Abstract

We give a general method for computing the cyclic cohomology of crossed products by étale groupoids, extending the Feigin-Tsygan-Nistor spectral sequences. In particular we extend the computations performed by Brylinski, Burghelea, Connes, Feigin, Karoubi, Nistor, and Tsygan for the convolution algebra $C_c^\infty(\mathcal{G})$ of an étale groupoid, removing the *Hausdorffness* condition and including the computation of *hyperbolic* components. Examples like group actions on manifolds and foliations are considered.

Keywords: cyclic cohomology, groupoids, crossed products, duality, foliations.

1 Introduction

In the general picture of non-commutative geometry, cyclic homology plays the role of compactly supported de Rham cohomology and is the target of the Chern character. The dual theory is cyclic cohomology, which plays the role of closed de Rham homology. The pairing between these two is an important tool in performing numerical computations of K-theory classes (indices).

Often the non-commutative space we have to deal with is an orbit space of an étale groupoid; in particular, any étale groupoid can be viewed as such a non-commutative space. This fits in with Grothendieck's idea of what a "generalized space" is ([1, 32]), and includes examples like leaf spaces of foliations, orbit spaces of group actions on manifolds, orbifolds. To say what the groups $HP_*(\mathcal{C}_c^\infty(\mathcal{G}))$ look like is an important step in solving index problems([3, 13, 14, 40]) and in understanding the connection between the topology and the analysis of "leaf spaces" (here we have in mind in particular the Baum-Connes assembly map [2]).

The computation of $HP_*(\mathcal{C}_c^\infty(\mathcal{G}))$ was started by Connes for the case where $\mathcal{G} = M$ is a manifold ([11]), Burghlea and Karoubi for the case where $\mathcal{G} = G$ is a group ([9, 26]) and by Feigin, Tsygan, and Nistor for crossed products by groups ([16], [38]). The general strategy is to decompose these homology groups as direct sums of localized homologies; there are two different kinds of components, which behave differently. Following the terminology introduced in [9], these are called elliptic and hyperbolic components. Usually the hyperbolic ones are more difficult to compute and involve in a deeper way the combinatorics of the groupoid.

In the general setting of smooth étale groupoids the results were partially extended by Brylinski and Nistor ([6]): for a Hausdorff étale groupoid \mathcal{G} , the localized homologies $HP_*(\mathcal{C}_c^\infty(\mathcal{G}))_{\mathcal{O}}$ are defined for any invariant closed-open set \mathcal{O} of loops; the *elliptic* components are computed in terms of double complexes; in particular the localization at units is related to the homology of the classifying space $B\mathcal{G}$. There are some important questions left:

- 1) Compute the hyperbolic components;
- 2) Remove the Hausdorffness condition (simple examples coming from foliations are non-Hausdorff);
- 3) Find a way to book-keep the computations; in particular give a more conceptual proof and a more conceptual meaning of the results.

In this paper we answer all the questions above, among some others. The main tool we use is the homology theory for étale groupoids which was introduced in [15]; in particular the results are stated in terms of this homology. This leads to various models (DeRham, Alexander-Spanier, Čech, etc) for representing cyclic cocycles. As immediate consequences we derive the Morita invariance, the Poincaré duality and the functoriality of the cyclic homology of étale groupoids.

The approach and the results of this paper owe a great deal to the previous work of several authors, especially Brylinski ([6]), Burghlea ([9]), and Nistor ([6], [38]). The computation we give for the localization at units is, beyond the formalism, the same as the one given in [6]; to the same paper we owe the important idea of reduction to loops (proposition 4.1). The method for computing the other localizations are inspired by the initial work of Burghlea [9]; the difficulty is that the topological arguments (at the level of classifying spaces) used in that paper do not work in this generality any more. An older idea ([32]) that working with classifying toposes (i.e. sheaves) might be easier than working with classifying spaces (and this was pointed out, for the first time in our context, in the same paper [6]) becomes essential for us. With this in mind, our job is to replace the classifying spaces used by Burghlea by suitable étale categories (for instance, in the case of groups, the diagram in the proof of Prop. 1.8 in [9], is obtained from the diagram in the proof of our Lemma 3.23 taking the classifying spaces), and the topological arguments by a suitable algebraic-topological formalism (long exact sequences and spectral sequences for homology of étale groupoids).

We conclude this introduction with an outline of the paper and of the main results.

In section 2 we review the basic definitions and properties of sheaves on étale groupoids and their homology and show how the Hausdorffness assumption can be dropped. It is important to point

out that our definition (see 2.14) of compactly supported forms on non-Hausdorff manifolds (which was first introduced in [15]) is related to, but not the same as the one given by Connes (section 6 in [10]). Ours has basic properties, like the existence of a de Rham differential, which are not shared by Connes' (as remarked in the introduction of [6]); it is also the right object for extending Poincaré-duality to non-Hausdorff manifolds ([15]). For this reasons we expect it to be useful also in other problems which deal with foliations with non-Hausdorff graph.

In section 3 we introduce the homology of groupoids with coefficients in cyclic sheaves (subsection 3.2); more generally, given a cyclic groupoid (i.e. a groupoid with an action of \mathbb{Z} on it, see 3.15) we consider twisted cyclic sheaves (for which the usual identity $t^{(n+1)} = 1$ is replaced by $t^{(n+1)} =$ the action of the generator $1 \in \mathbb{Z}$, see 3.20). In subsection 3.3 we prove the main technical results concerning these homologies like the Gysin sequence (Prop. 3.18), the Feigin-Nistor-Tsygan spectral sequences (Prop. 3.26 and 3.27); at the end we derive as a simple consequence the Eilenberg-Zilber-type spectral sequence for cyclic objects which is one of the main results in [17]. The older approaches to cyclic homology of crossed products by (discrete) groups can not be directly extended to the setting of étale groupoids; we show in subsection 3.4 how cyclic groupoids can be used to overcome this problem. In particular we extend the Feigin-Tsygan-Nistor spectral sequences ([16, 38]) and Nistor's description of the S boundary ([38]). See theorem 3.40, 3.41 .

In section 4 we come down to earth with more concrete applications; here is a list of them:

4) For smooth étale groupoids we extend the old results of Burghlea proving that the elliptic components $HP_*(\mathcal{C}_c^\infty(\mathcal{G}))_{\mathcal{O}}$ are computed by the homology of the normalizer $\mathcal{N}_{\mathcal{O}}$ of \mathcal{O} (see theorems 4.3, 4.4);

5) For hyperbolic components $HC_*(\mathcal{C}_c^\infty(\mathcal{G}))_{\mathcal{O}}$, we describe a $H^*(\mathcal{N}_{\mathcal{O}})$ -module structure which identifies S in the SBI -sequence with the product by an element $\epsilon_{\mathcal{O}} \in H^2(\mathcal{N}_{\mathcal{O}})$; in particular we get a vanishing condition for $HP_*(\mathcal{C}_c^\infty(\mathcal{G}))_{\mathcal{O}}$ (which extends a similar result of Burghlea [9] and Nistor [38]). For stable \mathcal{O} 's we also give a more concrete description of $HC_*(\mathcal{C}_c^\infty(\mathcal{G}))_{\mathcal{O}}$. See theorem 4.6;

6) In subsection 4.3 we show how the methods apply to cohomology. In particular we get that the pairing between HP_* and HP^* is a Poincaré-duality pairing, so it is highly non-trivial. See 4.12, 4.13 .

7) For group-actions on manifolds we get the old results for the elliptic components ([3], [6]), and a new description of the hyperbolic ones (see Corollary 4.15) ;

8) For foliations we prove that the cyclic homology is a well defined invariant of the leaf space of the foliation, in the sense that the process of reducing to the setting of smooth étale groupoids does not depend on the choice of the complete transversal (see theorem 4.17). We also give some examples.

Acknowledgments: I would like to thank Prof. I. Moerdijk for many helpful suggestions and for his support. And also Bella Baci, Victor Nistor, and Utpal Sarkar for interesting discussions. Thanks also to NWO (The Netherlands Organization for Scientific Research) for financial support.

2 Homology and Cohomology of Sheaves on Étale Groupoids

2.1 Étale Groupoids

In this subsection we review the definition of topological groupoids, fix the notations, and mention some of the main examples.

2.1 Groupoids : A groupoid is a small category \mathcal{G} in which every arrow is invertible; so it is given by a set $\mathcal{G}^{(0)}$ of "objects", a set $\mathcal{G}^{(1)}$ of "arrows" and maps $s, t : \mathcal{G}^{(1)} \rightarrow \mathcal{G}^{(0)}$ for source and target, $u : \mathcal{G}^{(0)} \rightarrow \mathcal{G}^{(1)}$ for units, $i : \mathcal{G}^{(1)} \rightarrow \mathcal{G}^{(1)}$ for inverse and $m : \mathcal{G}^{(2)} = \{(g, h) \in \mathcal{G}^{(1)} \times \mathcal{G}^{(1)} : s(g) = t(h)\} \rightarrow \mathcal{G}^{(1)}$ for multiplication. A topological groupoid is a groupoid \mathcal{G} with topologies on $\mathcal{G}^{(0)}$ and $\mathcal{G}^{(1)}$ such that all the structure maps s, t, u, i, m are continuous. It is called étale if s is an étale

map (i.e. a local homeomorphism). In this case all the other structure maps are étale; in particular $\mathcal{G}^{(0)}$ is open in $\mathcal{G}^{(1)}$ (see also 2.7 in [6]). A smooth groupoid is a groupoid \mathcal{G} with differentiable structures on $\mathcal{G}^{(0)}$ and $\mathcal{G}^{(1)}$ such that $\mathcal{G}^{(0)}$ is Hausdorff and all the structure maps are smooth, and s and t are submersions. It is called smooth étale if s is a local diffeomorphism. We shall denote $m(g, h) = gh$, $i(g) = g^{-1}$ and $g : c \rightarrow d$ to denote $s(g) = c$, $t(g) = d$. The space of arrows is also denoted by \mathcal{G} .

2.2 Examples:

1. Any space X can be viewed as an étale groupoid with $\mathcal{G}^{(0)} = \mathcal{G}^{(1)} = X$.
2. Any topological group G can be viewed as a topological groupoid with one object, G as the space of arrows and with the multiplication of G . It is étale if and only if G is discrete.
3. As a mixture of the previous examples, if G is a group acting on a space X , the cross-product groupoid $X \rtimes G$ is defined by $(X \rtimes G)^{(0)} = X$, $(X \rtimes G)^{(1)} = X \times G$, $s(x, g) = xg$, $t(x, g) = x$, $u(x) = (x, 1)$, $m((x, g), (y, h)) = (x, gh)$, $i(x, g) = (xg, g^{-1})$. It is a good replacement for the orbit space X/G (see [13]).
4. Many examples of groupoids arise in foliation theory: Haefliger's groupoid Γ^q , or the holonomy groupoid $Hol(M, \mathcal{F})$ of a foliated manifold (M, \mathcal{F}) . The latter is étale if one reduces the space of objects to a complete transversal, and is a good replacement for the leaf space of the foliation. See e.g. [22], [46], [10].
5. Orbifolds can be modelled by étale groupoids; they correspond to the étale groupoids \mathcal{G} with the property that $(s, t) : \mathcal{G} \rightarrow \mathcal{G}^{(0)} \times \mathcal{G}^{(0)}$ is a proper map (see [35]).

2.3 Actions: Let \mathcal{G} be an étale groupoid. A right action of \mathcal{G} on the space X consists of two continuous maps $\pi : X \rightarrow \mathcal{G}^{(0)}$ (the moment map), $m : X \times_{\mathcal{G}^{(0)}} \mathcal{G} = \{(x, g) \in X \times \mathcal{G} : \pi(x) = t(g)\} \rightarrow X$ (the action) such that, denoting $m(x, g) = xg$:

$$(xg)h = x(gh), x1 = x, \pi(xg) = s(g).$$

We shall call X a right \mathcal{G} space with moment map π . The associated groupoid for this action, denoted $X \rtimes \mathcal{G}$, is defined as a generalization of 1.2.3: $(X \rtimes \mathcal{G})^{(0)} = X$, $(X \rtimes \mathcal{G})^{(1)} = X \times_{\mathcal{G}^{(0)}} \mathcal{G}$, $s(x, g) = xg$, $t(x, g) = x$, $u(x) = (x, 1)$, $m((x, g), (y, h)) = (x, gh)$, $i(x, g) = (xg, g^{-1})$.

There is an obvious similar notion of left \mathcal{G} -space. Unless specified, all \mathcal{G} -spaces will have the action from the right.

2.4 Bundles: A (right) \mathcal{G} -bundle over the space B consists of a \mathcal{G} -space E and a continuous map $p : E \rightarrow B$ which is \mathcal{G} -invariant (i.e. $p(xg) = p(x)$). It is called principal if p is an open surjection and $E \times_{\mathcal{G}^{(0)}} \mathcal{G} \rightarrow E \times_B E$, $(e, g) \mapsto (e, eg)$ is a homeomorphism.

2.5 Morphisms of Groupoids ([20],[32]): Let \mathcal{G} and \mathcal{H} be two groupoids. A morphism $P : \mathcal{G} \rightarrow \mathcal{H}$ from \mathcal{G} to \mathcal{H} (or Hilsum-Skandalis map cf. [37]) consists of a space P , continuous maps (source and target): $s_P : P \rightarrow \mathcal{G}^{(0)}$, $t_P : P \rightarrow \mathcal{H}^{(0)}$, a left action of \mathcal{G} on P with the moment map s_P , a right action of \mathcal{H} on P with the moment map t_P , such that:

1. s_P is \mathcal{H} -invariant, t_P is \mathcal{G} -invariant;
2. the actions of \mathcal{G} and \mathcal{H} on P are compatible: $(gp)h = g(ph)$;
4. $s_P : P \rightarrow \mathcal{G}^{(0)}$, as an \mathcal{H} -bundle with the moment map t_P , is principal.

A nice intuitive motivation of this definition is that P can be viewed as a continuous map between the orbit spaces of \mathcal{G} and \mathcal{H} , described by its graph (see II.8.γ in [10]). A nice theoretical motivation is that these morphisms are exactly the topos-theoretic morphisms between the orbit spaces of \mathcal{G} and \mathcal{H} viewed as toposes (i.e. between the classifying toposes of \mathcal{G} and \mathcal{H} ; see [32] for the precise statements and descriptions). The composition of two morphisms $P : \mathcal{G} \rightarrow \mathcal{H}$, $Q : \mathcal{H} \rightarrow \mathcal{K}$ is defined by dividing out $P \times_{\mathcal{H}^{(0)}} Q$ by the action of \mathcal{H} : $(p, q)h = (ph, h^{-1}q)$, and taking the obvious

actions of \mathcal{G} and \mathcal{H} . We get in this way the category of groupoids and its full subcategory of étale groupoids.

2.6 Example: Any continuous functor $\varphi : \mathcal{G} \rightarrow \mathcal{H}$ can be viewed as a morphism by taking $P_\varphi = \mathcal{G}^{(0)} \times_{\mathcal{H}^{(0)}} \mathcal{H} = \{(c, h) \in \mathcal{G}^{(0)} \times \mathcal{H} : \varphi(c) = t(h)\}$, $s_P(c, h) = c$, $t_P(c, h) = s(h)$ and the obvious actions.

2.7 Morita Equivalences: Two groupoids \mathcal{G} and \mathcal{H} are called Morita equivalent if they are isomorphic in the category of groupoids (as defined in 2.5). An isomorphism $P : \mathcal{G} \rightarrow \mathcal{H}$ is called a Morita equivalence (cf. [32]).

2.8 Examples:

1. Recall ([32]) that an essential equivalence is a continuous functor $\varphi : \mathcal{G} \rightarrow \mathcal{H}$ with the property that $P_\varphi = \mathcal{G}^{(0)} \times_{\mathcal{H}^{(0)}} \mathcal{H} = \{(c, h) \in \mathcal{G}^{(0)} \times \mathcal{H} : \varphi(c) = t(h)\} \rightarrow \mathcal{H}^{(0)}$, $(c, h) \mapsto s(h)$ is an open surjection and the diagram:

$$\begin{array}{ccc} \mathcal{G} & \xrightarrow{\varphi} & \mathcal{H} \\ (s,t) \downarrow & & \downarrow (s,t) \\ \mathcal{G}^{(0)} \times \mathcal{G}^{(0)} & \xrightarrow{\varphi \times \varphi} & \mathcal{H}^{(0)} \times \mathcal{H}^{(0)} \end{array}$$

is a pull-back of topological spaces. It is easily seen that in this case φ induces a Morita equivalence $P_\varphi : \mathcal{G} \rightarrow \mathcal{H}$ (see 2.6). In fact we can prove (see 2.3 in [32] or [37]) that \mathcal{G} and \mathcal{H} are Morita equivalent if and only if there is a groupoid \mathcal{K} and essential equivalences $\mathcal{G} \leftarrow \mathcal{K} \rightarrow \mathcal{H}$.

2. If (M, \mathcal{F}) is a foliated manifold, $T \rightarrow M$ is a complete transversal ([?, 12, 23]), there is an obvious functor $Hol_T(M, \mathcal{F}) \rightarrow Hol(M, \mathcal{F})$ from the holonomy groupoid restricted to T to the holonomy groupoid. It is a standard fact that this is a Morita equivalence.

3. If $E \rightarrow B$ is a principal G -bundle (where G is a topological group), then the obvious projection $E \rtimes G \rightarrow B$ (see examples 1, 3 in 2.2) is a Morita equivalence.

2.9 Comma Groupoids: If $\varphi : \mathcal{G} \rightarrow \mathcal{H}$ is a continuous functor between groupoids, $d \in \mathcal{H}^{(0)}$, the comma groupoid d/φ is defined as follows. It has as objects pairs $(h, c) \in \mathcal{H} \times \mathcal{G}^{(0)}$ with $s(h) = d$, $t(h) = \varphi(c)$ (i.e. the space of objects is $\mathcal{G}^{(0)} \times_{\mathcal{H}^{(0)}} \mathcal{H}^{(1)}$), and as morphisms from (h, c) to (h', c') those $g : c \rightarrow c'$ in \mathcal{G} with $\varphi(g)h = h'$ (i.e. the space of morphisms is $\mathcal{G} \times_{\mathcal{G}^{(0)}} \mathcal{H}$). We have a commutative diagram:

$$\begin{array}{ccc} d/\varphi & \xrightarrow{\omega_d} & \mathcal{G} \\ \downarrow & & \downarrow \varphi \\ \bullet & \xrightarrow{d} & \mathcal{H} \end{array}$$

where ω_d is the continuous functor which send an object (h, c) to c and a morphism g , from (h, c) to (h', c') , to g . The comma category can be viewed as the fiber of φ above d .

2.2 Γ_c in the non-Hausdorff case

It is well known in sheaf theory that usual notions concerning compactness do not behave well on non-Hausdorff spaces. In the sequel, the notions of c -softness, compactly supported cohomology, the compactly supported sections functor Γ_c or, more generally, the functor $f_! : Sh(X) \rightarrow Sh(Y)$ induced by a continuous map $f : X \rightarrow Y$ (see [?, 25]) will have the usual meaning only on Hausdorff spaces. For locally Hausdorff spaces (i.e. spaces which have a Hausdorff open covering) a good extension of these notions is developed in [15]. In this subsection we briefly recall the main definitions and properties.

2.10 Assumption: Throughout this paper, all spaces are assumed to be locally Hausdorff, locally compact, of finite cohomological dimension ; all sheaves are assumed to be sheaves of complex (or real) vector spaces.

By “of finite cohomological dimension” we mean there is an integer n such that every point has a Hausdorff neighborhood of cohomological dimension $\leq n$. The smallest n with this property is called the cohomological dimension of the given space.

