Abstract

Aims: To investigate the impact of exogenous hydrogen sulfide (H₂S) and its endogenous biosynthesis on human adipocytes and adipose tissue in the context of obesity and insulin resistance.

Results: Experiments in human adipose tissue explants and in isolated preadipocytes demonstrated that exogenous H₂S or the activation of endogenous H₂S biosynthesis resulted in increased adipogenesis, insulin action, sirtuin deacetylase and PPAR γ transcriptional activity, whereas chemical inhibition and gene knockdown of each enzyme generating H₂S (*CTH*, *CBS*, *MPST*) led to altered adipocyte differentiation, cellular senescence and increased inflammation. In agreement with these experimental data, visceral and subcutaneous adipose tissue expression of H₂S-synthesising enzymes was significantly reduced in morbidly obese subjects in association with attenuated adipogenesis and increased markers of adipose tissue inflammation and senescence. Interestingly, weight loss interventions (including bariatric surgery or diet/exercise) improved expression of H₂S biosynthesis-related genes. In human preadipocytes, expression of *CTH*, *CBS* and *MPST* genes and hydrogen sulfide production were dramatically increased during adipocyte differentiation. More importantly, the adipocyte proteome exhibiting persulfidation was characterized, disclosing that different proteins involved in fatty acid and lipid metabolism, the citrate cycle, insulin signalling, several adipokines and PPAR experienced the most dramatic persulfidation (85-98% $p < 0.0000001$).

Innovation: No previous studies investigated the impact of H₂S on human adipose tissue. This study suggests that the potentiation of adipose tissue H₂S biosynthesis is a possible therapeutic approach to improve adipose tissue dysfunction in patients with obesity and insulin resistance.

Introduction

Adipose tissue dysfunction, characterised by increased inflammation and cellular senescence and reduced adipogenesis, is an important contributor to obesity-associated metabolic disturbances, including insulin resistance (10, 33, 44). Increased oxidative stress and reactive oxygen species (ROS) levels in adipose tissue have been extensively demonstrated in obesity in association to insulin resistance and adipocyte dysfunction (1, 2, 13, 24, 62). The attenuation of adipose tissue oxidative stress might be an important therapeutic approach to prevent adipose tissue dysfunction and improve obesity-associated metabolic disturbances (50).

Hydrogen sulfide (H_2S) is a gaseous mediator that plays important regulatory roles in innate immunity and inflammatory responses impacting on the development of cardiovascular and metabolic diseases (8, 23, 32, 70, 81). In mammalian systems, H_2S is endogenously generated from cysteine by pyridoxal-5'-phosphate (PLP)-dependent enzymes, cystathionine β -synthase (CBS) and cystathionine γ -lyase (CTH or CSE), through the transsulfuration pathway (34), but also in absence of PLP by 3-mercaptopyruvate sulfurtransferase (MPST) that converts 3-mercaptopyruvate into H_2S (39, 68).

H_2S exerts its biological actions attenuating oxidative stress through different molecular mechanisms, including scavenging of ROS (69) and protein persulfidation (63). Protein persulfidation is a post-translational modification in which thiol groups (R-SH) from reactive cysteine residues are converted into perthiols (R-SSH). Persulfidation is known to modulate the structure and biological activity of target proteins, preventing irreversible cysteine overoxidation, and in consequence, preserving protein function (22, 56, 63, 84).

3 A recent study reported increased serum sulfide levels in subjects with morbid obesity in
4
5 positive correlation with fat mass (17), but negatively associated with hyperglycemia (17,
6
7 77), showing decreased serum sulfide levels in obese subjects with altered glucose
8
9 tolerance. In line with this study, previous studies also demonstrated decreased plasma
10
11 sulfide levels in association to type 2 diabetes (77) or decreased adipose tissue H₂S
12
13 production capacity in mice models of obesity and diabetes (high fat diet and db/db) (35).
14
15 In fact, there is emerging evidence in the 3T3-L1 mouse cell line pointing to a possible
16
17 role of H₂S in adipocyte differentiation through the modulation of PPAR γ activity (9, 73,
18
19 80). The overexpression of the H₂S generation enzyme CTH and the administration of the
20
21 H₂S donor NaHS to 3T3-L1 cells in an environment of high glucose restored adiponectin
22
23 secretion and decreased the secretion of proinflammatory cytokines (59). However, the
24
25 impact of H₂S on human adipocytes has not been investigated, while its possible role in
26
27 human adipose tissue physiology and adipogenesis is not yet completely understood.

Results

To examine the impact of H₂S on adipose tissue, *ex vivo* experiments were performed in adipose tissue explants from cohort 1, in which paired SAT and VAT were obtained from 20 morbidly obese participants with different degrees of systemic insulin sensitivity. Anthropometric and clinical parameters are shown in Suppl Table 1. As detailed in methods, the effects of GYY4137 in 5 consecutive participants and induction of endogenous H₂S biosynthesis in all participants (n=20) were tested, **being with** sulfide levels **being** analyzed in 8 consecutive participants.

Exogenous H₂S administration increased adipogenesis, sirtuin and PPAR γ activity in human adipose tissue explants

The most common class of H₂S donors are the sulfide salts [such as sodium hydrosulfide (NaSH) and sodium sulfide (Na₂S)] and GYY4137. Sulfide salts produced a fast release of H₂S triggering acute supraphysiological effects, and then H₂S levels drop rapidly. In contrast, GYY4137 induces a slower but more prolonged H₂S release, with increased peaking time (10 min vs 10 s for NaSH), but decreased peaking concentration (400-fold lower than for NaSH) (63). In human adipose tissue *ex vivo*, GYY4137 (5 μ M, 16h at 37°C) administration increased *ADIPOQ*, *FASN*, *SLC2A4* and *SIRT1* mRNAs in parallel to sulfide levels in tissue culture media (Figure 2A). GYY4137 (200 μ M, 1h at 37°C) also increased sirtuin deacetylase (Figure 2B) and PPAR γ transcriptional (Figure 2C) activities in adipose tissue lysates.

***Ex vivo* stimulation of H₂S biosynthesis enhances the expression of adipogenic genes and *SIRT1* in association with insulin sensitivity**

Then, H₂S biosynthesis was examined in human adipose tissue explants (Suppl Table 1), after adding L-cysteine and pyridoxal 5'-phosphate (PLP), known to induce H₂S biosynthesis through CBS and CTH. We observed increased endogenous H₂S

Comas

1
2
3 biosynthesis (Figure 2D) in parallel to raised *CTH* and *CBS* mRNAs levels (Table 1,
4
5 Figure 2E-F), pointing that *CTH* and *CBS* gene expression is associated to H₂S
6
7 biosynthesis. The induction of endogenous H₂S biosynthesis resulted in increased sulfide
8
9 levels in tissue culture media and enhanced expression of adipogenic (*ADIPOQ*, *PPARG*,
10
11 *SLC2A4*, *CIDEA* and *FASN*) and *SIRT1* genes in both subcutaneous (SAT) and visceral
12
13 (VAT) adipose tissue (Table 1, Figure 2D). Sulfide concentration in the media positively
14
15 correlated with *ADIPOQ*, *PPARG*, *SLC2A4* and *SIRT1* gene expression in both SAT and
16
17 VAT (Figure 2E-F). The increase in SAT, but not VAT, *ADIPOQ*, *SLC2A4*, *FASN* and
18
19 *SIRT1* gene expression after endogenous H₂S biosynthesis induction in AT explants was
20
21 higher in those morbidly obese participants with decreased Hb1Ac (Figure 3A-D), but
22
23 increased insulin sensitivity (Figure 3E-H).

