenium(II)–neodymium(III) heterobimetallic complexes

The synthesis routes of three new mononuclear complexes denoted by (i) RuL^1 , (ii) RuL^2 and (iii) NdL^3 has been achieved in Supplementary Information (SI) section (Figure S1). Equimolar reaction of ruthenium complex bearing the bridging ligand, RuL^1 , with silylated tris(diketonate) neodymium complex, NdL^3 , gives rise to $\text{RuL}^1\text{-NdL}^3$ heterobimetallic complex (i, Scheme 1). On the other hand, the combination of RuL^2 complex, containing both silyl and bridging groups, with tris(diketonate) neodymium complex, $\text{Nd}(\text{TTA})_3$ denoted by NdL^4 (synthesis route and structure of NdL^4 were done in Figure S2, SI section), leads to heterobimetallic $\text{RuL}^2\text{-NdL}^4$ complex with the trialkoxysilyl functional group on the ruthenium moiety (ii, Scheme 1).

FTIR spectra (Figure 1) exhibit indicative bands for lanthanide units in NdL^3 , NdL^4 and both heterobimetallic complexes with the stronger vibration bands in the range 1603–1610 ($\nu_{\text{C=O}}$), 1539–1543 ($\nu_{\text{C-C-O}}$), 1411–1412 ($\nu_{\text{CS}_{\text{thienyl}}}$), 1300–1310 cm^{-1} (ν_{CF_3}) related to diketonate ligands. Concerning the NdL^3 and $\text{RuL}^1\text{-NdL}^3$ complexes (Figure 1a red and blue lines, respectively), the presence of bands at 1060 ($\nu_{\text{Si-O-CH}_3}$) suggests the successful synthesis of both methoxysilyl complexes. These results are in agreement with EA and MS (molecular peaks for RuL^1 and $\text{RuL}^1\text{-NdL}^3$ at $m/z = 286.1$ $[\text{M}^{2+}/2]$ and 286.1 $[\text{Ru}(\text{bpy})_2(\text{bpmd})]^{2+}/2$; 1551.0 $[\text{M} - \text{TTA-Si}]$, respectively).

For RuL^2 and $\text{RuL}^2\text{-NdL}^4$ complexes (Figure 1b red and blue lines, respectively), three bands 1072 and 1076 cm^{-1} ($\nu_{\text{Si-O-C}}$), respectively confirming that the reaction was performed avoiding the hydrolysis and self-polymerization of the ethoxysilyl groups. These results are in agreement with EA and MS (molecular peaks for RuL^2 and $\text{RuL}^2\text{-NdL}^4$ at $m/z = 409.4$ $[\text{M}^{2+}/2]$ and 1662.2 $[\text{M}^+ - \text{Cl}]$, respectively). The NdL^4 complex (Figure 1b, red line) was successfully prepared and characterized as already described in the Experimental section.

Figure 1. FTIR spectra for the (a) NdL^3 , $\text{RuL}^1\text{-NdL}^3$ and RuL^1 ; (b) NdL^4 , $\text{RuL}^2\text{-NdL}^4$ and RuL^2 complexes. All analyses were carried out as KBr pellets.

Raman spectroscopy allows accurate assignment of CCH stretching vibration bands at 1028, 1040, 1202, 1490 and 1580 cm^{-1} of heterocycles of the bpy and bpm� ligands of ruthenium units in $\text{RuL}^1\text{-NdL}^3$ and $\text{RuL}^2\text{-NdL}^4$ heterobimetallic complexes. The ruthenium(II) coordination was confirmed by the band observed at 1030 cm^{-1} ($\nu_{\text{Ru-N}}$).^{23,24} Both spectroscopies appeared well complement one another. Raman scattering spectra are shown in Figure S3 (SI section).

The steric arrangement of the ligands in the metal coordination sphere in NdL^3 and $\text{RuL}^1\text{-NdL}^3$ complexes have been elucidated by assignment of chemical shifts, $J_{\text{H-C}}$ and $J_{\text{H-H}}$ coupling constant and using complementary NMR studies such as TOCSY1D, $^1\text{H}\{^{13}\text{C}\}\text{-HSQC}$ and $^1\text{H}\{^{13}\text{C}\}\text{-HMBC}$ experiments (Figures S4, S5 for NdL^3 and S6-S9 for $\text{RuL}^1\text{-NdL}^3$, SI section). Numbering of the hydrogen and carbon atoms used in the further characterization is detailed in Figure S1 (SI section) and Scheme 1 for each complexes. Most probable because of the presence of the silyl group, compounds behave as hygroscopic powders and all attempts to grow single crystals have been unsuccessful.