2.11 c-Softness, $\Gamma_c[15]$: Let X be a space. A sheaf $\mathcal{A} \in Sh(X)$ is called c-soft if there is a Hausdorff open covering \mathcal{U} of X such that $\mathcal{A}|_U \in Sh(U)$ is c-soft for all $U \in \mathcal{U}$. In this case define $\Gamma_c(X, \mathcal{A})$ as the image of the map:

$$\bigoplus_U \Gamma_c(U; \mathcal{A}) \longrightarrow \Gamma(X_{dis}; \mathcal{A}) \quad (U \in \mathcal{U}),$$

where $\Gamma(X_{dis}; \mathcal{A}) = \{u : X \rightarrow \bigsqcup_{x \in X} \mathcal{A}_x : u(x) \in \mathcal{A}_x, \forall x \in X\}$ (X_{dis} is X , considered with the discrete topology) and $\Gamma_c(U; \mathcal{A}) \rightarrow \Gamma(X_{dis}; \mathcal{A})$, $s \rightarrow \bar{s}$ is given by:

$$\bar{s}(x) = \text{germ}_x(s) \text{ for } x \in U, \text{ and } 0 \text{ otherwise.}$$

The basic property which enables us to extend the usual results from the Hausdorff case is the Mayer-Vietoris sequence (like in [5], pp.139,186): for any open covering \mathcal{U} of X , there is a long exact sequence ([15], Prop.7.4):

$$\dots \rightarrow \bigoplus_{U, V} \Gamma_c(U \cap V; \mathcal{A}) \rightarrow \bigoplus_U \Gamma_c(U; \mathcal{A}) \rightarrow \Gamma_c(X; \mathcal{A}) \rightarrow 0 \dots$$

The compactly supported cohomology functor, $H_c^*(X, -)$ is defined by using c-soft resolutions (as in [?, 25]); in particular we define $\Gamma_c(X, \mathcal{S}) = H_c^0(X, \mathcal{S})$ for any sheaf $\mathcal{S} \in Sh(X)$.

For any continuous map $f : X \rightarrow Y$ and any c-soft sheaf $\mathcal{A} \in Sh(X)$, there is a unique c-soft sheaf $f_! \mathcal{A} \in Sh(Y)$ such that we have the (“usual”) isomorphisms $\Gamma_c(V; f_! \mathcal{A}) \simeq \Gamma_c(f^{-1}(V); \mathcal{A})$ for all $V \subset Y$ open, functorial with respect to the inclusion of opens in Y . Using c-soft resolutions in $Sh(X)$ one can define $f_!(\mathcal{S}) \in Sh(Y)$, or more generally $R^* f_!(\mathcal{S}) \in Sh(Y)$ for any $\mathcal{S} \in Sh(X)$ (see also [?, 25]).

2.12 Basic properties of $\Gamma_c, f_!$, [15]: The usual properties of $\Gamma_c, f_!$ in the Hausdorff case ([?, 25]) extend to our case by using the Mayer-Vietoris sequence:

1. ([15], Prop.7.7) $\Gamma_c(X, -)$ preserves quasi-isomorphisms between bounded below cochain complexes of c-soft sheaves. In fact, under our assumption (that X has finite cohomological dimension) this is true also for unbounded complexes.

2. ([15], Prop.7.8) If $A \subset X$ is closed, $\mathcal{A} \in Sh(X)$ is c-soft, then the obvious restriction $\Gamma_c(X, \mathcal{A}) \rightarrow \Gamma_c(A, \mathcal{A})$ induces an isomorphism $\Gamma_c(A, \mathcal{A}) \simeq \Gamma_c(X, \mathcal{A}) / \{u \in \Gamma_c(X, \mathcal{A}) : u|_A = 0\}$. If $A = \theta^{-1}(0)$ for some continuous map $\theta : X \rightarrow \mathbb{R}$, $u \in \Gamma_c(X, \mathcal{A})$ then:

$$u|_A = 0 \iff \exists \epsilon > 0 : u|_{\theta^{-1}((-\epsilon, \epsilon))} = 0.$$

3. ([15], Prop.7.9) If $f : X \rightarrow Y$ is continuous, $\mathcal{A} \in Sh(X)$ then:

$$\Gamma_c(Y; f_! \mathcal{A}) \simeq \Gamma_c(X; \mathcal{A}) \quad , \quad (f_! \mathcal{A})_y \simeq \Gamma_c(f^{-1}(y); \mathcal{A}) \quad \forall y \in Y.$$

2.13 Notation: Let $\mathcal{A} \in Sh(X), \mathcal{B} \in Sh(Y)$ be c-soft sheaves. Most of the maps we are going to deal with are of type:

$$(\alpha, f)_* : \Gamma_c(X; \mathcal{A}) \rightarrow \Gamma_c(Y; \mathcal{B}) \quad , \quad ((\alpha, f)_* u)(y) = \sum_{x \in f^{-1}(y)} \alpha_x(u(x)) \in \mathcal{B}_y \quad (y \in Y),$$

for some étale map $f : X \rightarrow Y$, and some morphism of sheaves $\alpha : \mathcal{A} \rightarrow f^* \mathcal{B}$. In other words, $(\alpha, f)_*$ is the composition:

$$\Gamma_c(X; \mathcal{A}) \xrightarrow{\alpha_*} \Gamma_c(X; f^* \mathcal{B}) \stackrel{2.12.3}{\simeq} \Gamma_c(Y, f_! f^* \mathcal{B}) \xrightarrow{int_!} \Gamma_c(Y, \mathcal{B}),$$

where $int : f_! f^* \mathcal{B} \rightarrow \mathcal{B}$ is, at the stalk at $y \in Y$ (see also 2.12.3):

$$\bigoplus_{x \in f^{-1}(y)} \mathcal{B}_y \rightarrow \mathcal{B}_y, \quad \sum_{x \in f^{-1}(y)} b_x x \mapsto \sum b_x.$$

Rather than writing the explicit formula for $(\alpha, f)_*$, we prefer to briefly indicate the maps f and α using the notation:

$$\Gamma_c(X, \mathcal{A}) \rightarrow \Gamma_c(Y, \mathcal{B}), \quad (a|x) \mapsto (\alpha(a)|f(x))$$

($x \in X, a \in \mathcal{A}_x$).

2.14 \mathcal{C}_c^∞ for non-Hausdorff manifolds ([15]): If M is a manifold, not necessarily Hausdorff, we put $\mathcal{C}_c^\infty(M) := \Gamma_c(M, \mathcal{C}_M^\infty)$ where \mathcal{C}_M^∞ is the sheaf of smooth (complex valued) functions on M . From the Mayer-Vietoris sequence, we have an alternative description of $\mathcal{C}_c^\infty(M)$, as the cokernel of:

$$\bigoplus_{U, V} \mathcal{C}_c^\infty(U \cap V) \rightarrow \bigoplus_U \mathcal{C}_c^\infty(U) \quad (U \in \mathcal{U}),$$

where \mathcal{U} is a Hausdorff open cover of M , and $\mathcal{C}_c^\infty(U)$ has the usual meaning for Hausdorff U (the definition does not depend on the cover \mathcal{U}). In the same way define $\Omega_c^k(M)$ by using the sheaf Ω_M^k of (complex) k -forms on M . These are the natural objects with the property that constructions performed in coordinate charts patch globally. For instance, this is the case for de Rham differential: the classical one does exist locally and defines a c -soft resolution of \mathbb{C} :

$$\mathbb{C} \rightarrow \Omega_M^0 \xrightarrow{d_{dR}} \Omega_M^1 \xrightarrow{d_{dR}} \dots$$

By applying $\Gamma_c(M, -)$ to it, we get a globally defined de Rham differential, and a (compactly supported) de Rham complex:

$$0 \rightarrow \Omega_c^0(M) \xrightarrow{d_{dR}} \Omega_c^1(M) \xrightarrow{d_{dR}} \dots,$$

computing $H_c^*(M; \mathbb{C})$.

Denoting by $\mathcal{C}_{c, Connes}^\infty(M)$ Connes' definition of the vector space of "compactly supported smooth functions" (see section 6 in [10]), it is not difficult to see there is a surjection:

$$\mathcal{C}_c^\infty(M) \rightarrow \mathcal{C}_{c, Connes}^\infty(M),$$

which is not injective in general (of course, if M is Hausdorff, the two definitions coincide and have the usual meaning).

2.3 Homology and Cohomology of Étale Groupoids

In this subsection we review the definition and the main properties of the cohomology and homology groups $H^n(\mathcal{G}; \mathcal{A})$, $H_n(\mathcal{G}; \mathcal{A})$ of an étale groupoid with coefficients in a \mathcal{G} -sheaf \mathcal{A} .

2.15 \mathcal{G} -sheaves ([1, 33]): Let \mathcal{G} be an étale groupoid. A \mathcal{G} -sheaf is a sheaf \mathcal{A} on the space $\mathcal{G}^{(0)}$, equipped with a continuous right action of \mathcal{G} . This means that for any arrow $g : c \rightarrow d$ in \mathcal{G} , there is a morphism between stalks $\mathcal{A}_d \rightarrow \mathcal{A}_c$, $a \mapsto ag$, satisfying the usual identities for an action.

Viewing \mathcal{A} as an étale space $\mathcal{A} \rightarrow \mathcal{G}^{(0)}$ (i.e. \mathcal{A} is the disjoint union of all stalks \mathcal{A}_c with the germ topology) it gives a map $m : \mathcal{A} \times_{\mathcal{G}^{(0)}} \mathcal{G} \rightarrow \mathcal{A}$, $(a, g) \mapsto ag$; the continuity of the action means that m is continuous.

There is an obvious notion of morphisms of \mathcal{G} -sheaves; this leads to the category $Sh(\mathcal{G})$ of \mathcal{G} -sheaves (of complex vector spaces cf. 2.10). If $P : \mathcal{G} \rightarrow \mathcal{H}$ is a morphism of étale groupoids, it induces a functor $P^* : Sh(\mathcal{H}) \rightarrow Sh(\mathcal{G})$. This construction is natural; in particular, a Morita equivalence of étale groupoids $\mathcal{G} \rightarrow \mathcal{H}$ induces an equivalence between their categories of sheaves; see 1.1, 2.2 in [32].

2.16 Examples:

1. The constant sheaf \mathbb{C} , with the trivial action is a \mathcal{G} -sheaf. The tensor product of two \mathcal{G} -sheaves is naturally a \mathcal{G} -sheaf.

2. The étale map $\alpha_n : \mathcal{G}^{(n)} = \{(g_1, \dots, g_n) \in \mathcal{G}^n : s(g_i) = t(g_{i+1})\} \rightarrow \mathcal{G}^{(0)}$, $(g_1, \dots, g_n) \mapsto t(g_1)$ induces a \mathcal{G} -sheaf, denoted $\mathbb{C}[\mathcal{G}^{(n)}]$. Its stalk at $c \in \mathcal{G}^{(0)}$ is $\mathbb{C}[\alpha_n^{-1}(c)]$ and the action is given by $(g_1, \dots, g_n)g = (g^{-1}g_1, g_2, \dots, g_n)$.

3. If \mathcal{G} is a smooth étale groupoid then $\mathcal{A} = \mathcal{C}_{\mathcal{G}^{(0)}}^\infty$ is a \mathcal{G} -sheaf, with the action described as follows. Let $g : c \rightarrow d$ be an arrow in \mathcal{G} . Choose V a neighborhood of g in \mathcal{G} such that $s|_V, t|_V$ are diffeomorphisms and put $\sigma_{g,V} := (t|_V)(s|_V)^{-1} : (s(V), c) \rightarrow (t(V), d)$. Its germ at c , denoted $\sigma_g : (\mathcal{G}^{(0)}, c) \rightarrow (\mathcal{G}^{(0)}, d)$ doesn't depend on the choice of V ; it induces multiplication by $g : \mathcal{A}_d \rightarrow \mathcal{A}_c, \varphi \mapsto \varphi \circ \sigma_g$.

4. As in the previous example, $\Omega_{\mathcal{G}^{(0)}}^k$ = the sheaf of (complex valued) k -forms on $\mathcal{G}^{(0)}$ is a \mathcal{G} -sheaf for all $k \geq 0$.

2.17 Cohomology: Let \mathcal{G} be an étale groupoid. The category $Sh(\mathcal{G})$ is an abelian category with enough injectives ([1]); due to this fact, the cohomology of sheaves on \mathcal{G} can be defined and used via elementary homological algebra tools; using standard resolutions, it can be computed by some kind of standard bar-complexes; see e.g. [15, 20, 33, 1] (a brief review will be given in 4.8).

More generally, one can define the bi-functors $Ext_{\mathcal{G}}^*(-, -) : Sh(\mathcal{G}) \times Sh(\mathcal{G}) \rightarrow \underline{Vs}$ (\underline{Vs} denotes the category of complex vector spaces) by:

$$Ext_{\mathcal{G}}^*(\mathcal{A}, \mathcal{B}) = R^*Hom_{Sh(\mathcal{G})}(\mathcal{A}, -)(\mathcal{B}),$$

with the particular case $Ext_{\mathcal{G}}^*(\mathbb{C}, -) = H^*(\mathcal{G}; -)$ (R^* stands for the right derived functors [24, 44]).

Homological algebra provides us an alternative description of the vector spaces $Ext_{\mathcal{G}}^p(\mathcal{A}, \mathcal{B})$ by means of Yoneda extensions (see [31], [44]). For $p \geq 1$, the elements in $Ext_{\mathcal{G}}^p(\mathcal{A}, \mathcal{B})$ are represented by p -extensions of \mathcal{A} by \mathcal{B} i.e. exact sequences in $Sh(\mathcal{G})$:

$$u : 0 \rightarrow \mathcal{B} \rightarrow X_1 \rightarrow \dots \rightarrow X_p \rightarrow \mathcal{A} \rightarrow 0.$$

The equivalence relation is generated by: $u \simeq \tilde{u}$ whenever there exists a morphism of complexes $u \mapsto \tilde{u}$. According to this, there is a simple description of the cup-product $Ext_{\mathcal{G}}^p(\mathcal{A}, \mathcal{B}) \times Ext_{\mathcal{G}}^q(\mathcal{B}, \mathcal{C}) \rightarrow Ext_{\mathcal{G}}^{p+q}(\mathcal{A}, \mathcal{C})$ for $\mathcal{A}, \mathcal{B}, \mathcal{C} \in Sh(\mathcal{G})$ as the concatenation of exact sequences (for the general setting of abelian categories see [31], pp. 82-87, [44], pp. 76-80).

We have also a simple description of the cap-products: for any homological δ -functor (2.1.1 in [44]) L_* : $Sh(\mathcal{G}) \rightarrow \underline{Vs}$ there are cap-product maps $L_n(\mathcal{A}) \times Ext_{\mathcal{G}}^p(\mathcal{A}, \mathcal{B}) \xrightarrow{\cap} L_{n-p}(\mathcal{B})$ ($p \geq 0, n, p$ integers, $\mathcal{A}, \mathcal{B} \in Sh(\mathcal{G})$). If $p = 0$, $Ext_{\mathcal{G}}^0(\mathcal{A}, \mathcal{B}) = Hom_{Sh(\mathcal{G})}(\mathcal{A}, -)(\mathcal{B})$ and \cap is the covariance of L_n . If $p = 1$, $u \in Ext_{\mathcal{G}}^1(\mathcal{A}, \mathcal{B})$ the cap-product by $u : - \cap u : L_n(\mathcal{A}) \rightarrow L_{n-1}(\mathcal{B})$ is the boundary of the long exact sequence associated to (any) short exact sequence $0 \rightarrow \mathcal{B} \rightarrow X \rightarrow \mathcal{A} \rightarrow 0$ representing u . If $p \geq 2$, we iterate the case $p = 1$.

For any \mathcal{G} -sheaf \mathcal{A} there is an obvious morphism $Ext_{\mathcal{G}}^p(\mathbb{C}, \mathbb{C}) \longrightarrow Ext_{\mathcal{G}}^p(\mathcal{A}, \mathcal{A})$ (tensoring by \mathcal{A}); we get in particular an action of the cohomology on any homological δ -functor:

$$L_n(\mathcal{A}) \times H^p(\mathcal{G}, \mathbb{C}) \longrightarrow L_{n-p}(\mathcal{A}) \quad , \quad \mathcal{A} \in Sh(\mathcal{G}) \quad .$$

2.18 Connection with the classifying space: Any \mathcal{G} -sheaf \mathcal{S} gives rise to a sheaf $\tilde{\mathcal{S}}$ on the classifying space $B\mathcal{G}$ and there are isomorphisms $H^*(\mathcal{G}; \mathcal{S}) \simeq H^*(B\mathcal{G}; \tilde{\mathcal{S}})$. This was conjectured by Haefliger and proved in [34].

2.19 Bar-complexes: Let \mathcal{G} be an étale groupoid. Denote:

$$\mathcal{G}^{(n)} = \{(g_1, \dots, g_n) \in \mathcal{G}^n : s(g_i) = t(g_{i+1}) \text{ , } \forall 1 \leq i \leq n-1\}.$$

For any $\mathcal{A} \in Sh(\mathcal{G}^{(0)})$, we consider for each n the pull-back of \mathcal{A} to $\mathcal{G}^{(n)}$ along $\mathcal{G}^{(n)} \longrightarrow \mathcal{G}^{(0)}$, $(g_1, \dots, g_n) \mapsto t(g_1)$. These sheaves on the spaces $\mathcal{G}^{(n)}$ are still denoted by \mathcal{A} (it will be clear from the context on which space they are considered). For any c-soft sheaf $\mathcal{A} \in Sh(\mathcal{G})$ (c-softness of \mathcal{G} -sheaves will always mean c-softness on $\mathcal{G}^{(0)}$), define the bar-complex $B_{\bullet}(\mathcal{G}; \mathcal{A})$ as the chain complex associated to the simplicial vector space $n \mapsto \Gamma_c(\mathcal{G}^{(n)}; \mathcal{A})$ with the structure maps:

$$d_i(a \mid g_1, \dots, g_n) = \begin{cases} (ag_1 \mid g_2, \dots, g_n) & \text{if } i = 0 \\ (a \mid g_1, \dots, g_i g_{i+1}, \dots, g_n) & \text{if } 1 \leq i \leq n-1 \\ (a \mid g_1, \dots, g_{n-1}) & \text{if } i = n \end{cases} ,$$

$$s_i(a \mid g_1, \dots, g_n) = (a \mid \dots, g_i, 1, g_{i+1}, \dots),$$

(see 2.13 for notations).

2.20 Homology ([15]): Despite to the fact that $Sh(\mathcal{G})$ does not have enough projectives in general, there is quite an obvious way to define the homology of sheaves on étale groupoids by using bar-complexes and c-soft resolutions. Looking at the classical homology of groups, one can state and prove "usual results" like long exact sequences, spectral sequences, etc. We review some definitions and properties we need, referring for a more detailed description to [15]. The analogous properties for cohomology are well known (see e.g. [1, 15, 20, 33]).

If $\mathcal{A} \in Sh(\mathcal{G})$ is c-soft, define $H_*(\mathcal{G}, \mathcal{A})$ as the homology of $B_{\bullet}(\mathcal{G}, \mathcal{A})$. If \mathcal{A}_{\bullet} is a chain complex of c-soft \mathcal{G} -sheaves, define $\mathbb{H}_{\bullet}(\mathcal{G}, \mathcal{A}_{\bullet})$ as the homology of the double complex $B_{\bullet}(\mathcal{G}, \mathcal{A}_{\bullet})$. If $\mathcal{S} \in Sh(\mathcal{G})$, take $\mathcal{S} \longrightarrow \mathcal{A}^0 \longrightarrow \mathcal{A}^1 \longrightarrow \dots$ a c-soft resolution in $Sh(\mathcal{G})$ and define $H_*(\mathcal{G}, \mathcal{S})$ as $\mathbb{H}_{\bullet}(\mathcal{G}, \mathcal{A}_{\bullet})$ where $\mathcal{A}_k = \mathcal{A}^{-k} \quad \forall k$ -integer. The notion of Cartan-Eilenberg resolutions (5.7.9 in [44]) by c-soft sheaves carries over to $Sh(\mathcal{G})$ and one can define $\mathbb{H}_{\bullet}(\mathcal{G}, \mathcal{S}_{\bullet})$ for any complex of \mathcal{G} -sheaves \mathcal{S}_{\bullet} . The existence of resolutions and that the result does not depend on the choices we make are proved in [15].

2.21 From the previous definition and 2.12.1 we see that any morphism $\alpha : \mathcal{S}_{\bullet} \longrightarrow \mathcal{S}'_{\bullet}$ of complexes of \mathcal{G} -sheaves which is a quasi-isomorphism (of complexes of sheaves on $\mathcal{G}^{(0)}$), induces an isomorphism $\mathbb{H}_{\bullet}(\mathcal{G}; \mathcal{S}_{\bullet}) \longrightarrow \mathbb{H}_{\bullet}(\mathcal{G}; \mathcal{S}'_{\bullet})$.

2.22 Example: If $\mathcal{G} = G$ is a group, we get the usual homology of groups ([8]). If $\mathcal{G} = X$ is a space we get $H_k(\mathcal{G}; -) = H_c^{-k}(X; -)$. In general, $H_*(\mathcal{G}; -)$ lives in degrees $* \geq -\text{cohdim}(\mathcal{G}^{(0)})$.

