15 **Abstract**

16 The basidiomycete white-rot fungus *Obba rivulosa*, a close relative of *Gelatoporia* (*Ceriporiopsis*)
17 *subvermispora*, is an efficient degrader of softwood. The dikaryotic *O. rivulosa* strain T241i
18 (FBCC949) has been shown to selectively remove lignin from spruce wood prior to depolymerization
19 of plant cell wall polysaccharides, thus possessing potential in biotechnological applications such as
20 pretreatment of wood in pulp and paper industry. In this work, we studied the time-course of the
21 conversion of spruce by the genome-sequenced monokaryotic *O. rivulosa* strain 3A-2, which is derived
22 from the dikaryon T241i, to get insight into transcriptome level changes during prolonged solid state
23 cultivation. During 8-week cultivation, *O. rivulosa* expressed a constitutive set of genes encoding
24 putative plant cell wall degrading enzymes. High level of expression of the genes targeted towards all
25 plant cell wall polymers was detected at 2-week time point, after which majority of the genes showed
26 reduced expression. This implicated non-selective degradation of lignin by the *O. rivulosa* monokaryon
27 and suggests high variation between mono- and dikaryotic strains of the white-rot fungi with respect to
28 their abilities to convert plant cell wall polymers.

30 **Keywords**

31 *Obba rivulosa*; white-rot; lignocellulose; solid state cultivation; transcriptomics

32

33 **Abbreviations**

34 AA, auxiliary activity; AAO, aryl alcohol oxidase; AE, acetylerase; AGL, α -galactosidase; AGU, α -
35 glucuronidase; AOX, alcohol oxidase; BGL, β -1,4-glucosidase; CAZy, CAZyme, carbohydrate-active
36 enzyme; CBH, cellobiohydrolase; CDH, cellobiose dehydrogenase; CE, carbohydrate esterase; CRO,
37 copper radical oxidase; EGL, β -1,4-edoglucanase; ENO, enolase; FBA, fructose-bisphosphate aldolase;
38 FET, ferroxidase; FPKM, Fragments Per Kilobase of exon model per Million fragments mapped; GAL,

39 β -1,4-endogalactanase; GE, 4-O-methyl-glucuronoyl methylesterase, glucuronoyl esterase; GH,
40 glycoside hydrolase; GLX, glyoxal oxidase; GMC, oxidoreductase glucose-methanol-choline
41 oxidoreductase; GND, 6-phosphogluconate dehydrogenase; GOX, glucose (1-)oxidase; GPD,
42 glyceraldehyde-3-phosphate dehydrogenase; GT, glycosyl transferase; ICL, isocitrate lyase; LAR, L-
43 arabinose reductase; LCC, laccase; LiP, lignin peroxidase; LN-AS, low nitrogen-asparagine-succinate;
44 LPMO, lytic polysaccharide monooxygenase; MAN, β -1,4-endomannanase; MB, mega base pairs;
45 MDH, malate dehydrogenase; MEA, malt extract agar; MND, β -1,4-mannosidase; MnP, manganese
46 peroxidase; OXA, oxaloacetase; PCA, principal component analysis; PCP, pentose catabolic pathway;;
47 PCWDE, plant cell wall degrading enzyme; PFK, fructose-2,6-bisphosphatase; PGA,
48 endopolygalacturonase; PGI, glucose-6-phosphate isomerase; PKI, pyruvate kinase; PL, polysaccharide
49 lyase; PPP, pentose phosphate pathway; qRT-PCR, quantitative real-time PCR; RNA-seq, RNA
50 sequencing; TAL, transaldolase; TCA cycle, tricarboxylic acid cycle; VP, versatile peroxidase; XDH,
51 xylitol dehydrogenase; XG-EG, xyloglucanase, xyloglucan-active endoglucanase; XLN, β -1,4-
52 endoxylanase

53

54 **1. Introduction**

55 Plant biomass, as the most abundant renewable carbon source on Earth, is important not only for
56 carbon cycling, but also as a feedstock for biofuels and newly derived value-added products (Isikgor
57 and Becer, 2015). The main polymeric components comprising the plant cell wall, i.e. cellulose,
58 hemicellulose, lignin and pectin, are responsible for its structural complexity. However, recalcitrance of
59 lignocellulose is mostly due to the amorphous aromatic polymer lignin and presents the biggest
60 obstacle in biotechnological exploitation of plant biomass.

61

62 Although a variety of microorganisms can attack lignocellulose, white-rot basidiomycete fungi are the
63 most effective plant cell wall degrading organisms as they efficiently decompose all lignocellulose
64 components by a variety of extracellular enzymes (Hatakka and Hammel, 2011; Mäkelä et al., 2014).
65 Major cell wall polymers are being degraded by action of extracellular hydrolytic and oxidative
66 enzymes, most of which have been categorized in the database of Carbohydrate-Active EnZymes
67 (CAZy, <http://www.cazy.org/>) (Lombard et al., 2013). The resulting monomeric sugars are taken up by
68 the fungal cells and metabolized as carbon and energy sources through specific pathways (Khosravi et
69 al., 2015).

