## 0. Executive Summary

An important reason for being concerned about low rates of retention in Higher Education is the concomitant wastage of resources from the perspective of both funding bodies and higher education institutions. However, another reason for concern with low retention rates is the implication that they carry for future cohorts of students. This is best encapsulated in the following statement:

“Increasing non-completion rates could undermine success in opening higher education to a broader spectrum of the population, put off potential students, and cause institutional instability.”

Parliamentary Select Committee on Education & Employment (2001, pp. v)

The central issue analysed in this paper is how the probability of a first year student proceeding to the second year of his/her studies is influenced by his/her personal characteristics and circumstances. We refer to this probability as the probability of survival<sup>2</sup> and the results reported here are in terms of the *marginal* probability of survival. This is the *change* in the probability of survival consequent upon a change in a specific determining variable (i.e. between female and male students or between middle-class and working-class students) *when the values of the other variables are left unchanged*.

The key findings are

**Gender** - the probability of women surviving the first year was 3.7 percentage points higher than that for men *ceteris paribus*.

---

<sup>2</sup> Survival refers to the student successfully completing their first year and proceeding to the second year of study.

**Socio-economic class** - compared to those students coming from an unskilled or semi-skilled social background, the probability of surviving the first year was 4.1 points higher for students from a professional social class; however, there was no significant difference between the survival rates of students from unskilled and skilled backgrounds.

**Religion** – compared to students from “other” religions, Catholic students were less likely to survive their first year by 4.0 points; however, there was no significant difference between the survival rates of students from “other” religions and Protestant students.

**Usual domicile** - Compared to students whose domicile was outside Northern Ireland (the residual domicile category), students from Northern Ireland were less likely to survive their first year by 8.4 points.

**Offer basis** - the probability of survival was not significantly affected by the quality of the student’s school leaving grades or by the fact that he/she had been made a “non-traditional” offer based on other than A-levels.

**Course type** - Compared to the probability of surviving the first year of an Accounting course (the residual category of course type), the probability of:

- surviving an Art and Design course type was 10.8 points lower
- surviving a Business and Management course type was 11.5 points lower
- surviving an Engineering course type was 26.2 points lower
- surviving a Humanities course type was 16.7 points lower

- surviving a Computing and Information Technology course type was 22.4 points lower
- surviving a Science course type (excluding Nursing and (non-Nursing) Health-related) was 14.0 points lower
- surviving a Social Science course type (excluding Nursing, Social Work and (non-Nursing) Health-related) was 18.4 points lower
- surviving Nursing courses was not significantly different from the survival rate for Accounting courses.
- surviving Social Work courses was not significantly different from the survival rate for Accounting courses.
- surviving (non-Nursing) Health-related courses was not significantly different from the survival rate for Accounting courses.

From these results, one can identify the Northern Ireland domiciled “student type” studying at the University of Ulster with the highest and lowest survival rates. Female, Protestant students, from a professional background, taking Social Work and (non-nursing) health-related courses had a survival rate of 96.1 percent while male, Catholic students, from an unskilled/semi-skilled background, studying Engineering had a survival rate of 65.2 percent.

## 1. Introduction and Literature Survey

### What is retention and why is it important?

The Higher Education Funding Council for England and Wales (HEFCE) confirmed in its evidence to the Parliamentary Select Committee on Education & Employment in January 2001 that there was no standard definition of retention

“There are no nationally or internationally agreed definitions of non-completion, and a wide range of possible constructions and interpretations exist.”

Parliamentary Select Committee on Education & Employment  
(2001, pp. 109)

For example, a student who successfully completes one or two modules but fails the year as a whole may still be in a position to transfer those module credits to another course within the same institution or possibly to another institution.

Besides the impact of retention on resource wastage from the perspective of the funding bodies<sup>3</sup> and also the institutions, the same Parliamentary Select Committee report noted that one reason for being concerned about retention was for the potential students of the future as

“Increasing non-completion rates could undermine success in opening higher education to a broader spectrum of the population, put off potential students, and cause institutional instability.”

