Four new bimetallic coordination polymers (CPs), $\{M[Pt(CN)_2(5,5'-dcbpy)] \cdot 4H_2O\}_n$ (M = Mg²⁺, Ca²⁺, Sr²⁺, Ba²⁺; 5,5'-H₂dcbpy = 5,5'-dicarboxy-2,2'-bipyridine) were synthesized using four alkaline-earth metal ions and a Pt(II)-diimine metalloligand [Pt(CN)_2(5,5'-H_2dcbpy)]. All four CPs are isomorphous

- ¹⁰ with the Zn complex, {Zn[Pt(CN)₂(5,5'-dcbpy])·4H₂O}_n, which exhibits effective metallophilic interaction between Pt(II) ions. These CPs exhibited colourful thermochromic behaviour and solid-state solvatochromic-like behaviours when suspended in various solvents. Thermogravimetric analysis and vapour-adsorption measurements revealed that the CPs can reversibly adsorb water and MeOH vapours. The emission energy of the triplet metal-metal-to-ligand charge-transfer (³MMLCT) state varied
- ¹⁵ markedly upon guest adsorption/desorption. The chromic and vapour-adsorption properties of these CPs depend strongly on the cross-linking M²⁺ ions.

Introduction

Porous coordination polymers (PCPs) have recently attracted considerable attention because of their unique gas adsorption ²⁰ properties, controllable frameworks and pores, among other

- characteristics.¹⁻³ Because of the momentous effort that has been devoted to achieving large surface areas,¹ strong host-guest interactions² and high catalytic activities,³ PCPs are now one of the most attractive materials for use as adsorbents and
- ²⁵ heterogeneous catalysts. One approach to creating new intelligent materials based on PCPs involves adding a guest sensing function by which the PCPs can indicate the kinds and/or amounts of adsorbed guest molecules by a *visual* response. Generally, the host-guest interactions in PCPs are not strong enough to affect the
- ³⁰ electronic transition in the host framework, which is usually observed in UV-Vis range. The utilization of chromophores and/or luminophores as bridging ligands is a promising method for realizing such intelligent absorbents. In fact, several groups have reported luminescent PCPs constructed from luminescent ³⁵ organic ligands; these PCPs show strongly guest-dependent
- emission properties that may be applicable to chemical sensors.⁴⁻⁵ Square-planar Pt(II)-diimine complexes are known to show interesting optical properties such as strong phosphorescence, colourful vapochromism etc.,⁶⁻⁸ and accordingly, our recent
- ⁴⁰ efforts have focused on the development of multichromic PCPs constructed with Pt(II)-diimine-based metalloligands. The key factor determining the characteristic properties of these complexes is the metallophilic interaction between the 5dz² orbitals of the Pt(II) ions which generates the emissive metal-⁴⁵ metal-to-ligand charge transfer (MMLCT) state.⁷ The energy

level of the MMLCT state depends strongly on the distance between adjacent Pt(II) ions. By taking advantage of this feature, several groups have recently reported vapochromic Pt(II)-diimine complexes which can *visually* indicate the presence of chemical ⁵⁰ vapours.⁸ This functionality is mainly based on the adsorption of vapour into the crystal lattice which induces changes in the metallophilic interaction. However, most vapochromic Pt(II)diimine complexes are molecular solids assembled by relatively weak non-directional interactions such as van der Waals and ⁵⁵ Coulombic interactions, resulting in collapse of their vapouraccessible channels upon guest release. The design of guest

Fig. 1 (a) Bright field images from left of ZnPt·4H₂O, ZnPt·2H₂O and ZnPt·0H₂O. (b) Crystal structure of ZnPt·4H₂O. Coordination sphere of Pt(II) and Zn(II) ions are shown as blue planes and green polyhedra, respectively.^{9,13}

selectivity or recognition capabilities in such molecular systems, therefore, remains challenging.

