Abstract

Listeria ivanovii is one of the two pathogenic species within the genus *Listeria*, the other being *L. monocytogenes*. In this study, we generated a stable pediocin resistant mutant Liv-r1 of a *L. ivanovii* strain, compared phenotypic differences between the wild-type and the mutant, localised the pediocin-induced mutations in the chromosome, and analysed the mechanisms behind the bacteriocin resistance. In addition to pediocin resistance, Liv-r1 was also less sensitive to nisin. The growth of Liv-r1 was significantly reduced with glucose and mannose, but less with cellobiose. The cells of Liv-r1 adsorbed less pediocin than the wild-type cells. Consequently, with less pediocin on the cell surface, the mutant was also less leaky, as shown as the release of intracellular lactate dehydrogenase to the supernatant. The surface of the mutant cells was more hydrophobic than that of the wild-type. Whole genome sequencing revealed numerous changes in the Liv-r1 chromosome. The mutations were found e.g., in genes encoding sigma-54-dependent transcription regulator and internalin B, as well as in genes involved in metabolism of carbohydrates such as glucose and cellobiose. Genetic differences observed in the mutant may be responsible for resistance to pediocin but no direct evidence is provided.

50 **1. Introduction**

51 Lactic acid bacteria (LAB) are a diverse group of Gram positive, catalase negative, and
52 oxidase negative bacteria with the GRAS (generally recognized as safe) status. LAB are
53 widely used as starters in food fermentations, but also as protective cultures against foodborne
54 pathogens and spoilage organisms, because they often produce antimicrobial compounds such
55 as bacteriocins. Most bacteriocins of LAB are small, heat-stable, cationic antimicrobial
56 peptides which can be classified into two main groups: post-translationally modified (class I)
57 and non-modified (class II) bacteriocins [1]. These classes can then be divided into several
58 subclasses, mainly based on their structures. Besides the class Ia bacteriocin nisin, which is
59 used as a food preservative, also class IIa (a.k.a. pediocin-like) bacteriocins are considered
60 promising candidates for industrial applications [2]. They have gained interest because of
61 their strong inhibitory effect on *Listeria* sp. More than 40 class IIa bacteriocins have been
62 identified and sequenced including pediocin, sakacin P, leucocin C, enterocin A etc [3, 4].
63 With the consumers' increasing demand for natural and minimally processed food, as well as
64 continuing emergence of antibiotic resistant bacteria, it has been suggested that class IIa
65 bacteriocins could have applications as antimicrobials in food industry as natural
66 preservatives, and in human and veterinary medicine as alternatives to antibiotics [5]. Even
67 though a few fermentation products based on pediocin have been commercialized,
68 bacteriocins are still underutilized by the food industry, at least partly due to insufficient
69 knowledge about how these antimicrobials work [6-8].

70 Positively charged class IIa bacteriocins easily bind to the negatively charged bacterial cell
71 surface, penetrate into the hydrophobic part of the cell membrane, and cause bacterial lysis by
72 forming pores [9]. The major uptake system for glucose and mannose, the mannose
73 phosphotransferase system (Man-PTS), and particularly its membrane proteins IIC and IID
74 form a receptor for class IIa bacteriocins [10]. By binding and inserting into Man-PTS, class

75 IIa bacteriocins form pores in cell membrane, which makes cells leaky, and eventually leads
76 to cell death. Although resistance against class IIa bacteriocins does not happen at high
77 frequency in nature, it has been reported to be developed in the laboratory, mainly by
78 downregulation of Man-PTS gene expression [11]. Ramnath et al. [12] and Xue et al. [13]
79 also demonstrated that there was a link between the expression of Man-PTS and resistance to
80 class IIa bacteriocins. In addition, structural changes in cell surface have been proposed to be
81 involved in the bacteriocin resistance [14].

82 Previous studies of class IIa bacteriocin resistance have mainly been focused on *Listeria*
83 *monocytogenes*, a foodborne human pathogen causing disease outbreaks and food recalls [15].
84 The objective of this study was to examine the pediocin resistance in *Listeria ivanovii*, a
85 pediocin highly sensitive strain and also of great economic importance as pathogen in
86 livestock [16]. Cells were made resistant by pediocin challenge, and the changes such as cross
87 resistance to antimicrobials, metabolic and surface properties, and chromosomal mutations
88 were investigated and compared with the wild-type strain. Understanding the mechanism
89 behind the bacteriocin resistance in different bacteria helps elucidate the bacteriocin-cell
90 interaction, which, in turn, may be useful for bacteriocin applications.

