34

35 **Abstract**

36 Encephalomyocarditis virus (EMCV) infects a wide range of hosts and can
37 cause encephalitis, myocarditis, reproductive disorders and diabetes mellitus in selected
38 mammalian species. As for humans, EMCV infection seems to occur by the contact
39 with animals and can cause febrile illnesses in some infected patients. Here we isolated
40 EMCV strain ZM12/14 from a natal multimammate mouse (*Mastomys natalensis*: *M.*
41 *natalensis*) in Zambia. Pairwise sequence similarity of ZM12/14 P1 region consisting of
42 antigenic capsid proteins showed the highest similarity of nucleotide (80.7%) and amino
43 acid (96.2%) sequence with EMCV serotype 1 (EMCV-1). Phylogenetic analysis
44 revealed that ZM12/14 clustered into EMCV-1 at the P1 and P3 regions but segregated
45 from known EMCV strains at the P2 region, suggesting a unique evolutionary history.
46 RT-PCR screening and neutralizing antibody assays for EMCV were performed using
47 collected tissues and serum from various rodents (n=179) captured in different areas in
48 Zambia. We detected the EMCV genome in 19 *M. natalensis* (19/179=10.6%) and

49 neutralizing antibody for EMCV in 33 *M. natalensis* (33/179=18.4%). However, we did
50 not detect either the genome or neutralizing antibody in other rodent species. High
51 neutralizing antibody titers (≥ 320) were observed in both RT-PCR-negative and -
52 positive animals. Inoculation of ZM12/14 caused asymptomatic persistent infection in
53 BALB/c mice with high antibody titers and high viral loads in some organs, consistent
54 with the above epidemiological results. This study is the first report of the isolation of
55 EMCV in Zambia, suggesting that *M. natalensis* may play a role as a natural reservoir
56 of infection.
57

58 **Introduction**

59 Encephalomyocarditis virus (EMCV) infects a wide range of animal species and
60 causes various conditions ranging from subclinical to lethal disease with myocarditis,
61 encephalitis, neurological disorders, reproductive failure and diabetes mellitus in humans
62 or animals (1). EMCV infection results in different outcomes depending on the host
63 animal species and the virus strains. For example, sudden death caused by EMCV
64 infection has been reported in primates, elephants and various captive animals in zoos (2–
65 11). Dogs show systemic symptoms with encephalitis and myocarditis (12). Importantly,
66 pigs are the most susceptible animal for EMCV, and EMCV infection causes a serious
67 threat to the pig industry with sudden death often associated with myocarditis and
68 reproductive failures including abortion (13–15). As for humans, serological surveys for
69 EMCV have shown seropositivity rates of up to 30%. In addition, higher seropositive
70 rates were observed in populations that have more frequent contact with wild animals
71 such as hunters, indicating that EMCV may be a zoonotic pathogen which could be
72 transmitted from animals to humans (16,17). Subclinical or mild infections are thought to
73 be predominant in humans, but there are some reports showing an association with febrile
74 illness (18,19). While EMCV infection provokes some symptoms in most animal species,
75 rodents such as *Rattus rattus* and *Mus musculus* exhibit mainly asymptomatic persistence
76 and disperse viruses for a relatively long period (20–22). A reservoir has been defined as
77 populations or environments in which the pathogen can be permanently maintained and
78 from which infection is transmitted to susceptible animals (23). Although there have been
79 no reports of direct transmission from rodents to other animals or humans, these rodent
80 species have been considered to be a potential EMCV reservoir for susceptible animals,
81 such as pigs, wild animals or potentially humans.