24
25 Supporting these experimental data, VAT and SAT H₂S-synthesising enzymes (*CTH*,
26
27 *CBS*, *MPST*) gene expression, which is in association to H₂S biosynthesis, were
28
29 associated to systemic insulin sensitivity and adipose tissue adipogenesis in two cross-
30
31 sectional (cohort 2 and 3) and three longitudinal (cohort 4, 5, 6) cohorts, in which bariatric
32
33 surgery or diet/exercise interventions were performed.

34 35 **Insulin sensitivity is associated to *CTH* expression in human adipose tissue**

36
37 In cohort 2, VAT and SAT *CTH*, *CBS* and SAT *MPST* gene expression were significantly
38
39 decreased in obese subjects (Suppl Table 2, Figure 4A-C) in association with homeostasis
40
41 model assessment – insulin resistance index (HOMA-IR) and fasting triglycerides (Table
42
43 2). HOMA-IR was the main factor contributing to decreased SAT *CTH* ($\beta = -0.29$, $p = 0.04$)
44
45 and SAT *CBS* ($\beta = -0.42$, $p = 0.02$) after adjusting for sex, age and body mass index (BMI).
46
47 In a subgroup of 12 participants, in which *CTH* protein levels were analysed, a positive
48
49 correlation between *CTH* protein and mRNA levels in both SAT and VAT were found
50
51 (Figure 4D).

Comas

In an independent cohort of morbidly obese participants (cohort 3, Suppl Table 3), insulin sensitivity (euglycemic clamp) was positively correlated with SAT *CTH* ($r=0.55$, $p=0.02$, Figure 4E) and *CBS* ($r=0.45$, $p=0.06$, Figure 4F), but not SAT *MPST* ($r=0.34$, $p=0.1$) after excluding participants with type 2 diabetes. VAT *CTH* gene expression was also negatively correlated with HOMA-IR (Table 3).

Association of *CTH*, *CBS* and *MPST* with markers of adipose tissue functionality and the effects of weight loss

In cohort 2, in both VAT and SAT, *CTH*, *CBS* and *MPST* gene expression was positively correlated with adipogenic (*FASN*, *ACACA*, *PPARG*), insulin signaling pathway-related (*IRS1*, *SLC2A4*), *SIRT1* and *PPARGC1A* gene expression and negatively associated with expression of *LEP*, *LBP* and *TNF* (only *MPST*) genes (Table 2). In cohort 3, concordant associations were found for *CTH* and *MPST*, but not for *CBS* gene expression (Table 3). *CTH* gene expression correlated with expression of adipogenic (*ADIPOQ*, *PPARG*), mitochondrial biogenesis (*PPARGC1A*), insulin signaling pathway-related (*IRS1*) genes, and markers of cellular senescence (positively with *SIRT1* and negatively with *BAX*, *TP53* and *TNF* gene expression (Table 3). *MPST* mRNA also positively correlated with *PPARG*, *ADIPOQ* and *SLC2A4* genes (Table 3).

In cohort 4, bariatric surgery-induced weight loss resulted in increased *CTH* (29.7%, $p=0.0005$), *CBS* (9.6%, $p=0.05$) and *MPST* (15.2%, $p=0.01$) mRNAs in parallel to improved insulin sensitivity and systemic inflammation (53, 57). Interestingly, the increase in *CTH* mRNA was positively correlated with the increase in *ADIPOQ* ($r=0.71$, $p=0.002$), *SIRT1* ($r=0.53$, $p=0.03$) and *PPARGC1A* ($r=0.56$, $p=0.02$) mRNAs. Similar findings were observed in an independent cohort after bariatric surgery-induced weight loss (cohort 6) and also after diet or exercise-induced weight loss (cohort 5), with increased SAT *CTH* mRNA levels (55% and 29%, respectively, both $p<0.01$).

1 Comas

2
3 In adipose tissue cell fractions, *CTH* and *MPST* gene expression significantly increased
4
5 in human adipocytes in comparison with stromal vascular cells (SVF) (Figure 4G-H),
6
7 whereas no significant differences in *CBS* gene expression between these 2 cell types
8
9 were detected (Figure 4I).

12 **Expression of H₂S-synthesising enzymes increases with adipocyte differentiation**

13
14 Next, H₂S biosynthesis was investigated at cellular level, in human preadipocytes and
15
16 adipocytes. We found that an adipocyte endogenous source of H₂S is prominent in human
17
18 adipocytes. Sulfide levels were detectable and quantified in the culture media of human
19
20 adipocytes and consistently increased by a ~30% with adipocyte differentiation (Figure
21
22 5A-B). *CTH* and *MPST* gene expression increased progressively during human adipocyte
23
24 differentiation (Figure 5C-D) in close parallelism with adipogenic genes (*ADIPOQ*,
25
26 Figure 5E). *CBS* increased slightly only in the last days of differentiation (day 12 and day
27
28 14, Figure 5F). These findings were confirmed at the protein level, observing high levels
29
30 of sulfide-producer enzyme accumulation after differentiation (Figure 5G).

35 **Exogenous H₂S potentiates insulin action and adipogenesis in human adipocytes**

36
37 GYY4137 had no apparent effects on PPAR γ transcriptional activity in preadipocytes
38
39 (Figure 6A) (72 h) but led to a significantly increased sirtuin deacetylase activity (Figure
40
41 6B). In contrast, GYY4137 increased PPAR γ transcriptional activity in adipocytes
42
43 (Figure 6C), without significantly affecting sirtuin deacetylase activity (Figure 6D).
44
45 GYY4137 treatment resulted in a 3-fold increase (p<0.001) in p^{Ser473}Akt/Akt ratio in
46
47 response to insulin (Figure 6E).

48
49 GYY4137 dose-dependently increased the expression of adipogenic genes (*ADIPOQ*,
50
51 *FABP4* and *CEBPA*) and *SLC2A4* in the last days of adipocyte differentiation and this
52
53 effect was reverted by the CTH inhibitor propargylglycine (PPG) (Figure 6F-I).

2
3 **Chemical inhibition of H₂S-synthesising enzymes attenuates adipogenesis and**
4 **impacts inflammation in human adipocytes**
5
6

7 Propargylglycine (PPG) is a known specific chemical inhibitor of the CTH enzyme,
8 which led to a significant reduction of intracellular lipid accumulation (Figure 7A), fatty
9 acid synthase protein levels (Figure 7B) and adipogenic gene expression (*ADIPOQ*,
10 *FABP4*, *PPARG*, *FASN*, *PLINI*) (Figure 7C-G) during adipogenesis. PPG led to raised
11 markers of cellular senescence (*BAX*, *TP53*), proinflammatory cytokines (*IL6*, *TNF*) and
12 pSer⁵³⁶NFκB (p65)/NFκB (p65) ratio, without changing LDH activity (a direct measure of
13 cellular damage and necrosis) ((Figure 7H-M).
14
15
16
17
18
19
20
21
22

23 In fully differentiated adipocytes, PPG also attenuated insulin-induced Ser⁴⁷³Akt
24 phosphorylation (Figure 7N), reduced *ADIPOQ*, *FASN*, *DGAT1*, *PPARG*, *IRS1*,
25 *PPARGC1A* and *SIRT1* (Suppl Figure 1A-G), but did not affect inflammatory or cellular
26 senescence-related gene expression or LDH activity (Suppl Figure 1H-L).

