**Abstract.** Archaeological investigations in Tornimäe in the eastern part of the island Saaremaa took place in 1963, 1968 and 2004. Artefacts found during the excavations are mainly dated to the Viking Age. Most of the finds are pottery shards, some metal artefacts were found, and also animal bones. The majority of mammal bones are bones of domestic animals. Nearly half of these are caprine bones, bones of cattle, pig and horse are less numerous. Wild game bones are few, only seals were hunted more often. Bird and fish bones are also represented. Only a few bone artefacts were among the finds, more fragments of bone items were found among the animal bones during the identification of osteological material. The bone artefacts found in Tornimäe are rather simple items which do not require special skills from the bone worker and could have been made by the users of these artefacts. The uses of bone artefacts are well suited with the location of the site at the seashore.

**Keywords:** Viking Age, Estonia, Island Saaremaa, animal bones, bone artefacts.

## Gyvūnų kaulai ir kauliniai dirbiniai iš vikingų laikotarpio Tornimäe gyvenvietės Saremos saloje

**Anotacija.** Archeologiniai tyrinėjimai Tornimäe gyvenvietėje, esančioje rytinėje Saremos salos dalyje, vyko 1963, 1968 ir 2004 m. Didžioji dalis kasinėjimų metu aptiktų radinių yra datuojami vikingų laikotarpiu. Tarp radinių daugiausia buvo keramikos fragmentų, aptikta keletas metalinių bei kaulinių dirbinių, taip pat nemažai gyvūnų kaulų. Dauguma žinduolių kaulų buvo naminių gyvulių, beveik pusė kaulų buvo avių / ožkų, o galvijų, kiaulių ir arklių kaulų aptikta mažiau. Laukinį sausumos gyvūnų kaulų fragmentų vos keletas, dažniau medžioti tiktais ruoniais, be to, aptikta ir paukščių bei žuvų kaulų. Didžioji dalis kaulinių dirbinių rasta atliekant osteologinės medžiagos tyrimus. Jie gana paprasti, nereikalaujantys specialių kauladirbio įgūdžių ir greičiausiai yra pasigaminti pačių jų naudotojų, o dirbinių pobūdis ir paskirtis atspindi pajūryje išskirusios gyvenvietės specifiką bei poreikius.

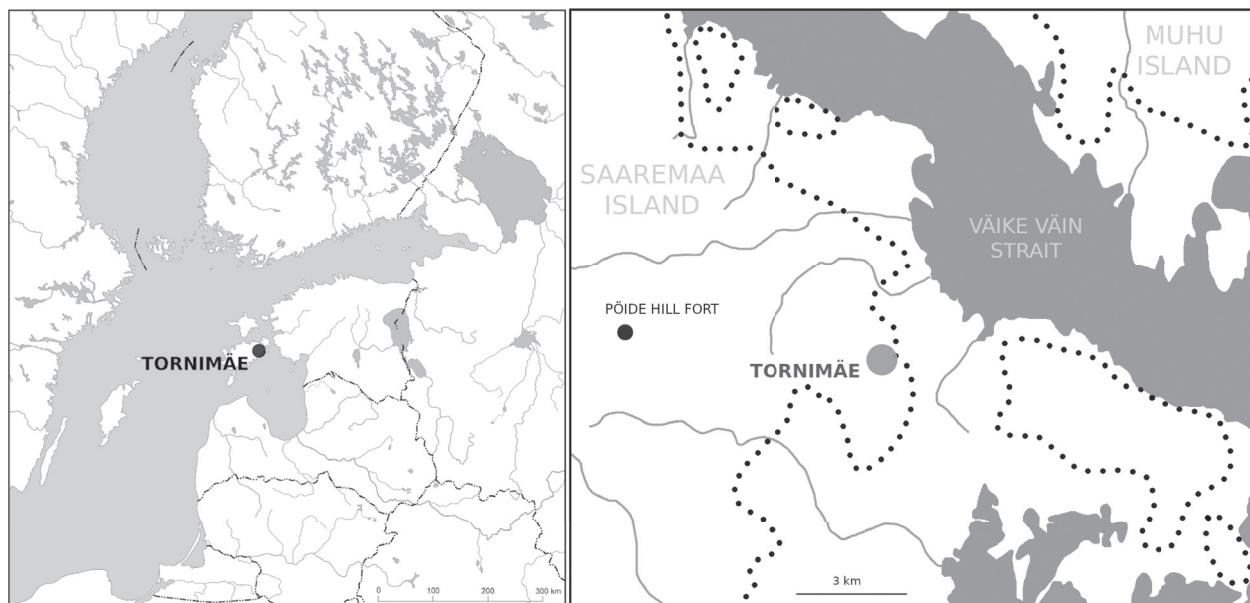

**Reikšminiai žodžiai:** vikingų laikotarpis, Estija, Saremos sala, gyvūnų kaulai, kauliniai dirbiniai.

## Introduction

The Tornimäe site is located in the eastern part of the island Saaremaa (Fig. 1). Nowadays it is about 2 km from the sea, but in the Viking Age the site was on the seashore, where, according to the contour lines, sea was deep enough to be navigated by sea-going vessels. The area of the cultural layer in Tornimäe is about 3.5 hectares (Mägi, 2005, fig. 1; 2010, p. 169–171, fig. 2–3).