70

71 Lignin degradation is a prerequisite for gaining access to carbohydrate polymers, which serve as a
72 carbon and energy source for fungi (Rytioja et al., 2014). White-rot fungi produce an array of
73 oxidoreductases from the families of auxiliary activities (AA) that are known to take part in lignin
74 modification and degradation. Of those, the key enzymes are fungal class II peroxidases, i.e. lignin
75 peroxidases (LiPs), manganese peroxidases (MnPs) and versatile peroxidases (VPs) that are present in
76 all efficient lignin degrading white-rot fungi in different numbers. In addition, laccases that are phenol-
77 oxidizing multicopper oxidases are suggested to participate in lignin conversion with peroxidases in the
78 presence of the aromatic mediator molecules (Zhao et al., 2016). Moreover, several extracellular H₂O₂-
79 generating enzymes are a part of ligninolytic system (Ferreira et al., 2015). These include glucose-
80 methanol-choline (GMC) enzymes alcohol oxidases (AOXs), aryl alcohol oxidases, (AAOs) glucose 1-
81 oxidases (GOXs), and copper radical oxidases (CROs) such as glyoxal oxidases (GLXs). White-rot
82 fungi are able to completely depolymerize the plant cell wall polysaccharides by secreting various
83 hydrolytic enzymes, including cellulases and hemicellulases, from several glycoside hydrolase (GH)
84 families (Rytioja et al., 2014). Besides hydrolytic enzymes, lytic polysaccharide monooxygenases

85 (LPMOs) and cellobiose dehydrogenases (CDHs) facilitate degradation of plant cell wall
86 polysaccharides by oxidative action (Vaaje-Kolstad et al., 2010; Langston et al., 2011).
87
88 Wood decay patterns differ among white-rot fungi (Cantarel et al., 2008). Most of the studied species,
89 including the model white-rot fungus *Phanerochaete chrysosporium*, remove cellulose, hemicellulose
90 and lignin simultaneously (Korripally et al., 2015). On the contrary, the species that degrade lignin
91 prior to polysaccharides are called selective lignin degraders, and include e.g. *Obba rivulosa* and
92 *Gelatoporia (Ceriporiopsis) subvermispora* (Akhtar et al., 1997; Gupta et al., 2011; Hakala et al.,
93 2004). These species are especially interesting in the biotechnological applications aiming to remove
94 lignin (Hakala et al., 2004; Maijala et al., 2008).
95
96 *O. rivulosa*, a member of the *Gelatoporia* clade, is relatively common in North America (Nakasone,
97 1981), but sparsely distributed in Africa (Hjortstam and Ryvarden, 1996), Asia (Núñez and Ryvarden,
98 2001) and Europe (Ryvarden and Gilbertson, 1994), where it has been mostly isolated from coniferous
99 softwood (Hakala et al., 2004). A dikaryotic *O. rivulosa* strain T241i (FBCC949) has been shown to
100 degrade spruce softwood selectively (Hakala et al., 2004). Moreover, the *O. rivulosa* genome encodes a
101 full set of lignocellulose-degrading genes, making it an interesting candidate for plant biomass research
102 (Miettinen et al., 2016). Except for two MnPs and two laccases (Hakala et al., 2005; Hildén et al.,
103 2013), no other lignocellulosic enzymes produced by *O. rivulosa* have been characterized, and
104 therefore its mechanisms for plant cell wall degradation remain largely unknown.
105
106 Here we report temporal transcriptome analysis of *O. rivulosa* grown on its natural substrate, spruce
107 wood. We used the genome-sequenced monokaryotic strain 3A-2, derived from the dikaryotic strain
108 T241i, which has been previously studied in terms of selective lignin degradation. The expression of

109 genes encoding putative plant cell wall degrading CAZymes was studied after 2, 4 and 8 weeks of solid
110 state cultivation in order to follow wood depolymerization in more natural like conditions. In addition,
111 central carbon metabolic enzymes and fungal cell acting CAZymes encoding genes were studied to get
112 insights into the nutritional demands during a prolonged cultivation on wood.

113

114 **2. Materials and methods**

115 *2.1 Fungal strain and culture conditions*

116 *O. rivulosa* monokaryon 3A-2 (FBCC1032) derived from the dikaryotic *O. rivulosa* strain T241i
117 (FBCC949) was obtained from the HAMBI Fungal Biotechnology Culture Collection, University of
118 Helsinki, Helsinki, Finland (fbcc@helsinki.fi). The fungus was maintained on 2% malt extract agar
119 plates (MEA) (2% (w/v) malt extract, 2% (w/v) agar agar). For pre-cultures, the fungus was cultivated
120 for 7 days at 28°C in 100 ml liquid low-nitrogen-asparagine-succinate medium (LN-AS), pH 4.5
121 (Hatakka and Uusi-Rauva, 1983), supplemented with 0.05% glycerol, in 250 ml Erlenmeyer flasks,
122 which were inoculated with five mycelium-covered agar plugs (ø 7 mm) from MEA plates. After the
123 homogenization (Waring Blender, USA), 4 ml of mycelial suspension was used for the inoculation of
124 spruce wood solid cultures, which consisted of 2 g (dry weight) of Norway spruce (*Picea abies*) wood
125 sticks (approx. 2 x 0.2 x 0.3 cm in size) on 1% (w/v) water agar (Mäkelä et al., 2002). Cultures were
126 incubated stationary at 28°C in the dark for 2, 4, and 8 weeks. Three replicate control cultures
127 inoculated with 4 ml of LN-AS supplemented with 0.05% glycerol were incubated similarly. After
128 reaching the specific time point, mycelium-colonized wood sticks were flash frozen in liquid nitrogen
129 followed by subsequent RNA extraction.