82 EMCV is a member of the species of *Cardiovirus A* in the genus *Cardiovirus* in
83 the family *Picornaviridae*, which is the largest group of small non-enveloped positive
84 sense RNA viruses with an icosahedral capsid of 30 nm in diameter. The EMCV genome
85 is approximately 7,800 bp in length and encodes a single open reading frame (ORF),
86 which is translated as a single polyprotein precursor and cleaved by a viral protease to
87 produce mature proteins. The genome organization is as follows: VPg+5' untranslated
88 region (UTR)^{IR_{ES}-II} [L/1A-1B-1C-1D-2A^{np_{gp}}/2B-2C/3A-3B^{VP_g}-3C^{pro}-3D^{pol}] 3'UTR-
89 poly(A). Precursor 1 (P1) composed of four proteins (1A-1D) is the capsid protein. P2
90 composed of 2A-2C and P3 composed of 3A-3D are nonstructural proteins (1,24).
91 Serologically, EMCV is classified as EMCV-1 and EMCV-2, both of which are assigned
92 to the species *Cardiovirus A* by the International Committee on Taxonomy of Viruses
93 (ICTV) (25). Recently, Vyshemirskii et al. have proposed a detailed genetic classification
94 of EMCV based on the nucleotide sequence identity, which contains four members of
95 *Cardiovirus A* (EMCV-1 to 4) and EMCV-1 is subdivided into 7 lineages (A to G) (5).

96 EMCV was firstly discovered in a gibbon ape in 1945 in Florida, USA (26).
97 Thereafter, EMCV was identified in wide range of domestic and wild animals, including
98 pigs, dogs, rodents, primates, elephants, antelopes, lions and birds in all continents except
99 for Antarctica (2,7,8,12,27). In Africa, there were outbreaks in domestic pigs and wild
100 elephants in South Africa (8,10) and primates in Democratic Republic of the Congo (11).
101 In addition, Grobler et al. reported that seropositivity in natal multimammate mice
102 (*Mastomys natalensis*: *M. natalensis*) captured in 1994 in the Kruger National Park, South
103 Africa for EMCV was 37.9% (100/264) (10). However, studies on the serosurveillance
104 of EMCV has not been reported in the subsequent 26 years. Furthermore, there have been
105 no reports on EMCV in either domestic or wild animals in Zambia. In this study, we have

106 isolated infectious EMCV from *M. natalensis* and screened for EMCV infection in
107 Zambian wild rodents using RT-PCR and neutralizing antibody tests. This study revealed
108 a unique molecular evolution of Zambian EMCV and suggests *M. natalensis* is a natural
109 reservoir of EMCV in Zambia. This is the first study of surveillance of EMCV in wildlife
110 in Zambia.

111

112 **Materials and Methods**

113 **Sample collection and ethical statement**

114 A total of 179 wild rodents, including *M. natalensis* and shrews collected in
115 three areas in Zambia from 2012 to 2013 were investigated: 67 rodents and shrews were
116 captured in Mpulungu, 41 in Solwezi and 71 in Mazabuka (Fig. 1). Rodents and shrews
117 were captured using Sherman traps and cage traps and euthanized with diethyl ether,
118 then sera, kidneys, spleens and lungs were collected and kept at -80°C until use. In
119 collected kidneys, spleens and lungs, we did not observe any macroscopical changes.
120 Captured rodents and shrews were classified into 13 species of rodents and 2 species of
121 shrews by nucleotide sequence analysis of the mitochondrial cytochrome *b* gene, as
122 described previously (28,29). Ethical approval to undertake the present study was
123 provided by the then Zambia Wildlife Authority, which is now the Department of
124 National Parks and Wildlife, Ministry of Tourism and Arts, Zambia.

125

126 **Cells and viruses**

127 Baby hamster kidney 21 (BHK-21 C-13, JCRB Cell Bank, Osaka, Japan) cells
128 were maintained in Dulbecco's Modified Eagles Medium (DMEM) with 10% fetal
129 bovine serum (FBS) and 100 U/ml penicillin and 100 µg/ml streptomycin (PS). Cells

130 were constantly cultured at 37°C with 5% CO₂. For EMCV propagation, BHK-21 cells
131 were infected with EMCV ZM12/14 at a multiplicity of infection (MOI) of 0.1 and
132 maintained for 2 days in static culture with maintenance medium: DMEM with 2% FBS
133 and PS. For virus titration, BHK-21 cells in 96-well plates were infected with EMCV
134 with 10-fold serial dilutions. Appearance of cytopathic effect (CPE) was monitored at 4
135 days post infection (dpi) and the 50% tissue culture infective dose (TCID₅₀)/ml was
136 calculated according to the Reed and Muench method.