28
29
30
31
32

33 **Gene knockdown (KD) of CTH, CBS and MPST in human preadipocytes impairs**
34 **adipocyte differentiation**
35
36

37 The effects of chemical compounds such as GYY4137 or PPG up- or downregulating H₂S
38 production could be due to off-target mechanisms acting at multiple levels. For this
39 reason, we studied how *CTH*, *CBS* and *MPST* gene KD affect adipogenesis during human
40 adipocyte differentiation. The silencing of all these genes resulted in significantly
41 decreased expression of adipogenic, lipogenic and insulin pathway-related genes while
42 increasing inflammatory gene expression (Figure 8A-C). *CTH* gene KD resulted in a
43 significantly decreased expression in adipogenic (*ADIPOQ*, *FABP4*, *FASN*, *PPARG*,
44 *CEBPA*) and insulin pathway (*SLC2A4*, *IRS1*)-related genes while increasing
45 inflammatory mRNAs (*IL6*, *TNF*) (Figure 8A). *CBS* gene KD also resulted in decreased
46 *ADIPOQ*, *FABP4*, *FASN*, *CEBPA*, *SLC2A4* and *IRS1*, and increased *IL6* mRNA levels
47
48

2
3 (Figure 8B). *MPST* gene KD led to decreased *ADIPOQ*, *FABP4*, *FASN*, *PPARG*, *CEBPA*
4 and *SLC2A4*, and increased *IL6* and *TNF* mRNA levels (Figure 8C). Of note, the most
5 antiadipogenic effect was observed in CTH gene KD, since expression of all adipogenic
6 and insulin pathway-related genes was reduced between 45-55% ($p < 0.005$).
7

12 **Persulfidation affects proteins involved in adipogenesis**

14 Between 10-30% of the cellular proteome is susceptible to being modified by
15 persulfidation as it has been reported in mammals and plants, being this a highly prevalent
16 protein post-translational modification (6, 60). For this reason, to gain insight into the
17 mechanism underlying the adipogenic effects of H₂S, whole proteome persulfidation in
18 preadipocytes and adipocytes was analysed and compared. To assess that, a sequential
19 window acquisition of all theoretical spectra-mass spectrometry (SWATH-MS)
20 quantitative approach with the tag-switch method (83) was combined for identification of
21 protein persulfidation in preadipocyte and differentiated human cell cultures. Protein
22 samples from four biological replicates extracted from preadipocyte and differentiated
23 adipocyte cell cultures were isolated and subjected to the chemoselective tag-switch
24 method to label persulfidated proteins. The enriched samples in persulfidated proteins
25 obtained were digested, and the peptide solutions analyzed in two sequential steps: a
26 shotgun data-dependent acquisition (DDA) approach to generate the spectral library, and
27 SWATH acquisition by a data-independent acquisition (DIA) method. In the first step,
28 after integrating the eight datasets, a total of 19,053 peptides [1% false discovery rate
29 (FDR) and 92.8 % confidence] and 2,016 unique proteins (1% FDR) were identified and
30 used as spectral library (Suppl dataset 1, available in PRIDE with identifier PXD018720).
31
32 In the second step, to quantify protein levels using SWATH acquisition, the same eight
33 biological samples were analyzed twice each (technical replicas) by a DIA method. For
34 quantitation, the fragment spectra were obtained for the sixteen runs and 1,590 proteins
35

Comas

1
2
3 were quantified (Suppl dataset 2, available in PRIDE with identifier PXD018720), of
4
5 which 954 were differentially more or less abundant in each culture with a fold change of
6
7 ± 1.5 and p value < 0.05 (Suppl dataset 3, available in PRIDE with identifier
8
9 PXD018720). From these proteins, 332 proteins were more persulfidated in differentiated
10
11 adipocytes and in addition, we detected in the spectral library generated by the DDA
12
13 approach 496 proteins that were only identified in the adipocyte samples and were under
14
15 the detection limit in preadipocyte cultures (Suppl Table 4). Therefore, a total of 828
16
17 proteins were only persulfidated or were more persulfidated in differentiated adipocyte
18
19 cultures.
20
21
22

23
24 In differentiated human adipocytes, persulfidation was significantly increased in proteins
25
26 involved in fatty acid and lipid metabolism, the citrate cycle, adipokine, PPAR and insulin
27
28 signalling (Figure 9A-B). Among them, we identified PLIN1, previously described as
29
30 susceptible of persulfidation (21), which validated the proteomic approach used, and
31
32 other important proteins and enzymes in adipocyte physiology, such as FASN, SCD,
33
34 ACACA, THRSP, PLIN4, LIPE, ACSL1, SLC2A4 (GLUT4) and FABP4 (all with
35
36 $p < 0.0000001$), but not non-adipogenic control proteins, such as ACTB, ENO1 and
37
38 PARK7 (61) that showed similar level of persulfidation in both cell cultures (Figure 9C).
39
40 Considering that persulfidation preserved protein integrity and function in conditions of
41
42 oxidative stress where cysteine residues may be partially oxidized (22, 63, 84), current
43
44 data suggested that persulfidation in adipocytes might have a crucial role preserving those
45
46 proteins involved in adipogenesis and adipocyte physiology. These proteins mainly
47
48 included enzymes, lipid droplet-associated proteins, membrane transporters and receptors
49
50 that modulate lipogenesis, lipolysis, mitochondrial function and insulin action (Suppl
51
52 dataset 2 and Figure 9A-B). On the other hand, in preadipocytes the proteins that were
53
54 persulfidated belonged to pathways involved in immune response, cell migration,
55

Discussion

The current study provides sound and novel evidences supporting the importance of H₂S biosynthesis in the physiology of human adipose tissue. Altogether current findings pointed to a crucial role of H₂S and H₂S-synthesizing enzymes in human adipose tissue physiology at different cellular levels. Even though, the specific molecular mechanism to explain the possible effects of H₂S on human adipogenesis has not been fully resolved in this study, some mechanisms might be inferred from current findings. These putative mechanisms were as follows:

i) Preserving adipogenic-related proteins through protein persulfidation. Persulfidation often increases the reactivity of target proteins, modulating their biological activities, whereas other post-translational modifications, such as S-nitrosylation often decreases protein activity (25). In fact, a recent study showed experimentally, for the first time, a higher chemical reactivity in proteins with persulfidated cysteines compared to proteins with cysteines with sulfur in the thiol state (26). Even though, the most reported impact of persulfidation is to activate protein function, some studies demonstrated inhibitory effects in some important proteins (26).

Taking into account that we found increased persulfidation in FASN, SCD, ACACA, THRSP, PLIN4, LIPE, ACSL1, GLUT4 and FABP4, and that an appropriate functionality of these proteins is required for adipogenesis and adipocyte physiology (3, 14, 19, 31, 42, 46, 66, 82), the current results suggest that endogenous H₂S biosynthesis might preserve the function of those proteins involved in adipogenesis. However, further experiments are required to confirm this suggestion.