130

131 *2.2 RNA extraction, cDNA library preparation and RNA sequencing*

132 Total RNA was extracted from the spruce cultures by using a CsCl gradient ultracentrifugation as
133 described previously (Patyshakuliyeva et al., 2014). Quality and quantity of RNA were determined by
134 using the RNA6000 Nano Assay (Agilent 2100 Bioanalyzer, Agilent Technologies, Santa Clara, CA,
135 USA). Purification of mRNA, synthesis of cDNA library, and sequencing (RNA-seq) was performed at
136 the BGI Tech Solutions Co. Ltd. (Hong Kong, China) as described in Patyshakuliyeva et al. (2015). On
137 average, 51 bp sequenced reads were constituted, producing approximately 557 MB raw yields for each
138 sample. RNA-seq data was analyzed and statistically treated as described previously (Patyshakuliyeva
139 et al., 2015). Raw reads were produced by base calling from the original image data. After that, data
140 filtering was performed. Adaptor sequences, reads with unknown bases (N) >10% and low quality
141 reads (more than 50% of the bases with quality values <5%) were removed. Clean reads were mapped
142 to the genome sequence of *O. rivulosa* 3A-2 (v1.0 annotation, <http://genome.jgi.doe.gov/Obbri1>,
143 (Miettinen et al., 2016)) using BWA/Bowtie (Langmead et al., 2009; Li and Durbin, 2010). On
144 average, 82% total mapped read to the gene was achieved. The expression level was calculated as
145 Fragments Per Kilobase of exon model per Million fragments mapped (FPKM) by using RSEM tool
146 (Li and Dewey, 2011). Genes with FPKM value <20 under all conditions were considered as not
147 expressed and filtered out of the analysis, and genes showing FPKM value ≥ 20 were considered as
148 significantly expressed. Genes with FPKM value from 20 to 100 were considered as lowly, 100 to 300
149 as moderately and over 300 as highly expressed (approximately top 10% of the genes). Differential
150 expression was identified by Student's T-test. A cut-off of fold change of >1.5 and P-value of <0.05
151 were used to identify differentially expressed genes between the time points. Genome-wide principal
152 component analysis (PCA) of the gene expression on duplicate samples of the three time points was
153 generated using FactoMineR package from Rcomander v.2.1-7 program in R statistical language and
154 environment 3.1.2. (Lê et al., 2008). The RNA-seq data have been submitted to Gene Expression
155 Omnibus (GEO) (Edgar et al., 2001) with GEO ID: GSE99871.

156

157 2.3 Validation of RNA-seq expression patterns by qRT-PCR

158 Smart RACE cDNA Amplification Kit (Clontech) was used for the cDNA synthesis according to the
159 manufacturer's instructions. 1 µg of RNA originating from two replicate cultures of *O. rivulosa* that
160 were used in RNA-seq was converted to cDNA in 20 µL reaction with Smart RACE cDNA
161 Amplification Kit (Clontech) and SuperScript III reverse transcriptase (Invitrogen) according to the
162 instructions of the manufacturers.

163

164 The relative amounts of nine selected gene transcripts were determined by qRT-PCR analysis to
165 validate the RNA-seq expression patterns. Gene-specific primers spanning exon-exon junction
166 (Supplementary Table 1) were designed according to the genome of *O. rivulosa* 3A-2
167 (<http://genome.jgi.doe.gov/Obbri1>, Miettinen et al., 2016) with PerlPrimer software (Marshall, 2004).
168 The amplification efficiency (E) of the primers was calculated from the slope of standard curve made
169 with template cDNA serial dilutions using the formula: $E = [10^{(-1/\text{slope})} - 1] \times 100$. The E-values of the
170 primer pairs varied from 94% to 102%, whereas, the R^2 values, ranged from 0.993 to 0.999
171 (Supplementary Table 1).