137

138 **Virus isolation**

139 Mixed tissue homogenates of kidney, spleen and lung of each rodent and shrew
140 were prepared using BioMasher II (Nippi, Tokyo, Japan). After centrifugation at
141 3,000×g for 5 min, supernatants were inoculated to BHK-21 cells with 2 ml isolation
142 medium [DMEM supplemented with 10% FBS, PS, 25 µg/ml gentamycin, 1%
143 antibiotic-antimycotic solution (Wako, Osaka, Japan) and 25 mM 4-(2-hydroxyethyl)-1-
144 piperazineethanesulfonic acid (HEPES)] in 15 ml tissue culture tubes. Cells were
145 cultured for 7 days in rolling condition of 0.3 rpm/min and inoculated cells were
146 subsequently blind passaged twice in BHK-21 cells.

147

148 **Viral genome sequencing**

149 Viral RNA was extracted from the supernatant of the infected BHK-21 cells
150 using TRIzol LS reagent (Invitrogen, Carlsbad, CA). Double-strand cDNA was
151 constructed by PrimeScript Double Strand cDNA Synthesis Kit (Takara Bio, Shiga,
152 Japan) and subjected to sequence library construction using Nextera XT DNA Library
153 Preparation Kit (Illumina, San Diego, CA). The 300 bp paired-end sequencing was

154 performed on an illumina MiSeq sequencer (Illumina). Sequence reads were trimmed
155 and assembled into contigs by *de novo* assembly using CLC Genomics Workbench 20.1
156 (Qiagen, Hilden, Germany). The obtained contigs were analyzed by blastn program
157 (National Center for Biotechnology Information, Bethesda, MD).

158

159 **qRT-PCR**

160 Total RNA was extracted from culture supernatants or 10% tissue homogenates
161 using TRIzol LS reagent and subjected to qRT-PCR using THUNDERBIRD Probe
162 One-step qRT-PCR Kit (TOYOBO, Osaka, Japan). The primer and probe sequences for
163 EMCV ZM12/14 were as follows: forward primer 5'-
164 TCTTCTTGTGGCGACGAATTA-3'; reverse primer 5'-
165 GTCTTGTTAGCGGGTGTATCT-3'; probe 5'-
166 /FAM/TCCTGTCTT/ZEN/TGCCAGATTTGTTCTCACCC/IABkFQ/-3' (Integrated
167 DNA Technologies, Coralville, IA). Serially diluted RNA from the culture supernatants
168 containing EMCV were used to generate a standard curve for the conversion of Ct
169 values to TCID₅₀.

170

171 **RT-PCR and sequencing**

172 Total RNA was extracted from kidneys of rodents and shrews from Mpulungu
173 and spleens from Solwezi and Mazabuka using TRIzol (Invitrogen). To detect multiple
174 EMCV strains with a high degree of nucleotide sequence diversity, a universal
175 degenerate primer set was designed based on the consensus amino acid sequence of
176 EMCV 3D gene from 50 strains previously registered to GenBank: forward primer 5'-
177 RARYCTVGCAAAGACAGG-3'; reverse primer 5'-CKGTACTCCACASTYTC-3'.

178 RT-PCR assay was performed using SuperScript IV One-Step RT-PCR System
179 (Invitrogen) with the following thermal cycling conditions: 50°C for 10 min, 98°C for 2
180 min, 40 cycle of 98°C for 10 sec, 50°C for 10 sec and 72°C 30 sec, followed by 72°C
181 for 5min. PCR amplicons (312 bp in length) were sequenced by direct sequencing
182 methods.

183

184 **Virus neutralization tests**

185 Sera from rodents and shrews were heat-inactivated at 56°C for 30 min and
186 two-fold serially diluted from 1:10 to 1:640 at the reaction steps with maintenance
187 medium. Then the diluted serum (12.5 µl) was mixed with an equal volume of
188 maintenance medium, containing 100 TCID₅₀ of EMCV. The mixture was incubated at
189 37°C for 2 h. After incubation, the serum-EMCV mixture was added to the suspension
190 of BHK-21 cells (2×10⁴ cells/175 µl) and cultured for 4 days in 96-well plates. Virus
191 back-titration was included in each test to validate input amounts of the virus. The
192 highest serum dilution which completely inhibited CPE development was adopted to the
193 neutralizing antibody titer, and a neutralizing antibody titer greater than 1:30 was
194 considered seropositive according to a previous report (30).

