Abstract

Data collected during multiple surveys of hydrography, velocity, and biological quantities are presented from a 9-day cruise aboard the *R/V Oceanus* near the island of St. Thomas, USVI and a subsequent transit to Bermuda during December, 2008. This cruise (OC449-09) was undertaken primarily to field test a newly acquired towed-undulating body, the Scanfish. The Scanfish and a second towed body, the Video Plankton Recorder (VPR), were used to survey hydrographic, optical, and biological properties north and south of St. Thomas. Conductivity-Temperature-Depth (CTD) casts and plankton net-tows were made at locations along the survey transects for inter-comparison. The VPR was also used to profile conditions between St. Thomas and Bermuda during transit. An overview of the cruise is given along with descriptions of the data collection methods, processing steps taken, and data products available for distribution.

1 Introduction

From December 1-10, 2008, a program of high-resolution physical, optical, and biological sampling was carried out from the *R/V Oceanus*. These observations form part of an ongoing effort to investigate the mechanisms responsible for the exchange of biota between the coral reef environment and the open ocean. The primary surveys, conducted in the waters of the U.S. Virgin Islands (USVI), were followed by a 1500-km transect in the western Atlantic, terminating at Bermuda. The reefs surrounding the USVI are home to varied and economically important species, and are subject to intense interaction on several timescales with both the Atlantic Ocean and the Caribbean Sea. A primary objective of this initial cruise was instrument testing and methodology development. The cruise also provided an opportunity, in a relatively controlled environment, for the science party to become familiar with new technologies and techniques.

This data report seeks to introduce the large and varied data set obtained during OC449-09, to describe the steps taken to ensure the quality of the data, and to catalog the data products available for future use. An overview of the sampling done on the cruise and general conditions present is given next. Afterwards, the steps taken to process the raw observations into finished, quality-controlled, data products are described along with the data products available. Finally, initial graphical representation of many of these data are presented in a series of appendices.

2 Scientific Party

The following individuals participated in OC449-09 as part of the science party:

- Dr. David Fratantoni, Chief Scientist, Woods Hole Oceanographic Institution
- Dr. Cabell Davis III, Woods Hole Oceanographic Institution
- Mr. Joshua Eaton, Woods Hole Oceanographic Institution
- Ms. Colleen Petrik, Woods Hole Oceanographic Institution
- Mr. John Lund, Woods Hole Oceanographic Institution
- Dr. Benjamin Hodges, Woods Hole Oceanographic Institution
- Dr. Nasseer Idrisi, University of the Virgin Islands
- Mr. Frank Bahr, Woods Hole Oceanographic Institution
- Dr. Anthony Kirincich, Woods Hole Oceanographic Institution
- Ms. Melissa Patrician, Woods Hole Oceanographic Institution
- Mr. Nicholas Woods, Woods Hole Oceanographic Institution
- Dr. Haitham Aljahdali, King Abdullah University of Science and Technology
- Dr. Yasser Kattan, Aramco Services Company
- Mr. Waring Partridge, Woods Hole Oceanographic Institution
- Mr. Alexander Dorsk, Woods Hole Oceanographic Institution

3 Cruise Overview

Cruise OC449-09 left St. Thomas on December 1st, 2008, spending 2.5 days south of the island and 2 days north of the island before beginning a 4 day transit from St. Thomas to Bermuda. Conductivity-temperature-depth (CTD) casts and net tows were carried out at stations distributed throughout the study area, but the primary method of investigation was towing two robotic profiling platforms: the Scanfish and the Video Plankton Recorder (VPR) towfish. Both platforms were equipped with CTDs and chlorophyll fluorometers. Scanfish also measured turbidity and dissolved oxygen. Each instrument platform was towed in accordian-type survey patterns just offshore of the coral reefs to the south of St. Thomas, and just offshore of the prehistoric reefs to the north of the island. In addition to basic physical and bio-optical sensors,

each platform carried a state-of-the-art optical plankton counting instrument. The Laser Optical Plankton Counter (LOPC) mounted on the Scanfish resolves particles into size classes ranging from 0.1 mm to 2 mm in 15-micron increments, and records the outline of larger particles up to 3.5 cm. The VPR on the VPR towfish photographs and automatically categorizes plankton on the basis of their shapes.

A chronological list of the sampling events undertaken and stations occupied during each of these three phases of the cruise is given in Table 1. After an initial CTD cast over the continental shelf south of St. Thomas, the Scanfish towed-undulating body was deployed nearby at line 1 to sample the hydrographic and optical properties of the top 100 m of the water column in the channel between St. Thomas and St. Croix (Figure 1). After approximately 15 hours of sampling, at the end of line 3, a problem developed with data transfer to the Scanfish, and the instrument was recovered for repair. The VPR system was used to finish the large area survey south of St. Thomas (event 3 on Table 1, blue tracklines in Figure 1), occupying the top 100 m of the water column on lines 4, 5, and 6 of the survey grid.

After finishing this first VPR survey, the *R/V Oceanus* returned to line 3 of the survey grid (the C line) to conduct CTD casts at 8 stations spaced between the two islands. At each station, the ship's main CTD was deployed and lowered to depths of 1000 m or approximately 10 m above bottom for shallower locations. Bottle samples were collected on each upcast to provide insitu calibration of the CTD's onboard fluorometer and to collect water for the analysis of nutrients present within the water column. The number of samples collected for each varied due to the depth of the cast and the depth of the local chlorophyll maximum. At all stations, 15- to 30-minute long tows of a pair of plankton nets were made to collect samples for future

analysis. The net meshes were 64 and 150 microns in size respectively and samples for both were collected, split, and preserved for future study. These tows generally went to depths of 500 m or 10 m above the bottom at shallower depths. To record hydrographic properties during the net hauls, an RBR XR-620 CTD was attached to the cable, 1 m above the net openings, and flowmeters were installed in each net opening. Work on these biological samples is ongoing, so only the RBR CTD data will be described here. After CTD station C9, the repaired Scanfish was redeployed and towed north along this "C" line, to test the cable repair made while underway and reoccupy this particular section. At the northern end of line 3 (of the "C" CTD stations) the Scanfish was recovered, and the *R/V Oceanus* transited to the waters north and slightly west of St. Thomas.

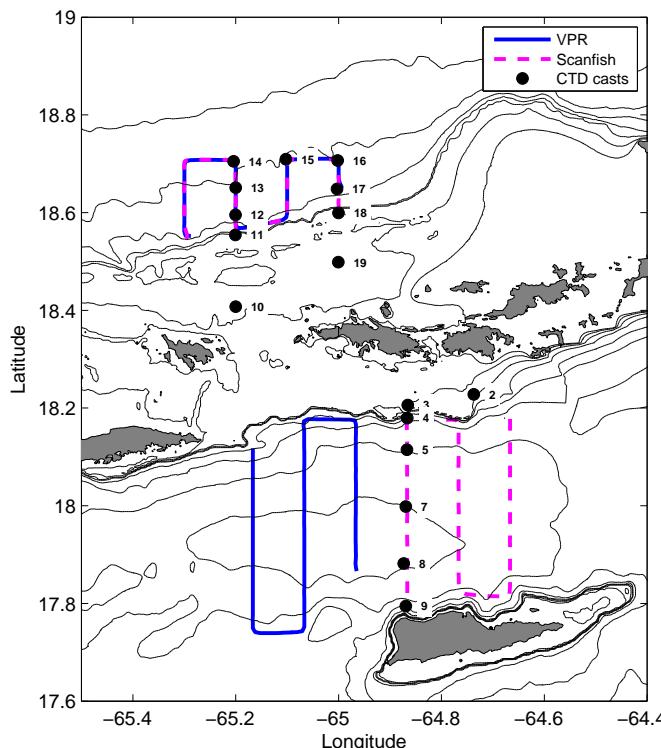

Figure 1. The study area around the island of St. Thomas. Tracklines of Scanfish tows #1 and 3, VPR tows #1 and #2, and the CTD stations are shown, along with bathymetric contours of 0 (shaded) 50, 100, 200, 500, 1000, and 2000 m.

departing the area for the 4 day transit to Bermuda. The VPR system was deployed in the late evening of the 6th to survey the upper water column during transit. During the VPR sampling, a series of 52 Expendable Bathymeterograph (XBT) casts were made to collect temperature measurements while underway. Maximum water depths sampled by the XBTs approached 760 m, but infrequently were as shallow as 300 to 400 m.

In addition to the Scanfish, VPR, and CTD sampling described, the *R/V Oceanus* collected velocity, surface hydrography, and local meteorological measurements throughout the cruise as part of the underway data collection system. Velocity measurements to depths as great as 800 m were collected using two Acoustic Doppler Current Profilers (ADCPs) mounted on the hull of the *R/V Oceanus*. Sea surface temperature, conductivity, and chlorophyll fluorescence were measured in an on-board pumped seawater system. Mete-

On the north side of the island, the Scanfish was redeployed and proceeded to sample the top 100 m along a smaller survey grid which took approximately 9 hours to complete. Despite its smaller spatial size, this survey pattern spanned the shelf break and slope, ranging from water depths of 50 to greater than 1500 m. After completion of this Scanfish tow (#3), the VPR was deployed and towed along the same survey track (Figure 1), starting from the southeastern corner. The combined Scanfish and VPR tows resulted in hydrographic and biological sampling of this shelf-slope boundary area for a period of 18+ hours. After completion of the northern survey area by these high-resolution systems, a series of CTD casts and net tows were made at ten additional stations spaced along and inshore of the survey grid. Casts and net tows here were performed the same as described above for the southern survey area.

On December 6th, 2008, the *R/V Oceanus* left the northern survey area and transited back to St. Thomas for a personnel transfer before

orological measurements, collected on the forward mast of the *R/V Oceanus*, were also obtained and are included in the data presented here.

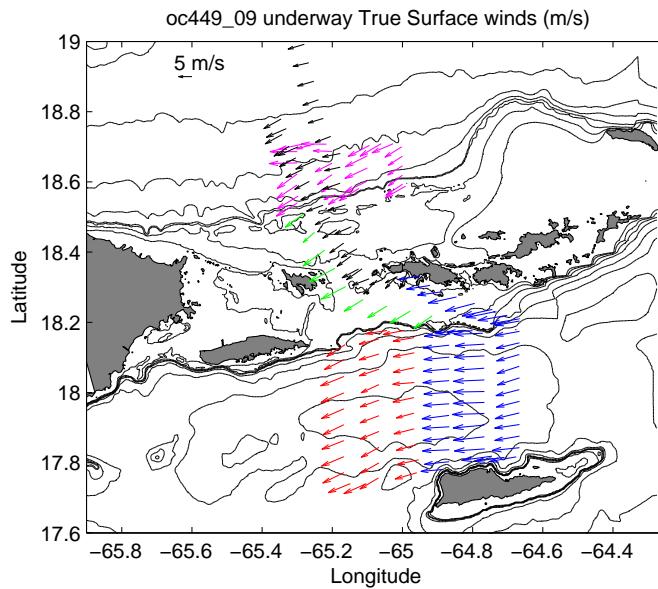

Figure 2. 20 minute averages of *R/V Oceanus* wind measurements, corrected for ship motions before and during Scanfish tow #1 (blue), VPR tow #1 (red), transit to the northern shelf (green), Scanfish tow #3 (magenta), transit to and from St.Thomas after December 6th, 2008 (black).

the southwest corner of the ship tracks. Surface salinity varied over a larger range (2 psu) and was saltiest on northern side of the island, offshore of the northern shelf. The fluorescence voltage shown in the bottom panel of Figure 3 follows that of salinity.

Water column velocities were collected by two separate ADCPs onboard the *R/V Oceanus*. Observations from both were combined to produce a data product of 20 minute ensemble averages of velocities from 13 m below the surface to as much as 800 m below the surface. This product was used to produce the layer-average plots shown in Figure 6 as well as the velocity sections included with the Scanfish and VPR data appendices. Layer-averaged velocities, shown in Figure 6, reveal a strong westward flow in the southern survey area during both the Scanfish and VPR surveys. In contrast, layer-averaged velocities during the Scanfish survey of the northern survey area were weak at most all locations. Isolating the velocities of the top 100 m of the water column where Scanfish and VPR sampling was concentrated shows sharply different results. A large eddy appears to exist adjacent to the shelf south of St. Thomas, while stronger along channel flows exist to the south and west. Along the northern survey area, surface layer velocities are much stronger than that seen in the rest of the top 800 m. These flows are generally directed eastward along the shelf and exceed 10 cm s^{-1} .

While the spatial structure of velocity and hydrography have been described here, it should be noted that the features described here and above were measured over a 5-day period. Thus, the variability seen could also represent temporal variability of the waters in and around St. Thomas, including that associated with tidal variability. Further analysis of those areas where repeated sampling by the Scanfish, VPR, and/or CTD casts was obtained would aid answering this question. However, this task is beyond the scope of this data

An initial look at the oceanographic and meteorological conditions present in and around St. Thomas can be seen in maps of the near-surface winds and surface hydrography obtained during the first two portions of OC449-09 (Figures 2 and 3), as well as the ADCP full depth-averaged and top 100 m average velocities (Figure 6). Winds above the sea surface were generally from the east at 5 to 10 m s^{-1} during the first 6 days of December. These wind directions and velocities are consistent with forcing from the easterly trade winds. The wind product (described later) during each of the major phases of sampling is color-coded by sampling event, as shown in Figure 2, to allow the winds associated with each event to be clearly seen.

Surface temperatures varied over a small, 1°C range at all locations sampled around St Thomas with the warmest waters occurring at

report.

