1 **Abstract**

2 A SiO<sub>2</sub>-supported bimetallic catalyst composed of copper (Cu) and a small amount of  
3 silver (Ag) by a one-step urea-assisted gelation method shows remarkable enhancements in  
4 catalytic performance for selective hydrogenation of dimethyl oxalate (DMO) to ethylene  
5 glycol (EG). Coupling with a series of ~~characteristics~~characterization and kinetic studies, the  
6 improved activity is rationalized essentially due to the formation of Ag nanoclusters and  
7 Cu-Ag alloys involved in Cu nanoparticles on SiO<sub>2</sub> surface. The coherent interactions  
8 between Cu and Ag species are beneficial for creating the active Cu<sup>+</sup>/Cu<sup>0</sup> species in a  
9 suitable proportion and restraining the transmigration of bimetallic nanoparticles during the  
10 hydrogenation process. In particular, an optimized Cu-Ag/SiO<sub>2</sub> catalyst with Ag/Cu atomic  
11 ratio of 0.05 that generates a balanced Cu<sup>+</sup>/Cu<sup>0</sup> proportion and highly dispersed bimetal  
12 particles affords the highest turnover frequency, over 97.0% EG selectivity and excellent  
13 catalytic stability longer than 150 h for the DMO hydrogenation to EG.

14

15 *Keywords:* Copper; Silver; Hydrogenation; Dimethyl oxalate; Ethylene glycol.

16

## 1 **1. Introduction**

2 Ethylene glycol (EG) is an important chemical that widely used as antifreezer, polyester  
3 fibers, solvents and so on [1]. However, the exhausting of crude oil resources and the  
4 increasing demand for EG urge a new promising approach for the synthesis of EG to  
5 substitute the traditional petroleum-derived one [2,3]. One of the possible approaches, the  
6 so-called coal to EG (CTE), is relatively green and economical. The CTE process involves  
7 gasification of coal to syngas, followed by the coupling of CO with nitrite esters to oxalates,  
8 and then the hydrogenation of oxalates to EG [1,4,5]. Selective hydrogenation of dimethyl  
9 oxalate (DMO) to EG as one of the key reactions for CTE route had drew tremendous  
10 attentions. Although great effort has been made to study the DMO hydrogenation process,  
11 many problems still leave to be solved. At present, the EG selectivity and catalytic stability  
12 remain to be improved, the perception of active sites is still controversial and the essence of  
13 catalyst deactivation needs further elucidation. More understanding and generic concepts for  
14 a more rational catalyst design is highly desirable.

15 Cu-based catalysts have been studied extensively for vapor-phase hydrogenation of  
16 DMO since they allow for selective hydrogenation of carbon-oxygen bonds and are relatively  
17 inactive in carbon-carbon bond hydrogenolysis [6]. So far, Cu-Cr catalysts have been still the  
18 preferred industrial catalysts for the CTE process because of their relatively high catalytic  
19 activity and long lifetime [7–9]. However, the use of toxic chromium will endanger the  
20 safety of environment and the security of workers. Therefore, different carriers (e.g., SiO<sub>2</sub>,  
21 Al<sub>2</sub>O<sub>3</sub> and ZnO) for Cr-free Cu-based catalysts were evaluated [10–12], among which the

1 Cu/SiO<sub>2</sub> catalyst showed the highest EG yield and was considered a potential alternative for  
2 the conventional CuCr catalyst. But the Cu/SiO<sub>2</sub> catalyst is relatively sintering-nonresistant  
3 and mechanically unstable for industrial operation [6,13–16]. Thus, considerable efforts are  
4 focused on modifying Cu/SiO<sub>2</sub> catalyst by various methods, including adding a second  
5 species [13–16], adopting different preparation methods [3,17–21], and using different  
6 structures of silica support [22–26]. Cu, Ag and Au are coinage metals in the same group of  
7 the periodic table, they all possess the face-centered cubic (fcc) structure with close lattice  
8 parameters, and their electronic structure and physical chemical properties are similar. They  
9 can form intermetallic or alloy phase with each other. Synergistic effect between Cu-Au  
10 [27,28], Cu-Ag [29,30], Au-Ag [31,32] bimetallic catalysts have been reported. Interestingly,  
11 recent results show that a bimetallic Cu-Au catalyst with large amount of Au could present  
12 improved performance in the DMO hydrogenation to MG [33], while that with small amount  
13 of Au exhibited remarkable enhancements in activity and stability for the DMO  
14 hydrogenation to EG [34]. Spectroscopic studies revealed that Cu-Au alloy nanoparticles  
15 (NPs) were formed on the catalyst surfaces, which were believed to be beneficial for  
16 retarding the surface transmigration of Cu species during the hydrogenation process. Further,  
17 the surface Cu<sup>+</sup> and Cu<sup>0</sup> proportion would be varied according to the amount of incorporated  
18 Au, showing different catalytic behaviors under same conditions as a result. The catalytic  
19 performance of Cu-Ag/SiO<sub>2</sub> catalysts prepared by a deposition-precipitation method has also  
20 been evaluated for the DMO hydrogenation reaction, affording MG as the main product [35].  
21 However, the structure and the structure-activity relationship of the Cu-Ag catalysts are

1 ambiguous.

2 In this work, we incorporate a small amount of Ag into Cu/SiO<sub>2</sub> through a urea-assisted  
3 gelation method and find that the bimetallic Cu-Ag/SiO<sub>2</sub> catalysts are efficient for  
4 hydrogenation of DMO to EG. Kinetic and spectroscopic studies will show that an intimate  
5 interaction between Cu and Ag NPs and a cooperative effect between them might be  
6 essentially responsible for the enhanced catalysis.

7

## 8 **2. Experimental**

### 9 *2.1. Catalyst preparation*

10 Bimetallic Cu-Ag/SiO<sub>2</sub> catalysts with a presetmetal loading of 10 wt% were prepared  
11 by urea-assisted gelation method [13]. Briefly, 4.5 g of 40 wt% LudoxAS-40 colloidal silica  
12 was dispersed in 100 mL of aqueous solution containing 6.0 g of urea, a certain amount of  
13 AgNO<sub>3</sub>, Cu(NO<sub>3</sub>)<sub>2</sub>·3H<sub>2</sub>O and aqueous ammonia (28 wt%) in a round-bottomed flask. The  
14 suspension was vigorously stirred at 353 K in an oil bath for 4 h. The precipitate obtained  
15 was separated by hot filtration, washed thrice with deionized water, and dried at 393 K  
16 overnight, followed by calcination at 623 K for 4 h. The catalyst precursor was denoted as  
17 Cu<sub>1</sub>-Ag<sub>x</sub>/SiO<sub>2</sub>, where x represents atomic ratio of Ag and Cu.