172

173 Three technical replicate qRT-PCR reactions were conducted for each sample and primer pair using
174 CFX96 Real-Time System C1000 Touch Thermal Cycler (Bio-Rad, USA). The 20 µL reactions
175 comprised of 30 ng cDNA template, 0,4 µM forward and reverse primer, 1 X DyNAmo HS SYBR
176 Green qPCR master mix (Thermo Scientific), and H₂O to the final volume of 20 µL. Cycling protocol
177 was: initial denaturation at 95°C followed by 35 cycles of (1) denaturation at 94°C for 10 s, (2)
178 annealing at 56°C for 20 s, and (3) extension at 72°C for 30 s. Fluorescence data acquisition was done
179 during the extension step. To confirm the specificity of the qRT-PCR primers, melting curve was

180 generated and inspected for the presence of a single peak. Relative expression levels were calculated by
181 $2^{-\Delta\Delta C_t}$ method (Livak and Schmittgen, 2001) for the *gapdh*-normalized cycle threshold (Ct) values and
182 the results are reported as relative fold changes.

183

184 **3. Results**

185 The monokaryotic *O. rivulosa* 3A-2 strain grown on solid spruce wood was subjected to the time-scale
186 transcriptomics study to compare the gene expression at different growth stages of the fungus. PCA
187 analysis showed that the duplicate RNA samples used for RNA-seq were highly reproducible
188 (Supplementary Fig. 1). In addition, the expression patterns obtained by RNA-seq analysis
189 corresponded well to the qRT-PCR results of the nine selected putative CAZyme-encoding genes (Fig.
190 1). Similar to other Polyporales species, the genome of *O. rivulosa* contains a full repertoire of putative
191 CAZyme-encoding genes targeted to plant cell wall degradation (Miettinen et al., 2016). In total, 259
192 different putative CAZyme-encoding genes were significantly expressed in *O. rivulosa* cultures, and of
193 these 110 were predicted to encode plant cell wall degrading enzymes (PCWDEs) (Fig. 2A) from 35
194 different CAZy families (Supplementary Table 2). Transcripts encoding putative GHs were the most
195 abundant ones with 138 detected transcripts (53% of total PCWDE CAZys). The CAZymes-encoding
196 transcripts from AAs, GTs, CEs, and PLs represented 15%, 30%, 7%, and 2.5% of the total PCWDE
197 CAZy transcripts detected, respectively. Of these, 20, 31, and 16 CAZy genes are putatively targeted
198 towards cellulose, hemicellulose and lignin, respectively (Fig. 2A). 16 genes encoding putatively H₂O₂-
199 supplying enzymes were detected, while 6 and 5 genes encoding pectin and starch depolymerizing
200 enzymes were expressed, respectively. Diverse activities included 16 CAZy transcripts, which can have
201 activity towards multiple substrates. Highly expressed PCWDE CAZyme encoding transcripts
202 belonged to 20 different CAZy families with varying gene numbers (Fig. 2B). All genes from cellulose

203 acting GH6, GH12 and AA8-A3_1, xyloglucan acting GH73 and pectin acting GH53 and GH88
204 families showed high expression (Fig. 2B).

205

206 As a typical white-rot fungal species, *O. rivulosa* harbors multiple genes predicted to be involved in
207 lignin degradation in its genome. Of these, two putative MnP (Protein IDs 806545 and 835392)
208 encoding genes were the highest expressed PCWDE CAZy transcripts during the cultivation.
209 Interestingly, they showed unusually high expression levels throughout the cultivation peaking from 20
210 000 to 22 000 FPKM after 4-week cultivation (Table 1). This may suggest an important role for the
211 corresponding enzymes in lignin degradation during the growth of *O. rivulosa* monokaryon on spruce.
212 Three putative AA1_1 laccases were also detected on spruce, but none of those was highly expressed
213 (Supplementary Table 3A). In addition to the laccases, *O. rivulosa* multicopper oxidase-encoding
214 transcripts included one AA1_2 ferroxidase (FET), which compared to the laccases was moderately
215 expressed. Production of hydrogen peroxide is essential for the lignin degradation since it is a
216 prerequisite for peroxidase activity. In accordance with that, 10 transcripts predicted to encode family
217 AA3_2 and AA3_3 glucose methanol choline (GMC) oxidoreductases were detected. Although most of
218 the transcripts encoding the putative GMCs showed low expression, interestingly, one of the transcripts
219 encoding an AA3_3 alcohol oxidase (AOX; 790443) was highly expressed in all time points, and was
220 the most abundant transcript among lignin degradation-related transcripts after two AA2 MnPs. These
221 findings confirm the major importance of peroxidases and hydrogen peroxide-producing machinery for
222 the lignocellulose conversion in *O. rivulosa*.

223

224 Of the transcripts predicted to encode cellulolytic activities, β -1,4-endoglucanases (EGLs),
225 cellobiohydrolases (CBHs), β -1,4-glucosidases (BGLs) and LPMOs were the most abundant ones
226 among all the growth stages of *O. rivulosa* on wood (Supplementary Fig. 2, Supplementary Table 3A).

