#### 1. Introduction

Acylation of alcohols is a fundamental and important organic reaction; that has been frequently used for the protection of alcohols in both simple and complex molecules. Although many acylation methods are already known, a new and more efficient method is required. Recently, we reported the selective fluorination of alcohols using a new fluorination reagent, N,N-diethyl- $\alpha$ , $\alpha$ -difluoro-m-methylbenzylamine (**DFMBA**). In the reaction, a relatively high temperature was required (>100 °C), and at a lower temperature, a significant amount of an ester (2) derived from alcohol (1) and **DFMBA** was formed as a by-product. From these results, it can be presumed that the formation of adduct (4) in the reaction of 1 and **DFMBA** is fast, but the subsequent fluorination step is slow and 2 is formed by quenching 4 with water. Therefore, we applied  $\alpha$ , $\alpha$ -difluoroalkylamines for acylation of the alcohols by carrying out the reaction under mild conditions (Scheme 1).

#### 2. Results and discussion

### 2.1. Benzoylation of alcohols with DFBA

As an acylation reagent, N,N-diethyl- $\alpha$ , $\alpha$ -difluorobenzylamine (**DFBA**)<sup>2d,3</sup> was used instead of **DFMBA** because it reacts with alcohols to afford benzoyl esters. Initially, the reaction of **DFBA** with 1-decanol (**1a**) was examined (Table 1). When the reaction was carried out at 0 °C for 30 min using 1.1 eq of **DFBA** to **1a**, decyl benzoate (**2a**) was obtained in 72% yield without the formation of decyl fluoride (**3a**). At 20 °C, the yield of **2a** increased to 77%, but the formation of **3a** (5%) was also observed. At 40 °C, a significant amount of **3a** (22%) was formed. These results suggested that the fluorination of **1a** proceeds at temperatures higher than 0 °C and can be prevented by carrying out the reaction at temperatures below 0 °C. Consequently, **2a** could be obtained in 97 % yield without the formation of **3a** by carrying out the reaction at 0 °C using 2 eq of **DFBA**. The benzoylation of 4-*tert*-butylphenol (**1b**) and cyclododecanol (**1c**) is slow, and a higher reaction temperature (20-40 °C) was required. However, the fluorination of these substrates is non-feasible or slower than that of **1a**, and the corresponding benzoate (**2b**) or (**2c**) was obtained without the formation of the fluoride (**3b**) or (**3c**) under these conditions.

#### 2.2. Mono-benzoylation of diols

Selective mono-benzoylation of diols is useful in organic synthesis, and many methods have been reported. In the fluorination of 1,2- and 1,3-diols with **DFMBA**, selective mono-fluorination occurred through a cyclic intermediate and acylated fluorohydrins were obtained. Therefore, we applied **DFBA** to the selective mono-benzoylation of diols. When *prim*-diols were used, the reaction was completed at 20 °C and the corresponding mono-benzoylated products were obtained in good yields (Entries 1-4 in Table 2). With cyclic diols, the reaction was carried out at 40 °C to afford mono-benzoates in good yields (Entries 8-10). The reaction of **DFBA** with diols is fast and is applicable to the mono-benzoylation of less-reactive catechol and the sterically hindered pinacol (Entries 7 and 11). Even when 2 eq of **DFBA** to the diols was used, mono-benzoates were obtained selectively (Entries 6-11). Furthermore, from the isolated mono-benzoate (6j), the di-benzoate (7j) was obtained in good yield under the mono-benzoylation conditions (Entry 12).

Scheme 2. Reaction mechanism in mono-benzoylation of diols with DFBA

Therefore, the selectivity observed in the mono-benzoylation of diols with **DFBA** is not attributed to the steric hindrance generated in the second benzoylation but to the reaction mechanism that includes a cyclic intermediate.<sup>8</sup> As in the case of the fluorination reaction of diols with **DFMBA**, a cyclic amide acetal (8) must be initially formed in the reaction of diol 5 with **DFBA**.<sup>2c</sup> The amide acetal 8 exists stably under the conditions and changes to mono-benzoate 6 upon the addition of water while excess **DFBA** is

decomposed to inert *N*,*N*-diethylbenzamide by the addition of water. Therefore, the benzoylation of **6** to di-benzoate **7** scarcely occurred during the reaction, and **6** was obtained selectively (Scheme 2).