To overcome these difficulties, we previously designed the bimetallic coordination polymer (CP), $\{[Zn(H_2O)_3][Pt(CN)_2(5,5'-$

- ${}^{5} dcbpy] \cdot H_2O_n (ZnPt \cdot 4H_2O; 5,5'-H_2dcbpy = 5,5'-dicarboxy-2,2'$ bipyridine) and found that this CP can*visually*indicate theamount of adsorbed water molecules as shown in Figure 1.⁹However, ZnPt is capable of adsorbing only water vapour,possibly as a result of a lack of affinity between other vapour
- ¹⁰ molecules and the Zn centre and/or coordinative saturation of the Zn ion. In this study, in order to enhance the host-guest interactions and to improve the vapour-adsorption properties of this class of CPs, we have synthesized the new bimetallic CPs, $\{M[Pt(CN)_2(5,5'-dcbpy)]\}_n (M = Mg^{2+}, Ca^{2+}, Sr^{2+}, Ba^{2+})$ by using
- ¹⁵ alkaline-earth metal ions. The higher coordination numbers of alkaline-earth metal ions relative to that of the Zn^{2+} ion may enable us to design new intelligent adsorbents which *visually* indicate the type and amount of adsorbed guest molecules. We report herein the syntheses, chromic behaviours and adsorption
- ²⁰ properties of these bimetallic CPs and demonstrate that these CPs can adsorb not only water but also MeOH vapour accompanied by remarkable colour and luminescence changes.

Experimental

Syntheses

²⁵ All starting materials, K₂PtCl₄ and 3-methylpyridine were used as received from commercial sources, and the solvents were used without purification. Pt(CN)₂,¹⁰ 5,5'-H₂dcbpy,¹¹ and K₂[Pt(CN)₂(5,5'-dcbpy)]⁹ were prepared according to published methods. Elemental analysis was performed at the analysis centre ³⁰ in Hokkaido University.

- ³⁵ orange precipitate formed immediately. After subsequent stirring for 1 h at room temperature, the solids were filtered off from the reaction mixture. The isolated precipitate was washed thoroughly with water and then dried in air for 1 day to afford the orange powder **MgPt**·4H₂O (72 mg, 123 µmol) in 70 % yield. Elemental

Yield: 95 mg, 77 % based on $K_2[Pt(CN)_2(5,5'-dcbpy)]$. Elemental analysis calcd. for $C_{14}H_6N_4O_4PtBa\cdot 4H_2O$: C 24.07, H 2.02, N 8.02; found: C 23.89, H 1.85, N 8.16.

60 Powder X-ray diffraction

Powder X-ray diffraction measurements were performed using a Rigaku SPD diffractometer at beamline BL-8B, Photon Factory, KEK, Japan. The wavelength of the synchrotron X-ray was 1.200(1) Å. The sample was placed in a glass capillary of 0.5 mm¢ diameter.

Photophysical measurements

Emission and excitation spectra were recorded under various conditions on a Jasco FP-6600 spectrofluorometer. The sample temperature was controlled by a JASCO ETC-273 Peltier-type ⁷⁰ temperature controller. About 1 mg of the sample was placed in a glass capillary with a diameter of 0.5 mmφ. The slit widths of excitation and emission light were 5 and 6 nm, respectively. The luminescence quantum efficiency was recorded on a HAMAMATSU C9920-02 absolute photoluminescence quantum ⁷⁵ yield measurement system equipped with integrating sphere apparatus and 150 W CW Xenon light source. Emission lifetimes of all of the samples in the solid state were recorded using a HAMAMATSU C4780 Picosecond Fluorescence Lifetime Measurement System equipped with a nitrogen laser light source ⁸⁰ (λ = 337.1 nm).

Thermogravimetric analysis

Thermogravimetry and differential thermal analysis were performed using a Rigaku ThermoEvo TG8120 analyzer.

Adsorption Isotherms

⁸⁵ The adsorption isotherms for water and MeOH vapours at 298 K were performed using an automatic volumetric adsorption apparatus (BELSORP-MAX and BELSORP-aqua; BEL Japan, Inc.)