Supporting the importance of H₂S in the physiology of adipose cells, *CTH*, *CBS* and *MPST* mRNA levels were detected at substantial levels in adipocytes, increasing during human adipocyte differentiation in parallel to *ADIPOQ*. The knockdown of *CTH*, *CBS*

Comas

1
2
3 and *MPST* promoted the development of dysfunctional adipocytes during adipocyte
4 differentiation, decreasing markers of adipogenesis and increasing the expression of
5 proinflammatory cytokines in parallel to decreased H₂S biosynthesis. Of note, the most
6 anti-adipogenic effect was observed in *CTH* gene KD. The chemical inhibition of CTH
7 activity resulted in decreased adipogenesis during human adipocyte differentiation and in
8 fully differentiated adipocytes. In fact, anti-adipogenic and inflammatory effects of high
9 PPG dose (250 μM) during human adipocyte differentiation were comparable with the
10 effects of *CTH* gene KD. In contrast, no significant effects of low PPG dose (25 μM)
11 were found. This discrepancy could be explained by the previously reported low potency,
12 low selectivity and the limited cell-membrane permeability of PPG (7). However,
13 considering that inhibiting CBS, CTH and MPST may have effects independent of H₂S,
14 such as perturbations in homocysteine metabolism, the results of PPG or gene knockdown
15 experiments should be interpreted with caution. In addition, it should be considered that
16 knockdown of one of these enzymes might be compensated by H₂S production by the
17 remaining ones. Otherwise, the administration of GYY4137 in the last stage of the process
18 resulted in a dose-dependent increased expression of adipogenic genes. Interestingly,
19 when endogenous H₂S production was inhibited with PPG (250 μM), GYY4137
20 sustained adipogenic gene expression (Figure 6), preventing the reduction observed in
21 Figure 7. Previous studies demonstrated that adipogenic (73) and anti-cancer (41) effects
22 of GYY4137 were not observed when cells were treated with ZYJ1122, its structural
23 analogue lacking sulfur, indicating that GYY4137 effects were dependent of H₂S moiety.
24 *Ex vivo* experiments also demonstrated that the activation of H₂S-producing enzymes in
25 adipose tissue increased expression of adipogenic genes in correlation to H₂S
26 biosynthesis. Consistent with the suggested impact of H₂S on protein persulfidation in
27 adipose cells (current study), a recent study demonstrated that persulfidation depends on

Comas

1
2
3 intracellular H₂S levels, observing in those situations of decreased H₂S biosynthesis, such
4
5 as aging, a significant decline in protein persulfidation, whereas conditions of enhanced
6
7 H₂S production (such as dietary restriction) were associated with increased protein
8
9 persulfidation (84).

10
11
12 ii) *Preventing inflammatory processes in human preadipocytes through the induction of*
13
14 *sirtuin deacetylase activity*. Specifically, in human preadipocytes, exogenous H₂S
15
16 (GYY4137) treatment enhanced sirtuin activity, whereas when endogenous H₂S
17
18 biosynthesis was inhibited (using PPG or in *CTH*, *CBS* and *MPST* KD) markers of
19
20 cellular senescence (*TP53*), apoptosis (*BAX*) and inflammation (*TNF*, *IL6*) increased.
21
22 These findings suggest that the previously reported anti-senescence effects of H₂S (20,
23
24 51, 65) might contribute to improve the adipogenic function of preadipocytes, and
25
26 preserve adipose tissue functionality (4). In addition, increased *SIRT1* mRNA levels and
27
28 sirtuin activity after transsulfuration pathway activation or GYY4137 administration in
29
30 *ex vivo* experiment (adipose tissue explants) or the consistent association between H₂S-
31
32 producing enzymes and *SIRT1* gene expression in human adipose tissue reinforced this
33
34 idea. Furthermore, both SAT and VAT *CTH* gene expression negatively correlated with
35
36 markers of cellular senescence (*TP53*), inflammation (*TNF*) and apoptosis (*BAX*) in
37
38 obese subjects, which were all associated to adipose tissue dysfunction and insulin
39
40 resistance (36, 37, 52, 71). Even though, TP53, inflammatory cytokines (IL6 and TNF)
41
42 or apoptosis markers has all been previously used to characterize senescence-associated
43
44 adipose tissue dysfunction (36, 37, 52, 71), a more accurate measurement of cellular
45
46 senescence (such as β -galactosidase activity) should be considered to confirm current
47
48 associations in further studies.

49
50
51 Strengthening current findings, increased SIRT1 activity led to enhanced adipose tissue
52
53 rejuvenation (characterized by increased cellular stemness) and decreased inflammation

55
56
57
58
59
60

Comas

(12, 29, 43, 64, 78) and H₂S administration resulted in enhanced Sirt1 expression and activity (20, 51, 65), preventing vascular aging (20) and cellular senescence in human fibroblasts (65). In line with these findings, in immortalized human adipose-derived mesenchymal stem cells, which unlike human preadipocytes and adipocytes (current study) displayed a much higher expression of CBS than CTH gene (18), CBS gene knockdown promotes a cellular senescence phenotype characterized by increased inflammation and oxidative stress, and decreased H₂S production (18). Of note, this cellular senescence phenotype resulted in adipocyte hypertrophy, when these cells differentiated into adipocytes, and attenuated their ability to differentiate into osteogenic lineage (18).

iii) *Increasing insulin action through the activation of PPAR γ transcriptional activity in differentiated adipocytes.* GYY4137 administration resulted in a significant increase of insulin-induced Akt phosphorylation at serine 473, whereas PPG administration had opposite effects. A fine regulation of insulin action is associated to adipogenesis and adipose tissue physiology (55, 67). *Ex vivo* experiments indicated that the adipogenic effect resulting from transsulfuration pathway activation was increased in association with insulin sensitivity, and negatively correlated with HbA1c levels, supporting the relationship between H₂S and adipose tissue insulin action. In addition, AT CTH gene expression was positively correlated to systemic insulin sensitivity in both cross-sectional studies (cohort 1 and cohort 2) and increased after bariatric surgery-induced weight loss similar to insulin sensitivity. H₂S improved insulin action in mice (28, 48, 49, 79). GYY4137 administration improved high fat diet-induced insulin resistance through the activation of PPAR γ in adipose tissue, whereas PPG exerted opposite effects (9). Mechanistically, H₂S-induced PPAR γ transactivation is mediated by enhanced PPAR γ persulfidation in cysteine residues from DNA binding domain (9, 80). Since PPG

Comas

administration also increased $p^{\text{Ser536}}\text{NF}\kappa\text{B}$ (p65)/NF κ B ratio and proinflammatory cytokines (*IL6* and *TNF*), another potential mechanism to explain H₂S effects on insulin action was the inhibition of NF κ B-induced inflammation (23).

In support of current findings, CBS deficiency is known to be associated with decreased fat mass in both mice and humans (30, 38). CTH is involved in adipogenesis in phylogenetically distant species from drosophila to mice (9, 73, 80) with *cth* knockout mice developing decreased fat mass under cysteine-limited diets (47).

Decreased levels of H₂S-synthesizing enzymes in morbidly obese subjects seems in contradiction with the relevance of these enzymes in adipogenesis and fat mass accretion.