18 The Cu/SiO<sub>2</sub> catalyst with 10 wt% Cu loading, and the Ag/SiO<sub>2</sub> catalyst with 10 wt%  
19 Ag were also prepared by urea-assisted gelation method.

20

### 21 *2.2. Catalyst characterizations*

1 N<sub>2</sub> adsorption–desorption isotherms for the catalysts were measured at 77 K using a  
2 Micromeritics TriStar II 3020 porosimetry analyzer. The samples were degassed at 573 K for  
3 3 h prior to the measurements. The specific surface area ( $S_{\text{BET}}$ ) was calculated using the  
4 Brunauer-Emmett-Teller (BET) method, adopting the isotherm data in a relative pressure  
5 ( $P/P_0$ ) range of 0.05–0.2. The mesopore size distributions were evaluated from the  
6 desorption branch of isotherm using the Barrett-Joyner-Halenda (BJH) method. The total  
7 pore volume depended on the absorbed N<sub>2</sub> volume at a relative pressure of approximate 0.99.  
8 X-ray diffraction (XRD) patterns for the catalyst samples were conducted on a PANalytical  
9 X’pert Pro Super X-ray diffractometer using Cu K<sub>α</sub> radiation ( $\lambda = 0.15418$  nm) with a  
10 scanning angle ( $2\theta$ ) range of 10–90°, a tube voltage of 40 kV, and a current of 30 mA. For *in*  
11 *situ* XRD measurement, a 5%H<sub>2</sub>-95%N<sub>2</sub> mixture was introduced at a flow rate of 50 cm<sup>3</sup>  
12 min<sup>-1</sup>. Temperature ramping programs were performed from room temperature to 523, 573,  
13 623, 673, 723, 773, 873, and 973 K at a rate of 2 K min<sup>-1</sup>. The XRD patterns were collected  
14 after samples reached the preset temperatures for 30 min. The diffraction pattern was  
15 identified by matching them with reference patterns included in the JCPDS data base. The  
16 full-width-at-half-maximum of Cu(111) diffraction at a  $2\theta$  of 43.2° was used to calculate the  
17 Cu crystallite size using the Scherrer equation.

18 Hydrogen-temperature-programmed reduction (H<sub>2</sub>-TPR) for the as-calcined catalyst  
19 samples was carried out on a Micromeritics Autochem II 2920 instrument connected to a  
20 Hiden Qic-20 mass spectrometer (MS). 100 mg of the calcined catalyst was loaded into a  
21 quartz U-tube and dried in an argon stream at 393 K for 1 h. After cooling to room

1 temperature under argon, a flow of 5% H<sub>2</sub>-95% N<sub>2</sub> (50 mL min<sup>-1</sup>) was fed into the catalyst  
2 bed, and then the temperature was ramped linearly from ambient temperature to 1073 K at a  
3 rate of 10 K min<sup>-1</sup>. A 5A zeolite trap was connected to the reactor outlet to remove moisture.  
4 Hydrogen consumption was simultaneously monitored by a thermal conductivity detector  
5 (TCD) and MS.

6 Transmission electron microscopy (TEM) images were obtained on a Tecnai F30  
7 apparatus operated at 300 kV. The composition analysis of each metal particle was carried  
8 out using energy dispersive X-ray spectroscopy (EDS) at scanning TEM-STEM mode.  
9 Catalyst powder was dispersed in ethanol with the assistance of ultrasound at room  
10 temperature. The as-obtained solution was dropped onto the carbon coated molybdenum  
11 grids.

12 Ultraviolet-visible diffuse reflectance spectroscopy (UV-vis DRS) of as-reduced  
13 catalysts was collected on a UV-vis-NIR Spectrophotometer CARY 5000 scan  
14 spectrophotometer. All catalyst precursors were freshly reduced in a 5% H<sub>2</sub>-95% N<sub>2</sub>  
15 atmosphere at 623 K for 4 h. Then the as-reduced samples were carefully collected under  
16 argon atmosphere at room temperature and sealed in glass bottles before UV-vis DRS  
17 measurements.

18 Cu K-edge and Ag K-edge XAFS measurements were performed in a transmission  
19 mode at BL12C and NW10 beam line in PF-AR and Photon Factory, Institute of Materials  
20 Structure Science, High Energy Accelerator Research Organization (IMSS-KEK), Japan.  
21 The storage ring was operated at 2.5 GeV with 450mA in a top-up mode. A Si (111) double

1 crystal monochromator was used in a quick scan mode. Samples after reduction under 5%  
2 H<sub>2</sub>-95% Ar at 623 K for 2 h were sealed in the glass cells under He(Cu) or Ar(Ag) and  
3 XAFS spectra were taken at room temperature. The analysis of EXAFS was performed using  
4 the REX version 2.5 program (RIGAKU). The Fourier transformation of the k<sup>3</sup>-weighted  
5 EXAFS oscillation from k space to r space was performed over the range 30–140 nm<sup>-1</sup> to  
6 obtain a pseudo-radial distribution function. The inversely Fourier filtered data were  
7 analyzed with a non-linear least square curve fitting method in the k range of 30–140 nm<sup>-1</sup>.  
8 For the curve fitting analysis, the phase shift and amplitude functions for the Ag–Cu, Ag–Ag  
9 and Ag–O shells were calculated using FEFF program.