100 2. Materials and Methods

101 2.1. Bacterial strains and growth conditions

102 *L. ivanovii* wild-type strain DSMZ 20750 (Liv) and resistant variant (Liv-r1) were cultured
103 in Brain Heart Infusion (BHI) purchased from Beijing Aobox Bio-Tech Co., Ltd. (Beijing,
104 China) at 37 °C. Three class IIa bacteriocin-producing strains used in this study were cultured
105 as follows. *Pediococcus acidilactici* PA003 and *Lactobacillus plantarum* CICC 24194 were
106 cultured at 37 °C in de Man, Rogosa and Sharpe broth (MRS; Beijing Aobox Bio-Tech Co.,
107 Ltd., Beijing, China), and *Lactobacillus curvatus* ATCC 51436 was grown in MRS broth at
108 28 °C. Tryptone Soy Broth (TSB; 15.5 g/L tryptone, 5 g/L soybean peptone, 6.5 g/L yeast
109 extract, 5 g/L NaCl) was used for monitoring *L. ivanovii* growth in the presence of different
110 sugars. For solid media, 2% (wt/vol) agar was added.

111 2.2. Bacteriocin activity assays

112 Pediocin was prepared from *P. acidilactici* PA003 according to the method of Wang et al.
113 [17]. The neutral cell-free culture supernatants (nCFS) containing class IIa bacteriocins were
114 prepared by centrifugation of cultures at 7,000 g for 10 min, adjustment of supernatants to pH
115 7.0 and filtration through a 0.22 µm pore size filter (Millipore, US). Nisin was purchased from
116 Zhejiang Silver-Elephant Bio-engineering Co., Ltd. (Taizhou, China). Bacteriocin activity
117 was assayed by the agar well diffusion method and expressed in units [18]. The arbitrary units
118 (AU) per milliliter were equal to $2^n \times (1000/x)$, where n is the number of wells showing clear
119 inhibition of the indicator zone and x is the sample volume.

120 2.3. Generation of bacteriocin resistant variant and antimicrobial susceptibility test

121 *L. ivanovii*-derived strain resistant to pediocin was isolated by cultivation on plates
122 containing gradually increasing pediocin concentration (50-200 AU/mL, determined
123 according to section 2.2). The stability of the pediocin resistance of the isolate Liv-r1 was
124 verified after 10 serial sub-culturings in the absence of pediocin. The susceptibility and

125 minimum inhibitory concentrations (MIC) for antibiotic agents including kanamycin and
126 ampicillin against *L. ivanovii* strains were determined by agar well diffusion method, for
127 determining the possibility of cross-resistance to antibiotics. The MIC was defined as the
128 lowest concentration resulting in a clear inhibition zone.

129 2.4. Growth situations with different sugars

130 The growth of the strains Liv and Liv-r1 on different sugars was examined in TSB
131 supplemented with 1% (wt/vol) glucose, mannose or cellobiose (Shanghai Yuanye Bio-Tech
132 Co., Ltd., Shanghai, China). The media were inoculated with 1% of the overnight cultures,
133 and the growth was monitored by measuring the optical density at 600 nm for 12 h with a
134 spectrophotometer (Infinite 200, Tecan, US).

135 2.5. Adsorption of pediocin onto *L. ivanovii* strains

136 *L. ivanovii* cells were collected after overnight cultivation by centrifugation at 7, 000 g for
137 10 min. Pellets were washed with 5 mM phosphate buffer (pH 6.0) for 3 times and
138 resuspended to 10^8 cfu/mL in the same buffer containing 640 AU/mL pediocin, determined
139 according to section 2.2. The mixture was incubated at 30 °C for 1 h. Pediocin activity of the
140 supernatant obtained after centrifugation at 7, 000 g for 10 min was determined. The
141 phosphate buffer containing 640 AU/mL pediocin was used as a negative control.

142 2.6. Assessment of extracellular enzymes for pediocin inactivation

143 The CFSs of *L. ivanovii* cultures were obtained after overnight cultivation and
144 centrifugation at 7, 000 g for 10 min. Pediocin was mixed with the CFSs and incubated at
145 30 °C for 0.5 and 1.5 h. Bacteriocin activity was assayed by agar well diffusion according to
146 section 2.2. Pediocin mixed with BHI broth was used as a negative control.