Results and Discussion

90 Structures

The reactions between K₂[Pt(CN)₂(5,5'-dcbpy)] and alkalineearth metal salts in aqueous solution led to immediate formation of the insoluble compounds, MPt·4H2O. Because these very fast reactions made it difficult to synthesize single crystals suitable 95 for single crystal X-ray structural determination, the insoluble compounds were characterized by powder X-ray diffraction (PXRD), IR spectroscopy and elemental analysis. Figure 2 shows the PXRD patterns of the four MPt·4H2O complexes at room temperature compared with that of **ZnPt**·4H₂O for which single 100 crystal XRD data had previously been obtained (Fig. 1). All of the observed PXRD patterns for MPt·4H₂O are very similar to each other and seem to be identical with the pattern of ZnPt·4H₂O. Elemental analyses suggest that the hydration numbers of each of these CPs is four which is also the same as ¹⁰⁵ that of **ZnPt**·4H₂O. In addition, the IR spectra of **MPt**·4H₂O are almost identical to the spectrum of **ZnPt**·4H₂O (See Figure S1) including the splitting width of the v(C=N) bands, indicating that the cyano group does not coordinate to any of the metal ions.

Fig. 2 PXRD patterns of MPt·4H₂O. (λ = 1.200(1) Å). Purple, green, red, blue, and black lines from the top show the pattern of, BaPt·4H₂O, SrPt·4H₂O, CaPt·4H₂O, MgPt·4H₂O, and ZnPt·4H₂O at 305 K, respectively. Indexes for main observed reflections of ZnPt·4H₂O are shown above the pattern.

Thus, it can be concluded that the structures of these CPs are isomorphous with ZnPt·4H₂O in terms of the one-dimensional infinite coordination chains formed by alternate arrangements of ¹⁰ alkaline-earth metal ions M^{2+} and the Pt(II) metalloligands. Metallophilic interactions between adjacent Pt(II) ions are

- operative along the *b* axis, in the structure of **ZnPt**·4H₂O, with inter-nuclear distances of 3.309 Å, resulting in the orange colour of the solid. The almost isomorphic PXRD patterns of **MPt**·4H₂O ¹⁵ may enable us to estimate the degree of metallophilic interaction between adjacent Pt ions in these CPs by comparing the locations
- of the (020) reflections. The (020) reflections were observed at 20.62° , 21.00° , 20.74° , and 20.94° for **MgPt**·4H₂O, **CaPt**·4H₂O, **SrPt**·4H₂O, and **BaPt**·4H₂O, respectively. The calculated Pt-Pt
- ²⁰ distances from the positions of the (020) reflections are as follows: MgPt·4H₂O: 3.40(3) Å, CaPt·4H₂O: 3.34(5) Å, SrPt·4H₂O: 3.39(3) Å, BaPt·4H₂O: 3.35(4) Å. These comparable distances are indicative of effective metallophilic interactions between Pt(II) ions in all of the CPs.

25 Thermochromic behaviour driven by water vapour adsorption/desorption

Because $ZnPt \cdot 4H_2O$ exhibits thermochromic behaviour driven by the desorption/adsorption of water vapour,⁹ the thermochromic behaviours of the $MPt \cdot 4H_2O$ complexes were also examined and

³⁰ it was found that the variation of the M²⁺ ion in the series of MPt·4H₂O CPs affected their chromic behaviours considerably. Figure 3 shows the emission spectra of the MPt·4H₂O CPs at room temperature and at 373 K. The emission energies, lifetimes and quantum yields of MPt·4H₂O are summarized in Table 1. As
 ³⁵ expected from the Pt-Pt distances, observed emission energies of