However, in conditions of obesity and insulin resistance, adipogenesis is attenuated (40, 54, 74), and size enlargement of pre-existing adipocytes acquires more relevance in fat mass sustaining (45). The findings in human adipose tissue are in agreement with decreased adipose tissue H₂S production reported in db/db and high-fat diet-fed mice (35).

Even though, adipose tissue as a possible source of increased serum sulfide levels, recently described in morbidly obese subjects (17), cannot be discarded. Alternative hypothesis should be investigated: i) Expression of H₂S-synthesizing enzymes could be higher in early phases of obesity but decrease in more advanced disease as a consequence of adipose tissue inflammation and insulin resistance. ii) In addition, H₂S production depends not only by the expression/activity of synthesizing enzymes but also on its oxidation. Decreased oxidation may be the result of environmental hypoxia as that present in adipose tissue from subjects with obesity (72). In this context, decreased oxidation could result in persistently higher serum sulfide levels.

Current data might anticipate clinical applications and also suggest that the modulation of adipose tissue H₂S biosynthesis may play a role in glucose metabolism. Dietary raw garlic homogenate (a complex mixture containing several H₂S precursors) administration

Comas

restored plasma H₂S levels in diabetic rats and led to increased insulin sensitivity (58). Therapeutically, the potentiation of adipose tissue H₂S-synthesizing enzymes to improve adipose tissue physiology in patients with type 2 diabetes should be investigated in depth in further studies.

Conclusions

This study sustains adipose tissue H₂S-synthesizing enzymes as important actors in human adipose tissue physiology and systemic insulin sensitivity, possibly avoiding cellular senescence and inflammation, and in consequence preserving adipose tissue adipogenesis.

Innovation

Even though the role of H₂S on adipogenesis has been previously studied in mice, no previous studies investigated the impact of H₂S on human adipose tissue. The current study demonstrates the relevance of H₂S biosynthesis in human adipogenesis and adipose tissue physiology. This study also shows the first whole proteome persulfidation analysis in human adipocytes, suggesting that persulfidation might preserve the function of those proteins involved in adipogenesis. Altogether these data point to the potentiation of adipose tissue H₂S biosynthesis as a possible therapeutic approach to improve adipose tissue dysfunction in patients with obesity and insulin resistance (Figure 1).

Material and Methods

Subjects' recruitment for adipose tissue samples

Ex vivo experiments in adipose tissue explants

Cohort 1. Paired SAT and VAT were obtained from 20 obese participants undergoing open abdominal surgery (gastrointestinal bypass) under general anesthesia after an overnight fast. Anthropometric and clinical parameters were detailed in Suppl Table 1. The study had the approval of the ethical committee, and all patients gave informed written consent.

These experiments were performed as previously described [14]. In brief, samples of adipose tissue were immediately transported to the laboratory (5–10 min). The handling of tissue was carried out under strictly aseptic conditions. The tissue was cut with scissors into small pieces (5–10 mg) and incubated in buffer plus albumin (3 ml/g of tissue) for 30 min. After incubation, the tissue explants were centrifuged for 30 s at 400g. Then ~100 mg of minced tissue was placed into 1 ml M199 (Life Technologies, Invitrogen) containing 10% fetal bovine serum (Hyclone, Thermo Fisher Scientific), 100 unit/ml penicillin (Life Technologies, Invitrogen), and 100 µg/ml streptomycin (Life Technologies, Invitrogen) and incubated for 16 h in suspension culture under aseptic conditions. The following treatments were performed: i) Vehicle or GYY4137 (5 µM) administration during 16 h at 37°C to evaluate the effects of exogenous H₂S administration (N=5); and ii) Vehicle or L-cysteine (10 mM) and pyridoxal 5'-phosphate (2 mM), as an inductor of the transsulfuration pathway (H₂S-synthesising enzymes), during 16 h at 37°C to evaluate the effects of endogenous H₂S biosynthesis (N=20). In addition, the effect of GYY4137 (200 µM, 1 h at 37°C) in adipose tissue lysates were also tested.

2
3 *Cross-sectional studies*

4
5 In cohort 2, a group of 241 [122 visceral (VAT) and 119 subcutaneous (SAT) adipose
6 tissues] from participants with normal body weight and different degrees of obesity, with
7 body mass index (BMI) within 20 and 68 kg/m², were analyzed. In a third cohort of
8 morbidly obese (BMI > 35 kg/m²) subjects with different degrees of insulin action
9 (measured using hyperinsulinemic-euglycemic clamp as detailed below), 35 paired SAT
10 and VAT samples (Cohort 3) were studied. Altogether these subjects were recruited at
11 the Endocrinology Service of the Hospital of Girona “Dr Josep Trueta”. All subjects were
12 of Caucasian origin and reported that their body weight had been stable for at least three
13 months before the study. Subjects were studied in the post-absorptive state. BMI was
14 calculated as weight (in kg) divided by height (in m) squared. They had no systemic
15 disease other than obesity or type 2 diabetes, and all were free of any infections in the
16 previous month before the study. Type 2 diabetes was diagnosed following the criteria of
17 the Expert Committee on the Diagnosis and Classification of Diabetes (85). The
18 characteristics of patients with type 2 diabetes are described in Suppl Table 2 and Suppl
19 Table 3. Liver diseases (specifically tumoral disease and HCV infection) and thyroid
20 dysfunction were specifically excluded by biochemical work-up. All subjects gave
21 written informed consent, validated and approved by the ethical committee of the Hospital
22 of Girona “Dr Josep Trueta”, after the purpose of the study was explained to them.
23 Samples and data from patients included in this study were provided by the FATBANK
24 platform promoted by the CIBEROBN and coordinated by the IDIBGI Biobank (Biobanc
25 IDIBGI, B.0000872), integrated in the Spanish National Biobanks Network and they
26 were processed following standard operating procedures with the appropriate approval of
27 the Ethics, External Scientific and FATBANK Internal Scientific Committees.

28 *Interventional studies*

Comas

1
2
3 In cohort 4, twenty-five Caucasian obese (BMI= 43.7 ± 4.6 kg/m², age= 47 ± 9 years
4 [mean \pm SD]) subjects, who underwent bariatric surgery through Roux-en-Y gastric
5 bypass in Hospital of Girona “Dr Josep Trueta” were part of an ongoing study [14].
6
7 Inclusion criteria were age between 30 and 60 years, BMI ≥ 35 kg/m² and ability to
8 understand the study protocol. Exclusion criteria were use of medications able to interfere
9 with insulin action and history of a chronic systemic disease. Adipose tissue samples from
10 the SAT depot were obtained during bariatric surgery. Postoperative samples of SAT
11 were obtained by subcutaneous biopsy at the mesogastric level after 2 years from surgery.
12 Fasting blood samples were obtained at the same day of the biopsy. All subjects gave
13 written informed consent, validated and approved by the ethical committee of the Hospital
14 of Girona “Dr Josep Trueta”, after the purpose of the study was explained to them.

15
16 In cohorts 5 and 6, SAT gene expression was analyzed before and 6 months after a
17 multimodal weight reduction program consisting of a -800kcal calorie restricted diet
18 combined with a structured (twice a week for 60min) exercise program (cohort 5, n=15;
19 mean age: 46.2 ± 2.5 years, mean BMI: 34.5 ± 1.8 kg/m², no type 2 diabetes, no concomitant
20 medication) and before and 12 months after bariatric surgery (cohort 6, n=32), as
21 previously described [15]. All study protocols have been approved by the ethics
22 committee of the University of Leipzig. All participants gave written informed consent
23 before taking part in the study.

