Abstract.

BACKGROUND: Quercetin is a flavonoid with reported antioxidant, anti-inflammatory and anti-aging effects, and may limit muscle wasting in cancer cachexia.

OBJECTIVE: To investigate the effect of quercetin on muscle wasting in the murine C26 cancer-cachexia model and assess the feasibility of non-invasive micro-CT analysis of skeletal muscle.

MATERIALS AND METHODS: Custom CRM(P) diets supplemented with 250 mg/kg quercetin (Q) were obtained. Thirty CD2F1 mice were equally randomized to non-tumor-bearing (NTB), C26 tumor-bearing (TB), TB + Q. All groups started their allocated diet and underwent hindlimb micro-CT. Bodyweight, food intake, and grip-strength were recorded periodically. After 21 days, repeat micro-CT was performed. Gastrocnemius (GCM) and tibialis anterior (TA) muscles were resected. mRNA expression of MuRF1, Atrogin-1, myogenin, and MyoD was determined.

RESULTS: NTB and TB + Q gained 9.4% and 5.3% bodyweight respectively, TB lost 3.9%. Hind limb skeletal muscle volume remained stable for NTB and TB + Q, whereas TB decreased from 242.0 mm³ to 212.8 mm³. Mean GCM muscle weight was 175.2 mg (NTB), 171.3 mg (TB + Q) versus 125.5 mg (TB). A tendency towards decreased expression of atrogin-1 and MuRF1 was observed in TB + Q.

CONCLUSION: Dietary quercetin supplementation limits bodyweight loss and muscle wasting in the C26-cancer-associated cachexia model.

Keywords: Quercetin, cachexia, cancer, muscle wasting

1. Introduction

Progressive muscle wasting is a characteristic feature of cachexia commonly observed in cancer patients [1]. This multi factorial syndrome cannot be fully reversed by conventional nutritional support and leads to progressive functional impairment [1, 2]. Up to 50 percent of all cancer patients are faced with cachexia during the course of their disease and up to 20 percent of all cancer-associated deaths may be attributed to cachexia [3–5]. The eti-

ology of cancer cachexia is not yet fully understood, however catabolic pro-inflammatory cytokines are suggested to be of key importance. The most frequently described cytokines associated with cachexia include interleukin-6 (IL-6), tumor necrosis factor alpha (TNF- α), interferon gamma (IFN- γ), and interleukin-1-beta (IL-1B) [6–8].

Treatment of cancer cachexia may be directed at reduction of synthesis or blocking the action of the aforementioned pro-inflammatory cytokines. By doing so, it may contribute to improving the patient quality of life and, possibly, even prolong survival [9]. Not just the development of novel pharmaceutical strategies has been suggested to limit the activity of catabolic cytokines in cancer cachexia, but also

dietary interventions have been proposed [9]. For instance dietary supplementation with long-chain omega-3 fatty acid eicosapentaenoic acid (EPA) in cachectic patients appeared promising in initial studies [10]. Later studies, however, conclude that there is insufficient evidence to support the clinical application of EPA for the treatment of cancer cachexia [11, 12]. In contrast, the leucine metabolite β -hydroxy- β -methyl-butyrate (HMB) limits muscle wasting in experimental cachexia [13–15] and has been found to attenuate muscle loss in a clinical trial [16, 17]. Additionally, quercetin has recently been described as to limit muscle wasting *in vivo* [14]. Quercetin is a plant pigment (flavonoid). It is found in many vegetables, herbs, and fruits such as capers, dill, cilantro, red onion, broccoli, berries, and apples [18]. Its antioxidant, anti-inflammatory, and anti-aging effects have previously been described [19–22]. Quercetin supplementation decreases circulating markers of inflammation [23]. In both an APC knockout cachexia model as well as an obesity model quercetin supplementation limited associated loss of muscle mass [14, 24].

In this current study, we sought to investigate the potential of quercetin in the C26 adenocarcinoma cancer cachexia model, a well-established model of cancer cachexia in mice [25], and assess the feasibility of micro-CT analysis as a novel non-invasive and potentially supplemental technique of skeletal muscle measurement.

