VERTICAL FLUX, ECOLOGY AND DISSOLUTION OF RADIOLARIA IN

TROPICAL OCEANS: IMPLICATIONS FOR THE SILICA CYCLE

KOZO TAKAHASHI

Submitted to the Woods Hole Oceanographic Institution-Massachusetts Institute of Technology Joint Program in Oceanography on October 30, 1981, in partial fulfillment of the requirements for the degree of Doctor of Philosophy.

ABSTRACT

Radiolarians which settle through the oceanic water column were recovered from three stations (western Tropical Atlantic-Station E, central Tropical Pacific-P₁ and Panama Basin-PB) using PARFLUX sediment traps in moored arrays at several depths. The taxonomic diversities of the radiolarian assemblages in the sediment traps were very high. A total of 420 taxa, including 23 newly identified taxa, were found at the three stations; of these, 208 taxa were found at station E. The polycystine radiolarians generally reach the sea floor with little change in abundance or species composition, although slight skeletal dissolution occurs throughout their descent. The phaeodarian radiolarians, on the other hand, are largely dissolved within the water column; only a few species reach the sea-floor and these dissolve rapidly at the sediment-water interface. Most radiolarian skeletons sink as individuals through deep water columns without being incorporated into large biogenic aggregates. Because significant numbers of nassellarian and phaeodarian species are deep-water dwelling forms the diversity index of radiolarians increases with increasing depth in the mesopelagic zone.

The vertical flux of the total radiolarians arriving at the trap depths (in $\times 10^3$ individuals/m²/day) ranged from 16-24 (E), 0.6-17 (P₁), and 29-53 (PB). Of these on the average 25 % and 69 % of the total radiolarian flux is transported by Spumellaria and Nassellaria, respectively, while 5 % is carried by Phaeodaria. The measured SiO₂ content of the skeletons averaged 91, 98 and 71 % of measured weight for Spumellaria, Nassellaria and Phaeodaria, respectively. The supply of

radiolarian silica ($\text{mg SiO}_2/\text{m}^2/\text{day}$) to each trap depth ranged from 2.5-4.0 (E), 0.9-3.2 (P_1), and 5.7-10.4 (PB). The Radiolaria appear to be a significantly large portion of the SiO_2 flux in $>63 \mu\text{m}$ size fraction and thus play an important role in the silica cycle. When the radiolarian fluxes at the three Stations are compared with Holocene radiolarian accumulation rates in the same areas it became apparent that several percent or less of the fluxes are preserved in the sediments in all cases and the rest is dissolved on the sea-floor. Estimated excess Si which is derived from SiO_2 dissolution on the sea-floor is fairly small relative to advective Si in the western North Atlantic and thus it appears to be insignificant to show any deviation in a simple mixing curve of deep water masses.

Weight, length, width, projected area and volume of 58 radiolarian taxa were measured. The density contrast of radiolarians, relative to seawater, generally falls between 0.01 and 0.5 g/cm^3 . The sinking speed of 55 radiolarian taxa, measured in the laboratory at 3°C , ranged from 13 to 416 m/day. Despite the wide variety of morphology between the species, sinking speeds were best correlated with weight/shell among all the possible combinations of the examined variables. The estimated residence times of these taxa in the 5 km pelagic water column ranged from 2 weeks to 14 months. Large phaeodarians reached the water-sediment interface relatively quickly and ultimately dissolved on the sea floor. Small-sized taxa dissolved en route during sinking.

The standing stock of 26 examined abundant taxa is on the order of 1 to 100 shells/m^3 . Total radiolarian standing stock ranges from about 450 shells/m^3 at Stations P_1 and E to 1200 shells/m^3 at Station PB. The rate of production of total Radiolaria is calculated to be 77 to $225 \text{ shells/m}^3/\text{day}$. The turnover time for these species ranges from several days to one month depending on the species and the assumption of the depth interval used for the estimation.

Thesis supervisor: Dr. Susumu Honjo

Title: Associate Scientist

This thesis is dedicated to my parents,
Yoshitaka and Mitsuko Takahashi
and to my wife, Kayoko Takahashi

ACKNOWLEDGMENTS

I thank Dr. Susumu Honjo, my thesis advisor, the most for his enthusiastic encouragement and guidance throughout the years. Countless opportunities for discussions with him on oceanography fascinated me and, indeed, sustained my motivation in completing this program. Without the cooperation of the PARFLUX Program supported by the National Science Foundation (Principal Investigators: Drs. S. Honjo, P.G. Brewer, and D.W. Spencer) this study would not have been accomplished. I also thank Dr. John D. Milliman who served as my academic advisor and guided me to the initiation of the silica cycle study. Professor Hsin Yi Ling of the Northern Illinois University initially inspired me on the biogenic-particle transport study and generously aided me in many aspects throughout. Professor Edward A. Boyle of M.I.T. has been helpful in solving problems, especially in geochemical areas, and I appreciate it very much. Dr. David A. Johnson has been generous with his literature including microfiche on radiolarian papers; his critical and constructive reviews and comments on the scientific results were most gratefully received. Drs. Brian E. Tucholke and L. Valentine Worthington gave invaluable tutorial sessions which helped me digest geophysics and physical oceanography.

My thesis advisory committee members include Drs. S. Honjo, J.D. Milliman, H.Y. Ling, E.A. Boyle. Dr. D.A. Johnson is the chairman of the final examination. My academic advisory committee consists of Drs. J.D. Milliman, S. Honjo, E.A. Boyle, V. Worthington and B.E. Tucholke.

I am very appreciative of the help of the members of the W.H.O.I. Education Office, Dr. C. Hollister, Mr. A.L. Peirson, Mrs. Constance Brackett, Abbie Alvin and Dixie Berthel, for their kind cooperation during my tenure as a Joint Program student.

Dr. Catherine Nigrini critically reviewed the systematics portion of the thesis as an outside referee which was extremely valuable. Dr. William R. Riedel of Scripps Institution of Oceanography kindly reviewed a paper on the Atlantic radiolarian flux which was incorporated in the thesis. Dr. Wiley Poag of the U.S. Geological Survey at Woods Hole has been a good teacher of the classics needed for completing the taxonomy for this investigation. Dr. David C. Hurd has collaborated with me in radiolarian dissolution/preservation problems. I have greatly benefited from many discussions with him. Dr. Neil Swanberg of Lamont-Doherty Geological Observatory provided useful comments in the colonial radiolarian study.

Vernon Asper frequently aided in preparing SEM samples and instructed me in SEM operation as well as providing frequent discussions on many aspects of this work. Steve Manganini has always been helpful in the laboratory and at sea. Mrs. Margaret Goreau spent much effort in helping in the laboratory in SEM work and diatom culture. I thank Steve Nolan

for his skillful computer work using the SPSS Program which produced most of the figures in this thesis. Steve Swift has been helpful as a consultant in much of the fluid dynamic aspect of this work. Dr. Bruce H. Corliss and Ken Miller have been cooperative in solving problems with taxonomic nomenclature. Drs. June Harrigan and Izja Lederhandler of the Laboratory of Biophysics, the National Institute of Health located at the Marine Biological Laboratory, Woods Hole, kindly provided a photo-optical digitizer for radiolarian dimension measurements. Alan Fleer and Cindy Pilskaln provided aid at sea. I have also benefited from discussions with Drs. K.O. Emery, J. Cole, J. Erez, R. Keir, G.P. Lohmann, W. Curry, C.C. Woo, F. Manheim, R. Guillard, T. Goreau, A. Shor, and those who I have forgotten to specifically mention.

My great appreciation goes to Mrs. Sandra Pelletier who has typed the thesis and many other papers whose conclusions are incorporated in this thesis. Her skillful coordination in organizing all of the complex tables in this thesis is gratefully acknowledged. Mrs. Emily Evans also gave me much secretarial aid. Kayoko Takahashi aided in photographic work for plates as well as much proof reading of the manuscript. Messers. Don Souza, Frank Medeiros, and many others in Graphic Services did an excellent job in producing figures and slides, sometimes in quite a rush. I also thank the members of AII Cruise 108, Leg 2 to the Panama Basin for sediment trap recovery and other field observations for their cooperation.

Finally, I sincerely thank my wife, Kayoko Takahashi, for her endurance of many years and moral support. My children, Alexander and Eileen, always gave me a cheerful time and made easier the completion of the thesis work.

This thesis work has been supported by the National Science Foundation, Submarine Geology and Geophysics Program, Grant OCE80-19386 and the Woods Hole Oceanographic Institution Education Office.

CHAPTER 1

VERTICAL FLUX, ECOLOGY, RESIDENCE TIME AND DISSOLUTION OF
RADIOLARIA: IMPLICATIONS FOR THE SILICA CYCLE

INTRODUCTION

Biogenic opal is one of the major sedimentary components in the oceans. It is particularly abundant in pelagic realms where little is influenced by land derived minerals. Constituents of biogenic opal are skeletons of radiolarians, diatoms, silicoflagellates, sponge spicules, ebridians, and dinoflagellate endoskeletons. The biomass of the first four groups of particles are more abundant in pelagic oceans than the others.

Silica budget in the ocean with respect to river input, continental weathering, diffusion from the bottom sediments and hydrothermal input has been approximately estimated and the major role of biogenic opal in the oceanic silica budget has become known in recent years (Schutz and Turekian, 1965; McKenzie and Garrels, 1966; Calvert, 1968, 1974; Lisitzin, 1972; Burton and Liss, 1973; Hurd, 1973; Edmond, 1973; Edmond et al., 1979; Heath, 1974; Kharkar et al., 1969; DeMaster, 1979).

It is generally known that biogenic opal remains contribute substantially to the three major latitudinal belts of siliceous sediments in the world oceans. According to Lisitzin (1972), radiolarians account for 62 and 99 weight % of the biogenic opal suspension in the tropical Pacific. Hence they are the major sedimentary components of biogenic opal in such regions. On the other hand, diatoms account for 99.8% in the Antarctic seas.

Since preservation of biogenic opal in the bottom sediments is principally a reflection of the rate of organic production in the overlying waters (Riedel, 1959; Heath, 1969), biogenic opal may retain more oceanic environmental records than other sedimentary counterparts such as carbonate. However, the processes of biogenic opal sedimentation

are poorly known. Berger's (1970) basin-basin fractionation model predicts that the Atlantic Ocean, in general, is the least favorable of the three major oceans for preservation of biogenic opal. Indeed, radiolarians in the surface sediments in the Atlantic (Goll and Bjørklund, 1971, 1974) occur generally in smaller numbers per unit weight of sediment than in the Pacific (Lisitzin, 1972). The description of radiolarian remains subsequent to their production and pre-burial is an important approach to understanding the geological and geochemical processes of oceanic opal. Previously, Heath (1974) pointed out that ecological studies of radiolarians bear a key to understanding the silica cycle in the oceans.

Geochemical studies, mainly based on dissolved silicon-alkalinity correlation, indicate that most of the dissolution of biogenic opal occurred on the sea-floor rather than in the water column (Edmond, 1974). Heath (1974) suggested that the major non-oxidative dissolution of biogenic opal occurred on the sea-floor, rather than in the water column. Lisitzin (1972) suggested that the dissolution of radiolarians and silicoflagellates occurred on the sea-floor, whereas most of the diatoms were destroyed in the water column. Previously, Kozlova (1964) studied distribution of diatom frustules throughout the water column and in the sediments of the Antarctic region and showed that only a few diatoms reach the benthic layers. Kanaya and Koizumi (1966) showed that diatom assemblages in the surface sediments in their North Pacific stations reflected the planktonic assemblages in the overlying surface layer. Skeletons of silicoflagellates have been regarded as less important than radiolarians and diatoms in terms of quantitative siliceous sedimentation (Lisitzin, 1972). Silicoflagellates are considered to be more susceptible to dissolution among other opaline particles (Schrader, 1972). Those previous discussions were based on the distribution of suspended biogenic opal particles utilizing an instantaneous standing crop. Those views can be further examined by studying the flux of settling particles which are collected by sediment traps.

Sedimentation of material by large size particles such as fecal pellets has been recently realized (Schrader, 1971; McCave, 1975; Honjo, 1975, 1976, 1978, 1980; Wiebe et al., 1976). Particles larger than 20 μm are rare (e.g. Carder et al., 1971; Sheldon et al., 1967) and they have a statistically low probability of being caught in standard-size water samplers. Even when large particles are caught, they may be extracted due to the design of water samplers and methods of filtration (Gardner, 1977a). This is particularly true for radiolarian shells which are relatively large.

It has been documented that sediment trapping is an efficient method for collecting vertically settling large particles and to approximately determine material fluxes of large particles (e.g. Wiebe et al., 1976; Gardner, 1977b; Soutar et al., 1977; Spencer et al., 1978; Honjo, 1978, 1980; Honjo et al., in press; Brewer et al., 1980; Knauer et al., 1979; Cobler and Dymond, 1980; Sediment Trap Intercomparison Experiment, 1980). The majority of biogenic opal particles, such as radiolarians, diatoms and silicoflagellates, are usually larger than 30-40 μm size; hence they are considered to be large particles or "settling particles" (Honjo, 1980).

Biogenic opal production has been crudely estimated (Lisitzin, 1972; Heath, 1974; Thomas and Dodson, 1974) by a conversion from organic carbon to silica which is based upon an assumption of silica/carbon conversion factor 2.3 (Lisitzin et al., 1967). However, the factor actually varies as large as two to three orders of magnitude depending on the latitude (Lisitzin et al., 1967). An alternative method is a stable isotope tracer method (Nelson and Goering, 1977) but this method has been applied only to primary producers (mainly diatoms) thus far. Vertical flux measurements will furnish important information for production, especially for dissolution resistant taxa. Since radiolarians are, as stated earlier, the most important taxa in biogenic opal production in the tropical oceans (Lisitzin, 1972), radiolarian flux information is most desired for understanding the biogenic opal production for the areas.

Detailed studies on radiolarian population in pelagic environments have been made by many investigators since the classical work by Haeckel

(1887) in the 19th century (e.g. Casey, 1971a, 1971b; Casey et al., 1971, 1979a, 1979b; Petrushevskaya, 1971a, 1971b; Bjørklund, 1974; Kling, 1976, 1979; Renz, 1976; McMillen and Casey, 1978; Leavesley et al., 1978; Boltovskoy and Riedel, 1980; Takahashi and Honjo, 1980, 1981a-c; Takahashi et al., 1981a,b). Renz (1976) compared the living radiolarian community (using plankton pumps and net tow samples) and its counterpart in core tops from the central Tropical Pacific. She reported an elimination of many radiolarian species during their transfer from the living layer to the underlying sediment layer. Petrushevskaya (1971a) did not find that many discrepancies between the two assemblages. However, net towed, cast or pumped samples applied in previous research may involve time and/or space limitations and may not represent realistic biocoenosis.

In this thesis the vertical fluxes of Radiolaria at 4-5 depths from three tropical PARFLUX sediment trap stations (Fig. 1) are quantitatively documented together with a qualitative notion from a temperate station, Sargasso Sea. The flux data are combined with other relevant measurements which are described in detail in the text in order to facilitate pertinent information on the silica cycle.

SOURCE OF SAMPLES; METHOD OF ANALYSIS

The samples used in this study were collected from sediment traps placed at four PARFLUX stations (Fig. 1): Western Tropical Atlantic - Station E, 13°30.2'N, 54°1'W, corrected water depth: 5,288 m; central Tropical Pacific - P₁: 15°21.1'N, 151°28.5'W, 5792 m; Panama Basin - PB: 5°21'N, 81°53'W, 3856 m; Sargasso Sea - S, 31°32.5'N, 55°55.4'W, 5581 m. These sediment traps were deployed for 98 days (E: 11/1977-2/1978), 61 days (P₁: 7-11/1978), 112 days (PB: 8-12/1979) and 110 days (S: 10/1976-1/1977) (Honjo, 1978, 1980; Honjo et al., 1980). Station E is located about 750 km from the Guyana Coast in a region where there is very little seasonal variation in zooplankton productivity (e.g. Moore and Sander, 1977). The underlying Demerara Abyssal Plain has a gentle topography and is covered with silty clay.

* Studied only for Phaeodaria

The North Equatorial Current flows in a northwesterly direction, but no deep current measurements have been reported in the study area. Station P₁ is located in the East Hawaii Abyssal Plain which is one of the largest basins in the North Pacific. The bottom sediment is consolidated clay with alternating thin ferro-manganese laminations (Honjo, 1980). Station PB is characterized by high productivity and is relatively close to land (250 km from the nearest shoreline). The Panama Basin has been defined by Heath et al. (1974) as a "mini ocean". Hydrography, geology, biology and physical oceanography are quite well known in this area (e.g. Stevenson, 1970; van Andel, 1973; Kowsman, 1973; Moore et al., 1973; Plank et al., 1973; Heath et al., 1974; Lonsdale, 1975, 1977; Swift, 1977; Swift and Wenkam, 1978).

The sediment trap array deployed at the above stations consisted of four or five traps, PARFLUX Mark II, with 1.5 m² opening (Honjo et al., 1980) and they were moored at several depths (Table 1). The receiving cup was sealed by a time-controlled spring shutter prior to recovery.

The samples were wet sieved upon arrival in the laboratory with a 1 mm mesh screen and split into four aliquots by an Erez-Honjo precision rotary liquid splitter (Honjo, 1978). An aliquot of material finer than 1 mm was further split into several aliquots (Table 1). The resulting aliquot of the original sample was wet sieved through 250, 125 and 63 µm screens. When necessary the samples were split further into smaller aliquots prior to filtration (Table 1). Samples of less than 63 µm size fraction from Station E are separately prepared by diluting a 1/64 aliquot to 250 ml in a measuring flask using filtered seawater from the deep Sargasso Sea water, and then 2 ml aliquot was taken by using a pipet.

The above aliquots were filtered through a 47 mm HA Millipore[®] grid filter with a nominal 0.45 µm pore size using a rectangular filtration funnel with 19 x 42 mm opening. The residue was rinsed with distilled water, then dried at 50°C in an oven. Large foraminiferal specimens in 1,000-250 µm and 250-125 µm size fractions were removed under a dissecting microscope. The dried filter sample was mounted on a standard glass slide after trimming off the excess margins. Drops of Cargile[®] type B compound was applied to clear the sample filter. It

took a few days for the bubbles to escape from all radiolarian shells prior to placing a cover glass over the sample area. No vacuum was applied during the preparation. Aliquot size and number of slides from the three stations which were used in this paper are summarized in Table 1.

The slides were studied to identify radiolarian taxa and to count individuals to the species level, under a transmission light microscope. Two or more of slides shown in Table 1 were used for the species identification (Pls. 1-63). The counts were converted to the flux term; number of individual shells/m²/day.

An abundant, medium sized radiolarian genus, Pterocorys (P. campanula Haeckel: Plate 42, fig. 5-8; and P. zancleus (Müller): Plate 42, figs. 1-4) was chosen in order to assess the range of errors induced during sample preparation, and the reproducibility of shell counting. The assessment was made by counting Pterocorys shells in a given slide. This taxon occurs mostly in 250-125 μm and 125-63 μm size fractions. The counting reproducibility by duplicate countings of an identical slide proved to be more than 90%. Statistical variability among four slides prepared from the coarse and medium size fractions is due to errors involving slide preparation including wet sieving and splitting. The standard deviation ranged from 0.14 to 0.26 at 95% confidence interval. The radiolarian species count applied in this dissertation is reproducible to better than 74%.

To prepare enough handpicked specimens for dimension, sinking speed, electron microscopy and SiO₂ content analyses, aliquots of 1/64 or 1/256 of wet samples from the sediment trap are sieved and desalted by the same method as above. Purple grid 47 mm HA millipore[®] filters with 0.45 μm pore size, are used to retain radiolarian samples. After drying, as many specimens of radiolarian taxa as possible are handpicked using an ultrafine Japanese calligraphy brush.

Reflected light micrographs are taken at x20 and x40 magnification of a dissecting microscope for each taxa. The micrographs are converted to positive slides and projected onto an image digitizer (LW International) for measurements of length, width and maximum projected area. The

obtained data are processed by a computer applying the SPSS Program.

After the photography, specimens were dried in high vacuum at 150°C for 2 days, then cooled in a desiccator for 10 minutes and quickly weighted. A Cahn 25 Automatic Electrobalance[®] was used in a room with humidity of less than 40 %. The number of specimens needed for this varies depending on weight/shell of different taxa which is presented in Table 9.

A portion of the picked specimens were mounted on an Aluminum stub with double-sided adhesive tape and coated with carbon and then Pd-Au for scanning electron microscopy (SEM). Samples for transmission electron microscopy were prepared by the method described by Asper (1981).

Silica content of the radiolarian skeletons was measured by Na₂CO₃ fusion method (Kido and Nishimura, 1975) modified by Asper (1981). Several to several tens or more of the radiolarian specimens (see Table 11) were weighed and placed in clean platinum crucibles and excess anhydrous Na₂CO₃ (ca. 15 mg) was added. The crucible was heated over a burner for 15 minutes to fuse the radiolarian silica in the molten Na₂CO₃. After cooling, the pellet of fused Na₂CO₃ sample was dissolved in distilled water in 10 ml volumetric flask. Then the standard silicomolybdate colorimetric method (Strickland and Parsons, 1972) was followed. The experimental errors were less than 8%.

To eliminate entrapped air within the shell structure during sinking speed measurement, the dry specimens are placed in 1 cm diameter with 2.5 cm height plastic vials. Methanol is added and the specimens are kept in a low vacuum for an overnight. About 20% of the methanol is replaced with an equivalent volume of filtered water by using a micropipet. After several hours the same procedure was repeated for a total of ten times; each time there was a gradual increase of the replacement volume of filtered water to completely replace the methanol. Then, Sargasso Sea water is used as a replacement by the same procedure. By the end of this process generally 80% or more of the specimens are maintained in the vial.

As illustrated in Figure 2, the system for the sinking speed experiment consisted of: (a) a narrow-neck graduated cylinder for the sinking column, 2.5 cm diameter, 16 cm high, Pyrex; (b) a temperature

Figure 2. A. Illustration of a system for the sinking speed experiment. B. An enlarged view of the sinking column. a. narrow-neck cylinder, b. temperature bath cylinder, c. thermostat, d. fiberglass optics, e. thermal filters f. dissecting microscope.

bath cylinder, 87 mm outer diameter with 6 mm-thick plexiglass (plastic), 18 cm high, closed by a lid with an O-ring and connected to a thermostat with plastic hoses; (c) a thermostat which controls the temperature up to $\pm 0.5^{\circ}\text{C}$; (d) a mobile illumination device of fiberglass optics; (e) thermal filters; (f) a dissecting microscope; and (g) a sheet of black background paper. The experiment was conducted in a dark room with the illumination device in order to enhance visibility with Tindal effect. The sinking column system was designed to become a lens (Figure 2B) so that a sinking specimen can be readily located without using a microscope. Since the plexiglass has poor thermal conductivity the plastic surface did not have water molecule condensation at 3°C under normal laboratory temperature and humidity. Temperature of the inner seawater column equilibrated with the circulating water in the outer column within an hour. The seawater column was examined for stability by using a dye and a satisfactory result for the sinking speed experiment was obtained.

A wet specimen, retained in a water drop, is individually picked using a brush, then placed just below the surface of the still seawater column. The temperature of the specimen generally equilibrates with the surrounding water within a few seconds according to heat flux calculations. The specimen usually reaches a steady settling rate well above a start-line of the measurement. The start-line is located 51 mm below the surface and a finish-line is located 23 mm from the bottom. The measured sinking time for an 83 mm interval is converted to m/day. Generally the particles sink through the center of the column but occasionally their pathways go off the centerline and drag the side wall in which case the data are discarded.

RESULTS AND DISCUSSION

Counts of radiolarian taxa

The majority of radiolarian specimens found in the slide samples were identified to the species level (Table 2, pls. 1-63). A total of 420

Table 2. The radiolarian (species) flux (no. of shells/m²/day) at three sediment trap stations. Data reported here include all size fractions from 63 um to 1mm-250 um.

* These two or three taxa are counted together

** Incomplete fragments are counted

*** Spicule swarms are counted

+ Each value is counted as a half (0.5) shell

++ Each tubule is counted

Table 3. The size fractioned radiolarian flux (no. of shells/m²/day), in each family from Station E. The proportion of counted specimens (%) with respect to the radiolarian flux (shells/m²/day) is given in the bottom row.

% = (suborder flux/total radiolarian flux) x 100

N/S ratio = nassellarian flux/spumellarian flux

Ph/s ratio = phaeodarian flux/spumellarian flux

Ph/p ratio = phaeodarian flux/polycystine flux

Figure 3. Vertical fluxes (no. of shells/m²/day) of Radiolaria and their suborders from Stations E, P₁ and PB. Horizontal bars on Station E radiolarian flux show representative standard deviation at 95% confidence level for all the data.

Figure 4. Vertical fluxes (no. of shells/m²/day) of Radiolaria and their suborders from Station E. Horizontal bars represent standard deviation at 95% confidence level.

taxa, including one new genus, 20 new species, one new subspecies, one new name for a species and 3 new names for subspecies, were recognized from the three stations; of these 208 taxa were found at Station E. According to Casey (1981, pers. comm.), based on all the published literature the best inference on total number of living Radiolaria species in the world ocean is about 600. It seems possible that this report covers majority of tropical species. The 420 taxa are comprized of three suborders: Spumellaria (175 taxa); Nasselaria (182); and Phaeodaria (63). The number of taxa contained in the counting slides (Tables 1,2) appeared to be less than that in slides used for species identification. This is because that I used only one or two slides for counting and one to four slides in each size fraction for species identification. When necessary several species were combined together as one group in counting (Table 2). Radiolarian spicules were not counted.

The radiolarian flux from the three stations is normalized to the number of individual shells/m²/day for each taxon (Table 2). The size fractioned fluxes of radiolarian families are presented in Tables 3 and 4. Percentages of actual specimens counted in each slide are also given in Tables 3 and 4. The fluxes of suborders are summarized in Table 5 and illustrated in Figs. 3 and 4.

Diversity Index Analysis

The diversity index used in this analysis is that of Pielou (1969), and is computed by the following equation:

$$H' \text{ (natural bels)} = - \sum_{i=1}^n P_i \ln P_i$$

where P_i is the proportion of the i th species of the total population being dealt with, n is the number of species, and H' is the diversity in natural bels, i.e., natural logarithms to the base 10. This index is highest with many species, each of which constitutes an equal part of the total population, and lowest when there are few species, or where one species predominates.

Diversity indices were computed for each suborder as well as total Radiolaria at each trap depth from Station E. The results are presented in Table 6 and Fig. 5. The computed diversity indices of total Radiolaria ranged from 3.3 to 3.6 (nat. bel. unit). These values are probably the highest values ever reported in the water column. This is mainly due to the difference in sampling and analytical methods: the present sediment traps collected all size particles as well as rapidly settling particles in the water column, whereas most of the previous works (Casey et al., 1971, 1979a,b; Petrushevskaya, 1971a,b; Kling, 1976; McMillen and Casey, 1978; Boltovskoy and Riedel, 1980) involved plankton tows and/or water bottles which are selective for certain size range. Renz (1976) was able to collect 137 species of Radiolaria in the Central Tropical Pacific by the using a pumping system with a 35 μ m mesh as well as plankton nets. McMillen and Casey (1978) reported living polycystine diversity indices of up to 1.2 from the surface to 2,000 m depth in the Gulf of Mexico and Caribbean Sea. Their sampling method involved a use of a Nansen closing net with a 76 μ m mesh size. Differences in the degree of taxonomic "splitting" by the various authors are probably responsible for part of the differences in reported diversities.

The diversity indices of Spumellaria and Nassellaria at 988 m and below show (Fig. 5) approximately uniform values with depth, indicating that species diversity of the suborders did not change significantly during their descent from 988 to 5068 m. A relatively low value of nassellarian diversity index at 389 m reflects to the total radiolarian diversity index at that depth. This is because the Nassellaria had a greater flux than the rest of the suborders. One possible explanation of the increase in nassellarian diversity index from 389 to 988 m is the introduction of tropical submergent species proposed by Casey and his associates (Casey, 1971a,b; Casey and McMillen, 1977; Casey et al, 1979a) and introduction of deep water species (Reshetnjak, 1955; Casey et al., 1979a). For example, many species in the families Plagiacanthidae and Theoperidae increased their fluxes between 389 and 988 m trap depth at Station E as shown in Tables 3,4. The representative species that agreed with the scheme of deep water species (Casey et al., 1979a) are:

Figure 5. Diversity index (H'), natural bels, of Radiolaria and their suborders from E Station.

Cyrtopera languncula Haeckel; Peripyramis circumtexta Haeckel; Litharachnium tentorium Haeckel; and Cornutella profunda Ehrenberg. An alternative explanation of the increase in nassellarian diversity index is dissolution of some nassellarian shells in the sediment trap receiving cup at 389 m, although I do not believe this is extensive as it will be shown in later sections. The diversity index of Spumellaria decreased slightly from 389 to 988 m.

Phaeodaria presented the lowest indices among the three suborders. They were more variable in the bathypelagic zone. Dissolution of shallow water forms and introduction of deep-water species (Reshetnjak, 1955) result in appearances and disappearance at each trap depth (Table 2, also see Fig. 11). Typical deep-water species are Euphysetta elegans Borgert, Lirella melo (Cleve), and L. bullata (Stadum and Ling) (see Fig. 11). Previously Borgert (1906, p. 174-175) reported occurrence of E. elegans between 1,000 and 5,000 m. Haecker (1908b, p. 557) reported L. melo from 1,500-5,000 m.

Percent Similarity Analysis

The percent similarity index S (Whittaker and Fairbanks, 1958) has been applied to measure differences in the relative proportion of species in pairs of sediment trap samples at different depths from Station E. Application of this index was analogous to the community comparison reported previously (e.g. Honjo and Okada, 1974). The index is computed by the use of the following equation:

$$S = 100 \times \left(1.0 - 0.5 \sum_{i=1}^n \left| P_{ij} - P_{ik} \right| \right)$$

where P_{ij} and P_{ik} are the proportion of the i th species in the j th and k th sample depths, and n is the number of species.

As shown in Table 7, the percent similarity indices of Spumellaria from Station E were less variable than other suborders and ranged from 73 to 79. They were within similar values between all the probable pairs of depths. This indicates that composition and population between all

possible pairs of depths involving Spumellaria were similar suggesting similar extent of dissolution and population addition effect throughout the depths.

The similarity indices computed for Nassellaria between 389 m and the rest of the depths (70-75%) differs significantly from those of between the rest (81-86%) (Table 7). This is due to an introduction of some deep water species between 389 and 988 m, as discussed earlier. Below 988 m the similarity indices between pairs of depths stayed similarly high, suggesting little change in nassellarian flux.

Phaeodaria presented a markedly decreasing trend in the similarity indices between 389 m and the progressively greater depths (50 to 28%, Table 7). This was attributed to the additions of deep water species as mentioned in the previous section and to dissolution of specimens probably during their descent. The index between 3,755 and 5,068 m showed about 78%; this was comparable to those of polycystines. Production of deep-dwelling phaeodarians may be accounted for this since the flux includes both effects of dissolution and addition of a population between the depths. Microstructure of phaeodarian shells, which have more porous shells than those of other suborders, contributes to the high rate of dissolution/destruction (Erez et al., in press; Hurd and Takahashi, in press). As stated earlier, since some phaeodarians were already lost in the mesopelagic and upper bathypelagic zones during their descent (Table 2), this is accounted for a continuous addition of the population in the bathypelagic zone which replaces the similar species composition and abundance at 5,068 m.

Vertical flux of Radiolaria and suborders at three tropical stations

Fluxes of three suborders as well as total Radiolaria were more or less uniform throughout the trap depths at the three stations (Table 5, Figs. 3,4), although there are some fluctuations with depth. The fluxes at 3,755 m from Station E were greater than the other depth. This flux maximum at 3,755 m was also true for biogenic opal (Honjo, 1980) and planktonic foraminifera (Thunell and Honjo, 1981) from the same trap

samples. The fluxes at 378 and 978 m from Station P₁ were anomalously less than those at deeper depths. This is probably due to exportation of the trapped samples by macro- and megaplankton such as Euphausiids (Honjo, 1980). The fluxes from Station PB appear to fluctuate with depth. Biogenic opal flux from the same samples show a similar trend to this (Honjo et al., in press). Horizontal transport of particles may be responsible for this.

Radiolarian shell flux as a whole showed no decreasing trend throughout the water column at all the three stations (Tables 2,3,4,5; Figs. 3,4). However a significant increase of shell fragmentation with increasing depth was noted; for instance percentage of broken shells to total Pterocorys (P. campanula Haeckel and P. zancleus (Müller)) shells was 12, 10, 20 and 36% at 389, 988, 3,755, and 5,068 m trap depths, respectively, from Station E (Table 8, Fig. 6) (a broken but more than a half preserved shell was counted as one broken shell). The number of shells counted at each depth ranged from 289 to 540. Although less significant than the above, a similar trend in shell fragmentation with depth was observed in Spumellaria, Nassellaria, Phaeodaria, as well as total Radiolaria (Fig. 6). The continuous increase in shell fragmentation with depth suggested that dissolution already initiates during their descent through the water column. Percentages of broken shells at 389 m were slightly higher than at 988 m for all of the taxa shown in Fig. 6 except for Phaeodaria. Field studies (Berger, 1968; Erez et al., in press) and in the laboratory observations (Hurd, 1972, 1973; Hurd and Takahashi, in press) demonstrated much higher dissolution rates of biogenic opal above about 400 m than below in the tropical Pacific. It is possible that some of the trapped radiolarian shells were dissolved within sediment trap receiving cups prior to retrieval. Thus, the higher percentage of broken shells at 389 m than at 988 m could be attributed to trap in situ dissolution rather than during their descent in the water column.

Generally the above trend of breakage increase with depth is also true in Phaeodaria. Although there is an opposite trend to this between 389 and 988 m (Fig. 6), this can be explained as follows. Similarity

Table 8. Percentages of broken shells and shells in biogenic aggregates in total counts of a given taxon of Radiolaria from Station E.

Figure 6. Percentages of broken shells in radiolarian taxa from Station E.

index of Phaeodaria between 988 and 3,755 m was 60 % which is the lowest among all the suborders. An apparent decrease of the percent shell breakage from 988 m to 3,755 m does not necessarily mean a true decrease of dissolution effect since species compositions are somewhat different between these two depths shown by the index. Lower values of the percentages of broken shells at 3,755 and 5,068 m than at 988 m were due to introduction of deep water species (Reshetnjak, 1955) which can supply unbroken shells (Table 2). Challengeron willemoesii Haeckel, Protocystis xiphodon (Haeckel), Euphysetta pusilla Cleve, and Conchidium caudatum (Haeckel) appeared to decrease their fluxes significantly as they descend, suggesting their rapid dissolution (see Fig. 11). Phaeodarian dissolution during their descent appeared to be greater than the trap in situ dissolution effect.

Only a few percent of radiolarian shells might be descending more rapidly than the rest of individual shells to the sea-floor. This is substantiated by the following observation where the following types of radiolarian shells were counted in biogenic aggregates: (1) a shell that was incorporated in a biogenically aggregated material (Takahashi and Honjo, 1981; Plate 15, figures 8-11); and (2) an individual shell that was fully or partially wrapped by organic substance which most probably disintegrated from the biogenic aggregates. The examination on Pterocorys (P. campanula Haeckel and P. zancleus (Müller)) showed that the percentages of shells in biogenic aggregates were 13, 4, 2 and 1 % at 389, 988, 3,755, and 5,068 m from Station E respectively (Table 8, Fig. 7). Since the organic components of the samples were preserved in situ in the receiving cups by continuous diffusion of sodium azide (Honjo, 1980) decomposition of the biogenic aggregates was regarded minimal. Total counts used were the same as in the broken shell percentages discussed above. The decrease of the shells in biogenic aggregates with depth is probably due to disintegration/oxidation of the biogenic aggregates during their descent through the water column. The decrease was most significant between 389 and 988 m. Thus, the disintegration of the biogenic aggregates appear to occur more frequently in the mesopelagic than in the bathypelagic zone. A similar trend was observed

Figure 7. Percentages of shells in biogenic aggregates in radiolarian taxa from Station E.

Figure 8. Plots of percentages of shells in biogenic aggregates vs. broken shells in radiolarian taxa from Station E. The shallowest (389 m) samples fall in the lower right side of the figure, whereas the deepest (5,068 m) samples scatter from the lower to upper end of the left side depending on taxon. Samples from 988 to 3,755 m fit in the middle of the curves.

Figure 9. Mode of vertical transport and dissolution model for sinking Radiolaria through mesopelagic and bathypelagic zones. Percentage of broken shells of soluble radiolarian species increases exponentially with depth, while resistant species settle without substantial dissolution effect on their shells.

on all suborders of Radiolaria (Fig. 7). The increasing values for Spumellaria and Phaeodaria between 988 and 3,755 m were probably due to experimental errors since the biogenic aggregates were rare.

The above shell breakage and the modes of shell transport are combined (Fig. 8) and the following scheme is presented. Generally, the dissolution in the mesopelagic zone is less significant due to their incorporation with the biogenic aggregates. As they descend to the bathypelagic zone, the effect of dissolution sharply increases (Fig. 9). Thus, it appears that the mode of vertical transport plays an important role in not only sinking speed but also skeletal dissolution of Radiolaria.

Percent fluxes of each suborder in total radiolarian shell flux are presented in Table 5. The ratios between two suborders are presented (Fig. 10): Nassellaria and Spumellaria (called N/S ratio in this thesis); Phaeodaria/Spumellaria (Ph/S); and Phaeodaria/Policystina (Ph/P). Nassellaria contributed more than 60% of the total Radiolarian flux counts at all stations and depths and hence this was the predominant suborder. Except between 339 and 988 m at Station E and 378 m and 978 m at Station P₁, the N/S ratio decreased with depth, indicating either an increase in relative Spumellarian flux, or a relative decrease of the Nassellarian flux, or both. The N/S ratios at 389 m at Station E and 378 m at Station P₁ were less than those immediately next depth. This difference is significant and is reasonable considering more input of deep water nassellarians than spumellarians between 389 and 988 m and a possibility of the in situ dissolution (Berger, 1968; Erez et al., in press) within the receiving cups.