these MPt·4H₂O CPs are in the energy range of emission from a ³MMLCT (triplet metal-metal-to-ligand charge transfer) state which is commonly observed for Pt(II)-diimine complexes with 45 effective Pt-Pt interaction, for example the ³MMLCT emission of [Pt(CN)₂(4,4'-H₂dcbpy)] at 614 nm.¹² The emission bands of all of the CPs shifted to longer wavelengths when the temperature was increased to 373 K. The original emission spectra at room temperature were regained after exposure of the complexes to 50 water vapour at room temperature. Interestingly, the extent of the red shifts induced by increasing the temperature followed the order: **ZnPt**·4H₂O (1430 cm⁻¹) > **CaPt**·4H₂O (641 cm⁻¹) > $MgPt \cdot 4H_2O$ (589 cm⁻¹) > $SrPt \cdot 4H_2O$ (372 cm⁻¹) > $BaPt \cdot 4H_2O$ (85 cm⁻¹) and the maximum emission wavelength for all of the 55 complexes after heating were comparable with each other in the region of 670 nm. It had been previously determined that the red shift observed in ZnPt·4H2O was due to the release of water molecules from the compound.⁹ Thermogravimetric analyses

Fig. 4 Thermogravimetric curves of MPt·4H₂O. Black, blue, red, green, purple lines show the TG curves of ZnPt·4H₂O, MgPt·4H₂O, CaPt·4H₂O, SrPt·4H₂O, and BaPt·4H₂O respectively. (1 K min⁻¹ heating, Ar flow rate: 300 ml min⁻¹)

were performed in order to clarify the relationship between the red shift in the luminescence spectrum and the amount of water desorbed. As shown in Figure 4, the alkaline-earth metal CPs also released water molecules upon increasing the temperature. The

- ¹⁰ observed weight loss for each **MPt**·4H₂O (6.86% for **MgPt**·4H₂O, 5.79% for **CaPt**·4H₂O, 7.92% for **SrPt**·4H₂O, 6.72% for **BaPt**·4H₂O) was smaller than that of **ZnPt**·4H₂O (9.95%), which implies that some of the water molecules remained in the structures even at 375 K. The hydration numbers at 375 K of
- ¹⁵ these CPs were estimated from the weight losses to be about 2.0 for **MgPt** and **CaPt**, 1.5 for **SrPt** and **BaPt**, and 0.5 for **ZnPt**. This result suggests two facts as follows: firstly, the four CPs with alkaline-earth metal ions bind water molecules more strongly than in **ZnPt**·4H₂O, which is substantiated by the water-
- ²⁰ vapour adsorption isotherms (discussed below). Secondly, MgPt·4H₂O and CaPt·4H₂O showed a larger red shift than that observed for SrPt·4H₂O or BaPt·4H₂O in spite of the smaller amount of water desorption. These differences suggest that the intermolecular Pt-Pt distance can be modified by water
- $_{25}$ desorption more effectively in $MgPt\cdot 4H_2O$ and $CaPt\cdot 4H_2O$ than in $SrPt\cdot 4H_2O$ and $BaPt\cdot 4H_2O$.

Solid-state (suspension) solvatochromic behaviours

Because **ZnPt**·4H₂O showed solid state (*insoluble*) solvatochromic behaviour driven by the release of water ³⁰ molecules in highly-polar liquids,⁹ the solvent responsive behaviour of **MPt**·4H₂O was also examined. Note that the solubilities of these CPs in common solvents used herein are negligibly small. Figure 5 shows the solid state emission spectral changes of **MPt**·4H₂O when immersed in various solvents. The

³⁵ observed emission maxima of MPt·4H₂O in the suspended states and the dielectric constants of the solvents are summarized in Table 2. As shown in the mainframe and inset pictures of Figure 5, MgPt·4H₂O and CaPt·4H₂O exhibited drastic colour and luminescence changes in highly-polar liquids such as MeOH and

Fig. 5 Emission spectra of (a) ZnPt·4H₂O, (b) MgPt·4H₂O, (c)
 CaPt·4H₂O, (d) SrPt·4H₂O, and (e) BaPt·4H₂O. Black-broken, blue-, red-, and purple-solid lines show the spectrum of MPt·4H₂O in air, immersed in water, MeOH, and DMF, respectively. Inset pictures from ⁴⁵ left show the bright field images of MPt4H₂O in air, immersed in MeOH and DMF.