All observations described here were processed after completion of the cruise to ensure the quality of the data set and organized into data products for distribution and analysis. These methods are described next for the Scanfish and VPR towed surveys, the at-station CTD casts and net-tows, the underway XBT casts, and the underway ADCP, meteorological, and surface hydrographic measurements. Additionally, a catalog of the data products available for each type is given. Processing of the VPR optical data and the biological samples collected during the net tows is ongoing.

4 Description of processing steps and data products

4.1 Scanfish towed surveys

The Scanfish sensor suite included a SBE 9+ unit with sensors for conductivity, temperature, pressure, and dissolved oxygen; a WETLabs Fluorometer & Turbidity Sensor (ECO FLNTU), measuring chlorophyll fluorescence and turbidity; and a LOPC. Data from each instrument were recorded at the native sampling rate: 24 Hz for the SeaBird sensors, 2 Hz for the LOPC, and approximately 1 Hz for the FLNTU.

There were three Scanfish deployments: two to the south of St Thomas and one to the north. Data from each of these tows were processed in MATLAB as follows. Pressure datapoints outside the range of -2 to 150 dB were rejected, as were conductivity datapoints outside the range of 5.4 to 6 S/m. The 24 Hz SBE data were smoothed with a 5-point running median filter. The effect of thermal lag on the conductivity measurements was corrected following Morison et al. (1994). The SBE data were then trimmed to remove non-profiling periods and block-averaged to 1 Hz. The processed data files for each deployment include these 1 Hz time series as well as arrays of the same data in which each column represents a single profile (up or down), along with vectors containing the corresponding average time and location for each profile. A third data product included in each file further averages the data in each column into 1-dB pressure bins. Oxygen measurements exhibited severe hysteresis which was not easily corrected, and these data are not included in this report. This sensor has been returned to Sea Bird for analysis. FLNTU measurements were converted from engineering to science units using the factory calibrations, and are included in the processed data files in the same three forms as the SBE data.

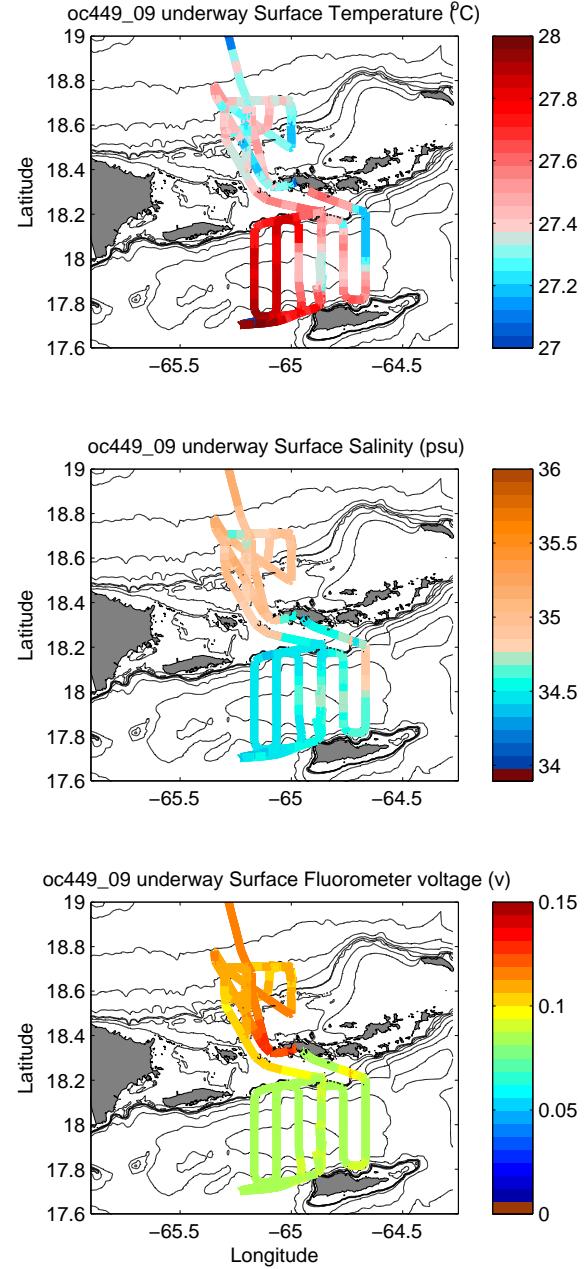

Figure 3. Underway surface temperature (top) salinity (middle) and chlorophyll fluorescence (bottom).

The LOPC counted the number of particles passing through its sensing volume in each of 128 size classes, each spanning a 15-micron range of equivalent spherical diameter. Outlines of the shapes of larger particles were recorded as well, but those data are not presented in this report. The particle size data are included in the processed data files in the same three formats, but with an extra dimension for bin size. Sections of the various data types from each Scanfish deployment are presented in Appendix A. As it is not practical to graphically show all the LOPC data, only the total particle volume and volume-weighted mean particle size are included.

4.2 Video Plankton Recorder towed surveys

Conductivity, temperature, and pressure measurements were collected during each of the VPR tows by an onboard SBE 49 FastCat Conductivity-Temperature (CT) sensor. Data from the instrument, converted to salinity, temperature, and pressure internally, were collected by the VPR's flight computers at the full 16 Hz temporal resolution output by the CT. These data were subsampled in real time to create CT log files of 1 Hz data as a separate data product from the main, image-intensive, VPR data stream. The 1 Hz CT log files were processed as described below for inclusion here, while the main VPR dataset will be analyzed and reported on at a later date.

Four main CT data files exist, one each from VPR tows #1 and #2, and two from the long VPR tow #3 during the transit to Bermuda. CT log files were processed within MATLAB to eliminate unrealistic temperature, salinity, or pressure observations using high and low thresholds of 20 and 30°C, 30 and 38 psu, and 0 and 120 dB for temperature, salinity, and pressure respectively. First-difference thresholds (5 dB, 1.5°C, and 1.2 psu) were then applied to eliminate spikes in the pressure, temperature, and salinity data before density, as σ_θ , was calculated following Fofonoff and Millard (1983). The datasets were then cut to isolate the in-water undulating portion of each file, eliminating the deployments and recoveries. Finally, the top and bottom of each up- and down-cast of the towed undulations were identified and the data between them were used to create vertical profiles of T,S, and σ_θ at 1-dB increments with each profile marked by the average time and location of the data between the peaks.

Data products for the VPR CT data include the raw ASCII log files collected by the instrument, and processed, cleaned MATLAB (*.mat) data files of both timeseries data and the vertical profiles described above. These profiles were used to produce the data products shown in Appendix B.

4.3 SeaBird CTD casts

Hydrographic casts were made at 19 stations using the *R/V Oceanus*'s main CTD, a Seabird SBE 911+ model with a rosette for collecting water samples. This CTD was a dual sensor system, equipped with two SBE 3 fast-response temperature sensors and two SBE 4 conductivity cells. A SBE 43 dissolved oxygen sensor and WET Labs ECO-AFL/FL fluorometer were included in the pumped system of the primary temperature and conductivity sensors. The sensors listed above were calibrated by Seabird in March of 2008 or by WET Labs, for the Fluorometer, in April of 2008. Additional sensors on the CTD included a WET Labs C-Star transmissometer, a WET Labs Turbidity sensor, and an upward-looking irradiance sensor. All data were sampled at 24 Hz by the SBE 911+ system. After the cruise, data from the CTD were reprocessed from the raw *.hex files using the standard SeaBird Data Processing Modules to create 1-dB binned-averages of all sensor and derived data. The SBE data processing modules and constants used are described here.

DATCNV was first used to convert cast data from hex format to ASCII text files (*.cnv files) and compile data for bottle summaries (*.ros files).

ALIGNCTD As the primary conductivity sensor is prelagged at the deck unit, only the secondary conductivity sensor was advanced by the standard 0.073 seconds to account for both the pumping lag and the time constant of the sensor. The SBE 43 Oxygen sensor voltage output was advanced by 3 seconds for the same reasons. This lag is relatively standard for the instrument setup used, but was checked by additional processing efforts that computed cross-covariances between oxygen and temperature for the down- and upcasts.

WILDEDIT marks and eliminates outliers by submitting the data to 2 passes of a standard deviation filter. The first pass uses a 100 scan window and flags data greater than 2 standard deviations from the mean of the window. The second pass uses a 20 standard deviation threshold for the same window size. Scans with flagged data are removed from the data files.

CELLTM applies a recursive filter to remove conductivity cell thermal mass effects from the measured conductivity. A standard thermal anomaly amplitude (alpha) and time constant (tau) of 0.03 and 7.0 respectively were used to construct the filter.

ROSSUM exports a summary of all the observations collected in the 3 seconds before each bottle was fired. Derived variables of salinity, density (as sigma theta), and oxygen content ($\mu\text{mol/kg}$) and percent saturation (%) were added to the bottle data exported.

FILTER performed a low-pass filter of the pressure data using a time constant of 0.15 seconds. The filter was run forwards and then backwards to produce no time shift.

LOOPEDIT removed data scans where the CTD package was moving downwards at less than a minimum speed of 0.25 dB s^{-1} due to ship roll.

DERIVE was used to compute salinity (psu) and density (as sigma theta) from both sensor pairs as well as oxygen content ($\mu\text{mol/kg}$) and percent saturation (%) for the remaining scans.

After the derive step the resulting data products were loaded into MATLAB to complete the processing steps. Here the data were merged with a digitized log file, further quality controlled by re-screening for outliers, and bin-averaged to 1-dB bins by pressure. In this process it was determined that the fluorescence sensor on the CTD appeared to collect unrealistic data at depths approaching 1000 m for the downcast and then for all of the following upcast. Because of this, only downcast data were used to compare to the extracted chlorophyll samples obtained from the bottles. Data from the downcast was then isolated from each dataset and the file was merged with bottle nutrient data and exported to ASCII text files for the cast and bottle summary. These data were also saved as data structures within a MATLAB data file (*.mat).

4.3.1 Chlorophyll calibrations

Seawater for extracted chlorophyll samples were collected at sea at 5-7 depths for each CTD station by filtering 1 liter of seawater through a standard filter. After collection, samples were kept in a -70°C freezer onboard the *R/V Oceanus* until the *R/V Oceanus* returned to Woods Hole Oceanographic Institution (WHOI) in late December. Once back, the samples were transferred from the -70 freezer to a

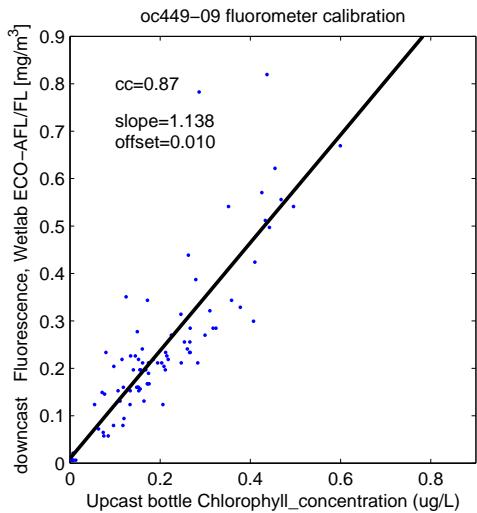

Figure 4. Shipboard CTD chlorophyll fluorescence calibration.

regression between the two had a slope of 1.138 and a near-zero offset of 0.012 $\mu\text{g/L}$. This regression was used to perform the final calibration to the CTD-derived chlorophyll measurements estimated throughout the water column. The bottle chlorophyll results are listed for each cast in Appendix C.

4.3.2 Nutrient samples

Water samples were also collected at 7-8 depths at each CTD station for nutrient analysis. After collection, samples were kept in a freezer onboard the *R/V Oceanus* until the *R/V Oceanus* returned to WHOI in late December. Once back, the samples were transferred from the ship's freezer to a dewar with liquid nitrogen, where they were kept until processing. These samples were processed at the WHOI Nutrient Facility during April, 2009 for levels of ammonia (NH_4), silicate, Phosphate (PO_4), and Nitrate + Nitrite (NO_3+NO_2). The results of these analyses are given on the bottle data table for each CTD cast in Appendix C and within ASCII (*.dat) and MATLAB (*.mat) data files of the bottle data results. For each of these nutrient measurements a value of 0.05 μM , (or <0.05) represents values below the detection limit of the testing equipment.

4.4 RBR CTD casts

An RBR CTD (model XR-620) was attached to the *R/V Oceanus*'s winch used to conduct the net tows. The temperature, conductivity, and pressure sensors of the RBR CTD were located approximately 1 m above the openings of the nets. The CTD was configured to collect measurements at 1 Hz frequency continuously during the first two parts of the cruise (south and north of St. Thomas), resulting in one data file for the whole deployment. However, valid data was only collected when the instrument was in the water. After the cruise the file was converted from the proprietary binary format to a MATLAB *.mat file by the instrument's PC software interface.

This raw data file was processed to quality control the data collected and to form individual files associated with each viable in-water portion and matched with a digitized log file of the cast, haul, and location information. The raw data file was loaded into MATLAB and screened for unrealistic temperature, conductivity, and pressure values, including temperatures greater than 40°C or less than 0°C, conductivities less than 3 S/m, and pressures greater than 700 dB or less than -10 dB. Data were then de-spiked using

a first-difference test with thresholds of 0.5°C, 0.5 S/m, and 5 dB for temperature, conductivity, and pressure. Pressure data were re-zeroed to the minimum found in the dataset to account for atmospheric pressure (recorded by the RBR as 10.375 dB), and the beginning and end of each haul was found by analyzing the dataset for consistent changes in pressure trend. Individual hauls were linked to the station location and net tow information by matching the timestamp of the RBR data file with digitized information from the cruise logs. Haul data were loop edited to eliminate decreasing pressures during downcast and increasing pressure during the upcast.