2. Materials & methods

2.1. Animal ethics committee approval

All animal experiments were performed with the approval of the Erasmus MC, Rotterdam, the Netherlands Animal Ethics Committee and in accordance to the Dutch National Experiments on Animal Act, and complied with the EU adopted Directive 86/609/EEC (1986).

2.2. Animals

Thirty male CD2F1 (BALB/c \times DBA/2) F1 mice of 8 weeks (\sim 25 grams) were obtained from Charles River, Maastricht, the Netherlands. Upon arrival, animals have been housed in individually ventilated cages and maintained at 22°C under a 12 h light-dark cycle with ad libitum access to CRM (P) chow (Spe-

cial Diet Services, Witham, Essex, UK) and water ($n=3-4$ animals per cage). Animals were acclimatized for one week prior to the start of the experiments.

2.3. Quercetin

Quercetin was obtained from Sigma-Aldrich, Zwijndrecht, the Netherlands (product code Q4951 SIGMA) and after arrival at our institution immediately shipped through to Special Diet Services for the purpose of manufacturing a custom quercetin supplemented diet.

2.4. CRM(P) chow

CRM (P) chow with and without supplemented quercetin was obtained from Special Diet Services, Witham, Essex, UK. Diet composition is detailed in Table 1. A concentration of 250 mg quercetin per kg chow was manufactured for purpose of this study. This concentration corresponds with an expected daily intake of 35 mg per kg of body weight per mouse per day. All mice started with their allocated diets on the first day of the experiment.

2.5. C26 Tumor-bearing mice

Colon-26 (C26) adenocarcinoma cells (kindly provided by Dr. D.O. McCarthy, Ohio State University, Columbus, OH, USA) were maintained in RPMI 1640 (Westburg BV, Leusden, The Netherlands) supplemented with 10% fetal bovine serum (FBS, Sigma-Aldrich, St. Louis, The United States of America), and 1% penicillin/streptomycin (P/S, Fisher Scientific, Waltham, The United States of America) at 37°C in a 5% carbon dioxide environment. On the first day of the experiment, animals allocated to tumor-bearing (TB) groups received a subcutaneous (SC) inoculation in the right flank with 0.5×10^6 C26 adenocarcinoma cells in 100 μ L sterile PBS under anesthesia by isoflurane inhalation (5% isoflurane induction). This is a well-established model of cancer cachexia in mice [25].

2.6. Assessment of grip-strength

Combined hind- and forelimb grip strength was measured twice per week by placing the animal on a grid attached to a force gauge (BIOSEB, Chaville, France), and steadily pulling the mice by the tail along the sensor axle until grip is released. Maxi-

The control diet used in the current study is the rat and mouse breeder and grower diet, pelleted (CRM(P)), obtained from Special Diet Services (SDS). *Added nutrients from manufactured and mined sources. Ingredients (wheat, wheat feed, barley, de-hulled extracted toasted soya, maize, macro minerals, soya oil, potato protein, hydrolyzed wheat gluten, full fat soya, maize gluten meal, vitamins, micro minerals, amino acids) and the calculated analysis in the table above are retrieved from the SDS CRM(P) product specification sheet [51]. The quercetin supplemented diet was manufactured with the addition of 250 mg quercetin per kg chow to the base diet detailed in this table.

imum strength produced before releasing the grid was registered in triplicate with one minute rest period for each animal. Obtained values were averaged to provide a mean force measurement for each indi-

vidual animal and subsequently normalized to each animal's grip-strength respectively on day 0. All measurements were performed blind with respect to treatment.

2.7. Skeletal muscle volumetric measurement by micro-CT

In clinical cachexia imaging modalities such as CT are frequently used to determine muscle mass [26, 27]. For rodents micro-CT is available as a non-invasive method for screening anatomical change [28]. High spatial resolution and temporal resolution allow capture of detailed anatomical imaging and monitor disease progression in rodents [28, 29]. The absorbed radiation dose from serial micro-CT imaging is low and likely below the threshold for carcinogenesis [30]. This makes micro-CT analysis an interesting novel approach in the assessment of muscle weight loss in experimental cancer cachexia.