147 2.7. Assessment of cell surface hydrophobicity

148 *L. ivanovii* cultures were centrifuged at 7, 000 g for 10 min. Cells were washed 3 times
149 with 50 mM phosphate buffer (pH 6.5) and resuspended in the same buffer to OD₆₀₀ of

150 approximately 0.5. Then, 4.8 mL of each bacterial suspension was mixed with 0.8 mL of
151 xylene in a glass tube, and vigorously shaken for 1 min. After incubation at room temperature
152 for 45 min, the aqueous phase was removed carefully and the OD₆₀₀ was determined. The cell
153 surface hydrophobicity was calculated with the following equation according to Pérez et al.
154 [19]: Adherence (%) = $(1 - A/A_0) \times 100$, where A₀ and A are the OD₆₀₀ of the bacterial
155 suspension before and after mixing with xylene, respectively.

156 2.8. Measurement of membrane permeability using extracellular lactate dehydrogenase 157 (LDH)

158 *L. ivanovii* strains were cultured 8 h and centrifuged at 11,000 g for 10 min. Cell pellets
159 were washed twice with 10 mM phosphate buffer (pH 7.2) and resuspended in the same buffer
160 to the concentration of 10⁸ cfu/mL. Then, the suspensions were mixed with 64 AU/mL
161 pediocin, determined according to section 2.2 and incubated at 37 °C. Samples were taken out
162 and filtered through a 0.22 µm pore size filter at 0, 1, 3 and 4 h. The filtrate was determined
163 for extracellular LDH using a LDH kit (Jiancheng Biology Engineering Institute, Nanjing,
164 China). *L. ivanovii* suspensions without pediocin treatment were used as controls.

165 2.9. DNA extraction and sequencing

166 Genomic DNA from wild-type *L. ivanovii* and the resistant variant was isolated from
167 overnight cultures using standard cetyl trimethyl ammonium bromide (CTAB) method [20].
168 DNA samples were submitted to the Biomarker Technologies (Beijing, China) and sequenced
169 using Illumina sequencer (NOVA seq) according to the instructions of the manufacturer.

170 2.10. Sequencing analysis

171 Pair-end reads from the sensitive wild-type strain and the corresponding resistant variant
172 were subjected to quality evaluation and filtering before obtaining clean reads, and then
173 compared to the fully annotated database reference genome of *L. ivanovii*
174 (<https://www.ncbi.nlm.nih.gov/genome/?term=Listeria+ivanovii>) using Burrows-Wheeler

175 Alignment tool (BWA) software [21]. Observed differences (SNPs or indels) between the
176 genomes of the two sequenced strains were analysed to identify the mutations possibly
177 causing pediocin resistance.

178 2.11. Statistical analysis

179 Results were presented as mean \pm standard deviation (SD) from three replicates. A one-way
180 analysis of variance in SPSS software version 17 was performed for evaluation of each pair of
181 strains, wild-type and pediocin-resistant mutant, based on post hoc analysis with significance
182 level of $P < 0.05$.

183

184 3. Results and Discussion

185 3.1. Generation of pediocin resistant *L. ivanovii*

186 Pediocin resistant *L. ivanovii* cells were isolated after exposure to gradually increasing
187 concentrations of pediocin at a frequency of 10^{-6} , consistent with reported class IIa bacteriocin
188 resistance frequency in *Listeria* depending on the conditions and strains [22, 23]. One mutant
189 of *L. ivanovii* with stable resistant phenotype, designated as Liv-r1, was chosen for
190 comparisons with the wild-type *L. ivanovii*. Wild-type strain was sensitive to the nCFSs from
191 three class IIa bacteriocin-producing strains, among which pediocin was the most effective
192 bacteriocin (Table 1). The Liv-r1 mutant was resistant to all tested nCFSs showing no visible
193 inhibition zones in agar well diffusion analysis. Besides, Liv-r1 displayed increased resistance
194 to class I bacteriocin nisin but not to ampicillin (Table 1 and 2). Cross resistance among
195 bacteriocins has been described in several reports. Pediocin 34 resistant mutant of *L.*
196 *monocytogenes* showed cross resistance to enterocin FH99, and the nisin resistant
197 *Enterococcus faecium* variant conferred cross resistance to both pediocin 34 and enterocin
198 FH99 [24]. Likewise, in the study by Kumariya et al. [9], pediocin resistant *Enterococcus*
199 *faecalis* was also resistant to nisin. However, there was no cross resistance to antibiotics in

200 Liv-r1, indicating that acquiring bacteriocin resistance in *Listeria* may not hinder the
201 antibiotic therapy. In fact, it may render the cells even more sensitive to antibiotics due to
202 fitness cost of developing bacteriocin resistant phenotype, as reported previously by Martínez
203 and Rodríguez [25].