---

<sup>3</sup> The relationship (and potential conflict) between the objective of widening participation in higher education and the performance indicators used to examine the functioning of higher education is examined in Pugh et al (2005).

Parliamentary Select Committee on Education & Employment  
(2001, pp. v)

The most recent national figures on retention from the Higher Education Statistics Agency cover the academic year 2003/04 (HESA (2006)). These figures indicate a national UK attrition rate (i.e. those no longer in any form of higher education) of 9.5% with another 2.8% transferring to another institution. The figures for the University of Ulster are higher than this with 14.7% no longer in any form of higher education and 1.7% transferring to another institution.

Such data has been collected annually by the 4 UK funding bodies since 1998<sup>4</sup> and an analysis of this reveals that UK attrition rates have been relatively stable at 9½ – 10% and UU attrition rates have been relatively stable at 10% – 14% despite growth rates in the 1<sup>st</sup> year undergraduate population of 10% and 90% respectively, over the period 1996/97 – 2003/04.

The attrition rates that we will observe in this analysis comprise the totality of 4 separate components:

1. Withdrawal entirely from higher education (the 14.7% figure quoted by HESA for the University of Ulster in the academic year 2003/04)
2. Transfer to another higher education institution to commence a programme of study in the following academic year (the 1.7% figure quoted by HESA for the University of Ulster in the academic year 2003/04)

---

<sup>4</sup> Initially by HEFCE [ <http://www.hefce.ac.uk/learning/perfind/default.asp> ] for 1996/97 - 2000/01 and then by HESA [ <http://www.hesa.ac.uk/pi/> ]

3. Transfer within the University of Ulster to commence a programme of study in the following academic year (not included within the HESA definitions).
4. Repeating the first year of a programme of study at the University of Ulster in the following academic year (not included within the HESA definitions).

For example, the definitional difference is that our observed attrition rate (elements 1, 2, 3 and 4) is higher than the HESA definition of the attrition rate (elements 1 and 2) by approximately 4% in 2002/03 and 2% in 2003/04<sup>5</sup>.

#### Literature Survey - Theory

The standard theoretical reference usually referred to in the student attrition literature is to the student integration model of Tinto (1975) where the likelihood of a student withdrawing from higher education is seen as being determined by individual attributes, familial attributes, prior qualifications, social integration, academic integration, individual commitment, institutional commitment and external family and societal factors taking place during the course of study.

One of the problems researchers are faced with when applying this model is that Tinto takes a sociological perspective to the situation and specifically focuses upon academic integration (grade performance, student's private judgement on the value of what they are learning, academic self-esteem, enjoyment of subject, enjoyment of studying, identification with academic norms and values) and social integration (number of friends, personal contact with academics, enjoyment of being at university?"); however, applications of this type of analysis have been attempted on a small scale e.g. Mackle (2001)

---

<sup>5</sup> HESA figures for 2004/05 entrants are not yet available.

looking at an intake of 450 1<sup>st</sup> year students at Bristol Business School in 1996/1997 and Lowe & Cook (2003) at the University of Ulster which we will return to later.

Thus most studies take a lead not dissimilar to that of Yorke (1999) who effectively has set the pattern of most subsequent research in the UK on student attrition. Yorke identified, from previous research such as Thomas, Adams and Birchenough (1996), three primary causes of withdrawal amongst full-time students: a mismatch between students and their chosen programme of study, financial difficulties for the student and poor quality of the student experience.

#### Literature Survey - US evidence

Reason (2003) provides a useful overview of the main studies for the United States prior to that date – here we will follow his approach which is to look at studies categorised by the independent variables under analysis.

