Background: This randomised phase II study evaluated the efficacy and safety of panitumumab added to docetaxel-based chemotherapy in advanced oesophagogastric cancer.

Methods: Patients with metastatic or locally recurrent cancer of the oesophagus, oesophagogastric junction or stomach received docetaxel and a fluoropyrimidine with or without panitumumab for 8 cycles or until progression. The primary end point was response rate (RECIST1.1). We planned to enrol 100 patients, with 50% expected response rate for combination therapy.

Results: A total of 77 patients were enrolled. A safety alert from the REAL3 trial prompted a review of data that found no evidence of adverse outcomes associated with panitumumab but questionable efficacy, and new enrolment was ceased. Enrolled patients were treated according to protocol. Response rates were 49% (95% CI 34–64%) in the chemotherapy arm and 58% (95% CI 42–72%) in the combination arm. Common grade 3 and 4 toxicities included infection, anorexia, vomiting, diarrhoea and fatigue. At 23.7 months of median follow-up, median progression-free survival was 6.9 months vs 6.0 months and median overall survival was 11.7 months vs 10.0 months in the chemotherapy arm and the combination arm, respectively.

Conclusions: Adding panitumumab to docetaxel-based chemotherapy for advanced oesophagogastric cancer did not improve efficacy and increased toxicities.

Most cases of oesophageal and gastric cancer present with locally advanced or metastatic disease. Median overall survival is <6 months for those who receive best supportive care alone for metastatic disease (Murad *et al*, 1993; Glimelius *et al*, 1997).

Cisplatin and fluoropyrimidine combination regimens are widely accepted as standard therapy for this disease (Wagner *et al*, 2006).

Recently, the REAL-2 study demonstrated that capecitabine is not inferior to 5-fluorouracil in this setting (Cunningham *et al*, 2008).

This alternative is easier to administer and obviates indwelling venous access.

Docetaxel has promising activity in advanced gastro-oesophageal cancer, as a single agent and in combination regimens (Muro *et al*, 2004; Van Cutsem *et al*, 2006; Cook *et al*, 2013). Our group showed that a docetaxel-based chemotherapy regimen given weekly (in combination with a fluoropyrimidine or fluoropyrimidine plus cisplatin) has comparable activity to 3-weekly administration, with a lower rate of haematological toxicity (Tebbutt *et al*, 2010). The triplet regimen appeared to have the most promising activity, leading to its incorporation into this subsequent trial.

The EGFR pathway is important to development of a number of tumour types, and has become a target for therapy in some gastrointestinal cancers, including colorectal cancer (Jonker *et al*, 2007; Van Cutsem *et al*, 2007). Strong EGFR expression has been found in epidermal oesophageal cancers (Langer *et al*, 2006), with some evidence that EGFR expression predicts poor prognosis (Lieto *et al*, 2008; Navarini *et al*, 2012). Oesophago-gastric cancers have low rates of *ras* mutation, suggesting that targeting of this pathway may add to the benefit received from chemotherapy alone. We have shown that the addition of an EGFR-targeted therapy to docetaxel achieves modest response rates in the docetaxel-refractory setting (Tebbutt *et al*, 2013).

Therefore, this study evaluated the activity of the combination of docetaxel-based weekly chemotherapy with the EGFR human monoclonal antibody panitumumab as first-line treatment of advanced oesophago-gastric cancer.

MATERIALS AND METHODS

Eligibility. The AGITG ATTAX3 study was approved by the research ethics committee of each participating institution. All patients provided written informed consent.

The ATTAX3 study was available for adult patients with histologically proven metastatic or locally recurrent cancer of the oesophagus, oesophago-gastric junction or stomach (squamous, adenocarcinoma or undifferentiated histology), who had received no prior therapy other than neoadjuvant or adjuvant treatment completed at least 12 months earlier or palliative radiotherapy completed at least 14 days before enrolment. Other inclusion criteria included WHO performance status (PS) 0, 1 or 2; adequate haematological function, including platelets $>100 \times 10^9 \text{ l}^{-1}$ and neutrophils $>1.5 \times 10^9 \text{ l}^{-1}$; normal renal function, including calculated creatinine clearance of at least 50 ml min^{-1} ; and adequate hepatic function, including serum total bilirubin $<1.25 \times$ upper limit of normal range, alanine transaminase (ALT) or aspartate transaminase (AST) $<2.5 \times$ upper limit of normal range and alkaline phosphatase $<5 \times$ upper limit of normal range. Women of childbearing potential were required to have a negative pregnancy test and adequate contraception. Exclusion criteria included medical or psychiatric conditions that compromised a patient's ability to consent to or comply with the study requirements; previous malignant disease other than non-melanotic skin cancer, carcinoma *in situ* of the uterine cervix or other cancer treated with curative intent at least 2 years previously and without evidence of relapse; uncontrolled metastatic disease of the central nervous system; pregnancy or breast-feeding; clinical evidence of peripheral neuropathy $>$ grade 2; and clinical evidence of interstitial pneumonitis or pulmonary fibrosis. Patients with any uncontrolled concurrent medical condition or who had previously used an EGFR-targeted agent or who were using a nucleoside analogue were also excluded.