McMillen and Casey (1978) reported the standing stock of suspended Radiolaria using plankton tows from the surface to a few km depth in the Gulf of Mexico and Caribbean Sea. An analysis by the author based upon their data showed that the N/S ratio decreased three orders of magnitude from the surface to a few km depth. Petrushevskaya (1971a) showed that N/S ratio decreased from her plankton samples to the surface sediments at two stations in the Central Tropical Pacific. The decreasing trend in N/S ratio with depth within the water column appears to be significant.

Figure 10. The Nassellaria/Spumellaria and Phaedaria/Spumellaria ratios from Stations E, P₁ and PB.

The reported N/S ratios in the bottom sediments (Berger and Soutar, 1970; Kowsmann, 1973; McMillen, 1979) were generally much lower than my observations in the deepest trap samples from all the three stations suggesting poorer preservation of Nassellaria than Spumellaria in the sediments.

The flux of Phaeodaria was more or less uniform and it was between 6 and 8% in total Radiolaria at all depths at Stations E and PB. Only 1-4% of Phaeodarian flux was observed at Station P₁. As stated previously, species composition of the Phaeodarian flux changed significantly with depth (Table 2). The following species comprised the majority (ca. > 30 shells/m²/day) of phaeodarian flux in the bathypelagic zone at Stations E and PB: Protocystis xiphodon (Haeckel); Euphysetta elegans Borgert; Euphysetta pusilla Cleve; Medusetta ansata Borgert; Borgertella caudata (Wallich); Lirella melo (Cleve); Lirella bullata (Studam and Ling); Challengeron willemoesii (Haeckel); and Conchidium caudatum (Haeckel). Except for the last two species of medium size, all belonged to the small size category.

Comparison of the radiolarian fluxes with previous work

Range of total radiolarian flux in the unit of $\times 10^3$ shells/m²/day at each Station was: (E) 16.0 - 23.7; (P₁) 0.6 - 17.0; (PB) 29.4 - 53.1 (Table 3). Of these, sum of the flux in 1 mm-250 μ m, 250-125 μ m, and 125-63 μ m size fractions in the unit of $\times 10^3$ shells/m²/day at each Station constituted: (E) 8.7 - 13.4; (P₁) 0.4 - 11.3; and (PB) 25.3 - 38.5 (Tables 3 and 4). These correspond to 56 - 67% (E), 62 - 70% (P₁) and 63 - 86% (PB) of the flux in all size fractions; the fine size (<63 μ m) fraction contained less than half of the radiolarian flux at all the depths at all the three stations.

Honjo (1978) placed a sediment trap at 5,367 m during winter months in the Sargasso Sea which is known to be one of the least productive areas in the Atlantic (Ryther, 1963). Honjo's total radiolarian shell flux of 14.0×10^3 shells/m²/day included 10.0×10^3 shells/m²/day (71%) in the fine size fraction and 4.0×10^3 shells/m²/day (29%) in

63 μm size fractions. The ratios between $>63 \mu\text{m}$ and the fine size fraction appear to be very different from tropical Stations to the Sargasso Sea. This may also be due to seasonal factors.

Hinga et al. (1979) measured material flux from sediment traps placed at 50 to 100 m above the sea-floor in the slope and rise waters off the Eastern United States. Their data included radiolarian flux of 2.0×10^3 to 6.0×10^3 shells/ m^2/day which did not discriminate the fine size fraction. Considering the geographic regions and the deployment depths, it seems possible that their flux measured primary and resuspended radiolarians as assumed by Rowe and Gardner (1979) in the same region. The radiolarian flux values of Hinga et al. (1979) are approximately one order of magnitude smaller than my observations at Station E; however, their total mass and organic carbon fluxes were one order of magnitude greater than those in the same samples from Station E (Honjo, 1980) as to the present study. Judging from their method cited in the text, it appears that their radiolarian flux was severely underestimated. It seems likely that they counted only visible specimens of all size on dry filters under a reflected light microscope.

Berger (1976) calculated supply rates of radiolarians, 0.5×10^3 to 1.1×10^3 shells/ m^2/day , to the surface sediments in the Santa Barbara Basin. This was based on Berger and Soutar's (1970) radiolarian counts in the fraction of surface sediments coarser than $62 \mu\text{m}$, assuming a sedimentation rate of 1 mm/yr (Emery, 1960). His values are one to two orders of magnitude less than my values of 1 mm- $63 \mu\text{m}$ size fractions from Station E. Considering that carbon flux in the Santa Barbara Basin is two orders of magnitude greater (Soutar et al., 1977) than that of Station E (Honjo, 1980), it seems reasonable to assume that radiolarian production in the former should be greater than at the latter. The radiolarians studied by Berger appear to be already significantly depleted through dissolution process.

Comparison of the radiolarian fluxes with accumulation rates in the
Holocene sediments

The total radiolarian flux can be compared with radiolarian accumulation rates in Holocene sediments cited in the literature in order to estimate an extent of preservation. When a unit is converted the flux is: (E) $5.83-8.66 \times 10^5$ shells/cm²/10³ yrs; (P₁) $0.21-6.22 \times 10^3$ shells/cm²/10³ yrs; and (PB) $10.72-19.40 \times 10^3$ shells/cm²/10³ yrs. For instance, the comparison of the flux from Station E with the Holocene sediments involves a sedimentation rate of <0.9 g/cm²/10³/yr (Lisitzin, 1972, Fig. 72) and radiolarian abundance of 6000 shells/g of dry surface sediment ($> 44 \mu\text{m}$: Goll and Bjørklund, 1971: p. 437, 442). These figures combined to yield a radiolarian accumulation rate of $<5,400$ shells/cm²/10³ yrs. This rate is equivalent to $<0.8\%$ of our observed average radiolarian flux. Goll and Bjørklund (1971) stated that their $<44 \mu\text{m}$ size fraction contained only small broken fragments of Radiolaria which made the above comparison possible. Furthermore, they noted that the core (raised from 13°29'N, 55°59'W which was located nearest to Station E) contained mostly incomplete radiolarian specimens. The above crude comparison suggests that a high percentage of radiolarians supplied to the bottom sediments has not been preserved due to dissolution process. This is in good agreement with general behavior of biogenic opal discussed by Heath (1974).

Holocene accumulation rates of radiolarian skeletons from the Panama Basin have been estimated by Swift (1976) using counts of whole radiolarians in $>63 \mu\text{m}$ size fraction (Kowsmann, 1973): (in the unit of $\times 10^3$ shells/cm²/10³ yrs) total Radiolaria: 104; Spumellaria: 82; and Nassellaria: 22. In order to compare with the above, average vertical fluxes of Radiolaria (30.8×10^3 shells/m²/day) and the suborders in $>63 \mu\text{m}$ size fraction (Table 4) are converted to the unit of $\times 10^3$ shells/cm²/10³ yrs: total Radiolaria : 1123; Spumellaria: 281; and Nassellaria: 787. The estimated total radiolarian preservation is 9.3%. This is an order of magnitude higher value than in the equatorial Atlantic Station E where productivity is much less. As it can be

predicted on the basis of change in N/S ratio with progress of dissolution, better preservation of Spumellaria is estimated (29.2 % of the flux) than Nassellaria (2.8 %).

Sediment accumulation rate at Station P₁ has been estimated by Honjo (in press). Renz (1976) reported radiolarian counts in >35 μ m size fraction per unit dry weight of surface sediments in nearby region: 1400 shells/g. Combining the above data and then comparing with the vertical flux of all size fractions (Table 5), radiolarian preservation of 0.004 % at Station P₁ is obtained.

Although the flux was not quantified, sediment trap samples from Station S were qualitatively studied at 976 m and 3694 m. Analogous to the three other stations, the species composition of flux was similar between the two depths. The surficial bottom sediments obtained by a box core consisted mainly of clay minerals and only a few specimens of robust polycystines such as Tetrapyle octacantha were found in 5 g (wet weight) of samples suggesting a significant dissolution effect to the radiolarian assemblage on the sea-floor.

In conclusion of this section, Radiolaria supplied to the sea-floor are generally largely dissolved there and only a few percent or less is preserved in the underlain Holocene sediments. The extent of preservation may be in part proportional to extent of sedimentation rates.

Effects of radiolarian dissolution in the water column

Since seawater is undersaturated with respect to biogenic silica (e.g. Hurd, 1972), dissolution of the biogenic silica occurs throughout the course of sedimentation. The extent of dissolution varies depending on taxa whose morphology, chemical composition and residence time vary a great deal. An extensive dissolution can dissolve most, if not all, of the descending population of dissolution susceptible taxa such as Challengerio willemoesii, a phaeodarian species, within the water column (Table 2; Fig. 11). On the other hand, polycystines are generally not much affected in their species composition and abundance within the water column and only large amounts of statistical data such as N/S ratio can

Figure 11. Representative phaeodarian taxa of shallow and deep dwelling species from Station E. The decrease of the shallow dwelling flux with depth is caused by dissolution during sinking. The flux of deep dwelling radiolarians is a mixture of an increase of settling individuals and dissolution of dead shells while sinking.

resolve slight change (Fig. 10). However, when morphology within a shell is examined, an increase of shell breakage with depth has been observed as stated earlier (e.g. Pterocorys).

The above pieces of independent evidence can be further substantiated by ultra- and microstructural evidence of dissolution effects in order to generalize its extent in different taxon groups. Polycystine skeletons from the sediment traps examined by TEM show that generally only approximately 0.1 μm or less of surface layer is porous which is apparently caused by dissolution (e.g. Pl. 43, figs. 10-11). This 0.1 μm or less represents generally very small portion of a cross sectional diameter unless the skeletal elements are extremely thin (e.g. Myelastrum). Therefore, apparent effect of dissolution on bulk morphology is generally insignificant in polycystines and this agrees well with the species counts (Table 2; Figs. 3, 4). Polycystines from the surface sediments are expected to have more porous skeletons than those from the trap samples since they have been exposed to seawater for a long period of time. In fact, they show a trend to be significantly porous (Hurd et al., 1981).

In the case of Phaeodarians, the original skeletal nature of plankton tow samples appears to be very different from the polycystine counterparts. Although they appear somewhat similar to polycystine skeletons at first glance (Pl. 47, fig. 14; Pl. 58, fig. 1), they are different in detail such as having small polygonal pores in the inner part of skeletons except in the surface solid layer of 0.40-0.45 μm thickness. They appear to be dissolved fairly quickly. By the time sediment traps are recovered within a few months, their original structure has drastically changed and become much more porous (e.g. Pl. 47, figs. 11-12; Pl. 53, figs. 9-10; Pl. 58, figs. 3-4). The resulting porous specimens of several taxa have tubular structure (e.g. Pl. 47, fig. 12; Pl. 58, fig. 3; Pl. 59, figs. 12-13). This may be due to a different constitution, e.g., water content, and growth features. The amphora-structure of Challengerids (e.g. Pl. 47, figs. 8-13; Pl. 48, figs. 8-11; Pl. 51, figs. 10-11) appears to be more dissolution-resistant than surrounding cementing parts which are relatively soluble. The

amphorae may be made of similar skeletal silica as the polycystine skeletons.

There are several phaeodarian taxa that are generally consistently recovered from bottle casting or plankton net tows but not from the traps. These include Euphysetta sp. (Pl. 63, figs. 12-13), Medusetta robusta Borgert (1902) and Medusetta armata Borgert (1901). It is apparent that such thin shells made of one or two layers of tubular skeletons, shown in the illustration, are quickly disintegrated and hence never found in the trap samples. The fate of Sticholonche, classified now as Heliozoa (Cachon and Cachon, 1978), is analogous to the above and has never been found as an intact shell but only as dispersed spines in the trap samples (Takahashi and Ling, 1980). Aulosphaerids and Aulacanthids are also readily disintegrated and only partial skeletons of the shells are recovered from the traps (Pl. 63, figs. 1-11).

Dimensions of radiolarian skeletons

Dimensions that are measured here are weight, length, width, maximum projected area (PA) and that computed are computed projected area (CPA), bulk volume (V_b) which includes a parcel of water within a shell, and volume of skeleton (V_{skel}) (Table 9). Since the length and width are normally readily accessible by using a microscope, their correlations with the rest of the dimensional data facilitate fundamental information (Figs. 12-13, 15-17). All the possible combinations of log-log relationships between the above dimension variables are presented (Table 10; Figs. 12-17). As it will be discussed in the following section, laboratory sinking speed of individual radiolarian shells is best correlated with weight values among all the variables of the dimensions. When combined with SiO_2 content data on weight/shell are of interest to geochemistry which will also be discussed in the later section. Previously, Petrushevskaya (1966, cited in Lisitzin, 1972) reported that approximate weight range of radiolarians from plankton samples is 0.33-1.00 $\mu\text{g}/\text{shell}$.

Weight values of fossil radiolarians have been reported from the equatorial Pacific ranging from 0.063 $\mu\text{g}/\text{shell}$ of Quaternary to ca. 0.30 $\mu\text{g}/\text{shell}$ of Eocene in age (Moore, 1969). The author also independently obtained $0.136 \pm 0.009 \mu\text{g}/\text{shell}$, an average weight of fossil radiolarians from a core V24-58, 777 cm (~ 1 Ma: Hays et al., 1969) raised in the central Tropical Pacific, by the same method (Moore, 1969) suggesting consistency with Moore's data. It is important to note that values obtained here from the traps are orders of magnitude greater than the above Quaternary samples.

Taxonomic consideration on samples from both sediment traps and bottom sediment preserved radiolarians have a clue to understanding the above difference in the weight between the two different groups. Phaeodarians and large-sized polycystines are generally absent in the sediment samples. The large and heavy polycystines are generally made of thin skeletal elements forming a network of spongy shells (e.g. Conicavus tipiopsis n.sp., Myelastrum trinibrachium n.sp.). Since preservation is a function of skeletal thickness but not the size of a shell (Hurd and Takahashi, in prep.) and hence these species are likely to be dissolved on the sea-floor or soon after burial. Some of the Phaeodaria are also significantly heavier (i.e. most of Castanellids, Haeckeliana porcellana and Conchopsis compressa) than the polycystine counterparts. For instance, a Castanellid weighing 130.0 $\mu\text{g}/\text{shell}$ was observed, although this value does not directly appear in Table 9 since only mean values are tabulated. This value is approximately 2000 times heavier than Pterocorys zancleus or Pterocorys campanula which are the most abundant taxa at Station E. Therefore, the heavy weight radiolarians appears to play an important role in transporting and releasing silica and its associated elements in the deep-sea as in the case of Foraminifera (Boyle, 1981). The extent of their vertical silica transport contribution is quantitatively considered in the last section of the discussion.

Table 9. Radiolarians from the sediment traps: size, laboratory sinking speed and residence time in the water column. The S.D. is at 95% confidence level (2σ) and n is number of measurements (specimens). See text for explanations for τ_n.

Table 10 (cont.)

PA:	Maximum projected area
WT:	Weight
SS(3,10,20):	Sinking speed in still water at 3, 10, 20°C respectively.
$\alpha(3,10)$:	Residual factor ($= W_{obs}/W_{theor}$) at 3, 10°C respectively.
$\Delta\rho(3,10)$	Bulk density contrast at 3, 10°C respectively.
τ_1 :	Residence time computed assuming 3°C - 5 Km water column.
τ_2 :	Residence time computed assuming 10°C - 800 m, underlain by 3°C - 4200 m still water column.
τ_3 :	Residence time computed assuming 20°C - 200 m, 10°C - 600 m, and 3°C - 4200 m water column.
** :	All of the available raw values rather than mean values are used.
*** :	Computed for the data fit with $\log Y = b \log X + a$.
* :	Number of specimens used for the relationships between PA and W (35 taxa involved) and PA and L (53 taxa).

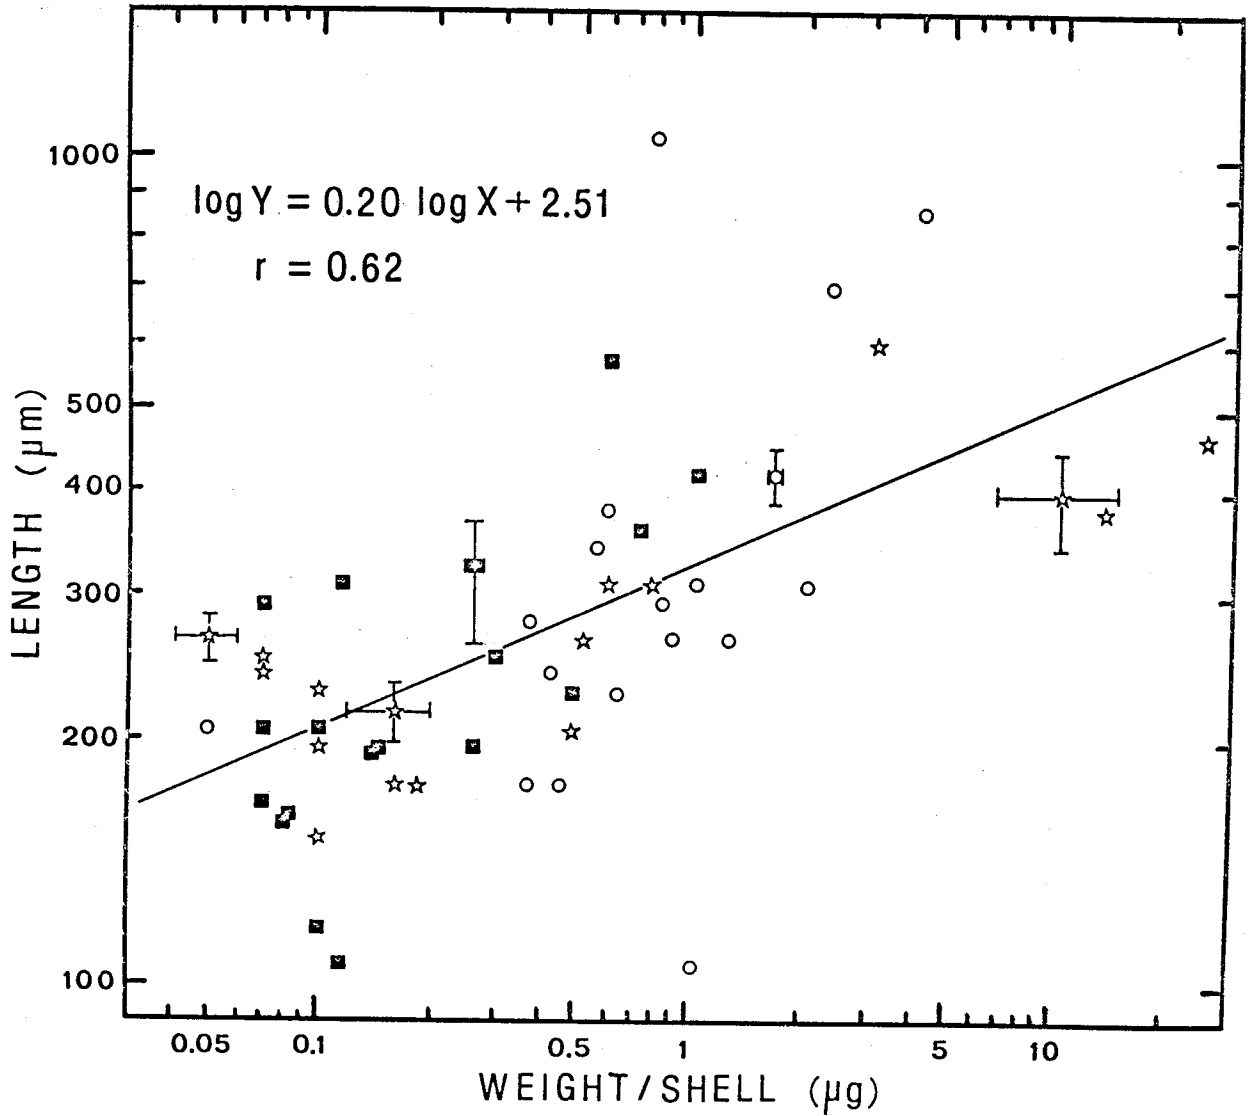

Figure 12. Plot of length vs. weight/shell. Each datum point represents each species. Only representative standard deviations/analytical errors are given to several species for simplicity of the illustration. Symbols used in Figures 12-13, 18-23, and 25 are: ○: Spumellaria; ■: Nassellaria; and ☆: Phaeodaria.

Figure 13. Plot of width vs. weight/shell. See Figure 12 for the legend of symbols.

Figure 14. Plot of projected area vs. weight/shell. Symbols are basically same as in Figure 12 but all the open symbols are for observed projected areas and black ones are for computed projected areas.

Figure 15. Plot of width vs. length for 927 data points of Radiolaria including 58 taxa. Symbols used in Figures 15-17 are: * : One datum point; numerals 2-8 correspond to number of data points superimposed upon; numeral 9: 9 or more of data points superimposed upon.

Figure 16. Plot of projected area vs. length for 724 data points of Radiolaria including 53 taxa. See Figure 15 for the legend of symbols.

Figure 17. Plot of projected area vs. width for 344 data points of Radiolaria including 35 taxa. See Figure 15 for the legend of symbols.

Silica content in radiolarian skeletons

Silica content with respect to weight value in 26 radiolarian taxa is reported in Table 11. The value tends to be consistent within a suborder. Nassellaria show the highest SiO_2 values among the three suborders. Conicavus tipiopsis has thin meshwork while the rest of the taxa in this group have thick and solid skeletons. It is possible that some skeletons have greater than 100% SiO_2 considering large analytical errors (<8%) as well as introduction of contaminants such as water molecules and salts despite of a thorough cleaning procedure prior to the analysis. Spumellaria give relatively uniform values ca. 90% among all. Acrosphaera murrayana has solid latticed simple one layer shell whereas the rest of the species have spongy framework with the exception of Actinimma arcadophorum. Phaeodaria are the lowest in silica content. The value of Challengeron tizardi is anomalously high and hence it is eliminated in discussion. A comparison was made between the values of clean shells and shells with a tan color tint in the skeleton or with organic aggregates inside of the sphere. The results show no significant difference between the two suggesting that the values are not governed by the amount of organic matter.

High values of silica appear to be associated with thick and simple structured skeletons and, in contrast, low values are associated with spongy or porous skeletons. Since thick nassellarian shells such as Lamprocyclus maritimalis maritimalis are rarely dissolved in the water column (pl. 43, figs. 10-11), there is little room where contaminants can remain. The skeletons with the high values appear to contain no water in $\text{SiO}_2 \cdot n\text{H}_2\text{O}$. This is very different from fossil radiolarian water content of 7-17% based on refractive index analysis (Hurd and Theyer, 1977). On the contrary, spumellarians have generally thin and numerous skeletal members than nassellarians. Thus, despite their similar solid microstructures to the nassellarians, their surface areas are larger and have more capacity to retain contaminants which may slightly lower the values.

Table 11. Silica content in selected radiolarian species from the sediment traps.

*Samples used in Erez et al. (in prep.): recovered from 3978 m; 36% weight loss.

It is not clear if the difference between the spumellarians and nassellarian values are related to different water contents or morphology-governed contaminants. A similar contrast to the above between values of polycystines and phaeodarians is observed: the high values with solid polycystines and low values with porous phaeodarians skeletons (pls. 47-63).

As a summary of this section, silica content observed here varies significantly from one suborder to the other, but is rather consistent within a suborder since the values are at least partially related to their morphology. For a later discussion of silica transport from the production depth to the dissolution depth, the $\text{SiO}_2/\text{shell}$ (μg) values given in Table 11 facilitate essential information.

Laboratory sinking speed of Radiolaria

Sinking speed measurements were conducted in the laboratory in the Sargasso Sea water (salinity $36.1^{\circ}/\text{oo}$) at 3°C for 55 taxa, at 10°C for 13 taxa and 20°C for 10 taxa (5 taxa each in Salinity $36.1^{\circ}/\text{oo}$ and $30.5^{\circ}/\text{oo}$) (Table 9, Figs. 18-23). The results at 3°C are the most essential among all three temperatures since 3°C water temperature is distributed extensively in the bathypelagic layer of the world's oceans (e.g. Reid, 1965; Worthington, 1976).

With the method used here specimens greater than ca. $200 \mu\text{m}$ (e.g. Anthocyrtidium ophirense) are readily recognized and traceable in the experimental column without using a microscope but those of ca. $100 \mu\text{m}$ (e.g. C. profunda) or smaller size required an effort to positively identify before they reach the start-line of the measurements. The majority of nassellarians were observed to sink upside down with respect to the orientation of ordinary illustrations widely appear in the literature. For instance, 10 specimens of Anthocyrtidium ophirense, a typical nassellarian, sinks with the apical horn downward and only one specimen obliquely and one specimen horizontally sunk out of 12 measurements. Cephalis and the apical horn are heavy and hence they are supposed to be playing a role in orienting a shell even for live

Figure 18. Plot of sinking speed in 3°C still water vs. length. See Figure 12 for the legend of symbols.

specimens (R. Goll, 1980, pers. comm.). Among many literature, Haecker (1908a) is one of the few that illustrated the nassellarians with the apical horn downward. Although the orientation widely used in the literature including this paper is misleading with respect to how radiolarians are oriented in the water, it may be better to keep the current usage with an awareness of the above notion considering vast amounts of literature already published. It is also of interest to note that sinking orientation of discoidal radiolarians is nearly always steadily vertical through the experimental water column but never will be as the way a sheet of paper falls through the air.

The obtained sinking speed ranged from 13 m/day of Euphysetta elegans to 416 m/day of Haeckeliana porcellana (Table 9; Figs. 18-21). Each datum point in Figs. 18-23 represent each species and standard deviations are only given to a few taxa in order to maintain simple illustrations, but the rest can be referred in Table 9. As is can be readily seen in Figs. 18 and 19, the correlations between sinking speed at 3°C and length or width are poor ($r=0.4$ and 0.3 respectively). When projected area which is analogous to square of diameter is used the correlation becomes better (Fig. 20; $r=0.5$), but still not satisfactory in order to furnish a predictive regression line. When weight/shell, which is equivalent to mass, is used the correlation becomes much better (Fig. 21). Despite of the fact that variety of taxa have wide range of morphology, the correlation between sinking speed and weight ($r=0.86$ at 3°C) is remarkably good suggesting a treatment as a whole Radiolaria is reasonable without dividing them into morphologically dependent groups. Nassellarians observed here sink somewhat slower (14-105 m/day) compared to spumellarians (25-177 m/day) mainly due to lesser weight. These two groups tend to separately cluster respectively in areas along the regression line (Fig. 21). Phaeodarians, on the other hand, spread out their values from 13 to 416 m/day mainly due to wide range of weight.

Existing data on radiolarian sinking speed in the literature include only one measurement on the 500 μm size specimen (350 m/day) by Kuenen (1950, p. 253) and unpublished data cited by Casey et al. (1979b, p. 232) (35.6 m/day for tropical species, and "three to ten times faster rates

for larger and heavier polar species"). Both of these data fall in the range of the present observations which include all the possible size of taxa except the smallest sized taxa such as Peridium spinipes. From a theoretical point of view, Lerman (1979) proposed a hypothetical sinking speed of Radiolaria based on laboratory sinking speeds on planktonic foraminiferal tests (Berger and Piper, 1972) and diatom frustule (Smayda, 1969, 1970, 1971). However, my observations do not agree with Lerman's model (Lerman, 1979, p. 268, fig. 6.3). Also, a classical and theoretical consideration of particle sinking by Munk and Riley (1952) is available.

Combining information on weight, V_b , and an assumed density of biogenic silica (2.0 g/cm^3), one can estimate bulk density contrast ($\Delta\rho$) which is the density difference between a parcel of water including the skeleton and adjacent seawater. The resulting values are shown in Table 9. When they are plotted against sinking speed, a positive correlation is found (Fig. 24). The majority of $\Delta\rho$ values fall between 0.01 and 0.5 g/cm^3 whose range is much narrower than other available biogenically originated particles such as fecal pellets (e.g. Komar et al., 1981; Honjo, pers. comm.). Previously, Bishop et al. (1977) used an assumption of $\Delta\rho = 0.1 \text{ g/cm}^3$ for radiolarian silica flux which was reasonable.

In order to determine whether a Stokes Law is applicable to the settling scheme of radiolarian skeletons Re, Reynold's number, of the sinking particle has to be examined:

$$\underline{Re} = \frac{\rho \cdot W_{\text{obs}} \cdot D}{\mu} \quad (1)$$

where ρ and μ are the water density and viscosity, W_{obs} , is the sinking speed of a particle, and D is the nominal diameter of the particle. The Reynolds number computed ranges from 0.02 to 1.4 at 3°C , and only the two species showed relatively high Re and the rest are less than 0.6. Thus the following Stokes equation is applicable (Raudkivi, 1976) to the sinking speed of radiolarian skeletons:

Figure 24. Plot of sinking speed in 3°C still water vs. density contrast, $\Delta\rho$. See Figure 12 for the legend of symbols.

$$W_{\text{theor}} = \frac{1}{18} \cdot \frac{1}{\mu} \cdot \Delta\rho \cdot g \cdot D^2 \quad (2)$$

where W_{theor} is the Stokes settling rate, $\Delta\rho$ is the bulk density contrast between the water and the sinking particle, g is the acceleration of gravity (981 cm/sec^2), and D is the nominal diameter of the particle.

The computed theoretical values by Stokes equation are compared with the observed values and presented in Table 9 and Fig. 25. Cladococcus scoparius and Saturnalis circularis showed abnormally high values of W_{theor} ; this can be readily explained by their characteristic morphology (Pl. 10, figs. 1-4; Pl. 15, figs. 15-18). For instance, in the case of Cladococcus scoparius, if full length of the spines were taken as the shell diameter instead of taking cortical shell diameter which is extraordinarily small compared with the spine length, the value would have been much smaller. The values for these two taxa (Table 9) are eliminated in the plot of Fig. 25.

A correlation between Stokes law and the measured sinking speed, residual factor α ($W_{\text{obs}}/W_{\text{theor}}$ ratio), are plotted against average diameter (Fig. 25). Up to ca. 250 μm in diameter the ratio follows the Stokes law (ca. $\alpha = 0.9 \pm 0.5$) where Re is fairly small and above it the ratio deviates (ca. $\alpha = 0.4 \pm 0.4$) where Re is relatively larger. As a whole, there is a negative correlation between the ratio and the diameter which is partially governed by Re .

Residence time of Radiolaria in the pelagic water column

The above sinking speed is used to estimate amount of time that individual radiolarians are expected to stay in a water column (residence time) assuming that steady state settling occurs without dissolution. In the case of dissolution susceptible taxa this is only hypothetical measure but it still supplies useful information especially when

Figure 25. Plot of the residual factor (W_{obs}/W_{theor}) vs. average diameter using length and/or width. The horizontal dashed line represents theoretical values using Stokes equation. Only 3 different shapes are separated since further divisions do not improve the understanding of sinking speed governing factors. Symbols: \odot : spherical group (sphere, ellipsoidal, hemispherical, cylindrical and box in the APPENDIX Table 1); \square : discoidal group (discs and plates); \star : Conical group (conical and pyramidal: this group includes only nassellarians).

combined with dissolution rate data. Applying the speed obtained in the laboratory water column with limited height at three temperatures the residence times is: (1) τ_1 : residence time computed assuming 3°C and 5 km still water column; (2) τ_2 : residence time computed assuming 10°C and 800 m, underlain by 3°C and 4200 m still water column; and (3) τ_3 : residence time computed assuming 20°C and 200 m, 10°C and 600 m, and 3°C and 4200 m still water column.

According to the correlations between τ_n and weight as shown in Table 9 and Figs. 26-27, and within the limits of present observations, the residence time range of τ_1 is from 2 weeks to over a year. A regression line of τ_2 is below that of τ_1 which is expected but it has higher slope than that of τ_1 (Fig. 26) which might be due to small number of taxa used since each species has different morphological characteristics which may influence sinking speed. A regression line of τ_3 is nearly identical to that of τ_2 and superimposed upon it and hence it is not illustrated in Fig. 27.

Nassellarian τ_1 ranges from ca. 2 months to slightly over a year. Taking 0.12 $\mu\text{g}/\text{shell}$, an average nassellarian stays 6 and 7 months during settling in the water column using τ_2 and τ_1 respectively. Taking 0.6 $\mu\text{g}/\text{shell}$, an average spumellarian stays 2 and 3 months using τ_2 and τ_1 , respectively. This suggests that spumellarian skeletons are least subjected to dissolution during their descent in the water column among all the suborders. Castanellids, and Circoporids which are large-sized phaeodarians, spend less than two months (majority of them stay less than a month) and the rest of the phaeodarian taxa spend three months to a year in a 5 km water column.

Based on TEM-SEM morphological observations (Pl. 43, figs. 10-11; pls. 47-63) sediment trap radiolarian counts (Tables 2-5) most of the polycystine assemblages eventually reach the bottom with different extents of dissolution effects depending on the residence time of the taxa. On the other hand, Phaeodarians behave differently: that is, species with heavy weight/shell sink quickly to the bottom without being dissolved and there they are dissolved within a few months based on an in situ dissolution experiment (Erez et al., in press; Hurd and Takahashi,

Figure 26. Plot of residence time (τ_1) vs. weight/shell.
See Figure 12 for the legend of symbols.

Figure 27. Plot of residence time (τ_2) vs. weight/shell. A regression line for τ_3 is almost superimposed upon that of τ_2 and hence not drawn here. See Figure 12 for the legend of symbols. Additional symbols used:
●: Spumellarian τ_3 ; □: Nassellarian τ_3 ;
★: Phaeodarian τ_3 .

in press). These are represented by Castanellids, Haeckeliana porcellana and Conchopsis compressa. Smaller and lighter phaeodarians represented by Challengeron willemoesii have little chance to reach the bottom due to their long residence time with dissolution susceptible nature. The phaeodarian species (Castanidium longispinum Haecker) used by Erez et al. (in press) is considered to be an end member of the phaeodarians in terms of dissolution susceptibility because its large size (i.e. $470 \pm 34 \mu\text{m}$). Since specimens of this species are mostly dissolved within 3-4 months period in the deep sea environment it is evident that small-sized phaeodarians will be dissolved within shorter period of time than them.

Radiolarian standing stock, production rate and turnover time

Not much is known about rate of production and turnover time for radiolarians and most of the published information on these are indirectly obtained. Radiolarian standing stock is moderately known especially in tropical regions (Renz, 1976; Bishop et al., 1977, 1978, 1980; Kling, 1976, 1979; Takahashi and Ling, 1980; Boltovskoy and Riedel, 1980).

Casey et al. (1971) have estimated turnover time of 11 polycystine species in the Santa Barbara Basin, off the coast of California, based on their abundance in plankton tow samples and in the underlying varved sediment layers of the past 10 years. The turnover time is the amount of time necessary to replace a whole population of a taxon. The turnover time ranges from less than a day to 43 days depending on the species. They further suggested that life span of two species (Teoconus zancleus and Eucytidium hexagonatum) are about one month judging from the turnover times. This indirect method involves many unestablished assumptions, e.g., no dissolution loss in the sediments. Anderson (1978) directly observed at least 3 weeks of life span for the skeletonless species (Thalassicolla nucleata) in the laboratory culture.

Berger (1976) estimated that residence time of radiolarians ($>61 \mu\text{m}$) in the upper 100 to 200 m of the Santa Barbara Basin is between 3 weeks and 3 months. This was based on radiolarian counts in bottom sediments

(Berger and Soutar, 1970) and a sedimentation rate (Emery, 1960) which give supply rates (0.5×10^3 to 1.1×10^3 shells/m²/day) to the sediment-water interface.

The standing stock, rate of production, and turnover time can be delineated as follows:

- (1) Flux of radiolarian species, F (no. of shells/m²/day), is obtained from species counts of sediment trap samples.
- (2) Descending speed of radiolarian species, D_s (m/day), is obtained by laboratory sinking speed experiment on the samples collected by the sediment traps.
- (3) Standing stock of radiolarian species, S (no. of shells/m³), is computed as follows:

$$F / D_s = S \quad (\text{no. of shells/m}^3)$$

- (4) Rate of production is computed as:

$$F / h_{\text{prod}} = R_{\text{prod}} \quad (\text{no. of shells/m}^3 \cdot \text{day})$$

- (5) Turnover rate is estimated as follows:

$$S \cdot h / F = T \quad (\text{days})$$

where h_{prod} is the height of water column where production occurs and assuming steady state condition of S and F during the sediment trap experiment. Although these assumptions are yet partially improved, they will suffice first order approximation.

The estimated standing stock shows abundant species being on the order of 10 individuals/m³ or more and ca. 0.1 or less for the minor species (Table 12). The standing stock for total Radiolaria ranges from ca. 430 shells/m³ at Station P₁ to 1230 shells/m³ of Station PB. This is in a good agreement with direct observations made by Bishop et al. (1977, 1978, 1980). For example, Bishop et al. (1980) reported that total radiolarian counts of 1220 shells/m³ in >53 μm size fraction from 1500 m depth of the Panama Basin in June-July. Considering different methods, seasons and that their exclusion of < 53 μm size fraction and inclusion of Sticholonche which is absent in my data, it is at least reasonable to state that the above values are similar each other. The standing stock can be used to compute for amount of radiolarian biogenic silica in unit amount of water. For instance,

Table 12. Estimation of standing stock, rate of production and turnover time of selected abundant radiolarian species and three suborders.