2.23 The long exact sequence ([15]): For any short exact sequence $0 \longrightarrow \mathcal{S}' \longrightarrow \mathcal{S} \longrightarrow \mathcal{S}'' \longrightarrow 0$ in $Sh(\mathcal{G})$ there is a long exact sequence of vector spaces:

$$\dots \longrightarrow H_n(\mathcal{G}; \mathcal{S}') \longrightarrow H_n(\mathcal{G}; \mathcal{S}) \longrightarrow H_n(\mathcal{G}; \mathcal{S}'') \longrightarrow H_{n-1}(\mathcal{G}; \mathcal{S}'') \longrightarrow \dots$$

and it is natural with respect to morphisms in $Sh(\mathcal{G})$. In other words, $H_*(\mathcal{G}; -)$ is a homological δ -functor on $Sh(\mathcal{G})$.

In particular we get (cf. 2.17) the cap-products $H_n(\mathcal{G}; \mathcal{A}) \times Ext_{\mathcal{G}}^p(\mathcal{A}; \mathcal{B}) \longrightarrow H_{n-p}(\mathcal{A}; \mathcal{B})$ and $H_n(\mathcal{G}; \mathcal{A}) \times H^p(\mathcal{G}; \mathbb{C}) \longrightarrow H_{n-p}(\mathcal{G}; \mathcal{A})$.

2.24 Basic spectral sequences ([15]): For any bounded below chain complex \mathcal{S}_\bullet in $Sh(\mathcal{G})$ there are two spectral sequences:

$$E_{p,q}^2 = H_p(H_q(\mathcal{G}; \mathcal{S}_\bullet)) \implies \mathbb{H}_{p+q}(\mathcal{G}; \mathcal{S}_\bullet),$$

$$E_{p,q}^2 = H_p(\mathcal{G}; \tilde{H}_q(\mathcal{S}_\bullet)) \implies \mathbb{H}_{p+q}(\mathcal{G}; \mathcal{S}_\bullet),$$

(compare to 5.6 in [8]). In the second spectral sequence, $\tilde{H}_q(\mathcal{S}_\bullet) \in Sh(\mathcal{G})$ denotes the homology sheaf of \mathcal{S}_\bullet . Given \mathcal{S}_\bullet we define an element:

$$u_q(\mathcal{S}_\bullet) \in Ext_{\mathcal{G}}^2(\tilde{H}_q(\mathcal{S}_\bullet), \tilde{H}_{q+1}(\mathcal{S}_\bullet))$$

as follows. Denote $\mathcal{K}_q = Ker(\mathcal{S}_q \longrightarrow \mathcal{S}_{q-1})$. The exact sequence $0 \longrightarrow \mathcal{K}_{q+1} \longrightarrow \mathcal{S}_{q+1} \longrightarrow \mathcal{K}_q \longrightarrow \tilde{H}_q(\mathcal{S}_\bullet) \longrightarrow 0$ defines an element $\epsilon_q \in Ext_{\mathcal{G}}^2(\tilde{H}_q(\mathcal{S}_\bullet); \mathcal{K}_{q+1})$. Using the projection $\pi : \mathcal{K}_{q+1} \longrightarrow \tilde{H}_{q+1}(\mathcal{S}_\bullet)$ and the covariance of Ext in the second variable, put $u_q(\mathcal{S}_\bullet) = \pi_*(\epsilon_q)$.

2.25 Lemma: *The d^2 -boundaries of the second spectral sequence are:*

$$d_{p,q}^2 = -\cap u_q(\mathcal{S}_\bullet) : H_p(\mathcal{G}; \tilde{H}_q(\mathcal{S}_\bullet)) \longrightarrow H_{p-2}(\mathcal{G}; \tilde{H}_{q+1}(\mathcal{S}_\bullet)).$$

proof: The spectral sequence is defined as follows ([15]). Take $\mathbb{C} \longrightarrow \mathcal{I} \bullet$ to be a bounded c-soft resolution of \mathbb{C} in $Sh(\mathcal{G})$ and put $\mathcal{I}_k = \mathcal{I}^{-k}$. Then $\mathcal{I} \bullet \otimes \mathcal{S}_\bullet$ is a Cartan-Eilenberg resolution of \mathcal{S}_\bullet so $\mathbb{H}_*(\mathcal{G}; \mathcal{S}_\bullet)$ is computed by the triple complex $B_*(\mathcal{G}; \mathcal{I} \bullet \otimes \mathcal{S}_\bullet)$, or, equivalently, by the double complex $C_{\bullet\bullet}$ defined by:

$$C_{p,q} = \bigoplus_{p_1+p_2=p} B_{p_1}(\mathcal{G}; \mathcal{I}_{p_2} \otimes \mathcal{S}_q).$$

One of its spectral sequences has $E_{p,q}^1 = H_q(C_p, \bullet) = \bigoplus_{p_1+p_2=p} B_{p_1}(\mathcal{G}; \mathcal{I}_{p_2} \otimes \tilde{H}_q(\mathcal{S}_\bullet))$ and $E_{p,q}^2 = H_p(\mathcal{G}; \tilde{H}_q(\mathcal{S}_\bullet))$. From the general description of the boundaries of the spectral sequence associated to a double complex, our boundary is described by a "zig-zag" of length two (see [5], page 164). This corresponds to two boundaries of long exact sequences i.e. to a cap-product by a Ext^2 -class; the relation $d_{p,q}^2 = -\cap u_q(\mathcal{S}_\bullet)$ becomes a standard checking inside the spectral sequence.

2.26 Hochschild-Serre spectral sequence ([15]): If $\varphi : \mathcal{G} \longrightarrow \mathcal{H}$ is a continuous morphism between étale groupoids, $\mathcal{S} \in Sh(\mathcal{G})$, there is a spectral sequence:

$$E_{p,q}^2 = H_p(\mathcal{H}; L_q \varphi_!(\mathcal{S})) \implies H_{p+q}(\mathcal{G}; \mathcal{S}).$$

Here $L_q \varphi_!(\mathcal{S}) \in Sh(\mathcal{G})$ is a sheaf with stalks:

$$L_q \varphi_!(\mathcal{S})_d = H_q(d/\varphi; \omega_d^* \mathcal{S}) \quad , \forall d \in \mathcal{H}^{(0)}$$

(compare to the similar result for cohomology, [33], pp 15-16).

For $q = 0$, denote $L_0 \varphi_! = \varphi_!$. As in the case of spaces ([44, 25]), the spectral sequence is a consequence of the second spectral sequence in 2.24 and of an equality: $H_*(\mathcal{G}; \mathcal{S}) = \mathbb{H}_*(\mathcal{H}; \mathcal{L} \varphi_!(\mathcal{S}))$. Here $\mathcal{L} \varphi_!(\mathcal{S})$ is a chain complex in $Sh(\mathcal{H})$ with $\tilde{H}_q(\mathcal{L} \varphi_!(\mathcal{S})) = L_q \varphi_!(\mathcal{S})$. In particular, the second boundary is of type:

$$d_{p,q}^2 = -\cap u_q : E_{p,q}^2 \longrightarrow E_{p-2,q+1}^2 \quad \text{with } u_q \in Ext_{\mathcal{H}}^2(L_q \varphi_! \mathcal{S}; L_{q+1} \varphi_! \mathcal{S}).$$

2.27 Morita invariance([15]): Any morphism $P : \mathcal{G} \rightarrow \mathcal{H}$ which is étale (in the sense that s_P is étale), induces a morphism in homology $P_* : H_*(\mathcal{G}; P^*\mathcal{B}) \rightarrow H_*(\mathcal{H}; \mathcal{B})$ for any $\mathcal{B} \in Sh(\mathcal{G})$. This construction is natural with respect to étale morphisms; in particular, $H_*(\mathcal{G}; -)$ is Morita invariant and any essential equivalence $\varphi : \mathcal{G} \rightarrow \mathcal{H}$ (see 2.8.1) induces an isomorphism $H_*(\mathcal{G}; \varphi^*\mathcal{B}) \simeq H_*(\mathcal{H}; \mathcal{B})$.

2.28 Duality: For any étale groupoid \mathcal{G} with $\mathcal{G}^{(0)}$ a topological manifold of dimension n , there is a Poincaré-duality isomorphism $H^k(\mathcal{G}; or) \simeq H_{k-n}(\mathcal{G}; \mathbb{C})^\vee$, $\forall k \geq 0$. Here $or \in Sh(\mathcal{G})$ is the complex orientation sheaf of $\mathcal{G}^{(0)}$ ([25]) with the obvious \mathcal{G} -action, and \vee denotes the vector-space dual. When $\mathcal{G} = M$ is a topological manifold, this is the usual Poincaré duality. See [15] for the full Verdier-duality for étale groupoids.

2.29 Étale categories: Some of the categories we will use are not groupoids. Remark that (see also [15]), without any changes, the definitions and the basic properties we have described so far in this sub-section work equally well for étale categories (i.e. small categories \mathcal{G} , with topologies on $\mathcal{G}^{(0)}, \mathcal{G}^{(1)}$ such that all the structure maps are étale) with only one exception: Morita invariance (to prove Morita invariance for *étale categories* we have to take care of what a morphism between étale categories is; see 5.4 in [32] or [33]). Because of this we need another technical tool when we deal with étale categories (see also [15] Prop.3.8); it is a variant of a well known principle due to Segal (see Prop.(2.1) in [41]):

2.30 Lemma and definition: Let \mathcal{G} and \mathcal{H} be étale categories. A continuous functor $\varphi : \mathcal{G} \rightarrow \mathcal{H}$ is called a strong deformation retract of \mathcal{H} if there is a continuous functor $\psi : \mathcal{H} \rightarrow \mathcal{G}$ (called retraction) and a continuous natural transformation of functors $F : \varphi \circ \psi \rightarrow Id_{\mathcal{H}}$ (called strong deformation retraction) such that $\psi \circ \varphi = Id_{\mathcal{G}}, F(\varphi(c)) = id_{\varphi(c)}$ for all $c \in \mathcal{G}^{(0)}$ and the maps φ, ψ, F are étale.

In this case, for any \mathcal{H} -sheaf \mathcal{A} , φ induces an isomorphism:

$$H_*(\mathcal{G}; \varphi^*\mathcal{A}) \xrightarrow{\sim} H_*(\mathcal{H}; \mathcal{A}).$$

proof: Denote $\varphi \circ \psi$ by l . Let Φ the map induced by φ :

$$\Phi : B_\bullet(\mathcal{G}; \varphi^*\mathcal{A}) \rightarrow B_\bullet(\mathcal{H}; \mathcal{A}), \quad \Phi(a|g_1, \dots, g_n) = (a|\varphi(g_1), \dots, \varphi(g_n)).$$

Since φ is étale, $\varphi^* : Sh(\mathcal{H}^{(0)}) \rightarrow Sh(\mathcal{G}^{(0)})$ preserves c-softness ([25]) so it is enough to prove that Φ is a homotopy equivalence of chain complexes, when \mathcal{A} is c-soft. Define a chain map:

$$\Psi : B_\bullet(\mathcal{H}; \varphi^*\mathcal{A}) \rightarrow B_\bullet(\mathcal{G}; \mathcal{A}), \quad \Psi(a|h_1, \dots, h_n) = (aF(t(h_1))|\psi(h_1), \dots, \psi(h_n)).$$

We have $\Psi \circ \Phi = Id$ and $\Phi \circ \Psi$ is homotopic to Id by the following homotopy:

$$h : B_\bullet(\mathcal{H}; \varphi^*\mathcal{A}) \rightarrow B_{\bullet+1}(\mathcal{H}; \varphi^*\mathcal{A}), \quad h = \sum_{i=0}^n (-1)^i h_i,$$

$$h_i(a|h_1, \dots, h_n) = (a|h_1, \dots, h_i, F(s(h_i)), l(h_{i+1}), \dots, l(h_n)).$$

3 Cyclic Homologies of Sheaves on Étale Groupoids

3.1 Cyclic Objects

Recall ([16, 28, 29]) some basic definitions concerning cyclic objects in an abelian category \mathcal{M} .

3.3 Examples: The basic example ([16], [38]) is the ∞ -cyclic vector space A_α^\natural associated to an unital algebra A , endowed with an endomorphism $\alpha : A_\alpha^\natural(n) := A^{\otimes(n+1)}$,

$$d_i(a_0, \dots, a_n) = \begin{cases} (a_0, \dots, a_i a_{i+1}, \dots, a_n) & \text{if } 0 \leq i \leq n-1 \\ (\alpha(a_n) a_0, a_1, \dots, a_{n-1}) & \text{if } i = n \end{cases},$$

$$t(a_0, \dots, a_n) = (\alpha(a_n), a_0, a_1, \dots, a_{n-1}),$$

$$s_i(a_0, \dots, a_n) = (\dots, a_i, 1, a_{i+1}, \dots).$$

Its Hochschild homology is denoted $HH_*(A, \alpha)$. If α is of order $r \neq \infty$ than A_α^\natural is an r -cyclic vector space; denote by $HC_*(A; \alpha)$, $HP_*(A; \alpha)$ the corresponding homologies.

For $\alpha = id$, we simplify the notations to A^\natural , $HH_*(A)$, $HC_*(A)$, $HP_*(A)$. These can be defined more generally, for non-unital algebras A , by using the (b, b') -complex (see [13, 29]):

$$\begin{array}{ccccccc} & & b \downarrow & & b' \downarrow & & b \downarrow & & b' \downarrow & & b \downarrow & & b' \downarrow & & \dots \\ A^{\otimes 3} & \xleftarrow{1-\tau} & A^{\otimes 3} & \xleftarrow{N} & A^{\otimes 3} & \xleftarrow{1-\tau} & A^{\otimes 3} & \xleftarrow{N} & \dots & & & & & & \\ & & b \downarrow & & b' \downarrow & & b \downarrow & & b' \downarrow & & b \downarrow & & b' \downarrow & & \dots \\ A^{\otimes 2} & \xleftarrow{1-\tau} & A^{\otimes 2} & \xleftarrow{N} & A^{\otimes 2} & \xleftarrow{1-\tau} & A^{\otimes 2} & \xleftarrow{N} & \dots & & & & & & \\ & & b \downarrow & & b' \downarrow & & b \downarrow & & b' \downarrow & & b \downarrow & & b' \downarrow & & \dots \\ A & \xleftarrow{1-\tau} & A & \xleftarrow{N} & A & \xleftarrow{1-\tau} & A & \xleftarrow{N} & \dots & & & & & & \end{array}$$

When A is a locally convex algebra, we use the projective tensor product ([19]).

3.4 Example: If $\mathcal{A} = \mathcal{C}_M^\infty$ is the sheaf of smooth functions on a manifold M , we define \mathcal{A}^\natural as in 3.3 by taking into account the topology, i.e. $\mathcal{A}^\natural(n) := \Delta_{n+1}^*(\mathcal{A}^{\otimes(n+1)})$ where $\mathcal{A}^{\otimes n} := \mathcal{C}_{M^n}^\infty \in Sh(M^n)$ and $\Delta_n : M \rightarrow M^n$ is the diagonal map. Keeping the same formulas as in 3.3 with $\alpha = id$, \mathcal{A}^\natural is a cyclic object in $Sh(M)$.

If $\varphi : (M, x_0) \rightarrow (M, x_0)$ is the germ of a smooth function, it induces an algebra endomorphism $\mathcal{A}_{x_0} \rightarrow \mathcal{A}_{x_0}$. Using the formulas from 3.3 we get an ∞ -cyclic vector space. Denote its b -boundary by b_φ . The following lemma belongs to folklore. A proof is included in the proof of 5.1 and 5.2 in [6] (see also [7]). Alternatively, one can extend the methods of [43] to this twisted case: replace the functions ρ_k used in [43], section 2, by their twisted versions $\rho_k^{tw}(x_0, \dots, x_k) = d(x_0, x_1)^2 + d(x_1, x_2)^2 + \dots + d(x_{k-1}, x_k)^2 + d(x_k, \varphi(x_0))^2$.

3.5 Lemma: We call $\varphi : (M, x_0) \rightarrow (M, x_0)$ stable if it satisfies the following three conditions:

- (i) $M^\varphi := \{x \in \text{dom}(\varphi) : \varphi(x) = x\}$ is locally around x_0 a submanifold of M ;
- (ii) $T_{x_0} M^\varphi = \text{Ker}(d\varphi_{x_0} - Id)$;
- (iii) $T_x M$ splits into a direct sum of $T_{x_0} M^\varphi$ and a φ -invariant subspace.

Any germ φ which preserves a metric around x_0 (in particular any germ of finite order) is stable.

If φ is stable, then:

$$((\mathcal{C}_M^\infty)_{x_0}^\natural, b_\varphi) \rightarrow ((\mathcal{C}_M^\infty)_{x_0}^\natural, b_{id}) \rightarrow ((\Omega_M^*)_{x_0}, 0),$$

$$(a_0, \dots, a_n) \mapsto (a_0|_{M^\varphi}, \dots, a_n|_{M^\varphi}) \mapsto a_0 da_1 \dots da_n|_{M^\varphi}$$

are quasi-isomorphisms of complexes of vector spaces.

3.2 Cyclic \mathcal{G} -sheaves

3.6 Definition: Let \mathcal{G} be an étale groupoid. By a cyclic \mathcal{G} -sheaf we mean a cyclic object \mathcal{A}_\bullet in $Sh(\mathcal{G})$. Its homology \mathcal{G} -sheaves, as defined in 3.2, are denoted $\widetilde{HH}_*(\mathcal{A}_\bullet)$, $\widetilde{HC}_*(\mathcal{A}_\bullet)$, $\widetilde{HP}_*(\mathcal{A}_\bullet)$.

3.7 Examples:

1. As an extension of 3.3, any sheaf of complex algebras $\mathcal{A} \in Sh(\mathcal{G})$ defines a cyclic \mathcal{G} -sheaf \mathcal{A}^\natural having the stalk at $c \in \mathcal{G}^{(0)}$: $(\mathcal{A}^\natural)_c = (\mathcal{A}_c)^\natural$. If \mathcal{G} is smooth and $\mathcal{A} = \mathcal{C}_{\mathcal{G}^{(0)}}^\infty$, then we reserve the notation \mathcal{A}^\natural for the cyclic \mathcal{G} -sheaf defined by taking into account the topology (see 3.4, 2.16).

2. The standard resolution of \mathbb{C} on $Sh(\mathcal{G})$ ([15, 20, 33]):

$$\dots \longrightarrow \mathbb{C}[\mathcal{G}^{(3)}] \longrightarrow \mathbb{C}[\mathcal{G}^{(2)}] \longrightarrow \mathbb{C}[\mathcal{G}^{(1)}] \longrightarrow \mathbb{C} \longrightarrow 0,$$

comes from the simplicial structure on the nerve of \mathcal{G} :

$$d_i(g_0, \dots, g_n) = \begin{cases} (g_0, \dots, g_i g_{i+1}, \dots, g_n) & \text{if } 0 \leq i \leq n-1 \\ (g_0, \dots, g_{n-1}) & \text{if } i = n \end{cases},$$

and s_i 's inserts units (as in 2.19). It inherits a structure of cyclic \mathcal{G} -sheaf by (compare to 7.4.5. in [29]):

$$t(g_0, \dots, g_n) = (g_0 g_1 \dots g_n, (g_1 \dots g_n)^{-1}, g_1, \dots, g_{n-1}).$$

3.8 Definition: If \mathcal{A}_\bullet is a cyclic \mathcal{G} -sheaf, define its Hochschild and cyclic hyperhomology by $HH_*(\mathcal{G}; \mathcal{A}_\bullet) = \mathbb{H}_*(\mathcal{G}; (\mathcal{A}_\bullet, b))$, $HC_*(\mathcal{G}; \mathcal{A}_\bullet) = \mathbb{H}_*(\mathcal{G}; (\mathcal{A}_\bullet, B, b))$ (compare to [26, 27]). If \mathcal{A}_n is c -soft for all n , define $HP_*(\mathcal{G}; \mathcal{A}_\bullet) = \mathbb{H}_*(\mathcal{G}; \lim_{\leftarrow} (\mathcal{A}_\bullet, B, b)[-2r])$ (in the general case one can define HP_* using resolutions; see [45]).

This is an extension of the definition given by Karoubi for groups (section II in [26]).