227 In total, 9 transcripts encoding putative EGLs from GH5, 12, 45 and 131 were detected. Six of those
228 were highly expressed after 2 weeks with a 98- to 17- fold downregulation at the later stages
229 (Supplementary Table 3A). The *O. rivulosa* genome possesses one GH6 cellobiohydrolase II (CBHII)
230 and two GH7 CBHIs, of which the CBHII (Protein ID 476379) as well as one CBHI (Protein ID
231 731121) were highly expressed after 2 weeks. Interestingly, their expression decreased to moderate and
232 low levels after 4 and 8 weeks of cultivation, respectively. A third important hydrolytic cellulose-acting
233 enzymes are encoded by the enzyme families GH1 and GH3. Although seven BGL encoding genes
234 were present in the transcriptome, only one GH3 BGL (Protein ID 14692) was highly expressed after
235 2-week cultivation. Genes encoding seven putative LPMOs oxidatively cleaving plant cell wall
236 polysaccharides were also expressed (Supplementary Table 3A). Of these, six were found to be highly
237 expressed, most of them after 2 weeks of cultivation. Interestingly, one LPMO (Protein ID 794851)
238 encoding gene was highly expressed throughout the cultivation.

239

240 The most abundant transcript predicted to act on hemicellulose was a GH5 mannanase (MAN; Protein
241 ID 641261), which was the third most abundant transcript in general (Table 1). Overall, three
242 transcripts predicted to encode GH5 MANs were detected. Among four detected GH27 α -
243 galactosidases (AGLs), only one was highly expressed (Protein ID 849432). Six genes encoding GH10
244 endoxylanases, 4 of which were highly expressed at the early cultivation stage (Protein IDs 838746,
245 851185, 762583 and 799009), were detected in the cultures. In addition, genes encoding one putative α -
246 glucuronidase (AGU; Protein ID 726547) and one putative xyloglucanase (XG-EG; Protein ID 808997)
247 showed high expression levels. Interestingly, almost all predicted hemicellulose degrading enzyme
248 encoding genes showed higher abundances in early stages of wood decay with subsequent decrease.
249 Only one GH2 mannosidase (MND; Protein ID 753990) was expressed at a constant, moderate level at

250 all three time points. High expression was not detected for any of the putative hemicellulases encoding
251 genes after 4 or 8 weeks of cultivation.

252

253 In addition to the hemicellulose specific GHs, differential abundances of transcripts predicted to encode
254 one hemicellulose acting glucuronoyl esterase (GE; Protein ID 762191) and three multiple substrates
255 acting acetyl esterases (AE; Protein IDs 749512, 724015 and 816606) from carbohydrate esterase (CE)
256 families 15 and 16, respectively, were detected. Similar to hemicellulose degrading GH families, their
257 expression trend showed the highest transcript abundances in early cultivation stage.

258

259 Overall, the expression of the PCWDE CAZy genes was highest after 2-week growth of *O. rivulosa*
260 and reduced markedly over time (Supplementary Table 3A, Supplementary Fig. 2). The only
261 exceptions were MnPs, LCCs, AAOs and a single copy of PGA and GAL. When the sum of the
262 transcript levels per putative CAZy enzyme activity was compared during the cultivation, MnPs were
263 the most highly expressed, followed by LPMOs, XLNs, CBHs and MANs, respectively
264 (Supplementary Fig. 2).

265

266 Altogether 22% (13 out of 60) of predicted fungal cell wall encoding CAZymes were highly expressed
267 in all three time points (Supplementary Table 3B). These genes showed an interesting trend of either
268 being highly expressed throughout the cultivation or showing high level expression at the early stage
269 with a decreasing trend after 4-week cultivation, followed by an upregulation at the last time point after
270 8 weeks (Supplementary Table 3B). This could suggest possible recycling of fungal cell wall
271 polysaccharides by *O. rivulosa*, such as α -1,3-, β -1,3- and β -1,6-glucans, which can be hydrolyzed to
272 glucose and reutilized by the fungus. The overall highest transcript abundancy was detected for one
273 gene encoding a putative GH131 β -glucanase (Protein ID 812963), acting on β -(1,3)-/ β -(1,6)- and β -

274 (1,4)-linked glucan substrates, after 2-week cultivation. Other highly expressed genes in the early time
275 point were two GH16 β -1,3(4)-endoglucanases, a GH18 chitinase and GH55 β -1,3-endoglucanase.
276 Constantly highly expressed transcripts included a CE4 chitin deacetylase, a GH16 β -1,3(4)-
277 endoglucanase, two β -1,3-endoglucanases from GH16 and GH128, a GH16 licheninase and a GH18
278 chitinase.