*: two species combined

h_{prod}: height of water column where production occurs

sinking speed used for each suborder's: S: Spumellaria - 80; Nassellaria - 30; and Phaeodaria - 80 m/day

taking the radiolarian suborder fluxes from Station PB (Table 5), weight and mean SiO_2 content (Tables 11,13), $225 \mu\text{g SiO}_2/\text{m}^3$ is estimated in the average water column between the trap depths at Station PB. This agrees well with particulate silica obtained from 1500 m of the Panama Basin by Bishop et al. (1980): $124 \mu\text{g SiO}_2/\text{m}^3$ in $> 53 \mu\text{m}$.

Values of production rate and turnover time are dependent on assumptions on h_{prod} , height of water column where production occurs. With the assumption of h_{prod} being 200 m the estimated R_{prod} , rate of production, is on the order of $0.01 \text{ shells}/\text{m}^3 \cdot \text{day}$ for minor species and $1-4 \text{ shells}/\text{m}^3 \cdot \text{day}$ for abundant species. The turnover time obtained appears to be on the order of a few days to several weeks depending on the species and assumptions. This generally agree with the previous reports of more indirect methods (Casey et al., 1971; Berger 1976). However, some values are one to two orders of magnitude differnt from Casey et al.(1971)(e.g. Cornutella profunda).

Biogenic opal transport to the deep-sea by radiolarian skeletons

Based on microscopic analysis combined with an inferred weight value Takahashi and Honjo (1981) quantitatively demonstrated an importance of radiolarian SiO_2 transport to the deep-sea at least in the equatorial Atlantic during a season. To further quantify the radiolarian SiO_2 flux it is necessary to combine radiolarian counts (Table 2), weight values and mean SiO_2 content in each suborder (Table 11). Choosing the weight values is the most critical for the estimation. Utilizing the data on 55 taxa (Table 2-4; Pls. 1-63) and taxon-morphological background, the most logically representative average values are subjectively chosen (Table 13).

Computation results show that spumellarian SiO_2 transport is generally 50% or more of the total radiolarian SiO_2 flux and nassellarians and phaeodarians follow them respectively at all the stations. Although phaeodarian SiO_2 transport appears to be up to a

few percent at Stations E and P₁ and ca. 20 % at Station PB (Fig. 28), as it has been discussed earlier they play an important role in quick silica release in the water column and on the seafloor (Fig. 29) due to their dissolution susceptible nature and high dissolution rate. Some of Castanellids are extremely large but rare and hence an introduction of a few such large specimens results in a significant contribution to the SiO₂ flux. Since the results in Table 13 are based on observations of microslides which may not always contain such a rare taxa due to small aliquots, an inclination toward higher phaeodarian flux should also be considered. A finding of a dense, large patch of monospecific Castanidium longispinum (whose size is 470±34 μm and weight is ca. 5 μg/shell) in the Gulf of Oman suggests its predominance in certain time and space (Erez et al., in press) .

Radiolarian SiO₂ flux ranges from ca. 3 mg/m²/day at Stations E and P₁ and 6-10 mg/m²/day at Station PB. When these values, especially the values from Station E, are compared with the existing data, it seems that Bishop et al. (1977) underestimated the radiolarian SiO₂ flux by several factors to an order of magnitude due to many assumptions involved.

The radiolarian SiO₂ flux is compared to biogenic opal flux values (Honjo et al., in press) and expressed as percentage in total biogenic SiO₂ (Table 13). That the percentages generally increases with depth suggests more dissolution of other components than intact radiolarian skeletons such as radiolarian and diatom fragments in the water column. When the radiolarian flux data from Station PB (the Panama Basin) are compared with size fractioned biogenic SiO₂ values, they appear to agree well: the radiolarian SiO₂ flux ranges from 22 to 30% which suggests that the rest of the SiO₂ is transported by silicoflagellates, small diatoms (< 63 μm) and fragmented SiO₂ particles including radiolarian fragments which are < 63 μm. The values of 20 - 30 % is approximately equivalent to biogenic SiO₂ flux of > 63 μm size fraction. Radiolarians appear to be only the major biogenic silica carrier that can be microscopically identifiable. Contributions of diatoms to biogenic SiO₂ flux at Stations PB and P₁ are

Table 13. An extent of biogenic opal transport to the deep-sea by radiolarians.

RADIOLARIAN SiO₂ FLUX

Figure 28. Percent contribution of Phaeodaria to radiolarian SiO₂ flux at Station PB which represents the highest phaeodarian SiO₂ flux among all Stations. Note that phaeodarian SiO₂ flux is ca. 20 % while their counts are only ca. 6 % of Radiolaria (Table 5).

Figure 29. Simplified illustration depicting production depth, sinking, dissolution and preservation of Spumellaria, Nassellaria and Phaeodaria in a pelagic realm.

insignificant. Large diatoms ($>63 \mu\text{m}$) are minor components except at E station; at Station E (Equatorial Atlantic) Rhizosolenia styliformis, a centric diatom, contributes approximately one quarter of total SiO_2 flux. The percentages of the radiolarian SiO_2 flux obtained for Stations E and P_1 appear to be too large because most of the weight data were obtained from 3769 and 3791 m samples at the Panama Basin which seems to be responsible for an overestimation. The datum at P_1 378 m anomalously deviates from the rest, but as stated earlier the recovery of this depth and 978 m samples was much less than the rest of the depths causing less reliability on the statistics. Microscopic examinations indicate that some taxa of the Panama Basin specimens are more robust and/or developed than the same taxa in other stations. For instance, patagium of Euchitonia elegans is generally present in samples from Station PB but absent in samples from Station P_1 . Such a morphological difference as well as composition difference in assemblages are accounted for the exceeding values at E and P_1 .

Estimation of excess Si relative to advective Si in the deep waters of the western North Atlantic

In the two studied areas of the western North Atlantic a major portion of the biogenic opal supply to the sediments appears to dissolve on the sea-floor. Consequently, an upward flux of dissolved silicon should be nearly equal to the supply rate assuming a steady state flux with time. This can be compared and further used to assess mixing regime of the deep waters in the North Atlantic. A linear relationship between Si and salinity below potential temperature 2° has been observed in the western North Atlantic, suggesting a simple mixing of North Atlantic Deep Water (NADW) and Antarctic Bottom Water (AABW) (Spencer, 1972; Broecker et al., 1980). A ventilation time of the deep western Atlantic is about 100 years (Broecker, 1979). If an upward flux of Si is significantly large relative to advective Si in the water column, a deviation from the above linear relationship should be detected.

Results of computations estimating upper and lower limits of excess Si (ΔSi) in the lowermost 1500 m of the water column are presented in

Table 14. Estimation of excess Si relative to advective Si in the deep waters of the western North Atlantic.

	Sargasso Sea Station S	Demerara A. P. Station E
Upward flux* (Si mg/m ² .yr)	51.1	712.0
ΔSi accumulation during a year below 3.5 km depth (Si μ mol/kg)	1.22 x 10 ⁻³	1.695 x 10 ⁻²
ΔSi accumulation during 100 years below below 3.5 km depth (Si μ mol/kg)	>0.12	<1.70

*Upward flux is assumed to be equivalent of 99 % of the biogenic opal flux to the sea-floor. Biogenic opal flux data are from Honjo (1980) and Honjo et al. (in press).

Table 14. This depth interval is chosen because Si concentration appears to be uniform below 3.5 km. It is possible to further mix Δ Si with overlain water masses during the ventilation time, then the resulting Δ Si values would be even smaller. The Sargasso Sea (Station S) and Demerara Abyssal Plain (E) perhaps represent close to lower and upper limits of the biogenic opal flux in the North Atlantic respectively. Over 100 years of the ventilation time $0.12-1.69 \Delta$ Si μ mol/kg is added to the advective Si. Obviously, the range of the values is insignificantly small and thus cannot be detected as a deviation in the mixing curve. This is consistent with the previous reports of a simple mixing of NADW and AABW in the western North Atlantic (Spencer, 1972; Broecker et al., 1980).

SUMMARY AND CONCLUSIONS

(1) Total number of radiolarian taxa encountered combining all three stations is 420: 175 Spumellaria; 182 Nassellaria; 63 Phaeodaria. They include 1 new genus, 20 new species, 1 new subspecies, 1 new name for a species and 3 new names for subspecies. From E Station alone 208 taxa were found. To my knowledge, such a diversified marine community from the water column has never been reported in science.

(2) The observed vertical flux of individual radiolarian shells in the unit of $\times 10^3$ shells/m².day at each Station was: (E) 16 - 24; (P₁) 0.6 - 17; and (PB) 29 - 44. The radiolarian SiO₂ flux is converted from the radiolarian counts, weight and SiO₂ content data resulting in a range of 22 to 30% of total biogenic SiO₂ flux at Station PB. The values for Stations P₁ and E are higher than realistic because weight values from Station PB were used. These percentages tend to slightly increase with depth indicating that radiolarians are less affected by dissolution in the water column than other components such as diatom fragments.

(3) A total radiolarian diversity index of 3.6 is obtained from Station E. Diversity indices of Spumellaria and Nassellaria from Station

E were uniform below 988 m, suggesting their sinking without much loss due to dissolution (Fig. 29). The diversity index of Nassellaria increased significantly from 389 to 988 m. This is mainly attributed to an introduction of deep water species.

(4) Most of the radiolarian shells recovered from below 1 km were observed to be single rather than being incorporated with biogenic aggregates. Only a few percent of radiolarian shells is in the form of biogenic aggregates and that appeared to be descending more rapidly than the rest of individual shells to the sea floor.

(5) Fragmentation of radiolarian shells are interpreted as an effect of dissolution. Percent broken shell counts of Pterocorys as well as three suborders of Radiolaria suggest that slow dissolution of radiolarian shells takes place through the water column.

(6) Nassellaria and Phaeodaria are decreasing with depth relative to Spumellaria shown by change in N/S and Ph/S ratios.

(7) Phaeodarians and dissolution susceptible polycystines (e.g. Myleastrum and Conicavus) whose sizes are often large, transport a significant amount of SiO_2 to the deep-sea. They quickly release Si either in the water column or on the seafloor depending on their residence time in the water column. Thus, they are playing an important role in quick silica transport and recycling in the ocean.

(8) Estimated excess Si which is derived from SiO_2 dissolution on the sea-floor is fairly small relative to advective Si in the western North Atlantic and thus it appears to be insignificant to show a deviation in a simple mixing curve of deep water masses. This is consistent with previous reports.

(9) When the radiolarian fluxes at the three Stations are compared with Holocene radiolarian accumulation rates in the same areas it became apparent that several percent or less of the fluxes are preserved in the sediments in all cases.

(10) Fundamental dimensions of 58 radiolarian taxa are presented. These include: weight, length, width, projected area, which were measured and computed projected area, bulk volume, skeletal volume and bulk density contrast which were computed.

(11) Mean values of silica content in the skeletons in each suborder show: Spumellaria: 91%; Nassellaria: 98%; and Phaeodaria: 71%.

(12) Observed laboratory sinking speed of 55 radiolarian taxa ranges from 13 to 416 m/day in 3°C still water. The values are best correlated with weight/shell among all the possible combinations of examined variables. The regression line is $\log Y = 0.50 \log X + 1.88$ ($r = 0.86$). By allowing a factor of two the Stokes equation is generally applicable to the sinking speed of less than 250 μm size radiolarians.

(13) Residence time of radiolarian skeletons estimated from the sinking speed ranges from 2 weeks to 14 months in 5 km sea water column; large phaeodarians spend only a few weeks in a water column and hence they reach the abyssal floor essentially intact despite of their soluble skeletons while small-sized species do not reach the bottom but dissolved during descent because of their longer residence times.

(14) Standing stock for abundant species is on the order of 1 to 100 individuals/ m^3 depending on the species and stations. Total radiolarian standing stock ranges from ca. 450 shells/ m^3 at Stations P₁ and E to 1200 shells/ m^3 at Station PB.

(15) Rate of production of total Radiolaria ranges from 77 to 225 shells/ m^3 /day assuming that their production occurs in 200 m of water column.

(16) Turnover time for the studied radiolarian species ranges from several days to a month.

CHAPTER II

SYSTEMATICS OF RADIOLARIA

INTRODUCTION

The high-level classification followed herein is based mainly on that proposed by Riedel (1967a, 1967b, 1971) for polycystines and by Haeckel (1887), Haecker (1908b) and Borgert (1901a, 1906, 1907, 1910, 1911) for phaeodarians with some emendations. A classification given by Takahashi and Honjo (1981) is slightly modified here. Synonymies of taxa include the original descriptions, those which reflect the current usage for polycystines, and relevant ones mainly from plankton and surface sediments. In the case of phaeodarians relatively little documentation has been accomplished thus far and available literature is much less than that for polycystines. Therefore, the author has attempted to list all references for phaeodarians where possible together with giving definitions of families and genera.

OUTLINE CLASSIFICATION

	Plate	Figure
Subclass RADIOLARIA Müller, 1858a		
Order POLYCYSTINA Ehrenberg, 1838, emend. Riedel, 1967a		
Suborder SPUMELLARIA Ehrenberg, 1875		
Family COLLOSPHAERIDAE Müller, 1858a		
<u>Acrosphaera spinosa</u> (Haeckel) <u>longispina</u> , new name	1	1,4
<u>Acrosphaera spinosa</u> (Haeckel) <u>coniculispinga</u> , new name	1	2
<u>Acrosphaera spinosa</u> (Haeckel) <u>coronula</u> , new name	1	5

<u>Acrosphaera murrayana</u> (Haeckel)	1	3,6-11
<u>Acrosphaera cyrtodon</u> (Haeckel)	1	1,13
<u>Acrosphaera spinosa</u> (Haeckel) <u>lappacea</u> (Haeckel)	1	14,16
<u>Clathrosphaera arachnoides</u> Haeckel	1	15
<u>Collosphaera tuberosa</u> Haeckel	2	1-3
<u>Collosphaera confossa</u> n.sp.	2	4-5
<u>Collosphaera armata</u> Brandt	2	6-7,12
<u>Collosphaera huxleyi</u> Müller	2	8-11
<u>Collosphaera macropora</u> Popofsky	2	13-18
<u>Collosphaera polygona</u> Haeckel		
<u>Disolenia collina</u> (Haeckel)	3	1,5-7
<u>Disolenia zanguebarica</u> (Ehrenberg)	3	2-4,8-9
<u>Disolenia quadrata</u> (Ehrenberg)	5	1-5
<u>Disolenia</u> sp. A	5	6
<u>Disolenia</u> sp. B		
<u>Otosphaera tenuissima</u> (Hilmers)	3	11
<u>Otosphaera polymorpha</u> Haeckel	3	12,14-15
<u>Otosphaera auriculata</u> Haeckel	3	10,13
<u>Siphonosphaera magnisphaera</u> n.sp.	4	1,3
<u>Siphonosphaera</u> sp. A	4	2
<u>Siphonosphaera martensi</u> Brandt	4	4-5,7-8
<u>Siphonosphaera</u> sp. B	4	6
<u>Siphonosphaera socialis</u> Haeckel	4	9-12,15-1
6		
<u>Siphonosphaera</u> sp. aff. <u>S. hippotis</u> (Haeckel)	4	13,14
<u>Siphonosphaera polysiphonia</u> Haeckel		
Family SPHAEROZOIDAE Haeckel, 1862, emend. Campbell, 1954		
<u>Rhaphidozoum pandora</u> Haeckel		
Family ETHMOSPHARIDAE Haeckel, 1862		
<u>Plegmosphaera pachypila</u> Haeckel	5	7-9
<u>Plegmosphaera coelopila</u> Haeckel	5	10
<u>Plegmosphaera</u> sp. aff. <u>P. lepticali</u> Renz	5	11
<u>Plegmosphaera</u> sp. A	5	14

	Plate	Figure
<u>Plegmosphaera</u> sp. B	6	1
<u>Plegmosphaera entodictyon</u> Haeckel	6	8,10-11
<u>Plegmosphaera oblonga</u> n.sp.	6	3
<u>Plegmosphaera lepticali</u> Renz		
<u>Plegmosphaera pachyplegma</u> Haeckel		
<u>Styptosphaera spongiacea</u> Haeckel	6	6-7,9
<u>Styptosphaera</u> sp. A	6	12-14
<u>Styptosphaera</u> sp. B	5	12
<u>Styptosphaera</u> sp. C	5	13
<u>Thecosphaera capillacea</u> Haeckel	6	2
<u>Thecosphaera inermis</u> (Haeckel)	11	9
<u>Carposphaera</u> sp. aff. <u>C. corypha</u> Haeckel	9	12
Family ACTINOMMIDAE Haeckel, 1862, emend. Riedel, 1971		
Subfamily ACTINOMMINAE Haeckel, 1862, emend. herein		
<u>Centrocubus cladostylus</u> Haeckel		
<u>Centrocubus octostylus</u> Haeckel	7	1
<u>Spongosphaera polycantha</u> Muller	7	2-3,5
<u>Spongosphaera</u> sp. aff. <u>S. helioides</u> Haeckel	7	4,7-8
<u>Spongosphaera streptacantha</u> Haeckel	7	6
<u>Spongosphaera</u> ? sp. B	7	9
<u>Lynchnosphaera regina</u> Haeckel	7	10
<u>Actinomma acadophorum</u> Haeckel	8	8-9,11
<u>Actinomma capillaceum</u> Haeckel	8	10
<u>Actinomma</u> sp.	13	11
<u>Trilobatum</u> ? <u>acuferum</u> Popofsky		
<u>Acanthosphaera actinota</u> (Haeckel)	8	1
<u>Acanthosphaera tunis</u> Haeckel	8	2,3
<u>Acanthosphaera castanea</u> Haeckel	8	4,5
<u>Acanthosphaera simplex</u> ? (Haeckel)	12	15
<u>Heliosphaera radiata</u> Popofsky		
<u>Cladococcus viminalis</u> Haeckel	8	6

	Plate	Figure
<u>Cladococcus viminalis</u> Haeckel	8	7
<u>Cladococcus abietinus</u> Haeckel	10	5
<u>Cladococcus scoparius</u> Haeckel	10	6-7
<u>Cladococcus cervicornis</u> Haeckel	10	8-10
<u>Arachnosphaera</u> sp.	7	12
<u>Arachnosphaera myriacantha</u> Haeckel	10	11-12
<u>Leptosphaera minuta</u> ? Popofsky	7	11
<u>Leptosphaera</u> sp. group		
<u>Actinosphaera tenella</u> (Haeckel)	9	1
<u>Actinosphaera acanthophora</u> (Popofsky)	9	2,3
<u>Actinosphaera capillacea</u> (Haeckel)	9	4,5
<u>Haliomma</u> ? sp.	8	12
<u>Haliomma castanea</u> Haeckel	9	7,11
<u>Heliosoma</u> spp. aff. <u>radians</u> Haeckel	9	6,8
<u>Elatomma penicillus</u> Haeckel	9	9-10
<u>Elatomma pinetum</u> Haeckel	10	1-4
<u>Astrosphaera hexagonalis</u> Haeckel	11	1-3
<u>Drymosphaera dendrophora</u> Haeckel	11	4
<u>Sphaeropyle mespilus</u> Dreyer	11	7-8
<u>Cromyomma villosum</u> Haeckel	11	10-11
<u>Xiphosphaera gaea</u> Haeckel	12	1,2
<u>Xiphosphaera tesseractis</u> Dreyer	12	3-5
<u>Staurolonche</u> sp. A group		
<u>Staurolonche</u> sp. B		
<u>Stauracontium</u> sp.	12	6
<u>Hexastylus triaxonius</u> Haeckel	12	7,8
<u>Hexastylus</u> sp.	12	9
<u>Hexalonche</u> sp. A	11	14,15
<u>Hexalonche</u> spp. B	12	10-11
<u>Centrolonche hexalonche</u> Popofsky		
<u>Cetracontarium hexacontarium</u> Popofsky		

	Plate	Figure
<u>Hexacontium</u> sp.	12	12
<u>Hexacontium</u> <u>amphisiphon</u> Haeckel	12	13-14
<u>Hexacontium</u> <u>hostile</u> Cleve	13	1-2
<u>Hexacontium</u> <u>arachnoidale</u> Hollande and Enjument		
<u>Hexacontium</u> <u>axotrias</u> Haeckel	13	3
<u>Hexacontium</u> sp. aff. <u>H. hostile</u> Cleve	13	6
<u>Hexacontium</u> <u>heracliti</u> (Haeckel)	15	8-9
<u>Hexacontium</u> <u>hystricina</u> (Haeckel)	15	10
<u>Hexacromyum</u> <u>elegans</u> Haeckel	13	4-5,7
<u>Heterosphaera</u> sp. A	13	9-10
<u>Heterosphaera</u> sp. B	13	8

SYSTEMATICS

Kingdom PROTISTA Haeckel, 1866

Phylum SARCODINA Hertwig and Lesser, 1874

Class ACTINOPODA Calkins, 1909

Subclass RADIOLARIA Müller, 1858a

Order POLYCYSTINA Ehrenberg, 1838, emend. Riedel, 1967a

Suborder SPUMELLARIA Ehrenberg, 1875

Family COLLOSPHAERIDAE Müller, 1858a

Definition: Colonial spumellarians with lattice-shells (and one genus with no skeletal elements) (Riedel, 1971).

Genus ACROSPHAERA Haeckel, 1881

Acrosphaera spinosa (Haeckel) longispina, new name

Plate 1, figures 1,4

Acrosphaera spinosa (Haeckel). - POPOFSKY, 1917, p. 253, text-fig. 16 (partim). - STRELKOV and RESHETNYAK, 1971, p. 340, pl. 6, figs. 39, 41 (partim)

Polysolenia flammabunda (Haeckel). - NIGRINI, 1967, p. 15, pl. 1, fig. 2; NIGRINI and MOORE, 1979, p. S13, pl. 2, fig. 2

Acrosphaera flammabunda (Haeckel). - JOHNSON and NIGRINI, 1980, p. 116, pl. 1, fig. 1, text-fig. 3a

Description: Shell smooth, polyhedron shape, with long radiated spines of up to 1/3 of shell diameter whose bases are elevated, with numerous circular to subcircular small pores of slightly variable size, with fewer number of large pores of about 3-5 times of the small pore diameter. Number of spines is one on the small pore margin and up to several (and occasionally forming coronas) on the large pore margin.

Remarks: Main differences of the present taxon from A. spinosa coniculispira and A. spinosa coronula are length and shape of spines and number of spines on the large pore margin. The author's concept of this subspecies is similar to that of Nigrini (1967) except elimination of forms close to Choenicosphaera flammabunda Haeckel. A view of Popofsky (1917) and Strelkov and Reshetnyak (1971) is lumping all of these three taxa together. On the contrary, Nigrini (e.g. 1967) and her co-workers' view is that they split A. spinosa longispina from A. spinosa coniculispira but lump A. spinosa longispina and A. spinosa coronula together. It is important to note that both Popofsky (1917) and Strelkov and Reshetnyak (1971) describe different forms from one colony (not necessarily in all of the present groups in question though). Such a kind of observation of the colony is the key to improving the taxonomy of colonial Radiolaria. Thus, the four forms presented here may well be the identical taxon in the true biological sense in which case splitting into several subspecies is invalid. However, until further satisfactory information on the colonies of these groups is obtained, the author proposes to classify them into four different subspecies.

Derivation of name: The latin meaning long thorn.

Acrosphaera spinosa (Haeckel) coniculispina, new name

Plate 1, figure 2

Collosphaera spinosa HAECKEL, 1860b, p. 845; 1862, p. 536, pl. 34, figs. 12,13

Acrosphaera spinosa (Haeckel). - BRANDT, 1885, p. 263, pl. 2, fig. 4.
- HAECKEL, 1887, p. 100. - STRELKOV and RESHETNYAK, 1971, p. 340, pl. 5, figs. 33-38, pl. 6, figs. 40,43 (partim). - JOHNSON and NIGRINI, 1980, p. 119, pl. 1, fig. 3. - BOLTOVSKOY and RIEDEL, 1980, p. 144, pl. 1, fig. 6. - TAKAHASHI and HONJO, 1981, p. 144, pl. 1, fig. 6

Polysolenia spinosa (Haeckel). - NIGRINI, 1967, p. 14, pl. 1, fig. 1.
- NIGRINI and MOORE, 1979, p. S19, pl. 2, fig. 5

Remarks: This form is the major component of the present species counts at all the three Stations.

Derivation of name: The name of this species is the Latin meaning conical thorn.

Acrosphaera spinosa (Haeckel) coronula, new name

Plate 1, figure 5

Choenicosphaera flammabunda HAECKEL, 1887, p. 103, pl. 8, fig. 5

Acrosphaera spinosa (Haeckel). - POPOFSKY, 1917, p. 254, text-figs. 14, 15 (partim). - STRELKOV and RESHETNYAK, 1971, p. 340, pl. 8, fig. 59 (partim)

Remarks: Although this taxon is morphologically very different from A. spinosa longispina and A. spinosa coronula, all of these taxa may well be identical taxon which depends on further investigations. This taxon is rare at all the three Stations.

Derivation of name: This subspecies name is a diminutive of the Latin corona meaning crown.

Acrosphaera spinosa (Haeckel) lappacea (Haeckel)

Plate 1, figures 14, 16

Xanthiosphaera lappacea HAECKEL, 1887, p. 120, pl. 8, figs. 10,11

Polysolenia lappacea (Haeckel). - NIGRINI, 1967, p. 16, pl. 1, figs. 3a,b. - NIGRINI and MOORE, 1979, p. S15, pl. 2, figs. 3a,b

Acrosphaera lappacea (Haeckel). - JOHNSON and NIGRINI, 1980, p. 119, pl. 1, fig. 2

Remarks: This taxon is very rare at all three Stations and it did not appear in any of the counting slides.

Acrosphaera murrayana (Haeckel)

Plate 1, figures 3, 6-11

Choenicosphaera murrayana HAECKEL, 1887, p. 102, pl. 8, fig. 4. - BENSON, 1966, p. 120, pl. 2, fig. 3

Trypanosphaera brachysiphon CLEVE, 1900b, p. 13, pl. 6, fig. 3

Polysolenia murrayana (Haeckel). - NIGRINI, 1968, p. 52, pl. 1, fig. 1a-b

Acrosphaera murrayana (Haeckel). - POPOFSKY, 1917, p. 259, text-figs. 22,23. - STRELKOV and RESHETNYAK, 1971, p. 347, text-fig. 25

Remarks: This species is very abundant at the Panama Basin station. Shell diameter is $176 \pm 18 \mu\text{m}$ (2 S.D.) (126 specimens), and its weight is $0.46 \pm 0.01 \mu\text{g}$ (207 specimens). Specimens of two shells splitting apart have been occasionally observed (Pl. 1, figs. 3, 9-10). An SEM view of this species' skeletal cross section (Pl. 1, fig. 11), typical of polycystine skeletons, shows solid silica in contrast to those of porous Phaeodaria (Pls. 47-63).

Acrosphaera cyrtodon (Haeckel)

Plate 1, figures 12-13

Odontosphaera cyrtodon HAECKEL, 1887, p. 102, pl. 5, fig. 6

Acrosphaera cyrtodon (Haeckel). - STRELKOV and RESHETNYAK, 1971, p. 344, pl. 7, fig. 51, pl. 8, fig. 54, text-fig. 24

See Strelkov and Reshetnyak (1971) for a more complete synonymy.

Genus CLATHROSPHAERA Haeckel, 1881

Clathrosphaera arachnoides Haeckel

Plate 1, figure 15

Clathrosphaera arachnoides HAECKEL, 1887, p. 119, pl. 8, fig. 7

Description: Shell elliptical with many elevated cones, numerous straight strands connecting among the cones forming triangular to polygonal geometric network of outer sphere, pores of numerous small subcircular and a few large quadrilateral shape.

Genus COLLOSPHAERA Müller, 1855

Collosphaera tuberosa Haeckel

Plate 2, figures 1-3

Collosphaera tuberosa HAECKEL, 1887, p. 97. - STRELKOV and RESHETNYAK, 1971, p. 336, pl. 4, figs. 24, 25, text-fig. 22. - NIGRINI, 1970, p. 166, pl. 1, fig. 1, text-fig. 2; 1971, p. 445, pl. 34.1, fig. 1. - NIGRINI and MOORE, 1979, p. 51, pl. 1, fig. 1. - JOHNSON and NIGRINI, 1980, p. 119, pl. 1, fig. 8. - BOLTOVSKOY and RIEDEL, 1980, p. 104, pl. 1, fig. 7. - TAKAHASHI and HONJO, 1981, p. 144, pl. 1, fig. 2. See Strelkov and Reshetnyak (1971) and Nigrini (1971) for more complete synonymies.

Collosphaera confossa n.sp.

Plate 2, figures 4-5

Description: Shell single lattice, thin-walled, smooth, spherical to slightly crumpled, with numerous circular to subcircular pores of variable size. Width of the interporous septa is about same as average pore diameter. Number of pores is about 23 on the half perimeter of the shell and twice as many as that of C. huxleyi.

Dimension: Shell diameter: 125-225 μ m

Type locality: 15°21.1'N, 151°28.5'W, sediment trap 5582 m.
Collected during July-November 1978.

Remarks: This taxon is different from C. huxleyi in shell diameter variability, number and size of pores.

Derivation of name: The name of this species is the Latin meaning full of holes.

Disolenia cf. variabilis (Haeckel). - BENSON, 1966, p. 123, pl. 2, fig. 5

Remarks: Bjørklund and Goll (1979, p. 1321, pl. 5, figs. 1-21) described a similar taxon to this species, Trisolenia megalactis megalactis Ehrenberg. The author regards it as a different taxon from the present species because of distinct morphological differences of tubules and pore size of the shells. See the synonymy of O. polymorpha below.

Disolenia sp. A

Plate 5, figure 6

Description: Shell small with three large tubules of cylindrical shape and obliquely truncated. The shell is part of the three connecting tubules and has subcircular pores of finer than interporous septa. Pore size significantly increases (up to more

than five times of the width of interporous septa) and become polygonal toward the terminal end of the tubules.

Dimensions of the illustrated specimen: length of long axis: 150 μm ;
diameter of tubules: 30 μm .

Remarks: This species occurs rarely at the three Stations.

Disolenia sp. B

Disolenia sp. - TAKAHASHI and HONJO, 1981, p. 145, pl. 1, fig. 10

Genus OTOSPHERA Haeckel, 1887, emend. Nigrini, 1967

Genus SIPHONOSPHERA Muller, 1858a

Siphonosphaera magnisphaera n. sp.

Plate 4, figures 1,3

Description: Shell large, spherical, with numerous subcircular to polygonal small pores and 10-17 large polygonal pores of 1/4-1/2 length of the shell diameter. Number of the small and large pores are ca. 30-40 and 2-4 respectively on the half meridian. The large pores form very short tubules.

Dimensions: Shell diameter: 175-220 μm (6 specimens); large pore diameter: 12-65 μm (6 specimens)

Type locality: 15°21.1'N, 151°28.5'W. Sediment trap 378 m.
Collected during July-November 1978.

Remarks: This species has relatively large shell among Collosphaeridae and is different from Siphonosphaera sp. A (Pl. 4, fig. 2) in shell size and number and shape of small and large pores.

Derivation of name: The name of this species is the Latin meaning having the nature of a large sphere.

Siphonosphaera sp. A

Plate 4, figure 2

Description: Shell small and smooth, spherical, with small and large circular to subcircular pores. Interporous septa is wider than large pore diameter. The small pores are much less abundant than those of S. brachyporosa and regularly distributed over the shell wall. The large pores form very short tubules of ca. 1/7 of the pore diameter.

Siphonosphaera martensi Brandt

Plate 4, figures 4-5, 7-8

Siphonosphaera martensi BRANDT, 1905, p. 339, pl. 9, figs. 9-12. -
HILMERS, 1906, p. 80. - STRELKOV and RESHETNYAK, 1971, p. 356, fig.
28. - BOLTOVSKOY and RIEDEL, 1980, p. 104, pl. 1, fig. 8. - TAKAHASHI
and HONJO, 1981, p. 145, pl. 1, fig. 9

Siphonosphaera tenera ? Brandt. - POPOFSKY, 1917, p. 262, text-fig.
27 (partim)

Remarks: The present taxon has pores of variable size which tend to protrude outward and some of the large ones form short straight or conical tubules. Many of the pores are much smaller than width of the interporous septa. Thus, the present taxon is different from S. macropora Strelkov and Reshetnyak (1971, p. 357, text-fig. 29).

Siphonosphaera sp. B

Plate 4, figure 6

Description: Shell spherical, with many large pores of about equal width as interporous septa and fewer small pores of ca. 1/3 of the large pore diameter. There are usually 4-6 large and 1-3 small pores in half meridian. The rims of the large pores are elevated and forming short tubules of ca. 1/4 length of the pore diameter.

Remarks: This species is different from S. partinaria and S. cyathina both described by Haeckel (1887) in height and shape (and size and number for the latter) of the tubules.

Siphonosphaera socialis Haeckel

Plate 4, figures 9-12, 15-16

Siphonosphaera socialis HAECKEL, 1887, p. 106, pl. 6, figs. 1-2. - HILMERS, 1906, p. 74. - POPOFSKY, 1917, p. 264, pl. 16, figs. 1-11, pl. 17, figs. 1-6, text-fig. 29. - STRELKOV and RESHETNYAK, 1971, p. 353, pl. 8, fig. 60, pl. 9, fig. 72, text-fig. 27

Remarks: Specimens shown by Popofsky (1917) and Strelkov and Reshetnyak (1971) are the closest to the ones presented here. Haeckel's specimens of original S. socialis have larger pores than those shown by other workers. S. cf. socialis shown by Benson (1966: p. 121, pl. 2, fig. 4) is similar to the present taxon. S. socialis is preferred to S. polysiphonia because (1) specimens observed here do not have as many prolonged tubules of original S. polysiphonia Haeckel (as pointed also illustrated by Boltovskoy and Riedel, 1980); and (2) There are well illustrated descriptions of this taxon under S. socialis in the above synonymy. All of the specimens of this species observed under SEM have small numerous rectangular prisms or cubic crystals on the shell surface (e.g. pl. 4, fig. 16). This is common to many collosphaerids but never been observed on any other families under the identical desalting procedure. Thus this may be due to the difference in skeletal nature from other groups.

Siphonosphaera polysiphonia HAECKEL, 1887, p. 106. - NIGRINI, 1967, p. 18, pl. 1, figs. 4a, 4b. - RENZ, 1976, p. 89, pl. 1, fig. 7. - NIGRINI and MOORE, 1979, p. S21, pl. 1, figs. 6a,b. - JOHNSON and

NIGRINI, 1980, p. 119. - BOLTOVSKOY and RIEDEL, 1980, p. 104, pl. 1, fig. 9. - TAKAHASHI and HONJO, 1981, p. 145, pl. 1, fig. 8. See Boltovskoy and Riedel (1980) for an additional synonymy.

Siphonosphaera sp. aff. S. hippotis (Haeckel)

Plate 4, figures 13-14

Siphonosphaera sp. aff. S. hippotis (Haeckel). - RENZ, 1976, p. 89, pl. 1, fig. 1

Description: Shell smooth and thick, spherical, with 5-10 tubules of 1/6 to 1/4 length of shell diameter, pores of much smaller and more abundant than those of S. socialis.

Remarks: The present taxon is identical to that shown by Renz (1976).

Family SPHAEROZOIDAE Haeckel, 1862, emend. Campbell, 1954

Definition: Growth exclusively colonial (Campbell, 1954).

Genus RHAPHIDOZOUM Haeckel, 1862

Rhaphidozoum pandora Haeckel

Rhaphidozoum pandora HAECKEL, 1887, p. 49, pl. 4, fig. 6. - TAKAHASHI and HONJO, 1981, p. 144, pl. 1, fig. 1

Family ETHMOSPHAERIDAE Haeckel, 1862

Definition: Without spines on shell surface (Campbell, 1954).

Remarks: Widely used name Liosphaeridae for this family is invalid. See Loeblick and Tappan (1961).

Genus PLEGMOSPHERA Haeckel, 1881

Plegmosphaera pachypila Haeckel

Plate 5, figures 7-9

Plegmosphaera pachypila HAECKEL, 1887, p. 88

Styptosphaera sp. - TAKAHASHI and HONJO, 1981, p. 146, pl. 1, fig. 13

Plegmosphaera coelopila Haeckel

Plate 5, figure 10

Plegmosphaera coelopila HAECKEL, 1887, p. 88

Plegmosphaera sp. aff. P. lepticali Renz

Plate 5, figure 11

Plegmosphaera lepticali RENZ, 1976, p. 115, pl. 1, fig. 14.

Description: Shell ovate, smooth, with single layer of spongy meshwork.

Plegmosphaera sp. A

Plate 5, figure 14

Description: Shell ovate, surface smooth and hollow with irregular spongy meshwork. Thickness of the spongy layer is ca. half radius of the cavity. Radii of axes ratio 1:2.2.

Plegmosphaera sp. B

Plate 6, figure 1

Description: Shell, large, smooth and spherical with single layer of fine spongy meshwork.

Plegmosphaera entodictyon Haeckel

Plate 6, figures 8, 10-11

Plegmosphaera entodictyon HAECKEL, 1887, p. 88. - HOLLANDE and ENJUMET, 1960, p. 103, pl. 48, fig. 1. - BOLTOVSKOY and RIEDEL, 1980, p. 106, pl. 1, fig. 16

? Styptosphaera spongiacea Haeckel. - RENZ, 1976, p. 116, pl. 1, fig. 13

Remarks: A specimen shown in Pl. 6, fig. 8 has inside shell wall closed by a less dense lattice than those of figs. 10-11.

Plegmosphaera oblonga n.sp.

Plate 6, figure 3

Description: Elongate hollow shell made of irregular polygonal spongy meshwork, without spines and with two large circular openings of different sizes on two opposite lateral sides. Either anterior or posterior half is slightly thicker in diameter than the other.

Dimensions: (3 specimens) Shell length: 220-580 μm ; width: 70-220 μm ; radii of axes ratio: 1:2.6-3.0; diameter of lateral openings: 10-60 μm .