3.9 SBI-sequences: From the general considerations in 3.1, there is a long exact sequence in $Sh(\mathcal{G})$:

$$\dots \xrightarrow{B} \widetilde{HH}_n(\mathcal{A}_\bullet) \xrightarrow{I} \widetilde{HC}_n(\mathcal{A}_\bullet) \xrightarrow{S} \widetilde{HC}_{n-2}(\mathcal{A}_\bullet) \xrightarrow{B} \widetilde{HH}_{n-1}(\mathcal{A}_\bullet) \xrightarrow{I} \dots,$$

and, using 2.23, a long exact sequence of vector spaces:

$$\dots \xrightarrow{B} HH_n(\mathcal{G}; \mathcal{A}_\bullet) \xrightarrow{I} HC_n(\mathcal{G}; \mathcal{A}_\bullet) \xrightarrow{S} HC_{n-2}(\mathcal{G}; \mathcal{A}_\bullet) \xrightarrow{B} HH_{n-1}(\mathcal{G}; \mathcal{A}_\bullet) \xrightarrow{I} \dots$$

3.10 First spectral sequences: Using the second spectral sequence in 2.24 we get two spectral sequences with E^2 -terms: $H_p(\mathcal{G}; \widetilde{HH}_q(\mathcal{A}_\bullet)) \implies HH_{p+q}(\mathcal{G}; \mathcal{A}_\bullet)$ and $H_p(\mathcal{G}; \widetilde{HC}_q(\mathcal{A}_\bullet)) \implies HC_{p+q}(\mathcal{G}; \mathcal{A}_\bullet)$.

3.11 Second spectral sequences: The spectral sequences of the double complex $B_\bullet(\mathcal{G}; T_\bullet)$ (see 2.19) where $T_\bullet = (\mathcal{A}_\bullet, b)$ or $(\mathcal{A}_\bullet, B, b)$ give two spectral sequences with E^2 -terms:

$$HH_p(H_q(\mathcal{G}; \mathcal{A}_\bullet)) \implies HH_{p+q}(\mathcal{G}; \mathcal{A}_\bullet) \quad \text{and} \quad HC_p(H_q(\mathcal{G}; \mathcal{A}_\bullet)) \implies HC_{p+q}(\mathcal{G}; \mathcal{A}_\bullet).$$

3.12 Lemma: If the morphism $f : \mathcal{A}_\bullet \longrightarrow \tilde{\mathcal{A}}_\bullet$ of cyclic \mathcal{G} -sheaves induces a quasi-isomorphism $f : (\mathcal{A}_\bullet, b) \longrightarrow (\tilde{\mathcal{A}}_\bullet, \tilde{b})$ of complexes of sheaves, then it induces isomorphisms:

$$HH_*(\mathcal{G}; \mathcal{A}_\bullet) \simeq HH_*(\mathcal{G}; \tilde{\mathcal{A}}_\bullet), \quad HC_*(\mathcal{G}; \mathcal{A}_\bullet) \simeq HC_*(\mathcal{G}; \tilde{\mathcal{A}}_\bullet).$$

proof: this is a consequence of 2.21, 3.9, 3.10 and comparison-theorem for spectral sequences (compare to 2.5.2 in [45]).

3.13 Assume that \mathcal{G} is an étale groupoid and \mathcal{A}_\bullet is a cyclic \mathcal{G} -sheaf such that any \mathcal{A}_n is c-soft. From the definition we see that $HH_*(\mathcal{G}; \mathcal{A}_\bullet)$ is computed by the bi-simplicial vector space $B_\bullet(\mathcal{G}; \mathcal{A}_\bullet)$; so, from the Eilenberg-Zilber theorem ([44]), it is computed by its diagonal, i.e. by the simplicial vector space:

$$\mathcal{C}(\mathcal{G}; \mathcal{A}_\bullet) : \dots \rightrightarrows \Gamma_c(\mathcal{G}^{(2)}; \mathcal{A}_2) \rightrightarrows \Gamma_c(\mathcal{G}^{(1)}; \mathcal{A}_1) \rightrightarrows \Gamma_c(\mathcal{G}^{(0)}; \mathcal{A}_0) ,$$

$$d_i(a \mid g_1, \dots, g_n) = \begin{cases} (d_0(a)g_1 \mid g_2, \dots, g_n) & \text{if } i = 0 \\ (d_i(a) \mid g_1, \dots, g_i g_{i+1}, \dots, g_n) & \text{if } 1 \leq i \leq n-1 \\ (d_n(a) \mid g_1, \dots, g_{n-1}) & \text{if } i = n \end{cases} ,$$

$$s_i(a \mid g_1, \dots, g_n) = (s_i(a) \mid \dots, g_i, 1, g_{i+1}, \dots) .$$

Combining the cyclic structure of \mathcal{A}_\bullet with the one on the nerve of \mathcal{G} (see [9] , pag. 358), we define the following cyclic structure on $\mathcal{C}(\mathcal{G}; \mathcal{A}_\bullet)$:

$$t(a \mid g_1, \dots, g_n) = (t(a)g_1 \dots g_n \mid (g_1 \dots g_n)^{-1}, g_1, \dots, g_{n-1}) .$$

The following is a particular case of 3.25 in the next sub-section:

3.14 Lemma: *If \mathcal{A}_\bullet is a cyclic \mathcal{G} -sheaf such that any \mathcal{A}_n is c-soft, then $HH_*(\mathcal{G}; \mathcal{A}_\bullet)$, $HC_*(\mathcal{G}; \mathcal{A}_\bullet)$, $HP_*(\mathcal{G}; \mathcal{A}_\bullet)$ are computed by the cyclic vector space $\mathcal{C}(\mathcal{G}; \mathcal{A}_\bullet)$.*

3.3 Cyclic Groupoids ; Gysin sequences

In this subsection we extend Burghlea's definition of cyclic groupoids to this topological setting, give some important examples, and describe the Gysin sequence, which will be an important tool in our computations of cyclic homology (due to the fact that the SBI sequence is, after all, a Gysin sequence). We also extend the definitions and the results of the previous subsection.

3.15 Definition: *We call cyclic category an étale category \mathcal{G} endowed with an action of the cyclic group \mathbb{Z} ; by this we mean there is given a continuous map $\theta : \mathcal{G}^{(0)} \rightarrow \mathcal{G}^{(1)}$, $c \mapsto \theta_c$ such that:*

1. $\theta_c \in \text{Aut}(c)$, for all $c \in \mathcal{G}^{(0)}$;
2. $g\theta_c = \theta_d g$, for all $g : c \rightarrow d$ in \mathcal{G} .

A morphism between two cyclic categories (\mathcal{G}, θ) , (\mathcal{H}, τ) is a continuous functor $f : \mathcal{G} \rightarrow \mathcal{H}$ such that $f(\theta_c) = \tau_{f(c)} \quad \forall c \in \mathcal{G}^{(0)}$.

For discrete groupoids this agrees with the old definition given by Burghlea ([9], page 358). There is an action of \mathbb{Z} on the space of arrows: the generator acts as $\mathcal{G}^{(1)} \rightarrow \mathcal{G}^{(1)}$, $g \mapsto \theta_{t(g)} g$. The localization of (\mathcal{G}, θ) , denoted $\mathcal{G}_{(\theta)}$, is obtained from \mathcal{G} by imposing the relations $\theta_c = id_c$, $\forall c \in \mathcal{G}^{(0)}$; to be more precise about the topology, put $\mathcal{G}_{(\theta)}^{(0)} := \mathcal{G}^{(0)}$, $\mathcal{G}_{(\theta)}^{(1)} := \mathcal{G}^{(1)}/\mathbb{Z}$ with the obvious structure maps. It is not difficult to see that $\mathcal{G}_{(\theta)}$ is still an étale category.

We call (\mathcal{G}, θ) elliptic if $ord(\theta_c) < \infty$, $\forall c \in \mathcal{G}^{(0)}$. We call it hyperbolic if for any $g : c \rightarrow d$ in \mathcal{G} , the equality $g\theta_c^n = g$ holds just for $n = 0$ (in particular $ord(\theta_c) = \infty$, $\forall c \in \mathcal{G}^{(0)}$; if \mathcal{G} is a groupoid, this is the only condition).

If (\mathcal{G}, θ) , (\mathcal{G}', θ') are cyclic categories, so is $(\mathcal{G} \times \mathcal{G}', \theta \times \theta')$. If (\mathcal{G}, θ) is a cyclic category then so is $(\mathcal{G}, \theta^{-1})$, provided that the map $\mathcal{G}^{(0)} \rightarrow \mathcal{G}^{(1)}$, $c \mapsto \theta_c^{-1}$ is continuous; in this case, for any other cyclic category (\mathcal{G}', θ') , the localization of $(\mathcal{G}, \theta^{-1}) \times (\mathcal{G}', \theta')$ is denoted by $\mathcal{G} \wedge \mathcal{G}'$.

3.16 Examples:

1. if \mathcal{G} is an étale category, then (\mathcal{G}, id) is a cyclic category and $\mathcal{G}_{(id)} = \mathcal{G}$.

2. (Λ_∞, T) , where $T([n]) := t_n^{n+1}$, is a hyperbolic cyclic category with $(\Lambda_\infty)_{(T)} = \Lambda$.
3. If G is a group, $g \in \text{Center}(G)$ then (G, g) is a cyclic category with $G_{(g)} = G / \langle g \rangle$.
4. If C_r is a cyclic group generated by γ , $\text{ord}(\gamma) = r + 1$ then $(C_r)_{(\gamma)} = \text{trivial}$ and $\Lambda_\infty \wedge C_r = \Lambda_r$, $\forall 0 \leq r \leq \infty$.
5. For any cyclic category (\mathcal{G}, θ) : $\mathcal{G} \wedge * = \mathcal{G}_{(\theta)}$, $\mathcal{G} \wedge \mathbb{Z} = \mathcal{G}$.

3.17 Lemma: *Let (\mathcal{G}, θ) be a hyperbolic cyclic category, $\varphi : \mathcal{G} \rightarrow \mathcal{G}_{(\theta)}$ the projection functor. Then for any $c \in \mathcal{G}^{(0)}$, the functor:*

$$\mathbb{Z} = \langle \theta_c \rangle \xrightarrow{\sim} c/\varphi,$$

which sends the single object $$ of \mathbb{Z} to (id_c, c) and $n \in \mathbb{Z}$ to $\theta^n : (id_c, c) \rightarrow (id_c, c)$ is a strong deformation retract of d/φ . Moreover, it is a Morita equivalence if \mathcal{G} is a groupoid.*

proof: Choose a set-theoretic map $\sigma : \mathcal{G}_{(\theta)}^{(1)} \rightarrow \mathcal{G}^{(1)}$ which is a retract of φ and:

$$s(\sigma(h)) = s(h), \quad t(\sigma(h)) = t(h), \quad \sigma(c) = c, \quad \forall h \in \mathcal{G}_{(\theta)}^{(1)}, c \in \mathcal{G}^{(0)}.$$

We get a map $n : \mathcal{G} \rightarrow \mathbb{C}$ uniquely determined by the equality:

$$g = \theta^{n(g)} \sigma(\varphi(g)), \quad \forall g \in \mathcal{G}^{(1)}.$$

Recall (2.9) that the discrete category c/φ has as objects pairs (h, d) with $d \in \mathcal{G}^{(0)}$, $h : c \rightarrow d$ a morphism in $\mathcal{G}_{(\theta)}$ and as morphisms from (h, d) to (h', d') those morphisms $g : d \rightarrow d'$ in \mathcal{G} with the property $\varphi(g)h = h'$. Define the retraction $\psi : d/\varphi \rightarrow \mathbb{Z}$ by sending a morphism $g : (h, d) \rightarrow (h', d')$ (in c/φ) to $n(g\sigma(h))$. The deformation retraction $F : \psi \circ \varphi \rightarrow Id$ is defined as follows: to an object (h, d) in c/φ it associates the morphism $F(h, d) = \sigma(h) : \psi(\varphi(h, d)) = (id_c, c) \rightarrow (h, d)$ in c/φ . That φ is an essential equivalence when \mathcal{G} is a groupoid is obvious.

Proposition 3.18 : *If (\mathcal{G}, θ) is a hyperbolic cyclic category, then for any $\mathcal{A} \in \text{Sh}(\mathcal{G}_{(\theta)})$ there is a long exact sequence:*

$$\dots \rightarrow H_n(\mathcal{G}; \mathcal{A}) \rightarrow H_n(\mathcal{G}_{(\theta)}; \mathcal{A}) \xrightarrow{d} H_{n-2}(\mathcal{G}_{(\theta)}; \mathcal{A}) \rightarrow H_{n-1}(\mathcal{G}; \mathcal{A}) \rightarrow \dots$$

*Here the boundary is of type $d = - \cap e(\mathcal{G}, \theta)$, the cap product by some cohomology class $e(\mathcal{G}, \theta) \in H^2(\mathcal{G}_{(\theta)}; \mathbb{C})$ which does not depend on \mathcal{A} and is called the Euler class of (\mathcal{G}, θ) . Moreover, $e(\mathcal{G}, \theta)$ has the naturality property in the following sense: for any morphism $f : (\mathcal{G}, \theta) \rightarrow (\mathcal{H}, \tau)$ of hyperbolic cyclic categories, $f^*e(\mathcal{H}, \tau) = e(\mathcal{G}, \theta)$.*

proof: The spectral sequence for φ (2.26, 2.29), $E_{p,q}^2 = H_p(\mathcal{G}_{(\theta)}; L_q\varphi_!\mathcal{A}) \implies H_{p+q}(\mathcal{G}; \mathcal{A})$, has:

$$(L_q\varphi_!\mathcal{A})_c = H_q(c/\varphi; \mathcal{A}) = H_q(\mathbb{Z}; \mathcal{A}_c).$$

The last equality follows from the previous lemma and 2.30 (or Morita invariance 2.27 if \mathcal{G} is a groupoid) and is continuous with respect to $c \in \mathcal{G}^{(0)}$. So we get $L_q\varphi_!\mathcal{A} = \mathcal{A}$ if $q \in \{0, 1\}$, and 0 otherwise, and this implies the long exact sequence.

From 2.24, 2.26 we know its boundary is of type $d = - \cap e(\mathcal{A})$ for some $e(\mathcal{A}) \in \text{Ext}_{\mathcal{G}_{(\theta)}}(\mathcal{A}, \mathcal{A})$. Recall (see 2.17, 2.23) that the action of $H^2(\mathcal{G}_{(\theta)}; \mathbb{C}) = \text{Ext}_{\mathcal{G}_{(\theta)}}(\mathbb{C}, \mathbb{C})$ on $H_*(\mathcal{G}_{(\theta)}; \mathcal{A})$ is defined using the morphism: $\text{Ext}_{\mathcal{G}_{(\theta)}}(\mathbb{C}, \mathbb{C}) \rightarrow \text{Ext}_{\mathcal{G}_{(\theta)}}(\mathcal{A}, \mathcal{A}), u \mapsto u \otimes \mathcal{A}$. So it is enough to prove that $e(\mathcal{A}) = e(\mathbb{C}) \otimes \mathcal{A}$. Recall also that the spectral sequence we used is obtained from the equality: $H_*(\mathcal{G}; \mathcal{A}) = \mathbb{H}_*(\mathcal{G}_{(\theta)}; \mathcal{L}_\bullet(\mathcal{A}))$, where $\mathcal{L}_\bullet(\mathcal{A}) = \mathcal{L}\varphi_!\mathcal{A}$ is a chain complex in $\text{Sh}(\mathcal{G}_{(\theta)})$ which can be described as follows (we spell out the general definition of $\mathcal{L}\varphi_!$, [15]). Define:

$$X_n = \{(g_1, \dots, g_{n+1}) : (g_1, \dots, g_n) \in \mathcal{G}^{(n)}, g_{n+1} \in \mathcal{G}_{(\theta)}^{(1)}, s(g_n) = t(g_{n+1})\},$$

and the maps $\alpha, \beta : X_n \rightarrow \mathcal{G}^{(0)}$, $\alpha(g_1, \dots, g_{n+1}) = t(g_1)$, $\beta(g_1, \dots, g_{n+1}) = s(g_{n+1})$. Then $\mathcal{L}_n(\mathcal{A}) = \beta_* \alpha^* \mathcal{A}$ has the stalk at $c \in \mathcal{G}^{(0)}$:

$$(\mathcal{L}_n(\mathcal{A}))_c = \bigoplus_{d \in \mathcal{G}^{(0)}} \mathcal{A}_d \otimes \mathbb{C}[\alpha^{-1}(d) \cap \beta^{-1}(c)],$$

and the action of $\mathcal{G}_{(\theta)}$ and the boundaries are:

$$(a, g_1, \dots, g_{n+1})g = (a, g_1, \dots, g_{n+1}g),$$

$$d_n(a, g_1, \dots, g_{n+1}) = (ag_1, \dots, g_{n+1}) + \sum_{i=1}^n (-1)^i (a, g_1, \dots, g_i g_{i+1}, \dots, g_{n+1}).$$

We get the following representative for $e(\mathcal{A})$:

$$0 \rightarrow \mathcal{A} \xrightarrow{j} \text{Coker}(d_1) \xrightarrow{d_0} \mathcal{L}_0(\mathcal{A}) \xrightarrow{\epsilon} \mathcal{A} \rightarrow 0,$$

where $\epsilon(a, g_1) = ag_1$, $j(a) = \widehat{(a, \theta, 1)}$. Denoting this extension by $u(\mathcal{A})$, remark there is a map:

$$\mathcal{L}_\bullet(\mathcal{A}) \rightarrow \mathcal{L}_\bullet(\mathbb{C}) \otimes \mathcal{A}, \quad (a, g_1, \dots, g_{n+1}) \mapsto (ag_1 \dots g_{n+1}, g_1, \dots, g_{n+1})$$

which induces a map $u(\mathcal{A}) \rightarrow u(\mathbb{C}) \otimes \mathcal{A}$. This proves $e(\mathcal{A}) = e(\mathbb{C}) \otimes \mathcal{A}$.

Denote by $\tilde{\mathcal{L}}_\bullet(\mathbb{C})$, $\tilde{u}(\mathbb{C})$ the analogous constructions for (\mathcal{H}, τ) and define a chain-map:

$$\mathcal{L}_\bullet(\mathbb{C}) \rightarrow f^* \tilde{\mathcal{L}}_\bullet(\mathbb{C}), \quad (g_1, \dots, g_{n+1}) \mapsto (f(g_1), \dots, f(g_{n+1})).$$

It induces a map of extensions $u(\mathbb{C}) \rightarrow f^* \tilde{u}(\mathbb{C})$ and this proves the naturality.

3.19 Remark: Applying 3.18 to (Λ_∞, T) (see 3.16) we get the usual *SBI*-sequence for cyclic vector-spaces as the Gysin-sequence for the projection $\Lambda_\infty \rightarrow \Lambda$ and the *S*-boundary as an Euler class $e(\Lambda_\infty, T) \in H^2(\Lambda; \mathbb{C})$. Our description of *S* in terms of extensions (as described in the previous proof) is very close to the one given in [39], pp. 565.

3.20 Definition: Let (\mathcal{G}, θ) be a cyclic category. A θ -cyclic \mathcal{G} -sheaf is a ∞ -cyclic object \mathcal{A}_\bullet in $Sh(\mathcal{G})$ (i.e. a contravariant functor $\Lambda_\infty \rightarrow Sh(\mathcal{G})$ cf 3.2) such that, for any $c \in \mathcal{G}^{(0)}$, the morphism $(t_{c,n})^{n+1} : (\mathcal{A}_n)_c \rightarrow (\mathcal{A}_n)_c$ coincides with the action of θ_c . In other words, a θ -cyclic object is a $\Lambda_\infty \wedge \mathcal{G}$ -sheaf. Define:

$$HH_*(\mathcal{G}, \theta; \mathcal{A}_\bullet) := H_*(\Lambda_\infty \times \mathcal{G}; \mathcal{A}_\bullet), \quad HC_*(\mathcal{G}, \theta; \mathcal{A}_\bullet) := H_*(\Lambda_\infty \wedge \mathcal{G}; \mathcal{A}_\bullet).$$

If \mathcal{G} is an étale groupoid, $\theta = id$, this agrees with the earlier definition of cyclic \mathcal{G} -sheaves (3.6) and their homologies (3.8).

