## ABSTRACT

More than 1.3 billion tons, a third of the total food produced, is wasted annually, and it has been predicted to increase in the coming years. Food waste significantly contributes to greenhouse gas (GHG) emissions resulting in the release of about 3.3 billion tonnes of CO<sub>2</sub> into the environment yearly. Hence this large amount of wastes, with adverse environmental effects, needs to be appropriately managed. New technologies such as Anaerobic digestion, fermentation, and gasification are being used to produce renewable energy, which in turn reduces the increasing level of food wastes in the environment. Pyrolysis of biomass materials or food wastes produces high-value energy products or bio-oil that can possibly replace non-renewable fossil fuels when it is upgraded.

In this study, pyrolysis (thermal treatment in the absence of oxygen) of plantain and yam peels to produce bio-oil, was investigated. The pyrolysis conditions, wide temperature ranges at an interval of 100 °C (200–700 °C), absence of a catalyst (AOC), the use of zeolite -Y catalyst using two separate heterogeneous catalysis procedures were imposed and

used to produced bio-oil. In the first procedure, the pyrolysis gases were allowed to rise through a zeolite-Y catalyst bed (HTC). And in the second procedure, the plantain or yam peel feedstock was first mixed uniformly with the zeolite-Y catalyst before pyrolysis (HMC). The GC-MS machine was used to analyze or characterize the obtained bio-oil while proximate analysis and XRF machine were used to characterize the plantain and yam peels feed. The residue, biochar, from the pyrolysis process, was also characterized using the XRF machine.

## Specifications Table

<b>Subject</b>	Chemical Engineering
<b>Specific subject area</b>	Waste conversion to bio-products
<b>Type of data</b>	Tables and figures
<b>How data were acquired</b>	Measurement, Proximate, X-ray fluorescence, and Gas Chromatography-Mass Spectroscopy analyses.
<b>Data format</b>	Raw
<b>Parameters for data collection</b>	The parameters considered were: yield and composition of the bio-oil and biochar obtained at the different temperatures, in the absence of a catalyst, and the presence of zeolite-Y catalyst using two heterogeneous catalysis procedures, HTC and HMC respectively.
<b>Description of data collection</b>	Data collected were through proximate analysis of the raw feed, X-ray fluorescence to characterize the raw feed and the residual biochar, and Gas Chromatography-Mass Spectroscopy analyses to characterize the bio-oil product at the different temperature ranges used during the pyrolysis process.
<b>Data source location</b>	Department of Chemical Engineering, Covenant University, Nigeria
<b>Data accessibility</b>	Data is with this article

## Value of the Data

- Pyrolysis process makes it possible to convert food waste materials and, in this case, plantain peel, to bio-oil useful for renewable energy generation, or the production of valuable biochemicals.
- The temperature dataset provides significant insight into the required optimum reaction temperature for optimal bio-oil production during the pyrolysis of plantain and yam peels.
- The dataset obtained from the pyrolysis process without the use of a catalyst, in comparison with the two heterogeneous catalysis processes (HTC and HMC), will guide researchers with the best reaction conditions during the pyrolysis of plantain and yam peels.
- The GC-MS dataset from the characterization of the obtained bio-oil from plantain and yam peels will provide researchers with the biochemical constituents and other possible applications of the bio-oil.

## Data

Kitchen waste refers to left-over organic matter from eateries, hotels, and homes [1]. They are usually rich in nutrients containing a high amount of carbohydrates, lipids, and other organic molecules [2]. According to the Food and Agriculture Organization (FAO), a whopping 1.3 billion tons, a third of the produced food in the world, is wasted annually. Usually, food wastes are disposed of by landfilling, with only a little percentage used to produce feeds, compost, and

biogas. The dataset presented in this report article shows the effect of variation of temperature with or without catalysis on the yield and chemical composition of bio-oil.

Bio-oils obtained from biomass, including food and agricultural wastes, have been reported as being a potential replacement of fossil fuels for renewable energy generation and the production of value-adding biochemicals [3–5]. It is, therefore, essential to investigate the feasibility of obtaining and characterizing bio-oils from plantain and yam peel, which are organic kitchen wastes, under varying conditions of temperatures and catalysis. The dataset presented in this article shows the yields, full characterization of the raw peels of plantain and yam feed, biochar, and the bio-oils obtained under the different pyrolysis conditions. Table 1 shows the proximate analysis of both the yam and plantain peels. Table 2 shows the XRF analysis of plantain peel, yam peel, and biochars, which are the by-products of the pyrolysis of the plantain and yam peels. Tables 3–6 show the bio-oil yields at the indicated temperature ranges for the pyrolysis

PY001/AOC – pyrolysis of yam peel without catalyst

PY002/HTC – pyrolysis of yam peel with heterogeneous catalysis (HTC)

