Of the Foxe

“Raynerd the Foxe am I, a craftie childe well knowne,
Yea better known than credited, w^t more than is mine own:
A baftard kind of curre, mine eares declare the fame,
And yet my wit and pollicie haue purchaft me great fame.”

George Turbivile, The booke of Hunting, 1576.

ABSTRACT

The European red fox (*Vulpes vulpes* L.) is a well known predator of native species and domestic stock, and is recognised as one of Australia's most devastating vertebrate pests. Current fox management relies heavily on poisoning using baits impregnated with sodium monofluoroacetate (1080). This reliance on 1080 is likely to continue given the lack of viable alternatives for controlling foxes, so that, in the meanwhile, it is important to improve the efficiency of the current techniques. Factors affecting the susceptibility of individual foxes to bait include their ability to locate it, as well as the bait's palatability and toxicity. The economic costs associated with using different bait types, the pattern and density of their distribution will also affect the efficiency of control programs. It is essential to examine and refine all such issues to ensure efficient use of the 1080 baiting technique.

This thesis focuses generally on problems associated with management of the fox in eastern Australia. More specifically, I investigate the factors affecting the efficiency of fox baiting practices on the central tablelands of New South Wales.

The study was conducted largely on agricultural lands near the town of Molong (33°10'37"S, 148°87'15"E) on the central tablelands of New South Wales. This area was chosen as it is broadly representative, in terms of land use, of a large region of eastern Australia. The highly modified, predominantly agricultural landscapes near Molong are well suited to foxes, and conflict with the predominantly pastoral community means that fox management is widely undertaken.

I determined the persistence of 1080 in two commonly used bait types, Foxoff[®] and chicken wingettes, under different climatic and rainfall conditions. The rate of 1080 degradation did not change significantly between the central tablelands and the relatively hotter and drier western slopes. Foxoff[®] baits remained lethal for longer than wingettes under all conditions, although their rate of degradation generally increased with increasing rainfall. I confirmed the presence of defluorinating micro-organisms in the

soils of eastern Australia for the first time, and suggest that, following removal from the bait, 1080 would not persist in the environment for long.

Bait should be attractive and highly palatable to ensure that the target species will find and consume it upon discovery. Caching, where discovered food is removed but not immediately consumed, may potentially reduce the efficacy and cost-effectiveness of baiting campaigns. I quantified the caching of chicken wingette, day-old chick and Foxoff[®] baits by inserting transmitters into bait material and assessing whether it was eaten or cached following removal. The intensity of caching did not change significantly between seasons. Type of bait had the largest influence on caching intensity, with a greater percentage of non-toxic Foxoff[®] baits (66.9%) being cached than either wingettes (5.7%) or day-old chicks (4.5%). The percentage of toxic (1080) baits cached was even greater, suggesting that 1080 bait may be less palatable, and detectable to foxes.

I also investigated the use of conditioned taste aversion to reduce multiple bait uptake by foxes. Levamisole, an illness-inducing chemical, was added to bait and the fate of removed bait was again monitored via radio-telemetry. Following consumption of a levamisole-treated bait, foxes avoided eating treated baits but consumed untreated baits. I concluded that a reduction in bait consumption was achieved through learned aversion to levamisole rather than via conditioned taste aversion to baits. Adding levamisole to baits, especially non-toxic bait such as rabies vaccines, could potentially be used to reduce bait monopolisation by individual foxes.

Fox density and den site preferences were assessed by investigating the distribution and density of fox natal dens on one property (9.6 km²) over three consecutive years. A total of 9 natal dens were located in 2000 and 2001, declining to 6 in 2002. No preference was shown for den sites on the basis of habitat, slope or aspect, but more dens were located under, or adjacent to cover. Assuming that each natal den represents a breeding pair and that the population sex ratio did not differ from parity (1:1), the site contained a pre-breeding density of 1.9 foxes/km² in 2000 and 2001, and 1.25 foxes/km² in 2002. Given that the mean number of cubs is 4.0, the post-breeding density was estimated at 5.6 and

3.75 foxes/km² in 2000/2001 and 2002, respectively. The results demonstrated that high densities of foxes occur on agricultural lands. The success and likely accuracy of the technique to monitor fox density suggests that it may be used to calibrate more efficient abundance estimates that will be essential for the strategic management of foxes in future.

Pest animal management strategies are traditionally assessed for their effectiveness, with less consideration being given to the efficiency or cost of achieving the desired effect. I used cost-effectiveness analyses to compare between different baiting strategies based on the longevity, palatability and handling/replacement costs associated with each bait type. The results indicated that, when measured on a total cost-per-bait-consumed basis, wingettes and day-old chicks were the most cost-effective baits for campaigns of up to 4 weeks duration. This demonstrates the importance of including the longevity, and particularly the palatability of bait, when assessing cost-effectiveness. However, it is recognised that other factors, including the consistency of dosage and uptake by non-target species, may be equally or more important in deciding the appropriate baiting strategy.