Archaeological investigations in Tornimäe took place in 1963, 1968 and 2004. In 1963, rescue excavations were carried out on an area of 160 square metres, supervised by Aita Kustin (Kustin, 1967; Mägi, 2005, p. 68, fig. 2; 2010, p. 170, fig. 3). Another rescue excavation, also by Kustin, was carried out in 1968, when about 1600 square metres of the settlement were destroyed by road building. This time only the soil piled up during road building was examined (Kustin, 1968). In 1997, several surface surveys were conducted in Tornimäe and the area of the cultural layer was located with phosphate-mapping (Mägi, 2005, p. 68–69; 2010, p. 170). In 2004, 80 square metres were investigated during archaeological excavation supervised by Marika Mägi (Mägi, 2005, p. 66 ff., fig. 2–5; 2010, p. 170–171). Aita Kustin (1967) interpreted the site as an ordinary settlement, in the opinion of Marika Mägi the site, located on the sea shore was used as a harbour (Mägi, 2002, p. 189, fig. 8; 2005, p. 66 ff., fig. 1, 2; 2010, p. 169–171, fig. 2, 3). Mägi (2005; 2010, p. 169–171) has already thoroughly discussed the situation of the site and the course of research, therefore it will not be described in more detail here.

Artefacts found during the excavations are mainly dated to the Viking Age. Most of the finds are pottery shards (Fig. 2), a couple of glass beads and some metal artefacts, including boat rivets, also bone tools and numerous mammal and fish bones were found (Kustin, 1967, 1968; Mägi, 2005, p. 68, 71–72, fig. 6; 2010, p. 170–171, pl. VI; Lõugas, 2016, p. 112). The aim of the present paper is to provide an overview of the animal bones and fragmentary bone objects collected during the excavations in Tornimäe, and to discuss the question of what can be found out about activities in the site using such fragmentary finds.

## Animal bones from Tornimäe

The osteological material of Tornimäe is poorly preserved and mostly consists of small fragments. The total of 2537 mammal bones and bone fragments were identified to the species level. The majority of them, 1961 bones, come from the excavations in 2004. It was possible to identify 465 and 117 mammal bones from the osteological material gathered in 1963 and 1968, respectively. Bones from the excavations in 1963 have been already sorted by someone, presumably quite soon after the excavations – the bones were placed in boxes by species, only a few fragments are unidentifiable. It is not possible to say whether smaller, unidentifiable bone fragments were not preserved, or they were not picked up during the excavations.

The majority of mammal bones in the material of all excavations are bones of domestic animals – 86.7–91.5% of all identified mammal bones. Seal bones make up 6.8–12.5% and terrestrial wild game are represented with only a few examples, making up 0.8–1.1% of mammal bones (Fig. 3).