24
25 Adipose tissue samples were obtained from SAT and VAT depots during elective surgical
26 procedures (cholecystectomy, surgery of abdominal hernia and gastric by-pass surgery).
27 Both SAT and VAT samples were collected from the abdomen, following standard
28 procedures. Samples of adipose tissue were immediately transported to the laboratory (5-
29 10 min). The handling of tissue was carried out under strictly aseptic conditions. Adipose
30 tissue samples were washed in PBS, cut off with forceps and scalpel into small pieces

Comas

(100 mg), and immediately flash-frozen in liquid nitrogen before stored at -80°C . The isolation of adipocyte and stromal vascular fraction cells (SVF) was performed from 8 SAT and 8 VAT non-frozen adipose tissue samples. These samples were washed three to four times with phosphate-buffered saline (PBS) and suspended in an equal volume of PBS supplemented with 1% penicillin-streptomycin and 0.1% collagenase type I prewarmed to 37°C . The tissue was placed in a shaking water bath at 37°C with continuous agitation for 60 minutes and centrifuged for 5 minutes at 300 to 500g at room temperature. The supernatant, containing mature adipocytes, was recollected. The pellet was identified as the SVF. Isolated mature adipocytes and SVF stored at -80°C for gene expression analysis.

Hyperinsulinemic-euglycemic clamp

Insulin action was determined by hyperinsulinemic-euglycemic clamp. After an overnight fast, two catheters were inserted into an antecubital vein, one for each arm, used to administer constant infusions of glucose and insulin and to obtain arterialized venous blood samples. A 2-h hyperinsulinemic-euglycemic clamp was initiated by a two-step primed infusion of insulin ($80\text{ mU}/\text{m}^2/\text{min}$ for 5 min, $60\text{ mU}/\text{m}^2/\text{min}$ for 5 min) immediately followed by a continuous infusion of insulin at a rate of $40\text{ mU}/\text{m}^2/\text{min}$ (regular insulin [Actrapid; Novo Nordisk, Plainsboro, NJ]). Glucose infusion began at minute 4 at an initial perfusion rate of $2\text{ mg}/\text{kg}/\text{min}$ being then adjusted to maintain plasma glucose concentration at $88.3\text{--}99.1\text{ mg}/\text{dL}$. Blood samples were collected every 5 min for determination of plasma glucose and insulin. Insulin sensitivity was assessed as the mean glucose infusion rate during the last 40 min. In the stationary equilibrium, the amount of glucose administered (M) equals the glucose taken by the body tissues and is a measure of overall insulin sensitivity.

Analytical methods

Comas

Serum glucose concentrations were measured in duplicate by the glucose oxidase method using a Beckman glucose analyser II (Beckman Instruments, Brea, California). Glycosylated haemoglobin (HbA1c) was measured by the high-performance liquid chromatography method (Bio-Rad, Muenchen, Germany, and autoanalyser Jokoh HS-10, respectively). Intra- and inter-assay coefficients of variation were less than 4% for all these tests. Serum insulin was measured in duplicate by RIA (Medgenix Diagnostics, Fleunes, Belgium). The intra-assay coefficient of variation was 5.2% at a concentration of 10 mU/l and 3.4% at 130 mU/l. The interassay coefficients of variation were 6.9 and 4.5% at 14 and 89 mU/l, respectively. HOMA-IR was calculated using the following formula: $[\text{Insulin (mU/l)} \times \text{Glucose mmol/l}] / 22.5$. Roche Hitachi Cobas c711 instrument (Roche, Barcelona, Spain) was used to do HDL cholesterol and total serum triglycerides determinations. HDL cholesterol was quantified by a homogeneous enzymatic colorimetric assay through the cholesterol esterase / cholesterol oxidase / peroxidase reaction (Cobas HDLC3). Serum fasting triglycerides were measured by an enzymatic, colorimetric method with glycerol phosphate oxidase and peroxidase (Cobas TRIGL). LDL cholesterol was calculated using the Friedewald formula.

Differentiation of human pre-adipocytes

Isolated human subcutaneous preadipocytes (Zen-Bio Inc., Research Triangle Park, NC) were plated on T-75 cell culture flasks and cultured at 37 C and 5% CO₂ in DMEM/nutrient mix F-12 medium (1:1, vol/vol) supplemented with 10 U/ml penicillin/streptomycin, 10% fetal bovine serum (FBS), 1% HEPES, and 1% glutamine (all from GIBCO, Invitrogen S.A, Barcelona, Spain). One week later, the isolated and expanded human sc preadipocytes were cultured (~40,000 cells/cm²) in 12-well plates with preadipocytes medium (Zen-Bio) composed of DMEM/nutrient mix F-12 medium (1:1, vol/vol), HEPES, FBS, penicillin, and streptomycin in a humidified 37 C incubator

1 Comas

2
3 with 5% CO₂. Twenty-four hours after plating, cells were checked for complete
4
5 confluence (d 0), and differentiation was induced using differentiation medium (Zen-Bio)
6
7 composed of preadipocytes medium, human insulin, dexamethasone,
8
9 isobutylmethylxanthine, and PPAR γ agonists (rosiglitazone). After 7 day (d7),
10
11 differentiation medium was replaced with fresh adipocyte medium (Zen-Bio) composed
12
13 of DMEM/nutrient mix F-12 medium (1:1, vol/vol), HEPES, FBS, biotin, pantothenate,
14
15 human insulin, dexamethasone, penicillin, streptomycin, and amphotericin. Negative
16
17 control (nondifferentiated cell) was performed with preadipocyte medium during all
18
19 differentiation process. Fourteen days after the initiation of differentiation, cells appeared
20
21 rounded with large lipid droplets apparent in the cytoplasm. Cells were then considered
22
23 mature adipocytes, harvested, and stored at -80°C for RNA/protein purification. For time
24
25 course experiment, Cells were harvested and stored at -80°C for RNA/protein purification
26
27 at day 0, 2, 5, 7, 9, 12 and 14. To evaluate cell integrity, lactate dehydrogenase (LDH)
28
29 activity was analyzed by Cytotoxicity Detection Kit (LDH) (Cat. n° 11644793001, Roche
30
31 Diagnostics SL, Barcelona, Spain) according to the manufacturer's instructions.

33
34
35
36

37 *Treatments* CTH inhibitor DL-propargylglycine (PPG, 25 and 250 μ M) administration
38
39 was performed during sc adipocyte differentiation. Otherwise, after adipocyte
40
41 differentiation (at d 14), sc fully differentiated adipocytes were incubated with fresh
42
43 medium (control) and fresh medium containing PPG (25 and 250 μ M) for 48h. GYY4137
44
45 (0.1, 1 and 5 μ M, a slow H₂S donor) was administrated during the last stage (from day 7
46
47 to 14) of sc adipocyte differentiation process. At the end of each experiment, cells were
48
49 harvested, and pellets and supernatants were stored at -80 °C. All *in vitro* experiments
50
51 were performed in three or four independent replicates.
52
53
54

55 **Short hairpin (sh) RNA-mediated knockdown of *CTH*, *CBS* and *MPST* gene**

Comas

Gene knockdown was performed using *CTH*, *CBS* and *MPST*-targeted and control (scrambled) shRNA lentiviral particles (sc-78973-V, sc-60335-V, sc-75821-V and sc-108080, Santa Cruz Biotechnology, CA, USA) following the manufacturer instructions in human subcutaneous preadipocytes at 80% of cell confluence. Adipocyte differentiation started 24 h after lentiviral transfection and no antibiotic selection was performed.