3.21 SBI-sequence: Since $\Lambda_\infty \times \mathcal{G}$ is always hyperbolic, 3.18 applies, so for any θ -cyclic \mathcal{G} -sheaf \mathcal{A}_\bullet there is a long exact sequence:

$$\dots \rightarrow HH_n(\mathcal{G}, \theta; \mathcal{A}_\bullet) \rightarrow HC_n(\mathcal{G}, \theta; \mathcal{A}_\bullet) \rightarrow HC_{n-2}(\mathcal{G}, \theta; \mathcal{A}_\bullet) \rightarrow HH_{n-1}(\mathcal{G}, \theta; \mathcal{A}_\bullet) \rightarrow \dots$$

3.22 Remark: If (\mathcal{G}, θ) is a cyclic category and \mathcal{A}_\bullet is a θ -cyclic \mathcal{G} -sheaf, then $HH_*(\mathcal{G}, \theta; \mathcal{A}_\bullet) = \mathbb{H}_*(\mathcal{G}; (\mathcal{A}_\bullet, b))$ (one way to see this is by applying the spectral sequence for the projection $\Lambda_\infty \times \mathcal{G} \rightarrow \mathcal{G}$). This implies that the analogue of 3.12 holds.

3.23 Lemma: *If (\mathcal{G}, θ) is a cyclic category and \mathcal{A}_\bullet is a θ -cyclic \mathcal{G} -sheaf, then the ∞ -cyclic vector space $n \mapsto H_q(\mathcal{G}; \mathcal{A}_n)$ is cyclic for every q , and there are spectral sequences:*

$$E_{p,q}^2 = HH_p(H_q(\mathcal{G}; \mathcal{A}_\bullet)) \implies HH_{p+q}(\mathcal{G}, \theta; \mathcal{A}_\bullet) \quad , \quad E_{p,q}^2 = HC_p(H_q(\mathcal{G}; \mathcal{A}_\bullet)) \implies HC_{p+q}(\mathcal{G}, \theta; \mathcal{A}_\bullet).$$

proof: Consider the diagram with columns coming from cyclic categories:

$$\begin{array}{ccccc} \Lambda_\infty \times * = & \Lambda_\infty & \xleftarrow{\pi_1} & \Lambda_\infty \times \mathcal{G} & \xrightarrow{\pi_2} & \mathcal{G} & = * \times \mathcal{G} \\ & \pi \downarrow & & \psi \downarrow & & \varphi \downarrow & \\ \Lambda_\infty \wedge * = & \Lambda & \xleftarrow{\pi'_1} & \Lambda_\infty \wedge \mathcal{G} & \xrightarrow{\pi'_2} & \mathcal{G}_{(\theta)} & = * \wedge \mathcal{G} \end{array}$$

Here $\pi_1, \pi_2, \pi'_1, \pi'_2$ are the projections. For any integer $n \geq 0$ we get from 3.17 strong deformation retracts:

$$[n]/\pi \leftarrow \mathbb{Z}, \quad [n]/\pi_1 = ([n]/\Lambda_\infty) \times \mathcal{G} \leftarrow \mathcal{G}, \quad [n]/\pi'_1 = ([n]/\pi) \wedge \mathcal{G} \leftarrow \mathbb{Z} \wedge \mathcal{G} = \mathcal{G}.$$

The spectral sequences induced by π_1 and π'_1 together with 2.30, give the desired spectral sequences.

3.24 Assume that (\mathcal{G}, θ) is a cyclic groupoid and \mathcal{A}_\bullet is a θ -cyclic \mathcal{G} -sheaf such that each \mathcal{A}_n is c -soft. From 3.22 we see that $HH_*(\mathcal{G}, \theta; \mathcal{A}_\bullet)$ is computed by the bi-simplicial vector space $B_\bullet(\mathcal{G}; \mathcal{A}_\bullet)$; so, as in 3.13, it is computed by the simplicial vector space $\mathcal{C}(\mathcal{G}; \mathcal{A}_\bullet)$. Define $\mathcal{C}(\mathcal{G}, \theta; \mathcal{A}_\bullet)$ as the cyclic vector space having $\mathcal{C}(\mathcal{G}; \mathcal{A}_\bullet)$ as underlying simplicial vector space and the following cyclic structure:

$$t(a \mid g_1, \dots, g_n) = (t(a)\theta^{-1}g_1 \dots g_n \mid (g_1 \dots g_n)^{-1}\theta, g_1, \dots, g_{n-1}).$$

3.25 Lemma and definition: *If (\mathcal{G}, θ) is a cyclic groupoid and \mathcal{A}_\bullet is a θ -cyclic \mathcal{G} -sheaf such that each \mathcal{A}_n is c -soft, then $HH_*(\mathcal{G}, \theta; \mathcal{A}_\bullet), HC_*(\mathcal{G}, \theta; \mathcal{A}_\bullet)$ are computed by the cyclic vector space $\mathcal{C}(\mathcal{G}, \theta; \mathcal{A}_\bullet)$. In this case, define $HP_*(\mathcal{G}, \theta; \mathcal{A}_\bullet) = HP_*(\mathcal{C}(\mathcal{G}, \theta; \mathcal{A}_\bullet))$.*

proof: On the standard resolution of \mathbb{C} in $Sh(\mathcal{G})$ (see 3.7), considered as a simplicial \mathcal{G} -sheaf, we define a structure of θ -cyclic \mathcal{G} -sheaf by:

$$t(g_0, \dots, g_n) = (\theta^{-1}g_0g_1 \dots g_n, (g_1 \dots g_n)^{-1}\theta, g_1, \dots, g_{n-1}).$$

Denote it by $\mathcal{B}_\bullet \in Sh(\Lambda_\infty \wedge \mathcal{G})$, and define $\mathcal{L}_\bullet \in Sh(\Lambda_\infty \wedge \mathcal{G})$ by $\mathcal{L}_n = \mathcal{A}_n \otimes \mathcal{B}_n$ with the structure maps given by the tensor-product of the structure maps of \mathcal{B}_\bullet and \mathcal{A}_\bullet . It is a standard fact that the projection $\mathcal{L}_\bullet \rightarrow \mathcal{A}_\bullet$ induces a quasi-isomorphism $(\mathcal{L}_\bullet, b) \simeq (\mathcal{A}_\bullet, b)$ (it follows, for instance, from the fact that \mathcal{B}_\bullet is a resolution of \mathbb{C} and from the Eilenberg-Zilber theorem); the "SBI-trick" (see 3.22) implies that $HC_*(\mathcal{G}, \theta; \mathcal{L}_\bullet) \xrightarrow{\sim} HC_*(\mathcal{G}, \theta; \mathcal{A}_\bullet)$. From this and 3.23 applied to the θ -cyclic \mathcal{G} -sheaf \mathcal{L}_\bullet , we get a spectral sequence with: $E_{p,q}^2 = HC_p(H_q(\mathcal{G}; \mathcal{L}_\bullet)) \implies HC_{p+q}(\mathcal{G}, \theta; \mathcal{A}_\bullet)$. It is enough to make a straightforward remark: $H_q(\mathcal{G}; \mathcal{L}_n) = 0$, for all $q \geq 1$ (all \mathcal{L}_n 's are free, [15]) and for $q = 0$, the cyclic vector space $n \mapsto H_0(\mathcal{G}; \mathcal{L}_n)$ is in fact $\mathcal{C}(\mathcal{G}, \theta; \mathcal{A}_\bullet)$.

Proposition 3.26 (elliptic case): *Let (\mathcal{G}, θ) be an elliptic cyclic groupoid, \mathcal{A}_\bullet a θ -cyclic \mathcal{G} -sheaf. For any integer n put $\mathcal{A}_{(\theta), n} := \varphi_!(\mathcal{A}_n) \in Sh(\mathcal{G}_{(\theta)})$, where $\varphi : \mathcal{G} \rightarrow \mathcal{G}_{(\theta)}$ is the projection. Then $\mathcal{A}_{(\theta), \bullet}$ is a cyclic $\mathcal{G}_{(\theta)}$ -sheaf and:*

$$HH_*(\mathcal{G}, \theta; \mathcal{A}_\bullet) = HH_*(\mathcal{G}_{(\theta)}; \mathcal{A}_{(\theta), \bullet}) \quad , \quad HC_*(\mathcal{G}, \theta; \mathcal{A}_\bullet) = HC_*(\mathcal{G}_{(\theta)}; \mathcal{A}_{(\theta), \bullet}),$$

and the analogue for HP_* .

proof: Assume for simplicity that each \mathcal{A}_n is c-soft (in general we work with c-soft resolutions). From 3.17 we have the Morita equivalences $\langle \theta_c \rangle \xrightarrow{\sim} c/\varphi$, $\forall c \in \mathcal{G}^{(0)}$; 2.26 gives $(L_q \varphi, \mathcal{A}_n)_c = H_q(\langle \theta_c \rangle; (\mathcal{A}_n)_c) = 0$, $\forall q \neq 0$ and $(\mathcal{A}_{(\theta),n})_c = \text{Coinv}_{\theta_c}((\mathcal{A}_n)_c)$. In particular, the ∞ -cyclic object $\mathcal{A}_{(\theta),\bullet}$ is cyclic. Also the spectral sequence of φ degenerates; this ensures that the obvious projection of bi-simplicial vector spaces $\{B_p(\mathcal{G}; \mathcal{A}_q) : p, q \geq 0\} \rightarrow \{B_p(\mathcal{G}_{(\theta)}; \mathcal{A}_{(\theta),q}) : p, q \geq 0\}$ is a quasi-isomorphism on the $q = \text{constant}$ columns. By the Eilenberg-Zilber theorem, it is a quasi-isomorphism between their diagonals, i.e. the projection $\mathcal{C}(\mathcal{G}, \theta; \mathcal{A}_\bullet) \rightarrow \mathcal{C}(\mathcal{G}_{(\theta)}, id; \mathcal{A}_{(\theta),\bullet})$ of cyclic vector spaces induces isomorphism in their Hochschild homologies; now 3.25 ends the proof.

Proposition 3.27 (*hyperbolic case*): *Let (\mathcal{G}, θ) be a hyperbolic cyclic groupoid, \mathcal{A}_\bullet a θ -cyclic \mathcal{G} -sheaf. Then $\widetilde{HH}_*(\mathcal{A}_\bullet) \in \text{Sh}(\mathcal{G})$ are in fact $\mathcal{G}_{(\theta)}$ -sheaves, and there are spectral sequences:*

$$E_{p,q}^2 = H_p(\mathcal{G}; \widetilde{HH}_*(\mathcal{A}_\bullet)) \implies HH_*(\mathcal{G}, \theta; \mathcal{A}_\bullet) \quad ,$$

$$E_{p,q}^2 = H_p(\mathcal{G}_{(\theta)}; \widetilde{HH}_*(\mathcal{A}_\bullet)) \implies HC_*(\mathcal{G}, \theta; \mathcal{A}_\bullet).$$

Moreover, $HC_*(\mathcal{G}, \theta; \mathcal{A}_\bullet)$ are modules over the ring $H^*(\mathcal{G}_{(\theta)}; \mathbb{C})$ and S in the SBI sequence is the (cap-) product by the Euler class $\epsilon(\mathcal{G}, \theta) \in H^2(\mathcal{G}_{(\theta)}; \mathbb{C})$.

proof: That θ acts trivially on $\widetilde{HH}_*(\mathcal{A}_\bullet)$ follows by using the homotopy between id and θ , $h : \mathcal{A}_\bullet \rightarrow \mathcal{A}_{\bullet+1}$ given by:

$$h_n = s_{-1}(1 + \tau + \dots + \tau^n) : \mathcal{A}_n \rightarrow \mathcal{A}_{n+1} .$$

From the construction in the proof of 3.17, we get strong deformation retracts:

$$c/\pi_2 = \Lambda_\infty \times (c/\mathcal{G}) \leftarrow \Lambda_\infty, \quad c/\pi_2' = \Lambda_\infty \wedge (c/\varphi) \leftarrow \Lambda_\infty \wedge \langle \theta_c \rangle = \Lambda_\infty .$$

Now the spectral sequences follow from the spectral sequences 2.26 induced by π_2, π_2' (see the diagram in the proof of 3.23), and 2.30. The last part follows from 3.18 applied to $\Lambda_\infty \times \mathcal{G}$ and the isomorphism $H^*(\Lambda_\infty \wedge \mathcal{G}; \mathbb{C}) \simeq H^*(\mathcal{G}_{(\theta)}; \mathbb{C})$. The last isomorphism follows from the spectral sequence induced by π_2' in cohomology (see e.g. [1, 15, 33]).

3.28 Eilenberg-Zilber Theorem in the cyclic case: As an application we give a new proof of the spectral sequence for cylindrical objects which is one of the main results in [17]. Recall ([17], pp. 164) that a cylindrical vector space is a functor $C_{\bullet\bullet} : \Lambda_\infty \wedge \Lambda_\infty \rightarrow \underline{V}\mathcal{S}$. Its diagonal is naturally a cyclic vector space.

3.29 Corollary: *If $C_{\bullet\bullet}$ is a bi-cyclic vector space which is cylindrical, then the ∞ -cyclic vector space $n \mapsto H_q(C_{n,\bullet})$ is cyclic for any $q \geq 0$, and there are spectral sequences:*

$$E_{p,q}^2 = HH_p(H_q(C_{\bullet\bullet})) \implies HH_{p+q}(\text{diag}(C_{\bullet\bullet})),$$

$$E_{p,q}^2 = HC_p(H_q(C_{\bullet\bullet})) \implies HC_{p+q}(\text{diag}(C_{\bullet\bullet})).$$

proof: With the same method as in the proof of 3.25 we see that the homologies $HH_*(\Lambda_\infty, T; C_{\bullet\bullet})$, $HC_*(\Lambda_\infty, T; C_{\bullet\bullet})$ are computed by the cyclic module $\text{diag}(C_{\bullet\bullet})$. Then apply 3.23 to (Λ_∞, T) .

3.4 Cyclic Homology of crossed products by étale groupoids

In this subsection we introduce the cyclic homology of crossed products by étale groupoids, and, relating them with the cyclic homology of cyclic groupoids, we derive the Feigin-Tsygan-Nistor spectral sequences. These will be essential in the next subsection when we will treat a particular case of crossed products, namely convolution algebras.

3.30 Recall that if G is a discrete group acting on a unital algebra A , the cross-product algebra $A \rtimes G$ is $A \otimes \mathbb{C}[G]$ with the convolution product $(a, g)(b, h) = (ahb, gh)$. We see that the induced cyclic vector space $(A \rtimes G)^\natural$ (see 3.3) has:

$$(A \rtimes G)^\natural(n) = A^{\otimes(n+1)} \otimes \mathbb{C}[G^{n+1}],$$

while the cyclic structure is given by the formulas (see also [38]):

$$d_i(a_0, \dots, a_n | g_0, \dots, g_n) = \begin{cases} (a_0, \dots, (a_i g_{i+1}) a_{i+1}, \dots, a_n | g_0, \dots, g_i g_{i+1}, \dots, g_n) & \text{if } 0 \leq i \leq n-1 \\ (a_n g_0 a_0, a_1, \dots, a_{n-1} | g_n g_0, g_1, \dots, g_{n-1}) & \text{if } i = n \end{cases},$$

$$s_i(a_0, \dots, a_n | g_0, \dots, g_n) = (\dots, a_i, 1, a_{i+1}, \dots | \dots, g_i, 1, g_{i+1}, \dots),$$

$$t(a_0, \dots, a_n | g_0, \dots, g_n) = (a_n, a_0, \dots, a_{n-1} | g_n, g_0, \dots, g_{n-1}).$$

3.31 Lemma and definition: Let \mathcal{G} be an étale groupoid such that $\mathcal{G}^{(0)}$ is Hausdorff, \mathcal{A} a c -soft \mathcal{G} -sheaf of complex algebras. If $u, v \in \Gamma_c(\mathcal{G}; s^* \mathcal{A})$, then the following formula:

$$(u * v)(g) = \sum_{g_1 g_2 = g} (u(g_1) g_2) v(g_2) \quad \forall g \in \mathcal{G},$$

gives a well defined element $u * v \in \Gamma_c(\mathcal{G}; s^* \mathcal{A})$. The resulting algebra, $(\Gamma_c(\mathcal{G}; s^* \mathcal{A}), *)$ is called the crossed product of \mathcal{A} and \mathcal{G} and is denoted $\mathcal{A} \rtimes_{alg} \mathcal{G}$.

proof: The element $u * v \in \Gamma_c(\mathcal{G}; s^* \mathcal{A})$ is obtained via the composition of:

$$\begin{aligned} \Gamma_c(\mathcal{G}; s^* \mathcal{A}) \times \Gamma_c(\mathcal{G}; s^* \mathcal{A}) &\longrightarrow \Gamma_c(\mathcal{G} \times \mathcal{G}; s^* \mathcal{A} \boxtimes s^* \mathcal{A}) \longrightarrow \\ &\longrightarrow \Gamma_c(\mathcal{G} \times_{\mathcal{G}^{(0)}} \mathcal{G}; s^* \mathcal{A} \boxtimes s^* \mathcal{A} |_{\mathcal{G} \times_{\mathcal{G}^{(0)}} \mathcal{G}}) \longrightarrow \Gamma_c(\mathcal{G}; s^* \mathcal{A}) \end{aligned}$$

where the first map is the obvious one, the second is the restriction to $\mathcal{G} \times_{\mathcal{G}^{(0)}} \mathcal{G}$ (which is closed in $\mathcal{G} \times \mathcal{G}$ since $\mathcal{G}^{(0)}$ is Hausdorff), and the third is:

$$(a, b | g_1, g_2) \mapsto (a g_2 b, g_1 g_2).$$

3.32 Examples:

1. If G is a discrete group acting on an algebra A , then $A \rtimes_{alg} G$ is the usual crossed product (described in 3.30).

2. If \mathcal{G} is a smooth étale groupoid, $\mathcal{A} = \mathcal{C}_{\mathcal{G}^{(0)}}^\infty$, then $\mathcal{A} \rtimes_{alg} \mathcal{G} = \mathcal{C}_c^\infty(\mathcal{G})$ is the convolution algebra of \mathcal{G} (we use that $\mathcal{C}_c^\infty(\mathcal{G}) = \Gamma_c(\mathcal{G}; \mathcal{C}_{\mathcal{G}^{(0)}}^\infty)$ and $\mathcal{C}_{\mathcal{G}^{(0)}}^\infty = s^* \mathcal{C}_{\mathcal{G}^{(0)}}^\infty$ since s is étale). We will come back to this example in the next subsection.

3.33 Definition: Let \mathcal{G} be an étale groupoid, \mathcal{A} a c -soft \mathcal{G} -sheaf of complex unital algebras. Consider Burghela's space ([6]): $B^{(n)} = \{(\gamma_0, \gamma_1, \dots, \gamma_n) \in \mathcal{G}^{(n+1)} : t(\gamma_0) = s(\gamma_n)\}$, and $\sigma_n : B^{(n)} \longrightarrow (\mathcal{G}^{(0)})^{n+1}$, $\sigma_n(\gamma_0, \dots, \gamma_n) = (s(\gamma_0), \dots, s(\gamma_n))$. Define the cyclic vector space $(\mathcal{A} \rtimes \mathcal{G})^\natural$ by:

$$(\mathcal{A} \rtimes \mathcal{G})^\natural(n) = \Gamma_c(B^{(n)}; \sigma_n^* \mathcal{A}^{\boxtimes(n+1)}).$$

For the structure maps, we keep the same formulas as in 3.30. Its homologies are denoted $HH_*(\mathcal{A} \rtimes \mathcal{G})$, $HC_*(\mathcal{A} \rtimes \mathcal{G})$, $HP_*(\mathcal{A} \rtimes \mathcal{G})$.

This definition is suitable for the main examples: the discrete case 3.30, and the smooth case (see Proposition 4.1). Here are some further motivations. First of all, $(\mathcal{A} \rtimes \mathcal{G})^\natural$ is the maximal object for which the formulas in 3.30 make sense; this allows us to use our methods in this general setting. A way to think of $(\mathcal{A} \rtimes \mathcal{G})^\natural$ is as follows (and this is in fact the main motivation). Usually our objects are endowed with topologies; in particular, the relevant cyclic homology of $\mathcal{A} \rtimes_{alg} \mathcal{G}$ uses the topology (i.e. certain topological tensor product [19] is used for defining $(\mathcal{A} \rtimes_{alg} \mathcal{G})^\natural$). We have inclusions:

$$(\mathcal{A} \rtimes_{alg} \mathcal{G})^{\otimes(n+1)} \hookrightarrow \Gamma_c(\mathcal{G}^{n+1}; s_{n+1}^*(\mathcal{A}^{\boxtimes(n+1)})) \quad , \quad (s_{n+1} = s \times \dots \times s ; (n+1) \text{ times})$$

and the vector spaces $\Gamma_c(\mathcal{G}^{n+1}; s_{n+1}^*(\mathcal{A}^{\boxtimes(n+1)}))$ are the best candidates for defining $(\mathcal{A} \rtimes_{alg} \mathcal{G})^\natural$ by taking into account the topology. From the first half of 2.12.2 we get (compare to Proposition 4.1 in [6]):

3.34 Lemma: $(\mathcal{A} \rtimes \mathcal{G})^\natural(n) = \Gamma_c(\mathcal{G}^{n+1}; s_{n+1}^*(\mathcal{A}^{\boxtimes(n+1)})) / \{u : u|_{B^{(n)}} = 0\}$.