Study design and treatment. The ATTAX3 study was a randomised, phase II, open-label, multicentre study of docetaxel-based chemotherapy with or without panitumumab. Patients

received docetaxel 30 mg m^{-2} d1 and d8, cisplatin 60 mg m^{-2} d1 and a fluoropyrimidine (investigator choice of 5-fluorouracil infusion 160 mg m^{-2} per day or capecitabine 500 mg m^{-2} b.d. continuous) alone or with panitumumab 9 mg kg^{-1} d1 q3w. Treatment was administered for 8 cycles or until the patient or physician requested cessation, or until disease progression was documented. In the absence of progression or significant toxicity, panitumumab could be continued beyond 8 cycles at the discretion of the investigator.

Evaluation and outcomes. Patients had clinical assessments at baseline, before every cycle of treatment, at the end of study treatment and then every 12 weeks. Patients were assessed radiologically at baseline, 6 weekly during the trial and then every 12 weeks until disease progression. Toxicity was graded using NCI CTCAE version 3.0.

Quality of life was assessed at baseline, every 3 weeks for the first 12 weeks, every 6 weeks for the next 12 weeks and then every 12 weeks until disease progression, with the European Organisation for Research and Treatment of Cancer Quality of Life Questionnaire (QLQ) C30, Version 3.0 (01/02/2003), together with the oesophageal-specific module (OES 18) or the gastric module (STO 22), depending on the site of disease.

Statistical design. The primary end point was the objective tumour response, as assessed by RECIST version 1.1. Secondary end points were overall survival, progression-free survival, treatment-related toxicity and quality of life. Tumour tissue was collected for future exploratory biomarker analysis.

Enrolment was planned for 100 patients in total, with participants randomised 1:1 to receive chemotherapy alone or in combination with panitumumab. A response rate of 50% was considered to be of interest for further study, and 50 patients in the experimental arm would provide a 95% confidence interval that excluded 35% (the expected response rate in the chemotherapy-alone arm). Patients were randomised by the minimisation method and were stratified by primary tumour site (oesophagus, oesophago-gastric junction or stomach), histology (adenocarcinoma, squamous or undifferentiated carcinoma), WHO performance status (0–1 vs 2), use of 5-fluorouracil vs capecitabine and institution.

Toxicity was evaluated by the Independent Data Monitoring Committee (IDMC) after 20 patients had been enrolled in the combination arm of the study and had completed at least 2 cycles of therapy and again after the REAL3 safety alert.

The 95% confidence intervals for response rates were calculated by the Wilson method. Time-to-event analyses were summarised with Kaplan–Meier curves. All analyses were by intention to treat. Analyses used SAS (version 9.2; Cary, NC, USA).

RESULTS

Patient characteristics. Between April 2010 and November 2011, 77 patients from 15 institutions in Australia were registered; 39 were randomised to receive chemotherapy alone and 38 to chemotherapy plus panitumumab (see consort diagram; Figure 1). All patients enrolled were eligible. One patient was randomised but did not commence treatment. Baseline characteristics were similar in the two groups (Table 1). Approximately 90% of participants had adenocarcinoma, and two-thirds received a capecitabine-containing regimen. Most patients (90.8%) had distant metastases at the time of study enrolment.

A safety alert from the REAL3 trial prompted a review of the trial data by the IDMC. This committee observed no evidence of adverse outcomes associated with panitumumab, but it was felt that it would be unlikely that the study would meet its primary end point even if it completed its accrual target. Consequently, it was

*Within 6 weeks of randomisation and early withdrawal due to toxicity, drug intolerance or patient's preference

^aWeekly docetaxel, cisplatin and a fluoropyrimidine (5-fluorouracil or capecitabine).

Figure 2. Progression-free survival in patients receiving chemotherapy (weekly docetaxel, cisplatin and a fluoropyrimidine), alone or with panitumumab.

Efficacy. Of the 77 patients recruited to the study, 71 were evaluable for response. In the chemotherapy-alone arm, no patients had a complete response, 19 (48.7%) had a partial response and 17(43.6%) had stable disease. In the combination arm, 2 patients had a complete response, 20 (52.6%) a partial response and 10 (26.3%) had stable disease. Overall, 48.7% of patients in the chemotherapy-alone arm had an objective tumour response (51.4% if early withdrawals were excluded) and 57.9% in the combination arm had an objective tumour response (64.7% if early withdrawals were excluded). After a median follow-up of 24 months, median progression-free survival was 6.9 months in the chemotherapy-alone arm and 6.0 months in the combination arm (Figure 2). Median overall survival was 11.7 months in the chemotherapy arm and 10 months in the combination arm (Figure 3).