Media sulfide quantification

Sulfide concentration in cultured medium was assessed as previously described (16), using a naphthalimide-based fluorescent sensor 6-Azido-2-[2-[2-(2-hydroxyethoxy)ethoxy]ethyl]benzo[de]isoquinoline-1,3-dione (L1). This probe was chemically synthesised in Institute of Computational Chemistry and Catalysis (Chemistry Department, University of Girona) as described previously (15). L1 probe (5 μ M) was included and incubated in adipose tissue (16h) or adipocyte (24h) maintenance media. In each experiment, a negative control that consisted in the incubation of cell culture media plus L1 probe (5 μ M) without adipose tissue explants or adipocytes was also performed. This negative control was used to subtract spontaneous H₂S production. After incubation, media were transferred to new eppendorf tubes to be homogenized, and were kept at –80°C in the dark, until the read. Fluorescence was read in a Biotek Cytation 5 reader at λ ex = 435 nm and λ em = 550nm in duplicate and quantified with a Na₂S standard curve (0, 7.8, 15.6, 31.25, 62.5, 125, 250 and 500 μ M). Media sulfide levels were normalized by total protein amount in cell lysates in *in vitro* experiments or by total adipose tissue amount in *ex vivo* experiments.

Oil red O staining

Intracellular lipid accumulation was measured by oil red O staining. For oil red O staining, cells were washed twice with PBS, fixed in 4% formaldehyde for 1 h, and stained

1 Comas

2
3 for 30 min with 0.2% oil red O solution in 60% isopropanol. Cells were then washed
4
5 several times with water, and excess water was evaporated by placing the stained cultures
6
7 at ~32°C. To determine the extent of adipose conversion, 0.2 ml of isopropanol was
8
9 added to the stained culture dish. The extracted dye was immediately removed by gentle
10
11 pipetting and its optical density was monitored spectrophotometrically at 500 nm using a
12
13 multiwell plate reader (Model Anthos Labtec 2010 1.7 reader).
14
15

16 **Insulin action, sirtuin and PPAR γ activities**

17
18 To study insulin signaling, basal- and insulin-induced Akt phosphorylation at Ser473
19
20 normalized by total Akt protein levels (p^{Ser473}Akt/Akt ratio) were measured after
21
22 adipocyte differentiation (at d 14). Insulin stimulus was performed with insulin (100 nM)
23
24 administration during 10 min. Sirtuin deacetylase and PPAR γ transcriptional activities
25
26 were measured using Sirtuin Activity Assay Kit (Fluorometric) (K324-100, BioVision,
27
28 CA, USA) and PPAR gamma Transcription Factor Assay Kit (ab133101, Abcam, UK),
29
30 respectively, strictly following the manufacturer's instructions.
31
32
33

34 **RNA expression**

35
36 RNA purification, gene expression procedures and analyses were performed, as
37
38 previously described [14,18]. Briefly, RNA purification was performed using RNeasy
39
40 Lipid Tissue Mini Kit (QIAGEN, Izasa SA, Barcelona, Spain) and the integrity was
41
42 checked by Agilent Bioanalyzer (Agilent Technologies, Palo Alto, CA). Gene expression
43
44 was assessed by real time PCR using a LightCycler® 480 Real-Time PCR System (Roche
45
46 Diagnostics SL, Barcelona, Spain), using TaqMan® technology suitable for relative
47
48 genetic expression quantification. The RT-PCR reaction was performed in a final volume
49
50 of 12 μ l. The cycle program consisted of an initial denaturing of 10 min at 95 °C then 40
51
52 cycles of 15 s denaturing phase at 95 °C and 1 min annealing and extension phase at 60
53
54 °C. A threshold cycle (Ct value) was obtained for each amplification curve and then a
55
56
57
58
59
60

Comas

Δ Ct was first calculated by subtracting the Ct value for human cyclophilin A (*PPIA*) RNA from the Ct value for each sample. Fold changes compared with the endogenous control were then determined by calculating $2^{-\Delta Ct}$, so that gene expression results are expressed as expression ratio relative to *PPIA* gene expression according to the manufacturer's guidelines. TaqMan® primer/probe sets (Thermo Fisher Scientific, Waltham, MA, USA) used were as follows: Peptidylprolyl isomerase A (cyclophilin A) (4333763, *PPIA* as endogenous control), cystathionine γ -lyase (*CTH*, Hs00542284_m1), cystathionine β -synthase (*CBS*, Hs00163925_m1), mercaptopyruvate sulfurtransferase (*MPST*, Hs00560401_m1), adiponectin (*ADIPOQ*, Hs00605917_m1), peroxisome proliferator-activated receptor gamma (*PPARG*, Hs00234592_m1), fatty acid synthase (*FASN*, Hs00188012_m1), acetyl-CoA carboxylase alpha (*ACACA*, Hs00167385_m1), CCAAT/enhancer binding protein alpha (*CEBPA*, Hs00269972_s1), solute carrier family 2 member 4 (*SLC2A4*, Hs00168966_m1), insulin receptor substrate 1 (*IRS1*, Hs00178563_m1), Leptin (*LEP*, Hs00174877_m1), lipopolysaccharide binding protein (*LBP*, Hs01084621_m1), interleukin 6 (interferon, beta 2) (*IL6*, Hs00985639_m1), tumor necrosis factor (*TNF*, Hs00174128_m1), CD68 molecule (*CD68*, Hs00154355_m1), BCL2-associated X protein (*BAX*, Hs00180269_m1), tumor protein p53 (*TP53*, Hs01034249_m1) and fatty acid binding protein 4, adipocyte (*FABP4*, Hs01086177_m1).

Protein analysis

Protein were extracted directly in radioimmuno precipitation assay (RIPA) buffer (0.1% SDS, 0.5% sodium deoxycholate, 1% Nonidet P-40, 150mM NaCl, and 50mM Tris-HCl, pH 8.0), supplemented with protease inhibitors (1 mM phenylmethylsulfonyl fluoride). Cellular debris and lipids were eliminated by centrifugation of the solubilized samples at 13000 rpm for 10 min at 4°C, recovering the soluble fraction. Protein concentration was

1 Comas

2
3 determined using the RC/DC Protein Assay (Bio-Rad Laboratories, Hercules, CA). RIPA
4 protein extracts (25 μ g) were separated by SDS-PPGE and transferred to nitrocellulose
5
6 membranes by conventional procedures. Membranes were immunoblotted with anti-
7
8 CTH, CBS, MPST, FASN, β -actin (sc-365382, sc-133154, sc-376168, sc-20140, sc-
9
10 47778, Santa Cruz Biotechnology, CA, USA), p^{Ser536}NF κ B (p65), NF κ B (p65), p^{Ser473}Akt
11
12 and Akt (Cell Signaling Technology, Inc, MA, USA). Anti-rabbit IgG and anti-mouse
13
14 IgG coupled to horseradish peroxidase was used as a secondary antibody. Horseradish
15
16 peroxidase activity was detected by chemiluminescence, and quantification of protein
17
18 expression was performed using Scion image software.
19
20
21
22