Type locality: 5°21'N, 81°53'W, sediment trap depth 667 m.
Collected during August-December 1979.

Remarks: This species is rare in the Panama Basin. Wide size variation is observed.

Derivation of name: The name of this species is the Latin meaning having the nature of longer than broad.

Plegmosphaera lepticali Renz

Plegmosphaera lepticali RENZ, 1976, p. 115, pl. 1, fig. 14. -
TAKAHASHI and HONJO, 1981, p. 146, pl. 1, figs. 15,16

Plegmosphaera pachyplegma Haeckel

Plegmosphaera pachyplegma HAECKEL, 1887, p. 89.-BOLTOVSKOY and
RIEDEL, 1980, p. 106, pl. 1. fig. 17

Genus STYPTOSPHAERA Haeckel, 1881

Styptosphaera spongiacea Haeckel

Plate 6, figures 6-7, 9

Styptosphaera spongiacea HAECKEL, 1887, p. 87

Octodendron nidum TAN and TCHANG, 1976, p. 233, text-fig. 10

Remarks: S. spongiacea shown by Renz (1976) has an inside cavity bounded by latticed wall and hence it should be placed in the genus plegmosphaera.

Styptosphaera sp. A

Plate 6, figures 12-14

Dimensions: Shell diameter (long axis) of the illustrated specimens:
fig. 12: 107 μm ; fig. 13: 190 μm ; and fig. 14: 34 μm .

Remarks: This could be the juvenile form of S. spongiacea.

Styptosphaera sp. B

Plate 5, figure 12

Description: Shell smooth and ovate with irregular polygonal meshwork on the surface which is connected to the central part with fine radial strands.

Dimensions of the illustrated specimen: Diameter of long axis: 240 μm ; short axis: 183 μm .

Styptosphaera sp. C

Plate 5, figure 13

Description: Shell large and ovate with smooth surface. Very fine spongy meshwork, rather dense in the central part and loose in the subsurface layer.

Dimension of the illustrated specimen: Diameter of long axis: 800 μm ; short axis: 710 μm .

Genus THECOSPHAERA Haeckel, 1881

Thecosphaera capillacea Haeckel

Plate 6, figure 2

Thecosphaera capillacea HAECKEL, 1887, p. 81

Thecosphaera inermis (Haeckel)

Plate 11, figure 9

Halionma inerme HAECKEL, 1860a, p. 815

Actinomma inerme HAECKEL, 1862, p. 440, pl. 24, fig. 5

Thecosphaera inermis HAECKEL, 1887, p. 80

Thecosphaera inermis (Haeckel). - BOLTOVSKOY and RIEDEL, 1980, p. 114, pl. 3, fig. 6

Genus CARPOSPHAERA Haeckel, 1881

Carposphaera sp. aff. C. corypha Haeckel

Plate 9, figure 12

Spongoplegma antarcticum Haeckel. - KEANY, 1979, p. 53, pl. 2, fig. 1

? Carposphaera corypha HAECKEL, 1887, p. 75

Remarks: Since specimens observed here as well as the one shown by Keany (1979) do not have spongy cortical shell the generic name of this species is not Spongoplegma. This species is close to Haeckel's illustrated description of Carposphaera corypha, but its cortical shell thickness seems to be much thicker than the latter.

Family ACTINOMMIDAE Haeckel, 1862, emend. Sanfilippo and Riedel, 1980

Definition: Solitary spumellarians with shells spherical or ellipsoidal or modifications of those shapes, but not discoidal, nor equatorially constricted ellipsoids, usually without internal spicules, generally much smaller than orosphaerids (Sanfilippo and Riedel, 1980).

Subfamily ACTINOMMINAE Haeckel, 1862, emend. herein

Definition: Actinommidae excluding Saturnalinae.

Genus CENTROCUBUS Haeckel, 1887.

Centrocubus cladostylus Haeckel

Centrocubus cladostylus HAECKEL, 1887, p. 278, pl. 18, fig. 1. -
TAKAHASHI and HONJO, 1981, p. 148, pl. 4, fig. 1

Centrocubus octostylus Haeckel

Plate 7, figure 1

Centrocubus octostylus HAECKEL, 1887, p. 278

Genus SPONGOSPHAERA Ehrenberg, 1847b

Spongosphaera polycantha Müller

Plate 7, figures 2-3, 5

Spongosphaera polycantha MÜLLER, 1858a, p. 32, pl. 4, figs. 1-4. -
HAECKEL, 1887, p. 282. - HOLLANDE and ENJUMET, 1960, pl. 46, fig. 1

? Spongosphaera streptacantha ? Haeckel. - POPOFSKY, 1912, pl. 8,
fig. 4

Spongosphaera sp. aff. S. helioides Haeckel

Plate 7, figures 4, 7-8

Spongosphaera helioides HAECKEL, 1862, p. 456, pl. 12, figs. 11-13;
1887, p. 283

Remarks: This taxon is similar to S. helioides, but not the same
because radial bi-spines are branching.

Spongosphaera streptacantha Haeckel

Plate 7, figure 6

Spongosphaera streptacantha Haeckel, 1862, p. 455, pl. 26, figs. 1-3; 1887, p. 282. - MAST, 1910, p. 187. - POPOFSKY, 1912, p. 109, text-fig. 22. - HOLLANDE and ENJUMET, 1960 ?, pl. 20, figs. 5-7, pl. 45, fig. 4, pl. 58, fig. 5. - TAN and TCHANG, 1976, p. 234, text-fig. 11

Spongosphaera ? sp. B

Plate 7, figure 9

Description: Shell large polyhedral and made of dense spongy meshwork with 20 thick branched radial spines. Bases of the spines are elevated and hence each shell surface plane becomes convex. Shell surface of pylome end is rather flat.

Genus LYNCHNOSPHERA Haeckel, 1881

Lynchnosphaera regina Haeckel

Plate 7, figure 10

Lynchnosphaera regina HAECKEL, 1887, p. 277, pl. 11, figs. 1-4

Genus ACTINOMMA Haeckel, 1860a, emend. Nigrini, 1967; Bjørklund, 1977

Actinomma acadophorum Haeckel

Plate 8, figures 8-9, 11

Actinomma acadophorum HAECKEL, 1887, p. 255, pl. 29, figs. 7,8. - NIGRINI, 1967, p. 29, pl. 2, fig. 3. - NIGRINI and MOORE, 1979, p. S29, pl. 3, fig. 4

Actinomma capillaceum Haeckel

Plate 8, figure 10

Actinomma capillaceum HAECKEL, 1887, p. 255, pl. 29, fig. 6

Actinomma sp. aff. A. arcadophorum Haeckel and A. medianum Nigrini. -
TAKAHASHI and HONJO, 1981, p. 147, pl. 2, fig. 4

non Actinomma capillaceum NAKASEKO, 1959, p. 11, pl. 3, fig. 2a, 2b.

Remarks: Heliomma capillaceum Haeckel (1862, p. 426, pl. 23, fig. 2;
1887, p. 236) is very similar to this taxon except for the absence of
outer medullary shell.

Actinomma sp.

Plate 13, figure 11

Actinomma sp. B. - TAKAHASHI and HONJO, 1981, p. 147, pl. 2, fig. 6

Description: Similar to Heterosphaera sp. A (Pl. 13, figs. 9, 10),
but this species lacks bi-spines and it has more and shorter
main-spines than the former.

Genus TRILOBATUM Popofsky, 1912

Trilobatum ? acuferum Popofsky

Trilobatum acuferum POPOFSKY, 1912, p. 132, text-fig. 48. - TAKAHASHI
and HONJO, 1981, p. 147, pl. 2, fig. 7

Genus ACANTHOSPHAERA Ehrenberg, 1858

Acanthosphaera actinota (Haeckel)

Plate 8, figure 1

Heliosphaera actinota HAECKEL, 1860a, p. 803; 1862, p. 352, pl. 9, fig. 3; 1887, p. 218. - SCHRÖDER, 1909, p. 20, text-fig. 10

Genus HEXASTYLUS Haeckel, 1881

Hexastylus triaxonius Haeckel

Plate 12, figures 7-8

Hexastylus triaxonius HAECKEL, 1887, p. 175, pl. 21, fig. 2. -
BENSON, 1966, p. 140, pl. 3, figs. 6,7

Hexastylus dictyotus HAECKEL, 1887, p. 176, pl. 21, figs. 8,9

Hexastylus sp.

Plate 12, figure 9

Description: Cortical shell spherical with mesh size of 3-4 times as wide as interporous bars. Six three-bladed spines of as long as shell diameter radiating from the cortical shell lye on two perpendicular planes.

Genus HEXALONCHE Haeckel, 1881

Hexalonche sp. A

Plate 11, figures 14-15

Description: Two small concentric latticed with six equal sized long main-spines (3-3.5 times of shell diameter) of straight or slightly curved and many bi-spines of 1.5 length of shell diameter.

Hexalonche spp. B

Plate 12, figures 10-11

Hexancistra sp. - TAKAHASHI and HONJO, 1981, p. 148, pl. 3, fig. 10

Genus CENTROLONCHE Popofsky, 1912

Centrolonche hexalonche Popofsky

Centrolonche hexalonche POPOFSKY, 1912, pl. 1, fig. 1. - TAKAHASHI and HONJO, 1981, p. 148, pl. 3, fig. 18

Genus CETRACONTARIUM Popofsky, 1912

Centracontarium hexacontarium POPOFSKY, 1912, p. 90, textfig. 4. - TAKAHASHI and HONJO, 1981, p. 148, pl. 3, fig. 17

Genus HEXACONTIUM Haeckel, 1881

Hexacontium sp.

Plate 12, figure 12

Hexacontium amphisiphon Haeckel

Plate 12, figures 13-14

Hexacontium amphisiphon HAECKEL, 1887, p. 182, pl. 25, fig. 2

Remarks: Specimens with more than 6 main-spines have been observed.

Hexacontium hostile Cleve

Plate 13, figures 1-2

Hexacontium hostile CLEVE, 1900a, p. 9, pl. 6, fig. 4. - SCHRODER, 1909, p. 14, text-fig. 6. - GOLL and BJORKLUND, 1971, p. 449, text-fig. 6. - BOLTOVOSKOY and RIEDEL, 1980, p. 112, pl. 2, fig. 13

Hexacontium pachydermum JØRGENSEN, 1905, p.115, pl. 8, figs. 31a,b. - BJORKLUND, 1976, pl. 1, figs. 4-9. - KLING, 1977, pl. 1, fig. 18

? Hexacontium setosum HAECKEL, 1887, p. 198. - CLEVE, 1900a, p. 9, pl. 5, fig. 6. - SCHRÖDER, 1909, p. 13, text-fig. 5

Hexacontium sp. aff. H. hostile Cleve

Plate 13, figure 6

Remarks: This species is similar to H. hostile but has finer mesh.

Hexacontium arachnoidale Hollande and Enjumet

Hexacontium arachnoidale HOLLANDE and ENJUMET, 1960, p. 96, pl. 53,
fig. 1. - BJØRKLUND, 1976b, p. 118, pl. 1, figs. D-F. - TAKAHASHI and
HONJO, 1981, p. 148, pl. 3, fig. 13

Hexacontium axotrias Haeckel

Plate 13, figure 3

Hexacontium axotrias HAECKEL, 1887, p. 192, pl. 24, fig. 3. -
BOLTOVSKOY and RIEDEL, 1980, p. 112, pl. 2, fig. 11. - TAKAHASHI and
HONJO, 1981, p. 148, pl. 3, fig. 14

Remarks: Size of the shell corresponds to Boltovskoy and Riedel
(1980) but much smaller than that illustrated by Haeckel (1887).

Hexacontium heracliti (Haeckel)

Plate 15, figures 8-9

Hexalonche heracliti HAECKEL, 1887, p. 187, pl. 22, fig. 7

Hexacontium cf. heracliti (Haeckel). - BENSON, 1966, p. 158, pl. 4,
figs. 8-10

Hexacontium hystricina (Haeckel)

Plate 15, figure 10

Hexalonche hystricina Haeckel, 1887, p. 187, pl. 25, fig. 6. -
TAKAHASHI and HONJO, 1981, p. 148, pl. 3, fig. 16

Remarks: Generic name is changed here because two medullary shells
were commonly observed in the Pacific Stations.

Genus HEXACROMYUM Haeckel, 1881

Hexacromyum elegans Haeckel

Plate 13, figures 4-5, 7

Hexacromyum elegans HAECKEL 1887, p. 201, pl. 24, fig. 9. - TAKAHASHI
and HONJO, 1981, p. 148, pl. 3, fig. 15

Remarks: Specimens with seven spines are rarely observed.

Genus HETEROSPHAERA MAST, 1910

Heterosphaera sp. A

Plate 13, figures 9-10

Description: Cortical shell very thick and rough surface with regular and circular pores of equal size as large as thickness of the interporous bars and with 7-9 three bladed radial main-spines of shell diameter long and numerous bi-spines as long as 1/3 shell diameter.

Heterosphaera sp. B

Plate 13, figure 8

Remarks: Similar to Heterosphaera sp. A but it has four denticles in the pores.

Genus CROMYECHINUS Haeckel, 1881

Cromyechinus ? sp.

Plate 13, figure 12

Cromyechinus sp. aff. C. borealis (Cleve)

Plate 13, figure 13

See the synonymy below under C. borealis.

Cromyechinus borealis (Cleve)

Actinomma boreale CLEVE, 1899, p. 26, pl. 1, fig. 5c

Chromyomma boreale (Cleve). - JØRGENSEN, 1900, p. 59

Cromyechinus borealis (Cleve). - JØRGENSEN, 1905, p. 117, pl. 8, fig. 35, pl. 9, figs. 36-37. - BJØRKLUND, 1974, p. 20, figs. 5-7; 1976a, pl. 2, figs. 7-15. - TAKAHASHI and HONJO, 1981, p. 147, pl. 2, fig. 8

Genus STOMATOSPHAERA Dreyer, 1889

Stomatospaera sp. A

Plate 13, figure 14

Remarks: Cortical shell ellipsoidal and smooth with circular pores of unequal size. The type species of this genus is S. dinoceras Dreyer (1889, p. 211, pl. 10, fig. 76)

Stomatospaera sp. B

Plate 13, figure 15

Remarks: This and the following sp. B resemble S. dinoceras Dreyer (1889, p. 211, pl. 10, fig. 76) but differ in size of shell and pores and cortical shell surface texture.

Stomatosphaera sp. C

Plate 13, figure 16

Remarks: About twice as large as the above sp. B otherwise similar to that.

Genus STYLACONTARIUM Popofsky 1912

Stylocontarium bispiculum Popofsky

Stylocontarium bispiculum POPOFSKY, 1912, pl. 2, fig. 2. - BENSON, 1966, p. 141, pl. 3, figs. 8-11. - TAKAHASHI and HONJO, 1981, p. 148, pl. 3, fig. 11

Genus STYLOSPHAERA Ehrenberg, 1847a

Stylosphaera ? sp. A

Plate 11, figures 5-6

Remarks: Lacking in polar spines and thus the generic name is tentative.

Stylosphaera melpomene Haeckel

Plate 14, figures 1-2

Stylosphaera melpomene HAECKEL, 1887, p. 135, pl. 16, fig. 1. - TAKAHASHI and HONJO, 1981, p. 147, pl. 2, fig. 14

Genus DRUPPATRACTUS Haeckel, 1887

Drupptractus ostracion Haeckel group

Plate 14, figures 3-4

? Drupptractus ostracion HAECKEL, 1887, p. 326, pl. 16, figs. 9,10

Genus ELLIPSOXIPHIMUM Haeckel, 1887

Ellipsoxiphium palliatum Haecker

Plate 14, figures 11-17

Ellipsoxiphium palliatum HAECKER, 1908a, p. 441, pl. 84, fig. 587

Drupptractus acqilonius Hays. - TAKAHASHI and HONJO, 1981, p. 147,
pl. 3, fig. 5

non Ellipsoxiphium elegans var. palliatum Haeckel, 1887, p.296, pl.
14, fig. 7

non Drupptractus acqilonius HAYS, 1970, p. 214, pl. 1, figs. 4, 5

Description: Two medullary shells spherical to ellipsoidal. Inner cortical shell ellipsoidal and thick with circular pores of relatively uniform size which is about 2-2.5 times as large as the thickness of interporous bars. There are about ten pores on a half equator. Outer cortical shell extremely thin and delicate, consisting of a polygonal meshwork; close to the inner cortical

shell. The meshwork is connected everywhere with inner cortical shell's interporous bars and hence it resembles a form of bi-spines in poorly developed or extensively dissolved specimens. Polar spines dissimilar in length, having ratio of 1:2. The spines are cylindrical up to halfway and become conical distally. The bases of the spines are simply jointed with the inner cortical shell and almost not bladed.

Dimensions: (12 specimens) Length of inner cortical shell major axis: $146 \pm 22 \mu\text{m}$ (2 S.D.); range 148-207 μm . Length of inner cortical shell minor axis: $154 \pm 17 \mu\text{m}$ (2 S.D.); range 136-179 μm . Length of major polar spine: $103 \pm 12 \mu\text{m}$ (2 S.D.); range: 91-119 μm . Length of minor polar spine: $51 \pm 7 \mu\text{m}$ (2 S.D.); range: 38-80 μm . Length of outer medullary shell major axis: 45-60 μm .

Remarks: This species resembles D. acqilonius Hays (HAYS, 1970, p. 214, pl. 1, figs. 4,5. - KLING, 1971, p. 1086, pl. 1, figs. 5,6. - LING, 1975, p. 717, pl. 1, figs. 17, 18; 1980, p. 367, pl. 1, fig. 1; Stylocantarium acqilonium (Hays). - KLING, 1973, p. 634, pl. 1, figs. 17-20, pl. 14, figs. 1-4. - LING, 1973, p. 777, pl. 1, figs. 6,7) but length of the dissimilar polar spines are generally longer and ratio between the spines differs. Delicate meshwork of the outer cortical shell similar to this species has been recorded on some specimens of D. acqilonius (see Ling, 1975, pl. 1, figs. 17,18; Kling, 1973, pl. 14, fig. 2). It is possible that D. acqilonius gave rise to the present species. The polar spines are always cylindro-conical, and not three bladed, and thus the present species differs from Ellipsoxiphus elegans var. palliatus Haeckel (1887, p. 296, pl. 14, fig. 7).

Genus AMPHISPHAERA Haeckel, 1881

Amphisphaera group

Plate 14, figures 6-7

Amphisphaera group. - TAKAHASHI and HONJO, 1981, p. 147, pl. 3, fig. 3

Genus AXOPRUNUM Haeckel, 1887

Axoprunum stauraxonium Haeckel

Plate 14, figures 8-10

Axoprunum stauraxonium HAECKEL, 1887, p. 298, pl. 48, fig. 4. - HAYS, 1965, p. 170, pl. 1, fig. 3. - PETRUSHEVSKAYA and KOZLOVA, 1972, p. 521, pl. 10, fig. 10. - NIGRINI and MOORE, 1979, p. 557, pl. 7, figs. 2,3

? Cromyatractus elegans Dogel. - DUMITRICA, 1972, p. 834, pl. 20, fig. 8

? Amphisphaera cristata Carnevale. - DUMITRICA, 1972, p. 833-834, pl. 20, fig. 10

Remarks: Specimens observed here have thinner shell and smoother surface than those described by Hays (1965) and Nigrini and Moore (1979). Interconnecting rods between medullary and cortical shells lie in the equatorial plane as Petrushevskaya and Kozlova (1972) noted.

Genus XIPHATRACTUS Haeckel, 1887

1a,b

Xiphatractus sp. A

Plate 15, figure 4

? Xiphatractus stahli DREYER, 1889, p. 129, pl. 6, fig. 17

Xiphatractus pluto ? (Haeckel). - TAKAHASHI and HONJO, 1981, p. 147,
pl. 3, fig. 4

Description: Two medullary shells are slightly ellipsoidal.
Cortical shell thick and thorny with dissimilar thick and short polar
spines.

Xiphatractus spp. B

Plate 15, figures 6-7

Description: Cortical shell single and medullary shell double. The
cortical and outer medullary shells are ellipsoidal and made of
hexagonal framework. The cortical shell has short bi-spines or
conical projections at every intersection of interporous bars and has

circular or hexagonal pores of 2-4 times as large as the thickness of the interporous bars. The outer medullary shell has circular pores bounded by interporous bars of the same width as the pore diameter. Cortical-medullary interconnecting rods, which are arising from every intersection of the medullary framework, lie in many planes. Two polar spines are short, smooth conical shape and dissimilar in length.

Remarks: There are variations among specimens in pore size and shape as well as length of the spines and thus these characteristics may correspond to more than one species.

Genus DRUPPATRACTUS Haeckel, 1887

Drupptractus ? sp.

Plate 15, figure 5

Remarks: This species is similar to Drupptractus ? sp. (Dumitrica, 1972, p. 833, pl. 20, fig. 5).

? Haliomma pyriformis BAILEY, 1856, p. 2, pl. 1, fig. 29

Drupptractus cf. pyriformis (Bailey). - BENSON, 1966, p. 177-180, pl. 7, figs. 2-6

Description: Medullary shell single and pear-shaped with circular pores of equal size and spines which become interconnecting rods when cortical shell is present. Cortical shell absent or single, usually thick but variable and rarely thick and hexagonally framed with

single three bladed polar spine of as long as length of the medullary shell main axis.

Dimensions (8 specimens): Length of cortical shell major axis: 74-91 μm ; Length of medullary shell major axis: 47-58 μm ; Length of medullary shell minor axis: 36-45 μm .

Type locality: 15°21.1'W, 151°28.5'W sediment trap depth 4280 m. Collected during July-November 1978.

Remarks: Bailey (1856) illustrated a pear-shaped (pyriformis) shell which may or may not correspond to medullary shell of the present species. However, he did not illustrate nor describe for the cortical shell and hence Benson (1966) was the first one to describe the species. Drupptractus irregularis Popofsky (1913, p. 114-115, text-figs. 24-26. - BENSON, 1966, p. 180, pl. 7, figs. 7-11) also has similar pear-shaped medullary shell to the present species but differs primarily in cortical mesh size.

Derivation of name: This species is named after Dr. Richard N. Benson.

Subfamily SATURNALINAE Deflandre, 1953

Definition: Spherical latticed or spongy shell, with two opposite spines jointed by a ring. In some species, there are no spines and the ring (or two incomplete half-rings) joins the shell directly (Riedel, 1971).

Genus SATURNALIS Haeckel, 1881, emend. Nigrini, 1967

Saturnalis circularis Haeckel

Plate 15, figures 15-18

Saturnalis circularis HAECKEL, p. 131. - NIGRINI, 1967, p. 25, pl. 1, fig. 9. - RENZ, 1976, p. 107, pl. 1, fig. 15. See Nigrini (1967) for a more complete synonymy.

Family COCCODISCIDAE Haeckel, 1862, emend. Sanfilippo and Riedel, 1980

Definition by Sanfilippo and Riedel (1980): Discoidal forms consisting of a lenticular cortical shell enclosing a small single or double medullary shell, and surrounded by an equatorial zone of spongy or concentrically-chambered structure, or forms with ellipsoidal cortical shell, usually equatorially constricted and enclosing a single or double medullary shell, the opposite poles of the shell generally bearing spongy columns and/or single or multiple latticed caps.

Subfamily ARTISCINAE Haeckel, 1881, emend. Riedel, 1967.

Definition: Ellipsoidal coccodiscids (Sanfilippo and Riedel, 1980).

Genus DIDYMOCYRTIS Haeckel, 1881, emend. Riedel, 1971.

Didymocyrtis tetrathalamus tetrathalamus (Haeckel)

Plate 21, figures 1-14

Panartus tetrathalamus HAECKEL, 1887, p. 378, pl. 40, fig. 3. - NIGRINI, 1967, p. 30, pl. 2, figs. 4a-4d

Ommatartus tetrathalamus (Haeckel). - RENZ, 1976, p. 107, pl. 1, fig. 6. - MCMILLEN and CASEY, 1978, pl. 2, figs. 13a, 13b. - BOLTOVOSKOY and RIEDEL, 1980, p. 114, pl. 3, fig. 3. - TAKAHASHI and HONJO, 1981, p. 148, pl. 4, figs. 2-6 (including both subspp. A and B)

Ommatartus tetrathalamus tetrathalamus (Haeckel). - NIGRINI and MOORE, 1979, p. S49, pl. 6, 1a-d. - JOHNSON and NIGRINI, 1980, p. 121, pl. 1, fig. 17

Remarks: Major thick cortical-medullary interconnecting rods lie in the vicinity of equatorial plane and additional minor (thin) rods lie randomly. Development of delicate cortical lateral meshwork as well as polar caps varies significantly. Distinction of two separate forms (subsp. A and B) was possible only at Station E. Juvenile form (pl. 21, fig. 1) of this species is counted separately and reported in the flux table. See Sanfilippo and Riedel (1980, p. 1010) for assignment of the generic name for this species.

Didymocyrtis sp.

Plate 21, figure 15

Description: Cortical shell ellipsoidal and not constricted in the equatorial plane, with coarser meshwork than that of D. tetrathalamus and a few short spines. Double medullary shells same as those of D. tetrathalamus.

Genus SPONGOLIVA Haeckel, 1887

Spongoliva ellipsoides Popofsky

Plate 22, figures 15-16

Spongoliva ellipsoides POPOFSKY, 1912, p. 117, text-fig. 28. - RENZ, 1976, p. 108, pl. 1, fig. 5

Spongoliva cf. ellipsoides Popofsky. - TAKAHASHI and HONJO, 1981, p. 148, pl. 1, fig. 17

? Spongoliva cf. ellipsoides Popofsky. - BENSON, 1966, p. 190, pl. 8,
fig. 6

Family PORODISCIDAE Haeckel, 1881, emend. Petrushevskaya and Kozlova, 1972

For a definition see Petrushevskaya and Kozlova (1972, p. 524).

Genus EUCHITONIA Ehrenberg, 1860b, emend. Haeckel, 1887

Euchitonia elegans (Ehrenberg)

Plate 16, figures 1-6

Pteractis elegans EHRENBERG, 1872a, p. 319; 1872b, p. 299, pl. 8,
fig. 3

Euchitonia elegans (Ehrenberg). - HAECKEL, 1887, p. 535. - NIGRINI,
1967, p. 39, pl. 4, figs. 2a,2b. - NIGRINI and MOORE, 1979, p. S83,
pl. 11, figs. 1a,b. - JOHNSON and NIGRINI, 1980, p. 127, pl. 2, fig.
7. - TAKAHASHI and HONJO, 1981, p. 149, pl. 5, fig. 2

Euchitonia sp. - RENZ, 1976, (partim) p. 93, pl. 3, fig. 2

Remarks: Morphology of the patagium varies considerably but that of
main spongy arms is fairly consistent.

Euchitonia cf. furcata Ehrenberg

Plate 16, fig. 8

Euchitonia furcata EHRENBERG, 1860a, p. 767; 1860b, p. 832; 1872a, p.
308; 1872b, p. 289, pl. 6 (III), fig. 6. - HAECKEL, 1887, p. 532. -
LING and ANIKOUCHINE, 1967, p. 1484, pls. 189, 190, figs. 1-2, 5-7. -
NIGRINI and MOORE, 1979, p. S85, pl. 11, figs. 2a,b. - TAKAHASHI and
HONJO, 1981, p. 149, pl. 3, fig. 6

Remarks: This taxon is usually much smaller than E. elegans and its spongy arms are truncated at the terminal ends. A patagium is rarely seen. Thus, the present taxon may be a juvenile form of E. furcata. Completely developed E. furcata was not observed in my samples.

Euchitonia sp.

Plate 16, figures 9,11

Description: Shell spongy triangular and plate shaped with three short arms of tapering toward terminal ends. The plate surface is slightly convex on both sides. Shell size much smaller than that of E. elegans. A central chamber surrounded by centric rings is about equal size as that of D. profunda.

Remarks: This taxon may well be a juvenile or poorly developed form of other species (e.g. D. profunda).

Genus AMPHIRHOPALUM Haeckel, 1881

Amphirhopalum ypsilon Haeckel

Plate 17, figures 1-3

Amphicraspedum wyvilleanum HAECKEL, 1887, p. 523, pl. 45, fig. 12

Amphirhopalum ypsilon HAECKEL, 1887, p. 522. - NIGRINI, 1967, p. 35, pl. 3, figs. 3a-3d. - LING, 1975, p. 725, pl. 14, fig. 2. - NIGRINI and MOORE, 1979, p. S75-S77, pl. 10, figs. 1a-e. - BOLTOVSKOY and RIEDEL, 1980, p. 117, pl. 3, fig. 16. - JOHNSON and NIGRINI, 1980, p. 121, pl. 2, fig. 5. - TAKAHASHI and HONJO, 1981, p. 149, pl. 5, fig. 1

Amphirhopalum straussii (Haeckel)

Plate 17, figure 4

Tessarastrum straussii HAECKEL, 1887, p. 547, pl. 45, fig. 8. - RENZ, 1976, p. 112, pl. 3, fig. 7

Amphirhopalum cf. Tessarastrum straussii Haeckel. - JOHNSON and NIGRINI, 1980, p. 121, pl. 2, fig. 4, pl. 5, figs. 1,2

Genus STYLODICTYA Ehrenberg, 1847a

Stylodictya validispina Jorgensen

Plate 19, figure 11

Stylodictya validispina JØRGENSEN, 1905, p. 119, pl. 10, figs. 40a,b.
- NIGRINI and MOORE, 1979, p. S103, pl. 13, figs. 5a,b

Stylodictya ? sp.

Stylodictya multispina Haeckel

Plate 20, figures 10,12

Stylodictya multispina HAECKEL, 1860b, p. 842; 1862, p. 496, pl. 29, fig. 5. - RENZ, 1976, p. 111, pl. 3, fig. 13. - MCMILLEN and CASEY, 1978, pl. 2, fig. 17. - BOLTOVSKOY and RIEDEL, 1980, p. 118, pl. 4, figs. 4a-4b. - TAKAHASHI and HONJO, 1981, p. 149, pl. 5, fig. 10

Genus CIRCODISCUS Kozlova, 1972

Circodiscus spp. group

Plate 20, figures 5-9

Ommatodiscus murrayi Dreyer. - TAKAHASHI and HONJO, 1981, p. 150, pl. 5, fig. 11

Description: Shell circular to elliptical and biconvex lenticular disc with a pylome, numerous very small pores, 2 to 4 central rings, and with or without spines.

Remarks: Observed major differences among specimens are number of the central rings and presence/absence of marginal or lateral spines. Porodiscus microporus (Stöhr) illustrated by Renz (1976, p. 109, pl. 3, fig. 15) is very similar to this group. Ommatodiscus murrayi Dreyer (1889, pl. 9, fig. 56) is included in this group. The generic name assigned here is that of Kozlova in Petrushevskaya and Kozlova (1972, p. 526).

Genus STYLOCHLAMYDIUM Haeckel, 1881

Stylochlamyidium venustum (Bailey)

Plate 20, figure 11

Perichlamidium venustum BAILEY, 1856, p. 5, pl. 1, figs. 16,17

Stylochlamyidium venustum (Bailey). - HAECKEL, 1887, p. 515. - LING et al., 1971, p. 711, pl. 1, figs. 7, 8, textfig. 5. - RENZ, 1976, p. 110, pl. 3, fig. 11. - BOLTOVSKOY and RIEDEL, 1980, p. 118, pl. 4, fig. 3

Spongotrochus ? venustum (Bailey). - NIGRINI and MOORE, 1979, p. S119, pl. 15, figs. 3a,b

Stylochlamyidium asteriscus Haeckel

Stylochlamyidium asteriscus HAECKEL, 1887, p. 514, pl. 41, fig. 10. - RENZ, 1976, p. 109, pl. 3, fig. 12. - MCMILLEN and CASEY, 1978, pl. 2, fig. 20. - BOLTOVSKOY and RIEDEL, 1980, p. 118, pl. 4, fig. 2

Genus PORODISCUS Haeckel, 1881

Porodiscus micromma (Harting)

Plate 20, figures 13-14

Flustrella micromma HARTING, 1863, p. 16, pl. 3, fig. 47

Porodiscus micromma (Harting). - BOLTOVSKOY and RIEDEL, 1980, p. 117, pl. 3, fig. 17. - TAKAHASHI and HONJO, 1981, p. 149, pl. 5, figs. 7,8

Family SPONGODISCIDAE Haeckel, 1862, emend. Riedel, 1967a and Petrushevskaya and Kozlova, 1972

Definition: Discoidal, spongy or finely-chambered skeleton which is disposed irregularly or in a dense spiral, or in closely disposed spheres, with or without surficial pore-plate, often with radiating arms or marginal spines, and without a large central phacoid shell. The central chamber is usually not visible (Riedel, 1971; Petrushevskaya and Kozlova, 1972).

Genus SPONGOBRACHIUM Haeckel, 1881

Spongobrachium sp.

Spongobrachium sp.-JONHSON and NIGRINI, 1980, p. 127, textfig. 8f, pl. 2, fig. 13, pl. 5, fig.3

Genus DICTYOCORYNE Ehrenberg, 1860b

Dictyocoryne profunda Ehrenberg

Plate 16, figures 10, 12-13, 15

Dictyocoryne profunda EHRENBERG, 1860a, p. 767; 1872a, p. 307; 1872b, p. 288, pl. 7, fig. 23. - HAECKEL, 1887, p. 592. - NIGRINI and MOORE, 1979, p. S87, pl. 12, fig. 1. - BOLTOVSKOY and RIEDEL, 1980, p. 115, pl. 3, fig. 10. - JOHNSON and NIGRINI, 1980, p. 127, pl. 2, fig. 9

Hymeniastrum euclidis HAECKEL, 1887, p. 531, pl. 43, fig. 13. - BENSON, 1966, p. 222, pl. 12, figs. 1-3. - LING and ANIKOUCHINE, 1967, p. 1488, pl. 191, fig. 3, pl. 192, fig. 3. - NIGRINI, 1970, p. 168, pl. 2, fig. 4, text-fig. 16. - NIGRINI and MOORE, 1979, p. S91, pl. 12, fig. 3. - JOHNSON and NIGRINI, 1980, p. 127, pl. 2, fig. 11. - TAKAHASHI and HONJO, 1981, p. 149, pl. 5, figs. 3-5

Dictyocoryne truncatum (Ehrenberg)

Plate 16, figure 14

Rhopalodictyum truncatum EHRENBERG, 1861b, p. 301. - HAECKEL, 1887, p. 589

Dictyocoryne cf. truncatum (Ehrenberg). - BENSON, 1966, p. 235, pl. 15, fig. 1

Dictyocoryne truncatum (Ehrenberg). - NIGRINI and MOORE, 1979, p. S89, pl. 12, figs. 2a,b. - JOHNSON and NIGRINI, 1980, p. 127, pl. 2, fig. 10

Remarks: The specimen illustrated (Pl. 16, fig. 14) is an end member of the present population close to D. profunda. This species usually has much wider arms which are truncated and the corners are rounded than the illustrated specimen.

Genus SPONGODISCUS Ehrenberg, 1854

Spongodiscus sp. A

Plate 16, figure 7

Spongodiscus sp. aff. S. resurgens Ehrenberg. - RENZ, 1976, p. 96,

Spongodiscus resurgens resurgens Ehrenberg. - PETRUSHEVSKAYA and
BJORKLUND, 1974, p. 40, text-fig. 6

Spongodiscus spp. B group

Plate 19, figures 2-3

Spongodiscus biconcavus Haeckel

Plate 19, figures 4-6

Spongodiscus biconcavus HAECKEL, 1887, p. 577. - POPOFSKY, 1912, p.
143, pl. 6, fig. 2. - TAN and TCHANG, 1976, p. 255, text-fig. 25

Spongaster disymmetricus (Dogel). - PETRUSHEVSKAYA and KOZLOVA, 1972,
p. 528, pl. 21, fig. 14

Elliptical" spongodiscid. - MCMILLEN and CASEY, 1978, pl. 3, fig. 13

See Boltovskoy and Riedel (1980) for a more complete synonymy.

Genus SPONGOTROCHUS Haeckel, 1860b

Spongotrochus sp. A

Plate 19, figure 7

Description: Shell circular flat disc, with numerous fine spines arising from surface as well as edge of the disc, pores small and irregular, and without a pylome.

Spongotrochus sp. B

Spongotrochus sp B.-TAKAHASHI and HONJO, 1981, p. 149, pl. 4, fig. 19

Spongotrochus glacialis Popofsky

Plate 19, figure 10

Spongotrochus glacialis POPOFSKY, 1908, p. 228, pl. 26, fig. 8, pl. 27, fig. 1, pl. 28, fig. 2. - RIEDEL, 1958, p. 227, text-fig. 1, pl. 2, figs. 1,2. - CASEY, 1971b, p. 337, pl. 23.1, figs. 4,5. - KEANY, 1979, p. 54, pl. 2, fig. 7; pl. 5, fig. 7. - BOLTOVSKOY and RIEDEL, 1980, p. 117, pl. 3, fig. 15. - TAKAHASHI and HONJO, 1981, p. 149, pl. 4, fig. 17

Spongotrochus arachnius Haeckel. - POPOFSKY, 1908, p. 227, pl. 26, figs. 5,6,6a,7, pl. 28, fig. 1

Spongotrochus multispinus Haeckel. - RENZ, 1976, p. 97, pl. 3, fig. 9

Genus STYLOSPONGIA Haeckel, 1862

Stylospongia huxleyi Haeckel

Plate 19, figure 8

Stylospongia huxleyi HAECKEL, 1862, p. 473, pl. 28, fig. 7

Stylotrochus huxleyi (Haeckel). - HAECKEL, 1887, p. 586

Genus SPONGOCORE Haeckel, 1887

Spongocore cylindrica (Haeckel)

Plate 17, figures 6-9

Spongurus cylindricus HAECKEL, 1860b, p. 845; 1862, p. 465, pl. 27, fig. 1; 1887, p. 334

Spongocore diplocylindrica HAECKEL, 1887, p. 346. - RENZ, 1976, p. 95, pl. 3, fig. 8

Spongocore puella HAECKEL, 1887, p. 347, pl. 48, fig. 6. - BENSON, 1966, p. 187, pl. 8, figs. 1-3. - NIGRINI, 1970, p. 168, pl. 2, fig. 3. - CASEY, 1971b, p. 341, pl. 23.3, fig. 20. - NIGRINI and MOORE, 1979, p. 569, pl. 8, figs. 5a-c. - TAKAHASHI and HONJO, 1981, p. 149, pl. 4, fig. 20

Spongocore cylindrica (Haeckel). - BOLTOVSKOY and RIEDEL, 1980, p. 116, pl. 3, fig. 12

Remarks: The predated species name cylindrica should replace widely used puella because long spines of cylindrica are dissolved and consequently broken off and become like puella.