During the quality control process it was found that the conductivity observations collected by the RBR (and therefore RBR-derived salinities) had unreasonable variations within the well-mixed surface layer and poor correspondence to the subsurface values collected the *R/V Oceanus*'s main CTD. Further investigation proved that these errors were apparent in other datasets recently collected by this particular instrument. Based on these results, the conductivity measurements collected by the RBR were determined to be unreliable and discarded from the dataset. Thus only the temperature observations from these net tows are presented in Appendix E and included in the cruise dataset.

Multiple data products are available for the RBR temperature data, including (1) the raw loop-edited up and down cast, and (2) the downcast data only, bin-averaged to 1-dB pressure bins. While both types are included for all hauls in a RBR data MATLAB data (*.mat) file, only the bin-averaged data is available as ASCII-text files and was subsampled for the plots and tables shown in Appendix D.

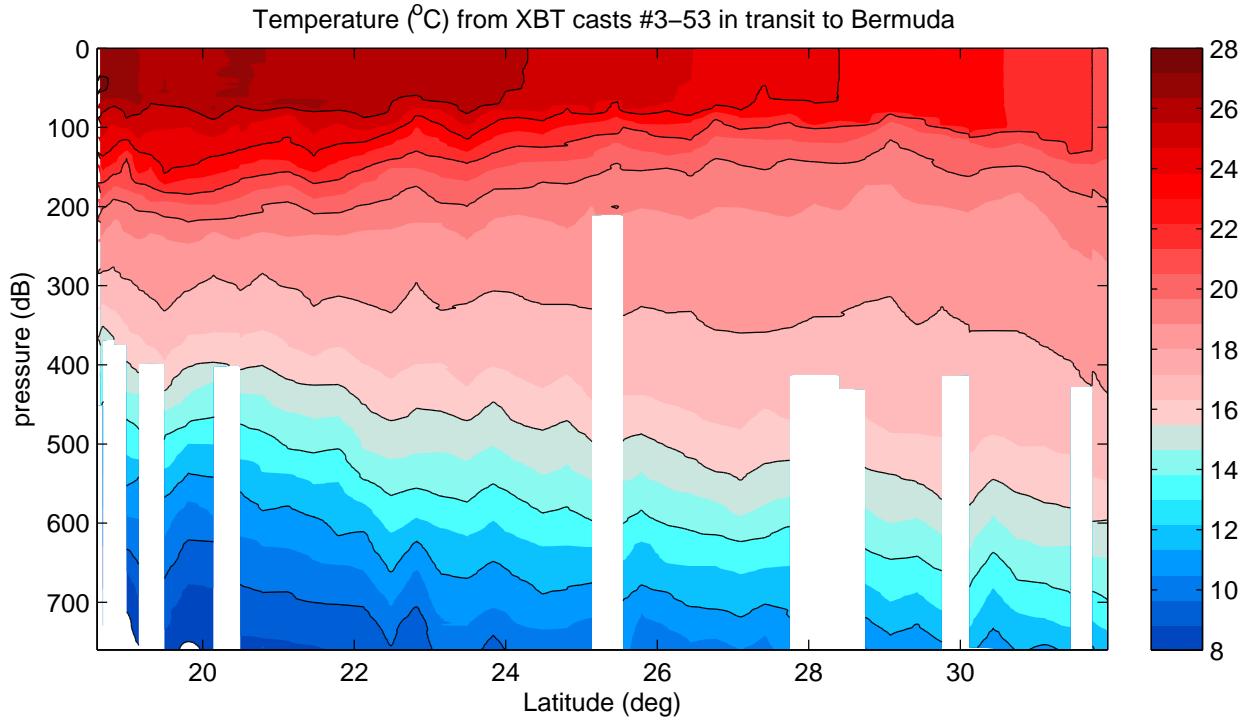

Figure 5. XBT-derived temperature between St. Thomas and Bermuda.

4.5 XBT casts

Lockheed Martin's Sippican XBT probes were utilized primarily during the transit to Bermuda to collect ocean temperature data to depths of 760 m. Deep Blue-type probes were launched over the side from a hand-held launcher and recorded using an MK21 deckbox. After the cruise, the raw binary data files for each cast were converted to ASCII text files using the PC software interface. Data from the raw files were loaded to MATLAB and cleaned and despiked using similar thresholds as those described above, and interpolated to 1-dB depth bins. Data products include a MATLAB data (*.mat) file containing data structures for all 52 casts and ASCII text files with the bin-averaged temperature and sound speed for each individual cast. These temperature data are shown in the figures in Appendix E and subsampled to form the data table listed for each cast. Additionally, the temperature observations for the 51 successful casts made in transit from St. Thomas to Bermuda are shown in Figure 5.

4.6 Underway ADCP

The *R/V Oceanus* had two shipboard ADCP's: a 75KHz Ocean Surveyor, and a 150KHz NB150 that were sampled almost continuously from the start of the cruise in St. Thomas to the ship's arrival in Bermuda. The data were collected with the UHDAS package developed and maintained by Drs. Firing and Hummon at the University of Hawaii (Hummon, 2009). Following the cruise, the data were post-processed using the standard ("CODAS") routines provided by the same group. Information on this package and these processing steps can be found at: http://currents.soest.hawaii.edu/docs/adcp_doc/index.html. The final data products consist of three MATLAB ("*.mat") files, containing post-cruise processed datasets from the two individual ADCPs as well as an attempt to combine the two datasets. In all products, the ship velocities have

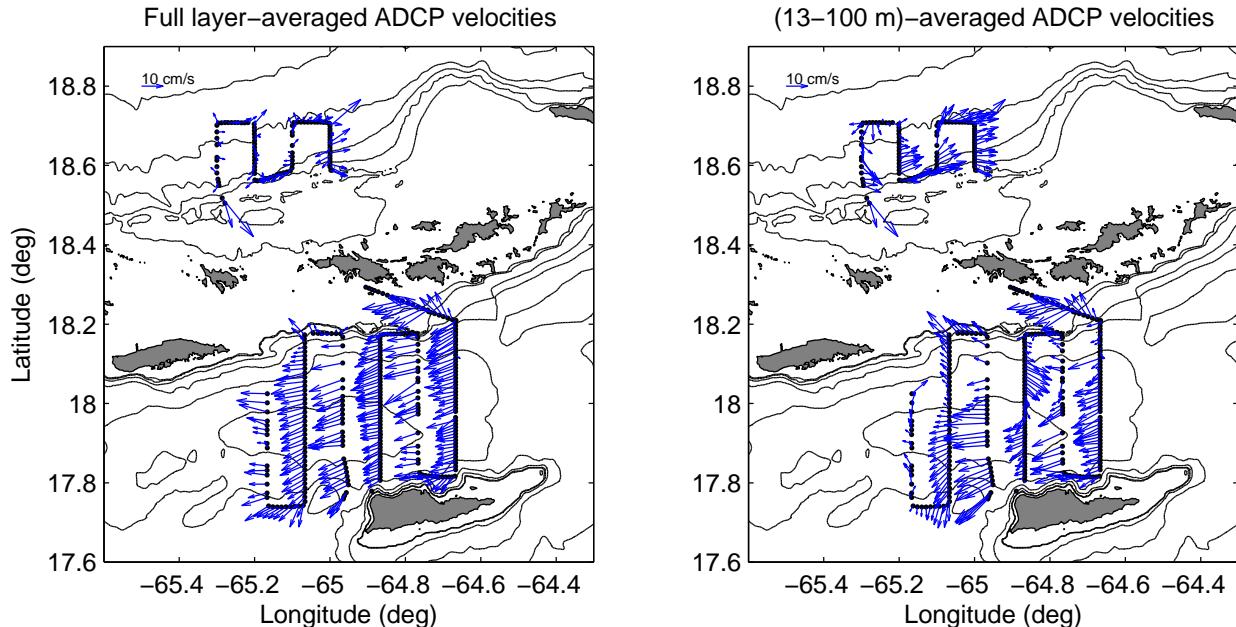

Figure 6. Vertically-averaged, 20 minute averaged ADCP velocities for the full measured portion of the water column (left) and the top 100 m (right). ADCP data shown here were collected during the same events highlighted in Figure 2: including Scanfish tow #1 and VPR tow #1 for the southern survey area, and Scanfish tow#3 for the northern survey area.

been removed, the data were quality controlled, and the individual pings were averaged to 20 minute long time ensemble averages. The data shown in Figure 6 are from this final data product.

4.7 Underway hydrographic, GPS, and Meteorological measurements

The daily data files produced by the *R/V Oceanus*'s underway data collection system were obtained and parsed using MATLAB to separate the underway GPS, meteorological, and surface water property measurements out into separate forms. For the GPS data, observations of Latitude, Longitude, Speed Over Ground (in knots), and Course Over Ground (in degrees) from the *R/V Oceanus*'s main GPS are included as a data product. Meteorological observations of: air temperature ($^{\circ}$ C), barometric pressure (hPa), shortwave radiation (raw milivolts), true wind speed (m/s), true wind direction (deg), relative humidity (%), wind direction (deg), wind speed average (m/s), rain accumulation (mm), and rain intensity (mm/hour) were recorded on the ship's forward mast at a height of 20 m above the waterline. Sea surface temperature and salinity data were collected by both a Seabird SBE45 thermosalinograph as part of the ship's pumped seawater system and at the intake for this system (near the bowthruster) by a Falmouth Scientific TSG. Additionally, a WET Labs Wet-star fluorometer located inside the system near the SBE45 recorded fluorescence voltages. These datasets were collated for the length of the cruise, screened for outliers, and averaged into 20 minute averages using a standard time stamp centered on the hour. The averaged data starts when the *R/V Oceanus* left the harbor in St. Thomas at 1800Z December 1st, 2008 and ends upon arrival in Bermuda at 0800Z December 19th, 2008. Data are stored in separate *.dat files (ASCII text) for each subset of data (gps, met, surfprop) and combined in a single MATLAB (*.mat) data file.

4.8 Temperature-Salinity inter-comparisons

No bottle samples were collected to perform in-situ calibrations of the conductivity sensors on the *R/V Oceanus*'s CTD or the CTDs of the Scanfish and VPR. However, as the same or nearly the same locations were sampled by each of these three CTDs, inter-comparisons of the temperature-salinity properties of the top 100 meters were made to ensure that the measurements obtained by each were at least consistent with each other. Data collected at or near CTD stations 7 and 13 (see map) provide the best data for comparison. Here VPR, Scanfish, and *R/V Oceanus* CTD data were collected at the same locations (or nearby for the VPR survey near station 7) and close in time to each other. Shown here, temperature and salinity relation-

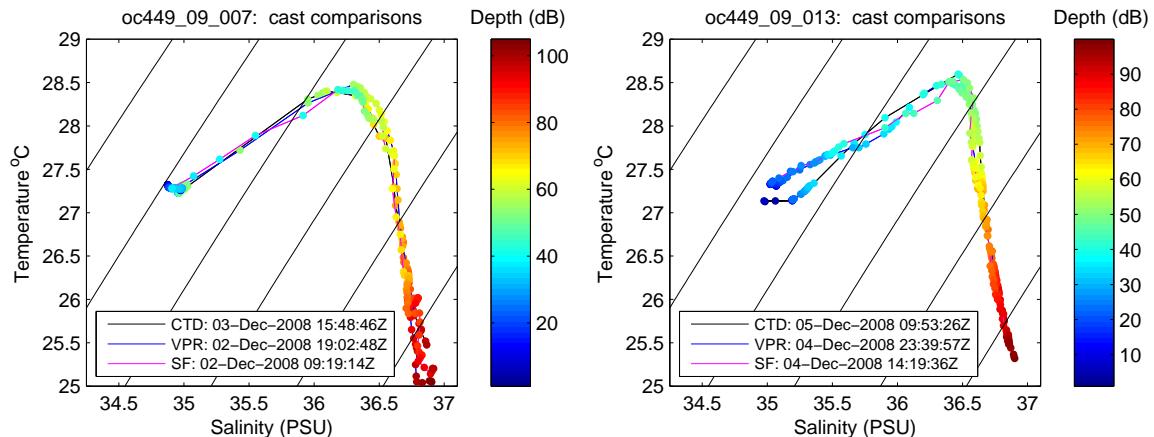

Figure 7. T-S comparisons for the Scanfish, VPR, and *R/V Oceanus* CTDs at CTD stations 7 and 13.

ships for all three data types have similar structures at both stations. Additionally, the distribution of these properties with depth are quite similar for all data sources. The largest amount of variability at both stations appears within the top 10-15 meters, while Temperature-Salinity (T-S) properties and depth distributions are identical below 60 m.