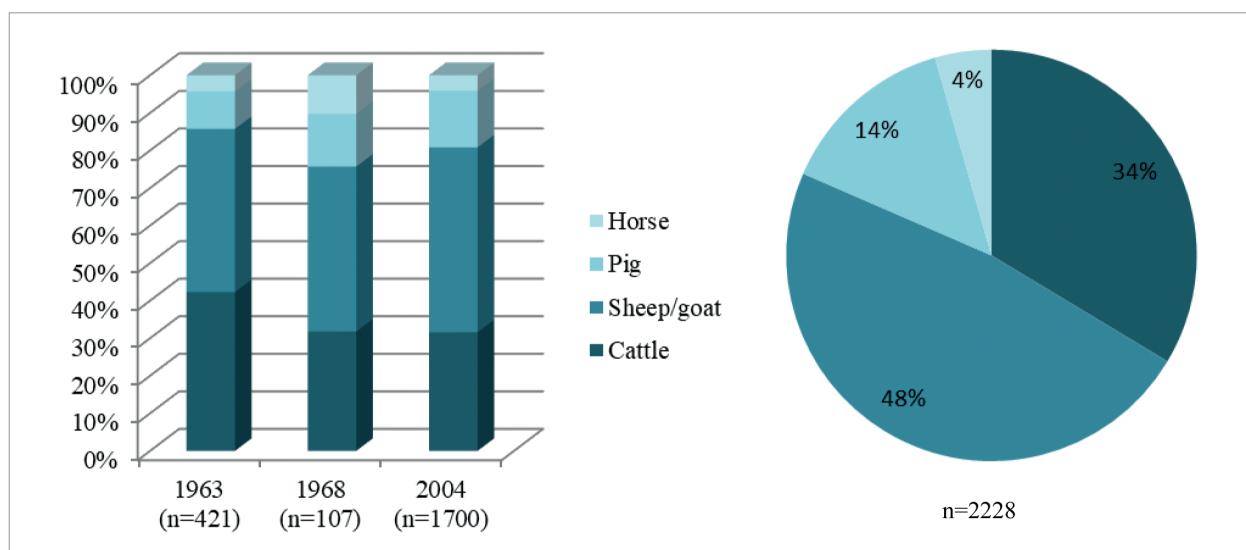

The most numerous are caprine (*Ovis aries* / *Capra hircus*) bones with the share in the range of 43.5–49.2% of all identified domestic animal bones. This is to be expected because the landscape of Saaremaa is naturally suitable for sheep and goat breeding. Bovine (*Bos taurus*) bones make up 31.6–42.3% and pig (*Sus domesticus*) bones 10.0–15.1% of the identified domestic animal bones. Horse (*Equus caballus*) bones were most numerous among the bones from the excavations in 1968 where they account for as much as 10.3% of domestic animal bones, but this is probably accidental and rather due to the small amount of material. Among bones from the excavations in 1963 and 2004 horse bones make up 4.3 and 4.1% respectively (Fig. 4).

Compared with the osteological material from other Estonian Viking Age settlements and hill forts, the ratio of different domestic animals in Tornimäe seems to resemble most closely the osteological material from the settlement of Linnaaluste, but the number of identified bones is rather small there (n = 312; Maldre, 2012, fig. 5.14). In most Viking Age sites of Estonia caprine bones do not have such a large proportion. On the other hand, the proportion of horse bones is significantly higher in most of the analysed Viking Age sites (Maldre, 2007, p. 62, fig. 2; 2012, fig. 5.14).

**Fig. 3.** Ratio of mammal bones in 1963, 1968 and 2004 (left) and total (right). *Figure by Liina Maldre.*

The analysis of the anatomical composition of domestic animal bones in Tornimäe shows that all body parts are represented. Skeletal elements are presented in five groups on the graph: bones of head, bones of trunk, bones of the proximal part of limbs, bones of the middle part of limbs and bones of the distal part of limbs (Fig. 5). The significant predominance of the bones of the head area is due to the large number of teeth, which is characteristic of the fragmented material. Thus, it is a typical settlement material consisting of both food and slaughter waste.

The inhabitants of the Tornimäe site were also involved in hunting, although to quite a small extent. The main focus has been on seal hunting; hunting for terrestrial wild animals has probably been of very little importance

**Fig. 5.** Anatomical composition of domestic animal bones. Figure by Liina Maldre.

**5 pav.** Naminių gyvulių kaulų anatominių pasiskirstymas. Liina Maldre paveikslas

(Fig. 3). The species composition of seal bones is not yet analysed, but the anatomical composition is more or less representative of the bones of all body regions. Seal bones are represented also in some Viking Age sites in North Estonia which are not far from the sea: Iru and Pada (Maldre, 2007, p. 74–75, fig. 11; 2012, p. 122–123, fig. 5.16). Nevertheless, seal bones are still less numerous there, and these sites were also not located directly by the sea.

Of the terrestrial game, there appears to be a wild boar (*Sus scrofa*) represented among bones from all excavations. Among the bones of 1963, one elk (*Alces alces*) phalanx and one bear (*Ursus arctos*) phalanx were identified. A tooth of unspecified mustelid and ten bones of white hare (*Lepus timidus*) were among the bone material of 2004, at least eight of the latter coming from the left hind paw of the same hare. Bones of elk and beaver (*Castor fiber*), which are the main identified wild species in the other Viking Age sites are represented by a single bone or totally absent in Tornimäe (Maldre, 2007, p. 74–75; 2012, p. 123–124, fig. 5.17). The occurrence of beaver in Saaremaa in the Late Iron Age, including the Viking Age, is questionable, since no beaver bones have been found at the sites of these periods (Maldre, 2012, p. 124).

Bird and fish bones are also represented in Tornimäe. At least 236 bird bones have been found (50 in 1963, 22 in 1968 and 164 in 2004), but these bones have not been analysed yet. The vast majority of fish bones – more than 4500 bones (including fish scales) – were found in 2004; in 1963 and 1964 only 18 and 11 fish bones were discovered. This can be explained by the fact that no screening was used in these earlier excavations. Bones were collected by dry sieving on 5 mm mesh in Tornimäe in 2004 (Lõugas, 2016, p. 112). Not the whole assemblage of fish bones has been analysed, but preliminary results which are based on ca 1000 identified specimens are published by Lembi Lõugas (2016). All identified bones belong to freshwater fish. Perch (*Perca fluviatilis*) bones are most abundant, ide (*Leuciscus idus*), pike (*Esox lucius*) and various cyprinids (*Cyprinidae*) are also represented and also a few bones of pikeperch (*Sander lucioperca*). No marine species, like herring, cod or flounder have been identified (Lõugas, 2016, p. 112, fig. 11.2). The composition of fish bones is similar also at Pöide hill fort, located about 6 km west from Tornimäe (Fig. 1). The assemblage of fish bones in Pöide is very small, but all the fish species identified are of freshwater origin (Lõugas, 2001, p. 131; 2016, p. 112, fig. 11.2).