Genus SPONGOPYLE Dreyer, 1889

Spongopyle setosa Dreyer

Plate 19, figure 9

Spongopyle setosa DREYER, 1889, p. 119, pl. 11, figs. 97,98. - ?

figs. 18,19. - GOLL and BJØRKLUND, 1974, p. 64, text-fig. 14. -
BOLTOVSKOY and RIEDEL, 1980, p. 116, pl. 3, fig. 11

Spongaster tetras tetras Ehrenberg. - NIGRINI, 1967, p. 41, pl. 5,
figs. 1a,1b; 1970, p. 169, pl. 2, fig. 7. - RENZ, 1976, p. 94, pl. 3,
fig. 4. - NIGRINI and MOORE, 1979, p. S93, pl. 13, fig. 1. - JOHNSON
and NIGRINI, 1980, p. 127, pl. 2, fig. 13. - TAKAHASHI and HONJO,
1981, 148, pl. 4, fig. 9. For a more complete synonymy see Nigrini
(1967).

Spongaster pentas Riedel and Sanfilippo

Plate 17, figures 12-16

Spongaster pentas RIEDEL and SANFILIPPO, 1970, p. 523, pl. 15, fig. 3; 1971, p. 1589, pl. 1D, figs. 5-7; 1978, p. 74, pl. 2, figs. 5-8. - MCMILLEN and CASEY, 1978, pl. 3, fig. 14

Spongaster cf. pentas Riedel and Sanfilippo. - TAKAHASHI and HONJO, 1981, p. 148, pl. 4, fig. 10

Description: Spongy disc typically pentagonal to hexagonal and often up to decagonal. Central area of the disc is elevated and forms a convex mound on one side and a concave depression on the other. The convex mound has much coarser spongy mesh than the rest of the area. The concave area has fine short spines perpendicular to disc plane.

Family MYELASTRIDAE Riedel, 1971

Original Definition: Spogodiscidae with arms much more delicately constructed than the small central area, which is the only part of the skeleton sufficiently robust to be preserved in sediments.

Remarks: Subfamily Myelastrinae of Riedel (1971) is elevated to family level here.

Genus MYELASATRUM Haeckel, 1881, emend. herein

Definition: Porodiscidae with three or four forked, spongy or chambered arms, without a patagium; shell bilaterally symmetric. In the case of three armed species, at least two arms of equal shape and length. In the case of four armed species, two equal anterior arms of different shape from the two equal posterior arms.

Remarks: Haeckel's (1887) definition includes only four forked forms. An appearance of three forked species which is closely related to the four forked group necessitates either establishment of a new genus or emendation of the existing genus. I hereby propose to emend Haeckel's definition.

Myelastrum quadrifolium n.sp.

Plate 18, figures 1-6

Description: Shell large, spongy disc, uniformly very thin and delicate, with four major arms. Central rings similar to those of Euchitonia. All of the four arms are about equal in length and width. Anterior arms are bifurcated and form lobes with slight incisions. Posterior arms are trifurcated and form lobes with more conspicuous incisions than those of the anterior. Sagittal incisions at the posterior end is deep and varying in width from one specimen to another, but the anterior one is shallow. Transverse incisions are shallow.

Dimensions: Length: $704 \pm 49 \mu\text{m}$ (2 S.D.) (n = 12 specimens); width: $757 \pm 51 \mu\text{m}$ (2 S.D.) (n = 12); weight: $2.32 \pm 0.16 \mu\text{g}$ (n = 13).

Type locality: $5^{\circ}21'N$, $81^{\circ}53'W$, sediment trap depth 3791 m.
Collected during August-December 1979.

Remarks: The present species differs from Myelastrum decaceros Haeckel (1887, p. 554, pl. 47, fig. 7) in sagittal and transverse incisions, width ratio between anterior and posterior arms and number of branched subarms. The delicate arms are often almost invisible in Cargile® type B mounting medium, but the central rings are clearly visible.

Derivation of name: The name of this species is the Latin meaning having the nature of four leaves.

Myelastrum trinibrachium n.sp.

Plate 18, figures 7-12

Description: Shell large, uniformly very thin, delicate spongy disc with three tapering arms. Central rings similar to those of Euchitonia. At least a pair of arms equal shape and length and the remaining one equal or slightly different length (longer or shorter). Length of arms 2-6 times diameter of the outermost ring.

Dimensions: Length between terminal ends of the two longest arms: $1027 \pm 120 \mu\text{m}$ (2 S.D.) (n = 7 specimens); weight: $0.75 \pm 0.13 \mu\text{g}$ (n = 16).

Type locality: $5^{\circ}21'N$, $81^{\circ}53'W$, sediment trap depth 1268 m. Collected during August-December 1979.

Remarks: The concentric central rings as well as three arms are generally slightly more conspicuous than those of M. quadrifolium in Cargile[®] type B mounting medium. This species as well as M. quadrifolium are so thin and delicate that specimens are easily broken with a touch of brush. Observations of skeletal cross sections under TEM show solid nature. However, the skeletons of the arms are so thin that only the central rings may be preserved in the bottom sediments.

Derivation of name: The name of this species is the Latin meaning having the nature of three arms.

Family LARNACILLIDAE Haeckel, 1887, emend. Campbell, 1954

Definition: Shell with open gates or annular constrictions; medullary shell trizonal (Campbell, 1854).

Genus LARNACALPIS Haeckel, 1887

Larnacalpis sp.

Plate 21, figures 16-18

Larnacalpis sp. - TAKAHASHI and HONJO, 1981, p. 150, pl. 6, fig. 1

Description: Single ellipsoidal cortical shell connecting with outer medullary shell in similar manner to Octopyle, thus it looks as if constricted in equatorial plane in lateral view. Cortical shell pores of 3-6 times as wide as interporous bars. Some specimens have two additional connecting bars to the medullary shell and/or a pylome with surrounding spines at one polar end. Medullary shell double.

Family PHACODISCIDAE Haeckel, 1881, emend. Campbell, 1954

Definition: Single lenticular latticed cortical shell and single or double medullary shell; without chambered equatorial girdles (Campbell, 1954).

Genus HELIODISCUS Haeckel, 1862

Heliodiscus ? sp.

Plate 22, figure 14

Description: Cortical shell bilaterally convex with numerous conical bispines and circular to subcircular unequal sized pores of as wide as interporous bars. Major spines conical and thicker but not much

longer than the bi-spines, lie on the marginal edge. Shell size is about same as H. asteriscus and H. echiniscus.

Heliodiscus asteriscus Haeckel

Plate 23, figures 1-3

Heliodiscus asteriscus HAECKEL, 1887, p. 445, pl. 33, fig. 8. - NIGRINI, 1967, p. 32, pl. 3, figs. 1a,1b; 1970, pl. 2, fig. 1. - RENZ, 1976, p. 92, pl. 2, fig. 1. - NIGRINI and MOORE, 1979, p. 573, pl. 9, figs. 1,2. - BOLTOVSKOY and RIEDEL, 1980, p. 115, pl. 3, fig. 8. - JOHNSON and NIGRINI, 1980, p. 121, pl. 2, fig. 2. - TAKAHASHI and HONJO, 1981, p. 148, pl. 4, figs. 7,8

Heliodiscus echiniscus Haeckel

Plate 23, figures 4-6

Heliodiscus echiniscus HAECKEL, 1887, p. 448, pl. 34, fig. 5. - NIGRINI, 1967, p. 34, pl. 3, figs. 2a,2b. - JOHNSON and NIGRINI, 1980, p. 121, pl. 2, fig. 3

Heliodiscus asteriscoides HAECKER, 1907a, p. 22, fig. 7; 1908a, p. 444, pl. 83, figs. 578-580

Family THOLONIIDAE Haeckel, 1887, emend. Campbell, 1954

Definition: Cortical shell with 2 to 4 or more annular constrictions separated by 3 to 6 or more cupolas; constrictions in diagonal planes, cupolas in dimensive axes (Campbell, 1954).

Genus THOLOMA Haeckel, 1887

Tholoma metallason Haeckel

Plate 11, figures 12-13

Tholoma metallasson HAECKEL, 1887, p. 672, pl. 10, fig. 13

Cubotholus regularis Haeckel. - RENZ, 1976, p. 113, pl. 1, fig. 18

Family PHYLONIIDAE Haeckel, 1881, emend. Campbell, 1954

Definition: Cortical shell latticed; with 2 to 4 or more symmetrically disposed gates (Campbell, 1954).

Genus HEXAPYLE Haeckel, 1881

Hexapyle dodecantha Haeckel

Hexapyle dodecantha HAECKEL, 1887, p. 569, pl. 48, fig. 16. - RENZ, 1976, p. 113, pl. 1, fig. 11. - TAKAHASHI and HONJO, 1981, p. 150, pl. 6, fig. 3

Hexapyle sp.

Plate 23, figure 7

Remarks: This species is about 1/4 size of H. dodecantha.

Genus OCTOPYLE Haeckel, 1881

Octopyle stenzona Haeckel

Plate 23, figure 8

Octopyle stenzona HAECKEL, 1887, p. 652, pl. 9, fig. 11. - BENSON, 1966, p. 251, pl. 16, figs. 3,4. - NIGRINI and MOORE, 1979, p. S123, pl. 16, figs. 2a,b. - TAKAHASHI and HONJO, 1981, p. 150, pl. 6, fig. 7

Genus TETRAPYLE Müller, 1858b

Tetrapyle octacantha Müller

Plate 23, figures 9-10

Tetrapyle octacantha MÜLLER, 1858b, p. 154; 1858a, p. 33, figs. 1-6.
- BENSON, 1966, p. 245, pl. 15, figs. 3-10. - MCMILLEN and CASEY,
1978, pl. 3, figs. 2a,2b. - NIGRINI and MOORE, 1979, p. S125, pl. 16,
figs. 3a,b. - TAKAHASHI and HONJO, 1981, p. 150, pl. 6, figs. 5,6

Family LITHELIIDAE Haeckel, 1862

Definition: Planispiral cortical shell (Campbell, 1954).

Genus LARCOPYLE Dreyer, 1889

Larcopyle butschlii Dreyer

Plate 22, figures 1-4

Larcopyle butschlii DREYER, 1889, pl. 10, fig. 10. - BENSON, 1966, p.
280, pl. 19, figs. 3-5. - NIGRINI and MOORE, 1979, p. S131, pl. 17,
figs. 1a,b. - TAKAHASHI and HONJO, 1981, p. 150, pl. 5, fig. 15

Larcopyle sp. A

Plate 22, figure 5

Description: Cortical shell ovate and about 1/2 size of L. butschlii
with irregular circular to subcircular pores of as wide as
interporous bars, numerous short spines lie every 2-3 interporous
bars on the cortical shell, and a pylome surrounded by divergent long
spines.

Larcope sp. B

Plate 22, figure 6

Description: Cortical shell smooth, ovate and same size as the above Larcope sp. A with irregular subcircular pores of smaller than interporous wall, conical spines much less than the species A, and a pylome surrounded by divergent spines.

Genus DISCOPE Haeckel, 1887

Discople elliptica HAECKEL, 1887, p. 573, pl. 48, fig. 20. -
TAKAHASHI and HONJO, 1981, p. 150, pl. 5, fig. 14

Genus THOLOSPIRA Haeckel, 1887

Tholospira cervicornis Haeckel group

Plate 22, figures 7-9, 12

Tholospira cervicornis HAECKEL, 1887, p. 700, pl. 49, fig. 5

Tholospira cervicornis Haeckel group. - TAKAHASHI and HONJO, 1981, p. 150, pl. 5, figs. 16-18

Remarks: The present species group is fairly abundant throughout depths in our sediment trap stations.

Tholospira dendrophora Haeckel

Plate 22, figure 11

Tholospira dendrophora HAECKEL, 1887, p. 700, pl. 49, fig. 6

Genus LITHELIUS Haeckel, 1862

Lithelius minor ? Jørgensen

Plate 22, figure 10

Lithelius minor JØRGENSEN, 1899, p. 65-66, pl. 5, fig. 24. - BENSON, 1966, p. 262, pl. 17, figs. 9,10, pl. 18, figs. 1-4

Larcospira minor (Jørgensen). - 1905, p. 121

Genus LARCOSPIRA Haeckel, 1887

Larcospira quadrangula Haeckel

Plate 23, figures 11-12

Larcospira quadrangula Haeckel, 1887, p. 696, pl. 49, fig. 3. - BENSON, 1966, p. 266, pl. 18, figs. 7,8. - NIGRINI, 1970, p. 169, pl. 2, fig. 9, text-fig. 21. - NIGRINI and MOORE, 1979, p. S133, pl. 17, fig. 2. - TAKAHASHI and HONJO, 1981, p. 150, pl. 6, fig. 2

Suborder NASSELARIA Ehrenberg, 1875

Family PLAGIACANTHIDAE Hertwig, 1879, emend. Petrushevskaya, 1971d

Definition: Plagiacanthidea with conical or ovate skeleton. Thorax nearly reduced. The apical spine may form a columella or may approach the front wall of the cephalis. The vertical spine is nearly always present. In the cephalis are developed eucephalic and antecephalic lobes. They are separated by means of the apical arches

which extend in the walls of the cephalis and makes deep furrows (Petrushevskaya, 1971d).

Subfamily PLAGIACANTHINAE Hertwig, 1879, emend. Petrushevskaya, 1971d

Definition: Plagiacanthidae with thorax reduced. The walls of the cephalis also may be reduced. In such cases the skeleton consists only of the spines and arches. The disposition of these elements, unlike all other nasselarian families, may vary within the limits of one species. The central capsule of the appoaxoplastique type (Petrushevskaya, 1971d).

Genus TETRAPECTA Haeckel, 1881, emend. herein

Definition: Plagiacanthidae with 4 equal radial spines, arising from either one of closely located 2 central points. The skeletons form a tetrahedron.

Tetraplecta pinigera Haeckel

Plate 24, figures 1-5

Tetraplecta pinigera HAECKEL, 1887, p. 924, pl. 91, fig. 8

Plectaniscus cortiniscus HAECKEL, 1887, p. 925, pl. 91, fig. 9

Remarks: A priority on genus Tetraplecta is given over Plectaniscus (Haeckel, 1887) since specimen observed here have 4 equal spines. Haeckel's P. cortiniscus has three equal and one short spine but the short one may have been broken since I observed many specimens like P. cortiniscus with four equal spines. Haeckel's two taxa, cited above, are apparently end members of the same species. The four main spines are cylindrical rods in the central area and become three bladed toward terminal ends in contrast to Haeckel's description of all three bladed spines.

Tetraplecta plectaniscus Haeckel

Plate 24, figure 7

Euscenium plectaniscus HAECKEL, 1887, p. 1146, pl. 98, fig. 1

Cladoscenium sp. - TAKAHASHI and HONJO, 1981, p. 150, pl. 6, fig. 13

Tetraplecta corynephorum ? Jørgensen

Plate 24, fig. 6

? Plectanium trigeminum HAECKEL, 1887, pl. 91, fig. 11

Eucenium corynephorum JØRGENSEN, 1900, p. 77; 1905, p. 133, pl. 15,
fig. 70. - BJØRKLUND, 1976a, pl. 7, figs. 1-4

Genus ARCHISCENIUM Haeckel, 1881

Archiscenium quadrispinum ? Haeckel

Archiscenium quadrispinum ? HAECKEL, 1887, p. 1150, pl. 53, fig. 11.
- TAKAHASHI AND HONJO, 1981, p. 150, pl. 6, figs. 10, 11

Genus PLECTANIUM Haeckel, 1881

Plectanium sp.

Plectanium sp.- TAKAHASHI and HONJO, 1981, p. 150, pl. 6, fig. 8

Genus PROTOSCENIUM Jørgensen, 1905

Protoscenium ? sp. - TAKAHASHI and HONJO, 1981, p. 150, pl. 6, fig. 9

Genus CLATHROMITRA Haeckel, 1881, emend. herein

Definition: Plagoniidae with nearly a tetrahedron-shaped latticed shell; five prismatic, three-sided spines.

Remarks: This genus is already classified under the present family by Riedel (1971).

Clathromitra pterophormis Haeckel

Plate 24, figure 8

Clathromitra pterophormis HAECKEL, 1887, p. 1219, pl. 57, fig. 8. -
TAKAHASHI and HONJO, 1981, p. 150, pl. 6, fig. 16

Remarks: Observed specimens here are about twice as large as Haeckel's.

Genus CLADOSCENIUM Haeckel, 1881

Cladoscenium ancoratum Haeckel

Plate 24, figures 9-14

Cladoscenium ancoratum Haeckel, 1887, p. 1149, pl. 53, fig. 13. -
GOLL, 1976, pl. 1, figs. 1-3, 6-8. - TAKAHASHI and HONJO, 1981, p.
150, pl. 6, fig. 14. - PETRUSHEVSKAYA and KOZLOVA, 1979, p. 118,
figs. 304, 476, 477.

Remarks: Mesh size of the cephalis significantly varies among specimens. Some fully grown specimens have bi-spines nearly at terminal end of main spines completely connected to other bi-spines on other main spines (e.g. pl. 24, fig. 10).

Genus SEMANTIS Haeckel, 1887

Semantis gracilis ? Popofsky

Plate 24, figures 15-16

Semantis gracilis POPOFSKY, 1908, p. 268, pl. 30, fig. 5; 1913, p. 298, pl. 28, figs. 7,8

Definition: It lacks a cephalis but has two characteristic glasses-shaped openings formed by connecting skeleton between spines.

Genus DEFLANDRELLA Loeblich and Tappan, 1961

Deflandrella cladophora (Jørgensen)

Plate 24, figure 17

Campylacantha cladophora JØRGENSEN, 1905, p. 129, pl. 12, fig. 47. - Bjørklund, 1976a, pl. 6, figs. 1-6

Deflandrella sp.

Campylacantha sp. - TAKAHASHI and HONJO, 1981, p. 150, pl. 6, fig. 12

Remarks: The generic name used here is that proposed by Loeblich and Tappan (1961, p. 227) which replaces Campylacantha Jørgensen, 1905.

Genus TALARISCUS Loeblich and Tappan, 1961

Talariscus pseudocuboides (Popofsky)

Plate 26, figure 1

Obeliscus pseudocuboides POPOFSKY, 1913, pl. 29, figs. 4,5. -
TAKAHASHI and HONJO, 1981, p. 150, pl. 6, fig. 15

Remarks: The generic name used here is that proposed by Loeblich and
Tappan (1961, p. 227) which replaces Obeliscus Popofsky, 1913.

Genus GONOSPHAERA Jørgensen, 1905

Gonosphaera primordialis ? Jørgensen

Plate 26, figure 2

Gonosphaera primordialis JØRGENSEN, 1905, p. 133, pl. 14, figs.
64-68. - BJØRKLUND, 1976a, pl. 9, figs. 7-10

Genus PHORMACANTHA Jørgensen, 1905

Phormacantha hystrix (Jørgensen)

Plate 26, figure 3

Peridium hystrix JØRGENSEN, 1900, p. 76

Phormacantha hystrix (JØRGENSEN), 1905, p. 132, pl. 14, figs. 59-63.
- TAKAHASHI and HONJO, 1981, p. 150, pl. 6, figs. 17-19

Genus NEOSEMANTIS Popofsky, 1913

Neosemantis distephanus Popofsky

Plate 27, figure 12

Neosemantis distephanus POPOFSKY, 1913, p. 299, pl. 29, fig. 2. -
PETRUSHEVSKAYA, 1971c, p. 152, figs. 77: I-III. - KLING, 1979, p.
309, pl. 1, figs. 15,16. - BOLTOVSKOY and RIEDEL, 1980, pl. 4, fig.
14. - TAKAHASHI and HONJO, 1981, p. 151, pl. 7, fig. 17

Subfamily LOPHOPHAENINAE Haeckel, 1881, emend. Petrushevskaya, 1971d

Definition: Plagiacanthidae with the skeleton consisting of two equal segments: cephalis and thorax. Cephalis with a large eucephalic lobe and a small antecephalic lobe which is not separated from the thorax (Petrushevskaya, 1971d).

Genus ACANTHOCORYS Haeckel, 1881

Acanthocorys cf. variabilis Popofsky

Plate 25, figure 1

Acanthocorys variabilis POPOFSKY, 1913, p. 360, text-figs. 71,72(Only)

Acanthocorys sp. aff. A. variabilis Popofsky. - RENZ, 1976, p. 155, pl. 6, fig. 20

Acanthocorys cf. variabilis POPOFSKY. - TAKAHASHI and HONJO, 1981, p. 151, pl. 7, fig. 1

Genus LOPHOPHAENA Ehrenberg, 1847b

Lophophaena cylindrica (Cleve)

Plate 25, figures 3-5

Acanthocorys variabilis POPOFSKY, 1913, p. 360, text-figs. 74-77 (only). - BENSON, 1966, p. 373, pl. 24, fig. 19

Lophophaena cylindrica (Cleve). - PETRUSHEVSKAYA, 1971c, p. 117, fig. 61, IV-VI. - RENZ, 1976, p. 159, pl. 6, fig. 21. - TAKAHASHI and HONJO, 1981, p. 151, pl. 7, fig. 2

Lophophaena cf. capito Ehrenberg

Plate 25, figures 6-9

? Lophophaena capito EHRENBURG, 1873, p. 242; 1875, pl. 8, fig. 6

Lophophaena cf. capito Ehrenberg. - BENSON, 1966, p. 378, pl. 24, figs. 22,23; pl. 25, fig. 1. - TAKAHASHI and HONJO, 1981, p. 151, pl. 6, fig. 22

Lophophaena decacantha (Haeckel) group

Plate 25, figures 2,8,10

Lithomelissa decacantha HAECKEL, 1887, p. 1208, pl. 56, fig. 2

Lophophaena circumtexta (Popofsky)

Lampromitra circumtexta POPOFSKY, 1913, p. 346, pl. 32, fig. 1, text-fig. 53. - TAKAHASHI and HONJO, 1981, p. 151, pl. 6, fig. 23

Remarks: The author proposes to place the present species under this genus.

Genus HELOTHOLUS Jørgensen, 1905

Helotholus histricosa Jørgensen

Helotholus histricosa Jørgensen, 1905, p. 137, pl. 16, figs. 86-88. - BENSON, 1966, p. 459, pl. 31, figs. 4-8. - TAKAHASHI and HONJO, 1981, p. 151, pl. 7, figs. 6,7

Remarks: Artostrobos joergenseni Petrushevskaya illustrated by Bjørklund (1976a, pl. 11, figs. 12,13) is similar to this species but different because its pores are in transverse rows.

Genus PEROMELISSA Haeckel, 1881

Peromelissa phalacra Haeckel

Plate 25, figures 11-15

Peromelissa phalacra HAECKEL, 1887, p. 1236, pl. 57, fig. 11. -
MCMILLEN and CASEY, 1978, pl. 4, fig. 20. - BOLTOVSKOY and RIEDEL,
1980, p. 122, pl. 5, fig. 3. - TAKAHASHI and HONJO, 1981, p. 151, pl.
7, figs. 3-5

Psilomelissa longispina CLEVE, 1900a, p. 10, pl. 4, fig. 4

Psilomelissa phalacra (Haeckel). - POPOFSKY, p. 283, 1908, pl. 32,
fig. 4

Psilomelissa tricuspidata POPOFSKY, 1908, pl. 32, fig. 9

Psilomelissa tricuspidata abdominalis POPOFSKY, 1908, pl. 33, fig. 4

Lithomelissa monoceras POPOFSKY, 1913, p. 335, text-fig. 43, pl. 32,
fig. 7. - RENZ, 1976, p. 158, pl. 6, fig. 12

Lithomelissa setosa Jorgensen

Plate 25, figures 16-22

Lithomelissa setosa JØRGENSEN, 1900, p. 81, pl. 4, fig. 21; 1905, p.
135, pl. 16, figs. 81-83, pl. 18, figs. 108a,b. - BJØRKLUND, 1976a,
pl. 8, figs. 1-13, pl. 11, figs. 19-23. - KLING, 1977, p. 217, pl. 1,
fig. 2. - BOLTOVSKOY and RIEDEL, 1980, p. 121, pl. 5, fig. 1.

For a more complete synonymy see Boltovskoy and Riedel (1980).

Genus PERIDIUM Haeckel, 1887

Peridium spinipes Haeckel

Plate 26, figures 4-6

Peridium spinipes HAECKEL, 1887, p. 1154, pl. 53, fig. 9. - TAKAHASHI and HONJO, 1981, p. 151, pl. 6, fig. 20

Peridium longispinum JØRGENSEN, 1905, p. 135, pl. 15, figs. 75-79, pl. 16, fig. 80. - BENSON, 1966, p. 359, pl. 23, fig. 27, pl. 24, figs. 1-2 (only) (partim).

Psilomelissa calvata HAECKEL, 1887, p. 1209, pl. 56, fig. 3. - RENZ, 1976, p. 160, pl. 6, fig. 15

Peridium sp.

Peridium sp. - TAKAHASHI and HONJO, 1981, p. 151, pl. 6, fig. 21

Remarks: One spine very long up to five times of shell length and otherwise similar to P. spinipes.

Genus TRISULCUS Popfsky, 1913

Trisulcus triacanthus POPFSKY

Trisulcus triacanthus POPFSKY, 1913, p.354, textfig. 59, 60. - RENZ, 1976, p. 161, pl. 6, fig. 10

Subfamily SETHOPERINIDAE Haeckel, 1881, emend. Petrushevskaya, 1971d

Definition: Plagicanthidae with skeleton consisting of the cephalis surrounded by latticed plates built with branches of the spines.

Three plates attached to a vertical spine and the cephalis and the remaining three plates which may be regarded as a thorax attached to divergent spines and the cephalis. Cephalis pyramidal.

Genus LITHOPILIUM Popofsky, 1913

Lithopilium reticulatum Popofsky

Plate 26, figure 10

Lithopilium reticulatum POPOFSKY, 1913, p. 379, pl. 35, figs. 4,5. -
RENZ, 1976, p. 164, pl. 7, fig. 2

Genus CLATHROCANIUM Ehrenberg, 1860a

Clathrocanium insectum (Haeckel)

Plate 26, figures 7-9

Dictyoceras insectum HAECKEL, 1887, p. 1324, pl. 71, figs. 6,7

Corocalyptra columba (Haeckel). - TAKAHASHI and HONJO, 1981, p. 153,
pl. 9, fig. 16

Description: Abdomen divided from the thorax by a constriction. The cephalis and spines similar to those of C. coarctatum. Abdominal mesh is very delicate and made of irregular polygons.

Clathrocanium coarctatum Ehrenberg

Plate 26, figures 11-13

Lychnocanium fenestratum EHRENBERG, 1860a, p. 767

Clathrocanium coarctatum EHRENBERG, 1872a, p. 303; 1872b, p. 287, pl.
7, fig. 6

Clathrocanium coarctatum HAECKEL, 1887, p. 1211. - POPOFSKY, 1913, p. 341, text-fig. 50

Clathrocanium triomma HAECKEL, 1887, p. 1211, pl. 64, fig. 3

Clathrocanium coronatum POPOFSKY, 1913, p. 342, pl. 33, fig. 1

Clathrocanium cf. coronatum Popofsky. - BENSON, p. 394, pl. 26, figs. 1,2

Clathrocanium ornatum POPOFSKY, 1913, p. 343, pl. 33, fig. 2

Remarks: Apical horn straight, three bladed and its branches are connected with fine strands extending from cephalis and thorax. The apical horn differs from a fenestrated and denticulate horn of C. diadema which is present at E station.

Clathrocanium diadema Haeckel

Clathrocorona diadema HAECKEL, 1881, p. 431

Clathrocanium diadema HAECKEL, 1887, p. 1212, pl. 64, fig. 2. - POPOFSKY, 1913, pl. 32, fig. 4. - MCMILLEN and CASEY, 1978, pl. 5, fig. 5. - TAKAHASHI and HONJO, 1981, p. 151, pl. 7, fig. 8

Genus CALLIMITRA Haeckel, 1881

Callimitra emmae Haeckel

Plate 26, figure 14

Callimitra emmae HAECKEL, 1887, p. 1218, pl. 63, figs. 3,4. - BENSON, 1966, p. 390, pl. 25, fig. 12. - TAKAHASHI and HONJO, 1981, p. 151, pl. 7, fig. 11

Remarks: This species differs from C. annae in absence of the marginal frame of dense geometric meshwork. Beams extending from cephalis toward margins commonly cross each other near the end.

Callimitra annae Haeckel

Plate 26, figure 15

Callimitra annae HAECKEL, 1887, p. 1217, pl. 63, fig. 2

Callimitra agnesae HAECKEL, 1887, p. 1217, pl. 63, fig. 5

Callimitra elisabethae HAECKEL, 1887, p. 1218, pl. 63, fig. 6. -
TAKAHASHI and HONJO, 1981, p. 151, pl. 7, figs. 9-10

Callimitra sp. - RENZ, 1976, p. 162, pl. 7, fig. 1

Remarks: Note presence of a laterally extending tubule from a middle part of the cephalis. The cephalis is made of this solid sheet rather than meshwork. Transverse beams of this species rarely cross each other whereas they commonly cross in C. emmae. The present species resembles the type species of this genus, C. carolotae Haeckel (1887, p. 1217, pl. 63, figs. 1,7,8) but differs in presence of basal marginal dense meshwork. Specimens like C. carolotae have not been observed here and hence it is not included in the synonymy. However, it is quite possible that it may become the name of this species depending on future studies. Sinking experiments show that specimens of this species typically settle in the water column upside down with respect to the orientation of the micrograph in the plate. This is common to most nassellarian species.

Callimitra solocicibrata n.sp.

Plate 27, figures 10-11

Description: Cephalis hemispherical made of thin wall combined with meshwork similar to that of C. annae; a tubule on the cephalis similar to C. giltschii. Three vertical wings are made of much coarser irregular polygonal meshwork than those of C. annae and without conspicuous transverse beams. Thorax pyramidal in the upper half (cephalis side) and become cylindrical near the basal opening; mesh size finer than that of the vertical wings. Terminal ends of spines dented from the vertical wings.

Dimensions: (6 specimens) Cephalis width: 40-80 μm ; Length between two terminal ends of divergent spines: 180-215 μm ; Height (top of apical horn to thorax opening): 235-380 μm ; Apical spine length: 132-182 μm .

Type locality: 5°21'N, 81°53'W Sediment trap depth 3791 m.
Collected during August-December 1979.

Remarks: Considerable difference in size has been observed.

Derivation of name: The name of this species is the Latin meaning having the nature of a coarse sieve.

Genus CLATHROCORYS Haeckel, 1881

Clathrocorys giltschii Haeckel

Plate 26, figure 16, Plate 27, figures 1-3,9

Clathrocorys giltschii HAECKEL, 1887, p. 1220, pl. 64, fig. 9

Genus ANDROSPYRIS Haeckel, 1887

Androspyris reticulidisca n.sp.

Plate 30, figures 12-14

Description: Shell flat disc with two branching feet and a sagittal ring of ca. $1/5 - 1/4$ as long as longitudinal shell length; meshwork with pores of irregular and polygonal shape and increasing in size toward margin where a thick skeletal frame is present. An apical spine small when present.

Dimensions: (20 specimens) Longitudinal length (excluding an apical spine and feet): $363 \pm 45 \mu\text{m}$ (2 S.D.); Width: $336 \pm 19 \mu\text{m}$ (2 S.D.).

Type locality: $5^{\circ}21'N$, $81^{\circ}53'W$ Sediment trap depth 3791 m.
Collected during August-December 1979.

Remarks: This species has finer mesh size and a proportionally smaller sagittal ring than A. huxleyi does. The former is discoidal and has a thick marginal frame whereas the latter is reticular and does not have such a thick frame.

Derivation of name: The name of this species is the Latin meaning a net-like disc.

Androspyris huxleyi (Haeckel)

Genus LIRIOSPYRIS Haeckel, 1881, emend. Goll, 1968

Liriospyris sp.

Plate 30, figure 11

Description: Similar to L. thorax laticapsa including shape, size and position of sagittal ring and its branches, but differs in mesh size and robust outer framework which is the extension of the sagittal branches which encloses the mesh.

Liriospyris thorax (Haeckel) laticapsa n. subsp.

Plate 31, figures 10-11,13

Amphispyris toxarium Haeckel. - BENSON, 1966, p. 293-297, pl. 20,
figs. 3,5-6 (partim)

Description: Sagital ring thick and similar shape to that of L. thorax (Haeckel) whose cross section look like a clover leaf; the ring is proportionally smaller compared to L. reticulata and as long as 1/3 of shell height. Major branches from the sagital ring thick and branch further and spread out fine surface meshwork made of irregular polygons with pores of equal to 3 times as broad as sagital ring thickness. The meshwork forms crests between the branches on lateral side. The meshwork wraps the sagital ring and branch system. Shape of the shell is more or less rectangular prism and length/width ratio is similar to reciprocal of that of L. reticulata.

Dimensions: (8 specimens) length: 160-280 μm ; width: 195-360 μm ;
width/length ratio: 1.15-1.35.

Type locality: 5°21'N, 81°53'W Sediment trap depth 3791 m.
Collected during August-December 1979.

Remarks: The name of this subspecies is the Latin meaning a wide box.

Liriospyris thorax thorax (Haeckel)

For a complete synonymy see Goll (1968).

Family SETHOPHORMIDIDAE Haeckel, 1881, emend. Petrushevskaya, 1971d

Definition: Plagiacanthoidea with flat cephalic skeleton. Thorax, if present, in the shape of an umbrella. Cephalis large, in the form of a tent; with thin walls. The walls of the cephalis are separated from those of the thorax by arches. Pores on the cephalis and on the thorax are different in size and shape (Petrushevskaya, 1971d).

Genus TETRAPHORMIS Haeckel, 1881

Tetraphormis rotula (Haeckel)

Plate 32, figures 1-3

Sethophormis rotula HAECKEL, 1887, p. 1246, pl. 57, fig. 9. - RENZ, 1976, p. 166, pl. 7, fig. 14. - TAKAHASHI and HONJO, 1981, p. 152, pl. 8, fig. 6 (non. fig. 7)

Tetraphormis dodecaster (Haeckel)

Plate 32, figure 7

Sethophormis dodecaster HAECKEL, 1887, p. 1248, pl. 56, fig. 12

Sethophormis cf. dodecaster Haeckel. - TAKAHASHI and HONJO, 1981, p. 152, pl. 8, fig. 8

Tetraphormis butschlii (Haeckel)

Plate 32, figure 6

Dictyophimus butschlii HAECKEL, 1887, p. 1201, pl. 60, fig. 2. - TAKAHASHI and HONJO, 1981, pl. 8, fig. 14

Remarks: The three divergent spines are usually long as Haeckel illustrated. The author proposes to place this species in the genus Tetraphormis.

Genus THEOPHORMIS Haeckel, 1881

Theophormis callipilium Haeckel

Plate 32, figures 9-12

Theophormis callipilium HAECKEL, 1887, p. 1367, pl. 70, figs. 1-3

Sethophormis umbrella HAECKEL, 1887, p. 1248, pl. 70, figs. 4,5

Sethophormis aurelia HAECKEL, 1887, p. 1248, pl. 55, fig. 3. - RENZ, 1976, p. 165, pl. 7, fig. 16

Remarks: Some specimens show faint radial ribs especially in basal view. The number and curvature of the ribs vary among the specimens. Illustrations of T. callipilium by Haeckel represent the best for this taxon and hence the name is selected here.

Genus LAMPROMITRA Haeckel, 1881

Lampromitra schultzei (Haeckel)

Plate 32, figures 4-5

Lampromitra cracentia n. sp.

Plate 32, figure 8

Lampromitra cf. coronata Haeckel. - BENSON, 1966, p. 452, pl. 30,
figs. 9,10 (only) (partim)

Description: Cephaliscap-shaped with small pores. Thorax with
three ribs which penetrate the perimeter and form spines and with
coarse irregular polygonal mesh; marginal mesh forms a zone of fine
mesh with small circular to subcircular pores. Number of short
spines on the perimeter is about 30 and they are conical. The
perimeter of the thorax is an irregularly curved circle.

Dimension: (5 specimens) Thorax diameter: 153-164 μm

Type locality: 5°21'N, 81°53'W, Sediment trap depth 3791 m.
Collected during August-December 1979.

Remarks: This species is rare at PB station.

Derivation of name: The name of this species is the Latin meaning graceful.

DUMITRICA, 1972, p. 838, pl. 24, figs. 8,9

Lampromitra spinosiretis n. sp.

Plate 34, figures 1-2,7

Helotholus histricosa Jorgensen. - BENSON, 1966, p. 459, pl. 31,
figs. 6,7 (only) (partim)

Description: Cephalis hemispherical with several short and long spines of up to thorax length and with circular pores. Thorax conical net-shaped and similar to L. cachoni but has coarser circular to hexagonal meshwork. Radial ribs absent in most specimens. The margin of the thorax thorny.