5 Acknowledgements

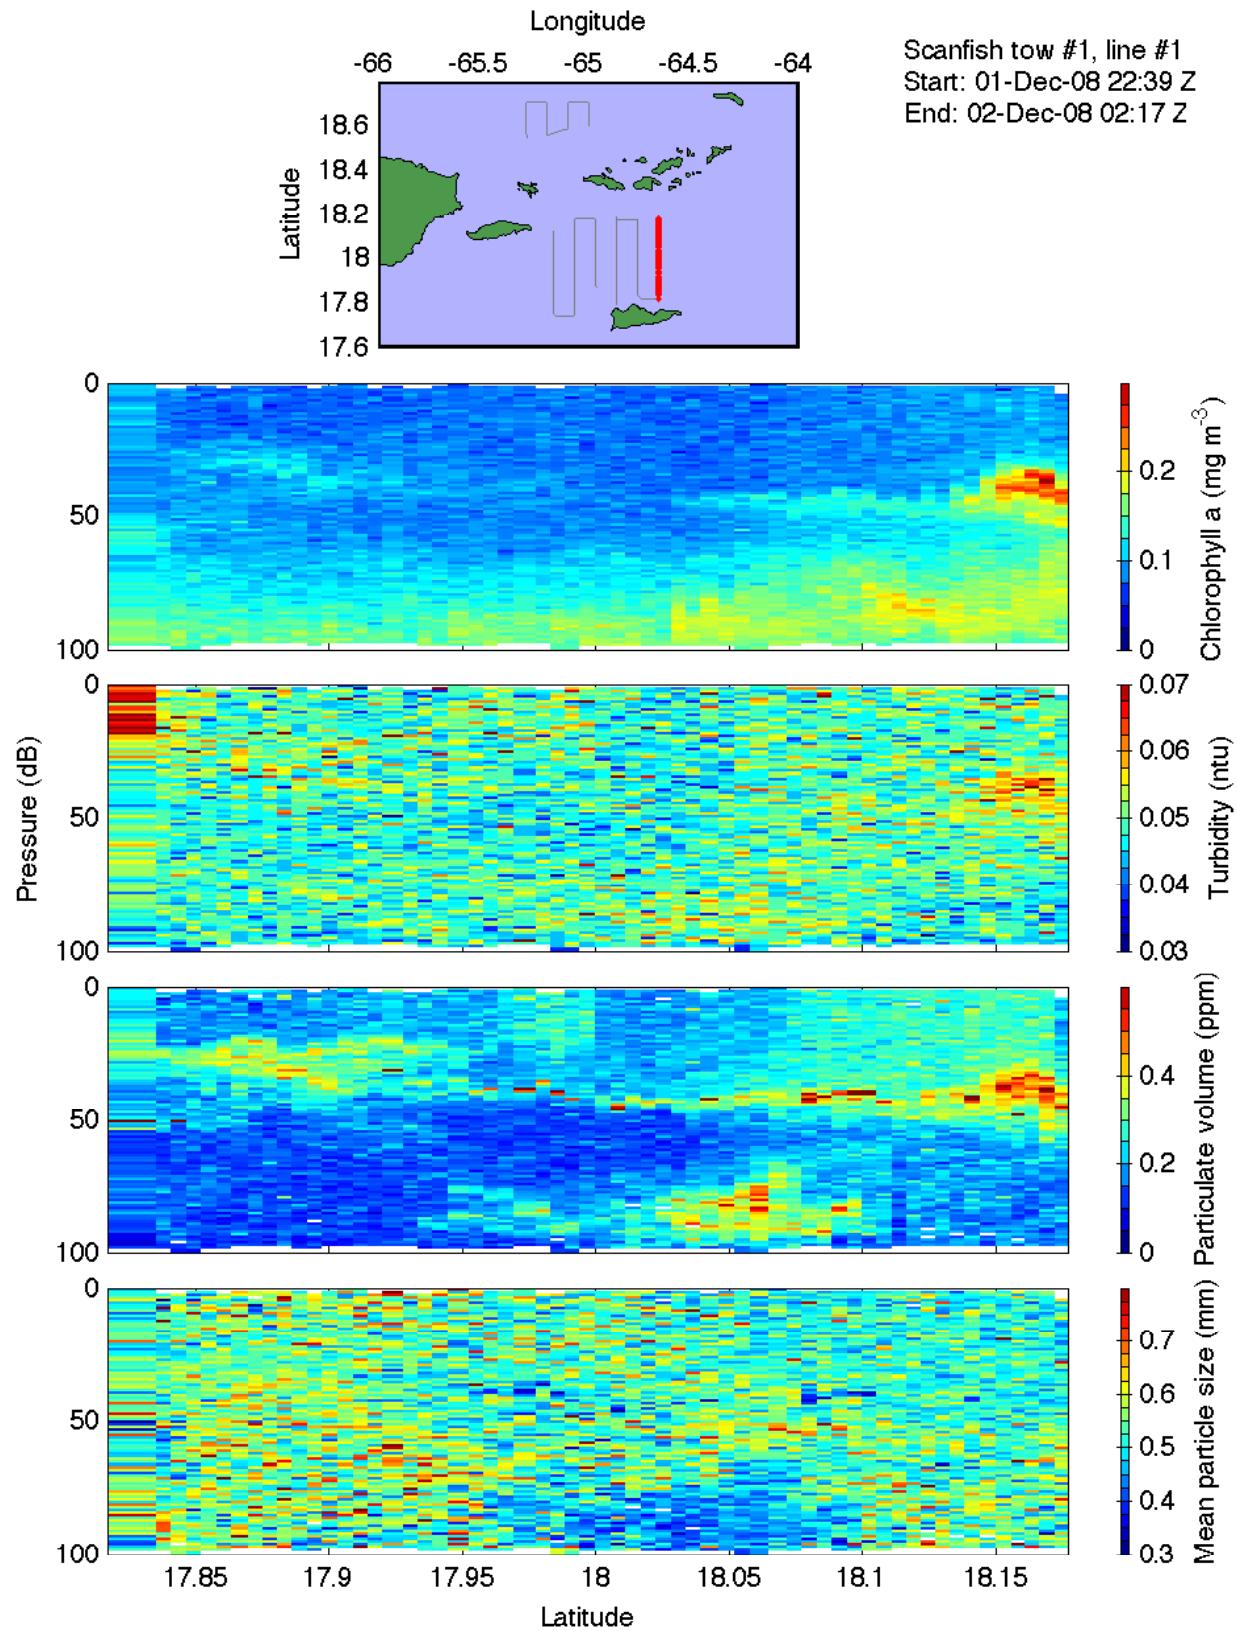

This publication is based in part on work supported by Award No. USA-00002, made by King Abdullah University of Science and Technology (KAUST). We thank Captain Diego Mello and the crew of the *R/V Oceanus* for their efforts in making this cruise a success. Additionally, we thank Melissa Patrician for processing all chlorophyll samples for the post-cruise calibration, Joshua Eaton and Cabell Davis for their work supervising the VPR sampling, Alexander Dorsk for his service as the shipboard scientific technician, and Nasseer Idrisi for arranging the small boat personnel transfer in St. Thomas.

A Appendix: Scanfish Sections

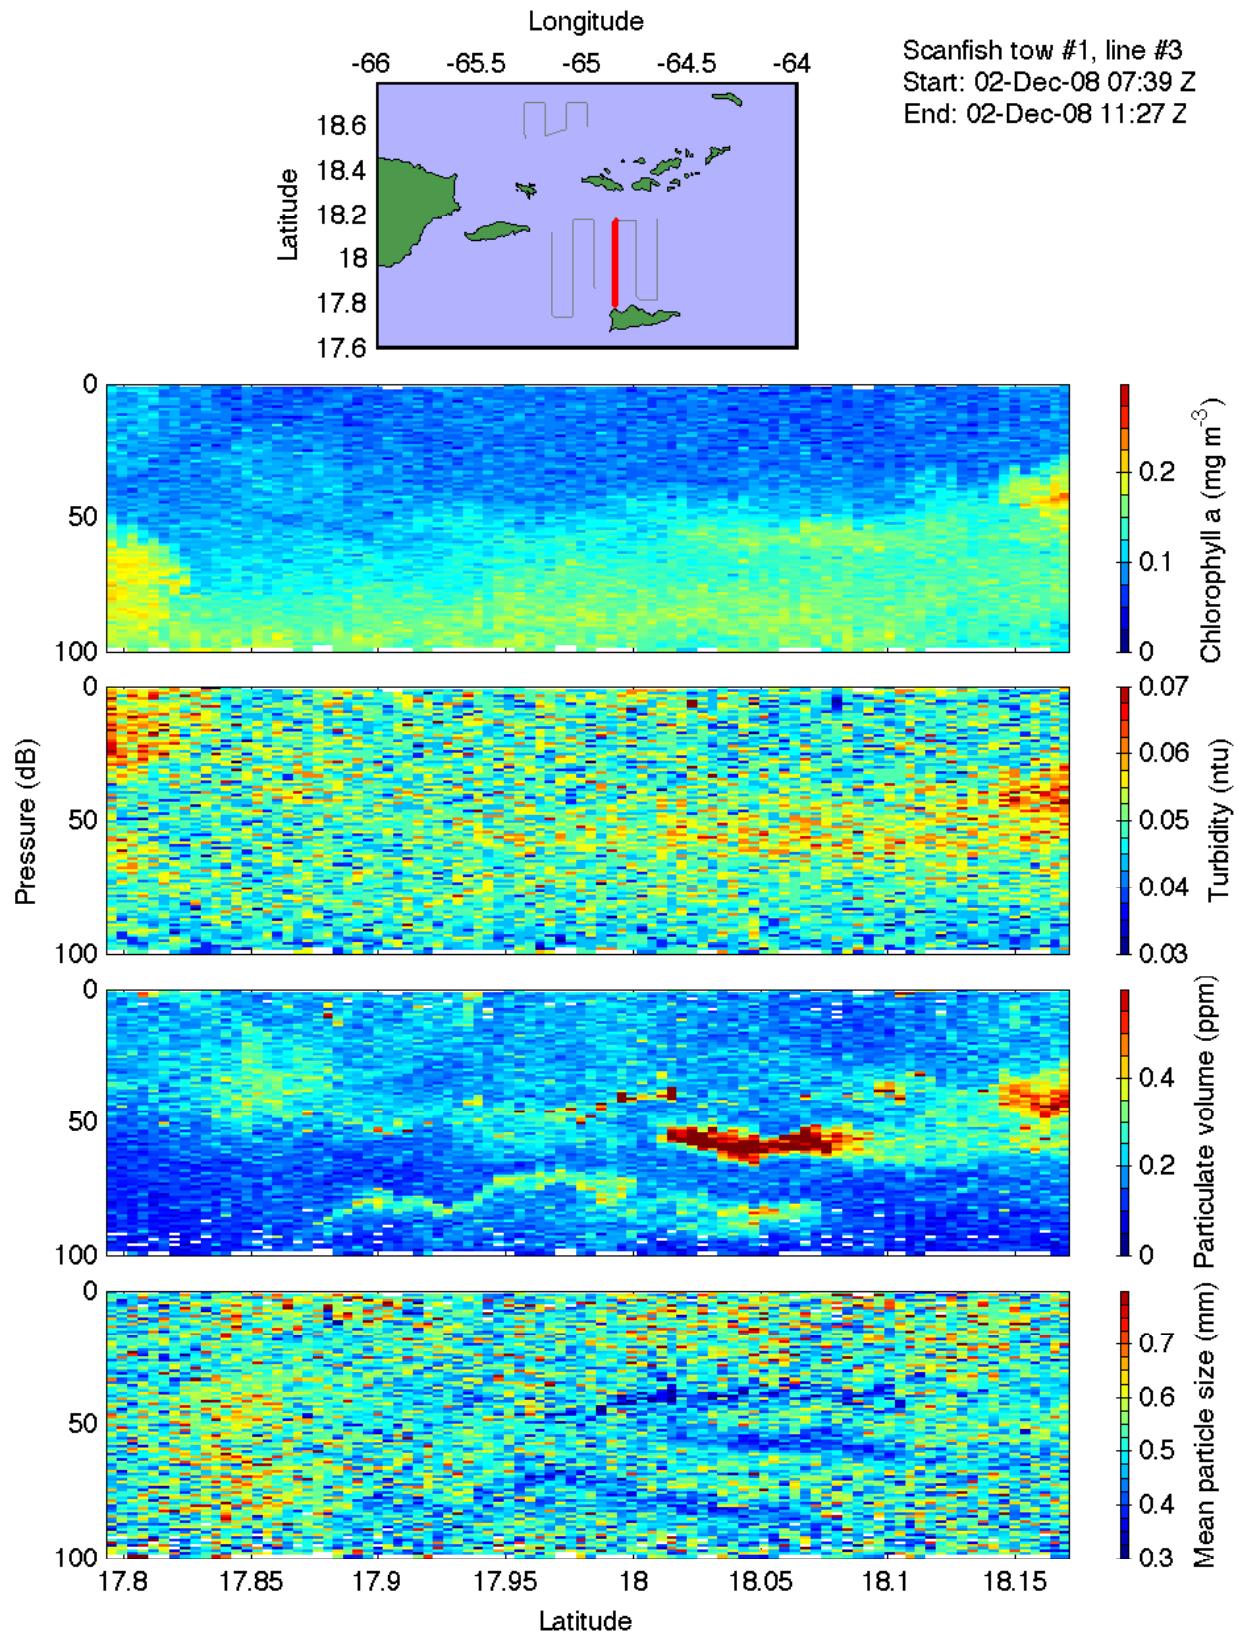

Scansurvey results are shown for: the three sections made south of St. Thomas during Scanfish tow #1, the resampling of line 3 south of St. Thomas during Scanfish tow#2, and the northern survey sampled during Scanfish tow #3. Each set of figures shows: (*at left from top to bottom*) a map of the relative location of the transect, and vertical sections of Chlorophyll *a* concentrations, Turbidity concentrations , the total particulate volume measured by the LOPC, and the volumetrically-weighted mean particle size. (*at right from top to bottom*) vertical sections of temperature, salinity, and density (as σ_θ), as well as shipboard ADCP East (U) and North (V) velocities. Different color map ranges are used for the southern survey area and the northern survey area.