195

196 **Phylogenetic analysis**

197 The genome sequence of EMCV ZM12/14 was aligned with reference EMCV
198 sequences from GenBank using ClustalW algorithm with default parameters and
199 applied to pairwise sequence identity comparison in CLC Genomics Workbench 20.1.
200 Phylogenetic trees were constructed by the Maximum-Likelihood (ML) method using
201 models of GTR+G+I for full-length of P1, P2, and P3 and K2+G for PCR amplicons, as

202 the best fit models, with bootstrap values of 1,000 replicates in the MEGA10 software
203 (31). Possible recombination events were searched using the RDP4 software with
204 default settings (32).

205

206 **Experimental infection of isolated EMCV in laboratory mice**

207 Five-week-old male BALB/c mice were inoculated intraperitoneally (i.p.) with
208 10^6 TCID₅₀ of EMCV. After the inoculation, clinical signs and body weight changes
209 were monitored for 14 dpi. At 14 dpi, heart, brain, spleen, testis, serum and feces were
210 collected from the mice. The neutralizing antibody titers of the serum were determined,
211 and the viral load of the organs and feces were estimated by qRT-PCR as described
212 above.

213

214 **Results**

215 **Virus isolation and genome sequencing**

216 Obvious CPE with cell rounding and detachment was observed in BHK-21
217 cells inoculated with tissue homogenates from one *M. natalensis* captured in Mpulungu,
218 which showed no macroscopic signs of serious infection. We tentatively named the
219 isolated virus as ZM12/14. Titration assays revealed the infectious titer of ZM12/14 in
220 the culture supernatant reached up to 2×10^9 TCID₅₀/ml. High-throughput sequencing
221 and *de novo* assembly with an average contig coverage of 14,172.4 allowed the
222 determination of nearly the complete genome sequence of ZM12/14 consisting of a
223 single ORF (6,879 nucleotides) encoding a polyprotein (2,292 amino acids), incomplete
224 5'-UTR (576 nt) and a complete 3'-UTR (120 nt) with poly A tail. The determined
225 sequence of ZM12/14 was deposited in GenBank (Accession No. LC585221). BLASTn

226 search revealed the genome sequence of ZM12/14 is the closest to that of EMCV strain
227 M (accession no. M37588). Overall the EMCV strain ZM12/14 was successfully
228 isolated from a *M. natalensis* in Mpulungu, Zambia.

229

230 **Sequence comparison and phylogenetic analysis**

231 To investigate the degree of sequence similarity between ZM12/14 virus and
232 EMCV reference strains, pairwise sequence identity was determined based on
233 nucleotide and amino acid sequences of P1, P2, P3 and ORF, as well as 1D, 2C and 3D
234 (Table 1). The results revealed that the ZM12/14 isolate shared the highest sequence
235 similarity with EMCV-1 strains in any examined regions and specifically P1 and 1D
236 region, which contain the main antigenic determinants located on the capsid protein,
237 ZM12/14 shared 80.7-77.5% nucleotide and 96.2-85.1% amino acid sequence identity
238 in P1, and 82.4-75.5% nucleotide and 92.8-89.8% amino acid sequence identity in 1D
239 with EMCV-1 strains. The highest P1 nucleotide sequence identity (80.7%) to that of
240 ZM12/14 was found in strains JZ1203 and YM13, which were isolated from mice and
241 pigs in China, respectively (Supplemental table 1).

242 We also performed ML phylogenetic analysis based on nucleotide sequences of
243 P1, P2 and P3 region separately (Fig. 2). Virus names and lineages were annotated to
244 the trees according to the previous study (5). EMCV-4 was not included in the
245 phylogenetic tree, because only a small part of P1 sequence was available. In the ML
246 trees of P1 and P3, ZM12/14 fell into a cluster of EMCV-1. Meanwhile, topology of P2
247 indicated that ZM12/14 were segregated from all EMCVs, including EMCV-1, EMCV-
248 2 and EMCV-3. The phylogenetic incongruence led us to conduct an exploratory
249 recombination analysis using RDP4 program based on the alignment of nucleotide

250 sequence of ZM12/14 and other EMCV strains; however, this analysis detected no
251 evidence of recombination in the genome of ZM12/14.