Dimensions: (8 specimens) Thorax diameter: 175-280 µm; Diameter of pores next to marginal thorns: 20-35 µm

Type locality: 5°21'N, 81°53'W, Sediment trap depth 3791 m.
Collected during August-December 1979

Remarks: This species has slightly convex cone, coarse mesh and many spines on the cephalis whereas L. cachoni has flatter and slightly concave cone, fine mesh and a few short spines on the cephalis.

Derivation of name: The name of this species is the Latin meaning a thorny net.

Genus EUCECRYPHALUS Haeckel, 1860

Eucecryphalus sp.

Plate 33, figure 1

Remarks: This species resembles T. gegenbauri but differs in detail of marginal meshwork.

Eucecryphalus tricostatus (Haeckel)

Plate 33, figures 4,6

Theopilium tricostatum HAECKEL, 1887, p. 1322, pl. 70, fig. 6. -
POPOFSKY, 1913, p. 375, pl. 37, fig. 6. - BENSON, 1966, p. 444, pl.
30, figs. 1,2. - TAKAHASHI and HONJO, 1981, p. 152, pl. 8, fig. 12

? Clathrocyclas latonae HAECKEL, 1887, p. 1389, pl. 59, fig. 7

Clathrocyclas ionis HAECKEL, 1887, p. 1389, pl. 59, fig. 9

Corocalyptra gegenbauri (Haeckel). - POPOFSKY, 1913, p. 384, pl. 34, figs. 1,2.

Theocalyptra gegenbauri - BOLTOVSKOY and RIEDEL, 1980, p. 126, pl. 5, fig. 18 (partim)

Remarks: Mesh size and morphology of the outermost circle varies significantly.

Eucecryphalus europae (Haeckel)

Plate 34, figures 5-6

Clathrocyclus europae HAECKEL, 1887, p. 1388, pl. 59, figs. 11, 12

Eucecryphalus clinatus n.sp.

Plate 35, figures 1-2

Eucecryphalus sp. - BENSON, 1966, p. 450, pl. 30, figs. 6,7. - RENZ, 1976, p. 130, pl. 5, fig. 3

Description: Cephalis hemispherical with small pores and spines. Thethorax smooth and characteristically beret-shaped with regular hexagonal meshwork whose pores are 2-5 times as wide as interporous bars. There are 11-14 rows of pores in thorax in the longest meridian.

Dimensions: (11 specimens) Minimum diameter: 120-145 um; maximum diameter: 150-175 um.

Type locality: 5°21'N, 81°53'W, Sediment trap depth 2869 m. Collected during August-December 1979.

Remarks: This species is abundant at PB Station.

Derivation of name: The name of this species is the Latin meaning slanted.

Genus COROCALYPTRA Haeckel, 1887

Corocalyptra cervus (Ehrenberg)

Plate 33, figures 9-12

Eucyrtidium cervus EHRENBERG, 1872b, p. 291, pl. 9, fig. 21

Corocalyptra cervus (Ehrenberg). - POPOFSKY, 1913, p. 383, pl. 34, fig. 3. - BENSON, 1966, p. 447, pl. 30, figs. 3-5. - RENZ, 1976, p. 129, pl. 5, fig. 2

For a more complete synonymy see BENSON (1966).

Genus PHRENOCODON Haeckel, 1887

Phrenocodon clathrostomium Haeckel

Plate 34, figures 3-4

Phrenocodon clathrostomium HAECKEL, 1887, p. 1434, pl. 70, figs. 7, 8

Genus CLATHROCYCLAS Haeckel, 1881

Clathrocyclas sp.

Plate 34, figure 8

Description: Cephalis cap-shaped with small apical spine and fine pores. Thorax conical, dilated and made of very thick skeleton. Pores on the thorax circular and smaller than interporous bars adjacent to cephalis and increasing their size and become elliptical toward the dilated opening.

Clathrocyclas monumentum (Haeckel)

Plate 34, figures 9-11

Calocyclas monumentum HAECKEL, 1887, p. 1385, pl. 73, fig. 9. - RENZ, 1976, p. 128, pl. 5, fig. 1

Clathrocyclas ? sp. - BENSON, 1966, p. 457, pl. 31, figs. 2,3

Remarks: The apical spine is a conical rod but not three bladed. The author proposes to put this species in the present genus because that it resembles to many species of Clathrocyclas (e.g. C. caassiopejæ listed below), although it does not very much like the type species of the genus, C. principessa Haeckel (1887, p. 1386, pl. 74, fig. 7).

Clathrocyclas cassiopejæ Haeckel

Plate 34, figures 12-14

Clathrocyclas cassiopejæ HAECKEL, 1887, p. 1390, pl. 59, fig. 5

Family THEOPERIDAE Haeckel, 1881, emend. Riedel, 1967a

Definition by Riedel (1967a): Cephalis relatively small, approximately spherical, often poreless or sparsely perforate, the internal spicule, homologous with that of plagoniids, reduced to a less conspicuous structural element than in the latter group.

Subfamily PLECTOPYRAMIDINAE Haecker, 1908a, emend. Petrushevskaya, 1971d

Definition by Petrushevskaya (1971d): Encyrtidiidae with a small dome-shaped cephalis and a vast thorax. Cephalis consists of the encephalic part only, poreless. Thorax sometimes with the upper part poreless. The pores on its middle and lower part quadrangular, disposed in longitudinal rows. Internal spines nearly reduced.

Genus CORNUTELLA Ehrenberg, 1838

Cornutella profunda Ehrenberg

Plate 35, figures 3-9

Cornutella profunda EHRENBERG, 1858, p. 31. - NIGRINI, 1967, p. 60, pl. 6, figs. 5a-5c. - RENZ, 1976, p. 149, pl. 7, fig. 11. - KLING, 1979, p. 309, pl. 1, fig. 21. - BOLTOVSKOY and RIEDEL, 1980, p. 123, pl. 5, fig. 6. - TAKAHASHI and HONJO, 1981, p. 152, pl. 8, fig. 9

Remarks: Significant variations in skeletal thickness and apical spine length have been observed.

Genus PERIPYRAMIS Haeckel, emend. Riedel, 1958

Peripyramis circumtexta Haeckel

Plate 35, figures 10-13

Peripyramis circumtexta HAECKEL, 1887, p. 1162, pl. 54, fig. 5. - RIEDEL, 1958, p. 231, pl. 2, figs. 8,9. - BENSON, 1966, p. 426, pl. 29, fig. 4. - NIGRINI and MOORE, 1979, p. N29, pl. 21, figs. 4a,b. - TAKAHASHI and HONJO, 1981, p. 152, pl. 8, figs. 10-11

Genus LITHARACHNIUM Haeckel, 1860b

Litharachnium tentorium Haeckel

Plate 35, figures 14-18

Litharachnium tentorium HAECKEL, 1860b, p. 836; 1862, p. 281, pl. 4, figs. 7-10; CASEY, 1971, p. 341, pl. 23.3, fig. 11. - RENZ, 1976, p. 150, pl. 7, fig. 6. - BOLTOVSKOY and RIEDEL, 1980, p. 125, pl. 5, fig. 14

Litharachnium eupilium (Haeckel)

Plate 36, figures 1-4

Sethophormis eupilium Haeckel, 1887, p. 1247, pl. 56, fig. 9

Remarks: This species is placed in Litharachnium because of its affinity to L. tentorium.

Subfamily EUCYRTIDIINAE Ehrenberg, 1847b, emend. Petrushevskaya, 1971d

Definition by Petrushevskaya (1971d): Eucyrtidiidae with a cephalis in which only the encephalic part is well developed. Very often it looks like a ball with thick, rough walls. The apical spine forms an apical horn, and the vertical spine may form a small occipital horn. Sometimes they are followed by tubes. The dorsal and lateral spines form the so-called feet. The postthoracic segments may be reduced or consist only of the abdomen. The pores are numerous, disposed in a checkerboard order.

Genus ARCHIPILIUM Haeckel, 1881

Archipilium sp. aff. A. orthopterum Haeckel

Plate 36, figures 5,7

See Archipilium orthopterum HAECKEL, 1887, p. 1139, pl. 98, fig. 7

Genus DICTYOPHIMUS Ehrenberg, 1847a

Dictyophimus sp. A
Plate 37, figure 1

Description: Cephalis nearly spherical with very fine pores and a stout conical apical horn of 2-3 times its length. Three divergent wing-like spines three sided (but not bladed) with grooves. Stout, slightly curved downward and slightly longer than thorax's transverse diameter. Thorax conical with small regular circular pores of narrower than its interporous bars and with numerous accessory spines. Abdomen stout and nearly cylindrical with large circular to hexagonal pores of 4-6 times its interporous bar thickness.

Dictyophimus crisi Ehrenberg
Plate 37, figure 2

Dictyophimus crisiae EHRENBERG, 1854a, p. 241. - NIGRINI, 1967, p. 66, pl. 6, figs. 7a,b. - NIGRINI and MOORE, 1979, p. N33, pl. 22, figs. 1a,b. - JOHNSON and NIGRINI, 1980, p. 127, pl. 3, fig. 9

Pterocorys hirundo HAECKEL, 1887, p. 1318, pl. 71, fig. 4. - LING et al., 1971, p. 715, pl. 2, figs. 8,9

? Pterocorys sp. - BENSON, 1966, p. 412, pl. 28, fig. 4 (partim)

Dictyophimus infabricatus Nigrini

Plate 37, figures 3-5

Dictyophimus infabricatus NIGRINI, 1968, p. 56, pl. 1, fig. 6. - NIGRINI and MOORE, 1979, p. N37, pl. 22, fig. 5

Dictyophimus macropterus (Ehrenberg)

Plate 39, figures 8-11

Lithomelissa macroptera EHRENBERG, 1875, p. 78 (partim), pl. 3, figs. 9-10 (only)

Carpocanarium sp. - RIEDEL and SANFILIPPO, 1971, p. 1599, pl. 11, fig. 21. - RENZ, 1976, p. 117, pl. 4, fig. 4

Remarks: Some specimens show characteristic shell surface ornamentation like ripple marks (e.g. pl. 39, fig. 9).

Dictyophimus sp. B

Plate 39, figure 12

Pterocorys cf. columba Haeckel. - BENSON, 1966, p. 414, pl. 28, fig. 7

Remarks: Three divergent spines extending obliquely downward from the thorax are as long as the length from tip of apical spine to end of abdomen. This species resembles illustrations of P. hirundo and D. insectum by Haeckel (1887, pl. 71, figs. 4,5).

Genus PSEUDODICTYOPHIMUS Petrushevskaya, 1971c

Pseudodictyophimus gracilipes (Bailey)

Plate 37, figures 12-14

Dictyophimus gracilipes BAILEY, 1856, p. 4, pl. 1, fig. 8. - HAECKEL, 1887, p. 1197. - CLEVE, 1899, p. 29, pl. 2, fig. 2. - POPOFSKY, 1908, p. 274, pl. 30, figs. 12,13, pl. 31, fig. 15, pl. 34, fig. 6. - RIEDEL, 1958, p. 233, text-fig. 5, pl. 3, fig. 5. - BOLTOVSKOY and RIEDEL, 1980, p. 124, pl. 5, fig. 8

Pseudodictyophimus gracilipes (Bailey). - PETRUSHEVSKAYA, 1971c, p. 93, fig. 48: I,IV,V. - BJØRKLUND, 1976a, pl. 9, figs. 1-5, pl. 11, figs. 6,7. - KLING, 1979, p. 309, pl. 1, figs. 23,24. - TAKAHASHI and HONJO, 1981, p. 153, pl. 9, figs. 3,4

Genus DICTYOCODON Haeckel, 1881

Dictyocodon elegans (Haeckel)

Plate 37, figures 6-7,9

Artopilium elegans HAECKEL, 1887, p. 1440, pl. 75, fig. 1

Pterocanium cf. elegans (Haeckel). - BENSON, 1966, p. 403, pl. 27, figs. 1,2

Remarks: The author proposes to place this species in the present genus because of the observed morphology shown in the plate including many terminal feet.

Dictyocodon palladius Haeckel

Plate 37, figures 8,10-11

Dictyocodon palladius HAECKEL, 1887, p. 1335, pl. 71, figs. 12,13. -
RENZ, 1976, p. 121, pl. 4, fig. 16

Remarks: Observed specimens have always two large, cephalic spines similar to those of D. elegans. The thorax is not constricted as that of D. elegans and always smooth without any accessory spines. The terminal feet are very delicate and usually poorly preserved. The present species and the above D. elegans are members of the most fragile nassellarians.

Genus CONICAVUS n. gen.

Definition: Conical shell semi-enclosed with very fine irregular, polygonal and non-segmented meshwork, one or two apical horns, three or more basal feet made of the meshwork, one or two apical openings. Basal end of the shell is enclosed by the mesh but has a few large basal pores. Sagital ring absent.

Remarks: The present genus differs from Cephalospyris Haeckel 1881 in the absence of a sagital ring and many other features. The type species: C. tipiopsis n.sp. Position of this genus is uncertain and hence it is tentatively assigned to the present family.

Derivation of name: The name of this genus is the Latin meaning a conical cage.

Conicavus tipiopsis n.sp.

Plate 38, figures 1-6

Description: Shell conical with semi-enclosed irregular and very fine meshwork; numerous triangular to polygonal irregular pores. Sagittal ring and constriction absent. A characteristic apical opening is located on a right or left side of the apical part next to one or two conical apical horns and forms a triangular cavity which has occasionally a frame extending from one of the apical horns. A few circular to oval basal pores vary considerably in size from 1/10 to 1/3 of the shell width. Three to four feet are made of the meshwork, ca. 1/8 of the shell length and extending parallel to a plane of the cone.

Dimensions: Length (31 specimens): $567 \pm 89 \mu\text{m}$ (2 S.D.); Width (36 specimens): $372 \pm 42 \mu\text{m}$.

Type locality: $5^{\circ}21'N$, $81^{\circ}53'W$, Sediment trap depth 3791 m.
Collected during August-December 1979.

Remarks: This species is large in size and commonly observed at PB station but poor preservation in the sediments is expected due to its fragile skeleton.

Derivation of name: The name of this species is from a diminutive of tepee and meaning having the appearance of a tipi.

Genus SETHOCONUS Haeckel, 1881

Sethoconus myxobrachina Strelkov and Reshetnyak

Plate 38, figures 7-8

Sethoconus myxobrachia Strelkov and Reshetnyak. - RENZ, 1976, p. 136,
pl. 5, fig. 4

Genus CONARACHNIUM Haeckel, 1881

Conarachnium polyacanthum (Popofsky)

Plate 39, figures 1-4

Lophocorys polyacantha POPOFSKY, 1913, p. 400, text-fig. 122. -
BENSON, 1966, p. 494 (partim), pl. 34, fig. 3 (only). - KLING, 1979,
p. 309, pl. 1, fig. 27

Remarks: Thorax length and extent of constriction varies
significantly. This and the following two species are apparently
closely related and thus the same generic name Conarachnium is
assigned for these.

Conarachnium parabolicum (Popofsky)

fig. 10. - RENZ, 1976, p. 120, pl. 4, fig. 7. - TAKAHASHI and HONJO,
1981, p. 153, pl. 9, fig. 14

Cyrtopera aglaolampa n.sp.

Plate 40, figures 7-8

Description: Cephalis spherical with a conical stout apical horn 2-3 times of its length and with very small pores. There are 6-8 equal length abdominal segments which gradually increase their width toward the last abdominal chamber. The chamber is ca. 4-6 times as wide as cephalic diameter. Constrictions between the segments are equal or less than those in C. laguncula. There are a few short spines on the thorax as well as on the basal side of the last chamber. Four to five abdominal ribs attached on the wall and extending out of the last chamber and become feet which are as long as the chamber's length and slightly curved inward. Pores circular and small in the thorax and gradually increase their size and become hexagonal toward the last chamber. The last chamber's pores are as wide as 2-3 times thickness of interporous bars.

Dimensions: (5 specimens) Length (cephalis to last chamber): 220-270 μm ; Width (last chamber): 120-195 μm .

Type locality: 15^o21.1'N, 151^o28.5'W, Sediment trap depth 2778 m. Collected during July-November 1978.

Remarks: The apical spines are usually straight and not curved as that of C. laguncula.

Derivation of name: The name of this species is from Greek meaning a beautiful lamp.

Genus STICHOPHORMIS Haeckel, 1881

Stichophormis cf. cornutella Haeckel

? Stichophormis cornutella HAECKEL, 1887, p. 1455, pl. 75, fig. 9

Lophocorys polyacantha Popofsky. - BENSON, 1966, p. 494 (partim), pl. 34, figs. 1,2 (only)

? Stichopilium anacor RENZ, 1976, p. 124, pl. 5, fig. 10

Remarks: Artopilium is a junior objective synonym of Triacartus whose type species, A. elegans, does not resemble this species. The type species of Stichopilium, S. bicorne, does not resemble this species either. Lophocorys is tentatively used here, although the generic assignment is uncertain.

Genus THEOCORYS Haeckel, 1881

Theocorys veneris Haeckel

Plate 40, figures 11-14

Theocorys veneris HAECKEL, 1887, p. 1415, pl. 69, fig. 5. - BENSON, 1966, p. 492, pl. 33, figs. 12,13. - RENZ, 1976, p. 137, pl. 5, fig. 11. - TAKAHASHI and HONJO, 1981, p. 153, pl. 9, fig. 17

Genus THEOCORYTHIUM Haeckel, 1887

Theocorythium trachelium trachelium (Ehrenberg)

Dictyoceras neglectum CLEVE, 1900a, p. 7, pl. 4, fig. 5. - POPOFSKY, 1913, pl. 34, fig. 4. - RENZ, 1976, p. 121, pl. 4, fig. 10

Dictyoceras prismaticum TAN and CHANG, 1976, p. 285 (partim), text-figs. 64,65a,c (only)

Genus LITHOSTROBUS Butschli, 1882

Lithostrobos hexagonalis Haeckel

Plate 41, figures 1-3

Lithostrobos hexagonalis HAECKEL, 1887, p. 1475, pl. 79, fig. 20. -
RENZ, 1976, p. 123, pl. 5, fig. 15. - TAKAHASHI and HONJO, 1981, p.
153, pl. 9, fig. 10

Lithostrobos cf. hexagonalis Haeckel. - BENSON, 1966, p. 508, pl. 35,
figs. 1,2

Genus THEOCALYPTRA Haeckel, 1881

Theocalyptra bicornis (Popofsky)

Plate 41, figures 4-6,8-11

Pterocorys bicornis POPOFSKY, 1908, p. 208, pl. 34, figs. 7,8

Clathrocyclas alcmanae Haeckel. - POPOFSKY, 1913, pl. 37, fig. 4

Theocalyptra bicornis (Popofsky). - RIEDEL, 1958, p. 240, pl. 4, fig.
4. - NIGRINI and MOORE, 1979, p. N53, pl. 24, fig. 1. - LING, 1980,
p. 369, pl. 2, fig. 3

Theocalyptra davisiana davisiana (Ehrenberg). - TAKAHASHI and HONJO,
1981, p. 153, pl. 9, figs. 19,20

Theocalyptra davisiana davisiana (Ehrenberg)

Plate 41, figure 7

Cycladophora ? davisiana EHRENBERG, 1861, p. 297; 1872b, pl. 2, fig.

Theocalyptra davisiana (Ehrenberg). - RIEDEL, 1958, p. 239, pl. 4, figs. 2,3, text-fig. 10. - BENSON, 1966, p. 441 (partim), pl. 29, figs. 14,15 (only). - NIGRINI and MOORE, 1979, p. N59, pl. 24, figs. 2a,b

Cycladophora davisiana davisiana Ehrenberg. - MORLEY, 1980, p. 206, pl. 1, figs. 1-5

Theocalyptra davisiana cornutoides (Petrushevskaya)

Plate 41, figures 12-16

Halicaliptra ? cornuta BAILEY, 1856, p. 5, pl. 1, figs. 13,14 (nomen oblitum)

Theocalyptra davisiana (Ehrenberg). - BENSON, 1966, p. 441 (partim), pl. 29, fig. 16 (only)

Cycladophora davisiana Ehrenberg cornutoides PETRUSHEVSKAYA, 1967, pl. 70, figs. 1-3. - LING et al., 1971, p. 714, pl. 2, figs. 6,7. - MORLEY, 1980, p. 206, pl. 1, figs. 7-10

? Cycladophora davisiana semeloides Petrushevskaya. - MORLEY, 1980, p. 206, pl. 1, figs. 11-14

Theocalyptra davisiana cornutoides (Petrushevskaya). - TAKAHASHI and HONJO, 1981, p. 153, pl. 9, fig. 18

Family PTEROCORYTHIDAE Haeckel, 1881, emend. Riedel, 1967a

Definition by Riedel (1967a): Cephalis subdivided into three lobes by two obliquely downwardly directed lateral furrows arising from the apical spine, in the manner described for Anthocytidium cineraria Haeckel and Calocyclus virginis Haeckel by Riedel (1959).

Genus TETACORETHRA Haeckel, 1881, emend. Petrushevskaya, 1971c

Tetracorethra tetracorethra (Haeckel)

Plate 41, figures 17-18

Tetraspyris tetracorethra HAECKEL, 1887, p. 1044, pl. 53, fig. 19

Tetracorethra tetracorethra (Haeckel). - RENZ, 1976, p. 145, pl. 6,
fig. 23

Genus PTEROCORYS Haeckel, 1881

Pterocorys zancleus (Müller)

Plate 42, figures 1-4

Eucyrtidium zancaeum MÜLLER, 1858a, p. 41, pl. 6, figs. 1-3

Theoconus zancleus (Müller). - BENSON, 1966, p. 482, pl. 33, fig. 4
(not fig. 5)

Pterocorys zancleus (Müller). - NIGRINI and MOORE, 1979, p. N89, pl.
25, figs. 11a, 11b. - TAKAHASHI and HONJO, 1981, p. 154, pl. 10, figs.
1-3

Remarks: The present species is distinguished from P. campanula by
its short conical apical spine, rounded thorax and abdomen and absent
or very small wings.

Pterocorys campanula Haeckel

Plate 42, figures 5-8

Pterocorys campanula HAECKEL, 1887, p. 1316, pl. 71, fig. 3. -
TAKAHASHI and HONJO, 1981, p. 154, pl. 10, figs. 4,5

Genus EUCYRTIDIUM Ehrenberg, 1847a

Eucyrtidium spp. A group

Plate 38, figures 11-13

Eucyrtidium sp. - JOHNSON, 1974, pl. 10, figs. 17,18

Eucyrtidium acuminatum (Ehrenberg)

Plate 42, figures 9-10,16-17,20

Lithocampe acuminatum EHRENBERG, 1844, p. 84

Eucyrtidium acuminatum (Ehrenberg). - EHRENBERG, 1854, p. 43, pl. 22, fig. 27. - POPOFSKY, 1913, p. 406, text-fig. 127. - NIGRINI, 1967, p. 81, pl. 8, figs. 3a,b. - RENZ, 1976, p. 130, pl. 5, fig. 5. - NIGRINI and MOORE, 1979, p. N61, pl. 24, figs. 3a,b. - JOHNSON and NIGRINI, 1980, p. 129, text-fig. 11d, pl. 3, fig. 15

Eusyringium siphonostoma HAECKEL, 1887, p. 1499, pl. 80, fig. 14. - BENSON, 1966, p. 498, pl. 34, figs. 6-9

? Eusyringium cannostoma HAECKEL, 1887, p. 1499, pl. 80, fig. 13

Stichopilium rapaeformis POPOFSKY, 1913, p. 404, text-fig. 126

Remarks: Specimens shown by Benson (1966) are very close to the specimens observed under the transmission light microscope in this study. Thoracic ribs form small wings extended from cephalis, attached on the thorax and terminate in the first abdominal segment. A significant variation in skeletal thickness has been observed.

Eucyrtidium hexagonatum Haeckel

Plate 42, figures 18-19

Eucyrtidium hexagonatum HAECKEL, 1887, p. 1489, pl. 80, fig. 11. -
NIGRINI, 1967, p. 83, pl. 8, figs. 4a,b. - RENZ, 1976, p. 132, pl. 5,
fig. 6. - NIGRINI and MOORE, 1979, p. N63, pl. 24, figs. 4a,b. -
JOHNSON and NIGRINI, 1980, p. 129, text-fig. 11e, pl. 3, fig. 16

Eusyringium siphonostoma Haeckel. - TAKAHASHI and HONJO, 1981, p.
154, pl. 10, fig. 7

Eucyrtidium cienkowskii HAECKEL, 1887, p. 1493, pl. 80, fig. 9

Remarks: A specimen illustrated by Boltovskoy and Riedel (1980, p.
124, pl. 5, fig. 9) has much wider thorax than those observed here
and thus excluded from the above synonymy.

Eucyrtidium anomalum (Haeckel)

Plate 42, figures 11-14

Lithocampe anomala HAECKEL, 1860, p. 839

Eucyrtidium anomalum HAECKEL, 1862, p. 323, pl. 7, figs. 11-13. -
BENSON, 1966, p. 496, pl. 34, figs. 4,5. - DUMITRICA, 1972, pl. 7,
fig. 11. - RENZ, 1976, p. 131, pl. 5, fig. 8. - MCMILLEN and CASEY,
1978, pl. 4, fig. 5

Eucyrtidium sp. aff. E. anomalum (Haeckel)

Plate 42, figure 15

Remarks: Thorax much smaller than that of E. anomalum.

Eucyrtidium dictyopodium (Haeckel)

Plate 42, figure 21

Stichopodium dictyopodium HAECKEL, 1887, p. 1447, pl. 75, fig. 6

Eucyrtidium hexastichum (Haeckel)

Plate 42, figure 22

Lithostrobos hexastichus HAECKEL, 1887, p. 1470, pl. 80, fig. 15. -
BENSON, 1966, p. 506 (partim), pl. 34, figs. 15,16 (only)

Stichopilium annulatum POPOFSKY, 1913, p. 403, pl. 37, figs. 2,3

Eucyrtidium hexastichum (Haeckel). - PETRUSHEVSKAYA, 1971c, p. 221,
fig. 99. - RENZ, 1976, p. 132, pl. 5, fig. 9. - BOLTOVSKOY and
RIEDEL, 1980, p. 124, pl. 5, fig. 10. - TAKAHASHI and HONJO, 1981, p.
153, pl. 9, fig. 12

Genus ANTHOCYRTIDIUM Haeckel, 1881

Anthocyrtidium zanguebaricum (Ehrenberg)

Plate 41, figures 19-22

Anthocyrtis zanguebarica EHRENBERG, 1872a, p. 301; 1872b, p. 285, pl.
9, fig. 12

Anthocyrtium zanguebaricum (Ehrenberg). - HAECKEL, 1887, p. 1277

Anthocyrtis ovata HAECKEL, 1887, p. 1272, pl. 62, fig. 13

Sethocyrtis oxycephalis HAECKEL, 1887, p. 1299, pl. 62, fig. 9

Anthocyrtium oxycephalis (Haeckel). - BENSON, 1966, p. 468, pl. 32,
figs. 3-5

Anthocyrtidium zanguebaricum (Ehrenberg). - NIGRINI, 1967, p. 58, pl. 6, fig. 4. - RENZ, 1976, p. 143, pl. 6, fig. 18. - NIGRINI and MOORE, 1979, p. N69, pl. 25, fig. 2. - JOHNSON and NIGRINI, 1980, p. 129, text-fig. 12b, pl. 3, fig. 19. - TAKAHASHI and HONJO, 1981, p. 153, pl. 9, figure 21

Anthocyrtidium ophirense (Ehrenberg)

Plate 43, figures 1-7

Anthocyrtis ophirense EHRENBERG, 1872a, p. 301; 1872b, p. 285, pl. 9, fig. 13

Anthocyrtidium cineraria HAECKEL, 1887, p. 1278, pl. 62, fig. 16

Anthocyrtidium ophirense (Ehrenberg). - NIGRINI, 1967, p. 56, pl. 6, fig. 3. - RENZ, 1976, p. 143, pl. 6, fig. 25. - NIGRINI and MOORE, 1979, p. N67, pl. 25, fig. 1. - KLING, 1979, p. 309, pl. 2, fig. 21. - JOHNSON and NIGRINI, 1980, p. 129, text-fig. 12a, pl. 3, fig. 18. - TAKAHASHI and HONJO, 1981, p. 154, pl. 9, fig. 22

Remarks: It appears that skeletons of this species are very little dissolved in the water column (Pl. 43, figs. 10-11) as are many other polycystines.

Genus LAMPROCYCLAS Haeckel, 1881

Lamprocyclas maritalis Haeckel polypora Nigrini

Plate 43, figures 12, 15

Lamprocyclas maritalis Haeckel polypora NIGRINI, 1967, p. 76, pl. 7, fig. 6. - KLING, 1979, p. 309, pl. 2, fig. 25. - NIGRINI and MOORE, 1979, p. N77, pl. 25, fig. 5. - JOHNSON and NIGRINI, 1980, p. 129, text-fig. 12e, pl. 3, fig. 22

Lamprocyclas maritalis maritalis Haeckel

Plate 43, figures 8-11, 13-14

Lamprocyclas maritalis maritalis Haeckel. - NIGRINI, 1967, p. 74, pl. 7, fig. 5. - NIGRINI and MOORE, 1979, p. N75, pl. 25, fig. 4. - JOHNSON and NIGRINI, 1980, p. 129, text-fig. 12d, pl. 3, fig. 21. - TAKAHASHI and HONJO, 1981, p. 154, pl. 9, fig. 26

Lamprocyclas maritalis HAECKEL, 1887, p. 1390, pl. 79, figs. 13,14

Genus LAMPROCYRTIS Kling, 1973

Lamprocyrtis ? hannai (Campbell and Clark)

Theoconus junonis HAECKEL, 1887, p. 1401, pl. 69, fig. 7

? Lamprocyclas junonis (Haeckel) group. - PETRUSHEVSKAYA and KOZLOVA, 1972, p. 545, pl. 36, fig. 8

Calocyclus hannai CAMPBELL and CLARK, 1944, p. 48, pl. 6, figs. 21,22

Lamprocyrtis ? hannai (Campbell and Clark). - KLING, 1973, p. 638, pl. 5, figs. 12-14, pl. 12, figs. 10-14. - NIGRINI and MOORE, 1979, p. N83, pl. 25, fig. 8. - JOHNSON and NIGRINI, 1979, p. N83, pl. 25, fig. 8.

Lamprocyclas ? hannai (Campbell and Clark).- TAKAHASHI and HONJO, 1981, p. 154, pl. 9, fig. 25

Lamprocyrtis sp.

Plate 43, figure 16

Conarachnium ? sp. - NIGRINI, 1968, p. 56 (partim), pl. 1, fig. 5b
(only)

Remarks: This taxon differs from L. nigrinia in its larger conical thorax and more hexagonal pores than the latter. However, it may be combined with the latter pending future studies.

Lamprocyrtis nigrinia (Caulet)

Plate 43, figures 17-19

Conarachnium ? sp. - NIGRINI, 1968, p. 56 (partim), pl. 1, fig. 5a
(only)

Conarachnium nigrinia CAULET, 1971, p. 3, pl. 3, figs. 1-4, pl. 4,
figs. 1-4

Lamprocyrtis haysi KLING, 1973, p. 639, pl. 5, figs. 15,16, pl. 15,
figs. 1-3. - SANFILIPPO and RIEDEL, 1974, p. 1022, pl. 3, figs. 9,10.
- RIEDEL and SANFILIPPO, 1978, p. 69, pl. 5, fig. 9

Lamprocyrtis nigrinia Caulet. - NIGRINI and MOORE, 1979, p. N81, pl.
25, fig. 7. - KLING, 1979, p. 309, pl. 2, fig. 26. - JOHNSON and
NIGRINI, 1980, p. 129, text-fig. 13a, pl. 3, fig. 24

Family ARTOSTROBIIDAE Riedel, 1967b, emend. Foreman, 1973

Definition: Radiolarians with six collar pores, a well-developed vertical tube, no appendages, and the pores of at least one major segment arranged in transverse rows. They may have a smooth or ridged surface, and the last segment is not flared (Foreman, 1973).

Genus SPIROCYRTIS Haeckel, 1881

Spirocyrtis scalaris Haeckel

Plate 44, figure 1-2

Spirocyrtis scalaris HAECKEL, 1887, p. 1509, pl. 76, fig. 14. - RENZ,
1976, p. 142, pl. 6, fig. 1. - NIGRINI, 1977, pl. 2, fig. 12. -
JOHNSON and NIGRINI, 1980, p. 135, text-fig. 14e, pl. 4, fig. 9. -
TAKAHASHI and HONJO, 1981, p. 154, pl. 10, fig. 15

Spirocyrtis subscalaris Nigrini

Plate 44, figures 3-6

Spirocyrtis subscalaris NIGRINI, 1977, p. 259, pl. 3, figs. 1,2. -
LING, 1980, p. 368, pl. 2, fig. 21

Spirocyrtis sp. aff. S. seriata Jørgensen and S. subscalaris Nigrini

Spirocyrtis seriata JØRGENSEN, 1905, p. 140, pl. 18, figs. 102-104. -
BJORKLUND, 1976a, pl. 10, figs. 7-12

Spirocyrtis subscalaris NIGRINI, 1977, p. 259, pl. 3, figs. 1,2

Spirocyrtis sp. aff. S. seriata Jørgensen and S. subscalaris Nigrini.
- TAKAHASHI and HONJO, 1981, p. 154, pl. 10, fig. 16

Spirocyrtis ? platycephala (Ehrenberg) group

Plate 44, figures 7-8

Lithomitra platycephala ? (Ehrenberg). - BJØRKLUND, 1976a, p. 1124,
pl. 11, figs. 17,18

Remarks: Pores are much larger and the angle of the siphon is larger than those of S. subscalaris.

Genus ARTOSTROBUS Haeckel, 1887

Artostrobos annulatus (Bailey)

Plate 38, figures 9-10

Cornutella ? annulata BAILEY, 1856, p. 3, pl. 1, figs. 5a,5b

Artostrobos annulatus (Bailey). - HAECKEL, 1887, p. 1481. - RENZ, 1976, p. 117, pl. 4, fig. 5. - LING, 1975, p. 731, pl. 13, fig. 10. - TAKAHASHI and HONJO, 1981, p. 154, pl. 10, fig. 8

Genus BOTRYOSTROBUS Haeckel, 1887

Botryostrobos aquilonaris (Bailey)

Plate 44, figures 9-13

Eucyrtidium aquilonaris BAILEY, 1856, p. 4, pl. 1, fig. 9

Eucyrtidium tumidium BAILEY, 1856, p. 5, pl. 1, fig. 11

Botryostrobos aquilonaris (Bailey). - NIGRINI, 1977, p. 246, pl. 1, fig. 1. - NIGRINI and MOORE, 1979, p. N99, pl. 27, fig. 1. - KLING, 1979, p. 309, pl. 2, fig. 18. - JOHNSON and NIGRINI, 1980, p. 135, text-fig. 14a, pl. 4, fig. 5. - TAKAHASHI and HONJO, 1981, p. 154, pl. 10, figs. 9,10

For a synonymy prior to 1977 see Nigrini (1977).

Remarks: Variations in pore size, shell surface texture and position of the largest post-cephalic segment have been observed.

Genus PHORMOSTICHOARTUS Campbell, 1951, emend. Nigrini, 1977

Phormostichoartus corbula (Harting)

Plate 44, figures 14-16

Lithocampe corbula HARTING, 1863, p. 12, pl. 1, fig. 21

Siphocampe corbula (Harting). - NIGRINI, 1967, p. 85, pl. 8, fig. 5.
- RIEDEL and SANFILIPPO, 1971, p. 1601, pl. 1H, figs. 18-25. - RIEDEL
and SANFILIPPO, 1978, p. 73, pl. 9, fig. 7. - RENZ, 1976, p. 141, pl.
6, fig. 8

Phormostichoartus corbula (Harting). - NIGRINI, 1977, p. 252, pl. 1,
fig. 10. - JOHNSON and NIGRINI, 1980, p. 135, text-fig. 14c, pl. 4,
fig. 7. - TAKAHASHI and HONJO, 1981, p. 154, pl. 10, figs. 13,14

Genus SIPHOCAMPE Haeckel, 1887

Siphocampe nodosaria (Haeckel)

Lithomitra nodosaria HAECKEL, 1887, p. 1484, pl. 79, fig. 1. -
PETRUSHEVSKAYA and KOZLOVA, 1972, pl. 24, figs. 29,30

Lithomitra eruca HAECKEL, 1887, p. 1485, pl. 79, fig. 3. -
PETRUSHEVSKAYA and KOZLOVA, 1972, p. 539, pl. 24, figs. 32,33

Siphocampe nodosaria (Haeckel). - NIGRINI, 1977, p. 256, pl. 3, fig.
11. - TAKAHASHI and HONJO, 1981, p. 154, pl. 10, figs. 11,12

Siphocampe lineata (Ehrenberg)

Eucyrtidium lineatum arachneum Ehrenberg, 1861b, p. 299

Lithomitra vanhoffeni POPOFSKY, 1908a, p. 296, pl. 36, fig. 9

Lithomitra arachnea (Ehrenberg). - RIEDEL, 1958, p. 242, pl. 4, figs.
7,8. - PETRUSHEVSKAYA, 1966, p. 232, text-fig. 7(4). - 1971b,
text-fig. 22.4b; 1975, p. 586, pl. 10, figs. 13-17

Remarks: Genus Siphocampe is assigned here in order to conform with
the generic name of other species in this group.

Genus ARTOBOTRYS

Artobotrys borealis (Cleve)

Plate 44, figure 24, Plate 45, figures 1-3

Theocorys borealis CLEVE, 1899, p. 33, pl. 3, fig. 5.

Artobotrys borealis (Cleve). - BJØRKLUND, 1976, p. 1124, pl. 11,
figs. 24-27

Family CARPOCANIIDAE Haeckel, 1881, emend. Riedel, 1967b

Definition: Cephalis small, not sharply distinguished in contour from thorax, and tending to be reduced to a few bars within top of thorax (Riedel, 1971).