## Finds from Tornimäe

The finds from archaeological excavations in Tornimäe belong mainly to the second half of the first millennium and the beginning of the second millennium AD, but later objects were also found in the upper part of the cultural layer (Mägi, 2005, p. 71–72).

Most of finds from Tornimäe, both pottery shards, and also bone objects, are preserved as quite small fragments (Fig. 6, 7). Only a few bone artefacts were among the finds. Ten artefacts and bone pieces with working traces were among the finds of the excavations in 1963, and only two items, which were called 'bone pins' in the list of the finds, were among the finds from 2004. A few dozens of unworked bone fragments were also picked up among the finds. More fragments of worked bones were found by one of the authors of the present paper, Liina Maldre, among the animal bones during the identification of osteological material: altogether 24 artefact fragments and bone pieces with working traces. So, the question is: what could be possible to find out about the activities in the settlement site from such fragmentary material?

Bone fragments with working traces indicate that bone artefacts were made at the site. The number of such working waste is still quite small. The bone artefacts found in Tornimäe are rather simple items which do not require special skills from the bone worker and could have been made by the users of these artefacts. Almost all waste is bone fragments, only one is a tooth with cutting traces and one is a piece of antler. Since most worked bones are preserved very fragmentarily it was possible to identify only a few of them. Most of the identified bones are fragments of long bones: metatarsals and metacarpals. A radius and a mandible were also identified. In five cases the species of cattle and in two cases horse has been identified. Other long bone fragments also come from the bones of large herbivores, most likely cattle. The mentioned mandible fragment is a cattle left lower mandible coronoid process (*Processus coronoideus*). One worked fragment is a caprine bone. It is not possible to identify the antler fragment, but most likely it is elk antler.

Although the finds are not numerous and are preserved quite fragmentarily, there are similarities with bone objects from other Viking Age sites in Estonia, in particular with finds from settlement sites of Pada, Linnaaluste and Iru, and the hill fort of Tartu (e.g. Lang, 1996; Tvauri, 2001; Luik & Maldre, 2005a; Luik, 2012). Finds from Otepää and Rõuge, located in south-eastern Estonia, are somewhat different, because antler has been used more

**Fig. 8.** Two bone points from Tornimäe (AI 6688: L 304, L 308). *Photo by Heidi Luik.*

**8 pav.** Tornimäe gyvenvietėje rasti antgaliai (AI 6688: L 304, L 308). Heidi Luik nuotrauka

often as raw material in these sites (Luik, 2005, p. 35–37; Luik & Maldre, 2005b). Nevertheless, since bone artefacts are more numerous at these sites than in Tornimäe, the finds are more diverse there and several artefact types are represented which are absent in Tornimäe. On the other hand, certain small bone points with oblique end which are characteristic to Tornimäe, are unknown at other sites, at least among bone objects found so far.

**Fig. 9.** A small burned fragment with sawn lines (1) (AI 6688: L 384) may be a fragment of a comb, presumably similar with double simple combs found e.g. from Valjala (2) and Otepää (3) (AI 4300: 533, 4036 I: 2176d). *Photo by Jaana Ratas. 9 pav. Nedidelis apdegės kaulinio dirbinio su įpjovomis fragmentas – greičiausiai šukų dalis (1) (AI 6688: L 384). Panašios dvipusės šukos rastos Valjala (2) ir Otepää (3) gyvenvietėse (AI 4300: 533, 4036 I: 2176d). Jaana Ratas nuotrauka*

Some bone fragments with working traces could have been simple *ad hoc* points, used for example as awls (Fig. 8). Similar quite roughly worked bone (and also antler) points have been found also from other Viking Age sites and hill forts in Estonia (Lang, 1996, pl. VIII: 8–9; Tvauri, 2001, p. 159–160, fig. 79; Luik & Maldre, 2005a, fig. 5; Luik, 2012, fig. 4.8).

One burnt fragment has parallel sawn lines (Fig. 9: 1). It may be a fragment of a simple double comb, similar to those found for example from the Valjala hill fort in Saaremaa and Otepää in South-East Estonia (Fig. 9: 2, 3; e.g. Luik, 1998, p. 47–58, fig. 24–29). Fragments of burnt bone combs have been found from some cremation burials in Saaremaa and West Estonia (Luik, 2003, p. 159–160, fig. 4). Double one-piece combs have been often made of antler, so it is possible that the fragmentary item from Tornimäe is also from antler, but since the object is burned, it is not certain.