10 Measurements of X-ray photoelectron spectroscopy (XPS) and Auger electron  
11 spectroscopy (XAES) were carried out on a JPS-9010MC photoelectron spectrometer  
12 equipped with an Al K<sub>α</sub> X-ray radiation source ( $h\nu = 1486.6$  eV). Prior to measurements,  
13 each sample was pressed into thin disk and pretreated in an atmosphere of 5% H<sub>2</sub>-95% Ar  
14 ( $5 \times 10^4$  Pa) at 623 K for 1 h in an auxiliary pretreatment chamber. After pretreatment, the  
15 sample was introduced into the XPS chamber avoiding exposure to air. The XPS spectra of  
16 as-calcined and pretreated samples were recorded at room temperature and the binding  
17 energy (BE) were calibrated using C 1s peak at 284.6eV as reference with an uncertainty of  
18  $\pm 0.2$  eV.

19 Cu dispersions of the catalysts were determined by dissociative N<sub>2</sub>O chemisorption and  
20 hydrogen pulse reduction on a Micromeritics Autochem II 2920 apparatus with a TCD.  
21 Typically, 100 mg of Cu/SiO<sub>2</sub> calcined at 623 K was reduced in 5%H<sub>2</sub>-95%N<sub>2</sub> (50 cm<sup>3</sup>

1 min<sup>-1</sup>) at 623 K for 4 h and cooled to 333 K. Then pure N<sub>2</sub>O (30 cm<sup>3</sup> min<sup>-1</sup>) was introduced  
2 for 30 min to completely oxidize surface Cu atoms into Cu<sub>2</sub>O. Hydrogen pulse reduction of  
3 surface Cu<sub>2</sub>O to metallic Cu was conducted at 573 K to ensure that the chemisorbed oxygen  
4 can immediately react with high-purity hydrogen supplied from a 0.4 mL loop, and moisture  
5 was removed by a 5A zeolite dehydration trap. Hydrogen pulse-dosing was repeated until the  
6 pulse area no longer changed. The consumed amount of hydrogen was the value obtained by  
7 subtracting the small area of the first few pulses from the area of the other pulses. Cu loading  
8 of all reduced catalysts was analyzed by inductively coupled plasma optical emission  
9 spectrometry (ICP-OES) on a Thermo Electron IRIS Intrepid II XSP. Cu dispersion was  
10 calculated by dividing the amount of chemisorption sites into total supported Cu atom in per  
11 gram of catalyst.

12

### 13 2.3. Catalytic testing

14 Catalytic performance for the DMO hydrogenation was evaluated using a fixed-bed  
15 microreactor equipped with a computer-controlled auto-sampling system. As a typical  
16 procedure, 200 mg of catalyst precursor (40–60 meshes) was loaded into the center of the  
17 reactor with both sides of the catalyst bed packed with quartz powders (40–60 meshes). The  
18 catalyst was activated in a flow of 5% H<sub>2</sub>-95% N<sub>2</sub> (50 mL min<sup>-1</sup>) at 623 K for 4 h, with a  
19 ramping rate of 2 K min<sup>-1</sup>. After cooling to reaction temperature, pure H<sub>2</sub> (99.999%) was  
20 switched to pass through the catalyst bed, a DMO methanol solution (0.01 g mL<sup>-1</sup>) was then  
21 pumped into the reactor by a Series III digital HPLC pump (Scientific Systems, Inc.) with a

1 system pressure of 3.0 MPa. The outlet stream was sampled using an automatic Valco  
2 6-ports valve system and analyzed by an online gas chromatograph with a flame ionization  
3 detector and a KB-Wax capillary column (30 m × 0.45 mm × 0.85 μm) at intervals of 30  
4 min.

5 The initial turn over frequency (TOF) of the reaction was measured under the conditions  
6 where the DMO conversion was lower than 35%. The TOF value was based on the Cu  
7 dispersion or the number of surface metal atoms estimated by metal dispersion according to  
8 the equation in previous literature [36], indicating the moles of DMO converted per hour by  
9 per mole of metal at the catalyst surface ( $\text{mol-DMO mol-metal}_{\text{surf}}^{-1} \text{ h}^{-1}$ , for short  $\text{h}^{-1}$ ).

10

### 11 **3. Results and discussion**

#### 12 *3.1. Catalytic activity and stability*

13 For a rigorous comparison of the catalytic activity between Cu/SiO<sub>2</sub> and Cu<sub>1</sub>-Ag<sub>x</sub>/SiO<sub>2</sub>,  
14 the DMO conversion was restrained less than 35% by adjusting the DMO weight liquid  
15 hourly space velocity (WLHSV<sub>DMO</sub>) (Table 1). The DMO conversion data were then used to  
16 calculate the TOF by DMO conversion according to the Cu dispersion (TOF<sub>Cu</sub>) and total  
17 metal dispersion (TOF<sub>M</sub>) as listed in Table 1. The TOF<sub>Cu</sub> exhibited a volcano-type  
18 improvement as the increase of Ag content in Cu<sub>1</sub>-Ag<sub>x</sub>/SiO<sub>2</sub> and reached a maximum (18.3  
19 h<sup>-1</sup>) at the Ag/Cu atomic ratio of 0.05/1. The TOF<sub>M</sub> of the catalysts presented a tendency  
20 similar to TOF<sub>Cu</sub>, but its value was slightly higher than TOF<sub>Cu</sub> when the Ag/Cu atomic ratio  
21 was below 0.1, indicating that there exist some interactions between Ag and Cu. Further

1 increasing Ag loading restrained the catalytic activity, and the restriction was more obvious  
2 when the monometallic Ag catalyst was taken into account. The results demonstrate that  
3 there is a synergistic effect between Cu and Ag for the hydrogenation of DMO to EG.

4 When the DMO hydrogenation was conducted under the conditions of  $1.05 \text{ h}^{-1}$   
5  $\text{WLHSV}_{\text{DMO}}$ , 463 K, 3.0 MPa  $\text{H}_2$  pressure, and 80  $\text{H}_2/\text{DMO}$  molar ratio, the bimetallic  
6 catalysts employed showed a DMO conversion higher than 97% ([Table 1S in the Supporting](#)  
7 [Information](#)), but  $\text{Cu}/\text{SiO}_2$  catalyst gave a DMO conversion of 87.2% and 30.7% selectivity  
8 to EG;  $\text{Ag}/\text{SiO}_2$  was almost inactive. That is, Ag incorporated  $\text{Cu}/\text{SiO}_2$  could get a resultant of  
9 dramatically improved yield of EG compared with monometallic  $\text{Cu}/\text{SiO}_2$  or  $\text{Ag}/\text{SiO}_2$ . It was  
10 noteworthy that the Ag/Cu atomic ratio had a significant effect on tuning the catalytic  
11 capability of DMO hydrogenation. Introducing a very small amount of Ag (Ag/Cu atomic  
12 ratio = 0.02, Ag loading = 0.26 wt %) into the  $\text{Cu}/\text{SiO}_2$  elevated the EG yield to 58.4%,  
13 which was twice as that of monometallic  $\text{Cu}/\text{SiO}_2$  catalyst. Increasing the Ag/Cu atomic ratio  
14 to 0.05, the catalyst thus resulted showed a maximal EG yield of 85.9%. When further  
15 increasing the Ag/Cu atomic ratio larger than 0.1, the catalyst gave a lower EG yield.