High School grade point average (GPA) and college admission test scores (SAT/ACT) have proved to be a statistically significant determinant of retention in a number of US studies (e.g. Astin et al (1987) and Tross et al (2000)) with a higher GPA or a higher college admission test score leading to a higher probability of retention; however, these variables do not predict more than a quarter of the variation in retention by themselves. A further issue highlighted by Wolfe & Johnson (1995) is that these two prior attainment variables are usually highly collinear.

Gender has proved to be statistically significant in some studies (e.g. Astin et al (1987)) although other more recent studies (Leppel (2002)) suggest that the effects of gender are more complicated. In this paper Leppel indicates that the interaction of marital status and gender may also have implication for

retention with married women less likely to persist in higher education than unmarried women.

Race & ethnicity have also been shown to be important determinants of retention in the United States but recent studies such as Murtaugh et al (1999) suggest that this effect has diminished substantially in recent years and may no longer be statistically significant.

Astin (1997) indicates that these four variables (High School grade point average, college admission test scores, gender and race) account for the bulk of variance in retention.

#### Literature Survey - UK evidence

Patrick (2001) uses data from a sub-set of a 1<sup>st</sup> year cohort at the University of Glasgow (1998/99 session) to undertake both logistic and multilevel regressions. The independent variables are entry routes (categorised into entry by Scottish Highers, entry by 'A'-levels, entry by Scottish Lowers and others) and the subject area which they are studying.

His findings on entry routes were that those with Scottish Highers (32%) were statistically significantly<sup>6</sup> less likely to withdraw and those with other qualifications (17%) were statistically significantly more likely to withdraw *ceteris paribus*.

The subject effects are that certain subjects (which are not identified by the author) do have different withdrawal rates than others after partly correcting for entry route differences. These differences are attributed by the author to three possible causes: a straightforward mismatch of students and courses,

---

<sup>6</sup> Statistical significance is being defined here as that the estimated coefficient is statistically significantly different from zero at the 95% level.

differences in the academic standard required by students upon entry or the nature of the course as students on vocational courses do seem to do better.

A more wide ranging study is that undertaken by Smith & Naylor (2001) who used individual level data for a one-year cohort from the whole of the 'pre-1992' universities (the former UFC funded institutions). This data included all of those who enrolled on their studies in the academic year 1989/1990 which was just over 76000 students. One slightly unusual factor in their work is that their definition of withdrawal is defined as leaving the course before the January of the final year of study – thus they include typically at least a year and a third more of educational participation than do most studies which focus on withdrawal before the commencement of the 2<sup>nd</sup> year of study. The more relevant descriptive statistics from their survey for our purposes are: (i) that amongst different subject disciplines, computer science has the highest attrition rate of 15% compared to the lowest of 6% for Law; (ii) the drop-out rate lowers as 'A'-level point scores rise and (iii) the drop-out rate is lower for those students with 'professional' or unskilled parents than for other groups<sup>7</sup>.

They then undertake a bivariate probit analysis for male and female students separately with the following statistically significant findings:

- the probability of withdrawal is reduced for both genders as the 'A'-level point score increases.
- the probability of withdrawal is increased for females studying sciences (but not statistically significantly so for males).

---

<sup>7</sup> The lower drop-out rate for those students who had unskilled parents may be explained for this period in time by the existence of a maintenance grant regime – in a post-maintenance grant system, some evidence on the relationship between employment and attainment at one University can be found in Hunt et al (2004). Some evidence on the extent of the labour market participation of students in Northern Ireland can be found in Bailey (2003).

- the probability of withdrawal is increased for both genders when studying social sciences.
- the probability of withdrawal is reduced for mature students generally but not statistically significantly so for females aged 34 or older.
- the probability of withdrawal is reduced for married male students but not statistically significantly reduced for married female students.
- the probability of withdrawal is reduced for those male students with parents in the 'professional' socio-economic class but not statistically significantly for any other type of parental socio-economic class.
- the probability of withdrawal is reduced for any non-UK students.