### Small bone points – fish hooks

Some points found from Tornimäe are quite similar to each other: these are small thin points having another bevel end with small cuts at the opposite side (Fig. 10). There are four better preserved points and also some fragments and some worked bone pieces that could be unfinished points.

It seems most likely that these points could have been parts of some fishing equipment. Small double pointed bone implements – gorges – were used for fishing already in the Stone Age, but also still in the Viking Age and even in later periods (e.g. Brinkhuizen, 1983, p. 11–13, 33–34, fig. 4, 40; Zagorska, 1991, fig. 2: 37–39; 5: 17–18; Riddler, 2006, p. 171–172, fig. 1; Biermann, 2008, p. 249, fig. 8). According to Ian Riddler (2006, p. 172) such gorges remain quite scarce in the early medieval period and, at least in the English context, they are mostly associated with riverine rather than coastal environments. A string was tied around the centre of the bone point and it was hidden into a small fish meant for bait (e.g. Sirelius, 1906, fig. 240: a; Torke, 1993, fig. 4, 5). It was

**Fig. 10.** Small bone points from Tornimäe (AI 4338: 48 (1), 6688: 146 (2), 4338: 945 (3), 240 (4)). Photo by Jaana Ratas.

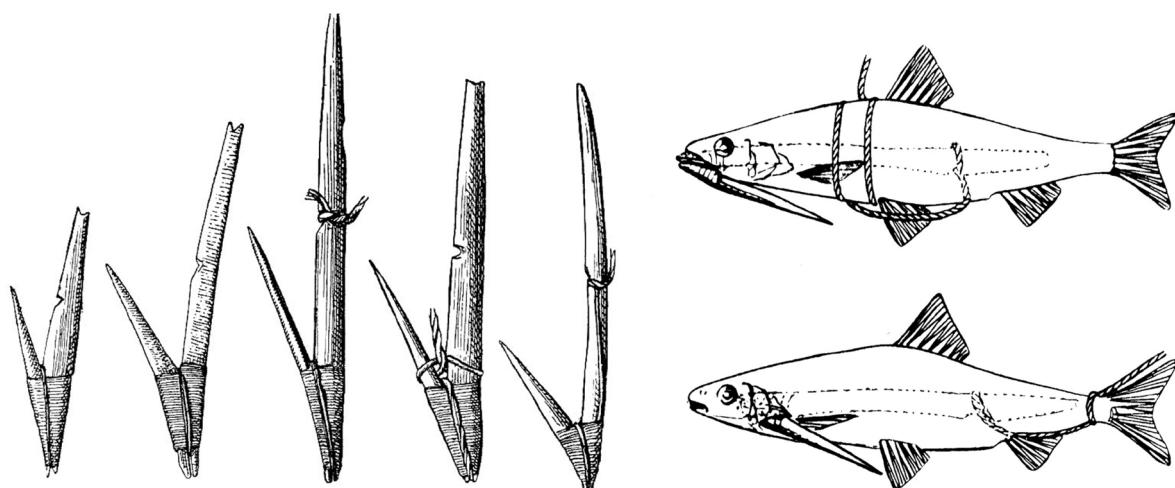

**10 pav.** Tornimäe gyvenvietėje rasti nedideli antgaliai (AI 4338: 48 (1), 6688: 146 (2), 4338: 945 (3), 240 (4)). Jaana Ratas nuotrauka

fixed so that when the fish swallows it and tightens the string, the gorge turns transversely (Brinkhuizen, 1983, p. 11; van Vilsteren, 1987, p. 30, fig. 19; Riddler 2006, p. 171). However, the pointed objects from Tornimäe have a somewhat different shape.

The shape of these points suggests that these may have been spikes of some composite tool, presumably a fish hook. The bevel end ensured that the point was attached at the correct angle and the notches cut into it helped to hold better the string or leather strip used for binding. Composite fish hooks were used at different times and places since the Stone Age (e.g. Zagorska, 1994, p. 138, fig. 5; Galili *et al.*, 2013, fig. 3; Biermann, 2008, p. 248–249; Allen *et al.*, 2016, fig. 14.4: C). Composite fish hooks have been found for example from Lake Lübana and also from Dviete in Latvia (Zagorska, 1991, fig. 5: 22, 23; 1994, fig. 5: 1, 8). The stem and the tip of the fish hooks were fastened together with plant fibres or tendons. One such hook with a fully preserved binding of a rope and the remains of a resinous coating was found at Dviete (Zagorska, 1991, fig. 5: 23). Bone fish hooks have been found from the Netherlands and Scandinavia, both from marine and freshwater contexts, but there are no certain examples of early medieval date (Brinkhuizen, 1983, p. 34–35, fig. 42; Riddler, 2006, p. 175). Fish hooks and their parts were often found in water bodies, both in lakes and rivers and also in the sea, where it is not possible to date them according to the find context (e.g. Brinkhuizen, 1983, p. 34).