279

280 Despite the downregulated expression of the genes encoding CAZymes targeted for carbon acquisition
281 from plant biomass, *O. rivulosa* showed active mycelial growth throughout the cultivation (Fig. 3).
282 This was also confirmed by the expression of the carbon metabolic genes showing that all central
283 carbon metabolic pathways were active in all studied time points. This suggests that *O. rivulosa* was
284 not under carbon starvation during the cultivation (Supplementary Table 3C, Supplementary Fig. 3). D-
285 glucose, D-mannose and D-xylose are the major monosaccharides originating from spruce wood
286 polysaccharides, while smaller amounts of D-galactose, L-arabinose and L-rhamnose are also present
287 (Rytioja et al., 2017). Hexose monomers can be converted through glycolysis, which is connected to
288 pentose phosphate pathway (PPP). Among the glycolysis genes, *pkil*, encoding pyruvate kinase,
289 catalyzing the last step of the glycolysis, as well as genes encoding glucose-6-phosphate isomerase
290 (*pgil*), fructose-2,6-bisphosphatase (*pfk2*), fructose-bisphosphate aldolase (*fba1*), glyceraldehyde-3-
291 phosphate dehydrogenase (*gpd1*), and enolase (*eno1*), showed high expression (Supplementary Fig.
292 3A). While *pgil*, *pfk2* and *fba1* showed decreasing expression during the cultivation, *gpd1* and *eno1*
293 were upregulated. Isocitrate lyase (*icl1*), malate dehydrogenase (*mdh1*) and related oxaloacetase (*oxa1*)
294 encoding genes involved in the tricarboxylic acid (TCA) cycle were highly expressed (Supplementary
295 Fig. 3A). A gene encoding 6-phosphogluconate dehydrogenase (*gnd1*) as well as one of the
296 transaldolases encoding genes (*tal2*) of the PPP showed constant high level expression throughout the
297 cultivation (Supplementary Fig. 3B). Pentoses D-xylose and L-arabinose originating from

298 hemicelluloses and pectin are catabolized through the pentose catabolic pathway (PCP). High level
299 expression was detected for two out of the three PCP genes identified in *O. rivulosa*, i.e. L-arabinose
300 reductase (*lar1*) and xylitol dehydrogenase (*xdh1*) (Supplementary Fig. 3B). However, all three PCP
301 genes were downregulated after 2-week growth. It should be noted that we were not able to identify
302 (based on similarity to known ascomycete genes) some of the carbon metabolic genes in *O. rivulosa*,
303 including half of the genes encoding PCP enzymes (Supplementary Fig. 3). The pathways for
304 catabolism of pectin-derived L-rhamnose and D-galacturonic acid, as well as the Leloir pathway for D-
305 galactose present in hemicelluloses and pectin were also active (Supplementary Fig. 3C).

306

307 **4. Discussion**

308 In this work, we studied the transcriptomic response of the white-rot fungus *O. rivulosa* during a
309 prolonged cultivation period of 8 weeks on solid spruce to evaluate changes in gene expression during
310 the lengthy process of fungal wood colonization. The genome-sequenced monokaryotic *O. rivulosa*
311 strain 3A-2 (Miettinen et al., 2016) was used, and the focus was on the analysis of the genes encoding
312 plant cell wall polymers degrading CAZymes that are responsible for carbon acquisition from plant
313 biomass. Also, carbon metabolic genes and fungal cell wall degrading enzymes were evaluated to get a
314 collective overview of ongoing metabolic processes.

315

316 Our results show that *O. rivulosa* highly expresses the genes encoding a complete repertoire of
317 enzymes for degradation of cellulose, hemicellulose and lignin on spruce, similarly to other white rot
318 species including *Dichomitus squalens* (Rytioja et al., 2017) and *Phlebia radiata* (Kuuskeri et al.,
319 2016). Interestingly, almost all of the detected plant cell wall acting CAZy genes were highly expressed
320 after 2-week growth of *O. rivulosa*, while most of them were strongly downregulated in the later time
321 points. Generally regarded as key enzymes of white rot fungal ligninolytic system, class II heme

322 peroxidases are abundantly represented in the genome of *O. rivulosa*, including 11 MnPs, and one LiP
323 from family AA2 (Miettinen et al., 2016). Among nine putative MnP encoding transcripts detected in
324 spruce cultivations, five genes were highly expressed of which two (Protein IDs 806545 and 835392)
325 exhibited unusually high FPKM levels throughout the cultivation and had the highest transcript
326 abundances at 4-week time point. MnPs have often been shown to be constantly produced by white-rot
327 fungi throughout the solid state cultivation on wood (Aguiar et al., 2006; Galliano et al., 1991; Hakala
328 et al., 2005), which is in line with the high expression of the two putative MnP transcripts of *O.*
329 *rivulosa*.

330

331 Expression levels of the LiP encoding gene were negligible (FPKM<20) suggesting only minor input in
332 lignin degradation by *O. rivulosa*. This is in accordance with the results from *G. subvermispora*, a close
333 relative of *O. rivulosa*, where a putative LiP was not upregulated in aspen cultures compared to glucose
334 medium (Fernandez-Fueyo et al., 2012). On the contrary, the non-selective white-rot fungi, such as *P.*
335 *chrysosporium* (Vanden Wymelenberg et al., 2010), *Phanerochaete carnososa* (MacDonald et al., 2011)
336 and *P. radiata* (Kuuskeri et al., 2016), have shown significant upregulation of several LiP encoding
337 genes on wood substrates, implying differences in lignin degradation approaches between the white-rot
338 fungal species.