23 **Label-free protein quantitation by SWATH-MS acquisition and analysis**

24
25 Protein samples from human preadipocyte cell cultures and differentially mature
26
27 adipocytes were isolated from three biological samples. Culture medium was removed by
28
29 aspiration and washed once with PBS solutions. Culture cells were incubated with a
30
31 trypsin solution at 37 °C for 5 min and collected by centrifugation at 2000 rpm for 5 min.
32
33 The supernatant was collected by aspiration and cell pellet freeze to -80 °C until used.
34
35 Samples were prepared by resuspension in 1 x Cell Lysis Buffer containing 20 mM Tris-
36
37 HCl (pH 7.5), 150 mM NaCl, 1 mM Na₂EDTA, 1 mM EGTA, 1% Triton, 2.5 mM sodium
38
39 pyrophosphate, 1 mM β -glycerophosphate, 1 mM Na₃VO₄, 1 μ g/ml leupeptin, 0.5 mM
40
41 PMSF, 1x protease inhibitor cocktail (Roche), at a ratio of 1 ml of buffer per 100 mg of
42
43 tissue. Cells were vortexed and incubated 25 min at 4 °C (on ice) and sonicated 4 times
44
45 in a sonicator bath for 10 s. The extract was centrifuged at 14000 g at 4°C for 15 min
46
47 and supernatant used as protein source. 1 mg of protein per sample were TCA/acetone
48
49 precipitated, resuspended in 50 mM TRIS-HCl, pH 8.0 containing 2.5% SDS, 1x protease
50
51 inhibitor (Roche) and submitted to the tag-switch labelling for persulfidation protein
52
53 enrichment as described (5). After elution from the streptavidin-beads proteins were
54
55
56
57
58
59
60

Comas

1
2
3 precipitated by TCA/acetone procedure. Precipitated samples were resuspended in 50 mM
4 ammonium bicarbonate with 0.2 % Rapigest (Waters) for protein determination. 50 µg of
5
6 protein were alkylated and trypsin-digested as previously described (27, 76), and the
7
8 SWATH-MS analyses were performed at the Proteomic Facility of the Institute of Plant
9
10 Biochemistry and Photosynthesis, Seville, Spain. A data-dependent acquisition (DDA)
11
12 approach using nano-LC-MS/MS was first performed to generate the SWATH-MS
13
14 spectral library as described by García *et al.* (27).
15
16
17

18
19 The peptide and protein identifications were performed using Protein Pilot software
20
21 (version 5.0.1, Sciex) with the Paragon algorithm. The search was conducted against a
22
23 Uniprot proteome database ID: UP000005640 (March 2019), specifying iodoacetamide
24
25 with other possible Cys modifications. The false discovery rate (FDR) was set to 0.01 for
26
27 both peptides and proteins. The MS/MS spectra of the identified peptides were then used
28
29 to generate the spectral library for SWATH peak extraction using the add-in for PeakView
30
31 Software (version 2.1, Sciex) MS/MSALL with SWATH Acquisition MicroApp (version
32
33 2.0, Sciex). Peptides with a confidence score above 99 % (as obtained from the Protein
34
35 Pilot database search) were included in the spectral library.
36
37
38

39
40 For relative quantitation using SWATH analysis, the same samples used to generate the
41
42 spectral library were analyzed using a data-independent acquisition (DIA) method. Each
43
44 sample (2 µL) was analyzed using the LC-MS equipment and LC gradient described
45
46 above to build the spectral library but instead used the SWATH-MS acquisition method.
47
48 The method consisted of repeating an acquisition cycle of TOF MS/MS scans (230 to
49
50 1500 m/z, 60 ms acquisition time) of 60 overlapping sequential precursor isolation
51
52 windows of variable width (1 m/z overlap) covering the 400 to 1250 m/z mass range with
53
54 a previous TOF MS scan (400 to 1250 m/z, 50 ms acquisition time) for each cycle. The
55
56 total cycle time was 3.7 s.
57
58
59

2
3 The targeted data extraction of the fragment ion chromatogram traces from the SWATH
4 runs was performed by PeakView (version 2.1) with the MS/MSALL with SWATH
5 Acquisition MicroApp (version 2.0). This application processed the data using the
6 spectral library created from the shotgun data. Up to 10 peptides per protein and 7
7 fragments per peptide were selected, based on signal intensity. Any shared and modified
8 peptides were excluded from the processing. Windows of 12 min and 20 ppm width were
9 used to extract the ion chromatograms. SWATH quantitation was attempted for all
10 proteins in the ion library that were identified by Protein Pilot with an FDR below 1 %.
11 The extracted ion chromatograms were then generated for each selected fragment ion.
12 The peak areas for the peptides were obtained by summing the peak areas from the
13 corresponding fragment ions. PeakView computed an FDR and a score for each assigned
14 peptide according to the chromatographic and spectra components. Only peptides with an
15 FDR below 5% were used for protein quantitation. Protein quantitation was calculated by
16 adding the peak areas of the corresponding peptides. To test for differential protein
17 abundance between the two groups, MarkerView (version 1.2.1, Sciex) was used for
18 signal normalization.

19 The mass spectrometry proteomics data have been deposited in the ProteomeXchange
20 Consortium via the PRIDE (75) partner repository with identifier PXD018720.

21 **Statistical analyses**

22 Statistical analyses were performed using SPSS 12.0 software. The relation between
23 variables was analyzed by simple correlation (Pearson's test and Spearman's test) and
24 multiple regression analyses in a stepwise manner. One factor ANOVA with post-hoc
25 Bonferroni test, paired t-test and unpaired t-test were used to compare *CTH*, *CBS* and
26 *MPST* gene expression in human cohorts and *ex vivo* experiment. Nonparametric test

1 Comas

2
3 (Mann Whitney test) was used to analyse *in vitro* experiments. Levels of statistical
4
5 significance were set at $p < 0.05$.

6
7 Electronic laboratory notebook was not used.
8

5
6

7 **Figure 1.** Graphic illustration summarizing how in patients with obesity and insulin
8 resistance adipose tissue H₂S biosynthesis is attenuated, and this attenuation results in
9 adipose tissue dysfunction, possibly promoted by decreased persulfidation in key
10 adipogenic proteins. This summary suggests that the potentiation of adipose tissue H₂S
11 biosynthesis might be a possible therapeutic approach to improve obesity-associated
12 adipose tissue dysfunction.

Suppl Table 1. Anthropometric and clinical characteristics of participants from *ex vivo* experiment in cohort 1.

	All participants
N	20
Age (years)	45.6 ± 9.7
BMI (kg/m ²)	44.9 ± 5.1
Waist circumference (cm)	123.9 ± 12.1
Fasting Glucose (mg/dL)	100.4 ± 13.2
HbA1c (%)	5.37 ± 0.36
M (mg/kg·min) ^a	5.73 (3.44-8.45)
Total Cholesterol (mg/dl)	181.7 ± 33.1
HDL Cholesterol (mg/dl)	50.4 ± 10.5
LDL Cholesterol (mg/dl)	111.1 ± 31.2
Fasting triglycerides (mg/dl) ^a	87 (58.2-146.2)

M, systemic insulin sensitivity measured by hyperinsulinemic-euglycemic clamp

^amedian and interquartile range