Hind limb imaging was performed in all animals prior to the start of the experiment, and once more directly preceding sacrifice. Under anesthesia by isoflurane inhalation animals were positioned on the left flank, and had their right hindlimb fixed in extended position. Images were obtained using a Quantum FX (Perkin Elmer, Waltham, MA, USA) low-dose micro computed tomography (μ CT) scanner which scanned at 90 kV of peak voltage, with 160 μ A of current, 40 mm field of view, and 4.5-minute scan time. Obtained scans were subsequently analyzed using Analyze 11.0 (Analyze Direct, Inc., Lenexa, KS, USA). This was done by manually delineating the skeletal muscle of the right hindlimb from the tibial surface proximally to the malleoli distally and segmenting the tissue of interest based on HU thresholds (-30 HU to $+150$ HU for skeletal muscle [26]).

2.8. Bodyweight, muscle mass, and tumor size

Bodyweight was recorded daily. Bodyweight was normalized to each animal's bodyweight on day 0. Tumor size was recorded every other day starting on day 9 after tumor inoculation using digital calipers. Tumor mass was estimated via the for-

mula $\text{mass}(\text{mg}) = \text{tumor volume} (\text{mm}^3) = \text{width}^2 \times \text{length}/2$ [31]. Animals were sacrificed by cervical dislocation under isoflurane anesthesia on day 21 or upon body weight loss exceeding 20%. Gastrocnemius (GCM), tibialis anterior (TA) and soleus (Sol) muscles of both hind legs and tumor were dissected and weighed. Muscle weight from the left and right hind leg were averaged to provide a mean muscle weight (GCM, TA, and Sol) for each animal. Muscle samples were immediately snap-frozen in liquid nitrogen and stored at -80°C until analysis.

2.9. RNA isolation and real-time polymerase chain reaction

Cancer-cachexia associated muscle wasting is known to be most pronounced in fast-twitch type II-containing muscles, such as GCM and TA [32]. Therefore, for gene expression analysis, total RNA was isolated from snap-frozen GCM muscle tissue using Trizol reagent (Invitrogen, Breda, the Netherlands), and subsequently purified by DNase treatment (RQ1 RNase-Free DNase) (Promega Benelux B.V., Leiden, the Netherlands). 1 μ g of total RNA was reversed transcribed to cDNA using random hexamer primers (Invitrogen, Breda, the Netherlands), and Superscript II RT (Invitrogen, Breda, the Netherlands). Quantitative real-time polymerase chain reaction (RT-PCR) was performed using an iCycler real-time PCR system (Biorad, California, The United States of America) using SYBR Green (Sigma-Aldrich, St. Louis, The United States of America). Used primer sequences can be found in Table 2. GAPDH was used as housekeeping gene for normalization. Relative gene expression fold change was calculated with the comparative delta-delta Ct method ($2^{-\Delta\Delta\text{Ct}}$)/(average $2^{-\Delta\Delta\text{Ct}}$ (healthy controls)) [33]. Each sample was tested in duplicate.

2.10. Statistics

Categorical data are expressed as number (percentage) and continuous variables as mean \pm SEM (normal distribution, visually assessed and by means of the Shapiro-Wilks test). Body weight and grip-strength were normalized to each animal's body weight and grip-strength respectively on day 0. Muscle weight from the left and right hind leg were averaged to provide a mean GCM and TA muscle weight for each animal. Multiple group comparisons were done by one-way ANOVA with a Bonferroni's *posthoc* test. Spearman-Rho rank correlation coefficient was used for testing bivariate correlations. All analyses were performed using IBM SPSS Statistics for Windows, version 21.0 (IBM Corp., Armonk, NY, USA). A *P* value <0.05 was considered statistically significant.