So our definition can be viewed as a “topological normalization” of the cyclic vector space associated to $\mathcal{A} \rtimes_{alg} \mathcal{G}$. Of course, in practice one more step is needed: to prove that passing to this “topological normalization” does not change the cyclic homology (see for instance Prop. 4.1).

And as a final motivation for our choice and notation, let us just remark that the usual formulas for the Chern-character (see e.g. [13, 27, 29]) define a Connes-Chern-Karoubi character: $Ch : K_*^{alg}(\mathcal{A} \rtimes_{alg} \mathcal{G}) \longrightarrow HP_*(\mathcal{A} \rtimes \mathcal{G})$.

Because of these we do believe that the results (or better: the methods) we describe here may be useful to a larger extent.

3.35 The cyclic groupoid $\Omega(\mathcal{G})$; the twisted sheaves $\mathcal{A}_{tw}^\natural$: An important role in understanding $(\mathcal{A} \rtimes \mathcal{G})^\natural$ (even in the discrete case 3.30) is played by the \mathcal{G} -space of loops $B^{(0)} = \{\gamma \in \mathcal{G}^{(1)} : s(\gamma) = t(\gamma)\}$; the action of \mathcal{G} is given by:

$$B^{(0)} \times_{\mathcal{G}^{(0)}} \mathcal{G} \longrightarrow B^{(0)} \quad , \quad (\gamma, g) \mapsto g^{-1}\gamma g.$$

Let $\Omega(\mathcal{G}) := B^{(0)} \rtimes \mathcal{G}$ be the associated groupoid (see 2.3); it is a cyclic groupoid with the cyclic structure θ defined by $\theta(\gamma) := (\gamma, \gamma)$. Define a θ -cyclic $\Omega(\mathcal{G})$ -sheaf $\mathcal{A}_{tw}^\natural$ by $\mathcal{A}_{tw}^\natural := s^*(\mathcal{A}^\natural)$ where $s : B^{(0)} \longrightarrow \mathcal{G}^{(0)}$ is the restriction of the source map, and $\mathcal{A}^\natural = \mathcal{A}^{\otimes(*+1)}$ was defined in 3.7; the formulas for the structure maps are defined in such a way that, at the stalk at $\gamma \in B^{(0)}$ with $s(\gamma) = c$, the ∞ -cyclic vector space $(\mathcal{A}_{tw}^\natural)_\gamma$ is $\mathcal{A}_{c, \sigma_\gamma}^\natural$, i.e. the one associated to the action of γ on the algebra \mathcal{A}_c (see 3.3). Compare to (9), (10) in [6].

Proposition 3.36 : $HH_*(\mathcal{A} \rtimes \mathcal{G}) = HH_*(\Omega(\mathcal{G}), \theta; \mathcal{A}_{tw}^\natural), HC_*(\mathcal{A} \rtimes \mathcal{G}) = HC_*(\Omega(\mathcal{G}), \theta; \mathcal{A}_{tw}^\natural), HP_*(\mathcal{A} \rtimes \mathcal{G}) = HP_*(\Omega(\mathcal{G}), \theta; \mathcal{A}_{tw}^\natural)$.

proof: The n -th nerve of $\Omega(\mathcal{G})$ is:

$$\Omega(\mathcal{G})^{(n)} = \{(\gamma | \gamma_1, \dots, \gamma_n) : (\gamma, \gamma_1) \in \Omega(\mathcal{G})^{(1)}, (\gamma_1, \dots, \gamma_n) \in \mathcal{G}^{(n)}\}$$

(here “|” is just a notation in order to separate the loops from the usual arrows). The isomorphism of vector spaces:

$$\Gamma_c(B^{(n)}; \sigma_n^* \mathcal{A}^{\boxtimes(n+1)}) \simeq \Gamma_c(\Omega(\mathcal{G})^{(n)}; \mathcal{A}_{tw}^\natural),$$

$$(a_0, \dots, a_n | \gamma_0, \dots, \gamma_n) \mapsto (a_0 \gamma_1 \dots \gamma_n \gamma_0, a_1 \gamma_2 \dots \gamma_n \gamma_0, \dots, a_n \gamma_0 | \gamma_1 \dots \gamma_n \gamma_0, \gamma_1, \dots, \gamma_n),$$

(compare to 4.1 in [6]) gives an isomorphism of cyclic vector spaces:

$$(\mathcal{A} \rtimes \mathcal{G})^\natural \simeq \mathcal{C}(\Omega(\mathcal{G}), \theta; \mathcal{A}_{tw}^\natural),$$

so it is enough to use 3.25.

3.37 The groupoids $\mathcal{Z}_{\mathcal{O}}, \mathcal{N}_{\mathcal{O}}$; the twisted sheaves $\mathcal{A}_{\mathcal{O}}^{\natural}$: For $\mathcal{O} \subset B^{(0)}$, \mathcal{G} -invariant we define the cyclic groupoid $\mathcal{Z}_{\mathcal{O}} := \mathcal{O} \rtimes \mathcal{G}$ (the restriction of $\Omega(\mathcal{G})$ to \mathcal{O}). Its localization $(\mathcal{Z}_{\mathcal{O}})_{(\theta)}$ (i.e. obtained from $\mathcal{Z}_{\mathcal{O}}$ by imposing the relations $(\gamma, 1) = (\gamma, \gamma)$, $\forall \gamma \in \mathcal{O}$; see 3.15) is denoted by $\mathcal{N}_{\mathcal{O}}$. These two groupoids play the role of the centralizer and normalizer of \mathcal{O} (see also subparagraph 4.3). We define a θ -cyclic $\mathcal{Z}_{\mathcal{O}}$ -sheaf $\mathcal{A}_{\mathcal{O}}^{\natural}$ in such a way that, stalkwise:

$$(\mathcal{A}_{\mathcal{O}}^{\natural})_{\gamma} = \mathcal{A}_{c, \sigma_{\gamma}}^{\natural}, \quad \forall \gamma \in \mathcal{O} \quad (c = s(\gamma))$$

(see 3.3, 2.16.3). In other words, $\mathcal{A}_{\mathcal{O}}^{\natural}$ is the restriction of $\mathcal{A}_{tw}^{\natural}$ to \mathcal{O} . Define also the cyclic $\mathcal{N}_{\mathcal{O}}$ -sheaf $\mathcal{A}_{(\mathcal{O})}^{\natural} := (\mathcal{A}_{\mathcal{O}}^{\natural})_{(\theta)}$ (see 3.26); the stalk of $\mathcal{A}_{(\mathcal{O})}^{\natural}$ at $\gamma \in \mathcal{O}$ is $\text{Coinv}_{<\gamma>}(\mathcal{A}_c^{\otimes(n+1)})$.

3.38 Localization: For \mathcal{O} as before, we can define the cyclic vector space $(\mathcal{A} \rtimes \mathcal{G})_{\mathcal{O}}^{\natural}$ as in 3.33 with the only difference we replace $B^{(n)}$ by $B_{\mathcal{O}}^{(n)} = \{\gamma_0, \gamma_1, \dots, \gamma_n \in B^{(n)} : \gamma_0 \gamma_1 \dots \gamma_n \in \mathcal{O}\}$. Denote its homologies by $HH_*(\mathcal{A} \rtimes \mathcal{G})_{\mathcal{O}}, HC_*(\mathcal{A} \rtimes \mathcal{G})_{\mathcal{O}}, HP_*(\mathcal{A} \rtimes \mathcal{G})_{\mathcal{O}}$. As in 3.36 we have:

$$HH_*(\mathcal{A} \rtimes \mathcal{G})_{\mathcal{O}} = HH_*(\mathcal{Z}_{\mathcal{O}}, \theta; \mathcal{A}_{\mathcal{O}}^{\natural}), \quad HC_*(\mathcal{A} \rtimes \mathcal{G})_{\mathcal{O}} = HC_*(\mathcal{Z}_{\mathcal{O}}, \theta; \mathcal{A}_{\mathcal{O}}^{\natural}),$$

and the analogue for HP_* . If \mathcal{O} is open in $B^{(0)}$, there are “extension by 0” maps: $HH_*(\mathcal{A} \rtimes \mathcal{G})_{\mathcal{O}} \rightarrow HH_*(\mathcal{A} \rtimes \mathcal{G})$; if \mathcal{O} is closed in $B^{(0)}$, there are “restriction” maps: $HH_*(\mathcal{A} \rtimes \mathcal{G}) \rightarrow HH_*(\mathcal{A} \rtimes \mathcal{G})_{\mathcal{O}}$. The same discussion applies to HC_*, HP_* . The following is obvious:

Proposition 3.39 *If $B^{(0)} = \bigcup \mathcal{O}$ is a \mathcal{G} -invariant disjoint open covering of $B^{(0)}$, then:*

$$HH_*(\mathcal{A} \rtimes \mathcal{G}) = \bigoplus_{\mathcal{O}} HH_*(\mathcal{A} \rtimes \mathcal{G})_{\mathcal{O}}, \quad HC_*(\mathcal{A} \rtimes \mathcal{G}) = \bigoplus_{\mathcal{O}} HC_*(\mathcal{A} \rtimes \mathcal{G})_{\mathcal{O}},$$

and the analogue for HP_* .

3.40 Elliptic case: We call $\mathcal{O} \subset B^{(0)}$ elliptic if it is \mathcal{G} -invariant and $\text{ord}(\gamma) < \infty$, for all $\gamma \in \mathcal{O}$. From 3.36, 3.26, 3.10, 3.11 we get (compare to A6.2 in [16], section 2 in [38]):

Theorem(elliptic case): *If \mathcal{O} is elliptic, then $\mathcal{A}_{(\mathcal{O})}^{\natural}$ is a cyclic $\mathcal{N}_{\mathcal{O}}$ -sheaf and $HH_*(\mathcal{A} \rtimes \mathcal{G})_{\mathcal{O}} = HH_*(\mathcal{N}_{\mathcal{O}}; \mathcal{A}_{(\mathcal{O})}^{\natural})$, $HC_*(\mathcal{A} \rtimes \mathcal{G})_{\mathcal{O}} = HC_*(\mathcal{N}_{\mathcal{O}}; \mathcal{A}_{(\mathcal{O})}^{\natural})$, $HP_*(\mathcal{A} \rtimes \mathcal{G})_{\mathcal{O}} = HP_*(\mathcal{N}_{\mathcal{O}}; \mathcal{A}_{(\mathcal{O})}^{\natural})$. In particular, there are Feigin-Tsygan-Nistor type spectral sequences:*

$$E_{p,q}^2 = H_p(\mathcal{N}_{\mathcal{O}}; \widetilde{HC}_q(\mathcal{A}_{(\mathcal{O})}^{\natural})) \implies HC_{p+q}(\mathcal{A} \rtimes \mathcal{G})_{\mathcal{O}},$$

$$E_{p,q}^2 = HC_p(H_q(\mathcal{N}_{\mathcal{O}}; \mathcal{A}_{(\mathcal{O})}^{\natural})) \implies HC_{p+q}(\mathcal{A} \rtimes \mathcal{G})_{\mathcal{O}},$$

and the analogue for HH_* .

The localizations at units (i.e. at $\mathcal{O} = \mathcal{G}^{(0)}$) are usually denoted by the subscript [1] instead of \mathcal{O} . We get they are equal to $HH_*(\mathcal{G}; \mathcal{A}^{\natural})$, $HC_*(\mathcal{G}; \mathcal{A}^{\natural})$, $HP_*(\mathcal{G}; \mathcal{A}^{\natural})$ and the corresponding spectral sequences have at the second level:

$$H_p(\mathcal{G}; \widetilde{HH}_q(\mathcal{A}^{\natural})) \implies HH_{p+q}(\mathcal{A} \rtimes \mathcal{G})_{[1]}, \quad HH_p(H_q(\mathcal{G}; \mathcal{A}^{\natural})) \implies HH_{p+q}(\mathcal{A} \rtimes \mathcal{G})_{[1]},$$

$$H_p(\mathcal{G}; \widetilde{HC}_q(\mathcal{A}^{\natural})) \implies HC_{p+q}(\mathcal{A} \rtimes \mathcal{G})_{[1]}, \quad HC_p(H_q(\mathcal{G}; \mathcal{A}^{\natural})) \implies HC_{p+q}(\mathcal{A} \rtimes \mathcal{G})_{[1]}.$$

In the case of crossed products by groups, this is 2.6 in [38]. We also know (from 2.25) the form of the boundaries $d_{p,q}^2$. This generalizes a similar result for crossed products by groups (see Prop. 3.2 in [4]).

3.41 Hyperbolic case: We call $\mathcal{O} \subset B^{(0)}$ hyperbolic if it is \mathcal{G} -invariant and $\text{ord}(\gamma) = \infty$, for all $\gamma \in \mathcal{O}$. Denote by $e_{\mathcal{O}} \in H^2(\mathcal{N}_{\mathcal{O}}; \mathbb{C})$ the Euler class of the (hyperbolic) cyclic groupoid $\mathcal{Z}_{\mathcal{O}}$. From 3.36, 3.27 we get (compare to A6.1 in [16], 1.8 in [9], section 3 in [38]):

Theorem (hyperbolic case): *If \mathcal{O} is hyperbolic, then the $HC_*(\mathcal{A} \rtimes \mathcal{G})_{\mathcal{O}}$ are modules over the ring $H^*(\mathcal{N}_{\mathcal{O}}; \mathbb{C})$ and S in the SBI-sequence is the (cap-) product by the Euler class $e_{\mathcal{O}} \in H^2(\mathcal{N}_{\mathcal{O}}; \mathbb{C})$. Moreover, the $\widetilde{HH}_q(\mathcal{A}_{\mathcal{O}}^{\natural}) \in \text{Sh}(\mathcal{Z}_{\mathcal{O}})$ are $\mathcal{N}_{\mathcal{O}}$ -sheaves and there are spectral sequences:*

$$E_{p,q}^2 = H_p(\mathcal{Z}_{\mathcal{O}}; \widetilde{HH}_q(\mathcal{A}_{\mathcal{O}}^{\natural})) \implies HH_{p+q}(\mathcal{A} \rtimes \mathcal{G})_{\mathcal{O}},$$

$$E_{p,q}^2 = H_p(\mathcal{N}_{\mathcal{O}}; \widetilde{HH}_q(\mathcal{A}_{\mathcal{O}}^{\natural})) \implies HC_{p+q}(\mathcal{A} \rtimes \mathcal{G})_{\mathcal{O}}.$$

4 Cyclic Homology of Smooth Étale Groupoids

4.1 Cyclic Homology of Smooth Étale Groupoids

In this subsection, using the results of the previous section, we compute the cyclic homology of the convolution algebra of a smooth étale groupoid.

Let \mathcal{G} be a smooth étale groupoid. Recall that if \mathcal{G} is Hausdorff then its convolution algebra is defined as $\mathcal{C}_c^{\infty}(\mathcal{G}) = \{a : \mathcal{G}^{(1)} \rightarrow \mathbb{C} : a \text{ is compactly supported and smooth}\}$ with the convolution product: $(ab)(\gamma) = \sum_{\gamma=\gamma_1\gamma_2} a(\gamma_1)b(\gamma_2)$. This is a locally convex algebra, which is non-unital in general. Its Hochschild and cyclic homologies are computed (cf. 3.3) by using the (b, b') -complex of $\mathcal{C}_c^{\infty}(\mathcal{G})^{\natural}$ and certain topological tensor product. As remarked in [6], the relevant definition is:

$$\mathcal{C}_c^{\infty}(\mathcal{G})^{\natural}(n) = \mathcal{C}_c^{\infty}(\mathcal{G}^{n+1}),$$

with the structure maps:

$$d_i(a_0, \dots, a_n) = \begin{cases} (a_0, \dots, a_i a_{i+1}, \dots, a_n) & \text{if } 0 \leq i \leq n-1 \\ (a_n a_0, a_1, \dots, a_{n-1}) & \text{if } i = n \end{cases},$$

$$t(a_0, \dots, a_n) = (a_n, a_0, a_1, \dots, a_{n-1}).$$

In the general (i.e. non-Hausdorff) case, $\mathcal{C}_c^{\infty}(\mathcal{G})$ still makes sense as an algebra (see 3.32.2). Rather than going into details concerning the topology, following [6], we take the previous equalities as definition of the cyclic vector space $\mathcal{C}_c^{\infty}(\mathcal{G})^{\natural}$ (this is the relevant object for defining the Chern-character). It is important to emphasize here that, in contrast with [6] where Connes' definition of $\mathcal{C}_c^{\infty}(M)$ for a non-Hausdorff manifold M is used, we work with our definition as given in 2.14 (and this is essential). The homologies of the cyclic vector space $\mathcal{C}_c^{\infty}(\mathcal{G})^{\natural}$ (see 3.2) are denoted by $HH_*(\mathcal{C}_c^{\infty}(\mathcal{G}))$, $HC_*(\mathcal{C}_c^{\infty}(\mathcal{G}))$, $HP_*(\mathcal{C}_c^{\infty}(\mathcal{G}))$.

Denote $\mathcal{C}_{\mathcal{G}(0)}^{\infty} = \mathcal{A}$; it is a \mathcal{G} -sheaf cf. 3.7. In the definitions of $\mathcal{A}^{\otimes n}$, $\mathcal{A}^{\boxtimes n}$ we take into account the topology, as explained in 3.4. The following is an extension of 3.2 in [6] to the non-Hausdorff case:

Proposition 4.1 : *For any smooth étale groupoid \mathcal{G} , $HH_*(\mathcal{C}_c^{\infty}(\mathcal{G}))$, $HC_*(\mathcal{C}_c^{\infty}(\mathcal{G}))$, $HP_*(\mathcal{C}_c^{\infty}(\mathcal{G}))$ are isomorphic to $HH_*(\mathcal{A} \rtimes \mathcal{G})$, $HC_*(\mathcal{A} \rtimes \mathcal{G})$, $HP_*(\mathcal{A} \rtimes \mathcal{G})$.*

Since \mathcal{G} is étale, the elements $u \in \mathcal{C}_c^\infty(\mathcal{G}) = \Gamma_c(\mathcal{G}; s^* \mathcal{A})$ can be viewed as functions $\mathcal{G} \ni \gamma \mapsto u(\gamma) \in (s^* \mathcal{A})_\gamma = \mathcal{A}_{s(\gamma)}$ and the convolution product becomes $(u * v)(\gamma) = \sum_{\gamma = \gamma_1 \gamma_2} (u(\gamma_1) \gamma_2) v(\gamma_2)$ (in other words, $\mathcal{C}_c^\infty(\mathcal{G}) = \mathcal{A} \rtimes_{\text{alg}} \mathcal{G}$). We will simply denote $u * v$ by uv . In the same way, the elements:

$$u \in \mathcal{C}_c^\infty(\mathcal{G})^{\natural(n)} = \mathcal{C}_c^\infty(\mathcal{G}^{n+1}) = \Gamma_c(\mathcal{G}^{n+1}; s_{n+1}^* \mathcal{A}^{\boxtimes(n+1)})$$

(here $s_n = s \times \dots \times s$ for n times and we use the notations from 3.4) can be viewed as functions:

$$\mathcal{G}^{n+1} \ni (\gamma_0, \dots, \gamma_n) \mapsto u(\gamma_0, \dots, \gamma_n) \in (\mathcal{A} \boxtimes \dots \boxtimes \mathcal{A})_{(s(\gamma_0), \dots, s(\gamma_n))}.$$

This is the only way we are going to look at elements in $\mathcal{C}_c^\infty(\mathcal{G}^{n+1})$. With this it is straightforward to write the formulas for the t 's and the d_i 's in the general case.

proof of 4.1: From 3.34 we get a projection (restriction to the $B^{(n)}$'s in fact) $\pi : \mathcal{C}_c^\infty(\mathcal{G})^{\natural} \longrightarrow (\mathcal{A} \rtimes \mathcal{G})^{\natural}$ which is compatible with the t 's and the d_i 's. It is enough to prove that π is a quasi-isomorphism between both the b and the b' complexes. Denote $C_\bullet = \mathcal{C}_c^\infty(\mathcal{G})^{\natural}$, $A_\bullet = \text{Ker}(\pi)$; so $(\mathcal{A} \rtimes \mathcal{G})^{\natural} = C_\bullet / A_\bullet$. We prove that $((\mathcal{A} \rtimes \mathcal{G})^{\natural}, b')$, (C_\bullet, b') and (A_\bullet, b) are acyclic. For the two b' complexes this is standard. Indeed, for the first complex we use the degeneracy s_n to get a contraction. For the second complex we use local units to get local contractions; more precisely, if $u \in C_n$ has $b'u = 0$, then $u = b'v$ where $v = u \otimes \varphi \in C_{n+1}$, $\varphi \in \mathcal{C}_c^\infty(\mathcal{G}^{(0)})$ such that $\varphi = 1$ around the compact $K = \{s(\gamma_n) : u(\gamma_0, \dots, \gamma_n) \neq 0\}$ in $\mathcal{G}^{(0)}$.