16 The catalytic performance of  $\text{Cu}/\text{SiO}_2$  and optimized  $\text{Cu}_1\text{-Ag}_{0.05}/\text{SiO}_2$  catalysts were  
17 further investigated under different  $\text{WLHSV}_{\text{DMO}}$  values ([Fig. 1](#)). The conversion of DMO  
18 remained above 99% over  $\text{Cu}_1\text{-Ag}_{0.05}/\text{SiO}_2$  catalyst when  $\text{WLHSV}_{\text{DMO}}$  varied from 0.3 to  
19  $1.05 \text{ h}^{-1}$ , that over  $\text{Cu}/\text{SiO}_2$  began to decline when  $\text{WLHSV}_{\text{DMO}}$  was set at  $0.6 \text{ h}^{-1}$ . The  
20 selectivity to EG was kept at about 97% over  $\text{Cu}_1\text{-Ag}_{0.05}/\text{SiO}_2$  catalyst, but that over  $\text{Cu}/\text{SiO}_2$   
21 declined to lower than 50% when  $\text{WLHSV}_{\text{DMO}}$  was up to  $0.75 \text{ h}^{-1}$ . Accordingly, it is ease to

1 obtain the EG yield over  $\text{Cu}_{1-x}\text{Ag}_x/\text{SiO}_2$  catalysts as a function of  $\text{WLHSV}_{\text{DMO}}$  (Fig. S1 in  
2 the Supporting Information), indicating that the influence of  $\text{WLHSV}_{\text{DMO}}$  was significant  
3 and the bimetallic Cu-Ag/SiO<sub>2</sub> catalysts presented much better catalytic performance and  
4 tolerance to  $\text{WLHSV}_{\text{DMO}}$  than Cu/SiO<sub>2</sub> for the hydrogenation of DMO.

5 The long-term catalytic behavior of Cu/SiO<sub>2</sub> and optimized  $\text{Cu}_1\text{-Ag}_{0.05}/\text{SiO}_2$  was further  
6 evaluated under reaction conditions of 463 K, 3.0 MPa, 80H<sub>2</sub>/DMO molar ratio, and 0.6 h<sup>-1</sup>  
7  $\text{WLHSV}_{\text{DMO}}$ . As shown in Fig. 2, the DMO conversion and the EG selectivity of Cu/SiO<sub>2</sub>  
8 catalyst dramatically decreased to about 60% and 10% respectively after 100 h, whereas the  
9  $\text{Cu}_1\text{-Ag}_{0.05}/\text{SiO}_2$  catalyst retained its initial excellent activity for over 150 h. The results  
10 suggested that adding proper amount of Ag into Cu/SiO<sub>2</sub> can not only remarkably enhance  
11 the DMO hydrogenation activity, but also effectively improve the catalyst stability.

## 12 3.2. Catalyst characterizations

### 13 3.2.1. Physicochemical properties of the catalysts

14 The metal loadings of the catalysts determined by ICP-OES are listed in Table 2. The  
15 actual loadings of Cu and Ag were slightly lower than the theoretical value because the  
16 metallic ions weakly absorbed on silica gel were eluted during the filtration process.  
17 However, the actual atomic ratio of Ag/Cu in the catalysts was close to the preset value.  
18 Physicochemical properties of the catalysts are also summarized in Table 2. The introduction  
19 of Ag had no obvious effect on the surface area of the catalysts, while the pore volume and  
20 average pore diameter slightly increased when the Ag/Cu atomic ratios were lower than 0.1,  
21

1 then decreased after further introducing silver. Since the reaction of N<sub>2</sub>O with metallic Ag  
2 species occurs at relatively high temperature (658 K) [37] or needs long reaction time (5 h) if  
3 temperature is below 373 K [38], and the Ag content was very low in the present bimetallic  
4 catalysts, the concurrent oxidation of metallic Ag species in the process of determination of  
5 Cu dispersion by N<sub>2</sub>O at 333 K was ignored. Thus, the Cu dispersions of bimetallic  
6 Cu-Ag/SiO<sub>2</sub> catalysts are summarized in Table 1. The Cu dispersion increased firstly and  
7 was maximized at Ag/Cu atomic ratio of 0.05 with a value of 43.1 m<sup>2</sup> g<sup>-1</sup>, and then declined  
8 mildly with further increasing Ag loading. The results suggested that the introduction of  
9 proper amount of Ag facilitated the higher dispersion of Cu particles. It should be noted that  
10 the Cu<sub>1</sub>-Ag<sub>0.05</sub>/SiO<sub>2</sub> with the highest Cu dispersion presented the optimal catalytic  
11 performance under identical reaction conditions.

12

### 13 3.2.2. TEM, EDS and XRD

14 The morphologies and structural details of the bimetallic catalysts were examined by  
15 TEM (Fig. 3). The metal nanoparticles were distributed uniformly on the surfaces of the  
16 silica, and the particle diameter distribution showed that mean particle size of all the samples  
17 was about 3 nm. High-resolution TEM (HRTEM) of a typical metal particle in the  
18 Cu<sub>1</sub>-Ag<sub>0.05</sub>/SiO<sub>2</sub> catalyst (Fig. S2 in the Supporting Information) indicated the 0.188 nm  
19 [KA1]interval of lattice fringes was smaller than those of the monometallic Ag(111) (0.236  
20 nm), Ag(200) (0.204 nm), and Cu(111) (0.209 nm), but larger than Cu(200) (0.181 nm). The  
21 result may be an indication for the formation of Cu-Ag alloy after reduction. The total metal

1 dispersion of catalysts calculated according to the TEM is listed in [Table 2](#). As can be seen,  
2 in line with the trend of Cu dispersion, the total metal dispersion of catalysts improved with  
3 increasing Ag/Cu atomic ratio. The dispersion of  $\text{Cu}_1\text{-Ag}_{0.05}/\text{SiO}_2$  was maximal with a value  
4 of  $38.4 \text{ m}^2 \text{ g}^{-1}$ .