## 2. Data Description

The data for the analysis reported in this paper pertained to a total of 15,123 *first-year* students at the University of Ulster enrolled in October 2002, 2003, and 2004. For each of these (first year) students, the university's records provided information about his/her:

1. Programme of study (for example, BA in Economics) and the course type (for example, Social Sciences): in total, there were 385 programmes of study across 10 course types.<sup>8</sup>
2. Whether the student proceeded, or did not proceed, to the next year of his/her programme of study (survived/did not survive).
3. Sex, social class, religion, ethnicity, disability (if any), domicile, marital status, year of entry, and basis for acceptance to the University (A-levels, HND etc.).

Table 1 shows the survival and attrition rates (defined, respectively, as the percentage of students who proceeded/did not proceed to the next year) by course type. The overall attrition rate for the University, over the three years, was nearly 19 percent but this rate varied considerably between course types: the attrition rate was *lowest* for professional course types (8 percent for Social Work and non-nursing health-related – for example, physiotherapy; 10 percent for Nursing; and 12 percent for Accounting) and *highest* for Engineering (31 percent), Computing and Information Technology (28 percent), and Social Sciences (20 percent).

Tables 2- 11 show, for each course type, the attrition and survival rates by programme of study. Of the 385 programmes of study offered by the

---

<sup>8</sup> See Table 1 for a listing of course types and Tables 2-11 for a listing of study programmes.

University of Ulster, 195 programmes admitted 10 or fewer students over three years; the majority of these being in the new modular degree programmes. On the other hand, 79 of the 385 programmes on offer had total intakes of 60 students or more over 2002-2004. These “low intake” and “high intake” programmes are listed in Tables 12 and 13, respectively. Of the 195 low intake programmes, 92 were from Humanities and Languages, 40 were from Business and Management, 25 were from Social Sciences, and 15 were from the Sciences. Of the 79 high intake programmes, 17 were from Business and Management, 13 were from Social Sciences, 12 were from Engineering, and 13 were from the professional programmes (Accounting, Nursing, and Social Work and (non-nursing) Health-related).

Table 14 shows that the probability of female students surviving their courses (85.2 percent) was significantly higher than that for male students (75.8 percent); Table 15 shows that the probability of surviving courses decreases as the social class of the students moves from a professional background (86.2 percent survival rate) to an unskilled background (76.9 percent survival rate); Table 16 shows that students from other religions had the highest survival rates (89.4 percent), followed by Protestant students (87.3 percent), followed by Catholic students (80.9 percent); lastly, Table 17 shows that students from outside the EU had the highest survival rates (97.1 percent), followed by non-UK EU students (92.7 percent), with the survival rates of students from Northern Ireland and Great Britain being roughly the same (80 percent).

### 3. Estimating the Probabilities of Continuing after the First Year at University

An important question is how the probability of a first year student proceeding to the second year of his/her studies was influenced by his/her personal characteristics and circumstances. In order to answer this question we estimated a logit model in which the dependent variable  $Y_i=1$  if student  $i$  “survived” (i.e. proceeded to the second year of study) and  $Y_i=0$  if he/she did not “survive”.<sup>9</sup> The results of estimating this (survival) equation on data for 8,631 students over the 3 years (2002/03 to 2004/05) are shown in Table 18<sup>10</sup>. A positive (negative) coefficient estimate indicates that the probability of continuing rises (falls) with an increase in the value of the variable associated with the coefficient. However, the coefficient estimates do not provide a guide to the amount by which the probability of survival increases or decreases in consequence of a change in the variable value.