204 3.2. Carbohydrate utilization

205 Bacteria transport carbohydrates mainly by specific phosphoenolpyruvate-dependent
206 phosphotransferase systems (PTS). In the genome sequence of *L. monocytogenes* EGDe,
207 seven families of *pts* genes have been recognized (Glc-PTS, Man-PTS, Lac-PTS, Fru-PTS,
208 Gut-PTS, Gat-PTS and Asc-PTS) [26, 27]. It has been reported that the class IIa bacteriocin
209 resistant *L. monocytogenes* grow slower on mannose and glucose than on cellobiose, which
210 indicates that the gene expression of the Man-PTS, the main receptor of class IIa bacteriocins,
211 is downregulated in the resistant mutants [11]. Similarly, spontaneous pediocin resistant *E.*
212 *faecalis* mutants have shown reduced glucose consumption [28]. Therefore, in the present
213 study, the growth of *L. ivanovii* strains was evaluated on different carbohydrates, i.e., glucose,
214 mannose, and cellobiose. When compared to the wild-type strain, the growth of the resistant
215 variant Liv-r1 was reduced with all three carbohydrates (Fig. 1). However, like in the study by
216 Tessema et al. [11] mentioned above, the variant grew remarkably better on cellobiose than on
217 glucose and mannose (Fig. 1), suggesting similar mechanism of bacteriocin resistance in *L.*
218 *ivanovii* and *L. monocytogenes*. According to Stoll and Goebel [27], cellobiose is transported
219 by both Glc-PTS and Lac-PTS in *L. monocytogenes*, whereas glucose and mannose are
220 transported by Glc-PTS and Man-PTS. Therefore, possible downregulation of Man-PTS
221 would have smaller effect on growth with cellobiose. In addition, it has been shown that
222 growth on glucose, mannose and fructose increased the sensitivity of *L. monocytogenes* to
223 leucocin A or carnocyclin A, while growth on cellobiose and sucrose increase the resistance to
224 bacteriocins [29]. In conclusion, it seems likely that carbohydrate metabolism plays a crucial

225 role in class IIa bacteriocin sensitivity in different bacterial species.

226 3.3. Adsorption of pediocin on *Listeria* cells

227 To test whether the pediocin resistance was based on poorer adsorption of the peptide onto
228 cell surface, pediocin was mixed with wild-type and resistant variant cells, and the bacteriocin
229 activity was measured from the supernatant after 1 h incubation in a buffer with pH 6.0.
230 Pediocin has been shown to adsorb onto cell surface in a pH-dependent manner, the strongest
231 adsorption occurring around at pH 6.0 [30]. As shown in Table 3, the residual concentrations
232 of free pediocin in PBS decreased both in wild-type and resistant cells, indicating that the
233 pediocin had adsorbed on the cell surface. However, the adsorption level of the wild-type cells
234 was twice as much of that of the resistant variant, suggesting that there may be less specific
235 receptor sites on the surface of Liv-r1, or that the cell surface of Liv-r1 may have changed
236 somehow, making it less adherent to pediocin. One way or another, less pediocin adsorbed on
237 the variant *Listeria* cells, which partly reduces the antimicrobial activity for taking effect.

238 3.4. Examination of pediocin inactivation by extracellular enzymes

239 Many bacteria, e.g., *Bacillus subtilis* and *Lactococcus lactis*, produce extracellular
240 proteases, which can degrade antimicrobial peptides [15, 31]. Even though this has never been
241 shown to happen with *Listeria* and class IIa bacteriocins, the secretion of proteases or other
242 bacteriocin-inactivating enzymes is a possible mechanism for resistance, and should not be
243 excluded without testing it. Therefore, to examine whether the resistant mutant excretes a
244 pediocin-inactivating enzyme, the bacteriocin was mixed and incubated in *Listeria* CFSs, and
245 the pediocin activity was determined. The results shown in Table 4 verified that neither the
246 wild-type, nor the pediocin resistant *Listeria* had any pediocin-degrading activity. This result
247 further supports the previous finding that pediocin resistance of Liv-r1 was, at least partly,
248 mediated by reduced pediocin adsorption onto the cell surface, and not by secretion of
249 proteases.