dimethylformamide (DMF). Similar red shift was observed in the UV-Vis diffuse reflectance spectrum of the MgPt·4H₂O suspended in DMF (see Figure S4). In contrast, the colour 50 changes observed for SrPt·4H2O and BaPt·4H2O were less distinctive than in the other two complexes. The emission maxima of the MPt·4H₂O CPs changed only marginally upon immersion in non-polar solvents such as hexane and toluene. Basically, the emission bands of the MPt·4H2O CPs shifted to 55 longer wavelengths upon immersion in highly-polar liquids, except for water and MeOH, and the observed red-shifts seem to be proportional to the dielectric constants of the liquids (see Figure S2). In addition, these emission shifts were negligible in the solvents that contained 10% or more water (see Figure S3) 60 and none of the MPt·4H2O CPs are able to adsorb the vapours of any of these liquids except for water and MeOH (discussed below). Thus, these solid state solvatochromic behaviours are thought to originate from the extraction of water molecules bound in the crystal lattice into highly-polar solvents as shown in 65 Schemes 1(a) and (b), leading to the red shift of the ³MMLCT emission generated by enhancing the Pt-Pt interaction. The relatively large red-shifts observed for every MPt in low-polar THF suspension are probably due to the high affinity of THF to water (e.g. the very large solubility of THF to water). The 70 thermochromic behaviours as well as the observed red shifts of

5 Scheme 1 Possible mechanism of chromic behaviours of MPt CPs. Upper and lower sections show schematic structural representations and energy diagrams of (a) anhydrous MPt, (b) tetrahydrated MPt·4H₂O and (c) MeOH adsorbed state.

the alkaline-earth **MPt**·4H₂O CPs were smaller than those of ¹⁰ **ZnPt**·4H₂O. This difference may be due to the strong binding of water molecules at the bridging M²⁺ ions. An interesting difference between **ZnPt**·4H₂O and alkaline-earth metal CPs was also observed in the water and MeOH suspended states. The emission bands of **MgPt**·4H₂O and **BaPt**·4H₂O shifted by 14 and

¹⁵ 12 nm (351 and 262 cm⁻¹), respectively, to lower wavelength (higher energy) upon immersion in water, whereas the emission bands of the Zn, Ca, and Sr complexes did not change

Fig. 6 (a) Water and (b) MeOH vapour-adsorption isotherms of MPt at 298 K.

significantly. In addition, the emission bands of MgPt·4H₂O, CaPt·4H₂O and BaPt·4H₂O shifted by 16, 24 and 16 nm (402, 596 and 351 cm⁻¹), respectively, to lower wavelength (higher energy) upon immersion in MeOH. Similar blue shift was ²⁵ observed in the UV-Vis diffuse reflectance spectrum of the MgPt·4H₂O suspended in MeOH (see Figure S4). Taking into account the fact that the ³MMLCT emission band of ZnPt·4H₂O, showed only red shifts, the observed blue shifts for MgPt·4H₂O, CaPt·4H₂O and BaPt·4H₂O reflect the substitution effect of the ³⁰ bridging M²⁺ ions. Judging from the vapour-adsorption isotherms, these CPs can adsorb about 2 mol·mol⁻¹ of MeOH vapour (see below). Thus, this adsorption of additional water or MeOH would elongate the Pt-Pt distances, resulting in the blue shift of the ³MMLCT emission(Scheme 1(c)).