252

253 **Prevalence of EMCV among wild rodents and shrews in Zambia**

254 We performed RT-PCR and virus neutralization test to investigate EMCV
255 prevalence among wild rodents and shrews in Mpulungu, Solwezi and Mazabuka. Of
256 the 179 serum samples of wild rodents and shrews, 33 samples (18.4%) were
257 seropositive for EMCV, and 19 of these were positive in both RT-PCR and
258 neutralization tests (Table 2). EMCV genome was detected in samples from Mpulungu
259 and Solwezi, whereas EMCV-seropositive individuals were confirmed in all three areas.
260 Notably, all of the animals that were positive for EMCV genome and/or neutralizing
261 antibodies for EMCV are *M. natalensis*. Most of serum samples that were positive in
262 EMCV neutralization test had high neutralizing antibody titers (≥ 320 in Fig. 3). In
263 addition, these high neutralizing antibody titers were observed in not only RT-PCR-
264 negative samples (n=14) but also RT-PCR-positive samples (n=19) (Table 2). All
265 amplicons were subsequently sequenced (Accession No. LC585222-40) and the partial
266 3D sequences were subjected to pairwise sequence comparison and construction of
267 phylogenetic tree (Fig. 4). EMCV strains from Mpulungu and Solwezi shared 86.6-
268 86.3% nucleotide sequence identity and independently formed clusters in EMCV-1,
269 inferring geographic range evolution of EMCV in Zambian *M. natalensis* (Fig.1).

270

271 **Experimental infection of isolated EMCV in laboratory mice**

272 It has been reported that EMCV strains isolated from symptomatic pigs and
273 dogs cause various symptoms in laboratory rodents (12,27,33,34). To investigate the

274 pathogenicity of EMCV isolated from *M. natalensis*, three laboratory mice were
275 experimentally inoculated with ZM12/14. All the inoculated mice did not develop
276 clinical symptoms or significant weight loss during the observation period of 14 days.
277 After euthanizing at 14 dpi, serum samples were subjected to a neutralization test, and a
278 neutralizing antibody titer of ≥ 260 was observed in all mice. The ZM12/14 genome was
279 detected by qRT-PCR in hearts, brains, spleens and feces with the wide titer range from
280 1.1×10^2 to 6.9×10^4 TCID₅₀/whole organ (Fig. 5). These results suggested that ZM12/14
281 causes asymptomatic persistent infection in rodents, which is consistent with the
282 screening results in *Zambian M. natalensis*.

283

284 **Discussion**

285 Wild rodents are considered to be the natural reservoirs of EMCV. In previous
286 studies, EMCV were isolated from a wide range of wild rodents; including rats (*Rattus*
287 spp.) (35–38), mice (*Mus* spp.) (39,40), squirrels (*Sciurus* spp.) (41), dormice (*Myoxus*
288 *glis*) (42), water-rats (*Hydromys chrysogaster*) (43), cotton rats (*Sigmodon hispidus*)
289 (44), spiny rats (*Proechimys guyannensis*) (45). In South Africa, serological survey of
290 wild rodents in the Kruger National Park revealed that *M. natalensis* showed high
291 seropositivity rates (37.9%); however, further integrated studies of genetic and
292 serological analysis are necessary to understand the distribution and evolution of EMCV
293 (10). In this study, an EMCV strain named as ZM12/14 was isolated from a wild *M.*
294 *natalensis*. Thereafter *Zambian* wild rodents and shrews were screened for EMCV
295 infection by RT-PCR and virus neutralization tests. Because available samples of the
296 wild rodents kept at -80°C were limited, we extracted RNAs from kidneys of Mpulungu
297 rodents and spleens of rodents in Solwezi and Mazabuka for RT-PCR screening, which

298 were examined in a survey of poxviruses, paramyxoviruses and parvoviruses
299 (29,46,47). As a result, a high prevalence of EMCV in *M. natalensis* was observed,
300 consistent with the previous report from South Africa (10). Interestingly, there were
301 certain number of *M. natalensis* which had both high neutralizing antibody titer and
302 detectable viral RNA. Wild rodents are considered to be natural reservoir of EMCV
303 (10-12) and our results provide evidence that *M. natalensis* is a possible reservoir of
304 EMCV in the African continent, including Zambia.