We are left with (A_\bullet, b) . We will construct two double complexes $\{C_{p,q}; p \geq -1, q \geq 0\}$, $\{A_{p,q}; p \geq -1, q \geq 0\}$ with $C_{-1,\bullet} = C_\bullet$, $A_{-1,\bullet} = A_\bullet$ and such that all the columns $A_{\bullet,q}, q \geq 0$ and all the rows $A_{p,\bullet}, p \geq 0$ are acyclic. Of course, it is enough to construct $A_{\bullet,\bullet}$ with these properties; the only role of $C_{\bullet,\bullet}$ is to facilitate the definition of $A_{\bullet,\bullet}$. For this we put for $p, q \geq 0$:

$$C_{p,q} = \mathcal{C}_c^\infty(\mathcal{G}^{q+2} \times \mathcal{G}^p), \quad A_{p,q} = \{u \in C_{p,q} : u|_{\mathcal{G}^{(q+2)} \times \mathcal{G}^p} = 0\},$$

and $C_{-1,\bullet} = C_\bullet$, $A_{-1,\bullet} = A_\bullet$. The boundaries are defined as follows:

The boundaries for the row $p = \text{constant}$ of $C_{\bullet,\bullet}$ are defined by analogy with $(C_\bullet, b') \widehat{\otimes} C_c^\infty(\mathcal{G}^p)$ i. e. :

$$\dots \xrightarrow{d^r} C_{p,1} \xrightarrow{d^r} C_{p,0}, \quad d^r = \sum (-1)^i d_i^r,$$

$$d_i^r(u_0, \dots, u_{q+1}; v_1, \dots, v_p) = (u_0, \dots, u_i u_{i+1}, \dots, u_{q+1}; v_1, \dots, v_p), \quad 0 \leq i \leq q.$$

We keep the same formulas to define the row $p = \text{constant}$ of $A_{\bullet,\bullet}$. To see that $A_{p,\bullet}$ is acyclic for $p \geq 0$ remark that $(C_{p,\bullet}/A_{p,\bullet}, b')$ and $(C_{p,\bullet}, b')$ are acyclic; this can be viewed in the same way as for $(C_\bullet/A_\bullet, b')$ and (C_\bullet, b') .

The boundaries for the column $q = \text{constant}$ of $C_{\bullet,\bullet}$ are defined by analogy with the complex computing $HH_*(\mathcal{C}_c^\infty(\mathcal{G}), \mathcal{C}_c^\infty(\mathcal{G}^{q+2}))$ together with an augmentation; more precisely, define them by:

$$\dots \xrightarrow{d^c} C_{1,q} \xrightarrow{d^c} C_{0,q} \xrightarrow{d_{(-1)}^c} C_{-1,q} = C_q, \quad d^c = \sum_{i=0}^p (-1)^i d_i^c,$$

$$d_i^c(u_0, \dots, u_{q+1}; v_1, \dots, v_p) = \begin{cases} (u_0, \dots, u_q, u_{q+1} v_1, v_2, \dots, v_p) & \text{if } i = 0 \\ (u_0, \dots, u_{q+1}; v_1, \dots, v_i v_{i+1}, \dots, v_p) & \text{if } 0 \leq i \leq p-1, \\ (v_p u_0, \dots, u_{q+1}; v_1, \dots, v_{p-1}) & \text{if } i = p \end{cases}$$

$$d_{(-1)}^c(u_0, \dots, u_{q+1}) = (u_{q+1} u_0, \dots, u_q).$$

The same formulas define the column $q = \text{constant}$ of $A_{\bullet,\bullet}$. To prove that $A_{\bullet,q}$ is acyclic, assume for simplicity of notation that $q = 0$. For any $\varphi \in \mathcal{C}_c^\infty(\mathcal{G}^{(0)})$, define a degree 1 linear map of $C_{\bullet,0}$ by:

$$h_\varphi : C_{p,0} \longrightarrow C_{p+1,0} \quad h_\varphi(u_0, u_1; v_1, \dots, v_p) = (u_0, \varphi; \varphi u_1, v_1, \dots, v_p), \quad p \geq 0$$

$$h_\varphi : C_{-1,0} \longrightarrow C_{0,0} \quad h_\varphi(u_0) = (\varphi u_0, \varphi).$$

For any $u \in C_{p,0} = C_c^\infty(\mathcal{G}^{p+2})$ we have the naive formulas (correct in the Hausdorff case):

$$(d^c h_\varphi u)(\gamma_0, \dots, \gamma_{p+1}) = \varphi^2(t(\gamma_1))u(\gamma_0, \dots, \gamma_{p+1}) + \varphi(\gamma_1)\varphi(t(\gamma_2))(d^c u)(\gamma_0, \gamma_2, \dots, \gamma_{p+1}),$$

which can be written in general:

$$\begin{aligned} (d^c h_\varphi u)(\gamma_0, \dots, \gamma_{p+1}) &= (1 \otimes \text{germ}_{t(\gamma_1)}(\varphi^2) \otimes 1 \otimes \dots \otimes 1) * u(\gamma_0, \dots, \gamma_{p+1}) + \\ &+ i_{\text{germ}_{\gamma_1}(\varphi)}^{(2)}((1 \otimes \text{germ}_{t(\gamma_2)}(\varphi) \otimes 1 \otimes \dots \otimes 1) * (d^c u)(\gamma_0, \gamma_2, \dots, \gamma_{p+1})). \end{aligned}$$

Here $i_v^{(2)}$ denotes "inserting v on the second place" and " $*$ " is the stalkwise product. In general we do not have: $h_\varphi(A_{p,0}) \subset A_{p+1,0}$. Fix a metric ρ defining the topology of $\mathcal{G}^{(0)}$. Take $u \in A_{p,0}$ to be a cycle. From 2.12 we can choose $\epsilon > 0$ such that:

$$\rho(s(\gamma_0), t(\gamma_1)) < \epsilon \Rightarrow u(\gamma_0, \gamma_1, \dots, \gamma_p) = 0.$$

For any $\varphi \in C_c^\infty(\mathcal{G}^{(0)})$ with $\text{diam}(\text{supp}\varphi) < \epsilon/6$ we see that $h_\varphi(u) \in A_{p+1,0}$. Now $u = d^c v$ is the boundary of $v = \sum h_{\varphi_i} u$ where $\varphi_i \in C_c^\infty(\mathcal{G}^{(0)})$ is a finite set of functions as before such that $\sum \varphi_i^2 = 1$ around the compact $K = \{t(\gamma_1) : u(\gamma_0, \dots, \gamma_n) \neq 0\} \subseteq \mathcal{G}^{(0)}$.

The following four theorems are generalizations of the computations performed by Burghelea for groups (Theorem I in [9]). In the case of smooth Hausdorff étale groupoids, the computation of the elliptic components was done by Brylinski and Nistor: Theorem 5.6 in [6] computes these components in terms of homology of some double complexes. Our Theorem 4.4 is an extension of that result, in a slightly more precise form. Emphasize also that our proof of Theorem 4.4, in contrast to the one given in [6], will make use of the quasi-isomorphism ensured by 3.5 just for $\varphi = id$.

From 3.38 we get (see also Proposition 3.3 in [6]):

Theorem 4.2 (localization): *For $\mathcal{O} \subset B^{(0)}$ a \mathcal{G} -invariant subset, the localized homologies at \mathcal{O} are defined. We have linear maps $HH_*(\mathcal{C}_c^\infty(\mathcal{G}))_{\mathcal{O}} \longrightarrow HH_*(\mathcal{C}_c^\infty(\mathcal{G}))$ if \mathcal{O} is open in $B^{(0)}$, and $HH_*(\mathcal{C}_c^\infty(\mathcal{G})) \longrightarrow HH_*(\mathcal{C}_c^\infty(\mathcal{G}))_{\mathcal{O}}$ if \mathcal{O} is closed in $B^{(0)}$, and the same applies to HC_* , HP_* .*

If $B^{(0)} = \bigcup \mathcal{O}$ is a \mathcal{G} -invariant disjoint open covering of $B^{(0)}$, then:

$$HH_*(\mathcal{C}_c^\infty(\mathcal{G})) = \bigoplus_{\mathcal{O}} HH_*(\mathcal{C}_c^\infty(\mathcal{G}))_{\mathcal{O}}, \quad HC_*(\mathcal{C}_c^\infty(\mathcal{G})) = \bigoplus_{\mathcal{O}} HC_*(\mathcal{C}_c^\infty(\mathcal{G}))_{\mathcal{O}},$$

and the analogue for HP_ ; moreover, everything is compatible with the SBI-sequences.*

Theorem 4.3 (localization at units): *For any smooth étale groupoid \mathcal{G} :*

$$HP_0(\mathcal{C}_c^\infty(\mathcal{G}))_{\Omega J} = \prod_{k \text{ even}} H_k(\mathcal{G}; \mathbb{C}),$$

$$HP_1(\mathcal{C}_c^\infty(\mathcal{G}))_{\Omega J} = \prod_{k \text{ odd}} H_k(\mathcal{G}; \mathbb{C}).$$

proof: First of all, using 3.5 for $\varphi = id$ we get a quasi-isomorphism of sheaves on $\mathcal{G}^{(0)}$:

$$(\mathcal{A}^\sharp, b) \xrightarrow{\sim} (\Omega_{\mathcal{G}^{(0)}}^*, 0).$$

It is well known (see [11]) that it makes the B -boundary compatible with de Rham boundary. This, 4.1, 3.40 for $\mathcal{O} = \mathcal{G}^{(0)}$ and 2.21 give the proof.

Theorem 4.4 (elliptic case): For any smooth étale groupoid \mathcal{G} , and any elliptic $\mathcal{O} \subset B^{(0)}$:

$$\begin{aligned} HP_0(\mathcal{C}_c^\infty(\mathcal{G}))_{\mathcal{O}} &= \prod_{k\text{-even}} H_k(\mathcal{N}_{\mathcal{O}}; \mathbb{C}) = \prod_{k\text{-even}} H_k(\mathcal{Z}_{\mathcal{O}}; \mathbb{C}), \\ HP_1(\mathcal{C}_c^\infty(\mathcal{G}))_{\mathcal{O}} &= \prod_{k\text{-odd}} H_k(\mathcal{N}_{\mathcal{O}}; \mathbb{C}) = \prod_{k\text{-odd}} H_k(\mathcal{Z}_{\mathcal{O}}; \mathbb{C}). \end{aligned}$$

(for the precise definition of the centralizer $\mathcal{Z}_{\mathcal{O}}$ and the normalizer $\mathcal{N}_{\mathcal{O}}$ of \mathcal{O} , see 3.37).

proof: From 4.1 and 3.40 we have $HP_*(\mathcal{C}_c^\infty(\mathcal{G}))_{\mathcal{O}} = HP_*(\mathcal{N}_{\mathcal{O}}; \mathcal{A}_{\mathcal{O}}^{\natural})$. From the description of $\mathcal{A}_{\mathcal{O}}^{\natural}$ (see 3.37) it is not difficult to see that $\mathcal{A}_{\mathcal{O}}^{\natural} = (\mathcal{C}_V^\infty)^{\natural}_{\mathcal{O}}$ where V is an open neighborhood of \mathcal{O} in $B^{(0)}$ which is a submanifold of \mathcal{G} (the existence of V is ensured by the first part of 3.5). Using 3.5 for $\varphi = id$ and the fact that $0 \rightarrow \mathbb{C} \rightarrow \Omega_M^0|_A \rightarrow \Omega_M^0|_A \rightarrow \dots$ is a c -soft resolution of $\mathbb{C} \in Sh(A)$ for any manifold M and any $A \subset M$ ([25]) we get, as in the previous proof, the relations expressing HP_* in terms of the homology of $\mathcal{N}_{\mathcal{O}}$. The passage to $\mathcal{Z}_{\mathcal{O}}$ is ensured by the spectral sequence for the projection map $\varphi : \mathcal{Z}_{\mathcal{O}} \rightarrow \mathcal{N}_{\mathcal{O}}$ (it degenerates since $\gamma/\varphi \simeq \langle \gamma \rangle$ is a finite cyclic group for all $\gamma \in \mathcal{O}$).

Remark that 4.2 and this result ensure us that, for any \mathcal{O} as in 4.4, such that \mathcal{O} is closed in $B^{(0)}$, there is a localized Connes-Chern-Karoubi character:

$$Ch_{\mathcal{O}} : K_*^{alg}(\mathcal{C}_c^\infty(\mathcal{G})) \rightarrow H_*(\mathcal{Z}_{\mathcal{O}}; \mathbb{C}).$$

4.5 Definition: We call $\gamma \in B^{(0)}$ stable if its germ $\sigma_\gamma : (\mathcal{G}^{(0)}, s(\gamma)) \rightarrow (\mathcal{G}^{(0)}, s(\gamma))$ (as defined in 2.16) is stable (see 3.5). We call $\mathcal{O} \subset B^{(0)}$ stable if it is \mathcal{G} -invariant and every $\gamma \in \mathcal{O}$ is stable.

Theorem 4.6 (hyperbolic case): For any smooth étale groupoid \mathcal{G} , and any hyperbolic $\mathcal{O} \subset B^{(0)}$, $HC_*(\mathcal{C}_c^\infty(\mathcal{G}))_{\mathcal{O}}$ is a module over $H^*(\mathcal{N}_{\mathcal{O}}; \mathbb{C})$ and the S in the SBI-sequence is the (cap-) product by the Euler class $e_{\mathcal{O}} \in H^2(\mathcal{N}_{\mathcal{O}})$.

Moreover, if \mathcal{O} is stable:

$$\begin{aligned} HH_n(\mathcal{C}_c^\infty(\mathcal{G}))_{\mathcal{O}} &= \bigoplus_{p+q=n} H_p(\mathcal{Z}_{\mathcal{O}}; \Omega_{B^{(0)}}^q|_{\mathcal{O}}), \\ HC_n(\mathcal{C}_c^\infty(\mathcal{G}))_{\mathcal{O}} &= \bigoplus_{p+q=n} H_p(\mathcal{N}_{\mathcal{O}}; \Omega_{B^{(0)}}^q|_{\mathcal{O}}), \end{aligned}$$

and the SBI-sequence is the Gysin sequence for $\mathcal{Z}_{\mathcal{O}} \rightarrow \mathcal{N}_{\mathcal{O}}$ (see 3.18).

Remark that if \mathcal{O} is stable, there is a neighborhood V of \mathcal{O} in $B^{(0)}$ which is a submanifold of \mathcal{G} . In particular $\Omega_V^* \in Sh(V)$ makes sense. The notation $\Omega_{B^{(0)}}^*|_{\mathcal{O}}$ should be understood as the restriction of Ω_V^* to \mathcal{O} ; when \mathcal{O} is open in $B^{(0)}$, this is simply $\Omega_{\mathcal{O}}^*$.

proof: The first part is a consequence of 4.1, 3.41. We are left with the last two equalities. We prove the second one (the first can be proved in the same way or as a consequence of 3.5, 4.1, 3.36). The proof is an improvement of the second spectral sequence in 3.27 for the cyclic category $(\mathcal{Z}_{\mathcal{O}}, \theta)$. There we used the spectral sequence of $\pi_2' : \Lambda_\infty \wedge \mathcal{Z}_{\mathcal{O}} \rightarrow \mathcal{N}_{\mathcal{O}}$ and the strong deformation retract $\gamma/\pi_2' \leftarrow \Lambda_\infty \wedge \langle \gamma \rangle = \Lambda_\infty$ for all $\gamma \in \mathcal{O}$. Assume for simplicity that \mathcal{O} is open in $B^{(0)}$. We have from 3.38:

$$HC_*(\mathcal{C}_c^\infty(\mathcal{G}))_{\mathcal{O}} = H_*(\Lambda_\infty \wedge \mathcal{Z}_{\mathcal{O}}; \mathcal{A}_{\mathcal{O}}^{\natural}).$$

Due to the *SBI* trick (see 3.22) and 3.5, we can replace $\mathcal{A}_{\mathcal{O}}^{\natural}$ by the θ -cyclic $\mathcal{Z}_{\mathcal{O}}$ -sheaf $\mathcal{B}^{\natural} = (\mathcal{C}_{\mathcal{O}}^{\infty})^{\natural}$. This is in fact a cyclic $\mathcal{N}_{\mathcal{O}}$ -sheaf. We use (see 2.26) that the spectral sequence for π_2' comes from an equality:

$$H_*(\Lambda_{\infty} \wedge \mathcal{Z}_{\mathcal{O}}; \mathcal{B}^{\natural}) = \mathbb{H}_*(\mathcal{N}_{\mathcal{O}}; (\mathcal{L}\pi_2')! \mathcal{B}^{\natural}),$$

where $\tilde{H}_q((\mathcal{L}\pi_2')! \mathcal{B}^{\natural}) \in Sh(\mathcal{N}_{\mathcal{O}})$ has the stalk at $\gamma \in \mathcal{O}$:

$$H_q(\gamma/\pi_2'; \mathcal{B}^{\natural}) = H_q(\Lambda_{\infty}; \mathcal{B}_{\gamma}^{\natural})$$

(the last equality follows from 2.30). We get in this way a quasi-isomorphism of complexes of sheaves on \mathcal{O} : $(\mathcal{L}\pi_2')! \mathcal{B}^{\natural} \simeq (\mathcal{B}^{\natural}, b)$, b = the Hochschild boundary. This is in $Sh(\mathcal{N}_{\mathcal{O}})$ so:

$$HC_*(\mathcal{C}_c^{\infty}(\mathcal{G}))_{\mathcal{O}} = \mathbb{H}_*(\mathcal{N}_{\mathcal{O}}; (\mathcal{B}^{\natural}, b)).$$

Using once more 3.5 (for $\alpha = id$): $(\mathcal{B}^{\natural}, b) \simeq (\Omega_{\mathcal{O}}^*, 0)$ and the second equality follows.

4.7 Corollary (compare to [38]): *If \mathcal{O} is hyperbolic and $\mathcal{N}_{\mathcal{O}}$ has finite cohomological dimension, then $HP_*(\mathcal{C}_c^{\infty}(\mathcal{G}))_{\mathcal{O}} = 0$.*

4.2 The case of cohomology

We recall first some standard facts about sheaves, and the cohomology of étale groupoids in order to make possible an analogous treatment of the cyclic cohomology for smooth étale groupoids.