3. Results

To study the effects of a quercetin supplemented diet, thirty CD2F1 mice were randomly allocated to three groups, i.e. non-tumor bearing (NTB) with access to regular chow, tumor-bearing (TB) with access to regular chow, and tumor-bearing with access to chow supplemented with 250 mg quercetin

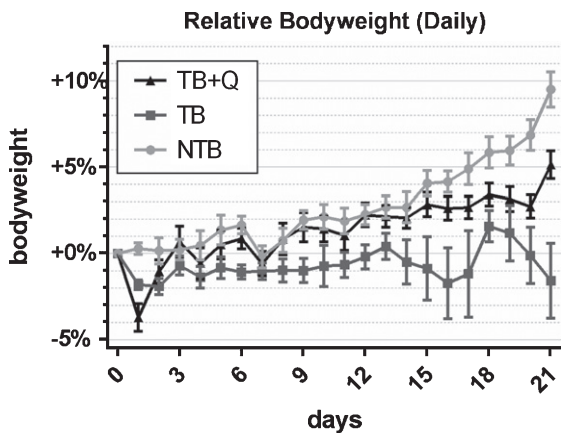

Fig. 1. Daily bodyweight throughout the experiment. Line chart depicting the mean \pm SEM daily bodyweights per group in non-tumor-bearing male CD2F1 mice (NTB, $n = 10$), C26 tumor-bearing (TB, $n = 10$) mice with ad libitum access to regular chow, and C26 TB mice with ad libitum access to quercetin supplemented chow (TB+Q, $n = 10$). Bodyweight was normalized to each animal's bodyweight on day 0 and is expressed as the percentage difference. Mice in the TB group experienced a significant loss of bodyweight in comparison to both TB+Q and NTB mice.

per kg chow (TB + Q), starting on the first day of the experiment. Simultaneously, mice allocated to tumor-bearing groups were inoculated subcutaneously with 0.5×10^6 C26 adenocarcinoma cells. Body weight was recorded daily. During the experiment NTB mice gained 9.4 % bodyweight, whereas TB mice lost 3.9% bodyweight ($p < 0.0001$) (Fig. 1). Tumor-bearing mice showed a decrease in body weight on the first day after changing the diet to quercetin supplemented, likely as a result of the different taste of this diet. Thereafter, however, they gained 5.3% bodyweight, which was significant when compared to tumor-bearing mice on a regular diet ($p = 0.0024$). Daily food intake was relatively constant for non-tumor-bearing mice throughout the experiment with a mean daily intake of 3.8 g chow per mouse (Fig. 2). For tumor-bearing mice, on a regular diet, comparable food intake was observed during the first two weeks of the experiment. Throughout the last 7 days of the experiment, these mice showed a gradual increase in daily food intake up to a mean of 7.9 g chow per mouse on the last timepoint. Mice on the quercetin diet had an increased intake throughout the experiment, starting rapidly after initiation of this

Fig. 2. Daily food intake throughout the experiment. Line chart depicting the mean daily food intake over the prior 24 hours per group in non-tumor-bearing male CD2F1 mice (NTB, $n = 10$), C26 tumor-bearing (TB) mice with ad libitum access to regular chow (C26 TB, $n = 10$) and mice with ad libitum access to quercetin supplemented chow (TB+Q, $n = 10$). Food intake was measured per cage and subsequently averaged per mouse. Food intake is expressed in grams (g). Food intake of TB mice was comparable to NTB mice throughout the first two weeks, subsequently, daily chow consumption more than doubled. TB+Q mice had an overall higher chow consumption throughout the first two weeks, subsequently, a minor increase in chow consumption was observed in the final days of the experiment.

diet, resulting in a mean daily intake of 4.7 g chow per mouse during the first two weeks of the experiment. These tumor-bearing mice on a quercetin diet too were observed to increase their daily food intake during the last 7 days of the experiment, up to a maximum mean of 6.2 g chow per mouse on the 20th day of the experiment.

3.1. Grip-strength assessment

Grip-strength was assessed twice per week. NTB mice showed an increase in grip-strength over the course of the experiment. This increase registered up to 24.7% at the end of the experiment (Fig. 3). TB mice, on the other hand, showed a limited increase of 6.7% at the end of the experiment, this difference did not reach significance ($p = 0.06$). Tumor-bearing mice on a quercetin supplemented diet had a comparable grip-strength to the tumor-bearing mice on a regular chow diet. These mice too showed a limited increase in grip-strength of 7.6%.