Generally, after the aqueous work-up, only mono-benzoate 6 was obtained and the presumed cyclic intermediate 8 could not be isolated. However, in the reaction of diethyl tartrate 5e with DFBA, the corresponding amide acetal 8e was isolated, and it changed to mono-benzoate 6e under acidic conditions (Scheme 3).

Scheme 3. Isolation and reaction of cyclic amide acetal 8e

Next, we examined the regioselectivity in the benzoylation of unsymmetrical diols. With 1,3-butandiol (51) having *prim*- and *sec*-alcohol, regioselectivity was not observed, and 3-hydroxybutyl benzoate (61) and 4-hydroxybut-2-yl benzoate (61) were obtained as a 1:1 mixture. On the other hand, in the reaction with 4-methyl-2,4-pentandiol (5m) having *sec*- and *tert*-alcohol, the benzoylation selectively occurred at *sec*-alcohol to afford 4-hydroxy-4-methylbut-2-yl benzoate (6m) in 83% yield (Scheme 4).

Scheme 4. Benzoylation of unsymmetrical diols with DFBA

The selective protection of one hydroxy group in sugars is important for their transformation to oligosaccharide. Therefore, we applied the present benzoylation reaction to sugars. When methyl 5-O-benzoyl- $\beta$ -D-ribofuranose (9) was subjected to the reaction with **DFBA**, selective mono-benzoylation occurred to afford methyl 3,5-di-O-benzoyl- $\beta$ -D-ribofuranose (10) and methyl 2,5-di-O-benzoyl- $\beta$ -D-ribofuranose (11) in 34% and 38% yields, respectively. With methyl 4,6-O-benzylidene- $\beta$ -D-glucopyranoside (12), methyl 3-benzoyl-4,6-O-benzylidene- $\beta$ -D-glucopyranoside (13) was obtained in 54% yield with minor products of 2-benzoyl-4,6-O-benzylidene- $\beta$ -D-glucopyranoside (14) (18%) and dibenzoate (15) (6%) (Scheme 5).

## 2.3. Acylation of diols with various $\alpha$ , $\alpha$ -difluoroalkylamines

As various difluoroalkylamines can be prepared from amides in two steps,  $^3$  the present mono-benzoylation reaction of diols can be extended to other acylation reactions. The selective mono-nicotinylation, formylation, and pivaloylation as well as 3-methylbenzoylation of diols were achieved by using N-(difluoro(pyridin-3-yl)methyl)-N, N-diethylamine, N-(difluoro-2,2-dimethylpropyl)pyrrolidine, and **DFMBA** as shown in Table 3.

 $^a$  If otherwise not mentioned, the reaction was carried out in CH<sub>2</sub>Cl<sub>2</sub> at 20 °C for 0.5 h using 1.1 eq. of difluoroalkylamine to substrate.  $^b$  Isolated yield based on substrate used. In parentheses, yield of diacylated product.  $\,^\circ$ 2 eq. of difluoroamine to substrate was used.  $^d$  The reaction was carried out at 40 °C.

## 3. Conclusion

The selective mono-benzoylation of 1,2- or 1,3-diols was achieved by using N,N-diethyl- $\alpha,\alpha$ -difluorobenzylamine (**DFBA**). The reaction was completed under mild conditions in a short reaction time, and *prim-*, *sec-*, and *tert*-diols and catechol could be converted to the corresponding mono-benzoates. It was shown that the reaction proceeded through a cyclic amide acetal. The selective *mono*-nicotinylation, formylation, and pivaloyation of diols were also performed by using the corresponding difluoroalkylamines.