For this reason, the estimation results are discussed in terms of “marginal probabilities” shown in the last column of Table 18. The *marginal probability* of survival, associated with a determining variable, is the change in the probability of survival consequent upon an unit change in the determining variable, the values of the other variables remaining unchanged. For discrete variables, the marginal probabilities refer to changes consequent upon a

---

<sup>9</sup> The logit equation is  $\frac{\Pr(Y_i = 1)}{1 - \Pr(Y_i = 1)} = \exp\left\{\sum_{k=1}^K X_{ik} \beta_k\right\} = \exp\{z_i\}$  for K coefficients,  $\beta_k$  and for

observations on K variables where  $\Pr(Y_i = 1) = e^z / (1 + e^z)$

<sup>10</sup> The reduction in the number of observations under analysis is due to the unavailability of data for one or more of the independent variables for a particular student, e.g. we have no domicile data for 0.03% of the students, no religion data for 14% of the students and no socio-economic class data for 36% of the students.

move from the *residual category*<sup>11</sup> for that variable to the category in question.<sup>12</sup>

Table 18 shows that the probability of women surviving was *ceteris paribus* 3.7 percentage points higher than that for men (the residual gender category). *Compared to the probability of surviving an Accounting course* (the residual category of course type), the probability of:

- (1) Surviving an Art and Design course type was 10.8 points lower
- (2) Surviving a Business and Management course type was 11.5 points lower
- (3) Surviving an Engineering course type was 26.2 points lower
- (4) Surviving a Humanities course type was 16.7 points lower
- (5) Surviving a Computing and Information Technology course type was 22.4 points lower
- (6) Surviving a Science course type (excluding Nursing and (non-Nursing) Health-related) was 14.0 points lower
- (7) Surviving a Social Science course type (excluding Nursing, Social Work and (non-Nursing) Health-related) was 18.4 points lower

There was no significant difference between the survival rate for Accounting and for Nursing and for Social Work and (non-Nursing) Health-related courses.<sup>13</sup>

---

<sup>11</sup> The residual categories for the variables are defined in the notes to Table 18.

<sup>12</sup> The marginal probability is defined as  $\frac{\partial \Pr(Y_i = 1)}{\partial X_{ik}}$

<sup>13</sup> In this analysis, variables are said to be significant when they are statistically significant at the 10% level or higher, i.e. the z-value is greater than 1.645.

Table 18 also shows that *compared to coming from an unskilled or semi-skilled social background* (the residual social class category), the probability of survival was 4.1 points higher for students from a professional social class; however, there was no significant difference between the survival rates of students from unskilled and skilled backgrounds. *Compared to students from “other” religions*, Catholic students were less likely to survive the first year of study by 4.0 points though this difference was only significant at the 10% level; however, there was no significant difference between the survival rates of students from “other” religions and Protestant students. *Compared to students whose domicile was outside Northern Ireland* (the residual domicile category), students from Northern Ireland were less likely to survive by 8.4 points. Lastly, the probability of survival was not significantly affected by the quality of the student’s school leaving grades or by the fact that he/she had been made a “non-traditional” offer based on other than A-levels.

It is important to note that the difference in survival probabilities between Accounting and the other course types as reported in Table 18 (the marginal probabilities) are considerably different from the differences reported in Table 1. This is because, the latter differences are the raw differences, resulting not only from differences in course types but also from differences in all the other factors (sex, social class, religion etc.) between the course types. The marginal probabilities, as reported in Table 18, focus solely on differences between course types by controlling for differences in the other factors. For example, the survival rate for nursing was 90 percent compared to 88 percent for Accounting (Table 1). However, 96 percent of nursing

students were female compared to only 52 percent of Accounting students. After controlling for gender, nursing was estimated to have a lower survival probability (6.8 percent though, admittedly, not significant) than Accounting.

From the results reported in Table 18, one can identify the Northern Ireland domiciled “student type” with the highest and lowest survival rates. Female, Protestant students, from a professional background, taking Social Work and (non-nursing) health-related courses had a rate of 96.1 percent while male, Catholic students, from an unskilled/semi-skilled background, studying Engineering had a survival rate of 65.2 percent.

#### 4. Earlier non-econometric analysis of retention at the University of Ulster

A localised example of an application of the Tinto student integration model is in Lowe & Cook (2003) which details the results of two surveys of first year students at the University of Ulster in the academic year 2000/01 with the first survey being undertaken prior to university entry (to measure expectations) and one being undertaken three months later (to analyse how far expectations met with actuality). There were 691 students who responded to both surveys – predominantly from the business and management & health science disciplines (64% of the sample).