Toxicity. Across both arms of the study, the most common significant adverse events (of grade 3 or higher) were anorexia, infection, vomiting, diarrhoea and fatigue (Table 2). The rate of

recommended that new enrolments cease, but patients already enrolled continued treatment according to protocol.

Treatment. Patients in the chemotherapy-alone arm received a median of 7 cycles of treatment (range 2–16) and those in the chemotherapy plus panitumumab combination arm a median of 6 cycles of treatment (range 1–12). Four (10.5%) patients in the combination arm and two (5.1%) in the chemotherapy-alone arm discontinued therapy early (within 6 weeks). The predominant reasons for early treatment discontinuation were patient or clinician preference.

Figure 3. Overall survival in patients receiving chemotherapy (weekly docetaxel, cisplatin and a fluoropyrimidine), alone or with panitumumab.

grade 2 or 3 infection with normal neutrophils was higher in the chemotherapy plus panitumumab arm (62.1% vs 33.3%), and 94.6% of patients in the combination arm experienced an acneiform rash of any grade (8.1% of grade 3). In the chemotherapy-alone arm, 31% (n = 12) required a dose delay of at least 7 days during treatment, compared with 49% (n = 18) in the combination arm.

Quality of life. Improvement in a specific disease-associated symptom or aspect of quality of life was defined as an increase of 10 points or more for that questionnaire item for more than 3 weeks. Of the participants, 95% completed at least one QOL assessment (4 patients did not participate because of insufficient English). Of these patients, 86% completed a baseline assessment and questionnaires until progression. In a combined analysis of all participants, significant improvement was seen between baseline and time of progression in pain (change from baseline, 11.36), with a trend to improvement in emotional functioning (change from baseline, 9.26). In those with gastric primary tumours who completed the QLQ stomach module, there was additionally an improvement in dysphagia and anxiety. Worsening of dry mouth and taste disturbance was significant across the combined group, with a trend to worsening of diarrhoea. Overall, global health status was stable across the trial period (change from baseline, 1.02).

DISCUSSION

In this trial, adding panitumumab to triplet chemotherapy using docetaxel, cisplatin and a fluoropyrimidine did not lead to a significant improvement in objective tumour response rate, progression-free survival or overall survival. The median overall survival (11.7 months in the chemotherapy-alone arm and 10 months in the chemotherapy plus panitumumab arm) was consistent with results from similar studies in similar populations (Van Cutsem *et al*, 2006; Al-Batran *et al*, 2008; Lordick *et al*, 2013). There was a higher rate of some toxicities in the combination arm, in keeping with the known side-effect profile of panitumumab. Overall, global quality-of-life scores remained stable throughout the trial.

There is now increasing evidence that, despite promising phase II evidence suggesting a role for the targeting of the EGFR pathway as a new option for treatment of oesophagogastric cancer, this has failed to translate to significant clinical benefit in larger randomised trials.

The randomised phase III EXPAND trial (Lordick *et al*, 2013), using a first-line regimen of capecitabine and cisplatin with or without cetuximab for advanced oesophagogastric cancer, also

^aWeekly docetaxel, cisplatin and a fluoropyrimidine (5-fluorouracil or capecitabine).

failed to show a benefit from the addition of EGFR-targeted therapy in an unselected population. This is also in keeping with results from the REAL 3 trial (Waddell *et al*, 2013) that randomised 575 patients to receive chemotherapy with epirubicin, oxaliplatin and capecitabine alone or with panitumumab (with dose modification of the chemotherapy backbone). REAL 3 showed no benefit to the combination arm, and in fact revealed an inferior survival for those receiving the EGFR antibody. It has been postulated that this finding of a statistically inferior survival outcome in the combination arm may result from the use of modified-dose chemotherapy, or a possible negative interaction between panitumumab and components of the chemotherapy regimen. Notably, this study did not show a significantly detrimental outcome in the panitumumab arm, suggesting that the modification of chemotherapy dosing in the REAL3 study may be the factor accounting for inferior survival.

The use of a biomarker-unselected population may contribute to the lack of benefit seen across these trials. Previous work using the ATTAX2 trial (Tebbutt *et al*, 2013) samples available showed all tumours were wild type for KRAS exon 2/BRAF exon 15 and PI3KCA exon 20, in keeping with similar work showing low levels of mutations in this population. However, with the increasing recognition of the presence and effect of other gene abnormalities that may be amenable to direct targeting, such as EGFR and MET amplification (Lee *et al*, 2011), further progress in the outcomes for gastro-oesophageal cancer is likely to require better identification of biomarkers and subpopulations most likely to respond to targeted therapies.

In conclusion, the ATTAX3 trial showed there was no significant improvement in activity for the combination of docetaxel-based chemotherapy and panitumumab over chemotherapy alone in the treatment of advanced oesophagogastric cancer.

ACKNOWLEDGEMENTS

Amgen Australia and Sanofi Australia provided funding to support the study. Neither company was involved in the study design, or data collection, analysis or interpretation. The content of the manuscript and the decision to submit was made independently by the authors.

CONFLICT OF INTEREST