305 EMCV can infect a wide range of animal species and impact especially on pig
306 production. EMCV causes an acute myocarditis (usually causing sudden death) in
307 young pigs and/or reproductive failure in sows, resulting in economic loss to pig
308 farmers (13–15). It has been reported that rodents contribute to outbreaks of EMCV in
309 pig farms as transmitters. (35,48–50). Although EMCV infection has not been reported
310 in any other animals in Zambia, our study demonstrated the high EMCV prevalence in
311 Zambian *M. natalensis*, highlighting the possible risk of EMCV infection in other
312 animals, such as pigs. In addition to pigs, EMCV infection can also cause fatal diseases
313 in a wide range of non-livestock species (2–4), including many kinds of non-human
314 primates (5–7), African elephants (*Loxodonta africana*) (8,9), considered endangered
315 species listed in the International Union for Conservation of Nature and Natural
316 Resources (IUCN) red list. Africa is the only continent in which outbreaks of EMCV
317 have been reported from a population of free-ranging wild animals (10,11), whereas
318 most of EMCV outbreak among exotic animals in other areas occurred in zoos. From
319 the perspective of species diversity conservation, EMCV transmission in wild rodents
320 would be considered. Further studies of prevalence of EMCV in pig farms and wild

321 animals should be directed to estimate the risk of EMCV outbreak and the need for
322 rodent control programs in Zambia.

323 EMCV was initially assumed to consist of a single genotype; however,
324 increasing numbers of EMCV sequence data have revealed high genetic diversity.
325 Recently, EMCV was serologically divided in two groups, (EMCV-1 and 2) (25), that is
326 also accepted by ICTV. It has been proposed that classification of EMCV based on
327 nucleotide sequence should be divided into EMCV-1, 2, 3 and 4, and EMCV-1
328 subdivided into 7 lineages (5). The group of EMCV-1 to 4 was defined by criteria
329 extrapolating from the genus *Enterovirus* (51,52); the same virus types share $\geq 75\%$ nt
330 ($> 85\%$ aa) identity in 1D region and $\geq 90\%$ aa identity in P1 region. In addition,
331 different lineages of EMCV-1 share $< 83\%$ nucleotide sequence identity in 1D and $<$
332 85% in P1. In accordance with these criteria, ZM12/14 can be assigned to a new lineage
333 H of EMCV-1. Phylogenetic trees of P1 and P3 region also indicated that ZM12/14 can
334 be classified in EMCV-1, which is consistent with pairwise sequence comparison
335 result; however, the phylogenetic tree of the P2 region showed that ZM12/14 separates
336 from the clade of EMCV-1 and even EMCV-2 and 3 without any recombination
337 evidence (Fig. 2). These results suggest that EMCV in Zambia has a unique evolutionary
338 history.

339 Pathogenicity and tissue tropism of EMCV seemed to vary depending on virus
340 strain and host species; however, detailed information is still unclear. The pathogenicity
341 of EMCV to laboratory mice and rats has been reported to vary from asymptomatic to
342 fatal accompanying encephalitis, myocarditis or diabetes mellitus (53). Previous studies
343 demonstrated that EMCV strains G424/90 and B279/95 isolated from pigs showing
344 clinical signs caused mainly asymptomatic infection in Wistar rats and BALB/c mice

345 (21,22). In contrast, strains NJ08 and BD2 were fatal for laboratory BALB/c mice
346 (27,33,34). Experimental infection of ZM12/14 to BALB/c mice showed no clinical
347 signs, despite the high neutralizing antibody titer and viral RNA detection in some
348 organs suggesting the establishment of systemic infection (Fig. 5). The pathogenicity of
349 ZM12/14 in pigs and other animals will require further study.

350 In conclusion, the EMCV strain ZM12/14 isolated from *M. natalensis* in
351 Zambia, had unique phylogenetic features. Given the high detection rate of the EMCV-
352 genome and neutralizing antibody for EMCV in *M. natalensis*, this rodent species may
353 be one of the reservoirs in African countries. Consequently, our study updates the
354 knowledge of the current situation of EMCV in wild rodents in the African continent
355 and highlights the potential risk of EMCV infection in domestic and wild animals and
356 potentially humans in Zambia.