5 The high-angle annular dark-field scanning transmission electron microscopy  
6 (HAADF-STEM) images of the as-reduced  $\text{Cu}_1\text{-Ag}_x/\text{SiO}_2$  bimetallic catalysts were shown in  
7 [Fig. S3 \(in the Supporting Information\)](#). The tiny bright spots in the images correspond to  
8 metal nanoparticles supported on the  $\text{SiO}_2$ . In combination with X-ray energy dispersive  
9 spectroscopy (X-EDS) system equipped with a sub-nanometer probe, we can locate the  
10 convergent electron beam (0.5 nm) at any position of the sample to obtain more detail  
11 features of metal nanoparticles such as element distribution, composition etc. under  
12 HAADF-STEM mode. The compositions of individual metallic particles on the several  
13 as-reduced  $\text{Cu}_1\text{-Ag}_x/\text{SiO}_2$  catalysts were measured via point EDS analysis on thirteen metal  
14 particles randomly chosen ([Fig. S3 in the Supporting Information](#)). The EDS results revealed  
15 that both Cu and Ag elements were detectable, and the Ag/Cu atomic ratio was considerably  
16 higher than the preset values in most of the metallic particles. The Cu contents were much  
17 higher than Ag in  $\text{Cu}_1\text{-Ag}_x/\text{SiO}_2$  catalysts, but the compositions detected by EDS indicated  
18 an segregation of Ag species, implying that most of bimetallic particles might be composed  
19 of small Ag and Cu-Ag alloy nanoclusters located on the surfaces of Cu NPs. In another  
20 word, the results implied that Cu and Ag atoms intimately contacted with each other,  
21 providing the premise of the synergistic effects.

1 The XRD patterns showed that the as-calcined catalysts were amorphous except the  
2 Ag/SiO<sub>2</sub> (Fig. S4 in the Supporting Information). Introduction of Ag into Cu/SiO<sub>2</sub> did not  
3 significantly change the XRD patterns of Cu/SiO<sub>2</sub> catalyst. Neither Cu nor Ag species could  
4 be detected in these precursors, implying that Cu and Ag were highly dispersed on the  
5 porous silica support using urea-assisted gelation method. However, well dispersed pure  
6 Ag/SiO<sub>2</sub> cannot be prepared by this method.

7 We then conducted *in situ* XRD characterization to monitor the phase evolution of  
8 Cu/SiO<sub>2</sub> and optimized Cu<sub>1</sub>-Ag<sub>0.05</sub>/SiO<sub>2</sub> catalysts with increasing reduction temperature  
9 under 5%H<sub>2</sub>-95%N<sub>2</sub> atmosphere. As shown in Fig. 4, a diffraction peak at 2θ of 43.2°, the  
10 characteristic peak of Cu(111) (JCPDS 04-0836), became detectable because some Cu<sup>2+</sup>  
11 species on the Cu/SiO<sub>2</sub> catalyst precursor were reduced to Cu<sup>0</sup> when the reduction  
12 temperature raised up to 523 K. According to the Scherrer equation, the Cu crystallite size of  
13 Cu/SiO<sub>2</sub> catalyst was smaller than 4 nm when the reduction temperature was lower than 773  
14 K, while the Cu crystallite size of Cu<sub>1</sub>-Ag<sub>0.05</sub>/SiO<sub>2</sub> catalyst was smaller than 3.2 nm at the  
15 same reduction temperature range. The diffraction peaks of Cu<sub>1</sub>-Ag<sub>0.05</sub>/SiO<sub>2</sub> catalyst were to  
16 some extent broader than those of the pure Cu catalyst, indicating that adding proper amount  
17 of Ag into Cu/SiO<sub>2</sub> catalyst could improve Cu dispersion. This was in accordance with the  
18 results of dissociative N<sub>2</sub>O chemisorption and TEM. Further increasing the reduction  
19 temperature under 5%H<sub>2</sub>-95%N<sub>2</sub>, the Cu diffraction of both Cu/SiO<sub>2</sub> and Cu<sub>1</sub>-Ag<sub>0.05</sub>/SiO<sub>2</sub>  
20 peaks became sharper, displaying a similar phase evolution behavior.

1 After long-term catalytic test, the catalysts were carefully collected under hydrogen  
2 atmosphere at room temperature and sealed in glass bottles to protect the samples from  
3 oxidation. The XRD diffraction peaks of metallic copper were significant different from each  
4 other for the Cu/SiO<sub>2</sub> and Cu<sub>1</sub>-Ag<sub>0.05</sub>/SiO<sub>2</sub> catalysts (Fig. S5 in the Supporting Information).  
5 The Cu diffraction peak of the spent Cu/SiO<sub>2</sub> catalyst at 2θ of 43.2° was sharper than that of  
6 Cu<sub>1</sub>-Ag<sub>0.05</sub>/SiO<sub>2</sub>. Insignificant changes occurred for the Cu<sub>1</sub>-Ag<sub>0.05</sub>/SiO<sub>2</sub> catalyst before and  
7 after long-term reaction. Furthermore, TEM images of these catalysts intuitively revealed the  
8 consistent results (Fig. S6 in the Supporting Information). Transmigration and aggregation of  
9 Cu happened on Cu/SiO<sub>2</sub> after long-term catalytic reaction. Thus, we speculated that Cu  
10 agglomeration was one of the key factors to cause the deactivation of the catalyst. Clearly,  
11 the addition of Ag played an important role in retarding the aggregation of metallic Cu  
12 crystallites.