3.2. Micro-CT hindlimb skeletal muscle volumetry

Hind limb skeletal muscle volumetric measurements by micro-CT (Fig. 4A) on day 1 were comparable for all three groups; 245.6 mm³ for NTB mice, 242.0 mm³ for TB mice, and 250.1 mm³

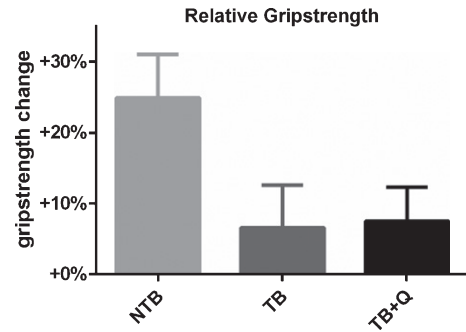

Fig. 3. Relative grip-strength at the end of the experiment. Bar graphs depicting the mean \pm SEM for final grip-strength normalized to starting grip-strength in non-tumor-bearing male CD2F1 mice (NTB, $n = 10$), C26 tumor-bearing (TB) mice with ad libitum access to regular chow (C26 TB, $n = 10$) and mice with ad libitum access to quercetin supplemented chow (TB + Q, $n = 10$). Multiple group comparisons were done by one-way ANOVA with a Bonferroni's *posthoc* test. All groups were compared against TB mice. A substantial, non-significant difference in relative grip-strength was observed between TB and NTB mice. TB + Q relative grip-strength was comparable to TB mice.

for TB + Q mice (Fig. 4B). No significant change was observed in skeletal muscle volume on day 21 for NTB mice and TB + Q mice; 253.8 mm³ for NTB mice, and 249.6 mm³ for TB + Q mice. Tumor-bearing mice on a regular chow diet experienced a decrease in skeletal muscle volume to 212.8 mm³ on day 21 ($p = 0.006$). These differences between NTB and TB, as well as TB + Q and TB, were significant

A

B

Fig. 4. Micro-CT hindlimb skeletal muscle mass volumetric. (A) Micro-CT image depicting the hindlimb musculature. (B) Bar graphs depicting the mean \pm SEM for micro-CT skeletal muscle volume on day 1 and day 21 respectively in non-tumor-bearing male CD2F1 mice (NTB, $n = 10$), C26 tumor-bearing (TB) animals with ad libitum access to regular chow (C26 TB, $n = 10$) and mice with ad libitum access to quercetin supplemented chow (TB+Q, $n = 10$). Multiple group comparisons were done by one-way ANOVA with a Bonferroni's *posthoc* test. All groups were compared against TB mice. Comparisons between multiple time-points were done by paired samples *t*-test. * $p < 0.05$ ** $p < 0.01$.

with respective p -values of 0.0078 and 0.0172. A high positive correlation is observed between skeletal muscle volume on day 21 and combined right hindlimb muscle weight (GCM, TA, and Sol) at sacrifice (Spearman's $\rho = 0.718$, $p < 0.0001$).

3.3. Muscle and tumor weight

All animals were sacrificed at 21 days following tumor inoculation. The gastrocnemius and tibialis anterior muscles were resected and weighed. Mean gastrocnemius muscle weight in NTB mice was 175.2 ± 12.4 mg versus 125.5 ± 27.3 in TB mice ($p < 0.0001$, Fig. 5B). Mean gastrocnemius muscle weight in TB+Q mice was 171.3 ± 17.8 mg ($p < 0.0001$ compared to TB mice). Mean tibialis anterior muscle weight in NTB mice was 64.1 ± 7.1 mg versus 48.9 ± 11.1 in TB mice ($p = 0.0024$, Fig. 5D). Mean tibialis anterior muscle weight in TB+Q mice was 63.7 ± 9.6 mg ($p = 0.0031$ compared to TB mice). Tumor mass increased until at day 21 a mean tumor weight of 478.3 ± 288.7 mg was recorded for TB mice and 288.7 ± 196.3 mg for TB+Q mice ($p = 0.14$) (Fig. 5C). Tumor mass was not correlated with tibialis anterior muscle weight (Spearman's $\rho = -0.261$, $p = 0.47$) and gastrocnemius muscle weight (Spearman's $\rho = 0.091$, $p = 0.80$) at sacrifice for TB+Q mice (Fig. 5E, 5F).