357

358 **Conflicts of interest**

359 The authors declare that there are no conflicts of interest.

360

361 **Ethical approval**

362 Ethical approval to undertake the present study was provided by the then Zambia
363 Wildlife Authority, which is now the Department of National Parks and Wildlife,
364 Ministry of Tourism and Arts, Zambia. All animal experiments were performed at the
365 Animal BSL-2 facility of the Research Center for Zoonosis Control of Hokkaido
366 University, which has been certified by The Association for Assessment and
367 Accreditation of Laboratory Animal Care International, and followed the basic
368 guidelines for animal experiments of the Ministry of Education, Culture, Sports,

369 Science, and Technology (MEXT) of Japan. All animal experiments were approved by
370 the President of Hokkaido University after review by the Animal Care and Use
371 Committee of Hokkaido University (No. 19-0019).

372

373 **Funding information**

374 This work was supported in part by the Japan Agency for Medical Research and
375 Development (AMED) (20wm0125008), AMED and Japan International Cooperation
376 Agency (JICA) within the framework of the Science and Technology Research
377 Partnership for Sustainable Development (SATREPS) (20jm0110019), and Scientific
378 Research on Innovative Areas (16H06429, 16H06431, 16K21723) and a Grant-in-Aid
379 for Graduate Student from the World-leading Innovative and Smart Education (WISE)
380 Program (1801) from the Ministry of Education, Culture, Sports, Science and
381 Technology (MEXT) of Japan.

550 **Figure legends**

551 Fig. 1. Map of Zambia showing the locations of rodent sampling. Rodent collections
552 were carried out in Mpulungu (Northern Province), Solwezi (North-Western Province)
553 and Mazabuka (Southern Province). EMCV strain ZM12/14 was isolated from *M.*
554 *natalensis* collected in Mpulungu area.

555

556 Fig. 2. Phylogenetic analysis of EMCV isolates based on the nucleotide sequence of P1,
557 P2 and P3 regions. The species of *Cardiovirus B* were included as the outer group.
558 Taxon of EMCV strain ZM12/14 was highlighted in the black square. In addition to
559 serotype EMCV-1 and EMCV-2, EMCV-3 and lineages A-G proposed by Vysheirskii
560 *et al.* are shown as indicated (5). Phylogenetic trees were constructed by the Maximum-
561 Likelihood method using Models of GTR+G+I with bootstrap values of 1,000
562 replicates.

563

564 Fig. 3. Distribution of neutralizing antibody titer of *M. natalensis*. Black or white bars
565 indicate RT-PCR-positive or -negative samples, respectively. The titer greater than 1:30
566 was considered as seropositive. The neutralizing test was performed twice.

567

568 Fig. 4. Phylogenetic analysis of Zambian EMCVs and EMCV genomes deposited in
569 GenBank, based on nucleotide sequences of partial 3D region (277 bp in length). In
570 addition to serotype EMCV-1 and EMCV-2, EMCV-3 and lineages A-G proposed by
571 Vysheirskii *et al.* are shown (5). Phylogenetic trees were constructed by the
572 Maximum-Likelihood method using Models of K2+G with bootstrap values of 1,000
573 replicates.

574

575 Fig. 5. Viral loads of ZM12/14 in the tissues and feces of challenged BALB/c mice
576 (n=3) by using qRT-PCR. The Ct values of viral genome in each sample were converted
577 to TCID₅₀ based on the standard curve. The values in the graphs were expressed as
578 mean \pm SD of three technical replicates.

579

DEMOCRATIC
REPUBLIC OF THE
CONGO

Mpulungu

Fig. 1

Solwezi

ZAMBIA

Mazabuka

0 150 km

A map of Zambia showing its geographical boundaries. Three locations are marked with black dots: Mpulungu in the northeast, Solwezi in the west-central region, and Mazabuka in the south-central region. The names of these locations are written in black text. The name 'Mpulungu' is enclosed in a grey rectangular box. The name 'ZAMBIA' is written in large, bold, grey capital letters in the center of the country. The name 'DEMOCRATIC REPUBLIC OF THE CONGO' is written in grey capital letters in the upper left corner. A scale bar in the bottom right corner shows a distance of 150 km, with a tick mark at 0.