13

### 14 3.2.3. H<sub>2</sub>-TPR

15 In many case, presence of a noble metal affected the reducibility of surface metal oxides.  
16 H<sub>2</sub>-TPR characterizations were carried out to investigate the reducibility of the as-calcined  
17 samples with different Ag/Cu atomic ratios. There was no obvious reduction peak for the  
18 as-calcined Ag/SiO<sub>2</sub> catalyst (Fig. S7 in the Supporting Information). The as-calcined  
19 Cu/SiO<sub>2</sub> presented a reduction peak at 518 K, assigned to the reduction of highly dispersed  
20 CuO to Cu<sup>0</sup> and copper phyllosilicate to Cu<sup>+</sup> [3,39]. The reduction peaks of bimetallic  
21 samples gradually shifted to lower value with the increase of Ag/Cu atomic ratio. The

1 tendency of Ag introducing to decrease the reduction temperature was consistent with the  
2 results reported by Zhou et al. [31], suggesting that some intense interactions between Cu  
3 and Ag species occurred.

#### 4 5 3.2.4. UV-vis DRS

6 The UV-vis DRS of as-reduced Ag/SiO<sub>2</sub> catalyst gave a strong absorption peak at 395  
7 nm, which is typical for the well-known surface plasmon resonance (SPR) band of Ag NPs  
8 (Fig. S8 in the Supporting Information). Meanwhile, Cu/SiO<sub>2</sub> showed a very weak and broad  
9 SPR band around 600 nm. The UV-vis DRS spectra of bimetallic catalysts showed a single  
10 SPR band between 400–600 nm, which revealed that it was not a physical mixture of the  
11 individual metals [40]. The SPR band gradually shifted to blue range with the increase of  
12 Ag/Cu atomic ratio, indicating that the electronic structure of the bimetallic samples changed  
13 after silver introducing, because the SPR bands of metal particles are caused by the  
14 collective oscillations of the conduction electrons and the d-band energy level continuously  
15 changed as a result of an increase in Ag composition [40,41].

#### 16 17 3.2.5. XPS and XAES

18 The XPS was employed to investigate the surface valence state of the as-reduced  
19 Cu-Ag/SiO<sub>2</sub> catalysts. For Cu/SiO<sub>2</sub> catalyst, the Cu 2p XPS peaks corresponding to Cu 2p<sub>3/2</sub>  
20 and Cu 2p<sub>1/2</sub> appeared at 932.5 eV and 952.4 eV, respectively (Fig. S9 in the Supporting  
21 Information). Nevertheless, the BE of Cu 2p<sub>3/2</sub> shifted to higher values with the increase of

1 Ag content, indicating the electronic effect was more obvious as the Ag content increase.  
2 The absence of 2d→3d satellite peaks at 934.9 or 933.5 eV suggested that Cu<sup>2+</sup> was  
3 successfully reduced to Cu<sup>0</sup> and/or Cu<sup>+</sup> after reduction at 623 K [13].

4 The Ag 3d XPS spectra of the as-reduced Ag/SiO<sub>2</sub> showed typical Ag 3d<sub>5/2</sub> and Ag 3d<sub>3/2</sub>  
5 peaks centered at 367.9 eV and 373.9 eV (Fig. S10 in the Supporting Information), which  
6 were coincident with the reported values (367.9–368.1 eV and 373.9–374.1 eV) of the  
7 metallic Ag [42]. In addition, it was reported that the Ag 3d<sub>5/2</sub> BE of the Ag<sub>2</sub>O and AgO were  
8 reported at 367.6–367.7eV and 367.2–367.4 eV, respectively [42], which is in contrast to the  
9 typical positive core level BE shifts of metal cations in ionic materials. As shown in Fig. S10,  
10 the Ag 3d<sub>5/2</sub> peak of the as-reduced bimetallic catalysts shifted to higher BE values  
11 compared to the monometallic Ag/SiO<sub>2</sub> catalyst, which implied that Ag species of the  
12 bimetallic catalysts had a greater tendency of electronic richness compared with those of  
13 monometallic Ag/SiO<sub>2</sub>, according to the anomalous spectral shift behavior of silver/silver  
14 oxide system.

15 Since BE value of Cu<sup>0</sup> and Cu<sup>+</sup> species is almost the same, the XAES spectra was  
16 conducted to further discriminate the surface Cu<sup>0</sup> and Cu<sup>+</sup> species of the as-reduced  
17 Cu<sub>1</sub>-Ag<sub>x</sub>/SiO<sub>2</sub> catalysts. In the Cu LMM XAES spectra (Fig. 5), asymmetry and overlapped  
18 Auger peaks were observed, which strongly indicated that Cu<sup>0</sup> and Cu<sup>+</sup> species were  
19 coexisted in the reduced catalysts. The deconvolution results are listed in Table 3. It was  
20 obvious that the surface Cu<sup>+</sup> and Cu<sup>0</sup> distributions were significantly affected by the Ag/Cu  
21 atomic ratio. The Cu<sup>+</sup>/(Cu<sup>0</sup>+Cu<sup>+</sup>) intensity ratio firstly enhanced and reached the maximized

1 value of 53.4% at Ag/Cu atomic ratio of 0.05, then dropped mildly with further increasing  
2 silver loading. The Auger parameter (AP) of  $\text{Cu}^+$  and  $\text{Cu}^0$  were close to the reported values  
3 that 1851.0 eV for  $\text{Cu}^0$  and 1847.0 eV for  $\text{Cu}^+$  [43].

#### 4 5 3.2.5. EXAFS

6 Extended X-ray absorption fine structure (EXAFS) measurements were conducted to  
7 further investigate the near-neighbor atomic environment of Cu and Ag. The Fourier  
8 transforms of Ag K-edge EXAFS spectra of  $\text{Cu}_1\text{-Ag}_{0.05}/\text{SiO}_2$ ,  $\text{Ag}/\text{SiO}_2$ , and Ag foil are  
9 shown in Fig. 6. Obviously, the first nearest neighbor distance of  $\text{Ag}/\text{SiO}_2$  was close to Ag  
10 foil. The  $\text{Cu}_1\text{-Ag}_{0.05}/\text{SiO}_2$  catalyst showed a relatively broad peak at a position that is lower  
11 than the peak for Ag foil and longer than the peak for  $\text{Ag}_2\text{O}$  at around 2.0 Å [29], implying  
12 the existence of a Ag–Cu bond. For Fourier transforms of Cu K-edge EXAFS, the first  
13 nearest neighbor distance of  $\text{Cu}/\text{SiO}_2$  and  $\text{Cu}_1\text{-Ag}_{0.05}/\text{SiO}_2$  catalyst showed no obvious  
14 difference from that of Cu foil ( Fig. 7).