Photophysical properties

Figure 2 shows the UV-Vis absorption spectra for the two types of heterobimetallic complexes and respective precursors. Figure 2a black line, shows the spectrum obtained for the RuL^1 complex. Strong and broad bands are observed at 245 and 424 nm attributed to $\text{d}\rightarrow\pi^*$ $^1\text{MLCT}$ transitions (RuL^1 to bpy and bpm� ligands, respectively) and a strong and sharp band at 286 nm attributed to $\text{p}\rightarrow\pi^*$ transitions of bpy and bpm� ligands.²⁵ For NdL^3 complex (Figure 2a, red line), the absorption bands at 269 and

340 nm were assigned to singlet-to-singlet transitions in the TTA-Si ligands.¹⁷ The spectrum obtained for $\text{RuL}^1\text{-NdL}^3$ complex (Figure 2a, blue line) shows the strong and broad absorption bands at 257, 285 and 423 nm, attributed to the $\pi\rightarrow\pi^*$ transitions of the ligands coordinated to the ruthenium center and $\text{d}\rightarrow\pi^*$ $^1\text{MLCT}$ transitions from the ruthenium center to bpy and bpm� ligands. The absorption bands at 270 and 339 nm are ascribed to singlet-to-singlet ligands transitions present in the neodymium(III) center. Concerning the RuL^2 complex, the bpy-Si was confirmed by bands at 250 and 443 nm, attributed to $\text{d}\rightarrow\pi^*$ $^1\text{MLCT}$ transitions from the ruthenium(II) center to bpy-Si and bpm� ligands (Figure 2b, black line) and a strong and sharp band at 287 nm attributed to $\pi\rightarrow\pi^*$ transitions of bpy-Si and bpm� ligands. Comparing spectra obtained for RuL^1 and RuL^2 one may note a red shift of around 20 nm for $^1\text{MLCT}$ state with the addition of the silylated ligand. The spectrum obtained for NdL^4 complex (Figure 2b, red line) displays two bands at 268 and 340 nm assigned to singlet-to-singlet transitions in the TTA ligands.¹⁷ The spectrum of $\text{RuL}^2\text{-NdL}^4$ complex (Figure 2b, blue line) displays strong and broad absorption bands at 258, 287 and 437 nm, characteristic of $\pi\rightarrow\pi^*$ transitions of the ligands coordinated to the ruthenium center and $\text{d}\rightarrow\pi^*$ $^1\text{MLCT}$ transitions from the ruthenium to bpy-Si and bpm� ligands. The absorption bands at 258 to 339 nm are assigned to the singlet-to-singlet ligands transitions present in the neodymium(III) complex.

The characteristic infrared emission from the lanthanide counterpart is observed when excitation is set in the visible at the MLCT ruthenium(II) band (at 450 nm). For $\text{RuL}^1\text{-NdL}^3$, neodymium(III) $^4\text{F}_{3/2} \rightarrow ^4\text{I}_{11/2}$ and $^4\text{F}_{3/2} \rightarrow ^4\text{I}_{13/2}$ transitions at 1065 (sharp band) and 1334 nm (low intensity band) were detected as depicted in Figure 3a blue line.^{9,25,26}

Figure 2. Absorption spectra (2.5×10^{-5} mol L⁻¹, ethanol) of (a) NdL³ (red line), RuL¹-NdL³ (blue line), RuL¹ (black line) and (b) NdL⁴ (red line), RuL²-NdL⁴ (blue line), RuL² (black line).

The RuL²-NdL⁴ (Figure 3b, blue line) displayed similar transitions bands at 1066 ($^4F_{3/2} \rightarrow ^4I_{11/2}$) and 1334 nm ($^4F_{3/2} \rightarrow ^4I_{13/2}$), respectively.^{9,25,26} Excitation spectra obtained by monitoring the NIR emission (λ_{em} : 1065 and 1066 nm for RuL¹-NdL³ and RuL²-NdL⁴, respectively) are also shown in Figures 3a-3b, red lines. For both heterobimetallic complexes, three sharp bands were detected in visible range and ascribed to neodymium(III) intraconfigurational f-f transitions at 581, 746 and 800 nm.^{9,26} The broad band from 270 to 400 nm were assigned to transitions centered at TTA-Si, bpy and bpm� ligands.^{14,17,18,26} Bands ranging from 400 to 600 nm were attributed to the ruthenium(II) ³MLCT transition.²⁵ Further information on the energy transfer from the ruthenium counterpart to the lanthanide one is these heterobimetallic compounds can be obtained by analyzing the changes observed for the Ru visible emission properties (Figures S10 and S11, SI section).

Table 1 shows results for excited state lifetimes. Considering bpm� as a planar bridging ligand that provides short metal-metal distance and a pathway that favors efficient energy transfer in heterobimetallic complexes, especially for neodymium(III) and ytterbium(III) ions,¹⁰ the lifetime values obtained for RuL¹ and RuL² substantially reduced in RuL¹-NdL³ and RuL²-NdL⁴ complexes suggesting energy transfer processes for both heterobimetallic complexes. The k_{EnT} and η_{EnT} may be evaluated from lifetimes as shown in Table 1.