3.4. Gene expression

Skeletal muscle E3 ubiquitin ligases and myogenic regulatory factors mRNA expression profiles were determined in gastrocnemius muscle samples. A substantial, non-significant difference in expression of E3 ubiquitin ligase atrogin-1 was observed between TB and TB+Q mice, as well as to a lesser extent in the expression of MuRF1 (Fig. 6A, 6B). Expression of MyoD and Myogenin was comparable between all groups (Fig. 6C, 6D).

4. Discussion

Cancer-associated cachexia is a common finding in patients afflicted by multiple types of malignancies [27, 34]. It has detrimental effects on survival as well as the quality of life [27, 34]. Unfortunately, there are no validated treatment modalities to halt or reverse the associated progressive muscle wasting. Our study investigated whether quercetin supplementa-

tion could attenuate muscle wasting in the murine C26 cancer-cachexia model. We found this to be true. C26 tumor-bearing mice on a diet supplemented with quercetin showed a preservation of gastrocnemius muscle weight as well as tibialis anterior muscle weight. In this group of mice, bodyweight was also preserved. These findings were accompanied by a tendency towards decreased expression of E3 ubiquitin ligases atrogin-1 and MuRF1 in tumor-bearing mice on a quercetin supplemented diet compared to tumor-bearing mice on a regular chow diet. As this study was not powered to detect differences in mRNA expression we consider it likely this lack of significance is due to a type II error. It has been shown that quercetin reduces the transcription of atrogin-1 and MuRF1 in obesity-induced skeletal muscle inflammation in mice, which has been attributed to diminished activation of ERK, p38 MAPK and NF- κ B [24]. Another study also reported NF- κ B inactivation along with the upregulation of heme-oxygenase-1 (HO-1) in mice treated with quercetin [35]. Despite preservation of muscle mass and body weight, we did not observe a difference in grip-strength between TB and TB+Q mice. Our findings are inline with the study of Velázquez et al. [14]. They showed quercetin supplementation to help preserve muscle mass and limit bodyweight loss in an $Apc^{Min/+}$ mice model. Furthermore, a recent study reported similar muscle preservation by quercetin treatment in nude mice with cachexia induction via A459 cells, a human alveolar basal epithelial adenocarcinoma cell line [36]. In contrast, C26 tumor-bearing mice given a cocktail of antioxidants, including quercetin, showed accelerated development of cachexia and even expedited death [37]. In our study food intake was higher in TB+Q mice compared to mice receiving control chow. Velázquez et al. found no difference in chow consumption between the quercetin-treated groups [14]. This difference in food intake is not readily explained. Although food intake of TB mice was comparable to NTB mice throughout the first two weeks, daily chow consumption more than doubled during the final days of the experiment. Despite the increased nutritional intake, a significant loss of body weight was observed. This suggests a hypermetabolic state for these mice, but was not quantified in this study.

Quercetin is a natural, bioactive and readily available flavonoid found in a selection of fruits, vegetables and herbs [18], as well as over the counter dietary supplements. The quercetin dose in