15 Structural parameters derived from curve fitting analysis are listed in Table 4 and Table  
16 S2. For Ag K-edge EXAFS of  $\text{Cu}_1\text{-Ag}_{0.05}/\text{SiO}_2$ , a Cu–Ag shell at bond distance (R) of 2.64  
17 Å with coordination number (N) of 11 was observed without considering Ag–Ag distance by  
18 neglecting the Ag–Ag contribution. When Ag–Ag coordination was taken into account, a  
19 Ag–Cu shell at bond distance (R) of 2.63 Å with coordination number (N) of 10 and a Ag–  
20 Ag shell at bond distance (R) of 2.89 Å with coordination number (N) of 2.7 were detected.

21 Herein, the Ag–Cu coordination number was corrected by using Ag–Ag coordination

1 ~~number reduction factor~~, since we did not have good Ag–Cu reference compound. For  
2 Cu<sub>1</sub>-Ag<sub>0.05</sub>/SiO<sub>2</sub>, the coordination number (N) of Ag–Cu took up 78% of the total  
3 coordination number (N) of Ag, which suggested that most of Ag bonded to Cu to form Cu–  
4 Ag alloy ~~and a small part of Ag (ca. 22%) formed Ag clusters~~[KA2]. ~~The much smaller Ag–~~  
5 ~~Ag coordination number of Cu<sub>1</sub>-Ag<sub>0.05</sub>/SiO<sub>2</sub> (2.7) than Ag foil (12) indicating the presence of~~  
6 ~~tiny metallic Ag clusters with sizes below a few nanometers [29]. Moreover, the total~~  
7 ~~coordination number around Ag was nearly 12, indicating that small Ag cluster was mainly~~  
8 ~~surrounded by Cu.~~ For Cu K-edge, Cu<sub>1</sub>-Ag<sub>0.05</sub>/SiO<sub>2</sub> sample gave a Cu–Cu shell at bond  
9 distance (R) of 2.52 Å with coordination number (N) of 9.2. For the Ag content was just 0.05  
10 and Ag–Cu shell determined from Ag K-edge was just 10, according to the relation of  $N_{\text{Ag-Cu}}$   
11  $\times C_{\text{Ag}} = N_{\text{Cu-Ag}} \times C_{\text{Cu}}$ , the calculated  $N_{\text{Cu-Ag}}$  was ca. 0.6, which was too small to be detected.  
12 The Cu/SiO<sub>2</sub> sample consisted of a Cu–Cu shell (N = 6.2 at R = 2.53 Å) and a weak Cu–O  
13 shell (N = 0.8 at R = 1.83 Å), which implied that Cu species was somewhat oxidized.

14 The Ag K-edge X-ray absorption near-edge structure (XANES) spectra of  
15 Cu<sub>1</sub>-Ag<sub>0.05</sub>/SiO<sub>2</sub> showed that Ag shifted to lower energy side compared with that of Ag/SiO<sub>2</sub>  
16 and Ag foil (not shown), indicating Ag was negatively charged in Cu<sub>1</sub>-Ag<sub>0.05</sub>/SiO<sub>2</sub>. The result  
17 was in good agreement with the aforementioned XPS analysis.

### 18 19 3.2.6 Structure-performance relationship

20 Based on the analysis of structure characterization results, a possible schematic diagram  
21 of Cu<sub>1</sub>-Ag<sub>x</sub>/SiO<sub>2</sub> catalysts varied with Ag/Cu atomic ratio is proposed and shown in Fig. 8.

1 Monometallic Cu/SiO<sub>2</sub> catalyst with relatively low Cu dispersion showed poor catalytic  
2 activity and stability. After incorporating with a small amount of Ag ( $0.02 \leq x \leq 0.05$ ), a kind  
3 of hybrid nanoparticles composed of Cu NPs, Ag nanoclusters, and Ag-Cu alloys are formed  
4 on the SiO<sub>2</sub> surfaces. These species are coherently interacted and may play important roles in  
5 modulating the Cu<sup>+</sup>/Cu<sup>0</sup> ratio and retarding the aggregation of Cu NPs during reaction  
6 process. With further increasing the Ag/Cu atomic ratio ( $0.1 \leq x \leq 0.2$ ), excessive Ag  
7 nanoclusters cover/block the surface of Cu NPs and disturbed the balance of Cu<sup>+</sup>/Cu<sup>0</sup> ratio,  
8 resulting in the decrease of the catalytic activity.

9 Using the catalytic results, the dispersion of Cu and metal, and the Cu<sup>+</sup>/Cu<sup>0</sup> ratio, we  
10 can discuss the effects of Ag/Cu atomic ratio and Cu<sup>+</sup>/Cu<sup>0</sup> on the TOF with respect to the  
11 number of surface metal atoms. As shown in Fig. 9, both Cu<sup>+</sup>/(Cu<sup>0</sup>+Cu<sup>+</sup>) intensity ratio and  
12 TOF showed a volcano-type dependence on the Ag/Cu atomic ratio, suggesting that suitable  
13 proportion of surface Cu<sup>+</sup> and Cu<sup>0</sup> was important to gain remarkable catalytic performance.  
14 In other words, adding proper amount of Ag could modulate proportion of surface Cu<sup>+</sup> and  
15 Cu<sup>0</sup> to obtain excellent activity and stability for the hydrogenation of DMO.

16

#### 17 **4. Conclusions**

18 Incorporating a proper amount of Ag into Cu/SiO<sub>2</sub> has been demonstrated significantly  
19 enhancing the catalytic activity and stability for the hydrogenation of DMO to EG. The EG  
20 yield over the optimized catalyst Cu<sub>1</sub>-Ag<sub>0.05</sub>/SiO<sub>2</sub> is 2.2 times higher than that over the  
21 monometallic Cu/SiO<sub>2</sub> under the conditions of 463 K, 3.0 MPa, 80 H<sub>2</sub>/DMO molar ratio, and

1 1.05 h<sup>-1</sup> WLHSV<sub>DMO</sub>. The Cu<sub>1</sub>-Ag<sub>0.05</sub>/SiO<sub>2</sub> catalyst can maintain almost 100% DMO  
2 conversion and above 97% EG selectivity under the optimized condition for 150 h.