The spatial and temporal application of fox baiting in the region overseen by the Molong Rural Lands Protection Board was examined between January 1998 and December 2002 as a case study to evaluate the apparent effectiveness of cooperative management practices. Most landholders (78.8%) did not bait for foxes during this period. Based on known dispersal distances, the effect of fox immigration into baited areas was determined. The results indicated that no areas baited for foxes were separated by a sufficient buffer distance (>9.58 km) from unbaited areas to be protected from fox immigration. This suggests that, at current levels of coordination, the effectiveness of most baiting operations in eastern Australia is compromised over the long term by fox immigration. However, it is recognised that short-term reductions in fox density may sometimes be all that are required to reduce predation to acceptable levels, especially for seasonally-susceptible prey. Ultimately, the cost-effectiveness of control should be evaluated in terms of the response of the prey rather than that of the predator.

This study has highlighted deficiencies in current 'best-practice' baiting techniques. Specific recommendations for current baiting practices, in addition to future research, are also given. In brief, these include minimising free-feed baiting, increasing the minimum distance between bait stations, and, where possible, presenting the most palatable bait. Continued research into conditioned taste aversion, aerial baiting, and techniques to reduce caching are recommended as potential techniques to improve the efficiency of baiting practices.

ACKNOWLEDGEMENTS

I would like to sincerely thank my supervisors, Glen Saunders, NSW Department of Primary Industries and Chris Dickman, University of Sydney for their friendship, guidance and support throughout this project. Many thanks also to Steve McLeod, NSW Department of Primary Industries who acted as a third 'unofficial' supervisor. All were encouraging, and their patience and enthusiasm were inspiring. I am especially indebted to Chris Dickman for his unflagging support during the write-up.

Many former and current members of Agricultural Protection and the Vertebrate Pest Research Unit helped at times either with advice and direct assistance: John Tracey, Suzy Balogh, John Druhan, Brian Lukins, Greg Jones, Sean Brown, Peter West, Peter Fleming, Lynette McLeod, Barry Kay, Eric Davis, David Croft, Heather McKenzie and Vicki Tuck-Lee. Sean Brown and Kate Wall from the University of Queensland assisted with some of the fieldwork and data entry. I'd like to sincerely thank them all for their friendship, good times and lunchtime soccer.

Many other staff at the NSW Department of Primary Industries assisted in some capacity: Rick Cother and Dorothy Noble kindly allowed me to use their laboratory and provided patient supervision and assistance in isolating and identifying soil microorganisms. Michael Priest identified the fungi species. Ron Hacker and staff from Trangie Research Station kindly allowed me access to their facilities during the bait degradation study and Jayne Jenkins and Greg Jones assisted with the setup and sampling. Richard Rodger and Peter Worsley assisted with the monumental task of matching property descriptions to landholder details – what a job it was! Remy Van de Ven and Arthur Gilmour provided very helpful statistical advice and assisted in the use of the statistical package *R*.

The Water Quality team, Orange City Council kindly allowed me to use their fluoride meter and laboratory for measuring the defluorinating ability of isolates. Laurie Twigg provided advice during the fluoroacetate laboratory work and other aspects (especially bait degradation) of the study. Bob Parker, Martin Hannan-Jones and Gina Paroz,

Queensland Department of Natural Resources and Mines were contracted to undertake the fluoroacetate bait assays.

Colin Somerset, Chris Lane, Ross Trudgett, Glen Walker and other staff (especially Mary Roberson) from the Molong Rural Lands Protection Board assisted in preparing bait, locating potential study sites and matching 'a property with a name' during the baiting coverage case study. Who said that it couldn't be done! They were also a friendly port of call and very forthcoming with a cuppa, especially on frosty mornings.

Jason Neville, NSW Department of Environment and Conservation and Rob Findlay State Forests, kindly supplied data on control practices on conservation lands. Molong Rural Lands Protection Board and the NSW Department of the Valuer-General kindly allowed access to their property description data. Mark Sayer (Countrywide Systems Network Inc.) provided advice on the TFS2 database download. Peter Collet and John Perfect (Land and Property Information) also provided valuable input into the matching process (many thanks chaps!).

Roger Pech and Chris Davey (CSIRO Canberra) provided some interesting discussions in the conditioned taste aversion technique. Many thanks to Giovanna Massei for her advice with the conditioned taste aversion experiments. Giovanna and Roger Quy, Julia Coats and David Cowan (Central Science Laboratory, York) were welcoming and supported my laboratory conditioned aversion experiments in the United Kingdom. The friendly staff at the Central Science Laboratory made me feel welcome during my brief stay and members of the Animal Services Team assisted in caring for the rats.

Thanks to all those who assisted in searching for dens: Brian Lukins, John Tracey, Greg Jones, Peter West, Kate Wall, Emma Hobbs and Sean Brown. Peter Worsley (NSW Department of Primary Industries) and 'Mulga' Daniel Huie assisted with the mapping component.

Sincere thanks to many landholders who were kind enough to allow me access to their properties for various parts of this study - especially Bill and Gina Dunlop (Nandillyan Heights), Peter and Wendy Reid (Fernleigh), Don Bruce (Myrangle), Will Lee (Claremont), Ian Atkinson (Gundabooka), Peter Welsh and family and Steve Brown (Larras Lake North). Special thanks to Peter Welsh for supplying me with comfortable accommodation during my stays on Larras Lake North.