250 3.5. *Pediocin-induced cell leakage*

251 Cell leakage caused by pore-forming activity of pediocin was evaluated by measuring LDH
252 enzyme in culture supernatants. The culture supernatant of the wild-type *L. ivanovii* had
253 significantly higher LDH activity in the presence of pediocin compared with that of Liv-r1 at
254 the same time (Fig. 2). Immediately after pediocin addition (time point zero), the wild-type
255 cells started to leak, and the leaking continued through the monitored four hours. On the
256 contrary, in Liv-r1 supernatants at time point zero, the LDH activity with and without
257 pediocin was approximately the same. During the 4-h test, the LDH activity in the Liv-r1
258 supernatant with pediocin still increased, but evidently less than in wild-type supernatant. The
259 results demonstrated that pediocin took effect in a rapid manner. Similar fast lytic effect of
260 pediocin has also been reported before. In 30 min after pediocin treatment, *Listeria* cells were
261 visibly leaking in SEM image [32]. Not surprising, the results also showed that the resistant
262 cells were more tolerant than the wild ones. The resistance could be explained by alterations
263 of cell surface properties either by decreased fluidity, increased rigidity or decreased negative
264 charges disrupting pediocin-receptor interaction [33].

265 3.6. *Cell surface hydrophobicity*

266 It has been previously shown that there are several mechanisms of class IIa bacteriocin
267 resistance, one of which is related to alterations in cell membrane or cell wall [34]. In this
268 study, we compared the hydrophobicity of cell surfaces of wild-type and the Liv-r1 mutant by
269 determining the cells' adhesion to xylene. Significantly higher cell surface hydrophobicity (P
270 < 0.05) was seen in resistant *L. ivanovii* variant compared with the wild-type (Fig. 3). In
271 Kumariya et al. [9] work, the increase in cell surface hydrophobicity was collinear with the
272 degree of pediocin resistance. In addition, Lather et al. [35] have also pointed out the
273 contribution of cell surface hydrophobicity as an adaptive reaction against antimicrobial
274 agents. As the bacterial cell envelope is negatively charged, the increased hydrophobicity may

275 suggest less negative charges on the surface, which decreases the interaction with cationic
276 antimicrobial peptides, leading to increased resistance.

277 3.7. Whole-genome sequencing

278 The technological progress of whole-genome sequencing (WGS) may grant access to
279 potential mechanisms of bacteriocin-resistance by providing high-throughput information at
280 bacterial molecular level. In this work, to find out which genes actually had been mutated in
281 the pediocin-resistant mutant Liv-r1, the genomes of the mutant and the wild-type strain were
282 sequenced. After filtering, 4463819 and 4802008 clean reads were obtained from Liv and Liv-
283 r1, respectively. The GC content of Liv was 37.14% with sufficient quantity (Q20 = 98.12%)
284 and quality (Q30 = 94.26%) of the data for further analysis. The GC content of Liv-r1 was
285 37.12% with sufficient quantity (Q20 = 98.04%) and quality (Q30 = 94.09%) of the data.

286 The genome sequences of the pediocin-resistant strain showed 12 single nucleotide
287 polymorphisms (SNP) compared to the wild-type reference, 6 of which belonged to non-
288 synonymous coding, 4 to synonymous coding and 2 to upstream regions of genes. Precise
289 locations of these SNPs, and the annotation results of predicted proteins in NR (non-
290 redundant) and Swiss-Prot databases are shown in Table 5. Three SNPs were related to genes
291 *i-inlB1* and *i-inlB2* (gene IDs 1383 and 503 in Table 5), encoding variants of internalin B,
292 surface proteins involved in invasion of multiple mammalian cell types in *L. monocytogenes*
293 by activating junctional endocytosis [36]. Two mutations in the *i-inlB1* gene caused amino
294 acid changes (V563I and I985V) in the GW-domains responsible for non-covalent binding of
295 the i-InlB1 internalin onto the bacterial cell surface. However unlikely, it cannot be excluded
296 that these two amino acid changes have had an effect on i-InlB1 protein and its binding or
297 release to/from the cell surface. Winkelströter et al. [37] demonstrated that in the presence of
298 bacteriocins from *Lactobacillus sakei*, *Leuconostoc mesenteroides*, and *E. faecium*, the