Fish hooks found from the Viking Age sites in Estonia, and also neighbouring areas are usually made from metal (mostly iron, but also bronze) (e.g. Aun, 1992, p. 58–59, pl. XXII; Tvauri, 2012, fig. 65; Mugurēvičs, 2008, p. 242, pl. IX: 11–13, 17, 20).

In Finland composite wooden and bone fish hooks were used still in the end of the 19<sup>th</sup> century and the beginning of the 20<sup>th</sup> century (Fig. 11). The stem of the hook was usually made of wood, but the hook was either from wood (e.g. juniper), bone, but also from copper or iron wire (Sirelius, 1906, p. 90–92, fig. 207–208; Brinkhuizen, 1983, p. 13–15, fig. 8). In some case both the stem and the hook were made from bone (Sirelius, 1906, fig. 207: g). Small fish was attached to the hook as a bait (Fig. 11); according to Sirelius such hooks were used for catching burbot (*Lota lota*), pike (*Esox lucius*), pikeperch (*Sander lucioperca*) and salmon (*Salmo salar*) (Sirelius, 1906, p. 92, fig. 240: d, 241: a–c). As mentioned above, bones of two of these species – pike and pikeperch – are also represented among fish bones found in Tornimäe. Presumably similar hooks were used also in the Viking Age – the small points found from Tornimäe suit well to be parts of such composite fish hooks. If the stem was made from wood, the small bone point would be the only part to preserve from such a hook.

**Fig. 11.** Composite fish hooks from Finland and some examples how small fish were used as a bait, attached to the hook (Sirelius, 1906, fig. 207: f–k, 241: a, b).

*11 pav. Suomijoje naudoti sudėtiniai žvejybos kabliukai ir jų naudojimas su nedidele žuvele (Sirelius, 1906, pav. 207: f–k, 241: a, b)*

## Fragments of bone skates

Another group of bone items from Tornimäe are bone fragments with one side carefully polished (Fig. 12). In cases it was possible to identify the used material, they have been made from cattle and horse bones. Most of these objects are quite fragmentary, but some of them have arcs left by the edges of holes made through the bones, indicating that they may be fragments of bone skates (Fig. 13). Presumably other pieces with polished surfaces are also skate fragments. According to identified bones, the fragments originate from at least four skates. Two of these were made from cattle bones – one from metacarpus and the other from metatarsus, the other two are horse bones, again one metacarpus and the other metatarsus. It was not possible to identify the material of other fragments. However, these smaller fragments may also be pieces of some of the identified skates. For example, one fragment of three matching pieces (Fig. 12, top right) was found close to a presumable skate fragment identified as horse bone (Fig. 12, top left).

The earliest bone skates in Estonia known to date have been found from Viking Age sites. These skates have transverse holes at both ends and are usually made of horse bones (Fig. 14; Lang, 1996, pl. IX: 7; Luik, 2000, p. 131–133, fig. 2–3; Luik & Maldre, 2005a, fig. 2). Skates are known also from the Final Iron Age and medieval sites, but these differ from the earlier skates for having no holes; in some coastal areas of North-West Estonia bone skates were used still in the 19th century and beginning of the 20th century (Luik, 2000, p. 133–134, 143–144, fig. 5, 6, 10–14; 2002, p. 316–317, fig. 9, 10). Also in neighbouring areas and further, skates are known from many Viking Age as well as medieval and later sites (Vilppula, 1941; Berg, 1943; MacGregor, 1976; 1985; Ulbricht, 1984; Luik, 2000; Küchelmann & Zidarov, 2005; Tilko, 2005; Edberg & Karlsson, 2015; 2016).

Several researchers have compared use wear on the artefacts made of horse and cattle long bones to interpret the function of these artefacts, since such bones were also suitable for making various tools, like textile or leather smoothers, fish-net weights-stiffeners etc. (Barthel, 1969; MacGregor, 1975; 1985, p. 141–144; Becker, 1990; Choyke & Bartosiewicz, 2005, p. 323–324; Arndt, 2006, p. 193, fig. 16). Fragments found in Tornimäe have use wear on their smooth facets, indicating their use as skates (Fig. 15–17; compare e.g. MacGregor, 1975, fig. 2, 3; 1985, fig. 75; Becker, 1990, fig. 4; Choyke & Bartosiewicz, 2005, fig. 6; Küchelmann & Zidarov, 2005, fig. 13).

## Discussion and conclusions

The osteological material indicates that mostly domestic animals were used for food. Goat and sheep, for the breeding of which Saaremaa had favourable natural conditions, have a particularly large share. Hunting was not important, only a few bones of wild terrestrial animals have been found. Seal bones are more numerous, which is related to the location of the site on the coast. There are quite a lot of fish bones among the found material, all these are freshwater fish that could also be caught in the coastal waters.