The National Feral Animal Control Program, Bureau of Rural Sciences and NSW Department of Primary Industries funded this study. The University of Sydney and Pest Animal Control Co-operative Research Centre, Canberra (now Australasian Invasive Animal CRC) provided a postgraduate scholarship and some much appreciated travel assistance for the United Kingdom component. Many thanks to current and former members of the Pest Animal Control CRC, including Tony Peacock, Barbara Van Leewen and Anthony Szell for their support.

All animal experimentation within Australia were approved by the Orange Animal Ethics Committee (ORA 00/006; ORA 01/010); The Department of Environment, Food and Rural Affairs Animal (DEFRA) Ethics Committee at the Central Science Laboratory approved the United Kingdom experiments under Home Office licences.

I am indebted to Joe Scanlan and Dave Berman, Queensland Department of Natural Resources and Mines, for their support and encouragement during the final stages of the write-up.

Many thanks and love to my family (Mum, Dad and Penn) and friends who supported me when I needed it most – I couldn't have done it without you. Aunty Rae always made me feel welcome during my stays in Sydney. Joe the 'oldest cat in the world' also gave me great company throughout – especially during the field trials - rest in peace mate. Lastly I would like to thank anyone I may have accidentally omitted who assisted during this study.

Figure 3.13: Survival of non-toxic and toxic cached baits during winter 2002.	91
Figure 3.14: The distance from the bait stations that non-toxic baits were eaten (n = 869) or cached (n = 124).	94
Figure 3.15: The distance from the bait stations that toxic baits were eaten (n = 65) or cached (n = 59).	94
Figure 4.1: The order of procedures undertaken on the varied and single diet groups in the CTA diet diversity experiment.	119
Figure 4.2: Logistic functions showing the probability of a fox visiting a station (Treatment or Control) and the probability of a fox consuming a bait from each group (treated and untreated bait) on each site (Treatment or Control).	123
Figure 4.3: The cumulative number of baits eaten on the treatment and control sites during the pre-treatment, treatment and post-treatment trial periods.	124

Figure. 4.4: The mean consumption of biscuits at the initial presentation vs. the number of post-conditioning tests before rats consumed >0.2 g of the biscuits.	126
Figure 4.5: The proportion of rats in the varied and single diet groups consuming >0.2 g of biscuits or wheat in each post-test.	128
Figure 4.6: The mean percentage (\pm SE) of biscuit eaten by rats from total food consumed in the varied and single diet groups in each post-treatments.	129
Figure 5.1: Location of the Molong Rural Lands Protection Board within New South Wales.	143
Figure 5.2: Number of landholders baiting and number of baits distributed to ratepayers between January 1998 and December 2002.	147
Figure 5.3: The number of landholders undertaking fox baiting in each month within the Molong RLPB pooled for the period.	149
Figure 5.4: Number of Foxoff [®] , chicken head and meat baits distributed by Molong RLPB between January 1998 and December 2002.	150
Figure 5.5: The total area of the Molong RLPB baited during 1998.	151
Figure 5.6: The total area of the Molong RLPB baited during 1999.	152
Figure 5.7: The total area of the Molong RLPB baited during 2000.	153
Figure 5.8: The total area of the Molong RLPB baited during 2001.	154
Figure 5.9: The total area of the Molong RLPB baited during 2002.	155
Figure 5.10: Number of hectares baited by ratepayers and government agencies in the Molong RLPB.	156
Figure 5.11: The proportion of landholders that completed one, two or greater than two baiting campaigns per annum in the Molong RLPB.	157
Figure 5.12: The number of ratepayers undertaking baiting in the Molong RLPB and the proportion of these with neighbours baiting.	158
Figure 5.13: The mean number of neighbouring landholders undertaking fox baiting in coordinated baiting campaigns in the Molong RLPB.	159

Figure 5.14: The built-up area boundaries, areas within a 2.0 km and 4.0 km radius of these boundaries, and baited areas within the Molong RLPB.	161
Figure 5.15: The proportion of Molong RLPB ratepayers in each enterprise and the proportion who undertook fox baiting from 1998-2002.	162
Figure 6.1: The locations of all active, inactive and natal fox dens.	183
Figure 6.2: The locations of natal, active and inactive fox dens found during 2000.	184
Figure 6.3: The locations of natal, active and inactive fox dens found during 2001.	185
Figure 6.4: The locations of natal, active and inactive fox dens found during 2002.	186
Figure 6.5: The proportion of all fox dens located in each habitat and the proportion of each habitat available (n = 231).	188
Figure 6.6: The proportion of all fox dens located in each slope class and the proportion of each slope class available (n = 231).	189
Figure 6.7: The proportion of all fox dens located in each aspect class and the proportion of each habitat class available (n=231).	191
Figure 7.1: The cumulative number of baits to be retrieved during a replacement baiting program (43 baits laid and checked/replaced every 3-4 days) at bait uptake rates of 10, 25 and 50%.	218
Figure 7.2: Decision tree illustrating the issues and sequence of decisions to be made in choosing the appropriate bait type for a fox baiting campaign.	229