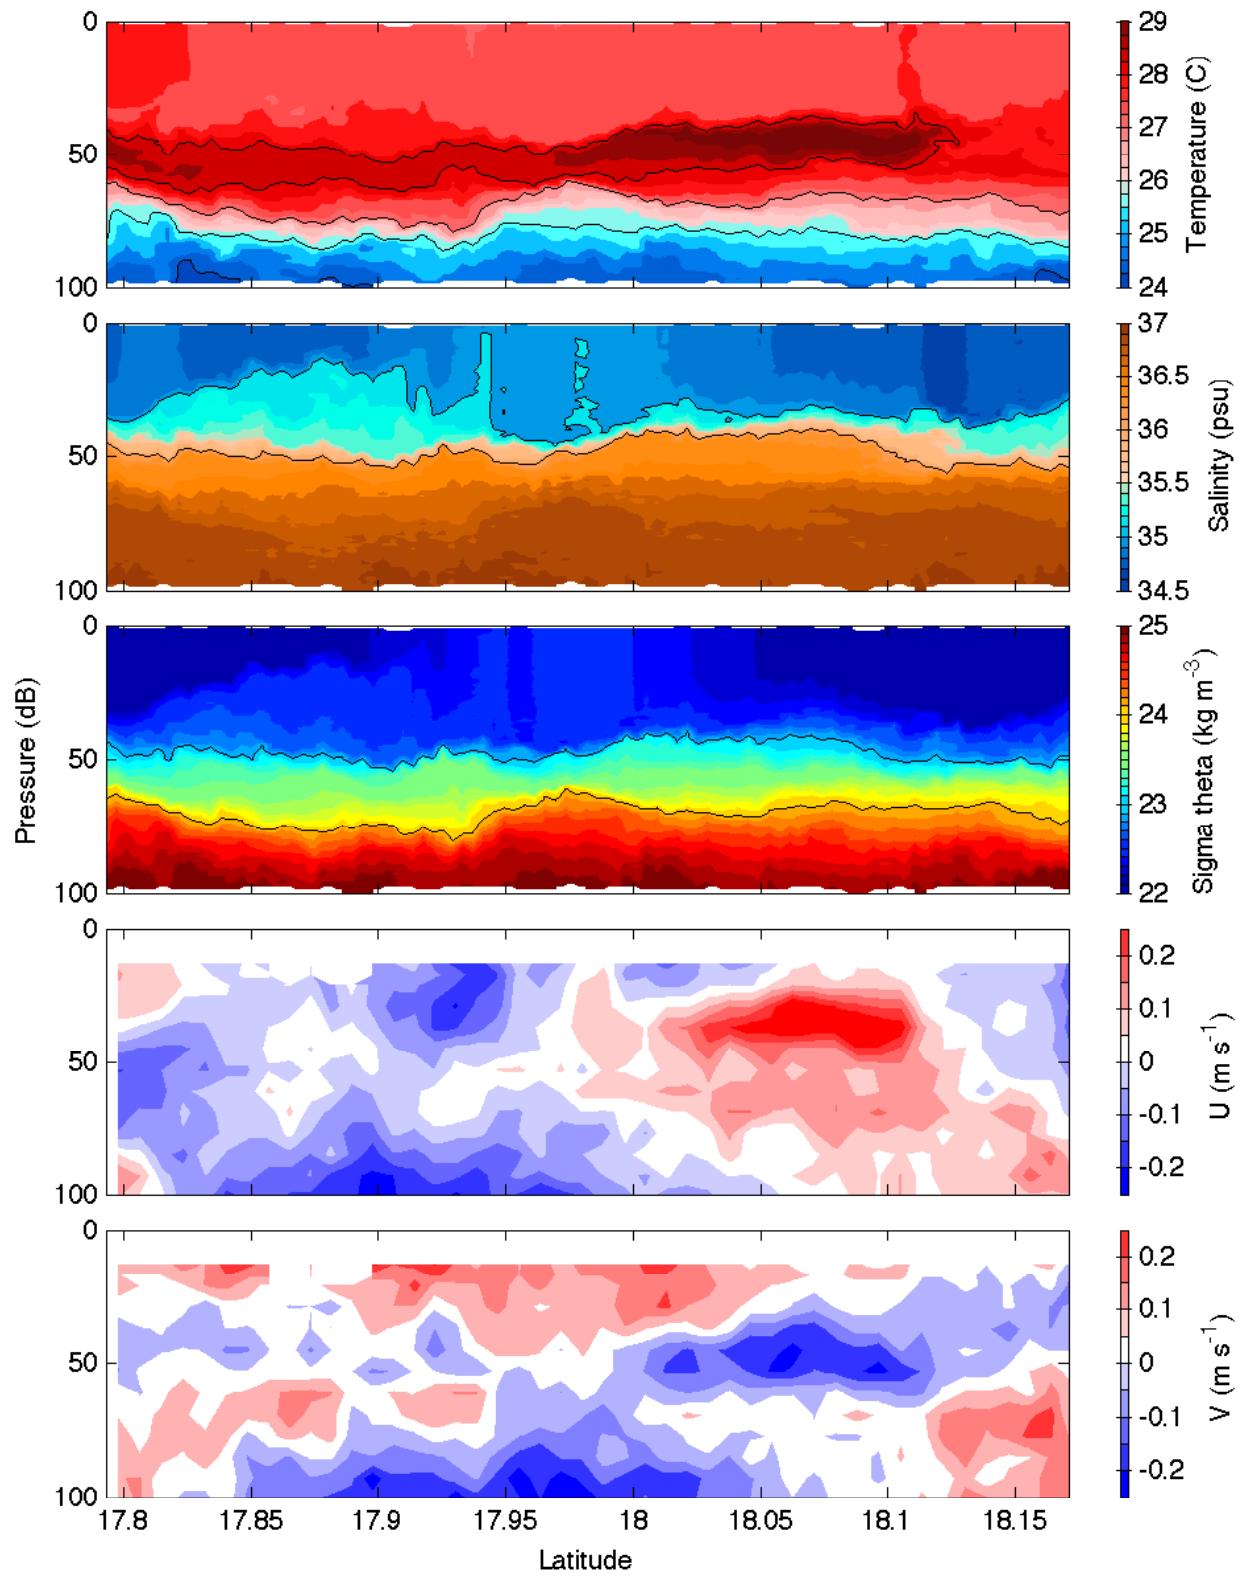

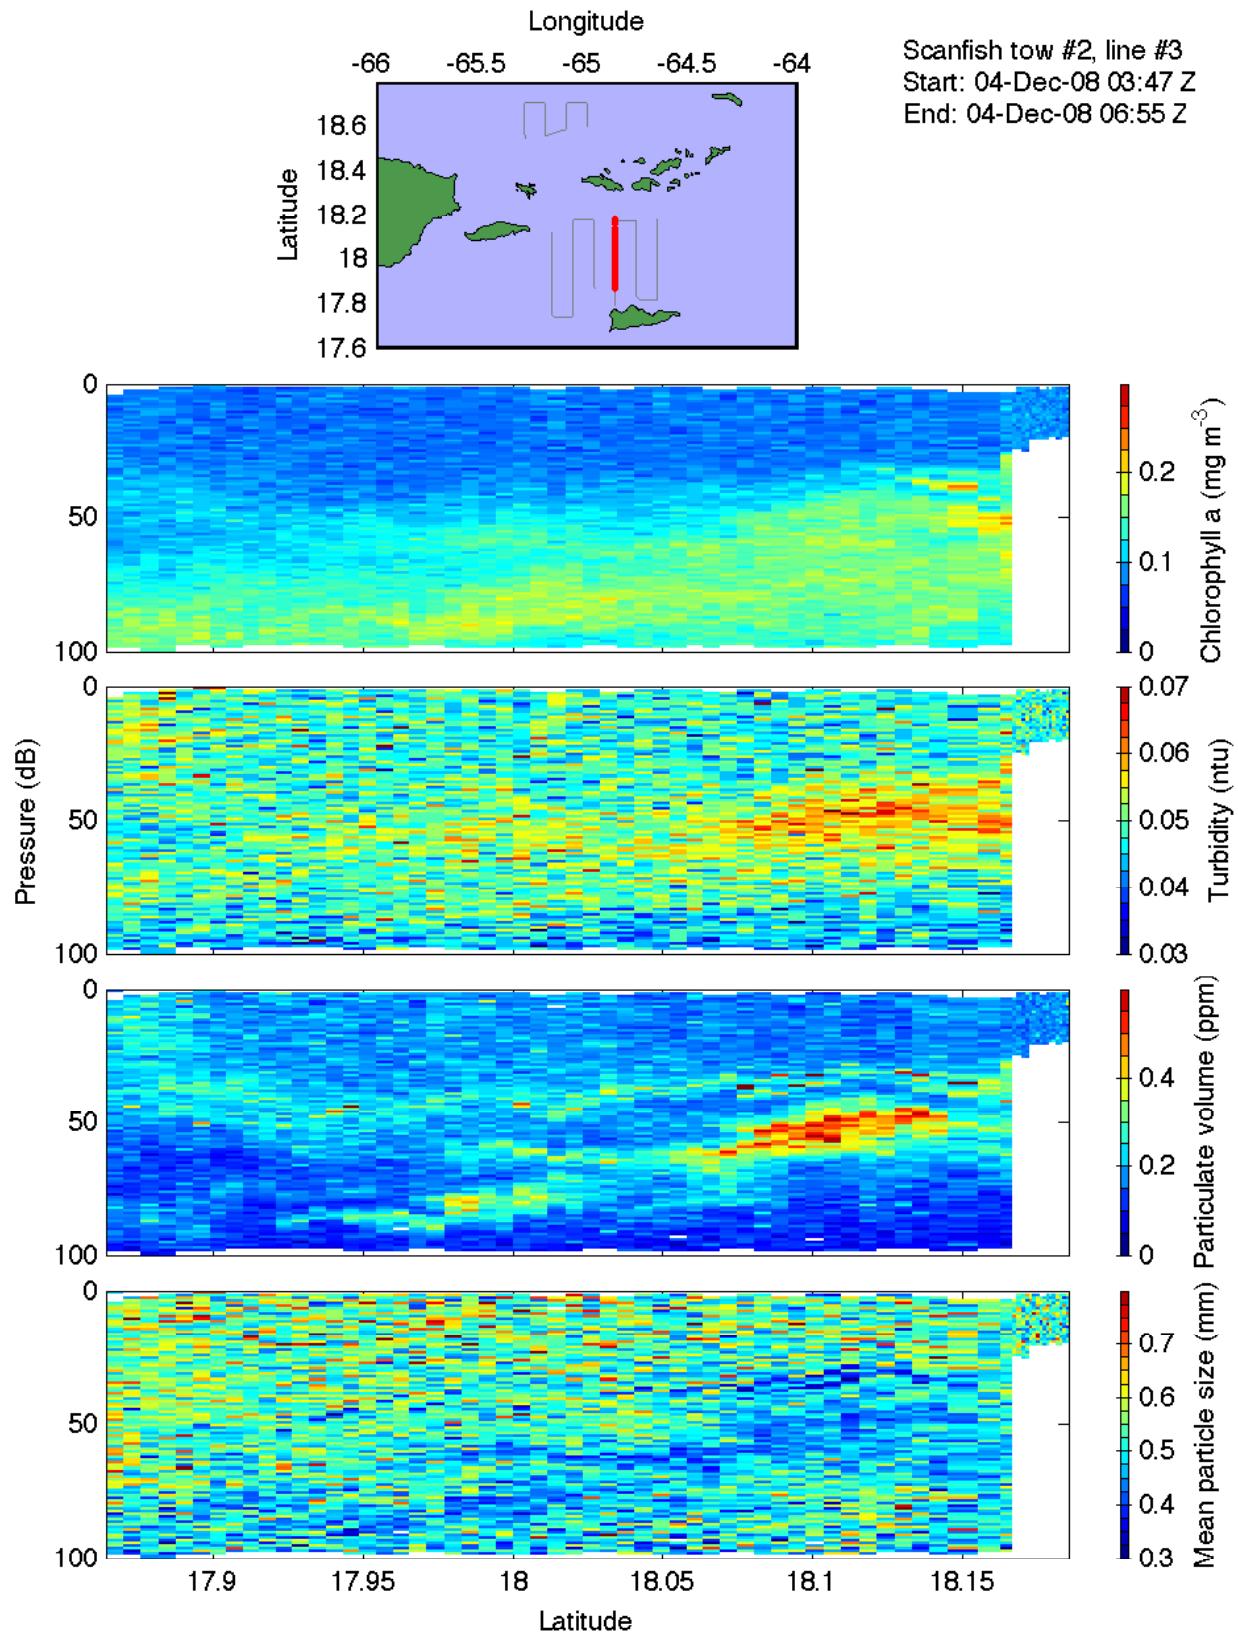

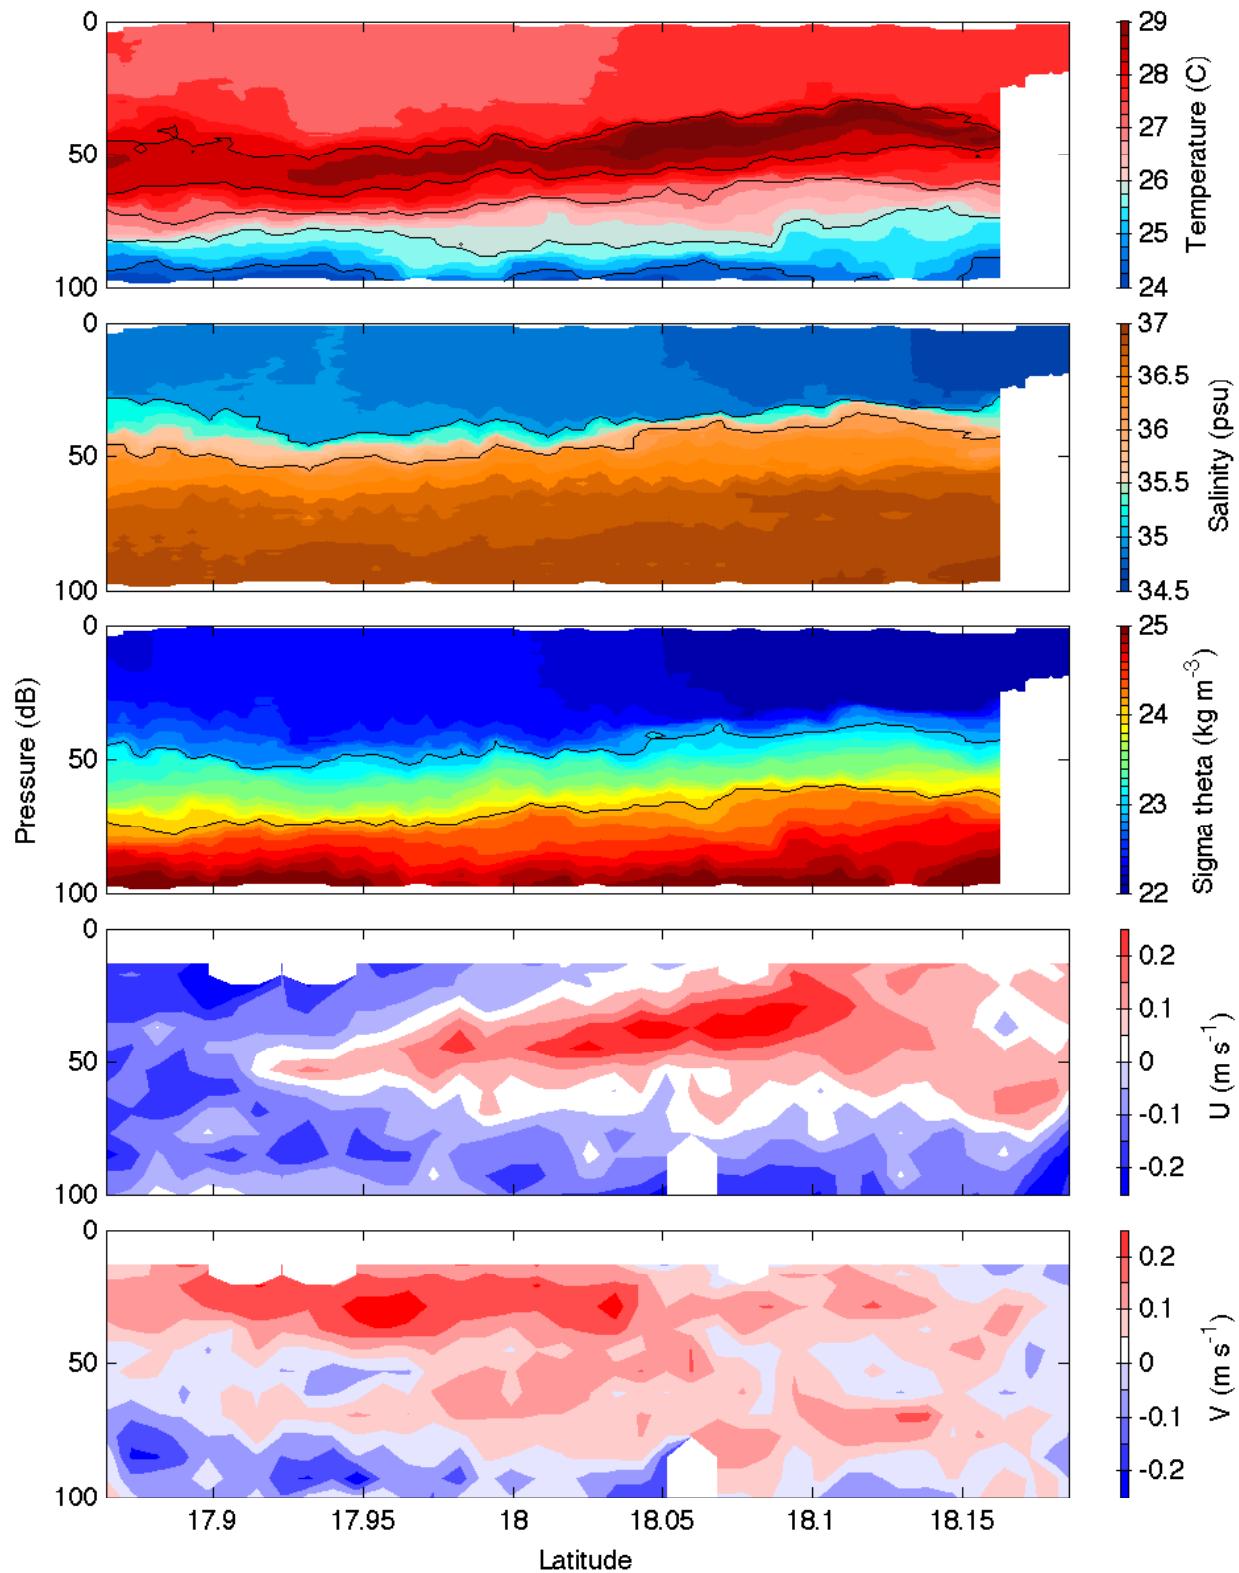

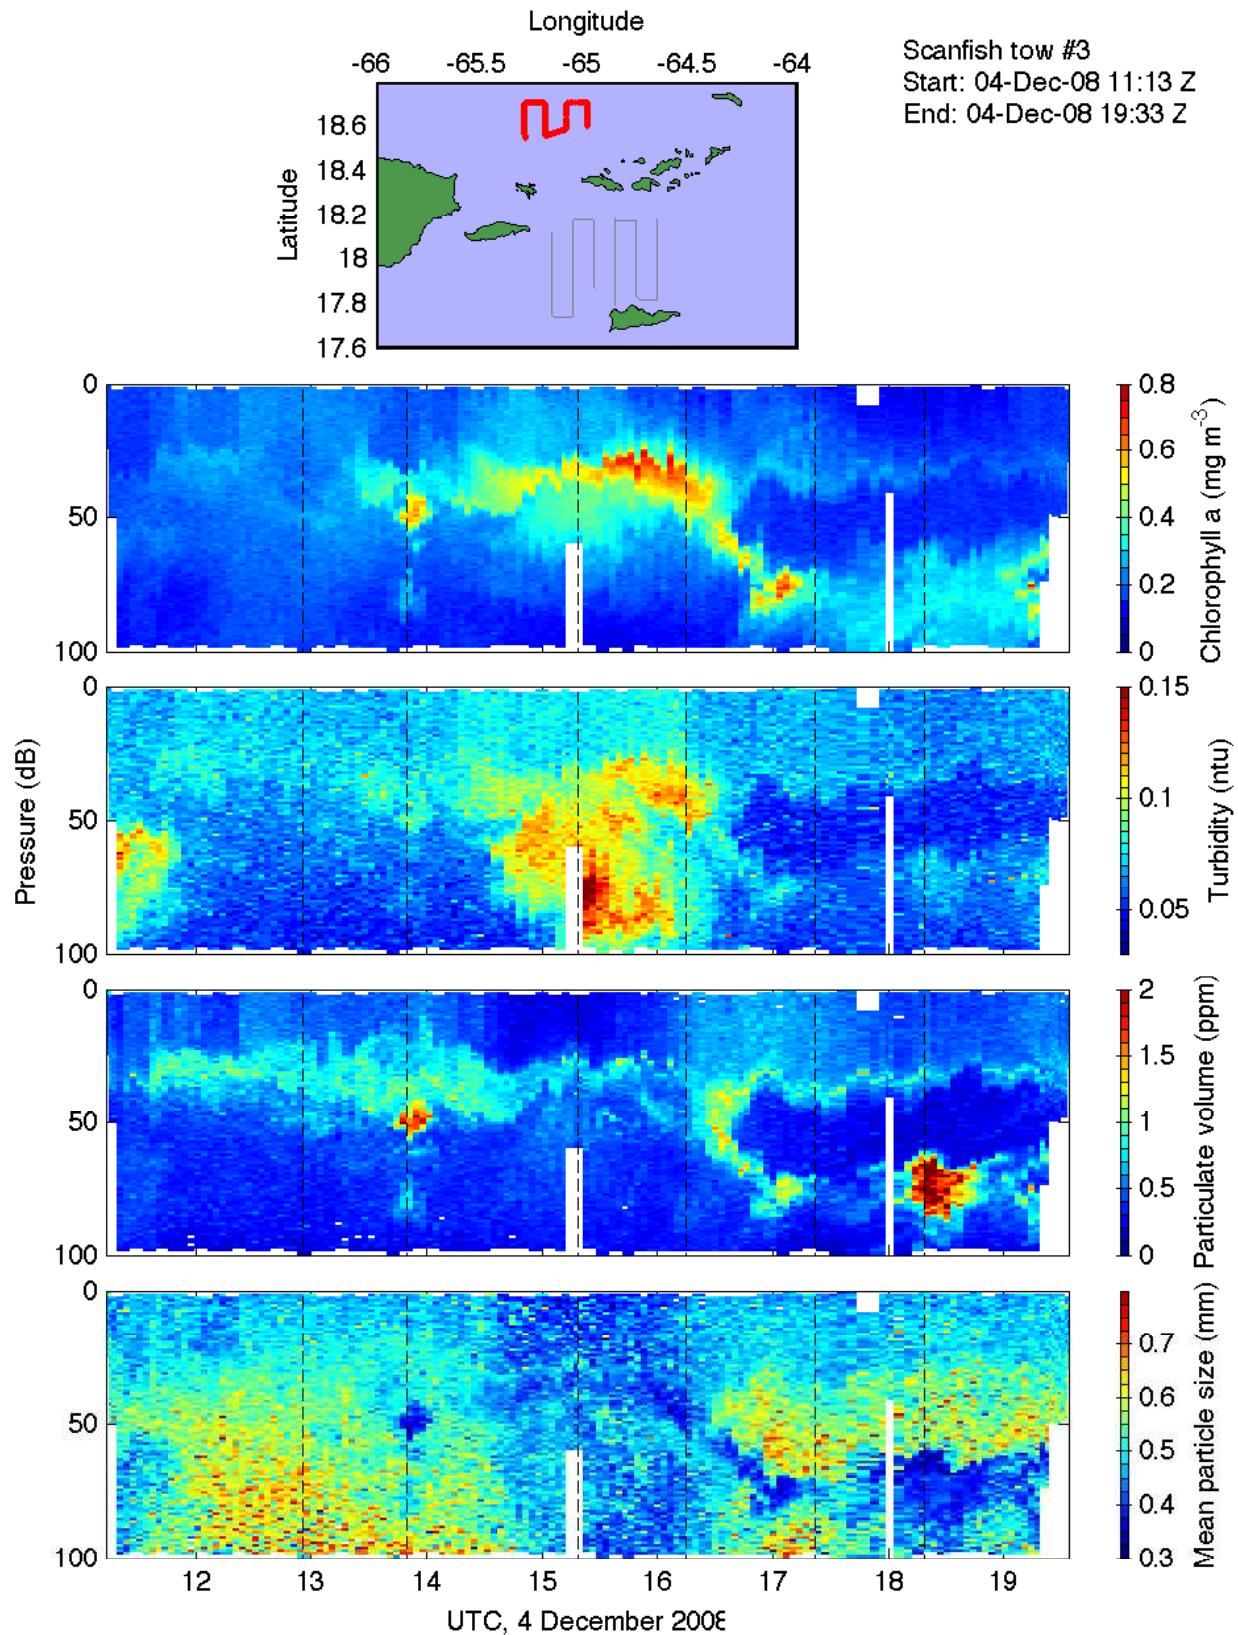

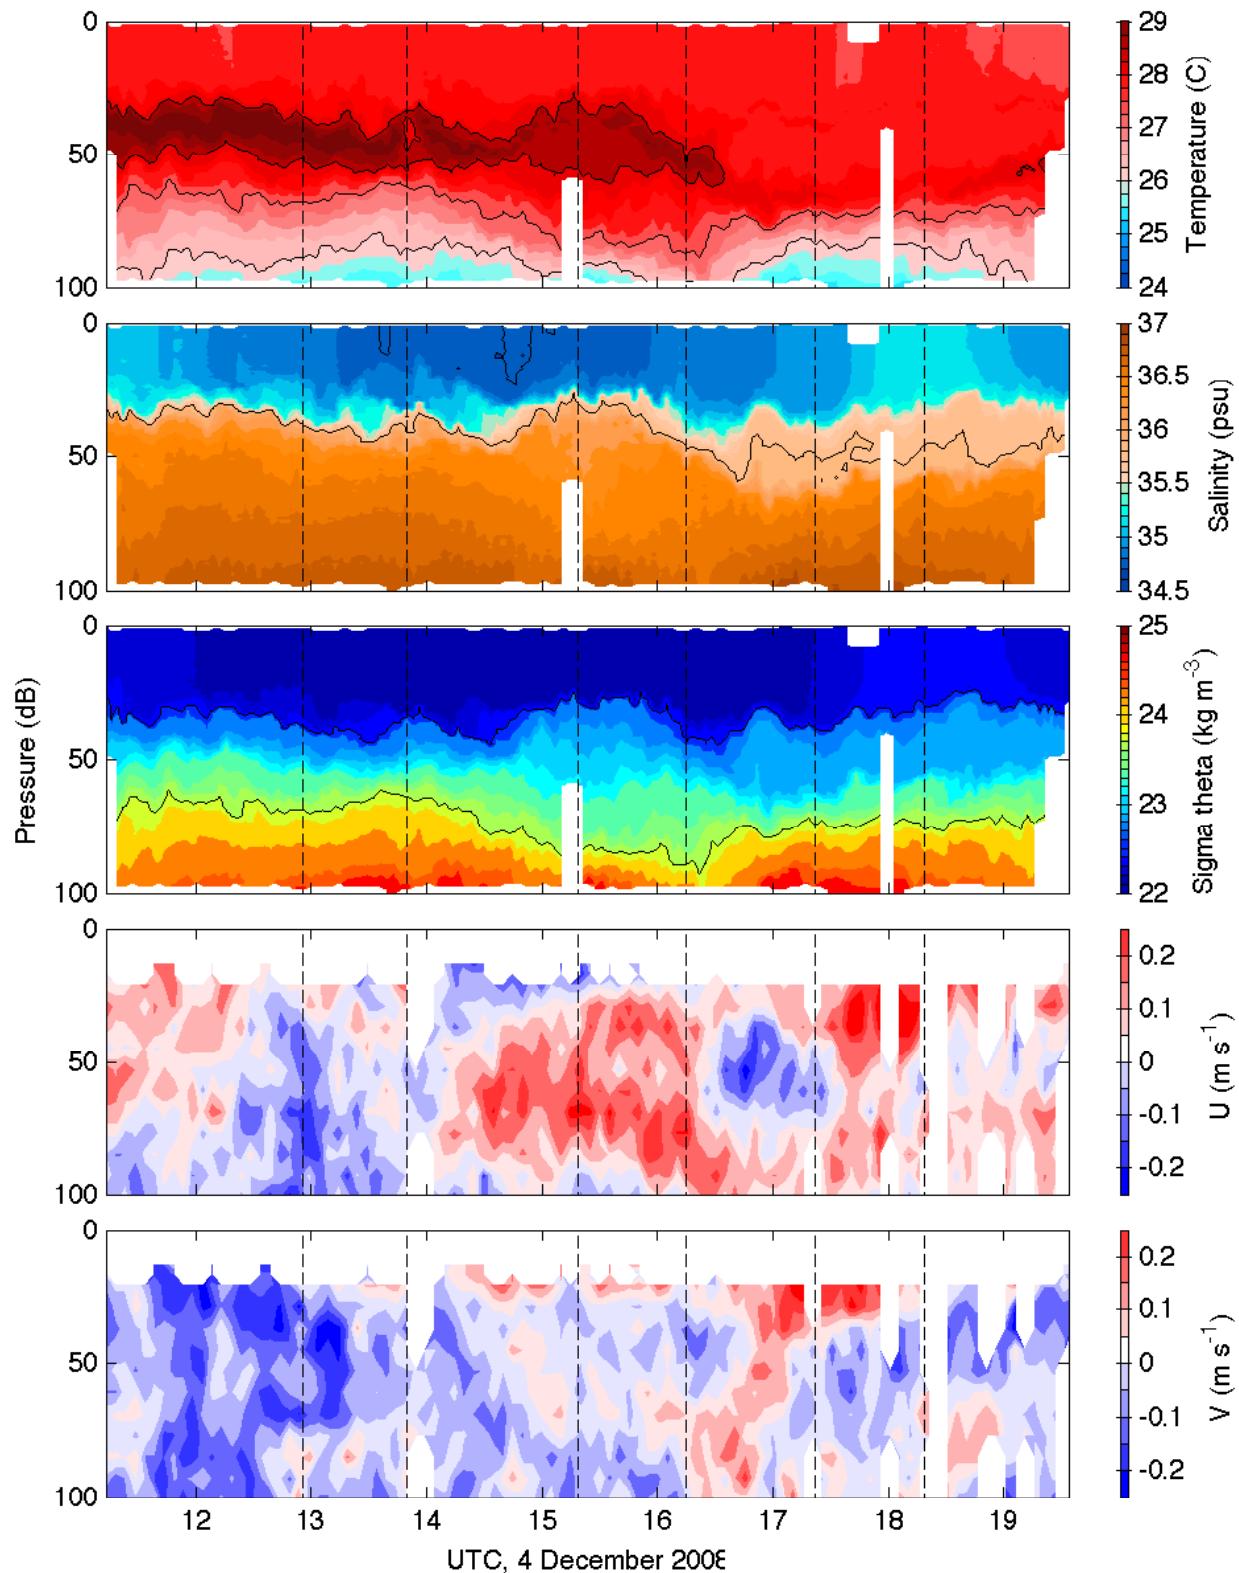

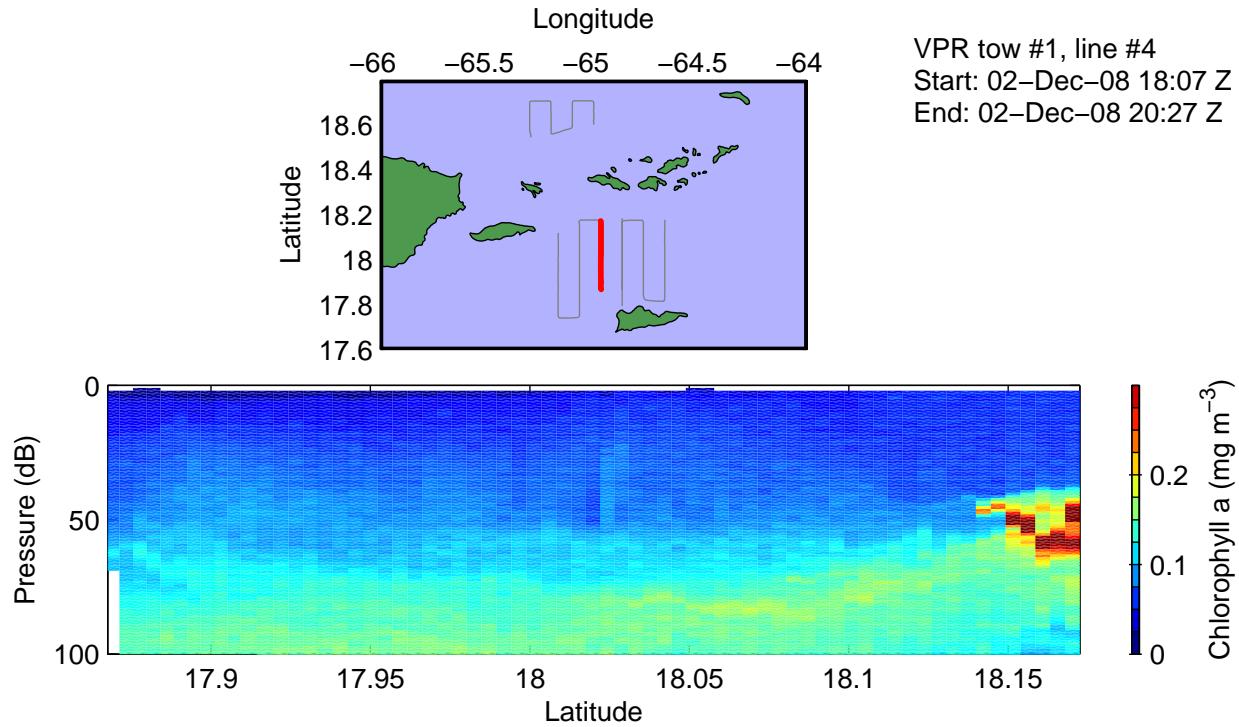