35 Vapour-adsorption properties

As mentioned in the Introduction, **ZnPt** can adsorb only water vapour.⁹ The vapour adsorption isotherms of **MPt** were measured in order to evaluate the substitution effect of the bridging metal ions on the vapour-adsorption properties. Prior to these ⁴⁰ measurements, the samples were dried at 373 K under vacuum. The observed weight losses in this drying process (13%, 13%, 11% and 10% for **MgPt**·4H₂O, **CaPt**·4H₂O, **SrPt**·4H₂O, and **BaPt**·4H₂O, respectively) suggest that each **MPt**·4H₂O CP released all of its water molecules to form anhydrous **MPt**. ⁴⁵ Figure 6(a) shows the water-vapour-adsorption isotherms of **MPt** at 298 K. All of the CPs can adsorb water vapour from 4 to 5 mol·mol⁻¹ at the saturated water vapour pressure. It should be emphasized that all of the **MPt** CPs except for **ZnPt** adsorbed water vapour in the very low pressure region below 0.1 P/P_0 , suggesting that the host-guest interaction between the **MPt** framework and water molecules is stronger than in **ZnPt**, consistent with the TG results. In addition, the saturated

- ⁵ adsorption amounts are also different: 4 mol·mol⁻¹ for CaPt and 5 mol·mol⁻¹ for MgPt, SrPt, and BaPt. In other words, MgPt·4H₂O, SrPt·4H₂O, and BaPt·4H₂O are able to adsorb an additional 1 mol·mol⁻¹ of water vapour to form the pentahydrate, MPt·5H₂O. The formation of these pentahydrates may account
- ¹⁰ for the origin of the slight blue shifts in the luminescence spectra of **MgPt**·4H₂O and **BaPt**·4H₂O immersed in water. In other words, the Pt-Pt distances of these CPs elongated upon adsorption of additional water, in the water suspension, resulting in the blue shift of the ³MMLCT emission. Figure 6(b) shows the MeOH-
- ¹⁵ vapour-adsorption isotherms of **MPt** at 298 K. In contrast to the fact that **ZnPt** cannot adsorb MeOH vapour at all, **MgPt**, **CaPt**, **SrPt**, and **BaPt** can adsorb MeOH vapour at low pressure. The saturated adsorption amounts are about 2 mol·mol⁻¹ for each CP. The emission spectrum of anhydrous **CaPt** upon exposure to
- ²⁰ MeOH vapour was almost identical to the spectrum obtained from the **CaPt**·4H₂O in MeOH suspension (see Figure S3). Thus, we believe that the blue-shifts observed in the MeOH suspensions of **MgPt**·4H₂O and **CaPt**·4H₂O originate from the guest exchange reaction of water with MeOH as shown in Scheme 1(c).
- ²⁵ Although we also measured the EtOH vapour adsorption isotherms for these CPs, the adsorbed amounts were negligibly small for all of the CPs (see Figure S5).

Substitution effect of the bridging metal ions

- As discussed above, the chromic behaviours and vapour-30 adsorption properties of MPt·4H2O depend strongly on the bridging metal ions in spite of their isomorphous structures. In this section, we discuss the substitution effect of the bridging metal ions. In the case of ZnPt·4H2O, the Zn²⁺ ion in the structure acted as the water adsorption site and the coordination ³⁵ geometry of Zn²⁺ ion changed by desorption of the all water molecules from 5-coordinated trigonal-bipyramid to 4coordinated tetrahedron accompanied by the change of coordination mode of the carboxyl group from the monodentate to bidentate fashion.9 Because the four MPt·4H2O CPs are 40 thought to be isomorphous with ZnPt·4H₂O, the bridging alkaline-earth metal ions should also act as the vapour-adsorption sites. All anhydrous MPt CPs can adsorb MeOH vapour in contrast to the lack of adsorption ability of ZnPt to MeOH vapour. This adsorption capability for MeOH vapour may 45 originate from the strong coordination abilities of the coordinatively-unsaturated M2+ ions. Although alkaline-earth metal ions rarely adopt the four-coordinate structure, the Zn²⁺ ion is well known to be able to adopt the four-coordinate tetrahedral
- structure. Consequently, the bridging M²⁺ ion in the anhydrous ⁵⁰ **MPt** would have strong adsorption ability on the basis of the coordinatively-unsaturated structure. In fact, the adsorption amounts of water and MeOH vapours for all of the **MPt** CPs increased sharply in the very low vapour pressure region, suggesting chemical adsorption.
- ⁵⁵ Remarkable differences in the thermochromic and suspendedstate solvatochromic shifts were also observed for the four CPs with alkaline-earth metal ions, demonstrating the dependence on the M^{2+} ion. Although **MgPt**·4H₂O and **CaPt**·4H₂O showed