The first survey focused on how prepared students were for higher education and what their reasons were for coming to University with the questions on how prepared students were for their higher education experience prior to entry revealing that 17% of the students knew nothing about their 1<sup>st</sup> year modules, 18% knew nothing of how they would be assessed, 26% did not know if the course would involve a placement and 57% knew nothing of the number of hours of contact per week. The overwhelming reasons for coming to University were liking the idea of going to university (78% of the sample agreed or strongly agreed), university being 'better than the dole' (58% of the sample agreed or strongly agreed), meeting social norms (25% of the sample agreed or strongly) or parental pressure (22% of the sample agreed or strongly agreed).

The remainder of the survey dealt with issues such as why did the students come to the University of Ulster, what their opinions were of the campus environment, concerns and difficulties with the style of teaching and

personal & practical problems with University life. It is these latter two categories to which we will now turn.

The survey found that issues such as homesickness, a lack of personal support from family and a lack of confidence were more feared (in the first survey) than actually experienced (in the second survey) – despite this 47% of students were experiencing feelings of homesickness from missing friends whilst 35% were experiencing feelings of homesickness from missing family (there is no measurement of the severity of these feelings in the survey so we cannot distinguish between mild discomfort and severe discomfort).

The questions on study and personal skills revealed further divergence between the experience of student life expected by students and that actually experienced, particularly with regard to the different styles of teaching and learning, with students experiencing particular problems with note taking in lectures and even the size of classes themselves.

Overall, from our perspective, the main conclusion reached by the authors is that up to 20% of students in their first year at the University of Ulster may be failing to come to terms with the academic and social demands of life at University with a caveat being expressed that the nature of the survey was biased towards those who enrolled on time and who were still attending classes late in the autumn term so it is conceivable that this figure might be an underestimate as it excludes those students who have effectively left the course but have not officially indicated their decision to University authorities.

## 5. Conclusions

The important question under analysis here is how the probability of a first year student proceeding to the second year of his/her studies is influenced by his/her personal characteristics and circumstances. In order to answer this question a logit model was estimated with the dependent variable set equal to 1 if the student “survived” (i.e. proceeded to the next year) and 0 if he/she did not “survive”.

The key findings are

**Gender** - the probability of women surviving the first year was 3.7 percentage points higher than that for men (the residual gender category) *ceteris paribus*.

**Socio-economic class** - compared to those students coming from an unskilled or semi-skilled social background (the residual social class category), the probability of surviving the first year was 4.1 points higher for students from a professional social class; however, there was no significant difference between the survival rates of students from unskilled and skilled backgrounds.

**Religion** – compared to students from “other” religions, Catholic students were less likely to survive their first year by 4.0 points though this difference was only significant at the 10% level; however, there was no significant difference between the survival rates of students from “other” religions and Protestant students.

**Usual domicile** - Compared to students whose domicile was outside Northern Ireland (the residual domicile category), students from Northern Ireland were less likely to survive their first year by 8.4 points.

**Offer basis** - the probability of survival was not significantly affected by the quality of the student's school leaving grades or by the fact that he/she had been made a "non-traditional" offer based on other than A-levels.

**Course type** - Compared to the probability of surviving the first year of an Accounting course (the residual category of course type), the probability of:

- surviving an Art and Design course type was 10.8 points lower
- surviving a Business/Management course type was 11.5 points lower
- surviving an Engineering course type was 26.2 points lower
- surviving a Humanities course type was 16.7 points lower
- surviving a Computing and Information Technology course type was 22.4 points lower
- surviving a Science course type (excluding Nursing and (non-Nursing) Health-related) was 14.0 points lower
- surviving a Social Science course type (excluding Nursing, Social Work and (non-Nursing) Health-related) was 18.4 points lower
- surviving Nursing courses was not significantly different from the survival rate for Accounting courses.
- surviving Social Work courses was not significantly different from the survival rate for Accounting courses.
- surviving (non-Nursing) Health-related courses was not significantly different from the survival rate for Accounting courses.