339

340 Three out of nine putative AA1_1 laccase genes of *O. rivulosa* were expressed on spruce, but none of
341 those was highly expressed. This is in contrast with *G. subvermispora* (Fernandez-Fueyo et al., 2012)
342 and *D. squalens* (Rytioja et al., 2017) laccases, which were significantly upregulated in the agitated
343 liquid cultures supplemented with milled aspen wood and spruce sawdust, respectively. However, our
344 finding was consistent with that from the solid spruce cultures of the white-rot fungus *P. radiata*,
345 showing low expression of laccase-encoding genes after 4-weeks of cultivation (Kuuskeri et al., 2016).

346 This may indicate that in the shaken liquid cultures, laccases defend the fungal mycelium against
347 oxidative stress (Jaszek et al., 2006; Joo et al., 2008), whereas in the more natural like solid state
348 cultivations, their role in lignin degradation is controversial. Nevertheless, acidic laccase isoforms have
349 been purified from the early phase of the solid spruce chip cultures of *O. rivulosa* despite of the minor
350 laccase activity detected from the cultivations (Hakala et al., 2005). This could indicate that laccases
351 may have a role in initial wood colonization.

352

353 The dikaryotic *O. rivulosa* strain T241i has been shown to selectively degrade spruce by decomposing
354 lignin prior to cellulose (Hakala et al., 2004). However, the results of our study do not indicate
355 selective lignin degradation by the monokaryotic *O. rivulosa* 3A-2, as genes encoding enzymes
356 targeted towards all plant biomass polymers were simultaneously highly expressed. A high level of
357 diversity within the white rot fungal species has often been reported. These include discrepancies
358 regarding enzyme production profile and lignin degrading ability between *Pleurotus osteratus*
359 monokaryon and its parental dikaryon. In solid state fermentation, the monokaryon showed higher
360 lignin-modifying enzyme activities, but a lower rate of lignin degradation compared to the dikaryon
361 (Eichlerová et al., 2000). Highly variable lignocellulose acting enzyme profiles have also been detected
362 between the mono- and dikaryotic strains of *D. squalens* (Casado-López et al., 2017). In addition,
363 higher levels of ligninolytic enzyme activities have been produced by monokaryotic strains of the
364 white-rot fungi *Pycnoporus cinnabarinus* (Herpoël et al., 2000), *Pycnoporus sanguineus* (Lomascolo et
365 al., 2002), *P. ostreatus* (Eichlerová et al., 2002) and *Trametes hirsuta* (Li et al., 2012) compared to the
366 parental dikaryon.

367

368 Selective lignin degradation seems also to be temporally regulated, as the selectivity is usually limited
369 to early stages of decay (Adaskaveg et al., 1995; Ferraz et al., 2000). It may be possible that the 2-week

370 time point was too late to detect the initial lignin degradation selectivity at the transcript level in the *O.*
371 *rivulosa* 3A-2 cultures, although its parental dikaryon T241i has maintained the selectivity during
372 prolonged cultivation (Hakala et al., 2004). Selectivity of white-rot wood degradation is also dependent
373 on the physical and chemical parameters, such as temperature, and oxygen and moisture content, in
374 wood (Adaskaveg et al., 1995; Blanchette, 1995). *O. rivulosa* T241i has been shown to degrade lignin
375 selectively when grown on spruce wood blocks at 25°C (Hakala et al. 2004), thus differing slightly
376 from the conditions used in this study for *O. rivulosa* 3A-2.

377

378 In addition to plant polymers degrading enzymes of *O. rivulosa* assessed in this study, we also
379 evaluated enzymes involved in the major carbon metabolic pathways. Carbon catabolic genes were
380 expressed throughout the 8-week cultivation demonstrating good metabolic activity of the fungus
381 during lengthy wood colonization and conversion in laboratory conditions. Overall, higher expression
382 was detected for genes encoding enzymes involved in glycolysis and PPP than for those involved in
383 PCP. A similar trend has been reported from the compost grown litter decomposing *Agaricus bisporus*
384 (Patyshakuliyeva et al., 2015), possibly suggesting a preferred use of hexoses over pentoses. Among
385 TCA and glyoxalate cycle related genes, malate dehydrogenase (*mdh1*) and oxaloacetase (*oxa1*)
386 showed the highest transcript levels during growth of *O. rivulosa* on spruce. Oxalate synthesis has been
387 suggested to be coupled with energy production in brown-rot fungi *Fomitopsis palustris* (Munir et al.,
388 2001) and *Postia placenta* (Martinez et al., 2009) by Mdh1, which generates energy by oxidizing
389 malate to oxaloacetate, which is then converted to oxalate by Oxa1. In addition, a number of roles for
390 oxalate with respect to lignocellulose degradation has been proposed, including acidification of fungal
391 extracellular environment to the levels that are usually needed for the activity of lignin acting enzymes
392 (Mäkelä et al., 2010). *O. rivulosa* has been shown to produce oxalate during growth on spruce wood

393 chips (Hakala et al., 2005), which is in line with the constant high expression of *oxal* in *O. rivulosa*
394 observed in our study.