relatively large chromic shifts, SrPt·4H₂O and BaPt·4H₂O 60 exhibited minimal chromic shifts. This tendency is probably owing to the relatively larger volume occupied by water molecules in the unit cells of MgPt·4H2O and CaPt·4H2O than those of SrPt·4H₂O and BaPt·4H₂O. The larger M ions make the volume occupied by water molecules relatively smaller, resulting 65 in smaller modifications in the Pt-Pt distances induced by water desorption. These relatively rigid structures of SrPt.4H2O and BaPt·4H₂O may contribute to their higher luminescence quantum yields and longer lifetimes than those of the other MPt. The lower quantum yield of BaPt·4H2O than that of SrPt·4H2O 70 would be due to the lower emission energy than that of SrPt·4H₂O. In addition, the observed water-vapour adsorption amounts (ca. 5 mol·mol⁻¹) of MgPt, SrPt and BaPt are larger than **CaPt** (*ca.* 4 mol·mol⁻¹). The larger water-vapour-adsorption capacity of MgPt (ca. 5 mol·mol⁻¹) is probably due to the large 75 hydration enthalpy of the Mg²⁺ ion, whereas the increased adsorption capacity of SrPt and BaPt may originate from the higher coordination numbers of these heavier alkaline-earth metal ions.

The selective vapour adsorption capacity of the CPs (lack of vapour-adsorption ability for vapours other than water and MeOH) may be attributed to instability of vapour-adsorbed structure in these CPs. The lack of adsorption capability of every **MPt** with alkaline-earth metal ion for EtOH vapour suggests that the larger coordinating vapour molecules than MeOH would not ⁸⁵ be able to enter the vapour accessible channels around the M²⁺ ions, resulting in the negligible small vapour uptake. Thus, the adsorption properties of **MPt** depend strongly on the kinds of bridging metal ions which produces remarkable effects on the chromic behaviours of the complexes.

90 Conclusions

new coordination polymers, {M[Pt(CN)₂(5,5'-Four dcbpy]·4H₂O}_n (M = Mg²⁺, Ca²⁺, Sr²⁺, Ba²⁺; 5,5'-H₂dcbpy = 5,5'-dicarboxy-2,2'-bipyridine) were successfully synthesized using alkaline-metal ions and the luminophoric Pt(II)-diimine ⁹⁵ metalloligand, [Pt(CN)₂(5,5'-dcbpy)]²⁻. The structures of all of the CPs are essentially isomorphous with {Zn[Pt(CN)₂(5,5'dcbpy)]·4H₂O}_n, which consists of one-dimensional polymeric chains formed by an alternating arrangement of M2+ ions and the $[Pt(CN)_2(5,5'-dcbpy)]^{2-}$ metalloligand, with effective 100 metallophilic interaction between Pt(II) ions. The vapouradsorption capability of this system was remarkably altered by replacement of Zn2+ ion with alkaline-earth metal ions, resulting in selective adsorption for water and MeOH vapours. These CPs exhibit interesting thermochromic and solid-state (suspension) 105 solvatochromic behaviours driven by water or MeOH adsorption/desorption. Variation of the bridging metal ions produced significant effects on the chromic behaviours in spite of the isomorphous nature of the structures, i.e., the chromic shift observed for CPs with larger alkaline-earth metal ions are 110 remarkably smaller than those for CPs with smaller ions. Further studies on the synthesis of novel CPs composed of other Pt(II)diimine-based metalloligands to achieve both gas sensing and adsorption functions are now in progress.