4.8 Cohomology via Bar-complexes: We will need a version of 2.19, 2.20 for computing the cohomology $H^*(\mathcal{G}; \mathcal{A})$ for an étale groupoid \mathcal{G} and a left \mathcal{G} -sheaf \mathcal{A} (i.e. $\mathcal{A} \in Sh(\mathcal{G}^{op})$ cf. 2.15). This is well known (see [1, 33] or [21] for a direct approach); we briefly review it. By definition, $H^*(\mathcal{G}; -)$ are the right derived functors of $\Gamma^{\mathcal{G}} = Hom_{Sh(\mathcal{G}^{op})}(\mathbb{C}, -)$. We have a sequence of étale groupoids:

$$\mathcal{G}^{(q)} \xrightarrow{\alpha_q} \mathcal{G}^{(0)} \xrightarrow{i} \mathcal{G}, \quad \alpha_q(g_1, \dots, g_q) = t(g_1), \quad i = \text{the inclusion}$$

(here $\mathcal{G}^{(q)}, \mathcal{G}^{(0)}$ are spaces, viewed as étale groupoids as in 2.2.1). We have the induced functors:

$$Sh(\mathcal{G}^{(q)}) \begin{array}{c} \xrightarrow{\alpha_{q*}} \\ \xleftarrow{\alpha_q^*} \end{array} Sh(\mathcal{G}^{(0)}) \begin{array}{c} \xrightarrow{i_*} \\ \xleftarrow{i^*} \end{array} Sh(\mathcal{G}^{op})$$

and i_* is right adjoint to i^* . Denoting $\mathcal{C} = i_* i^* : Sh(\mathcal{G}^{op}) \rightarrow Sh(\mathcal{G}^{op})$ and using the unit of the adjunction $\eta : Id \rightarrow \mathcal{C}$ we get for any $\mathcal{A} \in Sh(\mathcal{G}^{op})$, a resolution of \mathcal{A} by (left) \mathcal{G} -sheaves:

$$\mathcal{A} \longrightarrow \mathcal{C}(\mathcal{A}) \rightrightarrows \mathcal{C}^2(\mathcal{A}) \rightrightarrows \mathcal{C}^3(\mathcal{A}) \dots$$

From the spectral sequences induced by i_*, α_{q*} we have for any $\mathcal{A} \in Sh(\mathcal{G}^{op}), \mathcal{B} \in Sh(\mathcal{G}^{(0)})$:

$$H^*(\mathcal{G}; i_* i^* \mathcal{A}) = H^*(\mathcal{G}^{(0)}; i^* \mathcal{A}) \quad , \quad H^*(\mathcal{G}^{(0)}; \alpha_{q*} \alpha_q^* \mathcal{B}) = H^*(\mathcal{G}^{(q)}; \alpha_q^* \mathcal{B}).$$

Using also that $(i^* i_*)^q i^* = \alpha_{q*} \alpha_q^* i^*$, we get:

$$H^*(\mathcal{G}; \mathcal{C}^q(\mathcal{A})) = H^*(\mathcal{G}^{(q-1)}; \alpha_{q-1}^* \mathcal{A}).$$

We say that \mathcal{A} is \mathcal{G} -acyclic if the left side of the previous equality is 0 for each $* > 0, q \geq 1$; in this case we get that $\mathcal{A} \rightarrow \mathcal{C}^{\bullet}(\mathcal{A})$ is a resolution of \mathcal{A} by $\Gamma^{\mathcal{G}}$ -acyclic objects, so it can be used for

computing $H^*(\mathcal{G}; \mathcal{A})$. In other words, if \mathcal{A} is \mathcal{G} -acyclic, then $H^*(\mathcal{G}; \mathcal{A})$ is computed by a co-simplicial vector space with

$$B^\bullet(\mathcal{G}; \mathcal{A}) = \Gamma^{\mathcal{G}}(\mathcal{C}^{\bullet+1}(\mathcal{A})) = H^0(\mathcal{G}; \mathcal{C}^{\bullet+1}(\mathcal{A})) = \Gamma(\mathcal{G}^{(\bullet)}; \alpha_* \mathcal{A})$$

(after spelling out the co-boundaries, we get formulas which are similar to the ones in 2.19). More generally, if $\mathcal{S} \in Sh(\mathcal{G}^{op})$, then $H^*(\mathcal{G}; \mathcal{S})$ is computed by the double complex $B^\bullet(\mathcal{G}; \mathcal{A}^\bullet)$ where $\mathcal{S} \rightarrow \mathcal{A}^\bullet$ is any resolution in $Sh(\mathcal{G}^{op})$ by \mathcal{G} -acyclic sheaves. The same discussion carries over to étale categories.

4.9 Dual sheaves: Let M be a space, $\mathcal{A} \in Sh(M)$ c -soft. The correspondence $U \mapsto \Gamma_c(U; \mathcal{A})^\vee$ (recall that "v" stands for the algebraic dual) defines a sheaf on M , denoted \mathcal{A}^\vee ; it is flabby (even injective; see [25]). This is well known in the Hausdorff case and carries over to the general case ([15]). The construction has the property that for any $f : M \rightarrow N$ continuous, and for any c -soft sheaf $\mathcal{A} \in Sh(M)$:

$$f_!(\mathcal{A})^\vee = f_*(\mathcal{A}^\vee).$$

When applied to sheaves on an étale category, it gives a correspondence:

$$Sh(\mathcal{G}) \ni \mathcal{A}, c\text{-soft} \mapsto \mathcal{A}^\vee \in Sh(\mathcal{G}^{op}), \mathcal{G}\text{-acyclic},$$

and $B_\bullet(\mathcal{G}; \mathcal{A})^\vee = B^\bullet(\mathcal{G}; \mathcal{A}^\vee)$.

4.10 Currents: Let M be a manifold (not necessarily Hausdorff) of dimension n . There is an obvious notion of q -currents: $\Omega_q(M) = \{u : \Omega_q^q(M) \rightarrow \mathbb{C} : u|_U \in \Omega_q(U) \text{ for all local coordinates charts } U\}$ ($\Omega_q(U)$ has the usual meaning if U is Hausdorff). We get the sheaf of q -currents on M which is a kind of topological dual of the sheaf Ω_M^q ; we denote it by $(\Omega_M^q)'$. In general we have two different resolutions of the (complex) orientation sheaf: $or_M \rightarrow (\Omega_M^n)' \rightarrow (\Omega_M^{n-1})' \rightarrow \dots$ and $or_M \rightarrow (\Omega_M^n)^\vee \rightarrow (\Omega_M^{n-1})^\vee \rightarrow \dots$ ([5, 25]) and an obvious "forgetting continuity" map of complexes in $Sh(M)$:

$$((\Omega_M^*)', d'_{dRh}) \rightarrow ((\Omega_M^*)^\vee, d^\vee_{dRh}).$$

Applying to this the global sections functor, we get two cohomologies: de Rham cohomology with coefficients in or_M (or, equivalently, closed de Rham homology) and the sheaf cohomology of or_M , together with a linear map between them:

$$H_{dRh}^*(M; or_M) \rightarrow H^*(M; or_M).$$

In the Hausdorff case, all sheaves $(\Omega_M^q)'$ and $(\Omega_M^q)^\vee$ are soft and the map above is an isomorphism; in the non-Hausdorff case, $(\Omega_M^q)'$ may fail to be acyclic for cohomology and the two cohomologies are not isomorphic in general. The same discussion carries over to the case of étale groupoids (see [21]).

4.11 Definition: Let \mathcal{G} be a smooth étale groupoid. Define $HH^*(\mathcal{C}_c^\infty(\mathcal{G}))$, $HC^*(\mathcal{C}_c^\infty(\mathcal{G}))$, $HP^*(\mathcal{C}_c^\infty(\mathcal{G}))$ as the cohomologies of $(\mathcal{C}_c^\infty(\mathcal{G})^\natural)^\vee$.

Emphasize that these are not the algebraic cohomologies of $\mathcal{C}_c^\infty(\mathcal{G})$ since in the definition of $\mathcal{C}_c^\infty(\mathcal{G})^\natural$ we used the topology. It is possible also to use $(\mathcal{C}_c^\infty(\mathcal{G})^\natural)'$ for defining the cyclic cohomologies. Because of the facts explained in 4.10 they give the same *periodic* cyclic cohomologies in the case of Hausdorff groupoids. In the general case the difference between them is the same as the difference between the two cohomologies described in 4.10.

Remark that we chose the maximal definition such that we keep the pairing with the cyclic homology and such that it is a receptacle for "Chern character" maps ([13, 40]). And, as we shall see, it is "computable".

Theorem 4.12 : For any smooth étale groupoid \mathcal{G} , and any elliptic open $\mathcal{O} \subset B^{(0)}$ which is a topological manifold (not necessarily Hausdorff) of dimension q :

$$HP^0(\mathcal{C}_c^\infty(\mathcal{G}))_{\mathcal{O}} = \bigoplus_{k \text{ even}} H^{k+q}(\mathcal{N}_{\mathcal{O}}; or_{\mathcal{O}}),$$

$$HP^1(\mathcal{C}_c^\infty(\mathcal{G}))_{\mathcal{O}} = \bigoplus_{k \text{ odd}} H^{k+q}(\mathcal{N}_{\mathcal{O}}; or_{\mathcal{O}}),$$

and the pairing with $HP_*(\mathcal{C}_c^\infty(\mathcal{G}))_{\mathcal{O}}$ is in fact the Poincaré-duality pairing (see 2.28).

In particular, the Connes pairing $HP^* \times HP_* \rightarrow \mathbb{C}$ induces an inclusion:

$$HP^*(\mathcal{C}_c^\infty(\mathcal{G}))_{\mathcal{O}} \hookrightarrow HP_*(\mathcal{C}_c^\infty(\mathcal{G}))_{\mathcal{O}}^\vee.$$

proof: We explain how to make the analogy with the case of homology (and get more of the lemmas we need as consequences of that case). The analogue of 4.1 we get for free (as a consequence). The analogy with the sub-paragraph 2.4 is ensured by 4.8 and 4.9. To see this, keep the notations from 3.33, 3.35. Since our $\mathcal{A} = \mathcal{C}_{\mathcal{G}^{(0)}}^\infty$ is c -soft and since $(\mathcal{A} \rtimes \mathcal{G})^\natural(n)$ is isomorphic to $\Gamma_c(\Omega(\mathcal{G}); \mathcal{A}_{tw}^\natural)$ (see the isomorphism in the proof of 3.36) we get that $((\mathcal{A} \rtimes \mathcal{G})^\natural(n))^\vee$ is isomorphic to $\Gamma_c(\Omega(\mathcal{G}); (\mathcal{A}_{tw}^\natural)^\vee)$ and each $(\mathcal{A}_{tw}^\natural)^\vee$ is injective (cf. 4.9). From this point on, the analogy is ensured by 4.8 and the isomorphism in 4.9. The analogue of 3.5 we also get for free (just by dualizing) and we get down to the resolutions of the orientation sheaf given by the duals of the sheaves of forms. This also introduces the shifting in the result. The identification with the Poincaré pairing is straightforward.

We leave the statement of the hyperbolic case to the reader. As an obvious (but interesting) consequence we have:

4.13 Corollary: Let $\mathcal{O} \subset B^{(0)}$ be \mathcal{G} -invariant such that it is a disjoint union of manifolds. Assume that $\mathcal{N}_{\mathcal{O}}$ has finite cohomological dimension. Then:

1. if \mathcal{O} is elliptic: $HP^*(\mathcal{C}_c^\infty(\mathcal{G}))_{\mathcal{O}} \simeq HP_*(\mathcal{C}_c^\infty(\mathcal{G}))_{\mathcal{O}}^\vee$ (induced by the Connes pairing),
2. if \mathcal{O} is hyperbolic: $HP^*(\mathcal{C}_c^\infty(\mathcal{G}))_{\mathcal{O}} = HP_*(\mathcal{C}_c^\infty(\mathcal{G}))_{\mathcal{O}} = 0$.

4.14 At units: As a particular case of 4.12 we have the localization at units:

$$HP^*(\mathcal{C}_c^\infty(\mathcal{G}))_{[1]} = \bigoplus_{k \equiv * \pmod{2}} H^{k+q}(\mathcal{G}; or).$$

By using 2.18, we get the connection with the cohomology of the classifying space. But remark that the result in this form, as the cohomology of \mathcal{G} , gives us more freedom in constructing cocycles. For instance, any \mathcal{G} -vector bundle ξ gives its Chern classes $c_*(\xi) \in H^*(\mathcal{G})$ in explicit cocycles.

4.3 Group Actions on Manifolds

We use the previous results to describe the homologies of the cross-product (locally convex) algebra $C_c^\infty(M) \rtimes G$. Here G is a discrete group acting smoothly on the Hausdorff manifold M . This algebra coincides with the convolution algebra of the smooth étale groupoid $\mathcal{G} = M \rtimes G$ (see 2.2). For any $g \in G$, denote by $Z_g = \{h \in G : hg = gh\}$ and $N_g = Z_g / \langle g \rangle$ the centralizer and the normalizer of g , and by M^g the points fixed by g . Denote by " \sim " the conjugacy relation on G and put $\langle G \rangle = G / \sim$. The loop space of \mathcal{G} is $B^{(0)} = \{(x, g) \in M \times G : xg = x\}$ and is usually denoted

by \widehat{M} ([3]). Any $g \in G$ defines an invariant open $\mathcal{O}_g = \{(x, h) \in \widehat{M} : h \sim g\}$ and $\widehat{M} = \coprod_{g \in \langle G \rangle} \mathcal{O}_g$. In particular we have the well-known decomposition (see [7], [16], [38]):

$$HH_*(C_c^\infty(M) \rtimes G) = \bigoplus_{g \in \langle G \rangle} HH_*(C_c^\infty(M) \rtimes G)_{(g)},$$

and the analogues for HC_* , HP_* . For any g we have obvious Morita equivalences $\mathcal{Z}_{\mathcal{O}_g} \simeq M^g \rtimes Z_g$, $\mathcal{N}_{\mathcal{O}_g} \simeq M^g \rtimes N_g$.

In the elliptic case we get:

$$HP_*(C_c^\infty(M) \rtimes G)_{(g)} = \prod_{k \equiv * \pmod{2}} H_k(M^g \rtimes N_g; \mathbb{C}),$$

which, with 2.28 and 2.18 in mind, is similar to the description given in [6]. Remark also that if G acts properly on M we get (using 2.26 for $M^g \rtimes N_g \rightarrow M^g/N_g$ and 2.22):

$$HP_*(C_c^\infty(M) \rtimes G) = \bigoplus_{g \in \langle G \rangle} \prod_{k \equiv * \pmod{2}} H_c^k(M^g/Z_g)$$

as the target of the Chern character. This agrees with the target of the Chern character defined in [3].

Assume now that $g \in G$ is hyperbolic. We have a projection $(\mathcal{Z}_{\mathcal{O}_g}, \theta) \rightarrow (Z_g, g)$ of hyperbolic cyclic groupoids (see example 3 in 3.16) which induces a map:

$$H_{N_g}^*(pt; \mathbb{C}) = H^*(N_g; \mathbb{C}) \rightarrow H_{N_g}^*(M^g; \mathbb{C}) = H^*(\mathcal{N}_{\mathcal{O}_g}; \mathbb{C}).$$

From 3.18, $e_{\mathcal{O}_g} \in H_{N_g}^2(M^g; \mathbb{C})$ is the image by this map of the Euler class of (Z_g, g) . This Euler class is denoted by $e_g \in H^2(N_g; \mathbb{C})$; by the previous work of Nistor ([38]) we know it is represented by the extension $\langle g \rangle \rightarrow Z_g \rightarrow N_g$. We get the following :

4.15 Corollary: *For $g \in G$ hyperbolic, $HC_*(C_c^\infty(M) \rtimes G)_{(g)}$ is a module over the equivariant cohomology ring $H_{N_g}^*(M^g; \mathbb{C})$ and S in the SBI-sequence is the product by the image of the Euler class $e_g \in H^2(N_g; \mathbb{C})$ in $H_{N_g}^2(M^g; \mathbb{C})$.*

Moreover, if g acts stably (for instance if it preserves a metric) then:

$$HH_n(C_c^\infty(M) \rtimes G)_{(g)} = \bigoplus_{p+q=n} H_p(Z_g; \Omega_c^q(M^g)),$$

$$HC_n(C_c^\infty(M) \rtimes G)_{(g)} = \bigoplus_{p+q=n} H_p(N_g; \Omega_c^q(M^g)),$$

and the SBI-sequence is the sum of the Gysin-sequences for $\langle g \rangle \rightarrow Z_g \rightarrow N_g$.

Compare to [9, 38]. Also we have the dual results for cohomology. In particular:

4.16 Corollary: *If $g \in G$ is hyperbolic and the image of $e_g \in H^2(N_g; \mathbb{C})$ in the equivariant cohomology ring $H_{N_g}^2(M^g; \mathbb{C})$ is nilpotent, then $HP_*(C_c^\infty(M) \rtimes G)_{(g)}$ and $HP^*(C_c^\infty(M) \rtimes G)_{(g)}$ vanish.*

4.4 Foliations

Let (M, \mathcal{F}) be a foliated manifold. The holonomy groupoid (see 2.2), $Hol(M, \mathcal{F})$ is a smooth groupoid which is non-Hausdorff in general. When restricted to a complete transversal T it becomes an étale groupoid $Hol_T(M, \mathcal{F})$. As proved in [23], the choice of T is not important when we talk about the associated non-commutative spaces (i. e. the associated C^* -algebras). The case of their smooth convolution algebras seems to be slightly more difficult. However we have:

Theorem 4.17 : For any foliated manifold (M, \mathcal{F}) the correspondences:

$$T \mapsto HH_*, HC_*, HP_*, HH^*, HC^*, HP^*(\mathcal{C}_c^\infty(Hol_T(M, \mathcal{F})))$$

do not depend on the choice of the complete transversal T ; so they give well defined invariants of the (“leaf space” of the) foliation. These are denoted by $HH_*(M/\mathcal{F})$, $HC_*(M/\mathcal{F})$, $HP_*(M/\mathcal{F})$.

proof: Let T, T' be two complete transversals; $\mathcal{G} = Hol_T(M, \mathcal{F}), \mathcal{N}$ and $\mathcal{B} = \mathcal{A}_{\mathcal{B}(0)}^{\natural}$ be the constructions from 3.35 for \mathcal{G} ; the similar constructions for T' are denoted by $\mathcal{G}', \mathcal{N}', \mathcal{B}'$. Replacing T by $T \amalg T'$ if needed, we can assume $T \subset T'$. We have continuous functors $\mathcal{G} \rightarrow \mathcal{G}', \mathcal{N} \rightarrow \mathcal{N}'$ which are Morita equivalences. Since $HH_*(\mathcal{C}_c^\infty(\mathcal{G})) = \mathbb{H}_*(\mathcal{N}; (\mathcal{B}, b))$ (cf 4.1, 3.36, 3.22) and the analogue for \mathcal{G}' , it is enough to use Morita invariance for homology and an *SBI* argument.

4.18 At units: For the localization at units we get:

$$HP^*(M/\mathcal{F})_{(1)} = \bigoplus_{k \equiv q+* \pmod{2}} H^k(M/\mathcal{F}; or).$$

This is a common point between two different approaches to model the leaf-space M/\mathcal{F} as a generalized space: one in the spirit of non-commutative geometry and one in the spirit of Grothendieck, by looking at all the sheaves on $Hol(M; \mathcal{F})$ (see [32]). In particular, the right side is the cohomology of the orientation sheaf of M inside the category of sheaves of complex vector spaces on $Hol(M, \mathcal{F})$.

4.19 Examples:

1. Consider the foliation of the open Moebius band and the complete transversal T as in the picture. Then $\mathcal{G} = Hol_T(M, \mathcal{F})$ has $\mathcal{G}^{(0)} = (-1, 1), \mathcal{G}^{(1)} = (-1, 1) \cup_D (-1, 1)$ where $D = (-1, 0) \cup (0, 1)$. It is not Hausdorff and has just elliptic loops. Applying 4.4 we get:

$$HP_0(M/\mathcal{F}) = 0, \quad HP_1(M/\mathcal{F}) = \mathbb{C}.$$

2. Consider the Kronecker foliation on the torus (see I.4.β in [13]) which comes from the foliation of the plane by lines of slope $\alpha = 2\pi\theta$, $\theta \in \mathbb{R} - \mathbb{Q}$. Choosing T as in the picture, the reduced groupoid becomes $S^1 \rtimes \mathbb{Z}$ where \mathbb{Z} acts on S^1 by rotations by α . The only elliptic loops are the units. From 4.4 we get $HP_*(M/\mathcal{F}) = HP_*(M/\mathcal{F})_{(1)}$ and from 4.3 this is computable in terms of $H_*(S^1 \rtimes \mathbb{Z})$. An easy algebraic computation shows that the last group is \mathbb{C} if $* \in \{-1, 1\}$, $\mathbb{C} \oplus \mathbb{C}$ if $* = 0$ and 0 otherwise. So:

$$HP_0(M/\mathcal{F}) = HP_1(M/\mathcal{F}) = \mathbb{C} \oplus \mathbb{C}.$$

A similar result is obtained for cohomology. Compare to theorem 53 in [11].

3. For Haefliger's groupoid Γ^q (which is non-Hausdorff), the localization at units gives the homology and cohomology of Γ^q . The last one gives universal cocycles which induce characteristic classes for foliations of codimension q . This is the case for the Godbillon-Vey invariant or, more generally, for classes coming from Gelfand-Fuchs cohomology. It is this non-Hausdorff groupoid Γ^q the one which provides the link between these (topological) characteristic classes and the characteristic classes coming from non-commutative geometry (living in cyclic cohomology). See [21] and [12]. So our result describes precisely this connection.