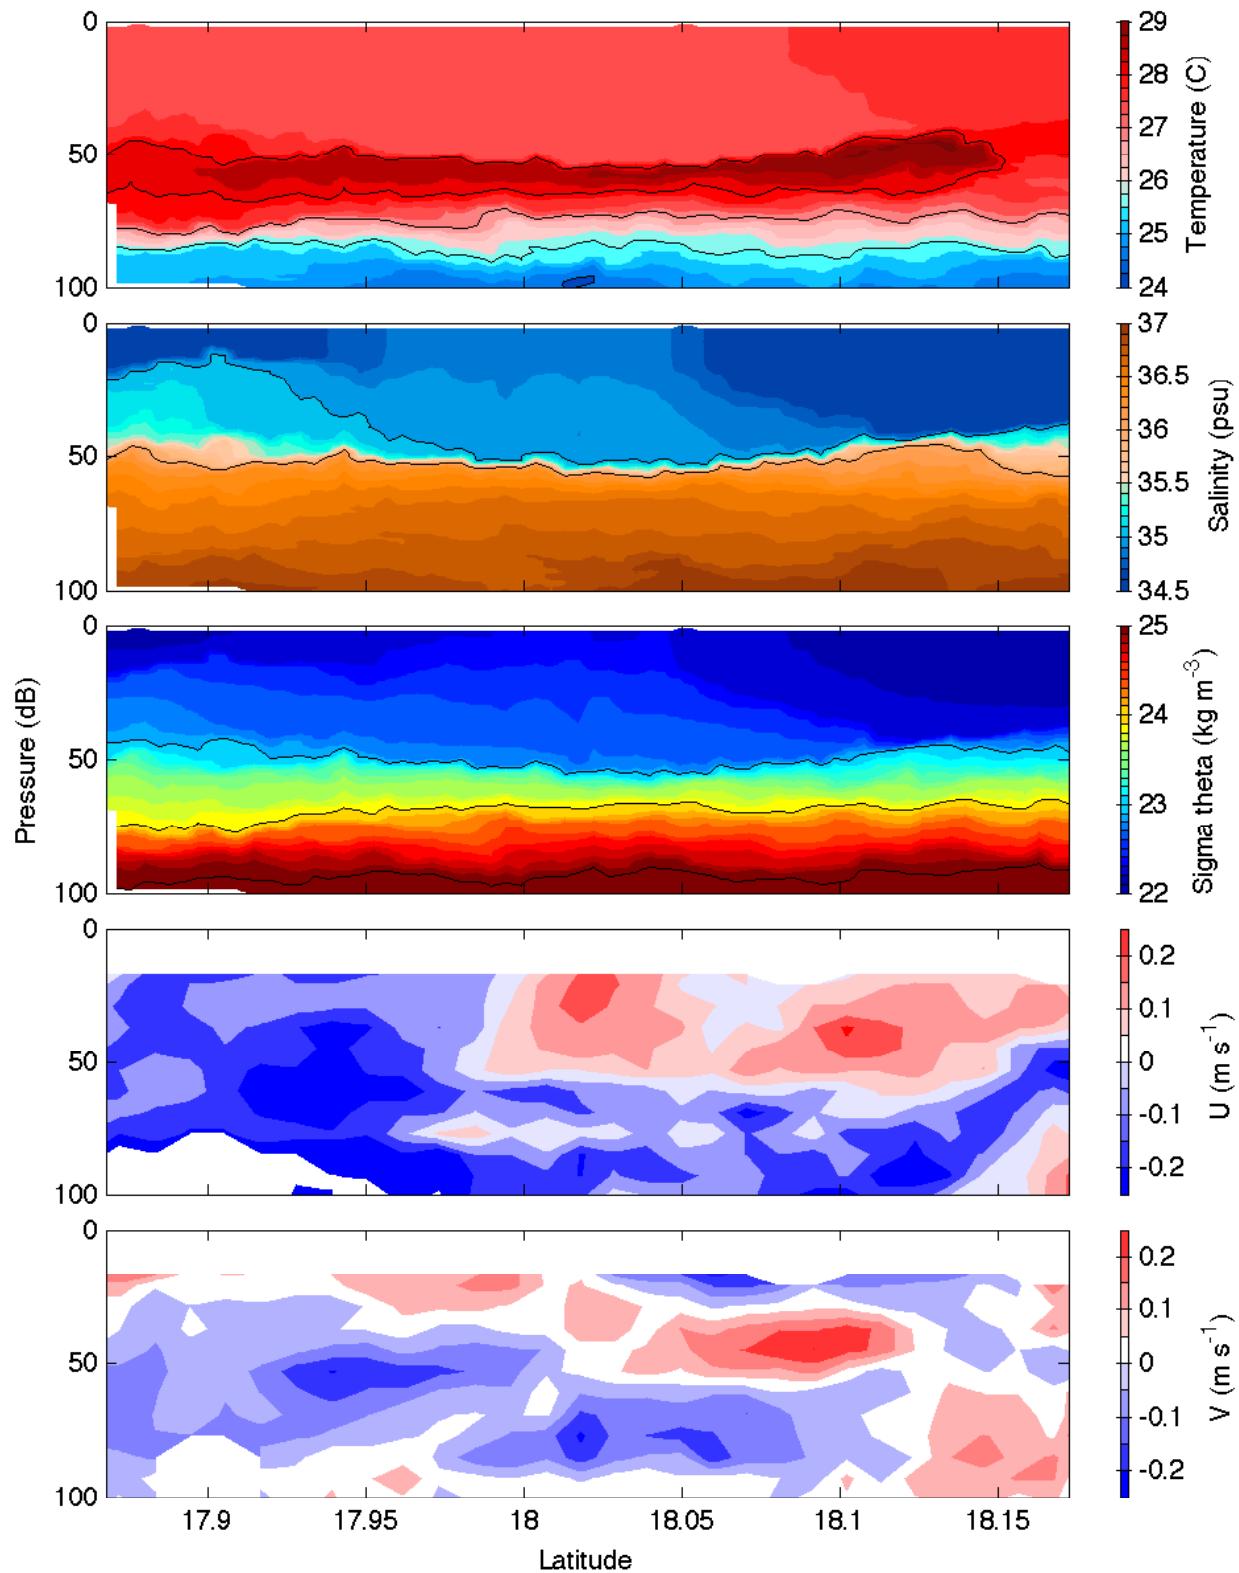

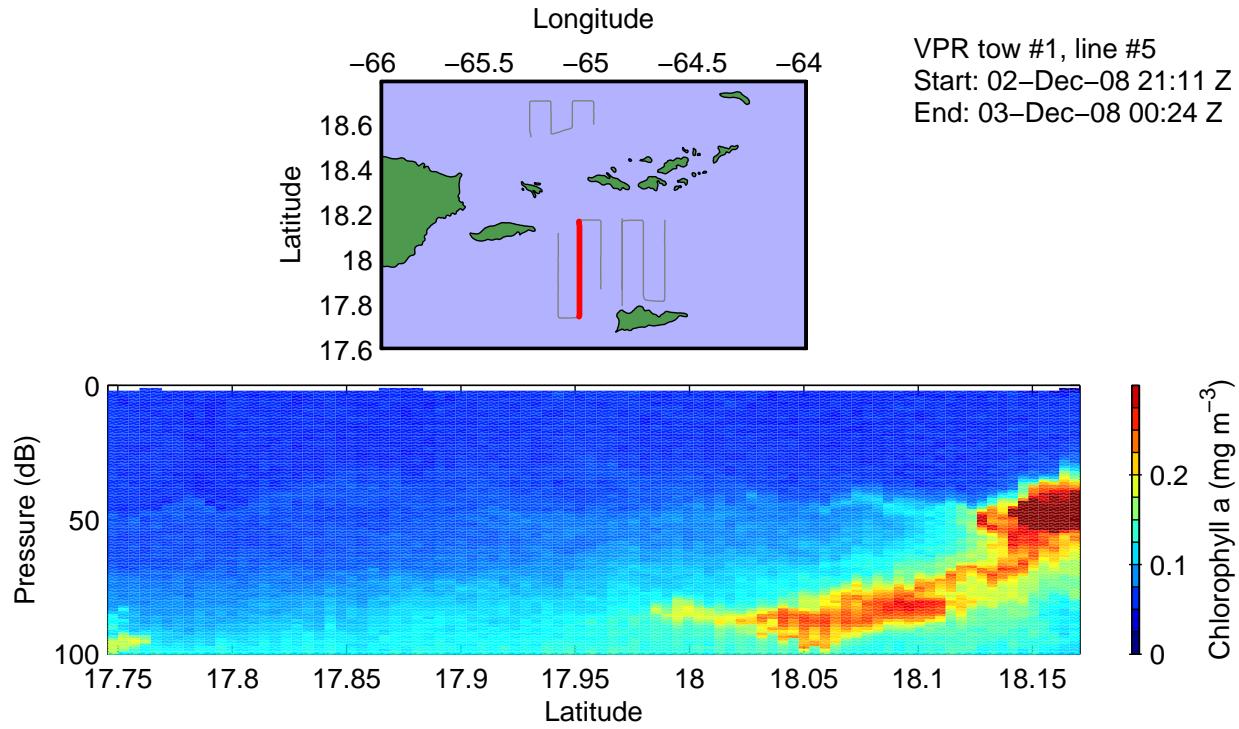

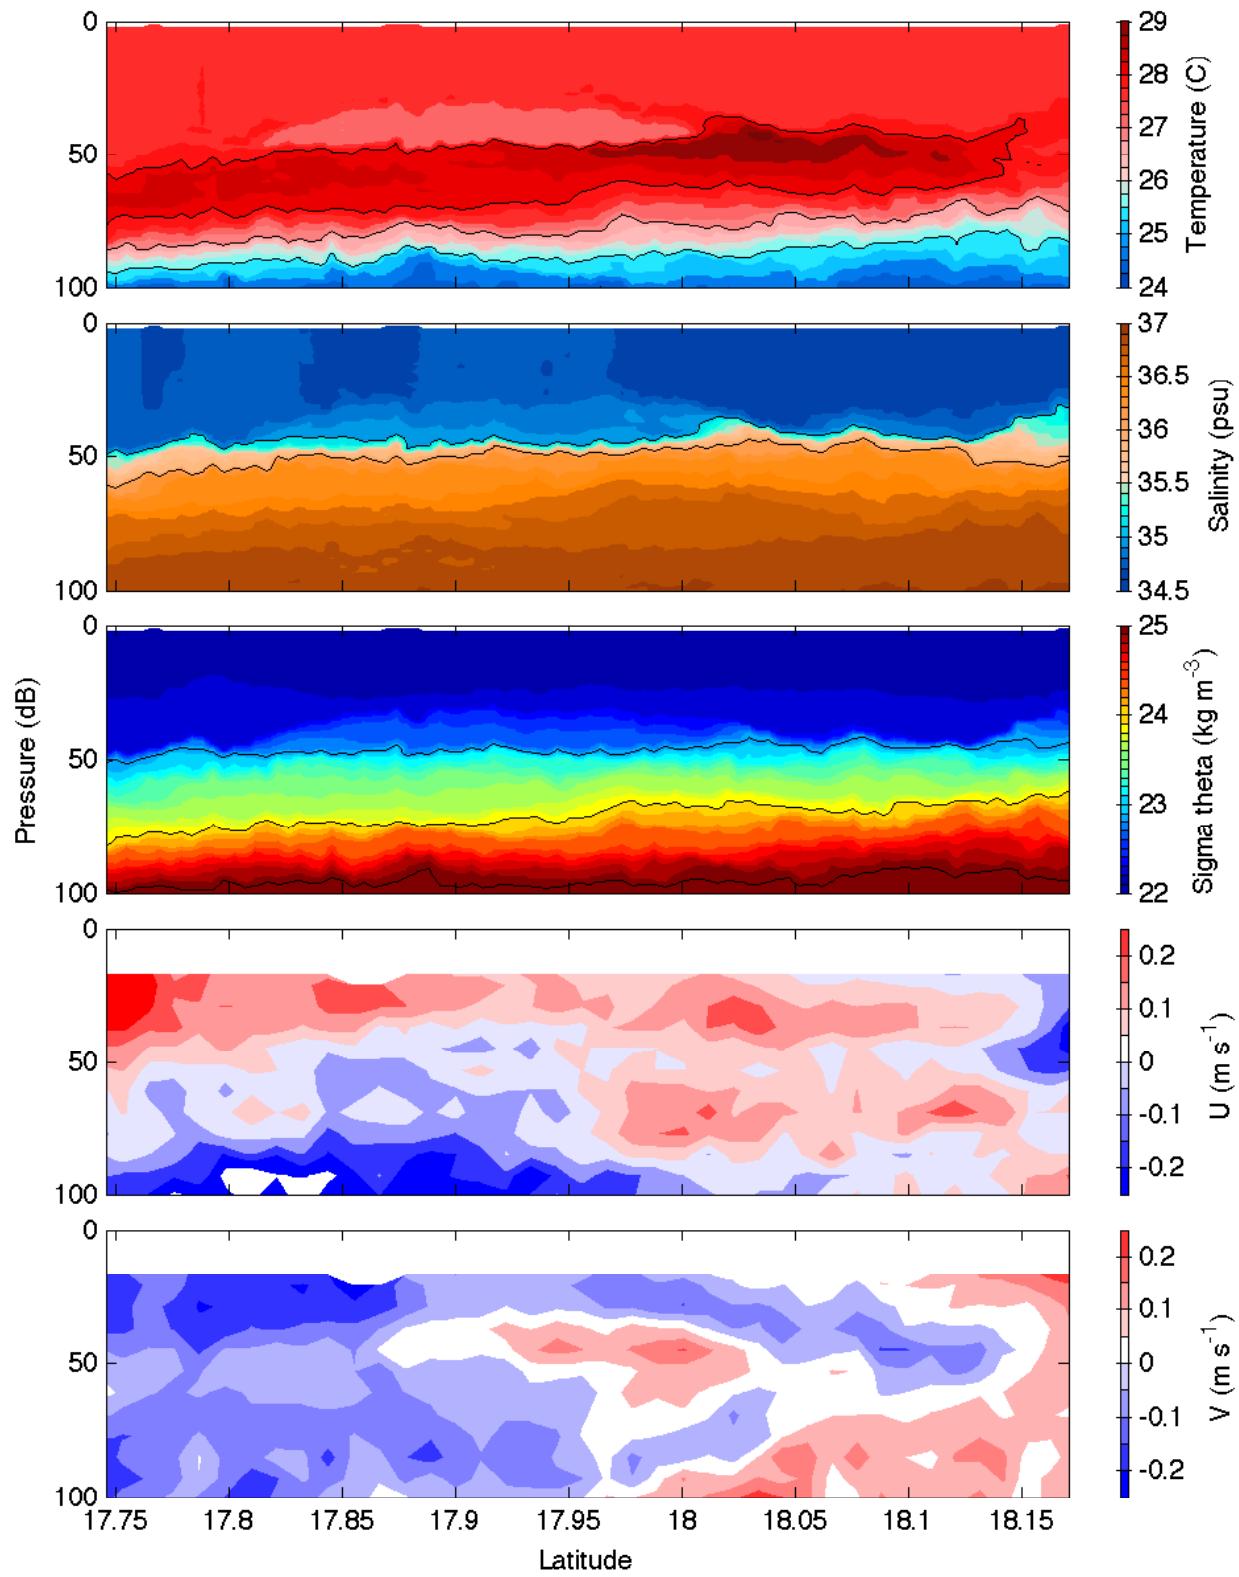

B Appendix: VPR Sections

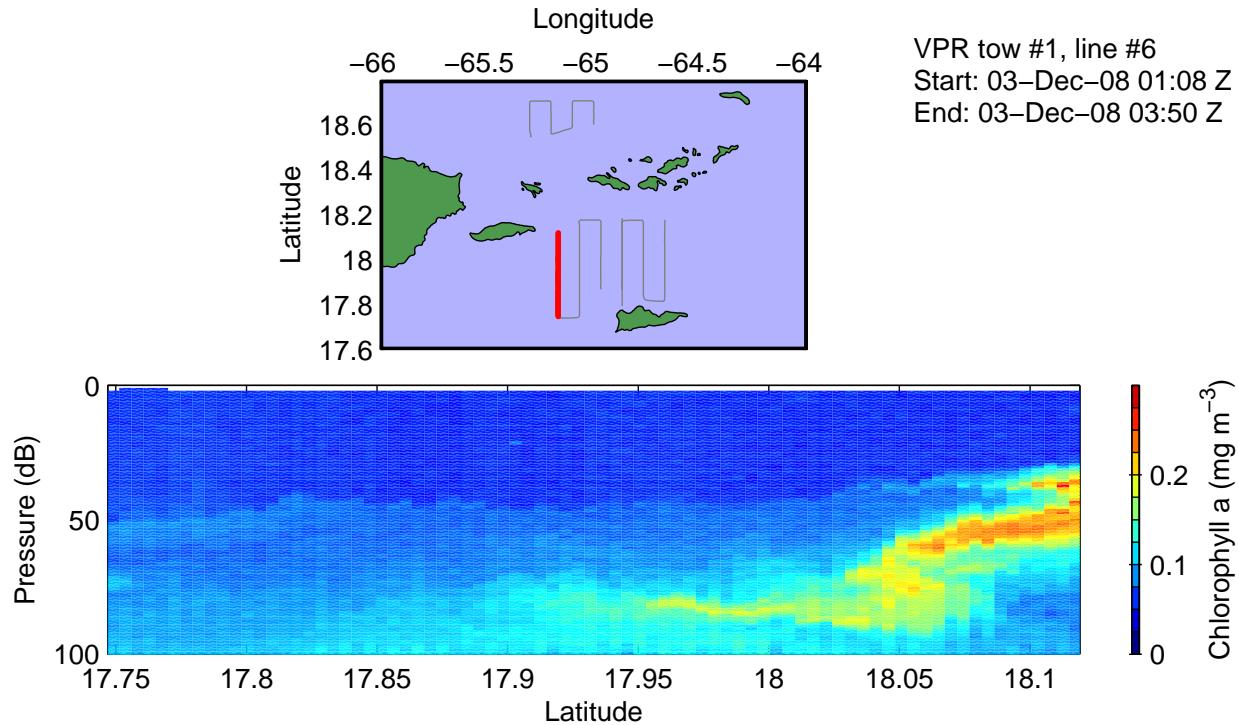

VPR surveys are shown for: the 3 sections made south of St. Thomas during VPR tow #1, the northern survey sampled during VPR tow# 2, and the transit to Bermuda, VPR tow #3. Each set of figures shows: (*at left*) a map of the relative location of the transect and vertical sections of Chlorophyll *a* concentrations. (*at right from top to bottom*) vertical sections of temperature, salinity, and density (as σ_θ), as well as shipboard ADCP East (*U*) and North (*V*) velocities. Different color map ranges are used for the southern survey area, the northern survey area, and the transit to Bermuda.