Genus CARPOCANISTRUM Haeckel, 1887

Carpocanistrum flosculum Haeckel

Plate 45, figures 4,6-7

Carpocanistrum flosculum HAECKEL, 1887 p. 1171, pl. 52, fig. 9

Carpocanium verecundum HAECKEL, 1887, p. 1284, pl. 52, fig. 12, 13

Carpocanium petalospyris Haeckel. - BENSON, 1966, p. 434 (partim), text-fig. 25, pl. 29, fig. 10 (only)

Carpocanium spp. - NIGRINI, 1970, p. 171 (partim), pl. 4, figs. 5,6

Carpocanistrum spp. - DUMITRICA, 1972, p. 838, pl. 14, fig. 4, pl. 15, figs. 11,12, pl. 24, fig. 1,3,6. - RENZ, 1976, p. 151, pl. 6, fig. 4. - NIGRINI and MOORE, 1979, p. N23 (partim), pl. 21, figs. 1b,c. - JOHNSON and NIGRINI, 1980, p.127 (partim), text-fig. 9f, pl. 3, fig. 5. - TAKAHASHI and HONJO, 1981, p. 155, pl. 10, figs. 21,22

Remarks: Pore size varies. Terminal teeth present on the peristome in well developed specimens.

Carpocanistrum cephalum Haeckel

Plate 45, figures 5,12

Carpocanistrum cephalum HAECKEL, 1887, p.1171, pl. 52, fig. 10

Carpocanistrum evacuatum HAECKEL, 1887, p. 1172, pl. 52, fig. 11

Carpocanium petalospyris Haeckel. - BENSON, 1966, p. 434 (partim),
pl. 29, fig. 9 (only)

Carpocanium sp. - BENSON, 1966, p. 438, pl. 29, figs. 11,12

Carpocanium sp. A. - NIGRINI, 1968, p. 55, pl. 1, fig. 4. - NIGRINI
and MOORE, 1979, p. N25, pl. 21, fig. 2

Remarks: This species is distinguished by its cylindrical shape
rather than amphora-shaped counterparts in the present genus.
Present species differs from Cryptoprora ornata Ehrenberg (see
Sanfilippo and Riedel, 1973, p. 530, pl. 35, figs. 3,4).

Carpocanistrum favosum (Haeckel)

Plate 45, figure 8

Sethamphora favosa HAECKEL, 1887, p. 1252, pl. 57, fig. 4

Carpocanistrum ? odysseus Haeckel. - DUMITRICA, 1972, p. 838, pl. 15,
fig. 10, pl. 24, fig. 2

Remarks: Basal opening rather small surrounded by terminal teeth
whose surface is smooth. Shell surface rough caused by numerous
rounded denticles. This species should not be confused with
Carpocanopsis favosa (Haeckel) (Sanfilippo et al., 1973, p. 224, pl.
6, figs. 7,8).

Carpocanistrum coronatum (Ehrenberg)

Plate 45, figure 10

Carpocanium coronatum EHRENBERG, 1875, p. 66, pl. 5, fig. 7

Carpocanistrum sp. D. - LING, 1975, p. 730, pl. 12, fig. 6

Carpocanistrum spp. - NIGRINI, 1970, p. 171 (partim), pl. 4, fig. 4 (only). - NIGRINI and MOORE, 1979, p. N23 (partim), pl. 21, fig. 1a (only)

Remarks: Pores smaller and more in number than in the relative species shown in Pl. 45. The number is ca. 16-18 in an equatorial half meridian.

Carpocanistrum sp.

Plate 45, figure 11

Remarks: This taxon resembles some of specimens shown by Riedel and Sanfilippo (1971, see Pl. 2F).

Carpocanistrum acutidentatum n.sp.

Plate 45, figures 9,13-15

Description: Shell thick and ovate with cephalis completely hidden, pores elongate but occasionally subcircular and smaller than longitudinal crests. There are ca. 14-18 such crests in a half meridian. Peristome surrounded by ca. 12-16 sharp conical teeth of 1/4 to 3/4 shell length which are straight or inwardly curved near the terminal end. One tooth is connected with 1-3 crests.

Dimensions: (11 specimens) Shell length (exclusive of teeth): 87-110 μm ; tooth length: 24-71 μm ; transverse width: 80-96 μm .

Type locality: 15°21.1'N, 151°28.5'W, Sediment trap depth 4280 m. Collected during July-November 1978.

Remarks: The present species differs from C. flosculum Haeckel primarily pore shape and presence of the strong crests.

Derivation of name: The name of this species is the Latin meaning sharp tooth.

Genus CARPOCANARIUM Haeckel, 1887, emend. Nigrini and Moore, 1979

Carpocanarium papillosum (Ehrenberg)

Plate 45, figures 16-17

Eucyrtidium papillosum EHRENBERG, 1872a, p. 310; 1872b, p. 293, pl. 7, fig. 10

Dictyocryphalus papillosus (Ehrenberg). - HAECKEL, 1887, p.1307. - RIEDEL, 1958, p. 236, pl. 3, fig. 10, text-fig. 8. - NIGRINI, 1967, p. 63, pl. 16, fig. 6. - LING, 1975, p. 731, pl 13, fig. 10. - RENZ, 1976, p. 139, pl. 6, fig. 9

Carpocanarium papillosum (Ehrenberg) group. - NIGRINI and MOORE, 1979, p. N27, pl. 21, fig. 3. - JOHNSON and NIGRINI, 1980, p. 127, text-fig. 10a, pl. 3, fig. 6

Carpocanarium papillosum (Ehrenberg). - TAKAHASHI and HONJO, 1981, p. 155, pl. 10, fig. 17

Family CANNOBOTRYIDAE Haeckel, 1881, emend. Riedel, 1967a

Definition by Riedel (1967a): Cephalis consisting of two or more unpaired lobes, only one of which is homologous with the cephalis of theoperids.

Genus ACROBOTRYS Haeckel, 1881

Acrobotrys teralans Renz

Plate 45, figures 18-19

Acrobotrys cf. disolenia Haeckel. - BENSON, 1966, p. 339, text-fig. 21, pl. 23, figs. 13,14

Gen. et sp. indet. - RIEDEL and SANFILIPPO, 1971, pl. 1J, figs. 17,18

Acrobotrys teralans RENZ, 1976, p. 152, pl. 7, fig. 8

? Neobotrys sp. - TAN and CHANG, 1976, p. 273, text-fig. 46

Acrobotrys tessarolobon n.sp.

Plate 45, figure 20

Description: Cephalis quadrilobate with a single tubule projecting laterally. The cephalic lobes of unequal size and shape. Main cephalic lobe spherical and exposing nearly half of its surface area and with fine circular pores and thick skeleton. A polar lobe of the cephalis is conical shape and characteristically projecting straight poleward. It has fine circular pores of much smaller than the interporous septae. The largest lobe lies between the conical polar lobe and post-cephalic lobe. A collar constriction forms an upside down wide angle "V" and has a few fine spines. Postcephalic lobe cylindrical and with circular pores which are at least latitudinally regularly arranged and with a large basal opening. There is no wing.

Dimensions: (3 specimens) Length: 95-110 μ m; Breadth (including the tubule): 85-98 μ m.

Type locality: 15°21.1'N, 151°28.5'W, Sediment trap depth 978 m. Collected during July-November 1978.

Remarks: This species differs from A. teralans in number and shape of the cephalic lobes and its absence of wings.

Derivation of name: The name of this species is Greek meaning four lobes.

Acrobotrys chelinobotrys n.sp.

Plate 45, figures 22-24

Botryopyle dictyocephalus Haeckel group. - RENZ, 1976, p. 154, pl. 7, fig. 10

Acrobotrys sp. A. - TAKAHASHI and HONJO, 1981, p. 155, pl. 10, fig. 18

Description: Cephalis trilobate with a single tapering tubule which is laterally or obliquely (toward postcephalic side) projecting. The three cephalic lobes unequal in size and shape. The central lobe of the cephalis is spherical, exposing 1/4 of its surface on outside and having the thickest skeleton and the smallest pore size among all of the lobes. A collar stricture between the cephalic lobes and a postcephalic lobe makes an arch. The postcephalic lobe nearly cylindrical but tapering toward basal opening. Both cephalis and thorax are made of meshwork with subcircular irregular pores whose diameter varies from 1-4 times the interporous bars. There is no wing.

Dimension: (11 specimens) Length: 80-105 μ m; Breadth (excluding the tubule): 40-60 μ m

Type locality: 15°21.1'N, 151°28.5'W, Sediment trap depth 978 m. Collected during July-November 1978.

Remarks: This species apparently differs from Botryopyle dictyocephalus group illustrated by Riedel and Sanfilippo (1971, p. 1602, pl. 1J, fig. 21-26) typically in presence of a tubule.

Derivation of name: The name of this species is from Greek meaning netted cluster of grapes.

Acrobotrys sp. C

Acrobotrys sp. C - TAKAHASHI and HONJO, 1981, p. 155, pl. 10, fog. 20

Genus SACCOSPYRIS Haecker, 1908b

Saccospyris preantarctica Petrushevskaya

Plate 45, figure 21

Saccospyris preantarctica PETRUSHEVSKAYA, 1975, p. 589, pl. 13, figs. 19,20

Remarks: The present finding of this species indicates that it has long range at least back to Miocene. This species resembles Bisphaerocephalus minutus Popofsky (1908a, pl. 33, fig. 9).

Genus CENTROBOTRYS Petrushevskaya, 1965

Centrobotrys thermophila Petrushevskaya

Plate 46, figures 1-2

Androspyris aptenodytes Haeckel. - POPOFSKY, 1913, p. 294, text-figs. 17,18

Genus NEOBOTRYS Popofsky, 1913

Neobotrys quadrituberosa Popofsky

Plate 46, figure 3

Neobotrys quadrituberosa POPOFSKY, 1913, p. 320-321, pl. 30, fig. 4

Botryocyrtis sp. A

Plate 46, figures 4-5

Description: Cephalis trilobate with very fine pores, spines and rough surface. Thorax cylindrical and short with irregular circular pores.

Remarks: This could be a juvenile form of B. scutum.

Genus BOTRYOCYRTIS Ehrenberg, 1860b

Botryocyrtis scutum (Harting)

Plate 46, figures 6-7

Haliomma scutum HARTING, 1863, p. 11, pl. 1, fig. 18

Botryocyrtis caput serpentis EHRENBERG, 1872a, p. 301; 1872b, p. 287, pl. 10, fig. 21

? Lithobotrys homunculus POPOFSKY, 1913, p. 317, pl. 31, figs. 5,6

Botryopyle erinaceus POPOFSKY, 1913, p. 319, text-figs. 28,28a

Botryocyrtis scutum (Harting). - NIGRINI, 1967, p. 52, pl. 6, figs. 1a-1c. - NIGRINI and MOORE, 1979, p. N105, pl. 28, figs. 1a,b. - TAKAHASHI and HONJO, 1981, p. 155, pl. 10, figs. 23,24

Botryocyrtis elongatum n.sp.

Plate 46, figures 8-9

Description: Cephalis trilobate with spherical lobes of increasing size from one side to another, a few spines longer than lobes, rough surface and very small pores. Thorax elongate and cylindrical and 2-3 times of cephalic length with fine spines and pores, rough surface in the anterior half and become porous and smooth in the posterior half which looks hyaline under the transmission light microscope. There is no segmentation in the thorax.

Dimensions: (8 specimens) Length: 65-160 μm ; Width: 35-64 μm

Type locality: 5°21'N, 81°53'W, Sediment trap depth 3769 m.
Collected during August-December 1979.

Remarks: This species is common at P₁ and PB stations.

Derivation of name: The name of this species the Latin meaning prolonged.

Family ARCHIPHORMIDIDAE Haeckel, 1881

Definition: Phaenocalpida with the basal mouth of the shell open (Haeckel, 1887).

Arachnocalpis ? sp. A

Plate 46, figure 10

Description: Large ellipsoidal shell with fine spongy and fragile network composed of irregular size polygons and without an apical horn, spines, and sagital ring.

Remarks: This species is very rare. The systematic position of this taxon position is uncertain.

Arachnocalpis sp. B

Plate 46, figure 11

Arachnocalpis?ovatiretalis n.sp.

Plate 46, figures 12-14

Description: Shell ovate with a fragile thin mesh composed of polygons and a basal opening at one pole, without an apical horn, spines, ribs and a sagital ring. Usually one pole is slightly protruded from the ellipsoidal perimeter but some specimens have smooth poles. The polygons of the network are mostly triangular. There are two kinds of interconnecting networks: thin and thick ones. Size of the polygons is ca. 1-4 times thickness of the thicker mesh.

Dimensions: (8 specimens) Length: 175-290 μ m; Width: 105-205 μ m;
Mean Length/Width Ratio: 1.62 ± 0.16

Type locality: 5^o21'N, 81^o53'W, Sediment trap depth 667 m.
Collected during August-December 1979

Remarks: Position of this species is uncertain because there is no closely related species to this has been reported and thus the present assignment is tentative.

Derivation of name: The name of this species is the Latin meaning having the nature of an egg-shaped net.

Arachnocalpis ? sp. C

Plate 46, figure 16

Description: Shell elongate fragile spongy network with tubules associated with 7-10 large pores.

Remarks: Very rare and systematic position is uncertain.

Genus ARACHNOCALPIS Haeckel, 1881

Arachnocalpis ellipsoides Haeckel

Plate 46, figure 17

Arachnocalpis ellipsoides HAECKEL, 1887, p.1172, pl. 98, fig. 13

Order TRIPYLEA Hertwig, 1879

Suborder PHAEODARIA Haeckel, 1879

Family CHALLENGERIIDAE Murray, 1876, emend. herein

Definition: Shell ovate or lens-shaped with a mouth and peristome and is usually provided with oral teeth, but without articulated feet. Surface of the shell usually smooth with numerous regularly arranged pores and some species bear a zone of dimples causing

alveolate surface. Skeletal unit of shell made of amphora structure cemented with soluble silica.

Remarks: The above emendation bases on the following reasons: 1) finding of a form without oral teeth (i.e. C. lingi n. sp.); 2) information on surface morphology (i.e. smooth and alveolate surfaces); and 3) SEM-TEM information on micro- and ultra skeletal structures.

Genus CHALLENGERON Haeckel, 1887, emend. herein

Definition: Challengerida without pharynx. Shell smooth without dimples. Marginal spines present in well developed individuals. Oral teeth may be present or absent.

Remarks: The emendation is made for the same reasons as 1) and 2) in the above Challengeriidae.

Challengeron willemoesii Haeckel

Plate 47, figures 1-14

Challengeron willemoesii HAECKEL, 1887, p. 1659, pl. 99, fig. 13 - BORGERT, 1911, p. 456, pl. 34, figs. 4-6 - TAKAHASHI and HONJO, 1981, p. 155, pl. 10, figs. 25,29

Challengeron rottenburgi BORGERT, 1892, p. 182, pl. 6, fig. 1; 1911, p. 458, pl. 35, figs. 1,2 - HAECKER, 1906a, p. 301, pl. 6, fig. 1, text-figs. f,k

Challengeron armatum BORGERT, 1901a, p. XV33, fig. 39; 1911, p. 454, pl. 34, figs. 7-9

Challengeron gracile BORGERT, 1911, p. 458, pl. 35, figs. 6,7

Challengeron gracilimum BORGERT, 1911, p. 459, pl. 35, figs. 3-5

Challengeron walwini WOLFENDEN, 1902, p. 359, pl. 2, figs. 1, 1a

? Challengeron wyvillei HAECKEL, 1887, p. 1660, pl. 99, fig. 15

Challengeron sp. LING and TAKAHASHI, 1977, p. 208, pl. 1, figs. 1-5

Remarks: The concept of this species herein is somewhat broader than Borgert's. Based on examinations of several tens of specimens the author believes that intra-species morphological variations of the present species occur to such an extent that previous authors separated this group into several species. The variations observed include size and shape of the shell, length, number and arrangement (i.e. alternation of longer and shorter ones) of spines. However, the angle between 2 pairs of divergent teeth is consistent. Splitting of ovate form from compressed ellipsoidal form was possible, but this may or may not be natural. A form with sabre-shaped terminal teeth such as those of Challengeron wyvillei Haeckel (1887, p. 1660, pl. 99, fig. 15) has not been recognized from the present study areas (Haeckel's specimens were from the eastern tropical Atlantic).

Micro- and ultra-structural studies shown in Plate 47 reveal that basic unit of skeleton is regularly arranged amphora-shaped structure cemented by relatively soluble silica. This structure is common to all of 17 species studied in the present family except Challengeranium diodon (Haeckel) as shown in Plates 47-52.

Challengeron lingi n. sp.

Plate 48, figures 1-5

Description: Shell ovate to compressed ellipsoid, usually with spines along longitudinal rim. Shell wall smooth with regularly arranged numerous pores which are one open end of amphora structure common to all of the species in the present family. Peristome smooth without teeth and the mouth opens obliquely.

Dimensions: Length 240 ± 30 (2 S.D.) μm (6 specimens); width: 159 ± 33 μm (7 specimens); weight: 0.07 ± 0.01 μg (15 specimens)

Type locality: $5^{\circ}21'N$, $81^{\circ}53'W$, sediment traps, 3769/3791 m.
Collected during August-December 1979

Remarks: The present species is closely related to C. willemoesii. Absent of oral teeth is the major difference from the latter. More than 30 specimens observed showed smooth peristome as shown in Plate 48 without any exceptions.

Derivation of name: This species is dedicated to Professor Hsin Yi Ling who inspired the present study.

Challengeron radians Borgert

Plate 48, figure 6

Challengeron radians BORGERT, 1803, p. 743, text-fig. J. - BORGERT, 1911, p. 453, pl. 34, fig. 3 - TAKAHASHI and HONJO, 1981, p. 155, pl. 11, figs. 1,2

Challengeron tizardi (Murray)

Plate 48, figures 13-16

Challengeria tizardi MURRAY, 1885, p. 226, pl. A, figs. 7-7b

Challengeron tizardi (Murray). - HAECKEL, 1887, p. 1656

Protocystis tizardi (Murray). - HAECKER, 1908b, p. 266, pl. 50, figs. 405-406

Remarks: Size of this species is fairly uniform based on 20 specimens and close to Murray's and larger than Haeckel's specimens. Dimensions obtained from Takahashi and Honjo (in prep.): length $340 \pm 25\mu$ (2 S.D.) (5 specimens); width: $272 \pm 30 \mu\text{m}$ (8 specimens); weight: 0.54 ± 0.16 (2 S.D.) μg (18 specimens).

Genus CHALLENGEROSIUM Haeckel, 1887, emend. herein

Definition: Challengeridae with marginal spines, oral teeth and two different kinds (smooth and dimpled) of surfaces on a lens-shaped shell.

Type species: Challengerosium avicularia Haecker, 1906a

Remarks: Subgenus Challengerosium of Haeckel (1887) is herein elevated and separated from Challengeron in analogous manner with what Haecker (1906a) proposed for Heliochallengeron for presence of alveolate girdle zone in H. channeri (Murray).

Challengerosium balfouri (Murray)

Plate 48, figures 7-10

Challengeria balfouri MURRAY, 1885, p. 226, pl. A, fig. 10

Challengeron balfouri (Murray). - HAECKEL, 1887, p. 1655. - BORGERT, 1901a, p. XV31, fig. 37; 1911, p. 449, pl. 33, figs. 5-9. - WOLFENDEN, 1902, p. 360, pl. 2, figs. 2, 2a, 3, 3a. - TAKAHASHI and HONJO, 1981, p. 155, pl. 11, figs. 5,6. See Borgert (1911) for additional references.

Protocystis balfouri (Murray). - 1908b, p. 268, pl. 50, fig. 395

Remarks: Surface texture of the shell of two kinds: smooth on lateral sides; alveolate on sagittal plane. Microstructure study by use of SEM show no significant difference in internal amphora structure in both smooth and rough surface areas of the shell wall. These two kinds of surface morphology also exist also in C. avicularia.

Challengerosium avicularia Haecker

Plate 49, figures 1-13

Challengerosium avicularia HAECKER, 1906a, p. 300, plate 11, figure 8

Challengeron avicularia (Haecker). - BORGERT, 1911, p. 466

? Challengeria bethelli MURRAY, 1885, plate A, figure 6

? Challengerosium bethelli (Murray). - HAECKER, 1906a, p. 299, text-fig. F, h.

Remarks: Contrast between smooth and dimpled rough surfaces is clear in most specimens observed under SEM except some determined to be dissolution effect. Number of marginal spines are generally close to 10 and occasionally 2 or 3 spines. None of the specimens here has as many spines as of C. bethelli (Murray) shown by Murray (1885) and Haecker (1906a).

Genus CHALLENGERANIUM Haecker, 1908b

Original Definition: Shell ovate. Peristome with two fenestrated perforations. Two oral spines. An apical spine often surrounded by secondary spines (Haecker, 1908b, translated by the author).

Challengeranium diodon (Haeckel)

Plate 52, figures 11-16

Challengeron diodon HAECKEL, 1887, p. 1654, pl. 99, fig. 6.-
BORGERT, 1901a, p. 30, fig. 34; 1911, p. 448, pl. 33, figs. 10,11. -
JØRGENSEN, 1905, p. 141. - BJØRKLUND, 1974, p. 28, fig. 10; 1976a,
pl. 12, figs. 8-11. - TAKAHASHI and HONJO, 1981, p. 155, pl. 12,
figs. 1-3. See Borgert (1911) for additional references.

Challengeron narthorsti CLEVE, 1899, pl. 1, figs. 9a,9b

Challengeron heteracanthum JØRGENSEN, 1900, pl. 3, figs. 16-17

Remarks: Microstructure of this species appears to be very different from other Challengerida in presence of: (1) alveolate surface; 2) clusters of small pores associated with individual amphora; and 3) thin and delicate amphorae which are different shape from other species of the family. Thus, the author prefers to choose Haecker's separate classification of the present genus from Challengeron.

Genus PROTOCYSTIS Wallich, 1869, emend. herein

Definition: Challengeridae without pharynx, with none or up to several oral teeth and without marginal spines.

Remarks: Wallich (1869), Borgert (1901a, 1911) and Haecker (1906a) defined the present genus having one or several oral teeth. However, appearance of specimens with peristome without oral teeth necessitated this emendation. Generic classification of the present genus as well as Challengeron and Challengerosium may be artificial and hence it may require further emendations in the future work.

Protocystis sp. A

Plate 49, figures 14-15

Description: Shell lens-shaped, without marginal spines. Compressed sides of shell relatively smooth and girdle zone of alveolate surface. Peristome smooth without teeth.

Protocystis harstoni (Murray)

Challengeria harstoni MURRAY, 1885, p. 226, pl. A, fig. 14a (not fig. 14). - HAECKEL, 1887, p. 1650

Protocystis harstoni (Murray). - BORGERT, 1901a, p. XV28, fig. 30. - BJØRKLUND, 1976a, pl. 12, fig. 5. - DUMITRICA, 1973, p. 755, pl. 8, fig. 5. - TAKAHASHI and HONJO, 1981, p. 156, pl. 11, fig. 11

? Protocystis harstoni (Murray). - HAECKER, 1908b, p. 49, text-fig. 150. - BORGERT, 1911, p. 436, text-fig. 4a. - STADUM and LING, 1969, p. 483, pl. 1, figs. 1-3. - BJØRKLUND, 1976a, pl. 12, figs. 6,7

Protocystis natuiloides BORGERT, 1903, p. 738, text-figs. Da, Db

Protocystis antarctica SCHRODER, 1913, pl. 21, fig. 1

? Challengeria zetlandica WOLFENDEN, 1902, p. 361, pl. 2, fig. 5.
See Borgert (1911) for additional references.

Remarks: Specimens shown by Haecker (1908), Borgert (1911), Stadum and Ling (1969) and Bjørklund (1976a, p. 12, figs. 6,7 of the Cleve collection) are different in angle, length and shape of peristome from the rest in the references listed above and the examined specimens. The former can be classified as a subspecies of the present species.

Protocystis honjoi n. sp.

Plate 50, figures 1-2

Protocystis sp. TAKAHASHI and HONJO, 1981, p. 156, pl. 11, figs. 8-9

Description: Shell lens-shaped and circular, with two characteristic wing-like oral teeth on the peristome. Shell surface texture of two kinds: rough girdle zone and smooth compressed sides. Contrast between the two surface texture is not as marked as in Challengerosium.

Dimensions: (12 specimens) Shell diameter: 147 ± 13 (2 S.D.) μm ;
weight: 0.10 ± 0.05 μg (4 specimens).

Type locality: $5^{\circ}21'N$, $81^{\circ}53'W$, sediment trap 2869 m. Collected during August-December 1979.

Remarks: This species is closely related to P. gravida Borgert (1903, p. 741, figs. Ga, Gb) and P. macleari (Murray) (1885, p. 226, pl. A, fig. 3; Haeckel, 1887, p. 1651). Specimens from the Pacific are slightly larger than those of the Atlantic (Takahashi and Honjo, 1981).

Derivation of name: This species is dedicated to Dr. Susumu Honjo for his contribution to this work in recovery of the samples.

Protocystis tridentata Borgert

Plate 50, figure 3

Protocystis tridentata BORGERT, 1903, p. 743, text-fig. H; 1911, p. 444, pl. 32, fig. 7. - HAECKER, 1906, p. 294, 295; 1908b, p. 266, pl. 50, fig. 404

Protocystis auriculata n. sp.

Plate 50, figures 4-7

Description: Shell lens-shaped and extending toward posterior end where peristome exists, with two ear-shaped winged teeth. The wings extend perpendicular to sagittal plane. The teeth as long as 1/2 to 2/3 of transverse shell diameter.

Dimensions: (8 specimens) transverse shell diameter: 98 ± 9 (2 S.D.) μm .

Type locality: $5^{\circ}21'N$, $81^{\circ}53'W$, sediment trap 2869 m. Collected during August-December 1979.

Derivation of name: Name of this species is the Latin meaning having the nature of ear.

Protocystis aduncicuspis n. sp.

Plate 50, figures 8-10

Description: Shell compressed and semi-triangular, with two divergent oral teeth on peristome causing a sharp bend on girdle circumference. Girdle zone is covered by dimples causing rough surface.

Dimensions: Transverse shell diameter; 139 ± 21 (2 S.D.) μm (13 specimens); longitudinal length including teeth: 174 ± 12 μm (6 specimens).

Type locality: $5^{\circ}21'N$, $81^{\circ}53'W$, sediment trap 3791 m. Collected during August-December 1979.

Remarks: Shape of the peristome and teeth thickness vary.

Derivation of name: The name of this species is the Latin meaning having the nature of bent and pointed ends.

Protocystis sp. B

Plate 50, figure 11

Description: Shell spherical, with two divergent teeth having similar angle to those of P. aduncispis. Specimen shown in the plate is 205 μ m in shell diameter.

Protocystis sloggetti (Haeckel)

Plate 50, figures 12-15

Challengeron harstoni MURRAY, 1885, p. 226, pl. A, fig. 14 (nomen oblitum)

Challengeria sloggetii HAECKEL, 1887, p. 1649, 1650, pl. 99, fig. 4

Protocystis sloggetii (Haeckel). - HAECKER, 1906, p. 297, 298; 1908b, p. 271, pl. 50, figs. 401, 402. - BORGERT, 1911, p. 435, text-fig. 3.

Remarks: Bifurcated oral teeth varies in thickness and length. Shape of compressed triangular lenticular shell is consistent and less round than the previous workers report.

Protocystis murrayi (Haeckel)

Plate 50, figures 16-18, Plate 51, figures 1-3

Challengeria aldrichi MURRAY, 1885, pl. A, fig. 4 (nomen oblitum)

Challengeria murrayi HAECKEL, 1887, p. 1653, pl. 99, fig. 1

Protocystis murrayi (Haeckel). - HAECKER, 1906, p. 299, text-fig. F, g; 1908b, p. 272, 273, pl. 50, fig. 409, 411, text-fig. 29, g. - BORGERT, 1911, p. 445, text-figs. 11a,b

? Protocystis thyroma HAECKER, 1906, p. 299, pl. 6, fig. 6

Protocystis sp. C

Plate 51, figure 4

Description: Shell strongly compressed, with winged teeth similar to those of P. murrayi (Haeckel), but extending beyond shell thickness.

Protocystis thomsoni (Murray)

Plate 51, figure 5

Challengeria thomsoni MURRAY, 1885, pl. A, figs. 2, 2a. - HAECKEL, 1887, p. 1650

Protocystis thomsoni (Murray). - HAECKER, 1906a, p. 291, text-fig. Fb; 1908b, p. 261, pl. 49, figs. 388-389, text-fig. 29b. - BORGERT, 1911, p. 440, text-figs. 7a,b. - RESHETNYAK, 1955, p. 98; 1 pl., figs. 1,2. - LING, 1966, p. 206, pl. 1, figs. 1-11; pl. 2, figs. 1-7. - LING and TAKAHASHI, 1977, p. 209, pl. 2, figs. 1-6. - TAKAHASHI and HONJO, 1981, p. 155, pl. 11, fig. 4

Protocystis bicornis BORGERT, 1901a, p. XV29, text-fig. 32, pl. 33, figs. 3,4

Protocystis xiphodon (Haeckel)

Plate 52, figures 1-3

Challengeria naresii MURRAY dwarf variety, pl. A, fig. 1b (nomen ablitum)

Challengeria xiphodon HAECKEL, 1887, p. 1648. - HAECKER, 1908b, p. 260, pl. 49, figs. 378-381

Protocystis xiphodon (Haeckel). - BORGERT, 1901a, p. XV27, fig. 28; 1903, p. 738; 1911, p. 433, pl. 31, figs. 5-7. - JØRGENSEN, 1905, p. 141. - STADUM and LING, 1969, p. 483, pl. 1, figs. 4, 5. - BJØRKLUND, 1976, pl. 12, fig. 4. - TAN and TCHANG, 1916, p. 297, text-fig. 78. - TAKAHASHI and HONJO, 1981, p. 156, pl. 11, fig. 14. See Borgert (1911) for additional references.

Remarks: This is the smallest species among one-toothed trio of Protocystis (including P. tritonis and P. naresi) whose shell is compressed ovate tapering toward oral tooth. Ratio of mouth/shell diameter is the largest among the trio.

Protocystis tritonis (Haeckel)

Plate 52, figures 4-5

Challengeria tritonis HAECKEL, 1887, p. 1649, pl. 99, fig. 5. - WOLFENDEN, 1902, p. 360, pl. 2, fig. 4

Protocystis tritonis (Haeckel). - BORGERT, 1901a, p. XV28, fig. 29; 1911, p. 434, pl. 31, figs. 8,9. - TAKAHASHI and HONJO, 1981, p. 156, pl. 11, fig. 13.

Protocystis naresi (Murray)

Plate 52, figures 6-8

Challengeria naresii MURRAY, 1885, p. 226, pl. A, figs. 1, 1a-1e. - HAECKEL, 1887, p. 1648

Challengeria naresi Murray. - HAECKER, 1906a, p. 290, text-figs. A, Fa; 1908b, p. 258, pl. 48, fig. 370; pl. 49, fig. 377; pl. 52, figs. 429, 430, text-figs. 27, 28. - RESHETNYAK, 1955, p. 95, pl. fig. 62

Protocystis naresi (Murray). - BORGERT, 1911, p. 432, text-fig. 2. -
TAKAHASHI and HONJO, 1981, p. 156, pl. 52, fig. 12

Remarks: This is the largest of the Protocystis one-toothed trio whose longer axis of compressed oval shell diameter range 480 to 680 um. Mouth is relatively small compared to the former two species of the trio. Examination of microstructure shows this species has elongated amphorae (pl. 52, fig. 9), but otherwise very similar to all other species of family Challengeridae studied.

Genus PHARYNGELLA Haeckel, 1887

Original definition: Challengerida with a pharynx, and with one or more teeth on the mouth, but without marginal spines (Haeckel, 1887)..

Pharyngella gastrula Haeckel

Plate 51, figures 6-14

Pharyngella gastrula HAECKEL, 1887, p. 1662, pl. 99, fig. 18. -
BORGERT, 1901, p. 34, text-fig. 41; 1903, p. 746, text-fig. N; 1911,
p. 461, pl. 31, fig. 3,4. - HAECKER, 1906, p. 303

Protocystis thomsoni (Murray). - TAKAHASHI and HONJO, 1981, p. 155,
pl. 11, fig. 3

Remarks: Presence of characteristic pharynx separate the present species from Protocystis thomsoni (Murray).

Genus ENTOCANNULA Haeckel, 1879

Definition by Haeckel (1887): Challengerida with a pharynx, without teeth on the mouth, and without marginal spines.

Entocannula infundibulum Haeckel

Plate 52, figs. 9,10

Challengeria bromleyi MURRAY, 1885, pl. A, fig. 5 (nomen oblitum)

Entocannula infundibulum HAECKEL, 1887, p. 1661, pl. 99, fig. 19. -
BORGERT, 1903, p. 745-746, text-fig. M; 1911, p. 460, pl. 31, fig. 1
- HAECKER, 1906a, p. 303-304; 1908b, p. 279, pl. 51, fig. 425

Family MEDUSETTIDAE Haeckel, 1887, emend. herein

Definition: Phaeodaria with an ovate, hemispherical or cap-shaped shell of alveolate, smooth or smooth with raised-striae texture, and with articulate hollow feet on the peristome.

Remarks: Shell surface texture has been observed to be variable depending on species. Observations of microstructures show significant variations between species of the present family and they are very different from amphorae of family Challengeridae. As Phaeodaria, shells of this family are small next to those of families Porospathidae and Lirellidae.

Genus EUPHYSETTA Haeckel, 1887

Original description by Haeckel (1887): Medusettida with four articulate feet on the peristome, one odd very large, and three small or rudimentary feet.

Euphysetta elegans Borgert

Plate 53, figures 1-10

Euphysetta elegans BORGERT, 1902, p. 569, text-fig. F; 1906, p. 154, pl. 11, figs. 7-9. - HAECKER, 1904a, p. 138; 1906a, p. 273; 1908b, p. 307, pl. 53, figs. 435, 438. - DUMITRICA, 1973, p. 756, pl. 5, fig. 8; pl. 6, figs. 1-3, pl. 12, fig. 8. - TAKAHASHI and HONJO, 1981, p. 156, pl. 12, figs. 4-5

? Euphysetta amphicodon HAECKEL, 1887, p.1670, pl. 118, fig. 3

Remarks: Length of an apical spine and odd large foot appear to vary such that E. amphicodon cannot be separated from the present species. The specimens observed here have always three small feet in contrast to Haeckel's nine small thorns of one specimen. Microstructure shown in Plate 53 demonstrates layers of circular pores.

Euphysetta staurocodon Haeckel

Plate 53, figures 11-14

Euphysetta staurocodon HAECKEL, 1887, p. 1670, pl. 118, figure 2

Remarks: Shell is usually much smaller and shell surface is much finely alveolated than that of E. elegans. The form studied here has always large foot extending toward terminal end but not bent like Haeckel (1887) described.

Euphysetta pusilla Cleve

Plate 53, figure 15

Euphysetta pusilla CLEVE, 1900a, p. 7, pl. 3, fig. 16; 1900b, p. 160. - BORGERT, 1902, p. 567, fig. D; 1906, p. 152, pl. 11, figs. 1-3. - DUMITRICA, 1973, p. 756, pl. 9, fig. 6; pl. 12, fig. 5. - TAKAHASHI and HONJO, 1981, p. 156, pl. 12, fig. 8

Remarks: The author also observed a few specimens with an apical spine, as noted by Borgert (1906).

Euphysetta lucani Borgert

Plate 54, figures 10-12

Euphysetta lucani BORGERT, 1892, p. 181, pl. 6, fig. 8; 1901a, p. 37, fig. 45; 1901b, p. 242, pl. 11, fig. 4; 1906, p. 151, pl. 6, figs. 4-6. - HAECKER, 1908b, p. 306, pl. 53, figs. 436, 439, 442. - DUMITRICA, 1973, p. 756, pl. 9, fig. 1; pl. 12, fig. 6. - TAKAHASHI and HONJO, 1981, p. 156, pl. 11, fig. 7

Remarks: Microstructure shows regularly arranged one layer of ovate shape amphorae cemented with silica. The amphorae are different shaped from those of Challengeridae.

Genus MEDUSETTA Haeckel, 1887

Original definition by Haeckel (1887): Medusettida with four equidistant articulate feet of equal size on the peristome.

Medusetta ansata Borgert

Plate 54, figures 1-7

Medusetta ansata BORGERT, 1902, p. 564, fig. B; 1906, p. 146, pl. 12, figs. 1, 2. - TAKAHASHI and HONJO, 1981, p. 156, pl. 12, figs. 6-7

Remarks: Two different forms exist: One has an ovate shell with feet obliquely extending and abruptly bent at the branching joints (Pl. 54, figs. 1-5) whereas the other has elongated shell with foot gently curved toward the terminal end (Pl. 54, figs. 6-7). At Atlantic E site, only the former form was found while both forms were found at Pacific P₁ and PB sediment trap sites. Cross sectional

microstructure shows one layer of square to rectangular shaped pores bounded by outer and inner shell walls.

Medusetta inflata Borgert

Medusetta inflata BORGERT, 1902, p. 563, fig. A; 1906, p. 146, pl. 11, figs. 10,11. - CLEVE, 1903, p. 354. - HAECKER, 1908b, p. 305, pl. 53, fig. 437. - DUMITRICA, 1973, p. 756, pl. 13, fig. 1. - TAN and TCHANG, 1976, p. 297, text-fig. 79. - TAKAHASHI and HONJO, 1981, p. 157, pl. 12, fig. 11

Medusetta sp. A

Plate 54, figures 8-9

Description: Shell longitudinally compressed spherical with four bifurcated feet on the peristome of large mouth. Alveolate shell surface similar to that of E. elegans. Other than shown in Plate 54, figs. 8-9 presence/absence of apical spines remains to be further examined upon collection of more specimens.