The found worked bone fragments refer to three activities: bone working, fishing and skating. According to bone working waste only simple bone objects that need just slight working have been made on spot. For example, the skates could have been made even by children (MacGegor *et al.*, 1999, p. 2005). The only more complicated artefact, the presumable comb, most likely has been brought from elsewhere, not made in Tornimäe. No bone or antler working waste indicating comb making was found in Tornimäe.

The found bone artefacts – details of fish hooks and skate fragments – suit well with the location of the site by the sea. According to the research made by Lembi Lõugas (2016, p. 112) in the eastern Baltic Sea region mostly freshwater fish were caught in the Viking Age, and also, although to a lesser degree, local marine fish in inshore waters. Among the fish bones identified among osteological material found in Tornimäe the same species (pike, perchpike) are represented, which according to Sirelius (1906, p. 92) were caught with composite fish hooks in Finland in the end of the 19<sup>th</sup> century to beginning of the 20<sup>th</sup> century.

It is assumed that bone skates were used by hunters and fishermen in the Viking Age, although in later times they were rather children's toys (Berg, 1943; MacGregor, 1976, p. 65; 1985, p. 144; Luik, 2000, p. 146; Küchelmann & Zidarov, 2005, p. 440–441). In the opinion of Rune Edberg and Johnny Karlsson (2016, p. 15) the Viking Age and medieval skates found at Birka and Sigtuna were rather used by children and youth for leisure and sports, although it was possible to use skates by fishermen also. In both early written sources and also in later times descriptions about games and competitions dominate (MacGregor, 1976, p. 61–63; Edberg & Karlsson, 2016, p. 11–13; cf. e.g. Olaus Magnus, 1996/1998, p. 57–58; Russwurm, 1855, p. 107). Whether a skate could belong to a child or an adult can be decided on the basis of its length (Cinthio, 1976, p. 385; MacGregor *et al.*, 1999, p. 1989; Edberg & Karlsson, 2016, p. 10–11, 14), but as the specimens found in Tornimäe have been preserved only fragmentarily, there is no information about their length.

No constructions that could be directly connected with a harbour were detected during the excavations (Mägi, 2010, p. 171). Marika Mägi still mentions some earlier descriptions about the remains of a ‘wooden palisade’ found by local peasants when ploughing on the slope, which in her opinion could have been a part of the harbour construction (Mägi, 2010, p. 171). Mägi (2005, p. 70) has drawn attention to the fact that no remains of ovens were found in the excavation plots both in 1963 and 2004. Remains of hearths were found some time ago by local people when building a house foundation, and also during the archaeological excavations in 1963 and 2004, but these cannot be interpreted as oven remnants (Tiitsmaa, 1922, p. 22; Kustin, 1967, p. 4–6; Mägi, 2005, p. 69–70, fig. 4). Mägi assumed that this may indicate the seasonal use of the buildings in Tornimäe. If the site was a harbour location, primarily used during summer months the lack of ovens may be explained because of no need for heating. Mägi still notes that the excavated area is not sufficient in size for drawing far-reaching conclusions and there could be dwelling houses with ovens in other parts of the site (Mägi, 2005, p. 70). In the case of activities, where found bone objects were used, fishing with hooks could take place both during the ice-free period and during the winter on ice. The skates, however, suggest that the site was inhabited also in winter. It is possible, of course, that only some of the buildings were in use during the winter, and that there were more dwellers in the settlement during the ice-free period when the ships and boats could land in the harbour.

**Acknowledgements.** We would like to thank Giedrė Piličiauskienė for inviting us to the conference “Investigating bones: diet, health, environment in the Baltic region”, and Estonian Cultural Endowment for financial support to participate at this conference. We are thankful to László Bartosiewicz and Kerstin Lidén for valuable comments and advice, to Helle Solnask for her help with English and to Jaana Ratas and Aive Viljus for their help with illustrations.

## Gyvūnų kaulai ir kauliniai dirbiniai iš vikingų laikotarpio Tornimäe gyvenvietės Saremos saloje

**Heidi Luik, Liina Maldre**

Santrauka

Tornimäe gyvenvietė yra rytinėje Saremos salos dalyje (1 pav.). Nors dabar ji yra apie 2 km nutolusi nuo jūros, vikingų laikotarpio gyvenvietė buvo pačioje pakrantėje ties gilia, jūriniams laivams plaukioti tinkama vieta. Archeologiniai tyrinėjimai gyvenvietėje vykdysti 1963, 1968 ir 2004 m., jų metu aptikta vikingų laikotarpio radinių. Daugiausia tai keraminių indų šukės (2 pav.), taip pat keletas stiklinių karoliukų, metalinių ir kaulinių dirbinių. Be to, rasta nemažai žinduolių bei žuvų kaulų.