Fig. 5. Bodyweight, muscle weight and tumor mass at sacrifice. Bar graphs depicting the mean \pm SEM for (A) final bodyweight normalized to starting bodyweight, (B) gastrocnemius muscle weight, (C) tumor weight, and (D) tibialis anterior muscle weight in non-tumor-bearing male CD2F1 mice (NTB, $n = 10$), C26 tumor-bearing (TB) mice with ad libitum access to regular chow (C26 TB, $n = 10$) and mice with ad libitum access to quercetin supplemented chow (TB+Q, $n = 10$). Multiple group comparisons were done by one-way ANOVA with a Bonferroni's *posthoc* test. All groups were compared against TB mice. Asterisk brackets are displayed for significant results only. ** $p < 0.01$ **** $p < 0.0001$. A possible tumor weight reduction in quercetin treated mice was noted, therefore the relationship between gastrocnemius muscle weight and tumor weight, as well as tibialis anterior muscle weight and tumor weight, were assessed to demonstrate that a possible reduction in tumor burden did not contribute to the attenuation in muscle atrophy. Scatter-dot plots depict no relationship between (E) gastrocnemius muscle mass and tumor mass (Spearman's $\rho = 0.091$, $p = 0.80$) and (F) tibialis anterior muscle mass and tumor mass (Spearman's $\rho = -0.261$, $p = 0.47$) in quercetin-treated mice. Considering these statistics, the attenuation in muscle atrophy cannot be sufficiently explained by differences in tumor burden.

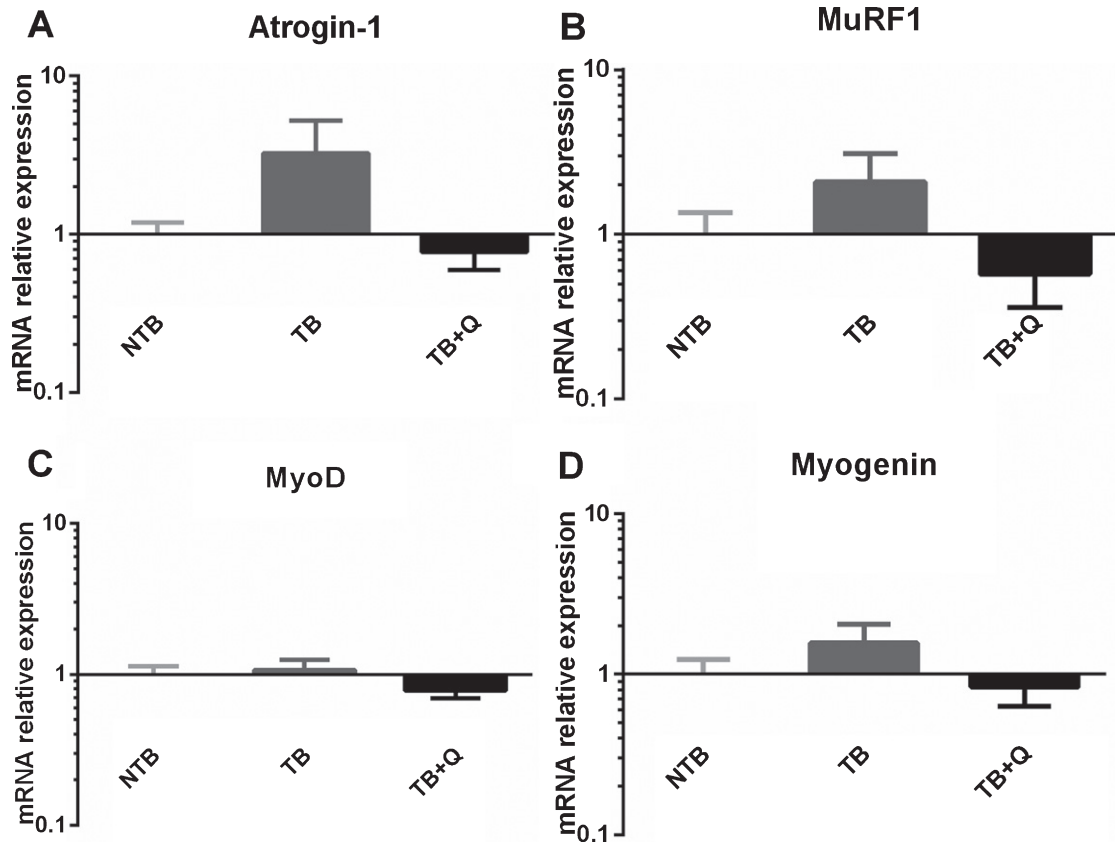

Fig. 6. mRNA expression levels in cachectic muscle. Bar graphs depicting the mean \pm SEM mRNA expression levels in gastrocnemius muscle of (A) Atrogin-1, (B) MuRF1, (C) MyoD and (D) Myogenin in non-tumor-bearing male CD2F1 mice (NTB, $n = 10$), C26 tumor-bearing (TB) mice with ad libitum access to regular chow (C26 TB, $n = 10$) and mice with ad libitum access to quercetin supplemented chow (TB + Q, $n = 10$). Multiple group comparisons were done by one-way ANOVA with a Bonferroni's *posthoc* test. All groups were compared against TB mice. A substantial but non-significant difference in expression of E3 ubiquitin ligase atrogin-1, and to a lesser extent MuRF1, was observed between TB and TB + Q mice.