3 A series of spectroscopic studies including N<sub>2</sub>O chemisorption, TEM, *in situ* XRD, EDS,  
4 H<sub>2</sub>-TPR, UV-vis DRS, XPS, XAES, and EXAFS has been used to explore the structure of  
5 the catalysts. Introducing a proper amount of Ag facilitates the higher dispersion of Cu NPs.  
6 Parts of Ag species are alloyed with Cu species and others form Ag nanoclusters, both are  
7 involved in Cu NPs and coherently interacted with each other on the SiO<sub>2</sub> surface. The  
8 distribution of surface Cu<sup>+</sup> and Cu<sup>0</sup> species can be modulated by varying the Ag/Cu atomic  
9 ratio. In short, the interactions between Cu and proper amount of Ag species help sustaining  
10 the suitable Cu<sup>+</sup>/Cu<sup>0</sup> proportion and restraining the transmigration of copper NPs, which are  
11 largely responsible for the excellent activity and stability of the bimetallic Cu-Ag/SiO<sub>2</sub>  
12 catalyst.

1 **Table 2**

2 Physicochemical properties of Cu<sub>1</sub>-Ag<sub>x</sub>/SiO<sub>2</sub> catalysts.

Catalysts	Cu loading <sup>a</sup> / wt%	Ag loading <sup>a</sup> / wt%	Ag/Cu molar ratio	S <sub>BET</sub> / m <sup>2</sup> g <sup>-1</sup>	V <sub>pore</sub> / cm <sup>3</sup> g <sup>-1</sup>	D <sub>pore</sub> / nm	Cu dispersion <sup>b</sup> / %	Metal dispersion <sup>c</sup> / %
Cu/SiO <sub>2</sub>	8.7	-	-	224.5	0.82	12.5	35.3	31.6
Cu <sub>1</sub> -Ag <sub>0.02</sub> /SiO <sub>2</sub>	8.3	0.26	0.018	216.9	0.90	13.8	38.6	33.8
Cu <sub>1</sub> -Ag <sub>0.05</sub> /SiO <sub>2</sub>	7.9	0.65	0.048	225.0	0.90	13.7	43.1	38.4
Cu <sub>1</sub> -Ag <sub>0.1</sub> /SiO <sub>2</sub>	7.3	1.2	0.097	216.6	0.96	14.9	40.5	37.2
Cu <sub>1</sub> -Ag <sub>0.2</sub> /SiO <sub>2</sub>	6.6	2.0	0.18	187.7	0.63	12.1	36.3	33.8
Ag/SiO <sub>2</sub>	-	9.1	-	109.4	0.45	15.2	-	7.1
SiO <sub>2</sub>	-	-	-	108.2	0.34	9.9	-	-

3 <sup>a</sup> Determined by ICP-OES analysis.

4 <sup>b</sup> Determined by N<sub>2</sub>O surface oxidation.

5 <sup>c</sup> Determined by TEM.

6

1 **Table 3**

2 Cu LMM deconvolution results of Cu/SiO<sub>2</sub> and Cu<sub>1</sub>-Ag<sub>x</sub>/SiO<sub>2</sub> catalysts.

Catalyst	K.E. <sup>a</sup> / eV		A.P. <sup>b</sup> / eV		Cu 2p <sub>3/2</sub>	X <sub>Cu<sup>+</sup></sub> <sup>c</sup> / %
	Cu <sup>+</sup>	Cu <sup>0</sup>	Cu <sup>+</sup>	Cu <sup>0</sup>	B.E. / eV	
Cu/SiO <sub>2</sub>	914.0	918.1	1846.5	1850.6	932.5	38.3
Cu <sub>1</sub> -Ag <sub>0.02</sub> /SiO <sub>2</sub>	914.2	918.1	1486.9	1850.8	932.7	40.7
Cu <sub>1</sub> -Ag <sub>0.05</sub> /SiO <sub>2</sub>	914.0	917.9	1486.8	1850.7	932.8	53.4
Cu <sub>1</sub> -Ag <sub>0.1</sub> /SiO <sub>2</sub>	913.9	918.0	1846.8	1850.9	932.9	46.4
Cu <sub>1</sub> -Ag <sub>0.2</sub> /SiO <sub>2</sub>	913.9	917.9	1846.8	1850.8	932.9	40.9

3 <sup>a</sup> Kinetic energy.

4 <sup>b</sup> Auger parameter.

5 <sup>c</sup> Intensity ratio between Cu<sup>+</sup> and (Cu<sup>+</sup> + Cu<sup>0</sup>) by deconvolution of Cu LMM XAES spectra.

6

1 **Table 4**

2 Curve fitting analysis of Ag K-edge EXAFS of Cu<sub>1</sub>-Ag<sub>0.05</sub>/SiO<sub>2</sub>, Ag/ SiO<sub>2</sub> and Ag foil.

Sample	Shell	N <sup>a</sup>	R <sup>b</sup> / Å	E <sup>c</sup> / eV	σ <sup>d</sup> / Å	R <sub>f</sub> <sup>d</sup>
Cu <sub>1</sub> -Ag <sub>0.05</sub> /SiO <sub>2</sub>	Ag–Cu	11	2.64	2.2	0.082	0.029
Cu <sub>1</sub> -Ag <sub>0.05</sub> /SiO <sub>2</sub>	Ag–Cu	10	2.63	1.5	0.076	0.012
	Ag–Ag	2.7	2.89	4.1	0.083	
Ag/ SiO <sub>2</sub>	Ag–Ag	8.9	2.85	3.6	0.081	0.052
Ag foil	Ag–Ag	12	2.85	2.8	0.082	0.044

3 <sup>a</sup> Coordination number.

4 <sup>b</sup> Bond distance between absorber and backscatter atoms.

5 <sup>c</sup> Inner potential correction to account for the difference in the inner potential between the  
6 sample and the reference compound.

7 <sup>d</sup> Debye–Waller factor.

8 <sup>e</sup> Residual factor.