A pathway of energy transfer (EnT) is presented in Scheme 2. The proposed energy level diagram suggests that the RuL² and RuL¹ ³MLCT energy are suitable for the sensitization of the neodymium(III) luminescence. The RuL² complex ³MLCT energy level is centered at 16129 cm⁻¹ and the energy transfer to neodymium(III) could be evaluated. Considering the RuL²-NdL⁴ complex,

Figure 3. Room temperature excitation (red lines) and emission (blue lines) spectra from (a) RuL¹-NdL³ (λ_{em} : 1065 nm and λ_{ex} : 450 nm) and (b) RuL²-NdL⁴ (λ_{em} : 1066 nm and λ_{ex} : 450 nm) complexes in solid state.

Table 1. Photophysical properties for MLCT-based visible emission and neodymium(III) based NIR. Lifetimes data (τ) were obtained for ruthenium(II) and heterobimetallic complexes in solid state

	MLCT-based emission (λ_{ex} 448 nm)			
	λ / nm	τ / ns	$k_{\text{EnT}}^a / (10^7 \text{ s}^{-1})$	$\eta_{\text{EnT}}^b / \%$
RuL ¹	670	128.1	–	–
RuL ¹ –NdL ³	670	72.0	0.61	43.8
RuL ²	620	178.8	–	–
RuL ² –NdL ⁴	620	27.8	3.04	84.4

^a k_{EnT} (energy transfer rate constant) = $1 / \tau_q - 1 / \tau_u$ (τ_q and τ_u refer to the “quenched” and “unquenched” lifetime of ruthenium(II) complexes before and after coordination with lanthanide(III)); ^b η_{EnT} (efficiency of energy transfer) = $1 - (\tau_q / \tau_u)$. MLCT: metal-to-ligand charge transfer.

the k_{EnT} and η_{EnT} were $3.04 \times 10^7 \text{ s}^{-1}$ and 84%, respectively. For RuL¹ complex, the ³MLCT energy level is located at 14925 cm^{-1} . Values of k_{EnT} and η_{EnT} for the RuL¹–NdL³ were $0.61 \times 10^7 \text{ s}^{-1}$ and 44%, respectively. It is worth emphasizing that higher EnT rate was observed for RuL²–NdL⁴ complex. This observation could be explained considering that neodymium(III) presents excited levels better located for energy transfer from RuL² ³MLCT states.

**Scheme 2.** Schematic energy transfer processes from RuL¹ and RuL² complexes (ruthenium(II)) to neodymium(III) (A = absorption; ISC = inter-system cross; P = phosphorescence; EnT = energy transfer; F = fluorescence) in the RuL¹–NdL³ and RuL²–NdL⁴ complexes.

Conclusions

New ruthenium(II) complexes, named RuL¹ and RuL², both containing the bridging ligand bpy and the last one containing also a silylated bpy ligand (L²) have been prepared. From these complexes and new NdL³ diketonate complexes (where L³ is methoxysilyl modified

diketonate), ruthenium(II)–neodymium(III) heteronuclear compounds have been prepared. A structural study was performed by EA, MS, FTIR and FT-Raman and 1D and 2D NMR techniques confirming the presence of the alkoxysilyl function and the fabrication of two new silylated d-f heterobimetallic complexes. UV-Vis spectra depicted characteristic transition bands in ruthenium(II) and neodymium(III) mononuclear precursors and both transition bands contributions in RuL¹–NdL³ and RuL²–NdL⁴ complexes corroborating all structural analysis. The luminescent properties of the silylated d-f heterobimetallic complexes were evaluated with energy transfer processes being established from the ruthenium(II) donor to neodymium(III) acceptor units in the IR region. The decrease of lifetime and ruthenium quantum yield resulting from ruthenium(II) units compared to ruthenium(II)–neodymium(III) confirm effective energy transfer in these systems. For RuL¹–NdL³ complex, k_{EnT} and η_{EnT} values of $0.61 \times 10^7 \text{ s}^{-1}$ and 44% were obtained whereas RuL²–NdL⁴ complex showed k_{EnT} and η_{EnT} values of $3.04 \times 10^7 \text{ s}^{-1}$ and 84%, respectively. Our results emphasize that new silylated heterobimetallic ruthenium(II)–neodymium(III) complexes can be excited in the visible range via ruthenium(II) MLCT transitions promoting energy transfer to neodymium(III) units emitting in the IR region. The successful preparation of the silylated ruthenium(II)–neodymium(III) complexes allow grafting onto any silicated matrix suggesting their application as new luminescent NIR-emitting biosensors or biomarkers.

Supplementary Information

Supplementary data (1D/2D NMR data (Table S1); synthesis routes of the mononuclear precursors, RuL¹, RuL² and NdL³ (Figure S1); NdL⁴ synthesis route and structure (Figure S2); Raman scattering spectra (Figure S3); 1D/2D NMR spectra (Figures S4–S9); FTIR spectra (Figure S10); luminescence spectra monitoring Ru units of the heterobimetallic complexes (Figure S11) and of the ruthenium(II) precursors complexes (Figure S12)) are available free of charge at <http://jbc.sqb.org.br> as PDF file.