Iki rūšies lygio identifikuoti 2 537 žinduolių kaulai ir jų fragmentai, tarp kurių naminių gyvulių liekanos sudarė 88 %, ruonių kaulai – 11 %, kitų laukinių gyvūnų kaulai – vos 1 % (3 pav.). Beveik pusė naminių gyvulių kaulų priklausė avims / ožkoms, galvijų, kiaulų ir arklių kaulų aptikta mažiau (4 pav.). Anatominė gyvūnų kaulų analizė parodė, kad aptikta įvairių skeleto dalių (5 pav.). Gyvenvietėje rastų paukščių kaulų tyrimai dar neatlikti. Iki galio neištirta ir žuvų kaulų kolekcija, tačiau preliminariais duomenimis, identifikavus apie 1 000 kaulų fragmentų, visi jie priklauso gélavandenėms žuvims.

Kauliniai dirbiniai išlikę fragmentiškai (6, 7 pav.), dauguma jų identifikuoti atliekant osteologinės medžiagos analizę. Kaulo apdirbimo liekanos rodytų, kad dirbiniai gaminti gyvenvietėje. Kaip įrankiai galėjo būti naudojami ir kai kurie neapdirbtini kaulų fragmentai (8 pav.) – jie naudoti tiesiog kaip ylos (*ad hoc* tipo dirbiniai). Vienas apdegės kaulo fragmentas su lygiagrečiomis įraižomis greičiausiai buvo paprastų dvipusių šukų dalis (9 pav.).

Viena didesnė dirbinių grupė – antgalių tipo dirbiniai. Jie yra labai panašūs – nedideli, siauri dirbinukai, išstrižai nupjauta apatinė dalimi su smulkiomis išplovomis jai priešingoje pusėje (10 pav.). Dirbinių forma rodytų, kad tai sudedamoji įrankio, greičiausiai žvejybos kabliuko, dalis, jo smaigas. Sudėtiniai žvejybos kabliukai buvo plačiai naudojami jau nuo akmens amžiaus. Suomijoje tokie mediniai ir kauliniai kabliukai naudoti iki pat XIX a. pabaigos–XX a. pradžios (11 pav.). Panašūs kabliukai naudoti ir vikingų laikotarpio, o kauliniai Tornimäe gyvenvietėje rasti smaigai greičiausiai ir yra tokų sudėtinių žvejybos kabliukų dalys.

Kita kaulinių dirbinių grupė yra jų fragmentai stipriai nugladinta viena puse (12 pav.), dalis jų – su buvusių skylių žymėmis. Sklyės rodytų, kad tokie fragmentai greičiausiai yra pačiūžų liekanos (13 pav.). Ankstyviausios kaulinės pačiūžos Estijoje žinomas iš vikingų laikotarpio gyvenviečių (14 pav.). Kadangi panašūs fragmentai gali būti ne tik pačiūžų, bet ir kitų dirbinių, pavyzdžiu, odai ir tekstilei minkštinti naudotų įrankių, tinklų pasvarų įtvarų ir kt. liekanos, siekiant išsiaiškinti tokio tipo dirbinių paskirtį buvo atlikti jų darbinių žymių tyrimai. Gauti rezultatai parodė, kad Tornimäe gyvenvietėje aptiki kaulinių dirbinių fragmentai gludintu paviršiumi turi specifines, pačiūžoms būdingas naudojimo žymes, o tai leidžia juos interpretuoti kaip pačiūžas (15–17 pav.).

Tornimäe gyvenvietėje rasti kaulinių dirbinių fragmentai yra siejami su trejopa veikla – kaulo apdirbimu, žvejyba ir čiuožinėjimu. Kaulo apdirbimo atliekos rodo, kad dirbiniai gaminti vietoje, jie buvo paprasti, nesudėtingai apdirbtini. Tyrinėta gyvenvietė buvo įsikūrusi pajūryje, o joje aptiktos kabliukų dalys ir pačiūžų fragmentai atspindi čia vykdytas veiklas bei gyventojų poreikius. Tyrinėtame gyvenvietės plote nebuvo rasta jokių krosnių liekanų, kas galėtų rodyti, kad pakrantėje gyventa sezoniškai: tai galėjęs būti vasaros uostas, todėl namai tiesiog nebuvo šildomi. Kadangi kauliniai kabliukai gali būti naudojami įvairiais metų laikais, jų radimas šiai prielaidai neprieštarautų. Kita vertus, pačiūžų liekanos rodytų, kad čia gyventa ir šaltuoju metų laiku. Tikėtina, kad gyvenvietė naudota ištisus metus – žiemą joje gyveno mažiau žmonių, naudoti tiktais kai kurie pastatai, o šiltuoju sezonu, kai pakrantėje galėdavo prisišvartuoti laivai ir valtys, čia gyvendavo gerokai daugiau gyventojų.