299 expression of the internalin A gene *inlA* was downregulated in *L. monocytogenes*.
300 Downregulation of internalins is likely to reduce the virulence of the strain. However, in our
301 study, the observed mutation related to the gene *i-inlB2* was quite far, 1289 bp upstream of
302 the gene, and thus probably did not have much effect on the expression level of the *i-inlB2*
303 gene. As cell surface proteins, internalins affect the cell's surface properties, and thus
304 mutations or changes in their expression level may also affect the binding or adhesion of
305 bacteriocins onto cell surface. However, the effect of the observed SNPs in the protein
306 properties or gene expression levels were not determined in this work, and therefore further
307 studies would be needed to clarify which SNPs, if any, actually had effect on the pediocin
308 resistant phenotype.

309 Altogether 87 indels were found in the resistant mutant Liv-r1, including frameshifts,
310 upstream and downstream mutations, codon deletions and codon deletion plus codon insertion
311 (Supplemental material). The most common mutation was frameshift. Annotation analysis
312 was conducted in COG database, and in total 10 indels were found to belong to carbohydrate
313 transport and metabolism, 9 were involved in transcription, 6 in inorganic ion transport and
314 metabolism, and 5 in amino acid transport and metabolism. Metabolism of carbohydrates
315 including glucose, cellobiose, lactose, and β -glucoside were identified in the indels (Table 6).
316 These results corresponded with the observed differences in carbohydrates metabolism of
317 wild-type and variant one. Laursen et al. [38] have previously pointed out that after exposure
318 to 180 min to pediocin-containing *Lb. plantarum* WHE92 supernatant, 25 genes related to
319 carbohydrate transport and metabolism were upregulated, while 31 related genes were
320 downregulated in *L. monocytogenes*. Thus, class IIa bacteriocin sensitivity may be associated
321 with genes in charge of carbohydrate transportation, metabolism and regulation.

322 Regarding the transcription class of the observed indels, gene 910 annotated as sigma-54-
323 dependent transcriptional regulator was found to have a frameshift. Sigma-54 is in charge of

324 regulating numerous genes, often related to sugar transport and metabolism, including Man-
325 PTS [39]. It has also been recognized to have a role in the resistance of class IIa bacteriocins
326 in *E. faecalis* and *L. monocytogenes* [40, 41]. In a study about class IIa bacteriocin resistance
327 in *Enterococcus* by Geldart and Kaznessis [42], a mutation in the sigma-54 transcription
328 factor and the disruption of the sigma-54-associated activator protein, ManR, were found after
329 genome comparison.

330 **4. Conclusion**

331 This study provides the characterisation of class IIa bacteriocin resistance in *L. ivanovii*.
332 The resistant cells exhibited reduced growth on glucose, adsorption of pediocin, and cell lysis
333 by pediocin attack. Additionally, increased cell surface hydrophobicity was detected in
334 resistant mutant compared with the wild-type. Lastly, results from whole-genome sequencing
335 provided evidence to suggest the vital role of the carbohydrate transportation, metabolism and
336 regulation in the development of pediocin resistance. PTS systems responsible for different
337 carbon sources will be further examined for their functions in *L. ivanovii* for in-depth
338 understanding of bacteriocin-cell surface interaction.

339 **Conflict of Interest**

340 The authors declare that they have no conflicts of interest.

462 **Legends to figures**

463 Fig.1. Growth situations of the wild-type Liv (A) and the pediocin resistant variant Liv-r1 (B)
464 in TSB broth containing glucose, mannose, or cellobiose. The growth of the variant strain
465 Liv-r1 is reduced stronger on glucose and mannose than on cellobiose.

466 Fig.2. LDH activity at different time points after pediocin addition. High LDH activity in the
467 wild-type strain Liv with pediocin indicates strong and fast cell leakage due to pore-forming
468 activity of pediocin. Cells of the resistant variant Liv-r1 leaked noticeably less, as seen as
469 lower LDH activity. Statistically significant difference between Liv and Liv-r1 was found ($*P$
470 < 0.05).

471 Fig.3. Cell surface hydrophobicity of the wild-type Liv and the pediocin-resistant variant Liv-
472 r1. The resistant variant showed higher cell surface hydrophobicity than the wild-type strain.
473 Statistically significant difference between Liv and Liv-r1 was found ($*P < 0.05$).