395

396 Fungal cell wall acting enzymes comprising mostly chitinases and various β -glucanases are important
397 for cell wall remodeling during active hyphal growth, as well as aging-related cell wall recycling
398 (Gruber and Seidl-Seiboth, 2012). The most numerous representatives of the genes encoding putative
399 fungal cell wall acting enzymes expressed by *O. rivulosa* were family GH16 members that are involved
400 in chitin- β -1,3-glucan formation, suggesting a role in the processing of the fungal cell wall
401 polysaccharides (Klis et al., 2007). Two out of 11 putative GH18 chitinases encoding genes of *O.*
402 *rivulosa* showed constant high-level expression suggesting continuous recycling of chitin during the
403 cultivation. In ectomycorrhizal fungus *Laccaria bicolor* GH18 chitinase genes are also found to be
404 upregulated in free-living mycelium implying possible degradation of exogenous fungal cell wall
405 (Veneault-Fourrey et al., 2014).

406

407 Our results suggest that during the growth of *O. rivulosa* monokaryon 3A-2 on its natural substrate,
408 spruce wood, the highest expression of genes involved in plant cell wall degradation occurs at early
409 stages of wood colonization. The simultaneous expression of genes targeted towards all lignocellulosic
410 polymers suggests that *O. rivulosa* 3A-2 does not selectively remove spruce wood lignin. Thus, these
411 results indicate high variation within mono- and dikaryotic strains of white-rot fungal species towards
412 lignocellulose degradation.

823190	<i>odc4</i>	Oxalate decarboxylase	0,7	0,6
Leloir				
784856	<i>gal1</i>	Galactokinase	53,3	37,1
822974	<i>gal7</i>	UTP-hexose-1-phosphate uridylyltransferase (UDP galactose)	28,8	18,8
834953	<i>gal10a</i>	UDP glucose 4-epimerase / UDP-galactose 4-epimerase	83,7	85,5
887644	<i>gal10b</i>	UDP glucose 4-epimerase / UDP-galactose 4-epimerase	22,5	22,1
742665	<i>ugp1</i>	UTP-glucose-1-phosphate uridylyltransferase (UDP glucose)	129,5	158,4
839559	<i>ugp2</i>	UTP-glucose-1-phosphate uridylyltransferase (UDP glucose)	128,5	326,4
432350	<i>pgm1</i>	Phosphoglucomutase	140,1	95,5
L-rhamnose catabolic pathway				
719159	<i>lra1</i>	L-rhamnose 1-dehydrogenase	36,2	6,1
750250	<i>kda1</i>	L-2-keto-3-deoxyrhamnonate aldolase	186,6	92,4
817972	<i>kda2</i>	L-2-keto-3-deoxyrhamnonate aldolase	66,3	43,8
Galacturonic acid catabolic pathway				
765275	<i>gar1</i>	Putative D-galacturonic acid reductase	170,2	80,1
794503	<i>gad1</i>	L-Galactonate dehydratase	118,0	29,1
807525	<i>kgal</i>	Putative 2-keto-3-deoxy-1-galactonate aldolase	382,4	85,6
Pentose catabolic pathway (PCP)				
482062	<i>lar1</i>	L-arabinose reductase/Glyceraldehyde reductase	392,2	72,6
811428	<i>xdh1</i>	xylitol dehydrogenase	502,6	249,4
830136	<i>xki1</i>	Xylulose kinase	146,2	89,1
Pentose phosphate pathway (PPP)				
764085	<i>rbt1</i>	Ribulokinase	58,5	41,8
787194	<i>gnd1</i>	6-Phosphogluconate dehydrogenase	644,1	470,2
771916	<i>gnd2</i>	Phosphogluconate dehydrogenase (decarboxylating)	39,7	35,7
765523	<i>pgl1</i>	6-Phosphogluconolactonase	61,5	130,5
791312	<i>rpi1</i>	Ribose-5-phosphate isomerase	48,9	46,8
78859	<i>rpe1</i>	Ribulose-phosphate 3-epimerase	94,7	50,6
788204	<i>tkt1</i>	Transketolase A/Dihydroxyacetone synthase	149,5	115,1
794540	<i>tal1</i>	Transaldolase	662,1	302,3
773377	<i>tal2</i>	Transaldolase	420,1	360,0
787617	<i>tal3</i>	Transaldolase	50,1	48,2
792586	<i>rbk1</i>	Ribokinase	12,4	6,7
Trehalose				
722898	<i>tps1</i>	Trehalose 6-phosphate synthase (Alpha alpha trehalose)	36,5	33,8
819781	<i>tppl</i>	Trehalose phosphatase (Trehalose-6-phosphate phosphatase)	62,7	91,1
437619	<i>tre1</i>	Acid trehalase (Alpha, alpha-trehalase)	34,8	7,8
790666	<i>tre2</i>	Neutral trehalase	89,8	80,5
809904	<i>trp1</i>	Putative trehalose phosphorylase with similarity to Ne	563,3	377,5

n metabolism and fungal cell wall acting CAZy enzymes by *O. rivulosa* grown on solid spruce wood during the mnose, D-galacturonic, Leloir, pentose catabolic and pentose phosphate pathways.