Medusetta sp. B

Plate 63, figures 12-13

Description: Shell smooth hemispherical cap with four equal articulate feet which have many spines. No apical spine has been observed.

Remarks: The above figures are TEM partial cross-sections. Note that skeletons shown here collected from plankton tows are made of one layer of very thin tubes. This species has never been found in the sediment trap samples.

Family LIRELLIDAE Ehrenberg, 1872c

Remarks: Present family represents the most abundant Phaeoadaria in the deep sea water column, although diversity is low. Only two genera and three species were encountered.

Genus BORGERTELLA Dumitrica, 1973

See Dumitrica (1973) for diagnosis of this genus.

Borgertella caudata (Wallich)

Plate 54, figures 13-17, plate 55, figures 1-6

Cadium caudatum WALLICH, 1869, pl. 3, figs. 7-10. - BUTSCHLI, 1882, pl. 32, fig. 15a

Cadium inauris BORGERT, 1903, p. 747, fig. 0; 1910, p. 402, pl. 30, figs. 4-10

Borgertella caudata (Wallich). - DUMITRICA, 1973, p. 755, pl. 8, figs. 6-8; pl. 12, figs. 13-17. - LING, 1975, p. 732, pl. 13, fig. 24. - TAKAHASHI and HONJO, 1981, p. 157, pl. 12, fig. 12

Genus LIRELLA Ehrenberg, 1872c

Remarks: Species of the present genus are characterized by a small ovate or ellipsoidal shell with straight or curved wavy lines of furrows and crests.

Lirella baileyi Ehrenberg

Plate 55, figure 7

Cadium marinum BAILEY, 1856, p. 3, pl. 1, fig. 2.

Lirella baileyi EHRENBERG, 1872c, p. 248, pl. 3, fig. 29a,b. -
LOEBLICH and TAPPAN, 1961, p. 231, 232. - LING, 1973, p. 781, 782;
1975, p. 732, pl. 13, fig. 28. - LING and TAKAHASHI, 1977, p. 209,
pl. 3, figs. 1-3

Lirella marina (Bailey). - DUMITRICA, 1973, p. 755, pl. 6, fig. 8,
pl. 8, fig. 8, pl. 12, figs. 10-12

Remarks: About 60-70 longitudinal striae terminate without reaching
the tapered ends and form smooth surfaces.

Lirella bullata (Stadum and Ling)

Plate 55, figures 8-11

Cadium bullatum STADUM and LING, 1969, p. 484, pl. 1, figs. 9-14

Lirella bullata (Stadum and Ling). - LING, 1975, p. 732, pl. 13, fig.
29. - TAKAHASHI and HONJO, 1981, p. 157, pl. 13, figs. 1-2

Lirella melo (Cleve)

Plate 55, figures 12-18, plate 56, figures 1-8

Beroetta melo CLEVE, 1899, p. 27, pl. 1, fig. 8

Cadium melo (Cleve). - BORGERT, 1901a, p. XV50, fig. 58; 1910, p.
401, pl. 30, figs. 3-5. - JØRGENSEN, 1905, p. 142, pl. 18, fig. 13. -
HAECKER, 1908b, p. 282, pl. 51, fig. 415. - SCHRÖDER, 1913, p. 168,
text-fig. 10. - STADUM and LING, 1969, p. 484, pl. 1, figs. 6-8. -
DUMITRICA, 1973, p. 755, pl. 7, figs. 3,4; pl. 12, fig. 9. -
TAKAHASHI and HONJO, 1981, p. 157, pl. 12, figs. 13,14,16

Remarks: Several forms of peristome have been observed: 1) Smooth
and significantly protruded; 2) Smooth, short and non-protruded; and

3) slightly obliquely open. Also two different kinds of microstructures have been recognized (Plate 56, figs. 2-4, 6-8). Even within a specimen the two kinds of microstructures have been observed. These are perhaps secondary features due to dissolution judging from observation of other species from plankton tows.

Lirella tortuosa n. sp.

Plate 55, figures 19-20, Plate 56, figures 9-11

Description: Shell ovate, with 25-35 coiled longitudinal striae and crests, with a short apical spine, and with peristome open straight.

Dimensions: (12 specimens), length: $105 \pm 5 \mu\text{m}$; width: $67 \pm 3 \mu\text{m}$.

Type locality: $15^{\circ}21.1'N$, $151^{\circ}28.5'W$, sediment trap depth 4280 m. Collected during July-November 1978.

Remarks: Both right and left coiled specimens have been observed.

Derivation of name: The name of this species is the Latin meaning twisted.

Family POROSPATHIDIDAE Borgert, 1901a, emend. Campbell, 1954

Definition: Shell covered by paneled or tubulated surface or covered by trizonal meshwork; radial spines on all sides.

Genus POROSPATHIS Haeckel, 1879

Remarks: This is the type genus of the family.

Porospathis holostoma (Cleve)

Plate 57, figures 1-8

Polypetta holostoma CLEVE, 1899, p. 32, pl. 3, figs. 4a,4b; 1900b, p. 180

Porospathis holostoma (Cleve). - BORGERT, 1901a, p. 48, figs. 56, 56a; 1903, p. 752; 1910, p. 387, pl. 29, figs. 1-8; pl. 30, figs. 1,2. - HAECKER, 1908b, p. 240, pl. 48, figs. 371-376; pl. 49, figs. 392, 393. - SCHRÖDER, 1913, p. 166, text-fig. 9. - RESHETNYAK, 1955, p. 95, fig. 66 (in plate); 1966, p. 166, fig. 52. - STADUM and LING, 1969, p. 485, pl. 1, figs. 16-18. - DUMITRICA, 1973, p. 754, pl. 5, figs. 1,2,6. - TAKAHASHI and HONJO, 1981, p. 156, pl. 11, fig. 15

Porospathis sp. aff. P. holostoma - DUMITRICA, 1972, p. 842, pl. 15, fig. 14

Family CASTANELLIDAE Haeckel, 1879

Definition by Haeckel (1887): Phaeodaria with a spherical or subspherical shell, exhibiting ordinary lattice-work, with circular or roundish pores. Radial spines without circles of basal pores. Mouth of the shell large, usually circular and armed with teeth. Central capsule excentric, placed in the aboral half of the shell-cavity.

The following systematics originally given by Haeckel (1887) and Haecker (1908b) and emended by Kling (1966) represents generic classification criteria for the present family.

A. Shells with pores distributed over the entire shell wall

Main spines absent	{ -Mouth without teeth or other ornamentation -Mouth with teeth		<u>Castanarium</u>
			<u>Castanella</u>
Main spines present	{ -Mouth without teeth or other ornamentation. -Mouth with teeth	{ -Main spines unbranched. -Main spines branched.	<u>Castanidium</u>
			<u>Castanopsis</u>
		{ -Main spines unbranched. -Main spines branched.	<u>Castanissa</u>
			<u>Castanea</u>

Main spines usually present, absent in some specimens. Mouth with thickened rim, blunt protuberances, or raised collar-shaped rim.

Castanura

B. Shell with some pore positions occupied by enclosed, hollow spaces.

Circocastanea

Remarks: Biogeography of the present family in the eastern North Pacific has been given by Kling (1966).

Genus CASTANIDIUM Haeckel, 1879

Castanidium longispinum Haecker

Plate 57, figures 9-13, plate 58, figures 1-4

Castanidium longispinum HAECKER, 1908, pp. 163-164, pl. 37, figs. 285-286, pl. 38, figs. 290-291, pl. 40, fig. 296; SCHRÖDER, 1913, p. 151; KLING, 1966, p. 115, pl. 5, figs. m-r; KLING, 1971, p. 664, pl. 2, figs. 5-7.

Description: Shell spherical, with unbranched main-spines and numerous short bi-spines of uniform length, with small pores circular to polygonal shape, with usually one main-spine on the rim of a small mouth. Main-spines slightly wavy and as long as shell diameter. Shell diameter of the specimens observed here range 310-450 μm and surface plankton tow samples from the Gulf of Oman (collected by J. Erez) range 390-510 μm ($470 \pm 34 \mu\text{m}$; $n = 40$ specimens).

Remarks: The above ranges of shell diameter are much smaller than that observed by Kling (1966: 240-630 μm). Mouth size is similar to Kling (1966) but smaller than that of Haecker (1908b). Cross sections of intervening bars show rectangular shape as Kling (1966) noted.

Castanidium abundiplanatum n. sp.

Plate 58, figures 5-8

Description: Shell relatively small as a Castanellid, without bi-spines, with slightly wavy main-spines, mouth usually with one main-spine on the rim, pores circular to polygonal. Bases of the main-spines fenestrated, shell wall often elevated there and forming polyhedral shell. Length of the main-spines 1/2 up to as long as shell diameter.

Dimensions: Shell diameter $308 \pm 21 \mu\text{m}$ (2 S.D.) (18 specimens); weight: $0.80 \pm 0.02 \mu\text{g}$ (22 specimens)

Type locality: 5°21'N, 81°53'W, sediment trap 1268 m. Collected during August-December 1979.

Remarks: The present species has narrow size range and is distinctly smaller than C. longispinum. Specimens of two shells dividing are occasionally observed.

Derivation of name: The name of this species is the Latin meaning having the nature of copious planes.

Castanidium sp.

Plate 58, figure 10

Description: Shell polyhedral, with very large pores of 1/4 to 1/5 of shell diameter combined with a few small pores of skeleton thickness, main-spines as long as 1/2 of shell diameter whose bases are elevated causing the shell shape, bi-spines of equal or shorter length than pore diameter.

Genus CASTANISSA Haeckel, 1879

Castanissa circumvallata Schmidt

Plate 58, figure 9

Castanissa circumvallata SCHMIDT, 1907, p. 301, fig. 6. - SCHMIDT, 1908, p. 257, pl. 20, fig. 6. - KLING, 1966, p. 123, pl. 3, figs. a-h; 1971 p. 665, pl. 4, figs. 1-4. - TAKAHASHI and HONJO, 1981, p. 157, pl. 13, fig. 4

Castanissa similis SCHMIDT, 1908, p. 257, pl. 20, fig. 5

Remarks: Specimen illustrated here has more developed teeth than those shown by the previous workers, although bi-spines are broken off thus not showing well in the illustration.

Genus CASTANELLA Haeckel, 1879

Castanella aculeata Schmidt

Plate 58, figure 11,13, Plate 59, figure 1

Castanella aculeata SCHMIDT, 1907, p. 299, fig. 4; 1908, p. 250, pl. 18, fig. 6. - KLING, 1966, p. 110, pl. 2, figs. j-o

Castanella macropora (Borgert)

Plate 58, figure 12

Castanidium macroporum Schmidt, 1908, p. 252, pl. 19, fig. 2

Description: Shell small as a Castanellid, pores circular and unequal size, bi-spines 1/10 length of shell diameter and variable in thickness, mouth circular and 1/5 to 1/4 length of shell diameter with divergently curved conical teeth.

Remarks: According to Schmidt (1908), main spines of his Castanidium macroporum were broken off, but his illustration suggests that the main spines could well be thicker bi-spines. The author proposes to make emendation in generic name of the present species and accordingly change the gender to the species name on the basis of absence of main spines observed here.

Castanella sloggetti Haeckel

Plate 59, figure 2

Castanella sloggetti HAECKEL, 1887, p. 1683. - BORGERT, 1903, p. 750.
- HAECKER, 1908b, p. 157, pl. 34, figs. 260-261

Remarks: Teeth observed here are four compared to more than five shown by the previous workers. The present species resembles Castanella maxima SCHMIDT (1907, p. 297, fig. 1; 1908, p. 251, pl. 18, fig. 8. - SCHRÖDER, 1913, p. 148), although the size of the latter is ca. 1 mm.

Castanella balfouri Haeckel

Plate 58, figure 3

Castanella balfouri HAECKEL, 1887, p. 1683. - SCHMIDT, 1908, p. 249,
pl. 18, fig. 3

Family CIRCOPORIDAE Haeckel, 1879

Definition: Phaeodaria with a spherical or polyhedral shell, exhibiting peculiar solid porcellanous structure, with a stellate circle of radial pores around the base of the hollow radial spines. Mouth usually with teeth. Surface of the shell tabulate, paneled or dimpled. Central capsule excentric, placed in the aboral half of the shell cavity (Haeckel, 1887).

Genus HAECKELIANA Haeckel, 1887

Original definition: Circoporida with spherical shell of a peculiar dimpled, porcellanous structure, and with a variable number of simple radial main spines which are usually not regularly arranged.

Haeckeliana porcellana Haeckel

Plate 59, figures 4-13

Haeckeliana porcellana Murray. - HAECKEL, 1887, p. 1701, pl. 114, fig. 6. - HAECKER, 1908b, p. 182, text-fig. 20, pl. 20, fig. 177. - SCHRÖDER, 1913, p. 155-156. - KLING, 1966, p. 137, pl. 8, figs. i-n

Haeckeliana maxima HAECKEL, 1887, p. 1701, pl. 114, fig. 5

Haeckeliana murrayi HAECKEL, 1887, p. 1702

Haeckeliana geotheana HAECKEL, 1887, p. 1702, pl. 114, fig. 3

Haeckeliana darwiniana HAECKEL, 1887, p. 1702, pl. 114, figs. 1-2. - TAKAHASHI and HONJO, 1981, p. 157, pl. 13, figs. 7-8

Haeckeliana laboradoriana BORGERT, 1901, p. 43, fig. 51; 1909, p. 330-331, pl. 24, figs. 1-3

Remarks: Some specimens entirely lack in bi-spines and thus shell surface appears very smooth in contrast to other thorny specimens. The author accepts classification by Kling (1966) which involves combining Haeckel's six species of Haeckeliana shown in the above synonymy. Cross-sectional microstructures show several different layers including the innermost part of polygons made of tubes (Plate 59, figs. 10-12).

Genus CIRCOPORUS Haeckel, 1879

Definition by Haeckel (1887): Circoporida with a spherical or regularly octahedral shell, composed of eight congruent, triangular plates, with six corners from which arise six radial spines, opposite in pairs in three diameters, perpendicular one to another.

Circoporus sexfuscus Haeckel

Plate 60, figures 1,3,5

Circoporus sexfuscinus HAECKEL, 1887, p. 1695, pl. 115, fig. 1. -
BORGERT, 1901b, p. 243-244, pl. 11, fig. 7; 1909, p. 336-337, pl. 24,
figs. 4-5, pl. 25, figs. 5-7. - HAECKER, 1908b, p. 186, pl. 20, figs.
174-175.

Remarks: This species has six major radial spines which are
divergently three-forked at the terminal ends in contrast to straight
terminal ends of C. oxyacanthus.

Circoporus oxyacanthus Borgert

Plate 60, figures 2, 4, 6-13

Circoporus oxyacanthus BORGERT, 1902, p. 571-572, fig. Hb; 1903, p.
753; 1909, p. 335-336, pl. 25, figs. 1-4. - HAECKER, 1908b, p. 185,
pl. 20, fig. 173. - TAKAHASHI and HONJO, 1981, p. 157, pl. 15, figs.
6-7.

Genus CIRCOGONIA Haeckel, 1887

Original definition: Circoporida with a regular icosahedral shell,
composed of twenty congruent, triangular plates, with twelve corners,
from which arise twelve radial spines.

Circogonia sp.

Plate 20, figures 9-10

Description: Shell icosahedral, smooth and delicate, with twelve
equal hollow major spines whose bases are fenestrated with 4-6 oval
pores and well elevated so that each plate of shell become convex,
mouth circular with several small spines.

Family CONCHARIIDAE Haeckel, 1879

Definition: Phaeodaria with a bivalved lattice-shell, which is spherical or lenticular, and composed of two equal or unequal boat-shaped valves, a dorsal and a ventral. The valves bear neither an apical latticed cupola or glea, nor hollow radial tubes. The central capsule is placed in the aboral half of the shell-cavity, and so enclosed between both valves, that its three openings lie in the open frontal fissure between them (the astropyle on the oral pole of the main axis, the two parapylae on both sides of its aboral pole, at right and left) (Haeckel, 1887).

The following is the synopsis of the genera of Concharidae originally presented by Haeckel (1887) and emended by Haecker (1908b) and Campbell (1954) and further emended herein:

I. Subfamily

<p><u>Conchariinae</u> Lateral edges of the two valves smooth, without teeth</p>	}	<p>- Valves without sagittal keel, nearly hemi- spherical or slightly compressed</p>	{	<p>- Aboral hinge without horns, - Aboral hinge with two horns (one on each valve)</p>	<p><u>Concharium</u> <u>Conchasma</u></p>
--	---	--	---	---	--

II. Subfamily

<p><u>Conchidiinae</u> Lateral edges of the two valves dentate, with a series of prominent teeth on both sides.</p>	}	<p>- Valves without sagittal keel, nearly hemi- spherical or slightly compressed.</p>	{	<p>- Aboral hinge without horns, - Aboral hinge with two horns. No apical horn. - Aboral hinge with two horns. Apex also with a horn.</p>	<p><u>Conchellium</u> <u>Conchidium</u> <u>Conchonia</u></p>
---	---	---	---	---	--

- No horn. Diatom like texture Conchocystis
- Like Conchophacus
Conchocystis,
but slitlike pores.

III. Subfamily

- | | | | | | |
|---|---|--|---|---|--------------------|
| <u>Conchopsidinae</u>
Lateral edges
of the two
valves dentate,
with a series
of prominent
teeth on both
sides. | } | Valves with a
sharp sagittal
keel, strongly
compressed on
both sides,
boat-shaped | } | - Aboral hinge
without horns. | <u>Conchopsis</u> |
| | | | | - Aboral hinge
with two horns
(one on each
valve). | <u>Conchoceras</u> |

Remarks: Skeletal cross-sections for this family represent similar morphology in all of the species examined here (e.g. pls. 61-62).

Genus CONCHELLIUM Haeckel, 1887

Conchellium capsula Borgert

Plate 61, figures 1-5, 7-8, 10

Conchellium capsula BORGERT, 1907, p. 208, pl. 17, figs. 1-4. -
TAKAHASHI and HONJO, 1981, p. 157, pl. 14, figs. 1-4

Remarks: This species has smoother shell surface, thinner skeleton and smaller shell size than those of Conchellium tridacna Haeckel. Measurements on longer axis of shell diameter represent $264 \pm 11 \mu\text{m}$ based on 11 specimens.

Conchellium tridacna Haeckel

Plate 61, figures 6, 9, 11

Conchellium tridacna HAECKEL, 1887, p. 1720, pl. 123, figs. 7, 7a

Remarks: This species is different from C. capsula in shell size, skeletal thickness and shell surface texture. The shell size ranges 350-500 μm in longer axis and the surface texture is rough (pl. 61, fig. 9) as described in Haeckel (1887).

Genus CONCHOPHACUS Haecker, 1906b

Conchophacus diatomeus (Haeckel)

Plate 61, figure 12

Concharium diatomeum HAECKEL, 1887, p. 1717, pl. 123, fig. 1. -
BORGERT, 1901b, p. 244

Conchidium diatomeum (Haeckel). - HAECKER, 1906b, p. 34

Conchophacus diatomeus (Haeckel). - BORGERT, 1907, p. 212, pl. 15,
figs. 5-8. - TAKAHASHI and HONJO, 1981, p. 158, pl. 15, fig. 2

Genus CONCHIDIUM Haeckel, 1887

Conchidium argiope Haeckel

Plate 62, figures 1-2

Conchidium argiope HAECKEL, 1887, p. 1722, pl. 124, figs. 7-9. -
BORGERT, 1903, p. 755-756, text-fig. R; 1907, p. 209, pl. 16, figs. 1-4

Remarks: Shell smaller than C. caudatum and it lacks in window at the base of a short horn. Dimensions from the Panama Basin samples: shell length: $196 \pm 14 \mu\text{m}$ (n = 19); width: $138 \pm 6 \mu\text{m}$ (n = 4).

Conchidium caudatum (Haeckel)

Plate 62, figures 3-8

Conchoceras caudatum HAECKEL, 1887, p. 1727, pl. 24, fig. 15. -
HAECKER, 1905, p. 351; 1906b, p. 34, fig. 1; 1908b, p. 331-332, pl.
58, fig. 457, pl. 60, figs. 467-468

Conchidium caudatum (Haeckel). - BORGERT, 1903, p. 756, fig. 5; 1907,
p. 210, pl. 16, figs. 5-7. - TAKAHASHI and HONJO, 1981, p. 158, pl.
14, figs. 5-7

Remarks: Formation of the keel is considered to be incomplete here
since it does not reach aboral end and also its thickness is
comparable to many other longitudinal lines (although it is elevated
and forms a conspicuous crest in the posterior part). Thus, the
present species should be placed in Conchidium rather than Conchoceras.

Genus CONCHOPSIS Haeckel, 1887

Conchopsis compressa Haeckel

Plate 62, figures 9-16

Conchopsis compressa HAECKEL, 1887, p. 1725, pl. 125, figs. 7,8. -
TAKAHASHI and HONJO, 1981, p. 158, pl. 14, figs. 8-10, pl. 15, fig. 1

Conchopsis aspidium HAECKEL, 1887, p. 1726, pl. 125, figs. 1-2

Conchopsis barca BORGERT, 1907, p. 215-216, pl. 17, figs. 5-7

Description: Lenticular shell composed of strongly compressed
bivalves, with narrow smooth keels, about 32-42 teeth on one side of
each valve, pores circular near the hinge and slitlike shape in the
rest of the shell, shell surface rough at highly magnified view.
Length and thickness of teeth are variable even in the same specimen.

Remarks: The following closely related species were excluded in the above synonymy since specimens like them were not found: C. orbicularis (type species of the genus), C. carinata, C. lenticula, C. navicula, and C. pilidium all described by Haeckel (1887). The criteria used in the above classification by the author are: (1) number and location of teeth; (2) width of keels; (3) shape of valves in lateral view; and (4) whether pores are surrounded by hexagonal framework.

Family AULOSPHAERIDAE Haeckel, 1862

Definition by Haeckel (1887): Phaeodaria with a large spherical or subspherical (rarely spindle-shaped) articulated shell, which is composed of hollow tangential tubes. Nodal points of the loose network stellate, with a nodal cavity and astral septa. Meshes either triangular or polygonal. Hollow radial spines arise usually at the nodal points of the surface. No peculiar mouth in the shell. Central capsule tripylean, placed in the centre of the shell.

Genus AULARIA Haeckel, 1887

Original description: Aulosphaerida with triangular meshes in the network, the tangential tubes of which form a simple smooth lattice-sphere. No radial tubes at the nodal points.

Aularia ternaria Haeckel

Plate 63, figures 1-2

Aularia ternaria HAECKEL, 1887, p. 1621, pl. 111, fig. 2

Family AULACANTHIDAE Haeckel, 1862

Definition by Haeckel (1887): Phaeodaria with an incomplete skeleton, composed of numerous hollow radial tubes, which pierce the spherical calymma and touch with their proximal ends the surface of the tripylean central capsule.

Genus AULOGRAPHIS Haeckel, 1879

Definition by Haeckel (1887): Aulacanthida with a veil of tangential needles, and with radial tubes, which bear no lateral branches, but at the distal end a vertical of simple terminal branches.

Aulographis stellata Haeckel

Plate 63, figure 3

Aulographis stellata HAECKEL, 1887, p. 1578, pl. 103, figs. 23a-c. -
HAECKER, 1908b, p. 41-42, pl. 1, figs. 4-7, pl. 2, fig. 19, pl. 42,
figs. 313-314. - TIBBS, 1976, p. 31

Aulographis tetrancistra Haeckel

Plate 63, figure 10

Aulographis tetrancistra HAECKEL, 1887, p. 1581, pl. 103, fig. 22. -
TIBBS, 1976, p. 32, text-figs. 6,7

Genus AULOCEROS Haeckel, 1887

Original defintion: Aulacanthidae with a veil of tangential needles, and with radial tubes, which bear no lateral branches, but at the distal end a verticil of ramified or forked terminal branches.

Auloceros spathillaster Haeckel

Plate 63, figure 4

Auloceros spathillaster HAECKEL, 1887, p. 1585, pl. 102, fig. 12

Auloceros arborescens Haeckel birameus (Immermann)

Plate 63, figure 9

Auloceros arborescens HAECKEL, 1887, p. 1584, pl. 102, figs. 11,13

Auloceros spathillaster (Haeckel) var. birameus IMMERMANN, 1904, p. 51, pl. 5, fig. 10

Auloceros arborescens birameus (Immermann). - HAECKER, 1908b, p. 53, pl. 3, figs. 21-25, 34-35, pl. 10, fig. 102

Genus AULOGRAPHONIUM Haeckel, 1887

Original definition: Terminal branche of the radial tubes armed with numerous lateral denticles, and with terminal spathillae (or whorls of small radial teeth).

Remarks: This genus was elevated from the original subgenus to the present level by Haecker (1908b)

Aulographonium bicorne Haecker

Plate 63, figures 5-6

Aulocoryne candelabrum IMMERMANN, 1904, p. 59, pl. 6, figs. 5-7

Aulographonium bicorne HAECKER, 1908b, p. 69-70, pl. 1, fig. 1, pl. 6, fig. 57. - TIBBS, 1976, p. 42

Genus AULOSPATHIS Haeckel, 1887

Original definition: Aulacanthidae with a veil of tangential needles, and with radial tubes, which bear two verticils of branches, a distal verticil of terminal branches, and a proximal verticil of lateral branches.

Aulospathis taumorpha ? Haeckel

Plate 63, figures 7-8

Aulospathis taumorpha HAECKEL, 1887, p. 1577, pl. 103, fig. 16

Aulospathis variabilis Haeckel bifurca Haecker

PLATE 1

Suborder: Spumellaria
Family: Collosphaeridae

Figure		Station Depth	Type of Micrograph	Magnification
1	<u>Acrosphaera spinosa</u> (Haeckel) <u>longispina</u> , new name	P ₁ 4280m	SEM	x260
2	<u>Acrosphaera spinosa</u> (Haeckel) <u>coniculispina</u> , new name	P ₁ 5582m	SEM	x300
3	<u>Acrosphaera murrayana</u> (Haeckel) Two shells linked together	PB3791m	LM	x210
4	<u>Acrosphaera spinosa</u> (Haeckel) <u>longispina</u> , new name	P ₁ 5582m	LM	x210
5	<u>Acrosphaera spinosa</u> (Haeckel) <u>coronula</u> , new name	P ₁ 2778m	LM	x210
6	<u>Acrosphaera murrayana</u> (Haeckel)	PB1268m	LM	x210
7	<u>Acrosphaera murrayana</u> (Haeckel)	P ₁ 4280m	SEM	x230
8	<u>Acrosphaera murrayana</u> (Haeckel)	PB3791m	SEM	x220
9	<u>Acrosphaera murrayana</u> (Haeckel) Two shells linked together	PB3769m	SEM	x120
10	<u>Acrosphaera murrayana</u> (Haeckel) Same specimen. Some of spines are still linked.	PB3769m	SEM	x880
11	<u>Acrosphaera murrayana</u> (Haeckel) A typical skeletal cross section which is common to most of polycystines, if not all.	PB3769m	SEM	x4700
12	<u>Acrosphaera cyrtodon</u> (Haeckel)	P ₁ 978m	SEM	x440
13	<u>Acrosphaera cyrtodon</u> (Haeckel)	PB3769m	LM	x210
14	<u>Acrosphaera spinosa</u> (Haeckel) <u>lappacea</u> (Haeckel)	PB3769m	LM	x210
15	<u>Clathrosphaera arachnoides</u> Haeckel	P ₁ 4280m	SEM	x370
16	<u>Acrosphaera lappacea</u> (Haeckel)	P ₁ 4280m	SEM	x340

SEM: scanning electron micrograph
TEM: transmission electron micrograph

LM: transmission light micrograph
RLM: reflection light micrograph

PLATE 2

Suborder: Spumellaria
 Family: Collosphaeridae

Figure		Station Depth	Type of Micrograph	Magnification
1	<u>Collosphaera tuberosa</u> Haeckel	P ₁ 5582m	SEM	x280
2	<u>Collosphaera tuberosa</u> Haeckel	PB2869m	LM	x210
3	<u>Collosphaera tuberosa</u> Haeckel	P ₁ 5582m	LM	x210
4	<u>Collosphaera confossa</u> n.sp. Holotype	P ₁ 5582m	SEM	x215
5	<u>Collosphaera confossa</u> n.sp. Paratype	P ₁ 2778m	LM	x210
6	<u>Collosphaera armata</u> Brandt	PB2869m	LM	x210
7	<u>Collosphaera armata</u> Brandt	P ₁ 5582m	LM	x210
8	<u>Collosphaera huxleyi</u> Müller	P ₁ 4280m	SEM	x210
9	<u>Collosphaera huxleyi</u> Müller	PB2869m	LM	x210
10	<u>Collosphaera huxleyi</u> Müller	P ₁ 978m	LM	x210
11	<u>Collosphaera huxleyi</u> Müller	P ₁ 2778m	LM	x210
12	<u>Collosphaera armata</u> Brandt	PB3769m	SEM	x350
13	<u>Collosphaera macropora</u> Popofsky	P ₁ 4280m	LM	x210
14	<u>Collosphaera macropora</u> Popofsky Two shells linked together	P ₁ 978m	SEM	x520
15	<u>Collosphaera macropora</u> Popofsky	P ₁ 4280m	SEM	x370
16	<u>Collosphaera macropora</u> Popofsky Same specimen as fig. 14	P ₁ 978m	SEM	x2200
17	<u>Collosphaera macropora</u> Popofsky	P ₁ 978m	SEM	x940
18	<u>Collosphaera macropora</u> Popofsky A group of shells probably derived from a colony.	P ₁ 2778m	LM	x240

PLATE 3

Suborder: Spumellaria
Family: Collosphaeridae

Figure		Station Depth	Type of Micrograph	Magnification
1	<u>Disolenia collina</u> (Haeckel) Two shells linked together	P ₁ 378m	LM	x210
2	<u>Disolenia zanguebarica</u> (Ehrenberg) Two shells linked together	P ₁ 978m	LM	x210
3	<u>Disolenia zanguebarica</u> (Ehrenberg) Two shells linked together	PB3769m	SEM	x230
4	<u>Disolenia zanguebarica</u> (Ehrenberg) Same specimen	PB3769m	SEM	x1650
5	<u>Disolenia collina</u> (Haeckel)	P ₁ 5582m	SEM	x226
6	<u>Disolenia collina</u> (Haeckel)	P ₁ 5582m	SEM	x230
7	<u>Disolenia collina</u> (Haeckel)	P ₁ 5582m	SEM	x226
8	<u>Disolenia zanguebarica</u> (Ehrenberg)	P ₁ 4280m	SEM	x450
9	<u>Disolenia zanguebarica</u> (Ehrenberg)	P ₁ 4280m	LM	x210
10	<u>Otosphaera auriculata</u> Haeckel A specimen without spines	P ₁ 5582m	SEM	x340
11	<u>Otosphaera tenuissima</u> (Hilmers)	p ₁ 978m	SEM	x520
12	<u>Otosphaera polymorpha</u> Haeckel	PB2869m	LM	x210
13	<u>Otosphaera auriculata</u> Haeckel	P ₁ 4280m	SEM	x350
14	<u>Otosphaera polymorpha</u> Haeckel	P ₁ 5582m	LM	x210
15	<u>Otosphaera polymorpha</u> Haeckel	P ₁ 2778m	LM	x210

PLATE 3 Spumellaria

PLATE 4

Suborder: Spumellaria
Family: Collosphaera

Figure		Station Depth	Type of Micrograph	Magnification
1	<u>Siphonosphaera magnisphaera</u> n.sp. Paratype	PB2869m	LM	x210
2	<u>Siphonosphaera</u> sp. A	P ₁ 4280m	SEM	x550
3	<u>Siphonosphaera magnisphaera</u> n.sp. Holotype	P ₁ 378m	LM	x210
4	<u>Siphonosphaera martensi</u> Brandt	P ₁ 2778m	LM	x210
5	<u>Siphonosphaera martensi</u> Brandt	P ₁ 2778m	LM	x210
6	<u>Siphonosphaera</u> sp. B	P ₁ 978m	SEM	x550
7	<u>Siphonosphaera martensi</u> Brandt	P ₁ 4280m	SEM	x560
8	<u>Siphonosphaera martensi</u> Brandt	P ₁ 4280m	SEM	x480
9	<u>Siphonosphaera socialis</u> Haeckel	P ₁ 4280m	SEM	x390
10	<u>Siphonosphaera socialis</u> Haeckel	P ₁ 4280m	SEM	x280
11	<u>Siphonosphaera socialis</u> Haeckel	P ₁ 978m	SEM	x250
12	<u>Siphonosphaera socialis</u> Haeckel Two shells linked together	P ₁ 978m	LM	x210
13	<u>Siphonosphaera</u> sp. aff. <u>S. hippotis</u> (Haeckel)	P ₁ 2778m	LM	x210
14	<u>Siphonosphaera</u> sp. aff. <u>S. hippotis</u> (Haeckel)	P ₁ 2778m	LM	x210
15	<u>Siphonosphaera socialis</u> Haeckel	P ₁ 4280m	SEM	x370
16	<u>Siphonosphaera socialis</u> Haeckel Same specimen. Note presence of many rectangular prisms to cubic crystals on the surface which are absent in those of other families with identical desalting preparation.	P ₁ 4280m	SEM	x2760

PLATE 5

Suborder: Spumellaria
Families: Collosphaeridae, Ethmosphaeridae

Figure		Station Depth	Type of Micrograph	Magnification
1	<u>Disolenia quadrata</u> (Ehrenberg)	P ₁ 4280m	SEM	x340
2	<u>Disolenia quadrata</u> (Ehrenberg)	P ₁ 4280m	SEM	x340
3	<u>Disolenia quadrata</u> (Ehrenberg)	P ₁ 5582m	SEM	x280

13	<u>Medusetta</u> sp. B Same specimen showing variable shape of pores	PB 0-100 m plankton tow	TEM	x1700

CURRICULUM VITAE

KOZO TAKAHASHI

Birthdate: January 17, 1948

Citizenship: Japanese

Marital Status: Married, one son and one daughter

Education:

B.A., Hokkaido University, Hakodate, Japan, 1972
B.Sc., University of Washington, Seattle, Washington, 1975
M.Sc., University of Washington, Seattle, Washington, 1977
Ph.D., Massachusetts Institute of Technology/
Woods Hole Oceanographic Institution, expected October 1981)

Professional Experience:

Research Laboratory Chemist, Mitsubishi Chemical Machinery
Manufacturing, Ltd., Kawasaki, Japan, 1972-1974
Research Assistant, University of Washington, 1975-1977
Teaching Assistant, University of Washington, 1977-1978
Graduate Research Assistant, Woods Hole Oceanographic
Institution, 1978-1981

Professional Societies:

Americal Geophysical Union;
North American Micropaleontology Section of Society of
Economic Paleontologists and Mineralogists
Plankton Society of Japan

Present Research Interests:

Biogeochemical intertactions of biogenic silica with
seawater in the water column and sediments. Ecology of
Radiolaria, silicoflagellates and diatoms. Silica budget
in the world oceans.

Awards:

Research grant: Pelagic opal: vertical flux and preservation
of radiolarians and silicoflagellates (NSF Grant OCE 80-19386)
Postdoctoral Fellowship 1981-1982, Woods Hole Oceanographic
Institution

INVITED PRESENTATIONS

In: 1st International Conference (NATO Advanced Research Institute) on ECOLOGY OF MARINE PLANKTONIC PROTOZOA held at Station Zoologique, Villefranche-sur-Mer, France, 10-23 May 1981:

- (1) On the methods of taxonomy of Radiolaria;
- (2) Morphological significance of phaeodarian Radiolaria (poster session);
- (3) Spacial distribution of Radiolaria;
- (4) On the sampling of radiolarian biocoenosis; and
- (5) Turnover time and sinking speed of Radiolaria.

BIOGRAPHY

I was born on January 17, 1948, in Oonohara-cho, Kagawa-prefecture, Japan. My childhood was spent in Kawasaki-shi, Kanagawa-prefecture, which was mostly surrounded by agricultural fields at the time. I received my primary and secondary school education there. As an undergraduate I attended Hokkaido University at Sapporo and Hakodate, graduating in 1972. I was married to Kayoko Murakoshi in October 1971. While I had been active in mountain climbing and skiing in the University Climbing Club there I was, on the other hand, very much interested in studying Oceanography. A decision of moving to the U.S. was inevitable for my strong desire in pursuing the best Oceanography in the world.

I came to the U.S. in February 1974 and began polishing my English at the Grays Harbor College, Aberdeen, Washington. Drs. John M. Smith and James Phipps of the College introduced me to fascinating marine sciences through engaged in a Sea Grant Project besides course work. I transferred to the University of Washington in September 1974 and continued more course work in Oceanography. I worked on biogenic suspended particles in the Deep Ocean Manganese Nodule Mining and Environmental Studies area with Dr. Edward T. Baker of Pacific Marine Environmental Laboratories, N.O.A.A. for my Master of Science. Interactions with Professors Hsin Yi Ling and Francis A. Richards at the University convinced me to further pursue blue-water particle oceanography.

I came to Woods Hole in the summer of 1978 to work with Dr. Susumu Honjo on biogenic opal particles. During the last three years here and a part of the time at M.I.T., I have been spending the most satisfactory and productive time during the past to become a full scientist mainly owing to extremely good advisors and scientists around me. Among many professional meetings that I participated in, the 1st International Conference on Ecology of Marine Planktonic Protozoa held at Villefranche-sur-Mer, France, 10-23 May 1981, was the most influential and beneficial for my career. We had a son in May 1979 and a daughter in March 1981.

I plan to continue doing research in the related field of this thesis work as a postdoctoral fellow at the Woods Hole Oceanographic Institution beginning December 1, 1981.