From these results, one can identify the Northern Ireland domiciled “student type” with the highest and lowest survival rates. Female, Protestant students, from a professional background, taking Social Work and (non-nursing) health-related courses had a survival rate of 96.1 percent while male, Catholic students, from an unskilled/semi-skilled background, studying Engineering had a survival rate of 65.2%.

Table 14 - Attrition and Survival Rates By Sex After Year 1 of University

	Attrition survive	Survival	Total
Male	1,502	4,709	6,211
Percentage of students not-surviving/surviving	24.18	75.82	100
Percentage of students in total students	53.30	38.27	41.07
Female	1,316	7,596	8,912
Percentage of students not-surviving/surviving	14.77	85.23	100
Percentage of students in total students	46.70	61.73	58.93
Total	2,818	12,305	15,123
Percentage of students not-surviving/surviving	18.63	81.37	100
Percentage of students in total students	100	100	100

Table 15 - Attrition and Survival Rates By Social Class After Year 1 of University

	Attrition	Survival	Total
Professional	67	420	487
Percentage of students not-surviving/surviving	13.76	86.24	100
Percentage of students in total students	3.66	5.39	5.06
Intermediate	646	2,949	3,595
Percentage of students not-surviving/surviving	17.97	82.03	100
Percentage of students in total students	35.26	37.86	37.37
Skilled non-manual	347	1,577	1,924
Percentage of students not-surviving/surviving	18.04	81.96	100
Percentage of students in total students	18.94	20.25	20
Skilled manual	485	1,712	2,197
Percentage of students not-surviving/surviving	22.08	77.92	100
Percentage of students in total students	26.47	21.98	22.84
Partly skilled	205	858	1,063
Percentage of students not-surviving/surviving	19.29	80.71	100
Percentage of students in total students	11.19	11.02	11.05
Unskilled	82	273	355
Percentage of students not-surviving/surviving	23.1	76.9	100
Percentage of students in total students	4.48	3.5	3.69
Total	1,832	7,789	9,621
Percentage of students not-surviving/surviving	19.04	80.96	100
Percentage of students in total students	100	100	100

Table 16 - Attrition and Survival Rates By Religion After Year 1 of University

	Attrition	Survival	Total
Protestant	575	3,965	4,540
Percentage of students not-surviving/surviving	12.67	87.33	100
Percentage of students in total students	26.92	36.48	34.91
Catholic	1,495	6,349	7,844
Percentage of students not-surviving/surviving	19.06	80.94	100
Percentage of students in total students	69.99	58.41	60.31
Other Religions	66	556	622
Percentage of students not-surviving/surviving	10.61	89.39	100
Percentage of students in total students	3.09	5.11	4.78
Total	2,136	10,870	13,006
Percentage of students not-surviving/surviving	16.42	83.58	100
Percentage of students in total students	100	100	100

Table 17 - Attrition and Survival Rates By Domicile After Year 1 of University

Area	Region	Attrition (%)	Survival (%)	Total	As of Total
<b>Northern Ireland</b>	<i>Northern Ireland in total</i>	20.3	79.7	13,205	87.34
	Antrim	15.2	84.8	3,668	24.26

Constant	3.387*** (9.52)	-
Observations	8631	8631

Notes:

Residual category for Sex is Male

Residual category for *Course Type* is Accounting

Residual category for *Social Class* is "Semi/Unskilled"

Residual category for *Religion* is "Other"

Residual category for *Domicile* is "Outside Northern Ireland"

Good School Leaving Grades: student entered with more than 360 UCAS points

Absolute value of z statistics in parentheses

\* significant at 10%; \*\* significant at 5%; \*\*\* significant at 1%