the current study equates to a human equivalent dose [38] of 2.85 mg/kg. For an average European or Northern American adult [39], this would equate to 202 mg or 230 mg quercetin respectively. Well within the limits of what has been safely used in prior studies [19, 40, 41], and below the threshold of what is commercially available in over the counter supplements in various western countries. The human equivalent dose of the dosage we used significantly exceeds the estimated 25–50 mg per day consumed per day in a western diet [42]. Quercetin has previously been used in studies, including athletes, military personnel, and elderly persons, to investigate its potential as a performance-enhancing supplement. These studies yielded ambiguous results with regard to lean body mass, basal metabolic rate, total energy expenditure and VO_{2max} [19, 40, 41, 43]. Moreover, quercetin has been investigated for its pos-

sible role as a senolytic compound with inconsistent results [44, 45]. Although quercetin has been suggested as a therapeutic candidate in cachexia [46], no studies have been published on quercetin treatment countering muscle wasting in humans [47]. Based on the present study and the aforementioned research by Velázquez et al. [14], quercetin supplementation may aid in limiting muscle wasting in cancer patients. Further research is however warranted to confirm its anti-catabolic effects.

A substantial, non-significant difference in tumor burden was observed between tumor-bearing mice on a regular chow diet and tumor-bearing mice on a quercetin supplemented diet. Anti-cancer effects of quercetin have been previously reported, although available evidence is limited [48–53]. In our study we found a negligible, non-significant correlation between tumor weight and muscle mass. However,

we cannot exclude that the anti-tumor effect has impacted on other outcome parameters, e.g. by selective down-regulation of tumor-derived mediators of cachexia.

Using resected hindlimb muscle tissue at the end of the experiment as gold standard we found a highly positive correlation with micro-CT hindlimb skeletal muscle volume measurement. This technique was found to be feasible and relevant in the current study and may allow for quantitative assessment of individual muscles, as well as allowing for tissue composition quantification, i.e. assessment of fatty infiltration of muscle.

Several limitations apply to the present study. The study was powered on an expected reduction in loss of muscle weight. As such, non-significant differences in secondary outcome parameters (e.g. relative mRNA expression levels) may have been subject to type II errors. Furthermore, survival was not included as one of the endpoints due to the strict ethical guidelines associated with the initiation of this study.

In conclusion, dietary quercetin supplementation limits bodyweight loss and prevents muscle wasting in a murine C26-cancer-associated cachexia model. These data add to a body of evidence supporting the use of quercetin to halt muscle wasting in experimental cancer-associated cachexia models and paving the way for clinical research on the efficacy of quercetin in the attenuation of muscle wasting in humans.

Acknowledgments

SL contributed to the research design, performed the research, analysed the data and wrote the paper. Svde and GA performed the research, aided in analysis of the mRNA expression data and in writing the paper. JNMIJ and RWFdB contributed to the research design and writing the paper. SL, Svde, GA, JNMI and RWFdB have read and approved the manuscript. This work was supported by the Applied Molecular Imaging Erasmus MC (AMIE) facility by providing the imaging equipment. We would like to thank R. Ridwan for the technical support of the micro-CT. Furthermore, we would like to thank Dr. G.M. van Woerden and prof. dr. Y. Elgersma from the dept. of neuroscience (Erasmus MC University Medical Center) allowing us to make use of the grip-strength meter. And lastly, we would like to thank

prof. dr. D.O. McCarthy (Ohio State University, OH, USA) for kindly providing us with the C26 cell-line.