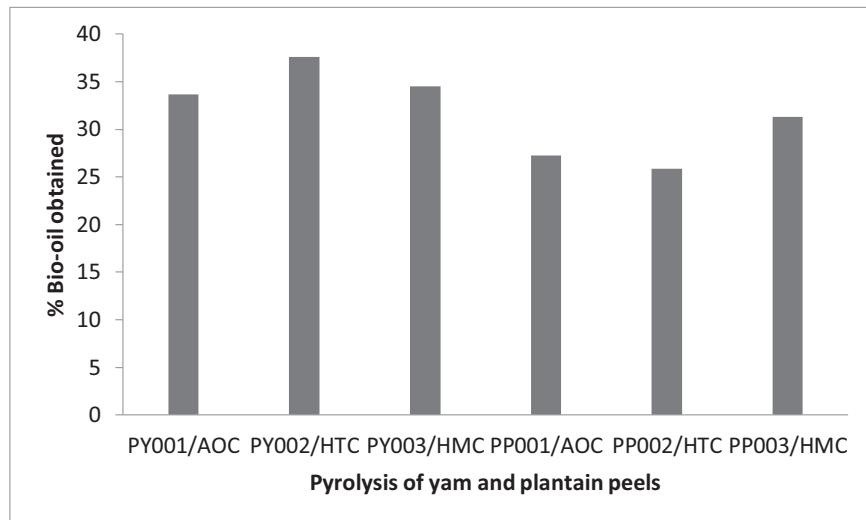

PY003/HMC – pyrolysis of yam peel with heterogeneous catalysis (HMC)

PP001/AOC – pyrolysis of plantain peel without catalyst

PP002/HTC – pyrolysis of plantain peel with heterogeneous catalysis (HTC)

PP003/HMC – pyrolysis of plantain peel with heterogeneous catalysis (HMC).

without catalyst (AOC) and heterogeneous catalysis (HTC) using zeolite-Y as the catalyst. And the bio-oil yields were calculated using Eq. (1). The temperature ranges were (250–350, 350–450, 450–550, 550–650 °C) and (200–300, 300–400, 400–500, 500–600, 600–700 °C) for the pyrolysis without catalyst (AOC) and heterogeneous catalysis (HMC) using zeolite-Y as the catalyst, respectively. The two temperature ranges were the same for the heterogeneous pyrolysis (HTC) of the yam peel. Table 7 gives the total percentage of each of the pyrolysis products for any given experimental run. And the yields of the biochar and the non-condensable products

**Fig. 1.** Total percentage yield of bio-oil from the different pyrolysis runs.

calculated using Eqs. (2) and 3, respectively. Tables 8–10, 11–13, 14–17, and 18–20, give the biochemical compositions of the obtained bio-oils at each of the above-stated pyrolysis conditions, (with and without catalysis, and the different temperature ranges). The bio-chemical compositions of the bio-oil were analyzed, using the Gas Chromatography-Mass Spectroscopy (GC-MS) machine. The chromatograms for the various bio-oil samples obtained, at the different pyrolysis conditions, are presented in the supplementary or chromatography file submitted to Data-in-Brief. The chromatograms (Figures 1–18) depict the biochemical compositions of the analyzed bio-oil samples, and they are interpreted and shown in Tables 8–20.

Fig. 1 provides a pictorial representation of the bio-oil yields obtained at each temperature ranges under the various processing conditions (absence of catalysts (AOC), HTC, and HMC).

$$\text{Bio-oil (wt\%)} = \frac{\text{weight of bio-oil}}{\text{weight of feed}} \times 100 \quad (1)$$

$$\text{Biochar (wt\%)} = \frac{\text{weight of char}}{\text{weight of feed}} \times 100 \quad (2)$$

$$\text{Non-condensables (wt\%)} = 100 - (\text{bio-oil (wt\%)} + \text{biochar (wt\%)}) \quad (3)$$

## Experimental design, materials, and methods

### Pyrolysis of plantain and yam peels to obtain bio-oil

The pyrolysis reactor was purged and kept air-tight to prevent the interference of air/oxygen with the pyrolysis reaction [6]. 150 g of each of the sample feed (dried and pulverized plantain and yam peels) was weighed and fed into the reactor. The reactor was then switched on while the required input temperature (at a 100 °C interval.) was then appropriately set. As the temperature in the reactor gradually increased, vapors were steadily released and made to pass through the condensers for condensation into bio-oil. The temperature ranges for the collection of bio-oil were; 250–350 350–450, 450–550, and 550–650 °C for the pyrolysis plantain and yam peels without catalyst and using heterogeneous (HTC) catalysis, while 200–300 300–400, 400–500,

70	25.0477	0.3287	4-Methyl-2-trimethylsilyloxy-acetophenone

500–600, and 600–700 °C temperature ranges were used for the heterogeneous (HMC) catalysis. The collected liquid product (bio-oil), as well as the biochar, for each of the experiments, was weighed and recorded.

#### Characterization of plantain and yam peels, bio-oil, and biochar obtained from the different temperature ranges

For the proximate analysis, the Kjeldahl method was used to determine the protein content [7], the Association of Official Analytical Chemists method [8] was used to determine the carbohydrate using Eq. (4).

$$\%CHO = 100 - (\%protein + \%fat + \%ash + \%crude\,fibre + \%moisture) \quad (4)$$

X-Ray fluorescence (XRF) was used for the compositional analysis of the biochar, while the Gas Chromatography-Mass Spectroscopy (GC-MS) was used for the biochemical analysis of the obtained bio-oils.

**Table 19**

Gas Chromatography-Mass Spectroscopy results of bio-oil from yam peels without catalyst (AOC) at 450–550 °C.

Peak	Retention Time	Area Percentage	IUPAC Nomenclature
